SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 15, PART 2

19TH ANNUAL MEETING
PHOENIX, ARIZONA
OCTOBER 29–NOVEMBER 3, 1989

Made in the United States of America.
International Standard Book Numbers:
Part 1 ISBN 0–916110–31–1
Part 2 ISBN 0–916110–32–X
Both parts ISSN 0190–5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:
Soc. Neurosci. Abstr., Vol. 15, Part 2, p. xxx, 1989.

Published by:

CHRONOLOGICAL LIST OF SESSIONS

(see page xii for Thematic List of Sessions)

TUESDAY

FRIDAY

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions, and symposia only.)

Session Number	Session Title	Type	Day and Time
Theme B: Cell Biology			
331.	Blood-brain barrier I	Slide	Wed PM
409.	Blood-brain barrier II	Poster	Thu AM
480.	Blood-brain barrier III	Poster	Thu PM
65.	Cytoskeleton, transport and membrane targeting	Poster	Mon AM
261.	Gene structure and function I	Slide	Wed AM
381.	Gene structure and function II	Slide	Thu AM
450.	Gene structure and function III	Poster	Thu PM
503.	Gene structure and function IV	Poster	Fri AM
230.	Membrane composition and cell surface macromolecules I	Poster	Tue PM
355.	Membrane composition and cell surface macromolecules II	Poster	Wed PM
142.	mRNA regulation I	Slide	Tue AM
205.	mRNA regulation II	Slide	Tue PM
339.	mRNA regulation III	Poster	Wed PM
393.	mRNA regulation IV	Poster	Thu AM
451.	mRNA regulation V	Poster	Thu PM
504.	mRNA regulation VI	Poster	Fri AM
10.	Neuroglia	Slide	Mon AM
209.	Neuroglia in disease	Poster	Tue PM
146.	Neuroglia: active membrane responses	Poster	Tue AM
145.	Neuroglia: myelin and myelin-forming cells	Poster	Tue AM
210.	Neuroglia: structure and biology	Poster	Tue PM
122.	Staining and tracing techniques	Poster	Mon PM
Theme C: Excitable Membranes and Synaptic Transmission			
11.	Calcium channels I	Slide	Mon AM
147.	Calcium channels II	Poster	Tue AM
264.	Calcium channels III	Slide	Wed AM
332.	Calcium channels IV	Poster	Wed PM
457.	Calcium channels: modulation and regulation	Poster	Thu PM
76.	Ion channel modulation and regulation I	Slide	Mon PM
514.	Ion channel modulation and regulation II	Poster	Fri AM
456.	Ion channels: cell function	Poster	Thu PM
36.	Ion channels: chloride and miscellaneous	Poster	Mon AM
387.	Ligand-gated ion channels I	Slide	Thu AM
458.	Ligand-gated ion channels II	Poster	Thu PM
333.	Ligand-gated ion channels: cholinergic	Poster	Wed PM
334.	Ligand-gated ion channels: glutamate	Poster	Wed PM
84.	Pharmacology of synaptic transmission	Poster	Mon PM
216.	Pharmacology of synaptic transmission: amino acids and calcium channels	Poster	Tue PM
79.	Postsynaptic mechanisms I	Slide	Mon PM
215.	Postsynaptic mechanisms II	Poster	Tue PM
516.	Postsynaptic mechanisms III	Poster	Fri AM
35.	Potassium channels I	Poster	Mon AM
139.	Potassium channels II	Slide	Tue AM
220.	Potassium channels III	Poster	Tue PM
395.	Potassium channels IV	Poster	Thu AM
396.	Potassium channels: modulation and regulation	Poster	Thu AM
83.	Presynaptic mechanisms I	Poster	Mon PM
197.	Presynaptic mechanisms II	Slide	Tue PM
189.	Presynaptic mechanisms: calcium	Poster	Tue AM
190.	Presynaptic mechanisms: facilitation and depression	Poster	Tue AM
85.	Sodium channels I	Poster	Mon PM
219.	Sodium channels II	Poster	Tue PM
105.	Synaptic structure and function I	Poster	Mon PM
276.	Synaptic structure and function II	Poster	Wed AM

Session Number	Session Title	Type	Day and Time

Theme D: Neurotransmitters, Modulators, and Receptors

29.	Acetylcholine I	Poster	Mon AM
165.	Acetylcholine II	Poster	Tue AM
226.	Acetylcholine III	Poster	Tue PM
472.	Acetylcholine IV	Poster	Thu PM
102.	Behavioral pharmacology: analgesics and NMDA	Poster	Mon PM
252.	Behavioral pharmacology: benzodiazepines and stimulants	Poster	Tue PM
422.	Behavioral pharmacology: dopamine	Poster	Thu AM
466.	Behavioral pharmacology: other	Poster	Thu PM
73.	Catecholamine receptors	Slide	Mon PM
173.	Catecholamine receptors: adrenergic	Poster	Tue AM
172.	Catecholamine receptors: dopaminergic	Poster	Tue AM
171.	Catecholamine receptors: dopaminergic (D1)	Poster	Tue AM
170.	Catecholamine receptors: dopaminergic (D2)	Poster	Tue AM
330.	Catecholamines I	Slide	Wed PM
399.	Catecholamines II	Poster	Thu AM
403.	Catecholamines III	Poster	Thu AM
482.	Catecholamines IV	Poster	Thu PM
517.	Catecholamines V	Poster	Fri AM
518.	Catecholamines VI	Poster	Fri AM
483.	Catecholamines: anatomy	Poster	Thu PM
402.	Catecholamines: neurotoxicity	Poster	Thu AM
203.	Cholinergic receptors	Slide	Tue PM
260.	Excitatory amino acids: anatomy and physiology I	Slide	Wed AM
372.	Excitatory amino acids: anatomy and physiology II	Poster	Wed PM
373.	Excitatory amino acids: anatomy and physiology III	Poster	Wed PM
374.	Excitatory amino acids: anatomy and physiology IV	Poster	Wed PM
195.	Excitatory amino acids: excitotoxicity I	Slide	Tue PM
305.	Excitatory amino acids: excitotoxicity II	Poster	Wed AM
306.	Excitatory amino acids: excitotoxicity III	Poster	Wed AM
307.	Excitatory amino acids: excitotoxicity IV	Poster	Wed AM
86.	Excitatory amino acids: receptors I	Poster	Mon PM
87.	Excitatory amino acids: receptors II	Poster	Mon PM
133.	Excitatory amino acids: receptors III	Slide	Tue AM
217.	Excitatory amino acids: receptors IV	Poster	Tue PM
218.	Excitatory amino acids: receptors V	Poster	Tue PM
380.	Excitatory amino acids: receptors VI	Slide	Thu AM
461.	Excitatory amino acids: receptors VII	Poster	Thu PM
462.	Excitatory amino acids: receptors VIII	Poster	Thu PM
463.	Excitatory amino acids: receptors IX	Poster	Thu PM
259.	GABA and benzodiazepine receptors I	Slide	Wed AM
335.	GABA and benzodiazepine receptors II	Poster	Wed PM
397.	GABA and benzodiazepine receptors III	Poster	Thu AM
459.	GABA and benzodiazepine receptors IV	Poster	Thu PM
199.	GABA and benzodiazepines I	Slide	Tue PM
272.	GABA and benzodiazepines II	Poster	Wed AM
398.	GABA and benzodiazepines III	Poster	Thu AM
95.	Interactions between neurotransmitters I	Poster	Mon PM
235.	Interactions between neurotransmitters II	Poster	Tue PM
326.	Interactions between neurotransmitters III	Slide	Wed PM
491.	Interactions between neurotransmitters IV	Poster	Thu PM
318.	**Mesopontine Cholinergic Neurons: The Neuronal Substrate of the Ascending Reticular Activating System?**	**Symp.**	**Wed PM**
515.	Muscarinic receptors	Poster	Fri AM
275.	Nicotinic receptors	Poster	Wed AM
285.	Opiates, endorphins and enkephalins: anatomy and chemistry I	Poster	Wed AM
392.	Opiates, endorphins and enkephalins: anatomy and chemistry II	Poster	Thu AM
340.	Opiates, endorphins and enkephalins: behavioral effects	Poster	Wed PM

Session Number	Session Title	Type	Day and Time
62.	Opiates, endorphins and enkephalins: physiological effects I	Poster	Mon AM
221.	Opiates, endorphins and enkephalins: physiological effects II	Poster	Tue PM

A LIGAND-GATED CHANNEL RECEPTOR FOR HISTAMINE. T. S. McClintock and B. W. Ache*. Whitney Lab. and Depts. of Zool. and Neurosci., Univ. of Florida, St. Augustine, FL 32086.

Histamine (HA) suppresses spiking when applied to the soma of lobster olfactory receptor neurons. In voltage-clamped somata, HA activates a Cl^- conductance. The Cl^- current was unaffected by external Co^{++} and Cd^{++}, or internal perfusion with activators and inhibitors of G-proteins. HA activated a Cl^- channel when pulsed onto outside-out (N = 35) but not cell-attached patches (N = 19). Intracellular GTP-gamma-S did not affect channel gating by HA. These data demonstrate that HA directly gates a Cl^- channel with a conductance of 66 pS in the Caribbean spiny lobster and 44 pS in the American lobster. The percent of time the channel spent in the open state (P_o) was a graded function of dose, beginning between 0.1 and 1 μM HA. Some kinetic properties of the channel were sensitive to voltage. The macroscopic current decayed rapidly as a single exponential (τ of about 100 ms) at -70 mV, as a double exponential between -60 and -35 mV (τ's of about 100 and 1000 ms), and did not decay above -35 mV. Similarly, the P_o of the channel was increased 10- to 15-fold when the potential was increased from -50 mV to 50 mV. This new ligand-gated channel shares some properties with the $GABA_A$ receptor.

Supported by the Grass Foundation, NIMH award F31MH09495 and NSF award BNS88-10261.

387.10

SOME PROPERTIES OF 5-HT_3 RECEPTOR CHANNELS: SINGLE CHANNEL AND WHOLE CELL RECORDINGS FROM SUBMUCOSAL NEURONS. A.Surprenant, V.A.Derkach*,K-Z.Shen* & R.A.North. Vollum Institute, Oregon Hlth.Sci.Uni., Portland, OR 97201

Results have accumulated to suggest that 5-HT_3 receptors are ligand-gated ion channels. We sought to provide direct evidence for such speculation by recording currents in response to 5-HT application from outside-out membrane patches obtained from dissociated guinea-pig submucosal neurones. External/internal solutions were:NaCl 164,$MgCl_2$ 1, $CaCl_2$ 1, glucose 11, HEPES 10/Cs-glutamate 160, $MgCl_2$ 1, CaCl 1, EGTA 10, HEPES 10. 5-HT (1-10 μM) caused the appearance of unitary inward currents of two discrete amplitudes whose chord conductances were 15 pS and 9 pS. Open probability (p_o) of the smaller, but not the larger, channel fell markedly during 2-5 min application of 5-HT; therefore we studied mainly the 15 pS channel. This channel showed fast openings and bursts of openings; uncorrected open times showed two exponentials (τ_1 = 0.4 ms, τ_2 = 6 ms) and at least three closed states were demonstrated. ICS 205-930, reduced p_o, primarily by altering the closed states.

Whole cell recordings (using identical solutions) were made to further characterize the 5-HT_3 response. 5-HT (1-10 μM) caused rapidly desensitizing inward currents which reversed at +3 mV with a $Na^+/K+$ conductance ratio of 2.3; the response did not require internal ATP or GTP and was not blocked by pertussis toxin pretreatment.

387.11

EXTRACELLULAR ATP ACTIVATES POTASSIUM CHANNELS IN CHICK SKELETAL MUSCLE. S. A. Thomas and R. I. Hume. Department of Biology, University of Michigan, Ann Arbor, MI 48109

In developing chick skeletal muscle, micromolar concentrations of extracellular adenosine 5'-triphosphate (ATP) elicit a late potassium conductance in addition to an early excitatory response. The potassium conductance activates with a delay of approximately one second and is greatly reduced at low temperature, suggesting that a second messenger may be involved. In order to examine the mechanism of activation, we voltage-clamped myoballs using the whole-cell patch clamp technique, which allowed us to internally dialyze the cells.

ATP elicited an outward potassium current at the reversal potential for the early excitatory current. Activation of the potassium current was calcium independent, since the magnitude of the current was unaffected by dialyzing cells with 20 mM BAPTA and no calcium. Activation was also independent of G protein alpha subunits, since the current was similar when cells were dialyzed for 10-15 minutes with either GTP, GDP-beta-S, or GTP-gamma-S. Activation of the current through protein phosphorylation was unlikely, since dialysis with an intracellular cocktail of metabolic inhibitors had no effect. Noise analysis yielded spectral estimates for the single channel conductance of approximately 20 pS. Activation of the potassium current by cytoplasmic second messengers was ruled out when we found that ATP activated 22 pS potassium channels in outside-out membrane patches. If a second messenger is involved, these results suggest that it is intramembranous. Possible candidates include arachidonic acid, released from lipids by phospholipase A_2, and its metabolites, prostaglandins and leukotrienes. We have found that several prostaglandins activate potassium channels in outside-out membrane patches, and are currently examining whether these channels are the same as those activated by ATP.

387.12

CATIONS AND ANIONS PERMEATE A SINGLE ATP-ACTIVATED CHANNEL IN CHICK SKELETAL MUSCLE. R. I. Hume and S. A. Thomas. Department of Biology, University of Michigan, Ann Arbor, MI 48109

Micromolar concentrations of extracellular adenosine 5'-triphosphate (ATP) elicit a rapid excitatory response in developing chick skeletal muscle. Excitation is the result of a simultaneous increase in membrane permeability to cations and anions. ATP does not induce the formation of large membrane pores, since ions such as tetraethylammonium and glucuronate are impermeant during the response. Here we test whether cations and anions permeate a single ATP-activated channel which does not discriminate by charge, or whether they permeate separate cation and anion channels concurrently activated by ATP.

Experiments were performed on myoballs using the whole-cell patch-clamp technique. This method permitted internal dialysis of the cells and control of the membrane potential. In order to determine if one or two types of ATP-activated channels were present, we analyzed the fluctuations about the mean current induced by ATP. Ionic conditions were arranged so that the reversal potential for cations was +50 mV and the reversal potential for anions was -50 mV. Under these conditions, if ATP activates a single channel that does not select by charge, ATP should not evoke an increase in noise at its reversal potential. However, if ATP activates separate cation and anion channels, ATP should evoke a significant increase in noise at its reversal potential. At both +40 mV and -50 mV ATP elicited a clear increase in noise, but at the ATP reversal potential of -5 mV no increase in noise above background was seen. These results indicate that there is only a single excitatory ATP-activated channel type, which is nonselective by charge. Based on analysis of the noise spectrum, the conductance of the channel was approximately 0.3 pS.

PEPTIDES: PHYSIOLOGICAL EFFECTS III

ROLES OF SOMATOSTATIN (SRIF) AND GROWTH HORMONE RELEASING FACTOR (GRF) IN ETHER STRESS INHIBITION OF GROWTH HORMONE (GH) RELEASE. M.C. Aguila*, R. Pickle*, W. Yu* and S.M. McCann. Dept. Physiology, Neuropeptide Div., Univ. TX Southwestern Med. Ctr., Dallas, Texas 75235.

In order to evaluate the release of somatostatin (SRIF) and growth hormone releasing factor (GRF) into the pituitary gland in response to ether stress, a push-pull-perifusion (PPP) technique has been used in freely moving rats. Push-pull cannulae (PPC) were implanted into the anterior pituitary (AP) gland of male rats (250-270 g). After a 7 day recovery period the rats were fitted with indwelling jugular catheters. The next day the animals were subjected to PPP of the AP during one hour followed by ether stress (2 min) and another hour of perifusion. The perifusion flow was 20 μl/min and 10 min fractions were collected and assayed for SRIF and GRF by RIA. Plasma GH levels were assayed every 10 min. At the end of the experiments, the accuracy of PPC tip placements was ascertained with a dissecting microscope. Under basal conditions SRIF and GRF output pulsed at 20-40 min intervals. SRIF and GRF output in the ten min period beginning with application of ether was increased two-fold ($p<0.005$ and $p<0.01$, respectively). Interestingly, the release of SRIF continued for an additional 10 min, whereas GRF output decreased and was almost undetectable. The release of both GRF and SRIF receded to basal values 20-30 min after stress. Plasma GH levels were significantly lowered 10 min after stress. Each of the 9 animals showed a restoration of pulsatile GH release to above basal levels within 20 to 30 min after stress. Our findings provide compelling evidence that somatostatin plays a prominent role in stress- induced inhibition of GH release in the rat by blocking the response to the transient elevation of GRF and continuing to suppress GH release for 20 min.

NEUROPEPTIDE Y STIMULATES GnRH RELEASE FROM SIMIAN HYPOTHALAMI. K.-Y.F. Pau*, A.H. Kaynard* and H.G. Spies. (SPON. Y.F. Chen) Oregon Regional Primate Research Ctr., Beaverton, OR 97006.

Feeding, cardiovascular, and reproductive functions are modified by neuropeptide Y (NPY) action. In the rat and rabbit, NPY alters the secretion of gonadotropin-releasing hormone (GnRH) and luteinizing hormone (LH), both *in vitro* and *in vivo*. We utilized simian (macaque and baboon) hypothalami in *in vitro* superfusion studies to examine the release of GnRH and ß-endorphin (ß-EP) from isolated fragments of the anterior hypothalamus (AH) and the mediobasal hypothalamus (MBH) in response to NPY treatment. Within 3 min after death, blocks of hypothalamic tissue in ice-cold Locke's medium were sectioned along the ventricular midline into left and right halves. The AH/MBH blocks were distinguished rostrally by the anterior commissure and caudally by the mamillary bodies; the AH and MBH were separated at the caudal end of the optic chiasm. These 4 fragments (left and right AH, left and right MBH) were placed into individual superfusion chambers submerged in a 40°C-water bath and were superfused with Hepes-buffered Locke's medium (pH 7.40). Samples (400μl) were collected at 10-min intervals into tubes containing 40μl of 1N acetic acid. Hypothalamic fragments received either 6 h of Locke's medium (controls) or 3 h of Locke's medium followed by 3 h of 80 nM of NPY in Locke's medium. GnRH and ß-EP in perfusate samples were measured by RIA and values were compared by two-way ANOVA followed by Newman-Keuls. GnRH levels rose within 20-30 min of NPY treatment ($p<0.01$) and elevated GnRH release by both the AH (n=12) and MBH (n=13) was sustained for the duration of NPY exposure. NPY caused no measurable change in ß-EP concentrations in perfusates of AH (n=10) or MBH (n=9). Exposure to Locke's medium alone for 6 h caused no increase ($p>0.05$) in GnRH or ß-EP release from AH (n=6) and MBH (n=7). These results suggest that NPY stimulates GnRH neurons via mechanisms that do not involve the release of ß-EP. Supported by RR-00163, HD-16631, HD-18185, HD-07044.

A NOVEL HYPOTHALAMIC NEUROPEPTIDE WITH 38 RESIDUES (PACAP38) STIMULATES ADENYLATE CYCLASE ACTIVITY IN PITUITARY CELLS, NEURONS AND ASTROCYTES. G. Katsuura*, R.R. Dahl*, A. Miyata* and A. Arimura (SPON: F. R. Domer), U.S.-Japan Biomedical Res. Labs, Tulane Univ. Hebert Center, Belle Chasse, LA 70037; and Depts. of Medicine & Anatomy, Tulane Univ. Sch. of Med., New Orleans, LA 70112.

We have recently isolated and characterized a novel hypothalamic neuropeptide with 38 residues from ovine hypothalamic tissues by monitoring adenylate cyclase activation in rat pituitary cell cultures during isolation. This peptide was named as PACAP38 (Pituitary Adenylate Cyclase Activating Peptide with 38 residues). It was found that PACAP38 had 68% homology with porcine VIP in the C-terminus region 1-28. We examined the effect of synthetic PACAP38 on intracellular accumulation in cultured rat pituitary cells, neurons and astrocytes in comparison with VIP. In anterior pituitary cell cultures, PACAP38 (10^{-9} M) increased cAMP 4-fold at 1 min after addition, as compared with control levels. Cyclic AMP increased by 15-fold at 10 min. Phosphoinositide hydrolysis in pituitary cells was not altered by PACAP38. A similar increment of intracellular cAMP was observed in cultured neurons with the peak occurring at 10 min after addition of the peptide. cAMP levels began decreasing after 10 min in both pituitary cells and neurons. On the other hand, an extraordinarily large increase in cAMP accumulation was demonstrated in cultured astrocytes after addition of PACAP38 (10^{-9} M). Cyclic AMP increased 30-fold at 1 min and 100-fold at 5 min after addition, and remained elevated during a 60 min incubation. It was interesting to note that VIP at the same concentration (10^{-9} M) failed to increase intracellular cAMP levels in pituitary cells, neurons, or astrocytes. Although distribution of PACAP38 in the brain remains to be elucidated, the possibility that various central actions which have been attributed to VIP may actually be regulated by PACAP38 cannot be excluded. (This study was supported by NIH grant DK09094.)

THE ORTHODROMIC RESPONSE OF CORTICO-MEDIAL AMYGDALA (AMYG) NEURONS TO SEPTAL AREA STIMULATION IS MODULATED BY ESTROGEN PRIMING. C.A. Dudley, Y. Lee*, and R.L. Moss. Department of Physiology, UT Southwestern Medical Center, Dallas, Texas 75235

One source of input to the AMYG is derived from GnRH neurons in the septal area (Jennes, Brain Res. 404: 339, 1987). The present electrophysiological study was designed to identify AMYG neurons receiving septal input, to determine the influence of estrogen priming on the orthodromic response, and to test the effect of iontophoretically applied GnRH. Ovariectomized female rats, primed (n=10) or not (n=18) with estrogen (EB, 2ug 44 hrs prior to recording) were anesthetized with urethane (1.4g/kg) and prepared for conventional *in vivo* extracellular recording. A stimulating electrode was positioned in the medial septal area to orthodromically drive AMYG neurons. A multi-barrelled glass pipette was used to record single-cell activity in the AMYG and to eject GnRH. Orthodromic responses were analyzed by collecting peristimulus-time histograms. In both primed and unprimed animals, a large percentage of neurons were orthodromically responsive (57 of 103 in primed animals and 46 of 70 in unprimed animals). EB-priming significantly increased the number of orthodromic inhibitory responses. In the small number of GnRH-responsive neurons, no consistent relationship between the GnRH response and the orthodromic response was observed. However, in a few instances, GnRH modulated the orthodromic response; i.e., decreased the amount of orthodromic excitation or inhibition. Although the identity of the neurotransmitter(s) remains to be established, the results demonstrate a substantial, estrogen-sensitive input from the septal area to the amygdala. LHRH BLOCKS ACCOMMODATION OF CA1 PYRAMIDAL CELL DISCHARGE IN THE *in vitro* HIPPOCAMPUS SLICE PREPARATION. R. L. Moss, M. Wong*, and M. J. Eaton. Dept.of Physiology, Univ. Texas Southwestern Medical Center, Dallas, Tx 75235.

Specific luteinizing hormone releasing hormone (LHRH) receptor binding sites have recently been visualized with autoradiography in the hippocampus of the rat brain, in particular in the pyramidal cell layer (Br. Res. 452, 156, 1988). A previous study has suggested that application of LHRH produces a long lasting depolarizing response in CA1 hippocampal cells (Neuroend. 44, 137, 1986). The present series of experiments were designed to elucidate more specifically the effects of LHRH on the intracellular electrophysiology of CA1 neurons in the *in vitro* hippocampal slice preparation. Transverse vibratome sections (425 microns) through the hippocampus were obtained from female rats and subsequently superfused with oxygenated, normal artifical cerebrospinal fluid (ACSF) at a flow rate of 2.0 ml/min at 32°C. Single barrel glass electrodes were filled with either 3M KCl (80-90 MΩ) or 3M K acetate (90-120 MΩ) and utilized for intracellular recording as well as for applying depolarizing and hyperpolarizing stimuli to the cell via a Medical Systems DC Amplifier. The findings reported here are based on intracellular recordings from over 40 cells with resting membrane potentials of greater than -55mV. Superfusion of LHRH (10^{-7} and 10^{-9}M) initiated a short latency, long duration depolarization of CA1 neurons of the hippocampus that was accompanied by an increase in input resistance of the cell and was not affected by the application of a low Ca^{2+}, high Mg^{2+} ACSF. This result suggests that LHRH acts directly on the pyramidal cell membrane. We have also found that LHRH blocks or reduces the spike frequency adaptation (accommodation) which normally occurs with depolarizing stimuli. Research is presently in progress to examine the underlying mechanisms of LHRH action on hippocampal pyramidal cells. (NIH MH-44591 & HD-09988).

PARAVENTRICULAR MICROINFUSIONS OF AII AND AIII IN NORMOTENSIVE RATS INDUCE PRESSOR RESPONSES. Laurie L. Jensen, Joseph W. Harding, and John W. Wright. Washington State University,Pullman, WA.. 99163. Angiotensin II (AII) immunoreactivity has been reported in cells of the paraventricular nucleus of the hypothalamus (PVH); (Lind & Swanson, 1985), and the microiontophoretic applications of AII and angiotensin III (AIII) has been shown to excite PVH cells with AIII inducing significantly shorter latencies of activity than AII (Harding & Felix, 1987). This finding was interpretted to suggest that AII may have to undergo conversion to AIII in order to serve as a ligand. In the present experiment anesthetized rats received microinfusions of AII and AIII at doses of 0, 10, 50, 100, and 250 pmoles in a total volume of 50 nl aCSF into the PVH. The figure below indicates dose dependent increases in blood pressure to both AII and AIII, thus extending earlier findings by Brosnihan et al. (1987) who tested only AII, and supporting the notion that AIII is an important ligand in the PVH. Supported by NIH grant HL32063 & TW01112 and the American Heart Association.

DES-LEU ANGIOTENSIN I IN THE RENIN-ANGIOTENSIN PATHWAY — IS THERE A SECOND CARBOXYL CLEAVAGE? D. G. Changaris* and R. S. Levy, Depts. of Surgery & Biochemistry & Lab. Biol. Psychiatry, University of Louisville School of Medicine, Louisville, KY 40292

Des-leu angiotensin I (AI-dl) is twenty to thirty times more potent hypertensively when injected into the brain of the rat as opposed to injection into the cardiovascular system. This peptide is nearly equipotent with angiotensin II (AII) in its ability to induce the drinking response when injected into the cerebroventricles (Regul. Pept. 20, 273-280, 1988). Since both captopril and saralasin can inhibit this response, it is likely that the drinking response requires the hydrolysis of AI-dl to angiotensin II (AII) or to the heptapeptide, des-phe angiotensin II. To explore the first possibility, D-amino acid substitutions of the carboxyl terminus were made during the synthesis of AI and AI-dl. The dipsogenic responses from intraventricular (IVT) injections of doses ranging from 1.0 to 2.5 nmoles of each peptide were recorded. D-leu AI was half as potent as the normal L-substituted AI after IVT injections of 1.0 to 2.5 nmoles. D-his AI-dl produced a negligible drinking response at these doses as compared with the normal L-substituted AI-dl. These data support the observation that a second, single carboxyl cleavage of AI-dl occurs before it can act as a dipsogen in the rat. (Supported by NIH-CIDA 531621; VA-DOD 002; and Glenmore Foundation.)

A CENTRAL VASOPRESSINERGIC MECHANISM MEDIATES SALICYLATE BUT NOT ACETAMINOPHEN-INDUCED ANTIPYRESIS. M.F.Wilkinson* and N.W.Kasting. Dept. of Physiology, Univ. of British Columbia, Vancouver, B.C., Canada.

We have recently demonstrated that the antipyretic action of indomethacin is dependent upon the vasopressin (AVP) V_1-receptor within the ventral septal area (VSA) of the brain. The purpose of this study was to assess the antipyretic effects of sodium salicylate (SALIC) and acetaminophen (ACETA) during V_1-receptor blockade within the VSA. Male SD rats were stereotaxically implanted with VSA and intracerebroventricular (icv) cannulae. Body temperature (T_b) was monitored remotely via radiotelemetry. Fever was induced by E.coli endotoxin icv. After 150 min the V_1-antagonist or saline was administered into the VSA immediately followed by SALIC or ACETA (75 mg/kg) ip. A 2h thermal index was calculated from the time of drug administration for statistical analysis. The V_1-antagonist attenuated SALIC-induced antipyresis in a dose-related manner: saline(VSA)+SALIC, -1.71 ± 0.20 °C hr; 1.0 µg V_1-antagonist(VSA)+SALIC, -0.57 ± 0.13 °C h ($p<0.05$); 10.0 µg V_1-antagonist(VSA)+SALIC, $+0.06\pm0.48$ °C h ($p<0.01$). However, the antipyresis induced by ACETA was unaffected by the V_1-antagonist. Neither dose of the V_1-antagonist or saline within the VSA affected non-febrile T_b. These results indicate that, like indomethacin, SALIC but not ACETA activate AVP V_1-receptors within the VSA during drug-induced antipyresis. (Supported by the MRC of Canada.)

BRADYKININ EVOKES AN INWARD CURRENT IN A SENSORY NEURON-DERIVED CELL LINE. John N. Wood, Philip M. Dunn*, Pat Hogan+, and Humphrey P. Rang* (SPON. L. Lillien) The Sandoz Institute, 5 Gower Place, London W.C.1, +Department of Neurobiology, Harvard Medical School, Boston, Mass 02115.

A battery of DRG-derived cell lines (ND cells) has been generated by fusing the HAT-sensitive neuroblastoma line N18Tg2 with neonatal rat DRG cells. After sub-cloning, lines that expressed the rat surface marker Thy 1.1, and the sensory neuron marker globoseries and lactoseries glycolipids were investigated. The sensory neuron-like characteristics exhibited by various lines include expression of δ-opioid receptors, depolarisation in response to capsaicin and susceptibility to latent infection with Herpes Simplex Virus. One line - ND7/23 - when differentiated with 1mM dibutyryl cAMP in the presence of 0.5% FCS and NGF, responded to bradykinin with an inward current and an increase in membrane conductance (18/50 cells). The mean latency of the response was 7.5 ±1.6 sec, the time to peak 47 ±6.8 sec, and the amplitude of the response was 0.2 ±0.05nA. The reversal potential (n=3) was 11.6 ±6mv. The characteristics of this response are shared by DRG neurons, and are distinct from the hyperpolarisation with an outward current demonstrated by other neuronal cell lines (e.g.NG108.15). ND7/23 cells, like DRG neurons, show elevated levels of cGMP on bradykinin application. Injection of mRNA from rat DRG and ND7 cells confers bradykinin sensitivity on Xenopus oocytes, which depolarise with the characteristics of an IP3-coupled response on bradykinin application. This cell line thus provides a useful model for the analysis of bradykinin-evoked activation of sensory neurons.

PERIVAGAL APPLICATION OF CAPSAICIN ABOLISHES THE RESPONSE OF VAGAL GASTRIC MECHANORECEPTORS TO CHOLECYSTOKININ. Helen E. Raybould and J.S. Davison. CURE/VA Wadsworth Medical Center, Dept of Medicine and Brain Research Institute, UCLA, Los Angeles, CA 90073 and Dept of Medical Physiology, University of Calgary, Alberta, T2N 4N1.

Exogenous administration of cholecystokinin-8 (CCK) in anesthetized rats decreases proximal gastric motility and delays gastric emptying partly via a capsaicin-sensitive vagal afferent pathway (Raybould & Taché, Am. J. Physiol. 255, G242, 1988). Recordings were made from single afferent fibers isolated from the cervical vagus of urethane-anesthetized rats (n=8). Gastric motility was monitored manometrically using a catheter placed in the gastric corpus. Four rats were pretreated by perivagal application of capsaicin (1% in 10% Tween 80 in olive oil) under pentobarbitone anesthesia 8-12 days prior to experiments. All units (n=20) studied were spontaneously active and increased their discharge in response to gastric distension (2-5 ml). In control rats, all 10 units increased their discharge following intravenous administration of CCK-8 (100 pmol); this was not associated with an increase in intragastric pressure. In capsaicin-pretreated rats, the response to gastric distension was indistinguishable from that obtained in control rats; in contrast only 1 of the 10 units increased their firing frequency in response to CCK-8. Conclusions: CCK stimulates the discharge of vagal gastric mechanoreceptors. The response to CCK, but not gastric distension, is capsaicin-sensitive. These results provide electrophysiological evidence for the capsaicin-sensitive changes in gastric motor function and feeding behaviors following peripheral administration of CCK. HER in receipt of an SKB fellowship. Supported by the MRC Canada.

NEUROANTIBODIES: MOLECULAR CLONING OF A MONOCLONAL ANTIBODY AGAINST SUBSTANCE P FOR ITS EXPRESSION IN CELLS OF THE NERVOUS SYSTEM. A.Cattaneo*, F.Ruberti* and P.Piccioli* (SPON: F.Tirone). CNR Institute of Neurobiology, Roma (Italy).

Recent results showing the efficient secretion of immunoglobulins by neuronal and glial cell lines (Cattaneo and Neuberger, EMBO J. 6: 2753, 1987) have led to the suggestion that it might be possible to engineer the secretion of specific monoclonal antibodies in the nervous system of an organism in order to perturb or modulate the activity of selected neuronal pathways or cell populations (neuroantibodies) (Cattaneo, Ann.Ist.Sup.Sanita' 24: 531, 1988). A prerequisite for the neuroantibodies technique is the molecular cloning of the desired monoclonal antibody from the corresponding hybridoma cell line. We now report the molecular cloning of the heavy and light chain of the NC1 monoclonal antibody which was produced against the neuropeptide substance P (Cuello et al. 1979), with the aim of expressing it in the CNS of a transgenic organism. The derivation and characterization of cDNA clones corresponding to the variable regions of the heavy and light chains of the NC1 antibody will be described, together with the reconstitution of DNA fragments encoding a functional NC1 antibody, in a suitable form for expression in the CNS.

388.12

FUNCTIONAL SIGNIFICANCE OF CHOLINERGIC AND VIP-ERGIC EFFECTS AT THE THYROID GLAND. L.J. Huffman*, M. Michalkiewicz*, J.M. Connors*, Z. Pietrzyk* and G.A. Hedge, Department of Physiology, West Virginia University Health Sciences Center, Morgantown, WV 26506.

In the thyroid gland, vasoactive intestinal peptide (VIP) and acetylcholine (ACh) are found in nerve fibers associated with secretory cells and blood vessels. We have, therefore, initiated studies to explore the actions and interactions of ACh and VIP in the regulation of thyroid blood flow (BF) and circulating hormone levels. Previously, we have shown that VIP increases thyroid BF in a dose-related manner. In order to evaluate whether VIP might exert any of its thyroidal effects via muscarinic receptors, we assessed the effects of ACh and VIP in the presence and absence of the muscarinic receptor blocker, atropine. Anesthetized male rats were treated iv with saline or atropine (3 mg/kg) 20 min before iv infusions of vehicle, ACh ($3x10^{-8}$ moles/100gBW), or VIP (10^{-11} moles/100gBW). Organ BFs were measured during this time using radiolabelled (^{141}Ce) microspheres. Mean systemic arterial pressure (MABP) was monitored and used in the calculation of organ vascular conductances (VC=BF/MABP). Atropine pretreatment tended to increase thyroid VC (170.7±37.3 vs. 104.8±19.7 μl/mmHg · min · g) and the vasodilatory effect of VIP was greater if the rats were pretreated with atropine. When the data were normalized for this stimulatory effect of atropine, the ACh-induced increase in thyroid VC was abolished during muscarinic blockade whereas the vasodilatory effect of VIP was unaffected. These results are consistent with the hypothesis that VIP and ACh exert their effects at the thyroid gland through independent mechanisms and that VIP release may be under prejunctional control via muscarinic receptors. (AM 35037)

388.13

ACETYLCHOLINESTERASE MODULATES MEMBRANE PROPERTIES AND SYNAPTIC TRANSMISSION IN MAMMALIAN CEREBELLAR CORTEX. H. Jahnsen* & M. Appleyard* (SPON: J. Mogensen). Institute of Neurophysiology, Blegdamsvej 3c, DK-2200 Copenhagen N, Denmark.

In addition to being a hydrolytic enzyme in the CNS acetylcholinesterase (AChE) may change membrane properties of central neurons. Indeed, in the substantia nigra AChE hyperpolarizes pars compacta cells thus changing their firing behavior (Greenfield et al., *Exp. Brain Res.*, 70:411, 1988). AChE is present in the cerebellar cortex, and can be released in a Ca^{2+} dependent manner by stimulation of climbing fibers (Appleyard et al. *Neurosci.*, 25:133, 1988). In order to measure possible effects on cerebellar neurons slices of guinea pig cerebella were cut and maintained using standard techniques. Intracellular recordings from Purkinje neurons revealed three different actions of AChE when added to the superfusing medium (10-20 U/ml). 1: The late part of the climbing fiber response was enhanced so that action potentials often was generated for tens of milliseconds after stimulation; 2: Responses to excitatory amino acids were increased in amplitude as well as in duration and 3: The threshold for firing of Ca^{2+} spikes in response to depolarizing intracellular current injection was increased. All the effects persisted when the catalytic site of AChE was blocked. These results indicate that AChE may have a role as modulator in the cerebellar cortex. An alternative possibility is that the enzyme has a tertiary structure similar to a natural endogenous modulator.

CYCLOPENTYLADENOSINE-INDUCED DOWNREGULATION OF A_1 ADENOSINE RECEPTORS IN EMBRYONIC CHICK HEART. T.A. Blair* and T.F. Murray (SPON:R.A.Dodson). Oregon State Univ., Corvallis, Oregon 97331.

Investigations utilizing embryonic chick atria had indicated that adenosine analogs elicit their negative chronotropic effect via an A_1 adenosine receptor (AdR). In the present study we have employed the developing chick heart as a model system to investigate the regulation of AdRs. Sustained activation of AdRs was accomplished with in ovo (day 9) injections of the A_1-selective adenosine agonist cyclopentyladenosine (CPA). Treatment with CPA resulted in a decreased AdR number as measured by the specific binding of the antagonist radioligand 8-cyclopentyl-1,3-[^{3}H]dipropylxanthine ([^{3}H]DPCPX). The binding parameters derived from nonlinear regression analysis of [^{3}H]DPCPX saturation isotherms indicated that in ovo treatment with 1 μmol CPA produced a 46$\pm$11% reduction in the density of A_1 receptors in cardiac membranes. The Kd value for [^{3}H]DPCPX binding to AdRs in CPA treated membranes was not significantly different from the saline treated value (CPA 2.9$\pm$0.1nM; saline 3.1$\pm$0.9nM). The decrease in receptor number was dose dependent suggesting a receptor mediated event. The maximum dose of CPA (10 μmol) resulted in a 77% decrease in the density of adenosine receptors with an ED_{50} for the CPA-induced down regulation of 2.5 μmol. Administration in ovo of 1 μmol CPA resulted in a decrease in the number of [^{3}H]DPCPX binding sites which was apparent by 4 hours and increased throughout the time span evaluated (24hr) when compared to saline treated controls. Co-injection of theophylline was able to attenuate the decrease in AdR number induced by 1 μmol CPA. These data suggest chronic exposure of embryonic day 9 chick hearts to an adenosine analog effects a downregulation of A_1 adenosine receptors.

389.2

REGULATION OF CELL SURFACE EXPRESSION AND FUNCTIONAL ACTIVITY OF NICOTINIC ACETYLCHOLINE RECEPTORS ON THE TE671 CLONAL LINE. Anna M. Joy* and Ronald J. Lukas (SPON. A.G. Shetter). Division of Neurobiology, Barrow Neurological Institute, Phoenix AZ 85013.

The TE671 cell line expresses a nicotinic acetylcholine receptor (nAchR) with many similarities to muscle nAChR, yet the regulation of functional activity and expression of nAChR following chronic agonist exposure is clearly different in each system. Effects on cell surface expression (measured as alpha-bungarotoxin binding sites per mg of membrane protein) and functional activity (evaluated using a Rb efflux assay) of nAChR on TE671 cells were assessed using various agents that stimulate or suppress activities of protein kinases A or C or modulate G protein coupling. Dibutyryl cyclic AMP (dbcAMP; 1mM) treatment induces down-regulation in cell surface nAChR expression within two days of drug exposure whereas the phorbol ester, PMA (10 uM), initially (one day) down-regulates and then increases the number of cell surface nAChR. By contrast, cholera toxin (200 ng/mL) induces a rapid (within 5 hours) down-regulation in the number of cell surface nAChR. At these concentrations of PMA, dbcAMP, or cholera toxin, functional nAChR responses (normalized to receptor number) are not changed. These results suggest that second messenger system perturbants have the capacity to regulate levels of nAChR expression without overtly altering nAChR functional activity.

EVIDENCE AGAINST THE INVOLVEMENT OF PROTEIN KINASE C IN AGONIST-INDUCED DESENSITIZATION OF NEUROTRANSMITTER RECEPTORS COUPLED TO PHOSPHOLIPASE C. D.-M. Chuang and O. Dillon-Carter. Lab. of Preclinical Pharmacology, National Institute of Mental Health, St. Elizabeths Hospital, Washington, D.C. 20032.

Primary culture of cerebellar granule cells express muscarinic cholinergic, α_1-adrenergic, serotoninergic 5-HT_2 and histaminergic receptors coupled to phosphoinositide (PI) hydrolysis. Exposure of granule cell neurons to a receptor agonist for each of these receptors resulted in time-dependent desensitization of the receptor-mediated PI response. The muscarinic receptor was relatively resistant to desensitization and the desensitization appeared to precede the loss of receptor binding sites. Although phorbol esters effectively inhibited the PI response mediated by each of these receptors, several lines of evidence speak against the involvement of protein kinase C in the agonist-induced desensitization. Thus, incubation of cells with a protein kinase C inhibitor H_7 (25-100 μM) prior to preexposure with carbachol, NE, 5-HT or histamine, did not affect agonist-induced desensitization. Depletion of majority of protein kinase C in granule cells by 24 hr incubation with a phorbol ester, PMA or PDB, also did not alter agonist-induced desensitization. Moreover, agonist-induced desensitization was detected even when cells were prestimulated with agonists at 4°C; at this temperature, agonist-induced PI breakdown was completely arrested.

389.4

PHORBOL ESTER INHIBITS AGONIST-INDUCED 3H-INOSITOL PHOSPHATE FORMATION BY ACTING ON A TARGET OTHER THAN PROTEIN KINASE C. S.V. Bhave*, R.K. Malhotra*, T.D. Wakade*, A.R. Wakade (Spon. R. Gala). Dept. of Pharm. Wayne State Univ., Detroit, MI 48201

It has been suggested that protein kinase C (PKC) is negatively coupled to phosphoinositide hydrolysis because phorbol esters inhibit agonist induce inositol phosphate formation. This hypothesis was investigated by using other agents known to activate PKC via membrane receptors. Formation of ^{3}H-inositol monophosphate (^{3}H-IP) was estimated in embryonic chick sympathetic neurons maintained in culture. Acetylcholine (ACh, 100 uM) caused 10-fold increase in ^{3}H-IP formation. Phorbol 12,13-dibutyrate (PDB) inhibited ACh-induced ^{3}H-IP formation in a dose-dependent manner. However, activation of PKC by serotonin (5-HT, 1 uM), ACh (100 uM) or muscarine (100 uM) had no inhibitory effects on ACh-induced ^{3}H-IP formation. Inhibitory effects of PDB on ACh-induced ^{3}H-IP formation persisted even in presence of H_7 (1 uM) or sphingosine (100 uM) which completely blocked PKC activity. Since other activators of PKC failed to mimic and since inhibitors of PKC failed to block the effects of PDB on phosphoinositide hydrolysis, we suggest that phorbol esters may act on sites other than PKC to modulate neuronal metabolism.

EFFECTS OF PHORBOL DIESTER ON THE INTERACTION OF ADRENOCEPTORS AND ADENYLYL CYCLASE IN RABBIT UTERINE MYOCYTES: MODULATION BY SEX STEROIDS. J. M. Savola* and J. M. Roberts. Reprod. Endocrinol. Center and C. V. R. I., Univ. California, San Francisco, CA 94143.

Previous studies from our laboratory indicate that the sex steroids, estrogen and progesterone, modulate contractility and other functions regulated by adrenergic β and α_2-adrenoceptors in the rabbit uterus. To study whether this modulation involves an action of the sex steroids on protein kinase C (PKC), we injected ovariectomized rabbits with sex steroids (with estrogen 50 μg/kg i.m., 4 days, or after a priming 4-day-period with estrogen with progesterone 5 mg/kg i.m., 4 days), isolated uterine myocytes, and measured β and α_2-adrenoceptor-mediated effects on adenylyl cyclase activity after 16 h in culture. We measured adenylyl cyclase activity using a [^{3}H]adenine-prelabeling technique, isolating [^{3}H]cAMP by sequential Dowex and alumina column chromatograhy. We found that activation of PKC with phorbol 12-myristate 13-acetate (1 μM, 1 h) in myocytes from rabbits injected with vehicle, estrogen, or progesterone impaired the increase in adenylyl cyclase activity induced by the β-adrenoceptor agonist isoproterenol. Furthermore, this effect was greater in the cells from the rabbits not injected with the sex steroids. In contrast, in the all groups PKC activation had no significant effect on the ability of epinephrine to activate α_2-adrenoceptors and inhibit adenylyl cyclase stimulated by forskolin or prostaglandin E_2. In conclusion, our results indicate that PKC activation impairs the β but not α_2-adrenoceptor-related signal transduction pathway of uterine myocytes, and this effect is modulated by the sex steroids.

MODULATION OF 5-HYDROXYTRYPTAMINE$_{2A}$ RECEPTOR DENSITY BY GUANINE NUCLEOTIDES. M.A.Harrington and S.J.Peroutka. Department of Neurology, Stanford University School of Medicine, Stanford, CA 94305.

The 5-hydroxytryptamine$_{2A}$ (5-HT_{2A}) is a subtype of the 5-HT receptor which is selectively labeled by ^{125}I-R-(-)2,5-dimethoxy-4-iodophenylisopropylamine (^{125}I-R-(-)DOI), ^{77}Br-R-(-)-4-bromo-2,5-dimethoxyamphetamine (^{77}Br-DOB) and ^{3}H-DOB. Radioligand binding studies were used to study the effect on affinity (K_D) and B_{max} of ^{125}I-DOI binding in rat cortical membranes after pre- or co-incubation with 10^{-4} M ATP, GTP or GTPYS. Co-incubation with either GTP or GTPYS significantly increased the K_D by 57 $\pm$ 10%, while co-incubation with GTP and GTPYS significantly reduced the B_{max} of ^{125}I-DOI binding by 37 $\pm$ 10% and by 51 $\pm$ 10%, respectively. Co-incubation with ATP increased the K_D and reduced the B_{max} of ^{125}I-DOI binding, but the changes were not significant.

The change in B_{max} observed in the presence of GTP and GTPYS is completely reversible as shown by pre-incubation studies. Pre-incubation of the membranes with GTP produced no significant change in either the K_D or the B_{max} of ^{125}I-DOI binding. By contrast, pre-incubation with GTPYS has no effect on the B_{max}, but significantly increased the K_D by 55 $\pm$ 15%. These data differ considerably from the results of analogous experiments performed with the 5-HT_{1A} and 5-HT_{1D} receptors, and may supprt a different mechanism of regulation of 5-HT_{2A} receptor density and affinity through the actions of G proteins.

CELLULAR ADAPTATION TO OPIATE EXPOSURE INVOLVES AN ADDITIONAL RECEPTOR-BASED PROCESS DISTINCT FROM DESENSITIZATION AND DOWNREGULATION. M v Zastrow*, J D Barchas and C J Evans, Pritzker Laboratory of Behavioral Neurochemistry, Stanford University.

We are using NG108-15 cells as a model system to study cellular mechanisms of opiate tolerance and withdrawal. NG108 cells, following exposure to peptide (DADL) or alkaloid (etorphine) agonist, show marked alteration of agonist binding that can be distinguished from desensitization and receptor downregulation by kinetic and pharmacologic criteria. This alteration is selective for peptide agonist; alkaloid agonist and antagonist binding characteristics appear to be largely unchanged. We are most interested in the observation that morphine is capable of reversing this effect completely. By use of a photoaffinity ligand developed recently in our laboratory, we have identified several opiate-binding species and are exploring this receptor-based adaptation further at the molecular level. These findings reveal an additional component of cellular adaptation to opiate exposure.

ENDOGENOUS MODULATORS FOR BRAIN L-GLUTAMATE AND GABA RECEPTORS. C.C. Liao,*[2,3] C.J. Lin,*[2,3] Y.H. Lee,*[1] J.Y. Ho,*[1] W.H. Tsai,*[1] and J.-Y. Wu.[1,2,3] [1]Inst. Biomed. Sci., Academia Sinica, Taipei, Taiwan; [2]Neurosci. Program & Dept. Anatomy, Penn St. Univ., Hershey, PA 17033; [3]Dept. Physiol. & Cell Biol., Univ. Kansas, Lawrence, KS 66045

It is known that the activity of L-glutamate receptors (GluR) and GABA receptors (GABAR) is greatly enhanced by repetitive freezing, thawing, and washing of the membrane preparations suggesting the presence of endogenous modulators (EM) that can modify the receptor activities. Indeed, when the membrane extracts were added to the binding mixture, they inhibited the binding of ^{3}H-L-Glu/^{3}H-muscimol to the receptor. The EM for GluR were separated into two components, one as activators and the other one as inhibitors, on Bio-gel P2 column. However, the EM for GABAR were found to be only inhibitory. The EM for GluR and GABAR are distinctly different from L-Glu or GABA itself as judged from the elution profile of standard ^{3}H-L-Glu or ^{3}H-GABA and that of the EM in both Bio-Gel P2 and HPLC C_{18} columns. The activators and inhibitors appear to have a molecular weight of 2,000-10,000 daltons and of 100-2,000 daltons, respectively. The activators are heat and acid sensitive while the inhibitors are quite stable. The EM for GABAR appear to be quite specific for GABA binding site since they have little effect on the diazepam binding site. (Supported by grants from National Science Council, Taiwan and grants NS 20978, NS 20922, and EY 05385 from NIH, U.S.A.)

INTRAMEMBRANE REDUCTION OF AFFINITY OF DOPAMINE D-2 RECEPTORS BY CHOLECYSTOKININ-8 AND NEUROTENSIN IN HUMAN POSTMORTEM BRAIN. G. von Euler*, P. Mailleux*, J.-J. Vanderhaeghen, L.F. Agnati* and K. Fuxe (SPON: B. Meister). Dept. of Histology and Neurobiology, Karolinska Inst., Box 60400, S-10401 Stockholm, Sweden, Lab. of Neuropathology and Neuropeptide Research, Université Libre de Bruxelles, 808 route de Lennik, B-1070 Brussels, Belgium, and Dept. of Human Physiology, University of Modena, Via Campi 287, 41100 Modena, Italy.

The effects of cholecystokinin-8 (CCK; 0.3-30 nM) and neurotensin (0.1-30 nM) *in vitro* were investigated on the binding of ^{3}H-N-propylnorapomorphine (^{3}H-NPA, a D-2 agonist *in vitro*) in cryostat sections and in membrane preparations of 8 postmortem normal human basal ganglia. CCK decreased the binding of 250 pM ^{3}H-NPA in the caudate by 50 % at 3 nM. Similar, bot not statistically significant modulations were seen in the putamen and in the nucleus accumbens. In membranes from the caudatus-putamen CCK increased the K_D of ^{3}H-NPA by 30 % at 10-30 nM, without affecting the B_{max}-value. Neurotensin also increased the K_D without affecting the B_{max} of ^{3}H-NPA. The maximal increase of 45 % was obtained at 3 nM of neurotensin. The induction of a reduced affinity of D-2 receptors by CCK and neurotensin are in agreement with results obtained in the rat, and suggest the presence of intramembrane modulation of D-2 receptors by CCK and neurotensin in the living human brain. This receptor-receptor interaction may be of importance for the pathophysiology and treatment of schizophrenia and tardive dyskinesias.

389.10

CHRONIC INTRATHECAL BACLOFEN REDUCES $GABA_B$ BINDING IN RAT SUBSTANTIA GELATINOSA. J.S. Kroin*, R. Singh*, R.D. Penn, and G.D. Bianchi*. Dept. of Neurosurgery, Rush Medical College, Chicago, IL 60612

Although chronic intrathecal baclofen has been shown to be an effective treatment for severe spasticity of spinal origin, tolerance does occur in patients over years (Penn, R.D., and Kroin, J.S., J. Neurosurg., 66:181, 1987). To investigate the possible origin of this decreased sensitivity to baclofen, normal rats were chronically infused with this drug intrathecally to see if $GABA_B$ receptor binding sites were decreased.

Normal rats were implanted with chronic intrathecal catheters and infused for four weeks with either racemic baclofen (0.5 μg/h) or saline vehicle using osmotic minipumps. The dosage chosen was the highest one that did not produce hindlimb muscle weakness. At the end of the infusion period, lumbar spinal cord sections were prepared for receptor autoradiography (Bowery N.G., et al., Neurosci., 20:365, 1987). In the substantia gelatinosa, the spinal region where $GABA_B$ binding sites have the greatest density, the number of sites was reduced by 36% in the baclofen infused animals as compared to the vehicle controls. The results indicate that there is a down-regulation of $GABA_B$ receptor numbers in the rat spinal cord following chronic high-level exposure to baclofen, and this may be the primary reason for tolerance in patients.

CHANGES IN MESOLIMBIC DOPAMINE FUNCTION FOLLOWING HIPPOCAMPAL KINDLING. J.G. Csernansky, C. Coronel-Bell*, E. Petrie*, L. Lombrozo*. Laboratory of Clinical Psychopharmacology, Stanford University, Stanford, CA 94305.

We have previously reported that two weeks following electrical kindling of the left hippocampus, a two-fold upregulation of dopamine (DA) D2 receptors in the ipsilateral nucleus accumbens occurs. (Csernansky et al., Brain Res., 449:357, 1988). In the present experiment, we sought to determine whether a concomitant change in presynaptic DA function also occurs.

DA turnover was assessed in rats kindled in the left hippocampus and controls two weeks following the last kindled seizure. In kindled rats compared to controls, a significant 26% decrease in dihydroxyphenylacetic acid (DOPAC) and a 22% decrease in homovanillic acid (HVA) concentrations were observed in the ipsilateral nucleus accumbens. No changes in DA concentrations in the ipsilateral nucleus accumbens, and no changes in either DA, DOPAC, or HVA in the contralateral nucleus accumbens were observed. In the ventral tegmental area, significant bilateral 100% increases in DA concentrations and 50% increases in DOPAC and HVA concentrations were observed in kindled vs. control rats. No changes were observed in the substantia nigra. These data suggest that hippocampal kindling has relatively long-lasting effects on DA synthesis and turnover in the area of mesolimbic cell bodies as well as their terminal fields.

390.1

ANALYSIS OF NEONATAL AND ADULT RAT OLFACTORY BULB GLIAL CELL LINES. M. N. Goodman*, J. Silver, J. W. Jacobberger* (SPON: R. C. Wilcott). Dept. of Genetics, Case Western Reserve Univ., Cleveland, OH 44106.

The rat olfactory bulb is reinnervated throughout life unlike other regions of the central nervous system, where glial differentiation affects loss of plasticity. In vitro, the differentiated phenotype of glial cells can be preserved by cell immortalization via oncogene transduction. We have used this approach to facilitate a study of the roles of glia in the innervation of the olfactory bulb.

Immortalized cell lines have been established from cultures of rat neonatal and adult olfactory bulbs and characterized concurrently with analogous primary cells. Two distinct phenotypes are evident within both neonatal and adult primary cultures: stellate, type I astrocyte-like, and fusiform (Anat. Record 210:385, Dev. Biol. 130:237) cells, each containing glial filaments. Both phenotypes are also present in uncloned immortalized cultures of neonatal and adult bulb.

Neurite outgrowth over monolayers of immortalized uncloned neonatal cultures as well as stellate and fusiform immortal neonatal clones has been compared with outgrowth over immortalized immature (postnatal day 1) and mature (adult) cerebral cortical astrocyte cultures. In assays of 24-hour neurite outgrowth from stage 31 chick retinal neurons, mean neurite length was equivalent for neonatal olfactory cell lines and the immature cortical line. In contrast, the mean length for the mature cortical astrocyte line was reduced by 40% which is close to the 30% reduction seen in primary immature and mature cortical astrocyte cultures (Smith, Silver, Rutishauser, and Miller, submitted). These results suggest that: 1) the neurite promoting properties of glial cells are preserved through immortalization, and 2) the neurite promoting properties of neonatal olfactory and cerebral astrocytes are similar. Assays of neurite outgrowth over adult olfactory glial cell lines are in progress.

390.2

EXPRESSION OF GLIAL FIBRILLARY ACIDIC PROTEIN IN THE RAT MAIN OLFACTORY BULB FOLLOWING SURGICAL AND CHEMICAL LESIONS OF THE OLFACTORY NERVE. M.R. Poston*, M.S. Bailey and M.T. Shipley (SPON: G.C. Blaha). Dept. of Anat. and Cell Biol., Univ. of Cincinnati, Cincinnati. OH 45267.

Severe injury to the mammalian olfactory nerve (ON) results in deafferentation of the main olfactory bulb (MOB), including changes in the glial environment. It is unclear whether axons of regenerating primary olfactory neurons (PONs) encounter a glial environment permissive to growth or must overcome a non-permissive environment. In this study, we observed the expression of glial fibrillary acidic protein (GFAP) by MOB astrocytes at timed intervals following deafferentation of the adult rat MOB. Unilateral deafferentation was performed by 1) surgically severing the ON at the cranial surface of the cribriform plate, and 2) chemically lesioning PONs with zinc sulfate placed in the olfactory epithelium. A polyclonal antibody to GFAP was used to visualize GFAP expression immunohistochemically in the MOB. At 4 days, the amount of GFAP expression in the deafferentated MOB was significantly greater than that in the control MOB. GFAP-positive, hypertrophied astrocytic processes were prevalent in the deafferentated MOB but not in the control MOB. Previous electron microscopic studies have suggested that hypertrophied glial (astrocytic) processes in the MOB are not evident by the tenth day following a lesion of the ON. However, in this study the increased GFAP expression in the deafferentated MOB was still observed at 14 days following both types of lesion. Studies to determine if GFAP expression decreases at longer survival times are in progress. (Supported by NS 23348 and U.S. Army DAMD 17-86-C-6005)

PLASTICITY OF LHRH-IMMUNOREACTIVE FIBERS IN ACCESSORY OLFACTORY PATHWAY. M. Ichikawa[1] and Y. Oka[2]. [1]Dept. Anat. Embryol., Tokyo Metro. Inst. for Neurosci., Tokyo 183 and [2]Zool. Inst., Fac. of Sci.,Univ. of Tokyo, Tokyo 112.

Recently, we showed a reorganization of neuronal connections in medial amygdaloid nucleus (MAN) following accessory olfactory bulb (AOB) lesion in adult rat. On the other hand, it has been known that the LHRH-immunoreactive (LHRH-IR) fibers are distributed in MAN. In the present study, we examined, using the immunohistochemical technique, if the LHRH-IR fibers in the MAN undergo the plastic changes after AOB removal. Under anesthesia, rat AOB was removed unilaterally and the rats were perfused at 6 hrs, 4 days, or 2 months survival time. The sections including the MAN was processed by the immunohistochemical method. The LHRH-IR fibers were clearly recognized in the MAN. The total length of LHRH-IR fibers in MAN on the side of AOB removal was compared with that on the intact side. Total length of LHRH-IR fibers increased significantly on the side of AOB removal at 4 days and 2 months survival time in each animal. This indicates the possibility that the sprouting of LHRH-IR fibers take place in MAN after the denervation of AOB fibers.

NEURAL REGULATION OF VASOPRESSIN PROTEIN AND mRNA LEVELS IN SUPRAOPTIC AND PARAVENTRICULAR NUCLEI AFTER MEDIAL FOREBRAIN BUNDLE LESIONS. C. J. Phelps, S. W. Carlson*, and D. L. Hurley*. Dept. Neurobiology & Anatomy, Univ. Rochester Med. Ctr., Rochester, NY 14642.

Vasopressin (VP) - secreting neurons of the hypothalamic supraoptic nucleus (SON) receive a dense noradrenergic (NE) innervation from medullary cells via the medial forebrain bundle (mfb). Electrophysiological studies have shown a stimulatory role for this innervation (Day and Renaud, Brain Res. 303: 233, 1984); mechanical deafferentation of SON leads to decreased peripheral VP correlated significantly with decreased NE levels in SON (Phelps, Carlson, Felten, Anat. Rec. 222: 223A, 1989). In order to investigate the mechanism of this neural regulation, VP expression in SON and paraventricular nucleus (PVN) was investigated by simultaneous immunocytochemical (ICC) and in situ hybridization morphological methods, and by monitoring peripheral secreted VP levels. Young adult (3m.o.) and aged (20m.o.) rats were subjected to SON-deafferenting mfb lesions. Urinary VP levels were monitored before and after surgery. Peripheral VP was decreased in aged, but not in young, rats. VP and VP mRNA were assessed simultaneously at 4, 14, 30 and 60d after lesion using "cryoprotected" fixed frozen thick sections of hypothalamus. SON VP protein (by ICC) was markedly decreased at all intervals in both age groups after lesion; VP mRNA was unaffected in either age group. In young rats, PVN VP protein and mRNA were visibly intensified; "intermediate" (between PVN and SON) VP cell groups, obscure in intact hypothalamus, were visualized using both techniques. A PVN compensatory activity was thus implied to explain "control"-level urinary VP. Since low peripheral VP levels precluded increased VP turnover, the collective results indicate a translational effect of NE deprivation, and a transcriptional effect in PVN compensatory VP elevation. Supported by NIH grant AG06139 (CJP).

MEDIAL PREOPTIC AREA KINDLING INDUCES SEXUAL BEHAVIOR IN SEXUALLY INACTIVE MALE RATS. A.E. Haller*, M.C. Manero*, R. Paredes*, R. Alvarado* and A. Agmo. Department of Psychology, Universidad Anahuac and Reticular Formation Lab., Instituto Nacional de Neurologia, Mexico, D.F.

In the present experiments, sexually experienced male rats were kindled in the medial preoptic area (MPOA) or the amygdala (AMG) with the purpose to investigate if the widespread modification of brain function produced by kindling induces sexual behavior in noncopulating rats and if kindling facilitates sexual behavior in copulating rats. The animals were stimulated 4 times daily on odd days and sexual behavior monitored on even days. The results showed that the MPOA required higher stimulus intensity to elicite an afterdischarge (AD) than the AMG. No difference was found in the development of kindling between these brain structures.

Kindling had no effect upon sexual behavior in copulating rats. In contrast, MPOA kindling induced copulation in noncopulating male rats. Seven out nine animals displayed sexual behavior. No significant facilitation was observed after AMG kindling in noncopulating male rats. Furthermore, the sexual behavior displayed by the previously noncopulating MPOA kindled rats was similar to the sexual behavior displayed by sexually experienced animals. It is proposed that sexual behavior is facilitated in these rats by local neural changes produced by kindling.

THE USE OF MICROWAVE IN FIXATION OF BRAIN TISSUE FOR IMMUNOELECTRON MICROSCOPY. J. Anderson, II*, M. Morales and E. Fifkova. Neuroscience Center, Department of Psychology, University of Colorado, Boulder, CO 80309.

It is generally accepted that vascular perfusion fixation with a standard aldehyde mixture is the only adequate method for preparing brain tissue for electron microscopy. However, perfusion is not always possible, e.g., in the case of human material or brain slices. Fixation by immersion is an alternate possibility. However, in the brain it yields preservation which is inferior to that obtained by perfusion. Recently it has been reported that immersion into 6% glutaraldehyde combined with microwave irradiation yields very good results (Jensen and Harris, *Soc Neurosci. Abstr.*, 550, 1988). We have adapted this procedure for use in immunocytochemistry. Blocks of brain tissue were immersed into a mixture of 4% paraformaldehyde and 1-1.5% glutaraldehyde for 20 and 40 sec of uniform heating to 50° C. The tissue was postfixed with uranyl acetate instead of OsO_4 and embedded at low temperature in Lowicryl K4M. The actin filaments were well preserved. In order to use this procedure for immunoelectron microscopy, we had to establish that antigenicity of the tissue did not suffer by the microwave irradiation. Therefore, we used monoclonal antiactin antibodies with a gold probe which were previously tested on perfused material. In comparing the pattern of actin labeling with the two fixation procedures, we could not detect any differences in the distribution of the gold label. Thus, it is possible to use a combined procedure of immersion fixation, microwave irradiation, and low temperature embedding for immunoelectron microscopy.

390.7

DISTRIBUTION OF MYOSIN IN THE CNS IDENTIFIED WITH MONOCLONAL BRAIN ANTIMYOSIN ANTIBODIES. M. Morales and E. Fifkova. Neuroscience Center, Department of Psychology, University of Colorado, Boulder, CO 80309.

Previously we have described that polyclonal human antiplatelet myosin antibody cross-reacts with brain myosin in rats and mice. This antibody recognizes myosin in dendritic spines, axon terminals, and in dendrites in an area subjacent to the postsynaptic density. With this antibody, we could not establish with certainty whether myosin is also present in other parts of the dendrites and axons. Since the antiplatelet myosin antibody may not have recognized myosin in all compartments of the neuron, we have developed monoclonal antibrain myosin antibodies using the rat brain myosin as an immunogen (in collaboration with the Cancer Center, Health Sciences Center, University of Colorado, Grant P30-CA46934). The clones were screened for a positive reaction on tissue by immunoelectron microscopy and the specificity of the antibodies was tested on immunoblots (Morales and Fifkova, *J. Comp. Neurol.*, 279:666, 1989). With these monoclonal antibrain myosin antibodies, we confirmed the presence of myosin in the dentate fascia, hippocampus, visual and cerebellar cortices, and its distribution in dendritic spines, axon terminals and dendrites where it was associated with actin filaments. In addition, we have established that myosin is also associated with microtubules in dendrites and axons. While myosin, in association with actin filaments in dendritic spines, may play an important role in the mechanism of synaptic plasticity, its association with microtubules in axons and dendrites may indicate a transport-providing function.

KINDLING-INDUCED INCREASE IN DIMENSIONS OF PERFORATED POSTSYNAPTIC DENSITIES. Y. Geinisman, L. deToledo-Morrell and F. Morrell. Dept. of Cell Biol. & Anat., Northwestern Univ. Med. Sch. and Depts. of Neurol. Sci. and Psychol., Rush Med. Coll., Chicago, IL 60611.

Kindling, which is associated with an exceptionally enduring augmentation of synaptic efficacy, is likely to involve structural alterations of synapses such as increases in their number and size. This study was designed to elucidate whether kindling induces an increase in dimensions of the postsynaptic density (PSD) which delineates the most concentrated area of postsynaptic neurotransmitter receptors and ion channels. Rats kindled via medial perforant path stimulation (1 msec pulses at 60 Hz, twice daily) were sacrificed 4 weeks after reaching a criterion of 5 generalized seizures. Unkindled but stimulated (coulombic control) and unstimulated but implanted rats served as controls. A differential analysis of perforated axospinous synapses with discontinuous PSDs and of nonperforated ones with continuous PSDs was performed in the middle (MML) and inner (IML) molecular layer of the dentate gyrus. For each PSD, all profiles were measured in serial sections to assess the maximal profile length and area (from the total profile length and section thickness estimated with the small-fold technique). The results showed that both the maximal profile length and the area of PSDs were selectively increased following kindling only in perforated synapses of the MML. In marked contrast, nonperforated synapses in the MML were not changed with respect to the measures used. In the IML, however, PSD dimensions were not altered in either of the two synaptic types. Thus, the observed modification is a manifestation of synaptic plasticity induced by kindling rather than a result of generalized seizures. Since perforated synapses are believed to augment the efficiency of transmission, the expansion of their PSDs may represent a structural rearrangement particularly appropriate for the sustained enhancement of synaptic efficacy which characterizes kindling.

KINDLED SEIZURES: AN EVALUATION OF SEIZURE CONTROL PROCEDURES FOR MOLECULAR BIOLOGICAL ANALYSIS. G.Samoriski* C.D.Applegate, J.L.Burchfiel (SPON:C.Lombroso). The Children's Hospital, Boston, MA 02115.

One of the major problems in identifying biochemical or molecular biological mechanisms involved in the kindled state has been dissociating changes due to acute ictal events from those responsible for the permanent alterations in seizure susceptibility produced by kindling. Seizure control procedures are necessary to make this dissociation. The ideal procedure should elicit behaviorally identical seizures in naive animals in a single brief trial, and should not result in positive transfer to kindling. In this study we have evaluated 3 seizure induction procedures electroconvulsive shock (ECS), low frequency train (LFT) stimulation to the amygdala and low frequency pulse (LFP) stimulation to the frontal cortex, against these criteria.

Amygdala implanted rats (6-10/group) were pretreated with one of the seizure induction procedures and following a 1-2 day rest were kindled using standard protocols. ECS elicited seizures were behaviorally distinct from kindled seizures, and did not result in positive transfer. LFT elicited self-sustained stage 5 seizures after 6.6±2.0m and resulted in robust positive transfer. LFP elicited self-sustained stage 5 seizures after 15.1±2.8s and did not result in positive transfer to amygdala kindling. The relative merits of these procedures will be discussed.

390.10

EVIDENCE FOR A STEPWISE PROGRESSION OF KINDLED SEIZURE DEVELOPMENT. J.L. Burchfiel and C.D. Applegate. Department of Neurology, The Children's Hospital, Boston, MA 02115.

Our investigations with the kindling antagonism model suggest that kindled seizure development is a stepwise process involving two discrete transitions or "gates" from one state of neural organization to another (Burchfiel & Applegate, Neurosci. Biobeh. Rev.,1989). Our data suggest that there is a forebrain gate which controls the transition from stage 1-2 to stage 3 and a brainstem gate which controls the transition from stage 3 to stage 4-5. If these gates control discrete steps in the kindling process, then one would predict that they could be opened independently. We tested this prediction. Rats (N=9) were pretreated by low frequency (2/s) train stimulation applied to the amygdala. This procedure produced stage 5 seizures in all animals with a latency of 3.6±0.3m. Following this, kindling from the entorhinal cortex showed a major acceleration of the transition from stage 3 to stage 4-5 ($\bar{x}$ trials=3.4±0.5 v. 9.2±1.1 in controls); whereas, there was no alteration of the transition from stage 1-2 to stage 3 ($\bar{x}$ trials=16.1 ±2.7 v. 12.6±1.7 in controls). These findings confirm our prediction of independence of the two transitions, support the hypothesis that kindling is a stepwise process and indicate that the amygdala is downstream from the forebrain gate.

390.11

ATTENUATION OF GENETIC RESPONSE TO SEIZURES FOLLOWING KINDLING. C.D. Applegate, L.R. Dawes, G. Samoriski, R.L. Neve. Harvard Medical School, Boston, MA 02115.

Research from our laboratory has indicated that baseline transcriptional activity for a variety of mRNAs is unchanged in cerebral cortex (CX) and hippocampus (HPC) following kindling. In this study we examined regional mRNA levels for fos and the alpha subunit of Ca^{+2}/calmodulin dependent protein kinase II (CaMII) in kindled and naive animals at 0.5, 1.0, 6.0 and 24 h following seizures (N=2-4/group/time). Rats were kindled from the amygdala using standard protocols until 6 consecutive stage 5 seizures were elicited. Stage 5 seizures were elicited in naive animals by 2/s, high frequency train stimulation of the amygdala. Fos mRNA levels in CX and HPC were significantly elevated at 0.5 and 1.0 h following seizures in both kindled and naive rats; however, the magnitude of this increase was significantly greater in naive (OD = 4.0±1.1) vs. kindled (OD = 1.00 ± 0.03) rats in the HPC at both time points. CaMII levels were significantly increased in naive but not kindled HPC 0.5 h post-seizure, but were not changed in either group in CX. These data may suggest that kindling attenuates the responsiveness of fos and CaMII mRNAs to seizures. However, a contribution of the seizure induction procedure in naive animals cannot be ruled out. Experiments are currently being conducted to resolve this issue.

390.12

PERSISTENCE OF SOMATIC SPINES TWO WEEKS FOLLOWING RECURRENT LIMBIC SEIZURES IN RATS. M.C.Bundman, R.M.Pico and C.M.Gall Departments of Pharmacology and Anatomy and Neurobiology, Univ. of Calif., Irvine CA 92717.

Unilateral, electrolytic lesions of the hippocampal dentate gyrus hilus produce recurrent limbic seizures which begin 2 hrs postlesion and recur for 8-10 hrs. Electron microscopic analysis has demonstrated that during this period of seizure activity there is a dramatic increase in the number of spines on the somata of the dentate gyrus granule cells. At 5 and 11 hrs postlesion there were 1.80 ± 0.10 (mean ± S.E.M.) and 1.59 ± 0.32 spines/cellular profile, respectively verses 0.19 ± 0.07 spines/cellular profile in controls. In the present study the persistence of these spines was examined in rats sacrificed 4 and 14 days following one hilus lesion-induced seizure episode. There are 0.83 ± 0.13 and 0.89 ± 0.07 spines/cellular profile at 4 and 14 days, respectively. These data were taken from analyses of 91 cellular profiles in 4 animals at 5 hrs; 88 cellular profiles in 4 animals at 11 hrs; 36 cellular profiles in each of 3 animals at 4 days and 14 days; and 118 cellular profiles in 6 control animals. Thus, approximately 50% of the somatic spines present during the period of seizure activity appear to be lost by 4 days post-seizure but the remaining 50% persist at least 14 days and possibly longer. While approximately 40% of the somatic spines found during the period of seizure activity are quite large and complex, sometimes completely engulfing presynaptic elements, those that remain at 4 and 14 days are all much smaller and 'nub' shaped. This latter population of spines are of the same morphological type found in control animals but are 4 times as numerous as seen in control rats.

These studies suggest that the increased neural activity experienced during recurrent seizures has long term structural effects in adult CNS neurons.

EFFECTS OF POSTOPERATIVE ENRICHMENT ON BEHAVIORAL RECOVERY ARE BOTH LESION- AND TASK-DEPENDENT. C.Kelche* and B.E.Will (SPON : N.Ropert). D.N.B.C., Centre de Neurochimie du CNRS, 12 rue Goethe, 67000 Strasbourg, France.

Deficits produced by hippocampal lesions are at least partially compensated by housing rats postoperatively in an "enriched" environment. Different results were obtained after entorhinal cortex and fimbria-fornix lesions.

In the present study, we examined the effects of postoperative environment on the behavior of rats with either entorhinal cortex or dorsal hippocampus lesions on different behavioral tests: spontaneous alternation in a T-maze, learning of an eight-arm radial (EAR) maze and of an Hebb-Williams (HW) maze. Both entorhinal cortex and dorsal hippocampus lesions impaired performance in each of these tasks. Enrichment of the postoperative environment failed to facilitate behavioral recovery of any of the entorhinal cortex lesion-induced effects. Similarly, postoperative enrichment failed to attenuate ($F < 1.0$) the deleterious effects of dorsal hippocampus lesions on spontaneous alternation. However, in the same rats, the "enriched" housing attenuated the deficits observed in the EAR maze just at the $P < 0.05$ level ($F\ 1/21 = 4.4$) and in the HW maze at the $P < 0.01$ level ($F\ 1/21 = 24.47$).

Thus, postoperative effects appear to be both TASK and LESION-LOCUS SPECIFIC.

EFFECTS OF TASK DIFFICULTY ON RECOVERY OF SPATIAL PERFORMANCE AFTER UNILATERAL ENTORHINAL CORTEX (EC) LESIONS IN RATS. J.J. Ramirez*, B. Fass-Holmes, K. MacDonald*, J. McClure*, and C. Tuite*. Psych. Dept., Davidson College, Davidson, NC 28036; Biol. Dept., UCSD, La Jolla, CA 92093.

Unilateral EC lesions impair performance on a learned alternation task from which the rats recover 8-10 days postlesion. Since the time course of this recovery parallels the time course of sprouting, these two phenomena are thought to be related (Loesche and Steward, 1977). The objective of the present investigation was to determine whether there are limits within which sprouting may effectively contribute to recovery. We examined the effects of unilateral EC lesions on a spatial alternation task (Y maze) with intertrial intervals of differing lengths (0, 40, 70, 100 sec). Whereas the performance of the 0 sec group was spared, the other groups showed a deficit from which they all required 10-12 days to recover. This finding indicates that the effects of EC lesions on spatial alternation depend upon task difficulty as determined by the length of the intertrial interval. Since the time course of recovery was comparable for the 40, 70, and 100 sec groups, such recovery evidently is independent of task difficulty. The known parallel between the time course of recovery and sprouting after EC lesions therefore implies that the recovery depends upon the sprouting instead.

INJECTION OF TETRODOTOXIN INTO THE ENTORHINAL CORTEX DEPRESSES CELL FIRING IN THE DENTATE GYRUS. R.Tomasulo*, B.Burger*, O.Steward (SPON: P.Trimmer) Dept. of Neuroscience, Univ. of VA, Charlottesville, VA 22908

Ablation of the entorhinal cortex (EC) of the rat induces a complex sequence of dendritic reorganization and axonal sprouting in the denervated dentate gyrus (DG). The signal that triggers these events is unknown. One candidate, however, is the reduction of granule cell firing which follows the EC lesion (Reeves and Steward. Exp. Neurol. 102:37-49, 1988). As a first step in comparing the effects of denervation with the effect of merely silencing the EC input, we recorded granule cell firing before and after injecting tetrodotoxin (TTX) into the EC.

Under urethane anesthesia, we isolated putative granule cells with a tungsten electrode. After defining baseline activity, we injected 0.2 to 0.4 ul of $2x10^{-5}$ M TTX in 0.9% NaCl into each of 14 stereotaxic sites along two parallel tracks in the EC. Cell firing and evoked responses were monitored for 8 hours. We found that TTX injection reduced granule cell activity to the same extent as did EC ablation. There was no recovery of evoked responses or cell firing in 8 hours. Saline injections did not alter granule cell activity.

We conclude that the previously described rate changes reflect, in the short term at least, lost presynaptic drive rather than an indirect metabolic effect of denervation or an effect dependent upon early degenerative events in presynaptic terminals. Biochemical and morphological studies will determine if silencing the EC reproduces the effects of denervation. Supported by NSF BNS-8818766 (OS). RT received NIH postdoctoral training grant 5T32NS07199.

Low-Frequency Depression Modulates Long-Term Potentiation Of The Perforant Path In Disinhibited In Vitro Dentate Gyrus. P. C. Rinaldi and E. M. Hookano*. Neurophysiology Lab, Div. of Neurological Surgery, College of Medicine, Univ. of California at Irvine, Irvine, CA 92717.

Low-frequency depression (LFD) was studied in the disinhibited in vitro dentate gyrus (rat) to determine its role in modulation of long-term potentiation (LTP) and thus its importance in computational and theoretical considerations of learning and memory. An electrode placed in the trajectory of the perforant path inputs to the granule cells delivered high-frequency stimulation (400 Hz) to induce LTP and low-frequency stimulation (0.5 Hz) to produce LFD. The dendritic field potential was recorded to assess synaptic activity. Following the induction of stable LTP in 11 slices ($\bar{x}$ increase 62%), low-frequency stimulation was delivered to the same inputs for 3 to 10 minutes. During the course of this stimulation synaptic depression averaged 29%. The post-LTP/LFD level indicated that LTP was modified in 8 of 11 slices. The decrease from LTP levels or reversal of LTP averaged 31% and was stable for up to 47 minutes. Compared to control experiments in which 10 minutes of low-frequency stimulation was studied in non-potentiated slices, response amplitude level was significantly reduced when LFD followed LTP. LFD appears to be capable of modifying or reversing LTP in the dentate. It may play a role in modulation of information in neural networks, particularly in extinction or forgetting. NEONATAL THYROID HORMONE TREATMENT ATTENUATES THE INDUCTION OF LONG-TERM POTENTIATION IN RAT HIPPOCAMPUS. C. Pavlides*, A.I. Westlind-Danielsson* & B.S. McEwen (SPON: J. Winson). The Rockefeller University, NY, 10021.

Thyroid hormone dysfunction at an early stage of development produces marked neurochemical, and morphological changes in the hippocampus. In order to better understand the functional significance of these effects, we examined LTP induction in the dentate gyrus (DG) of thyroid hormone treated rats (N=3) and control rats (N=3).

Thyroid hormone [3, 5, 3'-triiodo-L-thyronine (T3)] was administered to male rats on postnatal days 1, 2 and 4 (0.5 ug/g of body weight, s.c.) at approximately 2 months of age, the two groups of animals were tested for the induction of LTP by stimulating the perforant path (PP) and recording EPSP's in the DG granule cell region.

In both the control and T3 groups, tetanic stimulation of the PP produced a slight increase in the slope of the EPSP (5.93% +/- 4.02 SEM & 7.27% +/- 3.43 SEM, respectively). However, while the population spike of the control group increased significantly (46.5% +/- 3.55 SEM) following tetanization, the population spike of the T3 treated rats decreased significantly (-44.7% +/- 23.0 SEM). The present results suggest that brief T3 treatment at a critical stage of development may have drastic long-term changes in hippocampal physiology and function.

HIGH AFFINITY CHOLINE UPTAKE OF RAT HIPPOCAMPAL SYNAPTOSOMES IN RESPONSE TO ACUTE EXERCISE BOUTS OF TREADMILL RUNNING. D.E. Fordyce and R.P. Farrar. Dept. of Kinesiology and Institute for Neurosciences, University of Texas at Austin, Austin, TX 78712.

High affinity choline uptake (HACU) is the rate limiting step in acetylcholine synthesis. A variety of interventions have been demonstrated to affect acetylcholine turnover and synthesis. Previously we have observed that endurance running, 5 days a week for 6 months, resulted in a 30% decline in HACU when compared to sedentary age-matched controls. All rats had been sedentary for 24 hrs before being killed. It was of interest to determine whether this depression in HACU was due to the last bout of exercise or whether it represents a training adaptation. Therefore, rats 6 months of age, previously familiarized with the treadmill (5 min/day, 3 days/wk) were divided into four groups: two groups ran 25-30 min at a speed of 20 m/min, group R was killed immediately at the end of the run by decapitation, group R24 was rested for 24 hrs before decapitation, and the third group was familiarized with the treadmill, but had not been exposed to the treadmill for 48-72 hours prior to decapitation, the fourth group was a naive control. The HACU was determined on hippocampal synaptosomes incubated with 0.75 μM ^{3}H-choline, with and without sodium. There was no difference between the naive controls and the familiarized controls and these values are represented as control values (C). Both the R and R24 synaptosomes demonstrated a 50% increase in HACU compared to the control values. These data indicate that acute bouts of treadmill running elevated acetylcholine synthesis in the hippocampus, but that chronic endurance running produces a compensatory reduction in this synthesis.

RESPONSES TO VARYING INTENSITIES OF VAGINAL DISTENSION IN THE AWAKE RAT. K. J. Berkley and E. Wood*. Dept. of Psychology, Florida State Univ., Tallahassee, FL 32306.

It is known that sensory fibers in the pelvic nerve of anesthesized rats respond to gentle distension of the vaginal canal and that the responses increase as distension is increased into the noxious range. In order to examine the relation between this neural response and sensation, similar vaginal distension stimuli were delivered to rats that had previously been trained to perform an operant escape response to terminate a noxious somatic stimulus (tail pinch). At gentle levels of distension, rats oriented towards the stimulus, but failed to make escape responses. As the levels were gradually increased into the noxious range, however, the probability of the rats making an escape response gradually increased to 100 percent. This correspondance between electrophysiological and behavioral responses is consistent with the hypothesis that both pain and non-painful sensations arising from mechanical stimulation of the vaginal canal are subserved at least in part by activity in afferent fibers of the pelvic nerve.

GONADAL STERIODS REGULATE DENDRITIC SPINE DENSITY IN HIPPOCAMPAL PYRAMIDAL CELLS IN ADULTHOOD. C.S. Woolley*, E. Gould*, M. Frankfurt and B.S. McEwen (SPON: W. Yates). Lab. of Neuroendocrinology, The Rockefeller Univ., New York, NY 10021.

While gonadal steroids are known to influence hippocampal neuronal structure during development and in response to injury, steroid mediated morphologic plasticity in the intact adult hippocampus has not previously been demonstrated. We have used the single section Golgi impregnation method to show that removal of circulating gonadal steroids by ovariectomy of adult female rats results in a profound decrease in dendritic spine density in CA1 pyramidal cells of the hippocampus. Spine density in CA3 pyramidal cells and granule cells of the dentate gyrus is unaffected. Estradiol replacement reverses the observed decrease in dendritic spine density; progesterone augments the effect of estradiol within a short time period. These results demonstrate that adult CA1 hippocampal pyramidal cells are structurally plastic and suggest that dendritic morphology may undergo constant fluctuation during the estrous cycle.

EFFECTS OF NORADRENERGIC AGENTS ON PYRAMIDAL NEURONS IN IMMATURE RAT HIPPOCAMPUS. A.M. Moudy and P.A. Schwartzkroin. Departments of Physiology & Biophysics, and Neurological Surgery, University of Washington, Seattle, WA 98195.

In preliminary experiments, we have examined the effects of a noradrenergic agonist on individual hippocampal pyramidal neurons from immature rats. Transverse hippocampal slices (400 μm) were obtained from 7 day old Sprague Dawley rats and maintained in an *in vitro* interface recording chamber at 35° C. Intracellular recordings were made from pyramidal cells in the CA3c and CA1 regions of the hippocampal formation. Isoproterenol, a B-receptor agonist, was pressure-applied from the tip of a glass microelectrode positioned near the soma, as closely as possible to the intracellular recording electrode. Pressure pulse applications (30 psi) of 0.1 mM isoproterenol were given for 50-300 ms. Most cells recorded from in both CA1 and CA3c were sensitive to drug application. Voltage changes induced by isoproterenol were variable, however; while some cells showed a slight hyperpolarization, others were depolarized. An input resistance increase of 10-20 Mohms was seen during these responses in a majority of cells. Trains of action potentials triggered by 200 ms depolarizing current pulses showed accommodation in all cells under control conditions; isoproterenol reduced the degree of accommodation, and also reduced the after-hyperpolarization following these trains. These changes were, for the most part, qualitatively similar to noradrenergic effects in adult tissue.

THE DEVELOPMENT OF THE SYNAPTIC PAIRED-PULSE PROFILE IN AREA CA1 OF THE RAT HIPPOCAMPAL SLICE PREPARATION. II. STRATUM MOLECULARE. P.G. DiScenna & T.J. Teyler Neurobiology Dept., Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

We study the development of the trisynaptic circuit by examining the development of excitatory and inhibitory synaptic transmission in the dentate gyrus and hippocampus proper. While studying the development of paired-pulse facilitation in str radiatum of CA1, we noted that afferents in the distal apical dendritic field showed an unusual paired-pulse profile (PPP;10-5000ms) during development. We observed a triphasic pattern with paired-pulse depression at short interpulse intervals (IPI), facilitation at intermediate IPIs and a depression at long-latency IPIs. This pattern mirrors the synaptic PPP produced by the med. perforant path input to DG rather than the profile in adult CA1. We investigated this effect more closely. The rat hippocampal slice prep and a homosynaptic paired-pulse paradigm (10-5000ms IPI) were used to examine the development of the synaptic PPP in stratum moleculare of area CA1. Population EPSPs were evoked by str. moleculare stimulation at 40-60% max. Our initial results are based on two animals at each age. The paired-pulse effects ((Test/Cond)X100) developed as follows:

	20ms	80ms	200ms	2000ms	5000ms
PN4	64%	77%	78%	64%	83%
PN6	80	93	100	69	93
PN10	128	145	103	83	88
PN15	148	147	116	90	91

PHARMACOLOGY OF RETINOTECTAL TRANSMISSION IN *RANA PIPIENS* TECTAL SLICES. P. W. Hickmott* and M. Constantine-Paton (SPON: J. Paton) Dept. of Biology, Yale Univ., New Haven, CT 06511

We have developed a tectal slice preparation to examine the pharmacology of retinotectal transmission in *Rana pipiens* tadpoles. We use 500µm thick slices of the diencephalon and tectum. By electrically stimulating the optic tract, which runs through the diencephalon, we can record tectal evoked potentials (TEP) similar to those seen in the intact animal. Such TEP's consist primarily of a fast biphasic component, followed by slower positive and negative components. We have identified the fast biphasic component as presynaptic on several criterea: 1) It is relatively insensitive to zero Ca^{2+}-high Mg^{2+} bathing saline, and also to high concentrations of the calcium channel blockers Co^{2+} or Cd^{2+}, 2) It is not abolished by high-frequency stimulation and recovers immediately after a tetanus, 3) it does not exhibit paired pulse facilitation, and, 4) it is largest in superficial tectum. By using similar methods, we conclude that the later components of the TEP are postsynaptic.

Furthermore, low concentrations of NMDA reversibly block the postsynaptic components, while low concentrations of APV reversibly enhance them. Concurrent with the postsynaptic block due to NMDA, there is a marked increase in spontaneous activity in the tectum, and a substantial increase in the evoked presynaptic components. Since the increase in the presynaptic component is not blocked when transmission is blocked by Cd^{2+}, it is specific to presynaptic elements. We hypothesize that NMDA receptors are highly concentrated on inhibitory cells, which, when driven by exogenous NMDA, inhibit the postsynaptic TEP. Preliminary evidence further suggests that GABA may be involved in the actions of NMDA on the TEP.

EARLY HANDLING / ISOLATION DECREASES ADULT RATS' USE OF PLACE STRATEGIES. J. Willner* and L. Nadel. Dept. of Psychology, Univ. of Arizona, Tucson, AZ 85721.

Recent evidence suggests that environmental events occurring early in postnatal life can have long-lasting consequences for hippocampal function. In the present experiment, pups from litters of Long-Evans rats were handled for 5 min/day on PN 3-7, 9 and 11. They also received an isolation treatment on PN 8, 10 and 12, during which they were separated from the dam and maintained in a heated, lit environment for 8 hr . The pups were then weaned at PN21, and maintained on ad lib food and water in large metal hanging cages with same-sex littermates.

At 6 mo of age, experimental and control rats were trained on an appetitive position discrimination in a T-maze. Following habituation to the maze, the rats were reinforced for choosing the initially non-preferred arm of the maze and trained to a criterion of 8 correct choices in 10 consecutive trials. The rats then received a nonreinforced probe trial with the start arm of the maze rotated 180° away from it's original position to determine whether they were using a "response" strategy or a "place" strategy to solve the discrimination problem.

Rats receiving the handling / isolation treatment did not differ from controls in acquisition of the position discrimination, but were significantly less likely than controls to have used a place strategy to solve the task (36.8% vs. 83.3%, respectively). These data are consistent with previous work (Wilson et al., Beh. Br. Res., 21:223, 1986) showing that young rats display a more "immature" pattern of LTP after early handling / isolation, and suggest that this treatment has long-term consequences for hippocampal function.

391.6

DEVELOPMENT OF SPATIAL LEARNING (OBJECT LOCALIZATION) ABILITY IN INFANT RATS. K. L. Altemus* and C. R. Almli, Depts. Anat. & Neurobiol., Psychol. Pgms. Neural Sci., Occup.Therapy. Washington Univ. Sch. Med., St. Louis, MO 63110.

Spatial learning abilities are thought to be related to the functional status of the hippocampus. The present investigation studied the development of utilization of spatial cues to mediate object localization for albino rats beginning at 15 days of age. Independent groups of rats were tested in a Morris water maze under proximal (visible goal in fixed location), distal (non-visible goal in fixed location), and random (non-visible goal in random location) conditions. Animals were tested on 3 consecutive days with independent groups beginning on postnatal days 15,16,17,18,and 19. Latencies to enter the escape quadrant and latencies to escape were recorded for each session of 12 1-min acquisition trials. Each daily session concluded with a 1 min probe trial, during which escape was impossible. Latencies to enter the quadrant previously containing the platform, and the total time within this quadrant were recorded. Results indicate that spatial learning abilities based on visual cues are present early in development, that performance is influenced by previous experience, and that spatial learning is manifest prior to hippocampal maturation. (Conducted under NIH Guide for Care and Use of Laboratory Animals)

391.7

CONFOCAL SCANNING LASER MICROSCOPY OF INTRACELLULARLY INJECTED AMYGDALA NEURONS. E. W. Kairiss, P. E. Chapman*, C. L. Keenan, Z. Xiang* and T. H. Brown, Dept. of Psychology, Yale University, New Haven, CT 06520.

The amygdala has been implicated in a variety of important innate and learned behaviors. We have been developing the amygdala slice preparation (Keenan et al, *Brain Res. Bull.*, 1988) because virtually nothing is known about the cellular neurophysiology and neuropharmacology of this interesting region of the brain. Current- and voltage-clamp recordings have revealed that some amygdaloid synapses display long-term potentiation (Chapman and Brown, *Soc. Neuro Abst.*, 1988), which could be relevant to learning (Brown et al, *Science*, 1988). Here we report the successful use of confocal scanning laser microscopy to create 3D images of neurophysiologically-characterized amygdala neurons.

Horizontal amygdala slices were prepared as described previously (Chapman and Brown, 1988). Dye injections and recordings were done using microelectrodes containing 5(6)-carboxyfluorescein. Active and passive membrane properties were assessed from the voltage response to current steps. Synaptic properties were assessed by stimulating the external capsule. Following the neurophysiology, slices were cleared in glycerol with 5% n-propyl gallate added to reduce bleaching. Serial optical sections, taken at 1 to 5 μm intervals, were obtained using a confocal scanning laser microscope.

Reconstructions of the optical sections were used to produce a stereo pair or a red/blue stereo anaglyph. Four optically reconstructed neurons, which could be classified as pyramidal-type, had input resistances between 22 and 70 MΩ and resting potentials between -72 and -79 mV. They responded to depolarizing current steps with trains of spikes, burst discharges, or single spikes. The ability to obtain structure-function relationships in this heterogeneous cell population should prove useful in understanding the circuitry and ultimately the mnemonic functions of the amygdala. *(Supported by the Air Force Office of Scientific Research and the Office of Naval Research).*

391.8

CONFOCAL SCANNING LASER MICROSCOPY OF HIPPOCAMPAL NEURONS FROM CULTURED AND ACUTE BRAIN SLICES. C. L. Keenan, E. W. Kairiss, A. C. Greenwood*, A. C. Nobre, L. Rihm*, T. H. Brown, Dept. of Psychology, Yale University, New Haven, CT 06520.

We have been interested in optical methods that optimize spatial and temporal resolution of cellular and subcellular structure in acute and cultured brain slices (Keenan et al, *Brain Res. Bull.*, 1988). Here we report the successful imaging of hippocampal neurons with confocal scanning laser microscopy (see also Kairiss et al, *Soc. Neurosci. Abstr.*, 1989).

Acute hippocampal slices were prepared in the conventional way using a vibratome. Neonatal hippocampal slices were cultured as described previously (Ganong et al, *Soc. Neurosci. Abstr.*, 1988) and maintained in a roller drum for 3 to 6 weeks prior to their use. Intracellular recordings and dye injections were done with microelectrodes containing either lucifer yellow or carboxyfluorescein. Serial optical sections (3.0 - 15.0 μm intervals using a 10X or 20X objective and 0.1 - 1.0 μm intervals using a 40X or 60X objecive) of the fluorescently-labeled neurons were obtained with a confocal scanning laser microscope. Image reconstructions of the optical sections were then displayed as a stereo pair or as a red/blue stereo anaglyph.

These 3D images were particularly effective for visualizing the spatial relationships among dendritic processes and the interdigitation of processes of injected pairs of neurons. We were particularly interested in visualizing clearly the thorny excrescences, which are dendritic spines associated with the mossy-fiber synaptic input. The excrescences were seen to have extremely complex geometries, sometimes consisting of rosettes of small spines protruding from a central shaft.

We conclude that confocal scanning laser microscopy holds great promise for studies of hippocampal neurons and possibly even for real-time analysis of neuronal structure-function dynamics. This method may enable us to determine whether structural changes occur during activity-dependent synaptic modifications, such as long-term potentiation (LTP) (Brown et al, *Science*, 1988). LTP is a candidate synaptic substrate for certain forms of learning. *(Supported by the Air Force Office of Scientific Research and the Office of Naval Research).*

OPIATES, ENDORPHINS AND ENKAPHALINS: ANATOMY AND CHEMISTRY II

392.1

SIGMA RECEPTOR RECOVERY FOLLOWING MODIFICATION BY EEDQ: EVIDENCE FOR DIFFERENT AGONIST AND ANTAGONIST RECOGNITION SITES OR RECEPTOR SUBTYPES G. Battaglia, Department of Pharmacology, Loyola University, Maywood, Il 60153

Sigma receptor recovery following irreversible inactivation by N-ethoxy-carbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) was studied. Male SD rats were treated with either vehicle or EEDQ (10 or 20mg/kg, i.p.) and sacrificed at 6 hours or 4 days post-treatment. Other groups of rats were pretreated with 3mg/kg of either the agonist DTG (1,3-di-o-tolyl-guanidine) or the antagonist haloperidol (HAL) prior to 10mg/kg EEDQ to assess recognition site specificity. Sigma receptors in cerebellum were measured using the agonist ^{3}H-DTG (3nM) and two concentrations of the antagonist ^{3}H-HAL (1.2 and 11 nM) to detect changes in receptor affinity and B_{max}. Marked decreases in ^{3}H-DTG binding were observed following both 10mg/kg (48% of control) and 20mg/kg (38% of control) doses. A 39% recovery of ^{3}H-DTG binding was observed by day 4. In contrast, ^{3}H-HAL-labeled sigma receptors were not reduced by either dose of EEDQ. In addition, HAL pretreatment failed to protect against the EEDQ-induced decrease in ^{3}H-DTG binding while DTG pretreatment resulted in a partial protection. The differential effects of EEDQ on ^{3}H-DTG versus ^{3}H-HAL-labeled sigma sites indicate that agonist and antagonist recognition sites differ. These data also suggest that ^{3}H-DTG may label EEDQ-sensitive and EEDQ-insensitive subtypes of sigma receptors.

392.2

PRESYNAPTIC INHIBITION BY OPIOIDS OF GLUTAMATE-MEDIATED SYNAPTIC POTENTIALS IN RAT STRIATAL NEURONS. Z.G.Jiang* and R.A.North, Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Intracellular recordings were made from striatal neurons in 30° obliquely cut slices. Fifteen of 25 tested were identified as projection neurons by antidromic activation by a focal electrical stimulus to the globus pallidus. Focal stimulation of cortical projection fibers evoked a excitatory postsynaptic potential (epsp). In 96 of 112 cells this was unaffected by bicuculline (30 μM) but completely blocked by CNQX (10 μM) and APV (30 μM); it was also blocked by low calcium/high magnesium solutions, and by tetrodotoxin (TTX, 1 μM). [Met^{5}]enkephalin (3, 10, 30 & 100 μM) reduced the epsp amplitude by (%) 10.1 ± 6.7 (mean ± SD, n = 9), 24.3 ± 7.9 (9), 34.8 ± 11.1 (43) and 41.6 ± 8.6 (8), with little or no effect on membrane potential or input resistance. Depolarizations evoked by direct applications of glutamate (pressure pulse) were unaffected, whether (n = 3) or not (n = 5) TTX was present. The inhibition by [Met^{5}] enkephalin was completely antagonized by naloxone (1 μM) and was mimicked by both Tyr-D-Ala-Gly-MePhe-Gly-ol (DAGO, 1 μM; inhibition was 23.1 ± 8.4 % (15) and Tyr-D-Pen-Gly-Phe-D-Pen (DPDPE, 1 μM; inhibition was 23.3 ± 13.1 % (17)), though not by U50488H. It is concluded that some fibres providing excitatory synaptic input to striatal neurones express either μ or δ receptors, activation of which inhibits glutamate release.

392.3

ENKEPHALIN, ENDORPHIN AND DYNORPHIN IMMUNOREACTIVE CELLS AND FIBERS IN THE PITUITARY OF THE AXOLOTL. (Ambystoma mexicanum) M. Leon Olea*, M. Sánchez-Alvarez*, A.L. Piña*, M.Briones* and A. Bayón. División de Inv. en Neurociencias Instituto Mexicano de Psiquiatría. Instituto de Investigaciones Biomédicas, UNAM, AP-70228, 04510 México, D.F.

Recently Assai et al.(Neuropeptides, in press) showed that the enkephalin (ENK) content in the pituitary of the axolotl is several fold higher than that found in birds and mammals. In order to elucidate the cellular localization of this ENK and its relations to other opioid peptides in the pituitary, we carried out immunocytochemical studies through the indirect immunofluorescence method using antibodies directed against leu-ENK, met-ENK, dynorphin(1-10) (DYN) and β-endorphin-βLPH (END). Leu-ENK-immunoreactivity (ir) was found in neurohypophyseal fibers and in numerous cells scattered throughout the anterior lobe; here, END-ir cells constitute a separate population concentrated in the caudal pole (END is also present in intermediate cells). DYN-ir was intense in fibers of the neural lobe but undetectable in the anterior one. Met-ENK-ir could be detected in neurohypophyseal fibers but only a few cells were lightly fluorescent in the anterior lobe. From these data and since Pro-ENK-A genes in amphibians may not codify leu-ENK sequences (Martens and Herbert, Nature 310:251,1984), we suggest that putative Pro-ENK-B containing cells could generate leu-ENK, but not DYN, as a hormone in the hypophysis of the axolotl.

392.4

BIOCHEMICAL CHARACTERIZATION AND BRAIN DISTRIBUTION OF ^{3}H-NALOXONE BINDING SITES IN A URODELE AMPHIBIAN. P. Deviche and F.L. Moore. (SPON: S. EMERY). Inst. Arctic Biology, Univ. Alaska Fairbanks, Fairbanks, AK 99775 and Dept Zool. Oregon St. Univ., Corvallis, OR 97331.

Suspensions of partially purified membranes prepared from newt (Taricha granulosa) brains were incubated with ^{3}H-naloxone and brema-zocine HCl (competitor). ^{3}H-naloxone binding was found to be specific and saturable (Kd: 1 ± 0.3 nM; Bmax: 155 ± 39 fmol/mg protein), time- and temperature-dependent, fully reversible, heat- and trypsin- sensitive, dose-dependently and selectively increased by Na^+ in the incubation medium, and displaced by ligands that are selective for μ, δ, or κ opiate receptors. Using in vitro autoradiography, we found that ^{3}H-naloxone specifically and discretely binds to the urodele brain. The highest specific binding was observed in the medial pallium, the medial septum, the amygdala (pars lateralis), and various diencephalic nuclei. No specific binding was detected in the anterior pituitary. The biochemical characteristics and the neuroanatomical distribution of opiate binding sites of newts and of other vertebrates, therefore, present many similarities.

392.5

OPIOID PEPTIDE SCREENING OF DOG HEART EXTRACTS. B.A. Barron, J.F. Gaugl*,J.L. Caffrey*, Department of Physiology, Texas College of Osteopathic Medicine, Ft. Worth, TX 76107.

Opioids in dog heart extracts are characterized by opiate radioreceptor assay (RRA) using dog brain membranes, pretreated with Na^+ and GMP. ^{3}H-diprenorphine was used as a non-specific ligand to permit screening for a spectrum of opioids. Scatchard analysis provided computer fits equally consistent with 2 or 3 site models. K_{D1} (0.4 nM) and B_{MAX1} (66 fmol/mg protein) values agree with reports by others for rat brain. IC50s determined graphically [logit (ln %B÷[100-%B]) vs concentration] were 1.8 nM diprenorphine, 8.1 nM etorphine, 8.4 nM naltrexone, 33 nM DYN(1-13), 41 nM DADLE, 50 nM (-)-naloxone, 104 nM DYN(1-8), 164 nM met-enk, 200 nM DYN(1-9), 810 nM DAGO, 2640 nM U50488H, and > 100 μM (+)-naloxone when 1.5 nM ^{3}H-diprenorphine was used. Tissue unknowns were expressed as nM equivalents of etorphine standards. Canine heart was extracted (1 N acetic acid, 0.2% 2-mercaptoethanol, 0.1 N HCl), homogenized (polytron) and centrifuged. Supernatants were further purified by C-18 cartridge (SepPak, Waters). After evaporation of solvents, reconstituted samples were tested in the RRA. Methods to optimize peptide recovery during tissue collection are under evaluation. Preliminary results indicate opioid activity throughout the myocardium with some preferential concentration in the intraventricular septum. Supported by American Heart Association-Texas Affiliate grant #G-165.

EFFECT OF CATIONS ON GTP REGULATION OF [125I]β-ENDORPHIN BINDING: DIFFERENCES BETWEEN μ AND δ OPIOID RECEPTORS D.E. Selley and J.M. Bidlack. Department of Pharmacology, University of Rochester, Rochester, NY 14642.

The binding of agonists to μ and δ opioid receptors is inhibited by μM concentrations of GTP. However, we have shown that the binding of [^{125}I]β-endorphin ([^{125}I]β-EP) to rat brain membranes was not inhibited by GTP unless monovalent cations were present. These cations promoted GTP regulation of [^{125}I]β-EP binding with their order of potency being: $Na^+ > Li^+ > K^+$. [^{125}I]β-EP binding to δ opioid receptors in NG108-15 cell membranes was inhibited by GTP in the presence of Na^+, but not Li^+ or K^+. These studies have been extended to membranes prepared from the SK-N-SH cell line, which contain predominantly μ opioid receptors. GTP did not inhibit [^{125}I]β-EP binding to SK-N-SH membranes in the absence of cations, but did inhibit [^{125}I]β-EP binding in the presence of NaCl, LiCl, or KCl, with the order of potency being $Na^+ > Li^+ > K^+$. These cations were about equipotent in inhibiting [^{125}I]β-EP binding by themselves. These results are similar to those obtained in rat brain membranes, but differ from those obtained in NG108-15 membranes. [^{125}I]β-EP binding was not inhibited by GTP in the presence of the divalent cations, Mg^{2+}, Ca^{2+}, or Mn^{2+}, though these cations were about 20 times more potent than the monovalent cations in inhibiting [^{125}I]β-EP binding by themselves. Thus, both μ and δ receptors require monovalent cations for GTP regulation of [^{125}I]β-EP binding, but the specificity of this requirement differs between the two types of opioid receptor.

EFFECTS OF OPIOID RECEPTOR BLOCKADE ON HIPPOCAMPUS DEVELOPMENT IN ADOLESCENT RATS. J. Reyes*, D. Fish* and M.C. Diamond (SPON: N. Peterson). Department of Physiology-Anatomy, Univ. of California, Berkeley, Ca. 94720

Studies have indicated that regions of the CNS are increased in size and cellular content when opioid receptors are blocked by Naltrexone. Our study examines the relationship between opioid receptor blockade, size (thickness) and laterality in the hippocampus of 41-day-old rats. Male and female Long-Evans rats were injected subcutaneously with either saline, 1, 10, or 50mg/kg of Naltrexone, an opioid receptor antagonist, for the first 41 days of postnatal life. On day 41 rats were sacrificed and morphometric analysis of the hippocampus were made on transverse, frozen 40mu sections stained with a modified Thionine stain. Results indicated increases in male hippocampal thickness at each dosage ($p<0.05$) when compared to control (saline) rats. Furthermore, significant laterality differences were seen in the 1 mg/kg dosage group, with the left hippocampus being larger than right ($p<0.05$). These results are opposite to those seen in male rats treated for the first 21 days postnatally. Female rats showed no significant differences between dosage groups in hippocampal size or laterality. However, as the dosage of Naltrexone increased, the left hippocampus progressed from smaller than controls at the 1 and 10 mg/kg dosages to larger than controls at 50 mg/kg. These results are similar to what is seen in females exposed for 21 days postnatally to Naltrexone.

STIMULATION-INDUCED RELEASE OF ENDOGENOUS OPIOID PEPTIDES CAUSES DISPLACEMENT OF MU AND KAPPA LIGAND BINDING IN THE HIPPOCAMPUS. J.J. Wagner*, J.F. Neumaier, R.M. Caudle and C. Chavkin, Dept. of Pharmacology, Univ. of Wash, Seattle, WA 98195.

Previous studies have demonstrated that the hippocampus has two major pathways containing endogenous opioid peptides: the perforant path from the entorhinal cortex and the mossy fibers from the dentate gyrus. To determine the physiological conditions required to release opioids from these pathways and the anatomical sites within the tissue that could bind the released opioids, we used a radioligand displacement paradigm in which either 10 nM [^{3}H]-DAGO or 3 nM [^{3}H]-U69,593 was added to incubation wells containing hippocampal slices (500 μm) in oxygenated buffer at 34°C. We found that the specific binding of [^{3}H]-DAGO to mu receptors in rat hippocampal slices was reduced by depolarization caused by 3 μM veratridine or by focal electrical stimulation. [^{3}H]-DAGO displacement was calcium-dependent, blocked by 1 μM tetrodotoxin, and dependant on the presence of peptidase inhibitors. Electrical stimulation of opioid containing pathways caused a reduction in radioligand binding in discrete areas of the hippocampus as shown by quantitative receptor autoradiography. Similarly, [^{3}H]-U69,593 binding to kappa-1 sites in guinea pig hippocampal slices was reduced by both veratridine and electrical stimulation. These results indicate that opioid peptides released under physiological conditions bind to mu and kappa receptors in the rodent hippocampus. The pattern of displacement suggests that opioids can diffuse to distant sites of action under these conditions. Supported by DA-01423 and NS-023483.

KAPPA OPIOID RECEPTOR-MEDIATED PHOSPHOINOSITIDE TURNOVER IN RAT BRAIN. S. Periyasamy* and W. Hoss (SPON: H. Rosenberg), Department of Medicinal and Biological Chemistry, University of Toledo, Toledo, OH 43606

Both biochemical and pharmacological evidence support the existence of at least three subtypes of opioid receptors μ, δ, and κ in the CNS. Opioid receptors, including κ-receptors, are associated with the inhibition of adenylyl cyclase, stimulation of low-K_m GTP hydrolysis and more recently with the regulation of K^+ and Ca^{2+} channels. However, opioid receptors have not been previously associated with the phosphoinositide turnover response. We have investigated the effects of various subtype-selective opioid agonists and antagonists on PI turnover response in the rat brain. U-50,488H, a selective κ-agonist, enhanced the hydrolysis of inositol phospholipids, as reflected by increased [^{3}H]-inositol phosphates ([^{3}H]-IP's) formation in rat hippocampal slices prelabeled with [^{3}H]-inositol and treated with Li^+. The κ-selective agonists U-50,488H ketocyclazocine and D[Ala]^2-dynorphin-A (1-13) amide produced a concentration-dependent increase in the accumulation of IP's in hippocampal slices without altering the incorporation of [^{3}H] inositol into phospholipids. The EC_{50} values were 140, 23, and 16 μM, respectively. Dynorphin-A (1-13) amide also produced a significant increase in the formation of [^{3}H]-IP's. On the other hand the μ-selective agonists [D-Ala^2-N-Me-Phe^4-Gly^5-ol]-enkephalin and morphine, the δ-selective agonist [D-Pen^{2,5}]-enkephalin and etorphine were ineffective in stimulating IP's formation in hippocampal slices. The increase in IP's formation elicited by U-50,488H was partially antagonized by naloxone and more completely antagonized by the κ-selective antagonists nor-binaltrophimine and MR 2266. The formation of IP's induced by U-50,488H varies across different regions of the brain, being highest in hippocampus and amygdala, and lowest in striatum and pons-medulla. The results indicate that brain κ– but neither μ- nor δ-receptors are coupled to the PI turnover response in the brain. It is suggested that the effects of dynorphin in brain and perhaps other tissues are mediated by κ-receptors linked to the PI turnover response. Supported by DA04068.

CHANGES IN THE SUBCELLULAR DISTRIBUTION AND GTP SENSITIVITY OF OPIOID RECEPTOR BINDING IN UP-REGULATED NEUROBLASTOMA-HYBRID CELLS. M. Belcheva*, R.J. McHale+, O.Dillon-Carter*, D.-M. Chuang# and C.J. Coscia+ (Spon: M.H. Cooper). Dept. Biochem., St. Louis Univ. St. Louis, MO and #Lab. Preclin. Pharmacol., NIMH, St. Washington, DC.

Membranes from Con A-treated NCB-20 and NG108-15 cells were resolved into light (LM) and heavy (HM) fractions by sorbitol density gradient centrifugation. Marker enzyme distribution data indicated that HMs were enriched in plasma membrane whereas LMs contained most of the endoplasmic reticulum and Golgi bodies. In both cell lines, HMs constituted 80-90% and LMs 10-20% of the δ opioid receptor specific binding, as measured with ^{3}H[D-Ala^2,D-Leu^5]enkephalin (DADLE). ^{3}H-DADLE binding to HMs was inhibited to a greater extent by guanosine-5'-(βγ-imido) triphosphate (Gpp(NH)p) than that of LMs for both cell lines, in agreement with our results with adult rat brain. Up-regulation was achieved by pretreating NCB-20 cells with 1 mM Na butyrate for 3 d or NG108-15 cells with 1 μM Naltrexone for 2 d. LMs from both upregulated cell lines were elevated 2-3 fold while HMs displayed a 1-2 fold increase in ^{3}H-DADLE binding. Dose-dependent Gpp(NH)p inhibition of δ binding in up-regulated LMs was greater than in controls. HM δ binding sensitivity to Gpp(NH)p was unchanged. These results taken together with data from neonatal rat brain studies suggest that LMs from up-regulated cells contain more newly synthesized opioid receptors than controls.

REVERSIBLE LOSSES IN OPIOID RECEPTOR EXPRESSION BY NEUROBLASTOMA CELL LINE N18TG2 IN VIVO. G.E. Thomas*, W.T Bem*, M. Belcheva*, D.C. Palmer*, K.C. Tolman*, F.E. Johnson*, and C.J. Coscia (Spon: S. Horenstein). St. Louis Univ. Med. Ctr., St. Louis, MO 63104.

Opioids regulate neuroblastoma growth via receptor mediated mechanisms. A current experimental model is the murine neuroblastoma line N18TG2, but the stability of its expression of opioid receptors in vivo has not been reported. N18TG2 cells were injected into male nude mice and the tumors passaged serially. At each generation, tumors were excised at necropsy and analyzed for δ opioid receptor binding parameters using ^{3}H[D-Ala^2,D-Leu^5]enkephalin in homologous displacement assays. Kd and Bmax were determined using the LIGAND program. Bmax for cultured cells (184±35 fmol/mg protein) declined with successive transfer, reaching 0 by passage 3. Tumor cells from passage 4, which displayed no detectable opioid receptor binding, were then returned to culture medium; 6 weeks later their opioid receptors were up-regulated (Bmax, 509±82 fmol/mg protein). Light microscopy revealed no morphological differences between the original and recultured cells. Repassaging the recultured cells in vivo led again to a rapid decline in opioid receptor expression. The Kd for DADLE (2.5 nM) remained unchanged. δ Opioid receptor expression is thus a non-constitutive property of N18TG2. This alteration of receptor expression represents an important variable and may prove useful in delineating the mechanism of opioid modulation of tumor growth.

392.12

AFFINITY LABELING OF MU OPIOID RECEPTORS IN BRAIN BY BROMOACETAMIDO DERIVATIVES OF MORPHINE. J.M. Bidlack[1], D.K. Frey[1], A. Seyed-Mozaffari[2] and S. Archer[2]. [1]Dept. of Pharmacology, University of Rochester, School of Medicine and Dentistry, Rochester, NY 14642 and [2]Dept. of Chemistry, Rensselaer Polytechnic Institute, Troy, NY 12181.

After reduction of a disulfide bond at or near the μ opioid binding site in rat brain membranes, 14β-bromoacetamidomorphine (BAM) has been shown to alkylate this site, resulting in the irreversible inhibition of greater than 90% of the μ opioid binding to rat brain membranes. The analogues 14β-bromoacetamido, 7,8-dihydromorphine (H_2BAM), 14β-bromoacetamidomorphinone (BAMO) and 14β-bromoacetamido, 7,8-dihydromorphinone (H_2BAMO) were tested for their ability to alkylate the μ opioid binding site. In the absence of a reducing agent, all affinity ligands bound reversibly. Their order of potency in inhibiting the binding of the μ-selective peptide [^{3}H]DAGO was H_2BAMO > BAMO = morphine > H_2BAM > BAM. When membranes were incubated with dithiothreitol followed by one of the affinity ligands, and then extensive washing, μ opioid binding was irreversibly inhibited, while binding to δ and κ sites was not altered by the affinity ligands. Their order of potency in irreversibly inhibiting μ opioid binding was the same as their rank order under reversible binding conditions. Only opioid alkaloids and peptides that bind to μ opioid receptors protected the site from alkylation. These affinity ligands will facilitate the characterization of the μ opioid binding site. (Supported by USPHS grants DA03742 and DA01674.)

PRETREATMENT OF RATS WITH THE IRREVERSIBLE μ-RECEPTOR ANTAGONIST, β-FNA, FAILS TO PREVENT NALTREXONE-INDUCED UPREGULATION OF μ-OPIOID RECEPTORS. **R. B. Rothman[1], J. B. Long[2], V. Bykov[1], K. C. Rice[3] and J. W. Holaday[2]. [1]Unit on Receptor Studies, LCS, NIMH, Bethesda, MD 20892. [2]Neuropharmacology Branch, Walter Reed Army Institute of Research, Washington, DC 20307-5100.[3] Laboratory of Medicinal Chemistry, NIDDK, Bethesda, MD 20892.**

This study examined the effect of FNA, an irreversible μ receptor antagonist, on naltrexone-induced upregulation of μ opioid receptors. Rats were treated according to the following protocol. Day #1: two naltrexone or two placebo pellets were implanted subcutaneously in a nylon mesh. Day #8: the pellets were removed intact. Rats were administered either saline or 20 nmol of FNA in 10 μl of saline (i.c.v.) on day #1,3, 5 and 6, 60 min prior to pellet implantation. Day #9: frozen lysed-P2 membranes were prepared from whole brain (minus cerebellum) and μ binding sites were assayed using [^{3}H]FOXY (New England Nuclear, SA=40.1 Ci/mmol) as previously described. The results were:

	GROUP	Bmax	Kd
1.	Placbo/Saline	112±4.6	3.80±0.13
2.	Placebo/FNA	94±13	11.2±1.0*
3.	Naltrexone/Saline	173±3.0	2.87±0.05*
4.	Naltrexone/FNA	165±9.0	8.35±0.20*

These data demonstrate that functional blockade of μ receptors with FNA does not upregulate μ receptors or prevent naltrexone-induced upregulation.

392.14

NALTREXONE-AMPHETAMINE INTERACTIONS IN THE REGULATION OF STRIATAL PRODYNORPHIN PEPTIDES. K.A. Trujillo and H. Akil. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

We have previously reported that chronic treatment with either amphetamine or morphine will increase prodynorphin (PRODYN) peptides in the striatonigral system. In order to further study the regulation of this system by dopaminergic and opiate agents we examined the effects of amphetamine and naltrexone, administered either separately or together, on PRODYN peptides in forebrain and midbrain regions. Adult male Sprague-Dawley rats received a single subcutaneous injection each day for 7 days of either saline (SAL; 1ml/kg), d-amphetamine sulfate (AMPH; 5 mg/kg), naltrexone HCL (NTX; 10 mg/kg), or AMPH (5 mg/kg) and NTX (10 mg/kg) administered together. Animals were sacrificed 24 hours after the final injection and selected brain regions were radioimmunoassayed for PRODYN peptides. In dorsal striatum (caudate-putamen) AMPH caused a dramatic increase (approximately 100% increase over SAL-treated animals) in peptide content. NTX, while causing no effects alone, partially blocked the effects of AMPH in this brain region. In ventral striatum (nucleus accumbens-olfactory tubercle) AMPH caused a modest increase in peptide content. In addition, NTX caused a similar increase in this brain region. However, when AMPH and NTX were administered together, no increase in content was seen. These results suggest that PRODYN neurons in the dorsal and ventral striatum are differentially regulated by dopaminergic drugs and opiate antagonists, and demonstrate complex interactions between these drugs in the regulation of PRODYN peptides. Further studies are necessary to elucidate the mechanisms responsible for the complex interactions between these drugs in the two brain regions. Supported by NIDA NRSA DA05336 (K.A.T.) and NIDA DA02265 and NIMH MH422251 (H.A.)

DIFFERENTIAL EFFECTS OF ELECTRICAL STIMULATION IN THE MIDBRAIN PERIAQUEDUCTAL GRAY ON BETA-ENDORPHIN-ir PEPTIDE FORMS IN DIFFERENT TERMINAL FIELDS OF RAT BRAIN. D. Bronstein and H. Akil, Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Proopiomelanocortin (POMC) cell bodies in the arcuate nucleus of the hypothalamus send axonal projections which innervate a diverse number of brain regions, including the septum, amygdala, periventricular nucleus of the thalamus, various hypothalamic nuclei, and the midbrain periaqueductal gray (PAG). The purpose of the present study was to examine how electrical stimulation in one POMC nerve terminal region (i.e., the PAG) might affect the content of various beta-endorphin (BE)-ir peptides in other POMC projection areas. Acute (10 min) electrical stimulation in the PAG resulted in no changes in total BE-ir content in any of the brain regions examined. However, animals chronically stimulated tended to have higher BE-ir levels in the the arcuate nucleus, dorsal hypothalamus, and septum compared to control animals. Chromatographic analyses revealed that the concentration of BE_{1-31} was increased relative to that of BE_{1-27}-size peptides in the midbrains of acutely stimulated animals; conversely, the ratio of BE_{1-31}:BE_{1-27} concentrations was decreased in the dorsal hypothalamus. The stimulation-induced alteration in the relative amounts of BE_{1-31} and BE_{1-27} may be an important indicator of the physiological tone in specific terminal fields. These results also demonstrate that electrical stimulation in one nerve terminal region has disparate effects on other BE-containing brain regions, suggesting that these effects are probably not mediated by a single mechanism. (Supported in part by NIDA #DA02265 to H.A. and a MRC Fellowship to D.B.)

MET-ENKEPHALIN-LIKE IMMUNOREACTIVITY IN PORCINE TISSUE EXTRACTS. D.L. Lucas*, J.E. Bailey*, L.D. Aimone, T.L. Yaksh, V.L.W. Go*. (SPON: B.F. Westmoreland). Mayo Clinic, Rochester, MN 55905, Univ. of CA, San Diego, LaJolla, CA 92093, and Univ. of CA, Los Angeles, CA 90024.

We have developed a radioimmunoassay for met-enkephalin (Enk) using an antibody (N382) with a crossreactivity of 31, 25, 11, and 5% to Lys6, Arg6, Arg6-Phe7, and Arg6-Gly7-Leu8 carboxy terminus extensions of Enk, respectively. Pigs (n=4) were dissected immediately postmortem into 111 brain, cord, gut and ganglia sections and extracted in 0.1 N HCl. Total encrypted Enk was also evaluated in brain regions after trypsin/carboxypeptidase B treatment of extracts, and ratios of total Enk/Enk calculated.

Region	Enk[1]	Ratio[2]	Region	Enk[1]	Ratio
Pituitary	843	2.6	Nuc Accumb	139	3.7
Glob Pal/Putamen	292	1.6	Peri Gray	105	2.9
Caudate Nucleus	162	2.1	Septum	85	4.7
Sub Nigra	149	2.5	Mam Body	52	4.1
Hypothalamus	92	3.4	Medulla	36	5.7
Cerv Dor Horn	18.4	-	Duodenum	111	-
Sacr Dor Horn	37.1	-	Colon	10.4	-

[1]Enk=ng/gm; [2]Ratio=Total Enk/Enk

The varying ratios of total Enk/Enk in selected brain regions may be related to differential processing of opioid precursors reported by others.

396.17

STRUCTURE-ACTIVITY RELATIONSHIPS OF DTG AND ITS CONGENERS AT THE HALOPERIDOL-SENSITIVE SIGMA RECEPTOR. B. Tester, M. Scherz*, M. Fialeix*, J. Keana* and E. Weber. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201 and Department of Chemistry, University of Oregon, Eugene, OR 97403.

With an eye toward the full biochemical characterization of the haloperidol-sensitive sigma receptor, we have studied the structure-activity relationships of di-o-tolylguanidine (DTG) and its congeners at this site. A number of DTG analogs were synthesized and evaluated in in vitro radioligand displacement experiments with guinea pig brain membrane homogenates, using the highly sigma-specific radioligands [3H]DTG and [3H](+)3-PPP, and the PCP receptor-specific compounds [3H]TCP and [3H](+)-MK-801. The affinity of N,N'-diarylguanidines for the sigma receptor decreases with increasing steric bulk of ortho substituents larger than CH_3, and hydrophobic substituents are preferred over hydrophilic ones, regardless of their position on the ring. Furthermore, electroneutral substituents are preferred over strongly electron donating or withdrawing groups. Potent binding to the sigma receptor is retained as long as at least one side of the guanidine bears a preferred group (e.g.o-tolyl). Replacement of the aryl ring with certain saturated carbocycles (e.g.cyclohexyl, norbornyl or adamantyl) leads to a significant increase in affinity. By combining the best aromatic and best saturated carbocyclic substituents in the same molecule, we arrived at some of the most potent sigma ligands described to date, e.g. N-endo-2-nor-bornyl-N'-2-iodo-phenylguanidine (IC_{50} of 3 nM vs. [3H]DTG). All of the compounds tested were several orders of magnitude more potent at the sigma receptor than at the PCP receptor, with a few notable exceptions. This series of disubstituted guanidines is of great value in the development of potential antipsychotics, and in the further pharmacological and biochemical characterization of the sigma receptor. We thank Nam Hoang for his contribution to this project. Supported by NIMH grants MH40303 and MH42608, a grant from Cambridge NeuroScience Inc.

DYNORPHIN-SELECTIVE INHIBITION OF ADENYLATE CYCLASE IN GUINEA PIG CEREBELLUM MEMBRANES. C.S. Konkoy and S.R. Childers, Dept. of Pharmacology, Univ. Florida Coll. Med., Gainesville, FL 32610.

Kappa opioid receptors have been characterized by their binding and pharmacological properties, but the question of which second messenger systems are coupled to kappa receptors is not yet settled. Both mu and delta opioid receptors inhibit adenylate cyclase in brain membranes. Guinea pig cerebellum, which contains kappa receptors relatively uncontaminated by other opioid receptor types, was chosen to examine whether kappa receptors are coupled to adenylate cyclase. Membranes were prepared from guinea pig cerebellum and pretreated at pH 4.5 to increase inhibitory activity, and adenylate cyclase was assayed in the presence of dynorphin analogs as prototypical kappa agonists. Results showed that several dynorphin analogs inhibited adenylate cyclase by 30%-50%, whereas mu and delta preferring agonists had no effect. Dynorphin A and the kappa-selective compounds D-pro^{10}-dynorphin 1-11 and U-50,488H were the most potent agonists, with IC_{50} values of 0.03-0.05 μM, while other dynorphin gene products like dynorphin B and α-neo-endorphin were approximately ten-fold less potent. Like other G_i-coupled responses, dynorphin-inhibited adenylate cyclase required GTP and sodium. Naloxone was a competitive antagonist for dynorphin-inhibited adenylate cyclase, with 1 μM naloxone shifting the IC_{50} value of dynorphin A by 20-fold. The kappa-selective antagonist nor-binaltorphimine (nor-BNI) was even more potent, with 0.1 μM nor-BNI shifting the dynorphin IC_{50} value by 50-fold. These results suggest that dynorphin A and its analogs inhibit adenylate cyclase by binding to a G protein-coupled opioid receptor whose pharmacological specificity matches those of kappa receptors.

REGULATION OF TYPE I ASTROCYTE PROENKEPHALIN: TRANSCRIPTION, TRANSLATION, AND SECRETION. K. G. Low*, R. G. Allen, C. P. Nielsen*, R. P. Saneto, S. L. Young*, and M. H. Melner* (SPON: B. V. Critchlow). Oregon Regional Primate Research Center, Beaverton, OR 97006 and Oregon Health Sciences University, Portland, OR 97201.

The expression and regulation of proenkephalin, proopiomelanocortin, and prodynorphin was investigated in primary cultures of purified glial cells from the neonatal rat cerebral cortex. Northern blot analysis revealed that of all three opioid genes, only the proenkephalin gene was expressed in type I astrocytes. No proenkephalin expression was detected in bipotential glial precursor cells or oligodendrocyte progenitor cells. Treatment of the astrocytes with 10^{-6} M isoproterenol (ISO) or 5 X 10^{-4} M chlorophenylthio-cAMP (CPT-cAMP) for 20 hours stimulated proenkephalin mRNA levels 3-fold and 6-fold, respectively. Glial fibrillary acidic protein (GFAP) mRNA levels were also stimulated by ISO or CPT-cAMP treatments by 3-fold over untreated controls. Potential transcriptional regulation of the proenkephalin promoter was examined by transfecting the fusion gene construct pENKAT-12 containing 193 bp of the 5' flanking sequence, exon I, intron A, and 53 bp of exon II of the human proenkephalin gene fused to the bacterial chloramphenicol acetyltransferase (CAT) gene into astrocytes. Treatment of the transfected cells with 10^{-6} to 10^{-8} M ISO elicited stimulations of CAT activity from 7 to 19-fold over controls. CPT-cAMP treatment stimulated CAT activity 6-fold. Immunoreactive proenkephalin was measured by radioimmunoassay using antisera against met-enkephalin-arg-phe and HPLC-separation of acetic acid extracts of cells and media. Control cultures secreted 2.3 ± 0.4 pmoles/ml. Treatment with ISO or CPT-cAMP significantly stimulated proenkephalin peptide levels to 4.0 ± 0.1 and 4.3 ± 0.3 pmoles/ml, respectively. These data suggest that type I astrocytes from neonatal rat cortex express and secrete significant levels of proenkephalin under the regulation of β-adrenergic agonists. Supported in part by NIH DK-41035, RR-00163, and ONR N00014-88-K-0030, R&T Code 441F724.

AGE-DEPENDENT SUBCELLULAR DISTRIBUTION OF OPIOID RECEPTORS AND G-PROTEINS IN RAT BRAIN. C.J. Coscia, S.J. Yeung, M. Belcheva and W.T. Bem. Dept. of Biochem., St. Louis Univ. Med. Ctr., St. Louis, MO 63104.

Evidence for ontogenic differences in binding and structural properties of rat brain opioid receptors has been reported previously. In the present study we investigated the possibility that early neonatal membranes are enriched in newly synthesized μ opioid receptors as detected with ^{3}H[D-ala^2,mePhe^4,gly-ol^5] enkephalin. Membranes from 1-day-old neonatal (P-1) and adult rat forebrain were resolved into light (LM) and heavy (HM) populations. Marker enzyme distribution indicated that LMs were enriched in endoplasmic reticulum and Golgi apparatus, while HM contained most of the plasma membranes. P-1 LMs contained 43% of the total μ-opioid receptor binding compared to 16% in their adult counterpart. Sodium ions inhibited μ-opioid binding in LMs to a greater extent (65-71%) than in HMs (45-51%) but no significant differences were seen between P-1 and adults. P-1 LM binding displayed greater sensitivity to the GTP analog, Gpp(NH)p, and LMs possessed more G-protein α-subunit than adult LMs, as shown by quantitative immunoblotting experiments with anti-G peptide antibodies. The presence of a greater proportion of different intracellular sites may be responsible for some of the previously documented differences between adult and neonatal opioid binding.

CHARACTERIZATION OF [^{3}H](+)-PENTAZOCINE, A HIGHLY SELECTIVE SIGMA LIGAND. W.D. Bowen[1], B. DeCosta[2*], S.B. Hellewell[1*], A. Thurkauf[2*], K.C. Rice[2], and J.M. Walker[3]. [1]Div. Biology and Med. and [3]Dept. Psychology, Brown Univ., Providence, RI. 02912, and [2]Lab. Med. Chem., NIDDK, Bethesda, MD 20892.

(+)-Pentazocine appears to be a selective sigma ligand, and it binds to guinea pig brain sigma receptors with an apparent K_i of 1.2 nM. This compares to a K_i of 5,530 nM at phencyclidine receptors. By comparison (+)-SKF 10,047 exibits a sigma K_i of 62.2 nM and a PCP receptor K_i of 208 nM. We surmised, therefore, that [^{3}H](+)-pentazocine would be a more selective benzomorphan-based probe for sigma receptors than the currently available [^{3}H](+)-SKF 10,047. [^{3}H](+)-Pentazocine (26.6 Ci/mmol) was synthesized by tritiation of (+)-normetazocine, followed by attachment of the prenyl side chain. Scatchard analysis in guinea pig brain membranes yielded linear plots with a K_d of 5.1 nM and a B_{max} of 1,146 fmol/mg protein. Percent specific binding was greater than 90% at concentrations up to 25 nM. Competition of various unlabeled ligands against 3 nM [^{3}H](+)-pentazocine revealed the following order of potency: haloperidol = (+)-pentazocine > DTG = (+)-3-PPP > (+)-SKF 10,047 > (-)-pentazocine >> PCP. MK-801 and apomorphine were inactive. Thus, [^{3}H](+)-pentazocine exhibits high affinity and selectivity for sigma receptors.

EVIDENCE FOR MUTUAL INTERACTIONS OF ENKEPHALIN AND CCK ANALOGUES AT CCK AND ENKEPHALIN RECEPTORS R.B. Murphy, M. Davila-Garcia, E.C. Azmitia, P. Psyllas, G. Haraminian, A. Cann, M.R. Pincus, J. Chen, L.H. Schneider, J. Gibbs, and G.P. Smith. Depts Chem. and Biol., N.Y.U., N.Y. 10003 ; Dept. Psychiatry, Bourne Lab., NYH-CUMC, White Plains, NY 10605 ; Dept of Pathol., SUNY-Hlth. Sci. Ctr., Syracuse, NY 13210

We previously predicted interactions between enkephalin (ENK) and CCK at the receptor level, based upon molecular modeling (Pincus et al, Peptides 9: S145, 1988). We here present additional experimental evidence in support of this hypothesis. Unsulfated CCK (DS-CCK-8) significantly inhibits outgrowth of fetal rat hindbrain 5-HT neurons in culture, as quantified by [^{3}H]-5-HT uptake and morphometry. Leu-ENK produces a similar result (Davila-Garcia and Azmitia, Brain Res. in press, 1989). The DS-CCK inhibition is blocked by naloxone, but not by the CCK antagonist phenoxyacetylproglumide. In another series of experiments, we examined the effect of Met-ENK upon physiological response (contraction) produced by sulfated CCK-8 in the rat pyloric sphincter, a clean peripheral-type CCK receptor preparation (Murphy et al, Peptides 8: 127, 1987). Met-ENK antagonizes the CCK-8-induced contraction (IC_{50} = 110 nM); naloxone (10 uM) is without effect. These results further support the presence of receptor-level CCK-ENK interaction. Supported by NSF BNS8812892, NIMH RO1 40010, and Hoffman-La-Roche.

CHRONIC NALTREXONE INCREASES EXPRESSION OF PREPROENKEPHALIN AND PREPROTACHYKININ mRNA IN DISCRETE BRAIN REGIONS. R.S. Zukin, J.A. Kessler and A. Tempel (SPON: A.B. Johnson). Dept. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Long-term blockade of opioid receptors by the antagonist naltrexone increases met-enkephalin in the striatum and nucleus accumbens (Tempel et al., 1984). To determine whether these changes reflect increased peptide synthesis, we examined preproenkephalin (PPE) mRNA content in brain regions of control (placebo-treated) and naltrexone-treated animals by Northern analysis. Naltrexone treatment (8 days) led to an 11-fold increase in striatal PPE mRNA. No statistically significant change was observed in striatal cyclophilin (1B15) or actin mRNA. Small increases in PPE mRNA occurred in the hippocampus (+40%) and hypothalamus (+19%). Increases in mRNA occurred 24 hrs following onset of antagonist; increases in opioid receptors were half maximal 3-4 days after onset of antagonist. To determine whether substance P synthesis is altered by naltrexone, preprotachykinin (PPT) mRNA content was examined. Naltrexone (8 days) increases striatal PPT mRNA by 5-fold. Striatal substance P was increased 3-fold. These findings suggest that chronic blockade of brain opioid receptors leads to the increased synthesis of both enkephalin and substance P in the striatum, and that the changes are relatively specific. The finding of opiate antagonist-induced increases in PPT mRNA and substance P supports the concept of a role for enkephalin in the regulation of substance P gene expression. [Supported by NIH grants DA04439 (R.S.Z.); DA05440 (A.T.) and NS20778 (J.A.K.)].

mRNA REGULATION IV

393.1

ESTRADIOL REGULATION OF ESTROGEN RECEPTOR mRNA IN RAT HYPOTHALAMUS. A.H. Lauber, G.J. Romano, C.V. Mobbs, P. Chambon and D.W. Pfaff. Lab of Neurobiology and Behavior, Rockefeller University, New York, NY 10021.

In situ hybridization was used to investigate estradiol regulation of estrogen receptor (ER) mRNA. Ovariectomized (Ovx) rats were treated with 10 ug estradiol benzoate (EB) for 0,2,4,18 or 24 hrs. Brain sections were hybridized with a 3H-single-stranded DNA probe prepared from the pORF cDNA of the human ER gene and exposed to nuclear emulsion for 4 months. Specificity of labelling was determined by counting grains/cell in ventromedial nucleus of the hypothalamus (VLVM) compared to cells in thalamus and cortex, and by comparing to sections pretreated with RNAse or hybridized with a non-sense probe. Labelling for ER mRNA was not apparent in regions known to contain high concentrations of glucocoorticoid and thyroid receptor mRNAs. ER-expressing cells constituted 30-40% of cells in arcuate nucleus and VLVM, respectively, in close accordance with data from ER steroid autoradiography (Exp. Brain Res. 62:343). Highest levels of ER mRNA were present in the Ovx controls. ER mRNA levels were decreased 2 hrs following EB administration, fell 42% (VLVM) and 64% (arcuate) by 18 hrs, and remained depressed at 24 hrs. These data show that estrogen can down-regulate ER mRNA in neurons implicated in different estrogen-dependent functions, and as reported for ER mRNA in MCF-7 cells.

393.2

REGULATION OF THE GLUCOCORTICOID SENSITIVITY OF NEUROBLASTOMA AND MOUSE L CELLS BY TRANSIENT EXPRESSION OF A GLUCOCORTICOID RECEPTOR (GR) ANTI-SENSE RNA AND BY DESIPRAMINE. Marie-Claude Pepin* and Nicholas Barden. Ontogénèse et Génétique Moléculaires, Le Centre de Recherche du Centre Hospitalier de l'Université Laval, Ste-Foy, Québec G1V 4G2, Canada.

Depression is often characterized by increased cortisol secretion caused by hyperactivity of the hypothalamo-pituitary-adrenal (HPA) axis and by non-suppression of cortisol secretion following dexamethasone administration. This hyperactivity of the HPA axis might be caused by a reduction of GR in brain cells involved in the control of the axis. This hypothesis is in agreement with our results which show that antidepressants may normalize the HPA axis by increasing neuronal GR mRNA levels (PEPIN et al. Mol. Brain Res., in press.) In order to investigate the effect of reduced neuronal GR levels, we have blocked cellular GR mRNA translation by introduction of a complementary GR anti-sense RNA strand. Two cell lines, mouse LTK$^-$ cells and neuroblastoma NB41A3 cells were transfected with a reporter plasmid carrying the chloramphenicol-acetyl-transferase (CAT) gene under MMTV-LTR (a glucocorticoid inducible promotor) control. This gene construction permitted assay of the sensitivity of the cells to glucocorticoid hormones. Cells were also co-transfected with a plasmid containing 1800bp of GR cDNA in the reverse orientation downstream from a neurofilament gene promotor element and the sensitivity of CAT activity to exogenous dexamethasone subsequently measured. While, in control incubations, dexamethasone increased CAT activity by as much as 13 fold, expression of GR anti-sense RNA caused a 2-4 fold decrease in the CAT response to dexamethasone.When cells were incubated in the presence of antidepressant (desipramine), a two to three fold increase in the sensitivity of CAT activity to dexamethasone was seen. These results validate the use of antisense RNA to GR in order to decrease the cells response to glucocorticoids and confirm the antidepressant-induced modulation of cell sensitivity to glucocorticoids.

393.3

DISTRIBUTION OF CHOLINE ACETYLTRANSFERASE mRNA IN THE RAT BRAIN. M.V. Lorenzi*, D.C. Hilt, L.B. Hersh, C.F. Kong*, F. Hefti, and W.L. Strauss (SPON: L.T. Potter). Dept. of Pharmacology, Univ. of Miami, Dept. of Neurology, Univ. of MD School of Med., Dept. of Biochemistry, Southwestern Med. Ctr. at Dallas and Andrus Gerontology Ctr. U.S.C.

Choline acetyltransferase (ChAT) is the biosynthetic enzyme for the neurotransmitter acetylcholine. It has been observed that nerve growth factor (NGF) increases ChAT activity 3-5 fold in cultured fetal septal neurons (Hefti et al., Neuroscience 14: 55, 1985). In order to study this phenomenon further, we have identified a human genomic clone corresponding to ChAT using oligodeoxynucleotides directed against porcine and human ChAT (Hersh et al., this volume). A 2.8 kb Bam H1 fragment of this clone coding for the amino terminal region of the ChAT protein cross hybridizes with a 4000 nt rat mRNA on Northern blots, in agreement with Berrard et al. (PNAS 84: 9280, 1987). This RNA species was detected in poly A(+) RNA isolated from rat basal forebrain, cortex, and septum, but not from hippocampus. We currently are examining the effect of NGF on ChAT RNA levels in cultures of fetal rat septal neurons.

393.4

IN SITU QUANTITATION OF CEREBELLAR GAD mRNAs DURING RAT BRAIN DEVELOPMENT AND IN NERVOUS MICE. K. Groshan*, M. Willcutts*, R.N. Rosenberg and M.R. Morrison-Bogorad. Departments of Neurology and Biochemistry, U.T.-Southwestern Medical Center, Dallas, Texas, 75235 (Spon: J.L. Steinberg).

We have quantitated GAD mRNA levels in the different GABAergic cell types of the cerebellum and compared these to the levels of intracellular poly(A). In normal rat and mouse, all Purkinje cells contain GAD mRNAs, although the amount in individual cells fluctuates. The relative amount of GAD mRNA in different cell types does not differ more than 3 fold. In adult nervous mouse cerebellum, > 90% of Purkinje cells have degenerated. The remaining Purkinje cells have approximately the same levels of GAD mRNA as those in normal mice. GAD mRNA levels are also still high in the other GABAergic cell types. In developing rat cerebellum, GAD mRNA levels in the prenatally-formed Purkinje and Golgi cells is already high by P14. No GAD mRNAs are seen in the EGL and they are infrequent in the proximal parts of the molecular layer. GAD mRNA in stellate and basket cells increases as the cells migrate towards the IGL. These results show that GAD mRNA levels in Purkinje cells do not fluctuate greatly, either under normal physiological conditions or when Purkinje cell number is greatly depleted. Developmentally, GAD mRNAs are rapidly induced in Purkinje and Golgi cells and are induced in stellate amd basket cells as they migrate through the molecular layer. Supported by NIH 14886 (MRM-B) and Zale Foundation (RNR).

GABA RECEPTOR MODULATION OF TYROSINE HYDROXYLASE GENE EXPRESSION IN THE ADRENAL GLAND C. Hale*, M. Wessels-Reiker*, M.A. Moore*, and R. Strong. Geriatric Research, Education and Clinical Center, St. Louis VA Medical Center and St. Louis University School of Medicine, St. Louis, MO 63125

Several studies demonstrated the presence of GABA receptors on chromaffin cells of the adrenal medulla. Furthermore, other studies suggest that GABA receptors in the adrenal gland are important regulators of catecholamine release from chromaffin cells. For example, bicuculine has been shown to increase the release of catecholamines elicited by splanchnic nerve stimulation. Since those stimuli which increase catecholamine release from the adrenal often induce TH gene expression, we examined the role of GABA receptors in plasticity of TH gene expression.

We treated animals with a single injection of reserpine (7.5 mg./Kg./s.c.), or the GABA antagonist bicuculine (10mg/Kg/s.c.) twice a day for three days, or a combination of a single reserpine treatment and treatment with bicuculine for three days. At the end of three days the animals were sacrificed and the adrenal glands and brains were rapidly removed for assays of TH activity and TH mRNA content. Bicuculine treatment for three days had no effect on TH activity or TH mRNA. Reserpine treatment had the expected effect of increasing TH mRNA and TH activity by 2 fold. However, the combination of bicuculine and reserpine significantly increased TH activity and TH mRNA content as compared to the reserpine group. These data suggest a role for GABA receptors in regulation of TH mRNA in the adrenal gland.

STUDIES ON GENE EXPRESSION OF TYROSINE HYDROXYLASE (TH) IN ADRENAL GLANDS OF SHR AND WKY RATS. H. Zawadzka*, S. Tsuda*, D. Filer*, P. Benedetto*, W. Chan* and M. Goldstein. Neurochem.Res. Lab, N.Y. Univ. Med. Ctr., New York, NY 10016.

To determine whether the reported differences between adrenal TH activities of SHR and WHY rats are associated with changes in TH gene expression, we have analyzed the levels of TH mRNA in the adrenals of these two strains of rats (nine weeks old). The levels of adrenal TH mRNA were determined by Northern Blot analysis. The total mRNA was fractionated by gel electrophoresis, transferred to Gene Screen membranes, and baked at 80°C. The immobilized mRNA was hybridized with random primed TH cDNA (Pst 1) of 742 bp. The hybrids were detected by autoradiography and the density of the bands were determined. The levels of TH mRNA were found to be 30-50% higher in adrenals of WKY than that of SHR rats. These results support the previously reported findings that TH activity is higher in adrenals of WKY than in SHR rats (H. Grobecker et al., Nature 258:267-268, 1975). Supported by NIMH 02717 and NINCDS 06801.

HUMAN DOPAMINE BETA-HYDROXYLASE (DBH): IN VITRO TRANSCRIPTION AND TRANSLATION OF ENZYMATICALLY AMPLIFIED cDNA. C. M. Craft, T. H. Thai*, R. Gonzalez*, and J. D. Raese. Lab. of Molecular Neurogenetics, Schizophrenia Research Ctr., VA Med. Ctr. and Dept. of Psychiatry, Univ.TX Southwestern Med.Sch., Dallas, TX 75216.

The 5'coding region of human DBH was cloned using the polymerase chain reaction (PCR) and sequenced by dideoxysequencing. The predicted amino terminus of DBH was MetArgGluAla (MREA), in agreement with Lamouroux et al.(EMBO J. 6:3931, 1987). We discovered that this sequence is homologous to the amino terminus of beta tubulin (MREI) which mediates autoregulation of tubulin mRNA stability by free tubulin subunits (Yen et al.,Nature 334: 580, 1989). Mutagenesis of tubulin codon 2 (R) or codons 3 and 4 (EI) abolishes autoregulation of tubulin mRNA stability. A search of the Swiss Protein Data Base revealed no other mammalian protein with an amino terminal MRE{A,I}. We propose that the nascent amino terminus of DBH may interact with unassembled tubulin subunits and regulate DBH mRNA stability. Coupling of DBH synthesis and exocytosis could be accomplished through changes in the concentration of unassembled tubulin subunits.

To test this hypothesis, we amplified DBH cDNA of increasing size starting with the predicted initiation codon (AUG) using PCR. Chimeric oligonucleotides encoding a T7 RNA polymerase promoter and the 5'region of DBH were used in the amplification of cDNA. The PCR products of the predicted sizes were detected on 3% agarose gels and gel purified fragments were sequenced to verify their identity. Transcripts of these DBH templates were synthesized with T7 RNA polymerase and translated in vitro with a reticulocyte lysate system. This new PCR/transcription/translation system is being utilized to study the potential translational regulation of the nascent amino terminus of DBH by unassembled tubulin subunits.

393.8

MODULATION OF TYROSINE HYDROXYLASE GENE EXPRESSION IN SUBREGIONS OF THE LOCUS CERULEUS R. Strong, C. Hale*, M.A. Moore*, M. Wessels-Reiker*, and R.T. Zoeller.(SPON: J. Flood) Geriatric Research, Education and Clinical Center, St. Louis VA Medical Center and St. Louis University School of Medicine, St. Louis, MO 63125 and University of Missouri Medical School, Columbia Missouri.

The role of neurotransmitters and receptors in the reserpine elicited increases in TH mRNA and TH enzyme in the locus ceruleus is unknown. Furthermore, the neurochemical nature of many of the afferents to locus ceruleus is not completely known. In order to determine the relationship between locus ceruleus afferents and TH gene expression in response to reserpine, we mapped the topography of TH activity, TH mRNA and neurochemical markers of the cholinergic and GABAergic systems.

Rats were treated with a single injection of reserpine (7.5 mg./Kg./s.c.). or vehicle. Three days after injection, the animals were sacrificed and the brain rapidly removed and frozen in powdered dry ice. Brains were cut through the length of the locus ceruleus using a freezing microtome. Alternating 300 μm and 15μm sections were obtained. Tyrosine hydroxylase, glutamic acid decarboxylase and choline acetyltransferase were measured in 1mm punches from the locus ceruleus in three successive 300 μm thick sections. TH mRNA was measured by in situ hybridization in the thin sections, using a 48 oligonucleotide synthetic cDNA probe.

TH mRNA levels differed between subregions of the locus ceruleus. After reserpine, TH enzyme and TH mRNA increased, but only in selected subregions of the LC. The regionally selective change in TH and TH mRNA suggests that those neurotransmitters that are highest in the affected regions play a major role in regulation of TH gene expression.

393.9

CHRONIC ANTIDEPRESSANT REGULATION OF c-FOS EXPRESSION IN RAT CEREBRAL CORTEX. S.M. Winston*, M.D. Hayward*, E.J. Nestler, and R.S. Duman. Laboratory of Molecular Psychiatry, Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508.

Acute seizures and other stimuli cause a rapid induction in neurons of the nuclear protein c-fos, an effect which may underlie some long-term adaptive responses to acute neuronal activation. In the present study, we examined the influence of chronic electroconvulsive seizures (ECS) on the regulation of c-fos induction in rat cerebral cortex. We found that 4 hr after acute ECS, the induction of c-fos mRNA by a second ECS is blocked, in agreement with earlier findings, but, by 1 d, c-fos mRNA could be re-induced by a second ECS, indicating that the responsiveness of this system can be fully "reset" after 1 d. However, when rats received chronic (daily) ECS, c-fos induction in response to the most recent ECS showed a time-dependent decrease. This effect was maximal after 7-10 d of chronic ECS, when the induction of c-fos mRNA, as well as of Fos protein, by the most recent seizure was completely blocked. Chronic ECS similarly blocked the induction of c-jun, another nuclear protein. The blockade of c-fos induction observed 4 hr after acute ECS and after chronic ECS may involve different mechanisms, since it is known that Fos protein remains elevated 4 hr after acute seizure, but is at control levels after chronic ECS.

In preliminary studies, chronic (18 d) imipramine administration enhanced acute ECS induction of c-fos mRNA in cerebral cortex by approximately 2-fold. Chronic imipramine regulation of c-fos expression could reflect an altered responsiveness of cerebral cortical neurons to functional activity and may be related to chronic adaptations in these neurons thought to be critical to antidepressant efficacy.

393.10

CHRONIC ANTIDEPRESSANT ADMINISTRATION DECREASES THE EXPRESSION OF TYROSINE HYDROXYLASE IN RAT LOCUS COERULEUS. A. McMahon, E.L. Sabban, J.F. Tallman, E.J. Nestler and R.S. Duman. Depts. Biochem. and Mol. Biol., NY Med. Col., Valhalla, NY 10595 and Lab. Mol. Psychiatry, Yale Univ. Sch. Med., New Haven, CT 06508.

Chronic administration of many types of antidepressants down regulates the postsynaptic β-adrenergic receptor system in cerebral cortex. In the present study, we examined the influence of chronic antidepressant treatment on the expression of tyrosine hydroxylase (TH) in the locus coeruleus (LC), the major noradrenergic nucleus in brain, to assess the presynaptic state of the noradrenergic system. Rats were treated chronically with imipramine (IMI), tranylcypromine (TCP), electroconvulsive seizures (ECS) or fluvoxamine (FLU), and levels of TH immunoreactivity or mRNA were determined in micro-punches of LC and substantia nigra (SN, a dopaminergic nucleus). All 4 treatments resulted in a 50 to 65% decrease in TH immunoreactivity in the LC, while TH levels in the SN were not altered. Moreover, chronic administration of either IMI or TCP (FLU and ECS were not tested) decreased the levels of TH mRNA by 50% in the LC, but not SN, while dopamine β-hydroxylase mRNA levels were not altered in the LC.

The results demonstrate that four distinct classes of chronic antidepressant treatments specifically regulate the levels of TH in the LC and suggest that such regulation occurs at a pretranslational level. The down regulation of TH in the LC could be a long-term adaptation of the neurons to acute increases in synaptic levels of norepinephrine, although the action of fluvoxamine, a selective serotonin uptake inhibitor, to decrease TH suggests that these treatments may have additional sites of action.

393.11

INCREASING CELL-CELL CONTACT IN THE RAT PHEOCHROMOCYTOMA CELL LINE PC18 INCREASES TYROSINE HYDROXYLASE m-RNA LEVELS AND TRANSCRIPTION OF THE TYROSINE HYDROXYLASE GENE. C.D. Carlson*, A.W. Tank (SPON: S.A. Signs), Department of Pharmacology, University of Rochester, Rochester, NY 14642.

Cell-cell contact regulates the levels of tyrosine hydroxylase (TH) in bovine adrenal chromaffin cells and in rat pheochromocytoma cells. When rat pheochromocytoma PC18 cells are cultured at high density (HD) (2 x 10^5 cells/cm^2), TH activity increases over that observed in cells cultured at low density (LD) (1 x 10^4 cells/cm^2). The levels of TH-mRNA were determined by dot blot hybridization of total cellular RNA using a ^{32}P-labeled cDNA for TH-mRNA (pTH.3). After 24 hrs the levels of TH-mRNA in HD cells are 3-fold higher than those observed in LD cells; after 4 days TH-mRNA levels are 6-fold higher in HD cells. When cells are first cultured at HD and then recultured at LD, the elevated levels of TH-mRNA decrease rapidly, reaching baseline levels in 24 hrs. The HD-dependent increases in TH-mRNA may be due to an increase in the transcription of the TH gene or from a stabilization of the TH-mRNA. The relative transcription rate of the TH gene was measured with an in vitro "run on" assay using nuclei isolated from HD and LD cells. Our results indicate that the elevated levels of TH-mRNA in HD PC18 cells can be accounted for in part by an increase in the relative transcription rate of the TH gene.

393.12

TYROSINE HYDROXYLASE IS EXPRESSED IN THE PURKINJE CELLS OF THE ALLELIC MOUSE MUTANTS TOTTERING AND LEANER. E.J.Hess and M.C.Wilson. Research Institute of Scripps Clinic, La Jolla, CA 92037

The inherited autosomal recessive mutations, tottering (gene symbol: tg) and leaner (gene symbol: tg^{la}), are functional alleles of a single gene locus in mice. The tottering mouse mutant exhibits spontaneous absense seizures, focal motor seizures and mild hindlimb ataxia while the congenic mouse mutant leaner displays severe ataxia and no focal motor seizures. Because noradrenergic hyperinnervation of the cerebellum, hippocampus and thalamus has been observed in tottering mice (Levitt & Noebels, PNAS, 78:4630, 1981), tyrosine hydroxylase (TH) mRNA expression was examined by in situ hybridization in 12-14 week old tottering and leaner mouse mutants and age-matched heterozygous littermates. Hybridization of the ^{35}S-cRNA TH probe was detected in the major brain catecholaminergic nuclei, the locus coeruleus and substantia nigra, in control mice as well as tottering and leaner mice. Surprisingly, robust TH hybridization was observed in the cerebellar Purkinje cells of the tottering and leaner mouse mutants. Generally, cerebellar TH hybridization in tottering and leaner mice was restricted to clusters of Purkinje cells in the posterior region of the cerebellum. There was no detectable TH message in any cells of the control mouse cerebellum. Northern blot analysis confirmed these results; TH message was detected in the size fractionated cerebellar RNA of tottering and leaner mice, while little TH message was detected in control mouse cerebellar RNA. The presence of TH in the Purkinje cells of tottering and leaner mice may, in part, account for the ataxia exhibited in these mutants. These results suggest that the tg gene may play a role in the normal development of neuronal phenotypes including the assignment and maintanence of appropriate neurotransmitters. Supported by PHS NS23038.

THE EFFECT OF AGING ON THE RELATIVE mRNA CONCENTRATIONS OF MONOAMINE OXIDASE A AND B IN HUMAN BRAIN. Li-Jia Wang[1]*, Nancy Lan[1]*, Rachael Neve[2], and Jean C. Shih[1]. (SPON: J. Rho) School of Pharmacy, Univ. of Southern California, Los Angeles, CA 90033 and [2]Division of Genetics, The Children's Hospital - Boston, MA 02115

Based on substrate and inhibitor specificities, two types of monoamine oxidase (MAO), A and B, have been defined. Our recent cloning of the genes encoding MAO A and B suggest that the different enzymatic activities reside in their primary structures. By using subfragments of these cDNAs which are specific for MAO A or B, we found that MAO A and B exhibit similar patterns of expression in 14 brain regions examined; the relative concentrations of these transcripts are frontal cortex > locus coeruleus > temporal cortex > posterior pensylvian cortex-supra marginal gyri > anterior pensylvian cortex-opercular gyri ··>> hippocampus and thalamus.

Consistent with previous findings, MAO B catalytic activity increased with age whereas MAO A activity did not change. Interestingly, there is no statistical difference in mRNA levels of MAO A or B in the same aging brain samples examined. These data suggest that the increase in MAO B catalytic activity is not at the transcription level. Instead, it may be due to altered translation or post-translational modification of MAO B in aging brains. (Supported by MH39085, MH00796, and Welin professorship)

TWO MONOAMINE OXIDASE A mRNA SPECIES ARISE FROM SIZE HETEROGENIETY AT THEIR 3' TERMINI. J.-K.Huang[+], C. Huang*, L. Wen[+] and R.H. Huang, Univ. of Missouri-Kansas City, Sch. of Basic Life Sci., Kansas City, MO 64110-2499; [+]Kansas State Univ. Dept. of Biochem., Manhattan, KS 66506.

Monoamine oxidase (MAO, EC 1.4.3.4), an integral membrane enzyme, is involved in the biological inactivation of at least three different transmitter substances: dopamine; norepinephrine; and serotonin, intracellularly, in the brain. Monoamine oxidase A (MAO A) mRNA present in human placenta is comprised of two species with approximate molecular size of 2.2 and 4.2 kilobases (Kb). A cDNA clone (pMAO-A1) encoding human MAO A was isolated from a human placenta cDNA library. pMAO-A1 was 2731 base pairs long and was used to determine the molecular nature for the size heterogeneity of these mRNAs. pMAO-A1 differed from the previously published MAO A cDNA clone (Bach et al., 1988, PNAS, USA,85:4934) at their 3' termini. DNA sequencing indicated that pMAO-A1 contained an additional 1900 nucleotides at the 3' non-coding region. That pMAO-A1 corresponded to the larger mRNA (4.2 Kb) was confirmed by hybridization of a unique Hind III/EcoR1 fragment 3' to the first polyadenylational signal only to the 4.2 Kb MAO A mRNA. The result suggests that the 2.2 and 4.2 Kb mRNA species arise from the alternate use of different polyadenlylation signals. We have further isolated and characterized a MAO A genomic clone which included both the coding and non-coding regions. Southern genomic analysis suggested a single gene may encode MAO A. (Supported by grants from NIAAA and DOD to C.H. and R.H.H.)

TYROSINE HYDROXYLASE AND CHOLECYSTOKININ mRNA LEVELS IN THE SUBSTANTIA NIGRA, VENTRAL TEGMENTAL AREA, AND LOCUS CERULEUS ARE UNAFFECTED BY ACUTE AND CHRONIC HALOPERIDOL ADMINISTRATION. SL Cottingham, D Pickar*, P Montpied*, TK Shimotake*, SM Paul*, and JN Crawley. NSB, NIMH, Bethesda, MD 20892.

It is postulated that the pharmacological effects of haloperidol are mediated through dopaminergic neurons in the substantia nigra (SN) and ventral tegmental area (VTA). Cholecystokinin (CCK) coexists with dopamine in many of these neurons. To determine whether haloperidol affects tyrosine hydroxylase (TH) and CCK at the level of transcription, mRNA levels of TH, the rate-limiting enzyme in catecholamine synthesis, and of CCK, were studied.

Rats were treated with haloperidol (2 X 2 mg/kg i.p. daily) or vehicle for 3 days (acute) or 19 days (chronic) and sacrificed 16 hours after the last dose. In a separate experiment, reserpine (10 mg/kg i.p.) or vehicle was administered in a single dose 24 hours before sacrifice. Brains were frozen-sectioned at 12 µM through the SN-VTA and LC. In situ hybridization was performed using ^{35}S-labeled 48-mer oligonucleotide probes against TH and CCK (gift from W. Scott Young, NIMH). Labeled sections were exposed to Kodak XAR X-ray filmand quantitated on an image analysis system.

There was no difference in TH mRNA between control, acute haloperidol, and chronic haloperidol treatments in either the anterior, middle, or posterior VTA. There was no difference in TH mRNA in the SN between the three treatment groups. Similarly, there was no difference in CCK mRNA between control, acute haloperidol, and chronic haloperidol treatments in the anterior, middle, or posterior VTA. There was no difference in CCK mRNA in the SN between the three groups. TH mRNA was analyzed for the LC. There was no difference in mRNA levels between control, acute, and chronic haloperidol groups, although reserpine treatment produced a significant increase in TH mRNA levels in the locus ceruleus ($t = 5.938$, $p < .01$).

These data suggest that the effects of xphaloperidol on tyrosine hydroxylase and cholecystokinin in midbrain dopamine neurons do not involve regulation of gene transcription.

RESERPINE INCREASES BOTH TYROSINE HYDROXYLASE AND GALANIN MESSENGER RNA IN THE LOCUS COERULEUS. M.C. Austin, S.L. Cottingham, S.M. Paul* and J.N. Crawley, Clinical Neuroscience Branch, NIMH, Bethesda, MD 20892

Galanin (GAL), a 29 amino acid neuropeptide, coexists extensively with norepinephrine (NE) in perikarya of the locus coeruleus (LC; Melander, et al. 1986). GAL has been shown to inhibit NE-induced accumulation of cyclic AMP in rat cortical slices (Nishibori, et al. 1988). Previous studies have documented that activation of LC neurons either pharmacologically or by stressors increases tyrosine hydroxylase (TH) activity (Zigmond, et al. 1974) and TH mRNA (Mallet, et al. 1983). Utilizing in situ hybridization, we have examined the effects of reserpine on both TH and GAL mRNAs in adjacent sections of the LC. Male Sprague Dawley rats were administered with either vehicle or reserpine (2 or 10 mg/kg, i.p.) and sacrificed 24 hrs later. ^{35}S oligonucleotide probes for TH (48 bases) or GAL (39 bases), synthesized by B. Martin, NIMH, were applied to coronal brain sections (12 um) which were incubated for 24 hrs. Kodak XAR X-ray film exposed by the labeled sections was quantitated using a computerized densitometry image analysis system (W. Rasband, NIH). Reserpine significantly increased both TH and GAL mRNA in LC neurons. These results confirm previous reports that reserpine increases TH mRNA concentrations in the LC. In addition, the finding that reserpine also increases GAL mRNA raises the possibility that a common reserpine-sensitive mechanism regulates the expression of both the tyrosine hydroxylase and galanin genes.

393.17

STIMULATION OF PROTEIN KINASE C INCREASES EXPRESSION OF TH AND PNMT GENES IN CULTURED BOVINE ADRENAL MEDULLARY CELLS. J.S. Hong, R. Tuominen, B.B. Kaplan, A. Poisner and M.K. Stachowiak. LMIN, NIEHS/NIH, Research Triangle Pk., NC 27709, Univ. of Pittsburgh, Pittsburgh, PA 15260, Barrow's Neurol. Inst., Phoenix, AZ 85013.

We have previously demonstrated regulation of TH and PNMT genes by cyclic AMP in cultured adrenal medullary cells (AM). The analysis of the promotors of bovine TH and PNMT genes reveals sequences homologous to the phorbol regulatory elements, suggesting regulation by protein kinase C (PKC). In this study we examined whether expression of TH and PNMT genes is related to the activity of PKC in bovine AM cells. Incubation of AM cells with 0.1 uM TPA increased membrane-bound and reduced soluble activity of PKC and induced time-dependent increases in TH and PNMT mRNA levels. Effects of TPA were reproduced with 4 β-Phorbol didecanoate known to stimulate PKC activity, but not with its inactive 4 α-analog. Twenty-four hr preincubation with 1 uM TPA down-regulated total cellular activity of PKC by 80%, and attenuated increases in mRNA levels produced by subsequent incubation with phorbol ester. Effects of TPA were also reduced by sphingosine, an inhibitor of PKC. Thus, the expression of TH and PNMT genes is regulated by PKC. The association of PKC activity with membranes may underlay these effects.

PEPTIDES: RECEPTORS IV

COMPARISON BETWEEN BINDING OF 3[H]-PROPIONYL-NEUROPEPTIDE Y IN RAT AND HUMAN FRONTAL CORTEX MEMBRANES. P.S. Widdowson* and A.E. Halaris. Dept. of Psychiatry, Case Western Res. Univ, Cleveland, OH 44109.

Neuropeptide Y (NPY), a 36 amino acid peptide shows structural similarities with members of the pancreatic polypeptide (PP) family. It exists in large quantities in mammalian brains including humans, with high levels in cortex, hypothalamus and limbic areas. We compared NPY binding sites in human and rat brain using equilibrium and kinetic studies. Human frontal cortex was frozen on dry ice and stored at -70° C. ^{3}[H]-NPY binding was performed in Krebs-Ringer buffer at 37 ° C and the bound separated from unbound by rapid centrifugation (Unden, A. et al. Eur. J. Biochem., 145: 525, 1984). Bound ^{3}[H]-NPY was counted by liquid scintillation.

^{3}[H]NPY (0.05 - 1.0 nM) bound with a high affinity to both rat and human membranes which was sensitive to GTP and magnesium. Scatchard plots of the binding showed one binding site for both rat (Kd = 0.39±0.06 nM) and human (Kd = 0.33±0.08 nM). Displacement studies showed that peptide YY (Ki= 1.36 nM: rat, Ki= 1.45 nM: human) had a similar potency to NPY (Ki= 0.49 nM: rat, Ki= 0.43 nM: human) in its ability to displace the labelled peptide whilst human and rat PP were unable to displace ^{3}[H]-NPY at 10^{-6}M. Kinetic studies showed that rat and human cortex had similar association and dissociation constants. No evidence for multiple binding sites for NPY were found in either rat or human.

394.2

STRUCTURE-AFFINITY STUDY OF NEUROPEPTIDE Y ANALOGS IN THE RAT BRAIN. J.C. Martel[1], A. Fournier[2], M. Forest[*2], S. St-Pierre[*2] and R. Quirion[1]. (1) Depts. Psychiatry and Pharmacology and Douglas Hospital Research Center, McGill University, Montreal, QC and (2) INRS Santé, Pointe-Claire, QC.

Neuropeptide Y (NPY) is a 36 amino acid peptide originally isolated from porcine brain (Tatemoto et al., PNAS 79: 5485, 1982). Various behavioral effects of centrally administered NPY have been reported. However, the physiological role(s) of this peptide is most difficult to determine because of the lack of selective, potent and stable receptor agonists and antagonists. The present study was undertaken in order to better define the structural requirements of the brain NPY receptor. The effects of successive substitutions of the first 10 amino acid residues by alanine and of tyrosine residues in position 20 and 21 was therefore studied. The affinity of these analogs for central NPY receptors was evaluated as described before for a serie of NPY fragments (Martel et al., Peptides 7: 55, 1986). All substitutions in position 1 to 10 decreased the affinity of the analog for central NPY receptors, that of the proline residue in position 5 inducing the most marked deficit. Most substitutions of the tyrosine residue in position 20 also had major effects on the affinity for the NPY binding sites while modifications in position 21 were less critical. For example, substitution in position 20 by a phenylalanine reduced the affinity to 6 % as compared to NPY while the same modification in position 21 had no effect. These data are useful in order to determine which position of the NPY molecule is required to maintain receptor affinity.

NOVEL CHOLECYSTOKININ ANTAGONISTS OF HIGH AFFINITY AND SELECTIVITY FOR CCK TYPE A RECEPTORS.
J. F. Kerwin, Jr.*, F. Wagenaar*, H. Kopecka*, C. W. Lin*, T. Miller*, D. Witte*, A. M. Nadzan*, (SPON: R. S. Janicki), Neuroscience Research Division, Pharmaceutical Discovery D-47H, Abbott Laboratories, Abbott Park, Illinois 60064.

Recently we reported on the intriguing structural similarities of glutamic acid based CCK antagonists (CR-1409) and the benzodiazepine CCK antagonist L-364,718. In our search for novel CCK receptor antagonists we have attempted to include the weak CCK antagonist benzotript into our general construct of CCK antagonists. Utilizing a similar approach to that which enabled the development of potent and selective glutamic acid based hybrid antagonists (A-64,718, A-65,186), we have obtained novel CCK antagonist hybrids of benzotript with high affinity and selectivity for type A CCK receptors. We will report on our approach in the discovery of these compounds and provide preliminary *in vitro* chacterization of these derivatives. A prototypical example of this class is A-67,396 (IC_{50}= 30 nM). With these new agents it may be possible to further probe the peripheral type A CCK receptor.

DEVELOPMENT OF A BIOTINYLATED PROBE FOR INSULIN-LIKE GROWTH FACTOR-I (IGF-I) RECEPTORS USING A NOVEL DOT BLOT ASSAY WITH NEUROBLASTOMA CELLS.
M.G. King, T.H. Wimpy*, and D.G. Baskin. Depts. Biological Structure and Medicine, University of Washington, Seattle, WA 98195, and V.A. Med. Center, Seattle, WA 98108.

We have previously localized IGF-I receptors in the brain and retina using quantitative autoradiography (QAR). With the aim of identifying cells with IGF-I receptors, we evaluated the binding of biotinylated IGF-I (b-IGF-I) to rat B104 neuroblastoma cells. B104 cells were blotted (50,000 cells per dot) on nitrocellulose filters and incubated in 0.05 nM ^{125}I-IGF-I (16h, 5°C) with either native IGF-I (n-IGF-I) or b-IGF-I (using the biotinylation kit from Amersham) at 0.25-50 nM. Scatchard analysis of dot blot autoradiograms showed that the binding affinity of b-IGF-I and n-IGF-I were not significantly different (1-2 nM). To localize b-IGF-I with QAR, frozen sections from rat brain and bovine retina were incubated in 5 nM b-IGF-I (16h, 5°C), then incubated in ^{125}I-Streptavidin (2h, 23°C). Computer densitometry showed that b-IGF-I and ^{125}I-IGF-I co-localized to the same regions of the brain and retina. The results suggest that b-IGF-I is an effective probe for localizing IGF-I receptors. Furthermore, the results indicate that the dot blotting method is a valid approach for characterizing receptors on isolated cells. (Supported by NIH Grant NS 24809 and the V.A.).

394.5

BINDING CHARACTERISTICS OF ANGIOTENSIN II AND III TO NG108-15 CELLS.
M.D. Carrithers, S. Masuda*, K.A. Koide*, and J.A. Weyhenmeyer. Program in Neural and Behavioral Biology and College of Medicine, University of Illinois, Urbana, IL 61801.

Previously, we demonstrated that NG108-15 cells differentiated by treatment with 1.5% dimethyl sulfoxide (DMSO) and 0.5% fetal bovine serum for three to four days express both low and high affinity sites for angiotensin II (ANG II). The high affinity site is not expressed on undifferentiated cells, and its binding subunit has an approximate molecular weight of 74.5 ± 5.0 Kda by cross-linking analysis (Carrithers et al., FASEB J. 3(3):A732, 1989). In the present study, we further characterized the binding properties of both the low and high affinity sites. Using ^{125}I-ANG II, Scatchard analysis in the presence of 5 μM bestatin, a peptidase inhibitor, revealed a single low affinity site in undifferentiated cells (K_d ≃ 45 nM; B_{max} ≃ 320 fmol/mg protein) and a high and low affinity site in differentiated cells (K_{d1} ≃ 1.95 nM; B_{max1} ≃ 154 fmol/mg protein; K_{d2} ≃ 50.5 nM; B_{max2} ≃ 1676 fmol/mg protein). In competition studies, ANG III specifically displaced high affinity ANG II binding in differentiated cells (K_i ≃ 0.69 nM), but did not displace binding to the low affinity site in either differentiated or undifferentiated cells. We hypothesize that binding to the high affinity site in differentiated cells occurs through the carboxy-terminus of ANG II or ANG III and that it functions as a true receptor. It is further hypothesized that ANG II binds to the low affinity site through its N-terminus and that this site represents a bestatin-resistant aminopeptidase.

AFFINITY CYTOCHEMICAL LOCALIZATION OF RAT BRAIN ANGIOTENSIN RECEPTORS USING BIOTINYL-ANGIOTENSIN II (Bn-AII).
M.S. Brownfield and D.H. Harkness. School of Veterinary Medicine, University of Wisconsin, Madison, WI 53706.

Localization of brain AII receptors has previously been studied by quantitative autoradiography which has yielded valuable information on the distribution of receptors at the level of brain nuclei, but not at the cellular or subcellular levels. Therefore, we have developed a Bn-AII probe for use in the affinity cytochemical localization of AII receptors at the light and electron microscopic levels.

Bn-AII was prepared by incubating synthetic AII with an excess of biotinyl-N-hydroxysuccinimide ester (Bn-NHSE). The product was purified using Sephadex G25 chromatography or reverse phase HPLC. Bn-NHSE attacks amino groups, and since AII has one free amino at the N-terminal position biotin should be linked to the N-terminal residue. This biotin-extended AII should retain binding activity since other N-terminal modifications have produced AII analogues capable of specific binding to AII receptors.

Rat brains were fixed with 2% paraformaldehyde-0.02 % picric acid in 0.1 M phosphate buffer, pH 7.5. Cryostat or vibratome sections were first incubated in an avidin-biotin "block" sequence followed by Bn-AII (1-100 nM) and avidin-peroxidase complex. The receptor-BnAII-Av-Po complex was visualized by incubation with DAB-0.5% nickel ammonium sulfate using the glucose oxidase system. Binding of Bn-AII was validated by addition of 1-10 uM AII in the cytochemical system and by characterization of binding using radioreceptor assays of fresh and fixed brain membrane preps. Staining distribution was limited to nuclei known to contain AII receptors. However, receptor localization was shown for the first time at high resolution in association with plasmalemma of neuronal and glial cells. From these studies, Bn-AII provides a valuable tool for the high resolution localization of AII receptors.

394.7

BINDING CHARACTERIZATIONOF A BIOTINYLATED ANGIOTENSIN II.
D.H. Harkness and M.S. Brownfield. University of Wisconsin School of Veterinary Medicine, Madison, WI 53706.

Binding characteristics of biotinyl angiotensin II (BnAII) were studied in saturation and competition studies. Crude membranes of brain, adrenal cortex, adrenal medulla, pituitary, liver, and kidney cortex were prepared from Sprague-Dawley rats. Iodinated BnAII, Sar1,Ile8-AII, and AII (2175 Ci/mmol) were incubated with membranes for 1 hr at 25°C in 50mM Tris HCl, pH 7.2, 150mM NaCl, 5mM EDTA, 2.5mM DTT, 0.2% BSA, 0.1mM PMSF. Bound ligand was separated from free by centrifugation.

Scatchard analysis showed the following K_Ds:

	AII	BnAII	Sar1,Ile8-AII
brain	.309nM	.125nM	.025nM
adrenal medullla	.204	.078	.095
adrenal cortex	.564	.325	.213
pituitary	.128	NB	.775
liver	.879	NB	.742
kidney cortex	.275	NB	1.230

NB=no binding up to 200 pM tracer concentration.

Preliminary studies using another buffer system with $MgCl_2$, EGTA, and 0.5mM DTT showed detectable BnAII binding in liver and kidney, with binding in the brain similiar to the previous buffer. IC50s for BnAII in brain membrane competition curves against ^{125}I-Sar1,Ile8-AII and ^{125}I-AII were 2.5nM and 5.9nM, respectively; however, IC50 for BnAII in liver membrane competition curves against ^{125}I-Sar1,Ile8-AII was 2.1uM.

These studies show that BnAII binds to AII receptors and suggest that BnAII may be recognizing CNS AII receptor subtypes not present in some other tissues.

394.8

PURIFICATION AND CHARACTERIZATION OF AN ANGIOTENSIN BINDING PROTEIN FROM BOVINE ADRENALS.
G.N. Swanson*, J.M. Hanesworth*, V.J. Cook, and J.W. Harding. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

An angiotensin binding protein from bovine adrenal cortical cell membranes was purified to homogeneity using a combination of centrifugation and chromatographic techniques. The purified protein which was still capable of specifically and reversibly binding angiotensins was identified as a single band on silver stained SDS-PAGE with an apparent molecular weight of 65,000. This glycoprotein exhibited an isoelectric point of 4.5 in its native form and 6.2 following treatment with neuraminidase. Preliminary data suggests that this protein may preferentially bind angiotensin III as opposed to angiotensin II.

394.9

FLUORO-GOLD DOES NOT ALTER ANGIOTENSIN II BINDING IN THE DORSOMEDIAL MEDULLA OF THE RAT. D.B. Averill, D.I. Diz, and S.H. Andreatta-Van Leyen*. Research Institute, Cleveland Clinic Foundation, Cleveland, OH 44195-5070.

Retrograde tracers are employed to establish the anatomical projections of neurons whose function is being studied. We have used *in vitro* receptor autoradiography for angiotensin II (AII) binding to assess possible alterations in functional integrity of dorsal medullary neurons which were retrogradely labelled with fluoro-gold (FG). Fluoro-gold was injected unilaterally into the caudal pole of the nodose ganglion of rats 10-14 days before preparation of the tissue for determination of AII binding sites. Fluoro-gold transport was demonstrated by intense labelling of the dorsal motor nucleus of the vagus. Binding data were expressed as the ratio of AII binding on the side ipsilateral (ipsi) to FG injection versus binding on the contralateral (contra) side. Ratios for AII binding were determined in rats which had undergone either unilateral cervical vagotomy (VGX, 14 d), unilateral nodose ganglionectomy (NGX, 10 d) or with the vagi intact. The table below summarizes the effect of these maneuvers on AII binding.

	Intact	FG	NGX	VGX
% ipsi/contra	98	91±5	53±3	86±5
n	1	5	2	2

We conclude that after 2 week survival FG does not alter substantially AII binding in the dorsomedial medulla. The modest reduction in binding on the side of injection may be attributable to damage of fibers associated with injection of the tracer. These results suggest that FG may be used in combination with receptor autoradiography to determine the efferent projection of neurons whose binding sites are being studied. This work supported by NIH grants HL-6835, HL-36988 and HL-38535.

394.10

AUTORADIOGRAPHIC LOCALIZATION OF ANGIOTENSIN II RECEPTORS IN BRAIN AND PITUITARY OF DOCA-SALT HYPERTENSIVE RATS. D. P. Healy and N. Zhang*. Department of Pharmacology, Mount Sinai School of Medicine of the City University of New York, New York, NY 10029.

The activity of the brain angiotensin system (BAS) has been shown to be altered in several genetic hypertensive models and in response to changes in dietary sodium and to mineralocorticoid administration. In this report we examine the effects of deoxycorticosterone acetate-salt (DOCA-salt) induced hypertension on the expression of the brain angiotensin II (Ang II) receptor. Male Sprague-Dawley rats were uninephrectomized and assigned to one of four groups; either sham or DOCA-containing pellets on tap or salt water. After three weeks blood pressures were significantly elevated in the DOCA-salt group only. Animals were then processed for quantitative autoradiography using ^{125}I-sar^{1},ile^{8}-Ang II (^{125}I-SI-Ang II). There was a significant increase in the affinity and B_{max} of ^{125}I-SI-Ang II binding in the solitary-vagal area (SVA) from the DOCA-salt rats and an increased B_{max} in the DOCA rats. The density of ^{125}I-SI-Ang II binding was elevated in DOCA-salt rats in a variety of brain areas, including the circumventricular organs, the supraoptic nucleus and the paraventricular nucleus. In contrast, there was no significant change in ^{125}I-SI-Ang II binding in the anterior pituitary in any treatment group. These results suggest that the BAS may be involved in the expression of DOCA-salt hypertension. (Supported by USPH HL 42585.)

394.11

MODULATION OF ANGIOTENSIN II-INDUCED CYCLIC GMP PRODUCTION IN MURINE NEUROBLASTOMA N1E-115 CELLS BY PERTUSSIS TOXIN. X. Ye and S.J. Fluharty (Spon: M.A. Waraczynski) Depts. of Animal Biology and Biochemistry and Biophysics, and Institute of Neurological Sciences, Univ. of Pennsylvania, Phila., PA 19104.

In the murine neuroblastoma N1E-115 cell line angiotensin II (AngII) stimulated the rapid production of cyclic GMP (cGMP). cGMP production was maximal at 15 sec and continued agonist exposure resulted in diminished cGMP levels. Ang II stimulation was also dose-related with an apparent ED_{50} of 30 nM, and was maximal at 1 uM. Several AngII related agonists also increased cGMP levels and the rank order potency was AngIII > Ang II > Sarc^{1}-AngII > Angl. Sarc^{1},Ile^{8}-AngII, a high-affinity antagonist, completely blocked the stimualtion elicited by AngII. Finally, incubation of intact cells for 24 hr with pertussis toxin (100 ng/ml) resulted in an inhibition of subsequent pertussis toxin catalyzed incorporation of [^{32}P]ADP-ribose into a membrane protein of M_r 41kD. Pertussis toxin treatment also significantly attenuated AngII- and AngIII-induced cGMP production but did not alter the proportion of high affinity AngII receptors, or their regulation by guanine nucleotides. Collectively, these results suggest that cGMP may be an important intracellular mediator of Ang II actions within neuronal cells, and that pertussis toxin may modulate this transduction process through a mechanism independent of a change in agonist receptor affinity. Supported by NS 23986 and MH 43787.

394.12

A NOVEL PEPTIDE FUNCTIONS AS A BOMBESIN RECEPTOR AGONIST. M. Knight, T.R. Burke,Jr.*, S. Mahmoud* and T.W. Moody. Peptide Technologies Corp. Washington, DC 20017-1004 and Dept. Biochemistry, George Washington Univ. Sch. Medicine, Washington, DC 20037.

Bombesin (BN), a tetradecapeptide, is a neuromodulator in the CNS. The C-terminal octapeptide sequence of BN or gastrin releasing peptide is essential for binding to cell surface receptors, stimulating phosphoinositol turnover and elevation of Ca^{2+} cytosolic levels in rat brain slices and in the human glioblastoma cell line, U-118. Also BN stimulates the growth of Swiss 3T3 and human small cell lung cancer (SCLC) cells. Many linear BN analogs have been previously identified as BN receptor agonists or antagonists. Here a novel cyclic analog, cyclo[N-Ac,D-Lys^{5},D-Ala^{11},Met^{14}]BN(4-14) or cyclo mini BN has been synthesized. It inhibits the specific binding of [^{125}Tyr^{4}]BN with IC_{50} values of 0.5 uM in U-118 cells, 1 uM in rat brain and SCLC cells, and 2 uM in Swiss 3T3 cells. Also cyclo mini BN elevated cytosolic Ca^{2+} in SCLC and U-118 cells with ED_{50} values of 0.5 and 1 uM respectively. Additionally, the analog stimulated ^{3}H thymidine uptake in Swiss 3T3 cells with an ED_{50} of 0.3 uM, thus stimulating growth. Therefore this compound functions as a BN receptor agonist. The conformationally stabilized structure of cyclo mini BN may render it highly resistant to degradation and hence useful for in vivo studies. Grants SBIR NIH CA-44399 and NSF BNS-8815133

394.13

IDENTIFICATION OF HIGH AFFINITY ^{125}I-GASTRIN RELEASING PEPTIDE BINDING SITES ON RAT FOREBRAIN MEMBRANES. P.J. MONROE AND S.L. PEDROTTI. NOVA PHARMACEUTICAL CORPORATION, BALTIMORE, MD 21224.

In vivo and in vitro pharmacological and biochemical studies suggest that bombesin (BN) and gastrin releasing peptide (GRP) may act as neurotransmitters or neuromodulators in the central nervous system (CNS). In the present study, specific high affinity CNS sites for the putative mammalian analog of BN, ^{125}I-GRP, were characterized and compared to those previously reported for ^{125}I-tyr^{4}-BN (Moody, et al., Proc. Nat. Acad. Sci. 75, 1978).

Rat forebrain membranes were incubated with ^{125}I-GRP for 30 min. at 25°C in the presence of competing drug or buffer, then rapidly filtered under negative pressure onto Whatman GF/C filters. Specific ^{125}I-GRP binding, defined as that remaining in the presence of 1 uM BN, was routinely 66-75% of total radioactivity trapped onto the filters.

Analysis of saturation data indicate the existence of a single high affinity site (Kd = 0.23 nM; Bmax = 1.5 fmoles/mg tissue) comparable to that which has been reported for ^{125}I-tyr^{4}-BN. In addition, the rank order and selectivity of the ability of several related and unrelated peptides to compete for forebrain sites labelled by ^{125}I-GRP agree with that which has been previously reported for sites labelled by ^{125}I-tyr^{4}-BN. Thus, due to its mammalian origin, similar binding selectivity, and greater binding specificity, ^{125}I-GRP appears to be the preferred receptor probe for studying the sites mediating the action of BN in the mammalian CNS.

394.14

ONTOGENY OF BOMBESIN RECEPTORS IN THE RAT CNS. T.W. Moody, R. Getz*, C. Merchant* and Z. Merali. Dept. Biochem. & Molecular Biology, The George Washington Univ. Med. Ctr. Washington, D.C. 20037 and Dept. Psychology, Univ. Ottawa, Ottawa, Ontario, KIN 9A9.

Bombesin (BN), a potent grooming and satiety agent, represents one class of neuropeptides biologically active in the CNS. Previously, we found that BN-like peptides increase dramatically during the third postnatal week (Gillati, M.G. and Moody, T.W., Dev. Brain Res. 15:286, 1984). Here we investigated the ontogeny of BN receptors using in vitro autoradiographic techniques. Fresh frozen sections of rat brain were prepared and the distribution of (^{125}I-Tyr^{4})BN binding sites determined as described previously (Zarbin M.A. et al. J. Neurosci. 5:429, 1985). Autoradiagraphic grains were present in E18 and maximal in P1 animals. High densities of BN receptors were present in the olfactory bulb and tubercle, n. accumbens, hypothalamus, hippocampus, inferior colliculus and hindbrain. The density of BN receptors was increased in the P1 animals. The grain density declined during the first postnatal week especially in the inferior colliculus and hindbrain and in P7 animals the BN receptor density closely resembeled that of the adult. Because BN receptors undergo a major redistributions during development, they may facilitate the differentiation of the brain. Supported by NSF grant BNS-8815133.

394.15

CHARACTERIZATION OF RODENT PITUITARY AND CELL LINE GNRH RECEPTORS EXPRESSED IN RNA-INJECTED XENOPUS OOCYTES. S.C. Sealfon*, B. Gillo*, S. Mundamattom*, P. Mellon*, J. Windle*, E. Landau and J. L. Roberts (SPON: G. Cohen). Fishberg Center in Neurobiology, Neurology, Psychiatry, Mount Sinai School of Medicine, New York, N.Y. 10029 and Salk Institute, La Jolla, CA.

GNRH receptors were expressed in *Xenopus* oocytes micro-injected with RNA isolated from rat pituitary and from the αT3 cell line. 3-4 days after RNA injection, cells were recorded by voltage clamp. On exposure to 10^{-7} M GNRH an inward current of 532±87 nA (n=20) was obtained in pituitary RNA injected cells and 1163±526 nA (n=3) in αT3 RNA injected oocytes. The threshold for obtaining a response after pituitary RNA injection was $3X10^{-9}$ M GNRH. Equimolar concentration of a GNRH antagonist reduced the reponse to GNRH by greater than 90%, while the response to TRH was unchanged. Injection of sucrose gradient RNA fractions showed the receptor mRNA(s) has a sedimentation factor larger than 28S. Studying the molecular mechanism, the response to GNRH was not changed in calcium-free medium. In cells injected with a mixture of brain and pituitary RNA, the response to GNRH was eliminated by intracellular injection of EGTA whereas the response to GABA was not affected. Ramps studies revealed a reversal potential of the GNRH generated current of -22.5 ±1.0 mV (n=7) and -25.6±3.3 mV(n=3) in pituitary and cell line RNA injected oocytes respectively, consistent with the chloride reversal potential. The GNRH response is mimicked by intracellular injection of IP3. Normal rat pituitary and αT3 cell line RNA lead to the expression of functional GNRH receptors in Xenopus oocytes. The response is dependent on intracellular but not extracellular calcium and represents a calcium-dependent chloride conductance, suggesting signal transduction by inositol phosphate metabolism.

394.16

ASSESSMENT OF SOMATOSTATIN-ACETYLCHOLINE INTERACTIONS IN THE RAT CEREBRAL CORTEX. L.L. Cook, G.A. Faux,* D.L. Knight, G. Bissette and C.B. Nemeroff. Depts. Psychiat. & Pharmacol., Duke Univ. Med. Ctr., Durham, NC 27710.

Somatostatin (SRIF) fulfills many of the requisite neurotransmitter criteria and modulates certain neurophysiological and neurochemical actions of acetylcholine. These studies were designed to evaluate a possible localization of SRIF receptors on cholinergic afferents in the rat frontal cortex (FC), and a possible SRIF modulation of carbachol-stimulated phosphoinositol (PI) hydrolysis in FC slices. Nucleus basalis lesions were performed using 2 bilateral ibotenic acid infusions (22 and 8 days prior to sacrifice; 5 μg/0.5 μl/site, or 0.5 μl vehicle/site). Choline acetyltransferase activity was reduced by 41% in the FC and by 46% in the parietal cortex. Scatchard analysis of [^{125}I-Tyr-11]-SRIF binding in FC synaptosomal membranes showed that the mean Km and Bmax values in lesioned and control rats were not different ($p > 0.22$, ANOVA). In addition, the stable SRIF analog, SMS 201-995 (Sandoz), did not alter carbachol-stimulated PI hydrolysis in FC slices in concentration studies with this peptide or with carbachol. SRIF receptors are apparently not localized on cholinergic afferents in the FC, and SRIF apparently does not modulate the second-messenger activity associated with post-synaptic (M1) muscarinic receptors. (Supported by NIMH MH-40524 and NRSA ES07031).

394.17

CYCLIC ANALOGUES OF SOMATOSTATIN DISTINGUISH PHARMACOLOGICALLY AND FUNCTIONALLY DISTINCT SUBTYPES OF SOMATOSTATIN RECEPTORS IN BRAIN AND PITUITARY. K. Raynor and T. Reisine. Dept. of Pharmacology, Univ. of PA, Phila., PA 19104.

Somatostatin (SRIF) is a tetradecapeptide found widely distributed throughout the CNS where it serves as a neurotransmitter. SRIF induces its cellular effects in brain, including inhibition of adenylyl cyclase activity and modulation of ionic currents, through specific membrane receptors. The different physiological actions of SRIF may be mediated by distinct receptor subtypes. The lack of availability of subtype specific compounds has hindered the definition and functional characterization of SRIF receptor subtypes in the brain and periphery. Employing the SRIF analogues CGP 23996 and MK 678, we have demonstrated the existence of pharmacologically and functionally distinct SRIF receptor subtypes in the rat brain. Within the brain, [125I] MK 678 binding is of high affinity and saturable. It is also specific for SRIF receptors, being displaced by low nM concentrations of SRIF and its analogues, but not by other unrelated peptides. [125I] CGP 23996 labels a SRIF receptor which is poorly recognized by MK 678 and its structurally similar analogues, even at concentrations as high as 10 uM. These and other data suggest that [125I] CGP 23996 and [125I] MK 678 label distinct SRIF receptor populations in the CNS. In contrast, [125I CGP 23996 and [125I] MK 678 appear to label a single receptor population in pituitary. Both MK 678 and SRIF inhibit forskolin-stimulated adenylyl cyclase activity in pituitary. While SRIF also inhibits adenylyl cyclase activity in the corpus striatum, a region of brain with a high density of SRIF receptors, MK 678 has no effect. These findings suggest that in some tissues, subtypes of SRIF receptors may be coupled to different cellular effector systems. Subtype selective analogues of SRIF may therefore be useful in identifying the receptor subtypes involved in mediating the diverse biological actions of somatostatin in the brain. Supported by grants from the NIH (GM34781) and ONR (14-88-K-48).

BIOCHEMICAL PROPERTIES OF THE SOLUBILIZED BRAIN SOMATOSTATIN (SRIF) RECEPTOR. H-T. He*, S. Rens-Domiano, S. Borislow*, and T. Reisine. Dept. of Pharmacology, Univ. of PA 19104.

SRIF is a neurotransmitter in the CNS whose physiological actions are mediated by membrane-bound receptors. To gain insight into the molecular mechanisms by which SRIF exerts its actions in the CNS, we have investigated the biochemical properties of the solubilized brain SRIF receptor. Brain SRIF receptors were solubilized with CHAPS and detected with the high affinity SRIF agonist [125I] MK 678. The equilibrium binding of [125I] MK 678 to the solubilized SRIF receptor was saturable and selectively blocked by SRIF agonists. The solubilized SRIF receptor appears to be tightly associated with GTP binding (G) proteins since all specific [125I] MK 678 binding to the solubilized receptor was inhibited by GTPgS. Furthermore, antibodies directed against fragments of the alpha subunit of G proteins partially precipitated the solubilized SRIF receptor and pertussis toxin treatment of AtT-20 cells, a tumor cell line with high expression of SRIF receptors, caused the uncoupling of G proteins from the SRIF receptor and abolished [125I] MK 678 labeling of the solubilized SRIF receptor. The solubilized SRIF receptor appears to be a glycoprotein since the receptor could be eluted from a WGA column with the sugar TACT. Studies are in progress to determine whether subtypes of solubilized SRIF receptor couple with different G proteins and have different physical properties. Supported by NIH grant GM 34781 and ONR (14-88-K-0048).

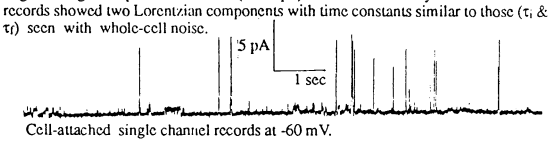
POTASSIUM CHANNELS IV

395.1

Three Kinetic Components to M-Currents in Bullfrog Sympathetic Neurons. W. Gruner*, N.V. Marrion* and P.R. Adams. Howard Hughes Medical Institute, SUNY at Stony Brook, Stony Brook, NY 11790, USA.

We have used noise analysis and time-course determination of whole-cell macroscopic currents, together with noise analysis of single-channel recordings and unitary current analysis to examine the kinetics of M-current in dissociated bullfrog sympathetic neurons. Whole-cell deactivation currents, evoked by hyperpolarizing voltage commands from holding potentials of ~-30 mV, in both 2.5 mM and 110 mM K^+ solutions, showed two muscarine-sensitive components; a slowly decaying portion (τ_s) in the 100's of msecs (c.f. Adams et al., *J. Physiol.*, 330:537-572) and a faster declining phase (τ_i). τ_i varied between 70 and 10 msecs over a voltage range of -30 to -90 mV, showing a slight voltage-dependence (~e-fold in 40 mV) at hyperpolarized potentials, while τ_s showed no obvious voltage-dependence. Fluctuation analysis of whole-cell currents revealed two Lorenztian components, one of which was similar to the macroscopic current τ_i, in both time course and voltage-dependence. The other, a much faster component, had a time constant (τ_f) between 3 and 5 msecs and showed no obvious voltage dependence. Both of these components were sensitive to muscarine (c.f. Neher et al, *Febs Letts.*,240:88-94, 1988, Marsh & Owen, *J. Physiol.*, 410:31P, 1988).

Single channel recordings of cell-attached patches with 110 mM K^+ in the patch pipette, have revealed two K^+ channels; one (~15 pS) which exhibited a voltage-dependence similar to that observed with whole-cell noise and current analysis, and a larger voltage-independent channel (~105 pS). Fluctuation analysis of the channel records showed two Lorentzian components with time constants similar to those (τ_i & τ_f) seen with whole-cell noise.



Cell-attached single channel records at -60 mV.

M-CURRENT NOISE IN RAT SYMPATHETIC NEURONES. **D.G. Owen[§], S.J. Marsh* and D.A. Brown. Dept. Pharmacology, University College London, London WC1E 6BT, U.K.**

Muscarine blocks the non-inactivating voltage-activated K^+ current, I_M, in rat sympathetic cervical (SCG) neurones (see Brown, 1988). In order to estimate the parameters of single ion channels underlying whole cell M-currents, we applied the technique of noise analysis to muscarine-sensitive currents. *Whole Cell* recordings were made from cultured (ca. 7 days) adult SCG neurones using a standard extracellular solution and patch pipette solution containing *inter alia* 100nM free Ca^{2+} and 1mM ATP at pH 6.8. Currents recorded under voltage clamp before, during and after the application of muscarine were stored on VCR, and subsequently bandpassed (0.05-50Hz) before acquisition by a PDP-11/23 via CED 502 interface. Spectral analysis was carried out using *NOIS* (D. Colquhoun). Data acquired at -30mV was found to lie within the low probability limit and power spectra at this potential were always fit by two Lorentzian Functions (*eg.* f_c^1 = 1.0Hz, $S(\phi)$ =1.5pA^2; f_c^2 = 32Hz, $S(\phi)$ = 0.02pA^2). Results were consistent with a single M-channel of about 1.6pS, having at least 3 states. The time constant corresponding to f_c^1 is 159ms which is similar to that of *macroscopic* I_M deactivation tails at the same membrane potential (-30mV).

ACETYLCHOLINE DOES NOT ALTER POTASSIUM INWARD RECTIFICATION ON XENOPUS SKELETAL MUSCLE IN CULTURE. F. Moody-Corbett and R. Gilbert. Div. Basic Sci. Memorial University of NF, St. John's, NF. Canada

Acetylcholine (ACh) causes an increase in the probability of opening inwardly rectifying K^+ channels on heart nodal cells. In this study we examined the effect of ACh on the K^+ inward rectifier of skeletal muscle. Muscle cultures were prepared from Xenopus myotomal muscle and macroscopic whole cell currents were recorded using a List patch clamp. The nicotinic ACh receptors and Na^+ currents were blocked with bungarotoxin (10^{-5} g/ml) and tetrodotoxin (10^{-6} g/ml), respectively. The external recording solution contained (mM) 140 NaCl, 5 KCl, 1 $CaCl_2$, 1.2 $MgCl_2$, 10 HEPES (pH 7.4) and the solution in the patch electrode contained (mM) 140 KCl, 1 EDTA, 5 $MgCl_2$, 10 HEPES (pH 7.4). Hyperpolarizing step potentials from resting membrane potential resulted in an inward current that was similar to the K^+ inward rectifier on adult skeletal muscle. Application of ACh (0.1-10 mM) to the bath did not alter the amplitude, time course or activation of inward current on these muscle cells. In contrast to the effects on heart nodal cells, ACh does not alter the properties of the classic inward rectifier. (supported by MRC, Canada)

MUSCARINIC AND NORADRENERGIC EFFECTS ON VOLTAGE DEPENDENT POTASSIUM CURRENTS IN CAT BLADDER PARASYMPATHETIC NEURONES.

Eva Vlckova* and Patricia Shinnick-Gallagher. Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77550

In cat bladder neurones, acetylcholine and noradrenaline have both excitatory and inhibitory effects. In this study we analyzed the effects of these neurotransmitters on voltage dependent K^+ currents using single-electrode voltage clamp. Several types of voltage dependent K^+ currents were observed in these neurones. These currents possess a similar voltage dependence and pharmacology as those described previously in other types of central and peripheral neurones and include: a M-current suppressed by Ba^{2+} (0.3-1.0 mM) and muscarine (10-20 uM); an A-current suppressed by 4-aminopyridine (1.0 mM); a Ca^{2+}-dependent K^+ current sensitive to Co^{2+} and Cd^{2+}, suppressed by apamin (1.0 uM) and not affected by TEA (2.0-4.0 mM), a Q-current blocked by extracellular Cs^+ (3.0 mM) and an anomalous rectifier current which is blocked by Ba^{2+} and Cs^+ and seems to be Ca^{2+}-dependent. Both muscarine (3-10 uM) and noradrenaline (10 uM) induced a net outward current and enhanced anomalous rectification. Muscarine (10-20 uM) suppressed I_M and $I_{K(Ca)}$, while noradrenaline appeared to have no effect on either of these currents. (Supported by NS16228)

395.5

CYCLIC AMP DEPENDENT CATION CURRENT IN DISSOCIATED BULLFROG SYMPATHETIC AND PRIMARY AFFERENT NEURONS. T. Tokimasa, H. Hasuo*, T. Nishimura*, M. Tsurusaki*, M. Shiraishi* and T. Akasu*. Dept. of Physiology, Kurume Univ. Sch. of Med., Kurume 830, Japan.

A hyperpolarization-activated sodium/potassium current (gH) was recorded from cultured bullfrog sympathetic neurons in the whole-cell configuration. gH activated between -130 and -60 mV (50 % activation between -90 and -95 mV). A hydrolyzable form of ATP in a pipette solution was necessary for gH. Bath application of ATP (1 μM) was without effects on gH while the drug selectively blocked the M-current (gM). The maximum conductance of gH was increased by intracellular "loading" of cyclic AMP (3-10 μM), or bath application of forskolin (0.1-10 μM), membrane permeable cyclic AMP analogues (1 mM) and IBMX (0.1-1 mM). Open/close kinetics of gH showed a depolarizing shift when it was facilitated by intracellular cyclic AMP. gM but not gH was depressed by C-kinase activator phorbol 12-myristate 13-acetate (3 μM). The amplitude of gH was approximately halved by protein kinase inhibitor H-8 (3 μM). Essentially the same results were obtained from cultured dorsal root ganglion cells. It is concluded that a voltage-gated cation current is also controlled by basal activity of cyclic AMP presumably via protein kinase-A. Supported by the Naito Foundation (#87-128).

***PANDINUS Imperator* VENOM BLOCKS VOLTAGE-ACTIVATED K-CURRENTS OF FROG SKELETAL MUSCLE.** D.L.Eng* and P.A.Pappone (SPON;A.J.Gabor). Dept. Animal Physiol., Univ. of Calif., Davis, CA 95616.

Venom toxins have been useful in the characterization of ion channels by the utilization of their specific channel binding properties. In this study we tested the effects of the K channel blockers *Pandinus imperator* scorpion venom, charybdotoxin (CTX), and apamin on frog skeletal muscle voltage dependent K-currents ($I_{K,DR}$) and inward rectifier K-currents ($I_{K,IR}$).

Bullfrogs were decapitated and pithed, and the semitendinosus muscle was dissected and placed in frog Ringers. Single muscle fibers were mounted in the Hille-Campbell vaseline gap chamber. The fiber ends were cut in 80mM K-EGTA to maintain internal calcium concentrations at low levels to prevent activation of contraction and calcium-activated K currents. Voltage clamp records were obtained in either 0.1% BSA frog Ringer, pH 7.4 to test for $I_{K,DR}$ or in a 0.1% BSA K-methylsulfonic acid, pH 7.4 solution to test $I_{K,IR}$ Holding potentials were -80mV in Ringers, and 0mV in 120mM KMSA. Currents were measured in the voltage clamp mode in response to both steps and ramps of command voltage. Untreated Pandinus venom (200 ug/ml) blocked 50% of $I_{K,DR}$ but had no significant effect on $I_{K,IR}$. *Pandinus*, neither heat-inactivated (200ug/ml) nor dialysed (500ug/ml) venom had any significant effect on $I_{K,DR}$. 200 uM zinc, a cofactor of *Pandinus* venom, had a similar but smaller effect than whole venom on $I_{K,DR}$. CTX (200nM) and apamin (500nM), two blockers of different Ca-activated potassium channels, had no significant effects on frog skeletal muscle K currents, $I_{K,DR}$ or $I_{K,IR}$. Previously it was believed that *Pandinus* venom did not block $I_{K,DR}$ of frog skeletal muscle, and that all the effects seen were due to zinc contained in the venom. Here we show that whole *Pandinus imperator* venom can have effects on the $I_{K,DR}$ of frog skeletal muscle. (NIH AR-34766, NS07300)

CROMAKALIM ACTIVATES A TETRAETHYLAMMONIUM-SENSITIVE VOLTAGE-DEPENDENT K+ CURRENT IN CULTURED RAT HIPPOCAMPAL NEURONS. D.M. Politi*, S. Suzuki* and M. A. Rogawski. Medical Neurology Branch, NINDS, NIH, Bethesda, MD 20892.

The whole cell voltage-clamp recording technique was used to study the effects of the benzopyran antihypertensive agent cromakalim (BRL 34915) on voltage-dependent outward currents in cultured embryonic rat hippocampal neurons. Extracellular perfusion with cromakalim (10-500 μM) produced a dose-dependent increase in the sustained (minimally inactivating) voltage-dependent outward current (I_K) without altering the transient outward current (I_A) or producing a change in the resting current at -60 mV. One-half maximal facilitation of I_K occurred at 40 μM and maximal facilitation (59%) at 100 μM. The increase in outward current occurred at all potentials where hippocampal neurons exhibited outward rectification (> -30 mV). The effect of cromakalim was slow to develop (requiring as long as 5-15 min to achieve maximal effect) and persisted for at least 10-15 min after cessation of drug superfusion.The outward current activated by cromakalim was blocked by 20 mM tetraethylammonium (TEA). However, despite the failure of cromakalim to have an observable effect in the presence of TEA, the outward current rapidly recovered to a potentiated level when the drugs were both withdrawn.These results indicate that cromakalim can enhance the activity of TEA-sensitive, voltage-dependent K+ channels in mammalian CNS neurons. Moreover, cromakalim appears to be capable of interacting with its acceptor even when current flow is blocked by TEA.

APAMIN-SENSITIVE CONDUCTANCE IN LOCUS COERULEUS NEURONS. S.S. Osmanović, S.A. Shefner and B.B. Beleslin*, Dept. Patho-Physiol. Med. Fac. Belgrade, Yugoslavia and Dept. Physiol. Biophys., Univ. Illinois. Col. Med., Chicago, IL.

Apamin, a bee venom neurotoxin, has been shown to selectively block one class of Ca^{2+}-activated K channels, $g_{K(Ca)}$. Intracellular recordings were made from rat locus coeruleus (LC) neurons in completely submerged brain slices under current- and voltage-clamp conditions. Bath superfusion of 100-500 nM apamin affected both the single spike after-hyperpolarization (AHP) and the post-stimulus hyperpolarization (PSH) which follows a train of action potentials. Apamin reduced the magnitude of the late part of the single spike AHP with no change in its peak amplitude. In most LC neurons, PSH elicited by a train of action potentials consisted of two distinct phases which could be fitted by a biexponential function. The initial, fast phase had a decay constant one order of magnitude smaller than that of the late, slow phase. Both phases were abolished in low Ca^{2+} medium and by Ca-channel blockers, which suggests that they are mediated by an activation of $g_{K(Ca)}$. Apamin abolished the initial, fast component of PSH and augmented the late component. Apamin also increased the number of spikes evoked by a long depolarizing pulse. These data suggest that apamin-sensitive $g_{K(Ca)}$ underlies the late part of the single spike AHP and a fast phase of PSH, and is involved in regulation of repetitive firing in LC neurons.

EFFECTS OF K CHANNEL BLOCKERS ON ATP-SENSITIVE, CA-ACTIVATED, AND DELAYED RECTIFIER K CHANNELS IN INSULIN-SECRETING HIT CELLS. S. Fatherazi and D.L.Cook*, Depts. of Physiology/Biophysics and Medicine, Univ. of Wash. and VA Medical Center, Seattle, WA, 98108.

Whole-cell and excised outside/out patch clamp techniques were used to study the effects and mechanisms of tetraethylammonium (TEA) and quinine on Ca-activated K [K(Ca,V)], ATP-inhibited K [K(ATP)] channels and delayed rectifier current in HIT cells. HEPES-buffered (pH 7.2) solutions (5mM K, 120mM Na ± Cd 200μM outside; 140mM K, ±100μM Ca, ±10mM ATP inside) was used at 20-22 °C. TEA reversibly and rapidly reduced the open channel conductances of K(Ca,V) and K(ATP) and reduced delayed rectifier current. It was more effective on K(Ca,V) (Kd≤200μM, n=8) than on K(ATP) (Kd≥20mM, n=8) and delayed rectifier current (Kd≥200μM, n=3). TEA did not affect gating of K(Ca,V) and K(ATP) channels. Quinine decreased open channel conductance of K(Ca,V) (Kd≥500μM, n=6) and reduced delayed rectifier current (Kd≥600μM, n=3). On the other hand, quinine did not affect K(ATP) single channel conductance but did reduce the frequency of channel opening (Kd≤100μM, n=7).

Conclusion: Low doses (<mM) TEA provides relatively specific block of K(Ca,V) channels while low doses (<100μM) of quinine is relatively specific for K(ATP) channels. Quinine inhibits K(ATP) by interfering with channel opening while it inhibits K(Ca,V) channels by directly blocking K flux through open channels.

VOLATILE ANESTHETICS BLOCK A POTASSIUM CHANNEL IN NOCICEPTORS. M.B. MacIver and D.L. Tanelian. Dept. of Anesthesia, Stanford Univ. Sch. of Medicine, Stanford CA 94305.

Although general anesthetic actions on free nerve endings are not thought to contribute greatly to anesthesia, few detailed studies are available to support this. The present study investigated the effects of halothane and isoflurane on A and C fiber nociceptors using a new in vitro preparation from rabbit cornea. The anesthetics produced concentration and time dependent changes in action potential discharge activity. Increased discharge frequency was produced by low concentrations (0.5-0.8 x MAC), burst discharges occurred at 1-2 x MAC and depression of discharge was observed at concentrations > 2.5 x MAC. The potassium channel blocker 4-AP (0.25 mM) produced a similar profile of excitation and burst firing; TEA, Ba, Gd and Quinine did not. The anesthetics and 4-AP also increased spike width and depressed the after potential in a concentration dependent manner, however 4-AP produced an increase in spike amplitude while the anesthetics depressed amplitude by 20% at 1 MAC. The results indicate that clinically relevant concentrations of volatile anesthetics excite free nerve endings by depressing a potassium current. In addition, the anesthetics produce a decrease in spike amplitude. These effects on peripheral fibers would be expected to antagonize the central depressant actions of the anesthetics by increasing excitatory afferent input to the CNS. Supported by the American Cancer Society and a Parker B. Francis Investigatorship in Anesthesiology.

POTASSIUM CHANNELS: MODULATION AND REGULATION

396.1

MODULATION OF FIRING BEHAVIOR AND AFTERHYPERPOLARIZATIONS IN SENSORIMOTOR CORTEX BY SEROTONIN (5HT). R.C. Foehring. Dept. of Anatomy and Neurobiology, Univ. of Tenn., Memphis, TN, 38163.

Neocortical neurons were studied *in vitro* in brain slices from pericruciate cortex of cats and the sensorimotor region of rat cortex. Neuronal firing behavior and responses to 5HT were similar for neurons from the two species. Bath application of 5HT (10-100 μM) resulted in (i) an initial hyperpolarization (brief and variably present), (ii) a prolonged depolarization which was usually associated with an increase in input resistance, and (iii) a reduction in the slow afterhyperpolarization seen following sustained repetitive firing. In the presence of 5HT, cortical neurons fired faster in response to a given current injection, exhibited less spike-frequency adaptation, and showed less habituation to repeated 1s suprathreshold stimuli. Single electrode voltage clamp suggests that the slow afterhyperpolarization reduction was due to a reduction in the slower Ca^{2+}-dependent K^+ current. 5HT also appears to reduce the duration of the medium afterhyperpolarization seen following a single action potential. Several agonists and antagonists were studied to deduce the 5HT receptor subtypes involved in the above responses.

MODULATION OF POTASSIUM CURRENTS IN CULTURED HUMAN CORTICAL NEURONS. S. E. Guggino (1,2), G.Ronnett (3), L. Hester* (2), and S.H. Snyder (2). Depts of Medicine (1), Neuroscience (2), and Neurology (3), The Johns Hopkins University School of Medicine, Baltimore, MD 21205

Whole cell currents from human cortical neurons were assayed for changes with growth conditions. Neurons isolated from a case of childhood megalencephaly were passed by trypsinization, plated for 2 days then differentiated with nerve growth factor, isomethylbutylxanthine (IBMX) and dibutyryl cyclicAMP (dibut cAMP) for 2 days. Cells grew long branched processes, expressed neurofilament protein, and neuron specific enolase. Whole cell currents were measured using patch pipettes containing in mM: 5 MgATP, 1 KEGTA, 40 KCl, and 110 Kaspartate buffered to pH 7.4 with Hepes Tris. The bath contained 140 NaCl, 5 KCl, 1 CaCl, 1 MgCl, 20 glucose and NaHepes pH 7.4. Under these conditions the major current was a voltage-dependent outward current which did not inactivate during 250 ms depolarizing pulses and increased 2x when the holding potential (HP) was shifted from -40 mV to -100 mV. At a HP of -100 mV and depolarization to +50 mV the outward current was 800 pA. With 0.5 mM IBMX and 0.5 mM dibut cAMP in the bath, a new outward current appeared which showed voltage-dependent inactivation. With HP -100 mV and depolarization to +50 mV this outward current was 120 pA and inactivated within 50 ms. We conclude that rapidly inactivating currents are by modulated increased intracellular cAMP.

396.3

CALCITONIN GENE-RELATED PEPTIDE (CGRP) DECREASES POTASSIUM CURRENTS IN RAT NEOCORTICAL NEURONES.
C. ZONA, E. PALMA*, F. EUSEBI*. Dipt. Med. Sper. Sci. Biochem. Univ. Roma "Tor Vergata" - Dipt. Med. Sper. Univ. L'Aquila, Italy.

CGRP, a 37 amino acid peptide, identified in spinal cord of vertebrate and in motor nerve endings of mammalian neuromuscolar junction, is known to stimulate the biosynthesis of cyclic AMP, the physiological activator of protein kinase A. In order to investigate whether CGRP may regulate the voltage-dependent channels function, experiments were performed on neocortical neurones from 15 - day rat embryos grown in dissociated cell culture for 1 - 6 weeks. Outward currents evoked by depolarization commands from - 80 mV holding potential exhibited a reversible decrease in size within 1-3 min CGRP application (500 nM - 1 μM). The effect of CGRP on the outward currents was more potent in decreasing the K+ fast transient current than the delayed rectifier K+ current and was mimicked by the stimulator of the adenylate cyclase forskolin (20 μM). It has been supported that CGRP may affect voltage-dependent K+ channels through the stimulation of protein kinase A.

GALANIN ACTIVATES A CALCIUM-DEPENDENT POTASSIUM CONDUCTANCE IN MUDPUPPY PARASYMPATHETIC NEURONS. L. M. Konopka and R. L. Parsons. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

The neuropeptide galanin initiates a slowly developing and longlasting hyperpolarization of neurons in the mudpuppy (Necturus maculosus) cardiac ganglion by activating a membrane K^+ conductance. (Konopka et. al, J. Physiol. 410: 107, 1989). We demonstrate in the present study that following substitution of Mn^{2+} or Mg^{2+} for extracellular Ca^{2+}, the amplitude of the galanin induced hyperpolarization is decreased reversibly. Also, following the addition of 0.1mM Cd^{2+} to the 3.6mM Ca^{2+} containing solution, the galanin-induced hyperpolarization decreased progressively. The galanin-induced hyperpolarizations were not reduced in the presence of 5-10 mM TEA, but were significantly decreased (40-100%) during exposure to 25uM apamin. The spike HAP also was decreased in many cells by 25uM apamin. These results indicate that galanin initiates hyperpolarization by activating a Ca^{2+} dependent K^+ conductance. Further, we suggest that the channels activated are similar to the Ca^{2+}-dependent K^+ channels mediating the spike HAP.

396.5

MODULATION OF MEMBRANE CURRENTS BY FMRFAMIDE AND MYOMODULIN IN TAIL SENSORY NEURONS OF *APLYSIA*. S.D. Critz, D.A. Baxter and J.H. Byrne. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225.

We have shown that the neuropeptides FMRFamide and myomodulin can reverse the increases in neuronal excitability and spike duration induced by the application of serotonin to tail sensory neurons in *Aplysia* (Cleary et al., 1987). Therefore, we were interested in determining which membrane currents mediate these effects. Clusters of sensory neuron somata, isolated from pleural ganglia and maintained at 15° C in a static bath of ASW containing 200 μM TTX, were examined by conventional two-electrode voltage clamp techniques. Membrane currents were activated by 200 msec voltage clamp pulses from a 15 sec prepulse to -70 mV. Voltage clamp pulses were separated by 60 sec during which the cells were held at the resting membrane potential. Current responses were digitized and stored for later display and analysis.

The effects of FMRFamide were complex. At low voltage clamp potentials (-30 to -10 mV), bath application of FMRFamide (50-100 μM) resulted in an increase in the net outward current at the end of the pulse. Computer subtractions indicated that the outward current increased by FMRFamide was similar to the S-current. It was slowly activating, non-inactivating, relatively voltage-independent, and insensitive to TEA and 4-AP. At higher voltages (0 to 20 mV), FMRFamide caused a large decrease in the net outward membrane current at the end of the pulse. This component of the FMRFamide response was blocked by a low concentration of TEA (2 mM), which blocks $I_{K,Ca}$, and was unaffected by 4-AP (1.0 mM), which blocks I_A and $I_{K,V}$ but not $I_{K,Ca}$ (Baxter and Byrne, 1989), in these cells. These results indicated that an $I_{K,Ca}$ was reduced at these depolarized potentials. In contrast, myomodulin (10-50 μM) resulted in a TEA and 4-AP insensitive increase in the net outward current at the end of all voltage steps. Thus, both FMRFamide and myomodulin appear to increase the S-current, but FMRFamide appears to reduce $I_{K,Ca}$, as well. We are presently investigating whether other currents are modulated by these peptides.

GTP-BINDING PROTEINS MEDIATE DOPAMINE ACTIVATION OF A POTASSIUM CURRENT IN IDENTIFIED RAT LACTOTROPHS. L.C. Einhorn and G.S. Oxford. The Neurobiology Curriculum, University of North Carolina, Chapel Hill, NC 27599.

Dopamine (DA) is the major physiological regulator of prolactin (PRL) secretion from the anterior pituitary, exerting a tonic inhibitory control. Utilizing the reverse hemolytic plaque assay and whole cell patch clamp techniques, we investigated the actions of DA on the membrane potential and ionic conductances in primary rat lactotrophs as well as the signal transducing mechanisms which may be involved. Application of DA (5nM-5μM) or a D2 agonist (RU24213) evoked a 20mV hyperpolarization of the membrane potential which was blocked by D2 selective antagonists and associated with an increased K^+ conductance. Whole cell current responses in voltage clamp revealed a DA-activated current whose reversal potential was near the K^+ equilibrium potential and varied with changes in extracellular [K^+]. The DA-activated current exhibited a slight inward rectification. The response to DA was present when both extracellular and intracellular Ca^{++} levels were buffered to < 10^{-7}M or when the cell was dialyzed with 2mM cAMP. The current was insensitive to TEA (10mM), only partially blocked by 4AP (≥5mM), and almost completely inhibited by quinine (100μM). Pretreatment of cells with *Pertussis* toxin (PTX; 500ng/ml, 4-8hrs) or intracellular dialysis with GDPβs (100-500μM) abolished the DA induced membrane hyperpolarization, whereas GTPγS (50μM) dialysis mimicked the DA response. These findings suggest that the mechanism linking D2 receptors to inhibition of PRL secretion involves G-protein activation of a K^+ current which functionally decreases membrane excitability. Supported by NIH Grant NS18788.

MODULATION OF NEURONAL ION CHANNELS BY PROTEIN PHOSPHORYLATION AND DEPHOSPHORYLATION. S. Chung*, P. Reinhart*, B. Martin*, D.L. Brautigan*, and I.B. Levitan. Biochem. Dept., Brandeis Univ., Waltham, MA 02254 and Section of Biochem., Div. Biol. and Medicine, Brown Univ., Providence, RI 02912.

Rat brain plasma membrane vesicles contain ion channels which can be incorporated into lipid bilayers. We have observed a family of four calcium-dependent potassium channels, which share some properties and differ in others (Reinhart et al, **Neuron**, 2:1031, 1989). All of the channels are highly selective for potasssium over sodium (and anions), and are activated by calcium in the micromolar range. Among them are two kinetically distinct maxi-channels. They have similar single channel conductances (about 240pS), and both are sensitive to TEA. However charybdotoxin blocks only the faster gating channel, and they also differ in their calcium sensitivity, gating kinetics, and modulatability. The activity of the faster gating channel is increased by addition of the catalytic subunit of cAMP-dependent protein kinase to the bilayer system. In contrast the activity of the slower gating channel is *decreased* by the catalytic subunit. In both channels the catalytic subunit effects are reversed by the addition of the purified phosphoprotein phosphatase 2A. The slower gating channel is up-regulated by ATP, and this effect is not reversed by phosphatase 2A but is reversed by phosphoprotein phosphatase 1. Since the regulation by ATP occurs in the absence of exogenous kinase, it may involve the action of some endogenous protein kinase, not cAMP-dependent, which is present in the plasma membrane vesicles and which may accompany the channel when it inserts into the bilayer. Thus this channel may be the target for modulation, in opposite directions, by two distinct protein kinases.

396.8

MODULATION OF SINGLE CALCIUM- AND VOLTAGE-DEPENDENT K^+ CHANNELS FROM RAT BRAIN BY A- AND C-KINASES. J. Farley, Prog. in Neural Science, Indiana University, Bloomington, IN 47405.

I have assessed the effects of purified A- and C-kinases upon the activity of a family of voltage-, calcium-dependent, and CTX-inhibited K channels of relatively large conductance (Biophys. J., 1988, 53; 919), found in rat brain synaptosomal membrane vesicles, incorporated into bilayers on the tips of patch-electrodes.

Catalytic subunit of cAMP-PK (A-kinase) (nM) increased the open-time probability of large (>200 pS) "BK" channels, as well as that of two intermediate-sized channels (~75 and 125 pS, respectively). Both the rate of opening and open-time duration were affected, depending upon the channel type. A fourth (~50 pS) K^+ channel was unaffected by A-kinase. Exposure of channels to a heterogeneous mix of purified PKC isozymes and activators (Ca^{2+} and diG) failed to consistently affect the BK channel, but produced profound decreases in open-time of the two intermediate-sized channels. The open-time of the fourth (~50 pS) channel was increased. All enzyme effects were ATP-dependent, and were not observed if heat-inactivated PKs were used. In some experiments, however, exposure of membranes to C-kinase activators alone (no exogenous enzyme) also produced closures of the intermediate-sized channels, suggesting that endogenous enzyme may have remained associated with these membranes.

ACTIVATION OF K^+ CURRENTS IN CULTURED SCHWANN CELLS IS CONTROLLED BY EXTRACELLULAR PH D. Hoppe, H.-D. Lux, M. Schachner and H. Kettenmann
Department of Neurobiology, University of Heidelberg, Im Neuenheimer Feld 504, 6900 Heidelberg, F. R. G.
Max-Planck-Institut für Psychiatrie, Abteilung Neurophysiologie, Am Klopferspitz 18A, 8033 Planegg-Martinsried, F. R. G.

K^+ currents recorded from cultured Schwann cells of mouse dorsal root ganglia were sensitive to changes in extracellular pH (pH_o). Currents were activated at potentials more positive than -50 mV, which is close to the resting membrane potential, and current amplitudes were affected by a change in (pH_o), being increased at alkaline and decreased at acidic pH_o. Analyzing the time course of current activation at different pH_o values indicated that the pH-sensitivity is due to changes in surface charges shifting the potential sensed by the gating process of the channel. The reversal potential of the currents was not affected by a change in pH_o. This observation and the finding that even a strong acidification to a pH_o value of 5.0 did not lead to a blockade of the fully activated channel indicate that the pH-sensitive charges are not located in the channel pore. Under the assumption that nerve activity in the peripheral nerve is associated with pH_o changes, as demonstrated for the optic nerve, the pH-sensitive K^+ channel of Schwann cells could serve to facilitate the spatial buffering of extracellular K^+.

REGULATION OF SCHWANN CELL K CHANNELS DURING INITIAL STAGES OF MYELINOGENESIS G.F.Wilson* and S.Y.Chiu. (SPON: T. Yin) Neuroscience Training Program & Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706.

In adult mammalian Schwann cells, ion channel expression is related to myelinogenic phenotype: K^+ currents are detectable at the soma of non-myelinating cells but not myelinating ones. We examine whether a developmental change occurs in K channel expression when the cell begins to form myelin. In cell-attached patches from myelin associated Schwann cells of rat sciatic nerve, delayed rectifying (DR) channels (~ 13-16 pS, 160 mM [K]o) are present in many somas as soon as myelin is visible (postnatal day 1, n=36). Inwardly rectifying (IR) channels also are observed and can be distinguished by their conductance (~ 35-37 pS, 160 mM [K]o), voltage dependence (IR channels being active at the resting potential), kinetics, and in inside/out patches, differential sensitivity to Cs^+ and 4-AP. Both IR conductance and reversal potential vary with external potassium, and in inside/out patches, rectification depends, in part, on [Mg^{++}]i. As myelination proceeds, somatic IR and DR channel density is down-regulated. The average IR current is reduced by 94% by day 8 (n=48) and the average DR current is reduced by 96% by day 45 (n=55), a time when IR channels have disappeared. This is the first report of an IR channel in normal mammalian Schwann cells. This, coupled with the observation that these channels are active at rest during rapid myelin formation may link them to myelinogenic processes.

INTERACTION OF GONADAL STEROIDS WITH $GABA_A$ RECEPTORS IN FRESH SLICES OF MEDIOBASAL HYPOTHALAMUS AND CEREBRAL CORTEX. W. Jacobson, D. March*, F Van Huizen*, M. Cynader, N. MacLusky and C. Shaw, Division of Reproductive Science, Toronto General Hospital and Department of Opthalmology, University of British Columbia.

GABA is the most ubiquitous neurotransmitter in the brain. It has been proposed that this neurotransmitter plays an important role in the regulation of LHRH release and ultimately gonadotropin secretion. We have examined the effects of a low dose regimen of gonadal steroids in ovariectomized females on $GABA_A$ receptors in slices of mediobasal hypothalamus (MBH) and cerebral cortex. Female Sprague Dawley rats which had been ovariectomized for 7 days were treated with estradiol benzoate (EB, 5 μg) or vehicle alone at 1000 hrs on day 0. On day 2, animals were treated with either progesterone (P, 500 μg) or vehicle alone at 1000 hrs. Animals were sacrificed at 1100 hrs, and $GABA_A$ receptor binding in slices of fresh brain tissue was determined using the $GABA_A$ antagonist [^{3}H]-SR-95531. Treatment with EB alone resulted in a decrease in the amount of [^{3}H]-SR-95531 bound in MBH. Subsequent treatment with progesterone resulted in a further decrease in [^{3}H]-SR-95531 binding in the MBH of a magnitude similar to that seen with EB treatment alone. In slices of cerebral cortex, binding determined with low concentrations of [^{3}H]-SR-95531 showed an identical pattern, however, when a high concentration of the radioligand was used the differences in binding between the three groups disappeared. We suggest that changes in behavior and in gonadotropin release normally seen in P treated, EB-primed animals may be reflective, in part, of a diminution in the inhibitory influence of GABAergic neural circuits. REGULATORY EFFECTS OF BARBITURATES AND STEROIDS ON THE $GABA_A$ RECEPTOR COMPLEX IN CULTURE. L. K. Friedman, T.T. Gibbs* & D.H. Farb, Dept. Anatomy & Cell Biol., SUNY HSC, Brooklyn, NY 11203.

Acute administration of barbiturates, benzodiazepines (BZDs) and steroids enhance GABA-mediated responses. Chronic BZD exposure reduces allosteric coupling between sites on the $GABA_A$ receptor. Here we report the effects of chronic barbiturate and steroid treatment of cultures derived from embryonic chick brain. Cultures were treated with barbital (1mM), pentobarbital (200μM), progesterone metabolites (5-ß-3-α- and 5-ß-3-ß-pregnan-ol-20-on; 10μM) or ß-estradiol (10μM) for 48 h. Allosteric interactions were measured by reversible binding with 1nM ^{3}H flunitrazepam in the presence and absence of 10μM GABA. Both barbiturates and steroids reduced allosteric coupling between GABA and BZD recognition sites, i.e. GABA's ability to enhance flunitrazepam binding was reduced by 30-50%. Steroids were more potent than barbiturates. Saturation analysis showed no change in receptor number. Direct enhancement of ^{3}H flunitrazepam binding by either barbiturates or steroids was abolished following chronic treatment. These results suggest that brain neurons in primary culture exhibit dynamic cellular regulatory responses to both barbiturates and steroids.

397.3

OPPOSITE EFFECTS OF PROGESTERONE ON GABA- AND GLYCINE-INDUCED CURRENTS IN CULTURED CHICK SPINAL CORD NEURONS. F.-S. Wu*, T.T. Gibbs* and D.H. Farb, Dept. of Anatomy and Cell Biology, SUNY Health Science Center, Brooklyn, NY 11203.

Certain metabolites of progesterone markedly potentiate neuronal responses to GABA. In the present study we show that in cultures of embryonic chick spinal cord neurons progesterone itself both enhances GABA-induced chloride currents and antagonizes those induced by glycine.

Using whole-cell recording methods cells were voltage-clamped at -70 mV. Drug solutions were applied to single neurons by pressure ejection from 7-barrel pipettes. Progesterone (10-100 μM) rapidly and reversibly potentiated responses to 3 μM GABA but reduced responses to 50 μM glycine. These effects on GABA and glycine responses were dose-dependent, with EC_{50}s of 26 and 15 μM, and maxima of +157% and -57%, respectively.

These results not only provide an interesting distinction between chloride-mediated GABA and glycine responses, but also suggest that endogenous progesterone may differentially modulate the inhibitory actions of these two neurotransmitters.

397.4

BINDING OF PREGNENOLONE SULFATE TO RAT BRAIN MEMBRANES: INTERACTION WITH THE $GABA_A$ RECEPTOR COMPLEX. S. Demirgoren* M.D. Majewska, H.N. Wagner, Jr.* and E.D. London (SPON: B. Gold), Addiction Res. Ctr., NIDA, Baltimore, MD 21224 and Division of Nuclear Medicine, The Johns Hopkins Medical Institutions, Baltimore, MD 21205.

The neurosteroid pregnenolone sulfate (PS) is synthesized in the CNS in oligodendroglia (Hu, Z.Y., et al., Proc. Natl. Acad. Sci., USA 84:8215, 1987). PS interacts with the $GABA_A$ receptor, presumably at the site of chloride ionophore, exhibiting GABA-antagonistic properties at micromolar concentrations (Majewska, M.D., et al., Brain Res. 339:178, 1985; Majewska, M.D. and Schwartz, R.D., Brain Res. 404:355, 1987; Majewska, M.D., et al., Neurosci. Lett. 90:279, 1988). We examined the binding of [^{3}H]PS to rat brain membranes. The binding of [^{3}H]PS was saturable and temperature- and protein-dependent; the optimal pH was 6.4 and equilibrium was reached after a 20 min incubation. At 5 nM, specific [^{3}H]PS binding was about 60% of total binding. A biphasic pattern of displacement of [^{3}H]PS by unlabeled PS suggested the existence of two populations of sites: Ki_1 = 2 μM and Ki_2 = 150 μM. Picrotoxin and antagonists of the $GABA_A$ receptor-coupled chloride ionophore inhibited [^{3}H]PS binding at the higher affinity site, suggesting that this site may be associated with the $GABA_A$ receptor complex. *In vitro*, PS interacted also with σ sites (Su, T.-P., et al., Science 240:219, 1988) but σ ligands (*d*-pentazocine and haloperidol) did not inhibit [^{3}H]PS binding, nor did progesterone, which also interacts with σ sites.

397.5

EFFECT OF STARVATION ON GABA CENTRAL AND PERIPHERAL BENZODIAZEPINE RECEPTORS. M. Bidder*, R. Weizman*, F. Fares*, and M. Gavish. Dept. of Pharmacology, Technion Fac. of Med., Haifa, Israel.

The effect of 5 days of food deprivation and refeeding for 5 days on GABA receptors, central benzodiazepine receptors (CBR), and peripheral benzodiazepine binding sites (PBS) was evaluated in adult female Sprague-Dawley rats in the estrous phase. Five days of food deprivation caused a significant reduction (20%) in body weight (control vs. deprived rats: 212±6 vs. 161±7 g; $p<0.01$). Starvation induced a significant down-regulation (30%; $p<0.01$) in PBS in the kidney. The alteration returned to normal values following 5 days of feeding. Ovarian PBS were not affected by food deprivation. [^{3}H]PK 11195 in the hypothalamus as well as the pituitary gland was unchanged. Starvation did not affect CBR binding to cerebral cortex, but it induced a significant decrease (35%; $p<0.01$) in [^{3}H]muscimol binding in this brain region. These results indicate that starvation stress affects GABAergic and benzodiazepinergic systems.

397.6

A PHYLOGENETIC STUDY OF THE EFFECTS OF UNSATURATED FATTY ACIDS ON THE GABA/BENZODIAZEPINE RECEPTOR COMPLEX Michael-Robin Witt and Mogens Nielsen, Research laboratories, Sct. Hans Hospital, Roskilde, Denmark.

Unsaturated fatty acids such as Oleic, Arachidonic and Docosahexaenoic acid stimulate the binding of the GABA/-Benzodiazepine receptor ligands 3H-Diazepam and 3H-Muscimol in rat brains in-vitro (Nielsen et al, Eur.J.Pharmacol.146,349,1988). In 6 species of mammals, Oleic acid (25 ul of a stock solution (4mM) was added to 1ml binding assay) increased the binding of these ligands by 100%. In the 9 species of birds studied, Oleic acid stimulated 3H-Diazepam binding to the same extent, while only weakly stimulating 3H-Muscimol binding (20%). The degree of 3H-Diazepam binding enhancement varied greatly depending on which of the 16 species of fish were studied. In some species such as coal fish, Oleic acid was inactive but stimulated the binding of 3H-Diazepam and 3H-Muscimol by 60% in other species (e.g. crucian carp). Modulation of the binding of 35S-TBPS by Benzodiazepine receptor agonist and inverse agonist ligands was less pronounced in e.g. the codfish, in contrast to the mammalian and avian species. Furthermore, incubations of brain membranes with Phospholipase A2 increased the binding of 3H-Diazepam in mammals and birds, while no increase was found in some fish brains (i.e. codfish). In conclusion, the allosteric interactions within the GABA/Benzodiazepine receptor complex differ between the species.

397.7

BENZODIAZEPINE-LIKE EFFECT OF A MONOCLONAL ANTIBODY ON PRESYNAPTIC GABA$_A$ RECEPTORS. B. Florán*, A. De Blas and J. Aceves* (SPON: J. Hernández). Dept. Physiology. CINVESTAV-IPN. Apartado Postal 14-740. 07000 México, D.F.

The aim of this study was to see how a monoclonal antibody raised for the purified GABA-A/benzodiazepine receptor could afect the activation of the presynaptic GABA receptors modulating the release of GABA in the pars compacta of the rat substantia nigra (Floran et al., Eur. J. Pharmacol. 150: 277, 1988). The experiments were done on slices of the nucleus. The release of [3-H] GABA was induced by high (15 mM) K^+. Muscimol inhibited GABA release (IC-50 = 35 nM). Both diazepam and pentobarbital caused a parallel shift to the left of the dose-response curve of the muscimol inhibition of the release. The monoclonal antibody (62-3G1) also shifted to the left the dose-response curve. The shifting of the curve by both diazepam and the antibody was blocked by the selective antagonist of the benzodiazepine receptors, Ro15-1788. The results suggest that the monoclonal antibody activates the benzodiazepine receptors of the GABA-A/benzodiazepine receptor complex increasing the affinity of the presynaptic GABA receptors for GABA agonists.

397.8

MODULATION OF CELL MITOGENESIS BY RO 5-4864 AND PK11195. H.E. Laird II, K.E. Gerrish* and D.H. Russell* Dept. of Pharmacol./Toxicol[1]., Univ. of Ariz., Tucson, AZ, 85721 & Pharmacol./Therap.[2], Univ. S. Florida, Tampa, FL.

We have used the Nb2 node lymphoma cell line as a model system in which the function of the PBZR may be studied. These cells possess high affinity PBZR sites and are dependent on prolactin (PRL) for mitogenesis. Ro 5-4864 (agonist) and PK11195 (antagonist) bind with high affinity to the peripheral benzodiazepine receptor (PBZR). We now report that Ro 5-4864 and PK11195 modulate the mitogenic activity of PRL in Nb2 cells. At 10^{-9}M, both Ro 5-4864 and PK11195 promoted PRL-directed cell proliferation while at 10^{-6}M only Ro 5-4864 inhibited the PRL effect. Further, Ro 5-4864 enhanced PRL-stimulated ODC activation at 10^{-9}M while 10^{-6}M inhibited the PRL effect. Next, studies were done to determine the effect of PK11195 on the Ro 5-4864 modulation of PRL. At 10^{-6}M, PK11195 blocked the PRL modulatory actions of 10^{-9}M and 10^{-6}M Ro 5-4864. In addition, Ro 5-4864 at 10^{-6}M blocked the ability of 10^{-9}M PK11195 to promote the mitogenic action of PRL. Finally, the presence of both agents at 10^{-9}M did not cause a greater effect on PRL-dependent mitogenesis than that shown by the agents individually. These data suggest that both ligands act on the same PBZR sites. Supported by Ariz. Dis. Contr. Comm.(YG-9290)(HEL) and Flinn Fdn. 062-100-099-86(HEL & DHR).

EXPRESSION OF GABA-RECEPTOR-LIKE IMMUNOREACTIVITY BY TYROSINE HYDROXYLASE CONTAINING HYPOTHALAMIC NEURONS IN DISSOCIATED CULTURE. **J. P. Grierson, H. M. Geller and H. D. Baker* Department of Pharmacology, UMDNJ - Robert Wood Johnson Medical School, Piscataway, NJ 08854. *Dept. of Neurology, Burke Rehabilitation Center, Cornell University, White Plains, NY 10605.**

The role of GABA as a neuroendocrine transmitter in the hypothalamus is a subject of considerable investigation. Especially interesting are putative interactions between GABA and dopaminergic neurons. Our previous immunocytochemical characterization of dissociated neurons from the embryonic rat hypothalamus in culture have shown two populations of cells immunoreactive for tyrosine hydroxylase (TH) and also that the majority of neurons are immunoreactive for GABA. We have also shown that the majority of neurons in our culture express GABA/benzodiazepine receptor (GABAr) immunoreactivity. In this study, we wanted to ascertain whether TH-containing cells express the GABAr. Cultures were fixed in a 4% paraformaldehyde (PFA) solution and then incubated with the monoclonal anti-GABAr antibody 6AA2 (J. Tallman), followed by rhodamine conjugated secondary antibody. A second PFA fixation and permeabilization with Triton was completed before staining with rabbit anti-TH (EugeneTech) and a fluorescein-conjugated secondary antibody.

The antibody 6AA2 possessed a highly characteristic staining pattern on cultured neurons with intensely stained plaques in restricted areas. These plaques are normally located on the neurites, although partial somatic staining is occasionally observed. Approximately 0.1% of neurons stain brightly for TH and initial results indicate that all have a few GABAr-positive plaques. Thus, our data provide direct evidence for a GABAergic modulation of dopaminergic neuronal activity. Supported by NIH NS-25168.

CENTRAL AND PERIPHERAL GABA RECEPTORS IN THE COCKROACH PERIPLANETA AMERICANA. M.E. Schnee*, S.D. Buckingham*, J.J. Rauh*, B. Hue*, M.E. Schroeder* and D.B. Sattelle (SPON: J. Meek). Agricultural Products Dept., E.I. DuPont de Nemours, Wilmington, DE 19898 and AFRC Unit, Dept. of Zoology, Cambridge, U.K.

Previous attempts to classify insect GABA receptors have lacked comparative information for central versus peripheral receptors. Our electrophysiological studies on identified neuronal cell bodies of the cockroach have revealed the presence of bicuculline-insensitive GABA-activated chloride channels. In contrast, bicuculline (100 μM) blocked IPSPs recorded from giant interneurone 2 (GI 2) following stimulation of nerve X, but failed to block the response to GABA ionophoresed onto the fine branches of GI 2 within the neuropile of the terminal abdominal ganglion. Thus, the block by bicuculline of IPSPs recorded from GI 2 resulted from an action at sites other than postsynaptic GABA-activated chloride channels. Bicuculline blocked neuronal nicotinic ACh receptors in cockroach CNS, which may explain the observed synaptic effects. Our preliminary findings indicate that bicuculline-insensitive receptors are also present on cockroach coxal muscles. Current studies are aimed at further electrophysiological characterization of these peripheral receptors in comparison to central insect receptors and to ligand binding profiles obtained from membrane preparations of the cockroach ventral nerve cord.

397.11

PHARMACOLOGICAL DIFFERENCES BETWEEN GABA RECEPTORS OF INSECTS AND VERTEBRATES. S.C.R. Lummis*, S.D. Buckingham*, J. Rauh* and D.B. Sattelle. AFRC Unit, Dept of Zoology, Cambridge, U.K. and Agricultural Products Dept, E.I. Du Pont de Nemours, Wilmington DE, U.S.A.

GABA receptors in the insect CNS show biochemical similarities to the vertebrate GABA$_A$ receptor, but their pharmacological properties differ. Electrophysiology, radiolabelled ligand binding and GABA-activated $^{36}Cl^-$ uptake have been used to study the actions of a variety of ligands at these receptors. Cockroach CNS contains a GABA receptor which is insensitive to bicuculline and possesses a benzodiazepine binding site more closely resembling that of the vertebrate peripheral benzodiazepine binding site. Selected steroids with IC_{50s} of 10-1000nM against ^{35}S-TBPS binding to rat brain have little or no effect on the insect GABA receptor; the most active (5α-Pregnan-3α-OL-20-ONE) inhibits only 26% of cockroach CNS GABA-stimulated $^{36}Cl^-$ uptake at 1μM. The cyclodiene heptachlor has an IC_{50} of 0.19μM against vertebrate ^{35}S-TBPS binding, but on cockroach CNS at 100μM it only blocks up to 50% of the electrophysiological response to GABA and 55% of the CNS GABA-stimulated $^{36}Cl^-$ uptake. We conclude that there are differences between insect and vertebrate GABA receptor Cl^- channel molecules at the sites of action of bicuculline, benzodiazepines, steroids and heptachlor.

397.12

EFFECT OF PRENATAL AND NEONATAL CHRONIC EXPOSURE TO PHENOBARBITAL ON CENTRAL AND PERIPHERAL BENZODIAZEPINE RECEPTORS. F. Fares,* A. Weizman,* C. G. Pick,* J. Yanai* and M. Gavish. Dept. of Pharmacology, Technion Fac. of Med., 31096 Haifa, Israel. (SPON: N. Allon)

Phenobarbital (PhB) was administered to mice during days 9-18 of gestation. [^{3}H]Muscimol binding to cerebellum, [^{3}H]flunitrazepam binding to cerebellum and olfactory bulb, and [^{3}H]PK 11195 binding to olfactory bulb, heart, and kidney were assayed in the offspring at 22 and 50 days of age. The chronic prenatal administration of PhB did not affect either GABA receptors, central benzodiazepine receptors (CBR), or peripheral benzodiazepine binding sites (PBS) in these tissues. In the next stage of the study, we investigated a possible modulatory effect of chronic postnatal PhB treatment during days 2-21 of age on the same receptors measured at 22 and 50 days of age. PhB exposure of neonates resulted in a significant down-regulation of GABA receptors and CBR in the cerebellum and of PBS in the heart. The effects were demonstrated on day 22 of age and were undetectable by day 50 of age. CBR at the olfactory bulb and PBS at the olfactory bulb and kidney were not altered by the drug treatment.

397.13

AHR-14749: A NEW BZ_1 BENZODIAZEPINE RECEPTOR SELECTIVE ANXIOLYTIC/ANTICONVULSANT. B. F. Kilpatrick, R. D. Tabor*, R. Young, B. E. Tomczuk*, C. R. Taylor* and D. N. Johnson. A. H. Robins Research Laboratories, Richmond, VA 23261.

Biochemical and pharmacological characterization of AHR-14749 (5-chloro-N,N-dimethyl-2-(4-methylphenyl)-3H-imidazo[4,5-b]pyridine-3-acetamide) indicates that this compound is selective for the BZ_1 benzodiazepine receptor and possesses potent anxiolytic and anticonvulsant activities. Competition curves of AHR-14749 for [^{3}H]flunitrazepam (FLN) binding in rat cerebral cortex membrane preparations were shallow with Hill coefficients of 0.634 and computer analysis indicated two sites with K_i values of 41 and 1400 nM. Analysis of AHR-14749 competition for [^{3}H]FLN binding to the BZ_1 receptor in rat cerebellum revealed a single site with a K_i value of 59 nM indicating that AHR-14749 had a 30 fold selectivity for the BZ1 receptor. GABA and barbiturate shift ratios of 2.75 and 2.65 indicated that AHR-14749 behaved as a full agonist and scatchard analysis indicated that AHR-14749 was a competitive inhibitor of BZ_1 receptors.

In vivo studies showed that AHR-14749 was an effective anticonvulsant as indicated by its ability to inhibite maximal electroshock-induced (ED_{50}=9.1 mg/kg,IP) and subcutaneous Metrazol-induced (ED_{50}=2.98 mg/kg,IP) convulsions in mice. AHR-14749 was also shown to be a potent anxiolytic as indicated by the minimum effective doses in the Vogel (3.16 mg/kg,IP) and in the light/ dark exploratory (0.10 mg/kg,IP) behavioral tests in mice. Using blockade of morphine-induced Straub Tail (ED_{50}=0.87 mg/kg,IP) and the rotorod motor performance (ED_{50}=17.8 mg/kg,IP) tests, AHR-14749 was shown to have less muscle relaxant activity than diazepam. Using values derived from the light/dark exploratory and Straub Tail tests, AHR-14749 had a 75 times better anxiolytic/muscle relaxant therapeutic index than diazepam.

397.14

KINDLING PRODUCED IN RATS BY PENTYLENETETRAZOL (PTZ) IS ASSOCIATED WITH A DECREASE IN THE GABA-STIMULATED 36Cl- UPTAKE IN THE CEREBRAL CORTEX. M.G. Corda, B. Longoni*, M. Orlandi*, D. Lecca*, E. Cancedda* and G. Biggio. Dept. of Exp. Biology, Univ. of Cagliari, Italy

We have previously shown that chronic treatment with FG 7142 produces chemical kindling in rats, and this effect is associated with a down-regulation of the GABA-A receptor complex (Brain Res. 384, 60, 1986). To further clarify the role of the GABAergic system in the development of chemical kindling, in the present study we evaluated in rats the sensitivity to convulsions and the function of the GABA-A receptor complex following chronic treatment with PTZ, a blocker of the GABA-coupled chloride ionophore. Repeated administration of subconvulsant amounts of PTZ (25 mg/kg i.p., 3 times a week for 10 weeks) resulted in the gradual development of kindling. Convulsions appeared by the 2nd-3rd week of treatment and 90-100% of the rats became sensitized to PTZ by the end of the chronic treatment. Sensitization to convulsions was long-lasting, being still present in rats challenged with PTZ (25 mg/kg i.p.) up to 4 months after the completion of the chronic treatment. In addition, rats kindled with PTZ showed an enhanced responsiveness to FG 7142 (30 mg/kg i.p.), Ro 15-4513 (20 mg/kg i.p.) and isoniazid (300 mg/kg s.c.). Biochemical studies, performed 3 days after the completion of the chronic treatment (10 weeks), revealed a reduction in the stimulatory effect of GABA on 36Cl- uptake to cerebral cortex microsacs and a decrease in the density of 35S-TBPS binding sites in unwashed cerebral cortex membranes from PTZ-treated rats. In addition, a significant increase in the total number of BZD receptors was observed in the cerebral cortex and hippocampus, but not in the cerebellum of rats kindled with PTZ. The results suggest that kindling produced by repeated exposure to PTZ is associated with a reduction in the function of the GABA-coupled chloride ionophore.

397.15

GABA A RECEPTOR ALTERATIONS FOLLOWING PERINATAL EXPOSURE TO DIAZEPAM. R.J. Gruen, J.D. Elsworth and R.H. Roth. (Sponsor: A. Rasmusson). Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

Studies examining the relationship between perinatal exposure to diazepam (DZ) and subsequent alterations in central benzodiazepine receptors have yielded inconsistent results. We have examined the effect of perinatal exposure to DZ on the low affinity GABA A receptor in the adult rat.

Rats were exposed to DZ from embryonic day 8 to postnatal day 7 (P7). Animals were sacrificed at P90 and several mesotelencephalic brain regions were removed. The binding of the GABA antagonist, [^{3}H]bicuculline methyl chloride (BMC), to P_2 membranes in potassium phosphate/thiocynate buffer was measured.

A significant decrease in BMC binding was found in cingulate cortex membranes from animals exposed to DZ, relative to untreated controls. In addition, the ability of GABA to displace BMC binding was significantly reduced in hypothalamus membranes from DZ-exposed subjects. Our results suggest that some of the behavioral and biochemical alterations previously seen in animals perinatally exposed to DZ may be associated with an alteration in the GABA A receptor. This work was supported in part by MH 14092 and the Abraham Ribicoff Research Facilities of the Connecticut Mental Health Center.

GABA MEDIATED CHLORIDE FLUX IS NOT ALTERED DURING MAXIMAL BENZODIAZEPINE (BZ) WITHDRAWAL (WD). Norman R. Boisse, Yu Xie, and Gary M. Samoriski, Sect. of Pharmacology, Northeastern University, Boston, MA 02115.

Chronic BZ anxiolytic-sedative-hypnotics can induce physical dependence. The mechanisms of WD are unknown. Spinal cord electrophysiological studies revealed GABA-mediated pre-synaptic inhibition is profoundly reduced during max. BZ WD in a rebound way (JPET 231: 464, 1984) supporting a GABA hypoeffectiveness hypothesis. To test whether the GABA-BZ receptor Cl channel complex is a locus for GABA transmission deficits, brain microsac GABA stimulated ^{36}Cl flux (Harris & Allan, 1985) was evaluated during WD. Rats got chlordiazepoxide (CDP) 150 mg/kg, b.i.d. or H_2O (controls) for 5 weeks; 3 1/2 days, at max WD flux was done. There was no change in the GABA dose-response. CDP and pentobarbital increased GABA flux 5% and 46% in both groups. Therefore, GABA receptor-Cl channel coupling is not altered in BZ WD. Disparity with in situ spinal reflex study suggests endogenous modulators of the GABA receptor complex, intact synaptic transmission and/or reduced GABA release may play a role in WD expression (BRSG S07 RR 05830-09).

DECREASED PERIPHERAL BENZODIAZEPINE BINDING CAPACITY IN DEPRESSED PATIENTS. D.L. Diorio, S.A. Welner, B.E.Suranyi-Cadotte Douglas Hosp. Research Center, Department of Psychiatry, McGill Univ., Montreal, Canada H4H 1R3

Peripheral benzodiazepine (PBZ) binding sites are widely distributed in peripheral tissues as well as in the CNS, however they are pharmacologically and physically distinct from the central benzodiazepine receptors which mediate the anxiolytic, sedative and anti-convulsant actions of the classical benzodiazepines. Although the precise function of the PBZ site is as yet unclear, a role in the stress response has been suggested since variable changes in the PBZ sites have been observed in peripheral and central tissues of animals exposed to stress. Additionally, the PBZ site may reflect changes occurring in anxiety, since a reduced binding capacity (Bmax) has been reported in platelets of anxious patients (Weizman et al., Eur. J. Pharm., 138:289, 1987). Due to the intimate relationship existing between anxiety and depression, we investigated the binding of [^{3}H]PK 11195 (a ligand highly specific for the PBZ site) to platelets in a group of depressed patients (RDC-major depression) and healthy controls matched for sex and age. We report here a significant decrease in Bmax values in depressed patients (2905.5±514.2) when compared to controls (4235.9±477.3); no change in the affinity (Kd) of the ligand was observed. These results provide further evidence suggesting a common biological component between depression and anxiety, where similar changes in PBZ receptor densities have been previously observed. Supported by FCAR & FRSQ.

DISCIMINATIVE STIMULUS EFFECTS OF MIDAZOLAM (MDZ) AFTER CENTRAL ADMINISTRATION IN RATS. C.A. Sannerud and R.R. Griffiths. Depts. of Psychiatry and Neuroscience, Johns Hopkins Univ. Sch. of Medicine, Baltimore, MD 21205.

Since the drug discrimination procedure has been shown to provide a highly specific assessment of the pharmacological actions of the benzodiazepines (BZ), a drug discrimination paradigm was used to investigate central sites of BZ activity. Male Long-Evans hooded rats were trained to discriminate 0.32 mg/kg MDZ i.p. vs. no drug (ND) in a two-lever drug discrimination procedure. Rats were implanted with bilateral intracranial cannulae in the basolateral amygdala and lateral ventricle. On selected test days, intracranial microinjections of MDZ was delivered into the specific brain regions of unrestrained rats. Compared to the i.p. route, central administration of MDZ in either brain area was 4-times more potent in producing increases in drug-lever responding (ED_{80}: 8 vs. 32 µg). Drug-lever responding occasioned by intracranial MDZ injections in the lateral ventricles or basolateral amygdala was antagonized in a dose-dependent manner by intraperitoneal administration of the BZ receptor antagonist, flumazenil. The antagonism by flumazenil was surmountable with a higher intracranial dose of MDZ. Thus, although no site specificity was demonstrated, these data suggest that the drug stimulus produced by MDZ administration was mediated via central BZ receptors. Supported by DA-04133.

398.1

GABA$_A$-RECEPTORS EXPRESSED FROM RAT α- AND β-SUBUNITS IN XENOPUS OOCYTES ARE MODULATED BY BENZODIAZEPINE RECEPTOR LIGANDS.

H.Mohler, P.Malherbe*, A.Draguhn**,
Institute of Pharmacology, University of Zurich, Switzerland;, *Hoffmann-La Roche, Basle, Switzerland;, **Max-Planck-Institute of Medical Research, Heidelberg, West-Germany.
(SPON: J.R. Martin)

The structural requirements for functionally active GABA$_A$-receptors were investigated in Xenopus oocytes by coexpression of clones coding for the α- and β- subunits of the receptor in rat brain. GABA-induced inward currents, recorded under voltage clamp at -70mV, were selective for chloride ions. They were inhibited by bicuculline and potentiated by pentobarbital as well as by diazepam (1-20 μM) and flumazenil (1-10 μM). Surprisingly, the inverse agonist DMCM (3-10 μM) likewise potentiated the GABA-response. Thus, benzodiazepine binding sites are present on GABA$_A$-receptors expressed from rat brain α- and β- subunits. They mediate, however, only a limited spectrum of intrinsic activities. The findings are in line with the biochemical localization of benzodiazepine binding sites on α-subunits of the native GABA$_A$- receptor.

THE LONG-TERM, CONTINUOUS RELEASE OF FG 7142 INCREASES GABA-STIMULATED CHLORIDE UPTAKE IN CORTICAL MEMBRANE PREPARATIONS.

R. J. Marley, C. Heninger and D. W. Gallager. Dept. of Psychiatry, Yale U. Sch. Med., New Haven, CT 06508.

Repeated, intermittent administration of the β-carboline, FG 7142, results in chemical kindling with a concomitant increase in seizure susceptibility (Little et al., Br. J. Pharm., 83:951, 1984). This treatment also produces an apparent decrease in the number of GABA and TBPS bindings sites and a decreased ability of muscimol to stimulate the uptake of $^{36}Cl^-$ into cortical membrane preparations (Corda et al., Brain Res. Bull., 19:379, 1987; Lewin et al., Eur. J. Pharm., 160:101,1989). We have previously reported a similar decrease in GABA-stimulated $^{36}Cl^-$ influx into cortical membrane preparations following the continuous, long-term administration of diazepam (Marley, R.J. and D.W. Gallager,. Eur. J. Pharm., 159:217, 1989). However, both kindling and the development of tolerance to benzodiazepines appear to be dependent on whether the drug is administered intermittently or continuously.

In the present study, FG-7142 was administered continuously for 10 days using osmotic minipumps modified with catheters which were stereotaxically implanted to release drug directly into the ventricles. This protocol allows for the administration of 50 μg/day over the entire treatment period. Cortical membrane preparations from rats administered FG 7142 continuously for 10 days exhibited an increase in GABA-stimulated $^{36}Cl^-$influx, suggesting that while the intermittent administration of FG 7142 leads to biochemical changes associated with kindling, the continuous administration of this inverse agonist has an opposite effect. This effect is also opposite in direction to that observed following chronic agonist exposure. These results indicate that the GABA/benzodiazepine receptor complex may homeostatically respond to continuous modulation by benzodiazepine ligands.

Further results from determinations of seizure susceptibility, the binding of TBPS to the chloride channel and GABA receptor binding parameters following continuous ICV administration of FG 7142 will also be presented.

398.3

ENANTIOSELECTIVITY IN THE POTENCY OF AGONISTS AT THE FUNCTIONAL GABA$_A$ RECEPTOR.

J.Kardos, I. Kovács* and M.Simonyi*. Central Res.Inst.Chem., Hung.Acad.Sci., Budapest, POB 17, H-1525, Hungary.

Membrane vesicles from the cerebral cortex of male Wistar rats were prepared for both binding studies and $^{36}Cl^-$ influx measurements. All experiments were performed under identical conditions (30° in Hepes buffered physiological salt solution pH 7.5, 2.5 mg protein/mL); incubation for binding was 30 min, Cl^- uptake was terminated after 7 sec by mixing with a quench-solution containing picrotoxin and furosemide (3 mM each). S(+)-dihydromuscimol (DHM) was about 6 times as potent as R(-)-DHM both in displacing specific ^3H-muscimol binding and in the activation of $^{36}Cl^-$ influx. S(-)-Ro11-3128 was found over 100 times more potent than R(+)-Ro11-3624 both in displacement of specific ^3H-flunitrazepam binding and in the facilitation of $^{36}Cl^-$ influx. Moreover, the potent effect of DHM enantiomers appeared at the same concentration in both experiments (0.7 uM for S(+)-DHM, 4 uM for R(-)-DHM) suggesting the presence of GABA$_A$ receptors exhibiting similar potencies in both binding and functional response.

398.4

GABA DESENSITIZATION IN HIPPOCAMPAL NEURONS IN CULTURE.

M. Dichter and I. Frey, Department of Neurology, Graduate Hospital and the University of Pennsylvania, Philadelphia, PA 19146.

Application of GABA to hippocampal neurons in culture (WC mode with symmetric Cl concentrations) via local perfusion, results in a dose-dependent desensitizing inward current ($\tau \cong 6$-7 seconds). Desensitization may be present during ongoing synaptic activity, as suppression of neurotransmitter release with Co increases the peak response to GABA and the desensitization rate while decreasing the steady state response.

We attempted to determine if the rate and extent of desensitization to GABA could be affected by a cAMP- or G protein-dependent process or modification of the high affinity GABA binding site. Neither internally perfusing the neurons with diB-cAMP, nor treatment of the cultures with pertussis toxin (to persistantly inactivate G proteins), nor intracellular perfusion with the non-hydrolysable substrate, GTPγS, dramatically altered the size of the GABA response or its desensitization. Addition of Mg and ATP to the patch pipette slowed "run-down" of the GABA responses but did not affect desensitization. Application of SCN, which has been suggested to mask high affinity GABA binding sites, decreased both peak and sustained currents without affecting the rate of desensitization.

We also examined the effects of somatostatin-14 and 28, peptides which commonly coexist with GABA in hippocampal neurons, on the GABA response. SOM-14 (100 nM) enhanced the peak GABA response in ca. 40% of neurons, and decreased it in ca. 15%. SOM-28 (100 nM) increased the GABA response in 9% of neurons and decreased it in 36%. Neither form of SOM appeared to have a significant effect on the extent or rate of desensitization. Thus, both forms of SOM can modulate the postsynaptic GABA receptor, but their effects are variable from cell to cell and can be positive or negative.

398.5

GABA ACTIVATED CURRENTS AND CHANNELS IN MAMMALIAN NEOCORTICAL NEURONS.

M. Frosch+, S. Lipton^, M. Dichter#, Departments of Pathology+ and Neurology^, Brigham and Women's+^, Children's and Beth Israel Hospitals^ and Department of Neurology#, Graduate Hospital and the University of Pennsylvania, Boston, MA 02115

Responses to GABA were analyzed in neocortical neurons recorded with WC patch clamp electrodes. Only $GABA_A$-Cl currents were activated; there were no currents which could be attributed to $GABA_B$ receptors. The GABA response decremented with maintained GABA due to two factors: changes in internal Cl (when Cl_i was initially low) and true receptor desensitization. Both desensitization and resensitization were voltage sensitive; at hyperpolarized membrane potentials, the neurons desensitized relatively rapidly (≅ 10-15 sec) and resensitized slowly. At positive membrane potentials, desensitization was slow and resensitization was rapid.

When GABA-activated Cl channels were examined in outside-out patches, desensitization occurred rapidly and was no longer voltage dependent. Moreover, a very rapid "run-down" of the channel responses was noted. Thus, the response in outside-out patches was quite different from that of the same channels in the WC mode. The channels averaged 27 pS in their main conductance states, but occasional 16 pS and 45 pS channels were noted. I-V curves were linear for all of the 27 pS channels examined.

Preliminary experiments were performed to identify regulatory mechanisms underlying the desensitization or resensitization of the WC responses. Neither addition of Mg and ATP, nor cAMP, cGMP, ATP or GTP, to the patch pipette, nor changes in levels of extra- (2 or 10 mM) or intracellular Ca (1 nM to 10 uM - buffered with EGTA), nor treatment of the cultures with forskolin or phorbol 12-myristate-13-acetate (PMA) produced a change in either the GABA response or its voltage dependent desensitization or resensitization.

ANATOMICAL AND PHYSIOLOGICAL PROPERTIES OF GABAergic INHIBITION IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURES.

Peter Streit, Scott M. Thompson*, and Beat H. Gähwiler. Brain Research Institute, Univ. of Zürich, Zürich, Switzerland and *Dept. of Neurology, Columbia Univ., NY, NY 10032 (spon: L. S. Benardo)

GABAergic inhibition develops primarily after birth, has been shown to be decreased following some forms of chronic deafferentation, and may decline over time in culture (McBain *et al.* 1988). We therefore used immunohistochemical staining with an anti-GABA antibody, and intracellular recording to examine the GABAergic system in hippocampal roller-tube slice cultures. Interneurons and terminal-like elements containing GABA-immunoreactivity had a similar morphology, distribution, and density to *in situ* tissue, and there was no loss of immunoreactivity in cultures kept for 13-26 days *in vitro*. Furthermore, after 8-30 days in culture, spontaneous and evoked IPSPs were observed in all CA3 pyramidal cells tested. These IPSPs resulted from an increase in Cl- conductance, and were mediated by activation of bicuculline-sensitive GABA receptors. Both the magnitude of the synaptic conductance underlying the maximal IPSP (mean = 130 nS) and the IPSP reversal potential (-66 mV) were comparable to *in situ* values, and did not vary with time in culture. Epileptiform bursting was not observed under control conditions. Taken together, the present physiological and immunohistological data show that GABAergic inhibition is well expressed in organotypic slice cultures and is maintained over periods of at least four weeks *in vitro*. Supported by Swiss National Fund grants 3.389.86, 3.390.86, and 3.534.86 (PS and BHG) and NIH Fellowship F32 NS08306 (SMT).

THE PUTATIVE ROLE OF Ca^{2+} CHANNELS IN THE CALCIUM-INDEPENDENT RELEASE OF GABA. S. Bernath and M.J. Zigmond. *Department of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.*

We have investigated whether external Ca^{2+} is crucial for GABA release from striatum. Tissue slices (350 um) were prepared from rat striatum, incubated with [3H]GABA, superfused with Krebs buffer (100 ul/min), and exposed to electrical field depolarization (2 Hz for 3 min). Tritium efflux was measured as an index of GABA release. Removal of external Ca^{2+} (and addition of 1mM EGTA) greatly increased resting and evoked efflux of GABA. However, there was no effect of Ca^{2+}-deficiency on resting release when Mg^{2+} was elevated to 10 mM, and evoked overflow was depressed (-88%). Verapamil (10 uM), a Ca^{2+} channel blocker, reduced evoked overflow under normal conditions (-45%) and in the absence of Ca^{2+} (-85%). 4-Aminopyridine (10 uM), a K^+ channel inhibitor, increased GABA release in the presence of external Ca^{2+} (+78%), but not in its absence. These results suggest that Ca^{2+} channels may play a double role in the regulation of GABA release, only one of which involves Ca^{2+} influx. (Supported in part by USPHS grants NS-19608, MH-43947, and MH-00058.)

AN EXCITATORY RESPONSE TO GABA IN CRUSTACEAN MOTONEURONS. R. M. Harris-Warrick and J-R Cazalets* Section of Neurobiology and Behavior, Cornell University, Ithaca NY 14853.

γ-aminobutyric acid (GABA) is normally thought of as an inhibitory neurotransmitter. However, in several invertebrate and vertebrate systems, GABA has now been shown to exert excitatory effects on neurons. Here we show that in the lobster, *Homarus americanus*, GABA elicits a depolarizing response in the pyloric motoneurons of the stomatogastric ganglion. These responses are excitatory and result in action potential generation. The depolarization is preferentially elicited by pressure application on the cell bodies, which can be studied by two-electrode voltage clamp. The response is dose-dependent with a threshold at 10^{-5} M and saturation at 10^{-3} M. The excitatory effect is mimicked by muscimol and blocked by picrotoxin but not by bicuculline. The response is TTX-, TEA- and 4-AP-resistant. V_{rev} is between -30 and -20 mV and is not altered by changes in extracellular K^+ and Ca^{2+} (from 20% to 400% of the normal concentration). Decreases in extracellular Na^+ cause a negative shift of V_{rev} while decreases in extracellular Cl^- produce a positive shift. We conclude that the GABA depolarizing response is a mixed response caused by conductance increases to Na^+ and Cl^- ions. Supported by NIH NS17323 and Hatch NYC191410.

398.9

DIFFERENTIAL EFFECT OF HALOPERIDOL ON GAD ACTIVITY IN DISCRETE BRAIN NUCLEI IN THE RAT. R. E. Wilcox, P. K. Randall, and R. D. Mayfield*. Institute for Neuroscience, Depts. of Pharmacol. and *Kinesiol., Univ. of Texas at Austin, Austin, TX 78712

It has been suggested that different motor behaviors produced by dopamine (DA) agonists and antagonists may be mediated though different striatal efferent systems. Further, different efferents may be characterized by distinct relationships with the DA receptor subtypes. If this is the case, experimental manipulations of striatal output should differentially affect the neurochemical characteristics of the output nuclei. We studied the effect of acute DA receptor blockade on glutamic acid decarboxylase (GAD) activity in the major striatal output nuclei.

Male Sprague-Dawley rats (n=33) were administered the predominantly D-2 antagonist haloperidol (0.5 or 5 mg/kg, ip) or 0.01M tartaric acid (vehicle). Micropunches were taken from the substantia nigra reticulata (SNr), globus pallidus (GP) and the entopeduncular nucleus (EP) and assayed for GAD activity using the method of Holdiness (Anal. Lett., 13: 1330, 1980). Acute challenge with 0.5 and 5 mg/kg haloperidol decreased GAD activity in the SNr by 24 and 59%, respectively. This dose dependent decrease was not observed in the GP or EP. Haloperidol produced a biphasic effect on GAD activity in both the GP and EP, with the effect being more pronounced in the EP. The 0.5 mg/kg dose of haloperidol decreased GAD activity by 30 and 77% in the GP and EP, respectively. The 5 mg/kg dose did not significantly affect GAD activity in the GP; however, it produced a 45% decrease in the EP. Thus, in GP and EP, the low dose of haloperidol was more effective in decreasing GAD activity than the high dose.

In conclusion, brain regional GAD activity may represent a useful approach for assessing the effects of typical and atypical neuroleptics on basal ganglia efferent activity. Comparisons of these results with those of nonselective or selective D-1 antagonists would be valuable in assessing the contributions of DA recepor subtypes to the function of striatal efferent systems. (Supported by NS20827, MH44799, BN58808129, NS22926, and the Texas Adv. Res. Tech. Prog.)

398.10

ONTOGENY OF GABA LOCALIZATION IN PAROXYSMAL CHICK BRAIN. P. A. Lewis* and M. M. Beck. Dept. of Animal Sci., Univ. of Nebraska, Lincoln, NE 68583.

GABA, an inhibitory neurotransmitter and metabolic substrate in brain, has been implicated in seizure syndromes, increasing in some (Roberts et al., 1985), decreasing in others (Ciesielski et al., 1981). In 10-20d paroxysmal (px) chicks, it increases (Firman and Beck, 1984). The px syndrome includes clonic-tonic audiogenic seizures in chicks beginning at 7-10d posthatching; seizures can also be electrically elicited by 5d. In this study, brains from px and normal chicks were removed at 5, 7, and 10d and stained for GABA using immunocytochemistry. Cells stained at 7 but not at 5d in 5 oculomotor and 2 auditory regions. Intensity of optical density staining was from 50-77% greater in 2 auditory and 1 oculomotor areas in px brains at 7d. Increased terminal staining in auditory nuclei was found in normal brains compared to px brains of the same age but increased over time in both groups. At 10d, cells in px cerebellum were more intensely stained than the 7d px or 10d normals. The results indicate accumulation of GABA in cells and decreases in terminals in px brain, possibly because of decreased transport along degenerated auditory tracts (Beck et al., 1983) or to an increase in glial metabolic pools.

398.11

GABA TERMINALS IN THE MOUSE DENTATE FASCIA LABELED WITH IMMUNOGOLD PROBE. P. Schaner* and E. Fifkova (SPON: T. D. McIntyre). Neuroscience Center, Department of Psychology, University of Colorado, Boulder, CO 80309.

Distribution of GABAergic terminals in the dentate fascia of mice was studied with the immunogold probe. Thin sections were incubated with an affinity purified antibody against GABA and then labeled with a 5 nm gold-conjugated secondary antibody.

Two types of labeled terminals are found in the granule cell layer synapsing upon the granule cell bodies and large dendrites. The first type, an asymmetrical synapse, is identified by a distinct postsynaptic density and numerous, tightly packed, large round vesicles. The second type, a symmetrical synapse, lacks the thick postsynaptic density but often exhibits presynaptic densities along the synaptic apposition. The vesicles are less uniform in size and appear loosely packed, except along the active zone, where they are tightly clustered. Preliminary results indicate that asymmetrical synapses occur more frequently (61% of those analyzed) than the symmetrical type. Dense core vesicles are found in both types. The relatively large proportion of asymmetrical GABAergic synapses is an unexpected finding. It is unlikely that the GABA antibody used cross-reacted with another transmitter metabolically close to GABA, like glutamate, because in the distal two-thirds of the dentate molecular layer where glutamatergic synapses form more than 85% of the total synaptic population labeled terminals are rare. Asymmetrical GABAergic terminals labeled with an anti-GABA antibody and a gold probe were also observed in the cerebellar glomeruli (Hamori and Takacs, *Exp. Brain Res.*, **74**:471, 1989). However, our observation is at variance with that of Kosaka et al. (*Brain Res.*, **293**:353, 1984) who have found that in the rat granule cell layer less than 1% of GABAergic terminals are asymmetric. Whether this discrepancy is caused by the difference in the procedure (GAD antibodies visualized with HRP immunocytochemistry in a preembedding mode) or in the species used will require further analysis.

IMIDAZOLEACETIC ACID, A GABA-A AGONIST, AND ITS CONJUGATE(S) IN CNS OF RAT: HETEROGENEOUS DISTRIBUTION AMONG REGIONS, SUBCELLULAR FRACTIONS AND CEREBROSPINAL FLUID. G.D.Prell, A.M.Morrishow* and J.P.Green. Dept. Pharmacology, Mount Sinai School of Medicine, CUNY, New York, NY 10029

Imidazoleacetic acid (IAA), which we demonstrated in rat brain and human CSF by GC-MS (J.Neurochem. 52:1107,1989), stimulates GABA-A receptors, stimulates phosphodiesterase activity and produces analgesia, hypnosis, hypothermia and hypotension. In brains of rats that had been anesthetized and cerebrally perfused to remove blood that contains IAA, levels of IAA are distributed heterogenously among regions. Mean (±SEM) levels (pmol/g) ranged from 291±47 (olf. bulbs) to 105±8 (frontal cortex), a three-fold difference (ANOVA: $F=14.8$, $p< 0.01$). Levels of IAA were heterogenously distributed (mean % of total) among the soluble (63%), P2 (mitochondrial)(23%), P1 (nuclear)(9%) and P3 (microsomal)(5%) fractions; levels in soluble and P2 fractions were negatively correlated ($r= -0.98$, $p<0.0001$). There was a concentration gradient of IAA in samples of CSF taken sequentially from the cisterna magna of anesthetized rats, i.e. last units of CSF collected had higher levels than portions removed earlier, suggesting that, like other substances showing concentration gradients, IAA in CSF may be derived from brain. We found high concentrations of an acid-hydrolyzable conjugate(s) of IAA in brain (> 20 nmol/g) and CSF, also heterogenously distributed, whose levels exceeded those of free IAA by up to 100-fold. Levels of IAA in homogenates heated at 100°C for 48 h in 2N HCl were unchanged, but increased after heating at 150°C in 0.1N HCl. These findings suggest that the conjugate(s) is likely to be IAA-ribotide or IAA-riboside, and its formation may be a means of terminating the actions of IAA. IAA in brain may be derived physiologically from histidine with imidazolepyruvic acid as an intermediate since IAA levels increased in rats after irrevesible inhibition of histidine decarboxylase and administration of histidine and increased in brain homogenates incubated with imidazolepyruvic acid. IAA may also be formed in brain from large, nonphysiological quantities of histamine. [Supported by NIMH grant 31805.]

AFFERENTS TO CALCIUM-BINDING PROTEIN CONTAINING BASAL FOREBRAIN NEURONS. W.E. Cullinan and L. Zaborszky. Dept. Otolaryngol. Univ. of Virginia, Charlottesville, VA 22908.

Parvalbumin (PV) and calbindin D-28k (CaBP) are calcium-binding proteins (CBP) important in sequestering free intracellular calcium. Antibodies against these proteins are thought to label two distinct populations of GABAergic neurons without the use of colchicine. Earlier studies (Zaborszky et al., 1986) have shown that local or projective GABAergic afferents in the basal forebrain innervate cholinergic projection neurons. Since little is known about afferents to basal forebrain GABAergic neurons, we were particularly interested in identifying afferents to CBP neurons in basal forebrain areas rich in cholinergic neurons. PHA-L was iontophoretically delivered to different hypothalamic and brainstem regions known to project to the rostral forebrain, and sections processed for the simultaneous detection of PHA-L labeled fibers/terminals and CBP-containing neurons using nickel enhanced DAB/DAB double labeling technique at the LM level. CaBP neurons in the lateral septal nucleus appear to receive contacts from the anterior hypothalamic nucleus, lateral hypothalamus, and locus coeruleus. PV containing neurons in the vertical and horizontal limbs of the diagonal band nuclei and lateral preoptic area are likely to be contacted by fibers originating from pontine tegmental regions and the ventral medullary reticular formation. Supported by USPHS Grant NS. 23945 and 17743.

IMMUNOCYTOCHEMICAL DEMONSTRATION OF GAMMA-AMINOBUTYRIC ACID IN ASTROCYTES LOCATED IN WHITE MATTER. M.S.Bull and A. Blomqvist, Dept. Cell Biol., Univ. Hospital, 581 85 Linköping, Sweden.

There is much biochemical evidence that astrocytes are involved with neurons in the uptake and degradation of gamma-aminobutyric acid (GABA). Since most of the evidence has been obtained from astrocytic preparations of gray matter, it remains unclear whether astrocytes in white matter also take up and degrade GABA. To better understand what role astrocytes play in regulating GABA, the purpose of this study was to determine whether astrocytes in white matter contain GABA.

Adult rats were injected with gamma-acetylenic GABA (GAG)(i.p.200 mg/kg), a GABA-transaminase inhibitor, and subsequently perfused with a 1% paraformaldehyde-2% glutaraldehyde solution. Vibratome sections were cut through the brain and spinal cord and processed for preembedding light and electron microscopic GABA immunocytochemistry. Light microscopic examination revealed immunoreactive neurons but also numerous smaller immunoreactive profiles in the corpus callosum, diencephalic fiber tracts and nuclei, and spinal cord, which in the electron microscope were identified as astrocytes.

These results show that GABA is present in astrocytes located in both white and gray matter when GABA degradation is inhibited with GAG. Since astrocytes do not synthesize GABA, the GABA present in astrocytes in white matter was most likely acquired from extracellular space. Thus, the results suggest that white matter astrocytes function in a manner complementary to gray matter astrocytes by removing GABA from the extracellular space of fiber tracts.

OSCILLATION OF INTERSPIKE INTERVAL LENGTH IN CENTRAL MONOAMINERGIC NEURONS. J.H. Carlson, C.W. Berridge and S.L. Foote. Dept. Psychiatry, UCSD, La Jolla, CA 92093.

The spontaneous discharge activity of individual monoamine-containing neurons was studied in halothane-anesthetized rats using extracellular recording techniques. Three measures were utilized: 1) mean discharge rates, 2) population characteristics of interspike interval (ISI) samples, and 3) ISI time series measures to examine patterns in the ordering of ISIs. The mean discharge rates of dopaminergic (DA) substantia nigra pars compacta and ventral tegmental area neurons and noradrenergic locus coeruleus neurons were 2.9±0.3 (n=16), 4.6±0.5 (n=12) and 1.4±0.2 (n=8) Hz, respectively. The ISI histograms for all 3 cell populations were similar to those described by others. Additionally, the time series analyses revealed a conspicuous oscillatory tendency in the sequence of ISIs in these neurons: Consecutive ISIs tended to alternate between short and long durations, although short bursts were evident in the DA cells. For all 3 cell types, long-short and short-long pairs of consecutive ISIs occurred significantly more frequently ($P<0.01$) than in the same samples when the order of ISIs was randomized. These oscillatory patterns are presumably produced by the operation of ionic conductances which terminate bursting activity, decreasing the probability of consecutive short ISIs, as well as conductances which serve to minimize the probability of consecutive long ISIs. The present analyses provide quantitative measures of the impact of these (and other) conductances on discharge activity.

399.2

EFFECTS OF MPTP ON THE ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL PROPERTIES OF MIDBRAIN DOPAMINERGIC NEURONS IN VITRO. G.L. Bernardini, S.G. Speciale and D.C. German. Depts. of Physiol. & Psychiat. UT SW Med. Cntr., Dallas, TX 75235.

The functional properties of midbrain dopaminergic (DA) neurons change following a loss of cells in the nucleus. The purpose of the present study was to determine whether the increase in dopamine turnover that results from DA cell loss is related, in part, to changes in DA neuronal impulse flow. Groups of BALB/cJ mice were treated with 40, 50 and 55 mg/kg 2'CH3-MPTP. Standard in vitro electrophysiological recording and HPLC procedures were used. The baseline firing rates of nucleus A9 neurons increased significantly (78%) as forebrain dopamine levels decreased. Autoreceptor-induced inhibition in cell firing (200 µM dopamine) was increased 40% in nucleus A10 but decreased in nucleus A9. There was also a 3 fold increase in cell incidence within nucleus A9 in the treated mice. These data suggest that as midbrain DA cell number decreases there is an increase both in the number of spontaneously active cells and in the firing rates of the active cells. EFFECTS OF APAMIN ON THE ELECTROPHYSIOLOGICAL RESPONSE PROPERTIES OF MIDBRAIN DOPAMINERGIC NEURONS IN VITRO. D.C. German, X. Gu* and A. L. Blatz* . Depts. of Physiol. and Psychiat., U. of Texas Southwestern Med. Cntr., Dallas, TX 75235.

Midbrain dopaminergic (DA) neurons in vivo exhibit either a regular, irregular or burst firing pattern. In vitro, however, these neurons characteristically fire with a non-burst pattern. The purpose of the present experiment was to determine whether apamin, which blocks calcium-activated potassium channels, influences the activity of all midbrain DA neurons. Mice (20-25 g) were studied with standard in vitro extracellular single unit recording procedures. Cells were tested with superfused apamin (1µM) and dopamine (10-200 µM). Apamin often caused cells to change from a regular to irregular or burst firing pattern (n = 6) and caused some cells to slow or stop firing altogether (n = 5). Two regular-firing cells increased in rate but did not change in pattern. Apamin did not block the inhibitory effects of dopamine on any cell (n = 7). The variability in response to apamin is consistent with the hypothesis that not all midbrain DA neurons possess calcium-activated potassium channels. Research supported by NIMH (MH-30546) and NIH (GM-39731).

399.4

EFFECTS OF RISPERIDONE (RIS) ON SUBSTANTIA NIGRA PARS COMPACTA (SNC) DOPAMINERGIC (DA) NEURONS: COMPARISON WITH HALOPERIDOL (HAL). C.B. Davis and P.S. Blum (SPON: B.P. Damiano), Department of Biological Research, Janssen Research Foundation, Spring House, PA 19477.

The effects of acute administration of RIS, a D2, S2 antagonist on DA neurons has been described. Little is known, however, about the chronic effects of RIS on the activity of DA neurons. In preparation for a study of chronic effects, the percent of midbrain DA neurons in the SNC that are active one hour after RIS was estimated by sampling the number of active DA neurons in multiple tracts through the midbrain (cell/tract sampling technique). The effects of RIS (0.5 mg/kg, i.p.) and the D2 antagonist HAL (0.5 mg/kg, i.p.) were compared with effects of saline. All drugs were administered one hour before the initial dose of anesthesia (chloral hydrate), and recording were begun about one-half hour later. In each experiment, 9-12 electrode tracts were made in the (SNC). DA neurons were identified using standard criteria. One hour following saline administration there was an average of 1.1 active DA cells per tract (C/T) in the SNC (n=7). HAL produced a 36% increase in active DA C/T in the SNC (n=9). This observation is consistent with other studies that have shown neuroleptics to increase the number of active DA neurons. RIS, on the other hand, produced a 27% decrease in the active DA C/T in the SNC (n=8). There were no differences in the mean discharge frequency of DA neurons in any treatment group. These results suggest that RIS is not typical of other neuroleptics since it does not increase the number of active DA C/T following i.p. administration.

399.5

EFFECT OF HALOPERIDOL (HAL) AND RISPERIDONE (RIS) ON DOPAMINERGIC (DA) NEURONS: CHANGE IN SPONTANEOUS ACTIVITY AND REVERSAL OF APOMORPHINE (APO)-INDUCED INHIBITION. P.S. Blum and D.M. Robisch, Dept. of Biol. Res., Janssen Res. Found., Spring House, PA 19477.

The antipsychotics RIS, an S-2, D-2 antagonist, and HAL, a selective D-2 antagonist, were administered intravenously to chloral hydrate anesthetized rats while recording from midbrain dopaminergic DA neurons using standard techniques. Fifty-five DA neurons were tested for altered spontaneous activity. Neurons with slow (<4.0 Hz) and rapid (<4.0 Hz) spontaneous activity were analyzed separately. HAL increased the activity of slow neurons (n=7; 165% of initial activity at 1.27 mg/kg) but did not affect rapid neurons (n=11; 108% of initial activity at 1.27 mg/kg). In contrast, RIS did not affect slow neurons (n=5; 100% of initial activity at 1.27 mg/kg), but decreased the activity of rapid neurons (n=10; 85% of initial at 1.27 mg/kg). The spontaneous activity of 18 other RIS-treated neurons (55% of total) ceased completely compared with 4 HAL-treated neurons (18%). In a previous study (Soc. Neurosci. Abstr., 14:1213, 1988), RIS was unable to block inhibition of DA neurons produced by APO, but in this study, intravenous RIS and HAL reversed APO-induced inhibition of activity in 34 additional DA neurons. The mean dose of HAL to produce a 50% reversal of neural activity (ED50) was 57 μg/kg. This value was about 2-3 times less than the mean ED50 for RIS (184 μg/kg). These data show that RIS and HAL can reverse the effect of a D-2 agonist on DA neurons, but they have a different effect on spontaneous activity of DA neurons.

399.6

D1 RECEPTOR STIMULATION INHIBITS THE ACTIVATION OF TUBEROINFUNDIBULAR DOPAMINE NEURONS INDUCED BY NEUROTENSIN, RESERPINE OR HYPERPROLACTINEMIA. S.A. Berry*, H.Y. Meltzer and G.A. Gudelsky. Departments of Psychiatry and Pharmacology, Case Western Reserve University, Cleveland, Ohio 44106.

In the present study we sought to determine the effects of D1 receptor activation on the activity of tuberoinfundibular dopaminergic (TIDA) neurons, as estimated from the accumulation of DOPA in the median eminence after decarboxylase inhibition. Treatment with the D1 agonist SKF 38393 (5-20 mg/kg) or CY 208-243 (10 mg/kg) alone did not alter the activity of TIDA neurons in male rats. However, SKF 38393 and CY 208-243 did inhibit the activation of TIDA neurons elicited by the injection of reserpine or neurotensin or by the induction of hyperprolactinemia with haloperidol. It is concluded that D1 receptor activation results in no effect on the basal activity of TIDA neurons, but that under conditions in which the activity of these neurons has been increased, D1 receptor activation elicits a marked inhibition of these neurons.

REPEATED ELECTROCONVULSIVE SHOCK (ECS) ALTERS SPONTANEOUS FIRING OF DOPAMINERGIC (DA) BUT NOT NORADRENERGIC (NA) NEURONES. J.A.Watson*# and T.H.Svensson. Pharmacology Dept., Karolinska Institute, S-104 01, Stockholm, SWEDEN. (SPON: Stone)

ECS is effective in treating various psychiatric illnesses including depression, in whose aetiology both DA and NA have been implicated. In addition, ECS has been shown biochemically and behaviourally to affect both DA and NA systems. We investigated neurophysiological changes induced in DA and NA neurones by ECS. Unanaesthetised rats received either repeated (one every second day for 10 days) or a single treatment (each being 800 ms of 120 V, 50 Hz stimulation). Sham rats received zero V. 24 h after the last treatment, spontaneous single cell discharge was examined under chloral hydrate anaesthesia in either the ventral tegmental area (VTA) or locus coeruleus (LC). VTA DA cell firing was more regular following repeated ECS than in sham rats, evidenced by a reduced variation coefficient (VC $P<0.01$). This reduced VC was significant for bursting ($P<0.02$) but not for non-bursting ($P>0.05$) cells. There were no significant differences in firing rate or the amount of burst firing after ECS. VTA cell discharge did not differ significantly after a single ECS treatment, although there was a trend for the VC to be lower in the ECS than the sham group ($0.05<P<0.1$). There were also no significant differences for VC, firing rate or burst firing in the NA cells of the LC after repeated ECS. These results show that the firing pattern of VTA DA cells is altered by repeated ECS treatment, in the absence of any significant change in NA cells of the LC. This change in firing pattern may have relevance for the use of ECS in treating, e.g., depression. #, Permanent address, Dept. Biological Sciences, Cumberland College of Health Sciences, Sydney, Australia

EFFECTS OF QUINPIROLE AND CHOLECYSTOKININ OCTAPEPTIDE ON DOPAMINE NEURONAL ACTIVITY IN THE MIDBRAIN SLICE. A.S. Freeman, D.J. Henry and L.A. Chiodo. Laboratory of Neurophysiology, Center for Cell Biology, Sinai Research Institute and the Cellular & Clinical Neurobiology Prog., Wayne State University, Detroit, MI 48235.

Dopamine (DA) and sulfated cholecystokinin octapeptide (CCK) coexist in a subpopulation of midbrain neurons and have been shown to influence the pre- and postsynaptic effects of one another. We report here preliminary data on the effcts of the D2 agonist quinpirole, CCK and the CCK antagonists proglumide and CR 1409 on the firing rate of DA cells in the in vitro superfused rat brain slice (450 um). Extracellular recording techniques were employed. Solutions of drugs were prepared in artificial CSF and sequentially delivered via a 4-way valve (2 ml/min). Quinpirole (5nM-1uM, n=7-15 cells/dose) produced dose-related inhibition of the spontaneous discharge of substantia nigra zona compacta (A9) DA cells (ED50 app. 40nM). CCK (0.1-100nM) excited most ventral tegmental area (A10) and medial A9 cells tested (29/40). Proglumide (10uM-10mM, n=13) generally had no effect on A10 and medial A9 cells although a few cells were inhibited. CR 1409 (10nM-1uM, n=12) exerted erratic effects on the firing rates of a similar population of cells but inhibitory responses predominated. Interactions among these compounds are under investigation. Supported by MH42136, MH41557 and Sinai Research Institute.

THE ROLE OF D1 AND D2 DOPAMINE RECEPTORS IN REGULATING THE ELECTROPHYSIOLOGICAL ACTIVITY OF CAUDATE NEURONS IN THE RAT. R. Shen, A.S. Freeman, D. Asdourian and L.A. Chiodo. Laboratory of Neurophysiology, Center for Cell Biology, Sinai Research Institute, the Cellular and Clinical Neurobiology Program and the Department of Psychology, Wayne State University, Detroit, MI 48235.

Extracellular single-unit recording and iontophoretic techniques were utilized to examine the effects of the selective D1 and D2 dopamine (DA) receptor agonists SKF 38393 and quinpirole on Type I caudate (Cd) neurons in paralyzed and chloral hydrate anesthetized rats.

SKF 38393 inhibited the basal firing rate of Type I Cd neurons in a dose-dependent manner in both alpha-methyl-para-tyrosine pretreated and normal rats, an effect blocked by the D1 DA antagonist SCH 23390. Quinpirole at ejection currents 10-40 nA exerted excitatory, inhibitory, or no effect on the basal firing rate of these neurons. A higher ejection current (80nA) inhibited the basal firing rate of most of the Type I Cd neurons, an effect blocked by the D2 DA antagonists sulpiride and eticlopride.

To date, no synergism between D1 and D2 agonists has been observed.

399.10

EFFECTS OF (+)-4-PROPYL-9-HYDROXYNAPHTHOXAZINE [(+)-PHNO] ON MIDBRAIN DOPAMINE NEURONS: AN ELECTROPHYSIOLOGICAL STUDY. M.D. Kelland, A.S. Freeman and L.A. Chiodo. Lab. of Neurophysiology, Center for Cell Biology, Sinai Research Institute and the Cell. and Clin. Neurobiology Program, Wayne State University, Detroit, MI 48235.

Standard extracellular single-unit and iontophoretic recording techniques were utilized to examine the effects of the D2 DA receptor agonist (+)-PHNO on identified nigrostriatal (NSDA) and mesoaccumbens (MADA) DA neurons.

(+)-PHNO administered i.v. inhibits the basal firing rate of NSDA neurons in a rate-dependent manner in both chloral hydrate-anesthetized and paralyzed rats. Significantly higher doses were required in the paralyzed preparation. Similar effects were observed with regard to the MADA neurons, with the exception that the inhibition was not rate-dependent in the paralyzed rats. (+)-PHNO administered iontophoretically also inhibited the firing rate of both NSDA and MADA neurons.

Neither SKF 38393 pretreatment nor hemitransection of the forebrain altered the rate-dependent responsiveness of NSDA neurons to (+)-PHNO. Likewise, depletion of brain 5-HT with either PCPA or 5,7-DHT failed to alter the rate-dependent responsiveness of these cells to (+)-PHNO. Thus, the ability of (+)-PHNO to inhibit NSDA neurons does not appear to be influenced by afferents.

REPEATED AMPHETAMINE ADMINISTRATION: RESPONSES OF NIGROSTRIATAL DOPAMINE NEURONS TO DOPAMINE AGONISTS.
D.K. Pitts, M.D. Kelland, A.S Freeman and L.A. Chiodo. Lab. of Neurophysiology, Center for Cell Biology, Sinai Research Institute and the Cell. & Clin. Neurobiology Program, Wayne State University, Detroit, MI 48235.

A previous study (Pitts et al., E.J.P. '89) examined the responses (change in discharge rate) of nigrostriatal dopamine neurons (NSDA) to i.v. apomorphine (APO) or quinpirole (QUIN) following repeated d-amphetamine (DAMP) treatment (4mg/kg/day i.p., 14 days). In that study NSDA neurons exhibited reduced sensitvity to APO but not to QUIN. Experiments utilizing SKF 38393 and SCH 23390 indicated that D1 receptor activation was important for the expression of reduced APO sensitivity. The effects of this DAMP regimen on NSDA neurons has recently been studied in experiments utilizing rats with a hemitransection of the midbrain/forebrain or in iontophoretic experiments examining the responsiveness of somatodendritic autoreceptors to dopamine in intact rats. Results from these experiments suggest that the D1 receptors which are responsible for the shift in the APO dose-response curve are located in the forebrain. A higher daily dose of DAMP (6 mg/kg/day, 14 days) decreased the sensitivity of NSDA neurons to quinpirole. Supported by MH41557 (LAC), MH42136 (ASF), MH09781 (DKP) and the Sinai Research Institute. MDK is a Tourette Syndrome Association Fellow.

WHOLE-CELL VOLTAGE-CLAMP ANALYSIS OF K CURRENTS IN ACUTELY DISSOCIATED, IDENTIFIED NIGROSTRIATAL DOPAMINE NEURONS.
L.A. CHIODO. Lab. Neurophysiology, Ctr. Cell Biol., Sinai Res. Inst. and Cell. and Clin. Neurobiol. Prog., Wayne State Univ. Sch. Med., Detroit, MI 48235.

We have been able to isolate identified, nigrostriatal dopamine (DA)-containing neurons from the mesencephalon of adult rats after retrograde labeling of their soma with rhodamine-conjugated latex microspheres (injected into the head of the caudate nucleus a minimum of 24 hrs earlier). These neurons have been studied electrophysiologically using whole-cell patch recording methods. The observed resting membrane potentials ranged between -53 to -64 mV, input resistances were 150-370 megohms and these cells had Na-dependent somatic action potentials (blocked by 1-10 uM tetrodotoxin). Voltage-clamp analysis, from a holding potential of -55 mV and after the removal of Na currents, revealed a late-onset, non-inactivating outward current in response to depolarization. This current was eliminated by the replacement of K ions in the patch electrode with Cs indicating that they were K-dependent. This K current could be separated into at least two components I_K (TEA-sensitive) and $I_{K(Ca)}$ (TEA-insensitive and blocked by Cd) with the latter accounting for 30-50% of the overall K current. (This work was supported by NIMH grant MH-41557 and the Sinai Res. Inst.)

DOPAMINERGIC NIGRO-STRIATAL NEURONS: EFFECT OF SKF 77434 ON FIRING RATE.
M. Diana, C. Okuda and P.M. Groves. University of California San Diego, La Jolla CA 92093.

Previous studies have indicated that stimulation of dopamine D1 receptors, either by peripheral injection or iontophoretic application in the substantia nigra does not affect the firing rate of dopaminergic neurons. However, virtually the totality of these studies have employed as a selective agonist the benzazepine SKF 38393. Recently SKF 77434, a N-allyl substituted benzazepine, has become available and classified as a D1 selective agonist on the basis of in vitro binding studies. We tested the possibility that this compound may influence dopaminergic neurotransmission by altering the firing rate of antidromically identified nigro-striatal dopaminergic neurons. Male Sprague-Dawley rats were anesthetized with urethane and placed in a stereotaxic frame. Dopamine neurons were identified according to well established electrophysiological criteria. SKF 77434 was administered intravenously through a catheter implanted in the femoral vein at exponentially increasing doses at 120 second intervals (3.9-125 µg/kg i.v.). Average firing rate of the entire 120 second period was compared to the predrug baseline. SKF 77434 produces a dose-dependent inhibition of the firing rate of nigro-striatal neurons. In some case SCH 23390 (D1 antagonist) was administered following SKF 77434. A reversal of the SKF 77434-induced inhibition was observed. Experiments are under way to ascertain if the SKF 77434 induced inhibition is a pre or a post-synaptic effect.

CALCIUM CURRENTS RECORDED FROM NIGROSTRIATAL DOPAMINE NEURONS ACUTELY DISSOCIATED FROM THE POSTNATAL RAT.
N.L.Silva and J.L.Barker, Laboratory of Neurophysiology, NINDS/NIH, Bethesda, MD 20892

Nigrostriatal dopamine neurons play a vital role in motor function. We injected fluorescent rhodamine labelled microspheres into the caudate nucleus of the postnatal (7-8 day) rat to retrogradely label nigrostriatal neurons. Cells visualized with fluorescence microscopy corresponded 89% of the time to neurons in the substantia nigra zona compacta (SNZC) which were identified as catecholaminergic following processing with FAGLU. Following a 4-5 day survival period the SNZC was enzymatically dissociated for 1 hr. Numerous neurons labelled with the fluorescent microspheres were observed to have phase bright somas. Cells were used for voltage clamp recordings for 6-8 hrs.

Calcium currents were isolated using an extracellular bathing medium which consisted of (mM) TEACl 145, HEPES 10, BaCl 3-5, MgCl 1, glucose 6 and the intracelluar medium contained NMGCl 120, Hepes 5, BAPTACs 5, MgATP 5, Tris phosphocreatinine 20, creatinine kinase 20U/ml. Two distinct components of calcium current were distinguished by their voltage and inactivation kinetics. A transient current (τ=150 ms) was activated with voltage steps more depolarized than -30 mV and had an inactivation range between -40 an -110 mV. A second sustained current ($\tau \geq$1.5s) was activated with voltage steps more depolarized than -20mV from a holding potential of -40 mV. The sustained current was sensitive to dihydropyridines. Both currents were blocked by low concentrations of cadmium and ω-Conotoxin. These results suggest that these two currents are similar to the "L" and "N" type currents which were originally described by Fox, Nowycky and Tsien (J. Physiol. 394:149-172, 1987).

399.15

ELECTROPHYSIOLOGICAL EFFECTS OF SELECTIVE OPIATE RECEPTOR AGONISTS ON A10 DOPAMINE (DA) NEURONS.
M. Jeziorski and F. J. White, Neuropsychopharmacology Lab, Lafayette Clinic, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State Univ. Sch. Med., Detroit, MI 48207.

The mesolimbic (A10) DA pathway has been implicated in the rewarding properties of opiates and other drugs of abuse. Mu and kappa opiate agonists have been shown to exert contrasting effects on several indices of DA cell functioning, including rewarding and aversive effects, respectively. The mu agonist morphine is known to increase the firing rate of A10 DA cells, but the effects of other opiate agonists on A10 DA cell electrophysiology are not well understood. Extracellular single unit recordings were conducted in chloral hydrate-anesthetized rats to investigate the ability of cumulative i.v. doses of the selective kappa opiate agonist U50488h to alter A10 DA cell firing. U50488h (total dose 8 mg/kg) inhibited the firing of 7 of 9 cells to an average of 54% of basal firing rate. One cell increased its firing to 137% of basal rate, while another was unaffected. The mu selective antagonist naloxone (NAL), adminstered i.v. at doses of .02-.16 mg/kg, reversed the inhibition caused by U50488h in a dose-dependent manner. However, NAL administered alone did not alter A10 cell firing in 3 animals tested. Future experiments will characterize the effects of the kappa antagonist binaltorphimine, as well as the effects of locally applied agonists and antagonists on A10 DA cell firing. (Supported by USPHS grants DA-04093 and MH-40832.)

399.16

CONTINUOUS ADMINISTRATION OF D1 DOPAMINE (DA) RECEPTOR ANTAGONISTS SELECTIVELY INACTIVATES A10 DA NEURONS IN THE RAT.
S.R. Wachtel and F.J. White. Wayne State Univ., Sch. of Med., Dept. Psychiatry, CCN Program, Neuropsychopharmacology Lab, Lafayette Clinic, Detroit, MI 48207

It has been proposed that D1 dopamine (DA) receptor antagonists may possess the characteristics of atypical antipsychotic drugs (APDs). The present experiments investigated the effects of the prototypical D1 antagonist SCH 23390 and the new D1 antagonist NO-112 [(+)-8-chloro-7-hydroxy-3-methyl-5(7-benzofuranyl)-2,3,4,5,tetrahydro-1H-3-benzazepin] on the activity of A9 and A10 DA neurons using an electrophysiological model predictive of the clinical profile of APDs. Following 28 days (0.29 mg/kg/day) of continuous administration of NO-112 or SCH 23390 via subcutaneous mini osmotic pumps, selective decreases, 28.9% and 28.2% respectively, in the number of spontaneously active A10 DA neurons were observed. This selective effect is similar to, though smaller than, that previously reported for the atypical APD clozapine. However, in contrast to other APDs, the decrease in the number of A10 DA cells/track did not appear to result from depolarization inactivation, since the DA agonist apomorphine (10 or 50 ug/kg, i.v.) did not reverse the effect of NO-112. These results suggest that D1 DA receptor antagonists may possess an atypical APD profile with respect to midbrain DA neurons that occurs via a mechanism other than depolarization inactivation. (Supported by MH-40832, DA-04093 and by NOVO Industri A/S.)

STIMULUS FREQUENCY-DEPENDENT DOPAMINE AUTORECEPTOR ACTIVITY INVESTIGATED IN VITRO USING RAT NIGROSTRIATAL "CORE" EXPLANTS AND MICROELECTRODE ELECTROCHEMISTRY. M.D. DAVIS* AND G.A. GERHARDT (SPON: W. MOOS). Parke-Davis Research Division, Ann Arbor, MI 48105, and Depts. of Psychiatry and Pharmacology, Univ. of Colorado, Denver, CO 80262.

Dopaminergic (DA) neurotransmission in the striatum is regulated in part via nerve terminal autoreceptors of the "D2" subtype. Autoreceptor agonists inhibit striatal DA release more efficiently during low frequency electrical stimulation, while autoreceptor antagonists facilitate release more effectively at higher frequencies. We studied the effects of DA autoreceptor agents on catecholamine (CA) overflow during short trains of stimuli using in vitro nigrostriatal "core" explants and electrochemical analysis.

Nigrostriatal explants containing the soma-to-terminal continuum were obtained from Sprague-Dawley rats and perifused in a flow-through tissue chamber. A stimulating electrode was placed in the MFB explant region while a nafion-coated 30um diameter carbon fiber recording electrode was inserted into the striatal region. Chronamperometry as well as fast-scan cyclic voltammetry were employed to detect rapid changes in CA overflow. Electrical stimulation of the MFB for one second evoked frequency-dependent transient (5-10sec) increases in putative DA overflow. Bath administration of apomorphine (100nM) attenuated stimulated overflow by a greater degree at 10 vs 20 Hz whereas haloperidol (50nM) administration elevated stimulus-evoked overflow greater at 20 vs 10 Hz.

PHARMACOLOGICAL PROTECTION AGAINST THE EFFECT OF REVERSIBLE HYPOFRONTALITY ON RAT MIDBRAIN DOPAMINE NEURONS IN VIVO. J. Grenhoff*, C.-S. Tung* and T.H. Svensson. Dept. of Pharmacology, Karolinska Institute, Stockholm, Sweden.

Clinical neurophysiological studies have demonstrated that low activity in prefrontal/ frontal cortex (PFC) is a relatively consistent feature of chronic schizophrenia with negative symptoms. To study the possible influence of hypofrontality on the mesolimbocortical dopamine (DA) system, we recorded the spontaneous activity of A10 DA neurons in the anesthetized male rat during PFC inactivation induced by application of dry ice to the skull overlying the PFC. Application of dry ice in the midline 2 mm anterior to bregma specifically affected A10 DA cell firing in a reversible way. PFC cooling regularized the firing and abolished burst firing of A10 cells, i.e. a pacemaker-like firing was seen. In contrast, A10 cell firing rate was unaffected. Ritanserin blocked the effect of PFC inactivation on all A10 neurons (10/10), while amperozide blocked the effect on 9/18 A10 neurons. The actions of ritanserin and amperozide are interesting in view of the reported therapeutic action of these drugs in chronic (negative, type II) schizophrenia, a disorder characterized by hypofrontality and poor response to traditional neuroleptic treatment.

ALTERED RESPONSIVENESS TO HALOPERIDOL FOLLOWING PARTIAL DOPAMINE DEPLETION IN RATS: BEHAVIORAL AND ELECTROPHYSIOLOGICAL ASPECTS. J.R. Hollerman and A.A. Grace *Departments of Behavioral Neuroscience & Psychiatry, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.*

Compensatory mechanisms within the nigrostriatal dopamine (DA) system enable it to recover functionality after extensive damage, as evidenced by the extent of DA loss required before the emergence of symptoms in Parkinson's disease. This can be modeled in rats by the intraventricular administration of 6-hydroxydopamine (6-HDA), which results in destruction of DA terminals and retrograde degeneration of nigral DA cell bodies. Previous studies showed that rats can receive striatal DA depletions of up to 90% without exhibiting overt motor deficits. Furthermore, rats with larger depletions, which initially result in motor deficits (i.e., akinesia and catalepsy), often recover and resume normal motor behavior within 2 to 4 weeks. Nonetheless, motor deficits can be uncovered in both cases by exposure to stressors or acute treatment with neuroleptics. In this study we examined the effects of haloperidol (HAL) on the activity of nigral DA neurons and motor behavior 4-6 weeks following administration of 6-HDA. In DA depleted rats, i.v. administration of as little as 0.1 mg/Kg HAL caused spontaneously active DA cells to increase their firing rate, display prominent burst firing activity and then cease firing. Activity could be reinstated by systemic administration of apomorphine or iontophoretic application of GABA, suggesting that the DA neurons had entered a state of depolarization block. Parallel behavioral studies showed that the same dose of HAL (i.p) could induce a profound akinetic and cataleptic state (as measured by open field and raised platform tests) in the DA depleted animals while having no effect on controls in these tests. Studies are underway to determine the time course for the development of this alteration in the behavioral and electrophysiological response to HAL. Supported by MH09660 & NS19608.

IN VIVO BIOCHEMICAL CORRELATES OF ACUTE DEPOLARIZATION INACTIVATION IN SUBSTANTIA NIGRA DOPAMINERGIC NEURONS. E.D. Abercrombie, J.R. Hollerman, and A.A. Grace. *Department of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260*

Although the chronic administration of neuroleptics abolishes the electrophysiological activity of dopamine (DA) neurons by means of depolarization inactivation (DI), DA turnover in postsynaptic regions is relatively unaffected. In this study, we used an acute model of DI combined with in vivo microdialysis to monitor DA release under these conditions. In this model, DI can be induced in substantia nigra DA neurons by administering a single dose of haloperidol (HAL; 0.5 mg/kg) to rats previously treated with 6-HDA, provided the striatal tissue DA depletion exceeds ~85% (Hollerman and Grace, 1989). This dose of HAL produced no significant alteration in extracellular DA from the basal level of 21 pg/sample (20 ul, corrected for recovery of the dialysis probe) in striata of 6-HDA treated rats (mean tissue DA depletion=90%; n=4). In intact rats, however, this dose of HAL increased both the firing rate of DA neurons and striatal extracellular DA (from a basal level of 41 pg/sample to 78 pg/sample; n=5). GBL (500 mg/kg), a compound that inactivates DA neurons via hyperpolarization, decreased extracellular DA in striatum to non-detectable levels in both 6-HDA treated (mean tissue DA depletion=89%; n=2) and control (n=3) rats. These data suggest that inactivation of nigral DA neurons by depolarization, as opposed to hyperpolarization, is not accompanied by a decrease in striatal DA release. Thus, DI may remove regulatory influences operative at the DA cell body while permitting DA release regulated at the nerve terminal to persist. Possible implications of these observations for a model of schizophrenia are discussed in the accompanying presentation (Grace et al., this meeting). Supported by the National Alliance for Research on Schizophrenia and Depression, and USPHS grants NS19608, MH42217, and MH09660.

399.21

PHASIC VERSUS TONIC DOPAMINE RELEASE AND THE MODULATION OF DOPAMINE SYSTEM RESPONSIVITY: A HYPOTHESIS FOR THE ETIOLOGY OF SCHIZOPHRENIA. A.A. Grace, E.D. Abercrombie & M.J. Zigmond. *Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.*

The dopamine (DA) hypothesis of schizophrenia, in its simplest form, suggests that this disorder is caused by DA system hyperactivity. However, there are several experimental findings that are inconsistent with this model: 1) increased DA metabolites have not been observed in schizophrenics, 2) there may be increased numbers of D2 receptors in schizophrenics, rather than the decrease that would be expected with overstimulation, and 3) homeostatic influences should compensate for simple increases in DA levels, thus restoring the system to normality.

Our model of schizophrenia is based on the premise that DA release occurs via two processes: 1) a transient or *phasic* DA release controlled by stimulus-induced changes in DA neuron firing, and 2) a more sustained, "background" *tonic* DA release which determines steady-state DA levels in DA terminal areas and is regulated by prefrontal cortical afferents. Behaviorally relevant stimuli (e.g., sensory inputs or affective states) would cause short-term activation of the DA system by increasing DA cell firing, thereby triggering phasic DA release. In contrast, the tonic component of DA release would serve to regulate the intensity of the response to phasic DA release by setting the background level of DA receptor stimulation (both postsynaptic and autoreceptor) in these sites. In the schizophrenic, a prolonged decrease in prefrontal cortical activity would markedly reduce tonic DA release. Over time, this would result in homeostatic compensations (e.g., receptor up-regulation, decreased feedback inhibition of DA synthesis & release) that would cause subsequent phasic DA release to elicit abnormally large responses. This DA system hyperresponsivity could be attenuated by neuroleptic-induced depolarization block of DA cells, since in this state stimuli would be incapable of activating DA cell firing, thereby averting the phasic response (see Abercrombie et al, this meeting).

ALTERATIONS IN DOPAMINE CELL ACTIVITY INDUCED BY PARTIAL DOPAMINE DEPLETIONS: EVIDENCE FOR DEPOLARIZATION BLOCK IN REMAINING CELLS. M.L.Pucak and A.A.Grace. *Depts. of Behavioral Neuroscience and Psychiatry, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.*

After partial depletions of the nigrostriatal dopaminergic pathway, remaining dopamine (DA) neurons exhibit increased firing rates (Hollerman & Grace, 1986) and can be driven into depolarization block (DB) by acute administration of the DA blocker haloperidol (Hollerman & Grace, 1988). We have investigated whether remaining DA cells in rats with 6-hydroxydopamine-induced partial depletions of the nigrostriatal tract undergo a spontaneous transition into DB by examining the effect of low doses of the DA agonist apomorphine (APO; 20 or 50 ug/kg, i.v.) on the number of spontaneously firing DA cells. Several lines of evidence suggest that some remaining DA cells may be in a state of DB by 4-6 weeks post-lesion (>85% depletion of striatal DA): 1) After administration of APO, the number of cells per track increased from .04±.08 to .13±.13 (n=8, p<.05). 2) DA cell firing rates were not as low after administration of APO as would be predicted if they had been spontaneously firing at the time of APO administration; that is, the firing rates of cells post-APO were not depressed (pre-APO, 50.7±9.5 (n=2); post-20 ug/kg APO, 60.4±25.9 (n=4); post-50 ug/kg, 48.7±13.7 (n=4)). 3) In one depleted rat, a DA cell was encountered which exhibited firing properties similar to that of DA cells entering DB. 4) Spontaneous firing has been elicited from a quiescent DA cell in a depleted rat by administration of iontophoretic GABA. These results may be of relevance in the treatment of Parkinson's disease, as clinical research has suggested that low doses of DA agonists decrease the number and severity of "off" periods in Parkinsonian patients (Stibe et al, 1988). TIME COURSE OF THE EFFECTS OF KAINATE-INDUCED PEDUNCULOPONTINE TEGMENTAL NUCLEUS (PPN) LESION SUGGESTS DEVELOPMENT OF SUBSTANTIA NIGRA PARS COMPACTA DOPAMINE CELL DEPOLARIZATION INACTIVATION RESULTS FROM LOSS OF PPN FUNCTION. M. Beninato, H.S. Pan and J.R. Walters. NINDS, Bethesda, MD 20892.

Previous studies (1) have shown a significant decrease in the number of spontaneously active (SA) substantia nigra pars compacta (SNc) dopamine (DA) neurons 7 days following kainate lesion of the PPN. Current studies using apomorphine pretreatment and GABA iontophoresis show that the silent DA neurons appear to be in a state of depolarization inactivation. Using previously described population study techniques (1) in chloral hydrate anesthetized rats, the time course of the development of this effect was studied. At 1 hour post lesion, the number of SA DA cells/pass (0.32±0.04, n=8) was significantly reduced from controls (0.82±0.09, n=6). Apomorphine pretreatment (80µg/kg) reversed this effect (0.92±0.13 cells/ pass, n=6). This indicated that the silent DA neurons are in a state of depolarization inactivation, resembling the condition seen at 7 days (0.50±0.07 cells/pass, n=9). At 12 hours post lesion, however, the number of SA DA cells/pass rebounded to control levels (0.95±0.07, n=6). These results suggest the depolarization inactivations observed at 1 hour and 7 days are due to different mechanisms. While the depolarization seen at 1 hour may be the result of an initial kainate-induced excitation of the PPN, this effect on the SNc DA neurons is apparently not sustained. The depolarization inactivation observed at 7 days may be due instead to the destruction of the PPN and subsequent alterations of neuronal influences on the SNc DA system.

THE EFFECT OF CHRONIC NICOTINE ON THE ELECTROPHYSIOLOGICAL RESPONSE OF A9 AND A10 NEURONS TO SYSTEMIC NICOTINE. K.-W. Yoon*, M.J. Curfman* and T.C. Westfall (SPON: K. Smith). Depts. of Pharmacology and Neurosurgery, St. Louis Univ. Sch. of Medicine, St. Louis, MO 63104.

We have previously observed that the systemic administration of nicotine (NIC) increases the firing rate of midbrain dopamine (DA) neurons (Eur. J. Pharmacol. 141:395, 1987). In the present studies, the effect of i.v. NIC on the firing rates of A9 and A10 DA neurons in naive or rats chronically treated with NIC (s.c. implants for 7 or 14 days 1 mg/kg/day) was studied by extracellular single unit recordings. I.V. NIC increased the firing rate of both A9 and A10 cells in naive rats and as previously observed by us, NIC was more potent and efficacious in activating A10 than A9 neurons. Implantation of the NIC pellets had no significant effect on the basal firing rate of A9 cells while the basal firing rate of A10 cells was decreased from 3.3 to 2.1 and 2.6 Hz after 7 and 14 days, respectively. Chronic treatment of NIC for 7 or 14 days did not alter the increase in the firing rate of i.v. NIC in A9 cells. In contrast, chronic treatment with NIC produced a significant shift of the NIC i.v. dose response curve in A10 cells. The maximum change to NIC went from an increase of 84% in naive rats to 352% in rats chronically exposed to NIC for 14 days. It is concluded that systemic NIC preferentially stimulates A10 compared to A9 cells and this difference is augmented further by chronic NIC exposure. (Supported by DA 02688.)

BIPHASIC MUSCARINIC-INDUCED CHANGES IN INTRACELLULAR CALCIUM OF SUSPENDED SINGLE HUMAN ASTROCYTOMA CELLS.
S.A. Oglesby and B.S. Pallotta. Curriculum in Neurobiology and Department of Pharmacology, University of North Carolina, Chapel Hill, NC 27599.

Using the intracellular fluorescent calcium-binding dye Indo-1 in conjunction with a fluorescence activated cell sorter, stimulation of 1321N1 human astrocytoma cells by muscarinic agonists was shown to result in a biphasic increase in the concentration of intracellular calcium of suspended cells. At least one component of this response is dependent on the presence of extracellular calcium. This component is not voltage dependent, and can be blocked by extracellular cobalt but not cadmium. Furthermore, this extracellular calcium-dependent component is not enhanced by higher concentrations of extracellular calcium and is not altered by the removal of extracellular sodium. Modeling of the kinetic components of the muscarinic calcium mobilization response in these cells suggest the involvement of at least three components which might be tenatively described as; a transient intracellular calcium release and resequestration of calcium that is not dependent on an influx of extracellular calcium, a more prolonged entry of extracellular calcium, and an efflux or further resequestration of cytosolic calcium.

GTP-γ-S DIFFERENTIALLY REDUCES CALCIUM CURRENT COMPONENTS IN RAT NODOSE GANGLION NEURONS. J.W. Wiley#, R.A. Gross, T.R.-Jastrow, R.L. Macdonald. Depts. of Neurology and #Internal Medicine, U of Michigan, Ann Arbor, MI 48104

Rat nodose ganglion neurons have 3 calcium current components similar to T, L and N currents in other sensory neurons. Neuropeptide Y selectively reduced the N current component via a pertussis toxin (PTX)-sensitive mechanism (Soc. Neurosci. Abstr. 14(1):645, 1988), suggesting that an inhibitory GTP binding (G) protein (G_i/G_o) couples certain receptors to voltage-gated calcium channels. We examined the effect of GTP and its stable thiol derivatives GDP-β-S (inactive ligand) and GTP-γ-S (activates G proteins) on the 3 calcium current components of rat nodose ganglion neurons. Currents were recorded from acutely-dissociated neurons from 7-10 d rats using the whole-cell variation of the patch clamp technique. The bath medium contained (mM): 10 HEPES, 67 choline, 100 TEA, 5.6 glucose, 5.3 KCl, 0.8 $MgCl_2$, 5 $CaCl_2$ (pH 7.4); the recording pipette (1-2.5 MΩ) contained 10 HEPES, 140 CsCl, 10 EGTA, 5 ATPMg and either 0.1 GTP, GDP-β-S, or GTP-γ-S. In control neurons (GTP), N and L current components decreased during the 20 min recording period. Substitution of GDP-β-S for GTP did not affect the amplitude, time to peak current, rate of inactivation, voltage ranges of activation or inactivation, or rate of "run-down" of calcium current components compared to controls. In contrast, GTP-γ-S differentially reduced the magnitude of calcium current components N>T>>L and increased the time to peak of N/L currents 3-4 fold. Pretreatment with PTX reversed the effects of GTP-γ-S. Thus, GTP-γ-S differentially affected the calcium current components in nodose ganglion neurons via a G-protein of the G_i/G_o type. Supported by VA Research Award to JWW, NIH 01019 to RAG, DA05345 to TR-J and DA04122 to RLM.

PROTEIN KINASE A ENHANCES, AND ATP-γ-S REDUCES CALCIUM CURRENT COMPONENTS OF RAT NODOSE GANGLION NEURONS. R.A. Gross, M.D. Uhler*# and R.L. Macdonald, Dept. of Neurology and the #Mental Health Research Institute, U of Michigan, Ann Arbor, MI 48104.

Acutely-dissociated rat nodose ganglion neurons have 3 calcium current components, similar to T, N and L currents of other sensory neurons. We used the purified catalytic subunit of protein kinase A (PKA) or the ATP analog ATP-γ-S, included in the recording pipette, to determine if kinase-mediated phosphorylation affected calcium currents in these neurons. In other preparations, cyclic AMP or PKA increases or removes inactivation from L-type currents (eg, Armstrong and Eckert, PNAS 84: 2518-2522, 1987). ATP-γ-S can serve as an irreversible phosphate donor in kinase reactions; we therefore compared its effect to that of PKA.

We used the whole cell variation of the patch clamp technique to record calcium currents from acutely-dissociated nodose ganglion neurons from 7-10 d rats. The bath medium contained (mM): 10 Hepes, 67 choline, 100 TEA, 5.6 glucose, 5.3 KCl, 0.8 $MgCl_2$, 5 $CaCl_2$ (pH 7.3); the recording pipette (1-2.5 MΩ) contained 10 Hepes, 140 CsCl, 10 EGTA, 5 ATPMg, 0.1 GTP. In control neurons, N and L current components declined throughout the recording period. PKA prevented "run-down" of the L current, evoked from holding potentials (V_h) = -40 mV, and enhanced the N current component (in currents evoked from V_h = -80 mV) while increasing its inactivation rate. ATP-γ-S had different effects, reducing calcium current magnitude and slowing the rate of current activation. These results suggest that PKA regulates both N and L current components. The effect of ATP-γ-S on calcium currents cannot be due to its ability to act as an irreversible phosphate donor via PKA.

INHIBITORS OF CALMODULIN AND PROTEIN KINASE C INFLUENCE INTRASYNAPTOSOMAL CALCIUM LEVEL AND TRANSMITTER RELEASE. M.H. Makman*, S.L. Garber and B. Dvorkin* (SPON: M.M. Rapport). Albert Einstein Col. of Med., Bronx, NY 10461

The Ca^{2+}-sensitive fluorescent dye, Fura-2, has been utilized to investigate regulation of internal [Ca^{2+}] in synaptosomes from specific regions of rat CNS including striatum. In striatal synaptosomes first equilibrated at 37° for 60 min and then loaded with Fura-2 acetoxymethyl ester, basal [Ca^{2+}] was stable at about 115 nM; following depolarization induced by 50mM K^+, within seconds [Ca^{2+}] increased to a new level of about 370 nM. Addition of 10µM 1-(5-isoquinolinyl-sulfonyl)-2-methyl piperazine (H7), an inhibitor of protein kinase C, caused a small but significant decrease (-20%) in basal [Ca^{2+}] and a major attenuation (-40%) of the effect of K^+-depolarization. The calmodulin inhibitor, N-(6-aminohexyl)-5-chloro-1-naphthalene sulfonamide (W7) at 10µM depressed basal [Ca^{2+}] slightly and almost completely aborted the K^+-induced increase in [Ca^{2+}]. The calmodulin inhibitor, calmidazolium (CMZ), at 10µM, unexpectedly increased [Ca^{2+}] to several-fold basal level, probably due to a calmodulin-independent effect. Correspondingly, CMZ, but not W7, caused release of transmitter (e.g. of -amino butyric acid and serotonin). H7 antagonized transmitter release. W7, H7 or CMZ did not alter striatal synaptosomal cyclic AMP. The effects of H7 and W7 support roles for calmodulin and protein kinase C in depolarization-induced [Ca^{2+}] influx and release of internal [Ca^{2+}].

REGULATION OF INTRACELLULAR CALCIUM BY CLONED MUSCARINIC ACETYLCHOLINE RECEPTOR SUBTYPES. J.D. Lechleiter, D.E. Clapham* and E.G. Peralta*. Dept. of Pharmacology., Mayo Clinic, Rochester, MN 55905 and Dept. of Molecular Biology, Genentech, Inc., San Francisco, CA 94143.

cDNA clones encoding human (H) muscarinic acetylcholine receptor (mAChR) subtypes HM1, HM2, HM3 and HM4 were introduced by the calcium phosphate method into chinese hamster ovary (CHO) cells lacking endogenous mAChRs. Stably transfected clonal cell lines were isolated as described previously (Peralta et. al. Sci. 236: 600-605, 1987). Single cell Ca^{2+} measurements were recorded using the Ca^{2+} dye indicators FLUO-3 AM (on a confocal microscope) and INDO-1 AM (on a flow cytometer). Acetylcholine (ACh)-induced increases in peak Ca^{2+} for flow cytometry are summarized below (concentrations are in nM).

	CONTROL		PTX TREATED	
TYPE	MAX / REST Ca^{2+}	ACh EC_{50}	MAX / REST Ca^{2+}	ACh EC_{50}
HM1	1985±32 / 45	177±11	1527±59 / 53	143±22
HM2	73±4 / 47	1070±220	no response / 47	---
HM3	194±5 / 72	14430±3600	65±10 / 88	9360±5950
HM4	2262±153 / 50	240±59	1838±89 / 64	111±23

The Ca^{2+} responses of HM1 and HM4 were the largest, the most sensitive to ACh and the least affected by PTX treatment (100ng/ml, 14-20 hrs). In contrast, the HM2 and HM3 responses were smaller and very sensitive to PTX. Chimeric mAChRs, stably transfected into CHO cells, are currently being examined. This work was supported by NIH (D.E.C.) and Genentech (E.G.P.)

PURIFICATION OF AN INOSITOL-1,4,5-TRISPHOSPHATE RECEPTOR FROM RAT SPLEEN. R.J. Mourey and S.H. Snyder. Johns Hopkins Univ. Sch. of Med., Dept. of Pharmacology and Molecular Sciences and Dept. of Neuroscience, Baltimore, MD 21205.

Inositol-1,4,5-trisphosphate (IP_3) binding sites in the rat have previously been described by our laboratory. In a screen of peripheral tissues, spleen and thymus displayed the highest source of IP_3 binding sites, while the cerebellum had by far the greatest binding in the CNS. Since spleen and thymus contain lymphocytes which, like neurons, are capable of intracellular communication, information transfer and long term memory, we decided to purify the IP_3 binding site from spleen and compare it to brain IP_3 receptors.

We have purified the spleen IP_3 receptor, which has similar high affinity and specificity for IP_3 as the brain IP_3 receptor. Interestingly, the spleen IP_3 receptor is smaller in molecular weight and does not cross-react antigenically to polyclonal serum made to the cerebellar IP_3 receptor. Antigenic cross-reactivity experiments with polyclonal serum made to spleen IP_3 receptor are underway. We have also shown that IP_3 potently releases calcium from both spleen and thymus microsomes, but not from microsomes preparted from tissue containing low amounts of IP_3 binding.

NEUROTRANSMITTER STIMULATED INCREASES IN MASS LEVELS OF INS(1,4,5)P_3 IN BRAIN SLICES AS MEASURED BY IP_3 RADIORECEPTOR ASSAY. D.S. Bredt, S.H. Snyder. Department of Pharmacology and Molecular Sciences and Department of Neuroscience Johns Hopkins Univ. Sch. of Med. Balt., MD 21205

The IP_3 receptor from crude rat cerebellar membranes was used to create a simple, sensitive, and specific radioreceptor assay for the determination of mass levels of IP_3 in biological tissues (Bredt, D.S., et al., BBRC, 159:976, 1989). The assay's detection limit is less than 1 pmole of IP_3, and it is specific for Ins(1,4,5)P_3 as demonstrated by both enzymatic and chromatographic studies. Using this assay we detect substantial increases in mass levels of IP_3 in in vitro slices of rat cerebellum in response to excitatory amino acids (EAA). Using 500 uM quisqualate, mass levels of IP_3 increase to 350% of baseline within 10 sec., decreasing to only 150% by 60 sec. The rank order of EAA's in terms of potency and efficacy is quisqualate > glutamate > kanate. These data demonstrate, for the first time, that neurotransmitters can stimulate large, transient increases in the mass levels of IP_3 in brain slices.

400.8

Ca^{2+}-DEPENDENT REGULATION OF INS-1,4,5-P_3 BINDING TO RAT CEREBELLAR RECEPTOR. S.K. Danoff, A. Theibert, R. Evans*, S. Snyder. Dept. of Neuroscience, Johns Hopkins Univ., School of Medicine, Baltimore, MD 21205

The Ins-1,4,5-P_3 (IP_3R) receptor purified from rat cerebellum (Suppatapone, S. et al, JBC, 263:1530, 1988) and recently functionally reconstituted (Ferris, C. et al, Neurosci. Abstr., 1989, in press) appears to act as an intracellular Ca^{2+} channel. Two distinct mechanisms of Ca^{2+} regulation have been demonstrated to function in this system. The first is a membrane-bound protein (calmedin) distinct from the IP_3R which mediates an EDTA reversible inhibition of binding with a Km for Ca^{2+} of 300nM.(Danoff, S. et al, Biochem. J., 254:701, 1988) This protein has been further purified and characterized.

A second mechanism is mediated by a membrane-bound, Ca^{2+}-dependent IP_3-phoshpatase. This protein has been partially purified and characterized. The phosphatase has a Km for IP_3 of ~10uM and an absolute dependence on Mg^{2+}.

CYTOSOLIC Ca^{++} TRANSIENTS IN BRADYKININ TREATED PC12 CELLS. F.Grohovaz[1,2], C.Fasolato[3], A Malgaroli[4] and G.Fumagalli[1,4] (SPON: L.Vicentini). [1]: CNR Ctr Cytopharmacol; [2]: Ctr Periph Neuropathies; [3]: Dept Pharmacol; [4]: San Raffaele Inst, Milano, Italy; [5]: CNR Ctr Biomembranes, Padova, Italy.

Recent studies on suspension of PC12 pheochromocytoma cells, loaded with fura-2, indicate that treatment with bradykinin (BK) elicits a redistribution of Ca^{++} from IP_3-sensitive stores and, in addition, activates Ca^{++} influx through voltage independent cationic channels (Fasolato et al. J. B. C. 263: 17350-59). From these studies it is not known whether the two effects on cytosolic Ca^{++} have a similar spatial localization or even whether all the cells display both these responses.

In order to addres these questions we have studied local $[Ca^{++}]_i$ changes by digital imaging of single PC12 cells loaded with fura-2. Cells exposed to BK (100 nM) in a Ca^{++}-free EGTA-containing medium showed rapid and uniform transient increases in $[Ca^{++}]_i$ occurring simultaneously over the whole cytoplasm. The reintroduction of Ca^{++}(2 mM) into the medium, gave way to sustained rises of $[Ca^{++}]_i$, mainly restricted to the periphery of the cell, whilst a subsequent addition of excess EGTA caused the rapid decline of $[Ca^{++}]_i$ in the same peripheral areas.

These data confirm the dual mechanisms of BK actions on $[Ca^{++}]_i$ and add the notion that IP_3 sensitive stores are evenly distributed throughout the PC12 cell cytoplasm.

400.10

STIMULATION OF CALCIUM INFLUX BY INOSITOLHEXAKISPHOSPHATE ($InsP_6$): POSSIBLE INVOLVEMENT OF A SPECIFIC CLASS OF MEMBRANE RECOGNITION SITES. V. Bruno*, S. Cavallaro*, M.A. Sortino, P.L. Canonico and F. Nicoletti* (SPON: M.J. Cronin). Dept. Pharmacology, University of Catania, Italy.

$InsP_6$ stimulates $^{45}Ca^{2+}$ uptake in cultured cerebellar neurons and anterior pituitary cells. The influx of extracellular Ca^{2+} is accompanied by translocation of protein kinase C and, in cerebellar neurons, by excitatory amino acid release. The action of $InsP_6$ is reproduced by inositolpentakisphosphate, but not by inositol-1,3,4,5-tetrakisphosphate ($InsP_4$). Low concentrations (5-100 uM) of divalent cations (Cu^{2+}, Mg^{2+}, Ni^{2+}, Co^{2+}) greatly enhance the stimulation of $^{45}Ca^{2+}$ influx by $InsP_6$. We have studied [^{3}H]$InsP_6$ binding in crude synaptic membranes from cerebral hemispheres or cultured cerebellar neurons, incubated at 37°C in Tris-HCl (pH 7.4). [^{3}H]$InsP_6$ binds to a single population of specific and saturable recognition sites, with a K_D value in the low nanomolar range. [^{3}H]$InsP_6$ binding is temperature-dependent, being virtually absent at 0°C. Specifically bound [^{3}H]$InsP_6$ is displaced by InsP6 and InsP4 but not by glutamate. We speculate that $InsP_6$ stimulates a specific class of membrane recognition sites, triggering the influx of extracellular Ca^{2+} in target cells.

400.11

PROLONGED PHORBOL ESTER PRETREATMENT DESENSITIZES THE κ OPIATE-INDUCED INHIBITION OF Ca^{2+} INFLUX IN RAT SPINAL CORD-DORSAL ROOT GANGLION COCULTURES. Z. Vogel, B. Attali*, D. Saya* and S.-Y. Nah*. Dept. of Neurobiology, Weizmann Institute of Science, 76100 Rehovot, Israel.

$^{45}Ca^{2+}$ uptake into rat spinal cord-dorsal root ganglion cocultures is stimulated by K^+ depolarization in the presence of Bay K8644, an agonist of the L type voltage-dependent Ca^{2+} channels. Opiate agonists of the κ type (e.g., U50488, tifluadom, ethylketocyclazocine, dynorphin) profoundly depress the K^+/Bay K-stimulated Ca^{2+} uptake (Attali et al., JBC, 264:347, 1989). Addition of the phorbol ester TPA (activator of protein kinase C) to the Ca^{2+} influx assay (5 min) decreased the K^+/Bay K-stimulated Ca^{2+} uptake ($IC_{50} \approx 70$ nM, 66% inhibition at 1 μM), but did not affect the inhibition produced by the opiates. However, prolonged preincubation (24 h) of the cells with 100 nM TPA (to allow down-regulation of protein kinase C) abolished the capacity of the κ opiatns, as well as of TPA itself, to inhibit the $^{45}Ca^{2+}$ influx through the voltage-dependent Ca^{2+} channels. A significant desensitization of the opiate effect was already observed following 1 h pretreatment with 100 nM TPA. This desensitization by TPA of the opiate inhibitory effect was dose-dependent with ED_{50} in the nanomolar range. The inactive phorbol ester (4β-phorbol 13 acetate) did not affect the opiate inhibition. These results suggest that protein kinase C affects Ca^{2+} channel activity and has a role in the modulation of Ca^{2+} channel activity by κ opiates.

400.12

LOW LEVELS OF INOSITOL PHOSPHATE FORMATION ARE ASSOCIATED WITH THE OPENING OF DIHYDROPYRIDINE-SENSITIVE Ca^{2+} CHANNELS BUT NOT Ca^{2+} MOBILIZATION IN BOVINE ADRENAL CHROMAFFIN CELLS. K.A. Stauderman, R.M. Pruss*, and M.M. Murawsky*, Merrell Dow Research Institute, 2110 E. Galbraith Road, Cincinnati, OH 45215

In single bovine adrenal chromaffin cells loaded with fura-2, histamine concentrations from 3-30 nM elicited slow, oscillatory increases of intracellular free calcium ($[Ca^{2+}]_i$). These responses were H_1-mediated, and were apparently due to Ca^{2+} entry through L-type channels as they were antagonized either by 0.1 μM mepyramine, 20 μM gadolinium (Gd^{3+}), omitting external Ca^{2+}, or by 1 μM (-)202,791, a dihydropyridine Ca^{2+} channel antagonist. In cell cultures, 3-30 nM histamine stimulated the accumulation of inositol 4- and 1-monophosphate (Ins(4)P and Ins(1)P), with Ins(1)P predominating.

Concentrations ≥ 100 nM histamine produced a rapid and relatively large transient of $[Ca^{2+}]_i$, often followed by a second transient of variable size, which then declined to a new plateau above prestimulation levels. Removal of external Ca^{2+}, 20 μM Gd^{3+}, or 1 μM (-)202,791 did not affect the initial transient, supporting a role for Ca^{2+} mobilization in this response. Interestingly, ≥ 100 nM histamine stimulated more Ins(4)P accumulation than Ins(1)P.

These data suggest that conditions causing preferential accumulation of Ins(1)P lead to activation of L-type Ca^{2+} channels, while Ca^{2+} mobilization occurs when conditions favor Ins(4)P accumulation.

400.13

BRADYKININ MODULATES POTASSIUM AND CALCIUM CURRENTS IN RAT PHEOCHROMOCYTOMA CELLS A. Villarroel*, N.V. Marrion* and P.R. Adams. (SPON: G. Matthews) Howard Hughes Medical Institute, Dpt. Neurobiol. SUNY SB, Stony Brook, NY 11794

PC12 cells fused with 50% polyethylene glycol and exposed to 50 ng/ml NGF for 2-8 days have been voltage-clamped in the whole-cell mode. The effects of bath- or puff-applied bradykinin (BDK) (1 μM) on ionic conductances were studied. BDK produced a membrane hyperpolarization mainly due to the development of an outward current (I_{BDKout}) that was blocked with 200 μM d-tubocurarine. The development of I_{BDKout} was accompanied by a two to threefold increase in $[Ca^{2+}]_i$, and was prevented when 10 mM BAPTA was included in the pipette (*cf.* Fasolato *et al.*, J.Biol.Chem. 263:17350, 1988). The hyperpolarization was followed by a depolarization attributable to inhibition of an M current (I_M). In contrast to NG108-15 cells (*cf.* Higashida H. & Brown D.A., Nature 323:333, 1986), neither bath-application of 1 μM Phorbol-12,13-Dibutyrate (PDBu), 250 μM L-α-Dioctanoyl-Glycerol, nor addition of 20 μM 1-Oleyl-2-Acetyl-Glycerol (OAG) in the electrode produced a reduction of I_M. (1,4,5)-IP_3 (up to 100 μM) or 10 mM BAPTA did not affect BDK-mediated inhibition of I_M when included in the recording pipette. After challenging with 10 mM caffeine, no effect on I_M and a negligible increase in $[Ca^{2+}]_i$ were detected.

Calcium currents were recorded in 0 K^+ and with CsCl and 1 mM EGTA in the electrode. Cells were held at -60 or -80 mV and jumped to 10 mV for 200 or 400 ms. Under these conditions, BDK produced a reversible reduction of the calcium current, without affecting significantly its decline during the pulse. In some cells a reduction of the holding current was observed. BDK's action on the voltage-dependent calcium current may be mediated by intracellular calcium, because it was suppressed by inclusion of 10 mM BAPTA in the pipette. PDBu (1 μM) produced a small increase in the initial inward current elicited by a jump to 10 mV, and a significant reduction of the current measured after 400 ms. This effect took several minutes to develop and was partially reversible.

400.14

MUSCARINIC RECEPTOR-MEDIATED INCREASE IN CALMODULIN ACTIVITY IN SK-N-SH HUMAN NEUROBLASTOMA CELLS. L.A. Mangels* and M.E. Gnegy. Department of Pharmacology, The University of Michigan, Ann Arbor, MI 48109.

The enzyme systems and processes mediated by the Ca^{2+}-binding protein, calmodulin (CaM), are thought to play an important role in stimulus-induced Ca^{2+} signalling. The effects of a muscarinic receptor-mediated Ca^{2+}flux on the activity and distribution of CaM was examined. We found that exposure of SK-N-SH cells to the muscarinic agonist carbachol results in a concentration and time-dependent increase in CaM activity in the cytosol. The EC_{50} for the response to carbachol is 1-2 μM, which correlates with the EC_{50} of carbachol for the phosphoinositide response of 10-30 μM, and the EC_{50} of 8 μM of the agonist oxotremorine-M for peak rise in intracellular Ca^{2+} ($[Ca^{2+}]_i$). The maximal increase in cytosolic CaM was with 10 μM carbachol from a control value of 2.9 ± 0.6 ng CaM/μg protein to 9.2 ± 2 ng CaM/μg protein. The increase in CaM activity for 100 μM carbachol occurred by 5 minutes and appeared to last for at least 30 minutes, with the maximal increase in the cytosol from 3.9 ± 0.3 ng CaM/μg protein to 10.7 ± 2 ng CaM/μg protein occurring at 15 minutes. There was no difference between the control cytosolic CaM levels and those measured after 2 hours of incubation with carbachol, and no difference in the CaM activity in the membrane fractions. The response to 10 μM carbachol was completely blocked by 1 μM atropine, and the response did not occur when the cells were stimulated with the nicotinic agonist dimethyl-4-phenyl piperazinium. These results suggest that the muscarinic receptor-mediated rise in $[Ca^{2+}]_i$ augments CaM activity in the cytosol of SK-N-SH cells. This increase in cytosolic CaM activity may represent the coupling of the $[Ca^{2+}]_i$ flux to enzyme activation.

SECOND MESSENGERS: PHOSPHOINOSITIDE TURNOVER

401.1

INCREASED $^{32}P_i$ INCORPORATION INTO BRAIN PHOSPHOINOSITIDES IN HEREDITARY MODEL OF EPILEPSY. J.M. Tuchek,* R.I. Wilcox,* D.D. Johnson and S.C.J. Pedder*. Dept. of Pharmacology, College of Medicine, Univ. of Sask., Saskatoon, Saskatchewan S7N OWO

Epileptic fowl are a consequence of an autosomal recessive mutation such that homozygous recessive birds have a low seizure threshold to a variety of stimuli including photic stimulation. Carriers (heterozygotes) have a normal seizure threshold. The rate of $^{32}P_i$ incorporation into phosphatidylinositol (PI), phosphatidylinositol-4-phosphate (PIP) and phosphatidylinositol 4,5 phosphate (PIP_2) was studied in synaptosomal preparations obtained from the forebrains of carrier and epileptic fowl. Synaptosomes were isolated in a standard ficoll/sucrose density gradient and resuspended in a buffer consisting of 110 mM NaCl, 5 mM KCl, 1.3 mM $MgCl_2$, 1.3 mM $CaCl_2$, 1 mM pyruvate, 10 mM glucose and 50 mM imidazole pH 7.4. An aliquot (1 mg Lowry protein) of this suspension was incubated at 37°C with 5 μCi ^{32} P_i (ICN) and buffer in a total reaction volume of 500 μl for periods up to 60 min. Labelling was terminated by the addition of a pre-mixed solution of $CHCl_3$/MeOH/2.4 N HCl (2/1/0.5). The aqueous layer was washed with $CHCl_3$ and the pooled $CHCl_3$ extracts were evaporated to dryness under N_2. The dried extract was resuspended in $CHCl_3$/MeOH (2:1) and the lipids were separated on silica gel 60 plates with $CHCL_3$/acetone/MeOH/acetic acid H_20 (80/30/26/24/16). PIP_2, PIP, PI and phosphatidic acid (PA) were identified with iodine vapor using appropriate standards. The lipid spots were scraped and the radioactivity was determined by liquid scintillation counting. The amount of $^{32}P_i$ incorporated into the phosphoinositol lipids and PA was approximately 35% higher in synaptosomes prepared from epileptic fowl than in the carrier birds. These data indicate that the low seizure threshold in epileptic fowl is associated with an increased basal turnover of the phosphatidylinositol system. Supported by the MRC.

401.2

STIMULATION OF INOSITOL PHOSPHOLIPID TURNOVER IN HUMAN RETINAL PIGMENT EPITHELIAL CELLS BY CARBAMOYLCHOLINE. E.L. Feldman, A.E. Randolph and D.A. Greene*. Depts. of Neurology and Internal Medicine, Univ. of Mich. Med. Ctr., Ann Arbor, MI 48109.

Human retinal pigment epithelial cells (HRPE) in culture demonstrate β-adrenergic activated adenylate cyclase activity (Friedman et al., Exp. Eye Res., 44:471, 1987). We report here the presence of a muscarinic cholinergic receptor in HRPE coupled to a different biochemical effector system, stimulation of phosphoinositide (PPI) turnover.

Cultured HRPE were incubated with ^{3}H-myo-inositol and treated with carbamoylcholine, resulting in a large accumulation of labeled inositol phosphates (>300% of control). Inositol phosphate accumulation was linear up to 60 min with an EC_{50} of 100 μM. Stimulation was calcium dependent (2 mM) and inhibited by atropine (10 μM). Sequential elution of inositol phosphates with ion exchange chromatography revealed that the major labeled component in stimulated HRPE was IP_1 (55% of total radioactivity), with smaller amounts of glycerophosphoinositol (12%), IP_2 (21%), and IP_3 (10%). In competition studies on HRPE, atropine (10 μM) inhibited a population of isolated ^{3}H-QNB binding sites. These results suggest the presence of a muscarinic receptor on HRPE linked to the PPI second messenger system.

401.3

STIMULATION OF INOSITOL PHOSPHATE METABOLISM BY EXCITATORY AMINO ACIDS IN NEONATAL RAT SPINAL CORD. M.N.Perkins*, K.Taylor* and G.M.Burgess*, (SPON: I.F.James). Sandoz Institute for Medical Research, Gower Place, London WC1E 6BN, UK.

Recent evidence suggests that excitatory amino acids (EAA's) activate polyphosphoinositidase C (PIC) in a number of neural tissues. As EAA's have been implicated in sensory neural transmission we have investigated the possiblity that EAA's activate PIC in spinal cord slices. Spinal cord slices from 1 day old rats were equilibrated with [^{3}H]-*myo*-inositol. The effect of EAA's (in the presence of atropine and lithium) on PIC activity was determined by measuring levels of [^{3}H]-inositol bisphosphate ([^{3}H]-IP$_2$). All EAA's tested caused an increase in [^{3}H]-IP$_2$ with EC$_{50}$ values of: glutamate (GLU) 500μM; kainate 40μM; NMDA 25μM; quisqualate 3μM. These responses were seen in the presence and absence of TTX. The response to NMDA was antagonised by MK801 (IC$_{50}$<500μM) and kynurenic acid (KYN IC$_{50}$<500μM) and by D(-)2-amino, 5-phosphopentanoic acid (AP5, IC$_{50}$ 60μM.). The response to quisqualate was not reduced by 500μM KYN, N-(p-bromobenzoyl)piperazine- 2,3-dicarboxylate (pBB-PzDA) or AP5. The response to kainate was reduced by 200μM pBB-PzDA but not by KYN. The response to GLU was not blocked by any of these antagonists, nor by L(+)2-amino-4-phosphonobutyric acid (500μM).

These results suggest that the increase in PIC activity induced by GLU is not mediated by a known EAA receptor in the neonatal rat spinal cord. It is not clear why NMDA receptor antagonists do not reduce at least a proportion of the GLU response.

401.4

EFFECTS OF DOPAMINE AND CHOLECYSTOKININ ON PHOSPHATIDYL-INOSITOL TURNOVER - CA^{2+} SIGNALLING SYSTEM IN THE RAT STRIATUM. S. Kito, R. Miyoshi, A. Tanaka*, Y. Kimura* and T. Mitsuno*. Third Department of Internal Medicine, Hiroshima University School of Medicine, Hiroshima 734, Japan.

Dopamine plays an important role on psychomotor functions in the central nervous system. In particular, the striatum contains the highest density of dopaminergic terminals from the substantia nigra within the brain. On the other hand, cholecystokinin (CCK) and its receptors richly exist in the striatum and a functional relationship between dopamine- and CCK-neuronal systems has been demonstrated. In the present study, the authors studied effects of dopamine and CCK on phosphatidyl-inositol (PI) turnover and intracellular Ca^{2+} concentration ([Ca^{2+}]i) in the rat striatum. PI turnover was measured according to a Berridge's method using striatal slices. The level of [Ca^{2+}]i was measured by fura-2 fluorometry in cultured striatal neurons on a single cell basis. It has been demonstrated that dopamine D2 receptors in the pituitary inhibit PI turnover. In our experiments, dopamine stimulated PI turnover dose-dependently in the striatum. CCK had no effect on PI turnover, while this peptide increased [Ca^{2+}]i. It is noteworthy that these novel actions of dopamine and CCK on the second messenger system were found in the striatum.

401.5

EFFECTS OF SIGMA COMPOUNDS ON AGONIST-STIMULATED PHOSPHOINOSITIDE METABOLISM IN RAT BRAIN. S.M. Candura*, T. Coccini*, L. Manzo[1] and L.G. Costa (SPON: J. Franck). Dept. of Environ. Health, Univ. of Washington, Seattle, WA and [1]Dept. of Pharmacology, Univ. of Pavia Medical School, Pavia, Italy.

Sigma receptors are non-opiod, non-dopaminergic receptors which are implicated in psychosis and in antipsychotic drug efficacy.The second messenger system coupled to these receptors is still unknown. Recently, an inhibitory effect of various sigma compounds on carbachol-stimulated phosphoinositide (PI) metabolism has been reported (Eur. J. Pharmacol. 149,399, 1988). We have investigated the effect of sigma compounds on carbachol - stimulated PI metabolism in rat cerebral cortex slices. (+) Pentazocine, 1,3,-di-o-tolylguanidine (DTG) and N-allylnormetazocine (SKF-10,047) inhibited carbachol-stimulated PI hydrolysis with IC$_{50}$s of 34, 53 and 230 μM, respectively. Haloperidol and 3-(hyproxyphenyl)-N-(1-propyl)-piperidine (3-PPP) caused a maximal 15-40% inhibition at 250-500 μM. In the presence of IC$_{50}$ concentrations of (+) pentazocine or DTG the dose-response curve for carbachol was shifted to the right and its EC$_{50}$ increased from 50 μM to 238 and 248 μM, respectively. Similar results were found in hippocampus and cerebellum. (+)Pentazocine, DTG and SKF-10,047 also inhibited the binding of ^{3}H-QNB to muscarinic receptors in cortical membranes with IC$_{50}$s of 21, 52 and 120 μM, respectively. These results suggest that sigma compounds can modulate muscarinic receptor-stimulated PI metabolism in brain tissue, possibly, at least in part, through an interaction with the muscarinic recognition site. (Supp. in part by grants from NIEHS, ES-04696, and Fondazione Clinica del Lavoro, Pavia).

401.6

EXCITATORY AND SULFUR AMINO ACIDS MODULATE BRAIN PI HYDROLYSIS. X. Li and R.S. Jope. Dept. of Pharmacology, Univ. of Alabama, Birmingham, AL 35294.

We reported earlier that glutamate inhibited NE-stimulated PI hydrolysis in rat brain slices by inhibiting phospholipid synthesis through a quisqualate-selective site. We further found that sulfur-containing amino acids also inhibited NE-stimulated PI hydrolysis in rat brain slices. Of the tested sulfur-containing amino acids, L-cysteine was the most potent, inhibiting the NE-induced response by 42% and 85% at concentration of 50 μM and 500 μM, respectively. L-homocysteate slightly potentiated PI hydrolysis at a concentration of 100 μM, but it was inhibitory at 500 μM. The D-isomers of cysteine and homocysteate were much less potent than were the L-isomers. L-cysteine, L-cysteine sulfinic acid and L-serine-O-sulfate also inhibited PI hydrolysis, but the effect was moderate or mild compared to L-cysteine. Sulfur-containing amino acids did not cause cell lysis and their inhibitory effect was partially reversible. These results demonstrate that several sulfur-containing amino acids, some of which have been proposed to be endogenous excitatory amino acid neurotransmitters, effectively modulate the response of NE of the PI second messenger system in the rat brain. The possible mechanisms of the inhibitory effect caused by excitatory amino acids and sulfur-containing amino acids are being studied. It is possible that some calcium-regulated processes may be involved in the modulatory effects of these amino acids.

401.7

PCP INHIBITS CARBACHOL INDUCED PHOSPHOINOSITOL HYDROLYSIS IN THE RAT BRAIN. J.M. Brog and M.C. Beinfeld. Department of Pharmacology, St. Louis Univ. School of Medicine, St. Louis, MO 63104.

We have previously reported that while phorbol esters increased CCK release in various regions of the rat brain, phencyclidine had an inhibitory effect. In order to examine a possible relationship between inhibition of CCK release and the phosphoinositol cycle, we examined the effect of PCP on carbachol-induced phosphoinositol hydrolysis in rat brain slices from cortex, caudate-putamen, and the hippocampal formation. In all three regions studied, PCP significantly inhibited the carbachol-induced ^{3}H-myo-inositol-1-phosphate accumulation, exhibiting the greatest potency in the cortex at 10^{-6} M. Since PCP has been shown to have agonistic properties at sigma opiate receptors, its actions were compared to those of (+)SKF 10,047, a sigma opiate agonist. (+)SKF 10,047 inhibited the carbachol-induced phosphoinositol hydrolysis in similar concentrations to PCP in the three areas studied. It is thus quite possible that PCP is at least partially acting through the sigma opiate receptor to inhibit the carbachol effect. However, further studies will be required to elucidate its mechanism of action, and how this action of PCP may be related to its effect on CCK release. Supported by NIH NS18667.

ATP INDUCES POLYPHOSPHOINOSITIDE BREAKDOWN AND AN INCREASE IN CYTOPLASMIC, FREE CALCIUM LEVELS IN NEUROBLASTOMA X GLIOMA HYBRID CELLS.
T-A. Lin*, K.D. Lustig*, M.G. Sportiello*, G.Y. Sun and G.A. Weisman*. Department of Biochemistry and Sinclair Research Farm, University of Missouri-Columbia, Columbia, MO 65203

Extracellular ATP exhibits hormone-like properties in the peripheral and central nervous systems. In the present study, the addition of ≥ 1μM ATP to a neuroblastoma X glioma hybrid cell line (NG108-15) was found to induce a transient increase in the level of cytoplasmic, free calcium (Ca^{2+}_i). The increase in the Ca^{2+}_i level was maximal within ten second after addition of ATP and then declined to the initial level within one minute. However, the ATP-induced increase in the [Ca^{2+}_i] was greater in the presence than in the absence of extracellular calcium. Increases in the [Ca^{2+}_i] correlated with the concentration of the fully ionized form of ATP (ATP^{4-}) in the medium. Other nucleoside 5'-triphosphates, including UTP, ITP, TTP and GTP, also induced an increase in the [Ca^{2+}_i]. The addition of ATP to cells prelabeled with $^{32}P_i$ or [2-^{3}H]inositol resulted in a rapid decrease in the level of phosphatidylinositol 4,5-bisphosphate (PIP_2), the lipid precursor of inositol 1,4,5-trisphosphate (IP_3) and diacylglycerol (DG). ATP also caused an increase in the level of $^{32}P_i$-labeled phosphatidic acid, presumably as a result of phosphorylation of DG. These findings suggest that extracellular ATP^{4-} activates a signal transduction pathway in NG108-15 cells involving the formation of IP_3 and the mobilization of Ca^{2+}.

401.9

CHARACTERIZATION OF THE INOSITOL PHOSPHATE RESPONSE TO BRADYKININ IN NG108-15 NEUROBLASTOMA X GLIOMA HYBRID CELLS: EFFECTS OF LITHIUM. J.E. Rubinstein and R.J. Hitzemann. Dept. Psychiatry, SUNY: Stony Brook, NY 11794-8101.

We have been using the NG108-15 clonal cell line as a model to investigate the regulation of Phospholipase C-mediated phosphoinositide (PI) hydrolysis. NG108-15 cells were grown in DMEM with HAT and 10% FBS and labeled for 2 days with [^{3}H]inositol. The media was removed and the cells pre-incubated for 15 min in Ringer-HEPES with or without LiCl. Bradykinin (BK) was then added for various times and the reaction terminated with perchloric acid. Inositol phosphates were separated by ion-exchange chromatography.

BK stimulated PI hydrolysis in a dose-responsive fashion reaching a maximum at a concentration of 10-25 μM. The response was extremely rapid; an increase in IP_3 was detectable at 5 sec and peaked at 15-30 sec at approximately 300% of basal values. Stimulation than gradually declined returning almost to baseline by 2 min. IP_2 accumulation followed a similar pattern after a slight time delay. Although basal values of both IP_1 and IP_4 were higher than either IP_2 or IP_3, minimal stimulation in response to BK was seen over this time period. Low (1-10 mM) concentrations of LiCl appeared to have subtle effects on the kinetics of IP3 production/metabolism in response to BK, slightly delaying the time point of peak accumulation. Thus at earlier times, Li appeared to inhibit IP3 while after longer stimulation, the response was equal or slightly potentiated.

401.10

HOMOLOGOUS DESENSITISATION OF BRADYKININ-INDUCED INOSITOL POLYPHOSPHATE FORMATION IN NEO-NATAL RAT DORSAL ROOT GANGLION NEURONES IN CULTURE. G.M. Burgess* and M. McNeill*. (Spon. E.A. Grove). Sandoz Institute for Medical Research. 5, Gower Place London WC1E 6BN, U.K.

Bradykinin (Bk) increases inositol tris-phosphate ($InsP_3$) in cultured dorsal root ganglion (DRG) neurones. Serotonin also increased $InsP_3$ formation in these cultures. The responses to maximally effective concentrations of the two agonists were not additive, suggesting that they act on the same population of neurones. Pretreatment of the neurones with Bk, followed by its removal, resulted in a decreased response to a second application of the peptide. The extent of this decrease was dependent on the desensitising concentration of Bk (IC_{50} value 30nM) and the duration of the pretreatment. Pretreatment with 30nM Bk caused both a five-fold shift to the right of the concentration-response curve for Bk-induced $InsP_3$ formation (EC_{50} increased to value 30nM) and a 50% reduction in the maximum response. Pretreatment with Bk had no effect on subsequent responsiveness to serotonin, likewise pretreatment with serotonin did not affect the responsiveness to Bk. After Bk pretreatment, a prolonged incubation (60min) restored responsiveness of the cells to Bk. Exposure of the cultures to dibutyrl cGMP or 4β-phorbol 12,13-dibutyrate (PDBu) also inhibited Bk-induced $InsP_3$ formation, causing a rightward shift of the Bk concentration-response relationship and a decrease in the maximum response. These findings indicate that Bk induces homologous desensitisation of inositol poyphosphate formation in DRG neurones which may involve cGMP-dependent kinase or protein kinase C.

401.11

LONG-TERM ACTIVATION OF PROTEIN KINASE C BY ANGIOTENSIN IN BOVINE ADRENAL MEDULLARY CELLS. R.K. Tuominen*, J. S. Hong and M. K. Stachowiak, (SPON: L. Lazarus). LMIN/NIEHS, Research Triangle Park, NC 27709.

Angiotensin II (AII) increases tyrosine hydroxylase and proenkephalin A mRNA levels in cultured bovine adrenal medullary (BAM) cells. The increases are inhibited by sphingosine, suggesting the involvement of protein kinase C (PKC). However, a 30 min incubation with AII, which activates PKC, is not sufficient to change the mRNA levels. Therefore, we examined whether long-term incubation with AII affects PKC. AII (200 nM) increased the particulate PKC activity by 50% and 58% after 6 and 18 hrs, respectively. Similar changes were produced by 2 nM AII at 12 hrs. Total (soluble + particulate) PKC activity was increased by 15% and 30% at 12 and 18 hrs. To determine the time required to induce changes in mRNA levels, cells were incubated with AII (20 nM) for 24 hrs and at 3, 6, 12 or 18 hrs saralasin (2 uM) was added. Twelve, but not 3 or 6, hr stimulation of AII receptors was sufficient to increase the mRNA levels. Thus, in addition to a short-term activation, AII induces a long-term increase in PKC activity. The long-term activation may mediate the effects of AII on the gene expression.

401.12

MECHANISM BY WHICH SIGMA LIGANDS INHIBIT STIMULATION OF PHOSPHOINOSITIDE METABOLISM BY MUSCARINIC CHOLINERGIC AGONISTS. P. Tolentino* and W.D. Bowen (SPON: R. Patrick). Div. Biol. & Med., Brown Univ., Providence, RI 02912.

We have previously reported that sigma ligands attenuate the ability of the cholinergic agonist, carbachol, to stimulate phosphoinositide (PPI) turnover in rat brain synaptoneurosomes (Eur. J. Pharmacol., 149:399, 1988). Here we investigate the mechanism of this effect. Synaptoneurosomes were prelabeled with [^{3}H]inositol, and [^{3}H]inositol phosphates collected after exposure to test compounds. (+)-Pentazocine and ditolylguanidine reduced the maximal stimulation by carbachol without affecting the ED_{50}, suggesting a non-competitive mechanism. Ligand concentrations 15-fold higher were required to attenuate norepinephrine-stimulated PPI turnover. Although some sigma ligands inhibited [^{3}H]QNB binding to muscarinic receptors at high concentrations, there was no correlation with potency in the PPI assay. (+)-Pentazocine reduced formation of all three [^{3}H]inositol phosphates and had no effect on their hydrolysis. When present during prelabeling, (+)-pentazocine did not affect incorporation of [^{3}H]inositol into the total inositol lipid pool. The differential sensitivity of muscarinic and adrenergic stimulation, and lack of effect at other points in the PPI pathway, suggests desensitization of muscarinic receptors.

401.13

LOSS OF MUSCARINIC RECEPTORS AND OF GUANINE-NUCLEOTIDE-STIMULATED PPI HYDROLYSIS IN HUMAN NEUROBLASTOMA CELLS UPON LONG-TERM TREATMENT WITH TPA OR MEZEREIN. C.L. Cioffi and S.K. Fisher. Neuroscience Laboratory, University of Michigan, Ann Arbor, MI 48104.

The actions of tumor promoters on the coupling of muscarinic receptors to hydrolysis of inositol lipids was investigated in human neuroblastoma SH-SY5Y cells. Addition of 50 nM 12-O-tetradecanoylphorbol (TPA) to these cells for 5 days led to neuronal differentiation, a 28% loss of specific [^{3}H]N-methylscopolamine binding and a consistently larger reduction (48%) in agonist-stimulated [^{3}H]-inositol phosphate generation. While mezerein could mimic the effect produced by TPA, the biologically-inactive 4α-phorbol-12,13-didecanoate was without effect on cell morphology, antagonist binding or phosphoinositide (PPI) turnover. Pretreatment with TPA or mezerein also led to a decline in the agonist-mediated rise in cytoplasmic [Ca^{++}] and a loss of protein kinase C activity. The ability of fluoride to induce [^{3}H]inositol phosphate release was significantly reduced in SH-SY5Y cells treated with TPA or mezerein. Treatment with these agents also impaired [^{3}H]-inositol phosphate formation induced by GTPγS or carbachol in digitonin-permeabilized cells. These results suggest that TPA and mezerein decrease PPI hydrolysis by both a reduction in muscarinic receptor number and inhibition of guanine-nucleotide-stimulated PPI turnover. (Supported by NIMH Grant MH42652 and NIMH Training Grant MH15794).

401.14

THE REGULATION OF PHOSPHATIDYLINOSITOL TURNOVER BY CYCLIC AMP MAY INVOLVE PRODUCTS OF ARACHIDONIC ACID METABOLISM. J. B. Schachter[1] and B. B. Wolfe[2]. Depts. of Pharmacology, [1]Univ. of Pennsylvania, Philadelphia, PA. 19104. and [2]Georgetown Univ., Washington, D.C. 20007.

The activation of adenosine A_1 receptors in DDT_1 smooth muscle cells resulted in a dramatic reduction of cyclic AMP (cAMP) accumulation. In addition to this reduction of cAMP accumulation, activation of adenosine A_1 receptors resulted in a potentiation of phoshatidylinositol (PI) turnover. While the adenosine A_1 selective agonist, cyclopentyladenosine (CPA) had no effect upon PI turnover by itself, it caused nearly a twofold increase in norepinephrine-stimulated (NE-stimulated) PI turnover. To ascertain whether the effect of CPA on NE-stimulated PI turnover was related to the effect of CPA on cAMP accumulation, 8-bromo cAMP (8-BrcAMP) was added exogenously. While 8-BrcAMP had no effect upon NE-stimulated PI turnover, the CPA-induced potentiation of NE-stimulated PI turnover was completely antagonized. The potentiation of PI turnover by CPA was also blocked by pretreating cells with pertussis toxin, an agent which blocks the inhibition of cAMP accumulation by CPA.

In addition to being regulated by cAMP, the potentiation of PI turnover by CPA was calcium dependent and was antagonized by inhibitors of phospholipase A2 and by inhibitors of lipoxygenase. Thus, cAMP may regulate PI turnover by regulating the production of products of the lipoxygenase pathway which stimulate PI turnover. (HL-07502 and GM-31155)

401.15

MECHANISM OF K-INDUCED ACTIVATION OF PROTEIN KINASE C. A. Bhave*, S.V. Bhave*, R.K. Malhotra*, T.D. Wakade* and Arun R. Wakade.(SPON.: J. Benjamins), Dept. of Pharmacol., Wayne State Univ., Detroit, MI 48201.

Increasing concentrations of KCl (17.5 to 75 mM) caused concentration-dependent activation of protein kinase C (PKC) in brain, adrenal medulla and cardiac cell cultures and sympathetic neurons (SN). Extent of PKC activation by 35 mM K was comparable to that seen with 100 nM phorbol 12, 13-dibutyrate or 30 uM acetylcholine (ACh). Biochemical pathway responsible for activation of PKC was studied in homogeneous cultures of chick embryonic SN. 35 mM K did not stimulate formation of ^{3}H-inositol phosphates in ^{3}H-myo-inositol loaded-SN but produced a significant increase (160%) in 1,2-diacylglycerol (DAG) content. ACh enhanced ^{3}H-inositol monophosphate formation (1500%) and (DAG) content (165%). Turnover of ^{3}H-choline was facilitated by 35 mM K but not by ACh. Qualitatively similar results were obtained with 35 mM K and ACh on DAG and ^{3}H-inositol monophosphate formation in the rat adrenal medulla. These data suggest that depolarizing stimulus activates phosphatidylcholine pathway to generate DAG whereas ACh acts via phosphatidylinositol pathway to produce DAG for activation of PKC.

401.16

METABOLISM OF INOSITOL 1,3,4,5-TETRAKISPHOSPHATE IN RAT BRAIN HOMOGENATES. P. Kurian*, L. J. Chandler* and F.T. Crews. Department of Pharmacology, Univ. of Florida College of Medicine, Box J-267, Gainesville, FL 32610.

A number of hormones, growth factors and neurotransmitters have been shown to stimulate the hydrolysis of membrane phosphoinositides, resulting in the formation of Ins(1,4,5)P_3 and other inositol phosphates. It is now clear that inositol phosphate metabolism is a complicated process that may be highly regulated. In addition to being dephosphorylated by the action of a 5-phosphatase, Ins(1,4,5)P_3 can be phosphorylated by Ins(1,4,5)P_3 3-kinase to form to Ins(1,3,4,5)P_4. Although the physiological significance of the higher inositol polyphosphates is not clear, recent evidence suggest that Ins(1,3,4,5)P_4 may also have second messenger function. To more fully understand the disposition of Ins(1,3,4,5)P_4 in brain, we investigated the metabolism of Ins(1,3,4,5)P_4 by adding [^{3}H]Ins(1,3,4,5)P_4 to rat whole brain homogenates resuspended in physiological buffers. Analysis of the inositol phosphate metabolites of Ins(1,3,4,5)P_4 by h.p.l.c. showed that [^{3}H]Ins(1,3,4,5)P_4 was first dephosphorylated to Ins(1,3,4)P_3 and then to Ins(1,3)P_2 and Ins(3,4)P_2. Three inositol monophosphates {Ins(1)P, Ins(3)P and Ins(4)P} were formed. Since no Ins(1,4)P_2 was detected, we concluded that Ins(1)P was formed from Ins(1,3)P_2, while Ins(4)P was formed from Ins(3,4)P_2. Ins(3)P came from Ins(1,3)P_2 and/or Ins(3,4)P_2. We report here an ion-exchange h.p.l.c. gradient system that separates all of these isomers in a single run.

401.17

PHOSPHOLIPASE D AND PHOSPHOLIPASE C IN HUMAN CHOLINERGIC NEUROBLASTOMA (LA-N-2) CELLS -MODULATION BY MUSCARINIC AGONISTS AND PROTEIN KINASE C-

J. Sandmann* and R.J. Wurtman, Laboratory of Neuroendocrine Regulation, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Stimulation of muscarinic receptors has been demonstrated to activate a phospholipase C [PLC, acting on inositol phospholipids, e.g. Brown, Brown-Masters, 1984, Trends Pharmacol. Sci. 5:417-419] and a phospholipase D [PLD, acting on phosphatidylcholine, Lindmar et al., 1988, Biochem. Pharmacol. 37:4689-4695]. The present study was aimed to characterize the modulation of PLD and PLC by muscarinic receptor activation in a cholinergic cell line, the human neuroblastoma LA-N-2 cells (e.g. Richardson et al., 1989, Brain Res. 476:323-331). LA-N-2 cells were prelabelled with [^{3}H]-inositol and [^{3}H]-oleic acid and then stimulated with the muscarinic agonist carbachol (CCh). When incubated in the presence of ethanol and lithium, CCh caused a time- and dose-dependent, atropine and pirenzepine sensitive formation of [^{3}H]-inositol phosphates, [^{3}H]-phosphatidic acid (PtdA) and [^{3}H]-phosphatidylethanol (Peth). The EC_{50}-values for CCh were about 30µM. Since the biosynthesis of Peth is considered as a specific indicator for PLD-activity (e.g. Kobayashi, Kanfer, 1987, J. Neurochem. 48:1597-1603) these data suggest an activation of PLD in LA-N-2 cells by muscarinic agonists. Activation of protein kinase C (PKC) is known to stimulate PLD (e.g. Liscovitch, 1989, J. Biol. Chem. 264:1450-1456). In LA-N-2 cells the PKC-activator, 12-O-tetradecanoylphorbol-13-acetate (TPA), stimulated the formation of PtdA and Peth but attenuated the CCh-induced formation of inositol phosphates. In contrast, the effects of TPA and CCh on the production of Peth were additive. The present data provide evidence that muscarinic receptors in LA-N-2 cells are coupled to both PLC and PLD. The activation of both enzymes is inversely regulated by PKC, raising the possibility that PLD may participate in signal transduction mechanisms either independently of the phosphoinositide-turnover or by modulating the initial "PI"-signal.

BRADYKININ AND CARBACHOL INCREASE PHOSPHOLIPASE D ACTIVITY IN PC12 CELLS. J. HORWITZ* (SPON: R.L. PERLMAN) Dept. of Pediatrics and Kennedy Mental Retardation Res. Ctr., The University of Chicago, Chicago, IL 60637

Bradykinin and carbachol increased the production of both [^{3}H]phosphatidic acid ([^{3}H]PA) and [^{3}H]diacylglycerol in PC12 pheochromocytoma cells prelabeled with [^{3}H]arachidonic acid. [^{3}H]PA was elevated within 30 sec, whereas [^{3}H]diacylglycerol did not increase until 2 min. This time course suggested that the increase in PA could be due to an activation of phospholipase D. This enzyme also catalyzes the transfer of phosphatidyl groups to various acceptors; in the presence of ethanol, this transphosphatidylation produces phosphatidylethanol. When cells were prelabeled with [^{3}H]palmitic acid and then incubated with 5% ethanol, bradykinin caused a significant increase in the accumulation of [^{3}H]phosphatidylethanol. The phospholipid source of the phosphatidic acid was also investigated. Different classes of phospholipids contain different proportions of stearic acid and palmitic acid. When cells were labeled with [^{14}C]stearic acid and [^{3}H]palmitic acid and then stimulated with bradykinin, the [^{14}C]/[^{3}H] ratio of the increment in PA was intermediate between the ratios of phosphatidylcholine and phosphatidylinositol; when cells were stimulated with carbachol, the ratio was similar to the [^{14}C]/[^{3}H] ratio in phosphatidylcholine. Bradykinin and carbachol may activate a phospholipase D that catalyzes the formation of PA from phosphatidylcholine and other phospholipids. (Supported by NS-22694 and HD-04583)

STIMULATION OF CHOLINE PHOSPHOLIPID HYDROLYSIS AND PHOSPHORYLCHOLINE PRODUCTION IS MEDIATED BY PROTEIN KINASES A AND C IN RAT ANTERIOR PITUITARY CELLS *IN VITRO*.

W.D. Jarvis and R.M. MacLeod. Departments of Neuroscience and Medicine and the Center for Cancer Research, University of Virginia Health Sciences Center, Charlottesville, VA 22908.

Recent evidence obtained in a variety of transformed cell lines has suggested a role for the hydrolysis of the choline-based phospholipids phosphatidylcholine (PtdCho) and sphingomyelin (SphMyl) in signal transduction; this study addressed the presence of such a system in primary cultures of female rat anterior pituitary cells.

[^{3}H]Choline-prelabeled cell cultures were exposed either to phorbol myristate acetate (PMA; 0.1-100 nM) or to dibutyryladenosine cyclic monophosphate (dbcAMP; 0.01-10 mM) for varying times. Both of these treatments produced time- and concentration-related increases in the extracellular accumulation of [^{3}H]phosphorylcholine ([^{3}H]PCho); respective EC_{50} values for PMA and dbcAMP were 0.1 nM and 1.0 mM during a 45-min exposure period. No significant changes in intracellular levels of [^{3}H]PCho were observed. Parallel reductions in cellular [^{3}H]PtdCho and [^{3}H]SphMyl levels accompanied these responses in both instances.

Choline phospholipid breakdown was also stimulated by neuropeptides known to promote prolactin release. Increased accumulation of [^{3}H]PCho in the medium was elicited by 45-min exposures to 100 nM thyrotropin-releasing hormone (229%), angiotensin II (210%), neurotensin (171%), bombesin (276%), or vasoactive intestinal peptide (367%). As before, intracellular [^{3}H]PCho levels were not significantly modified.

These data indicate that choline phospholipid hydrolysis accompanies receptor activation in the anterior pituitary, and may be mediated by the independent actions of protein kinases A and C. We suggest that this process may participate in the regulation of prolactin release.

SPHINGOSINE ACTIVATES PHOSPHOLIPASE D IN NG108-15 CELLS. M. Liscovitch* and Y. Lavie* (SPON: Eli Hazum). Dept. of Hormone Res., The Weizmann Inst. of Sci., Rehovot, Israel.

Sphingosine and other lysosphingolipids accumulate in tissues of patients with inherited lysosomal storage diseases collectively called sphingolipidoses. Although it has been suggested that lysosphingolipid accumulation plays a major role in the pathophysiology of these diseases, the mechanism(s) of their cytotoxic action remained unidentified. We here demonstrate that sphingosine, as well as some other long chain bases, are potent activators of phospholipase D (PL-D) in neural-derived NG108-15 cells. Sphingosine caused severalfold stimulation of phosphatidic acid and phosphatidylethanol formation. (The latter is an unusual phospholipid which is characteristically produced by PL-D when ethanol acts as the phosphatidyl group acceptor.) Sphingosine activation was concentration-dependent with a half-maximal effect observed at 15 µM and 40 µM, in the absence and presence of equimolar BSA, respectively. Activation of PL-D preceded the development of the acute cytolytic response to sphingosine. Galactosylsphingosine (psychosine) and octadecylamine (stearylamine) mimicked the action of sphingosine on PL-D activity. Octylamine and 1-octadecanol (stearylalcohol) were inactive, suggesting that a long aliphatic chain and the terminal amino group are important structural requirements for the activation of the enzyme. PL-D may thus constitute an important cellular target for sphingosine action.

EFFECTS OF INTRATHECALLY ADMINISTERED ISOQUINOLINESULFONAMIDES H7, H8 AND HA1004 ON ACOUSTIC STARTLE; N. Boulis, and M. Davis, Dept of Psychiatry, Yale Univ. Sch. of Med., 34 Park St., New Haven, CT, 06508.

The spinal synapse of the acoustic startle reflex is subject to several forms of plasticity. The present study sought to evaluate the role of two second messengers at this site. The isoquinolinesulfonamide H7, and the ganglioside GT1b, which inhibit protein kinase C activation, were infused intrathecally into the subarachnoid space of the lumbar spinal cord. H7 caused a marked, dose-dependent (10-300 μg) amplification of the startle reflex in comparison with its vehicle ($p<.001$). Like H7, GT1b (40 μg) produced a marked increase in the startle reflex versus its vehicle ($p<.03$). HA1004 (150 μg) and H8 (130 μg), which have substantially less C kinase inhibitory activity than H7, caused only modest increases in startle.

The isoquinolinesulfonamides have also been shown to inhibit A kinase activity. Of the group, H8 is the most effective. Previous work has shown that drugs thought to increase cAMP increase the startle response when infused intrathecally. In a second study, fifteen minutes after either H8 (130 μg) or vehicle infusions, animals received 50 μg of dibutyryl cAMP. By itself H8 had little effect on startle but completely blocked the normal excitatory effect of dibutyryl cAMP on startle ($p<.001$). The pharmacological specificity of H8 was shown by the fact that dibutyryl cAMP continues to elevate startle ($p<.006$) in the presence of H7. Further, the inability of H8 to inhibit the excitatory effect of intrathecal 8-OH-DPAT infusions ($p<.19$) demonstrates H8's behavioral specificity. Thus, while H8 inhibits A kinase-dependent increases in startle, it does not inhibit all increases in startle. Further, as evidenced by the primary increases in startle caused by intrathecal infusions of the isoquinolinesulfonamides and the ganglioside GT1b, spinal PKC inhibition elevates startle, perhaps because PKC tonically inhibits startle at the spinal level.

CATECHOLAMINES: NEUROTOXICITY

402.1

NEUROTOXIC EFFECTS OF DSP-4 ON LOCUS COERULEUS (LC) AXONS IN THE RAT: IMMUNOHISTOCHEMICAL EVIDENCE FOR MORPHOLOGICAL CHANGES REFLECTING DEGENERATION. J.-M. Fritschy[1], Michel Geffard[2] and R. Grzanna[1], 1) Dept. of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205, USA; 2) Laboratoire de Neuroimmunologie, CNRS - IBCN, 33077 Bordeaux, France.

Systemic injections of the neurotoxin DSP-4 produce depletion of norepinephrine (NE) and dopamine-ß-hydroxylase (DBH) in brain regions innervated by the LC. We have studied the effects of DSP-4 on the morphology of central NE axons over a 2 week period using antibodies to NE and to DBH. Rats were sacrificed at daily intervals following a single dose of DSP-4 (i.p., 50 mg/kg; gift of Dr. S.B. Ross). One day after DSP-4, staining with anti-NE revealed extensive loss of transmitter in LC axons. By contrast, there was no change in NE axon staining with anti-DBH until day 4. Thereafter, an abrupt loss of DBH staining was observed in brain regions innervated by the LC. This loss of LC axon staining coincided with the appearance of morphologically altered axons. These fibers were characterized by their thick diameter and intense staining; some of these axons showed prominent swellings and had numerous short branches, resembling axonal sprouts. They were most frequent in the deep layers of cortex and along ascending pathways of NE axons. These remaining fibers could be visualized with both antisera between days 4 and 10. By day 14, there was no staining with either anti-NE or anti-DBH in brain regions innervated by the LC.

We propose that the sequence of events following DSP-4 treatment can be divided into two phases: initially, there is rapid and profound loss of transmitter from LC axons; this phase is followed by morphological alterations of fibers and disappearance of staining. We suggest that the transient appearance of swollen axons and axonal sprouts and the loss of DBH staining mark the onset of LC axon degeneration. [Support NIH grant MH 41977]

DSP-4 HAS DIFFERENT AFFINITIES FOR THE NOREPINEPHRINE (NE) CARRIER IN CEREBRAL CORTEX AND HYPOTHALAMUS. R. Grzanna, R. Zaczek, J.-M. Fritschy, S. Culp* and E.B. De Souza. Department of Neuroscience Johns Hopkins University School of Medicine and NIDA, ARC, Baltimore, Md. 21205

A single systemic injection of the NE neurotoxin DSP-4 causes profound reductions in NE levels and NE-uptake in cerebral cortex but not in the hypothalamus. DSP-4 is thought exert its effects by binding selectively and irreversibly to the NE uptake carrier. In this study we tested the hypothesis that the differential effects of DSP-4 on NE axons in cerebral cortex and hypothalamus are due to differences in the affinity of DSP-4 for the NE uptake carrier. We have measured NE uptake into synaptosomes isolated from cerebral cortex and hypothalamus in the presence of 100 and 300 nM DSP-4 (gift of Dr. S.B. Ross). Uptake assays were conducted over a 5 min. period with 1 μM desipramine to assess non-specific incorporation of NE. At 100 nM DSP-4 inhibited NE uptake into cortical synaptosomes by 30% but had no effect on NE uptake into hypothalamic synaptosomes. At 300 nM DSP-4 produced a substantial increases in the Km of NE uptake into synaptosomes from both brain regions but caused only minor alterations in the Vmax indicating that the drug is a competitive inhibitor of NE uptake. DSP-4 had a 2.6-fold higher affinity ($p < 0.01$) for the NE uptake into cortical synaptosomes (K_i = 180 ± 38 nM) compared to hypothalamic synaptosomes (K_i = 460 ± 36 nM). The results suggest that the differential neurotoxic effects of DSP-4 in various brain regions may be related to differences in the affinities of the drug for the NE uptake carrier. [Support NIH grant MH 41977]

402.3

CORTICAL AND HYPOTHALAMIC NOREPINEPHRINE (NE) TRANSPORT PROCESSES DIFFER IN THEIR KINETIC AND PHARMACOLOGIC PROPERTIES. S. Culp*, R. Grzanna, E.B. De Souza, J.-M. Fritschy and R. Zaczek (SPON. M. Steinmetz). NIDA/ARC and Dept. Neurosci., Johns Hopkins Univ. School of Medicine, Baltimore, MD 21224.

Differential effects of the neurotoxin DSP-4 in rat hypothalamus and cortex led us to propose that NE uptake processes in these two areas may differ. We examined sodium dependent uptake of ^{3}H-NE into rat brain synaptosomes from cortex and hypothalamus using 1.0 μM desipramine (DMI) to measure non-specific ^{3}H-NE incorporation. Saturation studies revealed that NE possessed a significantly ($p < 0.05$) higher affinity for uptake in cortex (K_m = 39.5 ± 7.5 nM) than in hypothalamus (K_m = 100.3 ± 12.1 nM). The maximal velocity of ^{3}H-NE uptake was two fold higher in hypothalamus (V_{max} = 2.1 ± 0.1 nmoles/mg protein/min) than that observed in cortex (V_{max} = 1.1 ± 0.1 nmoles/mg protein/min). Preliminary pharmacological studies indicated that nisoxetine was equally potent at inhibiting cortical and hypothalamic ^{3}H-NE uptake processes (K_i cortex = 1.48 ± 0.09 nM; K_i hypothalamus = 1.34 ± 0.16 nM). This was also true for DMI (K_i cortex = 1.23 ± 0.09 nM; K_i hypothalamus = 1.17 ± 0.16 nM). However, DSP-4 was a more potent inhibitor of ^{3}H-NE uptake in cortex than in hypothalamus, with inhibition constants of 180 ± 38 nM and 460 ± 36 nM in these two areas, respectively ($p < 0.01$). On the other hand, mazindol possessed a higher affinity in hypothalamus (K_i = 0.30 ± 0.08 nM) than in cortex (K_i = 0.55 ± 0.05 nM; $p < 0.05$). These results suggest that NE is taken up by different carrier proteins in cortex and hypothalamus. Pharmacological differences in these carriers may be exploited to develop more specific therapeutic agents. [Support NIH grant MH 41977]

402.4

CHARACTERIZATION OF THE ORIGINS OF ASTROCYTE RESPONSE TO INJURY USING THE DOPAMINERGIC NEUROTOXICANT, MPTP. J.P. O'Callaghan, D.B. Miller and J.F. Reinhard[1]. U.S. Environmental Protection Agency and [1]The Wellcome Research Laboratories, Research Triangle Park, NC 27711.

Astrocytes hypertrophy following a variety of nervous system insults and the hallmark of this response is an enhanced expression of the astrocyte intermediate filament protein, glial fibrillary acidic protein (GFAP). 1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) causes degeneration of the nigrostriatal pathway, an effect which requires the MAO-B catalyzed formation of the 1-methyl-4-phenylpyridinium species (MPP^+) and its dopamine-carrier mediated uptake into nigrostriatal neurons. To characterize the origins of astrocyte reaction to injury, we administered MPTP (0-25 mg/kg, sc) to C57BL/6J mice and then assayed striatal GFAP. We found that MPTP caused a rapid and large increase in GFAP. This effect was completely blocked by inhibitors of MAO B and the dopamine uptake system but not by blockers of MAO A. Blood-borne or brain-derived interleukin-I did not appear to mediate the effect of MPTP on GFAP. The data indicate that factors derived from the dopamine terminal initiate the astrocyte response to MPTP.

402.5

EFFECTS OF THE MONOAMINERGIC NEUROTOXICANT, MPTP, IN C57BL/6J FEMALE MICE OF DIFFERENT AGES. D.B. Miller[1], J.P. O'Callaghan[1], L. Manzino*, B.A. Sieber*, A.Giovanni* & R.E. Heikkila*. [1]U.S. Environmental Protection Agency, Research Triangle Pk., NC, 27711 and *UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) causes degeneration of the dopaminergic nigrostriatal pathway in experimental animals including C57BL/6 mice. MPTP-induced neurotoxicity is dependent upon the monoamine oxidase-B (MAO-B) catalyzed formation of the 1-methyl-4-phenylpyridinium species (MPP^+) from MPTP. Here, we measured neostriatal levels of MAO-B in naive female C57BL/6J mice (3,6.5, 11 and 18 months of age). Age-related effects of a single dose of MPTP (15 mg/kg, s.c.) were determined by measuring neostriatal levels of MPP^+, dopamine and glial fibrillary acidic protein (GFAP). GFAP, the major intermediate filament protein of astrocytes, increases after CNS damage induced by MPTP and other neurotoxicants. The youngest group had lower levels of MAO-B and GFAP. After MPTP the 3-month old mice had 1) lower levels of neostriatal MPP^+, 2) less depletion of neostriatal dopamine and 3) lower levels of neostriatal GFAP relative to the other groups. Data are consistent with previous reports of age-related MPTP neurotoxicity.

402.6

STUDIES ON THE MECHANISM OF MPP^+-INDUCED NEUROTOXICITY. S.K. Youngster*[i], R.E. Heikkila[1], N. Castagnoli, Jr.*[2], and H. Rollema[3] (SPON: P. Manowitz). [1]Neurology Dept., UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854, [2]Chemistry Dept., Virginia Polytechnic and State University, Blacksburg, VA 24061, [3]Dept. of Medicinal Chemistry, State University Groningen, 9713 AW Groningen, The Netherlands.

The 1-methyl-4-phenylpyridinium ion (MPP^+) resulting from the monoamine oxidase (MAO)-catalyzed oxidation of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) is the actual neurotoxic species following systemic administration of MPTP to experimental animals. We have used in vivo dialysis of dopamine (DA) to determine the relative potencies of MPP^+ and several of its analogs as neostriatal dopaminergic neurotoxins in rats. These analogs were the predicted 4-electron oxidation products which would be formed via the actions of MAO on structural analogs of MPTP. The capacities of the compounds to be taken up by the neostriatal DA transport system and to inhibit respiration in isolated mitochondrial preparations were also determined. The correlation that exists between the abilities of the analogs to destroy DA neurons and their capacities to act as substrates for the DA carrier and inhibitors of mitochondrial respiration suggests that these parameters are important determinants in the toxicity of MPP^+ and some of its analogs.

402.7

EFFECT OF ALTERATION OF ENERGY METABOLISM ON 2'ET-MPTP-INDUCED TOXICITY IN PC12 CELLS. A.N. Basma*, R.E. Heikkila, H.M. Geller and W.J. Nicklas. (SPON: R.C. Duvoisin) Depts. of Neurology and Pharmacology UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, 08854.

2'Et-MPTP is, like MPTP, a potent dopaminergic neurotoxin. It has been proposed that 2'Et-MPTP-promoted neuronal death is a consequence of 2'Et-MPP^+-induced inhibition of mitochondrial respiration. In the present study, we have examined the mechanism of 2'Et-MPTP-induced toxicity in PC12 cells, which are neoplastic in nature and have a high rate of anaerobic glycolysis with a large production of lactate and a low utilization of glucose carbon through the Krebs cycle. We compared the effects of varying concentrations of 2'Et-MPTP on PC12 cells grown in RPMI 1640 medium supplemented with either glucose or with pyruvate. The latter substrate is directly metabolized via the Krebs cycle. 2'Et-MPTP was more toxic to PC12 cells grown in the pyruvate- supplemented RPMI 1640 medium than to cells grown in glucose-supplemented medium. For example after two days, 50 μM 2'Et-MPTP killed 69% of cells in the pyruvate medium but only 11% of cells in the glucose medium. These results demonstrate that an alteration in the energy metabolism of the cells can affect their susceptibility to 2'Et-MPTP. Results of these studies and reasons for this differential toxicity will be discussed.

402.8

MPTP-INDUCED NEUROTOXICITY IN THE RAT. A. Giovanni, P.K. Sonsalla, and R.E. Heikkila. Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

The rat demonstrates relative insensitivity to the neurotoxic actions of MPTP. The LD_{50} of MPTP in the rat is lower than the dose needed to produce marked dopaminergic neurotoxicity. This is perhaps the major difficulty in the ability to induce a parkinsonian syndrome in the rat. We have found that pretreatment with guanethidine, a peripheral adrenergic depleting agent, substantially decreases mortality in the rat in response to large doses of MPTP (60 mg/kg s.c.) without directly affecting the neurotoxic actions of MPTP. In the present study, MPTP was given in combination with guanethidine pretreatment to successfully induce dopaminergic neurotoxicity in the rat. This treatment resulted in a marked depletion of dopamine (DA) and its metabolites and loss of tyrosine hydroxylase (TH) activity in the rat caudate nucleus. Additionally, MPTP induced a significant but slightly less pronounced decrement of DA and TH activity in the substantia nigra of the rat. The relationship between the loss of DA and TH activity in the caudate to the loss of 1) DA, 2) TH activity and 3) dopaminergic neurons in the substantia nigra will be discussed.

402.9

DOPAMINERGIC NEUROTOXICITY OF MPTP ANALOGS. R.E. Heikkila, P.K. Sonsalla, I. Terleckyj* and S.K. Youngster*. Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) causes a degeneration of nigrostriatal dopaminergic neurons in monkeys and mice. Monoamine oxidase-B (MAO-B) catalyzes the oxidation of MPTP to 1-methyl-4-phenylpyridinium ion both in vitro and in vivo, and this oxidation is a necessary event in the neurotoxic process. In vitro, MAO-A oxidizes MPTP analogs having either a methyl or ethyl group in the 2'position and also plays a role in the bioactivation of these compounds to neurotoxins in vivo. In these studies we evaluated several analogs of MPTP for their abilities to be oxidized by MAO-A and MAO-B and to cause nigrostriatal dopaminergic neurotoxicity in mice. Several were found to be neurotoxic as evidenced by their capacities to cause reductions in the content of dopamine (DA) and its metabolites, binding of the DA uptake inhibitor 3H-GBR 12935, and tyrosine hydroxylase activity. Most of the neurotoxins were found to be bioactivated by MAO-A as well as MAO-B. Many of these compounds may turn out to be useful research tools.

402.10

NEUROCHEMICAL (CATECHOLAMINES) EFFECTS OF 6-OHDA LESIONS OF THE PRE-FRONTAL CORTEX IN 21 DAY OLD vs ADULT (9 WEEK OLD) RATS. V. Haroutunian, P.J. Knott, K.L.Davis*. Dept. Psychiatry, Mount Sinai School of Medicine, New York, N.Y.

Lesions of the dopaminergic innervation of the prefrontal cortex (PFC) affect indices of subcortical DA function (Pycock et al, Nature, 286:74-77, 1980). We investigated whether PFC lesions at 21 days of age would lead to greater perturbation of subcortical DA function than equivalent lesions sustained during adulthood. Twelve adult male (nine weeks old) and twelve male weanling (21 days old ±1) rats received 25 mg/Kg DMI (IP) prior to the bilateral infusion of 6-OHDA (4μg in 1μl in weanlings and 8μg in 2μl in adults) or the vehicle into the medial PFC. Levels of norepinephrine, dopamine and homovanillic acid were measured in the PFC, caudate nucleus (CPU), and n. accumbens (ACB) 7 days later. DA and NE in the PFC were significantly ($ps<0.01$) reduced in both age groups. Subcortically, levels of dopamine in the ACB were increased by 220% in weanling rats relative to the 142% increase seen in adult rats. DA activity in the CPU was unchanged. These data suggest that ontogenetic lesions of the PFC may lead to greater perturbation of subcortical DA function than similar lesions sustained in adulthood.

402.11

DOPAMINE D1 AND D2 RECEPTORS IN THE RAT CAUDATE-PUTAMEN (CPu): FUNCTIONAL SENSITIZATION AND LOSS OF D1-MEDIATED ENABLING BY 6-OHDA PRETREATMENT X.-T. Hu, M.P. Galloway, and F.J. White, Dept. Psychiatry, Neuropsychopharmacol. Lab., Wayne St. Univ. Sch. Med., Lafayette Clinic, Detroit, MI 48207

Extracellular single unit recording and microiontophoretic techniques were used to determine the sensitivity and interaction of D1/D2 receptors in the CPu of rats which were pretreated with either 6-OHDA (100 g/5 l, LV), ä-methyl-p-tyrosine (AMPT, 500mg/kg, ip) or 6-OHDA plus AMPT. Seven-ten days after 6-OHDA, CPu DA levels were reduced by 88%. Cells/tracks analysis revealed more spontaneously active CPu cells in 6-OHDA-lesioned rats. Current-response curves exhibited significantly enhanced inhibitory responses of CPu cells to both the selective D1 agonist SKF-38393 (SKF) and D2 agonist quinpirole (Quin). However, the potentiation of Quin-induced inhibition by co-ejected SKF observed in controls was abolished by 6-OHDA pretreatment. Moreover, the absolute requirement for SKF to enable Quin's effects in unlesioned rats acutely depleted (80%) of DA with AMPT was also eliminated by 6-OHDA (with and without AMPT). These findings indicate that 6-OHDA lesions result in (1) the functional sensitization of both D1 and D2 receptors and (2) the loss of D1-mediated enabling of D2 responses in the rat CPu (Supported by APDA, USPHS Grants DA-04093, and MH-40832 to FJW).

402.12

NGF POTENTIATES THE EFFECTS OF 6-OHDA-INDUCED NIGRAL LESION ON STRIATAL PROENKEPHALIN AND PROTACHYKININ mRNA IN RAT BRAIN. J.L. Cadet, J. Angulo, V. Jackson-Lewis, B.S. McEwen, and S. Fahn. Columbia Univ., Dept. Neurology, NY, NY 10032 and Rockefeller Univ., NY, NY 10021.

Lesions of nigral dopaminergic cells with 6-hydroxydopamine (6-OHDA) cause increases in proenkephalin (PEK) mRNA but decreases in protachykinin (PTK) mRNA in rat striatum (Angulo et al. 1987). In the present study, we have investigated the possibility that nerve growth factor (NGF) may influence these changes. Adult rats received unilateral 6-OHDA-induced nigral lesions. The animals were then tested until they developed stable apomorphine (APO)-induced rotation. They were then divided into two groups according to rotational behavior and were given intraventricular infusions of either NGF or saline for 28 days. The rats were then sacrificed and the brain processed for in situ hybridization histochemistry. As previously reported, 6-OHDA nigral lesions caused increases in PEK mRNA but decreases in PTK mRNA in rat striatum. These changes were potentiated by chronic infusion of NGF. The potentiation was more evident on the dorsolateral aspect of the caudate putamen. However, in situ hybridization for tyrosine hydroxylase (TH) mRNA in the SN showed no differences between the groups. The data will be discussed in relation to the topography of striatal dopamine afferents from the SN.

402.13

IMMUNOHISTOLOGICAL CHARACTERIZATION OF MPTP INDUCED DEGENERATION IN STRIATUM AND SUBSTANTIA NIGRA OF C57 MICE. K. F. Jensen, D.B. Miller, J.P. O'Callaghan and J.F. Reinhard[1] Neurotoxicology Division, U.S. Environmental Protection Agency and [1]Wellcome Research Laboratories, Research Triangle Park, NC 27711.

MPTP induced damage to substantia nigra neurons has been hypothesized to occur as a result of axonopathy followed by retrograde degeneration. To address this issue we have used glial fibrillary acidic protein (GFAP) and tyrosine hydroxylase (TH) immunohistochemistry as well as a silver degeneration stain to characterize alterations occurring at the terminal fields within the striatum and neurons within substantia nigra. C57 mice where given 12.5, 25 or 40 mg/kg MPTP and sacrificed at intervals from 12 hours to 5 days postdosing. Marked increase in GFAP immunoreactivity occurs in striatum of MPTP animals at times when only slight increases were observed in substantia nigra. Increases in GFAP parallel decreases in TH immunoreactivity and evidence of silver degeneration. These results further characterize the vulnerability of striatal axons to MPTP.

CATECHOLAMINES III

403.1

COMPARISON OF THE PHARMACOLOGICAL RESPONSIVENESS OF DOPAMINE IN THE RAT MEDIAL PREFRONTAL CORTEX AND STRIATUM, B. Moghaddam and B.S. Bunney, Dept. of Pharmacology & Psychiatry, Yale University School of Medicine, New Haven, CT. 06510.

Using the technique of in vivo microdialysis combined with a small-bore liquid chromatography system, we have measured the basal and drug induced fluxes of extracellular dopamine (DA) in the medial prefrontal cortex (mPFC) of chloral hydrate anesthetized rats and have compared our findings in the mPFC to those observed in the striatum. The results were as follows: (1) At a flow rate of 2 µl/min, basal level of DA in the mPFC, was 0.32±0.1 (n=28) fmoles/µl perfusate, which was nearly an order of magnitude less than that obtained from striatum, (2) α-methyl-p-tyrosine (150 mg/kg i.v.) significantly decreased DA release in mPFC and striatum. The magnitude and duration of response were similar in both regions. (3) Local perfusion with 30 mM K^+ had a more profound effect on DA release in striatum than in mPFC, the K^+-induced release in both regions was significantly attenuated in the absence of Ca^{++}, (4) The anxiogenic beta carboline FG 7142 (15 mg/kg i.p.) enhanced the release of cortical DA by about 50% while it was without an effect in striatum. (5) Similar to striatum, amphetamine (1 mg/kg, i.v.) significantly elevated while reserpine (5 mg/kg i.p.) rapidly attenuated the dopamine level in mPFC. These studies provide direct evidence that DA release in mPFC is K^+ and Ca^{++} dependent and is sensitive to pharmacological manipulations. INTRACELLULAR STUDY OF THE EFFECT OF NOREPINEPHRINE ON SOMATOSENSORY CORTICAL NEURONAL RESPONSE TO GABA. W. Liu, F.M. Sessler, C.S. Lin and B.D. Waterhouse, Dept. of Physiol. and Biophys., Hahnemann Univ., Phila., PA. 19102-1192.

Considerable evidence from extracellular recording studies suggests that norepinephrine (NE) may augment inhibitory synaptic transmission within local circuits of mammalian neocortex. For example, experiments in intact animals have shown that microiontophoresis of NE or activation of the coeruleo- cortical afferent pathway can enhance stimulus evoked or GABA-induced depressant responses of cortical neurons. Further studies using neocortical tissue slices have demonstrated that these noradrenergic modulatory actions involve the beta- adrenoceptor linked cyclic-AMP second messenger system. In the present investigation we have begun to examine the transmembrane electrophysiological events which are associated with NE and GABA interactions on somatosensory cortical cells. Intracellular recordings were made from somatosensory cortical neurons in a submerged tissue slice preparation. The resting membrane potential of the cortical neurons (N=24) examined was 68.7 $\pm$ 8.6 mV, with an input resistance of 33.1 $\pm$ 12 meghoms. Superfusion of GABA in concentrations greater than 0.5 mM produced a small decrease in membrane potential (5.6%) associated with a reduction in membrane resistance (24.2%). In four of five cells tested, superfusion of NE at concentrations producing little or no change in membrane potential was associated with an increase in input resistance. In 40% of the cases tested, superfusion of NE during GABA application produced a net increase in membrane conductance, suggesting noradrenergic facilitation of GABA mediated membrane action. NORADRENERGIC MODULATION OF CORTICAL NEURONAL EXCITABILITY: PHARMACOLOGIC CHARACTERIZATION IN TERMS OF ADRENERGIC AND AMINO ACID RECEPTOR SUBTYPES. R.D. Mouradian, F.M. Sessler and B.D. Waterhouse. Department of Physiology & Biophysics, Hahnemann University, Philadelphia, PA. 19102-1192

Previous studies from our laboratory indicate that under both in vivo and in vitro conditions norepinephrine (NE) can facilitate excitatory somatosensory cortical neuronal responses to threshold stimulation of afferent synaptic pathways or threshold iontophoretic doses of putative transmitters. Further characterization of these effects indicates that they are mediated by an alpha-1 type adrenoceptor which may be linked to intracellular activation of protein kinase C. Additional studies provided evidence of a noradrenergic "gating" action, whereby otherwise subthreshold iontophoretic doses of Glu evoked robust excitatory discharges but only during concomitant administration of NE. In each of these studies investigations, changes in the responsiveness of rat somatosensory cortical neurons to iontophoretic pulses of Glu were assessed by quantitative analysis of drug response histograms collected before, during and after NE, alpha agonist or phorbol ester microiontophoresis. Recent experiments in rat neocortical tissue slices have focused on which of the Glu receptor subtypes may be involved in these noradrenergic modulatory effects. Interactions between NE and iontophoretic doses of NMDA which were subthreshold for producing excitation resulted in "gated" responses similar to those observed with subthreshold Glu. NE was also capable of potentiating responses to threshold doses of NMDA. Overall, these data suggest that noradrenergic modulation of cortical neuronal excitability may be expressed as either an enhancement of threshold level spiking or as a shift in the ability of the membrane to respond to subliminal synaptic stimuli. A further goal is to determine the extent to which the other identified glutamate receptor subtypes are involved in either or both of these modulatory actions. MICROINJECTION OF LIDOCAINE, GABA, OR SYNAPTIC DECOUPLERS INTO THE VENTROLATERAL MEDULLA BLOCKS SCIATIC-EVOKED ACTIVATION OF LOCUS COERULEUS. C. Chiang and G. Aston-Jones, Div Behav Neurobiol, Dept Mental Hlth Sci, Hahnemann Univ, Philadelphia, PA 19102.

While it is well-documented that locus coeruleus (LC) is potently activated by footpinch or sciatic nerve stimulation, little is known about the circuit producing this sensory response. Recent work in our laboratory has identified the medullary nucleus paragigantocellularis (PGi) as the major excitatory afferent to LC. Here, we use reversible pharmacologic blockade to implicate PGi as a critical link in the pathway mediating sciatic activation of LC in rats.

Bipolar electrical stimulation of the contralateral sciatic nerve was presented through 26-gauge needles inserted in the hindpaw. Extracellular recordings from single LC neurons were obtained with micropipettes. All drugs were pressure ejected (125-400 nl over 2 min) through micropipettes (50-75 um tip).

Lidocaine HCl (2% in saline) attenuated sciatic-evoked activation of LC in 75/109 cells, with 35 complete but reversible blocks (10 min recovery). However, lidocaine disrupts impulses in fibers as well as somata. To verify that synapses within PGi are involved in this response, the inhibitory transmitter GABA, or a synaptic decoupling manganese/cadmium (Mn/Cd) cocktail, was microinjected into PGi. GABA (2 M) reduced the sciatic-evoked response of LC in 27/29 cells (7 complete blocks) and may act at GABA-A receptors as baclofen had no effect (0/25 cells). Mn/Cd (40 mM/20 mM or 20 mM/10 mM) also attenuated LC activation in 10/12 cells with 2 blocks. With each drug, the most effective injection placement for total blocks was ventromedial PGi; injections near this region produced attenuations. Vehicle injections (n=11) or control injection placements (inf olive, rostrolateral PGi, nuc tractus sol, facial nuc) were ineffective.

These results are consistent with previous findings that pharmacologic blockade of PGi-evoked LC activity also blocks LC sciatic responses (Ennis and Aston-Jones, J. Neurosci. 8: 3644), and support the view that sciatic and other sensory activations of LC are mediated through its major excitatory afferent, PGi. ELECTROPHYSIOLOGICAL EVIDENCE FOR MEDULLARY ADRENERGIC INHIBITION OF RAT LOCUS COERULEUS. B. Astier*[1] and G. Aston-Jones (SPON: G. Sterling) Div Behav Neurobiol, Dept Mental Hlth Sci, Hahnemann Univ, Philadelphia, PA 19102.
[1]Lab Neuropharm, CNRS UMR 12, Fac Pharm, Univ C Bernard, Lyon, France.

Stimulation of the nucleus paragigantocellularis (PGi) in the rostral ventrolateral medulla induces a dual response in locus coeruleus (LC): most cells are excited and a few are inhibited (Ennis & Aston-Jones 1988). However, when PGi-evoked excitation of LC is blocked by excitatory amino acid (EAA) antagonists, nearly all LC neurons exhibited inhibitory responses (ibid).

Anatomic studies have demonstrated adrenergic (Ad) inputs to LC from PGi (Pieribone et al. 1988), and many studies have shown that adrenaline inhibits LC discharge via alpha$_2$ receptors. Thus, it is possible that PGi-induced inhibition of LC is mediated by this Ad pathway. To test this hypothesis we studied the effect of the alpha$_2$ antagonist idazoxan (Ida) on (i) inhibition of LC by PGi without pharmacologic pre-treatment, (ii) inhibition of LC by PGi after EAA antagonism, and (iii) inhibition of LC by stimulation of the Ad medullary bundle (MB).

Ida (0.5-1 mg/kg, iv) potently attenuated purely inhibitory responses obtained in 2/3 LC neurons after PGi stimulation; in the third cell this drug revealed an underlying excitatory response. Ida either iv (0.5-1 mg/kg) or microinfused into LC (2.5 ng in 50 nl) blocked (3/9 cells) or decreased (5/9 cells) inhibition following PGi stimulation revealed by EAA antagonism with kynurenic acid (0.53 umol, icv), in the last cell such inhibition was unaffected. Stimulation of the Ad MB area inhibited 14/22 LC cells by at least 50%; 4 cells were less potently inhibited and 4 cells were unaffected, but no cell was excited by MB stimulation. In one cell tested to date, Ida (0.5mg/kg, iv) attenuated such inhibition.

These results favor the hypothesis that inhibition of LC from PGi is mediated by a direct input from the Ad MB, and indicate that this MB pathway may selectively convey inhibitory control over LC. This conclusion is consistent with our additional finding (Van Bockstaele et al., this meeting) of multiple distinct pathways from PGi to LC. Supported by PHS grant NS24698 and ONR/AFOSR contract N00014-86-K-0493.

RESPONSES OF MESOLIMBIC UNITS TO SENSORY INPUT IN RATS CONDITIONED BY REINFORCING BRAIN STIMULATION. Charles H.K. West and Richard P. Michael. Department of Psychiatry, Emory University School of Medicine, and Georgia Mental Health Institute, 1256 Briarcliff Road, Atlanta, GA 30306.

The relation between the midbrain dopamine (DA) systems and reinforcement and unit responses to sensory input suggests that DA might influence responses to sensory cues related to reward. Previously we reported that sensory-evoked unit responses in DA terminal regions were affected by electrical stimulation of DA neurons in the ventral tegmental area (VTA). Here we report that such units respond differentially to auditory stimuli that were and were not paired with reinforcing brain stimulation. Adult male rats implanted with stimulating electrodes in VTA were trained to perform self-stimulation to insure that the stimulus was reinforcing. Then in 3-4 conditioning sessions, animals (n = 8) received 500 msec auditory tone stimuli (CS+) beginning 1 sec before electrical stimulation of VTA. Auditory tones of another frequency (CS-) but equal in number and intensity were randomly administered throughout the sessions. For half the animals, CS+ was 2000 Hz and CS- was 100 Hz, and for the other half the situation was reversed. Subsequently, rats were anesthetized with urethane (1.4 g/kg, ip), and single units were recorded in striatum, nucleus accumbens and olfactory tubercle. Of the 61 units recorded to date, 15 units (25%) responded to auditory stimuli, and 12 of these showed a larger response to the CS+ than to the CS-. Although preliminary, this differential response to auditory stimuli that were or were not cues for reinforcing brain stimulation is consistent with the notion of a reward-related modulation of sensory input by DA.

DEXMEDETOMIDINE, AN ALPHA-2 ADRENOCEPTOR AGONIST, MODULATES THE ACTIONS OF THE VOLATILE ANESTHETIC ISOFLURANE ON RAT HIPPOCAMPAL SLICE. M.K.T.Savola*, M.B.MacIver, V.A.Doze*, M.Maze and J.J.Kendig (SPON: K.R.Courtney). Department of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305-5117.

Dexmedetomidine (d-med), a highly selective α_2-adrenoceptor agonist, has sedative properties and reduces volatile anesthetic ED_{50}. In order to understand how α_2-adrenoceptor agonists reduce volatile anesthetic requirements, we studied whether d-med modulates isoflurane effects on the electrophysiological responses of the rat hippocampal slice. Synaptically evoked field potentials were recorded from CA1 neurons using standard extracellular techniques. D-med was perfused onto the slice and isoflurane was administered via the surface gas stream. Isoflurane (0.14-1.4 v%) depressed excitatory postsynaptic potentials (EPSP) and population spike responses in a dose-dependent manner. D-med (10 nM-1 μM) itself had no effect on the EPSP, and only small and variable effects on the population spike. Rauwolscine (1-10 μM) was used to antagonize the effects of d-med. D-med enhanced the isoflurane-induced depression of EPSP and population spike amplitude. In addition, the rate of onset of isoflurane effects was increased. Thus, an α_2-adrenoceptor agonist, at a concentration which itself has little effect, potentiates volatile anesthetic depression of output in hippocampal CA1 neurons.

403.8

ALPHA-2 ADRENERGIC MODULATION OF SLOW NOCICEPTIVE AND FAST MONOSYNAPTIC REFLEXES IN NEWBORN RAT SPINAL CORD. J.J.Kendig, M.K.T.Savola* and M.Maze. Dept. of Anesthesia, Stanford Univ. Sch. Med., Stanford, CA 94305-5117

Dexmedetomidine (d-med) is a potent specific α_2 adrenergic receptor agonist with analgesic and sedative properties. To probe spinal α_2 adrenergic effects, the isolated superfused spinal cords of 1-4 day old Sprague-Dawley rats were arranged to stimulate a dorsal lumbar root and record from the corresponding ipsilateral ventral root. Evoked potentials consisted of the low threshold fast (2-50 msec) mono- and polysynaptic reflexes and a high threshold response of very slow time course (to 30 sec) which has been linked to nociception. D-med (1-5 nM) reversibly abolished the slow potential without affecting the monosynaptic reflex. L-medetomidine (l-med) (1 μM) had no effect. Depression of the slow potential was rapidly and completely reversed by the α_2 antagonists atipamezole and rauwolscine. At slightly higher concentrations d-med (10 nM), but not l-med (10 μM), reversibly depressed the monosynaptic reflex. Neither rauwolscine nor atipamezole antagonized depression of the monosynaptic reflex at concentrations at or above those which restored the slow response. The results show a potent α_2 adrenergic inhibition of presumed nociceptive transmission in this preparation. The monosynaptic reflex is also strongly stereospecifically inhibited, but a distinct receptor population appears to be involved.

MULTIPLE PROJECTION PATHWAYS FROM THE VENTROLATERAL MEDULLA TO LOCUS COERULEUS IN RAT. E.J. Van Bockstaele, B. Astier*, V.A. Pieribone, G. Aston-Jones and M.T. Shipley. Div Behav Neurobiol, Dept Mental Hlth Sci, Hahnemann Univ, Phila., PA 19102;[1]Dept Cell Bio Anat, U Cincinnati, OH 45267.

We have previously found that VLM (nucleus paragigantocellularis) is a major afferent to locus coeruleus (LC). Here, we examined efferent projections from this area using Phaseolus vulgaris-leucoagglutinin (PHA-L). Anterograde labeling was identified in LC as well as many other brain nuclei. We examined the projection from VLM to LC in detail to i) explore possible topography of innervation in LC and ii) describe the pathway(s) taken by VLM fibers projecting to LC.

Multiple iontophoretic deposits of PHA-L were made into VLM and sections were processed using PAP histochemistry. Alternate sections were subjected to fluorescent double labeling with antibodies against PHA-L and phenylethanolamine N-methyltransferase (PNMT), an adrenergic marker. These initial experiments revealed 2 distinct fiber pathways from rostral VLM to LC. Furthermore, these pathways appear to arise from different locations in VLM: caudomedial injections labeled a medial pathway and rostrolateral injections labeled a distinct lateral pathway. Few fibers were seen in the area of the adrenergic medullary bundle (MB), a previously suggested pathway from C1 neurons to LC.

To test the existence of VLM-LC projections through the MB pathway, another set of experiments was conducted with lesions of the MB (rostral medulla level) and 15 days later Fluoro-Gold (FG) was iontophoretically deposited into LC. Sections were processed for PNMT immunofluorescence and examined under UV and rhodamine epi-illumination for FG retrogradely labeled cells and PNMT immunoreactivity, respectively. In initial studies, MB lesions yielded a large (91%) decrease in doubly labeled PNMT/FG neurons and a 56% decrease in FG-only labeled neurons. The failure to label this pathway with PHA-L may reflect a sampling problem or insufficient uptake of PHA-L by PNMT neurons.

These results reveal 3 separate pathways from the VLM to LC. Additional studies are needed to characterize neurons projecting to LC by these pathways. Support: PHS grant NS24698 and ONR/AFOSR Contract N00014-86-K-0493.

INFLUENCE OF PERIACQUEDUCTAL GREY ON RAT LOCUS COERULEUS NEURONS. [1]M. Ennis, [1]M. Behbehani, [3]E. Van Bockstaele, [3]G. Aston-Jones, and [2]M.T. Shipley., [1]Dept. Physiol & [2]Dept. Anatomy, U. Cincinnati Coll. Med., Cincinnati, OH 45267; [3]Dept Mental Hlth. Sci., Hahnemann Univ. Philadelphia, PA 19102.

Recent anatomic studies reveal that locus coeruleus (LC) receives only few afferent inputs. The afferent status of areas nearby LC has been difficult to ascertain. Here, we have examined possible projections from one nearby area, periacqueductal grey (PAG), recently reported to project to the subcoeruleus (Bietz, 1988).

PHA-L injections in PAG laterally adjacent to the acqueduct labeled fibers that profusely innervate the region rostral and medial to LC, and nucleus parabrachialis. A few fibers appeared to terminate in LC. In agreement with these anatomic results, focal electrical stimulation of LC produced sparse antidromic activation in PAG; 3/34 PAG neurons were antidromically driven at latencies of 4-6 ms (mean threshold = 225 uA). These driven cells did not respond to electrical stimulation of the hindpaw, a manipulation that activates LC neurons.

Stimulation of PAG (.5 Hz) synaptically activated 60% of LC cells tested at onset latencies of 4-10 ms. Such excitation was weak and typically required high currents (>500 uA). Stimulation of PAG lateral to the acqueduct activated 77% of LC neurons usually at shorter latencies (4-7 ms), similar to those for PAG neurons antidromically driven from LC. Stimulation of ventrolateral PAG yielded antidromic or pure inhibitory responses.

These results indicate that PAG may provide sparse innervation of LC. Supported by PHS Grants NS20643 and NS24698.

DENDRITES OF RAT LOCUS COERULEUS ARE ASSYMMETRICALLY DISTRIBUTED: IMMUNOCYTOCHEMICAL LM AND EM STUDIES. Libang Fu[1]*, M.T. Shipley[1] and G. Aston-Jones[2] (SPON: H. Duncan) Dept Anatomy & Cell Biol. Univ of Cincinnati, Coll. Med. Cinti., OH 45267[1]. Dept. Mental Hlth. Sci., Hahnemann Univ., Philadelphia, PA 19102.

Nissl, Golgi and immunocytochemical (ICC) studies have described the morphology and ultrastructure of rat locus coeruleus (LC). However, much less is known about LC neuronal processes extending outside of the nucleus proper. Here, ICC LM and EM techniques were used to examine the distribution of TH- and DBH-labeled extranuclear processes in the pericoerulear region. DBH-labeled processes preferentailly extended into the rostromedial pericoerulear region. In horizontal sections it is clear that even neurons in the caudal pole of LC preferentially extend their dendrites in a medial and rostral direction and can extend rostrally beyond the rostral pole of the nucleus. Some labeled processes extend caudally but very few were observed in regions lateral to LC.

EM-ICC analysis revealed that of 160 TH- or DBH-labeled profiles identified in the rostral and medial pericoerulear regions all were dendrites. Labeled axons were not observed. These results indicate that the dendrites of LC neurons are very highly oriented. The vast majority of extranuclear LC dendrites extend and ramify in the rostromedial pericoerulear region. Our previous studies demonstrate that the major inputs to LC, from prepositus hypoglossi and paragigantocellularis, terminate in LC proper and also the pericoerulear region medial and rostral to LC. Recent studies demonstrate dense GABAergic and peptidergic terminals in rostral and medial pericoeruleus. Thus, this pericoerulear region may be a key site for regulation of LC. (Supported by PHS Grants NS20643, NS 24698 and NS23348.)

D_1 AND D_2 DOPAMINE RECEPTOR AGONISTS DECREASE INWARDLY RECTIFYING CURRENTS IN THE CENTRAL NUCLEUS OF THE RAT AMYGDALA. M.C. Schiess and P. Shinnick-Gallagher. Dept. Pharmacology, Univ. Texas Medical Branch, Galveston,TX 77550.

The membrane activity of dopamine (DA) and the specific D_1 agonist SKF 38393 (SKF) and the D_2 agonist Quinpirole (Quin) was studied at a postsynaptic projection site, the central nucleus of the rat amygdala (ACe). Micromolar concentrations were superfused onto 500 micron thick in vitro slice preparations and intracellular membrane activity was recorded under voltage clamp. There are multiple cell types within the ACe that show varying degrees of rectification. The effects of DA, SKF, and Quin are voltage dependent, but not dependent on the degree of rectification within each cell. In 13 cells DA, Quin and SKF produced outward currents at all potentials, creating a parallel shift of the I-V relation. In other cells, DA agonists produced outward currents at holding potentials of -60 and above; no effect from -60 to -90 mV; and from -100 to -160mV either blocked the anomalous rectifier or decreased rectification (N=16). In conclusion, both D_1 and D_2 agonists decrease inwardly rectifying currents. The voltage dependency of DA agonists explains their variable effects in unclamped neurons.

403.13

EFFECTS OF REPEATED COCAINE ADMINISTRATION ON THE SENSITIVITY OF D1 AND D2 RECEPTORS IN THE NUCLEUS ACCUMBENS: ELECTROPHYSIOLOGICAL STUDIES. D.J. Henry and F.J. White. CCN Program, Dept. of Psychiatry, Wayne St. Univ. Sch. of Medicine & Neuropsychopharmacology Lab., Lafayette Clinic, Detroit, MI 48207.

The dopamine (DA) neuronal projection to the nucleus accumbens (NAc) is important in mediating the rewarding effects of cocaine (COC). We have recently reported that NAc neurons are supersensitive to the inhibitory effects of iontophoretic DA following twice daily 10 mg/kg i.p. COC injections for 14 days. The present study will determine the relative contributions of D1 and D2 DA receptors in this sensitization phenomenon, using iontophoresis of selective D1 (SKF 38393) and D2 (quinpirole) agonists. Our preliminary results suggest that NAc neurons from COC-treated rats are inhibited to a greater extent by SKF 38393 as compared to NAc neurons from control rats. Slightly supersensitive inhibitory responses to quinpirole were also observed. Preliminary findings indicate that NAc neurons in COC-treated rats may also be supersensitive to serotonin, another important transmitter involved in mediating the effects of COC within the NAc. (Supported by DA 04093 and MH 40832 to FJW)

403.14

A10 DOPAMINE SOMATODENDRITIC AUTORECEPTOR SENSITIVITY FOLLOWING WITHDRAWAL FROM REPEATED COCAINE TREATMENT. J.M. Ackerman and F.J. White. Neuropsychopharmacol. Lab., Dept. Psychiat., CCN Program, Wayne St. Univ. Sch. Med., Lafayette Clinic, Detroit, MI 48207.

We have previously demonstrated that impulse-regulating autoreceptors on A10 dopamine (DA) cells in the rat ventral tegmental area become subsensitive to DA and DA agonists following repeated administration of cocaine. The present study sought to determine if this subsensitivity persists following cocaine withdrawal. Male rats were given twice daily i.p. injections of 10 mg/kg cocaine or saline for 14 days. Three groups were then tested at various times after cocaine withdrawal: 1, 4 or 7 days. Extracellular single-unit recording techniques were used to determine the sensitivity of somatodendritic autoreceptors on A10 DA cells as indicated by the inhibitory effects produced by i.v. apomorphine (APO). As previously reported, A10 DA neurons were subsensitive to APO 1 day after the last injection of cocaine. Following four days of withdrawal, subsensitive responses to APO were still observed, although the extent of this effect was reduced as compared to rats tested 1 day after the last injection. After seven days of withdrawal, the sensitivity of DA autoreceptors had recovered to the level of saline control animals. Thus, autoreceptor subsensitivity produced by repeated cocaine is a transient alteration that cannot account for long-lasting sensitization, although it may be necessary to trigger other permanent changes (Supported by DA-04093 and MH-40832).

MORPHINE WITHDRAWAL ACTIVATION OF LOCUS COERULEUS NEURONS: ATTENUATION BY LESIONS OF NUCLEUS PARAGIGANTOCELLULARIS. Kurt Rasmussen and George K. Aghajanian. Depts. of Psychiatry and Pharmacology, Yale Univ. Sch. Med., New Haven, CT 06508.

The locus coeruleus (LC) contains the densest aggregate of norepinephrine containing neurons in the rat brain. In anesthetized rats LC neurons are inhibited by systemic or local administration of opiates. Tolerance to the inhibitory effects of opiates develops in the LC with chronic administration and these neurons display a strong naloxone-induced withdrawal activation. However, LC neurons do not show withdrawal induced activation in vitro in brain slices taken from morphine dependent rats, indicating that this activation is mediated by afferents to the LC. Two major afferents to the LC were lesioned in an effort to block the withdrawal-induced activation. Morphine pellets (75 mg) were implanted subcutaneously daily for two days. Single unit recordings were made two days after the last morphine pellet was implanted. Withdrawal was induced by administering naltrexone HCl (10 mg/kg) subcutaneously. Radio-frequency lesions were placed in either the nucleus paragigantocellularis (PGi; unilateral) or prepositus hypoglossi (PrH; bilateral). Lesions of the PrH did not prevent the withdrawal-induced activation of LC neurons, while lesions of the PGi greatly attenuated (but did not completely block) the withdrawal-induced activation. In PGi lesioned animals, the withdrawal-induced activation was attenuated in the LC ipsilateral to the PGi lesion, but was not attenuated in the LC contralateral to the lesion. Since the excitatory projection from the PGi to the LC has been shown to employ an excitatory amino acid (Ennis and Aston-Jones, J. Neurosci. 8 (1988) 3644), some animals were pretreated with kynurenic acid (an excitatory amino acid antagonist). Kynurenic acid (1 µmol in 10 µl, i.c.v.) completely blocked the withdrawal-induced activation of LC neurons. These studies indicate that the morphine-withdrawal-induced activation of the LC is mediated at least in part by an excitatory amino acid projection from the PGi.

D-1 SPECIFIC AGENTS MODULATE DOPAMINERGIC TERMINAL EXCITABILITY: FURTHER STUDIES. C. Okuda, M. Diana , S. Young & P.M. Groves. (SPON. J.C. Linder)Dept. of Psychiatry, Univ. of California San Diego, La Jolla, CA 92093.

Previous evidence has shown that striatal infusion of a D1 specific agonist, R-SKF 38393, produces a decrease in the electrical excitability of dopaminergic nigrostriatal terminals which is reversed by subsequent infusion of SCH 23390, a D1 specific antagonist. These studies suggest that D1 receptors are present on these terminals. In order to provide further evidence for this possibility, we have used two new benzazepine molecules, SKF 77434 (D1 agonist) and SKF 83566 (D1 antagonist), which have been recently introduced as D1 selective agents, (O'Boyle and Waddington, 1987). An infusion cannula and an adjacent bipolar stimulating electrode were implanted in the neostriatum of urethane anesthetized rats. Terminal excitability of nigrostriatal dopaminergic neurons was assessed before and after drug infusions. Striatal infusion (300nl, 5 mins) of SKF 77434 (1 µM, 10 µM) produced a dose related decrease in terminal excitability. SKF 83566 (1µM, 10 µM) also decreased excitability. Although the inhibitory action of the antagonist SKF 83566 appears paradoxical, it is consistent with the effect of another antagonist, SCH 23390, observed previously. Experiments involving reversal of the action of SKF 77434 by SKF 83566 will also be presented. These results provide further evidence for the presence of D1 receptors on dopaminergic axon terminals in the neostriatum. (Supported by NIDA.)

RESPONSES OF SOMATOSENSORY CORTICAL NEURONS TO IONTOPHORETICALLY APPLIED MONOAMINES IN THE UNANESTHETIZED RAT. M.H. Bassant, K. Ennouri and Y. Lamour, INSERM, U. 161, 75014 Paris, France.

Experiments were performed on unanesthetized rats using a painless restraint system fixed on the skull. Electrode consisted of a recording micropipette (1M NaCl, 2% pontamine blue) attached to a multibarreled micropipette for iontophoresis. Electrode penetrations were reconstructed on camera lucida drawings of brain sections. The effects of 5-hydroxytryptamine (5-HT), dopamine (DA) and noradrenaline (NA) were studied in 130 neurons of the S-I cortex. The 3 amines had predominantly depressant effects. A comparison of the percentages of neurons inhibited revealed that NA was the most potent (80% of neurons inhibited) followed by 5-HT (73%) and DA (67%). When the amines were applied with equivalent current to the same neuron, the effect of NA was also the strongest. The laminar distribution of the responses showed that the neurons of the infragranular layers were clearly more sensitive to 5-HT and DA, compared to superficial layers while the responses to NA were distributed more uniformly, with the highest percentage of neurons inhibited in layer VI. After NA or 5-HT applications, the acetylcholine-induced excitation was suppressed or decreased in 60% of the cells tested. These results provide evidence of widespread effects of monoamines on S-I neurons in awake rats, but also of laminar specificity.

Supported by Bayer Pharma France.

403.18

THE FIRING RATE OF VENTRAL PALLIDAL NEURONS IS AFFECTED BY DOPAMINE AGONISTS. R.J. Maslowski* and T.C. Napier, (SPON: A. Karczmar). Dept. Pharmacol., Loyola Univ. Stritch Sch. Med., Maywood Il 60153.

The ventral pallidum (VP) receives monosynaptic inputs from a dopaminoceptive region, the ventral striatum. Thus, activation of dopamine receptors in the ventral striatum may also affect VP neuronal activity. The activity of VP neurons was assessed following systemic injection of apomorphine, a nonspecific dopamine agonist. The firing rate of 82% of the VP neurons tested (n=34) was affected by apomorphine (0.5mg/kg,iv) and the responses were equally distributed between increases and decreases. The D1 antagonist, SCH23390 (0.1mg/kg,iv) blocked 70% of the apomorphine-induced responses (n=16). Sulpiride (12.5mg/kg,iv), a D2 antagonist, reversed the responses in 50% of the cells (n=12). Subsequently, the effects of the D1 agonist, SKF38393 (0.1-25.6mg/kg,iv), or a D2 agonist, quinpirole (0.025-25.6mg/kg,iv), on VP neurons were examined. Cumulative dose-response curves were generated for each drug. Of the cells tested (n=26), 62% responded to SKF38393 with dose-dependent increases in firing rate (ED_{50}=0.9mg/kg and Vmax=3.2mg/kg). SCH23390 reversed the increase in 88% of the cells. Effects of quinpirole were variable and often insensitive to sulpiride. Thus, the dose-dependence and specific antagonism of D1-mediated responses indicate that the firing rate of VP neurons is sensitive to alteration in D1 receptor activity.

Subpopulations of Ventral Pallidal Neurons Respond Differentially to Microiontophoretically Applied Dopamine. T.C. Napier. Dept of Pharmacol, Loyola Univ of Chicago, Maywood, IL 60153.

The response of ventral pallidal (VP) neurons to microiontophoretically applied dopamine (DA) was studied in chloral hydrate anesthetized rats to determine if subpopulations respond differentially to this neurotransmitter. To characterize neuronal subpopulations, the following were recorded: histological placement, firing rate (Hz), firing pattern, action potential amplitude and duration, wave form (monophasic, biphasic or triphasic), and the direction of initial deflection of the action potential (negative or positive).

Forty-two percent of 101 VP neurons responded to DA (0.2M, 5-60nA); firing rates were decreased in 29 cells and increased in 13. Computer-generated cross tabulations revealed that, as compared to non-responders, cells which were suppressed by DA had a slower firing rate ($18.8^{\pm}1.9$ vs $11.6^{\pm}1.6$ Hz). Additionally, these cells had action potentials which were smaller ($716^{\pm}317$ vs $92^{\pm}46$ uV) and biphasic (61% vs 72%) with a negative initial deflection (53% vs 97%). Cells which were excited by DA did not differ from non-responders. These data suggest that a distinct subpopulation of VP neurons can be identified, based upon certain electrophysiological characteristics and their responses to DA.

ALTERATIONS IN CONCENTRATIONS OF 3-METHOXY-4-HYDROXYPHENYLETHYLENEGLYCOL (MHPG) IN THE PARAVENTRICULAR NUCLEUS (PVN) AND SUPRAOPTIC NUCLEUS (SON) REFLECT THE ACTIVITY OF NORADRENERGIC (NE) NEURONS PROJECTING TO THESE HYPOTHALMIC REGIONS. K.J. Lookingland, L. Ireland*, Y. Tian*, J. Manzanares and K.E. Moore. Dept. of Pharmacol/Toxicol, Mich. State Univ., East Lansing, MI 48824

In the rat brain MHPG, a major metabolite of NE, exists predominantly as a conjugate and, as such, cannot be quantified using HPLC coupled to a electrochemical detector. In the present study, an acid hydrolysis procedure for deconjugating MHPG was developed and utilized to determine MHPG concentrations in the PVN and SON following procedures that activate NE neurons. MHPG was not detectable in untreated samples, but following acid hydrolysis significant amounts of MHPG were measured in the PVN and SON. Activation of NE neurons by physical restraint or the administration of the α_2-adrenoceptor antagonist idazoxan increased MHPG concentrations in both the PVN and SON. On the other hand, electrical stimulation of the locus coeruleus increased MHPG concentrations in the PVN, but not in the SON, which is predominantly innervated by NE neurons originating in sub-coeruleus regions of the pons-medulla. These results indicate that procedures that activate NE neurons increase MHPG concentrations in the PVN and SON. The concentration of this metabolite should be a useful index of the activity of NE neurons projecting to these hypothalamic nuclei. (Supported by NIH grant NS24113.)

BEHAVIORAL SENSITIZATION TO APOMORPHINE DEVELOPS THROUGH BOTH ASSOCIATIVE AND NONASSOCIATIVE PROCESSES. B. A. Mattingly and J. E. Gotsick*, Department of Psychology, Morehead State Univ., Morehead, KY 40351

In three experiments, male rats received intermittent SC injections of apomorphine (APO:5.0 mg/kg) or vehicle (VEH) and were tested for locomotor activity. In Exp. 1, rats received either nine paired or unpaired exposures to APO and the test environment. In Exp. 2, rats were either tested for activity or returned to their homecage following each of ten APO or VEH injections. In Exp. 3, rats were given either daily VEH injections or APO and VEH injections alternated daily for 26 days. Following the pretreatment phase in each experiment, all rats were tested for activity following an APO injection. Major findings were: (a) both paired and unpaired APO exposures produced behavioral sensitization, but the magnitude of the sensitization effect was greater for the paired group; (b) rats sensitized to APO displayed no evidence of conditioned hyperactivity when tested following a VEH injection; (c) rats pretreated with APO without activity testing displayed significant sensitization when subsequently tested for activity; and (d) significant sensitization to APO was observed when neither test apparatus cues nor injection/handling cues were reliably associated with APO treatments. These findings indicate that behavioral sensitization to APO develops through both associative and nonassociative processes.

ELECTRON MICROSCOPIC IDENTIFICATION OF LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) IMMUNOREACTIVITY IN OLFACTORY PLACODE-DERIVED NEURONS L.M.Zheng, D.W.Pfaff and M.Schwanzel-Fukuda. Rockefeller University, New York, New York.

LHRH neurons originate in the olfactory placode and migrate into the forebrain along branches of the terminalis and vomeronasal nerves (Nature,1989, 338:161-164). The present study examined, in mouse, the ultrastructure of these LHRH-ir neurons during migration and found that the subcellular location and density of LHRH-ir product varied with the location of the LHRH-ir cells along the migratory route. LHRH-ir neurons, first detected at E 11 in the epithelium of the medial part of the olfactory placode just before migration, showed LHRH-ir product heavily accumulated around the outer nuclear envelope and in the lumen of the rough endoplasmic reticulum (rER) adjacent to the nuclei. From E 11.5 through E 14, large numbers of LHRH-ir cells were seen in cords on the nasal septum, with LHRH-ir product distributed throughout their cytoplasm as well as around their nuclei and in the lumen of the rER. Neither Golgi apparatus nor LHRH neurosecretory granules were seen in the LHRH neurons from E 11 to E 16, and no synapses were found on these cells. By E 18, LHRH neurons were seen in the forebrain and LHRH-ir beaded neurites formed dense plexuses in the OVLT and in the ME.

NEONATAL GONADECTOMY HAS GENOTYPE DEPENDENT EFFECT ON BRAIN DOPAMINE SYSTEMS AND BEHAVIOR.
P. Kabai*, I. Sziraki*, A. Lajtha and C. Vadasz. Div. Neurochemistry, The Nathan S. Kline Institute, Orangeburg, N.Y. 10962.

Recent studies demonstrated, that perinatal antiandrogene treatment lowered Tyrosine hydroxilase (TH) activity in dopaminergic brain areas in a strain dependent manner (Vadasz, Cs. et al., Hormones and Behav., 22:528, 1988). Here we wished to address the question whether this "critical period" is restricted to prenatal development, or neonatal orchiectomy would also have strain dependent organizational effects on brain dopamine systems.

Male offspring of three inbred mouse strains (BALB/cJ = C; C57BL/6ByJ= B6; CXBI/ByJ= I), known to have high (C), medium (B6) and low (I) TH activity, were gonadectomized within 24 hours after birth (25-28 animals per strain), and sham operated at adult age. Males of the same strains castrated at adult age served as controls.

Day-1 gonadectomy tended to lower TH activity in four brain areas and had a "fear-reducing" effect on open-field behavior in the C and B6 strains, however these variables were not affected significantly in the I strain.

The results provided evidence that in mice (1) the developmentally sensitive period of brain dopamine systems in terms of TH activity includes early postnatal development and (2) the "sensitivity" to testosterone deprivation by Day-1 orchiectomy is genotype dependent.

MORPHOMETRIC ANALYSIS OF CULTURED HYPOTHALAMIC TYROSINE HYDROXYLASE AND NEUROPHYSIN CELLS. M. Morris*, B.A. Bennett, J. Clodfelter*, D.K. Sundberg*, Department of Physiology and Pharmacology, Wake Forest University Medical Center, Winston-Salem, NC 27103.

Studies were performed to characterize the effect of a depolarizing KCl stimulus on specific hypothalamic cell types. Hypothalamic cultures were stained immunochemically for neuron specific enolase (NSE), neurophysin (NP) or tyrosine hydroxylase (TH) and neuronal density and size were quantitated. The cultures were prepared from neonatal hypothalami which were enzymatically dispersed. Control or KCl treated (25 mM) cultures were fixed after 7 days and stained for NSE, NP or TH. KCl caused a universal increase in cell size. The cell area was increased from 99.4 and 123 mm^2 in the controls to 140.3 and 167.7 mm^2 in the KCl cultures (NP and TH, respectively). A change in the pattern of NP cell size was also noted. The KCl treatment resulted in a greater proportion of large NP positive cells (144.2 vs.84.5 um^2). With regard to cell density, the most marked effect was on the NSE population. The cell density was 117.9/mm^2 as compared to 223.4/mm^2 in the KCl treated cutures. There was also an increase (29%) in the number of NP positive cells, while the density of TH cells was not altered. This morphometric study illustrates that treatment with a depolarizing stimulus has specific effects on cultured hypothalamic neurons. It enhances survival of the total neuron population as well as increasing the size of TH, NP and NSE cells.

DEVELOPMENT OF TYROSINE HYDROXYLASE (TH)-IMMUNOREACTIVE NEURONS IN THE CHICK EMBRYONIC BRAIN.
J.A. Wallace, A.J. Vallejos*, A.A. Romero*, P.C. Allgood*, and I. Lopez-Colberg. Dept. of Anatomy, Univ. of New Mexico Sch. of Med., Albuquerque, NM 87131.

The development of catecholaminergic (CA) neurons in the embryonic chick brain has been investigated previously by fluorescent histochemical methods. Here, we have compared the results of these earlier studies with an examination of the ontogeny of CA neurons investigated by anti-TH immunocytochemistry. TH-containing cells were demonstrated by the peroxidase ABC method of staining paraffin sections. Embryos were examined at intervals of 5,7,9,15 and 21 (E21) days of incubation. The earliest immunoreactive cells were found at E5. Numerous immature TH-immunopositive neurons were present in rostral portions of the lateral hypothalamus. By E7, at least 3 distinct groups of deeply-stained cells were observed throughout the hypothalamus, while also staining was detected in a small number of cells within the region of the developing substantia nigra. With further progression, the majority of CA cell groups defined histochemically in the adult chicken were recognizable in the E9 embryo. By E15, the mature distribution and number of cells in the various brainstem CA nuclei were clearly evident. The results of our immunocytochemical study demonstrate the presence of TH in neurons of the early chick embryo brain that far precedes the earliest histochemical detection of CA in these cells. Overall, though, the differentiation of CA nuclei appears to lag far behind that of central serotonergic systems.

SEROTONIN AND MORPHOGENESIS DURING NEURULATION AND CRANIOFACIAL DEVELOPMENT IN THE MOUSE. D.L. Shuey*#, R. Thomas*, M. Yavarone*, H. Tamir, T. Sadler* and J. Lauder. Dept. of Cell Biology and Anatomy and #Curr. in Toxicology, Univ. of North Carolina Sch. of Med., Chapel Hill, NC 27599.

We have previously identified numerous uptake sites for serotonin (5-HT) in epithelial structures of the developing craniofacial region of the gestational day (GD) 12 mouse embryo, and serotonin binding protein (SBP) in adjacent mesenchyme, suggesting a possible role for 5-HT in epithelial-mesenchymal interactions (Lauder et al., Develop. 102:709, 1988).In the present study, GD 9-12 mouse embryos were cultured in the presence of 5-HT or one of its precursors. In some cases, an MAO inhibitor and/or 5-HT uptake inhibitor were added. Sites of 5-HT uptake or synthesis and SBP localization were then identified using immunocytochemistry. 5-HT immunoreactivity (IR) was seen in the heart, visceral yolk sac, gut, thyroid, limb-bud epithelium, eye primordium and specific regions of the neural epithelium, in addition to the sites previously identified at GD 12. Only the heart and yolk sac seemed to be sites of 5-HT synthesis. At GD 9, SBP IR appeared throughout the mesenchyme but became more localized in the older embryos adjacent to epithelial sites of 5-HT uptake. 5-HT IR was also found in the ectoplacental cone at GD 9, and in the placenta of older embryos suggesting that the maternal embryonic blood supply may provide a source of 5-HT in vivo.

HELISOMA EMBRYOGENESIS: MORPHOLOGICAL, BEHAVIORAL AND NEURAL DEVELOPMENT. K. McKenney and J.I. Goldberg. Dept. of Zoology, Univ. of Alberta, Edmonton, T6G 2E9.

Embryos of the fresh water snail, Helisoma trivolvis, are accessible to developmental and behavioral studies throughout embryogenesis. In vivo and in vitro studies have established this as a useful model system for comparing neuronal development with adult plasticity and regeneration. The objectives of this study were to quantitatively describe the stages of embryogenesis and the temporal sequence of gangliogenesis. Morphological (scanning electron microscopy) and behavioral criteria were used to define embryo stages, which were expressed as a percentage of the duration of embryogenesis. Gangliogenesis was analysed using light microscopic histological techniques. Cilia-driven spinning, the first recognizable behavior, began at 20% of embryonic development (stage E20). Other embryonic behaviors and their onset were cardiac beating, body wall contractions (both at E45), ciliary crawling (E50) and coordinated buccal rasping (E70). Gangliogenesis also began at E20, with the formation of the cerebral ganglia. Next to form was the pedal ganglia, at E25, followed by the buccal ganglia (E30), the pleural ganglia (E35) and finally, the parietal/visceral ganglia at E40. Morphologically, the characteristic veliger and juvenile forms appeared at E30 and E50, respectively.

EFFECTS OF SEROTONIN ON INTRACELLULAR CALCIUM IN EMBRYONIC AND MATURE *HELISOMA* NEURONS. J. I. Goldberg, L. R. Mills and S. B. Kater. Dept. of Zoology, University of Alberta, Edmonton, Alberta, T6G 2E9 and Program in Neuronal Growth and Development, Colorado State University, Fort Collins, CO 80526.

In cultures of dissociated embryonic or adult *Helisoma* neurons, serotonin either stimulates or inhibits outgrowth in a large portion of the neurite population. Since calcium has been implicated in the regulation of neurite outgrowth in an identified neuron, we now examine intracellular calcium in dissociated embryonic and mature neurons using the Fura2 method. The main goals of this study are to compare calcium levels in developing and regenerating neurons, and to determine how serotonin influences intracellular calcium concentration throughout the neuronal population. In embryonic neurons, calcium levels declined significantly as a function of days in culture (day 3: 120.1 ± 9.8 nM, N=15; day 11: 68.9 ± 6.4 nM, N=49). In regenerating adult neurons, calcium levels were characteristically higher (149.4 ± 12.5 nM, N=110), and extended over a greater range than in the embryonic neurons. In both embryonic and adult cultures, the mean calcium concentration was increased after addition of 50 µM serotonin. When examined on an individual neuron basis, serotonin increased the calcium concentration in approximately 50% of the neurons. Thus, although the effect of serotonin on neurite outgrowth can be stimulation or inhibition, its effect on intracellular calcium is primarily stimulation.

DEVELOPMENT OF NEUROPEPTIDE EXPRESSION IN SYMPATHETIC GANGLIA OF THE BULLFROG TADPOLE; EVIDENCE FOR SPECIFICATION BY THE PERIPHERY. W.D. Stofer and J. P. Horn Dept. of Physiology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

These experiments determined the expression of immunoreactivities (-IR) for tyrosine hydroxylase (TH), 150 kD neurofilaments (NF), neuropeptide Y (NPY), leuteinizing hormone releasing hormone (LHRH), calcitonin gene-related peptide (CGRP) and substance P (SP) in the developing bullfrog sympathetic system. Staged tadpoles were perfused with 4% paraformaldehyde, and sections containing paravertebral ganglia 9 and 10 and the hindlimbs were processed for indirect immunofluorescence.

By stage III, axons containing NF-IR are already present in ganglia 9 and 10. Subsets of the axons contain LHRH-IR, CGRP-IR, and SP-IR. However, these fibers do not appear to make synaptic contacts with most postganglionic neurons based on their sparsity and the absence of synaptic boutons. At stage III, TH-IR is present only in a few postganglionic neurons. NPY-IR first appears in postganglionic neurons at stage XI. Some NPY-positive cells are TH-negative at stage XII. Subsequently, the proportions of neurons expressing TH-IR and NPY-IR gradually increase. Synaptic boutons and the adult pattern of NPY-IR appear after stage XVIII. Formation of functional nicotinic synapses in the ganglia (Marshall, Soc.Neurosci.Abst.8: 866,1982) thus occurs at least 15 stages after the arrival of preganglionic and sensory axons.

Tadpole stages are largely defined by the emergence and development of the hindlimbs which are the primary targets of neurons in sympathetic ganglia 9 and 10. We therefore examined developing hindlimbs for TH-IR and NPY-IR. Between stages IV-XI, TH-positive axons are found primarily within bundles in the mesenchyme. By stage XII, well before the appearance of bouton-like structures in the ganglia, TH- and NPY-positive axons are present around subdermal blood vessels. The adult pattern of TH and NPY staining in skin begins to emerge around stage XV in concert with differentiation of the skin glands. Together, our results suggest that postganglionic neurons contact their peripheral targets before being innervated by preganglionic axons and that ganglionic synapse formation and expression of NPY-IR may depend upon the differentiation of peripheral targets. Supported by NIH grant NS21065.

EXPRESSION OF NEUROACTIVE SUBSTANCES IN THE DEVELOPING CHICK SYMPATHO-ADRENAL SYSTEM. J.E.García-Arrarás, A.M. Lugo*, L.Medina* and R.Martínez. Dept. Biology, Univ. of Puerto Rico, Río Piedras, Puerto Rico 00931.

In the sympatho-adrenal system subpopulation of cells express different neuroactive substances. We have used immunocytochemistry and radioimmunoassays (RIA) to study the expression of immunoreactivity similar to met-enkephalin (M-ENK), neuropeptide Y(NPY) and serotonin (5HT) in the adrenal and in the paravertebral ganglia of the chicken throughout development. Immunoreactivities to the two neuropeptides and the monoamine are expressed from very early in both the adrenal and sympathetic ganglia primordia. The same cells are known to express catecholamines and somatostatin raising the possibility that some cells might be expressing five neuroactive substances at this early developmental stage. However, their pattern of expression differs. 5HT and NPY seem to be present in all chromaffin cells while M-ENK is preferentially expressed by a subpopulation. RIA shows that the amount of NPY/protein increases during embryonic and posthatching development reaching a maximal value in the adult. M-ENK/protein values decrease during development, with a maximal value early in sympathoadrenal differentiation. In the sympathetic ganglia M-ENK and 5HT are expressed transiently. NPY, on the other hand, is expressed all throughout development by about 30% of the neuronal population. The amount of NPY increases during embryonic development reaching its maximal value before eclosion.

Our results show that each neuroactive substance has a particular expression pattern in the developing sympathoadrenal system, suggesting that the phenotypic expression and development of each neuropeptide and monoamine are controlled by specific factors. DEVELOPMENT OF VASOACTIVE INTESTINAL PEPTIDE IMMUNOREACTIVITY IN NEURONS IN THE CHICK PROVENTRICULUS. Miles L. Epstein. Dept of Anatomy, University of Wisconsin, Madison, WI 53706.

Enteric neurons develop from neural crest cells which migrate, proliferate, and differentiate within the gut. Factors that regulate the number and the transmitter phenotypes of the enteric neurons are unknown. We have carried out studies to describe the development of neurons in enteric ganglia in different regions of the developing chick gut, with the aim of pinpointing the time when critical developmental decisions are made. Gut from embryos, hatchlings, and 4-5 week old chicks was fixed and immunostained with antisera to VIP. Tissue from hatchlings and 4-5 week old animals was removed, incubated in organs baths with media containing colchicine, fixed, and immunostained. Whole mounts of myenteric ganglia from the chick proventriculus (secretory portion of the avian stomach) were prepared and the number of VIP-stained cells in a ganglion was counted. At 6.5 days of incubation (d.i.), small clusters of VIP neurons (1 or 2) are found throughout the proventriculus with more VIP cells at the proventriculus-gizzard junction than at the proventriculus-esophageal junction. Fiber connectives between the ganglia became prominent at 7.5-8.5 d.i. The number of VIP neurons per ganglion peaks at 15.5 d.i. A large number of VIP cells (approximately 2/3 of the peak value) was observed in ganglia from 4-5 week old animals incubated in colchicine. This information will be useful in describing when decisions about neuron number and transmitter phenotypes are made. (Supported by NSF BNS 8820658 and NIH 32978.)

404.11

MODULATION OF ADRENERGIC EXPRESSION BY THE TRICYCLIC ANTIDEPRESSANT DESIPRAMINE (DMI). M. Sieber-Blum and J.-M. Zhang. Department of Anatomy and Cellular Biology, Medical College of Wisconsin, 8701 Watertown Plank Road, Milwaukee, WI 53226.

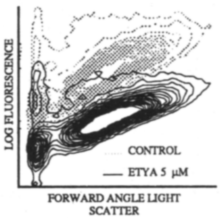
Catecholamine fluorescence (FIF) in clonal cultures of quail neural crest cells is suppressed by norepinephrine uptake inhibitors (Sieber-Blum & Silverman, Neurosci. Abstr. 11, 808, 1985). We here report that transport of tritiated NE was developmentally regulated and that the inhibitory effect was reduced when the addition of DMI (10uM) was delayed, indicating that the cells were most sensitive during the early stages of their in vitro development. Exposure to DMI for 3-day time blocks at various stages of development did not significanty decrease the number of colonies containing FIF-positive cells ($p > 0.57$). However, continuous exposure to DMI caused a pronounced decrease in the number of tyrosine hydroxylase ($p=0.0001$) and dopamine-β-hydroxylase ($p=0.0006$) immunoreactive cells. These data suggest that a) DMI acts before overt expression of the adrenergic phenotype, b) DMI is nontoxic, c) a chronic exposure is necessary, and d) the drug alters catecholaminergic enzyme levels. We conclude that the NE uptake system may play a role in adrenergic development, and that tricyclic antidepressants may influence adrenergic neurogenesis during embryonic development. Supported by USPHS grant HD21423.

BIOCHEMICAL AND PHARMACOLOGICAL CORRELATES OF DEVELOPMENT II

405.1

AN INHIBITOR OF ARACHIDONIC ACID METABOLISM, ETYA, DECREASES OXONOL FLUORESCENCE IN ACUTELY DISSOCIATED VERTEBRATE SPINAL CORD CELLS K.S. Madden*, A. Prasad*, S.V. Smith*, A.E. Schaffner and J.L. Barker. (Spon. R. Nelson) Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892

The function of essential fatty acid (EFA) metabolism in cells is often probed using drugs that reduce the release of eicosanoids from intact cells. We studied the effects of four of these drugs (indomethacin, BW755C, SKF525A or ETYA; 1 µM-1 mM) on cell populations (ca. 20,000/trial) from the embryonic chick (E4.5-8) or rat (E15-18) using flow cytometry and oxonol, a voltage-sensitive dye. ETYA, the acetylenic analogue of arachidonic acid (AA; 5,8,11,14-eicosatetraenoic acid), was the only drug to produce a highly consistent effect. As shown, the drug decreased the signal intensity of most cells, a dose-dependent effect (range: 1-15 µM). ETYA acted on cells depolarized by the cationophore gramicidin, but not when cells were polarized near the potassium equilibrium potential. ETYA seems to increase the potassium conductance of the dissociated cells (neurons, neuroblasts and glioblasts) but the mechanism is uncertain. Each drug used is known to block one or more of the oxygenase pathways that convert AA and certain other EFAs to eicosanoids. ETYA may polarize the embryonic cells by some action unrelated to oxygenase inhibition.



405.2

THE PRENATAL EFFECTS OF SKF 38393, A D-1 AGONIST, ON THE BIOCHEMISTRY AND BEHAVIOR OF NEONATAL RATS. A. Shemer and P.M. Whitaker-Azmitia. Dept. of Psychiatry, SUNY at Stony Brook, NY 11794.

We have developed an in vivo model to assess the role of neurotransmitters during development. In our present study we administered the D1 agonist SKF 38393 1mg/kg to pregnant Sprague Dawley rats from D12 of gestation to parturition. The resultant offspring showed lasting changes in the high affinity uptake of 3H-5HT, indicative of terminal density and in the binding to spiroperidol. On PND 15 the treated neonates were less active in the open field and alternated less than their controls in a spontaneous alternation paradigm. At 90 days neonates were trained in a fixed ratio operant task and, when challenged with serotonergic drugs and dopaminergic drugs, showed significantly less sensitivity to both classes of drugs in a dose dependant manner. The presence of a dopaminergic agonist during gestation produced changes in both the serotonin and the dopamine system which indicates an interaction between the two systems during development, causing a compensatory increase in the outgrowth of the unaffected transmitter system.

405.3

THYRIOD HORMONES ALTER THE POSTNATAL DEVELOPMENT OF THE 68 KD NEUROFILAMENT PROTEIN IN THE CEREBRAL CORTEX: AN IMMUNOCYTOCHEMICAL ANALYSIS. Nancy J. Woolf, Justin D. Oh*, and Larry L. Butcher. Laboratory of Chemical Neuroanatomy, Dept. of Psychology, University of California, Los Angeles, CA 90024-1563, U.S.A.

Rat pups were made hyperthyroid by administering 1 mg/kg triiodothyronine i.p. daily. Other pups were made hypothyroid by providing 0.3% propylthiouracil in the diet of the dams. Hyperthyroid, hypothyroid, and euthyroid pups were sacrificed at 1, 2, 3, and 4 postnatal weeks. Immunostaining for NF 68 was observed in pyramidal cells throughout the cerebral cortex. In the 1 week postnatal brain very weak NF 68 staining was observed. At 2 weeks postnatally the NF 68 immunoreaction product was increased in intensity and was concentrated in the perikarya and proximal apical and basilar dendrites. At 3 and 4 weeks postnatally, the immunoreactivity was greater in the distal apical and basilar dendrites of cortical pyramidal cells and less product was found in the cell body as compared to the second postnatal week. Thyroid deficient rat pups showed markedly fewer dendritic processes compared to normal and hyperthyroid pups. Moreover, hypothyroidism retarded the appearance of NF68 in distal dendrites during development. At 3 and 4 weeks NF68 was still restricted to proximal apical and basal dendrites and cytoplasm. [Support: USPHS grant NS 10928 to L.L.B.]

POST-MITOTIC NEUROMUSCULAR DIFFERENTIATION OF CREATINE KINASE IN POST-NATAL DEVELOPING RAT. O.C. Ramírez, G. Licea* and E. Jiménez*, Depto. de Bioquímica, Centro de Investigación y de Estudios Avanzados-I.P.N., México, D.F. 07000.

Shainberg *et al* (Dev.Biol.25:1,1971) reported 9.20,4.80, 2.27 and 2.20 creatine kinase (CK) U/mg prot. in rat extracts of white muscle, brain, red and heart muscles respectively, whereas liver, kidney and spleen extracts contained only about 0.06 U/mg prot. Irrespective of its blastodermic origin, white muscle and brain contained 4 and 2 times as much CK as either red or heart muscles. Such values could be used as post-mitotic tissue-specific molecular markers. However, we found that the differential expression of CK, in brain and heart only, is regulated in such a way that both tissues showed, almost in parallel, similar values of cytosolic CK specific activity along rat post-natal development and ageing. In contrast to the previous report, skeletal muscle CK values (at least 3 times higher than those of brain and heart) coincided only in morphology of CK developmental patterns. Skeletal muscle to heart-and to brain-CK specific activity ratios had always values greater than 4, except at 370 days, which was only about 2. Contrarily to the established view, it was found that "mature" heart and brain tissues synthesize the BB-CK and MM-CK isoenzyme type, besides their typical "tissue-specific" CK dimers. Shifts in peaks of CK activity and electrophoretic migration distance of isoenzymes seem to reflect differential tissue-specific requirements of ATP formation, that cannot be entirely covered by anaerobic glycolisis and the Krebs cycle.

405.5

THE RAT PUP ULTRASONIC ISOLATION CALL: STUDIES OF SEROTONERGIC AND ADRENERGIC NEUROTOXINS. I.T. Winslow and T.R. Insel. Lab. Clin. Sci., NIMH, NIHAC, Poolesville, MD. 20837.

Rat pups removed from their nest and siblings emit a highly stereotyped and well characterized isolation call in the ultrasonic range. This behavior is selectively sensitive to the effects of benzodiazepines, opiate agonists and antagonists, and monoamine reuptake inhibitors. To further characterize the role of serotonin and noradrenergic transmission in the postnatal development of social behavior, selected doses of MDMA and DSP-4 were administered subcutaneously to pups beginning 24 hr after birth. 10 mg/kg MDMA was administered once or twice daily, for 4 days. 50 mg/kg DSP-4 was administered once on day 1. To balance the experimental treatment design, both DSP-4 and vehicle control pups were injected with saline twice daily for 4 days, and pups in all treatment groups were tested 6, 9, 12, and 15 days postnatally. Body weight and core temperature of pups receiving the high MDMA dose were significantly reduced compared to DSP-4, and saline treated pups. The isolation call of MDMA, but not DSP-4 treated pups was reduced 40-80% depending on the total dose of MDMA received. The frequency of cell crossing and a measure of geotaxis were both unaffected by neurotoxins. Curiously, the effects of monoamine uptake inhibitors on vocal behavior (Winslow and Insel 1989) were not blocked in MDMA and DSP-4 treated pups when expressed as % pretreatment rate. Preliminary data indicate that early postnatal administration of MDMA is associated with a at least a 40% decrease in the number of cortical 5HT uptake sites indicating loss of 5HT terminals (as measured by ^{3}H-paroxetine binding), as well as decreased 5HT and 5HIAA content (as determined by HPLC). In additional experiments we are studying the effects of prenatally administered MDMA on the behavior of both pups and dams. Our data suggest an important role for serotonin in the maintenance of mother-infant attachment behaviors.

EARLY DEVELOPMENT OF THE CHOLINERGIC SYNAPSE IN RAT AND HUMAN DRAIN. A. Biegon, O. Bar-Peled* and M. Segal*. Weizmann Institute of Science, Rehovot, Israel.

The ontogeny of Acetylcholinesterase (AChE), muscarinic and nicotinic cholinergic receptors was investigated by quantitative histochemistry (Biegon, A. and Wolff M., J. Neurosci. Methods 16:37, 1986) and autoradiography (Biegon et al., J. Neurochem. 51:1381, 1988) in rats from day 16 of fetal life and in human abortuses (16, 18 and 24 weeks gestation). Each marker exhibits a unique and region-specific developmental pattern. Rat AChE activity increases very slowly in cortex, striatum and hippocampus and is still very low compared to adult levels on postnatal (PN) day 21. Cholinergic (e.g. medial septum) nuclei reach adult levels much earlier, between 7 and 14 days PN. In the human fetus, too, adult AChE levels are found in the substantia innominata by the 24th gestational week, while cortical, hippocampal and striatal activity is very low. Nicotinic (α-bungarotoxin) binding is very high at the earliest ages tested in rat and human hippocampus, followed by a decline towards adult levels. Muscarinic receptors in both species increase monotonously with age in most regions, reaching adult or higher levels by day 14 PN in rats and week 24 in humans. High receptor levels preceding the appearance of a presynaptic marker suggest the receptors may play a developmental role in the cholinergic synapse.

RETINOID REGULATION OF GENE EXPRESSION IN THE EARLY NERVOUS SYSTEM. S-C. Chen*, I. Lugo, A.K. Hall*, J. Hempstead*, R.Ziai* and J.I. Morgan*(SPON: R. Wurzburger). Dept. of Neuroscience, Roche Institute. of Molecular Biology, Roche Research Center, Nutley,NJ 07110.

Using HPLC techniques we have identified polypeptides whose expression; (a) alters during normal neuroembryogenesis and (b) are regulated by retinoic acid in neural cell cultures. Several candidate molecules have been isolated, sequenced and their mRNAs and genes cloned by recombinant DNA techniques. A 43 amino acid polypeptide, termed thymosin beta-10, was found to be very abundant in the early rodent nervous system but both the protein and mRNA disappeared shortly after birth. In several neuroblastoma cell lines, including B104, retinoic acid causes a marked increase in beta-10 protein and mRNA. These particular cell lines are thought to represent relatively immature neural cells. Cell lines that have a more differentiated character, such as PC12 as well as most glia, do not show regulation by retinoids. We have isolated a series of genes that encode proteins closely related to beta-10. A comparison of their structures reveal a number of interesting features. First, the 3'-flanking regions of the cDNAs are highly conserved (95%) whereas the 5' flanking sequence is not. Second, the 3' region of beta-10 contains a nuclease recognition motif that is absent in thymosin beta-4, a closely related homologue of beta-10. Since beta-4 is not regulated by retinoids neither does its expression change during neurodevelopment, retinoids might act by stabilizing the beta-10 mRNA. The promoter regions of the homologous genes are dissimilar and we are presently determining whether they contain retinoid response elements. In a general sense, the results reported here suggest that retinoids may regulate gene expression, and thereby development, in the early central nervous system.

PRENATAL COCAINE EXPOSURE INCREASES BRAIN GANGLIOSIDE AND NEUTRAL GLYCOLIPID CONTENT OF NEONATAL RATS. K.C. Leskawa*[1], G.H. Jackson*[1], C.A. Moody*[2] and L.P. Spear[2] (SPON: K. Reid). [1]Dept. Anat. Sci. & Neurobiol., Univ. Louisville Sch. of Med., Louisville, KY 40292, and [2]Dept. Psychol. and Centers for Develop. Psychobiol. and Neurobehav. Sci., SUNY-Binghamton, Binghamton, NY 13901.

Recent studies have reported behavioral dysfunctions in offspring exposed in utero to cocaine, along with alterations in the DA system, but few other biochemical studies have been conducted. Given their role in fiber extension and neuronal maturation, gangliosides and neutral glycolipids were analyzed in whole brains of offspring exposed gestationally to cocaine. Pregnant Sprague-Dawley rats were injected either with 40 mg/kg/3cc cocaine or saline on gestational days 8-20. Offspring were fostered to surrogate dams, sacrificed on postnatal days 1 (P1) and 11 (P11), and brain gangliosides and neutral glycolipids were purified and quantitated. Cocaine-exposed offspring exhibited markedly elevated levels of both total gangliosides and neutral glycolipids at P1 ($p<0.0001$), but not at P11. These transient elevations are in contrast to those reported after fetal alcohol exposure, where decreases in brain gangliosides have been observed. These data suggest that biochemical consequences of gestational exposure to cocaine, or its Ca^{++} chelating metabolite benzoylecgonine, may be far-reaching and not restricted merely to the DA system. Supported by DA04478 (L.P.S.) and NS21057 (K.C.L).

ANTIBODY 3D10 IMMUNOREACTIVITY IN MONOAMINERGIC NEURONS IN POSTNATAL RATS. S.A. Tobet, J.E. Crandall, R. Whorf*, and T.O. Fox. E.K. Shriver Center, Depts. of Biochemistry and Developmental Neurobiology, Waltham, MA 02254 and *Washington Univ., Div. Biology & Biomedical Sciences, St. Louis, MO 63110.

The 3D10 monoclonal antibody (Tobet & Fox, Dev. Brain Res., In press, 1989) recognizes an antigen(s) in developing monoaminergic cell groups. Significantly more 3D10 immunopositive cells are observed in perinatal compared to adult rats. The experiments reported here examine the neurotransmitter specificity of 3D10 immunopositive cells, as well as the presence of 3D10 immunoreactive antigen(s) in neuronal terminal regions and the protein(s) recognized.

Double-label immunofluorescence reveals that 3D10 is colocalized in multiple catecholaminergic cell bodies in the brainstem, specifically in cells immunopositive against tyrosine hydroxylase (TH) in the locus coeruleus, the sub coeruleus, and the A4 and A5 cell groups. In these regions all 3D10 immunopositive neurons were also TH immunopositive. The reverse was not true, i.e., some TH immunopositive neurons were not 3D10 immunopositive. Further characterization of co-localization with indoleamine cell groups is now in progress. The presence of 3D10 immunopositive neuronal terminals was examined in the cerebral cortex, a major target for fibers of brainstem monoaminergic neurons. 3D10 immunoreactive fibers appeared in different cortical lamina compared to serotonin or TH. Following gel electrophoresis and immunoblot procedures antibody 3D10 appears to recognize a single high molecular weight protein in brainstem regions.

We conclude that monoclonal antibody 3D10 recognizes a protein that is synthesized in developing monoaminergic cell bodies and transported to selected terminal regions. We hypothesize that the developmental disappearance of 3D10 immunoreactivity relates to maturational events in specific monoaminergic circuits. Supported by grants HD20327-TOF/SAT, NS24386-JEC and HD04147-MR.

EFFECTS OF PROMETHAZINE HCl ADMINISTRATION TO GRAVID RATS ON BRAIN AMINE LEVELS IN OFFSPRING. M.S. Stanford* and J.H. Patton. Department of Psychology, Baylor University, Waco, TX 76798.

Promethazine HCL (Phenergan®, Wyeth) is a phenothiazine widely used for its anti-emetic and sedative potential during human pregnancy. Previous research has suggested that neuroleptic administration to gravid rats results in neurochemical changes in their offspring (Rosengarten & Freidhoff, Science, 203:1133,1978). Sprague-Dawley rats were exposed to Promethazine HCL during both the gestation and lactation stages of development. The drug was injected into dams subcutaneously at a dose of 3.0 mg/kg per day. Offspring's brains were assayed at both 1 and 21 days of age for norepinephrine and dopamine. Assays for serotonin were done on 21 day old brains. Pup brain weights did not differ across groups at either 1 or 21 days of age. Catecholamine assays on 1 and 21 day old brains showed no statistically reliable difference in either NE or DA levels [1 day old brains: NE (Promethazine = 0.0391 µg/gm, Control = 0.0327 µg/gm, p = 0.2010), DA (Pro = 0.0216 µg/gm, Con = 0.0223 µg/gm, p = 0.9355); 21 day old brains: NE (Pro = 0.0873 µg/gm, Con = 0.0958 µg/gm, p = 0.9277), DA (Pro = 0.0348 µg/gm, Con = 0.0383 µg/gm, p = 0.9277)]. Serotonin assays on 21 day old brains did show a statistically reliable difference in serotonin levels (Pro = 0.4212 µg/gm, Con = 0.4936 µg/gm, p = 0.0480) with the promethazine group having 0.0724 µg/gm less brain 5-HT than controls. The results of this study suggest that the 5-HT2 receptor decreasing properties of promethazine HCl affect not only adults (Andree et al., Psychopharm. Bull., 20: 349, 1984) but can affect offspring when exposed transplacentally or through milk.

COCAINE AND AMPHETAMINE MODULATION OF ULTRASOUNDS AND ACTIVITY IN NEONATAL RATS: DIFFERENTIAL EFFECTS WITH DA AND NE DEPLETION. P.Kehoe,K.Wilson-Miller*,& A.Purbeck*
TRINITY COLLEGE, HARTFORD CT, 06106

Separation from the dam and siblings causes neonatal rats to emit ultrasonic vocalizations. Neurochemically, ultrasounds are influenced by opioids in that morphine decreases and naltrexone increases calling. Endogenous opioids may reduce vocalizations over time. The NE agonist, clonidine, greatly increases calling and NE antagonist, yohimbine, reverses the response and decreases them. Cocaine while increasing activity quiets the isolate. Amphetamine heightens activity and produces a dose-dependent flattening of the normal linear reduction in calling over time. At first the pup calls less but this calling continues over time with no abatement as seen in controls. To differentiate the DA and NE influence on these behaviors, pups were injected ICV on Day 3 with 6-OHDA and preinjected IP with either imipramine (NE uptake inhibitor) or GBR (DA uptake inhibitor). On Day 10 pups demonstrated a dissociation of cocaine's hyperactivity effect in that DA depleted pups were much less active than NE depleted pups who were as active as controls. Ultrasounds after the various treatments presented a more complex profile. In general, pups depleted specifically of NE vocalized less than DA-depleted pups while both groups called less than controls. Cocaine's quieting effects were not seen in DA-depleted infants. The data suggest that isolation calling in rat pups require the presence of NE while cocaine's activity and quieting effects are more specifically DA mediated.

405.12

DEVELOPMENTAL ANALYSIS OF ADENYLATE CYCLASE ACTIVITY AND ITS MODULATION BY SEROTONIN IN THE CNS OF *APLYSIA*. T.N. Chang*, E.A. Marcus, Y. Dudai, and T.J.Carew (SPON: N. Donegan). Depts. Biol. & Psychol., Yale University, New Haven, CT 06520

Sensitization in *Aplysia* is mediated at least in part by serotonin (5HT), which in turn is known to elevate cAMP by activation of adenylate cyclase. Since sensitization does not emerge until relatively late in juvenile development (Late Stage 12, Rankin & Carew, 1988), we were interested in whether development of cyclase activity or its capacity for modulation by 5HT plays a role in the developmental emergence of sensitization. As a first step in this analysis, we have begun to examine cylase activity and its modulation by 5HT at different stages of juvenile development.

Cyclase activity was assessed in whole-CNS homogenates by examining the conversion of [α-^{32}P]ATP into cAMP. To establish normative data, we first examined adult animals. Confirming previous results, significant cyclase activity was detected ($\bar{x}$ specific activity = 40 ± 5 pmol/min-mg protein, $p<.001$, N=12 [6 homogenates]), and was significantly increased by 5HT (10^{-4}M) ($\bar{x}$ increase over basal stimulation = 66%, $p<.003$, N=7 [6 homogenates]). We next examined Early Stage 12 juveniles. Here also, there was significant basal activity of the cyclase ($\bar{x}$ specific activity = 54 ± 4 pmol/min-mg protein, $p<.001$, N=5 [2 homogenates]), which was also enhanced by 5HT ($\bar{x}$ increase = 45%, $p<.02$, N=4 [2 homogenates]). Preliminary experiments show comparable results in Late Stage 12 juveniles.

Our results show that in Early Stage 12 adenylate cyclase is present in the CNS of *Aplysia* and can be modulated by 5HT. Thus far we have only studied the effect of 5HT on whole-CNS homogenates. We are currently examining: (1) other transmitters (e.g. SCP_B), and (2) homogeneous populations of neurons (e.g. sensory neuron clusters), to more quantitatively assess the role of adenylate cyclase and its modulation in the development of sensitization.

WHAT IS THE RELATIONSHIP BETWEEN THE DEVELOPMENT OF CHOLINERGIC SPINAL NEURONS IN MURINE SLICE CULTURES AND TOTAL CELL PROTEIN PRODUCTION? M.S. Pidherney and H.L. Stewart*, Dept. of Biology, Texas Woman's University, Denton Texas 76204.

The goal of our research is to establish an in vitro mammalian spinal preparation suitable for investigating the mechanisms underlying motor pattern generation. One model system currently under investigation is a slice culture consisting of 300 um thin transverse sections of fetal mouse lumbar spinal tissue. In order to determine the suitability of this preparation for future electrophysiological studies, we have characterized both the cholinergic neurons and the total cell protein production in the cultures at different ages.

Cultures were stained for identification of cholinergic neurons at day 0 (day of culturing), three weeks, and five weeks in culture. At corresponding intervals, cultures were incubated in medium containing ^{35}S-methionine and examined for 1) precipitable counts via scintillation counting, and 2) electrophoresis protein patterns. Preliminary data suggest that changes in size and density of cholinergic neurons at the sampled intervals in culture is clearly reflected in total cell protein profile. **(NIH1R29 NS 25250-01)**

NEONATAL NOREPINEPHRINE (NE) DEPLETION AND ENRICHED HOUSING: HANDLING METHOD IS IMPORTANT! M.J. Saari, B. Buchwald*, K. Fisher*, and J. Kleim*(SPON: B. Pappas).Neuroscience Research Unit, Nipissing University, North Bay, Ontario. P1B 8L7.

This experiment evaluated the effect of two handling methods on the development of enrichment mediated behaviour in NE depleted and vehicle (VEH) injected rats. Newborn male Wistar rats were injected sc., either with 6-OHDA (50 mg/kg) or vehicle (1.0 mg/ml; ascorbic acid in saline) within the first 12 and the first 24 hours after birth. After weaning at day 25, all rats were housed under "enriched" conditions for 35 days (social housing and daily, exposures to an open field containing "toys"). During the daily transfer of the rats into the open field half were lifted by the base of the tail and the rest were lifted while supporting the abdomen. Once a week, the rats were videotaped and the videotapes scored "blind" for rearing, activity and boli. Since the body-lifted rats reared more than tail-lifted the results suggest that different handling methods may influence the development of enrichment mediated behaviour.

PROTEIN EXPRESSION IN POSTNATAL HIPPOCAMPUS AS VISUALIZED WITH SDS/PAGE. M. Murtaugh*, L.L. Dix*, J.M. Miller*, R.S. Nowakowski+ (Spon: M.F. MacDonnell). *Dept. of Biological Sciences, Rutgers University, Piscataway, NJ 08855, +Dept. of Anatomy, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

Analysis of whole hippocampal tissue from C57Bl/6J or BALB/cByJ mice by polyacrylamide gel electrophoresis (SDS/PAGE) was performed on postnatal days: 0, 2, 5, 14, 38. Using 12% one-dimensional gels, the banding patterns characteristic of the younger ages (P0, P2, P5) were distinct from the banding patterns of the older mice. In the younger samples (P0, P2, P5), six distinct bands were identified which were clearly diminished or undetectable in the older tissue. The bands had approximate molecular weights of: 1) 200-225 kD, 2) 97-100 kD, 3) 62-68 kD, 4) 52-57 kD, 5) 45-48 kD and 6) 28-31 kD. In addition, two bands (approx. 52-57 kD and 45-48 kD) which were absent prior to P5 appeared or became increasingly more visible in the older mice. The differences between the two age groups were clear using silver stained gels but some of the differences could also be detected with Coomassie blue staining. The developmental significance of these differences in banding patterns is as yet unclear. They could represent changes in gene expression or changes in posttranslational modifications of proteins. Further fractionation of these complex protein samples followed by two-dimensional gel electrophoresis may more definitively demonstrate specific changes in protein composition during hippocampal development.

405.16

BRAIN NEUROTRANSMITTERS INCREASE DURING OLFACTORY IMPRINTING IN COHO SALMON *(ONCORHYNCHUS KISUTCH)* AND ARE AFFECTED BY EXPOSURE TO PROPYLTHIOURACIL. S. O. E. Ebbesson, J. Smith, C. Co*, and L. M. Cheek*. Institute of Marine Science, University of Alaska Fairbanks, Fairbanks Alaska 99775,USA and Department of Psychiatry, LSU School of Medicine, Shreveport, LA 71130, USA.

About the time coho salmon head for the ocean some 18 months after hatching a smolt transformation (ST) occurs that include a color change, the development of salinity tolerance, downstream migratory behavior, and conversion from territorial behavior to schooling. High plasma thyroxine levels at this time suggests the involvement of this hormone in some aspects of ST, including the olfactory imprinting. We report here that whole brain content (as determined by HPLC) of dopamine (DA), norepinephrine (NE), serotonin (5-HT), 5-HIAA, and glycine (Gln) increase significantly during this period of neural plasticity while other putative transmitters such as glutamate, aspartate and GABA show no such change. The ratio of 5HT/5HIAA as an indicator of serotonin turnover is also increased during the ST. The data suggest that 5-HT, DA, NE and Gln may be involved in the neural mechanisms underlying olfactory imprinting, behavioral changes and neural plasticity associated with smolt transformation. We also report here that plasma thyroxine levels increase dramatically at the beginning of ST, about a week before whole brain content of serotonin (5-HT), dopamine (DA), norepinephrine (NE) and glycine (Gln) increase suddenly and decrease to normal levels in 14 days. Fish treated with 10 ppm propylthiouracil showed essentially no increase in plasma T_4 levels, yet the brain levels of 5-HT, DA, NE and Gln spiked at the same time and to the same extent as the controls. Return to normal brain levels was significantly delayed in PTU treated fish demonstrating that this substance has very specific effects on the brain.

Supported by grants from NIH and Alaska Sea Grant College Program.

CHRONIC PERINATAL NALTREXONE ADMINISTRATION DECREASES NEURONAL PACKING DENSITY. J.V. Seatriz* and R.P. Hammer, Jr. Dept. Anatomy & Reprod. Biol., Univ. Hawaii Sch. of Med., Honolulu, HI 96822.

It has been suggested that endogenous opioid peptides may act as inhibitory trophic factors in the central nervous system during ontogeny. This study examined the effect of chronic opiate receptor blockade on packing density of neurons and glial cells in various brain regions.

Osmotic minipumps (Alzet, 2ML4) which administered 10 mg/kg/day naltrexone or saline vehicle until weaning were implanted subcutaneously on gestation day 12 in timed-pregnant Sprague-Dawley rats. Litters were culled to 8 at birth. Male pups were anesthetized by hypothermia at postnatal day 6 and perfused intracardially with 10% neutral buffered formalin, brains were removed to postfix and graded sucrose solutions, blocked and sectioned at 20 m on a freezing microtome, and sections were mounted and stained with thionin. Neuronal and glial packing density was determined by cell counts using calibrated, high resolution microscopy in each layer of primary somatosensory (S_1) and motor (M_1) cortices and in the preoptic area of the hypothalamus (POA). Constant perinatal opiate receptor blockade significantly reduced neuronal packing density in medial (42%) and lateral (36%) POA, layers II-V of S_1 (18-35%), and layer V of M_1 (33%). Glial cell packing density, however, was unaffected by naltrexone treatment in any region.

Thus, naltrexone treatment during the cell proliferation and growth period has effects which are selective by cell type and brain region. It is unclear, as yet, whether reduced neuronal packing density reflects increased cortical thickness or reduced neuronal number. (Supported by USPHS awards DA04081, NS01161, RR08125 and RR03061.)

CREATINE KINASE ACTIVITY IN PRIMARY CULTURES OF NEURONS, ASTROCYTES AND OLIGODENDROCYTES. P. Manos* and J. Edmond* (SPON: G. K. Bryan) Dept. of Biol. Chem., UCLA School of Medicine, Los Angeles, CA 90024

Creatine kinase (CK) catalyzes the reversible transfer of a high energy phosphate from ATP to creatine. The BB-isozyme is present in high quantities in brain and is thought to play a crucial role in energy maintenance reactions. Primary cultures of purified populations of neurons and glia, derived from embryonic and neonatal rat cerebra, respectively, were used to elucidate the cellular compartment and function of CK in developing brain. Cytosolic CK activity in neurons reached maximal levels of 4 U/mg protein by Day 4, and stayed constant throughout the 14 day culture time. The CK activity in astrocytes cultured for 20 days was comparable to the activity determined in whole brain at the time of birth (3 to 4 U/mg), and was 1.5-fold higher than the activity determined at the time the cells were isolated. In contrast, the CK activity in oligodendrocytes (Day 20) was about double that found in the mixed glia cultures, 3- to 4-fold higher than that determined in astrocytes and almost 7-fold higher than the activity measured when the cells were isolated. The activity of the myelin marker 2',3'-cyclic nucleotide phosphohydrolase was over 10-times greater in the oligodendrocytes than in astrocytes. The relatively higher levels of CK in oligodendrocytes indicate that CK may have an additional role in myelinogenesis. (Supported by NIH grant HD 06576).

DIFFERENTIATION, MORPHOGENESIS AND DEVELOPMENT: CHANNELS AND CURRENTS

DEPOLARIZATION INDUCED CHANGES IN SYNAPTIC VESICLE PROTEIN (P65) EXPRESSION IN SCG EXPLANTS. K.M. Linderman* and K.F. Greif. Bryn Mawr College, Bryn Mawr, PA 19010.

P65 is an integral membrane protein of synaptic vesicles which appears in synaptic vesicles of various transmitter types. We have shown p65 to be regulated transsynaptically in the superior cervical ganglion (SCG) of adult and neonatal rats (Greif and Trenchard, Synapse 2:1, 1988). Pharmacological studies suggest that impulse activity is at least partially responsible for this transsynaptic regulation in vivo (Greif, J. Neurosci. 6:3628, 1986).

In vitro studies in defined medium support the role of depolarization in the regulation of p65 levels. Neonatal SCG explants treated with the sodium channel ionophore, veratridine, or elevated potassium express 60% more p65 than controls. This effect is reversible by tetrodotoxin treatment.

P65 was metabolically labelled in neonatal SCG explants to determine the role of new protein synthesis in the increases of p65 caused by depolarization. SCG explants were treated with veratridine for 36 hours and then pulse-labelled with ^{3}H-leucine for two hours in the presence or absence of cycloheximide, a protein synthesis inhibitor. P65 was purified on a monoclonal antibody affinity column. Elutions were counted for two minutes on a scintillation counter. Veratridine treatment significantly increases ^{3}H-p65 over control levels by 64% (SEM=7, $P<0.005$, t-test). Concurrent cycloheximide treatment with veratridine lowers ^{3}H-p65 levels by 43-105%. Results suggest that increases of P65 seen after depolarization treatments are due to an increased rate of synthesis and not to the unmasking of a preexisting pool of antigen.

406.2

DIFFERENTIATION AND SURVIVAL OF ACETYLCHOLINESTERASE-POSITIVE NEURONS IN CULTURE: THE ROLE OF CHEMICAL DEPOLARIZATION AND COCULTURE WITH ASTROCYTES J.Dymshitz*, R.Malach, S.Amir and R. Simantov (SPON:S.Yehuda) Dept. of Neurobiology and Genetics, Weizmann Inst. Rehovot, Israel

Chemical depolarization of rat striatal primary cultures was used as a model for studying the influence of neuronal activity on the survival and differentiation of acetylcholinesterase (AChE)-expressing neurons. Embryonic (E15) striatal cells were plated on poly-ornithine or on a monolayer of astrocytes and cultured in serum-free or serum-containing medium. In all the four combinations veratridine had a dose-dependent inhibitory effect on AChE-expressing cells; at 5μM there was a loss in AChE-containing neurites whereas a higher concentration of veratridine led also to a marked reduction in the number of stained cell bodies. These effects could be elicited also by 40-60 mM KCl. The neurite loss induced by 5μM of veratridine was reversible, so that a partial recovery has been observed after veratridine removal. Blockers of voltage-sensitive Ca^{++} channels - verapamil and nifedipine - did not alter the effect of veratridine, while TTX blocked partially veratridine effect. These observations and the finding that astrocytes increased the basal number of AChE-positive cells in serum-free cultures indicate that the neuronal activation state and the interaction with glial cells affect the survival and expression of AChE-positive neurons.

CYCLIC AMP MIMICS NERVE GROWTH FACTOR IN THE INDUCTION OF SODIUM CHANNELS IN PC12 CELLS. D. Kalman[1], B. Wong[1], M. J. Cline[2], and P. H. O'Lague[1*], Departments of Biology[1] and Hematology-Oncology[2], University of California at Los Angeles, Los Angeles, CA 90024.

Nerve growth factor (NGF), a trophic agent for several classes of vertebrate neurons, acts as a differentiation signal for PC12 cells, a model neuronal system. NGF causes neurite outgrowth and expression of voltage-gated Na^+ channels. Neurite outgrowth involves in part activation of protein kinase C (PKC), but mechanisms controlling channel expression are not known. Using patch-clamp techniques to assay for functional channels, we found that agents activating cAMP-dependent protein kinase (PKA), but not PKC, mimicked NGF's ability to induce channels. p21, a ras oncogene product that can activate PKC and mimic NGF-dependent neurite outgrowth, also did not induce channels. Thus, Na^+ channel induction and neurite outgrowth in PC12 cells appear to occur by activation of different protein kinases. Supported by NSF (88-20861), NCI (CA15619) and the Giannini Foundation.

IN VIVO DEVELOPMENT OF POTASSIUM CURRENTS IN EMBRYONIC CHICK LIMB MOTONEURONS. D.P. McCobb and K.G. Beam. Physiology Dept., Colorado State Univ., Fort Collins, CO 80523.

The differentiation of many aspects of both muscle and motoneuron phenotype in the chick have been shown to be controlled by functional activity of the neuromuscular system. We have previously described developmental changes in Ca++ and Na+ currents in chick limb motoneurons which take place while other aspects of the system are developing, and might therefore control (and/or be controlled by) these other developmental events. Here we report large changes in motoneuronal K+ current expression, an immediate consequence of which is a maturational change in the action potential waveform. Whole-cell patch clamp methods were used to study voltage dependent K+ currents and action potentials in limb motoneurons isolated from E4, E6, and E11 chick embryos (HH stages 21-23, 28-29, and 37, respectively). During this span limbs differentiate from primordia to well-defined and motile structures. All recordings were made on the day following dissociation. Limb motoneurons were identified by retrograde labelling with the carbocyanine dye, DiI. Delayed rectifier type K+ currents (I_K), which were greatly reduced by TEA+, were relatively large even at E4, and increased moderately (25%) by E11. By contrast, A-type K+ current (I_A, identified by rapid voltage dependent inactivation and 4-AP sensitivity) was small or absent in E4 motoneurons, and increased greatly (~16 fold) by E11. The action potential duration was greatly affected by 4-AP but not TEA+, and was found to decrease during development by approximately 50%. We conclude that the development of I_A in embryonic motoneurons reduces the duration of the action potential, which, by affecting synaptic transmission, might influence activity-dependent developmental events in nerve or muscle. We are currently studying the effects of blocking neuromuscular transmission on the development of K+ and other currents in motoneurons using curare-induced paralysis.

MEMBRANE POTENTIAL RESPONSES OF EMBRYONIC RAT SPINAL CORD CELLS ANALYZED WITH DIGITAL IMAGING MICROSCOPY. M.K. Walton, A.E. Schaffner, and J.L. Barker. Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

The development of membrane excitability in embryonic rat spinal cord cells was examined using computerized digital imaging of fluorescent voltage-sensitive dye signals. The system included an epifluorescence microscope, image intensifier, video camera and digitizing frame grabber. Four independent images were averaged for each measurement. This technique allows simultaneous recording of an entire field of cells under baseline conditions and in response to successively applied electrolytes or ligands.

Rat spinal cords from embryonic days 13, 15 and 17 (E13, E15, E17) were enzymatically dissociated into single cell suspensions, placed in culture dishes and allowed to adhere for ca. 2 hours. Culture dishes were perfused with continuously flowing solutions containing 100 nM of the voltage sensitive oxonol dye $DiBaC_4(5)$. These cells all showed reproducible and reversible changes in fluorescence indicating membrane depolarization in response to increases in extracellular potassium concentration. Veratridine was used as a probe for the voltage sensitive sodium channel. The depolarizing response to veratridine was largely absent from cells dissociated at E13 but developed progressively so that by E17 almost all cells responded. This response was blocked by tetrodotoxin or use of sodium-free medium.

This preliminary data suggests that the sodium-selective voltage-sensitive channel activated by veratridine develops subsequent to E13 in the rat spinal cord, in agreement with previous reports using flow cytometry (Mandler, et.al., (1986) Neurosci. Abs. 12:1349). This technique will be useful for investigations of cultured cells as it allows for simultaneously recording multiple cells while at the same time monitoring each individual cell's response to successively applied conditions.

DEVELOPMENT OF VOLTAGE-GATED ION CHANNELS IN DIFFERENTIATING HYPOTHALAMIC NEURONS. **R. E. Petroski and H. M. Geller. Department of Pharmacology, UMDNJ Robert Wood Johnson Med. Sch. and The Graduate School, Rutgers University, Piscataway, NJ 08854.**

Neuronal proliferation occurs between E13 and E17 in the rat hypothalamus. Following terminal division, neuronal precursors undergo the complex process of cytodifferentiation producing a heterogeneous population of neurons. This process involves the expression of gene products which confer the mature neuronal phenotype. In order to study the events of neuronal differentiation, we use the embryonic rat hypothalamus as a source of precursors and newly differentiating neurons. We employ the whole cell patch-clamp technique to examine ion channel expression during the first week of development *in vitro*.

Recordings could be obtained from neurons as early as five hours following dissociation. These cells are small, round (10μm dia) and have one or two processes which are starting to "bud." In the first 24 hours, none of the neurons expressed Na^+ currents; 50% of these neurons exhibited small (50 pA) outward currents carried by K^+. At 1-3 d.i.v., neuronal somata grow to a maximum 15-20 μm dia. and acquire a more mature neuronal morphology: bipolar, tripolar and pyramidal shapes with longer processes. At this time Na^+ currents could be detected in 50% of the neurons and all neurons express sustained outward currents; additionally, an inactivating outward component is seen in most cells. The inactivating component is quite large relative to the sustained component when measured immediately after rupturing the cell membrane. However it "runs down" quickly suggesting that it may be Ca^{2+}-dependent. By the 4th day in culture, all neurons display Na^+ currents. Over this time course, ion channel density increases since the amplitude of both inward and outward increases until a steady state is achieved at about one week in culture.

These data taken together with our immunocytochemical studies support a coordinated temporal expression of ion channels and neurotransmitter phenotype in developing hypothalamic neurons in culture. Supported by NIH.

ANALYSIS OF CALCIUM FLUXES IN DISSOCIATED RAT NEURONS DURING EMBRYONIC DEVELOPMENT. **S. M. O'Connell*, J. P. Grierson, R. E. Petroski and H. M. Geller. (SPON. G. S. F. Ling) Department of Pharmacology, U.M.D.N.J. - Robert Wood Johnson Medical School and The Graduate School, Rutgers University, 675 Hoes Lane, Piscataway, NJ 08854.**

The development of functional voltage-sensitive Ca^{++} channels (VSCC) in the embryonic rat brain can be investigated using the technique of flow cytometry and the fluorescent probe, INDO-1. This approach obviates the possibility of premature differentiation when embryonic cells are placed into tissue culture. Freshly isolated cells were incubated in INDO-1,AM for 30 minutes followed by a rinse and a 30 minute post-incubation period. The efficiency of INDO-1 hydrolysis was tested for each experiment by permeabilizing to calcium with ionomycin. Analysis of dissociated cell preparations from the E14-E17 hypothalamus reveals that about 25 to 30% of cells respond to a stimulus of 25 or 50 mM KCl with a significant influx of Ca^{++}, whereas only 10 to 15% of cells obtained from the cerebral cortex are responsive under the same conditions and from the same embryonic ages. The Ca^{++} flux in dissociated cells from both regions is markedly attenuated by 1 μM nifedipine, however only the cortical cells appear to be potentiated by 1 μM Bay K. The responding cells from both regions have been shown to be neurons by sorting on the basis of $[Ca^{++}]_i$ maintaining in culture and then staining for MAP2 immunoreactivity. Furthermore, the detection of K^+-stimulated Ca^{++} uptake by astrocytes is believed to be negligible, since experiments with cultured astrocytes indicate a very low level of INDO-1 hydrolysis by these cells. It can be inferred that cells from the embryonic brain preparations also express voltage-sensitive sodium channels (VSSC) since the addition of tetrodotoxin attenuates the Ca^{++} response when compared with KCl alone, suggesting that in the control situation depolarization is augmented by Na^+ influx through VSSC. Supported by NIH NS25168.

DEVELOPMENT OF SPONTANEOUS ACTIVITY OF HYPOTHALAMIC NEURONS IN DISSOCIATED CULTURE. D.S.F.Ling, R.E.Petroski, W.Chou*, H.M.Geller. Department of Pharmacology, UMDNJ-Robert Wood Medical School and Graduate Programs in Biomedical Engineering and Pharmacology, Rutgers University, Piscataway, N.J. 08854.

Past studies have shown that many neurons in the hypothalamus exhibit spontaneous, phasic discharge of action potentials. Such neurons have been been associated with temperature control and regulation of hormone release. We have exmained the development of sponataneous firing in dissociated hypothalamic neurons using a loose patch recording method. Hypothalami were dissected from E17 rat brains and plated onto a confluent monolayer of cortical astrocytes. Extracellular recordings were made from neurons, which are 10-25 μM diameter, with patch electrodes beginning 1 day *in vitro*. Seal resistances ranged from 20-80 MΩ on these neurons in this recording mode, with optimal input resistances ranging from 40-60 MΩ. Over the course of 6 weeks *in vitro*, 45 of 165 neurons exhibited spontaneous discharge of action potentials. The percentage of neurons displaying spontaneous discharge patterns increased with time in culture, suggesting a developmental aspect to the production of action potentials. There did not appear be any correlation between basal firing frequency and time in culture. Preliminary studies using high Mg^{2+}/low Ca^{2+} bath solutions suggest that spontaneous activity in young neurons may not be dependent on synaptic activity.

The results of this study taken together with our patch clamp and immunocytochemical studies suggest that spontaneous activity in culture develops after ion channel expression and neurotransmitter synthetic activity. (Supported by NIH NS 25168)

NEUROTOXICITY: METALS AND ORGANICS

LOW DOSE HYDROGEN SULFIDE AND ITS EFFECTS ON THE DENDRITIC ARBORIZATION OF DEVELOPING CEREBELLAR PURKINJE CELLS. R.S. Hannah*, R. Bennington*, and S.H. Roth, Depts. of Anatomy and of Pharmacology and Therapeutics, and Div. of Toxicology, Faculty of Medicine, University of Calgary, Calgary, Alberta, Canada. T2N 4N1.

Hydrogen sulfide (H_2S) is an environmental pollutant which can produce severe effects on the adult CNS;however, little is known as to its effects on the developing CNS. Pregnant rats (Sprague-Dawley) were exposed to either 20 pmm or 50 pmm H_2S for 7 hours per day in an environment chamber from Day 7 postcoitus until Day 21 postnatal. Controls were similarly treated including placement in an environmental chamber flushed with room air. On Day 21 postnatal, representative pups from each litter were euthanized, the cerebella removed and processed for Golgi staining. Ten complete Purkinje cells were selected from each group and analysed, using vertex analysis (Berry & Finn, Proc. R. Soc. Lond. B. 221:321, 1984). At both exposure concentrations, there was a significant increase in vertex path length suggesting an increased distance between each new generation of branches. New growth occurred toward the pial surface and internally but was restricted laterally. The treated cells exhibited an unusually high non-random growth pattern. In summary, both treatments produced significant growth changes in the dendritic arborization. (Supported by Alberta Occupational Health and Safety Heritage Grant Program).

407.2

POSTNATAL LEAD EXPOSURE OF RATS DOES NOT PERTURB HIPPOCAMPAL ZINC CONCENTRATION. E. J. Kasarskis and T. M. Forrester*. Dept. Neurology and Toxicology, VA and Univ. of Kentucky Med. Ctrs., Lexington KY 40536-0084.

Postnatal lead (Pb) exposure alters the development of the hippocampus, a region of the brain rich in zinc (Zn). Because Pb is sequestered in this region, others have proposed that the manifestations of Pb toxicity may be caused by a Pb-induced reduction of hippocampal Zn. To test this hypothesis, we have measured Pb and Zn in microdissected hippocampal subfields after postnatal Pb.

Lactating dams ingested water containing either 0.2% or 2.5% Pb after parturition. Controls were either offered deionized water and food ad libitum or were pair-fed to the 2.5% Pb group. Pups were sacrificed at weaning. Hippocampal subfields were microdissected and analyzed for Pb and Zn using atomic absorption spectrophotometry. Despite a 6.3 fold accumulation of Pb in the 2.5% Pb group compared to controls, the concentration of Zn in the whole hippocampus was not perturbed. Moreover, the concentration of Zn in any hippocampal subfield was not altered by Pb exposure during postnatal development. Although Zn and Pb are both enriched in the hippocampus, these data indicate that they probably do not compete for binding to the same ligands. These results compliment the study of Petit and LeBoutillier (Neurotox 7:237, 1986) which demonstrated behavioral dissimilarities between postnatal Zn deficiency and Pb toxicity.

407.3

NEUROCHEMICAL EFFECTS OF PRENATAL LEAD EXPOSURE IN GUINEA PIGS. T.K. Rowles*, W.D. Blaker, and E. Tiffany-Castiglioni*. Va-Md Regional College of Veterinary Medicine, Blacksburg, Va 24061.

Blood lead (Pb) levels correlate with cognitive dysfunction in children, and umbilical cord blood levels indicate many children are exposed *in utero* to significant Pb levels. Since the effects of such exposure are still unclear, we are using the guinea pig as an animal model of prenatal exposure to further study this problem.

Guinea pigs were exposed to one of 3 levels of Pb daily during the last 2 trimesters of pregnancy. On postnatal day 38, their offspring were killed by head-focussed microwave irradiation and specific brain regions collected for analysis of neurotransmitter levels by HPLC-ED. Lead exposure resulted in no changes in maternal weight gain, litter size, birth weight, or neonatal growth rates. However, lead exposure did result in significant increases in metabolite levels of dopamine and serotonin in several brain regions. HVA levels increased with Pb treatment in frontal cortex, striatum, septum, thalamus, and inferior colliculus, but DOPAC levels did not change. Dopamine levels decreased only in the inferior colliculus. 5-HIAA levels also showed widespread increases, but serotonin levels did not change. There appears to be an increased metabolism of these neurotransmitters in animals exposed prenatally to Pb. Funded by BRSG, Virginia Tech.

INDUCTION OF NEUROFIBRILLARY DEGENERATION IN FETAL RABBIT MOTOR NEURON-ENRICHED CULTURES. R.M. Garruto and M.J. Strong*. LCNSS, NINDS, NIH, Bethesda, Maryland, 20892

A consistent feature of the aluminum-induced encephalomyelopathy of rabbits is the presence of neurofibrillary inclusions in motor neurons. To investigate the mechanisms underlying this phenomenon, we exposed fetal rabbit motor neuron-enriched cultures to varying concentrations of aluminum chloride.

At 16 days in culture, when all major neurofilament subunit proteins are present, the media was supplemented with either 10 mM, 1 mM or 100 uM aluminum chloride. Within 48 hours, the cultures exposed to 10 mM and 1 mM aluminum chloride developed refractile intracytoplasmic inclusions and rare focal neuritic swellings. By 96 hours these features were present in all cultures, with motor neurons exposed to 10 mM aluminum chloride developing signs of cell death. The inclusions demonstrated immunoreactivity with monoclonal antibodies against phosphorylated neurofilament.

These observations demonstrate that dissociated fetal rabbit motor neurons *in vitro* recapitulate the aluminum-induced neurofibrillary inclusions of rabbit motor neurons *in vivo*, thereby providing a dynamic model of aberrant neurofibrillary degeneration in nontransformed cells. (*Supported in part by a research fellowship from the Medical Research Council of Canada)

DEPRESSED HIPPOCAMPAL AND BASAL FOREBRAIN ACTIVITY OF CHOLINE ACETYLTRANSFERASE IN 15 DAY OLD PUPS FROM RATS INGESTING POLYCHLORINATED BIPHENYL. L.A. Meserve, L.M. Juarez de Ku, B.B. Surbeck*, C.A. Gaskins*, and J.A. Landis*.
Dept. Biol. Sci., BGSU, Bowling Green, OH 43403-0212

Polychlorinated biphenyl (PCB) is a ubiquitous environmental pollutant, the ingestion of which functions to the detriment of a number of physiological systems in adult animals. Recent studies in our lab have shown PCB feeding to pregnant and lactating rats to depress circulating thyroxine levels in their 15 day old pups. Since hypothyroidism has been shown to depress choline acetyltransferase (ChAT) activity in young rats it was of interest to determine whether PCB, administered through the mother, would have a similar effect. Female rats were fed PCB (Arochlor 1254) as 0.25% of a standard diet through pregnancy and lactation. Fifteen day old pups were decapitated, and the activity of ChAT in hippocampus and basal forebrain was estimated by the ability of an homogenate to incorporate ^{14}C-labelled acetyl-CoA into acetylcholine. When activity was expressed as nm labelled product generated/mg soluble protein/hr, PCB depressed hippocampal ChAT to about 60% of normal and that in basal forebrain to 40%. Thus it appears that PCB has undesirable effects on brain neurotransmitter systems. This may result from concomitant hypothyroidism or direct PCB effects. (Supported by BRSG #89-02).

POLYCHLORINATED BIPHENYLS DECREASE SPONTANEOUS AND D-AMPHETAMINE INDUCED LOCOMOTOR ACTIVITY IN THE ADULT RAT. R.F. Seegal, K.O. Brosch* and R. Okoniewski*. Wadsworth Center, NY State Dept. Health, Albany, NY 12201-0509.

Exposure of adult rats to polychlorinated biphenyls (PCBs) decreases regional brain biogenic amine function (Seegal et al., NSA, 14, Part 2 p. 885, 1988). To determine the functional significance of these changes we have examined the effects of PCBs and catecholaminergic drugs on locomotor activity.

We exposed adult rats to control chow or chow adulterated with 500 or 1000 ppm Aroclor 1254 for sixty days. Locomotor activity was determined every third day in infra-red photocell activity cages. Beginning on about post-exposure day 30 animals were injected i.p. with either saline, 0.25, 0.5 or 1.0 mg/kg d-amphetamine sulfate thirty minutes before testing.

Spontaneous activity in the PCB-exposed animals was significantly lower than in control animals. D-amphetamine significantly increased activity although PCBs attenuated the drug-induced increase in locomotor activity.

Thus, PCB exposure of the adult rat decreases both spontaneous and drug-induced locomotor activity. These effects on locomotor activity may be causally related to concomitant decreases in central catecholamines.

AGE-RELATED CHANGES IN CAPSAICIN-INDUCED DEGENERATION IN RAT BRAIN. T. Dinh* and S. Ritter (SPON: M. Hyde). Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

Capsaicin, a neurotoxin known for its ability to selectively damage small unmyelinated primary sensory neurons, is also capable of producing degeneration at certain highly specific sites along the entire neuroaxis in rats. In this experiment, we examined capsaicin-induced CNS degeneration in rats of different ages. Rats were anesthetized, injected systemically with a single high dose of capsaicin (75-100 mg/kg) or vehicle solution at 10, 15, 20, 25, or 30 days or 3 months of age and sacrificed at times optimal for observing capsaicin-induced degeneration (6-18 hr post injection). Brains and spinal cords were prepared and stained with cupric-silver. At sites where degeneration was present in all age groups, the staining was generally more intense in the 10-30 day old animals than in adults. Several areas of degeneration observed in 10-30 day old rat pups were not observed in adults: portions of the bed nucleus of the stria terminalis, the septohypothalamic nucleus, medial preoptic area, ventral reuniens nucleus, ventromedial hypothalamus, lateral habenula and sphenoid nucleus. In the ventrolateral geniculate and olivary pretectal nucleus, staining was intense in pups, but very light staining was sometimes also seen in adults. The intensity and location of staining was similar between 10 and 30 days except in the habenula and sphenoid nucleus where degeneration declined progressively between 10 and 30 days of age. Results suggest that the sensitivity of some CNS projections to capsaicin's toxicity is age-related. Factors contributing to this change in sensitivity are not known.

THE EFFECT OF CHRONIC ETHANOL CONSUMPTION ON CELL NUMBER IN THE MOUSE CEREBELLAR CORTEX, RMA Napper*and RJ Harvey
Dept Anatomy and Neuroscience Centre, Univ. of Otago, Dunedin, New Zealand.

In the present study, quantitative methods have been used to determine the changes in layer volumes and numbers of cells in the cerebellar cortex of adult mice following long term ethanol consumption. Three month old male BALB/C mice were exposed to ethanol vapour for nine hours per day. This regime was used on two groups (n=32) for 3 weeks; one group (A) was killed at the end of 3 weeks ethanol exposure while the second (B) had a 3 week 'ethanol free' recovery period (Phillips & Cragg, J.Stud.Alc., 45:475, 1984). Two further groups acted as controls. Individual layer volumes, Purkinje cell (Pcell) layer areas, total cerebellar volumes and Pcell numbers were estimated using the methods of Harvey and Napper (J.Comp. Neurol., 274:151, 1988). Cerebellar volumes (mm^3), cell layer areas (mm^2), Pcell densities ($x10^3/mm^2$) and Pcell total numbers ($x10^5$) (n=4) were respectively; 41.9±3.4, 157.2±5.0, 2.1±0.2, 3.24 (mean±s.d) (A-control); 37.9±2.9, 146.3±10.6, 2.2±0.3, 3.23 (A-alcohol); 40.5±8.0, 152.8±8.6, 2.0±0.3, 3.03 (B-control); and 40.0±6.7, 155.2±26.1, 2.1±0.3, 3.27 (B-alcohol). There is no significant difference in cerebellar volumes, Pcell layer areas, or total numbers in either group A or B. These results do not support the conclusions of Phillips & Cragg (op.cit.) and Tavares et.al. (Alc:Clin.Exp.Res., 11:315, 1987).

408.2

A MODEL TO STUDY THE EFFECTS OF CHRONICALLY INFUSED NEUROPHARMACOLOGICAL AGENTS ON DEVELOPING EMBRYOS. R. Roll*, T.A. Jones, UNMC College of Dentistry, Lincoln, NE 68583-0740 and B.J. Morley, Boystown Nat. Inst., Omaha, NE 68131.

The purpose of this investigation was to develop an experimental model that could be used to assess the effects of neuropharmacological agents on developing embryos in vivo. A method of chronic in ovo drug infusion was developed (fertilized eggs, *Gallus domesticus*). Neurophysiological effects of drug administration were assessed by recording compound action potentials of the vestibular nerve (Jones & Pedersen, Am. J. Otolaryn. in press, 1989). Nicotine (NIC) was chosen for the present study. Animals were divided into four groups: 1) control, 2) sham (vehicle only), 3) continuous drug and 4) drug followed by vehicle only. Catheters were implanted in 18 eggs and sealed in place under sterile conditions to enable continuous infusion of drug and vehicle (1cc 6.03 mg/ml over 10 days). The resulting nicotine levels in blood serum (SER) and extra- embryonic fluid (EEF) were determined (SER: 21.4 ± 6.5 ng/ml, COT 10.6 ±1.0 ng/ml; EEF: 97.0 ± 89.5 ng/ml). On the nineteenth day of development, the eggs were opened to access embryos and subcutaneous skull electrodes were placed. Vestibular response thresholds and input/output functions were determined. The animals were then decapitated, brains removed and prepared for receptor binding studies. H_3^* -nicotine was used in binding assays to estimate brain nicotinic acetylcholine receptor densities. The study demonstrates the usefulness of the avian model in research evaluating the consequences of exposing embryos to neuropharmacological agents.

408.3

THE EFFECT OF PRENATAL COCAINE EXPOSURE ON UMBILICAL CORD LENGTH IN FETAL RATS. S. Barron*, J.A. Foss* and E.P. Riley. Psychology Dept. University of New York, Albany, NY 12222.

With the dramatic escalation of cocaine abuse, there is increased concern regarding its' teratogenic potential. It has been suggested that cocaine may produce brief periods of fetal hypoxia. Since fetal hypoxia may be associated with reduced fetal movements, this study examined the effects of prenatal cocaine exposure on an indirect measure of fetal movement, umbilical cord lengths. Pregnant rats were intubated with either 0 or 60 mg/kg cocaine hydrochloride daily from gestation day (GD) 12 - 21 and umbilical cord lengths were measured on GD 21. Fetuses exposed to cocaine in utero had shorter umbilical cords than intubated controls. There were no differences in either placental or fetal body weights across the prenatal treatment groups suggesting that the cord length differences were not simply due to weight differences. These data suggest that maternal cocaine consumption may interfere with normal fetal movement. This work was supported in part by NIDA grant #DA04275 to EPR.

SWIMMING BEHAVIOR IN MICE SIRED BY ALCOHOL CONSUMING FATHERS. P.J. Bilitzke and E.L. Abel
Dept. of Ob/Gyn, Wayne State University School of Medicine, Detroit, MI 48201.

Male mice consumed liquid alcohol diets containing 25%, 10% or 0% ethanol derived calories (EDC). Animals receiving the 10 and 0% EDC diets were pair fed to those consuming the 25% EDC diet. After seven or fourteen weeks of consumption, males were bred to non-treated females. Offspring were tested for swimming behavior at 75 days of age. Offspring sired by alcohol-consuming males were more immobile regardless of duration of paternal alcohol consumption or housing conditions (group or isolated). Imipramine (5, 15 mg/kg) reversed this effect such that after drug treatment, alcohol-sired offspring were less immobile than controls. Propranolol (1, 3 mg/kg) eliminated the group differences. Yohimbine (1, 10 mg/kg) significantly increased immobility in all groups but did not reverse the effects of paternal alcohol consumption. Metergoline (1 mg/kg) increased immobility in all groups but did not reverse the effects of paternal alcohol exposure. AMPT (100 mg/kg) did not affect swimming behavior. These results extend the evidence for paternally mediated behavioral mutagenesis. Supported by P50 AA07606 and AA 06999.

EFFECT OF PRENATAL EXPOSURE TO ETHANOL ON GENE EXPRESSION DURING RAT BRAIN DEVELOPMENT. D. Maciejewski-Lenoir* and R. J. Milner.
Research Institute of Scripps Clinic, La Jolla, CA 92037.

There is considerable evidence that prenatal exposure to ethanol results in abnormal development of the nervous system. To investigate this phenomenon at the molecular level, we have analysed the effect of *in utero* exposure to ethanol on the postnatal expression of particular brain genes. Pregnant rats were exposed to ethanol vapor between days 8–21 of gestation, resulting in blood alcohol levels between 150 and 200 mg%. At birth, pups from the ethanol-treated rats and from untreated control animals were fostered to normal mothers. Ethanol-treated and control pups were sacrificed at different times after birth and RNA was extracted from four dissected brain regions: hindbrain, cerebellum, midbrain and cortex. The expression patterns of particular mRNAs were analysed on Northern blots and by solution hybridization. The mRNAs tested were chosen to represent genes expressed in different CNS cell types and included mRNAs encoding MAG/1B236, PLP, Tα1-tubulin and GFAP. The results show differences in mRNA expression between control and ethanol-exposed animals with some variation among brain regions. In general, the data indicate that ethanol causes a slowing or delay in the normal time course of expression of the marker genes during brain development and differences in their adult levels of expression. Supported in part by NIAAA Alcohol Research Center grant AA06420.

DEFICITS IN RADIAL MAZE LEARNING IN ADULT RATS FOLLOWING ALCOHOL EXPOSURE DURING THE BRAIN GROWTH SPURT: ASSOCIATION OF WORKING MEMORY IMPAIRMENTS WITH CA1 NEURON LOSS. C.R. Goodlett, D.J. Bonthius, E.A. Wasserman* and J.R. West, Univ. of Iowa, Iowa City, IA 52242.

The most serious aspects of fetal alchol syndrome (FAS) in humans are long-term deficits in cognitive function. Adequate models of permanent cognitive deficits in animals produced by alcohol exposure during development have been difficult to develop. We report here that alcohol exposure to neonatal rats during the brain growth spurt, comparable to that of the human third trimester, results in severe learning deficits in a radial maze task, including working memory deficits correlated with hippocampal cell loss in CA1. During postnatal days 4-9, rat pups were exposed to 7.5 g/kg (n=14) or 6.6 g/kg (n=16) of alcohol per day using artificial rearing procedures, which resulted in peak blood alcohol concentrations of 415 and 335 mg/dl, respectively. Control groups included artificially reared gastrostomy controls (n=16) and normally reared suckle controls (n=18). As adults, they were tested for 30 days on a 12-arm radial maze, in which six arms were consistently baited and six were unbaited. The alcohol-treated rats committed significantly more errors related to working memory (within-session repeated arm entries), and also more errors related to reference memory (initial entries into unbaited arms). However, the working memory deficits were much more severe. Cell counts on the rats sacrificed at 200 days old indicated that within the hippocampal formation, significant cell loss occurred only for field CA1 pyramidal cells, which were reduced by 16%-20%. There was a significant negative correlation (r=-.578) of working memory errors with CA1 cell counts, suggesting that in this model of FAS, deficient spatial information processing is associated with CA1 hippocampal cell loss. (Supported by NIAAA grants #AA05523 and AA07313).

408.7

ALCOHOL EXPOSURE DURING THE BRAIN GROWTH SPURT INDUCES PERMANENT MICROENCEPHALY AND NEURONAL DEFICITS IN RATS. J.R. West, D.J. Bonthius and C.R. Goodlett. (SPON: J.D. Coulter). Dept. of Anatomy, University of Iowa, Iowa City, IA 52242.

A rat model of alcohol-related developmental effects was used to examine the long-term morphological changes associated with developmental alcohol exposure. Sprague-Dawley rat pups were reared artificially over postnatal days (PD) 4-12 (a period of rapid brain growth similar to the human third trimester). On PD 4-9, alcohol-exposed groups received either 6.6 or 7.5 g/kg/day ethanol (administered as 7.5% and 8.5% v/v solutions, respectively) in 4 of the 12 daily feedings. Controls included artificially reared (gastrostomized) controls and normally reared suckle controls. Pups were fostered back to dams on PD 12, weaned on PD 21 and perfused on PD 200. Brain weights were measured. Cerebellar Purkinje cells in all 10 vermal lobules and hippocampal neurons in fields CA1, CA2/3 and CA4 were counted from single two-micron-thick sections. While adult body weights were not affected by the alcohol treatments, total brain weights were significantly smaller in both alcohol-treated groups, relative to controls. Both alcohol treatments resulted in permanent neuronal deficits. In the hippocampus, CA1 pyramidal cells were significantly reduced by both alcohol treatments, while CA2/3 and CA4 were not reduced by either treatment. There was a significant loss of Purkinje cells in the cerebellum, and some lobules were significantly more affected than others. The lobules in which Purkinje cells were most mature at the time of alcohol exposure (lobules I, II, IX and X) were the most vulnerable to Purkinje cell loss. Therefore, developmental alcohol exposure induces permanent neuronal loss which is population- and region-specific. (Supported by NIAAA grant AA05523.)

408.8

A SINGLE DAY OF ALCOHOL EXPOSURE IN NEONATAL RATS INDUCES CEREBELLAR PURKINJE CELL LOSS. B.L. Marcussen*, C.R. Goodlett and J.R. West. Univ. of Iowa, Dept. Anat., Iowa City, IA 52242.

The cerebellum in the neonatal rat is highly susceptible to ethanol-induced Purkinje cell death following exposure on postnatal days (PD) 4-10. We examined whether ethanol exposure on a single day during the brain growth spurt could induce Purkinje cell loss. Rat pups were assigned to one of four groups on PD 4: 6.6 g/kg/day ethanol group, 3.3 g/kg/day ethanol group, gastrostomy and suckle control groups. The ethanol and gastrostomy control groups were reared artificially. Ethanol-treated groups were given two consecutive ethanol-containing feedings on PD 4. All subsequent feedings were with milk formula alone. The rats given 6.6 g/kg ethanol had high peak blood ethanol concentrations (mean=353 mg/dl). Rats in the 3.3 g/kg group had significantly lower peak blood ethanol concentrations (mean=152 mg/dl). On PD 10 all rats were perfused, the brains extracted, postfixed and the cerebellar vermis isolated and embedded in JB-4. Purkinje cells were counted from 2 mm thick midsagittal sections stained with cresyl violet/saffronin O. Suckle and gastrostomy controls did not differ significantly in the overall number of Purkinje cells. The rats given 6.6 g/kg ethanol had significant reductions in Purkinje cells compared to all other groups ($p<.01$). Additional analysis revealed significant reductions in lobules 1-5 and 9-10 but not in lobules 6-8. The pups exposed to 3.3 g/kg ethanol demonstrated significant reductions in overall number of Purkinje cells compared to suckle controls but not compared to gastrostomy controls. The Purkinje cell loss in this study implies that a brief exposure to a relatively high blood alcohol level during the brain growth spurt, as may occur in "binge" drinking during the third trimester, may constitute an increased risk to vulnerable cell populations in the developing central nervous system. Supported by grant AA05523 to JRW.

408.9

ALCOHOL-INDUCED NEURONAL LOSS IN DEVELOPING RATS: DIFFERENCES IN VULNERABILITY AMONG CELL POPULATIONS. D.J. Bonthius, C.R.Goodlett and J.R. West. Dept. of Anatomy, University of Iowa, Iowa City, IA 52242.

A rat model of third trimester alcohol administration was used to examine differences in vulnerability to alcohol-induced cell loss among neuronal populations. Sprague-Dawley rat pups were reared artificially over postnatal days 4-10 (a period of rapid brain growth similar to the human third trimester). Alcohol-exposed pups received 4.5 g/kg/day ethanol in either 2 or 4 of the 12 daily feedings (administered as 10.2% or 5.1% v/v solutions, respectively). Controls included non-alcohol exposed gastrostomy controls and normally-reared suckle controls. On postnatal day 10, the pups were perfused with fixative, and the brains were removed. Two-micron-thick sections were cut horizontally through the midtemporal hippocampal formation, sagittally through the midline cerebellar vermis and coronally through the mid-olfactory bulb. From single sections, the following cell populations were counted: hippocampal neurons in fields CA1, CA2/3 and CA4, dentate gyrus granule cells, cerebellar Purkinje cells and olfactory bulb mitral cells. Cerebellar granule cells were estimated. Neuronal populations were not affected equally by the alcohol treatments. In the hippocampus, there was a significant loss only of CA1 pyramidal cells, and this reduction occurred only in the group receiving the high concentration (10.2%) solution. Cerebellar Purkinje cells and olfactory bulb mitral cells were significantly reduced in both alcohol-treated groups. Cerebellar granule cells were significantly reduced, but dentate gyrus granule cells were unaffected. These result demonstrate that neuronal populations differ considerably in their vulnerability to alcohol during development. (Supported by NIAAA grant AA05523 to J.R.W.)

EFFECTS OF MATERNAL ETHANOL CONSUMPTION PRIOR TO AND DURING GESTATION ON THE SPINAL CORD OF THE NEONATAL RAT. D.L. McNeill, E.L. Fagan*, C.H. Harris* and R.L. Shew*. Dept. of Anat. Sci., Univ. of Oklahoma, Oklahoma City, OK 73190

Maternal ethanol (ETOH) consumption during gestation has been demonstrated to induce alterations in the nervous system of the offspring. In this study the effects of maternal ETOH consumption on the neonatal spinal cord was examined. Six female Sprague-Dawley rats were placed on either an ETOH-containing liquid diet or an isocaloric ETOH-free liquid diet for 5 weeks, then mated. The diets were continued throughout gestation. On postnatal day 1, the litters were weighed and a mean weight/group determined. Four pups from each group whose weights were closest to the means were perfused, their C3 spinal cords removed, embedded and transverse thick sections of the entire cord obtained. Areal measurements were obtained using a computerized bit pad and the numbers of myelinated axons in the ventral funiculus (VF) assessed. While the mean weight of the pups exposed to ETOH was significantly reduced from the control group ($p<0.01$), no difference in the area of the C3 spinal cord or in the area of the grey matter was observed. However, the number of myelinated axons in the VF was significantly reduced ($p<0.01$) in the ETOH exposed pups. These results indicate that ETOH consumption prior to and during gestation does not effect the gross morphology of the spinal cord of the neonate, however, alterations at the axonal level are apparent.

DISTRIBUTION OF CALLOSAL PROJECTION NEURONS IN SOMATOSENSORY CORTEX OF RATS PRENATALLY EXPOSED TO ETHANOL. L.A. Kotkoskie* and M.W. Miller (SPON: R. Rieck). UMDNJ- Sch. Osteo. Med. & R.W. Johnson Med. Sch., Piscataway NJ 08854.

Prenatal ethanol exposure produces permanent laminar and cellular defects in neocortex. These malformations have been attributed to alterations in early developmental processes such as neuronal migration and differentiation. The present study examined the effect of gestational ethanol exposure on the laminar distribution of callosal projection neurons in mature rat neocortex. The subjects, 3-6 month old hooded rats, were the progeny of mothers prenatally fed a liquid diet containing 6.7% (v/v) ethanol, an isocaloric liquid control diet, or a chow diet. Horseradish peroxidase (HRP) was injected unilaterally into area 3 of primary somatosensory cortex. After a post-injection survival period of 2 days, each brain was processed for HRP histochemistry and stained with cresyl violet to identify laminar patterns. In control animals, callosal projection neurons were distributed in layers II-VI of the contralateral somatosensory cortex, but most HRP-positive neurons were in layers II/III and V of somatosensory cortex. In contrast, about 75% of the callosal projection neurons in ethanol exposed animals were in layers V and VI. We hypothesize that gestational ethanol exposure produces an abnormal distribution of callosal projection neurons in somatosensory cortex from the ectopic placement of cortical neurons or the abnormal differentiation of infragranular cortical neurons. MICRODIALYSIS,IN THE CISTERNA MAGNA,OF Na TRANSPORT INTO THE CEREBROSPINAL FLUID (CSF) SYSTEM. C.E. Johanson, N. Knuckey and A. Fowler*. Program in Neurosurgery, Dept. of Clin. Neurosciences, Brown Univer./ R. I. Hospital, Providence, RI 02902.

Microdialysis in vivo has been used to study extracellular compounds in CNS. This report describes intracranial dialysis to analyze CSF dynamics in rats. The choroid plexus is the major source of CSF, which is produced by active transport of Na from blood to ventricles. By injecting Na-22 into peripheral circulation and measuring its movement into CSF by microdialysis, one should obtain a measure of the rate of CSF formation.

Adult, Sprague-Dawley rats (200-300 g), anesthetized with ketamine and xylazine, were kept at 37 C while being prepared for implantation of the probe (CMA/10 Microdialysis Probe, Carnegie Medicin). In vitro probe efficiency for Na was 15%. Following arterial cannulation for MABP and plasma Na-22 analysis, the occipital skull plate and dural membrane over the cistern were exposed. A small hole was drilled at the external occipital crest. The probe, mounted on a stereotaxic holder, was visible through the membrane after its insertion. Agar gel around the hole prevented CSF leakage. The dialysis pump (CMA/100 Microinjection, Carnegie), containing artificial CSF, was turned on at 2 ul/min. Plasma turnover of Na-22 into the dialysate was reduced 45% by acetazolamide (25 mg/kg). Cisternal dialysis shows promise for testing drug effects on CSF.

DEVELOPMENT OF GLUCOSE TRANSPORTER IN BRAIN:IMMUNOCYTOCHEMISTRY AND IN SITU HYBRIDIZATION OF mRNA. A.M. Morin, D.S. Thomson*, K. CLegg* & H.V. Vinters*. Neurology Res. Lab. VA Med Center, Sepulveda, CA 91343 and Depts. Neurol. & Neuropath. and Brain Res. Inst. UCLA School of Med. Los Angeles, CA 90024.

The glucose transporter (GT) promotes the entry of glucose into brain through the blood brain barrier by means of facilitated diffusion. A previous description of the development of the transporter (Morin et al., J. Neurochem. 51(1)206-211, 1988) indicates that it is present in rat brain and enriched in cerebral microvessels as early as 4-7 days post-natal. The present work describes the appearance of GT detected with immunohistochemical staining and mRNA for the GT detected via in situ hybridization. At 4 days post-natal, capillaries can be seen to stain with antibody while immunoreactive material is seen in cell bodies adjacent to the capillaries. This "halo" of immunoreactivity is seen predominately in frozen, sectioned neonate brains and is relatively absent in adult brains. Results of in situ hybridization indicate the presence of mRNA transcripts in many cells as early as 4 days post-natal. This work supported by the Research Service of the Veterans Administration and a grant (BRSG) from the Neuropsychiatric Inst., UCLA.

CEREBROSPINAL FLUID (CSF) LEVELS OF MG DURING IV INFUSION OF $MGCL_2$ IN DEVELOPING SWINE. L.I. Rivera*, R-H. Lin*, P.M. Gootman, H.L. Cohen, N. Gootman, Div. Pediatr. Cardiol. Schneider Child. Hosp., LIJMC, A. Einstein Col. Med., New Hyde Park, NY, 11042 and Dept. Physiol. SUNY-Hlth. Sci. Ctr. Bklyn., Bklyn, NY 11203

It has long been thought that Mg does not pass the blood brain barrier (BBB) (Bradbury, 1979 for review) but rather that it's actions are all peripheral. Nervous system responses to changes in plasma [Mg] have been used as the example of the efficacy of Mg homeostasis in cerebral extracellular fluids. Further, it has been thought that by birth the BBB is intact for Mg. We decided to re-examine these results in light of observations made in developing swine to increasing plasma levels of Mg (Gootman, et al. Neurosci. Abst. 1988, 14:415; Rivera et al.FASEB J. 1989, 3:A1070). 0.2M $MgCl_2$ was infused for 1 hr and arterial plasma samples drawn at 10 min intervals. Aortic pressure, EKG, end-tidal CO_2 and intratracheal pressure were continuously monitored and blood gases and pH were measured at @ 45 min intervals. CSF was obtained either at 10 min intervals or prior to and at end of infusion. Parallel increases of [Mg] occurred in both plasma and CSF to @ 13 mg/dl; beyond this concentration, plasma levels continued to rise while CSF levels stablized. CSF [Mg] rose from 3.0±.35 to 13.4±1.5 mg/dl ($p < .01$). Our results indicate that Mg can pass the BBB as plasma levels of Mg rise, thus paralleling the increase in plasma concentration. (Support-NIH grant HL-20864.)

STRUCTURAL SPECIFICITY OF THE BRAIN CAPILLARY NEUTRAL AMINO ACID TRANSPORTER. Quentin R. Smith, M. Aoyagi*, and S. I. Rapoport. Lab. of Neurosciences, NIA, NIH, Bethesda, MD 20892.

Neutral amino acids are transported from plasma into brain by a high affinity, saturable mechanism at the brain capillary endothelium. This carrier is known to facilitate the brain uptake of several drugs (L-dopa, α-methyldopa, melphalan) and may provide a means of enhancing brain delivery of other CNS therapeutic agents. To characterize the structural requirements of the transporter, the ability of over 100 solutes to inhibit L-[14C]-phenylalanine uptake into brain was determined in anesthetized rats using the in situ brain perfusion technique of Takasato et al. (1984). Both a free carboxyl group and an unsubstituted α-amino group were found to be required for strong binding to the carrier. Amino acids with large side chains, such as α-aminononanoic acid and O-benzyl-L-tyrosine, bound readily, indicating minimal limitation of amino acid size. Affinity depended critically over a 10,000-fold range on side chain hydrophobicity. For a series of straight chain alkyl amino acids, the calculated ΔG for binding fell from ~1 kcal/mol/CH_2 for the first three CH_2 groups to 0.2-0.5 kcal/mol/CH_2 for the next four CH_2 groups, indicating interaction with a strongly hydrophobic region. The results suggest that the brain capillary neutral amino acid carrier can accept a wide variety of ligands and therefore may be useful in facilitating drug entry into the CNS.

NEUROHUMORAL REGULATION OF AMINO ACID TRANSPORT IN RAT CEREBRAL MICROVESSELS. P. Grammas*, T.M. Kwaiser* and M.L. Caspers. Dept. of Pathology, Wayne State Univ. Med. School, Detroit, MI 48201 and Dept. of Chemistry, Univ. of Detroit, Detroit, MI 48221.

Enzymatic functions of the blood-brain barrier (BBB) involved in amino acid transport i.e. γ-glutamyltranspeptidase are modulated by adrenergic and cholinergic receptors. In the present study, uptake of ^{14}C-α-methylaminoisobutyric acid (MeAIB), a nonhydrolyzable analog used to probe A-system transport, was examined under basal and agonist-stimulated conditions. Nonspecific binding was determined in the presence of 1 mM ouabain. The specific uptake of MeAIB at 37°C was time-dependent and reached a maximum at approximately 30 min. Neurohumoral control of amino acid uptake was explored using the α and β-adrenergic agonists phenylephrine (PE) and isoproterenol (ISO) and the muscarinic agonist carbachol (CA). Cerebral cortical microvessels incubated with 10 μM PE or 10 μM ISO demonstrated an increase in the uptake of MeAIB of 109 and 111% over basal, respectively. While 10 μM CA alone did not alter the uptake of MeAIB by microvessels, it blocked the stimulation of uptake evoked by adrenergic agonists. These data suggest that carrier-mediated transport of amino acids across the BBB are under dual adrenergic-cholinergic control. Supported in part by PHS HL 23603, ADRDA, U. Detroit faculty award and J.D. Rose.

BLOOD-BRAIN BARRIER [BBB] TO PEPTIDE ENTRY IN VITRO. B.R. Brooks, T. Schwartz*, G. Kaminska*, J. Turner* and J.M. Rozental*. Neurology Dept, Univ of Wisconsin Med Sch and Wm S Middleton VA Hospital, Madison, WI 53705

Peptide entry into the CNS requires transport without chemical modification through the BBB consisting of the endothelial cell [EC] and astrocyte [A]. Degradation of [^{3}H-pro] thyrotrotropin releasing hormone [TRH] was studied in three separate cultures of purified ECs from the brain [Br] or spinal [SC] of Balb/c mice. Media samples were collected at 0, 10, 20, 30 and 60 minutes following incubation at 37°C. TRH degradation measured by HPLC [J Chromatog 487:275,1989] was signficantly [$p < 0.05$] elevated in Br As [95 ± 57 (SD) femtomole/mg protein/min] and SC As [54 ± 2] compared with Br ECs [14 ± 11]. Cyclic histidyl-proline formation was signficantly [$p < 0.05$] increased in both Br [2030 ± 1435] and SC [1380 ± 153] As compared with ECs [165 ± 285]. Comparable product increases were seen also for TRH-OH and $ProNH_2$ but not Pro. Scraped cells contained essentially no labelled products. Surface peptidases are present on ECs, but the specific activity against a tri-peptide is 10 X increased on the surface of Br and SC As. These peptidases limit the spread of active peptides after diffusion across the ECs or through the interstitial space after intrathecal administration. **[Supported by MDA Midwest ALS Center]**

DIFFERENTIAL GROWTH RATE OF BALB/C BRAIN AND NON-BRAIN ENDOTHELIAL CELLS [EC] PREPARED BY DEXTRAN-PERCOLL STEP GRADIENTS. J.M. Rozental*, D. Schrader*, S. Scheibengraber*, and B.R. Brooks. (SPON: R.Daly) Neurology Dept, Univ of Wisconsin Med Sch and Wm S Middleton VA Hosp, Madison, WI 53705.

The growth potential in vitro of primary EC from different organs in 10 d Balb/c mice was studied. Rapid purification of vascular EC from cerebral cortex [CTX], subcortex [sCTX], cerebellum [CBL], spinal cord [SC], kidney [KID], lung [LUN], liver [LIV] and spleen [SPL] used an enzyme digestion, Dextran-Percoll step gradient technique. Aorta [A] was prepared without step gradients. Tissues were homogenized in 0.5% collagenase-0.2% DNAase. The first gradient through 15% dextran yields neurons and glia at the top and vascular stroma contaminated by rbc and wbc in the pellet. The pellet is resuspended for a second gradient in 45% Percoll. A monodisperse EC band just touches the upper margin of a microvessel remnant band. Viable cell recoveries are different from brain and non-brain organs. CTX, sCTX, CBL, and KID EC grow out equally well on fibronectin and gelatin while fibronectin is essential for A, LUN, LIV and SPL EC. Cultured EC are von Willebrand Antigen [Factor VIII], alkaline phosphatase [+] and GFAP, UEA-lectin [-]. A EC grow faster in vitro than non-brain and brain EC. The growth rate of CTX and CBL EC is faster than that of sCTX and SC EC. (Supported by VA Res Svc)

EFFECTS OF POLYMORPHONUCLEAR CELLS (PMNs) ON THE FORMATION OF EICOSANOIDS AND KININS BY A MURINE ENDOTHELIAL CELL (CEC) LINE. J. Xu*, J. Chao*, S.A. Moore, E.L. Hogan, C.Y. Hsu. Dept. of Neurology, Medical University of South Carolina, Charleston, SC 29425 and Dept. of Pathology, Univ. of Iowa, Iowa City, IA 52242.

Inflammatory mediators including eicosanoids and bradykinin have been implicated in the pathogenesis of tissue injury and edema formation following ischemic or traumatic CNS insults. Interaction of CEC with inflammatory cells may contribute to this process. Using a CEC line (Moore et al, Am. J. Physiol 254 C37, 1988) we studied the effect of PMNs on A23187-stimulated conversion of kininogen to kinin and formation of leukotriene B_4 (LTB_4), thromboxane B_2 (TXB_2) and 6-keto-PGF1α (6KF). Table shows concentrations of mediators in serum-free medium following incubation of confluent CEC (0.22 mg protein/well) with or without PMNs (10^6 cells/ml). Purified kininogen (2 μg/ml) and A23187 (10 μM) were added as indicated. Data shown are mean $\pm$ SE from 3 experiments of triplicate wells

Exp. Conditions			Kinin	LTB_4	TXB_2	6KF
PMN	CEC	A23187	(pg/ml)		(ng/ml)	
-	+	+	21 $\pm$ 2	-	-	82 $\pm$ 4
+	-	+	46 $\pm$ 12	36 $\pm$ 2	27 $\pm$ 4	-
+	+	-	47 $\pm$ 18	-	6 $\pm$ 1	24 $\pm$ 2
+	+	+	87 $\pm$ 17	48 $\pm$ 3	26 $\pm$ 3	110 $\pm$ 5

Results indicate that PMN-CEC interaction may enhance the formation of kinins, LTB_4 and 6KF but not TXB_2.

409.9

A PROCEDURE FOR THE ISOLATION AND CULTURE OF ADULT RAT BRAIN ENDOTHELIAL CELL-CONTAINING MICROVESSEL FRAGMENTS (ECCMF). D.A. Doron*, D.M. Jacobowitz, G. Feuerstein, H.B. Pollard and J.M. Hallenbeck*. U.S.U.H.S., Bethesda, MD 20814 and Lab. Clin. Sci., NIMH, Bethesda, MD 20892.

A number of laboratories have found the culture of endothelial cells from adult rat brain microvessels (MV) difficult to achieve. We therefore proceeded to develop a procedure for the isolation and culture of small ECCMF. We followed traditional methods for isolation of MV. The vessels were purified through a dextran/percoll gradient and a nylon mesh was used to isolate the microvessel fraction. ECCMF were plated on fibronectin or gelatin coated dishes. Although growth of cells were observed, they did not stain for Factor VIII related antigen (FVIIIag). However, when the ECCMF were plated on Matrigel (basement membrane collagen), positive staining for FVIIIag, transferrin receptor and incorporation of low density lipoprotein was observed. Initial studies were undertaken to test the viability of this preparation. Prostacyclin (PGI2) was measured after 24 hrs of equilibration as 6-Keto PGF1α by a RIA. ECCMF maintained in media containing 20% FCS produced 5.89 ng/ml after 10 min. Incubation with bradykinin, thrombin and ionomycin induced a significant increase of PGI2 production (104%, 223% and 88% respectively). It appears that this preparation will be useful for further studies on the effect of a variety of substances which are potentially active at the MV level.

409.10

ISOLATED CEREBRAL MICROVESSEL (ICMV) ENERGY STATE: ROLES OF GLYCOLYSIS & LIPID OXIDATION. A. McCall and C. Gaposchkin*. Depts. of Med. & Physiol., B.U. Sch. Med.,Boston, MA 02118

ICMV can undergo a "metabolic shock" indicated by low initial ATP levels and ATP/ADP ratios that recover on incubation in enriched medium. To determine which fuels best maintain microvessel energy state, we incubated ICMV with single metabolic fuels and measured their ATP and ADP contents hourly using a bio-luminescent assay. Below are ATP/ADP ratios for ICMV incubated fuel-free or in glucose.

Incubation	0h	1h	2h	3h	4h
Fuel-Free (x $\pm$SE)	3.2 $\pm$0.2	2.5 $\pm$0.3	2.1 $\pm$0.1	1.8 $\pm$0.1	1.6 $\pm$0.3
Glucose (5.5 mM)	---	3.8 $\pm$0.5	4.9 $\pm$0.4	5.0 $\pm$0.5	4.7 $\pm$0.6

The improvement with glucose was not seen with either pyruvate (2.0 mM), 3-hydroxybutyrate (2.0 mM), or glutamate (2.0 mM). Oleate (0.33 mM) increased microvessel ATP/ADP ratios slightly only when co-incubated with carnitine. Incubation with 2-tetradecylglycidate, a specific inhibitor of long chain fatty acid oxidation, further reduced the ATP/ADP ratio in fuel-free incubation by 75%; the effect was countered by glucose. Conclusions: Increases in ICMV ATP/ADP ratios with glucose but not pyruvate suggest that glycolysis is a major source of ATP for ICMV. However, oxidation of endogenous fatty acids may make a significant contribution in fuel deprived ICMV. This dependence on glycolysis might result from ischemia during isolation.

409.11

ATRIAL NATRIURETIC PEPTIDE STIMULATES GUANYLATE CYCLASE ACTIVITY IN ISOLATED RAT BRAIN MICROVESSELS. P. Homayoun* and S.I. Harik (SPON: R.B. Daroff) Dept. of Neurology, Case Western Reserve Univ. Sch. of Med., Cleveland, OH 44106

We tested the effect of several putative vasoactive substances, mostly peptides for which there is evidence that their receptors exist in brain microvessels, for their effect on cyclic GMP generation in isolated rat brain microvessels. Bulk isolated rat cerebral microvessels were incubated with atrial natriuretic peptide (ANP), 10^{-9} to 10^{-5}M; angiotensin II, 10^{-6} to 10^{-5}M; arginine vasopressin, 10^{-6} to 10^{-5}M; bradykinin, 10^{-6}M; carbachol, 10^{-4} to 10^{-3}M; or thrombin, 10^{-6} to 10^{-4}M for a period of 10 min after which the reaction was stopped and the microvessels were extracted with perchloric acid and the content of cyclic GMP in the extract was assayed by radioimmunoassay. In all experiments, the ability of sodium nitroprusside (10^{-5}) to increase guanylate cyclase activity was ascertained. Of all the agents studied, only ANP was potent in stimulating guanylate cyclase. This stimulation was dose dependent, with maximum stimulation at 10^{-6}M. Our results indicate that ANP receptor stimulation in brain microvessels is mediated, at least in part, by cyclic GMP. Receptors for the other vasoactive substances that were tested, if they exist in rat cerebral microvessels, are not related to cyclic GMP.

410.1

DEFICIENT NEURITE OUTGROWTH OF RETINAL EXPLANTS FROM ADULT MOUSE ON ASTROCYTES. R.L. Meyer, J. Miotke* and J. Fawcett. Dev. Biol. Center, Univ. Calif., Irvine, CA 92717 and Dept. Physiol., Cambridge Univ., Cambridge, UK CB2 3EG.

We previously reported that when the optic nerve is crushed in an adult mouse and the retina explanted onto laminin a week later, ganglion cells began extenting neurites by 24h and these were quite numerous by 1wk.

In this study, adult and embryonic retinal explants were made on astrocytes which were made from 1-2d old mouse and maintained in culture 8d to 7wk. In some preparations oligodendrocytes were removed by shaking or by anti-GalC plus complement. Neurites were visualized by anti-neurofilament immunohistochemistry. At 1wk, adult retinal explants had fewer and shorter neurites on these cellular substrates compared to laminin. In contrast, embryonic retina (E-15) sent out numerous long neurites on these same cellular substrate as early as 2d even when numerous oligodendrocytes were present.

We suggest that mature ganglion cells may be deficient in their ability to respond to astroglia, that old astrocytes can support embryonic neurite growth and that oligodendrocytes may not be a major factor in regulating this response. (Supported by NS26750)

DIFFERENT ARBORIZATION PATTERNS OF NASAL AND TEMPORAL OPTIC FIBERS REVEALED BY IN VIVO CONFOCAL MICROSCOPY. N. A. O'Rourke and S. E. Fraser Dept. of Physiology & Biophysics, Univ. of CA, Irvine, Irvine, CA 92717

In lower vertebrates, the axons of the retinal ganglion cells form a topographic projection in the optic tectum. During the initial formation of the projection in *Xenopus*, the optic fibers from the nasal and temporal retina first overlap in the tectum and later sort out into a topographic pattern over a period of days. Little is known about the growth and arborization of single fibers during this dynamic process. To follow these events, nasal and temporal retinal ganglion cells were labeled with the fluorescent carbocyanine dye "DiI", and their growth and arborization were directly visualized inside the transparent heads of living tadpoles. Three-dimensional images of identified terminal arbors were obtained daily for up to five days using a laser-scanning confocal microscope. The fibers grew into the tectal neuropil as relatively simple axons with large growth cones and then ramified to form extensive arbors through extension and retraction of branches. While fibers from the nasal and temporal retina both showed continual growth and remodeling, they showed dramatically different rates of caudal extension. The nasal fibers extended rapidly into new regions of the caudal tectum whereas the temporal fibers showed a much slower extension rate, remaining in the rostral tectum. In addition, while both nasal and temporal fibers extend branches as they first enter the tectum, the temporal fibers extend more branches at early stages. The nasal fibers don't increase their branch number until they have reached the caudal tectum. These differential growth patterns can account for the appearance of topographic order along the rostrocaudal axis of the tectum. (NSF BNS8608356)

410.3

MONOCLONAL ANTIBODY 8A2 TRIGGERS EVACUATION OF GROWTH CONE CONTENTS AND DISTO-PROXIMAL BULK REDISTRIBUTION OF AXOPLASM IN GROWING AXONS. S. Finnegan Sloan*, E. Koenig and V. Lemmon. Dept. of Physiology, SUNY at Buffalo, Buffalo, N.Y., and Center for Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106.

Monoclonal antibody 8A2 has been shown to recognize a class of O-acetylated ganglioside and to inhibit neurite outgrowth of chick *in vitro* (Soc. Neurosci. Abstr. Vol. 14, p. 272). Phase-contrast video-microscopic studies reveal that 8A2 (1:1000) induces a global evacuation of the contents of growth cones in regenerating retinal ganglion cell axons of goldfish explants *in vitro*. The onset of effects is rapid and signaled by an immediate cessation of elongation, a loss of lamellipodia and an emergence of a prominent filopodial morphology. A retrieval of axoplasm begins in distal filopodia, and the material accummulates at the base of the growth cone. With time, there is an *en masse* redistribution of accumulated axoplasm in the retrograde direction, such that distal evacuated segments measure 30-80 μm after an hour. Membrane filopodial ghosts mark the original site of attachment. D1.1 monoclonal antibody, which recognizes O-acetylated GD_3 ganglioside (courtesy of Dr. Joel Levine), does not induce a global disto-proximal evacuation. Fluorescence microscopy shows very strong 8A2 and D1.1 immunofluorescence distributed uniformly over the surfaces of axons. After treatment of living axons with 8A2, followed by Triton X-100 extraction, immunofluorescence is punctate, indicating an apparent stabilization of some antigen. Chloroform-methanol extraction of fixed axons appears to remove most, but not all immunofluorescence.

410.4

A MONOCLONAL ANTIBODY WHICH RECOGNIZES GROWING AXONS IN THE GOLDFISH VISUAL SYSTEM J. Vielmetter and C.A.O. Stuermer Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft 7400 Tübingen FRG

During the continuous growth of the goldfish retinotectal system, new ganglion cells are added at the peripheral retinal margin. The axons of these cells travel as a coherent, age related bundle through the optic nerve and tract (Easter et al. '81) and around the dorsal and ventral margin of the tectum (Stuermer and Easter '84). These young axons are specifically recognized by a new monoclonal antibody, ϵ587.

This antibody was obtained by immunizing mice with glycoproteins extracted from cell surface membranes of adult goldfish tecta and purified with lentil lectin and WGA affinity chromatography. On frozen sections ϵ587 stains axon bundles in locations identical to the position of newly added ganglion cell axons. After optic nerve section, the retinal axons regenerate. Most or all regenerating axons are ϵ587 positive in the nerve distal to the cut, in the tract, and in the retinorecipient layers, SO and SFGS, of the tectum. Unfixed axons *in vitro* emerging from retinal explants and growing on laminin, are stained by ϵ587 throughout their length including their growth cones and filopodia. Staining with ϵ587 does not require fixation or permeabilization of the cell membrane, indicating that the antigen is exposed on the cell surface. On western blots ϵ587 recognizes a protein of an apparent molecular weight of 200 kd. The antigen therefore is different from the antigen recognized by α-N-CAM (Bastmeyer et al. '89).

Thus the ϵ587 antigen is a cell surface protein which appears to be specific for growing retinal axons in fish.

410.5

MONOCLONAL ANTIBODY M802 RECOGNIZES REGENERATING RETINAL AXONS IN GOLDFISH K.A.Wehner and C.A.O.Stuermer, (Spon: A.D. de Lima). Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft, Tübingen, FRG.

Goldfish retinal axons regenerate after optic nerve transection (ONS). Mice were immunized with proteins which were extracted from cell surface membranes of the regenerating goldfish optic nerve and reconstituted in liposomes. We obtained an antibody, M802, that recognizes regenerating retinal axons in the retinotectal pathway.

On frozen sections of normal fish, M802 staining is restricted to bloodvessels. However, in fish with previously transected optic nerves, the retinal fiber layer in the eye, the optic nerve and tract and the retinorecipient layers of the tectum are labeled intensively. M802 staining in these regions appears to persist for more than six months after ONS but has decreased in intensity by 9 months.

Retinal axons and their growth cones growing from retinal explants *in vitro* carry M802 positive staining throughout their entire length. M802 staining does not require fixation or permeabilization suggesting that the antibody binds to an epitope on the axonal surface. On immunoblots M802 recognizes a band of an apparent molecular weight of 50kD.

Whether M802 interferes with axonal regeneration is tested in a special *in vitro* assay (Vielmetter and Stuermer, Neurosci. Abstr. 1988).

410.6

EARLY DEVELOPMENT OF THE POSTOPTIC COMMISSURE IN ZEBRAFISH EMBRYOS. S.W.Wilson and S.S.Easter Jr. Dept. of Biology, University of Michigan, Ann Arbor, MI 48109.

The zebrafish hatches at about 2.5 days post-fertilisation. We are studying the embryonic development of axon pathways in the brain. At 24 hours post-fertilisation the major pathway in the presumptive diencephalon is the stirrup-shaped postoptic commissure (PoC) and its associated tract (tPoC). We have made small injections of HRP into the PoC at 24-27 hours of development (survival times were 10 minutes or less) to retrogradely label those neurons contributing to it. They are : 1) a strip of diencephalic neurons alongside the tPoC, and 2) a small population of ipsilateral hindbrain neurons that ascend through the ventral midbrain. Anterograde labelling of axons and growth cones revealed three other contributors to the tPoC that do not decussate in the PoC (at this stage). They are : 1) axons of 2 or 3 dorsal diencephalic neurons just deep to, or perhaps within the anlagen of the epiphysis, 2) descending telencephalic axons, and 3) axons of midbrain neurons that enter the tPoC from the posterior commissure.

The tPoC intersects with three other tracts. At these intersections, the morphologies and trajectories of axons entering the tPoC change abruptly and we have interpreted these changes in the context of axonal pathfinding. Supported by NATO (BRF8217) and NIH (EY-00168).

DEVELOPMENT OF FIN NERVES IN WILD-TYPE AND MUTANT FISH EMBRYOS. H. Okamoto* and J.Y. Kuwada. (SPON: B. Oakley). Dept. of Biology and Gerontology, U. of Michigan, Ann Arbor, MI 48109.

The pectoral fin of the Japanese Medaka fish is a simple limb consisting of two muscles. We have studied axonal outgrowth by fin motor neurons and tested the role of the fin bud for axonogenesis by these neurons by labelling them in wild-type and mutant embryos with an monoclonal antibody to acetylated tubulin (G. Piperno and M. Fuller, J. Cell Biol., 101:2085, 1985) which labels all embryonic axons. Fin axons originate from S1-S4 and project ventrally between the axial muscles and the notochord to the ventral surface of the axial muscles where they turn and extend laterally in between the muscles and the pronephros. Here the axons turn: S1 axons posterior, S4 axons anterior, and S2 and S3 axons in both directions so that they fasciculate with each other to form a plexus. From the plexus axons emerge to invade the nascent fin muscles. To see if the outgrowth of these axons are dependent on the prescence of the fin bud, we analyzed axonal outgrowth both in embryos in which a fin bud was ablated early in development and in the "pectoral finless" mutant whose fin buds become arrested at the earliest stages of development. In both cases the fin axons fasciculated to form a plexus but failed to extend beyond the plexus. Therefore, plexus formation is independent of the fin bud, but extension beyond the plexus requires a normal fin bud. Supported by grants from NIH, March of Dimes, and the Office of VP for Research at U. of Michigan.

PATHFINDING BY IDENTIFIED NEURONS IN THE BRAIN OF ZEBRAFISH EMBRYOS. A.B. Chitnis* and J.Y. Kuwada (SPON: D. Rosenblatt). Dept. of Biology and Gerontology, U. of Michigan, Ann Arbor, MI 48109

We have begun to study pathfinding by growth cones in the brain of zebrafish embryos by methods which allow one to analyze the development of identified neurons. The embryonic zebrafish brain consists of a small set of axonal tracts which is established by a relatively small number of identifiable neurons found in discrete regions. These identified neurons have axons with stereotyped trajectories which are located in a cell specific subset of the existing pathways. We have examined pathfinding by the growth cones of one of these identified neurons and found that these growth cones extend along a cell specific route from the beginning of axonogenesis. Growth cones of neurons in the nucleus of the posterior commissure, a dorsolateral nucleus near the border of the diencephalon and mesencephalon, extend ventrally to the anterior tegmentum. At this site several different pathways meet, yet these growth cones always extend posterior into one of the pathways. This may indicate that identified growth cones select their pathways at such intersections in order to reach their targets in the brain. The early stereotyped trajectories of other identified neurons opens up the possibility that this may be a general feature of pathfinding in the zebrafish brain. Supported by grants from NIH, March of Dimes, and Office of VP for Research at U. of Michigan.

410.9

PATHFINDING BY SPINAL GROWTH CONES IN THE ZEBRAFISH EMBRYO. J.Y. Kuwada, R.R. Bernhardt, A.B. Chitnis*, and N. Nguyen*. Dept. of Biology and Gerontology, U. of Michigan, Ann Arbor, MI 48109.

We have followed the axonogenesis of 4 of the 5 earliest neuronal types found in the cord of zebrafish embryos by labelling cells via intracellular dye injections, application of axonal tracer dyes, a monoclonal antibody against microtubules which labels all embryonic neurons, and a monoclonal antibody which only labels 2 of the 5 types in the early cord including their growth cones. These neurons (RB, DLA, CoPA, and VLD) all projected growth cones from the ventral halves of their somata. Subsequently these growth cones followed cell-specific pathways to reach their targets in the CNS. Pathfinding by CoPA and VLD is interesting since initially both growth cones extend towards the floor plate, a single row of cells at the ventral midline. The CoPA growth cone crosses the ventral midline by extending under the floor plate and turns anterior, while the VLD growth cone comes into the immediate vicinity of the floor plate but never crosses the midline and turns posterior. These findings are interesting since in the rat embryonic cord the floor plate can specifically attract commissural growth cones (Tessier-Lavigne, et. al., Nature, 336:775, 1988). We are presently investigating whether the floor plate is necessary for the turns made by these growth cones and whether it prevents the VLD growth cone from crossing the midline as well as attract the CoPA growth cone. Supported by grants from NIH, March of Dimes, and OVPR at UM.

NEURONS IN THE DEVELOPING ZEBRAFISH SPINAL CORD. R.R. Bernhardt and J.Y. Kuwada. Dept. of Biology and Gerontology, U. of Michigan, Ann Arbor, MI 48109.

As a basis for an analysis of axonal pathfinding we have characterized the cellular anatomy of the simple spinal cord of developing zebrafish with intra- and extracellular dye injections and various antibodies. Nine classes of embryonic neurons have been distinguished based on soma postion, axonal trajectory, and time of axonogenesis (Co=commissural, Ci=circumferential, L=longitudinal, A=ascending, D=descending). There are 3 classes of Co-cells; early primary (CoPA), later secondary (CoSA), and bifurcating (CoB). Ci-cells are similar to Co-cells but have ipsilateral axons and fall into 2 classes (CiA and CiD). The L-cells consist of dorsal (DLA) and ventral (VLD) cells. Also there are Rohon-Beard (RB) and motor neurons. These cell types account for 50-75% of the 50-80 neurons per embryonic spinal segment. RBs and VLDs pioneer an early dorsal (DLF) and ventral (VLF) fiber tract, respectively. CoPAs establish the commissural pathway. Most of the embryonic cell types are also found in larvae (3-5 d). Larval CoPAs and RBs project to supraspinal levels (di-/mesencephalon and hindbrain, respectively). EM shows that the DLF and VLF are established by a small number of axons at 16-20 h. At this stage only scattered axonal profiles are found in the imtermediate lateral margin (presumably Co-axons). At 25-40 h addition of new axons, both to preexisting bundles and at intermediate levels, creates a continuous marginal zone. Reticulospinal axons establish a distinct ventral medial bundle (MLF) and commissural tracts are evident at 2-4 d. Supported by grants from NIH, March of Dimes, and OVPR at UM.

MOTOR INNERVATION OF DORSOVENTRALLY REVERSED WINGS IN CHICK/QUAIL CHIMAERIC EMBRYOS. M. Ferns* & M. Hollyday. (SPON: E. Thomas). Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

During the development of motor innervation of the chick limb, lateral and medially positioned motoneurons within the lateral motor column (LMC) have been shown to project selectively to muscles of dorsal and ventral origin respectively. We have examined the axonal guidance cues involved in this initial, specific pathway choice at the plexus by making dorsoventral (D/V) limb-bud reversals prior to innervation. Chick wing buds were surgically removed and replaced by quail in D/V reversed orientation at St 18, producing chimaeric embryos in which the level of the reversal could be determined. Specificity of the innervation of the reversed wing was assessed at St 28-29, prior to the onset of motoneuron death, by retrograde HRP labelling of either the dorsal radial or ventral brachialis inferior nerve trunks.

The ability of axons to correct for the reversal was found to be dependent on the level of the graft being proximal to the plexus, and on the reversed limb and gross nerve pattern being normal, particularly in the shoulder region. In such cases (n=8), after normal dorsoventral sorting in the spinal nerves, many motor axons clearly altered their trajectories in the graft tissue, at varying levels within the donor plexus region, and projected appropriately for their position in the LMC. The D/V pathway cues therefore are unlikely to be long range target derived signals, but rather appear to be closely associated with positional information in the plexus region (and perhaps more proximally). The correlation between active correction and the development of normal limb pattern leads us to suggest that axons may respond, in a specific fashion, directly to the positional information signal encoding the D/V axis, or indirectly to cues which differentiate in accord with D/V positional value.

410.12

COLLATERAL BRANCHING DURING DEVELOPMENT OF LIMB INNERVATION IN THE CHICK WING. M. Hollyday & M. Ferns*. Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

The initial pattern of innervation of the chick limb has been reported to be highly specific, with only few instances of segmentally erroneous projections being detected. One possible form of projection error however, which has received little attention, is collateral branching of axons to divergent targets.

Axons projecting in either the dorsal radial or ventral brachialis inferior nerve trunks in the wing were retrogradely labelled by direct HRP injections at St 28-29, shortly after the formation of muscle nerve branches, and detected immunohistochemically in paraffin sections with the sensitive peroxidase anti-peroxidase technique. Collaterals of retrogradely labelled axons were consistently observed to project into the subset of muscle nerves diverging from the nerve trunk proximal to the injection site. Collaterals were present in moderate numbers as compared to the number of labelled axons and extended varying, but often considerable distances (200-500μm) into the muscle nerves. Collateral branching at the plexus where the pathways to dorsal and ventral muscle masses diverge was only rarely observed. Therefore, whereas axonal branching at the muscle nerve branches may reflect localized regions of increased (but specific) substratum adhesivity, differing guidance mechanisms are perhaps operative at the dorsoventral pathway choice.

It remains to be determined whether such projection of collaterals to multiple targets involves motor and/or sensory axons, and what is the time course and mechanism of their presumed selective elimination. It appears however that axonal guidance mechanisms are, in some instances, of limited accuracy and resolution, producing some imprecision in the initial pattern of projections.

HNK-1 LABELS DEVELOPING XENOPUS NEURONS AND GROWTH CONES. R.H.Nordlander. Dept. Oral Biol., Case West. Reserve Univ. Sch. Dent. Cleveland, OH 44106.

The monoclonal antibody HNK-1 has been widely used to identify migrating neural crest cells. The present study examines the expression of the HNK-1 epitope in the developing nervous system of Xenopus embryos and larvae as viewed in wholemounts. In these preparations HNK-1 gives a readily accessible overview of the developing fiber scaffolding of the nervous system much like that provided by anti-HRP marking of the earliest neural elements of Drosophila.

The antibody was found to mark developing neurons from the time of initial axonal outgrowth. It appears on the surfaces of cell bodies, axons, and axonal growth cones of identifiable neurons. Marking is transient and its distribution follows a rostrocaudal developmental gradient in a pattern consistent with observations from earlier studies using neuronal tracers and electron microscopy.

The association of this epitope with the surfaces of developing neurons suggests a function in axonal outgrowth.

The author thanks E.Jaszczak for technical assistance and S.Landis for HNK-1. This work was supported by NS-18873.

COCULTURES OF MERKEL CELLS, SENSORY NEURONS & SYMPATHETIC NEURONS IN SERUM-FREE MEDIUM. P. Vos & R.N. Pittman, U. of PA., Sch. of Med., Dept. of Pharmacol., Phila. PA, 19104

Merkel cells may serve as targets for a specific class of cutaneous sensory neurons. The basis for this relationship is unknown. Tropic factors promoting sensory neurite outgrowth towards this target have not been identified. NGF, a trophic factor promoting survival of neurons innervating this target, has been demonstrated in epithelium. The cellular source of this NGF remains unknown.

Primary cultures of dissociated epithelium were obtained from E20 rat buccal pads. Morphologically distinct cells were identified in vitro as Merkel cells based on their labeling with markers that specifically label Merkel cells in situ. These same cells were distinguished by their unique expression of NGF-like immunoreactivity in vitro; implicating Merkel cells as a source of NGF.

Many sensory neurons require NGF for survival, while sympathetic neurons universally depend upon NGF for survival. Serum free medium (SFM) supplemented with NGF promoted the long-term survival of sympathetic neurons; but not sensory neurons. In contrast, cultures of epithelial cells containing Merkel cells promoted long-term survival of **both** sensory and sympathetic neurons. In these cocultures, antibodies against NGF reduced sensory neuron survival by 65% and reduced sympathetic neuron survival by 90%. Thus, NGF is necessary but **not** sufficient to promote long-term survival of sensory neurons in SFM.

Sensory neurons innervate the epidermis in situ, while sympathetic neurons do not. A similar discrimination was observed in vitro. Growth cones from 70% of sensory neurons were intimately associated with Merkel cells in cocultures examined 48 hrs after neurons were added. In contrast, only 10% of sympathetic neurons were in contact with Merkel cells. The fraction of sensory neurons contacting Merkel cells continued to increase with time in culture, while the fraction of sympathetic neurons contacting Merkel cells did not.

410.15

EXPERIMENTAL EVIDENCE THAT TARGET MATURITY CAN INFLUENCE AXON OUTGROWTH IN VIVO. K. W. Tosney, Department of Biology, University of Michigan, Ann Arbor, MI. 48109.

Axial cutaneous nerves emerge from the sensory ganglia several days after their counterparts that innervate cutaneous targets in the chick hindlimb. Despite the temporal differences in initial outgrowth, both axial and limb cutaneous nerves grow from nerve trunks toward the epidermis at the same time (stage 26.5) as though both were responding to a general maturation of their target. To test this notion, I am replacing chick epidermis with older or younger epidermis from quail and determining whether subsequent outgrowth of axial cutaneous nerves is proportionally advanced or delayed in time.

Preliminary results indicate that the formation of axial cutaneous nerves is temporally correlated with the maturity of the epidermis. Cutaneous nerves will form before stage 26 if their normal target is replaced with older epidermis. This stimulation of outgrowth is not likely to be an artifactual result, since younger target can suppress outgrowth. In addition, a small lateral patch of more mature epidermis can elicit formation of a novel cutaneous branch from the distal spinal nerve. The mature epidermis stimulates outgrowth despite the fact that it is usually well beyond filopodial reach. These results are consistent with a relatively long-distance cue emanating from the epidermis that attracts sensory growth cones. Alternatively, the epidermis may change or condition the more proximal pathway, rendering it more suitable for advance. These preliminary results provide the first experimental evidence that temporal alterations in the target may contribute to the control of axonal outgrowth.

DEVELOPMENT AND INNERVATION OF THE PRIMARY ABDOMINAL MUSCLE IN EMBRYONIC *XENOPUS LAEVIS*. K.L. Lynch* and S.E. Fraser. (SPON: R. Lewis) Dept. of Anat., USUHS, Bethesda, MD 20814-4799 and Dept. of Physiol. & Biophysics, University of California, Irvine, CA 92717

The primary abdominal muscle of *Xenopus* develops during embryonic stages 31 to 40, from cell clusters that bud from the ventrolateral margins of trunk myotomes II to VIII. Because of its thin flat shape, regular segmentation and superficial position, the abdominal muscle is an ideal subject for studies in *vivo* of cell migration, muscle morphogenesis and differentiation, and interactions between myogenic cells, extracellular matrix components, and the nerve fibers that innervate the muscle.

The undifferentiated cells from which the abdominal muscle develops migrate ventrally from the myotomes as clusters of tightly adherent cells, a relatively unusual form of cell migration. We have used the fluorescent tracer DiI to label the clusters and record their movement by time-lapse videomicroscopy. The tracer also enabled us to identify the most rostral of the myotomal buds as the source of the muscle fibers in the geniohyoid muscle. Silver stains, electron microscopy and enzyme histochemistry revealed that the first motor fibers to the abdominal muscle, from the ventral rami of spinal nerves 2 through 9, initially follow the paths of the cell clusters from which the muscle develops. When the cells of the clusters differentiate and fuse to form myotubes, however, the motor axons are in trunks located deep to the narrow zones between adjacent muscle segments. Fibers from spinal nerve 2 innervate the first segment of the abdominal muscle and the geniohyoid, consistent with the origin of the myogenic cells.

These data confirm and extend previous data on this system. With knowledge of the chronology and features of the abdominal muscle's development, we are in a position to manipulate it to expose underlying morphogenetic mechanisms.

410.17

POLYSIALIC ACID AS A REGULATOR OF NERVE BRANCHING IN DEVELOPING CHICK MUSCLE. L.T. Landmesser, L.M. Dahm, U. Rutishauser, and J. Tang*. Dept. Physiol. & Neurobiol., Univ. of CT, Storrs, CT 06269 and Case Western Reserve Univ. Sch. Medicine, Cleveland, OH 44106.

The polysialic acid (PSA) moiety of NCAM can regulate the strength of cell-cell interactions mediated by either NCAM or by G4/L1. We previously found that the strength of axon-axon adhesion due primarily to G4/L1 has a strong influence on the degree and spatial pattern of nerve branching in embryonic muscle. Further, in-ovo inactivation of G4/L1 with specific antibodies produced changes in the nerve pattern similar to those following dTC-induced neuromuscular activity blockade. We report here that activity block does not decrease the actual level of G4/L1; however, it does cause a large increase in PSA levels in nerve, which we propose indirectly decreases G4/L1 function. This increase in nerve PSA can account for most of the inactivity-induced changes in branching, since PSA removal via an endoneuraminidase prevents these changes in dTC-treated embryos. Since antibodies to G4/L1 but not to NCAM effectively reversed the changes in branching produced by PSA removal, we conclude that G4/L1 is the adhesive ligand most responsible for the PSA-regulated changes in nerve branching. During normal development, PSA levels in nerve were also regulated in a temporal-spatial pattern consistent with its postulated role in nerve branching.

TIME-LAPSE STUDIES OF ENCOUNTERS BETWEEN SENSORY NEURON GROWTH CONES AND NEURITES. M.G. Honig and S.M. Burden*. Dept. of Anatomy and Neurobiology, Univ. of Tenn., Memphis, TN 38163.

We are interested in elucidating the mechanisms by which sensory neurons (SNs) grow to their correct targets in the chick hindlimb during development. We are currently investigating how interactions of SN growth cones with axons they normally encounter may influence their pattern of outgrowth, using an in vitro model system (Honig, Neurosci. Abstr., 13: 1220, 1987). Here we report our results on the interactions of SN growth cones with the processes of other SNs in dissociated cell cultures. We have seen a variety of behaviors when we observe these encounters using time-lapse videotaping. As expected, based on work by Kapfhammer and Raper (J. Neurosci., 7: 1595, 1987), the most common response was crossing. This was often, but not always, preceeded by a delay during which the growth cone maintained contact with the neurite. Somewhat unexpectedly, we have also seen other types of responses. In some cases, the growth cone fasciculated with the neurite, and sometimes continued to grow along it for a considerable distance. In other cases, the growth cone turned after its filopodia contacted the neurite and grew roughly parallel to the neurite, maintaining filopodial contact but remaining separate from the neurite. Finally, in some cases, the growth cone retracted from the neurite, although this response was the least common one. Sometimes more than one type of behavior was exhibited in a given encounter, for example, fasciculation was followed by crossing. These experiments show that even in encounters between neurons of the same origin, there is a heterogeneity of responses. One possibility is that this variation is a consequence of the heterogeneous nature of neurons within the dorsal root ganglia. (Supported by NS26386 to MGH)

AXON INITIATION BY DORSAL ROOT GANGLION NEURONS *IN VITRO*. C.L. Smith and E.M. Munro*, Laboratory of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Axon formation signals the initiation of a neuron's differentiation and the beginning of a large increase in neuronal volume. We are investigating the intracellular changes underlying this process. Sensory neurons from embryonic chick dorsal root ganglia are dissociated and grown on polyornithine-coated glass coverslips in defined medium with nerve growth factor to promote neurite outgrowth. Live cultures are examined with video microscopy on an inverted microscope enclosed in an incubator. Immediately after plating, some neurons retain a remnant of their original axon but, within 1 to 2 hours, most neurons appear rounded and no axon is visible. These axon-less neurons extend a flat, veil-like lamellipodium evenly around their circumference. Filopodia protrude from the lamellipodium. In low density cultures, neurons can retain this shape for at least 48 hours. However, neurons can be stimulated to form neurites by the addition of non-neuronal cells. Contact with the non-neuronal cell is typically made by a filopodium. The adjacent lamellipodium then begins to elongate and thicken and its tip grows along the non-neuronal cell. During this period, the lamellipodium between the developing axon and the soma remains thin, allowing imaging of intracellular organelles such as mitochondria, endoplasmic reticulum and microtubules. Epifluorescence imaging of organelles stained with fluorescent markers is also feasible. Thus, this preparation allows direct observation of the movements of organelles and cytoskeletal elements during axon formation.

PURIFICATION AND CULTURE OF IDENTIFIED RAT MOTONEURONS. J.P. Ternaux, J.P. Guéritaud, P. Portalier and N. Sevfritz (SPON: S. Tyc-Dumont). INSERM U6, CNRS URA 142, 280 Bd Ste-Marguerite, 13009 Marseille, France.

It is well known that motoneurons can be retrogradely labelled by various substances. For example, motoneurons of the nucleus hypoglossi and of the oculomotor nuclei are labelled in adult rat, 48 hours following an injection of Rhodamine fluorescent latex microspheres (LUMA FLUOR INC.) in the tongue and the extraocular muscles, respectively. This retrograde neuronal marker as well as immunohistological detection of choline acetyl transferase (ChAT) can be used to detect the presence of motoneurons in histological sections. Following enzymatic dissociation (free calcium and magnesium medium, in presence of trypsin) of the area containing motoneurons, retrograde labelled motoneurones were identified in the neuronal dissociated population. These labelled cells are comparable in size to those detected using ChAT antibody on fixed or living cells. Dissociated neurons had lost their dendritic processes but were able to express new neurites when they were plated for seven to nine days on polyornithine coated petri dishes in DMEM medium. Experiments are actually performed in order to sort labelled motoneurons using various methods, including flow cytometry, and to study the growth of new processes when they are plated on various guidance surfaces.

EPILEPSY: BASIC MECHANISMS III

411.1

NEUROTRANSMISSION AT NMDA RECEPTOR AND HIGH PRESSURE NEUROLOGICAL SYNDROME IN RATS. B.S. Meldrum, M.H. Millan, B. Wardley-Smith* and M.J. Halsey*. Dept. of Neurology, Inst. of Psychiatry, London, SE5 8AF, UK. and *Northwick Park Hospital, CRC, Harrow, Middlesex, UK.

Involvement of excitatory transmission at NMDA receptor within the substantia nigra pars reticulata (SNR) entopeduncular nucleus (EP) and ventrolateral nucleus of thalamus (VLTh) in the high pressure neurological syndrome (HPNS) (tremor myoclonus convulsion) was studied in rats. Focal injection of NMDA (1-10 nmol) into each structure resulted in lowering the threshold pressure for the initiation of tremor and convulsions in hyperbaric conditions. Injection of APH (1-10 nmol) produced the opposite effect i.e. increased threshold pressure for the initiation of tremor and convulsions. The best protection against convulsions (38% threshold increase) was provided by APH injections into the SNR. The same injection into the EP was best in protection against tremor (48%). VLTh injections produced less pronounced effects but these were statistically highly significant.

CORTICAL BLOOD FLOW AND 0_2 DURING REPEATED HYPERTENSIVE EPISODES AND SEIZURES. J.C. Magee* and N.R. Kreisman. Dept. of Physiology, Tulane Univ. Sch. Med., New Orleans, LA 70112.

Although cortical blood flow (CBF) and oxygenation increase early in status epilepticus, the increase in CBF can drop below the critical level for adequate delivery of 0_2 after an hour or more of seizures. We tested the hypothesis that repeated seizure-associated increases in arterial blood pressure (BP) compromise cardiovascular function, leading to attenuation of CBF and 0_2 delivery. Rats were anesthetized with pentobarbital, paralyzed with curare and ventilated mechanically. Continuous measurements were made of EEG, BP, and the oxidation/reduction state of cytochromes a + a_3. CBF was measured by H_2 washout. Increases in BP from 120 $\pm$ 3 to 198 $\pm$ 2 mm Hg were induced at 5 min intervals by i.v. injection of a mixture of norepinephrine and angiotensin II. CBF increased from 1.1 $\pm$ 0.1 to 3.8 $\pm$ 0.2 $ml.min^{-1}.g^{-1}$ during the increases in BP. No attenuation of increases in BP or CBF were observed over a 2h period. Subsequently, 3-4 generalized seizures were induced individually at 5 min intervals by i.v. injection of pentylenetetrazol. BP increased to 187 $\pm$ 3 mm Hg and CBF increased to 5.4 $\pm$ 0.5 $ml.min^{-1}.g^{-1}$. Cyt a + a_3 oxidized slightly with each BP increase but oxidized more during seizures. The increases in CBF and cortical 0_2 did not attenuate during seizures. Therefore, repeated increases in BP are not sufficient to produce cardiovascular changes resulting in attenuation of CBF and 0_2 delivery during serial seizures. (Supported by the American Heart Association--LA, Inc.)

411.3

THE PATTERN OF 72KD HEAT SHOCK PROTEIN-LIKE IMMUNOREACTIVITY IN THE RAT BRAIN FOLLOWING GENERALIZED STATUS EPILEPTICUS.
D. Lowenstein*, M. Gonzalez*, R. Simon and F. Sharp (SPON: T Koch). Dept. of Neurology, U. of California - SF, San Francisco, CA 94143.

The inducible 72kD heat shock protein (HSP72) is a highly conserved stress protein that is expressed in CNS cells and may play a role in protection from neural injury. We used a monoclonal antibody to HSP72 and immunocytochemistry to localize HSP72 in the rat brain 24 hours following either 30 or 60 minutes of flurothyl-induced status epilepticus. Sprague-Dawley rats were anesthesized with halothane, paralyzed, and ventilated, and remained normothermic, normotensive, and well-oxygenated for the duration of the seizures. Seizure activity was quantified via analysis of the scalp EEG morphology. HSP72-like immunoreactivity (HSP72-LI) appeared in specific brain regions in a graded fashion that correlated with the duration and degree of seizure activity, and the amount of systemic acidosis. Milder seizures produced HSP72-LI limited to layers 2 and 3 of parietal cortex, dentate hilus cells, and CA1 pyramidal neurons. More extensive seizures led to HSP72-LI in layers 2,3, and 5 of parietal, temporal, and pyriform cortex, dentate hilus cells, CA1 and CA3 pyramidal neurons, and certain thalamic nuclei (including VPM, VL, VM, medial and lateral dorsal). These are similar to many (but not all) of the regions of irreversible injury described by Nevander et al (Ann Neurol 18:281-290, 1985) using a similar model. No HSP72-LI was observed in sham-treated controls or flurothyl-treated animals whose seizures were controlled with pentobarbital. Seizure-induced HSP72-LI thus appears to localize to certain regions of seizure-induced injury, and may provide a sensitive method of positively detecting neuronal injury relatively soon after status epilepticus. Whether or not HSP72 synthesis plays a protective or harmful role in the pathogenesis of seizures, or is only a marker for cell injury, remains to be determined.

411.4

ANATOMIC ORIGINATION AND SPREAD OF DISCHARGES IN THE LITHIUM-PILOCARPINE SEIZURE MODEL. A. Handforth and D.M. Treiman* (Spon: J. Engel). VAMC Wadsworth and Dept. of Neurology, UCLA, Los Angeles, CA 90024

We studied the stages of entry into status epilepticus in the lithium-pilocarpine model with the ^{14}C-2-deoxyglucose (2DG) method with the aim of determining the anatomic sites of seizure origination and subsequent spread. Status was induced in 16 LiCl-pretreated rats with pilocarpine, 20 mg/kg IP. 2DG, 40 uCi IV, was given either 1) at the beginning of discrete seizures (D), 2) during waxing-and-waning seizures (WW), 3) during continuous convulsive seizures with either fast-and-slow waves on EEG (FS); or 4) fast continuous spiking (FC). 10 min later the brain was removed; cut sections were apposed to X-ray film. The resulting autoradiographs revealed that the most restricted patterns of seizure-induced hypermetabolism occurred in D and WW subjects with minimal convulsive behavior. Intense activation was limited to orbital cortex and adjoining olfactory areas, substantia nigra, and part of striatum and pallidum. Convulsive activity in D and WW subjects was associated with activation of limbic, rostral neocortical and thalamic areas. In FS, forebrain activation was global but submaximal in caudal neocortex and parts of striatum. In FC, forebrain recruitment was completed. These results suggest that in this model, seizure activity originates in orbital cortex and nearby olfactory areas, then recruits successive anatomic shells.

411.5

NON-CONVULSIVE STATUS EPILEPTICUS PRODUCED BY ETHYLKETOCYCLAZOCINE AND PILOCARPINE CO-ADMINISTRATION. J.S. Kiefer* and G.G. Buterbaugh. Department of Pharmacology and Toxicology, University of Maryland School of Pharmacy, Baltimore, MD 21201.

Since opioid peptides are proposed to play a role in the regulation of seizure threshold and postictal activity, we evaluated the effects of the kappa receptor agonist ethylketocyclazocine (EKC) on pilocarpine induced seizures in rats. Pilocarpine (100 - 250 mg/kg; ip) produced stereotypies, but not convulsions. EKC (4 - 8 mg/kg; ip) caused EEG bursting and sedation but not convulsions. Administration of EKC (4 mg/kg) 5 minutes prior to pilocarpine (100 - 150 mg/kg) consistently resulted in the onset of status epilepticus (SE) in female and male rats within 20 - 25 min. EKC/pilocarpine induced SE was relatively mild compared to the high dose pilocarpine (400 mg/kg) model. SE was nonconvulsive throughout the 3 hour observation period; some rats showed clonic convulsions after about 2.5 hrs. Histological examination revealed mild pathology in the amygdala, piriform cortex, CA1 and CA3 of rats after three hours of SE. Preliminary results suggest age-related differences in sensitivity to the SE produced by EKC/pilocarpine co-administration. These results provide further evidence for a role for opioid peptides in seizure mechanisms in general and in particular, status epilepticus. (Supported in part by PHS NS 20670

411.6

EFFECTS OF NORADRENERGIC AGONISTS MICROINFUSED INTO THE PONTINE RETICULAR FORMATION ON MAXIMAL ELECTROSHOCK-INDUCED SEIZURES IN THE RAT. M. L. Lanker and R. A. Browning, Dept. Physiology, School of Medicine, Southern Illinois University, Carbondale, IL 62901

Recent research has implicated the midbrain and pontine reticular formation in the propagation of generalized tonic seizures. Specifically, inhibition of the tonic components of generalized seizures [e.g. maximal electroshock (MES), pentylenetetrazol & audiogenic)] has been observed following lesions of the nucleus reticularis pontis oralis (RPO) which include the superior cerebellar peduncles (Browning et al., Epilepsia 22:583, 1981). Furthermore, considerable evidence indicates that norepinephrine (NE) inhibits the tonic components of MES-induced seizures. Therefore, we investigated the effects of microinfusing noradrenergic agonists [NE, phenylephrine (PE) and isoproterenol (ISO)] into the RPO on tonic hindlimb extension (HLE) in the MES test.

Sprague-Dawley rats were pretested to ensure the presence of HLE in response to MES. The rats were bilaterally implanted with 23 gauge guide cannulae directed at the RPO. Two weeks after implantation the rats were infused with 0.5 µl NE (0.5, 1.0, 2.0 µg), PE (8.0, 16.0 µg), ISO (2.0 µg), or saline bilaterally and twenty minutes later subjected to transcorneal MES (0.2sec, 150mA). NE, PE and ISO in the doses used in the present study failed to alter the incidence, latency or duration of HLE compared to vehicle-infused controls.

These data suggest that neither alpha$_1$ nor beta adrenoceptor agonists are effective in attenuating MES-induced seizures when directly applied to the RPO. Additional doses of ISO as well as an alpha$_2$ agonist are currently being examined.

VENTRAL HIPPOCAMPAL DENTATE GRANULE CELL LESIONS POTENTIATE CONVULSIONS INDUCED BY A MU OPIOID RECEPTOR AGONIST. P.H.K. Lee and J.S. Hong. LMIN, NIEHS/NIH, Research Triangle Park, NC 27709.

The present study investigated the role of hippocampal dentate granule cells on convulsions and wet dog shakes (WDS) induced by PLO17, a mu opioid receptor agonist. PLO17 (5 ug) was injected into the left ventral hippocampus of rats 14 days after unilateral or bilateral colchicine (COL; 2 ug/site) lesions of ventral hippocampal dentate granule cells. PLO17 injected into control (ACSF-treated) animals produced convulsions and numerous WDS that lasted for less than 1 h. PLO17-induced WDS were significantly reduced in unilateral COL-pretreated rats, and completely inhibited in bilateral COL-pretreated animals. In contrast, generalized motor seizures evoked by PLO17 were potentiated and prolonged in COL-pretreated animals since status epilepticus was observed in both unilateral and bilateral COL-pretreated rats but not in control animals. Furthermore, PLO17 induced widespread, seizure-related damages of CA3/CA1 pyramidal cells in COL-pretreated rats, but not in control animals. These results suggest that dentate granule cells in the ventral hippocampus are essential for the elaboration of WDS. However, these neurons may play an inhibitory role in the spread of seizure activity within the hippocampus or limbic structures.

THE CENTRAL MEDIAL INTRALAMINAR NUCLEUS: THALAMIC SITE OF SEIZURE REGULATION. J.W. Miller, C. Hall* and J.A. Ferrendelli, Depts. of Neurology and Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

This study demonstrates that the central medial nucleus (CeM) of the thalamus controls the threshold and expression of generalized seizures. Injection of the selective $GABA_A$ agonist piperidine-4-sulfonic acid in or near the CeM significantly facilitated bicuculline induced myoclonic and clonic seizures but had no effect on tonic seizures. In contrast, the selective $GABA_B$ agonist (-)baclofen markedly facilitated all these seizure types and also altered the probability of tonic hindlimb extension (THE) with the tonic seizure. Low doses of (-)baclofen (0.3 to 3 nmoles) increased THE occurrence two to three fold, while higher doses did not. Both types of GABA agonists also depressed the animals' level of arousal. Systematic mapping of the midline thalamus with very small (-)baclofen injections (2 nmoles in 0.05µl) revealed that injections centered in the CeM produced the greatest depression of arousal, and significantly lowered all seizure thresholds while injections centered in adjacent nuclei did not.

This work indicates that different GABAergic neural mechanisms in the CeM are responsible for modulating both the threshold and expression of various seizure types. The results of this study are best explained by the concept that the CeM is not a site of seizure origination or spread by rather acts via widespread connections to regulate other structures involved in seizures. Supported by NIH grants NS01296 and NS **14834**.

SYNCHRONIZATION OF SEIZURE ACTIVITY IN THE HIPPOCAMPUS AND ENTORHINAL CORTEX OF THE PERFUSED WHOLE GUINEA-PIG BRAIN M. Mühlethaler* and B.A. MacVicar+ (Sponsor: R. Auer). *Department of Physiology, CMU, Geneva, Switzerland and +Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada.

Intracellular recordings were obtained from the entorhinal cortex (EC) and extracellular recordings were obtained simultaneously from the hippocampus (HIP) in perfused whole guinea-pig brains. Extracellular stimulation of the EC evoked a synaptic potential in EC neurons (and sometimes an antidromic potential) and evoked a population EPSP-spike in the HIP which facilitated at 1Hz. Higher frequency stimulation evoked ictal-type seizure discharges. Intracellular recordings in EC neurons indicated that ictal discharges were composed of a train of paroxysmal depolarizing shifts (PDS) superimposed upon a slow depolarization. EC PDS's were synchronized with population bursts in the HIP. As ictal discharges slowed and then blocked, PDS's occurred independently in the EC and HIP and extracellular stimulation in EC could not evoke synaptic potentials in the HIP. Therefore reciprocal excitatory connections between the HIP and EC could be important in synchronizing ictal discharges.

411.10

DIFFERENTIAL EFFECTS OF COLCHICINE LESIONS OF DENTATE GRANULE CELLS ON WET DOG SHAKES AND SEIZURES ELICITED BY PERFORANT PATH STIMULATION. M.I. Barnes* and C.L. Mitchell, (SPON: E.G. Drust). LMIN, NIEHS/NIH, Research Triangle Park, NC 27709.

Destruction of dentate granule cells (DGC) abolishes wet dog shakes (WDS) elicited by kainic acid (Grimes et al., J. Neurosci. 8:256, 1988) and induced by kindling of the entorhinal cortex (Frush and McNamara, Exp. Neurol. 92:102, 1986). However, the effect of destruction of DGC on seizure activity is not clear (cf. Grimes et al., ibid vs Okozaki and Nadler, Neurosci. 26:763, 1988). Previous studies destroyed DGC in both the dorsal (D) and ventral (V) hippocampus. We compared the effects of destruction of D vs V-DGC on WDS and seizures (S). Destruction of V-DGC almost completely abolished WDS ($\bar{x}$ = 1 ± 3.5) compared to artificial cerebrospinal fluid (ACSF) animals ($\bar{x}$ = 29 ± 3.5). However, both V and D colchicine lesions lowered S thresholds. S threshold was defined as the current required to elicit rearing accompanied by fore-limb clonus. The effect on S threshold was especially pronounced 8 weeks post colchicine lesions of the V-DGC where 7 of 10 animals exhibited seizures at 1 mA or less. Examination at even longer time intervals is thus warranted.

LONG-TERM ELECTROPHYSIOLOGIC AND BIOCHEMICAL MONITORING IN THE RAT INTRA-AMYGDALOID TETANUS TOXIN CHRONIC MODEL OF EPILEPSY.

D.S. Garant*, Y.-M. Chen*, T.P. Bleck, and R.G. Fariello.
Depts. Neurol. Sci. and Int. Med., Rush Univ., Chicago, IL 60612.

An infusion of picogram amounts of tetanus toxin into rat amygdala results in spontaneous seizures peaking in severity and frequency at 5-10 days. We used awake, behaving male Fisher rats with chronic electrode implants for EEG, and guide cannulae for toxin infusions and in vivo microdialysis.

Confirming our cat studies, rats showed early multifocality in epileptiform EEG activity, with spikes and seizures arising independently from amygdala, hippocampus, and cortex; by the peak of response the infused amygdala was the driving seizure focus, with secondary icti observed consistently from hippocampus.

Focal microdialysis demonstrated decreased basal and veratrine stimulated GABA levels, most consistent at the seizure peak, but appearing to persist some weeks thereafter. Basal levels of Asp and Glu were elevated during the first post-toxin days.

Studies are now underway to examine the effects of this model on hippocampal transmitter levels and synaptic plasticity, and on amino acid receptor binding.

411.12

INTRACEREBRAL MPP+ PRODUCES EPILEPTIFORM ACTIVITY INDEPENDENT OF CATECHOLAMINE RELEASE.

R.G. Fariello, U. Bonuccelli*, and D.S. Garant*.
Dept. Neurol. Sci., Rush Univ., Chicago, IL 60612.

Systemic administration of MPTP produces acute convulsions in all awake species studied. Mice with implanted hippocampal electrodes show EEG spikes and seizures after i.p. MPTP; this activity is dose dependent, attenuated by MAOIs, and exacerbated by diethyldithiocarbamate, suggesting dependence on intracerebral MPP+.

Rats with implanted electrodes and guide cannulae were infused with MPTP or MPP+ into brain. Both compounds were epileptogenic when infused into amygdala or hippocampus; MPP+ appeared faster-acting and more potent. Both amygdaloid and hippocampal infusion of MPP+ resulted in extrafocal discharges at lower doses (150 pmol to 60 nmol); doses of 3-6 umol MPP+ in hippocampus produced focal and behavioral seizures. Hippocampal MPP+ responses were unaffected by reserpinization (5 mg/kg for 3 previous days). No such abnormalities were observed after infusions (30 nmol) into substantia nigra, striatum, or deep prepyriform cortex.

These results indicate a unique excitatory action of MPP+ in brain independent of its acute catecholamine releasing effect.

411.13

EMBRYONIC BEHAVIOR AS A MODEL FOR POSTNATAL EPILEPTIFORM ACTIVITY. R. R. Provine. Dept. Psychology, UMBC, Baltimore, MD 21228.

Chick embryonic behavior is produced by spontaneous bursts of spinal cord neurons first described by Provine and associates (Brain Res. 29 (1971) p. 155; 41 (1972) p. 375; 45 (1972) p. 127; J. Neurobiol. 8 (1977) p. 217). The bursts are synchronized with movement in motile embryos and motor nerve discharges in curarized preparations. The bursts usually begin with a high amplitude "initiating" discharge that is usually followed by a longer, lower amplitude, and more variable "afterdischarge." Before 7 days, bursts consist only of "initiating" discharges. Dual electrode studies indicate that bursts occur almost simultaneously along the rostrocaudal axis of the cord; bursts are initiated at varying cord loci and are then propagated throughout the remainder of the cord. The burstiness and transregional coupling of discharges are not typical of the postnatal cord.

The transregionally synchronized bursts of cord and perhaps other parts of the healthy embryonic CNS may provide a useful model of adult epileptiform activity that does not require the poisons, trauma, or kindling necessary in other model systems. Indeed, some epileptiform disorders may be a postnatal remnant or recapitulation of an embryo-like state caused by developmental disorder, trauma or disease.

411.14

γ-HYDROXYBUTYRATE (GHB) MODEL OF ABSENCE: CORRELATION OF γ-BUTYROLACTONE (GBL) AND GHB LEVELS IN BRAIN WITH EEG CHANGES. O. C. Snead, Dept. Peds., Univ. of AL, Bham, AL 35294 and Childrens Hospital of Los Angeles, Los Angeles, CA 90027.

γ-Hydroxybutyrate (GHB) is a naturally occurring compound which produces absence like seizures when given to animals. The prodrug of GHB, GBL, is used to produce this animal model of generalized absence seizures. A time course study of levels of GBL and GHB in brain in freely moving animals given varying doses of either GBL or GHB was performed under continuous EEG monitoring. The threshold concentration of GHB in brain for absence-like seizure was 20 µg/g. This concentration was achieved earlier and at lower doses with GBL than GHB. GBL was detected in brain in levels one half that of GHB within one minute of GBL administration but dropped off rapidly such that 10 minutes after a dose of GBL the ratio of GHB to GBL was 40. The rapidity and consistency of onset of seizure produced by GBL can be attributed to pharmacokinetic differences between GBL and GHB, since the EEG changes in both GHB and GBL treated animals were dependent on achieving a certain level of GHB irrespective of the concentration of GBL.

411.15

INTRACELLULAR RECORDING OF THE SPONTANEOUS ACTIVITY IN DORSAL HORN INTERNEURONS INDUCED BY ELEVATED CA^{2+} IN MOUSE SPINAL CORDS *IN VITRO*.

E. Bernard*, L. Urbán*, G. G. Somjen (SPON: A. Sylvia). Div. Neurosurgery and Div. Physiology, Duke Univ. Med. Ctr., Durham, NC 27710

Elevated $[Ca^{2+}]_o$ as well as low $[Mg^{2+}]_o$ induce irregularly recurring "interictal" type spontaneous discharges in dorsal and ventral roots (DRs and VRs) and dorsal horn (DH) gray matter of isolated mouse spinal cords (Czéh & Somjen, Brain Res., in press). In the present study, hemisected spinal cords with attached roots were prepared from 9-14 day-old mice and maintained in an interface chamber at 34.5 C. Suction electrodes were used to stimulate and to record from DR and VR. DH neurons were sought by intracellular micropipette electrodes filled with 4M K-acetate. When $[Ca^{2+}]$ in the bath was elevated to 2.4 or 3.6 mM the membrane potential was about 2 mV more negative than in control solution (1.2 mM) measured in the same 9 cells. The threshold of spike generation did not change. EPSPs evoked by DR stimulation became more prolonged in high $[Ca^{2+}]_o$. In 2.4 or 3.6 mM $[Ca^{2+}]_o$ 17 out of 25 cells were spontaneously active, compared to 7 out of 17 cells in 1.2 mM $[Ca^{2+}]_o$ Spontaneous synaptic activity of 6 cells was synchronous with the dorsal root discharges in elevated $[Ca^{2+}]_o$. We conclude that only a part of the DH cell population is recruited into synchronized spontaneous activity in elevated $[Ca^{2+}]_o$. Waves of depolarization of primary afferent terminals appear to be responsible for the synchronization. (Supported by grants NS17771, NS06233)

411.16

HYPERAMMONEMIA PRODUCES SEIZURES BY NEURONAL DEPOLARIZATION.

D. Deupree and W. Raabe. Neurosurgery and Neurology, VA Med. Ctr. and University of Minnesota, Minneapolis, MN 55417.

Hyperammonemia can cause seizures. These seizures are thought to be of spinal origin, and to be initiated by the inactivation of Cl^--extrusion from neurons and decrease of postsynaptic inhibition. However, intracellular recordings from spinal motoneurons during the inactivation of Cl^--extrusion by NH_4^+ showed no paroxysmal discharges.

To investigate the occurrence of paroxysmal discharges from spinal motoneurons, monosynaptic excitatory potentials were recorded from ventral roots (VR-EPSP) in barbiturate anesthetized cats with spinal section at L_2. In addition, an extracellular electrode in the ventral horn recorded the field potential in response to stimulation of the ventral roots (ventral root field potential - VFRP). Ammonium acetate i.v., 6 mM/kg bodyweight, decreased the VR-EPSP and, nevertheless, inititated motoneuron discharges. Simultaneously, spontaneous paroxysmal discharges were observed, and the negative component of the VRFP was significantly increased.

These observations indicate that severe hyperammonemia depolarizes motoneurons and inititates spontaneous paroxysmal discharges. Since NH_4^+ inactivates Cl^--extrusion without (and before) depolarizing motoneurons, it is inferred that neuronal depolarization, and not a decrease of postsynaptic inhibition, initiates the seizures due to hyperammonemia.

411.17

GABA-SENSITIVE NIGRAL EFFERENTS MAPPED WITH 14C DEOXYGLUCOSE AUTORADIOGRAPHY IN RAT PUPS.
E.F. Sperber, L.L. Brown, D.M. Smith* & S.L. Moshé. Depts of Neurology & Neuroscience, Albert Einstein College of Medicine, Bronx, NY.

The substantia nigra plays a role in the modification of seizures. In rat pups, nigral infusions of baclofen, a $GABA_B$ agonist, have an anticonvulsant effect. To identify the brain regions involved in the baclofen induced, nigral-mediated seizure suppression, we used 14C deoxyglucose (DG) autoradiography. A unilateral cannula was implanted in the substantia nigra of each of 9 rat pups (age 14 days). Two days later, they were infused with 100 ng/0.25 µl of baclofen, the anticonvulsant dose, or an equivalent volume of saline. Thirty minutes later, the pups were injected with 10 µCi of DG, ip. Analysis of the autoradiograms demonstrated ipsilateral decreases in glucose utilization in the pontine reticular formation, auditory cortex, posterior thalamic nuclei, dorsal striatum and frontal cortex of the baclofen-treated pups as compared with controls. These results suggest that the baclofen mediated suppression of seizures in pups involves the reticular formation and thalamic areas which can have widespread cortical influence.

411.18

CURRENT SOURCE DENSITY ANALYSIS OF HIPPOCAMPAL SEIZURE ACTIVITY IN THE ANAESTHETIZED RAT.
W.J.Wadman, A.J.A.Juta* and G.G.Somjen. Dept. of Exp. Zoology, Univ. of Amsterdam, Amsterdam 1098SM, The Netherlands.

A sixteen channel multi-electrode (Otto Sensors, 150 µm contact distance) was used in the halothane anaesthetized rat to record electrical activity from the dorsal hippocampus: area CA1 and Fascia Dentata. A current source density (CSD) analysis, for which the necessary conductivity measurements were performed, allowed the localization of current sinks and sources during tetanic stimulation at the Schaffer collaterals (SC): 10-50 Hz for 2-10 seconds. DC-measurements revealed a dendritic sink that increased in amplitude during the tetanus. This profile was compared with potentials evoked by single or double stimuli to SC or to Alveus fibers in Stratum Oriens. From the same experiment we analysed the electrical seizure that often followed the tetanic stimulation. Bursts during a seizure in area CA1 showed a dendritic sink in Stratum Radiatum and a somatic source in Stratum Pyramidale. Under these conditions conductivity corrections were of marginal importance. In some animals a relative strong stimulus could lead to a spreading depression (SD) ending the seizure activity. In this case a strong dendritic sink is accompanied by a somatic source in CA1 pyramidal cells and in granular cells in both blades of the dentate, be it seconds apart.

411.19

CURRENT SOURCE DENSITY ANALYSIS OF PROPAGATING EPILEPTIFORM ACTIVITY IN RAT PIRIFORM CORTEX REVEALS INVOLVEMENT OF INTRINSIC ASSOCIATION FIBERS.
K.L.Ketchum* and L.B.Haberly. Dept. of Anatomy., Univ. of Wisc., Madison, WI 53706.

The importance of piriform cortex (PC) in experimental models of epilepsy has been demonstrated by the discovery that injection of picomole amounts of convulsants in deep ant. PC evokes generalized seizures (Piredda & Gale, Nature 317:623) and that interictal spikes in kindled animals (Racine et al, Br. Res. 454:251) usually are initiated in PC. CSD analysis was used to investigate the role of association fibers in the initiation and propagation of epileptiform activity in PC. Picrotoxin (Ptx) was applied focally to the ant. PC of urethane anesthetized rats. CSD analysis was performed on time-locked epileptiform activity evoked by shocks to the lateral olfactory tract (LOT). Interictal spikes occurred 5-10mm caudal to Ptx application sites in ant. PC prior to development within the sites. CSD analysis at caudal sites revealed an abnormally large inward current (sink) in sup. layer Ib where association fibers from the ant. PC terminate throughout the PC and entorhinal cortex. This peak was followed immediately by synchronous pyramidal cell firing and a subsequent high amplitude sink in layer Ib. An intriguing finding was that the latency between successive current peaks of epileptiform events was 20ms or integral multiples of 20ms at both ant. and post. sites.

CSD analysis of oscillatory responses to low strength shocks, resembling those recorded in response to odors, has revealed a stereotyped sequence of events that recurs during each cycle of a 20ms oscillation (Ketchum & Haberly, Soc. Neur. Abs. 14:1188). The correspondence in latency of peak dendritic currents during epileptiform activity to the period of synaptic events during this oscillation suggests a possible link between the evolution of epileptiform activity in the PC and the dynamics of the normal response to odor stimulation. CROSS CORRELATION VARIABLE LATENCY AVERAGING OF SYNCHRONIZED AFTERDISCHARGES RECORDED FROM HIPPOCAMPAL SLICES.
E.J. Smith*, D.K. Terry*, G.L. Klotz*, R.J. Brady and J.W. Swann. Wadsworth Ctr. for Labs & Res., NYS Dept. of Health, Albany, NY 12201.

Electrographic seizures are recognized to be physiologically complex. One feature of seizure discharges is that the latencies of the synchronized discharges of the afterdischarge are different from one seizure-like event to the next. Thus conventional signal averaging of these events is impossible. In order to begin a detailed analysis of these discharges we have developed an adaptive variable latency averaging procedure. Initially we analyzed after discharges of 2 sec. duration, each consisting of an initial epileptiform burst and 5-15 synchronized discharges. The computer program first detects each individual synchronized discharge in each electrographic event. This is accomplished either by zero crossings in a differentiated signal or by polynomial fitting procedures. After detection, cross correlation is used to align the signal in time with a template. The process is repeated with each succeeding after discharge and each new average updates the template. These procedures result in a smoothly filtered signal for each of the synchronized discharges. ULTRASTRUCTURAL PATHOLOGY OF SKELETAL MUSCLE IN PARANEOPLASTIC SYNDROME.
A. Márquez*, Y. Blanco*, P. Tonino*, H.J. Finol, J. Prieto* and L.A. Sosa*. Medicine and Sciences Faculties, Universidad Central de Venezuela and "José Ignacio Baldó" Hospital. Apartado 50587, Sabana Grande, Caracas 1050, Venezuela.

Patients suffering from cancer without muscle metastases may present muscular weakness and wasting. In order to study the ultrastructural basis of these phenomenons muscle biopsies were taken from rectus abdominis of patients with gastric (n=4) and colonic (n=4) cancers and from quadriceps femoris of patients with bronchogenic cancer (n=8). Two different types of damage were observed, biopsies from patients with gastric and colonic cancers presented slightly atrophied fibers mixed with many fibers with segmental necrosis, capillary alterations which included necrosis, and a mononuclear cell infiltration formed by lymphocytes and macrophages; biopsies from patients with bronchogenic cancer exhibited a varied degree of atrophy from slight to severe and occasionally necrosis was seen. Capillary alterations were similar. The differences between these groups could be partially explained because the biopsies were obtained from muscles with different dynamic properties and fiber composition. This work demonstrates that muscle alterations in paraneoplastic syndrome are associated with abnormalities of morphological integrity. Supported by grants from CDCH of UCV (C-03-17-86), Fundación Polar and British Council.

412.2

REDUCED ACETYLCHOLINE RECEPTOR EXPRESSION IN MUSCLES FROM CHRONIC ETHANOL-FED RATS.
I.R. Held, S.T. Sayers* and J.A. McLane, VA Hospital, Hines, IL 60141 and Dept. of Biochemistry, Loyola Univ. Sch. Med., Maywood, IL 60153

Our objective was to determine whether the gene expression of acetylcholine receptor (AChR) protein is altered in muscles from an animal model of chronic alcoholism. Test rats received a nutritionally complete liquid diet containing 6.7% ethanol. Age and weight-matched control rats were pair-fed an isocaloric diet. After a 16 week diet period, soleus muscles were obtained, and total RNA and poly(A)+ RNA were isolated. GeneScreen Plus membranes were slot-blotted with several levels of each RNA sample, and hybridized with a 32P-labeled complementary riboprobe to detect AChR α-subunit mRNA levels. This riboprobe was prepared by SP6 RNA polymerase transcription of a cDNA clone (BMA 407-12 obtained from J. Boulter) that encodes the AChR α-subunit. Autoradiographs of the membranes were quantitated by laser densitometry. As an internal control, stripped membranes were reprobed with a 32P-labeled riboprobe prepared from a linearized H-ras DNA template. The AChR α-subunit mRNA levels were significantly decreased by 39.6% in solei from the ethanol-fed rats versus pair-fed controls. As expected, H-ras expression was not changed. The reduced synthesis of AChR protein may contribute to the muscle weakness and alcoholic myopathy that commonly occurs during chronic alcoholism.

412.3

GUANETHIDINE NEUROPATHY IN RATS: A MODEL OF HUMAN SYMPATHETIC NEUROPATHY. E.E. Benarroch, J.D. Schmelzer*, K.K. Ward*, P.A. Low. Neurophysiology Lab., Mayo Clinic, Rochester, MN 55905

Guanethidine (GU) produces chemical sympathectomy in rats (GUSX). We examined GUSX as a model of human sympathetic neuropathy. Rats (250-350 g) received GU (40 mg/k i.p.) or saline for 6-12 w. Subsequently, they were anesthetized (Inactin) and canulated for mean arterial pressure (MAP) and heart rate (HR) recording. Tyramine (Tyr, 30 mmols) and phenylephrine (Phen, 0.06 or 0.6 μM) were infused intravenously. Norepinephrine (NE) levels in plasma, femoral artery (FA), superior cervical ganglion (SCG), atrium, and sciatic and vagus nerves were measured by HPLC. As compared to controls, GUSX rats showed (a) lower basal MAP but not plasma NE, (b) blunted responses to Tyr in terms of increase in MAP (3.5±6.8 vs. 90±3.3 mm Hg; $p<0.0001$) and plasma NE (0.12±0.11 vs. 6.16±0.41 ng/ml; $p<0.0002$), (c) exaggerated pressor responses to Phe (e.g., with 0.06 μmol, 59.2±3.2 vs. 12.3±6.74 mmHg, $p<0.001$), and (d) lower NE levels (ng/g) in all tissues (e.g., SCG: 0.54±0.14 vs. 16.73±3.37, $p<0.003$; FA: 0.09±0.02 vs. 1.62±0.15, $p<0.001$). There was correlation between NE content in SCG and FA and responses to Tyr and Phen, respectively. There was no correlation between NE levels in plasma and tissue. Thus, (a) GUSX reproduces findings of human sympathetic neuropathy and (b) pharmacological responses, but not basal plasma NE, reflect the degree of NE depletion.

412.4

OXYGEN-FREE RADICAL (OFR) EFFECTS ON THE SCIATIC NERVE IN EXPERIMENTAL DIABETES. K.K. Ward*, N. Parinandi*, P.A. Low (SPON: J.P. Whisnant). Neurophysiology Laboratory, Department of Neurology, Mayo Foundation, Rochester, MN 55905

We have previously reported the presence of endoneurial hypoxia, ischemia, impairment of the blood-nerve barrier and reduction of norepinephrine (NE) and 6-keto-prostaglandin $F_{1\alpha}$ in chronic streptozotocin diabetic neuropathy (SDN) and interpreted these findings as suggesting the involvement of OFR.[1,2] We now report our studies on sciatic nerve conjugated dienes, hydroperoxides, NE, and malondialdehyde (MDA) in SDN at 1, 4, and 12 months in male SD rats. Severe hyperglycemia was present throughout in SDN. Conjugated dienes were consistently increased at all time points, hydroperoxides were consistently reduced, and MDA was not significantly different in SDN when compared with controls.

These findings are consistent with the presence of OFR effect, and emphasizes the need to measure several indices.

PATCH CLAMP MEASUREMENTS OF VISCOELASTIC PROPERTIES AND MECHANOELECTRIC TRANSDUCTION IN DYSTROPHIC MUSCLE MEMBRANE. B.J. Cooper* and O.P. Hamill. Depts. Pathology and Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14853.

Recently, the gene which is defective in Duchenne muscular dystrophy (DMD) has been identified and its product, a 400 kD protein named dystrophin, has been shown to be absent or abnormal in patients with DMD as well as in the canine model of the disease (CXMD). However, at this stage there is no direct evidence on the mechanism by which dystrophin actually maintains healthy muscle function nor why its absence results in a progressive muscular weakness. Based upon its subcellular localization to the cytoplasmic membrane face, its cytoskeletal characteristics, the evidence of membrane injury in DMD, and the rise in intracellular Ca ions, a plausible hypothesis is that dystrophin plays some role in stabilizing the plasma membrane of healthy muscle cells, in its absence, the membrane may be more fragile and leaky to ions such as Ca^{++}. Another possible pathogenic feature is that there is abnormal activation of the stretch activated (SA) Ca^{++}-permeable channel that has been reported in cultured muscle cells. To test these ideas we carried out patch clamp measurements of acutely isolated adult muscle taken from toe muscle biopsies of normal dog as well as CXMD dog. We detected no difference between normal and dystrophic muscle in elasticity, as judged by the pressure required to break the membrane. In acutely dissociated adult muscle we were unable to detect SA channels in either healthy or dystrophic muscles, which may either reflect a real absence in fully developed muscle, or a particularly low channel density. Supported by the Cornell Biotechnology Program.

IMPAIRED SKIN FIBROBLAST CARNITINE UPTAKE IN HETEROZYGOTE PARENTS OF CHILDHOOD CARNITINE-RESPONSIVE CARDIOMYOPATHY. I. Tein*, D.C. De Vivo, S. Servidei*, E. Bertini*, F. Bierman*, S. DiMauro. Columbia-Presbyterian Medical Center, New York, NY 10032.

Evidence is emerging that primary systemic carnitine deficiency, a potentially lethal but treatable inborn error of fatty acid oxidation, involves a cellular defect in carnitine uptake (Eriksson et al., Eur J Pediatr, 147: 662, 1988; Treem et al., NEJM, 319: 1331, 1988). We also studied carnitine uptake in cultured skin fibroblasts from two unrelated children with carnitine-responsive cardiomyopathy and myopathy and present new studies in the heterozygote parents of one patient. The patients had low muscle and serum carnitine and a severe renal leak and responded dramatically to oral carnitine supplementation.

[^{3}H]L-Carnitine uptake was determined *in vitro* under linear time kinetics. Substrate concentrations were varied from 0.1 to 1,000 μM. Physiological uptake was determined at carnitine concentrations between 0.1 to 50 μM. Nonspecific uptake was determined at a concentration of 10 mM. The two patients showed no significant uptake in the physiological range, implying a marked deficiency in the specific, high affinity, low concentration uptake mechanism. Both presumed heterozygote parents of patient #1 had normal carnitine substrate concentration K_m values but significantly decreased V_{max} values for carnitine uptake (40% of controls). This, in addition to the reduced serum carnitine levels in both parents of patient #2, supports an autosomal recessive inheritance pattern.

ANTIBODIES FROM PATIENTS WITH LAMBERT-EATON SYNDROME RECOGNIZE BOTH PLASMA MEMBRANE AND CYTOSOLIC ANTIGENS IN CHROMAFFIN CELLS. M.P. Viglione, C.E. Creutz* and Yong I. Kim. Depts. of Neuroscience, Pharmacology, Biomedical Engineering and Neurology. University of Virginia, Health Sciences Center, Charlottesville, VA 22908.

Lambert-Eaton syndrome (LES) is a paraneoplastic (70% have associated small-cell carcinoma of the lung or SCCL) neurological disorder characterized by the decreased release of ACh at the neuromuscular junction. As LES autoantibodies have been shown to inhibit the function of voltage-dependent calcium channels in bovine adrenal chromaffin cells (Science, 239:405, 1988), we were interested in whether LES antibodies recognized calcium channel subunits on Western blots of chromaffin cell fractions. Post-nuclear supernatant, post-microsomal supernatant (cytosol) and plasma membrane (PM) fractions were obtained by sucrose gradient centrifugation, run on reducing SDS PAGE and Western blots probed with 0.1 mg/ml IgG from 9 LES patients, 1 SCCL patient and 6 normal individuals. Seven of the nine LES IgGs interacted with a wide range of PM (45-150 kDa) as well as cytosolic (25-135 kDa) proteins with no apparent pattern in regard to the association of LES with SCCL, efficacy of the LES IgG in reducing I_{Ca} or recognition of calcium channel subunits. Preincubation of LES IgG with cytosol before reacting with Westerns abolished IgG interaction with the PM fraction, confirming the presence of a cytosolic antigen that is also present on the PM. One control IgG reacted with a protein also recognized by LES or SCCL IgG.

Thus, LES autoantibodies react with antigens located in the PM and cytosol. It is not known whether this reaction is mediated by a population of autoantibodies distinct from those implicated in the functional inhibition of I_{Ca}. Therefore, we are investigating whether LES IgG is as effective in reducing I_{Ca} after interaction with cytosolic antigens.

MOLECULAR CLONING OF AN ANTIBODY THAT CROSS REACTS WITH DNA AND MYELIN FROM A PATIENT WITH CHRONIC LYMPHOCYTIC LEUKEMIA AND PERIPHERAL NEUROPATHY. **LA Spatz, KK Wong, M Williams and N Latov. Lab. of Neurology, Columbia University, College of Physicians and Surgeons, New York, NY 10032.**

Clones coding for the variable heavy (V_H) and light (V_L) chain genes of the IgM,k monoclonal autoantibody that binds to DNA and myelin from a patient with chronic lymphocytic leukemia (CLL) and peripheral neuropathy were isolated from a cDNA library, constructed with polyA RNA from a human hybridoma line secreting the autoantibody.

Sequence analysis revealed that the V_H gene has 96% homology to the VH26 germline gene which is a member of the V_HIII gene family and frequently utilized in anti-DNA antibodies. The V_K gene has 99% homology to the V_g gene of the K_KIIIa subgroup of the V_K gene family. Genes of the V_KIIIb subgroup which is assigned a separate subgroup from V_KIIIa on the basis of a single amino acid difference, have frequently been observed in antibodies with rheumatoid factor activity. This supports the theory that autoantibodies are often encoded by a restricted repertoire of variable region genes. Further comparison of the V_H and V_K sequences of the autoantibody with the germline sequences, suggest that the autoantibody arose by somatic mutation in the hypervariable regions which can alter antibody specificity and lead to autoimmune disease.

CLUES IN THE PATHOGENESIS OF THE MOTOR NEURON DEGENERATION (Mnd) MOUSE. **J.E. Mazurkiewicz*, L. Callahan* and A. Messer (SPON: G.A. Banker). Dept. of Anat., Cell Biol. & Neurobiol., Albany Med. Col. and Sch. of Public Health Sciences, SUNYA, Albany, NY 12208.**

The disease in the Mnd mouse is characterized by a progressive increase in motor dysfunction, leading to paralysis. Cytopathologic changes in spinal motoneurons correlate with the symptomology. In particular there is a dramatic rearrangement of neurofilaments in the perikarya. These cytoskeletal elements become marginated leaving large areas in the cytoplasm absent of immunostaining with antibodies to phosphorylated, to non-phosphorylated or to core (phosphorylation independent) neurofilament epitopes. These unstained regions, which appear to increase in volume with severity of the disease, are filled with inclusions that appear amorphous at the light microscopic level. Ultrastructurally, they assume a variety of forms: membrane bound vesicles filled with tubular profiles that are 25nm in diameter, sometimes containing paracrystalline arrays of undetermined substances; electron dense bodies with areas of fine lamellations; and ordinary lipofuscin. Light microscopic acid phosphatase histochemistry showed an increased, granular cytoplasmic staining in these neurons, commensurate with lysosomal localization. These data suggest that one aspect in the pathogenesis could include an increase in autophagocyctic activity leading to an abnormal accumulation of intracellular debris. If the tubular profiles present in the inclusions represent microtubule degradation, this could compromise axonal transport and lead to cell degeneration.

DIFFERENTIAL EXPRESSION OF FUNCTIONAL ABNORMALITIES IN MITOCHONDRIA FROM CARDIAC AND SKELETAL MUSCLE OF CHF-146 STRAIN DYSTROPHIC HAMSTERS (DH). J.H. Thakar, P.L. Johnson and S.K. Bhattacharya. Univ. of Tenn., Memphis, TN 38163.

Membrane-mediated excessive intracellular Ca accumulation (EICA) is a fundamental pathogenetic event associated with chronic muscle degeneration in Duchenne muscular dystrophy (DMD) (Bhattacharya & Johnson, Proc. 14th World Congress of Neurology, 881, 1989). EICA, necrosis, global muscle weakness, cardiomyopathy with EKG changes, and impaired mitochondrial function have been reported in the BIO 14.6 DH. Because of significant EICA in the CHF-146 strain DH (Soc. Neurosci. Abstr., 14:142, 1988), we studied the function of mitochondria (MIT) from cardiac and skeletal muscles of young (30-day) and old (>365-day) DH. CHF-148 strain normal hamsters served as controls. MIT were isolated and studied according to Thakar et al. (BBA, 314:8, 1973). MIT from skeletal muscles of young DH were uncoupled [ADP/O=0 and RCR=1], whereas those from the older DH were relatively normal. Conversely, myocardial MIT from young DH were functionally normal, although those from old DH revealed significant impairment of oxidative phosphorylation. We conclude that muscle weakness and MIT dysfunction in DH is expressed at an early age in the skeletal muscle, whereas these changes in the ventricular myocardium are manifested later. This parallels the clinical course in DMD, and further justifies the use of CHF-146 strain DH as an animal model for the study of DMD. (Supported by NIH Grant #AR-38540 to SKB.)

EFFECT OF LAMBERT-EATON MYASTHENIC SYNDROME (LEMS) PLASMA ON $^{45}Ca^{2+}$ UPTAKE IN RAT FOREBRAIN SYNAPTOSOMES. S.J. Simas and W.D. Atchison. Dept. of Pharmacol./Toxicol., Mich. State Univ., E. Lansing, MI 48824

LEMS, a disorder of neuromuscular transmission involving the reduction of nerve-evoked release of acetylcholine, has been transferred passively to mice by chronic injection of immunoglobulin G or plasma from affected humans. An autoantibody to the presynaptic Ca^{2+} channel has been suggested to mediate the pathogenesis of this disease. The objective of this study was to determine whether acute application of plasma from a patient with LEMS reduces depolarization-dependent Ca^{2+} uptake into synaptosomes. Rat forebrain synaptosomes were incubated under pure O_2 for 1 hr with varying concentrations of LEMS or control plasma (% total incubation volume). Heat inactivation of the LEMS plasma was necessary to prevent aggregation of the synaptosomes. Ca^{2+} uptake ($^{45}Ca^{2+}$) was measured during a 10 sec incubation period with either resting (5 mM KCl) or depolarizing (77.5 mM KCl) solution. Net potassium-stimulated influx was inhibited 15-20% by 6 and 12% LEMS plasma, while 24% plasma caused an approximate 30% reduction compared to synaptosomes incubated with equivalent concentrations of control plasma. These results indicate that LEMS plasma blocks depolarization-dependent uptake of Ca^{2+} into central axon terminals. This result is consistent with a site of action associated with presynaptic voltage-dependent Ca^{2+} channels in the nerve terminal. (Supported by the Muscular Dystrophy Association.)

Quantitative Analysis of Pendular Leg Motion in Normal and Spastic Subjects. D.C. Lin* and W.Z. Rymer (SPON: W.T. Rainey) Northwestern Med. School and Rehab. Inst. of Chicago, Chicago, IL 60611.

The purpose of the study was to examine oscillations of the leg in normal and spastic subjects. Specifically, the oscillation was in the form of a clinical test called the "pendulum test" in which gravity was used to oscillate the relaxed leg of a subject. The motivations for studying the pendulum test were to determine if realistic aspects of spasticity and neuromuscular control could be incorporated into a description of the motion and to better understand the underlying mechanisms involved. Data of a specific trial of the test were used to fit the parameters of a linear second order system model by a least squared error algorithm in order to simulate the passive motion. The model of spastic motion had additional components accounting for the abnormal stretch reflex activation found in spastics. These modifications, corresponding in time to muscle activation included: increased stiffness (K) and damping (B) values; changes in the zero length of the lumped stiffness element; and timing of changes and gains of mechanical parameters related to the EMG recorded.

The results showed a linear second order model was an inadequate description of the motion. First, the mechanical parameters (K and B) of the passive motion were found to be nonlinear. The nonlinearities included asymmetries for extension and flexion movements and amplitude dependence of K and B. These nonlinear properties were simulated in a model by making K and B a function of the direction of motion and the inverse of oscillation amplitude squared. Second, results from the spastic trials showed K and B did increase significantly, with a shift in spring zero length during stretch reflex activity. EMG recordings were useful in determining the timing and magnitude of these changes. A comparison of the model to other experimental data from the same subject showed the model could simulate different trials well; the variance accounted for by the model was usually over 90%. The analysis of the motion and model suggests that reflex thresholds for abnormal stretch reflex in spastics can be useful clinical measurements and obtained from the pendulum test.

PRESENCE OF DYSTROPHIN-LIKE MOLECULE IN NEURONS OF NORMAL AND DUCHENNE MUSCULAR DYSTROPHY HUMAN FETAL CULTURES. S. Torelli*, F. Muntoni*, A. Clerk*, P.N. Strong* & F. Gremo Dept.of Cytomorph.,Inst.of Child Neuropsych.,School of Med., Cagliari, Italy; Dept.of Paediatr.,Royal Postgrad. Med. School, London, England

Duchenne Muscular Dystrophy (DMD) is the result of the deficiency of a specific protein called dystrophin. Dystrophin is thought to be a cytoskeletal protein, binding to the inner plasma membrane and is present in all the types of muscle cells and in the brain. Since approximatly 30% of DMD patients are considered to be mentally deficient, it can be hypothesized that dystrophin deficiency can cause CNS defects. We have performed immunocytochemical studies on normal and DMD human fetal brain cultures, using polyclonal antibodies against dystrophin. Results showed that in normal cultures only neurons expressed dystrophin, whereas astrocytes and their precursor were always negative. Dystrophin-like staining was mainly present in cell bodies, neuronal processes were only faintly stained. DMD neurons showed peculiar morphological features, like membrane expansions similar to pseudopodia. Dystrophin-like staining was less intense respect to normal and the protein was unevenly distributed in patches in both cell bodies and processes.

SUBSTRATE-DEPENDENT RESPONSES OF NEURITES TO DC ELECTRIC FIELDS *IN VITRO*. Ann Rajnicek*, John Cork* and Kenneth Robinson* (SPON:C. Jaeger). Dept. of Biol. Sci., Purdue Univ., W. Lafayette, IN 47907.

It is known that neurites from the disaggregated neural tube cells of *Xenopus* embryos show a striking orientation toward the cathode (negative pole) in response to weak DC electric fields applied to cells growing on tissue culture plastic (Falcon). Since the substrate is known to affect neurite initiation and may also play a role in neurite guidance *in situ*, we have extended these studies to include the field-induced responses of *Xenopus* neurites growing on various substrates. Cells were grown in electrical field chambers constructed from tissue culture plastic dishes that were untreated or coated with poly-L-lysine (PL), laminin (L) or PL with an overlying layer of laminin (PL+L). Data were collected as photographs of each cell in the dish at the conclusion of the experiment. Negatives were analyzed with the aid of a digitizer interfaced with a microcomputer. Cells grown on PL and PL+L showed a strong orientation of neurites toward the anode but neurites on L substrates grew toward the cathode. Initiation sites were predominately on the cathodal sides of the cell bodies, regardless of substrate. Control cells showed random neurite initiation as well as random overall growth on all substrates. Experiments are currently underway to investigate the effect of surface charge on field-induced neurite guidance.

PATTERNED GROWTH OF HIPPOCAMPAL NEURONS ON MICROCIRCUITS. B.C.Wheeler, J.G.Eden* and G.J.Brewer. Southern Illinois Univ., Springfield, IL 62794 and Univ. of Illinois, Urbana, IL 61801.

To study synaptic specificity in CNS neurons, it would be helpful to provide conditions in which a limited number of growing axons and dendrites can be monitored for connective choices. Limited choices for neuronal connections can be controlled by growth of neurons on a patterned substrate (Soc. Neurosci. Abstr. 14:578). We have refined this UV laser-etched poly-lysine substrate by using a quartz mask fabricated with conventional electron beam lithography used in microelectronics. This permitted optimization of path width, path length and node size in a single complex array. Rat hippocampal neurons were dissociated and grown at low density (6,000 cells/cm^2) in defined medium (Brewer & Cotman, Brain Res., in press). A 3 μm path width was important to restrict process outgrowth to a single neurite per path. A node size of 30 μm diameter facilitated control of soma spacing. Apical dendrites typically oriented away from putative input to the proximal dendrites. Because individual cells can be regularly identified *in vitro* by light microscopy over many days, observations of process growth and "choices" will be possible. This model will facilitate studies of trophic influences on synaptogenesis. Supported in part by SIUSM Central Research Committee.

DIRECTED NEURITE OUTGROWTH FROM ETCHED COLLAGEN FIBERS. E. Wong, A. Rizvi*, D. Christiansen*, H.M. Geller and F. Silver*. Biomaterials Ctr. and Dept. of Pharm., UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

Collagen is an important substrate allowing attachment of neurons and their neurites. We previously reported neurite extension on collagenase-etched collagen fibers. In this study, we investigate neurite extension on etched fibers using immunocytochemical techniques.

Cortices were taken from the brains of Sprague-Dawley fetal rats at day 15 of gestation. Cortical cells were cultured for 48 to 96 hours on coverslips containing etched fibers. These cells were then fixed in an acid-alcohol solution and neurofilament-specific monoclonal antibody RT97 was added to the cells on coverslips, followed by the addition of fluorescein-conjugated IgG. The coverslips were mounted onto glass slides in glycerol containing 0.1% p-phenylenediamine. Neurite extension on etched fibers was examined under a microscope equipped with Normarski phase-contrast optics and an epifluorescence illuminator with a fluorescein filter.

Immunofluorescence of neurites and neurite fascicles was detected along the long axes of etched fibers. We conclude that etched collagen fibers allow the attachment of neurites and direct their extension.

OPIOID PEPTIDES STIMULATE THE GROWTH OF CGRP-IMMUNOREACTIVE DORSAL ROOT GANGLION AXONS IN ORGANOTYPIC TISSUE CULTURE. L. Takes* and S. Jeftinija (SPON: J. Carithers). Dept. Veterinary Anatomy, Iowa State University, Ames, Iowa 50011.

Ganglionic cells in the dorsal root ganglion (DRG) regenerate their axons after axotomy both in vivo and in vitro. Earlier reports have shown that opioid peptides stimulate outgrowth from the DRG in culture (Ilyinsky et al., 1987, Neurosci. 22:719-735.). The aim of the present study was to determine if the stimulatory action of opioids is exerted on neuronal elements directly, or indirectly by stimulating the growth of nonneuronal elements. By using immunocytochemistry we were able to identify calcitonin gene-related peptide (CGRP) positive axons and observe their relationship with the total population of cellular elements. DRG of 11 to 13-day-old rats were dissected and cultivated on chicken plasma-coated slides in Petri dishes or in rotating test tubes. Neurite outgrowth, size of the growth zone, and cell composition were estimated. Opioids stimulated both proliferation of nonneuronal elements and growth of CGRP positive neurites. A strong growth-promoting effect of opioids on neuronal and nonneuronal elements on tissue in culture has been observed in cultures grown in the presence of cytosine arabinoside. Opioids promoted the rate of migration of glial elements manifested as an increase in size of growth zone. The effect on the growth of CGRP positive neurites was dependent on the migration of glial elements. The present observations provide direct evidence that opioids promote the growth of DRG neuron CGRP immunoreactive neurites. In addition, the observations that glial migration outpaced neurite outgrowth, and that CGRP positive neurites almost always terminated in intimate contact with glial elements suggests that the stimulatory effect is an indirect one through the promotion of proliferation and migration of glial elements.

MORPHOLOGICAL FEATURES AND NEURAL DIFFERENTIATION OF NEUROBLASTOMA (N-2A) INDUCED BY REDUCED MEDIA SERUM CONCENTRATIONS. J. Rossi III, A.A. Messier*, E. Heyder* and A. B. Callahan*. Naval Submarine Medical Research Lab., Biomedical Sciences Dept., Groton, CT 06349.

Previous studies demonstrated that cloned cells extend neurites when incubated in media with low serum concentrations. In these studies N-2A cells were cultivated in media containing 10% fetal bovine serum (FBS). After 24 hrs the cells were subcultivated in media containing either 10%, 5%, or 1% FBS; or media containing 10%, 5%, or 1% NU-SERUM V (NSV). The cells were morphologically characterized after 24, 48, 72 and 96 hrs incubation. Reduced media serum concentration increased the proportion of differentiated cells, increased the neurite yield, increased the length of the neurites, increased the number of varicosities on the neurites, and increased the number of sites where varicosities on neurites from different cells overlapped or abutted. For all measures NSV substitution reliably induced greater neuritogenesis than equal concentrations of FBS.

THE EXPRESSION OF THE CLASS III BETA-TUBULIN ISOTYPE IN DEVELOPING NEURONS IN CULTURE. A. FERREIRA, A. CACERES, L. REBHUN AND A. FRANKFURTER. (SPON: G. Hall). Dept. of Biology, University of Virginia, Charlottesville, VA 22901

The expression of the class III beta-tubulin isotype was studied in cerebellar macroneurons and hippocampal pyramidal neurons in culture by means of a monoclonal antibody (clone J-1). The results obtained indicate that during cell nerve differentiation there is a progressive increase of this tubulin isotype, a phenomenon which is accompanied by modifications in its intracellular distribution and in its ability to incorporate into microtubules. The time course of its induction is different from the increase in total polymeric tubulin and the induction of MAP-2 and tau which parallel axonal and dendritic growth. On the contrary, its induction profile is similar to that of MAP-1a and MAP-1b. Besides, our results show that the appearance of colchicine-resistant microtubules containing this tubulin isotype is coincident with the one of stable microtubules containing high molecular weight-MAPs.

Taken collectively, the present observations suggest that the class III neuron specific beta-tubulin isotype is not a primary factor involved in the regulation of microtubule assembly during neurite growth, but that it may contribute to determine some unique binding property of MAPs to specific microtubule subsets.

413.7

GANGLIOSIDE ENHANCED NEURITE GROWTH: EVIDENCE FOR A SELECTIVE INDUCTION OF HIGH MOLECULAR WEIGHT MAP-2. A. Caceres*, A. Ferreira*, C. Landa*, and J. Busciglio* (SPON. L. Lampson), Inst. Ferreyra, Casilla de Correo 389, 5000 Cba. Argentina, and Dept. Quimica Biologica (U.N.C.) 5016 Cba. Argentina.

Neuroblastoma cells (clone S 26) maintained in serum free medium exhibit a progressive and significant induction of MAP-1a and Tau proteins, but not MAP-2; the time course of these inductions is highly correlated with an increase in microtubule mass which parallels neurite growth.

Bovine brain gangliosides (BBG) enhance the neurite outgrowth response of these cells. We report here that one effect of gangliosides is to selectively and dramatically induce the expression of MAP-2; our results also indicate a strong parallelism between this induction and the increase in microtubule mass which accompanies the growth of numerous, long, and highly branched neurites.

These observations suggest that MAP-2 induction in neuroblastoma cells may led to a further differentiation of neurites equivalent to that observed in mature neurons. Finally, our results indicate that gangliosides per se are not neuritogenic factors but rather substances capable of greatly enhancing cell derived influences which affect the neurite outgrowth response of neuroblastoma cells and the type of MAP that they express.

TYROSINE KINASES DERIVED FROM NERVE GROWTH CONE GLYCOPROTEINS. N. Cheng*, E. Suwita* and N. Sahyoun. Wellcome Research Laboratories, Research Triangle Park, NC 27709.

Glycoproteins were isolated from neonatal rat brain growth cones by wheat germ agglutinin-affinity chromatography. Phosphorylation of poly glu4tyr revealed the presence of a tyrosine kinase activity (1 nmol/min/mg protein) which required the presence of both $MgCl_2$ and $MnCl_2$. Tyrosine phosphorylation of several endogenous polypeptides was also observed in the presence of $MnCl_2$. Endogenous substrates included tubulin and a Mr 115,000 polypeptide whose electrophoretic mobility could be altered by the presence or absence of reducing agents. Insulin stimulated the phosphorylation of a Mr 90,000 polypeptide while IGF-I elicited phosphorylation of 90,000 and 97,000 polypeptides corresponding to the β-subunit of the insulin and IGF-I receptors, respectively. Tyrosine phosphorylation of endogenous substrates was confirmed by phosphoamino acid analysis, alkali hydrolysis and immunoprecipitation with phosphotyrosine antibodies. In contrast to growth cones, synaptosomal glycoproteins were relatively lacking in protein tyrosine kinases, suggesting that the expression of these enzymes may be regulated by the stage of neuronal development, and that they may play a significant role in growth cone transmembrane signalling.

Mathematical Analysis of Growth Cone Motility

H. M. Buettner* and R. N. Pittman, Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19101-6084

Mathematical modelling is a potentially valuable, but as yet, little used tool for investigating both cellular and molecular mechanisms of neurite outgrowth. Since neurite outgrowth depends critically on growth cone motility, a logical starting point in the mathematical description of neurite outgrowth is the quantitative analysis of growth cone movement. We have initiated a mathematical modelling study of growth cone motility that applies two methods previously used successfully to describe motility in other cell types:

1) measurement of the root-mean square speed and persistence time of individual growth cones (see: G.A. Dunn, Agents Actions [Suppl] 12 14, 1983)
2) measurement of growth cone shape and orientation based on the moments of growth cone area (see: G.A. Dunn and A.F. Brown, J. Cell Sci. 83 313, 1986)

Data is being obtained from primary cultures of rat sympathetic neurons grown on laminin using both time-lapse videomicroscopy of live cultures and morphometric analysis of fixed cultures. These results form the basis for a stochastic model of growth cone motility describing the trajectories traced out by individual growth cones. Such a model can be used to explore the effects of different homogeneous substrates, heterogeneous substrates and trophic factors on neurite outgrowth and guidance. (Supported by the Whitaker Foundation).

413.10

INTERACTIONS BETWEEN SYMPATHETIC GROWTH CONES IN VITRO. J.K. Ivins and R.N. Pittman. Dept. of Pharmacology, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA 19104.

The nerve growth cone is a highly motile and dynamic structure intimately involved in such diverse phenomenon as neurite outgrowth, pathfinding, target cell recognition and synaptogenesis. Recent evidence has suggested that environmental factors such as contact with other cell surfaces may be important for regulating growth cone motililty. We have used time-lapse videomicroscopy to determine events following contact between growth cones of sympathetic neurons from the rat superior cervical ganglion (SCG) and other cell surfaces, including other sympathetic growth cones and neurites.

45% of the contacts between growth cones of two sympathetic neurons resulted in the collapse of growth cone structure of one, but never both growth cones. Only 12% of the contacts between growth cones and neurites resulted in growth cone collapse. Contact with other cell surfaces, either red blood cells or fibroblasts never resulted in collapse. These studies suggest that the SCG may be composed of two subpopulations of neurons with different cell surface determinants, and that these determinants are more concentrated on the surface of growth cones than on neurites. Approximately half of the neurons of the SCG project rostrally, approximately half project caudally. Experiments are in progress to determine if these represent the two subpopulations that we detect in our culture system. Studies using the calcium indicator dye fura2 are also in progress to examine the mechanism of this collapse phenomenon. (*Supported by the McKnight Foundation and the PMA*).

DISTRIBUTION OF A 33KDA PROTEIN IN CULTURED PC12 CELLS AND SYMPATHETIC NEURONS DURING NEURITE OUTGROWTH. K. Kalil, M. Lu*, and J. Rosenheimer. Dept. of Anatomy, Dept. of Physiology, and Neuroscience Training Program, University of Wisconsin, Madison, WI 53706.

In a previous report (Kalil and Perdew, *J. Neurosci.*8:4797-4808, 1988), we described a 33kDa membrane protein whose expression declined sharply during development of the hamster CNS. To obtain insight into the growth related function of this protein, we examined its intracellular distribution in growing neurons in culture using fluorescence immunocytochemistry. PC12 cells and dissociated superior cervical ganglion (SCG) cells from 3-day old hamsters were grown in culture on polylysine coated coverslips. Immunocyto-chemistry was carried out on fixed permeabilized cells with monoclonal antibodies against the 33kDa protein. In the presence of NGF, PC12 cells and SCG neurons exhibited extensive process outgrowth with growth cones of various sizes and morphologies. Longer processes had relatively small simple tips whereas shorter neurites ended in large, spread out lamellipodia from which prominent filopodia often extended. Cell bodies, neurites, and growth cones of PC12 cells and SCG neurons were brightly fluorescent. The staining had a diffuse granular appearance, but in large lamellipodia the fluorescence resembled a filamentous mesh-work. Parallel experiments in which rhodamine-phalloidin was used to stain actin filaments and anti-tubulin antibodies were used to stain microtubules suggest that the distribution of the 33kDa protein is not identical with that of either of these cytoskeletal components. Preliminary results also suggest that the 33kDa protein is neuron-specific, since neither fibroblasts nor glial cells in the SCG cultures were immunoreactive. Although neuronal cell bodies were immunofluorescent prior to neurite outgrowth, PC12 cells exhibited significantly brighter fluorescence following NGF stimulation. Taken together, these results suggest that the 33kDa protein may be associated with growth cone function during process outgrowth. (Supported by NIH grant NS14428 to K. Kalil.)

414.1

AN IMPROVED STAINING METHOD FOR SENILE PLAQUES AND NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE: QUANTITATIVE COMPARISON WITH OTHER TECHNIQUES. R. Guntern*, C. Bouras*, and P.R. Hof (SPON: J.H. Morrison). Dept. of Psychiatry, Univ. of Geneva, Switzerland, and Research Institute of Scripps Clinic, La Jolla, CA, USA.

In an attempt to better quantify the number and distribution of the neuropathological hallmarks of Alzheimer's disease we used a modification of the classical thioflavine S staining method for neurofibrillary tangles (NFT) and senile plaques (SP). This method can be applied to human brains collected after a short post mortem delay and fixed for immunohistochemical purposes, as well as to brains kept in formalin for years or to paraffine-embedded materials.Sections were pretreated with 0.25% $KMnO_4$ and then immersed in 1% $K_2S_2O_4$ and 1% oxalic acid. Paraffin-embedded tissues were then treated with 1% NaOH and 3 ml of 30% H_2O_2. Thioflavine was then diluted up to 0.0125% instead of 1%. This treatment removes lipids autofluorescence. The method allows for the visualization of as much as 50% more SP and NFT as compared to the classical thioflavine S method or to argentic impregnations. Amyloid accumulation in the wall of small vessels was frequently observed. Extravascular amyloid deposits were also evident. A comparable method enhanced peptide immunostaining in human brains kept in formalin for 40 years. Finally, a very accurate automatic quantification of NFT and SP using a computer-assisted image analysis system was made possible by the heightened quality of the staining. This improved technique might be useful to further analyze the regional and laminar distribution of the pathological lesions in senile and presenile cases of Alzheimer's disease.

414.2

ALZ-50 IMMUNOREACTIVITY PRECEDES PHF FORMATION AND NEURITIC CHANGE IN DOWN'S SYNDROME. L.A. Mattiace, D.W. Dickson*, Y.S. Kress* and P. Davies*. Department of Pathology, Albert Einstein College of Medicine, Bx., NY 10461.

By sharing a constellation of neuropathological and clinical changes, Down's Syndrome (DS) appears to be an appropriate model to examine the sequence of changes which develop over the course of Alzheimer's Disease (AD). Twenty-four cases of DS ranging in age from two days to 60 years old were examined. Consecutive vibratome sections from the frontal cortex, hippocampus and the basal forebrain were immunostained with Alz-50, Ab39 (PHF), anti-ubiquitin (UBQ), BetaSP (amyloid) and thioflavin S. Sections immunostained for Alz-50 were also processed for EM.

Consistent Alz-50 staining of neurons was seen in infants up to 2 years of age. Age 29 appeared to be the earliest reexpression of Alz-50 positive neurons coinciding with an extensive array of immunoreactive beaded processes that were absent in the Alz-50 negative cases. Although both beaded processes and neurites appeared to coexist in Down's in the earlier stages of AD changes, these beaded processes disappeared as the AD pathology progressed to extensive neuritic change in the neuropil. Although Alz-50 usually immunostained a greater number of neuropil neurites than either Ab39 or UBQ, in two cases UBQ positive neurites were predominant. Alz-50 cells also were temporally coexistent with a small number of senile plaques and NFT, but were never associated with more than a few neurites in the neuropil. Alz-50 positive cells however did occur without deposition of amyloid in some cases. Thus, reexpression of Alz-50 immunoreactivity may precede both amyloid deposition and the extensive appearance of neurites in the neuropil.

414.3

CHROMATOGRAPHIC ANALYSIS BY HPLC OF ALZHEIMER'S DISEASE ASSOCIATED PROTEIN/S (ADAP) Barney E. Miller PhD , Allen B. Simon BS* and Hossein A. Ghanbari PhD* Mental Illness and Neurological Diseases Diagnostics, Abbott Laboratories, Abbott Park, IL 60064

The ADAP was purified ~1250 fold by differential centrifugation, detergent extraction and solubilization from Alzheimer's disease brain tissue homogenate and analyzed by three HPLC methods. The methods were: gel permeation (Beckman Spherogel TSK 4000 PW, in both native and denaturing conditions), Reversed phase by both C-8 (Beckman Ultrasphere Octyl 5u) and C-3 (Beckman Ultrapore RPSC) and finally affinity chromatography with the IgG iso-type of ALZ50, P42 (Beckman Ultraffinity-EP). Activity in column fractions was monitered both by UV (220 and 280 nm) and by ELISA using the ALZ50 antibody. The gel permeation column with native conditions showed a >100 kDalton immunoreactive material and the denatured conditions showed a multicomponent group clustered about molecular weight 64-68 kDaltons. The reverse phase results were: C-8 showed 4 peaks of activity, C-3 showed 2 peaks (the second peak was clearly multi-component). A single ("sharp") peak of immunoreactivity was eluted from the affinity column. Some fractions were analyzed by SDS-PAGE/Western Blots. The affinity column purified material showed triplet bands of activity by this analysis.

It is clear that ADAP is a mix of immunogenically similar proteins that may be iso-forms. Further work to purify and sequence ADAP is presently underway.

ATP-DEPENDENT LOSS OF ALZ-50 IMMUNOREACTIVITY WITH A68. I.Vincent, and P Davies*. Dept. of Pathology, Albert Einstein College of Medicine, Bronx, NY, 10461.

Preincubation of the Alz-50 immunoreactive proteins (A68) with 5mM ATP at 37^0C results in a subsequent loss of Alz-50 reactivity with A68 on immunoblots. This loss of antigenicity occurs progressively with time, being optimal after a 1 hour incubation. A dependency on temperature is indicated by prevention of the inhibition by boiling of the tissue, or by incubation at 4^0C. Other nucleotide triphosphates do not substitute for ATP, indicating that the dependence on ATP is stringent. The hydrolysis of ATP is also necessary for the inhibition, since the nonhydrolyzable analog Adenosinc-thio-triphosphate is not effective. Similarly, the ATPase inhibitors vanadate and oligomycin block the ATP-induced loss of the Alz-50 epitope. Upon further characterization, it was found that certain protease inhibitors i.e., TPCK, PMSF, and antipain, prevent the loss of antigenicity, whereas others i.e., aprotonin, pepstatin, leupeptin, and TLCK do not. This suggests that the destruction of the Alz-50 epitope on A68 is due to ATP-activated proteolysis. Two monoclonal antibodies specific for A68, i.e., 42 and 30, protect the antigen from the proteolysis induced by ATP. Since a variety of proteins are degraded by an ATP\ubiquitin dependent pathway, an involvement of ubiquitin in the ATP-effect on A68 was examined. Exogenous ubiquitin partially protects A68 from degradation, whereas, polyclonal antibodies to ubiquitin prevent the loss of Alz-50 reactivity. In addition, hemin a specific inhibitor of ATP-activated proteolysis of ubiquitin-protein conjugates, abolishes the ATP-induced proteolysis of A68. Taken together, these findings indicate that the Alz-50 epitope is destroyed by a ubiquitin-mediated, ATP-dependent proteolytic system. This mechanism may be relevant to the physiological action of A68 in Alzheimer's disease or, may simply represent an attempt to abort an aberrant protein.

THE ISOLATION OF A RELATIVELY SPECIFIC PAIRED HELICAL FILAMENT ANTIBODY. S.G.Greenberg* and J.Schein (SPON: J.Pearson) Albert Einstein Coll.of Med.,Bronx, NY 10461

We have isolated a monoclonal antibody (PHF-1) from mice injected with denatured preparations of relatively nonaggregated populations of paired helical filaments (PHF). PHF-1 reacted with neurofibrillary tangles (NFT) and with neuritic processes of AD cases. Double labeling of AD sections revealed that the staining of NFT and neuronal processes was more extensive with PHF-1, than Alz 50. However, unlike Alz 50, PHF-1 did not label neonatal normal tissue. Immunoelectron microscopy demonstrated that PHF-1 reacted with PHF in PHF-enriched preparations. Like other PHF antibodies, PHF-1 recognized the 57-68 kd PHF proteins, their degradation products and unresolved higher MW material present in PHF-enriched preparations. While it is difficult to detect PHF proteins in homogenates with PHF antibodies such as Alz 50, PHF-1 appeared to react with PHF proteins in both homogenates and cytoskeletal enriched preparations from AD cases. Weak or no reactivity was observed with normal cytoskeletal proteins, including purified human tau. Thus, PHF-1 appears to recognize a unique epitope present on PHF. While the PHF-1 epitope may result from either a unique sequence or a posttranslational modification of a normal cytoskeletal epitope, the relative sensitivity and specificity of PHF-1 indicates that this antibody will be useful for the specific detection of relatively low levels of PHF and their component proteins during different pathological conditions. This work was supported by NIH grant #AG06803.

UNMASKING CRYPTIC EPITOPES OF PAIRED HELICAL FILAMENT IMMUNOREACTIVITY IN ALZHEIMER BRAINS USING FORMIC ACID. D.R. Sparkman, R.M. Ameen*, S.J. Hill*, C.L. White, III*. Neuropathology Laboratory, Department of Pathology, University of Texas Southwestern Medical Center, Dallas, Texas 75235-9072.

Formic acid (FA) pretreatment of tissue sections has been used to enhance immunostaining of beta amyloid (bA) deposits in Alzheimer disease (AD) brains. A monospecific antiserum (A128) to highly purified AD paired helical filaments (PHF) which does not immunostain the bA deposits in AD brain tissue sections was used on FA pretreated sections to assess whether contaminating antibodies to bA were present. Paraffin sections of AD brain rich in neuritic plaques (NP) were incubated overnight with anti-PHF antiserum A128 at serial two-fold dilutions ranging from 1:50 to 1:1600, or anti-bA antiserum A14-88 (1:25 through 1:800). Reactions were developed using the avidin-biotin immunoperoxidase technique with diaminobenzidine as the chromogen. Half of the sections were pretreated overnight with 99% FA prior to immunostaining. FA pretreatment enhanced the ability of NP to immunostain at higher dilutions with both anti-PHF and anti-bA antisera. Of particular note was the enhancement of PHF staining of NP around blood vessels. Preabsorption of the anti-PHF antiserum with purified amyloid from AD brain did not neutralize staining of these NP, whereas preabsorption of the anti-bA antiserum did. We conclude that 1) enhanced immunoreactivity of NP with anti-PHF antiserum A128 following FA pretreatment is not due to contaminating anti-bA antibodies, and 2) many perivascular NP previously interpreted as bA NP are, in fact, composed of PHF-rich neurites.

DECREASE IN NEURONAL MRNA IN ALZHEIMER DISEASE CORTEX CORRELATES WITH THE NUMBER OF NEUROFIBRILLARY TANGLES. I.M. Parhad, A.W. Clark, K.L. Goodison*, C.A. Robinson*. Pathology Dept., U. of Calgary, Alta, T2N-1N4, Canada.

Neuronal mRNA levels are decreased in the neocortex of Alzheimer disease (AD) brains. Case to case variation in AD neuropathology may reflect stages of AD degeneration. In this study we asked at which stage the mRNA decrement first appears. Seventeen AD cases (60-91 yrs) and 13 controls (55-82 yrs) were selected. The AD cases had varying severity of neuropathological changes: neurofibrillary tangle (NfT) counts in the frontal cortex ranged from 0-52/mm^2, and neuritic plaques (NP) ranged from 5-84/mm^2. The frontal or parietal cortex was processed for quantitative Northern analysis with cDNAs for neurofilament light subunit (Nf-L) and amyloid precursor protein (APP). Our results show an overall decrease of 40% for the Nf-L and APP mRNAs in the AD cases. The Nf-L mRNA inversely correlated with the number of NfT (r: -0.70, $p<0.01$), especially in the older cases (>70 yrs). The APP mRNA also had an inverse correlation with the number of NfT (-0.49) but this did not reach statistical significance. No correlation was seen between the numbers of NPs and Nf-L or APP. We interpret these results to mean that in senile dementia of Alzheimer type, the decrease in neuronal mRNA in the cortex occurs with the appearance of NfTs.

INTIAL STAGES OF TANGLE FORMATION IN DEGENERATING NEURONS OF AGED AND ALZHEIMER PATIENTS. M.A. Morán & P. Gómez-Ramos Dept. Morfología.Fac Medicina Univ. Autónoma Madrid.España.

In the brain of aged controls we studied the morphology of tangles in several cortical regions where these lesions appear first. We consistently found delicate Thioflavine-S positive threads, which were arranged as proximal dendrites surrounding a Thioflavine negative perikaryon full of lypofucsin. We also observed slightly thicker threads in the neuropil, somo of them in continuity with a neuronal perikaryon that had the appearance of early tangles. Next to mature tangles there were thick strongly fluorescent neurites, some of them in direct contact with a tangle. Adjacent sections stained for cholinesterases (AchE and BchE) showed positive reaction in early and mature tangles and only in the thickest neurites. Similar images were observed in selected isocortical areas of Alzheimer' brains.

We suggest that the sequence in the evolution of tangle formation may be as follows: 1) Amyloid starts to accumulate as delicate threads within proximal dendrites that are negative for cholinesterases. 2) Next, the perikaryon gets involved too. At this stage, staining for AchE and BchE parallels Thioflavine fluorescence. 3) Finally, mature old tangles appear to broke into thick strongly fluorescent neurites, some of which are positive for cholinesterases. The begining of AchE and BchE accumulation may represent the threshold in the degeneration process when transport is interrupted, and these enzymes are trapped among the altered cytoskeleton. Supported by FISSS 88/922 and 89/635.

ALZHEIMER SENILE PLAQUES, DYSTROPHIC NEURITES AND NEUROFIBRILLARY TANGLES STAIN POSITIVELY WITH ANTIBODIES TO THE CLASSICAL COMPLEMENT PATHWAY. P.L. McGeer, H. Akiyama* S. Itagaki* and E.G. McGeer. Kinsmen Lab. of Neurol. Res., Univ. British Columbia,2255 Wesbrook Mall, Vancouver, B.C., V6T 1W5, Canada.

We and others (1) have previously reported evidence of chronic inflammation in Alzheimer brain tissue. This includes the presence of HLA-DR positive reactive microglia, and T4 and T8 lymphocytes. We now report positive staining of senile plaques, dystrophic neurites and some neurofibrillary tangles with antibodies to several components of the classical, but not the alternative, complement pathway. Positive staining of these elements of Alzheimer brain tissue was obtained with polyclonal antisera directed against C1q, C3d and C9. Positive staining was also obtained with mouse monoclonal antibodies directed against C4d, C7 and a neoantigenic site on C5b-9. Monoclonal antibodies directed against the specific, alternative complement pathway factors, fraction Bb of factor B and factor P, failed to stain Alzheimer tissue. These data, indicating the presence of the full spectrum of complement components of the classical pathway, including the membrane attack complex, in affected elements of Alzheimer brain tissue, are further evidence of chronic inflammation in this disease.

ALTERATIONS IN LOCALIZATION OF Ca^{+2}-ATPase IN ALZHEIMER DISEASE BRAINS. B. Sisken, W. Markesbery* and T. Vanaman*. Center of Biomedical Engineering, Departments of Anatomy and Neurobiology; Pathology and Sanders Brown Center on Aging; Department of Biochemistry, University of Kentucky, Lexington, KY 40506.

Calcium metabolism alterations are of major interests in Alzheimer disease (AD) since abnormally high levels of internal free calcium are associated with neuronal degeneration. Two classes of Ca^{+2}-pumping ATPases which maintain low intercellular levels of calcium exist; at the cell surface and in the internal membranes of the cell. We have localized in normal and AD hippocami one distinct isoform of plasma membrane Ca^{2}-ATPase which we have previously identified by molecular cloning. In normal brain, astrocytes, oligodendoglia and microglia are non-reactive while ependyma, choroid plexus, arachnoid, pia and endothelial cells are reactive. Hippocampal dentate granule neurons, CA-4 neurons and some synaptic clusters are positive; CA-3 neurons are highly reactive while CA-2 CA-1 and subiculum neurons are progressively less immunoreactive; the molecular layer of the dentate gyrus is nonreactive. By contrast in AD the proximal, middle and distal molecular layer of the dentate gyrus are positive. CA-4 neurons, dendrites and large granular clusters of synapses show pronounced immunoreactivity while CA-3 through CA-1 neurons are similar to that in normals. Reactive astrocytes show marked immunoreactivity; neurofibrillary tangle-bearing neurons and senile plaques are nonreactive. These findings suggest altered calcium metabolism in reactive astrocytes and commissural, associational and entorhinal fiber pathways in the AD hippocampus. NS21868, 5PO1-AG05119, 5P50-AG05144.

EXAMINATION OF THE 5'END OF BRAIN MESSENGER RNA IN ALZHEIMER'S DISEASE. E.M. Sajdel-Sulkowska and E.S. Burnside.* Harvard. Med. Sch., Ma. Gen. Hosp., Boston, Ma. 02115 and McLean Hosp., Belmont, Ma. 02138.

We examined possible translational differences between Alzheimer and control mRNA from postmortem brains. The focus was on the 5'cap structure of the mRNA since it is involved in the initiation step of protein synthesis. The translational activity of mRNA isolated from the control (n=7) and AD (n=7) cases was measured in the rabbit reticulocyte system in the presence and absence of the cap analogue 7methylguanosine 5'triphosphate (pppm^{7}G). In the absence of pppm^{7}G control mRNA showed a 45% increase in the incorporation of ^{35}S methionine ($1.6x10^6$ cpm/ug mRNA) as compared to AD mRNA ($1.1x10^6$ cpm/ug mRNA). The cap analogue inhibited translation of mRNA in controls by 26% and in AD cases by 13.6% Mouse mRNA translated under identical conditions ($2.8x10^6$ cpm/ug mRNA) showed a 38.4% reduction in the presence of pppm^{7}G. These results indicate that the AD mRNA may be relatively undercapped as compared to control mRNA and are consistent with the reduction in the protein synthetic activity of AD mRNA in vitro and in living patients afflicted with AD. Supported by AHAF.

RELATIONSHIP OF NEURODEGENERATION TO THE EXPRESSION OF ALZHEIMER-ASSOCIATED ANTIGENS IN CULTURED HIPPOCAMPAL NEURONS. J. Mattson* and M. P. Mattson (SPON: M. B. Nikitovitch-Winer). Sanders-Brown Center on Aging and Dept. of Anatomy & Neurobiology, Univ. of Kentucky Med. Center, Lexington, KY.

Alzheimer's disease is characterized by the abnormal accumulation of several proteins in selectively vulnerable brain regions, including the hippocampus. Antibodies that recognize neurofibrillary tangle (NFT)-associated antigens (5E2 and Alz-50) or ubiquitin were used to examine the relationship between the presence of Alzheimer-associated antigens (AAAs) and neurodegeneration in cultured rat hippocampal neurons. In untreated cultures 5E2 antigen was expressed in most neurons with considerable variability in staining between neurons. Low to moderate levels of Alz-50 immunoreactivity were present in about 50% of the neurons. All neurons expressed low levels of ubiquitin. Subtoxic levels of glutamate or K^+ increased the expression of 5E2 and Alz-50 antigens but did not alter ubiquitin expression. Glutamate and K^+ at levels that caused a progressive degeneration of neurons over a 24 hr period induced increases in the expression all three AAAs, particularly in degenerating neurons. There was a striking increase in ubiquitin levels only in degenerating neurons. Higher levels of glutamate which caused rapid cell death (2-4 hrs) also increased AAA expression. Cycloheximide did not prevent induced increases in AAA levels suggesting that the increased levels of AAAs might reflect the modification of existing proteins. Finally, a subpopulation of neurons that was resistant to glutamate neurotoxicity did not express detectable levels of Alz-50 suggesting that Alz-50 antigen is a marker for neurons vulnerable to glutamate neurotoxicity. Collectively, these results suggest that the increased presence of at least some AAAs can result from excitatory overactivity, and are consistent with a model in which normal proteins are modified by the activation of neuronal signal transduction systems. The data are also consistent with the involvement of glutamate in Alzheimer's neuropathology. (Supported by the French Foundation for Alzheimer's Disease).

GANGLIOSIDES PREVENT RECOGNITION OF BRAIN ANTIGENS BY SERUM ANTIBODIES FROM AGED MICE.

H. Lal, E.N. Ahanotu*, V. Apte* and M.J. Forster. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107-2690.

Gangliosides have been shown to protect against several types of central nervous system (CNS) tissue injury (Mahadik & Karpiak, *Drug Dev. Res.*, 15:337, 1988), suggesting that they could be useful in treatment of degenerative CNS disorders. Because immunologic injury could contribute to age-related CNS disorders (Lal & Forster, *Neurobiol. Aging*, 9:733, 1988), we investigated the potential for gangliosides to prevent recognition of brain antigens by autoantibodies. Sera from a subset of aged (26-30 months) C57BL/6NNia mice contained IgG3 recognizing 64kD and 45kD proteins in brain cell membrane extracts. To determine the effect of gangliosides upon IgG binding, brain cells were pre-incubated with monosialoganglioside (GM1) or mixed gangliosides (0, 1, 5, or 10 $\mu g/10^4$cells) for 60 min, washed, and incubated with sera from old mice which had previously exhibited "brain-reactive" IgG3. When probed with peroxidase-conjugated, goat antimouse IgG, only the cells incubated with saline or 1 µg gangliosides showed immunoreactivity. These findings suggest that ganglioside treatments might protect CNS neurons from immunologic injury. [Supported by NIH grants AG06182 (MJF), AG07695 (HL), and NIH-BRSG grant RR05879].

FUNCTIONAL CONSIDERATIONS OF NEUROIMMUNE MARKERS IN ALZHEIMER'S DISEASE. J. Rogers, S.D. Styren, S.A. Allen, and W.H. Civin. Institute for Biogerontology Research, Sun City, AZ 85351.

We have demonstrated presence and characteristics of numerous immune system markers in human brain, several of which are differentially expressed in Alzheimer's disease (AD). The more difficult question remains, however, whether the appearance of these markers is merely an epiphenomenon of the disease process or has functional pathogenerative significance. We present several lines of evidence that the latter may be the case. Studies using antibodies directed against the Fc portion of human immunoglobulins reveal labelled neurons in all AD brains tested, but only a few normal elderly brains. In AD, many of the labelled neurons appear dystrophic, with fine Thioflavin S positive filaments coursing in the perikaryon. Since it seems unlikely that neurons produce antibodies, we suggest that the antibodies have bound to neurons, with the expected pathogenic consequences of antibody binding to a targeted antigen (e.g., complement proteins have been demonstrated in AD brain, especially in the context of neuritic plaques). The expression of cytokines is also a functional measure of immune activity as opposed to mere immune presence. Our studies show that several cytokines, particularly IL-1 and TNF, are differentially expressed in AD brain. IL-1 has recently been suggested to stimulate expression of B-amyloid (D. Goldgaber, personal communication). Lastly, our quantitative studies of immune system markers such as HLA-DR reveal a universal co-localization with neuritic plaques, within which levels of immunoreactivity are elevated as much as 50-fold compared to normal neuropil. Taken together, these and other data to be presented strongly suggest that whatever the etiology of AD, neuroimmune mechanisms contribute importantly to its pathogenesis. Supported by NIA AGO 7367-01A1 (JR).

CELLULAR AND MOLECULAR CHARACTERIZATION OF THE HUMAN MAJOR HISTOCOMPATIBILITY COMPLEX ANTIGEN HLA-DR IN ALZHEIMER'S DISEASE. W.H. Civin, S.D. Styren, S.A. Allen, and J. Rogers. Institute for Biogerontology Research, Sun City, AZ 85351.

Despite reports of an absence or paucity of CNS immunoreactivity for major histocompatibility complex (MHC) antigens in normal humans and laboratory animals, we suggested several years ago that MHC type II antigens such as HLA-DR, -DP, and -DQ are abundantly expressed in white matter of normal elderly patients and white and gray matter of Alzheimer's disease (AD) patients (Rogers et al., Neurosci. Abs., 12:944, 1986). Our data have since been replicated and extended by McGeer and associates (McGeer et al., Neurosci. Lett., 79:195, 1987). Crucial questions remain, however, as to the exact molecular identity of the brain protein labelled by HLA-DR immunohistochemistry, and the cell types which express that protein in brain. We have performed Western blot analysis, and light and electron microscopic immunohistochemistry to resolve these issues. Our HLA-DR antibody detects a protein in AD and normal elderly brain with the expected molecular weight for HLA-DR (alpha chain), and which runs parallel to the HLA-DR immunoreactive band from lymph nodes on Western blots. At the light and electron microscopic level, HLA-DR immunoreactivity is detected on cells with the morphologic and ultrastructural characteristics of astrocytes, microglia, and perivascular cells. Neurons are never stained. Double-labelling studies confirm these observations. The majority of microglia in AD brain are HLA-DR positive, whereas HLA-DR immunoreactive astrocytes are relatively rare. HLA-DR immunoreactivity co-localizes universally with the neuritic plaques of AD, but not necessarily with neurofibrillary tangles. Supported by the Arizona Disease Control Research Commission (JR).

TRANSFERRIN AND FERRITIN IN THE HUMAN BRAIN IN NORMAL AGED AND ALZHEIMER'S DISEASE. James R. Connor[1], Sharon L. Menzies[1]*, Richard E. Fine[2], and Elliott J. Mufson[3]. [1]Dept. of Anatomy, M.S. Hershey Medical Center, Hershey PA, 17033, [2]GRECC Unit, ENR Veterans Hospital, Bedford MA and [3]Institute for Biogerontology Research, Sun City AZ.

Our approach to studying CNS iron regulation has been to focus on transferrin (Tf) the major iron mobilization protein and ferritin, the major iron storage protein. In the present study, 2 cerebral cortical areas were examined immunohistochemically in tissue obtained at autopsy from 8 normal adult human brains (non-neurologically related cause of death) and 5 patients with Alzheimer's disease (AD). Tf immunoreactivity (Boehringer-Mannheim; 1:250) in both the normal and AD tissue was predominantly confined to oligodendrocytes. Some cells in the white matter which appeared to be astrocytes were immunoreactive in the AD tissue. Ferritin (ICN immunobiologicals, 1:500) immunoreactivity is specific to oligodendrocytes in normal brain tissue. Some ferritin immunoreactive cells are found in association with senile plaques and these cells may be macrophages or microglia. Quantitative analyses of Tf and ferritin are in progress. The results of this study suggest that oligodendrocytes may play a role in iron regulation in the brain.

LACK OF ALUMINUM IN ALZHEIMER'S DISEASE (AD) BY "SMALL SAMPLE" FLAMELESS ATOMIC ABSORPTION ANALYSIS. R.W. Jacobs, G.A. Trapp, T. Duong and A.B. Scheibel, Depts. of Anatomy, Psychiatry, and the Brain Research Inst., Univ. of California, Los Angeles, CA 90024; and VA Medical Center and Dept. of Psychiatry, Univ. of Texas Southwestern Med. School, Dallas, TX, 75216.

We previously reported no detectable aluminum (Al) levels in seven AD and four control cases by X-ray microprobe analysis (Jacobs et al., Soc. Neurosci. Abstr., Vol. 14, Part 2, p.1083, 1988). We have attempted to verify these negative findings by the use of atomic absorption spectrophotometry (AAS). Fresh frozen, coronal sections from six of the seven AD (mean 80 yrs; range 68-102) and four control brains (mean 66 yrs; range 58-78) used in the previous study were obtained from the National Neurological Research Bank, Wadsworth VA Medical Center. Samples (ranging from 48-144 mg wet wt.) from Brodmann areas 9, 11, 28, 46, 47, and hippocampus were wet-ashed for atomic absorption analysis and an NH_3NO_4 matrix modifier to eliminate chloride interference on aluminum (Trapp, G.A., Anal. Biochem., in press). The remaining tissue surrounding each sample site was histologically prepared for thioflavin-S, and characterized for intensity of plaques and tangles. Our results show a range from undetectable to 1.80 ng/mg wet wt. [mean, 0.54 ± 0.58 (SD)] of Al in control tissue. AD samples revealed similar Al levels ranging from undetectable to 1.76 ng/mg wet wt. [mean, 0.28 ± 0.39 (SD)] independent of histopathology. There was also no correlation between age and Al levels suggesting that Al may not accumulate over time in the CNS. The confirmation of no abnormal amounts of Al by AAS in our AD specimens suggests that this metal may be unrelated to the pathogenesis of plaques and tangles in AD.

ALUMINUM ACCESS TO THE BRAIN: A POSSIBLE ROLE FOR TRANSFERRIN. A. Jane Roskams and James R. Connor. Center for Neuroscience and Department of Anatomy, M.S. Hershey Medical Center, Hershey PA 17033.

Transferrin (Tf), the iron mobilization protein from plasma utilizes a receptor on brain endothelial cells to transport iron across the blood-brain-barrier. In addition to iron, Tf binds aluminum. Indeed, as much as 30% of the Tf in plasma is bound to aluminum. Two studies are described here: 1) Using 125I-Tf on brain membrane preparations we found that the brain Tf receptor has a Kd of approximately 0.5nM; 2) We established that the Tf-aluminum complex behaves similar to Tf-iron in its interactions with the Tf receptor. Tf-aluminum ($Tf\text{-}Al^{+3}$) is prepared by incubating iron-free Tf (Sigma) with $AlKSO_4$ in the presence of bicarbonate (pH 7.4) and the $Tf\text{-}Al^{+3}$ complex is demonstrated spectrophotometrically. Direct competition assays were performed with 125I-Tf (0.25, 0.5 and 1.0nM) in the presence of an excess (5.0um) of either Tf-iron, $Tf\text{-}Al^{+3}$ or iron-free (Apo-Tf)Tf. Tf-iron and $Tf\text{-}Al^{+3}$ competed equally for the Tf receptor; whereas Apo-Tf was only 33-50% as effective. Following incubation with saturating concentrations of 125I-Tf, both $Tf\text{-}Fe^{+3}$ and $Tf\text{-}Al^{+3}$, but not Apo-Tf (5.0um) were able to displace 100% of bound 125I-Tf. These results suggest that aluminum could use the Tf-Tf receptor system to gain access to the CNS. This work is supported by the American Federation for Aging Research.

VISUALIZATION OF NON-MICROTUBULE TAU BINDING PROTEINS BY LIGAND BLOTTING. D. M. Wilson* and L. I. Binder* (SPON: L. E. Mays). Dept. of Cell Biology and Anatomy, Univ. of Alabama at Birmingham, 35205.

Understanding the normal in vivo function(s) of tau and those properties of tau which may lead to abnormal aggregation states, would be enhanced by a knowledge of the full repertoire of proteins capable of interacting with this microtubule associated protein (MAP). Towards this end we have developed a ligand blotting assay to identify possible tau binding proteins. The procedure involves incubating nitrocellulose bound proteins with purified bovine tau, followed by detection of bound tau with anti-tau mAb's. Incubation of rat cortex homogenates with 0.7 uM tau reveals high affinity binding to a triplet of proteins in the 100-130 kD range. These proteins are distinct from tau or tubulin dimers also seen in this range. Two of these proteins are enriched in preparations of taxol stabilized microtubules. Several protein bands are bound with lower apparent affinity; among these are tubulin, MAP1b, and MAP2. Work is underway to determine the prevalence of the high affinity tau binding proteins in human brain tissue of normal and Alzheimer's disease origin.

IN VITRO STUDIES OF THE INTERACTION BETWEEN THE ALZHEIMER COMPONENTS α_1-ANTICHYMOTRYPSIN AND β-PROTEIN. D. Dressler*, C.R. Abraham, P. Amsterdam* and H. Potter. Dept. Neurobiology, Harvard Med. Sch., Boston, MA 02115.

The protease inhibitor α_1-antichymotrypsin (ACT) has been shown to be an integral component of the amyloid deposits of Alzheimer's disease and the similar deposits arising in Down's syndrome and in normal aging in humans and monkeys. ACT was also found associated, together with the β-protein, in one non-Alzheimer amyloid—a variant of hereditary cerebral hemorrhage with amyloidosis found in Holland (Abraham et al., submitted). Together these results indicate that there is a special association of ACT and the β-protein, perhaps essential to the formation of amyloid. We are therefore examining the interaction between ACT and the β-protein *in vitro*. A radioiodine-labeled peptide corresponding to amino acids 1-28 of the β-peptide becomes bound to ACT in an SDS-resistant complex. The use of cross-linking agents stabilizes even a greater amount of the peptide onto ACT. Other experiments suggest that the 1-28 peptide may bind to the ACT protein at its active protease-inhibitory site: (1) the addition of chymotrypsin to ACT prior to the addition of the peptide prevents the association and (2) the peptide prevents ACT from being able to subsequently inhibit chymotrypsin. An examination of the amino acid sequence of the β-peptide reveals a region near the N-terminus, which shows striking homology to the active site of serine proteases. Studies with peptides having specific amino acids changed in this region are underway to test whether this protease-like region is the basis for the specific association of ACT and the β-protein.. A model for the Alzheimer-like amyloid filaments based on this interaction will be presented.

414.21

Polypeptide fragments derived from insoluble components purified from Alzheimer, Pick's and Parkinson's diseased cortex. G.D. Vogelsang[1], G.E. Dean[2]*, and F.P. Zemlan[3]. Depts. of [1]Physiology, [2]Molecular Genetics and [3]Psychiatry, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267.

Paired helical filaments (PHF) were electrophoretically purified from high density neurofibrillary tangle (NFT)-bearing Alzheimer (AD) parietal cortex. Straight filaments were isolated from identically prepared Pick's and Parkinson's brain tissue lacking NFT. Subsequent electrophoresis solubilized these relatively insoluble structures. Silver-stained protein profiles of these solubilized structures appeared identical on sodium docecyl-sulfate polyacrylamide gels. The predominant polypeptide fragments were limited to M_r ~55-66 kilodaltons. Identically derived material from normal brain tissue lacking NFT's had a similar protein profile, but only amorphous aggregates were observed in the material solubilized. PHF and straight filaments were equally insoluble, but straight filaments had a smaller diameter (≤ 10nm) and lacked the helical nature of PHF. Only the AD derived material had demonstrated PHF-specific immunoreactivity as judged by Western blot analysis. Actin immunoreactivity was indicated at the M_r ~64-66 kilodalton range. The other brain types also displayed a reduced amount of this unusual actin-immunoreactivity/ug protein at the exact molecular weight range. It appears that the proteins associated with PHF structure may be common to all brain types and the inherent insoluble components that can be derived from each, regardless of their ultra-structure. The feature which causes AD-specific immunoreactivity may be attributed to a conjugation or modification of these common proteins.

SUBCELLULAR THREE-DIMENSIONAL ANALYSES OF HUMAN CORTICAL PYRAMIDAL NEURONS WITH ALZHEIMER PATHOLOGY BY HIGH VOLTAGE ELECTRON MICROSCOPY AND COMPUTER-AIDED RECONSTRUCTIONS FROM SERIAL SECTIONS. S. J. Young, D. Hessler*, T.J. Deerinck, and M.H. Ellisman (SPON: J.M.LeBeau). Lab. for Neurocytology, U.C.S.D., LaJolla, Ca. 92093.

We have been studying alterations in the form, content and spatial distribution of subcellular elements of cortical pyramidal neurons obtained from human biopsy specimens exhibiting the pathology typical of Alzheimer's disease. We have compared neurons differing in pathology, as indexed by the amount of paired helical filament present. Differences between neurons were examined using (1) computer-assisted three-dimensional reconstruction of electron micrographs from serial sections, and (2) stereo-pair views of thick sectioned tissue obtained with the high voltage electron microscope. Series of 50-100 .25μm serial sections were obtained through selected neurons. The serial reconstruction was derived from digitized outlines of membrane bounded structures including the plasma membrane, the nucleus and the Golgi apparatus and line segments representing paired helical filaments (PHF). Digitization and generation of preliminary views, in the form of simple hidden line reconstructions, was performed on a personal computer. The digitized data was then ported to an Ardent Titan graphics mini-supercomputer to apply programs providing rapid computation and display from different orientations, with cut-away views of interior structure, employing sophisticated reconstruction and rendering techniques. These reconstructions, in conjunction with stereo-views from high voltage thick sectioned images, have revealed possible adaptive changes in the cytoplasmic organization and possible mechanisms underlying neuronal dysfunction in Alzheimer's disease. In contrast to neurons without PHF, pathological neurons display associations of the PHF with the membranes of the nuclear envelope and displacements of the Golgi apparatus. Supported by ADRDA IIRG88-106, PHS RR04050/RR00592.

GROWTH RELATED PROTEINS IN ALZHEIMER'S DISEASE. E. Masliah*, R. Terry*, T. Saitoh, (sponsored by R. Katzman). University of California, San Diego, School of Medicine, Dept. of Neurosciences, M-024, La Jolla, CA 92093, U.S.A.

Some theories explain the pathogenesis of Alzheimer's disease (AD) as the result of a decrease in the production of growth factors (GF's). Other studies, however, suggest a sprouting reaction in AD probably mediated through GF's. To get further insight into the involvement of GF's, we performed immunohistochemical studies of proteins that provided an index of GF stimulation, (eg: fos, PKC). We found, by comparing five AD and five control cases, a 40% decrease in the number of immunoreacting neurons in the AD nucleus basalis with anti-fos and anti-PKC α, βII and γ. In contrast, the neocortex and hippocampus of AD cases presented an increase in the number of immunostained neurons with anti-fos as well as immunolabeled neurites in the plaques with anti-PKC α, and βI. These data suggest a possible decrease of GF's stimulation in subcortical areas, probably related to the hippocampal deafferantation with an increase in the GF stimulation in the hippocampus and neocortex possibly in relation to compensatory sprouting reaction.

EPIDERMAL GROWTH FACTOR EXPRESSION IN BRAIN TISSUE OF ALZHEIMER'S AND OTHER NEUROLOGICALLY DEMENTED PATIENTS. S. D. Styren, S. Allen and J. Rogers. L.J. Roberts Center, Institute for Biogerontology Research Sun City, AZ

Epidermal growth factor receptor (EGFR) is a 170 KD integral membrane protein. It contains a tyrosine kinase moiety, and is activated by the binding of epidermal growth factor, transforming growth factor and vaccinia virus growth factor. EGFR binding results in increased mitotic activity and upregulation of cytoplasmic signalling pathways within the target cell. We have utilized light and EM immunohistochemistry as well as Western blot analysis to examine EGFR expression in the brains of nondemented and clinically demented patients (Alzheimer's disease, Parkinsonian dementia, multi-infarct dementia). Immunohistochemical analysis of EGFR distribution within these groups demonstrates a correlation between presence of dementia and the expression of EGFR. Ten patients with a variety of neurological dementia were positive for EGFR expression throughout all regions of brain examined. Eight patients without dementia did not exhibit any EGFR immunoreactivity. One patient without clinical diagnosis of dementia but with extreme Alzheimer's pathology reacted positively for EGFR, as did a nondemented patent with advanced malignancy of the spinal cord. In affected patients analysis of immunoreactivity at the ultrastructural level confirms the presence of EGFR on the lumenal surface of the endothelial cells lining the blood vessels. In addition to the vascular staining, preliminary analysis also shows EGFR immunoreactivity within the cytoplasm of glial cells. Based on these observations we conclude that EGFR expression 1) is associated with the presence of clinical dementia, 2) is present throughout the brain once induced, 3) is predominantly localized to the blood vascular endothelial cells of affected patients, and 4) may be inducible by factors common to physiological states which induce dementia. Supported by NIA AGO 7367-01A1 (JR).

Effects of Nerve and Epidermal Growth Factors on the Metabolism of the Alzheimer Amyloid Precursor in Cell Cultures. Lawrence M. Refolo*, Steven R.J. Salton, John P. Anderson*, Pankaj Mehta* and Nikolaos K. Robakis, Department of Psychiatry and Neurobiology, Mount Sinai School of Medicine, New York, NY 10029

Antisera against specific regions of the Alzheimer βAmyloid protein precursor (βAPP) were used to study the effects of nerve and epidermal growth factors on the expression and processing of this protein in PC12 cell cultures. Two major βAPP proteins containing the Kunitz-protease inhibitor (KPI) were detected in cell extracts of naive PC12 cells. One displayed an Mr of 100,000 and the other displayed an Mr of 145,000. Addition of nerve growth factor (NGF) to PC12 cell cultures resulted in a large decrease in the amount of the 100,000 kDa protein and in an increase in the amount of the 145,000 kDa protein. No detectable change was seen in the levels of βAPP mRNA. Medium from naive PC12 cell cultures contained minimal amounts of either the 145,000 or the 100,000 kDa βAPP. Treatment of these PC12 cultures by NGF resulted in the release to the medium of high levels of a 125 KDa βAPP form which derives from the KPI containing βAPP and lacks the carboxyl-terminal part of the precursor. Lectin chromatography revealed that the secreted βAPP consists of at least two different glycosylated forms. The cellular form of βAPP contains both N-linked and O-linked sugars, while the forms released in response to NGF treatment contain only O-linked sugars. Epidermal growth factor (EGF) also induced the release of a βAPP protein in the culture medium, although this factor had no specific effect on either the levels or mobility of the cell-associated form of βAPP. The level of the cellular 145,000 KDa form of βAPP increases with cell density, suggesting that the expression of the KPI-containing βAPP may be modulated by intercellular contact.

THE ALZHEIMER'S RELATED HIPPOCAMPAL cDNA CLONE pADHC-9 ENCODES A 52 kDAL PROTEIN SIMILAR TO A RAT TESTICULAR SULFATED GLYCOPROTEIN. P.C. May, M.A. Lampert-Etchells*, C.P. Anderson*, and C.E. Finch. Andrus Gerontology Center, Dept. Biol. Sciences, USC, Los Angeles, CA 90089.

Clone pADHC-9 encodes a 2Kb RNA which is overexpressed in Alzheimer's disease hippocampus. pADHC-9 was isolated by differential screening of a mixed Alzheimer's/Control hippocampal cDNA library. Nucleotide sequencing of pADHC-9 identified an open reading frame of 449 amino acid residues coding for a putative 52 kDal protein. To confirm this reading frame, ^{7me}GpppG-capped RNA was transcribed in vitro and translated using a rabbit reticulocyte lysate system. A prominent 52 kDal protein was observed following translation indicating an authentic open reading frame of the appropriate size. The nucleotide and deduced amino acid sequence of this protein share 75-80% identity to rat sulfated glycoprotein-2, the main secretory product of Sertoli cells in the rat testes. A consensus signal peptide, 6 presumptive ASN-linked glycosylation sites, 10 CYS residues and a proteolytic cleavage site are conserved between these two proteins. These data suggest that pADHC-9 may encode a highly processed glycoprotein related if not identical to a human analogue for rat sulfated glycoprotein-2; its function in brain is unknown. DEVELOPMENT AND CHARACTERIZATION OF SIX NEW MONOCLONAL ANTIBODIES THAT BIND TO ALZHEIMER'S DISEASE ASSOCIATED PROTEINS (ADAP) H. A. Ghanbari*, S. Riesing*, B. E. Miller, I. Tribby* (SPONS. C. Harrington) Mental Illness and Neurological Diseases Diagnostics, Abbott Laboratories, Abbott Park, IL 60064

We have developed and produced 6 new monoclonal antibodies (MAb's) that selectively bind to a group of proteins (isoforms) which appear as 3 major bands (53, 61, and 67 kDaltons) on SDS-PAGE/Western Blots using ALZ50 monoclonal antibody. These proteins, refered to as ADAP, are present in Alzheimer Disease (AD) and some Down's Syndrome brain tissue and absent in normal and other neurological disease specimens. The new MAb's have been produced against a highly ADAP-enriched fraction prepared by multi-step differential centrifugation and detergent extraction of AD brain homogenates. These antibodies (all IgG's) share the antigen (ADAP) with ALZ50 but not necessarily the epitope. Two of the antibodies, ADD-11 and ADD-38 have much higher affinity for ADAP than ALZ50 but demonstrate the same pattern of cross-reactivity against normal brain components by both ELISA and Western Blot. The antibodies ADD-9 , ADD-14, ADD-29 and ADD-36 however demonstrate minimal cross-reactivity with normal tissue extracts, particularily in the tau region of the Western Blots. An Alzheimer's test is being developed using these new antibodies.

ALZHEIMER-LIKE PATHOLOGY INDUCED BY HUMAN SERUM IN CULTURED HIPPOCAMPAL NEURONS. G.J.Brewer, L.Domino*, and J.W. Ashford. Southern Illinois Univ., Springfield, IL 62794.

Toxic or immunologic factors in human serum could contribute to the pathogenesis of Alzheimer disease(AD). To test this theory, we grew embryonic rat hippocampal neurons in a serum-free culture medium that supports growth of neurons but not glia at low density (Brewer & Cotman, Brain Res., in press). To test for the induction of AD-like changes, cultures grown for 4 days were treated with 10% human serum. After 24 hr., neurons were fixed, one of three AD-specific stains were applied, and digitized fluorescence intensities were recorded. 1) Thioflavin S binds to the β-amyloid found in AD plaques. In culture, 10 of 12 sera tested produced significantly more fluorescence than untreated neurons. Fluorescence was particularly strong among clusters of cells. 2) Alz-50 obtained from P. Davies is a monoclonal antibody (mAb) generated by immunization with an AD brain homogenate. 14 of 14 sera produced greater immunofluorescence either in the soma or processes compared to untreated neurons in which only minimal fluorescence was found. 3) a mAb specific for the β-amyloid in AD plaques obtained from Kim & Wisniewski produced immunofluoresceence in neurons treated with sera as follows: one AD serum >> one normal serum > no serum. These results show that a serum factor can induce AD-like neuropathology, which in the AD brain may be aided by a compromised blood-brain barrier. Funded by IDPH and the Pearson Foundation.

SELECTIVE DISCONNECTION OF SPECIFIC VISUAL PATHWAYS IN CASES OF ALZHEIMER'S DISEASE COMBINED WITH BALINT'S SYNDROME. P.R. Hof, C. Bouras*, J. Constantinidis*, and J.H. Morrison, Research Institute of Scripps Clinic, La Jolla, CA, and Dept of Psychiatry, Univ. of Geneva, Switzerland.

A quantitative neuropathological analysis was performed in a subpopulation of Alzheimer's disease (AD) patients that presented a visual defect referred to as Balint's syndrome (ADB) early in the course of the disease. Balint's syndrome is a defect in visuospatial skills and the distribution of pathology in the ADB cases suggests that the connections subserving this component of the visual system are devastated, whereas they are usually spared in AD. In area 17, neurofibrillary tangle (NFT) density in the ADB cases as compared to the AD cases increases up to 63-fold. A similar increase of up to 16-fold in area 18 and 8.9-fold in area 19 was demonstrated. NFT counts were significantly lower (50%) in the prefrontal cortex of ADB as compared to the AD cases. No differences in NFT density were observed in visual association area 20 of the temporal lobe. Neuritic plaques (NP) were more numerous in the occipital cortex of the ADB cases, with increases up to 3.4-fold. Area 9 showed less NP in ADB than in AD cases. Area 7 in the parietal lobe was characterized by increased NP densities (up to 2.4-fold) and larger NP in the ADB cases. No differences in NP density were noted in area 20. Finally, Meynert cell counts in area 17 were significantly lower (41%) in ADB. These data suggest that in some cases of AD, specific neurological symptomatology may be caused by the selective loss of specific corticocortical systems, as reflected by a differential distribution of the neuropathological markers of the disease. Supported by grants from NIA (AG06647) and FNRS (83.495.0.87).

DENDRITIC EXTENT IN HUMAN BASAL FOREBRAIN IN NORMAL AGING AND ALZHEIMER'S DISEASE. S. D. Hanks* and D. G. Flood (SPON: E. M. Grollman). Depts. of Neurology and Neurobiology & Anatomy, Univ. of Rochester Sch. of Med. & Dent., Rochester, NY 14642.

Previous studies of dendritic extent in normal aging have led to the suggestion that, contrary to long-accepted dogma, the adult human neuron is capable of a remarkable degree of plasticity. Evidence has accumulated that alteration or loss of this latent plastic capacity may be a pathophysiologic feature of Alzheimer's disease (AD). In the present study, dendritic extent was measured in human basal forebrain in normal aging and AD.

From over 80 cases obtained at autopsy through the Rochester Alzheimer's Disease Project (RADP), 12 subjects were assigned to each of the following two groups (6 per group): 1) normal aged adults (mean 81.7 years, range 79-84 years), and 2) AD (mean 81.8 years, range 77-87 years). All cases in the latter group had a history of dementia which proved to be AD at autopsy. All cases in the normal aged group lacked a history of any neurological or psychiatric abnormality and showed no significant neuropathology at autopsy. Fifteen neurons from each of three regions of the basal forebrain (Ch4am, Ch4al and Ch2, as defined by Mesulam, M.-M. and Geula, C., *J. Comp. Neurol.*, 275:216-240, 1988) were randomly selected for analysis from coded 200 µm sections of Golgi-Cox stained tissue. Camera lucida tracings of these cells were prepared and subsequently digitized and measured by an Apple II Plus microcomputer with attached graphics tablet. Computer-assisted analysis currently underway will provide comparative measures of cell body size and multiple parameters of dendritic extent, including total length, total number, and average length, for dendritic segments ordered in both a centrifugal and centripetal direction. These data will be compared with previous reports of dendritic extent in human basal forebrain as well as a variety of other brain regions. Supported by NIH grant AG 03644.

CALCIFICATION OF THE GLOBUS PALLIDUS FOLLOWING EXCITOTOXIC DESTRUCTION OF THE NUCLEUS BASALIS

G.R. Stewart, D.F. Wozniak, R.E. Schmidt, and J.W. Olney. Depts of Psychiatry and Pathology, Washington University School of Medicine, St. Louis, MO.

In studies aimed at clarifying the role of cholinergic degeneration in Alzheimer's disease, we have injected the excitotoxin, N-methylaspartate (NMA), into the rat nucleus basalis to destroy basal forebrain cholinergic (BFC) neurons. In long term survival experiments (up to 11 months post-lesion), we frequently found conspicuous mineralized deposits in the globus pallidus (GP). The deposits occurred in three forms: 1) large, translucent, spherical concretions; 2) smaller, more irregular-shaped deposits, sometimes with profiles resembling neurons; and 3) as a flocculant accumulation of material surrounding large blood vessels. Spherical concretions were the most common form encountered; these were quite variable with respect to the size and number of spherules and the extent of their areal involvement of GP. The longer the survival time, especially if it extended beyond 6 months, the more consistent and severe was the response. Applying mineral-specific stains, we found that the concretions contain calcium and iron.

Inducing GP deposits is not a property unique to NMA since other investigators, using a different excitotoxin (ibotenate) to produce BFC lesions, have noted similar GP deposits. It is puzzling that the location of these deposits and the placement of the BFC lesion do not precisely coincide. Typically, the deposits are absent from the center of the injection site where BFC cell loss is most severe, but are present ventrally and laterally in regions where there is substantial sparing of BFC neurons. Thus, it is unclear how these mineral deposits relate to the destruction of BFC neurons. However, their presence in relatively close proximity to a focus of excitotoxin-induced BFC neuronal degeneration is noteworthy, since basal ganglia calcification is occasionally found in human brain and reportedly occurs with increased frequency in Alzheimer's disease and Down's syndrome (Mann, 1988), both of which entail degeneration of BFC neurons. HYPOTHALAMIC-PITUITARY-ADRENAL FUNCTION IN ALZHEIMER PATIENTS AND AGED CONTROLS.

M.J. Meaney, M. Sharma, S. Sharma, M. Thakur, A. Issa, R. Quirion, R.M. Sapolsky, & N.P.V. Nair. Douglas Hospital Research Ctr., Dept. Psychiatry, McGill Univ., Montreal H4H 1R3, Canada and Dept. Biological Sciences, Stanford Univ., Stanford, CA 94305.

Basal hypothalamic-pituitary-adrenal (HPA) function appears unchanged in healthy, aged humans. However, HPA dysfunction is frequently associated with neuropathology in the aged, and the results of animals studies have indicated that increased HPA activity is selectively associated with hippocampal dysfunction and cognitive deficits among aged rats. Existing data suggest that increased basal HPA acitivity might accompany Alzheimer's disease (e.g. Greenwald, B. Am. J. Psychiatry, 1988).

We have examined basal cortisol levels in Alzheimer patients (n= 6) and same-aged, healthy controls (n = 12), implanted with indwelling catheters at 0700h. Samples were taken every hour for 25 h and cortisol levels were estimated using a radioimmunoassay (Krey et. al, Endocrinology, 1975). Plasma cortisol levels were significantly ($P<0.001$) elevated in Alzheimer patients during both the AM (9.6± 1.1 vs. 5.9±0.3 µg/dl/h) and PM (12.6± 0.7 vs. 8.7±0.4 µg/dl/h) phases of the cycle. The differences occurred during the mid to late AM and early PM time points. The two populations exhibited virtually identical curves for cortisol over the diurnal cycle, with peak cortisol levels achieved at about 0800-0900h. Preliminary data indicate a similar trend for ACTH.

These data are consistent with previous reports and suggest that there is an increase in basal HPA activity in Alzheimer patients.

414.33

THE EFFECT OF AGING ON NEURONAL LOSS IN THE ENTORHINAL CORTEX: A RELATIONSHIP TO ALZHEIMER'S DISEASE?

C.F. Lippa, J.E. Hamos and D.A. Drachman. Department of Neurology, University of Massachusetts Medical Center, Worcester, MA 01655.

To assess the effects of normal aging on the cells of origin of the hippocampal perforant path, large neurons comprising islands within layer II of the entorhinal cortex (ERC) were counted using a semi-automated image analysis system. Neuronal counts were obtained from different rostrocaudal levels of the ERC in 10 cognitively normal individuals of differing ages. To assess a possible relationship with Alzheimer's Disease (AD) we also evaluated 8 AD patients. Our data demonstrated that with aging, cognitively normal individuals lose neurons in the ERC and that this loss may become prominent in some aged individuals. As also reported by others, all AD patients we studied showed an extreme loss of ERC neurons. These results are compatible with the hypothesis that AD is an acceleration and/or exaggeration of a process that occurs in normal aging.

414.34

EXPRESSION OF HEAT SHOCK PROTEINS IN ALZHEIMER'S DISEASE.

J.E. Hamos, B. Oblas, D. Pulaski-Salo*, P.J. Apostolides* and D.A. Drachman. Dept. of Neurology, Univ. of Mass. Med. Ctr., Worcester, MA 01655.

Heat shock proteins (HSPs) are ubiquitous polypeptides expressed in response to a wide variety of cellular stressors. To investigate the changes of expression of these proteins during Alzheimer's Disease (AD), we examined medial temporal lobes of AD patients and age-matched controls.

Utilizing immunocytochemical techniques and monoclonal antibodies to two HSPs of M.W. 78Kd (D. Bole, Yale Univ.) and 72Kd (W. Welch, UCSF), we found that in control brains, HSP72 was present uniformly in neurons, glia, and neuropil. HSP78 antibodies stained neurons in the subiculum and CA1 intensely, and neurons and glia in the dentate gyrus, other hippocampal fields, and the entorhinal cortex moderately. Western blots confirmed the identification of these HSPs.

In AD brains, the pattern changed dramatically. HSP72 antibodies intensely stained neuritic plaques and neurofibrillary tangles. HSP78 was found only in cytologically normal neurons, and even increased in neurons in the entorhinal cortex and CA3. Double labeling with ALZ50 antibodies (P. Davies, Albert Einstein College of Med.), which stain plaques and tangles, showed that HSP78 did not colocalize with pathologically affected neurons.

These findings suggest that HSPs may undergo changes in expression during AD and, therefore, may be useful molecular tools in deciphering the underlying pathogenesis of AD.

414.35

MAGNETIC RESONANCE IMAGING OF THE HIPPOCAMPAL-ENTORHINAL CIRCUITRY IN ALZHEIMER'S DISEASE.

I.P. Kesslak, O. Nalcioglu* and C.W. Cotman. Departments of Psychobiology and Radiological Sciences, University of California, Irvine, CA 92717.

The neuropathology of Alzheimer's Disease (AD) shows a consistent and severe loss of hippocampal (HPC) and entorhinal (EC) neurons. However, neural pathology is characterized at autopsy, making identification of neural degeneration during the disease difficult. MRI can provide a means to quantify anatomical changes in select brain regions, such as HPC and EC, during the course of AD and these changes can then be related to behavioral changes associated with the structural degeneration.

To date, 4 patients with mild to moderate AD and 4 age and sex matched normal volunteers have received MRI scans of the brains. Scanning was done on a GE Signa Unit, with 1.5 Tesla superconducting magnet and a head coil. Three series of scans were taken at each examination: *Spin Echo* -(1) Saggital T1 weighted: TR 600, TE 20, 256 x 256, 5mm slice thickness with 2.5mm gap, 1 excitation, 11 slices, field of view 22 cm. (2) Transverse, T2 weighted: TR 3700, TEs 100, 256 x 256, 5mm slice thickness with 2.5mm gap, 1 excitation, slices to cover the head, field of view 24 cm. *Inversion Recovery* - (3) Coronal: TR 2500, TI 900, TE 20, 256 x 256, 5mm slice thickness with 1 mm gap, t2 excitations, slices through temporal lobe, field of view 20 cm. The coronal IR images were analyzed to determine the volume within a 29 mm section of HPC and EC. Matched-pair t-tests indicated that the AD groups HPC and EC were significantly smaller than the sex and age matched control groups (respectively, $t = 15.07$, $p > 0.001$ and $t = 22.21$, $p > 0.001$).

Compared to their age matched controls, patients with AD showed a reduction of 51 % in HPC and 31 % in EC size. Hippocampal and entorhinal atrophy was highly correlated with the mini mental status exam, olfactory match-to-sample and smell identification tests and had a low correlation with a visual match-to-sample test. Thus, MRI appears to be a sensitive technique to quantify neural degeneration and functional correlates during the course of AD.

SELECTIVE LOSS OF CENTRAL PATHWAYS FOLLOWING VIRAL INOCULATION IN THE RAT OLFACTORY SYSTEM.

J.H. McLean, M.T. Shipley and D.I. Bernstein*. Memorial Univ. of Newfoundland, St. John's, Nfld., Canada, A1B 3V6, Univ. of Cincinnati College of Medicine, Cincinnati, OH, 45267-052 and The Gamble Institute, Cincinnati, OH.

We previously indirectly examined the possibility that the olfactory system serves as a portal for environmental agents that may cause Alzheimer's disease (AD); we determined that the transneuronal spread of a virus in the rat olfactory system correlates well with the regions known to degenerate in AD (McLean *et al.* '87). In this study, the short and long term effects of viral transport and replication in olfactory pathways were determined in order to correlate these effects with the known neurochemical deficits observed in AD.

In anaesthetized rats, 200 nl of 10^7 PFU/ml HSV1 (F strain) was injected into the olfactory bulb. Following survival of 3-5 days, rats were sacrificed by perfusion and frozen sections of the brain were processed by immunocytochemistry to visualize neurotransmitter or virus location. Following these short survival periods, virus-infected cells could still express neurotransmitter in cholinergic neurons of the diagonal band, serotonergic neurons in the raphe nucleus, and noradrenergic neurons in the locus coeruleus. With survival periods of 17 days to 3 months following viral inoculation, serotonergic and noradrenergic innervation of the olfactory bulb and some cortical regions was dramatically reduced. Cholinergic input to the olfactory bulb (determined by AChE histochemistry) was slightly reduced. These results compare well to the deficits observed in AD although potentially important differences were apparent. The present results may also provide insights into the etiology of AD. Supported by the American Health Assistance Foundation, NIH NS 23348 and NIAID AI-23482.

414.37

OCCURRENCE OF DIFFUSE AMYLOID DEPOSITS IN THE PRESUBICULAR PARVOPYRAMIDAL LAYER IN ALZHEIMER'S DISEASE. S. Itagaki*, H. Akiyama*, H. Tago*, P.L. McGeer and E.G. McGeer. (SPON: S.C. Sung). Kinsmen Laboratory, Univ. British Columbia, 2255 Wesbrook Mall, Vancouver, B.C. V6T 1W5, Canada

The presubiculum is a significant destination for fiber projections from anterior thalamic nuclei. In turn, fibers from this area project to the entorhinal cortex to close the limbic circuit originally described by Papez. Immunostaining for β-amyloid protein or modified Bielschowsky's silver staining has revealed the occurrence of diffuse amyloid deposits in the presubiculum in all Alzheimer cases so far examined (n=14). Observations on serial blocks showed these deposits to be localized in the presubicular parvopyramidal layer of the presubiculum proper, the transsubiculum and the subiculum, while the parasubiculum was devoid of such deposits. Bielschowsky's staining indicated that the amyloid deposits preceded the appearance of neurofibrillary tangles and neuropil threads in this region. The aggregated microglial reaction which was characteristically associated with the classic senile plaques was absent. Since the presubiculum also receives afferents from frontal and parietal association cortices, the changes in this area in Alzheimer's disease could contribute to isolation of the hippocampal formation from other cortical areas. Furthermore, convergence of cortical inputs might play a significant role in the formation of diffuse amyloid deposits in the presubiculum.

414.38

QUANTITATION OF CELL NUMBER AND SIZE IN AMYGDALA IN ALZHEIMER'S DISEASE. S.A. Scott, C.Knox,* S.T. DeKosky,and Scheff, S.W. Depts. of Anat. & Neurobiol. and Neurology, Lexington VA and Univ. Kentucky Med. Ctrs. and Sanders-Brown Center on Aging, Lexington, KY 40536.

Alzheimer disease (AD) is associated with loss of neurons in numerous cortical and subcortical regions. The amygdala contains unusually high counts of senile plaques and neurofibrillary tangles in AD, and has been reported to show a reduction in volumetric cell density. Quantitative data on the size distribution of these cells, an important criterion for distinguishing neurons from glia, are lacking.

Six neuropathologically confirmed AD specimens and six age-matched control cases were selected. Fifteen micron thick coronal sections were prepared from formalin fixed, paraffin embedded tissue and stained with cresyl violet. For each case, 30 to 80 fields from the cortical and magnocellular basal nuclei each were analyzed, utilizing extensive on-line editing with a Kontron IBAS image analysis.

Significant shifts in the size distribution of cells of the cortical and basal nuclei were evident. There was reduction in volume density of the largest neurons and an increase in number of intermediate sized cells in the AD cases. Overall volumetric cell density was shown to increase in the basal but not cortical nucleus in AD. Combined with data showing significant loss of volume of these nuclei in AD, it is nonetheless evident that a true loss of cells occurs in the amygdala.

APPEARANCE OF DIVERSE BRAIN-REACTIVE ANTIBODIES IN SERA OF AGING NZB/BINJ MICE. V. Apte*, E.N. Ahanotu*, H. Lal, and M.J. Forster.(SPON: I. Korr). Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107-2690.

The appearance of brain-reactive antibodies (BRA) and behavioral impairments occur at relatively young ages in autoimmune-prone NZB/BINJ mice when compared with C57BL/6NNia mice, a non-autoimmune strain (Lal & Forster, *Neurobiol. Aging*, 9:733, 1988). The purpose of this experiment was to characterize the brain cell membrane antigens recognized by BRA of NZB/BINJ mice, for comparison with BRA of aged C57BL/6NNia mice (Ahanotu et al., *FASEB J.*, 3:A571). Cell membrane proteins were extracted from dissociated cells obtained from whole brains of young ICR mice using N-lauroyl sarcosinate. The extracts were then separated by polyacrylamide gel electrophoresis and immunoblots were performed with these antigens using serum from NZB/BINJ mice aged 2, 10, or 16 months (ns=15). While serum from all age groups recognized an 18 kD species, the 10- and 16-month-old groups recognized a variety of other antigens (including 21, 24, 35, 36, 43, and 47-kD species). These findings suggest that the appearance of age-related behavioral deficits in NZB/BINJ mice may be related to the appearance of one or more specific serum BRA populations.[Supported by NIH grants AG06182 (MJF), AG07695 (HL), and NIH-BRSG grant RR05879].

CULTURES OF HUMAN BRAIN CELLS FROM AUTOPSIES OF ALZHEIMER'S, PARKINSON'S AND CONTROL PATIENTS. U. Rovigatti, M. Notohanmiprodjo*, and P. Riely. Institute for Biogerontology Research, Sun City, AZ 85351.

Although a well-known dogma of neuroscience holds that adult brain cells are post-mitotic and therefore not capable of proliferating, we have attempted to maintain in culture cells from different regions of brain autopsies obtained from Alzheimer's, Parkinson's or normal patients. Different culture conditions have been evaluated and optimized for approximately fifteen different regions from brain autopsies on 12 Alzheimer's cases, 4 Parkinson's cases, and 4 control cases. Under optimal conditions, a small percentage of brain cells (.01-.001%) can be maintained in vitro in viable condition for variable periods of time. Although we are still investigating the nature of these cells, their neuronal or at least non-glial nature is suggested by the fact that 1) glial cells do not appear to attach and proliferate under our culture conditions; 2) cultured brain cells do not stain with endothelial or glial specific antibodies (e.g., Factor VIII, GFAP); 3) cultured brain cells are stained by the anti-neurofilament antibodies SMI-32 and SMI-33 and also, in a smaller percentage of cells, with antibodies against phosphorylated neurofilaments. Surprisingly, some of these brain-derived cells appear to divide under our culture conditions, as shown by increase of cell numbers and thymidine incorporation. We conclude that cells from adult brains can be maintained in culture for longer times than previously thought. Although further studies are required for their characterization, such cultured cells may provide an interesting model for studies of CNS cells in both normal and pathological conditions.

CIRCUITRY AND PATTERN GENERATION: VERTEBRATES

COSTS AND BENEFITS OF HIGH FIRING RATE SENSITIVITY IN NEURONS **J. Elek*, M. Hulliger*, A. Prochazka, R.S. Smith & S. Vincent*. Division of Neuroscience, University of Alberta, Edmonton, Alberta, T6G 2S2, CANADA**

Most mammalian neurons transmit time-varying signals in the form of rate-modulated trains of action potentials. If the depth of modulation in response to a given input increases, this represents an increase in gain. Increased resolution might also be expected, but the variability of inter-spike intervals generally increases along with gain. Is the net result an increase or a decrease in resolution? On the costs side, energy is required for axonal and synaptic transmission. Transmitter utilisation increases: depletion may exceed supply, leading to synaptic failure. We have examined these issues in ensembles of muscle spindle afferents, whose gain is known to be deeply modulated by fusimotor action from the CNS, according to behavioural context. Stretch responses of over 200 cat Ia afferents obtained in acute experiments with and without fusimotor action were summated in groups of varying size. The resulting ensemble pulse trains were used to drive a simple low-pass filter model of a neuronal membrane. We conclude that:

1) at the highest firing rates energy utilisation more than doubles over basal values; pacemaker and/or transmission failure may set in after 20-30s.
2) transmitter depletion may lead to synaptic failure even earlier.
3) increased variability of inter-spike intervals in individual afferents only erodes resolution in the decoded output of very small ensembles (<5).
4) thus increased gain and resolution are the benefits, the risk of transmission failure is the cost: this may explain why gains are not kept high permanently.

DIFFERENTIAL MODULATION OF DOUBLE BURSTING MUSCLES IN THE CHICK. R. M. Johnston and A. Bekoff. Dept. of EPO Biology, University of Colorado, Boulder, CO 80309

Many behavioral studies have examined the role of sensory feedback in shaping the typical features of the underlying motor patterns. It has been shown for cat locomotor behaviors that afferent input influences the activity of one burst of a double bursting knee muscle while not affecting the activity of the other burst. We are interested in determining if individual bursts of double bursting muscles in the chick show unique modulation by afferent feedback.

In this study, we examined EMG recordings obtained from intact chicks during walking, swimming and airstepping. These behaviors are similar in that they are locomotor behaviors involving alternating limb movements, but with clear differences in afferent feedback. Specifically, we examined two double bursting knee muscles: femorotibialis (FT) and iliofibularis (IF). FT is a uniarticulate knee extensor. IF is a biarticulate muscle which is involved in hip extension and knee flexion. To examine the effects of afferent input, muscle synergies and the association between individual burst durations of FT or IF and cycle periods were compared among the three behaviors.

Our results suggest that the motor output of the individual bursts of these two double bursting muscles is differentially regulated by afferent input. In addition, we found that modulation by afferent feedback changes the synergies for the uniarticulate knee muscle, FT, but does not change the synergies for the biarticulate knee muscle, IF.

FORCE/FREQUENCY RELATIONS IN SINGLE HUMAN THENAR MOTOR UNITS. B. Bigland-Ritchie, C. K. Thomas and R. S. Johansson. John B. Pierce Fndn, New Haven, CT. & Physiology Dept, Umeå University, Sweden.

Trains of pulses of 1-1.5 s duration, varying in rate from 1-100 Hz, were delivered to single motor axons of the median nerve by the method described previously (Westling et al. Neurosci Abst. 14. 1988). Stimulus rates were delivered alternately in both ascending and descending order. Force responses of individual motor units were recorded from thenar muscles in the directions of both flexion and abduction to calculate the magnitude and direction of vector summed forces. EMG was recorded from both proximal and distal muscle surfaces.

Conventional sigmoid force/frequency curves were generated for all units, with minimal twitch fusion evident at 5-8 Hz, 50% maximum force below 15 Hz, and maximum force between 50-100 Hz. The rates giving 50% maximum force were influenced by the sequence of stimulus pattern delivery and by the unit's previous activation history, but were not well correlated with twitch contraction or 1/2 relaxation times. When stimulating at 1-50 Hz EMG potentials remained constant throughout each pulse train; but during 100 Hz stimulation their amplitudes declined rapidly, despite a well maintained force plateau.

415.4

STIMULUS PATTERNS FOR FORCE GENERATION BY SINGLE HUMAN THENAR MOTOR UNITS. C. K. Thomas, R. S. Johansson and B. Bigland-Ritchie. John. B. Pierce Fndn, New Haven, CT. & Physiology Dept, Umeå Univ, Sweden.

The minimum excitation rates required for optimum force generation were investigated in 21 single human motor units of thenar muscles by stimulating individual motor axons of the median nerve above the elbow as described previously (Westling et al, Neurosci Abst. 14, 1988). First, two pulses were delivered 500 ms apart; then repeatedly at intervals reduced to 5ms in increments of 20-5 ms. The interval generating maximum twitch summation was then repeated as a third pulse was again delivered at progressively shorter intervals. This process was repeated until 6 such intervals were established; a procedure similar to that used for cat motor units by Burke et al (Brain Res. 109: 515,1976). Most human units generated maximum force in pulse trains where the first 2 shocks were delivered 5-10 ms apart, followed by longer intervals. These rates were compared to those seen in strong human voluntary contractions.

EXTRACELLULAR RECORDING OF RHYTHMIC SPONTANEOUS DISCHARGE IN UNTREATED AND DRUG-TREATED SYMPATHETIC GANGLIA. K. A. Alkadhi and Y. H. Hogan*. Department of Pharmacology, University of Houston, Houston, TX 77204-5515.

It is well known that mammalian enteric ganglia possess an integrative system for rhythmic discharge analogous to that of the vertebrate central nervous system. Sympathetic ganglia, on the other hand, have been traditionally considered as simple relay mechanisms with no such integrative function. However, observations made in isolated superior cervical ganglia (SCG) of rabbits and rats suggest that this ganglion can, under certain conditions, fire ongoing spontaneous rhythmic discharge as single spikes or bursts of spikes occurring at regular intervals. Ganglia were placed in oxygenated Locke's solution with its rostral end aspirated into a capillary suction electrode. Rhythmic discharge appeared on treatment with 4AP, emetine or Cs^+. In the majority of rabbit SCG intense, often rhythmic, discharge was observed in untreated ganglia. This discharge subsided in 10-60 min, but disengagement from the electrode and resuctioning caused reappearance of the discharge. This indicates that suction pressure may have caused sustained transmitter release which triggered the rhythmic firing. Chronic pretreatment of rats with 6-hydroxydopamine or reserpine did not interfere with the ability of drugs to induced rhythmic firing in the SCG. The results suggest that putative catecholaminergic SIF "interneurons" are not involved in the generation of rhythm and that sustained transmitter release by any procedure could trigger the rhythmic discharge. AGE RELATED DIFFERENCES IN SPONTANEOUS AND NMDA EVOKED SPINAL MOTOR PATTERNS: AN IN VITRO STUDY OF NEONATAL MICE. P. Hernandez*, K. Elbert* and M.H.Droge. Dept. of Biology, Texas Woman's University, Denton, TX. 76204

The objective of this study was to characterize the motor pattern generating capability of spinal cord-hind-limb explants taken from Balb/C mice aged birth to 4 days. Spontaneous and NMDA evoked EMG activity from the gastrocnemius (G) and tibialis anterior (TA) muscles was recorded and bursting sequences exhibiting the same timing as intact locomotion were included for analysis. Spontaneous locomotor rhythm occurred in only 4 of 76 experiments and those 4 cases involved explants $\leq$ 2 days of age. Separately, explants were tested with and without: 1) hemisection of the spinal cord; and 2) magnesium (1.0 mM) present in the perfusion solution. Of all combinations, nonhemisected explants perfused with magnesium free artificial CSF were most responsive to bath application of 1 - 5 µM NMDA. Using that preparation, motor rhythm was most often observed in 2 day old mice. The threshold dosage for evoking rhythm tended to be lower (1.5 - 2.0 µM) for animals $\leq$ 2 days of age. The EMG pattern for G and TA activity included sequences of: 1) synchronous bursting; 2) mixed synchrony and alternation; and/or 3) irregular alternation. The alternating activity observed in vitro was often an alternation of entire bursting sequences rather than a cycle-to-cycle phasing. (NIH Grant # 1 R29 NS 25250-01.)

VERTEBRATE RHYTHM GENERATION WITHOUT RECIPROCAL INHIBITION: SENSORY INTERNEURONES NOT INVOLVED. K.T. Sillar* & S.R. Soffe. (SPON: W.J. Heitler) *Gatty Marine Lab., Univ. St. Andrews & Dept. Zoology, Univ. Bristol, UK.

In Xenopus embryos, a role for glycinergic inhibition during swimming can be demonstrated by application of the glycine antagonist, strychnine. Rhythm generation that persists in the presence of strychnine depends critically on the activation of excitatory amino acid receptors, being abolished by 30 uM APV or 1mM kynurenic acid. While the normal excitatory drive for swimming from descending excitatory interneurones should be unaffected by strychnine application, it remained possible that activity in sensory interneurones (normally inhibited during swimming) is released by strychnine application and could contribute to rhythm generation.

We have therefore recorded intracellularly from sensory interneurones in the presence of strychnine. The interneurones discharge impulse bursts at the onset of rhythmic activity but are inactive thereafter. We conclude that they are not directly involved in rhythm generation, re-emphasising a central role for descending excitatory interneuronees.

RESPIRATORY NEURON POPULATIONS IN THE VENTROLATERAL MEDULLA OF THE *IN VITRO* NEONATAL RAT BRAINSTEM-SPINAL CORD PREPARATION. John J. Greer, Jeffrey C. Smith & Jack L. Feldman. Systems Neurobiology Laboratory, Department of Kinesiology, UCLA, Los Angeles, CA 90024-1568

An *in vitro* preparation of the isolated brainstem-spinal cord of the neonatal rat is presently being used in our laboratory to study cellular and synaptic mechanisms underlying the neurogenesis of respiratory movements in mammals. Previous studies utilizing this preparation have suggested that neuron populations in the ventrolateral reticular formation of the medulla are important for respiratory rhythmogenesis and motor pattern formation (Smith & Feldman, Soc. Neurosci. Abs.14:1060, 1988). We have now constructed detailed maps of the spatiotemporal patterns of neuronal activity in these areas. Extracellular recordings of neurons in the vicinity of nucleus ambiguus from the level of the caudal facial nucleus to areas caudal to the obex were made with dye-filled glass microelectrodes (2% pontamine sky blue in 0.5 M NaAc solution; impedance=7-12 MΩ). We identified and mapped five major respiratory cell types with distinct temporal discharge patterns: inspiratory (I), pre-I [discharge starting in late expiratory (E) phase and continuing into I phase], tonic E, late E, and biphasic E cells [discharge bracketing I phase]. Each of these cell types was found throughout the ventrolateral reticular formation with a relatively high concentration of tonic and late E phase neurons at the level of rostral nucleus ambiguus. This distribution resembles the spatial distribution of respiratory neurons in the ventral respiratory group of the medulla *in vivo*. These results demonstrate the presence of a complex spatiotemporal pattern of neuronal activity in the ventrolateral medullary reticular formation of the *in vitro* preparation. Neuroanatomical tract tracing techniques are currently being used to map the distribution of cranial motoneurons, bulbospinal and propriobulbar respiratory cells in these regions for comparison to the map of respiratory neuron activity. These studies provide the necessary groundwork for further analyses of the neuronal mechanisms underlying respiratory rhythm and pattern generation in the *in vitro* system. Supported by NIH Grants HL 40959 and HL 02204.

LOCATION OF TRIGEMINAL PRE-MOTONEURONS AND THEIR RELATIONSHIP TO GLUTAMATERGIC CELLS IN THE GUINEA PIG BRAINSTEM. J.E.Turman, Jr*., S.H. Chandler and R.S. Fisher. Dept. of Kinesiology and Psychiatry and the Brain Research Institute, UCLA, L.A., CA. 90024.

We initiated a series of anatomical studies to elucidate the neuronal circuitry underlying the generation of rhythmic jaw movements. Initial experiments using iontophoretic injections of WGA-HRP in the trigeminal motor nucleus identified trigeminal pre-motoneurons (Trig-PMn). Trig-PMn were found in the mesencephalic nucleus of V (Mes 5) ipsilaterally, principal sensory nucleus of V(Pr 5) bilaterally, spinal trigeminal nucleus oralis and interpolaris (Sp5O,Sp5I) bilaterally, intertrigeminal region ipsilaterally, and bilaterally in the parvocellular reticular formation extending from the hypoglossal nucleus to the caudal aspect of the trigeminal motor nucleus. No labeling was found in the large cells of the gigantocellular reticular nuclei. Previous physiological experiments from our laboratory have impicated an excitatory amino acid as a neurotransmitter that mediates reflex and cortically induced jaw movements. Therefore, we performed a series of glutamate mapping studies to determine which brainstem regions involved in jaw movements were also glutamatergic. Following a transcardial perfusion of 5% carboiimide and 5% glutaraldehyde, sections of the brainstem region were incubated for 24 hours in a monoclonal antibody directed against glutamate. The ABC immunohistochemical process was utilized. Glutamatergic cells were found in the inferior olive, solitary nucleus, external cuneate nucleus, prepositus hypoglossal nucleus, Sp5I, Sp5O, vestibular nuclei, ventral cochlear nucleus, superior olive, Mes.5, parabrachial nuclei, central nucleus of the inferior colliculus and portions of the reticular formation including nucleus gigantocellularis, paragigantocellularis and parvocellularis. Currently we are performing a double labeling study combining the retrograde tracer, gold bound WGA-HRP, with glutamate immunohistochemistry to determine the locations of specific glutamatergic trigeminal pre-motoneurons. Funded by NIH-NIDR grants DE 07618 and DE 06193.

A DESCRIPTION OF THE PROPERTIES OF TRIGEMINAL COMMISSURAL INTERNEURONS IN THE RABBIT. R. DONGA and J.P. LUND. Cent. Res. Sci. Neurol. Univ. de Montréal, Montréal, CANADA, H3C 3J7.

The physiological identification of trigeminal interneurons by antidromic stimulation of their terminals is usually difficult because of short conduction distances. One is left with the option of classifying interneurons by excluding first order afferents, motoneurons and lemniscal neurons. In the work to be described, we were able to identify groups of interneurons terminating in the contralateral fifth nerve motor nucleus (Mot. V) which were located in the intertrigeminal area and the most anterior portion of subnucleus oralis (Landgren et. al. Exp. Br. Res., 65: 98, 1986). It was possible to stimulate the Mot. V and record antidromic spikes on the contralateral side. Using standard criteria for antidromic identification, 37 neurons were identified as commissural interneurons. Their latency range was 0.4 to 2.0 ms and conduction velocities 3.5 to 17.5 M/s. 14 units had intra-oral, 4 had peri-oral, 2 had both intra- and peri-oral receptive fields. Peripheral receptive fields for the rest of the units were not determined. In addition, many of these neurons were excited at short latency (<3.5 ms) by stimulation of the contralateral sensorimotor cortex. The discharge pattern of eight of these units was phasically modulated during fictive mastication. The role of these neurons in the bilateral co-ordination of mastication and the jaw opening reflex is under investigation. Supported by the Canadian MRC.

CENTRAL OESOPHAGEAL CONTROL IN THE RAT - IS IT BILATERAL? D. Bieger and Y.T. Wang*. (Sponsor: P. Redfern), Faculty of Medicine, Memorial University of Newfoundland, St. John's, Nlfd. Canada A1B 3V6

The hypothesis that central control for the oesophageal peristalsis is intrinsically bilateral was investigated. In rats anaesthetized with urethane, deglutitive and cholinoceptor-mediated oesophageal peristalsis were produced by application of bicuculline methiodide and muscarine, respectively, to the surface of the nucleus of solitary tract (NTS; 50-100 pmol, 0.1 μl). **1.** Topical pretreatment with methscopolamine (5-10 pmol, 0.1 μl) selectively blocked the ipsi- but not contralaterally-evoked peristalsis. **2.** Ipsilateral acute or subchronic cervical vagotomy resulted in failure of distal and decrease in cervical oesophageal responses; supranodosal section of the IXth and Xth nerves abolished oesophageal, but not pharyngeal, activity evoked from ipsilateral NTS with a slight reduction of oesophageal response amplitude evoked from the contralateral NTS. **3.** Microinjections of the non-selective glutamate antagonist, gamma-D-glutamyl-glycine or the NMDA antagonist, D,L-2-amino-7-phosphono-heptanoic acid (25-50 pmol, 0.5-1 nl) into ipsilateral nucleus ambiguus (AMB) markedly inhibited the evoked oesophageal responses, while no effect was observed after microinjections of these drugs into the contralateral AMB. Our results are inconsistent with an obligatory bilaterality of central oesophageal motor control. Instead, they suggest that deglutitive projections from the NTS oesophageal premotoneurons to the AMB oesophageal motoneurons are predominantly ipsilateral and that glutamate or aspartate may serve as excitatory neurotransmitter in this pathway.

415.12

DARWINIAN VIEW OF LANGUAGE: A WELL-FORMED SENTENCE AS ANALOGOUS TO SPECIATION AND THE IMMUNE RESPONSE.
William H. Calvin, Biology NJ-15, University of Washington, Seattle WA 98195.

A possible preadaptation for the neural machinery underlying language and thought can be seen in that required for planning sequential movements. If it isn't a standardized movement sequence such as the basketball free-throw, one has to generate a family of variations on an approximate string of commands, and then judge each of those candidate strings against memories of what strings succeeded in the past for similar-but-not-identical conditions. Thus one needs an array of planning tracks rather like a railroad marshaling yard: a *massively-serial* architecture. **Consider the transition between such variations-on-a-theme and the nearly-identical strings of a "Choral Mode."** The easy way is for the most successful strings (the ones scoring highest in comparison to memories) to reproduce, replacing low-ranked strings -- but perhaps with some copying errors. Some daughter strings may be even better than their parent string, have an even better fit to emerging memories of past successes and failures. As this shaping is repeated during "get set," a near-uniform choral-like population of strings may emerge. I have called this a Darwin Machine (*Nature* 330:33-34, 1987).

Since hand-arm sequencing circuitry in the brain has a strong overlap with where language circuitry is located in left brain, maybe the same Darwin Machine can do double-duty for language and planning ahead. Instead of sequencing hand-arm commands and grading each candidate train by memories of previous successful throws, suppose that a track planned a tongue-lip sequence and graded each such candidate train by the rules of syntax and by the individual's memories of similar verbal situations. The massively-serial buffers' shaping-up process, from crude variation to a near-uniform population, is strikingly similar to the immune response shaping up antibodies to fit an invader, or biological evolution shaping a species' bodystyle and behavior to fit a new environmental niche. Thus the well-formed sentence, and the reliable plan of action, have some strong analogies to more familiar darwinian successes; evolutionary phenomena such as the Baldwin Effect and Gause's Principle may prove useful analogies in understanding language and consciousness.

CIRCUITRY AND PATTERN GENERATION: INVERTEBRATES AND MODELS

416.1

A 448-CHANNEL OPTICAL MONITORING OF NEURAL SIGNALS FROM APLYSIA GANGLION. M. Nakashima*, S. Yamada*, S. Shiono* and M. Maeda*. (SPON: O. Koizumi). Central Research Laboratory, Mitsubishi Electric Corp., Amagasaki, Hyogo 661, Japan.

The multi-channel optical recording method has an advantage to detect neural signals simultaneously from a large number of neurons. The 128-channel optical recording method was applied to observe neural activities from the abdominal ganglion during gill withdrawal reflex elicited by mechanical stimulation to siphon (Wu, J.-Y. et al., Experientia, 44:369, 1988).

To improve the spatial resolution of the optical method and thus to detect more active neurons, we made a 448-channel optical monitoring apparatus, using a round-shaped 448 photodiode array (Hamamatsu Photonics, Hamamatsu, Japan). One photodiode array element is 0.9x0.9 mm, with 0.23 mm wide isolation region and hence the active photodiode element size is 0.67x0.67 mm. An electrical output from each photodiode element was amplified, digitized through multiplexer (1 kHz/ channel) and stored in a magnetic disk.

The 448-channel optical apparatus was applied to the semi-intact abdominal ganglion preparation with siphon and gill remained. Action potential activites from the ganglion were observed. Some of the experimental results obtained will be presented.

416.2

CALCIUM CURRENTS AND SYNAPTIC TRANSMISSION IN HEART INTERNEURONS OF THE MEDICINAL LEECH. J.D. Angstadt and R.L. Calabrese. Dept. of Biology, Emory University, Atlanta, GA 30322.

Interneurons controlling heartbeat in the leech (HN cells) produce regenerative Ca-dependent plateau potentials with thresholds near -55 mV (Arbas and Calabrese, J. Neurosci. 7:3945-3952, 1987). We have investigated the ionic currents underlying these potentials using the single-electrode voltage clamp technique. All experiments were performed in 0 mM Na saline (Na replaced with N-methyl-D-glucamine). From a holding potential of -60 to -70 mV, inward currents are elicited by depolarizing voltage steps beginning at approximately -55 mV. Inward currents persist when Ca is replaced with Ba or Sr and are increased in amplitude when the extracellular Ca concentration is raised. In contrast, inward currents are eliminated when Ca is replaced with Co, Mn, or Ni. These data are consistent with the presence of a voltage-dependent calcium current in HN cells.

Each bilateral pair of HN cells in ganglia 3 and 4 are connected by reciprocal inhibitory synapses. We examined synaptic transmission between HN cell pairs in isolated ganglia 3 and 4 in the absence of spikes (0 mM Na saline). The presynaptic cell was voltage clamped at a holding potential of -50 to -60 mV and stepped to either -50 or -40 mV for 3 seconds (these voltage steps mimic the known voltage excursions of HN cells during normal rhythmic activity). The contralateral HN cell responded with a prolonged IPSP exhibiting a peak-plateau waveform. We are now attempting to relate these synaptic responses to the above calcium currents and assess their role in the generation of normal rhythmic activity.

416.3

KINETIC ANALYSIS OF MEMBRANE CURRENTS IN THE HEART INTERNEURONS OF THE MEDICINAL LEECH. T.W. Simon, J.D. Angstadt & R.L. Calabrese. Dept. of Biology, 1555 Pierce Drive, Emory University, Atlanta, GA 30322

A number of endogenous membrane currents contribute to the oscillatory properties of the network of heart interneurons (HN) of the leech. The initial step in modeling this network as a half-center oscillator is to develop kinetic descriptions of the currents based on voltage clamp and whole cell clamp recordings.

We have developed this method of analysis for three voltage dependent conductances by using measured τ's and steady state values over a range of clamp potentials to calculate rate constants for state transitions of these conductances. These rate constants are exponential functions of membrane potential (Hodgkin & Huxley, 1952, J.Physiol. 117:500-544).

We were able to model I_h, a hyperpolarization-activated inward current, which contibutes to recovery from inhibition (Angstadt & Calabrese, 1989, J. Neurosci. in press) and successfully simulated its behavior in current- and voltage-clamp experiments. Whole cell recording of an I_{K^+} resembling the delayed rectifier were also successfully simulated. We modeled an $I_{Ca^{2+}}$ with a rapid (τ = 10-20ms) and a slow component (τ = 100-300ms).

A preliminary model of the graded synaptic current underlying inhibition between HN cells was created from the voltage response of a postsynaptic cell to a presynaptic voltage step. The synaptic response consisted of a constant and a time-dependent portion, both of which were functions of presynaptic voltage.

The kinetic models of these four currents will form the basis for a half center oscillator model of two coupled heart interneurons.

416.4

QUANTITATIVE ANALYSIS OF NON-SPIKING SYNAPTIC TRANSMISSION BETWEEN SPIKING STOMATOGASTRIC NEURONS. K. Graubard, J.A. Raper* and D.K. Hartline, Dept. of Zoology, U. of Wash., Seattle, WA 98195; Max Planck Inst. Enwicklungsbiologie, Tubingen, W.Germany; U. of Hawaii, Honolulu, HI 96822

Spiking neurons of the pyloric system in the spiny lobster stomatogastric ganglion release inhibitory transmitter as a graded function of presynaptic membrane potential at voltages subthreshold for spiking (Graubard et al. *J. Neurophysiol.* 50:508,1983). The following characteristics in TTX were established when current was injected into the presynaptic soma and the inhibitory response was monitored in the postsynaptic soma:

1. In response to sinusoidal injected current the postsynaptic voltage showed oscillations with a broad peak in amplitude centered around 0.5 Hz, corresponding approximately to the natural frequency of the network. High frequency gain roll-off ca. 4 dB/octave; corner frequency ca. 1-2 Hz.
2. Current pulses, 2.5 secs in duration, were used to generate input-output curves. The postsynaptic soma voltage was a steeply increasing function of presynaptic soma voltage (tested up to 20 mV above TTX rest). For presynaptic PD cells, the relationship could be fitted well with an exponential having an e-fold increase in peak postsynaptic response for 11 mV of peak presynaptic depolarization (range 7-20 mV; n=7). The corresponding value for the maintained response was several mV larger.
3. Ca. 5 nA depolarizing or hyperpolarizing current pulses injected into the presynaptic soma just before a test pulse altered the input-output relationship. The X-axis intercept (postsynaptic response=0) shifted an average of 5 mV more positive for depolarizing conditioning pulses and 6 mV more negative for hyperpolarizing ones. Typically, the exponent was not much changed (less than 2 mV, on average, for presynaptic PD cells).

ACTIVATION OF THE GASTRIC RHYTHM OF THE CRAB STOMATOGASTRIC GANGLION BY SDRNFLRFamide. J.M. Weimann and E. Marder. Biology Department, Brandeis Univ., Waltham, MA 02254.

In the crab, Cancer borealis, the gastric rhythm of the stomatogastric ganglion (STG) is rarely spontaneously active in control saline, even when the STG is left attached to neural inputs from the anterior Commissural (CoG) and Oesophageal (OG) Ganglia. We have been applying a variety of putative neuromodulators, known to be present in inputs to the crab STG, in hopes of finding a substance or substances that will activate the gastric rhythm. We now find that the extended FMRFamide-like peptide SDRNFLRFamide, originally purified from Homarus americanus (Trimmer et al., J. Comp. Neurol. 266: 16-26, 1987) either applied alone (10^{-8}M to 10^{-7}M) or in conjunction with the muscarinic agonist, pilocarpine (10^{-8}M to 10^{-4}M), reliably initiates robust gastric activity. Both pilocarpine and SDRNFLRFamide also strongly activate the pyloric rhythm. Since many of the neurons of the STG can fire in both pyloric or gastric time, these substances allow us to explore the mechansims by which neurons are shifted from one motor pattern to another by modulators. Supported by NS17813.

416.6

THE ROLE OF THE BRANCHIOSTEGITE NERVE IN CRAB GILL VENTILATION. K.P.Rajashekhar* and J.L.Wilkens. Dept. of Biological Sciences, University of Calgary, Calgary T2N 1N4, Canada.

The branchiostegite nerves (BN) originate from the dorsal-lateral surface of the thoracic ganglion posterior to the scaphognathite nerves and innervate the walls of the branchial chambers.

The sensory components include mechanoreceptors and other as yet unidentified receptors. Stimulation of the BN modifies the ventilatory rhythm in several ways including changes in pumping rate, switch from forward to reversed pumping and cause pausing.

The five motoneurons in each BN innervate a band of anterior branchial enlarger muscles (ABEM). These muscles run from the dorsal carapace to the flexible dorsal roof of the branchial chamber, they receive bursts of spikes in phase with scaphognathite induced branchial pressure waves and their spike frequency is proportional to ventilation rate. The ABEM motoneurons are silent during ventilatory reversals when branchial pressure becomes positive. Artificially raising branchial pressure silences, while lowering the pressure increases ABEM spike frequency. Thus, these motoneurons demonstrate both programed and reflexive patterns of activity. Contraction of the ABEMs will facilitate the movement of water through the gills by expanding the roof of the gill chamber in a diaphragm pump-like manner. (N.S.E.R.C. Canada)

IN VITRO CONNECTIONS BETWEEN LYMNAEA AND HELISOMA NEURONS. Bulloch, A.G.M., Syed, N.I. and Lukowiak, K. Dept. of Medical Physiology, H.S.C., Univ. of Calgary, Alberta, Canada, T2N 4N1

In vivo, the giant pedal dopaminergic interneuron (R.Pe.D1) of the pond snail Lymnaea stagnalis makes monosynaptic connections with its follower cells in the parietal and visceral ganglia. These follower cells of R.Pe.D1 in Lymnaea are identified and their connections are well characterized. In order to test the appropriateness of these connections in vitro, the R.Pe.D1 and its follower cells were cultured in Lymnaea conditioned medium. Lymnaea R.Pe.D1 was found to make appropriate chemical connections with its follower cells. In related snail Helisoma trivolvis, the neuron homologous to Lymnaea R.Pe.D1 is found in the left pedal ganglion (L.Pe.D1). The follower cells of Helisoma L.Pe.D1 have been located but their connections have yet to be characterized. The R.Pe.D1 from Lymnaea was plated with the follower cells of L.Pe.D1 from Helisoma in Lymnaea/Helisoma conditioned medium. All these cell types exhibit extensive neurite outgrowth within 18-24 hr of plating. Electrophysiologically, R.Pe.D1 from Lymnaea makes either excitatory, inhibitory or biphasic connection only with the prospective follower cells from Helisoma. These studies demonstrate the ability of homologous cells from two different species to establish chemical connections, which appear specific.

IN VITRO RECONSTRUCTION OF THE CENTRAL PATTERN GENERATOR (CPG) UNDERLYING RESPIRATORY BEHAVIOR IN LYMNAEA. N.I. Syed, K. Lukowiak & A.G.M. Bulloch. University of Calgary, Calgary, Alberta T2N 4N1 Canada.

An interaction between inhibitory and excitatory rhythm generators has been shown to produce the mammalian respiratory rhythm, but little is known of the circuitry within these CPGs. The intraneuronal circuitry underlying respiratory behaviour in the pond snail Lymnaea has already been described. The interneurons IP3 and VD4 have reciprocal inhibitory connections with each other and are implicated in the opening (expiration) and closure (inspiration) movements of the pneumostome. Interneuron R.Pe.D1 can initiate the respiratory cycle by post-inhibitory rebound excitation (PIR) of the IP3 neuron, which in turn excites VD4 by PIR and the cycle repeats. In order to test the sufficiency, necessity, adequacy and modulatory role of these neurons in the CPG, these identified neurons were cultured in vitro. All these cell types exhibit extensive neurite outgrowth within 18-24 hrs of plating in conditioned medium. When all three cell types were plated together in the same dish, it was possible to initiate the respiratory cycle by the excitation of R.Pe.D1 and the network became coupled, IP3 and VD4 interneurons bursting alternatively. This mimics the situation seen during in vivo active respiratory behavior. These studies therefore suggest that at least a relatively simple CPG can be reconstructed in culture and its activities can be studied and manipulated in greater detail.

416.9

GABAERGIC MODULATION OF THE RESPIRATORY AND LOCOMOTORY CENTRAL PATTERN GENERATORS (CPG) OF LYMNAEA. J.E. Richmond, N.I. Syed, K. Lukowiak and A.G.M. Bulloch. Dept of Physiology, University of Calgary, Calgary, Alta. Canada T2N 4N1.

The pedal ganglia of Helisoma trivolvis contain a network of GABA-immunoreactive neurons. To date none of the Helisoma pedal neurons have been characterized. However, in the related basommatophoran pulmonate, Lymnaea stagnalis, the involvement of pedal neurons in respiratory and locomotory activity has been recently demonstrated. The circuitry underlying these behaviors has been partially characterized and therefore provides an opportunity to investigate the role of GABA in modulating the patterned activity generated in the pedal ganglia. This was tested by bath application of GABA while recording intracellular activity from pedal and visceral neurons known to be involved in the respiratory and locomotory rhythms. GABA caused an inhibition of spontaneous respiratory cycles. In addition, cycles of the respiratory rhythm stimulated by depolarization of the right pedal neuron 1 (R.Pe.D1) were abolished in the presence of GABA. GABA induced hyperpolarizations of both the right and left Pe.D1 neurons. Neurons of the pedal A and D clusters, which are part of the locomotory CPG, were also hyperpolarized by GABA. These preliminary data suggest that GABA has inhibitory effects on both respiratory and locomotory CPG neurons.

SENSORY INPUT AND EFFERENCE COPY IN AN INSECT CENTRAL PATTERN GENERATOR. J.H. Belanger and I. Orchard, Dept. Zoology, University of Toronto, Toronto, ON, Canada, M5S 1A1.

An important problem in the production of motor patterns is the interaction between central pattern generators (CPG) and other components of the nervous system. We are currently investigating this, using oviposition in the locust (*Locusta migratoria*) as a model system. Oviposition digging is a relatively stereotyped behaviour, produced at least in part by a CPG located in the VIIIth (terminal) abdominal ganglion (K.J. Thompson, *J. Exp. Biol.* 122: 387, 1986). The digging rhythm is produced by isolated ganglia taken from females interrupted during oviposition, but it generally ceases within 30 min. It can be restarted by electrically stimulating peripheral nerves that project from the ovipositor to the CNS. These nerves contain sensory axons from the ovipositor, but do not appear to contain any motor axons. The initiated rhythm outlasts the stimulation by several (often tens) minutes, and the process can be repeated several times. This suggests that sensory input may be important in either the initiation or maintenance of this centrally-generated rhythm.

We also have preliminary evidence that an efference copy of the motor output is sent to more rostral portions of the CNS. There are spikes ascending in the abdominal connectives which are time-locked with the rhythmic bursts in ovipositor motor nerves. We hypothesize that this information is used to co-ordinate the digging rhythm with the other phases of oviposition.

INTERSEGMENTAL COORDINATION IN THE LOCOMOTOR SPINAL CPG: THEORY AND EXPERIMENT. T.L.Williams, K.A.Sigvardt, N.Kopell* & G.B.Ermentrout*. SGHMS (U.London), UC-Davis, Boston U. & U.Pittsburgh.

Fictive locomotion in the lamprey spinal cord has been entrained by imposed movement. Data on a) entrainment frequency ranges, and b) phase coupling between forced movement and ventral root bursts, were used to test a mathematical model of the CPG as a chain of coupled nonlinear oscillators. The model predicts the following, which are borne out by the data: 1) the phase lag between movement and ventral root activity depends upon frequency; 2) 1:1 entrainment is lost at frequencies for which the phase lag goes out of a permitted range; 3) this permitted range is independent of the number of spinal cord segments in the chain; 4) the variation of phase lag with frequency depends on chain length in such a way that the entrainment frequency range decreases with increasing chain length. Additional data on entrainment frequency ranges are consistent with the model if a) interaction between segmental oscillators decreases their frequency, b) ascending coupling is stronger than descending, and c) ascending & descending coupling signals have different timing.

LONG-TERM PERIODICITY IN NEURAL NETWORKS WITH STRONG INHIBITION. D. P. Bashor and Q. Tang*, Dept. of Biology, University of North Carolina at Charlotte, Charlotte, North Carolina 28223

Neural network simulations lasting tens of sec extend the work of RJ MacGregor and T McMullen, Biol. Cybern. 28: 121, 1978. 13 excitatory (E) cells and 12 inhibitory (I) cells were connected in 2 different patterns, and the response of these networks was examined as mean random E and I input varied. The mean number of E synapses, I synapses and total synapses was fixed at one of 3 levels. Synaptic strength was fixed, E at 0.2 of threshold and I at -0.7. All cells in Pattern 1 synapsed randomly with both kinds of cells. Each cell could make multiple synapses and self connections. In Pattern 2, E cells only synapsed with randomly chosen I cells, and I cells only synapsed with randomly chosen E cells.

A range of E and I input values caused both networks to produce spikes in bursts with mean cycle lengths up to about 300 msec. Mean interburst gap (GAP) was about 140 msec for both patterns and all synaptic densities. Bursts shortened but GAP did not change in both patterns with increased E input. Increased I input lengthened mean GAP. In Pattern 1, mean burst duration went from 204 to 261 msec as number of synapses went from 250 to 375, then decreased to 171 as synapse number went to 500. In Pattern 2, mean burst duration increased from 80 to 280 msec as synaptic density increased.

CONVERGING AND DIVERGING CONNECTIONS IN NEURAL NETWORKS: HOLOGRAPHY AND COMPUTATIONAL POTENTIAL OF THRESHOLDS AND SYNAPTIC WEIGHTS. G. J. Mpitsos and R. M. Burton. Hatfield Marine Science Center, Newport, OR 97365, and Department of Mathematics, Oregon State University, Corvallis, OR 97334.

Findings of chaos and variability in buccal-oral motor patterns of our experimental animal, the sea slug Pleurobranchaea, motivated us to examine the ability of neural networks to learn to transmit analog chaotic signals (Mpitsos, G. J., Burton, R. M., and Creech, H. C., Brain Res. Bull., 21:539, 1988). We show here that simple connectionist networks can also learn to perform a variety of computations on chaotic signals, and, using different input pathways, that they can learn several different tasks at the same time. Trainable synaptic weights were sufficient for networks to learn many tasks, but by including trainable thresholds the range of tasks was greatly increased, suggesting that examination of trainable neuronal thresholds in biological systems may prove fruitful, as has been examined behaviorally (e.g., Mpitsos, G.J., and Cohan, C. S., J. Neurobiol. 17:499, 1986). When convergence is spatially separated from divergence, as in networks containing one input unit, one output unit, and only one layer of hidden units ("interneurons"), memory is distributed unevenly throughout the network. But when convergence and divergence are mixed, as between two hidden layers, memory is more holographically or evenly distributed. Although training set all synaptic weights to optimal levels, networks naturally generated many "lazy" synapses which had little effect when removed from network computations. Lazy synapses may be a natural product of converging/diverging biological networks, and epiphenomenally may find adaptive use in generating variable, shifting motor patterns. Thus, while connectionist networks are not biological they may be helpful for identifying simple, universally applicable principles, and, thereby, may provide insight into the types of phenomena to examine in biological systems. MODEL NEURAL NETWORKS FOR ADAPTIVE BEHAVIOR, R. D. Beer,*[1] H. J. Chiel,[2] and L. S. Sterling.*[1] Depts. of [1]Computer Eng. & Sci., [2]Biology, and Ctr. for Automation and Intelligent Systems Research, Case Western Reserve University, Cleveland, OH 44106

We have used neuroethological and neurobiological data to design model neural networks that can generate complex, adaptive, and autonomous behavior. We have devised a simulated insect and several controllers using neuron-like elements. The pattern of interconnections of a controller for hexapod locomotion was guided by those that have been described experimentally by Pearson (1976). This controller generates gaits similar to those described by Wilson (1966) in insects, and is remarkably robust to lesions of different elements. We have also constructed a controller for feeding behavior, using the data of Gelperin et al. (1971) and Weiss et al. (1986). The model insect can sense and follow odor gradients, and shows aspects of food arousal and satiation. In addition, the model insect can appropriately integrate different behaviors. For example, if it encounters an obstacle while following an odor gradient, it can follow around the edge of the obstacle, and then continue following the odor gradient. We intend to make the model more detailed and realistic so that it can be used to generate experimentally testable hypotheses about the neurobiology of insects. We also intend to use these ideas for the design of artificial devices capable of adaptive, autonomous behavior.

SIMULATION OF THE EXPERIMENTALLY ESTABLISHED SEGMENTAL, SUPRASPINAL AND SENSORY CIRCUITRY UNDERLYING LOCOMOTION IN LAMPREY. A. Lansner*, Ö. Ekeberg*, H. Tråvén*, L. Brodin*, P. Wallén*, M. Stensmo* and S. Grillner. Nobel Inst. for Neurophysiology, Karolinska Institutet, and Dept. of Numerical Analysis and Computing Science, Royal Institute of Technology, Stockholm, Sweden.

The lamprey nervous system in vitro serves as a model for the cellular basis of vertebrate locomotion. Briefly the segmental premotor interneurons which activate motoneurons during fictive locomotion are rhythmically active and their interactions can explain the segmental burst generation (Buchanan & Grillner, 1987; Grillner et al., 1988). This network is subject to a powerful sensory entrainment by intraspinal stretch receptor neurons (Grillner et al., 1981; 1984), which provide ipsilateral monosynaptic EPSPs on the network. The reticulospinal initiation is exerted via monosynaptic EPSPs in all network interneurons (Ohta & Grillner, 1989). Efference copy information from the spinal level modulates the reticulospinal discharge (Dubuc & Grillner, 1989). Realistic simulations of this entire circuitry has been made by modelling each type of neuron with relevant types of membrane channels (Na^+,K^+,K^+_{Ca},Ca^{2+}, conventional EPSP and IPSP channels, and voltage dependent NMDA channels). The latter are of particular importance during slow swimming (Brodin & Grillner, 1985, 1986; Sigvardt et al., 1985; Wallén & Grillner, 1987). The cells have soma and three dendritic compartments. The network simulates a large variety of experimentally established findings.

416.16

COMPUTER SIMULATION OF OSCILLATION IN MUTUALLY INHIBITORY HEART INTERNEURONS IN LEECH.

[1] E. De Schutter*, [2] T.W. Simon, [2] J.D. Angstadt and [2] R.L. Calabrese (SPON: P. Lennard). [1] Dept. of Neurology, University of Antwerp, Belgium; [2] Dept. of Biology, Emory University, Atlanta, GA 30322.

Heart interneurons (HN) of the medicinal leech *(Hirudo medicinalis)* oscillate between bursts of action potential firing and periods of IPSP-mediated hyperpolarization. This is caused by the interaction of endogenous membrane currents with reciprocal inhibition. Some of these currents have been fully characterized (Angstadt et al., Simon et al., this meeting).

The initial model consisted of 2 one compartment neurons, each with 6 membrane currents. The equations describing a fast and a slow I_{Ca} and the hyperpolarization-activated inward current I_h were based upon voltage clamp recordings in HN cells. The other currents, I_{Na}, I_K (delayed rectifier) and I_A, were adapted from equations developed for molluscan neurons (Connor and Stevens, 1971, J. Physiol. 213: 31). Amplitude of synaptic conductance was determined by transmitter release, which was a function of presynaptic voltage.

We will improve the model by using kinetics measured in HN cells for I_K and I_A and better representation of transmitter release when more experimental data are available. The model is used to examine the role of I_A in timing of the oscillatory frequency and to ascertain if I_h mediated repolarization of the inhibited HN cell is sufficient to cause the switch in firing from one to the other HN cell.

SIMULATIONS OF PAVLOVIAN CONDITIONING IN NEURAL NETWORKS WITH ELEMENTS CONTAINING AN ADAPTIVE POTASSIUM A-CURRENT. J. Berner*, J. Gordon*, R. Pay, C.D. Woody (SPON: J. Barlow). UCLA Med. Ctr., Los Angeles, CA 90024.

Recent studies have disclosed changes in currents of cortical neurons during Pavlovian conditioning. One current is reduced by aminopyridine and resembles $gK+_A$. Acetylcholine and cGMP-dependent protein kinase have been shown to reduce this current. We incorporated features of this outward current and its adaptive response to accumulated second messenger into a 6 x 6 real time network. Properties of the connections between elements (the sign, amplitude, duration, and transmission delay of the PSPs) were individually specified to conform with electrophysiological observations. The simulated current activated in proportion to depolarization, inactivated with sustained depolarization, and was active over a restricted range of membrane potential. Adaptation of the current was proportional to the product of the outward current and accumulated second messenger, which was in turn a function of excitatory inputs and exponential decay. Preliminary results indicated that the network by pairing a "conditioned" stimulus (CS) with an "unconditioned" stimulus (UCS) could acquire a new, conditioned response to the CS. It was also observed that the properties of the A-current only marginally affected the passage of sustained UCS depolarizations to the output layers but substantially reduced the magnitude and duration of more transient CS depolarizations before conditioning.

SIMULATION OF 1000-NEURON INHIBITORY-FEEDBACK NETWORK REVEALS MEMORY PROPERTIES: COMPUTER MODELING INSPIRED BY NEOSTRIATUM. C.D. Myre, S.F. Sawyer, D.J. Woodward, *Dept. of Cell Biology and Anatomy, UT Southwestern, Dallas, Texas 75235.*

This study was performed to determine functional properties of a three-dimensional array of mutually-inhibitory model neurons. The mutually-inhibitory structure was inspired by the extensive inhibitory feedback network of the medium spiny neurons in the neostriatum. Each neuron was represented by a realistic RC electrical model with a simple threshold operation to trigger impulses, but without long current decays which cause intrinsic oscillation. The neurons communicated over limited distances via inhibitory synaptic connections. Activation was provided by a normally-distributed "noise" conductance (equal in excitatory and inhibitory effect) for each neuron and an external pulsatile excitatory synaptic conductance under control of the user. Three experiments were performed using a Unix-based computer, with results displayed graphically. These experiments examined the effects of increasing noise, increasing anatomical feedback range, and external excitatory input. Increasing noise led to a "binary" on/off switching phenomenon in the firing of neurons in the array, the global pattern of which evolved to a more probable on/off pattern, or "state". Increasing the feedback range lessened the number of "on" cells in this pattern. A short, powerful, excitatory pulse to all (or even a plane of) cells in the network changed the subsequent sustained pattern of on/off activity with respect to a control pattern over the length of the experiment. This network demonstrates maintained patterns of activity produced by background synaptic activity, as represented by the noise. Our hypothesis is that these activity-dependent states of the network represent a model for short-term memory which acts in parallel with long-term mechanisms, such as the putative mechanism involving long term potentiation.

A COMPUTER SIMULATION ENVIRONMENT FOR IMPLEMENTING REALISTIC MODELS OF NEURAL SYSTEMS. M.A.Wilson*, U.S.Bhalla*, J.D.Uhley*, J.M.Bower, Division of Biology, Caltech, Pasadena CA 91125 (SPON: R.Lal)

We have developed a flexible neural systems simulator, written in C, running under the Unix operating system designed to facilitate the construction of neural models that are complex enough to provide data relevant to the organization and function of real neural networks using computers which are readily available to neurobiologists (c.f. Wilson and Bower, NIPS, AIP Press 1988). A graphics based front end using the X windowing system allows rapid, interactive specification and display of network circuitry and parameters. The built-in interpretive simulation language provides access to simulator structures and functions. The simulator is capable of generating output in the form of spike activity, EEGs, intracellular potentials and field potentials to facilitate the comparison of modeled results to physiological measurements. The hierarchical representation of components allows simulations ranging from single channels to detailed single cell models to large networks of simple or complex cells. The modular structure allows new components to be easily added to the existing library. Current models developed under this system include mammalian olfactory bulb and cortex, inferior olive, and invertebrate neural structures. (work supported by NSF grant EET-8700064, and the Lockheed corporation)

A LEARNING NEURAL-NETWORK MODEL OF THE OCULOMOTOR INTEGRATOR. D.B. Arnold* and D.A. Robinson (SPON: M.B. Sachs). Depts. of Ophthalmology and Biomedical Engineering, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Single unit studies show that the extraocular motoneurons carry an eye position signal, whereas many oculomotor neurons in the brain stem encode only an eye velocity command. The eye position signal is derived from the eye velocity signal by means of a neural integrator located in the vestibular and prepositus hypoglossi nuclei.

Models of the neural integrator have been constructed which are robust and accurately reproduce its long time constant. The model neurons are described by first order linear differential equations and are connected by synapses hardwired in a reciprocal (feedback) inhibitory fashion that allows the network to process a signal varying in time.

We modeled the integrator as a neural network capable of learning. Learning rules such as back-propagation are unphysiological, only useful for feedforward networks and do not generate functions of time. We used the difference between actual and desired eye position, or retinal image slip, integrated over time as the error. Synaptic weights were altered successively to reduce this error in a network containing feedforward and feedback pathways. A two neuron network, using simulated vestibulo-ocular reflex inputs, successfully converged to perform integration, and we are currently working on a multi-neuron model.

417.1

THE EFFECT OF EARLY ENVIRONMENTAL ENRICHMENT ON DEWHISKERED RATS. K. Buhrmann*, R.C. Tees and L.A. Symons*. Department of Psychology, University of British Columbia, 2136 West Mall, Vancouver, B.C., Canada, V6T 1Y7.

The intramodal and intermodal consequences of long term tactile restriction were investigated. The mystacial vibrissae of rats were bilaterally removed at an early age, either by plucking or cauterization of the follicles. After exposure to complex environmental stimulation, behavioral assessment was carried out when rats reached adulthood. Chronic restriction of somatosensory input was found to significantly affect the somatosensory system, as well as the visual system, particularly with respect to orientational/attentional responses. The treatment had less impact on certain spatial and precise manipulatory skills which were also tested. Following behavioral assessment, dendritic branching in both the somatosensory and visual cortex was measured. Elimination of sensory input from vibrissae appears to affect dendritic branching in both the somatosensory and visual cortices.

417.2

EFFECTS OF NEONATAL SEROTONIN DEPLETION UPON DEVELOPMENT OF RAT SOMATOSENSORY CORTEX. J.A. Daugherty and J.H. Haring. Dept. of Anatomy & Neurobiology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Serotonergic (5HT) innervation of rat somatosensory cortex (SmI) is particularly dense in lamina IV during the early postnatal period (D'Amato et al., PNAS 84:4322, '87). The purpose of this study was to determine whether neonatal depletion of 5HT would influence development in SmI.

Rat pups received one subcutaneous injection of para-chloroamphetamine (PCA; 10mg/kg) on the day of birth and a second injection 24 h later. The brains of PCA-treated rats and control littermates were studied 20 d later using cytochrome oxidase histochemistry, Golgi impregnation or Nissl staining. Anterograde HRP labeling of thalamocortical axons was also accomplished in PCA-treated and control rats.

Three d after PCA treatment SmI 5HT is reduced to 35% of normal levels. Some recovery of SmI 5HT occurs but a permanent loss of 25% remains into adulthood. Despite the loss of 5HT, thalamocortical patterning in SmI appears normal in both cytochrome oxidase preparations and after anterograde HRP labeling. Likewise, barrel formation by lamina IV granule cells was normal. Preliminary analysis of apical dendrites of lamina V pyramids suggests that 5HT depletion results in fewer branches ($p<.001$) than in normal SmI. Since fewer dendritic branches could reflect delayed development intermediate time points are being studied.

PATTTERNS OF RADIAL DENDRITES AND RADIAL GLIA IN BARREL CORTEX AFTER WHISKER REMOVAL IN NEONATAL MICE. J.E. Crandall, D.Butler*,V.S. Caviness, Jr. and J.-P. Misson. Departments of Developmental Neurobiology and Neurology, E.K. Shriver Center and Mass. Gen. Hosp., Waltham, MA 02254.

We have previously shown (Crandall *et al., Neurosci. Abst.*, 14:476) that a pattern of radial glia and cortical neuronal dendrites appears in barrel cortex at the same time that the cellular pattern of barrels emerges, i.e., postnatal day 4 (P4). We wished to examine the effects of surgical removal of the row C whiskers on the development of this pattern. Serial tangential sections were immunolabeled with monoclonal antibodies specific for MAP2 (neuronal dendrites and somata) and RC2 antigen (radial glia) 6 days after whisker removal on P1. The typical spatial pattern is evident in the unaffected barrels in adjacent rows B and D. Both glia and dendrites appear to be more densely distributed toward the walls (sides and septae) than the hollows (centers) of individual barrels. This non-random distribution within barrels adjacent to the deafferented barrels is less clear for the glia than for the dendrites. In contrast, the dendrites and glia in the region of where row C barrels would normally form do not show an obvious spatial distribution. These results suggest that developing thalamocortical afferents not only influence the development of cellular pattern in the barrel cortex but also play a role in determining dendritic patterns of infragranular neurons and radial glia.

417.4

THE ROLE OF THALAMIC AFFERENCE IN THE DEVELOPMENT OF CEREBRAL CORTEX. M.S. Windrem, K.Rothe,* J.G. Schwartz,* and B. L. Finlay Dept. of Psychology, Cornell University, Ithaca, New York, 14853.

Functionally distinct regions of cerebral cortex vary in cytoarchitecture. Areas which receive massive thalamic afference tend to have more cells in a standardized cortical column. Much of this difference is due to a more prominent layer IV, which is the main recipient of thalamic input in sensory cortex. In normal posterior cortex, regions which have high cell death rates in the neonate have low cell number in the adult. Here we extend the investigation of the role of thalamic afference and neonatal cell degeneration in normal and experimentally deafferented cortex to the remaining cortical regions (prefrontal, motor, forelimb, hindlimb, somatosensory, and auditory).

On the day of birth, hamsters received unilateral electrolytic lesions of the thalamus. In experimental and litter-mate control animals, cells in columns from eight cytoarchitectonic regions of cortex were counted in adults and postnatal day 7 (P7) animals. Degenerating cells were counted throughout the entire neocortex in 12 equally-spaced sections of P7 animals.

For the eight regions, both cortical field and incidence of degenerating cells contributed to variation in adult cell number, with cell death inversely proportional to adult cell number. For all these areas, ablation of the innervating thalamic nuclei increased the incidence of degenerating cells in neonates and reduced cell number in adults.

EMBRYONIC RAT NEOCORTEX TRANSPLANTED HOMOTOPICALLY INTO NEWBORN NEOCORTEX DEVELOPS AREA APPROPRIATE FEATURES. B.L. Schlaggar* and D.D.M. O'Leary (SPON: R. Grubb) Dept of Neurosurgery, Washington Univ Sch Med, St.Louis, MO. 63110

Embryonic rat visual cortex transplanted to the somatosensory region of newborn rats develops barrel-like morphologies. Barrels are aggregations of layer 4 stellate cells and thalamic afferents unique to rodent somatosensory cortex. We tested whether the observed barrel-like features are the result of transplantation per se by performing homotopic transplants of parietal and occipital cortex. A piece of cortex was removed from E17 donor fetuses which were exposed to 3H-thymidine in utero on E15. The donor cortex was placed in a cavity aspirated in a homotopic region in a newborn host. Hosts were perfused on P12 and alternate brain sections processed for AChE histochemistry which transiently reveals the afferent input from primary sensory thalamic nuclei, and Nissl staining which shows cortical cell distribution. In parietal cortex, AChE reveals the segregation of ventrobasal thalamic afferents, whereas in visual cortex it shows the homogeneous geniculocortical termination pattern. Aggregations of layer 4 stellate cells correspond with the disjunctive pattern of intense AChE staining in somatosensory cortex. In visual cortex, the continuous band of layer 4 stellate cells corresponds to the homogeneous pattern of AChE. Transplants are delineated by autoradiography of adjacent sections. Homotopic parietal and heterotopic occipital-to-parietal transplants form barrel-like structures (i.e. aggregations of layer 4 neurons coincident with intense AChE staining) equally well. However, homotopic occipital transplants do not contain barrel-like morphologies. These results suggest that transplantation per se does not cause the development of barrel-like morphologies. Rather, embryonic occipital or parietal cortex transplanted to the neonatal parietal region form barrel-like structures due to the influence of ventrobasal thalamocortical afferents. 417.6

DISTRIBUTION OF TYPE II CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE - IMMUNOREACTIVE NEURONS IN RAT SOMATOSENSORY CORTEX. C.A. Hunt and M.B. Kennedy. Division of Biology, California Institute of Technology, Pasadena, CA 91125

Type II calcium/calmodulin-dependent protein kinase (CaM kinase) is one of the most abundant brain protein kinases, and is particularly concentrated in neocortex and hippocampus, where it may regulate a variety of specialized functions. We used immunocytochemical techniques to examine the distribution of kinase-containing neurons in rat somatosensory cortex, a highly organized, well-characterized region suitable for future studies of activity-dependent regulation. Kinase-immunoreactive neurons are present throughout laminae II-VI; both pyramidal and non-pyramidal neurons are stained. Within some layers, the distribution of kinase-positive neurons is not homogeneous. A subtle pattern of alternating light- and dark-staining bands is present in sections taken through layer IV, in the vibrissal "barrel" subfield. Bands of lighter CaM kinase immunostaining correspond to cytochrome oxidase-intense rows of barrels, while darker immunostaining is present in the areas between rows. The difference in kinase staining intensity between the two regions is due to a difference in density of immunoreactive layer IV neurons, and of the apical dendrites of kinase-positive infragranular pyramidal cells cut in cross-section. This suggests that CaM kinase-immunoreactive pyramidal cells in layers V and/or VI are distributed in a pattern related to that of layer IV neurons.

417.7

THE DISTRIBUTION OF THALAMIC PROJECTION NEURONS IN DEVELOPING RATS. K.E. Forni* and L.-Y.M. Huang (SPON: F.H. Rudenberg). Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77550.

The distribution of thalamic projection neurons has been studied in rats ranging in age from postnatal day 2 (P2) to postnatal day 15 (P15). The projection neurons were identified by the retrograde transport of fluorescent latex microspheres following injections of microspheres on one side of ventral posterolateral (VPL) and/or ventral posteromedial (VPM) thalamus nuclei. The brain and spinal cord were removed from the animals after at least 48 h survival time. The tissue was frozen and sectioned transversely at 48-64 µm on a cryostat. We have shown previously that the pattern of distribution of the projecting neurons in P14-P18 rats is very similar to the pattern observed in adult rats (Brain Res., in press). The distribution of thalamic projection neurons in P1-P12 rats is different from that seen in adult rats. The projection neurons are not confined to a few defined nuclei, but are dispersedly distributed. The total number of projection neurons increases substantially during the first 10 days of postnatal life. These results suggest that thalamic projections are not complete at birth. During the first 2 weeks of postnatal development, a great deal of rearrangement of thalamic projections occurs. Some of the projections are eliminated while other projections arrive at their target areas. Supported by NS23061 and NS01050.

417.8

DEVELOPMENT OF SI FORELIMB BARREL REPRESENTATION IN NORMAL AND DEAFFERENTED NEONATAL RATS AS STUDIED USING PEANUT AGGLUTININ (PNA). C.A. McCandlish and R.S. Waters. Dept. of Anatomy and Neurobiolology, Univ. of Tennessee, Memphis, Col. of Medicine, Memphis, TN 38163.

The lectin, Arachis hypogaea, peanut agglutinin (PNA) has been used to study early pattern formation of the face barrel subfield representation in the somatosensory cortex. Using PNA, we extended those findings to include the entire body representation, and provided evidence for differential development between the face and limb subfield representations. In this report, we describe the role that afferent input plays on early pattern development of the forelimb barrel subfield representation.

Rat pups ranging from PND-1 through PND-8 were anesthetized, and the left forearm was removed. The skin was sutured, and the pup returned to the dam. On PND-8, pups were anesthetized with sodium pentobarbital and perfused with buffered saline followed by 4% paraformaldehyde and 2% glutaraldehyde in 0.2 M sodium cacodylate buffer. Brains were removed, hemispheres were separated, and flattened tangentially. The tissue was vibratome sectioned, placed in 2% bovine serum albumin, incubated in PNA at 4°C overnight and reacted by means of peroxidase histochemistry. Lectin-bound barrel subfields were then compared between the two hemispheres.

Deafferentations made between PND-1 and PND-4 resulted in an aberrant pattern of forelimb representation on the hemisphere contralateral to the amputated limb. The resulting pattern consisted of conspicuously absent digit and limb representation boundaries, or abnormal boundary patterns. These patterns showed variations within and between animals deafferented on the same postnatal day. The ipsilateral limb showed a normal pattern in all cases examined. Pups deafferented after PND-4 showed no differences in the forelimb representation between hemispheres.

These findings provide evidence for a critical period of development when afferent input is necessary to shape the underlying substrate into the adult pattern of barrel-field organization. (Supported by NSF Grant BNS 88-02766.)

DECREASED SEROTONIN CONTENT IN RAT SOMATOSENSORY CORTEX AFTER NEONATAL INFRAORBITAL NERVE LESION. J.H. Haring[1], C. Bennett-Clarke[2], R.W. Rhoades[2] & M.F. Jacquin[1]. St. Louis Univ. Sch. of Med.[1], St. Louis, MO 63104 and Med. Coll. of Ohio,[2] Toledo, OH 43699.

Serotonergic projections to rat SmI form discontinuous patches during the first 3 postnatal wks (D'Amato et al., PNAS 84:4322, '87). These patches appear to correspond to the pattern of thalamocortical afferents (TCA) to SmI. The organization of TCA in the vibrissa pad region of SmI (PMBSF) is disrupted by infraorbital nerve section on the day of birth. The purpose of this study was to determine if TCA reorganization would influence the PMBSF 5HT plexus.

Transections of the left infraorbital nerve were performed on rat pups on the day of birth and PMBSF tissue was harvested for HPLC analysis of 5HT and 5HIAA on postnatal days (PND) 7,12, and 17. On PND7, 5HT levels were about equal in the right (altered TCA) and left (normal) PMBSF. Right PMBSF 5HT was decreased slightly compared with the left in PND 12 rats. By PND17, right PMBSF 5HT content was reduced to about 50% of left 5HT levels. Changes in 5HIAA levels were equivalent to the changes observed in 5HT content at each postnatal period. Turnover rates indicated significant increases in 5HT neuronal activity on PND12 and 17, but turnover was not different between right and left PMBSF. These data suggest that the changes in right PMBSF 5HT levels are not due to changes in raphe neuronal activity but are perhaps the result of an altered 5HT axon plexus. SINGLE-DIGIT-DENERVATION-INDUCED IMMEDIATE PLASTICITY IN SOMATOSENSORY CORTEX IS BILATERAL. M.B. Calford and R. Tweedale. Vision, Touch and Hearing Research Centre, Department of Physiology and Pharmacology, University of Queensland, St. Lucia, Qld. 4067, Australia.

In adult mammals a small amputation, such as that of the thumb in a flying-fox or a toe in a rat, usually produces a rapid expansion of receptive fields at primary somatosensory (SI) cortical loci which originally represented the denervated area. This expansion is also seen when a small body region is locally anesthetized. Here we report that in anesthetized flying-fox not only is the representation of the denervated region in contralateral SI affected but that the representation of the mirror image body region, in cortex ipsilateral to the denervation, also shows an expansion. In normal physiological conditions we cannot show an effect of stimulation upon ispilateral SI in the form of direct excitation, direct inhibition or competitive inhibition. The expansion and contraction of the receptive fields within the representation of the body region contralateral to that denervated shows the same time-course as the direct effect in those cases where local anesthetic was used to create a temporary effect; when amputation was used the ipsilateral expansion also retracted although the period of expansion varied considerably. One simple aspect of the result which has consequences for the general understanding of plasticity in adult brain is that under conditions where conventional physiology could not demonstrate the influence of a pathway that pathway has been shown to have an inhibitory influence upon viable inputs and indeed is one of the influences which shape receptive fields.

SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS III

ORGANIZATION OF NOCICEPTIVE SI NEURONS IN THE PRIMATE. W.C. Perkins* and D.R. Kenshalo, Jr. NAB, NIDR, NIH, Bethesda MD, 20892 and Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013

Previous studies have reported a population of nociceptive neurons in the primary somatosensory cortex (SI) of anesthetized monkeys. However, the laminar distribution and somatotopic organization of nociceptive neurons remains unclear. Single neurons were recorded in SI cortex of young, adult monkeys anesthetized with alpha-chloralose and supplements of sodium pentobarbital. The receptive fields of nociceptive cortical neurons were classified as either wide-dynamic-range (WDR) or nociceptive specific (NS). The average receptive field areas of WDR neurons (mean=1897 mm^2) were significantly larger than NS neurons (mean=770 mm^2). Nociceptive neurons were somatotopically organized in SI. Those neurons with receptive fields on the foot were located more medial in SI than those with the receptive fields on the hand. NS neurons were only found in the anterior half of the distribution of nociceptive cells, while WDR neurons were distributed over a wider area of SI. The majority (81%) of nociceptive neurons were located in the middle layers of SI. Once a nociceptive neuron was encountered, small movements of the microelectrode resulted in a shift in the location of the receptive field, but nociceptive neurons were still isolated. These data suggest that nociceptive SI neurons are found in aggregations or clusters in the middle layers of SI and are somatotopically organized.

MODULATORY EFFECTS OF NOREPINEPHRINE ON RESPONSIVENESS OF CAT SOMATOSENSORY CORTICAL NEURONS. R.W. Dykes[1] and R. Warren[2]. [1]Dept. of Physiol., Univ. of Montréal, Montréal, Canada, H3C 3J7 and [2]Dept. Neurol. Neurosurg., McGill Univ., Montréal, Canada, H3B 4I4.

Norepinephrine (NE) was administered to neurons in cat somatosensory cortex in an effort to determine the effects of NE on neuronal excitability. Under halothane anesthesia, the somatosensory cortex was exposed and a multibarrel microiontophoretic pipette was introduced. From 59 cats, 368 neurons were held long enough to collect information about receptive field location, depth in the cortex and sensitivity to microiontophoretically administered glutamate. In this sample, 26% displayed peripheral receptive fields, 25% showed some afferent input during glutamate administration whereas for 49% we were unable to demonstrate the presence of peripheral input. Cells with receptive fields displayed spontaneous activity more frequently than cells without receptive field (57% vs 24%).

In general the effect of NE was to suppress both spontaneous and evoked activity. In a sample of 63 neurons, 26/42 that had spontaneous activity had their ongoing activity reduced in a greater proportion than the evoked activity, resulting in an increase in signal-to-noise (S/N) ratio. In 10 cases NE produced a decrease and in 4 cases there was no change in S/N ratio. In the majority of cells where spontaneous activity was absent, NE caused a reduction of activity whether it was evoked by somatic stimulation or by glutamate microiontophoresis and few cells appeared to be insensitive to NE.

The major action of NE in the somatosensory cortex seems to be an attenuation of neuronal excitability, this action being stronger on weak inputs than on strong inputs evoked either by peripheral stimulation or glutamate pulses, resulting in an increase in S/N ratio. (Supported by MRC of Canada).

418.3

PROLONGED EFFECTS OF NOREPINEPHRINE ON RESPONSIVENESS OF CAT SOMATOSENSORY CORTICAL NEURONS. R. Warren[2], L. Buyan*[2] and R.W. Dykes[1]. [1]Dept. of Physiol., Univ. of Montreal, Montreal, Canada, H3C 3J7 and [2]Dept. Neurol. Neurosurg., McGill Univ., Montréal, Canada, H3B 4L4.

The study of norepinephrine (NE) described in the abstract by Dykes and Warren (1989) was extended to examine the possibility that there may be long-term effects on neuronal excitability resulting from the treatment of neurons in somatosensory cortex with NE.

In the sample of 368 neurons isolated from the forelimb cortex of halothane anesthetized cats, 54 cells were studied for variable periods of time after the end of NE treatment. Neuronal excitability was tested regularly with somatic stimuli or with a pulse of glutamate, the timing being controlled by a computer. The impulses were converted to digital signals and stored on a computer. These responses were taken as measures of neuronal excitability and were compared to the responses during the control period that preceeded NE treatment.

Thirty one (58%) of these neurons showed an enhancement of excitability following the end of NE treatment of which 6 (over 13) had receptive fields and 25 (over 41) with no receptive fields. The effect developed within seconds to a few minutes of the end of NE administration and was generally more pronounced in the presence of glutamate. When cells were studied for longer periods of time, the enhanced responsiveness appeared to remain or to decline only very slowly and often lasted for as long as the cell was held. The role that such a change in excitability might play in cortical function has yet to be clarified. (Supported by MRC of Canada).

CHANGES IN RECEPTIVE FIELD ORGANIZATION OF PRIMATE SI NEURONS DURING IONTOPHORESIS OF A GABA ANTAGONIST. K. Alloway and H. Burton. Department of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

We characterized the receptive field (RF) properties of SI neurons to punctate stimuli before and during iontophoresis of bicuculline methiodide (BMI) in macaque monkeys that were anesthetized with either pentobarbital or nitrous oxide and halothane. Neurons in areas 3b and 1 having glabrous skin representation throughout the digits and palm were activated by constant amplitude indentations applied sequentially to multiple points in the RF.

Some slowly-adapting (SA) neurons responded to BMI with an expansion of RF size. Many SA neurons, however, failed to exhibit RF expansion and were also resistant to the inhibitory effects of GABA.

Rapidly-adapting (RA) responses were inhibited by iontophoretic application of GABA and this inhibitory effect was subsequently antagonized by BMI. During BMI iontophoresis, RA neurons usually exhibited an expansion of the RF into neighboring regions including digits that were outside the original RF. Contour maps frequently indicated that the pattern of RF expansion across digits was most pronounced at noncontiguous sites that would normally be juxtaposed to the most sensitive site in the original RF. We conclude that the geometry of the expansion tended to incorporate those parts of the skin that normally would be activated together during manipulation of the hand. Supported by NIH NS09809 and 22012.

418.5

RESPONSIVENESS OF REORGANIZED SOMATOSENSORY CORTEX (SI) AFTER INACTIVATION OF NORMAL SI CORTEX IN CHRONIC SPINAL CATS. C. Casanova, P. A. McKinley, C. Chau*, S.Molotchnikoff. McGill University, School of Physical and Occupational Therapy, Montréal, Canada, H3G 1Y5.

Major reorganization of the cortical somatotopic map occurs in cats deprived of hindlimb afferent input at 2-weeks of age (McKinley et al., Develop. Brain Res. 31:136, 1987). In these animals, the region normally devoted to the hindlimb becomes devoted to the trunk and forelimb and the somatotopic maps are characterized by two representations of the trunk and forelimb. We have investigated the possibility that intracortical connections are the anatomical substratum providing new input to the deprived cortex. Experiments were carried out on anesthetized adult cats that were cord-transected (T_{12}) at 2-weeks of age. Carbon fiber-filled micropipettes were used to record multi-unit activity. The cortex was mapped and the normal and new representations of the forelimb and trunk were clearly identified. The recording electrode was kept in the reorganized region while an injecting-recording micropipette filled with stained lidocaine was placed in a somatotopically corresponding region of the normal cortex. Our results indicate that the inactivation of the normal cortex failed to reduce the responses of the reorganized cortex. These results suggest that intracortical connections from the "normal" somatotopic sites are not the means by which the "novel" somatotopically corresponding sites are driven.

418.6

PLASTICITY OF RACCOON SOMATOSENSORY CORTEX: ROLES OF CONVERGENT SENSORY INPUTS AND CORTICO-CORTICAL EPSPS E. Smits*, D.C. Gordon*, P. Zarzecki and D.D. Rasmusson. Dept. of Physiology, Queen's Univ., Kingston, Ontario, K7L 3N6 and Dept of Physiology & Biophysics, Dalhousie Univ. Halifax, N.S., B3H 4H7, Canada

We tested two hypotheses: 1) that multidigit inputs are present in primary somatosensory cortex of raccoons and 2) that corticocortical connections are enhanced during plastic remodeling of cortex. Intracellular recordings were made, under barbiturate anesthesia, from 104 neurons in the representation for glabrous skin of digit four (D4) in two age-matched groups. In controls, electrical stimulation of D4 glabrous skin evoked epsps in 98% of neurons. However, inputs did not originate only from D4, since D3 or D5 stimulation produced epsps in 28% of these neurons. Six to nine months after removal of D4, the proportion of neurons with inputs from D3 or D5 was increased to 76%. Microstimulation (ICMS) in the rostral "heterogeneous" cortex evoked corticocortical epsps in 73% of neurons in controls and in 90% of neurons after amputation.

Epsps can be evoked from multiple digits and by a corticocortical path in normal cortex. The corticocortical path could relay the inputs from adjacent digits. Stronger corticocortical epsps after deafferentation could account for the new sensory properties of somatosensory cortex.

DIFFERENTIAL RESPONSIVENESS OF SII FOLLOWING SI LESIONS IN INFANT AND JUVENILE MACAQUES. K. Sathian, Shao Dian-Hua* and H. Burton. Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Pons et al (Science 237: 417-420, 1987) reported that lesions in primary somatosensory cortex (SI) of adult macaques abolish responsiveness in the corresponding representation in second somatosensory cortex (SII). We ablated the hand representation in SI in 2 juvenile and 3 infant (4-6 weeks postnatal) Macaca mulatta and recorded in ipsilateral SII (one hemisphere per animal). Substantial portions of the SII hand area were unresponsive. However, in each animal, some responses could be evoked in SII by mechanical stimulation of the hand. Relatively few responses were elicited by low-threshold cutaneous stimuli and no cutaneous receptive fields were restricted to the digits. Representations of body parts other than the hand were normally responsive and their location was consistent with normal somatotopy in SII. The proportion of cutaneous receptive fields was higher in neonatally-lesioned macaques than in the older animals. This may explain the greater tactile capacity of the former (Carlson and Burton, J. Neurosci. 8: 833-859, 1988). In the juveniles the SI lesions spared small parts of areas 3a and 3b, which could have contributed to the residual somatic drive. However, in the neonatally-lesioned monkeys this was not the case. Further, in one infant, injection of Fast Blue into SII at a site where cutaneous input was recorded from the hand retrogradely labeled cells in motor cortex and VPL, VPI and PO thalamic nuclei, but not in SI. Supported by NIH NS 09809 & NS 15070.

PARALLEL PROCESSING IN THE FIRST AND SECOND SOMATOSENSORY AREAS IN TREE SHREWS. P.E. Garraghty, S.L. Florence, W.N. Tenhula, and J.H. Kaas. Department of Psychology, Vanderbilt University, Nashville, TN 37240.

In monkeys, the second somatosensory area (SII) depends on inputs from anterior parietal cortical areas 3a, 3b, 1, and 2 ("SI") for its activation. Thus, if the hand representation of SI is removed, stimulation of the hand no longer drives neurons in SII. In contrast, neurons in SII of cats are unaffected by the removal of SI cortex. Because of this dramatic species difference, we are continuing a comparative analysis, and report here on the effects of SI lesions on the responsiveness of neurons in SII in the tree shrew. In these experiments, we first mapped, in anesthetized subjects, the forelimb representation in SII. We next mapped the forelimb representation in SI and then lesioned it by aspiration. We then remapped the SII hand representation. In all 5 cases, neurons in SII with receptive fields on the forelimb remained highly responsive to cutaneous stimuli after the lesion. These results, together with those mentioned earlier for other species, suggest that SI and SII are independently activated by thalamic projections in most mammals and that a dependency of SII on SI may be present only in monkeys, emerging relatively recently in evolution. We suggest that the pattern of thalamocortical relations with SI and SII can be used to predict whether or not a dependency exists. (NS16446)

SINGLE NEURON RESPONSE PROPERTIES IN SENSORIMOTOR CORTEX IN AWAKE CATS. J.C. Slimp and A.L. Towe. Dept. of Physiology and Biophysics, Univ. of Wash., Sch. of Med., Seattle, WA 98195

Three quasi-planar arrays of 10 closely-spaced microelectrode tracks were run in primary somatic and pericruciate sensorimotor forelimb cortex in two awake, passively restrained domestic cats. Guide chambers for the electrode carriers were affixed to the cranium while the cats were under deep barbiturate anesthesia. The modality sensitivity, receptive field (RF) location and size, adaptation rate, and state of arousal were recorded for 504 neurons isolated at 337 sites (2 or more neurons were isolated at 120 sites). The spatial distribution of these response properties failed to show any clear organization, other than somatotopy. Quantitative tests of the predictions of a strict columnar and of a random distribution model showed no difference from the random model, in all three arrays. Few simultaneously-recorded neurons shared the same modality and RF; 2/3 had limited or no RF overlap and 5/9 showed different modality sensitivities. Many pairs with modality sharing showed limited or no RF overlap, and many pairs with partial or complete RF overlap did not respond to the same modality. The data failed to support any model featuring local bounded regions within which modality sensitivity and RF location and size are the same. Local clusters sharing the same response properties were not excluded.

418.10

AN ANATOMO-PHYSIOLOGICAL STUDY ON THE FUNCTIONAL MATCHING BETWEEN RECEPTIVE FIELDS OF SII NEURONES AND ASSOCIATION INPUT FROM SI IN CATS. P.Barbaresi, S.Bernardi*, T.Manzoni.* Inst. of Human Physiology,University of Ancona,Italy.

In 6 cats HRP was iontophoretically delivered (2-4 uA, 15-20 min) through a micropipette (20-30 um tip diameter) into individual somatotopic zones (Zs) of SII which were preliminarily identified by microelectrode recording.After 72-96 h several Zs of ipsilateral SI were explored with microelectrodes to map neuronal RFs. Animals were perfused and their brains cut and processed for HRP. Tracer deposits in SII were 150-450 um in diameter. HRP-labelled cells were in all cytoarchitectonic areas (fewer in 3a) of ipsilateral SI and their number ranged from about 150 to 550 (counts from alternate sections). After injections in a single digit Z of SII,labelled cells were clustered in the same digit Z of SI,except few (less than 5%) found in Zs of the contiguous digits. After injections in the hand or forelimb Zs, whose RFs included the digit tips,labelled cells were in corresponding Zs of SI (palm,wrist and arm) and few (10-15%) also in the digit Zs. RFs mapped from labelled region of SI were smaller than those at the injection site, but always included in the latter.

BILATERAL INTERACTION IN CAT SII AND THE CORPUS CALLOSUM. N. Picard*, F. Lepore, M. Ptito, J.-P. Guillemot.Dépt.de Kinanthropologie et de Psychologie, Université du Québec et de Montréal, H3C 3P8.

Somatosensory area SII receives ipsilateral input mainly through the corpus callosum(CC). Previous studies of cat and monkey SII have indicated that this ipsilateral input can inhibit or facilitate the contralateral neural response to a tactile stimulus. This experiment was designed to systematically evaluate this interactive effect by comparing the response of bilateral cells to either ipsilateral, contralateral or simultaneous stimulation. The contribution of the CC to ipsilateral activation and bilateral interaction was also assessed by comparing normal cats to callosum sectioned cats. Unilateral and bilateral mechanical stimuli, equated on all parameters for a particular cell, were applied to the receptive fields (RF) of bilateral cells. Unilateral stimulation always elicited excitatory responses. The bilateral response was often stronger than the unilateral response. A cell was considered to show interaction when the bilateral response was at least 50% higher, in terms of total number of spikes evoked by the stimuli, as the strongest unilateral response. In normal cats, about one-fourth of the units showed interactive effects. Almost all had RF located on the forelimbs and most were responsive to deep pressure. In callosotomized cats, the interactive effects disappeared almost completely, indicating that callosal input is the main source of this interaction.

418.12

CONVERGENT INPUTS TO SINGLE NEURONS IN SmI FOREPAW DIGIT CORTEX OF RACCOONS. G.S.Doetsch, S.D.Stoney, Jr. and D.H.Hauge*. Dept. of Surg. (Sect. of Neurosurg.) and Dept. of Physiol. & Endocrinol., Med. Coll. of GA, Augusta, GA 30912

Neurons in digit 3 and digit 4 cortex of chloralose-anesthetized raccoons were tested for afferent convergence using mechanical and electrical stimulation of all digits in conjunction with condition-test (CT) interactions. Most neurons received strong facilitatory or weak excitatory influences from several off-focus digits as well as excitatory input from the on-focus digit. Strongest facilitation typically occurred with CT intervals of 1-5 msec. Off-focus excitatory responses usually had higher thresholds, lower probabilities, fewer spikes and longer latencies (1-10 msec) than on-focus responses. Neurons located in "heterogeneous" hairy skin representations had larger receptive fields (RFs) and were facilitated from more digits than neurons in glabrous skin representations. Application of the GABA antagonist picrotoxin sometimes enlarged excitatory RFs to include several off-focus digits. Unmasking or strengthening of convergent inputs may account for the SmI reactivation observed following peripheral nerve lesions (Kelahan & Doetsch, 1984). Supported by NSF Grant BNS-8419035.

THE EXCITATORY AMINO ACID ANTAGONIST (EAAA), MK-801, ATTENUATES SOMATOSENSORY-EVOKED POTENTIALS (SEPs) OF RATS. T.L. SAILER*,T. EMREY* AND R.R. NOTVEST. Wyeth-Ayerst Research, Princeton, NJ 08543-8000

The purpose of this study was to determine the effect of EAAAs on sensory processing within the CNS. SEPs were used as a functional measure of sensory processing and were recorded 0, 30, 60, 90, and 120 min post-drug in conscious, restrained male Sprague-Dawley rats (forelimb stimulation; 2-4 mamps, 100 µsec duration, 1.7/sec). MK-801 produced a dose-related decrease in the amplitude of the 8 msec peak. Percent change from baseline was +4% for vehicle control, -24% at 0.025, -87% at 0.05, and -93% at 0.10 mg/kg ip. The effect peaked at 30 min and generally reversed by 90 min. Reduced amplitude and increased latency were observed in later peaks. Attenuation of SEPs by low doses of MK-801 suggests that EAAAs interfere with sensory processing. Other EAAAs (ketamine and PCP), have dissociative anesthetic and psychotomimetic properties. The MK-801 change in SEPs may be the physiological correlate of dissociative/psychotomimetic properties of some EAAAs.

VIBRISSECTOMY CAUSES TRANSIENT CHANGES IN GAP-43 IMMUNOREACTIVITY IN THE ADULT RAT BARREL CORTEX. K. Wood*, [1]L. Benowitz, A. Dunn-Meynell and B. Levin (SPON: S.D. Cook), Neurology Svc., VA Med. Ctr., E.Orange, NJ 07050, [1]Dept. Psych., Harvard Med. Sch., McLean Hosp., Belmont,MA 02178.

Removal of mystacial vibrissae in adult rats leads to alterations in the representation of the vibrissae in the barrel cortex. We examined changes in the distribution of growth associated protein, GAP-43 immunoreactivity (GAP-IR) induced by vibrissectomy (vbx) as a possible index of sprouting. All but the central (C3) vibrissae were removed unilaterally from adult male SD rats. 6D or 14D later, the barrel cortices were removed, flattened, sectioned tangentially and reacted to reveal GAP-IR by immunocytochemistry. In layer IV of the cortex, barrel centers contained low GAP-IR, whilst the inter-barrel regions had higher GAP-IR. The area of the C3 barrel center defined by GAP-IR was unchanged by spared C3 vbx at either survival time. However at 6D post surgery, the average area of the deafferented barrels surrounding C3 decreased by 10.0% relative to the control side ($P<0.025$) whilst the interbarrel area showed a non-significant increase (4.6%, $P>0.10$). No such changes were apparent with 14D survival. These data provide evidence for structural remodeling in the adult brain, suggesting that GAP-43 containing terminals sprout into barrel centers after vbx induced deafferentation of the barrel cortex. Supp. by the VA Medical Research Svc. and NS25830.

TRANSIENT EXPRESSION OF GAP-43 IN THE DEVELOPING RAT BARREL FIELD CORTEX. R.S. Erzurumlu, S. Jhaveri* and L.I. Benowitz, M.I.T., Cambridge, MA, 02139 and Harvard Medical School, McLean Hospital, Belmont MA 02178.

GAP-43 is a neuron-specific phosphoprotein involved in development and regeneration of axonal processes. We used a polyclonal antibody against GAP-43 to study its expression in the rat barrel field cortex during normal development and after early injury to the sensory periphery. The immunostaining pattern was compared to the organization of vibrissal barrels seen with cytochrome oxidase (CO) histochemistry and Nissl stains.

GAP-43 was first evident in the differentiating layer IV on PND3 as an array of punctate densities which correspond to the pattern of vibrissae on the snout, and which are confined to prospective barrel hollows. The densities were most intense on PND5, at which time they were surrounded by newly emerging cell-dense barrel walls. Towards the end of the first postnatal week, the staining intensity in the barrels dramatically decreased, while the size of immunopositive densities increased and was comparable to that seen with CO. By PND8, GAP-43 immunostaining had virtually disappeared from the barrels, but was dense in the septa. This staining pattern was complementary to that seen with CO, and persisted into adulthood. Following partial or total row C vibrissae cautery on PND0, the distribution of GAP-43 densities representing the damaged whiskers formed a continuous band. This pattern was seen as early as PND3.Based on the pattern and time course of GAP-43 expression and on the effect of peripheral manipulations, we conclude that the GAP-43 staining reflects the distribution of ingrowing thalamic afferents.Thus, the disjunctive organization of these afferents occurs prior to cytoarchitectonic differentiation of cortical barrels.

SURVIVAL OF LABELED THALAMOCORTICAL NEURONS IN TISSUE CULTURE. L.M. Smith and K.A. Jones, Center for Neural Science, Brown University, Providence, R.I. 02912 and Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

Unlike many types of CNS neurons, thalamic projection neurons have been difficult to grow *in vitro* for extended periods. We attempted to optimize thalamic neuronal survival in culture by studying the 1) method of labeling the cortically projecting neurons, 2) age and method of dissociation, 3) source of glial feeder layer and 4) method of reducing excitotoxic effects. Thalamocortical neurons were prelabeled *in vivo* by retrograde transport of fluorescent latex microspheres. The parietal cortex of rat pups was injected with .2µl label through the uterine wall of the mother two days before birth. Within three hours after birth, the dorsal thalamus was dissected from the newborn brain, dissociated enzymatically using the enzyme papain and plated as a suspension of single cells (130 cells/mm^2) on a feeder layer of thalamic and/or cortical astrocytes (Huttner and Baughman '88). The excitatory amino acid antagonist, kynurenate (1 mM), was added to the dissociating and growth mediums to protect thalamic neurons from glutamate excitotoxicity (Choi et al., 1988).

Twenty four hours after plating most cells had a distinct bipolar or multipolar neuronal morphology; 4.0% of these cells were densely labeled. Three weeks after plating, 48% of the initially plated neurons survived, and 4.3% of these were still labeled with microspheres, suggesting that thalamocortical projecting neurons survived roughly in proportion to the number originally plated. Thus these conditions are sufficient to support prolonged survival of thalamocortical neurons in culture, and will allow future studies of their synaptic physiology. (Supported by NS13031 and EY03502).

418.17

NAAG-POSITIVE NEURONS AND TERMINALS IN THE SOMATIC SENSORY CORTEX OF RATS AND CATS. F. Conti, J.H. Neale§, T. Manzoni* Inst. of Human Physiol., Univ. of Ancona, Ancona (Italy); §Dept.of Biol., Georgetown Univ., Washington, D.C (USA).

N-acetylaspartylglutamate (NAAG) is implicated in chemical transmission at excitatory synapses in the neocortex. We studied the morphology and laminar distribution of neurons and terminals immunoreactive to an antiNAAG serum in the somatic sensory cortex of rats and cats. Animals were perfused with 4% carbodiimide and post-fixed for several days in 4% paraformaldehyde. 25 µm-thick sections were cut and processed for ICC.

In both rats and cats, numerous NAAG-positive neurons and dot-like structures (probably axon terminals) were present in all layers, although with significant differences: neurons were densest in layers II and V, while terminals were densest in layer I. In rats, the majority of positive neurons were non-pyramidal (NP) cells, while in cats pyramidal (P) neurons predominated. These results indicate that: 1) NAAG might have a role in excitatory transmission in the neocortex, as revealed by P cells labeling; and 2) this peptide might also have other actions, as suggested by the labeling of numerous NP (presumably GABAergic) neurons.

EFFECT OF SEQUENTIAL IMAGE PRESENTATION ON TEMPORALLY MODULATED RESPONSES OF STRIATE CORTICAL NEURONS. J. M. Watanabe*, T. J. Gawne*, B. J. Richmond, and L. M. Optican*. Laboratory of Neuropsychology, National Institute of Mental Health, and Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, Maryland 20892.

The responses of neurons in primary visual cortex show stimulus-dependent temporal modulation: when a stimulus is presented in isolation, the waveform of the response depends upon the spatial pattern and duration of the stimulus. However, images do not occur in isolation during normal vision. Thus, it is important to know how changes from one image to another affect the responses of visual neurons. In this study, responses to stimuli consisting of sequential images were compared to the responses to isolated images.

Single units in primary visual cortex were recorded in behaving monkeys. During fixation, 2-dimensional black and white stimuli were flashed on the neuron's receptive field. Stimulus pairs that gave disparate response waveforms were chosen. Each stimulus was presented in isolation for each of 18 durations. The stimuli were also shown sequentially, with varying durations (33 - 133 msec) and varying intervals between them (0 - 133 msec). The responses to the paired stimulus presentations were compared with the predictions of a superposition model, based on the linear addition of the responses to each stimulus presented alone.

When the interval between images was 66 msec or greater, the responses were independent and obeyed superposition. For shorter intervals, many were still predicted by superposition. When superposition failed, the initial peak of the response to the second stimulus was both decreased and delayed. However, the waveform returned to that predicted by superposition before its end. This suggests that less than 66 msec is required to change the temporally encoded messages about sequentially occurring images.

ESTIMATING INFORMATION TRANSMITTED BY NEURONS. T. J. Gawne*, L. M. Optican*, and B. J. Richmond. (SPON: J. Carl) Lab. Neuropsychology, NIMH and Lab. Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Shannon's information theory provides a model-free method for quantifying multidimensional stimulus-response relationships in neurons. Unfortunately, estimation of stimulus-response probabilities from data which are continuous, noisy, or few in number leads to biased overestimates of transmitted information, **T**. We have developed an improved estimator, $\mathbf{T}^*$, which corrects for these biases.

$\mathbf{T}^*$ can be obtained from **T** by subtracting a term that goes up as either the sample size goes down or the noise goes up. The information remaining after the stimulus-response relationship has been randomized, **B**, is a measure of the small sample bias. If the stimulus-response relationship is random, then further randomization will have no effect and **T** and **B** will be the same; otherwise, **B** will be less than **T**. Hence the ratio (**B**/**T**) can serve as a factor sensitive to the data's signal-to-noise ratio. Thus, a combination of these two factors gives the improved estimator: $\mathbf{T}^* = \mathbf{T} - (\mathbf{B}/\mathbf{T})\mathbf{B}$.

$\mathbf{T}^*$ is accurate within 5% for sample sizes as small as 7 in simulated data sets contaminated with both Gaussian and uniform noise. For neuronal data, $\mathbf{T}^*$ was a better estimator than **T** for sample sizes below 30. Thus, we propose $\mathbf{T}^*$ as a new estimator for transmitted information in biological signals since it minimizes errors caused by 1) quantization, 2) noise, and 3) small sample sizes.

LINKING SIMPLE CELLS WITH QUADRATIC MODELS OF MOTION PERCEPTION. H. Suarez* & C. Koch (SPON: M. Kennedy). Computation and Neural Systems, Caltech, Pasadena, CA 91125.

Behavioral experiments on insects as well as psychophysical evidence (Hassenstein & Reichardt, 1956; Van Santen & Sperling, 1985) support the notion that short-range motion perception is mediated by a system with a quadratic type of nonlinearity. However, there is little physiological evidence for quadratic nonlinearities in directionally selective cells. Both simple and complex cells of visual cortex appear to be linear in stimulus contrast, for low contrast (Holub & Morton-Gibson, 1981). Moreover, known biophysical mechanism do not seem to have quadratic properties, except under limiting conditions (Grzywacz & Koch, 1987). We discuss here a simple mechanism offering a solution to this problem, as well as a detailed model of simple cells. We assume a population of directionally selective cells with random thresholds (distributed uniformly in an interval) and a linear response above these thresholds, until saturation. In a linear threshold function, increasing the threshold is equivalent, with respect to the output, to decreasing the input of the same amount. The sum of the population responses to a given input, indicative of the perceptual response, is then the same as the sum of the responses of a single neuron with the lowest threshold to a group of inputs distributed uniformly in an interval. The perceptual response is thus approximately the integral of the linear neuronal response curve, as in Monte-Carlo integration, and proportional to the square of the input. Simulations with 50 neurons fit a square function well.

A BACKPROPAGATION TRAINED MODEL SIMULATES THE RESPONSES OF DISPARITY TUNED PRIMARY VISUAL CORTEX NEURONS. D. Zipser, Cognitive Science Dept., Univ. of Calif. San Diego, La Jolla, CA 92093.

Backpropagation learning has proven useful in programming model neural networks to simulate the observed responses of actual cortical neurons. While backpropagation is a supervised learning procedure, it can be used in an unsupervised mode, called identity mapping, in which the output target is exactly the same as the input pattern. The responses of the hidden units in backpropagation trained identity mapping networks represent an optimal feature encoding of the input patterns closely related to the principal components of the input correlation matrix. A model neural network was trained by backpropagation to do an identity mapping using as input a pair of retinas on which a stimulus was represented with a range of disparities. The disparity tuning of the hidden units in this network was compared to those found experimentally in areas 17 and 18 of the cat (LeVay, S. and Voigt, T. *Visual Neurosci.*, 1:395, 1988). The cat has two classes of disparity tuned neurons: one with narrow excitatory response functions tuned to very small disparity, the other broadly tuned to respond mostly to stimuli either in front of or beyond the fixation point. All the hidden unit disparity tuning patterns found in the backpropagation trained network are also found in the brain, and all of them correspond to the broadly tuned cortical neurons. No hidden units that matched the sharply tuned neurons were found.

RECEPTIVE FIELDS OF GENICULOCORTICAL AFFERENTS TEND TO BE ALIGNED ALONG PREFERRED ORIENTATION OF CORTICAL CELLS. B. Chapman*, K.R. Zahs*, & M.P. Stryker (SPON: A.J. Hudspeth). Dept. Physiol. & Neurosci. Grad. Program, Univ. California, San Francisco, CA 94143-0444.

In earlier experiments (*J. Neurophysiol. 59*:1410, 1988), we noted that the geniculocortical afferent receptive fields encountered in radial electrode penetrations through area 17 were commonly dispersed so as to cover elongated regions of the visual field. We now attempt to relate the axis of this elongaton to the orientation of the cortical cells recorded along the same penetration. Radial penetrations were made into visual cortex in normal adult ferrets and the orientation preference of the cortical cells was recorded. Cortical cell responses were then eliminated by superfusion of the cortex with either kainic acid, an excitatory neurotoxin, or muscimol, an agonist of the inhibitory neurotransmitter GABA. After drug treatment, we were able to record from many single units with distinct receptive fields. These units are presumed to be geniculocortical afferent terminals because their responses were characteristic of geniculate cells and their recording sites were found to be within layer IV in all penetrations reconstructed to date. The set of single-afferent receptive fields covered an elongated region of the visual field in each of 7 penetrations (2 kainate, 5 muscimol); in all of these cases, the line formed by the afferents' receptive fields paralleled the preferred orientation of the cells recorded within the penetration. In 3 penetrations (2 kainate, 1 muscimol), the afferent receptive fields did not cover an elongated region of the visual field, although the cortical cells in these penetrations were as orientation selective as those in the other 7 penetrations.

These results may throw light on the arrangement by which simple cells become selective for stimulus orientation.

IPSI-THALAMUS SUPPORTS MOST ACTIVITY IN THE IPSI-HEMIFIELD REPRESENTATION AT THE 17-18 BORDER. E.L. Noll* and J.G. Malpeli, Dept. Psych., Univ. Illinois, Champaign, IL 61820.

Receptive-fields at the cat 17-18 border extend at least 5° further into the ipsi-hemifield than those in the LGN. If all cortical activity were driven by the LGN's, all ipsi-hemifield activity would be due to callosal inputs. While callosal inputs have been shown to drive cells at the 17-18 border, we have previously found that not all cells in visual cortex depend on the LGN. In this study we examined the contributions of direct and callosal inputs to ipsi-hemifield activity. After locating such cells in cortex, we found the maximum extent of ipsi-fields in the LGN at the same elevation, and placed injection pipettes under the LGN near this site in both optic tracts. Since simultaneous injections of lidocaine under both LGN's reversibly silenced cortical activity, we were able to unequivocally determine the fraction of cortical activity supported by direct thalamic or callosal input. On average, direct thalamic inputs were capable of supporting 88% of normal activity, whereas callosal inputs supported 22%. Control experiments suggest that the medial interlaminar nucleus (MIN) is the source of most ipsi-hemifield activity along the 17-18 border. The fact that the MIN relays ipsi-hemifield activity only for the contra-eye may explain why only the contra-eye receptive fields extended well into the ipsi-hemifield, even though most cells in this study were binocular. (Supported by NIH grant EY02695)

RESPONSES OF NEURONS IN PRIMARY VISUAL CORTEX ARE INFLUENCED BY EYE POSITION. T.G. Weyand and J.G. Malpeli. Department of Psychology, University of Illinois, Champaign, IL 61820.

We have investigated the possibility that eye position influences the visual responsiveness of neurons in cat area 17. With their heads fixed and direction of gaze monitored via the scleral search coil technique, cats were trained to maintain fixation on a laser beam projected onto a rear-projection screen. When a single neuron was isolated, a bar of optimal size and direction was swept through the retinotopically defined receptive field while the position of the fixation point was varied. The bar was never of behavioral relevance to the animal. For 7 of 40 neurons tested, the visual response evoked by stimuli moving through the receptive field varied with direction of gaze by a least a factor of two. Effects on response magnitude were mainly observed for horizontal gaze shifts. For 6 of the 7 neurons, the larger response was obtained when gaze was directed away from the hemisphere containing the cell. Eye position affected general excitability, since for some cells spontaneous activity also varied as a function of direction of gaze. These gaze-related responses may serve to construct a head-centered frame of reference. (Supported by NIH Grants EY06818 and EY02695).

SEGREGATION OF SPATIOTEMPORAL RESPONSE PROPERTIES BETWEEN CAT VISUAL CORTICAL AREAS: A 2-DG DEMONSTRATION. **D. Kaufman, J. Greenberg and M. Reivich, U. of Penn. Med. Sch. Phila., PA.19104**

Strong evidence supports the concept that Areas 17 and 18 of cat visual cortex perform qualitatively similar neuronal operations at different spatiotemporal scales (Movshon, Thompson and Tolhurst J. Physiol. '78c, McLean and Palmer, ARVO '88). Recent evidence suggests that PMLS and PLLS contain unit populations with partially non-overlapping spatiotemporal response optima (Zumbroich and Blakemore J. Neurosci.'87). In order to demonstrate the known spatiotemporal segregation between the Area 17 and 18 population at the whole-cortical representation level, and to extend this analysis to the LS cortices, we performed standard C-14 2-DG autoradiography following stimulation in a split-field paradigm. The left visual field contained sinusoidal gratings drifting at 50 deg./sec. (High-velocity) which were presented, at random, from a stimulus list of gratings ranging from 0.1 to 0.5 cycles/deg. The right visual field contained gratings drifting at 1 deg./sec from a list ranging from 0.6 to 4.0 cpd. These spatial frequency ranges were selected to fit the Movshon '78c data for non-overlap of Area 17 vs. 18 spatial frequency response ranges. Each grating's temporal frequency coefficent was selected via Speed = Temp. Freq./ Spat. Freq. so as to maintain constant high (or low) velocity. All gratings were binocularly presented (convergence via a Risley prism), of high contrast, achromatic, of horizontal orientation (to reduce non-convergence artifact) and were drifted either up or down (at random) for 10 sec intervals during the 45 min. 2-DG infusion period. The resulting coronal autoradiograms showed orientation columns in Area 17 of the left hemisphere (Low-velocity stimulated) but no detectable columnar labelling in right Area17. Area 18 of the right hemisphere (Hi-veloc. stim.) displayed orientation columns while left hemisphere Area 18 and Lat. Suprasylvian cortex (bilaterally) showed no detectable columnar label. In other studies, the gratings were all drifted unidirectionally. In these cases no detectable columnar labelling was found in striate cortex. AMLS, and to a lesser extent PMLS, in the left (Low-veloc. stim.) hemisphere, demonstrated wide (~0.5 mm.) columns, supporting physiologic evidence for orientation (Hubel and Wiesel, J. Physiol., '69) and / or directional columns (Sherk , Soc. Neurosci.'88) in L.S. cortex. Presumably, a >40% reduction in the response of the striate population to unidirectional gratings underlies the failure to detect orientation columns in the latter cases.

RESPONSIVENESS OF CELLS IN AREA 18 AFTER LOCAL INACTIVATION OF AREA 17 IN CATS. Y. Michaud*, C. Casanova, P.A McKinley, S. Molotchnikoff. Université de Montréal, Département de Sciences Biologiques et Centre de Recherche en Sciences Neurologiques. Montréal, Canada, H3C 3J7.

It is well known that area 17 or striate cortex projects to other cortical areas, such as area 18 or V2. However, very little is known on the functional roles of these forward connections. We have studied the effects of a local reversible inactivation of area 17 on the responsiveness of cells in the second visual area (V2). Experiments were carried out on anesthetized and paralyzed adult cats. Tungsten-in-glass microelectrodes were used to record extracellular single-spike activity in V2. An injecting-recording micropipette filled with a stained lidocaine solution was placed in a retinotopically corresponding region in the upper layers of the striate cortex. So far, a total of 20 cells were tested. Out of these, 11 and 9 units were classified as simple-like and complex-like cells, respectively. Our results indicate that the response properties of two-third of the complex cells were modified after the blockade of area 17. In a few cases (2), responses were totally abolished. On the other hand, receptive field properties of only one-third of the simple cells were modified by the inactivation. These preliminary results suggest that the disruption of the feedforward connections is more likely to affect the complex cells of the second visual area.

DIRECTIONAL SELECTIVITY OF CORTICAL CELLS AND THE PRESENCE OF A CONDITIONING STIMULUS - S. Molotchnikoff, C. Morin * (Spon: M. Ptito), Dept. Sci. biol. et Cent. Rech. Sci. Neurol. Université de Montréal (Québec) Canada H3C 3J7.

Neurons of the visual cortex possess fine tuned trigger features which evoke optimal responses. These properties can be modified if a second stimulus (S2) is introduced outside the classical receptive field (CRF) boundaries.This study was aimed at analyzing the responses to a moving light bar when a second or a conditioning slit was also present. Rabbits were anesthetized and prepared for single cell recordings. The first, or test stimulus (S1) was a light slit moving back and forth at the optimal orientation in the receptive field. S2 moved in phase with S1. When presented in isolation, S2 had no effect on spontaneous activity of the cell. But, when the stimuli were applied simultaneously, responses to S1 were significantly altered (modifications > to 25%). Test responses may be increased ($X = 62,6 \pm 28.3$) or decreased ($X = 68,8 \pm 21.9$) $N = 46$. Mobile conditioning stimuli had a more pronounced influence than stationary stimuli (68.8% VS 45.3% $P < .005$, $N = 25$). As the index of directionality increased, the alterations became stronger, and the prefered direction was most strongly affected. The simple cells ($N = 6$) and the end stopping units ($N = 3$) were the most influenced while only 36% ($N = 19$) of complex units reacted to S2. These results indicate that movement sensitivity may strongly depend upon the visual background.

DIFFERENTIAL RESPONSE OF CAT VISUAL CORTICAL NEURONES TO MONOCHROMATIC AND POLYCHROMATIC MOVING BACKGROUND - A NEW METHOD FOR RAPID ASSESSMENT OF COLOR SENSITIVITY. **H.J. Koch* & H.R. Dinse (Spon. ENA) Strahlenklinik, University of Ulm, West-Germany, and Coleman Lab, USCF, San Francisco CA 94143.**

Because of their nocturnality, cats color vision is not highly developed or does not provide a very compelling source of environmental information. However, cats clearly posses some form of color vision, the nature of this capacity is not fully understood. It has been argued that cats can discriminate color only if the stimulus subtends a fairly large visual angle (Loop & Bruce, Science 199: 1221).

In order to assess color sensitivity in cat cortical neurons, we used two types of large background stimuli (50 x 50 degree visual angle) that consisted of a monochromatic and a polychromatic computer-generated noise process of identical luminance superimposed on a moving bar of light. As a rule, we measured the modulatory effect of the background onto the response of the cell to the moving bar. Background stimuli were moved at different speeds inphase or antiphase to the bar. In addition, we used on-off stimuli, which were flickered inphase to the motion of the background.

The most sensitive parameter to changes of spectral composition was directional selectivity that was effected in 80 to 90 % of all cells tested. In contrast, visual latencies, orientation selectivity, and RF-width turned out to be rather robust. Additionally, if the cells responded with excitation to the moving background alone (classical texture response), the spectral composition revealed differential responsiveness in 70 % of the neurons tested.

Under the described stimulus conditions, a very large portion of cat cortical neurons are sensitive to the spectral composition of the stimulus. However, we found no indication for any kind of general preferrence of the monochromatic over the polychromatic stimuli, or vice versa.

PROCESSING OF ORIENTATION IN V1 OF THE AWAKE MONKEY. **Y.Trotter*, S.J. Thorpe*, S.Celebrini*, A. Pouget* & M. Imbert* (SPON: J. Servière). Institut des Neurosciences CNRS, Univ. Pierre et Marie Curie, Paris, France.**

It has been suggested that competitive inhibitory interactions between orientation-tuned cortical neurons may be used to increase their orientation selectivity. One prediction of such models is that the orientation selectivity of the initial neuronal response should be relatively low, but that selectivity should increase over time, a suggestion supported by recent data from anesthetized, paralyzed cats (Best et al, in Neural Networks from Models to Applications, I.D.S.E.T, 1989). We have further tested this hypothesis by analysing the responses of neurons in area V1 of the awake primate. Stationary or drifting square-wave gratings, 7° in diameter were presented foveally for 1 second while the animal was performing a fixation task, and the responses of 102 neurons analysed. Eighty-six had visual responses, typically with latencies in the range 40 to 85 ms (mean 58.5 ms) although some had longer latencies (up to 150 ms). Approximately 75% of these responses were orientation selective. We analysed in detail the responses of 24 neurons for which at least five repetitions of all 16 test orientations were available. Mean activity during fixation was about 7 spikes/s. Within 10 to 20 ms of the start of the response, mean activity increased to about 100 spikes/s for the optimal orientation, while decreasing to only 2 spikes/s for the non-optimal one. Indeed, the largest difference between the responses to the optimal and non-optimal stimuli was seen after 10 to 20 ms. We were also able to estimate the bandwidth at half-height which had an average value of approximately 45° (range 15° to 72°). For many cells, this bandwidth was as small at the start of the response as it was later on. It is unclear why our results differ from those of Best et al, but the difference could be due to a species difference, or an effect of anesthesia. However, our results indicate that orientation selectivity can be generated without the use of feedback loops and probably does not require competitive interactions between orientation selective units.

419.13

CONTRAST DETECTION OF SINGLE CELLS IN THE MACAQUE STRIATE CORTEX. *D.P. Edwards and Ehud Kaplan* (SPON: J. Gordon), The Rockefeller University, NY, NY 10021.

Input to striate cortex of primates consists of two distinct streams: Magnocellular (M) and Parvocellular (P). Whether the M and P streams retain their separate identities or are combined in the striate cortex is a matter of current interest. We sought to answer two questions: 1) Is there a difference in contrast sensitivity between cells in cytochrome oxidase blobs and interblobs? 2) To what extent does contrast sensitivity vary within each (blob/interblob) population?

Using tangential penetrations through striate layers 2/3 in anesthetized and paralyzed monkeys, we measured the response of single cells to drifting sinusoidal gratings at several contrasts, at optimal orientation and spatial frequency. The cortex was stained for cytochrome oxidase and the electrode tracks reconstructed. Contrast gain can be used to reliably differentiate M cells (high gain) from P cells (low gain). However, since cortical cells exhibit thresholds while their subcortical inputs do not, a more complete measure was needed. We therefore derived detection probability *vs* contrast for each cell using ROC analysis, and determined threshold, slope and maximum detection probability from this function.

Our results to date show a remarkable variability in contrast detection across layers 2/3, with no obvious separation between blob and interblob populations.

STRUCTURAL MODELING OF NONLINEAR NETWORKS IN V1 OF THE MACAQUE MONKEY. J.P. Gaska*, L.D. Jacobson*, H-W Chen*, and D.A. Pollen. (SPON: D. Chad). Department of Neurology, University of Massachusetts Medical School, Worcester, MA 01655.

We have used 2-D spatial/1-D temporal N-ary white noise to visually stimulate cortical cells in V1 of the Macaque monkey. Stimulus-response cross correlation functions were then computed using the methods of Lee & Schetzen (Int. J. Contr. 2:237-254,1965). The resulting (three-dimensional) first order and (six-dimensional) second order cross correlation functions have been used to visualize the detailed space-time structure of interaction within the receptive fields of V1 cells. Examples of simple, complex, and unoriented cells will be shown using dynamic and static visual displays. Methods will be presented that employ such cross-correlation results to evaluate and parametrize nonlinear structural models of multi-input visual neural networks. Supported by NIH grant EY05156 and Air Force grant AFOSR-89-0247.

FUNCTIONAL CONNECTIVITY BETWEEN VISUAL CORTICAL NEURONS STUDIED BY CROSS-CORRELATION ANALYSIS. Y. Hata*, T. Tsumoto and H. Tamura*. Dept. Neurophysiol., Biomed. Res. Ctr., Osaka Univ. Med. Sch., Kitaku, Osaka, 530 Japan.

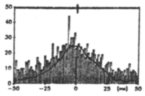
Neurons in the visual cortex are arranged in columnar organization according to their orientation and ocular preferences. However, little is known about functional neural connectivity through which visual information is processed between columns except a report on layer II/III (Ts'o et al. 1986). Present experiments were designed to study functional connectivity of neurons in the horizontal direction in layers II-VI of the striate cortex of cats anesthetized with N_2O in addition to halothane when necessary. Spike discharges were recorded simultaneously from a pair of cells that were separated horizontally by less than 1 mm in the cortex and interactions between them were studied by cross-correlation analysis. Many of the correlated firings showed an existence of common inputs to cell pairs separated by less than 500 μm. In this range of horizontal separation, correlated firings were observed mostly between cells located in the same layer. Also, the correlated firings were found mostly in cell pairs with similar orientation preferences in all the layers including layer IV, which receives inputs mainly from the lateral geniculate nucleus and layer VI. These results suggest that cortical cells which locate in the same layer and have similar orientation preferences tend to share the same input beyond orientation columns.

419.16

FUNCTIONAL CONNECTIVITY REVEALED IN AND OUTSIDE OF RECEPTIVE FIELD OVERLAP BY 3 CROSS-CORRELATION TECHNIQUES. J. I. Nelson[1], M.H.J. Munk*[1], J. Bullier[2] R. Eckhorn*[1]. [1]Biophysics, Philipps University, Marburg, W. Germany 3550; [2]Exptl. Neuropsychology Lab, INSERM 94, Bron, France 69500.

Recent anatomical information on INTERarea connectivity in the visual system increases the need for functional analysis of coupling between neurons and neural patches. We measured coupling between cell patches in A17 & A18 of cat cortex with several techniques: local field potentials (LFP), spike-triggered multiunit activity (MUA) and spike-spike cross-correlations. Measurements were made only during spontaneous activity.

All measures are most likely to show coupling when receptive fields (RFs) are overlapping. Here we distinguish two broad categories of coupling. Coupling is called diffuse when the MUA exhibits a broad hump 300 ms wide centered around the occurrence of the trigger spike. Coupling is focussed when a correlation peak of about 40 ms width appears in the MUA, the LFP shows a wave of hyperpolarization occurring after the trigger spike, and spike-to-spike cross-correlations are obtained. This is more likely to occur when the RFs are overlapping and orientation preferences are matched or crossed, than when they are oblique to one another. (Fig: A18 MUA correlation w/A17 spike is drawn on spike-spike correlation histogram, A17 = 0ms; X-axis 100 ms.)



Exceptionally, we observed focussed coupling without RF overlap. This result is consonant with a recent report on the lack of visuotopic correspondence of the connections between A17 & A18 (Salin, Bullier, Kennedy, J. comp. Neurol. in press).

FUNCTIONAL SPECIFICITY OF INTERLAMINAR CONNECTIONS IN CAT VISUAL CORTEX. Cornelius Schwarz * and Jürgen Bolz, Max-Planck-Institut, Friedrich-Miescher-Labor, 7400 Tübingen, West Germany.

In addition to the columnar connections, individual cells project over long distances parallel to the cortical surface (Gilbert and Wiesel, J. Neurosci. 3, 1116, 1983). One source of long range connections are pyramidal cells in layer 5 which project into layer 6. A possible role for this connection in generating the long receptive fields of layer 6 cells was suggested by inactivation experiments (Bolz and Gilbert, Eur. J. Neurosci., in press). These experiments demonstrated that local inactivation of layer 5 abolished length summation of layer 6 cells over the portion of their receptive fields corresponding to the blocked region of layer 5. This method, however, does not allow to study the presynaptic side of this connection.

We therefore used cross-correlation analysis to examine both, the pre- and postsynaptic cells involved in the layer 5 to layer 6 projection. Single units were recorded with an electrode advanced in layer 5 and a second electrode, horizontally separated by 0.5 - 3.5 mm from the first electrode, placed in layer 6. So far we obtained 34 peaked correlograms out of 109 cell pairs analysed. Our results reveal the specific nature of this particular cortical connection:

MATCHING ORIENTATION: The majority of cell pairs with correlated firing had similar orientation preference.

RECEPTIVE FIELD POSITION: The receptive fields of the layer 5 cells were within the summation area of the layer 6 cells in almost all cell pairs with peaked correlograms.

RECEPTIVE FIELD TYPE: Most correlations were found with layer 5 standard complex cells, but only rarely with layer 5 special complex cells.

RECONSTRUCTION OF LOCAL NEURONAL INTERACTIONS WITHIN SINGLE COLUMNS OF THE CAT CEREBRAL CORTEX. S. Reinis and D.S. Weiss. Department of Psychology, University of Waterloo, Waterloo, ONT., Canada.

Adult cats were immobilized with *Pavulon* and anesthetized with nitrous oxide and a long lasting local anesthetic *Marcaine*. Neuronal activity was recorded from Area 18 of the visual cortex using tungsten microelectrodes (1 to 2 Mohms). The electrical potentials were preamplified so that the maximum peak in the record (*leading cell*) was standardized at 1.0 V. Impulse energy below 0.375 V was defined as *mass firing* while all spike activity below 0.125 V was considered noise. Histograms of all interspike intervals within the multiple unit activity recording were calculated. These histograms were called *mass correlograms* when the input data consisted of the *mass firings*. The visual stimulus consisted of a moving light bar which was projected 81 cm in front of the animal. The *mass correlograms* recorded when the visual stimulus was presented along the axis of maximal directional preference contained slightly damped oscillations within the first 200 msec. This result indicated that the movement of a visual stimulus across the common receptive field of the system was accompanied by a circulation of nerve impulses between the participating units. Additional correlograms calculated between *mass firings* and *leading cell* activities showed significant peaks. The functional interactions within the complete neuronal system were reconstructed so that the most common intervals (which formed the peaks of the correlograms) were attributed to real pairs of spikes within the original multiple recording. Computer-generated graphs showed repeated interactions between the neurons which lasted from 1 to at least 50 msec. These interactions were both serial and parallel. The bootstrap procedure was used to verify that the neuronal systems presented in the *mass correlograms* and visual displays were not constructed from a random source of impulse energy. The position of all spikes within each 5 sec record was randomized. *Mass correlograms* were calculated from the randomized set. The bootstrap was replicated 100 times. In no instance did the results from the randomized data form continuous systems as evidenced by the original data.

419.20

EVIDENCE THAT GLUTAMATE IS THE MAJOR EXCITATORY TRANSMITTER IN CALLOSAL PROJECTIONS TO RAT VISUAL CORTEX. R. L. Berry, A. V. Nowicky, and T. J. Teyler, Dept. of Neuro., NEOUCOM, Rootstown, OH 44272.

To study the electrophysiology and pharmacology of rat visual callosal projections our laboratory has developed a slice preparation which preserves callosal fibers afferent to visual cortical areas OC1 (area 17) and OC2M (medial area 18). In the present study stimulation of white matter (700 to 2500 um medial to recording tracks) yielded field potential profiles recorded with 100 um spacing in tracks perpendicular to the cortex. Recordings were collected before, during and after perfusion with media containing 1 mM kynurenic acid (KYN)--a glutamate receptor blocker. Current source density analysis of field potential profiles allowed spatial localization of current sinks which were integrated to provide measures of excitatory synaptic activity.

Stimulation of callosal fibers yielded major current sinks in OC1 which were usually confined to supragranular layers. Perfusion of media containing KYN resulted in an 80-90% reduction in the area of these current sinks. Callosal stimulation resulted in large current sinks in supra- and infragranular layers in OC2. A 90% reduction of supragranular current sink areas and a 70-100% reduction of infragranular sinks followed perfusion of media containing KYN. Washout of KYN resulted in partial to full recovery of currents in all cases.

These data are consistent with the hypothesis that glutamate is the major excitatory transmitter in the callosal projection to OC1 and OC2.

BETA-ADRENERGIC EFFECTS OF NOREPINEPHRINE STUDIED IN THE RAT VISUAL CORTICAL SLICE. Alexander V. Nowicky, Richard L. Berry, and Timothy J. Teyler Neurobiology Dept. Northeastern Ohio Univ. College of Medicine, Rootstown, OH 44272.

Norepinephrine (NE) modulates neocortical activity. NE reduces the after-hyperpolarization (AHP) responsible for accommodation in cortical pyramdial cells. The actions of NE are via beta-adrenergic postsynaptic receptors. Voltage clamp studies have shown that NE reduces Ca^{++}- and Na^{+}-dependent K^{+} conductances responsible for slow AHPs in cat sensorimotor cortex, (Foehring, et.al., J. Neurophys. 61(2):245). Coronal slices of rat visual cortex (areas Oc1 and Oc2) were prepared. Stable intracellular recordings were obtained from layer V pyramidal cells. NE, 10-100uM, or the beta-agonist,(-)-isoproteronol (ISO, 1-10uM)) were perfused, or applied by pressure ejection (mM conc.) near the recording site. NE and ISO produced small (<5mV) depolarizations or hyperpolarizations of the membrane potential, without accompanying changes in input resistance. However, spike frequency adaptation and slow AHPs were markedly reduced by NE and ISO. 100uM Timolol (beta-antagonist) perfusions prevented these reductions. In order to examine the effects of NE on cortical synaptic activity, laminar profiles of extracellularly recorded field responses to white matter stimulation were also examined. Current Source Density (CSD) analysis indicated that 10uM NE and 5uM ISO produced increases in both supragranular and infragranular sinks. Our results suggest that beta-adrenergic modulation of visual cortical neurons may have both direct and indirect effects on cortical microcircuitry. (supported by grants from EPA and ONR)

RECEPTIVE FIELDS IN VISUAL CORTEX OF DJUNGARIAN HAMSTER: A DESCRIPTIVE STUDY. F.W.Grasso,spon:Alan P. Jones. Univ. of Massachusetts, Neuroscience and Behavior Program, Amherst, Ma. 01003

To broaden understanding of the comparative functions of cells in the visual cortex, receptive field maps were made from single unit recordings in a new model system: the visual cortex of the hamster, Phedopus sungorus. Maps were made using two methods employed previously in order to compareresults with work in cats and monkeys. 173 units were mapped with moving black hand-held bars against a white tangent screen. These maps were classified as simple(66%), complex(29%) or unclassified (4%). 110 of these units were also mapped using a computer automated system. This system presented a moving or flashing disc of light on a 27 by 27 grid on a crt screen and collected unit responses. These maps were classed disc(4%),Bar(33%),Composite(21%),diffuse (31%) and unclassified (9%). All bar and disc shaped RFs were found also to be simple while composite and diffuse RFs could be either simple or complex. A classification of the RFs based on the two methods organize the RFs in a way that explicity separates linear and non-linear RFs and maintains a diversity of spatial organization. These are: linear 1)Cicular(31%),Bar(20%),Composite(16%) and non-linear 2)Diffuse(18%) and Composite(6%). This classification shows marked differences between cat,monkey and hamster, yet all classes are present in each species. Thus, the scheme suggested by Djungarinans could be employed to examine the relationship between ecology and RF structure.

CHARACTERIZATION OF SCN AND IGL IN GOLDEN MANTLED GROUND SQUIRREL USING IMMUNOHISTOCHEMISTRY AND CHOLERA-HRP. L. Smale, J. Blanchard*, R.Y. Moore and L.P. Morin. Depts. of Psychiatry and Neurology, SUNY, Stony Brook, NY 11794.

The suprachiasmatic nuclei (SCN) act as a clock controlling circadian rhythms. The intergeniculate leaflet (IGL) of the thalamus provides a major input to the SCN. In this study, we examined the SCN and IGL of S. lateralis a diurnal ground squirrel. Five squirrels were used and immunoreactivity to GFAP, VIP, vasopressin (VP), substance P (SP), l-enkephalin (L-ENK), CRF, oxytocin (OXY), serotonin (5-HT) and neuropeptide Y (NPY) was evaluated as was the retinal input to the SCN and IGL. Cells containing VIP and VP are found in the ventral or dorsomedial SCN. Cells containing L-ENK are seen in the center. Dense terminal plexes for 5-HT and NPY are also evident. In addition, GFAP immunoreactivity is extremely dense. The ground squirrel SCN contains no immunoreactivity for SP, CRF or OXY. The IGL is identified by a group of NPY-containing cells. However, there is also a small group of L-ENK-containing cells in the IGL with a different distribution. SP and 5-HT-containing fibers and terminals are present in the IGL and the ventral LGN. Retinal input to the hypothalamus is restricted to the contralateral SCN. Within the contralateral LGN, retinal terminals partly overlap the regions containing NPY cells. However, there are clearly some clusters of NPY cells in the geniculate that do not receive input from the contralateral eye. (NS 22168)

420.2

THE EFFERENT PROJECTIONS OF THE HAMSTER SCN REVEALED BY PHA-L. N.L. GOODLESS,* R.Y. Moore and L.P. MORIN. Depts. of Psychiatry and Neurology, SUNY Stony Brook, Stony Brook, New York, 11794.

The circadian clock of mammals resides in the SCN, but little is known about the functional relations between the clock and effector systems. We have approached this problem by studying the efferent projections of the hamster SCN as identified with the anterograde tracer, PHA-L. Sections were immunoreacted according to a modified Gerfen and Sawchencko (1984). The injection site as well as filled cell bodies within the SCN were precisely identified using this method. The present results confirm and extend the distribution of projections previously outlined in the rat (Watts, et al 1987, Stephan, et al 1981). The densest terminal field they described was a relatively cell-sparse zone bordered by the SCN, the paraventricular nucleus, the periventricular nucleus, and the anterior hypothalamus. Analysis of hamster material underscores the dense distribution of fibers which travel within the midline, subparaventricular zone of the hypothalamus, and continue on to the paraventricular nucleus of the thalamus. Other sites that are innervated directly by the SCN are confined to the hypothalamus, adjacent areas of the septum and the thalamus. (NS 22168)

C-*FOS* PROTO-ONCOGENE EXPRESSION IN THE SUPRACHIASMATIC NUCLEUS: IMMUNOHISTOCHEMICAL CHARACTERIZATION. D.J. Earnest, L.A. Trojanczyk, J. Van Lare, H.H. Yeh, and J.A. Olschowka. Dept. of Neurobiology/Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642

In mammals, the generation and light-dark entrainment of circadian rhythms are governed by an internal timekeeping mechanism located in the suprachiasmatic nucleus (SCN). Since the c-*fos* proto-oncogene appears to function in signal transduction within the brain by coupling extracellular stimuli (e.g., signals causing synaptic activation) to intracellular effector pathways, c-*fos* expression may provide a cellular method for assessing the activation of SCN neurons by various stimuli. Consequently, the present study was conducted to characterize the basal expression of c-*fos* proteins in the SCN.

Following exposure to LD 12:12 (lights-on at 0600h), constant light or dark, Long-Evans rats were sacrificed and perfused at 1000h or 2200h. An antiserum raised to the M peptide, corresponding to amino acids 129-153, was obtained from Dr. Iadarola of NIH and brain sections were processed for the immunohistochemical characterization of c-*fos* proteins in the SCN.

C-*fos* protein-like immunoreactivity in the SCN was concentrated within the nuclei of neurons and was characterized by a pattern of immunostaining in which c-*fos* proteins were generally localized in neurons found in the ventrolateral SCN. These results are consistent with other immunohistochemical studies demonstrating that c-*fos* expression in neurons is confined to the cell nucleus and thus provide evidence that our immunostaining is to c-*fos* protein-like molecules. Since neurons exhibiting c-*fos* protein-like immmunoreactivity are localized in a subdivision of the SCN that receives the terminals of visual projections, further analysis is necessary to examine the possibility that c-*fos* expression in the SCN reflects an important signal coupling the electrical activation of neurons by photic stimuli to long-term transcriptional events mediating the photoentrainment of circadian rhythms. Supported by NS-24661(D.E.).

THE SUPRACHIASMATIC NUCLEUS (SCN) OF THE CHICK: INTRINSIC ANATOMY, ITS EFFERENTS AND AFFERENTS. D.B. Hodges Jr.* and V.M. Cassone. Department of Biology, Texas A&M University, College Station, TX 77843.

Avian circadian systems comprise multiple circadian oscillators and photoreceptors in the pineal gland, eyes and SCN. However, the site, anatomy and function of the SCN remains unresolved. In this study, immunocytochemical localization of GAD, AVP, VIP, Sub.P, 5HT and NPY was determined within the SCN of the chick. These data were correlated with the distribution of the retinohypothalamic tract (RHT) using intraocular cholera toxin-HRP as an anterograde tracer. Finally, SCN efferents and afferents were studied by stereotaxic microinjection of CTHRP into the SCN. As in previous studies in house sparrows and various mammals, the chick SCN contains GAD, VIP, and Sub.P immunoreactive neurons and 5HT and NPY immunoreactive fibers. No AVP-reactive cells could be found. Second, the SCN receives direct RHT input. Finally, major efferent pathwys of the chick SCN project to the contralateral SCN, PVM, LA, EW and ME. Major afferents to the SCN include the eyes of course, LH, PVM and the periventricular organ, which contains 5HT-immunoreactive cells. Together, the immunocytochemical characteristics, the efferents and afferents of the chick SCN are very similar to those previously described for mammals, further supporting a case for homology between the avian and mammalian SCN. The results of these studies will be valuable in the analysis of avian circadian systems physiology. Supported by NSF Grants BNS 85-19660 and 88-96225.

420.5

AChE POSITIVE NEURONS THAT PROJECT TO THE SCN. C.A. Fuller, R. Nayduch, D.M. Murakami. Dept. of Animal Physiology, University of California, Davis, Ca. 95616.

Previous studies have suggested that acetylcholine may play a role in the phase shifting effects of light on circadian rhythms. In addition, single unit recordings have demonstrated that neurons in the SCN are sensitive to cholinergic agonists. This study examines the potential source of cholinergic projection to the SCN.

Small HRP injections were placed into the SCN. Following a 48 hr. survival, time rats were sacrificed with barbituate overdose, transcardially perfused with fixative, and the brain prepared for histology. Coronal sections were reacted for HRP with TMB and counterstained for AChE. Neurons double labelled for HRP and AChE were identified as potential cholinergic neurons that project to the SCN.

Double labelled neurons were located in two neural regions, the diagonal band and the LASCN. Although the septum contains many cholinergic neurons, none of the cells were double labelled. AChE positive neurons in the LASCN were found to have large cell bodies and elongated soma shapes relative to the total population.

These results suggest that the diagonal band and LASCN may be involved in the association between acetylcholine and the phase shifting effects of light.

PHOTOPERIODIC, SUPRACHIASMATIC AND PARAVENTRICULAR CONTROL OF TESTIS FUNCTION AND VIP, VASOPRESSIN, BETA-ENDORPHIN AND GnRH IMMUNOSTAINING IN SIBERIAN HAMSTERS. E.L. Bittman, T.J. Bartness, and G.J. DeVries, Depts of Zoology and Psychology, Univ. of Massachusetts, Amherst, and Dept of Psychology, Georgia State Univ., Atlanta 30303.

Short days act through the suprachiasmatic and paraventricular nuclei (SCN and PVN) to regress the gonads of Syrian hamsters. In the European hamster, short photoperiods reduce vasopressin (VP) immunoreactivity in lateral septum (LS), medial amygdala (MA), and bed nucleus of the stria terminalis (BST). We examined the interactive effects of photoperiod, SCN and PVN lesions on testicular weight and neuropeptide staining in another photoperiodic species, the Siberian hamster (Phodopus sungorus). Intact (n=13), SCN lesioned (n=24), or PVN lesioned (n=17) hamsters were maintained in long days (LD, 16L:8D) or transferred to short days (SD, 8L:16D) for 10 weeks prior to acrolein perfusion. Short days induced testicular regression (combined testes weights 0.20±0.06g vs. 0.90±0.02g in LD, mean±SEM; $p<0.05$). Hamsters greater than 4 months old were significantly less responsive to photoperiod. Short days reduced the number of VP immunopositive cells in the MA and the VP fiber content of the LS and the BST, the number of GnRH immunopositive cells in the medial preoptic area at the level of the OVLT, and the number of beta endorphin (BE) immunoreactive neurons in the arcuate nucleus ($p<0.05$). SCN and PVN lesions blocked gonadal regression and eliminated all effects of daylength on neuropeptide staining. VIP staining was unaffected by daylength in the SCN, median eminence or amygdala. SCN lesions eliminated VP immunoreactivity in the thalamic paraventricular nucleus and raised the number of VIP-stained cells in the basolateral amygdala regardless of photoperiod. While the SCN and PVN participate in photoperiodic responses of Siberian hamsters, effects of daylength on GnRH, BE and VP neurons may be either causes or effects of gonadal regression. Supported by NSF BNS 86-16935, 88-09799 and NIH DK3524.

SYNAPTOGENESIS IN THE RAT SUPRACHIASMATIC NUCLEUS - A LIGHT MICROSCOPIC IMMUNOCYTOCHEMICAL SURVEY. K.B.REPKE*, L.K.LAEMLE, F.L.RICE and R.HAWKES*. Depts. of Anatomy, New Jersey Medical School,Newark NJ 07103 and Albany Medical College, Albany,NY 12208, and Laboratory of Neurobiology, Laval Univ.,Quebec GIJ5B3 Canada.

MabQ155, a monoclonal antibody which selectively binds to an integral polypeptide in synaptic vesicle membranes (Hawkes et al,'85), has been used to survey synaptogenesis in the rat suprachiasmatic nucleus using light microscopic immunocytochemistry in 50um frozen sections. The period studied, the day of birth (P0) to postnatal day 10 (P10), overlaps the reported time of arrival of retinal afferents and the development of circadian rhythms.

On the day of birth the SCN appeared as a relatively clear ovoid area in the ventral region of the otherwise highly immunoreactive hypothal amus. Between P0 and P10, presynaptic terminal density in the SCN increased so that the SCN became indistinguishable from the adjacent hypothalamus. Within the SCN, synaptogenesis followed a rostral to caudal and a peripheral to central gradient, and different regions of the nucleus exhibited different rates and different patterns of synaptogenesis.

420.8

LOCALIZATION OF THE CIRCADIAN PACEMAKER WITHIN THE SUPRACHIASMATIC NUCLEI (SCN). T.K. Tcheng, M.U. Gillette and R.A. Prosser. Neural & Behavioral Biology Prog. and Dept. of Physiol. & Biophys., Univ. of Illinois, Urbana, IL 61801.

The mammalian SCN contain a circadian pacemaker that is expressed *in vitro* as a 24 hr oscillation in the ensemble neuronal firing rate. We are attempting to determine the location and organization of the pacemaker within the SCN. Our approach has been to isolate progressively smaller regions of the SCN by microdissection of the hypothalamic brain slice, then look for circadian rhythms of neuronal activity (CRs) using extracellular recording techniques.

Our previous work has shown that a 500 μm coronal slice from 2-5 mo Long-Evans rats, which contains less than the anterior-posterior extent of the SCN, produces a stable CR for at least 3 days *in vitro*. Reducing the slice to within 100 μm of the paired SCN results in an unperturbed CR.

Our current studies further localize the pacemaker. Bisecting the SCN by severing the commissure connecting the two nuclei has no apparent effect on the CR (N=3). Analysis of activity in the natural dorsomedial (DM) and ventrolateral (VL) subdivisions in the intact slice shows that both regions exhibit CRs that peak synchronously at CT 6.9 on day 2 (N=8). Preliminary data suggest that subdividing the bisected SCN into DM and VL halves results in differential effects upon the CRs in these two regions.

420.9

THE ROLE OF SCN DORSAL EFFERENT PROJECTIONS IN THE TIMING OF THE PREOVULATORY SURGE OF FSH IN GOLDEN HAMSTERS. L. L. Badura,[1] C. L. Sisk, and A. A. Nunez, Physiology & Neurobiology, University of Connecticut, Storrs, CT 06269,[1] and Psychology Dept./Neuroscience Program, Michigan State University, East Lansing, MI 48824.

Horizontal knife cuts that interrupt the connections between the suprachiasmatic nuclei (SCN) and the paraventricular nuclei (PVN) prevent the vaginal acyclicity (anestrus) normally induced by short-day exposure in female golden hamsters. The present study extended these findings by examining the timing of the proestrous FSH surge in animals with hypothalamic knife cuts that blocked gonadal responses to photoperiod. Female hamsters received either a knife cut aimed between the SCN and the PVN, or sham surgery, and were housed under either long (16L:8D) or short (6L:18D) photoperiods for 11-12 weeks. A subset of the animals in each group were then fitted with an indwelling jugular cannula and blood samples were taken hourly over a 24-hr period. Plasma levels of FSH were determined by RIA. Both groups of animals in 16L:8D continued to show regular estrous cycles throughout the experiment. The cannulated animals from both groups in this photoperiod showed peak elevations of FSH on the day of proestrus 3-4 hr before lights out. Animals with knife cuts in 6L:18D also continued to show estrous cycles and peak elevations of FSH at a time identical to that displayed by animals in 16L:8D. In contrast, sham-operated anestrous females in 6L:18D showed peak elevations of FSH approximately 4-5 hr after lights out. Therefore, disruption of SCN dorsal efferent projections prevents the inhibitory effects of short days on estrous cyclicity, and preserves the typical long-day timing of the preovulatory FSH surge.

ISOLATED SUPRACHIASMATIC NUCLEI IN AGGREGATE CELL CULTURE. J. Ding, J. Buggy, and L. Terracio*. Depts. of Physiology and Anatomy, Univ. of South Carolina, Columbia, S.C. 29208.

Suprachiasmatic nuclei (SCN) were microscopically dissected from perinatal rat brain (from E17 to P4), dissociated, and incubated in rotary suspension to reform organotypic cell aggregates. Electrophysiological and electron microscopic analyses demonstrated the viability of these cells in rotary culture for up to 4 weeks. Immunohistochemical analysis of the aggregates with neurofilament, GFAP, and synaptophysin antibodies showed that outgrowth of cell processes and synaptogenesis are comparable to the intact SCN. Peptidergic neurons characteristic of SCN were also identified immunohistochemically in the aggregates: vasopressin, VIP, and somatostatin. However, clustered plexus groupings of these peptidergic neurons were not evident in the aggregates analyzed thus far, suggesting that organization of SCN-like structures may require unspecified growth factors or interactions with a host brain environment. Aggregates maintained in culture survived transplantation to cerebral ventricles and continued to express cytoskeletal markers and neuropeptides. The reaggregated cell culture system may be a good model to study the structural organization and neurotransmitter distribution of small brain nuclei such as SCN. A potential long-range application of these studies would be development of culture conditions suitable for storage, organization, and selection of brain tissues for neural transplants.

420.11

SUPRACHIASMATIC NUCLEUS (SCN) GLUCOSE UTILIZATION IN VITRO: CIRCADIAN RHYTHM AND EFFECTS OF TETRODOTOXIN (TTX).
F.E. Hospod, G.C.Newman and R.Y.Moore. Dept. of Neurology, SUNY at Stony Brook, Stony Brook, N.Y. 11794 (SPON: A. ROSEN).

In this study we demonstrate that the circadian rhythm of SCN glucose utilization previously demonstrated *in vivo* (Schwartz *et al*, J. Comp. Neurol., 1980) continues to be expressed in hypothalamic brain slices containing SCN. The effects of TTX on this rhythm are also described.

Hypothalamic brain slices were isolated from 175g Sprague-Dawley rats maintained in 12:12 L:D schedule for at least 3 weeks. The lights were kept off the day of sacrifice and rats were decapitated in dim red light. Brain slices were pre-incubated at 37°C. in K-R for 90 min, incubated with ^{14}C-2DG (0.2μCi/ml) for 45 min and rinsed for 30 min. Autoradiograms were obtained from cryostat sections and brain slice glucose utilization (SGU) calculated (see Newman *et al*, this meeting) at nine times of the circadian cycle. SGU was also measured at six times in the presence of TTX.

These studies reveal that SCN SGU is lowest at CT17 (lights on CT00), gradually rises from CT00 to a maximum at CT09 and gradually declines until CT15. Values of SGU from CT17 to CT06 are similar to those found *in vivo* but those from CT09 to CT15 are considerably higher. In the presence of TTX, SGU is reduced to about 60% of the values found in the absence of TTX for time points between CT17 and CT06. However, at CT09 and CT12, TTX dramatically reduces SGU to levels similar to those at CT17 with TTX.

The circadian rhythm of SCN glucose utilization persists in hypothalamic brain slices although signficant differences are observed between CT09 and CT15. In the presence of TTX, SCN SGU increases above baseline only between CT00 and CT06. These results suggest that slice isolation eliminates an inhibitory influence active *in vivo* during late subjective day.

420.12

IN VITRO OSCILLATION OF cAMP IN THE SUPRACHIASMATIC NUCLEI.
R.A. Prosser and M.U. Gillette. Neural and Behavioral Biology Program, and Dept. of Physiology and Biophysics, Univ. of Illinois at Urbana-Champaign, Urbana,IL 61801.

The suprachiasmatic nuclei (SCN) contain an endogenous circadian clock that survives in vitro, where it continues to oscillate with a 24 hr period. We have been investigating the possible involvement of cAMP in the biochemistry underlying the SCN clock. We have shown previously that daytime but not nighttime treatments that increase endogenous cAMP levels in vitro phase-shift the SCN clock by up to 5 hr (J.Neurosci.9:1073, 1989). To further elucidate the role of cAMP, we measured in vitro levels of cAMP within the SCN.

Hypothalamic brain slices containing the SCN were prepared during lights-on from adult Long-Evans rats housed in a 12:12 LD cycle. At circadian times (CT) 4, 10, 16 and 22 slices were removed from the slice chamber and rapidly frozen on dry ice. Punches containing the SCN or nearby hypothalamus were removed using a 26 gauge needle and pooled. cAMP levels were assayed by RIA after Steiner, and protein levels were assayed by the method of Bradford.

Significant peaks in cAMP (pmole/mg protein) were found in the SCN at CT 10 (43.56$\pm$ 6.93, N=14) and 22 (50.93$\pm$10.13, N=12), with low levels at CT 4 (30.01$\pm$4.57, N=10) and 16 (20.41$\pm$3.19, N=9) (ANOVA and Scheffe analyses). Hypothalamic cAMP levels showed no clear rhythm. Together with our previous data on phase shifting, these results suggest that cAMP may be an integral component of the SCN circadian clock.

420.13

EFFECTS OF TETRODOTOXIN ON THE CIRCADIAN PACEMAKER IN SUPRACHIASMATIC EXPLANTS *IN VITRO*.
S.M. DiGiorgio*, C.D. Sladek and D.J. Earnest (SPON: I. Shoulson). Dept. of Neurobiology/Anatomy, Univ. of Rochester School of Medicine, Rochester, NY 14642

Consistent with their central role in the generation of circadian rhythms, explanted neurons from the suprachiasmatic nucleus (SCN) release vasopressin (VP) in a circadian fashion *in vitro*. To study the role of Na-generated action potentials in the circadian timekeeping mechanism in the SCN, the present study examined the effect of tetrodotoxin (TTX), a Na-channel blocker, on the rhythm of VP release from perifused SCN explants.

SCN explants were dissected from the hypothalami of male rats and maintained individually in a perifusion culture system. On day 2 in culture, test explants were exposed to TTX for 6, 8 or 12 hrs near the onset of the subjective day or night. VP levels in the perifusate were determined by RIA.

TTX treatment during the subjective day blocked the peak in VP output that normally occurs during this portion of the circadian cycle while treatment during the subjective night had little influence on the basal levels of VP release expressed during this period. Most explants continued to express circadian rhythms in VP release without any sign of perturbation in the cycles subsequent to treatment, regardless of the time of administration. However, circadian timekeeping in some of the explants exposed to TTX during the subjective day was rendered arrhythmic by this treatment, such that VP output remained at basal levels without any sign of variation. This TTX-induced arrhythmicity is not indicative of a chronic disruption of mechanisms of peptide release because KCl exposure stimulated VP release from explants failing to express circadian rhythmicity after TTX treatment. These results further suggest that the expression of circadian rhythmicity by the SCN is dependent on Na-generated action potentials. Furthermore, the arrest of circadian rhythmicity in some TTX-treated explants may reflect the singular behavior of the pacemaker in the SCN in response to the inhibition of electrical impulses at a critical phase of the circadian cycle. Supported by NS-24661(D.E.).

MELATONIN RESETS THE SUPRACHIASMATIC CIRCADIAN CLOCK IN VITRO.
A.J. McArthur, R.A. Prosser, and M.U. Gillette. Dept. of Physiol. & Biophys. and Neural Biology and Behavior Program, Univ. of Illinois, Urbana IL., 61801.

The pineal hormone melatonin (MEL) has been implicated in circadian control mechanisms both because daily injections of MEL can entrain rodents (Cassone *et al.*, 1986) and the suprachiasmatic nuclei (SCN) have a high density of specific MEL receptors that varies diurnally (Laitinen *et al.*, 1989). We are examining the ability of exogenous MEL to directly reset the phase of the SCN pacemaker *in vitro*.

Coronal hypothalamic slices containing the SCN were prepared from 8 wk old male Long Evans rats housed in a 12L:12D cycle. At circadian time (CT) 2 or 10, the media in the brain slice chamber was replaced for 1 hr with freshly made media containing 10^{-9} M MEL. All measurements of phase were made by monitoring extracellular firing rates and determining the time of peak in the ensemble neuronal activity on day 2 *in vitro*. Phase shifts were determined by comparing this value with the time of peak neuronal activity on day 2 in untreated slices (CT 6.9 $\pm$ 0.2, N=8).

Treatment of the SCN with MEL at CT 10 induced significant advances (ϕ_A) in the time of the peak on day 2 (3.8 $\pm$ 0.1 hr ϕ_A, N=4), whereas the SCN rhythm was unperturbed by MEL applied at CT 2 (0.1 hr ϕ_A, N=2). These results suggest that MEL may play a role in regulating the SCN pacemaker in the late subjective day. (Supported by NINCDS grant NS22155).

INTERHEMISPHERIC RELATIONS

VISUAL CONTROL OF HAND POSTURES IN INDIVIDUALS WITH CALLOSAL AGENESIS OR CALLOSOTOMY.
M. Lassonde, M.T. Perenin*, M. Goodale, M. Labonté*, and L. Jakobson. Département de Psychologie, Univ. de Montréal, Montréal, Qué. H3C 3J7 and Univ. of Western Ontario, London, Ont. N6A 5C2, Canada.

Transporting a limb to a visual target involves mostly the proximal musculature which receives input from motor cortex in both hemispheres. The relatively independent movements of the hands and fingers, however, depend almost entirely on projection systems from the contralateral hemisphere. Thus, early work by Brinkman and Kuypers (1973) demonstrated that the information necessary for controlling posturing of the hand ipsilateral to the visually activated hemisphere depends on the integrity of the callosal system. The present study examined visual control of hand postures and finger movements in 2 subjects with callosal agenesis and in 2 epileptic patients who had undergone a therapeutic callosotomy. Subjects were submitted to two tasks: 1. reaching toward and placing their hand in a slot on a vertically mounted disk. 2. reaching toward the disk and retrieving a knob inserted in the slot. For some blocks of trials, the disk was located in the visual field ipsilateral to the hand being used, while in others the disk was placed in the contralateral field. Subjects were required to maintain central fixation while reaching. Age- and IQ-matched control subjects performed the tasks with little difficulty using either hand in either visual field. The acallosal and callosotomized subjects, however, were significantly more imprecise and displayed more shaping errors than their controls under all conditions. This was especially marked when the left hand was used and/or when the left visual field was the source of stimulus presentation. The results are discussed in terms of left hemisphere superiority for motor control.

421.2

DISCRIMINATION AND RECOGNITION OF COMPLEX TONAL SPECTRA BY THE CEREBRAL HEMISPHERES: DIFFERENTIAL LATERALIZATION OF ACOUSTIC-DISCRIMINATIVE AND SEMANTIC-ASSOCIATIVE FUNCTIONS IN AUDITORY PATTERN PERCEPTION.
M.J. Tramo* and M.S. Gazzaniga. Program in Cognitive Neuroscience, Dartmouth Medical School, Hanover, N.H. 03756.

The discrimination and recognition of complex tonal spectra by the left and right hemispheres of two callosotomy patients with bilateral language competence were tested using sound-picture and sound-word matching tasks. Two sets of probes were presented binaurally: 1) pairs of spectra composed of a fundamental and its first five harmonics, the timbres of which differed in the reciprocal intensities of the third and fourth harmonics in 50% of trials; and 2) individual spectra whose timbres were characteristic of different musical instruments. Visual targets were lateralized tachistoscopically and consisted of, respectively: 1) "same" and "different" choices presented simultaneously in alternate quadrants; and 2) instrument line drawings or names, which matched the probe in 50% of trials.

A double dissociation was observed, indicating that acoustic-discriminative and semantic-associative processes were differentially distributed within the right and left hemispheres, respectively. The results argue against a strict verbal/nonverbal dichotomy as the basis of hemispheric specialization in auditory pattern perception and are consistent with the notion that the meaningfulness of nonverbal sounds critically influences laterality effects. The functional basis of the left hemisphere advantage in semantic-associative processing may be a superior capacity for multimodal (auditory-visual-lexical) integration rather than lexical access alone.

421.3

EFFECT OF ADVANCE INFORMATION ON HEMISPHERIC ASYMMETRY FOR MENTAL ROTATION IN A COMMISSUROTOMISED SUBJECT. M.C. Corballis, Dept. of Psychology, Univ. of Auckland, New Zealand, and J. Sergent, Montreal Neurological Inst., Montreal, Que., Canada H3A 2B4.

The objective was to determine if the strong right-hemispheric advantage for mental rotation of letters shown by L.B., a commissurotomized subject, would be influenced by advance information allowing formation of an image of the letter (R) in the to-be-presented orientation. Without this information, RT analysis confirmed the right-hemispheric advantage: estimated rotation rate and overall RT were slower with RVF than with LVF presentation. This pattern was reversed with advance information, suggesting a left-hemispheric advantage in generating the appropriate image. However advance information impaired right-hemispheric performance as much as it benefited left-hemispheric performance.

421.4

HEMISPHERIC ASYMMETRIES IN MEMORY FOR REAL AND SURREAL ART. Dahlia W. Zaidel and Asa Kasher*. Dept of Psychology, UCLA, Los Angeles, CA 90024-1563.

Currently there is remarkable paucity of systematic data on the cognitive and brain mechanisms underlying the perception and production of paintings. The work that has been published to date deals largely with comparing art work in pre- and post- brain damage in the same artist.

Here, the hemispheric status of the way in which two art styles treat reality was investigated with the hemi-field tachistoscopic technique. A series of 24 "surrealistic" vs "realistic" paintings was first inspected briefly by normal subjects and then memory was probed by flashing the original plus decoys in the left (LVF) or right (RVF) visual half-fields. A recognition paradigm was used and a binary choice was made in responding. Results showed a RVF superiority for the surrealistic paintings. There was no hemi-field difference for the realistic paintings. In two additional experiments, 16 of the same paintings were used as targets in conjunction with metaphoric vs literal titles constructed for them. In one experiment, memory for the paintings alone was probed while in the other, memory for the titles alone was probed. A RVF superiority emerged for the metaphoric titles, especially if paired with surrealistic paintings. Taken together, the results suggest a left hemisphere advantage in processing meaningful, yet incongruous arrays, both pictorial and linguistic.

LATERALITY OF BRAZILIAN ADULTS AND ITS RELATIONSHIP WITH PERFORMANCE IN LEARNING A SECOND LANGUAGE. S.L.Schmidt*, A.A. Hofke* (SPON:R.Lent) I.BIOFISICA UFRJ,I.BIOLOGIA UERJ Rio de Janeiro - Brasil

In spite of the association of left-handedness with neurological deficits, there is little empirical evidence for performance differences between left-handers and right-handers. We described the distribution of laterality in adult Brazilians and looked for its relation with performance to learn a foreign language. The distribution of handedness of 1,017 Portuguese-speaking Brazilian students undertaking of English or German courses was evaluated using the abridged form of the Edinburgh Inventory. Information about handwriting posture, instruction level and foot preference were also obtained. Performance in learning a foreign language was evaluated by a standardized grade attributed to each student in three exams. Results revealed that the distribution of the laterality scores is J-shaped. Inverted handwriting posture was found to be more frequent among left-handers (40%) than among right-handers (5%). The number of dextral females (92%) was found to be greater than that of males (89%). An analysis of variance for handedness, sex, instruction level, and age showed a significant effect of handedness on the standardized grade. Strong right-handers have a better performance than weak right-handers. These results suggest that not only left-handers but also right-handers represent a heterogeneous group.

STUTTERING AND VOLUNTARY DIFFERENTIAL HEMISPHERIC ACTIVATION STUDIED WITH COMPUTERIZED EEG AND SPECT. P.S. Gott, C.M. DeGiorgio,* D.C.P. Chen* and E.C. Hughes*. Depts. of Neurology, Nuclear Medicine, and Otolaryngology, Univ. of Southern California Sch. of Med., Los Angeles, CA 90033.

We studied an extraordinary patient who reported he could voluntarily switch between two distinct conscious states associated with a dichotomy in fluency: I. uncontrollable stuttering, II. nonstuttering. Computerized EEG, regional cerebral blood flow (SPECT) and task performance were evaluated in each state. Findings indicated a state-dependent shift in left right hemispheric participation with superior results in the nonstuttering state. EEG alpha ratios were significantly different between states. Likewise, cerebral blood flow demonstrated hemispheric shifts in each state. Performance on verbal and spatial tasks suggested unusual lateralization.

Results support the probability that "at will" differential activation of each hemisphere was associated with each state and with concomitant stuttering and nonstuttering. Voluntary, or nonvoluntary, changes in lateralized hemispheric control may be a salient feature of stuttering and of potential therapeutic significance.

VISUAL EVOKED POTENTIAL ESTIMATES OF INTERHEMISPHERIC TRANSFER TIME IN HUMANS: EFFECTS OF VERTICAL POSITION WITHIN A HEMIFIELD. C. D. Saron*, R. J. Davidson* and J. Ellwanger* (SPON: P. Spear). Dept. of Psychology, University of Wisconsin, Madison, WI 53706.

Studies in Macaques have demonstrated asymmetries in callosal projections in dorsal compared with ventral visual cortex. This study examined whether visual evoked potential (VEP) estimates of interhemispheric transfer time (IHTT) might reflect such differences in humans.

Hemifield (LVF or RVF) checkerboards (29 cd/m^2, 85% contrast ratio, 4.0°V x 2.9°H, 1° checks, ISI=2-5 s, duration=10 ms) in each of three vertical positions (Lower (L), 10° Horizontal (H) and Upper (U)) with equal eccentricity (5.1° to mid-nasial edge) were presented in blocks of 100 per location to 18, 18-24 yr. old, right-handed males. L and U stimuli began 1.7° from the horizontal meridian. Ss lifted both index fingers in response to each stimulus.

VEPs were recorded from lateral occipital sites between O1/O2 and T5/T6 referred to linked ears. Estimates of IHTT were computed for P100 and N160 components by subtracting peak latency contralateral to the stimuli from the corresponding peak latency from the ipsilateral site.

Mean(sd) P100 IHTT estimates (in ms) and the percent of subjects showing effects in the anatomically predicted direction were: LVF-L=12(20), 69%; RVF-L=17(12), 92%; LVF-H=17(12), 100%; RVF-H=22(13), 100%; LVF-U=10(12), 76%; RVF-U=16(16), 93%. N160 IHTT estimates were: LVF-L=11(13), 83%; RVF-L=24(21), 91%; LVF-H=19(18), 94%; RVF-H=24(16), 100%; LVF-U=5(22), 61%; RVF-U=19(24), 73%.

The H conditions resulted in the greatest % of subjects with IHTTs in the anatomically predicted direction. The increased percentage of negative IHTTs in the L and U conditions makes interpretation of these results in terms of underlying callosal connectivity problematic. However, a main effect for Vertical Position on N160 latency for contra-, but not ipsilateral values suggests that the transferred response may be less sensitive to location.

EFFECTS OF LATERALIZED STIMULI ON CEREBRAL AROUSAL. K. E. Luh*, J. Levy*, and E. Jerison* (SPON: P. Teuting). Department of Behavioral Sciences, University of Chicago, Chicago, IL 60637.

There is evidence that the right hemisphere plays a dominant role in the allocation of arousal to the cerebral hemispheres. Also, it has been shown that performance is better following LVF (left visual field) than RVF (right visual field) stimuli. The purposes of this study were (1) to compare the processing of verbal stimuli presented to only one and to both hemispheres, and (2) to assess the effects of uni- and bihemispheric stimulation on subsequent performance.

A tachistoscopic syllable identification task was given to right-handed men and women (n = 64). Half viewed nonsense syllables in the LVF, RVF, and CVF (center, at fixation). The other half viewed them in the LVF, RVF, and BVF (bilateral redundant). Error patterns for LVF and RVF syllables differ, and CVF and BVF error patterns are intermediate to patterns in the unilateral fields. Therefore, subjects appear to rely on both hemispheres to process CVF and BVF syllables, rather than using only the language-specialized left hemisphere. Individual differences in this pattern may reflect differences in the degree to which subjects respond to a syllable task with differential arousal of the left hemisphere.

In addition, accuracy for identifying LVF and RVF syllables was strongly affected by the lateralization of the previous stimulus. Performance in the RVF was better following a LVF trial than following a RVF trial. In contrast, performance in the LVF was worse following a LVF trial than it was following a RVF trial. Effects of CVF or BVF trials on subsequent performance in the two unilateral fields were like those of LVF trials. These results suggest that the visual field of stimulus presentation has an effect on the pattern of arousal of the cerebral hemispheres.

STRIATE, PARASTRIATE AND PERISTRIATE LEFT-RIGHT VOLUMETRIC ASYMMETRIES IN NEONATAL AND JUVENILE HUMAN BRAINS. K.S. Pollan*, L.W. McCallister, D.J. Woodward, M-C de Lacoste (SPON: R. Lebovitz). *Dept. Cell Biology and Anatomy, U.T. Southwestern Medical Center, Dallas, TX 75235.*

We have previously reported significant left-right regional volumetric asymmetries in striate (ST) and extrastriate (XT) visual areas of the human brain (Soc. Neurosci., 1988; de Lacoste et al). The aim of this study was to determine if XT asymmetries in the neonatal and juvenile human are more pronounced in parastriate (PARA) or peristriate (PERI) cortex.

Neonatal and juvenile (n=3) occipital lobes were sectioned bilaterally in complete series at 50μm in the coronal plane with a large-stage freezing microtome. Adjacent mounted sections at 5mm intervals were processed using a basic Nissl and the Gallyas silver stain for cyto- and myeloarchitectural differentiation of ST, PARA and PERI visual areas. Nissl-stained sections were then videodigitized and the CARP software (Biographics, Inc.) was utilized for semi-automated 1) delineation of the external and internal boundaries of cortical gray and 2) computation of sectional areas. Regional volumes for ST, PARA and PERI cortex and left-right indices of asymmetry were calculated using previously described algorithms (de Lacoste et al., 1988).

Preliminary results indicate that in the neonatal and juvenile human brain, both ST and XT visual areas evidence left-right volumetric asymmetries. However, within XT cortex regional volumetric asymmetries of PERI or association cortex are several-fold more pronounced than those of PARA or belt cortex. The functional significance of asymmetry in visual association cortex remains to be determined.

ACCELERATED RECOVERY FROM NEGLECT AND BEHAVIORAL ASYMMETRIES IN RATS WITH MEDIAL AGRANULAR PREFRONTAL CORTEX LESIONS. M.R. Smith, J.M. Vargo, and J.V. Corwin. Dept. of Psych., Univ. of New Orleans, New Orleans, LA 70148.

Exposure to 48h of postsurgical light deprivation can prevent the demonstration of neglect seen following unilateral destruction of medial agranular cortex (AGm) (Crowne et al., 1983). The present study examined whether this environmental manipulation would be effective in producing recovery of function in subjects already demonstrating severe neglect.

Rat subjects (Ss) received aspiration lesions of either the left AGm (L-AGm, n=25) or the right AGm (R-AGm, n=16), and 3h later were tested for neglect (orientation deficits to visual, auditory, and tactile stimuli). Each Ss was again tested for neglect immediately following the environmental manipulation. In addition to the orientation test, slope and open field tests were conducted 3 times/week for 3 weeks.

The major statistically significant findings are: 1) lateralized differences in general responsivity were shown by 3h postsurgery; 2) L-AGm Ss displayed accelerated recovery of function following 48h exposure to light deprivation only; and 3) L-AGm Ss showed an ipsilesional turning preference, whereas R-AGm Ss showed no preference. These results support and extend earlier findings on laterality and recovery of function following AGm lesions. Supported by grant NS 24975 from NINCDS to J.V.C.

421.11

LATERALIZATION OF CONDITIONING-RELATED PROCESSES IN NORMAL RATS. R. Tomer, A. Laferriere, L. Burger and A. Robertson. Dept. Psychology, University of Alberta, Edmonton, AB, T6G2E9.

To determine whether functional assymmetries related to attentional phenomena could be shown in normal rats, forty two rats were given a set of tests in order to determine the presence of consistent side biases in sensorimotor responsiveness. Between 35 and 50 percent of rats displayed consistent and persistent side biases. 19 of the most lateralized rats were then conditioned by having a signal light come on before and during brief dipper presentations. One group received light presentations on the preferred side, the other on the neglected side. Rats receiving the light on their preferred side displayed evidence of having acquired a conditioned approach response to the light. Rats having received light presentations on the neglected side failed to display signs of effective conditioning. This suggests that, in a proportion of normal rats, some processes related to stimulus-reward conditioning are subject to lateralization. These effects could be useful for the study of assymmetry and its relation to psychopathology.

421.12

TESTOSTERONE AFFECTS SOME MEASURES OF RAT BEHAVIORAL ASYMMETRY. K.J. Schultz. Psychology Dept., Univ. of Winnipeg, Winnipeg, Manitoba, Canada, R3B 2E9.

The role of testosterone in rats' behavioral asymmetry was examined in 85 perinatally gonadectomized and 91 sham male Sprague-Dawley rats. Adult animals completed four trials on each of six behavioral tests. Laterality ratios were derived for each task. Principle factors extraction with varimax rotation was performed on the six laterality scores separately for gonadectomized and sham animals. Two factors were extracted for each group. For gonadectomized rats these were interpreted as Rotational Travel and Head Rotation, while for sham animals they were interpreted as Rotational Travel and Tail Posture. The first factors were virtually identical ($r = .93$), while the second were unique ($r = .06$). Oblique rotation revealed that the factors were unrelated. The divergent factor structures support testosterone involvement in head rotation and tail posture but fail to support a link between testosterone and rotational travel. Morphometric analyses of hemispheric differences in neocortical volume are in progress since behavioral asymmetry may reflect hormonally mediated hemispheric differences.

421.13

SPONGIFORM DEGENERATION IN A HIGHLY LATERALIZED MOUSE LINE G.F. Sherman, R.L. Collins, V.H. Denenberg, D.M. Press*, and A.M. Galaburda. Depart. of Neurol., Beth Israel Hospital and Harvard Med. School, Boston, Ma., 02215, Biobehavioral Sciences Graduate Program, Univ. of Ct., Storrs, Ct. 06268, and The Jackson Laboratory, Bar Harbor, Me., 04609.

Developmental brain pathology is associated with deviations of cortical asymmetry and anomalous handedness. In the present study we looked for evidence of CNS neuropathology in two lines of mice bred for either strong (HI) or weak (LO) paw preference and mice from the HET progenitor population [Collins, in S.D. Glick (ed.), *Cerebral Lateralization in Nonhuman Species*, Academic Press, 41-70, 1985].

Eighteen HI (9 male, 9 female), 16 LO (8 male, 8 female), and 18 HET (8 male, 10 female) adult mice were used in this study. Brains were embedded in celloidin, coronally sectioned at 35μm, and stained with cresyl violet. The sections were examined under the light microscope and the presence, type, and location of the abnormalities were recorded.

Surprisingly, 12 (67%) of the HI mice had severe spongiform degeneration involving neocortex, hippocampus, septum, and hypothalamus. The distribution and severity of the degeneration varied among animals, although all animals were affected bilaterally. The neocortex was the most severely affected structure. Layers V and VI contained the greatest density of vacuoles, although all cortical layers were affected. Eight (88%) females and four (44%) males from the HI line were affected, while only 1 male and no females from the LO line showed spongiform changes, and one male and two females from the HET group had a few vacuoles in the hippocampus and septum, but not the neocortex. In addition, ectopic neurons were seen in layer I of the cortex in 3 mice from the LO line and 1 mouse from the HI line. The ectopias were seen in mice with and without spongiform degeneration.

INTENSITY OF APOMORPHINE-INDUCED CIRCLING IS GREATER FOLLOWING LEFT NIGROSTRIATAL (6-OHDA) LESIONS THAN RIGHT-SIDED LESIONS. R. Sullivan*, M.G. Ziegler and H. Szechtman (SPON: J.M. Cleghorn) Dept. Biomedical Sci., McMaster Univ., Hamilton, Ontario, CANADA L8N 3Z5.

Circling in response to apomorphine (APO) was studied in rats with left or right nigrostriatal lesions (6-OHDA), who had been evaluated for directional bias prior to lesioning. Two weeks post-lesion, 21 male Wistar rats were injected with APO (0.25 mg/kg, sc) and placed in an automated rotometer. Rats performing more than 30 net contraversive full turns during the 15 min. test (19 of 21 rats) were compared statistically. Animals with left-sided lesions (N=9) were found to perform significantly more net contraversive turns (mean=120.6 circles) than those with right-sided lesions (N=10, mean=91.7; $p<0.05$, one-tailed t-test). Re-examination of earlier data of APO-induced circling in the rotometer, confirmed this side of lesion effect ($p<0.05$, one-tailed t-test). Combining the two sets of data (N=58) demonstrated a robust significant difference ($p<0.02$, one-tailed t-test). Pre-lesion measures of directional preference, based on the predominant direction of swimming in a 2m-diameter pool, were found to be unrelated to post-lesion circling. The data are consistent with left striatal dominance in the population of male rats, an asymmetry which may override individual directional preferences. [Supported by NSERC. DO CALLOSALLY PROJECTING NONPYRAMIDAL NEURONS EXIST IN RAT VISUAL CORTEX ? C. Hughes and A. Peters. Dept. of Anatomy, Boston Univ. School of Med., Boston, MA 02118.

Nonpyramidal neurons are known to possess the inhibitory neurotransmitter GABA and determination of whether such neurons project callosally will facilitate the development of functional schemes for interhemispheric communication. In male Sprague Dawley rats, horseradish peroxidase (HRP) injections were made into the callosal terminal zone located near the border of areas 17 and 18. Following a 36 hour survival period, tissue sections were reacted with either diaminobenzidine (DAB), intensified with nickel ammonium sulfate and cobalt chloride, or were reacted with tetramethylbenzidine (TMB) stabilized with ammonium molybdate. Tissue sections were prepared according to standard electron microscopic procedures. Control animals were saline injected and processed in a similar fashion. More than 600 neurons possessing a Golgi-like HRP filling were examined with the light microscope to identify potential nonpyramidal neurons. Following serial thin sectioning of four such neurons, one was confirmed by electron microscopy to be a smooth multipolar neuron. To investigate larger samples of callosally projecting neurons, several series of 1 um methylene blue stained plastic sections, containing neurons displaying punctate HRP label, were cut from parts of areas 17 and 18 (layer II/III) and camera lucida drawings were made. The number of black HRP granules within nuclear containing profiles of pyramidal and nonpyramidal neurons was determined. Neurons in control sections did not display any granules similar to those seen in neurons with punctate HRP label. A series of adjacent thin sections were used to support light microscopic findings. Preliminary data indicate that both pyramidal and nonpyramidal neurons transport HRP in similar amounts, although nonpyramidal neurons tend to label somewhat less robustly than pyramidal neurons which could explain why nonpyramidal neurons rarely demonstrate a Golgi-like filling. (NIH EY-06404)

421.16

ROLE OF MIDBRAIN IN INTERHEMISPHERIC TRANSFER IN CATS. J. M. Sprague and A. C. Rosenquist. Dept. of Anatomy, Univ. of Pennsylvania Sch. of Med., Phila., PA 19104-6058.

Contralateral hemianopia follows unilateral removal of all visual areas in occipital-parietal-temporal cortex. Orienting responses to stimuli in the "blind" visual field are restored by section of the tectal commissure. (Sprague '66; Sherman '74; Wallace et al. '87, '89). Midbrain commissurotomy also enhances cognitive functions. Split-chiasm cats show marked defects in interhemispheric transfer of shape discriminations when measured from intact hemisphere to side with lesion in suprasylvian gyri (Berlucchi et al. '79). (Deficit does not occur to easier discriminations of low frequency gratings.) When collicular commissure is sectioned after cortical lesion, normal transfer of shape discriminations is restored. Animals after suprasylvian lesions do not appear to have either sensory or motor deficits. Therefore it is possible that the deficit in transfer is due to visual neglect stemming from inattention in the lesioned hemisphere. The known role of the superior colliculi in selective attention directed by inhibitory fibers in the commissure, suggest that restoration of transfer after collicular commissurotomy is due to enhancement of attention required to make difficult discriminations. Not yet known is whether this function, like orienting, is related to the nigrotectal projection, part of which passes through the tectal commissure. (Supported by NIH · EY02654 and EY04906).

THE CORTICAL ORIGIN AND COURSE OF FIBERS IN THE PERIVENTRICULAR WHITE MATTER OF TWO COMPONENTS OF THE SPLENIUM OF THE CORPUS CALLOSUM IN MACAQUES. S. Demeter[1], D.L. Rosene[2], and G.W. Van Hoesen[3]. [1]Dept. of Neurol., Univ. Rochester Med. Ctr., Rochester, NY 14642; [2]Dept. of Anat., Boston Univ. Med. Ctr., Boston, MA 02118; [3]Dept. of Anat., Univ. Iowa Sch. of Med., Iowa City, IA 52242.

Previous observations suggested that the splenium of the corpus callosum is divided into two bundles by the atrium of the lateral ventricle. The larger bundle, derived from the dorsal splenium, corresponds to the classical *forceps major,* which passes dorsomedial and dorsalateral to the atrium and occipital horn of the lateral ventricle. By contrast, the smaller bundle, derived from the ventral splenium, corresponds to the *inferior forceps*, which passes ventromedial to the atrium of the lateral ventricle.

To determine the sources of these two splenial components, we examined by autoradiography 33 macaques *(M. macaca* and *M. fascicularis)* with small cortical injections of radioactively labeled amino acids in the ventral temporal and occipital lobes. In the temporal lobe the occipitotemporal sulcus formed the boundary between the fields of origin of the two components. The inferior temporal cortex, located lateral to the occipitotemporal sulcus, gave rise to fibers that coursed dorsolaterally around the atrium of the lateral ventricle and slightly rostrally thereto to cross the midline in the dorsal splenium and the caudal part of the body of the corpus callosum. By contrast, the posterior parahippocampal gyrus gave rise to fibers that coursed in the inferior forceps to cross in the ventral splenium.

In the occipital lobe there was a similar topographic division. Fibers that arose dorsal to the calcarine sulcus and in the dorsolateral and ventrolateral occipital lobe entered the forceps major to cross in the dorsal splenium. Fibers that arose between the calcarine and occipitotemporal sulci and slightly lateral to the latter, entered the inferior forceps to cross in the ventral splenium.

BEHAVIORAL PHARMACOLOGY: DOPAMINE

422.1

AN INCREASE IN NEUROLEPTIC CONCENTRATION AMELIORATES HALOPERIDOL INDUCED ABNORMAL LICKING PATTERNS: a necessary characteristic of an animal model for tardive dyskinesia. SJ Wasserman and KM Kantak. Lab. of Beh. Neurosci., Dept. of Psych., Boston Univ., Boston, MA. 02215.

Alteration in the control of oropharyngeal musculature has been indirectly observed in mice after chronic neuroleptic administration by recording their licking patterns. The development of aberrant patterns parallels the time course of tardive dyskinesia: first upon withdrawal and later occurring spontaneously. This behavioral change could however, be indicative of dystonia. The two side-effects of neuroleptic administration respond differentially to an increase in drug concentration. Tardive dyskinesia is ameliorated and dystonia is exacerbated.

Mice chronically treated with haloperidol (1mg/kg IP) and exhibiting the altered licking pattern were challenged with a higher concentration of the same drug (3mg/kg IP). When the effects on licking pattern were compared with those of appropriate saline control groups, the number of licks per bout increased to saline control levels. The higher concentration of haloperidol ameliorated the altered licking pattern.

422.2

HALOPERIDOL (HAL) SLOWS RATS' RESPONDING BY LENGTHENING THE TIME REQUIRED TO SWITCH FROM ONE MOTOR RESPONSE TO ANOTHER: A PARKINSON-LIKE EFFECT. **S.C. Fowler, M.A. Kirkpatrick*, P.D. Skjoldager*, and R.M. Liao*. Depts. of Psychology and Pharmacology, University of Mississippi, University, MS 38677.**

Classical dopamine-receptor-blocking neuroleptics decrease average rate of operant responding by rats in at least two ways: by producing a total cessation of responding before a session ends and by slowing the response itself. In order to extend this work, the effects of low doses of hal (0.04 and 0.08 mg/kg) were assessed in rats trained in operant chambers that permitted recording the time intervals between the successive behaviors occurring within a typical cycle of the operant/consummatory complex. Results showed that two intervals (latency from muzzle entry into the reward well to initial tongue protrusion and latency from muzzle exit to the next forelimb response) were proportionately lengthened more than others. Hal appears to disrupt response selection and initiation processes in rats. These results provide additional evidence for homology between neuroleptics' effects in man and rat. (Supported by MH 43429)

422.3

DRUG DISCRIMINATION: REBOUND FOLLOWING A SINGLE DOSE OF HALOPERIDOL. W.F. Caul, J.R. Jones, & R.J. Barrett. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240

Barrett and Steranka (1983) reported that 24 hr after a chronic regimen of 10 consecutive daily injections of 1 mg/kg haloperidol (HD) animals previously trained to discriminate between amphetamine (AM) and saline responded as if they had been injected with a small dose of AM. The experiments reported here were designed to assess whether a similar rebound phenomenon would result from a single dose of HD. Rats were trained to discriminate .5 mg/kg AM from distilled water (DW) (cf. Caul, Burgen, and Barrett, 1989). Four groups (n=8) were formed to allow testing of the drug's effect at 12, 18, 24, and 36 hr post-injection. Each animal was given 0, .5, 1.0, and 1.5 mg/kg HD at its appropriate injection time in a counterbalanced fashion with one week between each test. Although predicted patterns were observed, no reliable differences were found. Four weeks later, half of the animals were injected with 1 mg/kg HD 24 hr prior to testing, whereas the others were given DW. When tested, the HD group responded 36% of the time on the AM-correct lever, whereas the DW group responded at 28%. The failure to find significant temporal patterns of post-HD rebound phenomena using a within-subjects design and the observation of rebound in the between-subjects study have both theoretical and methodological importance.

422.4

BEHAVIORAL AND BIOCHEMICAL EFFECTS OF PERTUSSIS TOXIN ON DOPAMINE RECEPTORS IN VIVO. C. Marin, S.A. Parashos, and T.N. Chase. ETB, NINDS, NIH, Bethesda, Md 20892.

Dopamine receptors have been classified in two subtypes: the D-1, positively coupled to adenylate cyclase by the stimulatory Gs protein and the D-2, either not coupled or negatively coupled to the enzyme by the inhibitory Gi protein. Behavioral experiments suggest important functional interactions between D-1 and D-2 receptors, with the D-1 system normally acting to increase motor activity induced by stimulation of D-2 receptors. In this study D-1/D-2 receptor interactions were evaluated in rats by intrastriatal administration of pertussis toxin (PT), which inhibits the Gi protein linked to D-2 receptors. After unilateral injection of 1.5 ug, the animals developed a marked postural asymmetry towards the injected side. The selective D-2 agonist quinpirole (1 mg/kg, ip) produced significant ipsilateral rotation, while the selective D-1 agonist SKF 38393 (10 mg/kg, ip) had no such effect. Combined treatment with both drugs potentiated the effect of quinpirole alone. Rotation induced by quinpirole was blocked completely by the selective D-1 antagonist SCH 23390 (0.5 mg/kg, ip) and partially by the selective D-2 antagonist raclopride (1 mg/kg, ip). Treatments which resulted in rotation, quinpirole alone and with SKF 38393, also resulted in asymmetry in striatal cAMP levels. These findings provide support for a relation between D-1/D-2 behavioral interaction and alterations in cAMP levels and indicate an important role for G proteins in dopamine receptor interactions.

422.5

MODULATION OF YAWNING BY STRIATAL DOPAMINE AUTORECEPTOR SENSITIZATION. B.I. Diamond, A. Hitri*, N.A. DeMartines*, H. Nguyen*, E. O'Neal* and R.L. Borison*. Department of Psychiatry, Medical College of Georgia, Augusta, GA 30912.

Yawning is a behavior modulated by Dopamine (DA) D1 and D2 presynaptic autoreceptors. This behavior may be relevant to certain disease states. It was the aim of this study to examine these DA receptors in male Sprague Dawley rates (200 grams) treated chronically with a neuroleptic. Animals had bilateral striatal cannula implanted for injection of either the D1 or D2 agonist SKF38393 or LY171555 and the D1 or D2 antagonist SCH23390 or haloperidol. Fluphenazine (5 mg/kg; i.p.) was injected for a 2 week period. Animals were rated for yawning and stereotyped behaviors in response to apomorphine (0.05 to 0.2 mg/kg; s.c.) three days later. Yawning behavior was inhibited by 90% after chronic neuroleptic treatment. Moreover, the D1 agonist facilitation of yawning was abolished by chronic neuroleptic treatment as was the yawning induced by the intrastriatal administration of LY171555. Yawning inhibition observed after D1 and D2 antagonist treatment was still present after chronic striatal DA sensitization. These results suggest that D1 receptor involvement as well as autoreceptor sensitization play an important role in the abolition of yawning and in certain disease states.

422.6

QUANTITATIVE BEHAVIORAL ANALYSIS OF DA AGONIST/ANTAGONIST INTERACTIONS IN THE RAT. P.K. Randall, R.E. Wilcox, and J.S. Randall. Inst. for Neuroscience, Div. Pharmacol., Univeristy of Texas, Austin, Texas 78713.

Antagonist blockade of an agonist-induced behavioral response is a common technique in behavioral pharmacology. Unfortunately, IC_{50}'s derived from experiments in which increasing antagonist doses are run against a constant agonist dose are dependent not only upon the K_b of the antagonist, but also upon at least 3 other parameters, the K_A and dose of agonist, and the ED_{50} of the particular reponse measured. Determination of an "*in vivo* K_b" for an antagonist using pharmacological null methods should be dependent only upon antagonist characteristics. Since these methods were designed to be used in preparations in which tissue factors remain constant across different agonist and antagonist doses, it is questionable whether any valid information can be obtained with complex response systems such as behavior.

To determine the feasibility of utilizing such techniques in behavioral preparations, we examined the effects of 3 doses of each of 3 DA antagonists on the dose-response curve for apomorphine-induced behavior in Sprague-Dawley rats. Dose-response curves were assessed by non-linear estimation using the null model for competitive antagonists. Fluphenazine, at .1 and .25 mg/kg produced parallel shifts in apomorphine dose response curves suggesting an *in vivo* K_b of .04 to .06 mg/kg, IP. This was the case regardless of which of several behavioral measures were employed (number of animals showing stereotypic behavior, mean maximum stereotypic rating, gnawing). SCH23390 and spiperone affected the dose-response curves in a much more complex manner which was highly dependent upon the particular components of the behavioral response assessed. These data suggest that such techniques may be relatively robust in behavioral experiments when the antagonist employed interacts similarly with all populations of relevant receptor species affected by the agonist. Thus fluphenazine has almost equal affinity for D-1 and D-2 receptors and affects the dose-response curves of an equally non-selective agonist in a simple manner. Antagonists which discriminate between different sub-populations of receptors affected by the agonist (i.e. SCH23390 (D-1) and spiperone (D-2)) not surprisingly exert more complex effects.

422.7

COMPARATIVE EFFECTS OF D_2-DOPAMINERGIC AGONISTS ON COPULATORY BEHAVIOR OF MALE RATS. M.M.FOREMAN, R.D.TITUS* and J.M.SCHAUS*. The Lilly Research Laboratories, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN 46285.

The present studies have compared the effects of variety of potent and selective D_2-dopaminergic receptor agonists from different structural groups including an aporphine agonist [R-N-n-propylnoraporphine (PrAPO)], a hydroxy-napthoxazine agonist [(+)PHNO] and "BCD" partial ergolines (quinpirole, quinelorane, LY173452 and LY237917) on male rat copulatory performance. The animals chosen for these studies were 6-12 month old, male Sprague-Dawley rats, which exhibited constant ejaculatory latencies (time interval between intromission and ejaculation, EL) in repeated tests. Subcutaneous injections of solutions containing various concentrations of these dopaminergic agonists were made 30 minutes prior to behavioral testing with a sexually receptive female rat. Although all of these agents were capable of producing significant reductions in EL, there was a 100 fold variance in the minimum effective dose. PHNO, quinpirole and PrAPO required a minimum dose of 2.5 ug/kg to elicit changes in EL, whereas LY173452 required 250 ng/kg and quinelorane and LY237917 required 25 ng/kg. The evaluation of sexual behavior is an extremely sensitive in vivo method for comparing pharmacologic activities of D_2-dopaminergic agonists, which may provide a measure of preclinical efficacy of agents used to treat sexual disorders.

POTENTIATION BY ANTICHOLINERGICS OF THE INHIBITION BY D1-RECEPTOR ANTAGONISTS OF CONDITIONED AVOIDANCE RESPONDING (CAR) IN RATS. L.C. Iorio, R. Chipkin, M. Cohen-Winston* and V. Coffin*. Schering-Plough Inc., Dept. of Pharmacology, Bloomfield, NJ. 07003.

Many studies have confirmed the first demonstration (Iorio et al, 1984) that the specific D1 antagonist SCH 23390 blocked CAR in rats at relatively low doses. This effect of SCH 23390 was indistinguishable to that seen after specific D2 antagonists, and this raised questions about a possible interaction between these 2 sub-classes of receptors in the CAR.

We have recently found that the overt sedative effects of selective D1- and D2-receptor antagonists in Cebus monkeys can be discriminated by the anticholinergic drug benztropine (Coffin et al, in press). This report demonstrates that CAR blockade in rats by specific D1 and specific D2 receptor antagonists can also be discriminated by anticholinergics. Atropine and scopolamine, at doses which by themselves did not affect CAR, potentiated CAR blockade seen after oral SCH 23390 or SCH 39166 (shift in the D-R curve to the left) but blocked CAR blockade seen after D2 antagonists such as haloperidol (shift of the D-R curves to the right).

These results suggest that the D1- and D2-receptor systems involved in CAR are linked to a cholinergic mechanism in a reciprocal manner.

422.9

ANGIOTENSIN CONVERTING ENZYME INHIBITION AND APOMORPHINE-INDUCED STEREOTYPED BEHAVIOR. A. Sudilovsky, B. Turnbull, L. H. Miller*. Squibb Institute for Medical Research, Princeton, NJ 08540; Boston University, Boston, MA 02215.

Although the angiotensin converting enzyme (ACE) inhibitor captopril does not competitively bind to the dopamine receptor it attenuates apomorphine-induced stereotypy when given one hour prior to apomorphine (Sudilovsky et al, Soc. Neurosci. Abst., 9:1, 132, 1983). The current experiments, using male Sprague-Dawley rats (N=9/group) randomly injected i.p. with ascending doses of captopril (5, 10, 20 and 50 mg/kg) one hour before i.p. administration of apomorphine (2 mg/kg), demonstrated a dose response relationship for the earlier reported effect. Stereotypy was rated in blind fashion using a 0-3 point scoring method (Tarsy and Baldessarini, Neuropharmacol., 13, 927, 1974). Pretreatment of rats with another ACE inhibitor, SQ 29,852 (5 mg/kg), also produced a significant decrease in stereotypy ($p<0.05$), which was of comparable magnitude to that resulting from pretreatment with the antipsychotic dopamine receptor blocker fluphenazine at 1 mg/kg ($p<0.05$). The inhibitory effect of the latter was potentiated by its combined administration with SQ 29,852. In addition, pretreatment with epicaptopril, the virtually inactive diastereoisomer of captopril, did not significantly affect stereotypy.

These data suggest an antagonist interaction between the ACE inhibitors and the dopaminergic system underlying stereotypy and support an involvement of ACE inhibition.

LOSS OF STRIATAL NEURONS FOLLOWING 8 MONTHS OF FLUPHENAZINE-TREATMENT IN RATS. DV Jeste, JB Lohr, DS Segal, R Kuczinski, PM Groves. San Diego VA Medical Center and Univ. of CA, San Diego, San Diego, CA 92161.

Neuroleptic-induced persistent tardive dyskinesia, is believed to be associated with striatal pathology. Yet, there have been few quantitative neuropathologic studies of sufficiently prolonged neuroleptic treatment. METHODS: We treated 10 male Sprague-Dawley rats with fluphenazine decanoate, 5 mg/kg, (or vehicle) im q 2 weeks for 8 months. Three weeks after last injection, animals were sacrificed. One hemisphere from each animal was used for striatal neuronometry with IBAS-2000 image analysis system, and the other hemisphere for measuring striatal dopamine, HVA and DOPAC concentrations. RESULTS: Fluphenazine-treated animals showed a 46% reduction (p 0.05) in the number of large (15u) neurons (likely to be cholinergic), and a decrease in striatal dopamine (by 28%), HVA (50%) and DOPAC (29%) concentrations. COMMENT: Chronic neuroleptic-induced neurotoxicity is probably associated with a loss or shrinkage of cholinergic neurons and a loss of dopaminergic terminals in striatum.

A NEUROPHARMACOLOGICAL ANALYSIS OF ORAL BEHAVIOR INDUCED BY DOPAMINERGIC OR CHOLINERGIC STIMULATION OF THE VENTROLATERAL STRIATUM. J.M. Delfs* C.G. Lang*and A.E. Kelley (SPON: H.Mahut). Dept. of Psychology, Harvard University, Cambridge, MA 02138.

Amphetamine microinjection into the ventrolateral region of striatum results selectively in intense oral stereotypy. The present experiments investigated 1) the role of D1 and D2 receptors in amphetamine-induced oral stereotypy and 2) the response to cholinergic stimulation of the ventrolateral striatum (VLS). One group of rats received a VLS injection of amphetamine (20 ug) in combination with systemic pretreatment of the D1 antagonist SCH 23390, and a second group received VLS amphetamine and the D2 antagonist raclopride. Both antagonists effectively blocked oral stereotypy. In a second experiment, VLS injection of the D1 agonist SKF 38393 had no effect on behavior upon acute observation, although intense biting emerged 4 hours following injection. Quinpirole did not induce the full-blown oral syndrome, but did increase licking, head-down sniffing and biting of wood chips. Histological analysis of brain sections revealed that SKF 38393 caused extensive damage to the area surrounding the cannula tip. This neurotoxic effect may have been responsible for the delayed onset of biting. In other experiments, a combination of physostigmine and acetylcholine (PS/Ach) (0.5, 2.5, 5.0 ug) was infused into the VLS and behavior was recorded. PS/Ach induced non-directed mouth movements which were blocked by atropine.

422.12

EFFECTS OF DOPAMINE ANTAGONISTS ON ACQUISITION AND EXPRESSION OF THE AMPHETAMINE CONDITIONED PLACE PREFERENCE Noboru Hiroi and Norman M. White Department of Psychology, McGill University, 1205 Dr. Penfield Ave, Montreal, Quebec, Canada, H3A 1B1

Based on our previous demonstration that dopamine receptor activation is required for expression of the amphetamine conditioned place preference (CPP), we investigated the effect of selective dopamine receptor blockers on both acquisition and expression of the CPP. Using a 3-compartment CPP apparatus, rats were trained with 2 amphetamine (2mg/Kg) pairings in one compartment and 2 saline pairings in another compartment in a counterbalanced manner; they were tested for place preference on the following day. Antagonists were given IP before training trials (acquisition) or before testing (expression). A mixed antagonist (alpha-flupenthixol, 0.2-1.0mg/Kg), a D1 antagonist (SCH23390, 0.02-0.16mg/Kg) and a D2 antagonist (sulpiride, 10.0-120.0mg/Kg) all dose-dependently blocked both acquisition and expression. Higher doses of all drugs were required to block expression than acquisition; the difference was smallest for the D1 antagonist and largest for the D2 antagonist. These findings suggest that activation of dopamine receptors is required for both acquisition and expression of the amphetamine CPP. The fact that higher doses are required to block expression than acquisition suggests that different mechanisms may mediate these two processes.

422.13

EFFECTS OF SELECTED DOPAMINE D1 AND D2 DRUGS ON SCHEDULE-CONTROLLED BEHAVIOR IN RATS BEFORE AND DURING CHRONIC SCH 39166 ADMINISTRATION. V.L. Coffin* and M.B. Latranyi* (SPON:R.E. Chipkin). Schering-Plough Corp., 60 Orange St., Bloomfield, NJ 07003.

While there are a few studies on the effects of chronic D2 antagonists on schedule-controlled behavior there are none on dopamine D1 antagonists. To study this, the behavioral effects of SCH 39166 (D1 antagonist) its inactive enatiomer (SCH 39165), SKF 38393 (D1 agonist), and raclopride (D2 antagonist) were studied. Dose-effect curves for each drug were determined by administering cumulative doses sc in a single session. Acutely, these drugs produced dose-related decreases in responding under a fixed ratio (FR 30) schedule of food presentation. There was a hundred-fold selectivity between the active and inactive isomers. After these studies, daily treatment with SCH 39166 (0.1 mg/kg/day sc) was initiated. After 40 days of chronic treatment with SCH 39166, the dose-effect curve was redetermined with no rightward shift in the curve; therefore, no tolerance developed. During chronic SCH 39166, the dose-effect curve for raclopride was not altered; however, chronic SCH 39166 treatment slightly modified the effects of SKF 38393 as shown by a downward shift in the dose-effect curve. In summary, SCH 39166 showed stereospecific dose-related effects on a FR schedule to which tolerance did not develop over forty days during chronic administration.

422.14

DA D2 AGONIST-INDUCED DEPRESSION IS DUE TO DEPRIVATION OF DA AT D1 RECEPTORS. D.M.Jackson#, S.B.Ross* and L-G.Larsson*, Astra Research Centre, Södertälje 151 85, SWEDEN.

The D2 agonists quinpirole (Q), pergolide (P) , B-HT920 (BH) and (-)-3-PPP (PPP) produced depression (reduced sniffing, rearing and grooming) in mice using a subjective scoring system. Q-, P- and BH-induced immobility were reversed by the D1 agonists SKF38393 (S) and CY208 243 (CY). Q-induced immobility was only reversed by the active enantiomer of S. PPP-induced immobility was reversed by CY and S, but this was due to an increase in grooming in mice given the D1 agonists, whether or not PPP was also given. There was no reversal of the depression of rearing or sniffing. While CY and S antagonized BH-induced immobility, the reversal was evidenced by partial reversals of the depression of sniffing, rearing and grooming. The S and CY reversal of Q immobility was blocked by the D1 antagonist SCH23390. High doses of SCH23390 and raclopride increased immobility. All the D2 agonists tested, in combination with S, stimulated activity in DA-depleted mice as monitored in automated cages. It is concluded that the D2 agonist-induced depression was due to a deprivation of DA specifically at D1 receptors. Furthermore, the depressant doses of the D2 agonists were able to stimulate the postsynaptic (PS) D2 receptors, which could be demonstrated under appropriate conditions. Thus, D1 agonists reverse D2-induced depression by stimulating the PS D1 receptors thereby taking the place of the endogenous DA. The necessary PS D2 receptor stimulation is provided by the D2 agonist. DA autoreceptor agonists are probably functionally selective because of the PS D1/D2 interaction, rather than displaying an ability to preferentially couple with the autoreceptors. # and (permanent address) Department of Pharmacology, University of Sydney, Australia.

'PRIMING' PHENOMENON: PHARMACOLOGICAL AND BIOCHEMICAL STUDIES

Morelli M., Garau L*, De Montis G. and Di Chiara G.
Inst.of Pharmacol. and Exper. Toxicol. Cagliari (Italy)

'Priming' is a mechanism which strongly potentiates the action of a dopaminergic (DA) agonist in denervated animals. In unilaterally 6-hydroxydopamine lesioned rats in fact, the administration of a DA agonist ('priming') significantly increases the contralateral turning induced by the administration of a D-1 or D-2 agonist. Moreover in primed rats a dose of a D-1 agonist inactive in drug-naive rats become fully effective in eliciting contralateral turning. 'Priming' has a time and dose dependency. It's effectiveness was maximal 3 days after the administration of the primer drug and decreased 10 days later; moreover the response to the D-1 or D-2 agonist was different depending from the dose of the drug used for 'priming'. Turning in response to 'priming' although strictly dependent on the stimulation of supersensitive striatal receptors and on the full expression of the contralateral turning in response to this stimulation, is not influenced by conditioning. The molecular mechanism at the basis of 'priming' was investigated by studying the binding of D-1 receptors and the activity of adenylate cyclase. No changes were found in the number and affinity of D-1 receptors while an increase in the affinity of the adenylate cyclase stimulated by D-1 agonists was observed. Further studies with 2-deoxyglucose autoradiography are in progress in order to assess if 'priming' promotes the activation of specific brain areas.

422.16

D-1 AND D-2 RECEPTORS INTERACTION IN PARKINSONIAN MONKEYS. M.R. Luquin*, T. Herrero*, J. Del Rio*, J.A. Obeso*. (SPON: C. Cuello). Dpt. of Movement Disorders (Neurology) and Pharmacology, University of Navarra, Medical School, Pamplona, Spain.

Severe parkinsonism was induced in 3 monkeys (Macaca Fasciculata) by intravenous injections of MPTP. Six weeks were allowed for recovery and stabilization. The dose-response curve for motor improvement induced by CY 208-243 (D-1 agonist) and (+) PHNO (D-2 agonist) given independently for a minimum of 4 different doses, was studied. Subsequently a sub-threshold dose of CY 208 - 243 was given concomitantly with the (+) PHNO doses previously used. A positive interaction on the duration and intensity of the motor response was found between both drugs as reflected by a shift to the left of the (+) PHNO dose response curve. These results provide further evidence for a functional linkage of D-1 and D-2 receptors mediating motor response in primates with substantia nigra lesion.

ATTENUATION OF THE DEVELOPMENT OF BEHAVIORAL SENSITIZATION TO SYSTEMIC AMPHETAMINE BY MICROINJECTIONS OF SCH-23390 INTO THE VENTRAL TEGMENTAL AREA AND SUBSTANTIA NIGRA PARS RETICULATA. J. Stewart and P. Vezina. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montreal, Canada, H3G1M8.

We have reported that systemic administration of the D1 dopamine antagonist, SCH-23390, blocks the development of sensitization to the behavioral activating effects of amphetamine (Brain Research, in press). We now report that preexposure of rats to i.p. injections of 1.0 mg/kg d-amphetamine sulfate in the presence of microinjections of SCH-23390 (0.5 or 1.0 µg/side) into the VTA, and to a lesser extent into the SNR, attenuates the acute locomotor effects of amphetamine and blocks the development of sensitization seen in a test when only amphetamine is administered, both in a dose-dependent manner. Groups of animals were pretreated with either vehicle (VEH) or SCH-23390 (SCH) into the brain followed by amphetamine (AM) or saline (SAL) i.p. on four occasions, once every other day, and placed into activity boxes for two hours. On the tests for sensitization given two days later, all animals were treated with 0.5 mg/kg amphetamine only. These findings suggest that dopamine released from somatodendritic regions can act locally to bring about changes that may underlie the development of sensitization to amphetamine, and that SCH-23390 acts at D1 receptors in these regions to block these changes.

422.18

THE BEHAVIORAL AND NEUROCHEMICAL EFFECTS OF S-ADENOSYL-METHIONINE (SAM) IN RODENTS. J. M. Beaton, L. C. Tolbert, F. Antun* and A. M. Freeman*. Neuropsychiat. Res. Prog., Dept. Psychiat., Univ. of AL. at B'ham, B'ham., AL. 35294.

There is clinical interest in the use of SAM as an antidepressant and in the treatment of hyperactivity. We were interested in examining the effects of SAM on various mouse and rat behaviors. Several doses of SAM were tested after acute or chronic sub-cutaneous administration. Acute doses of 100,200,400 or 800 mg/kg SAM had no significant effects on analgesia, passive avoidance or open-field activity in mice. However, acute administration of SAM plus 4 mg/kg amphetamine did slightly increase the open field activity, over amphetamine alone. Chronic administration of 100,200,400 or 800 mg/kg SAM did significantly increase open-field activity in mice, after 4, 7 or 10 days of administration. The effects of 4 mg/kg amphetamine after 4 days of SAM were significantly increased over the effects of amphetamine alone. In rats with chemical lesions in the nigro-striatal dopamine pathway, treatment with 200 mg/kg SAM for 10 days, compared to saline, potentiated amphetamine (2 mg/kg) induced turning behavior. After testing, the rats were sacrificed and the caudates excised from the lesioned and intact hemispheres of both groups. The caudates were assayed for D_2 agonist binding. There was a decrease in B_{max} found in the lesioned caudates for both groups, as would be expected. An increase in B_{max} was found in the SAM treated animals in both the lesioned and non-lesioned caudates when compared to the appropriate saline control. These data indicate that SAM does modulate the dopamine system by increasing receptor density. (We acknowledge Bioresearch, S.P.A., Milan, Italy for providing the SAM).

EFFECTS OF AMPHETAMINE OR PARA-HYDROXY-AMPHETAMINE ON THE BEHAVIOR AND DOPAMINE LEVELS IN THE NEOSTRIATUM OF THE RAT

D. Chapman*, H. Obianwu* and S. Howard (SPON: D.E. Walters). MRRC, BRI, and Dept. of Pharmacology, UCLA, Los Angeles, CA 90024.

We examined the effects of pretreatment with amphetamine (AMPH) or para-hydroxy-amphetamine (P-OH-AMPH) on the ability of AMPH to release dopamine (DA) in the neostriatum and to stimulate locomotor activity or stereotyped behavior. Rats were injected with either AMPH (2 mg/kg) once daily for three days, a single dose of P-OH-AMPH (10 mg/kg) or saline (1 ml/kg) as pretreatment. On the following day DA release and behavioral responses to a challenge dose of AMPH (2 mg/kg) were examined. In vivo microdialysis samples were collected every 10 minutes and analysed for DA, DOPAC and HVA using HPLC-EC. Locomotor activity and stereotyped behavior were recorded every 10 minutes in an open field chamber equipped with photo cells. P-OH-AMPH pretreatment enhanced the release of DA compared to saline pretreatment. Both AMPH and P-OH-AMPH pretreatment decreased locomotor activity and increased stereotyped behavior compared to saline pretreatment. Pretreatment with P-OH-AMPH, a metabolite of AMPH, can enhance AMPH enduced DA release as well as produce typical behavioral changes seen with AMPH pretreatment. These results indicate that P-OH-AMPH is responsible for part of the dopaminergic and behavioral changes seen with AMPH pretreatment. USPHS Grant DA03020.

423.1

CHRONIC AND ACUTE PROGLUMIDE: ITS EFFECTS ON AMPHETAMINE INDUCED BEHAVIORS. W.E.MONTANA, M.CULLEN AND K.E.ASIN. Neurosci.Res.Div., Pharmaceutical Discovery,Dept.47H Abbott Labs., Abbott Park, Il 60064.

The CCK antagonist proglumide (PROG), given chronically, has been reported to increase the number of [3H]spiperone binding sites in the nucleus accumbens of the rat, which has also been seen after chronic administration of some neuroleptics. Given acutely, PROG has been shown to enhance haloperidol's (HAL) inhibition of apomorphine induced stereotypy. This experiment investigated the effects of chronic and acute PROG administration on dopamine mediated (amphetamine-induced) locomotion and rotation.

Adult, male rats were treated for 10 days with PROG (0, 5 or 20 mg/kg s.c.) and/or HAL (0 or 1 mg/kg s.c.). Other rats, with unilateral 6OHDA lesions of the nigrostriatal bundle, were treated for 10 days with PROG (0, 10, 20 or 40 mg/kg s.c.). Four days after the last injection rats were injected with PROG (0 or 20 mg/kg s.c.) 40 mins prior to d-amphetamine (A). Chronic, but not acute, treatment with PROG enhanced A (1 mg/kg i.p.) induced locomotion, but did not alter A (1.25 mg/kg i.p.) induced rotation. This effect of PROG was not altered by chronic coadministration of HAL. Our results demonstrate the ability of PROG to increase A induced locomotion, an effect also seen after chronic neuroleptic treatment. Furthermore, the inability of PROG to alter rotation suggest that chronic PROG may exert some of its behavioral effects through the mesolimbic, rather than nigrostriatal, dopamine system.

423.2

EFFECT OF A-68552, A CENTRALLY ACTIVE CCK AGONIST, ON CONDITIONED AVOIDANCE RESPONDING IN MICE, RATS AND MONKEYS. P. Curzon, M.D. Tufano*, A.M. Nadzan* and D.R. Britton. Neuroscience Res. Div., Pharmaceutical Discovery, Dept. 47H, Abbott laboratories, Abbott Park, ILL. 60064

A-68552 is a potent, centrally active Type A CCK receptor agonist. In mice (icv) it is 300 times as active as CCK-8-S in suppressing locomotion. CCK-8-S has been shown to reduce avoidance responding in the rat (Cohen et al.1982) at doses above 320 ug/kg i.p. We have tested A-68552, CCK-8-S as well as typical and atypical antipsychotics for disruption of avoidance responding in mice, rats and cynamologus monkeys.

In mice A-68552 was tested at up to 1000 nmol/kg i.p. with minimal disruption of the avoidance response; haloperidol was effective at 0.1 and 0.2 mg/kg i.p. In the rat A-68552 was tested on both acquisition and performance of the response both sc and icv with no significant effects. A comparison was made to both typical and atypical antipsychotics in the same paradigms. A-68552 was tested i.m. in the monkey conditioned avoidance at doses up to 200 nmol/Kg with no decrease in responding.

In summary, a potent CCK agonist fails to show antipsychotic-like activity in these preclinical tests.

423.3

EFFECTS OF THE CCK AGONIST A68552 ON AMPHETAMINE CONDITIONED ACTIVITY. K.E.Asin, L.Bednarz*, M.Tufano* & A.Nadzan*, Neuroscience Research Division., Pharmaceutical Discovery, D-47H Bldg AP10, Abbott Labs, Abbott Park, IL 60064.

A68552 is a CCK-7 analogue which we have shown to have nanomolar affinity for pancreatic CCK receptors but is more metabolically stable than is CCK. We used A68552 to investigate possible CCK/dopamine (DA) interactions in the acquisition or expression of environment specific conditioned locomotor activity (CLA) produced by d-amphetamine (Am). During 5 days of conditioning trials, male rats were injected with Am (0 or 2.5mg/kg,ip) and A68552 (0 or 100 ug/kg,ip) before being placed into locomotor activity boxes (AB) for one hour; controls received identical treatments after being removed from the boxes. On the test day, all animals were injected with either vehicle or A68552 1 min before being placed into the ABs. Compared to the appropriate control groups, Am injections prior to AB placements during conditioning produced significant CLA and rearing; these effects were not reduced by coadministration of A68552 during conditioning. However, administration of A68552 prior to testing significantly reduced both Am conditioned activity and rearing. In other animals, neither 10, 100 nor 1000 ug/kg A68552 suppressed the unconditioned locomotor response to Am. Our CLA results are directly opposite to those reported by Beninger and Hahn (1983) using the DA antagonist pimozide, and may suggest the involvement of CCK mechanisms in the expression of learned behaviors.

423.4

CCK FACILITATES ACQUISITION OF A DISCRIMINATED AVOIDANCE RESPONSE. J.Rodenhiser*, D.Grider*, M. Shuck*, and E.Quinton (SPON: R.Smith). Dept. of Psychology, University of Louisville, Louisville, Ky.40292.

The octapeptide fragment of cholecystokinin (CCK 26-33) seems to modulate a wide range of behaviors, but the data are inconsistent. We have previously shown that CCK facilitates the acquisition of passive avoidance. The present study seeks to determine whether exogenous administration of CCK can facilitate the acquisition of a multi-trial discrimination task. C57BL/6j mice were given injections of either saline or 200ug/kg of CCK-8 subcutaneously before each daily session of training (7 trials/session, 8 sessions). The task required the animal to discriminate an illuminated door from among 5 doors, and to exit through the illuminated door to escape/avoid shock. Attempts to exit through non-illuminated doors were counted as errors. Error reduction was significantly greater in the CCK group over the early sessions, although both groups were responding similarly over the last few sessions. These results suggest that CCK facilitates the acquisition of this task, and further supports the role of CCK in learning.

423.5

BEHAVIOURAL EVIDENCE THAT CHOLECYSTOKININ IS A FUNCTIONAL DOPAMINE ANTAGONIST IN THE NUCLEUS ACCUMBENS. C.Y.Yim and G.J.Mogenson, Dept. of Physiology, Univ. of Western Ont., London, Ontario, Canada, N6A 5C1.

Previous electrophysiological experiments showed that sulphated cholecystokinin (CCK) blocks the neuromodulatory actions of dopamine (DA) in accumbens (NAcc) neurones (Yim et al, Soc. Neuro. Abst. 14(1988)114). The present study investigates whether or not those observations have functional behavioural significance. Male Wistar rats were implanted with injection cannulae into the ventral tegmental area (VTA) and the NAcc. DA-mediated hyperlocomotor activity was produced by injection of picrotoxin (PIC), a GABA antagonist, into the VTA (Brain Res. 161(1979)311). The effects of simultaneous injection of CCK or its antagonist, proglumide (PRG), into the NAcc was investigated. At a dose of 25 ng, PIC produced 31% increase in locomotor activity (n=42) and at 50 ng, a 272% increase. PRG (30 ug) injection into the NAcc did not produce any significant change in activity by itself but enhanced the PIC (25 ng dose, n=25) induced activity by 17%. CCK (40 ng) injection into the NAcc produced an 18% increase in activity by itself but significantly attenuated (-36%) the PIC (50 ng, n=17) induced locomotor activity. These results show that CCK antagonizes the hyperlocomotor effects of endogenous DA, and suggest that endogenous CCK may be a functional antagonist of DA in the NAcc, a hypothesis which is consistent with conclusions from electrophysiological expts.

423.6

CCK MICROINJECTED INTO THE NUCLEUS ACCUMBENS ATTENUATES AMPHETAMINE-INDUCED FEEDING. T. L. Sills and F. J. Vaccarino. Department of Psychology, University of Toronto, Toronto, Ont., M5S 1A1.

Systemically administered d-amphetamine (AMP), in low doses, enhances intake of foods high in sucrose content. Further evidence indicates that this effect is dopaminergic and that the nucleus accumbens (Acb) may be an important site of action. Of interest here is the fact that CCK terminals exist within the Acb and that neuroleptic-like behavioral effects have been reported following intra-Acb CCK microinjections. The present study tested the effects of intra-Acb CCK on AMP-induced feeding.

Male Wistar rats were presented with both powdered chow and sugar in their home cages and baseline intake was measured for one hour each day for six days. On subsequent days, rats were taken from their home cages and injected with either saline or AMP (0.125 mg/kg) followed by CCK injections into the rostral Acb in doses of 0, 1 and 2 ng. Rats were then returned to their home cages and offered both chow and sugar; intake was recorded for one hour.

Consistent with previous results, the administration of AMP resulted in an increase in the intake of sugar relative to vehicle injection. Both doses of CCK attenuated the increase in sugar intake to the extent that intake returned to vehicle baseline levels. These results support the notion that the Acb is an important site of action for AMP-induced feeding and further indicate that Acb CCK may play a modulatory role in this effect.

This research was supported by a NSERC grant to FJV.

CHOLECYSTOKININ REDUCES BODY TEMPERATURE AND FOOD INTAKE IN VEHICLE BUT NOT CAPSAICIN PRETREATED RATS. E.H. South, R.C. Ritter and P.D. Huff*. Dept. Vet. Sci., Univ. of Idaho, Moscow, ID 83843 & Dept. of VCAPP, Washington State Univ., Pullman, WA 99164-6520.

Suppression of food intake by cholecystokinin (CCK) is a vagally mediated behavior that is abolished in rats pretreated with the sensory neurotoxin, capsaicin. We have observed that suppression of food intake by intraperitoneal CCK (4 ug/kg) is associated with reduced rectal temperature (RT) in vehicle treated (VEH) rats. Reduction of body temperature by CCK did not occur in capsaicin pretreated (CAP) rats. (Table below.)

		SALip		CCK4ugip	
TRT	MIN	RT °C.	FOOD g.	RT °C.	FOOD g.
CAP	20	0.8±0.2	2.4±0.3	0.6±0.1	3.0±0.4
VEH	20	0.3±0.3	4.0±0.7	-0.3±0.3**	1.8±0.6#

(all means ± SE; ** p<.02, RT significantly decreased;
# p<.05, food intake significantly reduced;
MIN, time post CCK or saline injection)

Additionally, there was no difference in CAP or VEH rectal temperature at 20 min post ip saline with no food present compared to 20 min with food present and consumed. This suggests that the CCK-induced rectal temperature decrease can not be accounted for by decreased feeding activity alone. These findings indicate that CCK-induced reduction of body temperature is mediated by capsaicin sensitive neurons which may be similar or identical to capsaicin sensitive neurons involved in CCK-induced satiety.

CCK-8 EFFECTS ON SLEEP AND FEEDING. A.Posadas-Andrews[1,3]*, O. Prospéro-García[2] and J.A. Rojas-Ramírez[1]* [1]Depto. Farmacología, Medicina and [2]Depto. de Neurociencias, Instituto de Fisiología Celular. [3]ENEP-Iztacala, UNAM, Apdo. Postal 70-600, México 04510, D.F. México.
(SPON: F. Velasco)

It has been reported that central or peripheral administration of cholecystokinin (CCK-8) induces sleep and inhibits food-ingestion in the rat. To study the relationship between these two behaviors, we treated normal and food-deprived rats with either saline or CCK-8 (10 ug/kg i.p.). Sleep recordings (3 h) started immediately after injection; at this time, rats had free access to food and water. CCK-8 decreased wakefulness and increased slow wave sleep (SWS) in all animals whereas REM sleep increased in sated-CCK-8 rats and did not change in the food-deprivation group. CCK-8 decreased latency to slow wave sleep, without change in REM sleep latency in sated rats, while food-deprivation-saline, reduced it, and increased latency to SWS. A combined effect was observed in the CCK-food-deprived group, CCK-8 did not modify the amount of food-ingested. We suggest that CCK-8 effect on food-ingestion may be secondary to the CCK-8-induced sleep.

NEUROPEPTIDES AND BEHAVIOR: CRF

424.1

EVIDENCE FOR INVOLVEMENT OF SEROTONIN IN BEHAVIORAL EFFECTS OF CRF. D.R. Britton, E. Indyk* and A. Lazosky*, Dept. Pharm. and Molecular Biol., Univ. Health Sciences/ Chicago Medical School, North Chicago, IL 60045.

Intraventricular (icv) corticotropin-releasing factor (CRF) elicits a variety of responses associated with "stressful" stimuli. These include suppression of eating and increased grooming. The locomotor response is enhanced in the home cage (HC) but suppressed in a novel modifiefd open field (MOF). We have examined the effects of the 5-HT depleting agent, 5,7-dihydroxytryptamine (5,7-DHT) on the subsequent response to CRF.

Male rats were given icv cannulas and injected icv with either saline or 5,7-DHT (200ug in 10ul). At least 10 days they were injected icv with saline or rCRF in doses of 60 or 120 pmol and observed for the following 60 min. in the HC or for 15 min in the MOF. In HC, 5,7-DHT alone increased locomotion to a level seen with CRF administration. There was no apparent additive effect of the two. In the MOF, animals previously give icv saline showed behavioral suppression in response to icv CRF. Animals which had been treated with 5,7-DHT were less active than the saline controls, but responded to icv CRF with increased activity. These data suggest that 5-HT plays a role in the expression of CRF-induced behavior.

424.2

EFFECTS OF CHRONIC CRF ADMINISTRATION: BEHAVIORAL, HORMONAL AND RECEPTOR CHANGES. L. Conti*, D. Costello*, R.Loftus*, L. Martin*, M.White* and M. E. Abreu*(SPON: W. Pickworth). Nova Pharmaceutical Corp., Baltimore, MD 21224.

Corticotropin releasing factor (CRF) is a physiological initiator of the stress response which includes the release of ACTH and the subsequent release of corticosterone in animals. Behaviorally, acute administration of CRF (icv) is anxiogenic in a number of models of rodent behavior including a footshock-induced freezing behavior model. We studied the effects of chronic administration of CRF (icv) on this response to footshock in rats. The ACTH and corticosterone responses to CRF were also examined in these chronically treated animals. Finally, CRF receptor binding in cortex of the chronically-treated animals was determined.

Male Sprague-Dawley rats received an icv injection of either ovine CRF (1.0ug in 5ul) or vehicle (5ul BSA 0.1% in saline) once a day for 10 days. On day 11, the two groups were divided so that half of the chronic CRF- and half of the chronic BSA-treated animals were given an acute challenge of CRF (1.0ug) 30 min prior to behavioral testing. The other half of each chronic treatment group received vehicle. For behavioral testing, animals were individually placed in a standard conditioning chamber and observed for a 7.5 min session. One and 1.5 min into this session each rat received a footshock (.5mA, .5sec) through the grid floor of the chamber. Five min after behavioral testing, rats were decapitated , trunk blood collected and brains were removed; cannula placement was verified and cortex and pituitary were taken.

Rats which were challenged with CRF spent more time freezing (immobile) after footshock than vehicle-treated animals. The response was greatest in rats which had been chronically treated with CRF.

424.3

CRF ACTS VIA A THIRD VENTRICLE SITE TO REDUCE EXPLORATORY BEHAVIOR IN RATS.
C. W. Berridge, F. Spadaro* and A. J. Dunn. Dept. Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130.

Corticotropin-releasing factor (CRF) may play a major role in coordinating the response of an organism to stress. In addition to its ability to activate the hypothalamic-pituitary-adrenal (HPA) axis, ICV CRF activates the sympathetic nervous system and cerebral catecholaminergic systems. ICV administration of CRF elicits neurochemical, physiological and behavioral responses that resemble those observed in stress. It increases locomotor activity and grooming, and decreases sexual behavior and feeding. In the multicompartment testing chamber (MCC), ICV CRF decreases the mean contact time with novel stimuli. This behavioral change resembles that observed following restraint. The CRF antagonist, alpha-helical CRF_{9-41}, reverses this effect of restraint. To determine the site of action of CRF, we injected 20 ng into the lateral or the fourth ventricle of rats using plugs of cold cream to block its access to various parts of the ventricular system. Blockade of the cerebral aqueduct prevented the behavioral response to fourth ventricle CRF, but not to lateral ventricle injections. Moreover, the response to lateral ventricle infusion of CRF was prevented when cold cream blocked its access to the anteroventral quadrant of the third ventricle (AV3V). These results indicate that the site of action of intracerebrally administered CRF on exploratory behavior in the MCC is not in the fourth ventricle, and suggest that the AV3V may be involved. This result is compatible with the sites of action of CRF in stimulating locomotor activity, and with the sites of action of other ICV-injected peptides.

SELECTIVE PROCONFLICT EFFECT OF CORTICOTROPIN-RELEASING FACTOR (CRF). E.F. Aulisi, R.G. Wehby*, J.L. Katz* and R.J. Valentino. Department of Pharmacology, George Washington University Medical Center, Washington, D.C. 20037, and NIDA Addiction Research Center, Baltimore, Maryland 21224.

CRF has been shown to suppress both punished and nonpunished food reinforced responding at similar doses. To determine whether CRF has selective proconflict effects, rats were trained to lever press for food on a multiple fixed ratio schedule in which different levels of shock were used to suppress responding. In one component of the schedule (nonpunishment), 30 responses resulted in food reinforcement (FR30). In the 2nd component (punishment), food was presented after 30 responses, however, the first lever press of the FR30 produced either a level of shock capable of suppressing responding (HS, 0.8 - 1.0 mA), a subthreshold level of shock not capable of suppressing responding (LS, 0.05-0.15 mA), or no shock (NS). These levels of shock were in effect during different sessions. The pattern of responding was such that during LS sessions, rates of both punished and nonpunished responding were similar, while during HS sessions, rates of punished responding were dramatically reduced compared to nonpunished responding. CRF (0.1 - 5.6 μg, i.c.v.) was administered 15 min prior to sessions in which LS was in effect. CRF caused a dose-dependent decrease in both nonpunished and punished responding. However, the dose-response curve for CRF effects on punished responding was shifted to the left of that for nonpunished responding. These results suggest that CRF has selective proconflict effects in rats trained on this schedule. Supported by PHS Grants MH 40008 and MH 42796.

CORTICOTROPIN RELEASING FACTOR ENHANCES THE ACOUSTIC STARTLE REFLEX: INVOLVEMENT OF THE AMYGDALA AND THE SPINAL CORD. K.C. Liang, M.J.D. Miserendino*, K.R. Melia* & M. Davis. Dept. of Psychiatry., Yale Univ., Sch. of Med., 34 Park St, New Haven, CT 06508

Corticotropin releasing factor (CRF) is implicated in stress- or fear-related behaviors. Intracerebroventricular (icv) injection of CRF enhances the startle reflex (Swerdlow et al., Psychopharmacol., 1986, 88, 147-152), but the site of action of this effect has not been localized. Previous findings indicate that the amygdala is involved in fear- or shock-potentiation of startle, and that the spinal cord mediates the startle facilitatory effects of certain drugs. Because CRF immunoreactivity and receptors are found in these structures, we investigated effects of intrathecal and intracisternal injections of CRF on startle as well as the effect of icv CRF on startle in amygdala-lesioned rats.

Startle was elicited by 95db, 50ms noise bursts (ISI=30s, background noise 55db). Fifteen min after the first stimulus, artificial CSF or CRF was remotely infused into the ventricle or lumbar spinal cord. CRF (0.5 or 1.0 µg) injected icv or intracisternally produced a profound, dose-dependent enhancement of startle, while intrathecal injection of 1.0 µg CRF produced a small increase. Lesions of the amygdala significantly attenuated the effect of icv CRF (1.0 µg). The magnitude of enhancement produced by icv CRF in the amygdala-lesioned rats was comparable to that produced by intrathecal CRF in intact rats. These findings suggest that part of the icv CRF enhancement of startle may result from a direct action on spinal neurons and that the amygdala may be the primary site of CRF action or a critical part of the neural circuitry mediating icv CRF augmentation of startle. Experiments are in progress to investigate the effects of local CRF infusions into brain regions with CRF receptors.

BEHAVIORAL DISRUPTION WITH CENTRAL ADMINISTRATION OF CORTICOTROPIN RELEASING FACTOR (CRF) IN PIGEONS IS ATTENUATED WITH REPEATED DOSING.
S. T. Ahlers, L. Zhang*, & J. E. Barrett. (SPON: D. C. Riccio) Environmental Medicine Department, Naval Medical Research Institute and Department of Psychiatry, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Intracerebroventricular (ICV) administration of o-CRF in pigeons produces dose dependent suppression of schedule controlled responding which, with repeated dosings, diminishes over 3-4 days. This tolerance effect is no longer observed after a 10 day hiatus in which CRF is not administered (Barrett et al.; JPET, in press). In the present experiment 8 pigeons were injected with 30µ/Kg o-CRF ICV either 30 min before (n=4), or just after (n=4), performing on a fixed ratio (FR) 30 schedule for food presentation for 3 consecutive days; on the 4th day all subjects received CRF before the session. A 2 week period in which CRF was not administered separated counterbalanced replication of these conditions. Over the 4 day period, pigeons that received CRF before the session displayed a gradual attenuation of the initial suppressive effects of CRF; responding on day 1 was significantly suppressed whereas responding on the forth day was not significantly different from baseline performance levels. Pigeons that received CRF after the sessions on days 1-3 and then CRF before the session on day 4 showed no suppression of responding on day 4. These data suggest generalized tolerance to the suppressive effects of CRF independent of behavioral variables. Supp. by PHS Grant DA-02873 and USARMDC Contract 86PP6814.

DOES CRF CONTRIBUTE TO THE COGNITIVE CHANGES SEEN IN DEPRESSION? T.L. Wall, R.I. Chaplin*, C.L. Ehlers. Department of Neuropharm., Research Institute of the Scripps Clinic, La Jolla, CA 92037

Recent studies have suggested that major affective episodes may be accompanied by cognitive impairment in some patients. Electrophysiological studies utilizing event related potentials (ERPs) have also reported that some late component amplitudes (P2, P3) which are associated with cognitive events are also affected during depressions. One neurohormonal factor which is known to be dysregulated in depression, and which may modify cognition is corticotropin releasing factor (CRF). In the present study we sought to evaluate the effects of CRF on ERPs in the rat in order to see whether CRF could produce changes in ERP morphology similar to those seen in human depression, using an auditory oddball plus novel ERP paradigm. Eight male Wistar rats were chronically implanted with electrodes stereotaxically placed in the frontal cortex and dorsal hippocampus (DHPC). Rats were administered saline and CRF intracerebroventricularly (ICV) in doses of 0.01, 0.1, and 1.0 µg per rat. The lowest dose of CRF (0.01 µg) produced significant reductions in the amplitude of the P2 component in cortex. Larger doses of CRF produced increases or no change in the P2 amplitude in cortex and significant dose dependent decreases in the P2 and P3 components in DHPC. These data are consistent with the idea that increases in CRF activity may contribute to the cognitive changes seen in depression. (Supported my NIAAA 00098, 06059, and the MacArthur Fnd.)

424.8

REVERSAL OF A NONMONOTONIC RELATIONSHIP BETWEEN FOOTSHOCK OR CRF AND THE ACOUSTIC STARTLE REFLEX BY BRIEF EXPOSURE TO A MILD STRESSOR. K.R. Melia*, K.C. Liang, M.J.D. Miserendino*, M. Davis. (SPON: T. Baker). Dept. of Psychiatry, Yale Univ. Sch. of Med., 34 Park St., New Haven, CT 06508.

Acute and chronic stressors potentiate the acoustic startle response in a number of species. The present study evaluated the relationship between the intensity of a stressor and subsequent modulation of startle amplitude using two different stressors: footshock and intraventricular (ICV) injections of the stress related peptide, corticotropin releasing factor (CRF).

Three groups of rats received ten 500 ms shocks (1/5 min) per day on 3 consecutive days. Shock intensity was 0.2, 0.6 or 1.4 mA depending on group. Startle amplitude was tested 2 days later in the chamber where shock had been presented. Other groups received ICV infusion of 0.1, 1.0 or 10.0 µg CRF and startle amplitude was measured over the next hour. A nonmonotonic relationship was found between both footshock intensity and CRF concentration and startle amplitude. Specifically, experience with 0.6 mA footshock or infusion of 1.0 µg CRF significantly facilitated startle amplitude whereas both higher and lower levels of shock or concentrations of CRF did not. Most striking is that a mild stressor (sub-cutaneous saline injection or mild, brief footshock) presented 15 min prior to testing produced a marked enhancement of startle amplitude only in animals exposed to 1.4 mA shock or 10.0 µg CRF resulting in a monotonic relationship between startle and the intensity of prior stress. Thus, the apparent inability of high levels of stress to potentiate startle is due to the active inhibition of an underlying facilitatory effect which can be released by mild stress.

NEUROPEPTIDES AND BEHAVIOR: OXYTOCIN AND VASOPRESSIN

425.1

EFFECTS OF HEXAPEPTIDE METABOLITES OF VASOPRESSIN (AVP) AND OXYTOCIN (OT) ON SPATIAL MAZE PERFORMANCE, FEAR CONDITIONING, AND BRAIN CATECHOLAMINE LEVELS IN THE RAT. J.D. Stoehr*, C.P. Cramer and W.G. North*, Department of Physiology, Dartmouth Medical School and Department of Psychology, Dartmouth College, Hanover, NH 03756.

It has been previously shown that AVP enhances while OT attenuates certain behavioral processes such as learning and memory (deWied, 1987). In the present studies we investigated the influence of C-terminal fragments of these peptides on brain neurotransmitter levels and their possible effects in other behavioral paradigms.

Intracerebroventricular administration of 0.5 pg AVP (4-9) hexapeptide had no apparent effect on the acquisition of a food reward on the eight-arm radial maze. There was no significant difference between AVP (4-9) and saline-treated animals in the number of spatial memory errors that occurred within each day's first eight arm choices; subsequent central treatment with 1 pg OT (4-9) had no significant effect on the number of errors after a previous error-free criteria had been reached.

However, both post-training and pre-retention peripheral injections of 0.3 µg of these hexapeptides significantly altered observable defensive freezing behavior of rats placed in conditioning chambers that 24 hours previously were paired with footshock. OT (4-9) treated animals froze significantly less, 12-16% of time observed, than controls, 27-29% and AVP (4-9) treated animals, 38%. Because AVP (4-9) alone, without shock, did not elicit freezing, and both peptides were effective when administered post-training, it is possible that they are affecting memory processes and not emotional or autonomic responses.

Further studies revealed that subcutaneous injections of 0.3 µg AVP hexapeptide significantly alters catecholamine turnover in certain limbic structures of the brain as determined by HPLC analysis. For instance, AVP (4-9) treatment increased the content of norepinephrine in the central amygdala and substantia nigra, dopamine and 5-HT in the hippocampus, and lowered norepinephrine in the locus coeruleus.

These studies indicate that the hexapeptide metabolites of oxytocin and vasopressin selectively modulate certain behaviors and possibly exert these effects through a mechanism that includes altering brain amine levels.

425.2

CHRONIC CENTRAL ADMINISTRATION OF VASOPRESSIN ANTAGONIST HASTENS EXTINCTION OF CONDITIONED TASTE AVERSION IN RATS. M. D. Brot, I. L. Bernstein and D. M. Dorsa. GRECC, VA Med. Ctr., and Depts. of Psychology, Pharmacology, and Medicine, Univ. of Washington, Seattle, WA 98108

The neuropeptide vasopressin (AVP) has been implicated as a memory enhancing hormone in studies of passive and active avoidance. Previous studies administering AVP in a single dose intraventricularly have shown facilitated learning. Conversely, the centrally active AVP receptor antagonist $d(CH_2)_5Tyr(Me)AVP$ impairs memory processes when injected acutely. In this study, we have examined the effect of chronic central treatment with AVP or its antagonist on retention using a conditioned taste aversion (CTA) paradigm.

Male rats were chronically administered AVP, antagonist, or saline via an Accurel device implanted in the lateral ventricle. Two weeks after implantation the three groups were tested in a conditioned taste aversion paradigm for 3 weeks. AVP-antagonist-treated rats showed a more rapid extinction of aversions than the other 2 groups during the 2nd and 3rd weeks, indicating impaired memory for the aversion. There was no difference between AVP-treated and control rats. These results offer additional evidence for the involvement of AVP in learning and memory processes as measured by the CTA paradigm.

425.3

COORDINATION OF HAMSTER LORDOSIS AND FLANK MARKING: ROLE OF ARGININE VASOPRESSIN (AVP) WITHIN THE MEDIAL PREOPTIC-ANTERIOR HYPOTHALAMUS (MPOA-AH). S. Rawls* & H.E. Albers (SPON: R. Sridaran). Lab. Neuroendocrinol. & Behav., Depts. Biol. & Psychol., Georgia State Univ., Atlanta, GA 30303.

The present study examined whether AVP within the MPOA-AH is involved in controlling the inverse relationship between lordosis and flank marking normally observed during the estrous cycle. AVP, but not saline microinjected into the MPOA-AH of ovariectomized (OVX) hamsters stimulated high levels of flank marking during tests with a sexually experienced male, or when tested alone. In contrast, AVP microinjected into the MPOA-AH of OVX hamsters given estradiol benzoate (EB) and progesterone (P) did not stimulate flank marking or inhibit lordosis during tests with a male. However these same females exhibited high levels of flank marking in response to AVP when tested alone. A second experiment demonstrated that P was not required for inhibition of AVP induced flank marking in OVX females given EB and tested with males. The present study provides no evidence that AVP acts within the MPOA-AH to inhibit lordosis, but demonstrates that ovarian hormones and male social contact block the induction of flank marking by AVP microinjected into the MPOA-AH. These data suggest that one component in the neural coordination of lordosis and flank marking is inhibition of the response of the MPOA-AH to AVP. (Supported by NSF BNS-8711373).

425.4

LOCALIZATION OF ARGININE VASOPRESSIN (AVP) INDUCED FLANK MARKING IN THE FEMALE HAMSTER HYPOTHALAMUS. W.T. Solomon*, S.Y. Liou*, & H.E. Albers (SPON: K. Wallen). Lab. Neuroendocrinol. & Behav., Depts. Biol. & Psychol., Georgia State Univ., Atlanta, GA 30303.

Microinjection of AVP into the hamster hypothalmus induces intense bouts of flank marking (FM) behavior. Mapping studies of AVP responsive sites in males have shown that AVP acts within the medial preoptic-anterior hypothalamic continuum (MPOA-AH). Since the MPOA-AH is sexually dimorphic the present study examined the sites where AVP induces flank marking in females. Female hamsters (n=21) were stereotaxically implanted with a guide cannula aimed at sites ranging from 2.2mm anterior to 0.1mm posterior to bregma. After surgical recovery, each animal was tested for AVP (9uM in a 20nl saline) induced FM during a 10 min test. Following the experiment the brains of all animals were histologically prepared to determine the site of AVP injection under light microscopy. The amount of flank marking observed ranged from 0-76/10 min. Forty-three% of the sites injected produced no response (0-5FM); 14% produced a partial response (6-19FM); and 43% produced a full response (>20FM). Sites producing full and partial FM responses were found throughout the MPOA-AH continuum. In summary, these data confirm that AVP stimulates flank marking in female hamsters, and suggests that the site of AVP action is similar to that in male hamsters. (Supported by NSF BNS-8711373).

425.5

NEUROPEPTIDES, PASSIVE AVOIDANCE BEHAVIOR AND THE IMMUNE SYSTEM. G. CROISET*, C.J. HEIJNEN* AND D. DE WIED* (SPON: A. Croeze). Rudolf Magnus Institute for Pharmacology, Medical Faculty, University of Utrecht, the Netherlands.

The impact of emotional stimuli on the reactivity of the immune system was studied in rats. To that end a one-trial learning passive avoidance test was chosen. As an in vivo immunological parameter a primary antibody response against Sheep Red Blood Cells (SRBC)(number of antibody secreting cells in the spleen (PFC)) was used.

Exposure of rats to the passive avoidance apparatus resulted in an increase in primary antibody response (apparatus control group). A decrease in primary antibody response was demonstrated in rats that showed passive avoidance behavior; an inverse relationship between avoidance latencies and the magnitude of a primary antibody response was observed.

Neuropeptides affect avoidance behavior. The effect of altered avoidance behavior, as a consequence of neuropeptide administration, on the immune response was studied. DGAVP facilitated avoidance behavior (avoidance latency control 62 sec. vs DGAVP treated rats 300 sec.; in DGAVP treated rats a decrease in number of PFC's was observed (control 930.10^6 PFC vs DGAVP treated rats 403.10^6 PFC). ACTH(4-10) also facilitated avoidance behavior (avoidance latency control 49 seconds vs ACTH(4-10) treated rats 300 sec.) in these rats however the inverse relationship between avoidance latency and number of PFC was disturbed (control 1300.10^6 PFC vs ACTH(4-10) treated rats 1900.10^6 PFC). CRF, intracerebroventricular administered, attenuated passive avoidance behavior (control 300 sec. vs CRF treated rats 44 sec.); in CRF treated rats an increase in number of PFC was observed (control 125.10^6 PFC vs CRF treated rats 425.10^6 PFC).

The involvement of the autonomic system in modulating the immune response will be discussed.

425.6

VASOPRESSIN-SENSITIVE NEURONS IN THE LATERAL SEPTUM AND BED NUCLEUS OF THE STRIA TERMINALIS ARE INVOLVED IN THE CONTROL OF FLANK MARKING BEHAVIOR IN GOLDEN HAMSTERS. R.W. Irvin*, P. Szot, D. Dorsa, C.F. Ferris. Physiology Dept., Univ. Mass. Med. Ctr., Worcester, MA 01655

It is known that the microinjection of arginine vasopressin (AVP) into the lateral septum, an area shown to have a high density of V1-receptors, has a pronounced effect on memory consolidation and temperature regulation in rats. The present study showed that microinjections of AVP into the lateral septum (LS), as well as the bed nucleus of the stria terminalis (BNST) were able to stimulate flank marking, a form of olfactory communication that functions to maintain dominant/subordinate relationships in hamsters. Microinjections of AVP (1ng/100nl), but not oxytocin or angiotensin, into the LS and BNST significantly elevated flank marking behavior, while microinjections outside these immediate areas were ineffective. In vitro receptor autoradiography showed a clear relationship between the effective sites of microinjection and the density of V1-receptors. It would appear that vasopressin-sensitive neurons in the LS and BNST are necessary for the expression of naturally-elicited flank marking since the microinjection of a V1-receptor antagonist into these sites was able to temporarily block flank marking triggered by the odors of conspecifics. Work was supported by grant #NS23657.

425.7

CONCENTRATIONS OF ARGININE VASOTOCIN (AVT) ARE SEXUALLY DIMORPHIC IN AMPHIBIAN BRAIN. S.K. Boyd* and F.L. Moore (SPON: R. Kingsley). Univ. of Notre Dame, Notre Dame, IN 46556 and Oregon State Univ., Corvallis, OR 97331.

Since the peptide AVT is a potent activator of reproductive behaviors in amphibians, we used Palkovits' microdissection technique combined with RIA (Zoeller & Moore, Neuroendo. 42:120, 1986), to determine concentrations of this peptide in the brain of two species of amphibians.

Brains were collected from sexually mature bullfrogs (Rana catesbeiana; n=10/sex) and rough-skinned newts (Taricha granulosa; n=12/sex). In bullfrogs, AVT concentrations were significantly greater in males, compared to females, in the amygdala pars lateralis, optic tectum, and tegmentum. Concentrations of AVT in the bullfrog nucleus of the solitary tract were significantly greater in females, however. In the newt, AVT concentrations were significantly greater in males in the tectum and interpeduncular nucleus.

In conclusion, concentrations of AVT are sexually dimorphic in some regions of the bullfrog and newt brain. AVT in these regions may play a role in the control of sexually dimorphic behaviors in these species. (Supported by NIH HD24653 and HD13508.)

425.8

REGULATION OF BRAIN OXYTOCIN RECEPTOR BINDING BY ESTRADIOL AND BY PROGESTERONE. H. Coirini, M. Schumacher and B.S. McEwen. The Rockefeller University, New York, N.Y. 10021

We have previously shown that progesterone (P) increases the area of oxytoxin (OT) receptor binding within the ventromedial hypothalamus in estrogen primed female rats by using the method of quantitative receptor autoradiography. Estradiol (E) induces OT binding within the ventromedial nuclei of the hypothalamus and surrounding area. P in turn causes the induced OT receptors to spread over OT fibers. By using the OT anatagonist [$d(CH_2)^5$, $[Tyr(Me)]^2$, Thr^4,$Tyr\text{-}NH_2^9$]-[I^{125}]OVT as a ligand, we recently found that the P-dependent spread of OT receptors is not limited to the ventromedial hypothalamus but that P treatment also causes a 80% increase in the area covered by OT receptors within the central amygdala. These results show that the P-dependent spread of OT receptors corresponds to a general mechanism of P action which can be observed within different hormone sensitive brain regions. The spread of OVT binding in both brain regions is dependent on the priming with estrogen and is rapid as it occurs within 4h of P administration.

425.9

BASAL FOREBRAIN FACILITATION OF LORDOSIS BY OXYTOCIN IS BLOCKED BY A UTEROTONIC ANTAGONIST. Caldwell, J.D., Barakat, A.S., Hruby, V.J.*, Smith, D.D.* and Pedersen, C.A. BSRC and Dept. of Psychiatry, Univ. of North Carolina, Chapel Hill, NC 27599-7250

In this study we compared the effects of equal doses of utero-tonic, antidiuretic or vasopressor antagonist analogues in blocking the facilitative effects of simultaneous infusions of oxytocin (OXT). Ovariectomized estrogen-treated animals were infused through chronic bilateral cannulas in the basal forebrain with 500 ng OXT alone or in combination with a uterotonic, antidiuretic or a vasopressor antagonist analogue. OXT significantly increased lordosis responding 20 and 40 minutes after its infusion into the medial preoptic area (MPOA) or anterior hypothalamus (AH) when compared to the receptivity of normal saline vehicle infused animals. The uterotonic antagonist significantly blocked the facilitation seen after OXT. The vasopressor and antidiuretic antagonists had no effect on the OXT-induced facilitation of lordosis postures. The vasopressor antagonist facilitated sexual receptivity 90 minutes after infusion. This work confirms our earlier finding that OXT infusions into the MPOA-AH were facilitative to female sexual receptivity (Beh. Neurosci. 103:671). The facilitative effect of OXT on receptivity appears to be mediated by central uterine-like receptors which may have a separate CNS site from inhibitory vasopressor receptors.

425.10

SENSITIVITY OF BRAIN OXYTOCIN RECEPTORS TO OVARIAN STEROIDS. M. Schumacher, H. Coirini, D.W. Pfaff and B.S. McEwen. The Rockefeller University, New York.

In estrogen primed females, progesterone (P) increases the area covered by OT receptors within the ventromedial hypothalamus (VMH) . This spread of OT receptors may be a key step to the facilitation of female mating as the infusion of OT into the VMH only facilitates lordosis behavior in female rats primed with both estradiol benzoate (EB) and P. By using the OT antagonist $[d(CH_2)^5,[Tyr(Me)]^2, Thr^4, Tyr\text{-}NH_2{}^9]$-$[^{125}I]$OVT as a ligand, we found that the area covered by OT receptors within the VMH of EB and P primed females is 60% larger in the the mid-dark (D) phase than in the mid-light (L) phase of the light cycle. If the spread of OT receptors is important for the facilitation of lordosis behavior, OT should be behaviorally more efficient during the D phase when the area covered by OT receptors is greatest. The infusion of a large amount of OT (1 ug) into the third ventricle of EB+P primed unanesthetized rats facilitates lordosis behaviour with the same efficiency during the L phase and during the D phase. However, the ICV administration of a smaller amount of OT (200 ng) only facilitates the lordosis reflex during the D phase. Thus, behavioral and endocrine changes correlated with the light cycle could interact with the OT effect.

REGULATION OF AUTONOMIC FUNCTIONS V

426.1

ALTERED NEURONAL CONTENT OF CALCITONIN GENE-RELATED PEPTIDE IN LAMINAE I AND II IN THE SPONTANEOUSLY HYPERTENSIVE RAT. K. N. Westlund, D. J. DiPette, O. B. Holland, The Marine Biomedical Institute and University of Texas Medical Branch, Galveston, TX 77550

Calcitonin gene-related peptide (CGRP), produced by alternative processing of the primary transcript of the calcitonin gene, is a potent vasodilator. We have shown that dietary calcium deficiency significantly decreases the neuronal content of CGRP in laminae I and II of the dorsal horn of the spinal cord in the growing rat. To determine if the neuronal content of CGRP is altered in the spontaneously hypertensive rat (SHR), a model characterized by calcium deficiency, neuronal CGRP was localized immunocytochemically. The density of immunocytochemical staining was quantitated by computer-assisted image processing of laminae I and II of the upper thoracic spinal cord of 12-14 week old male SHR (n=4) and Wistar-Kyoto (WKy)(n=4) normotensive, control rats. The SHR had significantly decreased neuronal CGRP content compared to the WKy rats (107±5 vs 121±6 arbitrary units, $p< 0.01$). In contrast, the neuronal density of substance P, which frequently co-exists with CGRP in this neuronal population, was not different between the two groups (SHR: 91±6 vs WKy: 88±3 arbitrary units). As expected, the SHR had a significantly higher tail-cuff systolic blood pressure than the WKy rats (214±10 vs 147±9, $p<0.001$; ± SEM). In conclusion, SHR have decreased neuronal content of CGRP which appears to be specific for CGRP since substance P was not altered. Therefore, this reduction of a potent vasodilator may contribute to the hypertension. Supported by NIH grant NS11255 and Am. Heart Assoc., TX Affiliate Grants 87R-654 and 88G-663.

PARABRACHIAL EFFERENTS INFLUENCE BOTH ANGIOTENSIN AND BLOOD PRESSURE SENSITIVE NEURONS IN AREA POSTREMA. S. Papas* and A.V. Ferguson. (SPON:V.C. Abrahams) Dept.of Physiology, Queen's University, Kingston, Canada K7L 3N6

The area postrema (AP) is a circumventricular organ which has been strongly implicated in autonomic regulation. Previous electrophysiological studies have characterized subpopulations of AP neurons specifically influenced by systemic angiotensin-II (AII) (AII-sensitive), or by changes in blood pressure (BP-sensitive). We have also established a variety of orthodromic influences on rat AP neurons from the parabrachial nucleus (PBN). The present investigation was undertaken to determine any functional relationship between these groups of AP neurons and the orthodromic inputs from the PBN. A stimulating electrode was positioned in the PBN of anaesthetized Sprague Dawley rats. Single unit activity was recorded in the AP and peristimulus histograms used to determine initial effects of PBN stimulation on a total of 127 AP neurons. Thirty of these cells were also classified as being either AII-sensitive (responding specifically to i.v. AII) or BP-sensitive (responding specifically to changes in BP). Neurons responding differently to AII and BP changes were placed in both the AII- and BP-sensitive groups. Twenty-five percent of AII-sensitive cells (n=12) were excited by PBN stimulation (latency 20-40 ms, duration 10-340 ms) while 8% showed an inhibitory response (latency 80 ms, duration 110 ms). Of the 13 cells determined to be BP-sensitive, an equal number (23%) exhibited excitatory (latency 20-40 ms, duration 10-40 ms) and inhibitory (latency 10-80 ms, duration 110-160 ms) responses. In both AII- and BP-sensitive groups, remaining neurons were unaffected by PBN stimulation. Nine cells were not influenced by AII or BP changes. Of these neurons (78%) were unaffected by PBN stimulation, 11% were excited (latency 8 ms, duration 10 ms) and 11% were inhibited (latency 8 ms, duration 60 ms). These data suggest the existence of a variety of PBN influences on both AII and BP sensitive neurons in the AP. They indicate however that there is no differential PBN innervation of these two functionally separate groups of AP neurons.

RESPONSES OF RAPHESPINAL NEURONS TO CORONARY ARTERY OCCLUSION. **A.R. Evans* and R.W. Blair. Dept. Physiol., Univ. Okla. Hlth. Sci. Ctr, Oklahoma City, OK, 73190.**

The excitatory response of spinothalamic and spinoreticular neurons to coronary artery occlusion (CAO) can be inhibited by stimulation of the raphe nuclei. The purpose of this study was to determine whether raphespinal neurons (RAS) respond to separate CAO of the left anterior descending (LAD) and circumflex (CX) coronary arteries. Extracellular potentials were recorded from RAS in 20 α-chloralose-anesthetized cats. Twenty-three RAS were examined for responses to CAO (duration 35 s) of the LAD and/or CX arteries. Thirteen responses out of 37 occlusions were observed. Ten responses were inhibitory; neuronal activity decreased from 13.7 ± 5.9 to 9.6 ± 4.8 spikes/s for occlusion of CX (N=6) and from 13.4 ± 9.6 to 9.6 ± 7.9 spikes/s for occlusion of LAD (N=4). Three RAS were excited by CAO. Of the 14 RAS tested for responses to CAO of both arteries, 3 exhibited qualitatively different responses to CAO of each artery, and 11 showed similar responses. Results indicate that 1) some RAS are responsive to CAO, 2) the primary response is inhibition, and 3) some RAS are differentially responsive to CAO of separate arteries. (Supported by grant OK-87-G1 from Okla. Affiliate of AHA, and NIH grant HL29618).

A ROLE FOR SYMPATHOEXCITATORY VENTROLATERAL MEDULLARY NEURONS IN THE PRESSOR REFLEX TO MUSCULAR CONTRACTION. R.M. Bauer, G.A. Iwamoto and T.G. Waldrop, Departments of Physiology & Biophysics and Veterinary Biosciences, Univ. of Illinois, Urbana, IL 61801

Studies from this laboratory have shown that the pressor reflex to muscular contraction (MC) is attenuated following microinjections of an excitatory amino acid antagonist into the ventrolateral medulla (VLM) and the firing patterns of VLM neurons are altered during MC. The purpose of the present study was to determine if the firing patterns of VLM neurons which are altered during MC show a temporal correlation with peaks in sympathetic discharge (SND). In anesthetized cats, stimulation of L7 and S1 ventral roots induced hind limb MC. Extracellular single unit activity was recorded from 45 VLM neurons with microelectrodes positioned 1-3 mm rostral and 4 mm lateral to obex and 4.5-5.5 mm below the dorsal medullary surface. Temporal relationships between VLM units and SND were examined at rest. Computer averages of SND demonstrated that bursts of SND slow wave activity occurred 106±6 ms after unit discharge in 26 VLM neurons. MC elicited 70% or greater increases in firing frequency in 20 of 26 VLM neurons which showed temporal correlations with SND. Similar results were observed in baroreceptor intact and barodenervated cats. These results suggest that 1) MC evokes increased firing rates in VLM neurons related to SND 2) VLM neurons which may modulate sympathetic drive participate in the pressor reflex to MC.

CYTOSKELETAL PROTEINS IN POSTGANGLIONIC NEURONS AND SIF CELLS IN THE CARDIAC PARASYMPATHETIC GANGLION OF NECTURUS. T.W. McKeon and R.L. Parsons. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

Two cells types are present in the cardiac ganglion of Necturus maculosus (mudpuppy): postganglionic parasympathetic neurons (principal cells) and small-intensely-fluorescent (SIF) cells. Principal cells have one major process and are considered "adendritic" whereas SIF cells have several processes. The present study was done to determine whether processes of these cell types contained axonal or dendritic cytoskeletal proteins. Control and deafferented cardiac ganglia were labelled using immunofluorescence techniques with antisera for either the high molecular weight forms of microtubule associated protein-2 (AP14; a gift from L.I. Binder) or for the phosphorylated form of the H and M subunits of neurofilament protein (SMI31). AP14 has been shown previously to label cell bodies and dendrites, whereas SMI31 preferentially labels axons. Identification of SIF cells was confirmed by double labeling with a serotonin antibody. In control and deafferented cardiac ganglia, principal cell somas and several hundred microns of their processes were labeled with AP14, but SIF cells and processes did not label. SMI31 labeled many axons in the cardiac ganglion but did not label the principal cell somas or their proximal processes. Following deafferentation, principal cell somas and proximal processes labeled with SMI31. SIF cells and their processes were not labelled with SMI31 in control or deafferented ganglia. These results indicate (1) SIF cells in the mudpuppy cardiac ganglion do not contain the same cytoskeletal proteins as the principal cells, (2) the proximal part of the principal cell process contains dendrite-like proteins, and (3) deafferentation promotes expression of phosphorylated forms of neurofilaments in parasympathetic postganglionic neurons. HYPOTHALAMIC-MEDIATED WITHDRAWAL OF SYMPATHETIC TONE IN RAT MUSCLE MICROCIRCULATION. R.W. Stremel*, J.W. Brock* and I.G. Joshua* (SPON: A.E. Jimenez). Dept. of Physiol. & Biophys., Univ. of Louisville, Louisville, KY 40292.

Activation of the posterior hypothalamus (PH) of the rat induces locomotion, tachycardia, hypertension, hyperventilation, and vasodilation within striated muscle; changes consistent with activating the "central command" for exercise. The purpose of this study was to determine the mechanism by which PH activation induces this microvascular dilation. Male Sprague-Dawley rats (190-290 gm) were anesthetized with pentobarbital (50mg/kg, ip) and the cremaster muscle was suspended in a tissue bath of Ringers solution. Arterioles (12-23μ) were observed by television microscopy while diaphragmatic EMG activity, blood pressure and heart rate were monitored. Bicuculline Methiodide (250ng/50nl) was microinjected into the PH before and after local blockade of β-adrenergic receptors (n=4) and substance-P receptors (n=5). To eliminate reflex dilation due to respiratory changes and/or local vasodilator metabolites from locomotion during PH activation, animals (n=6) were paralyzed and ventilated. PH-induced vasodilation was blocked only by local addition of 6-OHDA, eliminating changes in α-adrenergic activity (n=6). Thus the mechanism for the vasodilatory response to the "central command" for exercise in the rat is due to the withdrawal of sympathetic tone from the microcirculation. MATURATION OF CORRELATIONS BETWEEN PHYSIOLOGICAL MEASURES ACROSS SLEEP-WAKING STATES IN NORMAL INFANTS. V.L. Schechtman, R.M. Harper and K.A. Kluge*. Brain Research Institute and Department of Anatomy and Cell Biology, UCLA, Los Angeles, CA 90024.

Coordination between physiological measures has been suggested to be an index of physiologic maturity in infants. We examined the developmental patterns of correlations between physiological measures in full-term infants over the first 6 mo of life. Twelve-hr physiological recordings were obtained from 23 normal full-term infants at 1 wk and at 1, 2, 3, 4, and 6 mo of age. Each minute of data was classified as quiet sleep, rapid eye movement (REM) sleep, or waking by two trained observers. Pearson's r was used to assess the minute-by-minute correlations between heart rate and respiratory rate, heart rate and respiratory variability, and respiratory rate and respiratory variability during each sleep-waking state in each recording. The maturational patterns of the correlations were examined visually and assessed by 2-way (age x state) analysis of variance. Different developmental patterns were observed in each sleep-waking state. In quiet sleep, the correlations weakened over the first month of life, increased from 1 to 3 mo, then plateaued. In REM sleep, correlations tended to become stronger from birth to 3 mo, then correlations between heart rate and respiratory measures decreased while respiratory rate by respiratory variability continued to become more strongly correlated through 6 mo. During waking, all correlations increased from birth to 2 mo and decreased from 2 to 4 mo. The correlations between each of the three pairs of measures showed significant age x state interactions. The different developmental patterns suggest that over the first 6 mo of life, the coupling of physiological systems proceeds differently in each sleep-waking state. Supported by HD22506 and HD22695.

TRIGEMINAL PROJECTIONS FROM THE UPPER RESPIRATORY TRACT IN THE MUSKRAT. W. M. Panneton. Dept. of Anatomy & Neurobiol., St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

The upper respiratory tract (URT) serves as the first line of defense against inhaled irritants and is innervated by the ethmoidal, glossopharyngeal (IX), and superior laryngeal (SLN) nerves. The primary afferent projections of these nerves to the trigeminal sensory complex were studied using the transganglionic transport of a mix of HRP solutions injected into the respective peripheral nerves.

The ethmoidal nerve projected densely into ventrolateral laminae I&II and V of the rostral medullary dorsal horn (MDH), the ventral paratrigeminal nucleus (vPara V), and ventromedial parts of the subnuclei interpolaris (TrSi), oralis (TrSo), and the principal nucleus (PV). A more sparse projection to the dorsomedial TrSo also was seen. The pharyngeal branch of IX sends dense projections to laminae I&V of the MDH and the ventral and dorsal ParaV and sparse projections to TrSi and dorsal parts of the TrSo and PV. The SLN also projects to lamina I&V of the MDH and the ventral and dorsal parts of the ParaV; a sparse projection to the medial edge of TrSi was noted. In addition, the nucleus solitarius was labeled in SLN and IX cases, and the reticular formation in all cases.

Thus, afferent fibers from the URT have convergent projections to lamina I&V of the MDH and the ParaV; secondary neurons in these areas may be important for the cardiorespiratory adjustments seen after URT stimulation. Supported by NIH: HL38471.

RESPIRATORY EFFECTS OF ENDOTHELIN 3 IN CONSCIOUS RATS AFTER INTRACEREBROVENTRICULAR (icv) ADMINISTRATION. S. Vonhof, G. Feuerstein and A.- L. Sirén (SPON: T. P. Jacobs), Dept. Neurology, USUHS, Bethesda, MD 20814

Binding sites for the endothelium derived peptide, endothelin, were recently described in the rat brain. Moreover, modifications of cardiovascular functions were reported upon icv administration. In order to investigate the respiratory effects of endothelin icv, we measured changes of ventilation rate (VR) and relative tidal volume (rV_T) in conscious, unrestrained Sprague-Dawley rats after icv doses of endothelin 3. Prior to the experiment, guide cannulas were implanted over the right parietal cortex (AP -0.8, L -1.2) under halothane anesthesia. The animals were allowed to recover for at least 24 hours. VR and rV_T were measured in the Oxymax 85 system (Columbus Instr.) after icv injections of 0.1, 0.3, 1, and 2 nmoles/kg doses of endothelin 3 in a volume of 15 µl. Curve integrals of the changes were calculated and used for statistical evaluation. While VR in all groups was not significantly different from control (saline), rV_T increased dose dependently by 58%, 122%, 263% ($p< .005$), and 319% ($p<.005$) compared to saline, leading to a dose dependent increase of the relative ventilatory minute volume of 48%, 214%, 328% and 482% ($p<.05$). The results indicate that endothelin stimulates ventilation and may imply a role for endothelin in the central cardioventilatory control.

MEDULLARY CONTROL OF BRONCHIAL SMOOTH MUSCLE TONE IN GUINEA PIGS: IDENTIFICATION OF A BRONCHOCONSTRICTOR SITE. J. A. Hey, M. del Prado and R. W. Chapman, Schering-Plough Corp., Bloomfield, NJ.

The role of the CNS in control of airway smooth muscle tone is poorly defined. In fact, the autonomic nuclei that govern bronchomotor tone have not been identified. To investigate the role of the medulla on airway smooth muscle tone we measured changes in pulmonary insufflation pressure (PIP) following bilateral electrical stimulation of the medulla in anesthetized ventilated guinea pigs. Blood pressure was measured to determine cardiovascular responses to CNS stimulation. Stimulation of the medulla (10s, 32 Hz, 50-700 μA) elicited an intensity-dependent increase in PIP and hypertension. The greatest increase in PIP (567 $\pm$ 19% at 700 μA) occurred at: A 1.5-3.0 mm, L 1.5 mm and V 1.0-1.2 mm from obex. The CNS-induced increase in PIP was halved by unilateral vagotomy, abolished by bilateral vagotomy and blocked in a dose-dependent fashion by the muscarinic antagonist ipratropium (1 and 10 μg/kg iv). Neither vagotomy nor ipratropium blocked the hypertension due to CNS-stimulation. In contrast, spinal section with lidocaine blocked the hypertension but not the increase in PIP. These results identify a bronchoconstrictor site in the medulla, which projects to the lungs via an efferent, cholinergic pathway. It is speculated that this medullary bronchomotor area is an important site of convergence for reflex and supramedullary bronchoconstrictor pathways in the brain.

OSCILLATIONS IN BREATHING PRESSURE OR FLOW RECORDS DUE TO AIRWAYS SMOOTH MUSCLE ACTIVITY. J. García Ramos. Lab of Neurophysiology. University of Querétaro Medical School. México.

Breathing pressure or flow oscillations can be recorded in the conscious man or anesthetized cat and dog. Since irregularities in these records may be caused by events taking place in upper air ways or extrapulmonary organs (heart, muscles) or be artifacts introduced by the recording system, experimental observations were made to exclude or control such possibilities. It was found that the irregular oscillations depend mainly from sympathetic activity: They are exxagerated by a deep inspiration, the Valsalva maneuver, carotid occlusion, cold or painful stimulation, cigarette smoking, moderate asphyxia, and emotional situations in man. Conditions when sympathetic activity are also detected in other effectors (P.G.R., superficial veins, heart rate, and nictitating membrane). Furthermore, these oscillations appear in animals with the chest open, persist after the double vagotomy, but disappear after removal of both stellate ganglia with part of the thoracic chain. It is inferred that these oscillations represent physiological activity and it is related to events occurring in bronchial smooth muscle. That activity depends from sympathetic action.

426.12

MECHANISMS OF THE ACTION OF ACETYLCHOLINE ON GLOMERULAR ULTRAFILTRATION IN THE RABBIT. X. LIU*(SPON: Jon M. Walro). NEUROBIOLOGY DEPT., N.E. OHIO COLLEGE OF MED., ROOTSTOWN, OH 44272

Acetylcholine was injected into the renal artery to examine its effect on the glomerular ultrafiltration and the renal autoregulation in rabbits. First, acetylcholine injection produced variable changes: the renal blood flow(REF) increased greatly(40%). While the ultrafiltration coefficient(Kf) decreased dramatically(38%). Both afferent and efferent arteriolar resistance(Ra & Re) decreased. Because of these offsetting effects, Glomerular filtration rate(GFR) was unchanged. Then MnCl2 was injected and the contraction of mesangial cells was blocked. In such conditions, the injection of acetylcholine failed to reduce Kf, but RBF, RA, RE had the similar changes as before. Moreover, GFR increased significantly (30%). These data gave direct demenstration that Kf is a key factor of dissociation between autoregulation of renal blood flow and glomerular filtration rate.

EPILEPSY: BENZODIAZEPINES AND INHIBITORY AMINO ACIDS

427.1

CENTRAL BENZODIAZEPINE RECEPTOR CHANGES IN THE p,p'-DDT MYOCLONIC/EPILEPTIC RAT HIPPOCAMPUS. R.R.Trifiletti and M.R.Pranzatelli. Departments of Neurology and Pediatrics, Columbia University, New York,NY 10032.

Certain benzodiazepines (BDZs) have anti-myoclonic properties in human myoclonic disorders and in the p,p'-DDT myoclonic/epileptic models in the rat. To test the hypothesis that BDZ receptor abnormalities may contribute to the neurotoxicity of p,p'-DDT, we measured central BDZ receptors in adult rats given 1gm p,p'-DDT by orogastric intubation using in vitro [^{3}H]-flunitrazepam binding. The hippocampus was chosen for initial studies as it contains a mixture of BDZ receptor subtypes. Animals treated with p,p'-DDT displayed a 23% ($P<0.05$) increase in number of BZD sites as compared to controls. Pretreatment of animals with intracisternal 5,7-dihydroxytryptamine (DHT), which markedly reduces the potency of p,p'-DDT at producing myoclonus and convulsions in the rat, abolishes the receptor number increase observed with p,p'-DDT treatment alone. The effect of p,p'-DDT does not appear to alter the ratio of BZ1 and BZ2 sites as defined by displacment with CL 218,872.

427.2

THE BENZODIAZEPINE (BZD) RECEPTOR IN CULTURED ASTROCYTES FROM GENETICALLY EPILEPSY-PRONE RATS (GEPR-9). M.D. Norenberg and I. Ducis* (SPON: R. Rotundo). Lab. of Neuropathology, Veterans Adm. Med. Ctr. and Univ. Miami Sch. Med./Jackson Memorial Hospital, Miami FL, 33101

The BZD receptor has been strongly implicated in epileptogenesis (Paul and Skulnick, Science 202: 892, 1978; McNamara et al, Proc Natl Acad Sci 77:3029, 1980). It has generally been assumed that this receptor is the neuronal one which is associated with the the GABA-chloride ionophore complex. However, astrocytes also possess BZD receptors (Bender and Hertz, Brain Res 341: 41, 1985) although they are of the peripheral-type. It is thus possible that observed changes in BZD receptors in various models of epilepsy may reflect alterations in the astrocyte receptor. Since astrocytes have long been implicated in epileptogenesis (Norenberg et al, The Biochemical Pathology of Astrocytes, Alan R. Liss, 1988), we investigated the state of astrocytic BZD receptors in culture. Astrocytes were obtained from cortices of GEPR-9 neonates. After 2 weeks, the cultures were treated with dibutyryl cyclic AMP (an agent that induces maturation in astrocytes). Scatchard analysis of ^{3}H-Ro5-4864 (1-100 nM) binding to astrocyte homogenates showed a 34% decrease in BZD receptor number ($p<0.05$) as compared to controls. No significant changes in affinity were found. Our findings indicate that a significant reduction in peripheral-type BZD receptors occurs in GEPR-9 astrocytes. Furthermore, these observations suggest that BZD receptor changes described in other epilepsy models may also occur in astrocytes.

427.3

GLIAL GABA UPTAKE INHIBITORS: ANTICONVULSANT ACTIVITY IN CHEMICAL SEIZURE MODELS IN RATS. S.E. Gonsalves, B. Twitchell*, R.E. Harbaugh*, P. Krogsgaard-Larsen* and A. Schousboe*. Depts. of Surg. and Pharmacol., Dartmouth Med. Sch., Hanover, NH 03756 and PharmaBiotec Res. Ctr., Copenhagen, Denmark.

Evaluation of glial GABA uptake inhibitors as anticonvulsants has been hampered by their inability to cross the blood-brain barrier. We compared the antiseizure properties and neurotoxicity of intracerebroventricularly (i.c.v.) injected 5,6,7,8-tetrahydro-4H-isoxazolo[4,5-*c*]azepin-3-ol (THAO) and 4,5,6,7-tetrahydroisoxazolo[4,5-*c*]pyridin-3-ol (THPO) in acute models of chemoconvulsion in rats. Maximal tonic-clonic seizures were elicited by bolus i.v. injection of pentylenetetrazol (PTZ; 25 mg/kg) or isonicotinic acid hydrazide (INH; 822 mg/kg) 30 min after THAO or THPO (100-750 µg, i.c.v.). Seizure thresholds were evaluated using timed i.v. infusions of PTZ (10.2 mg/min). THAO and THPO increased the latency to INH seizures and blocked the extensor component of maximal PTZ seizures but did not increase PTZ seizure thresholds. THAO produced fewer deficits in motor function than did THPO. The ability of THPO and THAO to suppress maximal convulsions but not generalized minor seizures suggests that the compounds block seizure spread. (Support: American Health Assistance Foundation, Pfizer, Inc., and NATO)

BICUCULLINE KINDLING IN RATS INCREASES GAD ACTIVITY IN THE NIGROTECTAL TARGET AREA. M. Garnett*, S.E. Bachust & K. Gale (SPON: J. A. Childs), Dept. of Pharmacology, Georgetown Univ. Sch. Medicine, Wash. D.C., 20007; and †Maryland Psychiat. Res. Ctr., Baltimore, MD 21228.

The integrity of the deep layers of the superior colliculus is required for protection against maximal electroshock seizures conferred by intranigral application of the GABA agonist muscimol[1], suggesting that the GABAergic nigrotectal projection may mediate this effect. We have investigated whether this projection is involved in regulating seizure susceptibility by measuring tectal GAD activity after kindling.

Adult male Sprague-Dawley rats were 'kindled' by daily treatments (for 14 days) with bicuculline (BIC)(starting at 2 mg/kg s.c. per day and reducing the dose by 0.5 mg/kg every 4-5 days). After this period, the threshold convulsive dose of BIC was <50% of that required in non-kindled (saline-treated) controls. Ten days after the last BIC treatment, the rats were sacrificed, and the superior colliculus was divided into the deep and superficial layers, bilaterally. These tissues were assayed radioenzymatically[2] for GAD activity, and values for bilateral tissues averaged for individual rats.

GAD activity was significantly increased in the deep layers of superior colliculus, where nigrotectal fibers project, in BIC-kindled rats (.455 ± .013 µmol/mg protein/hr) relative to non-kindled controls (.379 ± .016) ($p<.001$). However, there was no significant difference in GAD activity between superficial layers of superior colliculus in kindled (.687 ± .022) vs. non-kindled (.666 ± .019) rats ($p>.10$).

Thus, GAD activity is augmented specifically in the nigrotectal target area, and not in the superficial layers of superior colliculus, following BIC-kindling. These results support the hypothesis that reduced inhibition of nigrotectal activity by substantia nigra, hence elevated tectal GAD activity, is a concomitant of sensitization to BIC-induced convulsions. [1]Garant & Gale, Exp. Neurol. 97:143,1987. [2]Sims & Pitts, J. Neurochem. 17.1607, 1970.

427.5

GABA AND GLUTAMATE RECEPTORS IN SUBSTANTIA NIGRA CONTROL SEIZURES EVOKED FROM AREA TEMPESTAS R. Maggio* and K. Gale (SPON: R. Meloni) Department of Pharmacology, Georgetown University Medical Center, Washington, D. C. 20007

We studied the functional relationship between the substantia nigra (SN), and the area tempestas (AT), an epileptogenic site in the deep prepiriform cortex from which bilateral motor seizures are elicited with unilateral microinjections of pmole doses of bicuculline. Bilateral microinjections of the $GABA_A$ agonist muscimol (219 pmol) or of the competitive NMDA-receptor antagonist, 2-amino-7-phosphonoheptanoic acid (AP7, 50 nmol), protected against convulsions evoked by the unilateral focal microinjection of bicuculline methiodide (118 pmol) into AT in freely moving rats. When muscimol was applied to the SN unilaterally (either ipsilateral or contralateral to the AT injection), no seizure protection was obtained. Bilateral intranigral application of morphine sulfate (26 or 53 nmol) did not protect against seizures elicited from AT, although it induced stereotyped sniffing and gnawing behavior similar to that evoked by intranigral muscimol and AP7.

Our data indicate that the bilateral convulsions evoked from the AT of one hemisphere are susceptible to suppression by augmentation of GABA transmission or blockade of NMDA receptors in SN, but only when the inhibition occurs in the SN of both hemispheres. This suggests that the seizure suppressant action evoked from SN is exerted during the course of propagation of the seizure, once it has spread bilaterally.

427.6

$GABA_A$ RECEPTOR CLONES FROM SEIZURE PRONE AND RESISTANT MICE. D.R. Burt, J.C.R. Fernando, P. Kofuji*, J.B. Wang* and D.K. Overman*. Dept. of Pharmacology, Univ. of Maryland School of Medicine, Baltimore, MD 21201.

DBA/2J inbred mice are prone to audiogenic seizures as juveniles, while C57BL/6J inbred mice are resistant to seizures at any age. Evidence has suggested that differences in the two strains' seizure susceptibilities arise in part from differences in the structure or regulation of their inhibitory $GABA_A$ receptors. To explore this possibility further, we have constructed size-selected cDNA libraries in lambda gt10 from whole brains of both strains and have screened them (c. 2 x 10^6 independent recombinants each) at low stringency with cDNA probes based on published bovine $GABA_A$ receptor sequences (Schofield et al., Nature, 328:221, 1987). This work, still in progress, has yielded over 300 positives, which, by differential cross hybridization, separate into a number of families of distinct but related sequences. End sequencing of the shortest clones of each of two families to date has indicated that these families include the mouse homologs of the bovine alpha-3 subunit and a bovine beta subunit (Levitan et al., Nature, 335:76, 1988). The nature of the strain differences, if any, in these clones' sequences or expression, and their possible relationship to the allelic differences we reported last year (Fernando and Burt, Soc. Neurosci. Abstr. 14:1035, 1988), is under investigation. (Supported by USPHS grant NS25525.)

427.7

ASSESSMENT OF GABA UPTAKE AND GLUTAMIC ACID DECARBOXYLASE (GAD) ACTIVITY IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR) BRAIN. R.A. Browning, M. Marcinczyk*, and P.C. Jobe. Southern Ill. Univ. Sch. Med., Carbondale, IL 62901 and Univ. Ill. Coll. Med., Peoria, IL, 61656.

Microinjections of GABA agonists into the inferior colliculus (IC) inhibit audiogenic seizures in severe seizure GEPRs (GEPR-9s) and iontophoretic application of GABA to cells in the IC causes less inhibition in GEPRs than in normal rats (Faingold, Gen Pharmacol. 19 331,1988). On the other hand, the GEPR-9 IC has increased numbers of GAD-immunoreactive (GABAergic) neurons compared to normal rats (Roberts et al., Brain Res. 361 324,1985). To further assess GABAergic neurotransmission in the GEPR-9s, we compared high affinity GABA uptake and GAD activity in the IC (and other regions implicated in audiogenic seizures) of GEPR-9 and normal rats. High affinity uptake of ^{3}H-GABA was measured in resuspended P_2 synaptosomes isolated from specific brain regions and GAD activity was determined in homogenates of specific brain regions by measuring the rate of decarboxylation of ^{14}C-glutamic acid. GABA uptake was found to be increased (16%, P<.05) in synaptosomes isolated from the IC of GEPR-9s when compared to normal rats, but was not changed in other brain regions (pontine reticular formation, substantia nigra, or hippocampus). GAD activity was increased (23%, P<.001) in the GEPR-9 hippocampus, but was not altered in the IC or other regions examined. The uptake findings are consistent with the increase in the number of GABAergic neurons in the IC of GEPRs, but the lack of a difference in GAD activity questions the functional significance of the increased neurons. Additional studies will be needed to determine if these differences contribute to the seizure prone state of GEPR-9s. Supported by The Deafness Research Foundation.

LONG-TERM CHANGES IN SENSITIVITY TO GABA IN DORSAL RAPHE NEURONS FOLLOWING AMYGDALOID KINDLING. T.D. Hernandez, J.B. Rosen, C. Heninger and D.W. Gallager. Dept. Psychiatry, Yale Univ. Sch. Medicine, New Haven, CT 06508

Work from our laboratory has shown that chronic exposure to diazepam produces a decrease in bicuculline seizure threshold which occurs in parallel with the progressive development of subsensitivity to GABA in dorsal raphe neurons. In addition, work from other laboratories have reported that manipulations within the midbrain raphe region affect amygdala kindled seizure threshold and expression. The present studies were undertaken to evaluate GABA sensitivity in dorsal raphe neurons following amygdala kindled seizures.

Amygdala kindling decreased bicuculline seizure threshold. Dorsal raphe lesions prior to amygdala kindling significantly lowered kindled seizure threshold. Dorsal raphe neurons of amygdala kindled rats exhibited significant subsensitivity to GABA, as measured electrophysiologically 3-4 weeks after the last Stage 5 seizure. Amygdala stimulation with currents that did not produce kindled seizures did not produce subsensitivity to GABA. The subsensitivity observed after kindling was equivalent in magnitude to that observed following chronic diazepam treatment. However, chronic diazepam exposure in fully kindled rats did not further decrease the sensitivity of dorsal raphe neurons to GABA. Additionally, while subsensitivity to GABA was reversed by bath application of Ro 15-1788 in chronic diazepam treated rats, the benzodiazepine antagonist had no effect on GABA subsensitivitiy in fully kindled rats. These findings suggest that GABAergic sensitivity within the dorsal raphe might reflect long-term neuronal changes associated with kindled seizures. These data also suggest that GABA sensitivity changes following chronic diazepam may involve different mechanisms than those observed after amygdala kindling.

GENETIC VITAMIN B_6 DEPENDENCY AS A DETERMINANT OF EPILEPTIC DIATHESIS. S. Dolina*, A. Keller*, A. Kozak*, (SPON: S.J. Shefchyk) Department of Biochemistry and Molecular Biology, University of Manitoba, Winnipeg, MB, Canada R3E 0W3; Ben-Gurion Univ. of Negev, Israel; Weizmann Institute of Sciences, Israel.

Genetic vitamin B_6 (B_6) dependency/relative deficiency is considered as a significant determinant of epileptic diathesis and starting point for expanding neurotransmitter disorders. The experiments were carried out in specially developed syngeneic epilepsy-prone (EP) and epilepsy-resistant (ER) substrains of BALB/c mice. A group of EP females was treated with B_6 (10 mg/kg in drinking water) throughout the entire period of pregnancy and lactation; then offsprings received the same treatment until their maturity. The treated EP mice differed from nontreated in the following way:

1) High tolerance to pentamethylentetrazol (PTZ) in a wide range of doses; B_6 withdrawal followed by decreased tolerance to PTZ.
2) Normalized number of GABA-neurons in inferior colliculi and in motor cortex, genetically increased in EP mice.
3) Normalized phosphatidylinositol (PI) level in brain stem plasma membranes with the same tendency in cerebellar ones. The membranes of both structures are characterized by increase PI level in non-treated EP mice.
4) Phosphatidylcholine accumulation in brain stem and cerebellar membranes.

Clinical application of longterm B_6 treatment (90 mg/day) in an infant with uncontrolled behaviour and nightmares (family history of epilepsy in both parents) have been followed by disappearance of epileptic EEG patterns and behavioral normalization. Early correction of B_6 dependency as an inborn error of metabolism is suggested as a new approach to the treatment of epilepsy at very early stages of the disease as well as to the prevention of the build-up of epileptic diathesis in cases of high family risk.

GLYCINE POTENTIATES DIAZEPAM AND SODIUM DIVALPROATE IN SUBCUTANEOUS PENTYLENETETRAZOL SEIZURES, S.L. Peterson Dept. of Medical Pharmacology and Toxicology, Texas A&M University, College Station, Texas 77843.

The purpose of this study was to evaluate the ability of glycine to enhance the effects of clinically effective anticonvulsants in a standardized model of experimental epilepsy in rats.

Minimal threshold seizures were induced by a s.c. injection of a 75 mg/kg dose of pentylenetetrazol. A clonic convulsion consisted of a 5 sec period of clonic spasms. Statistical significance between anticonvulsant dose-response curves with and without glycine were determined by nonlinear regression analysis.

Glycine (40 mmol/kg, p.o.) administered 1, 2, 4 or 8 hours before the seizure test had no effect on seizure response. However, glycine (40 mmol/kg, p.o.) significantly reduced the ED_{50} of diazepam (1.26 to 0.76 mg/kg, i.p.) and sodium divalproate (307.5 to 240.4 mg/kg, i.p.) without affecting the neurotoxicity induced by either drug. Glycine did not significantly affect the ED_{50} of phenobarbital or ethosuximide.

These findings do not support proposed glycine-GABA interactions and suggest that glycine acts by a variety of independent mechanisms to potentiate anticonvulsants. (Supported by NIH Grant 24566)

427.11

DETERMINATION OF LORAZEPAM IN RAT BRAIN USING COMBINED TECHNIQUE OF LIQUID-LIQUID EXTRACTION, SOLID-PHASE EXTRACTION AND HIGH-PERFORMANCE LIQUID CHROMATOGRAPHY (HPLC). S. Gunawan, N.Y. Walton and D.M. Treiman (SPON: A.V. Delgado-Escueta). Neurology and Research Services, VAMC, Los Angeles, CA 90073 and Dept. of Neurology, UCLA Sch. of Med., Los Angeles, CA 90024.

Lorazepam (LZP), a 1,4-benzodiazepine is used in the treatment of status epilepticus. In order to study the pharmacokinetics of LZP entry into brain, we developed a method for quantitation of LZP in rat brain using HPLC. LZP was extracted from 100 mg of brain tissue, which was homogenized by ultrasonic disruption in 1 ml 1.0 M Tris-buffer (pH=10.5). Type VIII alkaline protease was added to the homogenate and the mixture was incubated for 1 hr at 50°C. Toluene was used to extract the drug and internal standard. Chlordiazepoxide (CDX) served as internal standard. The organic phase was dried and the residue redissolved in methanol and washed against iso-octane. The resulting extract was applied into a 1 ml C18-Bond Elute column and washed with 2 ml of water. LZP and CDX were eluted with 250 ul of 70% methanol solution. LZP and CDX were separated using a Rainin C18-microsorb column (250 X 4.6 mm ID) and monitored by a UV detector set at 240 nm. The mobile phase was methanol/0.025 M Na_2HPO_4 (66/34, V/V) and the flow-rate was maintained at 1 ml/min. LZP eluted at 7.9 min followed by CDX at 10.0 min. Plots of peak height ratios versus concentrations were linear over the range of 20-200 ng LZP.

427.12

DISTRIBUTION OF VALPROIC ACID IN THE RAT BRAIN Thomas J. Hoeppner, Rush Medical College, Chicago, Ill. 60612

Valproic acid (VPA) is one of the most effective anticonvulsants available, yet its mechanism of action is unknown. The present studies were undertaken in the belief that determining the distribution of VPA in the brain would provide a guide to further studies to identify the specific mechanisms responsible for its action.

Radiolabeled valproic acid (as the sodium salt) was injected intravenously into anesthetized rats. One hour later (the time of maximal effectiveness of the drug) the animals were sacrificed and the brain removed and frozen. The distribution of VPA was determined in thaw-mounted brain sections using contact autoradiography. VPA concentrated in the glomerular layer of the olfactory bulb with almost no accumulation elswhere in the brain. VPA distribution was restricted to the medial and dorsal portions of the bulb (areas with notable concentration of GABA terminals and peripheral benzodiazepam receptors).

We have also compared the distribution of VPA in animals with and without perfusion with saline and fixative. Perfusion clears the isotope from the vasculature (where it binds to albumin), but leaves the high concentration in the olfactory bulbs.

The glomerular layer of the olfactory bulb may contain the long sought binding sites for VPA.

427.13

EFFECTS OF $GABA_B$-RELATED DRUGS IN TWO TYPES OF PAROXYSMAL ACTIVITY. S. Brailowsky, S. Badillo*, S. Meneses*[1] and G. Di Scala*[2]. Instituto de Fisiología Celular, U.N.A.M., México 04510 D.F., [1]Facultad de Psicología, U.N.A.M., [2]Centre de Neurochimie, C.N.R.S., Strasbourg, France.

In previous experiments, we have shown that chronic intracortical infusions of GABA induce, upon withdrawal, the appearance of spontaneous paroxysmal activity. This "GABA-withdrawal syndrome (GWS)", found in rats and baboons, has been proposed as a new model of partial epilepsy (Brain Res., 442:175, 1988).

Interested in elucidating the contribution of $GABA_B$ receptors in this phenomenon, we applied phaclofen, a new $GABA_B$ antagonist, in rats showing a GWS. Intracortical microinjections (0.2 ul, 10 nM) of phaclofen failed to show antiepileptic effects, while being effective in diminishing or arresting the paroxysmal activity induced by acute, intracortical injection of baclofen (0.2 ul, 10 nM). Phaclofen, applied unilaterally into the somatomotor cortex of normal, non-treated rats, had no behavioral (elevated beam walking test) or electrographic effects.

These data suggest that $GABA_B$ receptors have little or no involvement in the GWS, and confirm previous reports on the epileptogenic effects of intracerebrally administered baclofen. A laminar analysis of the GWS and of the baclofen-induced effects would be necessary to determine whether the two types of paroxysmal activity have a relationship with $GABA_B$ receptor distribution in the cortex.

STEROID REGULATION OF HIPPOCAMPAL NERVE CELL GROWTH IN CULTURE. B.R. Johnson* and R.E. Brinton, School of Pharmacy, University of Southern California, Los Angeles, CA 90033.

Steroid factors play a critical role in the development and adapation of the nervous system (McEwen and Brinton, 1987). We have recently found that the metabolite steroid, 5 α-pregnan-3α-ol-20-one (DHP) decreases nerve cell excitability in a GABA dependent manner and protects against chemically induced seizures (Gee et al., 1988). The purpose of this study was to determine the effect of the steroid DHP, which decreases nerve cell excitability, and 17 β-estradiol, which increases excitability, upon nerve cell growth in culture. Hippocampal nerve cells were cultured from E18 rat pups and seeded in serum containing media. Following attachment, media was exchanged for serum free. Nerve cells treated with 30 nM DHP showed a rapid response to the steroid. Within 15 min following DHP exposure the number of microspikes along the neuritic shaft was reduced by 20% and by 30 min was reduced by 80%. In addition to the decrease in microspike number, the total area of the growth cone was reduced. The length of the neuritic extension was also decreased but is probably reflective of the reduced area of the growth cone. In contrast to the effect of DHP, estradiol (30 nM), induced microspike formation along the neuritic shaft. This effect was maximally apparent within 30 min. Further characterization studies are in progress.

NEUROENDOCRINE REGULATION: NEUROHYPOPHYSIAL PEPTIDES

428.1

STIMULATORY EFFECT OF PROLACTIN ON OXYTOCIN SECRETION IN THE LACTATING RAT. W.E. Armstrong, C.E. Grosvenor, and W.R. Crowley. Depts. of Anatomy & Neurobiology, Physiology & Biophysics, and Pharmacology, University of Tennessee, Memphis, College of Medicine, Memphis, TN 38163.

In lactating rats, stimulation of dopamine (DA) receptors blocks suckling-induced oxytocin (OT) release, while blockade of DA receptors significantly increases OT release. Further studies with selective agonists and antagonists demonstrated that stimulation of the D-2 receptor with (±)-PPHT HCl completely prevented suckling-induced OT release, while a D-1 agonist, R (+)-SKF-38393 HCl, was ineffective. The selective D-2 receptor antagonist domperidone blocked the inhibitory effect of the D-2 agonist, and when given alone to nonsuckled rats, significantly stimulated OT release. To test whether DA acts within the neural lobe to suppress OT release, isolated stalk-neurointermediate lobes (sNIL) were perifused in Krebs-Ringer medium and stimulated electrically for 4 sec after 70 and 170 min of perifusion. Neither agent (1μM) affected basal or stimulated OT release, suggesting that DA does not act directly on the neural lobe to inhibit OT release. To test whether the effects of DA agents were secondary to a change in prolactin (PRL) secretion, biologically active ovine PRL (4 mg/kg), administered sc to nonsuckled, lactating rats, promptly increased plasma OT. Ovine GH was ineffective. Moreover, ovine PRL (600 ng/ml) enhanced electrically-evoked release of OT from sNIL *in vitro*. These findings suggest 1) that the effects of D-2 agonists to suppress and of D-2 antagonists to mimic suckling-induced OT release are secondary to their actions to prevent or increase, respectively, PRL release, and 2) that in lactating rats, PRL may exert a physiological effect to promote OT secretion.

428.2

Effect of short-term treatment with vasopressin (AVP) and desmopressin (DDAVP) on cerebral glucose utilization in Brattleboro (DI) rats. M.L.Terrell, E. Nermo-Lindquist*, M. Kadekaro, S. M. Kelly*, S. Freeman*, P.M.Gross# and H.M. Eisenberg. Div. of Neurosurgery, UTMB, Galveston, Tx. USA; #Dept. of Surgery, Queen's University, Kingston, Ontario, Canada.

Previous studies have shown that DI rats have high rates of glucose utilization in the neural lobe, which are not altered by chronic treatment with AVP in spite of regression of polydipsia and polyuria. To determine if this was due to the desensitization of AVP receptors, we studied with the [^{14}C]deoxyglucose method the effect of short-term treatment with AVP (5 U/kg,i.m.,twice a day) and DDAVP (100 ug/kg,ip, once a day) for two days on the activity of the hypothalamo-neurohypophysial system and related structures in DI rats (n=45). AVP and DDAVP reduced water intake, plasma osmolality and plasma Na+ concentration to the same extent. AVP decreased glucose utilization in the supraoptic n., subfornical organ, and median preoptic n., but did not alter the activity in the paraventricular n. and neural lobe. DDAVP, however, decreased glucose utilization in all these structures. These results indicate that DDAVP has a more potent action on the hypothalamo-neurohypophysial system than AVP and that the lack of response in the neural lobe from chronic treatment with AVP is not due to desensitization of AVP receptors.

428.3

BRAINSTEM ORIGINS OF SUBSTANCE P-IMMUNOREACTIVE PROJECTIONS TO NEUROSECRETORY CELL GROUPS IN THE PARAVENTRICULAR NUCLEUS. J.C. Bittencourt[1], R. Benoit[2] and P.E. Sawchenko[1]. The Salk Institute[1], San Diego, CA 92138 and Montreal Gen. Hosp.[2], Montreal, Canada.

Anatomical and pharmacological evidence suggests a role for substance P (SP) in the control of vasopressin (AVP) secretion, but the origins of SP-immunoreactive (IR) projections to the paraventricular (PVH) and supraoptic nuclei of the hypothalamus have not yet been identified. Axonal transport, immunohistochemical, and lesion approaches were used to address this issue. The results indicate that: (1). SP-IR varicosities are distributed broadly throughout the parvocellular division of the PVH, and preferentially to aspects of the magnocellular neurosecretory system in which AVP cells are concentrated. (2). Combined retrograde transport-immunohistochemical studies identified SP-IR in subsets of A1 and C1 catecholamine neurons that project to the PVH. The only other prominent brainstem contribution to the SP-IR projection arose from the laterodorsal tegmental nucleus (LDT), including some cholinergic cells. (3). Unilateral knife cuts at the level of the facial motor nuclei, which resulted in pronounced depletion of catecholaminergic varicosities in the PVH, also markedly reduced SP-IR, particularly in the magnocellular division. Coupled with the results of recent tracing studies, the results suggest that SP-IR inputs to the magnocellular system arise principally from the A1 catecholamine cell group. The LDT and C1 adrenergic cell groups appear to contribute to the innervation of the parvocellular division.

PROGESTERONE REGULATION OF OXYTOCIN MRNA LEVELS IN THE PARAVENTRICULAR NUCLEUS. Brooks, P.J., Caldwell, J.D., Lund, P.K.*, and Pedersen, C.A. The Curriculum in Neurobiology, Univ. of North Carolina at Chapel Hill, Chapel Hill, NC, 27599

The purpose of the present study was to determine whether exposure to late pregnancy levels of progesterone (P) regulates oxytocin (OXY) mRNA levels in the paraventricular (PVN) and supraoptic (SON) nuclei.

Ovariectomized female rats were implanted with 2mm Silastic capsules containing estradiol (E), and injected with either P (4 mg/day) or oil vehicle for 10 days. Total RNA was isolated from the PVN and SON using a small scale guanidine thiocyanate/CsCl method. Oxytocin mRNA levels were measured using a solution hybridization-RNAse protection assay. The probe was a 131 base antisense RNA transcript from linearized plasmid pGEM-OXY3c (a gift of Dr. Thomas G. Sherman, Univ. of Michigan).

No effect of P was detected in the SON. In the PVN however, P significantly decreased OXY mRNA levels relative to E alone. These results indicate that long term exposure to high levels of P, in the presence of E, decreases OXY mRNA levels in the PVN.

VASOPRESSIN SYSTEMS IN CHINESE HAMSTERS THAT HAVE DIABETES INSIPIDUS INDUCED BY MEDROXYPROGESTERONE ACETATE. H.J. De Vries*, G.J. De Vries, C.F Ferris, J. Brewer*, and J. Coe*, Neuroscience and Behavior, Univ. of Massachusetts, Amherst; Dept. of Physiology, Univ. of Massachusetts, Worcester; National Institute of Health, Hamilton, Montana.

Injections with medroxyprogesterone acetate (MPA or Depo-Provera) induce severe diabetes insipidus (DI) in Chinese Hamsters (Cricetulus griseus) that lasts for over three months. Injections with pitressin tannate temporarily eliminate the DI (Coe and Ross, 1986). We studied, therefore, whether MPA induced changes in central VP systems. Hamsters were made DI with two injections of 5 mg MPA spaced one week apart. Controls received cholesterol or saline injections. Two weeks after the first injection, controls drank 5ml per day or less whereas MPA-treated animals drank 29 mls per day or more. Animals perfused at that time showed a paraventricular (PVN) and supraoptic nucleus (SON) that stained equally well in brains of MPA-treated hamsters (n=5) and controls (n=5) in VP immunocytochemistry. Radioimmunoassay showed no statistically significant differences in AVP levels in blood, pituitary, PVN and SON (n=6 per group). As they tended to be higher in the MPA-treated animals, MPA does not seem to inactivate VP neurosecretion. (Supported by NSF grant BNS-8809799 to GJD and NIH grant NS-23557 to CFF)

428.6

DIFFERENTIAL LOCALIZATION OF ESTROGEN RECEPTORS IN VASOPRESSIN CELLS OF THE RAT BRAIN. J.F. Axelson[1] and F.W. van Leeuwen[2]. Holy Cross College[1], Worcester, MA 01610 and Netherlands Institute for Brain Research[2], Amsterdam.

Vasopressin (VP) cells in the bed nucleus of the stria terminalis (BST), medial amygdaloid nucleus (AME), supraoptic (SON) and paraventricular (PVN) nucleus are influenced by gonadal steroids. The goal of the present paper was to examine whether VP cells in the BST, AME, SON and PVN contain estrogen receptors. Brains from adult short-term castrated, colchicine-treated male rats were fixed for 8 hrs in 4% PAF and 0.5% glutaraldehyde. In the immunocytochemical double staining procedure vibratome sections were first incubated with estrogen receptor antibody (#H222, Abbott, Chicago) and stained with DAB-Ni^{+}. Following a methanol-H_2O_2 wash, sections were then incubated with anti-VP-neurophysin and stained with DAB. Parvocellular cells in the BST and AME were double stained with a blue-black nucleus (indicating the estrogen receptor) surrounded by brown cytoplasm (resulting from VP-neurophysin immunoreactivity). Our results provide the first direct anatomical evidence supporting the hypothesis that gonadal steroids' influence on parvocellular VP cells in the BST and AME is mediated directly via estrogen receptors localized in nuclei of VP neurons. We were unable to localize any estrogen receptors in magnocellular VP and oxytocin cells in the SON and PVN, suggesting that estrogen indirectly impacts magnocellular hypothalamic cells.

428.7

NEURAL LOBE EXTRACELLULAR SPACE AND ITS DEPENDENCY ON EXTRACELLULAR FLUID POTASSIUM (OR SODIUM?) AS OBSERVED AFTER ULTRA-RAPID FREEZING. M. Tian, J. Reger* and W.E. Armstrong. Dept. of Anat. Neurobiol., Univ. Tenn., Memphis, The Health Science Center, Memphis, TN 38163.

A large increase in extracellular potassium (5- 10 mM) accompanies increased neuronal activity in isolated neural lobes (Leng and Shibuki, *J. Physiol.* 392: 97, 1987). Elevated potassium levels could influence neural lobe morphology due to the ion's uptake by pituicytes, and ultimately affect stimulus-secretion coupling and/or hormone diffusion. The influence of altering the extracellular sodium/potassium ratio on neural lobe extracellular space was assessed *in vitro* by preserving fluid distribution with ultra-rapid freeze fixation.

Two groups of freshly isolated rat neural lobes were incubated for 15 min in identical oxygenated media with the exception that control medium contained 3 mM KCl, 124 mM NaCl, whereas the test medium contained 13 mM KCl, 114 mM NaCl (iso-osmotic with controls). The tissue was then rapidly frozen against a copper block, freeze-substituted in acetone-osmium and prepared for electron microscopy.

The extracellular space was dramatically reduced in the high KCl medium to ~14% of the total tissue surface area, compared with ~28% in controls. This reduction was not accompanied by a change in the average width between closely apposed processes (~23 nm in both groups), but the contribution of this narrow area to the total extracellular space was much greater in high KCl (16% vs 4% in controls). Much of this appeared due to a swelling of pituicytes and their increased enclosure of neurosecretory axons, a situation normally associated with *decreased* hormone demand (Tweedle and Hatton, *Neurosci.* 20: 241, 1987). Further studies will address the contribution of smaller ionic changes and also attempt to determine the relative influence of each ion's concentration (i.e., reduced sodium and elevated potassium) on the effect. Supported by NIH grant #NS23941 (WEA).

428.8

ESTROGEN AND PREGNANCY ALTER RAT NEUROINTERMEDIATE LOBE OXYTOCIN, VASOPRESSIN, METHIONINE ENKEPHALIN, AND DYNORPHIN. J. A. Schriefer. Department of Pharmacology, West Virginia School of Osteopathic Medicine, Lewisburg, WV 24901.

The magnocellular neurons of the hypothalamo-neurohyppophysial system (HNS) may contain opioid peptides such as methionine enkephalin (MENK) and dynorphin 1-8 (DYN) as well as oxytocin (OT) and vasopressin (AVP). The opioids may provide feedback control on OT and AVP release. If the opioids have such a functional role, the content or release of the opioids might be expected to change under conditions in which OT or AVP change. To examine this expectation, the neural lobe content and HNS release of the four peptides were determined under conditions in which OT is known to change.

Diestrus, diethylstilbesterol(DES)-treated, and day 22 pregnant rats were decapitated, the HNS excised and superfused in oxygenated Krebs buffer at 37° C. Following superfusion, neurointermediate lobes (NIL) were removed and homogenized. Peptide content of superfusates and homogenates were determined by specific RIAs. NIL OT was increased in DES-treated and pregnant rats. AVP and DYN increased in pregnant rats only. MENK content was decreased in DES-treated and pregnant rats. Release of the peptides from the HNS paralleled changes in NIL content. These data are consistent with a functional role for the co-localized opioids in the control of OT and AVP release.

Supported by NIH Grant HD 22362 and a WVSOM Intramural Research Grant.

ISOPROTERENOL ATTENUATES α_1 ADRENERGIC RECEPTOR EVOKED VASOPRESSIN (VP) RELEASE FROM PERFUSED RAT HYPOTHALAMO-NEUROHYPOPHYSEAL EXPLANTS (HNH). L.P. Renaud, R. Nissen, and D. Bichet*, Centre for Research in Neuroscience, Montreal General Hospital and Hôpital Sacré Coeur, Montreal, Canada, H3G 1A4.

Noradrenaline is both facilitatory and inhibitory to the firing of hypothalamic supraoptic neurosecretory neurones, a result of dose-dependent activation of α_1 or β adrenoceptors respectively. This study investigates the effects of α_1 vs β adrenoceptor activation on VP release from HNH. Rat HNHs were intra-arterially perfused with warmed, oxygenated artificial cerebrospinal fluid. The anterior lobe of the pituitary was removed and a suction pipette was positioned over the neurointermediate lobe to collect superfusate. Under basal conditions, samples assayed for VP by radioimmunoassay revealed baseline values of 0.5 - 11.6 pg/ml. VP levels were increased 4-13 fold when the perfusion media contained the α_1 agonist methoxamine (60 μM). In contrast, isoproterenol (60 μM) had no effect. However, addition of isoproterenol during methoxamine application attenuated the α_1 evoked response by 53 - 100%. This supports the hypothesis that β adrenoceptor activation suppresses VP release. (Supported by MRC and FRSQ).

428.10

SOMATOSTATIN-28, BUT NOT SOMATOSTATIN-14, HYPERPOLARIZES SUPRAOPTIC MAGNOCELLULAR NEURONS IN THE RAT. W.N. Raby, C.W. Bourque, R.A. Benoit and L.P. Renaud. Centre for Neuroscience Research, Montreal General Hospital and McGill University, Montreal, Quebec, Canada, H3G 1A4.

An ever increasing role is being ascribed to somatostatin (SS) as a CNS neurotransmitter. Within the rat hypothalamus, fibers displaying SS-28 like immunoreactivity are located in and around the supraoptic nucleus (SON). The inhibitory effect of SS-28 (0.1-10 μM) is most prominent on actively firing magnocellular neurons (MNCs) recorded in superfused rat hypothalamic explants. For 29/36 MNCs tested, SS-28 produced a hyperpolarization of 2 to 10 mV lasting between 2 to 5 minutes, which was sustained by a 10 to 200 % increase in conductance (n = 5). During this effect no changes were observed in the after-hyperpolarizing potential (AHP), action potential broadening, the depolarizing after-potential (DAP). No depolarizing effects were seen.

Infusions of SS-14 at similar concentrations in cells responsive to SS-28 failed to produced any change in membrane potential or conductance in 9 of 11 trials. This data suggests differential effects of somatostatin cleavage products within the rat hypothalamus. Funded by MRC of Canada.

428.11

FUNCTIONAL NEUROLOBECTOMY INDUCED BY CONTROLLED COMPRESSION OF THE PITUITARY STALK. Janos Dohanics*, G. E. Hoffman, and J. G. Verbalis (Spon: T. Plant). Depts. of Medicine & Physiology, Univ. of Pittsburgh, Pittsburgh, PA 15261.

Because selective surgical neurolobectomy is a relatively difficult procedure, we investigated an alternate method to produce selective functional neurolobectomy in rats. The pituitary stalk of anesthetized rats was compressed using a triangle-shaped wire which was introduced stereotaxically 4.0 mm caudal to the bregma in the midline and pressed against the floor of the skull for 30 sec. Water intake of rats was monitored postoperatively, and 3 weeks after surgery the rats' ability to secrete vasopressin (AVP) and oxytocin (OT) in response to 2M NaCl infusion was studied. At the end of the experiment, the neurointermediate lobes of the pituitaries were extracted for AVP and OT measurement. Additional rats were perfused and the brains immunostained for AVP-neurophysin (AVP-NP) and OT-neurophysin (OT-NP) to determine cell survival rate following the compression. Water intake of stalk compressed (SC) rats showed a characteristic triphasic response with a marked increase during the first 2d postoperatively, followed by a period of normal water intake for 1-3d and then a sustained 2-3 fold increase for the rest of the observation period. Pituitary AVP and OT content was reduced 95% in SC rats. Histologic examination of the pituitaries showed substantial degeneration in the posterior lobe, while the adenohypophysial tissue appeared to be intact. SC caused a 69% and 75% loss of AVP-NP magnocellular neurons in the supraoptic (SON) and paraventricular nuclei (PVN), respectively, while the loss of OT-NP neurons in the SON and PVN was only 30% and 32%, respectively. AVP and OT responses to iv. infusion of 2M NaCl were significantly blunted in SC rats compared to controls: $pAVP_{cont}$=2.57(pNa-141.8), r=0.68; $pAVP_{SC}$=0.06(pNa-46.3), r=0.19; pOT_{cont}=3.30(pNa-142.2), r=0.60; pOT_{SC}=0.002(pNa+5440), r=0.00. These results show that controlled compression of the pituitary stalk results in selective degeneration of the neural lobe without causing ischemic damage to the anterior pituitary, and produces marked sustained functional deficits in AVP and OT secretion. However, OT-NP neurons appear to be less significantly susceptible to damage than AVP-NP neurons following SC, suggesting the possibility of recovery of function over longer periods.

DENERVATION OF THE RAT POSTERIOR PITUITARY: VALIDATION OF A NOVEL SURGICAL APPROACH. G.B. Makara Inst. Exptl. Mod. Hung. Adac. Sci., H-1450 Budapest, Hungary.

The nerve fibers running to the posterior pituitary of the rat were interrupted without destroying of the hypothalamo-pituitary portal circulation. The pituitary stalk was compressed using a Halász-type rotating knife with a 2 mm blade (0.6 mm diameter, cutting edges at the sides, blunt tip) at 110° to the shaft. The knife was lowered in the midsagittal plane until it touched the bone at 5.3 mm behind the bregma (with the incisor bar 10° nose down), then withdrawn 0.5 mm, turned $\pm$ 45°, then repeatedly lowered 0.1 mm and turned $\pm$ 45° until friction against the basal bone surface was felt. The knife was withdrawn in the midsagittal plane. Successful operations were followed by an immediate increase in water consumption and urine output (over 80 ml/rat/day). At autopsy the continuity of the stalk could be seen and the anterior lobe appeared normal. One week after the operation Gömöri-positive neurosecretory material, neurophysin and arginine vasopressin-like immunoreactivity disappeared from the neural lobe, AVP and neurophysin piled up in the proximal part of the pituitary stalk and CRF immunoreactivity did not change appreciably in the median eminence. In a minority of rats the pituitary stalk was disrupted or the portal circulation severely damaged as shown by infarction in the anterior pituitary. Plasma corticosterone and prolactin levels increased within 15 min after surgery but returned to control levels 2 days later. In female rats the estrus cycle was temporarily disturbed after the operation. Denervation of the posterior lobe may help in studying the role of the neurohypophysial neurosecretion in various endocrine conditions

EFFECT OF CHRONIC HYPERTONICITY ON BASAL AND OSMOTICALLY STIMULATED VASOPRESSIN RELEASE. *C. Yagil and C.D. Sladek (SPON: ML Blair) University of Rochester School of Medicine, Rochester, NY 14642.

Effect of chronic hypertonicity on VP release from HNS explants was studied in explants maintained in static organ culture. The explants were positioned on a nylon mesh supported by a wire screen in individual culture wells and the dishes were maintained in a humidified incubator at 37°C under 95% oxygen and 5% CO2. The osmolality of the medium was established by altering the NaCl concentration and the explants were chronically maintained at different osmolalities for 24 hours (299-325mOsm/kg H20, 8-14 explants/group; 2 separate experiments). The next morning the explants were moved to fresh medium (at the same osmolality), allowed to stabilize for 2 hours, and basal VP release per hour for each explant was measured. All explants were then exposed to an acute hyperosmotic pulse of 15mOsm/Kg H2O, achieved by the addition of NaCl .The highest basal release of VP was observed in the explants maintained under isosmotic conditions (299-300 mosmoles) and was 614±110pg/hr in Experiment 1. and 330±40 pg/hr in the second experiment. These explants significantly increased VP release in response to the acute increase osmolality. Maintenance of HNS explants under chronic hypertonic conditions (above 304 mosm/kg H20) decreased basal VP release, and prevented the response to an acute hypertonic pulse.

These data indicate that chronic exposure of HNS explants to hypertonic culture medium decreases basal and osmotically stimulated VP release. This may reflect depletion of VP stores in the neural lobe, and may be comparable to the effects of chronic water deprivation or salt loading in vivo.

EVIDENCE FOR INVOLVEMENT OF EXCITATORY AMINO ACIDS IN OSMOTIC STIMULATION OF VASOPRESSIN RELEASE. C.D. Sladek, M. Gallagher, and C. Yagil. Departments of Neurology and Neurobiology, University of Rochester School of Medicine, Rochester, NY, 14642.

Osmotic regulation of VP release is abnormal in rats following electrolytic lesions of the region anterior and ventral to the anterior third ventricle. This suggests that osmoreceptors are located in this region, but the neurotransmitter utilized by these neurons has not been identified. In the present experiments, we examined the possibility that excitatory amino acids (EAA) are involved in this pathway by examining the effect of kynurenic acid (KA), a specific antagonist of EAA receptors, on the VP response to a 15 mOsm/kg H_2O increase in osmolality occurring over 2 hrs achieved by increasing the NaCl concentration of the culture medium. In previous experiments, this stimulus caused a significant and sustained increase in VP release. Upon returning the osmolality to baseline, VP release is inhibited, but this is followed by a paradoxical increase in VP release.

The addition of 2mM KA did not significantly alter basal VP release (39.6±5.5 pg/10 minutes, n=11) from perifused HNS explants maintained at 288 mOsm/kg H_2O. In the presence of KA, VP release was not significantly increased in response to a 15 mOsm/kg H_2O increase in osmolality occurring over 2 hours, but inhibition of VP release was observed when osmolality was returned to 288 mOsm/kg H_2O ($p=0.05$, n=5). The paradoxical increase in VP release previously observed following a decrease in osmolality did not occur. KA did not prevent stimulation of VP release in response to increasing the KCl concentration of the perifusion medium to 56mM ($p<0.01$). These observations suggest that EAAs are involved in the stimulation of VP release by increases in osmolality and also participate in the paradoxical increase in VP release observed following a decrease in osmolality. Supported by NIH RO1-DK-19761.

NUCLEUS TRACTUS SOLITARIUS (NTS) AND AREA POSTREMA (AP) PROJECT TO TUBEROMAMMILLARY NUCLEUS (TM) G.H. Beagley, M.L. Weiss, & G.I. Hatton. Psych. & Neurosci. Michigan State Univ. E. Lansing, MI 48824-1117.

Histamine-containing cell bodies of the brain have been shown to be in the TM area of the posterior hypothalamus. Projections from the histaminergic cells have been found to go to other hypothalamic nuclei, the limbic system, cortex, and subfornical organ, but few studies have investigated afferent projections to the TM. We injected the retrograde tracers, Fluoro-Gold or rhodamine labeled latex spheres, into the TM of 40 female rats to determine TM afferents. Analysis was based on the several most confined injections and the overlapping pattern of labeling. Previously reported projections were confirmed and new projections from the AP and NTS to the TM were found. Anterograde tracing studies are being done to confirm the AP-TM projection. This is evidence for chemosensory and cardiovascular input to the histaminergic cell group. Supported by NS 09140.

INHIBITION OF RAT SUPRAOPTIC NUCLEUS (SON) NEURONS BY HISTAMINE (HA) H_2-RECEPTOR ACTIVATION. Q. Z. Yang and G. I. Hatton. Neurosci. Prog. Michigan State Univ. E. Lansing, MI 48824-1117.

Histaminergic neurons of the posterior hypothalamus project to the SON and excite vasopressin cells via H_1-receptors. One immunocytochemically confirmed and two putative oxytocin neurons were reported (Soc. Neurosci. Abstr. 1988, 14:215) to be hyperpolarized by HA. We investigated intracellularly recorded responses of 24 SON neurons in hypothalamic slices to either bath or nanodrop application of HA, H_1, and H_2, agonists and antagonists. All putative or confirmed oxytocin cells were inhibited (decreased firing) and/or hyperpolarized (by 5-20 mV) by HA or the H_2-agonist dimaprit. Cimetidine (H_2-antagonist) either completely or partially reversed these effects. No effects on these cells were seen with H_1-agonists or antagonists. In one silent cell, a nanodrop of 10^{-3}M dimaprit produced a 20 mV hyperpolarization that was reversed by a similar drop of cimetidine. This cell was found to be vasopressinergic. Along with previous work, these results suggest that histaminergic input to SON differentially activates vasopressin and inhibits oxytocin neurons via H_1- and H_2-receptors, respectively. Supported by NS 16942.

RESPONSES OF PLASMA ATRIAL NATRIURETIC PEPTIDE AND ARGININE VASOPRESSIN TO OSMOTIC AND VOLUME STIMULATION. K. T. Kalogeras*, M. A. Demitrack*, L. G. Granger*, E. L. Papaioannou*, M. J. Hart*, G. P. Chrousos, and P.W. Gold* (SPON: D. LeRoith). Clinical Neuroendocrinology Branch, NIMH, and DEB, NICHD, NIH, Bethesda, MD 20892.

Arginine vasopressin (AVP) and atrial natriuretic peptide (ANP) exert both similar and dissimilar effects on salt and water metabolism. In studies of their interactions, it has been shown that ANP inhibits vasopressin actions as well as secretion, while AVP stimulates ANP release. These data suggest that ANP-AVP interactions may work preferentially to facilitate protection from hypervolemia. To further explore this question, we report here a study of the effects of 3% NaCL (given at a rate of 0.1 ml/kg/min for 2.5 hrs) on simultaneous plasma ANP and AVP secretion. ANP, AVP and Na concentrations, were measured at -30, -20, -10, and 0 min before infusion and every fifteen minutes, for 2.5 hours, thereafter. Eleven healthy males and six healthy females (studied during both the early follicular and late luteal phases) were included in the study. Hypertonic saline infusion induced a 6-fold increase in plasma AVP secretion from a basal value of 1.2±0.3 pg/ml to a peak value 7.2±1.2 pg/ml, with a parallel 3-fold increase in plasma ANP from 49.9±7.7 to 146.6±19.7 pg/ml. Both the rise in plasma AVP and ANP correlated significantly with the rise in plasma sodium, with a mean (±SEM) correlation coefficient of 0.90±0.02 for AVP and 0.88 ±0.02 for ANP ($p<0.001$ for both). No significant differences were observed in the correlation coefficient, the slope and the osmotic threshold, between male and female subjects and between follicular and luteal phase of the menstrual cycle. The rise in plasma ANP correlated significantly with the rise in plasma AVP with a mean correlation coefficient of 0.84±0.03 ($p<0.001$) and a slope or sensitivity of 20.71±2.75 pg/ml ANP per pg/ml AVP. The positive correlation between plasma AVP and ANP suggest that ANP and AVP work together to correct hyperosmolality.

ISOPROTERENOL-INDUCED MYOCARDIAL INFARCTION IN THE RAT: EXPERIMENTAL EVIDENCE. MJ Krieman* and WH Vogel, Department of Pharmacology, Thomas Jefferson University, Philadelphia, PA.

As a prelude to studying the stress response of rats with cardiac damage, we needed to establish in our lab the animal model for isoproterenol(ISO)-induced myocardial infarction. Male Sprague-Dawley rats between 350-450g had jugular catheters and bipolar EKG leads implanted. 48 hours later, baseline blood samples and EKG traces were taken. Rats then received a 300mg/kg ISO, 500mg/kg ISO, or .9% saline injection s.c. Blood samples and EKG traces were taken for 48 hours. The control group remained unchanged. The ISO-treated groups showed changes in all parameters. Total serum CPK activity increased acutely, peaking at three hours. Qualitative analysis of the isoenzymes showed CPK-MB bands apparent from 3-12 hours. Common EKG deviations were the appearance of S-waves and flattening or inversion of t-waves. Histological findings included widespread necrosis characterized by leucocyte infiltration and destruction of myofibril cells, especially in the left ventricle. Thus, our data provides comprehensive evidence for isoproterenol-induced myocardial infarction in the rat. Subsequent studies will focus on the sympathetic response to stress of these cardiac-damaged animals as compared to normal, healthy animals.

LAMINA TERMINALIS INPUT TO RAT SUPRAOPTIC NUCLEUS VISUALIZED WITH RETROGRADE TRANSPORT OF LABELED MICROSPHERES. J. T. Cunningham, R. Nissen, and L. P. Renaud. Center for Research in Neuroscience, Montreal General Hospital & McGill University, Montreal, Canada, H3G 1A4

The lamina terminalis region is a major input to the supraoptic nucleus (SON). To define these projections more precisely, we evaluated retrograde transport of rhodamine-labeled (Rh) or flourescent green-congigated (Gr) latex beads injected into each SON using a transpharyngeal approach. Animals were perfused 8-22 hrs later. Single SON injections yielded 15-40 labeled cells in the organum vasculosum of the lamina terminalis (OVLT), 130-200 in the median preoptic nucleus (MnPO), and 200-250 in the subfornical organ (SFO). Cells in the MnPO and SFO were widely distributed while the projection from OVLT was primarily ipsilateral. Bilateral SON injections using Rh and Gr beads double labeled up to 4% of retrogradely filled cells in the OVLT, 1% in the MnPO, and 5% in SFO. Bilateral projections from these midline structures represent a minority of their input to the SON. (Supported by MRC and NIMH fellowship MH09766-01X1 BPN-2)

A 16 KD NUCLEAR PHOSPHOPROTEIN MAY BE INVOLVED IN POMC GENE REGULATION. N. Margolis and T. Reisine. Dept. of Pharmacology, Univ. of Pennsylvania, Phila., PA 19104

Control of proopiomelanocortin (POMC) gene expression is an important event in the body's response to stress. Corticotropin releasing factor (CRF) and forskolin, which increase cellular cAMP levels, stimulate POMC gene transcription in the anterior pituitary by activating cAMP-dependent protein kinase. We are attempting to identify nuclear substrates of the kinase which might play a role in POMC gene regulation.

Using AtT-20 cells,a mouse anterior pituitary corticotroph tumor cell line, as a model for POMC gene regulation, we have identified several nuclear proteins which are phosphorylated in response to CRF and forskolin. Among these proteins is a 16 kd protein which appears to be tightly bound to a 9M urea-insoluble fraction of the nuclei and is only released from this fraction when it is sonicated. The phosphoprotein can be visualized on an SDS-PAGE gel by Coomasie blue staining, indicating its abundance in AtT-20 cell nuclei. Preliminary evidence indicates that the phosphorylated protein binds to DNA-cellulose, suggesting that this 16 kd protein might interact with DNA in the cell. The phosphoprotein has been partially purified by elution from SDS-PAGE gels and is currently being characterized using an *in vitro* phosphorylation assay. Future work will include examination of the ability of the phosphoprotein to bind to the 5' promoter region of the POMC gene. Supported by NIH grant DK37407 and an Americian Heart Association grant-in aid.

CALCIUM-DEPENDENT PROTEIN PHOSPHORYLATION IN THE RODENT ANTERIOR PITUITARY. J.C. Pryor, S.T. Cain, C.B. Nemeroff. Depts. of Psychiat. & Pharmacol., Duke Univ. Med. Ctr., Durham, NC 27710.

Calcium mobilization has been implicated in the sequence of steps that leads to the stimulated secretion of anterior pituitary hormones. Changes in the phosphorylation state of individual protein substrates is regarded as one of the predominant mechanisms by which calcium ions modulate hormone release. Previous reports have documented that calcium/phospholipid- and calcium/calmodulin-dependent protein kinases stimulate protein phosphorylation in both sheep and bovine anterior pituitary preparations. We have extended these investigations to evaluate the presence of calcium-dependent phosphoprotein substrates in the rodent anterior pituitary.

Adult, male rats were decapitated, and the anterior pituitaries were harvested and homogenized. Aliquots were phosphorylated in the presence of 10 μM ATP (final concentration) containing [γ^{32}P-ATP], along with either vehicle, calcium (10 μM,), calmodulin (0.05 μg/ml), phosphatidylserine (300 μg/ml), calcium/calmodulin, calcium/ phosphatidylserine. The reaction was carried out for 1 min. The phosphoproteins were separated on SDS-polyacrylamide gels and autoradiographs prepared. Densitometric analysis of the autoradiographs indicate the preferential phosphorylation of 54 and 74 KD MW anterior pituitary proteins by calcium alone. Proteins of 66, 32, and 17 KD MW were preferentially phosphorylated in the presence of calmodulin or phosphatidylserine. Calmodulin stimulated the phosphorylation of a 19 KD MW protein. (Supported by NIMH MH-42088 and the N.C. United Way Fund.)

429.3

CATECHOLAMINES AND THE ACTH RESPONSE TO NICOTINE. S.G. Matta*, K.M. McAllen*, and B. M. Sharp*. (SPON: F. Wilson) Minneapolis Med. Res. Fndn. and Depts of Medicine, Hennepin County Medical Cntr. and Univ. of Minnesota, Minneapolis, MN 55404.

Nicotine(N)-stimulated ACTH release depends upon the activation of central mechanisms, particularily in areas accessible to N from the fourth (IV) ventricle. This region contains catecholaminergic (CAT) nuclei and N stimulates the release of CATs. Moreover, CATs induce ACTH secretion via the release of hypothalamic CRF. Thus, the current studies determined whether central CATs are involved in N-stimulated ACTH secretion. 6-hydroxy-dopamine (6-OH-DA) or vehicle (SHAM) were injected into the lateral ventricle of rats; after 9 d, rats were given saline or 0.03 or 0.05 mg/kg bwt N i.v. ACTH values (pg/ml) are mean$\pm$sem:

	0min	3min	7min	15min	30min
Saline: SHAM	24$\pm$6	27$\pm$2	23$\pm$4	36$\pm$7	66$\pm$24
6-OH-DA	32$\pm$9	42$\pm$11	34$\pm$7	37$\pm$7	44$\pm$10
0.03 N: SHAM	17$\pm$6	199$\pm$97	264$\pm$114	183$\pm$51	113$\pm$26
6-OH-DA	11$\pm$5	53$\pm$12	57$\pm$4	46$\pm$5	53$\pm$8
0.05 N: SHAM	29$\pm$5	290$\pm$85	426$\pm$154	352$\pm$178	167$\pm$99
6-OH-DA	32$\pm$7	127$\pm$39	84$\pm$25	61$\pm$18	48$\pm$35

In addition, the ACTH response to either stress was reduced from 626$\pm$93 (SHAM) to 327$\pm$78 (6-OH-DA) ($p<0.05$). This indicates that CATs may be involved as mediators of the ACTH response to nicotine. (Supported by DA03977).

MONOAMINE MEDIATION OF COCAINE-INDUCED HPA ACTIVATION. **B.Borowsky and C.M.Kuhn. Department of Pharmacology, Duke University Medical Center, Durham, North Carolina, 27710.**

The acute administration of cocaine (5-20 mg/kg,ip) to rats produced a dose-dependent elevation in both serum corticosterone (CS) and plasma adrenocorticotropin hormone (ACTH). These rises were maximal at 30 min and returned to basal values by 60 min. More selective DA uptake blockers GBR12909 and nomifensine also stimulated hypothalamo-pituitary-adrenal (HPA) axis activity, while the local anesthetic, procaine, did not. Pretreatment with haloperidol (0.2 mg/kg) significantly attenuated the increases in CS and ACTH elicited by cocaine, as well as the elevation in ACTH produced by GBR12909. Pretreatment with the D1 antagonist, SCH23390, or the 5HT2 antagonist, ketanserin, but not the alpha-1 antagonist, prazosin, significantly decreased the ACTH rises following cocaine. Intracerebroventricular 6-OHDA lesions also significantly attenuated the ACTH response to cocaine. Following the repeated administration of cocaine (15 mg/kg, twice daily, 7 days), rats displayed a sensitized behavioral response to cocaine challenge while the HPA response to cocaine or saline was unaltered. The present results support a stimulatory role for dopamine, involving both D1 and D2 receptor subtypes, in regulation of HPA activity. However, both DA and 5HT could contribute to the adrenocortical stimulation by cocaine.

EFFECTS OF THE OPIATE-ANTAGONIST NALTREXONE ON STRESS-INDUCED PEPTIDE RELEASE FROM THE RAT INTERMEDIATE PITUITARY. **J.A. Carr, L.C. Saland, A. Samora*, E. Vigil-Palmer* and S. Desai*. Dept. of Anatomy, Univ. of New Mexico Sch. Med., Albuquerque, NM 87131.**

We have previously reported that acute restraint stress results in ultrastructural evidence for enhanced release of pro-opiomelanocortin (POMC)-derived peptides from the intermediate lobe (IL) of the rat pituitary (Carr et al., 1989, Anat. Rec. 223:22A). In this study, we investigated the possibility that endogenous opioid peptides mediate peptide release from the IL during stress. Male Sprague-Dawley rats were injected ip with saline or one of two doses of the opiate-antagonist naltrexone (1 mg/kg or 10 mg/kg) 30 min prior to being placed in plexiglass restraint cages. Unstressed rats received similar injections. Pituitaries were fixed in 2.5% glutaraldehyde-1% paraformaldehyde in 0.1 M phosphate buffer for subsequent TEM. IL cells in unstressed animals contained numerous membrane-bound granules of various electron densities. As expected, there was a significant decrease in the granular content of IL cells in saline-treated rats stressed for 30 min. Pretreatment of rats with either 1 or 10 mg/kg naltrexone did not attenuate the degranulation of IL cells during stress. Conversely, naltrexone treatment appeared to potentiate the degranulation of IL cells during stress. These results indicate that stress-induced release of POMC peptides from the IL is not mediated by opioid receptors. Supported by NIH NS21256 and RR08139 (LCS).

429.6

INTERACTIONS OF CORTICOTROPIN-RELEASING FACTOR (CRF) AND α-HELICAL CRF ON PEPTIDE RELEASE FROM RAT NEUROINTERMEDIATE LOBES IN VITRO. **E. Vigil-Palmer*, A. Samora*, S. Desai*, J.A. Carr and L.C. Saland.(SPON: S. Rogers). Dept. of Anatomy, Univ. of New Mexico Sch. Med., Albuquerque, NM 87131.**

CRF stimulates proopiomelanocortin (POMC) peptide release from both anterior (AL) and intermediate (IL) pituitary lobes. Dopamine, an inhibitor of POMC release from the IL, reduces CRF stimulation effects in the IL in vitro (Saland et al, 1988, Neuropeptides 12: 59). The synthetic antagonist, alpha-helical CRF (α-Hel), suppresses CRF effects in AL POMC cells. Here, we demonstrate inhibition of POMC secretion from the IL by α-Hel. Neurointermediate lobes (NILS) from ether anesthetized adult male Sprague-Dawley rats were incubated in Gibco medium including glucose, glutamine and 0.1 mM bacitracin, for 90 minutes. CRF (10^{-9} M) was added, with or without α-Hel (10^{-7} M). NILS were also incubated with CRF followed by addition of α-Hel at 30 minutes, or the converse. Aliquots of media were assayed for β-endorphin (END) immunoreactivity by radioimmunoassay. Alpha-Hel reduced β-END release in all cases, whether added with CRF, or before or after CRF. Immune staining for POMC peptides of tissue taken at 90 minutes confirmed inhibition of peptide release after α-Hel treatment. Electron microscopy of tissue fixed at 90 minutes showed cytologic changes consistent with modulation of granule secretion by α-Hel. POMC cells of the rat IL are thus responsive to a specific inhibitor of CRF to suppress peptide release. Supported by NIH NS 21256 and RR-08139 (LCS).

HYPOTHALAMIC AND PITUITARY METABOLISM ACTIVATED BY ELECTRICAL STIMULATION OF THE AREA POSTREMA. S.W. Shaver, D.S. Wainman*, K.M. Wall*, A.V. Ferguson and P.M. Gross. Depts. Surg. & Physiol., Queen's Univ., Kingston, ON K7L 3N6.

Polysynaptic pathways link hypothalamic nuclei and the neurohypophysis with the area postrema (AP), a medullary nucleus involved in viscerosensory, autonomic, and endocrine regulation. Using the [^{14}C]deoxyglucose method in halothane-anesthetized rats, we tested the effect of electrical stimulation (ES; 75-150 μA, 15 Hz, 1 ms) of the AP on metabolic activity in forebrain components of this neural circuit. ES produced reflex hypotension (-20% in mean arterial blood pressure) and 22 to 63% increases in glucose metabolism of first-order AP projections in the medulla and pons. Forebrain sites displaying elevated rates of glucose metabolism were the hypothalamic paraventricular (+38%), supraoptic (+22%), and suprachiasmatic nuclei (+47%), median eminence (+29%), and pituitary neural lobe (+104%). Equivalent hypotension induced by hemorrhage in rats not receiving ES altered neither hypothalamic nor neurohypophysial metabolism, results confirming the specific effects of ES. These studies identify selective functional responses in hypothalamic nuclei and the pituitary gland mediated over long neural pathways from stimulation of a brainstem nucleus. Thus, we speculate that controls for pituitary secretions, body fluid homeostasis, and blood pressure are influenced by ascending projections from the AP.

ATRIOPEPTIN INHIBITS PITUITARY CORTICOTROPIN RELEASE IN VITRO: INVOLVEMENT OF CYCLIC GMP AND POTASSIUM CHANNELS. F.A.Antoni* and G.Dayanithi* (SPON: BRA, U.K.) MRC Brain Metabolism Unit, Univ. Dept.of Pharmacology, Edinburgh, U.K. and Dept.of Human Anatomy, Univ. Oxford, Oxford, U.K.

The physiological role of atriopeptin produced by hypothalamic neurons that project to the external layer of the median eminence is unknown. Here we report the analysis of the action of 5-28 residue atriopeptin (ANF) on corticotropin (ACTH) release by isolated rat anterior pituitary cells in a perifusion system.

The secretion of ACTH was stimulated by the combined administration of 0.05 nM corticotropin-releasing factor and 0.5 nM arginine-vasopressin (CRF/AVP). Repeated exposure to CRF/AVP for 2.5 min at 30 min intervals resulted in a gradual increase of the net ACTH response from 3-4x basal release to a plateau of 8-10x basal by 2 h. ANF (0.1 nM) completely prevented the increase of the hormonal response while 0.01 nM of the peptide attenuated it by 40%. Once the maximal ACTH response was attained, ANF still inhibited CRF/AVP induced ACTH release, albeit with a lower (cca. 10x) potency. In contrast, ANF failed to inhibit ACTH release evoked by the combined stimulus of 10 nM phorbol dibutyrate and 200 nM ionomycin.

The actions of ANF in this system were mimicked by 8-Br-cGMP, moreover, ANF increased the level of cGMP in the cells, and an ANF analogue largely devoid of guanylyl-cyclase stimulating activity was a weak inhibitor of ACTH release. Finally, blockers of K channels, such as tetraethyl ammonium (5 mM), 4-aminopyridine (5mM) and quinine (0.1 mM) all blocked the inhibitory action of ANF, but had no marked effect on CRF/AVP induced ACTH release when given alone.

In summary, ANF inhibits secretagogue-induced ACTH release by activating guanylyl cyclase, and the cGMP produced may influence the flux of K^+ and/or Ca^{2+} through the plasma membrane. We propose that ANF is a hypothalamic ACTH-release inhibiting hormone.

INCREASED POMC GENE EXPRESSION IN ANTERIOR PITUITARIES OF SUICIDE VICTIMS: AN *IN SITU* HYBRIDIIZATION STUDY. J.F. Lopez*, S.J. Watson, M. Arato*, M. Palkovitz*, S. Burke* and H. Akil (SPON: M. Akil). Mental Health Research Institute, Ann Arbor, MI 48109-0720; National Institute for Nervous and Mental Diseases, Budapest, Hungary.

Suicidal behavior has been associated with hypothalamic-pituitary-adrenal overactivity in humans, as measured by increased corticosteroid secretion (Yehuda, et al., Neurol. Clin., 6:83, 1988). To investigate if this overactivity is reflected at the pituitary level, we have studied the accumulation of pro-opiomelanocortin (POMC) mRNA, the molecule coding for the ACTH/β-endorphin precursor, in human anterior pituitaries.

Pituitaries from 7 suicide victims and 11 cardiac deaths were sectioned in to 10 μ slides, stained with thionin and processed for *in situ* hybridization using a riboprobe complementary to human POMC mRNA. To correct for possible post-mortem cell loss, hybridization with P1B15, a cDNA complementary to rat cyclophilin mRNA, was used in adjacent sections. Quantification with a computerized image analysis system (ICC/LOATS) revealed a 25% increase in POMC message in suicide victims. Analysis of the corticotrophic cell clumps showed that the suicide victims had higher POMC mRNA density per cell (p=0.04, t-test) and larger corticotrophic cell size (p=0.04) than the cardiac death victims. There were no differences in P1B15 message between the two groups. No correlation with age or post-mortem time were detected. The relationship of human glucocorticoid receptor mRNA and β-endorphin peptide content to these changes is currently under investigation in the same pituitaries and will be reported. Supported by NRSA MH09632 (J.F.L.) and NIMH MH422251 (S.W. and H.A.)

SPECIES DIFFERENCES IN PLASMA ß-ENDORPHIN/ß-LIPOTROPHIN RATIOS. E.H. Mougey, K.L. Huhman, J.L. Meyerhoff and M.A. Marrazzi. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307-5100 and Department of Pharmacology, Wayne State University School of Medicine, Detroit, MI 48201.

Human and animal plasmas were extracted using PrepPAK-500/C_{18} and the endorphins (ß-EP and ß-LPH) were separated by sequential solvent elution. Plasma was added to 143 mg of the C_{18} adsorbent along with an equal volume of acidified water. After centrifugation of the tubes and aspiration of the supernatants the C_{18} was washed three times with water. ß-LPH was eluted with two 1 ml rinses of acetone:water and ß-EP was eluted with two 1 ml rinses of acetone:water:TFA. The extracts were evaporated to dryness under nitrogen gas at 45°C and the residues were taken up in RIA buffer and assayed using a commercial kit (NEN) for human samples and an in-house RIA for the animal samples. Both antisera cross-react with ß-LPH.

Male human subjects (N=10) had a mean ß-EP level of 7.2±2.4 pg/ml and a mean ß-LPH level of 27.7±5.9 pg/ml (expressed as ß-EP equivalents) for a mean plasma ß-EP/ß-LPH ratio of 0.263±0.078. Male Sprague Dawley rats (N=12, 90 days old) had a mean ß-EP level of 355±42 pg/ml and a mean ß-LPH level of 266±96 pg/ml, ratio=1.46±0.43. Female mice (N=8, CBA/J, Jackson Labs.) had a mean ß-EP level of 30.6±18.0 and a mean ß-LPH level of 293±39 pg/ml, ratio=0.104±0.058. Male Syrian hamsters (N=12) had a mean ß-EP level of 246±49 pg/ml and a mean ß-LPH level of 98±29 pg/ml for a ratio of 2.65±0.64.

429.11

HYPOTHALAMIC-PITUITARY-ADRENAL DYSFUNCTION IS ASSOCIATED WITH COGNITIVE IMPAIRMENTS IN AGED RATS. A. Issa, S. Gauthier, W. Rowe, & M.J. Meaney. Douglas Hospital Research Ctr., Depts. of Psychiatry and Neurology and Neurosurgery, McGill Univ., Montreal H4H 1R3, Canada.

Increased activity of the hypothalamic-pituitary-adrenal (HPA) axis is associated with age-related neuropathology. The hippocampus, a critical brain region in learning and memory, is especially sensitive to glucocorticoids (GCs), and chronic exposure to elevated GCs results in the loss of hippocampal neurons (Sapolsky et. al, J. Neurosci., 1985).

To assess the relationship between HPA activity and cognitive dysfunction in later life, we screened over 100 aged (24-29 month old) rats using the Morris swim maze. Three groups were then compared: aged cognitively-impaired, aged-cognitively unimpaired, and young adult (6-8 months of age). Plasma levels of ACTH and corticosterone (B) were significantly elevated during the PM phase of the cycle in the aged-impaired animals. Moreover, the aged-impaired animals hypersecreted B following the termination of a stressor. HPA activity under both basal and stressful conditions was similar in the aged-unimpaired and young adult rats. Type II, glucocorticoid receptor binding in hippocampus, measured using [3H]RU 28362, was lower in both groups of aged animals, however, the receptor loss was significantly greater in the aged-impaired animals.

These data suggest that HPA dysfunction in the rat is associated with neuropathology and does not occur merely as a function of age. Taken together with our previous studies (see Meaney et. al, Science, 1988) these findings also suggest that individual differences in HPA function in later life are a major predictor of neuropathology in later life.

BASAL HYPOTHALAMIC-PITUITARY-ADRENAL FUNCTION IN AGED HANDLED AND NONHANDLED RATS. V. Viau, S. Sharma, D.H. Aitken, & M.J. Meaney. Douglas Hospital Research Ctr., Dept. Psychiatry, McGill Univ., Montreal H4H 1R3, Canada.

Adult rats handled (H) for the first 3 weeks of life show increased negative-feedback sensitivity to circulating glucocorticoids, an effect that endures throughout the life of the animal (Meaney et al., Science, 1988; Neuroendocrinology, In press). With age, basal corticosterone (B) levels rise dramatically during the PM phase of the cycle in nonhandled (NH), but not in H rats. There is a moderate increase in basal plasma B during the AM phase with age in both H and NH rats. Plasma levels of corticoid-binding globulin (CBG) are similar in young H, young NH animals, and old H animals. During the PM phase of the cycle CBG levels in the old NH animals are significantly ($P<0.01$) reduced and free levels of B are 3-4 fold higher than in old H animals.

Type II, glucocorticoid receptor binding in hippocampus, measured using [3H]RU 28362, was lower in both groups of aged animals, however, the receptor loss was significantly ($P<0.05$) greater in the aged NH animals. Type I, glucocorticoid receptor binding in hippocampus, measured using [3H]B in the presence of cold RU 28362, was lower in both aged H and NH animals. These data indicate that hypersecretion of B in the aged NH animals is substantial, especially in the PM phase of the cycle. Differences in PM, basal B secretion appear to be associated with changes in type II receptors, whereas the moderate, aged-related increase in AM, basal B in both H and NH animals may be associated with the loss of type I receptors.

429.13

NEUROENDOCRINE RESPONSES TO m-CHLOROPHENYLPIPERAZINE (m-CPP), A RELATIVELY SELECTIVE $5HT_{1B}$ AGONIST. J. Saydoff, P.A. Rittenhouse, M. Carnes, M.S. Brownfield, and L.D. Van de Kar. Sch. Vet. Med., Univ. of Wisconsin, Madison, WI 53706, Sch. Med., Loyola Univ., Maywood, IL 60153, and Veterans Admin. Hosp. Madison, WI 53705.

To determine the potency of m-CPP in stimulating neuroendocrine function we compared the secretion of corticosterone, renin, and vasopressin in the rat. Groups of eight rats were administered m-CPP, 0-20 mg/kg, i.p. Thirty minutes later rats were killed and trunk blood was collected and processed for radioimmunoassay of plasma corticosterone, renin, and vasopressin. Corticosterone secretion was stimulated by m-CPP in a dose-response manner with a minimum effective dose of 3 mg/kg and remained elevated at all higher doses. In contrast, the renin dose-response curve was shifted to the right with a minumum effective dose of 10 mg/kg. Vasopressin secretion was unresponsive to m-CPP at any dose tested.

Comparison of the different potencies of m-CPP revealed in the dose-response curves for these hormones may suggest that different receptor mechanisms are involved. This conclusion would be consistent with previous studies that have previously shown that corticosterone secretion is stimulated by a $5HT_{1A}$ mechanism while renin and vasopressin are stimulated by a $5HT_2$ mechanism. It should be mentioned that the minimum effective dose of m-CPP needed to elict corticosterone secretion was about five to ten times higher than that required by $5HT_{1A}$ agonists, suggesting that m-CPP might have some $5HT_{1A}$ activity. Renin secretion is also stimulated by RU24969, a drug that is structurally similar to m-CPP, but this effect was blocked by ritanserin, a $5HT_2$ antagonist. This might imply that m-CPP has some $5HT_2$ agonistic properties.

The results show that m-CPP stimulates the secetion of corticosterone and renin, but not vasopressin. The specific receptors involved and their sites that mediate these neuroendocrine responses remain to be established.

429.14

ADRENOCORTICOTROPIN HYPERSECRETION ASSOCIATED WITH DIABETES MELLITUS RESULTS FROM AN INCREASED RELEASE OF HYPOTHALAMIC CORTICOTROPIN RELEASING FACTOR. C. A. Johnston and C. Chapman*. College of Pharmacy, Wash. State Univ., Pullman, WA 99164-6510.

Adrenal hypertrophy, and increased plasma levels of adrenocorticotropin (ACTH) and corticosterone have been observed in diabetics both experimentally and clinically. The central mechanisms responsible for this diabetes-associated hypersecretion of ACTH are not known. The present study examined the effects of experimentally-induced diabetes mellitus [streptozotocin (STZ), 65 mg/kg BW, iv] on the concentrations, release and anterior pituitary (AP) responsiveness to two major physiologically relevant central ACTH secretagogues, corticotropin releasing factor (CRF) and arginine vasopressin (AVP) in male Sprague-Dawley rats. Diabetes was confirmed by monitoring daily water intake and measuring blood glucose levels. Content of CRF and AVP were measured in acid extracts of medial basal hypothalamic (MBH) tissues dissected from diabetic or control animals using specific RIAs. Basal and potassium-induced release of CRF and AVP was evaluated in vitro from MBH tissues. The in vivo ACTH response to an iv injection of either CRF (1 ug/rat) or AVP (1 nmole/rat) was assessed using chronic indwelling jugular cannulae in unanesthetized, freely moving rats. The data indicate that the diabetes-associated hypersecretion of ACTH is not due to alterations in the content/release of central AVP or the ACTH response of the AP to CRF or AVP, but appears to be caused by an enhanced release of CRF from the hypothalamus. This work was supported by a grant from the Diabetes Research and Education Foundation.

LIPOCORTINS AND ASTROGLIAL PROSTANOID SYNTHESIS P.J.Gebicke-Haerter*, A.Schobert*, P.Dieter*, G. Hertting*, (SPON: J. Geer)Inst. of Pharmacol.& Biochem., Univ. Freiburg, 78 Freiburg, F.R.G.

Increased synthesis of lipocortins (LC) is believed an important part of the anti-inflammatory effects of glucocorticoids. WESTERN blot analyses of LC using specific antisera against LC I(resp. its 32 kDa fragment) and against LC II (Pepinsky et al., J.Biol.Chem.261,4239) revealed that : 1. LC I and II levels were very low in rat brain and liver, 2. LC I was specifically induced in cultured astrocytes, 3. LC I-32 kDa (or LC III, cross-reacting with antisera) was more prominent in microglia and was the predominant form in Kupffer cells. Hence, regulation of LC I-III synthesis is cell type specific.

4. LC I immunoprecipitated from ^{35}S-methionine-labeled astrocytes was increased upon dexamethasone treatment, 5. Glucocorticoids inhibited Ca^{2+}-ionophore A_{23187}-, TPA-, or ATP (Gebicke-Haerter et al., N.S.Arch.Pharm.338,704)-stimulated prostaglandin D_2 formation to various extent dependent from type of stimulus. 6. A 170 kDa lipocortin-like protein was found to cross-react with LC I antisera. Cultured astrocytes appear to be a good model system to study the regulation of phospholipase A_2 activity by LC I.

429.16

EFFECT OF HYPO- AND HYPERTHYROIDISM ON HYPOTHALAMIC-PITUITARY-ADRENAL AXIS RESPONSIVENESS TO NEUROPEPTIDE Y (NPY). E.O. Johnson*, T.C. Kamilaris*, A.E. Calogero,* A. Spalter*, P.W. Gold, and G.P. Chrousos. DEB/NICHD&CNB/NIMH, Bethesda, MD,

Hypothyroidism is associated with decreased and hyperthyroidism with increased activity of both the hypothalamic-pituitary-adrenal (HPA) axis and the sympathetic system. Neuropeptide Y (NPY), a 36 amino-acid peptide, is co-secreted with catecholamines during stress. We have shown that NPY activates HPA axis at both the hypothalamus and the adrenal cortex by causing CRH and corticosterone release, respectively. To examine the hypothesis that changes in thyroid status might affect the interactions between NPY and the HPA axis, we studied chronically cannulated, freely moving male rats with long-standing (60 days) hypothyroidism, hyperthyroidism, or euthyroidism. In all animals, we measured plasma concentrations of ACTH and corticosterone before and after an iv bolus of 10µg/100g BW NPY. Hypothyroid rats demonstrated significantly lower plasma ACTH and corticosterone concentrations after NPY administration than those of control rats. In contrast, no alteration in the basal and NPY-stimulated plasma ACTH was observed in the hyperthyroid animals. However, these animals had consistently elevated plasma corticosterone concentrations, confirming prior studies demonstrating hypercorticosteronism in hyperthyroid rats. We conclude that hypothyroidism is associated with decreases in NPY-induced HPA activation. The relative importance between this neuropeptide and the co-secreted catecholamines in regulating CRH secretion remains to be seen.

ADRENAL AND AUTONOMIC RESPONSES TO NOXIOUS STIMULI IN THE CAT: INTERACTION WITH BLOOD LOSS. D.A.Bereiter, A.P.Benetti* and K.V.Thrivikraman. Depts. Neurobiol. & Surgery, Brown Univ./R.I.Hospital, Providence, RI 02903.

The neuroendocrine responses to injury are mediated in part by nociceptive and cardiovascular afferent signals; however, the underlying central neural mechanisms are not well defined. Previously, we reported that glutamate activation of neurons within trigeminal subnucleus caudalis evoked adrenal and autonomic responses consistent with those seen after injury. Presently, the adrenal venous secretion of epinephrine (E) and plasma ACTH were assessed after noxious trigeminal stimuli (corneal heat, 52°C), after moderate blood loss (10ml/kg), and after pairing of both stimuli in chloralose-anesthetized cats. Also, the neurochemical input to the caudal raphe nuclei (Rpa) was examined by a push-pull perfusion technique to determine if monoaminergic input to this CNS region reflected the observed endocrine or autonomic responses. Perfusate was sampled (25µl art. CSF/min over 5 min) and processed by HPLC-EC. Corneal heat evoked an increase in arterial pressure (MAP) and in E (+7±2 ng/min), whereas plasma ACTH was not affected (-7±15 pg/ml). In contrast, blood loss evoked a decrease in MAP, but an increase in E (+14±3 ng/min) and in ACTH (+137±88 pg/ml). Presentation of corneal heat during blood loss evoked an exaggerated ACTH response (+233±97 pg/ml, P<.01), whereas the increase in E (+12±7 ng/min) was similar to that after blood loss alone. Noradrenergic input to the Rpa increased after corneal heat, but not after blood loss. Summary: corneal afferent nerve activity reliably increased the adrenal secretion of catecholamines (CA) and arterial pressure, but corneal heat alone did not affect ACTH. The potentiated release of ACTH by corneal heat during blood loss indicated an interaction between trigeminal nociceptive and cardiovascular afferents in the control of ACTH, whereas the adrenal secretion of CA was not affected by such an interaction. The perfusate results were consistent with a role for Rpa in the integration of nociceptive input and in control of cardiovascular function, but did not correlate well with the secretion of CA or with the interaction of stimuli that augmented plasma ACTH. Supported by NIH grant NS26137.

EFFECTS OF V1 VERSUS V1+V2 VASOPRESSIN ANTAGONISTS ON THE ACTH AND GLUCOCORTICOID RESPONSES TO HYPOTENSION IN CONSCIOUS DOGS. V.L. Brooks* (SPON: R. Boyle). Dept. of Physiology, Oregon Hlth Sci Univ., Portland, OR 97201.

Pretreatment of conscious dogs with the V1 vasopressin (VP) antagonist (V1-A), $d(CH_2)_5Tyr(Me)AVP$, attenuates the increases in plasma ACTH and glucocorticoid (GC) concentrations produced by hypotension. We investigated whether an attenuation of the ACTH and GC responses would also be found in dogs pretreated with the combined V1+V2 VP antagonist (V1V2-A), $desGly^9d(CH_2)_5[D\text{-}Tyr(Et^2)]VAVP$. In untreated dogs (n=14), four consecutive, 15 min IV infusions of the vasodilator nitroprusside (NP), at increasing doses of 0.3, 0.6, 1.5 and 3.0 $\mu g \cdot kg^{-1} \cdot min^{-1}$, gradually decreased mean arterial pressure from 103 ± 3 to 86 ± 3 mmHg (P<0.001), increased GC from 16 ± 2 to 71 ± 6 ng/ml (P<0.001) and increased ACTH from 31 ± 3 to 139 ± 25 pg/ml (P<0.001). Both V1-A (6 ± 1 µg/kg; n=7) and V1V2-A (100 µg/kg; n=7) reduced the CC and ACTH responses to hypotension; however, there was no difference in the effects of V1-A versus V1V2-A. In addition, the increases in GC associated with given increases in ACTH were less in dogs pretreated with either VP antagonist. These data indicate that endogenous VP is required for normal ACTH and GC responses to hypotension, and that this effect can be blocked by either a V1 or a combined V1+V2 antagonist. Furthermore, VP may increase GC during hypotension in part by an effect independent of the regulation of ACTH secretion. Supported by NIH Grant HL 35872.

IN SITU HYBRIDIZATION OF VASOPRESSIN mRNA IN PARVOCELLULAR PARAVENTRICULAR (PVN) NEURONS IS ABOLISHED IN ADRENALECTOMIZED (ADX) RATS BY LOW CORTICOSTERONE.

S.F.Akana, C.S. Cascio*, and M.F.Dallman*. Univ. California Medical Center, San Francisco CA 94143-0444.

ADX stimulates increases in CRF and vasopressin(AVP) secretion and expression in parvocellular PVN, resulting in marked stimulation of ACTH secretion. Corticosterone (B) replacement of ADX rats restores ACTH to normal. To determine whether inhibition by B of ADX-associated increases in AVP expression in parvocellular PVN is consistent with inhibition mediated by high affinity type I (K_D 0.5 nM) or lower affinity type II (K_D 2.5-5nM) B receptors, ADX rats were replaced with 0, 25 or 75% B pellets sc, and killed in the AM on d5. Blood and PVN brain sections were collected from these rats and sham controls; sections were hybridized with an ^{35}S-labeled 35-base oligomer for AVP, emulsion-dipped, developed and examined for location of silver grains. Grains over parvocellular cells in PVN were observed in ADX, but were restricted to magnocellular cells in Shams and both B-treated ADX groups. Plasma ACTH was normalized in the 25% B groups at plasma B concentrations of 80nM total, or 1 nM estimated free B (Endo. 121:1104, 1987). We conclude that free B concentrations lower than the K_D for type II, but higher than the K_D for type I receptors are sufficient to normalize ADX-induced increases in AVP mRNA in parvocellular neurons of the PVN, suggesting a type-I mediated effect.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION II

430.1

DENSITY OF SYNAPTIC INPUT IS IDENTICAL TO SMOOTH-CONTOURED AND THORNY GnRH NEURONS IN THE MALE RAT.

J.W. Witkin and K.A. Demasio*. Dept. Anatomy and Cell Biology, Columbia Univ. Coll. P&S, New York, NY 10032

GnRH neurons are typically smooth-contoured and fusiform in shape with a process extending at each pole. In the rat and other species, there is a subpopulation of these neurons which has an irregular contour with spiny projections from the cell soma and proximal processes. It is not known whether this difference is functionally significant, but the relative numbers of thorny GnRH neurons is reduced in immature (Wray and Hoffman, Neuroend.43:93,'86) and castrate rats (Witkin, Neuroend., in press). In order to discern whether the thorny neurons are more densely innervated (as has been suggested, Jennes et al., J. Comp. Neurol.,232:534,'85), 4 adult male rats were deeply anesthetized with pentobarbital and perfused with paraformaldehyde/glutaraldehyde and brain sections from the preoptic area were treated immunohistochemically for the ultrastructural demonstration of GnRH, using the LR1 antibody (Benoit). 5 smooth and 5 thorny neurons were identified in 1 um sections and a series of ultrathin sections at 3 depths prepared. From photomicrographs of these cells, the percent of plasma membrane in synaptic contact was determined, and found to be the same in the two groups of neurons.

To ascertain whether these cells might differ in some other aspects, the relative representations of subcellular organelles in the two shapes were compared using point counting stereology. Smooth contoured neurons had more and larger nucleoli but a smaller volume fraction of Golgi apparatus and mitochondria, while the representation of RER was similar in neurons of the two shapes. These results suggest that smooth contoured GnRH neurons are more actively transcribing message while thorny neurons are more actively engaged in peptide processing and packaging. These differences appear to be independent of synaptic input, but this must be confirmed by chemical identification of the synapses. NIH AG05366.

430.2

SEXUAL DIMORPHISM IN THE INNERVATION OF GnRH NEURONS IN THE RAT.

W.P. Chen, J.W. Witkin and A.J. Silverman. Dept. of Anat & Cell Biol., Columbia Univ. New York, N.Y. 10032

The pattern of gonadotropin secretion and presumably the release of GnRH varies between the sexes. To determine if dimorphic neurohormone release might be due to differences in the synaptic input to GnRH cells, we undertook a quantitative study identifying total input as well as two chemically identified inputs, the endogenous opiate beta-endorphin (B-E) and GnRH. Young adult (3-4 mos) Fischer 344 rats (2 male and 4 diestrus II female) were deeply anesthetized with sodium pentobarbital and perfused with 4% paraformaldehyde. Vibratome sections through the diagonal band and preoptic area were treated for the ultrastructural localization of B-E and GnRH immunoreactivity with DAB and TMB as the respective chromogens (Chen et al, Soc. Neurosci. 14:439, '88). In two of the females the antibodies were used in the reverse sequence to verify that there was no bias imposed by the order of the reactions. 20-30 serial ultrathin sections of 20 GnRH neurons (recognized by the presence of large TMB crystals) from the males and 15 from 2 females were photographed and analyzed for the presence of synapses. Synapses were categorized as B-E or GnRH containing, or were "non-identified". Dendrites from the same thin sections were also analyzed. Several categories of synaptic input did show a sexual dimorphism. These included twice as many synapses in total onto the cell soma of females ($p<0.001$) as well as twice as much B-E axosomatic and axodendritic input. Neither the total number of synapses to GnRH dendrites nor the number of GnRH-GnRH interactions varied between the sexes. In both sexes there were occasional GnRH/GnRH dendrosomatic appositions defined by the presence of membrane thickenings and clefts between the two elements, and occasional "synaptic" vesicles. Thus, we have demonstrated that the organization of the synaptic input to GnRH neurons differs between male and female and a portion of the dimorphism is due to the B-E input. China Medical Board (WPC), HD 10665 (AJS).

430.3

DIET RESTRICTION AND LHRH NEURON MATURATION.

W.S. Lee*, and G. E. Hoffman (SPON: M. S. Smith) Dept. of Physiology, Univ. of Pittsburgh, Pittsburgh, PA 15261

LHRH neurons show changes during postnatal development: their morphology shifts from smooth to irregular and plateaus at the time of puberty. We sought to determine whether the programming of morphological changes in LHRH neurons can be interrupted by delaying the onset of puberty by weight restriction. Female rat pups were fed ad libitum or maintained at 75g body weight from 24 days of age until 35-40 days (normal puberty). A third group of rats were weight-restricted, refed at 40 days, and then sacrificed after vaginal opening (approx. 4-5 days after refeeding). Tissue was prepared by perfusion with acrolein and stained for LHRH using standard immunocytochemical techniques and the LR-1 antibody. Weight restricted, refed and control animals all showed comparable cell numbers for LHRH, indicating that restricted animals had no significant impairments in LHRH cell viability or synthesis. The shift from smooth to irregular contours that normally accompanies postnatal maturation was maintained in the diet-restricted animals. However, pre- and post-pubertal LHRH neurons also differ in the apparent subcellular distribution of LHRH within the cytoplasm. In 24 day old rats, most LHRH cells are characterized by immunoreactivity within the entire cytoplasmic compartment; a small number of cells display distinct granules in the cytoplasm with little extragranular LHRH. In contrast, in the pubertal rats, a greater portion of the cells are distinctly granular. The diet-restricted rats maintained the prepubertal cytoplasmic pattern; refeeding rapidly established the pubertal pattern. These results suggest that granularity can be used to reflect the activity of the LHRH system, and may underlie changes in the processing or storage of LHRH.

430.4

GNRH-, VASOPRESSIN-, AND GAD-IR NEUROENDOCRINE NEURONS INTERACT SYNAPTICALLY IN THE SUPRAOPTIC NUCLEUS OF JUVENILE MONKEYS.

K.K. Thind, J.E. Boggan* and P.C. Goldsmith. Reproductive Endocrinology Center and Dept. of Ob/Gyn & Repro. Sci., Univ. Calif., Sch. Med., San Francisco, CA 94143.

Vasopressin (VP) and gamma-aminobutyric acid (GABA) are hypophysiotropic hormones also involved in control of gonadotropin-releasing hormone (GnRH) secretion. We examined whether GnRH, VP, and glutamic acid decarboxylase (GAD) immunoreactive (-IR) elements interact synaptically in the supraoptic nucleus (SON) of cynomolgus monkeys. Neuroendocrine (NEU) neurons in 4 juveniles were retrogradely labeled before aldehyde perfusion (see Soc. Neurosci. Abstr. 14:439, 1988). Frontal vibratome sections were each immunostained for GnRH with PAP, VP with 5 nm gold, and GAD with 15 nm gold. Most of the VP-IR and the few GnRH-IR cell bodies in the SON were NEU. VP-IR elements formed axodendritic and axosomatic symmetrical synapses (SS) with one another. Serial thin sections revealed SS between GnRH axon terminals and both VP-IR dendrites and NEU cell bodies. Conversely, VP-IR boutons also formed SS with NEU GnRH-IR neurons. Of 312 VP and GAD profiles, 38% were -IR for both VP and GAD. VP+GAD-IR axons made asymmetrical synapses with GAD-IR dendrites (suggesting coexistence of an unidentified transmitter), but did not synapse with GnRH-IR elements. Longi-cut VP+GAD-IR axons and somata had regions where either VP-IR or GAD-IR was dominant, the significance of which is unclear. Our study demonstrates anatomical synapses between GnRH-IR and VP-IR neurons in SON, in which postsynaptic neurons were NEU. The presence of VP+GAD-IR axons also suggests coordinated roles for VP and GABA in neuromodulation or neuroendocrine control. (Supported by NIH HD10907).

EVIDENCE FOR PROCESSING INTERMEDIATES IN THE METABOLIC PATHWAY FROM PRO-LHRH TO LHRH. W.C. Wetsel, C.A. Johnston, and A. Negro-Vilar. Reprod. Neuroendo. Sect., Lab. of Mol. and Integrative Neurosci., NIEHS, Res. Tri. Pk., NC 27709.

Previous studies from our laboratory suggest that the molar ratio of gonadotropin-releasing hormone-associated peptide (GAP) to LHRH is variable in cell bodies, fibers, and nerve terminals during the estrous cycle of the rat. In the present study, we have evaluated these changes in peptide levels during noon of diestrus 2. Punches from the medial preoptic nucleus (MPO), diagonal band of Broca (DBB), retrochiasmatic area (RCA), arcuate nucleus (AN) and median eminence (ME) were collected from 90 rats. Materials, that were separated according to molecular weight, were screened both for GAP-like immunoreactivity LI) with MC-2 antisera and for LHRH-LI with A772 and Rice #5 antisera. A concentration gradient of precursor to products was found from the cell body to the nerve terminal region(s). The MC-2 antisera detected materials in the MPO and DBB at approximately 14000-16000, 8500, and 6700 molecular weight, while the ME only contained the latter 2 forms. At least 3 different molecular forms of LHRH were bound in the MPO, DBB and RCA, while the AN and ME contained only mature LHRH. These data suggest that at least 3 additional post-translational steps must occur before the mature LHRH is produced from pro-LHRH. The regulation of these processing steps may have important functional consequences during the estrous cycle.

430.6

POSTNATAL DEVELOPEMENT OF proGnRH-GAP GENE EXPRESSION IN THE FEMALE AND MALE RAT BRAIN. M. Jakubowski*, M. Blum and J.L.Roberts. (SPON: V. Friedrich). Fishberg Center for Neurobiology, Mt. Sinai School of Medicine, CUNY, New York, NY 10029

The content of proGnRH-GAP mRNA in the rat preoptic area-anterior hypothalamus (POA-AH) was followed from postnatal day 15 through day 63. Sprague-Dawley rats were sacrificed by decapitation and cytoplasmic RNA fractionated from individual POA-AH homogenates was purified using proteinase K digestion. Cytoplasmic proGnRH-GAP mRNA was quantitated along with cyclophilin mRNA (an internal standard control) using solution hybridization-RNase protection assay. Cyclophilin mRNA levels normalized against the content of total RNA proved to remain constant across the different age groups (p = 0.3). However, proGnRH-GAP mRNA showed a significant sex-related increase with age (p = 0.0001). In females, the mean fg proGnRH-GAP mRNA/μg total RNA levels increased from 1.7, 3.0, 4.8, 3.8 and 3.7 on days 15, 20, 25, 29 and 34, respectively, to 7.2 and 15.5 on days 44 and 63, respectively. In males, the mean fg proGnRH-GAP mRNA/μg total RNA levels increased from 2.3 and 3.5 on days 15 and 20, respectively, to 6.2-7.3 in the older age groups.

These results show a sex difference in the postnatal development of proGnRH-GAP gene expression in the rat POA-AH. In males, proGnRH-GAP mRNA levels increase around the time of weaning (day 25) and remain unchanged thereafter. In females, proGnRH-GAP mRNA stores increase at the time of puberty (day 44) to levels shown by adult males, with a further 2-fold increase in adulthood.

430.7

DO CATECHOLAMINERGIC, NEUROPEPTIDE Y, SUBSTANCE P, AND GABAERGIC TERMINALS INNERVATE GONADOTROPIN RELEASING HORMONE (GNRH) NEURONS IN THE SHEEP? F.J. Karsch*, F.J. P. Ebling*, & M.N. Lehman. Reprod. Sci. Prog., Univ. Mich., Ann Arbor, MI; Dept. Anat. & Cell Biol., Univ. Cincinnati Coll. Med., Cinti, OH.

Pharmacologic evidence suggests that neurons which secrete GnRH are regulated by a wide variety of neurotransmitter systems. To unambiguously determine the neurochemical identity of synaptic inputs onto GnRH neurons in sheep, we used a double label immunocytochemical protocol which yields visibly different reaction products at both light and electron microscopic (EM) levels (Norgren & Lehman, *J. Histochem. Cytochem.*, in press). Suffolk ewes (n=12) were perfused intracranially during mid-breeding season and potential contacts examined between immunoreactive tyrosine hydroxylase (TH), neuropeptide Y (NPY), substance P (SP), or glutamic acid decarboxylase (GAD) terminals and GnRH neurons in the preoptic area and anterior hypothalamus. At light and EM levels, NPY-, SP-, and GAD-positive varicosities were more frequently apposed to GnRH somas and dendrites than were TH-positive boutons. In all thin sections, non-identified terminals contacting GnRH neurons were more numerous than immunoreactive ones. TH-, NPY-, and SP-positive axon terminals contained clear spherical vesicles (20-40 nm diam.) and larger dense-core vesicles (80-120 nm diam.); GAD terminals contained only small clear vesicles. Thus far we have seen synaptic modifications only between NPY and SP terminals and GnRH dendrites. [Supported by NIH grants HD 18337 (FJK) and HD 21968 (MNL)]

430.8

GONADOTROPIN RELEASING HORMONE (GnRH) FROM THE AMNIONIC FLUID BINDS TO GnRH RECEPTORS IN THE DEVELOPING RAT PITUITARY. L. Jennes. Dept. Anatomy, Wright State Univ. Sch. of Med., Dayton, OH 45435.

With *in vivo* and *in vitro* autoradiography, specific GnRH receptors were identified in the developing pituitary as early as at fetal day E13. Immunohistochemistry and radioimmunoassay (RIA) could not detect GnRH in fetal (E12-E14) brains, however, this peptide could be measured in the amnionic fluid (AF). GnRH levels in the AF were low at day E12 (0-30 pM/ml), they increased at days E15-16 to 250 pM/ml before they declined to 100 pM/ml at days E17-20. The identity of GnRH in the AF was verified by a) RIA of AF extracts using 3 different anti-GnRH antibodies, b) gel filtration of AF extracts followed by RIA and c) the ability of AF to stimulate LH release in pentobarbital anesthetized rats. Since ^{125}I-Buserelin injected intravenously into the maternal circulation can cross the fetal-placental barrier and since Buserelin injected into the amnionic fluid binds to fetal pituitary GnRH receptors, it is suggested that maternal GnRH from the placenta reaches the fetal pituitary and may play an important role in the development of fetal gonadotropes.

430.9

CO-EXISTENCE OF LUTEINIZING HORMONE RELEASING HORMONE (LHRH) AND GALANIN IN A SUBPOPULATION OF NEURONS IN THE PREOPTIC REGION OF THE RAT BRAIN. I. Merchenthaler* and A. Negro-Vilar (SPON: L.C. Towns). Lab. of Mol. Integrat. Neurosci., NIEHS/NIH, Res. Triangle Park, NC 27709

The presence of galanin (GAL) fibers and terminals in the median eminence of the hypothalamus suggests an involvement of GAL in neuroendocrine functions. GAL is broadly distributed and co-localized with several peptides and amines. The distribution of GAL and LHRH perikarya within the preoptic area (POA) is similar. Although the majority of GAL neurons are round and multipolar, a certain subpopulation of neurons in the POA are fusiform. The appearance of these neurons is similar to the typical LHRH nerve cells. Double labeling immunocytochemistry on paraffin and vibratome sections from rat brains revealed that a certain subpopulation of LHRH perikarya in the POA is also immunoreactive for GAL. Each of three major technical approaches, i.e. "adjacent section method", the "elution-restaining technique" and the "direct double-staining technique" indicated that a subpopulation of LHRH neurons in the POA co-express GAL immunoreactivity. This represents the first demonstration of co-localization of another peptide in an LHRH neuron. Co-localization of GAL with LHRH in the same perikaryon suggests that GAL (a) may influence the release of LHRH; (b) may participate in the autoregulatory mechanism of LHRH secretion; (c) may be co-released and interact in a cooperative mannner with LHRH on pituitary gonadotropes.

PITUITARY FUNCTION IN THE DEVELOPING MALE TREE SHREW (TUPAIA BELANGERI). P.M. Collins*, W.N. Tsang*, and H. Urbanski. Dept. of Biol. Sci., Univ. of California, Santa Barbara, CA 93106.

The pattern of postnatal development in the male tree shrew conforms with the general primate pattern yet occurs within a condensed time-frame (90 days) which allows the establishment of precise endocrine correlates of reproductive events (Collins, P.M. and Tsang, W.N., Biol. Reprod. 37:261, 1987). To evaluate the role of gonadotropins in gonadal development FSH and LH were determined by RIA from birth to sexual maturity. Both gonadotropins remained low during the infantile phase (birth to Day 30) varying within narrow limits. FSH rose continuously between Days 40-45 and Days 66-75 in association with the onset of spermatogenesis and the accelerated growth of the testis (> 2-fold increase, $p<0.05$). FSH levels then declined in relation to the appearance of spermatids and the progression of spermiogenesis. LH levels were higher in pubertal as compared with infantile animals ($p<0.05$) with initial elevations coinciding with maximum plasma testosterone levels (Days 50-55). The data suggest a role for FSH and LH in the establishment of the gametogenic and endocrine functions of the testis respectively. As in Man and other primates, puberty in the tree shrew follows an extended infantile phase and appears to be a response to the activation of the hypothalamo-pituitary axis.

COMPUTER 3D RECONSTRUCTION OF MEDIAN EMINENCE MICRO-CAPILLARIES AT HIGH RESOLUTION. L.S. Hibbard[1], B.J. Dovey-Hartman[2*], R.B. Page[2], [1]Washington University School of Medicine, St.Louis, MO 63110, and [2]The Pennsylvania State University College of Medicine, Hershey, PA 17033.

The microvasculature of the median eminence (ME) of the hypothalamus modulates hormonal communication between the brain and the pituitary. We are now reconstructing ME capillary loops with the aim of locating the cellular apparatus responsible for blood flow control. These loop structures were selected after examining the 3D reconstruction of a low magnification study of this same tissue block, reported earlier (Soc. Neurosci. Abstr., 14:630, 1988). In that study, we found several capillary structures projecting from the outer to the inner plexus of the ME, like those observed in previous work (Page, et al., Am. J. Anat., 146:273, 1976).

We are now reconstructing discrete capillary structures with attached cellular elements from TEM images at 1650X. Digital image processing techniques are being used to create mosaics of overlapping images on each level, and to align the resulting mosaics (Hibbard, et al., Comput. Bio. Res., 16:411, 1986). Edge detection and tracking on the mosaics will provide intercellular boundaries, and local texture measures may be used to denote intracellular contents. (Support: NSF BNS-8506479 and NIH NS15926.)

DOPAMINE DOES NOT PLAY A ROLE IN THE REGULATION OF BLOOD FLOW IN THE OVINE MEDIAN EMINENCE. R.B.Page,M.Gropper*, E.Woodard*, J.Townsend*,S.Davis* and R.Bryan. Dept. of Surgery (Div. of Neurosurgery) Milton S. Hershey Medical Center of the Pennsylvania State Univ., Hershey, PA 17033.

Blood flow was measured in the ovine median eminence and neural lobe prior to and after the intravenous infusion of dopamine (N=6), the D_1 angonist SK&F 38393 (n=4), the D_2 agonist bromocriptine (N=4), and the dopamine antagonist haloperidol (N=5). It was also measured prior to and following the intracarotid infusion of dopamine into 8 naive sheep and 7 sheep pretreated with phenoxybenzamine. Radiolabelled microspheres were used to determine regional cerebral (RCBF) and regional neurohypophysial blood flow (RNHBF) as well as blood flow in the choroid plexus and kidneys in these 34 adult female sheep anesthetized with pentobarbital. Samples for serum prolactin measurement by radioimmunoassay were obtained before and after drug infusion. Haloperidol caused a significant fall in blood flow in median eminence (from 560±90 to 379±66 ml/100gm/min [mean±SE]) as well as in neural lobe, choroid plexus, caudate nucleus and kidneys. Intravenous dopamine infusion increased renal and choroid plexus blood flow but did not change RNHBF. Intracarotid dopamine infusion decreased median eminence and neural lobe blood flow and increased choroid plexus blood flow. Pretreatment with phenoxybenzamine only partially blocked the vasoconstrictor effect of dopamine. These findings do not support a role of dopamine in the regulation of median eminence blood flow.

GLUTAMATE IMMUNOREACTIVITY IN THE RAT NEURAL LOBE: AN ULTRASTRUCTURAL ANALYSIS OF NEUROSECRETORY ENDINGS AND PITUICYTES. R.B. Meeker, D.J. Swanson*, R.S. Greenwood and J.N. Hayward, Neurobiology Curriculum and Dept. of Neurology, University of North Carolina, Chapel Hill, NC 27599.

To explore the possibility that the high level of glutamate immunoreactivity which we have previously observed in the neuroendocrine cell bodies of the supraoptic nucleus might represent a neurotransmitter pool of glutamate, we examined the distribution of glutamate immunoreactivity within the neurosecretcry terminal field in the neural lobe. Rat brains fixed by perfusion with 4% paraformaldehyde, 2% glutaraldehyde and 15% saturated picric acid in 0.1 M cacodylate buffer were cut on a vibratome and stained with a rabbit polyclonal antiserum to glutamate-hemocyanin. Both pre-embedding (1:5000 Ab, ABC technique) and post-embedding (LR White, 1:10,000 Ab, 10-15 nm goat anti-rabbit collidal gold) staining revealed a high level of glutamate immunoreactivity associated with pituicytes. Little or no immunoreactivity was found in endothelial cells, phagocytic structures or astroglia with the hypothalamus. Neurosecretory axons or swellings rarely stained while the neurosecretory terminals exhibited a low level of staining over the population of small clear vesicles. Two days of water deprivation increased the level of glutamate immunoreactivity in the pituicytes and neurosecretory endings. These observations suggest that glutamate might be used as a transmitter by the neurosecretory endings although the levels of glutamate are very low. Glutamate in the pituicytes may reflect a number of possible functions including: 1) uptake of extracellular glutamate, 2) neutralization of ammonia, 3) active GABA sythesis or 4) a specialized pool associated with local osmoregulation.

430.14

ULTRASTRUCTURAL ANALYSIS OF NEUROPEPTIDE Y IMMUNOREACTIVITY IN THE SUPRAOPTIC AND PARAVENTRICULAR NUCLEUS OF THE RAT HYPOTHALAMUS. D.J. Swanson*, R.B. Meeker, J.N. Hayward, Neurobiology Curriculum and Dept. of Neurology, University of North Carolina, Chapel Hill, NC 27599.

High concentrations of immunoreactive neuropeptide Y (NPY) varicosities exist in the periventricular nucleus, paraventricular nucleus (PVN), the median eminence (ME) and basomedial hypothalamus with lower levels in the supraoptic nucleus (SON). Within these regions NPY may function to control local blood flow (Edvinsson, et al., 1987) and/or regulate vasopressin secretion (Swanson, 1987). To more clearly understand the role of this peptide we examined the ultrastructure of the terminal fields in the SON, PVN and ME. The brain of male Sprague-Dawley rats was fixed by perfusion with 4% paraformaldehyde, 0.1% glutaraldehyde, 15% saturated picric acid in 0.1 M phosphate buffer, pH 7.4. Vibratome sections were cut at 50 um and stained utilizing a polyclonal antiserum to neuropeptide Y (1:2000) and the double-bridge PAP technique. We observed a high density of large terminal endings containing clear round and dense-cored vesicles making axodendritic or, in a few cases, axosomatic contact with cells in the parvocellular vasopressin and oxytocin subdivisions of the PVN and periventricular hypothalamus. A small number of terminals was observed in the SON, almost exclusively localized to the ventral dendritic neuropil. In the ME, little evidence was found for a direct interaction with neurosecretory axons. No evidence was found for direct interaction with blood vessels within these regions. We conclude that hypothalamic NPY terminals may provide extensive direct afferent input to vasopressin and oxytocin neurons in the PVN as well as more modest levels of input to the SON

HORMONAL CONTROL OF NPY IN THE SEXUALLY DIMORPHIC HYPOGASTRIC GANGLIA. B. SCHROEDER* AND R. W. HAMILL (SPON: M. Mangiapane). MONROE COMMUNITY HOSPITAL/UNIV. OF ROCH. ROCHESTER, N. Y. 14603

Gonadal steroids regulate the ontogeny and adult levels of tyrosine hydroxylase (TH) in sexually dimorphic hypogastric ganglia (HG). Neonatal castration (Cx) precludes neurochemical maturation (TH values are <10% of controls), and adult Cx decreases TH activity 85% by one month. Neuropeptide Y (NPY) is co-contained within peripheral noradrenergic neurons. The present studies test the hypothesis that hormones regulate NPY in HG and in the vas deferens (VD), a major target organ of the HG. Adult Sprague-Dawley rats were Cx'd at 70 days of age and NPY, TH and NE examined in HG and VD after surgery (animal surgery and care followed strict NIH guidelines) . Following Cx., NPY levels gradually declined: values of 84%, 60% and 30% of control at 1, 2, & 4 weeks (wks) respectively. TH and NE followed a similar profile. VD, NPY was unchanged 1 wk following Cx, but declined 35% by 2 wks and 59% by 4 wks. TH declined more rapidly but stabilized at a similar nadir (40% of control). T replacement fully corrects the observed alterations. NPY data expressed per gram wet weight of tissue reveal no significant decrease in NPY, suggesting target organ regulation of ganglion peptide content. These studies expand sexual dimorphic aspects of ganglia and indicate that gonadal steroids exert regulatory efects on NPY in sympathetic ganglia and target tissues.

TEMPORAL RELATIONSHIPS BETWEEN 17β-ESTRADIOL, LUTEINIZING HORMONE AND GALANIN DURING SEXUAL MATURATION IN THE FEMALE RAT. S.M. Gabriel, Department of Psychiatry, Mount Sinai School of Medicine, New York, NY 10029.

Recent studies suggest that the 29-amino acid peptide galanin is potently regulated by estrogen in neuroendocrine tissues of the rat (*Kaplan, Gabriel, Koenig et al, PNAS 85:7408-7412, 1988*). This estrogenic influence is first expressed during puberty when concentrations of galanin-like immunoreactivity (galanin-LI) increase in the anterior pituitary (AP), neurointermediate lobe (NIL) and median eminence (ME) of female rats relative to male rats. To evaluate the temporal relationship between estrogen and galanin during this period of development, prepubertal female littermates were observed daily for evidence of vaginal opening, as an indication of pubertal onset and the first proestrus luteinizing hormone (LH) surge. Animals were sacrificed between 1700 and 1900h when 30% of the rats showed vaginal opening. Concentrations of galanin-LI were measured by a newly developed radioimmunoassay specific to rat galanin. Elevated serum 17β-estradiol and LH concentrations preceded vaginal opening while elevated galanin-LI concentrations in the ME, NIL and AP followed vaginal opening. A similar temporal sequence of 17β-estradiol, LH and galanin-LI concentrations were noted in peripubertal female rats 1, 2 and three days after injection with pregnant mare serum gonadotropin *(PMSG, 10 IU, s.c., 1000h)*. The effects of PMSG were probably due to increased 17β-estradiol secretion, because galanin-LI did not increase in prepubertal male or ovariectomized female rats following PMSG injection. These studies indicate that galanin-LI is influenced by circulating estrogens at puberty in the female rat. They further suggest a role for galanin in sexual maturation of the neuroendocrine axis.

GONADAL STEROIDS MODIFY DENDRITIC SPINES IN HYPOTHALAMIC NEURONS: A GOLGI STUDY IN THE ADULT RAT. M. Frankfurt E. Gould* and B.S. McEwen Neuroendocrinology Lab, The Rockefeller University, New York, NY 10021

A golgi study of neurons in the adult rat ventromedial (VMN) and dorsomedial (DMN) hypothalamic nucleus was done in intact male and female rats and ovariectomized (OVX) rats treated with oil (O), estrogen (E) or E and progesterone (P). Golgi-impregnated neurons were drawn and then analyzed using SMI morphometry to determine possible differences in cell body size, number of primary dendrites, number of branchpoints and spine density. Statistical differences were determined using 1 way ANOVA followed by the Neuman-Keuls test ($p<.05$). In the VMN of OVX rats given E alone or E in conjunction with P, there was a significantly greater density of dendritic spines than in the OVX-O group. There were no sex differences in any parameter in the VMN. In the DMN, the OVX-E-P group contained a significantly greater density of dendritic spines than the OVX-O group. Moreover, in the DMN of intact males there was a greater density of dendritic spines than in the intact females. There were no differences in cell body size, number of primary dendrites or number of branchpoints in either the VMN or DMN. From these results it appears that steroid feedback can result in short-term morphological changes in the hypothalamus.

IMMUNOCYTOCHEMICAL LOCALIZATION OF AROMATASE IN THE QUAIL BRAIN

J. Balthazart and A. Foidart *, Laboratory of General and Comparative Biochemistry, University of Liège Belgium.

The presence of aromatase in the brain of vertebrates was detected a long time ago. In many studies, the activity of the enzyme was studied by in vitro radioenzyme assays. These showed that the enzyme has a discrete localization in the brain and that its activity is modulated by the physiological condition of the animal. Factors such as age, sex, castration or steroid therapy all affect enzyme activity. However, the precise neuroanatomical localization of the enzyme and the mechanisms underlying the activity changes (modification of enzyme concentration or regulation of enzyme activity) have not been determined so far. By a peroxidase-antiperoxidase immunocytochemical method using a polyclonal antibody raised against human placental aromatase and purified by affinity chromatography, we have for the first time successfully localized aromatase containing cells in the brain of a vertebrate, the Japanese quail. The specificity of the immunocytochemical reaction has been demonstrated. The cytoplasmic localization of the enzyme is confirmed. It is found primarily in neurons but double-labelling experiments using specific neuronal or glial markers should be performed to confirm this conclusion. Aromatase-positive cells are detected in all areas which were shown previously to contain aromatase activity by product formation assays, namely the preoptic area (POA) and various hypothalamic and septal nuclei. Within these areas, the distribution of the immunoreactive cells is however heterogeneous. In particular, within the POA most if not all positive cells are found in the sexually dimorphic preoptic medial nucleus (POM). In the POM, the number of immunoreactive cells and the intensity of their staining are drastically decreased by castration and restored to levels typical of sexually mature males by testosterone treatment. This demonstrates that the induction of aromatase activity which is caused by testosterone reflects real changes in enzyme concentration (enzyme induction) rather than a modulation in the activity of a constant number of molecules.

DISTRIBUTION OF β-ENDORPHIN IMMUNOREACTIVITY IN THE ARCUATE NUCLEUS AND SURROUNDING HYPOTHALAMUS OF THE FEMALE GUINEA PIG. J.E. Thornton, M.D. Loose*, M.J. Kelly and O.K. Ronnekleiv, Dept. Physiol., OHSU, Portland, OR 97201 and ORPRC, Beaverton, OR 97206.

Although β-endorphin (β-end) may play an important role in neuroendocrine function of the guinea pig, the distribution of β-end in the guinea pig brain has not been examined. Guinea pigs were ovariectomized, and one week later were injected with 25μg estradiol benzoate or oil. Animals were perfused 24h later with 4% paraformaldehyde. Brain sections (50μm) were cut on a vibratome. β-End was localized using avidin-biotin-HRP immunocytochemistry (Eskay BE2 antisera). No cell bodies were seen rostral to the retrochiasmatic area (RCA). In the RCA, cells (10-50/section) were seen lying basomedially and extending laterally. In the rostral ARC, cells were concentrated (100-200/section) beneath the third ventricle (IIIV) and extended dorsolaterally. As the IIIV descended and the median eminence formed, the cells separated into bilateral groups which lay in the basolateral part of the ARC and extended into the cell poor zone. In the central ARC, cells shifted more dorsomedially and extended dorsally into the periventricular part of the ARC. In the caudal ARC, cells again formed two basolateral clusters and were also seen along the floor of the IIIV. Cells were not seen in other parts of the hypothalamus. Preliminary data indicate that estrogen increased the number of β-end immunoreactive cells. (PHS DA 05158, HD16793)

HYPOTHALAMUS

EFFERENT CONNECTIONS OF THE ANTERIOR HYPOTHALAMIC AREA (AHA) STUDIED WITH THE NEW ANTEROGRADE TRACER PHA-L. J.M. Wyss and Th. van Groen. Department of Cell Biology and Anatomy, University of Alabama at Birmingham, Birmingham, AL 35294.

The projections arising in the anterior hypothalamic area (AHA) have been characterized previously using the autoradiographic method for detection of anterogradely transported [^{3}H] amino acids. In the present experiments we have employed the PHA-L method to determine the specificity of these projections in more detail. The PHA-L method facilitates the distinction between fibers of passage and synapsing fibers. Iontophoretic injections were made stereotaxically in the AHA. Following the immunohistochemical staining of the transported PHA-L using the PAP-method, the location of labeled cell bodies, axons and their terminals were mapped. Rostral to the AHA, labeled axons appeared to terminate in the medial preoptic area, the ventrolateral quadrant of the lateral septal nucleus, the horizontal limb of the diagonal band of Broca, and the medial part of the nucleus accumbens. Caudally projecting axons labeled by the AHA injections terminated ventromedial in the lateral and posterior hypothalamic areas, the periventricular and dorsomedial nuclei of the hypothalamus, the supramamillary region, the ventral part of the medial mamillary nucleus, the paraventricular nucleus of the thalamus, the amygdala, and the periaquaductal gray. A few labeled axons also were present in the raphe nuclei, the locus coeruleus and the nucleus solitarius. Finally, labeled fibers were present in the hippocampal formation, mainly in area CA_3 and the subiculum, where a relatively heavy projection was present in the temporal part of the hippocampus. Contralaterally, fibers were labeled in the lateral septal nucleus, the AHA, the periventricular nucleus of the hypothalamus, the ventromedial hypothalamus, the paraventricular nucleus of the thalamus, the central gray, and the nucleus solitarius.

HYPOTHALAMOSPINAL TRACT: QUANTITATIVE COMPARISON IN 24 SPECIES. D. P. Sutherland*, R. J. Nudo and R. B. Masterton (SPON: F. K. Stephan). Dept. Psychology, Florida State Univ., Tallahassee, FL 32306.

We have labeled the cell groups projecting to the spinal cord in 23 mammals and one reptile by hemisecting the spinal cord at the C1-C2 junction, applying raw HRP to the cut axons and then processing the resulting materials with TMB. After counting the labeled cells in the hypothalamus and correcting stereologically for overcounting, the variation in number was subjected to strict statistical analyses for its covariation with several non-neurological, neurological, historical, and ecological characteristics of the animals.

The results show that the total number of hypothalamospinal neurons is entirely unrelated to brain size, body size, or neocortical surface area though it is weakly related to the number of corticospinal, rubrospinal, or tectospinal neurons. Arranging the animals on the basis of their propinquity with mankind suggests that the absolute size of the tract probably remained nearly constant throughout the mammalian segment of the Anthropoid lineage (though it probably increased in the Carnivora lineage). Among 8 ecological characteristics tested, the tract is most closely related to the host's food preference with herbivores having the smallest, carnivores the largest. Supported by NIH-NINCDS # NS7726.

PEPTIDERGIC AFFERENTS TO THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS. M.M. Moga and C.B. Saper. Depts. of Pharm. & Physiol. Sci. and Neurology, University of Chicago, Chicago, IL 60637.

The paraventricular nucleus of the hypothalamus (PVH) contains large numbers of afferent fibers that are immunoreactive for a variety of neuropeptides. To determine the significance of these inputs, it will be necessary to identify their origins. We examined the chemical specificity of forebrain afferents to the PVH using six neuropeptide antisera combined with fluorescent retrograde tracing. After Fluorogold injections into the PVH, small numbers of retrogradely labeled neurons were found to be *enkephalin*-like immunoreactive (-ir) in the dorsal part of the lateral septum; *substance P*-ir in the lateral septal nucleus and the medial preoptic area; *somatostatin*-ir in the ventral lateral septal nucleus; *corticotropin releasing factor*-ir in the preoptic portion of the bed nucleus of the stria terminalis, the adjoining lateral preoptic area, and the median preoptic nucleus; *brain natriuretic peptide*-ir in the tuberomammillary nucleus, particularly its medial, posterior periventricular portion; and *neurotensin*-ir in the anteroventral periventricular and median preoptic nuclei. None of these peptides, however, accounted for more than a small percentage of the forebrain afferents to the PVH. Furthermore, immunoreactive cell bodies for each peptide were seen in the PVH, so that part of the peptide-ir innervation may be intrinsic.

431.4

TRANSFORMING GROWTH FACTOR α (TGFα) mRNA IS EXPRESSED IN THE DEVELOPING HYPOTHALAMUS AND TGFα STIMULATES LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) RELEASE. S.R. Ojeda, H.F. Urbanski, M.E. Costa*, D.F. Hill* and M. Moholt-Siebert*. Division of Neuroscience, OR Regional Primate Res. Ctr., Beaverton, OR 97006.

Little is known about the presence of trophic factors in the hypothalamus and the role they may play in regulating the functional development of hypothalamic neurons. We have examined the ability of epidermal growth factor (EGF) and TGFα to affect the release of LHRH, the peptide that controls reproductive development. We have also determined whether the genes encoding EGF and TGFα are expressed in the prepubertal hypothalamus. Median eminences from 28-day-old juvenile female rats were incubated in vitro in the presence of one of several trophic factors. Both EGF and TGFα (2-100 ng/ml) elicited a dose-related increase in LHRH release. TGFβ_1 and β_2 were ineffective. Northern blot analysis of poly A+ RNA utilizing a single-stranded cDNA probe failed to reveal the presence of EGF mRNA in the hypothalamus at any age studied (fetal day 18 to postnatal day 36). In contrast, both an antiRNA probe and a double-stranded cDNA complementary to TGFα mRNA recognized a 4.5 Kb hypothalamic mRNA species identical in size to TGFα mRNA. Levels of expression were highest on fetal day 18 and declined gradually thereafter. The results indicate that: a) EGF and TGFα release LHRH through a non-genomic mechanism, b) since EGF and TGFα share a common receptor, their effect on LHRH is probably mediated by the same receptor, and c) TGFα rather than EGF is the physiological ligand for this interaction. (Supported by NIH grant HD-09988, Project IV).

431.5

DEVELOPMENT AND CHARACTERIZATION OF MONOCLONAL ANTIBODIES DIRECTED AGAINST LHRH. H.F. Urbanski and J. Hackett* (SPON: C.L. Bethea). Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Monoclonal antibodies (MAbs) against luteinizing hormone-releasing hormone (LHRH) were developed for immunocytochemical (ICC) purposes. In essence, LHRH was conjugated to bovine thyroglobulin and 50 μg injected into the spleen of a BALB/c mouse. After 3 weeks, the animal received a second injection (25 μg) and killed 3 days later. The mouse spleen cells were fused with SP2/0 myeloma cells and grown in HAT selective medium. Surviving hybridoma colonies were screened by radioimmunoassay and out of a total of 92, 4 were found to be secreting LHRH antibodies of the IgG_1 sub-class. The secreted MAbs were purified by precipitation with 50% ammonium sulphate solution followed by affinity chromatography using Bakerbond ABx. Two of these LHRH MAbs were subsequently characterized in detail. MAb HU4H showed conformational specificity to both mammalian and chicken-I LHRH while MAb HU11B showed sequential specificity to the C-terminal of mammalian but not chicken-I LHRH. Neither HU4H or HU11B cross reacted with other brain peptides. Moreover, in PAP ICC these pure, specific MAbs labeled LHRH neurons in hamster hypothalami with little background staining.

431.6

ANGIOTENSIN (1-7) IMMUNOREACTIVITY IN THE RAT HYPOTHALAMUS C.H. Block, H. Vilsack *, and C.M. Ferrario. Research Institute of the Cleveland Clinic Foundation, Cleveland, OH 44195-5070

We have recently reported the immunocytochemical (ICC) distribution of a novel heptapeptide related to angiotensin (Ang) II in the hypothalamo-neurohypophyseal system (HNS) of the rat (Block, et al. Peptides,1988). Ang (1-7) was localized in neurons of the suprachiasmatic (SCN), paraventricular (PVN), and supraoptic (SON) nuclei and the bed nucleus/stria terminalis (BNST). Immunoreactive (ir) fibers were observed in the paraventriculo-neurohypophyseal tract and in the neurohypophysis. To establish a potential role of Ang (1-7) in fluid homeostasis, ICC studies were conducted in normally-hydrated rats; and 24-48 hr water-deprived and rehydrated rats.

In water-deprived rats, Ang (1-7)-ir found in PVN, SON, SCN, and BNST was similar to the control and rehydrated animals, however the intensity of staining was diminished within PVN and SON. Fibers of the median eminence, infundibular recess, and neurohypophysis contained Herring bodies and staining was diminished in dehydrated animals. To investigate the projections of hypothalamic Ang (1-7), True Blue was microinjected into the pituitary.

Many neurons within the SON and PVN contained True Blue, while only a small population of these retrogradely-labeled cells also contained Ang (1-7). These results indicate that Ang 1-7-ir in the pituitary originates, in part from neurons in the SON and PVN; however the possibility that the dense hypothalamic Ang (1-7) fibers project to other sites, such as brainstem and limbic forebrain, cannot be excluded. These findings coupled with the plasticity of Ang (1-7)-ir in the HNS of animals with altered fluid balance suggests a contribution of this heptapeptide in fluid homeostasis.

431.7

GABA: A DOMINANT NEUROTRANSMITTER IN MEDIAL HYPOTHALAMUS. C.Decavel* and A.N.van den Pol. (SPON: W.F.Collins) Sect. Neurosurgery, Yale Med.Sch., New Haven, Ct 06510.

Post-embedding colloidal gold EM immunocytochemistry was used to study the density and organization of immunoreactive axons with characterized GABA antisera in the rat suprachiasmatic, arcuate, paraventricular, and supraoptic nuclei. That the method was reliable was indicated by the finding that different GABA antisera stained the same boutons on serial sections. 3-D reconstruction with serial ultrathin sections through GABA immunoreactive terminals consistently revealed a population of dense core vesicles, often lateral to the synaptic cleft, suggestive of common co-localization of peptides with GABA. The synaptic characteristics of GABAergic axons were studied in the PVN with sections alternatively stained for GABA or for conventional EM. Successive boutons from the same GABAergic axon sometimes made repeated synaptic contacts with the same post-synaptic neuron. That GABA may play a role in the synchronization of neural activity was supported by the finding that other GABAergic axons made multiple synaptic contacts with dendrites or perikarya of neurons in close proximity to one another in the PVN. The density of gold labeling in immunopositive and negative axons and postsynaptic cells was quantified stereologically. As nearly 50% of all boutons in the medial hypothalamus are immunoreactive for GABA and glutamate decarboxylase, GABA may be considered the dominant neurotransmitter here.

431.8

GABA IN THE HISTAMINERGIC TUBEROMAMMILLARY NUCLEUS. H.Ericson*, A.Blomqvist and C.Köhler. Astra Research Centre, S-151 85 Södertälje, Sweden; Dept. of Cell Biology, Univ. Linköping, Fac. Health Sci., S-531 85 Linköping, Sweden.

The organization of GABAergic elements in the tuberomammillary nucleus was examined by using antibodies against gamma aminobutyric acid (GABA) and light and electron microscopy. Most neuronal perikarya of the tuberomammillary nucleus were GABA immunoreactive (GABA-i) and contained reaction product diffusely distributed throughout the cytoplasm and in addition, the nucleus presented intense immunoreactivity. The morphology of the GABA-i perikarya were similar to the morphology of histaminergic perikarya described previously by Hayashi et al., J. Comp. Neurol., 229:233, 1984. The GABA-i perikarya were contacted by relatively few terminals. The mean bouton covering ratio of GABA-i perikarya was 6.5%, whereas the mean bouton covering ratio for GABA-i dendrites in the tuberomammillary nucleus was 31%. Some of the presynaptic terminals were GABA-i and in the cases were these contacts presented synaptic densities they were always classified as being symmetric synapses. In addition, GABA-i perikarya and dendrites formed close contacts which did not present synaptic specializations. The results of the present study suggest that neurons of the histaminergic tuberomammillary nucleus contain the neurotransmitter GABA. Furthermore, GABA released from terminals in the nucleus may act as modulator of cellular processes within the tuberomammillary nucleus.

431.9

IMMUNOCYTOCHEMICAL ANALYSIS OF THE SUPRACHIASMATIC NUCLEUS IN ORGANOTYPIC CULTURES. H.Gainer, M.Castel[1] and S.Wray, LNC, NINDS, Bethesda, MD 20892,[1]Dept. Zool., Hebrew Univ., Israel, 91904.

Using the slice explant roller culture method for organotypic hypothalamic cultures (Wray et al., Peptides 9:1151-1175,1988), we have begun to study the viablity of rat suprachiasmatic nuclei (SCN) *in vitro*. In order to determine to what extent neurons within the SCN survive, express their appropriate phenotypes and maintain synaptic organization, we have immunocytochemically analysed this structure using light (LM) and electron microscopic (EM) techniques after 18 days in culture. Examination of this nucleus at the LM level showed that the SCN maintains a highly compact organization of neurons, similar to that found *in vivo*. Immunocytochemistry (ICC) revealed numerous neurophysin (NP)- and vasoactive intestinal polypeptide (VIP)-containing neurons within the cultured SCN. Many synaptic configurations onto SCN cell bodies were still present after 18 days *in vitro*. Pre-embedding EM-ICC, for either NP or VIP, resulted in specific immunolabelling of secretory granules within neuronal profiles. We are currently determining whether gastrin-releasing peptide- and GABAergic-containing neurons are present in these cultures after 18 days *in vitro*. The presence of an organotypic distribution of specific neuronal phenotypes and abundant synapses in the SCN after 18 days *in vitro*, indicates that this culture system could be a valuable *in vitro* model for the long-term study of SCN function and metabolism.

Supported, in part, by Grant No. 87-00168 from the U.S.-Israel Binational Science Foundation.

MONOCLONAL ANTIBODIES WHICH RECOGNIZE SUBSETS OF HYPOTHALAMIC MAGNOCELLULAR NEUROSECRETORY NEURONS IN THE RAT. S.J. Hapner, P.E. Marshall* and C.M. Paden. Dept. of Biology, Montana State University, Bozeman, MT 59717.

In order to determine if neurons of the magnocellular neurosecretory system (MNS) of the rat possess cell-type-specific surface molecules which could play a role in development and plasticity of the MNS, we have attempted to produce monoclonal antibodies (MAbs) against dissociated neonatal MNS neurons or membrane extracts of neonatal neural lobe using the tolerization protocol of Hockfield (Science 237:67, 1987). A large number of antibodies which bind specifically to the neurohypophysis were obtained, and dual-label immunocytochemical characterization of two such MAbs on adult brain revealed that they label primarily vasopressin neurons of the MNS but also bind to a smaller proportion of oxytocin neurons. The binding of one of these MAbs, SON1, has also been observed at the EM level in the neural lobe using pre-embedding peroxidase immunocytochemistry. Reaction product was located immediately subjacent to the axolemma in a subpopulation of neurosecretory axons, and did not appear to be associated with secretory granules. These results indicate that neonatal MNS neurons of the rat contain highly specific molecules which are immunogenic in mice. Further characterization of the antigens revealed by these MAbs is in progress. Rabbit anti-oxytocin and anti-vasopressin were provided by Dr. Gaj Nilaver. Supported by NIH grant NS23642 and RCDA NS01318 to CMP.

ORGANIZATION OF THE HUMAN SUPRACHIASMATIC NUCLEUS. J.K.Mai* and O.Kedziora* (SPON: European Neuroscience Association). Dept. of Neuroanatomy, University of Düsseldorf, D-4000 Düsseldorf, F.R.G.

Serial 20 um paraffin sections of five human hypothalami were processed by a modified Sternberger PAP-DAB method using antibodies (AB) against neurophysin (NPH), vasopressin (VP), neurotensin (NT), VIP, neuropeptide Y (NPY), somatostatin (SST), myelin-basic-protein (MBP), GFA, and the fucosyl-N-acetyl-lactosamine-(FAL)-epitope. Stereological evaluation and computer-aided reconstruction of discriminated immunoreactive (ir) cells revealed regional segregation except for NPY-positive neurons. As in rodents at least two subnuclei were distinguishable: first, the main area characterized by the presence of NPH- and VP-ir neurons. This area also comprised most of the NT-ir neurons. Second, an area located underneath, in the medial and posterior third of the SCN, where no NPH- but NT-, VIP- and NPY-ir neurons were identified. The FAL-epitope was expressed by neurons which were also positive for NPH and NT, and, in addition, by protoplasmic astrocytes, which were seen tightly packed around the margin of the SCN. Fibers immunoreactive for MBP, finally, could be traced to the optic chiasma, periventricular fiber system, the terminal lamina and the the supraoptic commissures.

INHIBITORY MECHANISMS OF KAPPA-AGONISTS ON SUPRAOPTIC NEURONS IN RAT HYPOTHALAMIC SLICE PREPARATIONS. K. INENAGA[1]*, H. YAMASHITA[1], K. NAKAO[2]* and H. IMURA[2]*. [1]Dept. Physiol., Univ. Occupational and Environmental Health, Kitakyushu 807, Japan and [2]Dept. Internal Med., Kyoto Univ, Kyoto 606, Japan

Inhibitory mechanisms of endogenous kappa-agonists, leumorphin (LM) and dynorphin (Dyn), were investigated by using intracellular recordings in the supraoptic (SON) neuron of the rat hypothalamic slice preparations. Bath application of LM and Dyn (10^{-7}-$3X10^{-6}$ M) elicited slight membrane hyperpolarization with decreased spontaneous firing rate. The effects were blocked by a selective kappa-antagonist, MR2266. LM and Dyn suppressed excitatory synaptic potentials evoked by focal stimulation dorsolateral to the SON and amplitude of membrane noises. On the other hand, mu- and delta-agonists, morphine and DADLE respectively, did not influence the synaptic potentials. LM and Dyn also decreased duration of action potentials which were prolonged by TEA and Cs. The prolonged Ca spikes were blocked by $MnCl_2$. From these results, we suggest that kappa-agonists inhibit the neural activities of neurosecretory cells in the rat SON, pre- and post-synaptically.

CHARACTERISTICS OF GUINEA PIG ARCUATE (ARC) NEURONS EXHIBITING A LOW THRESHOLD SPIKE (LTS) OR A TRANSIENT OUTWARD CURRENT. M.J. Kelly, M.D. Loose*, and O.K. Ronnekleiv. Dept. Physiology, OHSU, Portland, OR 97201.

ARC neurons have a higher incidence of LTS when hypothalamic slices are prepared from ovariectomized guinea pigs that are estrogen treated versus oil treated. The current underlying the LTS and the cell types which exhibit this conductance were characterized in current and voltage clamp recordings of 94 ARC neurons. Neurons exhibited an RMP > -50 mV (mean = 62.1±1.8mV); R_{in} > 85 MΩ (mean = 361±26 MΩ); and a fast (Na^+) spike > 50mV with overshoot. 32% of ARC neurons (N=30) had an LTS. The LTS was 6-20 mV in amplitude, 30-120 ms in duration, persisted in TTX (1μM; N=7) and was blocked by 500μM Cd^{2+} or 1mM Co^{2+} (N=4). In voltage-clamp (N=5), voltage steps from holding potentials of -70 to -110mV induced a transient inward current that activated near -70mV and exhibited maximun activation near -50mV. Deinactivation was voltage-dependent and increased from -70 to -110mV. Another 30% (N=28) of ARC neurons exhibited a delayed return to baseline after hyperpolarizing current pulses which in voltage clamp (N=5) was characterized as a transient outward current of up to 500 pA. Its activation/inactivation curves overlapped in the -55 to -70 mV range. Both cell types exhibited time-dependent rectification to hyperpolarizing steps and were hyperpolarized by μ-opioid agonists. A subgroup of the ARC neurons which exhibit an LTS contain tyrosine hydroxylase. (PHS DA 05158, HD 00718)

OPIOID ACTIONS ON ARCUATE (ARC) NEURONS: A VOLTAGE- AND CURRENT-CLAMP STUDY OF UNIDENTIFIED AND IMMUNOPOSITIVE β-ENDORPHIN AND TYROSINE HYDROXYLASE NEURONS. M.D. Loose*, O.K. Ronnekleiv and M.J. Kelly (SPON: C.J. Russell). Dept. Physiology, Ore Hlth Sci Univ., Portland, OR 97201.

Intracellular recordings were made from ARC neurons in brain slices prepared from ovariectomized guinea pigs pretreated with estradiol. Cells recorded with electrodes filled with biocytin were identified by staining with a streptavidin/FITC complex followed by immunocytochemistry for β-Endorphin (END) or tyrosine hydroxylase (TH). Neurons recorded using biocytin or K-citrate electrodes had similar membrane properties: RMP, -59±1 mV; R_{in}, 355±25 MΩ; τ, 19.6±2.0 msec. The μ-opioid agonist Tyr-D-Ala-Gly-MePhe-Gly-ol (DAGO) induced a decrease in firing and/or a membrane hyperpolarization of 3-21mV in >70% of cells tested (N=88). R_{in} was decreased by 6-57% and the reversal potential was -95±2 mV (N=12). Fifteen cells recorded with either biocytin or K-citrate were voltage clamped. DAGO induced an outward current of 50-180 pA at -60mV which reversed and became inward at potentials negative to -93±2 mV (N=6), near E_k (-94mV). Altering the concentration of K^+ in the medium shifted the reversal potential by 58mV/log unit change in $[K^+]_o$. 47 biocytin-filled cells were characterized morphologically. Both END (N=4) and TH (N=4) immunoreactive cells have been double-labeled and both types were hyperpolarized by DAGO. (PHS DA 05158, HD 16793, 00718).

ANTAGONISM OF FAST EXCITATORY POSTSYNAPTIC POTENTIALS IN SUPRACHIASMATIC NUCLEUS NEURONS BY EXCITATORY AMINO ACID ANTAGONISTS. Y.I. Kim and F.E. Dudek. Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

The possible role of excitatory amino acids (EAAs) in fast synaptic transmission in the suprachiasmatic nucleus (SCN) was investigated with intracellular recording. Seven SCN neurons were recorded in horizontal and coronal brain slices prepared from five male rats and two male guinea pigs, respectively. Fast excitatory postsynaptic potentials (EPSPs) were evoked by stimulating optic nerve, optic chiasm ventrolateral to the SCN or a site dorsolateral to the SCN. At resting potential, spontaneous action potentials often obscured the EPSPs. When cells were hyperpolarized 20-40 mV below threshold, depolarizing PSPs from optic nerve had mean amplitude and onset latency of 5.6 mV and 12.3 ms (n=4), while PSPs from other sites were 7.0 mV and 3.0 ms (n=6). Bath-applied kynurenic acid (1 mM), a wide-spectrum EAA antagonist, attenuated these PSPs from optic nerve (n=2) and optic chiasm (n=1) by 21-34%. In slices treated with bicuculline (a $GABA_A$ antagonist, 50 μM), 6,7-dinitroquinoxaline-2,3-dione (0.3-3.0 μM), a non-NMDA receptor antagonist, attenuated the PSPs from optic nerve (n=2), optic chiasm (n=1) and the dorsolateral site (n=2) by 15-76%. The data suggest that EAAs, presumably through non-NMDA receptors, mediate fast excitatory synaptic transmission in the SCN. This includes both retinal and non-retinal input. Supported by AFOSR87-0361.

COMPARATIVE ELECTROPHYSIOLOGY OF MAGNOCELLULAR AND PARVOCELLULAR NEURONS OF THE HYPOTHALAMIC PARAVENTRICULAR NUCLEUS. N.W. Hoffman*, J.G. Tasker and F.E. Dudek (SPON:R.S. Fisher). Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

The hypothalamic paraventricular nucleus (PVN) contains both magnocellular and parvocellular neuronal populations, which makes selective intracellular study of either one difficult. Virtually nothing is known about the electrophysiology of PVN parvocellular neurons. We recorded intracellularly from PVN neurons (n=32) in coronal hypothalamic slices. About 60% of recorded neurons displayed Ca^{2+}-dependent low-threshold spikes (i.e., LTS cells) capable of generating 1-2 action potentials. Most LTS cells had non-linear current-voltage (I-V) relations and a long membrane time constant (22.5 $\pm$ 2.0 ms, SEM). The remaining 40% of PVN neurons showed no low-threshold spike (non-LTS cells), linear I-V relations and a shorter time constant (15.5 $\pm$ 2.0 ms). The LTS and non-LTS neurons had similar input resistances (230 $\pm$ 18 MΩ and 200 $\pm$ 25 MΩ), resting potentials (60 $\pm$ 2.5 mV and 63 $\pm$ 3.0 mV) and action potential amplitudes (62 $\pm$ 1.0 mV and 66 $\pm$ 1.5 mV from threshold). Following electrophysiological characterization, some cells were injected with biocytin (Horikawa and Armstrong, J. Neurosci. Meth., 25:1, 1988) and neurophysin immunohistochemistry was performed (n=7). Two of 3 injected non-LTS neurons were neurophysin-positive, suggesting they were magnocellular; 4 of 4 LTS neurons were neurophysin-negative, suggesting they were parvocellular. We suggest, therefore, that magnocellular and parvocellular neurons can be distinguished based on their intracellular electrophysiology. Supported by AFOSR 87-0361.

CONTRASTING EFFECTS OF NMDA AND NON-NMDA ANTAGONISTS ON FAST EPSPs IN NEURONS OF THE PARAVENTRICULAR NUCLEUS. J.-P. Wuarin* and F.E. Dudek Mental Retardation Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024

Excitatory amino acids may mediate most of the fast excitatory synaptic transmission in the supraoptic nucleus (Gribkoff, V.K. and Dudek, F.E., Brain Res. 442:152, 1988). Using the paraventricular nucleus (PVN), we applied antagonists for specific amino acid receptors to determine the respective contribution of N-methyl-d-aspartate (NMDA) and non-NMDA receptor subtypes to the excitatory postsynaptic potential (EPSP) and current (EPSC). Intracellular recordings were obtained from slices of guinea-pig hypothalamus in 50 μM picrotoxin. Synaptic activation was obtained by electrical stimulation of the region dorsolateral to the fornix. The non-NMDA antagonist, 6-cyano-2,3-dihydroxy-7-nitroquinoxaline (CNQX), induced a dose-dependent decrease of the EPSP and EPSC: 1 μM had no detectable effect, 3 μM and 10 μM produced 30% and 70% decrease respectively, and 30 μM almost completely blocked the synaptic response. The NMDA-selective antagonist, D,L-2-amino-5-phosphonopentanoic acid (AP5), applied at 30 μM did not affect EPSP or EPSC amplitude or duration even when the cell was depolarized. These results suggest: 1) non-NMDA receptors mediate fast excitatory synaptic responses within the PVN and 2) although NMDA receptors may be present on PVN neurons, they seem to be less important than non-NMDA receptors in normal synaptic transmission. These data support the hypothesis that excitatory amino acids, acting primarily or exclusively on non-NMDA receptors, are the major excitatory neurotransmitter system in the hypothalamus. CELL PROPERTIES AND CHOLINERGIC RESPONSES OF NEURONS FROM THE GUINEA PIG SUPRAOPTIC NUCLEUS (SON). K.R. Erickson*, O.K. Ronnekleiv and M.J. Kelly. (SPON: O. Marin) Dept. of Physiology, Oregon Health Sci Univ., Portland, OR 97201

Intracellular recordings were made from 93 SON neurons in the guinea pig to study their properties and responses to cholinergic agents. 26 (28%) were identified as vasopressinergic (VP) by their phasic firing pattern and/or by immunocytochemical staining after injection with biocytin. No significant differences were found between this group and the remaining neurons for action potential height (58.6±0.8mV), RMP (-55.8±0.7mV), firing threshold (-51.9±0.8mV), or τ (20.5 ±1.0 ms). R_{in} differed significantly (404.1 ±27.9 MΩ for VP vs. 318.3±13.9 MΩ). A time-dependent rectification (TDR) to hyperpolarizing pulses below -80 mV was seen in VP (N=9), oxytocinergic (OX,N=1), and unidentified (N=10) neurons. In 2 VP and 1 OX neuron, Cs^+ (2mM) was applied and completely blocked the TDR. 18 VP neurons were tested with Ach (N=5), nicotine (N=10), and muscarine (N=8). Ach (10-100 μM) hyperpolarized all VP cells tested. Muscarine (10 μM) hyperpolarized all but one VP cell. Although nicotine (100 μM) depolarized 8 of 10 VP cells, it did not induce phasic firing, which could be induced by the α1-adrenergic agonist methoxamine at 100 μM dose (N=7). Thus, in guinea pig VP cells, nicotinic effects are limitted to depolarization, whereas methoxamine induces long-lasting phasic activity. (Support: AHA OR Affiliate, PHS DA 05158)

RECORDING FROM IDENTIFIED ISOLATED MAGNOCELLULAR NEUROENDOCRINE CELLS (MNCs) OF THE HYPOTHALAMUS. P. Cobbett and M.L. Weiss Pharmacology & Neuroscience Program, Michigan State Univ., E. Lansing, MI 48824.

A common problem with recordings from acutely dissociated central neurons is the identification of the recorded cells. We have made recordings from acutlely dissociated MNCs which have been identified by prior labeling in vivo. Neurons were obtained from the supraoptic nucleus of the hypothalamus of adult rats by enzymic and mechanical dissociation, 1-2 days after intravenous injection of Evans Blue (EB). This dye, applied i.v., specifically labels central neuronendocrine cells (see Weiss & Cobbett, this meeting). Isolated MNCs in these preparations were identified using epifluorescence: EB excitation and emission did not affect the viability of isolated MNCs based upon the appearance of the soma after exposure to exciting wavelengths of light. Whole cell patch clamp recordings were made from identified MNCs. Resting potentials were -30mV - -63mV, and spontaneous overshooting action potentials were recorded. Under voltage clamp, action potentials were seen to be generated by a TTX-sensitive Na current. Na action potentials lasted < 10ms, but longer spontaneous action potentials (5-20s) were recorded after addition of TTX and Ba (5mM) to the external medium. Supported by NS 08125 and by a grant from the Pharmaceutical Manufacturers Association Foundation.

RESPONSES OF RAT LATERAL HYPOTHALAMIC NEURONAL ACTIVITY TO FASTIGIAL NUCREUS STIMULATION. Y. Oomura, B-I. Min* and T. Katafuchi*. Dept. of Physiology, Fac. of Med., Kyushu Univ., Fukuoka, 812 JAPAN.

The aim of this study was investigation of neuronal mechanisms underlying inputs from the fastigial nucleus (FN) to the lateral hypothalamic area (LHA). In male acesthetized rats, 295 extracellular and 82 intracellular recordings of LHA responses to electrical stimulation of the FN were examined. Contralateral FN stimulation evoked three types of responses in 48% of spontaneously firing LHA neurons: inhibition with 11 ± 6 (SD) ms latency followed by excitation (30%), excitation with 15 ± 12.5 ms latency (14%), and excitation followed by inhibition with 6 ± 4 ms latency (4%). These reponses were unaffected by transection of the inferior cerebellar peduncle. Neuronal activity was recorded intracellularly from 82 LHA neurons, of which 36 (44%) responded to FN stimulation. Of the 36 neurons, 24 showed inhibitory postsynaptic potentials (IPSPs) with a mean latency of 7.5 ± 2 ms. Of the 24 neurons, 16 were checked for change in IPSP latency with stimulus intensity, and 11 were considered to be monosynaptically connected since their latencies were constant when FN stimulation intensity was changed. The remaining 12 exhibited excitatory postsynaptic potentials (EPSPs) with a longer latency of 10.5 ± 3 ms, which indicated polysynaptic conduction. The reversal potentials of the IPSP and EPSP were estimated to be about -77 mV and -13 mV, respectively. Most glucose-sensitive neurons (78%), which were identified by their inhibition in response to electrophoretically applied glucose, were inhibited by FN stimulation, whereas only 7% of the glucose-insensitive neurons responded to such stimulation. It was concluded that LHA neurons receive inhibitory monosynaptic and excitatory polysynaptic inputs from the FN, which may contribute to hypothalamic modulation of feeding behavior.

LOCOMOTION BY THE ANESTHETIZED RAT INITIATED BY ACTIVITY OF HYPOTHALAMIC NEURONS. H.M. Sinnamon, M. Marciello*, P. Brastow*. Lab. of Neuropsychology, Wesleyan University, Middletown, CT 06457.

Two experiments determined if locomotion in the Nembutal-anesthetized rat produced by electrical stimulation of the lateral hypothalamus (LH) was mediated by fibers of passage descending from the preoptic basal forebrain or by directly activated neurons in the LH. Six rats received large unilateral lesions of the preoptic area and later were subjected to mapping of the hypothalamus for electrically-elicited locomotion at currents of 25 and 50 uA. Ipsilateral to the lesion, fewer LH locomotor sites positive at 25 uA were found but 4 of 6 rats showed some 25-uA sites and all rats had ipsilateral positive sites at 50 uA. In the hypothalamus of 8 intact rats injections of glutamate (50 mM, 50 nl) were tested in 66 sites. Injections in the LH at the level of the posterior hypothalamus nucleus produced short-latancy (<20 s) episodes of hindlimb locomotion. Descending fibers of passage contribute to, but are not essential to, the elicitation of locomotion by electrical stimulation of the LH.

EVIDENCE FOR A FUNCTIONAL AND ANATOMICAL RELATIONSHIP BETWEEN THE LATERAL SEPTUM AND THE HYPOTHALAMUS IN THE CONTROL OF FLANK MARKING BEHAVIOR IN GOLDEN HAMSTERS C.F.Ferris, L.Gold* and M.Potegal. (SPON:S.B Gagliardi) Physiology, Univ. of Mass. Med. Ctr., Worcester, MA 01655

Golden hamsters communicate by flank marking, a behavior that is controlled by vasopressin-sensitive neurons in the anterior hypothalamus (AH). The magnocellular neurosecretory system is thought to be a source of neurotransmitter for the initiation of flank marking. The anatomical and functional connections between the lateral septum and the vasopressin (VP) neurons in and around the AH were examined by: 1) tracing afferent and efferent connections following injection of HRP into the lateral septum, and 2) recording odor-induced flank marking prior to and following ibotenate lesions in the lateral septum. The greatest number of retrogradely labeled perikarya were found in the lateral hypothalamus, ventral to the fornix. Anterogradely labeled nerve terminals were primarily localized perinuclear to the VP neurons of the medial aspect of the SON. The SON, PVN and SCN were devoid of HRP-reactive nerve endings and perikarya. The injection of ibotenate into the lateral septum significantly reduced odor-induced flank marking as compared to control injections of 0.9% NaCl. These data suggest that VP neurons of the medial SON receive excitatory input from the lateral septum to facilitate flank marking behavior. (NIH Grant #NS23557)

431.23

PROJECTIONS OF THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS TO THE SEXUALLY DIMORPHIC LUMBOSACRAL REGION OF THE SPINAL CORD. C.K. Wagner and L.G. Clemens. Neuroscience Program and Dept. Zoology, Michigan State University, East Lansing, MI 48824

The paraventricular nucleus (PVN) of the hypothalamus consists of several subnuclei, some of which project to the neurohypophysis, others to brainstem and cervical-thoracic regions of the spinal cord. Lumbar regions L5-L6 of the spinal cord contain the sexually dimorphic motor nuclei, the spinal nucleus of the bulbocavernosus (SNB) and dorsolateral nucleus (DLN), which innervate perineal muscles, the bulbocavernosus and the ischiocavernosus, respectively. These motoneurons and their afferent input are androgen-dependent. This study examined projections of the PVN to the L5-L6 region of the spinal cord.

WGA-HRP (0.5-0.8ul) was injected into the region of L5-L6 aimed at the SNB and DLN and their dendritic extents, in intact male, castrated male or female rats. Following a 4 day survival time animals were perfused and HRP was visualized using the TMB method of Mesulam, (1976).

WGA-HRP labelled cell bodies were found in the parvocellular subnuclei of PVN, as well as regions of the lateral hypothalamus (LH) and the dorsal hypothalamic area (DA). These results demonstrate that the PVN projects to lumbar levels of the spinal cord that are sexually dimorphic and androgen-dependent. This suggests that PVN may modulate the activity of these motoneurons.

EFFERENTS OF THE SEXUALLY DIMORPHIC AREA OF THE GERBIL HYPOTHALAMUS Patricia D. Finn*, Geert J. DeVries, and Pauline Yahr. Dept of Psychobiology, Univ of California, Irvine, CA 92717.

The sexually dimorphic area (SDA) of the gerbil hypothalamus (hyp) accumulates gonadal steroids and is implicated in the hormonal control of male sexual behavior and scent marking. To identify pathways for these behaviors, SDA efferents were traced in both sexes by injecting Phaseolus vulgaris leucoagglutinin (PHA-L) into the medial or lateral SDA (mSDA; lSDA) and locating PHA-L-filled fibers. SDA efferents were verified by injecting putative terminal fields with the retrograde tracer Fluoro-Gold.

The ventrolateral (vl) septum, medial bed nucleus (n) of the stria terminalis, medial amygdala (MeA), substantia innominata, anterior hyp, periventricular n, arcuate n, vl ventromedial n (vlVMN) and ventral premammillary n receive more mSDA than lSDA. The opposite is true for the lateral hyp and retrorubral field. Both mSDA and lSDA project to the posterior hyp, lateral and supramammillary n, paraventricular thalamic n, reuniens, central gray and most raphe n. The vlVMN and posterodorsal MeA were most heavily labeled when the PHA-L injection overlapped the SDA pars compacta, a cell group normally found only in males. Areas yet to be verified include rostral preoptic areas, dorsomedial n, supraoptic n, paraventricular hyp n, zona incerta, ventral tegmentum, locus coeruleus, laterodorsal n and solitary n. (Support: MH-14599 and MH-26481)

EFFECT OF OVARIAN CONDITION ON SEXUALLY DIMORPHIC BRAIN AREAS IN A WHIPTAIL LIZARD SPECIES. J. Wade*[1] and D. Crews.[1,2] Departments of [1] Psychology and [2] Zoology, and the Institute of Reproductive Biology, University of Texas, Austin, TX 78712.

Both the anterior hypothalamus-preoptic area (AH-POA) and the ventromedial hypothalamus (VMH) are sexually dimorphic in the whiptail lizard, *Cnemidophorus inornatus*. The AH-POA is significantly larger in males, while the VMH is significantly larger in females (D. Crews, J. Wade and W. Wilczynski, unpublished). To determine whether these brain areas change in volume with the breeding season, the AH-POA and VMH of females were measured under three conditions: reproductively active (during the breeding season); reproductively inactive (during a simulation of winter hibernation conditions); and ovariectomized. Measurements were taken on a Zeiss Videoplan by tracing the perimeter of the AH-POA and VMH on one side of the brain in every fifth section. The computer generated areas of these brain regions. The volumes were calculated from the areas based on the distance between the sections measured (125μ). An estimate of overall brain size was calculated by tracing the perimeter of one-half the brain at the most anterior section of the POA and again 30 sections later (approximately midway through the VMH). Volume was calculated from these areas as if they were the ends of a cone frustum. Relative to estimates of overall brain volume, there was no significant difference among the volumes of the AH-POA in the three groups (ANOVA on transformed ratios: $F(2,23)=2.19$, $p=.13$). However, the VMH of reproductively active animals was significantly larger than those of animals in the other two groups ($F(2,23)=5.78$, $p=.01$). These data suggest that the volume of the VMH may change seasonally, perhaps under the influence of ovarian steroids.

VERVET MONKEYS HAVE SEXUALLY DIMORPHIC, ESTROGEN-SENSITIVE HYPOTHALAMIC NEURAL MEMBRANES. F. Naftolin, C. Leranth, D.E. Redmond, Jr.+ and L-M Garcia-Segura*. (Spon: J. DeFelipe) Dept of Obs and Gyn and Psych+, Yale Med Sch, New Haven, CT and Inst Cajal*, Madrid, Spain.

Many sexually dimorphic characteristics of primates have neural bases. In rats, a similar picture exists in the hypothalamic nuclei which control reproductive function, and is associated with an estrogen-sensitive sexual dimorphism in the numerical density of intramembranous protein particles (IMP), (J Ster Biochem 30:195, 1988.) We studied the hypothalamic infundibular nucleus of mature vervet monkeys to assess whether similar findings are present in primates. EXPERIMENTAL: Monkeys were lightly anesthetized and perfusion-fixed using a physiologic saline wash followed by 1% glutaraldehyde - 1% paraformaldehyde. The infundibular nucleus was microdissected for freeze-fracture analysis. Neurons were recognized by morphologic characteristics of their cytoplasm. Three animals were studied in each group; for each the E- and P-faces of at least 10 μM^2 of neuronal membrane were evaluated. There was a clear difference in numerical density of P-face IMP between normal males and females (869 $\pm$ 34 SEM vs 1432 $\pm$ 31 IMP/μM^2, respectively; $p < 0.001$). The E-face, with a lower density of IMP, also showed a significant sex difference. While ovariectomy did not effect the density of IMP (1427 $\pm$ 41), ovariectomy plus estradiol treatment 48 hours before perfusion dramatically lowered the numerical density of IMP to that seen in males (812 $\pm$ 29). CONCLUSIONS: Vervet monkeys have sexually dimorphic hypothalamic neural membranes, and estrogen treatment abolishes the sex difference. These findings, including the actual range of IMP/μM^2 and the effect of estradiol, are the same as in the rat. They raise the possibility that other estrogen-sensitive characteristics of hypothalamic neurons, such as estrogen-induced synaptogenesis, synaptolysis and cyclic synaptic remodelling will also be found (J Ster Biochem, ibid) and may play important roles in estrogen-dependent states of health and disease in monkeys and other primates, including humans.

MECHANISMS OF THE INITIAL PHASE OF FEVER IN THE VSA AND MAHPOA OF RATS AND RABBITS. G.E. Resch*, C.W. Simpson*, W.D. Ruwe., and J.Clarke* Sch. Basic Life Sci., Univ. Missouri-KC, Kansas City, MO 64108 and Dept. Physiol. Biophys., Univ. Arkansas Col. Med. Sci., Little Rock, AR 72205.

Mechanisms underlying the initiation of pyrogen induced fever were studied at two brain heat-gain sites in rats and rabbits. Three questions were addressed. The first question was to identify brain sites at which microinjections of bacterial or endogenous pyrogens evoked a classically defined fever. The second question considered whether blockade of neuronal activity at these sites would modify the initial and subsequent phases of a fever evoked by bacterial pyrogens or endogenous leucotrienes. The third question tested the relationship of PGE_2 in the mediation of the fever response. E. coli, PGE2, alpha-interferon, and IL-1B elicited fever from the ventral septal area (VSA) and MAHPOA of rats and rabbits. The fever response consisted of an early peak within 1 hr. and a 2nd peak within 3-6 hrs. The PGE2 antagonist, SC19220, or atropine blocked fever from IL-1B in the MAHPOA. Blockade of the initial phase of the fever suggests PGE2 and Ach may mediate the initial events. The data demonstrate two brain sites, the VSA and the MAHPOA, in two species which are similar in their response to hyperthermic agonists, also responded to bacterial pyrogens and leucotrienes. Specific receptor antagonists at the MAHPOA site block the initial phase of a fever following microinjection of IL-1B. (Supported in part by USAFOSR-87-0297 and by NIH-NS26045).

AGE-RELATED CHANGES IN THE THERMOREGULATORY RESPONSES TO CYTOKINES IN THE NEW ZEALAND WHITE RABBIT. J. Clarke* and W.D. Ruwe (SPON: L. Plunkett). Dept. Physiol. Biophys., Univ. Arkansas for Med. Sci., Little Rock, AR 72205.

The ability of the male New Zealand white rabbit to develop fever in response to central administration of pyrogens is age dependent. Experiments were conducted in both young and old rabbits to characterize the thermal response to central injections of cytokines acting as endogenous pyrogens (EPs). Guide tubes were implanted bilaterally above the anterior hypothalamic, preoptic area (AH/POA) in young (<1 yr) and old (>3 yrs) rabbits. Bacterial pyrogen (E. coli), EPs (IL-1, α-IFN, and IL-6), and thermoregulatory mediators (PGE_2, NE, and 5-HT) were injected into the AH/POA (bilaterally, 0.5-1.0μl) and T_{core} and T_{skin} monitored for 6 hours following injection. E. coli elicited a fever in old animals that was significantly less than that evoked in the young. Fevers caused by IL-1 and α-IFN also were reduced in the older group. However, the fever evoked by IL-6 in the older rabbits initially was diminished but at 3-6 hrs was significantly greater. Thermoregulatory responses to PGE_2 and NE also were age-related. These results suggest that as the animal ages: (1) fevers evoked by pyrogens are consistently reduced; (2) responses to mediators of thermoregulation may be diminished likewise; and (3) fevers elicited by the EPs may be altered differentially. [Supported in part by NIH #NS26045 to W.D.R.]

INTRACELLULAR ANALYSIS OF INHERENT AND SYNAPTIC ACTIVITY IN HYPOTHALAMIC THERMOSENSITIVE NEURONS M.C. Curras and J.A. Boulant. Physiology Dept., Ohio State University, Columbus, OH 43210

To understand neuronal thermosensitivity, intracellular activity was recorded in rostral tissue slices of rat hypothalamus. Neurons had mean resting membrane potentials of -55 mV, and 30 neurons were classified according to thermosensitivity. Even though synaptic activity is present, warm sensitive neurons display inherent thermosensitivity due to a temperature dependent pacemaker potential. Neuronal cold sensitivity, however, is primarily attributed to temperature dependent changes in excitatory and inhibitory synaptic input. Cold sensitive neurons also show increased input resistance during cooling, which could enhance the effectiveness of the excitatory synaptic input. Some temperature insensitive neurons can display a "functional plasticity" in which transient periods of warm and cold sensitivity occur. This supports a previous study suggesting that temperature insensitive neurons possess a voltage dependent (thermosensitive) pacemaker current that is usually suppressed by an electrogenic Na-K pump. (Supported by NIH and the Bremer Foundation.)

DRUGS OF ABUSE: DOPAMINE MECHANISMS

432.1

DOPAMINE RECEPTOR REGULATION BY SUBCHRONIC COCAINE AND METHAMPHETAMINE TREATMENTS. A.B. Kelly*, S.S. Overman*, H.H. Osterburg*, G.M. Pasinetti, M.M. Myers*, B. Knapp*, C.E. Finch & D.G. Morgan. Dept. of Biological Sciences and Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA, 90089-0191.

Young male Fischer 344 rats were injected i.p. with 10 mg/kg methamphetamine HCl, 20 mg/kg cocaine HCl, or saline vehicle twice daily for 10 d. Striata from these animals (n=8 per group) were dissected 14 and 60 days after the last day of the drug treatments and frozen, and the hindbrain was immersion fixed in paraformaldehyde. Striatal dopamine receptors were measured using [3H]SCH-23390 (D-1 receptors) or [3H]spiperone (D-2 receptors). Striatal dopamine and DOPAC were measured by HPLC. For each rat, twelve 10 um paraffin sections of the substantia nigra were immunostained for tyrosine hydroxylase (TH) or GFAP. At the 14 day survival time, methamphetamine produced a 20% reduction in the Bmax of both D-1 and D-2 receptors, with no change in Kd. No changes were observed in the concentrations of dopamine or DOPAC, the number of nucleated TH immunopositive nigral neurons, or the number of GFAP immunopositive nigral astrocytes. Cocaine had no effects on any of these parameters. At the 60 day survival time, cocaine treatment produced a 20% increase in the Bmax of D-1 and D-2 receptors, with no change in Kd. Methamphetamine produced a 20% reduction in the Bmax of D-1 and D-2 receptors, but this effect was not statistically significant at the $P < 0.05$ criterion. Neither treatment influenced the number of TH immunopositive neurons, nor GFAP immunopositive astrocytes in the substantia nigra. Hence, methamphetamine can produce a decline in dopamine receptors without nigral neuron atrophy. Cocaine appears to produce a slowly developing increase in striatal dopamine receptors. Supported by the USC B.R.S.G. and the Anna Greenwall Award from the AFAR.

432.2

COMPARISON OF [^{3}H]GBR 12935 AND [^{3}H]COCAINE BINDING SITES IN MONKEY BRAIN. M.A.Fahey*, D.R. Canfield*, R.D. Spealman*, B.K. Madras (SPON: R. Milius). Harvard Medical School, New England Regional Primate Research Center, Southborough, MA 01772.

Both [^{3}H]GBR 12935 and [^{3}H]cocaine label elements of the dopamine transporter in striatal tissue. We have directly compared the binding of drugs to sites labeled with either [^{3}H]cocaine or [^{3}H]GBR 12935 in caudate-putamen membranes of monkeys (M. fascicularis). Assays were performed at 4°C in Tris-HCl (50 mM) buffer containing NaCl (120 mM). The sites labeled with [^{3}H]GBR 12935 and [^{3}H]cocaine were similar with respect to density, Na^+ sensitivity and rank order of displacement by neurotransmitters (dopamine > norepinephrine > serotonin). However, cocaine congeners including (-)-cocaine, CFT (WIN 35,428), WIN 35,065-2, N-allyl CFNT, and (+)-cocaine did not displace [^{3}H]GBR 12935 fully, and their IC_{50} values at [^{3}H]GBR 12935 binding sites were 5-20 times higher than their IC_{50} values at [^{3}H]cocaine receptors. Conversely, structurally unrelated monoamine uptake inhibitors including Lu 19-005, GBR 12909, and mazindol did not displace [^{3}H]cocaine fully, and their IC_{50} values were comparable at both sites. The results show that [^{3}H]GBR 12935 and [^{3}H]cocaine label related, though probably not identical, elements of the dopamine transporter. Supported by DA00499, DA00088, RR00168.

432.3

CELLULAR EFFECTS OF ACUTE COCAINE IN THE RAT NEOSTRIATUM. K. Nantwi and E.P. Schoener,* Dept. of Pharmacology, Wayne State University School of Medicine, Detroit, MI 48201.

Euphoria and reinforcement that occur with cocaine have been attributed to dopamine-mediated neurotransmission. The present study examined electrophysiologic manifestations and dopaminergic mechanisms of systemically administered cocaine in the rat neostriatum.

Cocaine was found to modify neuronal firing rate over a dose range of 0.1-1.0 mg/Kg, while administration of drug vehicle did not result in any significant change of neuron discharge. Of thirty-two (32) units tested at 0.25 mg/Kg cocaine, 53% were facilitated while 47% were inhibited. At higher doses of cocaine, a larger proportion of units exhibited depression after drug exposure. For example, 68% had reduced activity and 32% enhanced discharge after 0.5 mg/Kg. Similar changes in neuronal activity were produced by acute infusion of L-DOPA (0.01-1.0 mg/Kg) following pretreatment with carbidopa (0.1 mg/Kg). In control experiments, carbidopa itself did not modify neuronal activity. Cocaine effects were altered by pretreatment with dopamine antagonists. Experiments with the selective DA-1 antagonist SCH 23390 reversed, blocked, or attenuated the effect of cocaine in a dose-related manner. These data indicate that the changes in neuronal activity after acute cocaine exposure may be mediated by selective dopaminergic mechanism(s).

432.4

EFFECTS OF NON-COMPETITIVE NMDA ANTAGONISTS ON EXTRACELLULAR DA LEVELS IN THE STRIATUM AS AIMED WITH MICRODIALYSIS PROCEDURE. A. Mele*, K.M. Wozniak*, J.A. Monn, A. Thurkauf, K.C. Rice and A. Pert. (Spon. J.H. McDonough, Jr.) BPB/NIMH, LCS/NIAAA and IN/NIDDK, Bethesda, MD 20892.

Considerable evidence suggests important effects of noncompetitive NMDA antagonists like phencyclidine on dopaminergic function. The effects of a number of non-competitive NMDA antagonists on alteration of striatal extracellular DA were evaluated and compared to their ability to induce rotational behavior in rats lesioned with 6-OHDA unilaterally in the medial forebrain bundle. In the microdialysis experiment systemic injections of MK 801, SKF 10,047, dexoxadrol and levoxadrol even at high doses, did not produce any effects on extracellular DA concentration, whereas PCP(10 mg/kg) and TCP (25 mg/kg) increased levels significantly. The rank order of potency in the rotational study, however was found to be: MK> PCP> dexoxadrol> SKF. Since all drugs tested produced profound effects on rotational behavior but only TCP and PCP enhanced DA levels in the striatum, it appears that noncompetitive NMDA antagonists act on the intact nigrostriatal system through DA independent mechanisms to produce rotational behavior.

432.5

INDUCTION OF C-FOS BY DIRECT AND INDIRECT DOPAMINE AGONISTS S.T. Young*[1], L.J. Porrino[2], and M.J. Iadarola[3] (SPON: G. Dienel). [1]LCM, NIMH and HHMI; [2]CNB, NINDS; and [3]NAB, NIDR, Bethesda MD 20892

The proto-oncogene c-fos produces a nuclear phosphoprotein Fos which is thought to act as a genetic transactivator regulating gene expression. Reports of alterations in neuropeptide gene regulation following dopamine agonist treatment prompted us to assess whether c-fos induction was a component of dopaminergic stimulation. Fos expression was examined immunohistochemically in 30 um sections of rat forebrain. Rats treated with the indirect dopamine agonist, cocaine (30 mg/kg, IP), showed a significant increase in Fos expression in both the number of cells and intensity of nuclear immunoreaction in the caudate/putamen relative to saline controls. The highest density of immunoreactive neurons was in the dorsomedial and dorsocentral aspects of the caudate. This effect was apparent 1 hour after treatment, maximal at 2 hours, and not different from control levels 48 hours after treatment. Increases in Fos expression were also noted in the olfactory tubercle, although levels of Fos in the nucleus accumbens and primary olfactory cortex were not significantly different from saline controls in most cases. Animals administered the direct agonist, apomorphine (SC), also displayed a similar increase in Fos staining in the caudate/putamen (again mainly dorsomedial/dorsocentral) relative to saline controls. At low doses (0.1 mg/kg), the difference from control was small compared to the increase seen at 1 mg/kg and 5 mg/kg. These results demonstrate a role for dopamine in the induction of c-fos expression, and, by extension, suggest a change in expression of one or more striatal genes. They suggest that, in addition to acute changes in neuronal firing rate, activation of dopamine systems in the CNS may have other, longer-lasting effects on neuronal function via transcriptional modulation of certain target genes in activated cells.

432.6

METHAMPHETAMINE NEUROTOXICITY: RESIDUAL CAPACITY OF NIGROSTRIATAL DOPAMINE NEURONS STUDIED WITH MICRODIALYSIS. J. Yew*, P. Paulson*, D. M. Camp*, L. Ruddock*, L. Levy* and T.E. Robinson. (SPON. M.Alpern) Dept. Psychology, Neuroscience Program, The University of Michigan, Ann Arbor, MI 48109.

Repeated exposure to high doses of methamphetamine (MA) greatly depletes cerebral dopamine (DA) and serotonin (5-HT), but does not produce gross deficits in spontaneous behavior. We hypothesized that sparing of function may occur, at least in part, because the remaining DA neurons are able to maintain relatively high synaptic concentrations of DA. To test this idea the concentration of DA, dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA) and 5-hydroxyindoleacetic acid (5-HIAA) was measured in striatal extracellular fluid (ECF) by microdialysis in freely moving rats. The animals were pretreated one week earlier with either saline or MA (15 mg/kg/6 hr x 6). MA pretreatment produced a large decrease (50-90%) in the basal ECF concentration of DOPAC, HVA and 5-HIAA, presumably reflecting the loss of DA and 5-HT terminals in striatum. In contrast, the basal ECF concentration of DA was not changed significantly by MA pretreatment. Furthermore, both saline and MA-pretreated rats showed a large increase in motor activity and the ECF concentration of DA in response to a challenge injection of 1.5 mg/kg of *d*-amphetamine. It is suggested that residual DA neurons can compensate for the depletion of striatal DA produced by highly neurotoxic doses of MA. Whether residual 5-HT neurons have a similar compensatory capacity is currently under investigation.

432.7

PERSISTENT CHANGES IN BRAIN CATECHOLAMINE AND MONOAMINE LEVELS AFTER REPEATED COCAINE INJECTIONS. J. Peris and R. Dawson. Dept. Pharmacodynamics, Univ. Florida J. H. Miller Health Ctr., Gainesville, FL 32610.

Repeated administration of cocaine results in long-lasting sensitization to the initial locomotor activating and stereotypic effects of cocaine. Since cocaine inhibits dopamine (DA), norepinephrine (NE) and serotonin (5-HT) reuptake into neuronal endings, changes in one or all of these neurotransmitter systems may cause sensitization. We measured whether any changes in DA, NE, 5-HT or their metabolites are as long-lasting as the behavioral changes. Male Sprague-Dawley rats were injected with either saline or cocaine (10 mg/kg, i.p.; n = 6) daily for eight days and stereotypy and locomotor activity were measured after the first, second, and eighth injections. After a seven day withdrawal period from cocaine, rats were tested with either saline or cocaine and then seven days later were sacrificed for brain dissection. Levels of DA, NE, 5-HT, DOPAC, HVA, and 5-HIAA were measured in nucleus accumbens, striatum, frontal cortex, olfactory bulb, olfactory tubercle and ventromedial mesencephalon using reverse phase HPLC with electrochemical detection. Concentrations of 5-HT were significantly decreased in olfactory tubercle of cocaine-treated animals (538±38) compared to that of saline-treated animals (669±60) and 5-HIAA/5-HT ratios were increased in the cocaine-treated animals (0.64±.05 vs. 0.50±.05). There were no differences in catecholamine or monoamine levels due to cocaine treatment in any other brain region tested. These data suggest that some of the persistent effects of repeated cocaine administration on behavior may be mediated by serotonergic rather than catecholaminergic mechanisms.

432.8

METABOLIC MAPPING OF THE ACUTE AND CHRONIC EFFECTS OF METHAMPHETAMINE IN THE RAT. F.E. Pontieri*, Y.A. Ryan*^, M.S. Kleven~, L.S. Seiden~ and L.J. Porrino^ (SPON: C Kennedy). NIMH, Bethesda, MD 20892, ^NINDS, Bethesda, MD 20892, ~University of Chicago, Chicago, IL 60637.

Using the quantitative 2-[^{14}C]-deoxyglucose autoradiographic method (2-DG), we compared the acute and chronic effects of methamphetamine (MA) administration on local cerebral glucose utilization (LCGU) in freely-moving rats. Four groups of animals received 0.0, 0.5, 1, 2.5 mg/kg i.v. MA, respectively, 10 minutes before the 2-DG procedure. The acute i.v. administration of MA resulted in dose-dependent alterations of LCGU in the extrapyramidal system (e.g. caudate, globus pallidus, entopeduncolar nucleus, substantia nigra, subthalamus and lateral habenula). Cerebral metabolic rate was also increased in portions of the mesocorticolimbic system (e.g. nucleus accumbens, VTA and septum). This pattern of alterations is similar to those seen following the administration of other psychostimulants (cocaine and amphetamine). In addition, LCGU was significantly increased in structures related to the visual system, suggesting a possible neural substrate for visual hallucinations that accompany MA abuse in humans. A second series of rats was treated with 50mg/kg of MA or vehicle s.c. twice daily for 4 days, a regimen known to produce long-lasting depletion of dopamine and serotonin. LCGU was measured 14 days after treatment, when monoamine depletion is well-established. In contrast to rats treated acutely, rats treated chronically had depressed rates of LCGU, particularly in the extrapyramidal system. These data suggest that alterations in functional activity following chronic MA treatment are present in regions other than just those in which monoamine depletion is known to occur.

432.9

THE EFFECTS OF SCH 23390 ON REWARDING BRAIN STIMULATION: EVIDENCE FOR PARTIAL D1 MEDIATION OF THE THRESHOLD LOWERING EFFECTS OF MDMA. M. Bird and C. Kornetsky. Boston University School of Medicine, Boston, MA 02118.

Previous studies from our laboratory have provided pharmacologic evidence that the increased sensitivity to rewarding brain stimulation caused by abuse substances is mediated primarily by dopaminergic processes. Using this model of drug induced euphoria, we have recently shown that the reward threshold lowering caused by racemic 3,4-methylenedioxymethamphetamine (MDMA) is blocked by D2 but not by 5-HT2 receptor antagonism (Abst. Soc. Neurosci. 13:1323, 1987). To further examine the role of DA receptor subtypes in this reward system we studied the effect of D1 blockade on MDMA's enhancement of rewarding brain stimulation using the selective D1 antagonist SCH 23390. Four male albino F-344 rats were implanted with bipolar electrodes into the medial forebrain bundle and the effects of SCH 23390 alone and in combination with a maximally reinforcing dose of MDMA were determined. In each animal reward thresholds were systematically raised by SCH 23390 and MDMA's threshold lowering action was antagonized. This suggests that both D1 and D2 receptors are necessary but not sufficient substrates for MDMA's pharmacologic activation of central reward pathways.

432.10

^{3}H-WIN 35,065-2 (^{3}H-WIN) BINDING IS SIMILAR IN VARIOUS BRAIN REGIONS OF THE RAT. J.W. Boja and M.J. Kuhar. Neuroscience Branch, NIDA Addiction Research Center, Baltimore, MD 21224.

Present evidence suggests that cocaine binds to the dopamine transporter at both low and high affinity sites. In addition, previous studies have shown that cocaine binding in Tris buffer is sodium dependent at the cocaine binding site. Since dopamine terminals in the striatum (STR) arise from the nigro-striatal neurons while the dopamine terminals in the nucleus accumbens (NA) arise from mesolimbic dopamine neurons, other laboratories suggested that cocaine can interact differently at these two areas. This is of interest since the NA has been implicated as one of the sites of cocaine's reinforcing properties, while the STR has not. ^{3}H-WIN, a potent cocaine analog, was used to assess binding to the dopamine transporter in the STR and NA. Binding of ^{3}H-WIN in Tris buffer (50 mM Tris, 120 mM Na^+, 5 mM K^+ pH 7.4) was Na^+ dependent in both the NA and the STR at both the low and high affinity cocaine binding sites. (-)Cocaine inhibited ^{3}H-WIN binding in a dose dependent manner at both the NA (IC_{50} = 1.96 µM) and the STR (IC_{50} = 1.86 µM). These data suggest cocaine binding is similar in the NA and the STR.

432.11

^{3}H-WIN 35,065-2(^{3}H-WIN): A LIGAND FOR COCAINE RECEPTORS IN RAT STRIATUM. M.C. Ritz, J.W. Boja, F.I. Carroll*, A.H. Lewin* and M.J. Kuhar. Neuroscience Branch, Addiction Research Ctr., Baltimore, MD 21224 and Research Triangle Institute, Research Triangle Park, NC 27709.

Several radiolabeled compounds have been used to identify behaviorally relevant cocaine receptors in brain. WIN is a compound structurally similar to cocaine, more potent in behavior and binding assays, and relatively more resistent to metabolic breakdown. Thus, ^{3}H-WIN was synthesized and examined in receptor binding assays. Rat striatal tissue was homogenized in 50 mM Tris buffer containing 120 mM NaCl and 5 mM KCl. Incubations were carried out at 0-2°C for 60 min. ^{3}H-WIN binding was saturable and revealed two binding sites (K_{D1}=5 nM, B_{max1}=4.5 fm/mg tissue; K_{D2}=150 nM, B_{max2}=70 fm/mg tissue). The binding was stereospecific, sodium dependent and relatively insensitive to increases in incubation temperature. Compounds potent at the cocaine binding site and compounds potent in inhibiting dopamine uptake were also potent inhibitors of WIN binding (mazindol, GBR12909, nomifensine and (-)cocaine). Inhibitors of norepinephrine uptake such as desipramine and the serotonin uptake inhibitor citalopram were extremely weak inhibitors of ^{3}H-WIN binding. Thus, ^{3}H-WIN is a suitable ligand for cocaine receptors associated with the dopamine transporter and may have some advantages over other existing ligands.

432.12

SELF-ADMINISTRATION OF BRAIN-STIMULATION: A NOVEL MODEL OF DRUG SELF-ADMINISTRATION. K.B.J. FRANKLIN AND M. LEPORE*., Dept. of Psychology, McGill University, P.Q. Canada, H3A-1B1.

Intracranial self-stimulation (ICSS) has long been considered a model for the hedonic effects of drugs of abuse. However, direct comparisons between ICSS and drug self-administration has seldom been possible since the characteristics of responding for 150-500 ms trains of 0.1 ms pulses at 100 Hz are very different from those observed during self-administration of a drug with complicated absorption, distribution, and excretion kinetics. We have trained rats to self-administer long trains of brain stimulation which are frequency-modulated to mimick the pharmacokinetic characteristics of stimulant drugs. There are striking similarities between this novel form of ICSS and drug self-administration. Rats often "load up" at the beginning of a session. Increasing the "dose" administered or increasing the half-life of stimulation produces corresponding decreases in the rate of ICSS. Furthermore, low doses of the dopamine antagonists SCH23390, pimozide, and alpha-flupenthixol, increase the "dose" of stimulation the animal self-administers. Thus, differences observed between conventional ICSS and drug self-administration behaviors may be due to the parameters of brain-stimulation. This novel ICSS paradigm may be a useful model for studying the role of pharmacokinetics in drug self-administration.

432.13

PSYCHOACTIVE AMINES ACT BY A WEAK BASE MECHANISM IN CHROMAFFIN GRANULES AND CULTURED VENTRAL TEGMENTAL AREA (VTA) DOPAMINE CELLS. David Sulzer* & Stephen Rayport (SPON: Eric Holtzman). Dept. Psychiatry and Ctr. Neurobiol. & Behav., Columbia Univ. and New York State Psychiatric Inst., New York, NY 10032.

A number of psychoactive drugs reduce cellular uptake of catecholamines at lower concentrations and induce release at higher concentrations. We propose the novel hypothesis that these phenomena result from such drugs acting as weak bases which reduce the pH gradient across the storage granule membrane. We tested this idea in isolated adrenal chromaffin granules and cultured dopamine neurons.

Bovine adrenal chromaffin granules are incubated with the weak base vital dye acridine orange (AO) and the emission at 526 nm, which is pH sensitive, is recorded. The granules acidify with addition of ATP and valinomycin, resulting in quenching of fluorescence. The resulting pH gradient is rapidly abolished by the weak base ammonium chloride or the protonophore FCCP. Strikingly, the pH gradient is also reduced by the psychoactive amines cocaine, amphetamine, phencyclidine, tyramine, fenfluramine, ephedrine, and imipramine. These drugs act at low concentrations: 50% alkalinization is seen after incubation with 30 µM cocaine *vs.* 4.5 mM dopamine, or 1 mM ammonium chloride, a "classic" weak base. Moreover, the drugs generally act rapidly: for 30 µM cocaine τ < 1 min, whereas for 4.5 mM dopamine τ > 5 min.

In purified rat VTA dopamine neurons in culture (Rayport, Sulzer, and Batson, *this volume*), AO and neutral red (also a weak base vital dye) stain intracellular acidic compartments. Often, staining is seen in sites that correspond to the EM-localization of catecholamine-containing vesicles revealed by 5-hydroxy-dopamine uptake. Staining both at presumed vesicle sites and in lysosomes can be abolished by incubation with cocaine, amphetamine, phencyclidine, ammonium chloride, or FCCP.

433.1

NEURAL CELL-LINE TRANSPLANTATION IN THE RAT. V.W. Henderson, M. Cunningham,* N. Valtz,* R.D.G. McKay. Depts. of Neurology (Div. of Behavioral Neuroscience & Aging) and Gerontology, University of Southern Calif., Los Angeles, CA; and Depts. of Brain & Cognitive Sciences and Biology, Mass. Institute of Technology, Cambridge, MA

The HT4 and ST15A neural precursor cell lines were previously derived from rat embryonic hippocampus and neonatal cerebellum, respectively, using a temperature-sensitive conditional oncogene. In tissue culture at 33°C, HT4 and ST15A are rapidly dividing clonal cell lines; at 39°C in vitro they cease division and assume differentiated characteristics of neurons or glia.

HT4 and ST15A were labeled in vitro through incorporation of ^{3}H-thymidine or bromodeoxyuridine (BrdU). Cell suspensions were implanted into dorsal hippocampus or cerebellum of anesthetized neonatal Sprague-Dawley rats, and animals were sacrificed at intervals. In cryostat sections of fixed tissues, transplanted cells were readily identified by autoradiography (^{3}H-thymidine), immunohistochemistry (BrdU), or X-gal histochemistry for the lacZ gene product. In some animals, implanted HT4 cells assumed a position proximate to the hippocampal alveus; prominent labeling within the cerebellum granular layer occured in some ST15A-transplanted rats. There was no tumor formation. Findings confirm the feasibility of neural cell-line transplants and suggest new treatment strategies for human neurodegenerative disorders.

433.2

LONG-TERM FUNCTION OF GENETICALLY MODIFIED, NGF-SECRETING FIBROBLASTS GRAFTED INTO RATS WITH FIMBRIA-FORNIX LESIONS. M.B. Rosenberg, M.H. Tuszynski, R.C. Hayes, K. Yoshida,* D.M. Armstrong, T. Friedmann* and F.H. Gage. Depts. Pediatrics and Neurosciences, Univ. Calif. San Diego, La Jolla, CA 92093.

We have previously shown that cultured rat fibroblasts, genetically modified to secrete NGF and then grafted to the cavity formed in creating a fimbria-fornix lesion, prevent retrograde cholinergic degeneration two weeks after transplantation (Science 242:1575, 1988). The present studies were undertaken to evaluate long-term graft survival and effects on cholinergic neurons. Fibroblasts of the line Rat1, derived from embryonic Fischer rats, were infected with a retrovirus vector expressing mouse NGF cDNA and the bacterial gene for neomycin resistance. The clone with the highest NGF production, which secreted NGF at 770 pg/hr/10^{5} cells, was grafted into Fischer and Sprague-Dawley rats with unilateral aspirative fimbria-fornix lesions. Control animals received uninfected fibroblasts. Animals were sacrificed after 2 or 8 weeks, and the brains were examined for cholinergic neuron survival in the medial septal area by immunohistochemistry for choline acetyltransferase and NGF receptors. At 2 weeks there was a substantial savings of cholinergic neurons in the animals that had received NGF-secreting grafts but not in animals with control grafts. At 8 weeks, some animals still exhibited cholinergic survival. In situ hybridization with a riboprobe complementary to NGF mRNA indicated transcripts were present at 2 and 8 weeks. Immunohistochemical labelling for parvalbumin, a GABAergic neuron marker, showed that the effects of the NGF-secreting fibroblasts were apparently specific for cholinergic neurons. These studies indicate that genetically modified fibroblasts can exhibit survival and transgene expression for at least 2 months following intracerebral grafting. Additional experiments are underway to examine longer-term graft survival and function.

433.3

DEVELOPMENTAL TIME COURSE OF GRAFTS OF FETAL HIPPOCAMPUS PLACED INTO ASPIRATION LESION SITES IN ADULT RATS. D.J. Paul, R.H. Baisden, and M. L. Woodruff. Dept. of Anatomy, Quillen-Dishner Col. of Med., East Tennessee State Univ., Johnson City, TN 37614.

The mature structure of fetal hippocampal transplants associated with behavioral recovery (Woodruff et al. Exp. Neurol. 102, 130-143, 1988) differs from that of the normal hippocampus. To begin to understand the mature structure of the transplants we studied the growth of E16 fetal hippocampal transplants. In some rats the volume of the transplant was estimated 1,3,6,9,15,30 and 45 days posttransplantation. The volume was less than that transplanted until day 9 although the transplanted tissue had the appearance of healthy neuroepithelium but increased rapidly from Day 9 to Day 30. Other rats were implanted and given injections of tritiated thymidine either immediately or 12 hrs later, or 1,2,3,5,6,8,9,15 or 30 days posttransplantation. Fortyfive days following transplantation the brains were autoradiographically processed. Labeled neurons were found in the grafts through injection day 9, indicating that the rapid growth of the transplants after day 9 was due to development of neuropil. Labeled granule cells could also be observed in the host dentate gyrus several mm from the graft. These may have migrated from the transplant or be host cells induced into mitosis by the graft (e.g. Lundberg & Mollgard, Neurosci. Lett. 13, 265-270, 1979). (Supported by NIH grant ES04070-03 to MLW)

433.4

EFFECTS OF SCIATIC NERVE TRANSPLANTS ON MEDIAL SEPTAL CHOLINERGIC CELLS AFTER FORNIX/FIMBRIA LESION. D. J. Messersmith and L. F. Kromer. Dept. of Anatomy and Cell Biology, Georgetown University, Washington, DC 20007

Trophic and tropic effects of peripheral nerve transplants in the CNS were examined utilizing the septo-hippocampal pathway in adult Sprague-Dawley rats. Following a bilateral fornix/fimbria lesion, a segment of sciatic nerve was inserted on each side of the brain between the septum and dorsal hippocampus. After either 2 or 8 weeks post-transplantation, 6 animals in each experimental and control (lesion only) group were perfused. Brains were sectioned at 25u and stained for choline acetyltransferase (ChAT) or acetylcholinesterase (AChE). The number of ChAT(+) cells in the medial septum was counted in twelve sections rostral to the postcommissural fornix.

Two weeks post-transplantation there was a statistically significant increase ($p<.05$) in the number of ChAT(+) cells in the septum of animals receiving the transplant vs animals with lesions only [Mean ± SEM: 2003 ± 258 (transplant) vs 1011 ± 162 (control)]. However, after eight weeks there was no longer a statistical difference between transplant and eight week lesion control [1593 ± 117 (transplant) vs 1095 ± 240 (control)]. At both survival times, AChE(+) fibers were present within the nerve grafts.

Our results suggest that over time sciatic nerve transplants lose their ability to maintain viable septal cholinergic neurons even though these transplants contain cholinergic axons. Further studies will examine the mechanisms of this response in detail.

IN VITRO STUDIES OF LC-HIPPOCAMPUS DOUBLE BRAIN GRAFTS GROWN IN OCULO: AN IN VIVO ELECTROCHEMICAL STUDY. M.-T. Su*,[1], T.V. Dunwiddie[2,4], M. Mynlieff[2] and G.A. Gerhardt[2,3] (SPON: T.-H. YIN). Dept. of Pharmacology[1], National Defense Medical Center, Taipei, Taiwan, Republic of China and Depts. of Pharmacology[2] and Psychiatry[3], University of Colorado Health Sci. Ctr., Denver, CO 80262 and Medical Research[4], Veterans Administration Medical Center, Denver, CO 80220.

Double grafts of fetal brain tissue have been shown to survive and grow in the anterior eye chamber of the rat. In particular, locus coeruleus (LC) when co-grafted with hippocampus has been previously shown to invade the hippocampal tissue with an organotypic norepinephrine innervation that appears to function similarly to the normal LC-hippocampal projection. In the present study, LC-hippocampus double grafts which had been grown in oculo were removed from the host and placed in a standard brain-slice recording chamber. High-speed electrochemical measurements and pressure-ejection of KCl were employed to investigate the connectivity of the grafts. Local ejections of potassium into the LC portion of the double graft elicited overflow of NE in localized regions of the hippocampal portion of the double grafts. In addition, superfusion of the grafts with both phentolamine and nomifensine caused an augmentation in the potassium-induced responses. These data demonstrate that LC graft neurons are able to release NE in target tissues when stimulated in an appropriate manner. NEURAL TRANSPLANTATION IN ADULT RATS WITH EARLY RADIATION-INDUCED HYPOPLASIA OF FASCIA DENTATA GRANULE CELLS: SELECTIVE ATTENUATION OF BEHAVIORAL DEFICITS G. Andrew Mickley, J. Leland Ferguson, Thomas J. Nemeth* and Maureen A. Mulvihill.* BHS, AFRRI, Bethesda, MD 20184-5145 USA.

Partially shielded rat brains were X-irradiated during the first 16 days post partum. This procedure depleted 90% of the hippocampal granule cells while sparing other brain areas. When subjects were 147 ± 4 days of age, we conducted behavioral tests sensitive to hippocampal damage. Irradiated subjects later (average age = 182 ± 4 days) received intra-cerebral transplants from either fetal fascia dentata or cerebral cortex. Controls (both irradiated and sham-irradiated) experienced no surgery or sham-surgical procedures. Subjects were retested at 265 ± 5 and 350 ± 6 days of age. Both hippocampal and cerebral cortex grafts significantly reduced performance deficits on a passive avoidance task. Hippocampal transplants (especially those located in the damaged hippocampus) also significantly attenuated perseverative spontaneous rotation. Thus, selected behavioral deficits associated with early fascia dentata damage may be attenuated through the use of neural grafting in mature subjects. An assessment of graft-induced behavioral benefits depends on (1) the time after transplantation that particular behavioral tests are conducted, and (2) the source and final location of the grafted neural tissue.

433.7

THE RELATIONSHIP OF FETAL SEPTAL GRAFT TO SPATIAL LEARNING IN RATS WITH A TRIMETHLTIN-INDUCED HIPPOCAMPAL LESION. N.Kato, M.Akaike*, A.Masui* and T.Kobayashi* Dept. of Psychiat., Shiga Univ. Med. Sci., Otsu 520-21 and Pharma Res. Labs., Hoechst Japan Ltd., Kawagoe 350, Japan.

The spatial learning impairments in rats with a hippocampal lesion induced by single oral administration of trimethyltin hydroxide (TMT,9mg /kg) were examined and compared with those in TMT-treated rats with fetal septal grafts. TMT-treatment induced a permanent increase in open-field activity 3 days after the treatment and increased number of errors as detected by Biel water maze which appeared as early as 4 hr and reached to the steady level 5 days after the administration. Rats were treated with TMT followed a week later by implant of septal tissues taken from 14 day fetuses and digested by trypsin into bilateral 3 regions of the hippocampus. Spatial learning was evaluated by Morris water maze test 9 weeks postoperatively. The swimming time to find a submerged platform over 10 daily trials was recorded for 2 days. TMT-treated rats with sham operation exhibited a longer time spent in the water as compared with control rats and TMT-treated rats receiving septal grafts showed improved performance relative to TMT-rats, though still inferior to controls.

TRANSPLANTATION OF FETAL CHOLINERGIC NEURONS PROMOTES RECOVERY OF AF64A-INDUCED BEHAVIORAL AND NEUROCHEMICAL DEFICITS. T.J. Walsh, Black, B. and D.F. Emerich. Rutgers University, Department of Psychology, New Brunswick, N.J. 08903.

The studies presented here examined the effects of transplanted fetal cholinergic neurons on the behavioral and neurochemical alterations induced by AF64A. This cholinotoxin produces long-lasting decreases in high affinity choline uptake levels (HAChU) and the choline acetyltransferase (ChAT) activity in the hippocampus (HPC) together with pesistent cognitive impairments.

Sprague-Dawley rats were trained on a standard eight arm radial maze (RAM) task. Following training, rats received bilateral injections of AF64A (3 nmol/side/icv). Ten days later, suspensions of dissociated septal cholinergic neurons (E16) or the glucose-saline vehicle (VEH) were injected into the HPC at two rostrocaudal locations. Rats injected with AF64A (AF/VEH) were markedly and permanently impaired in their performance of the RAM task. In contrast, animals receiving transplants (AF/TR) were initially impaired but reacquired the task within 60 trials.

Rats were then trained to perform a working memory version of the RAM task in which they had to remember which 4 of the 8 maze arms they obtained food from prior to a one hour delay. Following the delay the rats were returned to the maze and allowed to choose freely among all 8 arms. Arms not previously chosen were baited and entry into previously entered arms constituted an error (delayed-non-match-to-sample). Both AF64A-treated groups (AF/VEH and AF/TR) were impaired on this version of the task and showed no evidence of recovery. AF64A produced decreases in hippocampal HAChU levels (31%) and ChAT activity (35%) that was attenuated (14 and 27%) in the AF/TR group.

These data suggest that the transplantation of fetal septal cholinergic neurons following AF64A promotes functional recovery in a task-dependent manner and that this recovery is associated with an attenuation of the AF64A-induced cholinotoxicity.

FETAL HIPPOCAMPAL TRANSPLANTS AMELIORATE SPATIAL MEMORY DEFICITS IN MONGOLIAN GERBILS WITH ISCHEMIA-INDUCED DAMAGE TO THE HIPPOCAMPUS. S. M. Onifer and W. C. Low. Department of Physiology and Biophysics. Indiana University School of Medicine, Indianapolis, IN 46223.

Cerebral ischemia produces a selective loss of CA_1 pyramidal neurons in the dorsal hippocampus in the Mongolian gerbil resulting in spatial memory deficits. The purpose of this study was to determine the effects of fetal hippocampal cells transplanted into the ischemic hippocampus on the restoration of spatial memory function. Transient cerebral ischemia was produced by bilateral carotid artery occlusion for 10 minutes. Ischemic and non-ischemic gerbils were trained in a Morris water-maze to swim to a hidden platform followed by a spatial probe test.

The number of platform crossovers (mean $\pm$ S.E.M.) in the training quadrant prior to and after transplantation was determined for each group. Ischemic gerbils with sham transplants showed no improvement in spatial probe behavior after transplantation (6.8$\pm$0.8 vs. 6.0$\pm$0.8, $p>0.05$). Similarly, no improvement was observed in sham-operated gerbils (12.7$\pm$0.9 vs. 10.5$\pm$1.1, $p>0.05$). In contrast, ischemic gerbils with hippocampal transplants exhibited a significant improvement in spatial probe behavior after transplantation (4.3$\pm$1.3 vs. 8.8 $\pm$1.2, $p<0.05$).

Bilateral degeneration of the host's CA_1 pyramidal neurons was observed in both the ischemic group with transplants and in the ischemic group with sham-transplants. In animals with grafts, transplanted cells, morphologically similar to CA_1 pyramidal neurons, were found in the CA_1 field. Frequently, they were in aggregates in stratum pyramidale, oriens and radiatum of regio superior and also individually scattered throughout the CA_1 field. Clusters of transplanted cells were also found dorsal to the hippocampus and partially embedded within the corpus callosum. These grafts were in contact with the hippocampus via penetrations through the alveus. Host-derived AChE-positive fibers innervated the grafts through these alvear penetrations and from the cortex. These data suggest that fetal hippocampal cells, morphologically similar to CA_1 pyramidal neurons, will survive when transplanted into the CA_1 field in the ischemic hippocampus of the Mongolian gerbil and are innervated by host-derived AChE-positive fibers. These grafted cells may in turn ameliorate deficits in spatial memory that result from cerebral ischemia. (Support by AHA and AHA, Indiana Affiliate, Inc.)

RELATIONSHIP OF HOST DEAFFERENTATION AND EMBRYONIC TRANSPLANTATION IN THE REINNERVATION OF ENTORHINAL TERRITORY IN THE ADULT MOUSE DENTATE GYRUS. C.-F. Zhou*-, Y. Li*-, P. M. Field* and G. Raisman, Lee Research Centre, Lab of Neurobiology, NIMR, London NW7 1AA, UK, and -Shanghai Physiology Institute, PR China.

Thy-1.1 to Thy-1.2 mouse congenic transplants were used to show that embryonic entorhinal area projects specifically to the appropriate entorhinal afferent territory of the outer two-thirds of the stratum moleculare of the adult host dentate gyrus. The projection requires that the terminal field is deafferented by removal of the host entorhinal area. Deafferentation is effective if carried out at the time of transplantation or for up to 2 months before transplantation. This indicates that for 2 months after host entorhinal lesions, host sprouting either does not occur or is not sufficient to prevent ingrowth of transplant entorhinal axons. Quantitative electron microscopic studies show the relationship between transplant and sprouting host fibres in their capacity to reinnervate the denervated entorhinal territory.

SELECTIVE INNERVATION OF CA3 HIPPOCAMPAL TRANSPLANTS BY ADULT HOST DENTATE GRANULE CELL AXONS. P.M. Field*, P.J. Seeley*, M. Frotscher-* & G. Raisman (SPON: Brain Research Association), Lee Research Centre, Lab. of Neurobiology, National Institute for Medical Research, London NW7 1AA, UK and -Dept of Anatomy, University of Frankfurt, FRG.

We have studied formation of characteristic mossy fibre synapses between granule cell axons of adult PVG rat hosts and embryonic transplants from syngeneic rat hippocampus. Late embryonic hippocampus was subdissected into its proto-cytoarchitectonic fields and the quality of this subdissection monitored from the cytology of neurons in semi-thin sections, birthdate analysis using tritiated thymidine, staining with an antibody (py) that is selective for large pyramidal neurons of CA3, and EM analysis of identified Golgi stained CA3 pyramids and mossy fibres.

Transplanted large pyramidal neurons receive mossy fibre synapses only when the transplant makes direct contact with the host mossy fibre system and these connections are selective for CA3 compared with CA1 pyramids.

CONNECTIONS OF THY 1.2 LABELED CROSS-SPECIES TRANSPLANTS IN THE DENTATE GYRUS USING EM. B.P. Vietje, J. Wells, and R. J. McKeon. (SPON: J. Held) Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

Neural cell suspensions from the septal/basal forebrain region of Thy 1.2-positive mouse embryos were transplanted into the hippocampus of Thy 1.1 rat hosts. A Thy 1.2 antibody was found on the external membranes and certain internal membranes of the transplanted neurons. Within the transplant, labeled presynaptic profiles contacted labeled postsynaptic profiles. Many unlabeled presynaptic profiles contacted labeled postsynaptic profiles. Most were asymmetric synapes on dendrites of a variety of diameters. In the host close to the transplant, the labeled fibers growing out of the transplant were often fasciculated into large groups. Each fascicle was surrounded by an unlabeled astrocytic process but there were no unlabeled processes within the fascicles. Further away from the transplant few fascicles were seen but labeled individual fibers were seen coursing through the host neuropil. There was not a consistent orientation between the labeled distal fibers and astrocytes, but a few labeled presynaptic profiles also were seen contacting unlabeled postsynaptic profiles of the host. Supported by PHS 23266.

GROWTH OF CHOLINERGIC SEPTAL-BASAL FOREBRAIN TISSUE FOLLOWING CROSS-SPECIES TRANSPLANTATION. R.J. McKeon, B.P. Vietje*, and J. Wells. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

Cell suspensions of septal-basal forebrain tissue from embryonic Thy 1.2-positive mice were transplanted to the dentate gyrus of cholinergically denervated Thy 1.1-positive rat hosts. Antibodies to Thy 1.2 and ChAT were used to compare the distribution of the donor tissue and ChAT-positive cells and processes following transplantation. Both Thy 1.2-positive and ChAT-positive cells and processes were similarly distributed within the host dentate gyrus. ChAT-positive staining was most dense within the transplant and ChAT-positive cells and processes were clearly evident within the hilus and intact molecular layer. The ChAT-positive cells and processes were determined to be of donor origin since they were not present in sections of normal or lesion control animals. Thus, ChAT immunocytochemistry corroborates the selective growth of xenogeneic Thy 1.2-positive tissue. Additionally, neither the Thy 1.2 nor ChAT staining matches reports of AChE staining following xenogeneic transplants. These data suggest that the AChE-positive ingrowth within the host following xenogenic transplants is derived from both the donor and the host. Supported by PHS 23266.

INCREASE OF ACHE IN THE MOLECULAR LAYER OF THE DENTATE GYRUS AFTER GRANULE CELL LESIONS IN THE ABSENCE OF EXTRINSIC ACHE INPUTS. J. Wells, R. J. McKeon and B. P. Vietje. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

Selective lesions of the granule cells of the dentate gyrus were made by fluid injection into the infragranular cleavage plane. The animals were sacrificed at various times after the lesions and sections were stained histochemically for AChE and immunocytochemically for choline acetyltransferase (ChAT). The AChE increased markedly in the molecular layer above the granule cell lesion but was unchanged in the molecular layer away from the lesion. The increase in AChE also was seen after combined granule cell and fornix lesions but no AChE was present in animals with a fornix lesion alone. The portion of the molecular layer which stained densely for AChE did not react with an antibody to ChAT. We suspect that the non-cholinergic but AChE-positive interneurons that normally project to the molecular layer have sprouted in response to the loss of their usual target. The molecular layer also shrinks after the granule cell lesion. The shrinkage may add to the dense appearance of the AChE but the AChE increase occurred independently of the shrinkage. Supported by PHS 23266.

FETAL MONKEY BASAL FOREBRAIN NEURONS GRAFTED INTO NUCLEUS BASALIS LESIONED CEBUS MONKEYS. J.H. Kordower[1], M.S. Fiandaca, and D.M. Gash. [1]Dept. of Anatomy and Cell Biology, Univ. Illinois Sch. Med., Chicago Ill. 60302. USA.

Grafts containing cholinergic neurons derived from the embryonic rodent basal forebrain have been demonstrated to survive transplantation and ameliorate some of the memory deficits which result from aging processes or lesions of either the septohippocampal pathway or nucleus basalis. To date, no studies have examined the extent to which such grafts survive in the primate CNS. Four young adult (1.5-2.5 kg) male *Cebus apella* monkeys received unilateral ibotentic acid lesions of the nucleus basalis. Six injections of this toxin were made in 1.2 µl volumes at a concentration of 10 µg/µl. Seven to ten days later, monkeys received cortical and amygdaloid implants of basal forebrain neurons obtained from E60 (n=2) or E90 (n=2) *Cebus apella* fetuses. All monkeys were sacrificed 10 weeks later. Nissl staining, nerve growth factor (NGF) receptor immunocytochemistry, and acetylcholinesterase (AChE) and diophorase (NADPH) histochemistry revealed comprehensive unilateral lesions of the nucleus basalis. Ipsilateral to the lesion, cholinergic fiber staining was clearly reduced within the external capsule and cortex and virtually eliminated within the amygdaloid basolateral nucleus. In monkeys receiving implants from the E90 fetus, few surviving grafted neurons were observed. In contrast, numerous grafted magnocellular, NGF receptor-immunoreactive and AChE positive neurons were observed in monkeys receiving E60 grafted tissue. The neurons were organized in clusters in a manner similar to that observed *in situ*. Long processes emanating from these cells abutted, but did not cross, the graft/host interface. In some instances, healthy appearing Nissl stained grafts failed to contain cholinergic neurons. Numerous NADPH-containing neurons with morphological characteristics similar to those seen within the Cebus basal forebrain were observed in these transplants. These data indicate that both cholinergic and noncholinergic fetal monkey basal forebrain neurons survive well following grafting into the primate CNS. (Support: NS25655 and The American Health Assistance Foundation (JHK)).

FETAL CHOLINERGIC GRAFTS TO THE BASAL FOREBRAIN IN THE AGED RAT. K.S. Chen*, G. Buzsaki, M. Benoualid*, and F.H. Gage. (SPON: R.T. Boyd) Dept. of Neuroscience (M-024), UCSD, La Jolla, CA 92093.

Rats exhibit behavioral, electrophysiological, and anatomical changes as a function of aging. Fetal grafts of basal forebrain cells into the hippocampus and/or cortex have been shown to ameliorate some of these age-related changes. In this study we implanted 3ul cell suspensions grafts of the basal forebrain region of fetal rats (E14-E16) bilaterally into the area of the nucleus basalis of aged (24 mos) Fischer 344 rats. These aged rats had been behaviorally characterized on the Morris water maze and exhibited an impairment on this task. Upon retesting on this task following implantation of the fetal grafts, the rats that had received grafts had significantly improved their performance to the level of aged rats that did not initially exhibit an impairment on the water maze task. The impaired aged rats that did not receive grafts did not show an improvement.

Aged rats also exhibit pathological EEG patterns as reflected by frequent long-duration high voltage neocortical spindles that did not correlate with their performances on the water maze. Graft survival was demonstrated by acetylcholinesterase (AChE) staining. Immunohistochemical staining for choline acetyltransferase (ChAT) and NGF receptor (NGFr) revealed the presence of ChAT-positive and NGFr-positive cells in the grafts. These results suggest that grafts of fetal cells to the nucleus basalis region survive well in the aged rat, and may be able to reverse some age-related functional deficits.

DRUGS OF ABUSE: CNS PATHWAYS

434.1

LACK OF TOLERANCE TO NICOTINE-INDUCED DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS OF RATS: AN *IN VIVO* MICRODIALYSIS STUDY. J. Day, G. Damsma and H.C. Fibiger. Div. of Neurological Sciences, Dept. of Psychiatry, University of British Columbia, Vancouver, B.C. V6T 2A1.

The extent to which repeated administration produces tolerance to nicotine-induced increases in dopamine transmission in the nucleus accumbens was investigated in rats. *In vivo* microdialysis was used to sample extracellular concentrations of dopamine and metabolites after a nicotine challenge (0.35 mg/kg) in (1) naive rats, (2) acutely pretreated rats (one prior nicotine injection), and (3) chronically pretreated rats (twelve to fifteen prior daily nicotine injections, 0.35 mg/kg/injection). Nicotine increased extracellular concentrations of DA and its metabolites, and these increases were not significantly altered by either acute or chronic prior exposure to the drug. The failure to find evidence of tolerance is compatible with the hypothesis that the mesolimbic dopaminergic system is a substrate for the reinforcing properties of chronically administered nicotine.

434.2

PROFILE OF THE EXTRACELLULAR CONCENTRATION OF COCAINE AND DOPAMINE UNDER SELF-ADMINISTRATION CONDITIONS. **H.O. Pettit, H. Pan* and J.B. Justice Jr.; Emory University; Dept. of Chemistry; Atlanta, Georgia 30322.**

Repetitive administration of cocaine leads to a buildup of both cocaine and dopamine (DA) concentrations in the extracellular fluid of the brain. A series of experiments were undertaken to monitor cocaine and DA concentrations in the nucleus accumbens under a variety of cocaine administration conditions. In vivo microdialysis coupled to high pressure liquid chromatography with ultraviolet detection or electrochemical detection was used to analyze cocaine and DA concentrations, respectively. Cocaine concentrations were measured following the intravenous administration of (1) a single infusion of 0.75 mg/kg cocaine; (2) 0.75 mg/kg/inj of cocaine delivered in five minute intervals; and (3) 1.5 mg/kg/inj of cocaine delivered in eight minute intervals. Concentrations of DA were quantified in animals during the intravenous self-administration of either 0.25, 0.5 or 0.75 mg/inj of cocaine (doses correspond to 0.75, 1.5 and 2.25 mg/kg/inj). Cocaine concentrations were observed to increase and stabilize during repetitive administration in a dose dependent manner. Cocaine concentrations were estimated to be approximately 20 and 30 μM for 0.75 and 1.5 mg/kg/inj doses, respectively. The extracellular concentration of DA was also observed to increase and stabilize at approximately 400% of basal levels during cocaine self-administration. Results indicate that extracellular cocaine and DA concentrations are maintained at an increased, but steady level by a repetitive cocaine administration schedule.

434.3

EFFECTS OF PHENCYCLIDINE (PCP), A NON-COMPETITIVE, AND NPC 12626, A COMPETITIVE N-METHYL-D-ASPARTATE ANTAGONIST ON MESOLIMBIC DOPAMINE SYSTEMS: AN ELECTROPHYSIOLOGICAL AND BEHAVIORAL COMPARISON. S.Levenson* and E.D.French, Dept. Pharmacology, Univ. Arizona, Coll.Med. Tucson, AZ 85724.

We have found that the potency of PCP-like drugs to activate VTA dopamine (DA) neurons is correlated positively to their potency as non-competitive NMDA receptor antagonists. However, aside from some behavioral effects similar to PCP, there is no data to indicate that competitive NMDA blockers will activate mesocorticolimbic DA neurons. These A10 cells are often considered the probable substrate for PCP's psychotomimetic effects.

Extracellular recordings from single VTA A10 neurons were made in chloral hydrate anesthetized rats during i.v. drug injections. From these recordings cumulative dose-response curves were established for MK-801, PCP and NPC 12626. MK-801 and PCP elicited maximum increases in neuronal firing of 40% at 0.5 and 1 mg/kg, respectively, while NPC 12626 altered firing only 4% with doses up to 100 mg/kg. The lack of an NPC effect would not appear to be due to limited access to the CNS since i.p. NPC (50 mg/kg) can produce locomotor hyperactivity and ataxia like that seen with PCP. In order to determine whether the behavioral effects, like those of PCP, were mediated via mesolimbic DA systems animals received bilateral intra-accumbens injections of 6-hydroxydopamine (4 ug/ul) or vehicle 14 days before challenge injections of NPC (50 mg/kg), PCP (5 mg/kg), or d-amphetamine (1.5 mg/kg) and activity measured in photocell cages. Unlike PCP and d-AMP, NPC's locomotor stimulatory effects were not blocked in 6-OHDA lesioned animals.

These results suggest that, in contrast to PCP-like psychotomimetic drugs, competitive NMDA antagonists do not stimulate A10 neuronal activity nor activate locomotor behavior via mesolimbic DA systems.

434.4

ACCUMBENS DOPAMINE LESIONS PRODUCE A TEMPORARY EXAGGERATION IN BEHAVIORAL ACTIVITY FOLLOWING OPIATE MICROINJECTIONS. P. Johnson*, G. Alsterberg*, J.R. Stellar (SPON: A. Skanveski). Psychology Department, Northeastern Univ., Boston, Ma., 02115.

Stinus et al. (Psychopharm. 85:323, 1985) have shown that following 6-OHDA lesions of the nucleus accumbens, microinjection of D-Ala-Met-enkephalinamide (DALA) produces a greater increase in behavioral activity than seen in pre-lesion baseline.

In 5 subjects receiving a DALA injection each week for 5 weeks, we report a similar increase in DALA-induced behavioral activation peaking at 632% (±169) of pre-lesion baseline 2 weeks after lesion, but we also report a reduction in this DALA increase to 164% (±71) by 5 weeks post-lesion. Baseline behavioral activity (no DALA) also increased and decreased over this period post-lesion peaking at 327% (±19) in the 2nd-3rd week after lesion. Current work concerns attempts to identify the mechanisms of this temporary increase and application to rewarding lateral hypothalamic self-stimulation.

434.5

CHRONIC COCAINE ADMINISTRATION ENHANCES EXTRACELLULAR CONCENTRATIONS OF COCAINE AND DOPAMINE FOLLOWING A CHALLENGE INJECTION. **H. Pan*, H.O. Pettit and J.B. Justice Jr.; Emory University; Dept. of Chemistry; Atlanta, Georgia 30322.**

Chronic cocaine administration produces significant increases in behavioral responses to a cocaine challenge injection. Cocaine-induced locomotor activity and stereotypy are enhanced in animals that receive daily cocaine injections. Supersensitive post-synaptic receptors, a down regulation of autoreceptors, and/or conditioning effects have been proposed to explain reverse tolerance effects of chronic cocaine administration. The present study used in vivo microdialysis techniques to monitor extracellular concentrations of both dopamine (DA) and cocaine in two groups of animals (N = 4/grp). One group of animals (acute group) received one subcutaneous (s.c.) injection of saline per day for 10 consecutive days. The other group of animals (chronic group) received one s.c. injection of cocaine per day for 10 consecutive days (days 1-5, 10 mg/kg; days 6-10, 20 mg/kg). On day 11, each animal was anesthetized, placed in a stereotaxic instrument and a microdialysis probe was lowered into the nucleus accumbens. Once baseline measurements were obtained, each animal received an intraperitoneal injection of cocaine (30 mg/kg). Cocaine and DA concentrations were quantified by microbore HPLC with ultraviolet or electrochemical detection, respectively. Both cocaine and DA concentrations were significantly higher in animals that received chronic vs acute cocaine administration (>200%). Results indicate that reverse tolerance effects observed following chronic cocaine administration may be due to significantly higher cocaine concentrations. Furthermore, the increase in DA concentration observed in chronic animals was higher than could be accounted for by the increase in cocaine concentration. Results indicate two physiological changes as a result of chronic cocaine administration: one that increases extracellular cocaine concentrations; and another that enhances the ability of cocaine to increase the extracellular concentration of dopamine.

IN VIVO BRAIN MICRODIALYSIS STUDIES OF Δ^9-TETRAHYDROCANNABINOL ON PRESYNAPTIC DOPAMINE EFFLUX IN NUCLEUS ACCUMBENS OF THE LEWIS RAT. J. Chen*, W. Paredes*, J. Li*, D. Smith*, and E.L. Gardner. Depts of Neuroscience and Psychiatry, Albert Einstein College of Medicine, New York, NY 10461.

Marijuana is the most widely used illicit drug in North America, yet the neurobiological substrates for its abuse liability remain unclear. Due to the postulated role of CNS dopamine (DA) systems in mediating the rewarding properties of drugs of abuse (Spyraki et al. Psychopharmacology 79:278 1983), it is possible that Δ^9-tetrahydrocannabinol (THC), the psychoactive ingredient of marijuana, may have agonist-like DA effects. In fact, we previously showed that THC acutely facilitates brain-stimulation reward in rat medial forebrain bundle (Gardner et al. Psychopharmacology 96:142, 1988), known to be sensitive to DA modulation, and produces acute augmentation of K^+-evoked presynaptic DA efflux in rat neostriatum (Ng Cheong Ton et al. Brain Res. 451:59, 1988). We have now carried out in vivo microdialysis studies of THC's effect on basal presynaptic DA efflux in the nucleus accumbens (Acc), a crucial anatomic convergence of brain-reward-relevant DA circuitry. Pharmacologically meaningful low doses of THC produced dose-dependent augmentation of basal DA efflux in Acc peaking at 20-40 mins post-THC and lasting approx. 1 hr; this augmentation was significantly attenuated by naloxone. We suggest that THC is not as anomalous a drug of abuse as some have suggested, and shares with other abused drugs a DA agonist-like action on reward-relevant mesotelencephalic DA circuits.

434.7

SIMULTANEOUS BEHAVIORAL AND NEUROCHEMICAL MEASUREMENTS DURING MICRODIALYSIS INFUSION OF COCAINE AND AMPHETAMINE IN THE NUCLEUS ACCUMBENS OF RATS **S.E. Hemby, H. O. Pettit, D.B. Neill, and J.B. Justice Jr. Departments of Psychology and Chemistry, Emory University, Atlanta, GA 30322**

The increase in locomotor activity and reinforcing effects of psychomotor stimulants are believed to be primarily mediated by dopamine (DA) transmission in the nucleus accumbens (N ACC). Rats will self-administer amphetamine (Hoebel et al., *Psychopharmacology*, 81:158-163,1983), but not cocaine (Goeders & Smith, *Science*, 221:773-775,1983) into the N ACC. Therefore, we examined the locomotor effects and the dopaminergic response in the N ACC during direct infusions of amphetamine and cocaine in the N ACC. Amphetamine (0, 27, 54, and 108mM) or cocaine (0, 118, 235, and 470 mM) was constantly infused through a microdialysis probe into the N ACC. Simultaneously, extracellular DA concentrations were quantified by HPLC-EC analysis of the dialysate every five minutes for two hours. Extracellular DA concentrations increased following cocaine and amphetamine infusions, while sustained locomotor activity was present only in the amphetamine infused rats. Subsequently, we examined the ability of cocaine infused through a microdialysis probe to affect the extracellular concentration of DA 2.0mm away from the infusion site and found increases in extracellular DA concentrations, indicating that a substantial area of the N ACC was affected. These results suggest that cocaine infused directly into the N ACC results in increased extracellular DA concentrations, but does not produce the expected behavioral effects.

434.8

EARLY COCAINE ABSTINENCE ALTERS GLUCOSE UTILIZATION IN DOPAMINERGIC REWARD PATHWAYS. D.W. Clow, S.J. Lee*, D. Yoshishige*, L.J. Porrino and R.P. Hammer, Jr. Dept. Anatomy & Reprod. Biol., Univ. Hawaii Sch. Med., Honolulu, HI 96822 and NINDS, Bethesda, MD 20892.

Chronic cocaine exposure may deplete neuronal dopamine (DA) stores by inhibiting reuptake. Systemic administration of DA receptor agonists, such as bromocriptine (BROM), could compensate for a subsequent reduction of DA output. We investigated the effects of chronic cocaine, followed by a brief period of abstinence (with or without BROM treatment), on local cerebral glucose utilization (lCGU) in rat brain.

In the first study, adult male rats were injected daily with 10 mg/kg cocaine HCl or vehicle i.p. for 14 days, and in the second study, this was followed by a three day period of cocaine abstinence in which the animals were injected daily with 10 mg/kg BROM or vehicle. Animals were then prepared for quantitative analysis of lCGU using [^{14}C]2-deoxyglucose. LCGU experiments began 10 min following cocaine administration (first study) or 2 hr following BROM administration (second study). Chronic cocaine resulted in a general increase in lCGU with significant increases in rostral nucleus accumbens (NAc), medial caudate, globus pallidus and substantia nigra (SN). In contrast, chronic cocaine followed by 3 days of abstinence resulted in a general decrease in lCGU in most regions studied, including NAc, SN and ventral tegmental area. Subsequent BROM administration returned lCGU to control levels in some of these regions. Moreover, correlation analysis of lCGU data revealed that metabolic activation of mesolimbic circuits occurs following chronic cocaine treatment, but not saline treatment. These results suggest that dramatic changes occur in dopaminergic reward regions during the period of early cocaine abstinence, and that these alterations may be influenced by dopaminergic pharmacotherapy during this period. EFFECTS OF 6-HYDROXYDOPAMINE LESIONS OF THE MESOCORTICAL/MESOLIMBIC PATHWAYS ON NOVELTY-SEEKING BEHAVIOR OF RATS. R.C. Pierce*, A.J. Nonneman, B.A. Mattingly and M.T. Bardo. Dept. of Psychology, University of Kentucky, Lexington, KY 40506.

The effect of a 6-hydroxydopamine (6-OHDA) lesion (8.0 µg in 2 µl per side) of the mesocortical/mesolimbic pathways (A +2mm, L ± 1.5mm, V -7mm relative to bregma) on the novelty-seeking behavior of rats was studied. Animals were habituated to a previously novel chamber thirty minutes daily over four consecutive days. On the fifth day, animals were allowed free access to both the habituated (familiar) and a distinct novel environment. Control animals displayed a novelty-preference as they spent significantly more time in the novel chamber relative to the familiar chamber. Novelty-seeking was blocked in lesioned animals as they showed no preference for either the novel or familiar chamber. Subsequent assays revealed that the 6-OHDA lesion reduced dopamine levels in the nucleus accumbens (67% depletion), striatum (75% depletion) and olfactory tubercles (68% depletion) as compared to controls. These results suggest that novelty-seeking behavior may be mediated by a brain dopamine pathway.

NEUROLEPTIC-LIKE EFFECTS OF INTRA-ACCUMBENS CHOLECYSTOKININ ON I.V. COCAINE SELF-ADMINISTRATION. F.J.Vaccarino,[1] F.Weiss and G.F. Koob.[2] [1]Depts. of Psychology and Psychiatry, Univ. of Toronto, Canada, M5S1A1; [2]Div. of Preclinical Neuroscience and Endocrinology, Research Institute of Scripps Clinic.

Increased dopamine (DA) transmission in the nucleus accumbens (Acb) is an essential mechanism underlying the rewarding properties of i.v. cocaine reward. Cholecystokinin (CCK) is present in Acb DA terminals as well as non-DA neurons associated with the mesolimbic system. The present experiment examined the possible modulatory effects of intra-Acb CCK on i.v. cocaine self-administration.

Male Wistar rats with bilateral cannulae aimed at the Acb were trained to self-administer cocaine intavenously during daily 3 h sessions. Following stable responding each rat was tested following intra-Acb microinjections of CCK (0, 0.5, 1 and 2 ng). CCK doses were administered in counterbalanced order. A minimum of 3 no pretreatment days separated drug tests.

The results demonstrated that intra-Acb CCK produced a dose-dependent attenuation of cocaine reward as reflected by an increase in responding for i.v. cocaine. The 1 ng CCK dose, which produced approximately a 75% increase in responding, was the most effective dose. These results demonstrate that CCK has neuroleptic-like effects on i.v. cocaine self-administration.

COCAINE AND BRAIN REWARD DOPAMINERGIC NEURONAL CIRCUITRY: NEUROBEHAVIORAL CONCOMITANTS. F.T. Phelan* and P.A. Broderick (SPON: L. Mitchell). Dept. Pharmacol., CUNY Med. Sch.: Depts. Biol. & Psych., CUNY Grad., NY 10031.

Brain reward is intimately associated with dopamine in mesolimbic neuronal circuitry. We studied the effect of cocaine on presynaptic mechanisms in nucleus accumbens, the terminal neurons for the ventral tegmental (A10) cell bodies. Dopamine in extracellular fluid was studied by in vivo voltammetry. Locomotor activity was studied by Activity Pattern Analysis (San Diego Instr., Calif.). Electrochemical (ELC) measurements of dopamine, before and after subcutaneous administration of cocaine (20mg/kg), were coupled with behavioral locomotor activity studies in freely moving, male, inbred Sprague-Dawley rats (350-450g). We then further studied the effect of cocaine on extracellular dopamine in striatum and again simultaneously recorded locomotor activity. The results show that the dopamine signal after cocaine, increased in nucleus accumbens of freely moving rats. The increase in dopamine was slow and progressive. By comparison, dopamine in striatum showed less change after cocaine administration. Interestingly, the dopamine alterations occurred before locomotor activity changes began. These data confirm cocaine's action in dopaminergic mesolimbic circuitry.(Spons.:DHHS, PHS Grant #2-S07-RR07132, PSC/CUNY Award #667234 and BRSG#442248 to P.A. Broderick.)

OPIATES INFLUENCE NUCLEUS ACCUMBENS NEURONAL ACTIVITY BY DOPAMINE AND NON-DOPAMINE MECHANISMS S.J. Henriksen and R.L. Hakan. Department of Neuropharmacology, The Research Institute of Scripps Clinic, La Jolla, CA 92037.

The nucleus accumbens septi (NAS) of the telencephalon is thought to mediate, in part, rewarding components of drug self-administration. Dopamine-containing cell bodies originating in the ventral tegmental area of Tsai (VTA) are a major afferent to the NAS. While VTA-derived dopamine has been implicated in psychostimulant reward, the role of this amine for the rewarding effects of opiates is unclear. We have investigated the effects of systemic and local infusions of morphine on spontaneous and evoked single unit activity of NAS neurons in anesthetized rats. Systemic or iontophoretically applied morphine generally inhibit randomly encountered spontaneously active NAS cells. However, phoretically or systemically applied morphine are uniformly ineffective in altering fimbria-driven NAS activity recorded from normally "silent" NAS units. On the other hand, micro-infusion of morphine (2.5 µg in 1 µl) into the VTA (VTA-M) inhibits this fimbria-driven unit discharge, and subsequent administration of morphine (s.c.) can reverse this VTA-M inhibition suggesting an opposing action of opiates at a separate, non-VTA site. In fact, micro-infusion of morphine into the ventral subiculum, but not into the amygdala, reverses the inhibitory effect of VTA-M on fimbria-evoked NAS activity. These data suggest that the effects of systemic morphine on NAS unit activity result from the integration of opiate-sensitive NAS afferents having potentially opposing actions on NAS activity. A METHOD FOR RECORDING SINGLE UNIT ACTIVITY DURING I.V. SELF-ADMINISTRATION OF DRUGS IN THE FREELY MOVING RAT. L.L. Peoples*, M. Wolske, S.I. Dworkin, J.A. Smith, S.A. Deadwyler, M.O. West. Dept. Psychol, Rutgers U., New Brunswick, NJ; Dept. Physiol/Pharm, Bowman Gray Sch. Med., Winston-Salem, NC

The mesocorticolimbic dopamine system has been implicated as an important neural substrate of psychomotor stimulant self-administration. The present experiments were undertaken to electrophysiologically record single unit activity in the nucleus accumbens of rats self-administering cocaine. Male Long-Evans rats (300g) were permanently implanted with microwires (25 micron diam.) in the nucleus accumbens, with a stimulating electrode in the ipsilateral fimbria, and with a catheter in the jugular vein. That recorded units were accumbens neurons was verified by stimulating the fimbria to evoke unit discharges at monosynaptic latencies (i.e., 4-11 msec) and by histological analysis. Computer-sychronized videotape analysis allowed the measurement of neural activity time-locked to particular behavioral events. During experimental sessions, each lever-press caused an infusion of 0.2 ml 1.65 mg/ml cocaine (i.e., 0.33 mg/infusion). Unit responses to cocaine were analyzed in terms of 1) neural correlations with motor activity (e.g., locomotion, lever-pressing) and 2) initial vs cumulative exposure to the drug. Preliminary results obtained during the shaping of self-administration behavior indicate that accumbens neurons exhibited overall firing rates with low means (0.08 - 0.97 Hz) and high standard deviations (0.65 - 0.87 Hz). Cocaine administration induced small and inconsistent changes in neural activity, typically accompanied by increases in the standard deviation of mean firing rate (perhaps due to induction of sterotypy). The present experiments demonstrate the feasibility of recording unit activity in self-administering rats but indicate the necessity of using appropriate motor and sensory controls. Supported by DA 04551 and RR 07058-21.

NUCLEUS ACCUMBENS AND AMYGDALA ARE SUBSTRATES FOR THE AVERSIVE STIMULUS EFFECTS OF OPIATE WITHDRAWAL. L. Stinus*, M. Le Moal, and G.F. Koob. I.N.S.E.R.M.U.259, Bordeaux, France, and Research Institute of Scripps Clinic, La Jolla, CA 92037.

Specific brain sites for the classic opiate abstinence syndrome of wet dog shakes, ptosis and teeth chattering appear to be widely represented in the brain. Using a more general motivational test in dependent rats, the brain site most sensitive to the response disruptive effects of intracerebral (IC) administration of the opiate antagonist, methylnaloxonium (MN), was the region of the nucleus accumbens, a site also implicated in the acute reinforcing properties of opiates. The present study examined whether IC administration of MN produced aversive stimulus effects as measured by the formation of place aversions. Rats implanted intracerebroventricularly (ICV) or with bilateral cannulas aimed at the medial dorsal thalamus, periaqueductal gray, ventral tegmental area, amygdala or nucleus accumbens were made dependent on morphine by subcutaneous implantation of two 75 mg morphine pellets. The animals were then subjected to place aversion training by pairing of a distinct environment with a single ICV injection of MN . Results showed that at high doses of MN (1000-2000 nanograms) all sites produced a place aversion. However lower doses (250-500 nanograms) produced significant brain site selectivity with the region of the nucleus accumbens most sensitive. Observational measures taken during the post-injection period with the high dose of MN showed various overt signs of opiate withdrawal at most sites except the amygdala where no classic abstinence signs were observed. Results suggest that the region of the nucleus accumbens, and perhaps the amygdala, are critically involved in the aversive stimulus effects of opiate withdrawal. INTRA-ACCUMBENS INJECTION OF THE GLUTAMATE ANTAGONIST GDEE INHIBITS THE LOCOMOTOR-ACTIVATING EFFECTS OF COCAINE AND AMPHETAMINE, BUT NOT CAFFEINE. N.R. Swerdlow[1], L. Pulvirenti[2,3] and G.F. Koob[2]. 1. Dept Psychiatry, UCSD, La Jolla, CA 92093. 2. Scripps Clinic & Res. Fdn., La Jolla, CA 92037. 3. Dept. Neurology, Univ. Pavia, Italy

Studies of the neural substrates of the locomotor-activating properties of psychostimulants have focused on brain dopamine (DA) systems, particularly the mesolimbic dopamine system and its terminal fields in the nucleus accumbens (NAC). Advances in our understanding of the efferent and afferent connections of the NAC suggest that the behavioral effects of psychostimulants might be modulated within the NAC by glutamate afferents originating within allocortex. We examined the effects of blockade of NAC glutamate activity on the locomotor-activating effects of cocaine (COC) and amphetamine (AMP) - drugs that stimulate locomotion by enhancing NAC DA activity - and caffeine (CAF), which stimulates locomotion independent of NAC DA.

Animals were equipped with bilateral cannulae aimed above the NAC. One week later, they were tested for locomotor activity in photocell cages following intra-NAC infusion of the glutamate antagonist GDEE (0-20 µg/side), and peripheral injection of COC (20 mg/kg ip), AMP (0.75 mg/kg sc) or caffeine (20 mg/kg sc). GDEE significantly decreased COC- and AMP-stimulated locomotion, but not CAF-stimulated locomotion.

These results suggest that the locomotor-stimulated effects of drugs that enhance NAC DA activity are modulated by NAC glutamate transmission. Glutamate projections to the NAC from allocortex may modulate the behavioral properties of NAC DA activity.

434.16

MICROINJECTION OF NMDA BUT NOT QUISQUALATE RECEPTOR ANTAGONISTS INTO THE NUCLEUS ACCUMBENS MODULATES INTRAVENOUS COCAINE SELF-ADMINISTRATION IN RATS. L. Pulvirenti[1,2] R. Sung*[1] and G.F. Koob[1] 1. Research Inst of Scripps Clinic, La Jolla, CA 92037. 2. Dept Neurology, Univ. Pavia, Italy.

The dopamine system in limbic structures is a critical neurosubstrate for drug reinforcement. In particular, the nucleus accumbens of the ventral striatum (NAC) seems to play a major role modulating i.v. self-administration of psychostimulant drugs. Recent evidence has shown that allocortical glutamate afferences to the NAC may be involved in regulating motivated behavior.This study was therefore designed to determine whether glutamate neurotransmission in the NAC would affect i.v. cocaine self-administration in rats.

We studied the effect of intra-NAC administration of 2-amino,5-phosphonovaleric acid (APV), and glutamic acid diethyl ester (GDEE), selective antagonists at NMDA and quisqualate receptor subtype, respectively. APV at the doses of 1.5 and 3.0 µg/side induced a decrease in the rewarding value of cocaine, measured as an increase in the number of responses for the drug in 3-hr daily sessions. GDEE at the doses of 10 and 20 µg/side was ineffective.

These results show that the endogenous glutamate activity in the NAC may be of importance for the maintainence of iv cocaine self-administration in rats. Since glutamate afferents to the NAC are thought to originate mainly from the hippocampus and the amygdala, this is the first evidence suggesting allocortical modulation of the NAC function in drug reinforcement. NORCOCAINE INHIBITS THE SPONTANEOUS ACTIVITY OF DORSAL RAPHE (DR) SEROTONIN NEURONS IN THE RAT. Joseph M. Paris, Kathryn A. Cunningham and Joan M. Lakoski, Dept. of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77550.

Cocaine has been demonstrated to inhibit the activity of catecholaminergic and serotonergic (5-HT) neurons in the CNS. Norcocaine is the primary oxidative metabolite of cocaine which also inhibits monoamine uptake and stimulates locomotor activity. The present series of experiments were undertaken in order to characterize the possible electrophysiological effects of norcocaine on spontaneously firing DR 5-HT neurons.

DR 5-HT neurons were identified utilizing standard in vivo extracellular single-unit recording techniques in chloral hydrate anesthetized male Sprague-Dawley rats. The cumulative dose of (-) norcocaine to inhibit DR 5-HT cell firing by 50% was 0.5 +/- 0.05 mg/kg, i.v. (n = 11); the mean dose to completely suppress activity was 1.5 +/- 0.22 mg/kg. Single bolus injections (0.5 mg/kg) depressed cell activity 54-92%. In addition, the dopamine and 5-HT_{1A} autoreceptor antagonist, spiperone (1.0 mg/kg, i.v.), was able to reverse norcocaine's inhibitory effects. These data suggest that the previously reported depressant effects of cocaine in the DR may be mediated, in part, via the active metabolite, norcocaine. Microiontophoretic studies are in progress to assess the mechanism of norcocaine's effects. Supported by NIDA DA04296.

FAILURE OF NALOXONE TO BLOCK THE EFFECT OF COCAINE ON INTRACRANIAL SELF-STIMULATION. P.Z. Manderscheid, R.A. Frank & H.P. Williams*. Dept. of Psychology, Univ. of Cincinnati, Cincinnati, OH 45221.

Midbrain dopaminergic pathways and opioid receptor systems have been implicated in the rewarding effects of intracranial self-stimulation. Evidence points to the ventral tegmental area as the site of the interaction of these two systems:e.g., both cocaine and morphine dose-dependently lower self-stimulation thresholds in animals with VTA electrodes. Recently, Bain and Kornetsky (1987) demonstrated that naloxone (an opiate receptor blocker) effectively blocks the threshold lowering effect of cocaine. The present study investigated the effect of naloxone on cocaine-induced changes on self-stimulation thresholds in an effort to replicate the aforementioned results.

Male Sprague-Dawley rats were implanted with electrodes in the ventral tegmental area. Animals were injected with either saline, cocaine HCl (25 mg/kg IP), or naloxone (4 mg/kg IP) plus cocaine (25 mg/kg IP). Thresholds were determined 15, 75, and 195 min post-injection. At all test periods naloxone failed to block or attenuate the threshold lowering effect of cocaine.

It is evident that the relationship between dopaminergic and opioid systems of reward needs further clarification. One explanation of the difference in results may be attributable to the methods used in determining self-stimulation thresholds.

LACK OF NEUROCHEMICAL EVIDENCE FOR NEUROTOXIC EFFECTS OF REPEATED COCAINE ADMINISTRATION IN RATS ON BRAIN MONOAMINE NEURONS. S.Y. Yeh* and E.B. De Souza. (SPON: R. Liu) Neurobiology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224.

There is an ongoing controversy concerning potential neurotoxic effects of cocaine administration in rats on brain monoamine neurons. Repeated cocaine administration in rats (10 mg/kg, i.p., 7 or 10 days) has been reported to produce significant long-lasting decreases in dopamine (DA) synthesis, tyrosine hydroxylase content, and increased ^{3}H-spiroperidol binding in several discrete areas of rat brain (Trulson et al., Brain Res. Bul. 19: 35, 1987) and depletion in levels of DA and its metabolites, DOPAC and HVA in frontal cortex and hypothalamus (Wyatt et al., JAMA, 259: 2996, 1988). On the other hand, others have been unable to demonstrate any long-term reduction in brain monoamines following chronic cocaine administration in rats. (Yeh, Fed. Proc. 404, 1987; Kleven et al., Brain Res. Bul. 21: 233, 1988). These conflicting observations led us to reinvestigate the potential toxic effects of chronic cocaine administration in rats on brain monoamines. Rats were injected with cocaine (20 mg/kg, s.c., b.i.d., 7 days) and sacrificed at 1, 8, 15, and 48 days after the last injection. The contents of DA, norepinephrine, serotonin and their metabolites, assayed by HPLC-EC, in frontal cortex, hippocampus, striatum, hypothalamus, midbrain, pons-medulla and spinal cord were not significantly different from levels in saline-injected control rats. These data suggest that repeated cocaine administration in rats does not produce any long-term depletion in brain catecholamine and serotonin content characteristic of neurotoxic actions of the drug.

COCAINE: ELECTROPHYSIOLOGICAL CHARACTERIZATION OF EFFECTS IN AMYGDALA NUCLEI. **K.A. Cunningham, P.M. Callahan and H.A. Lekan. Dept Pharmacology/Toxicology, Univ Texas Medical Branch, Galveston, Texas 77550.**

The limbic system may be an important substrate of action for cocaine since this stimulant alters psychological processes mediated by this circuitry, including mood and emotion. Cocaine inhibits the uptake of dopamine (DA), norepinephrine (NE) and serotonin (5-HT), systems which innervate limbic regions such as the amygdala which is sensitive to cocaine-induced "kindling". Using extracellular recording techniques, we have begun to characterize the effects of cocaine on the activity of amygdala neurons of rats anesthetized with chloral hydrate (400 mg/kg,ip). Of 20 neurons recorded to date, 14 were located in basolateral and 6 in central amygdala. The spontaneous activity of these neurons was slow and irregular with an average rate of 1.2 Hz (range: 0.1-8.5 Hz); triphasic (+/-/+) action potentials were most typical. Inhibitory responses to cocaine (0.25-2.0 mg/kg, IV) were observed in 50% of the neurons tested with an average percent inhibition from baseline of 54 ± 8.9 %. Cocaine (IV) excited 30% (6/20) of the neurons (71 ± 34 % excitation). Three neurons were excited then completely depressed (15%) while 1 neuron was unaffected by cocaine. Studies of the mechanisms underlying the effects of cocaine within the amygdala are in progress. **Supported by the John Sealy Memorial Fund.**

CHARACTERIZATION AND DISTRIBUTION OF ESTROGEN RECEPTOR (ER) IN THE DIENCEPHALON OF THE GRAY SHORT-TAILED OPOSSUM. R.J. Handa, E.W. Rodriguez, C.A. Fox, C.D. Jacobson. Dept. of Anatomy, Loyola Univ., Maywood, IL 60153 and Dept. of Veterinary Anatomy, Iowa St. Univ., Ames, IA 50011.

The Brazilian gray short-tailed opossum is a pouchless marsupial whose young are born sexually undifferentiated. This animal is well suited for developmental studies. Previously, Etgen and Fadem (Gen. Comp. Endo. 66:441;1987) detected ER in the hypothalamus-preoptic area (HPOA). In this study we characterized the ER and determined its distribution in brains of male and female opossums. ER were measured by the in vitro binding of ^{3}H-estradiol to cytosol of brain subregions punched from 300 μ frozen sections. Radioinert R2858 was used to define non-specific binding. Saturation analysis showed a single, high affinity binding site in HPOA with a Kd of 0.1×10^{-9} M. Binding was displaced by E_2, DES and R2858, but not by non-estrogenic steroids. High levels of ER were found in the medial preoptic /periventricular preoptic area (57.7±3.5 fmol/mg protein). Intermediate levels were seen in the ventromedial hypothalamus, medial amygdala and arcuate n./median eminence (29.1±1.3; 26.5±3.4; 19.2±1.5 fmol/mg prot., respectively). No sex differences were observed. The presence of a neural ER and its distribution in the adult opossum brain supports the use of this animal model in studies examining steroid dependent organization of the hypothalamus. Supported by Potts Foundation Award (RJH) and NIH HD 16148 (CDJ).

435.2

AROMATASE ACTIVITY IN THE BRAIN OF THE GRAY SHORT-TAILED OPOSSUM (MONODELPHIS DOMESTICA). Barbara H. Fadem and Neil J. MacLusky Department of Psychiatry, UMDNJ-New Jersey Medical School, Newark 07103 and Division of Reproductive Science, Toronto General Hospital, Toronto, Ontario, Canada.

While brain aromatase activity has been demonstrated in eutherian mammals, studies have failed to demonstrate such activity in the brains of adult marsupials. For the present report, hypothalamus and preoptic area obtained from adult male gray opossums were assayed for aromatase activity. Tissues were homogenized in 10 volumes of PKDE buffer (10mM potassium phosphate, 100mM KCl, 10mM dithiothreitol and 1mM disodium EDTA, pH 7.4). Aromatase activity was assayed in triplicate aliquots of the homogenates by the tritiated water release method, essentially as described by Roselli et al. (Endocrinology 114:192, 1984). Control incubates contained either no tissue, or the same quantities of tissue homogenate in the presence of the specific aromatase inhibitor,4-hydroxyandrostenedione (4-OHA).

Aromatase activity was measurable in both the hypothalamic and preoptic area tissue samples (hypothalamus 202.1 ± 14.22 pmol[3H2]O/g protein/h; preoptic area 77.5 ± 7.9 pmol/g protein/h; Means ± S.E.M., n=5). Tritium release from the [3H]A substrate was inhibited >70% in both tissues in the presence of 40μM 4-OHA. Kinetic studies revealed the reaction to be saturable, but with a Km somewhat higher (~0.1 μM) than that observed for rat brain aromatase (0.02-0.05 μM) using the same substrate. Supported by NSF grant BNS 8616514 to B.H.F.

435.3

PROTEIN SYNTHESIS IN THE VENTROMEDIAL HYPOTHALAMUS IS MODIFIED BY SMALL PULSES OF ESTRADIOL. C.D. Condon, D.M. Lynn*, and E.J. Roy Neural and Behavioral Biology Program, Univ. of Illinois, Champaign, IL 61820.

The role of estrogen and the ventromedial hypothalamus (VMH) in reproductive behavior of the rat has been well documented. A hypothesis of estrogen action in the VMH is that estrogen increases synthesis of specific proteins. The purpose of this investigation is to establish if estrogen's mechanism of action in the VMH is by modulating protein synthesis and if so, what proteins are affected.

Twelve, 60 day old Long Evans female rats were ovariectomized and bilaterally implanted with cannulas dorsal to the VMH (inner cannulas 28 g). After 4 days of recovery, 6 rats were injected with 2 pulses of 4 ug/kg 17ß-estradiol, 12 hrs apart (6 controls received alcohol vehicle). At the time of the second pulse, each rat was infused in the VMH for 4 hrs while unanesthetized and unrestrained with 190 uCi of 35-S methionine and cysteine (1:1). After the end of the infusions, the rats were decapitated and the VMH regions dissected by punch. Protein samples from brain tissues were solubilized and run on 2-dimensional SDS-PAGE electrophoresis. The gels were enhanced by fluorography, dried and then exposed to X-ray film. The resulting protein spots were analyzed by an Olympus Cue-2 densitometry system and the optical densities quantified. The results confirm that estrogen modulates VMH activity by altering protein synthesis. Interestingly, many of the low molecular weight proteins affected by estrogen are significantly reduced by the hormone.

435.4

THE EFFECT OF GONADAL STEROIDS ON THE BEHAVIORAL AND BIOCHEMICAL EFFECTS OF HIPPOCAMPAL SYMPATHETIC INGROWTH. A. Peagler*, M. Goyal*, D. Parsons* and L. Harrell; J. Halsey (SPON), Dept. Neurology, VA and University of Alabama Med. Ctr., Birmingham, Ala. 35294.

Following cholinergic denervation of the hippocampus via medial septal lesions (MSL), sympathetic fibers, from the superior cervical ganglia, grow into the hippocampus. Previous studies have demonstrated a detrimental effect of these fibers on recovery of a spatial-learning task in male but not female animals. In this study we assessed the role of male sex hormones on the behavioral and biochemical effects of sympathetic ingrowth (SI). For the behavioral studies all animals were gonadectomized (GDx) and taught a standard radial 8-arm maze task. Following attainment of criterion animals underwent one of three surgical procedures: sham, MSL, MSL + ganglionectomy. MSL were found to severely impair reacquisition of the task. However, GDx was found to block the detrimental effect of SI. For the biochemical studies hippocampal norepinephrine (NE) and choline acetyltransferase (ChAT) were measured eight weeks after surgery in sham GDx and GDx animals. MSL were found to significantly reduce the ChAT activity, regardless of circulating sex hormones. GDx was found to significantly reduce the level of NE associated with SI, while having no effect on central NE in CON or MSGx animals. These studies suggest that circulating male sex hormones can influence both the behavioral and biochemical processes associated with HSI.

SEXUAL BEHAVIOR ELICITED BY STIMULATION OF THE MONKEY MIDBRAIN. S. Aou, E. Okada*, A. Takaki*, and Y. Oomura. Natl. Inst. Physiol. Sci., Okazaki 444; Dept. of Physiol. Kyushu University 60, Fukuoka 812, Japan.

The effects of midbrain electrical (0.2 ms, 10-100 Hz, 125 pulses, 50-500 uA) and chemical (0.01-0.1M Na-L-glutamate, 2ul) stimulation on sexual behavior of male and female monkeys were examined. Six male and three ovariectomized, estrogen-treated female rhesus monkeys were used in accordance with the NIH Guide (1985). In three of the six male monkeys, touching, sometimes followed by mounting, was elicited during electrical stimulation of a wide area of the tegmentum; including the red nucleus, substantia nigra and reticular nucleus. Stimulation of the central gray was not effective. The responses were elicited with a mean latency of 1 s and ceased quickly after termination of stimulation. Chemical stimulation of the loci where electrical stimulation was effective, however, failed to elicit sexual behavior. In the female monkeys, two types of presenting responses were evoked with longer latency than was the case for male monkeys after electrical stimulation of the central gray and adjacent tegmentum. One response was elicited with a mean latency of 7 s. The other, with longer latency (>15 s), was a long-lasting repetitive presenting. The present study suggests that different areas of the midbrain are involved in the control of sexual behavior of male and female monkeys.

CENTRAL GRAY CONNECTIONS WITH THE VENTROMEDIAL HYPOTHALAMUS ARE ESSENTIAL FOR LORDOSIS IN FEMALE RATS. Ann C. Hennessey, Lael Camak* and David A. Edwards, Department of Psychology, Emory University, Atlanta, Georgia 30322.

The central gray is believed to play an important role in the control of sexual receptivity in female rats, but published reports relating central gray destruction to lordosis in female rats describe only modest deficits in sex tests with males. We show that appropriately placed central gray lesions and knife-cuts virtually eliminate lordosis, and we also provide compelling evidence that central gray connections with the ventromedial hypothalamus are essential for female sexual behavior. Details follow.

Electrolytic lesions of the midbrain-pontine central gray (CG) and its lateral surround eliminate lordosis in ovariectomized females injected with estrogen and progesterone. In a second study, sagittal knife-cuts which bracket the central gray at the level of the rostral pons also eliminate lordosis. The central gray is reciprocally connected with the ventromedial hypothalamus (VMH) by axons entering and leaving the central gray in the lateral and medial planes. Females with a sagittal transection lateral to the CG on one side of the brain combined with a contralateral sagittal transection at the level of the VMH almost never show lordosis. The asymmetric transections spare periventricular hypothalamic connections with the CG, but bilaterally destroy the lateral connecting pathway between the VMH and the central gray, and it seems clear that the "lateral pathway" connections between the ventromedial hypothalamus and central gray play an essential role in the control of lordosis. (Supported by NSF grant BNS-8718797)

435.7

ESTROGEN AND PROGESTERONE EFFECTS ON REPRODUCTIVE BEHAVIOR WHEN THE FEMALE RAT CAN AVOID SOCIO-SEXUAL CONTACT.
S. Schwartz-Giblin, J.J. Blackett and D.W. Pfaff.
Rockefeller University, New York, N.Y. 10021.

To establish an assay relevant to reproductive behavior which also tests for the female's disposition to receive somatosensory stimulation, we used a two-chamber apparatus which allows access to the second chamber only by the female rat. The male was tethered in the first chamber; the door leading from the first chamber was partially closed, thus requiring the female to deliberately leave the mating site. Females were ovariectomized and all received s.c. silastics containing 5mm of 10% estradiol (E) in cholesterol. Three hormone-treatment groups were compared: 4 days of E, 14 days of E, and 4 days of E plus 1 mg progesterone (P) s.c. in oil, 4-5 hr before testing.

The E + P -treated females were significantly different from the other two groups. They showed more lordoses per 20 min test ($p = .005$), fewer rejections per 20 min test ($p = .006$) and spent a smaller percent of the time out of the first chamber ($p = .04$). Thus, behavior paced by the female (cf. Emery, Behavioral Neuroscience, 1986) yielded a strong progesterone effect. These baseline data will be used to evaluate drugs relevant to somatosensation.

EFFECT OF REMOVAL OF THE VOMERONASAL ORGAN ON SEXUAL BEHAVIOR IN FEMALE RATS.
G.Rajendren*, C.A. Dudley, and R.L. Moss (SPON: E. Hollingsworth). Dept. Physiology, University of Texas Southwestern Medical Center, Dallas, Texas 75235

The role of the vomeronasal organ (VNO) on the display of mating behavior was studied in ovariectomized female rats under two experimental conditions. In the first experiment, VNO-removed (n=15) or sham-operated (n=11) females were primed with 2ug estradiol benzoate (EB) followed 42 hours later by 2.5 mg of progesterone (P). Four to six hours after P injection, the females were tested for reproductive behavior. The preference of the females for a sexually active male over a castrated male, proestrous female or an ovariectomized female was not affected by VNO removal. However, the VNO-removed females exhibited less proceptive behaviors and more resistive behaviors than the sham-operated controls ($p<0.005$). Even though the lordosis to mount (L/M) ratio was relatively high in the VNO-removed females (mean 81.2%), it was significantly less as compared with that in the sham-operated controls (mean 96.5%) ($p=0.018$).

In the second experiment, VNO-removed (n=12) or sham-operated (n=13) females were injected with 2ug EB. Beginning at 48 hours after EB priming, the females were tested for sexual receptivity once in every 30 min for a period of 5 hours. The enhancement of sexual receptivity following repeated mating was significantly reduced in the VNO-removed females as compared with that in the controls ($P<0.001$).

The results suggest that the VNO plays a modulatory role in sexual behavior in female rats. Supported by NIH-MH41784.

435.9

FACILITATION OF LORDOSIS IN INTACT, CYCLING FEMALE RATS FOLLOWING INTRAVENTRICULAR INFUSION OF ESERINE DURING PROESTRUS BUT NOT DIESTRUS.
C. S. Menard, G. P. Dohanich, and N. M. Estella. Dept. of Psychology and Neuroscience, Tulane Univ., New Orleans, LA 70118.

Both systemic and intraventricular administrations of the cholinergic muscarinic antagonist, scopolamine, have been shown previously to inhibit naturally occurring sexual behavior in intact, cycling female rats (Menard & Dohanich, Physio Behav 45:in press, 1989). The present study attempted to examine cholinergic facilitation of sexual behavior in intact, cycling female rats. In the first experiment, intraventricular infusion of the acetylcholinesterase inhibitor, eserine (10ug bilaterally), did not facilitate lordotic responding 15 min after administration when infused during Diestrus I, Mid-diestrus, or Diestrus II. In a second experiment, however, intraventricular infusion of eserine did facilitate lordotic responding 15 min ($p<0.0001$) and 1 hr ($p<0.0006$) after administration when infused during Early Proestrus and Proestrus. Cycling was determined by daily monitoring of sexual behavior and vaginal cytology. As previously reported with the administration of other cholinergic agents, infusion of eserine did not significantly interrupt cyclicity patterns. Because estrogen levels are highest during Proestrus and cholinergic facilitation appears to be limited to this time, it is suggested that estrogen priming of central cholinergic systems is necessary for the cholinergic regulation of sexual behavior in intact, cycling female rats.

LORDOSIS CAN BE ELICITED IN CHRONICALLY-DECEREBRATE RATS BY COMBINED LUMBOSACRAL AND VAGINOCERVICAL STIMULATION.
J. D. Rose and F. W. Flynn. Department of Psychology, University of Wyoming, Laramie, WY 82071.

Previous research has indicated that chronically-decerebrate, adult female rats are incapable of exhibiting lordosis in response to lumbosacral somatic stimuli. This finding suggested that the rat's brainstem-spinal unit couldn't mediate lordosis in the absence of a facilitatory forebrain influence. Since vaginocervical stimulation facilitates elicitation of lordosis by lumbosacral somatic stimuli, the present study investigated the possiblity that decerebrate rats could show lordosis to lumbosacral stimuli if vaginocervical stimulation was applied concurrently. Ovariectomized female rats were decerebrated at the midbrain-diencephalic junction in a two-stage procedure. One to two weeks after decerebration, the animals were tested for lordosis responses to manually-applied flank, rump and perineal pressure stimulation during concurrent probe-pressure on the cervix. Of 9 rats tested, 5 exhibited clear lordosis. Estrogen-progesterone administration was neither necessary for lordosis elicitation nor very effective in promoting the response in animals which failed to show lordosis without hormone treatment. These results show that the brainstem and spinal cord of the adult rat can mediate lordosis in the absence of forebrain neural influences. Supported by NIH grants NS13748 and NS24879.

IBOTENIC ACID OR 6-OHDA LESIONS OF THE VTA INHIBIT SEXUAL RECEPTIVITY IN HAMSTERS.
C.A. Frye* and J.F. DeBold. Dept. Psychology, Tufts University, Medford, MA 02155.

Progesterone (P) implants in the VTA facilitate receptivity in estrogen-primed hamsters, whereas electrolytic lesions to the VTA inhibit receptivity. Since electrolytic lesions are nonspecific, we assessed the ability of axon-sparing lesions of the VTA to inhibit P facilitated receptivity. 5 µg ibotenic acid was infused into the midline VTA. After one week these animals were given 10 µg EB and two days later either 10 or 100 µg P. Ibotenic acid lesions of the VTA substantially inhibited receptivity induced by EB and 100 µg P. Neither controls nor experimentals responded to 10 µg P.

Because the VTA includes the A10 dopamine (DA) cell group we also examined the effects of DA selective lesions on receptivity. 7.5 µg 6-OHDA was infused into the VTA, with desmethylimipramine given so 30 minutes prior. 6-OHDA treatment localized partially or entirely in the VTA reduced the facilitative affects of 100 µg P on the total lordosis duration. After 100 µg P the controls had longer mean lordotic bouts than the 6-OHDA animals.

These results with axon-sparing lesions indicate that damage to fibers of passage do not explain our earlier results with electrolytic lesions and further strengthen our hypothesis that the VTA is an important region in the control of sexual receptivity in hamsters.

MORPHINE INFLUENCES ON ESTROUS BEHAVIOR AND MONOAMINE RELEASE FROM THE VENTROMEDIAL HYPOTHALAMUS.
I. Vathy and A.M. Etgen. Depts. Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

It is well known that morphine (M) inhibits estrogen and progesterone-dependent female sexual behavior. M has also been shown to depress norepinephrine (NE) release in several brain regions. Our previous study employing microdialysis of the ventromedial hypothalamus (VMH) of freely moving rats demonstrated a substantial increase in NE release when females were actively engaged in mating behavior. Thus the present experiments used microdialysis to test the hypothesis that M inhibition of estrous behavior is associated with depressed NE release from the VMH. Monoamine levels in dialysates from awake, behaving animals were monitored throughout hormone priming (3 ug estradiol benzoate followed 44 hr later by 200 ug progesterone), M administration (10 mg/kg concurrently with progesterone) and behavioral testing. All animals were tested for estrous behavior with stimulus male rats beginning 4 hr after progesterone injection. As expected, reproductive behavior in hormone-treated females was associated with increased NE release from the VMH. M treatment was associated with inhibition of both estrous behavior and NE release from the VMH. Additional experiments will assess whether the opiate antagonist naloxone, which reverses M inhibition of sexual behavior, also reverses M suppression of NE release from the VMH. Supported by MH41414, NRSA MH15788, and RSDA MH00636.

CHANGES IN OXYTOCIN RECEPTOR BINDING ARE CORRELATED WITH CYCLIC FLUCTUATIONS IN OVARIAN HORMONE LEVELS. S. Pliskin*, A.E.Johnson and G.F. Ball (SPON: M. Numan). Section on Comparative Studies of Brain and Behavior, Laboratory of Clinical Sciences, NIMH, Poolesville, MD 20837 and Department of Psychology, Boston College, Chestnut Hill, MA 02167.

Oxytocin (OT) transmission is involved in the regulation of steroid-dependent sexual receptivity in the rat. Based on the results of hormone replacement studies, it has been suggested that 17ß-estradiol (E_2) sensitizes the brain to OT by increasing OT receptor binding in certain steroid-concentrating brain regions involved in the regulation of reproduction. In one of these brain regions, the ventromedial hypothalamic nucleus (VMN), dramatic changes in OT receptor binding occur after E_2 replacement. Furthermore, changes in binding occur within a time-frame relevant to steroid fluctuations characteristic of the estrous cycle. The purpose of these studies was to determine if steroid-dependent changes in OT receptor binding in the VMN occur in intact, cycling animals.

Adult female rats were exposed to sexually vigorous males and sexual receptivity was assessed. Animals were killed on the day in which sexual receptivity was observed (proestus) and 24 h (estrus) or 48 h (diestrus) later (N=4/group). Animals were killed by decapitation, blood was collected for plasma steroid assays and brains were removed and frozen on dry ice. Brain slices (20µm) through the VMN were cut on a cryostat and labeled with 50pM ^{125}I-d(CH_2)$_5$[Tyr(Me)^2,Thr^4,Tyr-NH_2^9]OVT (^{125}I-OVTA). Unlabeled OT (5µM) was used to define nonspecific binding. Receptor binding was measured using standard receptor autoradiographic methods (Kuhar, 1986) and plasma steroids were measured by RIA (Abraham, 1973).

Results of these studies showed that the highest levels of ^{125}I-OVTA binding in the vlVMN occurred during proestrous and early estrous with significantly lower binding values obtained in diestrus animals. Changes in OT receptor binding were correlated with fluctuations in circulating steroid levels. In agreement with other studies, high levels of E_2 and Progesterone were found in proestrous animals, with intermediate levels occurring late in diestrus and low levels during estrus. This study demonstrates changes in VMN OT receptors occur during the estrous cycle and may be involved in the regulation of steroid-dependent reproductive behavior.

435.14

CNS OXYTOCIN INFLUENCES SEXUAL AND SOCIAL BEHAVIOR IN PRAIRIE VOLES. D. M. Witt*, T. R. Insel and C. S. Carter*. (SPON: W. M. Saidel) Laboratory of Clinical Science, NIMH, Poolesville, MD 20837 and University of Maryland, Department of Zoology, College Park, MD 20742.

Sexual behavior is a potent stimulus for oxytocin (OT) release and centrally administered OT enhances sexual receptivity in rats. Unlike rats, female prairie voles are monogamous, reflex ovulators in which the first estrus is induced by male chemosignals. Durations and frequencies of postpartum matings (concurrent with lactation) are reduced significantly compared to mating obsserved during the male-induced estrus. It is hypothesized that OT released during birth, lactation, and sexual activity may inhibit female sexual behavior in prairie voles. Ovariectomized females (pretreated with estradiol benzoate) in confirmed estrus or non-receptive (oil-pretreated) females received OT in either intracerebroventricular (icv: 0.001, 0.3, or 1 µg OT or saline) or intraperitoneal injections (ip: 1, 3, or 10 µg OT or saline). There was a dose-dependent decline in the occurrence of lordosis following icv, but not ip, OT. Autogrooming increased following icv OT. Males paired with OT-treated females increased autogrooming. In non-receptive females, ip OT increased side-by-side contact and reduced aggression. Results suggest that OT may regulate female sexual behavior and may facilitate social behaviors leading to sexual arousal or social bonding.

Neural effects of OT presumably depend upon OT receptor availability. In other species, central OT receptor expression is influenced by ovarian steroids. In the present study, in vitro receptor autoradiography was used to examine the estrogen dependent induction of OT receptors in brain areas implicated in sexual behavior. OT receptor binding was compared in estrous versus non-estrous females (intact and ovariectomized). OT receptors were concentrated in several forebrain regions distinct from those previously reported in rats. Preliminary analysis indicates that exogenous or endogenous estrogen priming increased OT receptor binding in areas associated with olfaction, and in contrast to data from binding studies in rat brain, did not significantly increase in the ventromedial nucleus of the hypothalamus. Species differences in the neural activities of OT are suggested which may reflect an adaptive reproductive physiology and/or behavioral pattern.

LONG-TERM POTENTIATION IV

436.1

TOPOGRAPHICAL ORGANIZATION OF THE NIGROTHALAMIC PROJECTIONS IN THE RAT. I. Grofova Department of Anatomy, Michigan State University, East Lansing, MI 48824.

In the monkey, the major outflow of the substantia nigra pars reticulata (SNR) distributes to the motor thalamic nuclei (VAmc and VLm) which in turn project to the premotor and prefrontal cortices. However, in rodents, a corresponding connection is known to terminate exclusively in the ventromedial nucleus (VM) which gives rise to fibers terminating throughout the neocortex. We have previously reported that multiple iontophoretic injections of Phaseolus vulgaris (PHA-L) in the SNR labeled terminal fibers in the medial VL, dorsal zona incerta (ZI) and in the field of Forel (FF), in addition to the well known targets of nigrothalamic fibers (VM, PF, MD). The present report based on a series of single, small PHA-L injections in the SNR demonstrates that there exists a distinct topography of SNR projections. Fibers originating from the dorsal region of SNR distribute only to the VM, PF and MD while SNR cells in the ventral zone project also upon the medial VL, ZI, FF and the red nucleus. The dense terminal plexus of nigral fibers in VL has a patchy appearance, and the electron microscopic examination revealed that a significant proportion of the labeled terminals contact cell bodies and large dendrites.

These observations suggest that the portion of the rodent VL which receives nigral input may correspond to primate VAmc. Furthermore, it is notable that only the ventral zone of the SNR is related to structures which are associated with motor functions.

KINDLING-INDUCED HIPPOCAMPAL LONG-TERM POTENTIATION (LTP) IS NOT BLOCKED BY MK-801. G. B. Robinson. Univ. of New Brunswick, Fredericton, N.B. Canada, E3B 6E4.

Recent evidence has raised the possibility that a blockade of LTP may contribute to the effectiveness of MK-801 in inhibiting the development of kindled seizures, (Abraham et al., Brain Res., 462, 1988; Gilbert, Brain Res., 463, 1988; McNamara et al., Neuropharmacol., 27, 1988). To test this hypothesis, New Zealand rabbits, deeply anesthetized with halothane, were implanted with stimulation and recording electrodes in the perforant path (PP) and granule cell (GC) layer of the dentate gyrus, respectively. Following surgery, rabbits received penicillin then were allowed 2 weeks to recover. For three days prior to kindling, the GC response to 10 PP impulses, applied at each of 10 intensities, was determined. On the fourth day, MK-801 (0.5 mg/kg, i.p) was injected and 2 hours later kindling stimulation was applied to the PP.

Significant LTP of the PP-GC response occurred following kindling. The magnitude of LTP was greater at 24 hours than at 30 minutes post-kindling. The additional increase in LTP magnitude, 24 hours after the kindling stimulation, may, in part, result from a masking effect of MK-801 (i.e., suppression of the PP-GC population spike; Abraham et al., Brain Res., 462, 1988). Supported by NSERC.

436.3

BLOCKADE OF LTP, KINDLING, AND KINDLING-INDUCED POTENTIATION BY THE NMDA-ANTAGONIST, MK-801. M.E. Gilbert and C.M. Mack. NSI Environmental Sciences, RTP, NC, 27709.

Antagonists of the NMDA-receptor subtype of glutamate delay the development of kindling and block longterm potentiation (LTP). It has been suggested that these antagonists may retard kindling by reducing seizure spread through their blockade of LTP. The present set of experiments tested 1) the efficacy of the NMDA antagonist, MK-801, to block LTP of the perforant path (PP) to dentate gyrus (DG) synapse in the unanesthetized rat; 2) the ability of MK-801 to retard PP kindling; and 3) the effects of MK-801 on synaptic potentiation induced by kindling afterdischarges (AD). Input/output (I/O) functions of responses evoked in the DG by single pulse stimulation of the PP were monitored before and 24 hr after LTP trains (10 50 ms, 400 Hz trains, 0.1 ms pulse duration at 1000 ua). Trains were delivered 30 min following 0, 0.1 or 1.0 mg/kg MK-801. Both dosages of MK-801 blocked potentiation of the population spike 24 hr post train delivery. Kindling was induced by daily delivery of stimulus trains (2 s, 60 Hz, 1.0 pulse duration, 800 ua) to the PP 30 min following 0 or 1.0 mg/kg MK-801. MK-801 increased AD thresholds, AD durations, and the number of sessions required to reach Stage 5 seizures. I/O functions monitored before kindling, and 24 hr after the 1st, 4th, 7th, 10th and 13th AD indicated that MK-801 completely blocked kindling-induced potentiation of the EPSP and reduced the enhancement of the population spike relative to control kindled subjects. These data are consistent with the notion that LTP contributes to the development of kindling.

436.4

APV AND URETHANE ANESTHESIA ALLOW PHARMACOLOGICAL DISSOCIATION BETWEEN THE MECHANISMS OF LTP AND KINDLING. D.P. Cain, F. Boon and E.L. Hargreaves. Dept. of Psychology, Univ. of Western Ontario, London, Ontario. CANADA N6A 5C2.

Some authors have suggested that long term potentiation (LTP) may be a major component of the mechanism of kindling. If this is so treatments that affect LTP should affect kindling similarly and vice versa. We tested this by administering APV and urethane to different groups of rats and subjecting them to LTP or partial kindling of the perforant path-dentate circuit, or both. Afterdischarge(AD)-evoked potentiation was also measured.

Urethane did not block potentiation of the EPSP or population spike (PS), but it completely blocked our ability to evoke AD using normal stimulation currents. In another group of rats urethane markedly raised the AD threshold and attenuated the duration of AD and prevented the increase in AD duration when AD was evoked at hourly intervals. It also blocked potentiation of the EPSP and PS due to the evoked AD.

In a third group of rats APV completely blocked all LTP effects, even when LTP stimulation three times the normal level was used. However, APV did not block increases in the duration of AD after repeated ADs, and it did not block potentiation of the EPSP or PS due to the AD.

The differences between the effects of these compounds in LTP and kindling suggests that the mechanisms of the two models may be substantially different. Supported by NSERC.

MODULATION OF HIPPOCAMPAL PRIMED BURST POTENTIATION BY ADRENALECTOMY AND CORTICOSTERONE. M.C. Bennett, D.M. Diamond, M. Fleshner and G.M. Rose. Dept. of Pharmacology, University of Colorado Health Sciences Center and VA Medical Center, Denver, CO 80262

Previously, we demonstrated that a low threshold form of long-term potentiation, termed primed burst potentiation (PB-LTP), is inhibited in behaving rats by novelty stress (Diamond et al., Neurosci. Abst., 477, 1988). This inhibition was not found in adrenalectomized (ADX) rats. Presently, we are studying the role of adrenal hormones as modulators of PB-LTP.

We recorded CA1 population spikes evoked by commissural stimulation in urethane anesthetized rats that were ADX-, sham-operated (SHAM), or ADX with a corticosterone pellet implant (ADX+CORT). In SHAMs, the magnitude of PB-LTP was negatively correlated with plasma CORT concentration. Further, the magnitude of PB-LTP was significantly greater in ADX than in SHAM subjects. Finally, in ADX+CORT subjects (which had a wide range of plasma CORT levels), the magnitude of PB-LTP was also related to the plasma CORT level: The magnitude of PB-LTP evoked in ADX+CORT rats which had low (non-stress) levels of CORT was greater than that found in ADX rats; the magnitude of PB-LTP evoked in ADX+CORT rats which had high CORT levels was reduced. These results suggest that CORT produces an inverted-U shaped modulation of hippocampal plasticity.

436.6

OPIOID ANTAGONIST ELIMINATES THE STRESS-INDUCED IMPAIRMENT OF LONG-TERM POTENTIATION (LTP). T. J. Shors, S. Levine, R. F. Thompson. Dept. Psych., Univ. Southern Calif., LA, CA, 90089 and Dept. Psychiatry, Stanford Univ. Stanford, CA 93405

In 1987, Foy et al. (Behav. Neural Biol. 48, 138) reported that behavioral stress impaired LTP in the rat hippocampus. Here we investigated a possible role for opioid peptides. Rats (n=10) were injected with 14 mg/kg naltrexone or saline (n=10), restrained, and exposed to 30, 1-sec tailshocks (1mA, 60 Hz). Ten controls were given naltrexone and 10 saline. Hippocampal slices (400um) were prepared. Field potentials were recorded from CA1 in response to tetanization of the Schaffer collaterals. Mean (± SEM) percent of baseline amplitude at 30 min. was: naltrexone/shock, 180% ±13; naltrexone, 157% ±8; saline/shock, 118% ±10; and saline, 186% ±12. ANOVA [$F(3,36)=7.90$, $P<0.01$] and Newman-Keuls indicated that the saline/shock group differed ($P<.0.05$) from the other three groups. Blocking peripheral and central opioid receptors prior to exposure to inescapable shock eliminated the stress-impairment in LTP, suggesting a modulatory role for opioid peptides. NICH&HD (HD02881), ONR (N00014-88-K-0112) and NIMH (MH11936).

436.7

VASOPRESSIN INVOLVED IN THE POTENTIATION OF TRANSMISSION IN THE LATERAL SEPTUM ELICITED BY BEHAVIOR. I.J.A. Urban, Y. Shen. G.Croiset, and A. Ontskul. Rudolf Magnus Institute, The University of Utrecht, The Netherlands.(SPON: ENA)
Foot shocks and/or training in conditioned avoidance task are thought to release the propresophysin (PPP) peptides vasopressin (VP), neurophysin II (NPII) and C-terminal glycopeptide CPP 1-39 in the lateral septum (LS). VP and CPP 1-39, but not PII, facilitate the glutamate(Glu)-ergic transmission between the fimbria (FI) fibers and LS neurons. With the negative wave (N-wave) of field potential (FPs), evoked by stimulation of the FI fibers, we examine effects of training in shuttle-box on this transmission in the rat LS of. Three series of 10 trials were administered in the acquisition and extinction sessions and the responses of the rats were recorded. The FPs recorded before and after the acquisition and extinction were compared. All Wistar rats classified as learners (6 or more correct responses in the last acquisition trial), showed 20-30% increase in the N-wave of the FPs after the acqiosition training. The N-wave before extinction was still on average 10% higher compared controls. After extinction, the N-wave increased again. The bad learners (less than 6 correct responses) showed only a 10-20% decrease in the FPs N-wave after both the acquisition and exctinction. The diabetes insipidus rats of the Brattleboro strain, either good or bad learners, showed only a decrease in the N-wave of the FPs after the acquisition and extinction. Thus, the training in shuttle-box can release principles in the LS that for hours facilitate the Glu-ergic transmission between the fimbria fibers and LS neurons. These principles might be PPP-like peptides.

436.8

LONG-TERM POTENTIATION OF EARLY AND LATE EXCITATORY POSTSYNAPTIC POTENTIALS IN KITTEN VISUAL CORTICAL CELLS. Y. Komatsu* and K. Toyama. Dept. of Physiology, Kyoto Prefectural Univ. of Med., Kamigyoku, Kyoto 602, Japan.

Synaptic transmission during and after conditioning stimulation (CS) of white matter (2 Hz, 15 min) was studied by intracellular recording from layer II-III cells in slice preparations of kitten visual cortex under perfusion with solution containing 1 μM bicuculline. The early (eEPSP) and late excitatory postsynaptic potentials (lEPSP) produced by white matter stimulation demonstrated the following characteristics. 1) The l- and eEPSPs were mediated by N-methyl-D-aspartate (NMDA) and non-NMDA receptors, respectively. 2) eEPSP was depressed during CS and potentiated after CS, while lEPSP was potentiated during and after CS. 3) Long-term potentiation (LTP) of e- and lEPSPs occurred together (7/13) or separately (1/13 for eEPSP, 3/13 for lEPSP) after strong CS. 4) Weak CS produced only LTP of lEPSP in a few cells (2/8), in which the lEPSP was potentiated during CS. 5) NMDA antagonists did not affect LTP of eEPSP while they blocked lEPSPs. These results suggest that the two LTPs are based on different mechanisms.

436.9

LONG-TERM POTENTIATION IN THE PREFRONTAL CORTEX FOLLOWING STIMULATION OF THE HIPPOCAMPAL CA1/SUBICULAR REGION. S. Laroche[1], T.M. Jay[2] and A.M. Thierry*[2]. [1]Dépt. de Psychophysiologie, CNRS, 91190 Gif-sur-Yvette, France and [2]INSERM U114, Collège de France, 75231 Paris, France.

Anatomical studies have provided evidence for a direct projection from the hippocampal/subicular region to the prefrontal cortex (PFC) in the rat (Jay et al., this meeting). Extracellular single unit recordings were obtained from 120 neurons in the prelimbic area of the PFC in 7 rats anaesthetized with pentobarbital. Fifty neurons (42%) exhibited excitatory responses to single pulse stimulation of the CA1/subicular region (single action potential, mean latency 18.3 ± 0.6 ms). Paired pulse facilitation was obtained for delays ranging from 40 to 200 ms in 11 of 20 neurons tested. Extracellular field potentials evoked by stimulation of the CA1/subicular region (0.033Hz) were recorded in the PFC in 7 other anaesthetized rats. The negative component of the field potential (peak latency 19.4 ± 0.54 ms) was measured off line. Two sets of 10 high-frequency (HF) trains (250Hz, 200ms) at 0.1Hz were applied at a 20-min interval and testing was then resumed for a period of one hour. Tetanic stimulation produced a significant and persistent potentiation of the amplitude of the negative component (63.94 ± 8.39 %) accompanied by a reduction of the onset latency. These results show that long-term potentiation can be induced *in vivo* in the rat prefrontal cortex by HF stimulation of the hippocampal CA1/subicular region.

436.10

FAILURE TO ERASE LONG-TERM POTENTIATION (LTP) BY COUPLING SUSTAINED PRESYNAPTIC ACTIVITY WITH NMDA CHANNEL BLOCKADE L.E. Chavez-Noriega*, R.S. Goldman and C.F. Stevens. Section of Molecular Neurobiology, Yale University School of Medicine, New Haven, Ct. 06510

A key feature of LTP as a model of information storage is the prediction of specific mechanisms for its reversal. Anti-Hebbian processes are likely candidates. We have studied the hypothesis that presynaptic activity in the absence of postsynaptic N-methyl-D-aspartate (NMDA) receptor activation should result in a reduction of synaptic efficacy.

Evoked field EPSPs were recorded in stratum radiatum of area CA1 of rat hippocampal slices before and after LTP induction, and then after sustained high frequency stimulation (SHFS; 2000-5000 pulses) in the presence or absence of the NMDA antagonist 2-amino-5-phosphonovalerate (APV). The change in EPSP slope recorded 30-45 minutes after SHFS in 50 uM APV was not different from that observed in slices stimulated in control medium. Any possible decrease in synaptic strength associated with presynaptic activity and blockade of the NMDA channel is well under 1% of the increase associated with LTP.

These results indicate that presynaptic activity uncoupled with NMDA receptor activation does not result in a long lasting decrease in synaptic efficacy.

436.11

UNEXPECTED PROPERTIES OF 'HEBB-SYNAPSES' IN RAT HIPPOCAMPAL SLICE CULTURES T. Bonhoeffer*, V. Staiger* and A.M.H.J. Aertsen* (SPON: V. Braitenberg). Max-Planck-Institute for Biological Cybernetics, Spemannstrasse 38, 7400 Tübingen, FRG.

In order to study the nature of synaptic enhancement in more detail we investigated whether hippocampal slice cultures (Gähwiler, B.H., *J. Neurosci. Meth.*, 4:329, 1981) display phenomena of synaptic plasticity. After we showed that phenomena like LTP do exist in this preparation, we used a paradigm developed by Gustafsson et al. (*J. Neurosci.*, 7:774, 1987) to enhance CA1-synapses: single presynaptic stimuli to the Schaffer-collaterals were paired with postsynaptic depolarizations using an intracellular electrode in the cell body of a CA1-neuron. Gustafsson et al. showed that this enhancement is spatially restricted on the postsynaptic dendrite: if one input to the postsynaptic neuron is strengthened, the strength of a neighboring input to the same neuron is not affected. In order to assess whether this observation also holds for the presynaptic axon (i.e. whether enhancement is also spatially restricted on the input fiber) we performed the following experiment. A stimulating electrode was placed in the afferent fibers, two closely adjacent CA1-cells (distance 25-60 µm) were impaled with intracellular electrodes and responses to a test stimulus were recorded from both of them. We enhanced synapses by pairing 30 single extracellular stimuli to the afferent fibers with depolarizing current pulses in one cell but not in the other cell. We examined the responses of both cells before, during and after the pairing. In all experiments in which we could induce synaptic enhancement in the 'paired' cell (n=7 out of 13), we observed that the responses of *both* cells were enhanced, although only one of them had received paired stimulation. This result was confirmed with optical recordings using voltage-sensitive dyes: over an area of some 150 µm around the paired cell *all* 124 recording sites showed significant enhancement.

These findings suggest that synaptic enhancement by the 'paired stimulation paradigm' is not strictly local on the presynaptic axons; even local postsynaptic stimulation results in '*synaptic recruitment*': the synapses of many neighboring postsynaptic cells are enhanced.

LOCAL BLOCKADE OF INHIBITION UNMASKS A CAPABILITY FOR LTP IN THE DENTATE COMMISSURAL PATHWAY THAT IS OTHERWISE NOT EXPRESSED. O. Steward, R. Tomasulo*, and W.B. Levy. Depts. of Neuroscience and Neurosurgery. Univ. of VA, Charlottesville, VA. 22908

LTP can be readily elicited in a number of hippocampal pathways, but is not expressed in the dentate commissural pathway. This pathway is similar to the commissural/ Schaffer collateral projection to CA1, except that its activation produces powerful inhibition that occurs nearly concurrently with the excitation. The present study evaluates whether this inhibition prevents the pathway from expressing LTP.

Acute neurophysiological experiments were carried out in urethane anesthetized rats. To locally block inhibition in the dentate gyrus, a recording micropipette filled with a solution of 8mM bicuculline in saline was positioned in the dentate gyrus. A control saline-filled micropipette was positioned nearby. The commissural pathway was activated by stimulating electrodes in the contralateral CA3/CA4 region. High frequency stimulation of the commissural pathway reliably elicited LTP at the bicuculline electrode, but not at the control electrode. This LTP required a threshold level of stimulation for its initiation. The high frequency stimuli induced an extracellular negativity at the bicuculline electrode that was not present at the control electrode. This negative potential was selectively blocked by ketamine and MK801, suggesting that the negative potential reflects NMDA receptor activation.

These results suggest that LTP is not normally expressed by the dentate commissural pathway because the simultaneous inhibition clamps the postsynaptic membrane at a potential that prevents the depolarization-related relief of Mg^{++} blockade of the NMDA receptor. Removal of inhibition would then relieve this blockade of NMDA receptor activation, enabling LTP. Supported by NSF Grant #BNS8818766 to OS and RCDA MH00622 to WBL.

PRECISE TEMPORAL INTERACTIONS DISTINGUISH INDUCTION OF LTP FROM LTD IN THE RAT DENTATE GYRUS. H. Hashemzadeh-Gargari & W.B. Levy. Dept Neurosurgery Box 420, UVA, Charlottesville VA 22908.

Levy and Steward ('83) showed that temporally staggered activation of the ipsilateral (IPS) and the converging contralateral (CNT) entorhinal cortex projections to the dentate gyrus results in either potentiation or depression of the CNT synaptic response. Depression results when CNT activation follows IPS activation; potentiation results when CNT activation precedes or is just simultaneous with IPS activation. These earlier experiments used 8 pulse (400 Hz) trains which gave a temporal resolution of ≥ 17.5 ms regarding the timing during conditioning. The present study used 3 pulse (400 Hz) trains in a similar staggered conditioning paradigm. Conditioning periods consisted of 16 of these very brief trains (1 train/ 200 ms). Four responses were measured: the IPS and CNT responses of both sides of the brain. The paradigm consisted of three conditioning periods with baseline response size established for 30 minutes before and after each conditioning period. In the first conditioning period the time between trains was 7.5 ms; in the second the time between trains was 2.5 ms. The last period also used 2.5 ms but reversed the IPS/CNT order (intertrain times are measured from the last pulse of the leading train to first pulse of trailing train). The statistically significant results with the 9 rats confirmed the ordering effect: CNT potentiation ensued when a CNT train lead an IPS train; with the reverse ordering CNT depression ensued in all cases (that is, whether or not prior potentiation or depression had been induced). The IPS responses potentiated. These results imply that the biochemical/biophysical reactions which determine whether potentiation or depression ensues from all but identical activation paradigms must account for differences of 7.5 ms or smaller. W. Holmes pointed out that there is a delay in NMDA receptor conductances which might account for this temporal sensitivity. Supported by NS15488 and NIMH RSDA K02-MH00622 to WBL.

SELECTIVE EFFECTS OF D-AMINO-5-PHOSPHONOVALERIC ACID (D-APV) ON MEDIAL AND LATERAL PERFORANT PATHWAY-EVOKED RESPONSES IN DENTATE GYRUS OF RAT HIPPOCAMPAL SLICE. D. Dahl and J.M. Sarvey. Uniformed Services University of the Health Sciences. Bethesda, MD 20814.

Differential effects of certain ligands have been obtained on granule cells to selective activation of the medial and lateral perforant pathways (PPs). Norepinephrine (NE; 1 µM), in the presence of phentolamine (50 µM), induces a potentiation of medial PP-evoked excitatory postsynaptic potentials (EPSPs) and population spikes and a concurrent depression of lateral PP-evoked responses. These effects are persistent. Induction of long-lasting pathway-specific modifications prompted us to examine N-methyl-D-aspartate (NMDA) activity in the dentate gyrus using the antagonist D-APV, which blocks LTP induction and NE-induced long-lasting potentiation.

A 15-30 min perfusion with a 10 µM concentration of D-APV had no effect on any component of extracellularly recorded EPSPs to selective stimulation of the lateral PP. D-APV was without effect on the initial slope of the medial PP-evoked EPSP, but the peak amplitude and late repolarization component of this response were depressed. No differential effect was found on medial and lateral PP-evoked population spikes with 10 µM D-APV: responses to activation of either pathway were depressed. All D-APV effects reversed to control levels upon wash with drug-free artificial cerebrospinal fluid.

These results indicate that D-APV differentially affects synaptic activation of granule cells via the PP. Components of medial PP-evoked EPSPs occurring at or following attainment of peak amplitude are depressed. The lateral PP-evoked EPSP is unaffected. Since both medial and lateral PP-population spikes were depressed by D-APV, a different mechanism from that affecting the EPSP may be involved. (Supported by NIH grant NS23865 to JMS.)

CA^{2+} INFLUX THROUGH NMDA-RECEPTOR CHANNELS--ITS ROLE IN LTP. INSIGHTS FROM BIOPHYSICAL MODELS. W.R. Holmes and W.B Levy. Math. Research Branch, NIDDK, NIH, Bethesda, MD 20892, and Dept. of Neurosurgery, U. Virginia Med. School, Charlottesville, VA 22908.

The induction of LTP is thought to depend on Ca^{2+} influx through NMDA-receptor channels. Ca^{2+} influx at a synapse on a dendritic spine and the resulting change in free Ca^{2+} concentration in the spine head were studied in a model of a hippocampal dentate granule cell as a function of input frequency and the number of co-activated afferents. These modeling studies provided a number of interesting insights. First, in order for the description of the NMDA-receptor mediated synaptic conductance used in the model to be consistent with previous experimental observations, the average number of open, unblocked NMDA-receptor channels on a single spine head at a given moment had to be very small (usually less than one). Second, no more than a four-fold change in Ca^{2+} influx was observed by increasing input frequency or by increasing the number of co-activated synapses (to 115 in this study). Third, relatively small increases in Ca^{2+} influx could produce extremely large increases in free Ca^{2+} concentration in the spine head. These increases in free Ca^{2+} concentration were highly dependent on and sensitive to the concentration and location of Ca^{2+} binding sites in the spine head. Thus, even though the nonlinearity of Ca^{2+} influx through NMDA-receptor channels due to increases in input frequency and the number of co-activated synapses is very important, it is not sufficient to explain associative LTP. In contrast, the control of free Ca^{2+} concentration in the spine head by Ca^{2+} buffering systems during and after Ca^{2+} influx may provide the required nonlinearity which must govern associative LTP. (This work was supported in part by NS15488 and NIMH RSDA K02-MH00622 to WBL.)

WIDESPREAD CORTICAL DENERVATION IN RATS FOLLOWING RECOVERY FROM THIAMINE DEFICIENCY R.G. Mair, A.E. Ferguson*, University of New Hampshire, R.L. Knoth, Chapman College, and P.J. Langlais, San Diego State Univ.

Rats recovered from a subacute bout of thiamine deficiency and pyrithiamine treatment provide a model of diencephalic amnesia characterized by impaired performance of behaviors requiring representational memory and the consistent occurrence of thalamic lesions, commonly restricted to the area of the internal medullary lamina. To discover the effects of these lesions on thalamocortical projections, a group of six Long-Evans rats were subjected to the anti-thiamine treatment, recovered for 1 to 2 weeks, sacrificed, and brain tissue processed for Fink-Heimer and cresyl violet staining of alternate serial sections through cortex. Signs of dense axonal degeneration were observed in layers 3 and 4 in areas of frontal, parietal, and occipital cortex. In individual animals patterns of denervation were bilaterally symmetric. These data suggest that the apparently limited lesions of this model of amnesia affect specific thalamic inputs in widespread areas of cortex.

437.2

IMPAIRED REVERSAL LEARNING BUT PRESERVED EXTRA-DIMENSIONAL SHIFT PERFORMANCE FOLLOWING N-METHYL-D-ASPARTATE (NMDA)-INDUCED LESIONS OF THE SUBSTANTIA INNOMINATA/VENTRAL PALLIDUM (SI/VP) IN THE MARMOSET. A.C.ROBERTS*, J.L.MUIR*, B.J.EVERITT*, T.W.ROBBINS. (SPON:W.WINLOW). Depts. of Expt. Psychology and Anatomy*, Univ. of Cambridge, Cambridge,UK.

Previous findings have indicated that NMDA-induced lesions of the SI/VP in marmosets lead to a reduction in ChAT activity in anterior cortex and to a range of behavioural deficits that may be related to frontal dysfunction. The present study investigated the effects of the same lesion on performance of a computerised task, analogous to a test sensitive to human frontal lobe damage, the Wisconsin Card Sort test. Animals received a series of compound visual discriminations varying along two abstract dimensions, one of which was differentially reinforced, followed by an extra-dimensional (ED) shift in which the previously irrelevant dimension was differentially reinforced. The lesioned marmosets showed an initial retention deficit, as seen previously, but gradual improvement over 3 successive discriminations and normal ED shift performance, as compared to controls. This preserved attentional shifting capacity is in contrast to the significant perseveration of responding on reversals of a visual discrimination following the same lesion, and suggests that the deficits resemble the effects of orbitofrontal and amygdaloid lesions, rather than lesions of dorsolateral prefrontal cortex.

437.3

QUISQUALATE-INDUCED LESIONS OF THE SUBSTANTIA INNOMINATA & VENTRAL PALLIDUM (SI/VP) IN THE RAT:EFFECTS ON ACQUISITION AND SERIAL REVERSAL OF A VISUAL DISCRIMINATION. T.W. Robbins, A.C.Roberts*, J.Muir*, R.Parker*, M.Gore* and B.J.Everitt*, (SPON:I.P. Stolerman). Depts. of Expt. Psychology and Anatomy*, Univ. of Cambridge, Cambridge,UK.

Lesions of the SI/VP using quisqualic acid can be employed to produce more specific reductions in cortical cholinergic markers than other excitotoxins. Such lesions fail to replicate behavioural deficits on a range of tests, calling for a re-evaluation of the behavioural effects of excitotoxic lesions of the cortical cholinergic projection. The present study investigated the effects of quisqualate-induced lesions of the SI/VP (which produced ChAT reductions of 50-60% in frontal and parietal cortex), on an operant, discrete trial discrimination reversal paradigm which is also sensitive to ibotenate lesions of the SI/VP. A comparable deficit was demonstrated in which the SI/VP lesioned rats performed as well as controls on a brightness discrimination but were impaired when the contingencies were reversed. Lesioned rats inhibited the previously correct response normally but were slower than controls to learn the response that had been previously incorrect. These results will be discussed in relation to the role of the cholinergic projections within their various target sites, especially the frontal cortex and amygdala, and compared to those found following lesions of the SI/VP in the marmoset.

437.4

EFFECTS OF NUCLEUS BASALIS LESIONS AND CORTICAL CHOLINERGIC GRAFTS ON ATTENTIONAL PERFORMANCE IN THE RAT. J.L. Muir*, S.B. Dunnett, B.J. Everitt*, T.W. Robbins. (SPON:S.B. Dunnett) Depts. of Experimental Psychology and Anatomy*, University of Cambridge, U.K.

There has been considerable emphasis on the role of forebrain cholinergic projections in learning and memory, but somewhat less on their attentional functions. Relatively specific destruction of cholinergic cells in the nucleus basalis of Meynert (nbM) was achieved by infusing quisqualic acid into the substantia innominata (SI). Cortical ChAT activity was reduced by 50% and there was no damage to the globus pallidus. These lesions impaired the rats' accuracy in localising brief visual targets in a 5-choice serial reaction time task. The deficit in choice accuracy was exacerbated by interpolating bursts of white noise. Latency to respond correctly and to collect food reward (magazine latency), were lengthened post-operatively and showed little recovery over several months. Preliminary results suggest that certain of the deficits (e.g. the disruptive effects of distracting white noise), were ameliorated by cholinergic-rich grafts placed in frontal cortical sites, whereas others (e.g. magazine latency), were not. These results suggest that the task deficits are attentional in nature and may be attributable to cholinergic deafferentation of the neocortex.

437.5

NEUROTOXIC LESIONS OF THE NUCLEUS BASALIS INDUCED BY COLCHICINE: EFFECTS ON SPATIAL NAVIGATION IN THE WATER MAZE. W. R. Mundy, S. Barone and H. A. Tilson. Lab. of Molec. and Integrative Neurosci., NIEHS/NIH, Research Triangle Park, NC 27709.

Previous studies have used excitotoxins such as kainic or ibotenic acid to examine the behavioral consequences of nucleus basalis (NB) lesions. In the present study, rats were given bilateral injections of colchicine (1.0 ug/site) into the NB and examined for changes in learning and memory. Unlike excitotoxins, which can produce extensive subcortical damage, colchicine produced a lesion limited to the site of injection. Histological studies demonstrated that colchicine decreased the number of choline acetyltransferase (ChAT) positive cells in the NB, and resulted in a marked loss of cortical acetylcholinesterase staining. Separate neurochemical analysis showed that colchicine lesions decreased ChAT activity in the neocortex but not the hippocampus or caudate nucleus. Rats with NB lesions showed a large deficit in a passive avoidance task, and were transiently impaired during acquisition of a reference memory task in the Morris water maze. In a reversal test in the water maze, the learning deficit reappeared. These data suggest that colchicine may be useful in producing specific lesions of the NB, which primarily affects the rate of acquisition of a spatial reference memory task.

PERINATAL CHOLINE SUPPLEMENTATION PRODUCES LONG-TERM MODIFICATIONS IN THE MORPHOLOGY AND DISTRIBUTION OF CELLS IN THE DIAGONAL BAND REGION EXHIBITING NGF RECEPTOR IMMUNOREACTIVITY. C.L. Williams, W.H. Meck, and R. Loy, Depts. of Psychol., Barnard Col. & Columbia Univ., New York, NY 10027 and Dept. of Surgery, Univ. of Rochester, Rochester, NY 14642.

Choline chloride supplementation during development has facilitative effects on spatial memory that extends well into adulthood (Meck et al., Dev. Psychobio. 21, 1988). We now report initial findings comparing the morphology and distribution of cells in the VDB that show NGF receptor immunoreactivity in perinatally choline treated rats and their controls. After behavioral testing, animals were sacrificed and horizontal sections through the diagonal band at 3 levels (bregma -6.6, -7.34 and -8.1 mm) were examined morphometrically. Perinatally choline-treated rats had somata that were larger, rounder, and had greater uniformity than controls and the caudal-rostral distribution of cells in the VDB was altered by perinatal choline treatment. These data suggest that perinatal choline supplementation may alter cholinergic function and improve spatial memory through enhancement of the NGF/NGFR system.

INCREASED WORKING MEMORY CAPACITY AS A FUNCTION OF PRE- AND/OR POSTNATAL CHOLINE ENRICHMENT: A CORRELATED ChAT IMMUNOCYTOCHEMISTRY AND GOLGI ANALYSIS IN THE DIAGONAL BAND AND DENTATE GYRUS.

Warren H. Meck and Christina L. Williams. Departments of Psychology, Columbia University and Barnard College, New York, New York 10027.

Choline chloride supplementation during embryonic days (ED) 12-16 and later during postnatal days (PD) 16-30 has been shown to produce long-lasting facilitation of spatial memory processes (Meck et al., J. Neurosci., in press). We now report that these two time frames represent anatomically and morphologically distinct phases of choline related influence. The choline effect that is produced during ED 12-16 is associated with increased cholinergic cell body clustering in the horizontal limb of the diagonal band. In contrast, the choline effect that is produced during PD 16-30 is dependent upon steroid induced sexual differentiation of the hippocampus and related brain areas during PD 1-15 and is associated with increased dendritic length and branching in the dentate gyrus. These time frame differences can be related to neurogenesis, neuronal death, and synaptogenesis in the basal forebrain and hippocampus, respectively.

437.8

FUNCTIONAL INTERACTION OF THE NUCLEUS BASALIS AND RAPHE DORSALIS IN SPATIAL MEMORY. P.J. Riekkinen Jr.*, J. Sirviö*, R. Miettinen*, A. Valjakka* and P.J. Riekkinen. Departments of Neurology and Pathology, University of Kuopio, Finland.

In the current study we compared the effects of an ibotenic acid lesion of the nucleus basalis (NB), a 5.7-dihydroxytryptamine lesion of the raphe dorsalis (RD) and a combined nucleus basalis and raphe dorsalis lesion in rats using water-maze test. RD lesion produced a marked and significant reduction of frontal (-73 %) and occipital (-71 %) cortex serotonin levels, but the hippocampal serotonin levels were non-significantly lowered (-10 %). NB lesion reduced choline acetyltransferase (ChAT) activity in the frontal (-35 %) and parieto-occipital cortex (-19 %), but hippocampal ChAT activities remained unaltered. NB lesioned animals were impaired compared to controls in both finding the submerged platform during training and remembering the previous location of it. Although RD lesion alone did not affect spatial learning in the water-maze, the RD lesion greatly potentiated the learning impairment produced by NB lesion. The group of rats with combined lesions showed longer escape latencies compared to NB lesioned rats, because they did not develop any place navigational strategies to locate the escape platform. In the group of rats with combined lesion the retention of the previous platform location also was further impaired compared to NB lesioned rats. The current results suggest a functional interaction between RD and NB nuclei in spatial learning. Furthermore they indicate that the serotonergic-cholinergic pathology may be importantly involved in the cognitive decline in Alzheimer's disease.

437.9

DISSOCIATION BETWEEN WATER MAZE ACQUISITION AND CHOLINERGIC DEFICITS FOLLOWING MEDIAL SEPTAL LESIONS WITH COLCHICINE. S. Barone Jr.[1,2], K. P. Nanry[1], and H. A. Tilson[1]. [1]LMIN, NIEHS/NIH, RTP, NC 27709 and [2] Dept. Anatomy and Cell Biol., ECU SOM, Greenville, NC 27858.

Colchicine (COL) was infused bilaterally into the lateral ventricles (3.75 ug/site) or directly into the medial septum (MS)(5 ug) of adult, male Fischer-344 rats and effects of behavior and cholinergic markers determined. Rats receiving intracerebroventricular (icv) administration of COL were hyperaggressive during the first wk after administration and were hyperactive when tested during 60 min sessions at weekly intervals during the first 3 wks after COL. Icv COL also interfered with the acquisition of a spatial task in the water maze. It was subsequently found that COL given icv decreased choline acetyltransferase (ChAT) immunoreactive cells in the MS and decreased ChAT enzyme activity in both the right and left hippocampus to about 50% of control levels. Rats receiving COL directly into the MS were also aggressive and hyperactive, but were not impaired in the acquisition of the water maze task. Decreased ChAT immunoreactive cell bodies in the MS and enzyme levels in the right and left hippocampus were observed in these animals. The results of these experiments do not support the conclusion that spatial learning deficits seen in animals with MS lesions are soley due to a lesion-associated cholinergic deficit.

437.10

MEDIAL SEPTAL LESIONS IMPAIR WORKING-MEMORY ON BOTH SPATIAL AND NON-SPATIAL OPERANT DELAYED ALTERNATION IN RATS. R. Numan, J.R. Quaranta, Jr.*, P.J. Murphy* and J.W. Marlow*. Department of Psychology, Santa Clara University, Santa Clara, CA 95053.

The septo-hippocampal system regulates spatial behavior, memory, and response flexibility (Numan, R., Physiol. Psychol., 6:445, 1978). This experiment determined which of these functions is disrupted by medial septal (MS) lesions which impair operant delayed alternation (DA). Male hooded rats received either MS lesions or a control operation. Following recovery, they were reinforced for alternating left and right lever presses in an operant chamber. The effects of various delays (0, 10, and 20 sec), and exteroceptive cues were assessed.

MS lesions did not impair alternation performance at a 0-sec delay, but did produce severe impairments at 10 and 20-sec delays. An exteroceptive cue which reduced the spatial requirements of the task did not ameliorate this impairment. However, an exteroceptive cue which reduced the working-memory (WM) requirements of the task did ameliorate the MS lesion induced deficit on DA. While the MS lesioned rats also made more perseverative errors than the controls, statistically removing this influence from the data did not modify the results. These data suggest that MS lesions in rats impair DA by disrupting the general process of WM rather than spatial behavior or response flexibility.

437.11

FORNIX TRANSECTIONS DISRUPT THE ONTOGENY OF LATENT INHIBITION IN THE RAT. M.M. Nicolle*, C.C. Barry*, B. Veronesi, and M.E. Stanton. Dept. of Psychology, UNC-Chapel Hill, Chapel Hill, NC 27514 and Neurotox. Div., U.S. EPA, Research Triangle Park, NC 27711.

Three experiments examined the ontogeny of latent inhibition in a conditioned taste aversion paradigm. In the first experiment, 18-, 25-, and 32-day-old rats received a pairing of a Sanka solution with LiCl injection (.75% BW,.4 M) or physiological NaCl after either 4 preexposures to the taste or control treatment without taste preexposure. Interference with conditioning by taste preexposure (latent inhibition) was only evident on postnatal-day 32 (PND32). Experiment 2 established the parametric generality of our failure to find latent inhibition on PND18. In Experiment 3, sham or fornix lesions were performed on PND18 and latent inhibition was examined on PND32. Lesioned subjects exhibited equivalent conditioned taste aversions to the CS+ flavor but failed to show latent inhibition. Lesions were verified by histogical examination of the fornix and loss of AChE staining in the hippocampus.

Thus, latent inhibition of taste-aversion learning develops between PND18 and PND32 and this development is disrupted by fornix transection during infancy. These findings suggest a role for septohippocampal maturation in the ontogeny of latent inhibition.

437.12

ANTICHOLINERGIC TREATMENT MIMICS THE EFFECT OF HIPPOCAMPAL ABLATION ON THE HOMING BEHAVIOR OF PIGEONS. V.P. Bingman, L. Chaves*, J.T. Erichsen and J.R. Krebs*. Dept. of Psychology, Bowling Green Univ., Bowling Green, OH 43403.

A major source of hippocampal afferents in birds originates from the diagonal band of the medial septum. Relying on immunohistochemical techniques, choline acetyltransferase (ChAT)-like immunoreactivity was observed in fibers ascending to the hippocampal formation,as well as in terminal-like neuropil of the same region. Additionally, ChAT-positive cell bodies were observed in that region of the diagonal band where projection neurons to the hippocampus were identified. Taken together, these results indicate that like the mammalian hippocampus, the avian hippocampus is in receipt of a cholinergic projection from the diagonal band of the medial septum.

The possible importance of this projection in the regulation of avian spatial behavior was examined by intramuscular injection of the anticholinergic drug scopolamine into homing pigeons prior to their being released. Scopolamine treated homing pigeons successfully oriented homeward in a manner that did not differ from saline injected controls. Scopolamine treated birds, however, did take significantly more time to return home. This pattern of results is also seen in hippocampal-ablated pigeons, suggesting that anticholinergic treatment and hippocampal ablation produce similar cognitive spatial behavior deficits.

437.13

VISUAL REVERSAL-LEARNING DEFICITS AFTER THALAMIC LESIONS IN PIGEONS. L. Chaves* and W. Hodos, Dept. of Psychology, Univ. of Maryland, College Park, MD 20742.

Shimizu and Hodos (Behav. Neurosci., 1989) reported that lesions of two laminae of the visual wulst (IHA and HD), both targets of the thalamofugal pathway, resulted in increased errors in a color reversal-learning task. This finding suggested that the thalamofugal pathway might play a role in visual discrimination involving stimulus context changes.

In the present study, lesions of the OPT complex (the thalamic source of afferents to IHA and HD) were found to have no effect on reversal-learning performance. Instead, we found that damage to nucleus rotundus (the thalamic component of the tectofugal pathway) resulted in deficits that were far in excess of those that had been obtained after IHA and HD lesions. We suggest that the reversal-learning deficits after wulst lesions are not due to the wulst's connections with the thalamofugal pathway, but rather to its connections with the tectofugal pathway.

437.14

EFFECTS OF LESIONS OF THE CHICK FOREBRAIN ON ONE-TRIAL PASSIVE AVOIDANCE LEARNING. T.A. Patterson, D.B. Gilbert and S.P.R. Rose. Brain and Behaviour Research Group, Open University, Milton Keynes, MK76AA England.

Three distinct nuclei of the chick forebrain--the intermediate medial hyperstriatum ventrale (IMHV), lobus paraolfactorius (LPO), and paleostriatum augmentatum (PA)-- show metabolic, morphological, and neurophysiological changes following training of day-old chicks on a passive avoidance task. Several experiments examined the effects of lesions in the IMHV or the LPO on the ability of chicks to learn and retain the avoidance task.

Bilateral lesions placed 24 hr before training in the IMHV produced an impairment in avoidance responding tested three hours after training. Pre-training unilateral lesions in the left but not the right IMHV resulted in a similar impairment. Bilateral IMHV ablations, given either one or six hours post-training, did not impair retention. In contrast, pre-training bilateral lesions of the LPO were not amnestic. Bilateral lesions of the LPO given one hour post-training produced significant amnesia. We are currently examining the effects of post-training unilateral LPO lesions.

These results are consistent with other studies that have examined the effects of bilateral IMHV lesions on acquisition and extend these findings by demonstrating lateralization of acquisition involving the left IMHV. The results also suggest that the IMHV is not necessary post-training to retain the memory for the avoidance training. The results of the LPO lesions indicate that the LPO is not necessary for acquisition of the avoidance response, but may maintain the memory trace following training. Hypotheses to account for these results and indications of future research will be discussed.

Supported by NIMH 1F32 MH09626 and SERC Grant GRE 57413.

SYMPOSIA THURSDAY PM

439

Symposium. NEUROPEPTIDE REGULATION OF REPRODUCTION. Paul E Micevych, UCLA (Chairperson); R.B. Simerly, Salk Inst.; C. Malsbury, Memorial Univ.; S.P. Kalra, Univ. of Florida; S. Ojeda, Oregon Reg. Primate Ctr.

The regulation of reproduction by the nervous system involves the integration of endocrine and sensory cues. In the CNS, this integration has been attributed to a sexually dimorphic, gonadal steroid sensitive-circuit that includes specific loci in the amygdala, hypothalamus and brainstem. This symposium will examine both the role of gonadal steroids in mediating the function of this circuit and also the regulation of steroidogenesis by peptidergic inputs to the ovary. Paul Micevych will correlate the accumulation of gonadal steroids in sP- and CCK-immunoreactive cells with the distribution, expression and receptors of these peptides. Also discussed will be with the effects these peptides have on steroid-initiated sexual behavior. Richard Simerly will describe the selective gonadal steroid regulation of prepro-CCK mRNA as well as the regulation of androgen and estrogen receptor mRNA's. Charles Malsbury will present evidence that gonadal steroids maintain sP- and CCK- like inputs to loci in the circuit and that sP in this reproductively relevant circuit acts to facilitate reproductive behaviors in male and female rats. Satya Kalra will discuss the regulation of gonadotropin secretion, the effects of gonadal steroids on NPY secretion, and the interaction with the endogenous opioid system. Sergio Ojeda will complete the presentations by elucidating functional roles for the VIP-ergic and sympathetic innervation of the ovary and their effects on the development of this organ.

SYMPOSIUM. INHIBITORY INFLUENCES ON GROWTH CONES AND CELLS. M.E. Schwab, Univ. of Zurich (Chairperson); J. Raper, Univ. of Pennsylvania; F. Bonhoeffer*, Max Planck Inst. for Devel. Biol., FRG; R. Chiquet-Ehrismann*, Friedrich Miescher Inst., Switzerland; S.B. Kater, Collorado State Univ.

Substrates favoring neurite growth as well as outgrowth promoting and chemotactic soluble factors are crucially involved in nervous system development. Recently, however, several lines of evidence point to the existence of antagonistic, inhibitory mechanisms. Non-permissive substrate properties restricting neurite growth or cell migration can be associated with cell surfaces or ECM components. In addition, specific neurotransmitters can arrest growth cone mobility.

Inhibitory components were found in membranes of neurites of specific subsets of neurons (J. Raper), in a regionalized pattern in the embryonic chicken tectum (F. Bonhoeffer), and on oligodendrocytes and CNS myelin (M.E. Schwab). For tenascin, a non-permissive substrate found in the ECM of the developing PNS and CNS, the molecular analysis reveals a domain structure and leads to models for the mechanism of action (R. Chiquet). The drastic inhibitory effect of neurotransmitters on growth cones seems to involve calcium-mediated mechanisms (S.B. Kater).

Thus, neurite growth and tract formation in the developing NS may be crucially influenced by inhibitory mechanisms at various stages of development.

VISUAL CORTEX VI

441.1

PRIMARY VISUAL CORTEX IN MACAQUE IS A CONFORMAL MAP OF ITS TRUE SENSORY SURFACE, A COMPOSITE OF THE TWO RETINAS. Stanley J. Schein and Pablo Lapuerta*. Howe Laboratory, Mass. Eye & Ear Infirmary, Harvard Medical School, Boston, MA 02114.

Schwartz (1977) proposed that the mapping of the visual field surface to the surface of V1 was conformal. This elegant and powerful mathematical description requires isotropy, that linear cortical magnification at any point in V1 be independent of direction. Recent published data (Tootell et al) is not consistent with isotropy, a finding that may be related to replication of the visual field in adjacent ocular dominance (OD) stripes.

Our new mathematical analysis, applied to the recent data, shows that V1 may indeed be a conformal map, but only if what is mapped is a composite of 2 surfaces, the 2 retinas. The OD stripe system in V1, then, reveals how each retina is "sliced" before being interleaved to form the composite retina. The degree of local anisotropy in the map reveals how retinal slices are stacked to form the composite. The pattern of slicing and the method of stacking may be measured independently.

This analysis also provides a formal mathematical method for back-mapping V1 onto the retina. Contrary to previous reports, we find that OD stripes may back-map to horizontal "slices" in the visual field. Computation of binocular visual functions may take advantage of the horizontal arrangement of OD stripes. Conversely, the arrangement of the OD stripes could be configured postnatally by circuits that promote stripe formation along the direction of greatest disparity, that is, the horizontal.

441.2

NONINVASIVE COMPUTATIONAL CARTOGRAPHY OF HUMAN VISUAL CORTEX BASED ON MAGNETIC RESONANCE IMAGING (MRI) AND POSITRON EMISSION TOMOGRAPHY (PET). G.J. Carman and B.N. Mora*. Division of Biology, Caltech, Pasadena, CA 91125.

The development of algorithms for the production of unfolded maps of the cerebral cortex (1) has made it possible to map extensive areas of the human cortex for the first time. Here we report the application of these techniques to data obtained from MRI and PET scans of the brain of a single human subject so as to yield a mapping of cerebral blood flow (CBF) as a function of location on an unfolded map of the cortex. Contours delineating the surface of cortex were digitized from MRI scans and used to compute a three-dimensional reconstruction of the cortical surface through application of differential geometry. Since the cortical surface is intrinsically two-dimensional, it can be "unfolded" by computing a mapping of the reconstruction onto the plane. An approximately conformal mapping, in which measures of length and angle are preserved with an absolute minimum of distortion, can be obtained through application of the optimization technique known as "simulated annealing" (1). Once this mapping is obtained, PET data in register with the MRI data can be projected onto the unfolded cortex so as to yield a map of differential CBF as a function of cortical location arising from controlled visual stimulation.

THE MORPHOLOGY OF PRIMATE W-LIKE GENICULOCORTICAL AXONS WHICH ARBORIZE IN AREA 17. *E.A. Lachica* and V.A. Casagrande*. Dept. Cell Biology, Vanderbilt Univ. Sch. Med., Nashville, TN 37232 (SPON: J. Hutchins).

Previous studies have shown the lateral geniculate nucleus (LGN) of the prosimian primate, *Galago*, to be composed of three pairs of layers comprised of magnocellular (Y-like), parvocellular (X-like) and koniocellular (W-like) cells. In the present study, we injected PHA-L into the W-like LGN layers, reconstructed the arbors that terminated in striate cortex (area 17) then compared the location of these arbors to the patterns of cytochrome oxidase (CO) on alternately stained sections. The results show that all W-like arbors terminate within individual CO blobs in layer III of area 17. Many of these axons bifurcate in layers V or VI producing a collateral that arborizes in layer I. No axon possessed collaterals that terminated in more than one blob or in any other cortical layer. The W-like arbors are about the same size (0.027 $\pm$ 0.013 mm^2) as X-like arbors that terminate in layer IVβ. They are, however, smaller than Y-like arbors (0.08 $\pm$ 0.01mm^2) that terminate in layer IVα. While W-like arbors have fewer boutons than Y-like arbors, they have about the same number of boutons as X-like arbors. This suggests that the W-like pathway could provide significant input to the CO-blobs in these primates. (Supported by EY01778 to VAC & MH09754 to EAL).

LAYOUT OF ORIENTATION COLUMNS IN FERRET VISUAL CORTEX: A DOUBLE-LABEL 2-DEOXYGLUCOSE (2-DG) STUDY. C. Redies and M. Diksic*. Montreal Neurological Institute, Montreal, Quebec, Canada H3A 2B4.

The visual cortical organization in the orientational domain was studied in six NO_2/O_2 anesthetized ferrets using a simplified version of the quantitative double-label 2-DG technique (Redies and Diksic, *Neurosci.*, 1989). 5 mCi of [^{3}H]2-DG and 25 μCi of [^{14}C]2-DG were used as tracers. Stimulations lasted 60 and 30 min, respectively. Cortical activation patterns were separated in each animal using a subtraction procedure that corrects for uptake of the first tracer during the second stimulation (Redies et al., *Neurosci.* **22**: 601, 1987) and for cross-contamination between the isotopes.

Stimulation with two gratings of *orthogonal* orientation elicits activation patterns that are partially complementary and show little overlap between orientation columns. Patches not activated by either stimulation suggest a mosaic-like pattern with intermediate orientations represented in relatively large spaces between the orthogonal orientations. With orientations differing *by 45 degrees*, a complex pattern of partial overlap is observed. The orientational changes show frequent alterations in their magnitude and direction. No evidence of any modularity was found. The maps obtained in this study are strikingly similar to computer-generated maps simulating development of neural connectivity (Linsker, PNAS **83**:8779, 1986). Supported by MRC of Canada (MA-10233).

441.5

INFLUENCE OF A BINOCULAR CENTRAL RETINAL LESION ON THE GAD-IMMUNOREACTIVITY IN CAT VISUAL CORTEX AND dLGN. F. Vandesande, H. Demeulemeester*, G.A. Orban and U. Eysel. Lab. Neuroendocrinologie, Naamsestraat 59, B-3000 Leuven, Lab. Neuro- en Psychofysiologie, K.U.Leuven, Campus Gasthuisberg, B-3000 Leuven, Belgium and Dept. Neurophysiology, Ruhr-Universität Bochum, D-4630 Bochum, FRG.

Hendry and Jones (Nature, 320:750, 1986) reported that monocular deprivation in monkey results in a strong decrease of the number of ir-GABAergic neurons in the ocular dominance columns associated with the deprived eye. In the present study, we used a binocular paradigm in order to exclude the influence by the intact contralateral eye. Four normal and four experimental cats were involved. The latter received a central retinal lesion (diameter 10°) in both eyes. In such a paradigm each cat can serve as a control for itself. After four weeks survival the laminar distribution of ir-GAD neurons in area 17 and the dLGN was calculated and expressed as a percentage of the total neuronal population. In layer 2-6 of the cortex subserving central vision of experimental animals the proportion of GAD in cells was 3 to 5 times higher than that of control animals. In the cortex subserving peripheral vision the proportions were equal in experimental and control animals. In the part of the layer A and A_1 of the lateral geniculate nucleus subserving control vision the proportion of GAD in cells was reduced in experimental animals compared to control animals. These results show that the effect of visual stimulation of concentration of GAD in cortical cells is more complex than previously thought.

441.6

REGULATION OF CYTOCHROME OXIDASE PROTEIN LEVELS BY FUNCTIONAL ACTIVITY IN THE MACAQUE MONKEY VISUAL SYSTEM. R. F. Hevner and M. T. T. Wong-Riley. Dept. of Anatomy & Cellular Biology, Medical College of Wisconsin, Milwaukee, WI 53226.

Cytochrome oxidase (C.O.) is a mitochondrial energy metabolic enzyme used as a marker of neural functional activity. The histochemical activity of C.O. in the striate cortex (and in other brain regions) can increase or decrease in response to altered neural functional activity (Wong-Riley and Carroll, *Nature* **307**:262, 1984). Enzyme activity changes could be due to modulation of enzyme protein levels or turnover number. To determine if C.O. protein levels change with altered neural functional activity, we examined the distribution of C.O. protein immunohistochemically in the visual system of macaques treated for 3-4 weeks with monocular intravitreal injections of tetrodotoxin. The antiserum to C.O., and the immunohistochemical method, have been described previously (Hevner and Wong-Riley, *J. Neurosci.*, in press). In the striate cortex, as well as in the LGN and retina, changes in C.O. immunoreactivity were observed after tetrodotoxin treatment, and closely followed changes in C.O. activity. Ocular dominance banding was visible by both methods in most cortical layers, and was most pronounced in layer 4C. The results show that neuronal C.O. protein levels are regulated by neural functional activity. We propose that C.O. protein levels are constantly adjusted to meet neuronal energy metabolic requirements. (Supported by NIH NS18122 & EY05439 to MWR, and a MCW MSTP Fellowship to RFH.)

NEUROCHEMICAL PROPERTIES AND POSTSYNAPTIC TARGETS OF CHOLINERGIC SYNAPSES IN CAT VISUAL CORTEX. C. Beaulieu and P. Somogyi, MRC Anatomical Neuropharmacology Unit, South Parks Rd, Oxford, England.

GABA-content and synaptic connections of cholinergic terminals has been studied using combined immunocytochemistry for CHAT (pre-embedding) and GABA (post-embedding). To date, 101 CHAT(+) synapses were analyzed and of the identified postsynaptic targets, 18% were spines, 33% GABA(+) dendrites, 47% GABA(-) dendrites, and 1% GABA(-) somata. The proportion of cholinergic synapses contacting GABA(+) elements is very different from that found for the total population of synaptic contacts. From a sampling of 1061 synapses, only 8% of GABA(+) and 10% of GABA(-) boutons targeted GABAergic elements. This suggests that cholinergic terminals preferentially contact GABAergic cells; they terminate 3 times more frequently on GABAergic targets than the overall population of synapses.

Furthermore, 14% of the CHAT(+) synaptic boutons analyzed were also GABA(+). The distribution of these double-labelled boutons on postsynaptic elements is similar to that obtained for CHAT(+) boutons which were GABA(-). The source of GABA-containing cholinergic terminals could be the basal forebrain or they could arise from local cells as in the cortex of rat. However, we have not found any CHAT(+) cell in the cat cortex.

EXCITATORY TRANSMITTER AMINO ACID-CONTAINING NEURONS AND THEIR PROJECTIONS IN THE RAT VISUAL CORTEX J.G. Parnavelas*, I. Dori* and A. Dinopoulos* (SPON: European Neuroscience Association). Dept. of Anatomy, University College London, London WC1E 6BT, U.K.

The distribution and morphology of neurons labeled immunocytochemically with antisera to glutamate (Glu) or aspartate (Asp) were examined in the rat visual cortex. Using well-established light microscopical features as well as nuclear, cytoplasmic and synaptic criteria, we noted that Glu-labeled neurons were exclusively pyramidal distributed in layers II-VI with increased concentration in layers II & III. Asp-immunoreactivity was localized chiefly in pyramidal neurons located in layers II-VI but also in a small percentage (approximately 10% of labeled cells) of nonpyramidal cells scattered throughout the cortical thickness. In order to examine the amino acid-containing neurons in the visual cortex which give rise to various corticofugal and calloral projections, we utilized immunohistochemistry in conjunction with HRP histochemistry. The results of this study showed that Glu and Asp are the putative transmitters in substantially different proportions of neurons in the efferent systems examined suggesting a chemical heterogeneity of these systems.

DIRECT DEMONSTRATION OF THE RELATIONSHIP BETWEEN INTRINSIC AND EXTRINSIC CORTICO-CORTICAL CONNECTIONS USING DOUBLE LABEL TRACT TRACING. R. Malach Center for Neurosciences, Weizmann Inst. of Science, Rehovot, Israel 76 100.

The relationship between the intrinsic (within a cortical area) and extrinsic (between cortical areas) horizontal connections was studied using double label ,tract tracing approach. Single injections of the fluorescent tracer bisBenzimide were placed in cat area 18. The resulting label in area 17 consisted of a set of banded patches which were revealed in the whole, fixed, brain preparation. Under visual guidance, a crystal of the tracer DiI was inserted into one of the BB-labelled patches. Following 2 months of incubation, the DiI produced intense fiber labelling, which, in tangential sections, appeared to radiate from the injection site, forming several tongues and patches. Comparing the BB labelled extrinsic patches and the DiI labelled intrinsic connections revealed clear instances of overlap but no cases of interdigitation in the material studied . The applicability of the double tracer approach for revealing the relationship between intrinsic and extrinsic connections in different cortical areas and different mammalian species will be assessed.

MODULAR CONNECTIONS OF EXTRASTRIATE VISUAL AREA DM WITH AREAS 17, 18, AND MT IN MONKEYS. L.A. Krubitzer and J.H. Kaas, Vanderbilt University, Nashville, Tenn.

Injections of WGA-HRP in the dorsomedial visual area, DM (V3?) of owl monkeys (Aotus trivirgatus) labeled arrays of clusters of neurons in area 17 and rows of neurons crossing much of the width of area 18 (V-II). In addition, rows of clusters of neurons and terminals were labeled in the middle temporal visual area, MT. Thus, restricted locations in DM appear to relay information from a subset of neurons in area 17 and bands of neurons in area 18 to several aligned rows of neurons in MT. Inputs from aread 17 and 18 were from regions including both the representationd of the upper and lower visual quadrants, and microelectrode mapping experiments confirmed that DM, unlike V3d, represents the upper as well as the lower visual quadrant. Other connections of DM were with part of posterior parietal cortex and MT projection fields ST and FST. The pattern of connections indicates that DM is part of the "magnocellular" stream of cortical processing related to functions of the parietal lobe such as visual attention and localization. (EY-02686)

CORTICAL CONNECTIONS OF INFERIOR TEMPORAL CORTEX IN SQUIRREL MONKEYS. R. E. Weller, J. F. Hood* and G. E. Steele. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

All primates appear to have a large region of inferior temporal (IT) cortex that is visual in function. We determined the connections of caudal IT cortex in squirrel monkeys (Saimiri sciureus) by making injections of neuroanatomical tracers in different locations in caudal IT. Tracers such as the fluorescent dyes Fast Blue and Diamidino Yellow, and wheat germ agglutinated-horseradish peroxidase were injected under sterile conditions in anesthetized animals. After appropriate survival times, animals were sacrificed and the brains frozen, sectioned and processed histologically. Major input to IT cortex originated from the caudal part of the Dorsolateral Area, DLc. Weaker projections came from rostral DL, MT, lateral V II, and locations in the frontal lobe. Injections in central, caudal IT cortex also revealed connections with other parts of IT cortex, such as more rostral IT, dorsal IT in the superior temporal sulcus, and ventral IT in the inferior temporal sulcus and medial to the inferior temporal sulcus. These intra-IT connnections suggest the existence of subdivisions within IT cortex of squirrel monkeys.

ORGANIZATION AND CONNECTIONS OF THE CAUDAL DORSOLATERAL AREA IN SQUIRREL MONKEYS. G. E. Steele, C. G. Cusick and R. E. Weller. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294 and Dept. of Anatomy, Tulane Univ., New Orleans, LA 70112.

In monkeys, visual information reaches inferior temporal (IT) cortex via projections from an area of cortex called V4 in macaque monkeys and the Dorsolateral Area (DL) in owl monkeys. V4 extends from lateral to ventral cortex, while DL is restricted to the dorsolateral surface. The present study examined which of these organizational schemes exists for cortex in the location of caudal DL (DLc) in the squirrel monkey, Saimiri sciureus. This was accomplished by dorso-ventrally varying the locations of injections of neuroanatomical tracers in cortex rostral to V II and examining the resulting patterns of connections. All but the most dorsal injections resulted in a topographic pattern of connections with V II, strongly suggesting that cortex from dorsolateral to ventral comprised a single area, the extent of which was similar to V4 in macaques. We also found evidence that DLc projected to caudal IT in at least a crudely topographic fashion, with stronger projections originating from the parts of DL representing central vision.

Supported by NIH grants R29 EY07147 to R.W. and T32 EY07033 to G.S.

BIOCHEMICAL AND PHARMACOLOGICAL CORRELATES OF DEVELOPMENT III

442.1

INDUCTION OF A PLACENTAL-LIKE ALKALINE PHOSPHATASE AND REDUCTION IN PROTEIN TYROSINE PHOSPHORYLATION CONCURRENT WITH BUTYRATE-INDUCED NEURONAL TRANSFORMATION OF THE TE671 CLONAL CELL LINE. Mario B. Marrero* and Ronald J. Lukas (SPON. H.N. Siegel). Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

We have previously reported that cells of the TE671 human medulloblastoma clonal line exposed to the 'differentiating agent' sodium butyrate undergo morphological transformation to a state resembling that of mature neurons in a time- and concentration-dependent manner. These cellular morphological changes involving neurite extension, a 2-3-fold increase in alkaline phosphatase activity, and an induction of a placenta-like alkaline phosphatase isoenzyme as show by Western immunoblot procedures all are apparent following two-three days of treatment with 2 mM sodium butyrate. Western immunoblots probed with a monoclonal antibody against phosphotyrosine indicate that butyrate treatment induces a striking decrease in the phosphotyrosine content of a number of proteins, but that these effects occur within one hour of butyrate treatment. All of these effects are maintained for the duration of butyrate exposure. The results suggest that several mechanisms involving cellular protein phosphorylation/de-phosphorylation might be involved in butyrate-induced neuronal transformation of the TE671 clonal cell line.

442.3

CHARACTERIZATION AND PARTIAL PURIFICATION OF NEURON SPECIFIC GLYCOPROTEINS FROM *DROSOPHILA MELANOGASTER*. Muñoz-Maines, V.* and Salvaterra, P. (SPON: K. Ikeda). Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

Antibodies directed against the plant glycoprotein horse radish peroxidase (HRP) recognize an epitope expressed by all neurons at different stages of *Drosophila* nervous system development. The isolation and characterization of the specific neuronal antigen(s) bearing the anti-HRP epitope(s) could be a potentially valuable tool for studying neuronal development. We have used Western blots of *Drosophila* proteins, stained with anti-HRP antibodies, to characterize and partially purify the glycoproteins from 2nd instar larvae and adult fly heads.

Detergent extracts from larval stages show a single immunoreactive polypeptide with a molecular size of 52 kD. Immunostaining is no longer observed when the sample is oxidized with sodium periodate, indicating that the epitope recognized by the antibodies is a carbohydrate (i.e. a glycoprotein). This glycoprotein appears to be heterogeneous with respect to its carbohydrate composition. Purification of the antigen from second instar larvae, using detergent extraction, anion exchange chromatography and preparative gel electrophoresis results in a 30% pure sample of antigen which is being used to generate monoclonal antibodies to the protein core.

In contrast to larval stages, a homogenate from adult fly heads shows 2 immunostained polypeptides of 43 and 70 kD. Both bands are at least partially aqueous soluble. The anti-HRP staining of both bands is sensitive to periodate oxidation.

MOLECULAR MARKERS OF THE MOTOR AND MECHANOSENSORY NEURONS IN THE NEMATODE CAENORHABDITIS ELEGANS. S. S. Siddiqui and H. Yasuda *. Laboratory of Molecular Biology, Toyohashi University of Technology, Toyohashi 440, JAPAN.

We have previously described the staining pattern of a number of anti-tubulin monoclonal antibodies to the neural and non-neural cells of the nematode Caenorhabditis elegans. The antibodies also recognize specific tubulin isotypes from C. elegans separated by isoeclectric focusing on gels using ampholines(Siddiqui, S.S., Aamodt, E., Rastinejad, F., and Culotti, J. J. Neurosci, 1989 in press). Among the antibodies, 6-11B-1, raised against acetylated alpha tubulin, preferentially stains the six mechanosensory neurons, and 2-28-33, stains the inhibitory motor neurons VD and DD in the ventral cord of the nematode. Another antibody E6B6 is specific to beta tubulin, and stains the entire nervous system. Here we have screened a lambda gt11 library of C. elegans cDNA to screen the expression library with the tubulin antibodies. We have isolated positive clones using the E6B6 antibody, and two other alpha tubulin antibodies 3A5, and 4-1-B6, subcloned in pUC118 vector, and sequenced. The SQ#TbB03 clone shows a partial sequence of a beta tubulin, whereas, SQ# TA01, has a sequence of an alpha tubulin. This alpha tubulin gene is more homologous to a human alpha tubulin, then it is homologous to the yeast, or Drosophila melanogaster alpha tubulin gene. The sequence analysis of the beta tubulin gene is in progress, and the data for its cellular localization will be presented.

ENVIRONMENTAL ENRICHMENT RESULTS IN ENHANCED ACTIVITY OF HIPPOCAMPAL SUBICULUM AND VISUAL CORTEX IN YOUNG RATS: A 2-DEOXYGLUCOSE STUDY. E.M. Gonzalez-Lima*, P.A. Ferchmin, V.A. Eterovic and F. Gonzalez-Lima. Dept. Med. Anat., Texas A&M Univ., College Station, TX 77843, and Dept. Biochem., Sch. Med., Univ. Central del Caribe, Cayey, PR.

The goal was to determine functional changes in the rat brain resulting from 2 types of housing. Male, Tryon S1 rats were weaned and kept together for 4 days. Then pairs matched by weight were randomly assigned to: 1) rats housed individually in standard lab cages as the "impoverished" condition (IC), or 2) rats in the "enriched" condition (EC) in a complex environment of 2 large cages with inanimate objects and conspecifics. After 4 days, rats were injected with 2-DG, placed individually in a standard lab cage and killed after 90 min. Brains of EC rats were significantly heavier (57 mg) than IC, but no differences in body weights were found. EC brains showed significantly enhanced 2-DG uptake in the hippocampal subiculum (36%) and visual cortex (27%). There was also a 10% increase in thickness in the visual cortex but not a similar change in the subiculum. No changes were observed in other cortical areas (frontal, parietal, temporal, cingulate, piriform) or in the midbrain reticular formation. 2-DG changes in EC brains are consistent with activation of structures related to visual learning rather than nonspecific arousal. The findings provide a neural basis for the improved learning abilities shown by EC rats. (R01MH43353, NIH-RCMI)

DEVELOPMENT OF CYCLIC AMP-DEPENDENT PROTEIN KINASE SUBUNIT MESSENGER RNA LEVELS IN THE FETAL RAT BRAIN. J.S. Massa*, R.A. Maurer* & R.E. Fellows. Dept. of Physiology and Biophysics, Univ. of Iowa, Iowa City, Iowa 52242.

cAMP in the brain acts via cAMP-dependent protein kinase (cAMPdPK). Using rat cDNAs for all known isoforms of cAMPdPK regulatory (R) and catalytic (C) subunits (RIα, RIβ, RIIα, RIIβ, Cα, Cβ) we observe that, in the fetal rat brain from E12 to birth, while α subunit (RIα, RIIα, Cα) mRNA levels are abundant and relatively constant, β subunit (RIβ, RIIβ, Cβ) mRNA levels increase from undetectable or very low levels to abundant levels. Furthermore, while α subunit mRNAs are abundant in both primary neuronal and primary glial cultures, β subunit mRNA levels are very low (Cβ) or undetectable (RIβ, RIIβ) in primary glial cultures, but are abundant in primary neuronal cultures. Thus, prior to about E12, cAMP may act only via the α cAMPdPK subunits in neuronal and glial precursor cells. After about E12, the β set of cAMPdPK subunits may also mediate the effects of cAMP in neurons. 442.6

DEVELOPMENTAL CHANGES IN NMDA RECEPTOR FUNCTION STUDIED IN A GREASE-GAP PREPARATION OF HIPPOCAMPAL AREA CA1. M.A. Bowe and J.V. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Several reports suggest that the regulation of NMDA receptor-channel function changes during development. To follow these changes in CA1 pyramidal cells of the rat hippocampus, we have utilized a grease-gap preparation that allows a quantitative pharmacological characterization of responses to excitatory amino acids and their antagonists.

Longitudinal hippocampal slices that included only area CA1 and the retrohippocampal area were prepared from 10-36 day old rats. Each slice was transferred to a two-compartment superfusion chamber and a grease barrier was placed across the CA1-subiculum border. Agonists were applied to the CA1 portion of the slice and the depolarizing responses of pyramidal cells were recorded relative to their axons in the subiculum.

In the absence of Mg^{2+}, the mean EC_{50} for NMDA at 10-13 days of age was 6.8 uM and for AMPA it was 5.6 uM. Both values dropped about 25% between postnatal days 13 and 18. This change may be related to growth of the pyramidal cell dendritic tree. Between postnatal days 10 and 26, 1 mM Mg^{2+} reduced the response to NMDA less than in slices from adult rats. The dose-ratio was only about 2.8, compared with 3.8 in the adult. The effect of Mg^{2+} had reached the full adult level in about half the slices from 30-36 day old rats. These results suggest that NMDA receptor-channel function in CA1 pyramidal cells is less sensitive to Mg^{2+} during development than in adulthood. This may facilitate the NMDA receptor activation needed for learning and brain differentiation. (Supported by NIH grant NS 16064.)

442.7

DIFFERENTIAL EXPRESSION OF CATECHOLAMINERGIC AND ANGIOTENSIN II RECEPTORS IN ASTROCYTIC GLIAL CULTURES FROM NEONATAL AND 21-DAY-OLD RAT BRAINS.

M.K. Raizada,* L. Horky,* and S.P. Baker. Departments of Physiology and Pharmacology & Therapeutics, University of Florida, College of Medicine, Gainesville, Florida. 32610

Catecholaminergic and peptidergic receptors have been implicated to play a role in the development and differentiation of the CNS. However, attempts to investigate the mechanism of their involvement has been hampered, in part, due to the presence of hetogenous cell populations in the CNS. We have established astrocytic glial cells (AGC) in primary culture from the brains of neonatal and 21-day-old rats in order to address this issue. Radioreceptor assays were conducted in AGC from both age groups to quantitate α_1, β-adrenergic, muscarinic and angiotensin II (Ang-II) receptors with the use of [^{125}I]-HEAT, [^{125}I]-iodocyanopindolol (CYP), [^{3}H]-quinuclidinyl benzilate (QNB) and [^{125}I]-Ang II respectively. Comparison of Bmax and Kd's for these receptors indicated significant differences between the neonatal and 21-day-old AGC. Twenty-one day-old AGC expressed a 3.8 fold increase in the Bmax of [^{125}I]-HEAT, a two-fold increase in the Bmax of [^{125}I]-Ang II, and a 45% decrease in the Bmax of [^{125}I]-CYP binding compared with the AGC from neonatal rat brain. In contrast, no change in the Bmax or Kd of [^{3}H]-QNB binding was observed between the AGC of neonatal and 21-day-old brains. These observations indicate that AGC from immature and mature brains express differential receptor levels and may serve as a useful model for the study of CNS development. (Supported by NIH / HL-33610).

442.8

REGULATION OF OPIATE RECEPTORS IN NEONATAL RAT BRAIN FOLLOWING EXOGENOUS DRUG ADMINISTRATION. A. Tempel. Dept. of Neuroscience, Albert Einstein College of Med., Bronx, New York 10461.

Opioid analgesics are well known to produce tolerance and dependence in vivo and desensitization in vitro, although the mechanisms for these phenomenon are not clear. We have found that chronic pre- and postnatal morphine treatment of rat pups produces a significant decrease in brain μ opioid receptor density with no change in receptor affinity. This downregulation is accompanied by tolerance to the actions of morphine as measured by the forepaw withdrawal test (Tempel et al., Dev. Brain Res., 1988). In order to gain insight into the cellular and molecular mechanisms underlying downregulation, the effect of chronic morphine treatment in rat pups on the expression of the principal brain opioid peptide gene, preproenkephalin (PPE) was examined. For chronic prenatal treatment, pregnant dams were implanted with one morphine pellet (75 mg each) on gestational day 15. Pups were sacrificed on postnatal day zero, 4, 7, 14 or 21. For postnatal drug administration, rat pups were injected subcutaneously with either morphine (5 mg/kg daily) or saline for 7, 14, 21 or 28 days. Pair feeding and surrogate fostering techniques were followed. Pups were tested for morphine-induced analgesia or were sacrificed by decapitation following the indicated time. Brains were used for biochemical and molecular analyses. Changes in levels of PPE mRNA were determined by Northern blot analysis and were correlated with regions showing decreases in opiate receptor binding (using receptor autoradiography). These agonist-induced changes may contribute to the symptoms of opiate addiction and tolerance. (Supported by NIH grant DA05440).

442.9

ONTOGENY OF BRAIN GLUCOSE METABOLIC RESPONSE TO COCAINE: A QUALITATIVE AUTORADIOGRAPHIC STUDY. D.L. Dow-Edwards and L.A. Freed Lab of Cerebral Metabolism, SUNY-Health Science Center, Brooklyn, NY, 11203.

We have published long term metabolic changes in rats exposed to cocaine during the preweanling period (Dow-Edwards et al., 1988). However, the acute effects of cocaine on brain glucose metabolism during ontogeny have not been demonstrated.

At either 7, 14 or 21 days of age, nontreated pups were injected with either saline or 25 mg/kg cocaine-HCl, sc and held in an incubator at 35°C. Ten minutes later, [^{14}C] 2-deoxyglucose was injected and the animals were decapitated 45 minutes later. Brains were removed, frozen and processed for autoradiography. Optical density patterns of cortical and subcortical structures were determined using a computerized image analysis system.

At 7 days of age, none of the brain regions appeared to be stimulated, while the thalamus appeared to be metabolically depressed. At 14 days of age, patterns of increased activity appeared in several cortical regions as well as the zona incerta and subthalamic nucleus. At 21 days of age, brain glucose metabolic response to cocaine was similar to that seen in the adult rat (Porrino et al., 1988). The results are discussed in relation to the ontogeny of the behavioral responses to cocaine (Spear & Brick, 1979). Supported by ADAMHA Grant DA04118.

442.10

DEVELOPMENT OF SEX DIFFERENCES IN CATECHOLAMINE METABOLISM IN RAT SYMPATHETIC NEURONS. P. Beaston-Wimmer* and A.J. Smolen (SPON: L. L. Ross). Dept. Anatomy, The Medical College of Pennsylvania, Philadelphia, PA 19129.

At birth, superior cervical ganglia (SCG) of male and female rats contain equal numbers of neurons. No sex difference exists in the content of norepinephrine (NE) in these neurons, in the enzyme activity of tyrosine hydroxylase (TH), or in the expression of TH-mRNA, measured by quantitative in situ hybridization.

During the first two postnatal weeks, natural neuron death in the SCG results in the loss of significantly fewer neurons in males. At this time, neurons from both sexes express equivalent amounts of TH-mRNA, but both TH enzyme activity and NE content per neuron are lower in males. Since the adult sex difference in body weight and sympathetic target mass has not yet been established, the same target mass is innervated by more neurons in males.

In the adult, overall body weight, as well as target organ mass, is significantly greater in males. At this time, the the sex difference in neuron number is maintained, and expression of TH-mRNA remains equivalent in the two sexes. Both TH enzyme activity and NE content per neuron are now equal in males and females.

We conclude that normal amounts of message for TH are expressed even in neurons that are destined to undergo natural neuron death. Further, the development of both TH enzyme activity and NE content in sympathetic neurons appears to depend on target availability, while expression of TH-mRNA appears to develop independently.

ANDROGEN RECEPTORS ARE DIFFERENTIALLY DISTRIBUTED BETWEEN RIGHT AND LEFT CEREBRAL HEMISPHERES OF THE FETAL MALE RHESUS MONKEY. S.A. Sholl and K.L. Kim*. Wisconsin Regional Primate Research Center, University of Wisconsin, Madison, WI 53715.

In humans there are apparent sex differences in cognitive, spatial and mathematical abilities which may arise as the result of differences in the prenatal development of the cerebral cortex. With this in mind, we have examined androgen receptor (AR), aromatase (AROM) and 5α-reductase (5αR) levels in the brain of Day-70 fetal rhesus monkeys (*Macaca mulatta*). We have reported details of these assays previously (*Endocrinology* 119:1625, 1986; 124:627, 1989.). Receptor and enzyme levels were evaluated in the medial basal hypothalamus (MBH) and in both right (Rt) and left (Lft) temporal (TMP) and frontal (FR) lobes of the cerebral cortex. Five male and 5-6 female fetuses were used in this study. AR levels in FR-Rt of male subjects were higher than levels in FR-Lft (for each and every subject, $P < 0.05$), while in females, there was no consistent pattern in the distribution of the receptor between the two sides of FR. In contrast, AR values in TMP-Lft of male subjects were consistently higher than in TMP-Rt ($P < 0.05$). As with the FR, females exhibited no consistent pattern in the distribution of AR between the two TMP sides. AROM and 5αR levels were similar, regardless of sex, between both sides of the two cortical lobes. In both sexes, the concentrations of AR in the MBH were near the levels observed in the various cortical areas, while AROM and 5αR activities were 3 fold higher in the MBH than in the cortex. The differential cortical distribution of AR in fetal males versus females lends support to the hypothesis that prenatal androgens from the fetal testes may effect the differentiation of sexually dimorphic, side-specific activities in cortical activity. In addition, we recently demonstrated high 5αR activity in the corpus callosum (*Endocrinology* 124:627,1989) which may serve to convert testosterone to its more active metabolite, DHT, and concentrate DHT in the cerebrum. (Supported by NIH Grant HD-18865.)

ALZHEIMER'S DISEASE II

443.1

METABOLITES ELEVATED IN ALZHEIMER'S BRAIN ALTER MEMBRANE PROPERTIES. **J.W. Pettegrew, D. McKeag* and S. Strychor*. Laboratory of Neurophysics, Departments of Psychiatry and Neurology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261**

In vitro and in vivo ^{31}P NMR studies demonstrate that phosphomonoesters (PME) such as phosphocholine (PC), phosphoethanolamine (PE) and L-phosphoserine (PS) are elevated (5-7 mM) in Alzheimer's disease brain. The present study examines whether PME alter plasma membrane molecular dynamics. Erythrocytes were obtained from 11 normal adult volunteers and labelled with fluorophores that monitor molecular motion in specific areas of the membrane. The erythrocytes were incubated for 30 minutes at 37°C with either phosphate buffered saline or a given concentration (100 μM, 500 μM, 1.0 mM) of one of the PME (PC, PE or PS) or a combination of PME. Following the incubation period, anisotropy values were determined. Compared to buffer the PME increased molecular motion on the surface ($p = 0.0001$) and in the hydrocarbon core ($p = 0.01$) and decreased molecular motion at the aqueous-hydrocarbon interface ($p = 0.0001$). The PME could therefore alter membrane molecular dynamics in CNS cells and alter the function of membrane proteins such as receptors, channels and second messenger cascades. The circulating erythrocyte also could be a useful "reporter cell" for CNS molecular pathology and monitor disease progression and the response to therapeutic interventions.

443.2

CHROMOGRANIN A-LIKE IMMUNOREACTIVE NEURONS ARE RESISTANT TO TANGLE FORMATION AND DEATH IN ALZHEIMER'S DISEASE. D.G. Munoz and C. Caro*. Dept. of Pathology, University of Saskatchewan, Saskatoon, Sask., S7N 0W0

Chromogranin A-like immunoreactivity (CgA-li), as defined by the monoclonal antibody LK2H10, is widespread, but restricted to certain neuronal populations in the human brain. The distribution of CgA-li neurons in the hippocampus coincides with the pattern of resistance to seizure-induced damage (Munoz et al ASN 1988;14: 983). We have studied the entorhinal cortex and hippocampus of 5 patients with Alzheimer's disease (AD) and 12 controls. The principal neurons of entorhinal layers II and IV lacked CgA-li; layer III showed weak and layers V-VI moderate CgA-li. In addition, sparse, intensely CgA-li neurons were scattered in layers III to VI. Neurofibrillary tangles in AD predominantly occurred in layers (II and IV) lacking CgA-li neurons. Intense and moderately CgA-li neurons showed significantly better survival in AD than CgA-li negative neurons. Similarly, in the hippocampus, CgA-li neurons in CA2 survive and rarely develop tangles, whereas CgA-li negative CA1 and subicular neurons develop tangles and die. Thus, although CgA-li neurons contribute neurites to almost all plaques (Munoz, Neurology 1989;39: S396), their somata are relatively resistant to tangle formation and death. These data support a role for excitotoxicity in the pathogenesis of AD.

443.3

THE DISTRIBUTION OF CHOLECYSTOKININ-LIKE IMMUNOREACTIVITY (CCKLI) IN ISOCORTEX IN NORMALS AND ALZHEIMER'S DISEASE (AD). D.G. Cole* and N.W. Kowall (SPON: S.K. Kostyk). Neurology Service, Massachusetts General Hospital, Boston MA 02114.

We studied the pattern of CCKLI in the isocortex of brains of aged controls and patients with AD using immunoperoxidase methods and well-characterized polyclonal CCK antiserum (INCstar). In normals we found a characteristic laminar distribution of CCKLI terminals, with strong staining of layers II, IV, and VI, and trilaminar staining in layer I. The major regional variation in this theme was in area 17, where 4A stained mildly, 4B weakly, 4Cα strongly, and 4Cß weakly, with diminution of clear distinction between layers V and VI. Cell staining was rare in the perirolandic and striate regions but common in inferior temporal and medial infero-frontal areas. Fiber staining was rare. In AD brains we found the trilaminate layer I staining lost while the remainder of the laminar pattern was preserved. Layer IV often stained less prominently than in normals. Senile plaques predominated in layers II and III, and they were more plentiful in higher association cortex than primary sensory and motor cortex. Occasional dystrophic fibers were seen. Cell staining was unchanged compared to normals. Our results establish the distinctive pattern of CCKLI in homotypical and heterotypical isocortex and the changes in this pattern seen in AD. The absence of a simple proportional correlation between the distribution of senile plaques and terminals suggests preferential involvement of a subset of CCK neurons in AD.

443.4

INHIBITION OF HISTAMINE METABOLISM BY THA (9-AMINO-1,2,3,4-TETRAHYDROACRIDINE). P. Cumming, P.B. Reiner and S.R. Vincent. Kinsmen Laboratory of Neurological Research, Department of Psychiatry, The University of British Columbia, Vancouver, B.C., V6T 1W5, Canada.

Chronic administration of 9-amino-1,2,3,4-tetrahydroacridine (THA) has been reported to produce clinical improvement in some cases of Alzheimer's disease. The anticholinesterase activity of THA provided the original rationale for using this drug. However, the pathology of Alzheimer's disease is not restricted to cholinergic neurons. Decreased cortical histamine levels and neurodegenerative changes in the histaminergic tuberomammillary nucleus have been reported in this disease. We noted the structural similarity of THA to quinacrine and related antimalarial drugs which are potent inhibitors of histamine-N-methyl transferase (HNMT), the enzyme responsible for histamine catabolism in the brain. We therefore examined the effects of THA on partially purified rat brain HNMT assayed in the presence of 10 μM tritiated S-adenosyl methionine at histamine concentrations from 1 to 10 μM. Under these conditions, the enzyme exhibited a K_m for histamine of 3.5 μM. THA was found to be one of the most potent competitive inhibitors of HNMT yet described, with a K_i of 36 nM. In contrast, the structurally related compound 4-aminopyridine was 1000-fold less potent. Since therapeutic effects of THA have been reported with serum levels as low as 30 nM, substantial inhibition of histamine metabolism would be expected in the clinical situation. Thus, some of the clinical efficacy of this drug may be related to its ability to augment histamine neurotransmission in the brain.

443.5

LOSS OF GUANINE NUCLEOTIDE-SENSITIVE HIGH AFFINITY AGONIST BINDING TO M1 MUSCARINIC RECEPTORS IN ALZHEIMER'S DISEASE. D.D. Flynn and D.C. Mash, Departments of Pharmacology and Neurology, University of Miami School of Medicine, Miami, FL 33101.

Diminished cholinergic neurotransmission is thought to play a major role in the development of Alzheimer's disease psychopathology. The failure of cholinergic replacement therapies to ameliorate specific features of the symptomatology may reflect a diminished responsiveness of postsynaptic muscarinic receptors (putative M1 receptor subtype) to direct and indirect-acting cholinergic agnoists, since the number of these receptor sites appears to be unchanged throughout the course of the disease. A selective reduction in M1 receptor-G protein coupling has been suggested in a preliminary study which used one point carbachol-[^{3}H]-pirenzepine assays on cerebral cortex homogenates from AD subjects (Perry, E.K., et al., Neurosci. Lett. 82:277, 1987). Using full carbachol-[^{3}H]-pirenzepine displacement assays, we demonstrate that M1 receptors show nearly a 100-fold difference in their high (K_H) and low (K_L) affinity agonist states. High affinity binding is converted to low affinity by the addition of the nonhydrolyzable GTP analog, GppNHp (0.2 mM). Our results further demonstrate that the proportion of M1 receptors in the high affinity agonist state is significantly diminished in AD, with a concomitant loss in sensitivity of the K_H state of the receptor to GppNHp. We are currently attempting to correlate variations in agonist affinity states of the M1 receptor subtype in AD with age of onset, disease duration and severity. Supported by NS 19065 and NS 25785.

443.6

A COMPARISON OF THE DISTRIBUTION OF CEREBRAL GLUCOSE METABOLISM AND OF MUSCARINIC RECEPTORS IN VIVO IN DEMENTIA. D.R. Weinberger, U. Mann*, R.C. Reba*, D.W. Jones*, R. Coppola, R.E. Gibson* and T.N. Chase. CBDB, NIMH Neurosciences Center at St. Elizabeths, Washington, D.C. 20032.

PET studies of glucose metabolism in patients with Alzheimer's Disease (AD) and in patients with Pick's Disease (PK) often reveal reduced metabolism in parietal and frontal cortices, respectively. We have recently observed with SPECT similar regional patterns of uptake of the muscarinic receptor antagonist ^{123}IodoQNB. To evaluate the comparability of the data from these techniques, 10 subjects (4 AD, 2 PK, 4 controls) underwent both an ^{18}FDG PET scan and a high resolution SPECT scan. SPECT was performed approximately 20 hours after injection of ^{123}IodoQNB when nonspecific binding appears to be negligible. Overall, similar patterns of focal defects were seen. On the glucose PET scans, reduced metabolism was observed in parietal and frontal cortex. With SPECT, the distribution of muscarinic receptor binding was reduced in parietal cortex in AD patients and in frontal cortex in PK patients. However, one of the PK patients had basal ganglia hypometabolism despite good ligand uptake and the other had a greater anterior-posterior gradiant in ligand uptake than in metabolism. Asymmetries in posterior cortical regions tended to be more striking on the QNB images. ROI analysis on 4 patients supported these observations. These preliminary data suggest that ^{18}FDG PET and ^{123}IodoQNB SPECT provide different information about brain function in dementia and that the muscarinic receptor binding results reflect more than partial volume artifacts or flow dependent ligand uptake.

443.7

ANTIBODIES IN THE CEREBRO-SPINAL FLUID (CSF) OF ALZHEIMER'S DISEASE PATIENTS: INVESTIGATION USING CHOLINERGIC NEURONAL CULTURES A.Dahlström, A.Wigander*, K.Lundmark* and A.McRae, Institute of Neurobiology Univ. of Goteborg Goteborg, Sweden 40033

Our previous findings have indicated that there is an antibody in the CSF from some AD patients which recognizes cholinergic neuronal populations in the rat central nervous system (CNS). In order to further investigate the specificity of this CSF antibody neuronal cultures of cholinergic cells were employed. Cholinergic cultures were prepared from dissociated cells from the medial septum region of 17 day old fetal rats and were maintained in culture for 3 weeks. The cultures were fixed with 4% paraformaldehyde and then were doubled stained with AD CSF and anti nerve growth receptor antiserum (a-NGF-R). A considerable number of cells were doubled labeled with AD CSF and a-NGF-R antiserum. This supports the concept that an antibody in the CSF from AD patients recognizes cholinergic neurons in culture as well as in the rat CNS. Addition of a-NGF-R (1/200) to cholinergic cells destroyed the neuronal population within 5 days. Addition of CSF samples from AD, and other demented patients did not destroy cholinergic cells. However when a-NGF-R antiserum was added to neurons incubated with patient CSF samples only those cultures incubated with AD CSF survived the destruction induced by a-NGF-R antiserum. Our results support the concept that there is an antibody in CSF from AD patients which recognizes cholinergic neurons and that this antibody counteracts the destructive effects of a-NGF-R antiserum to cholinergic neurons. These data provide further support to our hypothesis that the presence of IgG in the CSF of AD patients may participate in the pathogenesis of this neurodegenerative disease.

ANTICHOLINERGICS REINSTATE SENSORIMOTOR DEFICITS IN RATS WITH NEOCORTICAL DAMAGE: PROTECTIVE EFFECTS OF SABELUZOLE. M. De Ryck, H. Duytschaever*, G. H. C. Clincke*, A. Wauquier* and P. A. J. Janssen*, Janssen Research Foundation, Department of Neuropsychopharmacology, B-2340 Beerse, Belgium.

Unilateral photochemical infarction of the sensorimotor cortex in rats produced enduring limb placing deficits. When such rats (n=120) traversed narrow beams, the contralateral, but not ipsilateral, hindlimb frequently slipped off. With consecutive test sessions, performance improved to an asymptotic, residual deficit, which ranged from severe (e.g., 30-40 contralat. versus 0-2 ipsilat. errors) to slight (e.g., 2-4 errors). Atropine SO_4, at a dose that did not affect performance of normals (10 mg/kg ip), increased contralateral placing errors in infarcted rats from 10 (5-34) to 33 (23-66) [median (interquart. range); n=16; Wilcoxon test, $p < 0.001$]. Scopolamine HBr (1 mg/kg ip) yielded similar effects, which are central in origin, as the quaternary salts of atropine and scopolamine did not alter performance. None of these treatments produced gross sensorimotor dysfunctions. Sabeluzole (10 mg/kg po), a cognitive enhancer in several species, including man (Clincke, G.H.C., et al., *Psychopharmacology*, 94:52, 1988), diminished the deleterious effects of atropine in brain-damaged rats to 17 (9-44) errors ($p < 0.01$). Sabeluzole was significantly active within the dose range of 5-20 mg/kg po. Cholinergic forebrain mechanisms may be more vulnerable to cholinergic blockade after cortical damage. The protective effects of sabeluzole on such mechanisms, and their relationship to age- or Alzheimer's disease-related brain disorders, need further clarification.

SPECIFIC ALTERATIONS IN CALCIUM BINDING PROTEIN GENE EXPRESSION IN NEURODEGENERATIVE DISEASES. A. M. Iacopino* and S. S. Christakos, Biochemistry and Molecular Biology, UMDNJ-New Jersey Medical School, Newark, NJ 07103.

We have utilized a specific cDNA for the vitamin-D-dependent calcium binding protein, calbindin-D_{28k}, in order to examine changes in its gene expression in the aging rat and human brain as well as in 3 neurodegenerative diseases (Parkinson's, Huntington's, Alzheimer's). Changes in calbindin-D_{28k} gene expression were characterized by Northern and slot blot analysis (all blots were reprobed with B-actin and calmodulin cDNAs to determine specificity). Using gross brain regions in the aging rat, significant decreases in calbindin-D_{28k} mRNA were found in the cerebellum (4-fold) and subcortical area (9-fold) but not in the cerebral cortex. Using more specific brain areas in the aging human brain, significant decreases in calbindin mRNA levels were seen in the cerebellum (6-fold), corpus striatum (5-fold), and nucleus basalis (7-fold) but not in the neocortex, hippocampus, locus coerulus, amygdala, or nucleus raphe dorsalis. Comparison of diseased human brain tissue with age/sex matched controls yielded significant, specific decreases in calbindin-D_{28k} mRNA for substancia nigra (Parkinson's, 5-fold), corpus striatum (Huntington's, 8-fold), and nucleus basalis (Alzheimer's, 8-fold) but not in the amygdala, neocortex, or locus coerulus. Since the calbindin-containing neurons in these areas are particularly affected in each of the disease processes, it is suggested that a decrease in calbindin may lead to a failure of intraneuronal calcium homeostasis and calcium-mediated irreversible cytotoxic events during the pathological processes.

443.10

ALTERED cAMP-DEPENDENT PROTEIN PHOSPHORYLATIONS IN POSTMORTEM BRAIN TISSUES AFFLICTED BY ALZHEIMER'S DISEASE. W. Wallace, K.M. Parks*, L. Bierer*, D. Perl*, and V. Haroutunian* Department of Psychiatry and Fishberg Center For Neurobiology, Mount Sinai School of Medicine, New York, N.Y. 10029

We have examined protein phosphorylation patterns in human postmortem tissues by the back phosphorylation assay, in which endogenous protein kinase activities are measured as the in vitro incorporation of phosphate into various endogenous phosphoproteins. The cAMP dependent phosphorylations were measured as the amount of phosphate incorporated into two specific and well characterized substrates, Synapsin I and pyruvate dehydrogenase (PDH). Although the degree of phosphorylation varied with the tissue sample, this variability was inherent to the sample and not due to the assay, itself. The sample variability did not correlate with either age of the brain ($r=-.17$ $p<.61$ $n=11$ range =66 to 97 years) or postmortem interval suffered by the tissue ($r=-.23$, $p<0.37$, $r=17$ range =84 to 910 minutes). Homogenates from the temporal cortex (TC) of Alzheimer's disease and age-matched control brains exhibited a 2.6-fold difference in phosphorylation of Synapsin I (267 vs 104 fmols phosphate/mg total homogenate protein, $n=7$, $p<.03$). No differences were observed in the phosphorylation of PDH in the same tissues (144 vs 120 fmols phosphate/mg total protein). In addition, no differences were detected with either substrate within the cerebella of the two groups. Numerous other proteins exhibited similar differences inphosphate content as judged by autoradiography. These differences are not due to the absolute amount or structural integrity of the substrates. Whether these differences in phosphorylation of Synapsin I in the TC are due to altered endogenous cAMP kinase activity or altered in situ state of phosphorylation of the substrate proteins is currently being determined. Funded in part by ADRDA.

443.11

TOPOGRAPHY OF GLUCOSE METABOLIC DEFICITS IN ALZHEIMER'S DISEASE: EVIDENCE FROM CROSS-SECTIONAL AND LONGITUDINAL STUDIES. G. Smith., M. deLeon, A. George, A. Kluger, S.H. Ferris, B. Reisberg, N. Volkow, A. Wolf. Depts. of Psychiatry and Radiology, New York Univ. Med. Ctr. 10016 and Dept. of Chemistry, Brookhaven National Labs.

PET VI and ^{11}C 2-DG was used to describe the location and progression of the glucose metabolic deficits in Alzheimer's disease (AD). 34 AD patients who met NINCDS-ADRDA criteria and 21 age-matched controls were evaluated. Patients were stratified into mild (n=14) and moderate-severe (n=20) cognitive impairment groups. 17 of the subjects were examined at 2 to 3 years follow-up.

In comparing the mild AD group to the controls, statistically significant differences were observed (15-19%) in parietal, temporal, somatosensory, frontal, and occipital areas. The moderate-severe cases showed even greater widespread change, with further reductions (an additional 8-12%) in the areas involved in mild AD. Deficits in basal ganglia and thalamus was observed in the moderate-severe group, relative to controls. The longitudinal data confirm that the regions which show progressive deterioration across severity levels also declined significantly within patients.

The presentation of diffuse cerebral metabolic deficits, accentuated in temporal, parietal and frontal cortices is more consistent with the distribution of neurotransmitter deficits and neuropathological markers in AD. Supported by RO1 MH43965

443.12

GANGLION CELL LOSS IN MACULA OF PATIENTS WITH ALZHEIMER'S DISEASE Y. Torigoe, J.C.Blanks, R.H.I.Blanks, J. Cabaret*, Department of Anatomy and Neurobiol., Univ. Calif. Irvine, Irvine, CA 92717 and Estelle Doheny Eye Inst., Dept. Ophthalmol., Univ. Southern Calif., Los Angeles, CA 90033.

Ten retinas from 8 patients with Alzheimer's disease (AD) were evaluated to determine the size and distribution of ganglion cells in the macula. Data from patients ranging in age from 79 to 89 yr (mean=83) were compared to 7 age-matched controls (range, 60-85 yr; mean=73). Eyes were removed 1.5-6 hrs after death and fixed in 2% paraformaldehyde and 2% glutaraldehyde. The diagnosis of AD was confirmed by the presence of plaques and tangles in representative brain regions. All neurons within the ganglion cell layer (GCL) were drawn, digitized and split-cell fragments corrected to obtain accurate cell numbers and diameters. Retinal ganglion cells (RGCs) in the control, aged retina are medium-sized; their frequency distribution histogram is unimodal, symmetrical and comparable across the population of AD patients (13.2±1.4 um) and controls (14.2±1.7 um). The fovea (0-6° eccentricity) of AD patients shows a significant loss of neurons within the GCL and there is a tendency towards smaller numbers in the parafoveal area (eccentricity 6-9°). The plexiform layers, inner and outer nuclear layer, and photoreceptor cell layer appear normal in thickness and cell number. GCL neuronal density (neurons/mm^2) for AD patients is 4,007±1,839 and 8,591±970 for eccentricities of 0-3° and 3-6°, respectively, which is significantly lower (two sample t-test) than counts of 9,855±3,446 and 12,896 for controls. The difference at eccentricities of 6-9° between AD patients (14,491±7,443) and controls (15,229±4,272) is not significant. Thus, AD patients have lost 59% (range 35-82%) of the neurons of the GCL from 0-3° of the foveola and 33% (range 25-45%) from 3-6°. These results confirm earlier findings of retinal defects in AD patients, and demonstrate a significant loss of RGCs from the macula. Neuronal cell counts from retinal whole-mounts of these patients are underway to assess possible degeneration in the peripheral retina. The loss of RGCs (and possibly displaced amacrine cells located in the GCL) from the macula provides the anatomical substrate for the documented visual deficits found in AD.

BENEFICIAL EFFECTS OF PLATELET ACTIVATING FACTOR (PAF) ANTAGONIST IN EXPERIMENTAL NEUROINJURY IN RATS. K.U. Frerichs,* P.J. Lindsberg,* J.M. Hallenbeck* and G.Z. Feuerstein. (SPON:B.Cox) Dept. of Neurology, USUHS, Bethesda, MD 20814

The pathomechanisms of secondary brain damage after ischemic or traumatic brain injury are far from understood. Since PAF has been recently discussed to be a potential mediator in neuroinjury, we studied the effects of the selective PAF antagonist BN50739 on lesion volume, local CBF (lCBF)(laser doppler flowmetry) and blood brain barrier integrity (evans blue albumin (EBA)) in a model of focal and highly discrete cortical neuroinjury (thermal; Nd:YAG laser) in anesthetized rats. Expansion of the lesion volume within the first 24h after injury in vehicle injected controls was reduced by pretreatment with BN50739 (10mg/kg) by 25% (n=10,p<0.01) at 24h. The progressive hypoperfusion (lCBF: 40±8% of baseline,n=7) 1mm from the lesion within the first two hours after insult was partially prevented by BN50739 (lCBF: 80±7% of baseline,n=5,p<0.05) at 2h. Improvement of lCBF by BN50739 was associated with decreased extravasation of EBA (p<0.05). The present study provides supporting evidence, that PAF may be a key mediator in the evolution of hypoperfusion dependent brain injury; PAF antagonists therefore may provide significant therapeutic protection in arresting secondary brain damage following cerebral ischemia and neurotrauma.

444.2

ROLE OF PLATELET-ACTIVATING FACTOR (PAF) IN THE PATHOPHYSIOLOGY OF TRAUMATIC BRAIN INJURY. A.I. Faden, P. Tzendzalian*, M. Lemke and F. Valone*. Depts. of Neurology and Medicine, Univ. of CA, San Francisco, and VA Medical Center, San Francisco, CA, 94121.

PAF, or 1-O-alkyl-2(R)-acetyl-sn-glycero-3-phosphocholine, has been implicated in the pathophysiology of cerebral ischemia. BN 52021 is a PAF antagonist, isolated from Ginko biloba extract, which reduces pathophysiological effects of PAF and limits biochemical and behavioral effects in brain ischemia models. In the present studies, we examined whether fluid-percussion-induced traumatic brain injury (TBI) causes release of PAF and whether pretreatment with BN 52021 can modify outcome. Pentobarbital-anesthetized rats were subjected to standardized trauma (2.85 atm). In one experiment, brain tissue from the trauma region was removed 5 min after injury. PAF levels were quantified by rabbit platelet aggregation; specific PAF antagonists and HPLC purification were used to confirm that the bioactive material was PAF. After TBI, PAF content was increased (7.9 ± 1.7 vs. 4.7 ± 2.4 fmoles/sample, each n=4). In other experiments, animals were randomly (n=21) assigned to treatment with BN 52021 (1 mg/kg or 10 mg/kg) or equal volume vehicle, given i.v. 15 min pretrauma and 2 h posttrauma. Animals treated with BN 52021 showed a significant, dose-related improvement in behavioral recovery at 2 weeks posttrauma. Taken together, these data suggest a potential role for PAF in the pathophysiology of TBI.

444.3

DYNORPHIN A ATTENUATES NMDA RECEPTOR-MEDIATED CORTICAL NEURONAL INJURY IN VITRO. [1]D.W. Choi, K. Rose*, J.H. Weiss and [2]A.I. Faden. [1]Dept. of Neurology, Stanford Univ. Med. Sch., Stanford CA 94305 and [2]Dept. of Neurology, Univ. California, San Francisco CA 94121.

Dynorphin A 1-17 (Dyn) is potently neurotoxic in vivo and may play a role in the pathogenesis of traumatic central nervous system injury. Whether exposure to Dyn injures neurons directly, or indirectly (for example through vasoconstriction), has not been established. We investigated Dyn A for neurotoxic efficacy in murine cortical cell cultures, and found that 24 hr exposure to Dyn alone, at concentrations up to 60-100 μM, produced little neuronal or glial injury.

In fact, addition of 60 μM Dyn to these cultures actually substantially reduced the neuronal degeneration induced by exposure to 20 μM NMDA for 24 hr. In one experiment, cultures exposed to NMDA alone developed by the next day a media lactate dehydrogenase signal of 283 +/- 16.5 U/ml (SEM, n = 4) over wash control; sister cultures exposed to NMDA in the presence of 60 μM Dyn showed a signal of only 27.3 +/- 15.4 U/ml (n = 4) (different at $p < 0.001$). These data support the idea that the neurotoxicity of Dyn in vivo is indirectly mediated, and furthermore suggest that high concentrations of Dyn can actually reduce NMDA receptor-mediated neurotoxicity.

444.4

PRETREATMENT WITH MK-801 REDUCES BEHAVIORAL DEFICITS FOLLOWING TRAUMATIC BRAIN INJURY (TBI) IN RATS. B.G. Lyeth, L.W. Jenkins, R.J. Hamm, L.L. Phillips, C.E. Dixon, J.J. Yao*, H.F.Young*, J.F. Stubbins*, G.L. Clifton* and R.L. Hayes. Division of Neurosurgery, Medical College of Virginia/Virginia Commonwealth University, Richmond, VA 23298

Several lines of evidence suggest that excitatory agonist-receptor interactions at muscarinic (Lyeth et al., Brain Research 452:39, 1988) and NMDA (Hayes et al., J. Neurotrauma 5:287, 1988) sites contribute to pathophysiological consequences of TBI. The present study examined the effects of the non-competitive NMDA antagonist, MK-801 on behavioral deficits associated with fluid percussion TBI in the rat.

Rats (n=10/group) were administered either saline or MK-801 (0.1, 0.3 or 1.0 mg/kg, i.p.) 15 min, and Metofane 5 min prior to moderate fluid percussion TBI. Rats were ventilated as necessary following injury. Rectal temperature was monitored prior to and for 40 minutes after injury. Brain temperature was monitored on 5 additional uninjured rats treated with 0.3 mg/kg MK-801. Behavioral assessments were made for 5 days after injury. Treatment with 0.3 mg/kg MK-801 resulted in significantly less weight loss and significantly reduced beam-balance and beam-walking deficits. MK-801 did not significantly alter rectal or brain temperature. These data suggest that NMDA agonist-receptor interactions contribute to the pathophysiology of brain injury. Supported by NS 21458, NS 12587 and Merck Sharp & Dohme.

444.5

MK801 NEUROPROTECTIVE EFFECTS IN A RODENT MODEL OF PEPTIDE INDUCED SPINAL CORD INJURY: A HISTOLOGICAL STUDY D.D. Rigamonti, A. Martinez-Arizala, R.F. Genovese, J.W. Holaday, and J.B. Long. Dept Med Neurosci, Walter Reed Army Inst Res, Wash, DC 20307.

Dynorphin A 1-17 (DYN) causes neuropathological changes associated with hindlimb paralysis, nociceptive loss and spinal cord ischemia when injected into the lumbar cistern. Since NMDA receptors have been implicated in the pathophysiology of ischemic CNS injury, we examined the effects of MK801, a non-competitive NMDA receptor antagonist, on DYN-induced histopathological changes. Adult S-D rats were divided and injected intrathecally as: Group I-saline, Group II-DYN, and Group III-DYN+MK801. After neurological evaluation for 72 hours, the rats were perfused, the lumbosacral cord was removed, and serial cross-sections stained using H & E, Nissl, Kluver-Barrera and Bielschowsky techniques. Samples were evaluated by three blinded observers. Interrater agreement and differences between groups were statistically analyzed. Spinal tissue from I appeared normal while tissue from II exhibited lumbosacral cord necrosis. The injury was characterized by widespread ischemic cell changes, neuronal cell loss and axonal degeneration in the gray and adjacent white matter, with diffuse gliosis and cellular infiltration. Tissue from III exhibited small islands of necrotic tissue or slight ischemic changes, restricted to the gray matter. In addition, there was mild gliosis and edema. Thus, MK801 improved neurological and neuropathological outcome in DYN-treated animals.

MUSCARINIC AND NMDA RECEPTOR BLOCKADE REDUCES POST-ISCHEMIC EEG SPIKE FREQUENCY FOLLOWING TBI AND ACUTE SECONDARY ISCHEMIA. L. Jenkins, B. Lyeth, D. DeWitt, R. Hamm, L. Phillips, H. Young*, G. Clifton*, and R. Hayes. Division of Neurosurgery, Medical College of Virginia, Richmond, VA 23298.

Following mild traumatic injury (TBI) subsequent brain vulnerability to cerebral ischemia is enhanced (Brain Research 477:211,1989) and receptor related since combined muscarinic and NMDA receptor blockade can significantly reduce enhanced delayed neuronal death after TBI followed by acute or delayed cerebral ischemia (J Neurotrauma 5:303,1988). We examined the effect of muscarinic and NMDA receptor blockade on the frequency of post-ischemic EEG spike activity as one possible mechanism for neural protection. Wistar rats (250-300g) were subjected to mild TBI followed 1 hr later by 6 min of forebrain ischemia. Two groups (N=6/group) were examined, one without drug treatment and another group with simultaneous i.p. 1mg/kg scopolamine and 4mg/kg phencyclidine (PCP) 15 minutes prior to TBI. Drug treated rats (21.1 ± 0.8 spikes/min) demonstrated a 27% reduction in post-ischemic spike frequency compared to the untreated group (29.1 ± 0.9 spikes/min). Regenerative neuronal spike activity and post-ischemic calcium entry (J Cereb Blood Flow & Metabol 8:799, 1988) are known to be influenced by both NMDA receptor linked inward calcium currents and muscarinic receptor linked outward potassium currents (TINS 10:59,1987). Thus, neural protection by combined scopolamine and PCP in mild TBI followed by acute secondary ischemia may be related to receptor modulation of these Ca^{2+} and K^+ channel protein conductance states.

EFFECT OF PHENCYCLIDINE (PCP) ON CENTRAL CHOLINERGIC ACTIVITY FOLLOWING TRAUMATIC BRAIN INJURY (TBI). S.E. Robinson, E.K. Enters*, M.G. Posner*, S.D. Foxx*, R.M. Martin*, C.A. Gyenes*, and T.R. Davis*. Dept.of. Pharmacology & Toxicology, Medical College of Virginia, Richmond, VA 23298-0613.

TBI has been found to produce changes in acetylcholine (ACh) turnover at early times following injury (Saija et al., Brain Res. 452: 303, 1988). Because PCP, a noncompetitive NMDA antagonist, reduces some of the behavioral deficits following TBI (Hayes, R.L,et al,Soc. Neurosci. Abstr. 17: 1254, 1987), we examined the effect of treatment with PCP prior to TBI on ACh turnover in the dorsal hippocampus, frontal cortex, and caudate nucleus, areas containing cholinergic and excitatory amino acid innervation. ACh turnover rate (TR_{ACh}) was measured by a mass fragmentographic technique, which quantitated the relative incorporation of deuterium label from infused phosphorylcholine into ACh and choline. Male Sprague-Dawley rats (275-290 g) were surgically prepared under Equithesin anesthesia 24 h prior to injury, and were administered either saline or PCP (4mg/kg) i.p. 15 min and methoxyflurane anesthesia 5 min prior to injury (2.2 atm) or sham-injury. Rats were infused through the tail vein at a constant rate with $^2H_9$-phosphorylcholine (15 μmol/kg/min) beginning 3 min after TBI and euthanized by focussed microwave irradiation (1.2 sec, 9.8 kW) 12 min after TBI. TBI reduced dorsal hippocampal TR_{ACh} to 22% of sham control. Moreover, PCP pretreatment prevented a significant reduction in TR_{ACh} after TBI. TR_{ACh} was not significantly affected in the other 2 areas. These results suggest that activation of NMDA receptors may lead to changes in cholinergic activity following TBI. These changes may contribute to long-term behavioral changes that occur after TBI. (Supported by NS 24413 and NS 07288).

TRAUMATICALLY INDUCED BLOOD-BRAIN BARRIER DISRUPTION: A CONDUIT FOR THE PASSAGE OF CIRCULATING EXCITATORY NEUROTRANSMITTERS. J.T. Povlishock and B.G. Lyeth Depts. of Anatomy and Surgery, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298

In rodent, traumatic brain injury (TBI) results in the release of excitatory neurotransmitters that participate in pathological agonist receptor interactions (Brain Res. 542:39,1988). It has been assumed that all excitatory neurotransmitters are derived from synaptic terminals, however, it is possible that some reach the brain via a compromised-blood-brain barrier (BBB). To test this, BBB status was assessed in brain regions previously linked with functional change. Rats were subjected to mild TBI and were processed for the immuno cytochemical detection of various circulating immunoglobulins and neurotransmitters normally excluded by the BBB. TBI resulted in the passage of immunoglobulins and excitatory amino acids such as glutamate into the interstices of both the cerebral cortices and dorsal hippocampi. These substances crossed the BBB without any overt endothelial change. Their passage was transient and interestingly was blunted by the administration of superoxide dismutase. Supported by NS-20193

RAPID GENOMIC RESPONSE TO LOCAL INJURY IN HIPPOCAMPAL DENTATE GRANULE CELLS. A.J. Cole, P.F. Worley, and J.M. Baraban. Dept. of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Recent studies suggest that brain injury elicits a rapid increase of c-fos protein in both neurons and glia. In our studies of the regulation of c-fos and other immediate early genes in brain, we noted that sham Hamilton syringe injections frequently elicited an increase in mRNA levels. To study this genomic response to injury in a systematic fashion, we determined that while introduction of fine glass recording microelectrodes had no effect, penetration of the hippocampus with a 28-gauge stimulating electrode reliable caused an increase in c-fos and zif/268 mRNAs. The increase is apparent as early as 5 minutes after injury, but not after 1 minute. Increased mRNA levels in the hippocampus are not produced by limiting the injury to overlying cortex, or to other brain areas such as cerebellum or striatum. By contrast, in a number of experiments, we noted widespread increases in these mRNA levels throughout ipsilateral, but not contralateral, cortex, regardless of the site of injury. These findings indicate that direct intracerebral injections may be sufficient to activate a neuronal genomic response. Moreover, this type of simple penetrating head injury offers a model system to elucidate the mechanisms of both local and hemispheric genomic responses.

Pressure Induced Trauma in Cell Cultures. E.J. Murphy* and L.A. Horrocks. Department Physiological Chemistry, The Ohio State University, Columbus, OH 43210.

In order to develop a cell culture model for spinal cord injury, mechanical trauma is produced by an increase in atmospheric pressure. A short pressure duration results in reacylation of released fatty acids (FA). The injury becomes sustainable by increasing the pressure duration to 3 min. In the following experiments pressure was varied (duration 3 min) between 5, 10, 15 and 20 atm. Recovery times of 1 and 10 min were used to monitor reacylation. In ROC-1 oligodendroglia cultures the maximum FA increase (2.7 fold over controls) occurs at 5 atm 10 min. At 15 and 20 atm the 1 min levels are greater than the 10 min values indicating reacylation. Arachidonic acid (20:4 n-6) was increased 9 fold over controls at 5 atm 10 min. In human umbilical vein endothelial cells (HUVE) the greatest FA release (2.3 fold over controls) occurs at 15 atm 1 min. FA levels return to normal by 10 min. 20:4 n-6 is increased 13 fold over controls at 5 atm 1 min and returns to normal by 10 min. In both cultures the primary FA released are 16:0, 18:0 and 18:1, and to a lesser extent 18:2 and 18:3 (n-6 and n-3). In ROC-1 cells a sustainable injury was produced, however, in HUVE cells only a transient perturbation of the membrane occurs. Support from NS-10165 and Doerenkamp-Zbinden Foundation.

THE EFFECT OF A DIRECT CURRENT FIELD ON CHRONICALLY INJURED MAMMALIAN SPINAL CORD AXONS. M.G. Fehlings * C.H. Tator (SPON: E. Theriault) Playfair Neurosci. Unit, Univ. Toronto M5T 2S8

Recent studies indicate that direct current (DC) fields promote the recovery of acutely injured axons; however, the effect of DC fields on chronically injured spinal axons is unknown. In this study, DC stimulators (14 uA; cathode caudal to lesion) were implanted in 30 rats (15 with functioning stimulators; 15 with sham units) 4 weeks after a 53 g clip injury of the T1 cord. Hindlimb function was assessed by the inclined plane method. At 12 weeks after injury, motor and somatosensory evoked potentials were recorded and HRP was introduced into the T6 cord. Labeled cells were counted in the brainstem and motor cortex and axons were counted at the injury site.

The inclined plane scores, evoked potentials, and axon counts of treated and control rats were similar ($p>0.05$). However, counts of HRP-labeled neurons were significantly higher in treated rats in the red nucleus (96.8 ± 29.5 vs 24.6 ± 7.5; $p<0.002$); reticular formation (46.8 ± 21.3 vs 6.1 ± 2.0; $p<0.01$) and raphe nuclei (83.8 ± 22.1 vs 15.8 ± 4.8; $p<0.001$). Thus, although ineffective in promoting recovery in chronic injuries, DC stimulation does upregulate retrograde axonal transport, as evidenced by increased labelling of neurons by HRP. This may be a mechanism by which DC fields promote recovery after acute injuries.

HEAD INJURY AND BRAIN ENERGY CONTENT:AN IN VIVO ASSESSMENT BY INTEGRATED MRI/31-P MAGNETIC RESONANCE SPECTROSCOPY. M.Rango*, R.E.Lenkinski*, T.Gennarelli*, W.Alves*, C.McGinnis*, and R.I.Grossman*(SPON:J.Saunders). Dept. of Neurology, Radiology, and Neurosurgery, Univ.of Pennsylvania, Philadelphia, PA 19104.

We have studied the content of brain phosphorus compounds in humans after acute head injury. 13 patients were evaluated at a mean interval of 14 days after trauma and follow-up examination (more than 30 days after injury) was carried out in eight of these cases. Most of the patients were on assisted ventilation. All MRI/MRS studies were performed on a 1.5 T MR Signa scanner equipped with the standard spectroscopic research accessory. Dress localization was employed in eight cases and a 3D-CSI sequence which yielded spectra from 4 cmx4 cmx4 cm voxels in the others. Spectra were processed off-line using a computer program written specifically for the anlysis of in vivo spectra.

In large focal insults the PCr/Pi ratio was reduced in the affected side of the brain. Moreover, in some of these cases little or no observable ATP resonances were detectable. Abnormal spectra in hyperventilated patients exhibited a more normal appearance when the patients were returned to unassisted ventilation. It is not clear, at this point, whether these changes are a reflection of a recovering brain function or are a direct result of the ventilation state of the patient. We are currently extending our studies into the first 48 hours.

NON-OLIVOCOCHLEAR CHOLINERGIC PERIOLIVARY CELLS. J.C. Adams, Dept. of Otolaryngology and Comm. Sci., Med. Univ. of S.C., Charleston, S.C. 29425.

A modified Koelle method was used to histochemically localize esterase and in the same brainstem sections of cat, choline acetyltransferase was visualized using immunocytochemistry. This procedure shows that the two enzymes are present in all cells that show the presence of either. Olivocochlear cells show markedly stronger esterase staining than cranial motor nuclei cells. This would be expected based on the assays of Godfrey and his colleagues. The present experiments also show cells that express both cholinergic enzymes but are not olivocochlear cells. These cells are small multipolar cells in the rostral portion of the lateral nucleus of the trapezoid body and have not previously been recognized as a specialized group. Their location and morphology are distinctly different from olivocochlear cells. They also differ by showing very weak esterase staining but show transferase immunostaining that is comparable to that of olivocochlear and cranial motor nuclei cells. Their location in a region where all or nearly all cells project to the cochlear nucleus suggest that these cells may contribute cholinergic descending inputs that nucleus.

445.2

ELECTRICAL STIMULATION OF THE INFERIOR COLLICULUS AT LOW RATES PROTECTS THE COCHLEA FROM AUDITORY DESENSITIZATION. R. Rajan*. (SPON: D.R.F. Irvine). Department of Physiology, University of Western Australia, W.A. 6009, Australia.

Electrical stimulation of the inferior colliculus (IC) contralateral to a cochlea presented a loud sound exposure significantly reduced temporary threshold shifts (TTS) in cochlear sensitivity caused by the exposure. Intra-cochlear perfusion of Hexamethonium blocked this effect, with a time course that paralleled the drug's action on both the classical cochlear effects and the recently-demonstrated TTS effects of electrical stimulation at the brainstem of the efferent pathway, the crossed olivocochlear bundle (COCB). The protective IC effects were obtained at much lower stimulation rates than required with COCB stimulation at the brainstem. Ipsilateral IC stimulation could also protect the cochlea, but only by smaller amounts and at higher rates. Thus the IC appears to provide a strong influence that modulates the excitability levels of the olivocochlear nuclei in the brainstem. Protective effects appear to be exerted by both crossed and uncrossed OCB, and may be due solely to the medial olivocochlear system of efferent fibres that terminate on outer hair cells in the cochlea.

SHAPE, SIZE, AND ORIENTATION OF THE DENDRITES OF THE COCHLEAR NUCLEUS NEURONS IN GUINEA PIG. L. I. Terr, W. Pimprapaiporn,* and J. K. Moore. Lab. of Neuroanatomy, House Ear Institute, Los Angeles, CA, and Dept. of Anatomical Sciences, SUNY at Stony Brook, NY.

This report provides quantitative and qualitative data on three-dimensional tracing of dendritic trees of the cochlear nucleus neurons and also qualitative 3-D study of them in three guinea pigs. The sections were from tissue blocks stained by the Golgi-Hortega technique and embedded in celloidin. A neuron tracing computer system to reconstruct the shape of the neurons as revealed by metallic impregnation was used. Dendrites and soma contours were traced and entered into a computer with a vector display processor. To characterize the reconstructed neurons as bushy, stellate, giant, granular, or octopus, we evaluated the following: total length of the dendrites; volume of the neurons, including that of the dendrites; cross-sectional area of the soma; number of main dendrite trees originating from the soma; number of the dendritic appendages; and number of branch points. The performed statistical analysis to determine the means and standard deviations of these parameters. We also studied the orientation of the dendrites in relation to the surface of the cochlear nucleus and the root of the cochlear nerve. Findings could be applied to anatomical studies of the pathological changes of dendritic networks in deafness or to physiological studies of the cochlear nucleus. A mathematical neuron model could be made to explore such problems as the relation between the time course and the soma-dendritic location of synaptic input.

A POPULATION STUDY OF THE COCHLEAR NUCLEUS AND THE AUDITORY NERVE: RESPONSES TO SPEECH SOUNDS. D.O. Kim, S.O. Chang and J.G. Sirianni, Div. Otolaryngol., Dept. Surgery and Neuroscience Program, University of Connecticut Health Center, Farmington, CT 06032

We conducted population studies of neurons of the posteroventral and dorsal cochlear nucleus (PVCN & DCN) and the auditory nerve fibers in decerebrate cats investigating responses to vowels [ɛ] and [a], and pure tones. Our goal is to elucidate how these signals are encoded in the auditory nerve fibers and how they are further processed in the PVCN and DCN. Several types of response profiles are computed: (1) driven discharge rate vs individual neuron's characteristic frequency (CF); (2) d' vs neuron's CF, where d' is a measure of detectability of rate increase a la signal detection theory; (3) spatially-weighted Fourier components of temporal discharge patterns vs neuron's CF a la Young & Sachs' (1979) "ALSR". We find that the response profiles derived from the mean driven rate and d' are generally similar. Our data indicate that the PVCN and DCN neurons' response profiles are different from those of the nerve fibers as follows. The response profiles derived from the driven rate of the primary nerve fibers with high spontaneous rates are severely degraded at 70 dB SPL by saturation of discharge rate limited to about 200 spikes/sec. In contrast, the PVCN and DCN neurons' response profiles are little affected by rate saturation. Some of the PVCN and DCN neurons' discharge rates reached 400-500 spikes/sec at 70 dB SPL. Our observations support the hypothesis that the PVCN and DCN neural mechanisms transform the primary nerve fiber representations of the vowel spectrum into enhanced representations. We postulate that a possible such mechanism is lateral inhibition in the cochlear nucleus. [Supported by a grant R01 NS23693 from NIH and grants from Univ. Conn. Health Center]

INTERAURAL INTENSITY CODING: AN INTRACELLULAR ANALYSIS USING THE BRAIN SLICE PREPARATION. D. H. Sanes. Depts. Otolaryngol., Physiol. & Biophysics, NYU Med Ctr, New York, NY 10016.

One way in which animals localize sounds in the azimuth is the intensity differences at the two ears. Neurons in the lateral superior olive (LSO) encode this cue by integrating the synaptic drive from ipsilateral excitatory and contralateral inhibitory connections. This synaptic integration has been analyzed in 500 um brain slices through the gerbil superior olive. Intracellular recordings from LSO neurons were observed following the application of independent or conjoint electrical stimuli to the excitatory afferent and inhibitory afferent pathways. Stimulation of ascending fibers from the ipsilateral cochlear nucleus reliably evoked EPSPs and action potentials. Stimulation of the medial nucleus of the trapezoid body (MNTB) consistently evoked IPSPs. MNTB stimulation suppressed synaptically evoked action potentials. When stimulus amplitude was increased to the excitatory pathway, it was generally found that a greater MNTB stimulus was necessary to suppress the action potential. These results confirm that the LSO integrates evoked EPSPs and IPSPs to encode interaural intensity.

SELECTIVE LOSS OF GABA NEUROTRANSMISSION IN THE INFERIOR COLLICULUS OF AGED FISCHER-344 RATS. A. Raza* and S.P. Arneric (SPON: W.H. Cline), Department of Pharmacology, Southern IL. University School of Medicine, Springfield, IL 62702.

Immunocytochemical studies have suggested an age-related loss of GABA-containing cells in the central nucleus of the inferior colliculus (ICC), a critical auditory nucleus (Caspary & Lawhorn, Neurosci. Abst.13:150.7, 1987). This study sought to determine: 1) Is there an age-related, specific decrease in Ca^{2+}-dependent release of GABA in the ICC? 2) If so, is the GABA impairment regionally specific? Amino acid concentrations were determined by HPLC. Release of endogenous GABA, glutamate (Glu), aspartate (Asp) and ^{3}H-acetylcholine (^{3}H-ACh) was measured from micropunches (1.5 mm dia x 0.5 mm thickness) of the ICC and compared with rostral ventrolateral medulla (RVL) and somatosensory cortex (SSCx) in young (3-7 mo.) and aged (24-26 mo.) Fischer-344 rats. GABA neurotransmission is involved in processing sensory information in these regions. Depolarization with 35 mM K^+-evoked release of GABA (200% of basal), Glu (215%), Asp (163%) and ^{3}H-ACh (309%) which was substantially Ca^{2+}-dependent ($n = 12$, $p < 0.05$). Basal and K^+-evoked release of GABA in the ICC of aged rats was reduced to 32-43% of young, ($n = 8$, $p < .05$), while other transmitters were unaffected. In addition, there was a corresponding 30% reduction in tissue levels of GABA ($p < .05$) while other amino acids were unaffected. This age-related GABA deficit was not observed in RVL or SSCx. CONCLUSIONS: 1) These data support the idea that GABA, Glu, Asp and ACh serve a neurotransmitter role in the ICC; 2) These results support and extend the finding of Caspary & Lawhorn (1987) that GABA neurotransmission is selectively impaired in ICC of aged Fischer-344 rats; 3) Loss of inhibitory GABA neurotransmission in ICC may be one of the neurochemical correlates to the deficits in auditory perception associated with presbycusis. (Supported by the Central Research Committee, Southern IL Univ. School of Medicine and NIA N01-AG-2104)

445.7

DIFFERENTIAL GABAERGIC INFLUENCE ON THE ORIGINS OF THE CORTICAL AND SUBCORTICAL PROJECTIONS OF THE PRIMITIVE MEDIAL GENICULATE. S. B. Frost*, B. N. Baker* and R. B. Masterton (SPON: J. C. Smith). Dept. Psychology, Florida State Univ., Tallahassee, FL 32306.

Previous experiments using retrograde degeneration and orthograde and retrograde axonal transport methods have shown that in a very neurologically primitive mammal, Monodelphis domestica, less than 15% of the cells in the MG project to neocortex while 67% to 80% project to lateral amygdala and putamen. The dominant subcortical projection originates in the caudal 2/3 of MG, while the cortical projection originates in the rostral 1/3.

Conventional receptor binding techniques show that the density of GABA-A receptors in MG parallels this caudal-rostral difference in subcortical projections while mACh and glycine receptors do not. However, anti-GABA immunocytochemistry reveals very few (<1%) GABAergic neurons in MG and these are scattered throughout its rostral-caudal extent. This mismatch of intrinsic GABAergic neurons and GABA-A receptors suggests that most of the GABA-A receptors in caudal MG, those modulating the subcortical pathway, may be accommodating extrinsic sources of GABAergic input.
Supported by NIH-NINCDS # NS7726.

GLYCINERGIC AND GABAERGIC AUDITORY BRAIN STEM NEURONS AND AXONS IN THE MUSTACHE BAT. G.D. Pollak and J.A. Winer, Dept. of Zoology, University of Texas, Austin, TX 78712, and Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

Neurochemically distinct pathways were studied in the bat, *Pteronotus parnellii*, with antisera directed against glycine conjugated to glutaraldehyde or glutamic acid decarboxylase (GAD) or gamma aminobutyric acid (GABA) to identify neurons and axon terminals (puncta). There are four main findings. The first is that the medial nucleus of the trapezoid body (MNTB) has predominantly Gl+ neurons. The second finding is that there is a pronounced gradient of increasing immunoreactivity along the caudal-to-rostral axis of MNTB, i.e., along an isofrequency contour. There is also a gradient of Gl+ axons and puncta along the rostro-caudal axis of the lateral superior olive (LSO). Since the LSO receives inhibitory input from the MNTB, it is possible that these gradients establish an orderly distribution of inhibitory thresholds of E-I neurons in LSO. If so, this may be the origin of the inhibitory gradients observed for E-I neurons in the 60 kHz contour of the mustache bat's inferior colliculus. The third finding is that several of the principal auditory nuclei are characterized by the predominance of their immunoreactivity. The MNTB is predominantly Gl+, whereas the LSO and dorsal nucleus of the lateral lemniscus are predominantly GABA+, as are inferior colliculus cells. The fourth finding is that distinct Gl+ and GABA+ axonal fascicles can be traced from the trapezoid body into the 60 kHz contour of the inferior colliculus. This suggests that parallel, putatively inhibitory glycinergic and GABAergic pathways converge within the central nucleus of the inferior colliculus.
Supported by RO1 NS 27286-06 (GDP) and RO1 NS16832-09 (J.A.W.). We thank R. Wenthold for antisera to glycine and GABA.

ORTHOGONAL TOPOGRAPHICAL REPRESENTATION OF CHARACTERISTIC AND BEST MODULATION FREQUENCY IN THE INFERIOR COLLICULUS OF CAT. G. Langner and C. E. Schreiner*. Zool.Inst.,THD, Schnittspahnstr.3 ,61 Darmstadt, FRG; *Coleman Lab., UCSF, San Francisco, USA

Three-dimensional reconstruction of the location of single and multiunit recordings revealed that the 30-40 neuronal laminae in the central nucleus of the inferior colliculus (ICC) do not -as often assumed- correspond to isofrequency planes with all units most sensitive to about the same characteristic frequency (CF). Instead CF increases roughly from medial to lateral on a given lamina by 10-16%, indicating a tonotopic fine structure.

In addition units in the ICC are tuned to temporal envelope modulations (BMF) up to 1000Hz (Langner,G. and Schreiner, C.E, *Neurophys*. 60: 1799, 1988). BMF was also found to be mapped in "isofrequency planes" with highest BMFs at the lateral-caudal border of the ICC (Schreiner,C. and Langner,G. *Neurophys*. 60: 1823, 1988).

New results verify these findings and indicate that CF and BMF are represented orthogonally: along each line of constant CF on a frequency-band lamina neurons seem to be tuned to a range of BMFs. Finally, response maps obtained by stimulation with a harmonic complex support the conclusion that these neurons are involved in coding periodicity pitch. These findings do not support a 'central spectrum' hypothesis as required for pattern models of pitch perception. *Supported by DFG, SFB 45.*

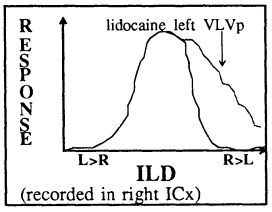
INHIBITION SHAPES RESPONSES TO INTERAURAL LEVEL DIFFERENCES IN THE INFERIOR COLLICULUS OF THE BARN OWL.

Ralph Adolphs, Div. of Biology 216-76, Caltech, Pasadena, CA 91125.
Terry T. Takahashi, Institute of Neuroscience, University of Oregon, OR 97403.

Barn owls use interaural differences in sound pressure level (ILD) to compute location of the source in elevation. The external nucleus of the inferior colliculus (ICx) maps auditory space. Elevationally restricted auditory receptive fields are coded for by non-monotonic neuronal responses to ILD.

ICx obtains polysynaptic input from lower brainstem nuclei. Information about ILD is carried in an anatomically and functionally distinct pathway into ICx. Important lower brainstem nuclei of the ILD stream include nucleus angularis and nucleus ventralis lemnisci lateralis, pars posterior (VLVp).

We injected the local anesthetic lidocaine hydrochloride focally into VLVp while recording neuronal responses to varying ILD in the contralateral ICx. VLVp was found to contribute functional inhibition at ILDs favoring the ear ipsilateral to the side on which responses were recorded in ICx (shown schematically in the figure). This result is consistent with the known hodology and with the functional response properties of VLVp. Preliminary results support the hypothesis that this inhibition is established directly by VLVp in the lateral shell of the central nucleus of the inferior colliculus.



R.A. is a Howard Hughes Medical Institute Fellow.

DYNAMIC CHANGES IN RECEPTIVE FIELDS OF BARN OWL AUDITORY-MIDBRAIN NEURONS. H. Wagner. Max-Planck-Institut für biologische Kybernetik, Spemannstrasse 38, D-7400 Tübingen, FRG

The receptive field has been a fruitful concept for characterizing the response of neurons in various stimulus dimensions. Auditory neurons in the barn owl's inferior colliculus have spatial receptive fields (Knudsen E.I. and M. Konishi, *J. Neurophysiol.* 41: 870 (1978)). The deviation of a sound source from the midsagittal plane, azimuth, is coded by the interaural time difference (ITD). I analysed the temporal properties of the ITD- and frequency tuning of these neurons, a hitherto neglected aspect of their response characteristics.

Standard extracellular recording techniques were used to record the ITD-tuning of 256 neurons and the frequency tuning of 100 neurons to dichotic stimulation with noise or tone bursts of 100 ms duration. The ITD- and frequency selectivity of the neurons in the inferior colliculus is broad first and improves to a final value with time. ITD-selectivity was higher in the interval from 21-40 ms after stimulus onset than in the interval from 1-20 ms in 87% of the neurons. The improvement amounted to a mean value of 40%. An improvement of frequency tuning was found in 67% of the cases.

It is concluded that a) dynamic improvement is due to a process within the network computing ITD- and frequency selectivity, possibly mediated by GABAergic inhibition (Fujita and Konishi, *Soc. Neurosci. Abstr.* 14: 1096 (1988)), b) the spatial tuning of single neurons is higher than previously thought, and c) dynamic improvement may be an adaptation to detect motion acoustically.

445.12

PHYSIOLOGY AND TOPOGRAPHY OF NEURONS WITH MULTIPEAKED TUNING CURVES IN CAT PRIMARY AUDITORY CORTEX. M.L. Sutter* and C.E. Schreiner (SPON. P.Leake) Coleman Laboratory and Bioengineering Group, University of California, San Francisco CA 94143-0526.

In previous studies, multiple-unit recordings revealed a systematic change of the sharpness of tuning along the iso-frequency domain of cat primary auditory cortex (AI).The most sharply tuned unit clusters were found in the central 2 mm of iso-frequency stripes. Approaching the dorsal and ventral limits of AI, neuronal responses became progressively more broadly tuned. This study investigated the properties and distribution of single units with multipeaked frequency tuning curves (FTCs) relative to the observed gradient of sharpness of tuning obtained for multiple unit responses. Single unit locations were roughly classified as 'central' (located within 2 mm of the area containing the most sharply tuned responses of AI), 'dorsal', or 'ventral'. In the dorsal area, 35% of encountered single units had multipeaked FTCs, i.e., FTCs with more than one distinct threshold minimum. In the central area, 3% of the studied neurons had multipeaked FTCs. No multipeaked units were encountered in the ventral area.

Eighty percent of the studied multipeaked FTCs had two peaks. The frequency separation of minima in multipeaked FTCs ranged from 0.36 to 2.8 octaves (mean separation: 0.77±0.5 octs.). Strong inhibition was often found between adjacent peaks. Disparate response latencies as great as 19 ms could be seen between two peaks of the same unit. Response latencies 30 dB above threshold were 22±8 ms. It is concluded that neurons with multipeaked FTCs represent a physiologically distinct neuron response subclass in the dorsal AI. INVERTEBRATE LEARNING AND BEHAVIOR I

446.1

INHIBITORY CONTROL OF IDENTIFIED SEROTONERGIC NEURONS IN THE LOBSTER. P.M.Ma*, W.A.Weiger*, and E.A.Kravitz. Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

The injection of serotonin into freely moving lobsters produces a posture resembling that seen in dominant animals in a hierarchy; injection of octopamine produces an opposing posture resembling that of subordinate animals. We have been examining the role of amines in the production of these postures by intracellular recording from identified aminergic neurons in the lobster ventral nerve cord. Immunocytochemical methods have identified over 100 serotonergic neurons in the lobster central nervous system. Our current focus is on two pairs of large serotonergic neurons, one each in the first abdominal (A1) and fifth thoracic (T5) ganglia. These cells are spontaneously active and their rate of firing is regulated both by an endogenous oscillatory mechanism and by external synaptic input. In other systems, inhibition appears to be important in suppressing certain behaviors, while removal of inhibition results in the emergence of new behaviors. Therefore, our recent efforts have centered on identifying the nature of the inhibitory inputs to the A1 serotonin cells. Three neurotransmitters inhibit these cells: GABA, octopamine, and serotonin. GABA mediates a rapid, short-term inhibition of the A1 serotonin cells; its role will be addressed more fully in the next abstract. Exogenous octopamine reversibly decreases the firing rate of the A1 serotonin cells while phentolamine, an octopamine blocker, increases the firing rate. The latter result suggests the presence of tonic octopaminergic inhibition *in vivo*. Octopamine acts independently of the GABAergic inhibitory system, and its effects appear to be mediated by a depletable second messenger. Exogenous serotonin slows the firing rate of the A1 serotonin cells, indicating a possible autoinhibition of the cells by released serotonin. Inhibitory control of these cells therefore appears to be a complex process involving rapidly acting short-term as well as slowly acting long-term components. (Supported by NIH.)

446.2

GABAERGIC INHIBITION OF IDENTIFIED LOBSTER SEROTONERGIC NEURONS. W.A.Weiger*, P.M.Ma*, and E.A.Kravitz (SPON: M.K.Worden). Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

Inhibition plays an important role in the control of behavior. Results in several systems suggest that inhibitory neurons suppress certain behaviors, and a decrease in activity of such neurons may release previously inhibited behaviors. Our recent efforts have focused on the nature of the inhibitory synaptic input to the pair of large serotonin cells in the first abdominal (A1) ganglion of the lobster. These A1 serotonin cells promote the adoption of a posture which resembles that seen in dominant animals in a hierarchy. In the previous abstract, three neurotransmitters were identified as inhibitory to these cells. Two of these, octopamine and serotonin, were discussed in the previous abstract; the third, GABA, will be the subject of the current abstract. Exogenously applied GABA reversibly slows the firing rate of the A1 serotonin cells, even in the presence of low Ca^{++}/high Mg^{++} saline. Picrotoxin, a GABA antagonist, acts in a reversible manner to cause the disappearance of all inhibitory post-synaptic potentials (IPSP's) recorded from the A1 serotonin cell somata and to produce a large increase in the firing rate of the cells. These data suggest that GABAergic neurons provide direct inhibitory inputs to the A1 serotonin cells and account for the IPSP's which can be detected in the soma. Lesion studies suggest that neurons located in the third abdominal (A3) ganglion are responsible for the production of most of the IPSP's seen in the A1 serotonin cells. These A3 neurons may be GABAergic inhibitory neurons or excitatory neurons which act through GABAergic inhibitory interneurons in the A1 ganglion. In our future work, we plan to find and record from the A3 inhibitory neurons and to investigate the inhibitory inputs to the A1 serotonin cells in lobsters of known position in a dominance hierarchy. We will test the idea that greater inhibition of these cells is found in subordinate lobsters, and that in dominant lobsters these cells show a lesser degree of inhibition. (Supported by NIH.)

446.3

CHARACTERIZATION OF SPECIFIC EARLY PROTEINS INDUCED BY 5-HT AND cAMP DURING ACQUISTION PHASE OF LONG-TERM FACILITATION IN *APLYSIA* SENSORY NEURONS. A. Barzilai, T.E. Kennedy, J. D. Sweatt and E. R. Kandel. HHMI, Columbia, N. Y., N.Y. 10032.

Induction of long-term memory for sensitization and long-term presynaptic facilitation by 5-HT and cAMP in sensory neurons is dependent on active transcription and translation during the acquisition phase, the 1.5-hour period during which 5-HT is present. To gain insight into these long-term events, we have focused initially on the earliest detected transcriptional changes induced by 5-HT and cAMP. Analysis of ^{35}S-methionine incorporation into proteins using analytical 2-D gels indicate that 5-HT rapidly induces transcriptionally-dependent changes in 15 proteins, within 15 to 30 minutes. These changes are transient, and subside within 1 to 3 hours. The same proteins were also induced by cAMP, suggesting that the induced genes might bear a cAMP recognition element. In these several features -- rapid and transient induction, transcriptional dependence, and requirement for a second messenger -- these proteins resemble the immediate early gene products induced in vertebrate cells by growth factors. To test this idea and to explore the regulatory and effector roles of these proteins in the induction of long-term sensitization, we have obtained partial amino acid sequence of three *Aplysia* early proteins using the method of Kennedy et al. (*Proc. Natl. Acad. Sci. USA*, 1988), and are attempting to obtain cDNA clones corresponding to the proteins.

446.4

A PROTEIN IN *APLYSIA* SENSORY NEURONS THAT INCREASES IN BOTH LEVEL OF PHOSPHORYLATION AND RATE OF SYNTHESIS DURING FACILITATION. K. Wager-Smith*, A. Barzilai, J.-F. Brunet*, E.R. Kandel, J.D. Sweatt. Columbia Univ. NY.,NY.

Short-term facilitation (STF) of *Aplysia* sensory-motor synapses (as induced by a 2 minute application of 5-HT) differs from long-term (24 hour) facilitation (LTF) (as induced by a two hour application of 5-HT) in that LTF requires protein and RNA synthesis. To study the basis of this macromolecular synthesis dependence we are characterizing proteins that have been shown by Barzilai et al. (*Neuron*, 1989) to change in their rate of synthesis during the acquisition phase of LTF. One of the first proteins to go up in synthesis (or a protein that migrates to the same spot on 2D gels: pI = 5.0, M.W. = 28 KD) also increases in its level of phosphorylation after two hours of 5-HT treatment. This delayed phosphorylation increase is distinct from the previously described, more rapid phosphorylation changes that occur in 17 other proteins (Sweatt and Kandel, *Nature*, 1989). Preliminary subcellular fractionation studies suggest that this protein is present in the nucleus. Perhaps this protein contributes to the switch from STF to LTF by detecting the 5-HT-stimulated kinase activity at a critical period after the protein's synthesis. Alternatively, the increase in phosphorylation might simply reflect the increase in the protein's mass. To further characterize this protein, we have obtained partial amino acid sequence and are now attempting to clone the corresponding cDNA.

446.5

CHARACTERIZATION OF CHANGES IN LATE PROTEIN AND mRNA EXPRESSION DURING THE MAINTENANCE PHASE OF LONG-TERM SENSITIZATION. T.E. Kennedy, D. Kuhl*, A. Barzilai, E.R. Kandel, and J.D. Sweatt. HHMI and Columbia Univ., NY, NY 10032.

Maintenance of long-term sensitization in *Aplysia* is associated with a sustained increase in the incorporation of ^{35}S-methionine into four proteins. Two of these proteins, #407 and #1603, show a similar change of expression in isolated clusters of pleural sensory neurons when 5-HT, rather than tail shock, is used to produce long-term facilitation. The expression of these proteins is blocked by inhibitors of macromolecular synthesis present during the period of 5-HT application. We have cloned the cDNA corresponding to protein #407 using partial amino acid sequence, and found no significant homologies in sequence data bases. By contrast, partial amino acid sequence, pI and M.W., indicate that protein #1603 is the *Aplysia* homologue of GRP78/BiP. *Aplysia* BiP also changes its expression in pleural sensory neuron clusters following application of cAMP or heat shock to 37° C. BiP is thought to function as a chaperon of newly synthesized proteins in the lumen of the E.R. This is consistent with the finding that *Aplysia* BiP first increases in expression at 3 hours following 5-HT application when overall protein synthesis is maximal (Barzilai et al., 1989). Using PCR, we have obtained a partial cDNA clone of *Aplysia* BiP and are examining the distribution and expression of both of the late proteins following long-term training.

446.6

PERSISTENT LOSS OF REGULATORY SUBUNITS OF THE cAMP-DEPENDENT PROTEIN KINASE IN APLYSIA SENSORY NEURONS REQUIRES SYNTHESIS OF NEW PROTEIN DURING THE CRITICAL PERIOD FOR THE INITIATION OF LONG-TERM PRESYNAPTIC FACILITATION (LTF) P.J. Bergold, J. D. Sweatt, E. R. Kandel, and J. H. Schwartz. Center for Neurobiology & Behavior and HHMI, Columbia University, NY 10032

Initiation of LTF in Aplysia has a critical period for protein synthesis during application of 5-HT. cAMP-dependent protein kinase, a heterodimer of regulatory (R) and catalytic (C) subunits, is activated in both short- and long-term facilitation. Presumably this explains the persistent cAMP-dependent phosphorylation seen during LTF that is dependent on protein synthesis (Sweatt and Kandel, Nature, 1989). In sensory cells of long-term sensitized animals, the amount of R is reduced with no change in C (Greenberg, et.al., Nature, 1987). To relate these observations we determined if the change in the R-to-C ratio is also dependent on protein synthesis. Treatment with 5-HT resulting in LTF changes the ratio of R-to-C 24 h later. Inhibition of protein synthesis during the treatment blocked the loss of R while inhibition of protein synthesis immediately after had no effect. Elevation of intracellular cAMP is sufficient to induce LTF. R is reduced 24 h after treatment with a cAMP analog plus phosphodiesterase inhibitor. Elevation of cAMP by 5-HT changes the ratio of R-to-C, and this is a new mechanism for long-term regulation of any protein kinase. The change in R may be transcriptional or due to increased turnover. cDNAs encoding Aplysia R and C have been isolated (Beushausen, et. al., Neuron, 1988; Bergold et. al., Neurosci.Abs., 1988) to test if the loss of R is transcriptional. We are also obtaining antisera against R to measure its turnover.

446.7

THE PKC CYCLE: A MECHANISM FOR LONG-TERM AUTO-ACTIVATION OF PROTEIN KINASE C. T.C. Sacktor, A. Calignano and J.H. Schwartz. HHMI, Ctr. for Neurobiol. & Behav., Columbia Univ., NY 10032

Aplysia neurons have two forms of PKC that can be distinguished by their response to arachidonic acid (AA). One is activated at high concentrations of AA (similar to vertebrate β), the other at low concentrations (analogous to γ). In Aplysia neurons, facilitatory stimuli (5-HT or phorbol ester) activate PKC, translocating the kinase from cytosol to membrane. On the membrane, lipokinin, a M_r 29,000 protein (Calignano, Piomelli, Wallner & Schwartz, Neurosci. Abstr. 1988, 14:131), when phosphorylated by PKC through either phorbol ester or 5-HT, activates PLA_2 to produce AA. AA continues to stimulate PKC after the transient second-messenger signal for the initial translocation is dissipated, thereby maintaining the kinase in an active form to enhance synaptic strength persistently: the cycle is thus completed and continued. This mechanism for persistence is relevant for models of learning and memory where PKC plays an important role: LTP in hippocampus, conditioning of the rabbit eye-blink response, and sensitization of defensive reflexes in Aplysia.

446.8

MEMORY MUTATIONS AFFECT AN ELEMENTARY EXPERIENCE-DEPENDENT MODIFICATION OF RESPONSE IN AN IDENTIFIED SENSORY NEURON OF DROSOPHILA. G. Corfas* and Y. Dudai. Dept. of Neurobiology, Weizmann Institute, Rehovot 76100, Israel.

Stimulation of the thoracic bristles of Drosophila elicits a cleaning reflex. The habituation of this reflex is defective in two memory mutants: rut, which lacks Ca^{2+}/calmodulin-activated adenylate cyclase, and dnc, which has a reduced cAMP phosphodiesterase (PDE) activity. We have now investigated the physiology of a sensory neuron that subserves the cleaning reflex. Extracellular recordings were performed from truncated bristles. The recording electrode was also used for mechanical stimulation. We have studied two plastic processes in the sensory neuron: the decrement of response to a sustained stimulus (adaptation), and the decrement of response to repetitive stimuli (sensory fatigue). The mutations rut and dnc did not affect adaptation but did alter sensory fatigue. rut mechanosensory neurons fatigued slower and dnc neurons fatigued faster than normal. The opposite effect of the rut and dnc mutations on sensory fatigue suggested that this process is cAMP dependent. To test this hypothesis we investigated the effect on sensory fatigue of systemic injection of drugs which affect the cAMP cascade. PDE inhibitors caused rapid fatigue in wild-type (CS) neurons, mimicking the effect of dnc. In contrast, rut neurons were not affected by PDE inhibitors. The adenylate cyclase activator forskolin decreased sensory response in naive CS and rut neurons. The protein kinase inhibitor H7 reduced the effect of repetitive stimulation in CS and dnc neurons. Our results indicate: a. the cAMP cascade is involved in sensory fatigue; b. memory mutations affect an elementary form of neuronal plasticity.

446.9

PKC ACTIVATION IS NECESSARY FOR BOTH SHORT- AND LONG-TERM LEARNING-PRODUCED EXCITABILITY CHANGES IN HERMISSENDA TYPE B CELLS. Schuman, Erin M. and Farley, J. Program in Neural Science, Indiana University, Bloomington, IN 47405

Introduction of the PKC inhibitor H-7 into Type B cells prior to in vitro conditioning resulted in a failure of these cells to exhibit the pairing-specific neural changes typical of controls: cumulative depolarization and increased input resistances. In contrast, inhibition of Ca^{2+}/CAM-dependent PK's before conditioning (via W-7 ionophoresis or bath application) had no decremental effect on the changes. Voltage-clamp analysis of ionic currents following in vitro conditioning revealed that H-7 pre-treatment also prevented the conditioning-produced reduction of I_A.

Comparison of I_A magnitudes in the presence or absence of H-7, 24-48 hrs. following standard behavioral training of intact animals, revealed pairing specific reductions in I_A only when recorded in the absence of H-7. I_A from trained animals recorded in the presence of H-7 was not significantly different from those of untrained animals recorded in normal ASW. These results suggest that persistent activation of PKC is necessary for the expression of plasticity during long-term retention. We are now undertaking studies to investigate whether similar differences exist for $I_{K\text{-}Ca}$.

446.10

SELF-TUNING BY A NEURAL CIRCUIT: THE DSI NEURONS OF THE TRITONIA ESCAPE SWIM CENTRAL PATTERN GENERATOR BOTH MODULATE AND MEDIATE CONNECTIONS IN THE SWIM CIRCUIT. W.N. Frost and P.A. Getting. Dept. Physiology & Biophysics, Univ. of Iowa Iowa City, IA 52242.

The marine mollusk Tritonia responds to noxious stimuli with an escape behavior consisting of a series of vigorous ventral and dorsal body flexions. This escape swim is mediated by an identified central pattern generator consisting of dorsal swim interneurons (DSIs), ventral swim interneurons (VSIs) and the interneuron C2. These interneurons also drive the motor elements of the circuit, the ventral flexion neurons (VFNs) and the dorsal flexion neurons (DFNs).

The central pattern generator interneuron C2 makes connections onto all of the circuit interneurons and flexion neurons. This study focussed on the C2 to DFN-A synapse, one of the output connections from the central pattern generator. We report here that the DSIs, which have previously been shown to contain serotonin, have a powerful modulatory influence on this connection. In high divalent sea water, DSI trains (5-7 Hz, 15sec) produced an average 3.3 fold amplification of the C2 to DFN-A monosynaptic EPSP (N=9, p<.001). This modulation developed within five seconds of the DSI train onset and disappeared within thirty seconds of the train offset. Since the DSIs fire at the onset and then phasically throughout the swim, this modulation should be invoked during the swim.

This finding indicates that the DSI neurons not only participate in mediating the oscillatory central pattern for the swim, but also modulate the strength with which this pattern is coupled to the circuit flexion neurons. This suggests that in the initial seconds of the escape response the circuit may actively "tune" itself into an effective state for swimming. We are now exploring the degree to which this tuning process extends to connections made by C2 within the central pattern generator itself.

ANALYSIS OF NON-ASSOCIATIVE LEARNING IN *C. ELEGANS* : I NEURAL CIRCUIT MUTATIONS. Catharine H. Rankin and Martin Chalfie. Department of Psychology, Univ. of British Columbia, Vancouver, B.C. V6T 1Y7 and Department of Biological Sciences, Columbia Univ. N.Y., N.Y. 10027.

A major advantage of *C. elegans* as a model system for the study of learning and memory is the wealth of genetic information available. Genetic analysis has played a major role in elucidating the neuroanatomical circuit underlying the touch reflex in this animal. A variation of this reflex, the reversal response to a vibrational stimulus produced by tapping the side of the holding dish, has been shown to be capable of habituation, dishabituation, sensitization and inhibition. We are now in the position to use the existing information about the neural circuit to determine the neural pathways involved in learning and to use learning to probe the interaction between various elements of the neural circuit.

An example of this type of analysis was determining whether the circuit underlying the reversal response was the same as the circuit for head touch. A mutant (mec-3) with defective primary touch receptor cells (the microtubule cells) did not reverse to taps; thus, the same sensory receptors transduce both head touch and taps. We have also examined whether the known neural pathway for tail touch also underlies the tail touch induced inhibition of reversal to tap. Two tail touch insensitive mutants failed to show inhibition. One mutant (Egl-5) showed that the same sensory receptors were necessary for both responses to tail touch and inhibition. Another mutant (Deg-1) showed that the primary interneuron (PVC) in the posterior tail touch circuit is necessary for inhibition. These types of experiments will allow us to determine the neural circuit involved in the learning as well as potential sites of plasticity.

446.12

ANALYSIS OF NON-ASSOCIATIVE LEARNING IN *C. ELEGANS*: II DEVELOPMENT OF BEHAVIOR AND PLASTICITY.
C. D. O. Beck*, C. M. Chiba* and C. H. Rankin (SPON: R. Lane). Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C. V6T 1Y7.

The touch circuit of *Caenorhabditis elegans* provides a unique opportunity to examine the relationship between known neuroanatomical development and development of learning. Using vibrational stimuli (taps to the side of the holding dish) we have demonstrated that *C. elegans* is capable of all forms of non-associative learning. Before analyzing the development of non-associative learning, the ontogenetic changes in the behavioral elements of the touch reflex were examined in the four larval stages and two adult stages (young adults and 4-day old adults). The frequency of spontaneous reversals was significantly higher in young adults than any other stage ($F(5,54)= 4.84$, $p=.001$). Although animals at all stages respond to a head touch by reversing direction, adult stages were significantly more likely to reverse to a tap than were the larval stages ($F(5,114)=13.18$, $p=.0001$). Larval stages were more likely to accelerate forward in response to the tap; this became more pronounced as stimulus intensity increased. The behavioral changes between the last larval stage and young adulthood correlate with known neuroanatomical changes.

Despite these developmental changes, animals from all stages exhibit habituation and inhibition of the reversal response. A detailed analysis of the parameters of these forms of learning will indicate whether they have the same characteristics as observed in adult animals.

CIRCUITRY AND PATTERN GENERATION

MULTISECOND AFTERDISCHARGE OF SPINAL CORD INTERNEURONS EVOKED BY CUTANEOUS STIMULATION IN THE ROSTRAL SCRATCH RECEPTIVE FIELD OF THE TURTLE.
Scott N. Currie and Paul S.G. Stein. Dept. of Biology, Washington University, St. Louis, MO 63130.

Stimulation of cutaneous afferents in the turtle increases the excitability of scratch reflex for several seconds following stimulus-offset (J. Neurophysiol. 60: 2122-2137, 1988). In the present study, we recorded from single cutaneous afferents and sensory interneurons in order to examine the neuronal mechanisms for multisecond increases in scratch excitability. A single segment of the midbody spinal cord was isolated in situ by transecting the cord at the segment's anterior and posterior borders. The isolated segment was left attached to its peripheral nerve that innervates part of the rostral scratch receptive field. A micro-suction electrode (5 µm I.D.) was used to record from descending axons in the white matter. We identified a subset of sensory interneurons that exhibited strong afterdischarge for as long as 10-30 seconds following a mechanical or electrical stimulus to the rostral scratch receptive field. These cells displayed robust temporal summation in response to single electrical pulses delivered to the shell at multisecond intervals. Cutaneous interneurons with long afterdischarge may serve as a neural locus for multisecond excitability changes in the spinal network for scratch reflex. Supported by NIH Grants NS07057 to S.N.C. and NS15049 to P.S.G.S.

A PERIPHERAL FEEDBACK LOOP MEDIATED BY NEUROMODULATORY SEROTONERGIC AFFERENTS COUPLES TWO CPGs IN A PHASE-INDEPENDENT FASHION. P.S. Katz and R.M. Harris-Warrick. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

In the foregut of the crab, *Cancer borealis*, serotonergic mechanosensory afferents, called GPR cells, are activated by movements of the gastric mill, but not by movements of the faster pyloric filter (Katz and Harris-Warrick, J. Neurophys. in press). However, these cells have slow neuromodulatory effects on neurons in the pyloric central pattern generator of the stomatogastric ganglion. The GPR cells cause prolonged enhancement of bursting in the PD/AB pacemaker cell group, excite the LP neuron, and inhibit the PY neurons. Some of these effects last only during the GPR stimulation, while others slowly decline over many cycles. GPR input alters the phase relationships between pyloric neurons by changing the relative levels of excitation of the pyloric cells in a manner that is mimicked by serotonin application. The effects of GPR stimulation on these cells are not mediated by discrete fast synaptic potentials and are therefore independent of the phase of the pyloric cycle at which the input occurs. Because the GPR cells are rhythmically active in time with the gastric mill, their effects on the pyloric pattern occur rhythmically with each gastric mill cycle. Thus, the slow neuromodulatory effects of these mechanosensory afferents coordinate the pyloric pattern to the gastric mill cycle through a mechanism that does not require the input to be precisely timed to the pyloric pattern. Supported by NIH NS17323 and Hatch Act Grant 191410.

447.3

TEMPERATURE DEPENDENCE OF GRADED CHEMICAL SYNAPTIC STRENGTH WITHIN THE PYLORIC MOTOR CIRCUIT OF THE LOBSTER STOMATOGASTRIC GANGLION.
B. R. Johnson and R. M. Harris-Warrick. Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

Spiking cells of the central pattern generator (CPG) for the pyloric motor pattern in the stomatogastric ganglion (STG) of the spiny lobster *Panulirus interruptus* use graded synaptic transmission (electrical coupling and chemical inhibition) to coordinate their rhythmic activity. We examined the temperature dependence of graded synaptic transmission between identified pyloric CPG cells in STGs isolated from animals maintained at 15°C. Synaptic input-output curves for graded transmission were gathered in 10-7M TTX by measuring the postsynaptic peak polarizations resulting from 1 sec presynaptic polarizations of varying sign and amplitude. As the temperature was lowered from 23 to 10° C, graded chemical synaptic potentials showed reductions in peak amplitudes of approximately 55 to 100% between different cell pairs. These reductions in graded chemical synaptic strength were not accounted for by general membrane resistance decreases; they were accompanied by increased antidromic action potential size in both pre- and postsynaptic cells, increased presynaptic soma input resistance, and increased electrical coupling between some presynaptic cells. These reductions occur within natural temperature ranges for the spiny lobster (12-21°C), suggesting that the balance of synaptic interactions producing this motor rhythm may be a dynamic function of environmental temperature. Supported by NRSA #NS07859 (BRJ) and NIH grant #NS17323 (RMH-W).

447.4

CONTROL OF THE INTERACTIONS OF TWO MOTOR PATTERN GENERATORS BY RED PIGMENT*CONCENTRATING HORMONE.
P.S. Dickinson, C. Mecsas and E. Marder, Depts. of Biology, Bowdoin College, Brunswick, ME 04011 and Brandeis University, Waltham, MA 02554

The stomatogastric nervous system of the spiny lobster, Panulirus interruptus, generates 4 motor patterns, which control the 4 parts of the foregut. A modulatory peptide, red pigment concentrating hormone (RPCH), activates the cardiac sac rhythm and increases the interactions between the cardiac sac rhythm and the gastric rhythm. In the presence of RPCH, with other inputs to the stomatogastric ganglion blocked, the neurons of the gastric pattern generator fire entirely in cardiac sac time. One mechanism which may account for this "take-over" of the gastric rhythm is a selective increase in the size of the synaptic potentials which the IV (inferior ventricular) fibers, of the cardiac sac pattern, generate on many of the gastric mill motor neurons. In the presence of RPCH, these synaptic potentials increase significantly in amplitude, so that they effectively drive the gastric mill neurons. The input impedance of the gastric neurons does not appear to change in RPCH, suggesting that RPCH may act presynaptically on the IV fibers. Supported by NSF BNS-8706568 and NIH NS-17813.

A NOVEL SLOW RHYTHMIC PATTERN GENERATED BY THE *APLYSIA* BUCCAL GANGLION.
S.L. Hooper, K.R. Weiss, and I. Kupfermann Cntr. Neurobio. & Behav., Columbia U. P&S and NYS Psych. Inst., NYC 10032

Prior work (Hooper et al., Soc. Neurosci. Abst. 14:608) has shown that crop dilation, a known satiation signal, excites certain buccal ganglion neurons. We therefore chronically implanted extracellular electrodes on various buccal nerves to monitor buccal ganglion activity during feeding and satiation. These recordings reveal that the buccal ganglion can produce an unusual rhythmic pattern that has no obvious visible external behavioral correlates. The pattern consists of organized bouts of spiking activity lasting 0.5 to 2 min that repeat every 3 to 10 min. This slow pattern differs from known buccal mass motor patterns (biting, swallowing, rejection) in two ways. First, the spiking activity in these patterns lasts only 5 to 10 sec. Second, these patterns have much shorter periods (during continuous presentation of food or rejection inducing stimuli), repeating every 10 to 20 sec.

The slow pattern is seldom observed in unfed animals, either aroused or unaroused, but is always seen following meals, and can continue for several days after a meal. The slow pattern can also be induced *in vitro* by crop dilation or electrical stimulation of the esophageal nerve (through which crop derived sensory input projects centrally). Preliminary work in semi-intact preparations indicates that the slow pattern induces contractions of (at least) superficial buccal mass muscles, but does not cause radula movements. These observations suggest that the slow pattern is specifically induced by food in the crop and may be involved in some aspect of food processing.

Both the slow pattern and satiation are induced by crop dilation and electrical stimulation of the esophageal nerve. However, we do not believe that the slow pattern and satiation are causally related, as sub-satiating meals induce the slow pattern, and animals that are expressing the slow pattern but are not satiated readily eat when food is again presented.

447.6

AN IDENTIFIED INTERNEURON TERMINATES PATTERNED MOTOR ACTIVITY IN THE BUCCAL GANGLIA OF HELISOMA.
A.D. Murphy, and F. Mehdizadeh-Namin*. Dept. of Biol. Sci., Univ. of Illinois at Chicago, Chicago, IL 60607.

Patterned motor activity (PMA) underlying feeding in the snail, Helisoma, must be regulated by descending inhibition from the "brain" (circumesophageal ganglionic ring). The buccal ganglia (BG) contain most of the interneurons comprising the central pattern generator that mediates feeding. The BG are connected to the brain via the cerebro-buccal connectives (CBCs). Severing the CBCs or applying a procaine block to the CBCs in a semi-intact animal typically activates rhythmic "feeding" movements. To localize putative inhibitory neurons in the brain we did retrograde staining of cut axons in the CBC using Lucifer Yellow. This revealed a neuron with a soma in the pleural ganglion and an axon that traverses the pleuro-pedal connective, the pedo-cerebral connective and the CBC. Subsequent intracellular recordings confirmed that this neuron, PLBI1 (pleuro-buccal inhibitory neuron 1), is a potent inhibitor of PMA in the BG. A train of action potentials in PLBI1 terminates PMA even in the presence of 10^{-6} M serotonin. Serotonin is an excitatory neuromodulator which induces vigorous PMA at that concentration. Intracellular injection of PLBI1 with Lucifer Yellow CH revealed a neuritic arbor in the pleural ganglion and axon branches arborizing in the ipsilateral parietal ganglion, the ipsilateral pedal ganglion, and the ipsilateral cerebral ganglion. The main axon traversed the ipsilateral CBC and innervated both buccal ganglia, crossing the buccal commissure. (supported by NIH Grant 1 RO1 NS26145-01).

CONNECTIONS OF IDENTIFIED INTERNEURONS IN THE LEECH ARISE IN NEURAL NETWORKS TRAINED BY BACK-PROPAGATION.
S.R. Lockery, G. Wittenberg, W.B. Kristan,Jr. and T.J. Sejnowski. U.C.S.D. and Salk Institute, La Jolla, CA 92037.

Interneurons in model networks generated by the back-propagation algorithm were compared to identified interneurons in the local bending reflex of the leech. Touching dorsal, ventral, or lateral skin causes a localized withdrawal from the stimulus (local bending). Four mechanoreceptors (P cells) with dorsal or ventral receptive fields provide the major input to the reflex. P cells connect to eight types of dorsal and ventral motor neurons via interneurons, of which nine types have been identified. Strengths of P cell to interneuron connections were measured as the peak synaptic potential produced by a standard P cell impulse train. Output connection strengths for two interneurons were measured as the amplitude of synaptic potentials in the motor neurons following fixed depolarization of the interneuron. We trained a model network of four sensory, eight motor, and nine pairs of interneurons using back-propagation to reproduce the amplitudes of synaptic potentials of the motor neurons during the three forms of local bending. The network included known lateral connections among motor neurons, but no constraints were placed on the pattern of interneuronal inputs and outputs. However, following training the model interneurons, like the real ones, received inputs from dorsal and ventral P cells, and connected to all eight motor neurons. Additional biological constraints, including recurrent connections and temporal response properties, can now be used to improve the predictions of the model.

INTERSEGMENTAL INTERNEURONS CONTRIBUTE TO MULTIPLE BEHAVIORS IN THE LEECH .
G. Wittenberg, S. R. Lockery, and W. B. Kristan, Jr. Dept. of Biology, Univ. of California at San Diego, La Jolla, CA 92093-0322.

Electrophysiological studies in the CNS of the leech, *Hirudo medicinalis*, were performed in order to define and understand the production of particular behaviors. When the leech receives a mechanosensory stimulus, it produces one of several types of motor patterns, three of which are local bending, swimming, and shortening. Local bending is a segmental withdrawal response produced by excitation of motor neurons (MNs) innervating longitudinal muscles on the side stimulated and by inhibition of MNs innervating muscles on the opposite side. Swimming involves the entire body and is produced by antiphasic rhythmic excitation and inhibition of the same longitudinal MNs. Shortening is a graded response, involving from a few to all segments anterior and posterior to the site of stimulation; shortening is produced by excitation of all longitudinal MNs. More than one interneuron (IN) contributes to shortening as unilateral lesions to the interganglionic connectives cause only a partial decrement in the response of segments distal to the lesion. INs which mediate local bending and swimming behavior have been identified and characterized. We have used intracellular recording and stimulation of these and other INs in an isolated CNS to begin to study their responses and effects in shortening behavior.

Local bending INs and swim INs both contribute to shortening behavior. Cell 115, which participates both in local bending and swimming, produces excitation of dorsal longitudinal MN two segments posterior to the segment in which it receives both dorsal and ventral sensory inputs. Cell 208, a swim IN, has the same motor effect, but receives a highly variable sensory input. In addition, previously unidentified INs participate in shortening. One of these causes excitation of dorsal MNs, but inhibition of ventral MNs, two ganglia anterior to the segment in which it receives a dorsal sensory input. It appears likely that shortening, like local bending and swimming, is produced not by a single IN dedicated to the task, but by a network of INs, some of which do not have input-output functions very similar to the overall behavior.

Supported by NIMH research grant MH43396 and PHS training grant GM07198.

CHEMICAL DEAFFERENTATION OF INSECTS BY THE ALPHA ADRENERGIC ANTAGONIST PHENTOLAMINE.

J.M.Ramirez* and K.G.Pearson (SPON: C.G. Benishin). Dept. of Physiology, University of Alberta, Edmonton, Canada, T6G 2H7.

A common approach for elucidating the function of sensory feedback in the generation of rhythmic motor activity is to remove afferent input and analyze the subsequent changes in the motor pattern. Usually deafferentation is done by transection of afferent fibers. However, this method is often technically complicated and usually cannot be done while maintaining records from single neurons. Another approach is to use drugs to inhibit the activity of sense organs. We found that the α_1-adrenergic antagonist Phentolamine inactivates sensory organs in insects when injected into the haemolymph. For the flight behaviour of the locust it can be demonstrated that Phentolamine treatment results in a motor pattern very similar to the deafferented motor pattern as observed after mechanical deafferentation. The inactivation of sense organs is not due to an anaesthetizing action of Phentolamine on the peripheral sensory nerves, since spikes are conducted if electrically evoked. Phentolamine used at concentrations just sufficient to inactivate sensory organs does not abolish efferent activity and muscle activation and has very little effect on the CNS. However, high concentrations of Phentolamine blocked nerve conduction. The inactivation of sense organs without affecting the CNS was specific for α_1-adrenergic antagonists, such as Phentolamine and Tolazoline. α_2-adrenergic antagonists (e.g. Yohimbine), β-adrenergic antagonists (e.g. Propranolol), 5-HT antagonists (e.g. Verapamil) or local anaesthetics (e.g. Lidocaine) could also inactivate sense organs, but only at concentrations which also had a strong central effect. (Supported by the MRC of Canada).

Timing in acoustical motor following. E.Pöppel, T.Radil.Institute of Medical Psychology LMU,8000 Munich,FRG and Institute of Physiology CSAS,1400 Prague,CSSR

Rhythmic acoustical sequences have been generated by means of a computer and the ability of subjects to follow them by finger tapping analyzed statistically.Usually tapping onset preceded stimulus onset by about 30ms (corresponding to one cycle of the hypothetical brain clock).The duration of this anticipation interval decreased to values close to zero when the pause between the preceding fingercontact with the response key and the following stimulus onset became short (fast tapping,prolongation of stimulus tones combined with an instruction to hold the key) and after training, and increased to values close to about 60ms and more (possible multiples of the basic timing cycle) when the task became more difficult (stimulus sequences with missing tones,false feedback on tapping).Tonal features of stimulus sequences influenced tapping regularity and key touching time was shorter in subjects with musical training.The results are interpreted in the frame of a theory on hierarchical mechanisms of timing in the human brain.

DIFFERENTIATION, MORPHOGENESIS AND DEVELOPMENT: CELLULAR AND MOLECULAR STUDIES III

FREEZING LESIONS OF THE NEWBORN RAT BRAIN: A MODEL FOR CEREBROCORTICAL MICRODYSGENESIS. P. Humphreys*, G.D. Rosen, G.F. Sherman, and A.M.Galaburda. Beth Israel Hospital and Harvard Med. School, Boston, MA 02215.

Freezing lesions of the neocortex of newborn rats have been suggested as a model of cerebrocortical microdysgenesis, specifically microgyria and *status verrucosus deformis* (Dvorák and Feit, *Acta Neuropath.*, **38**: 203-212, 1977; Dvorák et al., *Acta Neuropath.*, **44**: 121-129, 1978). Using an apparatus similar to that employed by Dvorák and colleagues, we applied freezing probes to the skulls of one day-old rats for periods ranging between 2-10 seconds and with temperatures ranging from -70°C to -110°C. The animals were sacrificed at either weaning or adulthood and their brains examined.

The application of a freezing probe to the skull resulted in substantial focal neuronal loss in the underlying cerebral cortex, with thinning and infolding of the cortex to form a pseudo-sulcus, and accompanying disruption of cortical lamination, thereby replicating the results of Dvorák and colleagues. Longer exposure times and lower temperatures resulted in more severe lesions. In the depth of the pseudo-sulcus, four distinct laminæ were seen which could be the result of (1) laminar necrosis and associated mechanical distortion of growth or (2) disturbed neuronal migration to the supragranular layers. There was no evidence of gliosis within the lesions, although aberrant tufts of myelin (reminiscent of *plaques fibromyeliniques*) were seen at the base of the pseudo-sulci. On the periphery of many lesions were zones of apparent verrucous deformity in layer I, but these resembled neither classic *status verrucosus* nor the ectopic collections of neurons seen in human dyslexic and autoimmune mice (Galaburda et al., *Ann. Neurol.*, **18**: 222-233, 1985;Sherman et al., *Acta Neuropath.*, **74**:239-242, 1987).

These results suggest that early focal cortical injury may mimic neuronal migration abnormalities and lead to significant focal cortical dysplasia.

This work was supported, in part, by NIH Grant 20806, and by the Orton Dyslexia Society.

448.2

CONNECTIONAL ANOMALIES ASSOCIATED WITH FREEZING LESIONS TO THE NEOCORTEX OF THE NEWBORN RAT. G.D. Rosen, P. Humphreys*, G.F. Sherman, and A.M.Galaburda. Beth Israel Hospital and Harvard Med. School, Boston, MA 02215.

Freezing lesions to the left somatosensory neocortex of newborn rats were performed for periods ranging from 2-10 seconds and with temperatures ranging from -70°C to -110°C. At 60 days of age the animals underwent corpus callosectomy. After one week, the animals were sacrificed, their brains removed, sectioned coronally, and processed for silver staining of degenerating axon terminals.

These lesions resulted in substantial focal neuronal loss and laminar dysplasia in the underlying cerebral cortex, and the pattern of transcallosal axonal terminations was disturbed in the surrounding regions. Thus, although transcallosal axonal terminations are rare in somatosensory cortex, there was a pattern of dense terminal degeneration in portions of somatosensory cortex adjacent to the lesions produced by freezing. This is in direct contrast to a paucity of axonal terminal degeneration in the homologous area of the opposite hemisphere, and in analogous regions of control brains. This pattern of callosal axonal degeneration is different from that previously reported in an area of spontaneous cerebrocortical microdysgenesis in the rat and may reflect differences in the etiology (cause or timing) of the cortical disruptions.

We have demonstrated that freezing lesions of the neocortex performed in the newborn rat during the later stages of neuronal migration lead to an alteration in callosal connections in the surrounding regions.

This work was supported, in part, by NIH Grant 20806, and by the Orton Dyslexia Society.

COMPARATIVE NEUROGENESIS OF PEPTIDE CONTAINING CELLS IN NEOCORTEX OF RAT. M.E. Cavanagh* and J.G. Parnavelas* (SPON: Brain Research Association) Dept. of Anatomy, University College London, London WC1E 6BT, U.K.

Immunocytochemistry, to identify somatostatin (SRIF) Neuropeptide Y (NPY) and vasoactive intestinal polypeptide (VIP) containing neurons, was combined with [3H]thymidine autoradiography (ARG) to determine birthdates and follow the maturation of these cells in rat neocortex. Timemated pregnant rats were injected with [3H]thymidine on days E14-E22. Pups were fixed from birth to 5 weeks of age. PAP immunocytochemistry was performed on 10 µm sections cut from wax-embedded brains, followed by ARG. The numbers, positions and degree of ARG-labelling of peptide-positive neurons were recorded. At two weeks, the peak generation of neurons was from E16 for SRIF, E17 for NPY and E19 for VIP. Neurons generated either side of the peak were usually to be found in the appropriate cortical layer whereas neurons from the peak were rather widely distributed giving the impression that they were not obeying the "inside-out" rule. The apparent numbers of all three types increased initially up to about 3 weeks, then declined. SRIF-neurons appeared first followed by NPY then VIP. The distinct peaks of generation of these neurons may indicate that they arise from a single precursor population which produces them successively.

DIFFERENTIATION OF PYRAMIDAL AND GABAERGIC NONPYRAMIDAL CELLS IN SLICE CULTURES OF THE HIPPOCAMPUS: GOLGI/EM AND IMMUNOCYTOCHEMICAL STUDIES. M.Frotscher,B.Heimrich* and H.Schwegler*. Inst. Anat.,Univ.Frankfurt/M., FRG.

Organotypic slice cultures offer the possibility of studying the development of neurons in the absence of their specific extrinsic afferents. The combined Golgi/electron microscope (EM) technique and glutamate decarboxylase (GAD) immunocytochemistry were used to study the differentiation of pyramidal and GABAergic nonpyramidal neurons in slice cultures taken from 4-6 day old rats and mice.

Golgi-impregnated cultures revealed all major cell types of the hippocampus. Abundant synaptic contacts on gold-toned pyramidal cell dendrites and spines, normally occupied by extrinsic afferents, suggest sprouting of the cultured neurons. In fact, intrinsic mossy fibers and terminals of intrinsic GAD-positive neurons formed numerous synaptic contacts.

Our results demonstrate that hippocampal neurons develop their cell-specific characteristics, including characteristic synapses, in the absence of extrinsic afferents.

448.5

EARLY DEVELOPMENT OF VAGAL SENSORY AND MOTOR FIBERS AND THEIR NUCLEI IN THE BRAIN STEM OF THE RAT. M. Kalia. Dept. Pharmacology, Thomas Jefferson Univ. Philadelphia, PA 19107.

This study examines the complex interactions between developing vagal afferents and efferents and their neurochemically identified central targets in the brain stem in order to better define the role of structural and neurochemical abnormalities in the brain stems of SIDS victims in the pathogenesis of that disease. Neonatal Sprague Dawley rats from 0-14, 21 and 39 days old were used. Three types of experiments were performed on littermates: 1) tracing vagal projections; 2) immunocytochemistry with antisera directed against catecholamine synthesizing enzymes, 5HT and selected peptides; 3) ultrastructural examination of vagal nuclei with and without labeling #1 and #2 above. 1) The right vagus nerve was injected with 3-5 ul of choleratoxin conjugated to horseradish peroxidase under hypothermia. Animals survived for 24 hours in a incubator following which the brains were processed using TMB as the chromogen according to the method of Kalia and Mesulam, '80. 2) 10 littermates were perfused at each age for immunocytochemistry (Kalia et al, '85). In view of the small size of the brain stem, serial 50 um sections of each brain stem were incubated in only one antiserum so that important rostrocaudal levels were not missed. 3) Brain stems of littermates perfused for electronmicroscopy were sectioned, stained, osmicated and embedded in plastic for ultrastructural examination. At day 3 vagal projections showed the most proliferation but terminals and neurons in the medulla were only weakly immunoreactive. By day 10 the density of vagal projections was greatly reduced but still not as restricted as in the adult. Immunoreactive neurons and terminals showed a greater dispersion and lagged behind developing vagal fibers during the period of early development. Supported by a grant from the SIDS Alliance.

TYROSINE HYDROXYLASE (TH) AND OLFACTORY MARKER PROTEIN (OMP) EXPRESSION IN RAT OLFACTORY BULB OF EMBRYOS AND IN CULTURE. Harriet Baker[1] And Albert I. Farbman[2]. [1]Cornell Univ. Med. Coll., White Plains, NY 10605 and [2]Northwestern Univ., Evanston, IL 60208.

TH expression in adult olfactory bulbs is regulated by peripheral afferent neuronal input, that is, either chemical or surgical deafferentation results in the loss of TH activity, mRNA and immunoreactivity (ir). The present studies investigated in the rat, both in vivo and in vitro, the existence of a similar relationship between peripheral afferent innervation and TH expression during development. Afferent innervation of the olfactory bulb in vivo, assessed by OMP-ir, preceded expression of TH-ir by about 5 days (Embryonic day [E]-14 vs E-19, respectively). However, TH-ir neurons, when present, were always found in association with OMP-ir fibers and primarily in a juxtaglomerular position. The lag in TH expression in bulbar neurons may be a consequence of delayed differentiation of the phenotype. En bloc organ cultures of E-15 olfactory bulb and epithelium exhibited extensive expression of both OMP and TH after 7 days in vitro. Cultures of olfactory bulb alone contained only a few lightly stained TH-ir cells. These data suggest that during both normal embryogenesis and in culture the presence of receptor afferent fibers is necessary for initiation of TH expression. Supported by Grant #'s NS23103 and NS06181.

ABNORMALITIES OF ENTERIC NEURONAL DEVELOPMENT IN TRANSGENIC MICE OVEREXPRESSING THE HOMEOBOX-CONTAINING GENE HOX-1.4. V.M. Tennyson, D. L. Sherman*, R.R. Behringer*, R. L. Brinster*, R. D. Palmiter*, J.Tasch*, D. Crotty*, D.J. Wolgemuth* and M.D. Gershon, Depts. Anat. & Cell Biology, and Genetics & Devel., Columbia Univ., P & S, New York, NY 10032; Lab. of Repro. Physiol., Univ. Penn. School of Vet. Med., Phila, PA, and Dept. Biochem., Univ. Wash., Seattle, WA.

Transgenic mice carrying multiple copies of the Hox-1.4 gene develop congenital megacolon and express elevated levels of Hox-1.4 mRNA in the gut. Megacolon also develops in *ls/ls* mutant mice because crest-derived neural and glial precursors fail to colonize the terminal bowel. The terminal bowel of adult transgenic mice was found to be hypoganglionic and not aganglionic, like that of *ls/ls* mice. The ganglia and nerves in the hypoganglionic zone of the transgenic gut had the ultrastructure of extraenteric peripheral nerve, rather than that of the enteric nervous system (ENS). Scattered neurons were present within thick nerve bundles. In contrast to normal enteric ganglia, these neurons, as well as the nerves in which they were found had a collagen-containing endoneurium; supporting cells were surrounded by basal laminae, often myelinated axons, and thus are Schwann and not enteric glial cells. An abnormal accumulation of material with the ultrastructure of elastic fibers was present. The smooth muscle layers of the most terminal region were unusually thickened and interrupted by fibrous septae. Immature neurons first appeared at E14, as in controls, but sometimes expressed an abnormal phenotype, such as that of sympathetic neurons with 50 nm dense cored granules. The development of the internal smooth muscle layer in the terminal gut of transgenic fetuses was markedly retarded. These data suggest that congenital megacolon develops in the transgenic mouse because the terminal bowel contains small numbers of abnormal neurons, which fail to mediate the local reflexes upon which intestinal propulsion depends. The condition is not identical to that which appears in *ls/ls* mice, although abnormalities of the developing smooth muscle and extracellular matrix are seen in both defects. Supported by NIH grants HD 17736, NS 15547, HD 18122.

EVIDENCE THAT MOVEMENT IN *DROSOPHILA* EMBRYOS IS NEURALLY EVOKED AND MEDIATED BY GLUTAMATE. M.D.S. Anderson and H. Keshishian. Dept. of Biol. Yale University, New Haven, CT 06511.

It is known that the initial neuromuscular contacts on the bodywall muscles of *Drosophila* occur during stage 16 of embryogenesis and at this time the growth cones of these axons show positive immunostaining for glutamate (Johansen et al., Soc. Neurosci. Abst. 14:451, 1988). This is also the stage when spontaneous muscle movement begins in the embryo. Due to the diffuculty of recording muscle potentials in embryos at this stage, it has not been possible to demonstrate the source of these muscle contractions. We have begun using a glutamate-blocking spider venom fraction to examine the basis of these early muscle contractions.

We have HPLC purified a component of the venom from the Orb Weaver spider *Araneus gemma* that postsynaptically blocks the glutamate response at the neuromuscular junction of *Drosophila* larval bodywall muscles. Glutamate-blocking activities of venom components were tested by physiological means using iontophoresis of glutamate in the presence of various HPLC fractions. We found several with robust postsynaptic effects as open channel blockers and have used one fraction to examine the development of neuromuscular contacts on the bodywall muscle fibers. By microinjecting the glutamate-blocking venom fraction into living embryos, we have been able to reversibly eliminate the muscle movements. Our results suggest that the embryonic muscle contractions are neurally evoked and likely due to glutamate release from the motoneurons. We are also examining similarities between our active fractions and other argiotoxins described in the literature (Adams et al., Bio. Biophys. Res. Comm.148:678 '87).

PRE-METAMORPHIC DEVELOPMENT OF SEROTONIN IMMUNOREACTIVITY IN *APLYSIA*. R. Marois and T.J. Carew. Departments of Psychology and Biology, Yale University, New Haven, CT 06520

Serotonin (5-HT) has been implicated in a variety of forms of behavioral and neuronal modulation in *Aplysia*. We have begun to explore complementary roles that 5-HT neurons may have in neurogenesis by tracing the expression of serotonin immunoreactivity (SIR) in embryonic and larval *Aplysia*.

The first SIR cells appear in the cerebral ganglia (CG) after about 50% of embryonic development. They consist of one bilaterally symmetrical pair of cells and one unpaired median cell. These cells send an anterior projection that follows the outline of the velar lobes and a medial projection to a SIR neuritic plexus in the CG. Some SIR fibers originating from the plexus project ventrally to the foot primordium. At hatching, a new pair of bilaterally symmetrical SIR cells appears in the CG and projects into the 5-HT plexus. Also at this time a caudal loop of SIR fibers extends from the CG into the visceral mass.

After hatching, the pattern of SIR undergoes little change until Stage 3 of larval development when 2-3 cells appear in each pedal ganglion (PeG). Some ventral projections from each PeG converge medially and innervate the developing foot and propodium, while others innervate the lateral aspects of the foot. Soon thereafter, SIR fibers cross the dorsal pedal commissure. By Stage 4 a single SIR cell appears along the visceral SIR loop, which is now twisted by about 90^{0}. This basic SIR scaffolding remains intact until animals acquire competence to metamorphose at Stage 6. By this time 2 more bilateral pairs of CG cells have been added and each PeG contains about 6-8 cells.

We are currently examining: (1) the impact of metamorphosis on the larval SIR pattern, and (2) the relationship of these SIR cells to identified 5-HT neurons of juvenile and adult *Aplysia*. We will then be in a position to address the hypothesis that identified 5-HT modulatory neurons of adult *Aplysia* might play organizational roles in the development of the CNS.

REGULATION OF NEUROPEPTIDE PHENOTYPES IN IDENTIFIED NEURONS OF MANDUCA EMBRYOS. J.B. Wall* and P.H. Taghert. Department of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

We are interested in the developmental regulation of transmitter phenotypes. We have studied two types of FMRFamide-immunoreactive (F-IR) neuroendocrine cells that project to a common nerve in the moth Manduca: the peripheral L1 neuron and the CF neurons of the CNS. The CF cells and the L1 cells contain distinct populations of immunoreactive secretory granules. Polyclonal antisera to four different epitopes of the Drosophila DPKQDFMRFamide gene stain the CF neurons specifically, but do not stain the L1 neuron. This suggests that the CF cells express the Manduca homologue of the Drosophila gene, while the L1 cells express a different gene encoding a separate set of FMRFamide-like peptides. Embryonic differentiation of the L1 and CF cells was monitored using intracellular dye fills and anti-FMRFamide antisera. The L1 neurons becomes F-IR at 42% of development, just after axonogenesis begins (axon ~35 um). In contrast, CF neurons become F-IR at 60%, only after extending a long (~300 um) axon from the CNS to the periphery. In both cases, the onset of neuropeptide expression correlates well with extensive contacts made by the respective neuronal growth cones onto an identified, mesodermally-derived syncytial cell that lies near the developing nerve. Identified motorneuron growth cones growing in the same vicinity do not display this affinity for the syncytial cell. L1 and CF axonal affinity for the syncytial cell is transient and typically not seen after ~80% of development. These observations suggest that cell type-specific initiation of neuropeptide expression seen in the L1 and CF peptidergic cell types may be influenced by cellular interactions with a common intermediate target. Electron microscopy, embryo culture and specific cell ablations are being used to investigate this phenomenon. Supported by NIH grant #NS21749 to PHT.

EFFECTS OF APORPHINES ON REGIONAL BRAIN NEUROTENSIN CONCENTRATIONS: IMPLICATIONS FOR DEVELOPMENT OF NOVEL ANTIPSYCHOTIC DRUGS. C.B. Nemeroff, C.D. Kilts,* B. Levant, A. Campbell,* G. Bissette, J.L. Neumeyer and R.J. Baldessarini. Depts. Psychiat. & Pharmacol., Duke Univ. Med. Ctr., Durham, NC 27710 and McLean Hosp., Harvard Univ., Belmont, MA 02178.

Considerable data have revealed interactions between neurotensin (NT) and dopamine (DA) neurons. Centrally administered NT possesses many properties in common with clinically efficacious antipsychotic drugs. We have suggested that antipsychotic-induced increases of NT in the n. accumbens (NA) are correlated with antipsychotic efficacy whereas NT increases in the caudate are associated with extrapyramidal side effect (EPS) liability. We sought to determine whether chronic treatment with S(+) NPA, an isomer of N-n-propylnorapomorphine (NPA) with selective inhibiting effects on mesolimbic DA systems alters regional brain NT concentrations. Adult male S-D rats were treated chronically with haloperidol (3 mg/kg), S(+) NPA (3 mg/kg tid), R(-) NPA or vehicle for 10-15 days. NT was measured in 11 brain regions. Both haloperidol and S(+) NPA, but not R(-) NPA, produced significant increases in NT concentrations in the NA. In the caudate nucleus, haloperidol increased NT concentrations but S(+) NPA and R(-) NPA did not. These data provide further evidence for increases in NA NT concentrations by putative antipsychotic drugs. (Supported by NIMH MH-39415, MH-39967, MH-34006 and MH-47370)

449.2

CSF NEUROTENSIN CONCENTRATIONS IN PSYCHOSES. G. Bissette, D. Garver, K. Kelly* and C.B. Nemeroff. Depts. Psychiatry and Pharmacology, Duke Univ. Med. Ctr., Durham, NC and Univ. Cincinnati, Cincinnati, OH.

Neurotensin (NT) is an endogenous neuropeptide transmitter that shares many of the pharmacobehavioral effects of antipsychotic drugs in laboratory animals. The CSF concentration of NT has been previously shown to be decreased in drug-free schizophrenic patients compared to controls. In the present study, the CSF concentration of NT of 6 normal controls and 20 psychotic (DSM-IIIR diagnosis of schizophrenia [N=15], schizophreniform disorder [N=2] or psychotic mood-incongruent affective disorder [N=3]) patients were compared after a drug-free period of two weeks. In the psychotic patients (N=8) with CSF NT concentrations below the 40th percentile, significantly greater "formal thought disorder", "behavioral disorganization", "impaired functioning" and "incidence of delusions and hallucinations" was observed in the drug-free state. Seven of eight of the patients below the 40th percentile in CSF NT concentrations were also delayed in their therapeutic response to haloperidol after failing to respond to lithium treatment. This data suggests that a subpopulation of psychotic patients with lowered concentrations of NT in CSF have more severe psychotic symptoms and exhibit a delayed response to antipsychotic drug treatment. Supported by NIMH MH-39415 and Scottish Rite Schizophrenia Research Foundation.

SPECIFICITY OF ACTION OF CCK-TETRAPEPTIDE IN PANIC DISORDER. J. BRADWEJN, D. KOSZYCKI*, C.SHRIQUI*, G. METERISSIAN*. Division of Psychopharmacology, St.Mary's Hospital, McGill University, Montreal, Quebec, H3T 1M5

Cholecystokinin (CCK) is a peptide, fulfilling criteria for a neurotransmitter, found in high concentrations in the mammalian CNS. CCK-tetrapeptide (CCK-4) has been reported to induce panic attacks in panic-disordered patients (PD) (Bradwejn J et al, Neuroscience 1988) and in healthy volunteers (HV) (de Montigny C, Neuroscience 1988). The purpose of this study was to determine the specificity of action of 50 ug of CCK-4 in panic disorder. 50 ug of CCK-4 were injected IV to 11 PD (5F, 6M), mean age (± SEM): 33.5 ± 3.6 years; and 15 HV (5F, 10M), mean age: 27.3 ± 7.1 years. A double-blind, randomized sequence of injections of CCK-4 and placebo (NaCl 0.9%) was used. Incidence, time of onset, number of symptoms and duration of CCK-4-induced panic attacks for PD and HV respectively were as follows: (mean ± SEM) 100% and 40%, 20 ± 3 and 21 ± 2 secs, 12.7 ± .66 and 14.3 ± .88, 20.7 ± 4.3 and 4.3 ± 2.7 mins. The significant difference in incidence ($P<.006$) and duration ($P<.003$) for PD and HV suggest a threshold specificity for panicogenic effect of CCK-4 in PD.

449.4

FENFLURAMINE STIMULATION OF HORMONE RELEASE IN OBSESSIVE COMPULSIVE DISORDER. W.A. Hewlett*,W.S. Agras and S. Berman Dept. of Psychiatry, Stanford University School of Medicine Stanford.CA. 94305.

Obsessive-Compulsive Disorder is a Psychiatric Disorder characterized by the presence of unwanted thoughts and stereotyped behaviors performed to reduce the anxiety associated with those thoughts. Serotonergic agents are known to affect the symptoms of this disorder and serotonergic hypotheses related to this disorder have been proposed. To study the relationship between CNS serotonergic state and the presence of OCD, 21 patients and 20 normal controls were administered a 60mg oral dose of fenfluramine, a substituted amphetamine which promotes the release of neuronal serotonin. Plasma hormone levels were measured in 2 baseline samples drawn prior to fenfluramine administration and at hourly intervals for 5 hours post-administration.Results indicate that fenfluramine produces a significant elevation in plasma prolactin levels in both patients (176%) and controls (285%). Female subjects have a significantly increased prolactin responce to fenfluramine stimulation when compared to male subjects($p<.0001$). Prolactin responses are blunted in Obsessive-Compulsive patients relative to controls. This effect is attributable to a blunting of the prolactin response in obsessive emales($p<.05$) since no differences are observed between obsessive males and their controls.

ALTERATIONS IN BILATERAL DISTRIBUTION OF BETA-RECEPTOR SUBTYPES IN SCHIZOPHRENICS AND SUICIDES

N. Lexow*, S. Senzon*, R. Artymyshyn, M. Cassanova, J. Kleinman, A. Winokur and J. N. Joyce. (SPON: J. Costello) Departments of Psychiatry and Pharmacology, University Pennsylvania School of Medicine, Philadelphia, PA

We have employed quantitative autoradiography to examine the distribution of $Beta_1$ and $Beta_2$ receptors in both hemispheres in several regions of postmortem brain tissue from: (i) schizophrenic patients that did not commit suicide, (ii) schizophrenic patients that did commit suicide, (iii) nonschizophrenic suicide cases and (iv) nonpsychotic, nonsuicide controls. In hippocampus, thalamus and striatum an asymmetric distribution of Beta receptors was evident in the controls. The $Beta_2$ subtype was higher in density in the right hemisphere of the hippocampus and thalamus, $Beta_1$ was higher in the right striatum. In schizophrenia this asymmetry was altered with an increase in $Beta_2$ receptor density in the left hippocampus and a decrease in the right hippocampus. Similar results for $Beta_1$ receptor density were observed in limbic cotrical but not other cortical regions. In a number of nuclei of the amygdala there was a decrease in the left hemisphere in total Beta density. Patients who committed suicide with or without a diagnosis of schizophrenia showed increased $Beta_1$ receptor density in the amygdala of the right hemisphere and decreased density in the thalamus. In contrast, schizophrenics who committed suicide showed different effects in hippocampus when compared to suicides without psychosis. Suicides showed consistent decreases in $Beta_2$ receptor density in both hemispheres, while shizophrenics committing suicide showed an increase in the left hemisphere (like nonsuicide schizophrenics). **Funded by NIH NS19597, MH 43852 and MH43880.**

DEFICITS IN SMALL INTERNEURONS IN SCHIZOPHRENIC CORTEX. F.M. Benes, J. McSparren*, J.P. Sangiovanni*, S.L. Vincent. Dept. of Psychiatry, Harvard Medical School and Mailman Research Center, McLean Hospital, Belmont, MA.

In order to replicate and extend an earlier finding of lower neuronal density in cerebral cortex of schizophrenics, a second patient cohort containing both chronic undifferentiated (N = 9) and schizoaffective (N = 9) subtypes of schizophrenia has been obtained. Nissl-stained sections of prefrontal and anterior cingulate cortex have been codified and subjected to a blind, random sampling paradigm. The results indicate that both types of schizophrenic patient showed lower densities of small interneurons in layers II through VI when compared to normal controls (N = 12). Two young patients (aged 23 and 32 yrs) with no neuroleptic exposure also showed lower cell counts. Since the laminar distributions of these findings overlaps that of basket, chandelier and neuroglia-form cells, we postulate that our data may possibly reflect a deficit of inhibitory GABAergic interneurons in chronically psychotic patients. It is not possible as yet to determine whether these changes arose before, during or after the onset of schizophrenia, although our current evidence shows that these differences are present early in the course of the illness and cannot be explained by various confounding effects. Supported by MH00423, MH42261, MH31154, MH/NS31862 and the Scottish Rite Foundation.

449.7

CYTOARCHITECTURAL ABNORMALITIES OF THE ENTORHINAL CORTEX IN SCHIZOPHRENIA. S.E. Arnold*, B.T. Hyman and G.W. Van Hoesen (SPON: S.A. Moore). Depts. of Neurology and Anatomy, Univ. of Iowa, Iowa City, IA 52242.

The cytoarchitecture of the entorhinal cortex was examined in the brains of 6 patients with a diagnosis of schizophrenia and in 13 controls. All 6 schizophrenic brains showed cytoarchitectural abnormalities of the rostral and intermediate portions of the entorhinal cortex. The abnormalities included aberrant non-sulcal invaginations of the anterior parahippocampal gyrus with disruption of cortical layers, heterotopic displacement of laminar-specific neurons and paucity of neurons in superficial layers. Such changes would be consistent with disturbed development. The entorhinal cortex is a pivotal point for neural systems that mediate cortico-hippocampal and hippocampo-cortical interactions. The disruption of these neural systems may have important neuropsychological sequelae, and contribute to the symptoms of schizophrenia. (Supported by: NS 14944.)

THE ROLE OF THE RIGHT BASOTEMPORAL CORTEX IN THE PRODUCTION OF SECONDARY MANIA H.S.Mayberg, S.E.Starkstein, R.G.Robinson, H.Wagner Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205

Secondary mania (SM) (i.e., mania after a brain injury) has been reported in association with lesions involving cortical (basotemporal and orbitofrontal) or subcortical (caudate or thalamus) regions of the right hemisphere (Starkstein et al., Arch Neurol 44:1069, 1987). We present a new series of 8 patients with SM having lesions involving cortical (right basotemporal cortex in 4 cases, and bilateral orbitofrontal cortex in 1 case), and subcortical (right head of the caudate in 2 cases and right frontal white matter in 1 case) brain regions. Positron Emission Tomography (PET) studies using 18-Fluorodeoxyglucose (^{18}FDG) were performed in 3 patients with subcortical lesions and SM, in two patients with subcortical lesions without mania, and in 3 normal, age-comparable controls. The ^{18}FDG-PET scan studies demonstrated right basotemporal cortex hypometabolism in all three manic patients, but in none of the lesion or normal controls ($F(2,5)=6.32, p<.05$). This finding suggests that the mechanisms leading to SM may involve the right basotemporal cortex. Dysfunction of the basotemporal cortex may result from remote hypometabolic effects (diaschisis) or from lesions directly involving the basotemporal cortex.

BIPOLAR AFFECTIVE VERSUS PURE MANIC DISORDER AFTER BRAIN LESIONS R.G.Robinson, S.E.Starkstein, P.Fedoroff*, M.L. Berthier*, H.S.Mayberg, P.R.McHugh Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205

Although mania is a rare complication of brain injury, recent studies have found that lesion location, genetic predisposition and subcortical brain atrophy are important correlates of this affective syndrome (Robinson et al., Am J Psychiat 145:172, 1988). In the present study we compared patients who developed a bipolar affective disorder (i.e., mania and depression) after a brain lesion (n=7), with patients that developed only mania (n=12) (i.e., unipolar disorder). Although no significant between-group differences were found in demographic variables, the manic depressed group had significantly greater cognitive impairment than the mania only group (Mini-Mental State Exam Scores [mean±SD]: 25.2±4.7 and 28.6±1.8, respectively, $t=2.21$, $p<.05$). In addition, all of the bipolar patients had subcortical lesions (mainly involving the right head of the caudate and the right thalamus). In contrast, 10 of 12 patients with unipolar mania had cortical involvement (mainly right orbitofrontal and basotemporal cortices) (X^2 Yates=7.38, $p<.01$). These findings suggest that subcortical and cortical right hemisphere lesions may produce different neurochemical and/or remote metabolic brain changes which may underlie the production of either a bipolar disease or a unipolar mania.

AMPHETAMINE AND CEREBRAL BLOOD FLOW (XE-133 DYNAMIC SPECT) IN SCHIZOPHRENIA. D.G. Daniel*, D.W. Jones*, J.R. Zigun*, R. Coppola, L.B. Bigelow*, K.F. Berman, T.E. Goldberg* and D.R. Weinberger. NIMH Neurosciences Center at St. Elizabeths, Washington, D.C. 20032.

Several lines of evidence suggest a monoaminergic role in the pathophysiology of reduced prefrontal metabolism in schizophrenia. Recently, we observed that apomorphine, a direct dopamine agonist, increased prefrontal cortex (PFC) blood flow (Xe-133 rCBF) during the Wisconsin Card Sort (WCS), a PFC-linked cognitive task. To further explore the role of monoamines on cerebral function we conducted a double-blind placebo controlled cross-over study of the effects of .25mg/kg dextroamphetamine on cerebral blood flow (CBF) as determined by Xe-133 dynamic single photon emission computed tomography (SPECT) during performance of the WCS and a simple control task. Subjects included 9 patients with chronic schizophrenia who had been stabilized for six weeks on .4mg/kg haloperidol.

Amphetamine produced a non-significant trend towards a diffuse reduction in rCBF that was independent of task. On placebo, no significant activation of CBF was seen during the WCS compared with the control task. With amphetamine, however, significant task specific activation of the left dorso-lateral prefrontal cortex occurred (paired $t = 4.75$, $p=.0015$). The results are further evidence that enhanced PFC monoaminergic activity may increase PFC metabolism and reverse "hypofrontality" in schizophrenia. In addition, on amphetamine, but not on placebo, a significant correlation ($r=.73$, $p=.04$) emerged between activation of PFC CBF and performance of the WCS task. These findings are consistent with animal models in which mesocortical dopamine activity modulates and enhances the signal to noise ratio of PFC activity.

VALIDATION OF PET D_2 DOPAMINE RECEPTOR QUANTIFICATION USING [C-11] NMSP AND [F-18] HALOPERIDOL D.F. Wong*, D. Young*, L.T. Young*, L.E. Tune*, G. Pearlson, E. Minkin*, C. Cidis Meltzer*, K. Midha*, R.F. Dannals*, H.T. Ravert*, A.A. Wilson*, E.D. London, H.N. Wagner,Jr.*, M. Casanova* J. Klineman*, M.J. Kuhar, A. Gjedde* (SPON: E.Broussolle). Johns Hopkins Med. Inst., U. of MD, Addiction Research Center NIDA, Baltimore. MD, U Sask., NIMH Washington, Montreal Neuro Inst.

We reported elevated D_2 dopamine receptor B_{max} in drug naive schizophrenics (SCZ) (Science 234:1558, 1986), as shown by PET with [C-11] 3-N-methylspiperone (NMSP). We have tested whether the following methodological issues contributed to our findings: [C-11] labelled metabolite corrections, plasma protein binding, and brain HAL partition coefficients. We found: (1) Multiple regression with a fitted curve showed no significant differences between plasma [C-11] NMSP metabolites measured by HPLC and modelled input function corrections (N=36). (2) There were no differences in plasma protein binding of either [C-11] NMSP in 21 patients, 8 SCZ (95.7 ± 0.4%),11 controls (95.6 ± 0.4%), and 3 bipolars (93.4 ± 2.0%); or [F-18] HAL in 10 SCZ (97.3 ± 0.2%), 6 normals (98.3 ± 0.2%), and 6 bipolars (97.2 ± 0.2%). (3) Biodistribution studies of [F-18] HAL in mouse brain performed in the presence of D_2 and *sigma* receptor antagonists gave results consistent with previous [H-3] HAL studies. No differences were found in [F-18] HAL partition coefficients in postmortem brain from 7 normals (3.1 ± 0.8 g tissue/ml plasma), 6 SCZ (3.1 ± 1.2), or 6 bipolars (2.9 ± 0.6), and values correlated closely with model assumptions. We continue to find elevated mean D_2 B_{max} with these methodologic improvements in 19 drug naive SCZ (34.2 ± 19 pmol/g) and 7 psychotic bipolars (28.7 ± 12) compared with 19 controls (15.1 ± 8.6) and 7 non-psychotic bipolars (16.9 ± 8).

449.12

VISUAL PATTERN-COMPLETION IN NORMAL AND SCHIZOPHRENIC SUBJECTS. B. Ott*, O.-J. Grüsser, Katharina Berndl* (SPON: ENA). Dept. of Physiol., Freie Universität Berlin, Arnimallee 22, 1000 Berlin 33 (West), Germany

In 37 schizophrenic subjects and a group of normal controls (age, gender and socially matched to subjects) visual object recognition was investigated in a slide projection test (b/w photographs and line drawings). Data were obtained from 9 different series of 12 slides each. The objects were presented as: (a) complete object; (b) partially visible object; (c) partially visible objects in context with other objects; (d) objects masked by meaningless patterns. (e) In another series a characteristic object in a simple scene was missing and had to be named. (f) A part lacking in a single object had to be named. (g) An event preceding a certain situation had to be named.

Total error score from all series was 12.4 + 1.0 (s.e.) percent for normals and 27.4 +2.0 percent for patients. No significant disparity between hebephrenic and paranoic adult schizophrenics was found. The average error score as well as the error scores in the 9 subtests differed for normals and schizophrenics at a significance level of $p<0.001$.

The data only slightly depended on the age of patients and normal subjects (linear correlation coefficient r=0.35 or 0.50 respectively), while level of education, duration of disease or hospitalization, and schizophrenic defect had an insignificant effect, if at all.

The data are interpreted as an indication of a *general cognitive deficiency* in schizophrenia, appearing in the present study for the visual domain. (Supported in part by a DFG-grant, Gr 161).

450.1

CHARACTERIZATION OF PROENKEPHALIN GENE EXPRESSION IN DEVELOPING FROG. M. Wong*, R. Rius*, W. P. Hayes, and Y.P. Loh. (SPON: R.Thompson). Laboratory of Developmental Neurobiology, NICHD, Bethesda, MD 20892.

In order to characterize factors which regulate the spatial and temporal expression of the opiate neuropeptide, met-enkephalin, the proenkephalin gene has been cloned in Xenopus laevis. A 2 kb probe consisting of the third exon of the frog proenkephalin gene (obtained from G. Martens; Martens, G., *Nature* 310:251, 1984) was used to screen a Xenopus laevis genomic library (obtained from I. Dawid, NICHD). Restriction enzyme map analysis showed that two positive clones in size 12 and 16 kb were isolated. These were shown to contain about 6 and 8 kb of 5' DNA sequences. Sequencing indicated that both clones were coding for the same gene. The 5' upstream flanking region of the 8 kb clone is currently being analyzed to identify the TATA box and other putative regulatory sequences.

In situ hybridization studies to localize the onset of brain and pituitary proenkephalin expression during embryogenesis are also in progress. The distribution of proenkephalin cells has been mapped in adult brain, and a similar pattern of expression was found to be present in tadpoles at developmental day 4.5 (Stage 46). In addition, cells expressing proenkephalin mRNA were found in the rostral part of the anterior pituitary.

Future studies will examine the effect of deleting the specific 5' upstream regulatory elements that have been identified on the initiation and patterning of proenkephalin gene expression.

450.2

GENE EXPRESSION OF A NOVEL MAMMALIAN NEUROENDOCRINE POLYPEPTIDE (7B2) IN LOWER VERTEBRATES AND IN THE MARINE MOLLUSK *APLYSIA CALIFORNICA*. L. Gaspar*, M. Mbikay*, M. Chrétien* and V.F. Castellucci. Clinical Research Institute of Montreal, Montreal, (Que), Canada, H2W 1R7.

A highly conserved polypeptide called 7B2 has been isolated from porcine and human pituitaries. This polypeptide is also widely distributed in the CNS but its biological role is not yet known.

The mouse cDNA sequence has been determined (Mbikay et al., 1989). Northern and Southern blot analysis shows the expression of the 7B2 gene in other mammalian species (cow, rat, monkey) and also in other vertebrates such as chicken and fish. Since the 7B2 gene appears to be highly conserved throughout evolution, we decided to study the presence of this polypeptide in the marine mollusk *Aplysia californica*. By using a probe derived from the mouse 7B2 sequence, Northern blot hybridizations under highly stringent conditions were carried out. They revealed signals in the mRNA population of different organs such as ovotestis, hepatopancreas, stomach, kidney and CNS of *Aplysia*. Similarly, signals were detected by Southern blot analysis in this invertebrate.

These preliminary results suggest that the 7B2 gene might be expressed in this system providing a useful tool for further investigation of the biological role of this polypeptide family.

450.3

ANGIOTENSIN II IS EXPRESSED IN SOLITARY VASOPRESSIN CELLS WITH A HETEROZYGOUS PHENOTYPE IN HOMOZYGOUS BRATTLEBORO RATS. F.W. van Leeuwen*, H. Imboden** and D. Felix**. *Netherlands Institute for Brain Research, Amsterdam, The Netherlands, **University of Berne, Switzerland.

In the homozgyous Brattleboro rat (di/di) an altered vasopressin (VP) precursor is synthetized resulting in reduced hormone packaging. The expression of Angiotensin II (Ang II) immunoreactivity is also disturbed, and although dynorphin (DYN) is present in smaller vesicles than in heterozygous controls, it is not affected in di/di rats.

Paradoxically, a small number of solitary hypothalamic neurons of di/di rats synthetizes the wild-type VP precursor (i.e. VP, C-terminal VP-neurophysin and a glycopeptide). Previously we provided evidence that during life an increasing number of these post-mitotic neurons (up to 3% of the VP cells) undergo a switch to a genuine heterozygous phenotype. Thus, as di/di rats age, these hypothalamic neurons exhibit both the wild-type and the mutated VP precursors. Here we report the presence of Ang II in these heterozygous cells indicating that for the expression of Ang II a normal VP precursor is necessary. It is hypothesized that in the Golgi apparatus the various neuropeptides which are present in VP cells are packaged in granules in the following order: DYN first, followed by VP and Ang II.

450.4

CALCIUM CHANNEL MODULATION AND RESPONSE ELEMENTS OF THE RAT PROLACTIN GENE. **R.N. Day*, B.A. Biagi* R.A. Maurer*, and J.J. Enyeart*. (SPON: A. Rotter). Dept. of Physiol. Biophys., Univ. of Iowa, Iowa City, IA 522242 and Dept. of Pharmacology, Ohio State Univ., Columbus, OH 43210.**

In some endocrine cells, hormone synthesis may be regulated by Ca^{2+} entry through voltage-gated ion channels. We have used dihydropyridine (DHP) Ca^{2+} channel modulators to explore the relationship between Ca^{2+} channels and prolactin (PRL) synthesis in pituitary cells, and to identify specific Ca^{2+} response elements within the 5' flanking region of the rat PRL gene. In patch clamp experiments, enantiomers of the DHP Bay K8644 produced opposing effects on Ca^{2+} current through L-type Ca^{2+} channels in GH_3 and GH_4C_1 pituitary cells. (-)-Bay K8644 enhanced the magnitude of Ca^{2+} currents 2-5 fold, while (+)-Bay K8644 blocked L channels. The enantiomers also produced opposite effects on PRL production by GH and normal rat pituitary cells in culture. Over 72 hours, cells treated with 500 nM (-)-Bay K8644 typically produced 3-4 times more PRL than controls while the (+)isomer inhibited PRL production by 30-50%.

To assess the role of the 5' flanking sequences of the rat PRL gene in conferring Ca^{2+} and DHP regulaton of transcription, several fusion gene constructs containing 5' flanking sequences were coupled to the reporter gene bacterial chloramphenical transferase (CAT) and transfected into GH_3 cells. Ca^{2+} addition stimulated CAT expression in cells containing a construct which included 1.9 kilobase pairs of the 5' flanking sequence and the effect was enhanced by (-)-Bay K8644. Constructs containing either proximal (positions -292 to -38) or distal (positions -1714 to -1495) enhancer elements of the PRL gene also responded to Ca^{2+} and the agonist with enhanced expression of CAT. The additive response observed with the two enhancer elements (9 fold) was equal to that observed with the 1.9 kilobase construct alone. In conclusion, the enantiomers of Bay K8644, by enhancing or blocking Ca^{2+} movement through "L" type channels in pituitary cells, produce opposing effects on PRL synthesis. These responses may be mediated by two separate Ca^{2+} response elements in the proximal and distal enhancer regions of the rat PRL gene.

REGULATED EXPRESSION OF α- and β-CGRP PROMOTERS IN TRANSFECTED CELL LINES.
M.A.Kirschner* and S.G.Amara, Section of Molecular Neurobiology, Howard Hughes Medical Institute, Yale Univ. School of Medicine, 333 Cedar Street, New Haven CT, 06510.

The calcitonin/α-CGRP and β-CGRP genes code for two, nearly identical neuropeptides that are expressed differentially and in discrete regions in the nervous system. Because they appear to be independently regulated and have highly divergent promoter sequences, they offer an excellent model system in which to explore the determinants of tissue-specific gene expression. We have investigated the regulatory role of 5' upstream sequences of α- and β-CGRP genes by analyzing the expression of gene constructs introduced into cells after transient DNA transfection. Promoter regions have been fused to reporter genes encoding chloramphenicol acetyl transferase (CAT) and β-galactosidase. Constructs containing 2.0 and 2.3 kilobases of α- and β-CGRP 5'-flanking regions, respectively, are sufficient to direct the expression of CAT activity in PC12 cells. Constitutive α- and β-CGRP promoter-driven expression is low in PC12 cells relative to a strong viral promoter (SV40). However, the α-CGRP promoter activity is induced two-fold after exposure to 10 μM forskolin, thus supporting a role for agents which elevate cAMP in the transcriptional regulation of the α-CGRP/calcitonin gene. Deletion mapping of the upstream promoters is currently being utilized to further delineate functional regions that mediate observed hormonal effects.

450.6

FOS AND JUN COOPERATE TO ACTIVATE TRANSCRIPTION OF THE HUMAN VIP GENE. M. Verhave*, R. Goodman* and J.S. Fink. Div. of Molecular Medicine, New England Medical Center Hospitals, Boston, MA 02111 and Lab. of Molecular Neurobiology, Department of Neurology, Massachusetts General Hospital, Boston, MA 02114 (SPON: A. Boukoms).

Transcription of the human VIP gene by cAMP or phorbol esters requires the integrity of an 17 bp enhancer element located near to its promotor. The sequence of the VIP second messenger-responsive element is similar to that of a TPA-responsive element (TRE) which interacts with the transcriptional activator protein AP-1. The AP-1 family of enhancer binding proteins includes the protein products of the *fos* and *jun* proto-oncogenes. Fos and Jun proteins form a heterodimeric complex that interacts with AP-1 binding sites in several TREs. In this study we sought to determine (1) if Jun /AP-1 interacts with the VIP second messenger enhancer, and (2) if Jun and Fos cooperate to activate transcription of the VIP gene. Expression vectors containing *v-jun* or human *c-fos* cDNAs were co-transfected into HeLa cells with fusion genes containing 94 bp of the 5'-flanking region of the VIP gene (containing the second messenger enhancer) linked to the reporter gene chloramphenicol acetlytransferase (CAT). There was little or no transactivation of the VIP-CAT gene by the *v-jun* or *c-fos* expression vectors when transfected alone with VIP-CAT. However, when *v-jun* and *c-fos* expression vectors were transfected together, there was a 10 to 20-fold transactivation of the VIP-CAT gene. Similar results were obtained when the 17 bp VIP enhancer element linked to a viral promotor was used as a target gene. In a DNase 1 footprinting assay purified AP-1, v-Jun or c-Jun protein protected a region of the VIP gene containing the second messenger enhancer. We conlcude that transcriptional activation of the VIP gene by second messengers such as cAMP or activators of protein kinase C may require the interaction of Jun/c-Fos complexes with the VIP second messenger enhancer.

450.7

CYCLIC AMP- AND GLUCOCORTICOID-MEDIATED TRANSCRIPTIONAL REGULATION OF RAT PROENKEPHALIN GENE EXPRESSION IN C6 RAT GLIOMA CELLS. J. Joshi* and S.L. Sabol. Lab. of Biochemical Genetics, NHLBI, NIH, Bethesda, MD 20892.

Glucocorticoids potentiate proenkephalin (pEnk) gene expression in several systems. Yoshikawa and Sabol (*Mol. Brain Res.* 1, 75, 1986) showed that glucocorticoids such as dexamethasone (Dex) and adenylate cyclase activators synergistically elevate the pEnk mRNA abundance in C6 rat glioma cells. We have investigated the mechanism of this effect by nuclear run-on transcription analyses and transfection assays. The pEnk gene transcription rate was not significantly altered by 1 μM Dex alone, transiently stimulated by 20 μM forskolin (up to 6-fold at 1 hr), and more persistently stimulated by Dex + forskolin (3-6-fold over 1-24 hr). Cycloheximide did not block these increases, indicating no requirement for ongoing protein synthesis. Increases in pEnk mRNA levels in C6 cells paralleled the transcription rate increases. Dex did not alter the basal or forskolin-stimulated cAMP content of the cells and produced only a modest (30%) cycloheximide-sensitive elevation of cAMP-dependent protein kinase activity. These results suggest that cAMP and glucocorticoids cooperatively elevate endogenous pEnk gene transcription.

To search for functionally cooperative glucocorticoid and cAMP regulatory elements, rat pEnk genomic clones, isolated by Dr. H. Higuchi, were used to construct plasmids containing the chloramphenicol acetyltransferase (CAT) gene placed under the control of pEnk sequences from bases -2800 to +750 in a promoterless vector. In C6 cells transfected with these constructs, forskolin increased CAT activity 5-17-fold. Unexpectedly, Dex reduced basal and forskolin-stimulated CAT activity by up to 10% and 48%, respectively. These results suggest that the sequences tested contain, in addition to cAMP-regulatory element(s), a negative glucocorticoid regulatory element (GRE), while the expected positive or cooperative GRE may be outside this region.

450.8

EXPRESSION OF NEUROPEPTIDES AND NEUROTROPHIC FACTORS IN THE MAMMALIAN TESTIS. H. Persson, C. Ayer-LeLievre, A. Ericsson, T. Hökfelt, L. Olson, M. Pelto-Huikko, J.F. Rehfeld, M. Ritzen, M. Schalling, O. Söder and M. Villar (SPON: R. Elde) Dept. of Chemistry1, Histology2, Endocrinology3, Karolinska Institute, Stockholm, Sweden. Dept. of Clinical Chemistry, Rigshospitalet, Copenhagen, Denmark.

Expression of the gene encoding the neurotransmitter/neuromodulator cholecystokinin (CCK) is demonstrated in testis of several different species. In situ hybridization revealed CCK mRNA expressing cells in the peripheral parts of the seminiferous tubule. Biochemical identification showed that the majority of preproCCK products in the testis represented proCCK. Immunofluorescence studies revealed CCK-like peptides primarily in spermatocytes/spermatids/spermatozoa of mouse, rat and monkey and immunoelectronmicroscopy on the monkey testis demonstrated CCK-like immunorectivity in the acrosomal granule of spermatids and spermatozoas. Hence, our results suggest that CCK peptides can be released during the acrosome reaction and thus may be of importance in the fertilization process. In addition, the genes encoding the neurotrophic factor β-nerve growth factor and its receptor were both shown to be expressed in the testis. NGF mRNA and protein were found in male germ cells whereas the NGF receptor was expressed in Sertoli cells. Evidence will be presented that expression of NGF and its receptor is controlled by gonadotrophic hormones.

450.9

EXPRESSION PATTERN OF NEUROPEPTIDE GENES IN TRANSGENIC MICE. D.A.Carter*, H.L.Ang* and D.Murphy*. (SPON: P.Wong). Institute of Molecular and Cell Biology, National University of Singapore, Singapore 0511.

Neuropeptide gene regulation has been studied in transgenic mice; bovine transgene expression is detected using species-specific mRNA and peptide probes. A 13.4 kb segment of bovine genomic DNA containing the vasopressin (VP)coding region and 7 kb of upstream sequence was expressed in the hypothalamus (low level) and ovary (high level) of one transgenic line. Observations throughout the estrous cycle indicate regulation of both transgene-derived mRNA, and VP in the ovary. Ovarian expression, which reflects the bovine pattern of endogenous expression, wasalso found in another line containing a chimeric VP/oncogene construct (1.25 kb of VP upstreamregion linked to the SV40 large T coding sequence).In a third line (4.2 kb of bovine genomic DNA containing the oxytocin (OT) coding region and 0.6 kb of upstream sequence) OT expression was detected in the cerebellum, testis and lung. We have demonstrated expression and regulation of bovine neuropeptide transgenes in mice. Additional control sequences may be required to direct a high level of expression to hypothalamic neurons.

450.10

GENOMIC DNA CLONING AND STRUCTURAL ANALYSIS OF THE PORCINE CHOLINE ACETYLTRANSFERASE GENE. C.M.Sampson* and E.E.Baetge. CNS Research, Bristol-Myers Company Wallingford, CT. 06492. Choline acetyltransferase(ChAT), catalyzes the biosynthesis of acetylcholine and is a specific marker for cholinergic neurons in both the peripheral and central nervous system. Recently, the cDNA's for both Drosophila and Porcine ChAT have been cloned.(Itoh.N. et.al. PNAS.,83:4081, 1986; Berrard.S. et.al PNAS.,84:9280, 1987). To begin studies aimed at delineating DNA elements responsible for targeting gene expression to cholinergic neurons we have isolated genomic clones corresponding to the porcine ChAT gene. Overlapping oligos specific to the 5' untranslated region of the ChAT cDNA sequence,(Berrard, S., et al, 1987),were employed as probes to isolate 3 clones from a porcine genomic library. A 2.7 Kb Sst 1 genomic fragment was shown by Southern analysis to hybridize to oligonucleotides specific to the first 50 bp of untranslated sequence as well as the first 50 bp of coding sequence beginning at the initiation codon. Approximately 600 bp of the 2.7 kb Sst I fragment was sequenced revealing the ATG start codon and 20 AA's before diverging at a 5' splice donor sequence. Proceeding 37 bp from the ATG start into the untranslated region, the sequence again diverges at a 3'splice junction. The intron at this junction spans approximately 2,225 bp where it rejoins the next exon at nucleotide 38 in the cDNA. This exon covers a distance of 177 bp where it is interrupted by a 3' splice sequence. Primer extension analysis using an end-labeled oligonucleotide complementary to nucleotides 24-53 in the cDNA, resulted in an extension product of 600 bases in length, indicating that at least 400bp of 5' flanking sequence remain before the end of the gene.

450.11

DEVELOPMENTALLY SPECIFIC ENHANCERS IN THE α AND β SUBUNIT GENES OF THE MOUSE MUSCLE NICOTINIC ACH RECEPTOR. C.A. Prody, V. Shah,* and J.P. Merlie. Dept. of Pharmacology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

The four subunits of the nicotinic acetylcholine receptor are coordinately regulated during skeletal muscle development. To define DNA sequences involved in the transcriptional regulation of the α and β subunit genes, the 5' flanking regions were fused to the chloramphenicol acetyl transferase (CAT) gene and transfected into C2 mouse myogenic cells. CAT activity was obtained in C2 myotubes, but not myoblasts when the -249 to -18 DNA segment relative to the translational start site was used in both orientations in conjunction with the SV40 early promoter. Further deletions resulted in decreased CAT activity, with a 40 bp fragment, 85% identical to the enhancer in the chick α subunit gene, giving 25% of the activity obtained with the long fragment. Relatively low CAT activity was observed in myotubes when β sequences from -890 to -1 relative to the translational start site were used; however, when the -156 to -1 region was fused to CAT, a 5 fold greater CAT activity was seen in myotubes, with low activity in myoblasts. This higher activity was also obtained when a -156 to -70 DNA fragment was used in both orientations with the SV40 promoter. Thus, there appear to be developmentally specific enhancers in both the α and β subunit genes, and a putative negative regulatory element in the β subunit gene.

450.12

STRUCTURAL AND FUNCTIONAL ANALYSIS OF THE CHICK MUSCLE ACETYLCHOLINE RECEPTOR γ-SUBUNIT GENE. H.-T. Jia*#, H.-J. Tsay*#, M. Ballivet*&, and J Schmidt#. #Dept. of Biochemistry, State University of New York at Stony Brook, Stony Brook NY 11794, and &Dept. of Biochemistry, Sciences II, University of Geneva, 1211 Geneva, Switzerland.

The coding regions of the chick muscle acetylcholine receptor δ- and γ-subunit genes are separated by only 743 bp (Nef et al., Proc. Natl. Acad. Sci. U.S.A. 81, 7975, 1984) likely to comprise regulatory elements responsible for the specific expression of the γ-subunit gene. This linker was sequenced, and the single γ-subunit transcription start site localized to position -57 upstream of the translation start site. An inspection of the sequence revealed neither canonical promoter elements nor any obvious similarities to the enhancers present in the α- and δ-subunit genes (Wang et al., Neuron 1, 527, 1988; and unpublished work). We have therefore begun a functional analysis. A 970-bp stretch upstream of the γ-translation start site and including the 12th exon of the δ-subunit gene was fused to the structural gene coding for chloramphenicol acetyltransferase. This construct was expressed at high levels after transfection into C2C12 myotubes, but not in myoblasts. 5' truncation to position -317 upstream of the transcription start site was tolerated; further deletions to -86 led to inactivation. Precise delineation of elements responsible for specific expression is in progress.

450.13

MULTIPLE MRNAS FOR THE TYPE I CORTICOSTEROID RECEPTOR IN RAT HIPPOCAMPUS. P. D. Patel, T. G. Sherman, R. C. Thompson, S. P. Kwak, H. Akil, and S. J. Watson. Mental Health Research Institute, University of Michigan Medical School, Ann Arbor, MI 48109.

We have recently cloned a cDNA for the type I, mineralocorticoid receptor (MR)-like, binding protein from rat hippocampus (Patel et al., *Neurosci. Abst.*, V. 14, 1988). Comparison to human MR cDNA (Arriza et al., *Science*, 237:268, 1987) demonstrates uniformly high homology throughout, except in the 5'-untranslated (5'-UT) region. RNase protection of cRNA with hippocampal mRNA revealed 5'-UT sequence heterogeneity, suggestive of multiple mRNAs. To determine the source of this observation, a genomic fragment spanning the 5'-translated/flanking regions of the rat MR gene was isolated and partially characterized. Sequences were found corresponding to the 5'-UTs for both the rat (β) as well as the human (α) MR cDNAs, and appear to exist as distinct exons separated by approximately 2 kb, situated more than 4 kb upstream of an exon coding for the N-terminal domain. Both the α and β 5'-UT exons display consensus donor sites for proper splicing to produce the observed mRNAs. Taq polymerase chain reaction is being used to determine if the homolog of the human MR 5'-UT is expressed in mature rat MR mRNA.

It it not yet known what role alternate 5'-UT sequences play in expression of the MR. Quantitation of α and β forms does not reveal a clear tissue specific distribution, although there is a tendency for the β form to be expressed at higher levels in CNS tissues. Potential correlations may be found with development or in the stability/translatability of the variant mRNAs.

450.14

IN VITRO TRANSLATION AND MITOCHONDRIAL TARGETING OF HUMAN MONOAMINE OXIDASE (MAO). C. Titlow, J. Hendrick, and X. O. Breakefield. Program of Neuroscience, Department of Neurobiology, Harvard Medical School, Boston, MA 02115

MAO is an enzyme in the metabolic pathway for neurotransmitters such as dopamine, norepinephrine, and serotonin. We have placed a full length 2.0 kb cDNA clone coding for human MAO-A into a Bluescript vector to allow transcription of sense message under control of a T7 promoter. This RNA has been translated in vitro with a rabbit reticulocyte lysate system using ^{35}S-methionine to label the polypeptide. SDS polyacrylamide gel electrophoresis of the translation products revealed a major band with a molecular weight of 66 kD. This band comigrated with authentic human MAO-A (provided by Walt Weyler). In addition, the translation product could be specifically immunoprecipitated with sheep antiserum prepared against MAO-A purified from human placenta (provided by John Pintar). Other experiments demonstrated that ^{35}S-MAO-A could be targeted to rat liver mitochondria. Current studies are underway to determine which regions of the MAO-A molecule are responsible for this targeting. (Supported by NIH grant NS21921)

450.15

PUTATIVE GENOMIC CLONES FOR HUMAN MAO A AND B. R. M. Denney and D. Pizzo*. Dept. of Human Biological Chemistry and Genetics, University of Texas Medical Branch, Galveston, TX 77550.

Human monoamine oxidases (MAO) A and B are homologous, X-linked enzymes which oxidize catecholamine and indoleamine neurotransmitters. We have screened a genomic DNA library (lambda Charon 35 vector; American Type Culture Collection) enriched in X chromosome-specific sequences with either (a) a synthetic oligonucleotide corresponding to a highly-conserved, 59-base pair sequence encoding the FAD-binding site of human MAO A and B (58/59 residues identical; Bach et al., PNAS 85:4934,1988), or (b) segments of cDNA isolated in this laboratory and corresponding ca. to nucleotides 180-1217, and 1218-1750 (MAO A cDNA) and nucleotides 1-249, 250-1291, 1292-2700 (MAO B cDNA). Most genomic clones hybridized strongly to both MAO A and MAO B cDNA fragments. Under the same hybridization conditions, MAO A and MAO B cDNAs hybridized significantly, but weakly, to each other. Therefore, strong hybridization of both MAO A and B cDNAs to individual genomic fragments may indicate that sequences related to MAO A and B are very closely linked (<20 kb apart) in human genomic DNA. EFFECT OF SECOND MESSENGER ACTIVATION ON EXPRESSION OF TH-CAT CONSTRUCTS INTRODUCED INTO MAMMALIAN CELL LINES. Joanne M. Carroll[1], Linda Hail*[1], Howard M. Goodman*[2], Tong H. Joh[1] [1]Dept. of Neurology and Neuroscience Cornell Univ. Med .College New York, New York 10021 and [2]Dept. of Molecular Biology Mass. Gen. Hospital Boston, MA 02116

Treatment of primary cultures of chromaffin cells with forskolin or TPA results in increased steady state levels of TH mRNA (Evinger et al., 1987). To determine if these agents act at the gene level, a fragment from the 5' end of the rat gene containing bases -151 to +27 was fused to the bacterial CAT reporter and introduced into C6 glioma and Ltk cells for transient assay by the calcium phosphate technique. Expression of the THCAT constructs was readily observed in several nonneuronal cell lines indicating that elements conferring tissue specific expression lie outside this region. The basal levels of expression differed in these two cell lines. While CAT activity measured in the C6 cells was 2 fold over promoterless plasmid controls, levels in L cells were barely above this background. However, when the transfectants were treated with activators of adenylate cyclase (forskolin 10 μM) and protein kinase C (TPA 100nM), the levels under induced conditions were comparable for the two cell lines. In the presence of forskolin, CAT activity in transfected C6 cells was increased by 4-5 fold. TPA increased expression by 1.5-2 fold. These results suggest that the activation of second messenger systems acting through cyclic AMP and protein kinase C leads to induction of TH transcription and that sequences residing within 151 bp of the transcription start site are sufficient to mediate these inductions. (Supported by MH24285-14 and grant from HoeschtAG to MGH.)

ISOLATION AND CHARACTERIZATION OF THE GENE ENCODING MURINE TRYPTOPHAN HYDROXYLASE. J. Stoll* and D. Goldman. Laboratory on Clinical Studies, National Institute on Alcohol Abuse and Alcoholism, Bethesda, MD 20892.

A full-length tryptophan hydroxylase cDNA was isolated from P815 cells, a mouse mastocytoma cell line. This tryptophan hydroxylase cDNA we isolated from mouse mastocytoma differs from pineal cDNA's previously cloned from rat and rabbit by the insertion/duplication of three amino acids near the N-terminus of the predicted amino acid sequence. Bacterial cells containing this cDNA fused to the gene encoding S. aureus protein A exhibit tryptophan hydroxylase activity. Different portions of the cDNA were fused to protein A and the tryptophan hydroxylase activity measured to delimit the portions of the gene which encode catalytic activity. An internal region encompassing approximately two-thirds of the gene is required. This region is highly similar in sequence to the other aromatic amino acid hydroxylases. The cDNA recognizes mRNA's from pineal, duodenum, and brainstem when used to probe Northern blots. The cDNA was used as a hybridization probe to isolate genomic clones from a library. These clones are used to reveal the structure of the gene. Characterization of the gene will allow the determination of elements important in the regulation of tryptophan hydroxylase.

450.18

CLONING AND CHARACTERIZATION OF THE RAT GLUTAMINE SYNTHETASE GENE, AND FULL LENGTH CDNA. J.F. Mill*, K.M. Mearow, and E. Freese. Lab. Molec. Biol., NINDS, NIH, Bethesda, MD 20851.

Glutamine synthetase (GS) catalyzes the synthesis of glutamine from glutamate and ammonia. GS plays a central role in nitrogen metabolism and ammonia detoxification in the central nervous system. Our interest in GS expression is due to its complex regulation by glucocorticoids, cAMP, insulin, and thyroid hormone, and its differential expression by astrocytes in the CNS.

We screened a rat cDNA library which was enriched in full length clones. A clone of 2.6 Kb in length was selected through complimentarity to a previously cloned GS cDNA which was not full length (Mearow et al., 1989). Sequence analysis of this clone shows it to be GS and to contain the 5' end of the message.

This cDNA clone was used to isolate the GS gene from a rat genomic library constructed in Charon 4a. The 16 Kb insert was subcloned as 4 Eco RI fragments. Sequence analysis has determined the first two exons and the 5' flanking region. The first exon extends 122 bp, from the transcriptional start site to upstream of translational start site. The first intron is approximately 2 Kb in length and is followed by the second exon which continues for 176 bases.

Sequences with homology to the glucocorticoid and cAMP response elements, and the AP-2 transcriptional activator have been found upstream from the start site for transcription. These regions may act as binding sites for the trans-acting factors responsible for transcriptional regulation of GS.

GLUTAMATE RECEPTORS MEDIATE IMMEDIATE-EARLY GENE EXPRESSION *IN VIVO*. R.A.Molinar-Rode, T.Curran* and J.I.Morgan*. Depts. of Neurosciences and Molecular Oncology, Roche Institute of Molecular Biology, Roche Research Center,Nutley, NJ 07110.

Cellular immediate-early genes are defined by their similarities with regulatory genes of eukaryotic viruses, notably their rapid induction by extracellular stimuli, even in the absence of protein synthesis. The products of three such genes, c-*fos*, c-*jun* and *jun*-B, are components of transcription factor AP-1, and may act as nuclear third messenger molecules, coupling stimulation to long-term transcriptional responses. Here we describe the temporal pattern of expression of a number of cellular immediate-early genes in mice (using Northern blot analyses). after activation of various classes ofexcitatory amino acid (EAA) receptors. BRAIN: Pentylentetrazole (PTZ), which activates the NMDA-type of EAA receptor, causes a rapid and transient increase in c-*fos* and *jun*-B mRNA levels in brain. In contrast, c-*jun* rises and remains elevated for at least 6 h after seizure. Kainate (KAI) stimulation results in a rapid, but much protracted, induction of c-*fos* and *jun*-B. However, c-*jun* is not strongly induced by this agent. LUNG: PTZ causes a minor, transient increase of c-*fos* and *jun*-B mRNA in lung. However, c-*jun* is constitutively high, both before and following treatment. KAI, in contrast, produces a large increase in c-*fos*, which remains elevated for at least 2 h. c-*jun* transcripts are also rapidly induced by KAI and peak 45 min after administration. decreasing gradually thereafter. The response of *jun*-B is similar to c-*fos*. GUT: PTZ and KAI caused small increases in c-fos, c-jun and *jun*-B expression. However, basal mRNA levels of all three are higher in gut than either lung or brain. We establish here that activation of EAA receptors *in vivo* results in a tissue and ligand specific induction of three of the immediate-early genes.

DIFFERENTIAL EXPRESSION OF ARPP-16 AND ARPP-19, TWO CLOSELY RELATED cAMP-REGULATED PHOSPHOPROTEINS. Atsuko Horiuchi*, Jean-Antoine Girault, Angus C. Nairn and Paul Greengard. Laboratory of Molecular and Cellular Neuroscience, The Rockefeller University, 1230 York Avenue, New York, NY 10021

ARPP-16 and ARPP-19 are two cAMP-regulated phosphoproteins (Mr=16,000 and Mr=19,000, respectively). Sequence analysis of the cloned cDNAs and the purified proteins indicate that the two proteins differ from each other by 16 additional amino acid residues on the NH_2-terminus, which are present only in ARPP-19. Comparison of the base sequence of ARPP-16 and ARPP-19 cDNAs reveals extensive segments of total identity in the translated and untranslated regions. The structure of the genes encoding for these two proteins has been analyzed by Southern hybridization of genomic DNA, using a variety of probes corresponding to the regions common to the two cDNAs and the regions specific to each of them. The regional, ontogenetic and phylogenetic distribution of ARPP-16 and ARPP-19 has been studied by Western blotting. ARPP-19 was found in the brains of all the vertebrate species studied and, at various levels, in all the tissues of adult rat. ARPP-19 was also present at high levels in several malignant cell lines and in normal embryonic tissues where it decreased during development. In contrast ARPP-16 was detected only in some specific neurons of the dopamine-innervated regions of the cerebral cortex and the basal ganglia, which are known to possess the D1 dopamine receptor. ARPP-16 was phylogenetically recent, being found only in birds and mammals and appeared late during ontogenesis, during the post-natal period. These observations suggest that the regulation of the expression of ARPP-16 and ARPP-19 is very different. ARPP-19 is expressed in all cell types especially when they are not fully differentiated, while ARPP-16 appears to be expressed only in neurons which possess the dopamine D1 receptor.

450.21

REGULATORY ELEMENTS IN THE 5' FLANKING REGION OF THE TYPE II SODIUM CHANNEL GENE CONFER CELL SPECIFIC EXPRESSION *IN VITRO AND IN VIVO* R. A. Maue, K. Ebert*, M. Low*, and G. Mandel*, Division of Molecular Medicine, New England Medical Center, Boston, MA 02111, and Department of Anatomy and Cellular Biology, Tufts University School of Veterinary Medicine, N. Grafton, MA 01536

The mammalian sodium channel genes exhibit tissue specific differences in their expression. To identify sequences in the brain type II gene required for its tissue specific pattern of expression, we have isolated a rat genomic DNA fragment containing approximately 1.1 kb of the 5' flanking region of this gene and have constructed a fusion gene between this fragment and the prokaryotic reporter gene chloramphenicol acetyltransferase (CAT). The expression of this fusion gene in transiently and stably transfected cells was significantly higher in neuronal cell types, such as rat pheochromocytoma (PC12) and human neuroblastoma (NB-5) cells, than in a variety of other cell types, including rat glioma (C6), rat myoblasts and myotubes (L6), mouse fibroblasts (3T3), and human hepatoma cells (HepG2). We subsequently introduced the same fusion gene into transgenic mice and found that the 5' flanking region is sufficient to direct tissue specific expression *in vivo*. When assayed in adult mice, high levels of CAT activity were detected in the brain, with no detectable expression in the liver, kidney, heart, skeletal muscle, or eye. Deletional studies in transiently and stably transfected cells indicate that the regulation of the type II gene depends on both positively- and negatively-acting elements in the 5' flanking region. Further localization and characterization of these elements will provide a foundation for elucidating the molecular mechanisms regulating the sodium channel gene family.

mRNA REGULATION V

THE FAMILY OF HEAT SHOCK PROTEIN 70 mRNAs ARE DIFFERENTIALLY INDUCED IN RAT CEREBELLUM, CORTEX, AND NON-NEURONAL TISSUES. E.K. Miller*, J.D. Raese and M.R. Morrison-Bogorad, Depts of Neurology, Biochemistry and Psychiatry, U.T.-Southwestern, Dallas, Texas, 75235 and the Schizophrenia Res. Ctr., V.A. Medical Ctr., Dallas, Texas, 75216.

Oligonucleotides were synthesized to hybridize to either the inducible HSP70 mRNA, the constitutively expressed cognate HSC70 mRNA, or the glucose-regulated protein, GRP78 mRNA. mRNAs encoding GRP78 (3.05 kb), and HSC70 (2.55 kb) were detected in all tissues. No HSP70 mRNA was detected in control tissues. After heat shock or amphetamine-induced hyperthermia, two HSP70 mRNAs (3.53 and 3.05 kb) were induced. These mRNAs were quantitated by slot blot analysis relative to the levels of 18S RNA. There were dramatic tissue-specific differences. The induction of HSP70 mRNAs was always several fold greater in non-neuronal tissues than in brain. In cerebellum, HSP70 mRNA induction was always several fold higher than in cortex. Both treatments also increased HSC70 mRNA levels, again more in cerebellum than in cortex. In amphetamine-treated animals, temperatures above 40°C were required for HSP70 mRNA induction but not for induction of the other mRNAs. This data suggests that neuronal tissue may be more susceptible to cellular stress than non-neuronal tissue. Furthermore, cortex may be more vulnerable than cerebellum. Supported by NIH AG08013 (MRM-B and JDR), NIH HD14886 and the Leland Fikes Foundation.

451.2

IN SITU QUANTITATION OF HEAT SHOCK 70 mRNAs IN RAT CEREBELLUM AFTER AMPHETAMINE-INDUCED HYPERTHERMIA. M.R. Morrison-Bogorad, K. Groshan*, E.K. Miller*, and J.D. Raese, Depts of Neurology, Biochemistry and Psychiatry, U.T.-Southwestern Medical Center, Dallas, Texas, 75235, and the Schizophrenia Res. Ctr., V.A. Med Ctr, Dallas, Texas, 75216.

We have synthesized oligonucleotide probes that specifically recognize the stress-induced (HSP70) or the constitutively expressed (HSC70) heat shock mRNAs. The two mRNAs were quantitated by in situ hybridization in different cell types of rat cerebellum relative to total poly(A) and 18S RNA. No HSP70 mRNAs were found in control rat cerebellum. HSC70 mRNAs were present at similar relative levels in Purkinje and granule cells, but the mRNA was sparse in all non-neuronal cells. After amphetamine-induced hyperthermia, HSP70 mRNA was dramatically induced in non-neuronal cells (pial cells, oligodendrocytes and, possibly, Golgi epithelial cells). Induction of the HSP70 mRNA was much less pronounced in neurons. Granule cells had the highest levels, and Purkinje cells were least responsive. These results show that the magnitude of the HSP70 response to amphetamine-induced hyperthermia differs in different brain cells and different neuronal classes. The extent of induction of this, or other, stress-related proteins may be important in determining the vulnerability of different brain cell populations to environmental or physiological stress. Supported by NIH HD P50-AG08013 (MRM-B and JDR), NIH 14886 and Leland Fikes Foundation (MRM-B).

451.3

REGULATION OF TRANSLATION BY STEROIDS: MYELIN PROTEIN mRNAs. J. M. Verdi*, S. W. Grant*, AND A. T. Campagnoni. (SPON: C. Clemente) U.C.L.A. Medical School, 760 Westwood Plaza, Los Angeles, CA 90024.

The translation of several myelin protein synthetic mRNAs were examined in reticulocyte lysates and myelin basic protein (MBP) mRNAs were found to translate less efficiently than other mRNAs tested. Among the transcripts encoding four different isoforms of MBP the 18.5kDa MBP mRNA translated more efficiently than the others. This indicates that coding regions of the mRNA, in addition to the untranslated regions, can influence the efficiency with which mRNAs are translated. The role of the 7me-guanosine cap in the translation of myelin protein mRNAs was also examined. Like most mRNAs, the CNPase message was translated more efficiently when it was capped. In contrast, MBP mRNAs translated 1.6x better when they were uncapped. Since the MBP mRNAs are capped in vivo, this places them at a further translational disadvantage compared to other myelin protein messages. We also observed that steroids could modulate the efficiency with which myelin protein mRNAs were translated. When MBP and PLP mRNAs were translated in the presence of 10^{-8} M hydrocortisone, synthesis of these proteins was stimulated two fold; but the translation of CNPase was inhibited 60%. Steroids had no effect on the translation of several other mRNAs. Thus, steroids may alter the translational efficiency of myelin specific mRNAs by increasing the efficiency of poorly translating messages such as MBP, and inhibiting the translation of favored mRNAs like CNPase, thereby altering the levels of polypeptides that are synthesized. Such findings may provide a molecular explanation for the changes in the proportions of these proteins known to occur with development. (Supported by NIH grants NS23022 and NS23322).

451.4

HEAT SHOCK RESPONSE IN GERBIL BRAIN AFTER ISCHEMIA -- IN SITU HYBRIDIZATION ANALYSIS. T. S. Nowak, Jr. Lab. of Neuropathology and Neuroanatomical Sciences, NINDS, NIH, Bethesda, MD 20892.

The distribution and induction time course of RNA encoding the 70 kDa stress/heat shock protein (hsp70) was determined in postischemic gerbil brain by in situ hybridization with a ^{35}S-labeled oligonucleotide selective for inducible species of the hsp70 family, and compared with that of immunoreactive hsp70 detected with a monoclonal antibody having similar selectivity. In control animals hsp70 hybridization and immunoreactivity were detected only in ependymal cells. Following 5 min bilateral carotid artery occlusion hsp70 RNA was evident in dentate granule cells within 3 h, with prominent induction in all hippocampal pyramidal cell fields by 6 h recirculation. Within 24 h the signal was greatly reduced in those neuron populations which eventually showed hsp70 immunoreactivity, while hsp70 RNA sequences remained elevated through at least 48 h in CA1 neurons which fail to express the protein. No hsp70 hybridization remained in the CA1 region following the loss of these neurons by 4 d. CA1 neurons vulnerable to ischemic injury thus demonstrate a robust and even prolonged heat shock response at the transcriptional level under conditions in which profound deficits in translational activity may preclude accumulation of immunoreactive protein. In CA3 neurons there was a notable lag between the disappearance of hybridizable RNA at 24 h and the detection of peak immunoreactivity at 48 h, raising the alternative possibility that hsp70 synthesized in CA1 neurons may be similarly inaccessible to the antibody during a period of active stress.

451.5

CONSTITUTIVE HEAT-SHOCK-70 mRNA IN BRAIN IS PRIMARILY NEURONAL AND IS INCREASED BY ESTROGEN IN HYPOTHALAMUS. C.V. Mobbs, K.L. O'Malley[1], A.H. Lauber, and D.W. Pfaff (SPON: Z. Wenzel). Rockefeller Univ., New York, NY, 10021, and [1]Washington Univ., St. Louis, MO 63110.

We previously showed that constitutive heat-shock-70 (hsp70) mRNA is increased by estrogen in uterine secretory cells. In this study we examined if estrogen would increase hsp70 mRNA in the arcuate and ventromedial hypothalamic nuclei (VMN), two areas containing estrogen receptors. Ovariectomized female Sprague-Dawley rats were given implants containing estradiol, or sham implants, and sacrificed 6 hours later. The brains were processed for in situ hybridization, using a 3H-labelled cDNA probe (pRC62) complementary to constitutive hsp70 mRNA. Grains were localized over neurons, with few grains over glia or ependyma. The results, representing 50 cells of each brain region and 50 glial cells from VMN from each animal, are shown below (grains/cell, mean ± SEM).

	VMN	Arcuate	Hippocampus	Glia
No E2	6.9 ± 0.3	4.5 ± 0.5	5.0 ± 0.6	1.0 ± 0.3
6h E2	16.8 ± 0.8	10.2 ± 0.4	6.6 ± 0.5	1.4 ± 0.3

These results indicate that constitutive hsp70 mRNA is found mainly in neurons and is increased by estrogen in hypothalamic nuclei which contain estrogen receptors, but not in hippocampus, which contains few estrogen receptors.

451.6

LOCATION OF THE PROMOTER REGION FOR THE LAMININ B2 GENE IN RAT C-6 GLIOMA CELLS. H. HALEEM-SMITH*, J.R. WUJEK, E. FREESE, P. BURBELO*, AND Y. YAMADA* (SPON: K. BICK). Lab. of Molec. Biol., NINDS, NIH and Lab. of Dev. Biol. and Anomalies, NIDR, NIH., Bethesda, MD 20892.

Laminin, a protein of the extracellular matrix with strong neurite outgrowth promoting activity, is transiently expressed during development of the rodent central nervous system (Letourneau et al., Dev. Biol., 1988, 125: 135). Astrocytes, which stimulate neurite outgrowth *in vitro*, have recently been shown to synthesize and secrete only the B2 chain of laminin (Wujek et al., Neurosci. Abstr. , 1988, 14: 1326). We have investigated the molecular mechanisms that regulate expression of the laminin B2 chain in astrocytes. We made constructs containing the promoter region (-830 to +106) of the B2 chain gene fused to a structural part of the chloramphenicol acetyltransferase gene (Ogawa et al., 1988, J. Biol. Chem. 263: 8384) and examined the promoter activity by transfecting them into rat C-6 glioma cells and F9 teratocarcinoma cells (differentiated F9 cells synthesize abundant quantities of laminin). This first construct exhibited significant activity in both cell lines. Further deletions of the promoter (down to nucleotide -94) were constructed and transfected into F9 and C-6 cells. In both cell lines, all deletion constructs exhibited significant activity. These results indicate that a sequence, located between nucleotides -94 and +106 of the laminin B2 chain gene, is needed for expression in both the rat C-6 glioma and mouse F9 teratocarcinoma cells.

451.7

ALTERNATIVE SPLICING AND POLYADENYLATION OF HUMAN SYNEXIN mRNA. K. Magendzo*, H. B. Pollard and A. L. Burns* (Spon: A. Basile). Lab. of Cel. Biol. and Gen.,NIDDK, NIH Bethesda MD 20892.

Synexin is a calcium dependent membrane binding protein that aggregates adrenal chromaffin granules and acts as a voltage-dependent calcium channel in artificial bilayers. The sequence of human synexin cDNA clones showed that synexin belongs to a family of endonexin II-like proteins, all of which bind to membranes in the presence of calcium (Burns, A.L. et. al., Proc. Natl. Acad. Sci.USA(1989) 86: in press). Northern blot analysis of human liver and adrenal medulla mRNA revealed the existence of two distinct synexin bands of 1.95 Kb and 2.4 Kb. The possibility of alternative splicing was examined by isolating and sequencing several human synexin cDNA clones. Two of the clones analysed contained a longer 3' untranslated region (336 bp) generated by the selection of an alternative polyadenylation site. We have also isolated a cDNA clone containing a presumed exon (66 bp) located at the 5' end region. The deduced aminoacid sequence of this exon introduces 3 acidic aminoacids to an otherwise highly hydrophobic, unique N-terminal domain. The prevelance of these transcripts is being analysed by screening specific regions of human synexin mRNA using the polymerase chain reaction technique and detecting the amplified products with oligonucleotide probes. The functional role of these putative alternative splicing is being investigated.

451.8

CNS-SPECIFIC PROBES FROM SUBTRACTIVE cDNA LIBRARIES. J.R. Hofstetter*, J.J. Wei*, B. Ghetti, J.I. Nurnberger, Jr., and M.E. Hodes* (SPON: B. Azzarelli). Departments of Medical Genetics, Pathology, Psychiatry and Institute for Psychiatric Research, Indiana Univ. Med. Sch., Indianapolis, IN 46223.

To identify morphologically important transcripts specific to CNS neurons, we constructed mouse subtractive cDNA libraries (cerebellum minus frontal cortex and cerebellum minus frontal cortex and liver). We identified several recombinant clones that were apparently brain-specific. We amplified one cloned insert, designated P8, from purified lambda phage DNA using the polymerase chain reaction, cloned it directly into M-13, and sequenced it by the Sanger method. The gene fragment corresponds to a 6.7-kilobase mRNA from mouse cerebellum and cortex. The sequence of the probe does not have homology with any sequences in the Gene Bank data base and contains a potential coding region for 60 residues of a protein.

Based on the sequence, we obtained two synthetic single-stranded probes, thirty nucleotides long. These are being used for in situ transcription and hybridization on mouse brain slices to determine the distribution of P8 in the CNS. We intend to find the extent of cross-species expression, chromosomal origin, and developmental onset of expression in the mouse of this new probe.

Supported by USPHS grant RO1-NS14426.

DIFFERENTIAL PROMOTER UTILIZATION GENERATES A NOVEL FAMILY OF RAT NEURONAL PROTEINS P.E. Danielson, S.Forss-Petter, E.Battenberg, R.J. Milner, F.E.Bloom and J.G.Sutcliffe. Research Institute of Scripps Clinic, La Jolla, CA 92037

Four forms of 1B426B mRNAs are generated from 2 genes by alternate transcriptional initiation and subsequent 5' end splicing. The mRNAs are most abundant in cortex and hippocampus, but are present at lower levels in other brain regions. Some forms are found in pituitary>adrenals> spleen, thymus and ovaries, but none is found in any of several other tissues. In situ hybridization shows enrichment in dentate granule cells and polymorphic neurons, and pyramidal neurons of the hippocampus (CA4>CA3>CA1) and neocortical layers 3,5 and 6. 1B426B mRNAs encode 4 distinct apparently secretory and/or membrane proteins of 125, 153, 457 and 485 amino acids that differ from each other only at N and/or C termini. Antisera to synthetic peptide fragments of the common region detect four proteins in brain extracts whose mobilities shift after endoglycosidase treatment, indicating that these are glycoproteins. Form-specific subprobes suggest developmentally regulated cell-specific expression of members of this mRNA family.

451.11

CHARACTERIZATION OF MRNA IN PREPARATIONS OF RAT CORTEX SYNAPTOSOMES. I. J. Weiler, G.S. Withers, C. S. Wallace and W. T. Greenough. Beckman Inst., Depts. Psych. & Cell & Struct. Biol., & Neur. & Beh. Biol. Prog., Univ. IL, Champaign, IL 61820.

Cortical synaptosomes from young (P 18-21) and old rats were prepared in buffers containing cycloheximide and RNase inhibitors (heparin, vanadyl complexes). After samples were taken for EM examination, synaptosome suspensions were lysed and polysomes were collected by ultracentrifugation through 1 M sucrose. RNA was isolated with guanidine isothiocyanate, followed by two precipitations out of guanidine-HCL. Total RNA was electrophoresed in 1% agarose gels containing 2M formaldehyde, and transferred to Gene screen. Radiolabelled oligo-dT probes have demonstrated the presence of polyadenylated mRNA. We are currently engaged in probing further samples for the presence of specific messages, among which are actin, GAP43, MAP2 (microtubule-associated protein), and synthetic oligonucleotides complementary to the sequences of N-CAM and calcium-calmodulin-dependent protein kinase II. Supported by MH35321.

CORTICOSTERONE REGULATED GENES IN THE HIPPOCAMPUS: REGULATION BY THE TYPE I OR TYPE II GLUCOCORTICOID RECEPTOR. J.N. MASTERS, N.R. NICHOLS, H.H. OSTERBURG AND C.E. FINCH. Andrus Gerontology Center, USC, Los Angeles, CA 90089-0191

We have used corticosterone (CORT) regulated cDNA clones isolated from a rat hippocampal library to analyze steroid and stress-responsiveness in individual rats. The clones include glial fibrillary acidic protein (GFAP), glycerol phosphate dehydrogenase (GPDH) and CR16 which codes for an unidentified gene product expressed in hippocampal neurons; GFAP RNA abundance decreases with CORT while both GPDH and CR16 increase with CORT. The steady state levels of total RNA for the three clones was measured by RNase protection or RNA blots quantified by videodensitometry. In adrenalectomized (ADX) rats, all clones exhibit maximal responses to RU28362 consistent with being regulated by the type II receptor. As the type II glucocorticoid receptor is thought to mediate stress responses, we analyzed the effects of stress on the RNA abundance of these clones in individual rats. The animal groups were 3d ADX, 7d ADX, intact (INT, sacrificed in the AM) and INT + Stress (2 hr stress). GPDH RNA was increased 4-fold in INT rats by vibratory stress. There was no significant difference between INT and ADX groups. In contrast, CR16 and GFAP showed near maximal responses in INT versus ADX rats and no further increase to stress. These data are consistent with GPDH being regulated solely by the type II glucocorticoid receptor as a stress response. CR16 and GFAP may also be regulated by the type I receptor since low AM CORT significantly alters their expression. We plan to confirm the type I component by adding low levels of CORT with Alzet osmotic pumps as well as analyze the expression of these genes during the circadian rhythm. Supported by ONR grant N00014-85-K-0070; NRN is a Brookdale National Fellow.

451.13

ANALYSIS OF mRNAS SHOWING REGION-SPECIFIC DISTRIBUTION IN NONHUMAN PRIMATE CORTEX. K.Chandrasekaran*, M.F. Matocha, S.P.Wise and S.I. Rapoport. Lab. of Neurosci., NIA, Bethesda, MD 20892 and Lab. of Neurophysiology, NIMH, PO Box 289, Poolesville, MD 20837.

It has been proposed (Rapoport, S.I. Rev Neurol, Paris 144:79, 1988) that Alzheimer's disease is a 'phylogenetic' disease afflicting the recently elaborated associative neocortices and their connections to older brain regions. To examine this hypothesis further, we have begun to identify mRNAs that show specific expression in associative neocortical regions of the Rhesus monkey. cDNA libraries were generated in λgt10 using mRNAs prepared from frontal pole and from visual cortex brain areas. Initially 10,000 plaques in the frontal pole cDNA library were screened by subtractive and differential hybridization. 31 cDNA clones were identified that hybridized specifically with the total cDNA probe prepared from the frontal pole but not with the probe from the visual cortex. A secondary screening confirmed that several of these clones retained a differential hybridization pattern. The results on the identification and characterization of these clones will be presented.

451.14

DIFFERENTIAL RECOMBINANT cDNA CLONES ISOLATED FROM A SUBTRACTED LIBRARY CONSTRUCTED FROM A QUIESCENT NEURONAL CELL LINE. P. Crisanti*, L. Bidou* and B. Pessac. Eq. de Neurobiologie Cellulaire et Moleculaire, CNRS LP 3101, 67 rue M. Günsbourg, 94205 IVRY S/SEINE (France).

In order to investigate if the negative control of cell proliferation can be correlated with the expression of specific genes, we have constructed a subtracted cDNA library from a quail neuroretina cell clone immortalized with the RVS mutant ts-NY-68 (a sister clone is described in Nature (302) 616-618). This clone is thermosensitive for transformation and multiplication; indeed, cells multiply at 36°C while they are quiescent 48 hours after a shift up to 41.5°C. At this time point, renewal of fetal calf serum containing culture medium does not induce DNA synthesis. However, cells in S phase appear 6 hours after a shift-down to 36°C. The cDNA library was constructed from cells that had become quiescent 48 hours after a shift up. To enrich the cDNA library in transcripts which might be expressed at a low level, single strand cDNA synthesized from poly(A)$^+$ mRNA of cells cultured at 41°C were subtracted by liquid hybridization with an excess of poly(A)$^+$mRNA of cells cultured at 36°C. Thus, a 13-fold enriched cDNA library containing 8000 clones was obtained. This library was differentially screened with "41°" and "36°" cDNA probes both subtracted with poly(A)$^+$mRNA of cells cultured at 36°C. About twenty clones hybridized to poly(A)$^+$mRNA of quiescent cells cultured at 41°C and not to poly(A)$^+$mRNA of cells cultured at 36°C.

We are currently investigating the expression of the mRNAs corresponding to the cDNA clones in various quiescent nervous and non-nervous quail tissues. In parallel, partial sequences of the cDNAs is being studied.

A NOVEL IN VITRO cDNA AMPLIFICATION METHOD: LINEAR AMPLIFICATION OF RAT CEREBELLAR cDNA. R.N. Van Gelder*, M. von Zastrow*, W.C. Dement, J.D. Barchas, J.H. Eberwine* (SPON: S. Leff). Basic Sleep Research Laboratory and Nancy Pritzker Laboratory of Behavioral Neurochemistry, Stanford U. School of Medicine, Stanford, CA 94305.

In order to isolate and characterize brain nucleus- and cell-specific messages from very small amounts of neural tissue, we have developed a novel in vitro cDNA amplification method. cDNA is prepared from total RNA using a synthetic primer which includes the T7 bacteriophage RNA polymerase promoter site. Addition of T7 RNA polymerase generates anti-sense, amplified RNA (aRNA). We have achieved up to 80-fold molar amplification of rat cerebellar RNA using this technique. The aRNA matches the parent cDNA exactly in size distribution. The amplified material is of high complexity as demonstrated by R_0t analysis and binding of aRNA to Northern and Southern blots. We are able to detect specific, low abundance messages in the amplified material. We anticipate this technique will be of great utility in cloning and characterizing messages of interest from limited amounts of very heterogeneous neuronal tissue.

INGESTIVE BEHAVIORS V

452.1

SOYBEAN TRYPSIN-INHIBITOR DECREASES INGESTION OF MILK IN NEONATAL RATS. A. Weller, G.P. Smith and J. Gibbs. Bourne Lab., New York Hospital-Cornell Medical Center, White Plains, NY 10605.

Trypsin-inhibitor (TI) is a potent releaser of endogenous CCK in adult rats (Liddle et al., Gastroenterol. 87:524, 1984). Assuming a similar effect in the young rat, TI was used to test the hypothesis that endogenous CCK would reduce the intake of milk diet by neonatal rats just as exogenous CCK inhibits intake (Robinson et al., Am. J. Physiol., 255:R14, 1988). Nondeprived rat pups, 10-12 days old, received an intragastric infusion of TI (100 mg/1 ml saline) or isotonic saline. 15 min later they were placed on a towel soaked with commercially available 'Half and Half'. TI significantly reduced the percent body weight gain in two separate replications: means= 1.28% vs 0.69% and 1.29% vs 0.034% for the saline-TI comparisons in the two replications ($p<.05$; N=8 rats per infusion group in each replication). These results suggest, but do not prove, that TI decreased intake by releasing CCK from the small intestine.

452.2

PSYCHOPHARMACOLOGY OF CONSUMMATORY RESPONSE EXTINCTION. C. F. Flaherty, K. Hrabinski*, J. Reese*, and J. Alvarez*. Psychology Dept., Rutgers University, New Brunswick, NJ 08903.

Anxiolytics may or may not retard extinction of consummatory behavior (empty tube licking) following access to water (e.g. Miczek & Lau, Psychopharm., 42:263269, 1975; Soubrie, et al., Psychopharm., 59:95-100, 1978). Drug effects on empty-tube licking following training with a 32% sucrose solution are reported here. Rats kept at 82% of their free-feeding weight were allowed daily (10 days) five minute access periods to 32% sucrose. A twenty-minute extinction session (empty tube) was administered on the eleventh day. All drugs were administered acutely in extinction.

Chlordiazepoxide (8 mg/kg) and sodium amobarbital (17.5 but not 20 mg/kg) enhanced initial resistance to extinction. Buspirone (0.5 and 2.0 mg/kg) had little effect, but tended to facilitate extinction. Cyproheptadine (3 and 6 mg/kg) had no effect on extinction. These results tend to parallel the effects of the same drugs on negative contrast, where rats are shifted from 32% to 4% sucrose. However, in the contrast procedure, CDP is maximally effective late rather than early in the 'post-shift' period, and cyproheptadine had potent anti-contrast effects. Ongoing experiments involve the comparative effects of amphetamine, imipramine, methysergide, ritanserin, and ethanol.

452.3

EFFECTS OF CORTICOSTERONE IN DRINKING WATER ON NATURAL FEEDING PATTERNS. M.Yamamoto*, D.Tempel and S.F.Leibowitz (Spon:G.Brennan). Rockefeller University, N.Y.,N.Y. 10021

Corticosterone(CORT) is known to be involved in natural feeding processes. Adrenalectomy(ADX) results in a suppression specifically of carbohydrate(C) intake, at the onset of the nocturnal cycle when ingestion of this macronutrient is normally high. C ingestion is restored by peripheral injection or central implants of CORT. In the present study, we provided ADX animals with free access to a CORT-supplemented saline solution(200ug/ml), or vehicle (0.9% saline), 17 or 3 hrs prior to dark onset, and recorded macronutrient intake during the 1st hr of the dark cycle. Results indicate that animals consumed similar amounts of the CORT and vehicle solution. CORT presentation, 17 or as little as 3 hrs before dark onset, resulted in a significant increase in 1-hr C intake(+2.7 Kcal, p 0.05) over vehicle baseline, with no change in fat or protein intake, and a tendency toward an increase in total food intake. In addition, a strong positive correlation(r=0.73, p 0.05) was observed between CORT intake(mls) and 1-hr C intake(Kcal) at dark onset. No similar relation was observed with vehicle consumption. These effects of CORT were observed after the ingestion of as little as 5-6 mls(approximately 1 mg CORT) during the 3-hr pretreatment period, and support a possible role for the glucocorticoid in natural feeding processes.

452.4

RACLOPRIDE DECREASES INTAKE OF SUCROSE IN RATS AS EARLY AS POSTNATAL DAY 14. G.P. Smith, C. Gayle*, J. Gibbs, R.D. Shindledecker* and S.H. Ackerman. E.W. Bourne Lab, NY Hosp-Cornell Med. Ctr., White Plains, NY 10605.

Raclopride, a D-2 dopaminergic antagonist, decreases the sham feeding of sucrose in adult rats (ID_{50}=150 ug-kg^{-1},ip, Schneider et al, 1988). To determine the ontogeny of this effect, pups were removed from the litter on postnatal days 7,14 and 21. Some pups were equipped with an anterior, sublingual catheter (Hall, 1979). Four h later, the intake of 10% sucrose was measured in one of two 20-min tests in a warm, humid environment: (1) continuous, sublingual, intraoral infusion or (2) independent ingestion in which a pup ingested 10% sucrose from tissues in the bottom of a test beaker. A dose of raclopride or saline alone was injected ip 15 min prior to an intake test. Each pup was tested only once. Raclopride was significantly more potent for decreasing intake in the independent ingestion test than in the intraoral infusion test after day 7 (Table).

POTENCY OF RACLOPRIDE (ID_{50}, ug-kg^{-1}, ip)

DAY	INTRAORAL CATHETER	INDEPENDENT INGESTION
7	>3333	>3333
14	1714 - 3429	109
21	>1333	83

Although the reason(s) for the differential potency in the 2 tests is not clear, the results suggest that D-2 receptor activity is necessary for the positive reinforcing effect of sucrose on independent eating as early as postnatal day 14.

452.5

CENTRALITY OF HISTAMINE AND CRF IN PEM-INDUCED SUPPRESSION OF FOOD INTAKE. J.D.Dunn, S.Dodds,* M.Weber,* D.Hampton* and L.P.Mercer.* Depts. of Anat. and Biochem., Sch. Med., Oral Roberts Univ., Tulsa, Ok 74171.

We have recently put forth the suggestion that histaminergic stimulation of corticotropin releasing factor (CRF) is central to the suppression of food intake (FI) observed in protein energy malnutrition (PEM). Brain histamine (HA) as well as histidine (HI) levels are increased during PEM, and PEM-induced suppression of FI is partially ameliorated by administration of HI decarboxylase.

To further pursue our hypothesis, we evaluated the effect of PEM on several parameters of pituitary-adrenal function. Additionally we assessed the effect of electrolytically ablating the paraventricular nucleus of the hypothalamus (PVN) on FI of rats fed a low protein diet (8% casein). In all studies adult male rats were assigned to treatment groups and studies were conducted according to a randomized block design. Control diets contained 25% casein. Body weight and FI were recorded daily and blood samples for Cpd B (RIA) were collected via rapid decapitation.

Both AM and PM non-stress plasma corticosterone (Cpd B) levels of rats fed a PEM diet were higher (P<0.05) than those of rats fed a control diet. Concomitant with decreased FI and elevated Cpd B levels, PEM rats showed a 75% increase in hypothalamic HA concentrations (RIA) compared to rats fed a control diet. Significantly, PVN ablation abolished the PEM-induced suppression of FI observed in controls.

Collectively these data, taken together with our previous studies, offer considerable support for our hypothesis that histaminergic stimulation of CRF is involved in PEM-induced suppression of FI.

452.6

FETAL DIETHYLSTILBESTROL (DES) EXPOSURE: A POSSIBLE RISK FACTOR IN THE DEVELOPMENT OF ANOREXIA NERVOSA. C.R.Gustavson,J.C.Gustavson*,K.L.Noller*,L.J.Melton,III*, P.C.O'Brien*,A.J.Pumariega*. Psych. Ethology Lab., Univ. of Texas Med. Br. Sch. of Med., Gal., TX 77550, & DESAD Project, Mayo Foundation, Rochester, MN 55905.

From data collected using rats as a model, & conditioned taste aversions as a measure of malaise, we proposed a neuroethological model of anorexia nervosa. We suggested fetally CNS masculinized females become nauseated at estrogen doses similar to males, lower than normal females & within the range normally produced by the ovaries (Gustavson, C.R. & Gustavson, J.C., Soc. Neurosci. meetings, 1986, & 1987; Gustavson, C.R., Gustavson, J.C., Young, J.L., Pumariega, A.J. & Nicolaus, L.K. Neur. Cont. Of Reprod. Func.: Proc. of Fifth Gal. Neurosci. Symp., 1988). We suggested that DES exposure may produce results similar to the testosterone masculinization we investigated previously.

This presentation reports: 1) the results of adult conditioned taste aversion establishment using 3 estrogen doses in post-natally DES & testosterone exposed, & unexposed male & female rats (N=> 6 rats/group); 2) an analysis of data from 1711 DES fetally exposed & 919 unexposed human females showing a rate of 18.7/1000 cases of unexplained low body weight (Weight<=80% of expected for age, sex & height) in the exposed group compared to 3.3/1000 cases in the unexposed group; a 5.72 to 1 ratio

452.7

PUTATIVE AMINO ACID NEUROTRANSMITTERS AND SOMATOSTATIN DYNAMICS OF THE VENTROMEDIAL AND LATERAL HYPOTHALAMUS DURING MEAL FEEDING. S.J. Dodds*, M.C. Starke*, and R.C. Burgus* (SPON: D.F. Peterson). Dept. of Biochem., Oral Roberts Univ. Sch. of Med., Tulsa, OK 74171.

The Ventromedial (VMH) and Lateral Hypothalamus (LH) have classically been considered hunger and satiety centers. Neuroanatomical experiments were undertaken to elucidate neurotransmitter relationships within these nuclei.

The VMH and LH were dissected and assayed for free amino acid and somatostatin concentration in response to meal feeding regimen in 18- and 3-month old rats. Frozen transverse sections (20 µm) were taken from the hypothalamic area with every fifth section stained for histological verification. Sections were freeze-dried and nuclei surgically removed under 25X mag. The VMH and LH fragments were weighed and stored under vacuum at -20°C until assayed.

Five putative neurotransmitter amino acids--asp, glu, gly, GABA, and taurine--were assayed by pre-column orthophthalaldehyde derivitization and HPLC. Somatostatin was assayed by a radioimmune technique.

Somatostatin and taurine varied significantly between the feeding stages, suggesting taurine's role as a neurotransmitter releasing the peptide hormone somatostatin. Taurine levels increased with initiation of a meal in the VMH and decreased in the LH. Linear patterns continued to the end of the meal ($p < .001$). Similar relationships were seen with somatostatin; the correlation was significant ($p < .01$). Other trends were seen with GABA, gly and glu.

452.8

LONG TERM STABILITY OF FEEDING BEHAVIOR IN RATS. R. Bauman and R. Pastel (SPON: R. Wylie). Dept. of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307.

Although previous research has documented the 24 hour patterns of feeding in rats, little if any data are available showing the long term stability of those patterns. Since the day to day stability of feeding patterns was considered a prerequisite to subsequent drug studies, the food intake of six rats was studied for 18 days. A 12 hour light/dark cycle was maintained in each rat's chamber. Rats could feed ad lib by pressing a lever once for each 45 mg food pellet. A meal was defined as a bout of eating not interrupted by a pause longer than 10 mins.

Food intake was much greater during the dark period. Hourly intake during the light was low and variable until the two hours preceding light offset, at which time food intake began increasing. Intake increased greatly at dark onset and peaked 3-4 hours into the dark period. The number (12 vs 3) and size (43 vs 32 pellets) of meals were significantly larger during the dark than during the light. However, the duration of a meal was not significantly larger during the dark period. Thus, the rate of eating (pellets/min) was greater during the dark, since meal durations were similar, but meal size was greater during the dark. Since the light/dark differences in meal structure and hourly food intake did not vary significantly over the 18 day period, the data strongly suggest that 24 hour patterns of food intake are very stable.

452.9

EFFECT OF FOOD TEXTURE ON TONGUE MOVEMENT DURING ANTICIPATION, CHEWING AND SWALLOWING IN CHILDREN SIX MONTHS TO TWO YEARS OF AGE.

E.G. Gisel. School of Physical and Occupational Therapy, McGill University, Montreal, Quebec, H3G 1Y5.

Tongue mobility changes rapidly in the human infant during weaning. The antero-posterior movements of suckling which are activated in concert with the mandible, hyoid and lower lip give way to more independent movements in a lateral direction, for placement of food between the teeth. Specific tongue movements in response to different textures of food (puree, viscous, solid) are not yet defined.

Our study describes the effect of food textures on tongue movement during anticipation, chewing and swallowing in 143 normal children from 6 months to 2 years of age. Taste was controlled by using sweet flavors. Children anticipate all three textures by holding the jaw and tongue quiet as food approaches the mouth. When initiating chewing, younger children (6-12 months) respond to puree by suckling, whereas older children (18-24 months) collect the food bolus in preparation for swallowing. The solid and viscous textures are chewed vigourously in a "munching" pattern where the tongue stays in mid-line in children up to 10 months, but with increasing lateral movements between 12 and 24 months. Three categories of swallow patterns were observed for all textures. Children either pressed their lips together to initiate the swallow, drew in the lower lip, or projected the tongue onto the lower lip with puree or the viscous texture. During anticipation, chewing and swallowing pureed textures elicit more immature patterns than solid or viscous textures.

Supported by NHRDP # 6605-2430.

IN VITRO AUTORADIOGRAPHIC MAPPING OF A PUTATIVE "ANORECTIC" BINDING SITE WITH [^{3}H] MAZINDOL IN RAT BRAIN. G. P. Vincent and B. E. Levin. Institute Animal Behav., Rutgers University, Newark, NJ 07102, Neurology Service, VA Medical Center, East Orange, NJ 07019.

Low affinity (µM) binding to hypothalamus of the anorectic agent mazindol (MAZ) correlates highly with its anorectic potency (Angel, et al., Brain Res. Bull. 17:873, 1986). These sites were mapped using quantitative in vitro receptor autoradiography. Coronal sections (20µm) were incubated with 10nM [^{3}H] MAZ (SA=15.8Ci/mmole) in 50mM Tris/5mM KCl, pH 7.9, at 4°C for 40min. Non-specific binding was assessed with 1mM MAZ. The distribution of these sites was different from that of the high affinity, sodium-dependent binding of [^{3}H] MAZ to catecholamine reuptake sites which were highly localized in the striatum. Areas of high specific [^{3}H] MAZ binding (>3.0pmol/mg protein; 53-69% of total binding) to the low affinity site were found in the dorsal raphe n., locus coeruleus, med. eminence, olf. tub., pineal gland. Moderate binding (1.6-3.0pmol/mg) was in the paraventricular, arcuate & ventromed. hypothalamic n., med. preoptic area, n. accumbens, amygdala, gustatory cortex, bed n. stria terminalis, periaquaductal gray, n. tr. solitarius. Low levels (<1.6pmol/mg) were in the caudate-putamen, dorsomed. n. & lateral hypothalamus, substantia nigra. This binding may thus represent a distinct class of sites related to the anorectic action of MAZ.

452.11

ACTIVITY-BASED-ANOREXIA AS A FUNCTION OF ACTIVITY-STRESS ULCERS. L.E. Doerries*, P.F. Aravich, E.Z. Stanley,* and J. Ang* (SPON: D.B.West). Dept. of Psychology, Christopher Newport College, Newport News, VA 23606; Dept. Anatomy & Cell Biology and Dept. Internal Medicine, Eastern Virginia Medical School, Norfolk, VA 23510.

Paradigms for studying activity-based anorexia (ABA) and activity-stress gastric ulcers (ASUs) involve concurrent introduction of restricted feeding and opportunity for exercise. While ABA is related to the simultaneous introduction of diet and exercise, it is possible that ASUs contribute to the phenomenon. Also, there is evidence suggesting that susceptibility to both ABA and ASUs may be gender specific. This study tests the hypothesis that ABA is unrelated to the formation of ASUs in body-weight matched, pubescent male and female rats. A 25% weight-loss criterion was used to define ABA. The rats (41-43 days old) were fed for 90 min. and allowed 22.5 hours access to an activity wheel. Although female rats ate less and ran more than males, both males and females reached the weight-loss criterion in the same number (6.13) of days. Sacrificed at 75% of their original body weight, no animal showed gross evidence of lesions or ulcers. We conclude that at this weight loss criterion ABA is not gender specific and is not attributable to the presence of gastric lesions or ulcers.

452.12

STUDIES ON THE INGESTIVE BEHAVIORS INDUCED BY INJECTIONS OF MUSCIMOL INTO THE MEDIAN RAPHE NUCLEUS OF THE RAT. D. Wirtshafter, T.R. Stratford, M.A. Klitenick, R. Trifunovic and J.C. Krebs. Dept. Psychol., Univ. Ill. at Chicago, Chicago, IL 60680.

We have demonstrated in the past that robust increases in food and water intake can be produced in nondeprived rats by injections of the GABA agonist muscimol into the median raphe nucleus (MR). Much larger effects are seen following injections into the MR than after injections into surrounding structures. In the present studies we have attempted to provide more detailed information as to the mechanisms underlying these effects.

Injections of muscimol into the MR induced wood gnawing and paper shreding, as well as feeding and drinking, suggesting that these injections may elicit both ingestive and noningestive oral behaviors. Intra-MR muscimol injections increased the rates of food reinforced lever pressing by nondeprived rats; in contrast, pressing of a nonreinforced lever was much less affected. This finding suggests that intra-MR muscimol injections render food reinforcing to nondeprived rats. Muscimol injections led to a mild hyperglycemia, but failed to alter plasma levels of insulin, ketone bodies or electrolytes. Like normal feeding, muscimol induced feeding was abolished in rats with large lateral hypothalamic lesions. Finally, haloperidol, amphetamine and fenfluramine were equipotent in suppressing deprivation and muscimol-induced feeding.

452.12

APOMORPHINE-INDUCED FLAVOR-DRUG ASSOCIATIONS: A DOSE-RESPONSE ANALYSIS BY THE TASTE REACTIVITY TEST (TRT) AND THE CONDITIONED TASTE AVOIDANCE TEST (CTA). L.A. Parker. Dept. of Psychology, Wilfred Laurier University, Waterloo, Ontario, N21 3C5.

Apomorphine is a positively reinforcing drug at low to moderate doses, but appears to lose its reinforcing properties at higher doses. Across a range of doses (0.5 - 15 mg/kg, intraperitoneally), apomorphine produced a CTA over 5 conditioning/testing trials which was not dose-dependent. The rejection TRT responses of chin rubbing and gaping, however, were only conditioned at the highest dose of apomorphine (15 mg/kg). Our results support the contention that CTAs produced by positively reinforcing drugs are not accompanied by a palatability shift.

452.14

c-fos INDUCTION IN NUCLEUS TRACTUS SOLITARIUS AND IN THE DORSOMEDIAL NUCLEUS OF THE HYPOTHALAMUS DURING FEEDING IN RATS. M.F. Gonzalez, S.M. Sagar, and F.R. Sharp, Depts. of Neurology and Physiology, UCSF and VA Medical Center, San Francisco, California 94121.

The CNS pathways involved in the production of satiety are still poorly understood. In order to test whether starvation or feeding would induce Fos, the protein product of the c-*fos* proto-oncogene, the following experiments were performed. Adult Sprague-Dawley rats were starved for 1,2,3 or 6 days. Half of the subjects were allowed to feed and sacrificed 4 hours later. Brains of starved subjects and starved subjects allowed to feed were processed for Fos immunocytochemistry using a polyclonal antiserum to a middle peptide of Fos raised in our laboratory. Fos was markedly induced throughout the nucleus tractus solitarius (NTS) and nucleus ambiguus (NA) in the medulla, and in the dorsomedial nucleus of the hypothalamus (DMH) of the subjects allowed to feed compared to the starved controls and compared to ad libitum controls. Fos induction in DMH but not NTS was increased with longer periods of starvation. It is proposed that at least one satiety signal arises in the GI tract, travels via the vagus to NTS, and from there to the DMH. Because of the proposed role of c-*fos* in regulating other genes, it is possible that neural signals and responses to feeding are programmed by Fos.

452.15

PERIFORNICAL HYPOTHALAMIC MICROINJECTIONS OF AMPHETAMINE AND PHENYLPROPANOLAMINE: EFFECTS ON FEEDING IN THE RAT. P.J. Wellman, R. Cockroft* and S. Keller*. Dept. of Psychology, Texas A&M University, College Station, TX 77843.

Amphetamine anorexia results from activation of dopaminergic and/or beta-adrenergic cells within the perifornical hypothalamus (PFH) but the locus of anorexia induced by the amphetamine analogue phenylpropanolamine (PPA) is as yet unidentified. In the present experiment, adult male rats were allowed to consume a palatable sweetened-mash diet for a 30 minute period after 14 hours deprivation of food, but not water. Microinjections (0.5 ul/40 sec) of either 20, 40, 80, 160 or 320 nm PPA or 100 nm d-amphetamine (calculated as the base) into the perifornical hypothalamus were given 5 minutes prior to a feeding trial with vehicle trials interspersed between drug trials. Amphetamine significantly lengthened latency to feed and suppressed feeding. PPA was without significant effect on feeding at any dose. These data support the contention that although amphetamine and PPA induce superficially similar anorexia, the mechanisms by which these drugs act on feeding are independent.

452.16

CIRCADIAN FLUCTUATIONS IN TASTE PREFERENCES IN RATS. D. Dracos and F.W. Flynn. Dept. of Psychology and Neuroscience Program, Univ. of Wyoming, Laramie, 82071.

Day/night fluctuations in internal state are thought to mediate the periodicity in ingestive behavior in animals. Since experimental manipulations of metabolism and water/electrolyte balance modify taste processing, the effects of circadian changes in internal state on taste preference were measured. Rats were entrained to a 12 h light/dark cycle. Two bottles, one containing water and the other the taste stimulus (sucrose - 0.01 M, 0.03 M, 0.3 M, 1.0 M; quinine HCl - 0.00003 M, 0.0003 M, 0.003 M, 0.03 M; HCl - 0.001 M, 0.003 M, 0.01 M, 0.03 M; NaCl - 0.01 M, 0.03 M, 0.1 M, 0.3 M), were presented at the onset of either the light cycle (N=15) or dark cycle (N=14). Intake was measured 12 h later and preference computed. During the dark period, the preference for 0.03 M. sucrose (87 $\pm$ 2%) and 0.1 M NaCl (85 $\pm$ 3%) were significantly greater than that recorded during the light period (55 $\pm$ 6% and 66 $\pm$ 6%, respectively), p's $<.05$. Also, during the dark phase, the rats' preference for QHCl concentrations was consistently lower than that of the light phase, p's $<.05$. There were no significant group differences in HCl preference. The results demonstrate that the rats' preferences and avoidances of taste stimuli are influenced by the light cycle.

453.1

1-METHYL-4-PHENYLPYRIDINIUM ION (MPP+)- INDUCED MOTOR DEFICITS IN THE RAT. S.L. Walsh, P. McCarty* and G.C. Wagner. Psychology Department, Rutgers University, New Brunswick, NJ 08903

MPP+ is the active metabolite of MPTP, a potent parkinsonian neurotoxin. MPTP administration produces a parkinsonian syndrome in primates, however rodents are comparatively resistant to the toxic effects of this compound. To assess motor deficits following administration of intrastriatal MPP+ (20ug/side), Sprague-Dawley male rats were tested using two behavioral procedures; the rotarod for balance and gait and the force lever task for fine motor control.

Following eight daily sessions on the rotarod, it was observed that control rats were able to maintain balance on the rotating rod (12 rpm) for an average of 130 sec of a possible 180 sec, whereas the lesioned rats were significantly impaired, averaging only 84 sec. In the force lever task, control rats (trained to exert between 10 and 15 g of paw pressure for 1 second in order to procure a water reinforcement) required an average of 4 band entrances/reinforcer, whereas lesioned rats were significantly impaired, requiring an average of 8 band entrances. This indicates that, although lesioned rats obtained a comparable number of reinforcers as the controls, they performed less efficiently. In addition, using drug challenge, it was observed that lesioned rats were sensitized to the acute effects of apomorphine on the rotarod task and were more sensitive to the acute effects of oxotremorine on the force lever task as measured by estimated ED-50 doses. These observations are evaluated in light of the magnitude of the MPP+-induced neurochemical lesion of the striatum and the degree of impairment observed.

453.2

HALOPERIDOL-INDUCED MOVEMENT DISORDERS IN YOUNG AND AGED RATS. S.K. Johnson*, J. Lee*, H. Fisher* and G.C. Wagner. Depts. of Psychology and Nutrition, Rutgers Univ. New Brunswick, NJ 08903

Movement disorders were studied in groups of young (60-day old) and aged (about one year) male rats for a period of three months following acute exposure to high doses (25 mg/kg) of haloperidol. It was observed that 2 injections of haloperidol spaced 3 weeks apart resulted in an increase in chewing behavior, head twitching and side-to-side movements beginning one week following the first injection and continuing through the three month observation period. Aged rats exhibited an increase in the intensity and frequency of these behaviors as compared to younger rats for both haloperidol and vehicle treatments. In addition, the high dose treatment with haloperidol produced a long-lasting disruption of rotorod performance, lasting 140 h in young rats and 300 h in aged rats. These observations are interpreted in light of haloperidol-induced changes in dopamine turnover and/or dopamine receptor proliferation, and in relation to the etiology of tardive dyskinesia.

453.3

Neural Mechanisms for Plan Execution and Plan Selection

David Hestenes, Arizona State University
Daniel S. Levine, University of Texas at Arlington

Some emerging data are suggesting functions for pathways from the midbrain with monoamine (norepinephrine, dopamine, and serotonin) neurotransmitters. One pathway, involving the basal ganglia, appears to be important in the selection of motor plans. Another pathway, involving the limbic system, appears to be involved in ensuring that plans once selected are actually executed. Different control functions are suggested for each of the transmitters in pattern matching. The prefrontal area of the cerebral cortex appears to be engaged in integration of these two circuits. Such characteristic motor disorders as Parkinson's disease, La Tourette's syndrome, and obsessive-compulsive disorder (which has both motor and ideational components) can be understood as breakdowns in one or another circuit.

453.4

ACUTE AND CHRONIC EFFECTS OF MONOAMINE UPTAKE BLOCKADE ON PGO WAVES IN THE CAT. R.J. Ross, W.A. Ball*, D.R. Levitt, P.J. Gresch* and A.R. Morrison. VA Med. Center and Depts. of Psychiatry and Animal Biology, Univ. of Penna. Schools of Med. and Vet. Med., Phila., PA 19104.

Spontaneous ponto-geniculo-occipital (PGO) waves are recorded in the lateral geniculate body (LGB) of the cat during paradoxical sleep (PS). They may signal alerting and are likely similar to waves that accompany orienting to intense or novel stimuli in waking (W). Depletion of norepinephrine (NE) or serotonin (5HT) results in PGO waves during W, and such waves are inhibited by drugs that block monoamine uptake and that have antidepressant effects in humans. We studied changes in spontaneous PGO waves after acute and chronic desipramine (DMI) and sertraline (SER), which are relatively specific in blocking NE and 5HT uptake, respectively. Nine cats were implanted with EEG, EOG, EMG, and LGB electrodes. Initial placebo days were compared with the first day (acute) of p.o. drug (0.75 mg/kg) and with days (chronic) that followed 2.5 weeks of p.o. drug (2.0 mg/kg q.d.). PGO rate (per min.) during PS was not significantly decreased by acute DMI (51.4 vs. 50.7, $p>.05$) or acute SER (59.5 vs. 56.4, $p>.05$). PGO rate dropped after chronic DMI (56.4 vs. 38.7, $p<.05$) and chronic SER (56.1 vs. 48.8, $p<.05$). Thus, chronic NE or 5HT uptake blockade suppresses PGO waves. The mechanisms may relate to antidepressant effects, since depression has features of hyperarousal (Gold, P.W. et al., N. Engl. J. Med., 319:413, 1988). Supported by VA Med. Res. Serv.

ELECTROPHYSIOLOGICAL INTERACTIONS BETWEEN SIGMA AND DOPAMINE RECEPTOR LIGANDS ON MIDBRAIN DOPAMINE NEURONS. G. F. Steinfels, B. Wolfson, L. Cook, S. W. Tam. DuPont Co., Med. Prod. Dept., Wilmington, DE 19880-0400, U.S.A.

Autoradiographic studies which have demonstrated the presence of sigma receptors on substantia nigra dopamine (DA) neurons have prompted the speculation that sigma receptors may have a modulatory role in DA neurotransmission. Support for this hypothesis comes from in vivo studies demonstrating that sigma receptor agonists [(+)-3-PPP, (+)-pentazocine, DTG] decrease the DA single unit activity, and the sigma receptor antagonist BMY-14802 increases DA single unit activity. This study evaluated the interactions between haloperidol and the sigma antagonist BMY-14802. Haloperidol, up to doses of 1 mg/kg, i.v., does not produce its typical increase of substantia nigra DA unit activity when pretreated with 1 mg/kg BMY-14802. This suggests a role of the sigma receptor in the nigro-striatal feedback loop which is thought to be responsible for the DA unit rate increases produced by haloperidol. The BMY-14802 dose response curve for producing DA unit rate increases was minimally affected following pretreatment with haloperidol. Since BMY-14802 does not bind to the DA agonist or antagonist receptor sites, we hypothesize that the sigma receptor-induced rate increases are mediated at the DA cell body.

SINGLE-UNIT ACTIVITY IN THE NEOSTRIATUM OF FREELY MOVING RATS: EFFECTS OF CORTICAL LESIONS ON THE BEHAVIORAL AND NEURONAL RESPONSES TO AMPHETAMINE AND NEUROLEPTICS. J.T. Tschanz*, J.L. Haracz, K.E. Griffith*, G.V. Rebec (SPON: R.M. Wightman). Prog. Neural Sci., Dept. Psychology, Indiana University, Bloomington, IN 47405.

Single neostriatal neurons in freely moving rats show either increases or decreases in firing rate in response to amphetamine (AMP), with increases predominating among cells showing enhanced activity during movements such as locomotion, rearing, or head movements (Haracz et al., Soc. Neurosci. Abstr. 14:664, 1988). These neuronal changes may reflect a direct action of AMP in the neostriatum or may be secondary to an action of the drug at some remote site. The neostriatum receives substantial input from cerebral cortex, which is known to respond to AMP. To study the role of the cerebral cortex in the response of neostriatal neurons to AMP, rats sustained bilateral ablations of frontal and sensorimotor cortex at least one week prior to single-unit recording. All animals were challenged with 1.0 mg/kg D-AMP during simultaneous videotaping of behavior and electrophysiological recording. As previously found in intact rats (Haracz et al., ibid), AMP-induced excitations and inhibitions predominated in motor- and nonmotor-related cells, respectively. Thus AMP activated 9 of 10 motor-related cells and inhibited all 4 nonmotor-related cells. These results differ from the predominantly inhibitory effects of AMP seen in multiple-unit recordings (Warenycia et al., Neuropharmacol., 26:1107, 1987). Despite an increased behavioral response to AMP in lesioned rats ($p < 0.05$), the AMP-induced enhancement of movement-related neuronal activity was significantly reduced as compared to sham-lesioned ($p < 0.05$) and intact controls ($p < 0.0005$). This reduction may be due in part to ceiling effects since both pre- and post-AMP movement-related unit activity were enhanced in lateral and central neostriatum of lesioned animals. Thirty min after AMP, animals were challenged with either 1.0 mg/kg haloperidol (HAL) or 10.0 mg/kg clozapine (CLZ). As reported previously (Haracz et al., op cit), HAL produced suppressions in all cells activated by AMP, whereas CLZ produced both excitations and inhibitions. In summary, a major portion of the AMP-induced enhancement of motor-related activity depends on intact corticostriatal projections. [Supported by USPHS grant DA 02451.]

453.7

SINGLE-UNIT ACTIVITY IN MEDIAL NEOSTRIATUM AND NUCLEUS ACCUMBENS: EFFECTS OF AMPHETAMINE, HALOPERIDOL, AND CLOZAPINE IN FREELY MOVING RATS. J.L. Haracz, J.T. Tschanz*, J.M. White*, Z.R. Wang*, D.W. Miller*, and G.V. Rebec. Prog. Neural Science, Dept. Psychology, Indiana Univ., Bloomington, IN 47405.

We previously reported that haloperidol (HAL) and clozapine (CLZ) differentially affected amphetamine (AMP)-induced changes in behavior and single-unit activity in lateral neostriatum of freely moving rats (Haracz et al., Soc. Neurosci. Abstr. 14:664, 1988). We now extend these observations to medial neostriatum and nucleus accumbens in rats subjected to simultaneous videotaping of behavior and recording of single-unit activity. To date, 17 neurons exhibited firing rates of 1.92±0.78 spikes/sec during quiet rest, 14 of which were activated during motor activity, such as locomotion (n=9) or head movements (n=5). Many neurons altered their activity in relation to the probing of specific body regions. D-AMP (1.0 mg/kg) was administered 30 min before either HAL (1.0 mg/kg) or CLZ (10.0 mg/kg). AMP-induced stereotyped behaviors developed in correspondence with increases (n=13) or decreases (n=4) in neuronal activity, with increases predominating among motor-related neurons. HAL inhibited behavior while suppressing the activity of all 13 cells tested. Compared to lateral neostriatal neurons (Haracz et al., ibid), cells in medial neostriatum or nucleus accumbens were suppressed significantly less by HAL ($p < 0.025$). Paradoxically, 3 cells were inhibited by both AMP and HAL. In contrast to HAL, CLZ produced both increases and decreases in activity. These findings differ from results obtained from immobilized rats, in which acutely administered neuroleptics either elevated or did not affect neuronal activity in neostriatum and nucleus accumbens (Rebec et al., Neuropharmacol., 19:281, 1980; Akaike et al., Life Sci., 32:2649, 1983; Le Douarin et al., Brain Res., 363:290, 1986). The regional variation in HAL effects and the differential effects of HAL and CLZ may underlie the different behavioral effects of these drugs. [Supported by USPHS grant DA 02451.]

453.8

A NEW COMPUTER PROGRAM FOR THE CONTROL OF IN VIVO BRAIN SELF STIMULATION: APPLICATION TO THE EFFECTS OF A NEW CLASS OF CENTRAL STIMULANTS. T. Kling-Petersen* and K. Svensson* (spon. J. Engel). Dept. of Pharmacology, Univ. of Göteborg, PO Box 33031, S-400 33 Göteborg, Sweden.

The in vivo brain self stimulation paradigm has been used for many years in order to investigate the biological substrates of reward or positive reinforcement. In general, central stimulants acting by the catecholamine neurotransmitters (e.g. d-amphetamine) or the opiod system (e.g. morphine) facilitate self-stimulation. Recently, our group presented a new class of central stimulants: "preferential dopamine autoreceptor antagonists" (K. Svensson et al., Naunyn-Schmiedeberg's Arch Pharmacol, 1986,334, 234-245). This class of compounds (exemplified by (+)-AJ76) produces mild stimulation over a wide dose-range. The degree of stimulation is however limited by the postsynaptic dopamine receptor blockade induced by large doses of the drug. It would be of great interest to have these types of compounds characterized in the self-stimulation paradigm.

A fully automated self stimulation method is currently being set up. This system will be based on standard sound-proof lever pressing boxes and physiological stimulators. The equipment will be controlled by an Apple MacIntosh™ IIx computer with 8 Mb primary memory and the National Instruments Lab VIEW program with a 12 bit analog/digital converting board. Our main objectives when setting up the method are: possibility to record at least 4 animals simultaneously, ability to vary the response rate of the different animals independently, to get total calculations at specified time intervals and continuously record them on disc.

The computer program will be presented and, if available, preliminary data on the new type of central stimulants as well as reference compounds.

DOPAMINE ANTAGONIST ACTIVITIES OF (+)-AJ 76. A.H.Tang, S.R.Franklin, C.S.Himes* and R.A.Code* CNS Research, The Upjohn Company, Kalamazoo, MI 49001

(+)-AJ 76 was reported by Svensson et al. (1986) to have a profile of activity suggestive of selective dopamine autoreceptor antagonism. This study compared (+)-AJ 76 to the specific D2 antagonist, sulpiride, in dopamine-related activities. Spontaneous locomotor activity of rats was significantly increased at low doses and reduced at higher doses by both compounds. (+)-AJ 76 is similar in potency to sulpiride. The locomotor depressant effect from a low dose (0.03 mg/kg) of apomorphine was partially reversed by both (+)-AJ 76 and sulpiride. Both compounds also antagonized yawning produced in rats by the selective D2 agonist, quinpirole (0.06 mg/kg). (+)-AJ 76 is slightly more potent than sulpiride. Hypothermia effect produced by quinpirole (1 mg/kg) in mice is completely antagonized by the pretreatment with either (+)-AJ 76 or sulpiride. On the other hand, stereotypic licking and chewing produced by a high dose (3 mg/kg) of apomorphine in rats was not antagonized by either compound even at a high dose of 100 mg/kg. The emetic effect of apomorphine (0.1 mg/kg) in dogs was effectively blocked by sulpiride (ED50=0.2 mg/kg). (+)-AJ 76 did not antagonize apomorphine in this test at doses up to 3 mg/kg. We conclude that (+)-AJ 76 is similar to sulpiride as a selective D2 antagonist. Both compounds preferentially antagonize dopamine at the autoreceptors.

FETAL NIGRAL DOPAMINE TISSUE TRANSPLANTS IN THE LATERAL STRIATUM OF RATS: EFFECTS ON LICKING. J.B. Richards, K.E. SABOL, and C.R. FREED. Univ. of Colo. Health Sci. Ctr., Denver, CO 80262.

The striatum is functionally heterogeneous in that anatomically discrete areas of the striatum control topographically different behaviors. Recently, Pisa & Schranz (Behav. Neurosci..102:429-440, 1988) using ibotenate-induced lesions, and Kelley et al. (Psycopharm..95:556-559, 1988) using micro-injections of d-amphetamine, have shown that the ventral lateral striatum is involved in mediation of tongue and mouth movements. We report the effects of placing fetal nigral dopamine tissue grafts in the striatum on the behavior of rats licking drops of water. The rats were first given unilateral 6-hydroxydopamine lesions and tested for amphetamine induced rotation to assure they had greater than 95% depletion. Fetal nigral transplants from 12 to 15 day old rat fetuses were then placed into the ventral lateral (n=7) and dorsal medial (n=5) striatum of the lesioned side. A control group (n=5) was lesioned but did not receive fetal grafts. Nine months after transplantation, the rats were exposed to a schedule of periodic water presentation in which they received a .025 ml drop of water every 30 sec over a 30 min period. There were no group differences in baseline licking behavior. When given 0.1 mg/kg d-amphetamine rats with lateral but not medial transplants licked more than controls.

453.11

BEHAVIORAL AND NEUROCHEMICAL EFFECTS OF ACUTE AND CHRONIC MICROINJECTIONS OF A K^+-CHANNEL BLOCKER INTO THE VENTRAL TEGMENTAL AREA OF RATS. J.D. Steketee and P.W. Kalivas. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

Apamin is an octadecapeptide which has been reported to block small conductance Ca^+-activated K^+-channels (SK). Shepard and Bunney (Brain Res. 463:380, 1988) have demonstrated that apamin increases dopamine (DA) neuron excitability in the substantia nigra of rat brain slice preparations. Increased activity in the mesolimbic dopamine system has been linked to increased motor activity. We investigated the effects of microinjections of apamin into the ventral tegmental area (VTA) of rats. Acute bilateral microinjections of apamin into the VTA led to a dose-related (0.1 - 3.0 pmoles/side) increase in motor activity. HPLC analysis of postmortem brain tissue obtained 30 min post-injection revealed a dose related increase in DA metabolism in both the VTA and the nucleus accumbens, an axonal terminal field of the VTA. Daily microinjections of apamin into the VTA appeared to initially lead to tolerance followed by an augmentation of motor activity one week after chronic treatment. These results support a role for SK channels in modulating DA stimulated motor activity.

RESTRAINT INDUCED ALTERATIONS IN INTRACRANIAL SELF-STIMULATION FROM THE NUCLEUS ACCUMBENS OF BALB/cByJ, C57BL/6J and DBA/2J MICE: EFFECTS OF DIAZEPAM. G. MacNeil, N. Gabora*, S. Collins* and R. Zacharko, Dept. Psychology, Carleton University, Ottawa, CANADA

Uncontrollable stressors induce disturbances in responding for electrical brain stimulation (ICSS) from both mesolimbic and mesocortical sites. Investigations in this laboratory focused on the effects of uncontrollable footshock on ICSS in both inbred and non-inbred mouse strains. In the present report the effects of restraint were evaluated on ICSS from the nucleus accumbens in the BALB/cByJ, C57BL/6J and DBA/2J strains. While protracted immobilization was associated with deficits in ICSS among BALB/cByJ and DBA/2J mice, such effects were absent in the C57BL/6J strain. These ICSS deficits were restricted to the anterior plane of the accumbens and prophylactic administration of diazepam produced an attenuation but not a complete reversal of the ICSS alterations. It is suggested that the anatomical/neurochemical integrity of the mesolimbic system in a rostral-caudal plane underlies the disparity in behavioral effects observed.

453.13

STRAIN DIFFERENCES IN RESPONDING FOR SELF STIMULATION FROM THE VENTRAL TEGMENTUM FOLLOWING ACUTE AND CHRONIC SHOCK. M. Kasian* and R.M. Zacharko, Dept. Psychology, Carleton University, Ottawa, Ontario K1S 5B6, Canada.

Acute and chronic footshock influenced self stimulation responding from the lateral aspects of the ventral tegmentum. However, the extent of the disruption induced by acute shock and the course of the adaptation associated with a chronic stressor varied across strains of mice. In C57BL/6J and CD-1 mice a single shock session provoked a persistent disruption of ICSS performance. Responding recovered to baseline rates within 5 shock sessions, and in C57BL/6J mice responding exceeded basal rates after 10 sessions. In contrast, in DBA/2J mice the decline of responding was not evident until 10 shock sessions were applied, and recovery of responding was evident after 15 sessions. Finally, in BALB/cByJ mice increased rates of responding were evident regardless of the number of stressor sessions applied. It is suggested that analyses of stressor related behavioral disturbances should consider genetic differences in the impact of acute stressors and in the adaptation associated with chronic stressor regimens.

Ontogeny of dopamine-mediated behavior and D1 receptors in three rat strains. Frances Petracca*, Jaime Diaz, and Alan S. Unis. Departments of Psychiatry and Psychology University of Washington, Seattle, Washington 98195

The F344 rat is a proposed model of Attention Deficit-Hyperactivity Disorder (ADHD) because of its increased locomotor behavior compared to the Buffalo (BUF) rat. Our preliminary observations regarding the ontogeny of this behavior are reported here. D-1 receptors, which mature functionally before D-2 receptors, were also examined. Ontogeny of developmental milestones, reflexes, and open field behavior were studied in pups from these two strains and the Sprague-Dawley (SD).

3H-SCH23390 autoradiography revealed anatomical localization to cortical regions in Day 4 pups which was eliminated by Day 21. Striatal binding was consistent from Day 4 to 21. Significant strain-related differences in indices of maturation and behavior are shown below:

	F344	SD	BUF
Weight (g)	32.5± 3.1	55.5 ± 4.7	38.4± 5.7
Eye opening (day)	17.7± .5	15.3 ± .5	16.1± .3
Free fall righting	16.5± 1.1	15.9 ± 1.0	17.8± 1.2
Open Field rears	20.2±12.7	22.6 ± 11.5	8.1± 8.2

These studies may support the use of the F344 rat as a model of ADHD.

NEUROETHOLOGY III

454.1

The One-Dimensional Protein Profiles of Gymnotiform and Mormyriform Electric Organ Homogenates are Similar. J. M. Patterson* and H. H. Zakon, The University of Texas at Austin, Dept. of Zoology, Austin, Texas 78712. The two orders of electric fish, the gymnotiforms of South America, and the Mormyriforms of Africa, possess distinct phylogenetic histories, distinct electric organ discharge patterns and waveforms, and show large differences in electric organ morphology. However, both groups have electrocyte cells which are embryologically derived from muscle cells. To determine what differences might exist in the proteins present in the Mormyrid and gymnotiform electric organ, and to compare the protein composition of both electrocyte cells and skeletal muscle cells from various species, one-dimensional gel electrophoresis was used.

Electric organ tissue from six species and muscle tissue from three species of electric fish were analyzed. Electric organs from four gymnotiform species (*Sternopygus* , Sach's and Main organ from *Electrophorus* , *Hypopomus* , and *Eigenmannia humboldtii*) and two Mormyrid species (*Gnathonemus petersii* and *Brienomyrus niger*) were compared. Muscle tissue from one gymnotiform (*Sternopygus*) and from the two Mormyrid species was obtained from a dorsal portion of the fish.

Segments of electric organ or muscle were cleaned of skin and immediately frozen in liquid nitrogen. The tissue was then homogenized in a SDS/BME sample buffer, placed in a 100° C water bath for 3 min., centrifuged at 10,000xG, and frozen at -20° C. Gels were run at constant voltage (125 v. for 7-8 hr.), stained with Coomassie Blue, destained, and photographed. Densitometry was performed on several gels for a more quantitative evaluation of protein composition.

Comparisons between the muscle cell and electric organ proteins show many shared constituent proteins, indicative of their common origins. However, several proteins are found in abundance in electric organ , yet are not present or present in low abundance in muscle. Of these non-muscle proteins, analysis shows marked similarities in the protein profiles from all the species of electric fish studied. This finding indicates that despite independent evolutionary histories, Mormyrid and gymnotiform fish have developed similar biochemical components for electric organ function.

454.2

Synaptic Plasticity in the Cerebellar Parallel Fiber Projection to the Electrosensory Lateral Line Lobe of Gymnotiform Fish. R.W. Turner* and L. Maler (SPON: W. Hendelman) Dept. of Anatomy, University of Ottawa, Ontario, Canada K1H 8M5

Pyramidal cells (PC) of the electrosensory lateral line lobe (ELL) of the weakly electric fish *Apteronotus leptorhynchus* receive direct afferent input from peripheral electroreceptors involved in the behaviour of electrolocation. PC apical dendrites in the ELL molecular layer receive a glutaminergic parallel fiber input from granule cells of the caudal cerebellar lobe that has been shown to regulate PC temporal and spatial receptive field properties (Bastian,86). As the molecular layer exhibits high densities of NMDA and Kainate receptors (Maler & Monoghan,89) frequently involved in plasticity of synaptic transmission, we used an *in vitro* slice preparation to examine PC responsiveness to parallel fiber stimulation.

Stimulation of the ELL molecular layer evoked a fast positive-negative and a slow negative-going field potential in the PC mid-dendritic region. Intracellular recordings and perfusion of low Ca^{+2} medium identify these potentials as a fiber volley and EPSP characteristic of that described for parallel fiber input in cerebellar cortex and dorsal cochlear nucleus. Low frequency stimulation (5-20 Hz) evoked a pronounced frequency potentiation of the dendritic field negativity that recruited PC discharge. High frequency tetanic stimulation (90-200 Hz, 15 pulses; 7X) evoked a long-term potentiation of the dendritic negativity (83 +/- 23% above control) that persisted for a minimum of two hours. One slice demonstrated post-tetanic potentiation (19 % above control) for 30 min while 3 slices showed no effect. Tetanic stimulation in low Ca^{+2} medium had no effect or evoked a depression of the parallel fiber volley for 20-30 min. The role of excitatory amino acid receptors in these forms of synaptic plasticity are under investigation.

454.3

DISTRIBUTION OF GLUTAMATE RECEPTORS IN THE ELECTROSENSORY SYSTEM OF GYMNOTIFORM FISH. L. Maler and D. Monoghan, University of Ottawa, University of California at Irvine.

Electroreceptor afferents of gymnotiform fish (Apteronotus leptorhynchus) project to the deep neuropil layer of a laminated hindbrain structure, the electrosensory lateral line lobe (ELL). The ELL projects to the nucleus praeeminentialis dorsalis (Pd) which has feedback projections to the ELL, both directly to the ventral molecular layer of the ELL, and indirectly (via the caudal cerebellar lobe LC) to the dorsal molecular layer of the ELL. The circuitry of the ELL has been analysed in detail and correlated with the spatial and temporal receptive field properties of the ELL pyramidal cells (PC). Bastian (1986) has demonstrated that the cerebellar feedback projection to ELL can modulate the PC receptive fields.

We examined the distribution of glutamate receptor subtypes (AMPA, Kainate and NMDA) in the ELL as well as in the midbrain. In the ELL AMPA receptors are found at low levels in the deep neuropil layer as well as throughout the molecular layer; AMPA receptors are also found at low levels in the molecular layer of the related caudal lobe, but are very dense in the cerebellar molecular layer. Kainate receptors are completely confined to the dorsal and cerebellar molecular layer, where they are very dense. NMDA receptors are present at high density in the molecular layer but only at low density in the deep neuropil, suggesting plasticity of the feedback loop.

454.4

MODULATIONS OF THE ELECTRIC-ORGAN PACEMAKER NUCLEUS OF GYMNOTIFORM ELECTRIC FISH BY PHARMACOLOGICALLY DISTINGUISHABLE PATHWAYS. M. Kawasaki, C.H. KELLER, W. Heiligenberg. UCSD, La Jolla CA 92093.

Both pulse and wave species of gymnotiform electric fish are capable of accelerating and decelerating the firing rate of their electric organ discharges (EODs) during social interactions. Modulatory inputs from the prepacemaker nucleus (PPN) to the medullary pacemaker, which drives the electric organ with a regular rhythm, are responsible for these frequency modulations. Physiological recordings from PPN neurons, stimulation of the PPN, and application of pharmacological blockers to the pacemaker nucleus have revealed a difference in the mode of the modulation between wave and pulse species. In a wave species, Eigenmannia lineata, the increase and the decrease of a tonic excitatory input to the pacemaker appears to be responsible for the acceleration and the deceleration of the EOD frequency, respectively. In a pulse species, Hypopomus brevirostris, on the other hand, direct GABA-ergic inhibition appears to decelerate the pacemaker, while glutaminergic excitation causes acceleration.

454.5

INTRACELLULAR LABELLING OF PHYSIOLOGICALLY DEFINED CELLS WITHIN A DIENCEPHALIC SENSORY-MOTOR INTERFACE OF WEAKLY ELECTRIC KNIFEFISH C.H. Keller, M. Kawasaki and W. Heiligenberg. UCSD, La Jolla CA 92093

The diencephalic complex of Eigenmannia's nucleus electrosensorius (nE) comprises a number of finely tuned neuronal filters for specific sensory-motor tasks. The nE can be subdivided into at least four distinct areas; three which receive electrosensory efferents of the torus semicircularis: nE↑ controls rises of the electric organ discharge (EOD) frequency, nE↓ controls falls of the EOD frequency, nEb contains neurons responsive to stimuli jamming the fish's EOD; a fourth area, nEar, receives acousticolateral but not electrosensory toral input. Intracellular labelling of cells within each subdivision demonstrates intranuclear patterns of connectivity and cell-specific efferent targets. We present data on a number of different cell types that are responsive to various electrosensory stimuli: e.g. ongoing jamming stimuli, rapid modulations in jamming stimuli similar to courtship signals, and changes in orientation of the jamming stimulus. Some neurons responsive to jamming stimuli project to the vicinity of electromotor control areas of the diencephalon and likely contribute to the jamming avoidance response. Also, cell-types that may provide information about socially relevant stimuli project to hypothalamic targets and may thereby modulate endocrine or motivational systems of the CNS.

454.6

ULTRASTRUCTURAL STUDIES ON THE SYNAPTIC ORGANIZATION OF THE PREPACEMAKER NUCLEUS IN WEAKLY ELECTRIC KNIFEFISH. W. Heiligenberg, G.K.H. Zupanc and L. Maler. UCSD, La Jolla, CA 92093; Univ. Ottawa, Ottawa, Ontario K1H 8M5.

Large multipolar neurons of the diencephalic prepacemaker nucleus (PPn) of knifefish (*Eigenmannia*) have been shown to control a communicatory behavior, namely abrupt frequency modulations ('chirps') of the otherwise very constant electric organ discharges. By retrograde labelling of the multipolar neurons with HRP we have investigated the synaptic organization of the PPn.

We found two classes, each with two subtypes, of chemical synapses contacting PPn neurons: (1a) Asymmetric synapse; only agranular, predominantly round vesicles (Ø 30-45 nm. (1b) 88-98 % agranular small vesicles as in 1a; otherwise, large (Ø 50-100 nm) dense-core vesicles. (2a) Symmetric synapse; small agranular pleiomorphic vesicles. (2b) 96-99 % small agranular pleiomorphic vesicles as in 2b; otherwise, large (Ø 50-70 nm) dense core vesicles. The synaptic cleft is wider in class 1 than in class 2 synapses. In addition to these chemical synapses we also identified dendro-dendritic gap junctions.

Electrotonic junctions might be responsible for a joint depolarization of PPn neurons during chirping. The chemical synapses are likely to mediate excitatory (class 1) as well as inhibitory input (class 2), each of which may be modulated by the release of the content of the dense-core vesicles (b-subtypes).

454.7

SOMATOSTATIN-LIKE IMMUNOREACTIVITY IN THE PREPACEMAKER NUCLEUS OF ADULT KNIFEFISH CHANGES WITH SEXUAL MATURITY. G.K.H. Zupanc, L. Maler and W. Heiligenberg. UCSD, La Jolla, CA 92093; Univ. Ottawa, Ottawa, Ontario K1H 8M5.

Knifefish (*Eigenmannia*; Gymnotiformes, Teleostei) can modulate their otherwise constant electric organ discharges by abrupt frequency modulations ('chirps'), a pattern which occurs almost exclusively during the tropical rainy season when these animals reproduce. Chirps are controlled by a subnucleus of the diencephalic prepacemaker nucleus, the PPn-C. The morphology of PPn-C neurons undergoes sexual maturity-dependent changes which might subserve the seasonal modifications in chirping behavior (Zupanc, G.K.H. & Heiligenberg, W., J. Neurosci., in press). In this study we investigated changes in somatostatin-like immunoreactivity (S-IR) in the PPn-C of mature and immature females.

We found three S-IR structures in the PPn-C region. While two were clearly expressed in both groups, the third pattern, a diagonal stripe (dS), was less pronounced in mature animals. The dS shows partial overlapping with dendrites of the ventral territory of PPn-C dendrites.

Somatostatin may act as a neuromodulator and thus cause reversible physiological changes in excitability of PPn-C neurons, or it could act in a hormone-like manner and lead to long-term morphological modifications as they occur during seasonal sexual maturation.

454.8

SEX DIFFERENCES IN THE ACTIVE SPACE FOR ELECTRIC SIGNALLING IN A SEXUALLY DIMORPHIC GYMNOTIFORM, *HYPOPOMUS PINNICAUDATUS* . C.D. HOPKINS[1], N. C. COMFORT[1], AND J. BASTIAN[2]. Section of Neurobiology and Behavior; [1] Cornell University; Ithaca, NY, 14853 and [2] Department of Zoology, University of Oklahoma, Norman, OK.

1) A newly described species, *Hypopomus pinnicaudatus* from French Guiana has a sexually dimorphic caudal filament. Large sexually mature males have long "feathered" tail filaments, females have short cylindrical filaments. The electric organ fills the caudal filaments in each.

2) The electric organ discharge (EOD) differs for the two sexes; male EODs average 1.6 ms in duration, female EODs are 1.1 ms. The power spectra of the male EODs peak at 652 Hz while those from females peak at 915 Hz.

3) The peak-to-peak voltages of the EODs of 34 fish were measured in the natural habitat using a monopolar electrode. The voltage declines according to the inverse square of the distance to the electrical null at the fish's midbody. The voltage increases in proportion to the animal's body length. Females have a higher peak-peak voltage per unit body length than males. Males with damaged tails have a reduced voltage compared to uninjured males of similar size. Males suffer more tail injury than females.

4) A computer model of the EOD suggests that the paradoxical reduction of the amplitude of the male's signal is a consequence of its increase in duration.

5) We hypothesize that sexual dimorphism in *H. pinnicaudatus* has evolved under the influence of sexual selection for long duration pulses. The amplitude reduction resulting from the change in EOD duration is compensated for by the increase in electric organ length, number of electrocytes, and electrocyte size.

Supported by NIMH grant 37972 to CDH, NIMH MB15793 to NC NIH NS19942 to JB.

454.9

SEX DIFFERENCES IN THE CAUDAL FILAMENT, ELECTRIC ORGAN, AND ELECTROCYTES OF *HYPOPOMUS PINNICAUDATUS*. N. C. Comfort, C.D. Hopkins, and A. Bass. Section of Neurobiology and Behavior, Mudd Hall, Cornell University, Ithaca, NY, 14853.

The South American electric fish *Hypopomus pinnicaudatus* (sp. nov.) possesses an electric organ typical among gymnotiform pulse fish in its basic morphology: it extends from the pectoral region to the tip of the tail, and consists of four bilaterally paired columns of drum-shaped electrocytes which diminish in size and spacing as the tail tapers towards the tip. The caudal filament—the portion of the tail caudal to the insertion of the anal fin—is sexually dimorphic in this species. In large (≥ 109 mm) adult males it is long and appears "feathered" in animals captured during the rainy (breeding) season. Females and smaller males have short, cylindrical tails. Caudal filaments of large males contained more electrocytes (55.3 ± .7 rows) than those of females (47.5 ± 1.9 rows) or smaller males (47 ± 4 rows). Single electrocytes in the caudal filament of large males are distinguished in at least four ways. First, they are greater in diameter, averaging 234.9 ± 12.1 µm, compared with 184 ± 6 µm for females, and 184.6 ± 9.3 µm for small males. Second, they are more widely spaced. Third, the electrocyte stalk—which emanates from the posterior face of an electrocyte and receives the cell's innervation—is swollen and triangular in large male fish. Fourth, male electrocytes show greater folding of the anterior face. Despite sex differences in electrocyte number and size, we found no sex difference in the ratio of cell size / cell spacing along the caudal filament, suggesting a sexual allometry in this communication organ. These dimorphisms in electric organ morphology correlate with sex differences in the electric organ discharge, and may represent the result of sexual selection on electric signals. Supported by NIMH Training Grant MH 15793 (NCC), NIH 37972 (CDH), and NIH NS19942 (AB).

SPIKE DURATION DEPENDS ON STIMULUS DURATION IN ELECTRIC ORGAN OF *STERNOPYGUS*. A. Mills and H.H. Zakon. Dept. Zoology, Univ. Texas, Austin, TX 78712-1064.

The electric organ discharge (EOD) of the gymnotiform wave fish *Sternopygus macrurus* is continually produced as a series of pulses, forming a quasi-sinusoidal waveform. The duration of each pulse is inversely related to EOD frequency; EOD pulse dur. is longer in mature males than in mature females, and this difference can be mimicked by androgen treatment. The basis of the EOD is the simultaneous spiking of the electric organ electrocytes, thus electrocyte spike dur. is expected to be highly correlated with EOD freq. and pulse dur., and to increase in response to androgen.

Recordings from intracellularly-stimulated electrocytes show two types of spikes with different dur., depending on stim. dur; both are similar in appearance to EOD pulses, and have a faster rise to peak than fall to baseline. "Long spikes" (stim.>10 ms) and some "short spikes" (stim. <1.5 ms) were measured from onset to end. Usually the onset of the short spike was obscured by stim. artifact, thus most were measured from peak to end and multiplied by two. Some long spikes showed a pronounced hump in the falling phase not reflected in EOD pulse, which accounts in part for spikes being longer than EOD pulses. Long spikes ranged from 5.2 to 10.0 ms in fish of pulse duration 4.9 to 9.1 ms. The short spikes were an average of 16 ± 11% shorter than the long spikes (N = 13 fish). The relationship to EOD pulse dur. was r = 0.6 (long spikes), and r = 0.3 (short spikes). Spike dur. change with stim. dur. is also seen in vertebrate cardiac fibers, which share with electrocytes the property of continuously firing regularly-spaced spikes. In electrocytes, this may indicate that there is an ion conductance that is activated by a long dur. stim. Since only the long spikes are correlated with EOD pulse dur., it is likely that late ion conductances are important in determining EOD pulse dur

In addition, preliminary studies suggest that long spike dur. in electrocytes increases in response to dihydrotestosterone treatment, resulting in the increase in EOD pulse dur. Similar results are seen in other electric fish species.

SEXUAL POLYMORPHISMS IN A "VOCALIZING" FISH: SONIC MOTOR AXON TERMINALS. A. Fluet* and A. Bass. (SPON: D. Tapper). Section of Neurobiology & Behavior, Cornell Univ., Ithaca, N.Y. 14853.

The midshipman, *Porichthys notatus*, has two classes of sexually mature males: Type "I" and "II". During the breeding season, both classes of males, along with gravid females, occupy nests. Midshipmen generate sounds by the simultaneous contraction of "drum" muscles attached to the lateral walls of the swimbladder. Only nesting Type I males are known to be sonic and generate a species-typical long duration (up to 1 hr) humming sound. Nevertheless, central brain stimulation shows that Type II males and females can generate a rhythmic sonic discharge with a similar fundamental frequency, although 20% lower than that of Type I males (see Bass & Baker, this mtg.). Type II males also resemble adult females in other traits including muscle fiber diameter and sonic motor axon diameter, both of which are greater in Type I males (Andersen & Bass, this mtg.). This analysis focused on sex differences in nesting animals in the terminal boutons of sonic motor axons. Neuromuscular junctions (NMJs) in all classes share several features including an absence of the postjunctional folds characteristic of mammalian NMJs. As regards differences, the terminal boutons of Type I males: (1) are larger, (2) are often invaginated below the muscle fiber surface, (3) have more Schwann cell wrappings, and (4) lack multiple boutons at single sites along the fiber. Although the differences were not significant at the 0.05 level, synaptic vesicle density decreased in the following order: females, Type II males, Type I males. Synaptic vesicle density was however significantly more in all classes of animals maintained in captivity for 1-4 months beyond the breeding season.

We hypothesize that these differences arise developmentally as a function of both an expanded peripheral target in Type I males and of sex and seasonal differences in the frequency and duration of sonic motor activity. Supported by NSF and NIH.

COMPARATIVE NEUROCHEMICAL STUDIES OF THE SONIC MOTOR SYSTEM IN TELEOST FISHES. M. Marchaterre, H. Baker, R. Baker and A. Bass. Section of Neurobiol. & Behav., Cornell Univ., Ithaca, N.Y. 14853, Lab. of Molec. Neurobiol., Cornell Univ. Med. Coll., White Plains, N.Y. 10605 and Dept. of Physiol. & Biophys., New York Univ. Med. Ctr.., N.Y., N.Y. 10016.

The Batrachoidiformes includes the oyster toadfish, *Opsanus tau* and the midshipman, *Porichthys notatus*, both of whom generate sound communication signals. The sound's fundamental frequency is determined by the synchronous activity of sonic motoneurons whose firing rate is determined by nearby pacemaker neurons. Our intracellular recording and staining (HRP) studies have suggested the presence of both local inhibitory and excitatory pacemaker neurons. Neurochemical studies were initiated to evaluate known interspecific differences in the sonic motor system. The position of GABA-, serotonin (5HT) and catecholamine- (using tyrosine hydroxylase, TH, antibodies) containing elements were identified in and around the sonic motor nucleus (SMN). Extensive GABA-like immunoreactivity was found in fibers and terminals throughout the SMN in both species. Labelled cell bodies were found in the nucleus, although they were more numerous along the nucleus' lateral margin. Both 5HT and TH fibers were present in the SMN of both species, although less dense than GABA. Both 5HT and TH are more abundant in the SMN of midshipmen although 5HT-containing cells are only present in the SMN of toadfish; however they appear outside the SMN of midshipmen. TH-containing cells surrounded the SMN in both species. The data suggest that GABA plays a major inhibitory role in the sonic discharge of both species. While it is unlikely that either 5HT or catecholamines are excitatory transmitters of the pacemaker system, the data suggest their regional and species variation may contribute to the modulation of the known differences (frequency, amplitude, duration) in sonic motor behavior. Supported by NSF and NIH.

454.13

SEXUAL POLYMORPHISMS IN A "VOCALIZING" FISH: SONIC MOTOR AXON NUMBER AND SIZE. K. Andersen* and A. Bass. (SPON: C. McCormick) Section of Neurobiol. & Behav., Cornell Univ., Ithaca, N.Y. 14853.

The midshipman, *Porichthys notatus*, has a midline sonic motor nucleus (SMN); each half innervates the ipsilateral sonic "drum" muscle which is attached to the lateral walls of the swimbladder. The synchronous firing of sonic motoneurons results in the simultaneous contraction of both muscles and the production of sound. Midshipmen have two classes of sexually mature males: Type "I" and "II". The smaller Type II males are more similar to sexually immature individuals in body size. Nevertheless, Type II males resemble adult females in a number of morphological and behavioral traits including sonic muscle mass and fiber diameter which are several fold greater in Type I males. The sonic discharge frequency in Type I males also exceeds that of females and Type II males which are similar to each other (Bass &Baker, this mtg). This analysis examined possible sex differences in both the number and size (cross sectional area) of sonic motor axons in the occipital nerve which innervates the drum muscles. Average axon number (1700-2500)/side; 0.4-7% difference between sides) was not significantly different between Type I males (n=21) and females (n=26 animals), although it was significantly less (by only 7%) in Type II males (n=25). In contrast, average axon size was 3-fold greater in Type I males (n=13) in comparison to females (n=6) and Type II males (n=6) which were not significantly different from each other. We conclude that: (1) all adult morphs have a similar number of sonic motor axons, (2) the increased sonic muscle mass in Type I males is accompanied by an increase in axonal size rather than number and (3) the differences (Type I vs. Type II & females) and similarities (II & females) in the central sonic discharge rate are paralleled by the profiles of axon size and not number. Supported by NSF and NIH.

SEX DIFFERENCES IN THE MORPHOLOGY OF PHYSIOLOGICALLY CHARACTERIZED NEURONS IN A "VOCALIZING" FISH. A. Bass and R. Baker. Section of Neurobiol. & Behav., Cornell Univ., Ithaca, N.Y. 14853 and Dept. of Physiol. & Biophys., New York Univ. Med. Ctr., N.Y., N.Y. 10016.

In sound-generating fishes, the sonic motoneuron discharge rate determines the fundamental frequency of acoustic communication signals. Previous studies have shown that midshipmen (*Porichthys notatus*) have two classes of sexually mature males. Large Type "I" males are sonic, but small Type "II" males, like females, are not known to generate sounds. The morphology of central (motoneurons) and peripheral (swimbladder "drum" muscles) elements of the sonic motor system in Type I males differ from those in Type II males and females, which are similar to each other. Sonic muscle mass is, for example, almost six-fold greater in Type I males. Despite these differences, midbrain stimulation demonstrated that females and Type II males could generate a rhythmic sonic discharge similar to Type I males, but distinctly lower (20%) in its fundamental frequency. Intracellular recording and staining (HRP) of 57 pacemaker neurons and motoneurons in 22 animals were carried out to establish the morphological correlates of the above physiological differences. The somata and dendrites of motoneurons and pacemaker cells were 100-300% larger in Type I males. These results demonstrate that a distinct sex difference in sonic behavior is paralleled by a major difference in the morphology of both motoneurons and their presynaptic pacemaker afferents. We further hypothesize that the development of sex differences in the peripheral sonic muscle induces comparable changes in central morphology, but changes in central physiological properties are far less dramatic. Supported by NSF and NIH.

CARBOCYANINE DYE LABELLED NEURONS AND PROCESSES OF APTERONOTUS LEPTORHYNCHUS PROJECTING TO THE PITUITARY: NEUROCHEMICAL IDENTITY. S.A. Johnston and L. Maler, Dept. of Anatomy, U.of Ottawa, Ontario, Canada, K1H 8M5.

Neurons projecting to the pituitary were retrogradely labelled following application of diI (1,i,dioctadecyl-3,3,3'3'-tetramethylindocarbocyanine perchlorate) crystals to the pituitary of brownghost knife fish perfused with 4% paraformaldehyde. The brain was sealed in a glass container for 4 to 6 wks. at 23°C, in the dark. Vibratome sections (30 um) were photographed through an epifluorescence microscope (rhodamine filter). Cell groups were identified following nissl staining of the sections. Both magnocellular and parvocellular populations were found in the anterior and posterior preoptic nucleus, the anterior periventricular nucleus, the hypothalamus caudal, ventral and lateral, nucleus lateralis tuberis anterior, posterior and nucleus recessus posterior. The nucleus recessus lateral and medial 1, and dorsal hypothalamus had only small cells. The superchiasmatic nucleus had a few large cells. These projections are similar to those in the goldfish (Sloan & Demski, '87) and the mammal (Swanson, '86). Some preoptic neurons contain CRF, vasotocin (magnocellular (n)) and dopamine (Da) and somatostatin (parvocellular (p)). Somatostatin (m & p) and Da(p) have been identified in other hypothalamic hypophysiotropic nuclei (Sas & Maler, '87, '88).

EVENT RELATED POTENTIALS IN RETINA AND OPTIC TECTUM OF FISH. T.H. Bullock, M.H. Hofmann*, F.K. Nahm, and J.C. Prechtl. Neurobiol. Unit, Scripps Inst. of Oceanog. & Dept. of Neurosci., Sch. of Med., UCSD, La Jolla, CA 92093 and *Dept. Anatomy, Sch. of Med., Univ. of Göttingen, F.R.G.

Compound field potentials were recorded with up to 18 microelectrodes deep in the optic tectum, and with suction electrodes from the distal stump of the cut optic nerve or from the optic nerve head in the opened eye in rays (Rhinobatos, Platyrhinoidis) and teleosts (Leuresthes). Diffuse light flashes of submaximal intensity (I) were delivered in trains with regular or irregular interstimulus intervals (ISI). ERPs are visible in single trials & begin at 50-200 ms after an occasional flash weaker by 20% or more.

One or more stimuli were omitted or the train terminated after various conditioning times (D). Deflections beyond the expected visual evoked potentials (VEPs) to the last flash are called omitted stimulus potentials (OSPs) and considered to be ERPs, without any necessary implication or denial of a temporally specific expectation. OSPs are prominent in single sweeps, even when VEPs have "fatigued" below the ongoing EEG, at ISIs of 300-500 ms or less. They occur approximately on schedule - when the next flash would be due.

Three components of OSP occur alone or in combination: an initial fast peak, a slow wave, and an oscillatory spindle at 25-30 Hz (Rh., 22°C) of 100-700 ms duration. This resembles the OFF response to steady light but OSP latency ca.= ISI + k and changes very little with I or D. The same mean ISI with quasi-random 25-66% jitter gives OSPs with longer latencies and smaller amplitudes, as though the OSP depends on an integrated prediction of ISIs. OSPs also depend on sufficient conditioning, D: under certain conditions (species, brain locus, ISI, I) at least 20 flashes and often more. Some properties of the OSP resemble those of the P300 of humans. It seems unlikely that the OSP requires higher cognitive events, since it is already present in the retina.

454.17

ELECTROSENSORY RESPONSES IN THE GRANULE CELL LAYER OF THE CEREBELLUM OF AN ELASMOBRANCH. J.G. New and T.H. Bullock. Neurobiol. Unit, Scripps Inst. of Oceanog., & Dept. Neurosci., Sch. of Med., Univ. of Calif., San Diego, La Jolla, CA 92093.

Single spikes and multiple unit activity in response to weak (<75 μV) electric field stimuli delivered via a 3 cm dipole perpendicular to the skin surface in the receptive field were recorded with glass micropipettes from the granule cell layer of the cerebellum of immobilized thornbacks (Platyrhinoidis triseriata). The single unit spikes apparently come from large cells, presumably interneurons.

Differences in temporal response properties between two discrete electrosensory regions in the caudal lobe of the cerebellar corpus were studied. Units in a caudo-medial region respond to DC-step stimuli with short latency (60 ms) rapidly adapting bursts following stimulus onset & offset. The intensity, latency and duration of these responses are similar regardless of stimulus polarity, although an asymmetry between onset & offset bursts is frequently observed. Such units respond to low frequency (<10 Hz) sinusoidal stimuli with bursts of spikes on each rising as well as falling phase.

Units in a rostromedial region exhibit polarity-specific excitation or inhibition with excitation following cathodal stimuli and inhibition after presentation of an anode. Excitatory responses consist of more slowly adapting bursts of activity after stimulus onset, with inhibition of similar latency and duration following offset. Units in this area respond to low frequency sinusoidal stimuli with excitation during the negative phase peaking at maximum amplitude and inhibition during the positive phase.

Units in both regions were unimodal, exhibiting no response to visual or tactile stimuli. The results of this study indicate that two discrete electrosensory regions in the caudal lobe of the cerebellar corpus respond to distinctly different aspects of electric field stimuli. The electrosensory afferent innervation of these areas is unknown.

Supported in part by NIH NS08114 to JGN.

ELECTRORECEPTIVE AND PROPRIORECEPTIVE REPRESENTATIONS IN THE DORSAL GRANULAR RIDGE OF SKATES. R. A. Conley* and D. Bodznick Wesleyan Univ. Biology Dept., Middletown, CT 06457

Physiological responses and receptive fields of proprioreceptive and electroreceptive neurons in the dorsal granular ridge (DGR) of *Raja erinacea* have been studied in decerebrate, curarized fish. DGR is part of the vestibulolateral cerebellum in elasmobranchs and projects topographically via parallel fibers to the electrosensory dorsal octavolateralis nucleus (DON) in the medulla. DGR probably has a major influence on primary electrosensory processing, yet its role is unknown. Of 178 neurons recorded in a blind mapping study, 99 (56%) had their discharges modulated when the pectoral fin was displaced and 79 (44%) were unaffected by fin displacement, but responded to DC electric fields. No bimodal units were encountered. Units were characterized as proprioreceptive since they increased their firing rate tonically in proportion to fin displacement, although some units had a phasic component during fin movement. For each proprioreceptive unit there was a limited area of sensitivity along the fin margin. The electroreceptive units had large ipsilateral receptive fields, whose exact boundaries were often unclear. But at threshold, nearly all units had a best area within the receptive field. In general, both proprioreceptive and electroreceptive units showed a progression of receptive fields from posterior to anterior body along the caudorostral axis of DGR. DGR forms a topographic projection onto DON such that caudal DGR projects to dorsal DON and rostral DGR projects to ventral DON. As a caudal to rostral body map is present along the dorsoventral axis of the DON, these results suggest that DGR's projection onto the DON is homotopic.

AUTORADIOGRAPHIC LOCALIZATION OF DIHYDROTESTOSTERONE CONCENTRATING NEURONS IN THE BRAIN OF THE OYSTER TOADFISH. M.L. Fine and D.A. Keefer*. Depts. of Biology, Virginia Commonwealth University, Richmond, VA 23284 and Loyola College, Baltimore, MD 21210.

Steroid-concentrating neurons in the brainstem have been reported in two teleosts, the toadfish and a mormyrid, both of which produce courtship sounds. In this study ^{3}H DHT-labelled neurons were found in the forebrain and brainstem. Positive sites included the supracommissural nucleus of the ventral telencephalon and the base of the lateral portion of the dorsal telencephalon. Small numbers of cells were labelled sporadically in the parvo- and magnocellular preoptic nucleus and in the ventral and dorsal hypothalamus. The caudal hypothalamus had a densely-labelled triangular-shaped nucleus and nearby scattered cells. The periventricular portion of the posterior tuberculum of the thalamus was also labelled. Scattered heavily labelled cells were present throughout the basal optic tectum and superficial torus semicircularis. In the medulla a dorsal accumulation of cells was present beneath the cerebellum on either side of the fourth ventricle rostrally and in reticular neurons caudally.

Compared with an earlier study with ^{3}H estradiol, estrogen labelling is generally more prominent in the forebrain, and with the exception of the torus semicircularis and tectum, no estrogen target neurons have been found in the brainstem. Supported by NIH MH38921 and NSF PCM8309144.

DESCENDING CONTROL OF ELECTROSENSORY PROCESSING

J. Bastian and B. Bratton. Dept. of Zoology, U. of Oklahoma, Norman, OK 73019

The electrosensory lateral line lobe (ELL), the first-order electrosensory processing station, receives major descending inputs in addition to afferents from the electroreceptors. The nucleus praeeminentialis (NP), which receives electrosensory inputs from the ELL and the torus semicircularis, is the principle source of descending input to the ELL. NP neurons were studied using extracellular and intracellular recording methods and Lucifer Yellow labeling for anatomical identification focusing on two categories of neurons.

Stellate (ST) neurons show no spontaneous activity, respond to stepwise changes in electric organ discharge (EOD) amplitude phasically and are insensitive to sinusoidal modulations of EOD amplitude of frequencies exceeding 30 Hz. Previously reported as the most common NP cell type, ST neurons respond vigorously to electrolocation targets moving along the contralateral side. Ipsilateral targets cause little or no response, hence the ST neurons receive excitatory input from the contralateral ELL. We found two populations of ST neurons, one responds to contralateral increases in EOD amplitude while the other responds to decreases, there were no differences in morphology or projection pattern.

Tufted neurons influence the ELL indirectly via their projection to the posterior eminentia granularis (EGP). These fire spontaneously at 60 - 80 spikes/s, have bilateral receptive fields, respond to EOD AMs in excess of 64 Hz, and respond tonically to prolonged changes in EOD amplitude. Examples of these have been seen which alter their firing rate by as much as 60 spikes/s per 100 μV change in transepidermal voltage. Earlier studies have shown that the sensitivity of ELL output neurons changes to compensate for alterations in EOD amplitude and the associated changes in receptor afferent input. The tufted cells may provide information about changes in EOD amplitude needed for this gain control mechanism to function. Supported by NIH Grant NS12337 and OCAST #1669

MAGNETIC ORIENTATION IN NORMAL AND TELENCEPHALON-ABLATED RAINBOW TROUT (Salmo gairdneri). G.L. Chew* (SPON: P. Ahluwalia). Dept. of Psychol., University of Lethbridge, Lethbridge, AB, Canada, T1K 3M4.

The orientation of juvenile rainbow trout (Salmo gairdneri) (age approx. 6 months) was tested under: (1) normal, (2) null, and (3) rotated magnetic field conditions. In the normal geomagnetic condition (magnetic field strength ≈ 0.5 Gauss), juveniles showed a statistically significant mean orientation in alignment with geomagnetic north. In contrast, individuals tested in a null magnetic environment were only randomly oriented. Rotation of the horizontal component of the geomagnetic field using a Rubens coil array also shifted the mean orientation in the direction of rotation although this relationship is nonlinear.

A second group of trout, with their dorsal telencephali removed, were also tested. Mean group orientation in the normal and rotated magnetic field conditions were, as in the null field case, random. These findings show: (1) freshwater salmonids are capable of using magnetic orientation in spatial behaviour, (2) the horizontal component of the local magnetic field vector is involved in such orientation, and (3) normal magnetic orientation is not possible without the dorsal telencephalon which contains the lateral zone of the dorsal telencephalon, a piscine hippocampal homolog.

454.22

ACOUSTIC PRESSURE ACTIVATION OF STARTLE IN THE RESTRAINED GOLDFISH. J.G.CANFIELD AND R.C.Eaton. Neuroscience Group, Univ. of Colorado, Boulder, CO 80309-0334.

In the Mauthner cell, we have identified an auditory EPSP which has a latency of 3.5 - 4.5 ms and exhibits a complex waveform to air-mediated sound. This auditory potential can be recorded extracellularly (EC) near the cell soma and intracellularly (IC) in both the soma and axon at the level of the vagal lobes. The axon-recorded potential disappears if the cell soma is damaged. The amplitude of either the EC- or IC-recorded EPSP declines with increasing background noise and the EC field remains intact when the posterior lateral lines are severed but declines when the swim bladder is deflated. A similar auditory EPSP has been recorded from other reticulospinal axons which fire at short latency to spinal stimulation.

We have also been able to initiate startle responses in an anesthetized, restrained, but unparalyzed preparation by application of air pressure pulses to the body surface dorsal-lateral to the anterior chamber of the swim bladder. This stimulus also elicits a similar EC field response.

Since acoustic stimulation mediated by the swim bladder appears to cause a large field potential and initiate a startle response, it may be that ostariophysine fishes normally use this input to trigger escape whereas the near-field displacement component of the acoustic stimulus is superimposed to code response trajectory. We also postulate that the response trajectory results from bias on the output of the system by similar auditory input to other reticulospinal neurons. [Supported by NIH grant NS22621].

ODOR-MODULATED NETWORK OSCILLATIONS IN THE PROCEREBRAL LOBE OF *Limax*. A. Gelperin, D. W. Tank, J. Flores*, L. Rhines*. AT&T Bell Laboratories, Murray Hill, N. J. 07974

We find that odor stimulation of the nose modulates the spontaneously oscillating field potential of the procerebral (PC) lobe. Using a nose-brain preparation, brief pulses of moist air or 2-ethyl-3-methoxypyrazine were delivered to the nose while the PC oscillation was recorded with a saline filled electrode in the PC neuropil. Odor pulses modulate the spontaneous oscillation, resulting in transient DC shifts and changes in frequency and waveform of the oscillation. Air pulses also modulate the oscillation, but to a lesser extent than odor pulses. Simultaneous field potential recordings from distal cell body and basal neuropil regions show in phase oscillations of opposite polarity. A suction electrode placed over the intact lobe provides a convenient measurement of whole-lobe oscillation(Fig. 1a). Intracellular recordings show that individual neurons generate action potentials during the depolarizing phase of large membrane potential oscillations (Fig. 1b). It will be of great interest to determine if there exist odor-generated spatial patterns of excitation in PC neurons.

CHOLINERGIC ANTAGONISTS BLOCK THE LYMNAEA FEEDING RHYTHM. C.J.H. Elliott * (SPON : G.P. Ferguson. Dept. Biol., Univ. York, York, YO1 5DD, U.K..

In the isolated CNS of the pond snail, Lymnaea stagnalis, the feeding rhythm persists at a slow rate, through the interaction of the N1, N2 and N3 premotor interneurones (Elliott, C.J.H. & Benjamin, P.R., J. Neurophysiol. 54:1396, 1985).

Phenyltrimethylammonium (PTMA, 0.5mM in normal saline) blocks all synaptic output from the N1 neurones and rhythmic activity then appears to be confined to these interneurones.

Hexamethonium or atropine (0.5mM) block the EPSPS (but not the IPSPS) produced by the N1 interneurones. These antagonists also abolish the spontaneous rhythm and slow the rhythm elicited by the stimulation of a modulatory interneurone, the SO.

These results confirm that the N1 neurones are cholinergic (Elliott, C.J.H et al., Symp. Biol. Hung. 36:697, 1988) and suggest that recurrent inhibition between the N1 and N2 neurones plays an important part in rhythm generation.

455.3

SWALLOWING IN THE NUDIBRANCH *MELIBE LEONINA* IS CONTROLLED BY THE BUCCAL GANGLIA. W.H. Watson III, A. Vetrovs, and J.R. Trimarchi, Zoology Department, Univ. of New Hampshire, Durham, N.H. 03824.

Molluscan buccal ganglia have been used extensively to study the neural basis of feeding behavior. However, detailed information about the underlying neural circuits is lacking for most buccal preparations because of their size and complexity. We have been investigating the buccal ganglia in the nudibranch, *Melibe leonina*, because their simplicity (30 neurons) makes them amenable to analysis at the cellular level. The goals of our initial studies were to: 1) describe the feeding behavior in detail; 2) quantify the influence of food availability on the feeding rate and; 3) determine the role of the paired buccal ganglia in feeding.

Melibe has a unique feeding behavior because it lacks a buccal mass. It captures food by opening and closing its oral hood at a frequency of 1 - 4 episodes per minute. The more prey, the faster the capture rate. When prey enter the outstretched oral hood it closes and the edges of the hood are brought together so that tentacles lining the inner rim of the hood form a sieve. Then the oral hood contracts, water is forced out through the tentacles and zooplankton are filtered from the water. Finally, the tentacles transport the food into the mouth and it is swallowed by peristalsis of the esophagus.

To examine the role of the buccal ganglia we removed them from a group of 10 *Melibe*, and compared their feeding with groups of sham-operated and control animals. The three groups were allowed to feed for 5 days in aquaria containing prey which could be easily recognized during subsequent analysis. Then animals were dissected and their gut contents analyzed. All animals captured food normally and ate comparable numbers of prey, indicating that the buccal ganglia do not play a role in food capture. Analysis of the distribution of food in the gut revealed that in lesioned animals up to 80% of the food ingested remained in the anterior esophagus. In contrast, in both control groups the majority of the food was in the stomach. These data indicate that the buccal ganglia in *Melibe* control swallowing, but not the capture of food.

455.4

AN IDENTIFIED CEREBRAL NEURON PROMOTES MULTIPLE EFFECTS ASSOCIATED WITH FOOD-INDUCED AROUSAL IN *APLYSIA*. T. Teyke*, K.R. Weiss and I Kupfermann. Center Neurobiology & Behavior, Columbia University and NYS Psychiat. Inst., New York, NY 10032.

The food-induced arousal state in *Aplysia* has multiple manifestations, including changes in consummatory behaviors (increased rate and magnitude of biting), appetitive behaviors (head-up posture), autonomic responses (increased heart rate), and defensive responses (depressed head withdrawal). To determine if these responses might be controlled by a central arousal system, we examined the neural control of appetitive arousal, which appears to precede all the other aspects of arousal. The role of neurons in the cerebral ganglion which project to the pedal ganglion was studied. A unique cerebral-pedal interneuron, CPA, was identified, which activates numerous neurons in the pedal ganglion. The CPA has either poly- or monosynaptic connections to more than 50% of the pedal ganglion neurons, including a large population of neck motor neurons. Firing the CPA evokes bilateral contractions of neck muscles, which could serve to lift the head of the animal into the feeding posture. The activity that the CPA evokes in the pedal ganglion provides excitatory drive to a number of other neurons which mediate various aspects of the food arousal state, including the MCCs, which modulate biting; the CBIs, which drive the biting program; and the RB cells, which increase heart rate. Finally, pedal ganglion activity driven by the CPA inhibits cerebral Bn cells, which mediate head withdrawal. Stimulation of the tentacles with seaweed excites the CPAs, with concomitant excitation of the MCCs, and inhibition of the Bn cells. Removing the CPA neurons from the circuit by hyperpolarizing them bilaterally, strongly reduced the effects of seaweed on both the MCC and the Bn cells. Therefore, it appears as if activity of the CPA may be necessary for some, and perhaps most aspects of the responses associated with the food-induced arousal state. It is possible that the CPA functions in the role of a command neuron or command element that evokes a behavioral state in the animal, rather than a specific behavior.

ESCAPE BEHAVIOR IN JUVENILE APLYSIA IS AFFECTED BY PROTEIN AND TRYPTOPHAN DEFICIENT DIET. S.Kurtz*, J.Flinn, R.Holt* J.Weber*, & K.Allen*, Dept. of Psych, George Mason, Fairfax, VA 22030.

In two studies Aplysia c. were fed from 50 to 110+ days post-hatching on either a protein & tryptophan rich Gracilaria or on a low protein & tryptophan Enteromorpha diet. At 110+ days Aplysia were tested for short-term sensitization, using escape locomotion following tail shock. The experimental paradigm consisted of two weak shocks 1.5x the current required for tail withdrawal, followed by the sensitizing shock and two more weak shocks. Number of steps in the two min. following each weak shock measured activity. No differences were seen between feeding conditions for tail withdrawal threshold but significant differences were found both in the baseline motor activity & in the level of short-term sensitization. Aplysia raised on Enteromorpha showed significantly higher levels of baseline activity than siblings raised on Gracilaria, $t(35)=2.24$ p .05 for study 1, & $t(42)=1.89$, p .05 for study 2. This result was surprising since tryptophan is the precurser to serotonin which triggers escape behavior (Mackay & Carew, J.Neurosci 3:1469,1983). As hypothesized Aplysia raised on Enteromorpha showed less sensitization than those raised on Gracilaria, as shown by ANOVA & planned comparisons ($t(35=1.78$ p .05 for study 1, & $t(42)=1.90$ p .05 study 2.) These results show that feeding regimes during development can affect both escape behavior and level of learning.

SEROTONIN AFFECTS BEHAVIORAL STATE AND FEEDING BEHAVIOR IN THE SNAIL, HELIX ASPERSA, BUT HAS NO EFFECT ON SEXUAL BEHAVIOR. S.A. Adamo and R. Chase. Department of Biology, McGill University, Montreal, Canada H3A 1B1.

The degree of activity in H. aspersa can be used as a measure of the snail's behavioral state. Behavioral state can be taken to represent an underlying level of general arousal, as has been done for Aplysia and Pleurobranchaea. Injections of serotonin (10 -7 moles/kg body weight) increased behavioral state scores in H. aspersa ($p < 0.01$), which is consistent with the effects of serotonin in Aplysia and Pleurobranchaea (Palovcik et. al., Behav. Neural Biol., 35:383, 1982). Handling the animals had a similar, but smaller effect ($p < 0.05$). Serotonin injections also increased feeding behavior as compared to controls ($p < 0.05$).

Serotonin had no effect on sexual arousal (monitored by observing changes in the snail's genital eversion). Serotonin also had no effect on sexual proclivity (i.e. the frequency of mating, $p >> 0.05$).

These data suggest that, in H. aspersa, mechanisms that mediate sexual behavior are distinct from those that control feeding and behavioral state. Therefore, sexual behavior is one 'motivated' behavior that does not appear to be significantly modulated by a postulated gastropod central serotonergic system (Palovcik et. al., 1982).

Mechanosensory Inputs Produce a New Type of Nonassociative Learning in Tritonia. G.Brown* and P.A.Getting (SPON: C.Cleland). Neuroscience Program, University of Iowa, Iowa City, IA 52242.

Previously it was thought that in Tritonia, reponses to mechanical and chemical stimulation were mediated by the same population of afferents. The "S-cells" which trigger escape swimming due to chemical input also show a brief phasic response to mechanical stimulation. Three recent observations however suggest that responses to mechanical and chemical stimuli are mediated by distinct populations of neurons: 1) Chemical stimulation at a site distal to the gills elicits gill withdrawl whereas mechanical stimulation at the same site elicits gill extension. 2) When a chemical stimulus (.15 ml of 4M NaCl applied to the tail) which normally (>95%) elicits swimming was given together with a mechanical stimulus (25 pokes to midbody region with a glass probe), swimming was not observed in 9 of 10 animals. 3) When the mechanical stimulus was given after the initiation of swimming, the duration of the swim was attenuated (N=11, p<.001).

Mechanical stimulation also produces longer lasting inhibition of the response. Animals were trained with ten trials of mechanical stimulation at ten minute intervals and tested with the chemical stimulus 30 min after the 10th trial. Six of 18 animals did not swim when given the chemical test stimulus, compared to 1 of 23 in animals which received no mechanical stimulation (p<.05).

More dramatic results were seen when training consisted of both mechanical and chemical stimulation. Control animals received 10 chemical stimuli at 10 min intervals and were then tested with the same stimulus 30 min later. All these animals swam to the test stimulus (11 of 11). However, when 10 mechanical stimuli were interspersed with the chemical stimuli, 8 of 14 animals failed to swim (p<.02). In addition, the 6 animals which did swim had a longer onset latency than controls (10.4 vs 5.0 s, p<.01). This long lasting inhibition of the swim response due to mechanical stimulation represents a new form of nonassociative learning in Tritonia. Supported by NS17325 and NS07247.

FMRFamide ACTS DIRECTLY ON ISOLATED APLYSIA GILL MUSCLE CELLS. D. Cawthorpe* & K. Lukowiak (SPON: K.E. Cooper). University of Calgary, Calgary, Alberta T2N 4N1 Canada.

Aplysia californica is a model system used in the study of the neural and biochemical basis of behavior. Both the central nervous system (CNS) and peripheral nervous system (PNS) have been shown to act in an integrated manner to mediate gill withdrawal behavior (GWR). This GWR has been shown to undergo both associative and non-associative forms of learning. To date most studies have concentrated upon the role of the CNS in learning due to the easier accessibility of the CNS pathways. As yet little is known about the PNS. The particular sites of action and the identity of neurotransmitters and/or neuromodulators in the PNS remain largely unknown. In response to this gap in our knowledge about the PNS, a primary culture of dissociated gill muscle fibers has been developed. This provides an opportunity to survey the neurotransmitters and neuromodulators known to act in the PNS. We report here that the endogenous peptide, FMRFamide, acts directly on isolated gill muscle fibers to bring about contractions at concentrations (10 nM) which have been shown to increase the GWR amplitude and prevent habituation in the in vitro reduced gill preparation (Cawthorpe et al, 1988; Higgins et al, 1989).

NEUROSECRETORY CELL R15 IN *APLYSIA* ACTIVATES RESPIRATORY PUMPING, MOTONEURON L7, AND THE HERMAPHRODITIC DUCT A. Alevizos, K. R. Weiss, and I. Koester. **Center for Neurobiology & Behavior, Dept. of Psychiatry, and Dept. of Physiology and Cellular Biophysics, Columbia University, N.Y., NY**

R15 is a neurosecretory cell in the abdominal ganglion, thought to be involved in water and electrolyte regulation. It also has central synaptic effects in the abdominal ganglion - exciting unidentified cells of the left lower quadrant and the LBvc vasoconstrictor cells. We describe here the modulatory effects of R15 and its bioactive α-1 peptide on 1) respiratory pumping 2) multimodal motoneuron L7 and 3) peristaltic activity of the large hermaphroditic duct.

Respiratory pumping consists of transient, synchronous pumping actions of the mantle organs and parapodia. It is driven by a network of about 30 electrically and chemically coupled interneurons in the abdominal ganglion. We found that if R15 is hyperpolarized for prolonged periods of time (1.5 - 2 hours) to prevent it from firing, and then allowed to burst spontaneously for 5-60 minute intervals, the basal frequency of respiratory pumping exhibits an increase of 2- to 6-fold, which gradually decays over 20 to 60 minutes. In the same long hyperpolarization protocol, R15 also excited the multimodal cardio-respiratory motoneuron L7. Dye-filling the R15 soma revealed that it also innervates the large hermaphroditic duct. With the hyperpolarization protocol described above, we found that R15 bursting generates peristalsis of the portion of the hermaphroditic duct involved in egg laying. All 3 of these effects of R15 are mimicked by the R15α-1 peptide. The R15α-1 peptide effects exhibit pronounced desensitization that lasts for hours, and all the effects of R15 can be cross-desensitized by previous application of the peptide. All the effects of R15 described above are robust, present in all preparations, and persist in solutions that block polysynaptic pathways, suggesting that R15 mediates these effects by direct action on its targets.

Our results suggest that R15, by virtue of its central and peripheral connections, may integrate several behavioral components of oviposition.

ACTIONS AND DISTRIBUTION OF THE ALTERNATIVELY SPLICED R15 PEPTIDE OF *APLYSIA CALIFORNICA*. D. Karagogeos, A. Alevizos, K. R. Weiss, L. B. Buck*, and I. Koester **Center for Neurobiology and Behavior, Dept. of Psychiatry, H.H.M.I and Dept. of Physiology, Columbia University, N.Y., N.Y.**

Buck et al. (1987) have characterized the cDNA of the major neuropeptide expressed in R15. This neuron, a well studied bursting cell in the abdominal ganglion, is involved in a variety of behaviors (Alevizos et al., these abstracts). The polyprotein precursor of this neuropeptide can be cleaved at five sites to produce a variety of peptides. The mRNA encoding the polyprotein can be spliced alternatively in different neurons, to produce an even larger diversity of peptides.

Using a three stage HPLC analysis, we showed that the alternatively spliced peptide (R15α-2; 24 amino acids long) is synthesized in the abdominal ganglion of *Aplysia* by as yet unidentified cells. Furthermore, the peptide was found to be bioactive on a variety of organs. It causes cardioexcitation, shortening and/or constriction of all the major arteries, contraction of the main hermaphroditic duct, the gill and esophagus.

We have raised a rabbit antibody against the R15α-2 peptide to study its distribution in the CNS and the peripheral organs of the animal. Since the alternative splicing affects only a small portion of the peptide, the antibody recognizes both the R15α-1 and R15α-2 peptides. Immunocytochemistry showed that the antibody is highly selective, staining about 20 cells in the total CNS. There is extensive innervation of a variety of peripheral organs by immunoreactive terminals, including the main arteries, the large hermaphroditic duct, the sheath of the hepatopancreas, the pericardium, and the base of the auricle of the heart. Dye fillings of R15 showed that some of these organs are sites of R15 innervation.

Current work is aimed at identifying individual cells that synthesize the peptide and describing their physiological outputs.

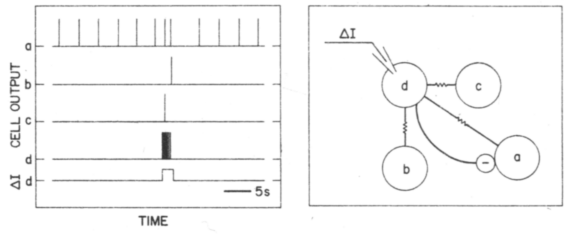
Synaptic interactions in assemblies of cultured *Aplysia* neurons. I: Analysis of optically recorded electrical activity. D. Kleinfeld, T. D. Parsons, F. Raccuia-Behling*, A. L. Obaid, and B. M. Salzberg. University of Pennsylvania School of Medicine and AT&T Bell Laboratories.

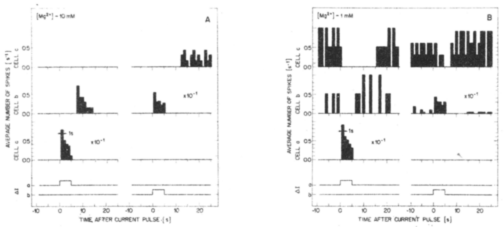
We constructed ensembles of *Aplysia* LUQ neurons in culture. These cells form chemical connections and may couple electrotonically. Their electrical activity was measured with multisite optical recording techniques and voltage sensitive dyes (Parsons *et al.*, Biophys. J., July 1989). These techniques allowed us to record for prolonged periods with a good signal-to-noise ratio and negligible phototoxicity (2 hr, S/N ≃ 10). However, the extensive outgrowth of the neurons caused each detector to monitor the activity of many cells. We show how individual spike trains were reconstructed from the spatial distribution of timing and amplitude information in the optical records. The effective connectivity was determined from the spike trains (Figure). Weak interactions could be deduced from repeated measurements. (Supported by AT&T and NS 16824)



455.12

Synaptic interactions in assemblies of cultured *Aplysia* neurons. II: Dynamic patterns of effective connectivity. T. D. Parsons, B. M. Salzberg, A. L. Obaid, F. Raccuia-Behling*, and D. Kleinfeld. AT&T Bell Laboratories and University of Pennsylvania School of Medicine.

We studied the *effective* connectivity between LUQ neurons co-cultured as 4 to 6 cell ensembles. These cells form biphasic chemical connections, with inhibition followed by excitation, as well as monophasic inhibitory connections. The effective connectivity was determined (preceeding abstract) when the neurons were quiescent ($[Mg^{2+}] \simeq 10$ mM) and when they were firing at ~ 0.5 Hz ($[Mg^{2+}] \simeq 1$ mM). Under conditions of quiescence the neurons exhibited excitatory interactions (Histogram A). In contrast, the same ensemble exhibited slow inhibitory connections when the cells were active (Histogram B). The change in effective connectivity could be understood in terms of the underlying monosynaptic connections. The excitatory phase dominated when the neurons were quiescent while inhibition dominated when the neurons were active. Similar mechanisms for dynamic changes in effective connectivity may occur *in vivo*. (Supported by AT&T and NS 16824)



455.13

EVIDENCE FOR ASSOCIATIVE LEARNING IN THE NEMATODE *C.ELEGANS* N. Kumar*, M. Williams*, J. Culotti† and D. van der Kooy, (SPON: A. Roach), Dept. of Anatomy and †Medical Genetics, Univ. of Toronto, Toronto, Canada, M5S 1A8.

A simple *in vivo* model for associative learning and memory offers many advantages in the search for the molecular basis of of these processes. The nematode, *C. elegans*, seems to be an ideal model system for associative learning because of its well characterized genetics, neuroanatomy and development. We developed a classical conditioning paradigm using chemotaxic responses to the conditioned stimuli (CS) Na^+ ($NaCH_3OO$) and Cl^- (NH_4Cl) ions, and *E. coli* (a food source) as an unconditioned stimuli (UCS). CS levels were balanced such that naive animals displayed equal preferences for either CS. The animals were then trained by exposing them to one ion paired with the UCS (CS+) followed by exposure to the other ion in the absence of the UCS (CS-). The experiment was counterbalanced for which CS was paired with the UCS and for order of presentation. The testing consisted of placing approximately 100 of the trained animals between point gradients of each CS (in the absence of the UCS) and allowing them to migrate towards one of the gradient centers. Immediately after one CS+ and one CS- pairing, 67.1±3.1% of the animals demonstrated a preference for the CS paired with the UCS. A five hour food deprivation prior to training increased the level of learning to 79.6±4.7%. These animals are also capable of retaining the association, as learning levels were still at 62.3±5.5% 7 hours post-training. By 27 hours post-training the level of learning was no longer significantly different (56.5±9.8 %) from controls. We have also been able to demonstrate conditioned aversion learning by replacing *E. coli* as the UCS with an aversive garlic extract. In this case nematodes can be trained to avoid the UCS paired CS (63.8±2.1 %). Thus, the nematode is capable of associative learning and should be useful in a mutational analysis of the molecular basis of learning and memory.

MALE-MATING DEFECTIVE MUTANTS OF *C. ELEGANS* K. Liu* and P. Sternberg* (SPON: S. Benzer). Div. of Biology, 156-29, Caltech, Pasadena, CA 91125.

To understand how genes specify an innate behavior, we are genetically dissecting male-mating in *C. elegans*. Since the hermaphrodites are self-fertilizing, mutations that affect or even eliminate male-mating behavior can be isolated and maintained for study. By mutagenizing with EMS a strain that segregates 40% XO males via non-disjunction of the X-chromosome, we have isolated mutants that have no immediately visible anatomical defects yet are copulation defective (Cod). We predict that such mutants might be blocked in mating behavior at any one of a number of neccesary steps: attraction to hermaphrodites, response to contact with hermaphrodites, location of the vulva, insertion of spicules into vulva, and sperm transfer.

Of the mutants isolated thus far, the majority (6 of 9) appear to be unable to insert their spicules, indicating a muscle or motor defect. One responds poorly to contact with hermaphrodites and two are unable to locate the vulva. These failures may indicate underlying sensory defects. In addition, two mutant strains give males that sire very few progeny, indicating either a defect in sperm transfer or sperm potency.

LEVER-PRESS CONDITIONING IN THE CRAB. Charles I. Abramson* and Richard D. Feinman, Dept. of Biochemistry. SUNY Health Science Center. Brooklyn, NY 11203.

Operant conditioning is the least well investigated learning procedure in animals with simple nervous systems. In particular, lever press and other traditional operant behaviors studied in vertebrates have been difficult to obtain in invertebrate species. We have developed an operant chamber for the green crab *Carcinus maenas* in which pressing a lever produces food reward. The operant chamber, submerged in seawater, contained a plastic rod attached to a microswitch and food was dispensed from a tube positioned at mouth level. In one series of experiments, two bars were presented on either side of the food tube. Pressing one lever (S+) was reinforced whereas, the other (S-) was not. Experimental animals pressed S+ with an average rate of 6 min^{-1} over the first 5 min and then gradually slowed down. Responses to S- averaged 3 min^{-1} and rapidly dropped out. Typical total responses for 20 min sessions were 75 responses to S+ and 25 to S-. (Naive animals placed in the chamber with the food dispenser turned off pressed the bars no more than 10 times in a 20 minute session without obvious discrimination). When the contingencies associated with the lever were reversed animals persisted in pressing the old bar (now S-) on the first day but learned to switch to the correct bar on the second. Trained animals maintained high rates of responding on a fixed ratio of 2 schedule (FR2, every other response reinforced) or even an FR3. In a second series of experiments, one group of animals was presented with a single bar and an FR1 schedule. A second group in a similar chamber was "yoked" to the first — received reinforcement whenever the first group did: effectively a variable time schedule. This non-contingent schedule caused a decrease in performance to one third the rate of the FR1 group. The performance of crabs in the "Skinner box" shows discrimination and dependence on the contingencies of reinforcement. POSTSYNAPTIC INHIBITION OF THE LATERAL GIANT NEURON DURING RESTRAINT-INDUCED SUPPRESSION OF CRAYFISH ESCAPE. E.T. Vu and F.B. Krasne. Neuroscience Program, Dept. of Psychology, and Brain Research Institute, University of California, Los Angeles, CA 90024.

The suppression of the crayfish lateral giant (LG) escape response by restraint is at least partially mediated by decreased synaptic transmission onto the LG. We have previously reported a 15% decrease in root-evoked LG postsynaptic potentials (PSP). We now report comparable decreases in both the electrical unitary PSP from the identified sensory interneuron, interneuron A, and in polarizing pulses injected into the electrically coupled contralateral LG. In contrast, axonally applied LG polarization is only decreased about 1%, thus suggesting that the LG receives a conductance increasing postsynaptic inhibition during restraint that operates distally in the dendrite. This site of action is different from that of recurrent inhibition of this cell, and is similar to that of another recently reported form of postsynaptic inhibition of the LG, post excitatory inhibition. Supported by USPHS grant NS08108 (FK) and a Predoct. NSF Fellowship (EV).

EFFECTS OF OCTOPAMINE ON UNITARY EPSPS IN A FIRST ORDER INTERNEURON OF CRAYFISH LATERAL GIANT ESCAPE CIRCUIT. J. Bustamante* and F. Krasne. Dept. Physiology, Faculty of Medicine, Universidad Complutense de Madrid and Dept. Psychology and Brain Research Institute, UCLA.

The excitability of the crayfish lateral giant escape reflex can be increased for hours by traumatic stimulation, LTP-like regimens, and exposure to octopamine. Viewing the octopamine augmentation as a possible model of the other types, we examined octopamine's effect on unitary EPSPs in interneuron A, the largest first order interneuron of the circuit. Octopamine exposure caused EPSP amplitude to increase (50%, SD 28%) within minutes, but recovery required hours of washout. Augmented EPSPs had more variable amplitudes (control cv of 7.8% increased by 56%, SEM 18%), peaked later, and decayed more slowly (4.4 ms half fall increased significantly by 5%) than controls. The results suggest a model in which octopamine brings into increased action a population of previously unexpressed synaptic transmission sites that have relatively variable release and slow decay kinetics (t approx 20 compared to 6 for control). Supported by CSIC Fellowship, Spain (JB) & NIH grant NS 08108 (FK).

ALTERED SYNAPTIC TRANSMISSION AND MEMBRANE CURRENTS IN THE *DROSOPHILA* LEARNING MUTANT *dunce* Yi Zhong* & Chun-Fang Wu (Spon: S. Singh). Dept. of Biology, University of Iowa, Iowa City, IA 52242

Several proposed models for cellular mechanisms underlying learning and memory involve regulation of neuronal plasticity by second messenger systems. A general question can be raised as to whether a discrete set of genes controls the molecular regulatory mechanisms exclusively required for learning and memory. Mutations of the *dunce* (*dnc*) locus in *Drosophila*, which cause reduced phosphodiesterase II activity resulting in elevated cAMP levels, reveal deficiencies in learning and memory paradigms but not in other behavioral tests. It is important to know whether *dnc* mutants affect synaptic plasticity and membrane currents and whether the effects are confined to subsets of neurons or more generally to excitable cells.

With the two-microelectrode voltage-clamp method, we examined neuromuscular transmission and muscle membrane currents in larval body wall muscle preparations. The excitatory junctional currents (ejcs) in *dnc* showed increased quantal contents with miniature ejcs of normal amplitude. With 0.2 mM Ca^{++} in saline, **facilitation** was induced by 4 Hz stimulation in normal larvae, but not in *dnc*. At 0.4 mM Ca^{++}, 4 Hz stimulation caused a significant **depression** in *dnc* in contrast to facilitation in normal. In addition, following 5 Hz stimulation for 2 min, **potentiation**, which lasts for minutes, was observed in normal, but not in *dnc*. Furthermore, we found an increase in the amplitude of both transient K^+ current (I_A) and inward Ca^{++} current in *dnc* muscle membrane. Interestingly, modification of synaptic efficacy and of these two currents has been implicated in other invertebrate model systems for learning and memory.

SEROTONIN DEPLETION REDUCES SEVERAL FORMS OF BEHAVIORAL FACILITATION IN THE LEECH. T. Karrer, J. Erlich*, N. Boulis and C. Sahley, Depts of Biology and Psychology, Yale University, New Haven CT. 06511

We have previously shown that the shortening reflex of *Hirudo medicinalis* undergoes two forms of facilitation, dishabituation and sensitization (Boulis and Sahley, 1988). Other labs have suggested a role for serotonin (5HT) in facilitation in *Hirudo* (Berton et al., 1987; Catarsi et al., 1987; Lockery et al., 1987). For this reason, we tested the role of 5HT in facilitation of the shortening reflex. Specifically, we depleted 5HT and observed the subsequent effects on habituation, dishabituation and sensitization.

5HT depletion and histological corroboration were done using a modified version of Lent's technique (1982). Two weeks after the injections half of the leeches were habituated to a low level shock stimulus (2.5-3.5v) applied to the skin of the leech, followed by dishabituation trials using a higher level shock (10V) also to the skin. The remainder of the leeches received sensitization trials using a 10 V stimulus prior to undergoing the habituation regimen.

Glyoxylic acid staining revealed that 5HT was always depleted in the Retzius cells of experimentals. Depletion of the smaller 5HT neurons was variable.

Behaviorally, 5HT depletion attenuated dishabituation and prevented sensitization. In addition, the intial facilitation shown by controls early in habituation training was absent in experimentals.

These results suggest that 5HT, and perhaps Retzius cells play an important role in facilitation of the shortening reflex of *Hirudo*.

ION CHANNELS: CELL FUNCTION

456.1

A DETERMINISTIC MODEL OF ION CHANNELS WITH CHAOTIC BEHAVIOR HAVING A MARKOVIAN-LIKE PROBABILITY FUNCTION. T. I. Tóth* and L. S. Liebovitch* (SPON: A. Sato) Dept. Ophthalmol., Columbia Univ., New York, N.Y., 10032

The most common way to characterize the behavior of ion channels is to analyze the statistical properties of the dwell times in the open and closed states. It is usually assumed that these kinetics are an inherently stochastic process and thus it is characterized by a Markovian stochastic model.

We present a model which is deterministic having chaotic behavior that has statistical properties similar to that of a Markovian stochastic model. This chaotic model is an modified version of a piecewise linear map first used by Lábos to generate neuronal spike-train-like processes. The open and closed time distributions of this chaotic model converge to exponentials similar to that of a two state Markov model. Hence, it cannot be decided alone from the probability distribution of open or closed times whether the underlying behavior of a channel is stochastic or deterministic chaos.

456.2

HH CHANNELS ALTER SUMMATION OF SYNAPTIC INPUTS IN A MODEL NEURON *J.W. Moore, M.L. Hines*, & J.K. Gobble**
Dept. Neurobiology, Duke Univ. Med. Cntr. Durham, NC.

We have examined the effect of insertion of Hodgkin-Huxley (HH) channels in passive neuron models of Rall. Computer simulations were carried out on a PC using a new simulation package **CABLE** (Int. J. Biomed. Comp., in press) We have followed, with minor changes, Dodge's (1979, *The Neurosciences, 4th Pgm.*, 439) assignments of morphology and HH channel densities for a motor neuron.

In testing for spike generation by "temporal summation" of two synaptic inputs, we found their **relative timing** to be **more important than their amplitudes** when Na & K channels were present. Contrary to the conventional notion (based on passive membranes and often used in nerve networks) that a spike can be produced by summation of EPSP's to a level exceeding a constant threshold, we find such synaptic inputs will sum to generate a spike only during a relatively brief period when both are rising.

For an "excitatory" synaptic input, the presence of Na channels causes a greater depolarization than in a purely passive neuron. The presence of K channels (with a slowly increasing and decaying conductance) both speeds the return toward rest and reduces the effectiveness of a following EPSP. This inhibitory effect is strong enough to prevent the generation of a spike, even by a train of closely spaced EPSP's.

Conversely, because IPSP's decrease gK and thus make the membrane potential more sensitive to current, they can have an **excitatory** effect for a long period following their peaks.

Neurons with voltage-sensitive channels offer much richer repertoires of integration than do passive membranes.

456.3

A PURKINJE NEURON MODEL WITH ACTIVE DENDRITES. G. T. Bartha* and R. F. Thompson (SPON: W.L.Byerly). Neural, Informational, and Behavioral Sciences, University of Southern California, Los Angeles, CA 90089.

The objectives of detailed modeling of Purkinje cells include reproduction of known physiology to gain insight into underlying mechanisms, exploration of input/output relations to put constraints on possible functions, and integration into a circuit level model.

The simulation code based on the compartmental method allows for the specification of arbitrary cell morphology, distribution of ion channels, and stimuli. The following active ionic conductances have been implemented using Hodgkin-Huxley type equations: 1) the ubiquitous voltage sensitive inactivating Na+, 2) a slower spike-generating Ca++, 3) a voltage sensitive K+, 4) a slow voltage and Ca++ dependent K+, and 5) a non-inactivating Na+ conductance.

Physiological data was better reproduced in Purkinje cell simulations with Na+ currents located in the soma and Ca++ related currents in the dendrite. Several conductance variations showed bursting behavior. Tests of synaptic input/cell firing output gave a near linear relation when somatic conductances dominated dendritic conductances.

Supported by NSF (BNS-8718300), the Mcknight Foundation, and ONR (N00014-88-K-0112) grants to RFT.

456.4

COMPUTATIONAL MODELS OF OLFACTORY RECEPTOR NEURONS: COMPARISON OF CONVENTIONAL AND WHOLE-CELL DATA. F. Pongracz*, S. Firestein and G.M. Shepherd. Section of Neuroanatomy, Yale University Medical School, New Haven, CT. 06510.

Studies of vertebrate olfactory receptor neurons have yielded differing estimates of membrane properties. Compared with conventional intracellular recordings in intact salamander olfactory epithelium (cf. Hedlund et al, J. Neurosci. 7: 2338, 1987), whole cell patch recordings in freshly-dissociated cells show a more negative E_m and a R_N in the Gohm range, implying a correspondingly greater τ_m and dendritic λ (cf. Firestein & Werblin, Proc. Nat. Acad. Sci. 84:6292, 1987).

We have analysed these discrepancies by constructing computational models of the receptor neurons in the two recording situations. The simulations have run on SABER (Analogy, Inc.), a general simulator program that permits rapid exploration of linear and nonlinear parameters.

Analysis of the models has shown that a leak around the electrode, coupled with differences in cell morphology, can account for the lower values of E_m, R_N and τ_m in the conventional recording mode. Peeled exponentials indicate an electrotonic length of the dendrite+cilia of less than 0.3. The results support studies in motoneurons demonstrating the importance of electrode leak in assessing membrane properties. We are extending the models by incorporating transduction-gated conductances in the cilia that are activated by sensory stimulation, and voltage-gated conductances in the soma and axon that generate the impulse response.

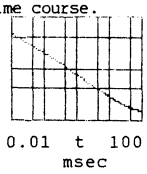
456.5

MODELING INTRACELLULAR ION DIFFUSION. N.T.Carnevale. Neurology Dept. and Dept. of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794.

To study the roles of intracellular ions in neural function, it is necessary to complement experimental observations with quantitative modeling. Electrotonus has been studied extensively, but simulation of diffusion in neurons has received relatively little attention. We have begun to develop guidelines for efficient modeling of diffusion.

One case of particular interest is a cell body of radius r. Assume: rapid Ca influx, so that [Ca] = 1 at time t = 0 in a shell of thickness dr; [Ca] = 0 in the core of the cell at t = 0; there are no binding proteins or pumps. For a cell with r = 20um and dr = 0.1um, Fick's second law predicts that [Ca] in the shell will have many closely spaced eigenvalues (see log-log plot), with the longest tau = 33msec.

The problem is how to design a computationally tractable model to fit such a complex time course. We show how to do this by taking account of the kinetics of Ca currents, Ca-gated conductances, transport mechanisms, and buffers.



456.6

SIMULATION OF PHARMACOLOGICAL RESTORATION OF CONDUCTION FOLLOWING DEMYELINATION. F. N. Quandt and F. A. Davis. Multiple Sclerosis Research Center. Rush University. Chicago, Il. 60612.

Many studies have suggested that the symptoms associated with Multiple Sclerosis are due to conduction block in central nervous system axons secondary to the loss of myelin. It is possible to overcome conduction block following demyelination in an experimental preparation using drugs which increase the duration of the action potential. The agents used to prolong the action potential include K channel blockers and compounds which inhibit Na channel inactivation. The relative effects of the two methods to overcome conduction block on the frequency response of the nerve were determined using a computer model. The method and parameters used for calculating the propagating action potential were similar to those given by Waxman and Wood (*Brain Res.* 294, 1984). In order to study the refractory period, twin current pulses were applied using a variable interstimulus interval. Reductions in the number of myelin wraps in one internodal region led to conduction block beyond the point of demyelination. Either a reduction in g_K or decrease in β_h, the rate of onset of inactivation, restored conduction. However, in the former case a subsequent action potential was blocked beyond the demyelinated internode when the interstimulus interval was short. The conduction velocity increased and the refractory period decreased when either g_K or β_h was reduced. However, for an equivalent change in the conduction velocity, the refractory period was always greater with a reduction in gK. Further, large reductions in g_K increased the refractory period. The results suggest that the demyelinated nerve fiber would have a higher frequency response if conduction is restored by inhibition of Na channel inactivation, compared to K channel block.

456.7

DIFFERENTIAL CONDUCTION IN BRANCHED AXONS: THE ROLE OF THE ELECTROGENIC PUMP. A. Passera* and G. E. Schneider. (SPON: W.A. Rosenblith) Dept. Brain & Cognitive Sciences, M.I.T., Cambridge, MA, 02139.

There has been indirect evidence that differential conduction, which is based on spike frequency, occurs at branch points of particular axons in crayfish and also in leech. However, the crayfish motor system and leech sensory system results appear to reflect different mechanisms. In both systems differential conduction occurs after an increase in threshold following a period of prolonged activity. However, in crayfish the prolonged activity is accompanied by a slight depolarization, while in leech prolonged activity is accompanied by hyperpolarization. In addition, artificial hyperpolarization relieves the conduction failure in crayfish, but mimics conduction failure in leech. Furthermore, inactivating the electrogenic pump enhances conduction failure in the crayfish preparation, but relieves conduction failure in the leech preparation.

A computer simulation has been used to explore the hypothesis that both differential conduction and the differences in excitability changes in the two preparations can be explained by different axon-specific densities of electrogenic pump sites. The mechanism to account for differential conduction involves sensitivity of the electrogenic pump to external potassium and internal sodium concentrations, which causes the pump to activate sooner in a thin branch than in a thicker branch. Consequently, there can be differences in excitability in two branches of the same axon, even though the density of pump sites per unit area of membrane is uniform. The differences in equilibrium potential accompanying prolonged activity in the two preparations can be accounted for by different overall densities of pump sites in the leech and the crayfish preparations with the density in the leech preparation being much higher.

ACTION POTENTIAL DURATION IN A RAT PITUITARY CELL LINE (GH3) IS DEPENDENT ON INTRACELLULAR CALCIUM ACCUMULATION. S. M. Simasko. Dept. of Physiology, State Univ. of New York at Buffalo, Buffalo, NY 14214.

Because the amount of calcium that would enter a GH3 cell through voltage-dependent calcium channels is dependent on action potential duration, experiments were performed to determine what factors regulate this duration. Action potentials were measured using the whole-cell variation of the patch-clamp technique. The effect of accumulation of free intracellular calcium on action potential duration was examined by manipulation of either the bath calcium concentration or the calcium buffering capacity of the pipette buffer. Under standard conditions (bath: 2 mM calcium; pipette: 2 mM EGTA/100 nM free calcium) action potential duration was found to be 240 ± 64 msec. When pipette calcium buffering capacity was reduced (0.2 mM EGTA/100 nM free calcium) action potential duration decreased to 79 ± 7 msec. When pipette calcium buffering capacity was increased (2 mM EGTA/no added calcium) action potential duration increased to 1880 ± 715 msec. When bath calcium was increased to 10 mM with either standard or reduced pipette calcium buffering capacity, action potential duration decreased (57 ± 4 % and 36 ± 3 % of control, respectively). These results indicate that action potential duration is determined by the speed at which intracellular free calcium accumulates. This would imply that without a change in the calcium sensitivity of the event that mediates repolarization (activation of a potassium channel or inactivation of the calcium current) any increase of intracellular calcium during a single action potential is self-limiting.

IONIC CURRENTS IN RAT LACTOTROPHS. D. Janigro, G. Maccaferri* and J. Meldolesi*. Dept. of Pharmacology, H San Raffaele 20132 Milan Italy.

Ionic currents were investigated in purified rat lactotrophs in primary culture. Patch clamp experiments using the whole cell configuration mode revealed large potassium currents elicited from a holding potential of -110 mV when recordings were performed in standard extracellular solution (in mM: 150 NaCl, 5 KCl, 2 $CaCl_2$, 2 $MgCl_2$, 5 HEPES, 5 Glucose). An early outward current required calcium influx for its activation since removal of extracellular calcium ions abolished this component thus permitting the study of a long lasting current. After blockade of potassium channels with intracellular CsCl (130 mM) and external TEA (130 mM), low and high threshold calcium currents were elicited from a holding potential of -100 mV and -40 mV, respectively. Partial inhibition of the inward currents was obtained after cell exposure to amiloride (250 uM) and nitrendipine (10 uM).

These results confirm the existence of multiple calcium and potassium conductances in rat lactotrophs.

SODIUM CONDUCTANCE GENERATES THETA RHYTHMICITY IN ENTORHINAL CORTEX LAYER II STELLATE CELLS *IN VITRO*. A. Alonso* and R. Llinás (SPON: J. Ransohoff). Dept. Physiol. & Biophys., New York Univ. Med. Ctr., New York, NY 10016.

Stellate cells from the entorhinal cortex (EC) layer II form part of the network that generates the theta rhythm and give rise to the most prominent component of the perforant path. Intracellular recordings were obtained from EC layer II stellate cells in rat brain slices. The neurons were identified on the basis of their location and, following biocytin injections, by their morphology. These cells have an input resistance of 25.3 ± 9.5MΩ (n=20) and a resting potential of -64.2 ± 3.6 mV and demonstrate pronounced delayed and anomalous rectifications. In addition to fast action potentials, the stellate cells showed rhythmic subthreshold oscillatory activity. Depolarizing constant current injection was accompained by rhythmic voltage oscillations having a sinusoidal-like appearence and a frequency which ranged from 5 to 11Hz. This oscillatory activity developed and reached rather maximum amplitude at a membrane potential of -59 to -54mV. Bath application of TTX, replacement of extracellular sodium by choline, and intracellular inyection of QX314, always resulted in a complete abolition of the oscillations, which persisted after calcium channels blockage. These results indicate that in the EC stellate cells the subthreshold oscillatory events observed upon depolarization are driven by a persistent voltage-dependant sodium conductance. Voltage-clamp analysis confirmed the presence of such current and revealed that the hyperpolarizing phase of the oscillation is due to time-dependant inactivation of the sodium current and to the delayed activation of an outward current. The finding described above indicates that the EC layer II have an intrinsic subthreshold oscillatory propertie that differs from those previously described in the CNS. The results are significant as they indicate that an invariant rhythmicicty in the brain (in this case the limbic theta rhythm) does not require a common ionic mechanism for the different cell groups involved in the particular network demonstrating the macroscopic rhythmicity.

SUBTHRESHOLD MEMBRANE POTENTIAL OSCILLATIONS MODULATE REPETITIVE FIRING OF MESOPONTINE CHOLINERGIC NEURONS *IN VITRO*. C.S. Leonard and R. Llinás, Dept. Physiol. & Biophys., NYU Med. Ctr. 550 First Ave. New York, NY 10016

The mechanisms underlying repetitive firing of cholinergic pedunculopontine and laterodorsal tegmental neurons were investigated by intracellular recording in guinea pig brain slices. Cholinergic neurons were identified physiologically and morphologically by combined intracellular injection of lucifer yellow and histochemical staining for NADPH-diaphorase (Leonard and Llinás, '88, Soc. Neurosci. Abst. 14: 297), which is a selective label for mesopontine cholinergic neurons (Vincent et al., '83, Neurosci. Letts. 43: 31-36). At just subthreshold potentials (-50mV), spontaneous 10Hz membrane potential oscillations were observed to underlie repetitive firing. The 10Hz oscillation was sustained for 3-8 cycles before breaking into oscillations composed of several frequencies (5-15Hz). Oscillations occurred at potentials between spike threshold and -60mV, were maximal (2-5mV) near threshold and were reduced in amplitude by membrane hyperpolarization. Blockage of high threshold Ca spiking and synaptic transmission with low- Ca/ 2mM Co or normal Ca/ 0.2mM Cd Ringer did not abolish the oscillations. However, they were completely abolished in Ringer containing TTX (1µg/ml). These observations imply that the oscillations are intrinsic and arise through activation of a persistent Na conductance. The intrinsic nature of the oscillations was also indicated by the fact that transient oscillations were evoked by brief (2ms) depolarizing current pulses from hyperpolarized membrane potentials. Furthermore, small hyperpolarizing pulses (<5mV, 2ms) were sufficient to reset the phase of spontaneous oscillations. Functionally, action potentials arise from the depolarizing phase of these membrane oscillations and thus, the temporal pattern of action potentials is established by the interplay between oscillations and the Ca- dependent post-spike hyperpolarizations also present in mesopontine cholinergic neurons. Membrane oscillations may also have important consequences for controlling the relative synchrony of these neurons, since a common, transient input to the population would reset the oscillations and, at least temporarily, promote phase-locked firing. Support NINCDS13742.

Na^+ AND Ca^{2+} VOLTAGE-DEPENDENT CHANNELS ARE INVOLVED IN PLATELET ACTIVITY. A. Gual*, L. Palacios-Araus* and J. Palés* (SPON: C. González). Lab. of Neurophysiology and Biomembranes, Faculty of Medicine, University of Barcelona, 08028 Barcelona, SPAIN.

The role of membrane potential and the involvement of voltage-dependent mechanisms in the stimulus-response coupling in platelets are controversial. Na^+ and Ca^{2+} fluxes seem to be involved in platelet activity (Wencel-Drake, J.D. and Feinberg, H., Thromb.Haemost., 53:75, 1985). We have therefore studied the effects of extracellular Na^+ and tetrodotoxin (TTX), and dihydropiridines (DPH) on platelet aggregation and platelet cytosolic free Ca^{2+} in normal and depolarized platelets. In control platelets, zero extracellular Na^+ or 3×10^{-8}M TTX block aggregation and inhibit the concomitant rise of cytosolic free Ca^{2+} induced by thrombin. Both manoeuvers fail to inhibit aggregation in high-K^+ depolarized platelets. In control platelets, 50×10^{-9}M nisoldipine blocks both platelet aggregation and the concomitant cytosolic free Ca^{2+} rise induced by thrombin; these effects were enhanced in K^+-depolarized platelets. These results indicate that the platelet activation is sensitive to extracellular Na^+, TTX and DHP, and suggest that platelet activity could be voltage-modulated. Supported by grant 87-1346 FISss, Spain.

A MODEL OF EXOCYTOSIS BASED ON THE DEPLETION OF IONS FROM THE SPACE BETWEEN VESICLE AND PLASMA MEMBRANES. G. Ehrenstein* and E.F. Stanley (Spons: K. Krebs) LB, NINDS, NIH, Bethesda, MD 20892.

We propose the following revised version of a model for the mechanism for calcium-dependent exocytosis: Increased cytosolic calcium concentration causes opening of a calcium-activated potassium channel located in the secretory vesicle opposite the plasma membrane. Opening of the channel causes influx of potassium ions into the vesicle. This tends to deplete salt concentration in the space between the vesicle membrane and the plasma membrane. In presence of calcium, this space is extremely narrow, limiting replacement of lost ions. Because of net ion loss, the space becomes hypoosmotic and water leaves, causing the two membranes to fuse.

Because of the small size of the space which becomes hypoosmotic, only a very small number of molecules leave. Therefore, it may be possible for sodium or sugar molecules to take the place of potassium in lowering the osmolarity of the space. Thus, the experimental evidence that replacement of cytosolic potassium by sodium or by sugar has no effect on the rate of exocytosis, does not necessarily contradict the model.

RELATIONSHIP BETWEEN HORMONE SECRETION AND CALCIUM CHANNEL ACTIVITY IN ANTERIOR PITUITARY CELLS. Miquel Puigmacia* & Susan A. DeRiemer. (SPON: C. Scheffey), Columbia University, New York, NY. 10027

Secretion in pituitary cells is dependent on calcium influx via voltage sensitive ion channels or release from intracellular stores. In order to understand the relationship between calcium influx and secretion we have characterized the actions of different calcium channel types in cultured rat anterior pituitary cells by measuring hormone secretion in isolated cells with the reverse hemolytic plaque assay and by release experiments on cell populations by RIA. In previous electrophysiological studies it was found that somatotrophs (GH cells) have only L type calcium channels (no T or N), while lactotrophs (PRL) have both T and L (no N). ω-Conotoxin, an L blocker, produced a clear decrease in the percentage of GH cells secreting and in the diameters of plaques. A similar, but less pronounced, effect was observed in PRL cells. Bay K8644, the dihydropyridine L channel agonist, caused a significant increase in hormone secretion from both cell types, but again was less potent in the PRL cells. The inorganic calcium channel blockers Cd^{2+}, Co^{2+}, and Gd^{3+} were also tested. The first two produced complete block of secretion at doses under 100 µM in both cell types. Preliminary evidence suggests that Gd^{3+} may also inhibit secretion despite the absence of N type channels. Alcohols had no effect on GH cells.

N-TYPE CA2+ CHANNEL-DEPENDENT AND INDEPENDENT RELEASE OF 3H-DOPAMINE FROM CULTURED MESENCEPHALIC NEURONS. M.G. Grilli, A.G. Wright, Jr.* and I. Hanbauer. H-E Branch, NHLBI, N.I.H., Bethesda, MD 20892.

Mechanisms involved in the release of ^{3}H-dopamine (^{3}H-DA) elicited by different membrane depolarizing agents were studied in primary cultures of dopaminergic neurons. Dissociated neurons of ventral mesencephalon from fetal rats grown in culture for five days were preloaded with ^{3}H-DA (5×10^{-8}M) and the basal ^{3}H-DA release in standard Krebs-Ringer-Henseleit buffer was determined. K^+ elicited a concentration-dependent increase of ^{3}H-DA release (25 mM K^+ elicited half maximal increase) that was blocked when cell cultures were preincubated with 10^{-5} M omega-conotoxin. The K^+-elicited increase of ^{3}H-DA release was not altered by nifedipine, amiloride or an endogenous Ca^{2+} channel modulator that was shown to block L- and T-type channels (Callewaert et al., Science 243:663, 1989). Veratridine also caused a concentration-dependent increase of ^{3}H-DA release (2×10^{-6}M veratridine elicited half maximal increase) that was tetrodotoxin sensitive, but was not inhibited by 10^{-5} M omega-conotoxin. Moreover, nifedipine, amiloride, or the endogenous Ca^{2+} channel modulator, failed to prevent the veratridine-stimulated ^{3}H-DA release. The present results show that ^{3}H-DA release elicited by K^+ involves the activation of the N-type Ca^{2+} channel while ^{3}H-DA release elicited by veratridine is independent of Ca^{2+} influx through voltage-gated Ca^{2+} channels.

456.16

ANTI-CALMODULIN AGENTS (ACA) AFFECT DEPOLARIZATION- AND CALCIUM IONOPHORE-INDUCED VASOPRESSIN (AVP) RELEASE BY AN ALTERNATIVE MECHANISM. N. F. Rossi. Dept. of Medicine, Wayne State Univ. School of Medicine, Detroit, MI 48201.

Calmodulin has been implicated in transducing the effects of calcium on synaptic transmission and hormone release, including osmotically-stimulated AVP release. If ACA block AVP release secondary to inhibition of calcium-calmodulin interactions, these drugs should inhibit AVP release to stimuli increasing calcium influx via different mechanisms. Hypothalamo-neurohypophysial complexes (HNC) in culture were exposed to 2µM ionomycin, 1µM Bay k 8644, or 75µM veratridine either alone; with an ACA (1µM TFP, 1µm W7, or 2µM R24571); or with calcium channel blocker (0.5µM D600). Ionomycin produced an 593±97% increase in AVP release compared with basal release ($p<0.001$, n=14). All the ACA significantly decreased the response to ionomycin (173±54%, 192±30%, 137±57% of basal AVP; n=7, 6, 8; $p<0.05$ vs ionomycin) while D600 did not. Bay k 8644 stimulated AVP to 499±74% of basal ($p<0.005$, n=8). None of the ACA inhibited this response, but D600 completely blocked it (66±17% of basal; n=6; $p<0.01$ vs Bay k 8644). Neither ACA nor D600 prevented the rise in AVP with veratridine (419±59% of basal; n=14; $p<0.001$ vs basal). These results are consistent with the hypothesis that ACA inhibit AVP release by membrane stabilizing effects rather than by antagonizing calcium-calmodulin in HNC. Depolarization initiated by sodium influx may stimulate sodium-calcium exchange independent of slow calcium channels.

MECHANISMS OF ANOXIA TOLERANCE IN THE TURTLE BRAIN. C.J Doll*, R.K. Suarez*, P.W. Hochachka* and P.B. Reiner (SPON: D. Schwarz). Depts. of Zoology and Psychiatry, Univ. of British Columbia, Vancouver, BC, Canada.

The brain of the turtle *Chrysemys picta* exhibits remarkable anoxia tolerance. One explanation for this phenomenon might be that turtles have low metabolic rates both during normoxia and anoxia, allowing glycolytic ATP production to satisfy neuronal energy requirements. Normoxic metabolic rate was measured using the [^{3}H] 2-deoxyglucose method *in vivo*. The turtle brain consumed 0.053 μM/g/min at 25°C, 1/12 the published glucose uptake rates for rat brain. Rat brain homogenates exhibited a 2-fold greater Na^+,K^+-ATPase activity on average as compared to the turtle brain at the same temperature. These data suggest that ion leakage and pumping in the normoxic turtle brain is less than that in the rat brain. To obtain a measure of ion leakage, intracellular recordings of cortical pyramidal neurons *in vitro* were performed during normoxia and anoxia. Time constants, which reflect the product of membrane resistance and capacitance, did not increase with anoxia, but were significantly greater in turtle than rat, suggesting lower normoxic ion fluxes in the turtle brain. In contrast to the results with time constants, apparent input resistance decreased with anoxia. Current efforts are directed towards determining whether increased synaptic activity is responsible for this change.

THE ROLE OF CALCIUM IN ANOXIC INJURY IN MAMMALIAN CENTRAL WHITE MATTER. P.K.Stys, B.R.Ransom,S.G.Waxman. Dept. of Neurology, Yale Univ., New Haven, CT 06510.

The effects of anoxia on the CNS have been extensively studied in gray matter, but much less is known about the consequences of oxygen deprivation in white matter. We have used the isolated rat optic nerve (RON), a typical central white matter tract, to study the pathophysiology of anoxic injury in mammalian white matter (Davis and Ransom,Soc.Neurosci.Abstr.,13:1634,1987). The area under the compound action potential, recorded with suction electrodes, was used as an indicator of functional integrity of the RON, allowing quantitative evaluation of recovery after anoxic insults and of the effects of various interventions. RONs from adult (50-70 days) animals were dissected free, placed in a perfusion chamber and subjected to a standard 60 minute period of anoxia in a N2/CO2 atmosphere. We confirmed previous findings of 20-30% recovery after anoxia (as judged by the area under the compound action potential) when the preparation was perfused with standard solution containing 2mM Ca2+; reduction of external Ca2+ to 0 mM greatly improved recovery (>80%). On the assumption that Ca2+ flux across the membrane is a critical factor responsible for irreversible anoxic injury, an attempt was made to interfere with its presumed entry through conventional channels. Pre-treatment with nifedipine (1-10μM), an organic Ca2+ channel blocker, did not significantly improve recovery. Likewise, divalent cations such as Co2+ (1-4 mM) and Zn2+ (0.1-1mM) were without benefit and, paradoxically, at the higher concentrations resulted in a complete and irreversible loss of activity after anoxia. However, high concentrations of Mg2+ (10mM) significantly improved recovery (mean 64%, $p<0.05$). We conclude that disordered regulation of Ca2+ homeostasis induced by anoxia plays a central role in producing irreversible dysfunction in the RON. Furthermore, redistribution of Ca2+ under these conditions may not utilize conventional channels, since known blocking agents conferred no increased resistance to anoxia.

VOLTAGE- AND LIGAND-GATED CURRENTS IN CULTURED OLFACTORY INTERNEURONS FROM AN INSECT BRAIN. J.H. Hayashi and J.G. Hildebrand. ARL Div. of Neurobiol., Univ. Arizona, Tucson, AZ 85721.

We are examining the voltage- and ligand-gated conductances of solitary neurons in primary cell cultures of dissociated neurons from antennal lobes (ALs -- the primary olfactory centers in the brain) of the moth *Manduca sexta* as part of our ongoing studies of mechanisms that underlie the central processing of olfactory information. There are two basic classes of neurons within the AL: local interneurons (LNs) and projection (output) neurons (PNs). In cultures derived from the medial group of AL neurons, consisting exclusively of PNs, we previously identified 6 different morphological types [*Soc Neurosci Abs* 14:380 (1988)]. We have now extended our analysis to cultures derived from the lateral group of AL neurons that consists of both PNs and LNs. Along with the previously reported PN cell types, we have found 3 new types of neurons in these culture. Cells of 2 of these new types clearly lack an axonal process. These neurons exhibit vigorous process outgrowth, but our patch-clamp studies have revealed that they fail to develop voltage-gated inward currents after 2 weeks *in vitro*. In contrast, all PNs develop inward currents after a comparable time in culture. We have also extended our analysis of PNs. A subset of PNs expresses tetrodotoxin-sensitive Na^+ channels. This current activates at about -40 mV and is associated with a delayed-rectifier type of K^+ channel. We also find slowly activating, slowly inactivating Ca^{++} channels that are blocked by Cd^{++}. "Whole-terminal" recordings have permitted accurate measurements of currents in the terminal region. Each type of PN displays a characteristic set of currents, and some exhibit an outward current in response to a puff of GABA solution applied externally. GABA is the putative neurotransmitter used by most of the LNs. [Supported by a grant from Monsanto Company and an NIH postdoctoral fellowship (to JHH), and in part by NIH grant AI-23253.]

The kinetics of M-currents (I_M) recorded in bullfrog sympathetic ganglion neurons. M.E.M. KELLY AND P.S. PENNEFATHER. Faculty of Pharmacy, University of Toronto, Toronto, Ontario, CANADA M5S 2S2.

In bullfrog sympathetic cells inhibition of a voltage-dependent K^+ current, I_M, by muscarinic agonists results in depolarization. I_M begins to activate at -60 mV and is fully activated at -20 mV, playing an important role in spike frequency adaption. The time dependence of I_M has been reported to be adequately accounted for by a two state kinetic model where the rates of channel opening and closing are voltage sensitive to an equal degree. (Adams et al., 1982, J. Physiol, 330, 537). That model predicts significant activation of I_M by individual action potentials. We have found, however, that brief action potential-like voltage-clamp commands activate much less I_M than predicted. We recorded I_M in acutely dissociated ganglion neurons using whole cell recording and discontinuous single electrode voltage-clamp. Under conditions where currents other than I_M were suppressed, I_M was defined as the difference between currents recorded in the presence and absence of muscarine. This allowed us to study I_M kinetics over a wide range of membrane potentials. We found significant delays in I_M activation lasting 4-10 ms depending on command potential. These delays are suggestive of multiple closed-states and ensure that I_M depends on mean membrane potential rather than action potential frequency.

MEMBRANE IONIC CURRENTS IN IDENTIFIED NEURONS OF A JELLYFISH. J. Przysiezniak and A. N. Spencer. Dept. of Zool., Univ. of Alberta, Edmonton, AB, CANADA, T6G 2E9 and Bamfield Marine Station, Bamfield, BC, CANADA, V0R 1B0.

Nervous systems first evolved in the Cnidaria. We have described several neuronal membrane ionic currents in a hydrozoan jellyfish, *Polyorchis penicillatus* to determine whether they differ substantially from those observed in 'higher' phyla and in Protozoa.

It is possible to isolate and culture a subset of large, identifiable motor neurons from *Polyorchis*. *In vitro*, 'whole-cell', current-clamp recordings show that these cells produce plateau action-potentials of variable duration, as they do *in vivo*. Voltage-clamp data have revealed that at least five distinct currents are at play. A large (~5nA), rapidly activating, transient, inward sodium current produces the upstroke of the action potential; this current is TTX-insensitive. A small (500pA), rapidly activating, transient (τ ~20ms) calcium current contributes to the rising phase, and together with a slow, sustained calcium current, underlies a slowly repolarizing plateau phase. A large (~3nA), sustained, potassium mediated, delayed rectifier contributes to spike repolarization. Spike repolarization is also effected by a large (~5nA) but transient (τ-off ~200ms), 'A-like' outward current which inactivates at depolarized voltages, thus regulating action-potential duration in a voltage-dependent manner.

It appears that the complement of membrane currents found in these primitive neurons resembles that seen in 'higher' phyla, and differs in quality, but not in diversity, from that observed in *Paramecium*.

456.23

VOLTAGE CLAMP ANALYSIS OF IONIC CONDUCTANCES IN TWO TYPES OF SENSORY NEURONS IN THE LEECH J. Johansen and A.L. Kleinhaus. Dept. of Zoology, Iowa State Univ., Ames, IA 50011 and Dept. of Neurology, Yale Univ. School of Medicine, New Haven, CT 06512.

With the ultimate goal of correlating the biological function of neurons with their biophysical properties we have begun a systematic analysis of the ionic conductances underlying excitation in the lateral nociceptive (N_l) and medial pressure (P_m) cells in the leech *Macrobdella*. The two cells differ in their functional sensory modalities and in their excitable properties. Using two electrode voltage clamp techniques we find that both N_l and P_m possess an I_{Na}, I_K, and I_{Ca}. The peak Na-conductance is for voltage steps from resting membrane potential (-40 mV) to 10 mV. At this membrane potential at 10 °C I_{Na} activates with a time constant of 1.6 ms and inactivates with a time constant of 9 ms. The kinetics of I_{Na} is best described by a Hodgkin-Huxley equation of the form $I_{Na}=g_{Na}m^4h$. The delayed rectifier current (I_K) activates with time constants of from 6 to 15 ms at 22 °C in response to membrane steps to between -15 mV and 15 mV. This current was sensitive to TEA. I_{Ca} does not inactivate appreciably during long voltage steps (>500 ms). The kinetic properties of these conductances were similar in both cell types. However, in addition to these currents N_l possesses an I_A-current with rapid activation and inactivation characteristics. In contrast, we have not yet been able to identify an I_A-current in the P_m cell suggesting a possible mechanism for the differences in the two cells' excitability. This possibility and a further characterization of the two cells' conductances are currently being investigated.

WHOLE CELL PATCH CLAMP RECORDINGS OF VOLTAGE-DEPENDENT CURRENTS IN THIN MEDULLA SLICE INCLUDING IDENTIFIED TRIGEMINOTHALAMIC NEURONS. L.Chen and L.-Y.M. Huang. Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77550.

In order to characterize the synaptic transmission to the trigeminothalamic neurons, we examined the electrical properties of neurons in caudal spinal trigeminal nucleus. Trigeminothalamic neurons were labeled with retrograde neuronal marker fluorescent latex microspheres. Thin slices were prepared from the lower medulla of the injected rats using the method described by Edwards, Konnerth, Sakmann & Takahashi (Pflugers Archiv, in press). The surface of the recording cells was blown clean with buffer, and whole cell recordings were then performed. Under voltage clamp conditions, both inward and outward currents were activated when a series of depolarizing pulses ranging from -60 to +150 mV were applied to the cell. Inward currents were examined by replacing K^+ with Cs^+ or N-methyl-D-glutamine intracellularly, and by treating cells with tetraethylammonium (TEA) and 4-aminopyridine. Most inward current could be eliminated by low concentration of tetrodotoxin (TTX). Na^+ was the principal ion carrier of the inward current. In the presence of 1 μM TTX and 5-10 mM Ca, slow inward current was observed. This current was sensitive to external Ca concentration and was abolished by Co^{++}. Voltage-dependent outward currents were carried by K^+ and were blockable by TEA. The voltage properties of these currents were similar to those observed in isolated dorsal horn projection neurons (J. Physiol. 411:161-177, 1989). Supported by NS23061 and NS01050.

EXPRESSION OF AMINO ACID TASTE RECEPTORS IN *XENOPUS* OOCYTES.
T.V.Getchell, M.Grillo*, S.Tate*, R.Urade*, J.Teeter and F.L.Margolis
Roche Inst. Molec Biol., Nutley, N.J.07110 and Monell Center, Phila. PA 19104

We report the first *in vitro* demonstration of functional expression of vertebrate taste receptor molecules. Isolation, characterization and cloning of the molecules responsible for the primary binding event in vertebrate chemoreception is dependent on functional *in vitro* assays encompassing the full range of transductive events from the initial ligand binding through changes in gated membrane conductances. Expression in the *Xenopus* oocyte has been used to identify, functionally characterize and clone receptors for many bioactive compounds. Getchell (1988) reported that *Xenopus* oocytes microinjected with rat olfactory RNA express functional olfactory receptor molecules as monitored electrophysiologically. We now show the ability of *Xenopus* oocytes microinjected with catfish barbel mRNA to express functional amino acid taste receptors. Electrophysiological recordings from these injected oocytes demonstrate the expression of amino acid specific conductance changes analogous to those in intact catfish. Injected oocytes manifest distinct and reproducible time-conductance profiles following stimulation with L-arginine or L-alanine both of which are taste stimuli in catfish. The responses exhibit molecular specificity, reproducibility, rapid onset and short duration. Repetitive stimulation at short intervals or prolonged stimulation results in adaptation that is reversible with full return of response capabilities. Use of brief pulses of the stimulus ligand prevented receptor desensitization enabling us to demonstrate the expression of taste receptors in *Xenopus* oocytes. This defined *in vitro* system permits physiological, biochemical and molecular biological studies of taste receptors. NIH-NS16340&F33NS08486(TVG).

COMPARISON OF ENDOGENOUS AND EXOGENOUS EXPRESSION OF ELECTRICAL COUPLING IN PAIRED XENOPUS OOCYTES.
L.C. Barrio*, J.C. Saez*, C. Samathanam*, R.S. Zukin and M.V.L. Bennett. Dept. Neurosci., A. Einstein Coll. Med., Bronx, NY 10461.

Xenopus oocytes (stage VI) were defolliculated and injected with rat brain, hippocampal or liver poly $(A)^+$ RNA or with water. After 1-3 days (to allow for protein synthesis) vitelline membranes were removed and pairs of cells placed in contact. One or more days later junctional conductance (g_j) at low transjunctional voltages (g_{max}) and voltage dependence of g_j were measured by dual voltage clamp. In water-injected (control) oocytes g_{max} ranged from <0.01 μs to 7.5 μs (n >30). In mRNA-injected oocytes g_{max} was as large as 12.5 μs but overlapped with values for control oocytes. Pairs injected with brain mRNA showed punctate immunoreactivity between them to a connexin 43 antibody, perhaps from expression of astrocyte mRNA. Cycloheximide (50 μg/ml) (but not actinomycin) prevented coupling of control oocytes. Thus, post pairing translation contributed to endogenous coupling. Junctions between most oocytes were voltage dependent. In almost all control oocytes the degree of voltage dependence was less than in amphibian blastomeres. Since transcription should be minimal in the period between oocyte maturation and gastrulation, the endogenous mRNA may selectively express a different connexin than do blastomeres, or there may be posttranslational modification that reduces voltage dependence. In liver-injected pairs voltage dependence must have arisen in channels with low sensitivity like those observed in hepatocytes. In brain-injected pairs voltage dependence could be accounted for by voltage dependent endogenous channels and voltage independent exogenous channels in parallel. Some junctions rectified, and in pairs injected with brain mRNA in only one cell, conductance decreased with the endogenous side positive as predicted from previous work. The data indicate that endogenous and exogenous expression occur and may interact.

FLUORESCENCE RECORDING OF ACTION POTENTIALS USING A SINGLE OPTICAL FIBER CARRYING EXCITATION AND FLUORESCENT LIGHT. V Krauthamer*, TA Bowmaster*, CC Davis*, and HJ Bryant, FDA Center for Devices and Radiological Health, Rockville, MD 20857, and USUHS, Dept. of Physiology, Bethesda, MD 20814.

Fluorescent dyes have been used previously to record voltage changes in a variety of preparations. Existing systems generally use separate optical paths for excitation and detection of the fluorescent signal or employ a microscope objective or other large lens system near the preparation which limits their use in confined areas. We used a single optical fiber to both excite and detect voltage-sensitive fluorescence signals from frog myocardium stained with WW781. Light from a He-Ne laser, after passing through a neutral density filter and a beam splitter, was coupled to an optical fiber with an inner light-carrying core diameter of 4, 50, or 100 μ. The various fibers used had outside diameters of 120 μ due to optical cladding. The longer-wavelength fluorescent light from the preparation was collected by the same fiber and reflected, through a blocking filter, into either a photomultiplier tube or a photodiode. Frog hearts, maintained in a 0 Ca^{++} solution to prevent movement artifacts, produced a fractional change in fluorescence of ~10^{-3} during the myocardial action potential. Large-core fibers yielded quieter signals, which allowed for reduced excitation light intensity with less dye bleaching, but at the expense of the higher spatial resolution obtained with the single mode 4 μ fiber.

SELECTIVE ACTIVATION OF Ca++ ENTRANCE THROUGH VOLTAGE-OPERATED CHANNELS OR THROUGH THE Na+-Ca++ ANTIPORTER IN RAT BRAIN SYNAPTOSOMES: METHODOLOGICAL AND PHARMACOLOGICAL INDICATIONS. M.Taglialatela*, L.Canzoniero*, A.Fatatis*, S.Amoroso*, G.F.Di Renzo* and L.Annunziato§. Ist. Pharmacology, 2nd Sc.Med., University of Naples,Via Pansini 5,80131 Naples,and Univ.of Chieti(§),Italy.

Ca++ entrance in nerve cells can also occur either through Voltage-Operated Ca++ Channels (VOCCs) or through the membrane Na+-Ca++ antiporter, which couples the bi-directional transport of Ca++ ions to that of Na+ ions in the opposite direction. The aim of the present study was to identify the appropriate conditions which selectively activate only one of the two pathways mediating 45Ca++influx in rat brain synaptosomes. Increasing extracellular concentrations of K+ ions caused: 1.a progressive depolarization of the synaptosomal membrane (5-70mM K+ ions), estimated by the potential-sensitive fluorescent dye bisoxonol, 2.a dose-dependent increase in 45Ca++ uptake, 3. a rapid and dose-dependent (10-30 mM extracellular K+ ions) increase in cytosolic Ca++levels monitored by FURA-2.45Ca++ uptake elicited by concentrations of K^+ ions up to 55 mM seems to occur selectively through VOCCs, since an equimolar concentration of choline,in presence of the same extracellular Na+ concentration (95 mM), failed to stimulate 45Ca++ uptake.A further decrease of extracellular Na+ concentrations from 95 mM to 0 (145 mM choline substitution),dose-dependently increased 45Ca++ uptake via the Na+-Ca++ antiporter,without any concomitant activation of VOCCs, since, under these conditions, membrane potential did not show any tendency to depolarization.Furthermore,the amiloride analogue 2',4'-dimethylbenzamil amiloride(2',4'-DMB,10-300 uM),a selective inhibitor of the Na+-Ca++ exchanger,inhibited 45Ca++ uptake elicited by extracellular Na+ ions removal, whereas it did not interfere with 55 mM K+-induced 45Ca++ uptake in purified synaptosomes.

CYTOSOLIC Ca++ LEVELS AND MEMBRANE POTENTIAL MONITORING IN BRAIN SYNAPTOSOMES: EFFECT OF MARINE TOXINS WITH AGONISTIC AND ANTAGONISTIC PROPERTIES ON Ca++ CHANNELS. L.Canzoniero*,M.Taglialatela*,A.Fatatis*,S.Amoroso*,G.F.Di Renzo* and L.Annunziato§ (SPON: A.Volterra). Ist.Pharmacology, 2nd Sc.Med., Univ.Naples, Via Pansini 5, 80131 Naples, and Univ.Chieti(§), Italy.

Toxins that act on ion channels have proven to be invaluable tools in the biochemical and functional characterization of these membrane proteins. The aim of the present study was to clarify the effects of maitotoxin (MTX), a marine toxin which has recently gained attention as a putative Ca++ channel activator, on cytosolic Ca++ levels and membrane potential variations in purified rat brain synaptosomes. MTX (3-25 ng/ml), dose-dependently enhanced cytosolic Ca++ levels, monitored with the Ca++-sensitive fluorescent dye FURA-2. This effect was prevented when Ca++ ions (plus 1 mM EGTA) were omitted from the extracellular medium. Furthermore, omega-conotoxin (wCTX), the recently described presynaptic neurotoxin provided with antagonistic properties on Ca++ channels,was unable (1-10 uM) to prevent the increase of cytosolic Ca++ levels induced by MTX.On the other hand,MTX (10 ng/ml) caused an intense depolarization of the synaptosomal membrane, estimated by means of the potential-sensitive fluorescent dye bisoxonol. This increase in membrane depolarization was unaffected by tetrodotoxin (TTX, 10 uM), and only slightly prevented by the replacement of extracellular Na+ions with an equimolar concentration of choline. By contrast, when sucrose replaced isoosmotically monovalent cations, MTX was unable to induce any change in the synaptosomal membrane potential.
Collectively, these results appear to suggest that MTX-induced stimulation of extracellular Ca++ influx can occur as a consequence of the depolarizing effect exerted by the marine toxin on the synaptosomal membrane.

457.3

INFLUENCE OF PERTUSSIS TOXIN PRETREATMENT ON DIHYDROPIRIDINE MODIFICATION OF K^+ AND MAITOTOXIN INDUCED INTRACELLULAR CALCIUM RISE IN PC12 CELLS. G.Schettini, O.Meucci*, M.Grimaldi* T.Florio*, E.Landolfi*, A.Scorziello*, C.Ventra* and A. Marino*. Inst. of Pharmacology, II School of Medicine Univ. of Naples, Via S.Pansini 5, 80131 Naples ITALY(SPON:U.DiPorzio)

Here we report the result of pertussis toxin (PTX) pretreatment on dihydropiridine inhibition of free intracellular Ca^{++}increase induced by both K^+depolarization and maitotoxin (MTX), a marine toxin known to increase cytosolic Ca^{++} levels, in PC12 cells. Nicardipine (Nic) 100 nM reduced K^+ induced Ca^{++}rise to 25%, while a complete inhibition of K^+ effect was obtained for Nic micromolar concentrations. Nic (from 10nM to 1uM) dose-dependently inhibited MTX-induced Ca^{++}increase with a maximal inhibiton (-87%) for Nic 1uM. Furthermore, the dihydropiridine derivative Bay K 8644 enhanced K^+evoked Ca^{++}rise in a dose dependent manner,an effect antagonized by equimolar concentrations of Nic. Finally pretreatment with PTX partially but significantly reverted Nic inhibition of MTX stimulation for all Nic concentrations tested (-58% in PTX vs.-87% in control, for Nic 1uM). PTX did not seem to affect Nic inhibition of K^+evoked Ca^{++}flux. Thus a PTX-sensitive G-protein seems to modulate Nic-MTX interaction in PC12 cells, without affecting Nic inhibition of K^+induced Ca^{++}rise.

FORSKOLIN AND 8-BROMO-cAMP ACT SIMILIARLY IN ENHANCING Ca^{++} CURRENTS IN BOVINE CHROMAFFIN CELLS. C.A Doupnik* and R.Y.K. Pun, Dept. of Physiology & Biophysics, University of Cincinnati, Cincinnati, OH 45267.

Recently, the modulation of ionic channels by forskolin has been suggested to be through a mechanism other than elevation of cytosolic cAMP. (Hoshi, T., et. al. Science 240:1652, 1988). To test whether forskolin affects voltage-dependent Ca^{++} currents in cultured bovine chromaffin cells via a cAMP-dependent mechanism, we compared the effects of forskolin with the cAMP analog 8-bromo-cAMP. Using the whole-cell voltage clamp technique, Ca^{++} currents were evoked by applying varying positive step pulses from a holding potential of -90 mV in the presence of 5 mM extracellular Ca^{++}. For each cell, a current-voltage (I-V) relation was determined before (control) and during local perfusion with forskolin (10 μM) or 8-bromo-cAMP (1 mM). Both compounds similiarly enhanced the peak currents; forskolin by 32 $\pm$ 5% (n=3) and 8-bromo-cAMP by 46 $\pm$ 17% (n=3). Neither compound however, significantly altered the voltage activation range. Half activation for the peak conductance occurred at -3 mV for control, -3 mV for forskolin, and -5 mV for 8-bromo-cAMP. In addition, using a single exponential sum of the least squares fit of the peak current decay, no significant differences were found between the calculated tau's of either compound. These preliminary results suggest that in chromaffin cells, forskolin acts via a cAMP-dependent mechanism and that Ca^{++} channel conductance is enhanced presumably via A-kinase phosphorylation of the Ca^{++} channel itself or an associated regulatory protein. Supported by NSF Grant DCB8812562.

DIFFERENTIAL EFFECTS OF ANTICONVULSANT AND CONVULSANT SUCCINIMIDES ON CALCIUM CURRENTS AND GABA RESPONSES OF THALAMIC NEURONS. D.A. Coulter, J.R. Huguenard, and D.A. Prince, Dept. Neurology, Stanford University Medical Center, Stanford, CA 94305.

We have previously reported that the petit mal anticonvulsants ethosuximide (ES) and dimethadione reduce the low-threshold, transient ("T") calcium current of thalamic neurons when applied in clinically relevant concentration ranges. This effect, coupled with the importance of the thalamic T current in thalamocortical oscillatory behavior (like the spike-wave discharges of petit mal), led us to hypothesize that the T current reducing action of these agents might be a mechanism mediating control of petit mal.

We analyzed the effects of the anticonvulsant succinimides ethosuximide (ES) and methylphenylsuccinimide (MPS) and the convulsant tetramethylsuccinimide (TMS) on calcium currents and GABA responses of acutely isolated rat thalamic neurons using voltage-clamp techniques. Thalamic neurons have at least two components of calcium current: a prominent T current, and a high-threshold, sustained ("L") current. MPS and ES reduced T current in a voltage-dependent manner, in clinically relevant concentrations. MPS was less potent than ES (IC_{50} of 1100 vs. 200 μM) but greater in efficacy (100% maximal reduction vs. 40% for ES). MPS was less specific than was ES, in that it also reduced the L current when applied in concentrations $\geq$ 500 μM. TMS had no effect on calcium currents except at very high concentrations, and did not occlude MPS effects when applied concurrently. TMS blocked GABA responses in a concentration-dependent manner, presumably accounting for the convulsant action of this drug. ES, in significantly higher concentrations, reduced GABA responses to a lesser degree, and occluded TMS block of GABA currents. This partial agonist action of ES on GABA responses may explain the ES anticonvulsant effect on chemically-induced seizures, but appears independent of the T current blocking actions of ES.

The finding that MPS, but not TMS, blocks T current provides additional support for the hypothesis that T current reduction is a cellular mechanism of anticonvulsant succinimides related to their effects in petit mal epilepsy. Supported by NIH Grants NS06477, NS12151, and NS07280.

COMPARISON BETWEEN THE ACTIONS OF ENDOTHELIN AND VASOPRESSIN IN PITHED RATS AFTER PRETREATMENT WITH BAY K 8644, NIFEDIPINE OR PERTUSSIS TOXIN. R. Tabrizchi* and C.R. Triggle. Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland

The pressor actions of endothelin 3 (ET) and arginine vasopressin (AVP) were compared to one another in pithed rats in the presence of the calcium channel activator BAY K 8644 or the calcium channel antagonist nifedipine i.a. and also after pretreatment (-3 days) with pertussis toxin i.v. Administration of BAY K 8644 increased the diastolic pressure (DP) and nifedipine caused a decrease in DP. DP pressure recorded in pertussis toxin treated animals was significantly lower than saline treated animals. Both ET and AVP dose-dependently increased DP. The actions of ET but not AVP were potentiated in the presence of BAY K 8644, furthermore nifedipine significantly impaired responses induced by ET but not those produced by AVP. Treatment with pertussis toxin caused the dose-diastolic pressure response curve to ET to be displaced to the right whereas the dose-diastolic pressure response to AVP was not affected by treatment with pertussis toxin. These results suggest that extracellular calcium is partly responsible for the pressor response induced by ET, whereas the response to AVP appears to depend upon activation of an intracellular source of calcium. Furthermore it can be suggested that in vascular smooth muscle ET activates a pertussis toxin-sensitive G-Protein, whereas responses induced by AVP do not appear to be mediated through a G-Protein that is sensitive to pertussis toxin. EFFECTS OF MEMBRANE POLYUNSATURATED FATTY ACIDS ON $^{45}Ca^{++}$ UPTAKE INTO N1E-115 NEUROBLASTOMA CELLS. J. Gupta*, Z. Byczko*, and M.G. Murphy. Dept. of Physiology and Biophysics, Dalhousie University, Halifax, Nova Scotia, CANADA B3H 4H7

We have examined the effects of increasing the membrane content of w6 polyunsaturated fatty acids (PUFA) of neuroblastoma cells (clone N1E-115) on $^{45}Ca^{++}$ uptake under basal conditions, and in the presence of A23187 or bradykinin. Addition of $^{45}Ca^{++}$ (1μci/ml) to the culture dishes, following a 15 minute preincubation in medium containing 1.8 mM Ca^{++}, resulted in a biphasic uptake of $^{45}Ca^{++}$. Initially, there was an increase in Ca^{++} influx which reached a peak between 20 - 30 seconds. This was followed by a second phase of increase which was almost linear up to 5 minutes. Neither the magnitude nor the time course of uptake were altered in PUFA-enriched cells. A time dependent increase in $^{45}Ca^{++}$ uptake was seen in the presence of A23187. Exposure of cells to varying concentrations of bradykinin (10^{-5}M - 10^{-8}M) for different time periods did not have any effect on Ca^{++} uptake. PUFA-enriched cells did not exhibit altered $^{45}Ca^{++}$ uptake in the presence of A23187 or bradykinin.

G PROTEIN-MEDIATED FMRF-AMIDERGIC MODULATION OF A CALCIUM CURRENT IN GIANT SYNAPSE. H.J. Man-Son-Hing and P.G. Haydon. Department of Zoology, Iowa State University, Ames, IA 50011.

The neuropeptide, Phe-Met-Arg-Phe-NH_2 (FMRFa) decreases the magnitude of a voltage-dependent calcium current and causes a presynaptic inhibition of transmitter release from cholinergic neuron B5 of *Helisoma* (Zoran et al., Neurosci. Abst. 1989; Haydon et al., Neurosci. Abst. 1989). In this study, we demonstrate that a G protein mediates FMRFa's action on the calcium current.

Various agents were included in the internal solution in the patch pipette during whole-cell recording from secretory somata. Four lines of evidence demonstrate G protein involvement in FMRFa's signal transduction pathway. 1) In the presence of either GTPγS (100μM; n=8) or GMP-P(NH)P (100μM; n= 5), FMRFa caused an irreversible decrease in the calcium current. 2) GDPβS (500μM; n=4) prevented FMRFa's action . 3) AlF_4 caused a rapid decline in the magnitude of the calcium current in the absence of FMRFa (n=8) and subsequent FMRFa application had no effect on the calcium current. 4) Addition of pertussis toxin prevented FMRFa's inhibition of the calcium current (n=6). These data demonstrate that a pertussis toxin-sensitive G protein is involved in mediating the inhibition of a calcium current by FMRF-amide.

DEPHOSPHORYLATION OF VOLTAGE-DEPENDENT CALCIUM CHANNEL BY PURIFIED PROTEIN PHOSPHATASES. Y. Lai* and W.A. Catterall (SPON: B.M. Curtis). Department of Pharmacology, University of Washington, Seattle, WA 98195.

The Ca currents mediated by L-type voltage-dependent calcium channels (CaCh) have been shown to be modulated by protein phosphorylation in a variety of cells. The CaCh purified from skeletal muscle contains five specifically associated subunits. Two of the subunits, α_1 with M_r = 170,000 and β with M_r = 55,000, are phosphorylated by cAMP-dependent protein kinase. Stoichiometric phosphorylation of these subunits activates purified CaCh reconstituted in phospholipid vesicles (Nunoki et al., *Proc. Natl. Acad. Sci. USA*, in press). Because of the importance of regulation of channel function by protein phosphorylation, we have studied the dephosphorylation of Ca channel by purified protein phosphatases.

Purified CaCh was first phosphorylated by cAMP-dependent protein kinase and then incubated with purified protein phosphatase 1 (PP1), protein phosphatase 2A (PP2A), or calcineurin (CN). PP1 and PP2A dephosphorylated both α_1 and β subunits at rates comparable to those for the dephosphorylation of phosphorylase a, a physiological substrate of both protein phosphatases. Similar results were obtained when CaCh reconstituted in phospholipid vesicles or CaCh in skeletal muscle transverse tubules were used as substrates. Recent results suggest that CN dephosphorylates β subunits of CaCh more rapidly than α_1 subunits, but both rates are slower than those of PP1 and PP2A. We are currently examining the sites on α_1 and β subunits that are dephosphorylated by the different protein phosphatases.

SEROTONIN DECREASES WHOLE CELL CALCIUM CURRENT IN ACUTELY ISOLATED NEURONES FROM DORSAL RAPHE NUCLEUS OF ADULT RATS N.J. Penington* and J.S. Kelly. Dept. of Pharmacology, Univ. of Edinburgh, Med.Sch., Edinburgh EH8 9JZ, U.K.

In peripheral and cultured central neurones and cell lines, voltage sensitive calcium currents ($I_{Ca}2+$) have been shown to be decreased or occasionally increased by several neurotransmitters and neuropeptides. Consequently, it is interesting to report that low concentrations of 5-HT and 8-OH-DPAT reduce $I_{Ca}2+$ in an isolated adult central neurone. 36 raphe neurones were voltage clamped and currents carried by Ca^{2+} (2mM) or Ba^{2+} (5mM) were isolated by blocking K^+ currents with external TEA and internal Cs^+. Cells were usually held at -100mV and stepped close to 0mV. 5-HT (10nM-200μM) was applied to 22 cells with a pipette (15μm tip). 10μM 5-HT reduced peak $I_{Ca}2+$ reversibly by up to 60% (n=8) with the largest effect occurring at the peak of the I/V relationship. Application of control solution had no comparable effect and 8-OH-DPAT (10-1000nM) the selective 5-HT_{1A} agonist had the same action as 5-HT (n=4). At the peak of the I/V relationship 5-HT caused in most cells a selective inhibition of a decaying component of $I_{Ca}2+$ (inactivated at a h.p. of -50mV (N-like)). In others, 5-HT caused a marked slowing of $I_{Ca}2+$ activation. This implies that 5-HT may alter the proportion of channels inactivated by current or voltage and hence the number capable of opening near the peak of the I/V relationship. Supported by the Wellcome Trust.

LHRH AND GTP-γ-S MODIFY CALCIUM CURRENTS OF ISOLATED FROG SYMPATHETIC NEURONS. Keith S. Elmslie, Wei Zhou*, and Stephen W. Jones. Dept. Physiology & Biophysics, Case Western Reserve U., Cleveland, OH 44106.

Chicken II luteinizing-hormone releasing hormone (LHRH) reduces whole-cell calcium current in frog sympathetic neurons, but only partially (~50%), and the remaining current activates more slowly. Similar results have often been interpreted as selective inhibition of a rapidly inactivating calcium channel. We suggest instead that the kinetics of a single type of current are modified, since (1) the kinetics become *more* complex in LHRH, not *less*, as activation is fit by the sum of two exponential processes rather than one, and (2) strong depolarizing prepulses largely reverse the effects (see Figure). One possibility is that, at negative membrane potentials, LHRH shifts a fraction of the channels into a state from which opening is delayed. Similar kinetics can be achieved by internal dialysis with GTP-γ-S.

Figure: Effect of 100 nM LHRH on whole-cell current (2mM Ba^{2+}). Note the slow kinetics and rapidly desensitizing response.

CONCENTRATION-DEPENDENT EFFECTS OF METHIONINE-ENKEPHALIN ON $[Ca^{2+}]_i$ OF ENTERIC NEURONS; INVESTIGATIONS WITH FURA-2. K.Hirai* and Y.Katayama, Dept. Autonom. Physiol., Med. Res. Inst., Tokyo Med. and Dent. Univ., Tokyo, 101 JAPAN.

Fura-2 measurement of $[Ca^{2+}]_i$ was made simultaneously with intracellular recordings from single neurons. Submucous plexus preparations were made from the isolated caecum of the adult guinea-pig sacrificed by heavy stunning and bleeding from the neck.

Action potentials elicited a transient increase in the $[Ca^{2+}]_i$ ($\Delta[Ca^{2+}]_{AP}$). Low concentration of met-enkephalin (ME, 1-30 nM) induced a small membrane hyperpolarization, a $[Ca^{2+}]_i$-increase and a $\Delta[Ca^{2+}]_{AP}$-augmentation. ME at 100 - 300 nM hyperpolarized the membrane, decreased the $[Ca^{2+}]_i$ and attenuated the $\Delta[Ca^{2+}]_{AP}$. When the hyperpolarization was nullified, the $[Ca^{2+}]_i$ increased and the attenuation of the $\Delta[Ca^{2+}]_{AP}$ was abolished. ME more than 1 μM irreversibly depressed the $\Delta[Ca^{2+}]_{AP}$. The concentration-dependent effects of ME on the $\Delta[Ca^{2+}]_{AP}$ may explain the findings that ME facilitates the sympathetic ganglionic transmission at low doses but inhibits it at high doses.

457.13

ENHANCEMENT OF RAT BRAIN CALCIUM CHANNEL ACTIVITY IN XENOPUS OOCYTES BY A PROTEIN KINASE C ACTIVATOR. Bradford P. Schmidt* and John P. Leonard(SPON: C.J. Siok) Department of Biological Sciences. University of Illinois at Chicago, Chicago, Illinois 60680

Xenopus oocytes were used as expression vectors for calcium channels encoded by exogenous rat brain RNA. Endogenous Ca channel activity in oocytes ranges from undetectable up to 50 nA while brain RNA-injected oocytes contain Ca channels exhibiting different properties with currents ranging from 200 to 1000 nA. The effect of 100 nM phorbol ester dibutyrate (PDBu), a C-kinase activator, on both endogenous and RNA-induced Ca channels was investigated. Oocytes were injected with RNA purified from the brains of two-week old rats. Currents through voltage-sensitive Ca channels were observed using two-electrode voltage-clamp. Barium was used in place of Ca since Ba often permeates Ca channels better than Ca and because Ba is a poor activator of an interfering Ca-dependent Cl current. To rule out any interference of the Cl current and possible effects on Na-dependent exchangers, experiments were done both in the presence and absence of Cl_o and/or Na_o. Controls consisted of application of the inactive stereoisomer 4-α-phorbol. Ba currents were enhanced to 142% and 137% of control currents for brain RNA-injected and non-injected oocytes, respectively. No change in the voltage dependence of activation or voltage of maximal activation was observed. (Supported by NIH NS26432)

PROSTAGLANDIN E_2 INHIBITS A CALCIUM CURRENT IN ADULT RAT SUPERIOR CERIVCAL GANGLION (SCG) NEURONS. S.R. Ikeda. Department of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912.

Prostaglandins (PG) have been demonstrated to be important modulators of autonomic neurotransmission (reviewed by Brody, J. and Kadowitz, P.J., *Fed. Proc.* **33**:48-60, 1974). Prostaglandins of the E series: 1) are released during autonomic nerve stimulation, 2) decrease norepinephrine release, and 3) modify sympathetic neuron electrical excitability. In this study, the effect of PGE_2 on the voltage-activated Ca^{2+} current of rat SCG neurons was investigated.

SCG neurons were acutely isolated from adult rats by enzymatic dispersion. Ca^{2+} currents were recorded using the whole-cell variant of the patch-clamp technique in solutions designed to isolated Ca^{2+} currents. Ca^{2+} currents were evoked from a holding potential of -80 mV by depolarizing command steps. Under these conditions, introduction of 0.1-1.0 μM PGE_2 produced a rapid and reversible inhibition of the Ca^{2+} current. Mean inhibition of current was 41±3 and 54±2%, respectively for 0.1 and 1.0 μM PGE_2 (measured isochronally 10 msec after a command to +10 mV). Maximal block was produced at the peak of the current/voltage curve (+10 to +15 mV). In addition, PGE_2 produced an apparent slowing of the rising phase of the current at potentials positive to +10 mV. If similar events occur at adrenergic nerve terminals, these results may explain the presynaptic inhibitory action of PGE_2. (Supported in part by a grant from the Pharmaceutical Manufactures Association Foundation)

Adenine and Guanine Nucleotides Reduce Voltage-Dependent Calcium Current in Isolated Rat Purkinje Neurons. P. Hockberger[1], L. Yousif,*[1] and S. Christakos.*[2] [1]Dept. of Physiology, Northwestern University Medical School , Chicago, IL 60611 and [2]Dept. of Biochemistry , New Jersey Medical School, Newark, NJ 07103.

Calcium currents were analyzed in cerebellar Purkinje cell bodies (PCs) acutely isolated from rats between postnatal days 7-13 following papain digestion (cf. Regan, L. Soc. Neurosci. Abstr. #31.7, 1987). Isolated PCs were identified using immunocytochemical staining for the PC-specific antigens PEP-19 and calbindin (1:2000 and 1:20,000 antibody dilution, respectively). Whole-cell recordings were performed as described elsewhere (Hockberger, P., Toselli, M., Swandulla, D. and Lux, H.D., Nature 338:340, 1989). High threshold (L-type) calcium currents were recorded from all cells examined at this stage of development (n=64). Low threshold (T-type) calcium currents were present in 28% of the cells (n=18). Extracellular application of 10^{-3}M 8-bromo-cGMP via a micropipet reduced the L-type current by 20-60% (n=27). Applications lasting several seconds resulted in reductions that recovered completely within 10 -20 sec, and this could be repeated several times without affecting the speed of recovery. Similar effects were induced by 10^{-3}M 8-bromo-cAMP, while weaker responses (10-20% decreases) were obtained with cGMP, 5'GMP, 5'AMP (10^{-3}M ea.), or IBMX (10^{-4}M). The adenosine analogue 2-chloroadenosine (10^{-4}M) was ineffective. Including 8-bromo-cGMP in the internal saline, or delivering it intracellularly through a second patch pipet, was also ineffective. These results suggest that PCs may have external nucleotide receptors that are coupled to L-type calcium channels.

This research is supported by NIH grants nos. NS-26915 & RR-05370 (PH), and NS-20270 (SC).

COUPLING OF NEUROTRANSMITTER RECEPTORS TO Ca^{2+} CHANNELS IN DORSAL ROOT GANGLION NEURONS USING PURIFIED RECOMBINANT G-PROTEINS. Maurine Linder†*, Alfred G. Gilman†*, Douglas A. Ewald and Richard J. Miller, Department of Pharmacology, University of Texas, Dallas† and Department of Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637.

We measured the effects of the neuropeptides bradykinin (BK) and neuropeptide Y (NPY) on Ca^{2+} currents (I_{Ca}) in rat dorsal root ganglion (DRG) neurons in vitro using the whole cell voltage clamp technique. In control neurons both of these peptides inhibited the I_{Ca} by about 60%. When cells were treated with pertussis toxin the inhibitory effects of both NPY and BK were completely abolished. We examined the role of G-proteins in the coupling of receptors to Ca^{2+} channels in these cells by using purified recombinant (r) G-protein α-subunits expressed in E. coli. We attempted to reconstitute receptor mediated inhibition of the I_{Ca} in pertussis toxin treated neurons using $r\alpha_o$, $r\alpha_{i1}$, $r\alpha_{i2}$ or $r\alpha_{i3}$ introduced into cells with a patch pipette. When any of these proteins were perfused into neurons (100nM), the BK induced inhibition of the I_{Ca} returned in a time dependent fashion. In contrast there was a considerable selectivity in the ability of the proteins to reconstitute inhibition produced by NPY. $r\alpha_o$ was the most potent followed by $r\alpha_{i1}$ and $r\alpha_{i3}$. However $r\alpha_{i2}$ was unable to couple NPY receptors to DRG Ca^{2+} channels. The effects of $r\alpha_o$ were manifest between 10 and 100 nM with an EC_{50} of about 30 nM. High concentrations of $r\alpha_{i1}$, $r\alpha_{i2}$, $r\alpha_{i3}$ or $r\alpha_o$ did not inhibit forskolin-stimulated adenylate cyclase purified from bovine brain suggesting that hormonal inhibition of adenylate cyclase is not directly mediated by an α_i/cyclase interaction. Furthermore the coupling effects observed with recombinant proteins confirm ($r\alpha_o$, $r\alpha_{i1}$, $r\alpha_{i2}$) and extend ($r\alpha_{i3}$) our previous studies on the selectivity of BK and NPY receptor coupling to Ca^{2+} channels (Neuron, 2, 1185, 1989).

MODULATION OF SYNAPTOSOMAL CALCIUM FLUX BY ARGININE VASOPRESSIN. M.L. Koenig, M.A. Oleshansky, and G.S. Dhillon, and M.A. Jackson*. Dept. Medical Neurosciences, Walter Reed Army Institute of Research, Washington DC 20307.

The neurohypophysial hormone arginine vasopressin (AVP) has been shown to have Ca^{2+}-mobilizing properties and to affect certain CNS processes including those involved in learning and memory. We have investigated the possibility that AVP can modulate Ca^{2+} influx in synaptosomes prepared from rat cortex and striatum.

$^{45}Ca^{2+}$ influx was measured in crude (P2) synaptosomal fractions which had been preincubated with AVP at 30°C for 10 min. AVP (1 μM) increased the net depolarization-dependent influx of $^{45}Ca^{2+}$ into cortical synaptosomes by 20% (1.87 + 0.09 vs 1.56 + 0.12 nmol/mg protein) when influx was terminated after a 1 sec exposure to radiolabelled Ca^{2+}. The peptide had no effect on net $^{45}Ca^{2+}$ influx measured at 15 sec. $^{45}Ca^{2+}$ influx in striatal synaptosomes was not affected by AVP at either 1 sec or 15 sec.

Separate experiments in our laboratory have demonstrated that AVP does not affect adenylate cyclase activity in cortical synaptosomes. AVP may be directly influencing the activity of the fast phase synaptosomal Ca^{2+} channel.

THREE COMPONENTS OF Ca-CHANNEL CURRENT AND THEIR MODULATION BY A GTP-BINDING PROTEIN. H. Kasai. Max-Planck-Institut für biophysikalische Chemie, D3400 Göttingen, FRG.

Ca-channel currents of mouse neuroblastoma NG108-15 cells were recorded with the whole-cell patch-clamp method using 10 mM Ba as a charge carrier. These Ca-channel currents could be separated into three components according to their sensitivity to dihydropyridines (DHPs) and w-conotoxin GVIA (wCTX). One component, $I_{\omega CTX}$, was irreversibly blocked by wCTX, resistant to DHPs, and activated at potentials more positive to -20 mV. A second component, I_{DHP}, was sensitive to DHPs, resistant to wCTX, and activated at -30 mV. Both $I_{\omega CTX}$ and I_{DHP} were sustained during depolarization. In contrast, a third component, I_{LVA}, was resistant to both wCTX and DHPs and was activated at -50 mV. I_{LVA} was inactivated in a voltage-dependent manner, being completely eliminated at a holding potential of -40 mV. The δ-opiate agonist, DPDP-Enkephalin, could reduce all three components of Ca-channel current. However, its effects could be specific to certain components of currents in certain cells and culture conditions. Reduction of $I_{\omega CTX}$ and I_{LVA} was voltage- and time-dependent and relieved by depolarization, while the reduction of I_{DHP} was voltage- and time-independent. All these effects were blocked by pertussis toxin. These results suggest that the three Ca-channels of this cell exhibit sensitivities to DHPs and ωCTX which differ from the expectations of the T, L and N-classification. These three Ca-channels can be modulated in different ways by a GTP-binding protein.

LOCALIZATION OF CALCIUM INFLUX THROUGH PHORBOL ESTER-INDUCED CALCIUM CHANNELS. L.A. Fink*, L.K. Kaczmarek, and J.A. Connor. Department of Pharmacology, Yale University School of Medicine, New Haven, CT 06510; Roche Institute of Molecular Biology, Nutley, NJ 07110

Activators of protein kinase C have been shown to enhance the calcium current in the bag cell neurons of Aplysia by unmasking a 24 pS voltage-dependent calcium channel in the plasma membrane. This species of channel is not observed in control cells in which the kinase has not been stimulated, although control cells possess calcium channels of lower unitary conductance (~12 pS). We have now used fluorescent imaging of the calcium-indicator fura-2 to compare the localization of calcium influx in control cells and in cells exposed to the protein kinase C activator, TPA (20 nM). Single bag cell neurons with extensive neuritic outgrowth after one day in culture were loaded with fura-2 through a microelectrode, and fluoresecent ratio images were generated with a cooled CCD-based imaging system. In control cells, a train of action potentials generated large increases in the calcium signal from the neurites, with little or no increase in calcium at the soma. In contrast, after exposure of the cells to TPA for 10-15 min, much larger elevations of calcium at the soma were observed in response to action potentials. The depolarization-induced elevation of calcium in the neurites was also enhanced by TPA. Our data suggest that the large conductance calcium channels induced by activators of protein kinase C are located both on the soma and the neurites of isolated bag cell neurons, whereas, calcium influx through the lower conductace channels in both control and activated cells occurs primarily in the neurites.

457.20

CHARACTERIZATION OF AN α-ADRENERGIC RECEPTOR MEDIATED DECREASE OF THE CALCIUM CURRENT OF ACUTELY ISOLATED ADULT RAT SUPERIOR CERVICAL GANGLION NEURONS. Geoffrey G. Schofield. Department of Physiology, Tulane University Medical School, New Orleans, LA 70112.

At sympathetic neuroeffector junctions norepinephrine can decrease transmitter release by the activation of α_2-adrenoceptors located on synaptic varicosities. Norepinephrine can also decrease the Ca^{2+} current recorded from neuronal somata via an α-adrenoceptor. However, the receptor subtype involved in the norepinephrine induced decrease of the Ca^{2+} current has not been fully characterized. Ca^{2+} currents were recorded from single neurons, acutely isolated from adult rat superior cervical ganglia (SCG) using the whole-cell patch-clamp technique. The Ca^{2+} current induced by step depolarizations to +10 mV from a holding potential of -80 mV was decreased by 1 μM norepinephrine by 50.1 ± 4.5%. In the presence of the α_2-adrenoceptor antagonist idazoxan, 1 μM norepinephrine reduced the Ca^{2+} current amplitude by 8.9 ± 2.2%. On the other hand, the norepinephrine-induced decrease of the Ca^{2+} current was not attenuated by the α_1-adrenoceptor antagonist prazosin (1 μM). Idazoxan and prazosin themselves did not decrease the Ca^{2+} current. The α_2-adrenoceptor agonist clonidine (1 μM) also induced a decrease of the Ca^{2+} current of 34.0 ± 3.3%, whereas the α_1-adrenoceptor agonist phenylephrine (1 μM) decreased the Ca^{2+} current by only 13.0 ± 5.9%. These results suggest that norepinephrine decreases the Ca^{2+} current of adult rat SCG neurons via an α_2-adrenoceptor. Supported by the Pharmaceutical Manufacturers Association Foundation.

THE BENZODIAZEPINE DIAZEPAM AND THE β-CARBOLINE DMCM MODULATE $GABA_A$ RECEPTOR SINGLE CHANNEL CURRENTS BY OPPOSITE MECHANISMS. C.J. Rogers, R.E. Twyman and R.L. Macdonald. Dept. of Neurology, Univ. of Michigan, Ann Arbor, MI 48104.

Diazepam (DZ) and DMCM bind to the benzodiazepine binding site of the $GABA_A$ receptor channel and increase and decrease GABA receptor current, respectively. The effects of DZ and DMCM on single channel $GABA_A$ receptor currents were studied to determine their mechanisms of action.

Outside-out patches from mouse spinal cord neurons grown in cell culture were held at -75 mV in symmetric chloride solutions. Data were digitized at 20 kHz with 2 kHz Bessel filtering. Data from different patches were pooled for descriptive and kinetic analyses. Only the main conductance state (~27 pS) was analyzed. DZ or DMCM (20-100 nM) was included in the bathing medium. GABA (2μM) alone or GABA plus DZ or DMCM was applied from pressure ejection pipettes to the patch.

DZ and DMCM increased and decreased, respectively, the frequency of GABA receptor single channel currents in a concentration dependent manner without altering mean open time. Open durations of $GABA_A$ receptor currents were placed into an open time frequency histogram best fit by three exponential functions similar for GABA, GABA+DZ and GABA+DMCM and with similar relative frequencies of occurrence. $GABA_A$ receptor currents occurred in bursts of openings (separated by closures greater than 5 msec) and bursts occurred in clusters (separated by closures greater than 50 to 150 msec). Burst and cluster frequencies were increased and decreased by DZ and DMCM, respectively. These data suggest that the major effect of DZ is to increase the affinity of GABA for the $GABA_A$ receptor, an effect opposite to that of DMCM which predominantly decreases the affinity.

CYCLIC AMP DEPENDENT PROTEIN KINASE DECREASES $GABA_A$ RECEPTOR CURRENT IN MOUSE SPINAL NEURONS. N.M. Porter, R.E. Twyman, M.D. Uhler*, and R.L. Macdonald. Dept. of Neurology and the Mental Health Research Institute*, Univ. of Michigan, Ann Arbor, MI 48104

The predicted structure of the neuronal bovine $GABA_A$ receptor places a consensus phosphorylation site for cAMP dependent protein kinase (PKA) on an intracellular domain of the receptor. To determine the role of PKA-mediated phosphorylation on $GABA_A$ receptor function, we measured GABA receptor chloride currents in the presence of PKA in mouse spinal neurons using the whole cell and patch clamp techniques. The bath medium contained (mM): 142 NaCl, 8.1 KCl, 1 $CaCl_2$, 6 $MgCl_2$, 10 glucose, and 10 HEPES; the recording pipette contained: 153 KCl, 1 $MgCl_2$, 2 Mg-ATP, 5 EGTA, and 10 HEPES. In whole cell recordings, application of GABA (5 μM) to the soma reproducibly evoked an inward chloride current and an increase in membrane conductance. Inclusion of the purified catalytic subunit of PKA (50 μg/ml) in the pipette solution reduced the peak conductance evoked by GABA by 59% (n = 35). The GABA receptor current was not reduced, however, in cells in which heat-inactivated catalytic subunit was substituted for the active subunit in the pipette solution (n = 8). Application of GABA to excised, outside-out patches evoked bursting inward chloride currents in control patches (n = 10). In PKA patches very few openings were recorded and the total GABA receptor current was reduced by 97% (n = 7). PKA decreased GABA receptor current primarily by reducing the frequency of channel opening.

These results suggest that phosphorylation of the $GABA_A$ receptor, or of a protein associated with the channel, regulates chloride channel opening. *Supported by NIH NS08216 to NMP and DA04122 to RLM.*

458.3

SINGLE CHANNEL INTRABURST KINETIC MODELLING OF THE $GABA_A$ RECEPTOR MAIN CONDUCTANCE STATE R.E. Twyman, C.J. Rogers and R.L. Macdonald. Dept of Neurology, Univ of Michigan, Ann Arbor, MI.

To determine gating kinetics of the $GABA_A$ receptor channel, intraburst properties of the main conductance state (27 pS) were investigated with the outside-out patch clamp recording technique. Patches obtained from mouse spinal cord neurons grown in cell culture were held at -75 mV in symmetric chloride solutions. Data were digitized at 8 kHz with a 1 kHz Bessel filter interposed. Frequency distributions of openings per burst, all intraburst openings, individual openings, successive openings and total open time of bursts containing 1 to 5 openings were analyzed by curve fitting to sums of geometric, exponential or gamma functions. Intraburst closed times were analyzed similarly.

The analysis confirmed the presence of 3 concentration independent open states (dwell times of 1.0, 2.9 and 8.1 msec) and 2 intraburst closed states (0.2 and 2.0 msec). The results suggested that the GABA receptor main conductance state opens into at least one brief open state from a singly liganded closed state and two longer duration open states from doubly liganded closed states. Channel openings were grouped into bursts with three different mean durations. Bursts were formed primarily by repeated openings of individual open states. The shortest open state opened on average 1.1 times, while the medium and longest duration open states opened on average 2.0 and 3.9 times, respectively. The brief intraburst closures may represent open channel blocked states or channel closed states which are independent of ligand associated gating. Each open state bursts, therefore, due to channel blocking or intrinsic channel closure rather than due to ligand associated channel gating. A kinetic model consistent with these observations will be presented.

DELTAMETHRIN ALTERS PENTOBARBITAL-INDUCED CHLORIDE CURRENTS IN CULTURED HIPPOCAMPAL NEURONS. J.M.Frey and T. Narahashi. Dept. of Pharmacology, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Alpha-cyano pyrethroid insecticides have been shown to interact with the GABA/Cl^- receptor-ionophore in a complex manner. We have found that the acute application ($\leq$ 2 min) of the cyano pyrethroids fenvalerate and deltamethrin [DM] at concentrations up to 50uM can enhance (not suppress as one might expect) GABA-activated Cl^- currents in cultured hippocampal [HC] neurons (Frey et al., *Toxicologist*, 9:149, 1989). In an effort to understand this phenomenon, we tested the effect of DM (1-100uM) on pentobarbital [PB]-induced Cl^- currents in HC neurons recorded in the whole cell mode. Application of PB (100-500uM) by puffer for 20-30 sec elicited inward currents (0.2-1.2nA) which reversed at the Cl^- equilibrium potential and were blocked by both picrotoxinin and bicuculline. DM dramatically enhanced PB-induced peak currents when co-applied with PB (>60% at 10uM). This increase in peak current was accompanied by an increase in the rate of decay of the falling phase of the response. Currents were also enhanced when DM was pre-applied for 2-3 min, followed by co-application of PB/DM; however, this enhancement was oftentimes much less than co-application alone. In such cases, pre-application of DM for 2-3 mins often resulted in a reduction (<25%) in PB-induced current, suggesting competing mechanisms. These results implicate the PB binding site as a site of action of the cyano pyrethroid insecticides. Supported by NIH grant NS14143.

LINDANE AND CYCLODIENE INSECTICIDES BLOCK GABA-ACTIVATED CHLORIDE CURRENT IN CULTURED RAT HIPPOCAMPAL NEURONS. T. Narahashi and J.M. Frey. Dept. of Pharmacology, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Lindane blocks GABA-activated Cl^- currents in cultured neurons (Ogata et al., *FASEB J.*, 2:2896, 1988; Frey et al., *Toxicol*. 9:149, 1989). We have compared the effects of lindane and the cyclodienes in cultured rat hippocampal neurons using the whole cell patch clamp technique. GABA (15 μM), delivered by puffer for 20-30 sec, produced rapid inward currents with distinct early transient (T) and late sustained (S) components (see Dichter and Frey, this meeting). Both T and S components were reduced reversibly (50 and 30%, respectively, 10 μM) by either coapplication or a single 2 min preapplication of lindane. The cyclodienes dieldrin (HEOD), endrin, heptachlor-epoxide (HE) and isobenzan (1-50 μM) also reduced GABA/Cl^- currents with a relative potency of endrin = isobenzan > HEOD = HE. However, the onset of action of the cyclodienes was much slower than lindane. Continuous application of HE or HEOD at 10 μM blocked 50% of the T component in ~6 min, and the current continued to decrease to <40% over 9-12 min. The S component was reduced by <25% within 2 min but remained unchanged with subsequent application. The effects on both components were irreversible. Thus, both lindane and the cyclodienes blocked GABA/Cl^- currents although their time course of action were markedly different. The results are compatible with the convulsant action of these insecticides. Supported by NIH grant NS14143.

ALLOSTERIC INTERACTIONS BETWEEN THE GABA, CHLORIDE AND BICYCLOPHOSPHATE BINDING SITES IN RAT BRAIN. R.G.Thompson, D.E. Menking* and J.J. Valdes. Biotechnology Div., Chem., Res. Devel. & Engr. Ctr., Aberdeen Proving Ground, MD 21010-5423.

This study investigated the degree to which GABA-A receptor agonists, chloride ions and bicyclophosphate compounds can influence the in vitro binding of radioligands to the multimeric GABA/anion/picrotoxin/benzodiazepine receptor complex isolated from rat brain.

Chloride ions, while stimulating membrane binding of ^{35}S-TBPS, inhibited ^{3}H-MUS binding to the GABA receptor by a maximum of 33% at 500 mM. Chloride also fully protected the ^{35}S-TBPS binding sites from heat inactivation (60^{o}C,30 min) but provided no protection for the GABA receptor. Cold TBPS also showed partial inhibition of ^{3}H-MUS binding to the GABA receptor and partially antagonized the effects of Cl^-. In addition, TBPS provided a small (10-30%) protective effect against thermal inactivation of the GABA receptor. Incubation of the membranes with cold MUS completely inhited ^{35}S-TBPS binding and also protected 67% of the binding sites from heat inactivation. Neither GABA receptor agonist nor the bicyclophosphates showed an ability to protect their own respective binding sites from heat inactivation.

In contrast to the interactions observed between Cl^- and bicyclophosphates on the receptor-gated ion channel, the results of studies on membrane preparations containing a voltage-gated Cl^- channel will also be presented.

SEROTONIN DIRECTLY EXCITES SPINAL MOTONEURONS. A.J. Berger and T. Takahashi* Dept. of Physiol., Faculty of Medicine., Kyoto Univ., Kyoto, Japan.

Serotonin (5-HT) increases excitability of spinal motoneurons (MNs) (Barasi, et al., Br. J. Pharmacol. 52: 339, 1974), but the mechanism for this effect is unknown. We studied this by applying whole-cell recording to neonatal rat MNs visually identified in thin spinal cord slices. In current clamp mode, bath-applied 5-HT (10 μM) in nominally Ca-free Mg (5 mM) Krebs solution depolarized MNs beyond firing threshold. In voltage clamp, at approx. -90 mV in Ca-free Krebs containing TTX, 5-HT generated an inward current (I_{5-HT}) associated with a conductance increase. External application of Cs (10 mM) but not Ba (2 mM) virtually abolished the I_{5-HT}. At higher external K concentrations (K_o), peak amplitude of the I_{5-HT} was larger. The I_{5-HT} current-voltage relation showed inward rectification. In 20 mM K_o, the I_{5-HT} reversal potential was -29 mV (n = 7 MNs). These I_{5-HT} characteristics are similar to those of the inward rectifying current seen in these MNs during membrane hyperpolarization. We conclude that 5-HT directly excites spinal MNs and this is probably mediated by the inward rectifying current present in MNs.

D_2 DOPAMINE RECEPTOR ACTIVATED K^+ CHANNELS IN SUBPOPULATIONS OF FRESHLY DISSOCIATED RAT CORPUS STRIATUM NEURONS. Jonathan E. Freedman and Forrest F. Weight. Sect. Electrophysiol., Natl. Inst. on Alcohol Abuse & Alcoholism, Rockville, MD 20852.

The corpus striatum (caudate and putamen) is a heterogeneous cell population rich in postsynaptic dopamine receptors. We have previously described an 85 pS K^+ channel activated by D_2 dopamine receptors in striatal neurons freshly dissociated from young adult rats (*Proc. Natl. Acad. Sci.*, **85**: 3618). We have now compared cells obtained by various modifications in our isolation procedure in order to (i) optimize dissociation conditions and (ii) assess whether this response is associated with a particular subtype of striatal neuron.

Among the modifications tested were cutting thin (100-250 μm) tissue slices on a vibrotome, treating the slices with less trypsin than in our original study (0.1-0.5 concentration and 0.5 incubation time), and substituting glucose or sucrose for NaCl in the dissociation medium in an attempt to decrease any ischemic or excitotoxic damage. Combinations of these methods increased cell yield, with greater diversity of cell size and shape, and better preservation of dendritic structure.

Cell-attached patch-clamp recordings indicated that not all dissociated cells displayed the D_2-activated channel; the proportion of responsive cells varied with the dissociation procedure. This raises the possibility that the response may be localized to a subpopulation of striatal neurons which survives various isolation procedures differentially. We are presently assessing whether D_2 responses are associated with a morphologically identifiable cell subtype, and whether other cells might have responses mediated by D_1 receptors.

458.9

ATP-ACTIVATED CHANNELS FROM PARASYMPATHETIC CARDIAC NEURONS. L.A. Fieber and D.J. Adams*, Dept. of Pharmacology, Univ. of Miami Sch. of Med., Miami, FL 33101.

Extracellular ATP activates a cation-selective channel in cardiac neurons of rat parasympathetic ganglia. ATP-activated whole cell currents exhibit inward rectification and a reversal potential near 0 mV. The characteristics of ATP-activated currents and ACh (nicotinic)-activated currents are similar, though pharmacologically distinct. The ATP-induced current is reduced during bath application of the non-hydrolyzable ATP analog α-β-methylene ATP and blocked by Reactive Blue (Kd 1 μM). Single ATP-activated channels were recorded in cell-attached and excised patches from cultured cardiac neurons. The patch pipette contained (mM) 140 CsCl, 10 HEPES-CsOH, pH 7.0 with 5 μM ATP. ATP-activated channels obtained from excised patches in a Ca-free bath solution had linear current-voltage relationships and a conductance of about 30 pS. Similar results were obtained from cell-attached patches. The reduction in the probability of opening (P_o) observed at depolarized membrane potentials may underlie the rectification of the whole-cell ATP-evoked current. The sustained activity of ATP receptor-channels in excised membrane patches suggests that ATP receptors are directly coupled to ion channels and do not require the continued presence of a cytosolic second messenger.

458.10

A PROTON-ACTIVATED SUSTAINED INWARD CURRENT IN RAT DORSAL ROOT GANGLION NEURONS. *S. Bevan* and J.C. Yeats** (SPON: Brain Research Association), Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN, UK.

A reduction in the external pH of the medium bathing rat and chick DRG neurons to <pH 7 elicits a transient inward current, which relaxes in 1-2s (Krishtal & Pidoplichko, 1980; Konnerth et al., 1987). We have found that lowering the pH to <6.4 also activates a sustained inward current in a sub-population of DRG neurons.

3-7 day old cultures of neonatal rat DRG neurons responded to acidification of the external medium to <pH 6.4 with an efflux of ^{14}C-guanidinium and ^{86}Rb ions. This efflux was abolished when cultures were pretreated for 24 hours with 2-10μM capsaicin to kill the capsaicin-sensitive cells. Freshly isolated adult rat DRG neurons were also examined by whole cell voltage clamp methods. In addition to the transient current, acid solutions (<pH 6.2) evoked a more sustained inward current in 30-50% of neurons studied at a holding potential of -80mV, with a standard NaCl-based external solution and either a CsCl- or KCl-based internal solution. Under these ionic conditions the reversal potential for this current was close to 0mV. Experiments were also made with NaCl solutions on both sides of the membrane: reduction of the external NaCl solution to 50mM from 130mM (with isosmotic replacement with sucrose) shifted the reversal potential for the sustained pH response by about -23mV which is close to the value expected for a cation selective conductance. We conclude that protons activate a relatively non-specific cation conductance in a sub-population of DRG neurons that are restricted largely, if not exclusively, to the capsaicin sensitive population.

VOLTAGE- AND RECEPTOR-ACTIVATED CURRENTS IN AR42J CELLS. K. Kusano and H. Gainer. LNC, NIH, NINDS, Bethesda, MD 20892.

Membrane currents were studied in AR42J cells, a rat pancreatic acinar cell line. A whole-cell configuration of the patch-electrode voltage clamp technique was used. The AR42J cells exhibited the following membrane voltage-activated ionic currents: $I_{K(Ca)}$, I_{Na}, $I_{Ca(t)}$ and $I_{Cl(Ca)}$. These currents were identified by their ionic dependencies, pharmacological properties and kinetic parameters. Spontaneous action potentials were seen in a small number of cells under current clamp condition. Receptor-activated membrane currents were studied by applying the following ligands: sulfated CCK-8(10^{-6}M), bombesin (10^{-6}M), substance-P ($5x10^{-8}$M), secretin (10^{-5}-10^{-6}M), vasopressin (10^{-6}M), and acetylcholine (10^{-4}M). Most of these ligands are known to be pancreatic secretagogues. All of these ligand-activated receptor currents were inward at the membrane holding potential of -70 mV, and were accompanied by a membrane conductance increase. Receptor-activated currents typically were inactivated within 30 sec in the presence of the ligands. The reversal potential of the I_{CCK} obtained from 8 cells was about 0 mV or slightly positive, but in 2 cells it was between -20 and -25 mV. Such reversal potentials were also observed for $I_{bombesin}$ and for I_{ACh}. It appeared that these three secretagogues activated similar ion channels. However, there was some variation between the cells with respect to their ionic selectivity and permeability. The above receptor-activated currents could not be recorded in "Ca-free" medium or with a pipette containing EGTA, but could be recorded in the presence of 500 μM Cd^{2+} in control saline which did block the calcium current. This suggests that receptor activation produces a rise of Ca^{2+} by the release of Ca^{2+} from intracellular stores. Thus AR42J cells possess many electrophysiological properties which are similar to primary rat pancreatic acinar cells, but have several currents (I_{Ca}, I_{Na}) not yet reported for the primary cells.

458.12

ISOLATION OF THE 58K SUBUNIT OF THE GLYCINE RECEPTOR OF RAT SPINAL CORD. G. Grenningloh*, P. Prior*, I. Pribilla* and H. Betz. (SPON: C.S. Goodman). ZMBH, Universität Heidelberg, Im Neuenheimer Feld 282, D-6900 Heidelberg, Fed. Rep. of Germany.

The inhibitory glycine receptor is composed of three polypeptides of 48K, 58K and 93K. The 48K and 58K subunits are transmembrane proteins combined in a pentameric complex which forms the glycine-gated chloride channel. The ^{3}H-stychnine binding 48K subunit has been cloned and shown to be homologous to other ligand-gated receptor polypeptides (Grenningloh et al., 1987). Furthermore, the 48K polypeptide is capable of assembling into a functional receptor homo-oligomer when expressed in frog oocytes (Schmieden et al., 1989). We report here the isolation of the second component of the glycine receptor core, the 58K subunit. Gas phase microsequencing of 58K tryptic peptides resulted in several amino acid sequences which were used to construct synthetic oligonucleotide probes for screening a λgt10 cDNA library. The deduced amino acid sequence of the isolated cDNA clones indicate strikingly high homology to the 48K subunit. The putative transmembrane regions M1 to M4 and two cysteine residues in the N-terminal hydrophilic domain are conserved. Most divergence occurs in the region connecting M3 and M4. These data show that the glycine receptor channel is composed of homologous subunits similar to nicotinic acetylcholine and $GABA_A$ receptors suggesting that these channels are built on the same structural plan.

GABA AND BENZODIAZEPINE RECEPTORS IV

459.1

PHENYTOIN MODIFIES DIAZEPAM ENHANCEMENT OF GABA-MEDIATED CHLORIDE FLUX. J. Francis, B. Sneddon*, S. Kish*, W.M. Burnham and L. Spero. Dept. of Pharmacology, University of Toronto, Toronto, Ontario and Clarke Institute of Psychiatry, Toronto, Ontario.

We have previously demonstrated that diazepam potentiates specific 3H-phenytoin binding in rat brain [Okazaki, M. et al. Life Sci., 33: 409, 1983]. The current study attempts to investigate, conversely, whether phenytoin interacts with the GABA-A receptor complex or any of its subunits.

GABA-stimulated chloride flux in a synapto-neurosomal preparation from rat cerebral cortex was used. GABA (10 uM) stimulated chloride uptake into synaptoneurosomes by 47% over basal flux. Diazepam (50 uM) had no effect on its own, but potentiated GABA-stimulated chloride flux by 25%. Phenytoin (10 uM) had no effect on basal or GABA-stimulated chloride flux. In the presence of GABA (10 uM) and diazepam (50 uM), however, phenytoin significantly enhanced chloride uptake by 18% ($p<0.05$) (n=4).

Taken together, these data suggest the possibility that, in mammalian brain, the phenytoin recognition site may be allosterically coupled to a benzodiazepine recognition site. These sites, in turn, may be functionally linked with the GABA-A receptor complex.

459.2

STEROID HORMONE METABOLITES POTENTIATE GABA RECEPTOR-MEDIATED CL^- UPTAKE: EVIDENCE FOR MULTIPLE ALLOSTERIC BINDING SITES. J. R. Pace*[1], R. H. Purdy*[2], S. M. Paul*[1], A. L. Morrow[1]. (SPON: L. L. Hsu) [1]Clinical Neuroscience Branch, NIMH, Bethesda, MD 20892 and [2]Southwest Foundation, San Antonio, TX 78284

Endogenous metabolites of progesterone and deoxycorticosterone potentiate GABA-mediated chloride ion flux in rat brain synaptoneurosomes. To investigate the interactions of various natural and synthetic steroids with the GABA-benzodiazepine receptor complex, concentration-response curves were generated for steroid potentiation of muscimol-stimulated $^{36}Cl^-$ uptake and analyzed using the computer program ALLFIT.

Cerebral cortical synaptoneurosomes were prepared from adult male S.D. rats. Muscimol-stimulated $^{36}Cl^-$ uptake was measured for 5 seconds in the presence or absence of steroids. The endogenous steroid metabolites 3α,21-dihydroxy-5α-pregnan-20-one (THDOC) and 3α-hydroxy-5α-pregnan-20-one (3α-OH-DHP) exhibited shallow biphasic concentration response curves with maximal potentiations of 14.5 and 10.9 nmoles $^{36}Cl^-$/mg. protein, respectively. Pseudo-Hill coefficients for THDOC and 3α-OH-DHP- induced potentiation of muscimol-stimulated $^{36}Cl^-$ uptake were 0.46 and 0.56. In contrast, concentration response curves for the synthetic derivative 3α, 21-dihydroxy-5α-pregnan-20-one 21-mesylate were monophasic with an Emax of 9.1 nmoles $^{36}Cl^-$/mg prot and a Hill slope of 0.94. The 3α-hydroxy-5α-androstane-17β-carbonitrile concentration response curves were steep and monophasic with a mean Hill coefficient of 2.2.

These data suggest that steroid hormone metabolites interact with multiple allosteric sites on the GABA-benzodiazepine receptor complex to potentiate GABA-mediated chloride uptake.

459.3

CHRONIC LITHIUM EFFECT ON GABA-MEDIATED SYNAPTONEUROSOMAL CHLORIDE UPTAKE. R.M. SALOMON*, and W.J. SHOEMAKER. Dept. of Psychiatry, Univ. of Connecticut School of Medicine, Farmington, CT 06032.

We have been investigating the role of γ-aminobutyric acid-A ($GABA_A$) receptors in the biological activity of chronic lithium (Li) exposure in the CNS. Using a synaptoneurosome preparation, the functional response following stimulation of the GABA-BZD-chloride channel complex is assessed by uptake of 36-chloride in a 5 second exposure. Cerebral cortical synaptoneurosomes from rats fed a lithium-containing (40 mMol) diet for 3 weeks are significantly more responsive to muscimol stimulation. (Serum Li levels for these animals were 0.90 meq/L.) At 20 μM muscimol, uptake stimulation increased (from control 166% above baseline to 236%) representing a 107% increase in muscimol stimulation ($p<0.05$). Acute Li exposure over a wide physiological range has no effect on muscimol stimulated chloride flux but at supraphysiologic concentrations of lithium an inhibition of Cl- uptake was observed. This may suggest that a chronic lithium effect in mania may be mediated in part by functionally altering GABA-mediated chloride flux. Another observed effect was an enhancement of chloride uptake in the absence of magnesium, which is not reversed by lithium. This work was partially supported by the University of Connecticut Health Center Research Advisory Committee.

SPECIFIC CHLORIDE INFLUX: RELATIONSHIP BETWEEN $^{36}Cl^-$ UPTAKE RATE AND GABA CONCENTRATION. Ewa Malatynska*, Monique L. Giroux*, Richard S. Jaeckle, Steven C. Dilsaver. Dept. of Psychiatry, Neuroscience Program, The Ohio State Univ., Columbus, OH 43210-1228.

GABA produces a concentration dependent increase of $^{36}Cl^-$ uptake in membrane vesicles prepared from rat cerebral cortex. The transformation of these data as specific chloride influx (SCI), defined as the rate of $^{36}Cl^-$ uptake in nmoles/3 sec/ mg protein/ nomol GABA reveals three distinct chloride conduction states which can be related to the GABA concentration. The first conduction state is characterized by a rapid increase in the SCI over a GABA concentration range of 0-10 μM and reaches a maximum at 10 μM GABA. The second conduction state is defined by a steady SCI value which occurs between 10-30 μM GABA. The third conduction state occurs at GABA concentrations over 30 μM, shows declining values of SCI, and is probably related to the desensitization of the GABA receptor. A fixed concentration (10μM) of the ß-carboline agonist for the BZ-receptor, ZK 93423, shifts to the left the GABA dose-response curve at lower GABA concentrations while depressing the maximal GABA response at higher GABA concentrations.The effects of ZK 93423 on SCI are (1) an increase in SCI value in the first and second conduction states; (2) a change in the second state from steady to very fast declining SCI; (3) a decrease of the SCI in the third state. Thus, the reduction of the maximal GABA response produced by ZK 93423 corresponds to an enhancement of GABA receptor desensitization.

PYRETHROID INSECTICIDES AND VERATRIDINE INCREASE BASAL CHLORIDE UPTAKE INTO RAINBOW TROUT SYNAPTONEUROSOMES. A.J. Eshleman* and T.F. Murray. Toxicology Program and College of Pharmacy, Oregon State University, Corvallis, Or. 97331.

γ-Aminobutyric acid (GABA)-gated chloride ionophores comprise the main inhibitory neurotransmitter system of the CNS of vertebrates. Insecticides such as endrin and dieldrin have been shown to interact with this receptor/ionophore. Evidence is emerging that pyrethroid insecticides also interact with this system at low micromolar concentrations as measured by effects on ligand binding; a contention exists as to the relevance of this interaction for pyrethroid toxicity as compared to their activity at voltage-gated sodium channels. Rainbow trout (*Oncorhynchus mykiss)* have been used in this study to investigate the ability of pyrethroids to modulate chloride flux due to their sensitivity to these insecticides. Deltamethrin, (1RαS)*cis* cypermethrin and 1R*cis* permethrin have been shown to inhibit 82, 87 and 67% of GABA-dependent ^{36}Cl uptake into trout brain synaptoneurosomes when GABA-dependent uptake is defined as the total uptake in the presence of GABA minus the total uptake in the absence of exogenous GABA, measured at each concentration of pyrethroid. Because these pyrethroids caused a significant increase in basal uptake, we characterized this pyrethroid-dependent uptake: 1. The increase in basal uptake was inhibited by tetrodotoxin (TTX). 2. Veratridine (VTD) caused a greater increase than deltamethrin in basal flux which was also inhibitable by TTX. 3. There was little or no synergy in basal chloride uptake with VTD and deltamethrin. These data suggest that pyrethroids may indirectly increase chloride influx into piscine synaptoneurosomes via a TTX-sensitive effect, most likely at voltage-dependent sodium channels. [Supported by HHS Grant ES04891.]

EFFECTS OF ATP ON BASAL AND PHENOBARBITAL-ENHANCED SPECIFIC GABA BINDING TO RAT BRAIN MEMBRANES IN VITRO. J.A. Richter and L.R. Curtis*. Indiana Univ. Sch. Med., Indianapolis, IN 46202.

We have shown previously that in an appropriate membrane preparation incubated at 37° in a complete medium, specific ^3H-GABA binding is enhanced not only by pentobarbital (PB) but also by phenobarbital (PheB). In another membrane preparation we and others find better specific binding but no PheB effect.

In the present work we have found that addition of ATP to the binding assay increases specific ^3H-GABA binding and reduces the PheB-enhancement of this binding in our membrane preparation. Preliminary experiments suggest that the ATP effects are also observed with GTP but not with the non-hydrolyzable ATP analog AMPPNP. In experiments to date the ATP effects are not duplicated by 8-bromo-cAMP or inhibited by W-7 (a CaCM kinase inhibitor), Polymixin B (a PK-C inhibitor), or heparin (a casein kinase inhibitor).

These results could suggest that in our membrane preparation there may be an unidentified kinase activity requiring exogenous ATP or GTP. Alternatively there may be an activated phosphatase the effect of which is overcome by the hydrolyzable nucleotides. These suggestions are consistent with the idea that phosphorylation increases GABA binding to high affinity GABA-A receptors and decreases the PheB-enhancing effect. (Supported by grant DA-00796).

THE INHIBITION OF [3H]-FLUNITRAZEPAM BINDING IN WASHED RAT BRAIN MEMBRANES AND BRAIN TISSUE SECTIONS BY β-CARBOLINES. P.A. Chmielewski* and J.A. Miller (SPON: R.J. Dinerstein), Merrell Dow Research Institute, Cincinnati, OH, 45215.

The radioligand [3H]-flunitrazepam ([3H]-FLU) which recognized both subtypes of the central benzodiazepine receptor (BZD1 and BZD2), was used to label these sites in washed rat brain membranes and sagittal sections. Localization of BZD binding sites was analyzed by quantitative autoradiography. Various β-carbolines were used to displace [3H]-FLU binding and Ki values calculated. The displacement analysis also examined the ability of these agents to distinguish between the two receptor subtypes based on the relative proportion of BZD1 and BZD2 in different brain regions. The BZD antagonist RO15-1788 displayed subnanomolar affinity. The inverse agonist β-carboline 3-hydroxymethyl-β-carboline (3-HMC) had a Ki of 0.5 μM and a Hill coefficient of 1.0. Other β-carboline, however, distinguished between the two receptor subtypes. Methyl-6,7-dimethoxy-4-ethyl-β-carboline-3-carboxylate (DMCM) had Ki's of 8.5 nM and 0.6 nM for BZD1 and BZD2 receptors respectively. The partial inverse agonist, N-methyl-β-carboline-3-carboxamide (FG-7142), was much lower in potency with Ki's of 14 μM (BZD1) and 0.2 μM (BZD2). Ethyl-β-carboline-3-carboxylate (β-CCE) demonstrated a higher affinity for the BZD1 subtype (Ki=0.7 nM) than for BZD2 (Ki=9 nM). These differences in potency and selectivity for the BZD receptor subtypes may explain some of the pharmacological differences among the β-carbolines.

BIOCHEMICAL EVIDENCE FOR A PARADOXICAL EFFECT ELICITED BY BENZODIAZEPINES. E. Sanna*, A. Concas*, M. Serra* and G. Biggio (SPON: L. Martini). Dept. of Experimental Biology, University of Cagliari, Italy

35S-TBPS binding to membrane preparations from rat cerebral cortex and from cerebellar granule cells in primary culture was used to study the changes in the function of GABAergic synapses induced by GABAergic drugs. Since the action of positive and negative modulators of GABAergic transmission is strictly dependent by the presence of GABA at the synaptic level, we used for this study unwashed membranes which are supposed to be rich of endogenous GABA. In these membrane preparations the "in vitro" addition of diazepam (1 μM) decreased by 46% 35S-TBPS binding to both cerebral cortex and granule cells. This effect was completely reversed by bicuculline (10 μM) which per se enhanced 35S-TBPS binding. Moreover, 35S-TBPS binding was also markedly enhanced by anxiogenic ß-carbolines. The effect of bicuculline was presumably due to the blockade of the inhibitory action of GABA. In fact, the removal of GABA by extensive washes of membranes mimicked the effect of bicuculline and ß-carbolines enhancing 35S-TBPS binding by 90%. Moreover, in well-washed membrane preparations (devoid of GABA), diazepam (1 μM) increased 35S-TBPS binding (+ 23%). Same results were obtained using cerebellar granule cells in primary culture. This finding suggests that in the absence of GABA, diazepam, like bicuculline and anxiogenic ß-carbolines has a negative modulatory action on GABAergic transmission. This conclusion is strongly supported by the result showing that diazepam further enhanced (26%) the bicuculline-induced increase of 35S-TBPS binding to unwashed membrane preparations. The data suggest that the increase of 35S-TBPS binding induced by diazepam in absence of GABA might reflect a paradoxical response similar to some paradoxical behavioural effects elicited by benzodiazepines.

BUSPIRONE ALTERS BENZODIAZEPINE BINDING BUT NOT GABAa RECEPTOR FUNCTION. F. Lopez,* L.G. Miller, A. Schatzki,* S. Chesley,* D.J. Greenblatt,* (SPON: T. Theoharides). Div. of Clinical Pharmacology, Depts. of Psychiatry and Pharmacology, Tufts-New England Medical Center, Boston, MA 02111.

Buspirone(B), an azospirodecanedione, has recently been introduced as a non-benzodiazepine(BZ) anxiolytic. Since some reports indicate effects of B at the BZ receptor, we assessed effects of B, an analog gepirone(G) and the major metabolite of both compounds, 1-(2-pyrimidinyl)-piperazine (1PP), on BZ binding in vivo and ex vivo and GABA-related chloride uptake ex vivo. BZ binding in vivo was increased in cerebral cortex and cerebellum in mice treated with acute doses of B and G, 5 mg/kg(B5,G5) but not at 1 mg/kg (B1, G1)(CX: Vehicle 1750; B1 1900; B5 2654; G1 1695; G5 2436; all fmol/g). No change was seen with similar doses of 1PP. BZ binding in vitro was unaffected by B and 1PP, but number of sites was increased by G, 5 mg/kg. Muscimol-stimulated chloride uptake was unaffected by B, G or 1PP (Vehicle 24.8; B 25.6; G 25.0; 1PP 25.7; all nmol/mg prot). Thus, buspirone and gepirone may affect BZ binding but do not appear to alter function of the GABAa receptor. The metabolite 1PP does not affect binding or receptor function.

QUANTITATION OF CELL-SURFACE VS. INTRACELLULAR BENZODIAZEPINE RECEPTORS USING A SULFONATED BENZODIAZEPINE DERIVATIVE. M.H. Jalilian Tehrani and E.M. Barnes, Jr. Dept. of Biochem., Baylor College of Medicine, Houston, TX 77030.

A membrane-impermeant derivative of the benzodiazepine 1012S was prepared by reaction with 4-sulfophenylisothiocyanate and purification by reverse phase HPLC. The resulting N-(4-sulfophenyl)thiocarbamoyl derivative (SPTC-1012S) retained the high affinity of the parent compound for central benzodiazepine receptors on chick cortical neurons in culture. Approximate IC_{50} values for displacement of [^{3}H]flunitrazepam binding to intact neurons were 2 nM and 5 nM for SPTC-1012S and 1012S, respectively. Permeabilization of neuronal surface membranes by exposure of cells to 0.005% saponin had no effect on the level of [^{3}H]flunitrazepam binding or on the ability of 1012S to displace this label. However, [^{3}H]flunitrazepam displacement by SPTC-1012S was increased by 10% following saponin treatment. The data suggest that 90% of cellular benzodiazepine receptors are exposed on the external surfaces of developing neurons. Thus, SPTC-1012S can be used to study the intracellular trafficking of GABA/benzodiazepine receptors.

^{35}S-TBPS BINDING EX VIVO AS AN INDEX OF IN-VIVO GABAERGIC ACTIVITY AND MODULATION. A. Concas*, E. Sanna*, M. Serra* and G. Biggio, Dept. of Experimental Biology, Chair of Pharmacology, University of Cagliari, Italy

The pharmacology of $GABA_A$ receptor was studied by measuring "ex vivo" ^{35}S-TBPS binding in unwashed membrane preparations from the rat cerebral cortex. Anxiogenic and convulsant ß-carboline derivatives produced a dose dependent (0.05-1 mg/kg i.v.) increase of ^{35}S-TBPS binding. On the contrary, benzodiazepines (BZ) and other agonists for BZ receptors markedly decreased ^{35}S-TBPS binding in the same brain area. The effect of anxiogenic and anxiolytic drugs was mimicked by isoniazid (150-600 mg/kg s.c.), an inhibitor of GABAergic transmission, and valproic acid (150-400 mg/kg), respectively. Ro 15-1788, a BZ receptor antagonist, prevented the effects of both anxiolytic and anxiogenic drugs but failed to antagonize the action of isoniazid and valproic acid. Ethanol (1-4 gr/kg) like anxiolytics elicited in 60-90 min. a small but significant decrease of ^{35}S-TBPS binding. The action of ethanol was also studied on both the convulsive pattern and the increase in ^{35}S-TBPS binding elicited by isoniazid. High doses (3-5 gr/kg) of ethanol prevented the convulsions elicited by isoniazid. Consistently ethanol antagonized by 50% isoniazid-induced increase in ^{35}S-TBPS binding. The results suggest that the "ex vivo" measurement of ^{35}S-TBPS is a suitable index of the functional state of $GABA_A$ receptors in vivo.

SELECTIVE ω_1 (BZ_1) SITE ACTIVATION IS SUFFICIENT TO MODULATE THE $GABA_A$ RECEPTOR-LINKED CHLORIDE IONOPHORE: STUDIES WITH THE HYPNOTIC IMIDAZOPYRIDINE ZOLPIDEM. K.G. Lloyd and F. Thuret*. Biology Dept., Synthélabo Recherche (L.E.R.S.), Paris, 75013, France.

Zolpidem (ZO), is a highly selective ligand for the ω_1 (BZ_1) site in the GABA receptor supramolecular complex (GRSC) (Langer, S.Z. and Arbilla, S. J. Fund. Clin. Pharm., 2: 159, 1988). In order to determine if selective ω_1 site stimulation is sufficient to modulate the GRSC function, we have presently examined the action of ZO at different subunits of the GRSC using ^{35}S-TBPS binding, ^{3}H-GABA binding and $^{36}Cl^-$ uptake. With well-washed rat cerebral cortex membranes in the presence of NaCl, ZO allosterically enhances ^{35}S-TBPS binding (EC_{50}= 80nM, Max. eff.= +36%) to the same extent as GABA (EC_{50}= 388nM, Max. eff.= +31%). This effect is competitively antagonized by flumazenil (1 and 10µM) but bicuculline (1mM) only partially (33%) inhibits the action in a non-competitive manner. The action of GABA is completely antagonized by bicuculline and unaltered by flumazenil. The enhancement of ^{35}S-TBPS binding by ZO appears to be due to an enhanced rate of association of ^{35}S-TBPS. Dissociation of the ligand is also modulated (introduction of a fast component of dissociation) suggesting that ZO increases the frequency of chloride ionophore opening and closing. The findings using ^{35}S-TBPS are confirmed by $^{36}Cl^-$ uptake studies. ZO increases ^{3}H-$GABA_A$ binding to rat cerebral cortex membranes, apparently by enhancing the number of sites available to the ligand. Thus, selective ω_1 site activation by ligands such as ZO is capable of activating the entire sequence of events within the GRSC.

CHARACTERIZATION AND DISTRIBUTION OF [^{35}S]TBPS BINDING TO RAT BRAIN SECTIONS USING AUTORADIOGRAPHY. Patricia P. Edgar and Rochelle D. Schwartz, Dept. of Pharmacology, Duke University Medical Center, Durham, NC 27710.

[^{35}S]TBPS binding to rat brain sections was characterized for subsequent autoradiographic analysis. Cortical brain mash slices were preincubated with EDTA to remove endogenous GABA. The association and dissociation rate constants were $0.377 min^{-1}pM^{-1}$ and 0.011 min^{-1}, resp. Dissociation was monophasic and slow ($t_{1/2}$=80 min). Scatchard analysis indicated a single population of binding sites (K_D = 21.0 nM, B_{max} = 1.59 pmol/mg prot.). Picrotoxin and muscimol inhibited [^{35}S]TBPS binding with IC_{50}s of 251 nM and 203 nM and n_Hs of 0.98 and 1.4, resp. Distribution of [^{35}S]TBPS binding sites in the rat brain resembles that of other ligands which bind to $GABA_A$ receptor complex with some regionally specific differences. Regions with a high degree of [^{35}S]TBPS binding included inf. colliculus, med. septal n., central thalamic n., olf. tubercle, zona incerta, dentate gyrus, and substantia nigra. [^{35}S]TBPS preferentially bound to the molecular vs granular layer of the cerebellum. Omission of the preincubation or addition of 1 uM GABA to preincubated slices markedly but variably decreased [^{35}S]TBPS binding. For example, [^{35}S]TBPS binding was inhibited to different degrees in the cell layers of the cerebellum. Our study shows that the distribution of [^{35}S]TBPS binding sites is influenced by the preincubation-incubation conditions.

DISTRIBUTION OF BENZODIAZEPINE/$GABA_A$ RECEPTORS IN THE MONKEY MEDIAL TEMPORAL LOBE: AN IMMUNOHISTOCHEMICAL ANALYSIS. H. M. Stroessner*, C. R. Houser, J. G. Richards and D. G. Amaral. (SPON: R. Evans) The Salk Institute, La Jolla, CA 92037; UCLA, Los Angeles, CA. 90024; and F. Hoffman-La Roche & Co. Basel, Switzerland

Monoclonal antibodies (bd-17 and bd-24) to the benzodiazepine/$GABA_A$ receptor complex purified from bovine cerebral cortex were used to study the localization of this receptor in immunohistochemical preparations of the macaque monkey amygdaloid complex and hippocampal formation. In the amygdala, the highest density of staining was observed in the lateral and accessory basal nuclei and the nucleus of the lateral olfactory tract. The staining in these nuclei had a particulate appearance and was presumably associated with dendrites. In the basal nucleus and periamygdaloid cortex (PAC), the overall level of particulate staining was low but numerous distinctly labeled neurons were observed. While most of these were small and round with several radiating processes, some larger neurons were also labeled, especially in the PAC. In the hippocampal formation, the densest particulate staining was observed in the molecular layer of the dentate gyrus, within layer II of the presubiculum and throughout the entorhinal cortex except for layer V. Large numbers of neurons were clearly stained throughout the hippocampal formation, particularly in the dentate gyrus and in field CA3 of the hippocampus. In the hippocampus, many of the smaller stained neurons had highly varicose dendrites. Other, larger stained CA3 neurons, however, had smooth dendrites and resembled pyramidal basket cells.

459.15

AUTORADIOGRAPHIC LOCALIZATION OF $GABA_A$ AND $GABA_B$ BINDING SITES IN THE VENTRAL HORN OF THE CAT SPINAL CORD. Debra A. Vascik, Joseph R. Holtman, Jr. and Bruce E. Maley, Dept. of Anatomy and Neurobiology and Dept. of Pharmacology, Univ. of Kentucky Med. Ctr., Lexington, KY 40536.

Gamma-aminobutyric acid (GABA) is considered to be a major inhibitory neurotransmitter in the central nervous system. Our previous studies have demonstrated a uniform distribution of GABA immunoreactive synaptic terminals in the ventral horn of the cat. In the present study we have examined the presence of $GABA_A$ and $GABA_B$ binding sites in cat spinal cord levels C_{4-6} using in vitro autoradiography with [^{3}H]muscimol to label high affinity $GABA_A$ binding sites and [^{3}H]baclofen for $GABA_B$ binding sites. Each ligand was used at a concentration at or below its calculated K_D. Autoradiograms of [^{3}H]muscimol labeled tissue sections demonstrated moderate grain density in a uniform pattern over the entire ventral horn. Although [^{3}H]baclofen labeled tissue sections had an overall lower grain density than $GABA_A$ binding sites, its binding sites were present in the same regions of the ventral horn as the $GABA_A$ binding sites. The distributions of $GABA_A$ and $GABA_B$ binding sites in a pattern similar to GABAergic immunoreactive terminals, suggests a possible morphological correlate for GABAergic receptors in the ventral horn of the cat. Supported by NIH Grant NS23861 to B.E.M.

459.16

AUTORADIOGRAPHIC COMPARISON OF PERIPHERAL-TYPE BENZODIAZEPINE BINDING SITES IN HUMAN AND RAT KIDNEY. J.M. Olson, B.J. Ciliax, W.R. Mancini and A.B. Young. Depts. of Pharmacology and Neurology and the Neuroscience Program, University of Michigan, Ann Arbor, MI 48109.

The affinity of isoquinolines, benzodiazepines and diuretics were compared autoradiographically in postmortem human and rat kidneys. No interspecies differences were observed in the binding of the isoquinoline PK 11195 (Human: K_D = 6.1± 1.5, B_{Max} = 5.3± 1.0 pmol/mg prt.; Rat: K_D = 7.2 nM, B_{Max} = 7.7 pmol/mg prt.). The benzodiazepines Ro5-4864, diazepam and flunitrazepam however, bound with lower affinity to human kidney (K_i = 217± 65 nM, 1.1± 0.9 μM, > 10 μM, respectively) than to rat kidney (K_i = 87± 12 nM, 810± 220 nM, 1.06± .3 μM, respectively). Homogenate studies confirmed the interspecies difference. In both species, the apparent affinity of benzodiazepines for PBBS was significantly higher in homogenate studies than in autoradiographic studies. The ability of some unlabeled diuretics to compete with [^{3}H]PK 11195 also differed between human and rat kidney. The percent of specific [^{3}H]PK 11195 binding which remained in the presence of 1 mM metolazone, diazoxide, hydrochlorothiazide, trichloromethiazide, ethacrynic acid, furosemide and acetazolamide was 7%, 80%, 70%, 100%, 33%, 62%, 82%, respectively in human kidney cortex and was 0%, 81%, 58%, 53%, 62%, 72%, 100%, respectively in rat. Standard errors were 5-10% for furosemide and acetazolamide and less than 5% for all others. Supported by NIH Grant NS 15655.

AUTORADIOGRAPHY OF LOCUST CNS GABA RECEPTORS. L.P.Schouest,Jr.,T.A.Miller* and R.W.Olsen*. Dept. of Entomol., Univ. of Calif.,Riverside, CA 92521.

Receptor autoradiography was used for the localization and characterization of insect CNS GABA receptors using $GABA_A$ agonists and antagonists as competitive binders to ^{3}H-muscimol and ^{3}H-TBPS. Competitive binding results were compared to sections incubated in ^{3}H-muscimol. Adjacent sections were utilized in the incubation procedure (Lunt, G.G., Robinson, T., Miller, T., Knowles, W.P. and Olsen, R.W. Neurochem. Int. 1985 7 751-754), so differently treated sections were anatomically equivalent. Locust brain and/or thoracic ganglia (*Schistocerca americana*) was dissected out, frozen, sectioned, incubated, dried and exposed to LKB Ultrafilm. Image analysis consisted of enlarging and digitizing the autoradiograms via a linear photodiode array 12-bit CCD camera. Digitized images were transferred to an image analysis program where the quantitated image was edited and analyzed. A four-page image board allowed comparisons between control and three adjacent sections. Tritium standards placed with the slides during the film exposure period provided quantitative calibration of optical density values. Composite images were constructed, stored as a new image thus allowing direct readings of optical density from each autoradiographic image. Optical density readings were automatically converted to DPM based on a standard curve obtained from digitizing calibration standards. Three-dimensional images of brain and thoracic ganglia were compiled from concurrent adjacent sections and transferred into a three-dimensional reconstruction program. Our results indicate competitive binding of GABA receptors was seen for muscimol and TBPS. Overlay subtraction of images showed specific GABA receptor locations for the lamina ganglionaris, some portions of the medulla, lobula plate and glomerulus. GABA receptors were also localized in the thoracic ganglia in specific lateral regions.

CHARACTERIZATION OF THE BENZODIAZEPINE RADIOLIGAND 125 I-RO 16-0154: POTENTIAL PROBE FOR SPECT BRAIN IMAGING . E.W. Johnson, S.W. Woods, and R.B. Innis. Department of Psychiatry, Yale University School of Medicine, 34 Park Street, New Haven CT 06508.

Benzodiazepine (BZ) receptor function has been implicated in the pathophysiology of several diseases, including epilepsy and anxiety disorders. Brain imaging of neuroreceptors is a noninvasive technique to directly measure in vivo receptor activity. We have examined an iodinated benzodiazepine ligand as a potential probe for Single Photon Emission Computed Tomography (SPECT) brain imaging.

Ro 16-0154 is a close analog of the benzodiazepine antagonist Ro 15-1788, differing only in the substitution of iodine for flourine on the adjacent number 7 carbon. We have used 125 I-labeled Ro 16-0154 in homogenate binding studies prepared from cerebral and cerebellar cortical tissue from both monkey (Macaca mulatta) and human. 125 I-labeled Ro 16-0154 binding was saturable, of high affinity (approx. 2 nM), and had high ratios of specific to nonspecific binding (approx. 40:1). The specificity of the radioligand binding to the BZ receptor was confirmed with multiple displacement studies. Studies are currently ongoing using the 125 I-labeled Ro 16-0154 for both in vivo and in vitro autoradiography of BZ receptors.

These preliminary studies indicate that 123 I-labeled Ro 16-0154 may be a potentially useful SPECT probe for in vivo imaging because of its pharmacological specificity, high affinity, and low nonspecific binding.

We gratefully acknowledge Medi-Physics, Inc. (subsidiary of Hoffman-La Roche, Inc.) for supplying 125 I-Ro 16-0154.

MONOAMINES AND BEHAVIOR IV

460.1

THE ACUTE DOPAMINERGIC ACTIVATING EFFECTS OF NICOTINE ARE REDUCED FOLLOWING REPEATED ADMINISTRATION. P. Vezina, G. Blanc*, J. Glowinski* and J.-P. Tassin*. Chaire de Neuropharmacologie, INSERM U.114, Collège de France, 75231 Paris Cedex 05, France.

Acute systemic injections of nicotine produce increased locomotion in rats and repeating these injections has been shown to produce a more pronounced or enhanced locomotor effect. Different lines of evidence suggest that mesolimbic dopaminergic (DA) activation may underlie the acute locomotor effects of nicotine. The present study assessed the effect of acute as well as repeated systemic injections of nicotine on DA transmission (DOPAC/DA) in different DA terminal fields in the rat.

Acute injections of (-)-nicotine bitartrate (0.4-0.8 mg/kg, base, s.c.) produced substantial increases (41-49%) in the DOPAC/DA ratio in the nucleus accumbens and more moderate increases (26-37%) in the antero-medial striatum. No effect was detected in the dorso-lateral striatum. Surprisingly, repeating these injections reduced or abolished these increases in DA activity: following five daily injections, nicotine produced much reduced increases in DOPAC/DA in the nucleus accumbens (15-26%) and no longer had an effect in the antero-medial striatum.

Given the evidence that enhanced DA transmission underlies behavioral sensitization to psychomotor stimulants and to opiates, the present results suggest that nicotine differs from these two classes of drugs in the manner in which it produces enhanced locomotor effects following repeated injection.

(Supported by NSERC, INSERM and Philip Morris Europe.)

460.2

INDUCTION OF BITING BEHAVIOR (BB) FOLLOWING INTRASTRIATAL INJECTION OF DOPAMINE (DA) AGONISTS INTO RATS WITH UNILATERAL SUPERSENSITIVE DA RECEPTORS. Y. Okamoto*, H. Nakashima* and M. Goldstein (SPON: B. Reisberg). Neurochem. Res. Lab, N.Y. Univ. Med. Ctr., New York, NY 10016.

The role of dopaminergic neuronal systems in behavioral abnormalities of Lesch-Nyhan syndrome and some mental retardation were investigated by measuring the effects of D_1 and D_2 DA agonists on supersensitive DA receptors in rats. Previous studies have shown that microinjections of amphetamine into the middle ventrolateral (MVL) portion of the striatum produce compulsive oral stereotypy (A. Kelley et al., Psychopharmacol. 95:356, 1988). We have now investigated the effects of microinjections of DA agonists into this striatal area of rats with supersensitive DA receptors rendered by unilateral denervation of the nigrostriatal DA neurons with 6 OH-DA. Surgical procedures were carried out under pentobarbital anesthesia and recovery from surgery was monitored. The microinjections of the mixed D_1/D_2 agonist apomorphine, the D_1 DA agonist SKF 38393, or the D_2 DA agonist quinpirole, dose-dependently induce BB for various periods of time. The BB induced by apomorphine is completely prevented by systemic administration of the D_2 DA antagonist raclopride (0.3 mg/kg; i.p.) in combination with the D_1 DA antagonist SCH-23390 (0.3 mg/kg; i.p.), and that induced by SKF 38393 is prevented by SCH 23390 (0.3 mg/kg; i.p.) alone, while that induced by quinpirole is prevented by raclopride (0.3 mg/kg; i.p.) alone. These results indicate that both D_1 and D_2 DA receptors are involved in mediating BB and that the MVL area of the striatum might be one of the centers involved in this abnormal behavior. Supported by NIMH 02717 and NINCDS 06801.

460.3

ENHANCEMENT OF CONDITIONED REINFORCEMENT: EFFECTS OF MICRO-INJECTION OF AMPHETAMINE INTO STRIATAL SUBREGIONS AND OF PEPTIDES INTO VENTRAL TEGMENTAL AREA. A.E. Kelley, J. Delfs* and C.G. Lang*. Dept. of Psychology, Harvard University, Cambridge, MA 02138.

Psychostimulant drugs have been shown to enhance conditioned reinforcement. In this study, hungry rats were trained to associate a compound stimulus (light/click) with delivery of a food pellet. During the test phase,two levers were introduced into the box and pressing the correct lever (CR lever) was reinforced by the stimulus alone. On four test days, amphetamine (0, 0.2, 2.0, 20 ug) was infused into the following regions in separate groups of rats: nucleus accumbens, ventromedial (VMS), ventrolateral (VLS), anterior dorsal (ADS), and posteral dorsal (PDS) striatum. Amphetamine infused into the nucleus accumbens enhanced conditioned reinforcement (CR). Infusion into the VMS selectively enhanced CR at the medium dose, but abolished responding at the high dose. Injection into the VLS produced strongly increased responding which was not selective for the CR lever. Amphetamine infusion into the ADS significantly increased CR only at the highest dose. Infusion into the PDS had no significant effect. In further experiments, substance P (SP) and d-ala-met-enkephalin were injected into the ventral tegmental area (VTA). SP caused a small increase in lever pressing, but this effect was not selective for the CR lever. DALA had no effect on lever pressing.

FURTHER STUDIES OF THE ROLE OF SUBPALLIDAL-PEDUNCULOPONTINE PROJECTIONS IN LOCOMOTOR ACTIVITY. G. J. Mogenson, M. Wu* & S. M. Brudzynski. Dept. of Physiology & Dept. of Clinical Neurological Sciences, Univ. of Western Ontario, London, Ontario, Canada N6A 5C1.

There is a good deal of experimental evidence implicating nucleus accumbens-subpallidal projections in locomotor activity. It has not been established, however, whether locomotion is mediated by subpallidal outputs to the pedunculopontine nucleus, the site of the mesencephalic locomotor region, or to the mediodorsal thalamus (Mogenson & Wu, Brain Res. Bull., 20:241-246, 1988; Swerdlow & Koob, Brain Res., 412:233-243, 1987). In the present study the role of subpallidal-pedunculopontine projections in locomotor activity was investigated further. Locomotion measured in an open-field was elicited by injecting dopamine unilaterally into the accumbens or by injecting picrotoxin unilaterally into subpallidal region of rats. The effects of unilateral electrolytic lesions or of unilateral injections of kainic acid or ibotenic acid into the pedunculopontine nucleus (PPN) were investigated.

A significant and consistent reduction of locomotor activity was obtained with unilateral electrolytic or kainic acid lesions of PPN. Ibotenic acid lesions of PPN had a smaller or no effect. These results provide an additional evidence that the subpallidal-pedunculopontine output plays an important role in locomotor activity.

METOCLOPRAMIDE ENHANCES SHOCK-INDUCED FREEZING: IMPLICATIONS FOR DISRUPTION OF AVOIDANCE BY NEUROLEPTICS. J.R. Blackburn and A.G. Phillips, Dept. of Psychology, University of British Columbia, Vancouver, BC, Canada, V6T 1Y7.

Administration of the neuroleptic drug metoclopramide (MET; 5.0 mg/kg) potentiated freezing responses of rats to 1.0 mA footshock, but did not produce any pre-shock freezing. To determine if inappropriate freezing responses could contribute to deficits in active avoidance produced by MET and other neuroleptics, drugged and undrugged rats received unavoidable footshock prior to each of ten one-way avoidance trials, in one experiment, or prior to the avoidance session, in a second experiment. In neither case was the performance of control rats adversely affected, but in each case the performance of MET-treated rats was significantly disrupted. A third experiment demonstrated that presentation of a conditional stimulus previously paired with shock disrupted the avoidance performance of MET-treated rats but enhanced the performance of saline-treated rats. We conclude that the enhancement of freezing by neuroleptic drugs contributes to the deficit in avoidance responding produced by their administration.

HISTAMINE AND NEUROLEPTIC-INDUCED CATALEPSY. **A.Yagi*, H.Azuma*, T.Nishimura*, T.Yamamoto*§, A.Yamatodani*# and H.Wada*# (Spon: K.Kanosue) Departments of Psychiatry and #Pharmacology II, Faculty of Medicine, Osaka University, Osaka 530 and §Faculty of Liberal Arts, Tezukayama University, Nara 631, Japan.**

The effects of histaminergic neuromodulation on the neuroleptic induced catalepsy was studied in male ddY mice (25-30g). Catalepsy was evaluated by forcing the mouse to grasp a glass bar of 7 mm diameter set horizontally at the height of 4 cm with its forepaws, and recording the duration of the behavior and the response to tail pinching as a score of 0 to 5. Histamine was determined by HPLC-fluorometry. The i.p. administrations of perphenazine (20 mg/kg) and haloperidol (10 mg/kg) induced cataleptic behavior and increases of 29% and 22%, respectively, in the brain histamine content 120 min after their administrations. Dose-dependent changes of brain histamine were observed in the dose ranges of 2 to 20 mg/kg of perphenazine and 2 to 10 mg of haloperidol. Pretreatment with L-histidine (1g/kg, i.p.) enhanced the cataleptic behavior, whereas pretreatment with alpha-fluoromethylhistidine (100 mg/kg), a specific inhibitor of histamine synthesis, reduced it. Furthermore, pretreatments with mepyramine (50 mg/kg, i.p.) and cimetidine (200 mg/kg, i.p.) attenuated the catalepsy. These results suggest that the histaminergic neuron system play some roles in the neuroleptic induced catalepsy.

LOCAL INJECTION OF DOPAMINE ANTAGONISTS INTO THE PREFRONTAL CORTEX OF MONKEYS INDUCES DEFICITS IN MEMORY-GUIDED SACCADES. T. Sawaguchi and P.S. Goldman-Rakic. Sec. Neuroanat., Yale Univ. Sch. of Med., New Haven, CT06510

While monkeys were performing an oculomotor delayed-response task, dopamine antagonists were injected locally into the prefrontal cortex. Monkeys fixated a central spot, and, following a delay of 1-7 sec, made a memory-guided saccade to the location which had been indicated prior to the delay by a visual cue. Following injection of SCH23390 or haloperidol (10-80ug/1-8ul), the accuracy of saccades to the remembered targets decreased, and the latency of the saccade was increased. These deficits were mainly contralateral to the injection site and always associated with a few specific locations, which varied with injection site. Moreover, the degree of change was dose dependent and also sensitive to the length of the delay period. No significant changes were observed for visually-guided saccades within the same drug sessions when memory-guided saccades were impaired. In addition, injections of sulpiride (up to 100ug/10ul) failed to induce any significant performance decrement either in memory-guided or visually-guided saccades. These results suggest that the activation of dopamine receptors, probably of D1 receptors, is normally involved in the initiation and control of eye movements guided by memory of visuo-spatial representations in the prefrontal cortex.

NONLINEAR SENSITIZATION OF ACTIVITY PRODUCED BY CHRONIC TREATMENT WITH THE D2 AGONIST QUINPIROLE. H. Szechtman, G. Canaran*, F. Ibrahim* and D. Eilam. Dept. Biomedical Sci., McMaster Univ., Hamilton, Ontario, CANADA L8N 3Z5.

An acute injection of quinpirole (0.5-2 mg/kg) has a biphasic effect on activity: in the first minutes after injection, it reduces activity; in the second hour after injection, it increases the amount of forward progression (Eilam et al, BR, in press; EJP 161 (1989) 151). In the present study, we investigated the change in activity produced by chronic treatment with quinpirole (0.5 mg/kg). Rats were tested in a large open field or in Digiscan Activity cages. Results showed that during the course of repeated injections, the profile of progression underwent 4 changes: 1) the period of inhibition diminished across injections, until inhibition was very brief or was not apparent altogether; 2) the onset of excitation advanced progressively, until ultimately excitation began within minutes after injection and did not terminate by the end of a 2 hour test; 3) the speed and the amount of activity increased profoundly, being more than 8 fold higher by end of treatment; and finally, 4) the amount of activity increased non-linearly across injections, rising abruptly after the second or third injection, and then continuing gradually to a new plateau. These data suggest that repeated exposures to quinpirole alter the dynamic properties of dopaminergic systems, shifting them to a new level of responsiveness in discrete steps.

460.9

COMPULSIVE AND RIGID LOCOMOTION PRODUCED BY CHRONIC TREATMENT WITH THE D2 AGONIST QUINPIROLE. D. Eilam, G. Canaran* and H. Szechtman. Dept. Biomedical Sciences, McMaster Univ., Hamilton, Ontario, CANADA L8N 3Z5.

An acute injection of quinpirole (2 mg/kg) induces hyperactivity, perseverative locomotion along fixed routes, and no stereotypy of movements (Eilam et al, BR, in press). In the present study, we investigated how this pattern is affected by chronic treatment. Rats (n=4) were injected with quinpirole (0.5 mg/kg) and placed in a large open field for 2 hrs for a total of 41 tests. Results showed that during the course of repeated injections, trajectories of progression became increasingly more rigid. Thus, from the 10th injection onwards, as many as 98% of all trajectories were confined to movement along one and the same path. This rigid and compulsive locomotion was rapid and incessant, yielding a very profound elevation in total distance traversed (see previous poster). Marked oral stereotypies or other perseverative movements did not develop. Interestingly, while the behavioural profile to an acute injection varied among the animals, by the end of treatment their behaviour was remarkably alike. Additional tests showed that an injection of saline was insufficient to evoke the drug-induced behaviour, and that the drug-induced profile persisted for at least 2 mo following the cessation of treatment. These results suggest that repeated stimulation of dopaminergic systems produces not only persistent activity (see previous poster) but also confines its spread in the environment to an ever narrower focus. Dopaminergic drugs differentially affect attack versus defense in play fighting by juvenile rats. H.M. Marshall*, S.M. Pellis, V.C. Pellis and P. Teitelbaum. Dept. Psychol., Univ. Florida, Gainesville, FL 32611.

Previous studies have reported that low doses of the dopaminergic agonist apomorphine increase the frequency of play fighting in juvenile rats (30-40 days old), whereas low doses of the antagonist haloperidol, decrease the frequency (e.g., Beatty W.W. et al., Pharmacol. Biochem. Behav. 20 : 747-755, 1984). These effects could have occurred via changes in playful attack, playful defense, or both. In the present study, attack (i.e., approach to the nape) and defense (i.e., withdrawal of the nape) were measured separately. After 24 h isolation, 15 min after injection, sibling rats were reunited and their behavior was videotaped under red light for 10 min. Apomorphine (0.05 and 0.3 mg/kg) significantly increased playful attack, whereas haloperidol (0.15 and 0.3 mg/kg) significantly decreased attack. Neither drug affected playful defense at these doses. Therefore, dopaminergic systems affect play fighting via the approach components, not those of withdrawal.

THE EFFECTS OF DOPAMINE AGONISTS ON THE DRL 72-S SCHEDULE. R. Dunn, D. Jolly* and L. Seiden. Dept. of Pharmacological and Physiological Sciences, Univ. of Chicago, Chicago, IL 60637.

Antidepressants increase the reinforcement rate and decrease the response rate of rats performing on a differential-reinforcement-of-low rate 72-second (DRL 72-S) operant schedule (Seiden et al, Psychopharmacol. **86**:55, 1985). The present work examines the effects of dopaminergic agonists on this antidepressant screen. PPHT, a selective D-2 agonist, decreased the reinforcement rate and increased the response rate of rats performing on a DRL 72-S schedule. Similar DRL 72-S schedule performance changes are seen with amphetamine. In contrast, up to 10 mg/kg of the D-1 agonist SKF 38393 did not significantly affect DRL 72-S schedule performance. These results are consistant with the effects of amphetamine on the DRL 72-S schedule being mediated by D-2 agonist activity. Low doses of apomorphine increased the reinforcement rate and decreased the response rate of rats on a DRL 72-S schedule. Low doses of apomorphine may have preferential activity at dopamine autoreceptors. The dopamine autoreceptor agonists TL-99 and 3-PPP also increased the reinforcement rate and decreased the response rate of rats on a DRL 72-S schedule. Thus, dopamine autoreceptor stimulation induced antidepressant-like effects on the DRL 72-S schedule. This research was supported by PHS MH-11191; RSA MH-10562 (L.Seiden).

INDUCTION OF SELF-INFLICTING BITING BEHAVIOR (SBB) FOLLOWING INTRASTRIATAL INJECTION OF DOPAMINE (DA) AGONISTS INTO RATS WITH UNILATERAL SUPERSENSITIVE DA RECEPTORS. Y. Okamoto*, H. Nakashima* and M. Goldstein (SPON: B. Reisberg). Neurochem. Res. Lab, N.Y. Univ. Med. Ctr., New York, NY 10016.

Since microinjections of amphetamine into the middle ventrolateral (MVL) portion of the striatum produce compulsive oral stereotypy (A. Kelley et al., Psychopharmacol. 95:356, 1988), we have investigated the effects of microinjections of DA agonists into this striatal area of rats with supersensitive DA receptors rendered by unilateral denervation of the nigrostriatal DA neurons with 6 OH-DA. The microinjections of the mixed D_1/D_2 agonist apomorphine, the D_1 DA agonist SKF 38393, or the D_2 DA agonist quinpirole, dose-dependently induce SBB for various periods of time. The SBB induced by apomorphine is completely prevented by systemic administration of the D_2 DA antagonist raclopride (0.3 mg/kg) in combination with the D_1 DA antagonist SCH-23390 (0.3 mg/kg), and that induced by SKF 38393 is prevented by SCH 23390 (0.3 mg/kg) alone, while that induced by quinpirole is prevented by raclopride (0.3 mg/kg) alone. These results indicate that both D_1 and D_2 DA receptors are involved in mediating SBB and that the MVL area of the striatum might be one of the centers involved in this abnormal behavior. THE EFFECTS OF APOMORPHINE ON ACTIVITY AND EXPLORATION OF RATS WITH FORNIX TRANSECTIONS. S. Wood* and B. Osborne. Department of Psychology, Middlebury College, Middlebury, VT 05753.

Previously we have demonstrated that selective dopamine agonists reduce the activity levels of rats with fornix transections back to control levels. The present work examines the possibility that the agonists are increasing dopamine by acting selectively on autoreceptors. Control and fornix lesioned rats were assigned to 3 groups and received a low dose of apomorphine, a high dose of apomorphine, or a vehicle injection. Ten minutes after the injection, the rats were placed in an open field environment for ten minutes. A detailed behavioral analysis was performed that noted total activity as well as latency to move, and number and duration of rearing bouts, object interactions, and stereotypy. Previous findings were replicated including an increase in total activity and number of object interactions with decreased durations for fornix lesioned animals. Apomorphine produced a general depression of total activity for all groups as well as increased object durations with fewer object interaction bouts. The control animals displayed more stereotyped behavior than the fornix animals. Interpretations of the data are difficult because of the strong effect of apomorphine on control animals. Either the dose levels of apomorphine were too high or previous reports are not due to stimulating autoreceptors.

GENETIC SELECTION FOR AGGRESSION IN MICE: REVERSAL BY LOW–DOSE APOMORPHINE. M.H. Lewis, J.L. Gariepy, L.L. Devaud, S. Southerland, R.B. Mailman, and R.B. Cairns*. Biol. Sci. Res. Ctr. and Depts. of Psychiatry, Pharmacology, and Psychology, University of North Carolina, Chapel Hill, NC 27514

ICR mice have been selectively bred over 19 generations for high or low levels of aggression. Low aggressive mice have decreased concentrations of dopamine, DOPAC, and HVA in nucleus accumbens and caudate nucleus, accompanied by an increased dopamine receptor density in these same terminal regions. The hypothesis that central dopamine systems mediate genetic selection effects was tested further in the present study. High (NC900) and low (NC100) aggressive lines of mice were treated with apomorphine (0.01–0.55 mg/kg), and their non–social and social behavior quantified. Apomorphine (ED_{50}=0.1 mg/kg) dramatically altered the behavior of the high aggressive (NC900) line, eliminating attack behavior and inducing freezing, behaviors characteristic of the low aggressive (NC100) line. Apomorphine also significantly altered the frequency of non–social behavior, decreasing jumping, climbing, rearing, and locomotion. These effects were not due simply to impairment of motor activity, as apomorphine significantly increased the frequency of active avoidance of the test partner, startle responses, reflexive kicking, and freezing. Low aggressive (NC100) mice also showed decreased attack behavior, and increased avoidance, startle, and reflexive kicking, as well as decreases in climbing, rearing, and locomotion. Neurochemical analyses showed that the behavioral effects were related to drug–induced decreases in the synthesis and release of dopamine. These data support the hypothesis that dopamine mediates line differences induced by genetic selection. (Supported, in part, by PHS Grants HD14648, HD03110, and HD07201.)

ASYMMETRICAL DOSE-RESPONSE FOLLOWING MICROINJECTIONS OF APOMORPHINE IN THE NUCLEUS ACCUMBENS. M.Honig*, I.Belcheva* S.E.Starkstein, T.H.Moran, R.G.Robinson

In previous studies, we reported that right but not left hemisphere electrolytic lesions of the nucleus accumbens (NA) produced a sustained (30 + day) period of spontaneous running wheel hyperactivity (Kubos, K.L. et al., Brain Res. 401:147-151,1987) and that right but not left fronto-lateral cortical suction lesions produced an increased turnover of dopamine in the NA (Starkstein, S.E. et al., Brain Res., 473:74-80,1988). In the present experiment, male Sprague-Dawley rats (N=9) were implanted with chronic bilateral cannulas in the NA and randomly given right or left NA injections of .32, 1, 3.2, or 10 ug of apomorphine or saline in 1 ul volume every 3 days. Post-injection activity was monitored in 20 minute intervals over 2 hours using computerized photocell (Omnitech) chambers. A 3-way ANOVA revealed significant effects of hemisphere of injection (F_1, 480 = 12.1, $p<.001$), dose (F_4, 480 = 12.7, $p<.001$) and time (F_5, 480 = 36.1, $p<.001$). The only interaction that was significant was side by dose (F_4, 480 = 5.2, $p<.001$). Post-hoc planned comparison t-tests demonstrated significant right versus left hemisphere differences over the 2 hour test period for the .32 ug and 1.0 ug doses (t-12.8 and 8.0, $p<.001$ respectively). These data are consistent with our previous suggestion that subcortical asymmetries in the NA or at another post-synaptic site may play an important role in spontaneous activity and the asymmetrical response to cortical or NA lesions.

DOPAMINERGIC EFFECTS ON MATERNAL BEHAVIOR AND MILK-EJECTION IN LACTATING RATS. J.M. Stern and L.A. Taylor
Rutgers University, Department of Psychology, New Brunswick, NJ 08903.

Dopamine (DA) is important in the maintenance of repetitive, stereotyped motor sequences. Moderate doses of haloperidol (HAL), a non-selective dopamine antagonist, disrupt the motorically active components of female sexual behavior (hops, darts; i.e., proceptivity), while leaving the lordosis reflex (i.e., receptivity) intact (Hansen, Stanfield, & Everitt, Neuroscience, 1981). Accordingly, we tested whether a similar dissociation occurs between the motorically active components of maternal behavior (retrieval, licking) and nursing behavior (posture characterized by immobility, a pronounced dorsal arch, and splayed legs). In addition, we re-examined the controversial issue of whether DA inhibits or stimulates oxytocin release, and therefore milk-ejection.

On day 7 or 8 postpartum, dams were separated from their litter for 4 hours. One hour prior to reunion, dams were injected i.p. with HAL (0, 200 ug, 400 ug, 5 mg, or 8 mg/kg). At five minutes after reunion, the experimentor gathered pups in the nest and placed the dam over them, if necessary.

We found a dose-dependent disruption of retrieval and licking of pups. Nursing behavior, however, was not impaired; rather, the crouching posture was enhanced. At 30 minutes after the onset of nipple attachment (by 6 out of 8 pups), the 200 and 400 ug litters gained about 4 times as much weight as controls; 5 mg litters gained about 2 times as much, while 8 mg litters did not differ from controls.

These data suggest that normally DA is necessary for the motorically active components of maternal behavior and inhibits milk-ejection (i.e., oxytocin release). Thus, nursing behavior and physiology depend on inhibition of DA, within physiological limits.

460.17

D1 AND D2 RECEPTORS IN THE MPOA REGULATE COPULATION AND PENILE REFLEXES IN MALE RATS. E. Hull, R. Eaton*, J. Thompson*, T. Bazzett* and V. Markowski*.
Dept. of Psychology, SUNY at Buffalo, Amherst, NY 14260.

We have reported that the D2 agonist LY-163502 (quinelorane) or the D1 antagonist SCH-23390, microinjected into the medial preoptic area (MPOA) of male rats, delayed the onset of copulation and slowed its rate, but then lowered the ejaculatory threshold (decreased the number of intromissions required to trigger ejaculation). We now report that the D2 agonist also decreased the number of erections and penile movements in reflex tests of restrained, supine animals. Seminal emissions were increased. Thus, the delayed onset and slowing of copulation may have reflected an impairment in erectile function, which is primarily controlled by the parasympathetic system. The decreased ejaculatory threshold in copula may have been associated with an increase in sympathetically mediated seminal emission.

The D2 antagonist raclopride in the MPOA also delayed the onset of copulation and decreased its rate, and lowered ejaculatory threshold, similar to the effects of the D2 agonist. Preliminary data suggest that its effects on penile reflexes are also similar to those of the D2 agonist. Thus, it appears that any shift in the D1/D2 ratio in the MPOA may alter the balance of autonomic influence on reflexive penile mechanisms, and thereby alter copulatory parameters.

DOPAMINE-2 AGONIST, LY163502, ACTS CENTRALLY TO STIMULATE MALE SEX BEHAVIOR OF RHESUS MONKEYS. S. M. Pomerantz. Dept. of Physiology, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261.

Recent studies demonstrated that dopamine agonists facilitate male sexual behavior of rhesus monkeys (Soc. Neurosci. Abstr. 14: 664, 808, 1988). In order to determine whether the D2 agonist, LY163502, acts centrally or peripherally to stimulate male sexual behavior, the ability of dopamine antagonists, domperidone (DOM, peripheral action only) or haloperidol (HAL, central and peripheral action) to block the sexual response to LY163502 was examined. Non-copulatory male sex behaviors of monkeys (penile erection and masturbation) were assessed in a testing situation in which monkeys were presented with a female monkey they could see, hear and smell, but not physically contact. Eight monkeys were rotated through treatments in which they recived either 50, 100 or 200 µg/kg DOM or vehicle forty min prior to testing and 5 µg/kg LY163502 or vehicle 10 min prior to testing. LY163502 facilitated penile erection ($p<0.001$) and masturbation ($p<0.05$) over vehicle levels, both in monkeys pretreated with DOM and those not pretreated with DOM. Evidence that DOM was acting as a peripheral dopamine antagonist was obtained from two male monkeys in which 100 µg/kg DOM markedly stimulated prolactin release. Administration of LY163502 following DOM in these monkeys failed to reduce prolactin to control baseline levels. In contrast to DOM, the centrally active dopamine antagonist, HAL, blocked the sexual response to LY163502. In monkeys pretreated with 10 µg/kg HAL 50 min prior to LY163502, male sexual behavior was markedly reduced compared to monkeys pretreated with vehicle prior to LY163502. These results indicate that systemically administered dopamine agonists act centrally to stimulate male sexual behavior of rhesus monkeys.

460.19

HALOPERIDOL SUPPRESSES LEVER PRESSING FOR FOOD BUT INCREASES FREE FOOD CONSUMPTION IN A NOVEL FOOD CHOICE PROCEDURE. J.D. Salamone, L.D. McCullough, and R. Steinpreis (SPON: W. Wilson).
Department of Psychology, University of Connecticut Storrs, CT 06269-1020.

An aspect of motivation that is related to motor function is that organisms will perform work to obtain access to significant stimuli. A novel procedure was developed to investigate how this phenomenon is related to dopamine function. Food-deprived rats were tested in an operant chamber in which they could press a lever to obtain a more-preferred food, or freely feed on a less-preferred food. Untreated rats pressed the lever to obtain the more-preferred food pellets, and ate little of the less-preferred food even though it was freely available. Injection of 0.1 mg/kg of haloperidol (HP) dramatically shifted the behavior of these rats, such that the number of lever presses was reduced, but the consumption of the less-preferred food increased significantly. Thus, a low dose of HP suppressed lever pressing for food, although the behavior of the animal still was directed towards food consumption. The present results may be related to the motor slowing that occurs in mild Parkinsonism and depression.

HALOPERIDOL IMPAIRS CLASSICALLY CONDITIONED EYELID RESPONSES AND CONDITIONING-RELATED ACTIVITY IN THE INTERPOSITUS NUCLEUS. L.L. Sears* and J.E. Steinmetz, Prog. in Neural Sci., Dept. of Psych., Indiana Univ., Bloomington, IN, 47405.

Previous studies of the effects of haloperidol (HAL) on a form of motor learning, classical conditioning of the rabbit eyelid response, showed a decrease in the number of conditioned responses (CRs) when intermediate intensities of an acoustic conditioned stimulus (CS) were used suggesting that the neuroleptic increased the threshold for detecting an auditory CS (Harvey, J.A. & Gormezano, I., J. Pharmacol. Exp. Therap., 218:712, 1981). In an initial attempt to describe the effects of HAL on neural activity associated with eyelid conditioning, the present study examined the effects of HAL administration on learning-related activity in the cerebellar interpositus nucleus, a structure known to be involved critically in classical eyelid conditioning.

While under ketamine/xylazine anesthesia, 8 rabbits were implanted with multiple-unit recording electrodes in the left interpositus. Following recovery, each rabbit was given 6 classical eyelid conditioning sessions with a tone CS and air puff US (12 blocks/session, 10 trials/block) while interpositus recordings were made. Four CS intensities were used during training (95, 85, 75, and 65 dB). Before Sessions 1-3, saline was injected as a control procedure. During Sessions 4-6, 4 blocks of training were given (1 block at each CS intensity), 250 µg/kg HAL was injected i.v., 10 min allowed to elapse, and 8 blocks of post-drug paired training then given. No differences in spontaneous activity of the interpositus were observed when pre- and post-HAL data were compared. No behavioral deficits or changes in interpositus firing patterns were observed when the 95 dB tone was used. However, a significant decrease in percent CRs and a significant reduction in learning-related interpositus activity were observed when 85 and 75 dB tones were used. Training with a 65 dB tone failed to produce CRs or training-related interpositus activity. These data indicate that in addition to disrupting CRs, HAL also disrupts CR-related activity in the interpositus nucleus when intermediate intensities of an acoustic CS are used. HAL apparently disrupts conditioning by altering interpositus activity directly or by altering activity in brain regions afferent to the interpositus nucleus. [Supported by NIMH Grant #MH44052.]

L-2-AMINO-4-PHOSPHONOBUTYRATE REDUCES CALCIUM CURRENTS IN HIPPOCAMPAL CA1 AND ENTORHINAL CORTICAL NEURONS MAINTAINED IN CULTURE.

R.A.J. Lester and C.E. Jahr. Vollum Institute for Advanced Biomedical Research, Oregon Health Science University, Portland, OR 97201.

The depression of synaptic transmission by the glutamate analog L-2-amino-4-phosphonobutyrate (L-APB) in certain hippocampal pathways is thought to occur presynaptically. Whole-cell recordings were obtained from neonatal rat hippocampal CA1 and entorhinal cortical neurons maintained in culture for 4-14 days. Sodium currents were blocked by TTX (0.5 μM) and outward currents by internal cesium (150 mM). ATP (5 mM), to reduce run-down of calcium currents, and GTP (1 mM) were included in the internal solution. In the presence of calcium (2mM) or barium (2mM) depolarizing steps from -70 and -40 mV produced inward currents that were completely blocked by external cadmium chloride (200 μM). L-APB (10-100 μM), applied by fast-perfusion, rapidly and reversibly reduced the peak calcium current by 5-25 % in 16/23 neurons examined. L-glutamate (1 μM) mimicked the action of L-APB under conditions in which activation of NMDA, kainate and quisqualate receptors was prevented by kynurenic acid (200 μM), D-2-amino-5-phosphonovalerate (20 μM) and 6-cyano-7-nitroquinoxalone-2,3-dione (20 μM). A reduction in calcium entry into presynaptic neurons may explain the depression of synaptic transmission induced by L-APB.

461.2

INTERACTIONS BETWEEN QUISQUALATE/KAINATE AGONISTS AT EXCITATORY AMINO ACID RECEPTORS ON STRIATAL NEURONS IN PRIMARY CULTURE.

F.W.Y. Tse, B.A. MacVicar and S. Weiss. Neuroscience Research Group, University of Calgary, Calgary, Alberta T2N 4N1.

We voltage-clamped striatal neurons (cultured 7-8 days from E15 mice) at -80mV (with KF patch-electrode) to examine interactions among the following excitatory amino acid agonists: kainate (KA), quisqualate (QA), glutamate (Glu) and AMPA (a selective QA agonist). Each agonist was applied either by pressure ejection from a micropipette, or by bath perfusion. In most cells, a sustained inward current (which reversed near 0mV) was activated by each of the agonists (10-100μM); at equimolar concentrations the relative amplitude of these currents was in the order of: KA >> Glu = AMPA > QA. When 100μM QA was applied to some cells by pressure ejection, a transient inward current was also activated; similar transient currents were never observed with pressure ejection of KA, at concentrations up to 10mM. In some cells, only a KA-activated current was observed; application of 100μM Glu, AMPA or QA on these cells did not induce a detectable inward current. In all cells, the current activated by pressure ejection of KA (10μM-10mM) was significantly reduced by bath application of 100μM QA, but not by Glu or AMPA. Identical results were observed when the methods of application were reversed. The fractional reduction in KA-activated current by 100μM QA was approximately constant for 10μM-10mM KA, suggesting that the interaction between QA and KA was not competitive. Our data suggest that cultured striatal neurons express at least two types of QA/KA receptors, one of which is selectively activated by KA; however, all QA/KA receptors are selectively inactivated or desensitized by 100μM QA. In addition, these data support the hypothesis (see Weiss and Bauce, Soc. Neurosci. Abs., this volume) that multiple receptor systems subserve specific roles in the regulation of striatal neuron function by excitatory amino acids.

KAINIC ACID-INDUCED SEIZURES: EFFECTS OF ANTICONVULSANTS AND NIFEDIPINE.

D.E. Braun* and W.J. Freed. Department of Neurosurgery, Naval Hospital Bethesda, MD 20814* and NIMH Neurosciences Center at St. Elizabeths Washington, DC 20032.

The quisqualate and kainic acid excitatory amino acid receptors are related, and antagonists of the kainic acid and quisqualate receptors have recently been identified (Science 241:701, 1988). Depakene and glutamic acid diethyl ester (GDEE) inhibit quisqualate-induced seizures. The purpose of the present study was to evaluate effects of anticonvulsant drugs and other compounds on kainic acid-induced seizures. A 1 μg intracerebroventricular injection of kainic acid produced seizures in 100% of 18 adult female Swiss- Webster mice lasting for an average duration of 35 minutes. Phenobarbital, baclofen, phenytoin, GDEE, and carbamazepine had no effect. Depakene, at dosages of 125 and 250 mg/kg, prolonged the average seizure duration to 54 and 59 minutes respectively. Diazepam in sedating dosages (2 mg/kg) reduced seizure duration (mean= 18 min). The calcium channel inhibitor nifedipine was the only agent found to markedly decrease these seizures. A dosage of 50 mg/kg produced about a 50% decrease, primarily as a result of decreases in the length of individual seizure episodes. Thus there are substantial differences in the antagonism of quisqualate and kainic acid-induced seizures. The ineffectiveness of clinical anticonvulsants in this model could be related to the unresponsiveness of certain intractable seizure patients.

HYDROGEN ION INHIBITS THE QUISQUALATE/KAINATE RESPONSE BY PROTONATION OF HISTIDINE GROUPS IN ISOLATED CATFISH HORIZONTAL CELLS.

B.N. Christensen and E. Hida*. Dept. Physiology and Biophysics, University of Texas Medical Branch, Galveston, TX 77550.

The whole cell patch technique was used to measure kainate (KA) or quisqualate (QA) induced membrane current from enzymatically dissociated catfish cone horizontal cells. Increasing the external hydrogen ion concentration reversibly decreased the agonist induced membrane current. The pK was estimated from a titration curve in which the membrane current was measured as a function of pH in a constant concentration of agonist. The pK was 6.5 which is near the pK for the imidazole ring of the amino acid histidine. To examine further the possibility that the amino acid histidine is involved with the ion permeation process at this channel protein we examined the action of the histidine group specific reagent diethylpyrocarbonate (DEP). DEP (1 mM) reduced the response to KA or QA by as much as 50% following a 5 min exposure at either pH 6.5 or pH 8.0. The specific sulfhydryl reagent iodoacetic acid (10 mM) had no effect on the agonist induced membrane current. These results suggest that the imidazole ring of the histidine amino acid is associated with the ion permeation process of the QA/KA channel protein. Supported by grant EY-01897 from the Department of Health and Human Services.

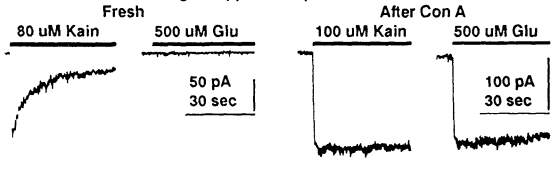
CURRENT GATED BY KAINATE IN RAT DORSAL ROOT GANGLION NEURONS: CON A ABOLISHES DESENSITIZATION.

J. E. Huettner. Dept. of Neurobiology, Harvard Med. School, 25 Shattuck St., Boston, MA 02115

Primary afferent C fibers in rat dorsal roots are depolarized by the excitatory amino acid, kainate (Agrawal and Evans (1986) Br. J. Pharm. 87:345). Under whole-cell voltage clamp, Kain and domoate increase the conductance of a subpopulation of small diameter (<35μm) sensory neurons, freshly dissociated from rat DRG's. The I-V is linear from -100 to +60 mV and reverses near 0 mV with internal Cs^+ or K^+ and internal Cl^- or $CH_3SO_3^-$ (NaCl + 2 mM $CaCl_2$, HEPES and TTX, external). The half-maximal dose is 15 μM for Kain and 0.8 μM for Dom. The currents desensitize with long agonist applications; decay is more rapid with Kain (τ-8 sec) than Dom (τ-18 sec). Kynurenate, PDA and DNQX block responses to Kain and Dom with rapid onset and recovery. Glu, Quis, Asp and NMDA do not evoke current, but simultaneous application of Glu or Quis antagonizes responses to Kain or Dom. Exposure to Glu or Quis also suppresses responses to a subsequent application of Kain or Dom ($t_{1/2}$ of recovery=2-3 min). Incubation with 10 μM Con A abolishes desensitization to Kain and Dom. After Con A, both Glu and Quis increase membrane conductance and no longer suppress responses to Kain or Dom.



461.6

PHARMACOLOGICAL CHARACTERIZATION OF A KAINATE (KA) RECEPTOR EXPRESSED IN *XENOPUS LAEVIS* OOCYTES INJECTED WITH RAT BRAIN mRNA.

M. A. Bolanowski*#, G. B. Watson, M. P. Baganoff*#, C. L. Deppeler*#, and T. H. Lanthorn, CNS Disease Research, G. D. Searle & Company, and #Biological Sciences, Monsanto Company, 700 Chesterfield Village Parkway, St. Louis, MO 63198.

Xenopus laevis oocytes express a wide variety of biological activities encoded by exogenous mRNA, including numerous receptors and ion channels. Kainate elicits an inward current in oocytes injected with rat brain mRNA, indicating the expression of a kainate sensitive receptor/channel complex. We have begun to characterize this functional kainate receptor in order to compare it to physiologically relevant kainate receptors. Voltage clamped oocytes responded to KA in a dose dependent manner (EC50=91 μM). These responses were antagonized by quisqualate (QA; IC50=1-10 μM), 6,7-dinitro-quinoxaline (DNQX; IC50=0.3-0.4 μM), and kynurenate (KYNA; IC50=90 μM). The N-methyl-D-aspartate (NMDA) receptor antagonist D-2-amino-7-phosphonoheptanoate (D-AP7) did not block responses to KA. The kainate analog domoate (DOM) was more potent (EC50=10 μM) than KA. DOM responses were blocked by QA and DNQX at concentrations similar to those which blocked KA responses. In addition, we have tested the activities of other KA analogs, including ß-kainate and dihydrokainate, as well as several non-NMDA agonists (e.g. willardiine and 5-bromo-willardiine). These characteristics demonstrate the presence of a low affinity KA receptor in oocytes injected with rat brain mRNA.

461.7

QUISQUALIC ACID MEDIATED INTRACELLULAR CALCIUM MOBILIZATION IS INHIBITED BY PHORBOL ESTERS BUT NOT BY PERTUSSIS TOXIN. Shawn N. Murphy*, James A. Holzwarth*, and Richard J. Miller, (SPON:W.J.Kinnier) Univ. of Chicago, Chicago, IL 60637.

We have previously demonstrated using fura-2 based microspectrofluorimetry that mouse hippocampal neurons in monolayer culture posses a glutamate receptor whose activation leads to mobilization of Ca^{2+} from intracellular stores and does not appear to be linked to a cation channel. In addition to glutamate, quisqualate (QA) and ibotenate activated this receptor but not α-amino-3-hydroxy-5-methylisoxazole proponate (AMPA). Furthermore the stimulatory effects of glutamate and QA were not blocked by 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). We have now further investigated the nature of the transduction mechanism involved in this process. Treatment of the neurons with 2.5 μg pertussis toxin (PTX) for 48 hours had no effect upon QA stimulated Ca^{2+} mobilization. Carbachol (CCh) and phenylephrine stimulated Ca^{2+} mobilization were also unaffected by PTX pretreatment although 2-chloro-adenosine inhibition of Ca^{2+} currents was reduced by PTX pretreatment (see Scholz et al. this volume). Treatment of the neurons with 1 μM phorbol 12,13-dibutyrate for 30 minutes prior to agonist application reduced the QA and CCh mediated Ca^{2+} mobilization by > 90%. Thus it appears that the pathway mediating QA induced Ca^{2+} mobilization may be subjected to an inhibitory protein-kinase C feedback as are many other systems involved in inositol-1,4,5-trisphosphate production.

EFFECTS OF QUISQUALATE AND NMDA ON PHOSPHATIDYLINOSITOL TURNOVER IN RAT CEREBELLUM. Joanna Feltham* and Sheryl S. Smith, Dept. of Anatomy, Hahnemann Univ., Phila., PA 19102. (SPON: Carlos Jimenez-Rivera).

We have previously shown that the excitatory amino acids (eaa) Quisqualate (QUIS) and NMDA produce long-term synergistic effects on QUIS-evoked excitatory responses of cerebellar Puirkinje cells recorded in vivo. In an attempt to delineate a mechanism for these findings, we have assessed eaa-stimulated phosphatidylinositol (PI) turnover in the present study, as well as the effect of possible modulating factors on this parameter. PI hydrolysis was measured in 160 x 160 μ chunks of cerebellar tissue from 6-9 day old female Long-Evans rats. Uptake of [^{3}H] myo-inositol took place in the presence of 1 mM EDTA, and the subsequent hydrolysis of PI in the presence of 3 mM $CaCl_2$. Inositol phosphate and PI were then separated by chloroform/MeOH extraction, and the PI turnover rate assessed as a percentage of basal under varying conditions. 10^{-6} M QUIS routinely produced robust increases in PI turnover as a dose-dependent effect, as shown by other investigators. Addition of NMDA (10^{-4} M) enhanced the ability of QUIS to increase PI turnover by 70% in the presence of the $GABA_B$ blocker phaclofen (10^{-3} M). Phaclofen alone decreased basal PI turnover by 20% and had no effect on QUIS stimulated values. However, administration of bicuculline methiodide exerted only minimal effects on this parameter. In addition, pulsatile application of QUIS (3 pulses at 3 x 10^{-7} M) produced a 70% increase in PI turnover above basal values in the presence of phaclofen, indicative of a QUIS-priming effect similar to that observed after multiple iontophoretic pulses of this amino acid. In the non-blocked condition, pulsatile application of QUIS produced a PI turnover rate 30% above basal, a value similar to that obtained with a single dose of QUIS. In contrast, 17 β estradiol (10^{-9} M) decreased QUIS-evoked PI turnover by 20%. Other reports have indicated that GABA blockers permit the induction of LTP in the cortex. These findings are consistent with the present results suggesting that under conditions of reduced GABAergic tone, the eaa QUIS and NMDA produce synergistic effects on the turnover of PI, a second messenger system which may lead to long-term changes in neuronal function in the developing cerebellum. *Supported by NS25809 to SSS.*

DIFFERENTIAL EFFECTS OF EXCITATORY AMINO ACIDS ON CYCLIC AMP ACCUMULATION IN RAT BRAIN SLICES. A. Pilc, W. Karbon*, J. Ferkany, J. Vetulani*, S.J. Enna. Institute of Pharmacology, Polish Academy of Sciences, 31-343 Krakow, Poland; Nova Pharmaceutical Corp., Baltimore, MD 21224-2788.

The effects of excitatory amino acids (EAA) on cAMP accumulation in rat brain cerebral cortical slices were measured using a prelabeling technique. Glutamate (0.1-5.0 mM), which by itself caused a slight increase in basal cAMP accumulation, inhibited up to 60% the cAMP response to NE, but not isoproterenol, in a concentration-dependent manner, suggesting that it modifies the alpha component of the NE response. The inhibitory effect of glutamate was mimicked by quisqualate (0.01-1.0 mM), but not by NMDA or kainate, at concentrations up to 5 mM. The inhibitory effect of glutamate was insensitive to CPP (0.10 mM), supporting the notion that the glutamate effect is not mediated by NMDA receptors. In contrast to glutamate, ibotenate (0.01-1.0 mM), which alone caused a modest increase in basal cAMP levels, enhanced the cAMP response to NE more than 5-fold.

These findings provide an additional mechanism by which EAA can influence second messenger production in brain, and the data suggests that a quisqualate receptor mediates the inhibitory effect of glutamate on NE-stimulated cAMP accumulation.

KAINATE EVOKES THE RELEASE OF ENDOGENOUS GLYCINE FROM STRIATAL NEURONS IN PRIMARY CULTURE. S. Weiss and L. Bauce*. Neuroscience Research Group, University of Calgary, Calgary, Alberta T2N 4N1.

The actions of selective excitatory amino acid (EAA) agonists and other depolarizing agents on the release of endogenous glycine and GABA from striatal neurons in primary culture was examined. The concentrations of endogenous amino acids released into the extracellular medium was determined by pre-column derivitization and separation with high performance liquid chromatography. Baseline levels of glycine and GABA, released by striatal neurons into the extracellular medium during a 3 min period, were 0.73±0.07μM and 0.09±0.02μM, respectively. When striatal neurons were exposed to 56mM KCl for a 3 min period, glycine and GABA levels increased to 1.11±0.10μM (1.5-fold) and 1.96±0.11μM (28-fold), respectively; 50% of these increases were dependent upon the presence of extracellular calcium. Exposure of striatal neurons to NMDA (100μM-1mM) increased glycine and GABA released to 1.11±0.16μM (1.5-fold) and 0.22±0.02μM (2.4-fold), respectively. Kainate was the most effective agent (of those tested) in evoking the release of endogenous glycine. After exposure of striatal neurons to 1mM kainate for 3 min, extracellular glycine levels were increased to 1.72±0.15μM, corresponding to a 2.4-fold increase over baseline; GABA levels were increased 4-fold. This action of kainate was independent of extracellular calcium and was blocked by co-incubation with 3μM CNQX, a selective kainate receptor antagonist. The kainate evoked increases in endogenous glycine release, to 1.72μM, correspond to those concentrations of glycine that significantly potentiate the actions of NMDA at it's receptor system on striatal neurons (see Kemp and Weiss, Soc. Neurosci. Abs., this volume). In conclusion, of the agents tested in this study, 56mM KCl is most effective in evoking the release of GABA from striatal neurons, while glycine release was most significantly increased by kainate. These data suggest that the modulatory actions of endogenous glycine at the NMDA receptor system on striatal neurons may be influenced by excitatory amino acid activation of the kainate receptor system.

MATURE HIPPOCAMPAL SLICES CULTURED 4 DAYS IN SYNTHETIC MEDIUM PLUS BSA, RELEASE D-^{3}H-ASPARTATE AND ^{14}C-GABA IN RESPONSE TO KAINATE(KA), QUISQUALATE(Q) OR 50mM K^+. N. Kleinberger-Doron* and M. Schramm. Dept. Biol. Chem. Herbew Univ. Jerusalem, Israel.

Slices from 45 day rats are sustained in a CSF-like, amino-acid medium. After 4 days slices show 90% of the uptake of the labeled amino acids, relative to fresh slices. 50mM K^+ releases D-^{3}H-aspartate and ^{14}C-GABA to the extent of 90% and 70% of that of fresh slices, respectively. In absence of added Ca^{2+} (10mM Mg^{2+}), release of both labeled amino acids is reduced by 68%.

Q and Ka, 60uM, induce in cultured slices a low, but significant, release of D-^{3}H-aspartate (1.2%-1.6% of total, after subtracting a basal release of 0.8%) and of ^{14}C-GABA (0.4%-0.7% after subtracting a basal release of 0.8%). Fresh slices demonstrate a similar release of ^{14}C-GABA, but rarely any of D-^{3}H-aspartate. A combined pulse of Ka+Q produces in the cultured slices an additive release of ^{14}C-GABA, but only half of the expected additive release of D-^{3}H-aspartate. Experiments with TTX and with Ca^{++} removal, suggest that Q may bring about inhibition of the Ka induced release. Our studies show that a mature CNS preparation can be maintained in vitro for days, retaining important functions of the tissue.

461.12

MODULATION OF ^{3}H-D-ASPARTATE RELEASE FROM THE RETINA DURING ONTOGENY. F. Somohano and A.M. López-Colomé. Instituto de Fisiología Celular, UNAM. Apdo. Postal 70-600. 04510 México, D.F. México.

Excitatory amino acids (EAA) participate as transmitters in the retina. We have previously demonstrated the presence of presynaptic receptors which modulate stimulated release of EAA. We have also demonstrated maturational changes in EAA synaptic receptors during ontogeny in the chick retina, which could be related to differentiation. Since the activity of these receptors depends on the availability of transmitter, which in turn is under presynaptic control, we studied the effect of EAA analogues on the K^+-stimulated release of ^{3}H-D-Aspartate from chick embryo retinas at days 7,8,11,14,18 and 21 of embryonic development (ED). Our results indicate the presence of K^+-stimulated release since day 7ED, however, the Ca^{++}-dependence of release increases gradually from 32% to 87% from ED7 to ED21. NMDA and KA were potent inhibitors of release, effect starting at day 14ED, while L-glutamate was less potent, showing effect from day 11ED. A ten fold increase in non-stimulated release of D-Asp was observed from ED 14 to 20, peaking at 18. Data suggest that while Ca^{++}-independent release of EAA could exert a trophic influence through the activation of postsynaptic receptors, once these structures acquire their mature characteristics, the amount of EAA present in the synaptic space, becomes controlled through presynaptic receptors.

461.13

MODULATION OF THE RELEASE OF ENDOGENOUS GLUTAMATE FROM RAT BRAIN SYNAPTOSOMES BY PUTATIVE PRESYNAPTIC RECEPTORS
S.Urwyler* and M.Puente* (SPON: A.Dravid). Sandoz Research Institute Berne Ltd., CH-3001 Berne, Switzerland

Rat brain synaptosomes were used as a model system for characterizing the modulation of the release of endogenous glutamic acid induced with high concentrations of K^+. L-2-amino-4-phosphono-butyric acid (L-AP4) inhibited the Ca^{2+} - dependent release of glutamate in a dose - dependent way, without affecting Ca^{2+} - independent or basal release. Kainic acid, N-methyl-D-aspartate (NMDA) and α-amino-3-hydroxy -5-methylisoxazole-4-propionate (AMPA) had weak or no effects on glutamate release. On the other hand, an inhibition was also found with L-AP7 and the L-enantiomer of the selective NMDA antagonist (E)-3-(2-carboxypiperazin-4-yl)-1-propenyl-1-phosphonic acid (CPP-ene, see Herrling et al., this volume), but not with D-CPP-ene. The non-NMDA-antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) was able to reverse the inhibition of glutamate release seen with L-AP4. This action of L-AP4 was found in synaptosomes prepared from hippocampus or striatum, but not in cortical synaptosomes. It is concluded that L-AP4 inhibits the depolarization-induced exocytotic release of glutamate via presynaptic receptors which are not uniformly distributed throughout the brain and which are pharmacologically different from NMDA-, kainate- and quisqualate - subtypes of excitatory amino acid receptors.

461.14

MODULATION OF VIP-STIMULATED cAMP FORMATION REVEALS THREE CLASSES OF EXCITATORY AMINOACIDS (EAA) RESPONSES IN MOUSE CEREBRAL CORTICAL SLICES.
N.C.SCHAAD[1], M.SCHORDERET[1,2] AND P.J. MAGISTRETTI[3] *1) Dépt de Pharmacol., CMU, CH-1211 GENEVE 4, 2) Ecole de Pharmacie, Place du Château 3, and 3) Inst. de Physiol., Rue du Bugnon 7, 1005 LAUSANNE.*

Glutamate (GLU) and aspartate (ASP) potentiated in a concentration-dependent manner the effect of VIP on cAMP formation. In order to characterize the type of receptor involved, we have used three prototypical EAA receptor agonists. Kainate (KAI) mimicked the effect of GLU, NMDA was inactive and quisqualate displayed an inhibitory action. Furthermore, ibotenate (IBO) also potentiated the effect of VIP, while L-homocysteate (L-HCA) exhibited a stereospecific inhibitory action. IBO was 4 fold more potent and 2.5 times more effective than GLU (EC_{50} = 60 and 200 µM respectively). However, the effects of KAI and IBO were not additive, suggesting an activation of a common receptor. Thus, based on their effects on VIP-stimulated cAMP formation, EAA can be grouped in the three classes: those that potentiate the effect of VIP, such as GLU, ASP, KAI and IBO; (ii) those that inhibit the effect of VIP, such as L-HCA and quisqualate and (iii) those that are ineffective, such as NMDA and D-HCA. The effects of GLU or IBO were completely inhibited by L-phosphoserine and only partially by kynurenate. In a low chloride medium, or in the presence of TMB-8, an inhibitor of calcium release from internal stores, EAA did not potentiate the effect of VIP, thus stressing the importance of these ions for the transduction of the glutamatergic signal.

CYTOSOLIC CALCIUM RISE MEDIATED BY NON-NMDA RECEPTORS IN CULTURED RAT HIPPOCAMPAL NEURONS.
A. Ogura*, K. Akita* and Y. Kudo*. (Spon: S. T. Inouye). Mitsubishi Kasei Institute of Life Sciences, Tokyo 194, Japan.

It is postulated that the elevation of intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) in the postsynaptic cytoplasm plays an essential role in the modulation of synaptic transmission. From electrophysiological evidence, NMDA(N)-subspecies of excitatory amino acid receptor is regarded to be responsible for the $[Ca^{2+}]_i$ rise. Does it then mean that the synapses devoid of the N-subspecies modulate the transmission by Ca^{2+} independent mechanism? We suggest here not necessarily so by presenting evidence that non-N-subspecies are capable of raising the $[Ca^{2+}]_i$ as well.

Fluorometry with fura-2 showed that the $[Ca^{2+}]_i$ of cultured rat hippocampal neurons rose significantly upon exposure to kainate (K) or quisqualate (Q), even when voltage dependent Ca^{2+} channel was totally blocked by La^{3+} or ω-conotoxin/nitrendipine. Neither aminophosphonovalerate or Mg^{2+} suppressed the K- and Q-mediated responses. When external Ca^{2+} was replaced with Mn^{2+}, extinction of fluorescence was triggered by K and Q. Withdrawal of external Ca^{2+} annihilated and reduced the K- and Q-mediated responses, respectively. After excluding the possibilities of Ca^{2+} entry through voltage dependent Na^+ channel by tetrodotoxin and of Ca^{2+} accumulation due to retarded Na^+/Ca^{2+} antiporter by Na^+ depletion, we concluded that the K-subspecies induced Ca^{2+} entry and that the Q-subspecies produced both Ca^{2+} entry and Ca^{2+} release from internal storage.

461.16

GLUTAMATE STIMULATES RELEASE OF Ca FROM INTERNAL STORES IN ASTROCYTES.
Z. Ahmed, C. Lewis* and D.S. Faber. Neurobiology Lab., Dept. Physiology, University at Buffalo, Buffalo, NY 14214.

We report here that activation of glutamate receptors in astrocytes in the absence of external Ca produces an increase in intracellular Ca (Ca_i). Dissociated fetal rat spinal cord cultures (1-3 wk old) were used. Ca_i from the soma was measured with Fura-2 using the ratiometric (~2 ms/ratio) method. Astrocytes were identified by immuno staining for GFAP. Agonists were added in Ca-free solution (1mM EGTA,500 nM TTX) 3-5 min after prewash in the same.

Glutamate (>1 uM) and quisqualate (>0.1 uM) consistently caused a transient increase in Ca_i, with both the response amplitude and latency being graded functions of agonist concentration. Repeated stimulation at 4-7 min intervals produced similar responses (±10%). Within 1-2 sec of application, 100 uM glutamate or quisqualate produced 300 ± 100 nM increases in Ca_i which peaked within 1-2 sec. Recovery to resting Ca_i level was 60-80% complete within 2-3 sec. Some cells produced multiple transients which persisted even after withdrawal of the agonist. NMDA, kainate and aspartate did not produce any response, but 2-amino-4-phosphonobutyrate was as effective as quisqualate. We conclude that the quisqualate subtype of glutamate receptors mediates release of Ca from internal stores in astrocytes. Supported by NIH grant no. NS 27144 to ZA.

461.17

ANTIPROLIFERATIVE ACTION OF EXCITATORY AMINO ACIDS IN CULTURED ASTROCYTES.
F. Nicoletti*, F. Ingrao§*, G. Magrì§*, V. Bruno*, M.V. Catania*, P. Dell'Albani§*, D.F. Condorelli§* and R. Avola§* (SPON: B.L. Roth) Depts. of Pharmacology and §Biochemistry, University of Catania, Italy.

Quisqualate, ibotenate and glutamate stimulate inositol phospholipid hydrolysis and reduce [^{3}H]thymidine incorporation in cultured astrocytes, but not in C6-glioma cells or in slices from human glioma. The action of quisqualate is attenuated by L-AP4, but not by other receptor antagonists, including kynurenate or CNQX. The antiproliferative action of quisqualate requires a lag time of at least 4 hours and occurs during the transition between G_o and G_1 phase of the mitotic cycle in cells synchronized to proliferate. This suggests that inhibition of [^{3}H]thymidine incorporation by excitatory amino acids is consequent to the activation of gene expression and induction of specific proteins. Accordingly, quisqualate and ibotenate induce a rapid and transient increase in the expression of the early inducible gene, c-fos, in cultured astrocytes. These results support the view that activation of specific excitatory amino acid receptors coupled to inositol phospholipid hydrolysis contribute to regulate proliferation of astrocytes in culture.

461.18

FLUORESCENCE MEASUREMENT OF CHANGES IN INTRACELLULAR Ca INDUCED BY EXCITATORY AMINO ACIDS IN CULTURED ASTROCYTES.
A. Jensen* and S.Y.Chiu. Neuroscience Training Program & Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706.

Astrocytes vastly outnumber neurons in mammalian brain and are potential targets for neurotransmitters. Indeed, cultured astrocytes are known to express receptors for glutamate, which is possibly the most widely used excitatory neurotransmitter in the brain. Agonist induced changes in intracellular [Ca] are thought to be an important mediator of cell activity. We now report measurements of intracellular [Ca] in confluent, monolayer cultures of neonatal rat cortical astrocytes (>95% GFAP+) using the indicator dye fura-2. Bath applications of 100-500 µm glutamate (GLU), quisqualate (QA), kainate (KA) and NMDA induce a rise in [Ca]i with an order of potency of GLU ~ QA > KA >>> NMDA. Both GLU and QA responses consist of a rapid initial transient (200-500 nM change in [Ca]i) often followed by a damped oscillation; KA responses, in comparison, are slower in onset and more sustained. Removal of external Ca (2 mM EGTA) virtually abolished the KA response, but significant [Ca]i rises still are elicited by GLU (~30% of control) and QA (~100%). Prior treatment with TPA (100 nM), a potent protein kinase C activator, leads to an almost complete block of the GLU response, but only a ~50% and ~30% block of the QA and KA responses, respectively. These observations are consistent with the hypothesis that GLU and QA induce both mobilization of internal Ca stores and Ca influx. In contrast, KA primarily induces Ca influx.

GLUTAMATE INDUCES OSCILLATING INTRACELLULAR AND PROPAGATING INTERCELLULAR CALCIUM WAVES IN ASTROCYTES. S. M. Finkbeiner*, A. H. Cornell-Bell*, M. S. Cooper*, C. F. Stevens and S. J Smith. Molecular Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Intracellular Ca^{2+} changes were studied in astrocytes cultured from the CA1 region of the rat hippocampus using time-lapse video microscopy, the Ca^{2+} indicator Fluo-3 AM and FITC optics. Intracellular Ca^{2+} rapidly rises upon bath application of 1-1000uM glutamate in almost all astrocytes. After this initial rise three responses were seen. In one response, the cell Ca_i^{2+} oscillates with nearly constant amplitude and frequency (period = 15 ± 3 sec, n = 20) during the experiment (5-10 min). In another type, the cell begins to oscillate with constant frequency while the amplitude dampens to an elevated baseline. In the third type, cells do not oscillate. Confluent glia may also participate in expansive Ca^{2+} waves which propagate from cell to cell and radiate from initiation centers. In Ca^{2+}-free/3 mM EGTA Ringers oscillations are seen, though damped, suggesting they are partly due to intracellular Ca^{2+} release. Quisqualate (100uM) induces transients and oscillations similar to 100 uM glutamate while NMDA (100 uM) with glycine (10 uM) has no effect. Kainate (100uM) causes a step-like rise in Ca_i^{2+}. Neither the selective NMDA antagonist APV (1mM) nor the putative glutamate receptor antagonist APB (1 mM) could antagonise glutamate's effects. However, the selective non-NMDA antagonist, CNQX (10-100 uM), markedly attenuates the oscillations and waves. Blocking the sodium-dependent glutamate uptake system by choline substitution enhances the amplitude of glutamate-induced oscillations. The above responses cease quickly when the agonist is removed. These results suggest astrocytes possess receptors preferring kainate and quisqualate. The oscillations are consistent with models of quisqualate activated phosphoinositol turnover. These findings indicate that intercellular communication, possibly through gap junctions, can establish long-range Ca^{2+} signalling in glial networks.

SODIUM-DEPENDENT D-ASPARTATE BINDING IS NOT A MEASURE OF PRESYNAPTIC NEURONAL UPTAKE SITES IN AN AUTORADIOGRAPHIC ASSAY. J.T. Greenamyre, D.S. Higgins* and A.B. Young. Univ. of Mich., Ann Arbor, MI 48104.

Binding of D-[^{3}H]aspartate to rat brain was examined in an autoradiographic assay. Binding was dependent on the presence of sodium ions, but not chloride ions, and was optimal at 2°C. D-Aspartate binding reached equilibrium in 20 min and remained stable for 45 min. Dissociation was rapid with a $t_{1/2}$ of 56 sec, but was not as fast as anticipated, perhaps because of some sequestration of ligand. Binding in striatum had a K_D of 6.8 ± 1.2 μM and B_{Max} of 49.4 ± 8.6 pmol/mg protein. L-Glutamate, unlabeled D-aspartate, and D,L-threo-hydroxyaspartic acid, each competed for D-[^{3}H]aspartate binding with IC_{50}s of 7.02 ± 4.3 μM, 5.4 ± 1.5 μM, and 2.54 ± 1.03 μM, respectively. N-methyl-D-aspartate, quisqualate, and kainate had no affinity for this site. The regional distribution of binding did not conform to that of neuronal uptake sites described by others. Striatal D-aspartate binding was unaffected by unilateral decortication or striatal quinolinic acid lesions. NMDA, quisqualate, and kainate receptors were reduced by 80-90% by quinolinate lesions. The lesion studies strongly suggest that this site is not associated with either presynaptic glutamatergic afferents or intrinsic neurons of the striatum; it may be associated with glia.

LOCALIZATION OF THE CEREBELLAR KAINATE RECEPTORS ON BERGMANN GLIAL CELLS. N. Eshhar[1,2], J.D.B Roberts[*2], V.I. Teichberg[1] and P.Somogyi[2], Neurobiol. Dept.[1], Weizmann Inst. of Science, Rehovot 76100, Israel; MRC Anat. Neuropharm. Unit[2], Dept. Pharmacol., Oxford, U.K.

A high density of kainate receptors has been reported to be present in the cerebellar molecular layer of the goldfish (Eshhar et al. Brain Res. 476, 57-70, 1989) and the chick (Gregor et al. EMBO J. 7,2673-2678,1988). The precise cellular and subcellular distribution of these kainate receptors has now been studied by EM immunocytochemistry using the monoclonal antibody IX-50 directed against the purified kainate receptor protein. Both pre- and postembedding immunoperoxidase and immunogold methods were used. Immunoreactivity was found associated only with Bergmann glial cells. Intracellularly, immunoreactivity is observed in the endoplasmic reticulum, Golgi apparatus and lysosomes, representing putative sites of the synthesis, glycosylation and degradation of the kainate receptor. Extracellular immunoreactivity appears to be uniformly distributed along the Bergmann glial plasma membrane as confirmed by high resolution light microscopy. Bergmann glial processes form nests to the parallel fibre /Purkinje cell spine synaptic complexes. The presence of kainate receptors on Bergmann glia in close association with the spine synapses provides a basis for parallel fiber signalling to the Bergmann glia, presumably via glutamate.

EXCITATORY AMINO ACIDS: RECEPTORS VIII

QUANTITATIVE AUTORADIOGRAPHIC DETERMINATION OF THE DISTRIBUTION OF BINDING SITES FOR ^{3}H-MK-801 IN HUMAN HIPPOCAMPUS. **P. McGonigle, N. Lexow, M. A. Dichter and M. J. O'Connor. Departments of Pharmacology and Neurology, University of Pennsylvania School of Medicine and Department of Neurosurgery, Graduate Hospital, Philadelphia, Pennsylvania.**

The binding of ^{3}H-MK-801, a noncompetitive antagonist of the NMDA subtype of glutamate receptors, was measured in hippocampal tissue obtained from post-mortem specimens and patients undergoing temporal lobectomy to alleviate epileptic seizures. 20 μm thick sections of tissue were incubated in a 30 mM EPPS buffer solution containing various concentrations of ^{3}H-MK-801 for 2.5 hr at 22°C. Glycine (100 μM) and glutamate (100 μM) were included in the buffer and nonspecific binding was defined with 200 μM ketamine. Following a wash in ice-cold buffer, the sections were rapidly dried and apposed to LKB ultrofilm for 15 d. In post-mortem tissue, the highest densities of binding sites were observed in the CA_1 region, followed by the CA_2, CA_3, CA_4 regions and the dentate gyrus. These measurements were in good agreement with previous determinations of NMDA receptor density carried out with ^{3}H-glutamate. In temporal lobectomy tissue, the density of binding sites in the dentate gyrus was much higher than in post-mortem tissue. In some subjects, the relative distribution of binding sites was markedly different from the post-mortem samples, with the highest density of sites in the dentate gyrus and little or no binding detectable in the CA_1 and CA_2 regions. These results suggest that there are significant changes in the density and distribution of NMDA receptors as a consequence of epilepsy. (Supported by USPHS GM 34781 and the Pew Charitable Trusts)

462.2

CHARACTERIZATION AND DISTRIBUTION OF ^{3}H-MK-801 BINDING SITES IN THE RAT BRAIN. **S. Subramaniam and P. McGonigle. Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.**

Kinetics and optimal conditions for the binding of ^{3}H-MK-801, a non-competitive antagonist at the NMDA receptor, were determined using sections of mash prepared from rat brain. 20 μM thick sections were incubated at 22° C with ^{3}H-MK-801 (2-50 nM) in 30 mM EPPS containing 100 μM glutamate and 100 μM glycine. Non-specific binding was determined in the presence of 200 μM ketamine. Equilibrium was reached at 150 min. Sections were then rinsed in ice-cold buffer, wiped off and counted in scintillation fluid. Equilibrium and kinetic determinations of K_d were in good agreement. For densitometric analysis, sections were rapidly dried after the rinse and exposed to Ultrofilm for 15-21 d. Scatchard analysis of ^{3}H-MK-801 binding in the CA_1 region of the hippocampus yielded a Kd of 6.2 nM. The density of ^{3}H-MK-801 binding sites was determined in 34 regions at a concentration of 32 nM. These values corresponded to the density of NMDA receptors reported previously suggesting a 1:1 stoichiometric relationship for the two sites. The highest density of ^{3}H-MK-801 binding sites was in the CA_1 (stratum radiatum) (4213 fmol/mg). High densities were also found in the frontal cortical regions (3370 fmol/mg), primary olfactory cortex (3146 fmol/mg) and the olfactory tubercle (2415 fmol/mg). The density of ^{3}H-MK-801 binding sites in the hippocampus of rats kindled with pentylenetetrazole appeared to change, which is consistent with a role for the NMDA receptor in the kindling model of epilepsy. (Supported by USPHS GM 34781 and the Pew Charitable Trusts).

462.3

A UNIQUE GLUTAMATE BINDING SITE IN AN AUTORADIOGRAPHIC ASSAY. DS Higgins*JT Greenamyre,JJ Cha,JB Penney,AB Young. Department of Neurology, University of Michigan, Ann Arbor, MI 48104.

Glutamate receptor pharmacology identifies 3 postsynaptic receptor types: N-methyl-D-aspartate, quisqualate and kainate, each of which is labelled by (3H)glutamate. We describe a unique neuronal glutamate recognition site measured in the presence of saturating concentrations of NMDA, quisqualate and kainate in rat brain. In Tris buffer binding was enhanced by the presence of chloride and calcium ions and was maximal at 2° C. Glutamate bound rapidly, reaching equilibrium by 15 min and dissociated with a $t_{1/2}$ of 24 sec. Kinetic analysis yielded a K_D of 0.96± 0.09uM while scatchard analysis gave a K_D of 1.05± 0.25uM and a B_{max} of 2.22± 0.36pmol/mgprot, with a Hill coefficient of 0.90± 0.04. Binding was highest in outer cortical laminae, dentate gyrus and striatum. A wide variety of glutamate agonists and antagonists, as well as SITS and DIDS, did not alter binding. Binding in striatum was unaffected by ipsilateral decortication but was reduced by 65% in striatal quinolinate lesions. These results suggest that this is a unique postsynaptic neuronal site; it's function is not yet known. Supported by USPHS grants NS19613, AG06155 and NS07222.

IBOTENATE DISPLACES [^{3}H] GLUTAMATE FROM AN AMPA-INSENSITIVE QUISQUALATE BINDING SITE. J.J. Cha, J.B. Penney and A.B. Young. Neuroscience Prog. and Dept. Neurology, Univ. Michigan, Ann Arbor, MI 48104-1687

[RS]-α-Amino-3-hydroxy-5-methylisonazole-4-propionic acid (AMPA) is a selective glutamate agonist at the quisqualate class of excitatory amino acid receptor. However, AMPA displaces only a portion of quisqualate-sensitive [^{3}H] glutamate binding in rat brain. We investigated the properties of this "AMPA-insensitive, quisqualate sensitive [^{3}H] glutamate binding" (AiQsGB) in rat brain using a quantitative autoradiographic assay.

AiQsGB was measured in 50 mM Tris HCl buffer plus 2.5 mM $CaCl_2$ and 10 μM AMPA. Nonspecific binding was determined in the presence of 2.5 μM quisqualate. AiQsGB had a unique distribution within the rat brain (highest to lowest): cerebellar molecular layer > outer cortex > hippocampus > inner cortex > striatum > globus pallidus. AiQsGB was increased at 4° C vs. 37 ° C, distinguishing it from other quisqualate-sensitive glutamate binding processes. Similarly, the anion channel blocker SITS, which inhibits the chloride dependent uptake of [^{3}H] glutamate into membrane vesicles, was an ineffective blocker of AiQsGB with an IC_{50} > 100 μM. Other agents which were relatively ineffective at blocking AiQsGB (i.e. IC_{50} > 100 μM) were cystine, kynurenate, L-APB, BOAA, CNQX and DNQX. Effective displacers of AiQsGB were (with approximate IC_{50} values) quisqualate (10-20 nM), glutamate (200-300 nM), and ibotenate (2-3 μM).

AMPA-insensitive, quisqualate-sensitive [^{3}H] glutamate binding may represent binding to the novel type of quisqualate receptor believed to be linked to phosphoinositide metabolism.

Supported by USPHS grant NS 19613 and NIH NRSA 5T32.

462.5

THIOCYANATE INCREASES THE AFFINITY OF A LOW-AFFINITY BINDING SITE FOR AMPA. Z.R. Hollingsworth, J.J. Cha, J.B. Penney and A.B. Young. Neuroscience Prog. and Dept. Neurology, Univ. Michigan, Ann Arbor, MI 48104-1687.

We have investigated the pharmacological properties and regional distribution of binding of the glutamate receptor agonist [^{3}H](RS)-α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid ([^{3}H]AMPA) in rat brain using quantitative autoradiography.

[^{3}H]AMPA binding was highest in the hippocampus, cortex and cerebellum. Quisqualate and the quinoxalinedione compounds CNQX and DNQX were the most potent displacers of AMPA binding with IC_{50} values in the nanomolar range. Glutamate and BOAA also displaced AMPA binding with IC_{50} values in the low micromolar range. Ibotenate had no effect on AMPA binding. Regional analysis confirmed that AMPA binds to a subpopulation of quisqualate-sensitive glutamate binding sites.

Potassium thiocyanate (KSCN) increased [^{3}H]AMPA binding at all concentrations of KSCN tested (0 - 100 mM). In the presence of 100 mM KSCN, Scatchard analysis revealed two binding sites for AMPA. In the absence of KSCN, Scatchard analysis revealed an apparent single binding site. However, in saturation experiments using very high concentrations of [^{3}H]AMPA, a second binding site was detected in the absence of KSCN. The regional distributions of [^{3}H]AMPA binding in the absence of KSCN and in the presence of 100 mM KSCN were identical (r = .96). Scatchard analyses performed in the presence of intermediate concentrations of KSCN (1 and 10 mM) suggest that KSCN stimulated [^{3}H]AMPA binding by increasing the affinity of a low-affinity site. These data suggest that AMPA binding sites can exist in two conformations, and that the equilibrium between these two sites can be influenced by KSCN. Supported by USPHS grant NS 19613 and NIH NRSA 5T32.

462.6

REGULATION OF CEREBELLAR QUISQUALATE RECEPTORS IN PURKINJE CELL DEFICIENT AND GRANULOPRIVAL MICE. R.L. Makowiec*, J.J. Cha, J.B. Penney, and A.B. Young. Dept. Neurology, University of Michigan, Ann Arbor, MI 48109.

Quisqualate and AMPA ([RS]-α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid) act as potent agonists at a subset of excitatory amino acid receptors linked to ion channels (the quisqualate receptor). The regulation and properties of quisqualate-sensitive [^{3}H]-glutamate and [^{3}H]-AMPA binding were investigated in normal, Purkinje cell deficient (nervous nr/nr mutants) and granuloprival (methylazoxymethanol, MAM) mouse cerebella using a quantitative autoradiographic assay.

In the molecular layer of nervous mice lacking Purkinje cells, quisqualate-sensitive [^{3}H]-glutamate binding sites were reduced to 47% ($p < .003$) of control. [^{3}H]-AMPA binding sites were reduced to 25% ($p < .001$) of control. In cerebella of MAM treated mice adjacent to severe granule cell depletion, quisqualate-sensitive [^{3}H]-glutamate binding sites were increased to 140% ($p < .02$) of control, while [^{3}H]-AMPA binding sites were increased to 156% ($p < .009$) of control.

The results suggest that quisqualate-sensitive [^{3}H]glutamate and [^{3}H]AMPA binding sites are located primarily on Purkinje cells in cerebellum and that these sites upregulate after denervation.

Supported by USPHS grant NS 19613 and 5T32 GM07863.

462.7

Excitatory Amino Acid (EAA) Receptor Binding in Epileptic Human Hippocampi. D.A.Hosford, Z.Cao*, B.J.Crain, D.W.Bonhaus, A.H.Friedman, V.J.Nadler, & J.O.McNamara. Epilepsy Res. Lab, Duke Univ. & V.A. Med. Ctrs. Durham, NC, 27705.

Studies of the kindling model suggest that EAA-mediated neurotransmission may contribute to complex partial epilepsy in humans. We therefore used quantitative radiohistochemistry to measure the binding of ligands to NMDA receptors ([^{3}H]-glutamate displaced by NMDA), NMDA channels ([^{3}H]-TCP), and quisqualate receptors ([^{3}H]-AMPA) in sections of hippocampi surgically removed from patients with medically refractory complex partial seizures. Controls were hippocampi from autopsies of patients without epilepsy and without neurologic causes of death. Measurements were corrected for pathologic changes in neuronal density.

[^{3}H]-TCP and NMDA-displaceable [^{3}H]-glutamate binding were significantly decreased (33% and 61%, respectively, ($p < .05$) in area CA3 in specimens with mesial sclerosis ($n = 8$) even after correction for decreased neuronal density. In contrast, [^{3}H]-AMPA binding was increased by 100% ($p < .02$) in dentate gyrus stratum moleculare from these same specimens, but was not significantly changed in CA3 or CA1. The decreased [^{3}H]-TCP and NMDA-displaceable [^{3}H]-glutamate binding may reflect a down-regulation of NMDA receptor/channel function in surviving neurons. The increased [^{3}H]-AMPA binding in epileptic human hippocampi may indicate enhanced function of the same type of synapses that underlie longterm potentiation in animal models.

462.8

EFFECTS OF AGE ON GLUTAMATE DISPLACEABLE KAINIC ACID BINDING IN MOUSE BRAIN. J.C. MATTHEWS DEPT. OF PHARMACOLOGY AND RESEARCH INST. OF PHARMACEUTICAL SCIENCES, SCHOOL OF PHARMACY, UNIV. OF MISSISSIPPI, UNIVERSITY, MS 38677

Female mice at 2,5,10 and 20 months of age, produced at the University of Mississippi by brother-sister matings from C57Bl6Nnia stock, were used for analysis of the effects of age on brain kainic acid preferring glutamate receptors. Upon sacrifice brains were divided into cerebral cortex, remaining forebrain and hindbrain. Washed, frozen and thawed, whole particulate membranes were prepared. Replicate groups of 4 mice each at each age were employed for analysis of glutamate displaceable [^{3}H]-kainic acid binding with a centrifugation method. In the hindbrain, the affinity constant for glutamate displaceable kainic acid binding decreased as a function of increasing age while the number and density of binding sites remained constant. In the cerebral cortex the affinity constant was increased in the 20 month old animals relative to the younger age groups which were not different from one another. The number and density of binding sites in the cerebral cortex was constant over all age groups. In the forebrain the affinity and number of binding sites were unaffected by age. The cerebral cortex and hindbrain tissues did not change in weight over the age range tested, but the forebrain increased in weight with increasing age. Since the number of receptors in forebrain remained constant with age it can be concluded that the density of receptors in the forebrain decreased with age.

462.9

DECREASED NUMBER OF N-METHYL-D-ASPARTATE RECEPTOR-GATED ION CHANNELS IN HIPPOCAMPAL MEMBRANES OF AGED RATS. W.B. Perry*, D.W.Bonhaus, and J.O.McNamara (SPON:T. Slotkin). Duke Univ. and VA Medical Centers, Durham, NC 27705.

Aging is associated with a reduction in several forms of neuronal plasticity: older rats learn spatial tasks and kindle at a slower rate than young adults. Pharmacological studies suggest that activation of N-methyl-D-aspartate (NMDA) receptors is critical to these events. A change intrinsic to the NMDA receptor-gated ion channel may be responsible for the observed age-related deficits. To test this idea, we measured the binding of [^{3}H]-N-1-thienyl[cyclohexyl]piperidine (TCP) to the NMDA channel of hippocampal membranes from 3 and 24 month old Fisher-344 male rats. Equilibrium analysis of TCP binding isotherms (0.5-100nM TCP, 500 min) showed a decrease in maximum binding with no change in Kd.

Age (months)	Bmax (pmol/mg)	Kd (nM)
3	3.14 ± 0.37	19.9 ± 1.7
24	1.95 ± 0.17*	16.3 ± 1.9

Values are mean ± S.E.M. *Significantly different by Student's t-test, $p<0.02$, $n=4$.

This reduction in the number of NMDA channels supports the idea that a change intrinsic to this receptor/channel complex contributes to the decreased plasticity observed in the aged brain.

462.10

AGE-RELATED CHANGES OF AMINO ACID RECEPTORS IN THE RAT BRAIN STUDIED BY IN VITRO AUTORADIOGRAPHY. R. Miyoshi, S. Kito, N. Doudou* and S. Katayama*. Third Department of Internal Medicine, Hiroshima University School of Medicine, Hiroshima 734, Japan.

Glutamate appears to be a major excitatory transmitter in the mammalian central nervous system. Central excitatory amino acid receptors have been thought to be divided into three subclasses referred as N-methyl-D-aspartic acid (NMDA)-, quisqualic acid (QA)- and kainic acid-sensitive sites. Among these subtypes, NMDA sites are proposed to be involved in various central events such as neuronal plasticity, hypoxic neuronal death and long-term potentiation. In addition, strychinine-insensitive glycine receptors seem to be strongly related to NMDA receptors. In the present study, autoradiographic distributions of ^{3}H-CPP (a NMDA receptor antagonist), ^{3}H-AMPA (an agonist for QA receptors) and ^{3}H-glycine were investigated in the rat brain. Binding sites of each ligand whose Kd values were nanomolar-order were obtained by Triton X-100 treatment of tissue sections. High densities of each ligand were observed in the hippocampus, cerebral cortex, amygdala, olfactory tubercle and striatum. In addition, alterations of receptor distributions were also studied using the aged brain. Amino acid receptors in the hippocampus were decreased in parallel with aging. Hippocampal amino acid receptors may play an important role in brain aging.

462.11

ANTI-IDIOTYPIC ANTIBODIES AS INTERNAL IMAGES OF GLUTAMATE AND THEIR IMMUNOCYTOCHEMICAL APPLICATION IN THE RAT BRAIN. G. CAMPISTRON, P. DUBOURG* M. GEFFARD and A. CALAS*. Neuroimmunology, IBCN-CNRS. and *Neurobiology URA 339 CNRS, Bordeaux, FRANCE.

Idiotypic poly- and monoclonal anti-conjugated glutamate (Glu) antibodies or Ab1 allowed us to induce anti-idiotypic Glu antibodies or Ab2 in rabbits after alternative immunization. These latters were affinity chromatographed on rabbit and mouse non-immune immunoglobulins in order to remove anti-isotypic and anti-allotypic antibodies. Using ELISA tests, we performed competition experiments between Glu-conjugates coated on well-plates and purified Ab2 previously incubated with poly- and monoclonal Ab1. The displacement curves showed that Ab2 were internal images of conjugated Glu. To demonstrate the Ab1-Ab2 recognition specificity, we incubated the Ab2 Glu with other idiotypic antibodies directed against conjugated neurotransmitters (serotonin, dopamine, acetylcholine) and their respective conjugates and found no idiotypic binding. Considering this, we attempted to use the Ab2 for immunocytochemistry. Vibratome sections of paraformaldehyde-fixed rat brains were treated with 1/500 Ab2 subsequently revealed by PAP technique. In the hippocampus at the ultrastructural level, most of the immunoreactive structures were post-synaptic thickenings on dendritic or occasionnally somatic spines. Combined treatments with Ab2 and Glu-conjugates induced a sharp decrease of immunoreactivity. These data suggest that our anti-idiotypic Glu antibodies can specifically recognize Glu receptors and open new possibilities for their ultrastructural and biochemical characterization.

462.12

DIFFERENTIAL RESPONSE OF HIPPOCAMPAL EXCITATORY AMINO ACID RECEPTORS TO DEAFFERENTATION AND REINNERVATION. J. Ulas*, D.T. Monaghan[1] and C.W. Cotman (SPON: ENA) Depts. of Psychobiology and [1]Surgery, University of California, Irvine, CA 92717.

In vitro autoradiography was used to monitor the response of two subclasses of excitatory amino acid receptors, N-methyl-D-aspartate (NMDA) and quisqualate (QA), in the rat hippocampus after unilateral lesions of the entorhinal cortex (EC).

In response to EC lesions changes in NMDA and QA receptor binding levels were found not only in the outer two-thirds of the ipsilateral molecular layer (IML) but also in the inner IML indicating that the response of receptors is not restricted to directly denervated areas. An early decrease (5-20%) in the binding density of NMDA and QA receptors in the IML during the first week postlesion was followed by an increase in binding levels. Thirty to sixty days postlesion the binding levels of both receptors in the IML were higher than those in unoperated rats. The response of NMDA receptors (20-50% increase over control) was more pronounced than that of QA receptors. An increase in NMDA receptor binding levels (10-15% over control) was also found in the contralateral ML three to sixty days postlesion. No such changes were observed for QA receptors.

The data indicate that NMDA and QA receptors are differentially regulated in response to deafferentation. Comparison of these results to the time course of deafferentation and reinnervation suggests that the observed changes may be important components in the functional restoration of partially damaged circuitry.

462.13

EXCITATORY AMINO ACID RECEPTORS IN HUMAN CEREBRAL CORTEX: AUTORADIOGRAPHIC DISTRIBUTIONS OF [^{3}H]TCP, [^{3}H]GLYCINE, L-[^{3}H]GLUTAMATE, [^{3}H]AMPA, AND [^{3}H]KAINIC ACID BINDING SITES. K.L.R. Jansen,* R.L.M. Faull and M. Dragunow. Anatomy Dept., Univ. Auckland School of Medicine, Private Bag, Auckland, New Zealand.

The distributions of [^{3}H]1-(1-(2-thienyl)-cyclohexyl) piperidine ([^{3}H]TCP), [^{3}H]glycine, L-[^{3}H]glutamate, [^{3}H]-α-amino-3-hydroxy-5-methyl-4-isoxazole propionic acid ([^{3}H]AMPA) and [^{3}H]kainic acid ([^{3}H]KA) binding sites were studied in the human cerebral cortex. Under the appropriate conditions, [^{3}H]TCP, [^{3}H]glycine and L-[^{3}H]glutamate label sites on the N-methyl-D-aspartate (NMDA) receptor, while [^{3}H]AMPA labels the quisqualate and [^{3}H]KA the KA receptor. Labelling methods were as previously described (Jansen, K. et al., Brain Res. 482: 174, 1989). [^{3}H]TCP, [^{3}H]glycine and L-[^{3}H]glutamate sites had a congruent distribution, supporting data indicating that these ligands bind to different sites on the same complex. [^{3}H]AMPA sites had a similar pattern, except in the striate (primary visual) cortex, where the band of NMDA sites in lamina IVCβ was not matched by [^{3}H]AMPA. The [^{3}H]KA pattern was usually complementary to the other ligands (eg. in neocortex there was a band of high [^{3}H]KA density over laminae V and VI, while the other ligands had high densities over laminae I-III), except in the primary motor area where the highest level of [^{3}H]KA binding was in the outer layer, supporting data from non-glutamatergic receptor studies suggesting a unique chemoarchitecture for this area (Lidow, M. et al., Soc. Neurosci. Abst. 14: 170, 1988). It thus appears that excitatory amino acid neurotransmission in the human brain, as in the rat, is mediated by anatomically distinct subsystems. Supported by NZ Medical Research Council.

463.1

INHIBITION OF GLUTAMATE-INDUCED FIRING IN HIPPOCAMPAL SLICES BY LOW GLUCOSE OR BY AMMONIUM IONS. Fan Ping* and J.C.Szerb. Dept.of Physiol.& Biophys.,Dalhousie Univ., Halifax N.S. B3H 4H7,Canada.

Synaptic transmission in hippocampal slices is depressed in low glucose medium (Cox & Bachelard, Brain Res.239:527,1982) or by NH_4^+ (Theoret et al. Neurosci. 14:798,1985). Whether this depression is pre- or postsynaptic is controversial. To test for a post-synaptic blockade, firing of units in the pyramidal layer in CA1 area induced by 100 msec pulses of electro-phoretic glutamate was tested. Lowering glucose from 5 to 0.2 mM reversibly inhibited glutamate induced firing by about 70%, but 2 or 5 mM NH_4Cl reduced it by only about 20%. If however, 25 μM bicuculline was present, which increased the response of neurons to glutamate, the effectiveness of NH_4Cl more than doubled. These observations agree with findings that neither low glucose (Szerb & O'Regan,Synapse, 1:265,1987), nor 5 mM NH_4Cl (Butterworth et al.Hepatic Encephalopathy,Humana Press, in press) inhibit stimulation-induced release of excitatory amino acids from hippocampal slices and suggest that synaptic transmission is blocked at a postsynaptic site. To reveal the blockade by NH_4^+ of glutamate-induced excitation, GABA-ergic inhibition has to be reduced, since, by interfering with the Cl^- pump, NH_4^+ also decreases this inhibition (Raabe, Brain Res. 210:311,1981). (Supported by the MRC of Canada.)

463.2

INHIBITION OF QUISQUALATE (QUIS)- AND IBOTENATE (IBO)-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS IN THE NEONATAL RAT HIPPOCAMPUS BY 2-AMINO-3-PHOSPHONOPROPIONATE (D,L-AP3). D. D. Schoepp and B.G. Johnson*, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

The pharmacological specificity of excitatory amino acid receptor coupling to brain phosphoinositide hydrolysis was characterized in hippocampal slices from 7 day old rats. Tissue slices were prelabeled with ^{3}H-inositol, washed with buffer containing 10mM LiCl, then incubated with agonists for 60 min. Antagonists were preincubated 20 min prior to the agonist incubation. Maximally effective concentrations of IBO (10^{-4}M) or QUIS (10^{-4}M) increased the formation of ^{3}H-inositol monophosphate (^{3}H-IP) by 11 to 12 fold over the basal values. L-Glutamate or L-aspartate enhanced ^{3}H-IP about 6-fold at 10^{-3}M. QUIS was the most potent agonist (EC50% 1.9μM), followed by IBO (EC50% 27μM), then L-glutamate (EC50% 458μM). AMPA or kainate increased ^{3}H-IP by 2-4 fold at 10^{-3}M. D,L-AP3 (10^{-3}M) completely inhibited IBO and QUIS stimulations, partially inhibited L-glutamate stimulation, but had no effect on AMPA-, kainate-, or carbachol-induced ^{3}H-IP. The ionotropic QUIS receptor antagonist DNQX (10^{-4}M) did not inhibit stimulations by QUIS or IBO. These studies show that excitatory amino acids stimulate phosphoinositide hydrolysis in the neonatal rat hippocampus by activating metabotropic QUIS receptors that can be selectively inhibited by D,L-AP3.

463.3

SR-95531 BLOCKS SELECTIVE UPREGULATION OF THE QUISQUALATE MEDIATED PHOSPHOINOSITIDE (PI) HYDROLYSIS IN CULTURED CEREBELLAR GRANULE CELLS INDUCED BY 7-DAY γ-AMINOBUTYRIC ACID (GABA) PRETREATMENT. Onnfoh Yu* and De-Maw Chuang, LPP, NIMH, St. Elizabeths Hosp., Washington D.C. 20032. (SPONSOR: An-Zhong Zhang)

Cultured cerebellar cells use glutamate as their neurotransmitter and express three l-glutamate receptor subtypes, namely; kainate, N-methyl-D-aspartate, and quisqualate receptors that are linked to PI hydrolysis by phospholipase C. Following 7 days of 50 μM GABA pretreatment, it was previously shown that the l-glutamate receptor subtype, quisqualate receptor was selectively upregulated. We examined the effect of SR-95531, a $GABA_A$-receptor antagonist and (±) baclofen, a $GABA_B$-receptor agonist to determine the type of GABA receptor involved in the upregulation of quisqualate receptor by 7-day GABA pretreatment. 7-day GABA pretreatment increased 100 μM quisqualate mediated PI hydrolysis (1.64 ± 0.31 fold of control, N = 5). SR-95531 produced a dose-dependent reduction of this GABA effect when added into the culture medium with GABA (SR-95531; 1 μM: 1.34 ± 0.16; 10 μM: 1.15 ± 0.20; 100 μM: 1.19 ± 0.09 fold of control; N = 5). In contrast, 7-day pretreatment of granule cells with 100 μM (±) baclofen did not significantly enhanced the PI hydrolysis induced by the excitatory amino acids. It is therefore concluded that $GABA_A$ receptor activation is involved in the upregulation of quisqualate receptor mediated PI hydrolysis by 7-day GABA pretreatment since $GABA_A$ receptor antagonist was able to block this effect and $GABA_B$ receptor agonist was not able to mimic the effect of GABA. This work was done while O.Y. was a Nat. Res. Council/NAS resident research associate at NIMH.

MECHANISMS OF ANTICONVULSANT ACTION OF CENTRALLY-ACTING ANTITUSSIVES IN HIPPOCAMPAL SLICES. J.P. Apland and D.J. Braitman, Neurotox Br, U S A Med Res Inst Chem Def, APG, MD 21010

Carbetapentane(CB), caramiphen(CM) and dextromethorphan(DM) are centrally-acting antitussives which block epileptiform bursting induced by Mg^{++}-free medium in hippocampal slices (Braitman and Apland, 1988). CM has cholinolytic activity (Kraatz et al., 1949), which might be considered to be the basis for its anticonvulsant properties. We present evidence here that the anticonvulsant activity of these antitussives is not based on their cholinolytic properties, but upon a mechanism common to all three. Extracellular recordings were obtained from area CA1 of guinea pig hippocampal slices in artificial cerebrospinal fluid (ACSF). Evoked responses were elicited by stimulation of the Schaffer collaterals. Atropine (5-300 uM) did not block spontaneous epileptiform bursting induced by Mg^{++}-free ACSF without also blocking evoked responses at the highest concentrations, whereas CM (30 uM) was effective. Pretreatment with DM (30-100 uM) blocked epileptiform afterdischarges following evoked responses in both Mg^{++}-free ACSF and NMDA-containing ACSF. In contrast, pretreatment with CB or CM (30-100 uM) prevented afterdischarges in Mg^{++}-free ACSF, but completely depressed evoked responses in ACSF containing NMDA without blocking NMDA-induced afterdischarges. This evidence suggests that neither cholinolytic properties nor NMDA antagonism are necessary for the anticonvulsant activity of these antitussives.

CHARACTERIZATION OF THE BINDING OF [^{3}H]CGP 39653 TO THE N-METHYL-D-ASPARTATE (NMDA) RECEPTOR. Matthew A. Sills, E. Jay Wilusz*, Christof Angst*, Derek E. Brundish*[1] and Michael Williams. Research Department, CIBA-GEIGY Corporation, Summit, NJ 07901 and CIBA-GEIGY Ltd, Horsham, England[1].

During the past several years, the NMDA antagonist radioligands [^{3}H]CPP (3-(±)-2-carboxypiperazin-4-yl)propyl-1-phosphonic acid) and [^{3}H]CGS 19755 (cis -4-phosphonomethyl-2-piperidine carboxylic acid) have gained utility as tools to measure binding to the NMDA receptor. CGP 39653 (E-2-amino-4-phosphonomethyl-3-heptenoic acid) was found to inhibit the binding of [^{3}H]CPP to the NMDA receptor with an IC_{50} value of 5.0 nM. The present study examined the characteristics of [^{3}H]CGP 39653 binding to rat forebrain membranes in a filtration assay. Specific binding of [^{3}H]CGP 39653 was saturable, reversible and reached steady state within 60 min and represented 70 - 80 % of total binding. Computer analysis of binding data from saturation experiments revealed a Kd value of 6.2 ± 0.6 nM and a Bmax value of 970 ± 222 fmol/mg protein. When a series of NMDA agonists and antagonists competed for the binding of 2.0 nM [^{3}H]CGP 39653, the following order of potency was generated (Ki) : CGS 19755 (43 nM) = L-glutamate (45 nM) > CPP (106 nM) > D-aspartate (460 nM) > NMDA (2700 nM). Quisqualate and kainate inhibited less than 65 % specific binding at 10 μM,generating steep inhibition curves with Hill coefficients near unity. In contrast, glycine produced a biphasic inhibition curve. Computer analysis indicated that 37 ± 1 % of the binding was inhibited with an IC_{50} value of 536 ± 98 nM, whereas 63 ± 1 % of the binding was inhibited with an IC_{50} value of 868 ± 103 μM. These results indicate that [^{3}H]CGP 39653 is a selective, high affinity radioligand for the NMDA receptor.

463.6

RECEPTOR-LIGAND INTERACTIONS OF THE NMDA-TYPE GLUTAMATE RECEPTOR AS STUDIED USING DIFFERENT N-(1-[2-thienyl] cyclohexyl)piperidine (TCP) DERIVATIVES. S.O. Casalotti*, W. Tuekmantel*, A. Fauq*, A.P. Kozikowski, and K.E. Krueger. FGIN, Georgetown Univ. Med. Sch., Washington, D.C. 20007 and Dept. of Chemistry, Univ. of Pittsburgh, Pittsburgh, PA 15260.

Different derivatives of TCP modified at the region corresponding to the piperidine substituent were synthesized and tested for their abilities to compete against specific [^{3}H]MK-801 binding to bovine cortical synaptosomal plasma membranes. Phencyclidine (PCP) and TCP inhibited [^{3}H]MK-801 binding with an IC_{50} of 150 nM and 20 nM, respectively. Substitution of the TCP piperidine ring with different N-alkyl substituents from one to five carbon atoms in length exhibited great variation in the ability to inhibit [^{3}H]MK-801 binding with the N-ethyl derivative being most potent. Additional compounds with much longer N-substituents demonstrate affinities comparable to that of the N-methyl compound. Introduction of polar groups on these N-substituted alkyl chains greatly reduces the apparent affinity for this receptor. These studies provide more extensive detail in understanding the structural features of the MK-801-TCP binding site and should be helpful in attempting to design affinity ligands for this site.

463.7

CORTICAL METABOLIC ACTIVITY IS DIFFERENTIALLY ALTERED BY COMPETITIVE (AP7) AND NONCOMPETITIVE (MK-801) NMDA ANTAGONISTS. S.J. Lee*, D.W. Clow, J.E. Margulies, D. Yoshishige* and R.P. Hammer, Jr. (SPON: D.H. Crowell). Dept. Anatomy & Reprod. Biol., Univ. Hawaii Sch. Med., Honolulu, HI 96822.

Noncompetitive NMDA antagonist compounds, such as ketamine, are known to preferentially decrease glucose utilization in primary sensory cortices and to shift glucose labeling in terminal afferent fields from layer IV to layer Va (Hammer and Henkenham, *J. Comp. Neurol.*, 220: 396). Selective activation of limbic cortical areas also occurs. We compared the pattern and density of cortical activity following various doses of DL-amino-7-phosphonoheptanoate (AP7), MK-801 or saline vehicle using the quantitative [^{14}C] 2-deoxyglucose (2DG) procedure.

Arterial and venous cannulae were implanted using halothane anesthesia in male, Sprague-Dawley rats. Four hours later, MK-801 (0.1 or 1.0 mg/kg) or AP7 (1.5 or 4.0 mmol/kg) were administered intravenously, and 2DG was given 10 min thereafter. Computer-assisted analyses of autoradiographs and the brain sections which produced them yielded lCGU values in defined laminae of various cortical regions. Histologic analysis allowed precise differentiation of primary somatosensory (S_I), visual (V_I), hippocampal and other cortical regions.

MK-801 selectively decreased lCGU in neocortex and increased lCGU in limbic regions. At the lower dose, the drug decreased lCGU in S_I, V_I and auditory cortex, but not in S_{II} or V_{II}, producing an apparent cortical columnar pattern. The effect was more pronounced in layer IV than Va, resulting in a relative activity shift to layer Va. In contrast, AP7 produced a generalized, dose-dependent reduction of lCGU in all layers of neocortical and limbic regions, with some sparing of motor and entorhinal cortex. Thus, the pattern of effect of these drugs in cortex is quite different, particularly in limbic and primary sensory cortex, suggesting differential mechanisms of action. (Supported by USPHS Award DA04081; AP7 was generously provided by J.B. Monahan at G.D. Searle & Co.)

463.8

DISCRIMINATIVE STIMULUS PROPERTIES OF THE NONCOMPETITIVE NMDA ANTAGONIST MK-801 IN THE RAT.
J. De Vry* and J. Traber*. (SPON: F.K. PIERAU), Department of Neurobiology, Troponwerke, Berliner Strasse 156, D-5000 Köln 80, F.R.G.

In order to characterize the discriminative stimulus properties of the noncompetitive NMDA antagonist MK-801 [(+)-5-methyl-10,11-dihydro-5H-dibenzo[a,d]cyclohepten-5,10-imine maleate], rats were trained to discriminate 0.1 mg/kg MK-801 (i.p.) from saline in a FR-10 food-reinforced two-lever procedure. Dose-dependent generalization was obtained with MK-801 (ED50 in mg/kg: 0.03), and with three other noncompetitive NMDA antagonists [phencyclidine (1.4), ketamine (5.4) and (+)-N-allylnormetazocine (12.9)]; but not with the competitive NMDA antagonist 3-(2-carboxypiperazin-4-yl) propyl-1-phosphonic acid (CCP). Partial generalization was obtained with diazepam and ipsapirone; possibly indicating a minor anxiolytic component of the MK-801 cue. No generalization was obtained with imipramine, apomorphine, (+)-3-PPP [(+)-3-(3-hydroxyphenyl)-N-(1-propyl)piperidine] and haloperidol. In antagonism tests, NMDA pretreatment failed to affect the MK-801 cue. Pretreatment with (+)-3-PPP or haloperidol partially antagonized the MK-801 cue, but this occurred at behaviorally disruptive doses. The results suggest that MK-801 shares the psychotomimetic properties of the dissociative anesthetics and that the behavioral effects of competitive and noncompetitive NMDA antagonists are dissimilar.

ACTIONS OF (-)SCOPOLAMINE AND ATROPINE ON NMDA RECEPTORS: IMPLICATIONS ON MEMORY AND LEARNING. I.N. Cestari[1]*, Y. Aracava[1,2]* and E.X. Albuquerque[1,2]. (SPON: M.P. Blaustein) [1]Lab. Mol. Pharmacol. II, UFRJ, Rio de Janeiro, Brazil & [2]Dept. Pharmacol., Univ. Md. Sch. Med., Baltimore, MD 21201.

(-)Scopolamine, an antimuscarinic agent, promotes amnesia and learning impairment at therapeutic doses. This effect was not reported for atropine and pirenzepine. In the hippocampus, the facilitation of NMDA-mediated synaptic transmission has been implicated in the acquisition of memory and learning processes which can be altered by many NMDA channel blockers. Therefore, the actions of (-)scopolamine and atropine on the kinetics of NMDA-activated currents were investigated in outside-out patches from cultured rat hippocampal neurons. In Mg^{2+}-free solution, NMDA (5-10 μM) activated bursts that showed increased flickering with hyperpolarization and two populations of closed times. At holding potentials between -75 and -120 mV, (-)scopolamine (5-100 μM) blocked the NMDA channels and reduced the frequency of bursts. The number of openings per burst increased with concentration and decreased with hyperpolarization. Mean open times was shortened while both populations of intraburst closures were prolonged with increased (-)scopolamine concentration. Comparatively, atropine (10-100 μM) produced lesser reduction of both frequency of openings and mean open time such that only at concentrations >50 μM could significant alteration be discerned. These results suggest that (-)scopolamine is the more effective of these drugs as a blocker of channels activated by NMDA. (Support: FINEP & CNPq, Brazil; US Army Med. Res. & Devel. Comm. Contract DAMD17-88-C-8119)

TACRINE AND AMINACRINE BLOCK CHANNELS GATED BY NMDA IN CULTURED HIPPOCAMPAL NEURONS. A.C.S. Costa* and E.X. Albuquerque. (Spon: A. Eldefrawi) Lab. Mol. Pharmacol. II, Fed. Univ. Rio de Janeiro, Brazil; Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

1,2,3,4-Tetrahydro-9-aminoacridine (tacrine) is an anticholinesterase agent which has been shown to be useful for long-term treatment of patients with Alzheimer's disease. This agent also has noncompetitive effects on peripheral nicotinic acetylcholine receptor (AChR)(see R.A.M. Reis et al., this meeting). Since many noncompetitive blockers of the AChR also have actions on the NMDA receptor, we decided to study the actions of both tacrine and the chemically related anti-infective agent 9-amino-acridine (aminacrine) on single channel currents (patch clamped in the outside-out configuration) mostly recorded at -85 mV from cultured hippocampal cells 8-21 days old. Tacrine and aminacrine significantly reduced the channel open time in a concentration-dependent fashion (10-50 μM range). Channel openings produced by NMDA (5-15 μM) occur in bursts, which seem to increase in length as we increased the concentration of either agent. We also observed a reduction in frequency of openings and single channel conductance at concentrations greater than 10 μM; however, at this point further analysis is needed to establish whether or not the latter effects represent a real ion channel blockade. The blocking effect of tacrine on NMDA-gated channels could be responsible for its protection against NMDA cytotoxicity and may represent an alternative mechanism of action for this and some related compounds on Alzheimer's disease. (Support: CAPES Proc. 4987/88-2; US Army Med. Res.& Devel. Comm. Contr. DAMD17-88-C-8119).

463.11

CPP AND PCP PRODUCE AMNESIA OF A PASSIVE AVOIDANCE RESPONSE IN RATS. V.J. DeNoble, K.W. Jones*, C.L. Schaeffer* and L.M. Bauerle*. E. I. du Pont de Nemours & Co., Med. Prod. Dept., Exp. Sta., P.O. Box 80400, Wilmington, DE 19880.

There are interactions between PCP and NMDA. PCP selectively antagonizes NMDA-induced neuronal excitation and EEA antagonists produce PCP-like behavioral effects. The NMDA antagonist CPP shares several characteristics with benzodiazepines (BZD). Since the amnestic effects of BZD have been established and are blocked by the BZD antagonist RO15-1788, the purpose of the present study was to first, directly compare the amnestic effects of CPP and PCP in a passive avoidance (PA) test; and second, determine if RO15-1788 would block the amnestic effects of CPP or PCP.

Pretraining administration with CPP (2.0-10.0 mg/kg sc) significantly decreased retention latencies 24 hrs after training. Similar effects were found with PCP at doses ranging from 0.3 to 1.7 mg/kg sc and diazepam at doses between 5.0 to 18.0 mg/kg sc. In contrast, pretraining administration of RO15-1788 at 0.1 to 15 mg/kg sc did not alter retention latencies. Co-administration of RO15-1788 (0.01 to 15 mg/kg sc) with CPP (6.0 mg/kg sc) or PCP (1.0 mg/kg sc) failed to block the amnesia. However, when RO15-1788 was co-administered with diazepam (9.0 mg/kg sc) a dose related antagonism of diazepam induced amnesia was found. These results suggest that the behavioral actions of CPP and PCP on PA retention are not mediated via the benzodiazepine receptor complex.

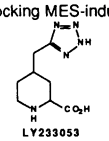
BEHAVIORAL PHARMACOLOGY AND DURATION OF ACTION OF LY233053: A STRUCTURALLY NOVEL NMDA RECEPTOR ANTAGONIST. J.D. Leander*, P.L. Ornstein, D.D. Schoepp, and C.R. Salhoff* (SPON: D. Goldstein). Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285

We report here the behavioral pharmacology profile, in mice, rats and pigeons, of the novel, selective and potent competitive NMDA receptor antagonist, LY233053 (cis-(±)-4-((2H-tetraazol-5-yl)methyl)piperidine-2-carboxylic acid). This compound was studied in a variety of *in vivo* assays. In mice, LY233053 protected against maximal electroshock-induced (MES) seizures and NMDA-induced lethality at lower minimal doses (10 mg/kg) than the minimal dose (40 mg/kg) which impaired horizontal screen performance. In rats, the ED_{50} against MES seizures was 3.5 mg/kg, i.p. In pigeons, LY233053 antagonized (ED_{50} = 1.3 mg/kg, i.m.) the complete behavioral suppressant effects of 10 mg/kg of NMDA. The dose of LY233053 estimated to shift the NMDA dose-response curve two-fold was 2.3 mg/kg. A dose of 40 mg/kg, i.m., did not produce the phencyclidine-like catalepsy described in pigeons. LY233053 blocked NMDA-induced convulsions in neonatal rats with a duration of action of 4 hours. This compared to a >12-hour duration of action for CGS-19755. The same relative duration of action was observed for LY233053 and CGS-19755 in blocking MES-induced convulsions in rats.



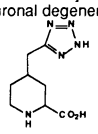
LY233053

LY 233053 demonstrates a short duration of action when compared to phosphonate substituted amino acids, good *in vivo* activity, and may be therapeutically advantageous in the treatment of certain excitatory amino acid related disorders.

463.13

IN VITRO AND *IN VIVO* CHARACTERIZATION OF LY233053: A STRUCTURALLY NOVEL COMPETITIVE NMDA RECEPTOR ANTAGONIST. P.L. Ornstein, D.D. Schoepp, J.D. Leander*, D.T. Wong, D. Lodge, C.R. Salhoff*, L.G. Mendelsohn, and N.R. Mason. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285 and Royal Veterinary College, London, NW10TU, UK.

This study reports the activity of a structrually novel excitatory amino acid receptor antagonist, LY233053 (cis-(±)-4-((2H-tetraazol-5-yl)methyl)piperidine-2-carboxylic acid), the first tetrazole-containing competitve NMDA antagonist. LY233053 potently inhibited NMDA receptor binding to rat brain membranes as shown by the *in vitro* displacement of ^{3}H-CGS19755 (IC_{50} = 107 nM), ^{3}H-CPP (IC_{50} = 164 nM), and ^{3}H-MK801 (IC_{50} = 1103 nM). No appreciable affinity in ^{3}H-AMPA or ^{3}H-kainate binding assays was observed (IC_{50}s > 10,000 nM). NMDA receptor antagonist activity was further demonstrated by selective inhibition of NMDA-induced depolarization in cortical wedges (IC_{50} = 6.4 μM versus 40 μM NMDA). The CNS effects of NMDA were also antagonized following *in vivo* systemic administration of LY233053. LY233053 prevented NMDA-induced lethality in mice (MED [minimum effective dose] = 10mg/kg, i.p.) and NMDA-induced rat striatal cholinergic neuronal degeneration (MED = 100 mg/kg, i.p.).



LY233053

Thus, LY233053 is a potent, selective, and competitive antagonist of NMDA excitatory amino acid receptors *in vitro* and *in vivo*. The antagonist activity of this compound following systemic administration demonstrates potential therapeutic value in conditions of neuronal cell loss due to NMDA receptor excitotoxicity.

463.14

NOVEL PEPTIDE NMDA ANTAGONISTS FROM THE VENOM OF CONUS

J. Haack, E. Mena+, T. N. Parks**, J. Rivier#, L. Cruz and B. Olivera. Dept. of Biology, Univ. of Utah and **Natural Product Sciences, Salt Lake City, Utah, +Pfizer Central Research, Groton, CT. and #The Salk Institute, La Jolla, CA.

Two homologous peptides, conantokin-G (formerly called conotoxin GV) and conantokin-T have been isolated from the venom of the fish-hunting cone snails Conus geographus and Conus tulipa respectively. Both peptides elicit a sleep-like state in animals under two weeks of age and a hyperactive state in older mice. These peptides contain 4-5 residues of the unusual amino acid, γ-carboxyglutamate (Gla) in homologous positions. The Gla residues are required for expression of the profound behavioral effects of these peptides. We examined the ability of these peptides to affect CNS systems which could potentially mediate these behavioral effects. Our results show that these peptides represent a novel, potent class of peptide NMDA antagonists. Conantokin-G blocked the NMDA-induced (100 μM) elevation of cGMP in the rat cerebellum in vitro with an IC50 of 32 nM but had no effect on kainic acid induced (100 μM) elevations at 1 μM. Comparison of this activity with other NMDA antagonists in this assay shows that this peptide is approximately 2 and 200-fold more potent than MK-801 and AP7, respectively. Both peptides were able to attenuate the NMDA mediated influx of calcium in cultured cerebellar granular cells as monitored by fura-2-fluorescence. Conantokin-G also inhibited [^{3}H]L-Glu binding to synaptic junctions (IC50 of 940 nM), but had no effect on [^{3}H]TCP binding (IC50>>1 μM). Conantokin-G enhanced [^{3}H]Gly binding to rat forebrain membranes similarly to the polyamine compounds (e.g., ARG636) isolated from several species of spiders (see E. Mena et al. and M. Gullak et al., this meeting). Conantokin-G, however, did not block the binding of [^{125}I]Arg636 to rat brain membranes. The conantokins are the first functional peptide antagonists of NMDA to be reported. The mechanism by which they block the activation of NMDA receptors is currently under investigation.

463.15

ASCORBIC ACID AND GLUTATHIONE ARE ANTAGONISTS OF THE NMDA RECEPTOR. M.D. Majewska, J.M.H. ffrench-Mullen and E.D. London, Neuropharmacology Lab., Addiction Res. Ctr., NIDA, Baltimore, MD 21224 and Neurophysiology Lab., NINCDS, Bethesda, MD.

Ascorbic acid (AA) and glutathione (GSH) exist in the CNS at high micromolar to millimolar concentrations (Schenk, J.O., et al., Brain Res. 253:353, 1982; Slivka, A., et al., Brain Res. 409:275, 1987). They are localized mostly in glia, nerve terminals and the choroid plexus, and are released into CSF during neuronal activity. We examined the interaction of AA and GSH with NMDA receptors in the rat brain. At physiological concentrations (μM), AA and GSH inhibited binding of [^{3}H]glutamate and reduced the binding affinity of N-[1-(2-thienyl)cyclohexyl]piperidine ([^{3}H]TCP), a steric blocker of the NMDA-gated cationic channel, to brain membranes. These effects resembled those of competitive NMDA antagonists. In electrophysiological recordings, AA and GSH reversibly inhibited NMDA-gated inward currents in isolated hippocampal neurons. Our data suggest that AA and GSH act in the CNS as endogenous antagonists of NMDA receptors. As hyperactivity of NMDA receptors is linked to neuronal damage associated with ischemia, edema, trauma and some neurodegenerative diseases, these data imply that AA and GSH may function as neuroprotective agents in the CNS. Also, since the plasma and CSF levels of AA and GSH increase after ACTH stimulation (Briggs, F.N. and Toepel, W., Endocrinol. 62:24, 1958; Lahiri, S. and Lloyd, B., Biochem. J. 84:478, 1962), these agents may act as stress hormones.

463.16

N-(PHOSPHONOALKYL AND -ARYL SUBSTITUTED)-α-AMINO ACIDS AS COMPETITIVE INHIBITORS OF THE NMDA RECEPTOR. C.F. Bigge,* G. Johnson,* F.W. Marcoux, A.W. Probert, L.L. Coughenour,* L.J. Brance* (SPON: F. Hershenson). Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48103.

Two novel series of N-substituted amino acids with terminal phosphonic acid groups were prepared as potential competitive N-methyl-D-aspartate (NMDA) antagonists to examine the steric and entropic requirements for retention of affinity. An assay using crude rat brain synaptic membranes and [3H]-4-(3-phosphonopropyl)-2-piperazinecarboxylic acid ([3H]-CPP) as ligand was used to determine NMDA receptor affinity. Antagonist action was confirmed by their ability to inhibit glutamate-induced accumulation of [45Ca++] in cultured rat cortical neurons. Compounds found to have significant receptor affinity in the [3H]-CPP NMDA receptor assay were N-(4-phosphono-2-butenyl)glycine (IC50=1.2μM), N-[[3-(phosphonomethyl)phenyl]-methyl]glycine (IC50=2.24μM), N-(4-phosphono-3-butenyl) glycine (IC50=2.45μM) and N-[[4-(phosphonomethyl)phenyl]-methyl]glycine (IC50=5.2μM). Antagonist activity in the [45Ca++] influx assay in cell culture was well correlated to their receptor affinity. The compounds described support a folded conformation for antagonist binding at the receptor. Entropy appears to be the most important factor responsible for high affinity. Each of the compounds reported above has either a double bond or a phenyl ring which allows the compound to obtain a reasonably stable conformation which can overlap with the three major functional groups of known competitive antagonists. Removal of the double bonds eliminates binding affinity. Alanine derivatives have reduced affinity for the receptor compared with the glycine derivatives, and isoleucine derivatives were shown to have no affinity. In each case, the α-substituent may disrupt the folding of the molecule into the preferred conformation for receptor binding.

463.17

PARADOXICAL EFFECTS OF TILETAMINE, A POTENT PHENCYCLIDINE [PCP] RECEPTOR AGONIST. T.S. Rao, J. Cler*, P.C. Contreras, S. Mick*, S. Iyengar, V. Dilworth*, J. Monahan and P.L. Wood. CNS Diseases Research, G.D. Searle & Co., St. Louis, Mo 63198.

The neurochemical effects of tiletamine [T], a PCP ligand [IC_{50} against ^{3}H-TCP, for T, MK-801 and PCP were 79 ± 2, 3.6 ± 0.6 and 44 ± 6 (nM) respectively] with weak affinity for quisqualate, kainate, glycine, dopamine [DA] D_1 and D_2 receptors, were examined on cerebellar cyclic GMP [cGMP] and rat pyriform cortical [PYR] DA metabolism. Parenteral administration of T resulted in stereotypy and ataxia, a characteristic feature of PCP receptor agonists. MK-801 and tiletamine decreased cGMP [ED_{50}, 0.35 and 4 mg/kg respectively]. While MK-801, dexoxadrol, ketamine and PCP increased PYR DA metabolism, T [2-25 mg/kg] was ineffective. T [1-10 ug/rat, icv] also did not affect PYR DA metabolism. The apparent lack of effect of T at increasing PYR DA despite its ability to decrease cGMP like other PCP agonists, tentatively suggests a selective interaction with N-methyl-D-aspartate [NMDA]-coupled PCP receptors.

463.18

(+)-N-ALLYLNORMETAZOCINE (NANM)-LIKE DISCRIMINATIVE STIMULUS EFFECTS OF N-METHYL-D-ASPARTATE (NMDA) ANTAGONISTS IN RATS. J. Willetts, A. Rice* and R.L. Balster*. Dept. of Pharmacology and Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298.

The effects of the competitive NMDA antagonists, NPC 12626 (2-amino-4,5-[1,2-cyclohexyl]-7-phosphonoheptanoic acid) and CPP (3-{[±]-2-carboxypiperazin-4-yl}propyl-1-phosphonic acid), were compared to those of the non-competitive NMDA antagonists, phencyclidine (PCP) and MK-801, in male Sprague-Dawley rats trained to discriminate 5 mg/kg (+)-NANM from saline under a standard two-lever fixed-ratio 32 schedule of food reinforcement. (+)-NANM (1.25-20 mg/kg), PCP (0.1-6.0 mg/kg) and MK-801 (0.01-0.17 mg/kg) all dose-dependently substituted for the training dose of (+)-NANM in all rats tested. The order of potency for (+)-NANM lever selection was MK-801>PCP>(+)-NANM. Conversely, NPC 12626 (10-100 mg/kg) and CPP (3.0-20 mg/kg) produced no more than an average of 70% (+)-NANM lever responding at doses that reduced response rates by more than 50% of corresponding control response rates. Methohexital (5.0-17.3 mg/kg) also produced an average of 50% (+)-NANM lever responding at doses that reduced response rates. In addition to supporting a role for the PCP receptor in transducing the discriminative stimulus effects of (+)-NANM, these results lend further support for differences in the behavioral effects of competitive and non-competitive NMDA antagonists. (Supported by NIDA Grant DA-01442).

463.19

THE EFFECT OF NONCOMPETITIVE N-METHYL-D-ASPARTATE (NMDA) ANTAGONISTS ON SELECTED NEUROTRANSMITTER UPTAKE SYSTEMS. D.K. Boyd and R.D. Schwarz, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105

Behavioral effects of phencyclidine (PCP) have been attributed to its binding to a site within the NMDA receptor complex, blockade of ion channels, or modulation of neurotransmitter release and/or uptake. While other noncompetitive agents also bind to the PCP site, it is unclear what their activity is in various neuronal uptake systems. Using slices from the appropriate rat brain region, inhibition of DA (striatum), NE (cortex) and 5-HT (cortex) high affinity uptake was measured for 5 min., using tritiated ligand at 37°C. PCP was found to have IC_{50} values of 2.2μM, 0.87μM, and 5.75μM respectively. The other noncompetitive agents showed a wide range of activity with the rank order for each assay being: ^{3}H-DA: PCP < ifenprodil < MK 801 < dextromethorphan (DM) < ketamine, ^{3}H-NE: ifenprodil < PCP < MK 801 = DM < ketamine and ^{3}H-5HT: DM < ifenprodil < PCP < MK 801 < ketamine. Additionally, the competitive NMDA antagonist, 3-(2-carboxypiperazin-4-yl)propyl-1-phosphonic acid (CPP), was inactive in all assays. In conclusion, there is no consistent pattern of activity for uptake inhibition with these agents. Thus, the observed activity may not be responsible for effects common to all non-competitive NMDA antagonists (eg. antischemic efficacy, psychotomimetic side effects).

Intoxicating Concentrations of Ethanol (EtOH) Inhibit NMDA Receptor-mediated EPSPs in Adult Rat Hippocampus David M. Lovinger*, Geoffrey White* and Forrest F. Weight, Section of Electrophysiology, LPPS, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852 U.S.A.

We recently reported that EtOH at intoxicating concentrations inhibits the ion current activated by the glutamate receptor agonist NMDA in cultured hippocampal neurons (Lovinger et al., Science, 243; 1721,1989). We now report that EtOH inhibits synaptic transmission mediated by NMDA receptors in the CA1 sub-field of hippocampal slices from adult rats. NMDA receptor-mediated population EPSPs (pEPSPs) were isolated using the kainate/quisqualate receptor antagonist DNQX (10 μM) and low Mg^{2+} (0.1 mM). Ethanol inhibited NMDA receptor-mediated pEPSPs. Inhibition increased as the EtOH concentration increased from 1 mM (little or no inhibition) to 50 mM (43% inhibition). NMDA receptor-mediated pEPSPs were also inhibited by EtOH in the presence of the $GABA_A$ receptor antagonist bicuculline (100 μM), suggesting that the inhibition of the pEPSP is not secondary to a change in GABAergic transmission. EtOH (50 mM) did not inhibit pEPSPs mediated by non-NMDA glutamate receptors recorded in the presence of physiological Mg^{2+} concentrations (1.5 mM) and the NMDA receptor antagonist APV (50 μM), suggesting that EtOH inhibition of NMDA receptor-mediated pEPSPs does not result from general depression of glutamatergic transmission. These findings support the hypothesis that EtOH inhibition of NMDA receptor-mediated transmission contributes to intoxication.

EFFECTS OF ALCOHOLS ON THE GLUTAMATERGIC TRANSMISSION. M.T. Lima-Landman*[1], A.C.S Costa*[1,2], M.M. Froes*[2] and E.X. Albuquerque[1,2]. (Spon: L. Goldman) [1]Dept. Pharmacol., Univ. Md. Sch. Med., Baltimore, MD 21201 & [2]Lab. Mol. Pharmacol. II, UFRJ, Brazil.

Recently, ethanol (EtOH) has been reported to modify the function of excitatory aminoacid receptors (Lovinger, D.M. *et al., Science,* 243:1721, 1989; Lima-Landman, M.T. and Albuquerque, E.X. *FEBS Lett.,* 247:61, 1989). The impairment of certain brain function under EtOH intoxication and the growing evidence that links the NMDA- subtype of glutamatergic receptors to the memory and learning processes raised questions about alternative pathways for EtOH actions in the CNS. In the light of these findings, the effects of some aliphatic alcohols were studied on the NMDA and quisqualate-activated single channel currents in hippocampal pyramidal cells in culture using the patch-clamp technique in outside-out configuration. EtOH (1.74-174 mM or 0.01%-1%) had two major effects on NMDA-activated single currents: at low concentrations (1.74-8.65 mM) the probability of opening (p_{open}) increased without affecting the mean channel open time; at higher concentrations (86.5-174 mM) the p_{open} decreased with a concommitant decrease of mean channel open time. In quisqualate-activated single channel currents, EtOH (5 mM) decreased the p_{open}. This effect was enhanced with increasing EtOH concentrations. Mean channel open time of quisqualate-activated single channel currents decreased only at 500 mM EtOH. All these EtOH effects on NMDA and on quisqualate-activated currents could be reversed by washing. Using several alcohols (methanol, 1-butanol and isopentanol) we have observed a differential potency on the NMDA receptor/ion channel. These results suggest that glutamatergic transmission could be involved in some of the central effects of EtOH. (Supp: NIH NS25296, NIMH P-50MH44211, CNPq, CAPES Proc. 4987/88-2).

463.22

EFFECTS OF POLYAMINE SPIDER VENOM COMPONENTS ON [3H]GLU AND [3H]GLY BINDING TO RAT CNS MEMBRANES. M. F. Gullak*, M. J. Pagnozzi*, K. E. Richter* and E. E. Mena. (SPON: L Reynolds). Dept. Neurosci., Pfizer Central Research, Groton, CT 06340

Venoms from several species of spiders contain compounds which are characterized by a polyamine linked to an aromatic group. These compounds exert their paralytic effects on their prey by blocking glutamatergic synapses at invertebrate neuromuscular synapses. We have previously shown that these compounds are also selective for the NMDA receptor in the mammalian CNS (see also Mueller, A.L. et al., and Parks, T. N. et al., this meeting).

We examined the effects of the polyamine argiotoxins (Arg659 and 636) on [3H]Glu binding and uptake and on [3H]Gly binding in rat CNS membranes. These compounds had no effect on either Na^+-dept, Cl^--dept ,or Cl^--indept [3H]Glu binding in rat CNS membranes or on Na^+-dept [3H]Glu uptake in brain P2 fraction. However, both polyamines appeared to enhance [3H]Gly binding to forebrain membranes 2 to 4-fold when measured with a filter assay (ED50's of 22 and 43 μM, respectively). In contrast, no effect was seen using a microfuge assay. This apparent enhancement of binding did not occured with spinal cord membranes. The Kd of Gly and the IC50's of D-Ser, cycloserine, kynurenic acid and 7-Cl-kynurenic acid were identical in the presence or absence of Arg636. Additional experiments showed that Arg636 slowed both the dissociation rate and the association rate of Gly with its receptor. As a result, there was no observable effect on the Kd of Gly or on total Gly binding using a microfuge assay. Several divalent cations were able to mimic this effect of Arg636 but were not additive with Arg636. These cations were also able to displace [125I]Arg636 binding (see Mena et al., this meeting). The polyamines may block NMDA mediated responses by blocking Gly interactions with divalent ion channels at the NMDA receptor complex.

463.23

CNS BINDING SITES OF THE NOVEL NMDA ANTAGONIST, ARG-636. E. Mena, M. Gullak*, M. Pagnozzi,* D. Phillips* and N. Saccomano*. Dept. of Neurosci. and Med. Chem., Pfizer Central Research, Groton, CT 06340.

Argiotoxin636 (Arg636) is a polyamine component isolated from the venom of the spider, *Argiope aurantia* which blocks NMDA-induced elevations of cGMP in the rat cerebellum noncompetitively and NMDA-stimulated release of [3H]norepinephrine from rat hippocampus, both *in vitro*. Additionally, it antagonizes seizures induced by injection of NMDA in mice (see Seymour and Mena, this meeting). Arg636 can be distinguished from other NMDA antagonists by its unique effects on [3H]Gly binding (see Gullak et al., this meeting). We studied the interaction of [125I]Arg636 with CNS membranes to characterize further the mechanism of action of this novel NMDA antagonist.

Both radioactive and nonradioactive [I]Arg636 were synthesized from Arg636 using a chloroamine-T procedure and purified by HPLC. The structure of nonradioactive [I]Arg636 was determined by FAB-MS and NMR techniques to be the 5-iodo-2,4-dihydroxyphenyl acetic acid derivative. Nonradioactive [I]Arg636 blocked NMDA-induced elevation of cGMP with an IC50 similar to Arg636 (IC50's of 48 and 34 μM, respectively).

[125I]Arg636 bound to rat forebrain membranes with Kd and Bmax values of 11.25 μM and 28.95 pmol/mg protein (80% specific). The ability of other known polyamines and recently discovered polyamines from *Agelenopsis aperta* to inhibit binding paralled their activity as functional NMDA antagonists. No other compounds tested were able to block specific binding. However, divalent cations were potent inhibitors of this binding (IC50's of Mn, Co, Mg and Ca = 0.4 , 1, 3.4 and 5 mM, respectively). The similar effects of divalent cations and Arg636 on [3H]Gly binding (see Gullak et al., this meeting) and the effects divalent cations on [125I]Arg636 binding suggest that these polyamines may antagonize responses to NMDA by interacting with membrane ion channels.

463.24

IN VIVO NMDA ANTAGONIST ACTIVITY OF THE POLYAMINE SPIDER VENOM COMPONENT, ARGIOTOXIN-636. P.A.Seymour and E.E.Mena. Department of Neuroscience, Central Research Division, Pfizer Inc., Groton, CT 06340

Argiotoxin-636 (Arg636), a polyamine component from the venom of the orb weaving spider *Argiope aurantia*, has previously been shown to be a functional antagonist at NMDA receptors in rat brain *in vitro* (Pagnozzi , M. J. et al., Soc. Neurosci. Abs.,14:482,1988; see also Parks, T. N. et al., and Muellier, A. L. et al., this meeting). To evaluate its NMDA antagonist activity *in vivo*, Arg636 was administered to seizure sensitive, 22-23 day old DBA/2 mice for antagonism of audiogenic seizures. Arg636 produced 100% protection at doses of 10 and 32 mg/kg, s.c. and i.p., respectively. Locomotor activity studies showed that Arg636 did not significantly affect locomotor activity at these doses. Since this test is responsive to anticonvulsants of different classes, Arg636 was subsequently examined for specific antagonism of seizures induced by NMDA (56 mg/kg,i.p.). When administered 15 or 30 (s.c.), but not 60 min prior to NMDA, Arg636 significantly antagonized NMDA-induced seizures with a minimal effective dose of 32 mg/kg, s.c., indicating that Arg636 exerts NMDA antagonist activity after systemic administration *in vivo*.

463.25

POLYAMINE SPIDER TOXINS BLOCK NMDA RECEPTOR-MEDIATED INCREASES IN CYTOSOLIC CALCIUM IN CEREBELLAR GRANULE NEURONS. T. N. Parks[1], R. A. Volkmann[2*], N. A. Saccomano[2*], L. D. Artman[1*] and E. F. Nemeth[1]. Natural Product Sciences Inc., Salt Lake City, UT 84108[1] and Pfizer Central Research, Groton, CT 06340[2].

Polyamine-containing toxins in spider venoms have been reported to antagonize transmission at a variety of glutamatergic synapses (Ann. Rev. Neurosci. 12; Ann. Rep. Med. Chem. 24, 1989). We investigated the effects of synthetic toxins on NMDA-induced changes in cytosolic free calcium concentration ([Ca]i) in cultures of neonatal rat cerebellar granule neurons studied by fura-2 fluorimetry (see Nemeth and Parks, this meeting). Increases in [Ca]i in response to 10^{-5} M NMDA or L-aspartate in these cells are enhanced by 10^{-6} M glycine and antagonized by Mg^{++}, MK-801 (IC_{50}= 35 nM), AP5 (IC_{50}= 20 μM) and CPP but not by DNQX. Synthetic polyamine toxins are potent inhibitors of NMDA-induced increases in [Ca]i: Argiotoxin 659 (IC_{50}= 50 nM); Argiotoxin 636 (85 nM); Nephilatoxin (NSTX; 370 nM); Agelenopsis aperta toxins B1 (500 nM) and E (700 nM); Joro spider toxin (JSTX; 850 nM); Philanthotoxin-433 (15 μM). These data, in conjunction with evidence that polyamine toxins specifically affect NMDA-mediated transmission in rat hippocampus (Mueller et al., this meeting), suggest that these compounds constitute a new class of potent NMDA antagonist (see also Mena et al. and Seymour and Mena, this meeting).

LEARNING AND MEMORY–PHARMACOLOGY: OTHER I

464.1

EFFECTS OF PERIPHERAL ADMINISTRATION OF SUBSTANCE P AND NALOXONE ON AVOIDANCE LEARNING AND HABITUATION. C. Tomaz, P.J.C. Nogueira and M.S. Aguiar. (SPON: J.A. Ricardo). Lab. of Psychobiology, University of São Paulo, FFCLRP-USP, 14049 Ribeirão Preto, SP, Brazil.

One of us has shown that peripheral post-trial administration of substance P (SP) improves retention test performance of a single-trial inhibitory avoidance task in a dose-dependent way. In the present study, we examined the effects of SP peripheral administration on learning of three avoidance tasks and habituation. Male Wistar rats were tested in three inhibitory avoidance tasks: step-down, up-hill and alcove. Habituation was measured in an open field by recording the number of rearings during 2 min of free exploration. Training and test sessions were indentical and 24 h apart. The animals were injected i.p. immediately after the trainning trial with all possible combinations of vehicle, SP (0,5 , 5, 50, 100, 250 or 500 μg/kg) and naloxone (0,5 , 1, 5 or 50 mg/kg). Rats injected with 50 μg SP/kg had significantly longer step-down and up-hill latencies at the retention test then control animals, whereas such differences were not observed for the alcove task. Pre-treatment with naloxone produced facilitation on the up-hill and step-down tasks. In the habituation test, there were significant effects for the doses of 5 and 50 μg SP/kg, lower and higher doses being ineffective. Additionally, for this test, we included a 5 h delayed injection group, which did not differ from the vehicle control.

PRETRAINING NALOXONE ENHANCES MORRIS WATER MAZE PERFORMANCE AND ALTERS TRAINING-INDUCED CHANGES IN HIGH AFFINITY CHOLINE UPTAKE (HACU). M. W. Decker, I. B. Introini-Collison, and J. L. McGaugh. Center for the Neurobiology of Learning and Memory and Dept. of Psychobiology, Univ. California, Irvine. CA 92717.

Posttraining administration of opiate antagonists enhances retention in a variety of learning and memory tasks. The role of opioid peptides in spatial tasks, however, is not established. We explored the role of opioid peptides in spatial learning by assessing the effects of pre- and posttraining naloxone on water maze acquisition.

Rats were given naloxone HCl (0, 1 or 3 mg/kg ip) either 5 min. before or immediately after each day's training session (2 trials/day) for 4 days. A 5th session was conducted without drug injections and was immediately followed by a free swim probe trial. Pretraining naloxone produced a dose-dependent increase in the rate of acquisition as measured both by escape latencies during training and search pattern analysis during the free swim. Posttraining naloxone had no significant effect.

In a parallel set of rats receiving daily pretraining naloxone (3 mg/kg ip), septohippocampal cholinergic activity, which is thought to be important in the acquisition of spatial information, was assessed by measuring hippocampal HACU 15 min. after the last trial on day 4. HACU was significantly reduced in place-trained rats and in swim-yoked controls relative to behaviorally naive rats. Naloxone significantly reduced HACU in behaviorally naive rats, but attenuated the swimming-induced decrease in HACU. These results suggest that naloxone alters the response of the septohippocampal cholinergic system to water maze training.

These experiments suggest that opioid peptides play an important modulatory role in the acquisition of spatial information and that they may produce some of these effects via an action on the septohippocampal cholinergic system.

DELAYED DEVELOPMENT OF AMNESIA FOLLOWING INTRACRANIAL INJECTION OF [LEU]ENKEPHALIN IN TWO-DAY-OLD CHICKS. P.J. Colombo, J.Tsai*, E.L. Bennett, M.R. Rosenzweig and J.L. Martinez Jr. . Department of Psychology, University of California, Berkeley, CA 94720.

[Leu]enkephalin (LE) impairs retention of peck-aversion training in two-day-old chicks (Patterson et al., Behav. Neurosci., 103:429, 1989). To characterize further the development of amnesia following intracranial (IC) injection of LE, chicks were tested either 5, 15, 30, 45, 60, 90, 120, 180, 240 min, or 24 hr after training. Chicks injected bilaterally in the region of the intermediate medial hyperstriatum ventrale with LE performed like saline injected controls during training as measured by latency to peck and number of pecks. LE injected chicks performed like controls when tested at each of the post-training time points between 5 and 180 min. At 240 min post-training, LE -treated chicks show a moderate impairment, and are amnesic when tested at 24 hr. Previous investigation of chicks indicates that amnesia develops within one of three temporal courses. The current findings suggest that IC injection of LE produces amnesia with novel temporal characteristics. Also, B-endorphin was found to produce amnesia more rapidly than other agents studied in our laboratory (Bennett, et al., Soc.for Neuroscience, 1988). These results suggest that opioids may affect memory formation through mechanisms other than those previously studied.

464.4

ENHANCEMENT OF MEMORY FOR A ONE-TRIAL PASSIVE AVOIDANCE TASK IN CHICKS GIVEN PERIPHERAL AND CENTRAL INJECTIONS OF NALOXONE. D.W. Lee, M.K. Means*, D.J. Afinowicz*, E.L. Bennett, J.L. Martinez Jr., & M.R. Rosenzweig. Dept. of Psychology, Univ. of California, Berkeley, CA, 94720.

To investigate memory enhancement for a one-trial passive avoidance task in chicks, a weak concentration (10%) of the bitter tasting liquid methylanthranilate (MeA) was used as the aversive stimulus. Naloxone (Nal), an opioid receptor antagonist known to generally enhance some forms of memory, was without effect when 100% MeA was used. Several experiments were conducted administering central (i.c.) bilateral injections directed to the region of the medial hyperstriatum ventrale or peripheral (i.p.) injections of Nal or saline (Sal). The effective doses for each injection route were determined by injecting either Sal or Nal i.c. or i.p. 5 min pretraining. When tested at 24 hrs, intermediate doses for both routes resulted in the highest levels of retention (u-shaped curves). For i.c., 60-96 nmol/chick and for i.p., 1000 nmol/chick (10 mg/kg) Nal were the most effective doses resulting in strong enhancement effects (80-85% retention) when compared to Sal (40-43% retention). The effective dose i.c. (96 nmol) also significantly enhanced retention when injected 5 min posttraining as well as 5 min pretraining. Central injections were 10 times more potent than peripheral injections. These results: 1) show a central action of Nal, 2) suggest that the apparent peripheral action may be central, but 3) do not rule out a peripheral action.

464.5

EFFECTS OF POSTNATAL TESTOSTERONE PROPRIONATE ADMINISTRATION ON MORRIS WATER MAZE PERFORMANCE IN RATS. R.L. Roof. Dept. of Psychology and Neuroscience Program, University of Wyoming, Laramie, WY, 82071.

To study the involvement of testosterone in the development of spatial abilities, male and female rats were injected with either 75 ug or 150 ug Testosterone Proprionate (TP) or an oil vehicle on days 4 and 6 after birth. At 90+ days of age, the rats were trained and tested on the Morris water maze (MWM). Rats were tested once a day for 6 successive days, and were retested after a 3 week delay. TP effects on MWM performance were observed for the trial at which the first significant drop in time and distance required to reach the platform occurred. TP treated females improved more quickly than control females, and control males improved more quickly than TP treated males. In addition, control males required less time than control females to reach the platform on 4 of the 6 initial trials. There were no differences between the groups on the trials after the delay.

These findings support the hypothesis that steroid hormones have an organizational effect on the developing brain that subsequently influences cognitive functioning.

464.6

EFFECTS OF FORSKOLIN, CAFFEINE, AND CYCLOHEXIMIDE ON MEMORY RECALL AFTER APPETITIVE CONDITIONING IN THE HONEY BEE. B.H. Smith, P.W. Hamlet, A.E. McNair and T.R. Tobin. ARL Div. of Neurobiology, Univ. of Arizona, Tucson AZ 85721.

Models of memory consolidation invoke a multi-stage process wherein the different stages are dependent upon specific biochemical mechanisms. Recall at intermediate intervals after associative conditioning may be dependent upon mechanisms involving cAMP, whereas longer term responding is thought to involve gene activation and protein biosynthesis. Using associative conditioning of the proboscis extension reflex of the honey bee, we undertook to determine time windows for sensitivity of recall to different substances that modulate these biochemical mechanisms.

Restrained honey bee workers were conditioned to extend their mouthparts to an odorant by 1 to 4 forward pairings (30 sec ITIs) of that odorant with a 2.0M sugar water reward. All bees were tested with a *single* extinction trial at one of several times ranging from 5 min to 120 min post-conditioning. In a control series to determine long-term recall levels, responses were equivalent among bees conditioned with 1, 2, 3, or 4 trials at all times through 120 min and involved associative and non-associative behavioral mechanisms.

In several subsequent experimental series, each bee received an abdominal injection containing either saline, or one of several concentrations of forskolin, caffeine, or cycloheximide in the same saline. Bees injected with caffeine or forskolin 45 min prior to a single conditioning trial had similar levels recall to bees injected with saline alone when tested at either 45 min or 120 min post-conditioning. Bees injected with cycloheximide 30 min prior to conditioning had decreased levels of recall 45 min and 120 min after conditioning with 4 trials. However, effects were mixed in groups injected 180 min prior to conditioning. Biochemical characterization of protein synthesis in these groups of bees may elucidate these phenomena.

464.7

THE INTERACTIVE EFFECTS OF CAFFEINE AND PHASE OF MENSTRUAL CYCLE ON FREE RECALL. M. E. Arnold*, B. E. Beckwith and T. V. Petros. Psychol. Depart., Univ. of North Dakota, Box 7187 Univ. Sta., Grand Forks, ND 58202.

The effect of caffeine on memory in women who were and were not taking oral contraceptives was examined. Thirty minutes after ingesting either 0, 2 or 4 mg/kg of caffeine at days 1-5 or days 9-13 of their menstrual cycle, subjects listened to lists of words and provided immediate free recall of each list along with a final free recall of all the lists. Caffeine facilitated recall of words in the primary positions of the lists and women on oral contraceptives recalled fewer primacy words than pill-free women. There were also complex interactions between treatment, phase of menstrual cycle, practice and rate of presentation of words. During the final recall, caffeine enhanced overall recall. Caffeine enhanced recall for those on oral contraceptives during the early but not the second phase of the menstrual cycle. These results suggest the need for further study of neuroendocrine modulation of the effects of caffeine.

EFFECTS OF PSYCHOACTIVE DRUGS ON LEARNING AND MEMORY AS ASSESSED USING A NOVEL WATER MAZE. G.J. Kant, C.P. D'Angelo*, A.J. Brown*, C. Myatt*, E. Lewis*, T. Robinson* and T. Eggleston*. Dept. of Medical Neurosciences, Walter Reed Army Institute of Research, Washington DC 20307.

We have recently reported on the usefulness of a novel water maze for the assessment of learning and memory not confounded by possible effects of the drug or physiological variable on appetite [Kant et al., Pharmacol. Biochem. Behav., 31:487,1988; Przybelski et al., Biomat Artif Cell Artif Organs, (in press)]. The maze consists of three sets of 4 walls arranged in concentric squares set inside a 5 ft dia. pool. Each of the walls has a door that can be opened or closed providing a variety of possible mazes of varying difficulty. In the present study, two groups of rats (10 rats/group) were trained on one configuration of the water maze. In subsequent testing, one group (B) was always tested on the same "training" maze while the other group (A) was tested on a different maze configuration of approximately the same difficulty each day. Each test day consisted of 3 timed trials begun 15 min following drug injection. Both time to finish and errors committed were recorded for each trial. The 3 trials were separated by 30 sec rest periods. Not surprisingly, the B group completed the maze each test day in less time and with fewer errors than did the A group rats, even when the A group was tested on the identical maze as the B group. Both groups, however, were sensitive to the disrupting effects (increased maze time and/or more errors) of diazepam, amphetamine and caffeine, while atropine did not disrupt maze performance.

RELATIONSHIP OF HIPPOCAMPAL PROTEIN KINASE C (PKC) ACTIVITY TO SPATIAL LEARNING PERFORMANCE. J.M. Wehner, S. Sleight* and M. Upchurch. Inst. for Behavioral Genetics, Univ. Colorado, Boulder, CO 80309.

C57BL/6 mice perform the Morris water task for spatial learning well while DBA/2 mice perform poorly (Upchurch and Wehner, Beh. Gen.18: 55, 1988). We have studied potential neural substrates that may mediate this difference. PKC activity was measured in cortex and hippocampus. C57BL had greater lipid-, and Ca^{++}-stimulated activities than did DBA/2 mice. Because this difference may be fortuitous and unrelated to learning ability, 11 C57BL X DBA/2 recombinant inbred strains (RIs) were assessed for spatial learning ability in the Morris water task and cortical and hippocampal tissue assayed for basal and stimulated PKC activity. Behaviorally, the RIs ranged in learning ability from those that resembled DBA mice to those superior to either parental strain. PKC activities also varied in cortical and hippocampal tissue. Significant correlations between hippocampal phosphatidyl serine-stimulated activity and a site-crossing preference score ($r=.80$, $P<.01$) or a search-time preference score ($r=0.7$, $P<.02$) were observed in these RIs. No significant correlation was observed for cortical PKC activity and any learning measure. These data support the conclusion that hippocampal PKC is associated with spatial learning performance as measured by the Morris test. (supported by NSF #BNS-8820076).

464.10

CHARACTERISTICS OF HIPPOCAMPAL COMPLEX SPIKE NEURONS DURING PERFORMANCE OF A DELAYED MATCH TO SAMPLE TASK. SELECTIVE INFLUENCES OF DELTA-9-THC. C.J. Heyser*, R.E. Hampson and S.A. Deadwyler Dept. of Physiology & Pharmacology, Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27103

Specification of hippocampal involvement in memory processes requires a precise description of the manner in which hippocampal cells participate in the coding and retrieval of sensory information. The delayed match to sample (DMTS) paradigm can be used to examine the participation of hippocampal cells in retention of sensory information. We examined the response characteristics of identified hippocampal complex spike cells in a DMTS task in which performance decayed from 92 to 70% mean correct responses over delay intervals ranging from 1-31 sec. Both the temporal and spatial correlates of hippocampal complex spike cell activity were investigated and characterized. Prior studies have shown that delta-9-THC, the psychoactive ingredient in marihuana, disrupts performance at longer but not shorter delays in the DMTS task, closely resembling the effects of hippocampal lesions. Results indicate that 90% of complex spike cells encountered in the dorsal hippocampus responded just after execution of the match response; 56% fired just prior to the sample press and just after the match response, and less than 10% of the cells fired prior to the sample press only. THC (2.0 mg/kg, IP) eliminated the response to the sample lever but not the match lever in all cells. THC did not alter the match cell discharge in any group of cells tested. These results suggest that the dissociation of the sample- and match-provoked cell discharges by delta-9-THC was responsible for the significant disruption of behavioral responding in the DMTS task. Possible cellular actions of THC on hippocampal pyramidal cells are discribed in terms of ongoing in vitro studies. [*Supported by Grants DA04441, DA03502, and KO5-DA00119 to S.A.D.*]

SLEEP AND MEMORY DEFICITS IN AMYGDALA-KINDLED RATS: EFFECTS OF GLUCOSE. W.S. STONE, R.J. RUDD, M. SMITH & P.E. GOLD. Dept. Psychol., Univ. Virginia, Charlottesville VA 22903.

Extensive amygdala kindling results in deficits in sleep and in inhibitory avoidance tests. Individual differences in sleep and memory deficits significantly correlated in these animals. The present study demonstrates that deficits in spontaneous alternation (SA) are also produced by amygdaloid kindling and are correlated with changes in sleep. Glucose, which improves memory in other amnestic conditions, attenuates kindling-induced alterations in SA. Male Sprague-Dawley rats had electrodes implanted in neocortex and in basolateral amygdala. After recovery, 3-hr baseline sleep samples were obtained. One group received daily kindling stimulation (biphasic square waves, 1 msec, 60 Hz, 250 uA, 1 sec train) for 4-5 weeks, while another group served as non-stimulated controls. One week after the last seizure, sleep records were again obtained. All rats were then tested for SA performance (20 trials, 1 min ITI) 30 min after glucose (100 mg/kg) or saline injection.

Compared to the implanted controls, kindled rats showed decreases in bout number and duration of both paradoxical and nonparadoxical sleep. SA performance was also significantly impaired. Individual differences in several sleep measures were significantly correlated with SA performance in kindled rats. Glucose administration improved SA performance to the level of the non-kindled control group. The results demonstrate relationships between sleep and memory deficits in kindled rats, and suggest that glucose might be useful in attenuating some forms of seizure-induced memory deficits. (Supported by NIMH 31141, ONR N00014-85-KO472, and NRSA AG 05408).

464.12

NO EVIDENCE FOR TIME-LOCKED EFFECTS OF EMETINE INJECTED INTO THE MHV OF THE CHICK BRAIN. P.A. Serrano, S.J. Ramus*, E.L. Bennett and M.R. Rosenzweig. Department of Psychology, University of California, Berkeley, CA 94720

Gibbs & Ng (1977) have proposed a three-stage model for the formation of memory in the 2-day-old chick. Each of the three stages, short-term, intermediate-term, and long-term memory, appear to depend upon a particular neurochemical event. Each stage is characterized by the time at which amnesia appears after training on a passive avoidance task. A protein synthesis inhibitor, emetine, disrupts long-term memory and exhibits its effects on memory 90 min after training (Patterson et al., 1986). To investigate whether the amnesia from emetine represents a time-locked effect of the drug's action in the brain, a time course for the appearance of amnesia was conducted using two different pre-training injection times: 5 min and 20 min.

Two-day-old chicks were given bilateral injections of 4.0mM emetine or saline into the region of the medial hyperstriatum ventrale (MHV). The MHV is an area of the chick brain where metabolic activity is elevated as a result of learning in both a passive avoidance task (Rose et al., 1986) and in imprinting (Horn et al., 1979). After injection, groups of chicks were trained using a one-trial passive avoidance task either 5 min or 20 min later. Subsequent tests were done at 60, 75, 90, 105 min, and 24hr. The results show that emetine produces amnesia at 90 min in both the 5 min and 20 min pre-training injection groups without recovery of the memory. This suggests that the amnesia seen from the injections of emetine are the result of inhibition of the formation of long-term memory and not an artifact of the time required for the drug to disrupt the memory. REVERSAL LEARNING IN RATS: CLASSICAL VERSUS INSTRUMENTAL CONDITIONING PARADIGMS. P.J. Bushnell. Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC 27711.

Reversal learning set formation provides a useful model for the study of complex learning in animals. Traditional methods have relied upon single-response instrumental discriminations with their concomitant limitations. Spatial reversal learning set formation was explored in Long-Evans rats using a two-lever automaintenance (AU) procedure, in which one lever (CS^+) was paired with food reward and the other (CS^0) was not. Reward was provided on every trial regardless of the responses emitted. Behavior of rats trained on the AU task (n=6) was compared to that of rats trained on a similar instrumental (IN) task (n=7), in which at least one response to the CS^+ was required for reward on each trial. Response accuracy was calculated as a discrimination ratio DR = CS^+ responses per 10 trials/ total responses per 10 trials. Overall response rates were higher in the IN group than in the AU group, but both groups acquired the original spatial discrimination (CS^+ = right, CS^0 = left) at equivalent rates. Both groups formed similar reversal learning sets, requiring fewer trials to reach criterion (DR $\geq$ 0.9 for 2 10-trial blocks) across consecutive reversals. Three of 7 IN rats extinguished during acquisition of R2; their performance was reinstated by 2 sessions of remedial training on the AU schedule. Reversal (R) was faster in the IN group on R1, but slower after the learning set had been acquired (R11 to R16). Fitting 2-parameter nonlinear functions to acquisition curves showed that, while asymptotic discrimination accuracy did not differ, rate of acquisition was faster in the AU group (0.13$\pm$0.02) than in the IN group (0.05$\pm$0.003). These results show that spatial reversal learning sets can be formed in an automaintenance environment, in which reward does not depend upon accurate responding.

STRAIN DIFFERENCE BETWEEN C57BL/6IBG AND DBA/2IBG MICE IN A SPATIAL WORKING MEMORY TASK. M. Upchurch, L. Wurtz* and A. Cuestas*. Psychology Dept., Benedictine Coll., Atchison, KS 66002.

Previous studies have indicated that C57BL/6Ibg mice differ from DBA/2Ibg mice in spatial learning ability in the Morris water task, a test of spatial reference memory. A spatial working memory task in a Y-maze was used to test for the generality of the spatial learning difference between the two strains. Male mice were trained to go down the arms of the Y-maze for a food reward. During a pre-training phase, animals learned that all arms of the maze contained food and that food was not replaced once it was eaten. Following pretraining, mice were trained either in a spatial match-to-sample (MS) or a spatial nonmatch-to-sample (NMS) task. For MS mice, the correct response was to turn in the same direction that they had taken during a forced-choice sample trial. This choice took them into a previously unvisited arm. For the NMS mice, the correct response was to turn down the arm that they had originally started from and that had not contained any food. C57 mice performed better than DBA mice at the MS task and were substantially worse than DBA mice at the NMS task. The results suggest that C57 mice had formed a cognitive map of maze locations where food was likely or unlikely to be. These results are consistent with earlier work on the spatial learning ability of these two strains of mice in the Morris water task.

LEARNING AND MEMORY IMPAIRMENT IN RATS FED A HIGH SATURATED FAT DIET. G. Winocur* and C.E. Greenwood (SPON: G.H. Anderson). Dept. Psychology, Trent University, Peterborough, Ont., K9J 7B8 and Dept. Nutritional Sciences, Univ. Toronto, Toronto, Ont., Canada M5S 1A8.

Our previous studies indicate that alterations in the type of dietary fats fed to rats influence a variety of behaviors, including learning and memory performance. To conduct a more systematic investigation of cognitive performance, three groups of male Long Evans rats (one month of age) were fed 20% (w/w) fat diets high in either saturated fatty acids (lard-based) or polyunsaturated fatty acids (soybean oil (SBO)-based) or laboratory chow (4.5% (w/w) fat with similar fatty acid profile to SBO). After three months, all rats were tested on Olton's radial arm maze, a variable-interval delayed alternation task (VIDA) and the Hebb-Williams maze series. The lard-fed group was impaired on all tests. The SBO group was slightly impaired on some measures, relative to the chow-fed group, but consistently performed better than the lard-fed group. The results suggested that the impact of dietary fat on performance was not confined to one brain region; that is, performance was altered to a greater extent when tasks required increased integration from a number of brain regions (eg. VIDA and Hebb-Williams mazes).

As a first step towards elucidating the physiological mechanism whereby fat is influencing brain function, whole brain regional phospholipid (PL) fatty acid profiles were determined using GLC with flame ionization detection. Regional differences in fatty acid profiles were observed, probably reflecting the distribution of myelin amongst regions and its different fatty acid profile in comparison to other subcellular membranes. Dietary fat composition influenced PL fatty acid profile, with phosphatidylethanolamine being more affected than phosphatidylcholine. No diet by region interaction was observed, suggesting that all regions were affected similarly. Collectively, these results suggest that dietary fat has a modest impact on neuronal function within specific regions. Neuronal membrane compositional changes are observed concomitantly with functional change and these changes are regionally nonspecific in agreement with the behavioral data. (NSERC and MRC).

EFFECTS OF VARYING TRAINING STRENGTH ON SHORT-, INTERMEDIATE-, AND LONG-TERM FORMATION OF MEMORY (STM, ITM, LTM) FOR A ONE-TRIAL PASSIVE AVOIDANCE TASK IN CHICKS. M.R. Rosenzweig, D.W. Lee, M.K. Means*, E.L. Bennett, J.L. Martinez Jr. Dept. of Psychology, Univ. of California, Berkeley, CA, 94720.

Upon presentation of a small metal bead dipped in 100% methylanthranilate (MeA), a bitter tasting liquid, chicks will peck the bead, taste the bitter liquid, then subsequently avoid a similar but dry bead presented at test. Test can be anytime from 10 s to 24 hrs after training. Gibbs & Ng (1977) reported that memory of chicks trained in this 1-trial passive avoidance task shows "dips" (lower percent avoidance) at about 12 and 55 min posttraining and suggest that these dips mark the transitions between STM & ITM and between ITM & LTM. The existence of two sharp dips has not yet been replicated. Since 80-95% of chicks avoid the bead at most test times, this task may result in a ceiling effect possibly obscuring more subtle aspects of memory formation. Studies with strong and moderate peck aversion training of chicks were undertaken both to explore the possible occurrance of transitional dips and to conduct studies using memory enhancing drugs.

Two-day-old chicks were injected with 10 µl saline. Five minutes later, they were trained by dipping the bead in either 5%, 10% or 100% MeA. Testing occurred at times from 10 s to 24 hrs after training. Diluted MeA results in progressively weaker training and retention: at every test time, chicks trained with the 100% MeA showed greater avoidance (90% at 24 hrs) than those trained with 10% MeA (40%) or those given 5% MeA (32%). Our results also show dips around 1, 15 and 60 min for both the 5% and 10% MeA groups supporting the notion of successive stages in memory formation.

465.1

EFFECTS OF BUSPIRONE AND ALPRAZOLAM ON A THREE-CHOICE WIN-STAY WATER-ESCAPE WORKING MEMORY TASK IN RATS. E.W. Bass*, B.A. McMillen and L.W. Means. Depts. of Psychol. & Pharmacol., East Carolina Univ., Greenville, NC 27858.

Two studies were conducted to determine if buspirone (BUS) or alprazolam (ALP) would either improve performance on a working memory water-escape task by reducing perseverative responding or impair performance by interfering with memory processes. Both studies involved giving rats 3 daily test trials, each trial consisting of an information run during which guillotine doors forced the rats to swim into the correct escape alley and a test run during which the rats could enter any of 3 alleys, but escape only upon entering the same alley to which they had been forced. In the first experiment, rats were trained to a 70% correct choice criterion with 5 min inter-run intervals and then tested for performance with 5, 20 and 60 min inter-run intervals. Rats injected 1 hr before testing with BUS (3mg/Kg s.c.) were significantly ($p<.05$) impaired relative to rats injected with vehicle, while rats injected with 0.5mg/Kg ALP did not differ significantly from controls. In a second experiment, rats in each of the drug groups were tested after receiving 1 of 3 different doses of their respective drug. All three doses of BUS (1,3,10mg/Kg) impaired performance ($p<.05$) while none of the doses of ALP (0.5,1,2mg/Kg) impaired performance. Thus, BUS impaired performance of rats on a water-escape working memory task. (Supp. by DA-04895)

CHLORDIAZEPOXIDE AND dl-PROPRANOLOL PRETREATMENT OF CONDITIONED HYPERGLYCEMIA. P. S. Grigson and C. F. Flaherty. Psychology Department, Rutgers University, New Brunswick, NJ 08903.

A history of insulin administration in a novel environment leads to a conditioned hyperglycemic response in rats when injected with placebo on the test day for conditioning. This hyperglycemic response is reversed to hypoglycemia when pretreated with chlordiazepoxide (CDP) during both the conditioning and test phase (Flaherty, et al., Physiol & Behav., 33:595-599, 1984). The present study was concerned with the further investigation of CDP and the beta-adrenergic blocker dl-propranolol on glycemic conditioning. Two groups were pretreated with CDP (10 mg/kg ip) either during conditioning or on the test day only. Three additional groups were pretreated with propranolol (5 mg/kg ip) during the conditioning phase only, on the test day only or during both the conditioning phase and on the test day. The results indicated that a history of insulin administration in a novel environment tended to lead to conditioned hyperglycemia, and this tendency was accentuated by propranolol pretreatment. There was no evidence for conditioning in the CDP pretreated groups - possibly due to generalization decrement or state-dependent learning.

FLUMAZENIL REDUCES POSTOPERATIVE AMNESIA AFTER MIDAZOLAM ANESTHESIA IN AMBULATORY SURGERY PATIENT. Y.F.Sung, M.D., Co-Investigator: N. Reiss, CRNA*. Department of Anesthesiology, Ambulatory Surgery Center, The Emory Clinic, Atlanta, GA 30322.

Benzodiazepines are known to induce anterograde amnesia - an action which may be desired in certain situations, e.g.: during preoperative and operative sedation, induction for general anesthesia, and maintenance for general anesthesia. Midazolam hydrochloride has anxiolytic and amnestic properties that are similar to those of other benzodiazopines, however, it is unique in that it is water soluble and does not require a solvent that may cause venous irritation during injection. The present report is from a double-blind study performed at our institution to assess the ability of flumazenil, a benzodiazepine antagonist, to reverse the postoperative amnesia after midazolam anesthesia. Midazolam resulted in anterograde amnesia. The patient could not recall picture shown after they received the drug.

In comparison to placebo, flumazenil significantly improved the recall postoperatively after midazolam anesthesia.

EFFECT OF DIAZEPAM, TRIAZOLAM AND Ro 15-1788 ON CLASSICAL CONDITIONING. J.A. Harvey, A.G. Romano & V. Smith. Med. College of Pennsylvania at EPPI, Philadelphia, PA 19129.

Three experiments were carried out to examine the effects of two benzodiazepines on associative learning as measured by acquisition of the rabbit's nictitating membrane response. In a first study, conditioning was accomplished by pairing light and tone CSs with a shock US. Diazepam (0.1, 0.3 and 1.0 mg/kg) produced a dose dependent reduction in the acquisition of CRs to both tone and light CSs. The dose of diazepam needed to block criterion acquisition in 50% of the animals was calculated to be 0.145 mg/kg. A second study, employing explicitly unpaired presentations of CSs and US, indicated that diazepam had no effect on baseline responding or on responding to the tone and light CSs but did produce a dose-dependent reduction in the amplitude of the UR elicited by the shock US. In a third study, conditioning was carried out through the pairings of a tone CS and an air puff US. Triazolam (0.05 mg/kg) retarded CR acquisition, while the benzodiazepine antagonist, Ro 15-1788 (3 mg/kg), had no effect. However, Ro 15-1788 completely prevented the retardation in CR acquisition produced by triazolam. It was concluded that diazepam and triazolam were retarding associative learning through an action on the benzodiazepine receptor and that part of this retardation might be due to an effect on the unconditioned reflex. Supported by NIMH Grant MH16841.

465.5

FLUMAZENIL (Ro 15-1788) IMPROVED LEARNING AND MEMORY IN MICE BUT NOT IN MONKEYS. L. Rumennik, G.P. Vincent, E. Schwam and J. Sepinwall. Department of Neurobiology and Obesity Research, Hoffmann-La Roche Inc., Nutley, N.J. 07110.

The benzodiazepine (BZ) antagonist flumazenil (F) was reported to improve learning and memory in mice at doses ranging from 2.5-40 mg/kg, i.p. (Lal, H. et al., FASEB J. 2:2707, 1988). We evaluated the cognitive effects of this compound in CF1 mice and squirrel monkeys. In an active avoidance procedure, 40 mg/kg, i.p. improved 24 hr. retention in mice when administered 10, but not 30, min. before the training session. This dose also enhanced retention when given immediately following the training session, suggesting an enhancement of memory consolidation. In contrast, in a delayed match-to-sample procedure (DMTS) in monkeys, 1-30 mg/kg, i.g. failed to improve short-term memory (0-182 sec). Similarly, when evaluated in a repeated acquisition procedure (RA) in monkeys, 3-30 mg/kg, i.g. failed to improve learning, with impairment of learning evident at 30 mg/kg. In separate studies in monkeys, 3 and 10 mg/kg, i.g. antagonized the disruptive effects of 0.04 and 0.08 mg/kg, i.g. triazolam on learning (RA) and memory (DMTS). Thus, F reliably antagonized triazolam, but it did not consistently improve cognition; enhancement was dependent upon dose, species, and experimental paradigm.

465.6

DOSE DEPENDENT REVERSAL OF DIAZEPAM-INDUCED DISCRIMINATION IMPAIRMENT BY RO 15-1788. S.O. Cole. Dept. of Psychology, Rutgers University, Camden, NJ 08102.

Diazepam (DZ) 4 mg/kg, administered on eight successive acquisition sessions, impaired a light-cued, successive discrimination in male Sprague-Dawley rats with the animals recovering on three post-drug vehicle sessions. The impairment in discrimination was accompanied by an increase in responding during no go periods of the task, indicating that DZ-drugged animals have difficulty withholding incorrect responses. The benzodiazepine (BDZ) receptor antagonist Ro 15-1788 (5 and 10 mg/kg) reversed the discrimination impairment and reduced the number of incorrect responses in a generally dose-dependent manner when co-administered with DZ. These findings suggest that the impairment of successive discrimination by DZ is mediated by central BDZ receptor sites. When administered alone, the 10 mg/kg dose of Ro 15-1788 (but not the 5 mg/kg dose) produced a significant BDZ-like impairment in discrimination, which was accompanied by a significant increase in incorrect responses. These findings suggest that Ro 15-1788 is not a neutral BDZ-receptor antagonist but may have some intrinsic action of its own which needs to be assessed independently of its use as a mediational research tool.

465.7

SELECTIVE IMPAIRMENTS IN EXPLICIT MEMORY PROCESSES ASSOCIATED WITH ACUTE ALCOHOL INTOXICATION. R.G. Lister, C. Gorenstein*, D. Risher-Flowers*, H.J.Weingartner* and M.J. Eckardt. Lab. Clinical Studies, NIAAA, DICBR, Bethesda, MD 20892.

The effect of alcohol on learning and memory was assessed in independent groups of student volunteers (total n=28). Subjects were shown a list of words and asked to form an image of a scene involving each word 90 min after drinking a mixture of alcohol (0, 0.3 or 0.6 g/kg) and tonic water. Following a distractor task, they recalled as many of the words as possible. After free recall, they were asked to read a number of words that had been typed backwards. Some of these words were from the list that had been imaged and some were new words. Finally, subjects performed a word completion task in which a number of words were presented with letters missing. They were asked to complete each word with the first response that came to mind. The words were either; words that had been imaged; words that had been read backwards; words that had been both imaged and read backwards; or new words. Alcohol caused a dose-related impairment in free recall ($p<0.02$). In the backwards reading test, both placebo- and alcohol-treated subjects read words faster if they had previously imaged them ($p<0.001$). In the word completion task, all groups completed more words if they had either read them backwards or imaged them previously ($p<0.001$). These priming effects did not differ across the groups. The data suggest that alcohol impairs performance in tests of explicit memory but may not impair memory for the same material when tested implicitly.

465.8

DISRUPTION OF TASTE AVERSION LEARNING BY PREEXPOSURE OR TOLERANCE TO ETHANOL AND OTHER DRUGS. B. M. Rabin and W. A. Hunt*. Behavioral Sciences, Armed Forces Radiobiol. Res. Inst., Bethesda, MD 20814-5145; Dept. of Psychology, Univ. of Maryland, Baltimore, MD 21228.

Hunt and Rabin (Life Sci, 43: 59, 1988) have shown that making rats tolerant to ethanol, in contrast to ethanol preexposure, disrupts the acquisition of a radiation-induced taste conditioned aversion (CTA). Additional studies have shown that there are some residual effects from tolerance on the CTA learning for up to 5 weeks following the termination of the ethanol intubation. Similarly, ethanol tolerance, but not preexposure, disrupts the acquisition of a CTA following injection of 1.5 mEq/kg, but not 3 mEq/kg, lithium chloride. Preexposure to diazepam or to morphine does not attenuate either radiation-or lithium chloride-induced CTA learning. However, tolerance to diazepam does attenuate CTA learning following exposure to ionizing radiation or lithium chloride.

465.9

VEHICLE INFUSION INTO THE BASAL FOREBRAIN PRODUCES TASK-SPECIFIC COGNITIVE DEFICITS IN THE RAT. JJ Chrobak, D An*, & TC Napier, Department of Pharmacology, Loyola University Medical Center, Maywood, IL 60153.

Basal forebrain nuclei, the ventral pallidum/nucleus basalis (VP/NB) and medial septum (MS), are the source of cholinergic neurons implicated in cognitive processes. Intraseptal infusion of the GABA agonist muscimol produces an impairment in radial arm maze (RAM) performance. The following study examined this phenomenon within the VP/NB. Rats, trained to perform a RAM task with a 1 hr delay inserted between the fourth and fifth arm choice, recieved vehicle (saline, artificial CSF), muscimol or sham injections into the VP/NB. Vehicle and muscimol infusions, but not sham, produced similiar impairments. Deficits persisted for two days; the largest decrement being observed 24 hrs post-infusion. Baseline performance was re-established with further daily testing. A vehicle-induced impairment was not observed in rats tested on a standard RAM task with no delay imposed. Thus, the deficit was dependent upon the mnemonic demands of the task. These findings: 1) indicate that vehicle infusions into the VP/NB can cause a neural perturbation that becomes manifest in particular cognitive testing paradigms; 2) support findings that vehicle infusions into the NB can produce biochemical and behavioral alterations; and, 3) highlight the importance of uninjected controls in protocols that involve treatments within the VP/NB.

MUSCIMOL INJECTIONS IN THE MEDIAL SEPTUM IMPAIR SPATIAL LEARNING. J. D. Brioni*, M. W. Decker, L. P. Gamboa*, I. Izquierdo, and J. L. McGaugh (SPON: J. L. Davis). Center for the Neurobiology of Learning and Memory and Dept. of Psychobiology, Univ. California, Irvine. CA 92717.

This study examined the role of GABA in modulating septohippocampal cholinergic influences on memory. Microinjections of the GABA-A agonist muscimol (0.5, 1.0 or 5.0 nmol) or physiological saline were administered (0.5 µl) into the medial septum of rats via chronic implanted cannulae 5 min. prior to each of 4 daily training sessions (3 trials per session) on the Morris water maze. Rats were trained to find a submerged platform located in a fixed position in a circular pool of water. A drug-free probe trial with no platform available was conducted 4 days after the last training trial. High affinity choline uptake (HACU), an index of cholinergic activity, was also measured in a separate group of rats 5 min. after intraseptal injections of these same doses of muscimol.

Analysis of escape latencies during training revealed that learning was significantly impaired in rats given pretraining muscimol injections into the medial septum at doses (1.0 and 5.0 nmol) that significantly reduced hippocampal HACU. A lower dose of muscimol (0.5 nmol) had no significant effect on either performance or hippocampal HACU. Analysis of the search patterns during the probe trial revealed that, in comparison to controls, animals that had received either of the two higher doses of muscimol prior to each training session were less likely to swim in the region where the platform had been located.

Our results are consistent with the view that septal GABAergic modulation of the septohippocampal cholinergic pathway is involved in regulating the acquisition of spatial information.

BICUCULLINE METHIODIDE IN THE MRF DOES NOT AFFECT LONG-TERM HABITUATION OF THE ACOUSTIC STARTLE RESPONSE. Wesley P. Jordan and Hilary Donovan*. Psychology, St. Mary's College of Maryland, St. Mary's City, MD 20686.

Short-term habituation of the acoustic startle response in the rat occurs within the response circuit, but long-term habituation is produced by an accruing inhibition of the reflex by neural activity in an separate, long-term habituation pathway. The mesencephalic reticular formation (MRF) is a part of the long-term habituation pathway because lesions there severely attenuate long-term habituation of acoustic startle. This study investigated the role of gamma-amino-butyric acid (GABA) within the long-term pathway. Drugged rats (n=8) received 50ng of bicuculline methiodide (BMI) to each side of the MRF 10-min before each of 5 test sessions. The 5 control animals received saline. BMI affected motor activities and depressed startle amplitudes, precluding a clear determination of habituation. Control rats habituated over sessions. A retest without injections found the startle amplitudes of controls and formerly drugged animals were at the long-term habituation asymptote of the controls, suggesting that long-term habituation had occurred during the drug sessions. Animals subsequently habituated normally to a tactile stimulus presented without drug injections, suggesting no lingering effects of the drug on startle habituation. GABA does not appear to be released at MRF synapses within the long-term pathway, but could be at other sites within the pathway.

465.12

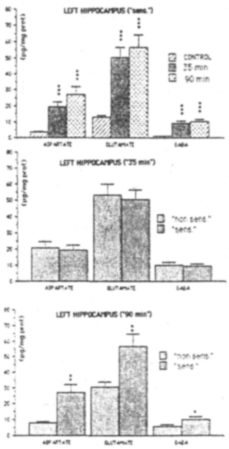
DIFFERENTIAL EFFECTS OF BACLOFEN ON ACQUISITION IN POSITIVE VS. NEGATIVE TRANSFER OF DISCRIMINATION TESTS. D.B. Clissold*, S. J. Enna, and M. J. Pontecorvo. CNS Pharmacology, Nova Pharmaceutical Corp., Baltimore, MD 21224.

Rats were trained to criterion in a two-choice, discrete trial auditory/visual discrimination task. Responses on the right lever were reinforced in the presence of a bright light and responses on the left lever were reinforced in the presence of a tone. 24 hours later, and daily thereafter, 1/2 of the rats were injected i.p. with 1.7 mg/kg baclofen, a $GABA_B$ agonist. The other 1/2 received an equal volume of saline. 30 minutes later, rats were trained on a second problem with two new stimuli but with the auditory/visual dimensions constant (i.e., dim light-right, clicker-left). The third problem reversed this dimension/response relationship (tone-right, dim-left). Baclofen-treated rats required significantly more responses than saline controls to reach criterion for the second problem, but required significantly fewer responses to criterion in the third problem. Baclofen did not affect the probability of a response in either problem.

A Baclofen-induced retrieval impairment could contribute both to the slow learning in Problem 2 (positive transfer task) and to the relatively rapid learning of Problem 3 (negative transfer task). Alternatively, baclofen could simply impair learning. Although both groups met criterion in Problem 2, poorer learning of Problem 2 could decrease negative transfer to Problem 3, and hence increase the rate of acquisition. These hypotheses are being tested by drugging only on Problem 3. The learning deficit hypothesis predicts slower acquisition for Problem 3, while the retrieval deficit hypothesis predicts that baclofen before Problem 3 should lead to more rapid acquisition.

465.13

Accumulation of glutamate, aspartate and GABA in the hippocampus of gerbil after transient cerebral ischemia. G. Delbarre, B. Delbarre, F. Calinon*, C. Loirel* and A. Ferger*, Faculté de Médecine,37032, Tours, FRANCE.



To study memory of the gerbils, Cheal (Cheal, M.L., J. Biol. Psycho., 20 : 26, 1978) had developed tests to measure investigation of novel stimuli. In this test, occlusion of left carotid during 10 min induced a lost of memory. Glutamate and aspartate had been implicated in cerebral ischemia. In the hippocampus, 35 min and 90 min after ligation, amino acids (Aspartate, glutamate and GABA) had been measured by HPLC method after left carotid ligation during 30 min. Aspartate,glutamate and GABA were significantly increased 35 min and 90 min after ligation. The results indicated the necessity to select gerbil by occular fundus (Delbarre, G., Stroke, 19 : 126, 1988) 90 min after ligation to study the modifications of amino acids in the brain.

PROTECTIVE EFFECTS OF DM-9384, A PYRROLIDONE DERIVATIVE, ON CYCLOHEXIMIDE-INDUCED DECREASE OF GABA AND ACETYLCHOLINE RECEPTORS. T. Kameyama*, T. Nabeshima, K. Tohyama* and T. Shiotani* (SPON: K. Kamata). Dept. of Chem. Pharmacol., Fac. Pharmac. Sci., Meijo., Univ., Nagoya 468, JAPAN.

We have reported that N-(2,6-dimethyl-phenyl)-2-(2-oxo-1-pyrrolidyl) acetamide (DM-9384) ameliorates GABA antagonist- and acetylcholine (ACh) antagonist-induced amnesia (Xth Int. Congr. Pharmacol., Sydney, Abstract P301, 1987; Psychopharmacology, 96: Suppl. 226, 1988). Cycloheximide (CXM)-induced amnesia is also improved by DM-9384 and this effect is attenuated by the treatment with bicuculline and picrotoxin. CXM-induced amnesia is known to be ameliorated by physostigmine, muscimol and baclofen (Nabeshima et al., Pharmacol. Biochem. Behav. 31: 405, 1988). These results indicate that DM-9384 affects the GABA and AChergic neuronal systems and improves amnesia. In the present experiments, we attempted to investigate whether DM-9384 protects the CXM-induced decrease in the number of binding sites for GABA and ACh. Mice of the ddY strain were used for the experiments. Synaptic membrane (P_2B fraction) was prepared from mouse brain 24 hr after the CXM (60 mg/kg, S.C.) treatment. DM-9384 (5 mg/kg, P.O.) was administered 15 min before CXM; [^{3}H] muscimol and [^{3}H] QNB were used as the ligands. Results were as follows: CXM significantly decreased Bmax of [^{3}H] muscimol binding sites in the synaptic membrane; DM-9384 protected $GABA_A$ receptors from the effect of CXM; CXM significantly decreased [^{3}H] QNB binding to muscarinic receptors; DM-9384 and muscimol protected QNB binding sites from the effect of CXM; DM-9384 displaced [^{3}H] muscimol binding to the membrane, but not [^{3}H] QNB binding. These results suggest that DM-9384 protects the CXM-induced decrease of GABA and ACh receptors by binding to $GABA_A$ receptor-like binding sites and increasing protein synthesis.

CHRONIC ANTIDEPRESSANT TREATMENT EFFECTS ON CONFLICT BEHAVIOR IN THE RAT. T.J. Hill*, C. Becker*, D.J. Fontana* and R.L. Commissaris. College of Pharmacy, Wayne State University, Detroit, MI 48202.

Antidepressant agents vary in their efficacy in the management of panic disorder in man. The present studies examined the effects of chronic post-test treatment with several antidepressants on behavior in the Conditioned Suppression of Drinking (CSD) conflict paradigm. The agents tested were the TCA desipramine (DMI; good anti-panic efficacy), buproprion (BUP; no efficacy) and trazodone (TRAZ; weak efficacy). Acute treatment (IP; 10-min pre-test) with these agents did not exhibit anti-conflict effects at any dose examined. As expected, chronic DMI treatment (5 mg/kg, IP, BID for 5 weeks) resulted in a time-dependent anti-conflict with a latency to onset of approximately 3 weeks. In contrast, chronic BUP treatment (up to 10 mg/kg, IP, BID over 8 weeks) did not affect CSD behavior. Finally, chronic TRAZ treatment (up to 40 mg/kg, IP, BID over 12 weeks) resulted in only a weak anti-conflict effect. These data indicate that not all antidepressant agents exhibit anti-conflict effects when administered chronically. Moreover, the efficacy of these antidepressants to increase punished responding when administered chronically correlates well with their efficacy as anti-panic agents in man. (MH#42501; protocol conforms to NIH guide).

BEHAVIORAL AND NEUROENDOCRINE CORRELATES OF I.C.V. CORTICOTROPIN RELEASING HORMONE ADMINISTRATION IN THE RHESUS MONKEY John R. Glowa, Clinical Neuroendocrinology Branch, NIMH, Bethesda, MD 20892.

Corticotropin releasing hormone (CRH, or factor) is now known to be released from hypothalamic nuclei in response to stressful events and initiate a pituitary-mediated adrenal glucocorticoid response. The current studies were designed to extend our knowledge of the behavioral consequences of the activation of this hypothalamic-pituitary-adrenal (HPA) response by directly administering CRH into the lateral ventricle of behaving monkeys. Four rhesus monkeys (macaca mulatta), previously trained to respond under a chain FI 5-min, FR 30 response schedule of banana pellet delivery until rates and patterns of responding were stable, were aseptically and stereotaxically implanted with a Heyer-Schulte peritoneal shunt in the left lateral ventricle. This catheter was then attached to a subcutaneously implanted vascular access port. After recovery there was no deficit in baseline rate of responding or effect of control injections (Elliott's B solution). Increasing concentrations (from 0.003 ng/kg-30 µg/kg) of CRH dose-dependently decreased responding in a manner that did not depend upon the schedule component in effect. When large rate-decreasing effects were obtained, monkeys did not eat pellets that were produced. Midazolam (0.03-3.0 mg/kg) increased responding and could block some of the rate-decreasing effects of CRH. These results are consistent with the notion that stress mediated release of CRH profoundly affects behavioral function, in particular food-maintained behaviors.
