The first order Lyapunov Characteristic Exponent was used to assess the relative stability (i.e. convergence or divergence) of the event-related potentials produced during an oddball paradigm. Five subjects were asked to keep a running mental count of one of two clearly discriminable tones, and report this at designated time intervals. The target tones (1500 Hz) occurred with a probability of 20% and evoked a large positivegoing wave, the P300, which was dramatically reduced or absent to non-target (500 Hz) tones. The brain's electrical response to these stimuli were recorded from the central (Cz) and parietal (Pz) midline locations. Twenty trials were averaged under each of the target and non-target conditions, producing a time series that was initially embedded in an 8-dimensional state space. Using the Grassberger-Procaccia algorithm, the correlation integral was obtained to derive some estimation of the signal's structure, and subsequently give information as to whether a larger embedding space would be necessary. In all cases, this procedure yielded dimension estimates of between 2 and 5, although there was considerable overlap both within and between subjects in terms of target and non-target stimuli. The Lyapunov Characteristic Exponent and variation in the first derivative of the time series data were computed using a method proposed by Wolf et al (1985). The averaged target stimuli consistently produced positive Lyapunov exponents indicating exponential divergence of nearby initial conditions, while the nontarget signals typically resulted in a marked reduction in this value, and in some instances yielded negative estimations suggesting convergence to a regime of lower periodicity. Variation in the first derivative also proved to be an effective measure for differentiating between the two stimulus conditions, with the targets having a substantial increase in this value relative to non-targets.

ELECTROPHYSIOLOGICAL INDICANTS OF VISUAL SPATIAL ATTENTION AND READING ABILITY: A LONGITUDINAL STUDY. L. Anllo-Vento. S.L. Miller* and M.R. Harter*. Psychology Dept., UNC-Greensboro, NC 27412-5001.

Event-related brain potentials (ERPs) were obtained to assess developmental changes in neural indicants of spatial attention in normal and reading disabled young males. Two spatial tasks were employed. Each required a reaction time response to a small square, flashed peripherally in the visual field cued by an antecedent, foveally presented arrow. ERPs were recorded from the same subjects when they were approximately 10.8 years old, and again at age 16.

Changes in P1-N1 and P3 amplitude due to stimulus relevance were comparable across groups, despite significant differences in verbal intelligence and reading ability. Thus, it appears that dyslexic subjects have normal visual-spatial abilities.

There was, however, a significant difference in the posterior-anterior gradient of P1-N1 amplitude. Dyslexics showed smaller differences in activation between posterior and anterior brain regions than did normal subjects. This difference was developmentally stable and consistent across tasks.

Thus, it appears that neural activation is less focal in disabled than in normal readers, even when attentional and verbal task demands are controlled. Supported by NINCDS Grant RO1 NS19413-07

SELECTIVE ATTENTION MODULATES PROCESSING IN NON-TONOTOPIC AUDITORY CORTEX IN HUMANS. D. L. Woods, A. Algazi, and K. Alho#, Dept of Neurology, U.C. Davis, VAMC, Martinez, CA, 94553, and #Dept of Psychology, University of Helsinki, Finland.

Attention alters auditory event-related brain potentials (ERPs). These attention effects can be isolated as attentional difference waves (ADWs) by subtracting ERPs evoked by ignored sounds from ERPs elicited by the same sounds when attended. We investigated the tonoto-pic organization of the generators of ERPs and ADWs by determining if their scalp distributions changed when evoked by tonebursts of widely different frequencies (250-4000 Hz).

In experiment 1 subjects attended either to auditory or visual stimuli, and ignored stimuli in the competing modality. In experiment 2 subjects attended to monaural tones of one pitch and ignored competing tones. In both experiments, the N1 component (latency 110 ms) evoked by nonattended tones changed progressively in scalp distribution as a function of frequency. In contrast, no frequency-related changes occurred in the distributions of ADWs. The results suggest that the cortical processing of nonattended tones occurs primarily in tonotopically organized fields, whereas auditory areas modulated by attention are largely non-tonotopic. MIDLATENCY AUDITORY EVOKED RESPONSES IN A PATIENT WITH A BILATERAL THALAMIC INFARCTION. R.J. Erwin, B. Malamut*, and M. Mawhinney-Hee*. Dept. of Psychiatry, Univ. of Penn., Philadelphia, PA 19104.

Evidence from both the human and cat model suggests that the P1 (50-65 msec latency) component of the midlatency auditory evoked response (MLR) is generated in midline thalamic regions (Erwin and Buchwald, EEG suppl., 40:461, 1987). To further investigate this hypothesis, the topographic distribution of Pl was examined in a previously healthy 31 year old male with bilateral and symmetrical midline thalamic infarctions. An MRI localized the lesion to include the anterior nuclei and portions of the medial dorsal nucleus. There was no evidence of damage to other subcortical or cortical regions. Recording procedures were identical to those previously described (Erwin et al.

Neurosci. Abst., 15:746, 1989) using a l/sec stimulus rate.
The distribution of Pl in this individual was characterized by distinct frontal maxima and temporal minima. In contrast, central maxima for Pl were observed in controls at the l/sec stimulus rate (Erwin et al., 1989). This distribution resembled that of controls at a faster stimulus rate (10/sec) where the central maxima was diminished. These findings provide further evidence that multiple MLR components exist at the Pl latency and that the Pl component observed centrally has a thalamic

EVIDENCE FOR AN ERP CORRELATE OF ATTENTIONAL FILTERING. S.J. Luck' & S.A. Hillyard. Deptartment of Neurosciences, M-008, University of California, San Diego, La Jolla, CA 92093.

In visual search tasks, subjects must determine whether or not a target item is present within an array of distractor items. In order to accomplish this

task, subjects may have to filter out the distractor items, allowing only the larget item to reach object identification processes. Here we report two experiments suggesting that an ERP component – an N2 wave that appears over contralateral posterior sites – may be an electrophysiological index of this fil-

tering process.

There were 8 items in each visual display, except as noted; the items were either identical or else one item differed from the others and appeared to "pop out." In Experiment 1, the target item was defined by its color or its orientation. In one condition, the target was presented within an array of distractor items; in a second condition, the same target item was presented in isolation, without any distractors. Attentional filtering was presumably unnecessary in the latter condition. As predicted, the N2 component was greatly attenuated in this condition compared to the condition in which the target was embedded in an array of distractors. Experiment 2 tested the effects of inembedded in an array of distractors. Experiment 2 tested the effects of increasing the amount of processing required to identify the target item. Each pop-out item was composed of four colors, and a pop-out item was classified as a target if these colors were presented in one spatial arrangement and as a non-target if any other spatial arrangement of the same colors was presented. The number of non-target arrangements was varied across conditions; as the number of arrangements increased, the difficulty of target identification increased. The amplitude of the posterior N2 component increased in parallel with the difficulty of the identification process. From these results, we conclude that the posterior N2 component indexes a spatial filtering process that is used to assist object identification processes. This component reaches its maximal amplitude near the occipital-temporal border, and may reflect the attentional processing that has been demonstrated in areas V4 and IT.

AUDITORY STREAMING INFLUENCES ONSET OF SELECTIVE ATTENTION EFFECT ON AUDITORY ERPs. C. Alain, A. Achim & F. Richer. Laboratoire de Neuroscience de la Cognition, Université du Québec à Montréal, Montréal, Canada.

We tested whether the attention effect on ERPs could be

manipulated by auditory context, while keeping constant physical separation of alternate attended channels. ERPs were recorded at Fz, Cz and Pz from 10 subjects paying attention to one pitch (1000 or 1682 Hz) and ignoring tones of three other pitches, all lasting 60 ms (p=.85) or 130 ms, presented at 200-500 ms intervals. In the baseline condition, the four channels were equally spaced by 3 half-tones (1000; 1189; 1414; 1682 Hz). In the grouped-channels condition, the middle pitches were replaced by two others, separated from the extreme tones by one half-tone (1000; 1059; 1587; 1682 Hz) creating two pairs of closely spaced channels. Subjects detected the longer tones in the attended channel. Reaction times were not different between conditions; subjects made more false alarms and misses in the grouped-channels condition. The mean amplitude of the difference potentials (Nds) for attended and unattended tones were measured over confor attended and unattended tones were measured over consecutive 40-ms periods. Significant Nds began at the 45-80 ms interval for the grouped-channels condition and at 125-160 ms for the baseline condition. Nds were different between the two conditions during the 45-120 ms interval. The data show that the onset of the Nd wave can be manipulated by the perceptual context created by auditory inputs and is not exclusively dependent on a stimulus matching process.

EFFECTS OF ASSOCIATION CORTEX LESIONS ON THE SOMATOSEN-

S.Yamaguchi S. Yamaguchi and R.T. Knight Dept. of Neurology, Univ. of California, Davis, VAMC, Martinez, CA 94553 Novel stimuli requiring no overt response generate a

frontal-central P3a whereas correctly detected target stimuli generate a parietal P3b. Iesion studies employ-ing auditory and visual stimuli support prefrontal and temporal-parietal junction cortex involvement in P3a and temporal-parietal junction cortex involvement in P3a and P3b generation. We investigated the contribution of anterior and posterior association cortex to somatosensory P3 generation by recording ERPs in controls (n=10) and patients with unilateral lesions in lateral parietal cortex (n=8), temporal-parietal junction (n=8) and dorso-lateral prefrontal cortex (n=10). Subjects pressed a button to mechanical taps of the fifth finger (targets, p=.12), randomly interposed in sequences of taps to the second (standards, p=.76) and third or fourth finger (tactile novels, p=.06). Occasional shock stimuli were delivered to the wrist (shock novels, p=.06). Temporal-parietal lesions abolished or reduced P3a and P3b at posterior sites to contralateral and ipsilateral stimuli.
Frontal lesions reduced the P3a and P3b at frontal scalp sites. Parietal patients produced no focal reduction of the P3b although the P3a to contralateral shock novel stimuli was reduced. The data indicate that multi-modal cortex in the temporal-parietal junction and dorsolateral prefrontal lobe contributes to the scalp P3a and P3b.

(2) Dept. of Neurosciences, UCSD, La Jolla, CA.

Past studies have reported polarity inversions in certain of the early occipital event-related potentials

(ERPs) with upper versus lower field stimuli. Such
changes can be related to cortical anatomy. In one
model, components that inverted in polarity were localized to striate cortex, while those that did not, were
localized to extrastriate cortical regions. The present
study examined the behavior of the early, attentionsensitive Pl and NI components with upper and lower field
stimuli in order to investigate their neural generators.

ERPs were recorded from 30 scalp sites in response to
stimuli flashed in rapid, randomized sequences to the
four quadrants of the visual field. Subjects attended
the stimuli in one quadrant while ignoring stimuli in the
other three quadrants: each quadrant was attended in a
different run. Spherical spline interpolation was used
to obtain topographic maps and current density maps and
waveforms. Stimuli in upper versus lower field locations elicited polarity inversions in a midline,
parieto-occipital N80 component that was not influenced
by attention. In contrast, the occipital P120 (P1) and
parietal N180 (N1) peaks did not invert in polarity, but
were significantly amplitude modulated with attention.

These data are interpreted in terms of the levels of
visual processing affected by sensory gating during
selective attention. Conducted at UCSD with grants to SAH.

241.11

SPATIOTEMPORAL DYNAMICS OF HUMAN WORKING MEMORY. Brian Cutillo*, Steve Bressler and Alan Gevins. EEG Systems Lab., San Francisco, CA 94107. Five USAF test pilots performed several hundred trials of a task requiring precise finger pressures proportional to the stimulus number seen 2 trials (about 12 seconds) previously. They had to maintain a constantly changing sequence of two numbers in working memory, and deal with numerical feedback about response accuracy on each trial. The control task eliminated the working memory component by having subjects respond immediately to the current stimulus number. 20% of the trials were no-response catch trials, which consisted of the number "0" in the control condition, and a match between the 2-back number and the current stimulus number in the memory condition. Cortical functional network activity patterns were computed from spatially and temporally enhanced evoked potentials during 4 split-second intervals. In the prestimulus interval, evidence was found for verbal codings for working memory in patterns focused on sites over left-hemisphere visual association and anteroparietal areas, while similar patterns were found in the control condition over the right hemisphere. Evidence was also found for very early (50 msec poststimulus) patsphere. Evidence was also boild in very early (or lise) possessimities) par-tern matching over left-hemisphere anteroparietal sites in the memory con-dition only. During the interval spanning the P300 wave in catch trials, anterocentral, central, and left anteroparietal patterns dominated the memory condition, while the control condition had a bilateral pattern over visual association and right anteroparietal areas. This implies that inhibition of response involved anterior premotor areas in the memory condition, and visual association areas in the control condition. During response execution, both conditions had the same left central and anteroparietal pattern we have seen previously with right index finger flexions. These results may be the first temporally and spatially detailed measures of the dynamics of working memory in the human brain.

MONKEY P3 IN A VISUAL AND A MULTIMODAL ODDBALL PARADIGM. J. Pineda, S. Howarth*, D. Swick, and S. Foote. Depts. of Cognitive Science (D-015) and Psychiatry (M-003) UCSD, La Jolla, CA 92093.

It has generally been assumed that human P3 reflects modality-independent mechanisms because of its "cognitive" nature, its scalp distribution, and the similarities in task and probability effects following auditory, visual, and somatosensory stimulation. These similarities suggest two models of P3 genesis: 1) that each modality engages comparable, but independent mechanisms; or 2) that aspects common to all modalities arise from the same neural source.

To test these hypotheses, ERPs were recorded from chronically 10 test these hypotheses, EKT'S were recorded from chromoshy implanted squirrel monkeys (Saimiri scircus) in a visual (VOP) or a multimodal (MOP) oddball paradigm. VOP consisted of blue rectangles (2.30 x 1.150, 90%, centered, 1 sec ISI), as background, and yellow rectangles (7.6° x 1.15°, 10%), as "oddballs", presented pseudorandomly in different locations on a screen. ERPs were recorded before and after administration of the adrenergic agonist, clonidine (0.1 mg/kg, IM), and the antagonist, L753,643 (0.05 mg/kg, IM). MOP consisted of tones (3 KHz, 300 msec, 70 dB nHL, 80%, 1 sec ISI), as background, a different pitch tone (1 KHz, 300 msec, 70 dB nHL, 10%), as "auditory oddball" (AO), and a red rectangle (7.60 x 1.150, centered, 10%) as "visual oddball" (VO). P3 amplitudes increased in five subjects following clonidine administration and decreased following L753,643. 10110wing common administration and detreased 10110wing L733,043.
P3s to VO were larger in amplitude, longer in latency, and exhibited a broader scalp distribution than AO responses. These data suggest that monkey P3 is the result of both modality-independent and modalitydependent mechanisms, and that one likely substrate for the modality-independent aspects is the noradrenergic system.

EVENT-RELATED BRAIN POTENTIALS AND SCALP CURRENT DENSITY MAPS DURING COLOR SELECTIVE ATTENTION IN HUMANS

EVENT-RELATED BRAIN POTENTIALS AND SCALP CURRENT DENSITY MAPS DURING COLOR SELECTIVE ATTENTION IN HUMANS K.S. Mangun(1), G.R. Mangun(2) and S.A. Hillyard(3).

(1) Division of Neurosurgery and (2) Dept. of Psychiatry, Dartmouth Medical School, Hanover, N.H., and (3) Dept. of Neurosciences, UCSD, La Jolla, CA.

Selective attention to stimulus color is usually associated with a broad negative event-related potential (ERP) deflection between 150-300 msec latency (selection negativity). The present study investigated the scalp distribution of ERP color attention effects using multichannel voltage and scalp current density analyses. Subjects (N=12) were presented with purple and blue squares flashed in rapid, random sequence to a single location on the vertical meridian above fixation. In separate runs, subjects were required to attend to one color while ignoring the other. Color selection effects were first observed over occipital scalp as a positivity between 120-260 msec latency that peaked at about 170 msec. This positivity tended to be larger over the right hemisphere and was associated with a current source-sink configuration over occipital scalp. A left occipito-temporal negativity elicited by the attended color was observed between 200-300 msec and was associated with a current sink-source configuration distinct from that associated with the earlier posterior, right hemisphere positivity. Over anterior scalp regions the principal effects of color selection were a fronto-central P200-N290 sequence. These data are interpreted in terms of the activation of cortical areas specialized for color processing during attention. (Conducted at UCSD and supported by grants to SAH).

SLOWING WITH AGE: MODERATE CORRELATIONS AMONG BEHAVIORAL AND ELECTROPHYSIOLOGICAL INDICATORS OF SPEED OF PROCESSING C. A. Christensen and S. R. Rubinstein, Department of Psychology, Vassar College, Poughkeepsie, NY 12601

Slowing is the change most characteristic of human aging. A central timing mechanism which slows with age has been advanced as a possible explanation. On this view all those processes which depend on timing slow as well. To evaluate this hypothesis 48 women (ages 20, 40, 60, 75±2 yrs) were tested on several perceptual (figural synthesis, CFF, backward and forward masking), reaction time (simple, choice RT; digit symbol substitution) and short-term memory (Sternberg) tasks, all of which measure various aspects of speed of processing. The EEG was recorded during testing. ERPs were extracted for the RT and memory tasks. For the perceptual data, power spectrum analysis of the EEG was performed. Mood, health, and intellectual status of subjects were also evaluated since these factors are thought by some to be related to speed of processing. Examination of covariation among timed behavioral and electrophysiological measures, mood, health and intellectual status and their association with age showed moderate support for the hypothesis that generalized slowing of a timing mechanism or mechanisms is associated with age-related slowing. While not all behavioral and electrophysiological measures were significantly correlated, a large number were. Clustering by type of measure was not observed, as would be expected if domainspecific timing mechanisms were operating.

A STATISTICAL MODEL BASED ON POOLED ACTIVITY PREDICTS VIBROTACTILE ATTENTIONAL ASYMMETRY. K. C. Whang, H. Burton, and G. L. Shulman. Depts. of Anatomy & Neurobiology, Neurology & Neurol. Surg., Washington Univ. Sch. of Med., St. Louis, MO 63110. (Supported by NIDCD 00096.)

Human performance studies showed that detecting the presence of a vibrotactile amplitude change does not demand selective spatial attention, but detecting the absence of such a change does.

The present model proposes a single mechanism to account for these asymmetrical attentional demands. Populations of detectors sensitive to amplitude change are postulated to feed into a pooled activity unit, which takes a weighted sum of inputs from multiple fingertips. The probability of a correct response in two-interval forced-choice trials is computed in terms of the means and variances of detector firing rates, given an assumed distribution of detector thresholds. The weights of the inputs from each fingertip are chosen to maximize predicted overall task performance.

The model predicts probabilities that are close to the human performance data when detector thresholds are distributed lognormally and the firing rates across fingertips are highly correlated. The relative weighting of the fingertips affects the probability of detecting the absence, but not the presence, of an amplitude change. A similar model based on Treisman and Souther's (1985) Weber fraction model did not predict attentional asymmetry in all of the experimental conditions in which it was observed.

VISUAL ATTENTION DISORDERS: NEUROPATHOLOGY AND DISSOCIATION Dr.D.Hodgkin* (Spon: Brain Research Association) Physiology
Department, Cambridge Univ. Cambridge, CB2 3EG
Disorders of visual attention are a frequent, transient

or permanent consequence of damage to several brain areas, principally right parietal,occipital and frontal cortex. Information processing techniques (Triesman, A. and Gormican S.Psychological Revue, 95:15,1988) were used to examine five patients suffering from right parietal/occipital damage. They demonstrate that pre-attentive and focal attentional processes can break down independently and in parallel, rather than sequentially and dependently, as much current theory predicts. These separable sub processes also recover at different rates. A long term study of one visual agnosic demonstrates quantitative and qualitative differences in demonstrates quantitative and qualitative differences in the rate and degree of recovery of pre-attentive and focal processes. A complementary study examined the physical bas-is for such variations in neural plasticity. Early lesions, associated with improved behavioral recovery, reduced astro -cytic scarring and dopamine production, also expressed increased levels of Heat Shock Protein which has a generally protective, developmental function in many biological ms. The combined information processing and physiological studies suggest that different attentional sub-systems may vary not only in their function, anatomy and neurochemistry but also in their resistance to damage. Ongoing experiments are examining differences in their developmental profiles.

SELECTIVE CORTICAL ENHANCEMENT EFFECTS PRODUCED BY A THALAMIC CIRCUIT MODEL BASED ON CURRENT NEURO-ANATOMICAL FINDINGS. David LaBerge, Vincent Brown, and Marc Carter, Department of Cognitive Science, University of California, Irvine, CA

PET and single-cell studies have suggested that a principal nucleus of the dorsal thalamus (pulvinar) may be involved in selectively attending to locations in visual space. We ask how the neural circuitry of a typical thalamic nucleus might operate to control selection in a cortical area to which it projects. A model of a thalamic circuit was constructed based on current neuroanatomical findings, and afferent inputs were compared with thalamocortical outputs. The neurons of the circuit model were afferent cells, thalamocortical (relay) cells, inhibitory interneurons, inhibitory reticular nucleus cells, and reciprocally connected corticothalamic cells. The net input to each cell was transformed by a function with a minimum value of zero and an asymptotic value based on current estimates of the maximum firing

rate of the particular type of cell.

An afferent input (e.g., from V1) to the circuit was introduced in a target cell (in the center) and flanker cells (in the surround) such that the output of the center cell was initially slightly greater than the output of a surround cell. Following afferent onset, thalamocortical and corticothalamic center and surround cells quickly increased their firing rates, but the center cells increased their rates considerably faster than the surround cell. This thalamic center-surround enhancement effect was also produced reciprocally when the corticothalamic cells provided the sole input to the thalamic circuit. It appears that an algorithm exhibited by this thalamic circuit model can ent center-surround differences originating in cells at both the input and output ends of the circuit.

941 14

PREATTENTIVE versus ATTENTIVE TEXTURE PERCEPTION BY THE TACTILE SYSTEM K.Sathian and H.Burton, Department of Anatomy & Neurobiology and McDonnell Center for Higher Brain Function, Washington University School of Medicine, St. Louis, MO 63110. (Supported by NIDCD 00096.)

Human subjects stroked four gratings simultaneously with the 2d and 3d fingerpads of each hand, to detect the presence of a target grating. A tap to one of the four digits cued the target location with a probability of 0.8. Values of grating spatial parameters were chosen to keep overall performance around threshold (75%) correct).

When the task was to detect (1) the presence of a change in roughness along the grating, performance did not differ significantly on validly and invalidly cued trials, suggesting that this target "pops out" preattentively. A significant cueing effect, suggesting that attention (spatially directed by the cue) is required for target detection, was found when the task was to detect (2) the absence of a change in roughness along the grating, (3) the direction of such a change or (4) a grating that differed in roughness from the others. In tasks (1) & (2), the results were similar whether groove width or ridge width was varied.

Thus, texture change is a feature that appears to be processed preferentially by the preattentive tactile system. Such processing is not restricted to surface spatial parameters (e.g. groove width) that are encoded in peripheral afferent firing rate.

241.16

INHIBITORY SPATIAL TAGGING AND VISUAL ATTENTION: CONTRI-

BUTION OF PREFRONTAL CORTEX AND BASAL CANGLIA. A. Henik*, Ben-Gurnion University, Israel. R.D. Rafal and R.T. Knight, UC Davis, Martinez VAMC CA 94553.

A peripheral visual signal has a biphasic effect on attention: the initial orienting is superseded by an inhibition of return which inhibits detection at that location. This mechanism favors novelty in visual scanning and has been shown to be generated through extrageniculate pathways. We measured inhibition of return in patients with unilateral lesions of prefrontal return in patients with unilateral lesions of prefrontal cortex or prefrontal cortex plus basal ganglia. Subjects made reaction time (RT) responses to targets appearing in the left or right field. Each trial began with the presentation of a flashing box (precue) in the periphery followed by a target which appeared with equal probability either at the cued location or in the opposite field. Inhibition of return was measured as a relative slowing of RT to targets at precued locations. Patients with lesions of prefrontal cortex showed deficient inhibition of return. Lesions involving both prefrontal cortex and striatum restored inhibition of return in the field contralateral to the lesion. We conclude that the inhibitory visual tagging system involves a neural circuit including superior colliculus, prefrontal cortex and basal ganglia.

241.18

ATTENTIONAL DEFICITS IN INDIVIDUALS WITH CANCER.*

B. Cimprich. The University of Michigan, Ann Arbor, MI 48109 Attentional fatigue typically follows intense exertion of mental effort and is manifested as a decline in the capacity to direct attention, i.e., inhibit competing stimuli. Despite intense mental demands associated with diagnosis of cancer, little is known about the problem of attentional fatigue. Sixteen women with localized breast cancer and no history of cognitive disorders were studied to determine whether there was a discernible pattern of decline in the capacity to direct attention over the initial phase of treatment. Repeated measures were obtained at 3, 18, 60, and 90 days following breast surgery. Measures included Digit Span Forward (DSF) and Backward (DSB) and Necker Cube Pattern Control (NCPC), a newly developed test requiring active inhibition of a competing pattern stimulus. At 3 days post-surgery, prior to receiving chemotherapy or radiation therapy, 44% of the subjects showed marginal or impaired performance on DSF (\leq 6) and DSB (≤4). Mean scores in DSF did not change significantly over time. Also, mean scores in DSB did not improve significantly until 60 days following surgery (X ± SD: 4.5 ± 1 vs 5.4 ± 1.5; 18 and 60 days, respectively; p=.02). Finally, there was a significant loss in NCPC at 90 days (X% Reduction in NCPC ± SD: 17% ± 35) compared to 3 days $(34\% \pm 26; p=03)$ and 18 days $(37\% \pm 25; p=.02)$ post-surgery. This study provides initial evidence of attentional deficits in individuals with cancer. The sustained decline in attentional capacity observed following surgery for

NEUROPSYCHOLOGICAL AND PSYCHOACOUSTIC EFFECTIVE BILATERAL LESIONS IN HUMAN AUDITORY CORTEX. EFFECTS OF S.W.

BILATERAL LESIONS IN HUMAN AUDITORY CORTEX. S.W. Anderson, H. Damasio, D.A. Robin, & L. Krain*. Div. of Behav. Neurology & Cognitive Neuroscience, U. Iowa College of Medicine, Iowa City, IA 52242.

There has been limited study of the effects of bilateral damage to auditory cortices in humans. Here we report on four patients in whom the primary and association auditory cortices were damaged bilaterally by stroke (demonstrated by analysis of magnetic resonance, computerized tomography, and emission tomography). The striking feature in all cases was a severe impairment in the recognition of speech and environmental sounds, despite normal audiometric thresholds for sound detection. More detailed psychoacoustic analysis of one detection. More detailed psychoacoustic analysis of one case revealed impaired reaction time to auditory stimuli, abnormal gap detection, and impairments of frequency discrimination and pitch matching. Sound localization, brain stem auditory evoked potentials, and recognition in visual and tactile modalities were normal. Repeated presentation of over 100 sounds revealed that 56% were never recognized, 14% were reliably recognized, and 30% were recognized inconsistently. These findings indicate that bilateral damage to human auditory cortex may not disrupt localization of sound or perception of volume but severely distorts auditory signals at an early perceptual level.

241 20

IMPAIRED PERCEPTION OF RELATIVE PURE TONE PITCH FOLLOWING BILATERAL LESIONS OF AUDITORY CORTEX IN MAN MJ. Tramo, Program in Cognitive Neuroscience, Dartmouth-Hitchcock Med Ctr, Hanover, NH 03756
While neurons within the primary auditory fields of the cat (Woolsey & Walzl 1942; Merzenich et al. 1975) and monkey (Merzenich & Brugge 1973; Imig et al. 1977) demonstrate frequency-specific responses to pure tones and topographical organization of frequency receptive fields, the results of lesion studies in animals have been interpreted as evidence that the discrimination of simple pitch differences is subserved by subcortical components of the central auditory system (Neff et al. 1975). However, recent data obtained following bilateral ablations of auditory cortex in monkeys have challenged the notion that "elementary" psychoacoustic functions do not rely upon the integrity of auditory cortex (Heffner & Heffner 1986). The examination of simple pitch perception following bilateral lesions of auditory cortex in man has been limited by the rarity of their natural occurrence, particularly in young, alert patients in whom peripheral hearing loss and/or dementia do not cloud experimental observations.

Data from a case with bilateral lesions involving all of Heschl's gyri and parts of the superior temporal gyri are presented. The patient is a thirty year old man who seven years ago presented with deafness following his second middle cerebral 1988). Pure tone sensation thresholds at 250-8000cps (duration=500msec) were normal at the time of the present observations (Tramo et al. 1990). However, on a standardized test requiring relative pitch judgments of two pure tones differing by 2-17cps (frequency centered at 500cps, loudness=55-40dB above threshold, duration=600msec, IS1-600msec, he scored in the 15th percentile (Seashore et al. 1960). When the two tones differed by 2-4cps, his performance fell to below chance (718); when the tones differed by 5-17cps, he scored well above chance (26/32). These results suggest that fineexperiment is likely to influence the interpretation of structure-function relation-ships governing simple pitch perception. Previous studies in the animal and clinical literature are reviewed in this light. (Supported by NIH 5PO1 NS17778-08)

DRUGS OF ABUSE: COCAINE AND OTHERS

242.1

NEUROANATOMICAL STUDIES OF COCAINE TREATMENT ON DOPAMINERGIC NEURONS: TH AND GFAP IMMUNOCYTOCHEMICAL STUDIES. X.L. Chen and M. Gupta. Dept. of Anatomical Sci. & Neurobiology, Univ. Louisville Sch. Med., Louisville, KY 40292.

Cocaine is a psychomotor stimulant that appears to exert its action by blockade of the reuptake of catecholamines resulting in increased dopamine and norepinephrine at synaptic levels. Vast majority of studies on cocaine research have focused on its behavioral effects and very little attention has been paid to its neuroanatomical actions. The present studies were undertaken to investigate the long-term effects of cocaine on the dopaminergic systems in mice and on gliosis in the striatum and nucleus accumbens following neuronal injury in the midbrain nuclei. Young adult male C57BL/6 mice at 2-3 months of age were given daily injections of cocaine HCl (10 or 20mg/kg) or saline vehicle for 9 consecutive days. The animals were sacrificed three weeks later and brains were processed immunocytochemically for tyrosine hydroxylase (TH) and Glial Acidic Fibrillary Protein (GFAP). The results of these studies show that cocaine treatment produced a significant decrease in the number of TH-positive neurons in the substantia nigra. The dopaminergic neurons of the ventral tegmental area appeared to be reduced in a dose-dependent manner but were not significantly different from controls. Quantitative analysis of the astrocytic response using GFAP immunocytochemistry in the striatum and nucleus accumbens is in progress. These data demonstrate that chronic coacine treatment produces loss of dopaminergic neurons in the substantia nigra. Supported by USPHS grant R29 NS24291 to MG.

CAFFEINE PREEXPOSURE SENSITIZES RATS TO THE MOTOR ACTIVATING AND REWARD PROPERTIES OF COCAINE <u>B.A. Horger and S. Schenk</u>, Dept. Psychol., Texas A&M Univ., College Station,

Rats were pretreated with 10 daily injections of either caffeine (20 mg/kg, IP) or the saline vehicle. Thereafter, the motor activating effects of cocaine (10 mg/kg, IP) activating effects of cocaine (10 mg/kg, IP) or the acquisition of intravenous cocaine self-administration (0.25 mg/kg/infusion) were assessed. The caffeine pretreated rats were more sensitive to the motor activating effects of cocaine. They exhibited higher cocaine-induced activity at 10 and 20 min following the drug injection when compared to the saline pretreated rate. The caffeine the saline pretreated rats. The caffeine preexposed rats also responded at higher rates for infusions of cocaine. Non-reinforced responding was not similarly increased thus ruling out the possibility of non-specific increases in activity as the basis for the enhanced responding for cocaine infusions. These data suggested a shift to the left in the dose/response curve (i.e. sensitization) for both behavioral actions of cocaine following caffeine pretreatment.

CAFFEINE FACILITATES RECALL OF NARRATIVE AND EXPOSITORY PROSE IN ORAL-CONTRACEPTIVE-FREE YOUNG WOMEN. B. E. Beckwith, T. V. Petros, and J. Brouse*. Psychol. Dept., Univ. of North Dakota, Box 7187, Grand Forks, ND 58202.

Although several studies have demonstrated

that caffeine has a complex effect on memory for simple stimulus materials as a function of gender, time of day, and impulsivity, no published study has explored the effect of caffeine on recall of complex stimulus materials. caffeine on recall of complex stimulus materials. In the present study, female subjects during the first 5 days of their menstrual cycle were administered 0, 2, or 4 mg/kg of caffeine and, 30 mins. later, asked to read and to immediately recall three expository and three narrative passages. Subjects receiving either 2 or 4 mg/kg of caffeine recalled a greater number of idea units of high importance than subjects given the placebo. Furthermore, there was a facilitation units of high importance than subjects given the placebo. Furthermore, there was a facilitation in recall of idea units of low importance as a function of dose of caffeine and no effect of caffeine on recall of idea units of medium importance. It appears that caffeine improves memory for essential and trivial details of narrative and expository prose when administered to healthy young women during the menstrual phase of their cycle.

ANXIOGENIC STIMULI PRODUCED BY COCAINE ARE POTENTIATED DURING PROTRACTED WITHDRAWAL FROM CONCURRENTLY ADMINISTERED COCAINE AND ETHANOL IN RATS. P.L. Prather and H Lal, Dept. of Pharmacology, Texas College of Osteopathic Medicine, Ft. Worth, TX

Cocaine abusers often experience persistent anxiety and panic attacks even after discontinuation of cocaine abuse. These experiences are likely to promote abuse of drugs with anxiolytic properties. Thus, ethanol, a mild anxiolytic, is often co-abused with cocaine. At present, the neurobiological consequences of the coabuse of ethanol with cocaine are not known Therefore, this study was undertaken to examine the anxiogenic effects of cocaine in subjects chronically treated with otherwise non-addicting doses of both ethanol and cocaine. Rats were trained to respond on one leve following an injection of saline and the alternate lever after the anxiogenic drug, pentylenetetrazol (PTZ) (20 mg/kg), according to a FR 10 schedule of food reinforcement. Animals were then treated for 5 days with either cocaine (20 mg/kg, ip) three times daily, ethanol (daily 100 ml of liquid diet containing ethanol, 2.25% w/v), or a combination of both. The ability of cocaine to produce a PTZ-like stimulus was determined 60 h after the last cocaine to produce a F12-like stimulus was determined on a lite tue last drug treatment. Cocaine produced a PTZ-like stimulus only in a small number of animals (30% at 10mg/kg) treated chronically with either cocaine or ethanol. In contrast, concurrent pretreatment with cocaine and ethanol resulted in dose-dependent and full elicitation of a PTZ-like stimulus by cocaine, with over 85% of the rats selecting the PTZ lever at the 10 mg/kg dose. These results indicate that during protracted withdrawal from co-administration of cocaine and ethanol, the anxiogenic stimuli produced by cocaine are markedly enhanced. (Supported by NIAAA grant AA06890)

CLINICAL NEUROBIOLOGY OF COCAINE WITHDRAWAL. L.H. Price, M.D., C.J. McDougle, M.D., J. Palumbo, M.D., T.R. Kosten, M.D., H.D. Kleber, M.D., G.R. Heninger, M.D., Yale Univ. Dept. of Psychiatry, 34 Park St., New Haven, CT

Three phases of withdrawal have been described in chronic cocaine abusers (Phase 1: Crash, Phase 2: Withdrawal, Phase 3: Extinction). Pharmacological challenge with L-DOPA 250 mg/carbidopa 25 mg (Sinemet) was used to investigate DA function during phases 1 and 2 of cocaine withdrawal in humans. Methods: Six male inpatients with phases 1 and 2 of occasine Dependence received 1.5 mg/kg of occasine p.o. 3X/day for three consecutive days (maintenance treatment period 1 (MTP1)). Subjects then received placebo occasine 3X/day for nine consecutive days (maintenance treatment period 2 (MTP2)). Subjects and ward staff were blind to the content of the cocaine capsules. placebo cocame 3X/day for nine consecutive days (maintenance treatment period 2 (MTP2)). Subjects and ward staff were blind to the content of the cocaine capsules. Each subject received randomized challenge tests of active or placebo Sinemet on the two days following MTP1 (Phase 1 withdrawal), and one week following MTP2 (Phase 2 withdrawal). Plasma prolactin (PRL), growth hormone (GH), MHPG, and HVA (all reported as ng/ml), were obtained following each challenge. Results: PRL (N=6) decreased following Sinemet during challenge sets 1 (mean±SD, -3.6±1.5 vs -1.1±1.4, p<0.04) and 2 (-4.2±1.7 vs -1.0±1.1, p<0.001) compared to placebo. Change in PRL was not different between challenge sets 1 and 2. GH (N=6) increased following Sinemet during challenge set 1 (2.6±15.4 vs 3.1±4.4, p<0.02) but not during set 2, compared to placebo. There was a trend toward increased GH response to Sinemet compared to placebo between challenge sets 1 and 2 (23.2±15.7 vs 6.3±11.2, p<0.08). MHPG (N=6) increased following Sinemet during challenge sets 1 (2.7±1.0 vs 1.1±1.0, p<0.0001) and 2 (2.3±1.4 vs 1.0±1.0, p<0.005) compared to placebo. Change in MHPG was not different between challenge sets 1 and 2. HVA (N=6) increased following Sinemet during challenge sets 1 and 2. HVA (N=6) increased following Sinemet during challenge sets 1 and 2. HVA (N=6) increased HVA response to Sinemet compared to placebo. There was also an increased HVA response to Sinemet compared to placebo between challenge sets 1 and 2 (367.4±99.5 vs 330.0±11.8, p<0.05). Conclusion: These data suggest that Phase 1 (27±4) of cocaine withdrawal may be associated with altered DA metabolism compared (Crash) of cocaine withdrawal may be associated with altered DA metabolism compared to Phase 2 (Withdrawal). Behavioral and neurobiological data will be presented.

TREATMENT OF COCAINE WITHDRAWAL WITH BUSPIRONE. Giannini, R.H. Loiselle, and D. J. Folts*. Department of Psychiatry, Ohio State University, Northeastern Ohio Universities College of Medicine, P. O. Box 2169, Youngstown, Ohio 44504 Chronic abuse of cocaine leads to dopamine and norepin-

ephrine and possible serotonin depletion. Buspirone, an anxiolytic, enhances dopaminergic and noradrenergic firing but suppresses serotonergic firing. Twenty cocaine abuse but suppresses serotonergic firing. Twenty cocaine abuseers volunteered to be detoxified in this study. Ten received buspirone 10 mg. t.i.d., p.o. and 10 received placebo t.i.d., p.o. Both groups were studied for 30 days. After the fifth day, the buspirone group reported significantly less symptoms (p < .05). Measurements on the 10th (p < .05), 15th (p < .02), 20th (p < .01), 25th (p < .001) and 30th day (p < .001) showed that this rate of improvement continued. All symptoms were evaluated by the BPRS scale. the BPRS scale.

ELECTROPHYSIOLOGICAL ACTIONS OF COCAINE ON RAT MEDIAL PREFRONTAL CORTICAL NEURONS. S.S. Jahromi and P.L. PREFRONTAL CORTICAL NEURONS. S.S. Jahromi and P.L. Carlen. Playfair Neuroscience Unit, Addiction Research Foundation, Departments of Physiology and Medicine (Neurology), The Toronto Western Hospital, University of Toronto, Toronto, Ontario, M5T 2S8.

It is well known that animals self-administer cocaine

into the medial prefrontal cortex (Goeders, N.E. and Smith, J.E., NIDA Res. Monogr., 55, 132-7). We perfused brain slices from the medial prefrontal cortex with cocaine hydrochloride at concentrations of 1-20 uM and recorded intracellularly from the deeper layers of the cortex with 3 M potassium methylsulphate electrodes in over 20 neurons.

over 20 neurons.

In the majority of cells, cocaine reduced both evoked excitatory and inhibitory postsynaptic potentials. This effect was reversible with washout. In some cells, there was a delayed depolarization on the falling phase of the EPSP with exposure to cocaine. At 10 and 20 uM, cocaine often increased the neuronal input resistance and increased the membrane threshold for spike generation. In most cells, spike frequency adaptation was either unaffected or increased, and the resting membrane potential was unchanged.

The spike train aftertwoerrolarization was usually reduced (10-20%) by potential was unchanged. The spike train afterhyperpolarization was usually reduced (10-20%) by cocaine. These preliminary results indicate both excitatory and inhibitory effects of cocaine on rat medial prefrontal cortical neurons. Supported by the MRC and The Hospital for Sick Children Foundation.

ANXIETY OR STRESS DUE TO COCAINE. N.E. Goeders, G.F. Guerin, X.M. Yang and A.J. Dunn. Dept. of Pharmacology & Therapeutics, LSU Medical Center, Shreveport, LA 71130.

initial cocalne use usually produces profound subjective feelings of well-being and a decrease in anxiety in humans. However, some of the major symptoms reported during cocaine withdrawal include severe agitation, anxiety, restlessness and depression. In rats, cocaine increases plasma ACTH, 8-endorphin and corticosterone, probably through a corticotropin-releasing factor (CRF)-related mechanism. Recent data from our laboratory demonstrated that chronic cocaine administration results in decreases in CRF binding sites primarily in brain areas associated with the mesolimbic-mesocortical dopaminergic system in rats. The experiments described below were designed to investigate the behavioral and physiological correlates of cocaine administration and the potential effects of exogenous CRF on cocaine reinforcement in rats. In the first experiment, the anxiogenic effects of cocaine were investigated using the defensive withdrawal paradigm in rats. Chronic (7 or 14 days) exposure to cocaine (20 mg/kg, ip) resulted in significant increases in the latency to emerge from a small enclosed chamber in an open field and in the total time spent in the chamber, a stress- or anxiety-related response. Plasma corticosterone concentrations were also increased 81% in the cocalne-treated animals compared to saline controls. In the second experiment, CRF pretreatment (20 to 100 ng, icv) produced dose-related changes in intravenous cocaine self-administration in rats suggesting that drugchanges in intraverous cocaine sen-administration in ratis suggesting that originitake can be influenced by the pharmacological introduction of a "stress-like" state in rats. Anxiety mediated via CRF-related mechanisms may therefore be involved in some of the behavioral and pharmacological effects of cocaine. COCAINE TOXICITY: DISTINCT NEUROTRANSMITTER SYSTEMS ARE ASSOCIATED WITH SEIZURES AND DEATH. M.C. Ritz* and F.R. George. NIDA-ARC, Baltimore, MD 21224

Cocaine use is increasingly associated with serious toxic effects, including seizures and lethality. This

study identifies brain receptors which appear to mediate these effects of cocaine and pharmacologically related compounds. The seizurgenic ED₅₀ values and LD₅₀ values for death within 15 minutes postinjection were determined concurrently for each drug in C57B1/6J mice. Binding potencies of all test compounds were assessed at dopamine, norepinephrine and serotonin transporter sites and at M₁ and M₂ cholinergic and sigma opiate receptor sites. Multiple regression analyses determined the proportion of influence of each of these receptors on seizurgenesis or lethality. The serotonin transporter is the primary binding site associated with the potency of cocaine and related drugs in seizurgenesis. However, the binding at either signs M₂. We received drug binding at either sigma, M1 or M2 receptors appears to attenuate this effect. In contrast, drug binding to to attenuate this effect. In contrast, drug binding to the dopamine transporter appears to be associated with the lethal potency of these drugs, while muscarinic receptors appear to play a secondary role in lethality. These biochemical findings are supported by pharmacological potentiation or antagonism of seizures by serotonin uptake inhibition or blockade of 5HT2 receptors, respectively. In contrast, cocaine lethality is antagonized specifically by D1 and M1 blockers.

242.10

CHRONIC COCAINE AND EEG POWER SPECTRA: EFFECTS OF DRUG HISTORY AND PREDICTORS OF LETHALITY G.T. Livezey and S.B. Sparber. Dept. of Pharmacology, University of Minnesota, Minneapolis, MN 55455

The effects of cocaine, at doses used to treat rats during their last trimester of pregnancy in a perinatal drug exposure study, were studied in nonpregnant females for its residual, acute and chronic actions upon the EEG. The effects of the high dose readministered 2 months after initial treatment were studied in order to determine if readministered 2 months after initial treatment were studied in order to determine it cocaine challenge was necessary to unmask otherwise undetectable residual effects (e.g. kindling). Twelve SD rats were given either water, 15 mg or 45 mg cocaine/kg, p.o. 3 times a day (9AM, 1PM, 5PM) for 7 days (History). Two months later all 12 were implanted with radiotransmitters for sampling EEG. Subsequent treatment for all 12 consisted of water for 19 days and cocaine (45 mg/kgX3) for 19 days. Six of the 12 consisted of water for 19 days and cocaine (45 mg/kgX3) for 19 days. Six of the 12 animals died between days 6 and 13 of cocaine gavage (2 from each History group). EEG was analyzed from one baseline day (prior to water Rx), one water day, one early cocaine day (day2) and the last day of cocaine upon which all animals were alive (day5). Five, 30sec EEG samples from 1 hr before morning gavage and 1 hr after morning gavage were used to derive averaged power spectra (1-100Hz). Power was analyzed as total (1-100Hz) or in 20Hz bins. The immediate response was measured between EEG samples after water and after cocaine (days 2,5). Animals originally treated with 45 or 135mg cocaine/kg/day, in divided doses, did not show evidence of a residual effect upon total power (1-100Hz) or upon distributed power (any 20Hz bin). However, treatment with cocaine after implantation of radiotransmitters caused a significant decrease in total power (1-100Hz) between the post-twater gavage value and the post-cocaine value on the power (1-100Hz) between the post-water gavage value and the post-cocaine value on the 5th treatment day. Cocaine treatment for 2 days failed to cause a significant change in total power. Bin 21-40Hz showed a significant reduction and bins 61-80Hz and 81-100Hz showed signnificant increases in power after both 2 and 5 days of cocaine. Bin 1-20Hz showed decreased power only after 5 days cocaine. Total power (1-100Hz) prior to starting water gavage, was increased and 61-80Hz activity was decreased for rats that did not survive chronic cocaine treatment, compared to survivors. Thus, predictors of chronic cocaine lethality may be evident prior to chronic treatment. Supported by USPHS DA 04979, T32DA07097 and NS 23289.

AMYGDALA CENTRAL NUCLEUS NEURONAL DISCHARGE FOLLOWING LOCALIZED MICROINJECTION OF COCAINE. H. Ni, J.X. Zhang, R.K. Harper and R.M. Harper. Brain Research Institute and Department of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

The central nucleus of the amygdala (ACE) projects heavily to cardiac and respiratory regions of the parabrachial pons, periaqueductal gray, and nucleus of the solitary tract in the cat; electrical stimulation and cold blockade of the ACE exert profound respiratory and cardiac changes. Intravenous and intraventricular cocaine administration lead to pronounced tachypnea and tachycardia. Using extracellular single-cell recording and microinjection techniques, we examined the effects of cocaine (100µg in 0.2µL) on activity of ACE neurons in chronically instrumented freely moving cats and used artificial CSF as a control. Thirteen single neurons were recorded during a baseline sleep-waking period. Six neurons slowed profoundly in response to cocaine administration relative to the slowest rates in any baseline condition; two neurons were depressed for 2 hours postadministration. One neuron increased its discharge rate by a factor of 10; discharge of the remaining cells was unchanged. A portion of the cocaine effect on cardiac and respiratory patterning may be mediated by ACE neurons.

RELATIONSHIP BETWEEN VENTRICLE/BRAIN RATIO, A MEASURE OF CEREBRAL ATROPHY, AND SUBJECTIVE RESPONSES TO INTRAVENOUS COCAINE IN HUMAN SUBSTANCE ABUSERS. M.J. Morgan, N.G. Cascella*, J.M. Stapleton, E.K. Shaya*, D.F. Wong and E.D. London, NIDA Addiction Research Center, Baltimore, MD 21224 and Johns Hopkins Medical Institutions, Baltimore, MD 21205.

The relationship between subjective responses to cocaine and the ventricle/brain ratio (VBR) (Synek, V. et al., Neurology, 26:231, 1976), measured by X-ray computed tomography, was examined in 8 human volunteers with histories of polydrug abuse. A negative rank correlation was found between a measure of the subjective effect of cocaine (40 mg, i.v.) and individual VBRs, (p < 0.05). This measure was the response to the question "How much do you feel the drug?", which was rated on a scale of 0 to 4 and was elicited by a "beep" prompt 1, 3, 4, 5, 7, 8, 9, and 10 min after cocaine injection. Negative rank correlations were also found between individual VBRs and subjective ratings of various drug effects on a visual analog scale. Subjects rated drug effects on this scale 30 min before and 30 min after I.v. administration of cocaine. The post-injection data were subtracted from pre-injection baselines to provide difference scores which were then examined for correlations with VBRs. The responses to the following questions yielded significant negative rank correlations: "How energetic did the drug make you feel?" (p < 0.05); "How much did you like the drug?" (p < 0.05); and "How much did you want to take the drug again?" (p < 0.05). These data suggest that the relative integrity of the brain may be a significant determinant of the stimulant and rewarding effects of cocaine in humans.

242.15

APOMORPHINE INDUCED HYPERLOCOMOTION: ELEMENTS OF PLASTICITY AND STERBOTYPY. Ernest N. Damianopoulos and Robert J. Carey VA Medical Center, Syracuse, NY 13210

Hyperlocomotion induced by repeated apomorphine stimulation in the intact rat was investigated using a Pavlovian conditioning protocol. Animals were administered apomorphine (2.0 mg/kg SC) daily for 7 days either paired or unpaired with a 10 min test environment placement. Direct recording of distance traversed (m) showed a gradual development of hyperlocomotion in response to repeated apomorphine stimulation but only in the animals of the paired treatment group. Locomotion rotation patterns, grouped into four categories of diameter size, were also analyzed. On Day 1, animals of both the paired and unpaired treatment groups exhibited equal distribution of rotation frequency across all four categories of diameter size. This pattern remained stable in the unpaired group. In the paired animals, however, a new pattern of rotation emerged by Day 7 which was a shift to a highly skewed distribution of rotations toward the highest possible diameter size. This unique pattern of rotation was retained after a 7-day drug withdrawal period but was exhibited only under drug test conditions. The results were interpreted as showing a learned, environment induced effect on the unconditioned drug response to apomorphine.

EFFECTS OF IV COCAINE ON REGIONAL CEREBRAL BLOOD FLOW IN THE RAT. E.A.Stein and S.A.Fuller*. Department of Psychiatry, Medical College of Wisconsin, Milwaukee, WI 53226. Cocaine is a potent CNS stimulant whose primary mechanism of action

Cocaine's a potent CNS stimulant whose primary mechanism of action is reuptake inhibition of the monoamines. Cocaine's reinforcing and motor activating properties are thought to be mediated primarily by dopamine and binding to components of the dopamine transporter has been observed. While metabolic mapping studies have recently been performed, due to cocaine's short duration of action and complex behavioral symptoms, we wanted to employ a short time-window marker to ultimately identify neuronal structures involved in different aspects of its pharmacologic profile. We now report the effects of cocaine on regional cerebral blood flow in the rat. Conscious rats were injected IV with either 0, 0.1, 0.5, 1 or 5 mg/kg cocaine, 1 min prior to radiolabel. [14C]Iodoantipyrene was used to determine rCBF according to the method of Sakurada et al. Analyses of variance indicated that all 58 measured structures were altered by cocaine. Biphasic responses were seen at the lowest dose (0.1mg/kg), with such limbic structures as the anterior, lateral, ventomedial and dorsomedial hypothalamus and MD thalamus depressed by this dose but activated, in a dose response fashion, by the two higher doses of cocaine. A second group of structures responded with a dose related activation including the nucleus accumbens, olfactory tubercle and LD thalamus at 0.5 mg/kg threshold. Higher threshold (1.0 mg/kg) effects were observed in such structures as the claustrum, frontal cortex and substantia nigra. Thus, not only does rCBF appear to be a sensitive measure of cocaine's effects, but as a brief temporal marker, may have significant advantages over other metabolic measures of early neuronal activity. (Supported by NIDA grant DA 05012).

242.14

BEHAVIORAL CHARACTERIZATION OF PCP-INDUCED CHANGES IN RAT SOCIAL BEHAVIOR: A POSSIBLE MODEL OF SCHIZOPHRENIC SYMPTOMS. R.E. Steinpreis, C. Longyhore* and J.D. Salamone. Department of Psychology, University of Connecticut, Storrs, CT 06269-1020.

PCP-induced psychosis in humans is virtually indistinguishable from an acute episode of schizophrenia. While the motor effects of PCP in rats have been well described, the effects on social interaction could provide a more useful tool in the understanding of psychotic behavior. An "intruder" paradigm was employed in which rats were injected with either saline, 1.0, 2.0, or 4.0 mg/kg PCP, placed in a stable colony of three other rats, and observed for 40 minutes to quantify the PCP-induced changes in social behavior. PCP produced a syndrome of abnormal behaviors characterized mainly by social withdrawal. There was no effect at lower doses, but at 4.0 mg/kg there was a reduction in aggressive and approach behaviors, and an avoidance of social contact. A second study employed microdialysis methods to measure PCP-induced increases in dopamine (DA) activity. The neurochemical and behavioral effects of PCP in rats provide additional evidence that PCP may serve as a useful drug model of schizophrenic symptoms.

242.16

GENETIC INFLUENCES ON NICOTINE TOLERANCE EVALUATED BY CONTINUOUS MONITORING OF RESPONSIVENESS. M.J. Marks, S.F. Robinson, J.R. Pauly and A.C. Collins, Institute for Behavioral Genetics, University of Colorado, Boulder, CO.

The ability of mice to develop tolerance to the effects of nicotine is influenced by the genotype of the animal. In general, those mice initially more sensitive to the effects of nicotine require chronic treatment with lower doses to induce tolerance. To test the hypothesis that nicotine must produce a physiological effect before tolerance develops, mice from several inbred strains were implanted with transmitters (Mini-Mitter) to measure body temperature and activity in their home cages before and during nicotine treatment. Nicotine was administered by intravenous infusion. Tolerance was assessed by administration of a pulse of drug once each day. The relative sensitivity of the mouse strains to the effects of nicotine were similar to that measured after acute injection of drug (C57BL/6>DBA/2>BUB/Bn). Those strains that were affected by the drug were more likely to develop tolerance to the effects of nicotine. The extent of tolerance development was also influenced by the dosage and timing of drug administration. The results indicate that the magnitude of tolerance development is closely related to the magnitude of initial effect both within and among strains.

NICOTINE MODULATES PROENKEPHALIN GENE EXPRESSION IN BRAIN AND PITUITARY. S.R. George, M. Kertesz* and J. Tsatsos*. Pharmacology Dept., University of Toronto, Toronto, Ontario, Canada M5S 1A8

Nicotine effects in brain have been postulated to be mediated through opioid mechanisms, at least in part. In the present study, the effect of nicotine administration on proenkephalin (PE) gene expression in brain and pituitary were examined. Male Sprague-Dawley rats were housed in environmental rooms and injected s.c. with nicotine 1 mg/kg/day or saline vehicle for varying lengths of time. Animals were sacrificed and brain regions analyzed for PE mRNA, free Met-enkephalin and cryptic Met-enkephalin as an index of PE peptide. Met-enkephalin was measured by radioimmunoassay; cryptic levels by sequential enzymatic digestion with trypsin and carboxypeptidase B, followed by RIA. PE mRNA was detected by Northern blotting with hybridization of a 32P-labelled 935 bp cDNA Nicotine treatment resulted in a decrease of free Metenkephalin peptide in striatum with no change in the levels of cryptic Met-enkephalin and an increase in PE mRNA. Met-enkephalin levels in medulla-pons and anterior pituitary were increased, with no apparent change in PE mRNA. In neurointermediate pituitary there was a decrease in the ratio of basal to cryptic Met-enkephalin and a decrease in PE mRNA. These results suggest that nicotine alters proenkephalin gene transcription and proenkephalin peptide processing in various brain regions.

PHENCYCLIDINE, BUT NOT MK-801, PRODUCES INCREASES IN EXTRACELLULAR DOPAMINE LEVELS AS ASSESSED BY *IN VIVO* MICRODIALYSIS. <u>C.B. Hubner and A. Pert. BPP.VIIMH. Bethesda.</u> MD 20892.

A. Pert. BPB/NIMH, Bethesda, MD 20892.

Both phencyclidine (PCP) and MK-801 produce behavioral effects such as locomotor stimulation which suggest involvement of the dopamine system. The purpose of this study was to evaluate the effects of these two compounds on extracelluar DA using in vivo microdialysis. Using a cumulative dosing regimen, the effect of systemically administered PCP (3.0-30.0 mg/kg) on extracellular DA levels in the striatum, nucleus accumbens, and frontal cortex of the rat were determined. When compared with vehicle, PCP produced a significant dose-dependent increase in extracellular DA levels in all three brain regions tested. The removal of Ca²⁺ from, and the addition of Mg⁺⁺ to, the dialysate significantly attenuated the increases in dopamine overflow induced by PCP, suggesting that the dopaminergic effects of PCP are due to an exocytotic process. These effects of PCP could be mediated either through its actions at the NMDA receptor or through its effects at the DA uptake site. MK-801 is a potent and selective non-competitive NMDA antagonist which has little affinity for the DA uptake site and a behavioral profile similar to PCP. Systemic injections of MK-801 (0.1-3.0 mg/kg) did not produce any increases in extracellular DA in the nucleus accumbens. These findings suggest that blockade of NMDA function is not sufficient to account for increases in DA produced by PCP. In addition, it does not appear that the locomotor stimulation produced by MK-801 is determined through DA activation.

242.1

CONDITIONED PLACE PREFERENCE (CPP) INDUCED BY VENTRAL TEGMENTAL AREA (VTA) INJECTIONS OF THE NICOTINIC AGONIST CYTISINE. E. Museo* and R. A. Wise. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montreal, Canada, H3G 1M8.

Male Long-Evans rats were given intracerebral injections of the nicotinic agonist cytisine (10 nmol/0.5 µL/side) when placed in one side of a balanced, 3-compartment, CPP apparatus. These injections alternated with saline injections that were paired with the opposite compartment. Four pairings of each were given. Animals given VTA injections (n=7) subsequently spent significantly more time in the cytisine-paired compartment than in the saline-paired compartment. Animals receiving cytisine injections dorsal to the VTA showed no such CPP. Nicotinic receptors are reported to be on dopaminergic cells in the VTA, and these cells are implicated in the CPP induced by morphine and amphetamine. The present data raise the possibility that these cells also play a role in the CPP established by systemic nicotine.

PERSEVERATIVE BEHAVIOR IN THE RADIAL ARM MAZE IS THE AUGMENTED BY DRUGS OF ABUSE. E.A. Loh. A. Smith* and D.C.S. Roberts Department of Psychology, Carleton University, Ottawa, Canada K1S 5B6.

The hypothesis that drugs of abuse induce perseverative patterns of foraging behavior was investigated. We have previously shown that the pattern of exploration for food becomes perseverative following injection of nicotine, amphetamine, cocaine, heroin, alcohol or diazepam. In the present experiment we tested two centrally acting drugs known to be without abuse potential - haloperidol and scopolamine. Food deprived rats were trained to obtain food positioned at the ends of an eight arm radial maze. The food cup was rebaited each time the animal left the arm; thus every arm entry was reinforced. In contrast to drugs of abuse, we found that haloperidol and scopolamine decrease the perseverative nature of the foraging pattern. We conclude that an examination of the effects of drugs on foraging behavior may be a useful method of evaluating drug-induced reinforcement. (Supported by M.R.C.).

DRUGS OF ABUSE: AMPHETAMINE

THE CHARACTERIZATION OF BRAIN PROTEINS IN AMPHETAMINE TREATED MICE BY GEL ELECTROPHORESIS. L.O. Chambers* and M.A. Blackshear. Dept. of Biological Sciences, Tennessee State University, Nashville, TN 37709-1561.

The toxic effects of amphetamine on crowded mouse behavior and brain polyribosomes have been previously reported (Blackshear et al., 1979). To further examine the effects of crowding on amphetamine-induced changes in protein synthesis, we studied the effects of amphetamine on brain proteins found in the pH 5 enzyme fraction and the polyribosomal fraction, the cellular components of protein synthesis. Swiss ICR male mice (20-26g) received a single injection of 20 mg/kg of dl-amphetamine and were crowded for thirty minutes. Control animals crowded in a similar manner received 0.01 ml/gm physiological saline. The whole brains (minus cerebellum) were dissected and the proteins in the pH 5 enzymes and polyribosomes were analyzed by polyacrylamide gel electrophoresis. The administration of amphetamine caused a decrease in the proteins contained in the pH 5 enzyme fraction and in the proteins contained in the polysome fraction in comparison to saline controls. These findings suggest that amphetamine acts post-translationally to inhibit protein synthesis. In addition, these findings suggest that amphetamine may act at more than one site to inhibit protein synthesis.

GENDER DIFFERENCES IN THE EFFECTS OF PRENATAL COCAINE EXPOSURE ON LOCOMOTOR ACTIVITY IN 21-22 DAY OLD RATS. H. E. Hughes. L. A. Freed. L. M. Donohue* and D. L. Dow-Edwards. Laboratory of Cerebral Metabolism, Department of Neurosurgery, SUNY Health Science Center, Brooklyn, N.Y., 11203.

Our lab has demonstrated that early postnatal cocaine exposure in female rats alters the adult behavioral response to amphetamine. The present study investigated locomotor activity in male and female weanling rats treated prenatally with cocaine. Pregnant rats were gastrically intubated with 30 or 60 mg/kg/day cocaine HCl or vehicle only during gestational days 8-22. Vehicle treated rats were pair-fed/watered to rats receiving 60 mg/kg cocaine. A non-treated control group was also maintained. At parturition, litters from all four groups were surrogate fostered. At 21 or 22 days of age, two offspring per litter were sequentially placed in a Digiscan Activity Monitor. Activity counts were collected in one minute intervals over a 15 min. baseline period. Subjects then received one of two doses of d-amphetamine sulfate sc followed by a 95 min. period of activity monitoring. The data suggest a gender difference in the baseline activity of control rats. Females traveled more distance than males. Baseline activity for both sexes in the 60 mg/kg group was similar to that of control males. Prenatal cocaine exposure appears to nullify the gender difference observed in control rats, with females displaying a "male-like" amount of locomotor activity. Whether prenatal cocaine exposure alters developing brain systems that directly underlie motor activity or whether it results in a masculinizing effect in females is unknown. Data indicating the effects of prenatal cocaine exposure on activity in response to amphetamine are forthcoming. Supported by ADAMHA grant #DAO4118.

THE EFFECT OF COCAINE AND AMPHETAMINE ON THE MICRO-EVENTS OF UNCONDITIONED LOCOMOTOR BEHAVIOR. M.P. Paulus and M.A. Geyer. Dept Psychiatry, Lab of Biol Dynamics and Theoret Med, Univ California at San Diego, La Jolla, CA 92093.

Substances influencing central dopaminergic systems have been suggested to change motor behavior either towards varied locomotion or increased perseveration. To test the hypothesis that substances having similar neurochemical effects will yield similar changes in behavior, measures derived from the thermodynamic description of dynamical systems and from the description of point processes in physics were applied to locomotor paths recorded for 60 min in the Behavioral Pattern Monitor. Briefly, amphetamine (0.25 - 4 mg/kg, s.c.) and cocaine (2.5 - 40 mg/kg, i.p.) were injected 10 min prior testing. Both drugs increased locomotion dose-dependently. A global geometric descriptor, the spatial scaling exponent d, a global dynamic descriptor, the metric entropy of the rat locomotor sequences h, the distribution of geometric singularities f(d), and the dynamic singularities s(h) were obtained from the rat locomotor paths. A wavelet transform was applied to the temporal sequence of measures to characterize the chronological order of drug-induced changes in the different local descriptors. The two substances produced different and dose-dependent changes in d and h. While amphetamine increased h without affecting d, cocaine, especially at high doses, decreased both h and d. The functions f(d) and s(h) specified particular changes induced by each drug in the distribution of local geometrical and dynamical scaling exponents. Specifically, amphetamine increases the frequencies of both probable and unpredictable sequences, cocaine increases the unpredictable and the highly predictable (perseverative) but not the probable sequences of micro-events. In conclusion, psychomotor stimulant drugs acting via dopaminergic systems lead to comparable increases in the amount of activity but have specific signatures in their effects on the structural and sequential characteristics of unconditioned locomotor behavior. Supported by DA06325.

DUAL EFFECT OF AMPHETAMINE ON LOCOMOTION OF

DUAL EFFECT OF AMPHETAMINE ON LOCOMOTION OF PONTINE-DAMAGED RATS. Rebecca M. Chesire. Univ. Hawaii-Manoa, Honolulu, HI 96822.

Damage of the nucleus reticularis tegmenti pontis (NRTP) can produce rapid forward locomotion that is not abolished by morphine, haloperidol or ethanol (1-6), indicating that the NRTP mediates some inhibitory locomotor effects of these drugs. A suggestion has been made that amphetamine (AMPH) might abolish NRTP damageof these drugs. A suggestion has been made that amphetamine (AMPH) might abolish NRTP damage-induced locomotion (7). This report describes both excitatory and inhibitory effects of AMPH on both excitatory and inhibitory effects of AMPH on NRTP-damaged rats. 16 male Long-Evans hooded rats were given bilateral electrolytic lesions of the NRTP or used as controls (n=4). Between postop. days 1 & 57 they were pretested for amount and form of locomotion, injected once with 5 mg/kg d-AMPH sulfate, and retested at 10-80 min. Control rats showed rapid locomotion and eventual "trapping" in stereotyped movement (8,9). NRTP-damaged rats showed: (1) an initial increase in amount and rapidity of locomotion followed by a decrease or (2) a repetitive alternation between more rapid locomotion and loss of support. The results suggest that NRTP damage can partly block the increase in damage can partly block the increase in locomotion and stereotypy produced by AMPH, but that such effects are not unitary, and appear to be biphasic.

THE ASSESSMENT OF THE ORGANIZING INFLUENCE OF AMPHET-AMINE ON BEHAVIOR: INTERACTION BETWEEN PLACE PREFERENCE AND TASTE AVERSION. A.L. Errico, D.V. Gauvin, & F.A. Holloway. Univ. of

AND TASTE AVERSION. A.L. Errico, D.V. Gauvin, & F.A. Holloway. Univ. of Oklahoma Health Sciences Center, Oklahoma City, OK 73190-3000.

Some psychoactive drugs such as amphetamine have been found to induce conditioned taste aversions (CTAs) within a dose range similar to that which is self-administered by laboratory animals. Such findings have been aptly described as presenting an "apparent paradox" (Hunt & Amit, Neurosci. & Biobeh. Rev., 11, 107-130, 1987). The present study assessed the interaction between the associative "valences" between a CTA and conditioned place between the associative "valences" between a CTA and conditioned place preference (CPP) using d-amphetamine as the conditioning stimulus (UCS). Male S-D rats were randomly assigned to two groups (N=12/group). One group received CTA with a 1% saccharin solution prior to CPP pairings (Grp. CTA/CPP) and the other group received CPP pairings prior to development of CTA (Grp. CPP/CTA). Each of these groups were further subdivided into saline control vs amphetamine treatment groups. Prior learning of either the aversive (Grp.CTA/CPP) or rewarding (Grp. CTP/CTA) properties of amphetamine did not interfere with the later development of "associative learning" of either CPP (approach, Grp. CTA/CPP) or CTA (avoidance, Grp. CPP/CTA). Both amphetamine tx groups developed CPP"s (p<01) and CTA's (p<001) which did not differ in magnitude between subgroups (i.e. Amphetamine subjects in CPP/CTA did not differ from their cohorts in CTA/CPP and vice versa). Saline treated animals developed neither CPP or CTA. At the and vice versal. Saline treated animals developed neither CPP or CTA. At the conclusion of the dual associative tasks, animals were tested in the CPP chambers with calibrated drinking tubes installed inside the alley-ways to test the interaction between associative approach (CPP) and avoidance (CTA). Saccharin solutions were placed on the CS(-) side and water on the CS(+) side. Data supports the view that associative learning of the "aversive" and "rewarding" properties of amphetamine may operate in parallel with no a priori dominant influence of one over the other.

THE EFFECTS OF REPEATED AMPHETAMINE AND VARIED OPEN-FIELD CONFIGURATION ON 8, A PUTATIVE INDEX OF LOCOMOTOR STEREOTYPY. P.M. Kunko and K. Mueller. Dept. of Psych., Texas Christian Univ., Fort Worth, TX 76129. Locomotor stereotypy, the tendency to repeat patterns of locomotion in a limited area of the environment, is an

Locomotor stereotypy, the tendency to repeat patterns of locomotion in a limited area of the environment, is an amphetamine (AM)-induced behavior which has recently drawn considerable attention. Attempts to quantify this behavior have resulted in a variety of procedures, including the gamma (3) statistic. Acute AM reliably produces a constellation of dose-dependent behaviors in rats. Changes in some of these behaviors also vary reliably following chronic AM administration. Two experiments were done to determine if changes in AM-induced locomotor stereotypy (3) following chronic AM administration are functionally related to changes in other AM-induced behaviors, or if 3 is a procedural artifact. In experiment one, 12 daily injections of AM (1 or 2mg/kg) were given and behaviors were assessed on the first and last days. In experiment two, rats were injected with saline, caffeine, or AM prior to assessment in two different configurations of an open field. Suprisingly, locomotor stereotypy changed little over the time course of repeated AM, suggesting that AM-induced behaviors are mediated by different neurochemical mechanisms. Additionally, locomotor stereotypy does not appear to be an artifact of open field configuration, as 3 scores from different configurations were highly correlated.

NEUROPHARMACOLOGICAL ASSESSMENT OF COCAINE-INDUCED CONDITIONED PLACE PREFERENCE USING INTRA-CRANIAL MICROINJECTIONS. S.E. Hemby, G.H. Jones, J.B. Justice, Jr. & D.B. Neill; Departments of Psychology and Chemistry, Emory University, Atlanta, GA 30322 Cocaine and amphetamine (AMPH) have both been suggested to exert their

reinforcing and locomotor effects via nucleus accumbens (NACC) dopamine. Rats will self-administer AMPH directly into the NACC and intra-NACC infusions of AMPH produce locomotor activation as well as a conditioned place preference (CPP). However, although intra-NACC cocaine increases locomotor activity, it has been shown that rats will not self-administer occaine into the NACC. Furthermore, 6-OHDA lesions of the NACC completely abolish IV AMPH self-administration whereas similar lesions merely attenuate IV self-administration of cocaine. This evidence suggests different mechanisms for AMPH and cocaine-induced reinforcement. The present studies were conducted to further delineate the neural substrates of cocaine-induced reinforcement using the CPP parentium. the CPP paradigm.

Male Wistar rats were implanted with bilateral guide cannula aimed at the

Male Wistar rats were impainted with bilateral guide cannula aimed at the NACC. Following pre-exposure, animals were assigned to either compartment of the CPP apparatus for drug pairing in a totally counterbalanced design. Rats received bilateral infusions of cocaine (12.5, 25, 50, or $100 \mu g/\mu t_1 = 10$ per group) into the NACC and were immediately placed in the drug-paired compartment. These doses were chosen as they produce pronounced locomotor activation). Two additional groups of animals received either intra-accumbens d-AMPH ($10 \mu g/\mu t_1$).

additional groups of animals received either intra-accumbens d-AMPH (10/g)µi, n=9) or IP cocaline (5 mg/kg; n=12). On alternate days rats received vehicle infusions and were placed in the opposite compartment. All animals were given two drug and two vehicle pairings.

Both the AMPH and IP cocaine groups exhibited a CPP for the drug-paired environment. However, no dose of intra-accumbens cocaine produced a place preference. These results are further evidence that the NACC may not be an essential substrate for cocaine reinforcement as measured by CPP.

243.8

POTENTIATION OF THE DISCRIMINATIVE STIMULUS PROPERTIES OF COCAINE AND AMPHETAMINE BY THE DIHYDROERGOTAMINE DERIVATIVE, PPI-389. B. Geter, D. Cick* and A.L. Riley. The American University, Washington, D.C. 20016.

Cocaine users often complain of migraine headaches following binges. Cocaine alleviates these headaches. The ergot alkaloid, ergotamine, does so as well (Satel, S.L. and Gawin, F.H., JAMA, 261:2995-2996, 1989). That ergotamine substitutes for cocaine in 261:2995-2996, 1989). That ergotamine substitutes for cocaine in relieving such headaches suggests that they have similar properties. The following studies assessed these similarities through the drug discrimination procedure. In experiment 1, following the establishment of drug discrimination learning with cocaine (10 mg/kg), rats were tested for the substitution potential of a range of doses of the dihydroergotamine derivative, PPI-389 (5.6 to 32 mg/kg). For all doses, subjects displayed vehicle-appropriate responding. However, when various doses of PPI-389 (5.6 and 18 mg/kg) were given in combination with the training dose of cocaine and when PPI-389 (5.6 mg/kg) was given in combination with various doses of cocaine (5.6 to 8.9 mg/kg), the dose-response function for cocaine was shifted to the left. In a second experiment, PPI-389 (5.6 mg/kg) also shifted to the left the dose-response function for amphetamine in cocaine-trained rats. The fact that PPI-389 was able to affect the dose-response function for cocaine (and amphetamine) suggests a potentiating effect of PPI-389. The mechanism remains unknown. The mechanism remains unknown.

AMPHETAMINE-INDUCED BEHAVIORAL SENSITIZATION OF MESOLIMBIC NORADRENERGIC SYSTEM IN RATS: ROLE CORTICOSTEROIDS. Cools, 6500 A.R. Dept. Pharmacology Nijmegen, University of Nijmegen, нв

The involvement of corticosteroids in the amphetamine-induced sensitization of the mesolimbic nor-adrenergic system was investigated. Locomotor activity injections of the alpha-adrenergic agonist induced by injections of the alpha-adrenergic agonist phenylephrine into the accumbens of rats primed 24 hr earlier with an intra-accumbens injection of 10 µg dexamphetamine (Cools et al., Beh. Pharmacol., 1, Suppl. 1: 6, 1990) was used to assess the effect of adrenalectomy and of corticosteroid replacement treatments (500 mg/kg, s.c., daily for 8 days). Sham adrenalectomy had no effect at all. Adrenalectomy the properties without attenuated the sensitization to phenylephrine without changing the response to amphetamine. Dexoycortisone and corticosterone re-instated fully and partially respectively the phenylephrine response without changing the amphetamine response. Dexamethasone and corticosterone re-instated fully and partially respectively the phenylephrine response without changing the amphetamine response. Dexamethasone increased the amphetamine response and re-instated the response to phenylephrine. It is concluded that mineralocorticoids are necessary for the sensitization of the mesolimbic alpha-noradrenergic system, and that glucocorticoids are necessary for the mesolimbic dopaminergic and, possibly, noradrenergic system.

INDIVIDUAL DIFFERENCES IN AMPHETAMINE-INDUCED LOCOMOTION COULD BE PREDICTED FROM AMOUNT OF SUGAR INGESTED. T. L. Sills and F. J. Vaccarino. Department of Psychology, University of Toronto, Toronto, Ont., M5S 1A1

Recent evidence suggests that there are individual differences in locomotor responsivity to amphetamine (AMP) and that these differences can be predicted from baseline activity (Piazza et al., 1989). Our lab has also demonstrated individual differences in feeding responsivity to AMP, which could be predicted from baseline feeding. The present study extended these findings by examining whether baseline feeding would be predictive of locomotor responsivity to AMP.

Sixteen male Wistar rats (Charles River, Quebec) were presented with powdered chow and sugar in their home cages and baseline intake was measured for one hour each day for seven days. Animals were divided into two subgroups on the basis of sugar intake level (above and below the median value); half (n = 7) were classified as low feeders and half (n = 7) as high feeders. Subsequently each group was tested for AMP-induced locomotion. Rats were administered vehicle (saline) and three doses of AMP (0.125, 0.25, 0.50 mg/kg) on separate days. To measure locomotion, rats were placed in cages equipped with photocell beams and counts of beam interruptions were recorded for 1.5 hours.

Results of beam interruptions were recorded for 1.5 nours.

Results indicate that low baseline feeders exhibited more baseline locomotion than high baseline feeders. Importantly, low baseline feeders were more responsive to AMP(at the highest dose) than high baseline feeders. These findings demonstrate that individual differences in locomotor responsivity to AMP can be predicted from how much sugar rats ingest under baseline conditions.

AMPHETAMINE-INDUCED CORTICOSTERONE DECREASE PREDICTS INDIVIDUAL VULNERABILITY TO DEVELOP AMPHETAMINE SELF-ADMINISTRATION IN THE RAT. S. Maccari*, P.V. Piazza*, J.M. Deminière*, P.M. Mormède*, M. Le Moal and H. Simon*, Lab. des Comportements Adaptatifs INSERM. U259-Univ. Bordeaux II. Domaine de Carreire 33077 Bordeaux Cedex-France.

An individual vulnerability to the reinforcing effect of addictive drugs is considered as an important factor influencing the development of addiction in human. Thus, the possibility to develop biological indices allowing an identification of individuals at risk is of great clinical interest. In a recent work we have shown that individual behavioral response to amphetamine (amph) provided a fairly good prediction of the reinforcing effect of the drug (Science 1989, 245: 1511-1513). In addition to this behavioral index we thought it was important to correlate a biological marker with the reinforcing value of the drug. It has been shown that amph modifies corticosterone levels and this hormone is related to the individual vulnerability to develop amph self-administration (SA) (Soc. Neurosci. Abst. 1989, 15: 1186). In the present, we have correlated the effects of amph (0.3 mg/kg, i.v.) on corticosterone release experiments with animal's propensity to develop SA. Four different groups of rats have been used for this study. Three groups were submitted to life events which increase amphetamine-taking behavior: repeated tail pinch, prenatal stress or social stress. The thourth group was raised in basal standard laboratory condition. Amphetamine injection induced an increase of corticosterone levels in control animals that showed later the lower levels of SA, while a significant decrease of the hormone levels was observed in stressed subjects which showed the higher levels of drug SA. These results suggest that an amphetamine-induced corticosterone decrease may be proposed as a biological predictive factor of the vulnerability to develop psychostimulant drug-seeking behavior.

GENETIC AND ENVIRONMENTAL FACTORS MODULATE SENSITIVITY TO THE BEHAVIORAL EFFECTS OF AMPHETAMINE. S. Puglisi-Allegra. S. Cabib*, Badiani*, Istituto di Psicobiologia e Psicofarmacologia (CNR), via Reno 1, I-00198

It has been shown that mice of the DBA/2 and C57BL/6 are characterized by different of adaptations of the brain dopamine (DA) systems to repeated stress (Cabib et al., 1985; Puglisi-Allegra et al., 1990). In the present study, the (cable et al., 1990, Polyisi-Anleya et al., 1990, in the present study, the behavioral effects of amphetamine were examined in mice of these two strains following repeated restraint stress (120 min daily \times 10 days).

Twenty four hours after the last stressful experience, mice of the DBA/2 strain exhibited a significant increase of responsivity to amphetamine in a locomotor test. By contrast, no changes in this behavioral effect of amphetamine was observed in chronically stressed C57BL/6 mice which exhibited a significant increase of spontaneous (drug-free) locomotion in comparison with unstressed controls. These genotype-dependent differences were observed either in mice habituated or naive to the test situation. Finally, pretreatment with DA antagonists selective for the D1 and D2 receptor types indicated that the two types of DA receptors are differently implicated in the hyperactivity responses induced by amphetamine and chronic stress in C57BL/6 mice.

These results are discussed in terms of the interaction between genetic and environmental factors modulating behavioral sensitivity to drugs of abuse acting on brain DA systems

Cabib S., Puglisi-Allegra S., Oliverio A. (1985) Behav. Neural. Biol., 44:239-248. Puglisi-Allegra S., Kempf E., Cabib S. (1990) Neurosci. Biobehav. Rev. in press.

RESPONSE TO NOVELTY AS A PREDICTOR OF THE EFFECTS OF ACUTE AND REPEATED DRUG ADMINISTRATION. M.S. Hooks, A.D. Smith, G.H.

AND REFEATED DRUG ADMINISTRATION. 19.35. FROMS. ASS. Smittle Crit.

Jones, J.B. Justice, Jr. Dept. of Chem., Emory Univ, Atlanta, GA, 30322.

Some behavioral effects of amphetamine (AMPH) in rats have been shown to be largely predictable from the locomotor response to a novel environment (Plazza, Science, 245, 1989). This experiment was designed to examine whether this relationship is consistent for both acute and repeated exposure to other classes of

relationship is consistent for both acute and repeated exposure to other classes of drug.

On day 1, subjects (male rats; n=64) were placed in individual photocell cages for a 3 h period. Animals were divided into high (HR) and low responders (LR) based on whether their locomotor activity (LA) scores for the first hour were above or below the median. On days 3, 5, and 7, rats were placed in the test cages for a 90 min habituation period prior to intraperitoneal administration of either AMPH (0.5 mg/kg), cocaine (COC; 10 mg/kg), scooplamine (SCOF; 0.5 mg/kg), or saline (n=16 for each drug; HR=8 and LR=8) and LA was measured for a further 2 hrs. On days 4 and 6 animals received the relevent drug in the home cage. Doses of drug were chosen to produce similar levels of locomotor activation.

HR rats had significantly greater LA than LR rats for all three drugs (p<0.005). There were no differences between HR and LR groups for the 30 min period before drug administration. Saline treated HR and LR rats did not differ. AMPH treated animals showed sensitization to locomotor stimulating properties of the drug (p<0.01). However, this effect was strikingly different in the HR and LR rats as only the HR rats showed increasing activity levels across days 3-7 (p<0.02). The COC treated rats showed a similar effect. SCOP treated HR and LR rats both showed tolerance to the drug with activity scores decreasing with repeated

(p<0.02). The COC treated rate showed a similar electric SCO it detect its and Large rates both showed tolerance to the drug with activity scores decreasing with repeated administration (p<0.01). LA for the habituation period on day 3 did not differ between HR and LR for any drug group. However, treatment with COC apparently reinstated the differences between HR and LR rats. Thus, on days 5 and 7 the HR rats in the COC group showed significantly greater LA than LR rats for the habituation period. The possible dopaminergic basis for these individual differences in LA was studied with microdialysis.

243.14

INDIVIDUAL VULNERABILITY TO AMPHETAMINE SELF-ADMINISTRATION IS CORRELATED WITH DOPAMINERGIC ACTIVITY IN FRONTAL CORTEX AND NUCLEUS ACCUMBENS. P.V. Piazza*, F. Rougé-Pont*, J.M. Deminière*, M. Kharouby*, M. Le Moal and H. Simon*, Lab. des Comportements Adaptatifs INSERM. U259-Univ. Bordeaux II. Domaine de Carreire 33077 Bordeaux Cedex-France.

Humans and animals show wide individual differences for the vulnerability to develop drug-taking behavior. In the rat, individuals at risk for psychostimulant nistration (SA) may be identified on the basis of their locomotor reactivity to a novel environment (Science 1989, 245: 1511-1513). Animals with the higher locomotor responses to novelly (HR group) will acquire amphetamine (amph) SA, while animals with the lower responses (LR group) will act. Since DA rons seem to be involved in behavioral response psychostimulants, we hypothesized that differential activity of the DA neurons was one of the biological substrates sustaining individual vulnerability to amph SA. Thus, we have compared DA activity in different brain regions of rats with an high (HR) and low risk (LR) to acquire amphetamine SA. Animals from both groups have been sacrificed in basal condition and after 2hrs of exposition to a novel ment. Various brain regions were dissected. The DOPAC/DA ratio has been computed as an index of DA utilization. The HR rats, with the higher risk to acquire amph SA displayed a specific neurochemical pattern: a higher ratio in the nucleus accumbens plus a lower one in the frontal cortex. These data reveal a selective imbalance between these two regions for these rats and suggest that dividual vulnerability to amph SA may depend on differences in the activity of DA neurons. Post-mortem studies were duplicated by *in vivo* microdialysis. In conclusion, animals at risk for drug SA present in basal conditions higher (accumbens) and lower (frontal cortex) dopamine utilization.

METHAMPHETAMINE LOWERS BRAIN STIMULATION REWARD THRESHOLD. M. Sarkar*, G.T. Bain* and C. Kornetsky. Laboratory of Behavioral Pharmacology, Boston Univ. Sch. of Med., Boston, MA 02118.

Most abused drugs increase the sensitivity of animals to brainstimulation reward (BSR) a model of drug-induced euphoria. Because of the recent increase in the abuse of methamphetamine (MAMP) (street name "Ice") we determined if (+) MAMP would lower the threshold for BSR in a similar manner to other psychomotor stimulants. Four F-344 (Charles River Laboratories) male albino rats were stereotaxically implanted with bipolar stainless steel electrodes aimed at the medial forebrain bundle at the level of lateral hypothalamus. A rate independent method was used to determine the BSR thresholds. Acute effects of MAMP (0.0325-2.0 mg/kg, ip) were studied in 4 animals. Three out of the 4 showed significant threshold lowering at 0.25 mg/kg with marked stereotypic head moving and sniffing behavior at doses greater than 1.0 mg/kg. The 4th animal showed significant threshold lowering only at 2.0 mg/kg with stereotypy at higher doses. The results of this study suggest that the reinforcing property of MAMP is mediated, at least partially, via the same reward pathway as the other abused psychomotor stimulants. (Supported by NIDA grant DA02326 and Research Scientist Award DA00099 to CK).

Effects of In-Utero Methamphetamine on Rat Derrig*, K. McCunniff*. USC, LA, CA 90089

Adult, female rats were injected with saline (SAL), low doses of methamphetamine (MAMP, maximum 2 mg/kg), or high doses of MAMP (max. 10 mg/kg). These drugs were given daily until drug-induced changes in temperature and food consumption returned to pre-drug levels. Females were then bred with naive male rats, and MAMP injections continued to the females throughout pregnancy. All pups born to MAMP or SAL mothers were fostered to SAL mothers, and all injections were discontinued. Beginning at 30 days of age, SAL and MAMP pups were dested in an eron field physically restrained. tested in an open field, physically restrained for 2 hrs then re-tested in the open field, and tested in a Morris water maze. High dose MAMP pups crossed significantly fewer squares in the open field, under no-stress and stress in the open field, under no-stress and stress conditions, as compared to controls. These pups did not differ from controls in latencies to find a platform in the water maze. Low dose MAMP pups did not differ from controls on any of the tests. Studies using 14C 2-deoxy-glucose are in progress to compare brain glucose utilization in the 3 groups of pups (NINDS #K07NS00979; USC FRIF and BRSG grants).

THE DISCRIMINATIVE STIMULUS PROPERTIES OF OVER-THE-COUNTER BINARY STIMULANT MIXTURES. D.V. Gauvin. K.R. Moore*, B.D. Youngblood, & & F.A. Holloway. University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190-3000.

It is becoming increasingly rare for drug users to encounter or use a single drug in isolation without co-administering a second drug concomitantly or in temporal sequence. Even over-the-counter (OTC) diet and cold remedies are usually manufactured as binary drug compounds containing caffeine (CAF), ephedrine (EPH), and/or phenylpropanolamine (PPA). Very little is known about the factors or "rules" that govern the perception of drugs in mixtures. The present study sought to examine the discriminative stimulus properties of binary drug mixtures of legal OTC stimulants. Three groups of male Sprague-Dawley tast (n = 12/group) were trained to discriminate between saline and either (1) drug mixtures of legal OTC stimulants. Three groups of male Sprague-Dawley rats (n=12/group) were trained to discriminate between saline and either (1) CAF-PPA (CP, 10+10 mg/kg), (2) CAF-PPH (CE, 10+5 mg/kg), or (3) EPH-PPA (EP, 6+12 mg/kg) in a two-choice, food-motivated lever-press operant task. Whereas both EPH and PPA were equally salient stimuli (i.e., each training dose tested singly resulted in approximately 50% drug-lever responding) in the EP group, EPH and PPA were perceptually dominant over the CAF stimulus in both the CP and CE groups. CAF alone failed to generalize across a wide range of doses to either the CP or to the CE binary compound stimulus. The EP and CE groups generalized both cocaine and amphetamine to the training stimuli. However, the CP group only generalized to amphetamine. These data suggest that (1) some legal OTC stimulants produce internal subjective states similar to both cocaine and amphetamine, and (2) the perceptual processing analyses of binary drug mixtures parallel those of (2) the perceptual processing analyses of binary drug mixtures parallel those of similar chemoreceptive systems (i.e., olfaction).

The data indicate: (1) 4-MAX and MET-AMP are more potent in stimulating DA release than NE release, (2) both significantly increased the DA release at the higher doses. This increase in DA release is in accord with the finding of Misenheimer and Glennon, (Soc. Neurosci. Abst., 15, Part 2, 1187, 1989), showing that 4-MAX produced amphetamine-like stimulating effects. (Supported in part by the Alabama Consumer Fund).

PHARMACOKINETICS OF SYSTEMICALLY ADMINISTERED 3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA) AND MONOAMINE RELEASE IN BRAIN DIALYSATE. M. Hiramatsu*1.7, E.W. DiStefano*2. T. Kameyama*1 and A.K. Cho². Topt. of Chemical Pharmacology, Meijo Univ., Nagoya 468, Japan and Dept. of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90024 MDMA (3,4-methylenedioxymethamphetamine) and its metabolite, MDA (3,4-methylenedioxymethamphetamine), were measured in the plasma of rats injected s.c. with enantiomers of MDMA. Microdialysis techniques were used to monitor monoamines and their metabolites in the striatum after (+)MDMA. MDMA concentrations in plasma reached peak values 70 min after administration of both isomers of MDMA. Plasma levels of MDA after (+)MDMA were about 3 times higher than those after (-)MDMA and reached peak values at 160-190 min, although the plasma concentrations of the parent drugs were comparable. (+)MDMA caused a rapid increase in dialysate levels of dopamine and a decrease in DOPAC and HVA immediately after dosage. Dopamine release in striatal dialysate correlated with plasma MDMA, but not with plasma MDA. These results indicate that MDMA interacts with dopamine neurons stereoselectively to release dopamine. The higher plasma MDA levels after (+)MDMA and/or high levels of extracellular dopamine may contribute to enantiomeric differences in the behavioral and neurotoxicological extracellular dopamine may contribute to enantiomeric differences in the behavioral and neurotoxicological effects of (+)MDMA. SILICONE PELLET FOR CONTINUOUS COCAINE ADMINISTRATION: COMPARISON WITH CONTINUOUS WILKINS*, and Gaylord Ellison. Depts of Psychology and Psychiatry, UCLA, Los Angeles, CA, 90024.

An inexpensive silicone pellet is described for the continuous administration of cocaine for up to 5 days. Rats implanted with this pellet show with minimal skin irritation and go through distinct behavioral stages, with an initial period of hyperactivity followed by motor stereotypies. Then, at 3-4 days after implantation, a variety of "hallucinogen-like" behaviors appear; these include limb flicks, sudden startle responses, and repetitive mid-air grasping movements. Compared to continuous d amphetamine, continuous cocaine induces decreased motor stereotypies but heightened "late-stage" behaviors. HPLC analysis of both the subcutaneous pellet and serum levels suggest a relatively stable rate of cocaine release for the first 4 days. Rats in automated activity cages developed tolerance to cocaine in a nine day administration (during which pellets were replaced on day 4). Their activity peaked by day 3 and gradually declined through day 9.

IDAZOXAN, AN ALPHA-2 ADRENOCEPTOR ANTAGONIST, REVERSES THE EFFECTS OF B-HT 920, A DOPAMINE AUTORECEPTOR AGONIST, ON CONDITIONED AVOIDANCE RESPONDING IN RATS. A.T. Shropshire and K.L. Marquis. Wyeth-Ayerst Research, CN8000, Princeton, NJ 08543.

Wyeth-Ayerst Research, CN8000, Princeton, NJ 08543. Antagonism of conditioned avoidance responding (CAR) in rats is a sensitive test for dopamine receptor antagonists; however, alpha 1 adrenoceptor antagonists such as prazosin and alpha 2 adrenoceptor agonists such as clonidine block CAR and appear as false positives in this test and others used to predict preclinical antipsychotic activity (Arnt, J., Acta Pharmacol. Toxicol. 51:321, 1982; Hawkins and Monti, Eur. J. Pharmacol. 58:53, 1979). Meltzer, et al., (Eur. J. Pharmacol. 170:105, 1989) have shown that alpha 2 adrenoceptor antagonists can unmask the postsynaptic dopaminergic agonist activity of the dopamine autoreceptor agonist B-HT 920 by blocking its alpha 2 agonist effects. Moreover, we have demonstrated that moderate to high doses of B-HT 920 block CAR in rats (Marquis et al., at this meeting). To define a possible mechanism for the CAR effect we treated rats, previously trained to avoid a shock by making a shelf jump or lever press response trained to avoid a shock by making a shelf jump or lever press response in a discrete trial procedure, with various doses of clonidine, prazosin and B-HT 920. All drugs reduced avoidance responding and increased escape responding at doses which did not increase the number of noresponse trials. Combined ad-ministration of the alpha 2 antagonist idazoxan and clonidine, or idazoxan and B-HT 920, reversed the avoidance deficits and the increased escape responding produced by each drug alone. These data suggest that some dopamine autoreceptor agonists which have activities at alpha adrenoceptors could inhibit CAR by an adrenergic mechanism as opposed to a dopaminergic mechanism.

EFFECT OF TYPICAL AND ATYPICAL ANTIPSYCHOTIC DRUGS (APD) ON FRONTAL CORTICAL (FC) SEROTONIN₂ (5-HT₂) AND STRIATAL (STR) DOPAMINE₂ (D₂) BINDING IN VIVO Herbert Y. Meltzer, Ying Zhang* and Craig Stockmeier, Dept. Psychiatry, Pharmacology and Neuroscience, Case Western Reserve University, Cleveland, Ohio 44106

It has been suggested that atypical APD can be distinguished from typical APD on the basis of higher ratios of pKi values for FC 5-HT₂ to STR D₂ binding sites for the atypical APD (JPET 254, 238, 1989). To determine if this distinction is also obtained in vivo, FC and STR binding of 3-H-N-methyl-spiperone was validated as measures of 5-HT₂ and D₂ binding by preliminary studies with ritanserin and raclopride, respectively. The typical APD haloperidol (0.15, 0.50 mg/kg), chlorpromazine (10 mg/kg), thioridazine (2.5 mg/kg) occupied STR D₂ receptors > FC 5-HT₂ receptors. The atypical APD clozapine (5,10,20,40,60 mg/kg), melperone (2.5, 5.0, 10 mg/kg) and amperozide (10, 20 mg/kg) occupied FC 5-HT₂ > STR D₂ receptors. Even at the highest doses of clozapine studied, D₂ occupancy did not exceed 50%, Amperozide did not decrease D₂ sites occupied by 3-H-N-methyl-spiperone in vivo. The results support the conclusion that the 5-HT₂/D₂ ratio may be important for atypical APD. Amperozide may achieve its antischizophrenic action without blocking D₂ receptors in vivo. CHRONIC HALOPERIDOL AND CLOZAPINE DIFFERENTIALLY ALTER THE DENSITY OF MET-ENKEPHALIN-LIKE IMMUNO-REACTIVE PERIKARYA IN RAT CAUDATE VERSUS ACCUMBENS NUCLEI. A.P. Auchus and V.M. Pickel. Dept. of Neurology and Neuroscience, Div. of Neurobiol., Cornell U. Med. College, NY, NY 10021 We examined the capacity of the classic neuroleptic haloperidol (HAL) and the atypical neuroleptic clozapine (CLOZ) to alter met-enkephalin-like immunoreactivity (MELI) in caudate vs accumbens nuclei. Rats received 1 mg/kg/d HAL or 20 mg/kg/d CLOZ via their drinking water. After 21 days, the animals (and controls) were sacrificed and their brains were processed using a 1:20,000 dilution of ME antibody and immunoperoxidase. In caudate, HAL, but not CLOZ, resulted in a significant (p<.05) increase in ME cell density (immunoreactive perikarya per unit area) cf controls. In accumbens, CLOZ, but not HAL, resulted in a significant (p<.05) decrease in ME cell density of controls. These results demonstrate an effective method for comparing intraperikarya MELI between different drug treatment groups and suggest the relevance of differential changes in caudate vs accumbens enkephalin systems to the pathogenesis of neuroleptic-induced movement suggest the relevance of differential changes in caudate vs accumbens enkephalin systems to the pathogenesis of neuroleptic-induced movement disorders. EFFECTS OF DOPAMINE AUTORECEPTOR AGONISTS ON CONDITIONED AVOIDANCE RESPONDING (CAR) IN RATS. K.L. Marquis, A.T. Shropshire, T.G. Demetriou*, T.H. Andree, and J.A. Moyer. Wyeth-Ayerst Research, CN8000, Princeton, NJ 08543. Typical and atypical antipsychotics, which may exert their therapeutic action by antagonizing the D2 receptor, block CAR in rats. However, many of these agents also produce extrapyramidal side effects (EPS). It has been proposed that a dopamine (DA) partial agonist or selective autoreceptor agonist will be antipsychotic without producing EPS autoreceptor agonist will be antipsychotic without producing EPS (Tamminga and Schaffer, Science 200:567, 1978); yet, there is very little information available regarding the ability of some of the more little information available regarding the ability of some of the more recently developed DA autoreceptor agonists to block CAR. Male Sprague-Dawley rats, previously trained to avoid a shock by making a shelf jump response, were treated with various doses of apomorphine, (-)3PPP, B-HT 920, EMD 23448, n-propyl-norapomorphine, PD 116795, OPC 4392 or CGS 15855A. All drugs were autoreceptor agonists as demonstrated by a reversal of GBL-induced accumulation of DOPA in rat limbic tissue and by a reduction in mouse locomotor activity. Only B-HT 920, PD 116795 and OPC 4392 significantly reduced CAR at doses which did not produce overt behaviors in mice (stereoty. Only B-HT 920, PD 116795 and OPC 4392 significantly reduced CAR at doses which did not produce overt behaviors in mice (stereotypy and climbing) indicative of postsynaptic D₂ agonism. EMD 23448 and (-)3PPP produced only modest decreases in CAR at high doses. Since each drug affecting CAR did so at doses well above those which produce hypolocomotion, it can be concluded that CAR effects may occur as a result of postsynaptic D₂ antagonism rather than autoreceptor agonism. In addition, other mechanisms within the noradrenergic sytem could also play a role in CAR (Shropshire and Marquis, this meeting).

EFFECTS OF HALOPERIDOL ON THE KINETICS OF ENDOGENOUS DOPAMINE RELEASE IN VITRO USING ROTATING DISK ELECTRODE VOLTAMMETRY. J.S. McElvain and J.O. Schenk Dept. of Chemistry and Program in Biochemistry, Washington State University, Pullman, WA 99164.
The rotating disk electrode (RDE) system used to montior the

The rotating disk electrode (RDE) system used to monitor the kinetics of endogenous dopamine (DA) release and reuptake from isolated rat striatal homogenates has been described previously (McElvain and Schenk, Neurosci. Abst., 48.20, 1989). Striatal homogenates were incubated at 37°C in 500 µL of physiological buffer in the presence or absence of haloperidol (HAL) and depolarized with 15 and 30 mM KCl. The resulting DA released was monitored by the RDE and was analyzed kinetically by treating the resulting DA concentration-time profile as intermediate between two consecutive, irreversible first order reactions (release and reuptake, respectively). In the presence of low concentrations of HAL (5-100 nM), it was found that the maximum of the 30 mM KCl stimulated DA release signal (Smax) and the first order rate constant for release (krel) increased (S_{max}) and the first order rate constant for release (k_{rel}) increased over control stimulations in a dose dependent manner. At higher concentrations of HAL (10-50 µM) it was found that the time to the maximum of the DA release signal increased over control values while the initial DA release rates, the S_{max}, and the k_{rel} decreased. HAL had little effect on the first order rate constant for the reuptake of DA (k_{up}) at low concentrations (1-1000 nM) but decreased the k_{up} significantly at higher doses (10-50 µM). Thus HAL has only an amplitude modulating influence on DA release at HAL concentrations relevent to autoreceptor functioning. At higher concentrations of HAL, frequency as well as amplitude modulation of DA release is observed. Supported by MH 42759 and the state of Washington.

MCPP EFFECTS IN SCHIZOPHRENIC PATIENTS: EFFECTS OF PHARMACOTHERAPY. <u>I.H. Krystal, J.P. Seibyl, L.H. Price, S.W. Woods, G.R. Heninger, D.S. Charney,</u> Schiz. Biol. Research Cntr., Psychiatry Svc., West Haven VA Med. Cntr., West Haven, CT 06516

M-chlorophenylpiperazine (MCPP) is a non-selective serotonin (5-HT) partial agonist. In order to evaluate the contribution of 5-HT systems to the symptoms of schizophrenia, MCPP effects were studied in schizophrenic patients (PTS) and healthy subjects (HS). Methods: In an ongoing study, PTS meeting DSM-III-R criteria for schizophrenia and HS (N=10) participated in 2 test days in a randomized order: MCPP (0.1 mg/kg, i.v. over 20 min.) or placebo. PTS were tested under 3 treatment conditions: 1) 2 wks. neurolepticfree (N=1), 2) 4 wks. haloperidol treatment .3 mg/kg/d, p.o. (N=5), and 3) after clozapine treatment (800 mg/d) (N=3). Results: 9/11 unmedicated PTS and 0/10 HS experienced increases in the positive symptoms of schizophrenia (visual and auditory hallucinations, conceptual disorganization, and suspicious MCPP-induced anxiety was comparable in unmedicated PTS and in HS and showed a time course distinct from positive symptoms. Neuroleptic-free PTS did not differ in the extent to which MCPP increased plasma levels of growth hormone, cortisol, or prolactin. Preliminary analyses suggest that clozapine produced greater reduction in MCPP behavioral effects than did haloperidol.

Implications: MCPP appears to exacerbate psychosis in a high percentage of PTS, suggesting a role for 5-HT in the symptoms of schizophrenia. The high affinity of MCPP for 5-HT1c, 5-HT2, and 5-HT3 receptors supports the impression antagonists of these receptors may be useful in the treatment of schizophrenia symptoms that are refractory to typical neuroleptic (i.e., haloperidol) treatment.

AUTORADIOGRAPHIC EVIDENCE FOR CLOZAPINE SITE-SELECTIVITY AT THE DOPAMINE RECEPTOR. T. F. Seeger, A.W. Schmidt and P. Suzdak. Neuroscience Dept., Pfizer Central Research, Groton, CT 06340

Using the technique of receptor binding autoradiography in rat brain sections, the atypical antipsychotic clozapine was found to displace the dopamine agonist ligand 3H-NPA from mesolimbic dopamine D-2 receptors with a greater affinity than it showed for D-2 receptors in the striatum. However, when this comparison was made using tissue homogenate binding, clozapine displaced 3H-NPA equally well in the two regions.

In order to investigate this discrepancy, a functional in vivo measure of dopamine interaction was devised using the quantitative 2-deoxyglucose method in rats. A fixed dose of the dopamine agonist D-amphetamine (1 mg/kg s.c.) was used to activate cerebral metabolism in both mesolimbic and striatal areas. Pretreatment with clozapine (5 mg/kg sc.) was found to partially antagonize the amphetamine-induced increases in glucose utilization while not causing significant changes when given alone. In agreement with the previous autoradiography studies, clozapine caused a preferential antagonism in limbic areas (nucleus accumbens and olfactory tubercle) relative to the striatum. These results support the concept of clozapine having a functional antagonist selectivity for the mesolimbic dopamine system.

244.9

SELECTIVE EFFECT OF CLOZAPINE IN DA TURNOVER IN THE PREFRONTAL CORTEX IN RATS. L. Hernandez^{1,2} and B. G. Hoebel¹. IDept. Psychology, Princeton Univ., Princeton, NJ 08544-1010; ²Laboratorio de Fisiologia de la Conducta, Escuela de Medicina, Universidad de Los Andes,

Epch. Fsychology, Frinceton Onny, Frinceton, NI 0544-1010; Laboratorio Dept. Fsychology, Frinceton Onny, Frinceton, NI 0544-1010; Laboratorio Fisiologia de la Conducta, Escuela de Medicina, Universidad de Los Andes, Merida, 5101-A, Venezuela

Triple microdialysis studies showed that acute injections of the typical neuroleptic haloperidol increase dopamine (DA) turnover in the prefrontal cortex (PFC), nucleus accumbens (NA) and striatum (STR) in rats. Chronic administration of haloperidol lowered the basal level of DA in the PFC; it also decreased DA turnover in the PFC and the STR but not in the NAC. No tolerance was observed. These effects may explain both psychotic symptom suppression (decreased DA turnover in the FFC) and extrapyramidal side effects (decreased DA turnover in the STR) caused by haloperidol¹. Clozapine (CLOZ), an atypical neuroleptic that is devoid of extrapyramidal side effects should not affect DA turnover in the STR usould do so in the PFC. To test this prediction, triple microdialysis was performed in 24 rats. Acute clozapine increased DA turnover in the PFC. A dose-response relationship was found. Only the highest dose of acute clozapine (40 mg/kg) significantly increased DA turnover in the NAC. No effect was observed in the STR. Chronic administration of clozapine (20 mg/kg) decreased DA levels and turnover in the PFC but din ont affect DA turnover in the NAC or STR. These results suggest that CLOZ preferentially affects the mesocortical system to ameliorate psychotic symptoms. ameliorate psychotic symptoms.

INTERACTION OF THE POTENTIAL ANTIPSYCHOTIC BMY 14802 AND STRUCTURALLY-RELATED SIGMA LIGANDS WITH M_1 MUSCARINIC SITES. Duncan P. Taylor, Jennifer Defnet, Susan H. Behling and Diana Marrero. CNS Biology, Bristol-Myers Squibb Company, Wallingford, CT 06492-7660.

A distinct class of sigma binding sites has been identified which can be differentiated from NMDA receptor-associated phencyclidine binding sites as well as dopamine and opioid receptors. Efforts to investigate the receptor role of the sigma binding site have been hampered by the lack of a functional assay. Bowen et al. (1988) reported that sigma ligands attenuated carbachol-stimulated that sigma ligands attenuated carbachol-stimulated phosphoinositide turnover in rat brain. They have recently shown that the rank orders of potency for ten unrelated compounds were similar for inhibition of in vitro binding to sigma sites or $[^3\mathrm{H}]$ oxotremorine-M binding to M1 muscarinic cholinergic sites (Spearman ρ = 0.88, p<0.01). We have investigated the correlation of the rank orders of potency for 32 structurally-related analogs of the nutriing sigma sites and the New 1,802 (Tables of of the putative sigma antipsychotic BMY 14802 (Taylor $\underline{\text{et}}$ al., 1990) in both sigma and M₁ binding assays. For these agents we find no statistically significant correlation between rank orders of potency in the two assays (Spearman ρ = 0.11). These data suggest that in the guinea pig brain the M_1 site does not have the same structural requirement for binding as the sigma site, or, alternatively, that these two sites are not allosterically coupled.

244.8

BEHAVIORAL COMPARISONS IN RATS OF CHRONIC CLOZAPINE WITH HALOPERIDOL. M.F. Egan, L.L.Wing, T.L.Bryant, D.G. Kirch and R.J. Wyatt. Neuropsychiatry Branch, NIMH @ St. Elizabeths, Washington, D.C. 20032.

The antipsychotic clozapine, unlike haloperidol, has

been demonstrated to possess serotonergic and cholinergic antagonist properties in addition to D1 and D2 receptor blockade. A comparison of the behavioral effects of chronic administration of both was made.

ic administration of both was made.

Thirty-six male Sprague-Dawley rats (350g ±15g) were given daily i.p. injections of either clozapine (10 mg/kg), haloperidol (4 mg/kg) or the vehicle (distilled water, NaOH and glacial acetic acid). Animals were tested for 1 hr in Omnitech activity monitors after 4 wks of treatment. Both clozapine- and haloperidol-treated animals displayed less clozapine- and haloperidol-treated animals displayed less locomotor activity than vehicle-treated controls. Nevertheless, while the overall activity of the drug-treated groups were not significantly different from one another, clozapine-injected rats spent significantly more time in the corners and along the walls of the test chamber. In contrast, the novel environmental stimulus cues of the test chamber were less aversive to the haloporidel injected. trast, the novel environmental stimulus cues of the test chamber were less aversive to the haloperidol-injected animals. Although less active than controls, the haloperidol-injected animals spent the most time exploring the center of the chamber, and the least time in the corners or along the walls of the test chamber than did either the vehicle- or clozapine-treated rats. Thus, both antipsychotics produced vastly different behavioral profiles.

DOPAMINE AUTORECEPTOR SUPERSENSITIVITY AND POSTSYNAPTIC SUBSENSITIVITY WITH CHRONIC NEUROLEPTIC TREATMENT.

M.R.Lynch, C. Haskins* and J. Woo*, Res. Serv., VAMC and Depts. Psychiat. and Pathol., SUNY Health Sci. Ctr., Syracuse, N.Y. 13210

Delayed onset antipsychotic effects of neuroleptics

Delayed onset antipsychotic effects of neuroleptics have been explained by depolarization block and autoreceptor supersensitivity hypotheses. We have previously reported a progressively enhanced locomotor suppression with chronic haloperidol(HAL)(Biol.Psychiat., 24:941, 1988), mimicking this delayed onset. To probe for neurochemical mechanisms of this enhancement, rats received 20 days of 0.1 mg/kg HAL or vehicle (VEH), were withdrawn for 48 hr and then tested with 0.07 mg/kg aponorphine (APO). (Prolactin assay results confirmed that HAL was no longer bound to central DA receptors at the 48 hr test.) HPIC-EC, to assess APO-inhibition of DA metabolism, revealed autoreceptor supersensitivity in mesol imbic (not nigrostriatal). receptor supersensitivity in mesolimbic (not nigrostriatal) tissue from HAL animals (significant decrease in HVA/DA tissue from HAL animals (significant decrease in HVA/IA ratio). Conversely, HAL rats failed to show the APO-induced hypomotility and yawning observed in VEH animals. Therefore, it appears that autoreceptor supersensitivity was induced concomitant with subsensitivity in an agonist-sensitive population of postsynaptic DA receptors mediating these APO behavioral effects. However, there was no evidence of depolarization block: At 48 hr withdrawal HAL activity returned to heading. PA temperature property activity returned to baseline; DA turnover was normal and was not increased by APO.

244.12

THE IDENTIFICATION OF PD 128483 AS A DOPAMINE AUTORECEPTOR

THE IDENTIFICATION OF PD 128483 AS A DOPAMINE AUTORECEPTOR AGONIST MITH ANTIPSYCHOTIC-LIKE PROPERTIES. L.D. Mise, J.C. Jaen*, B.W. Caprathe*, T.G. Heffner, L.T. Meltzer, T.A. Pugsley. Parke-Davis Pharmaceutical Research Division Warner-Lambert Company, Ann Arbor, MI 48105.

Although PD 118440, a compound previously proposed as a bioisosteric replacement for 3-PPP, is a potent, orally active dopamine (DA) agonist, it lacks sufficient pre- vs postsynaptic receptor selectivity for development as an antipsychotic agent (Soc. Neurosci. Absts., 13:461, 1987). To identify a more selective compound, a series of related 6-substituted-4,5,5a,6,7,8-hexahydrothiazolo[4,5-f]quinolin-2-amines was explored. The 6-methyl, ethyl, propyl, and allyl compounds are potent DA autoreceptor agonists; they bind to DA receptors in vitro, and in rats reverse GBL-stimulated increases in DOPA synthesis, inhibit DA neuronal firing activity, and inhibit spontaneous locomotion. PD 128483, the maleate salt of the methyl analog, was selected for development based on its overall profile. was selected for development based on its overall profile. While both of its enantiomers are partial DA agonists, optimal selectivity is observed with the racemate.

BIOCHEMICAL CHARACTERIZATION OF PD 128483, A NOVEL DOPAMINE AUTORECEPTOR AGONIST, IN RAT BRAIN. T.A. Pugsley, Y.H. Shih*, S.Z. Whetzel* and R.D. Schwarz. Department of Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor, MI

PD 128483 ((±) - 4,5,5a,6,7,8-hexahydro-6-methyl-thia- $\hbox{zolo[4,5-f]quinoin-2-amine)} \quad \hbox{and its enantiomers were evaluated biochemically for their dopamine (DA) agonist and other activities. In the (gamma)-butyrolactone (GBL)}$ evaluated biochemically for their dopamine (DA) agonist and other activities. In the (gamma)-butyrolactone (GBL) model of DA autoreceptor function, PD 128483 had an ED50 value of 0.7 mg/kg i.p., in striatum and the effect was haloperidol-reversible; the values for the (+) - and (-)-enantiomers were 0.5 and >10 mg/kg i.p. In the GBL model DA autoreceptor activity was retained for 6 hours after a single p.o. dose and no tolerance was seen after 10 days of treatment. PD 128483 exhibited affinity for DA D-2 receptors with negligible affinity for other receptors except for a2-adrenoceptor binding. PD 128483 exerted little activity on stimulated acetylcholine release from striatal slices, a test for postsynaptic D-2 receptors, indicating a relatively selective action on presynaptic DA indicating a relatively selective action on presynaptic DA receptors. It decreased DA synthesis and turnover without altering extensively that of norepinephrine and serotonin. These data suggest that PD 128483 is a selective DA autoreceptor agonist.

244.15

EFFECTS OF THE DOPAMINE AUTORECEPTOR AGONIST PD 128483 ON EFFECTS OF THE DOPAMINE AUTORECEPTOR AGONIST PD 128483 ON NEUROTRANSMITTER RELEASE AS ESTIMATED BY INTRACEREBRAL MICRODIALYSIS IN RATS. L.M. Ball, M.D. Davis and T.G. Heffner. Dept. of Pharmacology, Parke-Davis Pharmaceutical Research Divison, Warner-Lambert Co., Ann Arbor, MI 48105. PD 128483, (±)-4,5,5a,6,7,8-hexahydro-6-methylthiazolo-[4,5-f]quinolin-2-amine, is a dopamine (DA) autoreceptor agonist as shown in neurophysiological, neurochemical and behavioral tester.

behavioral tests. DA D2 agonists are known to depress DA neurotransmission by presynaptic actions. The present studies sought to determine if PD 128483 inhibits the release of DA from central neurons in vivo. Intracerebral release of DA from central neurons in vivo. Intracerebral microdialysis (ICMD) probes were placed in the striatum of rats and amines in striatal dialysates were measured by HPLC-EC. PD 128483 i.p. caused a substantial decrease in the levels of DA and its metabolites DOPAC and HVA in dialysates from anesthetized animals. Similar effects were produced by the DA autoreceptor agonist B-HT-920, while the DA antagonist haloperidol increased these levels. Striatal dialysate levels of the serotonin metabolite 5-HIAA were not altered by PD 128483. ICMD was also used in conscious freely-moving rats by inserting dialysis probes in chronically-implanted guide cannula. Behaviorally-active doses of PD 128483 given orally were found to produce effects in the conscious rat similar to those observed in anesthetized animals. These results suggest that PD 128483 decreases the release of DA from suggest that PD 128483 decreases the release of DA from central neurons and is orally active in rats.

244.17

EFFECTS OF THE NOVEL DOPAMINE AUTORECEPTOR AGONIST PD 128483 IN PRIMATES. T.G. Heffner, C.L. Christoffersen, L.M. Cooke, M.D. Davis, L.T. Meltzer and F.M. Ninteman*. Dept. of Pharmacology, Parke-Davis Pharmaceutical Res. Division, Marner-Lambert Co., Ann Arbor, MI 48105.

PD 128483,(\pm)-4,5,5a,6,7,6-hexahydro-6-methylthiazolo-[4,5- \pm]quinolin-2-amine, is a dopamine (DA) autoreceptor agonist as shown in neurophysiological, neurochemical and behavioral tests in rodents. Like known antipsychotics, PD 128483 inhibited Sidman avoidance in squirrel monkeys, a test commonly used to predict antipsychotic efficacy. In contrast, the nonselective DA agonists apomorphine and bromocriptine failed to inhibit avoidance responding in monkeys and caused only stimulation of responding. PD 128483 displayed oral activity in monkeys (ED $_{50}$: 4.8 128483 displayed oral activity in monkeys (ED_{50} : 4.8 mg/kg po) and its effects persisted for 6 hours. Intracerebral microdialysis in the squirrel monkey caudate putamen indicated that behaviorally-active doses of PD 128483 decreased the overflow of DA from central neurons. 128483 decreased the overflow of DA from central neurons. In squirrel monkeys sensitized to the acute extrapyramidal side effects (EPS) of haloperidol, PD 128483 did not cause the dystonias produced with a variety of antipsychotics that produce EPS in man. These preclinical results indicate that PD 128483 is a DA autoreceptor agonist with effects in primates that suggest antipsychotic efficacy, a DA autoreceptor mechanism of action and no liability for the acute neurological side effects of available DA antagonist antipsychotics. effects of available DA antagonist antipsychotics.

244.14

EFFECTS OF THE NOVEL DOPAMINE AUTORECEPTOR AGONIST PD 128483 ON THE ACTIVITY OF SUBSTANTIA NIGRA DOPAMINE NEURONS. C.L. Christoffersen, K.A. Serpa, T.G. Heffner and L.T. Meltzer. Dept. of Pharmacology, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

PD 128483, (±)-4,5,5a,6,7,8-hexahydro-6-methylthiazolo-[4,5-f]quinolin-2-amine, binds to dopamine (DA) D-2 receptors and is active in biochemical tests of DA autoreceptor agonist activity (Pugsley et al. this meeting) and in behavioral studies shows selectivity for the DA autoreceptors versus postsynaptic DA receptors (Corbin et al., this meeting). In the present studies we compared the effects of PD 128483 and its enantiomers with those of apomorphine and EMD 23448 on the firing activity of A9 DA apomorphine and EMD 23448 on the firing activity of A9 DA neurons recorded extracellularly in chloral hydrate anesthetized male S-D rats. PD 128483 produced a doserelated inhibition of A9 DA neuron firing. The maximal inhibition at 1.28 mg/kg IV was approximately 75% of the baseline firing rate. The (+)- and (-)-isomers of PD 128483 produced maximal inhibitions of 90% and 63%, 128483 produced maximal inhibitions of 90% and 63%, respectively. Apomorphine (128 ug/kg IV) and EMD 23448 (1 mg/kg IV) produced maximal inhibitions of 100% and 63%, respectively. PD 128483 inhibited DA neuron activity in rats depleted of DA by treatment with reserpine plus alpha-methyl-paratyrosine, indicating direct DA agonist actions. These data indicate that PD 128483 is a partial DA agonist, with intrinsic activity similar to EMD 23448, but less intrinsic activity than apomorphine.

EFFECTS OF THE NOVEL DOPAMINE AUTORECEPTOR AGONIST PD 128483 IN RODENT BEHAVIORAL TESTS. A.E. Corbin, J.N. Wiley* and T.G. Heffner. Department of Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-

PD 128483, (±)-4,5,5a,67,8-hexahydro-6-methylthiazolo-[4,5-f]quinolin-2-amine, is a dopamine (DA) autoreceptor agonist as shown in neurophysiological and neurochemical tests. PD 128483 inhibits spontaneous and amphetaminestimulated locomotion in mice and rats, consistent with activation of presynaptic brain DA receptors. Selectivity for pre- vs postsynaptic DA receptors is evidenced tivity for pre- vs postsynaptic DA receptors is evidenced by lack of stimulation and stereotypy in normal rats as well as in rats pretreated with reserpine or a D1 agonist. Absence of post-synaptic DA antagonist effects is indicated by lack of antagonism of the climbing induced by the direct-acting DA agonist apomorphine. Like other DA agonists, PD 128483 produces stimulation of locomotion in rats depleted of brain DA by central injections of 6-hydroxydopamine. PD 128483 has oral activity that persists for up to 6 hours and does not activity that persists for up to 6 hours and does not show diminished behavioral efficacy after daily dosing for 10 days. Postsynapatic DA agonist effects seen with the (+)-enantiomer of PD 128483 and the weak presynaptic effects of the (-)-enantiomer indicate that the racemate is the optimal form for development. These results indicate that PD 128483 is an orally active brain DA autoreceptor agonist.

Chromate Alters Haloperidol Brain/Plasma Concentration Ratio. T.M. Smith*, D. Allen*, H.L. Evans and G.C. Stone. N.S. Kline Inst., Orangeburg, N.Y. 10962 and Inst. Environ. Med., NYU Medical Ctr., Tuxedo, N.Y. 10987.

To equate blood levels of psychotherapeutic agents with clinical response is of value in psychiatry. Since the target tissue of these agents is the brain, it is of interest to determine how much of the drug would be in the brain compared to what is found in blood. This brain/ plasma concentration ratio has been determined for a number of drugs by others. Exogenous substances which change this ratio may effect treatment or lead to toxicity. We have investigated whether chromate $(K_2C_r0_4)$, a persistent environmental contaminant which has the potential for human exposure via drinking water, may effect the bio-availability of haloperidol (HAL) in brain. Steady state plasma levels of HAL in rats was obtained by Alzet pumps. At a dose of 1 mg/day the plasma levels of HAL in the rat mimicked the human therapeutic range. While receiving HAL, experimental rats also received chromate via drinking water at a level of 500 ppm. Control rats received only HAL. At the end of 12 days, blood and 5 brain regions were analyzed for HAL by GC. Except for the cerebellum, all tested brain regions of chromate exposed rats had higher ratios with the frontal cortex showing the greatest increase (p = < 0.02).

CHRONIC HALOPERIDOL ALTERATION OF LICKING PATTERNS IN RATS AND MICE: A BEHAVIORAL ANALYSIS FOR NIGROSTRIATAL FUNCTION. K.M. Kantak and J.J. Vogel*. Lab. of Behav. Neurosci., Dept. Psychol., Boston Univ., Boston, MA 02215.

Analysis of licking patterns in mice has previously revealed a progressive increase in the

Analysis of licking patterns in mice has previously revealed a progressive increase in the number of licks per bout over 3 months. When mice received daily haloperidol, alterations in the pattern of licking occurred upon haloperidol withdrawal and spontaneously after 2 and 3 months of injections. The pattern resulted from increases in the number of bouts of licking and decreases in the number of licks per bout, indicating a disrupted pattern of licking. In the present studies these effects in mice were replicated for a fourth time. In rats, there also was a progressive increase in the number of licks per bout over 3 months. Rats reacted differently to chronic haloperidol. Upon withdrawal of haloperidol after month 3, there was an increase in the number of licks per bout and decreases in the number of bouts of licking, indicating a more stereotypic pattern of licking than controls. Thus, the presumed dopamine supersensitivity which occurs following chronic haloperidol produces different types of alterations in licking patterns in rats and mice.

EFFECTS OF HALOPERIDOL ON NMDA AND GABAA RECEPTORS IN MEDIAL PREFRONTAL CORTEX. S.L. Vincent. R. Allen*, J.P. SanGiovanni* and F.M. Benes. Department of Psychiatry and Program in Neuroscience, Harvard Medical School and Mailman Research Center, McLean Hospital, Belmont, MA 02178.

Previous studies have shown that treatment with haloperidol (HAL) induces a change in the relative number of asymmetric and symmetric synapses in layer VI of rat medial prefrontal cortex (MPF) where the mesocortical projection terminates. Such neuroleptic induced shifts of excitatory and inhibitory cortical synapses raises the possibility that these drugs may affect the distribution of certain populations of receptors in MPF. To explore this question further, the present study has examined the relative distribution of NMDA and GABAA receptor sites using L-[3H]gutamic acid and [3H]muscimol, respectively, in rat MPF following treatment with haloperidol decanoate (dose equivalent of 1 mg/Kg/day) for 2 weeks. Quantitative high-resolution analysis of autoradiograms was carried out in neuropil regions and neuronal cell bodies in layers II/III, V and VI of MPF. In neuropil, specific NMDA-sensitive glutamate binding was similar between control and HAL-treated groups, while on neurons, it was decreased by 40% in layer V only. Specific GABAA-sensitive muscimol binding (bicuculline-inhibited) in neuropil was decreased by 19% for layers la and II in the HAL-treated group, but on cell bodies in layers II/III, V and VI, it was reduced by 76%, 61% and 71%, respectively. These data suggest that HAL administration is associated with a generalized down-regulation of GABAA receptors in the neuropil and on neuronal cell bodies of MPF; while it resulted in a highly focalized reduction of NMDA receptors on neuronal somata of layer V only. These data are consistent with the idea that neuroleptic drugs may after the activity of intrinsic transmitter systems in rat MPF. Supported by NIMH grant MH-00423.

ANTIPSYCHOTIC ACTION OF SM-9018, A CENTRALLY ACTING DOPAMINE D₂ AND SEROTONIN $(5-HT)_2$ RECEPTOR ANTAGONIST. M. Nakamura*, Y. Ohno, A. Hirose*, H. Shimizu*, H. Tanaka* and T. Kato*. Res. Labs., Sumitomo Pharmaceuticals Co., Ltd., Konohana-ku, Osaka 554, Japan. Studies were performed in rats and mice to clarify the

Studies were performed in rats and mice to clarify the pharmacological profile of SM-9018 (cis-2-{4-[4-(1,2-benzisothiazol-3-yl)-1-piperazinyl] butyl} hexahydro- 1H-isoindole-1,3-[2H]-dione HCl), a potential antipsychotic agent. In a receptor binding study, SM-9018 exhibited very high affinities both for 5-HT $_2$ and D $_2$ receptors and moderate affinities for α_1 , 5-HT $_1$ and D $_1$ receptors. Orally administered SM-9018 markedly inhibited 5-HT $_2$ receptor-mediated behaviors (i.e., head twitches, wet dog shakes and clonic seizures) induced by 5-HT stimulants and blocked dopamine agonist-induced behaviors (i.e., stereotypy, hyperactivity and climbing behavior), with ED $_{50}$ values of 1.4-5.8 mg/kg. Low-dose SM-9018 selectively inhibited the conditioned avoidance response in rats (ED $_{50}$ -3.3 mg/kg, p.o.) with a potency greater than that of chlorpromazine while only weakly reducing the escape response. In addition, SM-9018 was much weaker than chlorpromazine and haloperidol in producing catalepsy, bradykinesia in the pole-test, disturbance of motor coordination and suppression of spontaneous locomotion. These results suggest that SM-9018 is a novel antipsychotic agent with less extrapyramidal and CNS depressive side-effects and it produces a combined blockade of dopaminergic and serotonergic transmission.

MOTIVATION AND SELF-STIMULATION

245.1

REFRACTORY PERIODS OF DORSOMEDIAL HYPOTHALAMIC UNITS DIRECTLY DRIVEN BY REWARDING STIMULATION OF THE VENTRAL TEGMENTAL AREA MATCH PSYCHOPHYSICALLY-DERIVED ESTIMATES FOR REWARD-RELATED NEURONS. K.L. Conover and P. Shizgal, CSBN, Department of Psychology, Concordia University, Montreal, Quebec, H3G 1M8.

Neuroanatomical and behavioral data suggest that cell bodies in the Dorsomedial Hypothalamic Nucleus (DMH) contribute to the rewarding effect of electrically stimulating of the Ventral Tegmental Area (VTA). The present study reinforces this view by demonstrating that neurons with somata in or near the DMH can be antidromically activated by rewarding VTA stimulation in rats, and that the refractory periods of most of these directly-driven cells resemble those of neurons responsible for the rewarding effect.

responsible for the rewarding effect.
Responses were obtained from 186 units, 38 of which were antidromically-driven by VTA stimulation. Eighteen of the sites at which the antidromic responses were seen lay in the DMH or nearby (within 200 µm). Ten DMH units were driven using stimulation sites, currents and pulse durations that were previously shown to support self-stimulation and were used to psychophysically estimate recovery from refractoriness in reward neurons. The refractory periods of 8 of these 10 cells fell within the range of the psychophysically-derived estimates, as did the refractory periods of an additional 8 neurons driven by stimulation of VTA sites that had not been behaviorally screened.

CAUDAL MEDIAL FOREBRAIN BUNDLE TRANSECTIONS DISRUPT THE REWARDING EFFECT OF LATERAL HYPOTHALAMIC SELF-STIMULATION. Meg A. Waraczynski, Dept. of Psychology, Univ. of Pennsylvania, Philadelphia, PA 19104

This study investigates changes in self-stimulation of the lateral hypothalamic (LH) medial forebrain bundle (MFB) in the rat following transection of the caudal MFB and ventral tegmental area (VTA). Rate-frequency functions were collected daily at a single current intensity from 10 rats. Following baseline behavioral stabilization, a coronal plane knife cut was made behind the stimulating electrode. Three rats showed a long-term 0.4 to 0.6 log unit increase in the frequency required to sustain half-maximal responding; 3 rats showed a 0.1 to 0.2 log unit increase, and 4 rats showed no change. Cuts were most effective when the electrode was in the posterior LH/MFB and the cut was not more than 1 mm caudal to the electrode, and when damage was to the MFB just rostral to the anterior border of the VTA. Cuts were least effective when placed ventrally in the MFB, or in the VTA and substantia nigra (SN). One rat with considerable damage to the VTA and SN showed no change in frequency required to sustain half-maximal responding, suggesting that cut effectiveness did not result solely from damage to dopaminergic neurons.

CONDITIONED PREFERENCE PRODUCED BY INJECTION OF GLUTAMATE INTO THE ANTERO-LATERAL HYPOTHALAMUS. B. Murray and P. Shizgal. CSBN, Concordia University, Montreal, Quebec H3G 1MR.

A preference task was used to determine whether chemical stimulation of cells in the anterior lateral hypothalamus (LH) is rewarding. For 15 min per day, male rats were placed in an open field with a floor consisting of 4 removable panels made from either rods or wire mesh. on Days 1 and 3, the entire floor was composed of panels of one material (the CS $^{+}$), and 1-glutamatic acid (.5 μl , .5 M, pH 7.6) was injected into the anterior LH while the subjects were in the open field. On Days 2 and 4, the panels were of the alternate material (the CS $^{-}$), and artificial CSF (.5 μl , pH 7.8) was administered. On the test day, the floor was composed of two panels of each material, arranged in a checkerboard pattern. CSF was administered, and the position of the subject was recorded on videotape.

administered, and the position of the subject was recorded on videotape.

The group (n = 11) with histologically verified injection sites in the anterior LH spent significantly more time on the flooring paired with the glutamate injections than on the flooring paired with CSF. Two subjects with cannulae aimed 1 mm dorsal to this site failed to show a conditioned preference for the glutamate-paired flooring. These data suggest that activation of somata in the anterior LH is rewarding, a result complementary to the attenuation of medial forebrain bundle self-stimulation by lesions of the anterior LH.

A THRESHOLD TRACKING PROCEDURE FOR STUDYING BRAIN STIMULATION REWARD. M.A. Bozarth, C.M. Pudiak, J. Norcera*, & C.M. Specht*, Department of Psychology, University at Buffalo, NY 14260.

An experimental procedure is described that permits continuous tracking of brain stimulation reward (BSR) thresholds. This method determines the minimum stimulation frequency that maintains a predetermined response rate (e.g., 30 presses/min). Subjects are initially presented with a series of descending stimulation frequencies (0.1 log units/step). One-minute response rates are determined for each frequency, and the minimum frequency that maintains the criterion response rate is defined as threshold. When the response rate is less than the criterion, the stimulation frequency increases (0.1 log units/min) until responding is reinstated (\geq criterion).

Threshold tracking yields threshold values that are similar to those obtained using the frequency-rate method. The latter method, however, is laborious and requires 15 to 20 min for a single threshold determination, while threshold tracking is fully automated and can determine BSR thresholds in as little as 1 to 3 min. Thresholds obtained with this method are stable $(\pm\,5\%)$ over several months of continuous or intermittent testing. d-Amphetamine (0.1 to 1.0 mg/kg, i.p.) produces dose-dependent threshold lowering (14 to 60% \downarrow), with a detection limit of \leq 0.1 mg/kg. Threshold tracking provides a fast, reliable, and sensitive measure of BSR thresholds and may offer several important advantages over traditional BSR measures.

HALOPERIDOL PREVENTS THE ESTABLISHMENT OF BRAIN STIMULATION INDUCED CONDITIONED PLACE PREFERENCES BUT NOT AVERSIONS IN RATS. C.L. Duvauchelle and A. Ettenberg. Dept. Psychology, Univ. Calif., Santa Barbara, CA 93106

Male rats were implanted with indwelling intracranial electrodes aimed at either the lateral hypothalamus (LH), prefrontal cortex (PFC), ventral tegmental area (VTA) or the dorsomedial tegmentum (DMT). The pairing of brainstimulation with one of two distinct conditioning environments led to subsequent conditioned place preferences (CPPs) for the stimulation-paired environment in LH, PFC and VTA subjects and a conditioned place aversion in DMT-stimulated rats. Pretreatment on conditioning trials with the dopamine antagonist haloperidol (0.15-0.3 mg/kg), prevented the establishment of all CPPs but had no effect on the learned aversions of the DMT group. These results suggest that a) memory encoding processing remain intact under neuroleptic challenge, and b) haloperidol attenuated the rewarding properties of LH, PFC and VTA stimulation.

FAILURE OF ESTROGENTO ALTER LATERAL HYPOTHALAMIC BRAIN STIMULATION REWARD. <u>C.M. Pudiak & M.A. Bozarth,</u> Department of Psychology, University at Buffalo, Buffalo, NY 14260.

Several measures were used to determine the effects of ovariectomy and subsequent estrogen replacement on brain stimulation reward (BSR). Female, Long-Evans rats were implanted with monopolar electrodes aimed at the lateral hypothalamic level of the medial forebrain bundle. After 5 to 10 days recovery from surgery, they were trained to press for monophasic cathodal stimulation pulses using one of three different BSR techniques. The frequency-rate method determined 2-min response rates for a descending series of stimulation frequencies. The autotitration procedure determined the self-selected minimum current intensity necessary to maintain responding. And, the threshold tracking procedure determined the minimum stimulation frequency necessary to maintain 30 responses/min (see Bozarth et al., Soc. Neurosci. Abstr., 1990).

Ovariectomy had no effect on BSR thresholds obtained with any of the three measures. 17-\(\beta\)-Estradiol injections (0.2 to 20 \(\mu\)g) also failed to alter BSR thresholds. These data indicate that estrogen does not influence the rewarding impact of lateral hypothalamic BSR and that earlier studies reporting estrogen modulation of BSR are probably attributable to differences in electrode placements or to nonspecific enhancement of lever-press rates.

245.6

EFFECTS OF MEDIAL AND POSTERIOR HYPOTHALAMIC KNIFE-CUTS ON LATERAL HYPOTHALAMIC SELF-STIMULATION REWARD J.R. Stellar, F. Scott Hall, and Hugh Albert: Psychol. Dept., Northeastern Univ. Boston MA 02115.

Rats with a lateral hypothalamic (LH) electrode were given a sagittal knife-cut between the LH and the dorsalmedial nucleus of the hypothalamus (DMH). A second group with posterior LH electrodes were given a coronal knife-cut in the mid-LH. Both groups were tested on a self-stimulation (SS) task using a rate-frequency curve-shift method at up to five stimulation currents daily before and for three weeks after the knife-cut. In the first group, sagittal knife-cuts had little or no effect on SS reward. In the second group, coronal knife-cuts produced a substantial SS reward decrease (LOR increase) which was larger at lower currents. We conclude that DMH fibers do not directly mediate LH SS reward as may have been inferred from other work (cf. Glimcher et al., Neurosci Abst, 1989), and that previous lesion-SS studies with only one stimulating current per subject may have missed some SS reward effects.

EFFECTS OF ACCUMBENS OPIATE MICROINJECTION ON INTRACRANIAL SELF-STIMULATION FOLLOWING NEONATAL DOPAMINE LESION. P. Johnson1, K.S. Sidhu1, J.R. Stellar1, and J. Bruno2.

1-Psychol. Dept., Northeastern Univ., Boston, Ma., 02115; 2-Psychol. Dept. Ohio State University, Columbus Ohio 43210.

Neonatal day 3 rats given intraventricular

Neonatal day 3 rats given intraventricular injections of 6-OHDA yield adults with severe permanent dopamine (DA) lesions, but relatively spared lateral hypothalamic self-stimulation (LHSS) reward function (Stellar et al. Pharm Biochem & Behav 30:365,1988). We now report that neonatal DA-lesioned rats are hypersensitive to accumbens microinjections of d-ala-met-enkephalinamide (DALA) in a manner that parallels our previous report of DALA hyper-sensitivity in rats given accumbens DA lesions as adults (Johnson et al. Neurosci. Abst. 1989). However, unlike our adult lesion results, the DALA results with neonatal DA lesions are not temporary.

NUCLEUS ACCUMBENS SINGLE UNIT ACTIVITY IN THE RAT DURING VTA SELF-STIMULATION. M. Wolske, P-P. Rompre, R.A. Wise, and M.O. West Dept. of Psychology, Rutgers Univ., New Brunswick, NJ 08903 and Dept. of Psychology, Concordia Univ., Montreal, Quebec, Canada.

The present study used extracellular single unit recordings in the freely moving rat to study the effects of ventral tegmental area (VTA) self-stimulation on nucleus accumbens neurons. Male Long-Evans rats were implanted with a detachable microdrive for recording in the accumbens and with stimulating electrodes in the ipsilateral VTA and fimbria. A 500 msec duration train of VTA pulses (0.1-0.5 mA, 0.1 msec, 20-30 Hz) was used as a reinforcer for lever pressing (FT 1.5 sec). Unit responses (N=74 units) to trains of stimulation showed 4 different patterns in peri-event histograms: 1) Loosely time-locked neurons (LTL; N=15/74) showed excitatory time-locked responses of long duration (3-25 msec). 2) Tightly time-locked neurons (TTL; N=18/74) showed time-locked single spike responses with invariant latency (range 11-16 msec across units). 3) Excitatory responses (EXC; N=16/74) consisted of overall increases during the train, not time-locked to individual pulses. 4) Inhibitory responses (INH; N=25/74) consisted of overall decreases during the train, not time-locked to individual pulses. Statistical analysis showed that LTL exhibited significantly higher between-train firing rates (range 0.40 to 23.81 Hz) than neurons in all other categories (range 0.00 to 3.99 Hz). TTL tested for high frequency following (n=5) followed 200-1200 Hz stimulation. Two of these units were tested for collision and both collided. These results suggest that TTL responses reflect antidromic activation whereas LTL, EXC and INH represent orthodromic responses (mono- or polysynaptic) of accumbens neurons to VTA self-stimulation. Supported by BNS-8708523, DA 04551 and RR 07058-21

245.11

EFFECT OF RAPHE STIMULATION ON SINGLE UNIT ACTIVITY IN THE NUCLEUS ACCUMBENS SEPTI (NAS) OF THE RAT. C.W. Callaway. and S.J. Henriksen. Research Institute of Scripps Clinic, La Jolla, CA 92037.

The NAS is thought to be involved with the action of psychostimulant drugs and with the maintenance of rewarded behavior. Because behavioral and biochemical evidence suggests that the neurotransmitter serotonin (5-HT) can affect these NAS-mediated behaviors and because most forebrain 5-HT arises from the midbrain raphe nuclei, we examined the effects of raphe stimulation on firing of single NAS units. Stimulating electrodes were placed in the fimbria and the dorsal raphe nuclei of halothane-anesthetized male rats, and unit activity was recorded in the NAS using single-barrel glass micropipettes. Single pulse stimulation of the raphe was followed by 50-100 ms inhibition of spontaneous firing of NAS units, although a few cells responded with brief (50 ms) increases in firing rate. The inhibitory response was antagonized by cyproheptadine (2 mg/kg, s.c.). Stimulation of hippocampal afferents in the fimbria produced monosynaptically evoked discharges with latencies of 15-25 ms. Conditioning stimulation of the raphe (10-20 hz, 0.5-1.0 sec train) increased the current required to evoke the longer latency fimbria-evoked discharges, but did not affect units with monosynaptic latencies. Preliminary tests indicate that the 15-25 ms latency fimbria-evoked discharges result from stimulation of the hippocampal formation, suggesting that raphe stimulation may modify firing of NAS units in part by aftering input from at least one major afferent to the NAS.

245.13

SELF-STIMULATION THRESHOLDS ALTERED BY DOPAMINE AGONISTS AND ANTAGONISTS. S. Nakajima and N.B. O'Regan, Dalhousie University, Halifax, Nova Scotia, Canada

Dopamine antagonists generally attenuate brain selfstimulation, and some dopamine agonists facilitate it. Whether the behavioral changes are caused by alterations in the reinforcing effect of stimulation or by interference with motor performance has been controversial. One way to dissociate motor effects from reinforcement itself in such a situation is to examine the response rates across a range of stimulation frequencies and plot a frequency-response curve.

Rats were trained to press a bar for lateral hypothalamic stimulation, and tested 30 min after injection of a selective dopamine Dl or D2 agonist or antagonist. Either SKF 38393 HCl (Dl agonist) 0.4 mg/kg or quinpirole (D2 agonist) 0.1 mg/kg shifted the frequency-response curve to a lower range, and either SCH 23390 maleate (Dl antagonist) 0.04 mg/kg or raclopride (D2 antagonist) 0.04 mg/kg shifted it to a higher range. The results suggest that both Dl and D2 receptors are critically involved in producing the rein-forcing effect of brain stimulation.

245.10

ENHANCED RESPONSIVENESS OF NUCLEUS ACCUMBENS UNITS TO ODORS ASSOCIATED WITH AMPHETAMINE ADMINISTRATION IN RATS. Charles H.K. West and Richard P. Michael. Department of Psychiatry, Emory University School of Medicine, and Georgia Mental Health Institute, 1256 Briarcliff Road, Atlanta, GA 30306.

It has been proposed that the mesolimbic dopamine (DA) system is involved in sensory filtering and reward processes. We previously reported that the responsiveness of neurons in mesolimbic terminal regions to sensory stimuli was increased by conditioning animals to associate sensory cues with rewarding brain stimulation. Here we report that the effectiveness of odors in evoking responses in mesolimble units is increased by pairing the odors with the rewarding effects of a psychostimulant drug. Adult male rats were trained to associate administration of g-amphetamine (0.5 mg/kg, sc) with one odorant and administration of saline with another (4 sessions/drug, 40 min each). Additional rats were exposed in their home cages (4 sessions) to a previously unfamiliar odor. Subsequently, all rats (n = 16) were anesthetized with urethane (1.4 g/kg, ip), and single units were recorded in caudateputamen, nucleus accumbens (NAC) and olfactory tubercle and were tested with 10 odorants. Pairing odors with amphetamine increased their effectiveness at evoking unit responses. This effect was most marked in NAC where the proportion of units responsive to paired and non-paired odors was 72% and 24%, respectively. In contrast, pairing odors with saline did not alter the proportion of responsive NAC units. However, familiarizing an animal with an odorant increased the proportion of units responsive to that odorant from 17% (unfamiliar) to 43% (familiar). These results support a role for neurons in mesolimbic DA terminal regions in modulating sensory stimuli relevant to reward processe

CHARACTERISTICS OF REWARD NEURONS IN THE CAUDATE-PUTAMEN: REFRACTORY PERIOD ESTIMATES.

M. M. Trzcińska and C. H. Bielajew. University of Ottawa, School of Psychology, 275 Nicholas, Ottawa, Ontario, K1N 6N5.

The excitability characteristics of the substrate underlying brain-stimulation reward in the caudate-putamen were investigated. Male Hooded rats were implanted with a moveable electrode aimed at the rostral caudate nucleus (AP: +1.7 mm ML: 1.3-1.4 mm V: 1.8-3.3 mm). Stimulation consisted of 500 msec trains of 0.1 msec rectangular, cathodal pulses delivered on a continuous reinforcement schedule. Stable bar pressing behavior was observed at currents of 600-800 uA, with acquisition of self-stimulation occurring within the first shaping session. Maximum rates ranged from 10 to 40 responses per minute. Seven refractory period estimates were obtained from seven different sites in two animals. The time course of recovery from refractoriness had the following profile: Recovery was observed at 0.5 and 1.0 msec; the end of recovery increased from roughly 2.0 to 10.0 msec as the electrode was moved ventrally. In the first subject, asymptote effectiveness values did not exceed 50%, while in the second subject, almost 100% effectiveness was obtained. These results are consistent with the observation that the refractory periods underlying forebrain self-stimulation tend to be longer than the ones reported for midbrain regions.

This research was supported by NSERC grant #UO514 to C.B.

245.14

EFFECTS OF D1 AND D2 ANTAGONISTS ON LATERAL HYPOTHALAMIC SELF-STIMULATION REWARD IN ADULT RATS DOPAMINE-LESIONED ON NEONATAL DAY 3. K.S. Sidhu¹, J.R. Stellar¹, J. Bruno². 1-Psychology Department, Northeastern Univ., Boston, MA 02115, 2-Psychology Department, Ohio State Univ., Columbus, Ohio 43210.

Rats were given bilateral ICV 6-OHDA injections (75ug each side) on Day 3 of neonatal life to produce severe adult dopamine (DA) depletions. As adults, these rats were tested on a rate-frequency paradigm for lateral hypothalamic self-stimulation (LHSS) reward under 4 systemic doses of D1 (SCH 23370, 0.01- 0.15mg/kg) and D2 (Raclopride 0.02-0.6 mg/kg) DA receptor blockers. Results indicate that both drugs were effective in reducing LHSS reward (increasing LOR), but compared to sham-lesioned controls, the neonatal DA-lesioned rats appeared somewhat subsensitive to Raclopride in agreement with our earlier work (Stellar et al. PB&B 30:365,1988). Combining the 3rd highest dose from each drug produced a LOR increase that was similar to the arithmetic sum of the separate LOR effects of the two doses alone, indicating no strong advantage of the combination drug treatment. (Supported by the Whitehall Foundation)

DOPAMINE BLOCKADE IN NUCLEUS ACCUMBENS REDUCES BAR-PRESS BUT NOT PLACE PREFERENCE MEASURES OF LH STIMULATION REWARD. J. M. Goodman, D. B. Neill, and J. B. Justice, Jr. Depts. of Psychology and Chemistry, Emory University, Atlanta, GA 30322.

We used the conditioned place preference procedure as a rate-free measure of lateral hypothalamic stimulation reward. Rats received noncontingent hypothalamic stimulation while exposed to one of two environments. Conditioning took place on two consecutive days and consisted of one twenty minute exposure to one of the environments per day. When given free access to both environments, rats showed a preference for the one that was paired with the brain stimulation. This preference was impaired by systemic (0.8 but not 0.25 mg/kg), but not intra-accumbens (50 ug/ul bilaterally) administration of the dopamine receptor blocker cis-flupenthixol. The systemic and intra-accumbens doses which did not reduce place preference severely impaired barpressing for brain stimulation. We conclude that the reward of hypothalamic stimulation is not reduced by blockade of accumbens dopamine receptors and that a major portion of reduced bar-pressing for the stimulation is motoric in nature.

245.17

EFFECT OF REPEATED NICOTINE ADMINISTRATION ON DORSAL RAPHE BRAIN STIMULATION REWARD. P. Bauco and R.A. Wise. Ctr. Stud. Behav. Neurobiol., Dept. Psychol., Concordia U., Montreal, Canada.

The effects of nicotine (0.05, 0.1, 0.2, or 0.4 mg/kg, s.c.) on dorsal raphe self-stimulation were assessed daily for 10 days in independent groups of rats. Nicotine caused a leftward shift of the function relating response rate to stimulation frequency; thus nicotine reduced the "dose" of rewarding stimulation necessary to produce responding at normal levels. The effects of nicotine were consistent from day to day; there was no evidence of either tolerance or The reward-facilitating effects were sensitization. strongest with the 0.1 mg/kg dose. Duration of facilitation increased with nicotine dose. with the nicotine antagonist mecamylamine (1 mg/kg, s.c.) had no significant effect on baseline responding, but blocked the effect of nicotine at each of the doses Thus nicotine, like other habit-forming drugs, increases the impact of brain stimulation reward.

SUPPRESSION OF SEIZURES WITHOUT ALTERING EXCITABILITY PROPERTIES OF REWARD-RELATED NEURONS BY THE NOVEL BENZODIAZEPINE - BROTIZOLAM

T. Harris and C. Bielajew. School of Psychology, University of Ottawa, Ottawa, Ontario, Canada, KlN 6N5. Brotizolam, a novel benzodiazepine, with longer-acting and stronger anti-convulsant properties than the traditional diazepine derivatives, was investigated for its ability to control stimulation-induced seizures without altering the time course of the behaviourally derived refractory period profiles. Three rats were implanted with LPO electrodes and one rat with an LH electrode. Frequency thresholds were interpolated at a fixed criterion of 35 responses/minute from ascending rate/frequency functions. Brotizolam (7.5mg/kg i.p.) and its vehicle were administered on alternate days with at least two days between drug sessions. Three hours post-injection, refractory periods were determined at currents which maximized the probability of inducing seizures (800-1000µA). Seizure activity was rated using Racine's five-point classification system. Brotizolam suppressed overt seizures during the average 105 minute testing sessions without altering the recovery from refractoriness, estimated to be roughly 0.4 to 2.0 msec across animals. These results suggest that brotizolam could be a useful agent for investigating the properties of the directly stimulated substrate mediating brain-stimulation reward in seizure-prone sites.

AUTOTITRATION ANALYSIS OF CHOLINERGIC INVOLVEMENT IN REWARDING HYPOTHALAMIC STIMULATION. D. B. Neill and K. Krebs*. Dept. of Psychology, Emory University, Atlanta, GA 30322.

Enhanced transmission of the neurotransmitter acetylcholine (ACh) has been linked with depression in humans. We observed the effect of elevated ACh on an hypothesized animal indicator of depression, decreased responding to intracranial self-stimulation. The anticholinesterase physostigmine was injected *i.p.* (0.05-0.10 mg/kg) into rats trained in autotitration self-stimulation of the lateral hypothalamus. Physostigmine reliably produced suppression of responses, but had no significant effect on reset intensity. To explain this unusual pattern of results we hypothesize the existence of two separate cholinergic systems. Activation of one system decreases reward (higher reset intensity; anhedonia); activation of the other decreases behavioral activation (lower reset intensity; anergy). Simultaneous activation of these systems, such as by systemic administration of physostigmine, could result in a cancelling out and no change in reset intensity, the pattern observed in this study. Decreased responding, produced by activation of either system, remains as the most consistent result of physostigmine administration.

THE EFFECT OF CHRONIC INTRACRANIAL SELF-STIMULATION ON CYTOCHROME OXIDASE LEVELS IN CNS.

C. Gow, C. Kateb, K. Harman, and C. Bielajew School of Psychology, University of Ottawa, KlN 6N5. The relationship between cytochrome oxidase levels and the amount of activity in developing and mature CNS neurons has been previously demonstrated (Wong-Riley, TINS, 1989, 12, 94). We have reported slight increases in cytochrome oxidase levels in several CNS structures following longterm administration (20 min/day) of rewarding brain stimulation in the lateral hypothalamus. In order to enhance the metabolic demands of the critical substrate, enhance the metabolic demands of the critical substrate, we conducted the present study in which stimulation trials were significantly lengthened (4 hr/day) and cytochrome oxidase activity across the entire brain was quantified using optical densitometric methods. Immediately following the final stimulation session, animals were perfused and the brains prepared for cytochrome oxidase histochemistry using the procedure described by Wong-Riley (Brain Res, 1979, 171, 11-28). Generally, the stimulated hemisphere showed greater increases in cytochrome oxidase activity showed greater increases in cytochrome oxidase activity than did the unstimulated hemisphere, measured in relative optical density units. Additionally, darker reaction products were noted in central brain regions, as defined anteriorly by the caudate nucleus and posteriorly by the substantia nigra. Outside this region, enzymatic changes were less noticeable. Supported by NSERC grant #UO514 to C.B.

EFFECTS OF HOUSING ON RESPONSE TO HANDLING, LOCOMOTOR ACTIVITY AND THE ACQUISITION OF INTRACRANIAL SELF-STIMULATION IN RATS. G.J.Schaefer

INTRACRANIAL SELF-STIMULATION IN RATS. G.J.Schaeter and R.P. Michael, Department of Psychiatry, Emory University, School of Medicine, Georgia Mental Health Institute, 1256 Briarcliff Rd., Atlanta, GA 30306.

Rats (N = 24) were implanted with electrodes in the lateral hypothalamus. Following recovery from surgery, they were divided into two groups of equal mean body weights. Animals in one group were housed individually, while animals in the other group were housed four to a cage. These housing conditions were maintained throughout the experiment. After four weeks in these housing conditions, animals were tested individually for changes in locomotor activity (15 min/day for 5 days) and in their response to handling during the fifth week. During the sixth and seventh weeks, animals were tested for the acquisition (self-shaping) of intracranial self-stimulation (ICSS) (15 min/day, 5 days/week). Compared with animals housed individually, animals housed in groups were less re-active to handling and had higher bused in groups were less re-active to handling and had higher locomotor activity scores. Animals housed in groups also made more responses during the acquisition of the ICSS response than did animals housed individually. These results demonstrated that changes in housing conditions for a period of four weeks can influence both unconditioned behavior (locomotor activity and response to handling) and the acquisition of ICSS (Supported by response to handling) and the acquisition of ICSS. (Supported by the Georgia Department of Human Resources.)

EVIDENCE OF A NON-UNITARY SCALE OF REINFORCEMENT AS MEASURED BY PSYCHOPHYSICAL PREFERENCE TESTS. R. Raymond and E. Miliaressis. Behavioral Neurophysiology Lab. University of Ottawa, Ottawa, Ont., KIN 6N5. Since 1964, brain stimulation reward researchers have

considered the reinforcement system to be unitary.
Malette and Miliaressis (in press) have shown that pulse
frequencies that elicit identical proportions of the maximum self-stimulation (SS) rate within the same structure are equipreferred. The purpose of this study then, was to determine if upon stimulation of two different then, was to determine if upon stimulation of two different stuctures, such pulse frequencies would also be equipreferred. Therefore, male Sprague-Dawley rats implanted with monopolar moveable electrodes were given a choice between stimulation of the ventral tegmental area (VTA) and the lateral hypothalamus (LH). It was hypothesized that in the event that the rats fail to equate behaviorally two stimuli that elicit identical proportions of the maximum SS rate, two separate scales of reinforcement may be in play. Results of this study show that at pulse frequencies that elicit identical proportions of the maximum SS rate, rats did indeed choose the VTA over the LH at a mean preference ratio of .9. These results clearly support a non-unitary system of reinforcement. Supported by a Natural Sciences and Engineering Research Council grant, A8625, to E.M.

A STUDY OF THE AXONAL LINKS BETWEEN REWARD-RELEVANT A STUDY OF THE ARONAL LINKS BETWEEN REWARD-KELEVANT NEURONS IN THE BILATERAL HYPOTHALAMIC NUCLEI. J. Malette and E. Miliaressis, School of Psychology, University of Ottawa, Ottawa, On., Canada, KIN 6N5.
Unilateral self-stimulation (SS) has been reported to

Unilateral self-stimulation (SS) has been reported to result in a bilateral activation of the dopaminergic terminals (Porrino et al., <u>Science</u>, 1984, <u>224</u>, 4646). Forebrain ablations performed by Colle and Wise (<u>Brain Res.</u>, 1987, <u>407</u>) on self-stimulating animals suggest that the SS system may not entirely be unilateralized. The aim of our study was to investigate the reward-relevant bila-teral linkage within the medial forebrain bundle. Male Sprague-Dawley rats were implanted with moveable electrodes aimed bilaterally at the lateral hypothalamic nuclei (LH). The behavioral version of the collision test was used and consisted of the delivery of trains of pairs of pulses, with the conditioning pulse (C) delivered to a first electrode and the test pulse (T) delivered to the contralateral electrode. C-T intervals varied from 0.2 to 5.0 ms. Collision was inferred from an increase in SS thresholds at short C-T intervals. High SS thresholds were obtained at C-T intervals inferior or equal to the refractory period of the LH. Consequently, direct reward-relevant axons do not seem to link the bilateral LH. A heterosynaptic summation, rather, seems to take place between these bilateral nuclei. Supported by a Natural Sciences and Engineering Research grant, A8625, to E.M.

INVERTEBRATE LEARNING AND BEHAVIOR II

CHANGES IN LEARNING AND MEMORY THROUGHOUT THE LIFESPAN OF THE NEMATODE C. ELEGANS. C. D. O. Beck, S. R. Cerniuk & C. H. Rankin, Dept. of Psychology, Univ. British Columbia, Vancouver, BC, V6T

Adult C. elegans are capable of simple forms of non-associative learning such as habituation, dishabituation and sensitization as well as both short and long-term memory (Rankin, Beck & Chiba, *Behav. Br. Res.*, 37: 89, 1990). We have examined the changes in these forms of learning and memory over both early (prereproductive) and late (postreproductive) development. Based on anatomical evidence, there are three distinct patterns of neural connectivity: an embryonic pattern, a transitional larval pattern, and an adult pattern. Developmental studies of non-associative learning indicate that these different patterns of neural connectivity are reflected in differential learning abilities. C. elegans shows habituation in all stages of development; however larval animals require shorter ISI's than adults (adult=4 days old). In addition larval animals appear to recover from habituation more rapidly than adults. Dishabituation is expressed in all developmental stages except during the second larval stage. In postreproductive development, changes in the degree of habituation and the lack of apparent dishabituation in animals 7, 10, and 12 days of age suggest functional changes in the aging nervous system.

These studies of learning and memory throughout the lifespan of C. elegans will allow a characterization of some of the properties of the mechanisms underlying changes in learning and memory early in development when postembryonic neurons are arising and forming connections and during aging when the nervous system may be degenerating functionally.

ISOLATION OF NEW SINGLE-GENE MUTANTS AFFECTING MEMORY IN DROSOPHILA MELANOGASTER.

B. Boynton*, A. Villella*, and T. Tully. Department of Biology, Brandeis University, Waltham, MA. 02254.

Classical conditioning of an olfactory avoidance response produces strong learning and retention in wild-type *Drosophila*. Previous genetic dissection of conditioned behavior in *Drosophila* has isolated six mutant strains which exhibit reduced learning or memory of this task. In agreement with one current model of memory formation, memory in *Drosophila* appears to require normal cAMP regulation, as two of the learning/memory mutants affect enzymatic components of the cAMP pathway.

We have begun a screen for new mutations affecting conditioned olfactory avoidance behavior. Mutant strains, generated by a single offactory avoidance behavior. Mutant strains, generated by a single p-element transposition, were tested for memory loss three hours after training. Those strains consistently scoring less than 70% of wild-type then were studied further. One strain, *latheo*, shows abnormally low learning and retention, with a more rapid decay of memory in the first 30 minutes after training. The mutant *latheo* appears to be normal in its ability to smell the odorants, to locomote, and to sense electric shock. Genetic analyses confirm that the retention deficit in latheo indeed is a single-gene effect caused by a pelement insertion. Significantly, the p-element insertion in the latheo gene constitutes a "molecular tag," which can be used to obtain raureu gene constitutes a "molecular tag," which can be used to obtai the relevant DNA sequences. In this manner, we have begun to clone this new gene involved with memory formation in *Drosophila*. Supported by grants from the McKnight Foundation, NIH GM33205, and NIMH MH09946.

INCREASE IN BRANCHING AND NUMBER OF VARICOSITIES IN MOTOR AXON TERMINALS OF *DROSOPHILA* MEMORY MUTANTS WITH ALTERED cAMP LEVELS. Y. Zhong, V. Budnik & C.-F. Wu. Dept. of

ALTERED cAMP LEVELS. Y. Zhong, V. Budnik & C.-F. Wu. Dept. of Biology, Univ. of Iowa, Iowa city, IA 52242

Modulation of synaptic efficacy may result from changes in morphology or membrane properties at pre- or postsynaptic sites. Such cellular modifications have been demonstrated to accompany long-term behavioral acquisition. In these processes, modulation of membrane currents has been shown to be mediated by second messengers such as cAMP, Ca²⁺, and phospholipids. Drosophila memory mutants at the dunce (dnc) locus reduce or eliminate activity of phosphodiesterase (PDE) II so that cAMP level is increased. We have shown that the synaptic plasticity, such as facilitation and potentiation, at neuromuscular junctions of these mutants is altered (Zhong & Wu, Soc. Neurosci. Abstr. 15:1141). Therefore, it is of interest to determine whether morphological changes can also be induced by disrupted cAMP metabolism. We now report that the number of terminal branches and varicosities are significantly increased at the neuromuscular junction in dnc mutants.

Anti-HRP immunocytochemistry was employed to visualize nerve terminals innervating body-wall muscles of the third instar larva. Only the terminals on muscle fibers 13 and 14 in abdominal segment 3 were scored to examine the mutational effect. The general innervation pattern specific to each identified muscle fiber was preserved in different dnc alleles. However, the results indicated that both dnc^{l} and dnc^{Ml4} have a greater number of varicosities (338±55 and 313±36, respectively) than normal larvae (243±44, meant5D). The increase in terminal branching was due mainly to a larger number of higher-order branches. The heterozygote of dnc^{1}/dnc^{M1} showed an even stronger increase in number of varicosities (381±99) and terminal branches. Our results suggest a possibility that elevating cAMP levels can lead to an increase of synaptic contacts between nerve terminals and their targets. However, it remains to be determined how the increment in synaptic contact contributes to changes in synaptic efficacy.

APIS MELLIFERA AS A NEUROPHYSIOLOGICAL MODEL FOR UNDERSTANDING THE ROLE OF NEUROTRANSMITTERS IN BEHAVIOR. J. Last*, R. Rosse*, I. Mefford*, S. Sheppard and W. Goldberg. Dept. Psychiatry, Georgetown Univ. Hosp., Washington DC 20009 and VA Med. Center, Washington DC, 20422.

Different strains of the honeybee, Apis, mellifera, were studied to explore neurophysiological differences between more docile European strains and a highly aggressive Africanized strain. Africanized and one European bee strain specimens were collected from S. America by the USDA and preserved in frozen storage. Another European bee strain was collected in N. America (Maryland). Chromatographic analysis of brain neurotransmitters (dopamine, DOPAC, 5HT, 5HIAA), appear to demonstrate a significant lower brain level of dopamine in Africanized Behavioral studies were performed in the field on haloperidolfed Africanized bees (10mg/hive). Haloperidol treated hives appear to demonstrate a significant decrease in stinging response compared to placebo (glucose solution) treated Africanized hives as determined by stings/sq. inch on a mechanical Immunohistochemical studies of dopamine in brain tissue of Africanized bee brain appear to demonstrate increased density of dopamine reactivity when compared to the European strain.

MOTONEURONS INNERVATING THE MUSCULATURE OF THE FLY PROBOSCIS HAVE PROJECTIONS IN FUNCTIONALLY DISTINCT REGIONS OF THE SUBESOPHAGEAL GANGLION OF THE CNS. L. C. Sudlow and L.L. Murdock*. Purdue Univ., W.Lafayette, IN 47907.

We sought to better understand the cytoarchitecture of the subesophageal ganglion (SEG), the site of the control of feeding in the fly. We mapped CNS projections of the motoneurons involved in ingestion and proboscis extension and retraction. Experiments were replicated in Phormia regina and Calliphora vacina. Cobalt, introduced via modified suction electrodes, followed by Timm's intensification was used to label specific cut nerves. Additionally, Dil was used to label the Retractor furca motoneurons in both species. The muscles involved in extension (Protractor fulcrum, Extensor of the haustellum and Adductor of the apodemes) and retraction (Retractor rostrum, Flexor of the haustellum and Accessory Retractor rostrum) have projections found predominantly in the ventrolateral and ventral neuropil of the SEG. The Retractor furca, involved in labellar lobe spreading, has projections in the dorsomedial neuropil, slightly ventral to the labrofrontal nerve root. The Gracilis motoneuron and the motoneurons of the tabolional network for. The Grachis holohieuron and the monitorins of the anomalon medial cibarial dialator nerve have projections in an anterior region of the anterodorsal neuropil of the SEG, centered around the labrofrontal nerve roots. This region of the SEG receives sensory projections from the labellar and tarsal chemosensory hairs (Edgecomb, R.S. & L.L.Murdock, J. comp. Neurol., Ms submitted). The lateral cibarial nerves appear to contain only sensory neurons that arise within the rostrum. Many of these sensory neurons are cobalt-coupled to neurons in the anterodorsal neuropil. These secondary fills of SEG neurons were eliminated by labelling with Texas Red. These results suggest that the motoneurons of the proboscis musculature project to functionally distinct regions of the SEG neuropil.

IN SITU INTRACELLULAR RECORDINGS FROM PROCEREBRAL

IN SITU INTRACELLULAR RECORDINGS FROM PROCEREBRAL NEURONS DURING COHERENT NETWORK OSCILLATIONS IN THE OLFACTORY PROCESSING SYSTEM OF LIMAX MAXIMUS. A. Gelperin, J. Flores* and D. W. Tank. Biophysics Research Dept., AT&T Bell Laboratories, Murray Hill, N.J. 07974

Computational analysis of odor learning in Limax led us to examine the procerebrum (PC) of the cerebral ganglion, which receives direct olfactory input and contains the majority of the neurons in the CNS. The PC displays an endogenous oscillation in its local field potential (LFP) (1 Hz) which is modulated by odor input (Nature, in press). We have obtained stable long-term intracellular recordings from the small (8 µm diameter) PC neurons in the intact PC using nystatin-filled cell-attached patch electrodes. PC cells receive prominent IPSPs which appear unitary but which may represent input from a tightly coupled set of synchronously-active presynaptic cells. These hyperpolarizing IPSPs are periodic and occur phase-locked to the LFP oscillation. The onset of the IPSP is coincident with the onset of local current flow during the LFP oscillation. Between these hyperpolarizing events PC neurons show 0 - 5 action potentials. Depolarizing current applied to the somatic recording site greatly increases spike frequency within a burst but does not change the greatly increases spike frequency within a burst but does not change the rate of burst occurrence, which is determined by the periodic hyperpolarizing event. Hyperpolarizing current eliminates spiking without altering the frequency of the periodic hyperpolarizing event and can reverse the polarity of the hyperpolarizing event. Computer models of the neural circuit underlying LFP oscillation, which are consistent with known anatomy and electrophysiology, are being developed and studied to aid in the circuit analysis of the PC and the functional analysis of the oscillating

THE LARVAL AND JUVENILE CENTRAL NERVOUS SYSTEM OF THE NUDIBRANCH BERGHIA VERRUCICORNIS. D.J.Carroll* and S.C.Kempf. Dept. of Zoology and Wildlife, Auburn

University, Al. 36849.

In order to cultivate <u>Berghia verrucicornis</u> as an animal model for future neurodevelopmental and behavioral studies, the larval and post-metamorphic central nervous system was studied using 1 um serial sections. We found that ganglia characteristic of the adult nervous system are present when the lecithotrophic larvae hatch from the egg mass. The arrangement of the neural constituents is similar to that found for larvae of other opisthobranch species (Kempf et al., J. Neurobiology, 18:217-236, 1987; Bickell and Kempf, Biol. Bull., 165:119-138, 1983); however, the cerebral and pleural ganglia appear to be fused in newly hatched larvae. In serial sections of newly metamorphosed juveniles, the cerebral and pleural ganglia are discrete, connected to each other via a cerebral-pleural connective. In both larvae and juveniles, the paired pedal ganglia are joined by a commissure, and linked to their respective cerebral ganglia via a connective. Also linked to the cerebral ganglia are the buccal ganglia, situated posterio-dorsal to the developing buccal mass. In the juvenile, a visceral ganglion is present posterior to the buccal commissure. Analysis of serial sections suggest its presence as part of the pleurovisceral loop running from one pleural ganglion to the other.

Serotonin as a Postural Control "Gain-setter" in the Lobster. P.M.Ma and E.A.Kravitz, Dept. Neurobiology, Harvard Medical School, Boston, MA 02115. Serotonin (5-HT) injection triggers the appearance of a flexed posture in lobsters which resembles appearance of a flexed posture in lobsters which resembles the stance assumed by dominant animals. This suggests a role for the amine in the postural component of this behavior. In isolated ventral nerve cords, the application of 5-HT promotes the read-out of flexion motor programs. We have identified 5-HT-containing neurons in the lobster 1st abdominal ganglion which are likely to be involved in postural regulation and have attempted to examine the mechanism by which 5-HT might promote postural flexion. Direct stimulation of the 5-HT-containing cells does not affect motor output programs. Instead, 5-HT acts by facilitating command inputs to postural motoneurons. Flexion commands usually excite, while extension commands inhibit the 5-HT-containing cells. In further evoloring the relationship between command neurons and while extension commands inhibit the 5-H1-containing cells. In further exploring the relationship between command neurons and the 5-HT-containing cells, we found that simultaneous activation of the 5-HT-containing neurons and flexion command fibers significantly amplified the efficacy of the command input, whether excitatory or inhibitory, to about 25% of the postural motoneurons we monitored. Activation of 5-HT-containing cells along with postural extension commands, which usually inhibit the 5-HTpostural extension commands, which usually inhibit the 5-HTi-containing cells, also results in amplification of extension command effects. These results suggest that 5-HT can function as a "gain-setting" element enhancing excitatory and inhibitory inputs to cells in various settings, and may be recuited to do so via multiple circuitries under different physiological or behavioral conditions. (Supported by NIH and MDA).

VOLTAGE- AND CURRENT-CLAMP SIMULATION OF HERMISSENDA TYPE B CELL RESPONSES. M.Koide and J.Farley. Dept. of Psychology, Indiana Univ., Bloomington, IN 47405

Repeated pairings of light and rotation result in an

enhanced light-generated response (LGR) of H.c. Type B photoreceptors, which has been attributed to reductions in two K currents: I(A) and I(K-Ca). We have constructed Hodgkin-Huxley style models of the major voltage-, light, and calcium dependent ionic currents in B cells from voltage-clamp data, with the aim of reconstructing the LGRs measured from trained and control B cells under current-clamp. To simulate the previously documented 30-40% reductions in I(A) and 50-60% reductions in I(K-Ca) for conditioned cells, the maximal conductances for each current were correspondingly reduced, first alone and then in combination. Because it is difficult to completely separate I(Ca) and I(K-Ca) experimentally, they were modeled as a single current. The conductances for the light-induced current and I(leak) were unchanged. Reducing g max A by 30% resulted in a 2.2 mV enhancement of the transient component of the LGR and a negligible change in the steady-state component. The 30% reduction of g max A resulted in only an 8% reduction in peak I(A) during the LGR. Reducing I(K-Ca) by 50% had negligible effect upon the peak of the LGR, but enhanced the steady-state component by 2.3 mV. Reduction of both conductances enhanced all components of the LGR. These increases were greater than the additive effects of reducing each alone.

246.10

BAG-CELL PEPTIDE(S) INHIBITS TAIL-SIPHON WITHDRAWAL REFLEX AND ATTENUATES SENSORY TO MOTOR NEURON SYNAPSE UNDERLYING TAIL-WITHDRAWAL IN APLYSIA. J.R. Goldsmith and J.H. Byrne. Department of Neurobiology & Anatomy, University of Texas Medical School, Houston, TX 77225.

The peptides released prior to and during egg-laying in Aphysia californica are responsible for eliciting or modulating a repertoire of behaviors preceding and accompanying egg-laying. Our interest was in determining the role these peptides may play in modulating non-reproductive behaviors. Specifically, we examined the effects of the bag-cell peptides (BCPs) on a simple behavior, the tail-siphon withdrawal reflex, which has been well characterized and whose underlying circuitry is well defined. We recorded the total duration of siphon withdrawal in response to test stimuli, delivered once every 5 min, to the tail. Pretest and positest periods consisted of 5 trials each. Immediately following the last stimulus in the pretest, one of four solutions was injected: bag-cell extract (BCE, n=23), egg-laying hormone (ELH, n=22), artificial seawater (ASW, n=20) or abdominal ganglion extract (minus the bag-cell clusters; ABG, n=19). The positest was begun 20 min after the injection. Whereas both experimental solutions (BCE and ELH) inhibited the baseline tail-siphon withdrawal reflex (median values: 64.0% and 64.5% of pretest, respectively), only the BCE group differed significantly (p<0.05) from the control groups (ASW and ABG; median values: 104.5% and 93.0% of pretest, respectively).

We are presently using an in vitro analogue of the tail-component of the reflex to determine which peptide or peptides may mediate this effect as well as a possible site(s) of action. In these experiments single spikes are elicited in tail sensory neurons (SN) and the monosynaptic EPSFs elicited in motor neurons (MN) are recorded. As in the behavioral experiments, there are 5 trials (ISI=5 min) in each the pretest and the postitest. Peptides are bath applied 2.5 min afte

246 11

THE MOBILIZATION PROCESS OF FACILITATION PRODUCED BY SEROTONIN IS INHIBITED BY FMRFAMIDE IN SENSORY NEURONS OF APLYSIA. J.P. Pieroni and J.H. Byrne. Dept. of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225
Previous studies of sensory neurons (SNs) mediating defensive reflex responses in Aplysia indicated that at least two processes, spike broadening and mobilization, contribute to presynaptic facilitation of transmitter release (Gingrich et al., 1985, 1988; Hochner et al., 1986). Recently, we demonstrated that while both serotonin (5-HT) and small cardioactive peptide (SCP) generate spike broadening only 5-HT induces mobilization (Pieroni and Byrne, 1989). This mobilization effect was most pronounced 3-4 min after the application of 5-HT. In contrast to the facilitatory effects of 5-HT and SCP, FMRFA has inhibitory effects. Although FMRFA produces spike narrowing and decreases synaptic transmission (Abrams et al., 1984), it is not known whether FMRFA affects mobilization. To examine this issue, we have compared the effects of 5-HT on processes contributing to facilitation of EPSPs in depressed SN-follower neurons ynapses in the presence and absence of FMRFA.

Abdominal ganglia were pretreated with TEA (100 mM) in order to broaden the SN spikes into a range of durations for which additional broadening alone has little or no effect on release (Gingrich et al., 1985, 1988; Hochner et al., 1986). Under this condition, changes in release are believed to be due primarily to mobilization. Single spikes were evoked in LE SNs at 60 s intervals, and the resultant monosynaptic EPSPs were monitored in follower neurons.

Following the induction of moderate homosynaptic depression (4-6 spikes), FMRFA (15-30 µM) or vehicle was added to the bath. FMRFA decreased both the amplitude of the EPSP and the duration of the SN spike (although the spike duration was still within the aforementioned range) compared to vehicle during the subsequent 5 spikes (n=8). The effects of 5-HT (20-25 µM) were then as

SEROTONIN REGULATES THE EXPRESSION OF mRNA IN THE PLEURAL-PEDAL GANGLIA OF APLYSIA, AS DETERMINED BY IN VITRO TRANSLATION. R.E. Zwartjes, M.T. Crow**, J.H. Byrne*, and A. Eskin. Dept. of Biochemistry, Univ. of Houston, 77204, and U. T. Med. School*, Houston, TX 77225.

The formation of long-term memories in Aplysia and other animals appears to be dependent upon translation of proteins and perhaps gene transcription. For example, in Aphysia, inhibitors of protein synthesis disrupt the induction of long-term sensitization, and the turnover of a number of proteins is modified by treatments that produce or mimic long-term sensitization (Castelucci, et al. 1988, 1989; Montarolo, et al., 1986; Eskin, et al., 1989; Barzilai, et al., 1989; Noel, et al., 1989). Moreover, transcription also appears to be required for the induction of long-term presynaptic facilitation (Montarolo, et al., 1986). To further test the hypothesis that long-term sensitization is induced via alterations in gene expression, we have begun to investigate whether mRNA expression is altered by training procedures. *In vitro* translation of mRNA is being used to

determine which messages are transcribed during the induction of learning.

PolyA⁺ RNA was extracted from control and matched experimental pleuralpedal ganglia just after treatment with serotonin (5-HT) for 1.5 hr. pedal ganglia just after treatment with serotonin (5-HT) for 1.5 hr. ⁵⁶S-methionine-labeled proteins were produced by *in vitro* translation of the RNA using a rabbit reticulocyte lysate. The proteins were analyzed by 2D-PAGE. Several hundred proteins were visible on the autoradiograms and the pattern of these proteins corresponded quite well with the pattern obtained from gels of proteins labeled in intact ganglia. The 5-HT treatment increased incorporation of methionine into 4 proteins. Therefore, 5-HT affected the expression of mRNA and it probably did so by increasing the levels of mRNA for these 4 proteins. This preparation and these techniques appear well suited for studying the role of gene expression in learning and memory.

246.15

EXTRA 'POST-TRAINING UNCONDITIONED STIMULI DO NOT DECREASE ASSOCIATIVE PLASTICITY IN A CELLULAR ANALOGUE OF CONTINGENCY IN APLYSIA. D.V. Buonomano and J.H. Byrne. Dept. of Neurobiology and Anatomy, Univ. of Texas Med. Sch., Houston, TX 77725. Mechanisms for simple forms of both nonassociative and associative learning have been analyzed in Aphysia. As an initial effort in extending these analyses to higher-order forms of associative learning we have used a neural analogue of classical conditioning to study contingency. Contingency influences associative learning in that it reflects the probability that the unconditioned stimulus (US) will be predicted by the conditioned stimulus (CS). In vertebrates, extra USs before, after or intermixed with training can decrease conditioning. Extra USs interspersed in a classical conditioning protocol also decrease associative learning in Aphysia. (Hawkins et al., 1986). As an initial approach to a cellular analysis of contingency we used a paradigm with extra post-training USs. The analogue is similar to that used previously for classical conditioning (Buonomano and Byrne, 1989). In the control group, two pleural sensory neurons (SN), which synapsed onto a common motor neuron (MN), were fired to establish baseline EPSPs. Training consisted of activating one SN (SN+, analogous to a CS+) with a 1 s train of pulses 400 ms before the onset of a 500 ms electric shock to nerve P9 or P8 (analogous to the US). The second SN (SN-, analogous to a CS-) was activated with the same parameters either 2.5 min before or after the shock. There were a total of 3 training trials with an interval of 5 min. The effect of training was examined by testing the connections 5 and 20 min after the last train of action potentials in each SN. The experimental group (extra USs) was similar to the control group except that 3 extra nerve shocks were administered at 5 min intervals between the 5 and 20 min posttest. EPSPs were expressed as a percent of pretest. Associative plasticity was defined as the diffe

SHORT-TERM AND LONG-TERM CHANGES OF PROTEINS IN SENSORY NEURONS OF APLYSIA PRODUCED BY AN IN VITRO ANALOGUE OF SENSITIZATION TRAINING F. Noel, A. Eskin, R. Homavoni and J.H. Byrne. Dept. of Neurobiol. & Anat., Univ. of Tex. Mcd. Sch., Houston, T.X 77224.

A critical difference between short- and long-term changes in Aplysia sensory neurons (SNs) induced by sensitization training or procedures that mimic sensitization training is that long-term, but not short-term changes require synthesis of proteins (Castellucci et al., 1989; Montarolo et al., 1989). To study the proteins involved in long-term sensitization, we developed an in vitro analogue that mimics behavioral training and consists of stimulating peripheral nerves. Nerve stimulation of peripheral nerves. Nerve stimulation of peripheral nerves. Nerve stimulation of peripheral nerves. Nerve stimulation for peripheral nerves. Nerve stimulation and produced changes of specific proteins of SNs (Goldsmith and Byrne, 1989; Noel et al., 1989). Most of these protein changes were similar to those produced by 5-HT or extend these studies we investigated changes of proteins that occurred 24 hr after stimulation and compared these changes with those observed just after stimulation.

For each experiment three experimental and matched control ganglia were placed into two separate chambers. The ganglia were exposed to "5-methionine for a 2 hr period starting ½ hr before stimulation for the short-term experiments (n=4) or 24 hr after stimulation for the short-term experiments (n=4) or 24 hr after stimulation for the short-term experiments (n=4) or 24 hr after stimulation and produced the proteins of the short-term experiments (n=4) or 24 hr after stimulation for the short-term experiments (n=4) or 24 hr after stimulation of the short-term experiments (n=4) or 24 hr after stimulation of rothe short-term experiments (n=4) or 25 hr after stimulation or the short-term experiments (n=4) or 5 hr after stimulation or the short-term experiments (n=4) or 5 hr after stimulation or t

NOVEL EFFECTS ON PROTEINS PRODUCED BY PAIRING SEROTONIN WITH DEPOLARIZATION. A. Eskin, F. Noel, U. Raju, R.G. Cook, M. Núñez-Regueiro, J.H. Byrne. Dept. of Biochem., Univ. of Houston, TX, 77204, and Dept of Neurobiol. & Anat., Univ. of Tex. Med. Sch., Houston, TX, 77204, and Dept of Neurobiol. & Anat., Univ. of Tex. Med. Sch., Houston, TX, 77205.

A mechanism for classical conditioning in Aphysia is believed to involve the convergence of activity in a neuron with the diffuse modulatory effects of a transmitter on that neuron. One way to mimic associative learning at the cellular level is to treat cells with a modulatory transmitter while the activity of the cell is increased with a depolarizing agent such as elevated potassium (high k*) (Ocorr et al., 1983). We have begin to investigate the effects of pairing high k* and S-HT to determine potential sites of interactions of second messenger systems upon proteins and to set the stage for studying proteins involved in associative learning.

Abdominal ganglia were subjected to 4 different conditions: 1) 1 hr of high k* (80 mM) alone: 2) 2 hr of 5-HT (6 µM) alone; 3) high k* paired with 5-HT with the high k* overlapping by ½ hr the 2 hr of 5-HT, 4) no freatment. The ganglia were incubated in *H-leucine for 2 hr beginning at a time corresponding to 5 hr after the end of the 5-HT treatment. After incubation, ganglia were processed for 2D PAGE. We focused on proteins in which pairing high k* and 5-HT produced different effects than those produced by a summation of the individual treatments. At least 3 proteins seemed to be affected in a non-additive way by the pairing procedure. The incorporation of label into 2 proteins (*#) and *#45) was decreased by 5-HT alone, was not affected by high k* alone, but was increased in response to the paired procedure. The other protein (*#2) was decreased by both high k* and 5-HT alone and was not affected by the paired procedure.

NEURAL MECHANISMS OF RESPONSE SPECIFICITY. I. TAIL AND MANTLE NERVE SHOCK PRODUCE DIFFERENTIAL EFFECTS ON THE SIPHON-WITHDRAWAL NEURONAL CIRCUIT IN APLYSIA. X. Fang and G. A. Clark. Program in Neuroscience, Princeton University, Princeton, NJ 08544. Both sensitization and classical conditioning of the siphon-withdrawal response in Aplysia exhibit response specificity. For example, the conditioned siphon-withdrawal response to a tactile siphon stimulus resembles the response to tail shock (tailward bending) when tail shock has been used as the unconditioned stimulus (US) during training, but resembles the response to mantle shock (bending toward the mantle) when mantle shock has been used as the US. Various neural mechanisms have been proposed to explain this effect, including synapse-specific facilitation in siphon sensory cells, changes as the US. Various neural mechanisms have been proposed to explain this effect, including synapse-specific facilitation in siphon sensory cells, changes in "labeled-line" interneurons, and changes in specific motor neurons. As an initial step toward investigating these possibilities, we examined the responses to tall and mantle nerve shock in various neural elements of the siphon-withdrawal circuit, including the LFS (Type B) and LBS siphon motor neurons, as well as the interneuron L25 of the Interneuron II (respiratory pumping) network. We found that LFS-B motor neurons (which move the siphon tallward when stimulated intracellularly) fired significantly more during tail nerve shock than during mantle nerve shock (p < .001), and were in fact often inhibited by the latter. In contrast, LBS motor neurons (which move the siphon toward the mantle when stimulated intracellularly) and interneuron L25 both showed strong the latter. In contrast, LBS motor neurons (which move the siphon toward the mantle when stimulated intracellularly) and interneuron L25 both showed strong excitation during mantle nerve shock, but only weak excitation and/or inhibition during tail nerve shock (p < .005 and p < .01, respectively). Moreover, mantle nerve shock produced a differential increase in the number of Interneuron II events occurring during the five minute post-shock period (p < .001). These results suggest that LFS-B motor neurons are preferentially involved in producing siphon-withdrawal responses elicited by tail shock, while LBS motor neurons are preferentially involved in responses elicited by mantle shock. In addition, the greater increase in Interneuron II events Following mentle pene. addition, the greater increase in Interneuron II events following mantle nerve shock may contribute in part to mantle-like response specificity.

Crowding Affects Sensitization in Aplysia. J. Flinn, S. Kurtz, L. Alexander*, S. West*. Dept. of Psychology, George Mason University, Fairfax, VA 22030.

Juvenile Aplysia were raised from 30 to 124 days post-metamorphosis in crowded or uncrowded conditions. The survival rate was 82% in the uncrowded and 60% in the crowded group. The weight range ~.5-24 gms was similar, with fewer midrange animals in the crowded group. Sensitization, using number of steps moved following tail shock, was examined for the 2 groups matched by weight over the range of greatest weight overlap, .5-12 gms. Uncrowded animals showed a sigonificant increase in escape behavior following sensitizing shock (t=4.04,df=15,p<.01) while crowded animals did not (t=1.13,df=15,ns). Both groups in this weight range showed a significant correlation between weight and sensitivities. sitization level, r=.52, r=.67,p<.05 respective-ly. 5HT levels were examined in a subset of animals using HPLC, at Am. Med. Labs. There was a significant correlation between sensitization and 5HT levels for the uncrowded r=.71,p<.05. but not the crowded group, r=.17, ns. These results show that animals of the same age showed different levels of learning depending on both weight and rearing conditions.

AGE AND CHRONIC STIMULATION AFFECT HEMOLYMPH PROTEINS IN APLYSIA, M.Srivatsan*, B. Hallahan*, B.Peretz, and R.Talwalker*. Dept. of Physiology, Univ. of Kentucky, Lexington KY 40536.

With increased age the gill withdrawal reflex (GWR) weakens in Aplysia. Paralleling the age effects on the GWR we now have found that with SDS-PAGE the band patterns of hemolymph (Hml) proteins changed with age. Of the many ent, 6 were prominent in Hml from young animals (shell diam. - 11 mm, 80 days old), with MWs from 14,000 to 300,000. Hml from mature (s.d. - 26 mm, 160 days old) and old (s.d. - 59 mm, 240 days old) animals had fewer prominent bands, only 4 and 3, respectively; MWs were from 45,000 to 300,000. Two bands common to all three ages differed quantitatively. The topmost band of 300,000 was hemocyanin; the other prominent bands were not breakdown products of hemocyanin. Possibly changes of some Hml proteins are related to those of the GWR; factors in Hml can alter the responsiveness of the GWR (e.g. Lukowiak, Neurosci. Lett., 77:205,1987). In old Aplysia chronic stimulation (ChSt) of the siphon over a period of 4 weeks improved the GWR and its substrates (Zolman & Peretz, Behav, Neurosci., 101:1,1987). Taken together these results prompted us to examine the effects of Ch5t on Hml proteins. Freely behaving mature and old adults underwent Ch5t (1 sec., 8g/cm² water jet; applied 1/20 min., 10/day) for 4 weeks. Hml was drawn weekly before, during, and after the Ch5t period. Mature and old animals showed a significant change in the GWR after the ChSt period. Results from SDS-PAGE showed that one prominent band of ca 97,000 MW, which was well defined in unstimulated mature animals and poorly defined in old animals, increased in Hml from ChSt animals but not from a control group. Thus far no significant increase in the concentration of Hml proteins was measured. Yet, enhancement of the 97,000 MW band in both age groups suggests that ChSt may have triggered its increased synthesis, resulting in a redistribution of protein

246.21

THE EFFECTS OF THE FOOD AROUSAL NEURON CPR ON ANTERIOR POSTURAL MUSCLES INVOLVED IN FEEDING IN APLYSIA.

I. Nagahama*. T. Teyke*. K.R. Weiss and I. Kupfermann.
Center Neurobiology and Behavior, Columbia University and NYS Psychiat. Inst., New York, N.Y. 10032.

The cerebral neuron CPR may function as a command element for the complex food-induced arousal state in Aplysia. We previously reported that firing the CPR evokes bilateral contractions of the neck muscles, which could serve to lift the head of the animal into the feeding posture, the most apparent manifestation of food arousal. We now report that CPR activity increases activity in pedal nerves, particularly those innervating the anterior part of the body. Firing the CPR produced weak movements of the anterior foot region (via anterior foot nerve P1), which appear to relax the tissue. We found different types of neurons with axons in nerve P1. One type received monosynaptic EPSPs from the CPR. Firing these cells, however, did not cause contractions of the muscles. A second group of neurons, which contracted the anterior foot, received polysynaptic inhibitory input, which decreased their spontaneous activity, and may relax the muscles. Furthermore, contractions of the anterior foot, which were evoked by firing one of these motoneurons, were altered after the CPR was fired, indicating that the CPR also has indirect modulatory effects. In contrast, motoneurons which innervate the neck muscles (via nerve P4) received polysynaptic EPSPs from the CPR, and in some cases, brief stimulation of the CPR produced prolonged excitation of these neurons. These results indicate that the CPR can promote different types of motor effects by virtue of its connections to pedal motoneurons. First, CPR activity may promote relaxation of the anterior portion of the foot, which could serve to detach the foot from the substrate. Second, it may also cause contractions of the neck muscles which lift the head. Both motor effects are consistent with the notion that the CPR is involve

INDUCTION OF AN IMMUNE REACTION IN <u>APLYSIA</u> IS ACCOMPANIED BY LONG-TERM ENHANCEMENT OF SENSORY NEURON EXCITABILITY. <u>H.Alizadeh, A.L.Clatworthy, G.A.Castro, and E.T. Walters.</u> Dept. of Physiology & Cell Biology, Univ. Texas Medical School, Houston, TX 77225. Stress elicits integrated responses of the nervous and immune systems in many species. Long-term sensitization

Stress elicits integrated responses of the nervous and immune systems in many species. Long-term sensitization in <u>Aplysia</u> is produced by cutaneous shock, which mimics afferent input from peripheral injury. Because injury activates the molluscan immune system, factors released from immunocytes might contribute to the sensory changes involved in long-term sensitization. We induced an immune response by implanting a cotton string in the hemocoel under MgCl₂ anesthesia. The string was looped around either the left or right pedal nerves. One week around either the left or right pedal nerves. One week later, when string and nerves were thickly encapsulated by amoebocytes, 5-12 VC sensory neurons per pleural ganglion (with axons in pedal nerves) were stimulated intracellularly with 1 sec depolarizing pulses to test excitability of the soma. Mean responses of somata on the encapsulated side were significantly greater (p<.05) than responses on the contralateral side (14.9 vs. 8.8 spikes; n=12 animals), or in somata of sham-operated (7.8 spikes, n=11) or naive animals' (11.2 spikes, n=15). This suggests that defensive encapsulation causes a long-term enhancement of excitability of nearby sensory neurons, while surgical trauma decreases excitability of sensory neurons with receptive fields distant from the incision.

Aplysia's feeding apparatus modulates its force output in response to changes in mechanical load. II. J. Chiel, N. Weiner, M. Bamberger and D. W. Morton, Depts. of Biology, Neuroscience, and Mechanical and Aerospace Engineering, Case Western Reserve University, Cleveland, OH 44106.

Sensory inputs can have a profound impact on the rhythmic behaviors of animals. We have studied the ability of *Aplysia californica* to rapidly adapt its feeding behavior in response to changes in mechanical loads similar to those that it encounters behavior in response to changes in mechanical loads similar to those that it encounters in its natural habitat. We initially studied the responses of animals to two different seawceds on which it feeds. Laurencia and Ulva. The seawceds were attached to a force transducer, and the forces generated by animals were recorded while their behavior was videotaped. We observed significant variations in the force output by the animals in response to natural seawced. In order to quantify the response to a defined mechanical load, we have devised two techniques to measure forces generated during feeding: an "artificial seawced" consisting of a piece of canvas dipped in seawced extract and attached to a force transducer, and a pair of forceps to which strain gauges are attached. Animals were induced to swallow these stimuli, and their force output was measured while they were videotaped. Even though these were fixed mechanical loads, animals' responses were far more irregular than when their feeding apparatus was unloaded, which occurred when they attempted to bite, but were not allowed to consume food. Extracellular recordings from buccal nerves 1, 2, and 3 in intact animals provided evidence for rapid changes in the output of the neural allowed to consume food. Extracellular recordings from buccal nerves 1, 2, and 3 in intact animals provided evidence for rapid changes in the output of the neural controller for feeding in response to loads. Lesions of the cartilage of the jaws significantly reduced the ability of animals to "clamp down" on large mechanical loads, and to exert pulling forces. In contrast, lesions of buccal nerve 2, which innervates the jaws and provides sensory feedback to the buccal ganglion, reduced the animal's ability to clamp down, but animals showed increased pulling forces. These studies provide a basis for determining the neural correlates of adaptation to changes in mechanical load. [Supported by NSF grant BNS-8810757 to H.J.C.]

A MODEL OF DECISION-MAKING IN *APLYSIA FASCIATA*. I. Ziv*, C. Lustig* & A.J. Suswein, Dept Life Sci, Bar-llan Univ., Ramat Gan 52 900, Israel
To begin studying the neural basis of decision-making in *Aplysia*, we examined rules governing transitions between bouts of behaviors. Over 85% of transitions were via a single intermediate behavior, moving in place (MIP; consisting of head-waving, and similar activities), which tended to precede and follow crawling, swimming, immobile and feeding. After MIP, animals generally return to the behavior performed before MIP. Additional preferred sequences were countship to mating, and crawling to swimming.
The large number of transitions via MIP suggest that MIP is a behavioral correlate of decision-making *per se*. If this is so, since animals must return to MIP to decide after most bouts of other behaviors, MIP should always represent a fixed proportion of all bouts. When observation conditions were modified by adding or removing food or mates, the number of bouts of other behaviors varied markedly, while MIP always represented ~40% of all bouts.

include a lated proportion of all bodds. When observation continuous were modified by adding or removing food or mates, the number of bouts of other behaviors varied markedly, while MIP always represented ~40% of all bouts. Previous data suggested that feeding and mating are regulated by a common arousal (CA) mechanism that plays a major role in governing the time budget. If MIP is a behavioral monitor of decision-making, MIP and CA level should be significantly correlated. Formulas were developed to estimate the CA level, based on overall time spent feeding and/or mating. We then found a significant correlation (r=0.84) between CA and a normalized measure of MIP. Thus, MIP may be a behavioral monitor of CA.

A 1/day oscillator affects various behaviors. CA and MIP do not show a daily oscillation, suggesting that the daily oscillator affects other levels of behavioral control, perhaps transition probabilty from MIP to affected behaviors. A simulation can test whether integration over a full day of variability in CA, and change in transition probability, account for time devoted to each behavior, and specific times that behaviors are seen.

Muscles, nerves and neural circuits responsible for generating head-waving, a form of MIP, have been identified. This circuitry may be partially responsible for decision-making, raising the exciting possibility that the neural basis of higher-order decision-making in Aplysia will be accessible to analysis.

BEHAVIORAL CHANGES AFTER RIGHT AND LEFT CAUDATE LESIONS IN RHESUS MONKEYS. J.B.Bryer*, S.E. Starkstein, R. Richardson, J.P. Fedoroff*, J. Higley*, T.H. Moran, M. DeLong, R.G. Robinson, Dept. Psychiatry, Johns Hopkins Univ. Sch. Med., Balto., MD 21205.

Recent studies have demonstrated that patients with lesions in the head of the left caudate show a high frequency of depression. Right caudate lesions, however, produce indifference, euphoria, and even manic states. The aim of our study was to examine whether similar lesions in non-human primates produce similar behavioral changes The behavior of two male adult rhesus monkeys was recorded over a 6 month baseline period. Behaviors included locomotion, exploration, play, autoeroticism, stereotypy, passivity, and huddling. Both monkeys were given sham lesions followed, four weeks later, by either left (ibotenic acid) or right (radiofrequency) lesion of the head of the caudate. Neither of the monkeys showed significant behavioral changes after the sham surgery. The left head of the caudate lesion produced huddling behavior (a behavioral equivalent of depression in primates), that lasted for 6 weeks post-surgery. This was primates), that lasted for 6 weeks post-surgery. This was accompanied by weight loss, and a decrease in exploration and autoeroticism (less than 50% of the baseline values). The right head of the caudate lesion did not result in huddling, but produced repetitive locomotor activity (up 100% from baseline values), that lasted more than 6 weeks. This preliminary study suggests that a significant association between behavioral changes and side of lesion exists in both burson and one human primates. exists in both human and non-human primates.

RAT 22 KHZ ULTRASOUNDS TO PREDATORS: ALARM CRIES? R.J. Blanchard, D.C. Blanchard, S. Weiss* and R. Agullana Dept. of Psychology and Bekesy Lab. of Neurobiology, Univ. of Hawaii, Honolulu, HI 96822

Laboratory rats maintained in mixed-sex groups in a visible burrow situation (VBS) emit 22 kHz ultrasonic vocalizations when a nonattacking cat is presented in the open area of this habitat. One or more colony animals vocalized about 50% of the time while the cat was present and during the first 30 min. after the cat was removed, reliably more than when a plush toy cat was presented. During the high vocalization period virtually all group

animals remained in the tunnel/chamber system of the VBS.
When individual rats were confronted by the cat in an open area of similar size, they averaged only 10 sec. of ultrasonic vocalization in the 45-min cat and post-cat period, suggesting that concealment in a burrow system facilitates anti-predator ultrasonic vocalization, and/or that it may function primarily as a warning cry directed at conspecifics. The latter possibility is strengthened by preliminary studies suggesting that concealed group members not in visual contact with the cat, including pups as young as 4 weeks, may show recruitment of ultrasonic vocalization and subsequent changes in defensive behaviors. Ultrasonic vocalization may thus be an important mechanism for communicating the presence of a threat stimulus within social rat groups. The effects of and diazepam on these behaviors will be presented. The effects of ethanol

SEPTAL LESIONS INHIBIT FEAR REACTIONS IN THE ELEVATED PLUS-MAZE. C. Pesold* and D. Treit. University of Alberta, Canada T6G 2E9.

Recent research in our laboratory has shown that electrolytic lesions of the posterior (but not anterior) septum reduce fear reactions in animal tests of anxiolytic drug action (e.g., significant increases in rats' open arm activity in the elevated plus-maze). The purpose of the present experiment was to further characterize the neuroanatomical specificity of these anxiolytic-like effects by comparing kainic acid septal lesions to electrolytic septal lesions in the plusmaze test. Following sodium pentobarbital anaesthesia, rats were given either kainic acid, electrolytic, or sham lesions of the posterior septum and then tested 15 days later in the elevated plus maze. Both kainic acid and electrolytic lesioned animals showed significant increases in open arm activity compared to sham-lesioned controls. These results provide further evidence that posterior regions of the septum play an important role in the control of anxiety in the rat.

247 2

ENHANCEMENT OF GABA NEUROTRANSMISSION IN THE CARDIOSTIMU-LATORY REGION OF THE POSTERIOR HYPOTHALAMUS HAS ANXIO-LYTIC EFFECTS IN THE ELEVATED PLUS-MAZE. A. Shekhar and L. L. Sims*, Dept. of Psychiatry, Indiana Univ. Sch. of Med. Indianapolis, IN 46202. Blockade of GABA in the region of the posterior hypo-

thalamus (PH) of rats elicits a constellation of responses characterized by increases in heart rate (HR), blood pressure (BP), respiratory rate (RR), locomotor activity and the level of "anxiety" in the conflict test. The aim of the present study was to test the effect of enhancing GABA in the PH on the elevated plus-maze model of "anx-iety." Male Sprague-dawley rats with arterial and venous catheters in place for physiological measurements were implanted bilaterally with chronic microinjection cannulae in the region of the PH where bicuculline methiodide (25 ng/250 nl) elicited significant increases in HR and RR. After recovery, the effects of microinjecting saline and muscimol (1, 5 & 10 ng/250 nl) bilaterally into the PH in the elevated plus-maze were as follows: Treatment n Time-open arm (sec) Time-closed arm (sec) 42 ± 12 98 ± 17* 218 + 19 126 + 32*Musci.10ng 5 (*Significantly different from saline by ANOVA, P 0.05)
In addition, microinjection of muscimol attenuated the increases in HR and BP observed in the elevated plus-maze. These results suggest that enhancing GABA in the PH decreases anxiety. (Supported by R29 MH 45362-01).

SUBORDINATION AS AN ANIMAL MODEL OF DEPRESSION.

SUBORDINATION AS AN ANIMAL MODEL OF DEPRESSION.
D. C. Blanchard, R. J. Blanchard, R. Hammer, D. Clow, M. Bardo, and J. K. Rowlett. Békésy Lab. of Neurobiology, and Dept. of Psychology, Univ. of Hawaii, Honolulu, HI 96822.
Good animal models of human psychopathology make it possible to isolate behavior patterns and analyze their origins, pathophysiology and responsiveness to treatment techniques. Ethoexperimental analysis of social and agonistic interactions in rat groups in semi-natural burrowing situations has revealed complex patterns of behavior change for subordinate males, including increased alcohol intake, reduced social, sexual and aggressive activity, restriction of locomotor and exploratory activity, changes in sleep cycles, weight loss associated with lowered changes in sleep cycles, weight loss associated with lowered food intake, and impaired information processing, which appear to be isomorphic to the behavioral symptomatology of clinical depression. The magnitude of these changes clinical depression. The magnitude of these changes predicts early subordinate mortality as much as 200 days before death. This analysis provides a subordination model enabling experimental evaluation of the view that downward mobility in dominance hierarchies is a major experiential determinant of depression, also enabling detailed analysis of associated changes in brain regional neurochemical systems to elucidate the neurobiology of defensive patterns related to depression. We report increased regional 5.14 related to depression. We report increased regional 5-HT metabolism as indexed by levels of its major metabolite, 5-HIAA, in a number of brain areas from cortex to spinal cord, in subordinates relative to dominants or controls.

PRE- AND SUBTENTORIAL PERIAQUEDUCTAL GREY OF THE RAT MEDIATES DIFFERENT DEFENSE RESPONSES ASSOCIATED WITH HYPERTENSION K.A. Keay A. Depaulis* M.J. Breakspear and R. Bandler, Dept of Anatomy University of Sydney NSW Australia 2006. *DNBC Centre de Neurochimie du CNRS 67084 Strasbourg, France.

The midbrain periaqueductal grey (PAG) of the cat mediates two distinct behavioral and cardiovascular patterns of defense; threat display and flight, which are evoked from the pre- and subtentorial regions respectively. These responses resemble those evoked by natural stimuli in the freely moving cat. This raised the question, does a similar functional organization exist within the PAG of the rat? Two types of experiment were performed. A) Rats were prepared with chronic intracranial implants and, in the presence of another rat, the behavioural effects of microinjections of small doses (40 pmol) of kainic acid (KA) into the PAG were observed. B) Rats were decerebrated at a precollicular level and the effect of microinjections of DL-homocysteic acid (DLH 10mmols) on blood pressure and heart rate were observed. The decerebrate preparation precollicular level and the effect of microinjections of DL-homocysteic acid (DLH 10nmols) on blood pressure and heart rate were observed. The decerebrate preparation allowed the observation of both behavioural and cardiovascular variables without the interference of anesthesia. The data showed the following: 1) KA microinjections into the lateral pretentorial PAG of the freely moving rat evoked, in response to the approach of another rat, defensive upright postures and backing away from the partner; whereas, injections into the lateral <u>subtentorial</u> region evoked vigorous forward locomotion away from the partner. 2) DLH microinjections in the lateral pretentorial and subtential PAG of the decempents at audical lateral precessors approached. and subtentional PAG of the decerebrate rat evoked large pressor responses (+20% to +200%) accompanied by increases in heart rate. In addition, pretentorial PAG pressor responses were accompanied by "hunching" of the back and limb movements which were directed to push the animal backwards, whereas subtentorially, vigorous running movements were associated with the pressor responses. At many sites in the pretentorial region sonic vocalizations were also observed; these were rarely encountered pretentional region some vocalizations were also observed, these were largely entered in the subtentional region. These data indicate that the PAG of the rat controls two different types of defensive movements which are accompanied by pressor responses and tachycardia and suggests that the rat PAG may be organized functionally in a similar manner to that of the cat. (Supported by: NHMRC (Aust) and H.F.Guggenheim Fdn.)

ALARM RESPONSES IN ADULT SQUIRREL MONKEYS: GENDER DIFFERENCES AND STIMULUS SPECIFICITY. L. J. Crepeau and J. D. Newman Laboratory of Comparative Ethology, NICHD, NIH, Poolesville, MD 20837-0289.

Laboratory of Comparative Ethology, NICHID, NIH, Poolesville, MD 20837-0289.

Captive squirrel monkeys (Saimir) respond to alarming stimuli by modulating locomotor activity and vocalization rates. Alarm reactions of adult squirrel monkeys are mediated by cholinergic mechanisms (Glowa and Newman, Psychopharm 90: 457-460, 1986). We evaluated the relative potency of various stimuli to elicit alarm in the presence and absence of the central muscarinic antagonist benactyzine hydrochloride (BNZ) using socially-housed adult animals (6 males, 5 females). Animals received BNZ (2 mg/kg) or whicle a.e. 5 min prior to a 15 min isolation test, followed by alarm testing, Animals were presented with an alarm stimulus series twice per test session. The alarm stimulus series included: mirror-reflected self image (MIR); a large hand monkey puppet covered with synthetic für (PUP), a capterimenter 2 (EXPZ); and both experimenters (BOTH), facing the subject with a raised gloved hand. Inamirates timuli were presented for 30 sec without ISIs.

In isolation, undrugged males exhibited higher levels of isolation peps (IPs) and locomotion (LOC), indicated by test cage quadrant changes. Benactyzine eliminated this difference, and the two sexes were essentially identical following BNZ administration.

During stimulus presentation, undrugged males exhibited higher LOC levels, in a stimulus-specific manner. Male LOC levels were highest during PUP, GLO, & EXPL, moderate during MIR, NET, & EXPL2, and low during ISI & BOTH trials. Female LOC levels creamed low across all stimulus trials. Benactyzine eliminated this difference, and the two sexes were essentially identical following BNZ administration.

During stimulus presentation, undrugged males exhibited higher LOC levels, in a stimulus-specific manner. Male LOC levels were highest than male rates during EVP, GLO, & EXPL, moderate during BNZ administration. However, undrugged females exhibited higher levels of alarm calling attes in a stimulus-specific manner, as well as reliably lower levels

5HT1A RECEPTOR MODULATION AND SEPARATION DISTRESS IN DOMESTIC CHICKS. L. Normansell and J. Panksepp.
Muskingum College, New Concord, OH and Bowling Green State

University, Bowling Green, OH.
A series of experiments was conducted to evaluate the A series of experiments was conducted to evaluate the role of the 5HTIA receptor in the control of separation induced distress vocalization (DV) in chicks. Following i.p. injection of buspirone (1 & 5mg/kg), isolated chicks vocalized 3 times more often than control animals when tested in boxes containing mirrored inserts which normally act to suppress DVs. In plain boxes, BUS-treated normally act to suppress DVs. In plain boxes, bus-treater birds did not differ from controls. This effect was dose dependent and was apparent over the first 30 min of testing. Administration of lmg/kg 8-OH-DPAT produced an effect essentially identical to the high dose of BUS. Central injection of BUS (5 or 25µg administered free-hand into the vicinity of the 4th ventricle) also led to deep dependent interests in DVs in the riburate boxes.

dose-dependent increases in DVs in the mirrored boxes, whereas central DPAT (1,5, or 10µg) reduced DVs in both the mirrored and plain testing boxes.

Chicks injected 3 times per day with 1mg/kg BUS and tested for 4 days showed no indication of the development of tolerance. Chicks repeatedly injected with 5ug DPAT and tested (4 injections, once every 45 min) also showed no tolerance.

Both BUS and DPAT showed anxiolytic activity in a novel test of fear. The latency to jump from an elevated platform to rejoin the flock was reduced with either drug.

SOCIAL-ISOLATION INDUCED DESPAIR IN CHICKS AND MICE: SIMPLE ANIMAL MODELS OF REACTIVE DEPRESSION. J. Pankseco. G. Yates*. E. Nelson*. S. Ikemoto* and R. Conner*. Department of Psychology, Bowling Green State University, Bowling Green, OH 43403
Despair following social isolation promotes depression. Simplified animal models of isolation-induced despair useful psychobiological research remain to be developed. In this work, we eavaluted effects of social isolation on swimming

performance of young mice and distress vocalizations (DVs) of young chicks.

Previous work has failed to observe potentiation of despair-like immobility in the Porsolt swimming test following social isolation in adult Swiss mice (Hilakivi, et al. (1989) *Pharmacol Biochem Behav, 33*: 371). In the present work, a single day of social isolation was sufficient to increase immobility by > 500% in 17 - 18 day old Swiss-Webster mice but the effect dissapeared by 26 days of age. The effect was amplified by prolonged 15 min tests as compared to standard 5 min tests, and required a larger test chamber than traditionally used in this test. In short, the mouse exhibits only short periods of robust sensitivity to social loss. Individual housing of chicks at 1 (but not 5) days of age yielded a failure to

thrive syndrome resembling "anaclitic depression" in one third of our animals. Protest gradually diminishes following chronic social isolation, and this index of despair is potentiated more by low doses of reserpine (0.25-0.5 mg/kg) in isolated as compared to socially housed birds. During this despair phase, imipramine (5-10 mg/kg) was selectively effective in elevating DVs which had been reduced by reserpine. In socially housed animals, imipramine could also counteract the decline in DVs that normally occurs during extended periods of separation testing (e.g., 2-5 hrs). These findings suggest that one can obtain social-isolation induced despair effects in various lower animals. Such simplified models of protest, despair and depression may be useful in pursuing basic neuroscience issues that cannot be readily pursued in available primate models.

FUNCTIONAL MAPPING OF THE RAT BRAIN DURING VOCALIZATIONS: A 2-DEOXYGLUCOSE STUDY.

R.J. Frysztak & F. Gonzalez-Lima, Department of Anatomy,
College of Medicine, Texas A&M Univ, College Station, TX 77843
Autoradiographic [1°C] 2-deoxyglucose (2-DG) procedures were used to map the functional activity in the CNS during vocalizations elicited by electrical stimulation of the midbrain reticular formation (MRF) in behaving rats. Six male albino rats weighing 180-200g were used. Following injection of 2-DG, three rats received MRF stimulation through two stainless steel electrodes (0.5s duration, 40Hz, 0.2ms pulses) using irregular intervals (range 5-10s) over 90 min. Yoked controls received 2-DG injection followed by playback of the recorded vocalizations. Relative differences in peak isotope uptake (gray/white matter ratios) in 23 structures related to vocalization were compared between the two groups.

The major findings in this study were localized to hypothalamus, midbrain and brainstem structures. Significant increases in 2-DG uptake were noted in the following structures in MRF stimulated rats: dorsolateral central gray (PAG), MRF, lateral hypothalamus (LH), ventromedial hypothalamus (VmH), paraventricular nucleus (PVN) and nucleus ambiguus (NA). Cortical structures were not activated during MRF stimulation. The PAG and NA are known to be important relays in the production of vocalizations. The PAG is known to receive input from 'higher' vocalization centers such as the hypothalamus, amygdala and anterior limbic cortex, as well as the MRF. Additionally, LH, VmH and PVN have reciprocal connections with the PAG and have been previously associated with emotional states which induce vocalization. Stimulation of the MRF, therefore, may have resulted in the excitation of these areas. The laryngeal, pharyngeal and soft palate muscles are innervated by motoneurons in the NA, with the laryngeal motoneurons being located in the caudal two-thirds of the nucleus. MRF stimulation, therefore, activates the motor output pathways for vocalization, but does not appear to activate cortical and limbic motivational centers. (Supported by NIMH grant RO1-MH43353)

A POSSIBLE NEURAL SUBSTRATE FOR GENDER DIFFERENCES IN VOCAL BEHAVIOR BY RHESUS MACAQUE INFANTS DURING BRIEF PERIODS OF SOCIAL SEPARATION. I.D. Newman. J. Bachevalier. M. Michieda and S.J. Suomi. Lab. of Comparative Ethology, NICHD, NIH and *Lab. of Neuropsychology, NIMH, Bethesda, MD 20892.

During infancy, rhesus macaques (Macaca mulatta) exhibit a pronounced vocal

response to separation from familiar conspecifics, frequently used as a behavioral measure in previous studies of the physiological correlates of separation distress. While there is little information regarding the neural substrate mediating production while there is little information regarding the neural substrate mediating production of isolation calls in infant macaques, a previous study (Newman and Bachevalier, Neurosci.Abstr., 14. 1988) indicated that the amygdala might be involved in regulating the affective quality of separation-induced coos.' To investigate further the neural substrate of this behavior, we recorded vocalizations during brief periods of social separation in three groups of infant monkeys. Subjects, all less than one year of age, consisted of a group of 8 males and 5 females that had received neonatal bilateral ablations of the anterior inferotemporal cortical area TE, a group of 2 males and 4 females subjected to fetal hydrocephalus induced by injections of 10 mg/kg triamcinolone acetonide to pregnant females at 20-24 days gestation followed by corrective shunt surgery prior to delivery, and a control group of 10 males and 6 females which received only sham operations. All vocalizations during the 5 minutes following the first vocal utterance were viewed with a real-time sound spectrograph and classified as a 'coo', 'leap,' or 'scream' according to their detailed acoustic characteristics. Statistically significant differences between males and females occurred in the control group, with males making fewer noisy vocalizations (leaps and screams). This gender difference did not exist in either experimental group, where males and females both made more noisy vocalizations than control males. We conclude that the inferotemporal cortex may be part of a neural system important in determining gender differences in the vocal response to social separation by infant monkeys.

OLFACTORY BULBECTOMY AND ZONA INCERTA LESIONS ELIMINATE MATING IN MALE RATS: PARTNER-PREFERENCE TESTS DISCRIMINATE EFFECTS ON SEXUAL MOTIVATION AND SEXUAL PERFORMANCE. C. Tardivel, K. T. Griffis, S. D. Isaacs and D. A. Edwards.

Dept. of Psychology, Emory University, Atlanta, GA 30322.

Brain damage may affect the ability to perform the movements of copulation without necessarily affecting sexual motivation. Sexually active male rats prefer sexually receptive females to nonreceptive females, and partner-preference tests provide one measure of sexual motivation. Control and brain-damaged male rats were tested in an arena where the male could choose to spend time with (and mate with) a sexually receptive female, a nonreceptive female, or be in a neutral

After surgery, olfactory bulbectomized males did not mate. They showed no preference for a receptive female, spending their time equally between the receptive female and the nonreceptive female. Bulbectomized males almost never mounted, and episodes of anogenital investigation were rare.

After surgery, males with zona incerta lesions did not mate. Lesioned males continued to show a strong preference for a receptive female over a nonreceptive female. Although lesioned males did not mount females in the usual sense, mounts (invariably directed at the receptive female) without pelvic thrusting or palpation were common. Lesioned males showed frequent anogenital investigation of the receptive female.

Taking partner preference as a measure of sexual interest, olfactory bulbectomy is associated with a dramatic decrease in sexual motivation. In contrast, males with zona incerta lesions show a strong preference for receptive females, and the failure of lesioned males to mate presumably refects an inability to engage the ocomotor responses required for copulation. Supported by NSF grant BNS-8718797.

VENTRAL SOMATOSENSORY DETERMINANTS OF NURSING BEHAVIOR IN VENTRAL SUMATUSENSORI DELECTIONAL STREET STR

Psychology, Rutgers University, New Brunswick, NJ 08903.

By manipulating the quality and quantity of pups, Stern & Johnson showed that ventral stimulation from rooting and suckling pups causes the dam to become immobile and to flex her ventrum, resulting in a high crouch (Physiol. Behav., 14(5), 1990). We now show that a full litter of capable pups cannot effectively stimulate nursing behavior in dams without nipples or with their ventrum anesthetized.

In Expt. 1, nipples were removed (thelectomy) on day 7 of gestation; postpartum, litters were rotated daily with shamoperated controls and with a donor 9. In Expt. 2, all 12 nipples were anesthetized with 0.2 ml sc 0.375% bupivicaine nipples were anesthetized with 0.2 ml sc 0.375 bupivicathe (Sensorcaine, Astra) (which blocks milk-ejection) and in Expt. 3, all nipples + 4 mid-ventrum sites were anesthestized (0.28%); controls received Sensorcaine ip or saline injections of ventrum. Maternal behavior was observed for 30 min continuously following a dam-litter separation of 2 hr (on day 4, Expt. 1) or 4 hr (on day 7, Expts. 2 and 3) and at intervals up to 2 hr. In experimental dams, the high crouch posture was not observed and only a small portion of them became immobile, after a much longer latency than in controls, while retrieval and licking were normal. Thus, immobility and ventroflexion are dependent upon ventral somatosensory afferents, particularly from nipples.

PARADOXICAL EFFECTS OF MORPHINE AND NALOXONE ON PREFERENCE FOR SACCHARIN AS A FUNCTION OF SACCHARIN CONCENTRATION.

K.Akarid*, K. Touzani* and L.Velley, Lab. Psychophysiologie, URA CNRS 339, Univ. Bordeaux I, Av. Facultés 33405 Talence France.

The aim of this study was to further analyse our recent observation that, in rats, a moderate dose of morphine may induce either an increase or a decrease in preference for saccharin, the

direction of change depending on the concentration of the sweetener.

In a series of experiments, with drug administered subcutaneously, we studied the effects of increasing doses of morphine (0.1, 0.3 and 1 mg/kg) and naloxone (0.01, 0.1 and 1 mg/kg) on rats placed in a two-bottle choice task between water and one of three (0.3, 1 and 1.7 mM) saccharin concentrations. The results showed that, when the saccharin concentration was around the threshold value for mykg) acted in a direction opposite to their classically observed effects i.e. as an apparent antagonist and agonist respectively.

In an attempt to define the brain sites where these paradoxical

effects are mediated we tested the effects of increasing doses of morphine (50-800 ng) and methylnaloxonium (50-250 ng) directly injected into parabrachial area, the second gustatory relay-station. The results obtained using intracerebral injections were analogous to those obtained using subcutaneous administration. Considered together, these data suggest that the paradoxical effect could result either from stimulation of autoreceptors or from a differential influence on opioid receptor sub-types.

247.17

REWARDING AND REINFORCING EFFECTS OF DRINKING SUCROSE: ROLE OF OPIOIDS AND DOPAMINE. A. Galvan*, B. L. Talamantes* and A. Agmo. Dept. of Psychology, Universided Aná-huac, México City.

It has been proposed that place preference conditioning is a 3 stage process. First, the reinforcing event must produce an affective arousal. Second, this affective arousal must become associated with environmental stimuli. Third, this association must be remembered. The first stage corresponds to reward, and the third to reinforce ment. The purpose of the present studies was to evaluate

the neurochemical basis of these stages.

Male rats were trained to drink 18% sucrose in water in a lickometer apparatus. They were allowed to make 2000 licks or 15 min exposure to the sucrose solution, whichever occurred first. Immediatly after they were transferred to place preference cages for 30 min. Conditioning consisted of 3 reinforced and 3 nonreinforced sessions.

Sucrose produced a clear place preference. This was completely blocked by cis(z)-flupentixol, 0.5 mg/kg. The drug did not affect sucrose consumption. Naloxone, 16 mg/kg, not only blocked the place preference produced by sucrose drinking, but also induced place aversion. Sucrose consumption was drastically reduced. Indeed, drinking was similar to that observed in animals given plain water instead of sucrose.

These data suggest that opioid mechanisms are involved in reward and dopamine is critical for reinforcement.

247.14

ANTINOCICEPTION PRODUCED BY MATERNAL CONTACT IN INFANT RATS IS NOT MEDIATED BY MU RECEPTORS. D.J. Shide INFANT RATS IS NOT MEDIATED BY MU RECEPTORS. <u>D.J. Sinde and E.M. Blass.</u> Dept. of Psychology, Johns Hopkins Univ., Baltimore, MD 21218. The following experiments examined analgesia produced through maternal contact, and interactions between contact and gustatory stimulation. In Exp. 1, 10-day-old Sprague-Dawley rat pups were tested for responsivity to a focal thermal stimulus (45, 48, or 51°C; 0.3 cm diam.) across four contact conditions: individual isolation; housed with siblings; non-nutritive suckling; and suckling while receiving an infusion of milk through a tongue cannula. Withdrawal latential and the state of the control cy (WL) was defined as the latency with which a rat removed its head from the heat source. The first two WLs were averaged to represent the baseline (BL). After BL was determined for the last pup all rats were injected with naltrexone (1.0 mg/kg), and WLs were sampled 20 and 40 min after injection. Initial contact BLs differed significantly across the treatment groups (48°C). Isolated pups averaged 7 sec; contact with siblings essentially doubled this to 16 sec. WL increased to 33 sec in suckling pups, and to 85 sec in pups tested during infusion, a tenfold increase compared to isolates. Naltrexone had no significant effect on WLs at either 20 or 40 min postinjection. In Exp. 2, Day 10 pups were placed in one of four contact conditions: individual isolation; group housed; contact with the mother (no suckling); and non-nutritive suckling. After baseline WLs were obtained pups received an intraoral infusion (0.06 ml/min for 3 min) of either distilled water, 7.5% sucrose, or no substance. WLs were determined 0, 3, 6, 9 and 12 min after infusion termination. As in Exp. 1, initial BL WLs differed according to the type of contact; isolates averaged about 8 sec, contact with siblings or the dam increased this to 16 sec, while suckling pups averaged around 30 sec. WLs also differed according to infusion; pups receiving infusions of sucrose were significantly more analgesic than water-infused or no infusion controls. Sucrose was most effective in isolated rats, least in suckling rats.

247.16

PIMOZIDE DOES NOT BLOCK THE CONDITIONED INCENTIVE MOTIVATIONAL EFFECTS OF FOOD-RELATED STIMULI. J.C. Horvitz and A. Ettenberg. Dept. of Psych., U. of Calif.,

Santa Barbara, CA 93106.

Hungry rats were exposed to a LIGHT stimulus just prior to the delivery of their stimulus just prior to the delivery of their daily food. After approximately one month of these daily LIGHT-FOOD pairings, animals were treated with either 0, 0.5, 0.75 or 1.0 mg/kg of dopamine antagonist pimozide, and the (CS) was presented alone. Locomotor activity was measured during 10 minute intervals both before and after CS presentation. While pimozide produced a dose-dependent suppression of overall activity levels, the incentive motivational effects of the food-related stimulus appeared Both vehicle and pimozide unaffected. Both vehicle and pimozide-treated animals showed dramatic increases in locomotor activity following CS presentation; for all groups, activity during CS presentation was approximately 300% of pre-CS activity levels. For control animals, LIGHT OFFSET was established as the conditioned stimulus for food, and similar results were observed.

247.18

REDUCTIONS IN FOOD REINFORCEMENT QUALITY PRODUCE ELEVATIONS IN THE FORCE EXERTED DURING OPERANT RESPONDING IN RATS.

E.O'S.Hammond, P.Baskin*, & A.Ettenberg
Dept of Psyc, Univ of CA, Santa Barbara, CA 93106

Hungry rats were trained to press a forcesensing operandum for 2.5 sec access to sweetened condensed milk. In previous work, animals responding for food reinforcement have been shown to exert increased force both during conditions of extinction and during reinforced trials conducted in the presence of neuroleptic drugs. Is the increase in peak force seen with neuroleptics a result of a decrease in reward or, as others have suggested, a motoric-postural phenomenon? In the present study we examined the effects of manipulating reinforcer quantity (0.02 to 0.1 ml) or quality (25% to 50% dilutions) on the peak force emitted during 5 min operant test sessions. Increases in peak force were observed only after downward shifts in the quality of reinforcement. No such changes were produced by increases in reinforcer quality nor shifts in the quantity of reinforcement. These preliminary results suggest that neuroleptic-induced increases in peak force may reflect reductions in the rewarding quality of food reinforcement.

NEUROLEPTICS BLOCK THE DRIVE AND DRIVE REDUCTION, BUT NOT THE INCENTIVE, MOTIVATIONAL EFFECTS OF OPIATES AND FOOD.

A.Bechara. F.Harrington. T.Stefurak, and D. van der Kooy, Neurobiology Research Group, Dept. of Anatomy, Univ. of Toronto, Toronto, Ont., Canada, M5S 1A8.

The motivational properties of opiates and food are derived from both their incentive and their drive and drive reduction effects. Drug naive or food sated rats express conditioned preferences for morphine or food paired places, respectively, over unfamiliar neutral ones. In contrast, opiate dependent or food deprived rats avoid places previously paired with the absence of morphine (i.e.withdrawal) or the absence of food (i.e.hunger), respectively. The incentive effects produced by morphine in opiate naive, or food in food sated, rats are abolished by ibotenic acid lesions of the tegmental pedunculopontine nucleus (TPP). These lesions do not affect the drive and drive reduction effects associated with withdrawal in opiate dependent rats or with hunger in food derived rats.

We now report that interfering with dopamine systems blocks the motivational effects associated with the drive and drive reduction effects of both opiates and food. The place preferences seen in opiate dependent rats conditioned with morphine (2 mg/kg) or heroin (50 ug/kg) were blocked by pretreatment with effupenthixal or pimozide. The same place preferences seen in opiate naive rats were not affected by neuroleptics. Similarly, when using food rather than opiates, we found that effupenthixal blocked the conditioned aversions for places previously paired with the absence of food in food deprived (23 hours) rats (i.e. drive effects), but not the conditioned place preferences produced by food itself in food sated rats(i.e. incentive effects). These results double dissociate two idependent neural substrates subserving the incentive versus drive and drive reduction effects of motivation. The TPP serves as a nodal brainstem substrate mediating the impact of incentive stimuli, whereas a dopamine substrate appears to underly the drive and drive reduction effects of motivation.

247.21

STIMULUS CONTROL MODULATES EFFECTS OF IONIZING RADIATION ON OPERANT PERFORMANCE. P.C. Mele and J.H. McDonough. Behavioral Sciences Dept., Armed Forces Radiobiology Res. Inst., Bethesda, MD 20814-5145.

Rats responded under a fixed-consecutive-number (FCN) schedule of reinforcement. Milk was presented when eight or more responses on one lever were followed by a single response on a second lever. Under alternating conditions (a multiple schedule), the completion of eight responses on the first lever was either cued with external discriminative stimuli (lights and a tone) or was not cued. Separate groups of rats (n=7/group) received a single whole-body exposure to 6.0 or 7.5 Gray (Gy) of gamma radiation, or two exposures to 4.5 Gy delivered 2 wk apart. Response rates under cued and noncued conditions were reduced by each dose of radiation during the 1-3 wk post-exposure period. Dose-related reductions were evident in terms of the magnitude of effect and in the proportion of animals affected. Response rates were frequently reduced more in the noncued condition, especially at the 6.0 and 7.5 Gy doses. Rate reductions after the second 4.5 Gy exposure were not consistently greater than after the first. Intermittent decreases in response rates in the noncued condition occurred during wks 3-7 after exposure in a number of rats across dose groups. Accuracies of switching between the two levers were reduced in 6/14 rats by 6.0 and 7.5 Gy; accuracies were generally reduced more under the noncued condition. Strong stimulus control can attenuate radiation-induced disruptions in operant performance.

247 20

ILLUMINATION LEVEL AND OPEN-FIELD ACTIVITY IN GENETICALLY DEFINED MICE. <u>D. F. Peeler.</u> Neurosurgery Dept., Univ. Miss. Med. Ctr, Jackson, MS 39216

Dept., Univ. Miss. Med. Ctr, Jackson, MS 39216

A previous study comparing locomotor activity and investigatory activity in a runway (Peeler & Nowakowski, Behav. Neur. Biol.,48:90, 1987) did not assess the effects of illumination level. In the present study, 72 male mice from the progenitor strains C57BL/6ByJ and BALB/cByJ and the seven RI strains derived from them were tested for 5 min in an open field under bright and dim ambient light. The area was marked with a grid describing 36 squares, which were considered as periphery, interior, or center sections. Five objects, 4 in the interior and 1 in the center sections, were placed in the field. Activity was recorded as locomotor (line crossings) or investigatory (object contacts) by an observer. There were significant interactions (p<.05) of strain with level of illumination in all 3 open-field areas. The interaction was not significant for investigatory activity. Strain CXBD had greater locomotor and investigatory activity than all other strains under most conditions, and increased locomotor activity under bright light. BALB/c, CXBE, CXBG and CXBK had a decrease. The response to conditions of illumination is a function in part of genetic background.

247.22

FEAR-POTENTIATED STARTLE IN HUMANS DURING ANTICIPATORY ANXIETY. C. Grillon, R. Ameli*, S. W. Woods, K. Merikangas*, and M. Davis. Dept. of Psychiatry, Yale Univ. Sch. of Med., New haven, CT 06510

Fear-potentiated startle was investigated in humans using a paradigm involving anticipation of shocks to produce anxiety. The eyeblink component of the startle reflex was measured during either the anticipation of electric shocks (anticipatory anxiety) or periods in which no shocks were anticipated (safe period). The eyeblink was consistently earlier and larger during periods when the subjects (N=9) anticipated shocks, compared to the safe periods. This effect was statistically significant before the subjects actually received any shock. These results indicate that anticipatory anxiety can be measured objectively in humans using the fear-potentiated startle reflex in a paradigm not actually requiring any shock. Because a great deal is known about the neuroanatomical and pharmacological mechanisms of fear-potentiated startle in animals, this test procedure may be especially useful in humans to investigate the neurobiologic substrate of anxiety disorders and their pharmacological treatments.

DEVELOPMENT OF THE RETINO-HYPOTHALAMIC TRACT (RHT) IN FETAL SHEEP. K.L. Fletcher*, M. Terman, A.J. Silverman and R.I. Stark* Depts. Pediatrics & Anat. & Cell Biol., Columbia Univ. NY and NYS Psychiatric Inst. NY.

Circadian rhythms have been described in behavioral and endocrine functions of the fetal sheep in the last third of gestation (term = 147 d). Although fetal rhythms may be entrained by maternal signals, it is of interest to determine when the suprachlasmatic nucleus (SCN) becomes mature in this species. One aspect of maturity is the arrival of the RHT. Intraoccular injections of various tracers were made at 68, 98, 128 and 137d of gestation, after birth and in adulthood (n=2 per age). The most successful tracer was a 30% Dil solution containing in 0.9%NaCl, 0.1% TX 100 and 5% (v/v) DMSO. After hysterectomy with direct visualization, fetal injections were made with volumes based on the size of the eye (0.1 to 0.5 ml). Fetuses were delivered 7-10d after injection, perfused transcerebrally with 4% paraformaldehyde and vibratome sections cut. Selected sections were reserved for immunocytochemical localization of SCN peptides. In vivo application of Dil resulted in brilliant labeling of the optic nerve, chiasm and tract. Labeled axons were traced as far caudalward as the lateral geniculate nucleus and superior colliculus. At all ages studied the region of the SCN received a robust retinal innervation on both ipsilateral and contralateral sides. In cresyl violet stained sections, the cell-dense clusters just dorsal to the chiasm, the putative SCN, were small while the labeled terminals occupied larger oval areas similar in morphology to the SCN of the hamster. These data indicate that the RHT is well established as early as half-way through gestation. Ongoing immunocytochemical studies will assess the phenotypic maturation of the SCN neurons. 248.2

LOCALIZATION OF CHOLINERGIC AND NERVE GROWTH FACTOR-RECEPTOR NEURONS PROJECTING TO THE SUPRACHIASMATIC NUCLEUS OF THE RAT K.G. Bina. K. Semba and B. Rusak. Departments of Psychology and Anatomy, Dalhousie University, Halitax, Canada. B3H 4J1

Circadian rhythms in mammals are regulated by neural mechanisms centered in the suprachiasmatic nucleus (SCN) of the anterior hypothalamus Recent immunohistochemical findings indicate that both choline acetyltransferase (ChAT), the synthesizing enzyme for acetylcholine, and nerve growth factor-receptor (NGF-R) are present in the SCN. In order to identify the source of this immunoreactivity, a combination of retrograde tracing and immunohistochemistry for ChAT and NGF-R was performed. Following iontophoretic injections of fluorogold into the SCN, in addition to previously described areas, retrogradely labelled neurons were seen in the substantia innominata, the part of the magnocellular basal nuclear complex near the SCN. Some of these retrogradely labelled cells were also single- or double-labelled with ChAT and NGF-R. Unilateral knife cuts directed lateral to the SCN decreased NGF-R immunoreactivity in the ipsilateral SCN. Bilateral blinding had no effect on NGF-R labelling in the SCN. This work was supported by NSERC and MRC of Canada.

MORPHOLOGICAL FEATURES OF LUCIFER YELLOW (LY) FILLED RETINAL GANGLION CELLS INNERVATING THE SUPRACHIASMATIC NUCLEUS (SCN). G.E. Pickard and E. Friauf. Depts. of Psychiatry and Anatomy, University of Pennsylvania, Philadelphia, PA 19104 and Dept. of Neurobiology, Stanford University, Stanford, CA 94305.

The sub-type of retinal gangion cell projecting to the hypothalamic SCN is unknown. We have begun to describe these cells in the golden hamster retina. Ganglion cells were identified by the retrograde transport of rhodamine-labeled microspheres injected into the SCN in vivo. LY was injected intracellularly into microsphere-labeled cells in living retinas maintained in vitro to reveal their

complete structure. LY filled cells were photoconverted (Fig. 1 left), were photoconverted (rig. 1 lett), logged into a computer (Fig. 1 right) and rotated 90° about the X-axis to reveal dendritic stratification in the inner plexiform layer (IPL) (Fig. 1 bottom). Ganglion cells innervating the SCN have a large soma (dia = 13.5 μm), 3-4 primary dendrites, which branch sparingly and stratify in the inner half of the IPL and a large dendritic field (225-295 μ m). The morphology of ganglion cells afferent to the SCN implies a high degree of convergence with a subsequent

loss of spatial resolution. Supported by NIH grant NS 21165.

248.5

SYNAPTOGENESIS AND RETINOHYPOTHALAMIC TRACT

SYNAPTOGENESIS AND RETINOHYPOTHALAMIC TRACT (RHT) DEVELOPMENT IN THE HAMSTER SUPRACHIASMATIC NUCLEUS (SCN) J.C. Speh and R.Y. Moore, Depts. of Neurology and Neurobiology, SUNY, Stony Brook, NY 11794

Synaptogenesis in the rat SCN is a largely postnatal event with the largest production of synapses occurring in postnatal days 4-8 (P4-P8, Moore & Bernstein, 1989). This corresponds to the period of maximal development of RHT (Speh & Moore, 1988) but is significantly later than the onset of functional development, as demonstrated by the 2-deoxyglucose method (Reppert & Schwartz, 1984). We studied synaptogenesis and RHT development in the

the 2-deoxyglucose method (Reppert & Schwartz, 1984). We studied synaptogenesis and RHT development in the hamster using Synapsin I immunohistochemistry and anterograde transport of cholera toxin-HRP, respectively. In contrast to the rat, the hamster SCN contains numerous synapsin-like immunoreactive structures at Pl and is essentially comparable to the adult appearance by P4. However, there are only very sparse, scattered RHT axons in the SCN, lateral hyothalamus (LH) and anterior hypothalamic area (AHA) at P4, and no projections to the preoptic area (POA), retrochiasmatic area (RC) and basal forebrain. By P6-8 projections to the PCA, RCA and basal forebrain are present. On P15 all projections are present and appear comparable to the adult (Johnson et al, 1988). These observations indicate that there are striking differences between the rat and hamster in the timing of development of synapses and the RHT in the SCN. (Supported by NIH grant NS-15304).

VIP NEURONS IN THE HUMAN SCN FORM A DISCREET PROJECTION

VIP NEURONS IN THE HUMAN SCN FORM A DISCREET PROJECTION TO THE "SUBPARAVENTRICULAR ZONE"

Stopa, E.G., Chorsky, R.*, King, J.C. and Albers, H.E., Dept. of Path., SUNY Health Sci. Ctr., Syracuse, NY. Dept. of Path., SUNY Health Sci. Ctr., Syracuse, NY. Dept. of Anat. and Cell Biol., Tufts U. Sch. of Med., Boston, MA and Depts. of Biol. and Psychol., Georgia State U., Atlanta, GA.

The suprachiasmatic nucleus (SCN) in the anterior hypothalamus is essential for the neural control of circadian rhythms. In the rat, the majority of SCN efferent fibers project to immediately adjacent regions, including an area dorsal to the SCN designated the "subparaventricular zone" (Watts, A.G. & Swanson, L.W., J. Comp. Neurol. 258:230-252, 1987). In this study, we examined the efferent projection of the vasoactive intestinal peptide (VIP)-containing neurons within the human SCN. In the rat, these neurons receive the majority of SCN afferent fibers and are thought to be involved in the first order processing of light information.

Human hypothalami (n=15) were fixed by immersion in either 5% acrolein or Zamboni's fixative and sectioned in the coronal, sagittal, and horizontal planes. The immunocytochemical procedures were performed on serially obtained sections using either the ABC or PAP method after incubation in primary antibody for 72 hrs. VIP neurons were evident throughout the SCN, concentrated ventrally near the optic chiasm. Immunoreactive fibers were seen arborizing within the nucleus, and formed a discreet projection which could be traced to the "subparaventricular zone" may act as an integrator for photic circadian information in humans, as in other mammals, and that this information is relayed primarily by the VIP-containing neuronal subpopulation. (Supported by AG00295).

LOCALIZATION OF CHOLINE ACETYLTRANSFERASE IMMUNOREACTIVE (CAT-I) CELLS AFFERENT TO THE SUPRACHIASMATIC NUCLEI (SCN) IN THE GOLDEN HAMSTER. M.R. Dwyer, M.E. Harrington and T. Rahmani*, Dept. Psych., Smith College, Northampton, MA 01063 and Neurosci. and Behav. Program, Univ. Mass., Amherst, MA 01030.

Acetylcholine may play a role in mediation of photic responses of circadian rhythms (Physiol. Rev. 69:671-707, 1989). In this study, sources of cholinergic input to the putative circadian pacemaker in the SCN were localized.

Injections of rhodamine-conjugated latex microspheres (0.05ul) were aimed at one

SCN of golden hamsters. After 48 h or longer, animals were sacrificed with a sodium pentobarbital overdose. Tissue was processed for CAT immunohistochemisty using a polyclonal human placental CAT antisera (Chemicon). The avidin-biotin method was used with either diaminobenzidine or flourescein as the chomagen.

Distribution of CAT-1 cells was similar to that reported for the rat brain (Brian Res. 415:49-62, 1987; 495: 271-297, 1989) with a few exceptions. Notably, CAT-1 diagonal band cells were not continuous with CAT-1 cells in the medial septum. Cells afferent to the SCN were found in areas previously described (J.Comp.Neurol., 211:65-83, 1982) as well as in several other areas

Overlap in these markers was seen in the basal forebrain, arcuate, paradorsal raphe, dorsal tegmental nucleus/parabrachial area and the parabigeminal nuclei. Double-labeled CAT-I cells afferent to the SCN were observed in the dorsal tegmental/parabrachial area, extending laterally into the parabigeminal nucleus. A few double-labeled cells were also observed in the vertical limb of the diagonal band. Double-labeled cells which were only lightly CAT-I were located in the area immediately around the caudal SCN.

These results indicate that cholinergic input to the SCN may arise from several distinct groups of cells. Visually responsive parabigeminal or peri-SCN neurons may be involved in mediating light-induced phase shifts of circadian rhythms. (Supported by NIH.)

THE HUMAN SUPRACHIASMATIC NUCLEUS (SCN) R.Y. Moore and

THE HUMAN SUPRACHIASMATIC NUCLEUS (SCN) R.Y. Moore and J.C. Speh, Depts. of Neurology and Neurobiology, SUNY, Story Brook, NY 11794.

The human SCN has been characterized in Nissl material (Brockhaus, 1942; Braak and Braak, 1987) and using immunohistochemistry (Swaab et al, 1984; Stopa et al, 1984; Moore, 1989). The present study was undertaken to provide a more detailed analysis of the human SCN.

Human hypothalami were obtained from routine postmortem Human hypothalami were obtained from routine postmortem material fixed in buffered formaldehyde. Coronal sections were prepared with antisera to vasoactive intestinal polypeptide (VIP), neuropeptide Y (NPY), vasopressin (VP) and neurotensin (NT). The SCN is the most rostral definable hypothalamic nucleus. It appears as a cluster of cells within the dorsal chiasm which extend into the rostral chiasmatic hypothalamus immediately caudal to the lamina terminalis. More caudally the SCN is an ovoid nucleus adjacent to the third ventricle between the paraventricular nucleus dorsally and the supraoptic nucleus laterally. Caudally the SCN becomes smaller to disappear at the level of the caudal optic chiasm. VIP neurons form the central region caudal optic chiasm. VIP neurons form the central region of the SCN. NPY neurons are present in the VIP zone and extend beyond it. VP neurons extend beyond the NPY zone and there is an extensive group of NT neurons extending over the entire area. The human SCN differs from that of other mammals in that it contains NPY neurons and in the large number of NT neurons. Supported by a grant from the United States Air Force.

248.8

LABELING OF THE HUMAN RETINOHYPOTHALAMIC TRACT WITH THE CARROCYANINE DYE, Dil. 1D.I. Friedman, E.G. Stopa, and 2J.K. Johnson. 1Depts. of Neurol., Ophthalmol., and Path., SUNY Health Science Center, Syracuse, NY, 13210, and Inst. for Sensory Res., Syracuse Univ., Syracuse, NY 13244, A retinohypothalamic tract (RHT) has been demonstrated

in human post-mortem brains with documented optic nerve damage prior to death (Brain Res 1985;340:243) and in rats (J Comp Neurol 1972;146:1). It has been suggested that a RHT exists in animals to mediate endogenous rhythms. We used the lipophilic fluorescent probe, DiI, to attempt localization of the RHT in normal human post-mortem brain. Human brains (n=4) were obtained within 18 hours of

death. Hypothalami were removed and placed in 4% paraformaldehyde in 0.1M phosphate buffer. After 24 hours in fixative, crystals of DiI (1,1'-diocladecyl-3,3,3',3-tetramethyl indocarbocyanine perchlorate, Molecular Probes) were imbedded into either optic nerve. Tissue was maintained at 36°C in darkness for two to three months. Serial coronal vibratome sections (60 um) were cut, collected on gelatin-coated slides and mounted in an aqueous mounting

medium (Gelmount, Bicmeda Corp., Foster City, CA).

In all brains studied, labeled fibers were seen extending from the optic chiasm to the ventral surface of the SCN. Our data indicate that the membrane probe, DiI, provides a reliable method for demonstrating a RHT in normal human post-mortem brain tissue.

ENDOCRINE RHYTHMS IN SEASONAL AFFECTIVE DISORDER

ENDOCRINE RHYTHMS IN SEASONAL AFFECTIVE DISORDER DURING A CONSTANT ROUTINE. K.Dahl*, D.Avery*, M. Savage*, G.Brengelmann*, M.Kenny*, A.Lewy*, L.Larsen*, M.Vitiello*, and P.Prinz. University of Washington, Seattle, WA 98195.

The phase of circadian rhythms in 9 Seasonal Affective Disorder (SAD) subjects and 7 controls was assessed using a constant routine (CR). Eight SAD subjects were restudied following a minimum of one month early morning bright light therapy (2500 lux, 6AM to 8AM). During the CR subjects were sleep deprived at bed rest with light held at 60 lux for 27 hours. Blood samples for TSH and cortisol were drawn 1/hour. Samples to determine the Dim Light Melatonin Onset (DLMO) were drawn 2/hour from 6PM to 12AM. Rectal temperature was monitored 1/min. The cosinor acrophases of cortisol, TSH and temperature of SAD subjects were significantly (p<.05) phase-delayed relative to controls, while there was a nonsignificant trend for DLMO of SAD subjects to be phase-delayed. AM light therapy significantly phase-advanced the cortisol acrophase, and light therapy significantly phase-advanced the cortisol acrophase, and produced a nonsignificant trend toward phase-advance of melatonin, TSH and temperature rhythms in the SAD subjects. The endocrine rhythms correlated with the temperature rhythm as well as with each other (combined groups):

	Cortisol	<u>TSH</u>	DLMO
TSH	r = .80, p < .001		
DLMO	r = .85, p < .001	r = .47, $p = .014$	
Temp	r = 61, p < .01	r = .67, n < .001	r = 45, $p = .023$

248.11

HUMAN INTERLEUKIN-1 RECEPTOR ANTAGONIST (IL1ra) BLOCKS IL1-INDUCED FEVER AND NON-RAPID-EYE-MOVEMENT SLEEP (NREMS) IN RABBITS.

M. R. Opp and J. M. Krueger. Univ. of TN, Memphis TN 38163

IL1 is a cytokine that plays a fundamental role in regulating the host defense response. The interactions of IL1 with other cytokines are complex and poorly understood. Recently, a human IL1 receptor antagonist has been characterized and cloned (1), thus providing a means to further elucidate IL1 effects. IL1ra is a polypeptide of 18-22 kD that can block several IL1 effects, e.g. leukopenia (2). We report here that hu-r-IL1ra (Synergen) attenuates IL1-induced febrile responses and blocks IL1 somnogenic actions in rabbits for periods of 6-h or more. Sleep-wake activity and brain temperature (Tbr) were recorded IL1 somnogenic actions in rabbits for periods of 6-h or more. Sleep-wake activity and brain temperature (Tbr) were recorded for 6-h immediately after injection 100 ug IL1ra and/or 10 ng IL1-beta (R&D, Inc.). Injection of IL1 alone resulted in a characteristic fever that reached 1.8°C by the end of the 6-h period, while NREMS was increased by 13.3% across this same time period. Pre-treatment with IL1ra attenuated the IL1-induced febrile response; Tbr at the end of the recording period was only 0.5 C higher than SALINE control. IL1-induced NREMS was completely abolished by pre-treatment with IL1ra; NREMS across the recording period was -1.0 % relative to SALINE control. We conclude that hu-r-IL1ra is capable of inhibiting at least two of the CNS actions of IL1, sleep and fever.

THE APPLICATION OF AN ARTIFICIAL NEURAL NETWORK TO THE DISCRIMINATION OF SLEEP DEPRIVED FROM RESTED EEG. G. Belenky, H. Sing*, Y. Shaham*, M. Thomas*, N. Shepanek*, D. Thorne*, T. Balkin*, U. McCann, J. Fertig, D. Redmond*. Dept. of Behavioral Biology, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

We applied an artificial neural network (ANN) to the discrimination of EEG obtained from the same normal volunteer when sleep deprived and when well rested. In the sleep deprived condition, the subject spent 64 hours in the laboratory with no scheduled sleep. In the rested condition, the subject spent 64 hours in the laboratory but with the opportunity for 7 hours sleep each night. In both conditions, at 50 hours into the study, the subject was required and the study of the subject was required to do a computer-based serial addition and subtraction task for 30 min. EEG, EOG, and EMG were measured continuously. By standard polysomnographic criteria, the subject was awake during both runs, having less than 10 sec of scorable stage 1 sleep in either condition during the 30 min. The 30 min records were divided into 32 sec segments. Each segment was run through a fast fourier transformation (FFT) and expressed as relative EEG amplitude for each 0.25 Hz segments from 0.75-31 Hz. Alternate 32 sec FFT transforms for both sleep deprived and rested conditions (59 each) were assigned to either the training set or test set for the ANN. The ANN paradigm was a feed forward network with training conducted using back propagation and the generalized delta rule. The ANN consisted of 122 input units, 61 hidden units, and 2 output units. The ANN was run through the training set 6,000 times. Training took approximately 18 hrs on a 25 MHz 386 PC with math co-processor. Once trained, the ANN was run through the test set once. The ANN correctly classified 53/59 (91%) of the test set as rested or sleep deprived. Each classification took a fraction of a second. Trained ANNs have utility in the on-line, real-time assessment of alertness.

BIOLOGICAL RHYTHM DISTURBANCES IN SEVERELY AND PROFOUNDLY RETARDED INDIVIDUALS: PREVALENCE AND CHARACTERISTICS.

Ch. E. Olmstead, Robert H. Chaney* and Carolyne Givens.

Olmstead Assocs, Playa del Rey, CA 90296 and UCLA/MRRC
Group at Lanterman Developmental Ctr, Pomona, CA 91769.

The records of all residents of a state residential

facility for the developmentally disabled were surveyed for disorders of body rhythms and regulated behaviors. Of the 1082 residents, 22.5% showed disturbances of the sleep-waking cycle (N=132), defective thermoregulation (N-45), polydipsia (N-32), defective the minegaration (N-45), polydipsia (N-38) or dysphagia (N-82). Twenty-four hour observations of either behavioral activity (N=21) or body temperature (N=37) were carried out to

further characterize the rhythms.

Sleep-waking cycle disturbances ranged from mild to severe with total sleep times that ranged from 3.0 to 10.25 hours distributed in from 2 to 18 bouts. Only 7 of the 21 subjects showed normal periods of uninterrupted sleep during the night. The basic rest activity cycle (BRAC) estimated by a combination of activity and sleep measures ranged from 74 to 113 minutes. disturbances of core body temperature were seen ranging from no circadian variation to inverted or phase shifted rhythms. In general, those individuals whose brain damage was attributable to post-natal causes such as trauma or infection were the most likely to show near normal circadian variations, while those with prenatal etiologies were the most severely disrupted.

248.12

A PIECEWISE-LINEAR DIFFERENCE EQUATION MODEL OF THE HUMAN SLEEP-WAKE CYCLE Kevin A. O'Connor*, Amold J. Mandell, Suzanne Knapp. Department of Psychiatry, School of Medicine, Univ. of California San Diego, San Diego, California 92093

Human temporal isolation studies often show desynchrony, in which sleep onsets occur at a variety of phases of the temperature cycle. Despite the seeming disorder of the sleep onsets, desynchrony shows a number of regular features: (1) sleep length as a ramp-like function of sleep onset; (2) longer average wake length than in synchrony; (3) a relation between wake length and next sleep onset; (4) wake-maintenance zones; (5) sleepmaintenance zones; (6) longer average sleeps than in synchrony; (7) longer or shorter sleep fraction in desynchrony (Strogatz, S., The Mathematical Structure of the Human Sleep-Wake Cycle (Berlin: Springer-Verlag, 1986)). A variety of models can generate feature 1 (Strogatz, *ibid.*), but not all of the other features. Using features 1 and 2 we derive a difference equation model that produces features 3 to 7. The model also explains the appearance and disappearance of desynchrony as tangent bifurcations of the system, and phase-trapping as a noised system with a pair of near-tangent fixed points. The model assumes one oscillator, associated with temperanxed points. The model assumes one oscillator, associated with temperature cycle (normalized to 1), and a 3-piece ramp function, SF(n), yielding sleep length given sleep onset: $S(n+1) = S(n) + SF(n) + W \pmod{1}$, where S(n) is the temperature phase of the nth sleep onset, and W is the wake length. Parameters (wake length, maximum and minimum sleep wake length. Parameters (wake length, maximum and minimum steep duration) control transitions among phase-locked behavior, quasiperiodicity, period-doubling, and chaotic dynamics. Many of the findings are generalizable to piecewise sinusoidal or polynomial approximations of the sleep duration function. This model yields testable predictions of changes in sleep-wake pattern with certain manipulations of wake or sleep lengths.

AUTOMATED STAGING OF SLEEP USING NEURAL NETWORKS A.Mamelak*, J.Quattrochi and J.A.Hobson. Laboratory of Neurophysiology, Harvard Medical School, Boston, MA

Manual staging of sleep based on visual EEG criteria is a laborious and time-consuming task. In an effort to automate sleep staging, we have developed a neural network that "learns" to stage sleep on the basis of waveband count data alone in the cat. Waveband count data waveband count data alone in the cat. waveband count data are collected on a microcomputer, using period-amplitude analysis. Delta waves, spindle bursts, PGO waves, EOG, EMG, and movement artifact amplitudes are collected, and then used to "train" the network to score sleep by testing these data against the corresponding manually staged record which serves as a "teacher". We demonstrate that, when used to score the states of wake, slow wave sleep, desymptomorized sleep, and transition periods these desynchronized sleep, and transition periods, these neural networks agree with manual scoring a mean of 93.3% for all epochs scored. Neural network programs can learn both rules and exceptions, and since the nets teach themselves these rules automatically, a minimum of human effort is required. Because programming requirements are small, this approach is readily adaptable to micro-computer based systems, and is widely applicable to both animal and human EEG analyses. The utility of this approach for the evaluation of clinical disorders is discussed. Supported by NIH grant MH13923.

AN ANALYSIS OF THE BRAIN'S AMPLITUDE-FREQUENCY-CHARACTERISTICS DURING DIFFERENT SLEEP STAGES

J. RÖSCHKE*, K. MANN*, J.B. ALDENHOFF, Dept. of Psychiatry, University of Mainz, F.R.G.

We studied late components of auditory and visually evoked potentials during sleep. Ten healthy male subjects were randomly stimulated by tone bursts and light flashes. According to Rechtschaffen and Kales (1968) we performed an off-line scoring procedure of sleep-EEG and averaged the AEPs and VEPs of five different periods, corresponding to sleep stages I, II, III, IV and REM. From the averaged evoked potentials we computed the amplitude-frequency-characteristic (AFC) of the brain (Basar, 1980) during different sleep stages. In general AFCs characterize transfer properties of an oscillating system. The comparison of the AFCs at the different sleep stages has shown that the excitability of the brain depicts an clear alpha resonance during stage I, a pronounced delta resonance during REM sleep. Depending on the depth of sleep also other resonant frequencies were detectable. A comparison of these results from linear system theory with the nonlinear dynamical behavior of the CNS, such as dimensionality and the degrees of freedom of the sleep-EEG, was performed.

EEG PATTERNS DURING TM PRACTICE AND HYPNAGOGIC SLEEP, F.T. Travis, Maharishi International University, Fairfield, IA 52556

EEG patterns during TM practice, ie. alpha activity spreading anteriorly and slowing 1-2 c/sec, was first reported by Wallace (1). Later, Fenwick (2) and others (3,4) noted a marked similarity of this EEG pattern with EEG during the hypnagogic state experienced between waking and sleeping. They concluded that TM balances the awareness between waking and sleeping. The present study compared EEG patterns during TM practice (10 TM Ss), recorded from F₃,F₄,C₃,C₄,P₃,P₄, to that during an eyes-closed rest period (10 matched non-meditating Ss). Power and coherence were not significantly different between TM practice and the period between eyes-closed and Stage 1 in the comparison group; both peaked between 7-9 Hz (theta/alpha). However, during TM practice this EEG pattern persisted for 10 minutes (the entire session), while the hynagogic state in the control subjects lasted only three minutes on the average. While this supports the idea that awareness is balanced between waking and sleeping during TM practice, Maharishi (5) has also proposed a "junction point model": that waking, dreaming and sleeping are active modes of a continuous field of pure consciousness that can be experienced in the transition between active states of consciousness or, at will, during TM practice.

MODES OF R-R INTERVAL VARIATION DURING SLEEP AND WAKING STATES. S.L. Raetz. C.A. Richard, A. Garfinkel, R.M. Harper. Brain Research Institute and Department of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

Angeles, CA 90024.

Assessment of cardiac R-R intervals during different sleep states by procedures that evaluate total variation indicates that cardiac R-R interval variation is much higher in rapid eye movement sleep (REM) than in quiet sleep (QS). Measures such as total variance, however, suffer from their summary nature, and are unable to provide information on instantaneous or dynamic aspects of beat-to-beat control. A simple procedure for assessing beat-to-beat control is to plot each interval against the next; this procedure provides an indication of the probability of occurrence of one interval from its predecessor. Cardiac R-R intervals were determined over 3-12 minute periods of waking, QS, or REM from 4 cats; each cardiac interval was plotted on the x-axis against the next value on the y-axis. The resulting plots provide evidence that the correlation between successive R-R intervals was greater in REM than in QS, even though

the overall variance is greater in REM. The resulting plots scattered in a bimodal fashion across all states; short R-R intervals were under tighter control than longer intervals. These results suggest that cardiac control during REM may be influenced by much more closely regulated mechanisms than suggested by classic concepts. Supported by R01-HL-22418-13.

LEARNING AND MEMORY: ANATOMY I

PERFORANT PATH DEAFFERENTATION ALTERS EXPLORATION AND EXTINCTION BUT NOT SPONTANEOUS ALTERNATION IN RATS. R.L. Port, K.S. Curtis*, P.W. Parsons* and K.S. Seybold. Depts of Psychology, Slippery Rock University, Slippery Rock, PA, 16057 and Grove City College, Grove City. PA 16127.

Rock, PA, 16057 and Grove City College, Grove City, PA 16127.

The hippocampal formation is a highly structured brain system that is known to participate in a variety of learned behaviors. Among the effects of gross hippocampal damage are deficits in spatial learning and extinction. The present study investigates the specific networks responsible for these behaviors. Adult hooded rats were randomly assigned to control (n=8), lateral (n=8) or medial (n=8) perforant path (PP) deafferentation groups. Surgical procedures, adapted from Myhrer (Physiol Behav, 42:1988), involved mechanical severation of pathways using stereotaxic coordinates. Animals were tested in spontaneous alternation, acquisition and extinction of shuttlebox avoidance. Damage to the medial or lateral PP had no effect on spontaneous alternation. However, during adaptation, lateral PP animals were less active than controls. During extinction, medial PP animals were found to respond less frequently than other groups.

THE AUDITORY CORTICOPONTINE PROJECTION IN THE RABBIT STUDIED WITH HRP-WGA. B.J. Knowlton. C. Weiss. J.K. Thompson & R.F. Thompson, Neurosciences Program, University of Southern California, Los Angeles, CA. 90089-2520. The pontine nuclei may be a major site for cerebral

The pontine nuclei may be a major site for cerebral cortical modulation of the brainstem and cerebellar circuits involved in classical conditioning. In order to study the auditory corticopontine projections, HRP-WGA was injected into the auditory cortex in 11 rabbits. Recordings were made from the injection site to confirm placement in the auditory cortex. The injection volume was 30-100 nl of 1% HRP-WGA. Survival time after injection was 2 days. HRP was visualized with TMB processing. In all cases, retrogradely labeled cells in the thalamus were confined to the medial geniculate nucleus, demonstrating that the injection was confined to the auditory cortex. Anterograde labeling in the pontine nuclei occurred in 2 ipsilateral regions; a dorsolateral region in mid-rostral sections, and a region in the caudal pontine nuclei, that extended from the lateral pontine nuclei to the ventral edge of the cerebral peduncle. There was also some labeling in the caudal medial pontine nuclei in 5 rabbits. Anterograde labeling was also seen bilaterally in the inferior colliculus, most prominently in the ipsilateral pericentral and external regions.

ipsilateral pericentral and external regions.

A COMPARISON OF THE EFFECTS OF EXCITOTOXIC LESIONS TO SEPTAL NUCLEI AND THE HIPPOCAMPAL FORMATION ON THE ACQUISITION OF DECISION RULES. T.W. Robbins, H.M. Marston*, L.S. Wilkinson* and B.J. Everitt (Spon. EBBS) Depts. of Experimental Psychology and Anatomy, University of Cambridge, Downing Street, Cambridge, CB2 3EB, U.K.

The effects of (i) lesions aimed at the cholinergic septo-cortical projections and (ii) lesions of the hippocampal formation, were compared on the rate of acquisition of (i) a conditional visual discrimination (CVD) and (ii) the Morris swim maze task.

Septal lesions were made by infusing either 0.5 ul quisqualic acid (0.12 M) or vehicle at four sites bilaterally. Hippocampal lesions were made by infusing ibotenic acid (0.06 M) at 11 sites bilaterally. *Post mortem* biochemical analysis of choline acetyltransferase activity (ChAT) revealed that the septal group's lesions were of three types according to the primary region of ChAT reduction; (a) cingulate cortex (S-C group), (b) hippocampus (S-H) and (c) both structures (S-CH). Additional analysis confirmed that there were no significant reductions in the levels of cortical monoamines. Histological examination of the hippocampal ibotenate

group revealed extensive damage in the intended regions.

The CVD was between fast and slow flashing lights, responses having to be made either to the left or right, depending upon stimulus frequency. Hippocampal lesions produced only slight impairments in acquiring the task, but the S-C and S-CH groups were profoundly impaired. The S-H group learned normally. In the water maze task, the hippocampal group were impaired both in acquisition and on the memory probe trial. The septal group only showed minimal acquisition.

These results suggest that an intact cingulate cortex is a prerequisite for the efficient learning of conditional rules. The hippocampus, while not essential for rule learning, does appear to be important for the precise integration of spatial information

A TASK DESIGNED TO DEMONSTRATE A DECLARATIVE MEMORY REPRESENTATION OF ODOR CUES IN RATS. C.G

MEMORY REPRESENTATION OF ODOR CUES IN RATS. C.G. Wible, H. Eichenbaum, and T. Otto. Biology Department, Wellesley College, Wellesley, MA 02181.

A task was designed for rats that used nonspatial declarative memory similar to the memory requirements used in tasks with human amnesics. Correct performance on probe trials after training memory similar to the memory requirements used in tasks with human amnesics. Correct performance on probe trials after training on the task required the establishment of a representation of odors that was both flexible and could be accessed in a novel situation that did not simply reproduce the original training conditions. The serial order task consisted of initial training on 4 odor discriminations with shared elements (A+B-, B+C-, C+D-, D+E-). The task was designed to encourage a transitive representation between the odor representations such that A>B>C>D>E. Probe trials were given with the pairs A-E and B-D. The correct choice of odor A in pair A-E did not require the establishment of a transitive representation, because odor A was always rewarded and E was never rewarded in training. The correct choice of odor B in pair B-D did require access to a transitive representation of the odors, because B and D were rewarded equally often during training. Rats with fimbrial/fornix (FFX) lesions and SHAM rats learned the task to a criterion of 80% correct, with no difference in errors to criterion for the 2 groups. Rats were then given probe trials of A-E and B-D interspersed between regular trials. Choice accuracy remained high (between 70% and 90% correct) during sessions with probe trials. In a pilot study, SHAM rats performed correctly only on the pair not requiring a transitive representation, pair A-E. The results suggest that the hippocampal system is involved in forming transitive inference representations, which is a property of declarative memory. a property of declarative memory.

NEURONAL SOMATA IN THE OCTOPUS CENTRAL NERVOUS SYSTEM ARE INEXCITABLE AND LABEL RETROGRADELY WITH Dil AND DiO. Robertson, J.D., R. Gillette, P. Lee*, S. Meadows and J. Zitz*, Duke University Marine Lab., Beaufort, NC, and Department of Physiology and Biophysics, University of Illinois, Urbana, IL. Brains of Octopus vulgaris, cooled to 0°C, were removed to oxygenated

saline and 1 mm slices of supra- and subesophageal lobes were placed in flowing, oxygenated saline at 12°C. Intracellular recordings were made with 3 M KCl electrodes with 20-50 M Ω resistance. Recordings were made from most cell body containing areas of the brain. Intracellular recordings were also made from isolated buccal and stellate ganglia, recordings were also made from isolated buccal and stellate ganglia, whose connective tissue capsules were partially removed. Action potentials and PSPs were frequently seen. However, in over 200 recordings from cells with membrane potentials of -35 to -70 mV, action potential amplitudes never exceeded 20 mV, and in most cases were <10 mV. The most likely interpretation of these results is that the octopus neuron somata are inexcitable. This resembles the situation for arthropods, and contrasts with that for generally excitable somata of other molluses. We discuss inexcitable someta as an evolutionary adaptation of molluscs. We discuss inexcitable somata as an evolutionary adaptation of the molluscan CNS plan to the large and complex brain of the octopus. In related experiments we injected DiI or DiO into a cerebrobrachial

commissure. After 8 days, numerous large (~50-60 µm), presumptively motor cell bodies, were labeled both in the surface membranes and in 2-5 µm diameter organelles in the posterior buccal, subfrontal, subvertical and posterolateral basal lobes. The latter may represent a new motor nucleus. Numerous interspersed small unlabeled cells ~5 µm in diameter were also seen. Supp. by NSF Grants BNS-88-20409 and BNS-86-03816.

INVOLVEMENT OF THE LATERAL NUCLEUS OF THE AMYGDALA IN AMPHRTAMINE AND FOOD CONDITIONED PLACE PREFERENCES (CPP) N. Hiroi, R.J. McDonald* and N.M. White, Department of Psychology, McGill University, 1205 Dr. Penfield Ave, Montreal, Quebec, Canada H3A 1B1.

The CPP paradigm utilized an apparatus with two distinct, equally preferred environments. Rats experienced pairings of a primary reward with one of the environments and an equal amount of non-paired experience with the other environment, in a counterbalanced manner. When the primary reward was a subcutaneous injection of 2 mg/Kg damphetamine sulphate, electrolytic lesions localized to the lateral nucleus of the amygdala, made before or after training significantly attenuated the CPP. In contrast, electrolytic lesions localized to the central or basolateral amygdaloid nuclei, the endopyriform nucleus, ventral hippocampus or fornix/fimbria were without effect. Neurotoxic (NMDA) lesions including the lateral amygdaloid nucleus had the same effect as electrolytic lesions. Similar neurotoxic lesions also significantly attenuated the CPP when consumption of food was the primary reward. The results suggest that the lateral amygdaloid nucleus, but not other amygdaloid nuclei or the hippocampal system, is involved in mediating certain conditioned rewarding effects. Taken together with other findings (eg, Hiroi & White, Br Res, 510:33,1990; Cador, Robbins & Everitt, Neurosci, 30:77-86,1989), these results may imply that the lateral nucleus of the amygdala interacts with the nucleus accumbens in acquiring and expressing memory for stimulus-reward associations.

NEURAL MECHANISMS OF CONSPECIFIC DISCRIMINATION

NEURAL MECHANISMS OF CONSPECIFIC DISCRIMINATION IN PIGEONS. S. Watanabe. Dept. of Psychology, Feic University. Tokyo 108, Japan
Ectostriatal lesions in pigeons have caused deficits in discrimination of arbitrary classification of natural stimuli but not in discrimination of natural concepts. In the first experiment pigeons were trained on conspecific vs non-conspecific discrimination in an operant chamber. The chamber had a TV screen connected with a floppy-video player which produced visual with a floppy-video player which produced visual images of conspecific or non-conspecific on the screen. Pecking response was reinforced when screen. conspecific appeared and was extinguished when non-conspecific appeared. Lesions in intermedial hyperstriatum ventrale (IMHV) did not cause deficits in conspecific discrimination but ectostriatal damage resulted in deficits in the discrimination. In the second experiment pigeons were trained on discrimination of individual pigeons. Ectostriatal lesions impaired this discrimination. These results suggest this discrimination. These results suggest that the ectostriatum(which has been considered to be mammalian extrastriate cortex) has an important role in conspecific discrimination in pigeons.

CONTINUOUS RECOGNITION MEMORY PERFORMANCE AS A FUNCTION OF HIPPOCAMPAL, PARIETAL AND MEDIAL PREFRONTAL CORTEX LESIONS. P. Jackson-Smith and R. P. Kesner. Dept. of Psychology, Univ. of Utah, Salt Lake City, UT 84112.

Using a continuous recognition memory procedure, rats were trained within a 12-arm radial maze. They were allowed sequential access to 12 arms of the maze from the center platform on each daily session. Access required that the rat orient to a cue on the clear plexiglas door of the designated arm; upon orientation, the door was opened, and latency to reach the end of the arm was measured. Of the 12 presentations, three or four of the arms were repeated, but did not contain reinforcement. Repeated arms were repeated, but don't contain reinforcement. Repeated arms were presented with lags ranging from 0 to 6 (from 0 to 6 different arm presentations between the first and the repeated presentation). Prior to surgery all rats received 32 training sessions, and showed long latencies at the short lags with decreasing latencies as the lag between repeated presentations increased. Latencies were short for all lags post-surgery in the group of rats receiving total hippocampus ablation (electrolytic). Following aspiration lesions of the medial prefrontal cortex, latencies at each lag decreased relative to pre-surgery performance, however, the forgetting functions remained parallel. Following aspiration lesions of the parietal cortex, sham surgery, or electrolytic cortical control lesions, there were no deficits. These data further emphasize the role of the hippocampus in mediating spatial attributes, even with no temporal delay (a lag of 0).

Effects of Stimulation of the Amygdaloid Central Nucleus (ACe) on Cortical Electroencephalographic (EEG) Activity in the Rabbit. B.S. Kapp, W.F. Supple and J.L. Doherty. Dept. Psychol., Univ. of Vermont, Burlington, VT 05405

We have recently reviewed evidence suggesting that the ACe contributes to conditioned arousal, as manifested in its contribution to the expression of a variety of arousal-indicative responses which may enhance the detection and processing of sensory information (Kapp et al. 1990). In this study the effect of stimulation of the ACe and surrounding sites on neo-cortical EEG arousal (low voltage fast activity) and heart rate was examined. New Zealand rabbits were anesthetized with alpha-chloralose, and recording electrodes were positioned on or within the frontal cortex. Electrical stimulation (1.0 sec, 100 Hz, 100-500 uA) was applied every 0.5 mm as a stimulating electrode was lowered through the dorsal-ventral extent of the ACe and surrounding regions. Although EEG changes were obtained from sites immediately adjacent to the ACe maximal changes were obtained from sites within its dorsal Stimulation produced an immediate shift from large amplitude slow-waves to low voltage fast activity during and following stimulation. Maximal bradycardia was elicited from those sites eliciting maximal EEG changes.

These results are consistent with the hypothesis that the ACe contributes to the expression of responses which are indicative of heightened arousal and which may enhance sensory information processing.

RATS WITH HIPPOCAMPAL REMOVALS CAN LEARN SIMPLE, CONDI-

RATS WITH HIPPOCAMPAL REMOVALS CAN LEARN SIMPLE, CONDITIONAL AND TACTILE DISCRIMINATIONS USING ODDR AND TACTILE
CUES. I. Q. Whishaw and J. Tomie*. Dept. Psychology,
Univ. of Lethbridge, Lethbridge, Alberta, Canada TIK 3M4
A number of theories suggest that the hippocampus has
a selective involvement in learning and memory such that
it is not involved in simple stimulus-response learning but is involved in acquiring conditional and configural tasks. We examined the effects of hippocampal removal on tasks. We examined the effects of hippocampal removal on acquisition and retention of simple, conditional and configural tasks in a series of novel tasks using tactile and olfactory cues. The hippocampus proper was removed using the neurotoxins kainic acid and colchicine. Hippocampal damage had minimal effects on retention and acquisition of the three kinds of problems. These results suggest that whereas the hippocampus may have a selective role in certain forms of learning, this involvement may be restricted to only certain sensory domains or conbe restricted to only certain sensory domains or conjunctions. Alternatively, the hippocampus may control a class of movements that are required for the solution of certain kinds of problems irrespective of their stimulus conjunctions.

249.13

PERFORMANCE ON A SPATIAL TASK FOLLOWING LESIONS TO THE REGION OF THE MAMMILLARY BODIES. V. Sziklas and M. Petrides. Dept. of Psychology, McGill University, Montreal, Quebec, Canada H3A 1B1.

In the present study, rats were first trained on an eight-arm radial maze. They were subsequently given lesions confined primarily within the area of the mammillary bodies and the supramammillary nucleus(MB-SM), the hippocampus (H), or a control operation (OC). Post-operatively, the animals were tested on this task under two conditions. In the first condition, the rats were not confined to the center platform between choices; in the second, they were confined for a 15 sec period before being allowed to make a choice. Rats with lesions to the H were impaired in both conditions in comparison with the OC animals, whereas those with lesions to the MB-SM were

These findings indicate that restricted lesions within the MB-SM region may not be sufficient to impair performance on the radial maze under the conditions tested. In an earlier study (Saravis et al., Europ J Neurosci, 1990, in press), extensive lesions within the region of the mammillary bodies that damaged not only the MB-SM area but invaded adjacent nuclei impaired severely performance on this task.

A RAT MODEL OF MEDIAL-DIENCEPHALIC AMMESIA: NONRECURRING-ITEMS DELAYED NORMATCHING-TO-SAMPLE. D.G. Mumby* and J.P.J. Finel. Dept. of Psychology, University of British Columbia, Vancouver, B.C., Canada V6T 1Y7.

Medial-diencephalic amnesia has been modelled in monkeys using the nonrecurring-items delayed nonmatching-to-sample (DNMS) paradigm; monkeys with mediodorsal thalamic lesions perform poorly on this task. We tested rats with mediodorsal thalamic lesions on a new version of DNMS that was designed to mimic the monkey DNMS task. Lesioned rats were impaired whether they were trained pre- or postoperatively. Lesioned rats trained postoperatively took longer to reach a criterion of 17/20 correct trials on two consecutive sessions than did sham-operated rats; pretrained rats receiving mediodorsal thalamic lesions took longer to re-attain this criterion following surgery than did sham-operated rats. Lesioned rats scored significantly lower than sham-operated rats with delays of 4 s, 15 s, 60 s, 120 s, and 300 s. Intact rats and shamoperated rats performed at levels comparable to those commonly reported for monkeys. These results suggest that there is considerable continuity among humans, monkeys, and rats in the neural basis of recognition memory, and in so doing, they illustrate the potential of the rat model in its investigation.

249.12

TASTE AVOIDANCE, BUT NOT AVERSION, LEARNING IN RATS LACKING TASTE CORTEX. M.R. Orr* and S.W. Kiefer. Department of Psychology, Kansas State University, Manhattan, KS 66506.

Rats with ablations of the gustatory cortical area (GC) were compared to control rats in the acquisition of a conditioned taste aversion to either sucrose (Exp. 1) or sodium chloride (Exp. 2). Following aversion training, the rats were tested for taste reactivity to determine the palatability of the conditional taste stimulus in a test not involving consumption. In Experiment 1, control rats rapidly learned to avoid sucrose but showed only weak negative reactivity (e.g., gapes). The GC rats reduced sucrose consumption but the aversions were weaker than those found in control rats. The GC rats also failed to display any negative reactivity. In Experiment 2, control rats displayed rapid aversion learning to the sodium chloride solution. These rats also displayed strong aversive reactivity to the sodium chloride solution. GC rats also learned to avoid the sodium chloride solution (six of eight rats reached a learning criterion of 0.0 ml consumed) but did not show any negative reactivity to the taste. The results demonstrate that GC rats are capable of learning to avoid consumption of a taste but that the conditioning does not entail a hedonic or palatability shift of the conditional stimulus as it does in control rats.

BASOLATERAL AMYGDALA LESIONS DISRUPT TASTE-POTENTIATED ODOR AVERSION LEARNING WITHOUT AFFECTING SIMPLE ODOR DISCRIMINATION LEARNING. T. Hatfield¹, M. Henegar²², P. Graham⁴¹, and M. Gallagher¹. ¹Department of Psychology, ²School of Medicine, The University of North Carolina, Chapel Hill, NC 27599

The role of the basolateral amygdala (ABL) in taste-potentiated odor aversion learning was studied in rats. Simple taste aversion learning readily

The role of the basolateral amygdala (ABL) in taste-potentiated odor aversion learning was studied in rats. Simple taste aversion learning readily occurs when a novel taste is paired with illness: this learning can withstand long delays between the taste (CS) and illness (US). In contrast, it is difficult to establish a conditioned aversion with odor/delayed illness pairings. However, aversion to an odor can be established at long CS-US delays by presenting the odor in compound with a taste during training: subsequent testing with the odor alone then reveals a robust aversion. Rats with ABL neurotoxic lesions induced by N-methyl-D-aspartate were significantly impaired in acquiring taste-potentiated odor aversion learning. At the same time, these lesions had no effect on the acquisition of a simple taste aversion. A second experiment was conducted to assess whether ABL damage merely impaired olfactory processing. A within-subject design was used to examine taste/odor potentiation and simple odor discrimination learning with a counterbalanced set of three olfactory cues. Animals with ABL lesions that were significantly impaired in acquisition of the taste-potentiated odor aversion in this experiment were unimpaired in odor discrimination learning. Thus animals with ABL damage can learn a simple association between either a taste or an odor that is paired with an effective US, but have a selective deficit for taste/odor potentiation learning. PATH ANALYSIS OF LONG-TERM HABITUATION EFFECTS ON THE AUDITIORY SYSTEM. A.R. McIntosh and F. Gonzalez-Lima. Dept. Med. Anatomy, Texas A&M Univ., College Station, TX 77843.

Techniques for mapping brain metabolic activity hold some

Techniques for mapping brain metabolic activity hold some important advantages over traditional neuroscience methods. For example, 2-deoxyglucose autoradiography reveals the activity of the whole rat brain, allowing for simultaneous examination of changes in entire neural systems. In spite of this, however, an analytic method which enables data to be quantified from a systems approach is lacking. The purpose of this study was to use path analysis to model the changes in auditory system 2-DG uptake in relation to long and shorterm habituation of the acoustic startle reflex (Gonzalez-Lima et al, Brain Res., 489:67, 1989). Path analysis is a method to assess the relative strengths of directional links between elements in a system. The models revealed changes in the flow of information from the lemniscal to the extra-lemniscal system as a function of habituation. Probable sites in the system where modifications to the auditory processing took place were the superior olivary complex and the inferior colliculus. This analytic approach may prove to be a valuable tool in the exploration of the mechanisms through which functional activity in neural systems is altered during sensory processing, learning, and memory. Supported by NIMH grant R01 MH43353.

GLUTAMATE IS PRESENT IN PRESYNAPTIC TERMINALS OF THALAMO-AMYGDALA PROJECTIONS. C.R. Farb and J.E. LeDoux, Center for Neural Science, New York University, New York, NY 10003.

Projections from the acoustic thalamus to the lateral amygdala (AL) are involved in the transformation of acoustic stimuli into emotional memories. This thalamo-amygdala pathway is believed to be excitatory and may use glutamate (Gilu) as a neurotransmitter. Previous ultrastructural studies demonstrated that projections arising in the acoustic thalamus and terminating in AL form predominately asymmetric or excitatory contacts with spines or small dendrites. While similar profiles are seen for Glu-containing terminals in AL, the origin of these terminals is not known. Therefore, we have attempted to determine, using anterograde transport of WGA-HRP and Glu immunocytochemistry, whether Glu is contained in AL terminals that arise from cell bodies in the acoustic thalamus. Anterograde transport of WGA-HRP from the acoustic thalamus to AL was visualized using the tetramethylibenzidine reaction. The reaction was stabilized with diaminobenzidine and cobalt acetate. The presence of Glu was determined using an antibody against hemocyanin-conjugated Glu, IgG linked to colloidal gold, and subsequent silver enhancement. Electron microscopic analysis demonstrated that WGA-HRP was seen predominately in axon terminals. Glu-like immunoreactivity (Glu-Li) was seen in perikarya, dendrites, axons and axon terminals. Although the majority of labeled terminals contained either WGA-HRP or Glu-Li, some terminals contained both HRP and Glu-Li. These findings demonstrate that thalamo-amygdala terminals contain glutamate and suggest that glutamate may be a neurotransmitter in this pathway. Supported by MH38774.

EFFECTS OF FORNIX LESIONS ON RAT'S PERFORMANCE OF A NONSPATIAL CONTINUOUS NONMATCHING TO SAMPLE WORKING MEMORY TASK. M.J. Pontecorvo, D.B. Clissold, R.M. Hudson* and D.S. Olton. NOVA Pharmaceutical Corp., Baltimore, MD 21224 and Johns Hopkins University, Baltimore, MD 21218.

The present study examined the effects of fornix lesions on rat's performance of an operant, nonspatial working memory task. Rats had previously been trained (Pontecorvo and Clissold, Neurosci Abstr, 14:101.2) to remember across an intertrial interval (2.5, 10, 20 sec) which of two possible stimuli was presented on the previous trial. The rats were reinforced for responding on one lever if the present trial stimulus matched the previous stimulus and reinforced for a response on a second lever if the present stimulus differed from the previous. Performance of rats receiving Sham lesions (n=4), was contrasted with that of rats receiving bilateral radio frequency lesions producing (histologically determined) Complete (n=4) or Partial (n=5) destruction of the fornix. Rats with Complete lesions showed a significant, but transient, delay dependent reduction in choice accuracy (e.g., during post-operative week 1, A' at the 2.5, 5 and 10 sec intervals was .98, .93 and .91 for the Sham group vs .97, 95 and .89 for the Partial group and .93, .90, and .82 for the Complete group). By post-operative week 3, no differences in choice accuracy could be observed. Complete lesions also produced an increase in the probability of both trial and intertrial responding that persisted throughout the duration of the study. It remains to be determined whether the relatively modest accuracy reducing effects of the fornix lesions in the present study should attributed to the substantial training these rats received prior to the lesion, or to a relatively limited involvement of the septal-hippocampal system in performance of this task.

250.4

CONFIGURAL ASSOCIATIONS OF AUDITORY STIMULI ARE NOT IMPAIRED BY FIMBRIA-FORNIX LESIONS. A. Baker, R. Wax*, and M.L. Shapiro, Department of Psychology, McGill University, Montreal, Ouebec H3A 1B1.

Configural association (CA) theory predicts that the hippocampal system is needed when animals must remember relationships among stimuli (Sutherland & Rudy, 1988, $Psychobiology\ 17:157$). Negative patterning tasks exemplify CA learning, and are impaired by hippocampal lesions. Thus, a tone-light (TL) CA task that requires rats to press a bar for food when either a light or a tone was presented alone, but not to press the bar if the light and tone were presented simultaneously, is impaired by hippocampal lesions. To test the generality of CA theory, the TL task was compared to a tone-click (TC) task that substituted a clicking stimulus for the light but otherwise was identical to the TL task, and therefore was operationally a CA task. Discrimination performance was measured as the difference (d) between the number of bar presses to the compound stimulus and the mean of the single stimulus elements. Ten male S.D. rats were trained in the TL task and 10 rats were trained in the TC tasks. After 30 training sessions, the rats discriminated between the simple and compound stimuli in both the TL (d=17) and TC (d=15) tasks. Half of the rats in each group were then given bilateral fimbria-fornix (FF) lesions. After surgery, normal rats performed as well as they had pre-operatively on both tasks (TL d=22; TC d=18). FF lesions impaired performance in the TL task relative to the normal rats for the 2 week post-operative testing period (d=8). However, rats with FF lesions performed the TC task normally (d=17). Thus, hippocampal lesions do not impair all negative patterning tasks, and CA theory must be amended to predict correctly the types of associations that require the hippocampal system.

AMYGDALA LESIONS DISRUPT EXPLICITLY CUED AND CONTEXTUAL FEAR CONDITIONING. R.G. Phillips, L. Romanski, J.E. LeDoux, Center for Neural Science, New York University, New York, NY 10003.

Rats 'freeze' when exposed to a tone previously paired with footshock (explicitly cued fear conditioning) or when placed in an apparatus where shock was administered (contextual fear conditioning). A recent report report to the report to the condition and the conditioning of the c

Rats 'freeze' when exposed to a tone previously paired with footshock (explicitly cued fear conditioning) or when placed in an apparatus where shock was administered (contextual fear conditioning). A recent report suggests that explicitly cued but not contextual fear conditioning is dependent upon the amygdala. However, conditioning to explicit and contextual cues was evaluated using different test procedures. In the present study, we used a paradigm whereby the rate of acquisition of conditioned fear responses to explicit and contextual cues could be monitored using a single procedure. Rats were given blocks of 2 conditioning trials, during which a tone (800 Hz, 80 dB, 20 sec) was paired with footshock (0.6 mA, 0.5 sec), on three consecutive days. Freezing during the 20 sec preceding the first tone on day 2 and day 3 was used as a measure of contextual conditioning and freezing during the first tone on day 2 and 3 was used as a measure of explicitly cued conditioning. On day 2, the rats did not freeze before the onset of the tone but did freeze during the tone. On day 3, freezing was observed both before and during the tone. Electrolytic lesions aimed for the amygdala (histology pending) reduced freezing during the tone (days 2 and 3) and during the pre-tone period (day 3) in 3 of 4 rats. Thus, explicitly cued conditioned fear responses are acquired faster than contextually conditioned responses and amygdala lesions interfere with both. Supported by MH38774.

UNCONDITIONED STIMULUS TRANSMISSION TO AMYGDALA. L.M. Romanski, M.C. Clugnet, F. Bordi, LeDoux, Center for Neural Science, New York University, York, NY 10003.

LeDoux, Center for Neural Science, New York University, New York, NY 10003.

Auditory fear conditioning in the rat is mediated by projections from the medial geniculate body (MGB) and adjacent areas of the posterior thalamus to the lateral nucleus of the amygdala (AL). This area of the posterior thalamus receives both acoustic and somatosensory inputs. Thus, during fear conditioning both conditioned stimulus (CS) and unconditioned stimulus (US) information may be transmitted to the amygdala from the posterior thalamus. To examine this issue, three studies were performed. First, unit discharges were recorded in AL during electrical stimulation of the posterior thalamus or during electrical stimulation of the posterior thalamus or during electrical stimulation of the posterior thalamus or during electrical stimulation of the contralateral hindpaw in rats anesthetized with chloral hydrate. Many units responded to thalamic stimulation. Response latencies varied between 4 and 12 ms. Many but not all of the identified units also responded to hindpaw stimulation. Response latencies to hindpaw stimulation varied between 12 and 25 ms. Second, in some studies, after identifying units in AL that responded to hindpaw stimulation the MGB was lesioned. Hindpaw stimulation the MGB was lesioned. Hindpaw stimulation the MGB was lesioned unit responses in AL. Third, the MGB was lesioned unitaterally and after 1 week responses to hindpaw stimulation were tested. Responses were not found in the AL on the side of the MGB lesion but were found in the AL on the side of the MGB lesion but were found in the AL on the side of the intact MGB. These data suggest that during fear conditioning both the auditory CS and the somatic US may be transmitted to the AL by way of the MGB and/or adjacent areas of the posterior thalamus. Supported by MH38774.

250.9

DEPLETION OF CORTICAL NE IN RATS BY 6-OHDA PRODUCES MINIMAL IMPAIRMENT ON A PRETRAINED DELAYED NON-MATCHING TO SAMPLE (DNMTS) TASK. S. Koger, G.D. Fox*, D.M. Lacourse*, and R.G. Mair. Dept. Psychol., Univ. New Hampshire, Durham, NH 03824

Following pretraining on a spatial DNMTS task, rats received injections of either 6-OHDA (N=11) or vehicle (N=5) aimed at the dorsal NE bundle. Both groups showed a comparable and significant decay in performance as delays were increased from 0 to 15 sec. Subsequent extended training at delays of 3, 6, & 15 sec (500 trials each) demonstrated a trend towards impairment in NE depleted rats at 6 sec, but not 3 or 15 sec. 6-OHDA lesioned animals also tended to respond more slowly than controls at all delays. The effects of NE depletion on this task are considerably less severe than those produced by RF lesions of thalamus (cf Mair, et al, this meeting).

250.11

EFFECTS OF X-IRRADIATION-INDUCED HIPPOCAMPAL GRANULE-CELL HYPOPLASIA ON MEMORY-BASED LEARNING AND LEARNED PERSISTENCE IN THE INFANT RAT. J.L. Diaz-Granados*, P.L. Greene, T.J. Schallert, & A. Amsel. Dept. of Psychology & Inst.

for Neuroscience, University of Texas, Austin, TX 78712.

Electrolytic hippocampal insult in infant rats disrupts the acquisition of patterned alternation (PA; Lobaugh et al., <u>Behav.</u> Neurosci., 103:1159, 1989), a kind of memory-based learning and the partial reinforcement extinction effect (PREE; Lobaugh et al., Behav. Neurosci., 99:46, 1985), an indicant of learned persistence. Similar results have been shown with exposure to fetal and/or postnatal ethanol (Wigal & Amsel, Behav. Neurosci., 104:116, 1990).

We examined the effects of x-irradiation-induced hippocampal insult in rat pups on both PA and the PREE. Neonatal rats were exposed to varying doses of x-irradiation from postnatal day (P) 2 exposed to varying doses of x-irradiation from postnatal day (P) 2 to P15, resulting in differential agenesis in postnatally arising granule cells of the hippocampal dentate gyrus. Controls were sham-irradiated. Rat pups were tested at P16-17 for PA and at P20-21 for the PREE. X-irradiated subjects showed behavioral deficits on both schedules, PA and the PREE. Also, the high-irradiation groups displayed greater running speeds in both effects. Correlations between cell loss and behavior were significant. These results are further evidence that the appearance of learned behavioral effects such as these is related to the development of the hippocampus Supported by NSE grant BNS-8609877. the hippocampus. Supported by NSF grant BNS-8609877.

IN THE RAT, RF LESIONS OF THALAMUS AND FORNIX PRODUCE DIFFERENT PATTERNS OF IMPAIRMENT ON A DELAYED NON-MATCHING TO SAMPLE (DNMTS) TASK. R.G. Mair, D.M. Lacourse*, S. Koger, and G.D. Fox* Dept. Psychol., Univ. New Hampshire, Durham, NH

Eighty Long-Evans rats were given extensive pretraining (2400 to 3700 trials) on a DNMTS task. In Exp 1, 50 rats were given one of 5 treatments: RF lesions of midline thalamus (MT), bilateral (BIL) thalamus at 1 mm from midline, mammillary bodies (MB), combined MT-MB, or sham surgery. The BIL group was substantially impaired, while MT, MB, and MT-MB groups performed normally at all delays. In Exp II, 16 rats were given precommissural fornix (PF) lesions and compared to 8 sham controls. The PF impairment varied with delay, being largest at moderate delays (9-12s). The BIL deficit was more severe than PF and was apparent at short delays.

250.10

DOUBLE DISSOCIATION OF ITEM AND ORDER RECOGNITION MEMORY FOLLOWING LESIONS OF THE HORIZONTAL NUCLEUS OF THE DIAGO-NAL BAND OF BROCA AND THE NUCLEUS BASALIS MAGNOCELLULARIS.

D.L. Johnson and R.P. Kesner. Dept. of Psychology, Univ. of Utah, Salt Lake City, Utah 84112.

Rats were trained on an 8-arm radial maze on either a

spatial item or spatial order recognition task. In the spatial item recognition task, on every trial animals were allowed to visit 5 new arms followed by a test between an arm visited on that day and an unvisited arm. A win-stay rule was required to receive additional reinforcement. the spatial order recognition task, the animals visited 8 locations followed by tests between 1-2, 4-5, or 7-8 choice orders. In order to receive additional reward, the animal had to choose the arm that occured earlier in the sequence.

After the animals displayed better than chance performance, they received ibotenic acid lesions of the horizontal nucleus of the diagonal band of Broca (HNDB) or the nucleus basalis magnocellularis (NBM).

Following HNDB lesions, performance on spatial order recognition remained intact, but performance on spatial, item recognition fell to chance levels. NBM lesions produced a deficit in spatial order recognition, but had no effect on spatial item recognition. Thus, there appears to be a double dissociation between HNDB and the NBM, implying a clear functional dissociation among components of the basal forebrain.

250.12

CONDITIONED AND UNCONDITIONED EFFECTS OF VARYING NOISE SPECTRAL FREQUENCIES ON THE ACOUSTIC STARTLE REFLEX IN RATS. S. Campeau and M. Davis. Dept. of Psychology Psychiatry, Yale Univ. Sch. of Med., 34 Park St., New Haven, Ct 06508.

The intensity and spectral frequency of background noise have marked effects on the amplitude of the acoustic startle reflex. Low frequency noise elevates, whereas high frequency noise depresses, the amplitude of the startle reflex (Gerard & Ison, JEP:ABP, 16:138, 1990). Based on these unconditioned effects of background noise DEFINITE, 10:136, 1990). Based on these unconditioned effects of background noise on acoustic startle, it was important to examine how effective different auditory frequency bandwidths would be in the expression of fear as measured by the potentiated startle paradigm (enhancement of startle amplitude in the presence vs the absence of a stimulus previously paired with footshock). This was especially interesting because pure tone auditory stimuli often lead to unreliable potentiation of acoustic startle.

of acoustic startle.

Rats (10 per group) were given 20 paired presentations of a 3.2 sec, 70 dB, 0.1, 1-10, 10-20, or 0-20 kHz noise coterminating with a 0.5 sec, 0.6 mA footshock.

Additional groups were given the same number of stimuli in a specifically unpaired procedure. All animals were tested 2 days later with 100 startle-eliciting noisebursts in the presence or absence of the auditory conditioned stimulus (CS). The 0-1 and 1-10 kHz stimuli produced 100 % startle potentiation in virtually every animal. The 0-20 and 10-20 kHz stimuli produced less than 40 % potentiation. No startle amplitude changes were obtained in unpaired or untrained groups.

These results suggest that the expression of fear-potentiated startle using an auditory CS interacts with the unconditioned effect of auditory stimuli on the acoustic startle reflex. Experiments investigating the role of the medial geniculate nucleus in the mediation of potentiated startle using an auditory CS are under way (Ledoux et al., Neurosci., 17:615, 1986).

250.14

DIFFERENCES IN SPATIAL LEARNING AND MEMORY ABILITIES FOLLOWING MEDIODORSAL VERSUS POSTERIOR THALAMIC LESIONS IN RAT: S. W. Henderson* and P.J. Langlais. Dept. of Psychology, SDSU and Research Svc., VAMC, San Diego, CA.

Rats recovered from acute pyrithiamine induced thiamine deficiency (PTD) have cognitive and memory deficits and lesions within the mediodorsal (MD) nucleus, the intralaminar (IL) nuclei and the posterior nuclear group (Po) of the thalamus. To determine the behavioral importance of these thalamic lesions, spatial learning and memory were examined following discrete lesions of MD or Po while sparing IL.

Male Long-Evans rats with bilateral electrolytic lesions

Male Long-Evans rats with bilateral electrolytic lesions confined to MD (n=10) or Po (n=14) were studied. Three weeks following surgery, the two lesion groups and a sham-operated control group (CT, n=11) were trained on a food reinforced nonmatching-to-sample T-Maze task. The initial performance (% correct) of the MD group was significantly lower than both the CT and Po groups. By the 4th day of training all groups were performing > 90% correct. Subsequent testing at interrun delays of 60-600 seconds demonstrated no significant group differences in performance. These data suggest that: i) subtotal destruction of MD but not of Po results in an initial spatial learning impairment; ii) lesions restricted to MD or Po do not impair delay-sensitive spatial working memory; and iii) damage of IL nuclei and/or fibers coursing in this region are responsible for memory deficits observed in recovered PTD rats. (Supported by VA Medical Research and SDSU Funds).

NEUROTOXICITY: PNS AND RETINA

251.1

ACETYLCHOLINESTERASE ANTIBODIES CAUSE PREGANGLIONIC IMMUNOSYMPATHECTOMY. S. Brimijoin, V. A. Lennon, and P. Hammond. Depts of Pharmacology and Immunology, Mayo Clinic, Rochester MN 55905.

Systemic administration of monoclonal antibodies to neural acetylcholinesterase (AChE) caused selective and permanent, complement-mediated destruction of presynaptic sympathetic fibers in adult rats. Ptosis, hypotension, bradycardia, and postural syncope appeared within hours and lasted for months after a single intravenous injection. In the superior cervical ganglion, AChE activity disappeared from the neuropil but not from the nerve cell bodies; choline acetyltransferase activity (ChAT) and ultrastructurally defined synapses were also lost. Similar effects occurred in stellate, thoracic, lumbar, and coeliac ganglia, and in the adrenal medulla. Electrical stimulation of preganglionic sympathetic fibers failed to evoke end-organ responses, but direct ganglionic stimulation was effective. Parasympathetic function was preserved. Motor performance and the ChAT content of muscle also remained normal. This unique model of cholinergic autommunity represents a new tool for autonomic physiology. (Supported by grants NS 18170 and NS 15057).

251.2

BOTULINUM NEUROTOXIN TYPE A AT pH 5.0 BREAKS DOWN AT ABOUT THE MID-POINT OF HEAVY CHAIN. B. R. DasGupta and M. Tepp*. Food Research Institute, University of Wisconsin, Madison, MI 53706.

Hisconsin, Madison, MI 53706.

The 150 kDa botulinum neurotoxin (NT) binds to receptors on the cholinergic presynaptic membrane; the C-terminal half the 100 kDa H chain is presumed to have the receptor binding site, endocytosis brings the NT into the closed vesicles within the nerve cells. After the endocytic vesicles become acidified, the N-terminal segment of the H chain is thought to form channels (FEBS Lett. 226, 115) that allow a portion of the NT to pass through the membrane into the cytoplasm. The 50 kDa L chain on reaching the cytosol inhibits neurotransmitter release (J. Biol. Chem. 264, 10354). The L chain could enter the cytosol by itself or with a segment of the H chain following reduction of a -S-S- that links the L and H chains or a peptide cleavage of the H chain away from its N-terminus. We find that the dichain type A NT exposed to pH 4.2 or 5.0, 0.05 M ammonium acetate, 8°-25°C begins to break down within 5 min yielding N100 kDa fragment(s) i.e. L chain-S-S-N-terminal half of the H chain, and a N40 kD major band. The N-terminal residues of the N40 kDa fragment, Pro-Ile-Asp-(Trp/Lys)-Asn-Gln-Ile-Gln-Leu-Phe-Asn- align with the receptor binding segment of tetanus NT beginning at its residue #915 (Pro). The five underlined residues identical to tetanus (EMBO J. 5, 2495) show 45% homology. Funded by NIH, NS17742 and NS24545.

251.3

BOTULINUM NEUROTOXIN TYPES A AND E CLEAVED WITH PEPSIN GENERATES ~45 kDa C-TERMINAL FRAGMENTS. J. A. Gimenez*. B. R. Dasgupta and A. W. Clark. Food Res. Inst. & Dept. of Anatomy, University of Wisconsin, Madison, WI 53706. Botulinum neurotoxins (NT) are proteins composed of ~50 kDa L and ~100 kDa H chains, that correspond to the

Botulinum neurotoxins (NT) are proteins composed of ~50 kDa L and ~100 kDa H chains, that correspond to the N— and C—terminal segments of the parent ~150 kDa single chain. The NT binds via H chain to the receptors on the presynaptic membrane at the neuromuscular junctions; the L chain inhibits release of the neurotransmitter after its entry into the secretory cells. The N—terminal half of the H chain forms channels in lipid bilayer membrane and is believed to form channels on the neuronal cell membranes for the translocation of the L chain. The ~50 kDa C—terminus is presumed by analology with tetanus NT to contain the receptor binding site. We have digested the antigenically distinct type A and E NTs with pepsin (50—100:1 w/w, pH 4.2 and 6, 25°C) and isolated the C—fragments in one chromatographic step. The fragment from type A, although single band by SDS—PAGE, is heterogenous; the major sequence beginning with X.E.Y.I.K.N.I— aligns with residue #874 (Glu) of tetanus NT (EMBO J. 5, 2495). The first 48 residues of the pure C—fragment from type E NT, F.K.R.I.K.S.S.S.V.L.N. M.R.Y. K.N.D.K.Y.V.D.T.S.G.Y.D.S.N.I.N.I.N.G.D.V.Y.K.Y.P.T.N.K.N. Q.F.G.I.Y—, align with tetanus NT beginning at residue #877 (Asp). The 12 underlined residues identical to tetanus show 25% homology. Funded by NIH (NS17742 and NS24545).

ACRYLAMIDE AND 2,5-HEXANEDIONE INHIBIT GLYCERALDEHYDE-3-PHOSPHATE DEHYDROGENASE IN SYNAPTOSOMES. M. I. Sabri. Oregon Health Sciences University, Portland, OR 97201
Repeated exposure of rats to the neurotoxins acrylamide (AC) or 2,5-hexanedione (HD) results in blockade of fast axonal transport, distal axonal degeneration and hindlimb paralysis. The biochemical mechanism underlying axonal degeneration is not understood. Speculating that blockade of fast axonal transport results due to reduction in chemical energy (ATP), early investigations examined the effects of the neurotoxins on glyceraldehyde-3-phosphate dehydrogenase (GAPDH), an enzyme on which fast axonal transport is known to depend. Since GAPDH was studied in nerve tissue homogenates containing a heterogeneous population of cells, the sensitivity of this enzyme in the neuronal (axonal) compartment could not be selectively determined. The present study determines the effect of AC and HD on GAPDH activity and ATP levels in highly purified synaptosomes from rat forebrain. Purity of synaptosomes was assessed by enzyme markers and electron microscopy. Synaptosomes synthesized ATP (1.15 ± 0.16 nmol/mg protein) from glucose and iodoacetate (2.5-5.0 mM), a powerful inhibitor of GAPDH, blocked ATP synthesis by over 80%. Incubation of synaptosomes with AC or HD caused a concentration dependent inhibition of GAPDH; approximately 60% and 40% loss of GAPDH was observed after 2 h incubation with 10 mM AC and HD, respectively. The effect of AC and HD on ATP levels and fast and slow axonal transport in this model is under study. Supported in part by NS

CORRELATION OF ORGANELLE CONTENT IN SENSORY NERVE ENDINGS WITH CHANGES IN FAST AXONAL ORGANELLE TRANSPORT IN CHRONIC ETHANOL-FED RATS. J.A. McLane, J.A. McNulty, M.B. Atkinson, and A.C. Breuer. Hines VA Hospital, Hines, IL 60141, Loyola Univ. Sch. of Med, Maywood, IL 60153, and Cleveland Clinic Foundation, Cleveland, OH 44195

Exposure to neurotoxic substances often leads to a dying back peripheral neuropathy. Acrylamide, n-hexane, BPAU, and streptozotocin diabetes produce alterations in fast axonal transport (FAT) accompanying the dying back neuropathy. We have demonstrated the time-course of changes in FAT that result from chronic ethanol feeding (Soc. Neurosci. Abstr. 15:142, 1989). In order to examine the morphological effect that these changes in FAT have on peripheral nerves, we have examined the content of organelles in sensory nerve endings of muscle spindles from rats fed ethanol for 1 to 5 months. From electron micrographs (1) volume densities and (2) area densities of organelles, and (3) the density of "contacts" between nerve ties of organelies, and (3) the density of contacts between nerve ending and myocyte were estimated and correlated with changes in FAT. An early period of cellular damage was characterized by a reduced retrograde FAT frequency and an increase in the concentration of organelles in the nerve terminals. A later compensatory phase was evidenced by an increase in the rate of retrograde FAT, a return of FAT frequencies to normal, and a return of organelle concentrations to normal. These findings suggest that the neurons are capable of altering both speed and frequency of organelle traffic to maintain an equilibrium organelle concentration in the nerve ending.

RAPID AXONAL TRANSPORT IN EXPERIMENTAL ETHYLENE OXIDE NEUROPATHY. H.Nagata*, K.Arasaki, N.Ohkoshi*, I.Kanazawa* T.Nakanishi*, A.Ohnishi*(§) Dept. of Neurol., Inst. of Clinical Med., Univ. of Tsukuba, Tsukuba, Ibaraki 305, Japan. (§)Dept. of Neurol., Univ. of Occupational & Environmental Health, Kitakyusyu 807, Japan

Ethylene oxide (EO), widely used as sterilant gas, causes peripheral neuropathy in human due to chronic occupational exposure. To elucidate the pathogenesis of this neuropathy, we tested axonal transport velocity and amount of transported intrinsic enzyme in peripheral nerves using experimental model of this disorder. The rats (tests) were subjected to six-hour exposures of EO in a chamber at a concentration of 500 ppm three times a week for fifteen weeks. Rapid axonal transport and quantitative histological alterations of peripheral nerves were studied. After \$5-methionine injection in the dorsal root ganglion, the velocity of rapid anterograde axonal transport of radioisotope labeled protein was measured and a 33% reduction of the velocity was detected in the neuropathic rats compared with control rats exposed to filtered room air (p<0.01). In separate experiment, sciatic nerve was ligated at middle thigh and after 3 hour interval, the nerve was dissected. Acetylcholine esterase (AChE) activity in proximal portion of the ligation was measured and calculated as accumulation rate per hour (transport amount). 18% of decrease in the accumulation was detected in test rats compared with controls. Thus, both of axonal transport velocity and amount were decreased in the neuropathic rats. On the other hand, in morphometric studies, histological changes were very mild. Therefore, a decrease of the velocity and transport amount of anterograde axonal transport under the mild histological abnormalities of the peripheral nerve may be playing a causative role in the development of distal axonal neuropathy due to chronic EO exposure.

251.9

NEUROPATHY ASSOCIATED WITH A NUCLEOSIDE INHIBITOR OF HIV: A RABBIT MODEL OF ddc TOXICITY. M.Litwak, T.Anderson*, C.Brosnan, A.Davidovich*, and J.Arezzo. Albert Einstein Coll. of Med., Bronx, N.Y. 10461 and Hoffmann La-Roche, Nutley, N.J. 07110

The nucleoside, 2',3'-dideoxycytidine (ddC) is a potent inhibitor of HIV. In clinical trials it has been associated with a dose-dependant peripheral neuropathy. Studies in Cynomolgus monkeys have reported electrophysiological changes but little underlying neuropathology. We studied 36 New Zealand white rabbits, a control group and 5 treated groups (10, 50, 100, 150, 250 mg/kg/day), for 17 weeks. Electrophysiological measures of both motor and sensory peripheral nerves and visual evoked potentials (VEP) were taken at 0, 7, 13, and 17 weks. The VEP showed no significant changes over the course of the study. At 13 wks, sural conduction velocity (CV) was delayed by 6.1, 12.1, and 17.3% in the survivors of the 100 (N=6), 150(N=4), and 250(N=3) mg/kg dose groups, respectively. The peroneal motor CV was unchanged. At 13 wks, the 150 and 250 groups, along with 2 randomly selected controls, were sacrificed. Distal and proximal segments of the sciatic nerve and spinal roots of the treated animals showed both axonal and myelin changes, (myelin splitting, intramyelinic edema, demyelination), Schwann cell proliferation, and increase in endoneurial matrix. No CNS pathology was evident. At 16 wks, 3 of the 100 mg/kg and 1 of the 50 mg/kg rabbits showed clinical signs including: forelimb paresis, hindlimb paralysis, and muscle fasciculations. At 17 wks the sural CV was significantly delayed (p<0.01) in the bighest dose group remaining, 100 mg/kg(N=4). The peroneal CV was delayed by 19.5 (p<0.01) and 29.4% (p<0.01) in the 50 and 100 mg/kg groups, respectively. Amplitude changes were not significant. Histopathology in the 100 mg/kg group after 17 wks showed changes identical with those of the highest dose groups at 13 wks. These findings are consistent with ddC induced toxic polyneuropath

251.6

CONSEQUENCES OF CHRONIC LOW-DOSE EXPOSURE TO THE CARBAMATE PESTICIDE ALDICARB FOR RAT TRIGEMINAL VIBRISSA AFFERENTS. B.G. Klein, W.C. McCain*, L. Eng*, M. Ehrich*, & M. Farage— Elawar*. Dept. of Biomed. Sci., VA-MD Reg. Col. Vet. Med., Virginia Tech, Blacksburg, VA 24061.

The literature regarding effects of chronic low-dose exposure to carbamate pesticides is limited & equivocal. To address this deficiency, we examined trigeminal (V) primary afferents innervating C1 vibrissa follicles, at the periphery or in the V ganglion, after chronic aldicarb exposure. Rats received daily intragastric doses of 0.2 mg/kg of aldicarb in a corn oil vehicle (treated) or corn oil vehicle alone (control). After 100-106 days treated & 8 control rats received an injection of the fluorescent tracer true blue (TB) into the Cl vibrissa follicle. Following formalin perfusion, 25 um V ganglion sections were cut horizontally in a cryostat. After 110-114 days, 7 treated & 7 control rats were perfused with paraformaldehyde-glutaraldehyde. C1 vibrissa follicles were dehydrated, osmicated, embedded in plastic & cut at 1 um. Labelled ganglion cell profiles were counted at 250% under episcopic fluorescence & myelinated vibrissal nerve axons were counted at 1250% under brightfield oil immersion. Comparing treated rats with controls, no significant change was observed in the number of myelinated Cl vibrissal nerve axons or in the number of ganglion cell profiles labelled by TB injection of Cl follicles. Support: VA Tech Creative Match Grant & Col. Vet. Med..

USE OF A FUNCTIONAL OBSERVATIONAL BATTERY TO EVALUATE PYRIDOXINE-INDUCED ACUTE TOXIC SENSORY NEUROPATHY L.G. Shell*, J.B. Musser*, B.S. Jortner, K. Dyer* Virginia-Maryland Regional College of Veterinary Medicine, Virginia Tech, Blacksburg, VA 24061.

The Functional Observational Battery (FOB), a series of home-cage and open field observations and physiological and sensorimotor measurements, has been used to evaluate neurotoxicants in laboratory rats (Moser V.C., et al. Fund. Appl. Toxicol. 11:189, 1988). We used a modified FOB to assess pyridoxine-induced sensory neuropathy. Young adult male Sprague-Dawley rats were given 600 mg/kg pyridoxine hydrochloride ip twice daily for 4 days. The FOB was done prior to dosing (day -2) and 2 days after the last dose (day 6) in control (n=12) and treated(n=13) the last dose (day 6) in control (n=12) and treated(n=13) groups. No significant differences were found between the groups on day -2. Significant differences between the groups on day 6 included: weight loss (gms) 337.6 \pm 12.4 vs. 227.6 \pm 10 (mean \pm SEM, control values given first); rearing (numbers) 9.8 \pm 1.5 vs. 2.2 \pm 0.5; seconds on rotorod 21 \pm 3.0 vs. 2.5 \pm 0.1; pelvic limb grip strength 0.52 \pm 0.03 vs. 0.29 \pm 0.03 (n=5 for treated group in this test). All treated rats had gait changes such as ataxia and dragging of pelvic limbs. Neuropathological studies in treated rats showed prominent neuroological studies in treated rats showed prominent neuro-nopathy in peripheral sensory ganglia, progressing to neuronal necrosis. This study demonstrates usefulness of the FOB to assess pyridoxine-induced sensory neuropathy.

AIDS VIRUS COAT PROTEIN-INDUCED INCREASES IN [Ca²+]; AND NEUROTOXICITY ARE NOT PREVENTED BY ANTI-CD4-ANTIBODIES IN RAT RETINAL GANGLION CELLS. Evan B. Dreyer, Peter K. Kaiser, Jeffrey T. Offermann, and Stuart A. Lipton. Dept. of Neurology, Children's Hosp. & Harvard Med. Sch., Boston, MA.

Picomolar concentrations of native or recombinant coat protein gp120 from the human immunodeficiency virus type 1 (HIV-1) strikingly increased [Ca2+]; and subsequently injured rat retinal ganglion cell neurons in culture (Dreyer et al., Science 1990;248:364). As we reported last year (Kaiser et al. Soc. Neurosci. Abstr. 1989;15:143), both the increase in $[Ca^{2+}]_i$ and this form of neurotoxicity could be completely abrogated by anti-gp120 but not by control preimmune serum, suggesting that the lethal effects of the purified preparations of the envelope protein were due to gp120 and not to a contaminant.

In T lymphocytes, entry of HIV-1 is mediated by gp120 binding to a surface protein designated CD4. However, in the present study, two specific anti-CD4 antibodies, at concentrations known to block effects mediated by binding to CD4 on the surface of rat T cells, did not prevent the rise in CD4 on the surface of rat 1 cens, did not prevent the rise in $[Ca^{2+}]_i$ or the neuronal injury induced by gp120. These findings suggest that both the increase in $[Ca^{2+}]_i$ and the deleterious effects engendered by gp120 in neurons may not be mediated via binding to the CD4 molecule; an alternative mechanism must be sought.

FORMIC ACID INHIBITS CYTOCHROME OXIDASE ACTIVITY IN RETINA AND IN CULTURED RETINAL CELLS <u>J.T. Eells.</u> <u>T.G. Murray*</u>, <u>C. Rajani* and J. M. Burke*</u>, Dept. of Pharmacology and Toxicology and Dept. of Ophthalmology, Medical College of Wisconsin, Milwaukee, WI 53226.

Human methanol poisoning is characterized by formic acidemia, Human methanol poisoning is characterized by formic acidemia, metabolic acidosis and visual toxicity. Formate, the toxic metabolite in methanol poisoning, has been hypothesized to disrupt visual function by inhibiting the mitochondrial enzyme, cytochrome oxidase (c.o.) in the retina or optic nerve. The effect of formate on c.o. activity was investigated in bovine eye cup preparations and in cultured cells. Eye cups were incubated (8 hrs) in the presence of formate (1-100 mM) and c.o. activity was determined in different regions of the retina. Similar reatment protocols were followed for cultured Muller glial cells, retinal pigmented epithelium (RPE) and dermal fibroblasts. Formate inhibited bovine retinal c.o. activity with the greatest degree of inhibition (34% and 58% reduction in c.o. by 10 mM and 100 mM formate, respectively) observed in the region of the retina most proximal to the optic disk. In cultured Muller glial cells formate produced time and concentration dependent alterations in cell morphology (rounding and narrowing of cellular processes) and an 80% reduction in c.o. activity. RPE cells were less sensitive to formate toxicity exhibiting no morphological alterations and only a 15% reduction in c.o. activity. Remarkably, there was no effect on cellular morphology or c.o. activity in cultured dermal fibroblasts. These data are indicative of regional differences in formate action in the intact retina and further suggest that the tissue specificity characteristic of methanol toxicity may occur at a cellular level.

STUDIES OF THE MECHANISM OF FOLATE RETINAL NEUROTOXICITY Z.H. Zhang, J.C. Blanks, and S.R. Snodgrass, Depts. of Neurology and Ophthalmology, USC School of Medicine and Neurology Research Laboratory, Childrens Hospital, Los Angeles, CA 90027

We previously reported histological damage to frog retina caused by folic acid (FA) and quisqualate (Soc Neurosci Abstr 15:480, 1989). To study the mechanism of this neuro-toxicity, we incubated frog retinal eyecup preparations in toxicity, we incubated from retinal eyecup preparations in control buffer, 3 mM FA, 3 mM perin, 30 uM nimodipine (NM), and 3 mM FA/30 uM NM for 1 hr at RT. Pterin and FA produced similar lesions including cytoplasmic and muclear changes in inner and outler nuclear layers and ganglion cell change. The Ca⁺⁺ channel blocker NM did not prevent FA injury and caused some damage when used alone. We studied the effect of FA on 2-deoxyglucose accumulation by the frog retina, and found 45% increase in 2-DG accumulation after treatment with 3 mM FA (pc.05). This stimulation was blocked by ouabain but not by NM. These data are consistent with an excitant effect of FA. We also studied retinal proteins by SDS-PAGE after incubation with $^{32}P_1$. We observed decreased labeling of a small protein (Mr 12 Kd) in retinas incubated with FA or FA + NM. This low molecular weight protein may contribute to FA membrane effects and neurotoxicity.

ALZHRIMER'S DISRASE: PHARMACOLOGY

252.1

CSF MONOAMINE AND NEUROPSYCHOLOGICAL CORRELATES IN PRESUMPTIVE ALZHEIMER AND RELATED DEMENTIA PATIENTS. S.G. Speciale, J. Trocewicz*, J. Hom*, M. Weiner* & R. Tintner*. Depts. of Psychiatry & Neurol., UT S.W. Med. Ctr., Dallas, TX 75235-9070.

A number of groups, including our NIA AD Research Ctr., are studying biochemical and psychological indices of Alzheimer's disease (AD) that might be diagnostic or track its progression. A neuropsychological indices of Alzheimer's disease (AD) that might be diagnostic or track its progression. A neuropsychological battery included measures of reasoning, memory and motor skills. Cerebrospinal fluid (csf) was analyzed for norepinephrine (NE) and its metabolite, MHPG, dopamine and its metabolites, DOPAC and HVA, and the serotonin metabolite, 5HIAA, using HPLC-EC. Activities of two cholinergic enzymes, acetylcholinesterase (AChE) and butyrylcholinesterase, and protein concentrations were assayed, using spectrophotometric techniques.

Diagnostic classifications were made on the basis of interviews and testing by a neurologist, psychiatrist and neuropsychologist. At the end of the neurological examination, lumbar csf fractions were drawn (measures of the 15-20 ml fraction reported here). Several subgroups were made, the largest being AD/probable (N-46) and AD/possible (30). Other groups included multi-infarct (8), mixed (9) and other dementia (15), as well as several neurological, psychiatric and normal groups. Means were compared between subgroups and a Pearson correlation analysis carried out among variables. Normal and Parkinson groups had global ratings of 28, within the normal range, while dementia subgroups ranged from 50-72, classified as moderate to severe deficits. In general, 5HIAA was reduced in most subgroups, while MHPG, DOPAC and HVA values did not differ significantly, Both enzymes were lower in the dementia groups, while MHPG, DOPAC and HVA values did not differ significantly, Both enzymes were lower in the dementia groups.

HIPPOCAMPAL EXCITATORY AMINO ACID RECEPTORS IN ALZHEIMER'S DISEASE: I. N-METHYL-D-ASPARTATE RECEPTOR COMPLEX. J. Ulas, L.C. Brunner, J.W. Geddes ¹ and C.W. Cotman. Dept. Psychobiology and ¹Div. Neurosurgery, University of California, Irvine, CA 92717, USA.

The status of the N-methyl-D-aspartate receptor complex (NMDArc) in Alzheimer's disease (AD) is of great significance considering the suggestion that some of the cell loss observed in the hippocampus of AD brain may be mediated by NMDA receptors. In this study, receptor binding levels were assayed using in vitro autoradiography. Several regions of the hippocampus proper, dentate gyrus, and parahippocampal area were investigated in control (n=5) and AD brains (n=5) which were age and sex matched. The following components of the NMDArc were studied: 1) an NMDA-sensitive binding site ([3H]-L-glutamate binding), 2) an allosteric regulatory site ([3H]-glycine components of the NMDArc were studied: 1) an NMDA-sensitive binding site (13H1-L-glutamate binding), 2) an allosteric regulatory site (13H1-glycine binding), and 3) a channel site (13H1-MK801 binding). The ratio of binding to agonist-preferring sites (13H1-L-glutamate binding) sites) and antagonist-preferring sites (13H1-CPP binding sites) was also monitored. No statistically significant differences in the level of binding to any component of the NMDArc were detectable in the hippocampus proper, molecular layer of the dentate gyrus, and parahippocampal area when mean values of binding for control and AD brains were compared. However, some AD brains displayed pronounced changes in levels of binding. For example, in some AD individuals a dramatic loss of binding to every component of the NMDArc was found in the CA1 region, but only if profound (>50%) loss of neurons in this area was observed. An increase (10-60%) in the binding to the NMDArc was found only in the infragranular layer of the dentate gyrus. The data suggest that there is a correlation between pathology (cell loss) and decrease in binding to distinct sites of the NMDArc. The mechanism behind the elevation in the binding in the infragranular layer is unclear; it may reflect some adaptive changes of the NMDA receptor to diminished glutamatergic input. NMDA receptor to diminished glutamatergic input.

252.3

HIPPOCAMPAL EXCITATORY AMINO ACID RECEPTORS IN ALZHEIMER'S DISEASE: II. NON-NMDA RECEPTORS. <u>I.W. Geddes. L. C. Brunner. J. Ulas. and C.W. Cotman. Div. Neurosurgery and Dept. Psychobiology, Univ. Calif., Irvine CA 92717</u>

There have been several conflicting reports regarding the status of excitatory amino acid (EAA) receptors in Alzheimer's disease. We have therefore evaluated in detail the status of the NMDA (Ulas et al.) and non-NMDA EAA receptors in AD, using *in vitro* autoradiography. Results to date have been obtained from five AD individuals and from five corresponding age-matched controls. For each experiment, an AD tissue sample was paired with a control sample. Binding densities were determined at both anterior and posterior levels of the hippocampal formation. Binding of [3H] kainic acid (KA) and [3H] amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) was evaluated using computer assisted image analysis (MCID, St. Catherines, Ontario). Corresponding sections were stained with cresyl violet, Bielschowskys silver stain, and Thioflavin S. The results obtained for KA were similar to those described previously. A 20% increase in the density of [³H]KA binding was observed in the outer molecular layer of the dentate gyrus at both anterior and posterior levels of the hippocampal formation. A slight decrease in KA binding densities in CA1 was also observed, predominantly in posterior sections. Interestingly, added calcium, which in the rat blocks the high affinity KA binding sites, had little affect on the density of [3H]KA binding in AD or control human tissues. With [3H]AMPA, there was a marked increase (26%) in the binding densities in the infragranular zone of the dentate gyrus of AD patients, particularly in the anterior region. AMPA binding densities were decreased by an average of 24% in the CA1c region of the hippocampus, but otherwise were largely maintained. The losses in KA and AMPA receptor density appear to correlate with the extent of neuronal loss, whereas the increases in receptor density are thought to reflect neuronal plasticity.

U-80816: A NOVEL PARTIAL MUSCARINIC AGONIST. V.H. Sethy, J.W.Francis, R.R.Russell, R.J.Collins, R.F.Heier, and M.W.Moon. CNS Research, The Upjohn Company, Kalamazoo, MI 49001 USA

RS 86 (RS) and oxotremorine (Oxt) have been investigated in humans for treatment of cognitive disorders with limited success because of the central and peripheral side effects. The narrow therapeutic index of these drugs may be due to their high intrinsic activity. Therefore, we attempted to synthesize a novel compound which binds to muscarinic receptors and has a low intrinsic activity as compared to RS and Oxt. U-80816 was one of the mostpromising compounds synthesized. The Ki's of U-80816, RS, and Oxt in (3H)-QNB binding assays were 72, 1600, and 130 nM, respectively, and in the (3H)-Oxt binding assays the corresponding values were 3.24, 15.6, and 0.54. U-80816 produced tremors with an ED50 of 2.5 mg/kg, and did not produce salivation or lacrimation. However, both RS and Oxt produced tremors, salivation, and lacrimation with ED50's in the range of 0.1 to 0.2 for the former and 1 to 2 mg/kg for the latter. U-80816 blocked Oxt-induced lacrimation. U-80816 has a significantly low intrinsic activity as compared to RS and Oxt for increasing striatal acetylcholine (Ach), for inhibiting hippocampal Ach release, and for increasing PI hydrolysis response. The results of our research with U-80816 suggest that this drug may have a desirable pharmacological profile for its use in human cognitive disorders.

THE DISTRIBUTION OF NICOTINIC CHOLINOCEPTIVE NEURONS IN THE FRONTAL CORTEX IN ALZHEIMER'S DISEASE.

H. Schröder, ^{1,3}

E. Giacobini, ¹ R.G. Struble, ² K. Zilles, ³ and A. Maelicke, ⁴ Depts.

Pharmacology and ²Psychiatry, Southern Illinois Univ. Sch. Med., Springfield, IL 62794, ³Dept. Anatomy, Univ. of Köln, F.R.G. and ⁴Dept. Physiological Chemistry, Univ. of Mainz, F.R.G.

Studies of cortical nicotinic cholinergic receptor (nAChR) sites with radioligands show that their density is decreased in Alzheimer's disease (AD). Their cellular distribution, however, is not known. To elucidate their location, autopsy samples of human frontal cortex were incubated with the monoclonal antibody WF 6 (Fels et al., <u>J. Biol. Chem.</u>, 261:15746, 1986) directed to the α -subunit ligand binding site of the nAChR. Immunoprecipitate (IP) was shown at the light and electron microscopic level using immunoperoxidase in three groups of patients: (i) young controls [n=3; 55±5 yrs], (ii) aged controls [n=3; 73±6 yrs] and (iii) Alzheimer cases [n=6; 74±5 yrs]. Numbers of immunoreactive (ir) and cresyl-violet-stained [n=6; 74±5 yrs]. Numbers of immunoreactive (ir) and cresyl-violet-stained (cv) neurons were counted in a standardized area. Layer II/III and V pyramidal neurons were preferentially labeled. Ultrastructurally, IP was distributed to postsynaptic densities. Neuron counts revealed statistically significant differences (p<0.001) between all groups [(i) 253±29 (mean±s.e.m.); (ii) 132±28; (iii) 28±6] for ir, but not for cv neurons. The findings point to a postsynaptic location of cortical nAChRs and a decrease of nAChR-expressing neurons in AD, not attributable to a simple cell loss. It remains to be assessed whether the reduction of receptor protein is due to cholinergic denervation or to a process intrinsic to cortical neurons. Supported by the Deutsche Forschungsgemeinschaft (Schr 283/6-1), Southern III. Univ. Central Res. Committee award, and R.J. Reynolds Tobacco Co. Revnolds Tobacco Co.

HP 749, A POTENTIAL THERAPEUTIC AGENT FOR ALZHEIMER'S DISEASE: (II) NEUROCHEMICAL PROFILE. **F.P. Huger, C.P. Smith, W.W. Petko*, P.G. Conway, R.C. Effland* and J.T. Klein*.** Depts. of Biological and Chemical Research. Hoechst-Roussel Pharmaceuticals, Inc. Somerville, NJ 08876. HP 749, [N-(n-propyl)-N-(4-pyridinyl)-1H-indol-1-amine hydrochloride], was active in several learning and memory tests, blocked the M-current in hippocampal slices and displayed adrenergic and cholinomimetic activities in vitro and in vivo. HP 749 inhibited biogenic amine uptake (NE \cong DA > 5HT) and α₂-adrenergic receptor binding at sub-micromolar concentrations and increased electricallybinding at sub-micromolar concentrations and increased electrically-stimulated [³H]NE release from cortical slices at concentrations of 1 and 10 µM. This increase in stimulated [³H]NE release is due to combined α_2 -antagonist and uptake inhibitory properties of HP 749. At a concentration of 100 μ M, HP 749 increased basal [3 H]NE release. HP 749 also increased brain NE turnover at doses of 10 and 30 mg/kg, but did not down-regulate β-adrenergic or 5HT₂ receptors after chronic

administration.

HP 749 inhibited the binding of various muscarinic ligands at low micromolar concentrations and stimulated phosphatidylinositol (PI) turnover in cortical slices at higher concentrations. The stimulation of PI turnover by HP 749 was apparently not receptor-mediated. HP 749 was not active as a cholinesterase inhibitor and did not increase the stimulated release of [³H]ACh. The unique cholinomimetic properties of HP 749 may relate to its ion channel effects.

Evaluation of HP 749 in various in vitro radioligand binding assays revealed that it had negligible direct interactions with other

assays revealed that it had negligible direct interactions with other types of neurotransmitter receptors.

ACETYL-L-CARNITINE: A NOVEL APPROACH IN THE TREATMENT OF ALZHEIMER'S DISEASE

M. Calvani, A. Carta, Neurological Research Dept., Sigma Tau Pharm., Pomezia, Italy. G. Bartolomucci, Dept. Public Health, 2nd University of Rome, Italy.

G. Bartolomucc, Dept. Public Health, 2nd University of Rome, Italy.

Although the defect of the cholinergic neurotransmission still represents the major impairment of Alzheimer's disease, brain function and other systems of the neurochemical transmission are clearly involved in such disease as well. Moreover, a series of biological evidences suggest one consider AD as a systemic disease with a primary neurological expression. Therefore, a cholinomimetic therapy of AD should play only a pure symptomatic, although important, action leaving inadequate the impact on the progression of disease. Acetyl-1-carnitine (ALC) is a naturally occurring substance at the mitochondrial level, mainly involved in the B-oxidation of endogenous long-chain fatty acids. AIC shows cholinomimetic properties, (being structurally quite similar to Ach), together with a variety of metabolic actions able to restore in aging cells certain energetic processes. Interestingly, reviewing the overall data coming from 553 patients over 7 double-blind placebo controlled studies in AD patients, ALC demonstrated slowing down the progression of disease, modifying the course of the decay of neuropsychological (MMSE, BD) and clinical (CGI) profiles. Furthermore, the drugs was remarkably well tolerated and safe: 13.6% was the drop-out figure of ALC-treated patients, but only 12 of 272 subjects withdrew for possible adverse drug reactions, (mainly agitation), side effects involved less than 5% of the ALC treated patients.

HP 749: A PHARMACOLOGICAL PROFILE OF A THERAPEUTIC AGENT FOR ALZHEIMER'S DISEASE; I. M. Cornfeldt*, F. Wirtz-Brugger*, M. Szewczak*, R. Blitzer, V. Haroutunian, R. Effland*, J. Klein*, C. Smith. Depts. of Biological and Chemical Research, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, N.J. 08876 and Mt. Sinai Medical Center, New York, N.Y. 10029.

HP 749 [N-(n-propyl)-N-(4-pyridinyl)-1H-indol-1-amine hydrochloride] was active in tests predictive of efficacy in Alzheimer's disease (AD). HP 749 reversed the amnesic effects induced by scopolamine in a passive avoidance paradigm in mice (0.02-0.63 mg/kg, s.c.) and enhanced memory retention in normal rats in a similar paradigm (0.02 mg/kg, s.c.). HP 749 enhanced the retention of passive avoidance learning in rats (0.04 and 0.08 mg/kg, s.c.) with combined cholinergic and noradrenergic deficits where physostigmine alone was not effective. HP 749 (1.25 where physostigmine alone was not effective. HP 749 (1.25 mg/kg, i.p.) enhanced an electrophysiological correlate of cognitive processing (P300) in frontal rat brain regions. Wave VI of the brainstem auditory evoked response was increased by HP 749 (0.01-0.08 mg/kg, i.p.) and HP 749 reversed the depressant effects of hemicholinium (60 µg, icv) in this procedure. *In vitro* electrophysiological tests showed that HP 749 blocked the M-current, an effect which may enhance neuronal excitability, without effecting the I_{AHP} to the same degree. These results suggest that HP 749 should be efficacious in the treatment of AD particularly in those cases that are not responsive to cholinomimetic therapy alone.

HP 749, A POTENTIAL THERAPEUTIC AGENT FOR ALZHEIMER'S DISEASE: (III) PHARMACOKINETICS IN THE RAT, DOG AND MONKEY, R.S. Hsu*, J.W. Hubbard, S.M. Chesson*, E.M. DiLeo*, R.C. Effland* and J.T. Klein*. Departments of Chemical Research and Clinical Pharmacology. Hoechst-Roussel Pharmaceuticals, Inc. Somerville, NJ 08876.

HP 749 [N-(n-propyl)-N-(4-pyridinyl)-1H-indol-1-amine hydrochloride] has shown cholinergic and noradrenergic activities both in vitro and in vivo. Pharmacokinetic studies were performed both *in vitro* and *in vivo*. Pharmacokinetic studies were performed in the rat (20 mg/kg), dog (10 mg/kg) and monkey (10 mg/kg). The plasma and brain samples were analyzed by an HPLC method using an analytical Hypersil phenyl column, and the concentrations of HP 749 and metabolites were quantitated by UV detection. Following oral administration, HP 749 was rapidly absorbed and metabolized, primarily to the N-despropyl metabolite (7480) in the tested animals. HP 749 reached maximal plasma levels (Cmax) of 3.2, 3.0 and 1.7 µg/ml at 0.25, 2 and 1 hr postdose for the rat. dog and monkey respectively then plasma levels (Chiax) of 3.2, 3.0 and 1.7 µg/mi at 0.23, 2 and 1 nr postdose for the rat, dog and monkey, respectively, then disappeared with an elimination half-life of about 2-4 hr. The bioavailability of HP 749, estimated by AUC, in the rat, dog and monkey was 9.0, 18.9 and 5.9 µg-hr/ml, respectively. The plasma concentration-time profiles of 7480 paralleled those of HP 749 in the respective species. The ratios (HP 749/1480) of Cmax are about 4.5, 2.5 and 6.5, and AUCs about 1.5, 1.5 and 2.0 for the rat, dog and monkey, respectively. In addition, the rat study showed HP 749 and 7480 penetrated extensively into the brain with kinetic profiles paralleling those in the plasma.

SEROTONIN BINDING IN THE HUMAN PINEAL GLAND: AGE AND AD RELATED ALTERATIONS. <u>D.L. Sparks and T. Landers*</u> Sanders-Brown Center on Aging, Dept. of Pathology and the Medical Examiner's Program, Univ. of KY Medical Center, Lexington, KY 40536-0230.

It is well known that noradrenergic binding in the human pineal gland nediates melatonin production, and a recent report indicates that noradrenergic binding is altered in the pineal gland of AD patients (Jengeleski et al. Brain Res,481:378,1989). This laboratory has previously reported the initial finding of serotonin binding in the human pineal gland, and a reduction of that binding in the gland of some subjects that committed suicide (Sparks and Little, Psychiatr Res, in press). In that report, preliminary data indicates a lack of age related change in total serotonin binding (S-1) in the gland and the absence of the S-1a subtype.

the S-1a subtype.

In the present study we have investigated total serotonin binding, and its displacement by N-Acetyl-serotonin and the S-1a receptor inhibitor, 8-OH-DPAT, in the pineal gland of controls and AD subjects. Our non-heart disease controls were grouped according to their age at death as follows: 1) under 40 yr, N=26; 2) 40-65 yr, N=10; and 3) over 65 yr, N=6. The 9 AD subjects were all over 65 years of age.

over 65 yr, N=6. The 9 AD subjects were all over 65 years of age. There was no significant difference in the saturation isotherms of total S-1 binding among the control groups, and although not significant, the S-1 binding was reduced in the AD subjects. No S-1a type binding was found in the pineal gland in any subject group. N-Acetyl-5HT inhibited 5HT binding 30-35% in the two younger control groups, but was without effect in the older control group. In contrast, N-Acetyl-5HT inhibited 5HT binding 30% in the AD population. (Supported by NIH grants 1-PO1-AG05119 and 1-P50-AG05144)

A HEMIN-SENSITIVE KINASE ASSOCIATED WITH THE A68 PROTEINS IN ALZHEIMER'S DISEASE. <u>I.Vincent and P.Davies*</u>, Depts. Pathol. and Neurosc., Albert Einstein Coll. of Med., Bronx, NY, 10461.

We have previously described (Neurobiol. Aging, in press) a second messenger-independent, casein kinase I-like activity in purified preparations of A68 from Alzheimer brain. This activity phosphorylates the A68 proteins, and in addition, was found to comigrate, with A68 following active site labelling with the photoaffinity analog 8-azido-α-³²P-ATP. In continuing studies, we have found that limited chymotryptic cleavage of both ³²P and azido-ATP labelled A68 preparations yields similar labelled peptides. We have also examined the effects of various concentrations of hemin on the phosphorylation of these proteins. Starting with 1µM hemin, incorporation of phosphate into A68 is found to be inhibited. Phosphorylation of casein by the A68 preparation is also inhibited by 1µM hemin. In addition, it is found that subsequent immunorcactivity of A68 with Alz-50 on nitrocellulose blots is reduced following hemin treatment. This 1μM hemin. In addition, it is found that subsequent immunoreactivity of A68 with Alz-50 on nitrocellulose blots is reduced following hemin treatment. This observation is not accompanied by a loss of protein as indicated by positive reaction with other antibodies directed against A68, and by silver staining. When A68 preparations are boiled prior to incubation with 1μM hemin, the subsequent loss in Alz-50 immunoreactivity is also observed. Hemin-agarose affinity chromatography of the A68 preparation resulted in retention of the proteins by the resin. Elution of the bound protein was achieved with 6M urea. Thus, hemin appears to directly interact with A68. Since hemin inhibits the phosphorylation of casein by the A68 preparation, it is suggested that the kinase activity of the preparation is associated with the A68 protein itself. This possibility is strengthened by the results of the proteolysis experiments described above. It is presently unclear whether the action of 1μM hemin on the kinase is of any physiological significance in Alzheimer's disease. The property of hemin of any physiological significance in Alzheimer's disease. The property of hemin sensitivity is rather unique, having being ascribed to only one other kinase, the heme regulated inhibitor of reticulocyte protein synthesis (Ranu & London, 1976,PNAS,73, 4349-4353).

PERFORMANCE ON A DELAYED MATCHING-TO-SAMPLE TASK DURING A DOUBLE-BLIND TRIAL OF THA AND LECITHIN IN ALZHEIMER'S DISEASE PATIENTS

TASK DURING A DOUBLE-BLIND TRIAL OF THA AND LECTIHIN IN ALZHEIMERS DISEASE PATIENTS

K.M. Perryman, L.J. Fitten and D.J. McGinty. Cognitive Neurophysiology Lab., Sepulveda VAMC and Departments of Psychiatry, Biobehavioral Science and Medicine, UCLA School of Medicine, Los Angeles, CA 90024

Seven male subjects (Ss), 65-79 (mean=71.25, SD=+4.5) years of age meeting NINCDS-ADRDA criteria for probable Alzheimer's disease (AD) were enrolled in a double-blind, inpatient-outpatient tetrahydroaminoacridine (THA, tacrine) and lecithin trial. Memory measures on a delayed, 4-second, matching-to-sample task were made during baseline and THA administration periods using an interactive, computerized presentation of visual images ("X" and "O") and compared to the performance of 12, healthy, age-matched controls (Cs). AD Ss, performance was significantly different from Cs' during baseline periods for both in- and outpatient phases (p<.001). For THA periods, AD Ss also differed from Cs in reaction time (RT) and number correct (NC) responses (p<.001). AD Ss were slower in their RT and got fewer correct choices than Cs during both baseline and THA periods. However, when each patient was compared to the control group mean to compute standard Z scores, RT and NC performance associated with THA administration showed Z scores closer to the mean than did baseline measure. The anticholinesterase THA appears to produce a subtle improvement in memory retention IN AD patients.

RELATIONSHIP BETWEEN DOSE OF ARECOLINE AND COGNITIVE PERFORMANCE IN PATIENTS WITH DEMENTIA OF THE ALZHEIMER TYPE. K.C. Raffaele, P.P. Morris*, J.V. Haxbv*, S.I. Rapoport, T.T. Soncrant. Laboratory of Neurosciences, National Institute on Aging, NIH, 10/6C103, Rethesda, MD 20892.

The finding of a cholinergic deficit in dementia of the Alzheimer type (DAT) has led to therapeutic attempts to increase brain acetylcholine action. Although cholinergic precursor therapy generally has proven inefficacious, some improvements following cholinesterase inhibitor or cholinimprovements following cholinesterase inhibitor or cholinergic agonist therapy have been reported. In the current pilot study, the effect of arecoline, a direct muscarinic agonist, on cognitive performance of NAT natients was evaluated. Three patients with mild or moderate dementia (Folstein Mini-Mental scores 25, 17 and 21) were given arecoline by continuous intravenous infusion for two weeks. Arecoline was administered in a series of increasweeks. Arecoline was administered in a series of increasing doses; cognitive testing was performed at five dose levels: 1, 4, 16, 28 and 40 mg/day. Fight tests were given, examining a range of cognitive functions. Significant improvement across subjects (P < 0.05) was found on two measures of verbal function, Stroop Words Read (4 mg/day) and FAS Verbal Fluency (28 mg/day). Thus, in NAT non-memory cognitive function may be more sensitive to cholinergic enhancement or may improve at different dose levels than does memory function.

BLOCKADE OF AF64A (ETHYLCHOLINE AZIRIDINIUM ION)-INDUCED MEMORY IMPAIRMENT IN RATS VIA PRETREATMENT WITH NICOTINE. J.A. ROSECTAS*, J.R. James*, C. Stamford*, S.E. Robinson, & H.F. Villanueva, Dept. of Pharmacology/Toxicology, Va. Commonwealth Univ., Richmond, Va. 23298.

The present study investigated whether pretreatment with nicotine (NIC) desensitizes acetylcholinergic (ACH) receptors, thus preventing the short-term memory deficits produced by the intraventricular (IVT) administration of the cholinergic neurotoxin AF64A (ethylcholine aziridinium ion). Following training on a memory task in a radial arm maze, rats were pretreated with NIC, physostigmine (PHY), or saline via subcutaneous Alzet pumps for 14 days. On day 7 of drug infusion, rats were injected IVT with AF64A. After a recovery period of 7 days, be-AF64A. After a recovery period of 7 days, havioral testing was resumed. Rats were then sacrificed and ACH and choline levels were measured in the hippocampus, prefrontal cortex, striatum and pons via HPLC. Results indicate that NIC pretreatment partially attenuated the memory deficits produced by AF64A, suggesting that NIC may spare ACH neurons from neurotox-icity via receptor desensitization. Supported NIH grant # DA04002-04 and Va. Center on Aging grant # 9003.

TETRAHYDROAMINOACRIDINE (THA) REDUCES VOLTAGE-DEPENDENT CALCIUM CURRENTS IN RODENT SENSORY NEURONS. K.M. Kelly+, R.A Gross+ and R.L. Macdonald+#, Depts. of Neurology+ and Physiology#, U. of Michigan, Ann Arbor, MI 48104.

Tetrahydroaminoacridine (THA) is a centrally active anticholinesterase that may be useful in the palliative treatment of patients with Alzheimer's Disease. THA is also known to have effects on voltage-dependent K⁺ and Na⁺ currents in a variety of neurons. There is no information available on the effects of THA on neuronal voltage-dependent Ca²⁺ currents.

We studied the effects of THA on the Ti, N and L Ca²⁺ current components of acutely dissociated nodose ganglion neurons from 6-10 day old rats using the whole cell patch clamp technique. Recording electrodes old rais using the whole cere pactor claim technique. Recording electrodes contained (in mM): CsCl 140, CsOH 30, Hepes 10, EGTA 10, ATP 5 and GTP 0.1 (pH 7.2-7.3, ~300 mOsm). Neurons were bathed in (in mM): choline Cl 67, TEA 100, glucose 5.6, KCl 5.3, CaCl₂ 5.0, MgCl₂ 0.8, HEPES 10 (pH 7.35, ~320 mOsm). THA (500 nM-250 μM) was applied by passive diffusion from a blunt-tipped micropipette positioned 50 μm from the cell soma before and during voltage step commands. THA was tested on 18 neurons. THA reversiby reduced T, N and L $\rm Ca^{2+}$ currents in a concentration-dependent manner and was more potent in reducing T current. THA reduced peak T current by 14% at 500 nM and by 56% at 100 μ M. THA had no effect on N and L currents at 500 nM but reduced the peak currents by 5% at 10 μM and by 100% at 100μM. Recovery of current magnitude was complete by 1 min (T) and 4 min (N and L). These results suggest that an additional mechanism of action of THA in central neurons is the reduction of voltage-dependent Ca²⁺ currents. NIH NINCDS #1 T32 NS07222 and an American Academy of Neurology Research Fellowship Award (KMK), NS 01019 and NS 19613 (RAG) and DA04122 (RLM).

MU OPIATE RECEPTORS IN ALZHEIMER'S DISEASE: IN VIVO QUANTIFICATION BY C-11 CARFENTANIL AND PET. H.-W. Mueller-Gaertner*, H.S. Mayberg, C. Meltzer, L. Tune*, J. Brandt*, H.N. Wagner* Jr. R.F. Dannals* .A.A. Wilson *.H.T. Ravert *. J.J. Frost. The Johns Hopkins Medical Institutions, Baltimore, MD 21205

The neurodegeneration of Alzheimer's Disease(AD) is associated with changes in many pre- and post-synaptic neurochemical markers. Metabolic and blood flow imaging in AD demonstrate characteristic reductions in temporo-parietal cortex, but imaging in AD demonstrate characteristic reductions in tempore-planetar cortex, the chemical specificity of these changes is low. Improved chemical specificity, and possibly improved sensitivity in detecting early disease may be achieved by imaging selected pre- and post-synaptic chemical markers.

Postmortem AD studies demonstrate a 50% decrease in mu opiate receptors in the amygdala, a brain region associated with early and severe pathological changes in AD. Accordingly, PET quantification of mu opiate receptor binding with C-11 confeatent laws perfected in six AD positions and four gray method control whitest

AD. Accordingly, PE1 quantification of mu opiate receptor binding with C-11 carfentanil was performed in six AD patients and four age-matched control subjects. Imaging planes passing through the center of the amygdala and the long axis of the temporal lobe were selected by MRI. Quantification of C-11 carfentanil studies in the AD subjects (mean Mini-Mental score 17) demonstrated a decrease in mu opiate receptor binding in cingulate (18%), temporo-parietal cortex (24%), parietal cortex (22 %) and amygdala (30%). Mu opiate receptor binding in the thalamus, the frontal and temporal lobe and the caudate nucleus did not differ from normal

These results demonstrate reduced mu opiate receptor binding in vivo most markedly in the amygdala in AD patients. The relationship of these findings to decrements in neurocognitive functions, such as memory, is being explored. Recovery coefficients and MRI-based atrophy correction methods are also being applied in the analysis of this data. Reduced amygdala mu opiate receptors may be an early and specific marker of AD.

IGG, IGA, AND IGM CLASS SERUM ANTIBODIES AGAINST PERIPHERAL NERVOUS SYSTEM MYELIN IN GUILLAIN-BARRÉ SYNDROME: IMMUNOBLOT STUDIES. H. Bernheimer, H. Regele*, G Suchanek*¶, M Schmidbauer*, and B. Schwerer*, Neurological Institute, Univ. of Vienna, and ¶Brain Research Institute, Austrian Academy of Sciences, Vienna, A-1090, Austria.

Antibodies against peripheral nervous system (PNS) antigens are thought to play a pathogenetic role in Guillain-Barré Syndrome (GBS), an inflammatory demyelinating disease of the PNS. Serum samples of GBS patients (n=11) and controls (n=15) were tested for the occurrence of IgG, IgA, and IgM class autoantibodies against myelin on Western blots of PNS myelin proteins, which had been separated by sodium dodecylsulfate-polyacrylamide gelelectrophoresis. In each Ig class, immunostaining with GBS and control sera, respectively, gave very similar antigen binding patterns. However, incidence as well as intensity of positive immune reactions in GBS were different from controls: incidence of IgA antibodies was higher in the GBS than in the control group, and more intense immunostaining by IgA and IgM antibodies was observed with GBS than with control sera at equal serum dilution. Our results suggest that higher levels of autoantibodies against PNS myelin antigens seem to occur in GBS patients than in controls; on the other hand, no evidence for the occurrence of antibodies against a GBS-specific myelin antigen in sera from GBS patients was obtained in the present studies. (Supported by Otto-LOEWI-Fellowship K0011-MED and Project P6438M, Austrian Science Research Fund).

ALTERED PATTERNS OF NUTRIENT INTAKE IN HIV-1+ SUBJECTS WITH PYRIDOXINE (VITAMIN B₆) DEFICIENCY. G.Shor-Posner, J.Javier, R.Beach*, E.Mantero-Atienza* and M.Baum*. Biopsychosocial Center For Study Of AIDS, Univ. Miami Sch. of Med., Miami, Fl. 33101.

Our studies have indicated a high prevalence (35%) of pyridoxine deficiency during the early stages (CDC Stage III) of HIV infection. To determine the possible impact of B_6 status on dietary patterns, we examined nutrient intake in HIV+ males (n=36) at baseline (Time 1) and 26 weeks later (Time 2). Whereas B_6 deficient subjects (n=11) and individuals with normal B_6 status (n=25) consumed a similar proportion of protein, carbohydrate and fat at Time 1, distinct differences were noted at Time 2. In contrast to individuals with normal B_6 status, who consumed 16% of their intake as protein and 51% as carbohydrate, B_6 -deficient subjects ate significantly less protein (13.6%, p<0.002) and more carbohydrate (57%, p<0.03); percent fat intake was similar.

As pyridoxine is involved in the synthesis of serotonin, which appears to have a role in the modulation of appetite for protein and carbohydrate, the B₆-deficient pattern of intake may reflect a decreased level of serotonin. This may be of particular importance since patients with AIDS appear to exhibit disturbances in the various serotonin/tryptophan pathways that possibly contribute to the neurological symptoms associated with HIV infection.

STAGES IN HIV-1 LIFE CYCLE IN NEURAL CELLS. Y. Mizrachi, M. Shahabuddin*, M. Zeira*, G. Li* E.Golub* D.J.Volsky*. Molec. Virol Lab. Columbia Univ. St Luke's/Rsvelt Hspt, New York NY 1001.

New York, NY 10019.

HIV-1 infection of neural cells is characterized by restricted viral expression and replication and absence of cytopathic effect. Using 123I viral envelope glycoprotein (gp120), a quantitative fusion assay (fluorescence dequenching technique) and viral detection methods we have analyzed stages in HIV-1 infection of neural cell lines. We have found that neural cell infection is initiated by a specific binding of gp120 to a cellular receptor, followed by a fusion process which can be inhibited by purified gp120 in both neural and T cells. Soluble CD4 interfered in viral fusion with CD4 bearing T cells but not with virus neural cell fusion. HIV-1 neural cell fusion was restricted to neurotrophic viral isolates. Viral entry could be deduced from the detection of virally transcribed DNA thirty minutes after infection using PCR. While most non-human cells tested were not permissive to HIV-1 expression following transfection with infectious viral clones, similar levels of viral protein or viral LTR activity could be found in human cells of neural or T lymphocyte origin. We conclude, that neurotropic isolates can enter neural cells and following an initial permissivity for viral replication the neural cell restrict viral production.

253.2

CEREBROSPINAL FLUID (CSF) INTERFEROM-G (IFN-G IS INCREASED TROPICAL SPASTIC PARAPARESIS (TSP). <u>William A. Sheremata (Miami)</u> <u>D.E.</u> <u>McFarlin</u> (<u>Bethesda</u>, <u>MD)</u> University of Miami, PO 80x 016960, Miami, FL 33101.

Central nervous system (CNS) pathology in TSP includes demyelination with mononuclear infiltrates of white matter and meninges, but mechanisms of CNS damage have not been elucidated. Using a sensitive radio-immunometric assay we found that IFN-g, a potent macrophage activator, is present in normal CSF, but not serum, and levels increase with immune activation. We serum, and levels increase with immune activation, we have, therefore, studied 70 specimens (paired serum and CSF stored \mathbf{a} - 70^0 C) from our HTLV-1 seropositive TSP patients and 178 specimens from MS, AIDS and others with non-inflammatory degenerative CNS disease (DND). Serum IFN-g values (U/ml 3) were 0.13 \pm 0.21 in TSP; 0.01 in MS; 0.06 ± 0.11 in AIDS; and 0.12 ± 0.22 in DND. Corresponding CSF values (U/ml³) were 0.59 ± 0.56 in TSP, 0.18 \pm 0.12 in MS; 0.35 \pm 0.11 in AIDS and 0.10 \pm 0.04 in DND. IFM-g values in TSP are significantly higher than other MS (p <0.01) and DND (p <0.01). Systemic infection in advanced DND may explain raised some serum values but not decreases in CSF. Elevations of IFN-g in TSP are consistent with immune activation by retovirus. Correlation of CSF IFN-g with neopterin content suggests that IFN-g is physiologically activating CNS macrophages in vivo and is important in lesion pathogenesis.

253.4

NUTRITIONAL ABNORMALITIES ASSOCIATED WITH HIV INFECTION. J.Javier, G.Shor-Posner, E.Mantero-Atienza*, R. Beach* and M.Baum* Univ. Miami Sch. of Med., Miami, Fl. 33101.

Nutritional status may be an important cofactor in determining the course of HIV disease progression. Nutritional assessment of a cohort of asymptomatic HIV infected homosexual males (CDC Stage III, n=102), indicates that HIV seropositive (+) individuals experience multiple abnormalities relatively early during the course of their disease and demonstrate a decline, over time, despite adequate levels of intake. Changes in overall nutritional status, as measured by blood levels, revealed that the percentage of normal nutritional status individuals decreased from 31% at the baseline evaluation to 23% at the second and 17% at the third six-months visit.

Up to 67% of the subjects had at least one nutritional deficiency and 36% of the population had multiple abnormalities at the initial evaluation. Although HIV negative (-) subjects (n=23) exhibited similar proportion of nutritional deficiency, the types of abnormalities differed between the two groups. Deficiencies in vitamins A, C, and E, which are particularly important for immune function, were observed in HIV(+), but not HIV(-) subjects. These findings indicate that the homosexual male population has a high prevalence of nutrient deficiencies, which may influence immune status as well as susceptibility to HIV infection.

253.6

LOW AFFINITY, LONG TERM BINDING OF HIV TO NEURAL CELL LINES. F. J. Denaro, Texas Tech University Health Sciences Center, Lubbock, TX.

The premise that HIV can infect neural cells

The premise that HIV can infect neural cells is an important one that needs careful examination. In the present study HIV and an HIV-Amphotrophic variant, (HIV-A) was used to infect continuous neural cell lines. Because the HIV-A has a different capsule, it can infect cells without the need for CD₄ binding. These two viruses produce two strikingly different patterns of P-24 production. By day 3 the HIV-A is producing a massive infection as assayed by P-24. The high level of P-24 production remained high throughout the 4 months of the experiment. There was no sign of cytopathology. In contrast HIV produced a P-24 pattern which may be attributed to virus which has stuck to the cells and is eventually freed into the media. This sticking of HIV to the cells did not result in a productive infection. However, even after the passage of one month and a negative P-24 assay, HIV was detectable by co-culture with WBC's. One conclusion is that HIV can bind to the cells for long periods and not result in a productive infection. Perhaps this may be one important mechanism in the pathology of the CNS in patients with AIDS.

MECHANISMS OF HIV-1 INFECTION IN HUMAN AND NON-HUMAN NEUROBLASTOMA CELL LINES. H. Kulaga, A.J. Adams*. M. Coggiano*, Y. Shen*, L. To*, P.M. Sweetnam. NovaScreen®, a Division of Nova Pharmaceutical Corp., Baltimore MD 21244 NPR NIMH WASH D.C. 20032

Baltimore, MD 21224; NPB, NIMH, WASH. D.C. 20032
Neuroblastoma lines were exposed to lymphotropic
(LAV) and neurotropic (BR; SF-2) HIV-1 isolates at high multiplicities of infection. Cultures were tested for reverse transcriptase (RT) activity, production of p24 antigen, detection of viral nucleic acids and alteration of cell surface markers by flow cytometric analyses. The non-human neuroblastoma line NCB-20 and the human glioma HTB-17 were shown to be permissive to neurotropic viral stocks, although only low levels of RT were produced during infection. All other criteria indicating productive viral replication including protein and nucleic acid analyses were positive. Addition of soluble CD, or anit-CD, monoclonal antibody to these cultures did not inhibit infection in these cell lines. Immunogold labeling indicated that NCB-20 binds GP120. However, NCB-20 did not bind anti-human CD, monoclonal antibodies. These data indicate that HIV-1 infection of glioma neuroblastoma lines is possible but may proceed through a receptor other than CD.

UNIQUE GP120 BINDING SITES IN HUMAN BRAIN CELLS. M.R. Kozlowski, P. Sandler*, P.-F. Lin*, R. Datema*, A. Hatson . Departments of Screening and Biochemical Research and Virology Bristol-Myers Squibb Company, Wallingford, CT 06492-7660 and Oncogen, Seattle, WA 98121.

A growing body of evidence demonstrates that HIV, the causative agent of AIDS, infects brain cells. It is unclear, however, whether the initial event in this infection is the same in brain cells as in lymphocytes: binding of the viral envelope glycoprotein, gp120, to the cell surface CD4 antigen. The present study examines bigging of radio-iodinated recombinant HIV-1 gp120 (12 I-rgp120) to U-373 (human glioblastoma), U-138 (human glioblastoma), and CEM (human lymphoblastoma) cells. Binding of I-rgp120 to CEM cells (2h at 37C in INDS/CEM/Lymra)

Binding of "Largp120 to CEM cells (2h at 37C in PBS/BSA/glucose) was inhibited by anti-CD4a antigens (OKT4A, 617-2), Aurintricarboxylic Acid (ATA), and Evans Blue (EB). The anti-CD4 antibody, OKT4, and the dye, Aurin, were less active. In contrast, binding to U-138 and U-373 cells was poorly inhibited by OKT4A and 617-2, and showed no preference for OKT4A over OKT4 as a binding inhibitor (Table I). I-rgp120 binding to these cell types was, however, inhibited to the same extent as in CEM cells by ATA and EB, with Aurin again being less active.

These results suggest that brain cells contain gp120 binding sites different from those found in lymphocytes.

GP120-INDUCED RETARDATION OF BEHAVIORAL DEVELOPMENT IN NEONATAL RATS: PREVENTION BY PEPTIDE T. J.M. Hill and D.E. Brenneman² 1Peptide Design L.P., Germantown, MD 20874, LDN, NICHD, Bethesda, MD 20892.

In vitro studies with murine hippocampal cultures have indicated that purified HIV envelope glycoprotein, gp120, induced significant neuronal death which was prevented by peptide T, D-Ala peptide T amide (Brenneman et. al., Nature 335,639, 1988; Drug Dev. Res. 15,361,1988). The purpose of the present study was to determine if gp120 would influence behavioral development when administered to neonatal rats, and to establish if peptide T prevented gp120-induced deficits. Sprague-Dawley rats received daily injections of 100 µl of one of the following: gp120 (0.3 nM), peptide T (3 µM), gp120 (0.3 nM) and peptide T(3µM) or saline, from birth to day 14. Observations of 14 developmental milestones/behaviors were made daily without knowledge of treatment group. The following were significantly delayed by gp120 treatment: Surface righting, air righting, negative geotaxis, grasping and fore and hindlimb placing. Peptide T correatment prevented the delay in behavioral development induced by gp120. The following were not influenced by gp120 treatment: Eye opening, corneal reflex, auditory startle, crossed extensor reflex, and cliff aversion. Systemic administration of gp120 significantly retarded the development of multiple, complex motor behaviors, whereas many simple reflexes and developmental milestones were apparently unaffected. These data further support the beneficial action of peptide T in preventing gp120-induced neural deficits and suggest that peptide T may be useful in the treatment of pediatric AIDS.

SPREAD OF REOVIRUS SEROTYPE 3 INTO THE CNS FOLLOWING ENTERIC INOCULATION. L.A. Morrison*1, R.L. Sidman², and B.N. Fields*2. Depts. of Microbiology and Molecular Genetics¹ and Neuropathology, 2 Harvard Med. Sch., Boston, MA 02115

Infection of the central nervous system (CNS) by an enteric neurotropic virus was examined in newborn mice inoculated perorally with reovirus serotype 3, strain clone 9 (T3C9). Spinal cord and brain were dissected from formalin- and sucrose-perfused animals at various times after inoculation. Serial 30 µm cryostat sections were incubated with antireovirus antiserum and stained by the immunoperoxidase method to reveal presence of viral antigen. Neurons of the parasympathetic dorsal nucleus of the 10th cranial (vagus) nerve were specifically stained 4-5d post-inoculation. At this time no other stained cells were observed in the spinal cord, or within the brain. Staining of this nucleus was dependent on route of entry. By 6-7d post-inoculation, viral antigen was present in multiple nuclei of the brain; in sensory, motor, and sympathetic neurons of the spinal cord; and in the meninges of the spinal cord. The results indicate that reovirus T3C9 spreads to the CNS from the gastro-intestinal tract via nerves, initially the vagus parasympathetic fibers. Second, reovirus T3C9 spreads transsynaptically within the CNS. Third, viremia may play a role in later dissemination to, and promotion of infection in, the CNS.

SYMPOSIUM. RECAPITULATION OF DEVELOPMENTAL MECHANISMS IN NEURODEGENERATIVE DISORDERS.
M. P. Mattson, Univ. of Kentucky (Chairperson); A. Matus, Friedrich Miescher-Inst.; K. S. Kosik, Harvard Med. School; J. W. Geddes, Univ. Calif. Irvine; C. W. Cotman, Univ. Calif. Irvine.

Both growth and regression of neurons may occur in neurodegenerative disorders (NDs). This symposium addresses current views on the plasticity and vulnerability of neuronal cytoarchitecture by presenting data on cellular and molecular mechanisms that sculpt neuronal cytoarchitecture adaptively during brain development and plasticity, and destroy neuroarchitecture in NDs such as Alzheimer's disease. Three systems that control neuroarchitecture will be featured: 1) The neuronal cytoskeleton, with a focus on microtubules and microtubule-associated proteins (MAPs). Recombinant DNA techniques are revealing how cytoskeletal proteins regulate growth-related plasticity and adult stabilization of neural circuitry, and how their disregulation leads to aberrant neuroarchitecture and loss of function. 2) Proteases and protease inhibitors. Proteins such as 8-amyloid and protease nexins can influence neurite outgrowth; altered expression or processing of these proteins may contribute to the cytoarchitectural correlates of NDs. 3) Cellular signaling systems including growth factors, excitatory amino acids (EAAs), and intracellular calcium. By influencing the neuronal cytoskeleton, these systems play key roles in regulating growth cone behaviors and synaptogenesis during development. Imbalances in EAA and growth factor systems resulting in a loss of calcium homeostasis may underlie the breakdown of neural circuitry in NDs. The presentations emphasize the links between neural development and disease, and forward the hypothesis that many features of NDs are the result of reactivated or aberrant developmental mechanisms.

SYMPOSIA

257

SYMPOSIUM. GALANIN: MULTIDISCIPLINARY STUDIES. <u>S.F. Leibowitz</u>, The Rockefeller University (Chairperson); <u>A. Rokaeus*</u>, Karolinska Institute; <u>T.J. McDonald*</u>, University Hospital; <u>T. Hokfelt</u>, Karolinska Institute;

V. Chan-Palay, University Hospital.

The peptide galanin has received increasing attention with respect to its potential physiological role and pathophysiology in the central and peripheral nervous systems. This symposium will review our current knowledge of this peptide, in terms of its gene expression, anatomical projections, structure-function relationships; its actions on endocrine, autonomic, feeding and pain systems; and its role in learning, memory and dementia. Ake Rokaeus will examine the structure, regulation and expression of the galanin gene, the regulation of its mRNA, the processing of the precursor protein, and the expression of galanin-like immunoreactivity and a galanin message-associated peptide. Thomas McDonald will describe his research on the structure-function relationships, morphological aspects and the pathophysiological actions of galanin in inhibiting insulin secretion from the endocrine pancreas and altering smooth muscle function in the gastrointestinal tract. Sarah Leibowitz will present results pertaining to the endocrine and behavioral effects of galanin in the brain and will describe pharmacological and neurochemical studies relating central galanin to monoamine neurotransmitters, circulating steroids, nutritional state and circadian rhythm. Tomas Hokfelt will focus on two galanin-containing systems in the brain: the cholinergic forebrain neurons, where galanin may have a role in learning and memory, and also primary sensory neurons, where galanin along with other peptides may exist to modulate pain. Victoria Chan-Palay will describe findings pertaining to changes in galanin, relative to other neurotransmitters, in the forebrain of humans with Alzheimer's dementia.

EFFECTS OF PERIRHINAL CORTICAL LESIONS ON VISUAL RECOGNITION MEMORY IN RHESUS MONKEYS. M. Meunier, E.A. Murray, J. Bachevalier, and M. Mishkin. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

The rhinal cortex (Rh) includes both the entorhinal cortex (ERh) which occupies the medial bank of the rhinal sulcus and the ventral cortex medial to it, and the perirhinal cortex (PRh) which occupies the lateral bank of the rhinal sulcus. Earlier work showed that monkeys with Rh (ERh+PRh) removals had a severe visual recognition memory deficit (Murray et al., 1989, Soc. Neurosci. Abstr., 15: 342) as measured by the delayed nonmatching-to-sample (DNMS) task with trial-unique objects. As a first step to determine the relative contributions of PRh and ERh to this deficit, we have now examined the behavioral effects of lesions restricted to the PRh. Naive rhesus monkeys were trained on the DNMS task with 10s between sample presentation and choice test until they reached the criterion of 90 correct responses in 100 trials. They then received a bilateral PRh ablation and, after a 10-14 day recovery period, were retrained on the DNMS task with 10s delays. When the monkeys reattained criterion, they were given a performance test that taxed their recognition memory by requiring them to remember either single objects for increasingly longer periods of time (30, 60, reflections entire single objects for increasingly longer periods of little (30, 60, or 120s) or increasingly longer lists of objects (3, 5, or 10). Whereas controls relearned DNMS immediately, monkeys with PRh ablations required about as many trials to relearn as the monkeys with Rh lesions (PRh, \overline{X} = 470; Rh, \overline{X} = 540). On the performance test, by contrast, monkeys with PRh ablations scored 78% correct responses, which was lower than controls (92%), though significantly higher than monkeys with Rh lesions (68%). These preliminary results indicate that PRh alone makes a substantial contribution to visual recognition memory, but that other relays exist for transmitting sensory information to medial temporal and medial diencephalic limbic structures.

258.3

EFFECTS OF CORTICAL LESIONS ON VISUOSPATIAL PROBLEM-SOLVING. L.A. Miller. Psychology Dept., Montreal Neurological Institute, 3801 University St., Montreal, Quebec, CANADA, H3A 2B4.

Quebec, CANADA, H3A 2B4.

In a recent study, Miller & Tippett (in preparation) found that patients who had invasive, right-hemisphere parietal, central, or frontal-lobe lesions were impaired on a Matchsticks Test of adaptive flexibility. The test required subjects to demonstrate as many ways as possible of removing a designated number of sticks from different geometric figures in order to achieve specified resultant shapes. In the present study, 10 patients who underwent cerebral excisions for the relief of epilepsy were assessed on the same task in order to determine whether lesions limited to the cortex are sufficient to cause a deficit. It was found that patients with right parietal removals tended to make many errors. Furthermore, only the patient whose right frontal lobectomy included the orbital region (and not the two with right frontal parasaggital excisions) demonstrated a selective impairment in the ability to change response strategy. The latter finding is interpreted as evidence of the lack of behavioural flexibility caused by inferior frontal-lobe damage.

RETROGRADE AMNESIA: TEMPORAL GRADIENT IN LONG-TERM MEMORY FOLLOWING DAMAGE TO THE HIPPOCAMPAL FORMATION IN MONKEYS. S. Zola-Morgan, L.R. Squire, VA Med Center, San Diego and Dept. of Psychiatry, UCSD Sch of Med, La Jolla, CA 92093

Patients with hippocampal damage have loss of premorbid memory (retrograde amnesia) that is greater for the recent past than the more remote past. The interpretation of this finding depends on the precise shape of the performance curves, which cannot be determined with certainty using the tests that are available to assess remote memory retrospectively in humans. We have assessed retrograde amnesia in monkeys with bilateral lesions of the hippocampal formation (the H⁺ lesion). Monkeys were trained on different sets of 20 two-choice object discrimination problems at 16, 12, 8, 4, and 2 weeks prior to surgery (a total of 100 discrimination pairs). Two weeks after surgery, memory was assessed by randomly presenting a single trial of each of the 100 pairs. Unoperated monkeys (N-7) exhibited forgetting, ranging from 79% correct for object pairs learned 2 wks earlier to 70% correct for object pairs learned 16 wks earlier. The H⁺ group (N-11) exhibited temporally-graded retrograde amnesia (2 wk-62%; 4 wk-64%; 8 wk-65%; 12 wk-72%; 16 wk-67%). Importantly, older memories were remembered significantly better than recent memories (analysis of linear trend: p-.01). These findings suggest that the hippocampal formation is initially involved in memory storage and retrieval and that its role gradually diminishes with the passage of time.

258.2

AMYGDALAR INTERACTION WITH THE MEDIODORSAL NUCLEUS OF THE THALAMUS AND THE VENTROMEDIAL PREFRONTAL CORTEX IN STIMULUS-REWARD ASSOCIATIVE LEARNING IN MONKEYS. <u>E.A. Murray and D. Gaffan</u>. Lab. of Neuropsychology, NIMH, Bethesda, MD 20892 and Dept. of Experimental Psychology. Oxford University. Oxford OX1 3UD. U.K.

Psychology, Oxford University, Oxford OX1 3UD, U.K.

Behavioral results from studies of recognition memory in monkeys have led to the suggestion that the medial temporal limbic, medial thalamic, and ventromedial prefrontal cortical areas are part of an integrated memory circuit. Because the amygdala, in particular, contributes to learning about food reward, we tested the above hypothesis as it relates specifically to the amygdalo-thalamo-frontal circuit and stimulus-reward association. Accordingly, cynomolgus monkeys were trained on a series of 2-choice visual discriminations between colored stimuli presented on a monitor screen. The feedback for correct choice was the delivery of food. The rate of learning new problems was assessed before and after surgery in a total of 16 monkeys. Three groups of 3 monkeys received bilaterally symmetrical ablations of either the amygdala and subjacent cortex (A), the medial portion of the mediodorsal nucleus of the thalamus (MD), or the ventromedial prefrontal cortex (VF). Whereas before surgery each group learned with roughly 10% error rates, after surgery each learned with 30% error. Seven additional animals received an amygdalar ablation in one hemisphere and removal of either the mediodorsal thalamus or the ventromedial prefrontal cortex in the other hemisphere, a procedure designed to disconnect the amygdalo-thalamo-frontal pathway. The disconnection groups showed a significant impairment, but the effect of the disconnection surgeries was significantly milder than that of the symmetrical ones; before surgery each group learned with error rates of roughly 10%, but after surgery each learned with error rates of about 17%. The results indicate that although A, MD, and VF appear to be functionally related, they do not form a single, tightly-linked functional pathway.

258.4

IMPAIRMENTS IN MEMORY FOR SERIAL ORDER FOLLOWING LESIONS OF THE PRIMATE FRONTAL CORTEX.M.Petrides. Montreal Neurological Institute and Dept.Psychol. McGill Univ., Montreal, Quebec, Canada.

Monkeys with lesions restricted to different

Monkeys with lesions restricted to different parts of the dorsolateral frontal cortex were tested on a task developed to assess memory for the order of occurrence of a series of visual stimuli. Three monkeys had sustained bilateral excisions of the mid-dorsolateral frontal cortex (cytoarchitectonic areas 46 and 9), three monkeys had excisions of the posterior region of the dorsolateral frontal cortex (areas 8 and rostral 6), and another four animals served as the normal control subjects. Monkeys with excisions within the mid-dorsolateral frontal cortex were severely impaired, whereas animals with lesions of the posterior dorsolateral frontal cortex performed as well as the normal control subjects. All animals had previously been tested on a visual recognition memory task (delayed non-matching to sample). The two groups of operated animals were not significantly different from the normal control group on this task. The above findings indicate that the primate mid-dorsolateral frontal cortex is a critical component of a neural circuit underlying the monitoring of the order of occurrence of a series of stimuli.

258.6

LESIONS OF PERIRHINAL CORTEX, BUT NOT LESIONS OF THE AMYGDALA, EXACERBATE MEMORY IMPAIRMENT IN MONKEYS FOLLOWING LESIONS OF THE HIPPOCAMPAL FORMATION. R.P. Clower, S. Zola-Morgan, and L.R. Squire. VA Med Ctr., San Diego and Dept. of Psychiatry, UCSD Sch of Med, La Jolla, CA 92993. Studies in our laboratory have suggested that severe

Studies in our laboratory have suggested that severe memory impairment in monkeys associated with large medial temporal lobe lesions (the H⁺A⁺ lesion) results from damage to the hippocampal formation and adjacent, anatomically related cortex (e.g., perirhinal and parahippocampal cortex), and not from conjoint hippocampus-amygdala damage. We have evaluated memory impairment in a group of monkeys with bilateral lesions of the hippocampal formation, parahippocampal cortex, and perirhinal cortex (the H⁺⁺ lesion, N=3). Using the delayed nonmatching to sample task, the H⁺⁺ group was compared to four previously studied groups: H⁺A⁺ (N=4), H⁺ (hippocampal formation and parahippocampal cortex, N=8), H⁺A (H⁺ lesion plus amygdala, N=3), and N (normal, N=6). All operated groups had comparable H⁺ damage, and all were impaired on the task (mean score for 10-min delay: N=82X, H⁺⁺=54X H⁺A⁺=67X. The impairment associated with the H⁺⁺ lesion was as severe as that following H⁺A⁺ lesions, and significantly more severe than the impairment following H⁺ or H⁺A lesions. These findings suggest that damage to the perirhinal cortex, not damage to the amygdala, contributes to the severe impairment that follows H⁺A⁺ lesions.

NUCLEUS ACCUMBENS LESIONS SELECTIVELY IMPAIR SPATIAL BUT NOT VISUAL OR MOTOR REVERSAL LEARNING IN MONKEYS (MACACA FASCICULARIS) C.E. Stern^ and R.E. Passingham*, Dept. of Exp. Psych., S. Parks Rd., Oxford, U.K., OX1 3UD. ^Present address: Dept. of Physics, Univ. of CA at Irvine, Irvine, CA, 92717.

The nucleus accumbens (NA), which receives inputs from limbic structures and projects to the motor system, may be important for the integration of emotion and motivation with motor behaviour. Because the NA receives inputs from the amygdala and hippocampus, tasks which are known to be disrupted by lesions to these areas in monkeys were tested on animals with lesions of the NA. In addition, a motor reversal task, in which the animals were taught to turn or pull a handle, was used to test whether these animals were capable of associating movements with reward.

Twelve monkeys (Macaca fascicularis) were used in the present study. Six of these received ibotenic acid lesions of the NA. One group (3 NA, 3 control) was taught a visual discrimination task pre-operatively and performed visual and spatial discrimination. nation and reversal tasks post-operatively. A second group was taught the motor reversal task. Results indicate that ibotenic acid lesions of the NA do not impair the ability to learn visual discriminations (F(1,4)=0.2) or visual reversal (F(1,4)=0.2) paradigms. Initial spatial learning (prior to the first reversal) was spared (t=1.59, df=4), vever, these same animals were found to be impaired on spatial reversal learning (F(1,4)=14.1, p=0.02). Results of the motor reversal task revealed no impairment in the ability of NA lesioned animals to initially learn the task (t=0.75, df=4) or to perform the motor reversals (F(1,4)=0.98).

Our results on visual and spatial tasks mimic results obtained following hippocampal, but not amygdala, lesions in monkeys (Jones and Mishkin, 1972). In addition, these results challenge theories which suggest that the NA is important for general behavioural flexibility and response selection. Instead, we suggest that the NA may play a more specific role in the association of spatial cues with movement and reward.

258.9

LACK OF MEMORY IMPAIRMENTS FOLLOWING BASAL FOREBRAIN LACK OF MEMORY IMMAIRMENTS FULLOWING BASAL FOREBRAIN LESIONS IN MONKEYS. M.L. Voytko, D.S. Olton, R.T. Richardson, G.L. Wenk and D.L. Price. Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

The basal forebrain (BF) may play a role in mnemonic processes. The present study pursued this issue by examining monkeys with extensive damage of the BF on a

battery of behavioral tasks that assessed various forms of learning and memory. Five cynomolgus monkeys were preoperatively trained in a computer-controlled apparatus on the following tasks: delayed nonmatching-to-sample (0- to 60-second delays and list length of three); delayed response (0- to 10-second delays); single object discriminations; and 24-hour concurrent object discriminations; and 24-hour concurrent object discriminations. Retention of this test battery was examined immediately before surgery and again two weeks postoperatively. With the aid of nuclear magnetic resonance (NMR) imaging, ibotenic acid injections were made in the BF in two of the five monkeys; the three remaining monkeys were operated controls. Postsurgical NMR images indicated successful placement of injections within a projections. within BF sites. Lesions in the BF had minimal influence on the performance of monkeys on the behavioral tasks. To investigate these preliminary findings, we are currently presenting monkeys with more difficult versions of the tasks as well as new tasks.

EFFECTS OF ENTORHINAL, PARAHIPPOCAMPAL, OR BASAL FOREBRAIN LESIONS ON RECOGNITION MEMORY IN THE MONKEY. L. L. Beason, M. B. Moss, and D. L. Rosene. Dept. of Anatomy, Boston Univ. Sch. Med., Boston MA 02118.

The basal forebrain and temporal lobe are two areas of the brain that have been identified as possible neuropathological substrates of the marked anterograde memory impairment which characterizes the early stages of Alzheimer's Disease (AD). To determine if damage to either stages of Alzheimer's Disease (ÅD). To determine if damage to either of these areas produces memory impairments that parallel those seen in AD, we administered a recognition memory test (Delayed Recognition Span Task-DRST), that has been used extensively in the assessment of patients with AD, to rhesus monkeys with bilateral lesions of the basal forebrain (BF) and to normal control monkeys (N). Their performance was compared to that of animals that received lesions of the entorhinal cortex (EC) or lesions immediately outside the rhinal sulcus including perirhinal cortex, rostromedial area TE and the posterior parahippocampal gyrus (PHG). The DRST assesses the capacity of a subject to identify a new stimulus among an increasing array of stimuli, adding one new stimulus at a time until the subject commits the first error, vielding a "recognition span". The recognition span scores of adding one new stimulus at a time until the subject commits the first error, yielding a "recognition span". The recognition span scores of monkeys with lesions of the basal forebrain did not differ from that of normal controls. In contrast, monkeys in group EC and group PHG, though not significantly different from each other, had significantly lower span scores relative to the BF or N groups. The findings suggest that damage within the temporal lobe, rather than in the basal forebrain, may contribute to the anterograde memory impairment in AD. Supported by NIH grants AG04321 and NS16841.

THE ROLE OF LIMBIC AND PREFRONTAL CORTICAL AREAS IN CONCEPT FORMATION AND IMMEDIATE MEMORY IN RHESUS MONKEYS. J. Pizlo, E.A. Murray and M. Mishkin. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

Macaques with combined amygdalo-hippocampal (AH) removals can master

trial-unique delayed nonmatching-to-sample (DNMS) provided the delays are 10 seconds or less. Presumably, correct performance under these circumstances requires formation of the concepts (or categories) familiar/novel or same/different with the aid of immediate memory. If removal of inferior prefrontal cortex (IF), another major target of the occipitotemporal visual system, is added to AH removal, monkeys fail DNMS even with delays shorter than 10 s (Weinstein et al., <u>Soc. Neurosci. Abst</u>, 14:1230, 1988), suggesting that IF and AH are important for concept formation, immediate memory, or both. Here we analyzed the role of IF and AH in a concept formation task not requiring immediate memory. On each trial, two trial-unique pairs of objects were presented for choice, a like pair of objects (same), one of which was always baited, and an unlike pair (different), neither of which was baited. Following attainment of criterion (90 correct responses in 100 trials) the animals received the combined IF and AH surgery in two stages, in counterbalanced order, with interoperative retraining. The monkeys took progressively longer to relearn new sets of same-different discriminations at each stage (mean trials: 85 pre-op, 470 post-op 1, 925 post-op 2), but each did relearn. There was no effect of lesion order. The results suggest that IF, AH, or both make an essential contribution to immediate visual memory, and a substantial but not essential contribution to formation of the concepts same/different, familiar/novel, or

258.10

EFFECTS OF NEOSTRIATAL LESIONS ON VISUAL HABIT FORMATION IN RHESUS MONKEYS. J. Wang* T. Aigner, and M. Mishkin. Lab of Neuropsychology, NIMH, Bethesda, MD, 20892.

Monkeys with bilateral lesions of the amygdala and the hippocampus are impaired on tests of one-trial visual recognition memory, but are still able to learn a series of object discriminations, a test of habit formation, even when intertrial intervals are as long as 24 hrs. By contrast, animals with bilateral lesions of inferior temporal cortex (area TE) are impaired on both tests, suggesting that visual object discrimination learning is mediated by a TE-nonlimbic pathway. Because area TE has extensive fiber connections with the the tail of the caudate nucleus and the ventral putamen, we investigated whether lesions of these regions would produce selective impairment of object discrimination learning. Four female rhesus monkeys were shown 20 pairs of test objects during each daily session. Within each pair, one object was baited, the other unbaited. The 20 pairs were shown only once each session, and the left-right position of the baited objects was varied pseudorandomly across sessions. After each animal reached the criterion level of 90% correct choices on the first set of objects, ibotenic acid was injected bilaterally into the tail of the caudate nucleus and the adjoining ventral putamen using stereotactic coordinates derived from magnetic resonance imaging, which was also used to verify the accuracy of the lesion postoperatively. Subsequently, the animals were tested on 2 additional sets of objects. For each animal, the number of trials required to reach criterion was more than twice that for the initial set of objects. When tested on a visual recognition task (delayed nonmatching-to-sample), however, the animals performed as well as control animals. This pattern of impairment strongly suggests that visual recognition memory and visual habit formation are mediated by separate pathways and that the tail of the caudate nucleus and the ventral putam

258.12

UNILATERAL AND BILATERAL ELECTRIC STIMULATION OF MEDIAL TEMPORAL LOBE IN THE MONKEY. <u>J.L. Ringo</u> Dept. of Physiology, U. of Rochester Med Ctr, Rochester, NY, 14642.

Electric stimulation at 33 Hz was applied in a pseudo random pattern of 0.2 ms pulses to electrodes implanted in medial temporal lobe, in monkeys doing a visual delayed-matching-to-sample task. Stimulation in the sample or the match period drove performance to near chance levels.

In split chiasm monkeys, stimulation to just one hemisphere during the sample presentation and to just the other hemisphere during the match choice produced chance performance even when the view was, in each case, through the eye contralateral to the stimulation. With both sample and match presented to the same side, stimulation to the contralateral side created only moderate deficits.

Unilateral stimulation during the sample presentation was used to asymmetrically bias the engram to the side opposite the stimulation. The subsequent normal performances when presenting the match choice through what had been the stimulated side suggested that interhemispheric access to memory on the other side is excellent. Such access was good through either the anterior commissure or the splenium.

STEREOTAXIC LESIONS OF THE HIPPOCAMPUS IN MONKEYS USING MAGNETIC RESONANCE IMAGING: DETERMINATION OF COORDINATES AND ANALYSIS OF THE LESIONS. P. Alvarez-Royo, R. P., Clower, S. Zola-Morgan, G. A., Press*, C. S. Rebert* and L. R. Squire. UCSD Depts. of Neuroscience, Psychiatry and Radiology, L. Jolla, Ca 92093, V.A. Medical Center, San Diego, Ca, and SRI International, Stanford, Ca. The cynomolgus monkey has served as a valuable animal model for studies of

human learning and memory. As part of our research directed at understanding how selective damage to the hippocan pal formation affects learning and memory, we have developed two noninvasive anatomical techniques based on current magnetic esonance imaging (MRI) technology.

1. Determination of stereotaxic coordinates for individual monkeys; This approach

I. Determination of stereotaxic coordinates for individual monkeys; Inis approach was developed to address the problem of using a standardized brain atlas with monkeys whose brains vary considerably in size and shape. Prior to surgery, four small, glass beads filled with a copper sulfate solution (0.1M) were affixed to the monkey's skull. Monkeys were then placed in a nonmetallic stereotaxic headholder, and scanned using a high-resolution, inversion-recovery pulse sequence (1.5T magnet, head coil, TR=1500, TE=25, TI=708, 3mm interleaved slices) that produced high quality coronal images of the hippocampus along its full rostrocaudal extent. The glass beads (which have high signal intensity) were used both as reference points for establishing the coordinates for stereotaxic surgery and as landmarks during the surgery itself. In this way, individual lesion coordinates were used for each monkey.

surgery itself. In this way, individual lesion coordinates were used for each monkey.

2. Noninvasive postoperative analysis of lesions; The MRI protocol described above was modified in two ways in order to carry out postoperative analysis of the lesions. We administered a contrast enhancing agent (gadolinium, 0.2 ml/kg IV) and we used a scanning plane perpendicular to the long axis of the hippocampus. The images permitted preliminary verification of the extent and accuracy of the lesions and were useful in determining whether animals should undergo long term behavioral testing. Thus, MRI technology can be used to improve lesion techniques and to permit more efficient use of animal subjects.

258.14

LESIONS OF INFERIOR TEMPORAL AREA TE IN INFANT MONKEYS PRODUCE REORGANIZATION OF CORTICO-AMYGDALAR PROJECTIONS. M.J. Webster, L.G. Ungerleider and J. Bachevalier. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

Object recognition memory is severely impaired in monkeys that receive area TE lesions as adults but only mildly in those that receive the same lesion as infants. To determine the possible mechanisms mediating this sparing of function, we have examined the development of cortico-amygdalar connections in normal and brain-damaged monkeys. We reported earlier that area TEO in normal infants projects transiently to the lateral basal nucleus (LB), a projection that is partially retained in adults that had received TE lesions as infants. Other differences in the connections of TEO in the infantoperated as compared to the adult-operated monkeys were heavier projections to the claustral nucleus of the amygdala (CA) and a new projection to the lateral nucleus (L). The connectional pattern in the adultoperated monkeys was identical to that in normal adults. Thus, only after TE lesions in infancy, a small proportion of the projection from TEO to LB is retained, whereas that to CA intensifies and possibly sprouts into L to occupy the terminal zone vacated by TE. Sparing of memory function in adult monkeys that receive brain damage in infancy may thus be due to preservation of transient connections and axonal sprouting.

EXCITATORY AMINO ACIDS: RECEPTORS VI

259.1

DISSOCIATION OF METABOTROPIC AND IONOTROPIC EXCITATORY AMINO ACID (EAA) RECEPTOR EFFECTS *IN VIVO* USING *TRANS*- AND *CIS*-(±)1-AMINO-1,3-CYCLOPENTANEDICARBOXYLIC ACID (ACPD). D.D.

Schoepp, B. G. Johnson, C. R. Salhoff, and C. C. Hillman, Jr., Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

The trans- and cis- isomers of ACPD were characterized for 1) their ability to stimulate metabotropic EAA receptors coupled to phosphoinositide hydrolysis in slices of the rat hippocampus, 2) their relative affinities at ionotropic EAA receptors in rat brain membranes, and 3) their ability to produce in the produce in the stress ACPD was 13. produce in vivo excitatory or excitotoxic effects in rats. trans-ACPD was 13 times more potent as an activator of phosphoinositide hydrolysis (EC₅₀ 28.0 \pm 2.8 μ M) than as a displacer Of NMDA (3H -CGS-19755) receptor binding (IC50 374 \pm 78 μ M). In contrast, $\it cis$ -ACPD was 27-times more potent in inhibiting 3H -CGS19755 binding (IC50 3.3 \pm 0.4 μ M) than it was in stimulating phosphoinositide hydrolysis (EC₅₀ 89.4 ± 6.4 μM). Displacement of ³H-AMPA or 3H-kainate binding to rat brain membranes by *trans*- or *cis*-ACPD was negligible (IC_{50S} > 500μM). When administered i.p. to neonatal rats, *cis*-ACPD was 8-times more potent than *trans*-ACPD in producing convulsions ACPD was 8-times more potent than *trans*-ACPD in producing convulsions (ED₅₀s 12 and 100 mg/kg, respectively). *Cis-* or *trans*-ACPD convulsions were prevented by LY233053, a competitive NMDA receptor antagonist. When infused unilaterally into the rat striatum, 0.5 μmoles of *cis*-ACPD greatly reduced choline acetyltransferase (ChAT) activity (74 ± 6 % decrease). However, infusion of 1 μmole *trans*-ACPD did not significantly reduce ChAT activity (7.6 ± 4.7 % decrease). In contrast to *cis*-ACPD, *trans*-ACPD is a selective metabotropic EAA agonist *in vitro*. *Trans*-ACPD does not produce excitotoxicity *in vivo*, and its convulsant effects only occur at high doses and can be antagonized by an ionotropic NMDA receptor antagonist. Thus, unlike ionotropic EAA receptors, excitatory and excitotoxic effects do not appear to be a consequence of directly activating the metabotropic EAA receptor.

EXTRACELLULAR ZINC ANTAGONIZES THE EFFECTS OF NMDA, QUISQUALATE AND AMPA ON INTRACELLULAR CALCIUM (CAI) IN CULTURED CHICK CORTICAL NEURONS. G.A. Pritchard*, M.K. McMillian, J. E. Marchand and L.G. Miller. Div. of Clinical Pharmacology, Tufts-New England Medical Ctr., Boston, MA 02111.

Zinc has been localized within axon terminals of central neurons and may be released during excitatory amino acid (EAA) neurotransmission. Micromolar concentrations of zinc have previously been shown to attenuate NMDA receptor-mediated excitation in cultured cortical neurons. Cai was determined using Fura2 loaded 8d chick embryo neurons after 2d in culture. EAA alone elevated Cai in the order of kainate (KA)>NMDA>AMPA>quisqualate (QA) . Also, both AMPA and QA desensitized the Cai response to KA. Zinc (10-1000 $\mu\text{M})$ antagonized both the effects of NMDA alone (38-88%) and QA/AMPA-induced KA desensitization (19-85%) compared to control. However, at a concentration of 100 μ M, zinc augmented the Cai response to QA (63%) or KA (41%) alone. These results corroborate previous findings with respect to the effects of zinc on NMDA-induced excitability, but suggest that significant interactions also occur with non-NMDA sites.

INTRACELLULAR CALCIUM REGULATES RESPONSES NMDA IN HIPPOCAMPAL NEURONS. H. Markram

W.Segal. Center for Neuroscience, The Weizmann Institute, Rehovot, Israel.

We investigated the role of [Ca²⁺]; in the regulation of NMDA receptor activation. Intracellular recordings were obtained from CA1 neurons in the rat hippocampal slice. NMDA, applied ionophoretically, potentiated subsequent voltage or current responses to NMDA, by more than two fold. This auto-potentiation was reduced when NMDA, by more than two fold. This auto-potentiation was reduced when intracellular Ca²⁺ was chelated with BAPTA. A BAPTA-sensitive rise in [Ca²⁺]; could be detected electrophysiologically as an enhancement of the AHP that persisted for at least 20s after the membrane response to NMDA had recovered. Increasing [Ca²⁺]₁ using the Ca²⁺ ionophore, A23187, or by evoking intracellular release using either Intracellular release using either IP3-containing micropipettes, or following UV irradiation of cells loaded with a photolabile IP3, caused a 2- to 3-fold potentiation of responses to NMDA. These increases were suppressed in BAPTA-loaded cells. We conclude that [Ca²⁺]₁ plays a significant role in regulating the activation of NMDA receptors.

PROPERTIES OF SPONIANEOUS MINIATURE SYNAPTIC CURRENTS IN CHICK SPINAL CORD CULTURES. <u>L.O. Trussell & G.D. Fischbach.</u> Dept. of Anatomy & Neurobiology. Washington U. Sch. of Medicine. St. Louis, MO 63110.

We have examined the amplitude, shape, and frequency of spontaneous "miniature" inward synaptic currents (mepse's) recorded from chick spinal neurons maintained in culture for 2-14 days. Recordings were made using tight-seal whole cell voltage clamp, with an electrode solution containing KCl or CsCl as the major ions. 1 µM TTX, 100 µM Cd⁺⁺, 100 µM bicuculine and 2 μ M strychnine were included extracellularly. Mepsc's recorded with 1 mM bath Mg⁺⁺ at -60 mV were eliminated by 20 μ M CNQX and were markedly reduced in amplitude by 1 μ M CNQX, indicating that they are produced by non-NMDA receptors

Mepsc amplitude varied over a wide range, from 4 pA to >120 pA. No relationship was observed between the rise time and fall time of the events or between the rise time and amplitude. Events evoked in small (ca. 20 μ m) regions of dendrite, close to the cell body, by focal application of black widow spider verom, produced mepse's which also varied widely in amplitude. These data suggest that the variation in mepse size cannot be due to cable decay. Statistical analyses indicate that the largest event were not due to the coincident release of several smaller quanta. In the presence of TIX and Cd, it is unlikely that the large mepso's are associated with inward Na or Ca currents. Following local superfusion of veroum, mepso's appeared in bursts,

perhaps corresponding to the action of venom at different synaptic sites. Interestingly, bursts differed in the average amplitude of their mepse's. Considering the uniformity of the mepse's rise times, we suspect that variation in mepsc size is due to variation in postsynaptic receptor density. Supported by NS07821.

SELECTIVITY OF AMINO ACID TRANSMITTERS ACTING AT NMDA AND AMPA RECEPTORS EXPRESSED IN XENOPUS OOCYTES M. C. Curras and R. Dingleding Dept. of Pharmacology, Univ. of North Carolina, Chapel Hill, 27599
The neurotransmitter candidates, L-aspartate, L-cysteine sulphinic acid (L-CSA), L-glutamate, L-homocysteic acid (L-HCA) and quinollinate (Q) were compared for potency, efficacy and selectivity at N-methyl-D-aspartate (NMDA) and AMPA (non-NMDA) receptors in Xenopus oocytes injected with rat brain mRNA. Steady-state inward currents were measured at -60 mV in response to agonist application. Selective activation of NMDA receptors was achieved by deleting Mg and including 3-10 μM glycine in the perfusion medium, and by applying ligands in the presence of 30 μM quisqualate, which blocks the AMPA receptor and desensitizes the oocyte's Ca-dependent Cl current. Under these conditions, the potency sequence was L-glutamate (ECS0=2.2 μM) > L-aspartate (13 μM) = L-HCA (13 μM) > L-CSA (59 μM) > Q (2.7200 μM). All amino acids tested had similar efficacy, i. e, 1.2-1.5 that of NMDA. Hill coefficients were greater than 1 for all agonists except L-HCA (0.6), which might be explained by heterogeneity of NMDA receptors expressed.

To study agonist activity at AMPA receptors, glycine and quisqualate were omitted and 1 mM Mg was included to block NmDA receptors. Ca-dependent Cl currents activated by L-glutamate were prevented by inclusion of 0.4 M EGTA in the electrodes. All amino acids were less potent at AMPA han at NMDA receptors; potency ratios for activation of AMPA receptors were: L-glutamate (ECS0=11 μM) > L-HCA (430 μM) > L-CSA (3300 μM). L-aspartate and Q produced little or no inward current up to 10 mM, i. e. were inactive at AMPA receptors. The efficacy of all amino acids was only 5-10% that of kainate, presumably due to severe desensitization of the AMPA receptor by the natural agonists. We conclude that all endogenous amino acids tested have substantially lower affinity for AMPA receptors than for NMDA receptors. The mos

DEVELOPMENTAL REGULATION OF NMDA RECEPTORS BY MAGNESIUM AND GLYCINE N. W. Kleckner and R. Dingledine. Dept. of Phart Univ. of North Carolina, Chapel Hill, 27599.

Divalent cations play an important role in NMDA receptor regulation.

While Ca²⁺ permeates the channel, Mg²⁺ blocks it in a voltage-dependent manner, so that in the presence of Mg²⁺ membrane depolarization facilitates current flow into neurons through this channel. To examine whether NMDA receptor subtypes exist at different developmental stages, divalent cation receptor subtypes exist at different developmental stages, divalent cation block of NMDA receptors was studied in oocytes injected with mRNA isolated from hippocampi of 1-2, 7-8, 14-15 day, or 12 week old (adult) rats. Agonist-induced currents were recorded in the presence of Mg^{2^+} or other divalent cations. For NMDA receptors from adult rats, the EC_{c_0} of Mg^{2^+} block increased by e-fold (2.718-fold) for every 15 mV increase in membrane potential between -70 and -50 mV. The Mg binding site was calculated to be 31 % of the way through the membrane electric field. Mn^{2^+} and Ni^{2^+} were weak voltage-dependent belockers of the NMDA receptor whenever Tc^{2^+} and Cd^{2^+} through the membrane electric field. Mn^{2*} and Ni^{2*} were weak voltage-dependent blockers of the NMDA receptor, whereas Zn^{2*} and Cd^{2*} were voltage-dependent blockers. NMDA receptors from 1-2 day old rats were significantly more sensitive to block by Mg^{2*} over the entire range of significantly more sensitive to block by Mg over the entire range of membrane potentials tested (-90 to -30 mV) than receptors from 14-15 day old rats (P<0.03). The EC values for Mg $^+$ block at -60mV were 12.7, 18.2, 27.4, and 18.8 μ M for 1.2 day, 7-8 day, 14-15 day and adult receptors. The voltage-dependence of Mg $^+$ block did not change with developmental age. The sensitivity of NMDA receptors to glycine, but not NMDA, may also vary with developmental age. The charge EC values were 0.24 0.23, 0.35 and 0.54 μ M. developmental age. The glycine EC values were 0.24, 0.23, 0.35 and 0.54 μ M (n=5) for receptors from 1-2 day, 7-8 day, 14-15 day and adult rats. These studies suggest that different subtypes of NMDA receptor may be present that vary in their sensitivity to block by Mg²⁺ and activation by glycine.

259.9

EVIDENCE THAT KAINATE RESPONSES AND RAPIDLY-DESENSITIZING QUISQUALATE RESPONSES ARE MEDIATED BY THE SAME RECEPTOR. D. K. Patneau, C. A. Winters* L. Vyklicky Jr* and M. L. Mayer. Neurophysiology and Biophysics, LDN, NICHD, NIH, Bethesda, MD 20892. Responses to quisqualate and kainate are dramatically different. Quisqualate

produces a rapidly and strongly desensitizing response; kainate, a weakly-desensitizing response. Both ligands have been suggested to act at the same receptor. Quisqualate blocks kainate responses, apparently by cross desensitization (Kiskin et al., 1986); however, at high concentrations kainate can overcome the antagonist action of quisqualate, suggesting a competitive interaction (O'Brien & Fischbach, 1986). We will present kinetic evidence that kainate and quisqualate do act at the same receptor.

Our experiments used fast perfusion techniques during whole cell recording from

cultured mouse hippocampal neurons voltage-clamped at -60 mV. We made equilibrium and kinetic measurements of kainate responses during competitive antagonism by several quisqualate-like agonists. Over a 1000-fold range, antagonist equilibrium potency followed the same order of affinity as that for activation of quisqualate-like responses: quisqualate>AMPA>L- glutamate>L-homocysteic acid>L quisquatate-like responses: quisquatate which blocked 50% of receptors available for activation by kainate (0.9 µM) was similar to the IC₅₀ for desensitization of quisqualate responses by a prepulse of agonist (1.1 µM). Kinetic data provided further evidence that kainate and quisqualate compete for the same receptor. Kainate responses normally exhibit fast activation (t <10 msec) but in the presence of quisqualate activation is at least 10x slower. Likewise, the rapid desensitization of responses to quisqualate is approximately 5-fold slower in the presence of kainate.

Our data suggest a model for a single receptor with at least two states: quisqualate-like agonists exhibit higher affinity for the desensitized state, and antagonize the kainate response by binding to the desensitized receptor; kainate has a much lower affinity for the desensitized state and therefore acts as a full agonist.

259.6

INTERACTION OF Mg²⁺ AND PHENCYCLIDINE IN USE-DEPENDENT BLOCK OF NMDA CHANNELS. M.Y.L. Bennett, J. Lerma¹, and R.S. Zukin, Albert Einstein Coll. Med., Bronx, NY 10461, ¹Instituto Neurobiologia "S. Ramon y Cajal", 28002-Madrid, Spain. The interaction between Mg²⁺ and phencyclidine (PCP) in blocking open N-methyl-D-aspartate (NMDA) channels was studied

in Xenopus oocytes injected with rat brain mRNA. PCP block, measured as reduction in current under voltage clamp at -60mV, developed within seconds in the presence of agonist, but prior application of PCP had little effect. Upon removal of PCP and NMDA, recovery of responsiveness to NMDA was very slow until NMDA was again applied; recovery occurred gradually during NMDA application. Evidently PCP was "trapped" in the closed channels; thus the degree of PCP block could be measured as the decrease in the early the degree of PCP block could be measured as the decrease in the early phase of the response elicited by the second NMDA application, as well as by the reduction in steady state current in the presence of NMDA and PCP. By both measures the IC_{90} for PCP block was ca. 120nM. Application of Mg^{2+} with PCP and NMDA reduced the fraction of channels blocked by PCP as determined by increase in the responses to subsequent test applications of NMDA. Interaction between Mg^{2+} and PCP was competitive; 0.5mM Mg^{2+} caused a 2-4 fold increase in the IC_{90} value for block of NMDA responses by PCP with no decrease in maximum degree of block. In the presence of NMDA, Mg^{2+} speeded recovery from PCP block, suggesting that Mg^{2+} reduced replace of NMDA channels by PCP that had escaped from reduced reblock of NMDA channels by PCP that had escaped from open channels. These findings indicate that Mg²⁺ and PCP compete with each other and cannot occupy the channel simultaneously. Since depolarization is likely to reduce Mg²⁺ block more than PCP block, neural activity is likely to modulate actions of PCP and related drugs.

259.8

ACTIVATION AND DESENSITIZATION OF NMDA RECEPTORS IN OUTSIDE-OUT PATCHES W. Sather, J.F. MacDonald and P. Ascher. Lab.

Neurobiologie, Ecole Normale Supérieure, 46 rue d'Ulm 75005 Paris We have discovered a method for preparing "macro-patches". The key step in the preparation of such patches is to maintain suction on the patch pipette after the rupture of the membrane leading to the whole cell configuration. The suction leads to a slow displacement of the nucleus towards the pipette tip. Then, when the pipette is pulled away, the plasma membrane wraps around the nucleus, and eventually reseals around it when it separates from the enucleated cell body. The "nucleated patch" behaves as a classical outside-out in every respect, except that high concentrations of NMDA can open simultaneously hundreds of channels.

Using this new configuration we have analyzed the concentration dependence of the peak and steady-state current induced by NMDA in the presence of a saturating concentration of glycine (10 μ M). The apparent dissociation constant is about 50 μ M for the peak current, 5 μ M for the steady-state current. This suggests that, as in the case of the nicotinic receptor, the desensitized state of the NMDA receptor has a higher affinity for the agonist than the "resting" state.

POLYAMINES POTENTIATE NMDA RESPONSES OF RECEPTORS EXPRESSED IN XENOPUS OOCYTES. J.F. McGurk, R.S. Zukin and M.V.L. Bennett. Albert Einstein Col. Med., Bronx, NY 10461

In Xenopus oocytes injected with adult rat brain mRNA, spermine markedly increased responses to N-methyl-D-aspartate (NMDA) with glycine. Conductances were increased by up to three-fold with no change in reversal potential. Onset and recovery were rapid (<0.5 sec., limited by speed of bath application). Spermine alone did not produce a current or change the membrane resistance. Spermidine also potentiated NMDA responses; putrescine did not. Spermine potentiation increased with concentration (apparent $K_d \sim 40 \mu M$, Hill coefficient ~ 2.0) and then declined above 250 μM . The magnitude of potentiation depended on the glycine concentration, but not the NMDA concentration. At saturating levels of glycine (10 μ M) and NMDA (250 μ M), 250 μ M spermine increased the peak response approximately 2-fold versus control. At a lower glycine concentration (0.1 μ M) and 250 μ M NMDA, 250 μ M spermine potentiated the peak response about 3-fold. Neither the K_d nor Hill coefficient for spermine were effected by glycine or NMDA concentration. Concentration-response curves for NMDA in the presence of saturating levels of spermine and glycine showed that spermine increased the maximum response, but not the Kd or Hill coefficient. On the other hand, in addition to increasing the maximum current, spermine with 250 μ M NMDA produced a leftward shift in the concentration-response curve for glycine, reducing the K_d (from ~ 930 to ~ 330 nM). Moreover, desensitization was reduced at low glycine concentrations. These results suggest that polyamines may enhance NMDA responses by an "uncompetitive" interaction at the glycine site.

A Model of the Polyamine Recognition Site of the NMDA Receptor. C.Romano, K.Williams, R.Seshadri*#, M.Israel*# and P.B.Molinoff. Depts. of Pharmacology, U. of PA., Phila., PA and , U. of TN.#, Memphis,TN.

The polyamines spermic and spermidine have been shown to modulate the NMDA receptor acting at a specific polyamine recognition site. Polyamine agonists increase binding of [3H]MK-801 above the maximal seen with L-glu + gly, inverse agonists decrease binding of [3H]MK-801, and both of these actions are blocked by polyamine antagonists. The interactions of linear diamines and triamines with the NMDA receptor were examined. Binding of [3H]MK-801 was measured in the presence of 100 µM L-glu + gly in the presence or absence of 10 µM spermine. Short diamines such as putrescine and cadaverine have been shown to be spermine. Short duamnes such as putrescine and cadaverne have been shown to be polyamine antagonists. As length increased, the diamines inhibited the binding of [3H]MK-801 even in the absence of spermine. The inhibition (observed at 1mM) increased with diamine length. As this inhibition has been shown to be blocked by a polyamine antagonist, these compounds are acting as inverse agonists. The short triamine diethylenetriamine (TA[2,2]) was a polyamine antagonist. Longer triamines are polyamine agonists, most of which exhibited a bell-shaped concentration-effect are polyamine agonists, most of which exhibited a bell-shaped concentration-effect curve, with high concentrations stimulating less than intermediate concentrations. With increasing chain length, this inhibitory region of the curve became more pronounced. The longest triamines tested, TA[3,11] and TA[3,12], did not stimulate the binding of [³H]MK-801 and inhibited binding even in the absence of spermine. It is proposed that there are four amine interaction points, three in an activation locus and one in a remote locus. Polyamine agonists interact with all three sites in the activation locus and thereby enhance the binding of [³H]MK-801. Polyamine antagonists interact at only two sites in the activation locus and are therefore antagonists interact at only two sites in the activation locus and are therefore competitive antagonists. Longer polyamines can interact with a site in the activation locus and the site at the remote locus. This leads to negative modulation that can be blocked by antagonists. This model can explain the bell-shaped concentration-response to long-chain triamines as well as the inverse agonist actions of long-chain diamines. (Supported by USPHS GM34781, NCI-CA37802, and a grant from ICI Pharmacanticle) Pharmaceuticals.)

THE NMDA RECEPTOR COMPLEX: INTERACTIONS AMO GLUTAMATE, GLYCINE AND POLYAMINE SITES. J.Lehmann, H. Canton* and F.C. Colpaert*. Neurobiology Division, Fondax-Groupe de Recherche Servier, Puteaux, France.

Agonists of three individual recognition sitesglutamate (E), glycine (G), and polyamine (PA) promote opening of the cation channel associated with the NMDA receptor, reflected by increased [3H]MK-801 binding. These actions are not, however, independent. Stimulating the E-site increased the affinity (2-3 x) and maximal effect (Emax; 5x) of glycine, and the affinity (10x) and Emax (2x) of spermidine. Stimulating the G-site increased the affinity (6x) and Emax (4x) of glutamate, but not the Emax and only slightly the affinity of spermidine. Stimulating the PA site increased the affinity (4x) and Emax (7-10) of glutamate, and increased the affinity of glycine (3x) but not its Emax.

Thus of the rnus of the six possible interactions among the three sites, only four are robust. Specific geometry of the NMDA receptor complex is predicted by these data.

SENSORY SYSTEMS-VISUAL CORTEX: EXTRASTRIATE CORTEX

FACTORS AFFECTING RESIDUAL VISUAL SENSITIVITY IN A CASE OF HEMIANOPIA. L. Weiskrantz, Department of Experimental Psychology, University of Oxford, Oxford, OXI 3UD, England. J. L. Barbur and A. J. Harlow, The City University, Northampton Square, London, ECIV OHB, England. (SPON: European Brain and Behaviour Society).

Society).

A well-studied "blindsight" subject (G.Y) with visual cortex damage was tested in his hemianopic field with temporally modulated sine-wave and square-wave gratings. Both the spatial and temporal parameters could be Gaussian-weighted. Detection as a function of spatial frequency, contrast, temporal modulation frequency, grating size, and the slope of the temporal and spatial Gaussian functions was investigated systematically, using a two-alternative forced-choice procedure with monitoring of eye fixation position. The most important parameters for this subject were found to be the slope of the temporal Gaussian function found to be the slope of the temporal Gaussian function and the size and contrast of gratings. With optimum parameters the subject could reliably achieve a score of 100 percent correct in his "blind" field. The results are consistent with earlier studies of this subject, especially his ability to respond to moving stimuli, and also may account for why negative results had been reported for him when particular parameters were used.

260.2

CONFORMAL MAPPING OF THE VISUAL PATHWAY. George J. Carman. Salk Institute, San Diego, CA 92138.

The topographic organization of successive stages of the visual pathway can be regarded as a series of transformations of the visual Several investigators have attempted to model these transformations using variants of the complex logarithmic function, first proposed by Fischer (Vis. Res. 13: 2113, 1973), but thus far none have been able to account for the full variation in observed Here I report the determination of a composition of topography. conformal mappings which successively transform the visual field into the topographic representations observed within the LGN and cortical areas V1 and V2 of the macaque. When applied to the hemifield with perimeter, this composition of mappings also produces an approximation to the typical shape observed for each stage of the Limitations of earlier efforts are overcome by visual pathway. modelling the observed topography of LGN (Connolly and Van Essen, J. Comp. Neurol. 226: 544, 1984) by the first components of this composite mapping. Subsequent components reproduce numerous features of the known topography of V1, such as the anisotropic representation of the meridia, the central "bowing" of the isoeccentric lines, and the peripheral "convergence" of the isopolar lines (Van Essen et al., Vis. Res. 24: 429, 1984; Tootell et al., J. Neurosci. 8:1531, 1988). Remarkably, the same mapping which produces V1 when applied to LGN also generates V2 when applied to The significance of this composition of conformal mappings for the functional organization of the visual pathway will be discussed.

INDIVIDUAL AXONS (LABELED WITH PHASEOLUS VULGARIS) PROJECTING FROM AREA V2 TO V4 IN THE MACAQUE. K.S. Rockland. Dept. of Anatomy, Boston Univ. Sch. of Medicine, Boston, MA. 02118.

Injections of the anterograde tracer *Phaseolus vulgaris*-leucoagglutinin were made in area V2 in order to demonstrate the detailed configuration of axon arbors terminating in area V4. As of this date, 7 axons have been reconstructed in 2 monkeys. All of these axons had multiple arbors (usually 2-3); these varied in size but typically measured 150-200 µm in diameter. Scanning of isolated arbors confirmed the impression that these are restricted in size. Our reconstructions showed that arbors of a given axon diverged over distances of 0.75-2.0mm. Some arbors were concentrated in layer 4, but other terminations (even belonging to the same axon) were targeted instead to both layers 3 and 4. Consistent with their origin from pyramidal-type neurons, terminal boutons were spinous in shape. Axon trunks frequently branched in the white matter; axons could also travel 2-3mm in layers 3, 5, or 6 of the gray matter of area V4 before giving off terminal arbors. Perhaps because of our small sample, these axons seemed to vary widely in terms of specific numbers, size, shape, and laminar distribution of terminal arbors. Compared with axons projecting from area V1 to V2, however, those projecting from V2 to V4 share at least two characteristics; that is, they have multiple arbors distributed over relatively large distances, and each arbor is restricted in size. (Supported by EY07058)

CORTICAL CONNECTIONS OF THE PRIMARY VISUAL AREA, V-I, OF THE GREY HEADED FLYING FOX (<u>PTEROPUS POLIOCEPHALUS</u>): EVIDENCE FOR MULTIPLE EXTRASTRIATE CORTICAL FIELDS. <u>Leah A.</u> <u>Krubitzer and Mike B. Calford</u>, Dept. Physiol. and Pharm. University of Queensland, QLD 4072 Australia

The cortical connections of the primary visual area (V-I) were investigated in the flying fox by placing single or multiple injections of anatomical tracers into V-I. In all cases, the cortex was flattened and sectioned tangentially so that areal patterns of connections could be appreciated. Sections containing transported tracer were reconstructed and superimosed on sections stained for myelin or reacted for cytochrome oxidase. Connections of area 17 with area 18 were discontinuous and formed patches across the rostrocaudal extent of this field. Area 17 was also connected with a darkly myelinated oval of cortex just rostral to area 18 (a possible homologue of the middle temporal visual area, MT, of primates), and a more lightly myelinated strip of cortex just rostral to the medial portion of area 18 (a possible homologue of the dorsomedial visual area, DM, of primates). Injections of multiple tracers into different parts of V-I in the same animal, helped us determine the topographical organization of these extrastriate cortical fields.

Because of the unique position of the megachiropteran bat in mammalian evolution (a close relative of primates), information obtained in this species could provide a better understanding of the evolution of neocortex in primates. Our results indicate that some extrastriate cortical fields identified in the primate, such as MT and DM, may also be present in other members of the Grandorder Archonta. This suggests that some cortical fields found in extant primates may be more primitive than other cortical fields. The bat is also of interest because it is a flying mammal, and its expanded visual cortex may contain features related to this behavioral specialization.

CORTICAL ACTIVATION IN HUMANS DURING VISUAL AND OCULOMOTOR PROCESSING MEASURED BY POSITRON EMISSION TOMOGRAPHY (PET). C. L. Colby and T. Zeffiro. Lab. Sensorimotor Research, NEI and Human Motor Control Section, NINDS, NIH, Bethesda, MD 20892.

In order to determine the relative involvement of different cortical areas in the performance of visuomotor tasks, we have measured changes in regional cerebral blood flow under 6 conditions: rest with eyes closed; fixation; sinusoidal pursuit; leftward pursuit; rightward pursuit; and saccade. Visual stimuli were presented on a computer monitor in total darkness and in each of the latter 4 conditions target size, total excursion, and cycle time were held constant. Eye movements were continuously monitored by EOG recordings. Measurements were obtained in healthy volunteers (n = 6) with Positron Emission Tomography (Scanditronix 2048-15B scanner) utilizing 33 mCi injections of $H_{\alpha}0^{15}$.

The strongest cortical activation during both pursuit and saccadic eye movements was localized to the frontal eye fields. The FEF are located in the lateral portion of the motor strip, adjacent to the cortical region maximally activated by hand movement. This was confirmed in one experiment in which left and right hand stimulation replaced the left and right pursuit conditions. Additional zones of activation were observed in striate, extrastriate and parietal cortex. In frontal and occipital areas, eye movement tasks were associated with stronger activation than fixation alone.

EFFECTS OF V4 LESIONS ON VISUAL DISCRIMINATION PERFORMANCE AND ON RESPONSES OF NEURONS IN INFERIOR TEMPORAL CORTEX. R. Desimone, L. Li*, S. Lehky, L.G. Ungerleider, and M. Mishkin. NIMH, Bethesda, MD 20892. Lab. Neuropsychology

Two Macaca mulatta were trained to maintain fixation Two <u>Macaca mulatta</u> were trained to maintain fixation while performing delayed match-to-sample discrimination tasks with extrafoveal stimuli. The location of the task stimuli varied among the four visual quadrants from trial to trial; on a given trial, the sample and test stimuli were presented in the same quadrant. Following acquisition, the lower field representation of area V4 in one hemisphere was ablated. In the quadrant corresponding to the lesion, as compared to the control quadrants, luminance discrimination was nearly normal, but discrimination thresholds for color and orientation matching were highly elevated and and orientation matching were highly elevated and moderately impaired. Inferior temporal neurons, recorded in one monkey performing the task, clearly responded to stimuli presented in the quadrant corresponding to the lesion, but the responses were smaller and less discriminative than those to stimuli smaller and less discriminative than those to stimuli-presented in the control quadrant of the same hemifield. The results suggest that V4 is an important but not the sole source of both color and form information to the temporal cortex.

EFFECTS OF TASK RELATED STIMULUS ATTRIBUTES ON INFERO-TEMPORAL NEURONS STUDIED IN THE DISCRIMINATING MONKEY. R. Vogels and G.A. Orban. Laboratorium voor Neuro- en Psychofysiologie, K.U.Leuven, Campus Gasthuisberg, B-3000 Leuven, Belgium.

Single cells were recorded in infero-temporal cortex (IT) of a monkey performing a same-different orientation discrimination task (Orban & Vogels, <u>Soc.Neurosci.Abstr.</u> 1990). In order to asses the influence of order of presentation we calculated an index (S1-S2)/(S1+S2) which ranges from -1 to 1 depending on whether the cell only responds to the second grating stimulus (S2) or only to the first stimulus (S1). The distribution of this index for IT cells (n=116) was significantly broader than the distribution obtained in the same animal in V1 (n=78). This shows that in this sequential discrimination task the order of presentation influences IT cells more

A number of cells fired in the interval between the successive A number of cells lired in the interval between the successive grating presentations. In many instances these cells also responded to the grating presentation, but a number of cells fired only in the interval. With few exceptions, this delay activity was orientation tuned. Finally a number of cells fired much more when the second stimulus differed from the first one than when it did not. This difference in response could not be accounted for by the orientation or the order of presentation of the stimulus. This suggests that a number of the order of presentation of the stimulus. number of IT cells encode whether or not the second stimulus differs in orientation from the first. These results indicate that IT cells do not only encode the physical attribute of the stimulus but are also influenced by task related attributes of the stimulus.

FUNCTIONAL FIELDS IN THE HUMAN VISUAL CORTEX INVOLVED IN THE ANALYSIS OF COLOUR, FORM, AND BINOCULAR DEPTH INFORMATION, REVEALED BY POSITRON EMISSION TOMOGRAPHY (PET) B. Gulvás, P. E. Roland, S. Stone-Elander*, and S. Holte*
PET Section, Karolinska Institute and Hospital, Box 60500, S-10401 Stockholm,

The regional cerebral blood flow (rCBF) in 9 normal young male volunteers was measured with PET, while the subjects were performing visual tasks related to a reference state as well as to the detection of colour, form, and depth (functional states). ¹⁵O-butanol served as tracer and the changes in the radioactivity in the brain

states). ¹³O-butanol served as tracer and the changes in the radioactivity in the brain were monitored with an eight-ring Scanditronix PC2048-15B positron emission tomograph. Each PET measurement was preceded by a magnetic resonance (MR) scan. The head fixation used in the MR and PET scans was identical.

Both the MR and PET images were transformed to a computerized brain atlas (CBA) system. The individual images were transformed in size and shape into a standard brain (Bohm et al., Acta Radiol. Suppl. 369(1986):449-452). The images corresponding to the reference state were subtracted from those of the functional states. These "subtraction" images were then averaged over the 9 subjects. Correspondingly, Student-1 images were also created in order to display significant differences between images of the reference and functional states. With the help of the CBA, the rCBF

images of the reference and functional states. With the help of the CBA, the rCBF changes in the brain during different visual activations were quantified and localized. Stimulation with colour markedly activated fields along the posterior bank of the medial inferior part of the parieto-occipital sulcus and anterior to the collateral sulcus. In addition, a small part of the precuneus and the posterior superior part of the cingular gyrus were activated. Stimulation with form caused activation in the medial part of the inferior temporal gyrus, as well as in the posterior superior part of the cingular gyrus and in the left frontal eye field. Stimulation with binocular depth cues resulted in the activation of fields around the striate cortex in a ring-like manner; as well as a strong activation in the superior medial part of the occipito-parietal gyrus.

260.8

CODING OF ORIENTATION BY INFERO-TEMPORAL NEURONS STUDIED IN THE DISCRIMINATING MONKEY. G.A. Orban and R. Vogels. Laboratorium voor Neuro- en Psychofysiologie, K.U.Leuven, Campus Gasthuisberg, B-3000 Leuven, Belgium. Single cells (n=497) and multiunit activity (n=254) were recorded in infero-temporal cortex (IT) of a monkey extensively trained to perform fine orientation discriminations. The task of the monkey was to discriminate between a sequence in which two gratings presented in succession were identical and a sequence in which they differed in orientation. The orientation of the first grating was randomly changed between trials and the orientation difference was 15 deg in the standard condition. Thirty-two percent (157/497) single cells were driven by the grating presentation, the other cells either did not react or were inhibited. Sixty-seven percent (171/254) of the multiunit recordings responded excitatorily to the grating. Enough valid trials were collected in 103 responsive cells to estimate the 4 parameters determining the neuronal discriminative capacity in this task. Median orientation bandwidth was 66 deg (quartiles 43 and 99 deg). Median response strength (average firing rate) was 22 spikes/sec (quartiles 13 and 41 spikes/sec). Median normalized variance (variance divided by response strength) was 2.47 (quartiles 1.29 and 3.92). Median latency was 100-120 msec (quartiles 80-100 msec and 140-160 msec). Comparison of these characteristics with those obtained in V1 in the same animal suggests that on average orientation representation is not more accurate in IT than in V1.

In 23 cells we attempted to manipulate the level of attention by increasing the difficulty of the task. This was done by reducing the orientation difference from 15 to 7 deg. In 4 out of 23 cells this increased the slope of the tuning curves. This suggests that in IT the accuracy of the orientation representation can be improved by 'attention' as reported for V4 by Spitzer et al. (Sci. 240:338-340, 1988).

RIGHT INFERO-TEMPORAL CORTEX PET ACTIVATION DURING OBJECT RECOGNITION TASKS IN HUMANS. M.Corbetta. F.M.Miezin. P.T.Fox. S.M.Dobmeyer. S.E.Petersen. Dept. Neurol. and Neurol.Surgery, McDonnell Ctr. Higher Brain Function, and Mallinckrodt Inst. of Radiology, Washington Univ. School of Med., St.Louis, MO 63110; Neuroradiol. Sect., Johns Hopkins Univ., Baltimore; Dept. Neurol., Univ. of lowa, lowa City. Normal subjects were studied with PET activation methods during visual

recognition tasks of objects defined either by a simple feature (i.e. color) or by a feature conjunction (i.e. color by orientation). Four stimuli were simultaneously flashed for 100 msec at 1Hz around the fixation point. Subjects were instructed to search for a specific target (e.g. a red square among non-red squares, or a red bar oriented 90° among red and non-red differently oriented bars), and target probability was manipulated (50% vs 5%). One group had to report by key-press (overt task) the presence or the absence of the target. Another group had to monitor the probability of target occurrence, and report it only after PET data collection (covert task). Accuracy in all conditions was above 90%. PET subtraction images of blood flow change indicated that right infero-temporal cortex was more active when many targets (as compared to few targets) were presented in both simple feature and conjunction recognition tasks. In the overt task the activations were localized in posterior infero-temporal cortex (at or near area 37 of Brodmann). In the covert task the activations were located more anteriorly on the middle temporal gyrus (at or near area 21). Bilateral activations in the over task were also found in primary visual cortex, lingual and fusiform gyri. These results support the notion of functional asymmetry in humans for object recognition operations, and suggest multiple functional subdivisions in human infero-temporal cortex.

A NEURAL ANALOGUE IN MACAQUE LATERAL INTRAPARIETAL CORTEX (LIP) OF THE END-POINT UP-SHIFT OF MEMORY-GUIDED SACCADES MADE IN THE DARK. R.M. Bracewell. S. Barash and R.A. Andersen. Dept. Brain & Cog. Sci., MIT, E25-236, Cambridge, MA 02139.

We have previously shown that memory-guided saccades tend to show a systematic constant error; their end-points are shifted upwards with respect to the location of the target (Gnadt et al., Soc. Neurosci. Abst. 13: 1090, 1987). Here we report an analogue in the activity of area LIP neurones recorded whilst rhesus monkeys performed an identical delayed saccade task. We determined the preferred directions of individual neurones during the various phases of the task: visual (V), memory-related planning (M), and saccadic (S). In general, the vertical components of the M and S preferred directions were shifted upwards with respect to the V preferred directions. The up-shift was much greater for the S than the M activity. On the other hand, the horizontal components of the V, M and S preferred directions did not vary systematically. These results suggest that the up-shift in memory saccade end-points is largely due to the sensorimotor transformations underlying the production of such saccades, and not due to sensory processing.

CALCIUM CHANNELS I

261.1

MULTIPLE FORMS OF INACTIVATION OF THE N-TYPE CALCIUM CURRENT. Mark R. Plummer, Max Kanevsky* & Peter Hess*. Department of Cellular & Molecular Physiology, Harvard Medical School, Boston, MA 02115.

Calcium currents in mammalian neurons are subject to several forms of voltage- and current-dependent inactivation, and these properties have become important criteria in the characterization of different types of calcium channels. This is especially true for the N-type calcium channel where the time course of inactivation during a test pulse and the reduction of current at relatively positive holding potentials are the main physiological means of distinguishing N-type from L-type calcium current. However, inactivation of the N-type current has been shown to vary widely from one recording to the next, making a quantitative analysis of inactivation problematic. To understand better the sources of this inactivation, we have used a variety of voltage protocols and ionic substitutions to separate voltage-dependent from currentdependent inactivation. We have found that voltage-dependent inactivation develops slowly and is responsible for the observed holding potential dependence of the N-type current whereas the current-dependent inactivation produced by either calcium or barium acts on a more rapid time scale and may contribute to the variability of inactivation during a test pulse.

261.3

NEUROTRANSMITTER MODULATION OF N-TYPE Ca CHANNELS BY SHIFTS BETWEEN MODES OF GATING. K.R. Bley, D. Lipscombe & R.W. Tsien. Department of Molecular & Cellular Physiology, Stanford University, Stanford, CA 94305.

Stanford, CA 94305.

We have investigated the mechanism by which α -adrenergic and peptidergic agents inhibit Ca channels in frog sympathetic neurons. Norepinephrine (NE) or LHRH decrease N-type Ca channel activity via a G-protein, but not through readily diffusible second-messengers or H-7-sensitive protein kinases, consistent with inhibitory effects on K'-evoked transmitter release (Lipscombe et al. 1989; Bley & Tsien, 1990). In cell-attached recordings (110 mM Ba), the open time distribution of N channels displays two components, $\tau_{\rm fast} = 0.3$ ms and $\tau_{\rm Slow} = 1.7$ ms at -10 mV. With improved frequency resolution, we find that these components arise from two different patterns of N-type channel gating: one with a relatively low open probability $(\rho_0 < 0.04$ at -10 mV) and larger unitary amplitude (-0.9 pA), and the other with a higher channel open probability $(\rho_0 < 0.03)$ and smaller unitary amplitude (-0.7 pA). Switching between the two modes is relatively slow and occurs even in one-channel patches. In the "low ρ_0 " mode, the channels require at least 30 mV more depolarization to achieve the same opening probability as in the high ρ_0 mode (cf. Bean, 1989, Plummer et al. 1989). We find that inclusion of 30 mM NE in the patch pipetue greatly decreases the relative proportion of "high ρ_0 " sweeps and increases the percentage of "low ρ_0 " sweeps but leaves the pattern of gating within each mode unchanged. Thus, the average current carried by the N-type channel is strongly but not completely inhibited.

but leaves the pattern of gating within each mode unchanged. Thus, the average current carried by the N-type channel is strongly but not completely inhibited.

To observe reversible changes in N channel kinetics in the same patch, we have turned to outside-out patch recordings. Ca channel activity can persist for more than one hour with standard whole-cell internal solutions in the pipette. Moreover, N- and L-type Ca channels retain activation and inactivation properties similar to those in cell-attached recordings. We have seen instances of reversible inhibition of N-type channel activity by LHRH and NE, and irreversible inhibition by

PHARMACOLOGY OF N-TYPE CALCIUM CHANNEL MODULATION IN SYMPATHETIC NEURONS. Ann R. Rittenhouse, Mark R. Plummer, Max Kanevsky* & Peter Hess*. Dept. of Cell. & Molec. Physiol., Harvard Med. Sch., Boston, MA 02115.

Calcium currents in rat sympathetic neurons are modulated by a variety of neurotransmitters and second messengers. Controversy exists, however, over which type of calcium channel is affected. By analyzing tail currents carried exclusively by dihydropyridine (DHP) sensitive L-type calcium channels, we found that α -adrenergic and muscarinic agonists, the neuropeptide NPY, and GTP- γ -S reduced selectively the DHP-insensitive component of current which corresponds to N-type current in these cells. For example, 100 μ M norepinephrine (NE) inhibited peak current by 38% while having minimal effects (< 5% reduction) on the L-type tail current. Clonidine (100 μ M), which has no effect on chick DRG and frog sympathetic neurons, decreased peak calcium current while phentolamine (10 μ M) and yohimbine (10 μ M) reversed the inhibition produced by 1 μ M NE. In addition, 100 μ M acetylcholine (ACh) or bethanechol, and 100 nM NPY also reduced peak inward current by 29%, and 27%, respectively, with no significant effect on L-type current. Incubation with pertussis toxin eliminated the responses to both ACh and NE, confirming the involvement of GTP-binding proteins. Extracellular application of the protein kinase C activator OAG (50 μ M) reduced the peak current by 57% but, unlike all other substances tested, also reduced the L-type tail current by a comparable amount. Thus muscarinic and adrenergic modulation in these cells appears to target selectively the N-type calcium current and involve inhibitory G-proteins.

261.4

CALCITONIN-GENE RELATED PEPTIDE (CGRP) INCREASES THE N-TYPE CALCIUM CURRENT AND ACETYLCHOLINE (ACh) RELEASE IN VAGAL SENSORY (NODOSE) NEURONS VIA A PERTUSSIS TOXIN (PTX)-SENSITIVE MECHANISM. J.W. Wiley¹, R.A. Gross² and R.L. Macdonald², Depts. Internal Medicine¹ and Neurology², Univ. of Michigan Medical Center, Ann Arbor, MI.

CGRP is present in primary sensory neurons and may have important regulatory functions. Because neurosecretion is associated with calcium entry via voltage-gated channels we tested: 1. Whether CGRP affects calcium current(s) and classical neurotransmitter release in nodose neurons and 2. Whether the peptide's mechanism of signal transduction involves guanine nucleotide binding (G)-proteins. Whole cell patch clamp studies were performed on acutely dissociated nodose ganglion neurons from 7 - 10 d rats. Calcium currents were recorded using external and internal media which blocked sodium and potassium currents. Nodose neurons exhibited T, L and N-type calcium current components. CGRP (1 - 1000 nM) had no effect on isolated T and L current components (n=12) but produced a concentration-dependent increase in the combined N/L current in 24/36 of cells evaluated. CGRP (1 μ M) increased the combined N/L current by 24 + 4% (n=15) which was blocked by pretreatment with PTX (100 ng/ml for 12 h, n=12). CGRP did not alter the voltagedependence of the current-voltage relation and the peptide increased the peak current by the same magnitude when neurons were held at V_h = -60 or -90mV. CGRP (1 μM) produced a 22 \pm 5% increase in 3H -ACh release over basal levels (n=12) which was reduced by 76 \pm 8% (n=8) after pretreatment with PTX (250 ng/ml for 3 h). In summary, CGRF selectively increased the N current component and acetylcholine release in nodose neurons via a PTX-sensitive mechanism.

TIME COURSE OF NEUROTRANSMITTER EFFECTS ON VOLTAGE-DEPENDENT CURRENTS OF BULLFROG VOLTAGE-DEPENDENT CURRENTS OF BULLFROG SYMPATHETIC NEURONS. Stephen W. Jones. Dept. Physiol. & Biophys., Case Western Reserve Univ., Cleveland, OH 44106. Several transmitters inhibit the N-type calcium current and the M-type potassium current in bullfrog sympathetic

neurons. G proteins appear to be involved, but the receptorchannel coupling mechanism is otherwise unknown. Since the timing of the effects constrains potential mechanisms, a rapid (-100 msec) flow tube perfusion system was used to apply agonists to isolated cells, under whole-cell voltage clamp. High concentrations of low affinity agonists (salmon

LHRH or muscarine) were used to speed receptor kinetics.
Part of the effect develops and recovers rapidly, limited partially or entirely by the solution exchange time. However, much of the effect is slower (> 1 sec). An even slower leak increase is sometimes seen. This suggests that more than one mechanism may be involved in receptor-channel coupling.

Figure: 2 μ M Salmon LHRH was applied for ~0.4 s during a long voltage step (A) or for 30 s with brief test steps every 2 s, with maximal effect at 7 s (B). A and B are from the same cell. Calcium currents (2 mM Ba²⁺) for steps to -10 mV from -80 mV.

261.7

DYNORPHIN A REDUCTION OF NEURONAL CALCIUM CURRENT IS ENHANCED BY CYCLIC AMP-DEPENDENT KINASE.

R.A. Gross, H.C. Moises@, M.D. Uhler*# and R.L. Macdonald, Dept. of Neurology, @Physiology and the #Mental Health Research Institute, U of Michigan, Ann Arbor, MI 48104.

Dynorphin A (DYN), a x-selective opioid peptide, reduces neuronal adenylate cyclase (AC) activity and reduces voltage-dependent calcium currents, but the pathway by which it affects channel activity is not known. We tested the effect of DYN on the T, N and L calcium current components of acutely-dissociated rat nodose ganglion neurons and compared its effect to that of the catalytic subunit of cyclic AMPdependent kinase (AK-C). We reasoned that if a reduction in AC activity were required for DYN-induced reduction of neuronal calcium current, this effect would not be apparent in the presence of AK-C.

We recorded whole cell calcium currents from acutely-dissociated nodose ganglion neurons from 7-10 d rats. The bath medium contained (mM): 10 Hepes, 67 choline, 100 TEA, 5.6 glucose, 5.3 KCl, 0.8 MgCl₂, 5 CaCl₂ (pH 7.3); the recording pipette (0.5-1.25 MΩ) contained 10 Hepes, 140 CsCl, 10 EGTA, 5 ATPMg, 0.1 GTP or GTP-γ-S. DYN selectively reduced N current in a reversible, naloxone-sensitive manner. The effect was blocked by pretreatment with pertussis toxin and mimicked by GTP-y-S. In the presence of AK-C, run-down of N and L currents was prevented and the effect of DYN was greater than in the absence of AK-C. These results suggest that the acute reduction of calcium current by DYN was mediated by activation of G_I- or G_O-type G proteins, independent of an effect on the AC-cyclic AMP system, and that phosphorylated channels were preferentially inhibited by DYN. Supported b NIH NS01019 & NS19613 (RAG) DA03365 (HCM) and DA04122 (RLM).

EVIDENCE FOR TWO MODES OF Ca CHANNEL REGULATION BY PKC IN HIPPOCAMPAL NEURONS. D. Doerner & B.E. Alger, Dept. of Physiol., Univ. of MD Sch. Med., Baltimore, MD 21201

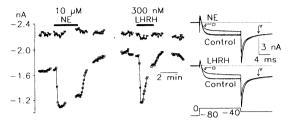

Previous studies have implicated protein kinase C (PKC) in the regulation of Ca channels in hippocampal neurons. We have now compared the effects of synthetic diacylglycerols, ${\rm DiC_8}$ and OAG, with those of phorbol dibutyrate (PDBu) on both whole-cell Ca channel current (IBa) and single Ca channels and find evidence of two modes of Ca channel regulation by PKC. High-voltage-activated I_{Ba} is predominantly suppressed by PKC activators in whole-cell recordings, although an initial, transient enhancement is frequently observed in cells treated with OAG (20-300 μ M), or DiC₈ (1-200 μ M), but not PDBu (0.05-5 μ M). The suppressant effects of DiC and PDBu are reversible with washing and blocked by dialysis with the peptide pseudosubstrate inhibitor (19-36 PKCI, n=11).

Diacylglycerols or PDBu caused an enhancement (3-10 min) followed by depression of the activity of single L-type Ca channels in cell-attached patches in 15/23 cases, although persistent increases (3/23) and monophasic decreases (3/23) were also seen. Similar results were obtained in preliminary experiments with carbachol (0.5-1 mM, n=5), an agonist that activates PKC in hippocampal neurons. Both enhancement and suppression of Ca channel activity appear to be due to PKC, possibly reflecting the activation of different isomers. Modulation of spontaneous synaptic activity in cultured neurons following DiC, application qualitatively resembles Ca channel modulation and is under study.

DOES LHRH OR NOREPINEPHRINE AFFECT L-TYPE CALCIUM CURRENT IN FROG SYMPATHETIC NEURONS? Keith S. Elmslie & Stephen W. Jones. Dept. of Physiology & Biophysics, Case Western Reserve University, Cleveland, OH 44106

Whole-cell calcium current in bullfrog sympathetic neurons is

Whole-cell calcium current in bullfrog sympathetic neurons is mainly comprised of N-current (~90%), which can be reduced by neurotransmitters (e.g. chicken II luteinizing hormone-releasing hormone (LHRH) and norepinephrine (NE)). We have examined the effects of NE and LHRH on cells exposed to ω -conotoxin (to reduce N) and +202-791 (to enhance L). Under these conditions current at 0 mV is a mixture of N & L. under these conditions current at 40 mV is L-current. NE and LHRH reduce current at 0 mV (33.4% \pm 11.9%) (s.d., n = 6) and the fast tail, but not the slow tail (3.3% \pm 3.3%). In several cells the slow tail (3.3% \pm 3.3%). In several cells the slow tail was slightly enhanced (~8%). Thus, LHRH and NE do not appear to significantly inhibit L-current in these cells.

261.8

THE EFFECTS OF PDAc, H-7 AND GM-1 ON THE HIGH THRESHOLD SLOWLY INACTIVATING CA CURRENT IN THE RAT HIPPOCAMPAL SLICES. N. Agopyan, P. Miu & K. Krnjević. Anaesthesia Res. Dept., McGill University, Montreal, Que., Canada.

Protein kinase C (PKC) activators, block the slow AHP mediated by the Ca dependent G_K we investigated the effects of a) phorbol 12,13-diacetate (PDAc), a PKC activator, and b) H-7 and GM-1, both PKC inhibitors (Hidaka et al. 1984, Biochem, 23, 5036; Kreutter et al. 1987, J. Biol. Chem. 262,1633; Cimino et al. 1987, Acta Physiol. Scand. 130, 317), on the high threshold Ca current recorded with Scl-filled electrodes at V_H -50 mV in hippocampal slices (at 32°) superfused with ACSF, containing TTX (1 μ M), TEA (10mM), Cs (4 mM) and 4-AP (0.5 mM).

PDAc (10 μ M) induced a persistent inward current, and increased the high

mM) and 4-AP (0.5 mM). PDAC (10 μ M) induced a persistent inward current, and increased the high threshold Ca current (62 \pm 20 %) as well as the leak conductance (29 \pm 9 %). H-7 (30 μ M) induced an outward current and reduced the high threshold Ca current by 85%. Like trifluoperazine, which acts as a dual PKC/Ca-calmodulin dependent kinase inhibitor, GM-1 (0.1 μ M) induced a persistent inward current and reduced the high threshold Ca current (24 \pm 4 %). All of the effects were reversed 30 min after the application ended. During a concomitant application of GM-1 or H-7 the effects induced by PDAc were not observed.

In conclusion, in contrast to observations obtained from acutely dissociated hippocampal neurones (Doerner et al. 1988, J.Neurosci. 8,4069) our data show that activation of PKC enhances the high threshold Ca current.

261.10

INACTIVATION OF HVA CALCIUM CURRENTS IN GRANULE CELLS FOLLOWING KINDLING-INDUCED EPILEPSY: THE Ca2+-BUFFERING ROLE OF CALBINDIN-D_{28K} (CaBP). G. Köhr, C.E. Lambert and I. Mody. Dept. of Neurology & Neurol. Sci., Stanford Univ. Sch. of Med., Stanford, CA.

In granule cells (GCs) of the dentate gyrus, kindling-induced epilepsy results in a progressive loss of a neuron-specific cytoplasmic high affinity calcium binding protein (Calbindin-D_{zex}; CaBP). The exact function of CaBP in neurons is unknown, but it has been postulated to serve as an effective high capacity intracellular Ca2+ buffer.

We have shown immunohistochemically that acutely dissociated kindled neurons have low levels of cytoplasmic CaBP and consequently might have lost their calcium buffering capacity. We have investigated this hypothesis by examining the Ca²⁺-dependent inactivation of Ca²⁺ currents in acutely examining the Cartospericent inactivation of Cartospericent in actively dissociated GCs from hippocampal silices of control and commissurally kindled (stage 5) rats. Maximal HVA Cartospericents could be evoked from holding potentials of 50 mV to command potentials of +10 mV. These were: 216.4±54.8 pA (mean±SD; n=10) in control GCs and 202.1±53.6 pA (n=11) in kindled GCs. Conditioning voltage steps to +10 mV induced inactivation of a subsequent test Ca2+ current evoked 50 ms later. In control GCs the test Ca²⁺ currents inactivated by 37.4±11.9%. In kindled GCs the inactivation was significantly increased to 58.3±8.3%. The recovery from inactivation of the Ca2+ currents was slower in kindled than in control GCs. The decay of HVA Ca²+ currents evoked by 1 s voltage steps was more rapid in kindled GCs than in controls. When neurons were loaded with the Ca²+ chelator BAPTA, Ca²+ current inactivation was prevented in both control and kindled neurons. These results strongly support the Ca²+ buffering role of CaBP in GCs and its involvement in the regulation of HVA Ca²+ current inactivation.

DOPAMINE SELECTIVELY INHIBITS HIGH-THRESHOLD CALCIUM CURRENTS IN RAT LACTOTROPHS. D. Janigro, G. Maccaferri* and J. Meldolesi*. Dept. of Pharmacology, Istituto Scientifico San Raffaele, Milano, ITALY.

Calcium currents were investigated in rat lactotrophs. Patch-clamp experiments, using the whole cell configuration mode, were performed on cells that had been kept in culture for different periods of time. Calcium currents were elicited (after blockade of potassium currents with intracellular CsCl and extracellular TEA) by depolarizing voltage steps from a holding potential of -100 mV. In cells cultured for one day, currents showed properties typical of high-threshold, L-type channels, while cells cultured for three days appeared to express both high-threshold and low-threshold, T-type channels. Application of dopamine (10 uM) reduced the L-type component. This effect was abolished by pretreatment of the cell with the D inhibitor, 1-sulpiride, and pertussis toxin. In contrast it was unaffected by 8-bromo-cAMP. We conclude that both L- and T- type calcium currents are expressed in rat lactotrophs. Their ratio can, however, vary depending on the culturing conditions, and only one of them (the L-type) is blocked by dopamine, possibly via a G protein-mediated interaction of channels with the activated D receptor.

LARGE PRE-DEPOLARIZATIONS, BUT NOT TRAINS THAT MIMIC ACTION POTENTIALS, REVERSE INHIBITION OF I_{Ca} BY 5-HT.

N.J.Penington, J.S.Kelly and A.P.Fox* Univ. Chicago, Dept.Pharm/Phys, Chicago, II. 60637. & Dept. Pharmacol. Univ. Edinburgh U.K.

5-HT $_{1A}$ receptor activation inhibits I $_{Ca}$ in acutely isolated adult rat dorsal raphe neurons (Penington & Kelly, Neuron, 1990). The effect is voltage dependent with little inhibition at positive potentials. The rate of activation of I_{Ca} is slowed (the channels may go from a "reluctant" gating state, to a "willing" gating state at positive potentials Bean, Nature, 1989). A prepulse to +80 mV for 150 ms, followed by a 10 ms return to the holding potential (-100 mV) completely reversed the 5-HT mediated inhibition potential (-100 mV) completely reversed the 3-11 mediated inholition of I_{Ca} elicited during a test pulse to -10 mV; similar results were obtained with LHRH inhibition of frog sympathetic neuron I_{Ca} (Elmslie & Jones Soc. Neurosci., 1989). Trains of voltage clamp steps designed to mimic action potentials in DR neurons were applied to see if they could also reverse the action of 5-HT. In 10 µM 5-HT (which inhibited I_{Ca}) a test depolarization to -10 mV from a H.P. of -60 mV was followed by a train of 21 voltage jumps to +30 mV, each 5 ms in duration applied every 60 ms. The train was followed 60 ms later by another test jump to -10 mV to measure $I_{\rm Ca}$. The train reversed the effect of 5-HT by only 4.6%. This finding suggests that under physiological conditions raphe neurons cannot significantly reverse the effect of 5-HT inhibition of I_{Ca} simply by firing faster. Periods of unusual excitation produce effects which do not persist long enough to alter the effect of 5-HT on subsequent action potentials. Supported by the Wellcome Trust.

PROCESS OUTGROWTH, GROWTH CONES AND GUIDANCE MECHANISMS V

262.1

PIONEERING GROWTH CONES IN THE EMBRYONIC ZEBRAFISH BRAIN.
S.W. Wilson, and S.S. Easter Jr. Department of Biology,
University of Michigan, Ann Arbor, MI 48109.

By 24 hours post-fertilisation axons in the embryonic
zebrafish brain have established a simple stereotyped
scaffold of axon tracts (Wilson et. al. Development
108:121, 1990). Using neuroanatomical tracing techniques
combined with light and electron microscopy, we have examined the development of one of these early tracts, the
dorsoventral diencephalic. We find that it is pioneered
at a precise time in development by the growth cone of a
single neuron present in an identified location. The soma
of this neuron is located in the anlage of the pineal and
extends a growth cone which courses superficially and
ventrally, between the end feet of neuroepithelial cells
located along its pathway. These same cells have processes
which envelop the axon, but we see no indication of any
specialisation ahead of the growth cone. Growth cone
filopodia extend in many directions, including deep into
the brain, occasionally inserting into the neuroepithelial
cells. Midway down the diencephalon the growth cone
encounters neurons and axons within the tract of the
postoptic commissure (TPOC), at which point it invariably
turns rostrally. It fasciculates with these TPOC axons
and passes contralaterally through the postoptic commissure.

262.3

ALTERATION OF MOTOR NERVE PATHWAYS BY ECTOPIC FIN BUDS IN THE JAPANESE MEDAKA FISH. H. Okamoto & J.Y. Kuwada, Dept.

of Biology, Univ. of Michigan, Ann Arbor, MI 48109.

The pectoral fin muscles of the Japanese Medaka fish are normally innervated by motor axons from segments 1-4. During embryogenesis these axons extend toward the fin bud and converge to form a plexus at the base of the fin bud in S2. Nerves in more posterior segments follow a pathway parallel with the segmental borders of the axial muscles. Previously we showed that the fin bud is necessary for outgrowth by the motor nerves of S1-4 to the base of the fin bud by ablating the fin bud. In such embryos motor nerves from S1-4 extended along a pathway parallel to the segmental borders of the axial muscles much like in the more posterior segments. This suggested that the motor growth cones in S1-4 normally extend to the base of the fin bud because they are attracted to it. We have now confirmed this hypothesis by transplanting fin buds to ectopic sites. When fin buds were transplanted to more posterior segments, motor nerves from S1-4 extended to the base of ectopic buds. In these cases the S2 motor nerve which normally extends laterally and S3 and S4 motor nerves which normally extend anteriorly instead all extended posteriorly. One possible mechanism for the attraction of motor growth cones by the fin bud is a long distance cue emitted by the fin bud. (Supported by Toyobo Biotechnology Foundation, NIH, MOD, and UM.)

MULTIPLE MECHANISMS OF GROWTH CONE GUIDANCE IN THE ZEBRAFISH BRAIN A.B. Chitnis & J.Y. Kuwada. Dept. Biology

& Neurosci. Prog., U. of Michigan, Ann Arbor, MI 48109.

The early zebrafish brain contains a simple scaffold of longitudinal tracts connected by commissures. Growth cones of neurons in the nucleus of the posterior commissure (nuc PC) follow a stereotyped pathway within the scaffold. Nuc PC growth cones extend ventrally along the PC to the anterior tegmentum where a number of tracts intersect. In principle the growth cones could extend along any of these tracts, but always turn posterior to descend in the tract of the postoptic commissure (TPOC) to the hindbrain without sending collaterals into the other tracts. To identify mechanisms that guide the nuc PC growth cones, we have manipulated embryos to see how nuc PC growth cones behave following elimination of the TPOC (n=46). In the absence of the TPOC nuc PC growth cones follow inappropriate tracts in 55% of embryos. This suggests that cues associated with the TPOC help guide nuc PC growth cones, and that nuc PC growth cones are not inhibited or prevented from entering other tracts. However, since in 45% of embryos nuc PC growth cones did follow their normal pathway despite the absence of the TPOC, other cues in the tegmentum, independent of the TPOC, may also be capable of guiding nuc PC growth cones. Thus multiple mechanisms may operate simultaneously to insure that all nuc PC growth cones follow their appropriate pathway. (Supported by NIH, MOD, and UM.)

GROWTH CONES OF ECTOPIC MOTONEURONS SELECT NORMAL PATHWAYS IN EMBRYONIC ZEBRAFISH. C. L. Gatchalian and J. S Eisen. Institute of Neuroscience, University of Oregon, Eugene, OR

The growth cones of identified primary motoneurons in embryonic zebrafish follow cell-specific pathways and innervate nonoverlapping regions of muscle. To learn whether the motoneurons are able to select their normal pathways when removed from their original positions we labeled CaP, the first primary motoneuron to extend a growth cone, and transplanted it to an ectopic location outside of the spinal cord in unlabeled host embryos. We found that the growth cones of most of the surviving transplanted CaPs (23 of 27) extended along the normal cell-specific CaP pathway into the ventral muscle. This result suggests that the pathway into the ventral muscle. This result suggests that the pathway itself may provide cues that guide the CaP growth cone. To learn whether these putative guidance cues are generally recognized by other growth cones, we transplanted labeled primary sensory Rohon-Beard neurons to the same location. In contrast to transplanted CaPs, 8 of 8 surviving transplanted Rohon-Beard cells elaborated a network of processes that projected in many directions, but showed no preference for the CaP pathway. These results suggest that primary motoneurons and primary sensory neurons are guided by different pathway cues. Supported by the NIH, NSF, and Proctor and Gamble Company.

CIRCUMFERENTIAL GUIDANCE CUES FOR PIONEER GROWTH CONE MIGRATION IN GRASSHOPPER EMBRYONIC LIMB BUDS. T. P.

CIRCUMFERENTIAL GUIDANCE CUES FOR PIONEER GROWTH CONE MIGRATION IN GRASSHOPPER EMBRYONIC LIMB BUDS. T. P. O'Connor. L. Gorodezky*. A. Toroian-Raymond* and D. Bentley. Dept. of Mol. and Cell Biol., University of California, Berkeley, CA 94720. Axonal growth cones in a variety of vertebrate and invertebrate systems appear to be guided by molecular information available at the basal surface of ectodermal epithelium or neuroepithelium. In embryonic grasshopper limb buds, for example, the Til pioneer afferent neurons arise at the limb tip and their growth cones migrate proximally to the CNS along a stereotyped pathway defined by cues provided by the ectodermal epithelium and nascent 'guidepost' neurons derived from it. The epithelium is a two dimensional surface with a proximo-distal axis and an orthogonal circumferential dorsoventral axis. While most analyses to date have addressed the nature of proximo-distal guidance, many cell and growth come migrations in both the anterior and posterior limb compartments include oriented segments along the dorso-ventral axis. We report three kinds of experiments which indicate that ventrally polarized guidance information is present in the epithelium. (1) selective elimination of specific cells by timed heat shocks indicates that ventral reorientation of growth cones is independent of the presence of ventrally located guidepost neurons; (2) time-lapse video of double labeled pioneer growth cones and ventral guidepost cells indicates that the ventral growth cones are presented with a binary choice indicates that ventral epithelial cells can mediate re-orientation. Double-labeling of neurons and compartments shows that growth cones from both compartments collect near the ventral compartment boundary and turn proximally toward the CNS along a series of cells at the ventral most region of the anterior compartment.

GROWTH CONES IN DROSOPHILA EMBRYOS SHOW STEREOTYPIC

GROWTH CONES IN DROSOPHILA EMBRYOS SHOW STEREOTYPIC MORPHOLOGY AND BEHAVIOR. A. Chiba. T.N. Chang. M.E. Halpern & H. Keshishian, Dept. of Biology, Yale Univ., New Haven, CT 06511

The neuromuscular synapses in *Drosophila* embryos are highly stereotypic. By characterizing individual motoneurons and the dynamics of growth cone movements in mid-embryogenesis (st. 15-16), we find that each growth cone shows a specialized response as it contacts its appropriate target. A specific set of motoneurons are consistently labeled when the motor nerve terminals on a muscle fiber are backfilled with the vital dye Dil. While Dil labeling demonstrates the cell body locations of all motoneurons, the detailed morphology of individual neurons is revealed through intracellular dye-filling with Lucifer yellow. From nerve SNb, motoneuron RPI (i.e. MN6-7) innervates muscle fibers 6 and 7. Two other motoneurons innervate muscle fiber 13 through the same nerve; the soma of MN13a is ipsilateral and in the same segment as its target, while the soma of the MN13b which innervates the same fiber is contralateral and one segment anterior. The locations and relative development of all SNb motoneurons are demonstrated by anti-HRP staining. Double labeling of dye-filled motoneurons shows that their growth cones exit the nerve from characteristic sites to grow directly to their target muscle fibers where they differentiate anatomically distinct synapses. We are able to visualize growth cone behavior in situ in living filleted embryos by time-lapse video microscopy and DiI injection. CNS injection labels one or a small ensemble of growth cones at the growing tip of nerves SN and ISN. These growth cones are capable of extending filopodia of various lengths (2-12 µm) were smallers. growth cones are capable of extending filopodia of various lengths (2-12 µm) and sampling the surfaces of muscle fibers adjacent to the nerve, including those which are not normal targets. These results indicate that motoneurons are matched to individual target muscle fibers, and that synaptogenesis in *Drosophila* may involve specific cell-cell recognition events between growth cones and their targets.

MUTATIONS AFFECTING AXONAL OUTGROWTH AND GUIDANCE OF THE MOTOR NEURONS IN THE NEMATODE C. ELEGANS. S. S. SIDDIQUI . Lab. of Molecular Biology, Toyohashi University of Tech

Toyohashi 440, Japan.

I have previously reported anti-tubulin monoclonal antibodies that preferentaially stain specific sets of neurons in the nervous system of the nematode \underline{c} . $\underline{elegans}$ (Society of Neurosci. Abstr. 1989), including \underline{mAb} $\underline{2-28-33}$, that stains 26 GABA immunoreactive neurons in C. elegans. These are six DDs, thirteen VDs, four RMEs, and three single neurons, RIS, AVL, and DVB. The DDs and VDs are known to be the inhibitory motor neurons, located along the ventral nerve cord of the animal. We have screened "uncoordinated" (unc) mutants of <u>C. elegans</u>, defective in locomotion, immunocytochemically using 2-28-33, on wholemount "squash" preparations, and identified mutants in 15 genes that show abnormal staining pattern of the DD and VD neurons. Mutants in 11 genes(unc-5, unc-6, unc-13, unc-34, unc-40, unc-51, nnc-62, unc-69, unc-71, unc-73, and unc-76) affect the out-growth and process placement of the dorsalward axons of the DD and VD neurons. Mutants in unc-30, lack the staining of the axonal processes, but the DD and VD cell bodies stain to a variable degree; whereas, mutants in unc-25 fail to stain both the cell bodies and the axonal processes. In mutants of two genes (unc-59, and unc-85), that are known to affect cytokinesis, multiple DDs and VDs are stained. Most of the mutants listed above also affect the axonal growth and guidance of other neuron classes.

262.6

PATTERNED SPECIFICATION OF EPITHELIAL SUBSTRATE OCCURS PRIOR TO PERIOD OF AXON OUTGROWTH IN THE DEVELOPING WING OF DROSOPHILA. S.S.Blair and E.Rulifson*. Dept. Zoology,

Univ. Wisconsin, Madison, WI 53706.

During metamorphosis of *Drosophila*, sensory neurons arise within the wing imaginal disc and project axons over the disc epithelium towards the CNS. These axons follow specific routes, establishing a stereotyped pattern of nerve bundles. Previous work strongly suggests that the cues responsible for guiding these axons are found within the epithelial substrate; however, the wing epithelium appears morphologically uniform during this period. We have therefore begun using the "enhancer trap" technique to examine patterns of differential gene expression in the epithelial substrate. Preliminary results (using trap lines kindly provided by Drs. Carroll, Laughon, and Ganetzky) indicate that complex patterns of gene expression are present in the wing epithelium prior to the period of axon outgrowth Moreover, many of the patterns observed define portions of the normal axon pathways.

Work is underway to develop tests for the possible

roles of known and unknown gene products in defining these pathways. We will report in particular upon a variation upon the mitotic recombination technique which uses beta-gal expressing inserts to mark clones in the developing wing, allowing the examination of the effects of lethal mutations during axon outgrowth.

DEVELOPMENT OF SITE-SPECIFIC SYNAPSES BY THE DROSOPHILA MOTONEURON RP1 INVOLVES STEREOTYPIC FILOPODIAL CONTACTS DURING EMBRYOGENESIS M.E. Halpem & H. Keshishian. Dept. of Biology, Yale Univ., New Haven, CT 06511.

Each muscle fiber in the bodywall of *Drosophila* larvae is innervated in an

Dept. of Biology, Yale Univ., New Haven, C1 00511.

Each muscle fiber in the bodywall of Drosophila larvae is innervated in an anatomically stereotypic fashion. During embryogenesis, these synapses arise through the selective projections of motoneurons onto specific muscle fibers. The motoneuron RP1 establishes a precise synaptic connection on the posterior portion of the two longitudinal skeletal muscle fibers 6 & 7. The target muscle fibers are generated between stages 12-15. We find that intra and intersegmental dye coupling has ended and myoblast fusion is complete when synapses are formed. Thus, fibers 6 and 7 are differentiated by the time the RP1 growth cone contacts their surfaces. Video imaging of intracellular dyefills of RP1 reveals the behavior of its growth cone as it differentiates at the target cells. The growth cone exits the CNS at stage 15, and projects along nerve branch SNb to the cleft between the adjacent fibers 6 & 7. Here it transiently sprouts a pair of anteriorly directed filopodia, one on each of the two fibers. Other filopodia make characteristic projections that contact and are retracted from neighboring fibers. The RP1 growth cone grows posteriorly along the intermally facing surfaces of the target fibers 6 & 7, where it divides to establish synaptic endings on both fibers. By comparing living, staged neurons using digital optical imaging we find that filopodial projections, rather than being random, are arrayed in stereotypic patterns during the development of the synapse. These contacts generate the basic morphology of the RP1 ending over a period of 2 to 3 hrs during embryogenesis. Our results suggest that larval innervation patterns are a consequence of precise filopodial projections from exploring growth cones in response to highly lecelized cues on the target cell surfaces. consequence of precise filopodial projections from exploring growth cones in response to highly localized cues on the target cell surfaces. ACCUMULATION OF LAMININ AND MICROGLIAL CELLS AT SITES OF INJURY AND REGENERATION IN THE C.N.S. OF THE LEECH.

ACCUMULATION OF LAMININ AND MICROGLIAL CELLS AT SITES OF INJURY AND REGENERATION IN THE C.N.S. OF THE LEECH. L. Masuda-Nakagawa, K.J. Muller, B. Sasse and J.G. Nicholls. Pharmacol. Dept., Biocenter, Basel University, 4056 Basel, Switzerland; Dept. of Physiol. & Biophys., Univ. of Miami Med. Sch., Miami, FL 33101 Profuse sprouting of leech neurons occurs in culture when they are plated on a substrate consisting of laminin molecules extracted from extracellular matrix that surrounds the C.N.S. To assess the role of laminin as a potential growth promoting molecule in the animal, its distribution was compared in intact and regenerating C.N.S. by light and electron microscopy, using a monoclonal anti-laminin antibody (206) and conjugated secondary antibodies. In frozen sections and electron micrographs of normal leech nervous system the label was restricted to the connective tissue capsule surrounding the connectives that link ganglia. Immediately after the connectives had been crushed the normal structure was disrupted but laminin remained in place. Two days after the crush, axons began to sprout vigorously and microglial cells accumulated in the lesion. At the same time labelled laminin molecules were no longer restricted to the basement membrane but appeared within the connectives in the regions of neurite outgrowth. The distribution of laminin at these new sites within the C.N.S. was punctate at two days, but changed over the following two weeks; the laminin became aggregated first as fibrils and then as condensed streaks running longitudinally along the connectives beyond the lesion. The close association of regenerating axons with laminin in electron micrographs suggests that it may promote neurite extension in the C.N.S. of the animal as in cultive. connectives beyond the lesion. The close association of regenerating axons with laminin in electron micrographs suggests that it may promote neurite extension in the C.N.S. of the animal as in culture. Supported by grants from the Swiss National Fund (J.G.N.) and USPHS NS 20607 (K.J.M.).

DIFFERENTIAL GROWTH OF APLYSIA NEURONS R2 AND L10 ON RUQ TARGET CELLS IS ASSOCIATED WITH THEIR CAPACITY TO FORM SYNAPSES. D. Hawver and S. Schacher. Dept. Pharm., Ctr. Neurobiol. & Behav., Columbia CPS & NYS Psych. Inst., New York, NY 10032.

Previous studies of Aplysia neurons L10 and RUQ in co-culture revealed that regenerating L10 neurites tend to avoid growing on RUQ target cells, due in part to the failure of L10 growth cones to fasciculate with RUQ neurites. This avoidance may help explain the paucity of L10-RUQ chemical synapses despite proper matching of ACh in L10 with AChR on RUQ. To determine whether this avoidance of RUQ is specific to L10, we used fluorescent dye injections to examine the pattern of neurite outgrowth from cholinergic neuron R2 in the presence of RUQ. In 14 of 17 cases, 2-8 major R2 neurites appeared to alter direction so as to converge upon the RUQ soma and major axon. All R2 cells showed growth of neurites in the RUQ area, often characterized by extensive branching on the soma and fasciculation along the major axon and neurites of the target cell. 12 of these R2-RUQ pairs were tested electrophysiologically for chemical connections, and 7 showed a 1-5 mV response in RUQ to a train of 3-5 spikes evoked in R2. Thus, R2 differs strikingly from L10 in its ability to form synapses with RUQ as well as in its propensity to grow on the RUQ target cell. Preliminary observations of early interactions show that, unlike L10 growth cones, R2 growth cones have a marked tendency to fasciculate with RUQ neurites. This suggests that the differences in the mature patterns of neurite outgrowth from R2 and L10, and the differences in synapse formation, may arise from selective fasciculation of initial contacts.

INVERTEBRATE LEARNING AND BEHAVIOR III

263.1

A MATHEMATICAL MODEL OF PROTOZOAN HABITUATION. D. C. WOOD. Dept. of Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15260.

Seven of the 9 parametric characteristics used to operationally define metazoan habituation have been observed when the contractile protozoan Stentor habituates to repeated mechanical stimuli. This behavioral habituation is correlated with a progressive decrement in mechanoreceptor potential amplitude. This decrement results from a increase in the voltage dependence of the mechanoreceptor channel conductance which reduces the number of channels opened by a mechanical stimulus. The mechanoreceptor channel modification occurs only when action potentials and contractions are elicited.

This simple form of learning has been mathematically modeled employing only conventional psychophysical (Steven's Power Function) and electrophysiological (Boltzmann equation and Ohm's law) formulations. The parameters employed in these equations and their variances were experimentally determined. The feedback modification of mechanoreceptor channels by action potentials or contractions and their recovery from it were presumed to be first-order processes. Using this model, data demonstrating 5 of the parametric characteristics of habituation were closely fit by varying only the 2 rate constants of the feedback processes. The other 2 characteristics could be fit with small extensions to the model.

263.3

FACTORS AFFECTING HABITUATION AND RECOVERY FROM HABITUATION IN C. ELEGANS C. H. Rankin and B. S. Broster*, Department of Psychology, University of British Columbia, Vancouver, B.C. VET 1Y7

Although habituation is the simplest and most ubiquitous form of learning the biological mechanisms of habituation are still incompletely understood. In these behavioral experiments we have investigated factors that affect the rate of habituation, the degree of habituation and the rate of recovery from habituation in a simple reflex circuit in *C. elegans*. One objective of these experiments was to determine the behavioral rules governing habituation; hypothesized cellular mechanisms of habituation must take these behavioral rules into consideration. In *C. elegans* the rate of habituation, amount of habituation and time to recover to baseline response levels are affected by the rate of stimulation. Habituation is deeper and more rapid, and recovery from habituation is more rapid, if stimuli are delivered at short interstimulus intervals than if they are delivered at long interstimulus intervals. The rate of recovery from habituation is dependent upon the interstimulus interval used and not upon the amount of habituation, nor upon the number of stimuli received. For example following habituation with a 5s ISI worms recover within 10 min, however after the same number of stimuli at 60s ISI worms took more than 30 min to recover.

These behavioral experiments show that the rules for habituation in *C. elegans* are similar to those observed in a large variety of species. Thus *C. elegans* is an appropriate model system in which to investigate biological mechanisms underlying habituation.

263.2

DISSECTING MALE-MATING BEHAVIOR IN C. ELEGANS
K. Liu, Y. Hajdu*, and P. Sternberg*. HHMI, Div. of Biology, 156-29,
Caltech, Pasadena, 91125.

C. elegans naturally occurs in two sexual forms, self-fertilizing hermaphrodites, and males, which must mate in order to produce progeny. Male mating behavior comprises a number of discrete (but not discreet) steps: males first respond to hermaphrodites by backing along its length, turn around the head and/or tail if necessary, locate the vulva, insert their spicules, and inject sperm. The copulatory structures and their associated neurons in the male tail appear to mediate this behavior. To understand the underlying neuronal circuitry, we are taking two approaches. First, to identify genes which specifically affect the participating neurons, we have isolated mutations which affect mating. Details of this screen were described previously (Liu, K. and Sternberg, P. Soc. Neurosci., 1989). To date, we have isolated 22 mutants defective in the steps outlined above, 19 of which exhibit defects at a single step. For example, 11 mutants are blocked at the level of spicule insertion. The fact that these steps are independently mutable suggests that separate neural components mediate these steps. Our second approach is to systematically ablate the different sensory structures specific to the male to ascertain their roles in mating behavior. Preliminary results indicate redundancy in the system. For example, the "hook" normally mediates the location of the vulva, as its ablation results in male initially unable to perform this step. However, after a few unsuccessful attempts, the spicules appear to be able to partially compensate for this defect. This redundancy in the system may explain why it has been difficult to isolate mutations which act early in the behavioral pathway.

263.4

MODELS OF LEARNING WITHOUT DETECTABLE SYNAPTIC PLASTICITY IN THE LEECH. <u>S.R. Lockery and T.J. Sejnowski</u>. Salk Institute, La Jolla, CA 92037.

Studies of neural mechanisms of learning have focussed on large changes at identified synapses. However, learning in even simple reflexes may be distributed over many synapses. We used a model network of the local bending reflex in the leech to investigate the distribution of synaptic plasticity underlying habituation in a parallel processing system. The model comprised 4 sensory, 20 inter-, and 8 motor neurons. Synaptic connections were trained by the recurrent backpropagation algorithm until the model reproduced the amplitude and timecourse of synaptic potentials recorded intracellularly from motor neurons in response to sensory cell stimulation in non-habituated preparations. This "naive" network was then "habituated" by retraining it until the amplitude of each synaptic potential was 40% of the non-habituated level. The training algorithm was allowed either to increase or decrease the strength of a connection. Final connection strengths in the model network were inferred from the heights of simulated synaptic potentials when the presynaptic neuron was stimulated with a standard current pulse. Comparison of connection strengths in naive and habituated networks revealed that habituation was distributed across all connections in the model, with the largest changes in the connections between sensory and interneurons. However, even these changes were small—on average, less than 1 mV. This result raises the possibility that substantial changes in behavior can occur in the absence of easily detectable changes in synaptic strength.

CLONING OF A NEURAL CELL ADHESION MOLECULE FROM APLYSIA THAT IS MODULATED IN THE SENSORY NEURONS IN RESPONSE TO 5-HT. Mayford*, F. Keller, A. Barzilai, S., Schacher, & E.R. Kandel. Ctr. Neurobiol & Behav., Columbia Univ., & HHMI, NY, NY 10032

Both long-term sensitization training and long-term facilitation of the Aplysia sensory-motor connection induced in culture by application of serotonin (5-HT), result in structural changes in the sensory neurons and in the motor neurons of the gill-withdrawal reflex Barzilai et al. (Neuron 2, 1577, 1989) found that a number of proteins are altered in their level of expression in the sensory neurons within one hour after exposure to 5-HT. Among these are four of 100-150 Kd M.W. that are reduced in their rate of synthesis within one hour after exposure to 5-HT. These proteins crossreact with a monoclonal antibody (mAb) that is specific to an Aplysia neuron specific cell adhesion molecule. Immunofluorescent studies with the mAb suggest that within one hour after the addition of 5-HT these antigens are also reduced on the membrane surface of cultured sensory neurons. We have obtained a cDNA clone from an Aplysia central nervous system lambda gt11 library that expresses a protein which cross reacts with the mAb Preliminary sequence data suggests that this protein may be a member of the immunoglobulin class of cell adhesion molecules. The down regulation of these adhesion molecules may be a necessary early component of the structural changes associated with long-term sensitization and facilitation.

263.7

SEARCH FOR ADDITIONAL SITES OF ASSOCIATIVE INTERACTIONS DURING ACTIVITY-DEPENDENT FACILITATION IN APLYSIA SIPHON SENSORY NEURONS. T.W. Abrams Dept. of Biology, Institute of Neurological Sciences, Univ. of Pennsylvania, Phila., PA 19104.

During conditioning of the withdrawal reflex in Aplysia, synaptic

transmission from sensory neurons (SNs) of the CS pathway is strengthened through activity-dependent presynaptic facilitation. One site at which SN activity and the accompanying Ca²⁺ influx, triggered by the CS, enhance the SNs response to facilitatory transmitter, released by the US, is the dually-regulated Ca2+/calmodulin-sensitive cyclase. In addition, activity and Ca2+ could enhance the facilitation response by other mechanisms downstream from the synthesis of cAMP. Using light induced release of cAMP from "caged cAMP" we are attempting to identify downstream sites of convergence. In these experiments, a UV light flash was given either immediately after a train of 5 spikes in a SN (Paired) or 4 sec after a spike train (Unpaired). Paired activity did not increase the spike broadening response to the cAMP transient. We are now attempting to identify downstream sites of activity-dependent interactions in the second facilitatory process responsible dependent interactions in the second facilitatory process responsible for reversing depression, a process distinct from the modulation of the S-K+ current spike broadening. Spike broadening lasts less than 2 min after a flash. At times at which spike broadening has decayed but reversal of synaptic depression persists, preliminary experiments indicate there is no effect of paired activity on the facilitatory effects of light induced cAMP release. This suggests the cyclase may be the major site of stimulus convergence during this form of associative synaptic plasticity.

263.9

STRUCTURAL REMODELING OF SENSORY NEURONS ACCOMPANIES FMRFAMIDE-INDUCED LONG-TERM DEPRESSION OF SENSORIMOTOR SYNAPSES OF *API.YSIA* IN CULTURE. <u>S. Schacher and P. G. Montarolo</u>,* Ctr. for Neurobiol. & Behav., Columbia University CPS and NYS Psych. Inst., New York, NY 10032.

Repeated applications of FMRFamide produce long-term depression of synapses established in cell culture between sensory and motor cells isolated from the abdominal ganglion of Aplysia. To determine whether the synaptic depression is accompanied by changes in sensory cell structure, low light epifluorescent video microscopy was used to image sensory cell neurites apposed and adjacent to the major axons of motor cell L7 both before and 24 hours after a) control treatment, b) one 5 min application (IX) of FMRFamide (1 µM), or c) 4 applications of FMRFamide (4X) at 25 min intervals. EPSPs measured before and after treatment confirmed previous results; little or no change with controls (0 \pm 4.2%, N = 17) or with 1X results, little or no change with controls ($0 \pm 4.2\%$, N = 17) or with 1% treatment ($-8 \pm 3.2\%$, N = 5), and a large decrease with 4X treatment ($-39 \pm 5.7\%$, N = 19). Both control and 1X treatments were accompanied by minor changes in sensory cell structure: $-1 \pm 2.6\%$ and $-2 \pm 2.8\%$, respectively, in the number of varicosities; 1.5 ± 0.6 and 1.6 ± 0.8 , respectively, in the number of neurite retractions. In contrast, 4X treatment resulted in a $-26 \pm 3.4\%$ decrease in varicosities, and 5.7 ± 0.9 neurite retractions. This loss of structure was not cell wide, however, since the number of sensory neurite extensions in areas adjacent to the motor axons was not affected by treatment. Because varicosities of sensory cells apposed to the axons of L7 contain transmitter release sites, these results are consistent with the idea that the loss of varicosities and the retraction of neurites by sensory cells contribute to long-term synaptic depression evoked by FMRFamide.

263.6

REGULATION BY 5-HT OF NEURAL CELL ADHESION MOLECULES IN THE NERVOUS SYSTEM OF APLYSIA. F. Keller, A. Barzilai, S. Grant*, M. Mayford*, I. Winicov*, S. Schacher, & E.R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., & HHMI, NY, NY 10032.

Among proteins in the sensory neurons of Aplysia that are transcriptionally regulated by 5-HT, a neurotransmitter involved in longterm facilitation (A. Barzilai, Neuron 2, 1577, 1989), five proteins have their rate of synthesis down-regulated. We now have characterized four of these proteins using monoclonal antibodies (mAb) and have found that they are related glycoproteins (100-150 kD M.W.), specific to neurons, that are enriched in the neuropil of ganglia and in neurites and growth cones in culture. In addition, these proteins are expressed in pregastrulation embryos. In cultures of sensory neurons, mAb against the proteins perturb axon fasciculation and increase the number of fine diameter neurites. Preliminary sequence data suggest that they are adhesion molecules of the immunoglobulin superfamily (M. Mayford et al., Abstract this meeting). Because long-term facilitation is associated with structural changes in sensory-motor synapses, the down-regulation of adhesion molecules may be one step of a growth program activated by 5-HT

We are now investigating the mechanisms by which the proteins are regulated by 5-HT. We find that sensory neurons release into the culture medium proteins crossreacting with the mAb recognizing the membrane-bound species. This is consistent with the finding that 5-HT appears to down-regulate the expression of the proteins on the cell surface.

263.8

FMRFAMIDE ACTS IN PARALLEL PRE- AND POSTSYNAPTICALLY, VIA ARACHIDONIC ACID. TO INHIBIT THE NEURAL CIRCUIT OF THE SIPHON WITHDRAWAL REFLEX OF APLYSIA. K.J. Belkin and T.W. Abrams. Dept. of Biol. & Inst. of Neurol. Sci., Univ. of Penn., Phila, PA 19104

Dept. of Biol. & Inst. of Neurol. Sci., Univ. of Penn., Phila, PA 19104
Electrical shock to the tail produces transient inhibition of the siphon withdrawal reflex of *Aplysia*, followed by sensitization. At least part of this inhibition is mediated by the neuropeptide FMRFamide (Mackey et al., 1987). FMRFa activates arachidonic acid (AA) production in siphon sensory neurons (Piomelli, et. al., 1987), causing an opening of S-K+ channels (Belardetti, et. al., 1987), thereby inhibiting the synaptic connection of sensory neurons to motor neurons. We found that FMRFa exerts a parallel inhibitory effect postsynaptically on LFS siphon motor neurons. A puff of 2 uM FMRFa onto the cell body of an LFS neuron blocks its spontaneous firing. The response to FMRFa is binhasic consisting of spontaneous firing. The response to FMRFa is biphasic, consisting of a transient depolarization followed by a prolonged hyperpolarization. The hyperpolarizing response is accompanied by an increase in membrane conductance, and has a reversal potential of -75 to -85 mV, which shifts in a depolarizing direction with elevated [K+]o. mV, which shifts in a depolarizing direction with elevated [K-1₀]. This suggests the hyperpolarizing response may be at least partially due to an increase in a K⁺ current. A puff of 30 uM AA onto the cell body causes hyperpolarization, but does not mimic the early depolarization caused by FMRFa. 100 uM 4-bromophenacyl bromide, a phospholipase A2 inhibitor, blocks the hyperpolarizing, but not the depolarizing, FMRFa response. Thus, FMRFa acts via a briggle second messagger but here, and postsynaptically in sonsory. single second messenger, both pre- and postsynaptically in sensory and motor neurons, to inhibit the siphon withdrawal reflex.

263.10

IN VIVO FIRING PATTERN OF THE FOOD AROUSAL NEURON CPR IN APLYSIA. T. Teyke*, K.R. Weiss and I Kupfermann.

Center for Neurobiology & Behavior, Columbia University and NYS Psychiat. Inst., New York, NY 10032.

Center for Neurobiology & Behavior, Columbia University and NYS Psychiat. Inst., New York, NY 10032.

The cerebral neuron CPR has appropriate input and output characteristics to function as a command element for the food-induced arousal state, which modulates feeding in Aplysia. We recorded extracellularly from the cerebral-pedal connective (which has the axon of the CPR) in free moving animals in order to correlate CPR activity with the behavior of the animal. Following the in vivo recordings, the ganglion was removed and the CPR was stimulated in order to characterize the extracellular spike on the basis of spike parameters, such as amplitude and rise time. These data were then used to identify the spike of the CPR in the previously obtained recordings in the freely behaving animal. When the animal was quiescent, or during locomotion, the CPR was not active, and only a few spikes occurred during head withdrawal and changes of the position of the head. A strong increase in activity of the CPR occurred during the appetitive head lifting behavior which was evoked by stimulating the animal with seaweed. 'Spontaneously' occurring appetitive head lifting responses were also associated with a strong increase in CPR activity. CPR activity remained elevated as long as the animal kept its head up, and decreased when the animal returned its head to the substrate. The spike frequency during head lifting was about 10 spikes/sec, which is a rate which produces clear effects on the activity of neurons involved in food arousal responses (e.g., the Metacerebral Cell). The indication that CPR activity is strongly correlated with the head lifting behavior of the animal provides additional support for the notion that the CPR operates as a command element for the food-arousal state in Aplysia.

NEURAL ORGANIZATION OF PREDATORY BEHAVIOR IN Pleurobranchaea californica. R. Gillette. Department of Physiology & Biophysics, University of Illinois, Urbana, IL 61801

Predatory feeding and avoidance behaviors are integrated by motivational state and learned recognition of dangerous prey in the opisthobranch Pleurobranchaea. Locomotion, orienting, and sensory avoidance are regulated by the functional state of the neural network of feeding behavior. Skin secretion of sulfuric acid in response to noxious stimuli both repels other predators and potentiates Pleurobranchaea's own avoidance behavior via nociceptive paths. The mechanisms of food-avoidance learning, and feeding and avoidance behaviors indicate a simplest connectionist scheme for integration of complex behavior. Briefly, weaker food stimuli simultaneously stimulate systems driving locomotion, orienting, and aversive turns. Stronger stimuli excite feeding. The feeding network has essentially two excited states: (I) oscillatory, driving feeding or rejection movements, and (II) non-oscillatory, in which it is locked up in the proboscis retraction phase of its cycle. State I suppresses locomotion and aversive sensory paths, while state II inhibits orienting pathways and releases locomotion. State transitions are core gulated by motivation and learning.

THE LOW MOLECULAR WEIGHT FORM OF STIMULATORY G-PROTEIN ALPHA SUBUNIT (Gsα) IN MOUSE BRAIN IS RESISTANT TO CHOLERA TOXIN-INDUCED ADP-RIBOSYLATION. James P. Whelan, Paula L. Hoffman* and Boris Tabakoff. DICBR, NIAAA, Bethesda, MD 20892. We have previously found quantitative differences in the ratio of the two major forms (46 kD and 52 kD) of the a subunit of Gs (Gsa), the stimulatory guanine nucleotide binding protein, in various mouse brain regions using Western blotting (Whelan et al., FASEB J. 4:A1119 (1990)). The level of the 52 kD form was similar in cortex, hippocampus, cerebellum and striatum, while the level of the 46 kD protein varied dramatically among brain areas, being highest in striatum and lowest in cerebellum. Cholera toxin-induced *P-ADP-ribosylation of membranes from each brain area demonstrates that the 52 kD form of Gs\(\alpha \) is ribosylated more efficiently than the 46 kD form in vitro. This difference may be due to conformational factors, or, alternatively, the 46 kD form of Gsa may be endogenously ADP-ribosylated in vivo which reduces further ribosylation by cholera toxin in vitro. Utilizing a sensitive avidin-biotin-peroxidase detection system for Western blots, we have identified doublet bands of both forms of Gsa in untreated brain membran which may reflect endogenous ADP-ribosylation (electrophoretic migration is altered by cholera toxin-induced ADP-ribosylation under our conditions). In the 46 kD doublet, the majority of the protein appears as the slowe (putatively ribosylated) band, while in the 52 kD doublet, the majority of the protein migrates as the faster (non-ribosylated) band. Basal (no stimulation) adenylate cyclase activities in brain membranes correlate positively with the relative amounts of the 46 kD form in each region. Since ADP-ribosylation activates Gs, it is possible that preferential ribosylation of the 46 kD form may account for this correlation. Studies under way using ADP-ribosylarginine hydrolase may provide a more direct evaluation of endogenous ribosylation.

DEAFFERENTATION INCREASES PROTEIN KINASE C-β-LIKE IMMUNOREACTIVITY (PKC-β-LI) IN THE RAT SUPERIOR CERVICAL GANGLION (SCG). R.Roivainen*and J.Koistinaho Dept. of Public Health, Univ. of Tampere, P.O. Box 607, SF-33101 Tampere, Finland Protein kinase C is a Ca²⁺/phospholipid-dependent enzyme, which plays an important role in neuronal signal transduction. We have studied immunohistochemically the expression of PKC-β-subtype in the rat SCG at different time points after preganglionic denervation. In unoperated subtype in the rat SCG at different time points after preganglionic denervation. In unoperated and sham operated ganglia as well as in ganglia 1 h postoperation (p.o.), the neuronal perikarya showed only faint PKC-B-LI. One day p.o. both the number of immunoreactive neurons and their staining intensity had increased. Two days p.o. the maximal etaining was soon. Savendays p.o. staining intensity had increased. Two days p.o. the maximal staining was seen. Seven days p.o. the staining intensity was decreased, but it was still above the control level. At 14 days p.o., no difference in the PKC-B-LI between the operated and sham operated ganglia was observed anymore. At light microscopic level, the subcellular distribution of PKC-B-LI was not changed at any time point after denervation. The results suggest that the preganglionic innervation is a factor regulating the amount of PKC contained in rat SCG neurons.

264.2

SPECIFICITY OF APLYSIA PROTEIN KINASE C ISOZYMES W.S. Sossin, T.C. Sacktor and J.H. Schwartz. Center for Neurobiology and Behavior. Howard Hughes Medical Institute, Columbia University College of Physicians & Surgeons, New York, NY 10032.

Aplysia sensory neurons express several isozymes of protein kinase

C (PKC). We find that these isozymes have different requirements for translocation and activation, suggesting that a specific isoform(s) might be responsible for the enhanced release of transmitter at sensory-to-motor synapses (Sacktor and Schwartz, PNAS 87: 2036,

One difference between isozymes is the ability of phorbol ester (TPA) alone to translocate PKC. While some kinase activity is translocated to neuronal membranes by TPA, the Aplysia β_1 isozyme, assayed by Western blotting, is not. This isozyme is translocated to neuronal membranes by Ca^{2+} , and TPA reduces the Ca^{2+} concentration required for translocation. Another difference is the dependence of PKC activity on Ca^{2+} . A kinase similar to $\operatorname{nPKC}\epsilon$, a Ca^{2+} independent isozyme, can be inferred from cDNA sequence information (Kruger, PhD thesis, Columbia Uiversity, 1990). A TPAinducible, Ca2+-independent activity remains after removal of Ca2+dependent activity from extracts of Aplysia neurons by precipitation with phosphatidylserine in the presence of Ca2+. This PKC preferentially phosphorylates a synthetic peptide related to the Aplysia nPKCs pseudosubstrate sequence. We are using these procedures for distinguishing Aplysia PKC isozymes to determine the enzyme(s) involved in the presynaptic facilitation underlying behavioral sensitization.

IN SITU HYBRIDIZATION LOCALIZATION OF BRAIN INOSITOL TRISPHOSPHATE RECEPTOR. C.A. Ross, S.K. Danoff, C. Donath, A. Ullrich, S.H. Snyder. Johns Hopkins Univ. Sch. of Med., Dept. of Neuroscience, Baltimore, MD 21205 and Max Planck Institute for Biochemistry, Martinsreid, FRG.

The inositol trisphosphate receptor (IP,R) releases calcium from the endoplasmic reticulum when phosphoinositide hydrolysis is stimulated by hormones or neurotransmitters. performed in situ hybridization analysis of expression of IP₃R using oligonucleotide probes based on the mouse IP₃R cDNA sequence (Furuichi et al, Nature 342, 32, 1989) or a 1.8 kb rat IP₃R fragment generated by PCR. Highest levels of expression were in cerebellar Purkinje cells, cerebral cortex, hippocampus, and striatum, as previously shown by receptor autoradiography. In the thalamus, highest levels were in the medial dorsal nucleus. In addition, transcripts were present in basal forebrain, pontine nuclei, and raphe complex. Using a cDNA for 1.5 kb of the 5' region of the human IP₃R as a probe, high levels of expression were found in human cerebral cortex, hippocampus, and Purkinje cells of the cerebellum.

FUNCTIONAL REGULATION OF PURIFIED AND RECONSTITUTED IP3 RECEPTOR. <u>C. D. Ferris. R. L. Huganir. R. J. Mourey, and S. H. Snyder.</u> Dept. of Neuroscience, The Johns Hopkins Univ. Sch. of Medicine, Baltimore, MD 20205.

IP3 receptor has been purified from rat brain and smooth muscle membranes and localized to portions of the endoplasmic reticulum including the nuclear envelope. The IP3 receptor is a glycoprotein of Mr, in the native state, by gel filtration, of 1000 kD; it is a homotetramer with a subunit size of 260 kD. Recently, we reported the functional reconstitution of the purified receptor from rat cerebellum and demonstrated that the single receptor protein contains both the IP3 recognition site and the associated calcium ion channel (Ferris, C. D., et al., <u>Nature 342</u>, 84-87). We now demonstrate a potent and selective allosteric regulation of calcium flux by ATP and other adenine nucleotides. ATP (or any of its non-hydrolysable analogues) enhances IP3 stimulated calcium flux by 50% at low micromolar doses; this effect is reversed at doses from 100uM to 1mM. This regulation is selective since it is not observed with guanine or other nucleotides, and we speculate that this regulation may participate in calcium oscillations. In reconstituted vesicles the IP3 receptor is stoichiometrically phosphorylated by protein kinase A. Phosphopeptide mapping indicates that a single peptide is phosphorylated on a serine residue and this phosphorylation appears to functionally regulate the reconstituted receptor. Also, magnesium ions potently inhibit IP3 stimulated calcium flux at micromolar doses; this regulation may also have physiologic significance. Purified IP3 receptor from smooth muscle can also be reconstituted using the same approach as that employed from the brain receptor. The reconstituted smooth muscle receptor appears very similar to the brain receptor in most of its properties.

264.7

CHARACTERIZATION AND PARTIAL PURIFICATION OF A MEMBRANE-ASSOCIATED INS 1,4,5-P₃ 5'-PHOSPHATASE FROM RAT CEREBELLUM. S.K. Danoff, W.A. Theibert, E.A. Davis*, R.K. Barrow* and S.H. Snyder. Dept. of Neuroscience, Johns Hopkins Univ., School of Medicine, Davis Company of Medicine, Neuroscience, Johns Formand Company of Medicine, Neuroscience, N Baltimore MD 21205

The rat cerebellar Ins $1,4,5-P_3$ receptor has been purified (Suppatapone, S. et al., <u>IBC</u>, <u>263</u>:1530, 1988) and reconstituted (Ferris, C. et al., <u>Nature</u>, <u>342</u>:87, 1990) and has been shown to act as a calcium channel. In cerebellum, the membrane-associated InsP₃ 5'-phophatase represents ~90% of the enzymatic activity leading to inactivation of InsP3. This enzyme is stimulated by physiological concentrations of free calcium (ED₅₀=~400nM). The protein has been highly enriched using conventional ion exchange and InsP3 affinity chromatography.

264.9

PAF ANTAGONIST DECREASES for EXPRESSION IN RAT HIPPOCAMPUS INDUCED BY SINGLE SEIZURE V.L. Marcheselli,* J.P. Doucet,* and N.G. Bazan, LSU Eye Center and Neuroscience Center, New Orleans, LA, 70112.

Neuronal stimulation activates the expression of immediate-early transcrip-

tional regulatory proto-oncogenes in the central nervous system. The convulsants pentylenetetrazol (Metrazole) and picrotoxin, as well as electroconvulsive shock (ECS), have been demonstrated to induce a rapid increase of fos mRNA expression in hippocampal neurons. One consequence of experimental convulsion is accumulation of the bioactive etherphospholipid platelet-activating factor (PAF). Ginkgolide PAF antagonist BN 52021 reduces cellular damage in the brain after ischemia/reperfusion. In SH-SY5Y neuroblastoma cells, PAF induces rapid transcriptional activation of fos and jun proto-oncogenes, an effect reversed by BN 52021 (J Neurosci Res, 24:558-566, 1989). We seek to correlate immediate-early gene expression with ECS-induced PAF synthesis. Here we demonstrate that BN 50730, a potent competitive PAF antagonist for high-affinity intracellular binding sites (J Biol Chem 260:9140-9145, 1990), partially inhibites the for temperature that ladged by ECS in the next higherenmyne. inhibits the fos transcription that is induced by ECS in the rat hippocampus. Brain cortex also reflects the same effect but to a lesser extent. Drugs were injected intraperitoneally 30 min before ECS and did not alter the seizure intensity. Total cellular mRNA was isolated 60 min after ECS and analyzed by Northern and slot blotting techniques. Unlike BN 50730, BN 52021 had no effect on fos mRNA levels, which suggests a correlation with ECS-induced fos expression and intracellular high-affinity PAF-binding sites. These results suggest a role for PAF as an intracellular messenger involved in seizureinduced immediate-early gene expression in brain. Supported by NIH grant NS 23002.

LOCALIZATION OF TWO FUNCTIONALLY DISTINCT NON-MITOCHONDRIAL CALCIUM POOLS IN RAT BRAIN A.Verma and S.H.Snyder , Johns Hopkins Sch. of Medicine ,Dept. of

CNS neurons contain intracellular Ca2+ stores capable of accumulating and releasing Ca2+. We used ATP-dependant 45 Ca2+ transport in fresh frozen sections and microsomes to characterize and localize functionally distinct non-mitochondrial Ca2+ stores in rat brain. Two Ca2+ stores are mitochondrial Ca2+ stores in rat brain.Two Ca2+ stores are distinguished by their permeability to the oxalate anion and by sensitivity to thapsigargin (Tg) and inositol-1,4,5-trisphosphate (IP3).Active 45Ca2+ accumulation in the absense of oxalate saturates by 60 min. and is enriched in the brainstem, thalamus, cerebral cortex, and inferior colliculus. Oxalate strongly stimulates 45Ca2+ uptake into a pool which is not saturated by 3 hrs. and is concentrated in cerebellar and cerebral cortices, hippocampus, striatum, basal forebrain nuclet, and olfactory bulb. Tg potently and selectively inhibits 45Ca2+ uptake into the oxalate permeable pool with an IC50 of ~30nM and maximal inhibition at 100 nM.45Ca2+ uptake in the absense of oxalate is insensitive to [Tg] upto 10 uM. IP3 of ~30nM and maximal inhibition at 100 nM.45Ca2+ uptake in the absense of oxalate is insensitive to [Tg] upto 10 uM. IP3 (10 uM) also selectively mobilizes Ca2+ from the oxalate permeable Ca2+ pool. Autoradiography reveals that while Tg inhibits oxalate stimulated 45Ca2+ uptake in all brain regions IP3 only mediates Ca2+ release from oxalate permeable stores which also contain IP3 receptors. Thus one brain Ca2+ accumulating pool is permeable to oxalate and inhibited by Tg while another displays neither of these properties. The IP3 sensitive Ca2+ pool is a subset of the Tg sensitive Ca2+ pool.

EFFECT OF ELECTROCONVULSIVE SHOCK (ECS) PHOSPHOSPHOINOSITIDE TURNOVER IN RAT BRAIN. G.N. Pandey, S.C. Pandey, L. Isaac and J.M. Davis Illinois State Psychiatric Institute, Chicago, IL 60612

It has been shown that that alpha₁-adrenergic and serotonin (5HT₂) receptors stimulate phosphoinositide breakdown and inositol phosphate formation in rat brain. Up and down regulation of these receptors in general produce corresponding changes in phosphoinositide breakdown. Chronic administration of ECS in rats produces upregulation of alpha-adrenergic and 5HT₂ receptors in rat cortex. In order to examine if changes in alpha₁ and 5HT₂ receptors are associated with changes in the phosphoinositide signalling system, we studied the effect of ECS on norepinephrine- (NE) and serotonin- (5HT) stimulated inositol-1phosphate (IP₁) and total inositol phosphate formation in rat cortical slices. Rats were treated with ECS (75mA/0.2 second) once daily for 14 days, and were sacrificed 24 hours after the last shock. Cortical slices were labeled with [3H]-inositol for 1 hour at 37°C. After washing, slices were stimulated with NE (10-4M) and 5HT (10-4M). It was observed that 5HT-stimulated total inositol phosphate and [3H]-IP1 formation were significantly higher in the brains of ECS-treated rats than in the brains of control rats. However, NE-stimulated [3H]-inositol phosphate formation, although higher in the brains of ECS-treated rats, was nonsignificantly different from control rats. Thus, our results indicate that changes in receptor number induced by ECS are in general accompanied by corresponding changes in the phosphoinositide signal transduction pathways.

EFFECTS OF CLONIDINE AND OTHER AGENTS INTERACTING WITH IMIDAZOLE RECEPTORS ON SECOND MESSENGER SYSTEMS AND CATECHOLAMINE RELEASE IN ADRENAL CHROMAFFIN CELLS. S. Regunathan, M.J. Evinger, M.P. Meeley and D.J. Reis, Div. of Neurobiol., Comell Univ. Med. Coll., New York, NY 10021.

In brain cloniding (CLON)

M.P. Meeley and D.J. Reis. Div. of Neurobiol., Comell Univ. Med. Coll., New York, NY 10021.

In brain clonidine (CLON), an imidazole, binds to a novel class of imidazole-preferring (IM) as well as to α₂-adrenergic receptors. In adrenal chromaffin cells, where it inhibits the carbachol-induced release of catecholamines (CA), CLON binds only to IM receptors. We sought to determine whether the signal transduction mechanism of IM receptors differs from α-2 receptors (inhibition of adenylate cyclase) and its relation to CA release in cultured (72h) bovine chromaffin cells. CLON did not change: (a) basal or GTPγs- (50μM; 5-fold) or carbachol-(100μM; 3-fold) stimulated PI tumover,(b) basal nor forskolin-stimulated levels of cAMP (3μM; 2-fold). However, CLON elicited a concentration-dependent (EC₃₆, 5μM), slow (peak response at 15 min), 50% increase in cGMP production not potentiated by the phosphodiesterase inhibitor IBMX, and suggesting a direct intracellular action of the drug. Other agents binding to IM receptors (naphazoline, oxymetazoline, idazoxan, rilmenidine, clonidine displacing substance) and norepinephrine, failed to alter CGMP. All agents binding to IM receptors inhibited, by 40%, the carbachol-mediated release of CA's, although CLON was the most potent one (about 60%). We conclude that the signal transduction mechanisms coupled to IM differs from adrenergic receptors and IM receptor occupancy may inhibit the release of adrenal medullary CA's.

THE PROTEIN KINASE C PHOSPHORYLATION SITES OF THE \$\rho_2\$-ADRENERGIC RECEPTOR CONTRIBUTE TO THE CROSS-TALK BETWEEN SECOND MESSENGER SYSTEMS. M. Bouvier. N. Guilbeault* H. Bonin* Department of Biochemistry, University of Montreal, Montreal, Quebec, H3C 3J7, Canada. Modulation of the \$\rho\$-adrenergic stimulated adenylyl cyclase activity by hormone known to stimulate the phosphatidyl inositol (PI) hydrolysis pathway has been widely reported. These observations were taken as evidence of the existence of a cross-talk between the second messengers reparation systems. Protein kineses C (PKC) phoepshyllotion of various generating systems. Protein kinase C (PKC) phosphorylation of various generating systems. Protein kinase C (PKC) phosphorylation of various components of the adenylyl cyclase stimulatory pathway have been proposed to contribute to this process. The β_2 -adrenergic receptor has been shown to be a substrate for the PKC. In the present study, we addressed directly the role of the receptor phosphorylation by PKC in this regulatory pathway. Using site directed mutagenesis, the potential PKC phosphorylation sites of the human β_2 -adrenergique receptor were destroyed by substituting alanine residues for the serines 261, 262, 345 and 346. This mutation completely abolished the phorbol ester induced phosphorylation of the receptor expressed in chines hamster fibroblasts. phosphorylation of the receptor expressed in chines hamster fibroblasts. Phorbol ester treatment induces a significant increase in β -adrenergic stimulated adenylyl cyclase activity in membranes derived from cells expressing either wild type or mutated receptor. This increase was accompanied by a rightward shift in the $\rm EC_{50}$ of the β -agonist isoproterenol to stimulate the adenylyl cyclase in cells expressing wild types receptor but not in cells expressing the receptor devoided of PKC phosphorylation sites. Similarly, the potency of isoproterenol to stimulate cAMP accumulation in phorbol ester treated cells was significantly increased in cells expressing the mutated receptor. These results therefore suggest that phosphorylation of the β_2 -adrenergic receptor by PKC decrease the potency of the receptor to stimulate the adenylyl cyclase even in the presence of an increased maximal response.

IDENTIFICATION OF A NOVEL SIGNAL TRANSDUCTION PATHWAY OF THE 5-HT1A RECEPTOR *IN WITRO*. Yatang Liu and Paul R. Albert. Dept. of Pharmacology and Therapeutics, McGill University, 3655 Drummond Str., Montreal, PQ, Canada, H3G 1Y6.

We used the mouse Ltk- cell line, which lacks 5-HT1A receptors, as a wodel to examine the second messenger system of the cloned receptor. The rat 5-HT1A receptor gene transcription unit was transfected into this cell line and the LZD-7 subclone, expressing 100,000 5-HT1A receptors/cell, was isolated. In LZD-7 cells, 5-HT stimulated two separate receptors/cell, was isolated. In LZD-7 cells, 5-HT stimulated two separate phases (fast phase and slow phase) of increase in [Ca++]_i in a dose-dependent manner (EC50 = 3 nM). The fast phase of 5-HT-induced change in [Ca++]_i was due to influx of calcium since1 mM EGTA or 5 μM nifedipine blocked this phase. The slow phase was due to alteration of intracellular calcium storage or buffering and was resistant to EGTA and nifedipine. Pretreatment of LZD-7 cells with pertussis toxin (10 ng/ml) inhibited totally both phases. TPA blocked separately the slow phase (0.1-1 nM) and fast phase of influx of calcium (5-10 nM). Forskolin (0.2-10 μM) or 8-Br cAMP (1-5 mM) blocked partially the fast phase of calcium influx, but completely abolished both phases at the lowest concentrations when 0.1-1 nM TPA was added. The effects of TPA were completely blocked by 24h pretreatment with 500 nM TPA to downregulate protein kinase C. These results suggest that the 5-HT1A receptor is coupled by pertussis toxin-sensitive G proteins to an alternate transduction pathway in LZD-7 cells. Receptor activation increases PIP turnover, and may stimulate different protein kinase C isoenzymes, which presumably regulate the opening of distinct calcium channels. There was interaction between protein kinase A and protein kinase C, which in turn synergisticly modulated influx of calcium (MRC, Canada). influx of calcium (MRC, Canada).

SENSORY SYSTEMS-DEVELOPMENT AND PLASTICITY I

265.1

DEVELOPMENT OF METABOLIC ACTIVITY PATTERNS IN KITTEN SOMATOSENSORY CORTEX. S.L. Juliano, W. Ma, and D.E. Eslin*. Dept. of Anatomy, USUHS, Bethesda, MD 20814.

The visual cortex of the cat exhibits a number of changes in anatomy and physiology indicative of a "critical period" during development. No comparable changes have yet been observed in cat somatosensory cortex. To begin analysis of cortical activity and anatomical relationships during the development of cat somatosensory cortex, kittens 3-5 wks of age were studied to evaluate their responses to somatic stimulation. To assess cortical activity, each kitten received a somatic stimulus during a 2-deoxyglucose (2DG) experiment. The evoked pattern of activity in the somatosensory cortex of kittens aged 3-4 wks was distinctly different from that found in adults or in 5 wk old kittens. The metabolic patterns in the younger animals were less distinctly patch-like and appeared more diffuse than in the adult. Evoked activity in 3 & 4 wk old kittens was 40-55% above background in density and localized in the center of the cortex only. Adult patches of activity are densest in the central layers, but extend into layers III & II, occasionally into layer V, and are 60-90% above background in density. Stimulus-evoked metabolic activity in the 5 wk old kittens was nearly adult-like and occurred in relatively dense (60% above background) patches that extended into layers III & II. Comparison of the metabolic patterns with Nissl-staining indicated that in the 3 wk old kittens, layers V & VI could be easily distinguished, but layers II-IV were not separable nto distinct entities as they are in the adult. In 4 wk old kittens, cortical layers II-IV were apparent, but not as clearly so as in the adult. The metabolic activity patterns in kittens appear to parallel the laminar development in somatosensory cortex. These morphologic and functional characteristics may correspond to developmental changes in visual cortex that indicate a critical period of development. Supported by NS-24014.

265.3

EARLY CHANGES IN TACHYKININ-LIKE IMMUNOREACTIVITY IN PRIMARY SOMATOSENSORY CORTEX OF ADULT SQUIRREL MONKEYS
FOLLOWING NERVE INJURIES. C.G. Cusick. Dept. of
Anatomy, Tulane Univ. Medical School, New Orleans, LA 70119.

Following nerve injuries in adult mammals, functional changes occur in the spinal cord, brainstem, thalamus, and primary somatosensory cortex. The purpose of the present study was to investigate changes in neurotransmitters that might occur within the intrinsic cortical circuitry in response to nerve injury. Squirrel monkeys (Saimiri sciureus) were deeply anesthetized with ketamine $\overline{\text{hydrochloride}}$ and Ace-promazine, and the median and ulnar nerves were unilaterally transected and ligated in the distal forearm. Nine-10 days later, the animals were euthanized with Nembutal and the somatosensory cortices were processed for immunocytochemistry using a monoclonal antibody raised against the carboxyl-terminal end of the tachykinin peptide substance P (NC1/34HL, Sera Labs). Contralateral to the nerve injuries, the numbers of cells containing tachykinin-like immunoreactivity were reduced by about 35% in layer IV of the area 3b hand representation, compared to equal lengths of layer IV in the area 3b face representation. Since many tachykinin immunoreactive cells in layer IV of monkeys colocalize GABA, the results suggest that cortical inhibitory neurons rapidly modify their content of neuroactive peptides in response to nerve injury.

265.2

TWO VIEWS ON FORMATION OF OLFACTORY GLOMERULI BASED ON NUMERICAL STUDY OF OLFACTORY NEURONS, GLOMERULI AND MITRAL CELLS IN RAT, HAMSTER AND RABBIT. E. Meisami, Physiol. Dept., Univ. of Illinois, Urbana, IL 61801.

Numerical study of the three main relay/integrative elements in the olfactory system [olfactory receptor neu-

rons (ORN), olfactory glomeruli (OG), mitral cells (MC)] in three altricial mammals with varying gestation periods (hamster 16 d, rat 21 d, rabbit 30 d) reveals that at birth, of all three elements, only MCs have reached adult The GLs and ORNs increase significantly postna tally, the increase being more pronounced for ORNs than for GLs and more marked in rat and hamster than in rabbit. The ORN increase includes both immature and mature neurons, resulting in increase in surface density, per counts of receptor knobs. The postnatal ORN increase occurs across all epithelial zones, particularly in posterior and lateral zones. If GLs are counted in sections staining their meuropil, instead of Nissl sections where periglomerular cell assemblies are counted, more GLs are seen in the neonatal bulb, i.e., less marked postnatal increase. Two hypotheses on glomerular formation and connectivity in the afferent olfactory pathway is sug-MCs and establish the total number of GLs at an early stage; some of the early GLs may be too small to be seen; 2) Some GLs form by birth; others from postnatally as new ORNs arrive in the bulb and find targets preoccupied.

265.4

EFFECTS OF THALAMOTOMY AT BIRTH UPON TRIGEMINAL BRAINSTEM CELL NUMBER, SIZE AND DISTRIBUTION. M.F. Jacquin, N.L. Chiaia, C.A. Bennett-Clarke, N. Hobart* & R.W. Rhoades.

Dept. of Anat. & Neurobiol., St. Louis Univ. Sch. Med., St. Louis, MO 63104, & Dept. of Anat., Med. College of Ohio, Toledo, OH. 43699.

Neonatal thalamic destruction deprives many trigeminal (V) brainstem neurons of their target and axotomizes many of these cells. Such lesions disrupt normal cell patterning in V nucleus principalis (PrV), yet we have no information about how they affect cell number in any portion of the V brainstem complex. To address this issue, unilateral right thalamotomy was performed (by electrocautery) at birth in 6 rats. They were sacrificed on postnatal day 6, and 10 micron thick paraffin sections of the brainstem were stained with cresyl violet. Four of the 6 cases had complete thalamic lesions and cell (nucleoli) number, cell diameter and V brainstem nucleus cross-sectional areas were sampled for left and right PrV and subnucleus interpolaris (SpVi). Relative to the control right side, cell number in left PrV was reduced by 59.1 + 7.3% (mean + SD), PrV transverse area was reduced by 20.5 ± 6.6%, cell density was reduced by 48.1 + 13.2%, and average cell diameters were increased by 35.8%. All of these effects were statistically reliable. In left SpVi, however, no reliable changes were observed. Mean cell number, transverse nuclear area, and cell density were +7.0%, -4.9% and +14.7%, respectively, of the values obtained on the control right side. These data indicate that thalamotomy reduces cell number in PrV, but not in SpVi. The change in PrV cell size distribution likely reflects the selective preservation of PrV cells that project to non-thalamic targets and are known to have larger diameters. Support: DE07734, DE07662, and DE08971.

AXON NUMBERS IN SPARED SUPRAORBITAL VIBRISSAE FOLLICLE NERVES FOLLOWING INFRAORBITAL NERVE SECTION AT BIRTH. P.H. Young, D.S. Zahm, J. Golden and M.F. Jacquin. Dept. of Anatomy and Neurobiology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Prior studies indicate that the central projections of ear (zygomaticofacial) and eye (supraorbital) vibrissae afferents occupy a supranormal transverse area in the rat trigeminal brainstem complex following neonatal infraorbital nerve injury (Renehan et al., <u>JCN</u> 289:493, '89; Waite, <u>Soc. Neurosci.</u>

<u>Abstr.</u> 15:92, '89). Enlarged central projections from these spared vibrissae could be due to central and/or peripheral sprouting, central arbor expansion and/or displacement, and/or preservation of an immature projection pattern. Here, we tested the hypothesis that central axon reorganization reflects an abnormal innervation of the spared vibrissae follicles. Six rats received left infraorbital nerve sections at birth; 3 were sacrificed on postnatal day 7 (PND-7), the other 3 on PND-17. Left (L) and right (R) supraorbital vibrissae follicle nerves were processed for EM analysis and montages of each nerve were made at 4300X. At PND-17, there were 166 \pm 12 and 156 \pm 38 axons in individual L and R nerves, respectively (mean \pm SD). The numbers of myelinated axons were 110 \pm 4 (L) and 110 \pm 33 (R); unmyelinated axon counts were 56 \pm 11 (L) and 46 \pm 7 (R). No L-R comparison reached statistical significance. At PND-7, there were 122 ± 6 and 118 + 9 axons in the L and R nerves. The numbers of myelinated axons were 99 ± 1 (L) and 97 ± 6 (R); unmyelinated axon counts were 23 ± 6 (L) and 21.3 ± 6 (R). Again, L-R differences were not significant. Thus, the enlarged central representation of the supraorbital vibrissae does not reflect the maintenance of an immature peripheral innervation pattern. These data also suggest that regenerate infraorbital axons do not grow into supraorbital vibrissae follicles. Support: DE07734, DE07662, NS23805.

RECEPTOR CELLS DIFFERENTIATE FROM SUPPORTING CELLS IN DEVELOPING ELECTRORECEPTOR ORGANS. H.A. Vischer. SIO, Neurobiol. Unit, UCSD, La Jolla, CA 92093.

South American, gymnotiform glassknife fish of the genus <u>Eigenmannia</u> were induced to spawn under laboratory conditions. In order to visualize developmental patterns, animals of various ages were either injected with 0.5-2µl 5-bromo-2'deoxyuridine (BrdU) or an eqivalent amount of [3H]-thymidine and processed for immunohistochemistry (marked cells are labelled with rhodamine) or autoradiography, respectively. In addition, BrdU-labelled [3H]-thymidine and processed for immunohistochemistry (marked cells are labelled with rhodamine) or autoradiography, respectively. In addition, BrdU-labelled specimens were counterstained with the nuclear stain Hoechst 33342. Ultrastructural analysis was performed by transmission electron microscopy (TEM). First primordial electroreceptor cells can be recognized within the striatum germinativum of the epidermis. In all cases, an unnyelinated axon of the afferent lateral line nerve lies underneath these cells but does not penetrate the basal unmyelinated axon of the afferent lateral line nerve lies underneath these cells but does not penetrate the basal membrane, which shows a significant indentation and strong apical vascularization in this area. The primordial cells undergo rapid cell division (t<2hrs) and differentiate into two cell layers: the prospective basal supporting cells and the apical receptor cells which exclusively arise from supporting cells (8hrs<t<12hrs). At this time, the afferent fiber penetrates the basal lamina and forms synaptic contact with newly differentiated receptor cells. Supported by a grant from SNSF.

DEVELOPING BARREL PATTERNS SHOWN BY SEROTONIN, LECTIN AND CYTOCHROME OXIDASE IN MICE

J.J.Christensen, C.A.Bennett-Clarke, T.A.Woolsey and R.W.Rhoades.

Dept. Neurosurgery & Neurology Wash.U.Med.Sch., St. Louis MO 63110 and Dept. Anatomy Med. Col. Ohio, Toledo OH 43699

Peanut lectin binding (PNA), cytochrome oxidase histochemistry (CO) and antibody binding to serotonin (5-HT) were used to identify emergent barrels in the postnatal mouse SI cortex. Littermates from several litters were prepared with each method to determine the relative time of appearance of the whisker- barrel pattern. The infraorbital nerve (IO) was sectioned surgically at birth (P0) to alter the barrel pattern. PNA barrel pattern is seen first on P4, declining by P10; CO pattern is first seen on P3, still rising on P10, 5-HT pattern is first seen on P3, mostly disappearing by P10. IO lesioned animals all had similar altered patterns of staining where barrels should have been. No barrel pattern appears before the clustered endings from VB. We conclude that all three markers follow the organization set by fibers from the thalamus. The exact role played by molecules binding PNA and 5-HT in the developing whisker map, if any, has yet to be determined.

DEVELOPMENT OF THALAMOCORTICAL RESPONSES IN BARREL CORTEX OF EARLY POSTNATAL MICE A. Agmon, D.K. O'Dowd and E. G. Jones Department of Anatomy and Neurobiology, California College of Medicine, Irvine, CA 92717

Layer IV of the rodent somatosensory cortex has discrete cytoarchitectonic structures, called barrels, that receive vibrissae input in a one-to-one manner from the ventrobasal (VB) nucleus of the thalamus. Barrels are first apparent on the third postnatal day, however it is not known when thalamocortical synaptic connections are first established. In order to examine this question we stimulated VB and recorded postsynaptic potentials and currents in a slice preparation that preserves functional connectivity between the thalamus and the barrel cortex (Agmon and Connors, Neurosci., in press). We used the whole cell recording technique as applied to thick slices (Blanton, LeTurco and Kriegstein, J. Neurosci. Meth. 30, 203-(Blanton, Leturco and Kriegstein, J. Neurosci. Meth. 30, 203-210, 1989). Prior to barrel formation, 0-2 days postnatal, some cells in layers V/VI received strong monosynaptic EPSP's. In animals older than 3 days, in which barrels could be visualized, cells in both deep layers and in layer IV received monosynaptic EPSP's. In animals 10 days old or older we frequently encountered disynaptic IPSP's in addition to monosynaptic EPSP's. Supported by NS08364 and NS21377.

QUANTIFICATION OF RADIAL GLIA AND RADIAL DENDRITES IN BARREL CORTEX AFTER WHISKER REMOVAL IN NEONATAL MICE: INITIAL APPROACHES WITH IMAGE ANALYSIS. J.E. Crandall, D. Butler*, and S.A. Tobet. Department of Developmental Neurobiology, E.K. Shriver Center, Waltham, MA 02254.

We have described a spatial pattern of radial glia and radially oriented dendrites that emerges in the mouse barrel cortex at a similar time to that of the cellular pattern of barrels (Crandall et al., Dev. Brain Res., In press). Both glia and dendrites appear to be more densely distributed toward the walls than the hollows of individual barrels. Six days after row C whisker removal on P1, serial tangential sections were immunolabeled simultaneously with monoclonal antibodies specific for MAP2 (neuronal dendrites and somata) and RC2 antigen (radial glia). Microscopic images were analyzed interactively using an IBAS 2000 workstation. Measuring numbers of elements rather than the optical density of individual elements minimized histochemical processing differences. Unreliable feature extraction, based on inspection of overlay images, averaged less than 1% of the total element number. The density of radial glia and radial dendrites was higher in the barrel walls compared to the hollows ipsilateral to the side of whisker removal. The density of radial dendrites in the walls was higher than in the hollows in the barrels sampled adjacent to the deafferented region as well. In contrast, the density of radial glia was similar in barrel walls and hollows. The ability to accurately measure large numbers of neural profiles allows analysis of changes in populations of interactive neuropil elements.

GLYCOCONJUGATE BOUNDARIES OUTLINE BARRELS THAT FORM IN VISUAL CORTEX TRANSPLANTED TO THE BARRELFIELD OF SI CORTEX. B.L. Schlaggar and D.D.M. O'Leary Depts of Neurosurgery and of Anatomy & Neurobiology, Washington Univ Sch Med, St Louis, MO 63110 The lectin, peanut agglutinin (PNA), reveals in developing rodent cortex a pattern of glycoconjugate "boundaries" that outline the barrels of primary somatosensory (SI) cortex. This transient pattern is unique to the SI barrelfield and is reported to precede the emergence of barrels (Cooper & Steindler 1986 J Comp Neurol 249:157; McCandlish et al. 1989 Exp Br Res 77:425). It is hypothesized that the lectin binds a framework of glycosylated molecules intrinsic to SI and responsible for establishing the barrel pattern (Steindler et al. 1989 Dev Biol 131:243). We have tested this hypothesis by transplanting E17 visual cortex to the prospective barrelfield of SI cortex in newborn rats and processing on P8 alternate sections with PNA to reveal any glycoconjugate pattern, and for AChE to mark ventrobasal thalamic afferents and Nissl to show the distribution of neurons. In layer 4 of normal P8 visual cortex processed in the same way, PNA binding is thalamic afferents and Nissl to show the distribution of neurons. In layer 4 of normal P8 visual cortex processed in the same way, PNA binding is uniformly absent while the AChE stained geniculocortical input and the distribution of neurons are uniformly dense. However, within layer 4 of transplanted visual cortex (prelabeled with vital dye and H-TdR) rings of PNA binding are present in a pattern that parallels a pattern of dense patches of AChE staining coincident with aggregations of neurons. These patterns are complementary, closely resemble those in normal SI cortex, and maintain continuity across borders between the host and transplanted cortex. Our results indicate that thalamocortical input molds the pattern of glycosylated molecules defined by lectin binding and that this molecular framework does not initiate the formation of individual barrels nor specifies the stereotypic pattern of barrels. We conclude that neither barrels nor the complementary glycoconjugate boundaries are predetermined in SI cortex and that thalamocortical input is a primary agent in the differentiation of area-specific features characteristic of the adult neocortex.

PLASTICITY PLASTICITY IN THE MOUSE WHISKER-TO-BARREL PATHWAY: EFFECTS OF PERIPHERAL DEPRIVATION IN NEONATES ON THE FUNCTIONAL MAP IN ADULTS; A DEOXYGLUCOSE STUDY

Laboratory of Carebral Metabolism, NIMH, 9000 Rockville Pike, Bethesda, MD

Lesions of whisker follicles in newborn mice result in an altered morphological whisker-map in the barrel region of the sensory cortex. We studied the effects of such perinatal lesions on functional maps in the whisker-to-barrel pathway of the mice in adulthood. The functional maps were obtained with the autoradiographic [14C]deoxyglucose (DG) method for the determination of local cerebral graphic Colectoryglucous (co) method for the determination of local cerebral glucose utilization (ICMR gl.). From 7 albino mice the folicies of left whiskers C1-3 were removed on the day of birth. After 3 months, the lesioned mice and 7 age-matched control animals were injected with DG, and left whiskers B1-3 & D1-3 were stimulated. Brain sections were cut tangential to the pial surface through the cortex and transverse through the brainstem. In the control mice, ICMR_{glc} was increased in two discrete areas of the barrel cortex contra-lateral to stimulation: barrels B1-3 & D1-3. In the lesioned mice, the two areas of high ICMR $_{\rm lc}$ were fused by an area of lower, yet elevated ICMR $_{\rm lc}$ Nissl and cytochrome oxidase (CO) staining showed that barrels C1-3 had not developed; the vacant territory was invaded by enlarged barrels of rows B & D, by C4 and by Υ . Increased 1CMR slc covered the full extent of enlarged barrels B1-3 & D1-3. No such fusion could be found in the trigeminal brainstem. Ipsilateral subnuclei caudalis and interpolaris showed, as in normal mice, two separate and distinct areas of increased ${\rm ICMR}_{\rm glc}$. In the territory where the removed whiskers are normally represented, CO activity was diminished, and segmentation was absent. This area was not filled in by adjacent segments.

PERIPHERALLY EVOKED CORTICAL RESPONSES IN NEONATAL RAT SI BARREL FIELD FOLLOWS A GRADIENT OF DEVELOPMENT. C.A. McCandlish, R.S. Waters, and C.X. Li*. Dept. of Anatomy and Neurobiology, Univ.

of Tennessee, Memphis, Col. of Medicine, Memphis TN 38163.

Previously, we reported that the peroxidase conjugated lectin (PNA) binds differentially to SI barrel sides/septa during the first postnatal week. The representation of the face barrel subfield is first detected by postnatal day 4 (PND-4), and is followed by the representation of the forepaw subfield on PND-5. These results led us to hypothesize that neurons in the face subfield may be responsive to peripheral natural or electrical stimulation before neurons in the forepaw and hindpaw subfields

To test this hypothesis, neonatal rat pups between PND-3 through PND-10 were anesthetized with Nembutal (40 mg/kg ip) and placed in a head-holding apparatus. A midsagittal slit was made in the skin overlying the skull and the skin retracted. The cisterna magna was opened. The bone overlying the sensori-motor cortex contralateral to the head-holding apparatus was removed and the dura opened. A single micropipette filled with 2M NaCl or carbon-fibre electrode was inserted into the cortex and natural or electrical peripheral stimulation was used to evoke single and multiple-unit responses from SI cortex. Following sensory mapping, rats were sacrificed, hemispheres removed and sectioned in a tangential or coronal plane, and the tissue processed using PNA-histochemistry. Using these techniques, the following results were obtained: 1. Evoked cortical responses were elicited in the developing face barrel subfield as early as PND-4.

2. Evoked cortical responses in the forepaw barrel subfield were elicited by PND-5, while evoked responses in the hindpaw barrel subfield appeared shortly thereafter. These results suggest that the face barrel subfield is functionally intact prior to the forepaw and hindpaw, corroborating our previous report of differential development of the SI barrel field in neonatal rats. BARREL SIZE IN MOUSE SOMATOSENSORY CORTEX IN-CREASES AFTER EARLY EYE REMOVAL. J.P. Rauschecker, S. Kröger* and B. Tian*. NIH Animal Center, National Institute of Mental Health, Poolesville, MD 20837 and Max-Planck-Institut für biologische Kybernetik, Tübingen, FR Germany.

Visual deprivation leads to compensatory changes in the auditory system of cats, which can be demonstrated on the physiological (Rauschecker & Harris, 1983), anatomical (Rauschecker & Aschoff, 1987), and behavioral (Rauschecker & Kniepert, 1988) level. Cats deprived of vision also have significantly longer vibrissae than normal controls (Rauschecker, Egert & Hahn, 1987). We therefore became interested in whether visual deprivation induces also modifications of the central somatosensory system. Since rodents have an anatomically distinct somatosensory cortex (the "barrel-field", Woolsey & Van der Loos, 1970), we decided to tackle this question in mice rather than cats

Twenty pigmented mice were unilaterally or bilaterally enucleated I week after birth. After 3 months, flatmounts of cortex were produced, fixed in formalin, and cut into 50 µm thin sections. Cytochrome oxidase staining was used to reveal the barrels in somatosensory cortex. They were then traced with a camera-lucida system and their areas measured with a Zeiss planimeter. It was found that the mean size of 362 barrels in 5 mice after binocular enucleation was 57.1 mm²/1000 while that of 520 barrels in 7 normal mice from the same litters was 51.8 mm²/1000 (t=3.78; p<0.001). When barrel size was compared directly in the two hemispheres of 8 monocularly enucleated mice, mean area was larger by more than 10% on the side contralateral to the enucleated eye (t=2.81; p<0.005). Our results indicate that a substantial rearrangement of the somatosensory system is generated crossmodally by visual deprivation.

TISSUE DISTRIBUTION, PARTIAL PURIFICATION, AND MODULATION OF THE GASTRIC MILL BY A CRUSTACEAN CHOLECYSTOKININ-LIKE PEPTIDE. G.G. Turrigiano. L. Ogden*, A. Van Wormhoudt*, and A.I. Selverston.

Dept. of Biology, UCSD, La Jolla, Ca 92093.

The output of the gastric mill neural circuit is highly flexible, and can be modulated by a number of neuropeptides, including mammalian cholecystokinin (CCK) (Turrigiano and Selverston, J. Neurosci. 9:2486, 1989). There is evidence that an endogenous CCK-like peptide is responsible for the feeding-induced activation of the gastric mill in intact lobsters (Turrigiano and Selverston, Nature, in press, 1990), but it requires high concentrations of the mammalian peptide to activate the gastric mill. We therefore wished to isolate and characterize the effects of the endogenous CCK-like peptide. To this end we have made methanol extracts of several lobster tissues known to contain CCK-like immunoreactivity, including the stomatogastric tissues known to contain CCK-like immunoreactivity, including the stomatogastric ganglion, the pericardial organs, the eyestalks, and the haemolymph, and partially purified these extracts by reverse phase chromatography. Five peaks immunoreactive for CCK were fractionated in this way, and were common to all of these tissues. An additional two peaks were present in the stomatogastric ganglion extracts. The physiological effects of the five peaks from pericardial organs were tested on the isolated stomatogastric nervous system. One peak, designated crustacean CCK E (C-CCK E) was found to modulate the activity of the gastric mill, in concentrations

estimated to be between 10⁻⁸ and 10⁻¹⁰ M. This peptide can initiate cycling in a

estimated to be between 10⁻⁸ and 10⁻¹⁰ M. This peptide can initiate cycling in a quiescent gastric mill, and can intensify ongoing gastric mill activity. The effects are dose-dependent, and can be blocked by the specific CCK antagonist proglumide, which also blocks the effects of mammalian CCK, and blocks the feeding-induced activation of the gastric mill in intact lobsters.

We are currently using an endoscope to test whether peptide C-CCK E can activate the gastric mill when injected into the hemolymph of intact lobsters, as is the case for mammalian CCK8 (see abstract by M. Boyle, G. Turrigiano, and A.I. Selverston), and to determine whether its behavioral effects are consistent with its effects on the isolated stomatogastric nervous system.

FMRFAMIDE-IMMUNOREACTIVITY IN THE CRAYFISH NERVOUS SYSTEM. A. J. Mercier, V. TeBrugge* and I. Orchard. Dept. of Biol. Sci., Brock University, St. Catharines, Ont., L2S 3A1, and Dept. of Zoology, University of Toronto, Toronto, Ont., M5S 1A1.

Previous work (eg. Kobierski et al, J. Comp. Neurol. 266: 1-15)

suggests that FMRFamide-related peptides act as neurohormones in crustacea. The present study was undertaken to determine whether FMRFamide-related peptides are present in <u>Procambarus clarkii</u>. Immunostaining with a commercial antibody to FMRFamide revealed reactive cell bodies and processes within each ganglion and two brightly stained axons traversing almost the entire length of the nerve cord. Immunoreactive varicosities were present in the nerve cord and in the pericardial organs (PO's). In addition, the antibody stained 5-6 axons that exit the sixth abdominal ganglion via the intestinal nerve and form an immunoreactive plexus of varicosities on the hindgut.

The presence of FMRFamide-related material in all the above site was confirmed and quantified with radioimmunoassay. The PO's had the highest levels of immunoreactivity; pooled PO's from one side of one crayfish contained the equivalent of about 64 pmol of FMRFamide. Extracts of the PO's were fractionated by HPLC using a C18 column and a Phenyl column with Acetonitrile gradients. Immunoreactive material co-eluted with two identified peptides from lobster PO's, with the sequences TNRNFLRF-NH₂ and SDRNFLRF-NH₂ (Trimmer et al, J. Comp. Neurol. 266: 16-26), and other peaks were also present. Immunoreactive fractions increased the rate and amplitude of contraction of isolated crayfish hearts, as did SDRNFLRF-NH₂. The results support a neurohormonal role for FMRFamide-related peptides. Supported by NSERC Canada.

ONLY TWO OF THE FOUR ACCESSORY NEURONS OF THE CRAYFISH MRO ARE GABAergic: PHENOTYPING NEURONS BY COMBINING BIOCYTIN BACKFILLS WITH IMMUNOCYTO-CHEMISTRY. B. Mulloney and W.M. Hall . Zoology and Neurobiology, Univ. California, Davis CA 95616.

The Muscle Receptor Organs in the abdomen transduce information about body position (Alexandrowicz, 1967). Each MRO is innervated by four Accessory neurons that are thought to use GABA to inhibit the MRO (Kuffler and Edwards, 1958, Leise et al., 1987). So we were surprised that the number of axons that labeled with GABA antiserum, four, in nerves innervating MROs in Pacifastacus Jeniusculus was less than the six predicted by the assumption that all leniusculus was less than the six predicted by the assumption that all Accessory neurons were GABAergic (Mulloney and Hall, 1990). To resolve this discordance, we examined the transmitter phenotype of each Accessory neuron.

We used a polyclonal antibody (Hoskins, et al., 1986) to label all GABAergic neurons in abdominal ganglia whose Accessory neurons had been filled with biocytin (Horikawa and Armstrong, 1988) by axonal backfilling (Iles and Mulloney, 1971). The cell bodies of the Accessory neurons lie in the ganglion posterior to the MRO they innervate; backfills of the nerve to an MRO fill only those four cell bodies in the next posterior ganglion. Wholemount preparations of these ganglia were analyzed and photographed using fluorescent optics: biocytin-filled neurons were visualized with Streptavidin-Texas Red, the antibody-labeled neurons with an FITC-conjugated secondary antibody. When all four Accessory neurons were filled clearly, two of them also labeled with antiGABA. In the same ganglia, the other two were not labeled by the antibody. We conclude that only two of these neurons use GABA as a transmitter; the transmitter phenotype of the rest is unknown.

266.5

NEUROSECRETORY CELLS IN THE LOCUST CORPORA CARDIACA ARE BORN THROUGHOUT DEVELOPMENT AND MATURATION. S Kirschenbaum and M O'Shea. Cell Biology Lab, London Univ (RHBNC), UK.

The glandular lobes of the corpora cardiaca (CC) in the locust <u>S gregaria</u> synthesise adipokinetic hormones (AKH).
Throughout post-embryonic development the total amounts of AKH peptides increase while the relative amounts change dramatically. To study the cellular mechanisms by which peptide amounts might be regulated, we provided cells of the CC with bromodeoxyuridine (BUdR) in vivo and in vitro. BUdR incorporated into glandular lobe cells was visualised by immunocytochemical methods allowing us to localise DNA replication in the CC. Replication is associated with cell division indicated by the presence of labelled cell pairs $\,$ rather than isolated cells which would indicate replication leading to polyploidy. Pairs of new cells observed throughout the glandular lobe resemble the existing ${\tt CC}$ cells. Cell division takes place throughout development including the adult stage when the animals become sexually mature. During a 16-hour period the cell number in adult glands increases by approximately 5%. In CCs cultured in vitro BUdR labelling is observed indicating that new cells arise from within the CC rather than from cells which might form elsewhere. Double labelling studies in which we localised peptide hormone precursor and BUdR indicate that new cells arise from undifferentiated cells of the CC that do not express peptides. Supported by NATO and SERC.

266.7

ROLE OF CENTRAL AND PERIPHERAL PEPTIDE RELEASE IN THE CONTROL OF ECDYSIS BEHAVIOR IN MANDUCA SEXTA. R.S. Hewes and J.W. Truman. U. of Washington, Seattle, WA 98195.

Insects perform highly specialized ecdysis behaviors at

the end of each molt to shed the old exoskeleton. logical and behavioral events at ecdysis are coordinated by a unique, 62-amino acid neuropeptide, eclosion hormone (EH). Although EH was thought to trigger ecdysis <u>via</u> the circulation, the recent discovery in Manduca sexta of a set of EH-containing neurons that project throughout the CNS as well as into the periphery prompted an evaluation of the roles of centrally versus peripherally released peptide.

Although blood-borne EH is sufficient to trigger ecdy sis, it is not necessary. Removal of the peripheral EH re-lease site (the proctodeal nerves) eliminated circulating EH but did not interfere with the subsequent ecdysis behavior in prepupae. In addition, antidromic stimulation from the proctodeal nerve stumps (following proctodeal nerve re-moval) elicited precocious ecdysis, and preliminary immunohistochemistry has revealed arborizations and varicosities of the EH cells in each of the ventral ganglia.

The presence of blood-borne EH is necessary, however, for activation of a peripheral target (the Verson's glands) responsible for secretion of the cuticle cement layer at ecdysis. EH therefore is released both within the CNS to act on central targets and also into the blood to act on targets in the periphery. (Supported by NIH grant GMD7108targets in the periphery. (Supported by 14 (RSH) and NSF grant DCB8615627 (JWT)).

SEROTONIN INDUCES PLATEAU PROPERTIES IN A STOMATOGASTRIC MOTONEURONE BY A MIXED CONDUCTANCE DECREASE AND INCREASE MECHANISM. Q. Kiehn and R. Harris-Warrick. Sect. of Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14853.

Stretch activated sensory cells synapse on neurones in the stomatogastric ganglion (STG) in crabs (Katz, P. & Harris-Warrick, R., J. Neurophysiol., 62:571, 1989). These cells, called gastro-pyloric receptor cells (GPR cells) contain acetylcholine and serotonin (S-HT). In the DG cell, a gastric mill motoneurone, GPR activity evokes cholinergic nicotinic EPSPs and induces bistable plateau properties. The transmitter responsible for the plateau induction was uncertain. We have examined the transmitter regulation and the underlying ionic basic of the plateau induction. plateau induction

When nicotinic and muscarinic receptors were blocked by d-tubocurarine (0.1mM) and scopolamine (0.1mM), stimulation of GPR cells evoked a slow depolarization in DG. This sometimes exceeded the threshold for triggering a uepolarization in DO. This sometimes exceeded the threshold for triggering a plateau. In other cases the plateau could be initiated by a brief depolarizing current pulse. A brief puff of 5-HT (10μM-1mM) onto the STG neuropil mimicked the non-cholinergic GPR plateau enabling effects in DG. The GPR- and 5-HT-elicited slow depolarization decreased upon hyperpolarization and was accompanied by an apparent increase in input resistance. The 5-HT-evoked depolarization, apparent apparent increase in input resistance. The 5-HT-evoked depolarization, apparent increase in input resistance, and plateau induction persist in TTX $(0.1\mu\text{M}-1\mu\text{M})$. The plateau was, however, blocked in low (0.25%) Ca²⁺ and reduced in normal Ca²⁺ and 10mM Co²⁺, leaving a slower, smaller depolarization. Under these conditions, 5-HT caused a decrease in the input resistance rather than an increase. The depolarization was practically eliminated in low Ca²⁺ and low Na⁺ (50%). We conclude that 5-HT is responsible for the GPR-evoked plateau properties in DG. The plateau potential appears to be Ca²⁺-dependent, while the induction

process seems to involve both a conductance decrease and a conductance increase mechanism. Supported by NIH#NS17323

TWO SMALL mRNAs PRODUCE THE THREE DIMERIC PROHORMONES OF AKH I & AKH II AND ARE TRANSLATIONALLY REGULATED. M O'Shea, M-F Schulz-Aellen*, S Hekimi* and J Fischer-Lougheed* Cell Biology Lab, Univ of London (RHBNC), UK

The neuropeptides adipokinetic hormones (AKH I and AKH II) are processed from 3 dimeric prohormones called P1, P2 & P3. These are produced, following removal of signal sequences, by the oxidation of cysteines contained in two small proteins, pre-proAKH I and pre-proAKH II, translated from two small mRNAs. Both mRNAs are expressed in all neurosecretory cells of the locust (S. gregaria) corpora cardiaca (CC) - a peptide factory much like the ELHproducing bag cells of Aplysia. Relative amounts of AKH I and AKH II and the three AKH-Precursor-Related-Peptides (APRPs) change dramatically post-embryonically. Early AKH I to II ratio is approximately 1:1 and later in mature adults almost 5:1. Dimer formation occurs rapidly in the ER and amounts of each formed can be explained solely by the relative synthetic rates of the two subunits. Differential production of subunits could depend on the relative amounts of the 2 mRNAs (transcriptional control) or by the regulation of protein synthesis from similar amounts of the 2 mRNAs - indicating translational control. Experiments measuring translation in the CC and in cell-free assays, and Northern analysis to measure levels of the two mRNAs suggest that the production of precursor subunits is regulated translationally. Supported by SERC and Ciba Geigy.

STAGE SPECIFIC EXPRESSION OF FMRFamide-LIKE IMMUNOREACTIVITY IN MOTONEURONS OF THE TOBACCO HORNWORM, MANDUCA SEXTA, IS MEDIATED BY STEROID HORMONES. <u>J.L. Witten and J.W. Truman.</u> Dept. of Zoology, U. Washington, Seattle, WA 98195.

FMRFamide-like immunoreactivity (FLI; antiserum provided by Drs. E. Marder, Brandeis U. and B. Trimmer, U. Oregon) was localized to identified motoneurons in abdominal ganglia of the moth where the peptide(s) may function as a co-transmitter. The expression is present in motoneurons only during the larval stage. A gradual decline in the number of immunoreactive motoneurons occurs during metamorphosis and is not due to cell death but is

temporally correlated to changes in the normal ecdysteroid titers.

The transition from larva to pupa is effected by two pulses of ecdysteroids, a small commitment peak (CP) followed by the larger prepupal peak (PP). To examine the role of these steroid peaks in the changing transmitter expression, we developed a novel in vivo ganglia culture system. Ganglia from specific larval stages, V+2(prior to the CP), W+0 (after CP) and W+3 (after PP) were implanted into a steroid-free environment, the abdomen of diapausing pupae. The results suggested that the CP regulated the decline in FLI. These conclusions were also supported by ecdysone infusions administered to mimic the CP or PP peaks. This is in contrast to the regulation of morphological changes in motoneuron dendritic arbors that occur during metamorphosis which are regulated by the prepupal rise in steroids. Supported by NIH NS13079(JWT).

TRANSMITTER SWITCH BY IDENTIFIED INSECT PEPTIDERGIC NEURONS IS CONTROLLED BY THE STEROID HORMONE ECDYSONE. N.J. Tublitz and P.K. Loi*. Inst. of Neurosci., U. Oregon, Eugene, OR 97403.

Recent work has demonstrated that mature neurons can alter their transmitter phenotype <u>in vivo</u>, yet little is known about the mechanisms controlling this biochemical plasticity. The moth, <u>Manduca sexta</u>, contains 4 individually identified neurosecretory cells that differentially express two neuropeptides postembryonically. In larvae, these cells predominantly secrete one peptide, Cardioacceleratory Peptide, (CAP2), whereas in pupae and adults, another peptide, bursicon, is produced. Because this transmitter switch occurs during mctamorphosis, we tested the hypothesis that this CAP₂-to-bursicon conversion is regulated by the same hormonal mechanisms controlling metamorphosis, specifically flucuations in the levels of the steroid hormone, ecdysone.

To precisely determine the time of this switch, individual 4 cell clusters were microdissected from animals at various stages and assayed for both CAP, and bursicon contents. Our results revealed that the levels of the two peptides followed independent time courses. CAP, decreased in two discrete steps, with an initial drop seen at wandering followed by a slower decline over the next few days. In contrast, bursicon was not detectible until pupal ecdysis, after which there was a rapid accumulation. Results from ligation experiments implicated ecdysone as the causal factor responsible for these changes, with the CAP $_2$ decline regulated by the 'commitment' pulse of ecdysone whereas bursicon levels were affected by the 'prepupal' ecdysone peak . These conclusions were confirmed by ganglion implantation manipulations in which pre-metamorphic ganglia containing these cells were implanted into host animals at key stages prior to pupation and assayed for both peptides when the hosts were midway through adult development. These results are consistant with the idea that this transmitter switch is under the control of the insect steroid hormone, ecdysone.

A GENETIC ANALYSIS OF THE FMRFamide NEUROPEPTIDE GENE IN DROSOPHILA. M.A. O'Brien and P.H. Taghert. Depart. of Anatomy & Neurobiology, Washington Univ. Sch. of Med., Saint Louis, MO 63110.

We are using Drosophila molecular genetics to investigate the functions of modulatory neuropeptides. The gene of interest encodes many diverse FMRFamide-related sequences; several features indicate that the >13 deduced peptides will have multiple functions. An analysis of expression throughout postembryonic development, using in situ hybridization, revealed that the gene is persistently expressed in different neuron types. Furthermore, stage-specific gene expression was displayed by certain neurons. We are in the process of creating mutations for the gene so that we may investigate the development and physiology of animals that lack its expression. Our first step has been to generate deficiencies in 46C, the cytological locus for the gene. Because the loss of a single copy of the FMRFamide gene would likely be invisible (behaviorally), we began with a strain containing an Adh (Alcohol dehydrogenase)-bearing P element inserted in the 46C-D region (from J. Hirsh, Harvard University). Flies were X-irradiated and progeny screened for loss of Adh gene function by selection on pentynol and pentenol. From ~43,000 progeny screened, 5 Adh* stocks were identified. These Adh revertants were further analyzed for the loss of adjacent genomic regions by cytological analysis, complementation tests and Southern blot analysis. The data indicated that in 1 stock the FMRFamide gene, does not display any abnormalities. Because the severity of the null phenotype for the gene is not known, current efforts to generate new alleles include both a lethal screen, as well as using antibodies to screen for the absence of peptides in the case of a non-lethal phenotype. This genetic analysis should complement traditional pharmacological and physiological analyses of such modulatory neuropeptides.

Molecular and Genetic Studies of Drosophila Glutamic Acid Decarboxylases. F.R. Jackson, S.J. Kulkarni,* K.A. McLaughlin,* L.M. Newby,* and B.J. Walker.* Worcester Fndn. Exptl. Biol., Shrewsbury, MA 01545

We previously reported molecular analyses of a Drosophila glutamic acid decarboxylase (Gad) gene mapping to chromosome region 64A3-5 (Jackson, F.R., Soc. Neurosci. Abstr. 14:30, 1988). Additional studies reveal that this chromosomal locus contains a pair of tandemly duplicated genes, one of which corresponds to the previously characterized Gad gene. We are presently engaged in cDNA sequencing studies to determine the similarity between the two genes. Concurrent immunoblotting studies have revealed the presence of at least three Drosophila proteins (43 kDa, 57 kDa, and 76 kDa) that cross react with anti-mammalian GAD antisera. The expression of these proteins appears to be developmentally and spatially regulated: the apparent ratio of the 57 kDa and 76 kDa forms changes between the pupal and adult stages, while the 43-kDa protein is detected in adult bodies (presumably due to expression in the thoracic ganglion), but not in adult heads.

As a corollary to these molecular analyses, we have initiated genetic studies of Drosophila GAD proteins. To produce Gad mutations, we have induced mutations in chromosome region 64AB that cause morphological phenotypes or result in lethality. Presently, we have isolated a minimum of 28 mutations, one of which maps to region 64A3-5 and is a candidate Gad mutation.

266.12

REGULATION OF THE FMRFamide GENE IN DROSOPHILA.
L. E. Schneider and P. H. Taghert. Dept. of Anatomy and Neurobiology, Washington University Medical School, Saint Louis,

Mo 63110. We have examined the expression of the *Drosophila FMRFamide* neuropeptide gene using *in situ* hybridization and immunocytochemical methods. Results from the two methods reveal that gene expression is restricted to a stereotyped subset of neurons in the CNS: -60 in larvat stages and ~100 in adults. The pattern of *FMRFamide* transcription develops gradually, beginning at ~70% of embryonic development, and the initial differences in steady-state levels of transcript are maintained. During metamorphosis, the basic pattern of transcription is retained, although a few hybridization signals are lost and new signals appear in several regions, including the optic lobes (MA O'Brien, LES and PHT, unpublished). We are interested in the molecular mechanisms that regulate these complex patterns of expression, including the cell-specific distribution of transcripts, the different times of developmental specific distribution of transcripts, the different times of developmental onset, the different steady-state levels of transcripts, and the postembryonic changes that occur during adult development. Many of these mechanisms are likely to occur at the level of transcription and, therefore, to identify potential gene regulatory regions, we have compared the sequence of regions upstream of the FMRFamide gene between two Drosophila species, D. melanogaster and D. virilis. Several small regions that display sequence conservation are candidate DNA elements for the control of FMRFamide gene transcription. Currently, the function of these and other potential circumstatory. Currently, the function of these and other potential cis-regulatory regions, in directing cell-specific neuropeptide gene expression, is being studied *in vivo* with P element transformation methods.

PAIN MODULATION: PHARMACOLOGY III

267.1

MU-OPIOIDS INHIBIT TWO TRANSIENT CALCIUM CURRENTS INACTIVATED BY VOLTAGE, BUT SPARE A CURRENT INACTIVATED BY Ca⁺⁺ <u>J.E. Schroeder, P.S. Fischbach</u>, M. Mamo, and E.W. McCleskey, Department of Cell Biology and Physiology, Washington University, St. Louis, MO 63110.

Three types of Ca current exist in adult rat dorsal root ganglia neurons. Low threshold T channels may influence firing threshold and bursting behavior. High threshold Ca current is composed of sustained and transient components. Availability of the latter depends on the rest potential and the prior electrical activity whereas the former seems to provide a baseline level of voltage-dependent Ca⁺⁺ entry that is lost only when intracellular [Ca⁺⁺]

We report now that activation of opioid receptors by 100nM-1000nM DAGO, an enkephalin analog selective for the mu receptor, inhibits T and high threshold transient currents and spares the sustained current. Both the DAGO-sensitive and DAGO-insensitive current components are sensitive to 10_µM omega-conotoxin, a calcium channel blocker. 10_µM naloxone, an opioid antagonist, abolishes the DAGO effect fully.

Surprisingly, either 500nM nor-binaltorphimine, a kappa receptor antagonist, or $10\mu M$ β -funaltrexamine, an irreversible mu antagonist, partially block the effect. When DAGO and dynorphin A, a kappa agonist, were applied to the same cells, DAGO consistently inhibited the Ca current more. This and the observation that dynorphin A does not inhibit T channels indicate that DAGO is not exerting its effects solely at kappa receptors. Others have reported that mu and kappa receptor activation cause increases in K and decreases in Ca currents, respectively. In addition to effects on K channels, our results indicate mu opioids inhibit multiple types of Ca channels in rat sensory neurons.

A PERTUSSIS TOXIN-SENSITIVE MECHANISM IS ASSOCIATED WITH THE ENHANCED EFFICACY OF BUPRENORPHINE IN A TONIC PAIN MODEL. H. Wheeler-Aceto' and A. Cowan. Department of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140.

In the rat tail-dip test buprenorphine (B) gives a bell-shaped dose-response curve, with low efficacy characteristic of 'agonist-antagonist' analgesics. We have compared this dose-response profile with that obtained in the rat paw formalin test (Wheeler-Aceto et al., Pain 40: 229, 1990). B attained maximum efficacy against the acute phase (0-10 m post-formalin) of the response but increasing doses were associated with reduced efficacy. However, full efficacy was maintained against tonic pain (20-35 m post-formalin). The demonstration of three distinct DRC's with B depending on the nociceptive stimulus employed is in contrast to morphine which gives linear, full efficacy DRC's in all three tests. Despite the fact that pretreatment with PTX (1 µg 1.h. 80-90 h prior to testing) markedly enhances formalin-induced nociception in both phases of the response, close to maximum efficacy was still achieved by B. The shape of the DRC against acute pain was unchanged; however, higher doses of B no longer maintained full efficacy against tonic pain. A PTX sensitive G protein is implicated in the action of B on ionic pain. (DA 03945 and DA 07237)

Contribution of Supraspinal Mu and Delta Opioid Receptors to Analgesia in the Rat. Y.O. Taiwo, C.A. Miaskowski and J.D. Levine Neuroscience, UCSF, Box 0724, San Francisco, CA 94143

The relative contribution of different opioid receptor classes in supraspinally mediated analgesia has remained controversial. In this study, we evaluated the antinociceptive effects of intracerebroventricularly injected selective mu-(DAMGO), delta- (DPDPE) and kappa- (U50,488H) opioid agonists (5fg-5ng) on mechanical nociceptive threshold using the paw-withdrawal test. DAMGO and DPDPE, but not U50,488H produced dose-dependent increases in mechanical nociceptive thresholds. The antinociceptive mechanical nociceptive thresholds, the antinociceptive effect of DPDPE, but not DAMCO, was inhibited by the selective delta antagonist ICI- 174,864 (3ug), suggesting that the actions of the agonists are mediated by different receptors. In addition, we observed that a low-analgesic dose of DPDPE (50fg) coadministered with sequentially increasing doses of DAMGO produced analgesic synergy. We conclude that mu and delta but not kappa opioid receptors contribute to supraspinal opiate-induced analgesia in the rat. Further examination of the contribution of supraspinal opioid receptors to analgesia, using other selective opioid antagonists, are currently in progress.

INTRATHECAL OPIATES AND α , AGONISTS PRODUCE A SYNERGISTIC ANTINOCICEPTION. M.H., Ossipov, E. Messineo , R. Lozito , J. Green , S. Harris and P. Lloyd , Anaquest/BoC Health Care, 100 Mountain Ave, Murray Hill, NJ 07974, U.S.A.

The spinal antinociceptive interaction of morphine, fentanyl, and meperidine with clonidine is described. Male Sprague-Dawley rats received fixed ratios of clonidine to fentanyl (10:1), meperidine (1:3), or morphine (10:1) by i.t. injection through implanted catheters terminating at the level of the lumbar cord. Antinociception was assessed in the tail-flick test before (Control) and several times in the tail-flick test before (Control) and several times after (Post) drug injection. A 7 sec cut-off time prevented tissue damage. Data were converted to % maximal possible effect (%MPE) by: [(Post - Control)/(7 - Control)] x 100. The A₅₀ doses (producing 50 %MPE) for clonidine, fentanyl, morphine, and meperidine are 44 µg, 1.2 µg, 1.4 µg, and 432 µg, respectively. For combinations of fentanyl, morphine, and meperidine with clonidine, the total drug A₅₀ values are 1.06 μ g, 0.82 μ g, and 35 μ g, respectively. These values are significantly less than those predicted if the interaction was purely additive; thus, isobolographic analysis indicates a synergistic interaction between α_2 adrenergic and opiate agonists. A pharmacokinetic effect is unlikely since fentanyl, unlike morphine and meperidine, does not produce an active metabolite yet still produces a synergistic effect with clonidine.

OPIOID AND NICOTINIC PROCESSES IN MEDULLARY HYPERALGESIA.

OPIOID AND NICOTINIC PROCESSES IN MEDULLARY HYPERALGESIA. M. R. Martin and S. Parvini*, Department of Pharmacology, University of Kentucky, Lexington, KY 40536.

Rats were prepared with an indwelling guide cannula which allowed the placement of a chemotrode in the mid 4th ventricle (4th V). The responses to ip and 4th V (0.5 or I ul) administered EKC, U-50,488 (U), morphine (M), (-)-nicotine (N), naltrexone (Na), and mecamylamine (Me) were studied in female Sprague Dawley rats (ca 250 gr) using a low intensity tail flick reflex (LITFR) with a mean control latency of ca 20 sec. EKC, U, and M administered ip produced a dose related increase in the latency of the LITFR whereas they produced a dose related decrease in the latency of the LITFR whereas they produced a dose related decrease in the latency of the LITFR when administered into the 4th V. High dose (40 ug) 4th V N also produced hyperalgesia. Na and Me prolonged the latency of the LITFR when administered ip and into the 4th V and antagonized the hyperalgesic and Me prolonged the latency of the LITFR when administered ip and into the 4th V and antagonized the hyperalgesic effect of EKC and N when administered ip. These data confirm the existence of a medullary hyperalgesic center and the role of both mu and kappa opioid and nicotinic mechanisms in its function. The analgesic effects of 4th V Na and Me may be a consequence of their antagonizing spontaneous activity of 4th V nicotinic and opioidergic hyperalgesic mechanisms. ORGANIZATION OF SOME FOREBRAIN INPUTS TO THE MIDBRAIN PERIAQUEDUCTAL GRAY. M. Ennis, T. Rizvi, M. Shipley and M. Behbehani. Depts. of Anatomy and Physiology, Univ. Cinti. Coll. Med., Cincinnati, OH 45267.

The midbrain periaqueductal gray (PAG) has been implicated in diverse functions such as analgesia, autonomic regulation, sexual behavior and defense\escape responses. Anatomical studies on the substrates of such functions have largely focused on connections of PAG with brainstem and medullary nuclei. The extensive input to PAG from forebrain structures has been largely unexamined. Here, we used axonal tracing to examine inputs to PAG from cortex, central nucleus of the amygdala (CNA) and the medial preoptic area (MPO).

PAG receives heavy input from medial prefrontal and lateral cortex (i.e. insular and perirhinal cortex). Anterograde labeling from both cortical regions was distributed along the entire rostrocaudal extent of PAG. Inputs from CNA and MPO also project along the entire rostrocaudal axis of PAG, however, in contrast to medial and lateral cortex, connections between PAG and CNA and MPO are strongly reciprocal. These forebrain regions gave rise to different patterns of terminal labeling in PAG.

terminal labeling in PAG.

Preliminary results indicate that at least some individual neurons in these 3 forebrain groups project to multiple rostrocaudal levels of PAG. These results indicate that PAG receives heavy and highly organized inputs from medial and lateral cortex, CNA and MPO. Projections from these forebrain areas gives rise to distinct longitudinal input columns that span the length of PAG. (Supported by PHS Grants NS20463, NS24698 and HL08097).

CONDITIONED AUTOANALGESIA: BLOCKADE BY INJECTIONS OF MORPHINE INTO THE ACCUMBENS NUCLEUS. R. F. Westbrook*, J. Harris*, A. J. Good* and G. Paxinos. School of Psychology, Univ. New South Wales, Sydney, NSW, Australia 2033.

Under some conditions, exposure to a heated floor aversively conditions associated cues and renders the rat analgesic when re-exposed to that heated floor. This aversive conditioning fails to occur when morphine-naive or morphine tolerant rats are given peripheral injections of or morphine tolerant rats are given peripheral injections of the drug in combination with exposure to the floor on the first exposure (Greeley, J. and Westbrook, R.F., <u>O. Il exp. Psychol.</u>, in press). The present experiment demonstrates a comparable failure of aversive conditioning when morphine is centrally administered on the first exposure to the heated floor. Specifically, unilateral injection of morphine into the accumbens nucleus (15µg in 1µl) did not provoke analgesia, but did block the aversive conditioning otherwise accruing from the initial exposure to the heated otherwise accruing from the initial exposure to the heated floor. Morphine blockade of aversive conditioning was reversed by peripheral injections of naloxone (5mg/kg), indicating an opioid inhibition of the processes which give rise to aversive conditioning and its resultant analgesia.

GABA VESICLE-CONTAINING DENDRITES: A CRITICAL ELEMENT IN PROCESSING SENSORY INPUT IN THE PRIMATE DORSAL HORN. S. M. Carlton and E. S. Hayes*. Univ. of TX Medical Branch & Marine Biomedical Institute, Galveston, TX 77550.

Several lines of evidence support a role of gamma-aminobutyric acid (GABA) as a major inhibitory transmitter in the mammalian nervous system. High concentrations of GABAergic cells in the dorsal horn of the spinal cord suggests it plays an integral role in the processing and modulation of sensory input. The purpose of this study was to identify the neurocircuitry of this system and determine how it related to dorsal horn elements. Three monkeys (M. fascicularis) were perfused with mixed aldehydes, the lumbar enlargement removed, cut on a vibratome (25µm), and immunostained with anti-GABA (1:1:000). The tissue was embedded in plastic, thin sectioned and analyzed at the EM level.

The majority of the input to GABAergic neurons occurred on the dendrites, not cell bodies. Furthermore, numerous GABAergic dendrites, containing synaptic vesicles, were observed presynaptic to labeled and unlabeled cell bodies and dendrites and to unlabeled spine heads and axon terminals; however, they were postsynaptic to primary afferents and other GABAergic dendrites. These data suggest that GABAergic dendrites play a role in feedforward and feedback inhibition in the spinal cord. Supported by NS11255, NS27910 and Bristol Myers-Squibb Corp.

POTENTIATED ANTINOCICEPTIVE EFFECTS IN A MODEL OF VISCERAL PAIN BY INTRATHECAL COADMINISTRATION OF AN ALPHA-2 ADRENOCEPTOR AGONIST AND A 5-HT-18 OR 5-HT-2 RECEPTOR AGONIST. R.M. Danzebrink and G.F. Gebhart, The University of Iowa, Iowa City, Iowa, 52242.

The interaction between adrenoceptor and serotonin receptor agonists in the spinal cord was evaluated in the present study following i.t. coadministration of clonidine (alpha-2 adrenoceptor agonist) with DOI or RU-24969 (5-HT-2 or 5-HT-1B receptor agonists, respectively). Colorectal distension (CRD) evokes a pressor response which was monitored before and after i.t. coadministration of receptor selective drugs; inhibition of the pressor response to CRD was indicative of antinociception. the pressor response to CRD was indicative of antinociception. Supra-additive antinociceptive effects were produced following the i.t. coadministration of subanalgetic doses of clonidine with DOI and similarly with clonidine and RU-24969. The potentiated antinociceptive effects produced following the i.t. coadministration of DOI with clonidine were antagonized by i.t. pretreatment with methysergide but not by yohimbine or phentolamine and the effects produced following i.t. coadministration of clonidine with RU-24969 were antagonized by heartsleine but not by your working interpretable to the progression with RU-24969 were antagonized by heartsleine but not by your working in the progression with RU-24969 were antagonized by phentolamine but not by prazosin, yohimbine or methysergide. These results suggest modulation of descending 5-HT-containing bulbospinal neurons by descending NE-containing neurons and provide evidence for an important interaction between spinal alpha-2 and 5-HT receptors in the modulation of visceral nociceptive transmission.

267.11

LIDOCAINE BLOCKS A? AND C FIBER INJURY DISCHARGE WITHOUT ALTERING NERVE CONDUCTION. M.B. Maciver and D.L. Tanelian. Anesthesia Dept., Stanford Univ. Sch. of Medicine, CA 94305.

Low serum concentrations of lidocaine (2 to 13 μg/ml) relieve both acute and chronic pain in humans. Conduction block of nerve fibers has not been demonstrated at these low concentrations. The present study investigated lidocaine's effects on discharge activity of acutely injured Að and C fiber nociceptors using an in vitro preparation of rabbit cornea. Corneas were maintained at normal temperature (35 °C) and intraocular pressure (18 mm Hg) and a standard 3 mm² abrasion was produced. The resulting injury discharges were recorded from nerve fibers using a glass suction electrode. Nerve fiber conduction velocity was measured following electrical stimulation using bipolar tungsten microelectrodes. Lidocaine produced a concentration-dependent depression of injury-induced action potential discharge. At 2.0 μ g/ml, discharge frequency was significantly reduced by 18+/-3.2 % (SD, n=5; p<0.005 ANOVA) and a concentration of 20 μg/ml produced nearly complete block (98+/-2.5 % depression). The time course for lidocaine-induced depression was comparable to times for pain relief in patients (20 min), and full recovery was observed following 30 min of wash. The depression of discharge did not involve conduction block since electrically evoked action potentials could be elicited at concentrations up to 250 μ g/ml. The results indicate that nerve endings are more sensitive to lidocaine than are axons, perhaps due to a lower Na+ channel density in sensory terminals and concomitant reduction in discharge 'safety factor'

THE NOCICEPTIVE RESPONSE TO IV 5HT IN RATS IS MEDIATED BY DUAL ACTIVATION OF 5HT₂ AND 5HT₃ RECEPTOR SUBTYPES. S.T. Meller, S.J. Lewis, M.J. Brody and G.F. Gebhart, Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242.

This study examined the specific receptor subtypes mediating the nociceptive response to IV 5HT. 5HT produced a dose-dependent (3-96µg/kg, IV) inhibition of the tail-flick (TF) reflex (ED50=24µg/kg) and complex cardiovascular responses. With doses greater than the ED50. complex pseudaffective responses were evoked Carniovascular responses. With uses greater than the ED50, complex pseudaffective responses were evoked (flattening of the ears, closing of the eyes to slits, contraction of the facial musculature). The ED75 dose of 5HT produced a passive avoidance behavior significantly different from saline. While crmethyl 5HT and 2-methyl 5HT produced dose-dependent (3-192µg/kg, IV) 5HT₂ and SHT3 receptor-mediated cardiovascular responses, neither drug inhibited the TF reflex, produced pseudaffective responses or a passive avoidance behavior. However, a 1:1 combination of these agonists (3-192 µg/kg, IV) not only produced a cardiovascular profile similar to that produced by 5HT, but also produced a dose-dependent inhibition of the TF reflex (ED50=80 µg/kg) and the same profile of pseudaffective behaviors found with 5HT. Rats administered with the ED75 combination dose also showed a passive avoidance behavior. These results clearly support the hypothesis that the noxious character of IV 5HT requires dual activation of 5HT₂ and 5HT₃ receptor subtypes.

267.12

DESYNCHRONIZATION OF THE EEG FOLLOWING LOW-DOSE MORPHINE. K. Grasing and H. Szeto*, Department of Pharmacology, Cornell University Medical College, New York, NY 10021.

We have previously shown that treatment with the upioid blocker naloxone can increase delta wave activity in the EEG of opioid-naive rats, if administered at the onset of active periods. This finding is suggestive of an excitatory effect of endogenous opioid peptides on level of arousal, that leads to a less alert EEG when an opioid antagonist is administered. To further investigate the hypothesis that onides can result in a more clark the hypothesis that opioids can result in a more alert level of arousal, we measured the effect of morhpine on

the EEG when administered to rats during active periods.

Rats were prepared with chronic jugular catheters and lectrocortical electrodes, and EEG was analyzed on-line y fast fourier transformation. Morphine was administered is an intravenous infusion over one hour, two hours following the onset of darkness, at doses of $0.1,\ 1.0,$ and 10.0 mg/kg-hr. The 10.0 mg/kg-hr dose resulted in ncreased total spectral power, with periods of delta wave activity. In contrast, 1.0 mg/kg-hr was followed by periods of sustained decreases in total power, without a predominant frequency. This desynchronized EEG is similar to the EEG pattern that occurs in rats at the onset of darkness. In addition to sedating effects that occur at relatively high doses, low doses of morhpine ause a desynchronized EEG that is suggestive of a more alert psychological state.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: CEREBELLUM I

OPTICAL IMAGING OF PARALLEL FIBER BEAM CHANGES TO APPLICATION OF GLUTAMIC ACID IN THE RAT CEREBELLAR CORTEX IN VIVO. S.A. Elias, H. Yae*, T.J. Ebner, Depts. Neurosurgery and Physiology, Univ. of Minnesota, Mpls., MN 55455.

and Physiology, Univ. of Minnesota, Mpis., Mn 55455.

Changes in the spatial patterns of neuronal activity in response to drugs are difficult to examine with conventional electrode recording. This study examines the effects of topically applied drugs on Purkinje cell responsiveness to parallel fiber (PF) input with optical imaging to measure amplitude and spatial changes. Rats were anesthetized with ketamine/xylazine, the cerebellum expected and placed under an orifluencesses minerary and anesthetized with ketamine/xylazine, the cerebellum exposed and placed under an epifluorescence microscope and stained with the dye RH795. The imaging detector was a Photometrics CCD camera (14 bit A/D, 576X384 pixels). A PF beam was elicited with a tungsten electrode and the field potential monitored. Application of 0.5mM glutamate increased the amplitude of the imaged PF beam, whereas 5-50 μ M quisqualate (QQ) reduced the width and beam amplitude, which may be due to activation of inhibitory interneurons. The optical beam was not significantly affected by N-methyl-D-aspartate (NMDA) but was abolished with 50 μ M kainate (KA). δ -D-Glutamylaminomethyl-sulfonic acid (QQ and KA antagonist). D-O-phosphoserine (KA antagonist). want KA antagonist), D-O-phosphoserine (KA antagonist), and kynurenic acid (NMDA and KA antagonist) reduced the imaged beam. It would appear that the optical signal is post-synaptic in origin and that KA and maybe QQ are the glutamate receptors activated by the PF input. Supported by NIH Grant #R01-NS-27210.

SPATIAL SPREAD OF VOLTAGE TRANSIENTS IN CEREBELLAR PURKINJE CELLS

T. Knöpfel, C. Staub and B.H. Gähwiler

Brain Research Institute, University of Zürich, CH-8029 Zürich (Switzerland)

The information processing capability of Purkinje cells is thought to critically depend on a segregation of specific conductances, together with an electrotonic non-compactness.

We applied multisite optical recordings using voltage sensitive we applied multisite optical recordings using voltage sensitive dyes to current- and voltage-clamped Purkinje cells to investigate these properties in cerebellar slice cultures. Voltage transients induced by intrasomatic current injection through the recording electrode were monitored optically from somatic as well as dendritic sites. Pharmacological blockade of potassium conductances resulted in an increased amplitude and a decreased rise-time of the dendritic signals.

These observations suggest that, under control conditions, part of the current spread between soma and dendrites is shunted by potassium conductances. We conclude that voltage signals are more or less independently integrated at the somatic and dendritic membrane of the Purkinje cell while the electrical coupling between compartments is controlled by potassium conductances.

SET-RELATED UNIT ACTIVITY IN THE PRECENTRAL CORTEX AND CEREBELLAR NUCLEI OF PRIMATE. L. Germain. Y. Lamarre and M.-T. Parent, CRSN, Université de Montréal, Montréal, Québec, Canada H3C 3J7

In a two-choice instructed delay paradigm a set-related cell is defined as a unit modulated during the delay between the instruction and the gosignal. In order to study the activity of cerebello-cortical pathways during an instructed immobile waiting period a monkey was trained in the following task. After a fixed 500 msec control period, the monkey was given an auditory instruction as to the movement to make (400 Hz tone for extension, 1000 Hz for flexion). The duration of the tone was 400 msec which was followed by a delay period of 500-1500 msec. The GO-signal at the end of the delay period was a small torque perturbation of the elbow. The biceps and the triceps were never observed to contract during the delay as shown by EMG recording. A total of 177 task- related cells were isolated and recorded during 100 trials each. In the motor cortex (MI) 30 the premotor cortex (PM) 64 the dentate nucleus (D) 47 and the interpositus (I) 36 cells were recorded. A significant (paired t-test, $p \leq 0.005$) change of the firing rate during the instructed delay as compared to the control period was demonstrated for 64% of PM cells 62% of D cells 55% of I cells and 49% of MI cells. In several trials a movement in the wrong direction was performed during recording of a cell. The analysis of these trials shows that the pattern of activity of set related cells is related to the direction of the intended movement and not to the auditory instruction. These results suggest a conribution of cerebello-cortical pathways in the preparation for movements. (Supported by MRC Group Grant in neurological sciences).

UNIFORM CONDUCTION TIMES OF CLIMBING FIBERS DETERMINED AT DIFFERENT FOLIAL DEPTHS USING A MULTIPLE ELECTRODE RECORDING PARADIGM. <u>I. Sugihara, E. I. Lang, R. Llinas</u> Dept of Physiology, New York University Medical Center, 550 First Avenue, New York, NY 10016.

The functional organization of olivo-cerebellar system has been studied using multiple electrode recording of complex spikes (CSs) in Purkinje cells. In a previous study it was found that simultaneous firing of CSs occurred in organized rostro-caudal bands of Purkinje cells on a given folium (Sasaki et al., European J. of Neurosci. 1: 572-586, 1989).

Here we measured the conduction times of the olivo-cerebellar fibers by recording the Purkinje cell CS responses to olivary tract stimulation at the brainstem in anesthetized adult rats. In 104 CS units recorded from the surface of the Crus IIa folium, the latency of the onset of the direct CS response ranged from 3.4 to 4.6 ms, however most latencies were close to 3.9 ms (3.92 ± 0.28 (mean ± SD, n=104)).

The conduction time of olivary fibers projecting to the Purkinje cells in the deep portions of the cerebellar folium (Crus IIa) was also measured. It ranged 3.4 - 5.0 ms, also close to 3.9 ms in latency $(3.93\pm0.28,$ n=26). It was nearly the same for the deep as that of the superficial portion of the folia, although the deep fibers are up to 20 % shorter than the superficial ones. Multiple electrode experiments in which electrodes measured CSs from the portion of the folium indicated that they tend to fire simultaneously with CSs in the follial surface and also with an approximate rostro-caudal organizations. These results indicate that the conduction velocity of the olivo-cerebellar systems seems to be organized such as to generate a synchronous activation of Purkinje cells independent of their location on a given folium.

268.7

COMPARISON OF SIMPLE AND COMPLEX SPIKE ACTIVITY IN IDENTIFIED SAGITTAL ZONES OF THE CAT CEREBELLUM DURING PERTURBATION OF THE LOCOMOTOR CYCLE USING A MULTIUNIT RECORDING TECHNIQUE. T.M. Kelly, F.J. Rubia*, F. Kolb*, J.D. McAlduff*, and J.R. Bloedel, Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

These experiments compare the characteristics of simple and complex spike activity in identified sagittal zones during modifications of the locomotor cycle and test the hypothesis that the information processing heach zone relates differently to the kinematics and EMG activity of the animal's forelimb during corrective movements. The study was performed in acutely decerebrated cats capable of locomoting on a treadmill. Two five-electrode arrays, each positioned in an electrophysiologically identified zone, were used to simultaneously record the activity of up to 10 Purkinje cells. Initially, the cat was conditioned to modify its gait in order to avoid a bar interjected into the forelimb's trajectory on successive step cycles. Once the animal acquired this behavior additional modifications in gait were generated by either changing the height of the bar or the speed of the treadmill.

The data support the view that neuronal interactions in several of the sagittal zones are uniquely associated with corrective changes in gait. Furthermore, these changes in activity are not restricted to a period immediately following the onset of the perturbation. Rather, in many trials, the modulation of simple and complex spike activity was most dramatic as the animal acquired and subsequently performed the new strategy during periods of prolonged perturbation. The data suggest that neuronal activity in these zones is principally related to characteristics of the movement and its performance rather than only with the acquisition phase of the task. VISUAL PONTINE PROJECTIONS TO THE CEREBELLAR HEMISPHERES OF MACAQUES. M. Glickstein, B. Mercier*, J. Stein*, C. Legg* and J. Voogd*. University College London, Gower St. London WC1E 6BT, England and Erasmus University, 3000 DR, Rotterdam, Netherlands.

Extrastriate areas MT, MST and adjacent visual areas of the parietal lobe project to

Extrastriate areas MT, MST and adjacent visual areas of the parietal lobe project to the dorsolateral region of the pontine nuclei. Cells in this region of the pons respond vigorously to appropriate visual targets. In this study small WGA-HRP injections were made into target zones in the cerebellar cortex. Injections into either dorsal or ventral paraflocculus lead to retrogradely labelled cells bilaterally in the dorsolateral pontine nuclei. Injections into the paramedian lobe result in labelled cells which border and extend into this region. The bilaterallity of pontocerebellar projections may account for the paradoxical sparing of visuomotor performance in monkeys deprived of cortical connections between visual and motor areas. These data help to establish the principle cerebellar targets of each of the extrastriate cortical areas projecting to the pontine nuclei.

INTERPOSITUS DISCHARGE DURING REACHING A.R. Gibson, K.M. Horn, P.L.E. van Kan. Barrow Neurological Institute, Phoenix, AZ, 85013

Single units in the interpositus nucleus of the cerebellum fire at high rates when a monkey reaches out and grasps a raisin. The goal of the present experiment is to understand what elements of reaching are important for eliciting discharge. The experimental paradigm separated the reaching motion into a coordinated limb movement with and without a grasping component. We trained monkeys to operate a lever device that described an arm trajectory similar to that of a reach. To date, 50 forelimb interpositus units have been tested during device operation and during reaching. Many units showed vigorous phasic firing when the monkey released the device handle and retrieved a raisin from a remotely opened box positioned near the end point of the lever trajectory, but few units fired well during device operation. The beginning and end points of the reach are the same as those of lever operation, and we conclude that the hand component of a reach is important for interpositus firing. Individual units show a distinctive pattern of firing during the raisin reach indicating that they serve different aspects of the movement. Some units fire discrete bursts at particular movement phases while others fire throughout the entire movement. We hypothesize that the interpositus is important for coordinating hand use with movements involving the entire forelimb.

VARYING THE SET OF RECEPTIVE FIELDS CHANGES WHICH OF THE STIMULUS ARRAYS EVOKE THE SAME ENSEMBLE RESPONSE G. McCollum, R.S. Dow NSI, Good Samaritan Hosp. & Med. Ctr., Portland, OR 97209

Stimulus arrays (complex stimuli considered as multipositional, multisensory combinations of simpler stimuli) are transformed by the nervous system into ensemble responses (response activity of many neurons). This talk will examine a construction of temporally simple ensemble responses assuming simple unions of single-cell responses in cat tactile receptive fields in cerebellar climbing fibers in the anterior lobe and paramedian lobule.

Complex stimuli may be reduced in the nervous system in order to extract the specific information required. To achieve such a reduction, different stimulus arrays may evoke the same ensemble activity, so that the information contained in the difference is lost.

Stimulus arrays that evoke the same ensemble response are response-equivalent. The set of all stimulus arrays is divided into equivalence classes according to available ensemble responses. The population of receptive fields determines the set of available ensemble responses, and therefore how the set of stimulus arrays is divided into equivalence classes.

The equivalence relation will be treated algebraically. When the set of stimulus arrays is mapped onto the set of ensemble responses and back again, the equivalence relation is expressed as a closure on the set of stimulus arrays.

PURKINJE CELL COMPLEX SPIKE MODULATION DURING VOLUNTARY MOTOR LEARNING IN THE PRIMATE. C.L.Ojakangas, T.J.Ebner, Depts. Neurosurgery and Physiology, Neuroscience Grad. Program, Univ. of Minnesota, Mpls., MN 55455.

The climbing fiber system's role in voluntary motor behavior during learning remains unclear. Two rhesus monkeys performed a two-dimensional, visually-guided arm movement, placing a cursor in target boxes using a manipulandum. When the relationship (gain) between cursor and When the relationship (gain) between cursor and hand position was altered, the animals gradually adapted to the imposed error and matched their arm movements to the new gain. Primates adapt to a novel gain over 100-200 trials by gradually scaling peak tangential velocity and movement amplitude while keeping time until peak velocity constant. Of 89 identified Purkinje celb, 43% showed complex spike modulation which increased significantly during learning. The increase occurred early in the movement (within the first 400 ms) with a mean of 233% +/- 167% of control (p<.0005, T test). Of these, 46% showed no subsequent peak following adaptation. For 35% of all P-cells the complex spike discharge increased during corrections later in the movement. Of these cells, 75% did not show this increase once corrections were eliminated. In summa-ry during the adjustment to a novel condition, P-cell complex spike discharge is engaged, suggesting a role for the climbing fiber system in the scaling and calibration of the metrics of voluntary movements. RETICULOSPINAL SYMPATHOEXCITATORY NEURONS MODULATE THE RESSOR REFLEX TO MUSCULAR CONTRACTION. R.M. Bauer and T.G. Waldrop, University of Illinois, Urbana, IL 61801

Previous studies have shown that many neurons in the ventrolateral medulla (VLM) with discharge related to sympathetic nerve activity demonstrate increased firing frequency during hindlimb muscular contraction (MC). These results suggest that sympathoexcitatory neurons in the VLM participate in the pressor reflex evoked by MC. In the present study extracellular single unit activity was recorded in anesthetized cats to determine if spin-ally projecting VLM neurons show altered firing patterns during MC. Hindlimb MC was induced by electrical stimula-tion of L7 and S1 ventral roots. Units were tested for antidromic activation by spinal stimulation in the intermediolateral nucleus (T2 or T5). VLM unit discharge was also related to cervical sympathetic nerve discharge or the cardiac cycle with a computer averaging program. VLM neurons (78%) which were activated antidromically displayed cardiovascular related discharge. Arterial pressure and the firing rate of most VLM units (64%) increased during MC. Nearly all of the reticulospinal VLM neurons (92%) with cardiovascular related discharge were excited by MC. Most VLM neurons unaffected by spinal stimulation or unrelated to cardiovascular rhythms were unaffected by MC. This suggests that reticulospinal VLM neurons with cardiovascular related discharge participate in the pressor reflex evoked by muscular contraction.

CARDIOVASCULAR EFFECTS OF NEUROTENSIN IN VENTROLATERAL MEDULLA AND NUCLEUS AMBIGUUS. J. Ciriello and T. X. Zhang, Dept. of Physiology, Univ. of Western Ontario, London, Canada, N6A 5C1.

The ventral medulla has been shown to be extensively innervated by neurotensin containing fibers. In this study the cardiovascular effects of microinjecting neurotensin at sites throughout the ventrolateral medulla (VLM) and nucleus ambiguus (AMB) region were investigated in chloraloseanesthetized, paralyzed and artificially ventilated male Wistar rats. Microinjections (20-50 nl) containing 100-250 pmol of neurotensin elicited a decrease in mean arterial pressure (89 \pm 9 mmHg) when the injections vere made at sites from the junction of the A1/C1 region rostrally into the C1 region. In addition, decreases in heart rate (45 \pm 5 bpm) were elicited when the injection sites were located in AMB. The cardiac slowing was not affected by spinal cord transection at the level of C1-C2 (51 \pm 9 bpm), but was abolished by ipsilateral vagotomy. The depressor response was reduced by approximately 60% following spinal cord transection and by 40% in spinal cord intact vagotomized rats, suggesting that a component of the depressor response was secondary to the vagal bradycardia. These data suggest that neurotensin containing fibers and terminals innervating the ventral medulla are components of a neuronal circuit controlling vasomotor tone and cardiac function.

CONVERGENCE OF DIFFERENT SENSORY INPUTS ONTO RETICULOSPINAL NEURONS IN VENTROLATERAL RETICULAR FORMATION. A.R. Evans and R.W. Blair. Dept. Physiol. & Biophysics, Univ. Okla. Health Sci. Ctr., Oklahoma City, OK, 73190.

The ventrolateral medullary reticular formation (VLRF) contains pools of neurons involved in cardiovascular, respiratory, and nociceptive functions. Few studies have examined whether neurons in VLRF respond to different sensory inputs. The goal of this study was to determine response characteristics of VLRF reticulospinal (RS) neurons to sympathetic, vagal, somatic, baroreceptor, auditory, and visual stimuli. Twelve cats were anesthetized with α -chloralose (40 mg/kg). Extracellular potentials were recorded from 21 neurons in VLRF whose axons were antidromically activated from the T₃ segment of the spinal cord. Mean conduction velocity was 28.6 M/s. Eleven neurons (52%) were excited by electrical stimulation of the left stellate ganglion. Two neurons (11% of 17 tested) were inhibited by vagal afferent stimulation, and three were excited. Ten of 19 (53%) and four (20%) of 20 neurons tested were excited by auditory and visual inputs, respectively. Eleven (59% of 19 tested) had somatic receptive fields. Three neurons were excited by decreases in blood pressure, and/or inhibited by increases in pressure, and one was the reverse, indicating that they received baroreceptor input. Nine neurons (60%) responded to stimuli from at least two sensory modalities. We conclude that RS neurons in the VLRF integrate afferent information arriving from different sources of sensory input. (Supported by NIH grant HL29618).

269.4

EFFECT OF PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS ON PLASMA RENIN ACTIVITY IN NEUROGENIC HYPERTENSION. T. X. Zhang and J. Ciriello, Dept. of Physiology, Univ. of Western Ontario, London,

We have previously shown that paraventricular nucleus of the hypothalamus (PVH) lesions alter the development and maintenance of the hypertension resulting after aortic baroreceptor denervation (ABD) in the rat. This study was done to determine if changes in plasma renin activity (PRA) were associated with the hypertension after ABD and if PVH contributed to these changes in PRA. Rats were instrumented with arterial cannulae for the recording of arterial pressure (AP) and the removal of blood samples. After ABD, the rats received either sham or bilateral electrolytic lesions of PVH. AP was significantly elevated (30-50 mmHg) in all rats after ABD. Similarily, PRA was increased (11.6 \pm 0.6 ng/ml/h) after ABD compared to pre-ABD levels (7.5 ± 0.8 ng/ml/h). PVH lesions significantly reduced the elevated AP and PRA (3.6 ± 1.1 ng/ml/h) to levels not different from pre-ABD levels. On the other hand, sham lesions of PVH did not alter the elevated AP and PRA (12.9 ± 0.9 ng/ml/h) after ABD throughout the experimental period. These data suggest that ABD results in an increased activity of PVH neurons which in turn increase sympathetic drive to the kidney which results in an increase the release of renin that likely contributes to the development and maintenance of neurogenic

NEUROTOXIN LESIONS OF THE PARAVENTRICULAR NUCLEUS (PVN) ATTENUATE HORMONAL AND CARDIOVASCULAR RESPONSES TO STRESS. M.F. Callahan, W.K. O'Steen, K.A. Gruber*, and M. Morris.
Depts. of Medicine, Anatomy and Physiology and
Pharmacology. Bowman Gray School of Medicine of Wake Forest University, Winston Salem, NC 27103.
Electrolytic lesions of the PVN or antagonism

vasopressin/oxytocin receptors attenuates tachycardia responses to stress. We have sought to determine whether damage to PVN cell bodies would attenuate stress responses.

Male Sprague-Dawley rats received neurochemical lesions of the PVN(5.0ug ibotenic acid/0.5ul/nucleus) or vehicle injection then intravenous and arterial catheters. Rats were subjected to a mild footshock stress and measures of arterial pressure, heart rate, plasma oxytocin and vasopressin were taken prior to, immediately after and five minutes after the stress. Two days later each rat received i.v. hypertonic saline (150ul/100g body wt. 18% NaCl sloution). Plasma samples were taken at baseline and five minutes post infusion. Brain sections were evaluated histologically for lesion placement and extent.

PVN lesions attenuated the tachycardia (78+8bpm -v- 131+11 bpm in controls) and oxytocin response to stress (400+91% increase -v- 2070+418% in controls). Plasma vasopressin failed to increase in response to stress with no differences seen between the two groups. In addition, the plasma oxytocin response to osmotic challenge showed no differences between the groups. Thus the lesion specifically attenuated plasma oxytocin and tachycardia responses to stress.

269.7

EPISODES OF PRIMARY CORONARY VASODILATION DURING

EPISODES OF PRIMARY CORONARY VASODILATION DURING PERIODS OF SLOW WAVE SLEEP INTERRIPTED BY EEG DESYNCHRONIZATION. LW Dickerson*, AH Huang*, BD Nearing*, RL Verrier. Georgetown University Medical Center, Department of Pharmacology, Washington, D.C. 20007.

We have previously observed sympathetically mediated surges in heart rate (HR) and coronary blood flow (CBF) with little or no change in mean systolic blood pressure (SBP) during REM sleep in dogs. In the present study, significant increases in CBF were preceded by transient asystole during slow wave sleep (SWS). Five beagles were instrumented with electrodes for polysomnography, ECG and arterial SBP, and with Doppler probes around the circumflex coronary artery to record CBF. We selected samples for analysis which were characterized by an increase in CBF occurring during deep slow wave characterized by an increase in CBF occurring during deep slow wave sleep interrupted by desynchronization of the EEG and by a pause in heart rhythm of at least 1.3 seconds (1.3-6.1 sec). The rate-pressure product (HR x SBP) is the standard index of cardiac metabolic demand. *P<0.05

SWS Pre-Asystole **SWS Post-Asystole**

 $12,786 \pm 705$

CBF (mean kHz shift/min) 84 + 8.0113* + 7.9

HR x SBP (bpm x mmHg) 12,128 ± 1028

We conclude that the CBF increases are not due to cardiac metabolic demands but instead to primary (neurogenic) coronary vasodilation, resulting from enhanced vagal discharge indicated by the associated asystole. The characteristic, brief desynchronization of SWS suggests that this phenomenon may represent the coronary vascular component of arousal/orienting responses.

FREQUENCY OF RESPIRATORY PAUSES IN INFANTS WHO DIE OF THE SUDDEN INFANT DEATH SYNDROME. Schechtman, R.M. Harper, A.J. Wilson* and D.P. Southall*. Brain Research Inst. and Dept. of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024; Dept. of Med. Phys. & Clin. Engineering, Univ. of Sheffield, England; National Heart & Lung Inst., London, England.

Infants who subsequently die of the sudden infant death syndrome (SIDS) are subtly different from other infants on a variety of physiological measures including heart rate, heart rate variation, and the coordination of cardiac and respiratory systems. The frequency of respiratory pauses has been shown to be altered in infants at risk for SIDS but not in infants who succumbed to the syndrome. In this study, we assess the frequency of apneas during quiet sleep and rapid eye movement sleep in control infants and infants who subsequently died of SIDS. Sleep states were identified in 12-hr physiological recordings of SIDS victims and matched control infants. The number of respiratory pauses > 4 sec was computed for each state. SIDS victims over 1 mo of age showed significantly fewer pauses than did age-matched controls. Short respiratory pauses (< 7 sec) accounted for most of the reduction in the SIDS victims during both states. During the first month of life, the frequency of respiratory pauses in SIDS victims was comparable to that of controls. The finding that this respiratory difference exists during the second month of life, just before the period of maximal risk for SIDS, but not earlier, may have implications for the etiology of SIDS

NEURAL PATHWAY MEDIATING VASOPRESSIN (AVP) RELEASE FOLLOWING SPLANCHNIC OSMORECEPTOR ACTIVATION. M.S. King* and A.J. Baertschi, Neuroscience Prog., Univ. of Virginia, Charlottesville, VA 22908.

To determine the central neural pathway by which splanchnic osmoreceptors stimulate AVP release, bilateral electrolytic lesions of selected brain areas were performed 6 days prior to gastric infusion of hypertonic saline through a naso-gastric tube in conscious rats (598 mOsm/kg, 2ml/4min). The most effective lesions were located in the locus sub-coeruleus (sub-LC), approximately 1 mm below the locus coeruleus. Bilateral sub-LC lesions (n=9) attenuated the AVP response to hypertonic gastric infusion by 61.6% (p<.05), as compared to sham-lesioned Bilateral lesions of the locus coeruleus (n=4), periaqueductal gray (n=5) and lateral parabrachial nuclei (n=5) were ineffective. Lesions of the median preoptic area (n=7)nonsignificantly decreased the AVP response by a maximum of 38.0%, suggesting that this area may play a minor role in this response. The sub-LC lesions interrupted a catecholaminergic pathway, as indicated by diminished DBH immunostaining in the SON and PVN following the lesion. This suggests that a catecholaminergic pathway, which traverses the sub-LC area, is necessary for the stimulation of AVP release following activation of splanchnic osmoreceptors. [Supported by NSF BNS-8819877].

EFFECTS OF GASTRIC VAGAL FIBER STIMULATION ON SINGLE NEURONS IN NUCLEUS ACCUMBENS IN THE CAT. C.S. Yuan* and W.D. Barber. Dept. of Anatomy, College of Medicine, Univ. of Arizona, Tucson, AZ 85724.

It has been suggested that the nucleus accumbens (NA) may serve as a functional interface between the limbic and motor systems (FASEB J., 4:A977, 1990). We conducted studies on anesthetized cats to evaluate 4.7377, 1990). We conducted studies on anestherized cars to evaluate gastric vagal input to NA. Unitary responses were recorded extracellularly in NA during electrical stimulation of gastric vagal branches serving the proximal stomach. The nerves were stimulated with a paired-pulse (10 msec interval), 0.3 msec in duration, 300 µA at a frequency pulse (10 msec interval), 0.3 msec in duration, 300 μA at a frequency of 0.5 Hz. In some experiments, the left greater splanchnic nerve was also stimulated. A total of 102 orthodromic gastric vagally-evoked unitary responses were recorded bilaterally from the NA. The mean latency of the unitary discharges in NA was 395 ± 44.3 msec (range 296-525 msec), while the mean latency in the medial and lateral hypothalamic gastric vagally-evoked unitary responses, recorded in our previous experiments, was 370 msec. Eighty eight units (87%) showed phasic responses while 14 tonic discharges (13%) had excitatory or inhibitory responses to gastric vagal input. Spontaneously discharging neurons recorded in NA were fewer in number than recorded in the hypothalamus. Convergent imput between gastric vagal and greater splant. hypothalamus. Convergent input between gastric vagal and greater splanchnic fibers upon single accumbens neurons was also observed. Our present data demonstrated that NA also receives visceral input from the proximal stomach. The gastric vagally-evoked unitary responses and convergent input from the splanchnic fibers suggested that the NA may play a role in integration of gastric signals concerned with the ingestive process. (Supported by USPHS Grants DK 36289 and DK 35434).

269.10

MODULATION OF RESPIRATION BY NEURONS OF THE CENTRAL NUCLEUS OF THE AMYGDALA DURING BEHAVIORAL AROUSAL. C.A. Richard. S.L. Raetz and R.M. Harper. Brain Research Institute and Department of Anatomy & Cell Biology, UCLA School of Medicine, Los Acceden Co. 000024 Angeles, CA 90024.

The central nucleus of the amygdala (ACE) plays a role in the behavioral expression of arousal, attention and defensive reactions. Coincident with natural or ACE-induced arousal and attention to the environment are respiratory changes, e.g. apneusis and/or tachypnea. Single-pulse stimulation of the ACE results in respiratory pacing, a phenomenon confined to the aroused state. We hypothesized that a subpopulation of ACE neurons should respond to environmental stimuli and also exhibit discharge patterns related to respiration. Bundles of 65µ microwires were placed in the ACE, and EMG leads were placed in the diaphragm of three cats under pentobarbital anesthesia. After at least 1 week of recovery, recordings were performed during the presentation of exteroceptive stimuli, e.g. taps or knocks on the recording box, hand claps, light flashes or dimming of ambient light. Single unit activity was quantified for 5 see before and after the stimuli. Respiratory relationships were assessed by linear regression of firing rate vs. total cycle time and cross-correlation analysis during epochs of 60-240 sec containing several stimuli. Fourteen cells were recorded, with 8 cells showing consistent increases in firing rate and 2 cells showing consistent decreases in discharge rate. Of these 10 cells, 7 were related to respiratory patterning. We suggest that a subset of ACE neurons that are modulated by arousal mechanisms contribute to the respiratory changes accompanying arousal. Supported by HL-22418-13.

IS XENOPUS RETINAL MELATONIN-DEACETYLATING ARYL ACYL-AMIDASE RELATED TO CHOLINESTERASES? Michael S. Grace and Joseph C. Besharse, Depts. of Anatomy and Cell Biology, Univ. of Kansas Med. Ctr., Kansas City KS, and Emory Univ. Sch. of Med., Atlanta GA.

Melatonin is deacetylated to produce 5-methoxytryptamine (5MT) in the retina of Xenopus laevis and in the eyes of other non-mammalian vertebrates by an aryl acylamidase (AAA)-like enzyme. This pathway appears to be the sole clearance mechanism for melatonin in the Xenopus retina. Previous reports have shown that mammalian AAA and acetylcholinesterase (AChE) activities are inseparable. We are therefore studying the relationship between cholinesterases and the Xenopus retinal melatonin deacetylase. Melatonin deacetylase activity occurs in retina, pigment epithelium/choroid and pigmented skin, all of which are affected by melatonin, but is absent in brain, blood, muscle and liver. Whereas acetylcholinesterase exists in both membrane-associated and soluble forms, retinal melatonindeacetylating activity requires detergent (0.5% Triton X-100 or 30mM octylthioglucoside) for solubilization. The AChE inhibitor eserine (physostigmine) at 100µM inhibits the the *Xenopus* melatonin deacetylase by approximately 75%, but 1mM acetylcholine (ACh) has no effect. Melatonin, 5MT and N-acetylserotonin inhibit ³H-melatonin deacetylation in a dose-dependant manner. Butyrylcholinesterase and AChEs from bovine erythrocytes and electric eel hydrolyze ACh, but fail to generate 5MT from melatonin. These results suggest that the melatonin deacetylase and cholinesterase activities are not associated. Support: NIH grant EY02414 and a Sigma Xi Grant-in-Aid of Research

NMDA RECEPTOR ANTAGONISTS BLOCK THE EFFECTS OF LIGHT ON CIRCADIAN BEHAVIOR IN THE MOUSE. C.S. Colwell, R. Foster. and M. Menaker. Department of Biology, University of Virginia, Charlottesville, VA 22901.

We report here the results of experiments designed to evaluate whether specific NMDA receptor antagonists, (+)-5-Methyl-10,11-dihydro-5H-dibenzo[a,b]cyclohepten-5,10-imine maleate (MK-801) and 3(2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid (CPP), block the phase shifting effects of light on the circadian rhythm of wheel-running activity in mice. Intraperitoneal administration of (+)MK-801 as well as CPP produced a dose dependent blockade of both light-induced phase advances and delays. Neither drug, by itself, caused any consistent effect on the phase of the rhythm. These data, coupled with previous findings, indicate that excitatory amino acid receptors play an important role in the transmission of light information from the retina to the circadian system.

270.5

THE EFFECTS OF TEMPERATURE ON THE CIRCADIAN OCULAR RHYTHM OF BULLA GOULDIANA. B.L. Bogart, G.D. Block. Biology Dept., University Of Virginia, Charlottesville, VA. 22901.

The free-running period of all circadian rhythms remains constant over a wide range of temperatures. This phenomenon is referred to as temperature compensation. The cellular mechanisms subserving temperature compensation are not yet understood.

We have recently begun studying the temperature dependency of the Bulla ocular pacemaker system with the goal of ultimately understanding the cellular basis of temperature compensation. The free-running period of the ocular pacemaker was found to be temperature compensated over a wide range of temperatures 12°C-25°C (Q10=1.02). The mean free-running periods were: 12°C (23.6 hrs. ±0.5 95% C.I.), 15°C (24.1±0.2), 22°C (23.8±0.3), and 25°C (23.6±0.6).

We also assessed the temperature sensitivity of the light entrainment pathway by measuring the phase angle of entrainment of eyes from animals maintained on L:D 12:12 at 12°C, 15°C, 22°C, or 25°C. We found no statistical difference in the phase angle for entrainment of eyes maintained at 12°C (ψ =-0.8 hr.), 15°C (ψ =+0.1), or 22°C (ψ =-0.5). The phase angle of eyes maintained at 25°C was highly variable and may reflect deterioration of Bulla maintained at high temperatures.

Taken together, these results indicate that the phase angle for entrainment is stable, suggesting that the entrainment pathway is relatively unaffected by ambient temperature. NS15264 to GDB.

DOPAMINE ACTS THROUGH D2 RECEPTORS TO MIMIC LIGHT IN PHASE-SHIFTING THE CIRCADIAN CLOCK IN THE RETINA OF *XENOPUS*. <u>G.M.</u> <u>Cahill and J.C. Besharse</u>. Department of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS 66103.

Melatonin synthesis in the retina of the frog, Xenopus laevis, is regulated by a retinal circadian oscillator. We have used a superfusion culture system to monitor rhythmicity of melatonin overflow from individual eyecups in experiments designed to identify input pathways of the circadian oscillator. The results indicate that D2 dopamine receptors are part of such an input pathway. The D2 receptor agonist quinpirole (100 nM) suppresses melatonin production and causes phase-dependent phase shifts of the melatonin rhythm that are similar to those produced by light. Specific receptor agonists and antagonists were tested for effects on the oscillator during the early subjective night, when light and quinpirole cause phase delays. Six-hour pulses of dopamine (0.1-1.0 µM) and quinpirole (10-100 nM) suppressed melatonin production and caused phase delays of 1.5-5.5 hr, but the D1 agonist SKF-38393 had no effect at 1 μM . The adrenergic agonists D1 agonist SKT-38393 nao no effect at 1 μm. The adrenergic agonists phenylephrine (α1), clonidine (α2) and isoproterenol (β), also had no effect at 1 μM. The ~3 hr phase delay caused by 500 nM dopamine was completely blocked by the D2 antagonist eticlopride (50 μM), but was not affected by the D1 antagonist SCH-23390 (100 μM). These data, together with the finding that dopamine release in *Xenopus* retina is increased by light (Boatright et al., 1989, Brain Res. 482:164), suggest that retinal dopamine may act through D2 receptors as part of the light signal for entrainment of the retinal circadian clock.

THE INTERACTION OF AGING AND CHRONIC LITHIUM TREATMENT ON MALE RAT ACTIVITY RHYTHMS. <u>D.L. McEachron and N.T. Adler.</u> Dept. of Psychology, Univ. of Pennsylvania, Philadelphia, PA 19104

Twenty-four male Sprague-Dawley rats were used in this crossover study to assess the effects of chronic lithium treatment on circadian wheel-

Twenty-four male Sprague-Dawley rats were used in this crossover study to assess the effects of chronic lithium treatment on circadian wheel-running rhythms. Rats were placed into individual cages in environmentally-controlled cabinets and initially exposed to a 12/12 light/dark cycle for 3 weeks and then to constant dim red light. The first 4 weeks were used to obtain baseline estimates of circadian period (tau). For Phase I, 12 rats were fed a lithium containing diet beginning with 7 days of 0.075% lithium carbonate (Li) followed by 7 days of 0.15% Li and then 0.3% Li for 8 weeks. Li diets contained 2.1% KCL as a buffer against Li's toxic side-effects, so that 1/2 of the remaining rats received a diet containing 2.1% KCL while the other 6 were fed normal Purina Rat Chow. At the end of Phase I, all rats received normal Rat Chow for 3 weeks. Phase II consisted of a complete crossover of the diets and lasted for 13 weeks. Although lithium treatment during Phase I lengthened tau values (a mean increase of 0.27 hrs vs. 0.09 hrs for KCL-fed rats and 0.12 for rats on the normal diet), this effect was not seen during Phase II (a mean increase of 0.11 hrs for Li-fed rats vs. 0.12 hrs for KCL-fed rats during Phase I and 2 of 12 rats during Phase I displayed such severe disruption of normal rhythmicity that no tau values could be obtained. This disruption ceased within 2-3 days after removal from the Li diet and was not observed in rats fed the KCL or normal diets. We conclude: 1. Lithium treatment may disrupt rather than lengthen rhythms; and 2. Age or length of time in the cages reduces lithium's efficacy in altering activity rhythms.

270.6

LOW pH AND PROTEIN SYNTHESIS INHIBITORS APPARENTLY STOP THE MOTION OF A NEURONAL CIRCADIAN PACEMAKER S.B.S. Khalsa and G.D. Block. Department of Biology, University of Virginia, Charlottesville, VA 22901 Supported by N509621 & NS15264

Retinal cells in the eye of the mollusc Bulla act as a competent in vitro circadian pacemaker. With extracellular pH at 6.9 (normally 7.8) the eyes become arrhythmic and express only a low constant frequency of impulse activity, suggesting that the pacemaker may have stopped. To evaluate this possibility, extracellular pH was lowered to 6.8 starting at CT 13 and then restored at progressively later times in 3 hour increments to separate eyes for up to 47 hrs. For pulse lengths up to 11 hr (CT 0), subsequent phases of the restored rhythms were related to the projected dawn of the previous LD cycle as for untreated control eyes. However, for longer pulses, phase was strictly a function of the end of the pulse, supporting the hypothesis that the pacemaker was stopped around subjective dawn during the treatment.

The transcriptional inhibitor dichlororibofuranosylbenzimidazole (DRB) and the translation inhibitor cycloheximide (CHX) greatly lengthen period at low concentrations (36 hr, 20µM DRB; 31 hr, 3mM CHX), suggesting that pacemaker motion may be stopped at higher concentrations. Using the same experimental paradigm as for low pH above, both DRB (100µM) and CHX (10mM) yielded data similar to that for the low pH treatments, including the critical phase specificity around subjective dawn. These data suggest that protein synthesis is also a phase specific requirement for pacemaker motion.

Although it is possible that these treatments reset the pacemaker to CT 0, rather than block its motion, at least in the case of DRB and CHX, the period lengthening argues that the pacemaker is stopped. The relationship, if any, between low intracellular pH and protein synthesis inhibition is uncertain. Their similarity in action raises the possibility that both may converge on the same dawn sensitive variable or process of the pacemaker.

REDUCED LIGHT SENSITIVITY OF THE CIRCADIAN CLOCK IN A HYPOPIGMENTED MOUSE MUTANT. M. M. Hotz, L. H. Pinto, and F. W. Turek. Dept. Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Hypopigmentation and albinism are known to affect

Hypopigmentation and albinism are known to affect visual pathways. Since the effects of these mutations on light information reaching the circadian clock is not known, we studied clock responses to light in C57BL/6J mice (+/+) and in C57BL/6J (p/p). Mice kept in constant darkness were given a series of four light pulses at three week intervals and the resulting phase shifts in the activity rhythm were measured. No differences in response to one hr white light at CT 16 (circadian time; CT 12 = activity onset) or at CT 0 were found, indicating that maximal clock resetting is not altered. However, five min 502 nm light pulses at CT 16 using light levels near the expected $\frac{1}{2}$ saturation resulted in significantly different phase shifts (p<.02). At $1x10^{1}$ photons/cm²/sec, the p/p mice had a mean phase shift of $1.27~\rm hr$. Upon transfer to constant light the period of +/+ mice was lengthened to a greater extent than that of p/p mice(p<.01). Preliminary data from $^{3}\rm H$ Proline tracing of retinal projections to the hypothalamic suprachiasmatic nucleus indicates that there is a reduced retinal innervation of this clock-containing area. This reduced innervation may underlie the decreased sensitivity of the circadian clock of p/p mice to light.

ANDROGENIZATION OF FEMALE SLEEP-CYCLE RHYTHMICITY BY PERINATAL INJECTION OF TESTOSTERONE (I). <u>H. Fishbein, J. Fang, S.H. Yang and S.J. Tien.</u> Neurocognition Program, CUNY, City College & Graduate School, N.Y. 10031

We previously reported that sleep-cyclicity is sexually dimorphic in mice (SN, 1987). In addition, we showed that prenatal stress completely sex-reverses the sleep pattern of males, but not females (SN, 1987). Sleep-cyclicity is also sexually dimorphic in rats (SN, 1988). In both species the sex-linked difference in sleep is due primarily to the frequency of paradoxical sleep (PS) bouts; it appears that the normal biological timing clock controlling the interval between PS episodes runs at a different speed in males than females. As a result the total amount of PS/24 hrs. is substantially different between the seres

Prenatal stress produces a reduction in fetal testicular enzyme activity with an attending reduction in plasma levels of testosterone (Ward, Psychoneuroendocrin, 1984). Since testosterone might be the catalyst of the sex difference, we undertook the present experiment to determine whether female sleep-cyclicity is subject to androgenization by perinatal injection of testosterone (1,000ug/50ul/animal injected <24 hours after birth).

The baseline data replicates our previous observation; namely, control (safflower oil, 50ul) injected male rats exhibit more PS bouts than control females. Perinatal testosterone loading in males had no effect, whereas perinatal testosterone injected females display significantly more PS bouts than control females. The sleep-cyclicity of testosterone injected females was indistinguishable from the vehicle and testosterone loaded males.

The results provide strong evidence that organization of the PS-Slow Wave Sleep cycle is genetically programmed, yet remains susceptible to modification by male gonadal steriods up to the time of birth.

270.11

MATERNAL ENTRAINMENT OF HAMSTERS WITH MUTANT CIRCADIAN CLOCK. N.Viswanathan and F.C.Davis. Department of Biology, Northeastern University., Boston, MA 02115.

of Biology , Northeastern University., Boston, MA 02115. In mammals, a circadian pacemaker begins to function prenatally and is entrained by the rhythms of the mother. Rodents exhibit circadian rhythms of wheel-running activity even on the day of weaning (~3-4 wks postnatal) and the phases of such rhythms are similar to those of their mother's. The present study examined the maternal entrainment of hamster pups heterozygous for the τ mutation (freerunning period ~ 22 hr). Pups were born to wildtype females (~24 hr) that had been mated to homozygous males (~20 hr). Pups from each litter were weaned on postnatal days 18 and 24 and rhythms were measured in constant dim light. The freerunning period of the τ mutation was fully expressed even at weaning. Unlike results with wildtype pups, the phases of their mothers, and pups left with the mother were clearly freerunning between days 18 and 24. However, pups within a litter as well as pups in different litters were synchronized among themselves, suggesting that they had entrained to a common signal sometime earlier in development. The results indicate that: 1. the signal, most probably maternal, is a strong entraining agent; despite the period difference between mothers and pups (24 vs. 22 hrs), the pups were entrained during development, and 2. the pups began freerunning at about the same time in development, therwise synchrony among the pups would not have been observed at weaning. Supported by NIH grant HD 18686 to FCD.

HIGH AFFINITY MELATONIN BINDING SITES IN THE DJUNGARIAN HAMSTER FETUS. Scott A. Rivkees, David R. Weaver, Steven M. Reppert. Laboratory of Developmental Chronobiology, Massachusetts General Hosp. Boston, MA 02114

Maternal melatonin readily crosses the placenta communicating time-of-day and daylength information to the fetus. To determine if melatonin may have a more widespread role during fetal development than presently recognized, we examined the distribution of high affinity melatonia binding sites in Djungarian hamster fetuses. Using [1]-2-iodomelatonin, a potent melatonin agonist, melatonin binding sites were examined at different gestational ages in whole hamster fetuses by in vitro autoradiography (total gestation length ca. 16-18 days; [125I]-2-iodomelatonin = 30 pM). At gestational day (GD) 5 (embryo size = 1.6 mm), specific binding was not detectable. At GD 8 (crown-rump length = 6 mm), specific binding was present in the nasal mucosa, the Harderian gland and the fetal adrenal region. At GD 12 and 16 (crown-rump length = 16 and 23 mm, respectively), specific binding was not observed in the the adrenal region, but was present in the nasal mucosa and Harderian gland. At GD 12, specific binding was also detectable in the suprachiasmatic nuclei, pineal and pituitary glands. The presence of melatonin binding sites at very early stages of development in neural and non-neural structures, suggests that melatonin may have a greater role during fetal development.

270.10

ANDROGENIZATION OF FEMALE SLEEP-CYCLE RHYTHMICITY BY PERINATAL OVARIECTOMY
(II). J. Fang, S.W. Yang S.J. Tien, and W. Fishbein. Neurocognition Program,
CUNY, City College & Graduate School, N.Y. 10031

We previously showed that sleep-cyclicity is sexually dimorphic in both mice and rats (SN, 1987, 1988). Yet one puzzling aspect of our findings is that the direction of the sex difference is just the opposite; namely, female mice have more paradoxical sleep (PS) than males, whereas male rats have more PS than females. Our previous studies employing prenatal stress in male mice (producing feminization; SN, 1987) and perinatal testosterone loading in female rats (producing masculinization; see joint abstract, Fishbein, et al.), suggests that the genetic organization of sleep-cyclicity is essentially modulated by male gonadal steroids.

However, another interpretation of these findings is that the sexual dimorphism is related to estrogen feminizing, rather than testosterone masculinizing influences. We therefore undertook the present experiment to determine whether perinatal castration (<24 hrs after birth) - orchidectomy (testosterone deficient males) or ovariectomy (estrogen deficient females) - produces alterations in sleep-cyclicity.

The baseline data replicates our previous observation; non-castrated (control) male rats exhibit more PS bouts than non-spayed (control) females. Perinatal castration of the males had no effect; the orchidectomized males were indistinguishable from the control males, whereas the spayed females display significantly more PS bouts that control females. Indeed, the ovariectomized females were indistinguishable from control and castrated males.

Taken together with our accompanying testosterone study, the results indicate that organization of the PS-Slow Wave Sleep cycle in females can be androgenized by perinatal ovariectomy (as well as by perinatal testosterone loading). The findings suggest that estrogen may also participate in the organization of sleep-cyclicity.

270.12

SPECTRAL SENSITIVITY OF THE EFFECTS OF LIGHT ON THE OSCILLATION OF MELATONIN RELEASE FROM CHICK PINEAL CELLS. L.M. Robertson and J.S. Takahashi. Dept. of Neurobiology and Physiology, Northwestern U., Evanston, IL 60208.

Chick pineal cells exhibit a circadian oscillation of melatonin release. The cells

are photoreceptive and light has two major effects: 1) acute inhibition of melatonin release and 2) entrainment of the circadian oscillator. There are striking homologies between retinal photoreceptor cells and pineal cells. Deguchi (Nature 290:706, 1981) has shown that the acute response is mediated by a rhodopsin-like photopigment. However, previous studies have indicated that some of the cellular processes involved in retinal phototransduction are involved in the acute but not the phase-shifting effect of light. Thus, it becomes of primary importance to characterize the photoreceptors mediating entrainment and to determine whether they are different from those mediating the acute response to light. In order to characterize the photoreceptors and photopigments involved, we measured the spectral sensitivity of both responses. We utilized a flow-through cell culture system in which cells were grown in monolayer cultures on multi-well cell culture plates. A fiberoptic system underneath the plates provided the photic stimulus. Interference filters were used to provide monochromatic light and neutral density filters were used to adjust the irradiance. Cells were exposed to wavelengths of 450, 500, 550 and 600 nm at various levels of irradiance for 6 hours during the subjective night of the second cycle in constant darkness. Both the acute and phase-shifting responses increased in magnitude with an increase in irradiance at each wavelength. The maximal sensitivity for both effects was achieved with wavelengths of 450-500 nm. The sensitivity functions were similar to the Dartnall nomogram for a retinalbased photopigment with a maximum at 500 nm. Therefore, these results are consistent with the hypothesis that a visual pigment with a λ_{max} near 500 nm mediates the acute and phase-shifting effects of light on chick pineal cells.

LIGHT INTENSITY-RESPONSE (I-R) FUNCTIONS OF INTERGENICULATE LEAFLET (IGL) NEURONS IN THE GOLDEN HAMSTER AND THE EFFECTS OF CHRONIC CLORGYLINE. M.E. Harrington and B. Rusak. Dept. of Psychology, Smith College, Northampton, MA 01063 USA and Dept. of Psychology, Dalhousi University, Halifax, NS B3H 4J1 Canada.

Chronic administration of the antidepressant compound clorgyline, an irreversible type A monoamine oxidase inhibitor, alters the I-R curve for phase advance shifts of hamster circadian rhythms (Soc. Nsci. Abstr., 14:907, 1988). Ablation of the IGL also alters light-induced advance shifts. We examined whether the responses of IGL cells to changes in illumination were altered by chronic clorgyline treatment.

25 adult male hamsters were housed under a 14:10 h light:dark cycle. 18 hamsters were implanted with osmotic mini-pumps (Alzet, Model 2002) filled with either clorgyline (n = 12; 2 mg/kg/day) or vehicle (n = 6; 0.9% saline) three weeks before electrophysiological recording. Responses of single IGL cells to diffuse retinal illumination were recorded using previously published techniques (Vis. Nsci., 2:367-375, 1989). Cells showing sustained responses to illumination were recorded for 20 min of darkness, followed by an 8 min presentation of increasing light intensity (0.8 to 1000 uW/cm²), 10 min of the highest light intensity, and 8 min of decreasing light intensity. Small lesions were placed to mark the locations of cells.

IGL cells from control and clorgyline-treated animals (n=14 in each group) showed both monotonic and non-monotonic I-R functions with a large range of thresholds. The only clear difference between the groups was that IGL cells from clorgyline-treated

animals showed lower firing rates during both light and dark conditions.

These results indicate that IGL cells show a wide variation in I-R functions. Clorgyline-induced alterations in I-R curves for phase-shifting are not reflected in obvious changes in I-R functions for individual IGL cells. A general reduction in firing rates of IGL cells, perhaps resulting from altered serotonergic influence on these cells, may affect the size of light-induced phase shifts after chronic clorgyline treatment.

EVIDENCE FOR SEROTONERGIC REGULATION OF THE HAMSTER CIRCADIAN RHYTHM SYSTEM. L.P. Morin, J.Blanchard. Dept. Psychiatry, Health Sci. Center, SUNY, Stony Brook, NY 11794.

The densest innervation of the SCN, other than that from the retina, is serotonergic. The present work demonstrates that rhythmicity of adult male hamsters housed under constant light (LL) is markedly altered following depletion of brain serotonin.

Animals were initially housed in LD 14:10. While under this lighting condition, each was administered 5,7-dihydroxytryptamine (DHT) intraventricularly to deplete brain serotonin or given a sham procedure (CON). Surgical and histological methods were the same as described in Smale et al. (Brain Res. '90, 515, 9-19). Following recovery for about 18 days, all animals were placed in constant light (LL) conditions.

Behavior of DHT animals under LD was the same as described by Smale et al. with activity onset occurring before lights off and activity offsets occurring during the late night. LL suppressed the daily number of wheel revolutions of CON, but not DHT, animals. LL quickly lengthened tau of DHT animals (24.43 \pm .04 vs 24.19 \pm .05, p<.001). In addition, 65% of DHT animals had rhythm splitting or desynchrony within 30 days of LL vs 0% of CON (p<.01). The results support the view that serotonin may regulate circadian rhythm stability, particularly rhythm "splitting," under LL conditions. Supported by NINDS NS22168.

DIFFERENTIATION, MORPHOGENESIS AND DEVELOPMENT: MOLECULAR CORRELATES

THE B30 GANGLIOSIDE IS A SPECIFIC MARKER FOR NEURAL CREST DERIVED NEURONS IN THE DEVELOPING MOUSE. D.Y.R. Stainier*, <u>D.H. Bilder*</u>, and <u>W. Gilbert</u>. Cellular and Developmental Biology, Harvard Univ., Cambridge, MA 02138 We have previously reported (J. Neurosci. 9, 2468-85) the

we have previously reported (3. Neurosci. 9, 2408-3) to isolation of a monoclonal antibody, mAb B30, that recognizes a rare ganglioside specifically expressed on a small subset of neurons -including the mesencephalic trigeminal nucleus (MesV)- in the developing mouse CNS. this study, we have characterized the B3O immunoreactivity in the developing PNS. We report that B3O is a specific marker for neural crest derived neurons. Consequently, we used B30 to follow the neuronal differentiation of neural crest cells in a serum-free chemically defined culture system. Within hours, neural crest cells migrate away from neural tube explant on a fibronectin substrate; by 24 hours, up to 15% of them have differentiated into morphologically identifiable neurons. While both undifferentiated and differentiated crest cells express the GD3 ganglioside recognized by our mAb B33, B30 specifically stains the neural crest derived neurons, reflecting the $\underline{\text{in}}$ $\underline{\text{vivo}}$ situation. The demonstration that the B30 ganglioside is a marker for neural crest derived neurons provides the first biochemical evidence for the neural crest origin of the centrally located MesV neurons. We also show the unique biochemical specificity of mAb B30 and provide experimental evidence for the role of the B30 ganglioside in the cellular adhesion process.

ZEBRIN II AND O-ACETYL GD3 DIVIDE ALL CEREBELLAR PURKINJE CELLS INTO TWO DISTINCT COMPLEMENTARY SETS. N. Leclerc, K. Herrup, R. B. Hawkes, G. Schwarting and

M. Yamamoto. Dept. of Dev. Neurobiology and Biochemistry, E. K. Shriver Center, 200 Trapelo Rd, Waltham MA 02254. Increasingly, use of molecular markers has revealed heterogeneity among cerebellar Purkinje cells. One such marker is a monoclonal antibody against a 36 kD polypeptide, Zebrin II (ZII). The pattern of ZII staining defines a series of 7 parasagittal bands in each hemi-cerebellum. This pattern is perfectly congruent with the discontinuous topography of the olivocere bellar projection as well as with the histochemical zonation of 5'-nucleotidase, AChE and cytochrome oxidase enzymes

O-acetyl GD3 is a ganglioside expressed on the plasma membrane of embryonic brain cells. Recently, an antibody directed against O-acetyl GD3 has been shown to stain adult rat Purkinje cells (Mendez-Otero et al. J. Neurosci.8: 564, 1988). Using an anti-O-acetyl GD3 monoclonal antibody called P-Path, we find that the antigen is expressed by a subset of Purkinje cells, organized in parasagittal bands. This antigenic pattern is precisely complementary to ZII. All P-Path-positive Purkinje cells are ZII-negative and vice versa. Neurological mutants that interfere with Purkinje cell placement (reeler and weaver) will be used to determine whether the binary ZII/P-path segregation is susceptible to experimental manipulation.

CARBOHYDRATE BINDING PROTEINS IN EMBRYONIC SPINAL CORD AND RRAIN. W. Niforatos*, M.G. Hvizd*, K.L. Knepper*, R.G. Higbee, S. Nakahara*, D.G. McLone and P.A. Knepper. Division of Neurosurgery, Children's Memorial Hospital and Northwestern University Medical School, Chicago, IL 60614. Embryonic and differentiating tissues of vertebrates

contain carbohydrate binding proteins (CBP), i.e. endogenous lectins, that agglutinate trypsinized and fixed rabbit erythrocytes. Developmental studies on the changing distribution pattern of spinal cord-specific oligosaccharides have opened the possibility that there are CBPs specific for each oligosaccharide. In this study, embryonic cerebrum, cerebellum, spinal cord, heart and lung of gestation day 18 C-57 BL/6J mice embryos were microdissected, the CBPs were extracted by homogenization with 9 volumes of MEPBS containing 0.3M lactose and centrifuged at 100,000 x g for lh. The supernatant was concentrated in Centricon-10 tubes to remove the lactose and fractionated on an HPLC size exclusion column. Each fraction was monitored using trypsinized and fixed rabbit erythrocytes and by polyacrylamide gel electrophoresis. The results to date indicate the presence of several CBPs with varying molecular weights and that the agglutination was most active in heart, although agglutination was observed in all tissues. Studies are in progress to determine the saccharide specificities and agglutination of CBPs in earlier spinal cord development.

MONOCLONAL ANTIBODIES AGAINST CELL NUCLEI: EXPRESSION IN MOUSE CEREBELLUM, MUTANTS, AND TISSUE CULTURE. A.M. Smith. C. R. Buck and R. J. Mullen. Dept. of Anatomy, University of Utah

MOUSE: CEREBELLUM, MOTANTS, AND TISSUE CULTURE. A.M., Smith. C. R. Buck and R. J. Mullen. Dept. of Anatomy, University of Utah Sch. of Med., Salt Lake City, UT 84132.

We have generated three MAbs which are useful markers to study the development of the murine nervous system. Two of these MAbs (F41 and A18) stain the cell nuclei of neurons throughout the nervous system and the third (A61) stains both neurons and glia. MAb F41, an IgG1, intensely stains mature granule cells in the cerebellum. However, at postnatal day 10 (P10) the cognate antigen is not detected in the external granular layer (EGL) nor in migrating granule cells. At P10 the cell nuclei of Golgi type II neurons are intensely stained by F41, but Purkinje cells are just beginning to show immunoreactivity. In the cerebellar mutant weaver (wv), whose Purkinje cells are relatively normal, the antigen is detected. Whereas in staggerer (sg), where the defect has been shown to be in Purkinje cells, the antigen for F41 is not detected in the Purkinje cells. In the cerebellum at P10, A18 appears to stain just the cytoplasm of granule cells in the EGL and the Purkinje cells, while the Golgi type II neurons show intense nuclear stainings. Later all three cell types show intense nuclear immunoreactivity. A18 is similar to F41 in that it stains the nuclei of ww/ww Purkinje cells but not those of sg/sg. MAb A61, an IgA, stains all cell types in the cerebellum including some glia, The immunoreactivity of the cognate antigen is sensitive to the type of fixative used with staining being either nuclear or dendritic, or both. A comparative study of the developmental expression of these three antigens will be presented and compared with A60, a previously reported antigen (Mullen, et al, Soc. Neurosci. Abstr:15:499, 1989). In addition, an immunohistochemical study of primary cerebellar cerebellar cultures and P19 reported anglet (witner), et al., 50c. Neurosci. Abstr.13-499, 1993. In adunton, an immunohistochemical study of primary cerebellar cerebellar cultures and P19 embryonal carcinoma cells stimulated with retinoic acid will be presented. Immunoblot analysis has been performed for all three MAbs and recently we have isolated at least one cDNA clone for one of these antigens from a gt11 expression library. (Supported by NIH Grant EY07017).

REGULATION OF SERPINS DURING MOUSE BRAIN DEVELOPMENT Jasti S. Rao, Riichiro Suzuki, Bokka R. Reddy and Barry W. Festoff, Department of Neurology, University of Kansas Medical Center, Kansas City, KS 66103, and Neurobiology (151), DVA Medical Center, Kansas City, MO. 64128.

Serpins inhibit the activity of several serine proteases including thrombin, trypsin and the plasminogen activators (PAS). Protease nexin I (PNI) and PA inhibitors 1,2 and 3 (PAI-1, 2 and 3) are all potential physiological inhibitors and play important roles in the development of tissues as well as in various pathological states. We report both qualitative and quantitative changes in PNI and PAI-1 serpins during mouse brain development. Cerebellum and cerebral hemispheres at embryonic day 14 and up to postnatal day 40 were studied by complex formation with labeled 1251-urokinase with and without SDS. Results indicated developmental regulation of active serpins. PNI was detected in embryonic brain maximally at birth and decreased thereafter. PAI-1 had essentially the same kinetics but was present at lower levels at birth. No regional differences were detected with these methods despite the known developmental differences between cerebellum and cerebral hemispheres in the mouse. These studies suggest regulatory roles for PNI and PAI-1 during brain development.

SPECIFIC EXPRESSION OF THE GAMMA ISOFORM OF PROTEIN KINASE C IN DEVELOPING FIBER TRACTS AND DISCRETE STEM CELL POPULATIONS OF THE BRAIN. R.Ferri and P.Levitt. Dept. of Anatomy. Med Coll of PA, Philadelphia, PA 19129.

The expression of protein kinase c (PKCy) was examined in the developing CNS of the fetal rat using immunocytochemical analysis employing a polyclonal antibody directed against the gamma isoform. At embryonic day 12 (E12), PKCy expression was very low throughout all areas of the brain. The first appearance of an increased expression in the prosencephalon was at E14 in developing fiber tracts, including the internal capsule and fasciculus retroflexus. The distribution in fiber tracts increases at later ages to include the corpus callosum, fornix, and anterior commissure. In addition to growing axons, PKCy immunoreactivity was seen in cell groups within the ventricular zone along the lateral and third ventricles and in adjacent migratory regions. At E16, the forebrain contained PKCy-stained cells in discrete foci in the ventricular and intermediate zones that give rise to the hippocampus, perirhinal and piriform cortex. This remained prominent at E18. In the diencephalon, discrete subpopulations of PKCy immunoreactive stem cells were distributed dorsal and ventral to the medial sulcus of His, giving rise to cells of the dorsal thalamus and hypothalamus, respectively. The patherns of PKCy expression demonstrate a precise localization in developing fiber tracts, consistent with a role for this enzyme in neurite elongation. In addition, this enzyme is produced during periods of neurogenesis and may be an early marker of stem cell populations that will ultimately reside in specific anatomical regions of the brain. (Supported by NIMH Grant MH45507).

271.9

DIFFERENTIAL EXPRESSION OF THE THYMOSIN β10 GENE DURING RAT DEVELOPMENT. D.I. Lugo. J. Hempstead* and J.I. Morgan Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110

Nutley, NJ 07110
In previous studies the expression of the thymosin β10 gene has been shown to be developmentally regulated in the brain. In addition, the expression of this gene has been shown to be regulated by retinoic acid in a variety of neuroblastoma cell lines. Here we present a detailed analysis of the expression of thymosin β10 during rat fetal/neonatal development. Steady state levels of β10 mRNA were analyzed in different areas of the fetus/neonate by Northern blot analysis and the spatial localization of the mRNA was investigated by in-situ hybridization to tissue sections. In addition, changes in mRNA level were correlated to changes in β10 peptide levels by HPLC analysis of isolated tissues. The β10 gene is widely expressed at moderate levels throughout the embryo at E13. By E15, marked regional differences in expression are apparent. High abundance of thymosin β10 mRNA is present in the brain, spinal cord, lungs, heart and gonads, while the liver contains very low levels of this transcript. Uniquely in the brain, levels persist at high abundance through birth, whereafter they decrease to adult values by P24. In parallel studies utilizing the mouse embryonic carcinoma cell line P19, the expression of this gene has been shown to increase dramatically following differentiation into a neuronal phenotype. These studies demonstrate a tissue-specific regulation of thymosin β10 gene expression during development. The elucidation of the regulation of the thymosin β10 gene may provide critical leads into the mechanisms that shape neuroembryogenesis.

271.6

VARIATION OF CEREBELLAR INSULIN-LIKE GROWTH FACTOR II GENE EXPRESSION IN EARLY POSTNATAL DEVELOPMENT. K.M. Rosen, R.L. Mozell*, and L. Villa-Komaroff, Dept. Neurology, Children's Hospital, Harvard Medical School, Boston, MA 02115.

We have investigated IGF-II gene expression in early postnatal (P2-P12) mouse cerebellum to determine the levels of IGF-II mRNA in developing neurons and glia. Since earlier reports indicated high levels of expression in choroid plexus and meninges, these structures were removed prior to the analysis. Using a novel, dual S1 nuclease protection assay, we identified a peak of expression in P4 cerebellum. In granule cell precursors purified by Percoll gradient centrifugation, IGF-II mRNA levels were constant through P4 and then dropped precipitously, mirroring the decline in whole cerebellum. The yield of isolated glia was insufficient to allow definitive S1 analysis; therefore, we utilized reverse transcription followed by the polymerase chain reaction to detect IGF-II mRNA in these cells and to confirm its presence in granule cells. We detected mRNA in granule cells from all ages examined and verified the expression of IGF-II mRNA in isolated glia. One key feature of the developing postnatal cerebellum is the differentiation and migration of the granule cells. It is intriguing that the decline in IGF-II gene expression occurs just prior to the peak of granule cell migration and mitotic activity in the mouse, suggesting that IGF-II may be involved in the regulation of granule cell development.

271.8

PROMOTER ANALYSIS OF A NEURON-SPECIFIC GENE, PEP-19. L. Sangameswaran, R. Smeyne, R. Wurzburger and J. Morgan, Department of Neurosciences, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110

Biology, Roche Research Center, Nutley, NJ 07110
PEP-19 is a neuron-specific polypeptide that is distributed in defined areas of the rodent central nervous system. PEP-19 levels, (both mRNA and protein), increase dramatically during the late maturation of the CNS, the mRNA being detectable at least four days before the protein. Within the cerebellum, the peptide is localized predominantly in Purkinje neurons. Using PEP-19 cDNA as a probe, we have investigated possible mechanisms that might control the expression of PEP-19 mRNA in the cerebellum. Analysis of the mRNA levels in neurological mutant mice and in rats after chemical lesions indicate that neither the climbing fibers from the olivary nucleus nor the parallel fibers from the granule cells influence the triggering of the PEP-19 gene.

fibers from the granule cells influence the triggering of the PEP-19 gene.

To dissect out the regulatory elements that are responsible for the spatial and temporal expression of PEP-19 we have isolated genomic DNA clones from a mouse library. We are currently pursuing biochemical analysis of the 5' flanking region of PEP-19 gene to gain insight into specific DNA binding proteins. Comparative sequence analysis of the 5' flanking region of PEP-19 with L7, another Purkinje cell marker, revealed regions of homology. Using synthetic oligonucleotides for these regions, electrophoretic mobility shift assays are being performed. Such assays are also being done with larger DNA fragments from the 5' flank sequence. In addition, experiments where PEP-19 genomic regions fused with Lac Z have been used as constructs for transgenic mice will be discussed.

271.10

SINGLE-STRANDED DNA BINDING PROTEIN IS DETECTED IN MITOTIC AND POSTMITOTIC EMBRYONIC RAT NEURONS. R.S. Lasken, L. Lyandvert and D.J. Reis. Div. of Neurobiol., Cornell Univ. Med. Coll., NY, NY 10021.

We sought to establish whether single-stranded DNA binding proteins (SSB), essential to DNA replication in prokaryotes, are present in mitotic or postmitotic neurons of rat brain. Cerebral cortex and caudate nucleus of embryonic day (E) 13-17 were dissociated and immunocytochemically stained for SSB using antibodies to the human SSB isolated from HeLa cells (Kenny, M.K. et al., J. Biol. Chem., in press). The SSB was localized in the nucleus of cells including neurons as identified by the presence of neuron specific enolase. The staining for rat SSB, using antibodies to human SSB, was competitively blocked by the human SSB protein. Furthermore, 3 different monoclonal antibodies for human SSB recognized the putative rat SSB. Double labeling for tritiated thymidine and rat SSB revealed the protein's presence in both postmitotic and actively dividing cells. Thus, this protein may play a role in nonreplicating cells in a function such as DNA packaging or RNA transcription. The ability of antibody to human SSB to recognize the rat protein suggest that a widespread occurrence of highly homologous proteins will be found among mammals. Detection of an SSB in rat neurons will allow its regulation to be investigated in normal developing tissue.

EXPRESSION OF PEP-19 AND L7 COGNATE AND TRANSGENES IN CEREBELLAR PURKINJE CELLS IN PRIMARY CULTURE. K. Schilling, J. Oberdick, R.J. Smeyne, and J.I. Morgan Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110

In previous studies two developmentally regulated genes, PEP-19

and L7, have been characterized, which, within the cerebellum, are expressed specifically in Purkinje cells. In this study, we have assessed the expression of PEP-19 and L7 in developing Purkinje cells in primary culture using immunocytochemistry and histochemistry for β -galactosidase in cultures established from a transgenic mouse carrying a L7-βGal fusion gene (Science 248, 233 1990). This approach permits us to investigate the role of epigenetic mechanisms in the regulation of these specific genes. In cultures derived from 16 day old fetal rats, neurons immunoreactive (IR) for PEP-19 are first seen after 3 days in vitro, but L7-IR cells appear only after 5 days. With ongoing cultivation, Purkinje cells develop only after 5 days. With ongoing cultivation, Purking cells develop increasingly complex neurites, which can be seen in preparations stained for PEP-19 as well as L7. At the peak of expression, PEP-19-IR neurons outnumber L7-IR cells by about twofold. In cultures derived from 16 day old fetal mice, PEP-19 and L7 are expressed about two days earlier than in rat cultures, but follow the same relative time course. Expression of the L7- β Gal transgene paralleled that of the cognate L7 gene. Comparison of these results to data obtained in intact animals shows that expression of PEP-19 precedes that of L7 and the L7-BGal transgene both in culture and in vivo. This suggests that developmental expression of these genes is independent of extracerebellar input, which are absent in these cultures. SUBSETS OF PURKINJE CELLS AND BIPOLAR NEURONS IDENTIFIED BY THE L7 PROMOTER. J. Oberdick*. R.J. Smeyne, J.G. Corbin*. R. Wurzburger, and J.I. Morgan. Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

L7 gene expression is restricted to cerebellar Purkinje cells and retinal bipolar neurons. We have recently shown that an L7βGal transgene in mice accurately reflects the restricted distribution of L7 cognate gene expression (Oberdick et al, Science, 248: 223, 1990). A bipolar subpopulation, the rod bipolars, expresses the cognate gene (Berrebi et al, Soc.Neurosci.Abs, 1990) and the β Gal staining pattern in transgenic retina is consistent with this. All Purkinje cells in adult cerebellum are positive for both L7 cognate and transgene, but during early postnatal development L7 expression is restricted to a progressive wave of discrete parasaggittal bands (Smeyne et al, Soc. Neurosci. Abs. 1990). We are addressing the mechanisms responsible for establishing these biochemically distinct subpopulations of bipolar neurons and Purkinje cells. Specifically, common elements (PCE's) have been identified in the putative control regions of several Purkinje cell-specific genes. All of these elements lie within less than lkb upstream of the L7 cap site. A deletion variant of the L7 β Gal transgene carrying only 1kb of upstream sequence showed reduced expression in Purkinje cells, although the primary sites of expression remained the bipolar and Purkinje neurons. The cerebellum of a 12d old mouse expressing this deleted construct had a pronounced mediallateral gradient of BGal staining seen only at much earlier times with the full length construct. This suggests that the PCE's influence the specificity of L7 transcription, but that sequences more 5' control the levels and/or timing of transcription.

271.12

EXPRESSION OF L78GAL TRANSGENE AND L7 COGNATE GENE IS CONFINED TO PARASAGITTAL CLUSTERS IN DEVELOPING CEREBELLUM. R.J.Smeyne, J. Oberdick, A.S.Berrebi, E. Mugnaini, and J.I. Morgan, Roche Institute of Molecular Biology, Nutley, NJ 07110 and University of CT, Storrs, CT.

In a previous study, we have shown that a fusion transgene, L7BGal, is expressed in cerebellar Purkinje and retinal bipolar cells. In this study, we compared the spatial and temporal expression of the cognate L7 gene with that of the $L7\beta$ Gal transgene during development in cerebellum to assess if the regulatory sequences within the transgene were sufficient to produce normal expression. E15 through P10 control and transgenic mice were perfused; then frozen sectioned or removed into buffer for in toto staining. L7\beta Gal gene expression is first seen at E17 in 2 bilateral bands. At P0, in L7 and L7\beta Gal staining, 3 bilateral bands are evident; the most lateral band being interrupted by on/off zones. Histochemically-reactive Purkinje cells in these bands are characterized by staining solely in the soma. At P4, 6 bilateral bands are seen, with reaction product found in the Purkinje cell soma, dendrites and axons of the transgenic animals. P7, expression has expanded across the cerebellum so that only the most lateral parts of the hemisphere do not express either the cognate host rateral pairs of the heimsphere do not express or the the Cognate and L78 Gal transgene, and by P9 expression is complete. This study demonstrates that the onset of L7 cognate and L78 Gal expression is organized into similar and discrete bands of parasaggitally organized clusters. This suggests that the information contained in the 5' flanking sequences and introns of the L7\$Gal transgene are necessary and sufficient to direct normal expression.

A ZINC FINGER PROTEIN INDUCED BY NGF. S.D.CROSBY,

NGFI-C. A ZINC FINGER PROTEIN INDUCED BY NGF. S.D.CROSBY, J.MILBRANDT. Department of Laboratory Medicine, Washington University School of Medicine, St. Louis, MO, 63110.

Nerve growth factor stimulation of the rat pheochromocytoma cell-line PC12 results in neuronal differentiation. Within minutes of this stimulation, transcripts from a number of "immediate early" genes (IEG) (e.g. c-fos, NGFI-A, NGFI-B) which encode transcriptional regulatory proteins are increased. Using reverse transcriptase polymerase chain reaction (RT/PCR), we have isolated a new IEG, NGFI-C, from NGF-stimulated PC12 mRNA. The RT/PCR oligonucleotides were poly-dT and a degenerate consensus sequence of the Cys-Cys-His-His zinc finger. Sequence analysis of the NGFI-C cDNA reveals 3 adjacent zinc fingers which have >95% homology to the NGFI-A and Krox 20 quence analysis of the NGF1-C cDNA reveals 3 adjacent zinc fingers which have >95% homology to the NGFI-A and Krox 20 zinc finger regions. Preliminary northern blot analysis suggests alternative splicing of the mRNA. A larger mRNA exists almost exclusively in JS-1 cells while a smaller form predominates in brain and PC12 cells, implying that the two protein products may have different functions.

DIFFERENTIATION, MORPHOGENESIS AND DEVELOPMENT: NEUROTRANSMITTERS, PEPTIDES, HORMONES

272.1

DEVELOPMENT OF LONGITUDINAL DENDRITIC BUNDLES IN RAT SPINAL CORD: ANALYSIS OF CHOLINERGIC SYMPATHETIC PREGANGLIONIC NEURONS. J.A. Markham, P.E. Phelps and J.E. Vaughn. Div. Neurosci., Beckman Res. Inst. of the City of Hope, Duarte, CA 91010.

In adult spinal cord, dendritic processes of sympathetic preganglionic neurons (SPNs) are arranged in transverse and longitudinal bundles that give rise to a ladder-like appearance in horizontal sections. Using ChATimmunocytochemistry, Phelps and coworkers (Soc. Neurosci. Abstr. 15:589, 1989) have shown that transverse dendritic bundles are detectable by embryonic day 15, extend between the intermediolateral (ILp) and central autonomic (CA) nuclei by E17, and also display a distinct periodicity at this latter time. In contrast, longitudinal dendrites were not detectable at any prenatal stage. Thus, we investigated the development of the ChAT-positive SPN longitudinal dendritic bundles at early postnatal ages. At birth (P1), SPN cell clusters were only occasionally interconnected by longitudinal dendrites. Dendritic bundles were found between adjacent cell clusters more frequently by P4 and were even more numerous at P7, forming a continuous structure between adjacent cell clusters. These longitudinal dendritic bundles were found in both the ILp and CA nuclei, but the former appeared to develop earlier. The adult pattern of dendritic bundling was present by P14. When combined with previous studies, the results support the view that SPN processes in the spinal cord develop in the transverse plane embryonically, whereas growth in the longitudinal plane occurs during early postnatal life. Studies are in progress to determine possible bases for this temporal developmental difference. Supported by NIH grant NS25784.

DETECTION OF LOW LEVEL CHAT GENE EXPRESSION IN ADULT CHROMAFFIN CELLS AND IN THEIR EMBRYONIC PRECURSORS. D.J. Vandenbergh*and D.J. Anderson Div. of Biology, Caltech, Pasadena, CA 91125.

Chromaffin cells of the adrenal medulla and sympathetic neurons share a common precursor.

sympathetic neurons share a common precursor. Chromaffin cells maintain an ability to transdiff erentiate into sympathetic neurons in response to NGF or FGF. These sympathetic neurons can be further converted to a cholinergic phenotype by CDF/LIF. We have demonstrated that the potential to express a cholinergic phenotype is reflected in an incomplete repression of the CHAT gene. Low level expression of CHAT is detected not only in adult adrenal medullary tissue, but also in MAH cells, an embryonic sympathoadrenal precursor cells, an embryonic sympathoadrenal precursor cell line [Neuron 4, 189 (1990)]. MAH cells are able to respond to CDF/LIF by inducing CHAT mRNA levels as well as reducing TH mRNA levels. These levels as well as reducing TH mRNA levels. These results indicate that progenitor cells in the sympathoadrenal lineage contain an active or potentially active CHAT gene, as well as the machin ery to induce this gene in response to environmental factors prior to their differentiation into either chromaffin cells or noradrenergic sympathetic neurons. Moreover, a low level expression of the CHAT gene may persist in fully differentiated chromaffin cells.

Characterization of a target derived cholinergic differentiation factor present in rat sweat glands Mahendra S. Rao*#, Paul H. Patterson* and Story C# Landis Dept of Neuroscience, Case Western Reserve Univ, Cleveland, OH 44106# and Div of Biology, Caltech, Pasadena, CA.91125.*

During normal development, the sympathetic innervation of rat sweat glands undergoes a switch from a noradrenergic to a cholinergic and peptidergic phenotype. Previous studies have demonstrated that this switch is target mediated. To characterize the molecular nature of the signal(s) involved, we have prepared low salt extracts of sweat glands. The extracts contain a soluble factor(s) which induces choline acetyltransferase activity and vasoactive intestinal peptide expression in a dose dependent fashion in cultures of sympathetic neurons. The extract also reduces the levels of catecholamines, tyrosine hydroxylase and neuropeptide Y. The cholinergic inducing activity is first detected at postnatal day 5 and is present throughout the time period in which the sweat gland innervation undergoes a phenotypic switch as well as in adult animals. An initial characterization indicates that the ChAT inducing activity is heat labile and inactivated by trypsin. It does not bind to a heparin agarose column but it does bind to an anionic column indicating that it is an actidic protein. Antibody immunopreciptation experiments with an affinity purified antibody to the N-terminal of LIF/CDF suggest that this differentiation factor is not LIF/CDF. The soluble cholinergic inducing activity present in low salt sweat gland extracts is a likely candidate for mediating the target-mediated noradrenergic to cholinergic switch seen in vivo. Supported by AHA and NINDS.

A NEUROGENIC CULTURE SYSTEM FOR CHOLINERGIC DIFFERENTIATION. M. Martinic. M.P. Lambert and W.L. Klein. Institute for Neuroscience, Northwestern University, Evanston, IL. 60208.

We have developed a system for studying differentiation of presumptive cholinergic neuroblasts in vitro. E15 rat basal forebrain cells were grown at low density with or without soluble proteins from olfactory bulb. Unsupplemented cultures died rapidly (t1/2 < 10 hrs.), and attempts to inhibit death by blocking induction of cytotoxic proteins, known to be effective for NGF-dependent peripheral neurons, were unsuccessful. Supplemented with proteins from olfactory bulb, cultures developed a predominant cholinergic phenotype (90% AChE-positive, 70% ChAT-positive); ChAT-positive cells preferentially aggregated with each other. Cultures supplemented with NGF, EGF, IGF, bFGF, or proteins from cerebellum, not a target of cholinergic forebrain neurons, did not survive. Cell survival with olfactory bulb supplement required DNA synthesis during the initial stages of culture, and on day 2 in culture, 25% of cells were still incorporating 3H-thymidine. Of these cells, 90% later became neurofilament-positive. These results show that growth factors in olfactory bulb support the terminal mitosis of cultured basal forebrain neuroblasts, with consequent enrichment of the cholinergic population. (Supported by NIH grant NS23348 to WIK)

REGIONAL ONTOGENY OF DARPP-32 mRNA IN MOUSE BRAIN BY IN SITU HYBRIDIZATION. R.M. Lewis and R. Perez. Dept. NACS, Univ. Pittsburgh, Pittsburgh, PA 15261.

NACS, Univ. Pittsburgh, Pittsburgh, PA 15261.
Dopamine stimulates the phosphorylation of the neuronal phosphoprotein phosphatase DARPP-32. Previous studies utilizing antibodies tentatively have identified regions of the brain in which DARPP-32 is enriched either in cell bodies, axons or terminals. Because we are interested in studying control of gene expression for DARPP-32, we wanted to determine the location of the DARPP-32 mRNA, and to quantify changes in mRNA levels that occur during development, and in response to specific stimuli. An existing bovine cDNA for DARPP-32 was utilized to screen a mouse brain cDNA was highly homologous to the bovine cDNA. The mouse brain cDNA was used to synthesize an 35S-labeled riboprobe. Frozen sections of mouse brain were hybridized with this probe to detect DARPP-32 mRNA. Label was quantified by counting grains in random selections of groups of cells. Conditions were adjusted such that label in the cell bodies of the caudate (which contain the highest level of DARPP-32 protein) was just below saturation. At early stages, it was possible to distinguish cells in the caudate which were highly labeled, contained no label, or contained intermediate amounts. Similar distinctions could be made for other brain regions which contained DARPP-32. Little label was detected in glial cells in fiber tracts.

272.4

SKELETAL MUSCLE PROTEINS STIMULATE CHOLINERGIC DEVELOPMENT IN HUMAN NEUROBLASTOMA CELLS. F.G.Crawford* and J.L.McManaman. Dept. of Neurology and Div. of Neuroscience, Baylor College of Med., Houston, TX 77030 Extracts of rat skeletal muscle contain substances which stimulate the development of choline acetyltransferase (ChAT), the enzyme responsible for the synthesis of acetylcholine, in the cholinergic human neuroblastoma cell line LA-N-2. The ChAT enhancing activity co-purifies with CDF (ChAT Development Factor), the skeletal muscle factor which rescues motoneurons from naturally occurring cell death in vivo and enhances ChAT activity in embryonic rat spinal cord cultures (McManaman et al., Neuron, in press). CDF produces a 7-fold increase in the ChAT activity of LA-N-2 cells after 8 days in culture, but does not affect their growth or metabolic activity. Basic fibroblast growth factor (bFGF) and insulin like growth factor (IGF-1) also stimulate ChAT in embryonic rat spinal cord cultures. However, in contrast to the effects of CDF, bFGF produces a relatively small increase in the level of ChAT activity in LA-N-2 cultures while IGF-1 appears to be inactive. These results demonstrate that exogenous factors can stimulate cholinergic development of neuroblastoma cells and suggest that CDF may play a role in cholinergic differentiation as well as affecting motoneuron survival.

272.6

DEVELOPMENT OF HUMAN FETAL BULBOSPINAL NORADRENALINE NEURONS IN VIVO AND IN VITRO.

E. Sundström* P. Almqvist* H. Pschera* and Å. Seiger. Dept. of Geriatric Medicine and Dept. of Gynecology, Karolinska Institutet, Huddinge University Hospital, S-14186 Huddinge, Sweden.

In the present study we characterise neurochemically and morphologically the development of the human bulbospinal noradrenaline (NA) neurons in vivo and in vitro. Fetuses from first trimester abortions were dissected and selected regions were either analysed for their NA content using HPLC-ED or immersionfixed for tyrosine hydroxylase (TH) immunohistochemistry. We observed an early appearance of NA in regions containing the noradrenergic perikarya with approximately 60 ng NA/g found in pons at 6.5 weeks. This concentration increased fourfold over the next five weeks. However, the total amount of NA in pons increased 30-fold owing to the increased weight of this region. A similar pattern was seen in medulla oblongata where there was only a slight increase in NA concentration but a 10-fold increase in the total amount of NA between 6 and 10 weeks. The noradrenergic innervation of the spinal cord was detectable at 6 weeks (5-15 ng/g) with a rapid increase of NA concentration during the next 5 weeks (35-50 ng/g). We were unable to resolve any clear differences between different parts of the spinal cord.

Morphological evaluation of a few selected stages and CNS regions confirmed the presence of TH-immunoreactive cells in the brain stem and nerve fibers in the spinal cord at 7.5 weeks as well as at 10 weeks of embryonic development. The TH-positive cell bodies in the lower brain stem showed a significant structural differentiation during this 2.5 week period.

Inis 2.3 week period.

Selected regions of the fetal nervous system were used to develop a culture system in which dissociated cells, grown on collagen and polylysine-coated plates, could be maintained in vitro for 6 months or more, without even brief exposure to antibiotics, specific growth factors or preconditioned media. The development of TH-immunoreactive neurons in culture was compared to that in vivo and the results will be discussed.

272.8

POSTNATAL EXPRESSION OF TYROSINE HYDROXYLASE IMMUNO-REACTIVE NEURONS (TH-IN) IN THE CEREBRAL CORTEX AND STRIATUM OF THE MOUSE: TREATMENT WITH DISULFIRAM OR THIRAM. J. Satoh and K. Suzuki. Dept. of Clin. Neuropathology, Tokyo Metropol. Inst. for Neurosciences, Japan and Dept. of Pathology, Univ. of North Carolina at Chapel Hill, USA.

We have reported transient increase of TH-IN in the cortex on the 2nd postnatal (PN) week in mice (Satoh & Suzuki, 1988). TH-IN in the striatum have been reported in primate and rat, but their transient change has not been noticed. Using the same method, we found a TH-IN in 22 out of 60 Swiss Webster mice of PN day (P)2 to P30. They reached their peak between P12 and P16, but none was found on P60. Mice treated with Disulfiram (tetraethylthiuram disulfide), a potent inhibitor of DBH, on the 2nd PN week revealed a striking increase of cortical and a TH-IN. The treatment on the 1st or 3rd PN week showed very little effect. Emergence of TH-IN was observed in Thiram (tetramethylthiuram disulfide) treated mice. In these brains, norepinephrine decreased and dopamine increased. In the brindled, murine model of congenital copper deficiency with decreasing DBH activity, similar enhanced expression of cortical and striatal TH-IN has been reported (Satoh & Suzuki, 1989). Thus, enhanced expression of TH-IN in both Disulfiram or Thiram treated mice and the brindled could be considered due to perturbation of catecholamine system during well defined PN periods.

TYROSINE HYDROXYLASE-IMMUNOREACTIVE NEURONS IN TYROSINE HYDROXYLASE-IMMUNOREACTIVE NEURONS IN THE CHICK HYPOTHALAMUS: LACK OF THE IMMUNOCYTO-CHEMICAL DEMONSTRATION OF DOPAMINE SYNTHESIS.

A.A. Romero*, A.J. Vallejos*, J.K. Lobner* and J.A. Wallace. Dept. of Anatomy, University of New Mexico Sch. of Med., Albuquerque, NM 87131.

In the chick diencephalon, numerous tyrosine hydroxylase-immunopositive (TH+) cells can be distinguished in patterns similar to that

observed for DA-containing neurons in mammals. observed for DA-containing neurons in mammals. However, with the exception of certain posterior hypothalamic groups, few cells can be detected by anti-DA immunocytochemistry in tissue from untreated control chick hatchlings (Wallace, et al., Anat. Rec. 226:107A,'90). Here we examined the potential of the majority of chick hypothalamic TH+ cells to synthesize DA by pretreating hatchlings with monoamine oxidase inhibitors (MAO-I) alone, or in combination with L-DOPA (the immediate precursor to DA synthesis). With either pretreatsor to DA synthesis). With either pretreatment, the number of hypothalamic DA-immuno-positive cells increased only slightly as compared to controls. Therefore, it appears that most hypothalamic TH+ cells in the chick do not possess dopa decarboxylase, or that this enzyme is present yet inactive. Supported by NIH grants MRC 1 T34-GM-08222 and GM-08319.

272.11

EXPRESSION OF D₁-DOPAMINE RECEPTOR BINDING SITES IN AN IMMORTALIZED MURINE CORPUS STRIATUM CELL LINE. M.S. Wainwright, B.D. Perry, P. Kontur and A. Heller. Dept. of Pharmacological and Physiological Sciences, The University of Chicago, Chicago IL 60637.

We examined the effects of a differentiating agent (n-butyrate) on expression of D₁ receptor binding sites in an immortalized cell line derived from murine CNS. Immortalized dopaminoceptive cells were prepared by the fusion of fetal (E18) corpus striatum (CS) cells with a neuroblastoma line (N18TG2). Following corpus striatum (CS) cells with a neuroblastoma line (N181142). Following treatment with n-butyrate (1 mM for 6 days), long neurites and a decrease in growth rate were observed in the CS, but not the N18 cell line. D₁ binding sites were labeled with ¹²⁵I-SCH 23982 (SCH) in 8 point saturation studies (0.03 to 5.0 nM) using standard techniques. In the untreated CS line the affinity (Kd) of SCH was 0.59 ± 0.28 nM with a Bmax (binding site density) of 214.9 ± 61.6 fmol/mg prot (n=3). n-Butyrate treatment did not alter SCH affinity (0.34 \pm 0.15nM) but increased binding site density to 700.8 ± 135.4 fmol/mg prot (n=3). In the untreated N18TG2 line, SCH affinity was 0.22 ± 0.14 nM with a Bmax of 75.3 \pm 25.5 fmol/mg prot (n=6). There were no significant changes in Kd (0.19 \pm 0.07 nM) or Bmax (30.7 \pm 1.6 fmol/mg prot: n=3) following n-butyrate treatment. In both lines, drugs inhibited SCH binding with a rank order of potency consistent with a D₁ receptor. In the treated CS cell line basal adenylate cyclase activity (13 pmol/mg prot/min) was enhanced by 56% (n=3) by DA (10⁻⁴M) in the the presence of haloperidol (10⁻⁷M). In treated and untreated N18TG2 cells, DA inhibited, but did not stimulate, adenylate cyclase activity

(23% decrease from basal; n=3).

These results suggest that this CS derived cell line may serve as a model for examining mechanisms of the developmental regulation of D₁ receptor/effector systems. Supported by MH-28942 and the Brain Research Foundation

272.13

CHARACTERIZATION OF THE NOREPINEPHRINE UPTAKE SYSTEM

CHARACTERIZATION OF THE NOREPINEPHRINE UPTAKE 5151EM EXPRESSED BY NEURAL CREST CELLS IN CLONAL CULTURE. <u>1-M.</u>
<u>Zhang and M. Sieber-Blum.</u> Dept. of Anatomy and Cellular Biology, Medical College of Wisconsin, 8701 Watertown Plank Road, Milwaukee, WI 53226. Previous results suggested that adrenergic differentiation of neural crest cells in clonal culture is blocked by norepinephrine (NE) uptake inhibitors, such as the tricyclic antidepressant, desipramine (DMI). This observation suggested that the extraction suggested in clonal culture is blocked by norepinephrine (NE) uptake inhibitors, such as the tricyclic antidepressant, desipramine (DMI). This observation suggested that the catecholamines present in the ventral migratory pathway, at a time it is traversed by presumptive adrenergic cells, may participate in a positive feedback mechanism that serves to enhance and stabilize expression of the adrenergic phenotype [Sieber-Blum (1989) \$Dev.Biol.\$ 136, 372]. We report here that as in the embryo, neural crest cells in clonal culture express a high affinity NE uptake system before other adrenergic traits become evident. Uptake of radioactive NE, visualized by autoradiography, indicated that the system first appears at clonal culture day 5, i.e. 2 days before the cells start to accumulate catecholamines at detectable levels. Rare uptake-positive cells were detected as early as culture day 3. On day 5, 5/27 (18%) unpigmented colonies and 19/75 (25%) mixed colonies contained uptake-positive cells. On day 6, 9/31 (29%) unpigmented and 33/96 (33%) mixed colonies were positive, whereas by day 7, 9/32 (28%) unpigmented and 43/101 (42%) mixed colonies were positive unpigmented colonies was as high as 64% and the number of positive mixed colonies 23% on culture day 5. The number of colonies containing uptake-positive cells was decreased by 79% in the presence of DMI. Uptake reached maximum by 5 min. The K_m was determined to be 0.8 to 4.8 µM depending on the control conditions. The data indicate that clonal neural crest cell cultures provide a useful experimental system for investigating the role of the NE uptake system in the differentiation of pluripotent neural crest cells into adrenergic cells. Supported by USPHS grant HD21423.

272.10

EFFECTS OF MUSCLE-DERIVED NEUROTROPHIC FACTORS ON DIFFERENTIATION OF IMR-32 NEURBLASTOMA CELLS. <u>E.D.Rabinovsky</u>, <u>W-D Lee</u>, and J.L.McManaman. Dept. of Neurology, Baylor College of Medicine, Houston, Tx. 77030.

The neuroblastoma cell line, IMR-32, exhibits both cholinergic and adrenergic properties. We have used IMR-32 cells to study the effects of two skeletal-muscle derived neurotrophic factors, CDF (ChAT Development Factor) and bFGF (basic fibroblast growth factor), on the development of neurotransmitter properties. Treatment with CDF increased CHAT activity in a dose dependent manner, independent of cell density. Time course studies showed that there is a 3-fold increase in the specific ChAT activity in IMR-32 cells, treated with CDF, after 6 days in culture. By contrast, CDF did not effect proliferation, metabolic activity, or the level of tyrosine hydroxylase (TH) activity. Basic FGF, on the other hand, increased cell proliferation, metabolic activity and induced TH activity 2.5-fold after 6 days in culture. However, bFGF had no effect on the CHAT activity of IMR-32 cells. These results indicate that CDF specifically induces IMR-32 cells towards cholinergic differentiation while bFGF induces adrenergic differentiation. Thus, IMR-32 cells appear to be differentially responsive to distinct neurotrophic factors, and provides a model for studying the specific intracellular events mediating the effects of neurotrophic factors on functional differetiation.

272.12

THE INFLUENCE OF DOPAMINE NEURONS ON D1-DOPAMINE RECEPTOR BINDING SITE DEVELOPMENT IN THREE DIMENSIONAL REAGGREGATE TISSUE CULTURE. B.D. Perry, M.S. Wainwright, L. Won, A. Heller and P. Hoffmann. Depts of Psychiatry and Pharmacological and Physiological Sciences, The University of Chicago, Chicago, IL 60637.

We examined D₁-dopamine receptor binding sites in a three-dimensional reaggregate tissue culture system containing dopaminergic (DA) cells from fetal mouse brain. DA-containing cells from rostral mesencephalic tegmentum (RMT) were grown in rotation-mediated cell culture with cells obtained from corpus striatum (CS), a target tissue for DA neurons, or from tectum (T), which is not a DA neuron target. RMT-CS reaggregates form highly organized structures in which the DA-containing cells from the RMT innervate the CS target cells and

which the DA-containing cells from the RMT innervate the CS target cells and make appropriate functional connections (Kotake et al., <u>J Neurosci</u> 2:1307, 1982). Reaggregates were prepared on embryonic day 14 and maintained in culture for 21 days. Three cell combinations were studied: 1) 10 x 10⁶ CS cells cultured alone (CS); 2) 5 x 10⁶ RMT cells co-cultured with 5 x 10⁶ CS cells (RMT-CS); 3) 5 x 10⁶ RMT co-cultured with 5 x 10⁶ T (RMT-T). On day 21, reaggregates were harvested and membranes prepared for radioligand binding studies. ¹²⁵1-SCH 23982 (SCH) was used to label the D₁ sites. Eight concentration saturation studies were performed on each flask using standard techniques.

At day 21 the RMT-CS cultures expressed twice as many D₁ binding sites as the

At day 21 the <u>RMT-CS</u> cultures expressed twice as many D₁ binding sites as the <u>CS</u> cultures and five times as many sites as the <u>RMT-T</u> reaggregates (<u>RMT-CS</u>: 162 ± 24.8, n=8; <u>CS</u>: 84 ± 8.9, n=10; <u>RMT-T</u>: 34.6 ± 4.5, n=8; values in fmol/mg prot \pm SEM).

These findings suggest that the developing cells of the RMT play a role in the phenotypic expression of the D₁-dopamine receptor.

POSTNATAL DEVELOPMENT OF THE ALPHA2-ADRENOCEPTOR SYSTEM IN THE TREE SHREW BRAIN, G. Flügge and E. Fuchs German Primate Center, 3400 Göttingen, FRG

In adult tree shrews (*Tupaia belangeri*), central adrenergic receptors have a very high affinity for alpha2-adrenoceptor ligands (Flügge et al. 1990). To gain insight into the maturation of the central alpha2-adrenoceptor system in these animals we studied its postnatal development by in vitro autoradiography with the specific antagonists ³H-rauwolcine and ³H-idazoxan.

Alpha2-adrenergic binding sites (a2-BS) are already present at birth and their pharmacological properties are similar to those in the adult. But in contrast to the adult brain which reveals high numbers of alpha2-binding sites in rostral areas (telencephalon, diencephalon), the brain of neonates is primarily labeled in its caudal regions (myelencephalon, metencephalon) and the labeling is more diffuse, although the septum, hippocampus and the geniculate nucleus already show a high number of a2-BS immediately after birth. Especially the rhombencephalic areas bearing the anlage for the catecholaminergic cell groups A1-A7 form a strongly labeled, continuous band. Furthermore, there is a high number of a2-BS in the lateral cerebellum which can be observed during the first 2 postnatal weeks. The number of the caudal a2-BS decreases gradually while that of the rostral BS increases to reach the adult pattern of distinct nuclear a2-BS distribution around postnatal day 25.

Our results show that the central nervous alpha2-adrenoceptor system in the tree shrew is already expressed at birth when a2-BS can be detected in the caudal parts of the brain and in the limbic system. Within the first 25 postnatal days, the caudo-rostral gradient in the pattern of a2-BS changes into a rostro-caudal gradient which is characteristic for adult tree shrews.

CHRONIC EXPOSURE OF THE CEREBELLA OF NEONATAL MICE TO THE NMDA RECEPTOR ANTAGONIST, AP5, DISRUPTS PURKINJE AND GRANULE CELL DEVELOPMENT. M.W. Vogel, M. McInnes*, and H. Cline. MD Psychiatric Research Center, Baltimore, MD 21228 and Stanford Univ. Medical Center, Stanford, CA 94305
Studies in the visual system have shown that NMDA receptor

activation plays an important role in the establishment of mature synaptic connections. Purkinje and granule cells are more sensitive to

Synaptic connections. Purkinje and granule cens are more sensitive to MMDA receptor activation in neonates compared to adults, and we have begun to test the role of synaptic activity and NMDA receptor activation on Purkinje and granule cell development.

Elvax strips with or without DL-AP5 (1mM) were implanted over the cerebellum of C57BL/6 mice at P5 and the mice were then killed at ages ranging from P17 to P33. The brains of 6 AP5 treated mice, 2 mice with drug-free elvax implants, and 5 age-matched control mice mice with drug-free elvax implants, and 5 age-matched control mice were then processed for Golgi-Cox staining and counterstained with cresyl violet. In the AP5 treated mice, but not the control mice, granule cells were found positioned ectopically within the molecular layer near the elvax implant. The quantity and position of the ectopic granule cells varied. In 2 of the AP5 treated mice there were extensive tracts of ectopic granule cells at the folia surface and in the folds between folia. Morphometric analysis of Purkinje cells near the AP5 treated elvax strip suggests that their dendritic trees are significantly smaller, less isoplanar, and occupy less of the upper half of the molecular layer. These preliminary results suggest that blocking the NMDA receptor during postnatal development can interfere with granule cell migration and the elaboration of Purkinje cell dendrites.

DEVELOPMENT OF MEMBRANE RESPONSES OF EMBRYONIC RAT SPINAL CORD CELLS. M.K. Walton, A.E. Schaffner, and J.L. Barker. Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

The presence of functional sodium channels, GABA receptors, and kainic acid receptors was examined in dissociated embryonic rat spinal cord cells across several developmental ages using computerized digital imaging microscopy and a voltage sensitive fluorescent dye. Cervical regions of spinal cords were removed from rat embryos from embryonic days 13,15,17,19,21 (E13 to E21) and were divided into dorsal and ventral The tissue was enzymatically dissociated into single cell suspensions, placed onto culture dishes and allowed to adhere for ca. 2 hours. Culture dishes were perfused with continuously flowing solutions, all nours. Culture dishes were pertused with continuously flowing solutions, all with 50 nM of the voltage-sensitive oxonol dye DiBaC₄(5). Voltage-sensitive sodium channels were probed for with veratridine (25 uM), GABA-A receptors were probed for with muscimol (2.5 uM), and kainic acid (50 uM) was used as a probe for non-NMDA glutamate receptors. The depolarizing response seen to each of these drugs could be eliminated by use of specific

blockers of their actions, tetrodotoxin, bicuculline or CNQX, respectively.

Overall, sodium channel appearance preceded appearance of responses to muscimol, and muscimol responses appeared earlier than kainic acid responses. This delay was more pronounced in the dorsal portion than in the ventral portion cells. Development of kainic acid responses progressed to include almost all cells by E19-E21, while veratridine and muscimol responding percentages remained lower. Individual cells could exhibit one or both receptor responses without sodium channel responses. Magnitude of the response of individual cells showed an increase during the developmental period examined, particularly for the kainic acid response

LATE GENERATION OF GABA-ERGIC SUBPLATE NEURONS IN THE RAT. H.B.M. Uylings and C.G. van Eden. Netherlands Institute for Brain Research, Meibergdreef 33,1105 AZ Amsterdam, The Netherlands. (Spon: European Neuroscience Association)
The subplate layer (SP) contains many GABA-ergic neurons during early prenatal cortical development (Van Eden et al., J.C.N. 289:213-227;1990). In order to estimate the percentage of GABA-ergic neurons in the SP of the rat, timed pregnant females were injected with 'H-thymidine (10 µCi/g., i.p.) at embryonic days (E) 13 and E14 (E1 is the day of insemination). Fetusses and pups were perfused at different ages between E16 and postnatal day (P) 25. Plastic sections were processed for GABA-ICC and autoradiography. After both injections at E13 and E14 heavy labelled cells were found in the plexiform primordium, the marginal zone (MZ) and the SP. E14 injections showed the highest number of heavy labelled cells in these layers in the dorsomedial frontal cortex, whereas in the ventrolateral cortex mainly cells of layer VIa were labelled. After birth these heavy labelled subplate cells were located in cortical layer VIb. No indication was found for a major decline in the number of labelled cells in the SP (layer VIb) uring the postnatal period. The MZ and the SP contained the highest number of GABA-IR cells during the prenatal period. However, only very few GABA-ergic cells were labelled by H-thymidine injections at E13 or E14. Also after birth, only a few GABA-ergic cells were labelled with 'H-thymidine in the COTEX. The few GABA-ergic cells that were generated at E13 or E14 were primarily situated within cortical layers Vand VIa. The present data demonstrate that although a large number of the SP cells are generated on E13 and E14, the GABA-ergic population in these layers must be generated later and subsequently added to the SP.

NMDA AND CALCIUM REGULATES THE ENKEPHALINERGIC PHENOTYPE IN DEVELOPING SPINAL CORD CULTURES

NMDA AND CALCIUM REGULATES THE ENKEPHALINERGIC PHENOTYPE IN DEVELOPING SPINAL CORD CULTURES D.V. Agoston, X.-R. Wu, L.E. Eiden* & D.E. Brenneman*, Lab of Cell Biology and Developmental Neurobiology, NIMH & NICHD, NIH, Bethesda, MD 20892

The establishment of the neuronal phenotype is developmentally regulated by epigenetic influences like electrical activity and soluble factors. In the developing embryonic spinal cord dorsal root ganglia (SC-DRG) cultures, spontaneous electrical activity is a major factor regulating the expression of neuropeptide genes including enkephalin. Calcium ionophore or NMDA cause a significant up-regulation in the expression of the enkephalin transcripts (mRNA*enk) in developing SC-DRG neurons (Agoston et al., in prep). Here we have pharmacologically characterized the receptor specificity of calcium flux regulation of enkephalin biosynthesis and secretion in embryonal neuronal cultures. SC-DRG cells were treated with NMDA (10-6 to 10-4 M) or +202 791 (10-6 to 10-4 M) - a selective agonist of L-type voltage-sensitive calcium channles (VSCC) - prior, simultaneously or without TTX treatment. Enkephalin transcripts were analyzed by Northern blot hybridization using a complementary DNA probe. Met-enkephalin (menk) was measured in a RIA system.

In electrically active cultures NMDA treatment increased the expression of mRNA*enk and the cellular menk content in a concentration-dependent manner. Menk secretion was slightly but significantly reduced by NMDA in active cultures but was not significantly altered in TTX-blocked cultures. The VSCC-agonist +202 791 was ineffective if it was applied simultaneously with TTX. However, 1 hour pre-treatment with + 202 791 could not only prevent the TTX caused downregulation of mRNA*enk

incltcctive it it was applied simultaneously with TTX. However, I hour pre-treatment with + 202 791 could not only prevent the TTX caused downregulation of mRNAe^{nk} expression in a concentration- dependent manner but increased mRNAe^{nk} over the TTX treated controls. Similarly, cellular menk content was also increased as compared to the TTX-blocked control. Similar pre-treatment did not increase menk secretion compared to the TTX-treated controls. These results indicate that a) the developmental expression of the enkephalin gene is regulated by calcium through NMDA and VSCc-stimulation and b) secretion and biosynthesis of enkephalin are regulated by parallel but separate calcium-dependent intracellular mechanisms. FUNCTIONAL GABA A RECEPTORS ARE CRITICAL FOR SURVIVAL AND PROCESS OUTGROWTH OF EMBRYONIC CHICK SPINAL CORD CELLS IN VITRO. A, Prasad and J.L. Barker. Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

Acutely dissociated chick embryonic (E) spinal cord cells are depolarized by GABAA agonists in a bicuculline sensitive manner as early as E4, as demonstrated using flow cytometry and voltage-sensitive dyes (Prasad et al.,(1989) Soc. Neurosci. Abstr. 15:295). However, with the exception of some behavioral studies little is known about the functional role of GABA during early embyrogenesis, prior to the onset of well-differentiated synapses in the spinal cord. We have investigated the effects of bicuculline, a GABA_A antagonist, and muscimol, a GABA agonist, on embryonic spinal cord cells differentiating in culture. Cells (E4.5-E9) were dissociated with papain, resuspended in MEM and serum, and plated on poly-lysine coated plastic plates. After overnight exposure to GABAergic agents, cells were fixed and stained for neurofilament-like-immunoreactivity.

Several hours were required before any visible changes between the experimental and control cultures were evident. Overnight exposure to 20-200 µM bicuculline consistently decreased cell number and neurite outgrowth relative to control cultures. No changes were seen with 2 µM, or lower, doses. The effects of bicuculline (at doses which block muscimol/GABA depolarization) were antagonized by co-incubation with $10\,\mu\text{M}$ muscimol. These results suggest important if not critical roles for GABAA receptors in the survival and differentiation of chick spinal cord neurons in vitro.

-GLUTAMATE MICROSPHERE STIMULATION OF THE L-GLUTAMATE MICROSPHERE STIMULATION OF THE TRIGEMINAL MOTOR NUCLEUS IN GROWING RATS.E.L. Hamilton-Byrd*, A.J. Sokoloff, A.J. Domb*, L. Terr and K.E. Byrd. Univ. of Southern California Sch. of Dent., Los Angeles, CA 90089. The purpose of this study was to investigate the efficacy of glutamic acid loaded microspheres for long-term stimulation of tri-

microspheres for long-term stimulation of trigeminal motoneurons as a possible treatment for growth disorders of the craniofacial skeleton. 10% glutamic acid:HCl in polyanhydride, P(FAD-SA) 1:1, microspheres (106 - 250 µm dia.) were implanted in the region of the trigeminal motor nucleus (TMNu) of 11 male Sprague-Dawley rats (33 - 38 days old) using the technique of Howard et al. (J. Neurosurg., 71:105 - 112, 1989). Control rats had implants of blank microspheres or actual penetration of the empty crospheres or actual penetration of the empty delivery system into the target region. All rats were killed and perfused 10-14 days post-operatively. 3 rats implanted with glutamate microspheres showed pronounced skeletal changes in the snout region when compared to control rats. $\underline{In\ vivo}$ sustained release of glutamic acid in proximity to the TMNu can effect significant changes of the craniofacial skeleton in growing rats. Supported by NIDR grant R29 DE07380 to K.E. Byrd and Nova Pharmaceutical Corporation.

IMMUNOCYTOCHEMICAL DETECTION OF PROENKEPHALIN-DERIVED PEPTIDES IN THE CORPUS STRIATUM OF THE DEVELOPING RAT. D.D. SONG AND R.E. HARLAN, Department of Anatomy, Tulane University School of Medicine, New Orleans, Louisiana 70112.

Immunocytochemistry using antisera to the C-terminal octapeptide of synenkephalin, proenkephalin (63-70), and to methionine enkephalin (met-Enk) was performed on serial cryostat sections through the corpus striatum from embryonic day 14 (E14) through postnatal day 10 (P10).

Immunostained cells were detected in the caudate-putamen by E16 with the synenkephalin antiserum. At E18 immunostained cells became more numerous. At E20 more cells were detected in the caudate putamen; however, the intensity of staining became weaker. Also by E20 immunopositive fibers in the globus pallidus first became detectable, suggesting increased axonal transport. By the day of birth (P0) an adult-like distribution of immunoreactivity became apparent; cells could no longer be detected in the caudate-putamen while immunoreactive fibers in the globus pallidus increased in density. At subsequent ages (P5 and P10), only immunoreactive fibers in the globus pallidus could be detected. Our met-Enk antiserum was unable to detect any cells or fibers in the caudate-putamen or globus pallidus at the ages studied, except for P10. It appears that met-Enk, prior to P10, may be stored in a cryptic form, possibly as part of a larger, unprocessed precursor.

ONTOGENESIS OF CGRP RECEPTORS IN THE RAT CEREBELLUM.

A. Rosina, S. Morara, G. Forloni* and L. Provini° (SPON:
ENA). Ist. Fisiol. Centri Nervosi CNR, *Ist. Mario Negri
and °Ist. Fisiol. Chim. Biol., Fac. Farm., Milano, Italy.

A quantitative autoradiographic study of the density and distribution of Calcitonin gene related-peptide (CGRP) bind ing sites was conducted in the rat cerebellum, in an attempt to discern what their relationship is to the postnatal morphogenesis of the cerebellar cortex. Autoradiography was performed using 0.1 nM 12 I-CGRP (human >-CGRP); nonspe cific binding was determined on adjacent sections by the ad dition of 1 uM unlabeled CGRP to the labeled ligand. Adjacent sections of cerebella at postnatal day (PD) 0,3,6,9, 12,15,20,26 were examined. CGRP binding sites started to be detected in the white matter, where they steadily increased from PD 0 to 20, to decrease to adult levels at PD 26. In the molecular layer, CGRP receptors were first detected at PD 6-9 and their density increased along a caudo-rostral and medio-lateral gradient, up to PD 26. CGRP receptors binding was undetectable or very low in the external or internal granular layers respectively. These findings indicate a close relationship between CGRP receptor expression and both the growth of the Purkinje cell dendrites and the climbing stage of the olivocerebellar fibers.

DIFFERENTIAL MORPHOLOGICAL RESPONSES TO ECDYSTEROID OF CULTURED NEURONS FROM INSECT ANTENNAL LOBE.

L.A. Oland and L.P. Tolbert, Arizona Research Labs Division of Neurobiology, University of Arizona, Tucson, AZ 85721.

Neurobiology, University of Arizona, Tucson, AZ 85721.

The titer of the hormone 20-hydroxyccdysone (20-HE) rises dramatically during metamorphic development in insects when neurons in the antennal lobe (AL) develop their adult morphology and synaptic connections. To isolate the effect of 20-HE from other influences on the morphological development of these neurons, we dissociated neurons from early pupal ALs (prior to the rapid rise in 20-HE titer) that had not been allowed to receive input from the antenna, and exposed them to doses of 20-HE that span the range seen in vivo. After 2-3 weeks, we examined particular cell types that consistently appear in these cultures, some of which were described by Hayashi and Hildebrand (1990). Of the approximately 400 cells examined, a quarter could be identified as belonging to one of 8 cell types. In all cases, the basic branching pattern of the neuronal type was maintained across all doses of 20-HE. Also in all cases, neurons exposed to 1µg/ml 20-HE generally were larger, reached a higher branching order, and consistently had more robust branches than did neurons grown in the absence of 20-HE. In three other types, exposure to 10µg/ml 20-HE enhanced these effects. In three other types, there was no morphological difference between 1 and 10µg/ml. In the final group of two types, the overall robustness of the cells was less at 10µg/ml than at 1µg/ml. The 8 cell types used in this study are known to include both local and output classes of AL neurons; each of the response patterns to 10µg/ml 20-HE was seen in at least one of the cell types belonging to each class, indicating that output and local neurons cannot be segregated on the basis of their responses to 20-HE. These data suggest that in vivo, the morphology of different types of AL neurons may be differentially regulated by the titer of 20-HE.

APPEARANCE OF PEPTIDERGIC NEURONS IN THE DEVELOPING CHICK GUT. M.L. Epstein and K.T. Poulsen*. Dept of Anatomy, University of Wisconsin, Madison, WI 53706.

Neural crest-derived cells are found in the ileum by embryonic day (ED)6.5. We are interested in the factors regulating the expression of neuropeptides in the gut. The appearance of vasoactive intestinal peptide (VIP)- and somatostatin (SOM)immunoreactive (IR) neurons in different regions of the gut was studied by immunostaining whole mounts of embryonic gut. The pattern of expression of these peptides in myenteric neurons showed a number of similarities. Both peptides first appeared in the region of the gizzard-proventriculus-duodenum; SOM at embryonic day (ED)4, VIP at ED5.5. Both peptides were found at later times in positions both rostral and caudal to the gizzard. By ED7.5 both peptides were found proximal to the proventriculus and in the descending loop of duodenum. Both peptides next appeared in cells in the cecum of the hindgut, although no immunoreactive cells were found in the midgut; SOM was observed at ED6.5 and VIP at ED7.5. VIP- and SOM-IR cells appear throughout the cecum and then in the terminal part of the rectum. Another similarity was that immunostained cells appear last in the ileum with VIP appearing at ED10-12 and SOM at ED15.5-17.5. Differences in the pattern of expression are also found. SOM-IR appeared in cells in the terminal part of Remak's Ganglion at ED5.5. These cells became segregated into clusters along the ganglion; cells sent fibers into the wall of the rectum and later into the ileum. No VIP-IR cells were found in Remak's Ganglion. These findings suggest that neural crest-derived cells first express peptides in the region of the gizzard of the foregut and then in the cecum of hindgut. The appearance of peptidergic cells in the hindgut before the midgut is consistent with a caudal source of neural crest-derived cells. Supported by BNS 8820658.

CHARACTERIZATION OF A SUBPOPULATION OF EARLY NEURAL CREST CELLS RECOGNIZED BY THE MONOCLONAL ANTIBODY B-1A11. <u>C.J. Langtimm and M. Sieber-Blum</u>. Department of Anatomy and Cellular Biology, Medical College of Wisconsin, Milwaukee, <u>WIL Espace</u>.

The monoclonal antibody B-1A11 recognizes a cell surface epitope on a small (10%) subpopulation of undifferentiated, cultured neural crest cells. The present data characterize the epitope and the immunoreactive cells. The epitope is trypsin resistant, diminished after chloroform-methanol treatment, and not detectable by Western hybridization, suggesting that it is part of a lipid rather than a protein. However, neuraminidase treatment and incubation with phospholipase C do not affect staining. The expression of the epitope is transitory. It first appears by 48 hr of culture. By 96 hr, early melanocytes and unpigmented cells resembling nerve supporting cells bind the antibody. Fully developed pigment cells are no longer immunoreactive. In older cultures, neuronal cells do not bind B-1A11, with the exception of rare sensory neurons. B-1A11 immunoreactive cells also occur in clonal cultures. Staining patterns are marked by considerable variability. By clonal culture day 4, 0% to >90% of all cells within a colony are immunoreactive in both unpigmented and mixed colonies. By day 5, this number drops to 0%-24% of positive cells per colony. In older clonal cultures, immunoreactive cells are only rarely observed. Neural crest cells from 48 hr primary explants can be enriched up to 5-fold by separation with magnetizable beads. When such purified, immuno-fluorescent cells are seeded out at clonal density, they attach, proliferate and form pigmented colonies. In whole mount stains of 48 hr embryos (stage 14; 22 somites) individual cells or small groups of 24 cells are located medially in mesencephalic areas as well as in somitic levels 8-12, above the triangular space outlined by two adjacent somites and the neural tube. By 96 hr of incubation, immunoreactive cells occur in groups throughout the ectoderm, suggesting their melanogenic nature. The data a) suggest that B-1A11 recognizes a differentiation antigen that characterizes cells in the melanogenic and possibly the nerve supporting cell lineages and b) show for the fi

273.2

PATTERN OF IN VITRO DIFFERENTIATION OF HNK-1 SORTED QUAIL TRUNK NEURAL CREST CELLS G.D. Maxwell and M.E. Forbes*. Dept. of Anatomy, Univ. of Connecticut Health Center, Farmington, CT 06032.

We have continued our analysis of the spectrum of phenotypes which differentiate in tissue culture from populations of quail trunk neural crest cells isolated as HNK-1+ and HNK-1- by fluorescence activated cell sorting. We have found that tyrosine hydroxylase and somatostatin immunoreactive cells developed consistently from the HNK-1+ sorted cells. In contrast, few if any cells with these markers differentiated in the HNK-1- sorted population. These observations are in agreement with our previous work showing that catecholamine containing cells arose preferentially from the HNK-1+ sorted population (Maxwell et al. 1988 Neuron 1: 557-568). When we examined the differentiation of AZB5, E/C8, and middle molecular weight neurofilament protein immunoreactive cells, substantial numbers of these cells developed from both the HNK-1+ and the HNK-1- sorted cell populations. These results indicate that, under the in vitro conditions used in these experiments, the presence of the HNK-1 antigen(s) on early trunk neural crest cells is correlated rather selectively with the development of adrenergic cells and some of their peptidergic subsets, but not with other cell classes bearing neural markers. This work is supported by grant NS 16115 from the NIH.

THE GENERATION OF CELL DIVERSITY IN THE SUPERIOR CERVICAL GANGLION. A.K. Hall and S.C. Landis, Dept. Neuroscience, Case Western Reserve University School of Medicine, Cleveland, OH 44106

The neural crest contains multipotent cells that give rise to different types of daughter cells including neurons and glia of the PNS. In the superior cervical ganglion (SCG), principal neurons, small intensely fluorescent (SIF) cells and glial satellite cells are derived from the neural crest.

To investigate how the specific cell types found in the mature SCG were generated from their precursors, the lineage relationships and the phenotypic development of cells in the embryonic rat SCG were examined. Analysis of dissociated E14 SCG cultures with BrdU and antibodies to NF160 indicated that neuroblasts divide for several days in vitro. Retrovirus-mediated gene transfer with the beta-galactosidase marker was used to examine lineage relationships in cultures of embryonic rat SCG. Retrovirus-labelled clones from ganglia dissociated at E13, E14 or E17 contained cells of either neuronal or non -neuronal morphology. These data suggest that neuronal and glial precursors are committed before or shortly after gangliogenesis. In situ, clusters of non-neuronal cells were observed transiently at E18 and may represent the expansion of a glial precursor. These cells lacked detectable immunoreactivity for tyrosine hydroxylase (TH), fibronectin and laminin. Non-neuronal clusters were no longer observed by birth, suggesting that cells subsequently migrate and associate with principal neurons. Before the completion of neurogenesis, neuronal precursor cells contained variable levels of catecholamines, and stained brightly with antibodies for TH, but did not contain the numerous dense-cored vesicles characteristic of mature SIF cells. Individual cells with a SIF phenotype appeared at E16/18 near blood vessels, and smaller, clustered SIF cells were seen after birth. Because the embryonic SIF-like cells were larger and found individually, these cells may represent SIF precursors which divide to give rise to smaller postnatal SIF cells in groups. These studies reveal that both lineage restrictions and environmental signals are important in the generation of cell diversity in the developing SCG.

Cell Type-Specific Expression of Phosphomyristin C in Glial Cell Lines and the Murine Nervous System. D Hilt. Farrand, P Fishman, and D Kligman. Dept. of Neurology, University of Maryland School of Medicine, Baltimore, Md. 21201

Phosphomyristin C (PMC-also known as the 80k or the MARCKS protein) is an approximately 80kD protein kinase C (PKC) substrate. PMC is phosphorylated rapidly after PKC activation and may function as an important mediator of PKC action. PMC is expressed in a variety of tissues but the cell type-specificity of expression in the nervous system has not been well studied. Using an antisera raised against a tryptic oligopeptide from purified rat brain PMC the expression of PMC in the RT4 cell culture system was examined. By Western blot analysis it was determined that PMC is present in a bipotential precursor cell type (AC36) and in a glial daughter cell line (D6) but is not expressed in two separate neuronal daughter cell lines (B8 and E5). Conversely, GAP43, a putatively neuron-specific protein kinase C substrate in the nervous system, was expressed in the two neuronal cell lines but not in the glial cell lines. Experiments to demonstrate the phorbol ester induced phosphorylation of these two important kinase C substrates in the RT4 cell lines will be shown.

The glial cell type-specific expression of PMC in the RT4 cells suggested that in the nervous system PMC was primarily expressed in glial cells. Therefore, the distribution of PMC in the adult murine nervous system was determined by immunocytochemical techniques. Within the CNS anti-PMC antisera revealed a dense network of fine glial processes without labeling of neurons. Both astrocytes and microgila were stained in the brain and the spinal cord. Schwann cells showed consistent cytoplasmic labeling in the PNS. These results suggest that PMC may serve as an important mediator of PKC action in glial cells in the nervous system

CO-EXPRESSION OF PNMT AND NEUROFILAMENT IN ADRENAL CHROMAFFIN CELLS. G. Teitelman. CELLS. S. <u>G. T.</u> Neurobiol., Teitelman, l., Cornell M.J. Evinger and M. Ehrlich, Div. Univ. Med. Coll., New York, NY 10021. Div.

The epinephrine synthesizing enzyme phenylethanolamine N-methyltransferase (PNMT) appears at embryonic day 16 (E16) in the rat adrenal in a subset of neural crest derived chromaffin cells. *In vitro*, these cells can be induced to extend neurites containing neurofilament (NF). We sought to determine whether adrenal medullary cells may simultaneously express neuronal traits and PNMT. Rat adrenals were removed and processed for neurofilament immunocytochemical localization of PNMT and NF in the same tissue section. We found that, in embryos, a tissue section. We found that, in contain percentage of chromaffin cells contain significant percentage of chromaffin cells contain both markers (E16=20%; E17=40%; E20=17%). In contrast, PNMT cells of adults do not contain NF. To ascertain whether the loss of neuronal properties from mature epinephrine cells is irreversible, adult bovine chromaffin cells irreversible, cells adult maintained for two weeks in glucocorticoid free media were immunostained. The cultures contained many PNMT(+) cells, some of which extended long various processes. cells, some of which extended long varicose processes. Sister cultures contained many NF(+) cells. We conclude that embryonic chromaffin cells co-express adrenergic and neuronal traits and that suppression of the neuronal phenotype during maturation is coverille. phenotype during maturation is reversible.

CHARACTERIZATION OF GLIAL CELL DIVERSITY IN THE NEONATAL RAT SPINAL CORD. Robert H. Miller and Vilma Szigeti. Department of Neuroscience, Case Western Reserve University School of Medicine, Cleveland, OH. 44106.

Considerable evidence suggests that many regions of the vertebrate CNS contain more than one type of astrocyte, in addition to oligodendrocytes. Three different approaches were used to examine whether the developing spinal cord also contained multiple glial cell types: Single cell cloning, retroviral lineage tracing in vitro, and the generation of cell type specific monoclonal antibodies

type specific monocional antibodies.

Single cell cloning studies demonstrated that the neonatal rat spinal cord contained six morphologically distinct glial cell populations whose precursors differed in abundance and proliferative capacity. Labeling with antibodies against glial fibrillary acidic protein showed that at least four of these populations were astrocytes. To determine if such morphologically distinct subpopulations of glial cells could be identified in a more complex cellular environment, retroviral lineage analysis was performed on complete neonatal rat spinal cord cultures. In this case, morphologically discrete labeled

neonatar fat spinal cord cultures. In this case, morphologically discrete labeled clones of cells were also seen. In addition, the vast majority of labeled clones contained cells with a homogeneous morphology.

Novel monoclonal antibodies generated against spinal cord glia specifically labeled the surface of subsets of astroctyes, suggesting that these cells are antigenically, morphologically and developmentally distinct.

These studies suggest that a cytoarchitecturally complex tissue such as the mammalian spinal cord may contain as many as six different types of glial cell, each of which presumably subserves distinct functions in the developing and adult spinal cord.

MIGRATION OF LHRH NEURONS FROM THE OLFACTORY PLACODE TO

THE BRAIN IN THE CHICK. R.B. Norgren and M. N. Lehman. Dept. Anat. & Cell Biol., Univ. Cincinnati Med. Coll., OH 456267

Recent findings in the mouse suggest that luteinizing hormone releasing hormone-immunoreactive (LHRH-IR) neurons do not originate in the brain, but rather migrate into the brain from the olfactory placode early in development. We have examined the distribution of LHRH-IR neurons in the developing chick. Chick embryos were immersion-fixed in 4% paraformaldehyde, and horizontal cryostat sections were incubated in an antisera to LHRH (LR-1, gift of Dr. R. Benoit) and the LHRH visualized with either an avidin-biotin-HRP technique or avidin-Texas red. In E4 chick embryos, a small cluster of cells of LHRH-IR neurons were found just lateral to the brain, immediately ventral to the olfactory pit. A few labeled cells were also apparent in the epithelium of the ventral olfactory pit. In E7 chick embryos, many more labeled cells were observed. A few LHRH-IR neurons were observed in the nasal epithelium. Clusters of LHRH-IR neurons appeared to form a chain stretching along the olfactory tract and dorsal-caudally in close proximity to the medial edge of the telencephalon. In dorsal sections, a few LHRH-IR neurons were found in the brain and had labeled processes that appeared to make contact with the lateral ventricle. Our results suggest that LHRH-IR neurons arise from a cell group associated with the olfactory placede and migrate along the olfactory tract before entering the brain. We are currently examining other stages of chick embryos to substantiate this hypothesis. [Supported by NIH grant HD 21968 (MNL)]

A NEURONAL INTERMEDIATE FILAMENT PROTEIN, IS EXPRESSED A NEURONAL INTERMEDIATE FILAMENT PROTEIN, IS EXPRESSED IN THE RAT INSULINOMA CELL LINE M.M. Portier, M. Escurat, K. Diabali, C. Huc, A. Prochiantz, C. Bécourt* and C. Boitard* Collège de France, 75231 Paris Cedex 05 and *Service d'immunologie, 161 Rue de Sèvres, 75743 Paris Cedex 15, France

The developmental lineage of endocrine pancreatic cells has long been a matter of controversy and two possible origins have been proposed; either endodermal or neuroectodermal. However, a study of the nature of intermediate filament proteins (IFP) expressed in the rat RIN 5F insulinoma cell line by biochemical and immunological methods reveals that these cells express neuronal IFP : neurofilaments proteins (NFP) and peripherin which has been shown to be expressed in well defined neuronal populations and particularly in every neuron from neural crest origin. However, these IFP are not expressed in the islets of Langerhans.

Interestingly, NFP and peripherin are present in the rat PC 12 pheochromocytoma cell line although they are expressed neither in the adrenal medulla nor in the tumor from which the PC 12 cell line is derived. A parallel can thus be established between the expression of IFP in the rat insulinoma RIN 5F cell line and in the rat pheochromocytoma PC 12 cell line suggesting a common neural crest origin for the cells from which these cell lines originate.

PROLIFERATION IN THE NEURAL PLATE OF THE ASCIDIAN EMBRYO: BIRTH-DATES OF CELLS IN THE LARVAL CNS. T. Bollner and I. A. Meinertzhagen, Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia. CANADA B3H 4J1

The tadpole larva of ascidians possesses a dorsal tubular CNS which is derived from an ectodermal neural plate in the embryo and contains only 370 or so cells. Two contemporary accounts differ as to whether all anterior neural plate cells contribute to the CNS. Descriptive studies in *Ciona* indicate that they contribute only CNS cells (Nicol, D.& I.A.Meinertzhagen, *Dev. Biol.*, 130:737, 1988); Whereas HRP blastomere injections in *Halocynthia* imply that anterior neural plate cell rows migrate anteriorly nd acquire non-neural ectodermal fates (Nishida, H., Dev. Biol., 121:526, 1987). The interpretation of these differences rests upon when proliferation in the CNS actually ends. Thymidine incorporation has been reported in neural plate cells up to the tenth cleavage (Reverberi, G., et al., Acta. Embryol., 3:202, 1960), too early to arbitrate. In resolution, we have examined 5-bromo-dcoxyuridine (BrdU) incorporations in neural plate cells of the ascidian Ascidia ceratodes, using anti-BrDU immunocytochemistry. Embryos were exposed to BrdU (1 mM in sea-water) at 7hrs (38%), 14hrs (75%), or 15 hours (81%) post fertilization, or at hatching (100%), and left in the BrdU until fixation 6hrs post-hatching. Larvae labelled from 7hrs development showed immunostaining in both anterior and posterior parts of the larval CNS, as well as in the so-called neurohypophysis, progenitor of the adult neural complex. Exposure at 14 and 15hrs produced staining in the anterior CNS even though of fewer cells than in the 7hrs group. In the neurohypophysis, labelling seemed as frequent as in the earlier group. Embryos exposed to BrdU at hatching exhibited no CNS incorporations. Although it is not certain whether the labeled CNS cells are neurons, glial or ependymal cells, we conclude that cell division occurs later than 70%, currently the best previous estimation for cersation time. The similarity in labelling patterns between the 14 and 15-hr groups is possibly explained by the relatively long cell-cycle during late neural development. Supported by NSERC grant A 0065 (to I.A. M.).

DIFFERENCES IN CELLULAR LABELING BY TRITIATED PROLINE IN NEURONAL TISSUES OF DIFFERENT EMBRYOLOGICAL ORIGIN. C. Hubscher and K. J. Berkley. Dept. of Psychology, Florida St. Univ., Tallahassee, FL 32306-1051.

It has been shown that tritiated proline (³H-pro) is selectively

It has been shown that tritiated proline (3H-pro) is selectively incorporated into macroglial, but not neuronal proteins throughout the brain. In dorsal root ganglia, however, 3H-pro is incorporated into neuronal (ganglion cell) proteins (Contos, N., Molinari, H. H. and Berkley, K. J., Brain Res., 479:172, 1989). The basis for this difference is unclear. Brain and dorsal root ganglion tissue differ not only in their embryological origin (i.e., neural tube and neural crest, respectively) and location, but also in their synaptic and cellular configurations. In order to determine if configurational rather than embryological factors accounted for 3H-pro's incorporation into neuronal proteins in dorsal root ganglia, 3H-pro was injected, in adult rats, into autonomic and sensory ganglia that differ in their synaptic and cellular configurations. The ganglia were then examined with light microscopic autoradiographic techniques. Included were the following: C2 dorsal root and nodose ganglia, superior cervical and pelvic ganglia. Unlike brain tissue, neurons were labeled in every ganglion. These results support the conclusion that it is the neural crest origin of the dorsal root ganglion, and not a specific configurational arrangement, that accounts for the labeling of its neurons by 3H-pro. Such results further suggest that the selective incorporation of 3H-pro by macroglial cells in the brain may be due to their derivation from the neural tube.

CONTROL OF SEGMENT IDENTITY IN THE LEECH EMBRYO. <u>L. Gleizer and G. S. Stent</u>. Graduate Group in Neurobiology, Univ. of California, Berkeley, CA 94720.

Although the 32 segments of the leech body arise from homologous sets of mesodermal and ectodermal blast cell clones, they are distinguished by characteristic sets of morphological features that reflect unique segmental identities. For instance, in *Theromizon rude*, nephridia are present in only 14 and genital primordia in only 2 segments. To ascertain whether the segment-specific distribution of these features, which are of mesodermal origin, is attributable to a mechanism which is intrinsic to the mesodermal blast cells, their bandlet was induced to slip out of segmental register so that the mesodermal cell clones were made to take part in the formation of segments for which they are not normally destined. Such shifted mesodermal blast cells autonomously expressed their original segment identity, giving rise to segment-specific structures according to their original birth rank rather than to their new position. It appears, therefore, that the origin of longitudinal differentiation in the mesoderm is intrinsic to the mesodermal blast cell bandlet.

This procedure also allowed us to investigate whether segment-specific features are determined by their mesodermal environment since in experimental embryos the mesoderm is shifted out of segmental register relative to the ectoderm. The results of these studies indicate that some segment-specific features of ectodermal development, such as the soma size of the identified Retzius neurons, are controlled by the segmental identity of the local mesoderm, while others, such as the presence or absence of the identified ams neurons, are not.

FLUORESCENT LABELING OF DEVELOPING ENDOTHELIUM AND BLOOD VESSELS IN *XENOPUS LAEVIS*. <u>C.M.Rovainen</u>. Dept. Cell Biology and Physiology, Washington Univ. School of Medicine, St.Louis, MO 63110

The goal of this work has been to observe the behavior of single endothelial cells during angiogenesis. Clones of cells were labeled by pressure injections of tetramethylrhodamine-dextran (MW 10,000) into single blastomeres in 16-128 cell stage embryos of "albino" Xenopus laevis. Early tadpoles with labeled endothelial cells and blood vessels were selected for detailed sequential examinations with an epifluorescence microscope, SIT camera, and video recordings. None of the early blastomeres produced clones which consisted exclusively of vascular endothelium. Other labeled cells included muscle fibers, lymphatics, mesodermal stellate cells, circulating blood cells, gut, and some epidermis. Fluorescence was intitially cytoplasmic but later became vesicular. Small fractions of total endothelial cells were labeled. Single endothelial cells and small groups could often be recognized and followed in case histories in vessels of the tail fin, brain, external gills, and aortic arches. In established vessels the patterns of fluorescent endothelial cells typically were stable for several days and occasionally for weeks until fluorescence faded. In a few clear cases single labeled cells migrated distally in elongating endothelial sprouts. Fluorescent dextrans are suitable clonal markers for observations in vivo of developing cells in Xenopus tadpoles over days and weeks

LTP AND PTP IN A SIMPLIFIED PIRIFORM CORTEX SLICE: EFFECTS OF APV, APB AND DIVALENT CATIONS. N. Hori, P. McCauley* and D. O. Carpenter. Wadsworth Labs, NYS Dept. Health and School of Public Health, Albany, NY 12201.

Using a simplified slice containing only apical dendrites of pyramidal neurons we have demonstrated LTP in the lateral olfactory tract (LOT)-piriform cortex nother lateral offactory tract (LDT)-piriform cortex pathway. Population EPSPs were evoked by 0.5 - 1.0 Hz supramaximal stimulation of the LOT. Tetanization (100 Hz for 1 sec.) induced a transient PTP (peak time 2-5 sec. post tetanus) and a stable LTP lasting greater than 2 hrs. LTP was seen in almost all preparations, and peak EPSP was increased an average of about 15%. PTP was significantly enhanced by perfusion with low Ca²⁺ high Mg²⁺ medium and local anesthetics. Aminophosphonobutyric acid (APB) (10⁻⁴M) depressed the EPSP but dramatically enhanced PTP. These observations are consistent with the conclusion that PTP is presynaptic and that APB acts at a presynaptic site. LTP was unaffected by APB but was blocked by aminophosphonovaleric acid (APV) (5 x 10^{-5} M) or perfusion with a high ${\rm Mg}^{2+}$ (6.3 mM) solution. These results are consistent with the view that LTP is at least primarily post-synaptic and is dependent upon activation of NMDA receptors.

274.3

DITHIOTHREITOL INCREASES THE MAGNITUDE OF LTP. D. L. Tauck and G. A. Ashbeck*, Department of Biology, Santa Clara University, Santa Clara, CA 95053.

In several neuronal preparations, currents evoked by exogenous NMDA are potentiated by treatment with the sulfhydryl reducing agent dithiothreitol [DTT] (Aizenman, et al., 1989, Neuron 2:1257). Since activation of NMDA receptor/channel complexes underlies long-term potentiation, we used LTP as an assay for NMDA receptor activation in rat hippocampal field CA1. Applied in the perfusate, DTT had no effect on field potentials recorded either in stratum pyramidale or s. radiatum in response to low frequency stimulation. Prior treatment with 10 μ M DTT greatly increased the effects of high frequency stimulation (100 Hz for 1s). Slices exposed to DTT developed more than twice as much LTP of both the population spike and the EPSP than controls. The effect of DTT could be modulated by agents known to act at the NMDA complex. Glycine (100 nM) further potentiated the effect of DTT through a kynurenate-sensitive mechanism. APV blocked LTP although a higher concentration was required in DTT-treated slices. These results suggest that reduction of sulfhydryl groups in NMDA complexes or closely related proteins greatly increases the efficacy of synaptic transmission mediated by NMDA channels in intact tissue.

FACTORS CONTROLLING THE TIME COURSE OF SYNAPTIC POTENTIATION

FACTORS CONTROLLING THE TIME COURSE OF SYNAPTIC POTENTIATION IN AREA CA1 OF THE HIPPOCAMPUS. <u>R.C.Malenka</u>. Depts. of Psychiatry and Physiology, University of California, San Francisco, CA. 94143
A variety of experimental manipulations result in a decremental potentiation of synaptic transmission distinct from LTP. Recording in the CA1 region of the hippocampal slice, I have examined some of the factors which can convert a decremental enhancement of synaptic transmission to LTP.

In a single slice, the time course of synaptic enhancement was affected by the concentration of D-APV. In high (20-40 uM) D-APV, a tetanus (50-100 hz, 5-1 sec) caused PTP lasting only 20-50 sec. In 1-2 uM D-APV, the same tetanus resulted in a decremental potentiation (3-30 min). Upon wash out of the D-APV, the tetanus induced non-decremental LTP (lasting 1 hour).

The interval between brief conditioning trains and single test stimuli evoked in independent afferents also could affect the time course of synaptic enhancement. Using a fixed number of pairings in a single slice, decremental potentiation was elicited when the tetanus followed the test stimulus by 20-40 msec whereas non-decremental LTP was induced when initiation of the tetanus preceded the test stimulus by 20-30 msec.

Using intracellular recording, a number of manipulations could control the

preceded the test stimulus by 20-30 msec.
Using intracellular recording, a number of manipulations could control the time course of synaptic enhancement in single cells. Pairing 10 stimuli (1-2 hz) with different levels of postsynaptic depolarization converted a decremental (5-20 min) potentiation to LTP. Similar results were obtained by varying the timing between a brief depolarizing current pulse and afferent stimulation or by changing the frequency of a fixed number of afferent stimulation or by changing the postsynaptic cell to a constant level.

These findings are consistent with the proposal that the magnitude of NMDA receptor-dependent postsynaptic calcium accumulation can control the time course of synaptic enhancement. Specifically, a "moderate" postsynaptic calcium increase may cause a decremental synaptic enhancement whereas a higher, "threshold" level of postsynaptic calcium may be required to generate non-

"threshold" level of postsynaptic calcium may be required to generate nondecremental LTP.

DEPENDENCE OF TETANUS INDUCED LONG-TERM POTENTIATION IN HAMSTER HIPPOCAMPAL SLICES MAINTAINED IN 4.5 mM EXTRACELLULAR CALCIUM. M. S. Krelstein and J. Horowitz, Animal Physiol., Univ. of Calif., Davis, CA 95616

Previously we have shown that the initial expression of long-term potentiation (LTP) is temperature dependent and is blocked at 20°C in CAl pyramidal cells. In addition, the thermal block of LTP at low temperatures is calcium dependent, since it can be overcome if a tetanus is applied during a high calcium (4.5 mM) pulse. However, the effects of temperature on tetanus induced LTP in maintained elevated extracellular calcium remains to be determined. Using standard procedures (Living in the Cold, John Libbey, London, pp 245-253, 1989), in the hamster (Mesocricetus auratus) we measured field PSPs from the stratum radiatum auratus) we measured field PSPs from the stratum radiatum in area CAl before and after tetanizing the Schaffer collateral/commissural fibers in slices maintained in 4.5 mM calcium. We found that though tetanus induced LTP is clearly observed in slices maintained in 4.5 mM calcium at 30° C and at 25° C, LTP cannot be observed in slices maintained in 4.5 mM calcium at 20° C. However, initial triggering events are operational at 20° C, since LTP is observed relative to control responses (recorded at 24° C) when, following a tetanus at 20° C, a slice is warmed back to 24° C. [Supported by NSF grant RNS-88-19973] to 24°C. [Supported by NSF grant BNS-88-19973]

LOW CONCENTRATIONS OF NMDA BLOCK THE INDUCTION OF CA1 LONG-TERM POTENTIATION. Y.Izumi, D.B.Clifford

univ., St.Louis, Mo63110.

N-methyl-D-aspartate(NMDA) receptors play a critical role in the development of long-term potentiation(LTP) in CAl of the hippocampus. However, previous studies have demonstrated that pretreatment with NMDA inhibits the development of LTP produced by perfusion of conditioning solutions (Neurosci.lett.,88:201,1987), suggesting that untimely NMDA receptor activation may have an antagonistic effect on LTP-development.

To extend this observation we have examined the effects of NMDA agonists on LTP produced by tetanic stimulation of the Schaffer collateral pathway. A five-minute application of NMDA(0.2pathway. A five-minute application of NMDA(0.2-2.0 μ M, N=15), aspartate(5-100 μ M, N=20) or glutamate(50 μ M, N=5) reliably inhibited the development of CA1 LTP measured 20 minutes after tetanic stimulation. Quisqualate(1-5 μ M, N=7) had no effect on LTP. TEA(5mM) blocked the inhibitory effect of NMDA on LTP(N=2).

Preliminary intracellular recordings indicate

that NMDA produced an augmentation of a synaptic afterhyperpolarization. The afterhyperpolarization may contribute to the inhibition of LTP by NMDA.

DEVELOPMENTAL CHANGES IN SYNAPTIC PROPERTIES AND ONSET OF LTP IN ORGANOTYPIC HIPPOCAMPAL CULTURES.

D. Muller, and L. Stoppini Department of Pharmacology, Centre Médical Universitaire, 1211 Geneva 4, Switzerland.

In order to study the mechanisms responsible for the onset of long-term potentiation (LTP) during the second week after birth, we have developed a simple method to maintain hippocampal slices in culture

and analyse synaptic properties during the first days of culture. Hippocampal slices (450-500 um thick) of 4-6 day old neonates were prepared. They were then placed on a poreous and translucid membrane at the interface between a regular culture medium (MEM + 25% horse serum) and an atmosphere containing 5% CO2. In those conditions slices survive for several weeks, keep their organotypic organization and tend within a few days to flaten into a mono- or bilayer. Both extra- and intracellular recordings have been obtained at different times of culture. In all slices we observed that synaptic responses disappear within a few hours of culture. This silent period lasts for about 48 hours. At days 3-5, excitatory field potentials of 1-2 mV can again be evoked in the different hippocampal areas with a selectivity which is compatible with a preserved organotypic organization. EPSPs are characterized by a very small degree of paired-pulse facilitation, LTP is absent and there is no evidence of inhibitory responses. At days 10-12, field potentials of 3-10 mV are obtained, paired-pulse facilitation is significantly increased, LTP can be induced by high frequency stimulation and strong inhibition is present. It is concluded that the same developmental changes take place with the same time course in in vitro organotypic hippocampal cultures as in vivo. Work supported by FNRS 3.173.0.88.

ENVIRONMENTAL MANIPULATIONS CAN REPEATEDLY INFLUENCE HIPPOCAMPAL PB POTENTIATION IN THE BEHAVING RAT D.M. Diamond, M. Fleshner and G.M. Rose. Dept. of Pharmacology, University of Colorado Health Sciences Center and VA Medical Center, Denver, Colorado 80262

Exposure to a novel environment, which is stressful to a rat, interferes with the induction of primed burst (PB) potentiation (Diamond et al., *Psychobiology*, in press). In the present report, we have manipulated the stress-induced blockade of hippocampal plasticity repeatedly within animals. We hypothesized that the experimenter can influence the efficacy of PB stimulation by placing an animal into either a familiar (*facilitatory*) or a novel (*inhibitory*) environment.

We recorded CA1 population spikes in behaving rats (see Diamond et al., *J. Neurosci.*, 8:4079, 1988 for details). PB potentiation occurred when subjects had acclimated to CHAMBER 1. One week later, we recorded from the same subjects when they were in a novel environment (CHAMBER 2). PB potentiation did not occur in CHAMBER 2. When the subjects were returned to CHAMBER 1, PB potentiation again occurred. Correlative data indicate that PB potentiation was more likely to occur when placement of the animal in a recording chamber did not increase serum corticosterone levels.

These findings indicate that, as with learning and memory, hippocampal plasticity in behaving rats is acutely sensitive to environmental manipulations. Novel environments impair, and familiar environments enhance, the effectiveness of PB stimulation.

LTP INDUCED BY PATTERNED STIMULATION IN THE CAI REGION IS DIFFERENT IN PROXIMAL AND DISTAL APICAL DENDRITES. G. Capocchi*, R. Corradetti, G. Della Torre* and M. Zampolini*. Ist. Clin. Malattie Nervose e Mentali, Univ. of Perugia, 06100 Italy.

The induction of long-term potentiation (LTP) at distal (dAD) and proximal (pAD) level of Apical Dendrites in the CAl region was investigated in rat hippocampal slices. The stimulating and recording electrodes were placed in the stratum radiatum at pAD or dAD level. LTP was evoked by short bursts (4 pulses at 100 Hz), repeated (2-10 times) with different intervals (2-1-0.2-0.1-0.05 sec) in different slices. The results showed that: 1) in pAD but not in dAD two bursts were able to induce LTP; 2) in pAD but not in dAD an interburst interval of 0.1 sec was as effective as a 0.2 sec interval in eliciting LTP; 3) in pAD the increase in amplitude and slope of the field potential during LTP was greater (P<0.05) than that obtained in dAD; 4) the same differences were observed regardless the position (pAD or dAD) of the stimulating electrode.

The results suggest that the expression of LTP differs in pAD and dAD, reflecting different properties of somatic and dendritic components.

274.11

DEVELOPMENT OF HIPPOCAMPAL LTP IS SUPRESSED BY CALPAIN INHIBITORS. S. Del Cerro. J. Larson. M.W. Oliver and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717, U.S.A.

University of California, Irvine, CA 92717, U.S.A.

We have previously proposed that calpains (calcium-activated proteases) could play a role in the establishment of long-term potentiation (LTP). In the present study we have examined the effects of two recently synthesized inhibitors of calpains, calpain inhibitors I and II (CII and CiII), on the development of LTP in field CA1 of rat hippocampal slices. Theta burst stimulation (TBS) induced stable LTP (defined as a potentiation of at least 15% that did not detectably decay between 20 and 30 min. after TBS) in 80% of pathways tested in control slices. However, only 37% of slices treated with CII (100 mM) and 40% of slices treated with CiII (100 mM) showed stable LTP by the same criterion. Neither CiI nor CiII had any significant effects on the postsynaptic responses to the high frequency stimulation used to induce LTP, indicating that the drugs did not disturb the physiological processes that trigger the effect. It appears that the calpain inhibitors impair the development of stable LTP rather than blocking its induction mechanism.

mechanism.

These results confirm and extend previous findings using the protease inhibitor, leupeptin, since Cit and Cill are both more potent and selective inhibitors of calpains than leupeptin. Therefore, they strengthten the hypothesis that calcium influx through NMDA receptor channels during high frequency synaptic stimulation triggers a calpain-mediated proteolytic event that is involved in the development of stable synaptic potentiation.

LONG-TERM POTENTIATION (LTP) INDUCED BY PATTERNED STIMULATION OF THE COMMISSURAL PATHWAY TO HIPPOCAMPAL CAI REGION IN BEHAVING RATS. <u>L. Stan Leung.</u> Depts. Clin. Neurol. Sci. and Physiology, Univ. Western Ontario, London, Ontario N6A 5A5 Canada.

Patterned stimuli (typically 8 bursts of 1 pulse followed 130 msce later by 10 pulses at 100 Hz) of 0.1 ms duration and various intensities were delivered to the contralateral hippocampus while recording from the CA1 region in freely moving rats. Single-pulse responses to the commissural stimulation were recorded before and after the patterned bursts, typically during awake immobility or slow-wave sleep. The responses consisted of early population excitatory postsynaptic potentials (EPSPs), sometimes accompanied by a population spike, and late - (30-50 msec) latency potentials. Single-pulse stimulation of str. oriens of the contralateral CA1 or CA2/CA3 gave mainly basal-dendritic EPSPs that were (alvear-) surface negative and deep-positive. Single-pulse stimulation of str. radiatum of the contralateral CA1 gave mainly apical-dendritic EPSPs that were surface-positive and deep-negative. The basal-dendritic response in CA1 showed a consistent and robust LTP. Potentiation of the slope of the population EPSP was 222 ± 22% (mean ± S.E.M., 9 rats) at 30 min after the patterned bursts, and decayed exponentially with a time constant of about 5 hr. Population spikes were potentiated for a shorter duration. In contrast, patterned bursts delivered to sites evoking an apical-dendritic response in CA1 were only successful in cliciting LTP in 1 of 7 rats. Even when afterdischarges were evoked, another 14 rats showed little LTP of the apical-dendritic response. The results were confirmed using other tetanic stimuli. The difference in the LTP propensity of intrinsic hippocampal pathways may have functional implications for memory and information processing (Supported by NS25383).

274.10

EVIDENCE THAT LTP EXPRESSION IS NOT DUE TO CHANGES IN SPINE NECK RESISTANCE. M. W. Jung, J. Larson and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

Long-term potentiation (LTP) could be expressed by morphological changes in dendritic spines that decrease their longitudinal electrical resistance and, hence, enhance the synaptic current produced by a given amount of synaptic conductance. One prediction of this hypothesis is that synaptic current in potentiated spines should be more affected by changes in synaptic conductance than current in unpotentiated spines. This was tested by using field potential recordings of synaptic responses in CA1 pyramidal cells in hippocampal slices in response to stimulation of Schaffer/commissural inputs that either received LTP-inducing stimulation or did not. Two manipulations were used to systematically reduce synaptic conductances: reductions of extracellular Ca^{++} and partial blockade of postsynaptic receptors with 6,7-dinitroquinoxaline-2,3-dione (DNQX) or kynurenic acid. The initial slopes of the control and potentiated (56.9±11.0 % LTP) responses were reduced by 67.1±3.9 % and 68.6±2.9 %, respectively, by lowering extracellular Ca++ from 3.4 mM to 1 mM. The initial slopes of the control and potentiated (43.1 \pm 5.2 % LTP) responses were reduced by 66.4 \pm 4.7 % and 65.1 \pm 5.1 %, respectively, by bath application of DNQX (final concentration 1-2 μ M). Finally, the initial slopes of the control and potentiated $(49.4\pm7.8\% \text{ LTP})$ responses were reduced by $47.8\pm3.3\%$ and $43.3\pm3.3\%$, respectively, by perfusion of 500 μM kynurenic acid. Statistical analysis revealed no significant differences in response reduction between control and potentiated pathways by each manipulation. These results suggest that LTP expression is not due to a change in the ratio of synaptic current to synaptic conductance as would be predicted by the spine resistance hypothesis. ENHANCED SENSITIVITY OF METABOLOTROPIC GLUTAMATE RECEPTORS AFTER LONG-TERM POTENTIATION (LTP) IN RAT HIPPOCAMPUS. E. Aronica*. K. Reymann*#. M. Krug*#. U. Frey*#. H. Schroeder*#. C. Speciale and F. Nicoletti*, Inst. of Pharmacol. Univ. of Catania, Italy; and #Inst. of Neurobiol. and Brain Res., Acad. of Sci. of G.D.R., Magdeburg, G.D.R. Recent studies have implicated a role for metabolotropic glutamate receptors in activity-dependent synaptic plasticity (Dudek, S.M. and Bear, M.F., Science, 246:673, 1989). We now report that stimulation of [3H]inositolmonophosphate formation by ibotenate (IBO) was potentia-

Recent studies have implicated a role for metabolotropic glutamate receptors in activity-dependent synaptic plasticity (Dudek, S.M. and Bear, M.F., <u>Science</u>, 246:673, 1989). We now report that stimulation of [3H]inositolmonophosphate formation by ibotenate (IBO) was potentiated in hippocampal slices after tetanization of the Schaffer collateral-commissural pathway or the perforant pathway projecting to the dentate gyrus. The increased response to IBO developed slowly (after 4-6 hours), and was not observed when tetanization was performed in the presence of AP5 or AP7, which prevented LTP formation. LTP was also studied in rats repeatedly injected with LiCl, which blocks the recycling of inositol into membrane phospholipids. In these animals, tetanization of the perforant pathway induced a decremental form of LTP, that decayed within 4-5 hours. These results support a role for metabolotropic glutamate receptors in the synaptic events enabling the expression and/or maintenance of LTP.

LONG - TERM POTENTIATION (LTP) IN RAT DORSAL LATERAL SEPTAL NUCLEUS (DLSN) IS NOT BLOCKED BY DL - 2 - AMINO - 5 - PHOSPHONOPENTANOATE (APS). Fang Zheng and J.P. Gallagher, Dept. of Pharmacology & Toxicology, Univ. of Texas Medical Br., Galveston, TX 77550. Intracellular recordings were made from DLSN neurons following orthodromic low frequency (0.1 Hz) stimulation. Synaptic potentials, including a fast EPSP, fast IPSP, and LHP were elicited focally in a coronal slice of basal forebrain. Combinations of the NMDA receptor antagonist, AP5 (50µM), and the non-NMDA receptor antagonist, CNQX (20µM), or, the non-selective excitatory amino acid antagonist, kynurenic acid (5 mM), failed to block EPSPs, completely. AP5 pretreatment increased EPSP amplitude following 0.1Hz stimuli to a value 20 to 40% above control.

LTP was induced at this synapse with high frequency trains of stimuli (100 Hz, 1s duration, at an interval of 20 sec). LTP was defined as an increase of EPSP amplitude to greater than 120% of its control value. Following tetanization, EPSP amplitudes ranged from 130 to 300% greater than control. AP5 alone or the combination of AP5 with CNQX could not block the induction of LTP. LTP could also be induced in the absence of bicuculline, demonstrating that LTP can be induced without blocking GABA_A mediated inhibition in the rat DLSN. Preliminary experiments showed that L-alpha-aminophosphonobutyrate (L-AP4, 150µM) could block the induction of LTP.

We suggest that L-AP4 - sensitive - quisqualate receptors, possibly coupled to a phosphoinositol second messenger system, are necessary for the induction of LTP in the DLSN.

CELLULAR MECHANISMS UNDERLYING LONG-TERM BETA-

CELLULAR MECHANISMS UNDERLYING LONG-TERM BETA-ADRENERGICALLY MEDIATED POTENTIATION IN THE CAI REGION OF RAT HIPPOCAMPUS. M. Taylor, T.V. Dunwiddie and W.R. Proctor. VA Med. Center and Univ. of Colorado Hith. Sci. Ctr. We have previously demonstrated that isoproterenol (ISO) and norepinephrine (NE) can produce a persistent excitatory effect in the CAI region of rat brain slices, which we have termed b-adrenergic potentiation (BAP). The purpose of the present study was to investigate the cellular mechanism(s) underlying BAP. Isoproterenol (500 nM) was found to produce a long lasting potentiation of only the population spike amplitude, which outlasted the duration of the drug superfusion by as much as an hour. Because ISO had no effect on the EPSP response, this suggested that the primary change was in the excitability of the pyramidal neurons. To test this hypothesis we examined the effects of ISO on repetitive bursting evoked by antidromic stimulation of the CA1 pyramidal neurons in medium containing 0.24 mM calcium. Under these conditions, ISO produced an increase in burst amplitude that far outlasted the duration of drug superfusion. Intracellular recording experiments demonstrated directly that some of the postsynaptic effects of ISO (e.g., the reduction in the afterhyperpolarization) were quite persistent. We also investigated the actions of cAMP analogs and forskolin to see what role they played in BAP. Both 8-bromo-cAMP (500 µM) and forskolin (1 µM) mimicked the effects of ISO on orthodromic population spike responses. Pretreating slices with 8-pcpt-cAMP (100 µM) completely blocked subsequent responses to ISO, indicating that they acted upon a common mechanism. These experiments suggest that the long-term increase in the evoked ospecies for the property of the subsequent responses to ISO, indicating that they acted upon a common mechanism. These experiments suggest that the long-term increase in the evoked population spike response can occur in the absence of synaptic transmission and may be mediated by an increase in intracellular cAMP. MUSCARINIC MODULATION OF RAT HIPPOCAMPAL CA1 LONG-TERM POTENTIATION (LTP). P.E. Schulz & D. Johnston, Div of Neurosci & Dept of Neurol, Baylor College of Medicine, Houston, Tx 77030.

LTP is a use-dependent form of synaptic plasticity thought to underlie some forms of information storage in the nervous system. Alzheimer's dementia (AD) is associated with deficiencies of memory and cholinergic neurons. The hippocampus is prominently involved in AD and has a role in memory storage. Thus, an abnormality of cholinergic innervation of the hippocampus may contribute to the AD memory deficit; and, if the cholinergic system modulates memory in the hippocampus, then it may modulate hippocampal LTP. Our lab previously showed that muscarine inhibits mossy fiber synapse LTP (Williams & Johnston, Science 1988, 242, 84). Using extracellular recordings in the rat in vitro hippocampal slice preparation, this study extends that previous investigation to area CA1 where the LTP induction mechanism is different. Except for one series of experiments, slices were tetanized with 1.3mV pEPSPs.

Control slices showed LTP (128±13% of pretetanus pEPSP slopes at 1 hour

post tetanus, n=7). Bath applied carbachol (CCh) and muscarine (Mus) de pressed pEPSPs so that in their presence, the stimulus intensity was adjusted to obtain a 1.3mV pEPSP for tetanus. To control for the increased stimulus into obtain a 1.3mV pEPSP for tetanus. To control for the increased stimulus intensity, several slices were tetanized at 1.5mV (133±8%, n=5). CCh (0.1 μ M), a mixed muscarinic-nicotinic agonist, enhanced LTP (160±8% 2 hours post tetanus, n=4). Atropine (0.1 μ M) washed in with CCh blocked the LTP enhancement (139%, n=2), and Mus alone (0.5-10 μ M) enhanced LTP (178±19%, n=8), suggesting that the cholinergic effect is muscarinically mediated. Atropine alone (0.1 μ M) did not reduce LTP (143±7.4% at 1 hour, n=6). We conclude that the cholinergic system enhances LTP in CA1 via muscarinic receptors, and any endogenous acetylcholine released during tetanus in vitro does not significantly affect LTP (MH4754 AG0M32) not significantly affect LTP. (MH44754, AG00432)

LONG TERM INCREASES IN THE EVOKED POPULATION SPIKE IN THE CA1 REGION OF RAT HIPPOCAMPUS INDUCED BY BETA-ADRENERGIC RECEPTOR ACTIVATION T. V. Dunwiddie

BETA-ADRENERGIC RECEPTOR ACTIVATION T. V. <u>Dunwiddie</u> and <u>L. R. Thomas</u>. Dept. of Pharmacology, University of Colorado Health Sciences Center and VA Medical Center, Denver, CO 80262.

The effects of the selective β-adrenergic receptor agonist isoproterenol (ISO) were characterized in the CA1 region of the rat hippocampal slice preparation. As we have previously reported, 500 nM ISO increased the amplitude of the evoked population spike response without any corresponding effect upon the field EPSP responses. In the present studies we have demonstrated that the increase in this response is quite persistent and is not reversed by ~30 minutes of washout in the without any corresponding effect upon the interests in this responses is quite persistent, and is not reversed by >30 minutes of washout in the majority of the slices tested; we have termed this prolonged increase in pyramidal neuron sensitivity β -adrenergic potentiation (BAP). As with the acute effect of ISO, BAP is confined to an increase in the population spike response and not the EPSP. In input-output curves, this was clearly observed as a prolonged leftward shift in the EPSP-population spike relationship. Similar long-term increases could also be elicited by superfusion of the slices for 10 min with 20-50 μ M norepinephrine (NE). Although both the acute and the long-term effects of ISO were blocked by pretreatment with timolol, a β -adrenergic antagonist, they could not be reversed by timolol once the increased response was established. However, BAP was not blocked by pretreatment with 50 μ M APV, an NMDA receptor antagonist that blocks LTP and some other forms of NE-induced plasticity. Time course studies suggested that the $T_{1/2}$ for the decay of BAP was approximately 2 hours. These experiments demonstrate that NE can induce a novel and long-lasting increase in the excitability of the pyramidal neurons following relatively brief activation of β -adrenergic receptors. brief activation of β -adrenergic receptors.  β -ADRENERGIC RECEPTOR ACTIVATION INCREASES PHOSPHORYLATION OF SYNAPSINS I AND II AND INCREASES SYNAPTIC TRANSMISSION IN DENTATE GYRUS, BUT NOT IN AREA CAI OF THE HIPPOCAMPUS. M.D. Browning K.D. Parfitt V.A. Doze and D.V. Madison Dept. of Pharmacology, Univ. of Colorado Hth. Sci. Cntr., Denver, CO 80262; and Dept. of Molecular and Cellular Physiology, Stanford Univ. Sch. of Med., Stanford, CA 1205 94305.

Previous studies have shown that norepinephrine (NE) or isoproterenol (ISO) enhance the slope of the field excitatory postsynaptic potential (epsp) in the dentate gyrus of the rat hippocampal formation. In contrast, NE and ISO cause no increase in excitatory transmission in area CAI of the hippocampus. The molecular mechanism underlying this brain region-specific increase in synaptic transmission is not known. The phosphorylation of synapsins I and II, two homologous presynaptic vesicle-associated proteins, is thought to promote neurotransmitter release. We have previously observed ISO-enhanced phosphorylation of the synapsins in the dentate. The purpose of this study was to determine whether ISO-stimulated phosphorylation also occurs in area CAI where NE has no effect on excitatory transmission. These studies were correlated with electrophysiological studies in in viro hippocampal slices. Dentate and CAI minislices were incubated for 90 min in 3²PO₄ in unlabeled PO₄-free buffer followed by 10 min incubation in 1 µM ISO or control buffer. In some experiments, the ISO treatment was followed by a 30 min wash with drug-free buffer. Iso produced significant increases in the phosphorylation of the synapsins in dentate slices but had no effect on these proteins in CAI slices. Enhanced phosphorylation was not observed in the dentate following the 30 min of ISO free wash. Similarly, electrophysiological studies showed that ISO potentiated excitatory as studies have shown that norepinephrine (NE) or isoproterenol (ISO) wash. Similarly, electrophysiological studies showed that ISO potentiated excitatory transmission in the dentate but not in the CAI, as previously observed. Like the synapsin phosphorylation, the enhanced epsp in dentate gyrus returned to baseline levels within 30 minutes of washout of ISO. This close temporal and brain regional correlation between synapsin phosphorylation and ISO stimulation of synaptic transmission suggests that the synapsin proteins may play a role in the potentiating effect of ISO in the desirate. effect of ISO in the dentate.

MUSCARINIC RECEPTOR ACTIVATION BLOCKS 8-ADRENERGIC-INDUCED SYNAPTIC PLASTICITY BY A PERTUSSIS TOXIN-INSENSITIVE DEPRESSION OF EVOKED RESPONSES IN THE DENTATE GYRUS. E. C. Burgard and J. M. Sarvey. Department of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

We have previously demonstrated that bath application of 1µM muscarine can facilitate the induction of long-term potentiation (LTP) of evoked responses recorded in the rat dentate gyrus (Burgard and Sarvey, Neurosci Lett., in press). Here we show that a higher concentration (10µM) of muscarine produces a pertussis toxin (PT)-insensitive depression of evoked responses that blocks the induction of isoproterenol-induced long-lasting potentiation (LLP), but does not affect LTP induction.

In the hippocampal slice, stimulation of the medial perforant path evoked a

responses that blocks the induction of Isoproterenol-induced long-lasting potentiation (LLP), but does not affect LTP induction.

In the hippocampal slice, stimulation of the medial perforant path evoked a population spike (PS) and a dendritic EPSP recorded extracellularly in the dentate gyrus. A 10min bath application of D,L muscarine-Cl depressed evoked responses with an approximate EC₅₀ = 3µM. This depression could be blocked by muscarinic receptor antagonists with a relative potency of 4-DAMP > pirenzepine > AFDX-116, and is therefore probably mediated by M3 or M1 receptors. 10µM Muscarine depressed the PS to 12% of baseline and the EPSP to 81%. In vivo pretreatment with PT (1µp PT intradentate 3 days before slice preparation) had little effect on the depression produced by 10µM muscarine (PS: 30% of baseline, EPSP: 74%). This treatment significantly reduced GABAB-mediated responses. In other studies, bath application of isoproterenol (1µM for 20min) produced LLP of the evoked population spike amplitude (191% of baseline) and EPSP slope (170%). 10µM muscarine blocked this induction of LLP (PS: 98% of baseline, EPSP: 97%) but did not affect the induction of LTP (PS: 202% of baseline, EPSP: 134%) induced by high frequency stimulation (100Hz for 2sec). This data suggests that a PT-insensitive muscarinic receptor can depress evoked responses and modulate B-adrenergic-induced synaptic plasticity in the dentate gyrus. (supported by NIH grant NS23865)

BEHAVIORAL AND BIOCHEMICAL EFFECTS OF INTRASTRIATAL IMPLANTATION OF HUMAN NEUROBLASTOMA
CELLS IN THE RAT. J. L. Cadet, R. Last*,
V. Kostic, S. Przedborski, and V. Jackson-Lewis.
Columbia University, New York, New York 10032.
Unilateral injections of 6-hydroxydopamine into the rat striatum
result in amphetamine-induced rotation. This behavior was
essecited with an almost complete loss of departing (DA) untake

associated with an almost complete loss of dopamine (DA) uptake sites in the basal ganglia. Quantitative receptor autoradiography revealed significant increases in striatal DA D2 receptors. In revealed significant increases in striatal DA D2 receptors. In contrast, there were no significant changes in striatal DA D1 receptors. Intrastriatal implantation of human neuroblastoma cells LAN-5 attenuated the circling behavior observed in the operated animals. Transplantation of these cells caused a crescent-like reappearance in dopamine uptake sites on the medial hemisphere of the lesioned striatum without evidence of any survival of the transplanted cells. In addition, there were increases in DA uptake transplanted cells. In addition, there were increases in DA uplake sites in the contralateral substantia nigra and ventral tegmental area of the transplanted animals. Nevertheless, the increases observed in striatal DA D2 receptors were not altered by transplantation. DA D1 receptors were also not affected. These studies show the deasibility of using receptor autoradiography to document, in a quantitative fashion, the recurrence of dopamine terminals in the lesioned basal ganglia. The present results support the possibility that trophic factor-induced regeneration might play an important role in behavioral recovery after transplantation of various tissues in the injured brain.

RECOVERY OF SPATIAL MEMORY PERFORMANCE IN RATS WITH HIPPOCAMPAL EXCITOTOXIC LESIONS AND FETAL CELL IMPLANTS. Yvonne Wilsdon¹, Hugh A. Tilson², and Richard A. King¹ Psych. Dept., Univ. of N.C. Chapel Hill, N.C. 27599 ² Neurotox. Div., Mail Drop 74B, U.S. Environmental Protection Agency, Research Triangle Park, N. C. 27711.

Young adult male Fischer 344 rats were anesthetized and injected

Young adult male Fischer 344 rats were anesthetized and injected intracerebrally with 10µg, per site of N-methyl-D-aspartate (NMDA) or artificial cerebrospinal fluid (the vehicle) in each of four hippocampal sites, targeting either CA3 pyramidal cell fields or dentate gyrus granule cell fields. Two weeks after original lesion surgery, half of the subjects were injected with E-17/18 fetal hippocampal cell suspensions and the other half received vehicle. Three weeks, six weeks, or four months after the original lesion surgery, rats were trained in a standard Morris water maze place task procedure, with a free swim (probe trial) after seven days of four-trial per day acquisition training.

A statistically significant impairment in memory for place was observed at 3 weeks and at 6 weeks post-lesion in the lesion-only subjects. However, at 4 months post-lesion, lesion-only animals performed at the same level as unlesioned controls. Thus, spontaneous recovery of memory performance occurred within 4 months after the lesion. Lesioned animals which received hippocampal cell injections, and in which Nissl staining indicated that the implanted cells had survived, showed some improvement in memory performance at 3 weeks post lesion. Implant effects at 4 months could not be assessed due to the spontaneous recovery described above

FETAL TRANSPLANTS SPEED RECOVERY OF LOCOMOTION AFTER SENSORIMOTOR CORTEX REMOVALS IN RATS. ${\sf J}$

Wermont, Burlington, VT 05405
This study evaluated if fetal sensorimotor
(S-M) cortex transplants would reduce the initial deficit or enhance recovery of locomotion in rats which have had S-M cortex removals. 47 mature male Sprague-Dawley rats were preoperatively trained and postoperatively tested on a narrow elevated runway. 14 rats were sham-operated (SHAM), and 33 underwent bilateral S-M cortex (SHAM), and 33 underwent bilateral S-M cortex removals. 8 days later, one group of 16 lesioned rats received fetal transplants from S-M cortex of 15 day old fetuses (SM15) while the other 17 lesioned (LES) plus the SHAM rats had a sham operation. Both LES and SM15 rats were found to be impaired on the first day of postoperative testing; however, SM15 rats recovered faster than LES rats. Movement analysis revealed that both LES and SM15 rats demonstrated aberrant patterns after recovery. Thus, although fetal transplants speeded behavioral recovery, they did not restore speeded behavioral recovery, they did not restore normal movement patterns. HRP tracing suggests normal movement patterns. HRP tracing sugges some interconnections with host brain. Supported by UVM Committee on Research and

TRANSPLANTS OF EMBRYONIC CORTEX OR ASTROCYTES BUT NOT BASIC FGF PROMOTE RECOVERY FROM LONG-TERM SPATIAL LEARNING DEFICITS AFTER SOMATO SENSORY CORTEX ABLATION. JP. Kesslak, V. Valouskova*, C.W. Cotman. Dept Psychobio, Univ. Calif, Irvine, CA 92717; Inst Physio, Czechoslovak Acad Sci, 142 40

Recovery from behavioral deficits induced by neural loss in the CNS may be induced by transplants of neural and nonneural tissue and administration of neurotrophic factors. Somato sensory cortex damage results in long-term deficits on the Morris water maze, a spatial learning task. Embryonic somato sensory cortex transplants have been shown to facilitate recovery from these deficits (Valouskova & Macias-Gonzales, Soc Neurosci Abst, 15: 108.2, 1989). Recovery from somato sensory cortex damage was assessed in the present study after transplants of embryonic cortex or cultured astrocytes or after

present study after transplants of embryonic cortex or cultured astrocytes of after chronic infusion of basic fibroblast growth factor (FGF).

Embryonic neocortex (EC; n = 14) or cultured astrocytes (AS; n = 10) were transplanted into the cavity in the left hemisphere immediately after bilateral aspirative lesion of the somato sensory cortex. Chronic infusion of basic FGF (FGF; n = 7) into the left lateral ventricle was also initiated immediately after cortical ablation. These groups were compared with undamaged control animals (CNT; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and animals with bilateral ablation and no treatment (LES; n=11) and n=11(CNT; n = 11) and animals with bilateral ablation and no treatment (LES; n = 9). Rats were tested for three consecutive days on a Morris water maze at 14 days, 2, 4 and 6 months post-lesion. Analysis of variance showed that bilateral ablation of somato sensory cortex produced long-term deficits on the Morris task. Groups EC and AS performed significantly better than did group LES and did not differ from CNT during each test period. Administration of FGF did not significantly improve performance during any of the test sessions. These results can be interpreted to indicate that neural tissue and astrocytes can be enterpreted to the behavioral deficits observed after damage to the beneficial in reducing the behavioral deficits observed after damage to the

CHANGES IN MOTOR COORDINATION AND SPONTANEOUS NOCTURNAL LOCOMOTION AFTER HOMOTOPIC AND HETEROTOPIC GRAFTS INTO THE LESIONED STRIATUM.

HETEROTOPIC GRAFTS INTO THE LESIONED STRIATUM.

M. Giordano and P.R. Sanberg. Division of Neuroscience, University of Cincinnati College of Medicine, Cincinnati, OH 45267.

Neural grafts can reverse behavioral, pharmacological and biochemical deficits induced by a variety of lesions. However, the mechanisms underlying this recovery are not clear. Grafts may act by diffusion of trophic factors and neurotransmitters, by rebuilding the damaged neural circuitry, or by providing anatomical support for sprouting axons. sprouting axons

sprouting axons.

Using the kainic acid (KA) animal model of Huntington's disease, this study examined the effects of post-lesion delay, and homotopic vs heterotopic grafts on behavioral recovery. We previously reported that with regard to drug-induced behaviors, homotopic grafts successfully attenuated KA-induced deficits. On the other hand, heterotopic grafts had inconsistent effects dependent on the length of the post-lesion

had inconsistent effects dependent on the length of the post-lead delay.

We are now presenting data on spontaneous nocturnal locomotion and sensorimotor function. KA induced a temporary deficit in motor coordination which was not present in those animals with homotopic and heterotopic grafts, regardless of post-lesion delay.

These data seem to indicate that homotopic grafts are needed to restore pharmacological integrity to the lesioned striatum, whereas both homotopic and heterotopic grafts have generalized beneficial effects on spontaneous motor behaviors. This hypothesis will be tested against the results of the spontaneous locomotion tests. Supported by NINDS, TSA, HDSA, STRC and Omnitech.

MONOAMINERGIC NEURAL TRANSPLANTS TO THE NEOCORTEX REDUCE IMMOBILITY TIME IN RATS DURING BEHAVIORAL DESPAIR TESTING <u>C.E.</u> Sortwell* and J. Sagen. Dept. Anat. and Cell Biol., Univ. IL at Chicago, Chicago,

Sortwell* and J. Sagen. Dept. Anat. and Cell Biol., Univ. IL at Chicago, Chicago. IL 60612.

According to the classical monoamine theory of depression, depression may be caused by a central imbalance in norepinephrine and serotonin function, and effective antidepressant therapies work by correcting this imbalance. A novel approach towards the restoration of imbalanced functioning in the CNS is the transplantation of pharmacologically relevant tissues into local CNS regions. Previous work in our laboratory has demonstrated that monoaminergic neural transplants into the rat frontal neocortex prevent the development of learned helplessness, a condition that models human depression. Another popular model for depression is the behavioral despair (BD) model, which is widely used for screening potential antidepressant therapies. In order to assess the ability for monoaminergic transplants to reduce BD, either adrenal medullary tissue, pineal gland tissue, a combination of adrenal medullary and pineal tissue, or equal volumes of sciatic nerve were transplanted into the rat frontal neocortex. BD testing began 6-8 weeks following surgery. During a pretest session, rats were forced to swim in a plexiglass swim cylinder for a 15 min period. Twenty-four hours later, the rats were forced to swim again for a 5 min test session during which immobility time was measured. The duration of immobility may indicate a level of despair, and immobility times are reliably reduced by antidepressant therapies. Immobility times were reduced in rats with adrenal medullary grafts, pineal grafts, and a combination of both adrenal and pineal grafts to the frontal neocortex. In contrast, Immobility times were not reduced by control sciatic nerve tissue grafts. This reduced immobility times probably not due to non-specific effects on motor function, since the transplants did not produce alterations in motor activity in an open field test. Morphological studies revealed that the grafted monoaminergic tissues survived well and continued to produce

FUNCTIONAL ENHANCEMENT OF INTRASTRIATAL DOPAMINE CELL GRAFTS BUT NOT CHROMAFFIN CELL GRAFTS BY THE CO-TRANSPLANTATION OF SCIATIC NERVE TISSUE IN 6-HYDROXYDOPAMINE LESIONED RATS. Craig G. van Horne, Ingrid Strömberg, Wayne L. Witenberg* John Hudson*, Lars Olson, and Barry Hoffer, Dept. of Pharmacology, Univ. of Colorado Health Sciences Center, Denver, CO 80262, and Dept. of Histology and Neurobiology, Karolinska Institute, Stockholm, Sweden.

Peripheral nerve "bridges" demonstrate the ability to facilitate axonal growth and

regeneration of adult and fetal central nervous system tissue. The purpose of this study was to determine if co-grafted peripheral nerve tissue could enhance the ability of fetal dopamine (DA) cell or adrenal medullary cell transplants to reinnervate host striatum that had been denervated unilaterally. Male Fisher-34 reinnervate host striatum that had been denervated unilaterally. Male Fisher-344 rats were unilaterally lesioned with 6-hydroxydopamine to eliminate the nigrostriatal DA pathway. A total of 41 rats demonstrated a pattern of rotation indicative of a greater than 98 % depletion in DA. Rats were either kept as nongrafted controls (n=6), grafted with sciatic nerve (SN) minces (n=6), grafted with fetal ventral mesencephalon (VM) (n=10), co-grafted with VM and SN minces (n=9), grafted with adrenal chromaffin tissue (n=5), or co-grafted with chromaffin tissue and SN minces (n=5). All groups were then tested for changes in apomorphine-induced rotational behavior. The SN control group showed no significant differences in rotation when compared to pre-grafting levels, and to the apomorphine-induced rotational benavior. The SN control group showed no significant differences in rotation when compared to pre-grafting levels, and to the lesioned non-grafted group. Both the VM grafted group and the VM-SN co-grafted group showed significant (p<0.01, one way ANOVA) decreases in rotations beginning group showed significant (p<0.01, one way ANOVA) decreases in rotations begining at 1.5 weeks post-grafting. There was a progressive decrease in rotations up to 12 weeks, the last test point. Interestingly, the co-graft group revealed a significantly greater decrease in rotation (p<0.05) than the VM group beginning at 5 weeks and continuing out to the 12 week test point. While the chromaffin grafts and the chromaffin co-grafted animals both showed a slight decrease in rotation at 5 weeks, there were no differences between the two groups. Taken together, these findings suggest that SN tissue enhances the ability of fetal VM grafts but not chromaffin grafts to reinnervate host brain. Supported by (NS09199, AG04418, PMA).

NORMALIZATION OF CIRCLING INDUCED BY INTRA-NIGRAL MUSCIMOL BY FETAL NIGRAL GRAFTS IN THE STRIATUM. D. Gaudin, J.A. St-Pierre*, L. Tremblay, P.J. Bédard and M. Filion. Lab Neurobiol. Depts. of Anatomy and Physiology Univ. Laval, Québec, (Qc), CANÁDA GIK 7P4.

In the present study, we have investigated the effects of a fetal migral graft in the striatum on circling induced by unilateral microinjection of muscimol in the target structure of the striatum, the substantia nigra pars reticulata (SNr). In a group of 28 ovariectomized female rats, 20 received a unilateral nigral lesion with 6-OHDA. The lesioned animals were then tested for circling with amphetamine 5 mg/kg and apomorphine 0.25 mg/kg. The animals which displayed circling with these two drugs were divided into two groups. One group received a graft of 1.5 x 10° cells taken from the ventro-mesencephalon of 13-14 day old rat embryos. The other group was not grafted. 4 to 6 months after the graft, all animals received one microinjection of muscimol (25 ng/0.5 µl) (gabaergic agonist) into the SNr using indwelling guide cannulae (20 ga) situated 2 mm above the target site. The injection site was determined by stereotaxic and electrophysiologic techniques. Circling was monitored during ninety minutes after the injection, Unilateral injection of muscimol into the SNr of the intact side of controls, lesioned and grafted animals induced a similar contralateral circling (800 counts/90 min). In the SNr of the lesioned side the contralateral circling was decreased by 80%. Circling after the muscimol injection on the grafted side was similar to the intact side of the three groups. Our results show that a fetal nigral graft implanted into the striatum can normalize the changes in GABAergic sensitivity in the SNr caused by dopaminergic denervation. Supported by MRC of CANADA

THE EFFECT OF EMBRYONIC NIGRAL GRAFTS ON STRIATAL DOPAMINE RECEPTORS IN UNILATERALLY LESIONED RATS FOLLOWING CHRONIC LEVODOPA TREATMENT. K. Steece-Collict. D.M. Yurek, T.J. Collier, and J.R. Sladek, Jr. Department of Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, NY 14642.

We have been interested in what effect chronic treatment with levodopa, a drug

we have been interested in what effect chronic treatment with levodopa, a drug which increases striatal dopamine (DA) turnover, may have on the viability and morphological development of embryonic nigral DA neurons grafted into a lesioned caudate. Previously, we reported that twice daily injections of Sinemet (50 mg levodopa: 5 mg carbidopa/kg) for 6 weeks has a derimental effect on embryonic nigral DA neurons (Soc. Neurosci Abstr.. 15:1354, 1989). While there was no significant difference in number of grafted neurons between control and levodopa treated animals, the grafted neurons in the levodopa treated animals had significantly treated animals, the gratted neurons in the levotodpa treated animals had significantly reduced cell body size, reduced staining for tyrosine hydroxylase in a majority of these neurons, increased infiltration of macrophages within the grafts and less extensive neurite outgrowth. The functional efficacy of grafts in control and levodopa treated animals has been investigated by monitoring rotational behavior in rats with unilateral nigrostriatal DA lesions elicited by DA agonists before and after neural grafting (Soc. Neurosci. Abstr., D.M. Yurek et al., 1990). The results from these behavioral studies indicate that chronic levodopa impairs recovery of the rotational behavior in animals recieving grafts. This apparent decreased functional effect as a consequence of chronic receiving grains. In a spiparent decreased functional effect as a consequence of circonic levodopa may be related to impaired graft function, an alteration in DA receptor mechanisms or a combination of these. To better elucidate the mechanisms involved in these morphological and behavioral results, we are currently examining the impact of neural grafts on striatal D1 and D2 receptors and DA uptake binding sites in control and levodopa treated animals. Results of these receptor binding studies will be presented and discussed. (Supported by grants from the UPF and the Pew Foundation.)

EFFECTS OF ADRENAL MEDULLA GRAFTS ON PLASMA CATECHOLAMINES AND ROTATIONAL BEHAVIOR.

H.Takashima, M.Poltorak, W.J.Freed and J.B.Becker NIMH Neuroscience Center at St. Elizabeths, Washington D.C. 20032 and Dep. of Psychol. and Neurosci. Prog., Univ. of Michigan, Ann Arbor, MI 48104

In an animal model of Parkinson's disease adrenal medulla grafts located in the lateral ventricle reduce the behavioral manifestations of nigrostriatal dopamine depletion. The reasons for the functional effects of adrenal medulla grafts are, however, uncertain. We have hypothesized that changes in blood catecholamines and a compromised blood-brain-barrier may mediate behavioral recovery following transplantation of adrenal medulla into the brain.

Male Sprague-Dawley rats received unilateral 6-OHDA lesions of the substantia nigra and either bilateral adrenalectomy (n=50) or a sham operation (n=50). Animals were tested for rotational behavior following 0.05 mg/kg apomorphine S.C. and 0.75 mg/kg amphetamine I.P. and then received intraventricular adrenal medulla (n=25), sciatic nerve (n=15) or sham (n=10) grafts. After transplantation, animals were tested for apomorphine, amphetamine and nicotineinduced rotation. Blood samples were collected before and after transplantation. Catecholamines in the plasma were assayed using HPLC with electrochemical detection. This experiment is currently in progress.

275.10

CHRONIC LEVODOPA TREATMENT IMPAIRS RECOVERY OF ROTATIONAL BEHAVIOR IN DOPAMINE-GRAFTED RATS. D.M. Yurek, K. Steece-Collier, T.J. Collier, and J.R. Sladek, Jr. Dept. of Neurobiology & Anatomy, Univ. of Rochester School of Medicine, Rochester, New York 14642

The effect of chronic levodopa treatment on the function of embryonic mesencephalic tissue grafts was assessed in rats by monitoring rotational behavior elicited by dopamine (DA) agonists before and after neural grafting. Rats were given unilateral 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal pathway and baseline measures of rotational behavior induced by D1 receptor stimulation, D2 receptor stimulation, or amphetamine were determined. Subsequently, DA grafts were implanted into the lesioned striatum and chronic regimens of either saline or levodopa [50 mg/kg, i.p., twice daily] began one day after neural grafting and were continued for 7 weeks. Rotational behavior elicited by the D1 agonist, SKF 38393, was completely attenuated throughout the six week period following the commencement of levodopa treatment, regardless of the absence or presence of a DA graft. Conversely, rotational behavior elicited by the D2 agonist, quinpirole, was significantly elevated in ungrafted animals receiving chronic levodopa. Grafted significantly elevated in ting area animals receiving chronic reduction in rotational behavior, whereas grafted animals receiving chronic saline showed a significant 67% reduction in quinpirole-induced rotational behavior. Amphetamine-induced rotational behavior was reduced in both levodopa and saline treated animals, however grafted animals receiving chronic levodopa treatment showed a reduction of rotational behavior that was uncharacteristic and less compensatory than that observed in grafted animals receiving chronic saline treatment. The results of the present study suggest that the impaired recovery in quippirole- and amphetamine-induced rotational behavior that the impaired recovery in quiniprotes—and ampinetamine-induced rotational adelaytor in grafted animals receiving chronic levodopa treatment may be related to (1) impaired graft function, (2) an alteration in pre- and postsynaptic mechanisms in the host DAergic system, or (3) a combined effect of (1) and (2). The morphology of DA grafts will be examined using catecholamine histofluoresecence and tyrosine hydroxylase immunocytochemistry. Supported by the United Parkinson Foundation.

275.12

PAIN REDUCTION BY THE TRANSPLANTATION OF ADRENAL MEDULLARY EXPLANTS IN THE RAT SPINAL SUBARACHNOID SPACE. H. Wang and J. Sagen. Dept. Anat. and Cell Biol., Univ. II at Chicago, Chicago, IL 60612.

Sagen. Dept. Anat. and Cell Biol., Univ. II at Chicago, Chicago, IL 60612. Previous studies in this laboratory have demonstrated that transplants of adrenal meduliary tissue or isolated chromaffin cells can reduce pain sensitivity as assessed by both acute and chronic analgesiometric tests. This analgesia is most likely mediated by the local release of neuroactive substances, including opioid peptides and catecholamines, from the transplanted cells. We have recently found that adrenal meduliary tissue can survive and continue to release these agents for at least one month in explant tissue culture. The advantage of maintaining tissue in explant culture is that it appears to allow for recovery from anoxic trauma following dissection. In addition, it may reduce immunologic responses by allowing for the migration of passenger leukocytes out of the tissue. The purpose of the present study was to assess the potential for using adrenal meduliary explants as a graft source for the reduction of pain sensitivity. Rat adrenal meduliary were mantained in explant culture for 0 - 30 days adretial inedualise were maintained in explant culture for 0 - 30 days following dissection from cortical tissue. The explanted tissue was transplanted in the subarachnoid space of host rats following various intervals in culture. Control animals received equal volumes of control explanted striated muscle. Pain sensitivity was assessed using acute analgesiometric tests from 2 - 16 weeks following implantation. Results indicated that adrenal medullary tissues maintained in culture for up to 30 days were able to reduce pain sensitivity when transplanted into the subarachnoid space. Ten to 15 days in culture appeared to be optimal, since the most potent analgesia was observed in animals with explants from this time period. Morphological studies revealed the presence of clusters of healthy looking chromaffin cells in the explants 16 weeks after transplantation into the rat spinal subarachnoid space. Results of this study suggest that adrenal medullary explants may be a potential graft source for the reduction of pain. (Supported by NIH grant NS25054)

TIME OF IMPLANTATION AFTER SUPRACHIASMATIC NUCLEUS (SCN) LESION AFFECTS THE OUTCOME OF SCN TRANSPLANT. M.A. Vogelbaum and M. Menaker, Department of Biomedical Engineering and

Department of Biology, University of Virginia, Charlottesville VA 22901.

We implanted \(^{7}_{88}\) (period about 20 hours) golden hamster fetal hypothalamic blocks into partially SCN lesioned normal hamster hosts with residual 24 hour rhythmicity. These implants were done either about 30 days after lesioning ("delayed"), or immediately thereafter, to evaluate the effects of recovery from neuronal injury on the physiology of coupling between graft and

When transplantation is delayed, both 20 and 24 hour locomotor rhythms are expressed in the host: about 30 days after implantation, a rhythm with period close to 20 hours appears and lasts for 7 to 10 cycles, at which point a 24 hour rhythm takes over. This alternation of rhythms continues with each rhythm typically lasting 5 to 7 cycles, at which point there is a transition to the other rhythm. There is very little temporal overlap of the two rhythms, and there does not appear to be phase shifting of one rhythm by the other.

When transplantation immediately follows the lesion, a single rhythm is

expressed with a greater amplitude than in the case of delayed implants. In most cases, the period of the restored rhythm was close to that of the donor SCN, but we do have one case with an intermediate (21.7 hour) period. In no case were two alternating rhythms seen, although in some a beat frequency of

about 24 hours is present throughout the activity record.

These results suggest that the stage of recovery from neuronal injury influences the degree of coupling between the SCN implant and the host SCN. We hypothesize that a physical barrier is formed after lesioning due to the development of a glial scar. Perhaps neural integration within the SCN is prevented after a glial scar is allowed to develop. Accordingly, we have examined glial scar formation in both the delayed and immediate implant cases.

CORTICAL GRAFTS PRESERVE THALAMIC FUNCTION IN MATURE RATS FOLLOWING LESIONS OF SOMATOSENSORY CORTEX. M. F. Gonzalez. S. Ciricillo*, M. P. Jasper* and F. R. Sharpt. Depts. of Neurology and †Physiology, UCSF, and VA Medical Center, San Francisco, CA 94121.

Previous work has shown that unilateral tactile stimulation of the mystacial vibrissae of normal rats elicits an increase of ¹4°C 2-deoxyglucose (2DC) uptake in the contralateral ventrobasal (VB) thalamic nuclei. In this study we examined this phenomenon in mature rats with primary whisker somatosensory cortex (S1) lesions, or with fetal cortical tissue grafts surviving in injuries of this site. Lesions consisted of removing cortical gray matter from 0 to 3 mm posterior to bregma, and from 3 to 6 mm to the right of the sagittal suture. Cortical transplants were performed by placing slabs of fetal cortical tissue in these cavities one week after injury.

fetal cortical tissue in these cavities one week after injury.

Tactile stimulation of the left whiskers of rats with S1 cortical lesions resulted in an 9.8% inhibition of 2DG uptake in the VB thalamic nucleus, as compared with the unstimulated left side (N=4, t-5.097, P<0.015). The same treatment produced opposite effects in 4 subjects that had large surviving cortical grafts. Their VB thalamic nuclei exhibited a 24% increase in 2DG uptake (t-il.15, P<0.002). An additional subject with a surviving graft did not exhibit any thalamic activation following stimulation. This data suggests that some cortical transplants may prevent the functional atrophy of host brains' structures caused by cortical injury.

275.17

FETAL CORTICAL GRAFTS USED IN THE REPAIR OF ASPIRATION AND NMDA NEOCORTICAL LESIONS MADE IN ADULT RATS. A SINGLE UNIT STUDY. E.J. Neafsey. T.P. Hogan* P.L. Shaw*.

E.B. Pedersen* and A.J. Castro. Dept. of Cell Biology, Neurobiology and Anatomy, Loyola University Chicago Stritch School of Medicine, Maywood, IL 60153.

Rat fetal (E15) presumptive sensorimotor neocortex was grafted into the adult rat sensorimotor cortical area using two procedures: 1) a tissue BLOCK into an aspiration lesion cavity in the cortex (n=3) or 2) a cell SUSPension injected into a cortical lesion made by multiple intracortical NMDA injections 5 days prior to grafting (n=6). Two to three months later the rats were anesthetized with ketamine HCl (100 mg/kg, IP), and the responses of single units in the transplant to electrical stimulation (0.1 msec pulses) of the thalamus (THAL; current < 500 uAmp) and contralateral and ipsilateral forepaws (CFP, IFF; 1 mAmp) were examined. The table below summarizes our findings.

Graft	# of	Resp	Mean Laten	Resp	Mean Laten
Type	units	THAL	msec (SEM)	CFP	msec (SEM)
BLOCK	10	80%	6.6 (1.1)	40%	21.5 (3.7)
SUSP	20	81%	6.7 (0.9)	60%	15.2 (1.4)

These results are similar to those seen in controls and in block transplants which have been placed in newborn hosts (Neafsey et al., BR 493:33, 1989) and demonstrate that such transplants can receive sensory input from the body. (Support by NIH grant NS13230)

275.14

DEVELOPMENT OF THE LIGHT-ACTIVATED PUPILLARY RESPONSE IN RATS, AS MEDIATED BY OPTIC INPUT FROM NORMAL OR TRANSPLANTED RETINAE. R.D. Lund, J.D. Radel and S. Das*. Dept. Neurobiology, Anatomy & Cell Science, Univ. Pittsburgh Sch. Med.,

We have shown in mature rats that pupilloconstriction can occur in response to illumination of retinae that had previously been transplanted to the rat's midbrain. Because the transplanted retina is developmentally 1 week younger than host retinae at the time of transplantation (E13 vs. P1), we questioned if this developmental handicap would be reflected in a

delayed acquisition of the pupillary reflex.

The eyelids of normal rats or rats with transplanted retinae were opened, then one eye or the transplant was illuminated and the pupillary response recorded. We first detected a sluggish pupillary constriction at P7 in normal rats but not until P14-16 if driven through a transplant. The 14-10 in Informat rats but not until F14-10 in direct infough a transplant. The response matured to a brisk, adult-like constriction in normal rats by P12-14, and in host rats by P20-22. All animals were processed for ultrastructural analysis immediately after testing. In both normal and host rats, the initial pupillary response occurs as the retina develops rudimentary outer segments and asymmetric, ribbon-less synaptic contacts in the inner plexiform layer (IPL). Mature responses coincide with the

in the inner plexitorm layer (IPL). Mature responses coincide with the appearence of ribbon synapses in the IPL.

We conclude that the development of light-activated pupilloconstriction is regulated by the developmental stage of the retina rather than by non-retinal elements, and that the timetable of development for transplanted retinae is determined by endogenously rather than by the host. USE OF c-FOS TO DETERMINE THE NEURAL PATHWAY ACTIVATED BY INTRACRANIAL RETINAL TRANSPLANTS IN RATS S.L. Craner, G.E. Hoffman, J.S. Lund, and R.D. Lund. University Pittsburgh School of Medicine, Pittsburgh, PA 15261.

University Pittsourgh School of Medicine, Pittsourgh, PA 15261.

We examine here activation patterns in the host brain after illumination of intracranial retinal transplants, using e-fos labelling techniques. Embryonic (E13) retinae were transplanted over the midbrain of postnatal (P1) rat hosts and one host eye removed to enhance the transplant projection. At maturity, the remaining host eye was removed from those animals which had a demonstrable ransplant projection. After a witchle recovery transplant-mediated pupillary reflex. After a suitable recovery period, these rats were anesthetized and the transplanted retinae stimulated with flashes of light (800 msec duration every 3.5 seconds) for one hour. The animals were terminated after a further 30 mins and the brains processed for immunohistochemical labeling of the cfos protein. Suitable control groups of non-transplanted animals
provided information regarding stimulus-specific c-fos activation
following light flashes presented to the eye.

Several visual centers, connected with the stimulated eyes, both in
situ and transplanted, showed levels of c-fos that were higher than in

unstimulated controls. Most prominent were the superior colliculus and several divisions of the pretectum. This provides further evidence of stimulus activation of host visual centers by way of a retinal transplant in a manner differing little from normal animals studied after visual stimulation. Supported by NIH grants EYO5282, EYO5308 & EYO6194.

HYPEREXCITABILITY IN TRANSPLANTED STRIATAL NEURONS: MODULATION BY EXCITATORY AMINO ACIDS. S.M. Siviy, J.P. Walsh, M.S. Levine and N.A. Buchwald. MRRC, UCLA, Los Angeles, CA 90024.

Previous work from our laboratory has characterized the electrophysiological properties of transplanted striatal neurons grafted into the striatum (Synapse, 2:37) or substantia nigra (<u>Soc Neurosci Abs.</u> 15:1353). The grafted cells become hyperexcitable and develop large amplitude, long duration depolarizations along with bursts of action potentials. These depolarizations occur spontaneously or following extracellular stimulation of host tissue and are never observed in host striatal cells. In the present study, we assessed the extent to which hyperexcitability in transplanted striatal cells is due to activation of excitatory amino acid (EAA) receptors. Cell suspensions obtained from 17 day old fetal striata were grafted into both the striatum and substantia nigra of adult rats. One to 4 months after transplantation, the rats were sacrificed, brains removed and 400 μm thick slices were taken through the transplant for intracellular recording. Stimulation of the host tissue resulted in large amplitude (> 20 mV), long duration (> 150 msec) depolarizations accompanied by bursts of action potentials. Responses were similar for cells grafted into the striatum and into the substantia nigra. Bath application of the broad spectrum EAA antagonist kynurenic acid (0.5 mM) abolished almost all post-synaptic activity, as did the specific kainate/quisqualate antagonist CNQX (1-3 μ M). The effects of the specific NMDA antagonist AP5 (20 μ M) were more variable, ranging from no effect to an 80% reduction in amplitude and duration of the depolarizations. NMDA receptor antagonists like AP5 are usually ineffective in blocking responses in host striatal cells unless the voltage dependency of the receptor is negated by removing Mg²⁺ from the bathing medium. These data suggest that EAA receptors contribute significantly to the hyperexcitability of transplanted striatal cells. Supported by USPHS HD05958.

INDUCIBILITY OF AN EARLY GROWTH RESPONSE GENE IN SONGBIRD BRAIN: LINKS WITH ADULT NEURAL PLASTICITY

C. Mello and D.F. Clayton. Lab. of Animal Behavior, The Rockefeller Univ., New York, NY 10021

RNAs for several presumed regulators of gene transcription rise rapidly following stimuli associated with neuronal differentiation and depolarization. To test the possibility that early growth response genes may be involved in regulating plasticity in the adult nervous system, we examined expression of one (the canary homologue of zif-268, egr-1, NGFI-A and Krox-24) in the brain of songbirds following metrazole-induced seizures. The anatomical pattern of activation of the gene (revealed by in situ hybridization) closely coincides with sites in the brain that receive new neurons in adulthood in canaries. Furthermore, substantially lower levels of induction were seen in the stable song control circuit of adult male zebra finches, who are incapable of modifying their song. These results suggest the inducibility of the gene may reflect or predict sites of synaptic plasticity in the adult nervous system.

B-50/GAP43 GENE EXPRESSION IN THE DEVELOPING AND AGING RAT OLFACTORY SYSTEM. J. Verhaagen I. C.A. Greer 2.
F.L. Margolis 3. 1:Dep. Pharmacology, Rudolf Magnus Institute,
Utrecht, The Netherlands, 2:Yale University School of Medicin,
Section of Neurosurgery and Neuroanatomy, New Haven, Connecticut. 06510, 3:Dep. Neuroscience, Roche Institute of Molec. Biol., Nutley, NJ, 07110, USA.

The olfactory neuroepithelium exhibits neurogenesis throughout adulthood, and in response to lesions, a phenomenon that distinguishes this neural tissue from the rest of the mammalian nervous system. It has been suggested that denervation and reinnervation of olfactory bulb neurons by primairy olfactory neurons may occur throughout life. Thus, these properties enable the study of neurogenesis and synaptogenesis in the adult animal. In this study we reported the expression of the growth associated protein B-50/GAP43 and its mRNA in the olfactory system during postnatal development and aging. In neonatal rats B-50/GAP43 mRNA was expressed in virtually all primary olfactory neurons and in their target cells in the olfactory bulb, the mitral- and juxtaglomerular cells. In contrast in 6 and 18 month old animals B-50/GAP43 expression was restricted to neurons in the basal region of the neuroepithelium and to some of the target mitral- and juxtaglomerular cells in the olfactory bulb. If the persistance of B-50/GAP43 expression in mitral- and juxtaglomerular cells reflects the continuously changing input from primary olfactory neurons in the olfactory bulb then it implies longterm mitral cell synaptic plasticity in the pyriform cortex.

ACTIVATION OF BRAIN PROTEIN KINASE C SUBTYPES BY OMEGA-3 CIS-FATTY ACIDS. S.G. Chen, K. Conley* and K. Murakami Dept. of Biochem. Pharmacol., State Univ. of New York, Buffalo, NY 14260.

Protein kinase C (PKC) plays an important role in the regulation of synaptic plasticity. Cis-fatty acids such as oleate and arachidonate have been shown to strongly activate purified brain PKC in the absence of phospholipids, diacylglycerol, and Ca²⁺ (JBC 261, 15424, 1987). It has been further demonstrated that cis-fatty acids differentially activate brain PKC subtypes (BBRC 145, 797, 1987).

Here we report that PKC subtypes can be activated by omega-3 cis-fatty acids such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in the absence of phospholipids and diacylglycerol with different sensitivity to Ca²⁺.

PKC was purified from rat brain by four-step liquid chromatography. Three PKC subtypes (type I, II, and III) were further separated on a hydroxyapatite column. In the presence of ${\rm Ca}^{2+}$, EPA and DHA can significantly activate these three PKC subtypes at concentrations well below 100 The concentrations required for half maximal activation (Ka values) for type I, II, and III were 22, 14 and 23 μ M for EPA and 21, 17 and 31 μ M for DHA, respectively. In the absence of Ca²⁺, EPA and DHA showed a 3-9 fold lower affinity for type III as compared to the other subtypes.

Since omega-3 cis-fatty acids are enriched in retina and brain, the ability of these cis-fatty acids to activate PKC subtypes suggests their involvement in neuronal processes.

A CANARY SONG CENTER-ENRICHED RNA ENCODES THE HOMOLOGUE OF N-CHIMAERIN, A PROTEIN RELATED TO THE BCR ONCOGENE AND PRÓTEIN KINASE C.

J.M. George and D.F. Clayton. Lab. of Animal Behavior, The Rockefeller Univ., New York, NY 10021

We are characterizing RNAs enriched in the plastic regions of the songbird brain, and describe here a clone we call hvc-2. Localization by in situ hybridization reveals a largely neuronal distribution throughout the neo- and hyperstriatum, with a particularly high level of expression in the plastic song center Area X. The sequence encodes a presumed protein of 299 a.a., the N-terminus of which shares 40% identity with the regulatory domain of protein kinase C, including the zinc finger consensus C-X₂-C-X₁₃-C-X₂-C-X₇-C-X₇-C believed to mediate phorbol ester binding. The C-terminus is 43% identical to ber, the product of the breakpoint cluster region gene, involved in the Philadelphia chromosome (Ph1) translocation. Our clone, hvc-2, shows 97% a.a. identity to n-chimaerin, a recently described human gene with a predominately neuronal distribution and greatest abundance in hippocampus and cerebral cortex (Hall, C. et al. J. Mol. Biol. 211:11, 1990). This high degree of conservation between human and avian species suggests a fundamental role for the gene product, perhaps as a component of signal transduction mechanisms involving phospholipid metabolism.

276.4

MAP-2 IS MORE SUSCEPTIBLE TO CALPAIN HYDROLYSIS THAN IS SPECTRIN. G.V.W. Johnson, J.M. Litersky and R.S. Jope. Departments of Neurology, Psychiatry and Cell Biology & Anatomy, University of Alabama, Birmingham, Alabama 35294.

In brain, MAP-2 and spectrin are major components of the neuronal cytoskeleton and therefore the processing and degradation of these proteins is likely to play an important role in the modulation of the form and function of neurons. In this study we examined the in vitro degradation of these two proteins by calpain using quantitative immunoblot analysis

quantitative immunoblot analysis.

Like tau (BBRC 163:1505, 1989), there are at least two populations of MAP-2 in brain based on calpain-sensitivity, a calpain sensitive form associated with microtubules (2XMT MAP-2) and a calpain-resistant form (total MAP-2) that represents another population of MAP-2. 2XMT MAP-2 is approximately 10 times more sensitive to calpain than total MAP-2. The two brain spectrin isoforms (240 and 240E) also show differential sensitivities to calpain. Brain spectrin (240) is significantly more sensitive to calpain than spectrin (240E), which is degraded at a rate similar to total MAP-2. Calmodulin significantly increases the rate and extent of calpain indeed degraded states. calpain-induced degradation of both isoforms of brain spectrin, but does not alter the breakdown of either 2XMT or total MAP-2. However even in the presence of calmodulin, both isoforms of brain spectrin are significantly less sensitive to calpain than is 2XMT MAP-2.

Given these results and the similar subcellular localization of MAP-2 and brain of wen these results and the similar subcellular localization of MAP-2 and brain spectrin (235/240E) (i.e., in dendrites and postsynaptic densities), it is likely that the calpain-mediated breakdown of MAP-2, as well as spectrin, contributes to neuronal plasticity, such as may occur with long term memory, and calcium-mediated neurodegeneration which may be associated with ischemia or neurodegenerative diseases, such as Alzheimer's disease.

SIGNAL-SELECTIVE PHOSPHORYLATION OF PROTEIN KINASE C SUB-STRATES IN NEUROBLASTOMA N1E-115. K. Murakami, S.G. Chen and A. Routtenberg#. Dept. of Biochem. Pharmacol. State Univ. of New York, Buffalo, NY 14260 and #Cresap Neurosci-

ence Lab. Northwestern Univ., Evanston, Illinois 60208. At least seven subtypes of protein kinase C (PKC) are expressed in the brain (Nature 334, 661, 1988). Our previous studies have shown that cis-fatty acids can activate purified brain PKC independently of Ca²⁺, diacylglycerol and phospholipids and we proposed that cis-fatty acids liberated by the action of phospholipase A2 may play a second messenger role in the activation of PKC (FEBS Lett. 192, 189, 1985).

In this study, we examined the effects of different PKC activators on protein phosphorylation in a neuroblastoma clone, NIE-II5. Endogenous PKC activation by cis-fatty acid and ${\rm Ca}^{2+}$ /diacylglycerol/phospholipids lead to distinct subsets of PKC substrate phosphorylation in N1E-115 cells. One particular type of PKC substrate, a 40 kDa protein, was selectively phosphorylated by oleic acid in the absence of Ca²⁺. This phosphorylation was also stimulated by exogenous PKC but suppressed by both H-7, a PKC inhibitor and in PKC-depleted cells by TPA. Ca²⁺/diacylglycerol/phospholipids did not fully phosphorylate this protein.

Existence of a cis-fatty acid sensitive PKC substrate

indicate that the heterogenous PKC subtypes may be selectively activated by different signals and each subtype may phosphorylate specific sets of PKC substrate.

SYMAPTIC PLASTICITY: MOLECULAR AND CELLULAR APPROACHES TO THE STUDY OF PROTEIN KIMASE C (PKC) REGULATION OF PROTEIN F1/GAP-43 PMOSPHORYLATION. P. Meberg*. F-S. Sheu*. X. Xiang, Y.Y. Huang*. P. Colley*. B. Kapella*. E. Valcourt* and A. Routterberg. Northwestern Univ., Evanston, IL 60208.

In situ hybridization of protein F1 mRNA demonstrates selective regional expression. Brainstem cells containing biogenic amines (e.g., locus coeruleus, dorsal raphe, substantia nigra-pars compacta) show extensive F1 mRNA expression, while other brainstem cells (e.g., red nucleus and pontine nucleus) and cholinergic cells (e.g., medial habenula) show little. The most striking selectivity is seen in adult hippocampus: pyramidal cells are heavily labeled while granule cells are at near background levels as quantified by image analysis (also, Rosenthalet al., EMBO. J. 6:3641, 1987). Developmental analysis of F1 mRNA shows peak expression in pyramidal cells at 12 days, and in granule cells at 16 days; pyramidal cell F1 mRNA expression is 4- to 8-fold greater than the granule cells at all ages.

Protein F1 is phosphorylated by PKC, whose subtype distribution, Like F1, is regionally selective (Brandt et al., Cell 49:57, 1987). Protein F1 and beta-PKC mRNA are expressed at parallel levels (high-pyramidal; low-granule) in hippocampus, while gamma-PKC is expressed similarly in both cell types. Furthermore, beta-PKC, compared to gamma-PKC, preferentially phosphorylated either purified protein F1 or recombinant F1 made with protein-secreting bacteria.

bacteria.

**KC regulates long-term potentiation (LTP; Routtenberg, Behav. Neural Biol.

44:186, 1985). Use of PKC inhibitors in the synaptic zone suggests PKC regulation of LTP persistence not its initiation. The role of PKC in regulating plasticity in the cell body is currently under study using intracellular injection of PKC inhibitors into CA1 pyramidal cells in the hippocampal slice preparation. A protocol has been implemented to enable recording baseline activity with inhibitor-filled pipettes and ejection either before or after LTP. It is attractive to think that beta-PKC regulates persistence of LTP by phosphorylating presynaptic proteins. (Supported by NIMH 25283 and AFOSR 90-0240).

KINDLING INDUCED CHANGES IN CALMODULIN KINASE II IMMUNOREACTIVITY. J.M. Bronstein, D.B. Farber, P.E. Micevych, R. Lasher, and C.G. Wasterlain. Dept. of Neurology, UCLA School of Med., Los Angeles, CA

The distribution of Type II calmodulin kinase (CaM kinase) immunoreactivity was studied in control and septally kindled rat brains. CaM kinase was and septally kindled rat brains. Can kinase was concentrated in limbic structures, such as the hippocampus, lateral septum, and amygdala. Within the hippocampus, the molecular layer of the endal limb of the dentate gyrus, the statum radiatum, and lacunosum moleculare of CAl were the most heavily stained regions. The cerebellum was stained only in the molecular and Purkinje cell layers, and very low amounts of immunoreactive protein were present in the brainstem and white matter. Kindling resulted in a significant decrease in CaM kinase immunoreactivity in CA3 and the dentate of the ventral hippocampus but not in the lateral septum. These data suggest that kindling decreases the number of CaM kinase molecules or alters its antigenic distribution, and provides further evidence that alterations of this enzyme may be important in the kindling phenomenon.

RAPID SEPTAL ASTROCYTIC RESPONSE FOLLOWING ENTORHINAL CORTEX LESION. C.Zarow and C.E.Finch. Ethel Percy Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089.

Astrocytic responses to entorhinal cortex lesion (ECL) by the hippocampus suggest that astrocytes play a role in phagocytosis of debris as well as nutritive support for new sprouts. As part of a study of septal responses to the ECL, changes in glial fibrillary acidic protein (GFAP) message and protein product were examined. Unilateral electrolytic ECL were performed on young male rats, with 2, 6, 10, or 14 d post lesion survival. Unoperated animals served as controls. RNA was extracted from ipsilateral and contralateral hippocampi and combined septa. Labeled cRNA corresponding to a portion of the coding region of mouse GFAP (clone a gift of E. Lazarides) was used as a probe in region of mouse GFAP (clone a gift of E. Lazarides) was used as a probe in all studies. Another group of brains was paraffin-embedded, sectioned at $10~\mu m$, and labeled for GFAP message (in situ hybridization (ISH)) and product (immunocytochemistry (ICC)). By Northern blot and RNA solution titration analyses, GFAP mRNA peaked at 2d post lesion in each region and decreased to control levels by 6d in septum and the contralateral hippocampus. In contrast, GFAP mRNA in the ipsilateral hippocampus returned more slowly to baseline by 1dd GFAP mRNA length was increased user control by \$6416. baseline, by 14d. GFAP mRNA levels were increased over control by 5-fold in the septum, 3-fold in the contralateral hippocampus and >10-fold in the ipsilateral hippocampus. In the ipsilateral septum, ISH signal was increased at 2d, but increases in protein were not apparent (ICC) until 10d post lesion. These data suggest a rapid and robust astrocytic response in the septum. The 5-fold increase in message is apparently limited to the ipsilateral septum, suggesting a specific interaction between the astrocytes and the neurons which are sprouting. It is an open question whether these astrocytes are responding directly to the ECL induced degeneration or indirectly as a result of septal sprouting. (Supported by NIA AGO7909)

TRANSIENT RISE IN IMMEDIATE EARLY GENE PRODUCTS IN HIPPOCAMPAL NEURONS AFTER ELECTROCONVULSIVE TREATMENT Y Nakabeppu*, J.M. Baraban, B. Christy*, P.F. Worley. Howard Hughes Medical Institute, Depts. of Molecular Biology and Genetics, and Dept. of Neuroscience, Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

Cell surface receptor of invited in the control of the contr

Cell surface receptor stimulation by neurotransmitters growth factors can elicit a rapid and transient activation of a set of genes, referred to as immediate early genes (IECs), thought to play a key role in long-term changes in cellular activity. Electroconvulsive treatment produces a robust rise in mRNA levels for several IEGs that code for known or putative transcription regulatory factors in dentate granule cells. Accordingly, we have used this stimulation paradigm to characterize the

expression of these gene products in brain neurons.

Immunoblot analysis of hippocampal nuclear extracts with affinity purified polyclonal antisera demonstrates a rise in Zif/268, c-Jun, Jun-B and c-Fos that peaks at 1-2 hrs and returns to basal levels by 4-8 hrs. These IEG products contribute to increased binding activity to DNA consensus sequences previously identified for Zif/268 and Jun-Fos complexes. By contrast, binding activity for the consensus sequence of Spl, a constitutively expressed transcription factor, is unchanged. Immunohistochemical studies with these antisera demonstrate prominent increases in staining in nuclei of dentate granule cells. These results suggest that activation of these genes in brain neurons leads to transient increased expression of their gene products.

276.10

ENTORHINAL CORTEX LESION INDUCES C-FOS IN THE RAT HIPPOCAMPUS. S.S.Schreiber, G.Tocco, N.J.Laping, J.R.Day, A.A.Blain, C.E.Finch. Andrus Gerontology Center and USC School of Medicine Department of Neurology, University of Southern California, Los Angeles,

The induction of c-fos in the deafferented rat hippocampus was examined by in situ hybridization as part of an ongoing study of molecular events associated with reactive synaptogenesis. Adult male rats were subjected to unilateral electrolytic entorhinal cortex lesion (ECL) under pentobarbital anesthesia. The animals were sacrificed by decapitation either one or four hours after surgery. Unoperated but anesthetized, and sham operated animals served as controls. In situ hybridization was performed on cryostat sections (10um) fixed in 4% paraformaldehyde. A full length c-fos antisense riboprobe labeled with 35S-UTP was hybridized to sections for three hours at 50 C. In intact and sham-operated control animals levels of c-fos expression were unchanged indicative of a low level of basal expression. One and four hours after ECL c-fos expression was increased in the ipsilateral cortex (n=2). However, at four hours increased signal was also detected in both hippocampi (3 out of 4 animals). These results suggest that c-fos induction occurred by way of trans-synaptic activation from the lesioned afferent pathway. Furthermore, the uncharacteristic delay in, and bilaterality of, this response suggests a role for proto-oncogene fos in adaptation to changes in neuronal circuitry. Characterization of the response in terms of time course and cellular localization will be reported. (Supported by NIH Grant NS01337 to SSS; NIA AGO5142; NIA AGO7909)

RECOMBINANT HUMAN NERVE GROWTH FACTOR STIMULATES ACETYL-CHOLINE SYNTHESIS IN CHOLINERGIC NEURONS SURVIVING PARTIAL SEPTO-HIPPOCAMPAL LESIONS. P.A. Lapchak, E. O. Junard and F.F. Hefti. Andrus Gerontology Center, U.S.C., Los Angeles, CA, 90089.

In adult rats with lesions of the septo-hippocampal STR. Database Capath footography Control Particles

S-H) pathway, nerve growth factor (NGF), given intra-ventricularly (icv), prevents the loss of cholinergic cell bodies in the septum and increases ChAT activity in ventricularly (icv), prevents the loss of cholinergic cell bodies in the septum and increases chAT activity in the hippocampus. The present study determined whether the NGF-induced increase in ChAT activity results in changes of presynaptic cholinergic function in the hippocampus. Adult rats received partial unilateral transections of the fimbria as described previously (Befti et al. Brain Res. 293: 305-311, 1984). They were injected icv (during 3 weeks) every second day with 1 µg of rhNGF through chronically implanted cannulas. We then determined whether NGF treatment altered the amount of 3H-acetyl-choline(ACh) formed from 3H-choline by hippocampal slices in vitro. 3H-ACh formed by hippocampal slices of cyto-chrome c (cc)-treated lesioned animals was reduced to 55.4 ±5.7 % of the contralateral intact tissue. Following treatment with NGF, 3H-ACh synthesis was increased to 81.7 ± 10.9 % of the contralateral intact tissue. NGF did not alter the amount of 3H-ACh formed by the unlesioned contralateral intact tissue. These results are compatible with the idea that NGF treatment stimulates presynaptic cholinergic function following brain injury (Supported by FRSQ, Quebec).

GM1-ENHANCED RECOVERY OF DRL-20 AND OPEN FIELD ACTIVITY AFTER BILATERAL ENTORHINAL CORTEX LESIONS IN RATS. J. J. Ramirez, B. Fass-Holmes, S. E. Karpiak, C. Tuite*, C. Alexander*, and A. Grewal*. Dept. of Psychology, Davidson College, Davidson, NC 28036, N.Y.S.P.I., Columbia Univ., N.Y.C., NY 10032.

Administration of gangliosides accelerates recovery of function after bilateral entorhinal cortex (EC) lesions on open field activity and learned spatial alternation tasks. We previously demonstrated that a reduction in heterologous sprouting is associated with this enhanced recovery. The present study examined whether gangliosides (GM1) enhance recovery from bilateral EC lesions on a timing task (i.e., differential reinforcement of low-rate responding -- DRL) as well as open field activity. Optical densitometry measurements were taken to assess sprouting by the septo dentate pathway. Eighteen rats were assigned to sham/GM1, lesion/GM1, or lesion/saline conditions, tested on both tasks preoperatively, and tested postoperatively for 30 days. Rats in the lesion/GM1 group showed enhanced recovery on the DRL-20 and the open field tasks. Optical densitometry analyses revealed a reduction of septal sprouting in the molecular layer of the dentate gyrus for the lesion/ GM1 group. GM1 treatment may be facilitating recovery from bilateral EC lesions by reducing the trauma of injury and denervation, reducing heterologous sprouting, or both. Supported by NC Board of Science and Technology.

CORTICOSTERONE DECREASES GLIAL FIBRILLARY ACIDIC ROTEIN mRNA AND SULFATED GLYCOPROTEIN-2 mRNA IN THE HIPPOCAMPUS OF ADRENALECTOMIZED AND ENTORHINAL CORTEX LESIONED MALE RATS. N. J. Laping, N. R. Nichols, J. R. Day, and C. E. Finch. Gerontology Center, University of Southern California, Los Angeles, CA 90089.

Glial fibrillary acidic protein (GFAP), a marker of astrocyte activation, and sulfated glycoprotein-2 (SGP-2), a marker of programmed cell death in peripheral tissues, are elevated during neurodegeneration. As shown previously unilateral entorhinal cortex lesion (ECL) increases GFAP and SGP-2 mRNA in the hippocampus (Poirier et al, 1988; Lampert-Etchells, these Proceedings). Moreover, GFAP mRNA is increased in the hippocampus following adrenalectomy (ADX). This study examined the effect of corticosterone (CORT) (200 µg/ml in drinking water) on GFAP and SGP-2 mRNA levels in the hippocampus of ECL rats. CORT decreased GFAP mRNA in ADX rats. The combination of ADX + ECL increased GFAP mRNA additively in the ipsilateral hippocampus over the ADX and intact groups. CORT reduced GFAP mRNA to intact levels in the contralateral hippocampus of ADX+ECL rats and to a lesser degree in the ipsilateral hippocampus. CORT decreased SGP-2 mRNA in the ADX and ADX+ECL group as well. These experiments show that CORT can independently regulate both GFAP and SGP-2 mRNA in ADX and ECL conditions. Also, the ECL-surgery induced surge of CORT probably does not play a major role in the long term regulation of GFAP mRNA. (Supported by: J.D. & C.T. MacArthur, Program in Successful Aging; ONR Grant N00014-85-K-0770; NIA 07909).

EVIDENCE FOR SYNAPTIC REMODELLING IN HIPPOCAMPAL CA1 FOLLOWING ENTORHINAL CORTEX LESIONS. M.A. King, D.W. Walker, and B.E. Hunter, Gainesville VA Medical Center and Dept. of Neuroscience, University of Florida, Gainesville, FL 32610. Entorhinal cortex (EC) lesions provoke a well documented reactive synaptogenesis in the dentate gyrus which is reflected by changes in the pattern of acetylcholinesterase (AChE) staining. Since the entorhinal cortex (EC) also projects to regio superior we examined AChE staining patterns in CA1 to determine whether and how synaptic remodelling occurs there. Unilateral electrolytic EC lesions in adult male Long-Evans rats were followed by a 40 d. survival. Digital images of AChE-stained sections from the ipsi- and contralateral dorsal hippocampus were sampled from the alveus to the fissure at lateral (->CA3), central, and medial (subicular) CA1. Intensities at each 1% of normalized stain profiles were analyzed for lesion and CA1 position effects with 2-way ANOVA and Duncan's means tests. CA1 location effects were found mainly in distal strata radiatum and lacunosum-moleculare losilateral to the lesion significant AChF intensification was observed in distal apical lateral CA1, similar to that seen in the dentate. Central and medial lesion effects were characterized more by an AChE clearing in distal stratum radiatum. Effects in strata pyramidale and oriens were minor. In the context of the meaning of AChE reorganization in the dentate gyrus these data indicate that synaptic reorganization may also occur in CA1 following deafferenting lesions. The data furthermore offer a quantitative description of variations in AChE parallel and transversely perpendicular to the primary dendritic axis of CA1 pyramidal cells

THE EFFECT OF FEMALE CIRCULATING SEX HORMONES ON HIPPOCAMPAL SYMPATHETIC INGROWTH. L. E. Harrell, D. S. Parsons*, A. Peagler* and J. Litersky. Department of Neurology, Veterans Administration and University of Alabama Medical Center, Birmingham, Alabama 35294

Previously, we have demonstrated an interaction between male circulating sex hormones and the behavioral and biochemical effects of peripheral sympathetic ingrowth, which occurs in the hippocampus after medial septal lesions (MSL). In this study we assessed the effect of female circulating sex hormones. Seventeen adult female Sprague-Dawly rats underwent sham ovariectomy (SOX), while 21 were Ox. Animals within each group then underwent 1 of 3 neurosurgical procedures: CON-sham MSL + sham ganglionectomy (GX); MS-MSL + SGX; MSGX - MSL + GX. Eight weeks later, animals were sacrificed, the brain dissected into a septal block (to assure appropriate lesion placement) and a hippocampal block, which was dissected into dorsal (D) and ventral (V) regions. Norepinephrine (NE) and choline acetyltranferase (ChAT) were then measured in the hippocampus. MS lesions were found to reduce ChAT activity in both D and V of both SOx and OX groups when compared to CON (pc.0001). This reduction was less in the Ox than SOx group (p<.05) in both D and V (p<.0006). Analysis of NE revealed that Ox did not alter NE in CON. However, Ox MS animals were found to have significantly greater levels of NE in both D and V (p<.05), while Ox MSGx animals were found to have significantly greater levels of NE in both D and V (p<.05), while Ox MSGX animals were found to have levels of NE than SOX MSGX. This suggests that circulating female sex hormones interact with both MS lesions, as measured by ChAT activity, and hippocampal sympathetic ingrowth in a complex fashion. Further studies are ongoing to assess the behavioral effects of female sex hormones in HSI.

GONADECTOMY ELICITS A SEXUALLY DIMORPHIC PATTERN OF GENE EXPRESSION IN THE RAT HIPPOCAMPUS AFTER ENTORHINAL CORTEX LESION. J.R. Day, N.J. Laping and C.E. Finch. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089.

Unilateral lesion of the rat entorhinal cortex (ECL) induces synaptic remodeling in the adult hippocampus. Following deafferentation, dramatic changes in gene expression and morphology occur as the synapses of the perforant pathway are gradually replaced by remaining afferents. The pattern of gene expression induced by this lesion is similar to that seen during aging and in Alzheimer's disease. Specifically, the astrocyte marker glial fibrillary acidic protein (GFAP) and a putative neuronal constituent, sulfated glycoprotein-2 (SGP-2), are elevated in the hippocampus after ECL in rats as they are during neurodegeneration in humans. Northern blot analysis showed SGP-2 and GFAP mRNAs to be elevated 21 days post-castration, and by 2 days post-ECL. SGP-2 and GFAP mRNAs increased 5-fold after castration alone and an additional 3- to 5-fold respectively, in castrate males after ECL. In females, ovariectomy did not increase these mRNAs above those levels induced by ECL in intact females, and ovariectomy alone had no effect. These results indicate that the hormonal control of gene expression, subsequent to injury in the brain of females is different from males. (Supported by: J.D. & C.T. MacArthur Program in Successful Aging; NIA 07909)

NMDA RECEPTOR ACTIVATION INCREASES AXON TERMINAL EXCITABILITY IN VITRO: A NOVEL FORM OF NEURONAL PLASTICITY. S. F. Stasheff and W. A. Wilson, Depts. of Pharmacology and Medicine, Duke University and Durham Veterans Administration Medical Centers, Durham, NC.

We previously reported that kindling-like stimulation increases the occurrence of ectopic action potentials ("baseline spikes" (BLSs)) in CA3 cells of the hippocampal slice, via NMDA receptor activation (Neurosci, Lett. 111:144-50, 1990; Neurosci, Abst. 478.2, 1989). Like known forms of CNS plasticity such as LTP, this increase in excitability is long-lasting and, once established, no longer dependent on NMDA receptor activation. However, the initiation site of these action potentials, and thus of the alteration in excitability, is clearly not somatic. We have now used three approaches which suggest that the increase in BLS firing results from the development of hyperexcitability in CA3 axon terminals.

First, we performed intracellular collision tests. We collided known anti- and orthodromic spikes to find the critical period for collision in each cell. We then tried to collide BLSs with known antidromic spikes. We usually found that they failed to do so, indicating that BLSs are antidromic. Second, we analyzed the waveforms of spikes triggered by various means. We found that antidromic spikes possess an inflection on their rising phase which is not present in orthodromic (synaptic, current evoked, or spontaneous) spikes. BLSs also exhibit such an inflection, indicating their antidromic origin. Finally, we performed intracellular excitability tests before and after the induction of BLSs, measuring the threshold for antidromic activation at putative terminal and non-terminal sites along the Schaffer collaterals. This threshold decreased only at terminal sites, in parallel with the development of BLSs

These results suggest the novel idea that NMDA receptors can mediate lasting increases in the excitability of not only dendrites and somata, but also axon terminals of CNS neurons. Such changes may contribute to phenomena such as epileptogenesis and LTP. Supported by NS 17701 and the Veterans Administration

VISUALIZATION OF LIVING HIPPOCAMPAL SYNAPSES USING CONFOCAL SCANNING LASER MICROSCOPY. C. L. Keenan, A. C. Nobre, B.J. Claiborne, and T.H. Brown. Dept. of Psychology, Yale Univ., New Haven,

CT 06520 and Div. of Life Sciences, Univ. of Texas, San Antonio, TX 78285.

We have been interested in optical methods that offer good spatial and temporal resolution of cellular and subcellular details in brain slices (Keenan et al., <u>Brain Res. Bull.</u>, 21:373, 1988; Keenan et al., <u>Soc. Neurosci. Abstr.</u>, 15:980,1989). Here we report the successful use of confocal scanning laser microscopy (CSLM) for visualizing the mossy-fiber (mf) synapses of hippocampal region CA3.

Hippocampal slices were placed into a chamber attached to the stage of an inverted

microscope, which was equipped with a long-working distance (500 µm), oil-immersion objective (63X, 1.25 NA). The (presynaptic) mf expansions were stained by pressure ejection of DilC18(3) into either the stratum lucidum, the hilus or the stratum granulosum. The (postsynaptic) thorny excrescences were stained by intracellular injection of lucifer yellow into the CA3 neurons. Serial optical sections of mf expansions and thorny excrescences were then obtained using CSLM. Sections were taken at intervals of $0.1 - 2.0 \,\mu m$ and then reconstructed to yield 3-D

Using appropriate scanning times and filtering for the particular dye, we were able to visualize clearly both the mf expansions and the thorny excrescences. High resolution images were obtained in as little as 6 sec, at 1 scan/sec, with relatively low laser power. Sometimes we could see small filamentous extensions of the mf expansions, reminiscent of growth cone filopodia.

We have been particularly interested in possible structural changes that may

accompany use-dependent synaptic modifications, such as long-term potentiation (LTP) (reviewed in Brown et al., In: Byrne and Berry, Neural Models of Plasticity, 266, 1989). If there are in fact LTP-associated structural modifications, as suggested by electron microscopic studies, the present methods may enable them to be visualized in real time. EFFECTS OF CARBACHOL AND L-AP4 ON PAIRED-PULSE PLASTICITY IN THE PERFORANT PATHWAYS OF THE DENTATE GYRUS OF THE RAT. J. S. Kahle and C.W. Cotman. Department of Psychobiology, University of California, Irvine, CA 92717. The pharmacological profile of paired-pulse (PP) plasticity in the dentate gyrus was studied in order to further define the mechanisms underlying

gyrus was studied in order to further define the mechanisms underlying these phenomena. Lateral and medial entorhinal layer II cells both terminate on dentate granule cells, but the lateral perforant path exhibits PP potentiation whereas the medial perforant path exhibits PP depression at interstimulus intervals (isi) between 40-800msec. Previously, carbachol (CARB; an acetylcholine agonist) has been shown to preferentially reduce medial perforant path field potentials. Conversely, L-2-amino-4-phosphonobutyric acid (L-AP4; a glutamate analog) has been shown to specifically reduce lateral perforant path field potentials. The effects of CARB and L-AP4 on PP plasticity as a function of isi were compared. Pairs of evoked extracellular field potentials were recorded differentially from the medial and lateral perforant pathways from rat hippocampal slices the medial and lateral perforant pathways from rat hippocampal slices maintained in vitro.

In CARB (20μM), PP depression reversed to PP potentiation (30%) at

In CARB (20µM), PP depression reversed to PP potentiation (30%) at short isi, was attenuated (50%) at intermediate isi, and not affected at longer isi. Furthermore, in CARB, PP potentiation tended to increase at short isi. In L-AP4 (10µM), PP depression was attenuated (50%) at intermediate isi, whereas PP potentiation increased (240%) at all isi investigated. The effects of CARB and L-AP4 were not due simply to the reduction of the field potential amplitude.

The effects of L-AP4 may be explained in part by the blockade of a late, slow inhibitory post synaptic potential that may be part of feed-forward inhibition onto the dentate granule cells. The effects of both CARB and L-AP4 on PP depression in the medial perforant path appear to be dependent on the pattern of activity of this pathway.

2-AMINO-3-PHOSPHONOPROPIONATE (AP3) BLOCKS INDUCTION OF ASSOCIATIVE LONG-TERM DEPRESSION (LTD) IN HIPPOCAMPAL FIELD CA1. S. Chattarji, P.K. Stanton 1 and T.J. Scinowski,

Salk Institute, La Jolla, CA 92037 and ¹Albert Einstein Coll. Med., Bronx, NY 10461.

A test input, which by itself does not elicit long-term potentiation (LTP), exhibits an associative form of LTP when it is activated at the same time as a separate conditioning input. Recently, we have reported an associative long-term depression (LTD) in field CA1 that is produced when a low-frequency test input (TEST) is negatively correlated in time with a high-frequency conditioning input (COND), LTD can also be produced by activating presynaptic terminals while a postsynaptic neuron is hyperpolarized. The present study investigates the effect of 2-amino-3phosphonopropionate (AP3), a putative antagonist for a metabotropic quisqualate receptor, on the induction of LTD in hippocampal field CA1.

Extra- and intracellular recordings were made in rat hippocampal slices (400µm thick) in an interface chamber at 34°C. The COND stimulus, activating Schaffer collateral/commissural fibres, was trains of 10 bursts of 5 pulses each (100 Hz burst frequency, 200 msec interburst interval). The TEST stimulus, activating separate subicular inputs, was a 5 Hz train of single shocks. The single shocks of the TEST

subclust inputs, was a 3 rd zulin of single shocks. The single shocks of the rest input were given either superimposed on the middle of each burst of the COND input (in phase), or symmetrically between the bursts (out of phase).

In control experiments, the TEST stimuli alone induced no change and the COND stimuli alone induced homosynaptic LTP of the COND input without affecting the stimuli alone induced homosynaptic LTP of the COND input without affecting the TEST input. In extracellular experiments, out of phase stimulation induced associative LTD at the TEST input (Acpsp slope = -25.1±2.1%, Apop. spike = -44.2±3.7%, n=17). In contrast, 25µM bath applied AP3 blocked induction of LTD at the TEST input (Acpsp slope = +5.6±2.2%, Apop. spike = -2.9±1.6%, n=13), without affecting LTP of the COND input. In intracellular experiments, pairing of hyperpolarizing current injection with synaptic stimulation elicited LTD (Acpsp slope = -26.4±4.6%, n=6), which was blocked by AP3 (Acpsp slope = +18.7±14.9%, n=8). Thus, a metabotropic quisqualate receptor may be involved in the induction of LTD.

BETA-ADRENERGIC AGONIST-INDUCED LONG-LASTING SYN-

BETA-ADRENERGIC AGONIST-INDUCED LONG-LASTING SYNAPTIC MODIFICATIONS IN HIPPOCAMPAL DENTATE GYRUS REQUIRE ACTIVATION OF NMDA RECEPTORS, BUT NOT ELECTRICAL ACTIVATION OF AFFERENTS. D.Dahl, Univ Texas-Dallas and J.M.Sarvey, Uniformed Services University, Bethesda, MD.
Norepinephrine (NE) in the presence of an alphadrenergic receptor antagonist has differential effects on activation of granule cells by separate components of the perforant path (PP): medial PP responses potentiate (LLP) and lateral PP responses depress (LLD). LLP requires co-activation of the NMDA receptor subtype of glutamate, as D [-]APV and CPP, both antagonists, block its induction. D[-]APV and CPP also show a pathway selectivity limited to medial PP EPSPs.

It is not known whether induction of beta-adren-

It is not known whether induction of beta-adrenergic LLP or LLD requires electrical activation of the PP. Furthermore, although D[-]APV and CPP block NE-induced LLP, it is not known whether LLP

block NE-induced LLP, it is not known whether LLP or LLD induced by the specific beta-adrenergic agonist isoproterenol (ISO) is also blocked by NMDA receptor antagonists. We have found that electrical stimulation of the PP is not required for LLP or LLD induction and that D[-]APV blocks ISO-induced LLP and LLD, but prior exposure to D[-]APV and ISO prevents induction of LLD, but not LLP, by a subsequent exposure to ISO. INDUCTION OF TYROSINE HYDROXYLASE MRNA BY KC1 DEPOLAR-IZATION IS SEX DEPENDENT. <u>D.R. Studelska and K.L.</u>
<u>O'Malley</u>. Anatomy & Neurobiology, Washington Univ. Sch.
Med., St. Louis, MO 63110.

Increased extracellular K+ has been reported to increase levels of tyrosine hydroxylase (TH) in sympathetic neurons. Here we report that this effect is restricted Superior cervical ganglion (SCG) neurons were dissociated from male or female E21 rat fetuses and cultured on collagen in a medium containing 10% human placental serum, 2% chick embryo extract, and 20 ng/ml nerve growth factor. After 3 to 5 days, the cells were switched to a defined medium (N2) with or without 40 mM KCl. After 6 to 16 days in culture, total RNA was isolated and reverse-transcribed using oligonucleotide primers complementary to TH. Primers complementary to actin mRNA and 18S rRNA were used in parallel reactions as internal controls. The resulting cDNAs were amplified using the polymerase chain reaction. In 3 separate experiments K+ depolarization led to 5-fold increases in TH mRNA from males but not from females when compared with actin transcript levels. 18S rRNA levels were correlated with actin mRNA levels except in male neurons treated with KCl where 18S rRNA also exhibited a 5-fold increase with respect to actin mRNA. Estradiol treatment for 6 to 18 h had no effect on TH message levels in SCG neurons cultured from either sex. Together these results suggest that sex differences in SCG may be modulated transynaptically in vivo.

277.2

ANDROGEN AND ESTROGEN RECEPTOR mRNA EXPRESSION IN THE PREOPTIC AREA OF MALE AND FEMALE RAT
BRAINS. J.N. BICKNELL, C.D. REFSDAL*, M.A. Miller and
D.M. DORSA, GRECC, VAMC, Seattle, WA 98108.
We have examined sexual dimorphism of expression of androgen

receptor (AR) and estrogen receptor (ER) mRNA in the rat brain. The brains of 60 day old male and female Wistar rats were hand dissected, the various regions pooled by sex, and RNA extracted. Total RNA was size fractionated on agarose formaldehyde gels and transferred to Nytran membranes and then hybridized with either an AR or ER randomly primed probe.

In previous studies we found that male rat brain contains two forms of AR mRNA (9.5kb and 11kb transcripts). Both forms were also evident in female brain. In both male and female preoptic area (POA), these two AR messages are present in about equal abundance. This pattern of expression is similar to the hippocampus, but different from the other brain areas which express the smaller message in greater

Estrogen receptor probe preferentially hybridized to a single band of RNA from the POA of both males and females and was equilvalent in size to that observed when probing RNA from the uterus. ER message levels were elevated in female POA when compared to that of the male. We propose that sex related differences in circulating gonadal steroids

underlie sexual dimorphism of steroid receptor gene expression.

We conclude that the two isoforms of AR mRNA are present in the POA of male and female rat brain. In addition, ER mRNA levels may be greater in the POA of females than in males.

DECLINE OF VASOPRESSIN mRNA AND IMMUNOREACTIVITY IN THE BNST FOLLOWING CASTRATION: A TIME-COURSE STUDY. M.A. Miller, D.M. Dorsa and G.J. DeVries, GRECC, VA Medical Center, Seattle, WA 98108, and Department of Psychology, University of Massachusetts, Amherst, MA 01003.

Vasopressin (VP) neurons in the bed nucleus of the stria terminalis (BNST) of the rat are steroid dependent. Castration of adult male rats makes VP cells virtually undetectable throughout the BNST by both immunocytochemical (ICC) and in situ hybridization (ISH) techniques. In this study, we have compared the decline over time of VP mRNA and VP-immunoreactivity in the BNST following castration. Male Wistar rats (90 d) were sacrificed as sham-operated controls or at 1,3,or 8 wks post-castration. All animals used for ICC and some animals used for ISH were pretreated with colchicine. The peak number of VP mRNA expressing cells sampled unilaterally in $20\mu m$ sections decreased significantly (p \leq 0.01) by 1 wk post-castration (37±4 vs. 5±3, mean±SEM). The remaining cells exhibited a reduced number of grains/cell (p \leq 0.01). No VP expressing cells were detectable at 3 or 8 wks post-castration. Preliminary evidence suggests that colchicine treatment may significantly reduce grains/cell (p ≤0.05) but not cell number. VP-immunoreactive cells (50µm section) were not decreased at 1 wk post-castration (64±12 vs. 46±9, mean±SEM) but were significantly reduced ($p \le 0.001$) at 3 and 8 wks post-castration (10±3 and 6±1, mean±SEM, respectively). Fiber density showed a similar rate of decline. These results indicate that decreases in VP mRNA levels occur much more rapidly than changes in peptide

CORTICOSTERONE REGULATES CALBINDIN-D28K MRNA AND PROTEIN IN RAT HIPPOCAMPUS. <u>S. Christakos</u> and <u>A.M.</u>
UMDNJ-New Jersey Medical School, Newark, NJ 07 07103

UMDNJ-New Jersey Medical School, Newark, NJ 07103. Corticosterone administration (10 mg/day for 7 days) to intact rats significantly increased levels of the 28,000 M $_{\rm T}$ calcium binding protein (calbindin) (43%) and calbindin mRNA (125%) in hippocampus. Adenalectomy (ADX) (animals were sacrificed 7 days after ADX) produced (ADX) (animals were sacrificed / days after ADX) produced a significant decrease in hippocampal calbindin protein (85%) and mRNA (80%) compared to intact controls. Immunocytochemical analysis of tissue sections indicated a marked depletion of calbindin immunoreactivity in ${\tt CA}_1$ and the dentate gyrus of the hippocampus 2 weeks after ADX. When ADX rats were treated with corticosterone, calbindin protein and mRNA levels in hippocampus were restored to levels observed in intact controls. No changes in calbindin in kidney, cerebellum, striatum or cerebral cortex were noted in ADX rats or in intact rats treated with corticosterone when compared to controls, indicating the specificity of the effect on calbindin for the hippocampus. Since CA1 and the dentate gyrus of the hippocampus contain the highest concentration of brain corticosterone type I receptors, our findings suggest glucocorticoid receptor mediated regulation of hippocampal calbindin gene expression. These studies present the first evidence of a hormonal regulator of calbindin gene expression in the brain.

277.7

REGULATION OF POMC mRNA BY DEXAMETHASONE AND 8-Br-cAMP IN ANTERIOR AND INTERMEDIATE LOBES OF THE RAT PITUITARY DURING EARLY POST-NATAL DEVELOPMENT. R.E.M. Scott and <u>I.E.Pintar.</u> Department of Anatomy and Cell Biology, Columbia University P&S, NY, NY. 10032.

NY, NY, 10032.

POMC RNA synthesis in the adult anterior lobe (AL) is under negative regulation by glucocorticoids. However, glucocorticoids have very little, if any, positive or negative effect in the adult intermediate lobe (IL). The non-responsiveness of the IL to glucocorticoids is thought to result from a lack of functional glucocorticoid receptors in this lobe. Using the reverse haemolytic plaque assay, our laboratory has previously shown that the glucocorticoid analogue dexamethasone (DEX) inhibited CRH stimulated secretion from dispersed melanotrophs at fetal and early post-natal ages but that this inhibition disappeared at

p3.
Solution hybridization/RNA protection assays with a POMC cRNA probe were used to measure changes in neurointermediate lobe (NIL) and AL POMC mRNA levels in short term cultures in response to 8-Br-cAMP and DEX at early post-natal ages. In the AL, at p1, 8-Br-cAMP (1mM) increased POMC mRNA levels above ages. In the AL, a pt, 6-3e-AMF (1mm) increased POWE InkiNA levels above control. Incubation with DEX (10⁻⁶M) for I hour prior to addition of 8-Br-cAMP inhibited the cAMP mediated increase in POMC mRNA, which remained at the level of control. Similar results were observed at p10, where 8-Br-cAMP alone increased POMC mRNA levels while addition of DEX inhibited this increase. In the NIL, at p10, 8-Br-cAMP increased POMC mRNA levels, but DEX inhibition of 8-Br-cAMP mediated increase was not detected. However, at p1, 8-Br-cAMP of 8-Br-CAMP mediated increase was not detected. However, at p1, 8-Br-CAMP mediated increase in POMC mRNA was inhibited by pretreatment with DEX and POMC mRNA levels remained at the level of control. These results, along with those reported earlier, indicate that corticosteroids effect both POMC secretion and mRNA levels in the NIL at early post-natal ages but that the responsiveness disappears as the IL undergoes a maturation process that is closely linked with the arrival of the dopaminergic input into the IL at p3.

277.4

ESTROGEN RECEPTOR mRNA EXPRESSION IN RAT HYPOTHALAMUS AS A FUNCTION OF SEX AND ESTROGEN DOSE. A.H. Lauber, C.V. Mobbs, M. Muramatsu*, and D.W. Pfaff. Laboratory of Neurobiology and Behavior, Rockefeller University, New York, NY 10021.

Recent in situ hybridization experiments confirm our previous findings (Soc. Neurosci Abst, 1989, p. 984; J. Neuroendo, in press) that estrogen down-regulates estrogen receptor (ER) mRNA in female rat mediobasal hypothalamus. Here, we show that ER mRNA level is regulated according to EB dose and genetic sex. Ovariectomized (ovx) rats were treated with 10 ug estradiol benzoate (EB) for 0, 2, 6 or 18 hrs; gonadectomized males (gdz) for 0, 6 or 18 hrs. Tissue sections were hybridized with *H-single stranded DNA probe prepared from the region of the rat cDNA corresponding to the steroid binding domain. Relative ER mRNA level was assessed by counting the number of grains over cells in ventrolateral-ventromedial nucleus (VLVM), arcuate, dorsomedial nucleus (DM) and amygdala. Values were expressed as mean grains/cell after subtracting background (mean grains/cell in thalamus and cortex of the same brain section). There was no effect of sex or EB on ER message levels in DM background (mean grains/cell in thalamus and cortex of the same brain section). There was no effect of sex or EB on ER message levels in DM or amygdala. EB decreased ER mRNA level in female VLVM by 42% (2 hr) to 55% (18 hr) and in the arcuate by 65% (6 hrs) to 74% (18 hr) as compared to ovx. Notably, gdz males had significantly lower ER mRNA levels than ovx females (51% VLVM; 56% arcuate) and EB failed to downregulate significantly ER message level in males. In a separate study ovx rats were implanted for 2 wks with sillastic capsules containing 0%, .1%, 1%, 10% or 100% estradiol. Estradiol induced a monotonic dose-dependent decrease in ER mRNA levels in females. Message levels declined in VLVM by 28% (1%) to 57% (100%) and in arcuate by 36% (1%) to 62% (100%). The data show regional specificity and sex differences in the relative level The data show regional specificity and sex differences in the relative level and hormonal regulation of ER mRNA expression. Further, ER mRNA down-regulation in females exhibits dose-dependence at a time point following EB treatment which ensures the system is at steady-state.

277.6

REGULATION OF VASOPRESSIN EXPRESSION IN CULTURED MAGNOCELLULAR NEURONS BY GLUCOCORTICOIDS Ch. Pilgrim¹, P. Oeding^{2*}, H. Schmale² and K. Schilling¹ Abt.Anatomie und Zellbiol.¹, Univ.Ulm, D-7900 Ulm, and Inst.f.Zellbiochem.², Univ. Hamburg, D-2000 Hamburg, Fed. Rep. Germany

We used primary diencephalic cultures to investigate why adrenalectomy-induced up-regulation of vasopressin (VP) expression affects only parvocellular but not magnocellular (MC) hypothalamic neurons. In cultures derived from 14 day old fetal rats, which contain MC but no parvocellular VP neurons, selective neutralization of glucocorticoids (GC) in the culture medium by the drug RU 38 486 increased numbers of MC VP cells and levels of VP mRNA 2-3-fold. This effect was specific for VP neurons, as neither the expression of oxytocin nor of general neuronal marker proteins was affected by RU. RU was not mitogenic for VP neurons. RU increased VP expression also in cells that were grown in 14 mM Mg⁺⁺, showing that the effect was not mediated transsynaptically. These results show that GC can regulate VP expression in MC hypothalamic neurons. The absence of such an effect in vivo may be best explained by an inhibitory synaptic input, which is lacking in vitro. Supported by the DFG (Ri 192/17-6, Schi 271/1-2).

277.8

COLD INCREASES THYROTROPIN-RELEASING HORMONE mRNA LEVELS IN PARAVENTRICULAR NUCLEUS DESPITE ELEVATED T. R.T. Zoeller and H.E. Albers. Dept. Anat/Neurobiol., Univ. Missouri Sch. Med., Columbia, MO and Dept Biol. Georgia State Univ, Atlanta, GA TRH neurons are found throughout the CNS; however, TRH neurons in PVN control pituitary-thyroid function. TRH mRNA levels in PVN appear

linked to neuronal activity: hypothyroidism increases TRH secretion and TRH mRNA levels, and thyroid hormones $(T_{\overline{z}})$ reverse these effects. Cold exposure increases thyroid activity perhaps by activating PVN TRH neurons. If so, TRH mRNA levels should become elevated in PVN after cold. We exposed male Sprague-Dawley rats to 5°C for 6, 24, 30, and 48 hours and measured plasma TSH and T₃ by RIA and TRH mRNA by in situ hybridization (ISH). ISH allowed us to measure single cell levels of TRH mRNA and multiple mRNAs in the same animal. TSH and T₂ were elevated in plasma after 6h of cold, and TRH mRNA was elevated in PVN compared to controls maintained at 25°C. The effect of cold was specific for TRH mRNA in PVN: TRH mRNA levels were not altered in thalamus, and \(\beta\)-actin and oxytocin mRNA levels were not altered in PVN. TSH and T_3 in blood and TRH mRNA in PVN were higher in 25°C controls at 24h than in 25°C controls at 6h, and cold did not produce This pattern was repeated at 30h and 48h cold. The 24-h profile of TRH mRNA changes in PVN of resting animals corroborated these findings. Thus, time of day, not duration of cold, was the important variable in observing an effect of cold on TRH expression. We found no evidence that cold activates a subset of TRH neurons separate from those inhibited by T. These findings indicate that TRH gene expression in PVN neurons is linked to neuronal activity which is regulated hormonally (T₃) and neurally (cold), and these signals interact within TRH neurons of the PVN during the physiological response to cold.

EFFECT OF STARVATION ON GROWTH HORMONE MRNA LEVELS IN GENETICALLY OBESE AND LEAN ZUCKER RATS. J. A. Finkelstein and I. Ahmad. Dept. of Anatomy, N.E. Ohio Univ. Coll. Med., Rootstown, OH 44272.

Ohio Univ. Coll. Med., Rootstown, OH 44272.

Plasma growth hormone (GH) levels are known to be diminished by both starvation and obesity. In genetically obese Zucker rats, the decrease in plasma GH is associated with a decrease in GH gene expression as measured by the steady state level of GH mRNA. The purpose of the present study was to investigate the effects of starvation on GH mRNA levels in both lean and obese Zucker rats. Groups of 5-month-old male genetically obese (fa/fa) (mean body weight 560 g) and lean (Fa/-) (380 g) rats were studied. Half of the animals of each genotype were deprived of food for 72 hours, and the other half were not. After sacrifice, the pituitaries were removed and processed for determination of GH mRNA levels using the dot blot technique. The largest difference was seen between the two ad libitum groups, with the obese animals having 55% lower level of pituitary GH mRNA. Starvation resulted in similar decreases in GH mRNA levels in the lean group (26%), and the obese group (23%). Therefore, the chronic metabolic abnormalities associated with genetic obesity are more effective in lowering GH mRNA levels than those associated with an acute bout of food deprivation.

EFFECT OF ANESTHESIA AND ADRENALECTOMY ON HEAT-INDUCED HSP70 mRNA EXPRESSION IN BRAIN REGIONS MEDIATING THE NEUROENDOCRINE STRESS RESPONSE. M.J. Blake, D.D. Norton* and N.J. Holbrook*. Lab. of Mol. Genet., NIA/ Geront. Res. Cntr., Baltimore, MD 21224

We have recently demonstrated that exposure of animals to increased ambient temperatures induces the expression of the cellular stress protein, HSP70, in several regions of the rat brain known to coordinate the neuroendocrine stress response. Areas showing selective expression included the paraventricular nucleus, dorsomedial hypothalamic nucleus, supraoptic nucleus, dentate gyrus, and medial habenula, as well as choroid plexus, cerebellum and a global expression in the epithelial cells of the cerebral microvasculature. In order to delineate the neural mechanisms responsible for this site-selective HSP70 mRNA expression following heat-stress, adrenalectomized (ADX) and control rats given either saline or pentobarbital injections were exposed to an ambient temperature of 40°C for 90 min and subsequently processed for in situ hybridization. Adrenalectomy did not alter the ability of unanesthetized rats to thermoregulate in response to heat-stress. HSP70 mRNA expression in unanesthetized ADX and Control rats was restricted to the paraventricular nucleus, choroid plexus, cerebellum and microvasculature. Pentobarbital injections resulted in a reduced ability of both ADX and Control rats to thermoregulate as evidenced by a rapid rise in colonic temperature (Tc) that continued throughout the duration of exposure. The increased Tc attained by anesthetized control rats resulted in the addition of the dentate gyrus, medial habenula, and dorsomedial hypothalamus to areas showing heat-induced HSP70 mRNA expression. However in ADX rats these additional areas were not recruited. The blunting of thermoregulatory mechanisms by pentobarbital and the removal of endocrine factors by adrenalectomy greatly affects which brain regions display HSP70 mRNA expression in response to heat-stress.

GENE STRUCTURE AND FUNCTION III

278.1

THE GENOMIC ORGANIZATION OF HUMAN MAO B GENE.

Joseph Grimsby, Kevin Chen, Nancy Lan and Jean C. Shih. Div. Biol.
Sci., Sch. of Pharm., Univ. of South. California, L.A. Calif. 90033

Monoamine oxidase A and B (MAO A and B) play an important role in oxidative deamination of neuroactive and xenobiotics amines including the parkinsonism-producing neurotoxin MPTP. These two forms of the enzyme are defined by their substrate and inhibitor specificities. The deduced amino acid sequences from the previously cloned human liver MAO A and B cDNAs share 70% identity and they may be derived from separate genes (PNAS, 85, 4934-38, 1988). This report describes the genomic organization of human MAO B gene. Subfragments of human MAOBcDNA were ³²P-labeled to screen a partial digested human multiple X chromosome library. The complete MAO B gene, contained in 7 overlapping & clones, has 15 exons and 14 introns spanning larger than 40 Kb. Positive Hind III or EcoR1 genomic fragments were subcloned into pUC 19 and extensively mapped. Conveniently sized positive fragments were then subcloned into M13 and sequenced. The exon-intron organization, the structural significance of the exon boundaries, and the functions of protein domain encoded by individual exons will be discussed. (Supported by NIMH grants R37 MH39085 (Merit Award), K05 MH00796 (Research Scientist Award), and Welin professorship).

278.2

THE ROLE OF CYSTEINE RESIDUES IN MAO B CATALYTIC ACTIVITY. H.F. Wu, K.Cher, N. Lan and J.C. Shih. Divi. Biol. Sci., Sch.of Pharm., Univ. of Southern Calif., L.A., Calif. 90033

We and others have shown previously that sulfhydryl reagents like N-ethylmaleimide, iodoacetamide and 5,5'-dithiobis (2-nitrobenzoic acid) (DTNB) inhibited purified bovine MAO B activity. These results suggested that cysteine residues may be important to MAO B catalytic activity. The deduced amino acid sequence from human liver cDNA encoding MAO B showed that there are 9 cysteine residues in MAO B (PNAS,85,4934,1988). We report here the role of each cysteine studied by site-directed mutagenesis. We altered each cysteine by oligonucleotide-directed mutagenesis. Each mutagenic clone was sequenced then cloned into an expression vector, pECE. Highefficiency CaPO₄ precipitation transient transfection was performed. The amount of MAO B mutants transfected was determined by Western blotting, and the catalytic activity was determined by radioassay using ¹⁴C-phenylethylamine as substrate. Our results indicate that some mutants exhibited no activity, some with partial activity, and some with full activity when compared with the controls. The role of each cysteine residue in MAO B catalytic acitivity will be discussed (Supported by NIMH grants R37 MH 39085 (merit award) and KO5 MH00796 (research scientist award); and Welin professorship).

278.3

ISOLATION OF SEQUENCES AT OR NEAR THE 5' ENDS OF THE HUMAN MAO A AND B GENES. R. M. Denney, Sanat Dave* and Abha Sharma*. Dept. of Human Biological Chemistry and Genetics, University of Texas Medical Branch, Galveston, TX 77550.

Monoamine oxidases (MAO) A and B oxidize catechola-

Monoamine oxidases (MAO) A and B oxidize catecholamine and indoleamine neurotransmitters and are encoded by X-linked genes in man. We screened a human X chromosome-enriched, genomic library with synthetic oligonucleotides representing the most 5', untranslated 48 nucleotides of the human MAO A and B cDNAs (Bach et al. PNAS 85:4934, 1988). For comparison, protein coding sequences start at nucleotides 75 and 78 of the MAO A and B cDNAs, respectively. Both the MAO A 5' 48-mer and a cDNA fragment (nucleotides 96-552, protein-coding sequence) hybridize to a .67 kb Hae II-Pst I fragment from the 16 kb putative MAO A clone, which therefore may encode some or all the 5'-untranslated region and the first protein-coding exon of MAO A cDNA. The MAO B 5' 48-mer hybridizes to a small Hae II fragment (ca. 200 bp) within the putative, 15 kb MAO B clone. Proximity of a Hae II site to the 48-mer hybridizing region of the MAO B clone is interesting, since MAO B cDNAs (Bach et al. 1988; our laboratory) have a Hae II site 28 bp downstream from the 48-mer. Sequencing and transfections with appropriate reporter constructs are needed to test whether these putative 5' MAO A and B genomic fragments contain promoters and cis controlling elements involved in cell type-specific expression of MAO A and B. [Supported by NS 19543.]

278.4

ISOLATION AND CHARACTERIZATION OF A PARTIAL cDNA FOR A PLASMA MEMBRANE CALCIUM-ATPASE FROM EXCITABLE TISSUES.

P. Brandt, T.C. Vanaman*, R.L. Neve. Dept. of Psychobiology, Univ. of California, Irvine, CA 9217 and Dept. of Biochemistry, University of Kentucky, Lexington, KY 40536.

Complementary DNA (cDNA) clones for the 3'-terminus of a unique isoform of the plasma membrane Ca²⁺-ATPase,

Complementary DNA (cDNA) clones for the 3'-terminus of a unique isoform of the plasma membrane Ca2'-ATPase, designated PMCA5, have been isolated from bovine brain and human fetal brain cDNA libraries. The deduced protein sequences contain putative calmodulin-binding and transmembrane domains, as well as a potential recognition site for N-glycosylation. The transmembrane domains were similar in structure to those of the sarcoplasmic reticulum Ca2'-ATPase which are thought to be involved in high affinity Ca2'-binding and transport. Examination of a gene fragment corresponding to this region of human PMCA5 showed that an intron separates the proposed regulatory domain from the calmodulin-binding domain. The mRNA for the PMCA5 isoform was localized in excitable tissues by polymerase chain reaction amplification of cDNA synthesized from tissue-specific RNAs. Further examination of the tissue distribution of other plasma membrane Ca2'-ATPase isoform mRNAs by this method showed that PMCA1 was localized exclusively in tissues of the central nervous system. PMCA2 mRNA was localized in these tissues as well as in liver and skeletal muscle. Analysis of the tissue distribution and developmental expression of additional Ca2'-ATPase isoforms is in progress.

ISOLATION AND CHARACTERIZATION OF TWO NOVEL PITUITARY cDNAS HOMOLOGOUS TO KEX2 AND FURIN: CANDIDATES ENCODING cDNAS HOMOLOGOUS TO KEX2 AND FURIN: CANDIDATES ENCODING PROHORMONE PROCESSING PROTEINASES. L. Gaspar, P. Mion*, M. Marcinkiewicz*, M. Mbikay*, M. Chrétien and N.G. Seidah*. J.A. DeSève Labs of Molecular and Biochemical Neuroendocrinology, Clinical Research Institute of Montreal, Montreal, Que. H2W 1R7

In neuroendocrine cells specific converting enzymes are

responsible for the processing of prohormones. One of such candidates, the yeast KEX2, has been characterized at the molecular level. More recently, human furin was shown to be a possible mammalian counterpart to KEX2. We applied the technique of PCR to mouse pituitary cDNAs using oligonucleotide primers designed according to the well conserved active sites of subtilisins Ser* and Asn* found in human furin. Two distinct but similar cDNA sequences (mPCl and mPC2) were isolated and completely characterized from a mouse pituitary cDNA library. The sequences showed ≥ 50% homology to KEX2 and human furin. Northern blot hybridization revealed mRNAs 3.0 and 2.8 kbp in sizes, respectively. By in situ hybridization and Northerns mPCl was found mostly in pituitary, adrenals, hypothalamus and brain as well as in AtT20 pituitary tumor cell line. mPC2 transcripts are abundant in pituitary, brain, GH3 tumor cells and pancreatic beta-T3 tumor cells but relatively much rarer in AtT20 cells. The hybridization signals were absent from cells which normally do not process polypeptide prohormones.

278.7

STRUCTURAL ORGANIZATION AND SEQUENCE OF THE HUMAN CILIARY NEUROTROPHIC FACTOR GENE. B.Cordell, A.Lam*, F.Fuller, NEUGUROPHIC FACIOR GENE. B. Cordell, A. Lam*, F. Fuller, J. Miller*, S. Varon*, and M. Manthorpe*, California Biotechnology Inc. 2450 Bayshore Pkwy, Mountain View, CA 94043; Dept. Biology, UCSD, La Jolla, CA 92093.

Ciliary Neurotrophic Factor (CNTF) is a potent

polypeptide hormone whose actions appear to be restricted to the nervous system where it promotes survival, neurotransmitter synthesis and neurite outgrowth in responsive neuronal populations. Recently cDNAs encoding rat and rabbit CNTF have been described (Stockli, K.A., et al, Nature, 342:920, 1989; Lin, L.F.H., et al, Science, 246:1023, 1989). We have cloned the gene encoding human CNTF which appears to be a unique copy gene with a simple genetic organization - the coding domain is interrupted by only a single intron. The chromosomal localization of the human CNTF gene has also been determined. The CNTF protein has been well conserved in evolution with amino acid sequences of rat and rabbit sciatic nerve CNTFs displaying ~85% homology to the inferred amino acid sequence for human CNTF.

278.9

SEQUENCE AND EXPRESSION OF THE RAT MELANIN CONCENTRATING HORMONE (MCH) GENE. Robert C. Thompson, Sharon Burke*, Huda Akil and Stanley I. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720 Melanin concentrating hormone (MCH) is a neuropeptide first identified in the salmon where it appears to be involved in the regulation of body color. Additionally, this peptide has been suggested to play a role in the hypothalamic-pituitary axis. The amino acid sequence (Kawauchi, et al. 1983) of this peptide was confirmed through the cloning and sequencing of cDNA clones from this species which contains two MCH encoding mRNAs (Ono, et al. 1988 and Minth, et al. 1989). Recently, the mammalian MCH peptide has been isolated, sequenced (Vaughan, et al. 1989) and the protein precursor deduced from isolated cDNA clones in the rat (Nahon, et al. 1989). This work suggested that in addition to MCH, other peptides could be derived from this protein precursor (NEI, NGE). These same authors have described the anatomical localization of MCH- and NEI-like immunoreactivity in the lateral hypothalamic region (Nahon, et al. 1989). Our laboratory has also been interested in this lateral hypothalamic region and thus MCH-precursor derived neuropeptides. To further our understanding of this neuropeptide and its relationship to both magnocellular components as well as other peptide-regulators of pituitary functions, we isolated rat hypothalamic cDNA clones and used these clones as hybridization probes to isolate the rat MCH gene. We report here the complete nucleotide sequence of the rat MCH gene and examine the central nervous system expression by Northern blot and in situ hybridization analysis. This work supported by NIMH Fellowship MH09904-01 to R.C.T. and NIMH MH422251-04 to S.J.W. and H.A..

PRELIMINARY CHARACTERIZATION OF THE HUMAN THYMOSIN BETA 10 GENE AND ITS EXPRESSION IN THE DEVELOPING HUMAN BRAIN. Michael R. Condon 1, Thomas W. Lysz Joseph J. Seebode and Alan K Hall. *1 Urology Research Laboratory and 2 Department of Surgery, UMDNJ, Newark, N.J., 07103 U.S.A.

Two overlapping cDNA's of the human thymosin beta 10 (B10) gene were used to investigate its genomic structure, and expression in the developing human brain. Restriction mapping, revealed a pattern consistent with multiple genes and/or introns. However, using the gene specific 3' non-translated (NT) region of the human cDNA a single Eco RI fragment of approximately 10 kilobase (Kb) was observed, suggesting the B10 gene may be composed of a single exon. Previous studies by us, have shown the B10 peptide isolated from fetal and adult human brain tissues is subject to developmental regulation. Hybridization analysis of total RNA from human fetal and adult brain tissues with the 3' NT cDNA fragment, Hybridization analysis of total kwa from numan letar and adult brain tissues with the 3' NT cDNA fragment, detected a mRNA species of approximately 600 nucleotides, with the highest levels of expression occurring in the fetal brain and declining to near occurring in the retail brain and declining to hear undetectable levels in the adult brain tissue. Present studies are aimed at the isolation and identification of the promoter/enhancer region of the human BlO gene. (Supported by NIH/NCI grant CA49422-01 to A.K. Hall)

ISOLATION AND CHARACTERIZATION OF THE MOUSE CORTICOTROPIN-RELEASING HORMONE GENE. A.F. Seasholtz, F. Bourbonais*, T. Saunders*, S. Keller*, and S.A. Camper*. Mental Health Research Institute and Dept. of Human Genetics, University of Michigan, Ann Arbor, MI 48109

The mouse corticotropin-releasing hormone (CRH) gene has been

isolated from a mouse Balb/c liver genomic library and characterized by DNA sequence analysis. The gene exhibits a structural organization similar to that of the human, rat and ovine CRH genes. The mouse CRH peptide exhibits 100% conservation to the rat and human CRH peptides at the amino acid level, with only 3 nucleotide changes from the rat sequence in the peptide-encoding region.

Additionally, the mouse CRH gene displays extensive nucleic acid homology to the rat CRH gene in the 5' flanking sequence.

homology to the rat CRH gene in the 5' flanking sequence. The sequence information from the mouse CRH gene is being used to localize transcriptional control elements. Central to these studies is the use of transgenic mice for the identification of tissue-specific DNA elements in the rat CRH gene. The information gained from the mouse CRH gene sequence allows the production of specific probes which can discriminate the endogenous mouse CRH gene and mRNA from the mRNA produced from the injected rat CRH gene or rat

CRH-reporter gene constructs.

ANTI-CYTOCHROME AN IMMUNOREACTIVE PROTEIN AND ITS CDNA IN RAT BRAIN. S.A. Signs, M.D. Schechter and J.P. Hardwick, Depts. of Pharmacology and Biochemistry, Northeastern Ohio Univ. College of Medicine, Rootstown, Ohio 44272

Antibody raised against rat hepatic lauric acid ω -hydroxylase (cytochrome P-450_{LA(α}) was used to screen a λ gtll expression library constructed from Sprague-Dawley rat brain mRNA. Immunoreactive fusion proteins were identified using alkaline phosphatase-conjugated goat anti-rabbit ${\tt IgG}$ using alkaline phosphatase-conjugated goat anti-rabbit IgG and upon plaque purification, seven recombinant cDNA clones were isolated all of which cross-hybridized with the largest cDNA of the group; a cDNA insert of 3200 basepairs (ω -9). $^{32}\text{P-labeled}$ ω -9 cDNA hybridized with a single mRNA of approximately 4000 bases on a Northern analysis of total RNA isolated from whole rat brain as well as from dissected striatum, hippocampus and cerebellum. Anti-cytochrome P-450_{LA(I)} antibody was also used for Western analysis of rat brain subcellular protein fractions. SDS-PAGE resolved a prominent immunoreactive protein ($M_{\rm r}$ -55,000)in rat brain synaptosomes, mitochondria, and plasma membranes (less abundant), but absent from microsomes. Synaptosomal preparations from rats treated for 4 days with chlofibric acid (100 mg/kg/day) or ethanol (12g/kg/day) exhibited increased immunoreactivity to anti-cytochrome P-450_{LA(j)}. Studies are ongoing to examine the role of this gene and its protein in central nervous system eicosanoid metabolism

CLONING AND PARTIAL CHARACTERIZATION OF A PUTATIVE cDNA ENCODING HUMAN BRAIN SEPIAPTERIN REDUCTASE (SR).

R.A. Levine^{1,2}, 1. Solus³, S. Goustin³, S. Tait¹, S.K. Demetriou¹, B. Citron⁴, and S. Kaufman⁴. ¹Laboratory of Molecular Neurobiology, Lafayette Clinic and ²Department of Psychiatry, Wayne State University, Detroit, MI, ³Center for Molecular Biology, Wayne State University; and ⁴Laboratory of Neurochemistry, National Institutes of Mental Health, Bethesda, MD.

Sepiapterin reductase catalyzes the final reaction in the synthesis of tetrahydrobiopterin (BH₄), the essential cofactor for tyrosine and tryptophan hydroxylase. Cloning of sepiapterin reductase and other BH₄-related genes will assist in studying the coordinate regulation of BH₄ and biogenic amine synthesis. Anti-SR serum was used to isolate a positive clone upon screening a lambda ZAPII rat liver cDNA library. Eco RI digestion of the insert yielded 2 bands (.67 and .48 kb). The P-32 labelled 0.67 kb rat cDNA fragment was used to screen a lambda ZAP human frontal cortex cDNA library. Following screening of 300,000 clones (40% formamide, 42°C), one positive clone was identified on duplicate filters and remained positive upon rescreening. Following plasmid isolation and Eco RI digestion, the excised inserts were 1.67 kb on agarose minigels. A southern blot of insert DNA was then probed with the P-32 labelled .48 kb Eco RI fragment of the rat SR-cDNA, which also hybridized with the excised insert, thus helping validate the authenticity of the putative human SR-cDNA. The size of 1.67 kb for the putative SR-cDNA (1.2 kb), based on rat SR-cDNA sequence information and the molecular weight of rat sepiapterin reductase. Thus, we may have obtained the full-length human SR-cDNA. This will be determined through sequencing the insert, which is currently underway.

278.13

CLONING AND ANALYSIS OF THE PSEUDOGENE FOR HUMAN EPINEPH-RINE SYNTHESIZING ENZYME, PHENYLETHANOLAMINE N-METHYLTRAN-SFERASE(PNMT). Y.H. Suh, I.S. Park*, W. Choi*, J.I. Woo* and C. W. Park*. Dept. of Pharmacol., Seoul Nat. Univ. College of Med., Seoul 110-460, Korea

A intronless pseudogene for human phenylethanolamine N-methyl transferase(PNMT), terminal enzyme catalysing the final step in the catecholamine biosynthetic pathway, was isolated from a human recombinant DNA library by hybridization with a bovine cDNA probe and characterized in detail. This gene has five distinct sequence characteristics found in processed pseudogene. First, this gene lacks completely the intervening sequences. Second, this gene is truncated at the 5' end peptide encoding region by 435 base pairs. Third, the 502 base pairs of this gene containing poly(A) singnal are completely identical to the 3' half of mRNA encoding region of functional gene. Fourth, this has a poly(A) tail. Fifth, this gene is flanked by direct repeat of 6 base pairs. Here we report the complete sequence of a human pseudogene for phenylethanolamine N-methyltransferase and this is the first report of cloning of pseudogene for catecholamine biosynthetic enzymes.

278.12

ISOLATION OF G-PROTEIN COUPLED RECEPTOR cDNAs FROM LOCUS COERULEUS BY PCR. J. M. Rimland, E. J. Nestler and R. S. Duman Laboratory of Molecular Psychiatry, Depts of Psychiatry and Pharmacology, Yale Univ. Sch. Med., New Haven, CT 06508.

We are interested in isolating and characterizing cDNA clones for a number of G-protein coupled receptors enriched in the locus coeruleus (LC), particularly the VIP, CRF, μ-opiate and GABA-B receptors. The approach we used was the *in vitro* amplification, by the polymerase chain reaction (PCR), of cDNA derived from bovine LC mRNA. Two degenerate oligonucleotide primers, containing the consensus nucleotide sequences for conserved amino acids in transmembrane regions III and VI of the G-protein coupled receptor family were used to selectively amplify such receptors. The amplified cDNAs were bluntend cloned into pBluescript to create a PCR cDNA library. Various clones were screened for inserts using PCR and four clones were chosen for further study. Partial DNA sequencing revealed that all four clones had predicted amino acid sequences with some degree of homology to other members of the G-protein coupled receptor family. PCR clone 3 is 92% similar to the human β₂-adrenergic receptor and thus is considered to be the bovine equivalent of this β-adrenergic receptor subtype. PCR clones 1, 2, and 9 have 42-65% homology and similar hydrophobicity plots to other members of the G-protein coupled receptor superfamily, making them candidates for novel receptors. We are currently screening a LC cDNA library to obtain the complete coding sequence of each clone. The full length clones will then be expressed so that the nature of their receptor binding and functional properties can be determined. (Supported by USPHS grant MH45481)

NEUROGLIA AND MYBLIN II

279.1

ELECTROPHYSIOLOGICAL AND NEUROCHEMICAL RESPONSES OF THE FASCIA DENTATA TO MICRODIALYSIS WITH HIGH K*: ROLE OF GLIA. J.C.Szerb. Dept.of Physiol.& Biophys., Dalhousie U. Halifax, N.S.B3H 4H7.

Transmitter release is often evoked in vivo by microdialysis with high K⁺. To see the effects of high K⁺, maximal extracellular EPSP in the fascia dentata due to 0.1 Hz angular bundle stimulation was established in anesthetized rats. The tip of a 3 mm BAS microdialysis probe was lowered 1.5 mm below and 1.5 mm caudal to the recording electrode. Perfusion (3.4 \(\mu I / \mu in \)) with 25 mM KCl reduced glutamine (GLN) release without changing that of glutamate (GLU) or the EPSP. In about half of the experiments with 50 mM KCl several large (40.60 mV) spreading depression-like waves (SDW) appeared while EPSP-s nearly disappeared. GLU release was increased about three fold, whether SDW-s were present or not. 100 mM K⁺ regularly induced 6.8 SDW-s during 30 min and about 8 fold increase in GLU release. Perfusion with 20 mM fluoroacetate (FAA), an inhibitor of glial Krebs cycle, reduced the spontaneous release of GLN and GLU and SDW-s appeared even with 25 mM K⁺, accompanied by a suppression of EPSP-s. Results suggest increased release of transmitters, evoked by perfusion with 50 or 100 mM KCl, is accompanied by spreading depression and inhibition of electrical activity. The effects of lower conc. of K⁺ are limited by the activity of glia. (Supported by the MRC of Canada).

279.2

PURIFICATION OF A MEMBRANE-ASSOCIATED PROTEIN MITOGENIC FOR SCHWANN CELLS. M. Nordlund. X. Fei, D. Hong and N. Ratner. Department of Anatomy and Cell Biology, Univ. of Cincinnati Col. Med., Cincinnati, OH 45267.

Neuronal membranes contain a heparin binding mitogen for Schwann cells (Ratner, N., PNAS 85:6992-6996). We have partially purified this mitogen from fetal cow brain membranes by heparin affinity chromatography, carboxymethyl ion exchange chromatography and elution from non-denaturing 12% polyacrylamide SDS gels. The mitogen has an apparent molecular weight of 50,000 daltons.

Mitogen eluted from polyacrylamide gels retains its ability to stimulate proliferation of cultured rat Schwann cells, but is not mitogenic for NR6-3T3 cells, which respond to the heparin-binding mitogens acidic and basic FGF. These data confirm that the neuron-derived growth factor (NDGF) is distinct from acidic and basic FGF.

Partial characterization of NDGF has revealed that 1) NDGF activity is abolished following reduction by 2-mercaptoethanol 2) NDGF activity is also extremely sensitive to exposure to pH<6 and >8 3) NDGF activity can be stabilized by low levels of the detergent Tween-20 during purification. These characteristics, together with our ability to purify large quantities of mitogen from bovine CNS, should facilitate purification of NDGF to homogeneity.

Supported by the National Multiple Sclerosis Society.

MICROGLIA ORIGIN: NEW INSIGHTS WITH VAULT IMMUNOFLUORESCENCE. D. C. Chugani, N. L. Kedersha* and L. H. Rome. * UCLA School of Medicine, Los Angeles, CA 90024.

The developmental appearance of microglia in rat brain has been examined by immunofluorescent localization of vaults, recently described ribonucleoprotein particles (Kedersha and Rome, 1986). In brain, vault antiserum is highly specific for both ameboid and ramified microglia. The developmental profile of vault immunoreactivity (IR) in rat brain slices suggests that microglia enter the brain by 2 routes with different time scales for each. The first migration, which begins before embryonic day 15 and subsides between postnatal days 7 and 14, was identified by vault-IR and Bandeiraea simplicifolia B4-isolectin. Cells appear to enter from blood vessels and display a ramified morphology as soon as they are detected in brain. The second microglial migration occurs in the first postnatal week when ameboid microglia appear in large fiber tracts. Ameboid microglia appear to differentiate into ramified microglia between postnatal days 4 and 14. Vault IR, as a very early microglial marker, provides new insight regarding the much debated origin of the ramified microglia. It is quite clear that ameboid cells can be detected before the influx of ameboid microglia. Colocalization studies with monocyte/macrophage markers ED1 and OX42 show that both ramified and ameboid microglia originate from monocyte lineage. DEGRADATION PRODUCTS OF MYELIN PROTEINS IN A CNS SUBCELLULAR FRACTION. <u>H. Persson</u>. Dept. of Anatomy, Section of Neuroanatomy. University of Göteborg, Box 33031, S-400 33 Göteborg, Sweden.

The fraction floating on 0.32 M sucrose when normal mammalian spinal cord homogenate after discontinuous density gradient centrifugation is highly enriched in Marchi-positive material. *In situ* this material is located along paranodal myelin sheath segments. We show here by immunoblotting that a 26 kDal degradation product of the myelin oligodendrocyte glycoprotein (MOG) is present in the Marchi-positive floating fraction which is not found in the myelin fraction. Also a monoclonal antibody, FD1, has been produced which in myelin binds to a protein of a MW of 40-41 kDalton and in the floating fraction to an additional band with a MW of 25 kDal. This protein is absent from other membrane fractions in the CNS. Immunohistochemistry showed that this antibody bound preferrably to paranodal regions of myelin sheaths and cells identified as oligodendrocytes by a monoclonal antibody against galactocerebroside (kindly provided by Dr. Barbara Ranscht). Previous biochemical analyses of the floating fraction have demonstrated a gross composition closely resembling myelin and the presence of degradation products of MAG (myelin-associated glycoprotein) and CNP (2',3' cyclic nucleotide 3'-phosphodi-esterase) has been established in earlier studies (Persson, H., and Corneliuson, O., Neurochem. Res. 12:1177, 1989). These data in conjunction with metabolic studies showing the specific activity of incorporated amino acids to proceed with time from heavier to lighter myelin subfractions (Smith, M.E., and Benjamins, J.A. Model systems for study of perturbations of myelin metabolism. In Morell, P. (ed.), Myelin, Plenum Press, New York 1984, pp. 441-487) strongly suggest that normally occurring Marchi-positive bodies represents an intermediate stage in myelin catabolism.

ALTERED REGULATION OF TRANSCRIPTION OF MYELIN GENES IN THE SHIVERER MUTANT MOUSE. A. Roach and M. Wiktorowicz, Samuel Lunenfeld Research Institute of Mount Sinai Hospital, Toronto, Canada M5G 1X5.

The shiverer mutation consists of a deletion of the 3' end of the myelin basic protein gene, which completely prevents production of mature mRNA and protein, and results in severe dysmyelination and a trembling behaviour. We have used the transcription run-on technique to measure the MBP transcription rate in brains from mice of wild-type and homozygous shiverer genotypes at several ages spanning postnatal development. In wild-type brains a major factor in the developmental regulation of MBP expression is the control of transcription rate. In shiverer brains, the transcription rates for the undeleted 5' end of the gene follow closely those seen in wild-type animals up to the age at which maximal myelination normally occurs. Total MBP transcripts follow a similar profile but at less than 5% the level seen in wild-type, and, as expected, no mature mRNA is detected. Thus the shiverer deletion does not remove information required for efficient, developmentally-regulated transcription, and the low level of MBP transcripts must be a result of their reduced stability. A 2-3 fold higher than normal MBP transcription rate in older shiverer animals suggests the possibility of a feedback mechanism which might normally down-regulate gene expression in response to accumulation of mature myelin.

HIGH MOLECULAR WEIGHT POLYPEPTIDES RELATED TO GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP), ISOLATED FROM MAMMALIAN SPINAL CORD. G. Shaw and J. Hawkins. Department of Neuroscience, JHM Health Center Box J-244 Gainesville FL 32610. USA.

Hawkins. Department of Neuroscience, JHM Health Center Box J-244, Gainesville Fl 32610, USA.

A group of proteins of apparent molecular weight around 140kDa have been identified in cytoskeletal preparations of spinal cords from several different mammalian species. These proteins are recognized by several antibodies to distinct epitopes on GFAP and by anti-IFA, a pan specific antibody to intermediate filament subunits, but are not reactive with antibodies to neurofilament subunits or vimentin. The proteins coelute with GFAP in ion-exchange chromatography, cosediment with GFAP under polymerization conditions and have an amino acid profile close to that of pure GFAP. They produce very similar chemical digests to that obtained with GFAP. They are unaffected by disulphide reducing agents and are also found in material prepared rapidly in the presence of transglutaminase inhibitors. The simplest explanation for their origin is that they are formed by in vivo covalent multimerization of GFAP protein, possibly under the activity of endogenous transglutaminases.

THREE-DIMENSIONAL FINE STRUCTURE OF CYTOSKELETAL-MEMBRANE INTERACTIONS AT THE NODE OF RANVIER. <u>Takao</u> Ichimura & Mark H. Ellisman. Department of Neurosciences, Laboratory for

Neurocytol., University of California San Diego, La Jolla, California, 92093
Descriptions of the ultrastructural morphology of the nodal and paranodal regions of the node of Ranvier have been based mainly on images obtained with conventional freeze-fracture EM techniques. It has been established that the myelinating cells form intimate associations with the axon at the paranodal and nodal regions with characteristic intramembrane particles. Some of the particles in the nodal regions with characteristic intramembrane particles. Some of the particles in the nodal region are thought to be correlates of voltage sensitive Na+ channels while those of the paranodal "glial axonal junction" (GAJ) are suspected correlates for K+ channels. In order to learn more about the structure of PNS and CNS nodes in these regions we have applied two EM imaging techniques, deep-etch rotary shadowing and selective staining. The images obtained have yielded additional information about the 3-D fine structure in three important areas: 1) beneath the nodal membrane where the axoplasmic cytoskeleton associates with the nodal axolemma; 2) extracellular to the nodal region, where structures link the Schwann cell microvilli or astrocyte processes with the nodal axolemma; and 3) at the GAJ where there are characteristic associations observed between axoplasmic intermediate filaments and the paranodal axolemma. Here there are also systematic connections with the myelinating cell via cytoskeletal and membrane specializations within the myelinating glia. These intricate connections, which effectively cross the GAJ, are the most complex and appear to involve many interlinked components. For example, spectrin-like microfilaments, and axoplasmic intermediate filaments appear anchored to the axolemma by filaments of approximately 4mn in diameter. In the most revealing images these filamentous structures are seen to form a continuum connecting paranodal intramembrane particles to cytoskeletons on both sides of the junctional complex. The paranodal lo

DISTRIBUTION OF MYELIN PATCHES IN THE MOSAIC OPTIC NERVES OF THE MYELIN DEFICIENT RAT HETEROZYGOTE. <u>I.D. Duncan. J. P. Hammang. K.F. Jackson.</u> <u>D. Marren and C. Iida</u>, School of Veterinary Medicine, University of Wisconsin, Madison, WI.

Previous work has shown that the female carriers of the myelin deficient (md) rat trait show extensive myelin mosaicism in the optic nerve (Duncan et al. J. Neuropath. exp. Neurol. 1988, 47, 384). The present study was designed to examine the distribution of myelin patches along the optic tract and nerves from the md rat heterozygotes and relate these findings to the embryological population of the nerve with glia cell precursors.

The optic nerves and tracts from both known and putative md rat heterozygotes were dissected from chiasm to retina after the rats were perfused with aldehyde fixative. Those optic nerves which showed a gross myelination defect, being transparent or containing only "streaks" of myelin, were embedded whole, and skip-serial sections cut at 50-100µ intervals. Examination of these sections showed that patches of myelin were often discontinuous along the course of the nerve. While the majority of nerves showed this deficit along their entire length, 15 nerves had a more severe defect towards the retina. 3-0 images of certain areas showed that patches of myelin appeared to arise from a single clone. Mosaicism was also seen in the optic tracts of those rats which had severe optic nerve abnormalities. The spatial distribution of the patches might confirm the longitudinal migration of the 0-ZA progenitor cell. However, a radial migration from the embryonic optic stalk also cannot be entirely ruled out by these results. (Supported by NIH NSS3124 and NMSS RG 179).

CHARACTERIZATION OF THE MYELIN-LIKE MEMBRANES IN EARTHWORM CNS USING IMMUNOLABELLING TECHNIQUES. BEATRICE CARDONE and BETTY I. ROOTS. Dept. of Zoology, Univ. of Toronto, Toronto, Canada, M5S 1A1.

The ventral nerve cord of the earthworm Lumbricus terrestris contains three dorsal giant axons (2 lateral and I medial). These axons are ensheathed by multi-lamellar myelin-like membranes. We are exploring the relationships which exist between these membranes and true myelin. Previous studies in our laboratory have resulted in the isolation and partial characterization of these myelin-like membranes (Pereyra and Roots, <u>Neurochem. Res.</u> 13:893, 1988). In order to localize component proteins of this sheath, we have generated both polyclonal and monoclonal antibodies against two subfractions (F_1 and F_2) of the nerve cord preparation which are enriched in these myelin-like membranes. The clones were screened using Western immunoblotting for cross-reactivity to the protein bands P28, P32, P42 and P80 which are the major protein bands of the subfraction. These antibodies were then used to identify the location of cross-reactivity in frozen tissue sections of earthworm nerve cord using immunofluorescence. The localization of the antibody binding to specific membrane proteins was visualized by immunogold electron microscopy. The production of these antibodies will now allow us to investigate the phylogenetic distribution of these myelin-like membrane proteins and the relationship to the evolution of myelin.

EFFECTS OF ASTROCYTIC SWELLING ON Ca²⁺ TRANSPORT AND RELEASE OF ³H-D-ASPARTATE. E.R. O'Connor, A. Schneider, and H.K. Kimelberg. Dept. of Pharmacology/Toxicology and Div. Neurosurgery, Albany Medical College, Albany, NY 12208.

Swelling of astrocytes in hypotonic media causes regulatory volume decrease (RVD), membrane potential depolarization, and release of amino-acids. We are examining whether such swelling results in increased Ca2+ uptake. Swelling of astrocytes in hypotonic medium (removal of 50 mM NaCl) causes increased influx of $^{45}\text{Ca}^{2+}$, which is partially blocked by 1 μM Nimodipine and 1-10 μM Verapamil. This finding suggests that voltage-gated L-channels are being opened, possibly due to the swelling induced depolarization (Kimelberg and O'Connor, Glia 1:219 (1988)). In contrast, gadolinium, up to $10 \mu M$, which has been reported to block stretch-activated non-specific cation channels (SACS), did not inhibit the swelling induced increased uptake of Ca²⁺. Although cell swelling leads to increased uptake of Ca²⁺, nominally Ca²⁺ free media (20 μ M) appeared to have no effect on RVD or swelling induced ³H-D-aspartate release. Intracellular [Ca²⁺] will be measured using Fura-2 to determine (i) if Ca2+ is released from internal stores during astrocytic swelling and (ii) if events associated with astrocytic swelling are dependent on an increase in cytosolic free Ca2+. (Supported by grant NS 23750 to H.K.K.).

279.13

THE CONCEPT OF THE INTERNAL CORTICAL GLIAL LIMITING ZONE.
T.I. Mandybur and S. Guy. Dept. of Pathology and
Laboratory Medicine, Univ. of Cincinnati, Cincinnati,

OH 46267.

The concept of the cerebral cortical external glial limiting membrane (EGLM) is well established. Herewith we postulate existence of an internal glial limiting zone (IGLZ) of the cortex. GFAP stained sections of normal human (and animal) cerebral cortex with neighboring white matter exhibited a concentration of fibrous astroglial cell bodies (AB) in a zone approximately 1-2 mm underneath the lamina 6, partly involving also the deeper lamina 6.

The density of AB in this zone was approximately up to 10x greater than in the deeper white matter in a given segment of the cortex, the number of AB in this zone was roughly similar to those in the EGLM, although the density here of the AB was of much lesser degree. Curiously, such zone was not observed about the basal ganglia or other deep gray structures. One role of the IGLZ could be in providing a sealer to the cortex from the white matter by producing here a denser astrocytic fiber network.

279.10

CYTOARCHITECTURE OF SCAR FORMATION FOLLOWING KAINIC ACID INDUCED LESIONS IN RAT HIPPOCAMPUS._CM_SEVERIN, CL_BOWMAN AND JW SWANN. SCHOOL OF MEDICINE, SUNY-BUFFALO, BUFFALO, NY 14214, AND WADSWORTH CENTER, NYS DEPARTMENT OF HEALTH. ALBANY. NY 12201.

An electron microscopic and cell culture study was performed on kainic acid induced scar formation in the rat hippocampus. Following a unilateral stereotaxic injection of 4 nmols of kainic acid into the hippocampal CA3 region, the animal was allowed to survive from 1 hour to 6 months. In two different series of animals, the resultant scar tissue was then processed for either electron microscopy or cell culture. In the electron microscopic study the animals were sacrificed and perfused with a glutaraldehyde-paraformaldehyde solution. Two cores of tissue were taken from the center of the scar, sectioned and stained. Examination of serially sectioned tissue showed the scar to be composed of 6 cellular elements and numerous myelinated and unmyelinated fibers. Consistently present in the 1 hour to 6 month scars were astrocytes, endothelial cells, microglia, fibrocytes, and oligodendroglia. Neurons were present only in 1 to 3 hour lesions. Long cellular processes containing a dark cytoplasm, numerous vacuoles, and lamellar-like endings were also prominent in the scars. Examination of dissociated scar tissue in cell cultures also verified the presence of astrocytes. microglia- and fibrocyte-like cells. This investigation demonstrates a complex cellular network in the kainic acid induced lesions of the rat hippocampus

VOLTAGE-ACTIVATED K* AND CA** CHANNELS IN ACUTELY DISSOCIATED HIPPOCAMPAL ASTROCYTES. S.Duffy, F.W.Tse, D.Hochman, D.D.Fraser and B.A.MacVicar. Neurosci.Res.Group, University of Calgary, Calgary, Alberta T2N4N1.

Astrocytes in primary culture have been shown to express several voltage- and ligand-gated ion channels. We have developed a technique which permits the acute isolation of hippocampal astrocytes from mature brain. Dissociated astrocytes were identified by their morphology and by immunocytochemical staining for glial fibrillary acidic protein. Whole cell voltage clamping of astrocytes revealed two prominent voltage-activated K⁺ currents similar to the neuronal delayed rectifier and the Acurrents as well as a high threshold Ca⁺⁺ current. Experiments employing the Ca⁺⁺ sensitive dyes, indo-1 or fura-2 to measure intracellular Ca⁺⁺ revealed that these cells have a resting Ca⁺⁺ level of 100-150 nM which increased several fold in response to depolarization. This Ca⁺⁺ transient is dependent on the presence of extracellular Ca⁺⁺ and is attenuated by the Ca⁺⁺ bolcker verapamil (100-200 uM). These results indicate that astrocytes in the hippocampus normally express voltage-activated K⁺ and Ca⁺⁺ channels and that the functions of the cells in regulating the extracellular milieu might be dynamically modulated. α , β AND 5HT₂ RECEPTORS REGULATE THE UPTAKES OF GLUTAMATE, GABA AND TAURINE IN ASTROCYTES. Elisabeth Hansson, Institute of Neurobiology, University of Göteborg, P.O.Box 33 031, S-400 33 Göteborg Sweden.

From experiments using dissociated primary astroglial cultures from newborn rat cerebral cortex, stimulation of monoamine receptors (α , β and $5HT_2$) was shown to affect the kinetics of the high affinity uptake of glutamate, GABA and taurine. In the presence of the α_1 agonist phenylephrine, there was an increased

active uptake of glutamate, while β -adrenoceptor activation caused a slight inhibition of the glutamate uptake and a stimulation of the GABA and taurine uptakes. $5HT_2$ receptor stimulation caused a slight inhibition of the taurine uptake. The mechanisms behind these effects were also studied. The GABA uptake seems to be regulated by the G-protein / adenylate cyclase complex in the receptor domain. Also the K+-channel seems to be involved. The taurine uptake seems not to be regulated by the same mechanism as for GABA uptake nor did the glutamate uptake. By the expression of receptors, uptake carriers and interaction between these systems , astrocytes might supervise, control, facilitate and partly regulate synaptic transmission in many synaptic regions.

INHIBITION OF POTASSIUM UPTAKE BY CALMODULIN ANTACONISTS: A POSSIBLE ROLE OF ASTROCYTES IN EPILEPTOGENESIS. J.T. Neary. A.S. Bender, L. Baker', J. Blicharska', L.O.B. Norenberg' and M.D. Norenberg. Lab. Neuropath., Vet. Admin. Med. Ctr. and Univ. of Miami, Miami, FL 33101.

It has been suggested that a defect in K' buffering by astrocytes may contribute to epileptogenesis. In support of this, we previously reported that K' uptake was reduced in astrocyte cultures derived from genetically epilepsy prone rats, GEPRs (Soc Neurosci Abst 13:943, 1987). We also found that astrocytes from GEPRs have decreased calcium, calmodulin-dependent protein phosphorylation (Trans Amer Soc Neurochem 20:230, 1989), a mechanism which has also been linked to epileptogenesis. These findings led us to speculate that the reduction in K' uptake may be due to the decrease in calcium, calmodulin-dependent protein phosphorylation. To test this hypothesis, we investigated the effect of calmodulin antagonists on K' uptake in cultured astrocytes from normal rats. We found that W-7 and W-13 inhibited K' uptake (IC50-90 and 200uM, respectively) whereas W-12, which has a very low affinity for calmodulin, was ineffective. Calmidazolium (IC50-25uM) and trifluoperazine (IC50-55uM) also inhibited K' uptake. Since the latter drugs can also inhibit protein kinase C (PKC), we tested this possibility by down-regulating PKC with extended phorbol ester treatment. Since K' uptake was only minimally diminished, it is unlikely that these drugs are acting via PKC. These findings indicate that calmodulin antagonists potently inhibit K' uptake in astrocytes and, together with previous results, suggest that the regulation of K' uptake by calmodulin-dependent protein phosphorylation may contribute to epileptogenesis.

THE ROLE OF PHOSPHOINOSITIDE HYDROLYSIS IN VOLUME REGULATION IN ASTROCYTES. A.S. Bender, J.T.Neary, J.Blicharska*, L.O.B.Norenberg* and M.D.Norenberg. Laboratory of Neuropathology, Department of Pathology, University of Miami School of Medicine and Veterans Administration Medical Center, Miami, FL 33101.

Astrocytes, when exposed to hypotonic stress, undergo swelling with subsequent volume decrease, i.e., regulatory volume decrease (RVD). Calcium mobilization plays an important role in this phenomenon. Since phosphoinositide (PI) hydrolysis is thought to be involved in intracellular signaling via mobilization of calcium, we tested the effect of hypotonic stress on the formation of inositol phosphates (IPs) in astrocytes. Astrocytes were prelabelled with ["H]-myo-inositol, cultures were then exposed to hypotonic stress (45 mM Na*) and IPs were separated from myo-inositol by Dowx anion-exchange chromatography. A transient rise of 70-80% in the content of IPs was found at 0.5-1 min after hypotonic exposure. This was followed by a decline in the formation of IPs which paralleled RVD. We also found that agents which are known to induce receptor-mediated formation of IPs in astrocytes such as endothelin-1 (20 mM), bradykinin which paralleled RVD. We also found that agents which are known to induce receptor-mediated formation of IPs in astrocytes such as endothelin-1 (20 nM), bradykinin (15 uM) and ATP (0.5 mM) were able to accelerate RVD when added to the hypotonic medium. These findings suggest an important role of PI hydrolysis and calcium in the regulation of volume in astrocytes following hypotonic stress. CULTURED TYPE 2 ASTROGLIA EXHIBIT REGIONAL DIFFERENCES IN THEIR EXPRESSION OF NEUROTRANSMITTER RECEPTORS THAT INFLUENCE INTRACELLULAR CALCIUM LEVELS. K.D.McCarthy and V.Daye*, Department of Pharmacology, The University of North Carolina at Chapel Hill, NC 27599

Recent studies completed in this laboratory indicate that cerebral type 2 astroglia exhibit at least seven different receptor types linked to the mobilization of calcium. Experiments indicate that cerebral type 2 astroglia are heterogeneous with respect to their expression of neuroligand receptors influencing calcium levels. We have essed the ability of cerebellar and optic nerve type 2 astroglia to respond to neuroligands with elevation of calcium levels in order to further examine the question of pharmacological heterogeneity among type 2 astroglia. Type 2 stroglia were prepared from neonatal cerebral cortex, 4 day old cerebellum, and 14 day old optic nerve segments. The influence of neuroligands on calcium levels was examined using a video-based imaging system and fura-2 loaded cells. All analyzed cells were subsequently identified as type 2 astroglia through their glial fibrillary acidic protein and A2B5 immunoreactivity. A similar percentage of type 2 astroglia isolated from cerebellar and cerebral tissue responded to carbachol (>60%), 2-methyl thio ATP (2mt-ATP; > 60%), serotonin (<15%), and glutamate (<15%). Compared to cerebral type 2 astroglia, a smaller percentage of cerebellar type 2 astroglia responded to norepinephrine, histamine and bradykinin. In striking contrast to the responsiveness of cerebral and cerebellar type 2 astroglia, very few optic nerve type 2 astroglia responded to any of the neuroligands examined. 2mt-ATP appears to be the most effective for increasing calcium in these cells and to date only 5 of 32 optic nerve type 2 astroglia have been observed to respond to this agonist. Our results indicate that type 2 astroglia isolated from any given brain region are pharmacologically heterogeneous and that the set of receptors exhibited by these cells varies between brain regions.

ACTIONS OF EXTRACELLULAR ATP ON ASTROCYTES IN PRIMARY CULTURE: POTENTIAL ROLE IN REACTIVE GLIOSIS.

ACTIONS OF EXTRACELLULAR ATP ON ASTROCYTES IN PRIMARY CULTURE: POTENTIAL ROLE IN REACTIVE GLIOSIS.

M.D.Norenberg., J.T.Neary, L.Baker, J.Blicharska, and L.O.B.Norenberg.* Lab. of Neuropathol., Vet. Admin. Med. Ctr. and Univ. Miami Sch. of Medicine, Miami, FL 33101.

A number of factors have been implicated in the proliferative and hypertrophic processes which characterize reactive astrocytosis. One such factor we have been exploring is ATP, an agent that is released by injured cells following tissue destruction. Activation of F2 purinergic receptors by ATP leads to increased intracellular levels of calcium (EC50-10uM) (BBRC 157: 1410, 1988) and to the phosphorylation of a protein which co-migrates with glial fibrillary acidic protein (GFAP) (Soc Neurosci Abstr 15: 352, 1989). Since calcium appears to be involved in astroglial stellation (MacVicar BA: Brain Res 420: 175, 1989), and since the degree of GFAP phosphorylation appeared to be affected by ATP, we investigated the possibility that ATP might be a factor in triggering reactive astrocytosis. For this purpose, we used primary astrocyte cultures derived from neonatal rats. Light microscopic studies disclosed marked stellation of astrocytes after 1 hr exposure to extracellular ATP (100 uM). As measured by ELISA, GFAP content increased by 40%. Additionally, [3H]thymidine incorporation was increased 3-fold following treatment with ATP for 3 days, consistent with cellular proliferation. These findings show that extracellular ATP reproduces many of the features associated with reactive gliosis and suggest that extracellular ATP may be involved in the activation of astrocytes following CNS injury.

PRESENCE OF THE TYPE II (β) AND III (α) FORMS OF PROTEIN KINASE C IN ASTROCYTE CULTURES PREPARED FROM THE RAT NEOCORTEX. L. Rochat* and P.L. Mobley. Dept. of Pharmacology, Univ. of Texas Hlth. Sci. Cntr., San Antonio, TX 78284.

Previous studies have demonstrated the presence of protein kinase C in cultured astrocytes from rat neocortex. The present studies were conducted to determine which forms of the kinase are present in these cultures. Using monoclonal antibodies for the type I (γ) , II (β) , and III (α) forms of protein kinase C and immunocytochemical staining techniques, staining was observed with the antibodies for the type II and III forms of the enzyme but not with the antibody for the type I form. To confirm that binding was to protein kinase C, cells were subjected to 1-dimension gel electrophoresis and electroblotted to nitrocellulose. antibody overlay and peroxidase staining techniques, the antibody to the type II and III forms of the kinase were found to associate only with an M_R 80,000 band. No staining was observed with the antibody to the type I form even though this antibody reacted with western blots of protein kinase C obtained from adult rat brain. These studies suggest that astrocyte cultures obtained from the neocortex of newborn rats contain only the type II and III forms of protein kinase C. (Supported by N.I.H. grant NS25766.)

MECHANISM OF REGULATORY VOLUME DECREASE IN HUMAN ASTROCYTES. <u>S. Medrano and E. Gruenstein</u>. Dept. Mol. Gen., Biochem. and Microbiol. Univ. of Cincinnati, Cincinnati, OH 45267.

Swelling of astrocytes occurs after brain injury and stroke. Since these cells constitute 20-25% of human brain volume, their swelling is a major factor in the morbidity and mortality associated with cerebral edema Here we report the results of studies designed to elucidate the mechanisms of the regulatory volume decrease (RVD) which occurs after astrocytes are swollen by exposure to hypotonic medium. Using UC-11MG cells, a well characterized human, astrocytoma-derived line (Lomneth et. al., Brain Res. 486:95, 1989), we observed an increase in membrane permeability to both K' and Cl during RVD, consistent with a net loss of these ions. In some cell types RVD has been found to occur via activation of a stretch activated, cationic channel (SAC), which causes an influx of Ca²⁺ and membrane depolarization. In UC-11MG cells RVD was blocked by Gd³⁺, an intion. In UC-IMM cells RVD was blocked by G^{a} , an inhibitor of the SAC. Although increases in intracellular free Ca^{2+} (Ca^{2+}) were also observed, they only occurred well after the onset of RVD. Furthermore, the RVD was not affected by blocking the Ca^{2+} , increase with dm-BAPTA or removal of extracellular Ca^{2+} . These results indicate that the RVD in UC-11MG cells is due to the activation of an SAC, is independent of changes in Ca²⁺_i, and is therefore probably dependent on membrane depolarization.

PREFERRED PATHWAYS FOR ASTROCYTE MIGRATION. C. Andersson, M. Tytell, J. K. Brunso-Bechtold. Department of Neurobiology and Anatomy, Wake Forest University, Winston-Salem, NC 27103

Neurobiology and Anatomy, Wake Forest University, Winston-Salem, NC 27103

A central issue in understanding the migration of transplanted astrocytes is the question of preferred pathways guiding the migration. LM analysis has shown that the major pathways for donor astrocytes migrating into host tissue are on fiber bundles, and along blood vessels and pial surfaces (Goldberg and Bernstein, 1987). However, we have reported that donor astrocyte migration patterns in neonates change dramatically over time. At 1- wk post-injection (PI), donor astrocytes were located in cingulate and parietal cortex only, but by 3- and 5-wk PI, the cells were observed solely in corpus callosum, hippocampus and septal nucleus (Andersson et al, 1989). These results suggest that the pathways utilized for short distance migration may differ from those pathways which guide long distance migration. Therefore, we examined donor astrocyte migration in neonatal rats at 3 developmental stages: post-natal day (PND) 5 (premyelination), PND 20 (early stage myelination), and PND 35 (late stage myelination). A cell suspension of cultured type 1 astrocytes, labeled with either Fast Blue (LM) or 15 nm colloid gold beads (EM) were injected into the right parietal cortex. Preliminary LM findings correlate long distance migration of donor astrocytes primarily with myelinated fiber pathways. EM studies are underway to determine the cellular interactions between the transplanted astrocytes and host oligodendrocytes. Supported in part by NSF grant BNS-8811178 to MT, EYOS028 to JB-B.

HISTAMINE-INDUCED INTRACELLULAR CALCIUM ELEVATION IN TYPE-2 ASTROCYTES. N.Inagaki*, H.Fukui*, S.Ito*#,
A.Yamatodani and H.Wada*. Dept. Pharmacol. II, Faculty
of Med., Osaka Univ., Osaka 530, and #Osaka Bioscience
Institute, Suita 565, Japan.
In the previous study (Soc. Neurosci. Abstr. 15; 235, 1989),
we reported that histamine induced intracellular calcium

elevation in type-2 astrocytes and the calcium elevations were classified into 4 patterns, i.e.; transient, oscillatory, sustained and biphasic patterns. In this study, we further investigated the histamine-induced intracellular calcium elevation in rat type-2 astrocytes in primary culture using fura 2-based microfluorimetry. The histamine induced calcium elevations were first observed in the processes of type-2 astrocytes and calcium waves propagated to the cell soma within a few and carried waves prograted to the cent solid which a test seconds. In some cells calcium elevations were seen only in the processes. Some of the calcium elevations in the processes were oscillatory. These observations suggest that the processes are sensitive to histamine signals. The calcium elevations were blocked by H1-antagonists but not by H2-or H3-antagonists and induced by H1-agonists but not by H2-or H3-agonists. Phorbol ester inhibited the calcium elevations but pertussis toxin and voltage dependent calcium channel blockers had no effects. When extracellular calcium was omitted or La was added into extracellular medium, sustained phase of calcium signals disappeared and only transient and oscillatory patterns were observed. this suggests sustained and biphasic patterns are composed of intracellular calcium mobilization and extracellular calcium influx.

IONS CHANNELS: CHLORIDE AND OTHER CHANNELS

280.1

FAST CHLORIDE CHANNELS ARE PRESENT IN MOST DISSOCIATED RAT CEREBRAL CORTEX NEURONS. A. L. Blatz. Dept. of Physiology, UT Southwestern Medical Center, Dallas, TX 75235.

Chloride-selective channels with fast gating kinetics have been described in tissue-cultured rat skeletal muscle (Blatz and Magleby, 1985, <u>Biophys. J. 47:</u>119). Cl channels with essentially identical properties have now been observed in most acutely dissociated rat cerebral cortex neurons. Neurons were obtained with a trypsin dissociation technique. Cell-attached and inside-out configurations of the patch clamp technique were used. Single Cl channel currents were recorded mainly in inside-out patches with the extracellular solution containing 140 mM KCl and the intracellular solution containing 1000 mM KCl. The excised patch temperature was maintained at either 22 or 7 °C. Both solutions contained 1 mM EGTA and 5 mM TES buffer at pH 7.0. Under these conditions fast neuronal Cl channels exhibited the following properties that were very similar to muscle CI channels: 1) unitary conductance of 140 pS at room temperature and 75 pS at 7° C; 2) CI/K selectivity ratio of about 5-7; 3) dependence on membrane potential with the percent time open decreasing with hyperpolarization; 4) complex gating kinetics with at least two open kinetic states with similar mean lifetimes and at least six closed kinetic states with mean lifetimes ranging from tens of microseconds to several seconds; 5) presence of altered modes of kinetic activity including the "buzz" mode and an inactivated state of very long duration; 6) subconductance states with apparent unitary conductance of 2/3 times the normal level. Fast Cl channels in neurons often do not become active until several seconds to minutes following excision from the soma. Supported by NIH Grant GM39731.

280.3

IMMUNOHISTOCHEMICAL AND BIOPHYSICAL CHARACTERIZATION OF ADULT AND NEONATAL RAT DORSAL ROOT GANGLION CELLS IN MONOCULTURE. P. G. Thomas*, J. Caffrey, A.H. Cornell-Bell, J.D. Kocsis and S.G. Waxman. Dept. of Neurology, Yale Univ.Sch.Med., W.Haven V.A. Med.Cntr., New Haven, CT 06510

Enriched monocultures of rat dorsal root ganglion neurons and satellite cells were used to study physiological and immunohistochemical properties of peripheral were used to study physiological and immunonistochemical properties of peripheral GABA, receptors. L4 and L5 ganglia were digested in 1 mg/ml type II collagenase and 20 U/ml papain in HEPES-buffered physiological saline for 40 min; then triturated in Earle's MEM, 5% FBS, 1 mg/ml BSA and 1 mg/ml trypsin inhibitor with a siliconized pipet. Cells diluted into 0.75% BSA/Ca++-free saline were loaded onto a 3-6% continuous BSA gradient using a STA-PUT SP-120 sedimentation chamber at an initial rate of 10 ml/min for 5 min and brought to a final volume of 250 ml at 40 ml/min. 6 ml fractions collected following 40 min sedimentation were centrifuged (225 g x 5 min). Cells were resuspended in DMEM:F12 (1:1) + 5% FBS and plated on polyornithine/laminin-coated coverslips. Neonatal neuronal diameter distributions were multimodal, having four main peaks at 12 μ m (15%), 20 μ m (51%), 28 μ m (28%) and 40 μ m (4%) (n=510). Using patch voltage clamp methods, all cells expressed "L-type" Ca++ currents; Na+ and "T-type" Ca++ currents were small or undetectable in cells < 20 μm. Using intracellular recording techniques, cells > 20 μm displayed a prominent depolarization and conductance increase to bath-applied GABA. Fixed cells were permeabilized with 0.1% Triton X-100 (2 min) and labelled with rabbit α-GABA (30 min). Cells were incubated in biotinylated secondary (horse α-rabbit IgG) followed by avidin-FITC. Cells having diameters >20 μm preferentially labeled with α-GABA receptor antibodies. These results indicate that rat DRG cells separated by size into monocultures show distinct differences in biophysical and immunohistochemical properties. Supported by Medical Research Service., V.A. CHANGES IN GABA SENSITIVITY OF ACUTELY DISSOCIATED LARGE DORSAL ROOT GANGLION (DRG) NEURONS MAINTAINED IN CULTURE D.L. Eng. J.D. Koesis, J. Caffrey, A.H. Comell-Bell, Dept. of Neurology, Yale Univ.Sch.Med., West Haven V.A.Med.Cntr., New Haven, CT 06510

DRG neurons from L4 and L5 of adult rats were acutely dissociated and cultured for 1 to 5 days on PORN/laminin-glass coverslips in the absence of neuronotropic growth factors (DMEM:F12 (1:1), + 10% FBS and antibiotics). Large DRG neurons (40 to 60 microns) were impaled under visual control with glass microelectrodes. The cultures were continuously washed with a modified Krebs' solution. Single electrode current and voltage clamp experiments were carried out to characterize action potential, resting potential, input resistance, nward rectification, and conductance and membrane potential changes elicited by GABA or the GABA, receptor agonist muscimol. These properties were studied over time in order to determine if they could be maintained in the absence of neuronotropic growth factors such as NGF. The mean depolarization elicited by GABA on dissociated DRG neurons tested between 0 and 24 hrs was 16 mV (n=9) which is comparable to responses in intact DRG, declined to 9.4 mV (n=22) for neurons studied between 2 and 5 days. However, neurons, exhibiting reduced GABA responses, maintained similar action and resting potentials, input resistance, and a prominent inward rectification throughout the tested period. These results indicate that there is a selective reduction in GABA receptor function in isolated large DRG neurons maintained in culture. One interpretation of these data is that a trophic factor present in vivo, but absent in the culture media, maintains the expression of DRG GABA receptors. Experiments to test this hypothesis are currently underway. Supported by the Medical Reseach Service of

MOLECULAR CLONING OF A NEONATAL GLYCINE RECEPTOR FROM RAT CORTEX E.Barbosa*, S.Logan, and M.Van Der Ent*, Dept of Neurol., Johns Hopkins School of Med., Balto., MD

Glycine and γ-aminobutyric acid (GABA) are the major inhibitory neurotransmitters in the CNS of the adult rat, with GABA acting predominantly in the cortex, and glycine in the brainstem and spinal cord. cDNA cloning has established the existence of a gene super-family for neurotransmitter gated ion channel receptors. Recent studies have indicated that a developmentally regulated neonatal form of the glycine receptor exists both in the spinal cord and the cortex. By low stringency screening of a Day 1 rat cortex cDNA library using using a redundant oligo to the conserved cystein region from the published adult receptor (Betz et al., Nature, July 87), we identified a cDNA whose nucleotide sequence shows 74.6% homology to the adult glycine receptor and 57% identity to the Bovine alpha subunit of GABA. The primary structure of this clone exhibits similarities characteristic of other genes in the super-family: a putative 21 amino acid (21 a.a.) hydrophobic signal sequence, a disulfide bonded extracellular domain with two cysteine residues spaced 14 a.a. apart and the four hydrophobic transmembrane domains. Like GABA alpha subunits, low sequence conservation characterizes the extended putative intracellular loop between the M-3 and M-4 domains. Northern analysis of RNA extracted from rat cortex identified a single 3.8 kb RNA species which is most abundant at Days 1 through 10 and subsequently declines to low but detectable levels at Day 15 into adulthood indicating that it is developmentally regulated. Current studies focus on the expression in Xenopus oocytes in an effort to determine sensitivity of the channel both to glycine and its antagonist strychnine.

WHOLE-CELL AND SINGLE-CHANNEL ANALYSIS OF SWELLING-INDUCED CHLORIDE CURRENTS IN NORMAL AND CYSTIC FIBROSIS EPITHELIAL CELLS. C. K. Sole and J. J. Wine. Cystic Fibrosis Research Laboratory, Stanford University, Stanford CA 94305-2130, USA.

C. K. Sole and J. J. Wine. Cystic Fibrosis Research Laboratory, Stanford University, Stanford CA 94305-2130, USA.

Two recent reports have characterized a swelling-induced Cl⁻ current at the whole-cell level in normal epithelial cells (Worrell et al., Am J Physiol 256:C1111-9, 1989; McCann et al., Len Physiol 94:1015-36,1989). In the present study, we extend this work by identifying the single channels underlying the current, and investigate if the induction or properties of these channels are altered in cells from CF individuals. Outwardly-rectifying Cl⁻ channels in T84, sweat coil, sweat duct and tracheal epithelial cells were induced by exposure of the cells to hypotonic solutions or by perfusion in the whole-cell configuration. There was no apparent difference in the induction, single-channel or whole-cell properties between CF and normal cells. Whole-cell outward current at +100 mV, carried primarily by Cl⁻ (CsCl in the pipet), was typically 2 to 4 pA/pF in unswollen cells and 10 to 40 pA/pF in swollen cells. The underlying Cl⁻ channels were mostly open at negative voltages but inactivated above ~+50 mV. The time constant of inactivation ranged from 100 to 600 ms at +100 mV. Whole-cell currents were blocked by bath-applied DPC, NPPB and DNDS. DNDS block was voltage-dependent, with more effective inhibition of outward currents (inward Cl⁻ movement) than inward currents. Outwardly-rectifying single-channel currents (25-50 pS near 0 mV) with voltage-dependence, kinetics, selectivity, and pharmacology corresponding to the whole-cell current were recorded in cell-attached and outside-out patches. Open probability was not affected by altering the hydrostatic pressure inside the pipet. Mean open durations at voltages above 0 mV were 100 to 400 ms. In all patches studied, the maximum number of channels in the patch was observed immediately after obtaining a tight seal, and the channels typically patch was observed immediately after obtaining a tight seal, and the channels typically patch was observed infinediately after obtaining a tight seal, and the channes typically disappeared with time during the experiment. The conductance, selectivity, and pharmacological properties of these channels are very similar to those of the voltage-induced outwardly-rectifying Cl' channels thought to underlie the CF defect in airway epithelia, but induction and gating properties are, at least in part, different. c-AMP-DEPENDENT PROTEIN KINASE-MEDIATED ACTIVATION OF CHLORIDE CURRENT BY PGE1 IN JURKAT T-LYMPHOCYTES. M.A. Schumann, D. Maldonado*, and P. Gardner. Dept. of Medicine, Stanford Univ., Stanford, CA 94305.

The prostaglandins are inflammatory mediators that modulate cell secretion in the immune system. We have used tight seal-whole cell recordings to investigate the effect and mechanism by which Prostaglandin E1 affects a Cl- current in Jurkat lymphocytes. Addition of PGE1 to the bathing solution induced, within .5-1 minutes, a dose-(range 1µM-10µM) and time-dependent increase in current peak amplitude. Diphenylcarbox-ylamine, DPC, (8 x10-4M), a blocker of anion transport added to the bath, diminished the CI- current response to PGE1 (10µM). The mechanism by which PGE₁ induces an increase in Cl- current was then investigated. IBMX, a phosphodiesterase inhibitor, was found to augment the effect of PGE1 on the Cl current when added to the bath. The peak increase in amplitude attained with PGE_1 without the use of IBMX was 53.0%, SE 11.6, (n=4) after 3 minutes, compared to 101.9%, SE 14.2 (n=4) with IBMX (1x10-4M) after 1 minute. The time constant increased 2-3 times (n=4) with PGE1 and IBMX. The PGE1-induced Cl- current was inhibited with the use of Walsh inhibitor, a competitive inhibitor of cAMP protein kinase, in the pipette. The CI-current was decreased by 19.7%, SE 5.9 (n=3) with 1 μ M Walsh inhibitor. The effect of PGE₁ was also inhibited by the peptide, R_p cAMP, (1mM; n=4), a competitive analog of cAMP which antagonizes the activation of cAMP-dependent kinase. The data illustrate the increase in CI-current induced by PGE₁ on T lymphocytes and are consistent with an cAMP-dependent phosphorylation mechanism.

DEPOLARIZATION PREVENTS MAGAININ CYTOLYTIC ACTIVITY ON TUMOR CELLS. R. A. Cruciani 1. O. Colamonicci2* H.-C. Chen3* and J. L. Barker 1. 1 Lab. of Neurophysiology, NINDS, ² Endocrinology and Reproduction Research Branch, NICHD, NIH Bethesda MD 20892 and ³Dept. of Medicine, Section of Hematology/Oncology, University of Chicago, IL 60637.

The magainins are a family of antibiotic peptides recently isolated from the skin of the African Clawed frog Xenopus Laevis. Previously we reported the ability of these peptides to form cation-selective channels in artificial lipid bilayers. of these peptides to form cation-selective channels in artificial lipid bilayers. Magainins exhibit cytolytic activity against human hematopoietic and solid tumors cells studied in vitro. The viability of tumor cells was compromised at peptide concentrations that had little effect on circulating human blood cells (red blood cells, lymphocytes and neutrophils) and neural cells from different stages of embryonic development and differentiation. The IC50's of magainins G, A and B was 10-20 µg/ml, while magainins 1 and 2 were less effective. To study the effect of magainins on membrane potential we utilized a membrane potential-sensitive dye (oxonol). Changes in fluorescence signals were studied utulizing a fluorescence spectrophotometer. In order to determine the potentiometry of the fluorescence signal we incubated the cells in the presence of 200 nM gramicidin D, a Na+-K+ ion selective peptide. Gramicidin increased the fluorescence signal when the cells were incubated in Gramicidin increased the fluorescence signal when the cells were incubated in regular saline. When NaCl was replaced by 140 mM NMG-Cl the polarity of the regular saine. When NaCl was replaced by 140 mM NMG-Cl the polarity of the signal was inverted. At low, non-cytolytic concentrations magainin produced fluorescence signals comparable with non-selective cation channels. Remarkably, tumor cells remained vital, excuding trypan blue, when depolarized either by resuspension in 150 mM KCl or by 200 nM gramicdin in physiological saline and then exposed to cytolytic concentrations of the petitide. The selectivity of the ionophoric peptide for tumor cells and the protection afforded by depolarization may be related to physico-chemical differences between tumor and normal cell membranes.

ION SENSITIVE MICROELECTRODE STUDY OF CHLORIDE BALANCE IN THE SOMATIC MUSCLE BAG CELLS OF ASCARIS SUUM. H. Rheinallt Parri*, M.B.A. Djamgoz*1, L. Holden-Dye* and R.J. Walker. Dept. of Neurophysiology, University of Southampton, Southampton SO9 3TU, 1Dept. of Pure and Applied Biology, Imperial College, London SW7 2BB.

Ion sensitive microelectrodes incorporating the exchanger Corning 477813 were used to determine

exchanger Corning 477913 were used to determine intracellular chloride levels in Ascaris muscle cells. Resting membrane potential was -25 + 1 mV, free internal chloride concentration was 18 ± 0.5 mM, and Ecl -47.1 ± 0.7 mV (n=49). In other experiments the reversal potential of the GABA event was determined to be -54 ± 1 mV (n=62). Membrane potential decreased by 9 ± 1.7 mV (n=3) per 10 fold change in external chloride. Internal chloride did not fall as much as expected on exposure to low chloride solutions, and indicated an interfering ion concentration of 12.1 ± 2.4 mM. The apparent high resting conductance to chloride, and displacement of Em positive to Ecl indicates the presence of an outwardly directed cl pump in these cells.

We are grateful to the SERC for funding. exchanger Corning 477913 were used to determine

MUTANT OF <u>ESCHERICHIA COLI</u> WITH ALTERED PRESSURE AND DRUG SENSITIVITY OF THE MECHANOSENSITIVE ION CHANNEL.

MUTANT OF ESCHERICHIA COLI WITH ALTERED PRESSURE AND DRUG SENSITIVITY OF THE MECHANOSENSITIVE ION CHANNEL. C. Li, B. Martinac, C. Kunq and J. Adler. Departments of Biochemistry and Genetics and Laboratory of Molecular Biology, University of Wisconsin, Madison, WI 53706 We have studied the effect of chlorpromazine (CP2) on the pressure sensitivity of the mechanosensitive (MS) ion channel of E. coli by use of the patch-clamp recording technique. We have isolated several CP2-resistant mutants of E. coli. One of the isolates with aberrant morphology has MS channels which differ from wild-type MS channels in two ways: (i) CP2 does not affect the opening probability of the channels as it does in the wild-type extrain, and (ii) the MS channels in the mutant have reduced pressure sensitivity as compared with the wild-type channels. We do not know yet what causes the altered properties of the MS channels in the mutant strain. Parallelly to the electrophysiological studies we are characterizing the mutant by genetic approach. The localization of the mutant by gross and fine mapping is in progress. Supported by NIH grant DK39121 and by a grant from the Lucille P. Markey Trust.

THE MUTATION SLO ALTERS MEMBRANE EXCITABILITY AND CA-ACTIVATED K CURRENT IN CULTURED DROSOPHILA "GIANT" NEURONS. M. Saito and C-F. Wu, Dept. of Biology. Univ. of Iowa. Iowa City, IA 52242.

The mutation slowpoke (slo) in Drosophila is known to eliminate a Caactivated transient K current in larval and adult muscles. Consequently, the Ca action potential in slo muscle is prolonged. This phenotype is enhanced when repetitive action potentials are induced with sustained current injection which inactivates A current. It is important to ask whether slo also affects the neuronal membrane current and excitability. We have developed a "giant" neuron culture system which allows collection of both current- and voltage-clamp data from the same cells. Embryonic neuroblasts treated with cytochalasin B differentiated without cytokinesis and became multinucleated giant neurons with well-developed neurites. In wild-type giant neurons, four different types of voltage responses were observed under current-clamp: all-ornone, graded multiple-peak, graded single-peak, and "passive" responses. In slo neurons, all 4 types of responses were present. However some all-or-none action potentials showed longer duration (10 to 26 ms) than that in wild-type neurons (7 to 15 ms). In addition, slo neurons displayed irregular responses which did not fall in any of the above categories, such as variable voltage oscillations or bursts of action potentials riding on slow depolarizing fluctuations. Voltage-clamp studies showed that slo eliminates a Ca-activated current in a subset of neurons. However, the defect was not limited to the transient component of Ca-activated current, as observed in muscle, but often affected a sustained component. The differential effects of slo in nerve and muscle suggest molecular diversity of Ca-activated K channels.

K⁺ CHANNEL SUBFAMILIES HIGHLY CONSERVED IN DROSOPHILA AND MOUSE. Michael D. Pak*, Manuel Covarrubias*, Ann Ratcliffe*, Alice Butler*, and Lawrence Salkoff. Dept. Anatomy and Neurobiol., Washington Univ. Sch. Med., Box 8108, 660 S. Euclid Avenue, St. Louis, MO 63110.

We show that mouse and Drosophila Shab (mShab and fShab) represent an instance of K + channels in distantly related species that are

We show that mouse and *Drosophila Shab* (mShab and fShab) represent an instance of K⁺ channels in distantly related species that are both functionally and structurally conserved; most kinetic, voltage-sensitive, and pharmacological properties are similar for the two channels. The greatest functional difference between the currents is recovery from inactivation which is several times slower in mShab than fShab. Another interesting difference is the delay in current rise in response to depolarization, which is greater for mShab than fShab. This difference is interesting because it occurs between two channels which are structurally very similar with mostly conserved differences. mShab and fShab are, thus, naturally occurring structural variants which may prove valuable in analyzing channel kinetics in the future. In addition to conserved structure, mShab has an unusually long nonconserved region at the carboxyl end produced no noticeable change in voltage-sensitive, kinetic or pharmacological properties. Thus, the measured functional properties of mShab are determined by the remaining 564 residues, most of which are conserved. The properties of mShab closely resemble those of a native delayed-rectifier type potassium channel in hippocampal neurons. A Shal homolog from mouse brain which has very high homology to Drosophila Shal is currently being expressed. Supported by NIH 1 ROI NS24785-01, a research grant from the Muscular Dystrophy Association, and grant from Monsanto-Searle.

ESTABLISHMENT OF TRANSFORMED FIBROBLASTS WITH POTASSIUM CHANNEL GENES, NGK1 AND NGK2. T. Kawamura **.

S. Yokoyama*, I. Yamashita* # and H. Higashida.

Departments of Biophysics and *Neurosurgery, Kanazawa Univ. Sch. of Med., Kanazawa 920, Japan.

Sch of Med, Kanazawa 920, Japan.

Two types of potassium channels expressed in NG108-15 mouse neuroblastoma x rat glioma hybrid cells have been identified by molecular cloning technique (Yokoyama et al. FEBS Lett., 259: 37, 1989). NGK1 is identical with a rat brain potassium channel BK2, and NGK2 is structually related to the Drosophila Shaw gene. Both channel proteins expressed in Xenopus oocytes have properties of delayed rectifiers. We have established transformed B82 mouse fibroblast cells which stably express voltage-dependent potassium channels, NGK1 and NGK2 gene products, respectively. Each of the NGK1 and NGK2 cDNAs was ligated to the mammalian expression vector, pKNHneo, containing the SV40 early promotors and an aminoglycoside-3'-phosphotransferase gene. These recombinant pKNH-NGK1 or pKNH-NGK2 plasmids were independently introduced into B82 cells by a cationic liposomemediated transfection method and the cell lines were selected by geneticin. Northern blot analysis of total RNA from two types of isolated clones probed with the entire coding region of NGK1 or NGK2, respectively, identified proper transcripts. Electrophysiological studies in the two types of clones by whole cell voltage clamp and single channel recording technique revealed the appearance of voltage-dependent potassium channels with difference in kinetics.

281.2

MOLECULAR CHARACTERIZATION OF THE SLOWPOKE CODING REGION. G.A. Robertson, N.S. Atkinson and B. Ganetzky. Laboratory of Genetics, University of Wisconsin, Madison,WI 53706. Calcium-activated potassium channels are key elements in the

Calcium-activated potassium channels are key elements in the control of membrane excitability. The mechanisms of gating and modulation of these channels are incompletely understood, however, due to the lack of information regarding their molecular structure. Even less is known about how the expression of these or other ion channels is regulated by the genome. In *Drosophila*, a mutation in the gene slowpoke (slo¹) eliminates a specific calcium-activated potassium current in muscle and neurons (Elkins, Ganetzky and Wu, PNAS, 83:8415, 1986). We generated additional mutations to localize the gene cytogenetically and to clone DNA from the region (Atkinson, Robertson and Ganetzky, Soc.Neurosci. Abs.15:541,1989). The immediate goal of this project is to determine whether slo encodes a structural component of the calcium-activated potassium channel or a polypeptide otherwise governing its function or expression.

governing its function or expression.

We have identified several related cDNAs within the *slo* region. These cDNAs were isolated on the basis of their homology to genomic DNA that spans two genetic lesions associated with a *slo* phenotype. One cDNA was used to probe Northern blots of wild-type head mRNA and hybridizes to two transcripts of 10.5 and 5.8 kb. These transcripts are not present in head mRNA from flies carrying a *slo* mutation. We have begun sequencing this cDNA and from the deduced amino acid sequence we hope to gain insight into the structure and functional role of the *slo* gene product.

Supported by postdoctoral fellowships from the NIH (GAR) and the Muscular Dystrophy Assn (NSA) and by NIH grant NS-15390 (BG).

281.4

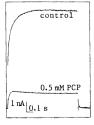

FUNCTIONAL EXPRESSION OF BOTH TRANSIENT AND DELAYED OUTWARD K' CURRENTS IN XENOPUS OOCYTES RESULTING FROM INJECTION OF A CLONED HUMAN K' CHANNEL mRNA. R.E. Hice, L. Philipson', D.J. Nelson', G. Bell', K. Schaefer', and D. Steiner', Depts, of Medicine, Biochemistry and Molecular Biology, Neurology, and the Howard Hughes Medical Institute, University of Chicago, Chicago, IL 60637.

A cDNA clone encoding a voltage dependent K' channel was isolated from a human fetal skeletal muscle cDNA library by screening at low stringency with a related human K' channel cDNA probe. The 4kb cDNA contained a 1959-base pair open reading frame. The deduced 653-amino acid protein is 95% identical to RCK4, a previously described rat cortex K' channel clone (Stühmer et al., EMBO 8:3235,1989). The two proteins are highly conserved, with most of the amino acid substitutions occurring in the N-terminal domain. Nine of the 22 substitutions (plus one deletion) are conservative. A 2.3kb segment of the cDNA containing the open reading frame was subcloned into the sP64T vector for production of in vitro transcribed RNA using SP6RNA polymerase. After microinjection of gpm amounts of sRNA into Xenopus oocytes, large outward K' currents (>10µA) could be observed by 12 hours. Outward current during depolarizing steps from holding potentials more negative than -40 mV was composed of both transient and delayed outward K' conductances. The delayed K' current could be observed in isolation by either holding at -40mV or more positive or by adding 10mM 4-AP to the external solution. The I_A is activated by -40mV with a time to peak of ca. 7 msec at 22°C. Inactivation of the I_A is largely complete at the end of 200 msec depolarizations. The delayed outward component was present even when total outward current was kept below 3µA and was present in sRNA produced from multiple independently subcloned plasmids. The presence of two distinct kinetic components in the expressed outward current indicates that variability in K' channels could be due to differential oligomeric interactions or post-translational modifications. Supported by NIH GM36823 (DIN).

281.6

POTASSIUM CURRENTS WITH DELAYED RECTIFYING PROPERTIES IN FIBROBLAST CELLS STABLY TRANSFECTED WITH A POTASSIUM CHANNEL GENE. T.R. Werkman¹, T. Kawamura*², S. Yokoyama*², H. Higashida² and M.A. Rogawski¹. Medical Neurology Branch, NINDS, NIH, Bethesda, MD 20892, and ²Kanazawa University School of Medicine, Kanazawa 920, Japan.

The pharmacological properties of a voltage-dependent K* channel were studied in a fibroblast cell line (CL1023) stably transfected with a potassium channel gene (NGK1) from the NG108-15 neuroblastoma-glioma hybrid cell line (Yokoyama et al., FEBS Lett., 259: 37, 1989; Kawamura et al., this meeting). NGK1 is identical with the rat brain K* channel protein BK2. Upon step depolarization to potentials more positive than -20 mV we recorded a large (up to several nanoamperes) outwardly directed current that slowly rose to a plateau and showed minimal time dependent inactivation. Tail current analysis revealed the outward current to be carried by K* ions. The K*

the outward current to be carried by K* ions. The K* current was relatively insensitive to tetra-ethylammonium (100 mM: ~ 50% block) but was more sensitive to 4-aminopyridine (1 mM: ~ 60% block; 3 mM: ~ 80% block) and the dissociative anesthetic phencyclidine (PCP) (50 μ M: ~ 50% block; 500 μ M: ~ 90% block; figure: depolarizing steps from -60 to +60 mV). In view of the recently described heterogeneity of voltage-dependent K* channels, non-neuronal cells expressing a single K* channel subtype provide a useful system to characterize the unique pharmacological properties of the various molecular species.

CLONING, EXPRESSION, AND MODULATION BY SEROTONIN OF A MOUSE BRAIN POTASSIUM CHANNEL. J.H.Hoger*, A.E.Walter*, D.Vance*, Lei Yu¹, C. Labarca, H.A.Lester, and N.Davidson. Divs. of Biology and of Chemistry. Caltech, Pasadena CA 91125, and Dept. Medical Genetics, Indiana School of Medicine, Indianapolis, IN 46202.

Modulation of ion channels by neurotransmitter and hormone receptors is a common mechanism for the regulation of cellular excitability. We have used $\underline{Xenopus}$ oocytes to study the modulation of a cloned ion channel by a cloned receptor. A mouse brain potassium (K) channel was cloned (MBK la) and expressed in $\underline{Xenopus}$ oocytes. The K current expressed in the oocytes displayed characteristics similar to delayed rectifier type K currents. This current underwent slow inactivation (r=5-7s) and was blocked by external tetraethyammonium (IC $_{50\mu}$ =0.4 mM). The K channel was coexpressed with a mouse brain serotonin receptor ($5HT_{1c}$) in $\underline{Xenopus}$ oocytes. Activation of the $5HT_{1c}$ receptor by 0.1µM serotonin resulted in suppression of 56% of the K current amplitude over a period of 20 min. In contrast, other cloned K or Na ion channels were not suppressed by the $5HT_{1c}$ receptor in oocytes. The K current amplitude could also be suppressed by intracellular injections of GTP- γ -S or Ca. The suppression of the K current was blocked by EGTA, confirming that the suppression requires an increase in intracellular Ca. We have found that the suppression is sensitive to the calmodulin antagonists W-7 and trifluoperizine. In addition, experiments indicated that protein kinases of type A, type C or calmodulin kinase II were not involved in the suppression of 1_k . Support: GM-29836 and 10991.

SITE-DIRECTED MUTAGENESIS OF SHAKER POTASSIUM CHANNELS. G. A. Lopez*, Y.N. Jan & L.Y. Jan. Howard Hughes Medical Institute and Departments of Physiology and Biochemistry, UCSF, San Francisco, CA. 94143

The recent cloning of several potassium channel genes has made it possible to carry out structure-function studies. The approach taken in this study is to examine the potential function served by those hydrophobic residues that are highly conserved. A comparison of the primary amino acid sequences of several potassium, sodium, and calcium channels reveals dramatic conservation in the S4 segment which is the hypothesized voltage sensor. The S4 segment consists of a repeated triplet containing a positively charged amino consists of a repeated inject containing a positively charged animo acid, usually an arginine, and two hydrophobic amino acids. It has been shown previously that charge neutralizations in S4 affect voltage dependence. We now show that conservative hydrophobic substitutions in S4 also give a similar phenotype in voltage dependence. Using site-directed mutagenesis, we have substituted each of several hydrophobic amino acids in various transmembrane segments with hydrophobic residues. Mutated channels were expressed in Xenopus oocytes and analyzed using two electrode voltage clamp. We have found that mutating certain hydrophobic residues in the S4 segment altered the position of the activation curve but not its slope. No effect was seen in channel kinetics or potassium selectivity. These results reveal that the S4 sequence as a structural entity is important in the voltage-dependent channel gating.

COMPARATIVE PHARMACOLOGY OF CLONED RAT BRAIN DELAYED RECTIFIER POTASSIUM CHANNELS. M. Taglialatela, J.A. Drewe, S. Verma, A.M. Brown, R.H. Joho and G. E. Kirscht. †Dept. of Anesthesiology and Dept. of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX 77030.

We have begun a comparative analysis of the pharmacological properties of rat brain K* channels from the drk, ngk and rck families, expressed in Xenopus oocytes. Our results show that drk1 and an ngk2-like clone are the most pharmacologically inert; they are blocked by 4-aminopyridine (4-AP) and tetraethylammonium (TEA) at millimolar concentrations, but are insensitive to peptide toxins at micromolar concentrations. By contrast rck6 (Drewe et al., this meeting) and an rck1-like clone were sensitive to dendrotoxin, noxiustoxin and mast cell degranulating peptide at nanomolar concentrations. The rck clones also showed a voltage- and frequency-dependent response to 1 mM 4-AP which resembles that observed in the squid axon and frog node of Ranvier delayed rectifiers; repetitive depolarizing test pulses to +40 mV at a frequency 1 Hz resulted in a progressive relief of block. These results provide further support for the idea that rck is a mammalian delayed rectifier homolog. SHAW, A K⁺ CHANNEL FROM DROSOPHILA, HAS UNUSUALLY LOW VOLTAGE SENSITIVITY AND POOR K⁺ SELECTIVITY. K. Baker, and L. Salkoff. Dept. Anatomy and Neurobiology, Washington U. Sch. of Med., Box 8108, 660 S. Euclid Ave. St. Louis MO. 63110.

Ave. St. Louis, MO. 63110.

The Shaw gene from Drosophila (Butler et al. Science 234) expresses a voltage-gated potassium current in Xenopus oocytes (Wei et al. Science in press). The putative gating charge region (S4) is novel because it only has 4 positive charges in an uninterrupted +00 format. In addition, 2 negative charges are found in positions occupied by positive charges in other K⁺ channels. Thus, Shaw may have a lower equivalent gating charge than other cloned K⁺ channels. This predicts that the probability of being open will change gradually over a broad voltage range. A clear 'threshold' for activation is therefore not expected. Experimental observations support these predictions. Active current is observed at -100 mV and conductance continues to increase beyond +50 mV. Thus, Shaw activates over an extremely broad voltage range (-100 mV to +50 mV) and shows no clear 'threshold'. Another anomalous property of Shaw is poor K⁺ selectivity compared with other cloned K⁺ channels. Shaw's sodium to potassium permeability ratio ($P_{NA} + P_{K} + 1$) is over 2 times larger than other cloned K⁺ channels. We are presently characterizing a site-directed mutant that alters the selectivity of Shaw. Although no in vivo role has been ascribed to Shaw it will likely be unique due to its unusual properties as compared to other K⁺ channels. Supported by NIH 1 RO1 NS24785-01, and research grants from the MDA and Monsanto-Searle.

281.10

CLONING OF RAT BRAIN POTASSIUM CHANNELS: A NEW MEMBER OF THE RCK FAMILY AND REPRESENTATIVES OF TWO NOVEL FAMILIES. J.A. Drewe, G.E. Kirscht, S. Verma, A.M.J. VanDongen, A.M. Brown and R.H. Joho, Dept. of Molecular Physiology and Biophysics and Dept. of Anesthesiology, Baylor College of Medicine, Houston, TX 77030.

Voltage-activated potassium (K*) channels in rat brain are represented by three families, rck, drk and ngk. We report here the cloning of a novel K* channel (rck6) whose amino acid homology suggests membership in the rck family, and the isolation of two additional putative K* channel clones. rck6 was isolated by hybridization to an oligonucleotide corresponding to seven amino acids (NEYFFDR) located in the amino terminus within all three families. The characteristics of the expressed K* currents is presented at this meeting (Kirsch et al.). Two additional clones were obtained via low-stringency cross-hybridization screening, utilizing nick-translated drk1. They have been sequenced in their entirety, with single open reading frames of 547 and 505 amino acids. Sequence homology within the six transmembrane core region suggests that the clones correspond to K* channels which would represent new families. However, no expression of K* currents was observed in Xenopus oocytes injected with cRNA from the latter two clones. Supported by the NIH, the Advanced Technology Program of the State of Texas and the American Heart Association (Texas Affiliate).

EXPRESSION AND CHARACTERIZATION OF A NOVEL MEMBER OF THE RCK FAMILY OF RAT BRAIN POTASSIUM CHANNELS. G.E. Kirscht, J.A. Drewe, S. Verma, A.M. Brown and R.H. Joho. †Dept. of Anesthesiology and Dept. of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX 77030.

We have cloned from rat brain a novel voltage-activated K^* channel (rck6; Drewe, et aL; this meeting) belonging to the rck family. RNA transcripts of rck6 injected into Xenopus oocytes expressed delayed rectifier K^* channels. Test pulses to +50 mV evoked K^* current (2-6 μ A) which did not inactivate in 5 s. The conductance-voltage relationship followed a Boltzmann distribution with midpoint and slope factors, -12.3 and 11.9 mV, respectively. Single channel conductance in frog Ringers was 8.2 pS. Current was blocked by 4-aminopyridine, tetraethylammonium, dendrotoxin, noxiustoxin, and mast cell degranulating peptide; but not by charybdotoxin ([CTX] < 200nM). A short amino terminus (175 residues), similar to that of other non-inactivating rcks, may be responsible for the lack of inactivation in rck6. CTX resistance may reflect differences in the extracellular domains; rck6 has longer S1-S2 and S3-S4 linkers than the other rcks. Supported by the NIH, the Advanced Technology Program of the State of Texas and the American Heart Association (Texas Affiliate).

POTASSIUM CHANNEL GENE STRUCTURE AND EXPRESSION AND AUDITORY FUNCTION IN THE DEAF WADDLER MOUSE, L.A. Adams*. P.Weisleder, N. Copeland, N. Jenkins, L. Lock, E. W Rubel, and B.L.Tempel. Depts. of Pharmacology, Medicine, and the Hearing Devel. Labs., Univ. of WA, 98195; GRECC, Seattle Veterans Admin. Med. Center, Seattle, WA, 98108; and Natl. Cancer Inst., Frederick, MD, 21701.

Potassium channels are a diverse class of membrane proteins important in controlling the activity of excitable cells. We are studying one such potassium channel gene (MK1) in the deaf waddler (dfw) mouse, a mutant strain in which the homozygotes (dfw/dfw) exhibit a wobbly gait when walking, and appear to be deaf. Brainstem electrodes were used to record auditory evoked responses to tone bursts ranging in frequency from 0.5-16 kHz, which were presented in a free field. Heterozygotes (dfw/+)had thresholds comparable to those reported in the literature for normal mice. In dfw/dfw, on the other hand, we were unable to evoke replicable responses at any frequency, even when stimuli exceeded 100 dB SPL. The confidence interval for the chromosomal locus of MK1 and the dfw mutation overlap on mouse chromosome 6. Northern blot analysis of MK1 expression in brain tissue reveals a 30-40% decrease in MK1 mRNA levels in dfw/dfw compared to their heterozygote (dfw/+) littermates. In situ hybridization studies in normal mouse brain demonstrate that MK1 is expressed in brainstem auditory and motor relay nuclei; an examination of the expression of MK1 in the dfw/dfw brain is presently underway. Genomic DNA from dfw/dfw is being examined by direct nucleotide sequencing and by Southern blot analysis of restriction fragment length polymorphisms. Supported by NIH NS 27201 and DC 00395.

REGULATION OF THE BRAIN K., POTASSIUM CHANNEL GENE IN PITUITARY CELLS. L. Hemmick, E.S. Levitan, D. Saal, J. Marshall, N. Birnberg, and L.K. Kaczmarek. Yale Univ. Sch. Med., New Haven, CT 06510.

The rat brain gene K_y, encodes a delayed rectifier K⁺ channel when expressed in frog oocytes (Swanson et al., 1990). Here we report that Northern blots indicate that a 3.5 kb polyA+ k₁-like transcript is expressed in native anterior pituitary and rat GH pituitary tumor cells. No transcript was detectable in AtT-20, PC12 or NG108 cells, suggesting that expression is cell type specific. A GH cell cDNA library was screened and a clone was isolated. Preliminary DNA sequence and RNAse protection data indicate that the GH cell gene is identical to K₁. Dexamethasone increased the K₂ transcript level ~2 fold. Thus, corticosteroids may regulate secretion, in part, by altering ion channel gene expression. Treatment of GH cells with secretagogues (TRH, gene expression. Treatment of GH cells with secretagogues (TR TPA, cAMP analogs, Bay K, high K*) failed to alter K₁ mRNA levels. Interestingly, GH cells do not have a simple delayed rectifier. Rather, their K* channels either inactivate or are Ca^{2*} sensitive. We hope to use hybrid arrest to identify the component of current that is carried by the K_{v1} channel protein and to determine its role in GH cells.

A POTASSIUM CHANNEL HOMOLOGOUS TO SHAB IS PRESENT IN THE APLYSIA NERVOUS SYSTEM.

E. A. Quattrocki, R. J. Knox, J. Marshall*, and L. K. Kaczmarek
Dept. of Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

Potassium channels, by their diversity and ability to undergo modulation underlie many of the complex changes in electrical excitability occurring in neurons. The modulation of K^+ currents has been extensively studied in *Aplysia californica*; yet, at the molecular level much remains unknown. In an effort yet, at the molecular level much remains unknown. In an effort to study the molecular basis for modulation of K⁺ currents we have isolated putative K⁺ channel clones from the *Aplysia* nervous system. Screening head ganglia libraries with a rat brain K⁺ channel, Kv1, as a probe, yielded two cDNAs of approximately 400 and 700 bases that exhibit a high degree of similarity to other K⁺ channels. These cDNAs code for a single peptide sequence that spans from the S4 region of a K⁺ channel vertex to the sequence of the spans from the S4 region of a K⁺ channel out towards the 3' end, including two other potential membrane spanning regions, S5 and S6. Comparisons with other known K⁺ channels show that this clone is most similar, approximately 80%, to the *Drosophila* K⁺ channel Shab; the membrane spanning regions being the most similar. Characteristic to Shab and Shaw, but unlike Kv1 or the other Shaker-like channels, this Aplysia clone has only five positively charged amino acids instead of seven in the S4 region, the presumed voltage sensor. Efforts now focus on obtaining the full length clone for expression studies and on investigating this putative channel's role in intact cells using antisense hybrid arrest techniques.

SENSITIVITY TO BLOCKING AGENTS OF COLUMN SENSITIVITY TO BLOCKING AGENTS OF COLUMN SENSITIVITY TO BLOCKING AGENTS OF COLUMN SENSITIVITY TO BLOCKING AGENTS OF COLUMN SENSITIVITY OF COLUMN SENSITIVE OF COLUMN Sci. Univ. Portland, OR
Clones were expressed in Xenopus occytes and membrane

currents were evoked (-80 to 0 mV) by depolarizing pulses. RBKI currents were inhibited in a dose-dependent manner by four fractions of dendrotoxin (DTX) and by the related toxin I which are derived from the venom African mamba. The order of potency was δ -DTX < toxin I α -DTX = γ -DTX < β -The order of potency was δ -DIX < toxin 1 α -DIX = γ -DIX < β -DIX (respectively IC₅₀ values in nM: < 0.03, 0.1 ± 0.02, 0.3 ± 0.02, 0.3 ± 0.3 and 5.1 ± 3). The interaction of TEA with the channel was also studied. RBK1 and the structurally homologous clones RBK2 and RGK5 have widely different sensitivities to TEA (respective Kp's: 0.3 mM, > 100 mM and 10 mM). Chimeras were constructed utilizing a conserved restriction site (Mscl) immediately N-terminal to the S4 putative transmembrane segment. The TEA sensitivity of the expressed channels could be correlated with the of the expressed channels could be correlated with the source of the C-terminal region beginning at S4. Chimeras with the RBK1 sequence in this region had $K_{\rm d}{}^{\prime}{}^{$ had RBK2 or RGK5 sequence in this region had respective K_d's of > 100 mM and in the 10-50 mM range. These data suggest that the putative extracellular loop between S5 and S6 is a critical determinant of TEA sensitivity.

IDENTIFICATION OF A DELAYED RECTIFIER K+ CHANNEL IN RABBIT SCIATIC NERVE BY CDNA CLONING TECHNIQUE. J-H Hsu*, G.K. Wang, and S-Y Wang. Dept. of Anesthesia, Harvard Med. Sch., Boston, MA 02115 and Dept. of Biology, SUNY at Albany, Albany, NY 12203.

Neuronal-like delayed rectifier K⁺ channels are present in dissociated Schwann cells from rabbit sciatic nerve (Chiu, J. Physiol. 396:173). It was suggested that these channels are synthesized <u>in vivo</u> in the sciatic nerve. We performed Northern blot analysis to demonstrate that mRNA transcripts homologous to the cDNA clone of RCKI (delayed rectifier K channels) were indeed present in adult rabbit sciatic nerve. The hybridization signal of these mRNA transcripts was comparable with its brain counterpart in its mobility (~8 Kb) and intensity. cDNA cloning and sequencing further indicate that both the rabbit brain and rabbit sciatic nerve express identical delayed rectifier K⁺ channels. The sequence analysis also shows that the coding region of the RCK1 gene is highly conserved (over 90%) among rat, mouse, and rabbit. We conclude that rabbit sciatic nerve expresses neuronal K⁺ channels in vivo. The origin of these gene transcripts in sciatic nerve is most likely from Schwann cells. (Supported by NIH GM39939.)

R.B.Stein *and J.B.Williams. Depts. of Pharmacology and Biological Chemistry, Merck, Sharp & Dohme Res. Labs, West Point, PA 19486 and Dept. of Pharmacology, Yale U. School of Med., New Haven, CT 06510

K_v4, a cDNA clone which encodes a K⁺ channel, was isolated K_V^{4} , a cDNA clone which encodes a K^+ channel, was isolated from a rat brain library with a probe derived from K^+ channel clone K_V^{1} (Swanson, R., Neuron, 4, 1990). The clone spans 4 kb and contains an ORF which encodes a protein of 585 amino acids ($M_T = 65,353$). Isolation of several genomic clones spanning regions of the cDNA clone indicates that the coding sequence of K_V^{4} is interrupted by introns. K_V4 possesses 6-7 transmembrane regions and is very similar to K^+ channel clone NGK2 (Yokoyama, S., et al., FEBS Lett, 259: 37, 1989) but diverges significantly at the C-terminus. The protein is encoded by a 4.5 kb mRNA which Northern analysis has revealed to be present only in brain; no hybridizing species were evident on Northern blots prepared from heart, spleen, kidney, skeletal muscle or lung mRNA. The abundance of the mRNA increases in the rat over the course of development from neonate to adult. In vitro transcribed K_v4 RNA, when injected into Xenopus oocytes, elicits a voltage-activated current which displays delayed rectifier characteristics.

ICCALIZATION AND TOPOLOGY OF K*-CONDUCTING MEMBRANE PROTEIN ISK IN RAT KIDNEY CELLS. T. Sugimoto, T. Ueyama, T. Houtani*, M. Ikeda*, H. Ohkubo**, T. Takumi**, Y. Tanabe** and S. Nakanishi**, Dept. of Anatomy, Kansai Medical Univ., Moriguchi, Osaka 570 and *Inst. Immunology, Fac. Med., Kyoto Univ., Kyoto 606 Japan.

A novel rat membrane protein that induces selective permeation of K* ions by membrane polarization was previously identified (Science 242: 1042-1045, 1988). This protein termed ISK consists of 130 amino acids with a single putative membrane domain. We raised antisera against several oligopeptides representing parts of the ISK protein. Tissue sections obtained from the perfusion-fixed rat kidney were immunostained for ISK protein using different antibodies which recognized aminoterminal (N-I) and carboxyterminal (C-I) peptide fragments. Both antibodies recognized the apical membrane portion of epithelial cells in the proximal tubule as reported recently (J. Membrane Biol. 113: 39-47, 1990). At the ultrastructural level, the immunolabel was densely and uninterruptedly distributed over the apical membrane of the epithelial cells and of the microvilli. N-I immunoreactive product was also present in the surface coat portions; C-I immunoreactive product was localized to the membrane and the contiguous submembranous zone of the cytoplasm. Basolateral cell surfaces were virtually free from the immunolabel. The results indicate that ISK protein in renal tubular cells is situated at the apical membrane with its aminoterminal portion directed toward the tubular lumen, and support our previous conclusion that ISK protein plays an important role in K* permeation from the epithelial cells to the lumen.

281.20

CLONING OF POTASSIUM CHANNEL cDNAS FROM RAT LEUKOCYTES AND HUMAN T CELLS K. Folander, C.S. Lin, J.S. Smith, R. Swanson, and R.B. Stein Departments of Pharmacology and Immunology Research, Merck Sharp and Dohme Research Labs

A cDNA encoding a potassium channel was cloned from rat peripheral white blood cell mRNA using the polymerase chain reaction. The DNA sequence of the clone is identical to K_V3, a delayed rectifier K⁺ channel previously cloned from rat brain (Swanson *et al.*, Neuron, 1990). Injection of RNA transcripts of the clone into *Xenopus* oocytes resulted in the expression of K⁺ currents with properties intermediate to those of the *n* and *n'* type K⁺ currents previously characterized in mouse T cells. Thus, the rat channel (like the n' channel) is half activated by depolarization to -10 mV, is blocked by charybdotoxin (IC₅₀= 1 nM), and is relatively insensitive to block by TEA (IC₅₀ >40mM). The current, however, does display some use-dependent inactivation upon repetitive depolarization, as

does the *n* type current. Human T lymphocytes were purified from peripheral blood by density gradient centrifugation, sheep erythrocyte rosetting, nylon-wool column purification, and plastic adherence. These T cell preparations were >98% OKT3⁺ and contained both CD4⁺ and CD8⁺ populations were 350% of the animode action and sold of the populations as assessed by flow-cytometry analysis. An ~1100 bp cDNA was cloned from these T cells and encodes a partial protein with >90% amino acid identity to rat K_{ν} 3. The region of the protein that has been cloned consists of 364 amino acids that extend from upstream of the first hydrophobic domain to within the carboxy terminal region of the channel. Work is now in progress to clone cDNAs to complete the entire protein coding sequence

A COMPARISON OF KINETIC MODELS OF THE NEUROMUSCULAR JUNCTION USING MONTE CARLO SIMULATION. T.M. Bartol Jr., E.E. Salpeter M.M. Salpeter. Section of Neurobiology and Behavior, and ¹Laboratory of Nuclear Studies Cornell University, Ithaca, NY 14853.

Inhaca, NY 14853. Previous studies have modelled the kinetics of the nicotinic acetylcholine receptor (AChR) at the neuromuscular junction (NMJ) using simultaneous differential equations. For case in solving these equations, the full kinetic scheme,
$$A+R \xrightarrow{\{k_1\}} A+AR \xrightarrow{\{k_2\}} A_2R \xrightarrow{\beta} \xrightarrow{\alpha} A_2R^*$$
 can be replaced by an approximate the properties of
(Adams in Myasthenia Gravis, Albuquerque & Eldefrawi eds., Chapman & Hall publ., 1983, p. 131). This scheme uses a reduced forward binding rate constant $k'_{+2} = k_{+2}(\alpha+\beta)/(\alpha+\beta+2k_{-2})$, and a factor $(1-g) = \alpha/(\alpha+\beta+2k_{-2})$, which effectively gives the fraction of doubly bound receptors which are in the closed state and from which the actual unbinding occurs. If unbinding is slow compared to isomerization, $2k_{-2} < (\alpha+\beta)$, there is no doubt about the validity of the simplified scheme; for such cases k'_{+2} reduces to k_{+2} and (1-g) reduces to $\alpha/(\alpha+\beta)$. If unbinding is fast, on the other hand, it is not obvious how well the simplified scheme would mimic the full scheme. We have developed a Monte Carlo method for modelling the NMJ, which follows the fate of each individual ACh molecule in the cleft. This method allows an accurate we have developed a Monte carlo menor to moderning the NAD, which flowed the fate of each individual ACh molecule in the cleft. This method allows an accurate evaluation of each of the two kinetic schemes. We have carried out such calculations for a number of cases, ranging from slow to fast unbinding. We have established that, for both conditions, the shape (and amplitude) of a miniature endplate current described by the simplified scheme does indeed approximate that given by the full scheme. This research was conducted using the Cornell National Supercomputer Facility, a resource of the Center for Theory and Simulation in Science and Engineering and was funded by NIH grant NS09315.

FREEZE-FRACTURE ULTRASTRUCTURE OF THE FROG NEUROMUSCULAR JUNCTION ACTIVE ZONE REVEALS NO MARKED PROXIMAL-DISTAL GRADIENT IN SYNAPTIC STRUCTURE. P. A. Pawson and A. D. Grinnell, Jerry Lewis Ctr, UCLA Sch. Med., Los Angeles, CA, 90024.

To resolve disagreements in the literature, we have looked again for structural correlates of the commonly observed decrease in release efficacy from the distal regions of frog motor nerve terminals. Since the relevant synaptic structure is believed to be the pre-synaptic active zone (AZ), we have examined quantitatively the proximal-distal distribution of AZ structure, using a freeze-fracture technique that produces replicas of large fractions of terminals, including the region of nerve entry, so that we know the proximal/distal position of each branch. From 18 endplates we obtained fractures of 66 branches, 28 of which exceeded 20 micrometers in length. We selected for analysis the nine branches that measured > 50 micrometers (from 8 endplates). Only one of these branches showed a marked distal decrease in AZ length/unit length of terminal, while several had short regions (5-10 micrometers), either proximal or distal, that exhibited amounts of AZ that were substantially greater or smaller that the average value for that terminal branch. In general, however, these branches did not display a significant proximal-distal gradient in AZ length/micrometer terminal length. (Supported by NIH, NSF, MDA).

REGULATION OF SINGLE QUANTAL CURRENT AT THE SNAKE NEUROMUSCULAR JUNCTION. R.S. Wilkinson and J.J. Stevermer*. Department of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO 63110.

The strength, or efficacy, of a synapse depends not only on the number of transmitter quanta released (quantal content) but also on the postsynaptic current produced by each quantum. Thus one potential mechanism for regulation of synaptic strength is regulation of quantal current. To test this possibility we compared spontaneous miniature endplate currents (mepc's) among fibers of different type (faster twitch, F; slower twitch, S; and tonic, T) and input resistance (R_{in}) in the thin transversus abdominis muscle of the garter snake.

Muscle fibers were identified by anatomical criteria as F, S, or T and impaled near their endplates with 2 microelectrodes. $R_{\rm in}$ was determined from the slope of current-voltage plots near resting potential. Amplitudes of mepc's were either calculated by dividing miniature endplate potential amplitudes by R_{in} or recorded directly by voltage clamping the endplate region of fibers (-100 mV). Mean mepc amplitudes (average of 100-200 events/fiber) ranged from 0.5-5 nA. The mean amplitudes varied inversely with R_{in} (range, 0.3-4 M Ω) such that larger fibers (smaller $R_{\rm in}$) received larger mepc's. The slope of this relation was steeper for F fibers; their mepc's were generally larger than those of S or T fibers having similar resistance. These results suggest that single quantal current is regulated at the snake motor endplate, and are consistent with the theoretical needs of larger and faster cells for more synaptic current. Supported by NIH grant NS24752 and the MDA.

CABLE ANALYSIS OF RAT HIPPOCAMPAL NEURONS IN CULTURE: A NOVEL APPROACH. <u>J. M. Bekkers* and C. F. Stevens.</u> The Salk Institute, Howard Hughes Medical Institute, La Jolla, CA 92037.

Groups of neurons in cell culture provide a useful model system for the study of synaptic currents. Our objective was to characterize the cable properties of the dendrites of such neurons in order to estimate the fidelity with which currents originating in distal synapses are recorded at the soma. Hippocampal neurons, 2-3 weeks post-plating, were whole-cell voltage clamped at the soma via a patch electrode containing Lucifer Yellow. Bath solution made hypertonic by the addition of sucrose was applied to localized lengths of dendrite, eliciting miniature excitatory postsynaptic currents (mepscs) at the point of application As solution was applied more distally, the mean mepsc measured at the soma became slower and smaller, compatible with increasing cable distortion. For example, in one dendrite with diameter ~0.8 um the mean mepsc amplitude and decay time constant (at a holding potential of -60 mV) were 67 pA and 1.2 ms when solution was applied at the soma, 38 pA and 2.6 ms at 70 um, and 21 pA and 3.5 ms at 120 um. Averaging across 6 cells, the mean mepsc amplitude declined with distance x (in um) approximately as exp(-x/170), after normalizing all dendritic diameters to 1 um. In contrast, charge transfer to the soma (which reflects the DC length constant) was much less attenuated.

Neurons were afterward fixed and their dendritic arbors accurately measured under a fluorescence microscope. Assuming homogeneity of membrane and mepsc properties, we are currently modeling neurons as a passive network in which a known current (the mean mepsc elicited at the soma) is injected at known points on the dendritic tree. Comparison of the calculated and observed cable filtering of the mepscs will allow estimation of passive membrane properties. A conclusion is that significant cable attenuation of the amplitudes of distally originating fast synaptic currents occurs in our system.

282.7

RECURRENT EXCITATORY SYNAPSES (AUTAPSES) IN CULTURED RAT HIPPOCAMPAL NEURONS.

G.D. Clark ¹, L.L. Thio ², D.B. Clifford ³ and C.F. Zorumski ². Dept. of ¹Neurology, LSU School of Medicine, New Orleans, LA 70112 & Depts. of ³Neurology, ²Psychiatry, ²Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Observations of depolarizations following action potentials have been made in the rat hippocampal slice preparation. Some of these have been speculated to result from the release of transmitter from an autapse, a recurrent process forming a synapse on or near the neuron cell body. We have observed early (< 5ms) depolarizations following action potentials in cultured rat hippocampal neurons studied in synaptically connected pairs. Presynaptic neurons manifesting an afterdepolarization always produced an excitatory (probably glutamate mediated) postsynaptic event (N=16). The latencies of the after action potential events were such that at most one synapse could be interposed (range 3.5-5 ms). 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) (.5 μ M) reversibly diminishes the size of afterdepolarizations by 24 \pm 11%, N = 3 suggesting that these are synaptically mediated events. Wheat germ agglutinin, a potent recruiter of desensitized glutamate postsynaptic receptors, augments both the postsynaptic excitatory events and the afterdepolarizations (increase of 20 $\pm\,$ 4%, N=5). Zinc ions potentiate only postsynaptic events not the afterdepolarizations. These results provide evidence for the existence in cell culture of autapses. Autapses, because of their proximal location, could serve as important feed-forward potentiators of central nervous system synaptic transmission.

EVOKED MINIATURE SYNAPTIC CURRENTS IN THIN HIPPOCAMPAL SLICES. G.B. Richerson and C.F. Stevens. Dept. of Neurology, Yale University School of Medicine, New Haven, CT 06510, and The Salk Institute, Howard Hughes Medical Inst., La Jolla, CA 92037.

The characteristics of evoked miniature synaptic currents were studied using whole cell patch clamping from thin hippocampal slices. 100 uM rat hippocampal slices were prepared using a vibratome. Neurons in the CAl region were visualized using Nomarski optics on an inverted microscope, and the cell membrane was cleaned with a fire-polished patch electrode (2-3 Mohms). The same electrode was then used to voltage clamp neurons in the whole cell patch clamp mode. Miniature excitatory postsynaptic currents (mepscs) were induced by a puff of hypertonic sucrose onto the dendritic field of neurons. These mepscs sucrose onto the dendritic field of neurons. These meps: had a reversal potential near 0 mV, and were blocked by Kynurenic acid (1 mM), a glutamate receptor antagonist. Movement of the sucrose pipette by 20-30 uM resulted in loss of the mepsc response, suggesting that mepscs were only induced in a localized region. The mepscs had a large variability in amplitude which did not appear to be related to a difference in electrotonic decay, since the amplitude was not inversely proportional to the decay time constant. This data suggests that quantal release may not be uniform in size in central neurons. Supported by the Howard Hughes Medical Institute and grant NS12961 from the National Institutes of Health.

282.6

ELEMENTARY EXCITATORY SYNAPTIC CURRENTS IN DENTATE GRANULE AND HIPPOCAMPAL PYRAMIDAL CELLS

M. Raastad, J.F. Storm, P. Andersen. Institute of Neurophysiology, Karl Johans gt. 47, 0162 Oslo, Norway.

Excitatory postsynaptic currents (EPSCs) were recorded at the soma of dentate granule cells and CA1 pyramidal cells in slices (19-24°C, 10µM bicucculline) using a granule cells and CAI pyramidal cells in sites (19-24 t., 10km bicuculinie) using a whole-cell patch-clamp technique (Edwards et al., 1989). EPSCs from three different conditions were compared: (1) spontaneous EPSCs, probably due to asynchronous discharge in afferent fibers, since they were blocked by 1µM TTX; (2) EPSCs elicited by ejection of ruthenium red (RR) from a pipette; these were TTX-resistant and are probably caused by spike-independent release of transmitter quanta; and (3) EPSCs elicited by electrical stimulation of a small number of afferent fibers. In some cells there was a clear amplitude step between the failures and the smallest EPSCs, suggesting that these

represent input from a single afferent fiber.

The three groups of EPSCs showed no obvious differences in either amplitude (0-20pA, typically 4pA), rise-time (RT, 4-12ms) or half-decay time (HDT, 7-30ms). This supports the idea that the smallest stimulated EPSCs were due to input from a single fiber. Furthermore, if RR gives release of single transmitter quanta, the spontaneous and stimulated EPSC which are equally small, may each be due to a single quantum. This supports the idea that central excitatory boutons contribute only one or a few quanta per impulse. The scatter in amplitude, RT and HDT was remarkably wide for all three groups of EPSCs. Still, in a given cell RT varied less for electrically stimulated EPSCs than for spontaneous or RR elicited EPSCs, as expected if the former is generated in a restricted part of the dendritic tree. However, for a given RT the large amplitude variation suggests that the variability in amplitude is not only due to electrotonic attenuation. There may be genuine differences in the elementary EPSC sizes, perhaps reflecting different functional states of the synapses.

282.8

CAMP-DEPENDENT PROTEIN KINASE INJECTIONS ENHANCE ELECTROTONIC AND CHEMICAL EXCITATORY RESPONSES AT MIXED SYNAPSES ON THE MAUTHNER CELL. Alberto Pereda, Angus C. Nairn. Paul Greengard and Donald S. Faber, Dept. of Physiology, SUNY-Buffalo, Buffalo NY 14214 and The Rockefeller Institute, New York NY 10021.

It was previously shown that intracellular injection of cAMP in the goldfish Mauthner cell lateral dendrite (Wolszon and Faber, 1989) enhanced both the electrical and the chemical glutamatergic components of the mixed EPSPs evoked by stimulation of posterior 8th nerve. Due to the presence of gap junctions in these terminals and the low molecular weight of cAMP, this effect may have occurred pre- or post-synaptically. In order to localize their origin, the catalytic subunit of cAMP-dependent Protein Kinase (bovine heart), which has a molecular weight of 40.000, was injected into Mauthner cell lateral dendrites (n=5). Injection produced a sustained increased in both excitatory responses, which on the average were: 20.9% for the electrical and 19.8% for the chemical components. Resting potential remained unchanged during the experiments, and antidromic spike height, a measure of the Mauthner cell input resistance, showed no significant changes. Control injections using vehicle solution (n=3) or heat inactivated kinase (n=2) produced a decrease in both components of the EPSP.

The data suggest that the cAMP effect is, at least partially, of post-synaptic origin, and imply that phosphorylation of gap junctions and the glutamate receptor may be involved.

WEDNESDAY AM

HEMI-GAP JUNCTIONS IN SOLITARY HORIZONTAL CELLS. S. H. DeVries* & E. A. Schwartz. Committee on Neurobiology, The University of Chicago, Chicago, IL 60637.

We have studied gap junctions that form between isolated pairs of catfish horizontal cells (DeVries & Schwartz, J. Physiol. 414: 351-375, 1989). Junctional conductance can be decreased by 50% within seconds after exposure to 10 nM dopamine. The intracellular pathway involves a rise in cAMP concentration and activation of a cAMP-dependent kinase. Two additional 2nd messengers, cGMP and protons, independently decrease junctional conductance. We now describe a membrane current of solitary horizontal cells which is modulated by dopamine thru a cAMP-dependent kinase. This current is also independently modulated by cGMP and protons. When measured in the same cell pair, cAMP, cGMP, and protons reduce membrane current and junctional conductance with similar rates of onset and recovery, and with the same relative magnitude of effect. The current-voltage properties of both the dopamine-sensitive membrane current and the junctional conductance were determined. The current is fully activated at depolarized voltages and undergoes a slow voltage-dependent inactivation during steps to hyperpolarized voltages. The junctional conductance displays voltage-dependent behavior consistent with the end-to-end anastomosis of two "hemi-junctions". We conclude that horizontal cells express hemi-junctions and that these hemi-junctions can join with those in apposed cells to form a full gap junction. The voltage-dependent properties of the whole gap junction follow directly from those of the hemi-junction.

282.11

EXCITATORY AND INHIBITORY SYNAPTIC TRANSMISSIONS ON CANINE INTRACARDIAC GANGLION CELLS. X. Xi, W.C. Randall and R.D. Wurster. Physiol. Dept., Loyola Univ. Med. Ctr., Maywood, IL 60153.

Vagal control of the sinoatrial node in dogs is mediated by intracardiac ganglia located in the pulmonary vein fat pad of right atrium. The synaptic transmission properties of mammalian intracardiac ganglia have not been previously investigated. Thus, canine intracardiac ganglia were intracellularly studied in vitro. Presynaptic fibers were activated by stimulating interganglionic nerves using a bipolar suction electrode. In each ganglion cell, a single stimulation (0.1 ms) evoked one or more fast excitatory postsynaptic potentials (f-EPSPs) which normally reached threshold and initiated an action potential. The f-EPSPs of one ganglion cell may have different time delays and thus, summate into different patterns. These f-EPSPs were blocked by hexamethonium (10 4 M) and low Ca⁺⁺, high Mg⁺⁺ Krebs solution but not by atropine (10 M). Train stimulation (20 Hz, 0.2 - 0.9 S) evoked a slow hyperpolarizing inhibitory postsynaptic potential (s-IPSP) on 43 of 60 neurons. These s-IPSPs lasted for a few seconds with varying amplitude, depending on the frequency, duration and voltage of stimulation. Slow IPSPs were not evoked by repetitive action potential activation via intrasomal current injection. Atropine (10 M, n=7) and low Ca⁺⁺, high Mg⁺⁺ Krebs solution (n=11) blocked the s-IPSPs, but hexamethonium (10 M, n=5), propranolol (10 M, n=3) or phentolamine (10 M, n=4) had no effect. Little or no conductance changes accompanied these s-IPSPs. These data suggest that: 1). Canine intracardiac ganglion cells receive multiple synpases. 2). Synaptic excitation and inhibition involve nicotinic and muscarinic receptors, respectively. (Supported by HL 27595)

ELECTRONIC COMMUNICATION BETWEEN GLOMUS CELLS OF RAT CAROTID BODY. L. Monti Bloch, V. Abudara* and C. Eyzaguirre. Depts. Physiol. Facult. Med., Montevideo, Uruguay and Univ. Utah Sch. Med., Salt Lake City, UT, USA

The carotid body is an arterial chemoreceptor whose glomus cells synthesize, store and release dopamine, ACh and peptides when stimulated by hypoxia, hypercapnia or acidity. Many glomus cells are electrically, and bidirectionally, coupled at rest (L. Monti Bloch and V. Abudara, 1988). We now report on the effects of hypercapnia, hypoxia, lactate and dopamine on intercellular coupling. Carotid bodies, excised from 50 g anesthetized rats were superfused with oxygenated physiological saline, pH 7.4 at 30°C. Two adjacent glomus cells were simultaneously impaled under visual control with 3 M KCl-filled micropipettes (80-100 Ma). Their membrane potential was -30 to -50 mV. Current pulses (0.1-1.0 nA) were delivered through the recording electrode to measure input resistance ($R_{\rm o}$). The coupling resistance ($R_{\rm c}$) and coupling coefficient ($K_{\rm C}$) between cells were calculated. At rest $R_{\rm o}=69.2\pm10$, $R_{\rm c}=17.5\pm4.7$ Ma and $R_{\rm C}=0.54$ (n=22). Applications of 100% CO₂ depolarized to eclls and $R_{\rm o}$ increased. $R_{\rm c}$ augmented to 37 ±3.7 Ma and $K_{\rm C}$ decreased to 0.16. Applications of 100% $N_{\rm 2}$ (hypoxia) had similar effects but changes had longer latencies. Lactic acid (10 50 M) increased $R_{\rm o}$ and cells depolarized for 5-10 min. $R_{\rm c}$ increased to 61.8 ±5.3 Ma and $K_{\rm C}$ decreased to 0.08. Finally, dopamine 1 μ M also uncoupled the cells while producing 2-5 mV depolarization. Thus, natural stimulation and dopamine uncouple glomus cells. Results suggest that, as in other organs, secretory activity of glomus cells is accompanied by uncoupling, and that dopamine plays an important role. Supported in part by NS grants 05666 and 07938.

CALCIUM CHANNELS II

283.1

CALCIUM CURRENT IN AXOTOMIZED X-ORGAN CRAYFISH NEURONS. García-Colunga, J.; García, U.; Aréchiga, H. and Valdiosera, R.* Dept. of Physiol., Biophys. and Neurosci. CINVESTAV-IPN Ap. Postal 14-740, México, D. F. 07000.

Calcium current (Ica) was recorded with whole cell clamp in ligatured x-organ somata perfused with: NMGC1154, CaCl₂ 20, CsCl 30, TEACl 20 and HEPES 10; the pipette solution contained: CsCl 214, CaCl₂ 2.86, EGTA 10, MgATP 2 and HEPES 10 (mM). Ica activates at -30 mV with a sigmoidal time course and increases gradually with depolarization reaching a maximum peak value of 1.17 \pm 0.47 nA (n = 11) at 30 mV in 3.8 ms declining exponentially afterwards. Tail currents could be fitted with a single exponential (τ = 300 µs). Changing the holding potential between -90 and -50 mV had no effect on Ica. In the presence of Ba²+ the current did not decline indicating calcium dependent inactivation. This possibility was further explored with double pulse experiments. Ica during the test pulse depends on calcium entry during the conditioning pulse. This phenomenon did not occur when Ba²+ was substituted for Ca²+. The permeability sequence for divalent cations was: Ba²+ 3Cr²+ when 2 mM of each ion was added to the external solution. Nifedipine (100 µM) had no effect on Ica.

283.2

ION CHANNELS IN APLYSIA SMOOTH MUSCLE: CURRENTS ACTIVATED BY VOLTAGE AND ACETYLCHOLINE (ACh). J.L. Ram and L.-X. Liu, Physiology, Wayne State U., Detroit, MI 48201 Buccal muscles of Aplysia are smooth muscles used in voluntary feeding movements. The objective of this study was to determine whether voltage-dependent calcium channels (VDCaCh) mediate the contractile response to the physiological activator, ACh. Buccal muscle I5 was dissociated with collagenase (2-4 hr at 30 °C). With K in the patch electrode (whole cell recording) and the fiber in normal medium (SW), depolarization elicited outward current. With TEA and 4-AP SW outside and Cs as the major pipet ion, depolarization elicited inward current. Inward current was blocked completely in O Ca SW and La*** SW and reduced 80-90% in 1 µM nifedipine SW, suggesting this current to be VDCa. Lowest voltage to elicit inward current averaged -43 mV and peak current (mean=2.6 nA) was elicited by -2 mV. ACh elicited inward current at -80 mV which reversed (in most cells) above -35 mV. The I-V curve for ACh-elicited current had two slopes, changing to a shallower angle just above or below reversal. In intact muscles, ACh depolarized muscle fibers to no greater than -35 mV and the contractile response could be blocked 50% by nifedipine. A role of VDCaCh in ACh-elicited contraction is supported by a) the voltage sensitivity of VDCaCh (within range of ACh depolarization) and b) a drug that blocks VDCaCh reduces the contractile response. Supported by MDA and NIH RR 08167.

VOLTAGE-SENSITIVE CALCIUM CURRENTS IN IDENTIFIED NEURONS OF A JELLYFISH. J. Przysiezniak and A. N. Spencer. Dept. of Zool., Univ. of Alberta, Edmonton, AB, CANADA, T6G 2E9 and Bamfield Marine Station, Bamfield, BC, CANADA, VOR

Calcium currents from a primitive invertebrate, the jellyfish *Polyorchis penicillatus*, were studied using the tight-seal, whole-cell, voltage-clamp technique, applied to identified, isolated 'swim' motor neurons (SMNs). Depolarizing voltage steps elicited a rapidly-activating (Tpeak 3-10ms), rapidly-inactivating (tinact ~25ms) calcium current. This fast Ica was blocked by 0.1-0.5mM cadmium applied externally, which also 'shaved off' the plateau phase of action potentials recorded in current-clamp. The fast Ica first activated around ~20mV, reached a maximum about +10mV, and reversed around +50 to +60mV. This Ica was half-

around -20mV, reached a maximum about +10mV, and reversed around +50 to +60mV. This Ica was half-inactivated at -18mV.

Inactivation was sometimes incomplete at the end of 1 sec. depolarizing pulses, suggesting the presence of a slow, non-inactivating Ica. In some of the cells studied, the I-V curve exhibited a shoulder at ~+50mV, also suggesting the presence of a second Ica with a maximum of them; positive voltages.

maximum at very positive voltages.

Pharmacological characterization of these two currents will allow us to distinguish what their roles are in synaptic transmission and/or spike propagation.

283.5

LOW THRESHOLD TRANSIENT Ca++ CURRENTS IN ACUTELY DISSOCIATED HIPPOCAMPAL LACUNOSUM-MOLECULARE INTERNEURONS. D.D.Fraser and B.A.MacVicar. Neurosci.Res.Group, Univ. of Calgary, Calgary,

Intracellular recordings from lacunosum-moleculare (LM) interneurons suggested that these cells might have low-threshold spikes (Lacaille and Schwartzkroin, 1988). To determine the types of ion currents present in these cells we have developed a method to acutely isolate these cells from hippocampal slices. Following incubation of slices in trypsin-hyaluronidase, the LM was dissected free and this area was mechanically triturated. Cell morphology of dissociated LM interneurons was distinct from that TTX-insensitive low threshold of CA1 pyramidal neurons. transient inward currents were observed during every stable whole cell voltage clamp. They were similar to T-type Ca++ currents described in other cells in that they were blocked by Ni+ uM) but not by low concentrations of Cd⁺⁺ (200 uM). The current was inactivated when holding potential was -60 mV. At a holding potential of -100 mV the current was observed to activate at -60 mV and had a peak of 400 pA at -30 mV. Low threshold Ca⁺⁺ currents could be important in generating rhythmic activity in LM interneurons and possibly the hippocampus as in the thalamus and the inferior olive. Supported by MRC (Canada).

283.7

UNITARY CALCIUM CURRENTS IN ADULT RAT HIPPOCAMPAL NEURONS. Vazquez, M.*, Rodriguez, V.*, Larrazolo, A.*, Guevara, R. and Garcia, D. Depto. de Fisiologia, Fac. de Medicina, UNAM. Apdo. Post. 70250, Mexico 04510, D.F. Mexico. It is known that an increase in the strenght of synaptic transmission is produced when repetitive stimulation is delivered to excitatory pathways in the hippocampus (J. Physiol. 232: 331-356, 1973). Thus it has been proposed that some amino acids produce synaptic responses in these excitatory relays (Nature 297: 496-498, 1982). Even calcium influx has been involved in this neuronal hyperexcitability (J. Neurochem. 28: 63-70, 1977). The aim of these experiments was to investigate the unitary calcium current activity in control and in glutamate conditions. Method: proteolytic treatment of hippocampal slices; granule cells in cell-attached configuration; solutions formulated to block all potassium and sodium currents, bath (mM): 125 Cs⁺; patch pipette: 10 Ba²⁺, pH= 7.35. Current records were filtered a 10 KHz and sampled at 5 KHz. Results: in a preliminar approach it can be observed that glutamate (1 mM) increases the single calcium channel activity (see below).

Control Glutamate

WHOLE-CELL CALCIUM CURRENTS IN ACUTELY DISSOCIATED MEDIAL SEPTUM/DIAGONAL BAND NEURONS. W.H. Griffith, L. Taylor and M.J. Davis*. Depts. of Medical Pharmacol. & Toxicol. and Medical Physiol. College of Medicine, Texas A&M University,

College Station, TX 77843.

We have identified both low-voltage activated (LVA) and high-voltage activated (HVA) calcium (Ca²⁺) currents in acutely dissociated neurons from adult guinea pig. Whole-cell patch clamp procedures were used with trypsin (65,000 units/treatment) dissociated cells. Barium (Ba²⁺) (2 mM) was used as the charge carrier and both Na⁺ and K⁺-free solutions were used to reduce interfering conductances. An ATP-regenerating system (4 mM MgATP, 0.1 mM GTP, 5 mM creatine phosphate and 20 units/ml creatine phosphokinase) enabled currents to be recorded for up to 2 hrs. All drugs were applied by bath perfusion. From a V_h of -100 mV, LVA currents could be induced by step depolarizations positive to -75 mV and showed marked voltage-dependent inactivation at -80 mV. These transient currents were reduced by nickel (20 - 100 μ M) and cadmium (10 - 500 μ M). A non-inactivating HVA current began positive to -50 mV and was sensitive

ing nVA current began positive to -30 mV and was sensitive to nifedipine (5 - 10 μ M) as well as the divalent blockers. Selective expression of these Ca²⁺ currents could be observed in different cell types within the basal forebrain, suggesting that LVA and HVA calcium currents play a critical role in the firing pattern of these cells. (Supported AG07805, NS22456, HL-38104, AHA-881161).

283.6

ASYMMETRICAL REGIONAL DISTRIBUTION OF TETRODO-

ASYMMETRICAL REGIONAL DISTRIBUTION OF TETRODOTOXINE-SENSITIVE CALCIUM-CONDUCTING CHANNELS IN THE RAT HIPPOCAMPUS. N. Akaike and K. Takahashi*. Dept. of Neurophysiology, Tohoku Univ. Sch. of Med., Sendai 980, JAPAN Experiments were performed on the pyramidal neurons freshly isolated from rat hippocampal CA1 region. Voltage-dependent Ca^{2+} currents (ICa_{S}) in the neurons can be classified into T-, N-, and L-types on the basis of their current kinetics, voltage-dependence, and pharmacological sensitivities. We found an additional tetrodotoxin (TTX)-sensitive transient Ca^{2+} current (termed 'TTX-ICa') through the Na+ channel in the dissociated pyramidal neurons. The TTX- IC_{Ca} was not affected by Ca^{2+} channel blockers but was sensitive to Na+ channel blockers and scorpion toxin. The TTX- IC_{Ca} developed linearly with increasing extracellular Ca^{2+} concentration, and the selectivity was $\text{Ca}^{2+} > \text{Sr}^{2+} > \text{Ba}^{2+}$. We first report here an asymmetrical regional distributions of the TTX-I. port here an asymmetrical regional distribution of the $TTX-I_{Ca}$ and T-type I_{Ca} in the CAl region: the former is observed dominantly at the dorsal portion while the latter at ventral portion.

283.8

PROPERTIES OF TWO LONG-LASTING CALCIUM CURRENTS IN NON-DISSOCIATED, ADULT HIPPOCAMPAL CAI PYRAMIDAL CELLS. L.W. Campbell, O. Thibault', S-Y Hao', P.W. Landfield. Department of Physiology & Pharmacology., Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27103.

It is clear that there are multiple calcium currents in peripheral and central nervous system neurons (Llinas and Yarom, 1981; Fox et al., 1985; Tsien, 1987; Miller, 1987). Recent studies in dissociated hippocampal neurons (Gray and Johnston, 1987; Madison et al., 1987; Mogul & Fox, 1989, O'Dell and Alger, 1989) have also found rapidly inactivating (T,N) currents and a slowly inactivating, long-lasting (L) Ca current. Most studies of multiple Ca currents have used dissociated-cell/patch-clamp methods. In the present studies, conducted with intracellular single electrode voltage-clamp in non-dissociated adult rat hippocampal slice neurons, we also found evidence of at least 3 types of Ca currents.

However, in contrast to previous studies, we find 2, rather than 1, long-lasting Ca currents. The 3 types observed, in order of activation ranges, are as follows:

1. "Recurrent ("resistant"); low voltage activated (-55 to -50 mV, holding potential of -80 mV); low amplitude; highly resistant to voltage or Ca inactivation, and to dihydropyridines (DHP) or ω-Conotoxin (CgTx).

2. "N" current (similar to the peripheral N, but may have T-like components); medium-range activation (approximately -45 to -40 mV, holding at -80 mV), relatively rapid inactivation (~100 ms time constant), and sensitivity to CgTx and Cd.

3. "L" current (many properties similar to L-type); medium-range activation (-40 to -35 mV), slow inactivation (>1000 ms) and sensitivity to DHPs, CgTx and Cd. This current is also charaterized by unusually long tail currents. Several factors suggest that the tail is not entirely due to space-clamp problems: the tail is extremely sensitive to changes in holding potential, and is present in somata after severing apical dendrites.

EXPRESSION OF CALCIUM CONDUCTANCES IN PURKINJE NEURONS IN CULTURE. <u>D.L. Gruol and C.R. Deal*</u>, Dept. of Neuropharm., Res. Inst. Scripps Clinic, La Jolla, CA 92037. During maturation, cerebellar Purkinje neurons (PNs) acquire

During maturation, cerebellar Purkinje neurons (PNs) acquire the ability to generate patterns of high frequency spike activity. We are investigating the ionic basis for this developmental change using current and voltage clamp techniques. In intracellular recordings from immature PNs at 7 days *in vitro* (DIV), small depolarizations evoked repetitive, fast TTX (1 μM) sensitive Na+ spikes. Strong depolarizations evoked fast Na+ spikes and slow Cd²+ (30 μM) sensitive Ca²+ spikes. At 14-16 DIV, when PNs have well developed dendritic structure and exhibit high frequency firing patterns, small and large depolarizations elicited an initial Cd²+ sensitive burst event followed by repetitive TTX sensitive Na+ spikes. A similar burst event was evoked at the termination of a hyperpolarizing current pulse. In voltage clamp recordings from the older PNs, in the presence of Na+ and K+ channel blockers, depolarization from a holding potential of -90 mV evoked a low threshold transient Ca²+ current and a high threshold Ca²+ current with a transient and a sustained component. The transient currents were not evident when the potential was held at -40 mV. At 7 DIV, Ca²+ currents were small but appeared to include both transient and sustained components. These date indicate that the contribution of Ca²+ currents to PN activity increases with development. Supported by NS21777.

283.11

HIGH- AND LOW-THRESHOLD CALCIUM CURRENTS IN RAT SENSORIMOTOR CORTICAL NEURONS. R.J. Sayer, P.C. Schwindt, and W. E. Crill. Dept. of Physiology & Biophysics, Univ. of Washington Sch. of Med., Seattle, WA 98195.

The Ca²⁺ currents of rat neocortical neurons were investigated by

The Ca²+ currents of rat neocortical neurons were investigated by voltage clamping acutely isolated cells. Slices of sensorimotor cortex from rats 14-28 days old were treated with papain for 1.5 h and then mechanically dissociated to produce single cells. Whole-cell recordings of Ca²+ currents were made at 20-23°C. High-threshold (HT) and low-threshold (LT) components of the current were observed in all neurons. The HT current was evoked by commands positive to -40 mV, was maximal at about -10 mV and was slowly inactivating. The LT current was only seen when holding potentials were more negative than -70 mV. It was activated by commands positive to -65, and was maximal at about -30mV. The LT current was transient, with a time constant for inactivation of approximately 70 ms at -30 mV. After 800 ms hyperpolarizations to -100 mV, which removed inactivation from the LT current, the ratio of maximal LT to maximal HT amplitude averaged 0.33. In comparison to the LT current, the HT current was more sensitive to block by Cd²+ and less sensitive to block by Ni²+. Racemic BAY K 8644 (1µM) enhanced the HT current at potentials between -40 mV and -10 mV, but had no effect on the LT current. Nimodipine (10 µM, by puffer pipette) reversibly suppressed both currents by about 60%. ω-Conotoxin (16 µM, by puffer pipette) reduced the HT currents by a mean of 23%, with little recovery on washing, but did not affect the LT current. Supported by NINDS grant NS16792.

283.13

CALCIUM CHANNELS PARALLEL SODIUM CHANNEL MATURATION IN MOUSE NELFOCEVELOPMENT B.B.Grover, *S.M.Saderup & M.J.Litzinger Depts. of Pediatrics, Biology, Naurology & Physiology, Univ. of Utah, 9.C.UT. & Albert Eistein College of Medicire, N.Y.,N.Y.* Recent studies on the Na⁺/Ca⁺⁺ exchange mechanism have suggested the importance of the Na⁺ & Ca⁺⁺ ion concentration gradient to be in place for neurodevelopment to occur (Mills et.al., 1989). The maturation of these ion channels is crucial to the establishment of this gradient. H³- TTX (Na⁺channel probe) showed a two fold increase in binding between days 10 & 15 in mouse neurodevelopment (Hafemann & Unsworth, 1972). Erman et.al., 1987, reported a sudden increase in Nitrendipine binding in mouse brain between days 7 & 21.

The present study seeks to establish more closely the parallel maturation of Ca++ channels during mouse neurodevelopment. Nimodipine (L type Ca++channel)binding site density increases between days 10 \$ 15. A 50% increase in N type Ca++ channels (with w-conotoxin) was demonstrated between days 11 \$ 14. This time period corresponds to a "critical period" noted by Himwich, 1962, which signaled the activation of electrocortical maturation. These binding studies show the parallel maturation of Na+ \$ Ca++ channels during this period of rapid mouse neurodevelopment and suggests the need for the availability of these ion channels for the maturation of the Na+/Ca++ exchange system.This work was sponsored by NICHO KOS 00385-01.

283.10

DEVELOPMENT OF CALCIUM CURRENTS IN CULTURED RAT CEREBELLAR GRANULE CELLS. C. Marchetti, C. Carignani* and M. Robello* Istituto di Cibernetica e Biofisica, CNR, Genova, Italy.

We have characterized a voltage-dependent calcium current in cerebellar granule cells from 8-day-old rats. Currents were measured with the patch-clamp technique in an external bath containing barium or calcium (20 mM) and TEAC1, and with cesium in the pipette to minimize the other ionic currents. During the first 3 days in vitro (DIV) only 16% of granule cells displayed barium currents with amplitude ≥ 50 pA, whereas from 5 to 13 DIV all the cells had a current ≥100 pA. This current activated around -25 mV, reached a peak between +10 and +20 mV and reversed around +70 mV. The dehydropyridine BayK 8644 (0.1 - 5 µM) produced: (i) an increase in the current amplitude, (ii) a shift of its activation in the hyperpolarizing direction and (iii) a slowing down of deactivation kinetics. The effects were dose-dependent and independent of DIV. The barium current was also rewersibly depressed by 100 µ.M Baclofen (28±7% inhibition in 9 cells, from 5 to 13 DIV). These results suggest that cerebellar granule cells possess a high-voltage-activated calcium current which develops during the first 4 DIV and can be modulated by GABAb agonists.

CALCIUM CURRENTS IN NEURONS ISOLATED FROM HUMAN NEOCORTEX. W. E. Crill, R.J. Sayer and P. C. Schwindt, Dept. of Physiology & Biophysics, Univ. of Washington Sch. of Med., Seattle, WA 98195.

Ca²+ entry plays a key role in the control of neuronal excitability, so it is important to characterize the Ca²+ currents in cells from regions prone to epileptic activity. Neocortical tissue was obtained from adult patients during resection of epileptic foci from the temporal lobe (either side). We used samples from areas which needed to be removed but which were considered to be relatively more "normal" than the epileptic foci. The tissue was sliced, treated with papain for 1.5 h and then mechanically dissociated to produce single cells. Ca²+ currents were recorded under whole cell voltage clamp at 20-23°C. Two components of current were identified by their thresholds for activation: (a) a high-threshold (HT) current evoked by commands positive to -40 mV, which was slowly inactivating, and (b) a low-threshold (LT) current activated positive to -60 mV which was rapidly inactivating. The LT current was only seen with holding potentials more negative than -70 mV, and its peak amplitude was always much smaller than the HT current. The HT current was more sensitive than the LT current to block by Cd²+, while the reverse was true for Ni²+. Racemic BAY K 8644 (1 µM) increased the HT current most strongly for command potentials between -40 mV and -10 mV, but had no effect on the LT current. Nifedipine (10 µM, by puffer pipette) reversibly reduced the maximal HT current by approximately 60%. These results indicate some similarities between the Ca²+ currents of human neocortical neurons and those of other mammals. Supported by NINDS grants NS16792 & NS20482.

283.14

DIFFERENTIAL MODULATION OF CALCIUM CHANNELS BY GUANINE NUCLEOTIDE ANALOG IN HUMAN NEUROBLASTOMA CELLS. <u>E. Reuveny and T. Narahashi</u>. Dept. of Pharmacol., Northwestern Univ. Med. School, Chicago, IL 60611.

Guanine nucleotide-binding proteins (G-proteins) couple

Guanine nucleotide-binding proteins (G-proteins) couple the membrane receptors for neurotransmitters to a variety of enzymes and ion channels. The L-type calcium channels are modulated by leucine enkephalin via δ receptors, whereas the N-type calcium channels are modulated by norepinephrine via α_2 -adrenergic receptors. G-proteins are believed to be involved in these two systems. We have previously shown that human neuroblastoma cells (SH-SY-SY) express N- and L-like calcium channels (Reuveny and Narahashi, Biophys. J. 57 520a, 1990). We now report the effect of direct activation of G-proteins on calcium channels in these cells. N-like calcium channel currents were reduced by the internal perfusion of cells with the non-hydrolyzable analog of GTP, GTP γ S (100 μ M), while L-like currents were not reduced. Interestingly, the activation kinetics of L-like calcium channel currents were slowed. In contrast, internal perfusion of cells with GTP up to 5 mM was not effective in reducing either the N- or L-like calcium channel currents. The effects of GTP γ S on the N- and L-like calcium channel currents were attenuated by preincubation of cells with pertussis toxin (100 ng/ml) for 18 hr. These results suggest that the N-like calcium channels in SH-SY-SY cells are tonically suppressed by G-proteins. Supported by NIH grant NS14144.

INTERACTION OF "L"-TYPE CALCIUM CHANNELS AND PROTEIN KINASE C IN MODULATING [3H]-5HT RELEASE FROM RAT SPINAL CORD SYNAPTOSOMES. V.C. Gandhi and D.J. Jones. Depts. Anesth. & Pharm., Univ. Texas Hlth. Sci. Ctr., San Antonio, TX 78284-7838

Previous studies demonstrated that protein kinase C (PKC) modulates the

release of monoamines from central neural tissues. Since we have shown previously that Ca⁺⁺ channel agonists modulate release under similar conditions, the present studies investigated the role of PKC in the Ca⁺⁺-dependent release of 5-HT from spinal cord synaptosomes along with the possible involvement of dihydropyridine (DHP)-sensitive "L" Ca⁺⁺ channels in regulating this release.

agonists such as Bay K 8644 maximally enhance K+-stimulated release at a K* concentration of 15 mM. Similar to these results, the PKC activators phorbol 12-myristate 13-acetate (PMA) and 1,2-oleoyl acetylglycerol (OAG) also demonstrated peak enhancement of ¹³HJ-5HT release at 15 mM K* when tested over a range of 5-60 mM K*. This increase in ¹³HJ-5HT release with submaximal depolarization of the synaptosomes was dependent on the concentration of PMA or OAG and was not evident when inactive phorbol esters were added to the perfusion medium. Facilitation of [³H]-5HT release by both PMA and OAG was dependent on the concentration of Ca⁺⁺ in the superfusion media. The effects of PMA and Bay K 8644 were additive when added together at submaximal concentrations. Nimodipine, an "L" Ca⁺⁺ channel antagonist, while having no independent effect on K⁺-induced [³H]-5HT release, abolished the Bay K 8644 as well as PMA-induced enhancement. In addition the PKC inhibitor polymyxin B well as PMA-induced enhancement. In addition the PKC infinitor polymyxin be blocked both PMA- and OAG- enhanced release, as well as Bay K 8644 enhanced release in the presence of 15 mM K⁺. These results demonstrate that PKC-dependent mechanisms are involved in the release of [³H]-5HT in rat spinal corons synaptosomes. Moreover, these studies also indicate a possible linkage between PKC-dependent release of [³H]-5HT and ^{*}L* type voltage-sensitive Ca^{*+} Supported by NSF BNS-8820008.

NOREPINEPHRINE DECREASES THE CALCIUM CURRENT OF ADULT RAT SYMPATHETIC NEURONS VIA A G-PROTEIN.

Geoffrey G. Schofield. Department of Physiology, Tulane University Medical School, New Orleans, LA 70112.

Norepinephrine decreases the Ca²⁺ current of acutely isolated adult rat superior cervical ganglion (SCG) neurons via an α2-adrenoceptor (Schofield, Eur. J. Pharmacol. in press). In dorsal root ganglion neurons the norepinephrine-induced inhibition of the Ca²⁺ current is ransduced via a guanine nucleotide binding protein (G-protein) (Holtz, et al. Nature 319: 670, 1986). Experiments were performed to investigate if a G-protein is involved in the norepinephrine-induced inhibition of Ca²⁺ currents in acutely isolated adult rat SCG neurons. Ca²⁺ currents were recorded using the whole-cell patch-clamp technique in solutions designed to isolate Ca²⁺ currents. Inclusion of 500 μM GTP-γ-S in the patch-pipette mimicked the effect of norepinephrine, decreasing the Ca²⁺ current amplitude as well as slowing the rising phase of the current. In GTP-γ-S dialysed neurons norepinephrine did not produce further inhibition of the Ca²⁺ current. Incubation of SCG not produce further infinition of the Ca²⁺ current. Incubation of SCG neurons with pertussis toxin (200 ng/ml) eliminated the norepinephrine-induced inhibition of the Ca²⁺ current. On the other hand, intracellular application of 500 μ M c-AMP and 500 μ M IBMX had no effect on the norepinephrine-induced inhibition of the Ca²⁺ current. These results suggest that the norepinephrine-induced decrease of the Ca²⁺ current of adult rat SCG neurons is transduced by a pertussis toxin sensitive G-protein independently of c-AMP. Supported by the Pharmaceutical Manufacturers Association Foundation and American Heart Association, Louisiana Affiliate.

A HIGH-THRESHOLD, DIHYDROPYRIDINE-RESISTANT CA^{2*} CURRENT IN N1E-115 NEUROBLASTOMA CELLS. Andrew G.

CURRENT IN NIE-115 NEUROBLASTOMA CELLS. Andrew G. Knapp, Lee Margolin and Deborah Daly. Cambridge NeuroScience, Inc., Cambridge, MA 02139.

We have confirmed that NIE-115 neuroblastoma cells induced to differentiate with 2% DMSO express two kinetically distinct components of calcium current (Narahashi et al. J. Physiol. 383, 1987): a low-threshold current that requires negative holding potentials, activates at potentials positive to -60 mV and inactivates completely within 200 msec; and a high-threshold current that is insensitive to holding potential, activates at potentials positive to -20 mV, and shows little inactivation over hundreds of msec. In common with classical L-type currents, the high-threshold component conducts Ba² more effectively than Ca², and is blocked by relatively low concentrations of Cd²; however, it is unaffected by dihydropyridine antagonists (nimodipine and/or nitrendipine) in concentrations as high as 10 µM. Antagonists at 100 µM block both components of the calcium current. as high as 10 μ M. Antagonists at 100 μ M block both components of the calcium current. These results suggest that NIE-115 cells may be a useful model for central neuronal high-threshold Ca^{2*} channels, a subset of which displays a similar insensitivity to dihydropyridines (e.g., Sah et al. <u>Soc. Neurosci. Abstr.</u> 15, 1989).

D, RECEPTORS ACTING VIA A CAMP/ PROTEIN KINASE A PATHWAY ACTIVATE "FACILITATION" Ca²⁺ CHANNELS IN CHROMAFFIN CELLS C.R. Artalejo", M.A. Ariano, R.L. Perlman, & A.P. Fox", The University of Chicago, & The University of Vermont.

Bovine chromaffin cells exhibited two components of whole-cell Ca²⁺ current. The "standard" Ca²⁺ current was activated by brief depolarizations. The standard Ca²⁺ current was carried by a dihydropyridine insensitive 14 pS channel. The other component, called "facilitation", was activated by prolonged pre-depolarizations to very positive potentials (Fenwick et. al., 1982; Hoshi & Smith, 1987), or by repetitive small depolarizations in the physiological range. Facilitation Ca²⁺ currents were carried by a dihydropyridine sensitive 27 pS Ca²⁺ channel that was relatively inside to the control of th Ca²⁺ channel that was relatively inactive in unstimulated cells. Dopamine (100 nM) or apomorphine (10 nM) activated facilitation Ca²⁺ channels in the absence of pre-depolarizations or repetitive activity. This response could be mimicked by the specific D₁ dopamine receptor agonist SKF 38393. The effect of SKF 38393 could be blocked by the specific D₁ dopamine antagonist SCH-23390. The D₁ effect was mimmicked by 8-4-Chlorphenylthio-cAMP and inhibited by a specific protein kinase A inhibitor peptide (PKI). D2 dopamine agonists like quinpirole had no effect on whole-cell current at concentrations up to 100 µM. Previous studies reported the existence of D₀ but not D₄ receptors in chromaffin cells. Using fluorescence microscopy the rhodamine conjugate of the 4'-amino derivative of the D₁ antagonist SCH 23390 (Ariano et. al., 1989) was found to bind to almost all of the cells in culture. This binding was displaced by 10 µM SCH 23390 but not by the 5-HT antagonist ketanserine, identifying specific D₁ receptors in bovine chromaffin cells. Dopamine release from chromaffin cells may provide a positive feedback signal capable of regulating secretion.

FREQUENCY-DEPENDENCE OF AFTERHYPERPOLARIZATION IN BULLFROG SYMPATHETIC NEURONES. B.S. Jassar* and P.A. Smith. Dept. of Pharmacology, Univ. Alberta, Edmonton, Canada, T6G 2H7.

Edmonton, Canada, T6G 2H7. The action potential afterhyperpolarization (ahp) in bullfrog sympathetic neurones involves a voltage-insensitive $G_{\rm K,Ca}$ termed $I_{\rm AHP}$ (Pennefather et al., PNAS. 82, 3040, 1985). When neurones were stimulated once every 2s, the duration of the ahp (recorded with intracellular microelectrodes and measured at 50% amplitude) was microelectrodes and measured at 50% amplitude) was 70.1±3.8% (n=34) of that seen when neurones were stimulated once every 90s. This slow frequency-dependence was partly attributable to frequency-dependence of Ca²⁺ influx as demonstrated by a change in duration of 'Ca²⁺ spikes' (recorded in 100mM TEA/2uM TTX) or by a change in the amplitude of the peak Ca²⁺ current studied by whole-cell of the peak Ca" current studied by whole-cell patch-clamp recording (100ms voltage command from -55 to 0mV: Cs⁺ replacing K⁺ inside, 105mM TEA outside). The frequency-dependence of the ahp was enhanced by 5mM caffeine and reduced by 5µM ryanodine suggesting that Ca²⁺-induced Ca²⁺ release may also be significant under physiological conditions. Changes in ahp duration reflect an may also be significant under physiological conditions. Changes in ahp duration reflect an intrinsic mechanism which enhances ganglionic transmission during high frequency activation, yet depresses transmission during low frequency activation. Supported by MRC/NSERC/AHFMR.

ROLE OF NMDA RECEPTORS IN DOPAMINE D1-, BUT NOT D2-, MEDIATED CHANGES IN STRIATAL NEUROTENSIN. N.A. Singh, K.M. Merchant, L.G. Bush, J.W. Gibb and G.R. Hanson. Dept. Pharmacol. and Toxicol., Univ. of Utah, Salt Lake City, UT

Previous studies have demonstrated that methamphet-amine-induced increases in striatal neurotensin (NT) levels amine-induced increases in striatal neurotensin (NT) levels are completely blocked by dopamine DI receptor antagonists as well as noncompetitive N-methyl-D-aspartate (NMDA) antagonists. To elucidate further these D1- and gluta-mate-mediated NT changes, we coadministered selective dopaminergic drugs with the noncompetitive NMDA antagonist, MK801. Animals were given a combination of MK801 (1 mg/kg) 15 min prior to SKF 38393 (20mg/kg; a D1 agonist) for 3 doses at 6-hr intervals and sacrificed 18 hr after the last dose. MK801 alone did not alter striatal NT levels but completely blocked the increases caused by SKF 38393. The possibility of interaction between D2 and NMDA receptors possibility of interaction between D2 and NMDA receptors was also tested by combining MK801 with treatments of quinpirole (selective D2 agonist) and sulpiride (selective D2 antagonist) which cause significant decreases and D2 antagonist) which cause significant decreases and increases, respectively, in striatal NT levels. Pretreatment with MK801 did not alter the changes in NT levels mediated by either the selective D2 agonist or antagonist. These results suggest that NMDA-glutamate systems play a role in the regulation of striatal NT systems mediated by D1 receptors but not those associated with D2 receptors. (Supported by USPHS grants DA 00869 and DA 04222).

PARTIAL CHARACTERIZATION OF KAINIC ACID-INDUCED STRIATAL DOPAMINE RELEASE USING IN VIVO MICRODIALYSIS. D.P. Carrozza*, T.N. Ferraro, G.T. Golden, P.F. Reyes and T.A. Hare. Departments of Pharmacology & Neurology, Thomas Jefferson University, Phila, PA 19107. Three major subtypes of EAA receptors have been described which preferentially recognize the ligands N-methyl-D-aspartate, quisqualate and kainate (KA). The aim of this study was to partially characterize interactions between striatal EAA receptors and dopamine (DA) release using in vivo microdialysis. Male Spraque-Dawley rats underwent surgery while anesthetized with ketamine (100 mg/kg) acepromazine (10 mg/kg) and pentobarbital (10 mg/kg) for placement of bilateral guideshafts at coordinates signed to allow striatal microperfusion. After a 24-48 hour recovery period, animals were lightly anesthetized for insertion of a removable, concentric microdialysis probe and perfused with modified Ringer's solution at 2,75 μ/Jmin. Samples were collected at 15-minute intervals and analyzed using HPLC with EC detection. After baseline DA release was established, an isosmotic solution of 100 mM KCl in Ringer's was perfused for 10 minutes to standardize DA release. All subsequent pharmacological manipulations were compared to KCl-induced release and expressed as a percent value. In one group of animals, KA (12.5 mM in Ringer's) was administered via the microdialysis probe in 2, 3, 5 or 10-minute pulses resulting in release of DA which was 15.7±3.9%, 30.3±11.3%, 67.5±15.0% and 92.9±19.8% of KCl-induced DA release, Results showed a significant reduction of KA-induced DA release after cadmium treatment when compared to control values (from 29.9±19.8% to 45.5±10.8%, p<0.0005, n=6). The effect of i.p. administration of anesthesia on KA-induced DA release was also investigated. Microdialysis probes were inserted in freely-moving rats followed by establishment of baseline and standardization with 100 mM KCl. After a 3-minute KA pulse, animals were anesthetized with ketamine,

N-METHYL-D-ASPARTATE STIMULATED DOPAMINE RELEASE FROM RAT STRIATAL SLICES IS GREATLY ENHANCED BY ALUMINUM FLUORIDE. John J. Woodward. Dept. of Pharmacology and Toxicology,

Medical College of Virginia, Richmond, VA 23298.
N-methyl-D-aspartate (NMDA) stimulated the release of endogenous dopamine from striatal slices prepared from adult Sprague-Dawley rats. The EC50 for NMDA was approximately 140 uM. Release was inhibited by the specific glycine antagonist 7-Cl-kynurenic acid, magnesium, and the competitive NMDA antagonist, AP-5 indicating that release was due to activation of the NMDA receptor-coupled ionophore. Sodium fluoride (NaF; 5 mM) significantly potentiated the NMDA stimulated release of dopamine. This effect was further increased when a mixture of NaF and aluminum chloride (AlCl3) was added to the slices prior to NMDA stimulation. NaF (2.5 mM) and AlCl3 (5 uM) doubled the NMDA stimulated release over that of the control containing no added fluoride. A seven-fold increase in NMDA stimulated dopamine release was obtained with 5 mM NaF and 10 uM AlCl3. The NaF/AlCl3 mixture had no effect on the nonstimulated basal release of dopamine. No increases in NMDA stimulated release were observed when NaF was replaced with NaCl. Similarly, AlCl3 alone had no effect on NMDA stimulated release. The fluoride induced increase in NMDA stimulated dopamine release was totally blocked by 7-Cl-kynurenic acid or magnesium and was markedly reduced by 1 uM tetrodotoxin. Striatal slices depolarized with KCl also released dopamine and this release was similarly potentiated by the fluoride mxiture. However, KCl-stimulated dopamine release from striatal synaptosomes was not potentiated by concentrations of fluoride that greatly increased release from striatal slices. These results suggest that aluminum fluoride may enhance depolarization-induced dopamine release from striatal slices through activation of a GTP binding protein. INCREASE IN STRIATAL DOPAMINE RELEASE FOLLOWING LOCAL PERFUSION OF THE NMDA RECEPTOR ANTAGONIST AMINO-5-PHOSPHONOPENTANOIC ACID. R.J. Gruen, R.H. Roth, B.S. Bunney and B. Moghaddam. Depts. Psych. & Pharm., Yale Univ., New Haven, CT 06510 and Dept. Psychol., New York Univ., New York, NY 10003.

It has been suggested that excitatory amino acids tonically enhance striatal dopamine (DA) release by acting on the N-methyl-D-aspartate (NMDA) receptor. In vivo microdialysis techniques were used to examine the effect of local application of the NMDA receptor antagonist 2-amino-5-phosphonopentanoic acid (AP5) on DA release in the striatum of chloral hydrate anesthetized adult rats. AP5 was perfused for 15 minutes at a rate of 2 μ 1/minute through concentric microdialysis probes. Perfusion of 1 μ M and 100 μΜ AP5 was without a significant effect on extracellular DA while 1 mM AP5 significantly enhanced DA release. Our findings do not support the idea that excitatory amino acids have a tonic facilitatory effect on DA release which is mediated through the NMDA receptor. The enhancement of DA release following 1 mM AP5 may be due to Ca⁺⁺ channel agonist or partial NMDA agonist properties of that drug at higher concentrations. An alternative explantation for the observed increase in DA is that excitatory amino acids have tonic facilitatory effects on neuromodulators which inhibit DA release. Supported by MH28849 and MH14092.

INDIA RECEPTORS MODULATE STRIATAL DOPAMINE RELEASE AND METABOLISM IN VIVO: A MICRODIALYSIS STUDY. James P. Bennett, Jr. (1,2,3) and Catherine A. Leslie (2) Departments of Neurology (1), Behavioral Medicine and Psychiatry (2) and Pharmacology (3) University of Virginia School of Medicine, Charlottesville, VA

Pharmacology (3) University of Virginia School of Medicine, Charlottesville, VA 22908.

Studies in striatal slices suggest that excitatory amino acids (EAAs), principally glutamate (GLU), are the neurotransmitters of the massive corticostriatal/accumbens projections, and that GLU modulates dopamine (DA) release. We have examined the influence of the EAA agonist N-methyl-d-aspartic acid (MMDA) on levels of striatal extracellular fluid (ecf) DA and metabolites and amino acids in vivo using the technique of intracerebral microdialysis combined with simultaneous animal activity monitoring.

Guide cannulas were placed 48 hours prior the insertion of 3 mm length dialysis probes (Carnegie Medicin) into the dorsolateral striata of awake, freely moving animals. Probes were perfused with Mgy2-free artificial csf at 1 ul/min and dialysates were collected in 30 minute fractions while activity was continuously monitored (Columbus Instruments). After two hours of stable baseline, perfusate was switched to Mgy2-free csf with 10 mM NMDA. Intense stereotypic behavior followed, ecf DA increased 370% from baseline control levels by the third fraction after beginning NMDA infusion and then decreased to 130% of baseline two hours later. Ecf DDPAC, NVA and GLU fell to 49%, 39% and 30%, respectively, of baseline. The specificity of these effects was tested by systemic treatment with the NMDA cation channel antagonist MK801. MK801 (2 mg/kg i.p.) injected 30 minutes prior to NMDA infusion blocked the stereotypic behavior and increase in ecf DA. NMDA cation channel antagonist MK801. MK801 (2 mg/kg i.p.) injected 30 minutes prior to NMDA infusion blocked the stereotypic behavior and increase in ecf DA. MNDA cation channel antagonist MK801. mcsessed by systemic treatment with the NMDA cation channel association with the moduced fall in ecf DOPAC and HVA was also blocked by MK801. MK801 alone did not alter basal ecf DA levels but increased ecf DOPAC and HVA 20-30%. MK801 had no effect on the MMDA-induced decline in striatal ecf glutamate.

THE EFFECT OF SELECTIVE AGONISTS AND ANTAGONISTS OF EXCITATORY AMINOACID RECEPTORS ON DOPAMINERGIC AND CHOLINERGIC NEUROTRANSMISSION IN AWAKE RATS: POSSIBLE CLINICAL IMPLICATIONS. A. Imperato, L.H. Jensenŝ, L. Alivernini*, M.G. Scrocco*, S. Bacchi* and L. Angelucci. Farmacologia Medica 2a, Università "La Sapienza", Roma, Italia, and § Neurosearch, K-2600 Glostrup, Denmark.

Perfusion with the selective agonists kainate (KA) and quisqualate (QA) enhaced the release of dopamine (DA) in both caudate and accumbens nuclei inducing behavioural activation; both effects were prevented perfusion with the QA-KA antagonist DNQX. On the N-methyl-D-aspartate (NMDA) did not affect the release of DA in these areas, while was very potent in stimulating acetylcholine (ACh) release in the hippocampus. The selective NMDA antagonist, CPPene, decreased cholinergic transmission in the hippocampus. Moreover, perfusion of the nucleus accumbens and striatum with CPPene and MK801 enhanced DA release, also inducing a strong behavioural activation. This study suggests that the DA system is under an excitatory control through KA and QA receptors, while not through the NMDA ones, and that the QA-KA antagonists might be used to modulate DA release in case of its hyperactivity. On the contrary, the ability of NMDA antagonists to enhance DA release suggests that the blockade of these receptors could indirectly releave DAergic neurons from an inhibitory control, and that these compounds might have a therapeutical efficacy in syndromes linked to DAergic deficits. Moreover, the hippocampal cholinergic system is under a strong NMDA control, and the ability of NMDA antagonists to reduce the release of ACh indicates the <u>in vivo</u> biochemical basis of their learning and memory impairing effects.

MK-801, AND GLYCINE DIFFERENTIALLY MODULATE NMDA-EVOKED RELEASE OF ADENOSINE AND [3H]NORADREMALINE FROM RAT NEOCORTEX K. Hoehn, C.G. Craig and T.D. White, Dalhousie University, Halifax, Nova Scotia, Canada, B3H 4H7

Adenosine is an important inhibitory neuromodulator in the cortex. NMDA is more potent at releasing adenosine (EC₅₀-10_M) than ['H]NA (EC₅₀-330_MM) from superfused rat cortical slices. Block of NMDA-evoked adenosine release by each of 3 uncompetitive antagonists, that act at different sites on the NMDA receptor-ion channel complex, can be overcome by high NMDA concentrations. Thus 1.2mM Mg²⁺ (channel antagonist) blocks 10 and 20_MM NMDA-evoked adenosine release but does not block 500_MM NMDA-evoked adenosine release; release of [³H]NA evoked by 500_MM NMDA is blocked by 1.2mM Mg²⁺. With 500_MM NMDA release of both [³H]NA and adenosine are blocked by 3_MM K-801 (channel antagonist); however, 0.3_MM MK-801 blocks [³H]NA release without affecting adenosine release. The glycine site antagonist, 7-chloro-kynurenate (100_MM) blocks adenosine release evoked by 20_MM NMDA but does not block release evoked by 500_MM NMDA; release of [³H]NA evoked by 500_MM NMDA is blocked by 100_MM 7-chlorokynurenate. These results suggest that maximal adenosine release requires activation of only a small fraction of available NMDA receptors (i.e. there are spare receptors for NMDA-evoked adenosine release). The adenosine release at low levels of NMDA receptor activation could provide an inhibitory threshold against further NMDA-mediated neurotransmission in the cortex. (Supported by the MRC of Canada).

EFFECTS OF GLYCINE AND Mg⁺² ON QUINOLINATE-INDUCED ENDOGENOUS AMINO ACID RELEASE FROM CULTURED CEREBELLAR NEURONS. M.A. Barry, F. Stastny and G.R. Dutton, Department of Pharmacology, University of Iowa. College of Medicine. Iowa City. IA 52242.

University of Iowa, College of Medicine, Iowa City, IA 52242. Quinolinic acid [QUIN], a metabolite of tryptophan, mimics the neurotoxic action of N-methyl D-aspartate [NMDA] resulting in selective necrosis of granule cells in the rat cerebellum. Thus, we studied amino acid release from cultured cerebellum stimulated with QUIN in the presence and absence of Mg 1 man amino acid release was measured using HPLC. In the presence of Mg 2, QUIN increased the release of aspartate, glutamate, alanine, CABA, serine and adenosine in a dose dependent manner. Taurine release increased only in response to 10 mM QUIN. Removal of Mg 2 increased basal release levels of only serine and GABA. Stimulation with QUIN under these conditions further increased the release of adenosine, serine, taurine and GABA in a dose dependent manner. In the presence of Mg 2, glycine [1 mM] potentiated the effect of 10 mM QUIN alone on GABA and adenosine release. On the other hand, in the absence of Mg 2, glycine potentiated the effect of QUIN on GABA and taurine release. Glycine alone had no effect in either the presence or absence of Mg 2. These results suggest that the QUIN-evoked release of taurine and GABA may be modulated through the glycine site on the NMDA receptor.

3 H-D-ASPARTIC ACID RELEASE IN CORTEX AND HIPPOCAM-PUS OF ADULT AND AGED FISCHER 344 RATS. M.J. MELDRUM, P. GLENTON*, R. DAWSON, DEPT. OF PHARMACODYNAMICS, COLL. OF PHARMACY, UNIV. OF FLORIDA, GAINESVILLE, FLORIDA. 32610.

Endogenous excitatory amino acid induced excitotoxicity has been implicated in several neurodegenerative diseases. Age-related increases in glutamate release may contribute to the neuronal loss attributed to the "normal" aging process. The present study used basal and stimulated 3H-D-Aspartic acid (3H-D-ASP) release as a marker for glutamatergic activity in adult (6 month) and aged (28-30 month) male Fischer 344 rats. KCL (40,56 mM) and electrical induced stimulation of 3H-D-ASP release was measured in superfusion studies in cortical (frontal and temporal) and hippocampal slices. KCL (56 mM) induced 3H-D-ASP release was elevated in hippocampus but not in frontal cortex of aged Fischer 344 rats compared to adult animals. Frequency dependent (2,5,10,15,20 Hz) 3H-D-ASP release was elevated at 10 Hz in hippocampus and 15 Hz in temporal cortex in aged vs. adult animals. In comparison to 3H-norepinephrine (3H-NE) release measured in the same brain areas, 3H-D-ASP release required much higher levels of stimulation to induce release. Ornega-Conotoxin GVIA (5 x10-9 M, 30 min) failed to decrease 3H-D-ASP release in both adult and aged animals in either brain area but decreased 3H-NE release > 70 %. These data suggest that 3H-D-ASP release is altered in temporal cortex and hippocampus but not frontal cortex of aged Fischer 344 rats. The data also suggest differences in the glutaminergic neuronal release system when compared to catecholamines. (Supported by American Federation for Aging Research)

EXCITATORY AMINO ACIDS AUGMENT MET-ENKEPHALIN RELEASE FROM SLICES OF THE RAT STRIATUM AND GLOBUS PALLIDUS. K. Jhamandas and B.B. Ruzicka. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

PALLIDUS. K. Jhamandas and B.B. Ruzicka. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, KTL 3MC. To determine if a functional interaction exists between excitatory amino acids (EAA's) and opioid-containing neurons, the effects of four EAA's and quisqualate (GLU), M-methyl-D-aspartate (NMDA), kainate (KA) and quisqualate (QUIS) - on the release of endogenous met-enkephalin (ME) from slices of the rat striatum or globus pallidus were examined. GLU and NMDA (1-5 mM), in the absence of Mg^2+ , increased the ME release from both striatal and pallidal slices in a concentration related manner. A higher concentration (10 mM) of the two EAA's produced smaller increases in the ME release. The NMDA (5 mM)-induced elevations in striatal and pallidal ME release were attenuated by Mg^2+ (1.2 mM) and the NMDA receptor antagonists, TCP (10 μ M) and CPP (5 μ M). KA (1-10 mM) also stimulated ME release from both the striatum and globus pallidus. The striatal release response was concentration-dependent, and was greater than that observed in the globus pallidus In the striatum, the KA (5 mM)-evoked ME release was Ca²⁺-dependent and was partially reduced by tetrodotoxin (0.3 μ M), Mg^2+ (1.2 mM) and CPP (5 μ M), suggesting that a component of the KA action involved the activation of NMDA receptors. QUIS (5-10 mM) only weakly stimulated the release of ME from both the striatum and globus pallidus. These results show that activation of EAA receptors increase the release of ME from the Medical Research Council of Canada)

Psychiat., Gumma Univ.Med.Sch., Maebashi371, Japan. We found the treatment with glutamate to neonatal rats resulted in an elevation in immunoreactive(IR)-SRIF in the limbic structures after matured. It was reported that lesions by quinolinic acid, a NMDA-receptor agonist, spares SRIF neurons. To clarify the role of excitatory amino acid receptor subtypes on SRIF neurons, changes of IR-SRIF in the rat brain were examined following intraventricular administration with QUIS (2, 10ug; 1h to 14 days after the treatment) and compared with those following kainate treatment. QUIS(10 ug) induced a reduction in IR-SRIF in the hippocampus, amygdala, hypothalamus and piriform/entorhinal cortex. This was most evident and long lasting in the hippocampus. Preliminary data exhibited the kainate treatment without effect on brain IR-SRIF levels. The effect of Joro-spider toxin, a putative QUIS-receptor antagonist, on SRIF is currently under study, but it appears the toxin fails to inhibit QUIS-induced changes in IR-SRIF.

A CONFORMATIONALLY DEFINED INHIBITOR OF SYNAPTOSOMAL L-GLUTAMATE UPTAKE R.J. Bridges. M.A. Anderson*, T.N. Blakely*, E.R. Whittemore, C.W. Cotman and A.R. Chamberlin*, Depts. of Neurology, Psychobiology, and Chemistry, University of California, Irvine, CA 92717.

L-Glutamate binds to several different proteins during the course of excitatory synaptic transmission (e.g., transmitter receptors, transport systems). In vivo, endogenous L-glutamate binds to all of these sites, while in vitro, analogues of L-glutamate that mimic specific conformations exhibit selective affinities and can, thus, differentiate among the binding sites. In the present study we have identified a conformationally restrained analogue of L-glutamate (L-trans-2,4-pyrrolidine dicarboxylate; L-t-2,4-PDC) that potently and selectively blocks the transport of ³H-D-aspartate through the sodium-dependent uptake system in rat cortical synaptosomes. When included in the uptake assay at an equal concentration with ³H-D-aspartate (50µM), the novel analogue reduced the rate of uptake by about 50%. In contrast to its ability to block transport, L-t-2,4-PDC was ineffective at inhibiting the binding of ³H-KA, ³H-AMPA and ³H-L-glutamate to kainate, AMPA, and NMDA receptors, respectively. The D-trans, L-cis, and D-cis isomers of 2,4-PDC did not inhibit the synaptosomal uptake of the ³H-D-aspartate. These results suggest that L-t-2,4-PDC embodies specific structural/conformational characteristics necessary for the binding to the sodium-dependent uptake system that are distinct from those required for binding to the, KA, AMPA, and NMDA receptors.

EFFECT OF SYSTEMIC KAINATE ADMINISTRATION ON THE PRODUC-TION OF KYNURENIC ACID IN THE RAT BRAIN IN VITRO AND IN VIVO. W.A. Turski, H.-Q. Wu and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD 21228.

Kynurenic acid (KYNA) possesses anticonvulsant properties in animal models of epilepsy. Conversely, KYNA function may be compromised by convulsant agents. We therefore examined the effect of kainate (KA; 10 mg/kg, s.c.) on KYNA production from its bioprecursor L-kynurenine (KYN) in vitro and in vivo.

Slices from piriform cortex, hippocampus and striatum were obtained at various timepoints following KA administration and incubated with 50 μ M KYN for 2 h. No changes in extracellular KYNA were observed in slices obtained during status epilepticus. After one month, KYNA production was increased in the piriform cortex (+370%) and the hippocampus (+218%) but not in the striatum. Subsequently, microdialysis (perfusion with 200 μM KYN) experiments were performed in the piriform cortex of unanesthetized rats.
KA, administered after attainment of steady-state KYNA levels, did not change extracellular KYNA levels during an additional 4 hours (i.e. during status epilepticus). One month after KA, KYNA production from KYN was doubled as compared to controls. These data demonstrate 1) qualitative resemblence of <u>in vitro</u> and <u>in vivo</u> assessment of KYNA function; 2) a lack of KYNA involvement in KA-induced seizures and 3) an increase in KYNA function in chronically KA-lesioned brain areas. (Supported by grant NS 16102).

AMAA - A POTENT AND SELECTIVE EXCITATORY AMINO ACID AGONIST AT NMDA RECEPTORS.

U. Madsen*, J.W. Ferkany#, B. Ebert* and P. Krogsgaard-Larsen, Department of Organic Chemistry, The Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark, #Nova Pharmaceutical Corporation, Baltimore, Maryland, USA.

Much pharmacological and therapeutic interest is focused on receptors for excitatory amino acids (EEAs). The NMDA subtype of EAA receptors has been characterized in some detail, especially due to the availability of a number of competitive as well as non-competitive antagonists. However, very few potent and selective NMDA agonists have been described. In binding studies and neuropharmacological experiments in different rat cortical tissue preparations (RS)-2-amino-2-(3-hydroxy-5-methylisoxazol-4-yl)acetic acid (AMAA) has been shown to be a very potent NMDA agonist, slightly more active than NMDA, with no significant activity at other EAA receptor subtypes. In contrast to NMDA, AMAA is also a very potent neurotoxin slightly more toxic than kainic acid and considerably more toxic than quinolinic acid. Two series of analogues of AMAA and AMPA (a selective AMPA agonist) have been characterized biochemically and pharmacologically. Distinct differences in the structural requirements for activation of NMDA and AMPA receptors have been revealed. The pharmacological and toxicological profiles of AMAA and the bicyclic analogue, 4-HPCA, as well as quinolinic acid are consistent with heterogeneity of the NMDA receptors.

CARDIOVASCULAR RESPONSES TO COMPETITIVE AND NON-COMPETITIVE NMDA ANTAGONISTS. <u>L.A. Martin*, M.E.Abreu and J.W. Ferkany.</u> Nova Pharmaceutical Corporation, Baltimore, MD 21224

Several lines of evidence suggest that excitatory amino acid (EAA) antagonists and in particular antagonists of the NMDA receptor are effective in attenuating neuronal damage following ischemic or hypoxic insult to brain. Included in this would be hypoxia or ischemia associated with myocardial arrest. For this reason, EAA antagonists are of considerable interest as novel theraneutics.

In the current study competitive and noncompetitive NMDA antagonists were evaluated for effects on cardiovascular function following intravenous administration in urethane-anesthetized rats. Cumulative doses of the compounds were administered at 10 minute intervals and arterial pressure (MAP) and heart rate (HR) were monitored. The noncompetitive antagonist (+) MK-801 produced dose-dependent transient decreases in MAP with a maximal hypotensive effect (50% reduction in MAP) observed at 0.5 mg/kg. Similar MAP decreases were observed with (-) MK-801 although 5-10-fold higher doses were required. The competitive NMDA antagonists, CPP and CGS 19755, elevated MAP 15-20% above baseline at the lowest doses (5 and 0.5 mg/kg, respectively) while hypotension was evident at higher doses (40-50 mg/kg). Interestingly, NPC 12626 (competitive NMDA antagonist) had virtually no effect on arterial pressure, producing only minor decreases at the highest doses

tested (250 mg/kg). Heart rate was not affected with any compounds tested. These results suggested that NPC 12626 elicits fewer cardiovascular effects than other NMDA antagonists when evaluated in anesthetized animals. Since other pharmacological actions of NPC 12626 occur at doses similar to CPP and CGS 19755, NPC 12626 may represent a physiologically safer alternative in the treatment of ischemic insult.

EXPRESSION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR

EXPRESSION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR GENES IN CELLS OF, THE SH-SY5Y HUMAN NEUROBLASTOMA. S. Norman, L. Lucero and R.J. Lukas. Division of Neurobiol., Barrow Neurol. Institute, Phoenix, AZ 85013. SH-SY5Y is a human neuroblastoma clonal cell line of presumed neural crest origin (Ross et al. JNCI 71:741-747, 1983). These cells express functional ganglia-type nicotinic acetylcholine receptors (nAChR) that mediate nicotinic agonist-stimulated 80 Rb+ efflux sensitive to blockade by mecamylamine but not by aloha-bungarotoxin blockade by mecamylamine but not by alpha-bungarotoxin (Lukas, *Soc. Neurosci. Abst.* 15:497, 1989). SH-SY5Y cells also express neuronal nicotinic alpha-bungarotoxin binding sites (nBgtS), which bind radiolabeled toxin with high affinity and appear to have pharmacological features and subunit profiles similar to those of nAChR, but do not

appear to function as nicotinic ligand-gated ion channels.
Northern blot analysis of SH-SY5Y cell RNA, using rat
neuronal nAChR subunit cDNA as probes (Deneris et al.
Clin. Chem. 35:731-737, 1989), demonstrates that these
cells express transcripts homologous to neuronal nAChR alpha3 and beta2 subunit genes but distinct from those identified on Northern blot analysis of rat PC12 cell RNA (see Boulter et al. *J. Biol. Chem.* 265:4472-4482, 1990). These results suggest that human alpha3-like and beta2 like subunits may be part of a human ganglia-type nAChR. Rat neuronal probes are being used to screen an SH-SY5Y cell cDNA library for clones corresponding to the human alpha3-like and beta2-like transcripts.

AMPLIFICATION OF GENOMIC SEQUENCES IDENTIFIES A NEW GENE, ALPHA 6, IN THE NICOTINIC ACETYLCHOLINE RECEPTOR GENE FAMILY. E. Lamar, K. Miller*, and J. Patrick, Div. of Neuroscience, Baylor College of Medicine, Houston TX

It is well established that the subunits of nicotinic acetylcholine receptors (nACHR) are members of a gene family. Five members of the family have been classified as alpha (α) subunits on the basis of contiguous cysteines at positions 192 and 193 (α 1-5); four of these (α 1, 2, 3, and 4) participate in the formation of functional nACHRs in vitro.

We used the polymerase chain reaction technique with highly degenerate primers to amplify rat genomic DNA. Oligonucleotides made to conserved regions of nACHR subunits in the extracellular and membrane-spanning I domains amplified a 321 base-pair open reading frame between amino acids 134 and 241 (corresponding to Torpedo a 1 numbering scheme) that was 76% homologous on the amino acid level to the previously described α 3 subunit. The sequence contained cysteines at positions 142, 192, and 193; these amino acids are conserved in all nicotinic α subunits characterized to date. In addition, the sequence contains a tyrosine residue at position 190, a feature common to all functional nicotinic α subunits. Therefore, we identify our sequence as part of a gene encoding a new member of the nACHR-

related gene family, α 6.

Alpha 6 mRNA appears to be more abundant in early developmental stages than in adult rat: Northern blot analysis of brain mRNA showed strong hybridization of α 6 riboprobes to a dominant 3 kilobase band in day 11 and day 22 rats, and only faint hybridization to adult mRNA.

DEVELOPMENTALLY REGULATED AND BUNGAROTOXIN SENSITIVE AVIAN NEURONAL nAChR SUBUNIT.

J-M. Matter, S. Couturier*, D. Bertrand and M. Ballivet. Depmt.

of Biochemistry, 30 Quai Ansermet, 1211 Geneva 4, Switzerland. We have isolated from a chicken brain cDNA library a clone defining the novel neuronal nAChR subunit alpha7. The cDNA, 2500 bp in length, contains an ORF encoding a mature protein of 479 residues preceded by a signal peptide and showing homology throughout with all other alpha and non-alpha nAChR subunits. Its amino-terminal sequence closely matches the published amino-terminal 24 residues of one of the subunits of the chick optic lobe alpha-bungarotoxin binding protein. Northern blot analysis and in situ hybridizations demonstrate that alpha7 transcripts transiently accumulate in the optic tectum between E5 and E16, at the time when tectal neurons form their connections with retina and other regions of the brain. Bilateral eye removal at E2 does not prevent this accumulation. The alpha7 cDNA was subcloned into an expression plasmid and injected into Xenopus oocyte nuclei, either alone or in combination with other neuronal and muscle nAChR subunit cDNAs. ACh sensitivity of the injected oocytes was then examined in voltage clamp. The only tested combination of subunits yielding ACh-induced currents was alpha7/beta/gamma/delta and these currents were blocked by alpha-bungarotoxin. We conclude that alpha7 is probably one of the subunits of a developmentally regulated, bungarotoxin binding protein and that these proteins may function as ACh gated ion channels.

LOCALIZATION OF HUMAN NEURONAL NICOTINIC RECEPTOR SUBUNITS. M. Cimino ζ* D. Fornasari ξ* B. Chini ξ* P. Tarroni ξ* F. Cattabeni ζ and F. Clementi ξ. Inst. of Pharmacology, Univ. of Urbino and Milano ζ; CNR Center of Cytopharmacology, Univ. of Milano ξ,

Urbino and Milano ζ; CNR Center of Cytopharmacology, Univ. of Milano ξ, Milano, 20133 Italy.

Neuronal nicotinic receptors (nAchRs), expressed in rodents and chicken, are multimeric proteins constituted of two different subunits, alpha and beta. Although nAchRs appear to be involved in human degenerative disorders, no information was available on their primary structure and localization in the human nervous system. We have cloned from a human IMR 32 neuroblastoma cell line cDNA library two neuronal alpha subunits, alpha 3 and alpha 5, and a beta subunit which are highly homologous to the rat nicotinic subunits. The anatomical localization of the human alpha 3 subunit was studied using in situ hybridization histochemistry. Both sense and antisense ³⁵S radiolabeled riboprobes were transcribed from an insert subcloned in a pGEM 4 Z vector. Sections (10 μm) of autoptic human brain, monkey brain (Cynomolgus), rat brain, containing the medial habenula and the hippocampal formation and sections of human sympathetic lumbar ganglia were hybridized with the radiolabeled probes. A strong specific signal was observed in the human sympatethic lumbar ganglia were hybridization in most of the neurons, but up to now no positive hybridization signal was observed in the other examined tissues. A moderate cross hybridization in the rat brain was noticed in the medial habenula. On the hears of our data we can conclude that a human alpha 3 subunit of the neuronal nicotinic receptor is strongly expressed in human simpathetic ganglia. ganglia.

PHARMACOLOGICAL CHARACTERISATION OF AN ACETYL-PHARMACOLOGICAL CHARACTERISATION OF AN ACETYLCHOLINE RECEPTOR ON THE SOMATIC MUSCLE CELL OF
ASCARIS SUUM. L. Colquhoun*, L. Holden-Dye* and
R.J. Walker. (SPON: Brain Research Association).
Dept. of Neurophysiology, University of
Southampton SO9 3TU.
Acetylcholine is the excitatory neurotransmitter

Acetylcholine is the excitatory neurotransmitted in the parasitic nematode, Ascaris suum. We have extensively characterised this cholinoceptor using conventional electrophysiological recording techniques. The agonist profile indicates a nicotinic ganglionic type of receptor; hydroxyphenylpropyltrimethylammonium (HPPT) and dimethylphenylpiperazinium (DMPP) are potent dimethylphenylpiperazinium (DMPP) are potent agonists, bethanechol and methacholine are agoinsts, bethatehol and methalonthic are ineffective up to 1 mM. Although mecamylamine is a potent antagonist, indicating a ganglionic-type receptor, hexamethonium is weak. α -Bungarotoxin partially blocks at 1 μ M, curare, atropine and pancuronium all block in the low micromolar range.

The results indicate the receptor is nicotinic and resembles the frog ganglionic receptor.
Further experiments including expression of the

receptor-channel protein in Xenopus occytes are being carried out to study receptor characterisation, subunit structure and structure-function

We are grateful to the SERC and JEA for funding.

AFFINITY CHROMATOGRAPHY OF A NICOTINIC ACETYLCHOLINE RECEPTOR FROM RAT BRAIN. A.J. Dwork and J. Desmond*. Department of Neuropathology and Neurotoxicology, N. Y. State Psychiatric Institute; Division of Neuropathology, Columbia University, New York, NY 10032 An acetylcholine affinity resin, prepared by reacting bromoacetylcholine bromide with Affi-Gel 401 (Bio-Rad), is commonly used for the purification of nicotinic acetylcholine receptor (NACHR) from electric tissue. We report the use of this affinity gel for the isolation of NACHR from rat brain. Triton-solubilized extract of a membrane fraction from rat brains was affinity gel for the isolation of NACHR from rat brain. Triton-solubilized extract of a membrane fraction from rat brains was incubated with the affinity gel. After extensive washing of the gel, the receptor was specifically eluted with nicotine. Typically, the affinity resin removed 75-90% of [4H]l-nicotine binding sites from solution, and 10-20% of the bound sites were recovered from the resin. Polyacrylamide gel electrophoresis yielded two protein bands, of apparent molecular weights 80,000 and 49,000, only in the specifically eluted fractions. Minor contaminating bands in these fractions were identically present in the previous wash fraction (which lacked nicotine-binding activity), and thus are not part of the receptor. Preliminary results indicate a dissociation constant for l-nicotine of -8nM both in the original Triton extract and in the specifically eluted material.

Our results provide independent confirmation of the subunit size and composition reported for rat brain NACHR isolated by

size and composition reported for rat brain NACHR isolated by immunoaffinity methods (Whiting, P., and Lindstrom J., <u>Proc. natl. Acad. Sci. USA</u>, 84:595, 1987). Our technique should prove applicable to the study of NACHR from brains of other species. Supported by the Smokeless Tobacco Research Council

MOLECULAR CLONING OF A NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR FROM DROSOPHILA. X.chang, P.Wu, J.Wu, L.C.Yang, H.Meones, S.Bobin, and T.Schmidt-Glenewinkel, Department of Biological Sciences, Institute for Biomolecular Structure and Function, Hunter College of CUNY, New York, NY 10021

The central nervous system of <u>Drosophila</u> contains an bungarotoxin binding site with the properties expected of a nicotinic acetylcholine receptor. The receptor was purified 6000-fold by affinity chromatography. Sodium dodecyl sulfate polyacrylamide gel electrophoresis revealed two subunits with apparent molecular weights of 42,000 and 57,000. Polypeptides of identical size were also identified by in situ photoaffinity labeling of the membrane fraction. From sedimentation analysis in H₂O and D₂O a molecular weight of 270000 was determined. The individual polypeptides were blotted on a nitrocellulose membrane, digested <u>in situ</u> with trypsin and separated by microbore HPLC. Isolated peptides subjected to amino acid sequence analysis. Mixed oligo-nucleotide probes derived from the amino acid sequence were constructed and used for screening of a cDNA library in either SSPE or tetramethylammonium chloride. Several cDNA clones were isolated corresponding to the peptide sequences indicating receptor heterogeneity.

EXPRESSION OF mRNAs IN HUMAN THYMUS CODING FOR THE CC3 SUBUNIT OF A NEURONAL ACETYLCHOLINE RECEPTOR. M. Mihovilovic and A.D. Roses, Dept. of Medicine and Dept. of Neurobiology, Division of Neurology, Duke University Medical Center, Box 2900, Durham, NC 27710.

Myasthenia gravis (MG) is an autoimmune neuromuscular disease in which the breakdown of tolerance comprises a number of muscle antigens, the best characterized is the nicotinic acetylcholine receptor (AcChR). The association of thymic abnormalities with MG, and the expression in thymus of material that binds α bungarotoxin and/or shows immunological cross-reactivity with antibodies raised against the neuromuscular AcChR led to propose that thymic AcChRs or AcChR-like material may be involved in the triggering and/or maintenance of this autoimmune condition.

To investigate the nature of the AcChR expressed in thymus we searched for cDNA clones present in cDNA human thymic libraries that would hybridize to cDNA probes whose nucleotide sequences encode for the subunits of the neuromuscular AcChR. This experimental approach resulted in the isolation of clones from a human thymus library that code for the α3 subunit of a neuronal acetylcholine receptor (AcChR). The clones hybridize to a major 3.0 Kb mRNA thymic species and 4 minor ones of approximately 2.3, 4.0, 5.0 and 6.5 Kb, but they do not hybridize to human muscle mRNA. In contrast a cDNA probe that encodes for the C subunit of the neuromuscular AcChR hybridizes to a 2.3 Kb mRNA expressed in muscle, but that is not evident in thymus

Reported findings suggest thymic expression of nicotinic neuronal AcChR could be responsible for cholinergic immunoreactivity found in thymic (epithelial) cells. These thymic clones will be valuable in defining the cholinergic thymic make-up and putative role that thymic AcChR may have in triggering and/or maintenance of an anti-AcChR response in MG.

INTERACTION OF THYMOPOIETIN WITH NICOTINIC RECEPTORS IN C2 MUSCLE CELLS IN CULTURE. M. Greenbaum*, T. Audhya*, G. Goldstein and M. Quik. Dept. Pharmacol., McGill Univ., Montreal, Canada and Immunobiol. Res. Inst., Annandale, NJ, USA.

Thymopoietin is a thymus derived polypeptide which

potently binds to the nicotinic α -bungarotoxin (α -BGT) receptor population in neuronal tissues and electroplax Current work in our laboratory also indicates that thymopoietin interacts at the nicotinic receptor at the neuromuscular junction. The present experiments were done to determine whether muscle nicotinic receptors could be regulated by thymopoietin using a muscle cell line (C2 cells in culture). Initial studies showed that thymopoietin potently inhibited $[^{125}I]_{\alpha}$ -BGT binding to C2 muscle cells in culture with an IC50 of 2 nM; this was similar to the IC50 for α -BGT, while nicotinic receptor ligands were effective in the uM range. posure of the cells in culture to various concentrations of thymopoietin (followed by extensive washing of the cells to remove unbound polypeptide) resulted in a marked reduction in the binding of $[^{125}\mathrm{I}]\alpha\text{-BGT}$ to the cells, with an IC50 of approximately 3 nM; the decrease in binding was observed as early as 4 hr after exposure to thymopoletin. Thus the present results show that the polypeptide thymopoietin can potently interact at and regulate nicotinic receptors in muscle cells culture.

DEFINITION OF T CELL EPITOPES IN RECOMBINANT HUMAN ACETYLCHOLINE RECEPTOR α SUBUNIT SEGMENT 1-210. M. Hayashi*, D.J. McCormick*, S. Talib*, T. Okarma*, V.A. Lennon. Mayo Clinic, Rochester, MN 55905 and Applied ImmuneSciences, Inc., Menlo Park, CA 94025. The pentameric complex of human skeletal

The pentameric complex of human skeletal muscle's nicotinic ACh receptor (AChR) is the target for pathogenic antibodies in myasthenia gravis. Potential T cell regulatory segments in the α subunit's N terminal (extracellular) domain were investigated by testing in vivo delayed hypersensitivity and in vitro lymphocyte responses to synthetic peptides in rats immunized with a recombinant human AChR α subunit protein comprising residues 1-210.

protein comprising residues 1-210.

Of 27 peptides (each 16 residues, overlapping its neighbor by 8 residues), 4 were stimulatory for immune T cells: 9-24 and 41-56 identified two previously unknown T cell stimulatory regions; 121-136 and 129-144 helped define at least two T cell epitopes (provisionally 125-131 and 132-144) in the previously identified myasthenogenic region 125-147 (Ann NY Acad Sci 505:439, 1987; J Immunol 139:2615, 1987).

Recombinant and synthetic autoantigens offer tools for investigation and potential therapy of myasthenia gravis. Supported in part by NIH NS15057/NS24694 and the Wm.K. Warren Foundation.

DIFFERENCES BETWEEN THE ADULT AND EMBRYONIC #-SUBUNIT OF TORPEDO ACETYLCHOLINE RECEPTOR. M.C. Sourcujon, S. Carmon*, A. Safran* and S. Fuchs.

Of Israel and Department of Chemical Immunology, The Weizmann Institute of Science, Rehovot 76100, Israel.

During development in some mammalian species, the embryonic #-subunit of acetylcholine receptor (AChR) is

During development in some mammalian species, the embryonic 1-subunit of acetylcholine receptor (AChR) is replaced by an adult c-subunit. It is of interest to find out whether Torpedo AChR also displays two alternative forms of the 1-subunit. The known Torpedo 1-subunit possesses a putative phosphorylation site that is present in all known c-subunits, but is absent in their respective 1-subunits. Antibodies against a synthetic peptide corresponding to residues 346-359 of the Torpedo AChR 1-subunit, and containing this phosphorylation site, react strongly with adult and hardly with embryonic Torpedo 1-subunit. The differential reactivity of the anti-1 peptide antibodies does not reflect differences in the state of phosphorylation. Also, the 1-subunit of the adult Torpedo AChR is phosphorylated by exogenous cAMP-dependent protein kinase to a much higher extent than its embryonic counterpart. Thus it appears that the known Torpedo 1-subunit represents an adult form of this subunit and is different, at least in the region of the phosphorylation site, from the crossreactive embryonic form. It should still be tested whether the embryonic and adult forms of the Torpedo AChR 1-subunit are coded by two different genes.

285.10

THYMOPOIETIN-INDUCED PROCESS FORMATION IN PC12 CELLS IN CULTURE IS DISTINCT FROM THAT INDUCED BY NOF. J. Philie*, S. Geertsen, T. Audhya*, G. Goldstein and M. Quik. Dept. Pharmacol., McGill Univ., Montreal, Canada and Immunobiol. Res. Inst., Annandale, NJ, USA.

Previous studies had shown that thymopoietin (TPO), a thymic polypeptide, potently decreased [125][a-

bungarotoxin (BGT) binding to a nicotinic receptor population in PCl2 cells. In addition, TPO resulted in process formation in the cells in culture. NGF also results in neurite extension in PC12 cells. present experiments were done to determine the relationship between the NGF and TPO induced process A Mab to NGF, which completely prevented outgrowth. the NGF induced changes in PC12 cell morphology, did not alter the neurite extension which occurred in the presence of TPO. Experiments were also done in which the cells in culture were exposed to both NGF and TPO the process formation which occurred in the presence of the two polypeptide was greater than additive. posure of the cells in culture to $\alpha\text{-BGT}$ resulted in process formation which was not altered by the NGF Mab the effect of both NGF and $lpha ext{-BGT}$ was also more than additive. These results suggest that the TPO induced process extension is distinct from that induced by NGF, and furthermore, that the two polypeptides potentiate each others action to initiate process outgrowth.

THE DISTRIBUTION OF α -BUNGAROTOXIN BINDING PROTEIN IN THE CHICK RETINA: AN IMMUNOHISTOCHEMICAL STUDY. <u>K.T. Keyser</u>, <u>#R. Schoepfer</u>, <u>*#W.G. Conroy</u>, *@P.J. Whiting, *#M. Gore, *A. <u>Prechl-Brzozowska</u>, <u>H.J. Karten</u> and <u>#J. Lindstrom</u>. Department of Neurosciences, UCSD, La Jolla, CA 92093, *Receptor Biology Lab, The Salk Institute, La Jolla, CA 92138 and @Merck, Sharp and Dohme Laboratorics, Essex, England.

Alpha bungarotoxin (α Bgt) binds to proteins in the CNS which are related to, but distinct from, acetylcholine receptors in muscle and brain. Their function is unknown. Antibodies that recognize the ligand binding subunit of two subtypes of the α Bgt binding protein (α BgtBP) have been prepared to purified α Bgt and to bacterially expressed peptides from cDNAs. The antibodies were used to investigate the distribution of α BgtBP in chick retina.

Neurons in the inner nuclear layer (INL) and ganglion cell layer (GCL) exhibited α BgtBP immunoreactivity. Stained medium to large cells were found in the inner tiers of cells in the INL while a population of smaller stained cells was restricted to a region closer to the outer plexiform layer (ONL). The dendrites of both populations of cells could be traced to the inner plexiform layer (IPL) where they contributed to a complex pattern of stratified processes. The dendrites of some of the labeled cells in the outer INL projected to the OPL. Many cells of various sizes were labeled in the GCL. The dendrites of these cells also contributed to the complex pattern of fibers in the IPL. Although the function of these proteins is undetermined, their distribution in the retina suggests that they may be important for retinal function. Supported by EY07845 (KTK), EY06890 (HJK) and grants from NIH, MDA & CTR (JL).

EFFECTS OF BARBITURATES ON CHOLINERGIC BINDING TO NEURONAL NICOTINIC RECEPTORS. B.A. Dodson and L.M. Braswell*. Dept. of Anesthesia, UCSF, San Francisco, CA 94143

This study examines the effect of secobarbital, amobarbital, pentobarbital, methohexital and thiopental on high affinity postsynaptic, nicotinic, cholinergic binding to synaptosomes prepared from freshly dissected rat cerebral cortex. The binding of 3 H-acetylcholine (3 H-ACh, 10nM) to neuronal nicotinic acetylcholine receptors (nAChR) (200 μ l of 5% brain homogenate = 50-60 ACh binding sites/mg protein) with and without barbiturate (10-6-10-2 M) was determined by feltration assay (Schwartz, RD, Molec Pharm 22:56, 1982). Experiments were performed in triplicate at 4°C in TRIS buffer containing atropine to block muscarinic binding. Binding in the presence of 0.1mM carbachol was defined as nonspecific. Secobarbital produced the greatest effect of the barbiturates examined, decreasing ³H-ACh binding to 60% of control values. Amobarbital and pentobarbital were less efficacious with maximum decreases of approximately 20% Methohexital and thiopental had minimal effects on ³H-ACh binding. These results differ from those obtain in previous studies using *Torpedo* nAChR; in which amobarbital and pentobarbital decreased binding by 75% and 60%, respectively (Dodson, BA, Molec Pharm 32:119, 1987), and secobarbital, methohexital and thiopental increased ³H-ACh binding (Dodson, BA, J. Neurosci 14:914, 1988). These findings suggest that barbiturates may have different mechanism(s) of action for different nicotinic receptor subtypes. (Supported by NIH Grant GM35997)

(*H)CYTISINE BINDING TO NICOTINIC CHOLINERGIC RECEPTORS IN BRAIN. L.A. Pabreza*, S.R. Wheeler* and K.J. Kellar. Department of Pharmacology, Georgetown Univ. Medical Center, Washington, DC 20007.

Cytisine, a ganglionic type nicotinic agonist, has high affinity for neuronal nicotinic receptors in competition studies against other [³H]agonists. We have characterized the binding of [³H]cytisine to rat brain homogenates. [3H]Cytisine was labeled to a specific activity of 12.4 Ci/mmol by Dr. E. Do (NEN Dupont). Brain homogenates were incubated with 0.2-12 nM $[^3H]$ cytisine at 2°C for 75 min in the absence or presence of 10 μ M nicotine Picytisine at 2°C for 75 min in the absence or presence of 10 µM nicotine to measure total and nonspecific binding, respectively. Specific binding represented 50-80% of total binding at all concentrations of [*H]cytisine tested. The K₄ of [*H]cytisine for its binding sites is approximately 0.7 nM, which represents an affinity 5-15 times higher than that of other available [3H]nicotinic ligands. The density of sites labeled in various areas of brain is similar to that found using other labeled nicotinic agonists. Drug competition studies indicate that the binding site has a nicotinic cholinergic pharmacology. Thus nicotine, acetylcholine (in the presence of a cholinesterase inhibitor) and carbachol compete with high affinity for [3H]cytisine binding sites. Among antagonists tested, only dihydro-8-erythroidine (D8E) has high affinity for the site ($IC_{90} = 100 \text{ nM}$). Saturation studies of I^{3} Hlcytisine binding in the presence of DBE indicated that this antagonist binds in a competitive manner. Mecamylamine, though of much lower affinity, also appeared to bind competitively. If confirmed, this would be in contrast to mecamylamine's noncompetitive binding to sites labeled by [3H]n-methylcarbamylcholine. These results indicate that [3H]cytisine will be a useful ligand for further studies of nicotinic cholinergic receptors. (Supported by DA 06486)

USE OF MECAMYLAMINE (MEC) AND LOBELINE (LOB) TO ESTIMATE NONSPECIFIC BINDING OF RADIOLABELED NICOTINE (NIC) IN VIVO A.S. Kimes, D.F. Wong, and E.D. London. NIDA Addiction Res. Ctr. and Johns Hopkins Medical Inst., Baltimore, MD.

Toxicity of nic has hampered previous attempts to define nonspecific binding of [3H]nic to nicotinic acetylcholine receptors (nAchrs) in vivo using unlabeled nic as the competing ligand (Broussolle, E.P. et

In this report, we describe alternative approaches to estimate nonspecific binding of [3H]nic *in vivo* either by blocking toxicity of nic or by using other competing drugs. Mec antagonizes the behavioral and cerebral metabolic effects of nic (London, E.D. et al., <u>J.</u> Neurosci., 8:3920, 1988) as well as nic-induced toxicity, despite weak activity in competing for nic binding sites in vitro (e.g., Takayama, H. et al., JPET, 253:1083, 1989). We observed that mec (5 mg/kg) slightly facilitates the entry of [3H]nic into the brain, but does not affect nonspecific binding estimated by nic (5 mg/kg) pretreatment. In the presence of mec, 10 mg/kg unlabeled nic is no more effective at inhibiting binding of [3H]nic than 5 mg/kg,

confirming that this dose saturates nic binding sites in mouse brain.

We also used lob (s.c., 0.3 to 30 mg/kg as base), a nAchr ligand with similar affinity to nic in vitro (Abood, L.G. et al., Pharmacol. Biochem. & Behav., 30:403, 1988) to inhibit specific [3H]nic binding in vivo. High doses of lob (≤ 30 mg/kg) can be given without toxicity. We found that 3 mg/kg lob was sufficient to define nonspecific binding of [3H]nic, suggesting that lob may offer a viable approach to define nonspecific binding of radiolabeled nic to nAchrs.

NICOTINIC CHOLINERGIC RECEPTOR BINDING USING ACETYLCHOLINE NICOINIC CHOLINERGIC RECEPTOR BINDING USING ACETYLCHOLINE RECEPTOR IMMOBILIZED ON A FIBER OPTIC SENSOR. R. G. Thompson, D. E. Menking*, K. Rogers*, J. J. Valdes and M. E. Eldefrawi*. Dept. of Army, Chem. Res. Dev. & Engr. Ctr., Biotechnology Div., Aberdeen Proving Ground, MD 21010-5423 and Dept of Pharmacol. & Exptl. Therapeutics, Univ. of MD Sch. of Med., Baltimore, MD 21201 A fiber optic-based biosensor is described in which the nicotinic acetylcholine receptor from Torpedo electric organ is noncovalently immobilized on quartz rods and

organ is noncovalently immobilized on quartz rods and ligand occupancy of the receptor binding site is measured using fluorescein isothiocyanate (FITC) conjugates of the using fluorescein isothiocyanate (FITC) conjugates of the quasi-irreversible receptor probe, a bungarotoxin, or the the slowly reversible — najatoxin probe. Competetion curves for binding of the FITC-toxin probes to the immobilized receptor indicated that the IC50 values for agonists such as nicotine and carbamylcholine were higher than those previously reported from radioisotopic measurements in membrane preparation. IC50 values for antagonists such as d-tubocurarine, however, were similar to those reported using radioisotope probes. The fiber optic sensor's lower sensitivity for detecting agonist interactions with the receptor may be due to several factors: 1) agonistinduced desensitization of the receptor, 2) greater sensitivity of the agonist binding site to steric hindrance imposed by receptor immobilization, and/or 3) differences in the lipid environment of the receptor in the different binding protocols. binding protocols.

BRAIN NICOTINIC RECEPTORS ISOLATED BY BRAIN NICOTINIC RECEPTORS ISOLATED BY A MONOSPECIFIC ANTIBODY AGAINST A SYNTHETIC ALPHA-3 RECEPTOR ANALOGUE COMPARED TO AN ANTI-NICOTINE IDIOTYPIC ANTIBODY, T.C. Madhok, S.G. Matta, A. Hong, R.J. Biercke, * J.J. Langone, * and B.M. Sharp*. Endocrine Neuroscience Lab., Department of Medicine, Hennepin County Medical Center and University of Minnesota, Minneapolis, MN 55415 and Department of Medicine and Biochemistry, Baylor College of Medicine, Houston, TX 77030.

This study aimed at characterizing nicotinic cholinergic receptor (nChR) proteins purified from rat brain by immunoaffinity chromatography using the anti-alpha-S₃ antibody (BBRC 165: 151-157, 1989) and the 422 F11 anti-idiotypic antibody (BBRC 162: 1085-1092, 1989). We have purified to homogeneity the anti-alpha-S₃ antibody from rabbit sera using (NH₄)₂SO₄ precipitation, DEAE chromatography and affinity chromatography with thyroglobulin - Sepharose 4B and S₃-peptide-Sepharose 4B. The anti-alpha-S₃-Sepharose 4B was shown to deplete ³H-nicotine binding sites from rat brain membranes. SDS-PAGE of nChR isolated from the 422 F11 column showed a major component (silver stained) with a MW of 45-47K (both by nicotine and citrate, pH 3, elutions) and minor components with MWs of 53K and 63K. nChR isolated from the antialpha-S₃ column showed a major protein with MW of 48.5K and a minor protein with a MW of 45.5K. These results show the similarity in molecular size among receptor proteins isolated by these two antibodies, and the usefulness of the anti-alpha-S3 antibody in isolating nChRs proteins from rat brain. Neurological Sciences, University of Pennsylvania, Phila., PA 19104. The murine neuroblastoma N1E-115 cell line possesses membrane associated receptors for the neuroactive peptide angiotenisn II (Angll). In an attempt to solubilize these receptors we treated N1E-115 membranes with several detergents which have been used successfully to solubilize AnglI receptors (AnglI-Rs) from peripheral target tissues. Sodium cholate (0,5%) and CHAPS (1%) were effective in solubilizing binding sites for ¹²⁵I-AnglI or the high affinity antagonist ¹²²I-Sarc', Ile AnglI (SARILE), while digitonin (1%), Triton X-100 (0,5%) and NP-40 (1%) appeared to impair the ability of the solubilized protein to bind the ligand. Further analysis with CHAPS indicated that the solubilized binding sites were specific for AnglI-related peptides, although their affinity was less than that observed in intact N1E-115 membranes. Covalent cross-linking of ¹²⁵I-AnglI to solubilized N1E-115 membranes with disuccinimidyl suberate (DSS) followed by size exclusion chromatography or SDS-PAGE identified a specific binding protein of M₁ 73 kDa. Similarly, affinity chromatography using AnglI as the ligand also revealed a 73 kDa binding protein on SDS-PAGE as well as a larger protein of M, 112 kDa under non-reducing conditions, whereas only lower molecular weight binding sites were observed in the presence of reducing agents. Collectively, these results suggest that CHAPS can be used to solubilize and characterize AnglI-Rs from a neuron-like cell line. Supported by NS 23986 and MH 43787.

CROSS-LINKING OF 125 I-ANGIOTENSIN II TO SPECIFIC RECEPTORS ON DIFFERENTIATED NG108-15 CELLS. M. D. Carrithers, K. A. Koide, V. K. Raman, S. Masuda and J. A. Weyhenmeyer.

Neuroscience Program and College of Medicine, University of Illinois, Urbana, IL 61801.

We previously demonstrated that differentiated NG108-15 cells express a high affinity angiotensin (ANG) receptor that is not detectable on undifferentiated cells, has specificity for ANG II and ANG III, and mediates phosphatidylinositol breakdown (Carrithers et al., BBRC, 167: 1200, 1990). A low affinity site that binds ANG III but not ANG III is present on both differentiated and undifferentiated cells. In the present study, we used the homobifunctional crosslinker BIS (sulfosuccinimidyl) suberate (BS³) to analyze these binding sites Membranes from NG108-15 cells were incubated with 1 nM 125I-ANG II in PBS, pelleted, and resuspended in BS³ (0.5, 1.0, and 5.0 mM). PAGE analysis (7.5% resolving gel) revealed a single major band of ~ 78 kD in membranes prepared from differentiated cells. 1 µM of unlabeled ANG II or ANG III blocked labeling of this site. The estimated K₁ (~ 3 nM) for ANG III was similar in differentiated cells as determined by gel densitometric analysis and pharmacological assay. No bands were specifically labeled in undifferentiated cells. These results suggest that the 78 kD band represents a component of the high affinity receptor expressed in differentiated NG108-15 cells.

USE OF NON-PEPTIDE ANGIOTENSIN II RECEPTOR ANTAGONISTS TO DEMONSTRATE ALL RECEPTOR SUBTYPES IN BRAIN. Wamsley, W.F. Herblin¹, M. Hunt. Neuropsychiatric Res.
Inst., Fargo, ND 58103; E.I. du Pont de Nemours and Co.,
Medical Products Department, Wilmington, DE 19880.
Subtypes of angiotensin II (AII) receptors have been

described in the adrenal gland and some vascular tissues, but not in brain. We used the subtype specific AII-type 1 antagonist DUP 753 and the type 2 specific antagonist PDI23177 (EXP658) to displace [1251]AII binding in brain

PDI/231/7 (EXPOSE) to displace [157]AII binding in brain and demonstrate the presence of these subtypes.

DUP 753 effectively inhibited [125]AII binding in specific brain regions of the rat as follows: subfornical organ (SFO) 94%, median eminence (ME) 90%, subfornical organ (SFO) 94%, median eminence (ME) 90%, anterior hypothalamic area (AHy) 60%; habenula (Hb) 48%, superior colliculus (SC) 43%, dorsal nucleus of the medial geniculate body (MGD) 60%. In contrast, PD123177 displaced [1251]AII specific binding quite differently: SFO 18%, ME 0%, AHy 0%, Hb 22%, SC 0%, MGD 58%.

These data clearly demonstrate the presence of both AII receptor subtypes in the mammalian brain. Previous investigations have shown AII receptors to be concentrated in brain regions known to be involved in

concentrated in brain regions known to be involved in blood pressure regulation and thirst. These are precisely the areas where AII-type 1 receptors predominate as determined by the selective displacement of [125I]AII by DUP 753. These results imply a central role for this potent non-peptide antihypertensive agent.

REGULATION OF DEVELOPMENTAL MEMBRANOUS CYTOSOLIC ANGIOTENSIN II RECEPTORS IN RAT BRAIN AND ADRENAL. S.Y. Chow. A.N. Epstein and S.J. Fluharty. Depts. of Animal Biology and Psychology, and Institute of Neurological Sciences, University of Pennsylvania, Phila., PA 19104.

Sciences, University of Pennsylvania, Phila., PA 19104.

The actions of angiotenisn II (AngII) are mediated by receptors (AngII-Rs) located within its target tissues. AngII binding proteins, which may function as receptors, are present in the plasma membrane and the cytoplasm. In this study, we have examined the relationship between these membranous and cytosolic AngII-Rs during development in the rat using the high affinity antagonist ¹²⁰-Sarc', Ile⁵-AngII (SARILE). In the adrenal, SARILE labelled a homogenous population of membranous AngII-Rs, the density of which was highest at 3 days post-partum (B_{max} = 880 fmols/mg prot.). During the next two weeks, however, membranous binding activity rapidly declined and adult levels were less than 40% of those observed at day 3. Cytosolic binding activity exhibited the reverse relation, that is, binding activity was lowest at day 3 and increased to maximal levels of 1530 Cytosolic binding activity exhibited the reverse relation, that is, binding activity was lowest at day 3 and increased to maximal levels of 1530 fmols/mg prot in adulthood. A similar pattern was observed in the hindbrain, although the changes were more gradual. More specifically, membranous binding was highest at day 3 (B_{max} = 29 fmols/mg prot) and thereafter declined to adult levels which were only 30% of the neonatal values. Cytosolic binding, on the other hand, increased over the same time period from 104 to 140 fmols/mg prot. Collectively, these results suggest that there is a reciprocal relationship between membranous and cytosolic Angli-Rs during development in the rat. It remains to be determined if the decline in membranous Angli-Rs, and corresponding increase in binding activity membranous Angli-Rs, and corresponding increase in binding activity within the cytoplasm, is the result of receptor internalization. CYTOSOLIC BINDING PROTEIN FOR ANGIOTENISN II: RELATION TO MEMBRANOUS RECEPTORS IN MURINE NEUROBLASTOMA N1E-115 CELLS. K.M. Moody, K. Addya, S.Y. Chow, M.A. Ravi Kiron, R.L. Soffer and S.J. Fluharty. Depts. of Animal Biology and Psychology, and Institute of Neurological Sciences, University of Pennsylvania, Phila., PA 19104 and Depts. of Biochemistry and Medicine, Cornell University Medical College, New York, NY 10021.

In addition to membranous angiotensin II receptors (AnglI-Rs),

In addition to membranous angiotensin II receptors (AngII-Rs), many cells appear to possess a cytosolic binding protein which may also function as a AngII-R. In the present study we have characterized this putative cytosolic AngII-R in N1E-115 cells. Binding of the agonist ¹²⁸I-AngII or the antagonist ¹²⁸I-Sarc I,IIe ⁸AngII or the antagonist ¹²⁸I-Sarc I,IIe ⁸AngII or the organomercurial PCMIS, EDTA and CHAPS (0.4%). Cytosolic binding was also specific for AngII-related peptides exhibiting somewhat greater affinity for AngIII than AngII. Covalent cross-linking of ¹²⁸I-AngII to N1E-115 cytosol with disuccunimidyl suberate (DSS) followed by SDS-PAGE indicated that binding occurred to a single protein of M, 75 kDa. In addition, polyclonal antisera developed aganist the rabbit liver protein immunoreacted with the N1E-115 protein. Interestingly, as the density of membranous AngII-Rs increased during in vitro differentiation, binding activity in the cytosol decreased. Moreover, PCMS increased binding in differentiated membranes solubilized with CHAPS (1.0%), binding activity in the cytosol decreased. Moreover, PCMS increased binding in differentiated membranes solubilized with CHAPS (1.0%), and most significantly, polyclonal antisera aganist the liver cytosolic protein immunoprecipitated approximately 40% of solubilized Angli-Rs from differentiated, but not undifferentiated membranes. Collectively, these results demonstrate that N1E-115 cells contain a putative cytosolic Angli-R, and suggest that this protein may be recrutied to the membrane during in vitro differentiation. Supported by NS 23986 and MH 43787.

ANGIOTENSIN II DEPOLARIZES SUPRAOPTIC NEURONES RECORDED IN RAT HYPOTHALAMIC EXPLANTS. M.I. Phillips, C.R. Yang, C.W. Bourque and L.P. Renaud. Dept. of Physiology, University of Florida, Gainsville, FL32610; Centre for Research in Neuroscience. Montreal General Hospital & McGill University, Montreal, Canada, H3G

Angiotensin II (AII) induces firing in rat magnocellular neurosecretory neurones (MNCs) in the supraoptic nucleus (SON), and releases vasopressin following its central administration in vivo via an unknown mechanism. We have used intracellular recording techniques to investigate the cellular mechanisms of AII actions in a superfused rat hypothalamic explant

preparation in vitro.

Superfused application of Ile⁵-AII and Val⁵-AII (0.5-10µM) induced a slow onset (1-2.5min before peak response) and prolonged membrane depolarization (4-12mV for 5-15mins) in 16 of 20 MNCs. This depolarization was accompanied by a mean increase of 20±5.3% in input conductance and persisted when synaptic transmission was blocked in the absence of [Ca^{*+}]o (with 6mM Mg^{*+} or Mn^{*+}). At equimolar concentrations, Val⁵-AII was 2-3 times more potent than Ile⁵-AII. Extrapolation of the steady-state voltage-current plot for the AII response (from -50 to -110mV) revealed reversal potentials (V_R) between -20 and -38mV. Bath application of a non-peptide AII antagonist, DuP753 (1-5µM), had no effect on resting membrane potential or glutamate-induced depolarization but appeared to membrane potential or glutamate-induced depolarization but appeared to block the AlI-induced depolarization (n=4 cells). These results indicate that AlI acts directly on MNCs to induce a specific receptor-mediated depolarization via activation of a non-selective cationic conductance. (Supported by FRSQ, FCAR & MRC).

IMMUNOPRECIPITATION OF ANGIOTENSIN II RECEPTORS BY AN

IMMUNOPRECIPITATION OF ANGIOTENSIN II RECEPTORS BY AN ANTI-PHOSPHOLIPASE C POLYCLONAL ANTIBODY IN MURINE NEUROBLASTOMA N1E-115 CELLS. S.J. Mah, R. Mir, R.O. Davies, J.R. Williamson, and S.J. Fluharty. Depts. of Animal Biology and Biochemistry, and Institute of Neurological Sciences, University of Pennsylvania, Phila., PA 19104.

Angiotensin II (Angll) stimulates phosphoinositide hydrolysis in a variety of cells through an association between Angll receptors (Angll-Rs), GTP-binding proteins, and phosphoinositide specific phospholipase Cs (PI-PLCs). In order to examine the relationships between Angll-Rs and these other integral membrane proteins, we have solubilized membranes from differentiated N1E-115 cells using CHAPS (1%). CHAPS effectively solubilized approximately 40% of membranous binding sites for ¹²⁵I-Angll, and resulted in a 2.9-fold enrichment of specific PI-PLC activity. Moroever, Western blot analysis using polyclonal antibodies aganist one form of PI-PLC, PLC 60 purified from guinea pig uteri by Bennett and Crooke (J. Biol. Chem. 262:13789-1397, 1987), identified the presence of an immunoreactive protein with an M, of 60 kDa. Further analysis indicated that the anti-PLC 60 antisera percipitated a, 60 kDa protein solubilized membranes from cells labelled with [¹⁵S]-methionine, which immunoblot analysis indicated comigrated with PLC 60. Finally, and tell life and label labelled. in solubilized membranes from cells labelled with [\$^{55}\$]-methionine, which immunoblot analysis indicated comigrated with PLC 60. Finally, anti-PLC 60 antisgra also immunoprecipitated Angli-Rs, prelabelled with the agonist \$^{125}\$-Angli. Successful precipitation of binding activity appeared dependent on prior agonist occupancy of the receptor insofar as the antisgra did not precipitate receptors labelled with the antagonist \$^{125}\$-Sarc^*_llle^*_Angli. Collectively, these results suggest that detergent solubilized NIE-115 membranes can be used to study the factors regulating the coupling amongest Angli-Rs and PI-PLC 60 within neuronal cells. Supported by NS 23986 and MH 43787.

ENDOTHELIN BINDING IN NORMOTENSIVE AND SPONTANEOUSLY HYPERTENSIVE RAT BRAIN. J.L. Banasik*, H. Hosick*, J.W. Wright and J.W. Harding. Dept. of VCAPP, Washington State Univ., Pullman, WA 99164-6520.

Endothelins (ET), a newly discovered family of three peptides (ET1, ET2, ET3), have 21 amino acids and two disulfide bonds. ET binding and biological activity have been reported in a variety of tissues and organ systems including vascular and nonvascular smooth muscle fibroblasts, adrenal, cardiac and brain tissues. The endothelins appear to be involved in hemodynamic regulation, having potent vasoconstrictor properties and dose-related effects on blood pressure. Little is known about the role of endothelin in brain, although its function as a neurotransmitter has been postulated. Our studies have aimed to characterize binding properties of the various endothelins in the brain of normotensive (WKY) and spontaneously hypertensive (SHR) rats. ¹²⁸IET was prepared using the enzymobead lactoperoxidase method and purified with reverse-phase HPLC. Membrane fractions were prepared from homogenates of various brain structures including cerebellum, hypothalamus and brainstem. Our results indicate a wide distribution of ET1 binding in rat brain, brainstem and cerebellum having the highest binding while the cortex demonstrated little binding. Competition experiments demonstrated an IC_{50} value of between .1 and .5 nm for all three endothelins in the cerebellum, hypothalamus and brainstem of WKY rats. Saturation experiments indicate the presence of two receptor binding sites with different affinities. Site one has an apparent K_d of 2x10⁻¹¹ M while site two has an apparent K_d of 8.5x10⁻¹⁰ M. Initial comparisons between SHR and WKY rats suggest differences in the ratio of these two sites.

ONTOGENY OF ENDOTHELIN-1 RECEPTORS IN THE SPINAL CORD. <u>L. Weston*, M. Connolly*, P. Sweetnam.</u> NovaScreen*, Nova Pharmaceutical Corp., Baltimore, MD 21224

Endothelin-1 (ET-1) is a 21 amino acid vasoactive peptide isolated from endothelial cells. Receptors which mediate the action of ET-1 have a wide tissue distribution, e.g. CNS. ET-1 has been isolated and ET-1-like immunoreactivity has been demonstrated in motorneurons and fibers of the dorsal horn. Physiologically ET-1 has been shown to depolarize ventral roots in newborn rat spinal cord. We have demonstrated the ontogeny of ET-1 receptors in the rat spinal cord by receptor binding assay. ET-1 receptors appear as early as embryonic day 14 and have binding characteristics similar to those found in the adult spinal cord, e.g., $\rm K_{\rm i} = 3.5~nM$.

It has been reported that intrathecal injection of ET-1 results in severe spinal dysfunction, possibly the result of motorneuron degeneration. ET-1's ability to induce degeneration was examined by monitoring choline acetyl transferase (ChAT) activity in dissociated spinal cord neurons maintained in culture. Using a number of different ET-1 treatment paradigms we were unable to detect a significant alteration in ChAT activity from that of control levels. This suggests ET-1 binding to neuronal elements may not directly result in the motorneuron degeneration reported *In Vivo*.

IDENTIFICATION OF ENDOTHELIN RECEPTORS ON CULTURED CEREBELLAR NEURONS. <u>P.G. Lysko, G. Feuerstein, M. Pullen* and P. Nambi*</u>. Dept. of Pharmacology, SmithKline Beecham, King of Prussia, PA 19406.

The endothelin family of 21-amino acid peptides represents the most potent vasoconstrictors known. Three isoforms (ET-1, ET-2, ET-3) have been identified, and are found widely distributed in mammalian tissue, including the brain. The non-vascular distribution pattern of endothelin in brain and the high densities of endothelin binding sites in the granule cell layer of the cerebellum prompted our investigation of primary cultured rat cerebellar granule cells for the presence of endothelin receptors. Endothelin binding assays were performed on 8-day old neurons growing in 24-well culture dishes. Iodinated ET was incubated with cells in buffer at 4C; 1 μ M unlabeled ET was used to define nonspecific binding. ET-1 binding was saturable ($K_{\rm D}=88~{\rm pM})$, time-dependent (equilibrium at 2-3 hr), and specific (90% of total binding). Analysis of binding data revealed $B_{\rm max}$ of 180 fmol/mg protein, corresponding to about 7400 receptors/cell. ET-3 binding to these cells was also detected, and demonstrated a $K_{\rm D}$ of 340 pM and a $B_{\rm max}$ of 4000 receptors/cell. Thus, cerebellar granule cells may be a useful model system to explore the function of the endothelin neuropeptides, which have been ascribed various roles as neuromodulators, such as overseeing CNS regulation of cardiovascular function.

286.1

DOWN REGULATION OF ENDOTHELIN RECEPTORS IN GERBILS WITH TRANSIENT FOREBRAIN ISCHEMIA. P. Nambi*, M. Pullen*, C.F. Sauermelch*, G. Feuerstein, and R.N. Millette, Dept. of Pharmacology, SmithKline Beecham Pharmaceuticals, Philadelphia, PA.

Endothelin-1 (ET-1) is a vasoactive 21 amino acid peptide which appears to be part of a small family of endothelin isopeptides. In addition to its vascular effects, ET also elicits direct neuronal effects, causing depolarization in the ventral root of the spinal cord and increased phosphoinositol turnover in cerebellar granular cells. However, correlative evidence for a role of ET-1 in the pathophysiology of stroke is lacking. We studied the effects of transient forebrain ischemia (10 min) on ET receptors in ischemic and non-ischemic regions of gerbil brain. Hippocampi and brainstems were removed from sham and ischemic animals at 15 min, 60 min, 6 hr, and 72 hr intervals and assayed for ET-1 binding. There was no significant change in the receptors in brainstem between the two groups. In contrast, the ET-1 receptors in the hippocampus were downregulated by 8% (p=.01) at 15 min, 15% (p=.002) at 60 min and 12% (p=.05) at 6 hr. At 72 hr there was no significant change. The changes in ET-1 binding did not correlate with histopathologic changes in the hippocampus, but paralled the onset of neurologic deficits and recovery in the ischemic group. In conclusion, the release of ET-1 may contribute to the neurologic deficit and the down regulation of ET-1 receptors associated with transient forebrain ischemia.

ENDOTHELIN RECEPTORS: EXPRESSION IN XENOPUS OCCYTES. S. Shimada and G.R. Uhl. Lab. of Mol. Neurobiol., NIDA/ARC and Depts. of Neurol. & Nsci., Johns Hopkins Sch. of Med., Bx 5180, Baltimore, MD 21224.

Receptors for the endothelin peptides have been identified based on physiologic actions, ligand binding, and changes in phosphatidyl inositol metabolites. The Xenopus oocyte system frequently allows detection of receptors that can couple to changes in PI turnover. We have thus injected Xenopus oocytes with poly A[†] RNA isolated from brain and peripheral regions and sought responses to application of endothelin, sarafotoxin, and related peptides.

Ocytes injected with 30 ng of poly A⁺ RNA prepared from brain and cerebellum gave responses to endothelin peptides (usually endothelin 1, $10^{-7}\mathrm{M}$) that were present in ocytes tested in 5 separate experiments. These responses ranged from 10 to 50 nA under voltage clamp conditions (-60 to -70 mV holding potential). The responses reversed at -10 mV, consistent with the reversal potential for chloride. Responses desensitized to a marked degree; the second application of endothelin produced almost no response, and this effect persisted for more than 30 min. Endothelin 3 and sarafotoxin showed similar responses.

These results suggest that endothelin receptors can be expressed in the Xenopus oocyte, and provide a approach to sib-selection cloning of this neuropeptide receptor.

MECHANISMS IN TRANSPORTER PHYSIOLOGY

287.1

STUDIES ON [3H]VESAMICOL BINDING IN ISOLATED RAT BRAIN SYNAPTIC VESICLES. J.R.Haigh and S.M.Parsons. Dept. of Chemistry, University of California, Santa Barbara CA 93106 We have investigated the binding of [3H]Vesamicol [(-)-(trans)-2-(4-phenylpiperidino) cyclohexanol] to isolated rat brain synaptic vesicles, and crude rat brain membrane fractions. [3H]Vesamicol binds specifically and saturably with a kg of 100nM and Bmgx of 3.2pmol/mg of protein. Under pseudo-first order conditions, the association rate constant for [3H]Vesamicol is 0.15 and 0.23 min-1 at 27nM and 260nM [3H]Vesamicol, respectively. Bound [3H] Vesamicol can be displaced by non-radioactive vesamicol, with a dissociation rate constant of 0.13 min-1, a value similar to that found in cholinergic synaptic vesicles from Torpedo electric organ and slide-mounted sections of rat forebrain (Bahr and Parsons., PNAS, 83:2267, 1986; Marien, et al., PNAS, 84:876). A structure-activity study using several vesamicol and acetylcholine analogues showed that both classes of drugs bind to rat brain synaptic vesicles and inhibit [3H]Vesamicol binding. In common with Torpedo vesicles, derivatives of isonipecotic acid were the most potent, inhibiting competitively, and exhibiting a 1000-fold increase in potency compared to acetylcholine. However, most analogues of vesamicol tested were between 3 and 20-fold less potent at inhibiting [3H]Vesamicol binding in brain, compared to Torpedo vesicles, although acetylcholine analogues displayed almost equal potency in both membrane systems.

287.2

ISOLATION, CHARACTERIZATION AND PRODUCTION OF ANTIBODIES TO A SOLUBLE VESAMICOL BINDING PROTEIN FROM TORPEDO. Stanley M. Parsons and Barry W. Hicks. Dept. of Chemistry and Neuroscience Research Institute, Univ. of CA, Santa Barbara, 93106

Vesamicol is a potent inhibitor of active transport of ACh into synaptic vesicles. Over 50 publications describe the action of the drug on a variety of preparations. It is presumed that vesamicol exerts its effects by binding to a site on the cytoplasmic side of a transmembrane receptor in cholinergic synaptic vesicles. This receptor has been partially purified and characterized. We report here the isolation of a second, lower affinity (Kpulm), vesamicol binding protein. Isolation was accomplished using soft gel and HPLC chromatography. The pure protein elutes at about 450KDal in non-denaturing size exclusion chromatography, yet shows only two bands of about 30KDal and 24KDal in SDS PAGE. The polyclonal antibodies raised to the 30KDal protein showed cross reactivity with the 24KDal protein and to proteins at the same molecular weights in mammalian brain and various tissues from Torpedo. The antisera did not however show any cross reactivity with highly purified synaptic vesicles. This protein differs from the vesicular receptor in its pharmacology, sensitivity to amino acid modification reagents and its pH binding maximum. The physiological role of this protein is currently unknown, but investigators working with vesamicol should be aware that higher concentrations may produce secondary effects.

PARTIAL PURIFICATION OF THE [³H]RESERPINE BINDING SITE ON THE CATECHOLAMINE TRANSPORTER PRESENT IN THE CHROMAFFIN GRANULE MEMBRANES ISOLATED FROM BOVINE ADRENAL GLANDS. <u>J.D. Deupree, and R. Zielinski*</u> Department of Pharmacology, University of Nebraska Medical Center Orapha NE 68198

R. Zielinski*. Department of Pharmacology, University of Nebraska Medical Center, Omaha, NE 68198.

Purification of the catecholamine transporter present in chromaffin granule membranes isolated from adrenal glands has been difficult due to lack of a functional transport assay. I³H]Reserpine, bound to the catecholamine site on the transporter, does not dissociate in the presence of 1 % CHAPS but does dissociate in the presence of 1 % CHAPS but does dissociate in the presence of 1% SDS. By prelabeling the transporter with [³H]reserpine, we have been able to follow the elution of the transporter under different chromatographic conditions. Over 50% of the [³H]reserpine, still bound to protein, was solubilized using either 1 % deoxycholate or 1 % CHAPS. Chromatography of the [³H]reserpine binding site, solubilized with 3 CHAPS, on a Superose 6 column resulted in the elution of three major protein peaks. The tritium eluted with the first major protein peak with an estimated molecular weight of 400,000. SDS polyacrylamide gel electrophoresis of the this peak indicated three major peptide bands with molecular weights of 70,000, 40,000 and 20,000. It is not known which of these peptides is associated with the transporter since [³H]reserpine dissociates in SDS. These results indicate that it may be possible to purify the catecholamine transporter by first prelabeling it with [³H]reserpine. This work was supported by NSF grant (BNS-8800887) and NIH grant (NS15187).

287.5

NICOTINIC-RECEPTOR MEDIATED CATECHOLAMINE SECRETION FROM SINGLE ADRENAL MEDULLARY CHROMAFFIN CELLS: CHEMICAL EVIDENCE FOR EXOCITOSIS. D. J. Leszczyszyn, J. A. Jankowski*, O. H. Viveros, E. J. Diliberto, Jr.*, J. A. Near, and R. M. Wightman. The Wellcome Research Laboratory, Division of Medicinal Biochemistry, Research Triangle Park, NC 27709, Medical Sciences Program, Indiana Univ., Bloomington, IN 47405 and Dept. of Chemistry, Univ. Of North Carolina, Chapel Hill, NC 27599-3290. Secretion from individual cultured adrenal

Secretion from individual cultured adrenal medullary cells has been measured following local application of nicotine by a micropipette. Secretion is detected with a polymer-coated microelectrode placed adjacent to the cells, and voltammetry demonstrates that the detected substances are catecholamines. Nicotine-induced secretion is sensitive to Ca²⁺ channel blockers and is characterized by a large increase in chemical noise. With uncoated electrodes, the electrochemical spikes can be temporally resolved into the apparent secretion of discrete packets of attomole quantities of easily oxidized molecules. These data are consistent with a chemical measurement of exocytosis.

CNS LOCALIZATION OF A NOVEL TRANSPORTER-LIKE PROTEIN USING ANTIPEPTIDE ANTIBODIES AND NORTHERN BLOT ANALYSIS. LA. Gingrich*, P.H. Andersen†, T.N. Joergensen*, B.S. Guldhammer*, S. El Mestikawy. R.T. Fremeau Jr., M. Tiberi, M.G. Caron. Dept. of Cell Biology, Duke Univ. Med. Ctr, Durham, NC 27710 and Depts. of Biochem. Pharm†, Biolabs**, and Pathology**, Novo/Nordisk Industries, Copenhagen, Denmark.

We have recently identified an 85 kDa protein which copurifies with the D1

We have recently identified an 85 kDa protein which copurifies with the D1 dopamine receptor through four chromatographic steps (biospecific affinity, anion exchange, lectin, and size exclusion). This protein was separated from the D1 receptor by preparative SDS-PAGE, electroeluted, and cleaved with cyanogen bromide. Peptides were isolated by reverse phase HPLC and sequenced. An oligonucleotide derived from the sequence of one of these peptides was synthesized, labelled, and used to screen a bovine brain cDNA library. A clone was isolated which contained three of the isolated peptides within a single open reading frame of 742 amino acids (predicted MW 82.5 kDa). The sequence and predicted structure of this protein are similar to those of several known transport proteins such as the mammalian glucose transporters and the bacterial transporters for arabinose, citrate, xylose, and tetracyline. The mRNA for this protein has a message size of ~4-5.5 kb (depending on species) and is localized primarily to the brain. No signal was detected in peripheral tissues such as liver, kidney, heart, lung, spleen, and skeletal muscle. To futher characterize the regional distribution of this transporterile protein, peptides were synthesized, coupled to a hapten, and used as an immunogen in rabbits and mice. The resulting antibodies recognize a band of ~80-90 kDa on western blot analysis of crude bovine and rat striatal membranes. The labelling of this band is blocked by the antigenic peptide. Western blot analysis of several dissected brain regions suggests that this protein has a wide distribution which includes striatum, cortex, hippocampus, brainstem, and cerebellum. These antibodies should prove to be invaluable tools in elucidating the subcellular distribution and function of this protein.

227 4

FOURPHIT BINDS IRREVERSIBLY TO THE STIMULANT RECOGNITION SITE ON THE DOPAMINE TRANSPORTER. M.M.Schweri. A.Thurkauf*, and K.C.Rice*. Mercer Univ. Sch. Med., Macon, GA 31207, Neurogen Corp., Branford, CT 06405, and NIDDK, Bethesda, MD 20892.

The effect of the phencyclidine derivative Fourphit (4-isothiocyanato-1-[1-phenylcyclohexyl]piperidine) on the binding of $[^3H]$ methylphenidate $(^7H]$ MP) to the stimulant recognition site in the P_2 fraction of rat striatal tissue was studied. Fourphit inhibited $[^3H]$ MP binding (determined by a modification of a previously described method [Schweri et al, Life Sci. 45:1689 (1989)]) with an IC50 of 7.1 \pm 2.1 μ M. The reaction proceeded rapidly at 0°C, and the resulting inhibition of $[^3H]$ MP binding persisted after three washes. Scatchard analysis of $[^3H]$ MP binding in tissue reacted with 29 μ M Fourphit and then washed three times showed a significant decrease in the $B_{\rm max}$ (controls, 8.3 \pm 0.8 pmols/mg protein; Fourphit, 4.7 \pm 0.3 pmols/mg protein), but not the KD (controls, 97.3 \pm 33.3 nM; Fourphit, 99.8 \pm 25.1 nM). Preincubation of tissue with saturating amounts of MP afforded little or no protection from inactivation by Fourphit. Equivalent off-rates were observed, however, whether high concentrations of methylphenidate or Fourphit were used to initiate the dissociation of $[^3H]$ MP binding. Because Fourphit appears to bind rapidly and irreversibly directly to the $[^3H]$ MP binding site, it may prove to be useful as an affinity label for the dopamine transport complex.

INVOLVEMENT OF GTP-BINDING PROTEINS IN THE MECHANISM FOR EXOCYTOSIS IN ADRENAL CHROMAFFIN CELLS. K.Kumakura, M.O.-Imaizumi* and N.Kawae*. Life Science Institute, Sophia Univ, Tokyo, Japan 102.

We studied effects of pertussis toxin (PTX) and GTP- γ -S on the secretory function of cultured adrenal chromaffin cells. In the digitonin-permeabilized cells pretreated with PTX, marked increase of Ca²+-dependent release of catecholamine due to an increase of the affinity for Ca²+ was observed. Exposure of permeabilized cells to GTP- γ -S inhibited the Ca²+-dependent exocytosis by reducing the affinity for Ca²+. On the other hand, GTP- γ -S by itself evoked catecholamine release from the permeabilized cells in the absence of Ca²+. This Ca²+-independent action of GTP- γ -S was blocked by pretreatment with IAP. IAP-pretreatment of the cells blocked secretagogue action of mastoparan which is also Ca²+-independent. These results suggest that PTX-sensitive GTP-binding proteins are involved in the mechanism for exocytosis in two defferent ways. One controles the Ca²+-triggered process by reducing the affinity for Ca²+. The other one directly coupled with the exocytosis mechanism following the Ca²+-triggered process.

EXPRESSION OF SEROTONIN TRANSPORTER mRNA IN XENOPUS OOCYTES R. J. Haber and D. Goldman Laboratory of Clinical Studies, National Institute on Alcohol Abuse and Alcoholism, NIH, Bethesda, Md. 20892

Serotonin (5HT) is removed from the synapse and its action terminated by the 5HT transporter. $\label{eq:continuous}$

We have taken an initial step towards cloning the serotonin transporter by obtaining its expression in *Xenopus* oocytes. We find that mouse brainstem is a suitable source of serotonin transporter mRNA and that synthesis of 5HT transporter occurs steadily over a 3 day period post injection. The ability of mRNA-injected cells to take up ³H-5HT is enhanced by imposition of a sodium gradient, with a high sodium concentration outside the cell. Oocytes injected with mouse brainstem mRNA exhibited a 10-fold increase in uptake of ³H-5HT was inhibited by 18 nM citalopram, a specific inhibitor of the serotonin transporter.

STUDIES ON BINDING SITES FOR DOPAMINE UPTAKE INHIBITORS IN PRIMARY CULTURES OF VENTRAL MESENCEPHALIC NEURONS. <u>I. Hanbauer</u>, M.G. Grilli and A.G. Wright, Jr*. Lab. of Chemical Pharmacology, NHLBI, Bethesda, MD 20882.

The expression of dopamine (DA) transporter and tyrosine hydroxylase immunoreactivity in primary cultures of ventral mesencephalic neurons is developmentally linked to axonal outgrowth. We have used primary cultures of ventral mesencephalic neurons to study the properties of binding sites for cocaine and mazindol. [3H]cocaine or [3H]mazindol binding sites were detectable in intact neurons attached to culture dishes containing Krebs-Ringer-Henseleit (KRH) buffer but were not detectable in washed membrane preparations of neurons cultured for 12 days. [3H]cocaine did not bind to poly-D-lysine coated culture dishes themselves. The specific binding of [3H]cocaine at 4°C was similar to that at 24°C or 37°C indicating that [3H]cocaine was not taken up by an active transport system. [3H]cocaine binding was not altered by four consecutive washes of the cells, ruling out ion trapping of [3H]cocaine. Thus, it is concluded that [3H]cocaine may be sequestered by cytosotic compartments or organelles that were not preserved in membrane preparations. Substitution of Na* in KRH buffer by choline chloride or sucrose completely impaired [3H]DA uptake, but failed to alter [3H]cocaine binding, suggesting that in intact cells, unlike in membrane preparations of adult rats, [3H]cocaine binding does not require Na*. In mesencephalic neurons [3H]DA uptake and [3H]cocaine binding sites were expressed after 1 day in culture and continued to increase proportionally. These data suggest that [3H]cocaine binding sites may be functionally linked to the DA transporter.

 $[^3h]$ BENACTYZINE BINDING SITES IN RAT BRAIN - IN VIVO AUTORADIOGRAPHY STUDY.

T. Kadar*, R. Davidovici*., S. Chapman*, and G. Amitai.
Dept. of Pharmacology, Isr. Inst. for Biol. Research,
Ness Ziona 70450, Israel.
Since the anticholinergic compound benactyzine (BNZ)

Since the anticholinergic compound benactyzine (BNZ) may induce central adverse effects we have studied its distribution in rat brain in vivo. [$^3\mathrm{H}]-\mathrm{BNZ}$ (4.2 mC1/mmole, 0.5 mg/kg was administered to rats i.m. with or without pretreatment by atropine (1 mg/kg, i.m). Animals were sacrificed 15 min following administration and whole heads were immediately frozen. 40 mp frozen sections were cut in a coronal plane, freeze dried and attached to [$^3\mathrm{H}]$ Ultrofilm. The autoradiographic distribution of [$^3\mathrm{H}]$ BNZ revealed moderate labeling in grey matter areas. Radioactivity was spread homogeneously in cortex, striatum, hippocampus, thalamus, cerebellum and hind brain. However, concentrated labeling was noted in the pyramidal layer of the hippocampus. A decrease in whole brain labeling was observed after pretreatment with atropine. The labeling was spread in a diffused manner (e.g. cortex and thalamus) in contrast to a more localized distribution of either [$^3\mathrm{H}]\mathrm{micotine}$ or [$^3\mathrm{H}]\mathrm{NNZ}$ labeling appeared in both muscarinic and nicotinic sites. These results conform with our previous data that BNZ inhibits the physiological response of peripheral muscarinic and nicotinic receptors. Supported by DAMD17-84-C-4016.

288.3

LOCALIZATION OF MUSCARINIC CHOLINERGIC RECEPTORS ON SINGLE NEURONS IN RAT HIPPOCAMPAL CULTURES. J.M.R. Harrison*, C.A. Levesque, G.A. Banker, G.F. Wooten, and O. Steward. Depts. of Neuroscience and Neurology, Univ. of Virginia, Charlottesville, VA 22908. Although the distribution of muscarinic receptors in the rodent brain has been extracted little to known bebut the ubsolution.

Neuroscience and Neurology, Univ. of Virginia, Charlottesville, VA 22908. Although the distribution of muscarinic receptors in the rodent brain has been extensively investigated, little is known about the subcellular localization and regulation of these receptors. Hippocampal neurons maintained in culture develop elaborate axons and dendrites, allowing the subcellular distribution of receptor to be assessed directly. In the present study, we used [*H]-quinuclidinyl benzilate ([*H]-QNB) in conjunction with autoradlography to investigate the distribution of muscarinic receptors on cultured neurons. Living neurons were exposed to [*H]QNB and then fixed with 1% glutaraldehyde. The neurons were then prepared for autoradlography or scintillation counting. Kinetic studies showed that the binding of [*H]QNB reached steady state levels within 15 minutes at 37°C. Saturation of binding sites occurred at 0.5 nM [3H]-QNB, a concentration similar to that obtained in sections and homogenates. Autoradiographic analysis revealed [*H]QNB binding sites on both cell bodies and dendrites of cultured neurons, but little binding to glia. The amount of nonspecific binding (in the presence of 1 µM atropine) was always less than 10% of the total binding. Pharmacological competition curves suggest that the binding was specific for muscarinic cholinergic sites. Competition with carbachol (an M2 selective agonist) and with pirenzepine (an M1 selective antagonist) indicated that the receptors are predominately of the M1 subtype. These results are consistent with data obtained in sections. Therefore hippocampal pyramidal cells in culture express cholinergic receptors pharmacologically indistinguishable from those expressed in situ. providing an opportunity to study their regulation at a subcellular level. Supported by NS12333 to O.S. J.H. and C.L. were the recipients of postdoctoral fellowships from NIH (5T32HD07192 and 5T32NS07199, respectively).

CARBON-11 LABELED 5-(N-METHYLAMINO)BENZOVESAMICOL, A MARKER OF PRESYNAPTIC CHOLINERGIC NEURONS. M.R. Kilbourn. Y-W. Jung*. M.S. Haka*. D. Gildersleeve*. F. Buck*. K.A. Frey. and D.M. Wieland*. Div. Nuclear Medicine, Univ. Michigan Med. Sch., Ann Arbor, MI 48109

Radiotracers for in vivo study of presynaptic cortical cholinergic neurons using PET would be of great value in the diagnosis and characterization of Alzheimer's disease and related dementias. We have prepared high specific activity carbon-11 (β+, t1/2 = 20 min) labeled 5-(N-methylamino)benzovesamicol ([11C]MABV) as a ligand for binding to acetylcholine storage vesicles. Mouse brain distribution at 45 min after i.v. injection shows regional selectivity (striatum>cortex>hippocampus> hypothalamus>cerebellum: STR/CER = 8.1 ± 0.44) and stereoselectivity ([-)MABV > (±)MABV]. Specific binding can be blocked by pretreatment with cold (-)vesa-micol. PET tissue time-activity curves in monkeys (bolus intracarotid inj) were fitted to a three compartment, four parameter model. Data showed high brain extraction (65%) and similar nonspecific binding levels in cortex and striatum. Kinetic estimates of specific binding are 2- to 3-fold higher in striatum than cortex, consistent with in vitro binding estimates. (-)-[11C]MABV shows regional selectivity, stereoselectivity, pharmacological specificity, and in vivo pharmaco-kinetics which support its further development as a presynaptic marker for study of the cholinergic system using PET.

288.4

BINDING TO PRE- AND POST-SYNAPTIC CHOLINERGIC SITES IN THE STRIATUM AFTER A VOLKENSIN INJECTION TO THE SUBSTANTIA NIGRA. M.B.Harrison, R.G.Wiley#, and G.F.Wooten. Univ. of Virginia, Charlottesville, VA 22908 and #Vanderbilt University, Nashville TN 27232.

Following injection of the retrogradely transported neurotoxin, volkensin, into the SN, both D1 and D2 binding in the striatum show a time-dependent decrease. This effect is seen as early as 5 days, and the decrease is much greater for D1 than D2 at all time points, suggesting a selective localization of D1 receptors on striatonigral neurons. To further Investigate the effects of the toxin, we examined binding in the striatum of [3H]-hemicholinium ([3H]-HC), a marker for presynaptic Ach uptake sites and [3H]-QNB, which labels muscarinic cholinergic receptors. Eight rats received 2-2.7 ngs. of volkensin by microinjection into the left SN. After survivals of 5 (n=4) or 21 to 37 (n=4) days, brains were processed for autoradiography with adjacent pairs of sections examined for binding of [3H]-HC and [3H]-QNB. Specific binding in the striatum ipsi- and contralateral to the lesion was compared. At 5 days, [3H]-HC binding on the lesioned side was 97% of that on the intact side (57.7 fmol/mg ± 4.4 vs. 61±7.8 (mean±S.E.); n.s.); [3H]-QNB binding was 99% (383.2±17.4 vs. 388.3±30.9; n.s.). At the later time points, 16 % of [3H]-HC binding sites remained on the lesioned side (7.3±1.4 fmol/mg vs. 46.3±8.1*) with 45% of [3H]-QNB binding remaining (183.2±17.6 vs. 408.1±18.3**). The absence of a significant effect at 5 days suggests that neither [3H]-HC nor [3H]-QNB binding sites are located on striatonigral neurons and that the neurons on which they are located are not subject to the immediate primary neurotoxic effects of volkensin. The nature of its secondary effects is unknown but these results suggest that reuptake sites located on axon terminals are more affected than post-synaptic receptor binding sites on the soma and dendrites. *=p<.05.***=p<.01

IMMUNOCYTOCHEMICAL MAPPING OF M2 MUSCARINIC RECEPTOR SUBTYPE IN OLFACTORY BULB. M.I. Fonseca*, J.S. Aguilar*, A.F. Skorupa and W.L. Klein. Institute for Neuroscience.
Northwestern University. Evanston. 71, 60208.

Northwestern University. Evanston, IL 60208.

Polyclonal antibodies that recognize the M2 subtype of muscarinic receptors (mAchR) have been raised and used to map the cellular distribution of this subtype in rat olfactory bulb. The antibodies were obtained by injecting BALB/C mice with a BSA conjugated synthetic peptide whose sequence corresponded to the cytoplasmic loop of porcine cardiac M2 subtype. The antiserum recognized the synthetic peptide in ELISA assays and stained a band corresponding to the peak fraction of radiolabeled heart mAchR in Western immunoblots. Immunostaining of rat olfactory bulb sections showed that the antibodies labelled cell bodies and multiple dendritic processes. The patterns of labelling were homogeneous in some cells and punctate in others. M2 positive cells throughout the bulb were mainly present in three layers, representing small fractions of the cells in each region: glomeruli, 6%; external plexiform layer, 16%; granule layer, 3%. The results show that the antibodies raised against specific sequences of different receptor subtypes can be used to localize the subtypes in situ, and that the M2 subtype within the olfactory bulb is broadly distributed. The mapping of M2-positive cells in olfactory bulb is of clinical interest because loss of M2 subtype and degeneration of olfactory system are observed in Alzheimer's disease.

MEASUREMENT OF BENZODIAZEPINE RECEPTOR BINDING IN VIVO WITH N-ω-IF-18|FLUOROETHYL FLUMAZENIL AND POSITRON EMISSION TOMOGRAPHY. S.M. Moerlein and J.S. Perlmutter. Mallinckrodt Institute of Radiology and Department of Neurology and Neurological Surgery, Washington University School of Medicine, St. Louis, MO 63110

Flumazenil (Ro 15-1788) is a selective benzodiazepine (BZP) antagonist that is useful for studies of central BZP receptors in vivo and ex vivo. We have evaluated an F-18 (t_{1,0}= 110 min) labeled analogue of this ligand, N-ω-[F-18]-fluoroethyl flumazenil (FEF), for measurement in vivo of BZP receptor binding kinetics with positron emission tomography (PET). [F-18]FEF was produced via a two-step synthetic sequence that involved the reaction of bis-tosyl ethane with no-carrier-added [F-18]fluoride preceding N-alkylation of the nor-methyl precursor Ro 15-5528. Radiotracer purification was achieved using normal phase HPLC to yield [F-18]FEF in 25-30% radiochemical yield and specific activity > 1000 Ci/mmol within an overall preparation time of 110 min. Separate PET studies were performed on the same baboon, with and without coinjection of unlabeled flumazenil 0.55 mg/kg. Regional cerebral blood flow (CBF) and blood volume (CBV) were measured using [O-15]water and [O-15]carbon monoxide. After [F-18]FEF injection, sequential PET scans were obtained for 3 hours in intervals ranging from 1 minute to 10 minutes. The F-18 labeled ligand selectively localized in vivo within regions rich in BZP receptors (at 38 min: temporal cortex (T)/ cerebellum (C)/white matter (W) = 690/508/443 cps/ml/mCi). Co-injection of unlabeled flumazenil dramatically reduced brain uptake of [F-18]FEF and completely abolished the selective accumulation of the ligand in BZP receptor-rich tissues (at 38 min: T/C/W = 249/323/229 cps/ml/mCi). Non protein-bound [F-18]FEF in blood as determined with micropartition (Centrifree) techniques was 56.15 ± 1.45%. These data indicate the utility of [F-18]FEF for the noninvasive study of central BZP receptor pharmacology in vivo with PET.

IN VIVO BENZODIAZEPINE RECEPTOR BINDING IN HUMAN BRAIN: COMPARTMENTAL ANALYSIS OF [11C]FLUMAZENIL DISTRIBUTION AS DETERMINED BY POSITRON EMISSION TOMOGRAPHY. K.A. Frey. V. Holthoff, R.A. Koeppe, D. Jewett, T.J. Mangner, and D.E. Kuhl Division of Nuclear Medicine. The University of Michigan, Ann Arbor, MI 48109.

Alterations in the number or function of benzodiazepine binding sites have been suggested in a variety of neurologic and psychiatric disorders. Methods for measurement of in vivo radioligand binding with the use of positron emission tomography may allow direct hypothesis testing in clinical populations. We have developed a tracer kinetic model for the compartmental analysis of [11C]flumazenil (FMZ) distribution and binding, which allows estimation of both tracer delivery and uptake in brain as well as local high-affinity binding. Six normal volunteers underwent imaging of [11C]FMZ distribution following intravenous administration. A series of dynamic PET images was obtained over 90 min with the use of a Siemens 931/08-12 scanner. Arterial blood samples were obtained during the imaging period, plasma was chromatographed to exclude labeled metabolites and the [11C]FMZ time course determined. Compartmental analysis of the brain and plasma tracer time courses was conducted on a pixel-by-pixel basis, resulting in maps of both tracer uptake (transport) and distribution volume (proportional to receptor concentration). Estimates of receptor density varied over a 5-fold range (mean±S.D.): pons - 1.0±.1; cerebellum - 2.8 ± 4 ; thalamus - 2.9 ± 4 ; caudate - 2.3 ± 2 ; putamen - 3.1 ± 4 ; frontal cortex - 4.8 ± 6 ; occipital cortex - 5.4 ± 7 . The present method thus provides reproducible relative receptor density estimates which are in good agreement with results of in vitro binding studies. In addition, pixel-by-pixel maps of relative receptor density allow rapid visual inspection of the entire brain, which may prove invaluable in clinical research applications.

IN VITRO AUTORADIOGRAPHIC BINDING AND IN SITU
HYBRIDIZATION OF MUSCARINIC CHOLINERGIC RECEPTORS IN
RHESUS MONKEY THALAMUS. M.V. Wagster, D.M. Weiner*,
A.I. Levey, M.R. Brann, L.C. Cork and D.L. Price.
Neuropathology Laboratory, The Johns Hopkins University
School of Medicine, Baltimore, MD 21205, and Laboratory
of Molecular Biology, NINDS, Bethesda, MD 20892.

Muscarinic cholinergic receptor binding site distribution was mapped in monkey thalamus and compared with muscarinic receptor gene expression. In rat brain, the pharmacology of M1 receptor binding appears to correspond to m1, m3, m4, and m5 receptor mRNAs. In rat thalamus, high levels of m2 and m3 mRNAs are expressed, whereas very low levels of m1 and m4 mRNA expression are evident. Based on these previous findings, adjacent sections of thalamus from four rhesus monkeys 9 years (n = 2) and 25 years (n = 2) of age were examined for M1 muscarinic receptor binding sites using [³H] pirenzepine (PZ) and for expression of m2, m3, and m5 receptor mRNAs using a mixture of three 48-base oligodeoxynucleotide probes. Moderate levels of [³H] PZ binding were observed in laterodorsal nucleus, medial dorsal nucleus, and basal ventral medial nucleus of thalamus. Preliminary observations indicate that receptor binding distribution and distribution of receptor mRNAs examined differ somewhat in anatomical localization. Studies are in progress to clarify these distributions.

288 5

AUTORADIOGRAPHIC LOCALIZATION OF BENZODIAZEPINE RECEPTORS LABELED WITH [3 H]ALPRAZOLAM: COMPARISON WITH [3 H]DIAZEPAM. L.L. Longlet, M.E. Alburges, M. Hunt, D.R. Mahan and J.K. Wamsley. Neuropsychiatric Research Institute, Fargo, ND 58103; 1 The UpJohn Company, Kalamazoo, MI 49001.

The characterization and localization of sites labeled by [3H]alprazolam has been compared to [3H]diazepam in tissue slices. Both ligands label a finite receptor population and the binding is readily reversible and highly specific. Scatchard analyses indicate a K_d of 7.5 nM and a B_{max} of 197 fmoles/mg tissue for [3H]diazepam, and 4.0 nM and 129 fmoles for [3H]alprazolam. Competition studies indicate a similar profile for the two compounds. [3H]diazepam was then used to label tissue sections in the presence of increasing concentrations of alprazolam, and [3H]alprazolam was used in the presence of increasing concentrations of diazepam. The radioactive ligands overlap in their labeling distribution, but have unique sites as well. Alprazolam uniformally displaced those sites labeled by [3H]diazepam except for areas where the binding was presumably represented by peripheral BZ sites (i.e. the choroid plexus and ependymal lining of the ventricles). Diazepam showed a similar ability to interact with the sites occupied by [3H]alprazolam. These data indicate that, for the most part, the two BZ compounds are labeling similar sites in the brain with comparable binding characteristics.

288.10

PENTOBARBITAL (PB) ALTERS THE BINDING PARAMETERS OF RAT BRAIN BENZODIAZEPINE RECEPTOR (BZR) IN A REGIONALLY SPECIFIC MANNER. B.X.Carlson and H.A.Baghdoyan. Department of Anesthesia, Penn State Univ., College of Medicine, Hershey, PA 17033.

In cortical homogenates barbiturate-induced enhancement of benzodiazepine binding is due to an increase in BZR affinity. With in vitro receptor autoradiography we have shown regional differences in PB-induced [$^3\text{H}]$ flunitrazepam (FLU) binding in intact rat brain (Carlson et al.,FASEB J.4:Al006,1990). The present study is testing the hypotheses that the BZR will exhibit regional differences in K_{D} and B_{max} , and in PB-induced enhancement of FLU binding. Saturation analysis of FLU binding in 6 regions (cortex, diencephalon, midbrain, pons, medulla, cerebellum) was carried out using fresh brain. Both K_{D} and B_{max} showed statistically significant differences between brain regions. The highest affinity ($K_{\text{D}}{=}1.07\text{nM}$) and lowest B_{max} (0.52pmol/mg protein) were observed in the medulla. The lowest affinity ($K_{\text{D}}{=}2.01\text{nM}$) and highest B_{max} (1.98pmol/mg protein) occurred in the cerebral cortex. PB increased the affinity of BZR for FLU in all brain regions with the greatest increase occurring in the medulla. There were no PB-induced changes in B_{max} . These data show, for the first time, that PB alters binding parameters for BZR in a regionally specific manner.

Supported by Ciba-Geigy and MH45361 to HAB.

EFFECT OF PARA-CHLOROAMPHETAMINE (PCA) ON 3H-CYANO-IMIPRAMINE (3H-CN-IMI) BINDING TO SEROTONIN UPTAKE SITES J. Hensler, R. Ferry*, G.B. Kovachich and A. Frazer, Depts. of Pharmacol. & Psychiatry, Univ. of Pa. & Vet. Affairs Med. Ctr., Phila. PA 19104.
There are two distinct serotonin (5-HT) raphe-forebrain projections pre-

ferentially innervating different forebrain areas. Treatment of rats with PCA lesions fine 5-HT axons arising from the dorsal raphe (DRN) while sparing beaded 5-HT axons from the median raphe (MRN); 5-HT cell bodies are spared (Exp.Neurol.102.23,1988). It also appears that different regions of brain receive variable innervation from the DRN or MRN. To obtain more quantitative information on the degree of innervation of terminal field areas from the DRN, we have examined by quantitative autoradiography the binding of ³H-CN-IMI to 5-HT uptake sites in rats treated with PCA. Fourteen days after PCA treatment (6mg/kg, i.p., for 2 days) the binding of 3H -CN-IMI in the DRN and MRN was unchanged and 5-HT cell bodies as visualized by 5-HT immunohistochemistry appeared morphologically unaffected. The extent of loss of ³H-CN-IMI binding in different areas was variable: 62±7% in the piriform cortex; 47±3% in the parietal cortex; 40±6% in the frontal cortex; 51±3% in the CA₁ and 38±3% in the CA_{2,3} region of the hippotal cortex; 51±3% in the CAI and 30±3% in the CAI 31 region of the Inppo-campus; 53±3% in the basolateral amygdala. PCA treatment resulted in a loss of fine 5-HT axons as visualized by 5-HT immunohistochemistry and the apparent sparing of beaded 5-HT axons. Beaded axons do contain ³H-CN-IMI binding sites as treatment of rats with 5.7-dihydroxytryptamine results in extensive loss of ³H-CN-IMI binding (>85%) and all types of 5-HT axons in terminal field areas. The differences in the extent of reduction in ³H-CN-IMI binding in these forebrain areas after PCA treatment may reflect the degree of 5-HT innervation from the DRN. (Supported by research funds from the Dept. of Vet. Affairs and USPH grant MH09834).

MELATONIN BINDING SITES IN SYRIAN HAMSTER MELANOMA CELLS. D.S. Pickering, L.P. Niles and S.-W. Ying*. Dept. of Biomedical Sciences, Division of Neuroscience, McMaster University, Hamilton, Ontario, Canada L8N 325

In addition to a picomolar melatonin receptor, a nano-molar-affinity site has been observed in various hamster molar-arithity site has been observed in various nameter central and peripheral tissues. In order to further char-acterise this site, we desired to find a continuous cell line expressing this site. The Syrian hamster derived melanoma cell line RFMI 1846 was found to contain a binding site which preliminary pharmacological studies suggest resembles the central nanomolar-affinity binding suggest resembles the central nanomolar-arrinity binding size: $({\rm IC}_{50}{}'s)$ iodomelatonin, 4.6 nM; 6-chloromelatonin, 25 nM; N-acetylserotonin, 67 nM; melatonin, 155 nM. Scatchard analysis of saturation binding of $2-[^{125}{\rm I}]$ iodomelatonin indicates a ${\rm K}_{\rm d}$ of 5.1 \pm 1.9 nM at 0°C. Measurements of adenylate cyclase activity in semi-purified RPMI 1846 plasma membranes revealed a 5-fold stimulation by 10 MM forskolin, however, neither melatonin nor iodomelatonin significantly affected the basal or forskolin-stimulated cyclase activity at concentrations from 10⁻¹⁰ to 10⁻⁵ M. The nanomolar-affinity melatonin binding site therefore does not seem to be coupled to adenylate cyclase. This is in keeping with the lack of inhibition by quanine nucleotides reported for this site in hamster brain membranes. Studies are underway to explore possible coupling mechanisms of this site. (This work was funded by the OMHF and MRC. D.S.P. is supported by the MRC.)

FUNCTIONAL MELATONIN RECEPTORS IN ARTERIES INVOLVED IN THERMOREGULATION. M. Viswanathan, J.T. Laitinen and J.M. Saavedra. Sec. on Pharmacology, Lab. of Clin. Sci., NIMH, Bethesda, Maryland 20892. Melatonin receptors were localized and characterized in the vasculature

of the rat, using the melatonin analogue 2-[125]-iodomelatonin, and quantitative in vitro autoradiography. The expression of these receptors was restricted to the caudal artery and to the arteries which form the circle of Willis at the base of the brain. Specific binding in these arteries was localized exclusively in the smooth muscle layer. 2-[128 i]-lodomelatonin binding in the arteries was stable, saturable, and reversible. Saturation studies revealed that the binding represented a single class of high affinity binding sites with a dissociation constant (K_a) of 33.5 pM in the anterior cerebral artery and 104.9 pM in the caudal artery. The binding capacities (B_{max}) in these arteries were 19.3 and 14.6 fmol/mg protein, respectively. The arterial binding sites had high specificity for melatonin (lodomelatonin > Melatonin > Nacetylserotonin > prazosin > 8-OH-2(di-n-propylamino) tetraline > > 5-HT). Norepinephrine-induced contraction of the caudal artery in vitro was significantly prolonged and potentiated by melatonin in a concentration dependent manner, suggesting that these arterial binding sites are functional melatonin receptors. Neither primary steps in smooth muscle contraction (phosphoinositide hydrolysis) nor relaxation (adenylate cyclase activation) were affected by melatonin.

Melatonin, through its action on the tone of these arteries, may cause circulatory adjustments in these arteries which are believed to be involved in thermoregulation.

HIGH RESOLUTION AUTORADIOGRAPHIC COMPARISON OF

HIGH RESOLUTION AUTORADIOGRAPHIC COMPARISON OF

3H-IMIPRAMINE BINDING IN HUMAN AND RAT
HIPPOCAMPUS G.E.Duncan, K.Y.Little*, G.R.
Breese, and W.E. Stumpf Dept. of Cell Biology
and Anatomy, UNC, Chapel Hill, NC 27599
Within the hippocampal formation we have
found substantial species differences between
rats and humans in the topographic
distribution of binding sites for ³Himipramine. In the rat, the highest densities
of binding sites were found in the dentate
molecular layer, CA-3 stratum oriens and CA-3
stratum radiatum. Very low densities of
binding sites were observed throughout the
pyramidal cell layer in the rat hippocampus.
In contrast, in the human hippocampus, the
highest densities of binding sites for ³Himipramine were found in the CA-3 and CA-4
pyramidal cell fields and low densities of
binding sites were detected in the CA-3
stratum radiatum. The results raise the
possibility that functional consequences to
pharmacological actions of imipramine
may
differ in the rat and human hippocampus pharmacological actions of imipramine may differ in the rat and human hippocampus. Supported by USPS grants MH-33127, HD-03110, and MH-39144.

MELATONIN BINDING IN CHAPS-SOLUBILISED FRACTIONS FROM CHICK BRAIN. S.-W. Ying* L.P. Niles and D.S. Pickering. Dept. of Biomedical Sciences, Division of Neuroscience, McMaster University, Hamilton, Ontario, Canada 18N 375 Binding sites for [125 I]melatonin (125 I]mel) were solubilised from chick brains using 5 mM CHAPS (3-[(3-100)])

solubilised from chick brains using 5 mM CHAPS (3-[(3-chol-amidopropyl)-dimethylammonio]-1-propane sulfonate). Binding of [125 I]MEL to solubilised fractions at 0-4°C was rapid, reversible, saturable and of high affinity. Scatchard analyses revealed a single site with K_0 = 328 ± 22 pM and B_{max} = 36.2 ± 2.0 fmol/mg protein (solubilised); K_0 = 302 ± 26 pM and B_{max} = 49.5 ± 6.6 fmol/mg protein (crude membranes). Inhibition studies for both preparations yielded the following order of potency: iodomelatonin > melatonin > 6-chloromelatonin > N-acetylserotonin > serotonin. GTPYS and GTP >> N-acetylserotonin > serotonin. GTPYS and GTP inhibited binding of [1251]MEL to both preparations by 50-60%. Functional studies indicated that melatonin did

50-50%. Functional studies indicated that melatonin did not alter besal nor forskolin-stimulated adenylate cyclase activity in chick brain membranes. These findings demonstrate: (1) that the pharmaco-logical properties and guanine nucleotide sensitivity of [¹²⁵I]MEL binding sites remain intact following CHAPS solubilisation; (2) the putative melatonin receptor sites in chick brain do not appear to be coupled to adenylate cyclase.

LOCALIZATION BY IN SITU HYBRIDIZATION OF GABA, RECEPTOR ALPHA, AND GAMMA, SUBUNITS IN LONG-SLEEP AND SHORT-SLEEP MOUSE BRAINS. N.R. Zahniser, P. Curella Dept. Pharmacology, Univ. Colorado Hlth. Sci. Ctr., Denver, CO 80262. The genetically selected long-sleep (LS) and short-sleep (SS) mouse lines provide a model for studying mechanisms underlying differences in initial sensitivity to ethanol. Differential sensitivity in GABAergic

initial sensitivity to ethanol. Differential sensitivity in GABAergic function is one such mechanism that has been identified. Our goal was to determine whether differences in the subunits composing the GABAA receptor in the two lines of mice could contribute to the difference in GABAergic function. Northern analyses of inbred LS and SS brain mRNA, utilizing probes derived from mouse α_1 and γ_2 GABAA receptor subunit cDNAs, revealed no differences between LS and SS mice for either probe. For in situ hybridization, the autoradiograms were analyzed with an image analysis system. In every case, the 45 S-sense probes showed weak, relatively uniform hybridization. In contrast, in adjacent brain sections the patterns of hybridization for the 45 S-antisense probes were region-specific. For example, specific hybridization for the α_1 -probe was highest in the inferior colliculus, cerebellum and cerebral cortex whereas that for the γ_2 -probe was highest in the cell layers of the dentate gyrus and hippocampus, olfactory bulb and cerebral cortex. While α_1 and γ_2 subunit probes gave differing patterns of hybridization, regional differences between LS and SS mice were not observed for either subunit probe. Our results do not rule out the of hybridization, regional differences between LS and SS mice were not observed for either subunit probe. Our results do not rule out the possibility that expression of these subunits or that other subunits making up the GABA_A receptor may differ between LS and SS mice, but they do suggest that qualitative differences in mRNA for the α_1 and γ_2 subunits cannot explain functional differences between LS and SS mice. THE EFFECTS OF STEROIDS ON GABAA RECEPTOR FUNCTION IN LS AND SS MICE. <u>B.J. Bowers and J.M. Wehner</u>. Institute for Behavioral Genetics, University of Colorado, Boulder, CO

Recent studies have shown that steroids are widely distributed in brain and are capable of producing a variety of neurological and behavioral effects. The GABA_A receptor complex has been implicated as a primary site of action. Excitatory and inhibitory modulation of GABA-related responses may be dependent on structural characteristics of the steroid. To determine whether differential responses may also be due to genetic factors the effects of two structurally different steroids, tetra-hydrodeoxcorticosterone (THDOC) and pregnenalone-sulfate (PS), and the steroid anesthetic, alphaxalone (ALPH), on sleep-time and steroid anesthetic, alphaxalone (ALPH), on sleep-time and GABAA receptor function were examined in LS and SS mice. ALPH produced longer sleep-times in LS mice; however, THDOC-induced sleep-times did not differ between the lines. Enhancement of receptor inhibition, measured by [³H]-flunitrazepam (FNZ) binding and ³6cl uptake, was demonstrated by both ALPH and THDOC with LS\SS differences observed only for ALPH-enhanced [³H]-FNZ binding. The effects of PS suggested a disinhibition of GABA function which did not differ between LS and SS mice. These differences among the steroids on GABA-related responses suggest different sites or mechanisms of action which appear to be due to specific characteristics of the compound. Supported by AA-03527, AA-07567 and MH-16880. compound. Supported by AA-03527, AA-07567 and MH-16880.

289.5 STRESS-INDUCED ELEVATION OF GABAA RECEPTOR-ACTIVE 3α -HYDROXYSTEROIDS IN THE RAT BRAIN. R. H. Purdy¹*, A. L. Morrow², P. H. Moore, Jr.¹*, S. M. Paul², ¹SW Found., San Antonio, TX 78284 and ²NSB, NIMH, Bethesda MD 20892. The endogenous anxiolytic steroids, 3α , 21-dihydroxy- 5α -pregnan-20-one (allotetrahydrodeoxycorticosterone, THDOC), a metabolite of deoxycorticosterone and 3α -hydroxy- 5α -pregnan-20-one (allopregnanolone, AP), a metabolite of progesterone, are amongst the most potent known ligands of the GABAA-receptor complex in the CNS. These steroids potentiate GABAA receptor-mediated chloride ion conductance in neurons, and have anxiolytic, sedative, and analgesic effects in vivo. We have developed specific radioimmunoassays to measure >25 pg amounts of THDOC and AP in extracts of plasma and brain tissue after purification of the steroids by HPLC. Control levels in plasma (ng/ml) and cerebral cortex (ng/g) of adult male purification of the steroids by HPLC. Control levels in plasma (ng/ml) and cerebral cortex (ng/g) of adult male Sprague-Dawley rats were 0.19 and 0.15 for THDOC and 0.06 and 0.39 for AP. Within 5 min after exposure to ambient temperature swim stress there was a 7-20 fold increase in circulating THDOC and AP respectively, and a concomitant 4-7 fold increase of THDOC and AP in cerebral cortex. These increases in plasma and brain were maintained for 1 hr following stress, and then declined to baseline levels by 2 hr. These stress-induced increases did not occur in by 2 hr. These stress-induced increases did not occur in adrenalectomized animals. We conclude that THDOC and AP are modulators of central GABA $_{\rm A}$ -receptors which may play an important role in the response of the CNS to stress.

ADRENALECTOMY INCREASES BICUCULLINE-INDUCED SEIZURE SUSCEPTIBILITY IN LONG-SLEEP AND SHORT-SLEEP MICE. Wehner, B.J. Bowers, T.Z. Bosy*. Institute for Behavioral

Genetics, University of Colorado, Boulder, CO 80309.

Long-sleep (LS) and short-sleep (SS) mice differ in seizure susceptibilty to GABAergic agents, differ in some properties of the GABA receptor complex, and in responsiveness to stimulation of the hypothalamic-pituitary-adrenal axis (HPA). Therefore, the effects of adrenalectomy (ADX) was examine in these mice. Within the sham-operated group, SS mice were more susceptible to seizure onset than LS mice. Susceptibility to bicuculline (BIC)-induced seizure onset and tonus was increased in both lines at 7 days after ADX. However, after ADX latencies did not differ between the two lines. Replacement with 10% corticosterone (CCS) pellets in ADXanimals resulted in a return to sham-operated control latencies. In SS mice, dexamethasone (10%) pellets and cholesterol pellets were as effective as CCS replacement. In LS mice, dexamethasone was only effective at a low BIC dose. These results suggest that seizure thresholds may be regulated, at least in part, by the HPA axis and that the effects of ADX on GABA-related seizures may be the effects of ADX on GABA-related selzures may be influenced by genotype such that genetic differences in GABA, receptor function and in the HPA of LS and SS mice may be responsible for their differential susceptibility to BIC-induced seizures. Supported by AA-03527, AA-07567, and MH-16880.

DEHYDROEPIANDROSTERONE SULFATE, A NEUROSTEROID, BINDS TO RAT BRAIN MEMBRANES AND MODULATES THE FUNCTION OF GABA-A RECEPTORS. S. Demirgören, M.D. Majewska, and E.D. London, NIDA Addiction Research Center, Baltimore, MD 21224

Steroids, such as dehydroepiandrosterone, pregnenolone and their sulfated metabolites (called neurosteroids), are synthesized in the CNS primarily by the oligodendroglia (Hu, Z.Y. et al., Proc. Natl. Acad. Sci. USA 84:8215, 1987). Pregnenolone sulfate (PS) is an allosteric antagonist of the GABA-A receptor (Majewska, M.D. et al., <u>Brain Res.</u> 404:355, 1987). As dehydroepiandrosterone sulfate (DHEAS) inhibits the binding of PS to brain membranes (Demirgören, S. et al., Soc. Neurosci. Abst., 15:994, 1989), it appears that DHEAS may also interact with GABA-A receptors. In the present study, we have examined the binding of [3H]DHEAS to rat brain membranes, and the interaction of DHEAS with GABA-A receptors. Binding of [3H]DHEAS is saturable and protein dependent. The optimal pH for binding is 6.4, and equilibrium is reached after 1.5 hr. At 25°C, the specific binding of 2 nM [³H]DHEAS is 70-80% of the total binding, but at 4°C it is only 50%. The binding is sensitive to heat denaturation as well as to treatment of membranes with phospholipase A2 and protease. Scatchard analysis of equilibrium binding indicates that [3H]DHEAS binds to two populations of sites: Kd1= 2.9 \pm 0.8 μM and $Kd_2 = 554 \pm 98 \mu M$ (N=6). The binding is inhibited by barbiturates and PS. DHEAS also interferes with barbiturate-induced enhancement of benzodiazepine binding, shifting the barbiturate dose-response curve to the right. The data indicate that DHEAS is a negative modulator of the GABA-A receptor complex.

289.6

TISSUE-SPECIFIC MODULATION BY STEROIDS OF 35S-TBPS BINDING ON THE GABA-A RECEPTOR. D.M. Turner, D.W.Sapp, U. Witte*, N. Kokka*, and R.W.Olsen. Dept. of Pharmacology, UCLA, Los Angeles, CA 90024 Steroids have been shown to enhance [3H] muscimol and [3H]flunitrazepam binding, and inhibit [35S]TBPS binding to the GABA receptor as well as enhancing both pentobarbital and muscimolstimulated chloride flux through the GABA-R channel. Steroids inhibit [35S]TBPS binding when present in high concentrations or when GABA is present; we now present evidence that low concentrations of some steroids enhance binding in certain brain regions. [35S]TBPS binding was measured in rat brain sections by autoradiography and in homogenates. Alphaxalone (1 \(\mu M \)) enhanced TBPS binding in inferior colliculus > cerebral cortex = hippocampus > cerebellar molecular layer cortex = hippocampus > cerebellar molecular layer
with little change in the cerebellar granule cell with little change in the cerebellar granule cell layer. 5α -Androstan- 3α , 17β -diol (10 μ M) enhanced TBPS binding in cerebral cortex deep layers > inferior colliculus = hippocampus > cerebellar molecular layer, while binding in the cerebellar granule cell layer and superficial cerebral cortex were inhibited. 5α -Pregnan- 3α -hydroxy-20-one showed little or no effect on TBPS binding at 1 μ M, but at 10 μ M inhibited binding in all tissues assayed. Thus, steroids differentially modulate the GABA receptor in a subtype-specific manner. receptor in a subtype-specific manner.

EFFECTS OF GONADAL STEROID HORMONES ON BENZODIAZEPINE RESPONSES AND RECEPTORS. M.A. Wilson, R.Biscardi* and K.J.Long*. Dept. Pharmacology, Univ. South Carolina Sch. of Medicine, Columbia, SC 29208.

Steroid hormone derivatives have been shown to interact with the GABA/benzodiazepine receptor complex and to modify GABAergic responses. Since benzodiazepines (BZs) similarly modulate GABA responses, we examined if changes in the hormonal milieu modify responses to acute and chronic BZ exposure. Bicuculline seizure thresholds were determined in groups of male, intact female and ovariectomized (OVX) rats following ACUTE diazepam (DZ) treatment or CHRONIC exposure (3 wk) to DZ-filled silastic capsules. Both basal seizure thresholds and anticonvulsant effects of acute DZ treatment (0.5 mg/kg,iv) were similar in these hormonally-distinct groups. Binding studies of several brain areas indicated benzodiazepine receptor levels were comparable in males, females and OVX rats and did not fluctuate over the estrous cycle. Seizure threshold values and BZ binding parameters failed to correlate with circulating levels of estrogen or progesterone. As seen previously in male rats, chronic exposure to DZ resulted in tolerance to the anticonvulsant effects of DZ (Gallager et al., Brain Res. 342:26,1985). Early results suggest intact females, but not OVX rats, also develop tolerance to DZ's anticonvulsant effects after chronic DZ exposure. All groups had similar brain DZ levels following acute and chronic BZ treatments. Support: PHS R29 DA05932-01, PHS RR05815, & USC RPS Grants.

OVARIAN ENDOCRINE STATUS INFLUENCES BEHAVIOR IN THE ELEVATED PLUS-MAZE AS WELL AS THE ANXIOLYTIC EFFECT OF DIAZEPAM. Daniel Bitran and Carol K. Kellogg. University of Rochester, Department of Psychology, River Campus, Rochester, NY 14627.

There are well documented barbiturate-like effects of the reduced metabolite of

There are well documented barbiturate-like effects of the reduced metabolite of progesterone (P), $S\alpha[\beta]$ -pregnane, 3α -ol, 20-one (tetrahydroprogesterone - THP), both physiologically and neurochemically, at the level of the GABA/BDZ receptor complex. Based on findings from *in vitro* studies, one would predict that anxiolytic effects should be most apparent at times of high circulating progesterone, i.e., estrous and pregnancy.

The following experiments were aimed at documenting the relationship between ovarian endocrine status and activity in the elevated plus-maze - a behavior that is sensitive to the anxiolytic effects of BDZs. Female Long-Evans rats (200-300 g) were either ovariectomized (OVx) or left intact and cycling. Other females were mated and tested at gestational day 19 or postparturient days 2 and 7. Diazepam (DZ) was administered IP for 6 consecutive days, in order to produce tolerance to its sedative effects. Thirty minutes after the last injection, locomotor activity was ponitored for 5 min in a novel areas followed by a 5 min test in the plus-maze.

monitored for 5 min in a novel arena, followed by a 5 min test in the plus-maze. Spontaneous behavior in the plus-maze was not different between OVx and estrous females. However, the anxiolytic effect of DZ (1 mg/kg) was dependent on gonadal status. In intact cycling females, DZ significantly increased the number of open arm entries and the time spent in the open arms. There was no response to DZ in OVx rats, but a DZ response was observed in OVx females given a hormonal regimen that results in estrus behavior (estradiol + P). Behavior in the plus-maze also varied as a function of pregnancy and parturition. Postparturient females spent significantly more time on the open arms than did virgin females, whereas the behavior of pregnant and virgin females did not differ. In addition, DZ at 1.0 or 2.5 mg/kg, had no effect on the plus-maze behavior of pregnant females. Together, these data indicate that ovarian hormones are permissive to the anxiolytic effect of BDZs, and, in contrast to predictions from in vitro studies, the postpartum period is accompanied by a reduction in anxiety-related behavior. MH31850 and MH00651.

EFFECT OF ACUTE ADMINISTRATION OF BENZODIAZEPINES (BZD) ON GABA, RECEPTOR & SUBUNIT MRNAs IN RAT CEREBRAL CORTEX. P. Damschroder-Williams*, P. Montpied, A. L. Morrow, S. M. Paul. Section on Molecular Pharmacology, Clinical Neuroscience Branch, NIMH, Bethesda, MD 20892 It is generally acknowledged that many of the pharmacological actions of

It is generally acknowledged that many of the pharmacological actions of BZDs are mediated via an augmentation of GABAergic neurotransmission. In order to investigate the effect of BZDs on the expression of GABAA, receptor mRNA expression, rats were administrated a single acute dose of the short-acting BZD, diazepam (10 mg/kg) or the long-acting BZD, flurazepam (100 mg/kg). Total RNA was extracted from the cerebral cortices of individual animals and a subunit mRNAs were quantified by Northern blot analysis using a human 32P-labelled GABAA, receptor α subunit cRNA probe (J. Neurochem. 51, 1651, 1988). An internal standard (600bp sense β-actin fragment) was added to each tissue sample to control for identical RNA recoveries. Three hours after diazepam or vehicle administration, a significant reduction in GABAA (α1 subunit) mRNA was observed in rat cerebral cortex (n=4, -55%, p<0.05) from diazepamtreated rats compared to controls. This effect was not observed 24 hours after BZD administration. In contrast, flurazepam administration resulted in a similar reduction at 3 hrs (n=4, -50%, p<0.05), that persisted for at least 24 hours (n=3, -50%, p<0.05). No significant alteration in the glutamic acid decarboxylase mRNA levels was observed following acute BZD administration. These data suggest that acute administration of BZDs alters the level of GABAA receptor (α1 subunit) mRNAs in rat cerebral cortex. This reduction in mRNA levels may represent BZD-induced alterations in GABAA, receptor mRNA levels.

GONADAL STATUS IN MALE RATS AFFECTS FUNCTION OF THE BENZODIAZEPINE/GABA RECEPTOR COMPLEX IN REPONSE TO ENVIRONMENTAL CHALLENGE. Rence Primus and Carol K. Kellogg. Dept. of Psychology, University of Rochester, Rochester, N.Y. 14620.

Function at the benzodiazepine (BZD)/GABA receptor chloride channel complex during social interaction (SI) in a familiar vs. an unfamiliar environment was evaluated in young adult male rats as a function of pubertal gonadal status. Male rats were either castrated or left intact at 19 days of age and then subjected to the SI test of anxiety at 60 days. Chloride (CI-) enhancement of Flunitrazepam (Flu) binding and GABA-mediated CI- transport were both measured immediately following the test.

Chloride enhancement of Flu binding was facilitated to a greater extent in intact rats exposed to the unfamiliar environment than in intact rats exposed to the familiar environment. There was no differential effect of the two environments on GABA-mediated Cl- transport, but a decrease in the EC50 for GABA stimulation of Cl- uptake was evident in rats exposed to the SI test (regardless of the environment) when compared to naive intact male rats. Cl- enhancement of 3H-Flu binding in juvenile castrated rats was also differentially affected by the two environments, but now facilitation of Flu binding by Cl- was greater in the familiar environment than in the unfamiliar environment. GABA-mediated Cl- transport in juvenile castrated rats, however, was unaltered during environment-related SI and was comparable to that measured in naive intact male rats.

The findings suggest that function at the BZD/GABA receptor complex in intact male rats is differentially affected by various aspects of the SI test. In addition, the finding that juvenile castration alters functional changes at the BZD/GABA receptor complex in response to challenge suggests a role for gonadal function during development in the expression of an organism's response to challenge. Sponsored by Grants MH31850 and MH00651.

DEFEAT STRESS IS ASSOCIATED WITH INCREASED GABAA RECEPTOR SUBUNIT mRNAs. I. Kang. M.L. Thompson. J. Heller*, L.G. Miller. Div. of Clinical Pharmacology, Depts. of Psychiatry and Pharmacology, Tufts-New England Medical Ctr., Boston, MA 02111.

Stress has been shown to affect a number of neurotransmitter systems. The defeat stress paradigm is a model of social stress involving defeat of an intruder by a resident male. Defeat stress leads to transient increases in binding at the benzodiazepine site on the GABA_A receptor; other stress paradigms augment GABA_A receptor function. To assess effects of defeat stress on GABA_A receptor mRNAs, we evaluated mRNAs for the alpha1 and gamma2 subunits in cortex using Northern hybridization in sham, defeated, and resident mice. Control hybridization was determined in each case for GAPDH mRNA. For the alpha1 subunit, mRNA was unchanged from controls immediately after stress. However, at 4 hrs after stress, mRNA was increased by appoximately 20%; at 8 hrs, by 60%; at 24 hrs by 100%; and at 72 hrs, by 120%. mRNA was unchanged in dominant mice up to 72 hrs. mRNA was also unchanged in dominant mice at 0 and 24 hrs after stress. Results for the gamma2 subunit were similar; mRNA was increased by 20% at 4 hrs; 50% at 8 hrs; 50% at 24 hrs; and 120% at 72 hrs. No alterations were observed in mRNA of sham mice up to 72 hrs, or resident mice at 0 and 24 hrs. GAPDH mRNA was not affected in any group. Defeat stress is associated with a persistent increase in GABA_A receptor subunit alpha1 and gamma2 mRNAs, which appears to be specific for the defeated animal.

 γ -Aminobutyric acid (GABA), the major inhibitory neurotransmitter in brain, is known to interact with a subclass of GABA receptors that activate a ligand-gated chloride ion channel. Chronic exposure of cultured embryonic chick neurons to physiological concentrations of GABA results in a time-dependent down-regulation of these GABAA receptors. To delineate the cellular mechanism(s) responsible for agonist induced down-regulation of GABAA receptors we quantified the levels of GABAA receptor α subunit messenger RNAs, which encode the subunit(s) containing agonist recognition site(s); and observed a marked reduction in α subunit transcripts following exposure of embryonic chick neurons to GABA. Both the down-regulation of GABAA receptors and α subunit mRNAs induced by GABA are completely antagonized by the specific GABAA receptor antagonist SR-95531. These data demonstrate the presence of an agonist-induced receptor-mediated mechanism for regulating the expression of receptor subunit-encoding mRNAs that may be involved in the development of tolerance to the pharmacological actions of drugs known to act via GABAA receptors.

PRENATAL EXPOSURE TO DIAZEPAM SELECTIVELY INCREASES SEIZURE SENSITIVITY ONLY TO DRUGS ACTING AT THE GABA/BDZ CHLORIDE CHANNEL RECEPTOR COMPLEX. Carol K, Kellogg and Daniel Birran Univ. of Rechester. Dept. of Psychology. Rochester. NY 14627

<u>Daniel Bitran.</u> Univ. of Rochester, Dept. of Psychology, Rochester, NY 14627
We reported that adult male rats prenatally exposed to diazepam (DZ) exhibited a decreased threshold to bicuculline-induced scizures and, in parallel studies, a corresponding increased sensitivity to the *in vitro* antagonistic effects of bicuculline on GABA-stimulated chloride influx (Bitran et al., <u>Soc Neurosci Abst</u> 15, 1989). We now report that prenatal exposure to DZ results in an enhanced sensitivity to chemoconvulsants that show pharmacological specificity to the GABA/BDZ receptor

now report that prenatal exposure to DZ results in an enhanced sensitivity to chemoconvulsants that show pharmacological specificity to the GABA/BDZ receptor. Pregnant Long-Evans rats were injected SC with vehicle or DZ (1.0 or 2.5 mg/kg) from gestational days 14 to 20. Adult male offspring (400-500 g) were anesthetized (12 mg/kg Ketamine, 10 mg/kg Xylazine) and the jugular vein cannulated. Threshold dosages to facial clonus, myoclonic jerk, forelimb clonus, and extensor tonus were determined during the intravenous infusion (2 ml/min) of the following chemoconvulsants: bicuculline methiodide, a GABAa antagonist (BMI, 0.05 mg/ml); DMCM (0.5 mg/ml), a benzodiazepine inverse agonist; picrotoxin, a GABA-gated chloride channel blocker (PIX, 1 mg/ml); and non-GABAcrgic convulsants pentylenetetrazol (PTZ, 10 mg/ml), caffeine (CAFF, 20 mg/ml), and strvchnine (STRY, 0.1 mg/ml).

strychnine (STRY, 0.1 mg/ml).

Prenatal treatment with DZ decreased the threshold for BMI- and DMCM-induced facial clonus and myoclonic jerk by 35-40% and 20-40%, respectively. Threshold dosages of BMI and DMCM to forelimb clonus and extensor tonus were not affected by prenatal DZ treatment. A 25 to 40% reduction in the thresholds to PIX-induced facial clonus, myoclonic jerk, and forelimb clonus was observed with prenatal DZ treatment. There were no differences in the seizure threshold dosages of PTZ, CAFF, and STRY in adult males prenatally exposed to DZ. These results corroborate and extend previous findings that exposure to diazepam in utero induces long-lasting changes in the seizure threshold to chemoconvulsant agents, but only those that act at the GABA/BDZ chloride channel receptor complex. Supported by grant MH31850.

LOCALIZATION OF BENZODIAZEPINE RECEPTORS: COMPARISON OF IN VIVO SPECT IMAGING, EX VIVO AUTORADIOGRAPHY, AND IN VITRO RECEPTOR AUTORADIOGRAPHY.

E. Sybirska, M. Al-Tikriti, E. W. Johnson, S. Zoghbi and R. B. Innis. Dept. Psychiatry, VA Medical Center and Yale University, West Haven, CT 06516.

To assess the quantitative accuracy of neuroreceptor imaging with SPECT (Single Photon Emission Computed Tomography), we have compared SPECT images of the distribution of benzodiazepine (BZ) receptors in monkey brain with immediate postmortem analyses of the tissue.

Vervet and rhesus monkeys were injected with the BZ antagonist radioligand 1231-Ro16-0154. After SPECT scanning, the animal was killed and the brain sectioned in transaxial planes corresponding to the multiple levels of the SPECT images. Ex vivo autoradiography was used to quantitate the distribution of total 1231 radioactivity in 30µm tissue sections. After decay of the 1231 radionuclide (T_{1/2} = 13 hr), standard in vitro receptor autoradiography with 1251-Ro16-0154 was used to quantify the distribution of BZ receptors.

SPECT scans showed excellent regional correlations with the actual distribution of tissue radioactivity determined with ex vivo autoradiography. In addition, tissue punches confirmed the concentration of radioactivity in gray matter areas, with Brodmann's area 17 having the highest ratio of gray to white matter of 50.1

Comparison of \underline{ex} \underline{vivo} with \underline{in} \underline{vito} results generally showed an excellent correlation, which confirmed that the distribution of 123 radioactivity corresponds to the actual distribution of BZ receptors. However, some limited brain areas (like cerebellar cortical layers) showed moderate discrepancies between \underline{ex} \underline{vivo} and \underline{in} \underline{vito} results. The causes of these relatively small differences could be due to metabolites of the radioligand, the effect of endogenous modulators, or regionally differential washout of the \underline{in} \underline{vivo} radioligand.

289.17

IN VIVO CEREBRAL DISTRIBUTION OF THE PUTATIVE BENZODIAZEPINE RECEPTOR LIGAND I-123 Ro 16-0154 IN MAN. S. W. Woods, S. S. Zoghbi*, A. W. Goddard, J. P. Seibyl, I. G. Zubal*, R. M. Baldwin*, D. S. Charney, G. R. Heninger, P. B. Hoffer*, R. B. Innis. Dept. of Psychiatry, Yale U. Sch. of Med., New Haven, CT 06508.

The present study aims to evaluate the cerebral distribution in humans of 1-123 Ro 16-0154, a putative benzodiazepine receptor (BZR) ligand for use with single photon emission computed tomography (SPECT). METHOD: Healthy subjects undergo intravenous injection of 5 mCi 1-123 Ro 16-0154, followed by serial single slice SPECT acquisitions and repeated whole body scans. RESULTS: In the single subject studied to date, activity peaked in striatum and white matter (WM) at the first measurement 16 min p.i., and in other regions at 40-60 min. p.i. Activity declined after peak at approximately 35%/hr. in striatum and thalamus and approximately 20%/hr. in other regions. 7.3% of the injected dose was present in brain at 3 hrs p.i. The regional distribution of activity was occipital > frontal > temporal = parietal = cerebellum > thalamus > striatum > white matter. The occipital:WM ratio was 10:1 at 90 min p.i. DISCUSSION: The high brain uptake and relatively slow washout suggest that displacement studies are feasible using this ligand. The regional radioactivity pattern is consistent with a BZR distribution but volume averaging effects and more subjects must be investigated.

289.14

INTERNALIZATION OF GABA/BENZODIAZEPINE RECEPTORS IN CHICK CORTICAL NEURONS. M.H. Jalilian Tehrani and E.M. Barnes, Jr. Baylor Col. of Med., Houston, TX 77030.

Previous studies have shown that chronic exposure of chick cortical neurons to GABA or benzodiazepine agonists leads to a reduction in the density of GABA/benzodiazepine receptors. In order to study the role of receptor internalization in this process, we have utilized N-(4-sulfophenyl)thiocarbamoyl-1012S [SPTC-1012S] as an impermeant displacer of [$^3\mathrm{H}]\mathrm{flunitrazepam}$ binding to intact neurons. A $24+\mathrm{ir}$ treatment of the cells with 200 $_\mathrm{H}\mathrm{M}$ GABA increased the fraction of intracellular receptors, defined by SPTC-1012S insensitive [$^3\mathrm{H}]\mathrm{flu}$ binding, from 8.0 \pm 2.0% to 30.4 \pm 2.5% of the cellular total. A similar treatment with 100 nM clonazepam raised the proportion of internal receptors to 19.2 \pm 2.3%. The overall level of [$^3\mathrm{H}]\mathrm{flu}$ binding declined by 20% and 12%, respectively, during the exposure to GABA or clonazepam. After a 24-hr treatment of neurons with 10 mM NH_Cl or 50 $_\mathrm{H}\mathrm{M}$ chloroquine, the fraction of internal receptors was increased to 26.6 \pm 3.9% and 14.5 \pm 3.3%, respectively, compared to untreated controls (7.0 \pm 1.5%). Both compounds produced a decline in the total receptor pool (by 32% and 23%, respectively). The data suggest that both GABA and benzodiazepine agonists accelerate the sequestration of receptors. Permeant amines, however, are more likely to interfere with the recycling of internalized receptors to the neuronal surface. (Supported by NIH grants DK 17436 and NS 11535).

QUANTITATIVE SPECT IMAGING OF THE BENZODIAZEPINE RECEPTOR IN NON-HUMAN PRIMATE BRAIN. R.B. Innis. S.W. Woods. S. Zoghbi, E.W. Johnson, M. Al-Tikriti, E. Sybirska, J. Seibyl, R. Malison, P.B. Hoffer, D.S. Charney, and G.R. Heninger. Dept. Psychiatry, VA Medical Center and Yale University, West Haven, CT 06516.

Ro16-0154 is a benzodiazepine (BZ) receptor antagonist analog of the better known agent Ro15-1788. 1251-Ro16-0154 binding to brain tissue homogenates has high affinity ($K_1 = 0.5$ nM at 37°C) and high ratios of specific:non-specific binding (50:1). We have examined the high energy gamma-emitting 1231-Ro16-0154 as an in vivo BZ receptor probe with SPECT (Single Photon Emission Computed Tomography).

In a series of 20 studies, female baboons were injected with 1-18 mCi ¹²³I-Ro16-0154 and scanned for 2-6 hours in the Strichman 810X Brain Imager. Radiolabel uptake was concentrated in cortical areas with highest density in occipital cortex. Maximum uptake was reached within 30-90 min and relatively stable for the following 180 min. Whole body scans showed brain uptake of 11-12% of injected dose at 60-120 min and clearance of greater than 96% of total body radioactivity via urine in 24 hours. Approximately 90% of brain radioactivity could be displaced by Ro15-1788 (0.1 mg/kg i.v.) within 30-45 min, and, thus, appeared to be associated with the BZ receptor. Displacement studies were performed with stepwise increasing i.v. doses of three agonists (diazepam, clonazepam, alprazolam) and two antagonists (Ro15-1788 and "cold" Ro16-0154). The in vitro receptor affinities (K₁) were strongly correlated with the in vivo displacing potencies (ED₅₀) for these five agents (r=.94 on log-log plot). Ex vivo autoradiographic analysis of monkey brain tissue sections obtained a distribution of radioactivity which exactly mirrored the distribution of BZ binding sites determined with standard in vitro receptor autoradiographic methods.

289.18

BENZODIAZEPINE RECEPTOR ACTIVE COMPOUNDS FROM PLANT MATERIAL. M.R.Witt* and M.Nielsen. Research Laboratories, Denmark. Hospital, Roskilde,

Amentoflavone, a biflavonoid, was purified from a plant extract and shown to have high affinity to benzodiazepine receptors in-vitro (Nielsen, M. et al. Biochem. Pharmacol., 37:385, 1988). An estimation of structure/activity on 13 flavone derivatives (obtained from H. Geiger, Stuttgart, Germany) showed that e.g. methylation of hydroxylgroups in amentoflavone decreased the affinity for the benzodiazepine receptor.

Recently we have analysed a series of African medicinal plants. After extraction of plant material and screening for brain receptor interactions using high affinity ligand binding in-vitro, receptor active fractions were purified using HPLC. We have isolated Oxayohimbin-16-carboxylic acid-didehydro-19-methyl, methyl ester (Mayumbin; IC50 = 0,8 µM on inhibition of 3H-diazepam binding) and 2,6 (3,4 methyl-enedioxyphenyl) = -3,7 dioxabicyclo [3.3.0] octane (Sesamin; IC50 = 6 µM for inhibition of 3H-diazepam binding). Sesamin has been reported to have calming and axiety reducing effects in humans and animals (Benecke H.P. and Sherwood B.E, U.S. patent 4,427,694, 1984).

DISTRIBUTION OF SEROTONERGIC BINDING SITES IN CAT SPINAL CORD. L.M. Pubols, L. Kane* and S. Dawson*. R.S. Dow Neurological Sciences Institute, Good Samaritan Hospital and Medical Center, Portland, OR 97209

The spatial distribution of serotonin (5HT) binding sites in the lumbar spinal cord grey matter of the cat was studied autoradiographically, using 1-2 nM [³H]5HT, with and without 10 μ M unlabelled 5HT, to determine non-specific and total binding, respectively. Binding was quantified, using the video counting mode of a Bioguant image analysis system to calculate the percent of total area occupied by silver grains over spinal cord laminae II, III-IV, V-VI, VII, IX, and X. Significant levels of specific binding were found in all of these regions. Specific binding as a percent of total binding was highest in laminae II (84%) and X (72%), and lowest in lamina VII (51%). By analysis of variance, the effect of laminar location on the degree of binding was highly significant for specific binding, but insignificant for non-specific binding, indicating that laminar differences in specific binding were not due to differential quenching of radioactivity.

In contrast to an earlier study (Seybold, 1985), which described dense labelling of serotonin binding sites by [3H]LSD in laminae II and X of the cat, and a lack of labelling in the ventral horn, the present study reveals serotonin binding sites throughout the dorsal and ventral horns in this species. (Support: NIH NS19523)

290.3

IDENTIFICATION OF SPINAL 5-HT1C BINDING SITES. R.Pluchino,* M.R. Pranzatelli, and S. DiMauro. Neurology, Pediatrics, Columbia University, NY

We identified recognition sites in rat spinal cord with the properties of 5-HT $_{1C}$ receptors. The sites were labelled using (3 H)mesulergine (10uM 5-HT displacer) or (3 H)5-HT (5-HT displacer, pindolol blocker). Bmax values (pmol/g) were 3.8 \pm 0.3 and 4.3 \pm 0.5, respectively (n=4-7). The corresponding percent maximum specific binding was 70 and 38. Kds (nM) were 1.8 \pm 0.1 and 4.7 \pm 0.6, respectively. Inclusion of 20 nM spiperone to block potential 5-HT2 sites reduced the Bmax for binding sites labelled by (^{3}H) mesulergine 32% without changing kd or nH. However, drug affinities were similar in the presence or absence of spiperone, and the order of drug potencies was consistent with drug affinities for the 5-HTlC receptor: 5-HT, mesulergine, mianserin> Ru24969, ketanserin, DOD spiperone> 8-OH-DPAT, pindolol. Using either (3H)DOB (5-HT displacer, cinanserin blocker) or (3H)mianserin (5-HT displacer, spiperone blocker), no specific binding attributable to 5-HT1C sites was obtained. These data suggest that a substantial population of spinal 5-HT1 receptors are of the 5-HT1C subtype and that (3 H)mesulergine and (3 H)5-HT are useful radioligands for spinal 5-HT $_1$ C sites. (Supported by NIH grant 1-K08-NS01158 (CIDA), the Myoclonus Research Fund, the United Cerebral Palsy Education and Research Fund (R381-88), and the William Randolph Hearst Foundation)

290.5

A NEW SELECTIVE RADIOIODINATED PROBE FOR LABELING SEROTONIN 1B AND SEROTONIN 1D RECEPTORS. LIGAND-BINDING STUDIES ON THE CENTRAL NERVOUS SYSTEM OF RAT AND GUINEA PIG USING QUANTITATIVE AUTORADIOGRAPHY. P. Boulenquez* J. Chauveau*2, L. Segu*1, A. Morel*2, J. Lanoir1 and M. Delaage*2

1CNRS, Lab. de Neurobiologie E6, BP 71, 13402 Marseille Cedex 09; ²Immunotech, Luminy, Case 915, 13288 Marseille Cedex 09, France.

The serotonin-O-glycyl-tyrosinamide (S-CM-GTNH2) was radioiodinated on the tyrosine residue. The binding of 0.02 nM S-CM-G[125I]TNH2 on rat and guinea pig brain sections was reversible and saturable ($K_d = 1.3$ and 6.4 nM, respectively). The anatomical distribution of the labeling was heterogeneous and corresponded exactly to those of serotonin-1B sites (5-HT_{1B}) in the rat, or 5-HT_{1D} sites in the guinea pig. Hippocampus (5-HT_{1A}) and choroid plexus (5-HT_{1C}) are not labeled. The binding of 0.02 nM S-CM-G[125 I]TNH $_2$ in substantia nigra is inhibited with low concentrations of 5-HT, S-CM-GTNH $_2$ and CGS-12066B (IC50 = 1.7, 3.9 and 79.5 nM respectively in the rat and 1.1, 18.0, 25.4 nM in the guinea pig). Other compounds which selectively bind to 5-HT₂, 5-HT₃, dopaminergic and noradrenergic receptors did not inhibit the radioligand binding at 10⁻⁵M in the anatomical structures which contain these receptors. S-CM-G[¹²⁵I]TNH₂ is therefore a new, powerful probe for 5-HT_{1B} binding sites which does not interact with β-adrenergic receptors. Furthermore, this is the first radioiodinated probe for 5-HT_{1D} binding sites and it could be useful for studying this subtype in human brain. Since the binding of S-CM-G[¹²⁵]]TNH₂ had a low dissociation kinetic constant and was immobilized with chemical fixatives, we are now studying the subcellular distribution of 5-HT_{1B} and 5-HT_{1D} sites.

LOCATION OF SEROTONIN RECEPTORS MEDIATING RENIN RESPONSE TO DOI. P.A. Rittenhouse, E.A. Bakkum*, K. Kunimoto*, J. Yracheta*, L.D. Van de Kar. Loyola Univ. Chicago, Stritch

<u>Stracheta*</u>, <u>L.D.</u> <u>Van de Kar</u>. Loyola Univ. Chicago, Stritch Sch. Medicine, Dept. Pharmacology, Maywood, IL, 60153.

The serotonin (5-HT_{2/IC}) agonist DOI increases plasma renin activity (PRA), in conscious rats, via activation of 5-HT₂ receptors (Rittenhouse et al., The Pharmacologist, 32 1990). The aim of this study was to differentiate central from peripheral receptors which mediate this response. We injected DOI (0, 0.5, 1.0, 10.0 mg/kg, ip) to rats pretreated with saline or 0.1 mg/kg xylamidine, a peripheral 5treated with saline or 0.1 mg/kg xylamidine, a peripheral 5-HT₂ antagonist. DOI dose-dependently increased PRA. The dose response curve was shifted to the right in the xylamidine pretreated rats, suggesting a role for peripheral 5-HT₂ receptors in the effect of DOI. Subsequently, we injected DOI into the lateral cerebral ventricles (ICV), using doses lower than the peripherally effective doses: 0, 1, 10, 100, and 200 μ g/kg. Only 200 μ g/kg DOI significantly elevated PRA. To determine if blood pressure (BP) changes were responsible for DOI's effects, we measured BP through implanted femoral arterial catheters. Injection of DOI ICV at 0, 10.0 and 200 μ g/kg produced a dose-dependent rise in implanted femoral arterial catheters. Injection of DOI ICV at 0, 10.0 and 200 $\mu g/kg$ produced a dose-dependent rise in BP of 3, 7, and 36 mm Hg respectively, within 5 minutes post-injection. In contrast, intra-arterial injection of 200 $\mu g/kg$ DOI caused a slower rise (15-30 minutes post-injection) of 20 mm Hg in BP. These data suggest that DOI's elevation of PRA and BP may have both peripheral and central components. Supported by NIDA DAO4865.

AUTORADIOGRAPHY OF 5-HT1A SITES IN RATS WITH NEONATAL 5,7-DHT LESIONS. M.M. Durkin.* M. R. Pranzatelli, A.I. Barkai.* B.S. McEwen, and T.A. Pedley. Neurology, Pediatrics, & Psychiatry, Columbia Univ. and Laboratory of Neuroendocrinology, Rockefeller Univ., New York, NY.

We recently reported that rats with brainstem hyperinnervation showed altered behavioral responses to 5-HT agonists after neonatal 5,7dihydroxytryptamine (5,7-DHT) lesions made by intraperitoneal (ip) compared to intracisternal (ic) injection (Dev Brain Res 50: 89, 1989). To investigate the role of 5-HT1A receptors in these differences, we labelled 5-HT1A sites autoradiographically with 2 nM [3H]DPAT (10 µM 5-HT as displacer) 4 months after ip or ic 5,7-DHT or saline (n=16). The regional distribution of 5-HT1A sites conformed to previous reports of highest receptor densities in hippocampus (CA1, dentate gyrus), septal nuclei, dorsal and median raphe, mammillary body, and certain cortical regions (cingulum, claustrum). 5-HT1A sites were significantly decreased (-87%) only in the dorsal raphe (p<0.0004, ANOVA), and only after ic-made 5,7-DHT lesions. No reductions were found after lesions made by ip injection compared to controls. Further studies will be required to determine if dorsal raphe 5-HT1A sites recovered or were never reduced. 5-HT1A receptor density in the dorsal raphe may contribute to the different behavioral consequences of the route of neonatal 5,7-DHT injection. LOCALIZATION OF 5-HT_{1a} RECEPTOR mRNA IN RAT BRAIN.
D. Brousseau. R. Artymyshyn. and P. McGonigle. Department of Pharmacology, University of Pennsylvania, Phila, PA. 19104.
Using the nucleotide sequence for the human 5-HT_{1a} receptor, a unique 183 base segment of the rat 5-HT_{1a} receptor gene was amplified from a rat genomic library by using PCR technology and subsequently ligated into the transcription vector PGEM.3Z. Seven clones were selected for dot-blot screening against a ³²P-labelled probe which was directed against the middle 36 bases of the 183 base 5-HT_{1a} receptor segment. DNA sequencing of a positively labelled clone determined that it contained the desired gene product. Nucleic acid sequence homology between the rat and human 5-HT_{1a} receptor HT1a receptor segment. DNA sequencing of a positively labelled clone determined that it contained the desired gene product. Nucleic acid sequence homology between the rat and human 5-HT1a receptor was determined to be approximately 70% in this region. Similar amounts of homology have been observed within discrete regions of other mammalian G-protein linked receptors, particularly around the amino and carboxy termini. Identification of the appropriate clone permitted the synthesis of ³⁵S-CTP labelled anti-sense probe to cellular mRNA for the 5-HT1a receptor. In situ hybridization to normal rat brain tissue sections has demonstrated an appropriate and selective regional mRNA distribution for the 5-HT1a receptor as compared with the known distribution of the receptor itself using the radiolabelled ligand 8-OH-DPAT. In particular, regions which were labelled most heavily included the CA fields of the hippocampus as well as the dentate gyrus, the entorhinal cortex, the raphe nuclei, and the anterior olfactory nuclei. This contrasted with a low level of hybridization in the thalamus and basal ganglia and an intermediate level in the frontal cortex. In many areas, including the olfactory nuclei and entorhinal cortex, there was an apparent mismatch between the mRNA and 8-OH-DPAT binding such that mRNA fields surrounded fields of ligand binding. GABA-A RECEPTORS ON DORSAL COLUMN AXONS IN NEONATAL RAT

SPINAL CORD. K. Sakatani, M. Chesler, Z. Hassan W. Young Dept. of Neurosurgery, NYU Medical Center, 550 First Ave. New York, NY, 10016 GABA has a depolarizing action on peripheral myelinated sensory axons and their dorsal horn terminals. We sought to determine whether these receptors continue along ascending dorsal column axons, using isolated segments of thoracic dorsal column from 11-17 day-old neonatal rats. Segments were excised from isolated spinal cords under chilled (4-10° C), oxygenated Ringer, placed in a recording chamber, then superfused with room temperature Ringer for 1-2 hours prior to recording. Bipolar platinum electrodes were used to deliver constant current, submaximal stimuli (100 phantain electrodes were used to deriver constant current, submarian summul (remediate) misec, 2 mA, 0.2 Hz). The elicited compound action potential (CAP), was recorded with a glass micropipette (1 M NaCl, 1-2 MΩ) placed 0.5-2mm from the stimulating electrode. And the end of experiments, the isolated tissue was examined histologically to exclude possible contamination of gray matter.

GABA (10⁻⁴-10⁻³ M) reversibly depressed the CAP amplitude (10⁻³ M: 56±7% of control; mean±SD, n=5), and prolonged the latency (119±8%). The GABA-A receptor agonist isoguvacine (10⁻⁴-10⁻³ M) caused a similar reduction in amplitude $(10^{-4} \text{ M}: 57\pm10\%: \text{n=3})$ and increase in latency $(111\pm4\%)$. However, at lower concentrations (10^{-5} M) , GABA and isoguvacine increased the CAP amplitude $(118\pm5\%, \text{n=3})$ and decreased the latency $(92\pm9\%)$. By contrast, the GABA-B agonist baclofen (10-4 M) had no detectable effect on the CAP (n=2),

The results of this study indicate that in spinal cord, GABA-A receptors are present not only on the terminals of primary afferents, but can also be found on ascending dorsal column axons. Whether GABA has similar effects on conduction in the adult spinal cord remains to be determined. While the role of these receptors in the function of neonatal axons is not apparent, their presence suggests that axonal conduction could be subject to modulation by an extra-synaptic mechanism.

EVIDENCE FOR GABAA RECEPTOR SUBUNIT HETEROGENEITY IN THE RAT PITUITARY ANTERIOR AND INTERMEDIATE LOBES. J. Berman*. Depritchett. G. Kuchel and J. L. Roberts. Fishberg Center For Neurobiology, Mt. Sinai School of Medicine, NY, NY 10029 and Department of Pharmacology, U. of Penn, Phila., PA 19104.

The heterogeneity of GABAA receptor 8 subunits is believed in most

instances to confer distinct pharmacological and regulatory properties upon GABA receptors in a cell and tissue specific manner. Studies utilizing *in situ* hybridization have shown that more than one subunit subtype may be localized to a single specified cell population (Ymer et al., EMBO, 8: 1665). Here, we present results implying expression of all known GABAA receptor B subunit genes in lactotrophs and melanotrophs. Using the polymerase chain reaction, and for ß1 and ß3 subunits, ribonuclease protection assays, we have demonstrated the presence of ß1, ß2 and ß3 subunit mRNA in both the anterior and intermediate lobes of the rat pituitary. The ß1 subunit is less abundant than 63 in both tissues, and both messages are substantially more abundant in the anterior pituitary. This finding may reflect the high proportion of anterior pituitary cells which are GABAA receptor bearing lactotrophs. The anterior and intermediate lobes of the rat pituitary are not known to contain any GABAA receptor bearing cells other than lactotrophs and melanotrophs respectively. Thus the observation of multiple GABAA receptor subtypes in these tissues suggests that either multiple receptor types coexist in single cells or that microheterogeneity with respect to receptor composition exists in these cell populations.

DIFFERENTIAL DISTRIBUTION OF THE mRNAS ENCODING TWO FORMS OF GLUTAMIC ACID DECARBOXYLASES IN THE RAT BRAIN: INSIGHTS ON THEIR FUNCTIONS. S. Feldblum, N.J.K. Tillakaratne, M.G. Erlander, and A.J. Tobin. Department of Biology, UCLA, Los Angeles, CA 90024.

In the mammalian brain, GABA synthesis depends on two forms of glutamic acid decarboxylase (GAD) which differ in the mass subsolution less than 100 miles to the control of
forms of glutamic acid decarboxylase (GAD) which differ in size, subcellular location and affinity for the cofactor pyridoxal-5'-phosphate. These two enzymes, GAD₆₅ and GAD₆₇, are encoded by two mRNAs that are the product of two genes. To investigate the possible functional significance of two GADs in different types of neurons we have compared the distribution of the two GAD mRNAs throughout the rat brain using Northern analysis and in situ hybridization. Both forms of GAD were present in all the examined regions except for the triangular nucleus of the septum and the globus pallidus, where only GAD₆₇ mRNA was detected. With several exception, GAD₆₇ mRNA was present at higher levels than GAD₆₅ mRNA throughout the brain. In the olfactory bulb, globus pallidus, and visual and auditory systems GAD₆₇ mRNA was more abundant in neurons with no or short axons and restricted dendritic arborization, while short axons and restricted dendritic arborization, while ${\sf GAD}_{\sf 65}$ predominated in cells with a more complex spiny dendritic field. We suggest the involvement of the two forms of GAD in different types of synapses, possibly allowing different means of modulating the synaptic GABA. Supported by NS22256 to AJT.

GABAERGIC TERMINALS ON DENDRITES AND DENDRITIC SPINES IN THE PROJECTION ZONE OF THE PERFORANT PATH OF THE DENTATE MOLECULAR LAYER. E. Filkova, H. Eason* and P. Schaner*. Department of Psychology, University of Colorado, Boulder, CO 80309.

We have studied GABAGY:
We have studied GABAGY:
in the dentate molecular layer of 8 mice using postembedding immunogold electron microscopy. In the perforant path (PP) projection zone of the dentate molecular layer (DML), we have regularly observed labeled axon terminals syntapsing on dendritic shafts in the form of symmetrical contacts. The dendrites receiving these synapses were GABA negative. In addition, we found dendritic spines contacted by GABA antibody labeled axon terminals. In most instances observed, the labeled axon terminal made a symmetrical contact on the spine stalk, while an unlabeled asymmetrical terminal contacted the spine head. The symmetrical contacts sometimes could be seen extending onto the spine head. GABA positive unmyelinated axons were seen making "en passant" synaptic contacts.

One possible source of the GABAergic terminals is the entorhinal cortex (EC). A small population of GABAergic sparsely spinous horizontal-bipolar cells and multipolar cells, located among the projection neurons of layers II and III of the EC, were also shown to terminate in the PP projection zone of DML (Germroth et al., Brain Res., 494, 187. terminate in the Projection Zone of DML (Seminori et al., Brain Hes., 349, 187, 1899). In addition, strong lendritic inhibition has been observed in the dentate fascia following PP stimulation which appears to be GABA-mediated, as it is alleviated by a GABA antagonist picrotoxin (Wigström and Gustafsson, Brain Res., 295, 153, 1983). It is a feedforward type inhibition of dendrites as it occurs in the absence of granule cell firing. The observed GABAergic terminals synapsing on dendrites and dendritic spines in the PP projection zone could underlie this inhibition. This is the first time that a morphological substrate of a monosynaptic inhibition of dentate granule cell dendrites and spines is described. The authors acknowledge the help of Dr. M. Morales with the immunogold technique. Supported by AAA #AA06196 and MH #41834.

MOLECULAR IDENTITY OF BRAIN GLUTAMIC ACID DECARBOXYLASE (GAD) FORMS IN RAT OVIDUCT AND TESTIS. N.J.K.Tillakaratne, M.G.Erlander, K.F.Greif, G.D. Frantz*, and A.J.Tobin, Dept. of Biology, UCIA, Los Angeles, CA 90024.

The mammalian brain has two forms of GAD, GAD₆₅ and GAD₆₇, encoded by two different genes. GAD₆₅ and GAD₆₇ differ in size, affinity for the cofactor pyridoxal phosphate (PLP), and sub-cellular localization. We examined the distribution of the two forms in we examined the distribution of the two forms in non-neural tissues of the rat by immunoblotting, Northern blotting, and GAD activity measurements. GAD₆₅ is present in brain and oviduct. GAD₆₅ cDNA hybridizes to a 5.7 kb RNA in both brain and oviduct, where it is present in mucosal epithelial cells. The RNA of kidney, liver, pancreas, adrenal gland, uterus, or ovary contains to GAD₁₀ acquences. In contrast GAD₁₀ cDN₁₀ acquences. no ${\rm GAD_{65}}$ sequences. In contrast, ${\rm GAD_{67}}$ cDNA hybridizes to multiple RNA species in the testis. In the prepubertal testis, a 1.9 kb RNA predominates, and its expression coincides with the temporal course of Sertoli cell development. In the adult testis, the predominant form of GAD₆₇ RNA is 2.3 kb long, and its appearance coincides with postmeiotic spermatogenesis. <u>In situ</u> hybridization demonstrates that the presence of GAD₆₇ RNA in adult Sertoli cells, spermatids, and spermatozoa. The expression of both GAD forms in non-neural cells suggests that GABA may serve functional roles other than as a neurotransmitter. (Supported by NS22256 to AJT.)

291.6

REGIONAL COMPARISON OF BINDING OF DIFFERENT LIGANDS TO THE GABAA RECEPTOR. A. M. Mans. K. M.

LIGANDS TO THE GABAA RECEPTOR. A. M. Mans. K. M. Kukulka* and R. A. Hawkins. Dept. of Physiology and Biophysics, The Chicago Medical School, North Chicago, IL.

The GABAA receptor mediates inhibitory GABA neurotransmission throughout the brain. It contains a chloride ionophore and three allosterically interacting binding sites: a GABA-, benzodiazepine- and chloride-channel site. To learn more about the regional distribution of this receptor and its subtypes in brain, we measured the binding of four different ligands to rat brain sections in vitro using quantitative autoradiography, with computer analysis and three-dimensional autoradiography, with computer analysis and three-dimensional reconstruction. The ligands used were: ³H-muscimol (GABA site), ³H-flunitrazepam (benzodiazepine site), ³H-flumazenil (antagonist at the benzodiazepine site), and ³⁵S-TBPS (chloride-channel site). Nonspecific binding was determined in the presence of excess unlabeled competing ligand in each case. Major differences were found between flunitrazepam and muscimol binding reflecting the different distribution of the low- and high-affinity receptor subtypes respectively. Muscimol binding was generally lower except in the cerebellum, and completely absent in the brainstem structures. The pattern of flumazenil binding was similar to that of flunitrazepam with some subtle differences, e.g., in the superior colliculus and red nucleus. Binding of TBPS was more related to that of flunitrazepam than muscimol; however, significant differences were found, e.g., in the cortex, globus pallidus, thalamic nuclei and inferior colliculus. The results are consistent with the presence of heterogeneous populations of the GABAA receptor in the brain. Supported by NIH grant NS 16389.

WITHDRAWAL FROM CHRONIC COCAINE DECREASED DOPAMINE TRANSPORTER SITES IN THE RAT NUCLEUS ACCUMBENS (NAc). L.G. Sharpe, N.S. Pilotte, W.M. Mitchell*, E.B. De Souza and E.M. Dax*. NIDA, Addiction Res. Ctr. Baltimore, MD

Cocaine increases the synaptic level of dopamine (DA) by inhibiting DA uptake at terminal transporter sites This study was designed to assess whether DA-uptake sites changed after chronic cocaine or after cocaine withdrawal. Rats were infused i.v. with saline or 1 mg/kg cocaine Rats were infused i.v. with saline or 1 mg/kg cocaine every 12 min for 2 hr over 10 days and then killed within 15 min of or 10 days after (withdrawal) the last infusion. Brains were sectioned (10 um) and processed for DMI-insensitive [3H]mazindol binding. Total [3H]mazindol binding in saline control animals was highest in caudate putamen and NAc (250 to 540 fmol/mg protein Eq), moderate in ventral tegmentum, ventral pallidum, and medial prefrontal cortex, and least in substantia nigra, pars reticulata. Although the DMI-insensitive [³H]mazindol binding to DA uptake sites was not changed by chronic cocaine in any of the sites, 10-days of withdrawal from cocaine significantly reduced the density of binding when compared with controls only in the NAc (82%). The reduction of DA uptake sites during cocaine withdrawal may be involved in the development of sensitization to the pharmacologic effects of cocaine.

291.9

CALCIUM-BINDING PROTEIN IMMUNOREACTIVITY IN THE HUMAN MIDBRAIN: RELATIONSHIP TO NEURONS. D.C. German, K.F. Manaye, J. Brown* and C.R. Gerfen. Depts. of Psychiatry and Physiology, UT Southwestern Med. Cntr., Dallas, TX 75235; Lab of Cell Biology, NIMH, Bethesda, MD 20892.

In the rat, some dopaminergic (DA) neurons in the In the rat, some dopaminergic (DA) neurons in the retrorubral area (nucleus A8), substantia nigra (nucleus A9), and ventral tegmental area (nucleus A10) contain a 28 kDa calcium-binding protein (calbindin D28k or CaBP) (Gersen et al., PNAS 82:8780-8784, 1985). The present experiment sought to determine whether there is a comparable distribution of CaBP-containing neurons within the human midbrain DA neurons. Alternate 50 um thick sections were stained with an antibody to CaBP (1:2000) or tyrosine hydroxylase (TH, 1:2000). CaBP-containing cells were observed in: the region surrounding the red nucleus (in the dorsal portion of nucleus A9, along the midline and dorsal and lateral to the red nucleus); midline and dorsal and lateral to the red nucleus); nucleus paranigralis; and nucleus parabrachialis pigmentosus. In many cells both CaBP and neuromelanin pigment were present, providing direct evidence of CaBP within DA neurons. The distribution of CaBP/TH-containing cells in the human brain is similar to the distribution of DA neurons which remain in post-mortem parkinsonian brains (Garman et al. App. Neurol. 26:577.514, 1989). Supported (German et al. <u>Ann. Neurol.</u> 26:507-514, 1989). Supported by AG-08013 and Dallas Area Parkinsonism Society.

291.11

DIFFERENTIAL EFFECTS OF D2 ANTAGONISTS ON SPONTANEOUS ELECTRICAL ACTIVITY OF SUBSTANTIA NIGRA AND VENTRAL TEGMENTUM. K.A.Bonnet, X.-K.Gao* and A.J.Friedhoff, Millhauser Labs., New York Univ. School of Medicine, New York, NY 10016

The differential effects of D2 antagonists on rat brain functional activity has been reported to show selective effects on substantia nigra (SN) and ventral tegmentum (VTM). We have studied the relative interaction between ipsilateral VTM, SN, amygdala (AMY), frontal cortex (FC), caudate nucleus (CN) and nucleus accumbens (ACC). Animals were then studied with at least one session each with baseline and (2mg/kg,i.p.) haloperidol (HAL) and separately with baseline and (5 mg/kg) clozapine (CLO) at 15 minute intervals after injection of drug. Each record was analyzed for coherence within wavebands from 1.0 to 30 Hz. With CLO, there is a time-dependent increase in the influence of SN on AMY activity, in the 4-10 Hz wave band, and a decrease in the 12-16 Hz waveband. With CLO there, is an increase in VTM coherence with the AMY and SN and ACC in the 1-8 Hz frequency bands, but a decrease in the same frequency bands in the frontal cortex. With HAL there is a time-dependent increase in the influence of SN activity in the 4-8 Hz frequency bands upon CN and AMY, and a significant decrease in the 8-16 Hz activity that is shared by the SN and the ACC. With HAL, there was no change in the relationship between SN and VTM unlike CLO. We conclude that these differential effects of CLO and HAL will provide more direct information about the pharmacological effects of receptor pharmacology at mesencephalic and diencephalic cell groups and their influence on the functional and adaptive activity in distal, more rostral areas receiving input from those sites.

MIDBRAIN DOPAMINERGIC NEURONS (NUCLEI A8, A9 & A10) IN THE RAT: 3-DIMENSIONAL RECONSTRUCTION.

K.F. Manaye, M. Sadeq and D.C. German. Depts. of Psychiat. and Physiol., UT Southwestern Med. Cntr., Dallas, TX 75235.

The midbrain dopaminergic (DA) neurons reside within the retrorubral area, substantia nigra, and ventral tegmental area (nuclei A8, A9 and A10 respectively). The present experiment sought to quantify the number of DA neurons within each of the three subnuclei, and map their 3-dimensional distribution within the midbrain. Three 3-dimensional distribution within the midbrain. Three male albino rats (175-225 g) were perfuse fixed with 10% neutral buffered formalin, and the brains were blocked in a standard coronal plane. 30 um thick sections were cut on a freezing microtome. Every 3th or 4th section, from rostral to caudal within the midbrain (2.75 mm), was stained with an antibody against tyrosine hydroxylase (1:4000; Eugene Tech), and adjacent sections were stained with cresyl violet. The distribution of cells was bilaterally symmetrical, and on one side of the brain there was an estimated total of 12,430 +/- 694 (mean +/- SD) A8/A9 cells, and 10,771 +/- 847 A10 cells (numbers corrected for split cell counting error). Information about the number and distribution of midbrain DA neurons will be used in conjunction with future studies to will be used in conjunction with future studies to further characterize these cells in terms of their co-transmitters and afferent and efferent projections. Research supported by NIDA (DA-05314).

THE DISTRIBUTION OF DOPAMINE D1 AND D2 RECEPTOR mRNA'S IN RAT BRAIN. D. M. Weiner, H. B. Niznik, R. K. Sunahara, B. F. O'Dowd, and M. R. Brann, LMB/NINDS, HHMI/NIH Research Scholars Program, Bethesda MD 20892 and Dept. of Pharmacology, and Addiction Research Foundation, Univ. of Toronto.

Based on the sequence of a dopamine D1 receptor (Sunahara et al, submitted), we synthesized three 48 base oligodeoxynucleotide probes to measure the pattern of mRNA expression in the rat CNS by in situ hybridization histochemistry. Three similar probes to a by in situ hybridization histochemistry. Three similar probes to a dopamine D2 receptor have been previously described (Weiner et al, FEBS LETT, 253, 207). Based on several criteria, all of the probes selectively hybridized to their respective mRNA's on both blots and tissue sections. For both the D1 and D2 mRNA's, the strongest signal was observed in the striatum, including the caudate/putamen, the nucleus accumbens, and the olfactory tubercle. Within the caudate-putamen, approximately 50% of the medium sized neurons expresse each of the mRNA's. Both receptors are also expressed in the frontal and entorphial cortex, habenula, and distinct expressed in the frontal and entorhinal cortex, habenula, and distinct nuclei of the amygdala and hypothalamus. For the D2 receptor only, hybridization was seen in the septum, superior colliculus, and substantia nigra, pars compacta. These results are consistent with both the known distribution of dopamine receptor binding sites as determined by receptor autoradiography, and the dopaminergic innervation of the rat brain.

IMPROVED D-2 DOPAMINE (DA) RECEPTOR AUTORADIOGRAPHY USING 3H-YM-09151-2, A POTENT BENZAMIDE. B.L. Waszczak and R.F. Cox. Pharmacol. Sect., Northeastern Univ., Boston, MA. Dopamine D-2 autoradiography is usually performed with 3H-spiperone. A major disadvantage of spiperone is its affinity at \(\alpha - 1 \). 5-HT2 and spirodecanone sites. 3H-raclopride has better D-2 selectivity but possesses relatively low affinity. A 3H-form of YM-09151-2 (YM), a potent and selective D-2 antagonist, has recently become available and has been used to label D-2 sites in striatal homogenates. We have developed an autoradiographic assay using 3H-YM in order to permit measurement of losses of DA D-2 receptors after treatments with dopamine receptor alkylators (see Cox. Martin and Waszczak, this meeting). Slide-mounted slices of rat brain (12 u) were incubated with 3H-YM at room temperature in a buffer of 25 mM Trie, 100 mM NaCl, 1 mM MgCl2, 1 uM pargyline and 0.001% ascorbate, pH 7.5. Sections were exposed to Hyperfilm for 3 to 4 weeks and regional film densities were analyzed using a computer-assisted imaging system. Association studies indicated that binding equilibrium occurred within 2 to 3 hours. Saturation studies showed a mean Kd of 85 ± 10 pM with regional Bmax values of 0.77 ± 0.04, 0.37 ± 0.04

TOTAL SYNTHESIS AND BIOLOGICAL STUDIES OF POTENTIAL AFFINITY LIGANDS FOR THE CANNABINOID RECEPTOR.

S. Richardson, S. Mirsadeghi, A. Lynn, A. G. Wilken, M. R. Johnson, S. L. S. Melvin, M. Herkenham, A. Howlett, S. K. C. Rice Laboratory of Medicinal Chemistry, NIDDK, Bethesda, MD 20892; Unit on Functional Neuroanatomy, NIMH Bethesda, MD 20892; Department of Pharmacology, St. Louis University School of Medicine, St. Louis, MO 63104; Pfizer Central Research, Groton, CT 06340; Glaxo, Inc., Research Triangle Park, NC 27709.

We have prepared a number of non-classical cannabinoids, using the highly potent compound CP-55, 244 as a template for our studies. These compounds bind to the cannabinoid receptor with varying affinities in the nM range. The chemical syntheses of our analogs, binding results, and modulatory effects on adenylate cyclase will be presented, along with our progress to date relating the absolute configuration of CP-55, 244 to that of Δ^9 -THC.

CHARACTERIZATION AND LOCALIZATION OF AMINOALKYLINDOLES (AAI) IN RAT BRAIN. E.M. Jansen, S.J. Ward, D.Haycock and Y.S. Seybold. Dept. of Cell Biol. & Neuroanat., Grad. Prog. in Neurosci., Univ. of Minnesota, Minneapolis, MN 55455: Sterling Research Group. Rensselaer. NY 12144.

Minneapolis, MN 55455; Sterling Research Group, Rensselaer, NY 12144. Aminoalkylindoles (AAI) have analgesic activity in rodents and humans. Using [³H]WIN55212-2, AAIs have been shown to bind selectively to cannabinoid receptors in studies of homogenates of rat brain. The localization of cannabinoid receptors in mammalian brain has recently been reported by Herkenham et al., (PNAS 87:1932,1990) using a tritiated analogue of Δ°-THC (CP55,940 Pfizer). The goal of our study was to determine the regional distribution of [³H]WIN55212-2 binding in rat brain and to compare specific binding determined by an unlabeled AAI analog with that of Δ°-THC analogue desacetyllevonantrodol. Ligand binding with [³H]WIN55212-2 (specific activity 59 Ci/mmole) was done in 20mM Hepes with 0.5% BSA. Tissue was incubated with ligand for 90 min at 30°C; four 10 min washes gave optimum specific binding. Biochemical studies using fresh frozen rat cerebellum tissue sections indicated that [³H]WIN55212-2 had a K_d of approximately 1 nM. Competition studies showed that CP55940 and desacetyllevonantrodol had K₁'s of approximately 1 nM. Autoradiographic studies of [³H]WIN55212-2 (1nM) binding to coronal sections of rat brain showed very high amounts of specific binding in substantia nigra and the internal capsule. Moderate levels of binding were observed in cerebellum (molecular layer), basal ganglia, hippocampus, cingulum and layer VI of the cerebral cortex. There was no apparent difference in the regional distribution of [³H]WIN55212-2 specific binding as determined by competition with an unlabeled AAI analog (1μM) or CP55,940 (1μM). These studies confirm the localization of cannabinoid binding sites in rat brain by a compound structurally unrelated to Δ°-THC. Studies funded by Sterling Research Group.

HIGH AFFINITY HISTAMINE BINDING IN THE MAMMALIAN BRAIN. Paul Cumming, Chris Shaw¹ and Steven R. Vincent, Kinsmen Laboratory of Neurological Research, Dept. of Psychiatry, & 1 Dept. of Ophthalmology, University of British Columbia, 2255 Wesbrook Mall, Vancouver, B.C. Canada V6T 1W5.

In addition to the two classical histamine receptor types, a pharmacologically distinct receptor, H_3 , has recently been characterized. H_3 was initially described as an autoreceptor, because specific agonists and antagonists altered the synthesis and release of histamine in slices. In the present study, the binding of the H_3 agonist $[^3H]\text{-N-methylhistamine}$ was characterized in 25 μm cryostat sections from rat forebrain: The K_d was 2 nM and the B_{max} was 25 fmole/section. $[^3H]\text{-Histamine}$ binding under similar conditions yielded a K_d of 8 nM and a B_{max} of 22 fmole/section. Displacement studies with thioperamide, burimamide, $R(\text{-})\alpha\text{-methyl-histamine}$, and impromidine indicated that the two ligands bound to an identical site, the high affinity histamine site, which had the pharmacological profile of the H_3 receptor.

Autoradiographic studies using [³H]-N-methylhistamine were done in rat, cat and monkey. Specific binding was inhomogeneous and did not match patterns of histamine innervation. Highest binding was observed in the basal ganglia. Unilateral striatal quinolinic acid lesions destroyed histamine binding in the striatum and substantia nigra pars reticulata, but 6-OHDA lesions to the MFB were without effect on striatal H₃ binding. Thus, in addition to their proposed role as autoreceptors, H₃ receptors may be responsible for specific postsynaptic actions of histamine in the basal ganglia.

AMINOALKYLINDOLE BINDING DATA SUGGESTS A NEW APPROACH FOR STUDYING CANNABINOID ACTIVITY J. E. Kuster, D. Haycock, A.C. Howlett, B.Subramaniam, S. J. Ward, Dept. Neurosci. Sterling Research Group, Rensselaer, NY; Dept. Pharmacol. St. Louis Univ. Sch. Med., St. Louis, MO.

Aminoalkylindole (AAI) compounds are potent antinoceptive agents. Characterization of AAI binding in rat cerebellar membranes using [3H]-WIN 55,212-2 has revealed a single class of sites (Kd = 2 nM; Bmax = 1.2 pmoles/mg protein) which are saturable, heat-labile, reversible and stereospecific. Of >60 reference compounds tested, only AAIs (Ki 1 nM-3 uM) and cannabinoids compete for this site. Inhibition of binding by AAIs and cannabinoids (1) is competitive (2) correlates with ability to inhibit electrically-induced contractions in mouse vas deferens (NVD) (r=0.98, P<0.001) and (3) correlates with binding affinity in a CP55-940 cannabinoid binding assay (r=0.93). Some AAI analogs produce concentration-dependent rightward shifts in the concentration-effect curves of 55212-2 and THC (pA2 6.5) in the MVD. These data suggest that AAIs & cannabinoids appear to share a common site of action and that AAIs may provide a route to the synthesis of cannabinoid antagonists.

THE ONTOGENY OF ADENOSINE A1 RECEPTORS IN RAT BRAIN USING RECEPTOR AUTORADIOGRAPHY. B.A. Etzel and R. Guillet. Dept. of Psychology, Univ. of Rochester, Rochester, NY 14627.

Previous research using brain homogenate assays with rats 14-90 days of age has shown that specific binding to adenosine A1 receptors (A1R) increases as a function of age in cerebellum (with adult levels evident at 42 days) and hippocampus (adult levels at 21 days), but not in cortex, brain stem, or hypothalamus (adult levels at approximately 14-21 days for these three areas). Autoradiography was performed to further specify the regional ontogeny of A1R in the above areas as well as others.

Frozen brain sections from rats 14, 18, 21, 31, and 42 days of age (corresponding to ages at which homogenate assays were done previously) were treated with adenosine deaminase and incubated with 3H-cyclohexyladenosine (3H-CHA) in the presence or absence of L-phenylisopropyladenosine. Sections were examined for specific and nonspecific 3H-CHA localization after a 4-week exposure period

nonspecific 3H-CHA localization after a 4-week exposure period.

3H-CHA binding was confined primarily to the hippocampus (CA1, CA2, and CA3) and the thalamus at the youngest age studied (14d). With advancing age, binding to the molecular layer of the cerebellum became more apparent and binding appeared to become more localized to the CA1 region of the hippocampus and less to the CA2 and CA3 regions. Thalamic staining was relatively unchanged with age. Little staining of brain stem or hypothalamus was evident at any age. Cortical staining was nonhomogeneous; its regional ontogeny is currently being examined in more detail. In addition, quantitative analysis of 3H-CHA binding is underway.

Thus, adenosine A1 receptor autoradiography corroborated initial findings using the tissue homogenate assay. It also allowed more specific localization of adenosine A1 receptors in the developing rat as a function of age.

receptors in the developing rat as a function of age. Supported in part by NIH grant no. HD22782.

LOCALIZING BETA ADRENERGIC RECEPTORS AND THEIR MESSENGER RNA'S IN THE HUMAN EYE

N. Gupta, M.S. Cynader, S.M. Drance*, Eye Care Centre, University of British Columbia, Vancouver, B.C., Canada.

Several beta adrenergic agents have been clinically exploited for their pressure lowering effects in the treatment of glaucoma. In spite of their wide use, their targets and mechanisms of action in the eye remain unclear. Using in situ hybridization and in vitro autoradiography, sections of entire human eyes were examined for the distribution of beta adrenergic receptors and the mRNA's encoding them. The beta 2 adrenergic receptor had several specific loci of concentration in the anterior segment, including the epithelial and endothelial layers of the comea, the trabecular meshwork, the ciliary body, and the lens. Both the retina and the retinal pigment epithelium were clearly identified in the posterior segment of the eye. Beta 1 receptors were less inhomogeneously distributed than were the beta 2 receptors, and overall, were of lower density. Quantitative analysis of the distribution of each of these receptors was performed using computerized densitometry. The maps of beta 1 and beta 2 receptors obtained using receptor autoradiography, and of their corresponding messenger RNA's obtained with in situ hybridization, show close correlation. Noted differences between the methodologies will be discussed. These results may be important in understanding the effects and side effects of beta adrenergic therapy in the human eye.

A DIURNAL COMPONENT TO STRESS RESPONSIVENESS IN THE RAT. M. Bradbury, S.F. Akana, C.S. Cascio*, K. Scribner*, C.D. Walker* and M.F.Dallman*, Division of Neuroscience, UCSF. San Francisco CA, 94143. In most rat studies, stress-induced increases of adrenocorticotropin (ACTH)

and corticosterone (CORT) are largest in the A.M. when these hormones are at their basal, or unstressed, circadian minima. These results have been commonly ascribed to circadian patterns of CORT mediated negative feedback. To study diumal stress responses in both the presence and absence of CORT mediated

administress responses in both the presence and absence of CONT mediated negative feedback, we compared the responses of both normal and adrenalectomized (ADX) rats to restraint stress.

Male rats, ADX or sham-ADX 5 days previously, (160-180g), were stressed with restraint for 3 to 90 minutes in either the A.M. or the P.M. Plasma ACTH and CORT concentrations were measured to assess responses to both the development of and recovery from the stress.

development of and recovery from the stress. In sham-ADX rats, the peak response to restraint stress occured at 30 minutes. The ACTH response was larger in the A.M. than in the P.M. (595 \pm 55 vs 360 \pm 52 pg/ml) (915% vs 396% of basal ACTH, both p \leq 0.05). There was no diurnal difference in the recovery from the stress. Basal P.M. CORT was 18 times higher than that in the A.M.(0.6 \pm 0.1 vs 10.6 \pm 1.0 µg CORT/dl). 25µg CORT/dl, a concentration of CORT sufficient to fill ~50% of the type II glucocorticoid receptors, (Reul and DeKloet, 1987), was reached at 3 minutes in the P.M., but not until 15 minutes in the A.M. This difference in the rate of receptor occupation may explain the A.M.-P.M. difference in stress responses in sham-ADX rats. sham-ADX rate

Surprisingly, the same diurnal pattern of stress-induced ACTH secretion was Surprisingly, the same diurnal pattern of stress-induced AC11 secretion was found in ADX rats. In ADX rats, the A.M. peak was $1407 \pm 85 \text{ pg/ml}$ ACTH (428% of basal ACTH, $p \le 0.05$) while in the P.M., the response was negligible. A depletion of pituitary ACTH content does not explain the lack of response in the P.M. ADX rats. Therefore, we suggest that in addition to a diurnal difference in the timing of negative feed back signals, there is a neuronal input that facilitates stress-induced ACTH responses in the A.M.

PULSATILE ACTH AND CORTISOL IN GOATS: EFFECTS OF INSULIN-INDUCED HYPOGLYCEMIA AND DEXAMETHASONE. M. Carnes, M. Brownfield, S. Lent,* and Vet. School Classes of 1991-92*. VA Hospital and Univ. of Wisconsin Dept. of Medicine and School of Vet. Med., Madison, WI 53705.

ACTH and cortisol (cort) are secreted in episodic bursts. We investigated the pattern of ACTH and cort

ACTH and cortisol (cort) are secreted in episodic bursts. We investigated the pattern of ACTH and cort response to the stress of hypoglycemia and the effect of dexamethasone (dex) on this response. Five goats were given dex (0.1 mg/kg) and 5 were given saline 2 h before blood sampling. Blood samples were taken from jugular catheters every 2 min for 60 min before and 60 min after insulin (2.5 U/kg, i.v.). Plasma was assayed for ACTH, cort (all samples), and glucose (selected samples). Data sets were analyzed for pulses with the Cluster Analysis program. Plasma glucose was lower than pre-insulin levels. sets were analyzed for pulses with the Cluster Analysis program. Plasma glucose was lower than pre-insulin levels at 10 min with a nadir 30-60 min post-insulin in all goats. Control goats showed a rapid rise in ACTH and cort beginning 30 \pm 10 min post-insulin. Analysis of pulse parameters for 30 min segments suggested a relatively quiescent secretory period before the rapid rise in ACTH and cort with a reduction in pulse frequency and amplitude compared to preceding and succeeding time intervals. The highest autocorrelation between ACTH and cort occurred at a lag of 0 min. Dex-treated goats had lower mean ACTH and cort levels, no apparent change during hypoglycemia, and lower autocorrelation with no consistent lag.
Supported by US-DVA and NIH grant 1RO1-DK-40759.

HYPOTHALAMIC-PITUITARY-ADRENAL ACTIVITY IN FRONTAL CORTEX LESIONED RATS. D. <u>DIORIO AND M.J. MEANEY</u>. Douglas Hospital Research Center, Depts of Psychiatry and Neurology and Neurosurgery, McGill Univ., Montreal, H4H 1R3, Canada.

Montreal, H4H IR3, Canada. High densities of corticosteroid receptors (CSR) are found in the frontal cortex (FC) and can be regulated by corticosterone (CORT) in a manner similar to that observed in the hippocampus; CORT treatment results in a downregulation of these receptors while an upregulation is observed following adrenalectomy. The results of earlier electrophysiological studies (Feldman and Conforti, 1985) have implicated a role for the FC in the regulation of the HPA axis, in order to examine the influence of the FC on the HPA axis, we measured ACTH and CORT levels under both basal and stress conditions in FC lesioned rats.

rec on the FFA axis, we measured ACTH and CORT levels under both oasat and stress conditions in FC lesioned rats.

Following a 20-min immobilization stress the lesioned animals showed significantly (p < 0.05) higher plasma ACTH levels 20 and 40 min following the termination of stress. Likewise, plasma corticosterone levels were also significantly (p< 0.05) elevated in lesioned animals following stress. Hormone levels did not differ during immobilization. In contrast to these findings, our preliminary data indicate that lesioned animals do not differ from controls in either ACTH or corticosterone levels following ether stress. Basal values (10AM and 10PM) of both CORT and ACTH appear to be unchanged in the lesioned group. Type II CSRs in the hippocampus, which have previously been shown to regulate the HPA stress response, were unchanged in the FC lesioned animals (lesion=88±11.6; sham= 99±16.8; control=111±16.8). Preliminary data indicate presence of both Type I and Type II CSRs in the FC. Current studies are examining the specific role of these receptors subtypes in the FC in the regulation of HPA activity. These findings suggest that the FC is involved in post-stress corticosteroid negative-feedback inhibition of HPA activity, and that this involvement may be determined by the nature of the stressor.

292.2

STRESS FACILITATES SUBSEQUENT ACTIVITY IN THE

ADRENOCORTICAL SYSTEM. S.F. Akana and M.F. Dallman*. Dept. of Physiology, UCSF, San Francisco CA 94143-0444.

Stress activates the hypothalamic-pituitary-adrenal (HPA) axis yielding increased ACTH and corticosterone (B) secretion; B alone inhibits subsequent ACTH, but B with stress does not. Logically, this suggests that stress facilitates subsequent activity in the adrenocortical system. We used cyanoketone (CK), an inhibitor of B synthesis, to system. We used cyanoketone (CK), an inhibitor of B synthesis, to impair B responses to stress in a test of whether stress-induced facilitation occurs. Restraint stress of 30 min accompanied by tail-nick blood collection (0,15 & 30 min) was imposed on separate groups of vehicle (VEH) and CK rats at different times in the 12:12 light cycle (0,3,6,9 h after lights on);rats were returned to their home cages and then decapitated at 12 h (time of peak diurnal activity) together with unstressed rats. There was a <u>negative</u> correlation (r=-53;p<0.05) between the time of restraint and ACTH or B at 12 h in VEH. By contrast, there was a <u>positive</u> correlation (r=-50; p<0.05) between the time of restraint and ACTH (no relationship to B) in CK. We conclude that when the B response to stress is blocked (by CK), an underlying. that when the B response to stress is blocked (by CK), an underlying, time dependent, stress-induced facilitation of subsequent HPA activity is revealed; when there is a B response to stress, both time dependent facilitation and B-induced inhibition occur (supported in part by DK28172).

292.4

BASAL AND STRESS HYPOTHALAMIC-PITUITARY-ADRENAL ACTIVITY IN CYCLING AND OVARIECTOMIZED-STEROID TREATED RATS. V.VIAU & M.J.MEANEY .Douglas Hospital Research Ctr., Dept. Psychiatry, McGill Univ., Montreal H4H 1R3, Canada.

To determine the relationship between HPA activity and gonadal steroids we have examined the adrenocorticotrophin (ACTH) and corticosterone (CORT) responses to 20 min. of immobilization stress during different phases of the estrous cycle. Peak ACTH and CORT responses following stress were significantly higher during Proestrus (PRO) versus Estrous (EST) and Diestrous (DI) phases: ACTH; PRO > EST = DI; 432.6 ± 65.7 , 188.9 ± 25.7 , and 194.0 ± 19.5 pg/ml, respectively. CORT; PRO > EST = DI; 62.7 ± 2.5 , 50.5 ± 3.8 , and 42.5 ± 2.6 ug/dL, respectively. Basal AM HPA activity was equal between phases prior to stress. To demonstrate the role of gonadal steroids, we mimicked the estrous cycle with physiological doses of estradiol (E) and progesterone (P). Rats were OVX and either maintained on low E and P (O') for 3 days, O' plus high E (O' + E'), or with both high E and P (O' + EP'), to mimic Diestrous, Proestrous, and late Proestrus-early Estrous phases, respectively. In response to immobilization, ACTH levels were significantly higher in the E' versus the O' and EP' groups: 336.2 \pm 66.4, 214.5 \pm 36.0, and 169.5 ± 33.7 pg/ml, respectively. However, both the E' and EP' groups showed increased CORT levels. Taken together, it appears the HPA axis is most sensitive to stress during Proestrus. These results suggest that estrogen regulates the HPA response to stress during the esrous cycle in the rat. More specifically the data are suggestive of gonadal influence on both the activational and feedback components of HPA activity.

292.6

COMPARISON OF TWO COMMERCIAL KITS FOR MEASURING HUMAN PLASMA ACTH. E.H. Mougey, M.A. Oleshansky and J.L. Meyerhoff. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307.

Adrenocorticotropic hormone (ACTH) is an important com-

ponent of the hormonal responses to stress. Secreted by the corticotrophic cells of the pituitary it is transported via the general circulation to the adrenal glands where it initiates synthesis and release of cortisol in humans. For measuring levels of ACTH in plasma (EDTA) samples obtained during stress experiments, RIA kits obtained from INCSTAR Corp. were compared with IRMA kits obtained from Nichols Institute. Extracted was used for extraction of the plasma samples. The RIA antibody was generated against a conjugate of human ACTH (1-24), whereas, the IRMA is a sandwich assay involving the use of two whereas, the IRMA is a sandwich assay involving the use of two different antibodies sensitive to opposite ends of the ACTH molecule. Overnight incubation in 12X75 mm polypropylene tubes was employed and aspiration was used to remove supernatant in both assays. The RIA tubes were maintained at 4°C throughout the assay including the addition of second antibody.

was carried out at room temperature.

Both assays appear to detect stress-induced changes in plasma levels of ACTH. In general, the extracted vs direct assay values using the IRMA were comparable, whereas, when using the RIA the extracted values were sometimes lower than the direct assay values. The direct assay IRMA values were more similar to the extracted RIA values than to the direct assay RIA values.

N-METHYL-D-ASPARTATE (NMDA) INCREASES PLASMA LEVELS OF ADRENOCORTICOTROPIN (ACTH) IN POSTNATAL RATS. M.E. Bardgett, G.T. Taylor*, K.E. Coyne* and J.M. Farah. University of Missouri-Saint Louis and G.D. Searle & Co., St. Louis, MO 63121. NMDA is reported to accelerate the onset of puberty in rats by precocious elevation of gonadotropin (Urbanski & Ojeda, Neuroendocrinoj. 46:273, 1987). Recently, NMDA was found to increase ACTH in adult male rats (Iyengar et. al., Neuropharmacol. 29:299, 1990) indicating a role for excitatory amino acid neurotransmission in activation of the hypothalamic-pituitary-adrenal (HPA) axis. In rats, the HPA exhibits reduced responsive to stress during the postnatal period but the duration of this stress hyporesponsive period (SHRP) might be susceptable to developmental alteration by NMDA. Female and male rats at either postnatal day (PND) 10 or 21 were injected with NMDA (30 mg/kg, sc) or vehicle and trunk blood was collected 15 min after treatment. T-tests were used to compare the values of ACTH measured by radioimmunoassay. NMDA increased plasma ACTH 2-fold in both females (p<0.002) and males (p<0.004) at PND 10; similar increases were evoked by NMDA treatment at PND 21 in both females (p<0.001) and males (p<0.004). These results indicate that the postnatal quiescence of the HPA can be overcome by an excitatory amino acid receptor agonist, a finding which may facilitate studies of the SHRP during maturation of the this neuroendocrine system.

292.9

CHANGES IN CORTISOL AND $\beta-END-LIKE$ IMMUNOREACTIVITY IN PERIMENSTRUAL SYNDROME. $\underline{C}\cdot\underline{A}\cdot$ Cahill. University of Arizona, College of

Nursing, Tucson, AZ 85748.

The cause of Perimenstrual symptoms (PS) is not clear, but the effects of changes in some hormones have been investigated. Nine women with PS like endogenous depression and 18 women without symptoms were studied over three consecutive cycles. Plasma samples were collected by acute venipuncture twice per week.

B-END-like immunoreactivity, cortisol, prolact-in and progesterone were determined by RIA. Endogenous depression has been associated with alterations in regulation of the hypothalamic/pituitary/adrenal axis. Similar differences in regulation of the hypothalamic/pituitary/ovarian axis may be associated with similar symptoms in PS. Since cortisol is secreted from the adrenal in response to ACTH and ACTH and β -END are co-secreted from the anterior pituitary, cortisol and β -END-like immunoreactivity were expected to be corre lated. In this study, they were not correlated in either group. In the third cycle, a trend toward correlation was observed. Therefore, "stress" associated with blood collection may influence these levels.

292.11

EFFECT OF IMIPRAMINE ADMINISTRATION AND SWIM STRESS ON THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS.. J. F. López, D. M. Vázquez, Stanley J. Watson and Huda Akil. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Stanley J. Watson and Huda Akil. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Overactivity of the Hypothalamic Pituitary Adrenal (HPA) axis is a well documented phenomena in depressed patients. Depression is most commonly treated with tricyclic antidepressants, therefore the potential effect of these medications in modifying HPA activity is an important issue. We have investigated the effect of chronic imipramine (IMI) administration (10 mg/kg) in the HPA axis of rats undergoing 14 days of swim stress and in non-stressed rats. Twenty four male rats were divided in 4 groups: saline (S), IMI (I), swim + saline (SS), swim + IMI (SI). All received i.p. injections of either IMI or saline for 14 days and were decapitated on day 15. Corticosterone (CS), ACTH and Nacetyl β endorphin (NAc βE) were measured in plasma. ACTH, β endorphin (βE) and POMC mRNA content was measured in the neurointermediate lobe (IL). Chronic swim stress caused a significant CS increase. Chronically stressed rats treated with IMI showed a significant decrease in CS levels, but these values were still higher than the nonstressed groups. An ANOVA revealed a significant effect in plasma Nac βE for swim but not for drug treatment. No significant differences in plasma ACTH were detected. In the IL, IMI caused significant decreases in both POMC peptide content and POMC mRNA levels, although chronic swim animals had a tendency for higher peptide content. We conclude that chronic IMI administration may alter CS levels in plasma. In Hal also seems to cause an inhibition of POMC IL activation. Because of the multiple neurotransmitter effects of IMI, more specific pharmacological agents are needed to elucidate the mechanisms of this inhibition. THE EFFECT OF LEARNED HELPLESSNESS BREEDING ON CORTICOSTERONE AND ACTH REGULATION., F.A.Henn, M. McKenzie* and E. Edwards. Dept of Psychiatry, SUNY at Stony Brook, NY 11794.

A selective breeding of Sprague Dawley rats for Learned

A selective breeding of Sprague Dawley rats for Learned Helplessness has been established in our laboratory and has reached the 19th generation of two strains of rats: LH (showing susceptibility to Learned Helplessness); NLH (a strain resistant to the development of helpless behavior).

We have examined some neuroendocrine parameters of rats from either strain LH and NLH and compared them with naive Sprague Dawley rats, Plasma corticosterone levels of LH strain rats were remarkedly low (38 ± 6.8 ng/ml) as compared to plasma corticosterone levels measured in NLH strain rats and naive Sprague Dawley rats (300 ± 27 ng/ml). There was no difference in ACTH levels measured in all three groups.

When Sprague Dawley rats and rats from the LH and NLH strain

When Sprague Dawley rats and rats from the LH and NLH strain When Sprague Dawley rats and rats from the LH and NLH strain are subjected to the Learned helpless paradigm (shock training and shock escape testing), they could also be differentiated by their overall response to the stress paradigm. We measured plasma corticosterone in these three groups of rats one day after the shock escape test. While plasma corticosterone were similar to endogenous levels in Sprague Dawley rats and rats from the NLH strain, a significant increase in corticosterone levels was still present in rats from the LH strain (+42% of endogenous levels).

Changes in endogenous and post stress plasma corticosterone were seen in both male and female LH strain rats. The present data give additional support to our hypothesis that a dysregulation of the HPA axis mediates Learned Helplessness. (Supported by BNS 8614098 to E.E.)

REGULATION OF POMC PRIMARY TRANSCRIPT LEVELS IN THE ANTERIOR PITUITARY IS TIGHTLY LINKED TO PEPTIDE SECRETION. S.P. Kwak. E.A. Young. H. Akil. and S.J. Watson. Neuroscience Program and Mental Health Res. Inst. University of Michigan, Ann Arbor, MI 48109.

We have successfully detected the heteronuclear species of propoint produced in the production of the primary POMC transcript by probing a blot containing total RNA from the anterior pituitary with an intron A specific cRNA (all genomic clones were gifts from Dr. J. Roberts). Two major bands migrating at 6.0 Kb and 4.1 Kb were detected. The size of these fragments matched the predicted length of the primary transcript (hnRNA) and the intron A containing processing intermediate of POMC, respectively, and further analysis confirmed that these two species are localized only in the nucleus. Based on the genomic sequence an intron B containing processing intermediate is predicted to migrate at 3.0 Kb. However, fragments of such size were not detectable from the nuclear fraction when reprobed with an intron B specific cRNA. Furthermore, a cRNA probe from the exon 3 region (common to all nuclear intermediates) detected only the 6 and 4 Kb bands along with the 1Kb mRNA species. The results are consistent with the data obtained from S1 nuclease assays (Autelitano et al., 1990) and suggest that intron B is spliced more rapidly than intron A in the anterior pituitary. Physiological manipulations were conducted to determine the changes in the hnRNA levels. Anterior pituitaries from adult male rats were assayed after various conditions. Acute 30 minute swim produced a 133% increase in POMC hnRNA levels over controls. Acute swim after a chronic treatment of 14 days resulted in a 240% increase over chronic rest levels. Injection of metyrapone, a steroid synthesis inhibitor, increased hnRNA levels within 1-2 hours. Finally, preliminary circadian studies indicate that th chronic treatment of 14 days resulted in a 240% increase over chronic rest levels. Injection of metyrapone, a steroid synthesis inhibitor, increased hnRNA levels within 1-2 hours. Finally, preliminary circadian studies indicate that there may be an upregulation of POMC transcription in the evening when ACTH secretion is increased. Parallel changes observed in hnPOMC levels and plasma ACTH suggest that POMC transcription is closely coupled to ACTH secretion in the anterior pituitary. BIPHASIC CORTICOTROPH SECRETION RESPONSE TO SHORT TERM METYRAPONE. E.A. Young, S. Kwak, S.J. Watson and Huda Akil Mental Health Research Institute, Ann Arbor, MI 48109

Mental Health Research Institute, Ann Arbor, MI 48109 Metyrapone is a compound that inhibits the 11- β -hydroxylase reaction in glucocorticoid synthesis, resulting in the production of 11-deoyxcorticosterone, in rats, or 11-deoxycortisol in man. When administered in humans, metyrapone blocks cortisol synthesis and results in stimulation of ACTH secretion 4-10 hours following metyrapone administration. To study the effects of short term glucocorticoid inhibition on the HPA axis in rats, metyrapone was administered by subcutaneous injection every 8 hours for 24 and 72 hours, beginning in the evening, with a final injection 1 hour before sacrifice. At 24 hours, no change in plasma β -endorphin levels were observed. At 72 hours, β -endorphin plasma levels were elevated. However, pituitary content data suggested that a secretory peak had occurred before 24 hours. To pursue this finding, shorter time periods were examined. By 30 minutes following the initial injection of metyrapone, there is clear corticotroph secretion of both ACTH and β -endorphin, which precedes the steroid initial injection of metyrapone, there is clear corticotropia secretion of both ACTH and β-endorphin, which precedes the steroid inhibitory effect. This suggests that metyrapone acts as a stressor at initial injection. The ACTH plasma levels remains elevated at 1 and 2 hours, but have returned to near normal levels by 4 hours. No increases in corticotroph secretion were observed at 8, 12 or 24 hours. Corticosterone corticotroph secretion were observed at 8, 12 or 24 hours. Corticosterone data suggest that the block of corticosterone is incomplete, and thus results in relative hypocortisolism, at 24 hours. However, at 72 hours, when ACTH levels are highest, the efficacy of the metyrapone blockade is low with 75% of the adrenal secretory product being authentic corticosterone. The mechanisms by which the secretory response to metyrapone disappears following the initial injection, then reappears at 72 hours are unclear. However, it is possible that non-steroidal feedback mechanisms may play a role.

GENOMIC EFFECTS OF COLD AND ISOLATION STRESS ON VASOPRES-SIN mRNA-CONTAINING CELLS IN THE HYPOTHALAMUS OF THE RAT, J.A.Angulo, M.Ledoux*, and B.McEwen, Laboratory of Neuro-endocrinology, The Rockefeller University, New York, N.Y. We assessed the effects of cold and isolation stress

on arginine vasopressin (AVP) mRNA in the paraventricular (PVN) and supraoptic nuclei (SON) of the hypothalamus AVP mRNA levels were determined by in situ hybridization histochemistry. In the magnocellular neurons of the PVN isolation stress for 7 or 14 days increased AVP mRNA levels 28 and 29%, respectively, compared to group-housed controls. No significant alterations in vasopressin gene expression were observed in the SON after 7 or 14 days of isolation stress. AVP mRNA-expressing cells of the parvo-cellular PVN showed increases of 19 and 34% after 7 and 14 days of isolation, respectively. We also studied the effect of cold or combined cold and isolation stress on vasopressin gene expression in the PVN and SON. Coldstress for 3 h daily for 4 consecutive days increased AVP mRNA levels in the magnocellular PVN by 15%. Cold-isolated animals showed an increase of 21%. No significant effect on AVP mRNA levels in the SON was observed. In contrast to the magnocellular PVN, cold or cold-isolation stress increased AVP mRNA in the parvocellular region of the PVN creased AVP midwa in the parvoceillular region of the PVN by 25 and 43%, respectively, relative to control rats. These results suggest that increased expression of AVP in the PVN may be a compensatory mechanism permitting the organism to cope with the adverse effects of stress.

VASOPRESSIN OF SUPRACHIASMATIC ORIGIN CONTROLS CORTICOS-

VASOPRESSIN OF SUPRACHIASMATIC ORIGIN CONTROLS CORTICOSTERON RELEASE. R.M. Buijs, A. Kalsbeek*, T.P. van der Woude*, J.J. van Heerikhuize*. Netherlands Institute for Brain Research, Amsterdam, The Netherlands.

The suprachiasmatic nucleus (SCN) is the major central nervous system pacemaker responsible for many behavioural and endocrine rhythms. The efferent projections of this nucleus are relatively well established and are largely confined to hypothalamic and thalamic brain structures. A major target arge of SCN fibres appears to be the pagaconfined to hypothalamic and thalamic brain structures. A major target area of SCN fibres appears to be the paraventricular dorsomedial hypothalamic nucleus, a major area in the control of CRF release. The physiological significance of these efferents was investigated using experiments whereby vasopressin (VP) or vasoactive intestinal peptide was infused in this SCN projection area. It appeared that in SCN lesioned rats VP was able to suppress elevated plasma corticosteron (B) levels to basal daytime values. On the other hand, infusion of VP antagonists induced a ten-fold increase of basal B levels in intact rats, but it remained without effect in SCN in intact rats, but it remained without effect in SCN lesioned rats. These results demonstrate that via its peptidergic neurotransmitters the SCN controls the release of this important stress hormone and that via these peptidergic transmitters the SCN may execute its phythmic functions. rhythmic functions.

292.17

POSTNATAL DEVELOPMENT OF FMRF-NH, -LIKE PEPTIDE, Arg -VASOPRESSIN AND DYNORPHIN IN PITUITARY GLANDS OF RATS.

H.-Y.T. Yang and J. Rubenstein, Lab. of Biochem.

Genetics, NIMH, St. Elizabeths, Washington, DC 20032.

Neuropeptide Phe-Leu-Phe-Gln-Pro-Gln-Arg-Phe-NH, Che-F-NH1), initially detected by the FMRF-NH4, antiserum, was isolated from bovine brain and found to have morphine modulating activity. In rats the highest level of F-8-F-NH1 and activity. In rats the highest level of F-8-F-NH1 and activity. In rate the highest level of F-8-F-NH1 immunoreactivity (IR) has been detected in the posterior pituitary and there are studies indicating a possible interaction between F-8-F-NH1 -IR and Arg -vasopressin (AVP). In order to further understand this interaction, postnatal development of these two peptides in rat pituitaries was studied. Low levels of F-8-F-NH1 -IR was found to remain at a high level at ages around 10 to 20 days and then gradually decline to a steady level by the age of around 30 days. A similar pattern of postnatal development was observed for AVP except that F-8-F-NH1.

IR was found to reach the maximum level slightly ahead for AVP procepting with NW in development was observed for AVP except that $F-8-F-NH_3-IR$ was found to reach the maximum level slightly ahead of AVP. Dynorphin, known to be colocalized with AVP in the pituitary, was found to have a developmental pattern substantially different from those of $F-8-F-NH_3-IR$ and AVP. These results are in good agreement with the hypothesis that there may be an interaction between $F-8-F-NH_2-IR$ and AVP.

292.14

Differential changes in the hypothalamic AVP mRNA and peptide levels in rats after exposure to cold and novel environments. P. Wu, D. Rougeau and G. Childs. University of Texas Medical Branch, Galveston, Texas 77550.

Arginine vasopressin (AVP) mRNA and peptide levels were studied in male rats exposed to cold and novel environment. AVP mRNA was detected in hypothalamic frozen sections with a 45mer photobiotinylated oligonucleotide probe and streptavidin alkaline phosphatase. mRNA and peptide immunolabeling were quantified by the Cue-3 image analysis system. Exposure to +3--5 C for 30 min caused a 5.4--fold increase in AVP mRNA in the paraventricular nucleus (PVN) compared with that of control rats and a 1-4--fold elevation in serum ACTH. After 30 min of a novel, thermoneutral (24 C) environment there was a 3.6--fold increase of AVP mRNA in the PVN, and no significant changes in serum ACTH. No changes were observed in AVP mRNA in the supraoptic nucleus (SON) following exposure to either cold or novel environments. Furthermore, neither stress caused significant changes in the storage of AVP peptide in the PVN, SON, median eminence and posterior lobe of pituitary. This *in vivo* study demonstrates that PVN and SON neurons respond differentially to cold and novel environment exposures. The increased synthetic activity of AVP in the hypothalamus correlated with the elevation of serum ACTH, suggests that AVP may play a role in regulation of pituitary-adrenal responses to cold and novel environment stresses. PITUITARY-ADRENAL AXIS RESPONSE TO ARGININE VASOPRESSIN IN PATIENTS WITH DEPRESSION. BT Carroll, WH Meller*, RG Kathol, TL Gehris*, J Carter*, SD Samuelson, and AF Pitts, The University of Iowa College of Medicine, Iowa City, IA 52242.

Vasopressin, a hypothalamic neuropeptide, has been used to investigate

hypothalamic-pituitary-adrenal axis functioning. Previous studies with arginine vasopressin (AVP) have demonstrated that cortisol response is greater in depressed patients than in controls.

AVP (0.18 pressor units/kg) was given intramuscularly to 10 patients with major depression (MD) and 15 normal controls. Plasma ACTH and cortisol levels were drawn at specific times prior to and after injection. A one mg overnight dexamethasone suppression test (DST) was also done on each subject. Six (60%) MD were DST-nonsuppressors (post-DST cortisol level >

The MD group had non-significantly lower ACTH baseline, peak, delta max levels and net area under the curve (AUC) and significantly lower gross ACTH AUC when compared to controls (t=2.12; p=.045). No significant differences were observed for any of the absolute cortisol measurements. The MD group tended to have an increased cortisol response to endogenous ACTH as estimated by the gross cortisol AUC to log gross ACTH AUC ratio (t=1.85; p=.078). No significant differences were observed for ACTH or cortisol levels when groups were separated with respect to DST suppressor status.

This study replicates a previous study (Meller, WH, et al., <u>J. Psychiat.</u> Res., 21:269, 1987) and supports the hypothesis that there is no vasopressin receptor downregulation as suggested for corticotropin-releasing hormone in depressed patients. Furthermore, we also observed an adrenal hyper-responsiveness to endogenous ACTH.

A POSSIBLE INTERACTION BETWEEN ARG®-VASOPRESSIN (AVP) AND MAMMALIAN FWRF-NH,—LIKE PEPTIDE IN THE HYPOTHALAMO-NEUROHYPOPHYSEAL AXIS OF THE RAT.

T. Yang. Lab. of Biochem. Genetics, NIMH, St. Elizabeths, Washington, DC 20032.

The neuropeptide FLFQPQRF-NH, (F-8-F-NH,), initially detected by FWRF-NH, antiserum and subsequently isolated from bovine brain, is highly concentrated in the hypothalamo-neurohypophyseal axis of the rat. Previously, we have shown that F-8-F-NH,—IR in the pituitary gland of the AVP deficient Brattleboro (DI) rat is below the level of detection. F-8-F-NH,—IR in pituitary of salt-loaded rats is also greatly reduced. These experiments suggest an interaction between AVP and F-8-F-NH,—IR in the posterior pituitary. In order to test this hypothesis, we have measured the effect of two different peripheral modes of AVP replacement therapy on F-8-F-NH,—IR in pituitary and hypothalamus of the DI rat. While continuous infusion of 900 ng/day of synthetic AVP for six days reduces water intake of the DI rat by 50%, the pituitary levels of F-8-F-NH,—IR are still below the level of detection. Likewise, daily subdermal bolus injections of 500 mU pitressin tannate to the DI rat for six days also fail to restore the F-8-F-NH, content to the pituitary although water intake is normalized. These results suggest that restore the F-8-F-NH, content to the pituitary although water intake is normalized. These results suggest that the interaction may occur at a central site. Alternatively, the depletion of pituitary F-8-F-NH,-IR could be related to alterations in dynorphin or oxytocin.

Licl Increases adrenal amines in the absence of ARGININE VASOPRESSIN. E.F. O'Connor, S.K.

Naylor* and J.E. Lawler. Physiology Program and Department of Psychology, University of Tennessee, Knoxville, TN 37996.

Arginine vasopressin (AVP) decreases locomotor

Arginine vasopressin (AVP) decreases locomotor activity and facilitates memory processes. In these actions AVP is similar to LiCl (Li+). Thus, the adrenal amines may mediate the actions of both agents on behavior. For example, exogenous epinephrine stimulates tissue and behavioral responses similar to those elicited by both AVP and Li+. AVP also increases adrenal amine stores, an action which we have found with Li+. Our hypothesis was that AVP may mediate this action of Li+. To test this, we gave LiCl, 3mmol/kg/day, i.p., to Long Evans rats (LE) and to Brattleboro rats (DI) for 3 weeks. Control LE and DI rats were given saline. Data are means (S.E.M.)

N NE(ng/gland) E(ng/gland)

293.1

REGIONAL VARIATION IN SPATIAL RESOLUTION AND SENSITIVITY OF THE HUMAN HAND. H.Hämäläinen, K.Saarhelo* A.Antervo*and J.Kekoni*. Dept. Psychol., Univ.Helsinki, Finland.
Two-point thresholds (airpuff stimuli) and de-

Two-point thresholds (airpuff stimuli) and detection thresholds to mechanical vibration were determined at several locations on the hand and fingers.

Increasing 2-point thresholds were measured on both glabrous and hairy skin areas at more proximal locations. The threshold increase from the volar tip of finger to the palm well coincides with the increasing values of the cortical magnification factor (M $^{\circ}$) determined for corresponding areas of monkey SI cortex (M.Sur et al., J. Neurophysiol. 44:295, 1980). On the glabrous skin lowest thresholds for 20 Hz vibration were measured at distal phalanges of fingers, and those for 240 Hz at palm. On the hairy skin, higher detection thresholds were obtained with all frequencies compared to those for glabrous skin. The detection thresholds for especially 240 Hz vibration were highest at distal locations. These results indicate the basic difference in innervation of the glabrous and hairy skin of the hand and also differences in proximo-distal innervation patterns of these skin areas.

293.3

STIMULUS FEATURES RELEVANT TO THE PERCEPTION OF SHARPNESS AND MECHANICAL PAIN. J.D. Greenspan and S.L.B. McGillis*, Depts. of Neurosurgery and Physiology, SUNY Health Science Center, Syracuse, NY 13210

This project examined the influence of stimulus size

and shape upon thresholds for the perception of sharpness and mechanically-induced, cutaneous pain. We used an ascending method of limits protocol with 26 subjects. Flat, circular probes were placed on the subject's finger, with a resting force of 0.2-0.5g. One set of probes varied in size, ranging from 0.01-5.00mm². A 2nd set were the same size, but varied in the angle at the tip's edge (30-90°).

size, our varied in the angle at the tip's edge (30-90°). The threshold for sharpness was consistently lower than the threshold for pain by 20-40g. Thresholds measured as force were similar for probes between 0.01 and 0.1 mm²: sharpness $\approx 10 \rm g$; pain $\approx 35 \rm g$. These thresholds progressively increased with larger probes, but not at an even rate with area. Rather, thresholds increased in proportion to the probe circumference over the range of 0.1-1.0 mm². As tip angle decreased, thresholds for sharpness remained constant until 45°, at which time it increased dramatically. In contrast, pain threshold gradually increased over the same range of angles.

The thresholds for sharpness and pain are similarly influenced by stimulus area, but differentially influenced by stimulus angle. The relationship between force and area is not simple, but with flat surfaces, thresholds are more consistent when expressed as force/circumference.

This research was supported by NSF grant #BNS-8808337.

293.2

MECHANOSENSORY RESPONSES FROM AXONS SERVING ALLOGRAFTED PRIMATE SKIN CONTAINING SPARSE OR NONEXISTENT MECHANORECEPTOR POPULATIONS. D.D. Samulack, R.W. Dykes and B.L. Munger*. Dept. of Physiology, McGill Univ., Montreal, PQ H3G 1Y6 and Dept. of Anatomy, Pennsylvania State Univ., Hershey, PA 17033.

The long-term survival of transplanted primate skin (baboon; Papio h. anubis) was achieved by host immunosuppression using cyclosporine and methylprednisolone. The stability of the histologic integrity of the allografts was dependent upon the level of immunosuppression maintained and the degree to which the immunologic processes of graft rejection led to tissue disruption. Control (autografted) tissues were compared to allografted tissues which had undergone minimal, minor or major enjodes of rejection.

major episodes of rejection.

The cellular destruction resulting from allograft rejection, together with processes associated with nerve transection and reinnervation, led to alterations of mechanoreceptor population, structure and physical milieu in these tissues; the most dramatic changes resulted in the total destruction of hair follicles in allografted hairy skin. Yet, well-defined receptive fields for low-threshold rapid and slow adapting responses were able to be identified by recording single axons serving either allografted glabrous or hairy skin. Correlation of the histologic and electrophysiologic data derived from this study further implicates the axon as the site of mechanoelectric transduction in cutaneous mechanoreceptive afferents. The presence of the mechanoreceptor (i) may serve to lower sensory thresholds possibly by optimizing mechanoelectric transduction, and (ii) sharpen tuning curves, thereby providing frequency filtering. Axons in contact with a receptor may also be less likely to fatigue.

293.4

PSYCHOPHYSICAL MEASUREMENTS OF PRICKING PAIN SENSATION MECHANICALLY EVOKED BY PROBES OF DIFFERENT DIAMETERS. M.K.C. Mengel* and R.H. LaMotte. Yale University School of Medicine, Dept. of Anesthesiology, New Haven CT 06510.

The threshold and magnitude of pricking mechanical pain were determined in human subjects. The stimuli were delivered to the volar forearm by truncated epoxy cones with tip diameters of 150, 200, 250, 300 and 600 μm . The probes were applied manually with a quick indentation and immediate retraction. The cones were mounted to a handle equipped with a strain gauge in order to measure the peak force of skin indentation and the indentation velocity. Subjects estimated the magnitude of the pricking (first) pain sensation produced by each stimulus and also reported the presence of any other sensory quality such as aching and itching.

The threshold of pricking pain (minimal force for evoking pain on 50% of the trials) was found to be inversely proportional to the tip diameter. The thresholds for the smallest and the largest diameter probes differed more than tenfold. The threshold of the 600 µm probe was reached at forces that evoked pain on nearly 100% of the trials with the two smallest diameter probes. The thresholds decreased with increasing force and indentation velocity. Pricking was less frequent and aching pain more prevalent at slower indentation velocities particularly as the diameter of the probe was increased. Both the quality and magnitude of mechanically evoked pain are a function of the diameter of the probe and the force and velocity with which it is applied to the skin. (ONR Contract N00014-88-K0604).

293 5

COOLING HUMAN NERVES AFFECTS TACTILE ROUGH-NESS SENSATIONS. J.R. Phillips and P.B.C. Matthews*. University Laboratory of Physiology, Parks Road, Oxford. OX1 3PT. U.K.

Cooling the arm interferes with the transmission of sensory messages from the hand by prolonging the refractory period of nerve fibres and by increasing conduction delay dispersion between fibres. We have employed cooling to investigate which features of the afferent discharge might account for the sensation of roughness. The left arm was cooled between wrist and axilla. Conduction effects were monitored by stimulating the ulnar nerve and recording the F wave in a hand muscle. Subjects scanned the little finger over plastic surfaces embossed with patterns of dots. On the uncooled side, a standard pattern was repeatedly presented. On the cooled side, a series of test patterns with different dot spacings were presented. As the test arm cooled, progressively coarser test patterns were perceived as equivalent to the standard (a 2.6 mm pattern and a 2.0 mm standard were perceived as equally rough.) The reduction in perceived roughness with cooling was not accompanied by a change in the subject's discriminative capacity on the cooled side. The longer refractory period of the cooled afferents would have prevented them transmitting any high frequency discharges evoked by the patterns, thereby reducing the peak-to-peak modulation of the afferent response. The results are consistent with the idea that roughness magnitude increases with depth of modulation of the afferent response.

293.7

MECHANICAL SENSITIZATION OF HTMS AND ITS RELATION TO TISSUE COMPLIANCE. B. Cooper, M. Ahlquist*, R. Friedman, B. Loughner*, and M. Heft, Depts. of Oral & Maxillofacial Surgery, Oral Biology and Neuroscience, University of Florida, Gainesville, FL, 32610

Unit recordings from the goat trigeminal ganglion identified two subgroups of HIMs in the goat palate (Cooper et at., 1988; Friedman et al., 1988). One HIM group transduced pressure into the noxious range (intense pressure receptors or IPRs; after Burgess and Perl, 1967). The responses of IPRs to intense pressure were described by power functions that were bounded by pressure. The product of t produced a minimum or asymptotic frequency (Pressure-Frequency Threshold and Asymptote, PFT and PFA). PFTs of IPRs matched human pain thresholds (1.59 Nhm² vs 1.65 N/mm²), while activation thresholds did not. PFTs and PFAs of IPRs matched the human pressure-pain range from "WEAK" to "INTENSE" pain. After carrageenan inflammation (CI) or 5HT, IPR sensitization was manifested as: 1) decreased mean response interval (MRI), 2) increased slope; and 3) decreased IPIC and IPA of pages from the production of the Representation of the Production of th

FT and PFA of power functions fit to pressure-interval data (9/12 cass). We then examined the contribution of edema to CI sensitization of IPRs. We observed that CI induced changes in tissue compliance (TC) varied with tissue site (10 to (.078 mm/g, ventral palatal zone; .144 to .173 mm/g) sulcal zone. An artificial edema was mmg, ventral palatal zone; .144 b. 173 mm/g) sulcal zone. An artificial edema was used to compare the effect of tissue fluid contesnt to antigen-induced changes in indices of IPR sensitization. These observations were made: 1) Changes in activation threshold followed tissue dependent shifts in compliance, but changes in HFI, PFA and MRI did not (5/6 cases); 2) Changes in slope produced by artificial edema were independent of TC and tissue site (66 cases).

In conclusion: 1) IPRs are sensitized by CI σ SHI; 2) Edema contributes to this sensitization via increased power function slope; 3) Edema decreases activation threshold only when edema produces in increases in compliance, and this depends upon tissue site; 4) Changes in PFT, PFA, and MRI are independent of edema and might be due, in part, to 5HT (NIDR DE08701, IRB 5-86, AWA 3377-01, 7136)

293.9

SOME PROPERTIES OF MECHANORECEPTORS IN THE RAT HIND FOOT. J.W. Leem, K. Sheen, B.S. Chung, J.M. Chung and W.D. Willis. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77550.

The aim of this study was to analyze the properties of mechanoreceptors in the glabrous skin of the rat hind foot.

Single unit activity was recorded from a filament dissected from the sural or plantar nerve of 26 anesthetized (sodium pentobarbital, 50 mg/kg) rats. The receptive fields (RF) of mechanoreceptive units were mapped and various mechanical stimuli were tested

From a total of 68 mechanoreceptive units identified, 39 were slowly adapting type II mechanoreceptors (SA-II). The remainder were 3 slowly adapting type I, 20 rapidly adapting, and 6 Pacinian corpuscles. The discharge rate of SA-II correlated better to graded forces than to pressure. Five of the 12 SA-II units that generated a resting spontaneous discharge were found to have one or two "inhibitory fields" that situated adjacent to excitatory RF. Mechanical stimuli applied to the inhibitory field depressed the spontaneous

The results indicate that SA-II are the dominant slowly adapting mechanoreceptors in the glabrous skin of the rat hind foot. For their activation, constant force can be used as a reliable stimulus parameter. It is also suggested that SA-II afferents may play a possible role in a lateral inhibition for spatial discrimination via a peripheral mechanism. (Supported by NIH grants NS21266, NS09743 and NS11255 and a grant from Bristol-Myers Co.)

SPATIAL LOCATION OF MAGNETIC TRIGEMINAL SOMATOSENSORY RESPONSE BY TACTILE STIMULATION

AND CORRELATION OF THE MRI M. Nomura, U. Ribary, L. Lopez, A. Mogilner, F. Lado and R. Llinás, Dept. of Physiology, New York University Medical Center, New York, NY 10016 U.S.A.

Magnetic trigeminal somatosensory responses from human subjects were recorded using a 14-multichannel cryogenic neuromagnetic measuring system (BTi) in order to locate the evoked responses to the tactile stimulation of upper and lower

The stimulation was produced by 15 ms vibration burst from a Piezo electric buzzers at frequencies of 50 Hz, 150 Hz and 250 Hz, given at a rate of 1-2 times per second. Recordings were obtained from the contralateral scalp by using the probe position indicator (Yamamoto et al, '88 Proc. Natl. Acad. Sci). 500 responses were averaged. The spatial locations are being mapped on the MRI of each subject.

The sources activated by upper and lower lips stimulation were separated by approximately 10 mm (using the response to 150 Hz), and their spatial location corresponded to the posterior wall of the central sulcus. Compared with the component of the dipole moment at each stimulating frequency, the stimulation at the frequency of 150 Hz produced the largest response. Moreover, the location of the response shifted with the change of the stimulation frequency.

These results demonstrate that a large area of the somatosensory cortex is

utilized for lip representation and suggest that the spatial displacement of the trigeminal somatosensory response may be related to the discrimination of frequency. Supported by 13742 from NINDS.

AXONAL ORIGIN OF PROLONGED DISCHARGES OF SOME CUTANEOUS RECEPTORS. J.M. Chung, J.W. Leem, B.S. Chung and K. Sheen. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX

A previous study in our laboratory have shown that some afferent axons produce prolonged discharges after complete isolation. We have attempted to identify the type of afferent fibers displaying such activity

Single unit activity was recorded from a filament dissected from the distal stump of cut sural or plantar nerve of anesthetized rat (Sprague-Dawley). After thorough identification of the receptor type, the nerve was cut at a site between the recording electrode and the cutaneous receptive field, isolating the nerve being recorded completely. Spontaneous activity was recorded up to 1 hour after sectioning the nerve

Upon sectioning the nerve, many units showed brief injury discharges lasting only a few seconds. However, 6 of 16 units exhibited prolonged discharges at least a half hour after isolation from their receptors. These 6 units included 5 slowly adapting type II mechanoreceptors and 1 Paccinian corpuscle.

These results suggest that prolonged discharges can be produced in the middle of axons of the slowly adapting type II and Paccinian corpuscle afferent fibers. This phenomenon may explain parasthesias in patients often associated with peripheral nerve injuries. (Supported by NIH grants NS21266 and NS11255 and a grant from Bristol-Myers Co.)

SERIAL ELECTRON-MICROGRAPHIC RECONSTRUCTION OF PRESUMED TRANSDUCER SITES IN PACINIAN CORPUSCLES. J. E. Landcastle*, N.B. Slepecky* and S.J. Bolanowski, Institute for Sensory Research, Syracuse University, Syracuse, NY 13244.

The Pacinian corpuscle (PC) is composed of a neurite surrounded by an accessory capsule. The portion of the neurite discussed here is elliptical in cross-section and has filopodial structures projecting only along the major elliptical axis. They are the presumed transduction sites. Based on physiological experiments, we have proposed that two populations of filopodia, organized in morphofunctional opposition, exist. In order to test this, PCs obtained from cat mesentery were processed for electron microscopy using standard techniques. Reconstructions were made of selected regions from several sets of serial thin sections. We evaluated filopodial location, inclusions, shape and size. The density of filopodia was found to be approximately $2.8 \mu m$ or over 1,400 per terminal neurite. While the full complement of cellular inclusions (e.g., vesicles, amorphous ground substance, mitochondria at inclusions (e.g., vesicles, amorphous ground substance, mitochondria at the filopodium base, etc.) were found, there also appeared to be two different types of filopodia: T-shaped, with the arms extending over 0.75 μm (s.d., $0.12\mu m$) parallel to the neurite's long axis and I- or Y-shaped, extending 0.24 μm (s.d., 0 μm) along that direction. The maximum perpendicular projection of both types is roughly 7.4 μm . No obvious relation between filopodial type and location along the neurite was found, although the filopodia seemed to project alternately from either side of the neurite along the proximo-distal direction. That is, filopodia seemed never to project from both sides of the neurite in the same region, although most regions of the neurite did contain a filopodium. It is although most regions of the neurite did contain a filopodium. It is possible that the two filopodial types contribute oppositely to the receptor potential during the transduction process. Supported by NS23933.

A VISCOELASTIC CONTACT-MECHANICS MODEL OF SKIN PREDICTING SPATIOTEMPORAL RESPONSE PROPERTIES OF CUTANEOUS MECHANORECEPTORS.

M.N.H. Waller* and J.R.Phillips. University Laboratory of Physiology, Parks Road, Oxford. OX1 3PT, UK.

(SPON: Brain Research Association)
The local physical conditions at the receptor terminal governing the responses of cutaneous mechanoreceptors are unknown and cannot be investigated empirically. We have used contact-mechanics theory to compute the time dependent patterns of stress and strain within the skin resulting from embossed stimuli scanned across the surface. These stress/strain patterns are then compared with neural responses recorded from the three classes of mechanoreceptive afferents in order to establish which components of

strain determine their response.

Embossed stimuli are modelled as collections of vertical point forces applied to the surface summed with horizontal frictional forces. The skin medium is taken as an ideal, elastic half-space in which the principle of superposition is valid. A significant development of the model is the inclusion of a viscoelastic (spring and dashpot) element. Its effect on the surface forces is expressed in two ways: an enhancement of the leading relative to trailing forces and a "dynamic lift" of the stimulus. The alterations to the surface force profile result in modifications of the stress and strain patterns, making them closely match the form of the empirical responses.

5-HT AND ATP MODULATE THE ACTIVITY OF CUTANEOUS TYPE I MECHANORECEPTORS IN THE RAT: AN "IN VITRO" STUDY. Hervé A. Martin. Robert P. Tuckett and Kathy English. Dept. Physiology, Univ. of Utah, 410 Chipeta Way, Salt Lake City, UT 84108. To determine whether Merkel cells are the transducer element in the Merkel cell neuronal complex, we have studied the effects of intra-arterial injections of 5-HT and ATP contained in Merkel cell. To minimize the side effects of these putative neurotransmitters, we have developed an "in vitro" model. Rats (n=27, 75-150 gram) were anesthetized with nembutal (35 mg/kg). The saphenous nerve and accompanying blood vessels were removed along with the dorsum skin of the leg and foot and placed in a chamber perfused with a freshly oxygenated bicarbonate saline buffer (pH=7.35; 32 °C). To inject drugs, the femoral artery was canulated. The activity of single type I units was recorded by placing the whole nerve on a silver chlorided electrode in an oil chamber from which thin filaments were dissected out and placed on a second silver chlorided recording electrode. Type I receptive fields were localized with a 1 gram von Frey stimulator. Then, mechanical stimuli were delivered using a rigidly-mounted mechanical stimulator that indented individual domes at a rate of 10 µm/sec with a 200 µm plateau for 60 sec. In a delivered using a rigidly-mounted mechanical stimulator that indented individual domes at a rate of 10 µm/sec with a 200 µm plateau for 60 sec. In a first series of experiments, we studied the effects of increasing doses of serotonin (1; 5; 10; 25; 50; 100; 250; 500 µM-100µl); each dose injected 1 min prior the mechanical stimulus. After 5-HT injections, we studied the effects of ketanserin (500 µM;200µl), a 5HT, receptor antagonist. In a second series of experiments, we studied the effects of ATP (same range of concentrations), of a mixture of ATP and ketanserin (250 µM;200µl), and of ATP and serotonin (250 µM;200µl).

We have demonstrated inhibitory effects of serotonin on the tonic discharge of type I units which can be reversed by ketanserin "in vitro". ATP has been found to activate type I units and may facilitate their discharge during indentation. Evidence is suggesting that a mixture of ATP and ketanserin reverses 5-HT-induced inhibition.

WIDEBAND SYSTEMS ANALYSIS OF TACTILE RECEPTORS. F.J.

Looft, Dept. Elect. Engin., Worcester Polytechnic
Institute, Worcester, MA. 01609
In a previous study, a vibrotactile indenting stimulus
with a 85 Hz bandwidth was used to study the linear transfer characteristics of cutaneous mechanoreceptors (Looft et al, IEEE-Trans. BME, in press). Recently, the bandwidth of this stimulator was increased to 400 Hz and used in preliminary experiments to determine the first and second order Wiener kernels (Marmarelis et al, <u>Biol</u>. <u>Cyber</u>, 54:115-123, 1986) of cat slowly adapting Tl, T2 and 'field' receptors. Further, because of the potential for a vibrotactile stimulus to tap the skin's surface, these experiments were performed when the stimulus tip was/was not glued (cyanoacrylate) to the skin surface.

Spectral analysis of the linear transfer functions confirmed our earlier results that, to varying degrees, these receptors responded as fractional order differentiators (increasing sensitivity with frequency). Cementing the tip of the vibrotactile stimulus to the surface of the skin overlying a unit had little effect on the shape of the first order kernel. By contrast, the second order kernels were modified, although the topographic changes were not major. Such changes portend interesting questions regarding the specific mechanism by which stimulus energy is transformed by skin and receptor dynamics and, ultimately, results in an AP event stream.

PAIN: PATHWAYS I

FOS ONCOPROTEIN-LIKE IMMUNOREACTIVITY EVOKED BY NOXIOUS HEAT AND ELECTRICAL STIMULATION IN THE ANESTHETIZED RAT AND MONKEY H.H. Willcockson*, A.R.Light, E. Bullitt, and C.J.Vierck. Depts. of Physiology, Neurosurgery, UNC-Chapel Hill, Chapel Hill, NC 27599-7545.

The proto-oncogene c-fos is expressed in various brain regions following synaptic activation (Hunt, 1987). This study compares the effect of electrical vs heat stimulation in two species. Electrical stimuli were delivered via electrodes designed previously for psychophysical studies of pain in monkeys and humans (Vierck et al 1983). Fifty stimuli (40 msec on, 200 msec off, 60 Hz, total 3 seconds each, intertrial interval 25 sec) ranging from 0.2mA to 4 mA were delivered. Noxious heat stimuli (paw immersed in 52° water) was applied 20 times for 20 sec every two minutes. An antibody (Cambridge) against fos proteins revealed somatotopically appropriate labeling of cell nuclei in histological sections of lumbar spinal cord. Electrical stimulation greater than 2 mA and noxious heat evoked profuse labeling of neuronal nuclei in laminae I, II and V ipsilateral to the stimulus in rats and monkeys. Labeled nuclei were also found in lesser numbers in all other dorsal and ventral horn laminae except IX. Less than 1 mA labeled fewer neuronal nuclei which were confined to a narrow transverse region in the lumbar cord mostly in laminae II, III, and IV. Thus, noxious heat and noxious electrical stimuli evoke a similar pattern of fos labeling in both rat and monkey. Supported by PHS grants DA04420, NS16433, and NS14899.

C-FOS AS A MARKER FOR SUBSETS OF VISCERAL SECOND ORDER C-FOS AS A MARKER FOR SUBSETS OF VISCERAL SECOND ORDER NEURONS IN THE RAT LUMBOSACRAL SPINAL CORD L.A. Birder, J.R. Roppolo, M.J. Iadarola, and W.C. De Groat, Dept. of Pharmacol., Univ.of Pittsburgh, Pgh, Pa. 15261.

C-Fos immunocytochemistry was used to identify neurons in the rat spinal cord that receive afferent input from the urinary bladder (UB). Physiological distension, and

the urinary bladder (UB). Physiological distension, and noxious stimulation (overdistension and chemical irritation, formalin 3%) were used to stimulate UB afferents in urethane anesthetized rats in which preganglionic neurons (PGN) and spinal tract neurons projecting to the rostral pons were labeled with fluorescent dyes. Noxious stimulation of the UB produced 3 times the number of c-fos cells than nonnoxious stimulation. C-fos positive cells were located in laminae I and II, laminae $^{\circ}$ X and laminae VII near the sacral parasympathetic nucleus. A small % (5%) of PGN exhibited c-fos, however many cells in lamina VII dorsal to the PGN were c-fos positive, and 20-30% of dye labeled spinal tract neurons in this and other laminae were c-fos positive. Capsaicin pretreatment (70 mg/kg) blocked the c-fos response to all stimuli. Administration of hexamethonium (60mg/kg) decreased the number of c-fos cells. These findings indicate that both noxious and nonnoxious stimulation of the UB increases the number of c-fos positive cells in the spinal cofd via activation of capsaicin sensitive afferents. The respondingly include spinal tract neurons as well as PGN. The responsive cells

NOXIOUS AND NON-NOXIOUS COLORECTAL DISTENTION RESULTS IN C-FOS INDUCTION IN THE RAT SPINAL CORD. R.J. Traub and G.F. Gebhart, Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242.

The spinal mechanisms involved in visceral pain processing are not well understood. In order to further elucidate pathways activated by visceral stimuli, immunocytochemical methods were used to localize the cellular proto-oncogene protein Fos following colorectal distention. Rats were lightly anesthetized with halothane and the descending colon and rectum were distended with pressures of 20, 40, or 80mmlg for 30s every 2min for 2h. The rats were sacrificed within 30min and the lumbosacral spinal cord was processed for Fos-like immunoreactivity (Fos-li, antisera donated by Dr. M. Iadarola). Greater distending pressures resulted in an increased number of cells with Fos-li in the L5-Sl spinal segments. In the most heavily labeled sections (>300 nuclei), Fos-li was observed bilaterally in laminae I-VII, X, and the sacral parasympathetic nucleus (SPN). The most densely stained nuclei were observed in the lateral 2/3 of laminae I/II, laminae V, VI, X, and the SPN. Very lightly stained nuclei were more prevalent in laminae III, IV, and VII. Rats that received the greatest stimulus intensities had a greater number of densely stained nuclei. These data suggest that noxious and non-noxious visceral stimulation result in the induction of Fos protein that may parallel the increase in stimulus intensity.

DIRECT GLUTAMERGIC INNERVATION OF PRIMATE SPINOTHALAMIC TRACT NEURONS. K.N. Westlund, S.M. Carlton, D. Zhang, and W.D. Willis. Univ. of TX Medical Branch, Marine Biomedical Institute, Galveston, Texas 77550.

Since glutamate excites spinothalamic tract (STT) neurons, the possibility that glutamergic terminals directly innervate STT neurons was investigated. One STT cell (lamina IV and V) in lumbar spinal cord in each of two monkeys was identified and characterized. The cells were characterized as a wide dynamic range and a brush inhibitory high threshold neuron. Following intracellular injection of the cells with HRP, the animals were perfused with mixed aldehydes. The tissues were reacted for HRP, dehydrated and embedded. Thin sections were reacted for postembedding immunogold (10 nm) using antibodies specific for glutamate (1:20,000)(Arnel). Glutamergic synapses were observed on the soma and dendrites (lamina III-V) of the STT neurons. The synapses were numerous and of both symetrical and assymetrical type. Glutamergic profiles comprised 48% and 51% of the population of terminals apposing the soma and dendrites respectively, of one of these cells. The profiles contained round, clear vesicles and many contained a variable number of large dense core vesicles. It was concluded that glutamergic terminals comprise a large portion of the profiles apposing STT neurons. The presence of large dense core vesicles suggests that some terminals are of primary afferent origin. Supported by NS11255 and Bristol Myers-Squibb Corp.

SPINAL NEURONS LIKELY TO MEDIATE LOW BACK AND REFERRED LEG PAIN. R.G. Gillette*, R.C. Kramis* & W.J. Roberts, R.S.Dow Neurol.Sci.Inst., Good Samaritan Hosp. & Med. Ctr. Portland, OR 97209.

Low back pain (LBP) typically is felt diffusely, even after focal injury, and it often radiates into the leg. We are investigating the physiological bases for LBP by recording from spinal neurons with paraspinal receptive fields in anesthetized cats. The principal goals are: to characterize the receptive fields of single units; to test for expansion of receptive fields after noxious stimulation; and to test for responses to sympathetically evoked afterent activity, which may impose a sympathetically maintained pain (SMP) component in LBP (Roberts, 1986; Brenna et al., 1980).

Recordings to date from 70 neurons indicate that: 1) many neurons with large paraspinal receptive fields receive convergent input from the zygapophysial joint capsule, paraspinal and thigh muscles and skin, and the anterior longitudinal ligament; 2) injection of an algogen into paraspinal tissues causes expansion of the receptive field into the thigh in many neurons; and 3) stimulation of sympathetic efferents activates about 75% of the WDR neurons tested.

These results demonstrate a neuronal substrate for the diffuse nature of LBP and for the tendency of LBP to radiate into the leg. They also demonstrate a mechanism through which sympathetic activity may contribute to LBP. (NIH NS13447)

DISTRIBUTION OF FOS-LIKE IMMUNOREACTIVE NEURONS IN THE CAUDAL MEDULLA OF THE RAT INDUCED BY NOXIOUS STIMULATION OF FACIAL SKIN AND CORNEA. A.Strassman. J.Leite. and R.Maciewicz. Pain Physiology Lab, Dept. of Neurology, Massachusetts General Hospital, Charlestown, MA 02129.

General Hospital, Chanestown, MA 02129.

Peripheral somatosensory stimulation can induce neuronal expression of the proto-oncogene c-fos in the spinal dorsal horn. To evaluate further the use of c-fos expression as a marker for neuronal activity in somatosensory pathways, the distribution of immunocytochemically labelled fos-positive neurons was mapped from the obex to C2 following acute noxious stimulation of the facial skin and cornea. Electrical (1 msec, 5mA pulses at 1 Hz), mechanical (repeated cutaneous pinch or corneal brushing), and thermal (50c C., 20-second pulses, every 1-2 minutes) stimuli were delivered over a period of 15 minutes to the cornea or to localized (<50 mm2) cutaneous sites within the V1, V2, or V3 dermatome in rats anesthetized with pentobarbital or urethane. Animals were sacrificed 2 or 4 hours following stimulation.

The pattern of neuronal labelling in the medullary and upper cervical

The pattern of neuronal labelling in the medullary and upper cervical dorsal horn exhibited a precise somatotopic organization, with rostral and dorsal facial sites represented rostrally and ventrally. This pattern of labelling is generally consistent with the somatotopy described previously in single-cell recording studies. For both electrical and natural forms of stimulation, the labelling in the superficial laminae (I-II) of the dorsal horn was both denser and more widespread than in the deeper laminae (III-V). Outside the dorsal horn, labelled neurons were most densely distributed in the nucleus of the solitary tract, the ventrolateral medulla adjacent to the lateral reticular nucleus, and in a highly restricted region in the ventral corner of the nucleus interpolaris at levels caudal to the obex. The distribution of labelled neurons outside the dorsal horn was bilateral and did not appear to be somatotopically organized. The results suggest fos localization may provide a useful tool to study the functional organization of central pathways involved in trigeminal nociception.

ANALYSIS OF GABAERGIC AND GLYCINERGIC INPUT TO SPINOTHALAMIC TRACT CELLS IN PRIMATE DORSAL HORN. H. Lekan, E.S. Hayes*, K.N. Westlund, D. Zhang, W.D. Willis and S.M. Carlton. University of Texas Medical Branch & Marine Biomedical Institute, Galveston, TX 77550.

Inhibitory interneurons containing either gamma aminobutyric acid (GABA) or glycine are located in the dorsal horn. The relationship of GABAergic and Glycinergic profiles to spinothalamic tract (STT) cells is unknown; however, iontophoresis of either substance results in inhibition of these cells. The purpose of this study was to determine the relationship between these inhibitory systems and cells at the origin of the STT. In primates, STT neurons iontophoretically injected with HRP in the lumbar enlargement were immunostained with anti-GABA or anti-glycine using a postembedding immunogold technique.

Analysis at the EM level of cell bodies and proximal dendrites demonstrated that both GABAergic and Glycinergic terminals synapsed on lamina V STT neurons. Analysis of several levels through one STT cell demonstrated that 25% of the terminals were GABAergic and 13% were Glycinergic. These data indicate that STT cells are under considerable inhibitory control by dorsal horn interneurons. We hypothesize that disruptions of this inhibitory input may lead to aberrant pain sensations. This work was supported by NS11255, NS27910 and the Bristol Myers-Squibb Corp.

A PROJECTION FROM LAMINA I TO THE LATERAL CERVICAL NUCLEUS OF THE CAT. A. Blomqvist, J. Broman and A.D. Craig, Jr. Department of Cell Biology, Faculty of Health Sciences, University of Linköping, S-581 85 Linköping, Sweden, and Divisions of Neurobiology and Neurosurgery, Barrow Neurological Institute, Phoenix, AZ 85013, U.S.A.

The lateral cervical nucleus (LCN) receives ascending input from spinoenvical tract cells legated in the publicus receives.

The lateral cervical nucleus (LCN) receives ascending input from spinocervical tract cells located in the nucleus proprius of the dorsal horn. However, the results of retrograde tracing experiments have suggested that also neurons in lamina I project to LCN. In the present study the question of lamina I input to LCN was addressed by anterograde tracing with Phaseolus vulgaris leucoagglutinin (PHAL). Injections of PHAL into lamina I at different spinal segments resulted in terminal labeling in the most medial portion of the LCN (mLCN). The labeled fibers were fine and longitudinally oriented, with reticular arborizations. They were clearly different from the large-diameter fibers with dense bursts of terminals in the topographically appropriate portions of the lateral LCN that were seen in cases with lamina III-IV injections. The observations corroborate the earlier identification of nociceptive neurons in the mLCN. The mLCN contains GABAergic neurons that are probably local inhibitory interneurons; thus, the present findings may help explain the inhibitory effects of noxious stimuli on the majority of LCN neurons and support the hypothesis that in the intact animal the spinocervicothalamic pathway does not subserve nociception.

POSTSYNAPTIC DORSAL COLUMN FIBERS IN THE CUNEATE

POSTSYNAPTIC DORSAL COLUMN FIBERS IN THE CUNEATE NUCLEUS OF THE MONKEY (MACACA FASCICULARIS) REVEALED BY PHA-L. K.D. Cliffer and W.D. Willis, Jr. Marine Biomedical Institute, The University of Texas Medical Branch, Galveston, TX 77550
Postsynaptic cells in the cervical spinal cord of cats, the majority of which receive nociceptive input, have been previously shown to project to the non-cluster regions of the cuneate and gracile nuclei and sparsely if at all to the cluster regions. In monkeys, pars rotunda of the cuneate nucleus, considered to be the equivalent of the cluster region in cats, has been reported not to receive a projection from postsynaptic cells in the cervical spinal cord. We made multiple iontophoretic injections of the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L) into the cervical enlargement of a cynomologous monkey (Macaca Jascicularis). After 34 days survival the animal was deeply anesthetized and perfused, and the tissue processed for immunohistochemical detection of the PHA-L, using the avidin-biotin fluorescence technique. Many labeled fibers and varicosities were detected in a widespread distribution in the cuneate nucleus, including most of pars rotunda and part of pars triangularis throughout their lengths. Fibers and varicosities in a substantial portion of the external cuneate nucleus were also labeled. These results indicate that the postsynaptic projection to the cuneate nucleus series widespread, and includes pars rotunda and areas from which cells project in the medial lemniscus to the ventrobasal thalamus. Such projections could contribute to transmission of information originating in nociceptors through the dorsal column-medial lemniscal system to the ventrobasal thalamus. We have previously recorded nociceptive responses in cells in the gracile nucleus that project to the ventrobasal thalamus in monkeys (Ferrington et al., J. Neurophysiol., 59:886-907, 1988) and cats (Cliffer et al., Soc. Neurosci. Abs., 15:1190, 1989). Soc. Neurosci. Abs., 15:1190, 1989).

FORMALIN PAIN BUT NOT ANALGESIA IN BRAIN STEM TRANSECTED . Matthies, and K.B.J. Franklin. Psychology Dept.,

McGill University, Montreal, Canada.
Rats with transections of the brain stem 1-2mm anterior to the interaural line (Paxinos and Watson, 1986) were tested for pain responses and morphine analgesia in the formalin and tailflick tests. Cuts passed through the inferior colliculus dorsally and the pontine nuclei ventrally. Rats were aphagic and adipsic but regained an upright posture, locomotor activity and grooming. Animals responded to formalin injection by lifting and favoring the injured paw, but attempts to groom the paw were inaccurate and often resulted in loss of balance. Responses to pain differed from normals in several ways:

a) formalin pain is normally high immediately after formalin is injected, falls to a low point 15 minutes later, then rises again to a level which remains steady for 30 to 40 minutes and then falls. In transected animals pain ratings remained high for 60 min. and then fell off as in normal rats. b) In normal rats the ED50 for morphine analgesia in the formalin test is 4 mg/kg but 8 mg/kg morphine had no effected in transected rats. c) The tailflick reflex was not impaired, but the animals response to 8 mg/kg morphine was attenuated. The results suggest that the neural mechanisms involved in protective and recuperative responses to injury produced pain lie in the brainstem, but structures critical for the analgesic effect of morphine appear to be more rostrally located.

THE DORSAL SPINOTHALAMIC PATHWAY IN THE MONKEY: A LIGHT AND ELECTRON MICROSCOPIC STUDY. D.D.Ralston and H.J.Ralston, III, Department of Anatomy, University of California, San Francisco, California,

A recent study by Apkarian and Hodge (J.Comp. Neurol. 288: 474, 493, 1989) showed that lamina I cells of the spinal dorsal horn (which are primarily nociceptive neurons) give rise to a dorsal spinothalamic pathway (STT). We have studied this pathway by making microinjections (0.02µl) of WGA-HRP into the cervical enlargement of anesthetized macaque monkeys, with a unilateral high cervical anterolateral cordotomy. We have found that the dorsal STT travels in the white matter at the level of the denticulate ligament and terminates primarily in the ventral caudal region of the somatogensory, thalamus. This area was called Very the halams. caudal region of the somatosensory thalamus. This area was called Vc.pc. by Hassler, who stated that electrical stimulation of this region in humans elicited reports of contralateral burning pain. Recent studies by Dostrovsky (personal communication) support Hassler's earlier report. Nathan (Pain 40: 239, 1990) has described a patient with loss of cold and pinprick sensation following a lesion of the intermediate aspect of the lateral column white matter at the level of the denticulate

Electron microscopy revealed that dorsal STT terminals formed axodendritic synapses upon thalamic neurons without involving the GABAergic local circuit neurons which characterize lemniscal terminations. We conclude that the dorsal STT from cervical segments occupies the lateral column white matter opposite the denticulate ligament and terminates primarily in a restricted zone of the thalamus shown to be associated with pain sensation in humans. The dorsal STT information is not subject to GABAergic modulation in the thalamus. Supported by NS21445 from N.I.H..

MEDULLARY DORSAL HORN PROJECTIONS TO THE DIENCEPHALIC NUCLEI IN THE RAT. K. Iwata, R.L. Nahin and D.R. Kenshalo, Jr. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

Previous studies revealed that a major projection of the medullary dorsal horn (MDH) is to diencephalic nuclei. However, the localization and the pattern of MDH afferent terminations in the diencephalon remains unclear. The present study employed injections of the anterograde tracer, Phaseolus Vulgaris-leucoagglutinin (PHA-L), into the MDH in rats. Injections of a 2.5% solution of PHA-L (0.01ul each point, 5-10 points) were made into the rostro-caudal extent of the MDH. Following a survival period of 14-21 days, animals were deeply anesthetized with sodium pentobarbital and perfused transcardially. Transverse serial sections (30 µm) were cut and incubated in a 1:2000 dilution of goat anti PHA-L for 48 hours and then processed with the avidin-biotin technique. Labeled fibers and varicosities were seen in the N. ventralis posteromedialis (VPM), N. submedius (SM) and N. posterior hypothalamus (PHT). Non-varicose axons were videly distributed in the caudal half of VPM, whereas the majority of axonal varicosities were found in the middle portion of VPM. In SM and PHT, axonal varicosities and non-varicose axons were intermingled and were distributed in the dorsal portions. Varicosities in SM and PHT were much smaller than those observed in VPM and were predominantly of the en passant variety. These data suggest that information originating in the MDH is processed in at least three different nuclei of the diencephalon.

294.12

AMYGDALOID PROJECTIONS OF THE EXTERNAL PARABRACHIAL AREA IN THE RAT: A PHA-L STUDY WITH REFERENCE TO PAIN TRANSMISSION. J.F. BERNARD* and J.M. BESSON, Unité de Recherches de Physiopharmacologie du Système Nerveux, I.N.S.E.R.M. U 161, 2 rue d'Alésia 75014 PARIS

We have demonstrated that a high proportion of neurons that were located in the external parabrachial (PBe) area (i.e. external lateral (PBel) and external medial (PBem) subnuclei) and that projected to the nucleus centralis (Ce) of the amygdala was implicated in pain processes (Bernard and Besson J. Neurophysiol. 1990, 63: 473-490). Futher investigations at the Ce level showed that regions not detailed in previous anatomical studies were also implicated in pain processes. The aim of the present study was to precisely investigate the efferent projections of PBe area to the amygdaloid complex and the adjacent areas.

In anaesthetized Sprague-Dawley rats PHA-L (5%) was electrophoretically injected into the PBe area. Two weeks later, the rats were perfused transcardially, the brain was removed and cut in serial sections which were reacted with PHA-L antibody and an ABC kit of Vector. The location of labeled terminal fibers varied dramatically with the location of the very restricted injection sites $(200-400\mu m)$ in the parabrachial area. The caudal PBel subnucleus projects mainly to the peripheral region of the Ce. The caudal PBem subnucleus projects mainly to the rostrolateral portion of the Ce and the adjacent striatopallidal region. The location of these efferent projections precisely corresponds to the location of neurons responding to noxious stimuli. Thus this study details and extends the terminal area of the spino(trigemino) - ponto-amygdaloid nociceptive pathway that could be implicated in the affective-emotional aspects of pain.

EFFECT OF NUCLEUS SUBMEDIUS THALAMUS LESIONS ON NOCICEPTIVE RESPONDING IN RATS. <u>Vicki I. Roberts and Willie K. Dong.</u> Dept of Anesthesiology & Multidisciplinary Pain Center, Univ of Washington Sch of Med, Seattle, WA 98195. The effect of nucleus submedius thalamus (SM) lesions on

nociceptive responding in rats was assessed using both the radiant heat tail-flick test (TF) and the pain-induced (tail-shock) vocalization test. Results indicate that the intensity of electrical shock required for vocalization responses is significantly decreased in rats following SM lesions. The postlesion increase in nocifensive behavior is observed for vocalization responses which are briefer than the electrical stimulus as well as for vocalizations which outlast the stimulus. No changes in vocalization responses were present in the sham lesion group. In contrast, both the sham and SM lesion group exhibited a significant postlesion increase in and SM lesion group exhibited a significant postlesion increase in TF latencies. This decrease in nociceptive responding is attributed to conditioned analgesia, since analgesia on TF measures has been demonstrated following exposure to environmental cues previously paired with tail-shock. We are currently assessing whether or not lesion effects on tail-flick response to radiant heat may have been masked by conditioned analgesia. Preliminary results indicate that there is no nostlesion change in tail-flick latencies in either sham or there is no postlesion change in tail-flick latencies in either sham or lesion groups when the vocalization test is omitted. This suggests that the SM is not important for spinally mediated reflexes. The postlesion increase in nocifensive vocalization responses suggests that the SM may be important in affective reactions to nociceptive stimuli. Supported by NIH grant NSO7217.

ACTIVATION OF NEURONES IN THE ORBITAL REGION OF RAT CORTEX BY NOXIOUS STIMULATION AND BY STIMULATION OF NUCLEUS SUBMEDIUS. N. El-Yassir and J.O. Dostrovsky. Dept. Physiology, University of Toronto, Toronto, Ontario, M5S 1A8, Canada

Anatomical studies have delineated a major reciprocal connection between the Orbital Region (OR) of the cortex (specifically the lateral and ventrolateral orbital cortex) and the thalamic nucleus submedius (Sm). The objective of this study was to confirm these anatomical findings using electrophysiological techniques and to determine the characteristics of OR neurones receiving an input from Sm or projecting to Sm. Experiments were carried out on rats anesthetized with X -chloralose and urethane. Glass-coated tungsten electrodes were used both for stimulation and recording. A total of 69 OR cells activated by Sm stimulation was studied. Stimulation in Sm antidromically activated 32 OR units (mean latency of 4.5 \pm 3.2 ms; range 1.7 to 15.2 ms). Most of these units had no spontaneous activity and only 3 out of 9 tested responded to cutaneous stimulation (only to noxious stimuli). Sm stimulation orthodromically modulated the firing rate of 37 cells. Many of these cells fired spontaneously in bursts and 18 of 20 tested responded to noxious cutaneous stimuli (15 excited, 3 inhibited). Receptive fields were large and usually bilateral. The effect of a train of stimuli to Sm on 2 of the 3 neurons inhibited by peripheral stimulation was inhibitory. These results confirm the presence of a reciprocal connection between the Sm and OR and further suggest that nociceptive information reaching the OR may be relayed through the Sm

LASER EVOKED CEREBRAL POTENTIALS IN MONKEYS A Beydoun*1.3 T.J.Morrow*1.2.3, and K.L.Casey*1.2.3. Depts of Neurology*1 and Physiology*2, U. Michigan and Neurology Research Laboratories*9 VAMC, Ann Arbor, Mi. Purpose: Cutaneous stimulation with CO2 laser pulses activates small diameter sensory afferents and evokes a pain-related potential recorded from the vertex (CZ) of humans. We here report the first successful recording of laser evoked cerebral potentials from awake monkeys. Methods: We delivered laser pulses (60 msec, 9mm beam, 4-12 watts) to the shaved tail of awake African green monkeys and recorded averaged responses from CZ to linked ears (sweep 500 msec, bandpass 0.4-40 Hz, sensitivity 200uV). Twenty five stimuli were delivered in each of 2 trials. Stimulus intensity was adjusted to the lowest level giving reproducible potentials. Throughout recording, monkeys occasionally oriented toward the stimulus but were otherwise quiet and did not vocalize. No evidence of tissue damage was seen. The proximal and distal tail were stimulated in order to calculate the conduction velocity of the fibers. Results: At low laser intensities (4-6 watts), no potentials were recorded. As the stimulus intensity was increased (8-12 watts), a tail flick response was elicited and a reproducible, triphasic positive-negative-positive potential complex (P1-N-P2) was recorded. Collowing stimulation of the proximal tail, the average peak latencies were as follows: P1=104 msec(98-113), N=163 msec(152-179), and P2=234 msec(217-249). Average amplitudes were: P1=6.1uV (2.0-11.3), N=6.9uV (2.3-11.5), and P2=9.0uV (4.7-16.7). In one monkey, a latency-intensity, amplitude-intensity study revealed that, as stimulus intensity increased, the peak latency of the potentials decreased. Amplitude increased up to an intensity of 8 watts, then decreased with higher stimulus intensities. The calculated conduction velocity of the fibers activated was 8 m/sec. Conclusions: Based on the morphology and topography of these potentials chericated afferent

OPERANT RESPONSE MAGNITUDE AS AN INDICATOR OF NOXIOUS HEAT INTENSITY IN RATS. D.K. Douglass, I.G. Campbell*, E. Carstens and L.R.

Watkins Dept. Animal Physiology, University of California, Davis, CA 95616.

The present study was designed to explore the relationship between the magnitude of an operant response and the intensity of noxious heat stimuli in rats. Rats were trained to push a lever upward with their noses to terminate mild electrical stimulation of the tail. The lever was connected to a force transducer, allowing measurement of the force and duration of pushing. The electrical stimuli used for the initial training were not and duration of pusting. The electrical stimuli used for the initial training were not sufficient to cause any noticable damage to the tail. When the rats consistently pressed in response to the electrical stimulus, radiant heat trials were added to the training, using a quartz halogen bulb with thermocouple feed back. The initial radiant training stimuli were either 53 or 55°C, and the rats quickly learned to press in response to these stimuli. Rats were tested by applying noxious heat to the tail at 51, 53, 55, 57 and 59°C. It should be noted that tail-flick threshold with this radiant heat device is 51°C, and such stimuli cause no damage to the tail skin. Our earlier studies with this paradigm suggested it was useful only as a threshold test when the push terminated the test stimulus. The current study was designed such that during the actual test sessions, the stimuli were given for 5 sec, regardless of whether the rat pushed the lever or not. Each rat was used in three test sessions; on days between sessions, rats were given stimuli that could be terminated to prevent extinction of the response. The integrated wave forms, latency, force and number of pushes in response to each stimulus were

recorded to disk and stored for later analysis.

There is a positive correlation between the integrated wave (magnitude) of the operant response and the stimulus temperature, as well as between the temperature and the peak force of the response, number of pushes per stimulus, and the inverse of the latency. The correlation coefficients are low however, due to wide variability between rats (integrated wave, r^2 =0.27; force, r^2 =0.24; latency, r^2 =0.38; push number, r^2 =0.23). With refinement of the training technique, one or more of the parameters measured by this method may prove a useful indicator of stimulus intensity above pain threshold. Supported by NIH NS 20037.

ANATOMIC EVIDENCE FOR A THALAMIC RELAY FOR NOCICEPTIVE INFORMATION TO SECONDARY SOMATOSENSORY CORTEX (SII). S.M. London and A.V. Apkarian, Dept. of Neurosurgery, SUNY Hith. Sci. Center, Syracuse, NY, 13210.

Physiologic, behavioral, and clinical evidence implicate the second somatosensory cortex (SII) in processing nociceptive information. A small number of thalamic nuclei project to SII, some of which are known to receive spinothalamic tract (STT) terminations. In this study, the relationship between STT terminals and thalamocortical cells projecting to SII was investigated. Ketamine/nembutal anesthetized squirrel monkeys received injections of fluorescent tracers in electrophysiologically defined hand area of SII and injections of 2% wheatgerm-agglutinin conjugated HRP in the contralateral cervical enlargement. Some animals also received injections of a different fluorescent tracer in the hand area of primary somatosensory cortex (SI). Anterogradely labeled terminals and retrogradely labeled cells were plotted and digitized for every fifth section, throughout the thalamus. The number of fluorescent thalamic cells varied with the number of SII injection sites, spread from the injection site, and the tracer used. However, certain findings were common to all experiments. Labeled thalamic neurons were noted in the ventroposterior lateral nucleus (VPL), the ventroposterior inferior nucleus (VPI), the anterior pulvinar (Pa) and the posterior nucleus (Po). Labeled neurons in the ventroposterior medial nucleus (VPM) were attributed to contamination of the SI face region. Close proximity of a small number of thalamocortical neurons to STT terminals was noted in VPL, VPI and Po, but not in Pa. Overlap of the labeled cells and terminals is being quantified. Coincidence of these thalamic neurons and terminals suggests the possibility for synaptic contact and these findings indicate a sparse, though potentially significant anatomical relay pathway for pain signals from the thalamus to SII.

FUNCTIONAL NEURAL SUBSTRATES INVOLVED IN PROCESSING TONIC NOCICEPTIVE STIMULATION .J. Helmstetter & F.Gonzalez-Lima Dept. Medical Anatomy, Texas A&M Univ., College Station, TX 77843 [14C]2-Deoxyglucose (2DG) autoradiography

was used to map metabolic changes in brain and spinal cord resulting from a subcutaneous injection of dilute formalin. Unrestrained rats were injected with 15% formalin into the dorsal surface of the right hindpaw and left undisturbed for 45 min after 2DG administration. Autoradiographs were examined for regional changes in isotope uptake. A bilateral decrease in labeling was observed in a number of structures including the sulcal frontal cortex and intralaminar thalamus while a bilateral increase was observed in the paramedian raphe. Structures showing a unilateral increase included the ventrobasal thalamus contralateral to the treated hindlimb. This study represents the first functional mapping of CNS activity in a rodent model of chronic pain. (supported by NIMH grant R01-MH43353)

SUBSTRATES FOR INTERACTION OF VISUAL CHANNELS WITHIN AREA V1 OF MONKEY VISUAL CORTEX. V1 OF MONKEY VISUAL CORTEX. $\underline{\text{T. Yoshioka and J.S. Lund.}}$ Department of Psychiatry and $\underline{\text{Center for Neuroscience.}}$

University of Pittsburgh, Pittsburgh, PA 15261.

Two distinct channels of visual input from the lateral geniculate nucleus (dLGN) terminate in the middle layer 4C geniculate nucleus (dLGN) terminate in the middle layer 4c of monkey VI cortex. Magnocellular dLGN neurons project to layer 4C alpha and parvocellular dLGN neurons project to layer 4C beta. In turn, the spiny stellate neurons of 4C project to more superficial layers, 4C beta projecting to layers 4A and 3B and 4C alpha projecting to layer 4B. These recipient zones are known to differ in physiological response properties and efferent neuron projection patterns. We have found from study of Golgi impregnations that the layers 4B, 4A, and 3B are richly interconnected by the axons and dendritic processes of spine free or sparsely spined local circuit neurons which are usually GABAergic. This suggests that although visual cortex excitatory intrinsic relays may tend to preserve the separate identities of the channels of visual information presented by geniculate relays, there is a substrate for considerable functional interaction between them. Interestingly while we have previously found excitatory links to pass between these layers in a virtually one-way direction, from layer 4B to the superficial layers, local circuit neuron projections pass in both directions. NEUROTRANSMITTER REGULATION IN OCULAR DOMINANCE COLUMNS OF NEW WORLD MONKEYS. R.K. Carder, S.H.C. Hendry, E.G. Jones. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717 In Old World monkeys loss of neural activity in one retina leads to

chemical changes in neurons of area 17. To determine whether chemical plasticity is a feature of area 17 in other primates, we examined a species of New World monkey (Cebus capuchinus) in which ocular dominance columns have been demonstrated. In normal Cebus monkeys, staining in neuronal somata and terminals for GABA and and its synthesizing enzyme, glutamic acid decarboxylase (GAD) was uniform and intense in layer IVC. Following monocular deprivation by tetrodotoxin injections, stripes of normal staining were found to alternate with stripes of light immunostaining in layer IVC. Comparison with adjacent sections stained for GABA or GAD and cytochrome oxidase, indicated that the stained for GAD and cytochronic oxtuase, indicated that the reduced immunocytochemical staining occurred within deprived-eye columns. In these same monkeys, 5HT immunoreactivity and acetycholinesterase histochemical staining exhibited highly irregular yet complementary lattice patterns. This contrasts with normal monkeys in complementary lattice patterns. This contrasts with normal monkeys in which 5HT immunostaining and acetylcholinesterase histochemical staining were relatively uniform within the various cortical laminae. These findings demonstrate that visual cortical neurons in both Old and New World monkeys display activity dependent changes in neurotransmitter and enzyme immunoreactivity and suggest that this mechanism of plasticity may be a feature of the primate visual cortex. In addition, in New World monkeys chemical plasticity may extend to "non-credition" control afferences. 'non-specific" cortical afferents. Supported by EY06432 and EY07193

IMMUNOCYTOCHEMISTRY OF GABAERGIC NEURONS IN VISUAL CORTEX OF DOLPHINS. I. I. Glezer, C. Leranth, P.J. Morgane, K. Baimbridge and J. Solomon*. Dep. Cell Biol. Anat. Sci. of CUNY Med. Sch., New York, NY 10031, Yale Univ. School of Medicine, New Haven, CT 06510, Worcester Foundation for Exp. Biology, Shrewsbury, MA 01545, Univ. of British Columbia, Vancouver, Canada, Dep. of Biology of the City College, New York, NY 10031

An immunocytochemical technique was used for light and electron microscopic analyses of GABA localization in different layers of visual neocortex of several species of toothed whales. GAD-positive synaptic boutons both of the axosomatic and axodendritic synapses were found in all cortical layers. The highest density of the boutons per mm3 was found in layer III and the lowest density was found in layer I. The special class of GABAergic neurons, immunopositive to Calbindin-28 (CB) were found in layers I and II of the dolphin visual cortex. Almost all CBpositive neurons are of bipolar or fusiform type. In layer I they form columns of perikarya perpendicularly oriented toward pial surface. The morphology of the perikarya and dendrites of these neurons as well as localization are similar to those found by us for CCK-positive neurons and different from mostly multipolar, CBpositive neurons in primates. (Supported by NSF grants 87-42032, and NIH grants HD-06364, NS26068, P50MH44866).

SUBLAMINAR ORGANIZATION WITHIN LAYER VI OF THE STRIATE CORTEX IN GALAGO. M. Conley and D. Raczkowski. Depts. Psychol. & Neurobiol., Duke University, Durham, NC 27706 We studied projections from the striate cortex to the dorsal lateral geniculate (GL) and pulvinar (PUL) nuclei in the prosimian <u>Galago</u> using retrograde transport methods. Injections of WGA-HRP into the PUL labeled two bands of cells in the striate cortex: one in the upper half of layer V and another located in the deepest part of layer VI. The labeled cells in layer VI coincided with a layer VI. The labeled cells in layer VI coincided with a distinct sublayer, VIb, which contains fewer and paler staining cells than VIa. Injections of WCA-HRP that were restricted to one or a few GL layers revealed a further refinement of the subdivisions within layer VI. Injections into the parvicellular and intercalated layers labeled neurons mainly in the upper half of layer VIa, whereas injections restricted to the magnocellular layers labeled neurons in the lower half of layer VIa and in layer VIb. To determine whether single neurons in layer VIb send axon collaterals to both the GL and PUL, we injected WGA-HRP into one nucleus and rhodamine beads into the other. In three experiments, we found only one double-labeled cell. In sum, these results show a <u>tri</u>laminar division of layer VI that is sufficiently discrete to propose the existence of multiple, descending pathways from Layer VI of the striate cortex that complement those ascending from the GL and PUL. Aided by MH04849, BNS8519709 & EY06821.

ULTRASTRUCTURAL ASTROCYTIC LOCALIZATION OF INTRACELLULAR DOMAINS OF β-ADRENERGIC RECEPTOR IN VISUAL CORTEX: COMPARISON TO AREA POSTREMA EXPOSED TO CIRCULATING AND ENDOGENOUS CATECHOLAMINES by Chiye Aoki', Catherine D. Strader* and Virginia M. Pickel', Cornell Med Coll, NYC 10021 & "Merck Sharp & Dohme Res Labs, Rahway, NJ 07065. Astrocytes may influence visual cortical (VC) plasticity (Muller & Best, Nature 342:427) and also mediate central action of catecholamines (CA) (Stone et al., Brain Res Rev 14:297). The CA stimulus in VC is exclusively derived from afferents whereas, in area postrema (AP), a circumventricular organ, the astrocytes are exposed to both neuronal and circulating CA. We comparatively examined the VC and AP to determine whether the localization of β-adrenergic receptor (βAR) in neurons or astrocytes might reflect these differences of CA in rat and cat brain. We used immunoperoxidase methods and antibodies directed against synthetic peptides corresponding to either the intracellular third loop (3i) or the C-terminus (C') of βAR-protein. In supragranular laminae of visual cortex, C'-immunoreactivity (ir) was most frequently seen along cytoplasmic surfaces of plasmalemma of selective populations of astrocytic processes. These were associated with dendrites, terminals and basement membranes of blood vessels. In contrast, 3i-ir was evident within axons, dendrites and Golgi apparatus of neurons but rare in astrocytes. In AP, the astrocytes showed more extensive vesicular C'-ir. Neuronal 3i-ir was similar to VC. We have established a cellular basis by which neuronally released CA may interact with blood vessels and neurons through astrocytes in VC and AP. (Supported by grants EY08055 and HL18974)

295.6

ARCHITECTONIC DIFFERENCES IN THE DISTRIBUTION OF PARVALBUMIN IN THE RAT NEOCORTEX <u>H-Y. Tseng¹</u>, <u>K.G. Baimbridge² and A.R. Kay¹</u>. ¹Biophys. Dept., AT&T Bell Labs, Murray Hill, NJ. 07974, and ²Dept. Physiology, Univ. British Columbia, Vancouver, BC, Canada V6T 1W5.

The Ca binding protein parvalbumin (PV) appears to be exclusively localized in gabaergic nonpyramidal cells in the neocortex of rat, cat and monkey. We have studied the distribution of PV-IR (immunoreactivity) in rat (Long Evans) neocortex using polyclonal antibodies raised against rat muscle PV. Both cell bodies, processes and terminals exhibit PV-IR. In contrast to monkey, PV-IR is not present in the corpus callosum, nor in any of the regions that provide significant synaptic input to neocortex. Hence most of the PV-IR evident in neocortex probably derives from intrinsic neurons. In all neocortical cortical areas PV-IR cell bodies are excluded from layer I, although some processes do penetrate this layer. Auditory cortex shows a higher density of PV-IR cells and a greater concentration of cells in layer II-III than visual cortex

Cortical slices when viewed under low power exhibit PV-IR bands running parallel to the pial surface, which correspond mostly to PV containing terminals. In most isocortical regions of the neocortex two clear bands are found flanking layer IV. However, in most of visual cortex only the subgranular band is present. The distribution of PV-IR provides a graphic image of differences in cortical inhibition across different functional areas.

SPONTANEOUS EXCITATORY POST SYNAPTIC POTENTIALS SPONTANEOUS EXCITATORY FORT SIMAFTIC FOTENTIALD IN LAYER V CELLS ARE PRODUCED BY ACTYLCHOLINE APPLIED IN LAYERS I-II OF RAT VISUAL CORTEX. G. Vaknin and M. Segal. Center for Neuroscience, Weizmann Institute of Science, Rehovot 76100,

Apical dendrites of pyramidal cells ascend to layer I where they branch and form synaptic contact with a horizontal fiber system contact with a horizontal fiber system containing cholinergic afferents. This study examined the effect of ACh applied in layers I-II on spontaneous and evoked (white matter stimulation) EPSP's of layer V cells using the visual cortical slice preparation. ACh was applied by pressure pulses (20-100ms, 3Kg/cm²) to a broken micro-electrode containing AChchloride (20-40mM). A single microdrop of ACh in layers I-II resulted in EPSP's (2-5mv) lasting for 10-20s with no detectable change in membrane potential. Continuous application of ACh (microdrop applied every 3s for 20s-3min) produced depolarization associated with an increased input resistance. A long-lasting (up to 3min) barage of large EPSP's (5-10mv, 10-15Hz) often producing spikes, was observed. The effect of Ach on evoked EPSP's was mixed; increases, decreases, no change.

295.9

LASER RETINAL LESIONS REVEAL DIFFERENTIAL CYTOCHROME OXIDASE REACTIVITY IN FOUR ISOECCENTRIC REGIONS OF THE MACAQUE STRIATE CORTEX. T.C. Trusk and M.T.T. Wong-Riley Dept. of Anatomy & Cellular Biology, Medical College of Wisconsin, Milwaukee, WI 53226.

Focal blue-green argon laser lesions (3 mm in diameter) were unilaterally placed in the superior parafoveal retinae of 2 Japanese macaques so that lesioned, transitional, and normal visual cortex could be analyzed in the same hemisphere of the same monkey. After 5 and 7 weeks' survival, laser damage at the center of the lesion included the destruction of photoreceptors, outer nemisphere of the Same monkey. After 5 and 7 weeks survival, laser darinage at the center of the lesion included the destruction of photoreceptors, outer nuclear layer, and the outer plexiform layer. While much of the inner nuclear layer was vacuolated, the inner plexiform layer, ganglion cells, and nerve fiber layer remained intact. Optical densities of cytochrome oxidase (C.O.) reaction product within 4 isoeccentric regions of the striate cortex were measured: (A) Within ocular dominance columns (ODC) associated with laser-damaged portions of the treated eye; (B) within ODC representing the homonymous retinal portions of the untreated fellow eye; (C) in the transitional region (no visible ODC) adjacent to the laser-affected area; and (D) in regions 10-20 mm away from the edge of histochemically visible ODC. Within each defined region, reaction product density was sampled in puffs and interpuffs of lamina 3B, and in lamina 4CB. For puffs, C.O. activity was equally high in regions B and D, moderate in C, and lowest in A. Interpuff enzyme activity was highest in regions B and D, significantly lower in C, and still lower in A. These results suggest that: (1) Striate cortex responds metabolically to retinal insults even when ganglion cells remain intact; (2) cortical metabolic plasticity extends beyond the zone representing the core of the retinal lesion into a transitional area; and (3) C.O. activity in the interpuffs of spared-eye ODC increases above the normal when homonymous regions of the fellow retina are destroyed. [Supported by NIH EY07016 to TCT and EY05439 to MWR.] are destroyed. [Supported by NIH EY07016 to TCT and EY05439 to MWR.]

295.11

TOPOGRAPHY OF INTERHEMISPHERIC CONNECTIONS THROUGHOUT STRIATE CORTEX IN THE RAT. I. W. Lewis* and I. F. Olavarria. Division of Biology 216-76, Caltech, Pasadena, CA 91125. In mammals, interhemispheric connections are concentrated at the lateral

border of striate cortex, where the vertical meridian of the visual field is represented. Presumably these connections facilitate fusion of the two halves of the visual field, and may also subserve midline stereopsis. In the rat, callosal connections are also found in infragranular layers throughout striate cortex, including medial regions representing peripheral portions of the field (Olavarria and Van Sluyters, Brain Res., 279:233, 1983). Determining the topographic organization of this widespread interhemispheric pathway may be important for understanding the function of the callosal projections

We investigated the topography of callosal connections by charting the location of retrogradely labeled cells within striate cortex of one hemisphere after combined injections of two or more fluorescent tracers into multiple sites in the contralateral striate cortex. We also labeled the entire callosal pathway with larger injections of an additional tracer in order to relate the location of cells labeled by the small injections to the overall callosal pattern within striate cortex.

We found that injections into medial striate cortex labeled cells predominantly in medial, mirror-symmetric portions of contralateral striate cortex, and rarely in lateral portions of this area. Conversely, injections into lateral striate cortex labeled cells in lateral portions of contralateral striate cortex, with few or no labeled cells in medial portions of this area. Thus, in addition to permitting interactions between midline portions of the visual hemifields, callosal connections of rat striate cortex appear to be capable of mediating interactions between widely disparate inputs from mirror-symmetric peripheral portions of the hemifields.

295.8

EARLY ENTRY OF GENICULOCORTICAL AXONS INTO THE CORTICAL PLATE DURING THE FORMATION OF LAYER IV IN VISUAL CORTEX OF NEONATAL RAT AND HAMSTER. Glenn H. Kageyama & Richard T. Robertson. Dept. Anatomy & Neurobiology, Univ. of California, Irvine, CA 92717.

The developing visual system in mammals is amongst the most intensely studied in neurobiological research, however, the precise temporal development of the studied in neurobiological research, however, the precise temporal development of the geniculocortical (GC) projection into the cell dense cortical plate (CP) of visual cortex has not been adequately described in detail. Using eye injections of WGA-HRP, combined with transneuronal transport and TMB histochemistry, we labeled geniculocortical terminal fields as early as postnatal day 0 (PO) in rat pups and P1 in hamsters. Intraocular injections of 0.5 µl 2% WGA-HRP (10 µg) were made close to the retina with a micropipette and animals allowed to survive for 0.6-3d. Tissue sections were treated with TMB for light microscopy (Mesulam'78) or EM (Naus et al., '85). Adjacent sections were used for cytochrome oxidase (CO) or Nissl staining. The light microscopy results are summarized below:

Event	Hamster	Rat	
WGA-HRP labeled GC projection to:			
Subplate (layer SPu or VIb)	P1	(Before P0)	
Cortical layers V-VI	P3	` P0	
Developing layer IV (top of CP)	P4	P1	
First distinct layer IV (Nissl)	P6	P2	
Initial elevation of CO in Laver IV	P7	P3	

At the EM level, transneuronal WGA-HRP was localized within presumed GC terminals. The results demonstrate that GC terminals enter the CP much earlier than terminals. The results demonstrate that Oct. Erminals enter the CF much earner than previously thought and appear to penetrate the cell dense CP prior to the appearance of a distinct granular layer IV. It is possible that GC axons may play a role in the histogenesis of layer IV. The elevation of CO in layer IV 2 days after the arrival of GC axons and one day after the histogenesis of layer IV suggests that elevated oxidative metabolic activity closely follows the development of GC input. Supported by NSF 87-08515 and NIH NS 25674.

TOPOGRAPHY OF CORTICAL EFFERENTS OF V1 IN <u>CEBUS</u> <u>apella</u> MONKEY. M.C.G.P. Piñon*, A.P.B. Sousa and R. Gattass.

Depto. Neurobiologia, Inst. de Biofisica Carlos Chagas Filho, UFRJ, Rio de Janeiro, RJ. Brazil. Cortical projection fields of area V1 in the <u>Gebus</u> monkey were examined by the use of radioautographic tracing technique. In five monkeys the topographic organization of the fields was determined by injecting tritiated proline-leucine into selected V1 sites. The receptive fields corresponding to these sites were electrophysiologically identified and their eccentricities ranged from 2 to 60 degrees in the upper and lower visual quadrants. The results showed that projection sites were found in homotopic regions of V2, MT and V3 following found in homotopic regions of V2, MI and V3 following central, intermediate and peripheral injections in V1. Projections to area V4 were only found following central and intermediate injections while projections to areas P0, MST and prostriata were only observed following peripheral injections. In addition to these projecting sites we also observed projections to TVP and FST in one animal that received multiple injections at different eccentricities. In the intraparietal region we only observed projections following intermediate injections in the lower quadrant of the visual field. (Financial support: FINEP, CNPq and CEPG/UFRJ).

295.12

INTRINSIC SYNAPSES OF CALLOSAL PROJECTION NEURONS IN MOUSE VISUAL CORTEX. <u>D. CZEIGER</u> AND <u>E.L. WHITE</u>, DEPT OF MORPHLOGY, BEN-GURION UNIV. BEER SHEVA, ISRAEL.

Neurons at the borders of area 17 with areas 18a and 18b in mouse visual cortex were labeled by the retrograde transport of horseradish peroxidase (HRP) transported from severed callosal axons in the contralateral hemisphere. "Intrinsic" terminals of the local axon collaterals of these neurons were identified in areas 17/18a and 17/18b, and their distribution and synaptic connectivity were examined. A postlesion survival time of 3 days was chosen because by this time extrinsic callosal axon terminals were all degenerating, whereas the intrinsic terminals were labeled by HRP.

Intrinsic callosal axon terminals formed only asymmetrical

Intrinsic callosal axon terminals formed only asymmetrical synapses. Analyses of serial thin sections through layers II and III in areas 17/18a and 17/18b show 96% of the intrinsic terminals synapse onto dendritic spines, likely those of pyramidal neurons. The remainder synapse onto dendritic shafts of both spiny and nonspiny neurons. The high shafts of both spiny and nonspiny neurons. The high proportion of axospinous synapses formed by intrinsic callosal axon terminals differs from the proportion of asymmetrical, axospinous synapses that occur in the surrounding neuropil; a result essentially identical to that obtained for the synaptic connectivity of intrinsic callosal axon terminals in mouse somatosensory cortex. Taken together, these results indicate that axonal pathways are highly selective for the types of elements with which they synapse. NIH 20149 and BSF 86000-

THE RETINAL ORIGIN OF THE IPSILATERAL FIELD REPRESENTATION IN THE AREA 17/18 TRANSITION ZONE IN THE CAT. J.D. Mendola, S.G. Lomber & B.R. Pavne, Department of Anatomy. Boston University School of Medicine, Boston, MA 02118.

Anatomy, Boston University School of Medicine, Boston, MA 02118.

In the cat, the transition zone between areas 17 & 18 contains a representation of the ipsilateral visual field adjacent to the vertical This representation is not equal for all elevations in the visual field, for it is smallest closest to the visual axis and it enlarges with increasing and decreasing elevations in the visual field. The purpose of this study was to relate this representation to the patterns of projections of ganglion cells in the retina. This was achieved by mapping the representation of the visual field in the cortical transition zone using standard electrophysiological recording methods and then injecting horseradish peroxidase into the ipsilateral lateral geniculate nucleus to identify ganglion cells in the contralateral temporal retina with crossed projections to the lateral geniculate nucleus. As has been shown previously for the lower visual field, the representation in the expands to an azimuth of -20° at -30° elevation. Analyses of labelled cells in the retina showed that they lay increasingly temporal in location as the vertical distance from the area centralis increased. Conversion of these locations to visual field coordinates show that the region viewed by α cells matches the representation of the ipsilateral field demonstrated in the cortex very closely for all elevations. This correspondence between the retina and the cortex suggests that the crossed projections from temporal ganglion cells may be responsible, at least in part, for the ipsilateral field representation in the cortex. THE REPRESENTATIONS OF THE VISUAL FIELD IN THE TRANSCALLOSAL SENDING AND RECEIVING ZONES IN CAT AREA 17. B. R. Payne. Department of Anatomy, Boston University School of Medicine, Boston, MA 02118.

The purpose of the present study was to identify the callosal sending and receiving zones in area 17 and the adjacent area 17/18 transition region by application of anterograde and retrograde pathway tracers, and to assess, by recording the activities of neurons and plotting their receptive fields, the extent of the visual field represented in each zone. The assessments of the representations were made for all elevations in the visual field and are based on receptive fields plotted for neurons recorded at over 1900 sites. The results show that extent of the representation in the callosal sending zone is not equal at all elevations in the visual field. In regions close to the visual axis, receptive fields could be plotted from the vertical meridian to an azimuth of only +4° in the contralateral hemifield. In contrast, at representations of increasingly positive and negative elevations in the visual field receptive fields could be plotted at increasingly greater distances from the vertical meridian up to +15° to +20° into the contralateral field. This representation in the callosal sending zone overlaps the representation in the callosal fiber recipient zone of the opposite hemisphere which extends into that hemisphere's ipsilateral field out to -3° azimuth close to the visual axis and out to -15° or so toward the extremes of the upper and lower fields. The congruence of these representations indicate a considerable potential for interaction between the two hemispheres and that, for positions high and low in the visual field, the interactions can be evoked by stimuli displaced away from the vertical meridian. NEURONAL DYSFUNCTION AND ASSOCIATED IMMUNOHISTO-CHEMICAL CHANGES AT THE BORDER OF FOCAL LESIONS IN THE CAT VISUAL CORTEX.

U.T. Eysel and R. Schmidt-Kastner.* Department of Neurophysiology, Faculty of Medicine, Ruhr-Universität Bochum, D-4630 Bochum, F.R.G.

We used small heat lesions (1 mm in diameter) produced by photocoagulation of the visual cortex to study the local effects of focal brain damage. The lesions were visualized by high resolution thermography. After survival times of 1, 2, 7 and 30 days recordings were made under halothane/N₂O/O₂ anesthesia at distances between 0.5 and 2.5 mm from the center of the lesion. Single cell activity in the borderzone was characterized by depressed activity close to the lesion and hyperactivity with bursts or continuous high frequency discharges up to 700 Hz at distances between 1 and 1.5 mm. In this region orientation tuning was weak and order in orientation columns appeared disturbed. The histology of the lesions showed coagulation necrosis surrounded by tissue with some dark stained neurons as well as neurons with cytoplasmic vacuolation. Immunostaining for parvalbumin was reduced in the borderzone. A zone of serum-protein staining indicated massive vasogenic edema in the adjacent cortex and the white matter below. This vasogenic edema and the disturbance of inhibitory interneurons might be important pathophysiological factors leading to the observed neuronal dysfunction in the surrounding of focal cortical lesions. Supported by the DFG grant Ey 8/13-1.

THE ROLE OF THE MEDIAL INTERLAMINAR NUCLEUS IN THE REPRESENTATION OF THE IPSILATERAL VISUAL FIELD IN THE AREA 17/18 TRANSITION ZONE OF THE CAT. S.G. Lomber, B.R. Payne & D.F. Siwek. Department of Anatomy, Boston University School of Medicine, Boston, MA 02118.

In the cat, the transition zone between areas 17 & 18 in the cerebral cortex and layer 3 of the medial interlaminar nucleus (MIN) both contain a significant representation of the ipsilateral visual field adjacent to the vertical meridian. The purpose of the present experiment was to determine if the representation in MIN contributes to the representation present in the cortex. This was achieved by recording the activity and plotting the receptive fields of neurons in MIN and the immediately adjacent laminated part of the lateral geniculate nucleus. Layer 3 of MIN was identified by the presence of neurons with receptive fields well into the ipsilateral field. The neurons representing an azimuth of ~-12° in the ipsilateral field and adjacent cells were then destroyed by electrolytic ablation. The representation of the visual field in the area 17/18 transition zone was then assessed immediately afterwards. Unlike the representation of the ipsilateral field in the intact cat, which extends to -3° azimuth at the horizontal meridian and to -20° azimuth at an elevation of -30°, the representation in the ablated cat was virtually eliminated, for it extended only to an azimuth of ~-3° in the ipsilateral field. In addition, no neurons were detected in cortex that responded to the region of the visual field known to be at the center of the ablation in MIN. These results show that MIN mediates, at least in part, the representation of the ipsilateral field in the area 17/18 transition zone. (Supported by EY06404)

295.16

THE VISUAL FIELD MAP IN THE CORPUS CALLOSUM OF THE CAT. D.F. Siwek and B.R. Pavne. Department of Anatomy, Boston University School of Medicine, Boston, MA 02118.

University School of Medicine, Boston, MA 02118.

In the cat, the corpus callosum conveys all the fibers connecting areas 17 & 18 in the two cerebral hemispheres; areas that both contain well-ordered maps of the visual field. The purpose of the present study was to ascertain the organization of the visual map in the corpus callosum. This was achieved by injecting anterograde and retrograde pathway tracers into the callosal zones of areas 17 & 18. The positions of the injection sites were varied systematically to include all visual field elevations represented along the marginal and posterolateral gyri. Overall, the results show that callosal fibers arising: (1) from the marginal gyrus, where the lower visual fields are represented, pass through the body of the corpus callosum; (2) from the junction of the marginal and posterolateral gyri, where central fields are represented, pass through the dorsal splenium of the corpus callosum; and (3) from the ventral posterolateral gyrus, where upper fields are represented, pass through the ventral splenium. Within this pattern a finer arrangement exists, making it possible to generate a map of visual field elevations in the corpus callosum. In this map, the representations of the different elevations is not regular. In the body the map appears to reflect cortical magnification of the lower fields, whereas the map of the central and upper fields in the splenium is highly compressed. This compression is reflected in the higher packing density of visual fibers in the splenium compared to the body, where visual fibers are intermixed with axons arising from other sources such as auditory cortex. THE CORTICAL CONTRIBUTION TO THE VISUAL FIELD REPRESENTATION IN THE PRETECTUM OF MONKEYS. K.-P. Hoffmann, C. Distler, U. Ilg, B. Preilowsky*, Allgemeine Zoologie und Neurobiologie, Ruhr-Universitaet Bochum, Postfach 102148, 4630 Bochum 1, FRG *Universitaet Tuebingen, FRG

Receptive fields of neurons in the nucleus of the optic tract (NOT) in the pretectum of macaque monkeys include the fovea and extend up to 20° into the ipsilateral visual hemifield. In primates there is no direct retinal projection from the temporal retina to the contralateral midbrain as in most other vertebrates. The subcortical representation of the ipsilateral visual field can therefore only originate via projections across subcortical or cortical commissures.

Brain areas with extensive ipsilateral visual field representation can be found in the superior temporal nucleus of neocortex (STS). To test the hypothesis that cortical pathways are essential to create an ipsilateral visual field representation which is then projected to the pretectum we investigated two macaca mulattas with total transsection of the corpus callosum. In the pretectum of these animals all receptive fields stopped precisely at the vertical 0-meridian. Thus, the NOT-neurons were no longer able to respond to moving stimuli in the ipsilateral visual field. Other response properties remained unchanged.

In another set of experiments we electrically stimulated the NOT in normal

In another set of experiments we electrically stimulated the NOT in normal monkeys via a microelectrode while recording with a second microelectrode from STS to antidromically identify those neurons providing the visual information from the ipsilateral hemifield. Such neurons with response properties very much like NOT neurons (receptive fields including the fovea and covering the central 20°-40°, direction specific responses to a moving bar or random dot patterns) were found in the floor of STS. The consequences of these findings will be discussed in the context of optokinetic reflex.

CORTICAL INFLUENCES ON VISUAL PREDATOR AVOIDANCE IN THE MONGOLIAN GERBIL. C.G. Ellard and D.G. Chapman*. Dept. of Psychology, Mount Allison University, Sackville, New Brunswick. Previous work has demonstrated heavy involvement of subcortical visual pathways in the fleeing response of the gerbil to a sudden, overhead visual threat (Ellard and Goodale, Exp. Brain Res., 71:307, 1988). In this study, we examined the effects of lesions to some posterior cortical areas on the predator avoidance response. Gerbils received either sham operations, aspiration lesions of area 18b or of posterior cingulate cortex (areas 29c and 29d). Following recovery, animals were placed in an open field containing a refuge and videotaped during presentation of unpredictable overhead visual stimuli of varying sizes.

Shams and animals with 18b lesions responded consistently to overhead

movement by running to the refuge, even when the stimulus was only slightly larger than the resolution acuity threshold for gerbils. Cingulates showed severely depressed responses to overhead threat. Comparison of behaviour both before and after threat presentation showed a post-stimulus increase in risk assessment in shams and cingulates, but a tendency for animals with 18b lesions to spend

snams and cingulates, but a tendency for animals with 18b lesions to spend abnormally long periods of time in the refuge following the threat.

These results suggest that there are cortical modulatory influences on the tectal mechanisms for predator avoidance. In light of connectional and physiological properties of these areas, as well as the present behavioural evidence, it is suggested that these areas modulate an animal's responsiveness to threat on the basis of environmental contextual variables, rather than the properties of the threat stimulus.

CELL CLUSTER VARIATIONS WITHIN ISOAZIMUTH LAMELLAE OF

TURTLE VISUAL CORTEX. P. S. Ulinski. Dept. Organismal Biology and Anatomy, Univ. Chicago, Chicago. IL 60637. Cerebral cortex of turtles receives a projection from the dorsal lateral geniculate complex in which individual geniculate axons course from lateral to medial across the Visual area, bearing varicosities en passant (Mulligan and Ulinski, J. Comp. Neurol., 295: in press, 1990). Visual corte: Visual cortex, consequently, contains lamellae representing the azimuth lines of visual space. Casual observation suggests there are regional variations in neuron properties within these isoazimuth lamellae.

isoazimuth lamellae.

This possibility was explored using computer-assisted, 3-D analysis methods to reconstruct regions of visual cortex from transverse and horizontal sections of cortex. The study confirms that the lateral, or "pallial thickening", region of cortical area D2 of Desan contains clusters of many neurons with apposed somata. It also shows for the first time that the modified processing the production of D2 consists of clusters of the first time that the medial region of D2 consists of clusters containing smaller numbers of neurons embedded within a continuous sheet of neurons in layer 2 of this trilaminate cortex. Thus, individua geniculate axons synapse first upon neurons in the lateral, large cluster region, and then upon neurons in the medial, small cluster region of the visual area. Correlation with data on the dendritic morphology of cortical neurons and of Thus, individual geniculate axons in these two regions suggests an individual geniculate axon has different functional interactions within one isoazimuth lamella. SENSORY SYSTEMS-SUBCORTICAL VISUAL PATHWAYS: RETINAL PROJECTIONS AND THALAMUS

α-HERPESVIRUSES ARE DIFFERENTIALLY TRANSPORTED THROUGH THE RODENT VISUAL SYSTEM AND ASSOCIATED CIRCUITRY. J.P. Card. M.E. Whealy*, A.K. Robbins*, R.Y. Moore 1 and L.W. Enquist*. Central Res. & Dev. Dept., The Du Pont Co., Wilmington, DE 19880 and ¹Dept. of Neurology, SUNY @ Stony Brook, Stony Brook, NY 11794.

Precise, circuit-specific transport of neurotropic herpesviruses has

recently been shown to result from trans-synaptic passage of virus through synaptically linked populations of neurons. We have examined the transport of two strains of pseudorables virus through visual circuits of the rat CNS following injection of virus into the vitreous body of the eye. The viral strains included a virulent field isolate (Becker, PRV-Be) and an attenuated vaccine strain (Bartha, PRV-Ba) harboring mutations which reduce virulence. Both strains of virus were taken up by retinal ganglion cells and transported to retinal recipient regions of the forebrain. However, distinct differences were noted in the rate of transport and the distribution of infected neurons. Transneuronal passage of PRV-Be was detected within 50 hours of injection and occurred predominantly in the dorsal lateral geniculate nucleus (dLGN). By contrast, PRV-Ba could not be detected prior to 72 hours post-injection and, rather than being localized in the dLGN, was concentrated in neurons of the intergeniculate leaflet. PRV-Ba also led to pronounced labeling of neurons in all regions of hypothalamus shown to receive retinal innervation and, with increasing survival, appeared to pass through the efferent projections of these cell groups to infect their target neurons. The two distinct patterns of infectivity observed following intraocular injection of PRV-Be and PRV-Ba suggest that differences in uptake and/or transport of virus may be related to the mutations know to exist in PRV-Ba.

RESPONSE OF ADULT CAT RETINAL GANGLION CELLS TO LOSS OF POSTSYNAPTIC TARGET NEURONS IN THE DORSAL LOSS OF POSISYNAPIRE TARGET NEURONS IN THE DORSAL LATERAL GENICULATE NUCLEUS. H.E. Pearson and D.J. Stoffler. Department of Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA 19140.

To investigate the effects of target cell removal on the survival and

maintenance of mature retinal ganglion cells, kainic acid (3 nmol/ul) was injected bilaterally at multiple sites within the dLGN of adult cats. Following post-operative survivals of 2,4 and 6 months, the cats received multiple injections of HRP into the dLGN. After a further 72 hr, the cats were sacrificed and the retinae were reacted for the presence of HRP and counterstained with cresyl violet. Adjacent brain sections were processed for thionin staining and HRP histochemistry. Thionin staining showed large regions of dLGN to be degenerated, as characterized by the absence of neurons and increased numbers of glia. At each survival, counts of retinal ganglion cells were made at comparable locations in peripheral nasal retina, at a site corresponding retinotopically to regions of degeneration within the dLGN. Cell densities were determined separately for cells labelled retrogradely with HRP and for unlabelled cells stained for Nissl. There was a gradual decline in overall ganglion cell density with increased survival after target neuron loss. Approximately 20% of cells survived at 6 months. The proportion of cells labelled with HRP declined more sharply, with less than 10% labelled at 6 months. These results demonstrate that postsynaptic targets are essential for the survival of mature retinal ganglion cells. In the absence of normal targets, ganglion cells will first retract their axon terminals and then subsequently degenerate. Supported by NS25196.

FURTHER DEMONSTRATION OF IPSILATERAL PREPONDERANCE OF RETINAL PROJECTIONS IN THE PRIMATE VISUAL SYSTEM. G. Mick*, M. Magnin and H. Cooper*. Vision et Motricité, I.N.S.E.R.M. 94, 16 avenue Doyen Lépine, 69500 Bron, FRANCE

We recently reported an unusual ipsilateral preponderance of the retinal input to the suprachiasmatic nucleus (SCN) in several primate species (Magnin, M., Brain Res., 488:390, 1989). The aim of the present study is to determine whether a similar ipsilateral preponderance is also characteristic of other primary visual structures. Following monocular intravitreal injections of tritiated amino acids in 12 different mammalian species the relative density of terminal label of retinal projections was measured using quantitative image analysis. In Old World monkeys (Macaca fascicularis, Hylobates concolor), a predominance of the ipsilateral retinal projection is present in the olivary pretectal nucleus (OPN). In other primates (Callithrix jacchus, Galago demidovii) and non primates (Felis domesticus, Mustela putorius, Philander opossum, Heliosciurus rufobrachium, Rousettus aegyptiacus, Erinaceus europaeus, Manis tricuspis, Bradypus pilosa) the OPN shows a mainly contralateral retinal input. Preliminary results also indicate that one subdivision of the pregeniculate nucleus (PGN) receives a predominantly ipsilateral input in macaque and gibbon, although the homologue of the intergeniculate leaflet in primates remains to be defined.

The predominant ipsilateral retinal input, the anatomical connections and the presence of luminance responsive cells in all three structures suggest that not only the SCN and the PGN but also the OPN is involved in the photic regulation of circadian rhythms.

THE STRUCTURE OF RETINAL AND COLLICULAR AXONS THAT TERMINATE ON PRIMATE W-LIKE LGN CELLS. <u>E.A. Lachica² and V.A. Casagrande¹².</u> Depts. Psy. 1 and Cell Biol.², Vanderbilt Univ., Nashville, Tennessee 37232

The connections of the smallest relay cells of the lateral geniculate nucleus (LGN) of primates differ from large and medium relay cells in two nucleus (LGN) of primates differ from large and medium relay cells in two ways. Only the smallest relay cells receive projections from both the superior colliculus and the retina, and only the smallest cells project directly to the cytochrome oxidase (CO) blobs. In this study we examined and compared the morphology of retinal and collicular axons that terminate on small cells in the LGN of Galago, by injecting HRP into the optic tract, and biocytin into the superficial gray layer of the colliculus. The small LGN cells in Galago have W-like physiology and are found in the konlocellular (K) layers and the interlaminar zones (ILZs). Results show that distinct population of retinal and cells light across braces the K layers and ILCs extensively. interiaminar zones (ILZs). Results show that distinct population of retinal and collicular axons innervate the K layers and ILZs, and may be distinguished from one another in the following way. Both retinal and collicular axons arborize in a single K layer. However, the arbors of retinal axons are larger in area, and have a greater number and density of boutons than collicular arbors. In the ILZs, retinal and collicular axons terminate in multiple patches. However, collicular ILZ arbors are larger in area and have a greater number and density of boutons than retinal ILZ arbors. The following conclusions can be made based upon these differences in arbor morphology. First, the K layers and ILZs arbors are larger in distinct population of retinal W-like cells. Second, the K layers and ILZs may also receive input from distinct populations of collicular cells. Finally, W-like cells in the K layers may be dominated by visual input from the retina, while W-like cells in the ILZs could receive their main visual input from the colliculus. The latter conclusion suggests that the CO blobs may be receiving different kinds of input from W-like LGN cells. Supported by EYO1778 to VAC and MHO9754 to EAL.

MORPHOLOGY OF PHYSIOLOGICALLY IDENTIFIED RETINAL AXONS IN THE CAT'S THALAMUS AND MIDBRAIN AS REVEALED BY INTRA-AXONAL INJECTION OF BIOCYTIN. N. Tamamaki^{1,2}, D.J. Uhlrich¹, and S.M. Sherman. ¹ Dept. of Neurobiology¹ and Howard Hughes Medical Institute², SUNY, Stony Brook, NY 11794-5230.

The retina provides a direct projection to visual centers in the thalamus and midbrain, but the nature of this divergent innervation is little understood, particularly at the single-axon level. We thus studied this projection via intra-axonal labeling with biocytin in anesthetized and paralyzed cats. Single retinal axons were recorded from the optic tract ventral to the lateral geniculate nucleus (LGN), physiologically characterized, impaled, and pressure-injected with 5-6% biocytin dissolved in 0.5M KCl. After a two day survival period, we perfused the cats transcardially with an aldehyde fixative and processed the tissue with an ABC reaction procedure. Thus far, we have recovered and reconstructed 12 retinal Y axons, 5 projecting ipsilaterally and 7 contralaterally. Each of these innervates the LGN, the pretectum, and the superior colliculus (SC). For each axon, there is good retinotopic correspondence between the location of the terminal field in the LGN and that in the SC. The retinotopic projection to the pretectum is less evident. In the SC, the Y axons innervate the ventral portion of the retinal-recipient zone. Each axon from the ipsilateral eye tends to form a single, circular puff 250-300μm wide, while each from the contralateral eye tends to extend further mediolaterally and dorsoventrally. These termination patterns from the two eyes are thus consistent with the interdigitated pattern revealed by bulk-fill anterograde labeling studies in which segregated puffs of label from the ipsilateral eye contrast to the more continuous labeling seen contralaterally. Finally, in both the LGN and SC, arbor size and bouton number vary with the eccentricity of the axon's receptive field: axons with greater eccentricities would be positively correlated.

MONOCLONAL ANTIBODIES RECOGNIZE SUBPOPULATIONS OF CELLS IN THE LATERAL GENICULATE NUCLEUS OF THE CAT. N. Tumosa+, J.R. Baker+* and P.D. Spear#, School of Optometry, University of Missouri-St. Louis+, MO 63121 and Department of Psychology, Center for Neuroscience, University of Wisconsin#, Madison, WI 53706.

Several classes of cat retinal ganglion cells can be distinguished on the basis of their morphology. These cell classes form parallel functional outputs from the retina to visual areas of the brain. We previously produced monoclonal antibodies (MAbs) that recognize different subpopulations of retinal ganglion cells (Tumosa et al., 1987). The ent study examined whether these MAbs recognize subpopulations of cells in the cat's LGN. PAP methods were used to visualize antigenantibody reactions for each of 4 IgM MAbs on fifty-micron sections.

One of the four MAbs recognized no cells in the LGN. The remaining three MAbs labeled cells in both the A and C layers. One MAb labeled cell bodies and proximal dendrites of about 40% of the layer A neurons and the labeled cells were 20-120 um² in area. The two remaining MAbs labeled cell bodies only. One labeled about 30% of the layer A neurons, which were 25-180 um² in area. The other MAb labeled about 35% of the layer A neurons, which were 20-140 um² in area. These results suggest that antigens that distinguish subpopulations of retinal ganglion cells also distinguish LGN cells. Future studies will examine the relationship between the classes of retinal and LGN cells labeled by a single MAb. which may have implications for understanding the molecular bases of retino-geniculate connectivity.

296.9

THE CAT MEDIAL INTERLAMINAR NUCLEUS IN DIM-LIGHT VISION. D.

THE CAT MEDIAL INTERLAMINAR NUCLEUS IN DIM-LIGHT VISION. <u>D. Lee* and J. Malpeli</u>. Neuroscience Program and Dept. of Psychology, University of Illinois, Champaign, IL 61820.

The medial interlaminar nucleus (MIN) receives inputs only from the region of retina backed by the reflective tapetum, suggesting a special role in dim-light vision (Lee et al., <u>J. Neurophysiol.</u>, 5:848, 1984). To test this idea, we compared the sensitivity of MIN and lateral geniculate nucleus (LGN) cells over the same range of eccentricities. The contrast sensitivity of single cells was determined as a function of spatial frequency (0 to 2 cyc/deg) and adaptation level. The lowest adaptation level tested was 0.5 log units below the absolute threshold of the most sensitive cells, and adaptation levels were examined in logarithmic steps up to 6.5 log units above this level. On average, MIN cells had higher contrast sensitivity than LGN cells for low spatial frequencies (.125 cyc/deg and below) cells for low spatial frequencies (.125 cyc/deg and below) and a wide range of adaptation levels (within 5 log units of the lowest level).

the lowest level).

Lee et al. proposed that the MIN trades off acuity for sensitivity through high convergence of retinal afferents, whereas the LGN maintains high acuity at the cost of sensitivity. Our data are consistent with the hypothesis that the retinal conflict between sensitivity and acuity is ameliorated in the central nervous system through separate thalamic relays with different degrees of afferent convergence. (Supported by NIH grant EY02695)

RELATIONSHIPS BETWEEN CHOLINERGIC AND GABAERGIC INNERVATION OF THE CAT'S LATERAL GENICULATE AND PERIGENICULATE NUCLEI: AN EM DOUBLE-LABELLING STUDY. C. Beaulieu and M.S. Cynader. University British Columbia, Dept Ophthalmology, 2550 Willow Street, Vancouver, B.C. CANADA.

The relationship between cholinergic axons and gamma-amino butyric acid (GABA) containing cells in the lateral geniculate (LGN) and the perigeniculate nuclei (PGN) was assessed by combining pre-embedding immunocytochemistry of choline acetyltransferase (ChAT) with post-embedding immunogold GABA localisation at the EM level. In the LGN, all 152 ChAT positive vesicle-containing profiles studied to date contacted dendritic profiles within or outside synaptic glomeruli. Only 7.1% of the recipient dendrites tested for the presence of GABA were positive. In the PGN, of the 34 ChAT synapses analyzed, the vast majority targeted dendritic profiles (94%) and only a few were found on somata (6%). In this nucleus, all targets tested were GABA-positive. This is not surprising since all PGN neurons are GABA-positive. We thus suggest that cholinergic synapses show a preference to target LGN relay neurons without a strong innervation of GABA interneurons. In the PGN however, ChAT synapses provide a powerful input to the GABA cells.

296.8

RESPONSES TO STIMULUS OFFSET OF GANGLION AND GENICULATE X AND Y CELLS IN THE CAT. S. Lehmkuhle, J.A. Baro*, H. C. Hughes. School of Optometry, Univ. of Missouri-St. Louis, St. Louis, MO 63121 and Dept of Psychology, Dartmouth College, Hanover, New Hampshire 03755.

Depending upon the direction of the luminance change, on- and offcenter cells respond to stimulus onset or offset. These responses for ganglion and geniculate cells, however, differ in amplitude and latency. The magnitude of this difference depends upon cell site (ganglion vs. geniculate), cell type (X vs.Y), and stimulus duration.

The responses of the receptive-field center to stimulus onset and offset were measured for ganglion and geniculate X and Y cells in the anesthetized, paralyzed cat. The direction of the luminance change of the spot was set to elicit either onset or offset responses for on- and off-center cells. The maintained luminance of the spot was 11.6 cd/m2, and modulated to either 23.2 or 5.8 cd/m². Stimulus duration was varied from 5 to 160 ms in octave steps. Visual latencies and response amplitudes were measured with a criterion based, trial-by -trial analysis

The response rates of geniculate X and Y cells were equivalent for stimulus onset and offset across all stimulus durations, whereas responses were less for stimulus offset than onset for both ganglion X and Y cells. Visual latencies to stimulus offset were longer for all cell groups. The difference in latencies between stimulus onset and offset varied with stimulus duration (≈∆60 ms at a stimulus duration of 10 msec to $\approx\!\!\Delta20$ ms at a stimulus duration of 160 ms). The difference in the visual latencies between X and Y cells is greater for stimulus offset ($\approx \Delta 20$ msec) than for stimulus onset (≈∆5 ms).

BIPOLAR CELL DENSITY IN THE MACAQUE MONKEY RETINA Paul R. Martin* and Ulrike Grünert. Dept.Neuroanatomy, Max-Planck-Institut für Hirnforschung, D-6000 Frankfurt/M., W.Germany.

The macaque retina contains rod and cone bipolar cells. Several types of cone bipolar cells can be distinguished, whereas rod bipolar cells are a homogeneous population which can be labelled with an antibody against protein kinase C (PKC) (Grünert and Martin, Inv. Ophthal. Vis. Sci. 3: (4) p536, 1990).

We have measured the density of rod bipolar cells in the macaque monkey retina, in sections processed for PKC immunoreactivity. We compared this with the density of the total bipolar cell population, which could be distinguished in semithin Nissl stained sections and low-power electron micrographs. Our main findings are:

1) Bipolar cells outnumber ganglion cells in central as well as peripheral retina. In three monkeys where the average peak ganglion cell density (measured in temporal retina) was 50 000 cells/mm², the average bipolar cell density at the same eccentricity was 92 000 cells/mm². Taking post-receptoral displacement into account and integrating cell densities over retinal volume we obtain an average of 1.7 bipolar cells per ganglion cell within the first 900 mm of the fovea.

2) Rod bipolar cells are relatively scarce in the central retina. Their average density within the first 900 μm of the fovea was 6000 cells/mm². Discounting these cells gives a cone bipolar-ganglion cell ratio of 1.6:1.

3) There are at least three cone bipolar cells per cone up to 5mm eccen-

3) There are at least three cone bipolar cells per cone up to 5mm eccentricity. The density of cone bipolar cells is thus high enough to allow for the existence of independent populations which contact single cones up to this eccentricity.

297.3

SYNAPTIC TRANSMISSION FROM PHOTORECEPTORS TO BIFOLAR CELLS (BCs). H.G. Kim and R.F. Miller. Washington Univ. St. Louis, MO, and Dept. Physiol. Univ. of Minnesota, MPIS, MN 55455 Synaptic transmission from photoreceptors to BCs were

Synaptic transmission from photoreceptors to BCs were studied in the mudpuppy retinal slices, using dual, whole-cell recordings from synaptically connected pairs. Compared to on-BCs (r=12), off-BCs (r=24) showed significantly shorter response delay (27.8 vs. 80.6 msec) and peak delay times (50.5 vs. 150.8 msec)

times (50.5 vs. 159.8 msec).

Photoreceptor inputs to off-BCs were blocked by kynurenic acid (Kyn), but, rod inputs to off-BCs were more resistant to Kyn, compared to cone inputs. The rod inputs to off-BCs were indistinguishable from those to horizontal cells (HCs) in terms of Kyn sensitivity. However, the cone inputs to off-BCs were more resistant to Kyn than those to HCs. These data suggest that three pharmacologically distinct excitatory amino acid receptors are involved in the sign-conserving pathway of the outer retina.

The sign-reversing rod and cone inputs to on-BCs were blocked by 2-amino-4-phosphonobutyric acid (APB). The effect of APB was permanent. However, after, and sometimes during APB application, current injections into photoreceptors produced sign-conserving inputs in on-BCs. These sign-conserving inputs persisted after washing away the APB. With one exception, the sign-conserving inputs were never observed before the APB application. Possible mechanisms to account for these observations are considered. (ROIEY03014)

EFFECTS OF GLUTAMATE ANALOGUES ON BIPOLAR AND HORIZONTAL CELLS IN THE TIGER SALAMANDER RETINA. <u>Samuel M. Wu and Xiong-Li Yang</u>. Cullen Eye Institute, Baylor College of Medicine, Houston, Texas 77030.

Overwhelming evidence in recent years has suggested that L-glutamate is the photoreceptor neurotransmitter in the vertebrate retina. It is important to determine what subtypes of glutamate receptors are used to mediate postsynaptic signals in various second-order neurons. In an earlier study, we found that at least four subtypes of glutamate receptors subtypes exist in the tiger salamander horizontal cells (HCs): kainate (KA) receptors, e-amino-3-hydroxy-5-methylisoxazole-4-propionate (AMPA) receptors, 6-cyano-7-nitroquinoxaline (CNQX)-resistant quisquate (QA) receptors, and trans-l-aminocyclopentane-1,3-dicarboxcylic acid (ACPD) receptors (ARVO abstract 2628.1990). In the depolarizing bipolar cells (DBCs), 20 \(\mu \) MCNQX (the satuarating dose for blocking HC light responses) cererts little action on either the resting potential or the light responses. On the other hand, 20 \(\mu \) M. L-2-amino-4-phosphonobutyrate (L-AP4) (exert no effect on HC and HBC) abolishes the depolarizing response of the cell to whole field illumination and converts it into a hyperpolarizing response. This result suggests that L-AP4 receptors probably only exist in the photoreceptor-DBC synapses and that at least part of the HC-DBC input (antagonistic surround response) is mediated by the forward synaptic pathway (direct HC-DBC). In the hyperpolarizing bipolar cells, 20\(\mu \) MCNQX reduces the light responses but rarely abolishes them completely. These results indicate that the HC, DBC and HBC in the tiger salamander retina use different combinations of glutamate receptor subtypes to process their postsynaptic responses, although they all receive inputs from the same glutamatergic synapses.

they all receive inputs from the same glutamatergic synapses.

SYNAPTIC EVENTS UNDERLYING TRANSMISSION FROM PHOTO-RECEPTORS TO OFF-CENTER BIPOLAR CELLS. <u>B.R. Maple and</u> <u>F.S. Werblin</u>, Div. of Neurobiology, Univ. of California, Berkeley,Ca 94720

Bipolar cells were voltage clamped in salamander retina slices and filled with lucifer yellow. Excitatory conductances were activated by pressure ejection of glutamate at the outer plexiform layer and by ejection of hyperosmotic sucrose solutions which elicited transmitter release from photoreceptors. Miniature excitatory synaptic currents were observed and their time course fit by a difference of two exponentials.

Cells with telodendria ramifying in the distal 1/4 of the inner plexiform layer gave responses to glutamate and sucrose ejection that were sustained and resistant to cobalt. These cells displayed miniature synaptic events fit by mean time constants of .98 and 1.7 msec. Off cells ramifying more centrally in the IPL gave responses which rapidly desensitized and were reversibly abolished by cobalt. These cells displayed slower events characterized by time constants of 1.3 and 6.4 msec. Thus glutamatergic transmission to off bipolar cells may be mediated by two different receptors, possibly associated with rod and cone transmission, respectively.

possibly associated with rod and cone transmission, respectively.

The quantal structure of transmission to the distally ramifying cells in cobalt was studied. An analysis of current variance over short segments of bandpass filtered records suggested that quantal events in these cells, ranging up to 660 pS in amplitude, were composed of 60 pS subunits. The overall variance to mean ratio for osmotically induced release corresponded to an event far smaller than this subunit amplitude and was close to the variance to mean ratio for glutamate responses (2 pS). Photoreceptors may release transmitter by two mechanisms: quantal release involving the synchronous discharge of vesicles, and nonquantal release resulting in uncorrelated channel openings.

RESPONSES OF DISSOCIATED ROD BIPOLAR CELLS OF THE RAT RETINA TO 2-AMINO-4-PROSPHONDBUTYRIC ACID (APB).

M. Yamashita* and H. Wässle. Max-Planck-Institut für Hirnforschung, Frankfurt, Germany

Rod bipolar cells were dissociated from adult rat retina and identified by PKC-immunocytochemistry. Recently a wash-out of ON-bipolar responses to glutamate was reported during conventional whole-cell patch clamp recordings (Nawy & Jahr, Neurosci. Lett., 108:279, 1990). This was prevented in the present study by using the nystatin method (Horn & Marty, J. Gen. Physiol., 92:145, 1988). Tonic inward currents (3.7-79.3pA) were observed in 29 of 57 cells held at -33mV. APB decreased the amplitudes of these currents to 58.9±25.3% of the predrug level (n=27). In cells, which showed no APB-sensitive current, this current could be evoked by application of the calcium ionophore A 23187 (1 μM). The mean reversal potential of the APB-sensitive current was -10.824.5mV (n=7) in normal saline solution. Lowering the external [Na] changed the inward currents into outward. We conclude that the refractoriness of rod bipolar cells to glutamate reported previously (Karschin & Wässle, J. Neurophysiol., 1990) was due to a wash-out of internal Ca, and that APB <u>closes</u> a Ca-dependent non selective cation channel. Since <u>APB</u> acts selectively on ON-bipolar cells as a glutamate agonist to decrease membrane conductances (Slaughter & Miller, J. Neurosci. 5:224, 1985), rod bipolars of the rat retina are likely to be ON-bipolar cells.

297.6

EFFECTS OF GABA AND DOPAMINE ON THE ELECTRICAL COUPLING OF ROD-DRIVEN HORIZONTAL CELLS IN SKATE RETINA. H. Oian, *^ R. P. Malchow, *+and H. Ripps. +^ Depts. Ophthalmology*, and Anatomy & Cell Biology^, Univ. of Illinois College of Medicine, Chicago, Il. 60612.

The large receptive fields of fish horizontal cells are due primary to intercellular coupling via gap (electrical) junctions. For cone-driven horizontal cells, the degree of coupling is modifiable by light and by neuroactive substances (e.g. dopamine, GABA). For rod-driven horizontal cells, we have previously reported that background illumination does not significantly alter the receptive fields of skate horizontal cells. In this study, we investigated the effect of GABA and dopamine on the receptive field properties of rod-driven horizontal cells in the skate (R. ocellata and R. erinacea) retina.

Intracellular recordings from horizontal cells were obtained from eyecup preparations; responses to either a 60 um light slit moved across the retina or a circular spot of varying diameter was used to measure the receptive fields. The cells were identified by their positions in the retina, by their response to light, and by dye marking after recording. The receptive fields of skate horizontal cells can be descirbed by a simple exponential equation to a light slit stimulus and by a modified Bessel function to a spot stimulus. When 500 uM GABA or 200 uM dopamine were superfused on the skate eyecup, no significant change of the receptive field characteristics of horizontal cells was observed. Purther, the ratio of responses to spot va annular stimuli did not appear to change during the time course of drug application. These observations again suggest that there may be fundamental differences between the gap junctional properties of rod- and cone-driven horizontal cells. Supported by EY-06516.

PROTEIN CONTENT AND CAMP-DEPENDENT PHOSPHORYLATION OF FRACTIONATED WHITE PERCH RETINA. <u>D.G. McMahon</u>, <u>J.C. Rischert</u> and <u>J.E. Dowling</u>, The Biological Laboratories, Harvard University, Cambridge, MA. 02138.

Dopamine modulates the activity of both gap junctional and glutamate-receptor channels in teleost retinal horizontal cells through cAMP-dependent protein phosphorylation. To identify horizontal cell-specific phosphorroteins we have fractionated the white perch (Roccus

ylation. To identify horizontal cell-specific phosphoproteins we have fractionated the white perch (Roccus
americana) retina on Percoll density gradients and studied
the protein content and phosphorylation of horizontal cell
enriched and non-horizontal cell enriched fractions.
Visual examination of Coomassie blue-stained SDS-PA
gels from 8 fractionations revealed that proteins of ca.
76, 50, 43, and 28 kDa consistently coenriched with
horizontal cells, while proteins of 75, 36 (rhodopsin),
and a doublet at 30 kDa were enriched in non-horizontal
cell fractions. This doublet was also enriched in 4/8 of
horizontal cell fractions, but to a lesser extent than in
the non-horizontal cell preparations suggesting that it is horizontal cell fractions, but to a lesser extent than in the non-horizontal cell preparations suggesting that it is not horizontal cell in origin. The 43 kDa protein and the 30 kDa doublet were phosphorylated upon stimulation of endogenous kinase with cAMP (N=4). The 43 kDa phosphorytein is of interest since our results suggest that it is contained in horizontal cells. While the identity of this protein remains to be determined, it is similar in molecular weight to the gap junction protein connexin43 which is also regulated by cAMP.

ORIENTATION BIAS OF HORIZONTAL CELL RESPONSES IN THE RABBIT RETINA. Stewart A. Bloomfield. Dept. Ophthalmology, NYU Medical Center, New York, N.Y. 10016.

The sensitivity of horizontal cell (HC) responses to the angle of orientation of visual stimuli was examined. Intracellular recordings were obtained from HCs in the isolated, superfused retina-eyecup of

were obtained from HCs in the isolated, superfused retina-eyecup of the rabbit during which a moving, rectangular slit of light was presented at four angles of orientation. Physiologically-characterized cells were injected with HRP for morphological identification.

Responses of B-type HC somas (n=12) and axon terminals (n=5) showed no sensitivity to the orientation of visual stimuli. However, 32% (n=17/53) of A-type HC responses showed an orientation bias. Of these orientation bias HCs, 82% preferred (i.e., displayed the greatest hyperpolarization) slits of light oriented parallel (90°) to the visual strake, whereas the remainder preferred light stimuli oriented. visual streak, whereas the remainder preferred light stimuli oriented orthogonal (0°) to the visual streak. All orientation bias HC responses were recorded within or slightly superior to the visual streak. HRP-labeled orientation bias HCs which preferred stimuli oriented at 90° displayed asymmetrical dendritic arbors with the long axis oriented parallel to the visual streak. Oppositely, orientation bias HCs with preference for the 0° orientation had dendritic fields oriented orthogonal to the visual streak. These cells corresponded to the elongated A-type HCs reported previously by Bloomfield & Miller (1982) and Kolb & Normann (1982). The present results suggest that the orientation bias of rabbit HCs reflects a marked asymmetry in their dendritic arbors. These cells may contribute to the orientation bias of

neuronal responses in the proximal retina (Bloomfield, 1990). Supported by EY07360, BSRG S07 RR05399-28 and RPB Manpower Award.

Light evoked glutamatergic inputs to amacrine cells in the tiger salamander retina. D. B. Dixon and D. R. Copenhagen Dept. of Ophthalmology, UCSF; San Francisco, CA 94143

We investigated the excitatory synaptic inputs into amacrine cells in the salamander retinal slice preparation using standard whole cell patch clamp techniques. Light evoked excitatory currents were measured in control saline, and in salines containing 30 µM AP7, an NMDA antagonist, or 2 µM CNQX, a non-NMDA glutamatergic antagonist, or both AP7 and CNQX. Inhibitory currents were blocked by 100 µM bicuculline and 500 nM strychnine.

The sustained light responses (LR) of the ON-cells were completely blocked by CNQX. AP7 had no discernible effect on the time course or amplitude of these LRs. Current-voltage (I-V) relations of these LRs in control and AP7 salines were nearly linear between -90 mV and +30 mV. Reversal of the response was at +6.3 mV. Thus, the synaptic inputs generating these responses appear mediated exclusively by non-NMDA glutamatergic inputs.

In contrast, the transient LRs of the ON/OFF or OFF cells had concurrent NMDA and non-NMDA synaptic inputs. The I-V curve in control salines had a distinct negative slope region between -75 mV and -50 mV and reversed at +7.2 mV. AP7 produced a shortening of the LRs at potentials positive to -70 mV when compared to control responses and the I-V curve in positive to -70 mV was nearly linear between -90 mV and +30 mV. The LR in CNQX lacked a fast rising phase as compared to the controls and the I-V curves of these LRs had a distinct negatively sloped region between -75 mV and -50 mV, characteristic of NMDA-receptor activation. The combined application of AP7 and CNQX eliminated the entire LRs in these cells.

DOPAMINERGIC CELLS AND DOPAMINE DIFFUSION IN THE XENOPUS RETINA. P. Witkovsky and M. Schütte*. Depts. of Ophthalmology and Physiology & Biophysics, NYU Medical Center, New York, NY 10016.

Catecholaminergic cells and fibers in the Xenopus retina were characterized with an antiserum directed against tyrosine hydroxylase. TOH+ cells were interplexiform-like with an extensive network of processes in the inner retina. Fine distally directed processes emerged from TOH+ perikarya that reached the level of the outer plexiform layer (OPL) but arborized not at all or to a very limited degree within it. A second TOH+ system consisted of a few centrifugal fibers and some smooth, relatively stout processes that reached the OPL within which they coursed horizontally. It remains to be shown whether the latter processes are extensions of centrifugal fibers. These anatomical findings suggested that dopamine reaches target cells in outer retina (horizontal, photoreceptor and pigment epithelial cells) by diffusion. We examined this postulate by studying the release of 3H-dopamine from isolated retinas dissected from eyecups incubated in 1 µM 3H-dopamine. 3H-dopamine was taken up in a time and dose-dependent manner. Specificity of uptake was checked by relase with D-amphetamine, blockage of serotonin uptake mechanisms and by autoradiography. Baseline release of 3H-dopamine was low; by reference to date of Boatright et al. (Brain Res., 482:164, 1989), 3H-dopamine represented 0.5-1% total retinal dopamine so that dopamine release = 1-2 pMoI retina min Presently we are comparing efflux of 3H-dopamine across vitreal and photoreceptoral surfaces. These data will be used to estimate the extracellular concentration of dopamine in outer retina. Supported by NIH Grant EY03570 to P.W.

GABA INHIBITS ACH RELEASE FROM THE RABBIT RETINA: A DIRECT EFFECT OR BIPOLAR CELL FEEDBACK? <u>David M. Linn and Stephen C. Massey*</u>, Sensory Sciences Center, GSBS, UTHSC, 6420 Lamar Fleming Avenue, Houston TX 77030 The cholingrgic amacrine cells of the rabbit retina may be labeled with ⁹H-Ch and the activity of the cholinergic population monitored by following the release of ³H-ACh. ACh release may be produced directly by exogenous glutamate analogs or physiologically via bipolar cells by light stimulation. Muscimol, a potent GABA agonist, blocked the light evoked release of ACh with an IC₅₀ of 1.0 μM but the KA and NMDA evoked release was not reduced by concentrations of muscimol as high as 100 μM. Thus we have been unable to demonstrate a direct effect of GABA on the cholinergic amacrine cells. GABA on the cholinergic amacrine cells.

GABA antagonists such as picrotoxin caused a large increase in the base release and potentiated the light evoked release of ACh. Both these effects were blocked by DNQX, a KA antagonist which blocks the input to cholinergic amacrine cells from bipolar cells. This implies that the dominant site of GABA inhibition is on the bipolar cell input to the cholinergic amacrine cells.

EFFECTS OF PICROTOXIN ON THE ELECTRORETINOGRAM

EFFECTS OF PICROTOXIN ON THE ELECTRORETINOGRAM B. Oakley II. B.J Katz*, R. Wen*, J. Zheng*, and Z. Xu*. Vision Research Laboratory, University of Illinois, Urbana, II. 61801 We recorded transretinal and intraretinal ERGs, Müller cell voltage, and [K⁺]₀ in the isolated retina of Bufo marinus, in response to diffuse light flashes (0.1-10 s). Picrotoxin (PTX, 10-100 μM), a GABA_A antagonist, enhances K* increases in the IPL and Müller cell depolarizations at ON and OFF by ~250%, and leads to the appearance of an ON-M-wave and a positive OFF-response in the vitreal ERG, as well as a PNR and M-wave in the intraretinal ERG. These effects likely are due to blocking GABA-mediated inter-amacrine inhibition that occurs with diffuse flashes. By removing this inhibition amacrine cell responses to diffuse light become removing this inhibition, amacrine cell responses to diffuse light become equivalent to superposition of individual cells' responses to small spots, which are optimal for evoking the M-wave. Since with PTX the M-wave is generated over a large area, it contributes to the vitreal ERG, where it is and OFF-response have waveforms similar to the IPL K^+ increases and these potentials are blocked by $100 \,\mu M$ Ba $^{2+}$, supporting the hypothesis that these potentials result from Müller cell current sinks that arise in the IPL in response to K⁺-evoked membrane depolarization distal to the cell's neutral zone. The pattern of intraretinal reversals of these components is consistent with current sources on the Müller cell membrane both distal consistent with current sources on the Mulier cell memorane both distal and proximal to the IPL. The OFF-response reverses at a depth distal to where the M-wave reverses, consistent with the OFF-K⁺ increase having its amplitude maximum distal to the ON-K⁺ increase. Finally, comparison of control ERGs evoked by rod-matched 600 nm and 500 nm flashes shows that a small M-wave contributes to the ERG under control conditions. Supported by NIH grant EY04364.

INTRACELLULAR ACIDIFICATION SUPPRESSES THE CALCIUM ACTION POTENTIAL OF ISOLATED HORIZONTAL CELLS FROM CATFISH RETINA.

K. Takahashi and D.R. Copenhagen. Departments of Ophthalmology and Physiology, UCSF Sch. of Med., San Francisco, CA 94143

Brief depolarizing current pulses injected into isolated horizontal cells via an intracellular microelectrode evoke norizontal cells via an intracellular microelectrode evoke sustained action potentials that can last for several minutes (Tachibana, M., J. Physiol., 321:141, 1981; Shingai and Christiansen, J. Neurophysiol., 56:32, 1986). Pharmacological manipulations suggest that these are calcium action potentials. Changes in intracellular pH affected the duration of the action potentials: alkalinization induced by bath application of NH4Cl prolonged the depolarization, while acidification induced by bath replication of seattle as the proposed of the control of the con

prolonged the depolarization, while action and induced by oath application of acetate or the washout of NH₄Cl shortened and often eliminated the action potential. The pH-dependency was observed in the presence of IBMX (0.5 mM), or BAPTA-AM (70 μ M), or TEA (30 mM), or low sodium(0 mM). These findings suggest that the pH effects were not being mediated via pH-dependence of the property of the presence of the pH effects were not being mediated via pH-dependence of the property of the presence of the property of the presence of the pH effects were not being mediated via pH-dependence of the property of the presence of the property of the presence of the pH effects were not being mediated via pH-dependence of the presence of the pH effects were not being mediated via pH-dependence of the pH effects were not being mediated via pH-dependence of the pH effects were not being mediated via pH-dependence of the pH effects were not being mediated via pH effects were not being mediated via pH-dependence of the pH effects were not being mediated via pH effects we dependent, sodium or delayed rectifier-type potassium conductances and did not result from a pH-dependent reaction in

conductances and did not result from a pH-dependent reactio a cyclic nucleotide second-messenger system.

We postulate that the pH effects are mediated by a direct action of H⁺ ions on the calcium conductance underlying the action potential. Similar H⁺ ion suppression of calcium conductances has been reported in paramecium (Umbach, J., Proc. R. Soc. Lond. 216:209, 1982)

 $[{\tt Ca^{2+}}]_o$ GRADIENTS AND LIGHT-EVOKED $[{\tt Ca^{2+}}]_o$ CHANGES IN CAT RETINA, IN VIVO. R.P. Gallemore*, F. Yamamoto* and R.H. Steinberg.

Physiology and Ophthalmology, Univ. of Calif., San Francisco, CA 94143. We report the first measurements of Ca²⁺ gradients and light-evoked Ca²⁺ changes in the mammalian retina, <u>in vivo</u>. Double-barreled Ca²⁺-selective microelectrodes were used to record intraretinally from the intact cat eye. Depth profiles in the dark revealed [Ca²⁺]_o in the subretinal space surrounding rod outer segments to be 1-2 mM <u>higher</u> than in the vitreous, with [Ca²⁺]_o highest near the RPE. In addition, a trans-RPE gradient was

boserved with choroidal $[Ca^2+]_0 \ge 1$ mM higher than subretinal $[Ca^2+]_0$. Light-evoked $[Ca^2+]_0$ changes were maximal at two retinal depths. Deep in subretinal space, near the RPE, maintained illumination evoked a sustained $(Ca^2+)_0$ decrease that peaked in 30-45 sec after light-onset and was as large as 1 mM. At light-offset, Ca^2+ returned to baseline with a similar time course. The dark-adapted sensitivity of this response indicated its dependence on rods. These results were unexpected since, in vitro, measurements in other species have revealed a light-evoked increase in subretinal Ca^{2+} of ≤ 50 uM, followed by a decrease of similar magnitude at light-offset and these responses are thought to reflect changes in light-dark Ca²⁺ fluxes across rod outer segments. In the <u>inner plexiform layer</u>, light-evoked a transient *increase* that peaked in ~20 sec and was as large as 0.5 mM. At light-offset, Ca²⁺ triat peaked in ~2 sec and was as large as 0.5 min. At light-onset, Ca²⁺ underwent a translent decrease similar in time-course and amplitude. Experiments are in progress to elucidate the origins and mechanisms of the observed Ca²⁺ gradients and light-evoked Ca²⁺ changes. Given the exquisite sensitivity of photoreceptors to [Ca²⁺lo and the proposed roles of Ca²⁺ in light-adaptation and the transduction process, these results may have important implications for photoreceptor function in vivo. (NIH grant EY01429)

297.14

CHANGES IN INTRACELLULAR CALCIUM CONCENTRATION OF DISSOCIATED RETINAL GLIA AND NEURONS OF THE LARVAL TIGER SALAMANDER MEASURED WITH FURA-2 IMAGE ANALYSIS. S.A. Keirstead & R.F. Miller. Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455

We have examined alterations in intracellular calcium of single, dissociated cells from the neotenous tiger salamander retina using fura-2 imaging techniques. Cells were studied from acutely dissociated preparations, or from preparations that had been cultured for several days, after plating them onto a matrix of Sal-1 (kindly provided by P. Macleish). Neurons and glia were loaded with fura-2 by incubating them in a 0.5 to 1.0 uM solution of the acetoxymethyl ester of fura-2 (Molecular Probes) in amphibian Ringer's for 15 to 30 minutes and then rinsed extensively with Ringer's. Images of the intracellular calcium concentration of retinal cells were obtained using a commercially available system (Quantex, Sunnyvale, CA) configured with a Nikon Diaphot inverted microscope and a dual monochrometer (PTI, South Brunswick, NJ) with excitation wavelengths of 340 and 380 nM. An insert was placed within the culture dishes to reduce dead space and the cells were continuously superfused using a perfusion pump connected to a group of ganged syringes for changing the bathing medium.

We have observed substantial increases in intracellular calcium concentration in retinal cells as a result of increasing extracellular potassium concentration and as a result of application of excitatory amino acid agonists.

Time-Domain Models of the Horizontal Cell Network Implemented on a Massively Parallel Processor R. L. Winslow, A. L. Kimball*. Department of Physiology & Army High Performance Computing Research Center, University of Minnesota, Minneapolis, MN 55455.

Previous studies have investigated the ways in which voltage-dependent mem brane currents, synaptic input from photoreceptors, and gap junction coupling between neighboring horizontal cells interact to determine the steady-state response properties of isolated horizontal cells and horizontal cell networks (J. Neurophysiol., 62(3): 738; J. Neurophysiol. in press). We have extended these results to timedomain models of the horizontal cell network of the whiteperch retina. Hodgkin-Huxley type models of membrane current kinetics based on data from isolated whiteperch horizontal cells (provided by A. Knapp) have been formulated. Ca mediated inactivation of the Ca current is modeled using the approach of Eckert & Chad. Network models are constructed by interconnecting cells to form a square mesh of typically 128x128 cells. Gap junction coupling between neighboring cells is adjusted to match the space constant measured in horizontal cell bodies of the carp, and the point-to-point transfer impedance measured in catfish retina. Light responses (e.g., photoreceptor inputs to the network) are modeled by adjustment of the synaptic conductance value within the region of the network illuminated by the stimulus. State variables are computed by mapping individual cells in the network onto a single processor of a massively parallel computer known as the Connection Machine. A fourth order Runge-Kutta adaptive step-size algorithm is used to update values of the ten state variables describing each horizontal cell concurrently. The model has been used to investigate the effects of cell-to-cell coupling on reponse to light spot, slits, and drifting sinusoidal gratings. Decoupling of cells, as has been reported to occur during dark adaptation, increases spatial resolution at the expense of greatly reduced temporal resolution. (Supported by The Whitaker Foundation, NIH Grant PO1NS17763-07, The Northeast Parallel Architecture Center, Syracusc University, and Thinking Machines Corp., Cambridge, MA).

SENSORY SYSTEMS-AUDITORY SYSTEM: CENTRAL PATHWAYS I

298.1

EMBRYONIC DEVELOPMENT OF THE MAMMALIAN HINDBRAIN AUDITORY DECUSSATION. J.K.Brunso-Bechtold, C.K.Henkel, and S.L.Vinsant, Department of Neurobiology and Anatomy, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, N.C. 27103. The proper formation of fiber decussations is essential for normal auditory function which depends upon the convergence of information from the right and left ears. In order to begin to address the issue of mechanisms which may be involved in regulating the development of decussating auditory fibers, we have studied the development of the trapezoid body decussation in ferrets. In Bodian silver-impregnated material, fibers can be observed crossing midline in the hindbrain during embryonic development. In order to determine whether the fibers observed at midline in the embryonic hindbrain are actually trapezoid body fibers, we have placed gelfoam pellets impregnated with the at munic in the entroyence initiation and are actuary trapezoid body fibers, we have placed gelfoam pellets impregnated with the carbocyanine dye, Dil, into the cochlear nucleus of embryonic brains which had been immersion-fixed in 2% paraformaldehyde. The brains were stored in the dark at room temperature for 1-2 The brains were stored in the dark at room temperature for 1-2 months, cryostat-sectioned, and viewed with epifluorescent microscopy. As early as embryonic day 34, fibers extend from the cochlear nucleus to enter the ipsilateral superior olive, often in discrete fascicles. In addition, labelled fibers cross the midline and enter the contralateral superior olive. Thus converging ipsilateral and contralateral cochlear nucleus inputs are present in the superior olivary complex at least three weeks before the major period of synaptogenesis and five weeks before the onset of hearing. Supported by DC00335 and March of Dimes.

298.2

LATERALITY OF SUPERIOR OLIVE PROJECTIONS TO THE INFERIOR COLLICULUS IN ADULT AND DEVELOPING
FERRET. Craig K. Henkel and Judy K. Brunso-Bechtold.
Department of Neurobiology and Anatomy, Wake Forest
University, Bowman Gray School of Medicine, Winston-Salem, NC 27103.

The connections of the lateral superior olivary nucleus (LSO) with the inferior colliculus (IC) were investigated in adult and immature ferrets. The proportion of cells labeled in LSO on each immature ferrets. The proportion of cells labeled in LSO on each side in retrograde tracing experiments depended on both the specific marker and location of the injection in adult IC. Large wheat germ agglutinin-HRP injections labeled nearly all LSO cells on both sides. When HRP alone was injected in adult IC even in very large amounts, two populations of cells were found in each LSO, one labeled and the other unlabeled. Large, bilateral injections of two fluorescent markers in IC resulted in two populations of single-labeled cells, supporting the conclusion that nearly all cells in LSO have ipsilateral or contralateral projections to IC but not bilateral projections. In the HRP experiments the contralateral lateral limb of LSO contained 61-75% of the labeled cells when compared to the ipsilateral lateral limb, suggesting that areas of different frequency representation project differently to the two sides. At birth LSO projections have arrived at IC based on similar retrograde experiments. As in the adult in neonatal on similar retrograde experiments. As in the adult in neonatal ferrets there appears to be a contralateral bias in the LSO projection to IC and this bias is greater in the lateral limb than in the nucleus overall.

Supported in part by NIH Grant DC00335.

AGE-REIATED CHANGES IN GABA AND ACH IN THE BRAINSTEM AUDITORY NUCLEI OF FISCHER-344 RATS. A. Raza, D.M. Caspary & S.P. Arneric. Dept. of Pharmacology, Southern IL Univ., Springfield, IL 62794-9230 Our previous studies have suggested a selective, age-related deficit of GABA immunostaining, release and tissue levels in the central nucleus of the inferior colliculus (CIC) (Soc. Neurosci. Abstr., 1989, 15, 115; J. Neurosci., 1990, In Press). This study sought to determine whether there are additional age-related alterations in the biosynthetic enzyme, the degradative enzyme and the uptake system for GABA in the CIC. The cochlear nucleus (CN) and nuclei of the lateral lemniscus (NLL) were also examined for comparison. The cholinergic neuronal system was studied concurrently. Results were compared in young (3-7 mo), intermediate (15-17 mo) and aged (24-26 mo) Fischer-344 rats. In young animals glutamic acid decarboxylase (GAD) activity ranged 6-fold and was highest in the CIC (219 mol/mg protein/h; N=5). Choline acetyltransferase (ChAT) activity was highest in NLL and CN, while GABA-transaminase (GABA-T) activity showed a more uniform distribution. Age-related reductions in GAD activity were seen in the CIC of intermediate (-31%) and aged (-30%) rats when compared to young controls, p < 0.05 (N=5). Neurotransmitter selectivity of this deficit in CIC is supported by the modest, non-parallel changes in ChAT activity (-22%, aged ys. intermediate, p < 0.05). High-affinity uptake processes (K_m and V_m) for ¹C-GABA and ³H-D-Asp were not significantly altered in the CIC synaphosomes with aging. Similar to the CIC, the NLL showed remarkable age-related deficits in GAD and ChAT activities, but these deficits were more substantial for the cholinergic system (ChAT activity in the CN. No area examined showed a significant loss of GABA-T with aging. Taken together these data suggest: 1) The CIC of Fischer-344 rats shows consistent, age-related loss of GABA as reported previously which is not attributable to changes in upta

SOME ASPECTS OF THE ORGANIZATION OF THE AUDITORY FOREBRAIN AND MIDBRAIN IN THE PIGEON. J.M. Wild, B.J. Frost and H.J. Karten. Dept. of Neurosciences, Univ. of California, La Jolla, CA 92093.

Telencephalic projections of thalamic auditory nuclei ovoidalis (Ov) and semilunaris parovoidalis (SPO) define a cytochrome oxidase positive field L2a and an adjacent, wider, dorsolateral end-zone, L2b. Regions flanking L2 dorsally (L1) and ventrally (L3) are not labelled by these methods. Ov and SPO are represented within L with an inverted dorsoventral topography. For instance, SPO, which receives a major input from lateral lemniscal nuclei and a lesser input from the mesencephalon (MLd), is retrogradely labelled specifically lesser input from the mesencephaton (MLd), is retrogradely labelled specifically by injections in L2b. Within L2a there is a tight tonotopicity with higher frequencies (<4kHz) represented ventromedially and lower frequencies (>200Hz) progressively more dorsolaterally. In contrast, L2b is not tonotopically organized and units are broadly tuned. These two regions, L2a and L2b, together with L1 and L3, are further functionally distinguished by 2-DG autoradiography following acoustic stimulation with white noise. Some efferents of the L region terminate in a diffuse neostriatal zone dorsolateral and caudal to L (Nd) and the medial paleostriatum, but not Ov or SPO. Retrograde labelling from Nd, however, is confined to L1 and L3. Nd projects to the ventromedial archistriatum (Avm), which then projects bilaterally to L. Avm also supplies a major descending projection to peri-ovoidal regions, and to intercollicular regions surrounding MLd which may be characterized by their reactivity to antibodies directed against nicotinic acetylcholine receptors. Together, these studies indicate the existence of at least two parallel auditory streams ascending through the forebrain, but how far they remain separate remains to be determined. Supported by NIH grant NS24560-04 and ONR Contract N00014-88-K-0504 (HJK).

Auditory fibers are present in the cochlear nucleus during inward migration of precochlear neurons of the opossum, Monodelphis domestica, F.H. Willard, Department of Anatomy, University of New England, Biddeford, Maine, 04005.

The mammalian cochlear nucleus (CN) contains multiple cell types, of which at least three, principal and giant cells of dorsal CN and large multipolar neurons of ventral CN, are derived embryologically from a migrating, precochlear group found in the dorsomedial brainstem (Willard and Martin, J. Comp. Neurol., 248:119, 1986). Developmental interactions between precochlear neurons and central processes of the auditory nerve are being examined in the opossum, *Monodelphis domestica*, a species born 14 days after conception with its auditory system in a very immature state (Willard and Munger, Neurosci. Abst., 14:425, 1988; Willard, Neurosci. Abst., 15:742, 1989). In Monodelphis, the precochlear cells are seen approaching the CN on postnatal day (PND) 4; from PND-6 through 9, they enter the nucleus passing over the presumptive dorsal acoustic stria; subsequently, cytoarchitectural organization develops during PND-10 to 19. Biffid central processes of the auditory nerve, labelled by HRP placement into the cochlea, are present throughout ventral CN and extend into the subventricular zone of presumptive dorsal CN, at least by PND-6 (the youngest age examined to date). On PND-8 labelled axons extend through the nucleus to the ventricular zone and are present in between precochlear cells as they inhabit the subventricular zone of presumptive dorsal CN. We conclude that auditory axons are present in the CN as precochlear neurons arrive and, as such, could play a role in the final positioning of these neurons. (NIH 1-R15 NS25978-01)

THE OCTOPUS CELL AREA OF THE PVCN IS NOT INNERVATED BY TUBERCULOVENTRAL NEURONS AND COULD ENCODE ECHOES Robert E. Wickesberg* and Donata Oertel. Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI 53706 Tuberculoventral neurons in the deep layer of the

dorsal cochlear nucleus (DCN) inhibit bushy and stellate cells in the anteroventral cochlear nucleus (AVCN) topographically. To determine whether they also innervate the posteroventral cochlear nucleus (PVCN) extracellular injections of horseradish peroxidase (HRP) were made in brain slices. HRP injections into the multipolar cell area of the PVCN labeled tuberculoventral neurons in the deep layer of the DCN within the band of auditory nerve fiber terminals labeled by the same injection. Injections into the octopus cell area failed to label cells in the deep DCN.

The inhibition from the deep DCN to the AVCN could suppress echoes monaurally (Wickesberg and Oertel, J. Neurosci. 9:, 1990). While echoes are suppressed monaurally in localization tasks (Harris et al. J.A.S.A., 35:672, 1963), they do contribute to the perception of "timbre and loudness." If tuberculoventral neurons suppress echoes, then octopus cells, which are not innervated by tuberculoventral neurons, could carry information concerning echoes and thus contribute to the encoding of timbre and loudness.

PREFERRED ORIENTATION OF BASKET CELL AXONAL ARBORS IN RABBIT AUDITORY CORTEX: THREE DIMENSIONAL RECONSTRUCTION USING COMPUTER MICROSCOPY Nathaniel T. McMullen. Department of Neurology,

University of Arizona College of Medicine, Tucson, Arizona 85724

Current network formulations of cerebral cortical circuitry feature GABA-ergic "basket cells" whose axonal fields mediate lateral inhibitory interactions. Although several examples of computer-aided reconstructions of cortical basket cell axons have appeared, no quantitative population studies exist. During the course of Golgi studies of auditory cortical development (McMullen et al, 1988, JCN:278), we encountered examples of basket cells whose axons were exceptionally well-impregnated. The present study is based on the reconstruction of 22 basket cells from lamina III/IV of the auditory cortex of NZW rabbits 12-30 days of age. The dendritic and axonal territory of each cell was digitized from 300-400 um thick Golgi-Cox sections using a computer microscope system equipped with oil-immersion optics. Tangential (parallel to the pial surface) projections and spatial analyses revealed a preferential orientation of axonal arbors parallel to the dorsal-ventral axis of the brain. In some cases, a distinct slab-like axonal orientation was present. In fortuitous sections with two adjacent cells impregnated, their tangential orientations were nearly identical. Because the orientation of the presumptive inhibitory fields is roughly orthogonal to the isofrequency bands in this species (McMullen & Glaser, 1982, Exp. Neurol: 72), these cells may mediate feedforward lateral inhibition, and participate in the formation of isofrequency strips (Supported by The Deafness Research Foundation).

MOLECULAR MARKERS IDENTIFY NEURONAL SUBSETS IN GERBIL AUDITORY BRAINSTEM NUCLEI. <u>I.R. Schwartz</u>^{1,2}, <u>P. Eager</u>^{1*} and <u>I. R. Naegele</u>³, Sections of Otolaryngology¹, Neuroanatomy², and Dept. of Opthalmology and Visual Sciences³ Yale University School of Medicine, New Haven CT. 06510.

A panel of immunocytochemical markers used previously to identify functionally distinct subsets of neurons in the visual system, has now been functionally distinct subsets of neurons in the visual system, has now been used to identify subsets of auditory neurons, particularly those containing GABA. Serial sections of adult gerbil brains were incubated in antibodies to: 1) an N-linked carbohydrate associated with certain integral membrane proteins (monoclonal antibody VC1.1); 2) parvalbumin (PV) (an intracellular calcium binding protein); 3) GABA or, 4) in a lectin specific for N-acetylgalactosamine (VVA). Each marker showed a characteristic and selective labeling pattern of distinct neuronal subsets. VC1.1 staining selective labeling pattern or distinct neuronal subsets. VC.1. staining patterns were generally similar to those reported for Cat-301 (Schwarz & Hockfield, Soc. Neurosci. Abstr. 15: 110, '89). Like VC1.1 and Cat-301, VVA labeling was limited to the surfaces of cells. It labeled posterior ventral cochlear nucleus (PVCN) octopus cells and large multipolar subcollicular neurons but, in contrast to VC1.1 and Cat-301, it also stained neurons in the lateral external nucleus of the inferior colliculus (IC) and a different subset of anterior ventral cochlear nucleus (AVCN) neurons. Like GABA, PV immunoreactivity was restricted to cartwheel and Golgi neurons in the dorsal cochlear nucleus (DCN). PV antibody also labeled small neurons throughout the lateral extent of the central nucleus of IC, but large multipolar subcollicular neurons and octopus cells of the PVCN were unlabeled. Patterns of co-localization with these markers may demonstrate neuron resultances in the property relationships between auditory neuron propulations and their new relationships between auditory neuron populations and their transmitters. DESCENDING INPUT FROM THE CENTRAL NUCLEUS OF THE INFERIOR COLLICULUS TO THE MEDIAL OLIVOCOCHLEAR SYSTEM IN RAT: A COMBINED PHA-L AND CT-HRP STUDY. D.E. Yetter and E. Saldaña. Lab. of Neuromorphology, Univ. of Connecticut, Storrs, CT 06269-4154.

The descending input to the superior olivary complex (SOC) from the central nucleus of the inferior colliculus (ICC) is tonotopic (Saldaña, Soc. Neurosci, Abstr., 1990) and terminates in the ventral nucleus of the trapezoid body (VNTB), which contains neurons of the medial olivocochlear (OC) systems. Rajan (Hearing Res., 1990) has shown that electrical stimulation of the inferior colliculus (IC) reduces temporary threshold shifts in the cochlea, apparently via the OC system. We have combined antercorade transport of *Phaseolus vulgaris*-leucoagglutinin (PHA-L), which delineates axonal arbors, and retrograde transport of HRP conjugated to cholera toxin B subunit (CT-HRP), which delineates dendritic arbors, to investigate where and how the IC can influence the OC systems in the rat. PHA-L was injected unilaterally into the ICC of adult rats 7-9 days prior to injection of CT -HRP into the contralateral cochlea. The animals were perfused 2-3 days later with an appropriate aldehyde fixative. Sections of the SOC were reacted sequentially for the presence of CT-HRP and PHA-L. PHA-L labelled axons originating in the ICC entered the ventral portion of VNTB. Most labelled fibers were observed ipsilateral to the PHA-L injection site, and they were not found near LSO. The collicular fibers intermingled with CT-HRP labelled cell bodies and dendrites. PHA-L labelled boutons only rarely seemed to contact CT-HRP labelled cell bodies, but they were often observed in close apposition to labelled dendrites, suggesting that synapses between these two elements may be present. (Supported by PHS grant NS-09904).

GLYCINE IMMUNOREACTIVE PROJECTIONS FROM THE DORSAL TO THE ANTEROVENTRAL COCHLEAR NUCLEUS. R. L. Saint Marie, C. G. Benson, E. -M. Ostapoff and D. K. Morest. Department of Anatomy and Center for Neurological Sciences, University of Connecticut Health Center, Farmington, CT 06032

Neurons in the deep layer of the dorsal cochlear nucleus (DCN) have axons that ramify in the three principal subdivisions of the cochlear nucleus. They are ideally situated to influence all of the outputs of the cochlear nucleus and, consequently, to influence monaural and binaural processing throughout the auditory brainstem. The aim of the present study was to determine if projections from the DCN to the anteroventral cochlear nucleus (AVCN) use either of two inhibitory transmitters, glycine or GABA. Retrograde HRP labeling of DCN-to-AVCN projection neurons was combined with postembedding immunocytochemistry in the DCN of guinea pigs. Following injections of HRP in the anterior or posterior divisions of AVCN, large numbers of neurons were labeled in the DCN. All of these were located in the deep layer, except for a few granule cells. Nearly all (96%) of the projection neurons were immunoreactive for glycine and most had dendritic and somatic morphologies corresponding to those of elongate neurons (so-called "corn" cells). A few may have been small stellate neurons. Few retrogradely labeled neurons (3%) were immunoreactive for GABA. The results suggest that projections from the DCN to AVCN are formed primarily by glycinergic elongate neurons and, therefore, could have inhibitory influences on the output of neurons in AVCN. Supported by NIH grants DC127 & DC199.

FINE STRUCTURE OF GABA-LABELED AXONAL ENDINGS IN THE INFERIOR COLLICULUS OF THE CAT. IMMUNOCYTO-CHEMISTRY ON DEPLASTICIZED ULTRA-THIN SECTIONS.

D.L. Oliver and G.E. Beckius*. Dept. Anatomy, Univ. CT Health Center. Farmington. CT 06032.

D.L. Oliver and G.E. Beckius*. Dept. Anatomy, Univ. CT Health Center, Farmington, CT 06032. Numerous GABAergic endings in the inferior colliculus (IC) arise from several sources that include the dorsal nucleus of the lateral lemniscus and neurons within the IC itself. Despite this, little is known of their fine structure and synaptic organization.

GABAergic axonal endings in the IC were identified at the EM level with affinity-purified (Wenthold, NIH) and Pel-Freez polyclonal antisera against protein-conjugates of GABA. Serial ultra-thin sections were used to compare immunostaining and normal fine structure in the same axonal endings. Most GABA-labeled endings had a similar morphology. Most endings contained pleomorphic synaptic vesicles and made symmetrical synapses. This morphology is consistent with inhibitory function. Although most GABA-labeled axonal endings synapsed on dendrites, a number of labeled axo-somatic synapses also were found. These might be related to different postsynaptic cell types or different receptor types.

THE RAT COLLICULO-OLIVARY PROJECTION IS TONOTOPIC. E. Saldaña. Dept. of Cell Biology and Pathology, Univ. of Salamanca, 37007 Salamanca, Spain.

It is generally accepted that the descending input to the superior olivary complex (SOC) originates mostly in the external cortex of the inferior colliculus (Faye-Lund, 1986, Anat. Embryol.). In an attempt to determine:

1) to what extent the central nucleus of the inferior colliculus (ICC) innervates the SOC, and 2) what is the topography of this projection, Phaseolus vulgaris-leucoagglutinin (PHA-L) was iontophoretically injected unilaterally into the ICC of adult rats. After 7-12 days, the animals were transcardially perfused with an appropriate aldehyde fixative. Brainstem sections were reacted for PHA-L immunocytochemistry.

From the ICC, the labelled axons descend in the lateral and rostral aspects of the ipsilateral lateral lemniscus (LL). At the ventral border of the LL the fibers curve caudally to innervate the ventral nucleus of the trapezoid body (VNTB), particularly the ventral half. The collicular fibers run rostrocaudally, in parallel to the main axis of the nucleus, creating a dense terminal plexus with abundant *en passant* and terminal varicosities. After injections in the dorsolateral, low frequency, areas of the ICC, the terminal field in the VNTB occupies a lateral position, whereas injections in the ventromedial, high frequency, regions of the ICC produce a medially located terminal field. This clear tonotopic arrangement of the colliculo-olivary projection suggests that the VNTB could have a tonotopic organization not previously described.

In each case a few fibers innervate the ipsilateral superior periolivary nucleus and the contralateral VNTB; only rarely were labelled fibers seen in other nuclei of the SOC.

Neurobiologia "Santiago Namán y Cajal'.

In the work PHA-L was injected iontophoretically into the
primary auditory cortex. The ipsilateral cortico-cortical

In the work PHA-L was injected iontophoretically into the primary auditory cortex. The ipsilateral cortico-cortical projections are arranged in a structure of bands formed of axons and axonic endings. These bands are predominantly oriented in the antero-posterior direction and extend from the site of injection in the anterior and ventral sense until the parietal cortex (for a distance of about 1800 mi crons). In the posterior sense, they extend to the Te 2 area (for a distance of approximately 1600 microns). The number of bands varies, depending on the animal injection, but is usually 2 to 3 bands in the anterior sense situated ventrally to the area of injection, and 1 to 2 bands in the sense posterior to the injection and dorsal to the site of injection. The bands form a continuous structure constituted of axons and axonic endings that course throughout the six layers of the cortex. Among them there are spaces with few or no labelled fibres. Contralaterally, the projection is disposed in the contralateral auditory cortex, also for ming from 1 to 2 bands in the anteroposterior sense, although its extension on this axis is less than that of the homolateral bands (some 2200 microns).

298.14

COLOCALIZATION OF GABA-LIKE AND GLYCINE-LIKE IMMUNOREACTIV-ITY IN THE COCHLEAR NUCLEI OF THE BABOON (PAPIO ANUBIS). J.K. Moore and K.K. Osen.*Dept. of Anatomical Sciences, SUNY at Stony Brook, Stony Brook, NY 11794 and Anatomical Institute, University of Oslo, O162 Oslo, Norway. GABA and glycine (Gly) have been described as the major

GABA and glycine (Gly) have been described as the major inhibitory neurotransmitters in the cochlear nuclei. In the present study, pairs of adjacent 0.5 mm Durcupan-embedded sections were treated with antibodies raised against GABA-and Gly-glutaraldehyde-protein conjugates (0.P. Ottersen and J. Storm-Mathisen, Trends Neurosci. 10:250-255, 1987) and treated with the PAP technique. GABA-LI and Gly-LI was observed in neuronal somas, axons and terminals. The relative staining intensity of cell somas was evaluated by optical densitometry.

In baboon, as in other mammals, immunoreactive cells are concentrated in the dorsal cochlear nucleus (DCN) and in the cap area of the ventral cochlear nucleus (VCN). The majority of the reactive cells in these areas show colocalization of GABA-LI and Gly-LI. In DCN neurons, the baboon appears to show a higher degree of colocalization of GABA-LI and Gly-LI than is seen in nonprimate mammals. More colocalization is also seen in fascicles of fibers running between DCN and VCN and in terminals in the central part of the VCN. These structures may constitute a system of association projections from the DCN to the VCN. In the magnocellular part of the VCN, the few immunoreactive cells tend to be large and to show only Gly-LI. These cells may give rise to the population of large Gly-positive axons in the acoustic stria.

STRONG PROJECTION TO THE PONTINE GRAY FROM THE INFERIOR COLLICULUS OF THE MUSTACHED BAT. [effrey I. Wenstrup. Dept. of Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272 and Div. of Neurobiology, Dept. of Mol. and Cell Biol., University of California, Berkeley, CA 94720.

Anterograde tracing methods were used to examine projections to the

pontine nuclei from physiologically defined regions in the central nucleus of the inferior colliculus (ICC). The goal was to describe how isofrequency representations in ICC, analyzing major components of the bat's biosonar echoes, project to the cerebellar relay nuclei of the pontine gray. Multiple tracer deposits of horseradish peroxidase (HRP) or [³H]leucine were placed at sites in ICC tuned near 25, 30, 54, 61, 80, and 93 kHz.

The ICC projected strongly to the pontine gray; only its projection to the medial geniculate body was stronger. Each frequency representation in ICC projected to multiple loci in the ipsilateral pons, where the lateral and dorsolateral nuclei were principal targets of ICC input. There were clear differences in the target zones of different frequency representations; however, some overlap may occur. When one or a few HRP deposits were placed in restricted regions of an ICC isofrequency representation, labeled regions in the pons were subsets of those observed with larger or more numerous deposits in the same representation. Single or restricted deposits nonetheless labeled multiple pontine loci.

The results demonstrate that the ICC is an important source of auditory

input to the pons, and they suggest a patch-like representation of sound frequency within the pontine nuclei as a result of the ICC projection.

CORTICAL AND THALAMIC AFFERENTS OF THE TEMPORAL AUDITORY FIELD OF THE CAT. E.M. Bowman and C.R. Olson. Lab. Sensorimotor Res., NEI, Bethesda, MD. 20892 and Dept. Psychol., George Mason Univ., Fairfax, VA. 22032.

Feline auditory cortex consists of a core of tonotopically organized areas and a surrounding ring of auditory association cortex. The degree to which the different sectors of the nontonotopic association ring constitute distinct areas is poorly understood. One sector of the ring - "the auditory belt" of the posterior ectosylvian gyrus - is connected to established auditory structures but also to the lateromedial-suprageniculate nucleus of the thalamus and to frontal, parietal and cingulate areas (Bowman & Olson, J. Comp. Neurol., 272:15-42). The experiments described here characterized the inputs of an adjacent auditory association area, the "temporal auditory field" (Area Te). We placed emphasis on the question of whether the afferents of Area Te justify regarding it as a distinct entity. We analyzed thalamic and cortical retrograde labeling following

deposits of multiple distinguishable tracers at restricted cortical loci in four cats. Area Te receives its strongest thalamic input from neurons forming a caudal cap on MGd, the dorsal division of the medial geniculate nucleus.

These neurons are caudal to neurons projecting to the auditory belt and to Area All. The projection from caudal MGd to Area Te is topographically organized, as indicated by the fact that tracers deposited at separate loci within Area Te label segregated groups of neurons within MGd. Cortical projections to Area Te arise primarily from other auditory association areas projections to Area 1 e arise printarily from other autonory association areas and from insular and perirhinal cortex. Projections from tonotopic auditory areas and other association areas are minor. These findings justify regarding Area Te as a distinct entity. They suggest that the Area Te is not a portal through which auditory information passes to supramodal cortical centers of the frontal, parietal and cingulate districts.

CHEMICAL IDENTIFICATION OF PHYSIOLOGICALLY CHARACTERIZED MONKEY AI CORTEX. S. H. C. Hendry, L. M. Kitzes & M. N. Semple Dept. of Anatomy & Neurobiology, Univ. of California, Irvine, CA 92717

The tonotopic organization of auditory fields in the monkey (Macaca fascicularis) cerebral cortex was correlated with immunocytochemical staining for the calcium binding protein, parvalbumin. In the superior temporal gyrus (STG), parvalbumin immunoreactivity is present in numerous nonpyramidal somata and in dense bundles of axons in the underlying white matter. The axons can be traced from the medial geniculate nucleus to the posterior half of the STG, where they invade the cortex, intermingle with the immunostained neurons and form a band of intense immunostaining in layers IIIB and IV. The cortical region which contains this band is flanked first by narrow regions that are much less intensely stained and then by secondary zones of moderate immunostaining. Physiological mapping of best frequency responses in the STG indicates that the region of the intense parvalbumin immunostaining corresponds to a cortical field in which there is a complete, tonotopically organized representation of the cochlea. We interpret this to be the primary auditory area (AI). Secondary zones of parvalbumin staining appear to represent surrounding, non-primary auditory areas. These data suggest that monkey AI is a chemically distinct region that can be accurately localized by the intense parvalbumin immunoreactivity of its afferents and interneurons. Supported by NS 25674.

EM OBSERVATION OF PHA-L-LABELED INPUTS TO THE GUINEA PIG SUPERIOR OLIVARY COMPLEX. A.M. Thompson and C.J. Haaksma*. Dept. of Otorhinolaryngology, Univ. of Oklahoma, Hlth. Sci. Ctr., Oklahoma City, OK

We have previously found that after injection of Phaseolus vulgarisleucoagglutinin (PHA-L) into the guinea pig ventral cochlear nucleus (VCN) or inferior colliculus (IC), PHA-L-labeled swellings, associated with labeled fiber segments, were located in the superior olivary complex (SOC). This finding was interpreted as evidence that VCN and IC neurons provided inputs to the SOC. This EM study was done to determine whether the labeled swellings are indeed indicative of synaptic inputs.

PHA-L was injected into either the VCN or IC (7-10 day survival time) and after perfusion-fixation and sectioning, brain sections were treated nunohistochemically to detect the PHA-L using DAB or TMB/DAB/Cobalt as the chromagen. Following osmication, the sections were flat-embedded in

Polybed-812, thin-sectioned, and viewed with a JEOL 2000-FX EM scope.

Within the SOC, positive staining was observed in structures containing typical synaptic specializations such as synaptic vesicles. Pre- and post-synaptic membrane densities were also observed in association with many of the labeled endings. These results suggest that the PHA-L-labeled swellings observed in previous studies indicate synaptic inputs to the SOC originating in VCN and IC. (This research was supported by the Deafness Research Foundation)

CHEMICALLY DISTINCT MEDIAL GENICULATE CELLS PROJECT TO DIFFERENT LAYERS OF MONKEY AI CORTEX. T. Hashikawa*, E. Rausell, M. Molinari and E. G. Jones Neural Systems Lab., Frontier Research Program, RIKEN, Wako 351-01, Japan, and University of California, Irvine, CA 92717

Immunocytochemistry shows that the medial geniculate complex of M. fuscata contains three principal cell types: GABA immunoreactive interneurons and neurons immunoreactive for either of the calciumbinding proteins, parvalbumin or 28Kd calbindin. The three are distributed throughout all subnuclei of the complex but parvalbumin and calbindin cells show differential concentrations. Parvalbumin cells dominate the ventral nucleus and the large-celled part of the magnocellular nucleus, while calbindin cells dominate the posterodorsal nucleus and small-celled part of the magnocellular nucleus.

Retrograde tracing studies, using fluorescent dyes in combination with immunocytochemistry, show that cells containing the calcium binding proteins are thalamocortical relay cells. Among ventral nucleus cells projecting to AI, parvalbumin cells project to middle cortical layers and calbindin cells to layer I. These observations suggest the presence of parallel thalamocortical projection systems based upon chemically distinct cell types with differential cortical projections.

COLLICULUS FUNCTIONAL INFERIOR PLASTICITY COCHLEA AND COLLICUIUS. N. K. Woolf and A.F. Ryan. Div. of Otolaryngology, UCSD Medical Ryan. Div. of Otolaryngology, UCSD Medical Center and Veterans Administration Medical Center, La Jolla, CA 92161.

Early unilateral cochlear destruction in the Early unlateral cochlear destruction in the Mongolian gerbil leads to limited anatomical and functional plasticity in the auditory central nervous system [e.g., Kitzes, L.M., <u>Brain Res</u>. 306:171, 1984], but does not alter broad patterns of neural activity in IC as reflected by sound evoked 2-deoxyglucose (2-DG) activity [Ryan, A.F. and Woolf, N.K., Neurosci. Abstr.,

To determine whether the loss of a CNS neuronal target increases the extent of neuronal target increases the extent of developmental plasticity, we destroyed one cochlea <u>and</u> the ipsilateral IC at 0-2 days after birth (DAB). At 45 DAB, acoustic stimulation of the surviving cochlea with pure tones inappropriately increased 2-DG uptake in the ipsilateral IC. This suggests that extensive developmental plasticity can be induced in the CNS when a population of neurons is deprived of its normal target and, simultaneously, a homologous target is deprived of its normal functional inputs.

THE COMPUTATION OF SOUND ELEVATION IN THE BARN OWL: MODEL AND PHYSIOLOGY. J.C. Pearson¹, C.D. Spence^{1*}, R. Adolphs², David Sarnoff Research Center, CN5300, Princeton, NJ 08543. ²Div. of Biology 216-76, CalTech, Pasadena, CA 91125

In the barn owl, the elevation of sound source direction is largely determined by the interaural level difference (ILD). We present a network model of the ILD processing of nucleus ventralis lemnisci lateralis pars posterior (VLVp) and the lateral shell of the central nucleus of the inferior colliculus (ICL). The model explains several of the most significant physiological findings (*J. Neurosci.* 8: 2665; SN-89 50.5), and makes strong predictions about the anatomy of these nuclei: (1) criss-cross pattern (with respect to the dorsal-ventral axis) of reciprocal inhibition between the right and left VLVp; (2) dorsal-ventral gradient (high ventral, low dorsal) of cell density in the VLVp; (3) excitatory contralateral input from nucleus angularis to the VLVp and ICL that is uniform within an iso-frequency band; (4) inhibitory topographic projection from the contralateral VLVp to both the sensitive and tuned cells of the ICL; (5) inhibition from the sensitive to the tuned ICL cells, such that a sensitive cell with a given ILD threshold inhibits tuned cells with a smaller optimal ILD (ILD defined as contra. - ipsi. sound pressure level.).

We also present the results of experimental tests that are consistent with computer simulations of the model: (1) injections of bicuculline in the VLVp cause the optimal ILD of ICL neurons to increase, while injections of lidocaine have the opposite effect; (2) there are transient responses to all non-optimal ILD's in the ICL, but not in the VLVp. ILD's less than the optimal produce a more pronounced transient reponse than ILD's greater than the optimal.

STIMULUS CODING OF COMPLEX SOUNDS BY SMALL GROUPS OF NEURONS IN THE COCHLEAR NUCLEUS. D.R. Kipke*, B. M. Clopton and D.

J. Anderson. Kresge Hearing Research Institute, University of Michigan, 1301
E. Ann St., Ann Arbor, MI 48109.
The cochlear nucleus, receiving direct inputs from the cochlea via the auditory nerve and possessing a number of primary cell types and interneurons, is thought to have a significant role in the encoding of complex sounds. In this research we investigated the relative influences of commonsounds. In this research we investigated the relative influences of commonstimulus driving and intranuclear connectivity in the spike activities of small
groups of neurons in the dorsal cochlear nucleus and the anteroventral
cochlear nucleus. Solid-state, thin-film microelectrodes were used to
simultaneously record the spike activities of groups of up to five neurons.
Short-duration tonebursts, tone sweeps, and periodic pseudo-random white
noise sequences were used for acoustic stimulation. Standard toneburstbased single unit characterizations were generated (peri-stimulus time
histogram at unit's characteristic frequency and/or response map). Single unit
characterizations derived from the reverse-correlation of a unit's spike train to a
time-frequency representation of the noise provided an estimate of the unit's characterizations derived from the reverse-correlation of a unit's spike train to a time-frequency representation of the noise provided an estimate of the unit's stimulus encoding properties (spectro-temporal receptive field, STRF). Cross-correlation analysis of the spike trains of each pair of units within a group was used to identify functional relationships between the units. The shift-predictor cross-correlogram was used to estimate common-stimulus driving effects, while the algebraic difference between the raw cross-correlogram and the shift-predictor was used to estimate connectivity effects. It was found that the relative influences of common-stimulus driving and connectivity were sensitive to stimulus context. For tonebursts, the functional relationships depended on frequency and intensity. For noise stimulation, specific features in cross-correlograms were associated with relationships between the units' STRFs yielding an estimate of the encoding of specific features of sound by a group of neurons. This work was supported by NIH grant NS-05785 and contract NS-7-2397, and NSF equipment grant BN8609850.

RESPONSE PROPERTIES OF NEURONS IN AUDITORY CORTEX OF THE BIG BROWN BAT. S.P. Dear, T. Haresign, M. Ferragamo*, J. Fritz*, C.F. Moss¹ and J.A. Simmons. Dept. of Psychology and Section of Neurobiology, Brown University, Providence, RI 02912 & ¹Dept. of Psychology, Harvard University, Cambridge, MA 02138

The big brown bat, Eptesicus fuscus, uses temporal and spectral cues to determine target range (Simmons, J.A., Cognition, 33:155, 1989). As a prelude to investigating the neural basis of this echolocation behavior, we have mapped the response properties of neurons in the auditory cortex to trace inappear in the response properties of neutrons in the addition, of the cones, FM sweeps and pulse-echo pairs. Using single and multi-unit recordings with carbon-fiber electrodes in awake bats, most auditory neurons exhibited phasic responses to single tones or FM sweeps and were not delay-tuned to pulse-echo pairs. We found a tonotopic distribution of auditory neurons covering an area of 5 mm². Paradoxical latency shift was observed in some of these neurons, while other neurons showed a facilitated response to the combination of pulse and echo but were not delay-tuned.

Our preliminary data indicated that delay-tuned neurons were diffusely distributed in the cortex, exhibited columnar organization and formed two populations. Neurons with longer best delays (>10 ms) had short latencies $(9.2 \pm 2.3 \text{ ms})$ and were found in the dorsal region. Some of these delay-tuned neurons responded to a narrow range of pulse and echo amplitudes, suggesting coding for both target range and size. Neurons with shorter best delays (<10 ms) had long latencies (24.7 ± 6.9 ms) and were found in the ventral region. Together, the organization of these two populations suggests a neural axis of echo delay-tuning orthogonal to the tonotopic neural axis. (Work supported by NIMH grant MH19118 and ONR grant N00014-89-J-3055)

AUDITORY DIRECTIONAL SENSITIVITY OF SINGLE NEURONS IN THE ONTINE NUCLEI OF THE FM BAT, EPTESICUS FUSCUS. H. Teng and P. H-S. Jen Div. Bio. Sci. University of Missouri-Columbia, MO 65211
Auditory directional sensitivity of 82 pontine neurons of the FM bat, Eptesicus

fuscus, was studied under free field stimulation conditions. For each pontine neuron its best frequency (BF) and lowest minimum threshold (MT) were first determined with a sound (4 msec duration, 0.5 msec rise-decay times) broadcast at a specific azimuthal angle (the best angle). Then the neuron's MT, discharge rate and response latency to pure tone and/or FM sound(s) delivered at 1-3 intensities (10, 20 dB re MT and best intensity at which the neuron discharged maximally) from 9 chosen azimuthal angles within ±800 were recorded. Directional sensitivity of each neuron appeared similar when determined with both stimuli. Most pontine neurons had their angles of lowest MT (81%) and maximal discharge rate (67%) at 0-40°0 contralateral (relative to the recording site). The discharge rate of one-third neurons changed drastically over a limited range of azimuthal angle regardless of stimulus intensity. Thus the directional sensitivity curves of these neurons obtained at all intensities were almost congruent. Conversely, the discharge rate of remaining two-third neurons varied with both sound direction and intensity resulting in different profiles of directional sensitivity curves. While high BF neurons had their angles of lowest MT and maximal discharge rate located more medially than low BF neurons did, the former might not necessarily have a sharper directional slope (dB/deg or impulse/deg) than the latter. The response latency of pontine neurons also varied with sound direction. Most (90%) neurons had a shortest latency at 0-400 lateral. Beyond this azimuthal range, the latency increased drastically resulting an inverted bell-shaped latency directional sensitivity curve. Compared with previous studies in the inferior colliculus (IC), our present observations suggest that the pontine neurons preserve, if not integrate, the directional sensitivity of IC neurons before relaying it to the cerebellum.

EFFECTS OF CONTINUOUS TONE MASKERS ON SPECTRO-TEMPORAL RECEPTIVE FIELDS FOR WIDEBAND NOISE IN GUINEA PIG COCHLEAR NUCLEUS. P.M.Backoff* and B.M.Clopton. Kresge Hearing Res. Inst., U. of Mich. Ann Arbor, MI 48109.

Studies of lateral supression and masking of tonal stimuli for single unit responses have utilized either tone or noise maskers to suppress firing rate. This study of neurons in the ventral(VCN) and dorsal cochlear nuclei(DCN) used continuous tones as the masker, and examined their effect on unit responses to wideband noise stimuli, estimated in the spectrotemporal receptive field(STRF). Masking tones at the unit best frequency(BF), and 1/4 octave above and below BF were presented at approx. 10dB above the

spectral level of the noise and/or at 0-5dB below.

Masked and unmasked STRFs were derived for characterized neurons using a set of periodic wideband noises and a reverse-correlation analysis. Period histograms(PHs), collected for 150-200 repetitions of each noise, cross-correlated with the corresponding time-frequency representations of the noise stimuli. Taken across the noise set, this estimated the time-frequency energy patterns in the stimuli which preceded spike occurrence, represented as peak and trough areas on the STRF display. In the unmasked condition, all neurons showed at least one restricted peak region, with a maxima at the unit BF. Presumably, these peaks reflect short latency, excitatory response areas. Troughs were often seen for DCN units, which are known to have numerous inhibitory inputs. The effect on average spike rate of introducing the masker tones varied with unit type: e.g., onsets showed little change in rate with addition of the continuous tone. Maskers disrupted temporal patterning in the PH and altered response areas on the STRFs for all units, especially for higher level BF tones. The findings for representative unit types from DCN and VCN will be summarized and discussed.

DIFFERENT PATTERNS OF UNIT ACTIVITY SUPPORT DISCRIMINATION OF A CLICK CS FROM HISS DS IN DIFFERENT AREAS OF THALAMUS.

OF A CLICK CS FROM HISS DS IN DIFFERENT AREAS OF THALAMUS.

X.F. Wang, V. Chizhevsky*, E. Gruen*, O. Melamed* and C.D.

Woody. UCLA Med. Ctr., MRRC, BRI, Los Angeles, CA 90024.

Patterns of unit activity were recorded during conditioned blinking produced by 70 db click CS (forward paired with glabella tap and hypothalamic electrical stimulation; 570-10ms ISI; see Hirano et al., Br. Res. 1987) but not by a backward paired hiss DS of comparable intensity. Different averaged patterns of response were found in anterior, LD (lateralis dorsalis), CL (centrolateral), and posterior thalamus. After conditioning, the following changes were observed relative to prior baseline findings:

Region	Spont. firing	Resp. to CS	No. CS resp. cells
ant.	decrease	increase	increase
LD	no change	sl incr.	no change
CL	increase	increase	no change
post.	decrease	no change	no change

Differences in magnitudes of response to CS, background activity, and the proportions of CS responsive cells were the major variants. The CR was discriminatively elicited by the click CS as opposed to the hiss DS, and so was the unit activity after conditioning. (Supported by NS25510.)

A COMPARISON OF THE DIRECTIONAL PROPERTIES OF NONMONOTONIC NEURONS IN THE AUDITORY THALAMUS AND PRIMARY AUDITORY CORTEX (AI) OF CAT. P. Barone, W. A. Irons*, J.C. Clarey, and T.J. Imig. Dept. Physiol., Univ. Kansas Med. Ctr., Kansas City, KS 66103.

Data on the azimuthal and sound pressure level (SPL) sensitivity to free-field noise-burst stimuli were collected from single neurons in free-field noise-burst stimuli were collected from single neurons in the medial geniculate body (ventral division and posterior nucleus: N=325; BFs ranging from 1.8 to 24 kHz) and Al (N=333; BFs ranging from 1.5 to 28 kHz) of barbiturate-anesthetized cats. To provide some indication of cells' sensitivity to azimuth, they were arbitrarity classified as either "high directional" (HD) or "low directional" (LD). The average azimuth functions of HD cells showed greater than 75% reduction from maximum response. Cells were greater than 75% reduction from maximum response. Cells were classified as nonmonotonic (NM) if their average rate-level functions showed a maximum response at a single SPL, and a decrease in discharge rate of greater than 50% from maximum at higher SPLs. NM cells were less frequently encountered in thalamus than cortex (16% and 40%, respectively). The proportions of HD and LD nonmonotonic cells in the thalamic and cortical populations differed. HD response were observed in 55.8% of NM thalamic cells and 82.4% of NM cortical cells, and a Chi-squared test revealed that these two populations differed significantly (Pr<0.01). The distributions of azimuthal preferences of HD cells (i.e., contralateral, ipsilateral or midline) were similar in the two areas. There are two general possibilities to explain these findings. First, a subset of the HD nonmonotonic responses are generated at the level of cortex. Second, a subset of the nonmonotonic thalamic cells that show LD responses project to cortical areas other than Al.

EFFECTS OF SUPERIOR OLIVARY COMPLEX LESIONS ON BINAURAL RESPONSES RECORDED FROM THE RAT'S INFERIOR COLLICULUS. S. L. Sally and J. B. Kelly. Laboratory of Sensory Neuroscience, Carleton University, Ottawa, Ontario, K1S 5B6

This study was undertaken to determine the extent to which binaural responses in the central auditory system survive destruction of the brain stem superior olivary complex (SOC). Cells in the SOC of the adult albino rat were selectively destroyed by micro-injections of kainic acid. Following a period of approximately one month, the binaural response properties of neurons in the inferior colliculus were examined using microelectrode recording techniques. Both summation and suppression binaural responses were found in animals with complete unilateral or bilateral lesions of the SOC. Interaural intensity difference (IID) sensitivity was assessed by comparing near threshold contralateral intensity with the lowest ipsilateral intensity that unequivocally produced a summation or suppression response. Interaction IIDs for animals with unilateral SOC lesions did not differ from those previously obtained from normal rats; however, IIDs for the bilateral lesion cases differed significantly. Modal IID values for bilateral lesion cases were elevated in comparison with normals. Thus, binaural interactions were affected but not eliminated by bilateral destruction of the SOC. (Supported by NSERC).

TEMPORAL AND SPATIAL PATTERNS OF NEURONAL RESPONSES TO AMPLITUDE MODULATED AND HARMONIC SOUNDS IN FREQUENCY BAND LAMINAE IN THE INFERIOR COLLICULUS OF CAT. G. Langner and C.E. Schreiner*
Zool. Inst., THD, 61 Darmstadt, FRG; *Coleman Lab., UCSF, San Francisco

A relation between the topographical representation of characteristic frequency (CF) and best modulation frequency (BMF) of neurons has been pre-viously demonstrated in the central nucleus of the inferior colliculus of cat (Langner, G. and Schreiner, C.E., Soc. Neurosci. Abstr., Vol. 15, Part 2, p. 1116, 1989). Reconstruction of the location of single and multiunit recordings provided evidence that the anatomically defined neuronal laminae of the ICC are not equivalent to 'isofrequency planes' but represent small frequency bands with a tonotopic fine structure which may be described by isofrequency lines running from rostral to caudal. Temporal selectivity results in isoperiodicity lines which are approximately orthogonal to the isofrequency lines.

The current investigation shows how responses to sinusoidal amplitude modulations (AM) and harmonic complexes are represented with respect to the tonotopic and periodotopic maps. The spatial distribution of the responses to these signals corroborate the measured periodicity maps, since the response maxima are located at positions where neurons have adequate BMFs. Q10dB, characterizing the bandwidth of tuning curves, is also systematically distributed over the laminae and maximal near the place where neurons with maximal BMFs were recorded. The map for onset-latency is in line with the finding that this parameter correlates statistically with 1/BMF (Languer, G. et al., Hearing Res. 31, 197, 1987). The spatial distribution of response rate and synchronization of neurons in a frequency band lamina during stimulation with harmonic complexes shows significant fluctuations during the first 30 ms of response. (Supported by DFG, SFB 45)

299.10

FUNCTIONAL ORGANIZATION OF SOUND DIRECTION AND SOUND PRESSURE LEVEL (SPL) IN PRIMARY AUDITORY CORTEX (Al) OF CAT. <u>I.C. Clarey, P. Barone and T.I. Imig.</u> Dept. Physiol., Univ. Kansas Med. Ctr., Kansas City, KS 66103.

The present study was undertaken to examine the organization of neurons' responses (CFs from 3 to 26 kHz) to free-field noise-burst stimuli that varied in frontal azimuthal location and SPL. Extracellular recordings were made in barbiturate-anesthetized cats from single and/or multiple neurons at successive locations within microelectrode penetrations oriented parallel to the cortical surface and isofrequency contours (N=19), and normal to the cortical surface (N=22). The majority of tangential penetrations (15: 79%) showed evidence of clustering of neuron/s with the same azimuthal sector preference, i.e., contralateral, ipsilateral, or midline. Three of these penetrations showed evidence of a systematic shift of azimuthal preference covering the entire frontal sound field. The remaining tracks (4) showed no clear organization and were often associated with a mixture of broad and/or complex responses. The majority of normal penetrations (14: 64%) showed greater than 80% registration in sector preference and sound location that elicited the maximum response; 8 of these tracks showed 100% registration, and little variation in the best azimuthal range. All tangential tracks showed evidence of long sequences of successively recorded neuron/s (from 5 to 21) with the same SPL response (monotonic or nonmonotonic), often segregated by regions of mixing of response type. Half of the normal penetrations showed greater than 80% registration in SPL response type. These data suggest segregation of both azimuthal and SPL response along an isofrequency band, and evidence for radial homogeneity of these properties, especially apparent in the middle cortical layers.

299.12

CHARACTERIZATION OF CELLS IN THE CORTEX OF THE RAT INFERIOR COLLICULUS USING THE BRAIN SLICE TECHNIQUE. P. H. SMITH. Dept. of Anatomy, University of Wisconsin, Madison, WI 53706.

Coronal brain slices from 24-78 day-old hooded rats have been utilized to begin to characterize the intracellular responses of cells in both the external and dorsal cortices of the inferior colliculus (IC). Shock stimulation of the commissural fiber tract (CC) connecting the left and right IC often produced a characteristic sequence of synaptic events distinguished by a short latency ipsp which could last for 20-40 ms and was interrupted by a slightly longer latency epsp. Kynurenic acid, but not APV, significantly reduced the amplitude of the EFSP and eliminated the late portion of the IPSP indicating that the excitatory crossed connection activates non-NMDA type glutamate receptors not only on the cell being recorded from but on other cells that provide the late inhibitory input to the recorded cell. The persistence of the early IPSP indicates a direct CC inhibitory component as well. Both the early and late inhibitory components are GABAergic. Picrotoxin not only blocked all inhibitory drive from the CC but, as described previously in guinea pig (P. Smith, '86) and rat (Pierson et al., '89) a large NMDA-mediated depolarizing event (PDS) could be elicited by much lower shock strengths applied to the CC. That this event was NMDA-mediated was shown by its occurence when the slice was bathed in 0 Mg* ringers, in ringers containing NMDA, and its significant reduction in ringers cont

EXCITABILITY AND FREQUENCY TUNING IN THE GUINEA PIG MEDIAL GENICULATE BODY. Robert C. Lennartz and Norman M. Weinberger, Centr. Neurobiol. Learning and Memory and Dept. Psychobiol., Univ. California, Irvine, Ca. 92717

Excitability changes following an acoustic stimulus involve periods of inhibition and facilitation in the medial geniculate body (MGB) but their relation to other major features of auditory information processing is largely unknown. To determine if frequency tuning is related to tone-evoked excitability patterns, measures of both were obtained from single neurons in the MGB of anesthetized guinea pigs. Tuning was determined by measuring bandwidth (20 dB above threshold, square-root transform of range to eliminate frequency bias, Calford et al, <u>Hear. Res.</u>, 11:395,1983). Excitability was determined by presenting pairs of tones at or near the characterisitic frequency (20 dB above threshold, 50 ms, 15-2000 ms intervals). As revealed by responses to the second tone, the first tone usually produced varying duration periods of suppression and facilitation. For each neuron, an index of excitability change was computed and correlated with tuning bandwidth. A significant negative correlation was obtained; cells with the greatest excitability (sometimes including no suppression even at the 15 ms interval) had the smallest frequency bandwidth. These findings suggest that the most narrowly tuned neurons can process frequency informa tion with the highest degree of reliability and that two-tone excitability functions may provide a convenient index of the degree of "lemniscal" prop erties. MEASUREMENT OF THE STRENGTH OF SYNCHRONY OF CHINCHILLA COCHLEAR NUCLEUS UNITS IN RESPONSE TO COS+ NOISE. W.P. Shofner, Parmly Hearing Institute, Loyola Univ. of Chicago, Chicago, IL 60626
Rippled noise produces the perception of pitch in humans. Cos+rippled noise is generated when a wideband noise is delayed and added to the undelayed noise. Some cochlear nucleus units can synchronize to the delay of cos+ noise as shown by a peak in the renewal density (autocorrelogram) [Shofner, W.P., Abstr. ARO, p. 400, 1990). The strength of synchrony in response to cos+ noise can be measured as the height of the peak in the renewal density. However, correlations that strength of synchrony in response to cost noise can be measured as the height of the peak in the renewal density. However, correlations that may exist among higher-order intervals will contribute to the height of this peak. In order to evaluate the contributions that correlations may have on the peak in the renewal density, a new spike train is generated by randomly shuffling the intervals. Random shuffling of the intervals removes any correlations among higher-order intervals, but does not affect the first-order interval distribution [Moore et al, Ann. Rev. Physiol., 28:493, 1966]. Single units were recorded primarily from the AVCN of barbiturate anesthetized chinchillas using tungsten or indium electrodes. Units that show phase-locking at BF generally have a peak AVCN of barbiturate anesthetized chinchillas using tungsten or indium electrodes. Units that show phase-locking at BF generally have a peak in the renewal density at the delay of cos+ noise; for these units, a slightly reduced peak remains in the renewal density computed from the shuffled intervals. The presence of peaks in the shuffled renewal densities which are only slightly reduced suggests that the heights of these peaks in the unshuffled renewal densities predominately reflect contributions of first-order intervals, but that correlations among higher-order intervals can also contribute to the measured strength of synchrony. It may, therefore, be more appropriate to use shuffled renewal densities to measure the strength of synchrony. (Supported by a Center Grant from NIDCD and a grant from AFOSR)

NEURAL RESPONSES TO INTERAURAL PHASE MODULATION IN THE INFERIOR COLLICULUS. M.W. Spitzer, M.N. Semple. Dept. of Anatomy and Neurobiology, Univ. of California, Irvine, CA 92717.

We used interaural phase modulation (IPM) to study the responses of single isolated neurons in the central nucleus of the inferior colliculus to dynamic manipulations of interaural phase. Digitally synthesized stimuli were presented dichotically to anesthetized gerbils. The phase angle of a number to research of the presented to the strength of the phase angle of a part of the phase angle of a number to research of the phase angle of a part of the phase angle of a pure tone stimulus presented to one ear was linearly modulated relative to the stimulus at the other ear. Modulation depth varied from 10 to 360°.

Two types of response to IPM stimuli were observed. The discharge rate of some neurons was strictly dependent on absolute interaural phase. Such units responded to two overlapping IPM sweeps (α and β) toward some phase angle, ϕ , with congruent discharge profiles (see fig., A). For the phase angle, w. with congruent discharge priorites (see fig., A). For the majority of neurons studied, however, over-lapping IPM sweeps generated incongruent discharge profiles (B). Over a wide range of phase angles, discharge of these units depended upon the depth of modulation relative to the starting point of a sweep, with much less dependence on absolute phase angle. The former class of neurons may encode information about sound source location; whereas, the latter may encode information about sound source profitor.

EARPHONE SIMULATION OF A FREE-FIELD SOUND SOURCE AND ITS APPLICATION TO STUDIES OF CORTICAL MECHANISMS OF SOUND LOCALIZATION IN THE CAT. J.C.K. Chan , R. Kochhar* A. Musicant*, R.A. Reale*, J.E. Hind, and J.F. Brugge. Department of Neurophysiology and Waisman Center on Mental Retardation and Human Development, University of Wisconsin, Madison, WI 53706. Studies of the neural mechanisms of sound localization have been

limited by the difficulty of generating and analyzing the spectrally complex, critically timed acoustical signals reaching the two tympanic membranes as the direction of a sound source is varied. Recently, we measured free-field to eardrum acoustic transfer functions in anesthetized cats in an anechoic chamber using a broad-spectrum stimulus (click) whose location was varied over 360% in azimuth and 120^ø in elevation (Musicant et al., <u>J. Acoust. Soc. Am.</u> 87:757, 1990). Using these data, which reflect the effects of the head, pinnae and ear canals, we have synthesized the signals required to drive a pair of specially designed insert earphones so as to reproduce the same sound pressure waveforms at the eardrums as had been produced for a particular source location in the free field. We have presented these dichotic stimuli to the barbiturate-anesthetized cat while recording from single neurons in the primary auditory cortical (AI) field. Preliminary experiments have shown that AI neurons respond robustly to many of these broad-band signals. Systematic presentation of the 1800 synthesized pairs of signals that represent the azimuth and elevation coordinates reveals that certain AI neurons exhibit spatial receptive fields. The shapes and positions of these fields vary among neurons in the same animal. Supported by NIH grants NS12732, NS07026, NS24559 and HD03352.

MEDIAL GENICULATE BODY UNIT RESPONSES TO KITTEN CALL J. Buchwald. J. Harrison. L. Dickerson* and C. Hinman. Department of Physiology, Brain Research Institute and Mental Retardation Research Center, UCLA, Los Angeles, CA 90024 We have been investigating central processing of behaviorally significant sounds. The medial geniculate body, pars principalis

significant sources. The medial geniculate body, pars principalis (MGBp) in the cat projects to cortical areas AI, AII and Ep, the pars magnocellularis (MGBm) projects to insular cortex, and the dorsocaudal division (MGBd) projects to temporal cortex. Lesions of AI do not cause a deficit in discrimination of vocal stimuli or of Al do not cause a deficit in discrimination of vocal stimuli of temporal sequences of auditory stimuli, whereas lesions of insular and temporal cortex do. To test whether particular thalamocortical systems preferentially respond to certain stimulus types, we compared unit responses in the 3 subdivisions of the MGB to various sounds. Units were recorded in awake cats. Stimuli included digitized vocalizations derived from a kitten isolation call. tone pulses and clicks. Of 809 units studied, only 23% responded to any of the auditory stimuli. In MGBp, 39% of responsive cells responded only to clicks. In contrast, 39% of responsive cells in MGBd were pure call responders, while only 12% of responsive cells in MGBp and MGBm responded only to the kitten call. These data support behavioral and anatomical data which suggest functional separation of auditory forebrain projections, with vocal stimuli selectively activating a dorsocaudal MGB-temporal cortex subsystem. (Supported by USPHS HD-05958.)

POPULATION RESPONSES OF AUDITORY NERVE (AN) FIBERS TO PURE TONES: ANALYSIS OF d 'MEASURE FOR INTENSITY DISCRIMINATION. K. Parham and D.O. Kim, Div. Otolaryn., Surg. Res. Ctr., Ctr. Neurol. Sci., Univ. Connecticut Health Ctr., Farmington, CT 06032.

Res. Ctr., Ctr. Neurol. Sci., Univ. Connecticut Health Ctr., Farmington, CT 06032.

The de' is a sensitivity measure used in signal detection theory (Green and Swets, 1966). This measure was recently applied to AN population responses by Kim et al. (J. Acoust. Soc. Am., 1990). In the present study, we examined the de' as a measure of intensity discrimination performance as applied to populations of AN fibers in unanesthetized decerebrate cats. At each of several stimulus levels of 1 and 5 kHz pure tones and for each of an array of AN fibers, we analyzed the mean and standard deviation, a, of spike counts which occurred during 0.2 sec tone bursts. From two sets of mean and a corresponding to a pair of stimulus levels, we computed the demeasure for discrimination between the stimulus levels. We found that: (1) for discrimination between the stimulus levels, de'-versus-CF profiles of both low and high spontaneous rate (SR) fibers (SR, or > 15 spikes/sec, respectively) exhibited distinct peaks of high de' scores at the characteristic place (CP); (2) for discrimination between two high stimulus levels, de'-versus-CF profiles of high-SR fibers exhibited quite low scores of de' in a region around the CP reflecting saturation of spike counts but the profiles of low-SR fibers exhibited a valley of low de' at the CP with region(s) of high de' closely adjoining on one or both sides. These findings suggest that microscopic spread of excitation within a relatively limited region around the CP, e.g., spanning about 1 octave of CFs, may play a role in the psychoacoustically measured intensity discrimination of pure tones.

PHYSIOLOGICAL MECHANISMS OF DIRECTIONAL SELECTIVITY IN THE CAT'S PRIMARY AUDITORY CORTEX (AI) REVEALED BY EAR OCCLUSION. F. R. Samson* and T. J. Imig. Dept. of Physiol., Kansas University Med. Ctr., Kansas City, KS 66103.

Neurons in Al are selective to sound source location in the horizontal plane (azimuth). To elucidate mechanisms of azimuth selectivity we evaluated the effects of unilateral ear occlusion on the responses of 67 single units (CFs from 6 to 28 kHz). Single unit recordings were obtained from barbiturate-anesthetized cats. Noise bursts stimuli varying from 0 to 80 dB SPL, were delivered from various azimuths by loudspeakers mounted on a horizontal hoop encircling the animal's head Ear occlusion effected a frequency-dependent attenuation of 20-60 dB and revealed both binaural and monaural mechanisms of azimuth and revealed both binaural and monaural mechanisms of azimuth selectivity. The most common binaural interaction was of the E/I type in which one ear was excitatory and the other inhibitory (48%). In some cases E/I responses were strongly nonmonotonic with respect to SPL and they received nonmonotonic input from the excitatory ear (28%). A less frequently encountered binaural interaction was mutual facilitation (21%). These cells were often tuned to a limited range of azimuth and SPL, and their responses appeared to be the product of nonmonotonic excitatory inputs from both ears. The azimuth selectivity of some cells was determined by monaural cues (6%). Occlusion of the excitatory ear abolished the response, and occlusion of the other ear had no effect. Azimuth selectivity in these cells is presumably derived from spectral cues as they were much less selective to tones than noise. Many cells showed evidence of both monaural spectral and binaural mechanisms of azimuth selectivity.

INTRACORTICAL DISTRIBUTION OF HORIZONTAL COLLATERALS OF PYRAMIDAL NEURONS IN CAT PRIMARY AUDITORY CORTEX.
H. Ojima, C.N. Honda and E.G. Jones. Neural Systems Laboratory, Frontier Research Program, RIKEN, Wako, Japan

Eight pyramidal neurons in primary auditory cortex (AI) were intra-cellularly injected with HRP (2 cells) or biocytin (6 cells). Each neuron was functionally characterized relative to the antero-posterior sequence of best frequencies that form a tonotopic map in AI. All labelled somata were

in layers II or III and gave rise to typical apical and basal dendritic arbors

in layers II or III and gave rise to typical apical and basal denurtic allows as well as extensive axional systems.

Two major collateral systems emerged from the main axion, one ending in the vicinity of the cell and the second at a distance. Superficial recurrent collaterals originating in layers II and III coursed vertically or obliquely towards the pial surface. Upon reaching layers I or II, these ran parallel to surface. Deep collaterals given off in layer V ran roughly appearable to the pial surface and were confined to a region of layer V. parallel to the pial surface and were confined to a region of layer V immediately below the soma. A few collaterals were given off in layer IV and distributed to other layers.

and distributed to other layers.

Each cell also gave rise to 2 to 4 thick long-range collaterals in layers III and V. These ran parallel to the pial surface for several millimeters. At several points along these long horizontal collaterals, vertically directed branches emerged to form a columnar pattern of collaterals distributed in layers I through V. When viewed in the tangential plane, most of the horizontal collaterals were oriented dorsoventrally. This may correspond to the orientation of isofrequency bands as described in cat. Boutons were found sparsely on the horizontal branches, but were densely distributed in column-like arrays in the vicinity of the cell and at a distance.

AMINO ACID CONCENTRATIONS IN COCHLEAR NUCLEUS OF

AMINO ACID CONCENTRATIONS IN COCHLEAR NUCLEUS OF PERFUSED RAT BRAIN SLICES. D. A. Godfrey, H. J. Waller and W. B. Farms, Depts. of Otolaryngology, Neurological Surgery, Physiology & Biophysics, and Anatomy, Medical College of Ohio, Toledo, OH 43699. Although *in vitro* slices have been extensively used for electrophysiological and pharmacological studies, there has been relatively less chemical evaluation of the slice metabolism. We have begun a chemical evaluation of slices from which electrical activity was recorded in the cochlear nucleus (Waller and Godfrey, Soc. Neurosci. Abstr., 1990). Following the recording session, the slices were removed from the perfusion chamber and frozen within 5 seconds. Frozen sections were cut at 20 μm thickness and alternate sections either freeze dried overnight or mounted onto slides for staining with thionin Frozen sections were cut at 20 μm thickness and alternate sections either freeze dried overnight or mounted onto slides for staining with thionin. Freeze-dried sections were dissected into samples, which were weighed (0.2 · 2 μg) and loaded to the bottoms of plastic tubes for measurement of amino acid concentrations using high performance liquid chromatography (HPLC). Data were analyzed for 10 amino acids: aspartate, glutamate, glycine, γ-amino-butyrate (GABA), serine, glutamine, throonine, arginine, taurine, and alanine. Slices containing dorsal and posteroventral cochlear nucleus, which had been incubated for 7-8 hours and displayed many active neurons throughout this insubstition paried showed difference in several names of a group of the property of t

incubation period, showed differences in several amino acid concentrations from values in cochlear nucleus of rat brain removed and immediately frozen. from values in cochlear nucleus of rat brain removed and immediately trozen. The averages of the concentrations for the slices as percentages of those for control brain were: aspartate 48%, glutamate 25%, glycine 95%, GABA 29%, serine 168%, glutamine 12%, threonine 98%, arginine 79%, taurine 24%, alanine 95%. The results suggest that several aspects of amino acid metabolism, notably glutamate metabolism including its precursor glutamine and products aspartate and GABA, may be quite different in perfused brain slices than in intact brain. (Supported by NIH grant DC00172)

SPONTANEOUS DISCHARGE PATTERNS OF DORSAL COCHLEAR NUCLEUS NEURONS IN RAT BRAIN SLICES. H. J. Waller and D. A. Godfrey. Depts. of Neurological Surgery, Otolaryngology, Physiology & Biophysics, and Anatomy, Medical College of Ohio, Toledo, OH 43699. Neuron recordings in vivo have shown that spontaneous firing of dorsal cochlear nucleus (DCN) neurons persists after deafferentation, while ventral (AVCN and PVCN) neurons become silent (Koerber et al., Exp. Neurol. 16:119 (1966)). We have identified rhythmic, irregular, and bursting spontaneous firing patterns of neurons within or close to the fusiform soma layer of DCN by extracellular recordings from slices of rat brainstem (Abstr. 13th Midwint. Mtg., ARO. 1990. 13:398). The present study more systematically identifies the extracellular recordings from slices of rat brainstem (Abstr. 13th Midwint, Mig., ARO, 1990, 13:398). The present study more systematically identifies the distribution and possible origins of the spontaneous discharge. No spontaneously active neurons were found in multiple penetrations of AVCN or PVCN in experiments showing active DCN neurons. DCN activity probably does not depend upon inputs from other structures because a high density of active DCN neurons was found in slices containing no discernible AVCN or PVCN, trapezoid body, dorsal or intermediate acoustic stria.

When K* of the slice medium (ACSF) was lowered from 6.25 to 3.25 mM.

body, dorsal or intermediate acoustic stria.

When K' of the slice medium (ACSF) was lowered from 6.25 to 3.25 mM, spontaneous firing rates of rhythmic neurons decreased 21-48% and showed greater variability, but the rhythmicity persisted. When Ca'* and Mg'* were changed from 2 mM to 0.2 and 3.8 mM, respectively, firing rates of rhythmic neurons usually increased (up to 3.7-fold) and those of bursting neurons always increased (2.5- to 4.6-fold); interval variability of rhythmic neurons decreased, while bursts were prolonged and more frequent. The results suggest that spontaneous firing is generated within DCN, probably does not require synaptic activity, and may reflect specific membrane characteristics of DCN neurons. ELECTRICAL PROPERTIES AND MORPHOLOGY OF SOME NEWLY IDENTI-FIED AUDITORY RESPONSIVE UNITS FROM THALAMUS OF CONSCIOUS CATS. C.D. Woody, E. Gruen*, V. Chizhevsky*, O. Melamed*, and X.F. Wang. UCLA Med. Ctr., MRRC, BRI, Los Angeles, CA

Electrical properties of 366 neurons (resting poten-tials averaging -55 mV) were measured intracellularly: 172 from LD and CL thalamus, 103 anteriorly from areas bordering dorsal thalamic peduncle, and 91 from pulvinar and LP nucleus. Over half the cells of these areas responded to 70 db click or hiss with increased discharge; 65% had naturally occurring bursting (sustained) discharges, and 17% had spindle waves or sequences. Low threshold spike discharges were observed in <3% of cells given +1nA intracel lular current pulses of 40 ms duration. Over one-third of all cells had non-bursting, unsustained firing responses during 1nA depolarizing pulses.

Very large (400-600 um') cells with thick, primary

dendrites were marked with PHA-L in the anterior thalamus that responded to auditory stimuli and sent projections toward the rostral cortex through the dorsal thalamic peduncle. These cells constituted about one-fourth of those marked in that area; the remaining cells of the anterior thalamus had morphologies that corresponded with those previously described (Chizhevsky et al. <u>Soc. Neurosci. Abstr.</u> 1989). (Supported by NS25510.)

AMPA RECEPTORS, NOT KAINATE RECEPTORS, MEDIATE SYNAPTIC TRANSMISSION IN THE AVIAN AUDITORY NUCLEI MAGNO-CELLULARIS AND LAMINARIS. N. Zhou and T. N. Parks, Dept. of Anatomy, Univ. of Utah Sch. of Med., Salt Lake City, UT 84132.

Because kainic acid (KA) is more potent than other excitatory amino acid (EAA) agonists in blocking synaptic transmission, previous reports have concluded that

primary afferent neurotransmission to the cochlear nucleus in birds and mammals is mediated by KA receptors (Neurosci. Lett. 59:297,1985; Hear. Res. 17:153, 1985; Brain Res. 486:39, 1989). We studied the pharmacology of synaptic 1985; <u>Brain Res.</u> 486:39, 1989). We studied the pharmacology of synaptic transmission between the cochlear nerve and nuc. magnocellularis (NM) and between NM and nuc. laminaris (NL) in chickens, using previously-described methods for bath application of drugs and recording of electrically-evoked field potentials in brain slices (Neurosci, 16:171,1985). Postsynaptic responses in NM and NL, but not compound action currents in the afferent axons, were blocked fully and reversibly by the broad-spectrum EAA antagonist kynurenic acid (2 mM) but not by the selective NMDA antagonists MK-801 (3 µM) or CPP (50 µM). The selective non-NMDA antagonist DNQX also blocked transmission, with IC50's of T μM for NM and 10 μM for NL. KA, domoic acid, quisqualic acid and AMPA also produced complete, dose-dependent and reversible transmission blockade, presumably by desensitization or depolarization. At 0.5 mM, the EAA antagonist g-D-glutamylaminomethylsulphonate (GAMS) prevented or reversed the antagonist action of KA in NM and NL but did not affect either synaptic transmission itself or the antagonist action of AMPA. Since these data rule out NMDA or KA receptors as mediators of synaptic transmission, we suggest that normal transmission in NM and NL is mediated by AMPA receptors, with KA receptors probably acting as modulators of transmission.

INTRACELLULAR RECORDINGS FROM CELLS IN THE RAT SUPERIOR OLIVARY COMPLEX (SOC) LABELLED WITH BIOCYTIN. M.I. Banks and P.H. Smith. Neurosciences Training Program and Depts. of Anatomy and Neuro-physiology, Univ. of Wisconsin, Madison, WI., 53706. Cells in the lateral superior olive (LSO) and the medial nucleus of the trapezoid

body (MNTB) are believed to be involved in computing interaural level differences as a cue for sound localization. We have recorded intracellularly from cells in the LSO and MNTB using 400μ brain slices from 3-5 week old hooded rats. Cells ere either injected with biocytin or the recording location was marked to verify their location.

LSO cells usually have linear current-voltage (IV) curves for both depolarizing LSO cells usually have linear current-voltage (IV) curves for both depolarizing and hyperpolarizing currents and high input resistances (typically > 70 M Ω). When stimulated with small sustained depolarizing currents, LSO cells often fire repetitively only after a long delay. At higher currents, a short latency spike is often followed by a pause, then a resumption of the discharge. Synaptic potentials can be evoked by stimulating both the ipsilateral trapezoid body (TB) and the TB at the midline. LSO cells have small, elongated somata (typically $24\mu \times 14\mu$) and long, thin, aspinous, bipolar dendrites often stretching >300 μ from the soma in the dorso-ventral direction and a significant distance rostro-caudally. One LSO cell whose axon could be followed a considerable distance had collaterals within the SOC. One cell injected in the hilus of the LSO that responded similarly to cells in the LSO had axon collaterals terminating in the medial superior olive (MSO).

Soc. One cell injected in the fulus of the LSO that responded similarly to cells in the LSO had axon collaterals terminating in the medial superior olive (MSO).

Principal cells in the MNTB respond to depolarizing current with only a single onset spike, have lower input resistances (typically <50MΩ) and IV curves that rectify for depolarizing current. Synaptic potentials can usually be elicited only by stimulating the TB at the midline. MNTB cell morphology resembles that of their principal excitatory inputs, cochlear nucleus bushy cells. The axon of one MNTB cell sent collaterals to the MSO and superior para-olivary nucleus, before entering the LSO.

PROPERTIES OF FETAL TECTUM GRAFTED TO ADULT AND NEONATAL

RAT INFERIOR COLLICULUS. M.C. Zrull and J.R. Coleman. Depts. of Psychology and Physiology, Univ. of South Carolina, Columbia, SC 29208 Whole fetal tecta were grafted to lesion sites in inferior colliculus (IC) of adult (HA) and neonatal (HP) rats. Under anesthesia, tecta were taken from Long Evans rat fetuses at 17 to 19 days of gestation, bisected, and the caudal half injected into lesion cavities in HA or HP conspecifics. Host were used in ne of three procedures: 1) HRP-WGA injection to medial geni-culate body (MGB) ipsilateral to graft (0.1 μi; 24 h); 2) white noise stimulation (85 dB, 1 h) following ³H-2-deoxy-glucose (200 μCi/100 g ip), and autoradiography; 3) postmortem tracing of graft connections with the carbocyanine dye Dil.

At 2 months post-implant, graft survival was 73% in HA and 80% in HP rats. In 60% of HA and HP tectal grafts neurons with fusiform somata, similar to discoid principal cells of normal central nucleus of IC (CNIC) were retrogradely labelled by HRP-WGA injections to MGB. Preliminary Investigation of autoradiograms indicated 75% of HA and 50% of HP rats showed differential activity in tectal grafts driven by auditory stimulation. At present only HP rats have been processed for DII tract tracing. In 75% of these hosts, Dil diffused along fiber tracts coursing rostrally and ventrocaudally from crystals placed directly in grafts located above remnants of host IC. The visualized tracts appear to correspond to the location of brachial and lemniscal fibers that exit and enter the normal rat IC and CNIC

Whole tectal grafts survive in both young and mature rat IC. The grafts contain neurons similar to normal CNIC cells that comprise the midbrain component of the central auditory pathway, and these neurons make connections with the target of CNIC in thalamus. Finally, early evidence suggests graft neurons receive afferents from lower brainstem nuclei and are responsive to auditory stimulation.

WITHDRAWN

CALBINDIN AND PARVALBUMIN REACTIVITY IN GRAFTED AND INTACT INFERIOR COLLICULUS. J.R. Coleman, B. Pinek*, M.C. Zrull, A.J. McDonald and K.G. Baimbridge. Depts. of Psychology, Physiology and Anatomy, Univ. of South Carolina, Columbia, SC 29208; Dept. of Physiology, Univ. of British Columbia, Vancouver, BC V6T 1W5.

The rat inferior colliculus is an excellent site for study of neura grafting into the central auditory system. Immunohistochemical labeling was used to identify major structural proteins in normal and graft tissues of the colliculus. Discoid and stellate neuron populations of the central nucleus were infrequently immunostained by calbindin, as were large portions of the core of graft tissue. Stellate and other neuron classes of dorsal and lateral cortex commonly labeled with calbindin as did graft margins. In contrast, discoid neurons in central nucleus and in graft tis were reactive for parvalbumin which labeled few neurons of the dorsal and lateral nuclei

Immunolabeling for tubulin-glutamate was pervasive in the inferior colliculus, but most intense in the central nucleus. Pure tone stimulation (8 kHz) enhanced activity of central nucleus tubulin-glutamate immunoreactivity in discoid and stellate neurons of the normal central

These results show that neuron immunoreactivity patterns for calbindin, parvalbumin and other structural proteins provide important markers for identifying architectonic features of host and graft tissue in the inferior colliculus.

DEAFENING DECREASES STAINING FOR THE NERVE TERMINAL PROTEIN NT75 IN AUDITORY NUCLEI. T.C. Ritchie, S. Angeli*, S. Anastaplo* and P.J. Abbas*, Depts. of Anat., Otolaryngol. & Head & Neck Surg., and Speech Path. & Audiol., Univ. of lowa, lowa City, IA 52242. NT75 is a 75 kD membrane protein concentrated in nerve terminals of selected CNS pathways including the auditory system. During development, NT75 staining in axons and then in nerve terminals of the auditory pathway correlates with synaptic penesis and the onset of hearing. In this study, NT75 staining was performed in deaf animals to determine the effect of lowering synaptic activity on the level of NT75 in auditory nuclei. For comparison, the synaptic vesicle protein synaptophysin was also localized. Animals (guinea pigs, rabbits) were deafened unilaterally by intracochlear injection of neomycin, or bilaterally by peripheral injection of kanamycin and ethacrynic acid. These ototoxic drugs deafen primarily by destroying cochlear hair cells. Brainstem auditory responses evoked by click stimuli were normal prior to the injections, but were markedly decreased or absent afterward. Immunocytochemical staining for NT75 with the S-7B8 antibody and for synaptophysin with the SY38 antibody was performed after survival periods of 3 days to 4 months. In normal animals, brainstem nuclei of the auditory system, including the cochlear nuclei (CN), the superior clive complex, the inferior colliculus (IC) and the medial geniculate nucleus, contain moderate to dense NT75 immunoreactivity. Three to 10 days after unilateral deafening, a small decrease in NT75 staining is detectable in the ventral CN lipsilateral to the deaf ear and in the medial nucleus of the trapezoid body on the contralateral side. In bilaterally deaf animals at longer survival periods (3-4 months), larger and more widespread decreases are seen, with decreases detectable between synaptophysin staining in deaf and normal animals. The results indicate that the level of NT75 staining of verticence is detectabl

CELLULAR GENERATORS OF THE BRAINSTEM AUDITORY EVOKED POTENTIAL IN CAT. I.R. Melcher*, B.C. Fullerton, I.I. Guinan, N.Y.S. Kiang, I.M. Knudson*, Eaton Peabody Lab., Mass. Eye and Ear Infirmary, Boston, MA 02114 and Dept. Elec. Eng., M.I.T., Cambridge, MA 02139.

We tested the hypothesis that individual peaks in the brainstem auditory

evoked potential (BAEP) are generated by specific cell populations. The BAEP (vertex to ipsilateral earbar) was recorded in barbiturateanesthetized cats before and after creating lesions in cochlear nucleus (CN) by injecting kainic acid which destroys cells near the injection site. Since different parts of the CN contain different cell populations, we could create different parts of the CN contain different cell populations, we could create lesions limited to specific populations by varying the injection site. The BAEP following N1 was virtually eliminated when a lesion involved almost all of the CN. When a lesion was confined to the dorsal (DCN) and posteroventral (PVCN) cochlear nuclei, there was no significant change in the BAEP. Lesions that included posterior AVCN, but largely avoided anterior AVCN (4 cases), resulted in greater changes in P2 than in P4. In one case P2 was reduced by 90% while P4 was unchanged. Furthermore, P2 was reduced by 90% while P4 was unchanged. Furthermore, P3 was reduced by 90% while P4 was unchanged. Furthermore, P3 was reduced by 90% while P4 was unchanged. Furthermore, P3 was reduced by 90% while P4 was unchanged. Furthermore, P3 was reduced more for the three cases with large posterior AVCN lesions than in reduced more for the three cases with large posterior AVCN lesions than in the one case with a small lesion. In contrast, lesions confined to anterior AVCN (2 cases) resulted in larger reductions in P4 than in P2. In one case, P4 was reduced by 48% and P2 by 13%. These results, combined with previous was reducted by 40% and 12 by 13%. I ness results, combined with previous measurements of single unit response latencies and our results for kainic acid lesions in the superior olivary complex, are consistent with three hypotheses: 1) DCN and posterior PVCN cells do not contribute significantly to the BAEP, II) globular bushy cells located in posterior AVCN are the primary generators of P2, and III) cells that receive projections from spherical bushy cells in anterior AVCN are major generators of P4. AUDITORY PONTINE GREY: CONNECTIONS AND RESPONSE PROPERTIES IN THE HORSESHOE BAT. E. Covey, I.H. Casseday and G. Schuller*. Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710 and Zoologisches Institut, Munich, Federal Republic of Germany.

To investigate the role of the pontine grey (PG) as a link between the auditory system and the cerebellum, we recorded response properties of single units in the PG and injected WGA-HRP in areas responsive to sound. The stimuli were pure tones and frequency modulated (FM) sounds. Retrograde transport identified two sources of auditory input to the pons: 1) The inferior colliculus, mainly the central nucleus, contained a large number of labeled cells; 2) An area of neocortex responsive to FM sounds contained some labeled cells. There was little evidence either of tonotopy or topographic distribution There was little evidence either of tonotopy or topographic distribution of binaural response types. Units responsive to pure tones had best frequencies that fell into one of two classes, both related to the harmonic structure of the biosonar signal: 1) near the first harmonic (35 kHz), or 2) near the second harmonic (78 kHz). Although all but 17% of the units could be driven by a pure tone, the most effective stimulus for 70% of all PG auditory units was some type of FM sound. Taken together, these results indicate that the PG processes specialized information about the biosonar signals used by this bat. CYTOMORPHOLOGICAL DIFFERENCE OF 2 TYPES OF FM CELLS IN THE RAT IC. P.W.F. Poon*, X.Y. Chen* and J.C. Hwang. Dept. of Physiology, Medical Faculty, Univ. of Hong Kong, Sassoon Rd., HONG KONG.

The cytomorphology of electrophysiologically identified inferior collicular (IC) neurons in the pento-barbital anaesthetized rat was studied using intracellular HRP techniques. Prior to the impalement and dye injection, extracellular activities of single units were analysed in terms of their response to triangular frequency modulated (FM) tones and pure tones. Of the 30 cells so labelled, 20 were 'mixed' (responded to both FM and pure tones), and 10 'FM specialized'

responded to FM but not pure tones), and 10 FM specialized (responded to FM but not pure tone).

All cells were multipolar with large dendritic fields. The 'FM specialized' cells showed profuse dendritic spines, whereas the 'mixed' cells were practically non-spiny. Results suggest that the cytomorphological difference may account for the functional specialization of FM cells.

MEDIAL AND LATERAL SUPERIOR OLIVES RECEIVE PROJECTIONS FROM THE MEDIAL AND LATERAL NUCLEI OF THE TRAPEZOID BODY. N.Kuwabara and J.M.Zook. Dept. of Zool. & Biomed. Sci. & COM, Ohio Univ., Athens, OH 45701.

The medial (MSO) and lateral (LSO) superior olives are the first cell The medial (MSO) and lateral (LSO) superior olives are the first cell groups of the auditory brainstem which show binaural interactions. The MSO receives excitatory inputs bilaterally from the ventral cochlear nucleus (VCN). The LSO receives excitatory input from ipsilateral VCN and inhibitory input from the ipsilateral medial nucleus of the trapezoid body (MNTB). The MNTB functions to relay signals from the contralateral VCN to the LSO. Histochemical and ultrastructural studies suggest that there are other sources of input to MSO and LSO in addition to the aforementioned major inputs (Clark '69, Schwartz '80, Cant '84).

We have characterized the axonal inputs to the MSO and LSO by intracellular recording and dye labeling of cells in the MNTB and in the lateral nucleus of the trapezoid body (LNTB). This work was based on a tissue slice preparation of the auditory brainstem using two bat species, *Pteronotus parnellii* and *Eptesicus fuscus*, as well as the mouse, *Mus musculus*, and the gerbil, *Meriones unguiculatus*. In addition to the main projection, axon collaterals from MNTB principal cells were traced to MSO cell soma. Axons from large cells in the LNTB formed perisomatic terminals in both the MSO and LSO. These findings suggest that the MSO and LSO may have similar local circuits and patterns of activity. (Supported by NIH Grants NS 26304, NS 01394 and the OUCOM)

PROJECTIONS OF SPHERICAL BUSHY CELLS TO MSO IN THE CAT: EVIDENCE FOR DELAY LINES. P.X.Joris*. P.H. Smith. and T.C.T. Yin. Dept. of Neurophysiology, Univ. of Wisconsin, Madison. In order to characterize projections of cochlear nucleus spherical bushy cells, we did intracellular recording and labeling of axons in the trapezoid body (TB) of the cat. Single fibers showing a primary-like or phase-locked response pattern were iontophoretically injected with HRP or biocytin, and their projection fields were reconstructed.

their projection fields were reconstructed.

Characteristic frequencies (CFs) of labeled fibers were biased to low frequencies. For CFs below 1 kHz, the degree of phase-locking was often much higher than that found in the auditory nerve. Spontaneous rate was high (mean: 60 spks/sec). The axons labeled were thin compared to globular bushy cell axons, and coursed in the dorsal component of the TB. Consistent projections were found bilaterally in MSO and ipsilaterally in LSO. The ipsilateral projection to the lateral limb of the LSO consisted of several branching collaterals from the main axon or from collaterals projecting to the insilateral MSO. Projective projecting collaterals projecting to the branching collaterals from the main axon or from collaterals projecting to the ipsilateral MSO. Profusely branching collaterals projected to the lateral side of the ipsilateral MSO and to the medial side of the contralateral MSO, spanning a considerable rostrocaudal extent. The contralateral projection gave off collaterals projecting caudally to the MSO. Their branching pattern is reminiscent of the delay lines proposed in Jeffress' model of azimuthal sound localization (Jeffress, J. Comp. Psychol., 41:35-39, 1948). Ipsilateral fibers showed a more variable pattern: the parent axon tended to give off axons anteriorly as well as posteriorly. A consistent contralateral projection was present to VNLL. Sparse projections were occasionally found in DMPO and the nuclei of the TB (LNTB, VNTB, MNTB).

The projections to MSO are consistent with extracellular MSO recordings (Yin & Chan, 1990, J. Neurophys., in press) showing a predominance of positive characteristic delays, indicating a longer conduction time for the contralateral input, at the caudal pole of the MSO.

PREVENTION OF DEAFNESS-RELATED SYNAPTIC CHANGES BY COCHLEAR PROSTHETIC STIMULATION. R.A. Altschuler, J.W. Horn*,

COCHEAN PROSTHETIC STIMULATION. H.A. Attschuler, J.W. Horri, E.A. Plattner*, and J.M. Miller. Kresge Hearing Research Institute & Dept. Anatomy & Cell Biology, Univ. of Michigan, Ann Arbor, MI 48109.

Studies have shown deafness-related changes in auditory nerve synapses with chemically induced and genetic deafness and acoustic deprivation (Gulley et al, 78; Rees et al, 85). Changes included flattening of the active zone and a decreased number of synaptic vesicles. Interestingly, such changes were not observed in the genetically deaf white cat (Larsen '88,89). We have investigated whether chronic stimulation with a cochlear prosthesis could prevent or reduce auditory nerve synapse changes in chemically deafened guinea pigs.

A cochlear implant was unilaterally placed in the scala tympani of adult guinea pigs. They were bilaterally deafened with systemic kanamycin and ethacrynic acid and then stimulated for 2 hr/day, 5 days/wk for 9 weeks. Evaluation of cochleae showed loss of the inner and outer hair cells and a large loss of spiral ganglion cells. In the rostral anteroventral cochlear nucleus (AVCN) contralateral to the implant, auditory nerve synapses on spherical cells had flattened active zones and a somewhat reduced number of vesicles. Other spherical cells completely lost their primary afferent input. In the rostral AVCN ipsilateral to the cochlear implant (stimulated side), most auditory nerve synapses on spherical cells had the normal pre-synaptic invagination and post-synpatic evagination of the active zone and numerous large round vesicles. Some active zones, however, were flattened and had a decreased number of vesicles. Occassionally a flattened active zone was seen in the same terminal as an active zone with normal morphology. Cochlear prosthetic stimulation therefore appeared to reduce but not completely prevent deafness related changes in auditory nerve synapses.

INTERACTIONS OF TWO NEUROPEPTIDES IN MODULATING THE CARDIAC SAC RHYTHM IN LOBSTERS. P.S. Dickinson. W.P. Fairfield* and E. Marder. Dept. of Biology, Bowdoin College, Brunswick ME 04011 and Dept. of Biology, Brandeis University, Waltham, MA 02254

Brandeis University, Waltham, MA 02254

In the intact stomatogastric nervous system of the spiny lobster Panulirus, the cardiac sac rhythm can be activated by application of either of two neuropeptides, proctolin or Red Pigment Concentrating Hormone (RPCH), to the stomatogastric ganglion (STG). However, when the STG is isolated, proctolin can no longer initiate a cardiac sac rhythm, although RPCH can still do so. If, however, proctolin is applied shortly after an RPCH application (but after the RPCH-induced cardiac sac rhythm has ceased), it does initiate a cardiac sac rhythm, suggesting the possibility that RPCH "primes" the proctolin response. In addition, both proctolin and RPCH cause an increase in the size of the PSPs from the IV cells, which drive the rhythm, onto the cardiac sac dilator neuron 2 (CD2). This increase is much more pronounced in RPCH than in proctolin and is dosedependent. When RPCH and proctolin concentrations are adjusted to give the same increase in PSP amplitude, a cardiac sac rhythm is still induced in RPCH but not in proctolin. These data suggest that, although both the increase in PSP amplitude and the initiation of rhythmicity involve the IV cells, they are separately controlled.

EVIDENCE FOR DOPAMINERGIC MODULATION OF CRUSTACEAN VENTILATORY PATTERN GENERATOR AND ITS ACTIVATION BY NICOTINE. K.P. Rajashekhar and J.L. Wilkens, Department of Biological Sciences, University of Calgary, Calgary, AB. TON INA. Canada.

AB, TZN 1M4, Canada.

Dopamine (DA) is known to elevate ventilatory rates in intact shore crab, Carcinus maenas. When perfused into isolated thoracic ganglia DA increases the burst frequency of the ventilatory pattern generator (CPG). Perfusion of domperidone, a potent dopamine D? receptor antagonist, first eliminates some motor units from bursts and after a few s depresses the frequency of the rhythm. This action is reversible. Nicotine which is known to release DA from neural tissue in mammals, dramatically enhances the burst rate in isolated ganglia, an action not elicited by acetylcholine or blocked by curare. The excitatory action of nicotine is reversed by domperidone and nicotine fails to activate the CPG in the presence of domperidone. The CPG recovers from domperidone induced depression when washed for several min.

depression when washed for several min.

These observations suggest that DA is involved in the generation and maintenance of the ventilatory motor pattern in crabs. Nicotine appears to activate this CPG through a dopaminergic pathway, while it stimulates the vertebratemedullary ventilatory rhythm via cholinergic pathways. Characterization of DA receptors is under progress. Supported by NSERC, Canada.

THE STRENGTH OF A SYNAPSE BETWEEN TWO NEURONS IN THE LOBSTER STOMATOGASTRIC GANGLION CAN BE CONTROLLED IN A GRADED MANNER N. Herterich and A.I. Selverston, Dept. of Biology, UC San Diego

We are developing a technique to control the strength of connections between neurons in a quantifiable manner over a broad range of numerical values. This technique will give us greater flexibility in "sculpting" circuits, enabling us to explore the relationship between circuitry and neural activity to a degree not previously possible. Our aim is to make predictions about the neural circuitry underlying neural function.

We report a simple means to successfully emulate the functional effects of a synapse between two cells in the pyloric CPG. We stimulate the PD cell with current pulses that are triggered by spikes in the LP cell, which normally makes a strong inhibitory synapse onto PD. The synapse can be blocked pharmacologically with picrotoxin (PTX), thereby increasing the pyloric pattern frequency. Hyperpolarizing pulses restore the cycle frequency, as well as the intracellular voltage timecourse in PD effectively mimicing the normal synapse. Conversely, depolarizing pulses delivered prior to PTX increase the pattern frequency to the same extent as PTX, and therefore effectively cancel the influence of the normal synapse. The pulses which cancel the synapse are the same amplitude as the pulses which mimic the synapse, but of opposite sign. The pulses are therefore functionally equivalent to normal synaptic input.

The strength of the connection from LP onto PD can be controlled by changing the amplitude of the pulses. The pattern period varies roughly linearly with pulse amplitude over a range at least twice as great as the pulse amplitude which is equivalent to normal synaptic function, and the slope of the relationship is independent of the presence of PTX. We conclude that pulse amplitude is a good measure of connection strength.

301.5

CONTROL OF THE CRUSTACEAN PYLORIC PATTERN GENERATOR BY AN IDENTIFIED MODULATORY NEURON: MODULATION OF BURSTING PROPERTIES IN PYLORIC NEURONS ISOLATED IN SITU. T. Bal*, F. Nagy and M. Moulins, Lab. Neurobiologic et Physiologic Comparées, CNRS, Univ. Bordeaux I. 33120 Arcachon France.

The pyloric central pattern generator (CPG) of the crustacean stomatogastric nervous system displays a spontaneous rhythmic activity, which depends on the intrinsic bursting properties of the pyloric neurons. It has been shown (see Nagy et al. in this issue) that this spontaneous activity is controlled by identified modulatory inputs from higher centers. A brief discharge of such a neuron (APM) induces a complex and long lasting alteration of the ongoing activity of the CPG. To better understand this complex effect, we study the neuromodulatory control exerted by APM on the bursting properties of individual pyloric neurons, by isolating them from their counterparts in the CPG (photoinactivation or pharmacological blockade of presynaptic neurons).

We found that: 1) APM controls the regenerative properties of every pyloric neuron but to different extent depending on the neuron. Thus APM discharge induces oscillations in all previously non oscillating neuron, but with a different latency for each neuron. Also, characteristics of oscill tions induced (period, plateau duration....) and duration of effects are different for each type of neuron. 2) A brief discharge of APM induces a prolonged increase in input resistance of isolated pyloric neurons, which could mediate the long term modulation of their bursting properties. This increase of input resistance is associated with a long lasting decrease of a K⁺ current.

Taken altogether, these different modifications of bursting properties of individual pyloric neurons, account for the complex changes of the pyloric motor pattern, provoked by APM's discharge when the network is intact.

AN ENDOSCOPIC ANALYSIS OF GASTRIC MILL MOVEMENTS PRODUCED BY THE PEPTIDE CHOLECYSTOKININ. M.E.T. Boyle*, G.G. Turrigiano, and A.I. Selverston. Dept. of Biology, UCSD, La Jolla, Ca 92093.

Turrigiano, and A.I. Selverston. Dept. of Biology, UCSD, La Jolla, Ca 92093.

The gastric mill of lobster is composed of three teeth in the stomach, two lateral and one medial, which masticate food. The neural circuit which controls movements of these teeth is highly flexible, and can be modulated by a number of neuropeptides, including cholecystokinin (CCK). There is evidence that an endogenous CCK-like peptide is necessary for the feeding-induced activation of the gastric mill, and injections of CCK into the haemolymph of intact lobsters can activate the gastric mill (G.G. Turrigiano and A.I. Selverston, 1990, Nature, in press). The goal of this study is to use an endoscope to observe and quantify the gastric mill movement natterns produced by CCK.

the gastric mill movement patterns produced by CCK. Intact lobsters were restrained, and an endoscope was inserted through the esophagus and into the cardiac sac (the stomach sac) until the gastric mill was in view. Peptides were dissolved in saline and injected into the dorsal heart sinus, and the resulting gastric mill movements recorded on video cassette. Injections of CCK (doese between 5 and 200 µg) were able to activate a quiescent gastric mill in 18 of 19 cases. In some preparations CCK was able to activate the cardiac sac rhythm as well. The most common chewing pattern produced by CCK was a "cut and squeeze" mode, in which the lateral teeth closed strongly (cut), opened while moving backward, and then closed again to meet the cusp of the medial tooth (squeeze). The "cut" phase of the chew was commonly associated with contractions of the cardiac sac. Several variations on this basic pattern were observed. This pattern differs from that produced by proctolin, as reported by Heinzel (J. Neurophy. 59:2, 1988) and as observed by us; proctolin produced either a "cut and grind" movement in which the lateral teeth remain closed as they move backward to meet the medial tooth cusp, or a "squeeze" mode in which there is no strong lateral tooth closure. We are currently quantifying and comparing the movement patterns produced by these two peptides.

CONFOCAL MICROSCOPY OF CRAB STOMATOGASTRIC NEURONS. D. Baldwin* and K. Graubard, Dept. of Zoology, University of Washington, Seattle, WA 98195.

Pylonic neurons of Cancer irroratus and C. borealis were injected with Lucifer Yellow, fixed and examined as whole mounts with a confocal microscope. Data were analyzed as serial images through the ganglion and as stereo pair reconstructions. In agreement with the electron microscopic results of D. King on Panulirus interruptus (J. Neurocytology 5:207-237, 1976), we find that the crab ganglion has a central core containing only major processes and a surround containing fine neurites, which is largely dorsal and lateral in the crab. Preliminary studies have not shown any sign of regional differences in the area of fine neuropil. Instead, pyloric neurons have branched widely, covering much of the peripheral neuropil with fine neurites.

Supported by NIH Grant NS25505.

COMBINED ENDOSCOPIC AND ELECTROPHYSIOLOGICAL RECORDINGS OF MULTIPLE STG RHYTHMS IN INTACT CRABS H.G. Heinzel and J.M. Weimann. Inst. of Zoology, Univ. Cologne, 5 Köln 41, FRG; Biology Dept., Brandeis Univ., Waltham, MA 02254.

A method was developed to correlate the motor patterns produced by the stomatogastric ganglion (STG) and the movements of the gastric mill of the crab Cancer radurus.

patterns produced by the stomatogastric ganglion (STG) and the movements of the gastric mill of the crab, Cancer pagurus.

An endoscope was inserted via the oesophagus into the stomach thus allowing video analysis of the movements of the gastric teeth. Intracellular recordings from STG neurons and extracellular recordings of the nerves exiting the STG were simultaneously displayed with the movements of the gastric teeth. These methods allowed elucidation of the role of many of the gastric motor neurons during ongoing behavior.

Intra/extracellular recording of the intact preparation were remarkably similar to the invito recordings. Importantly, many of the switches between CPGs seen in vitro (Meyrand et al.,1988 Neurosci Abs) produced relevant movements of the gastric mill. For example, the pyloric timed IC neuron not only controls the cardiopyloric valve but also cause the anterior movement of the lateral teeth during gastric activity. When the gastric IG neuron fires in pyloric time the lateral teeth produce a mixing movement possibly to stir the contents of the stomach.

Altshuler, E.*, Garfinkel, A., Segundo, J.P.,
Garfinkel, A., Segundo, J.P.,
Comp. Sciences &

Nonlinear Dynamics has clarified obscurities of pacemaker driving by periodic IPSPs. Preparations: crayfish SAO, simulated (e.g., v.d. Pol). Methods: Poincare sections, spectra, etc. RESULTS. a. POSTSYNAPTIC DISCHARGES MAY BE PERIODIC AND CHAOTIC; they also show INTERMITTENCIES, WALK-THROUGHS AND ACCELERATIONS. b. SITUATIONS MAY BE NON-STATIONARY along unchanging arrivals (apart from initial settlings). E.g.: cross-intervals vary even during invariant discharges; steady epochs alternate. c. BEHAVIOR DEPENDS ON PRE-SYNAPTIC AND ON POST-SYNAPTIC NONDRIVEN RATES. E.g.: chaos differ with fast or slow drivings; fast pacemakers accelerate because soma spikes re-excite rebounding trigger zones. CONCLUSIONS. The above, compatible with canonical formulations for non-linear oscillators, allows deeper, broader biological and formal under-standings. Achieved are norms for underlying mechanisms and testable hypothesis. Network comprehension benefits, for periodicity and arrhythmias pervade Physiology and Pathophysiology. SUPPORT: T.J. Wells, Jr., Inc.; UCLA Sch. of Medicine (BRSG), Department of Anatomy and Cell Biology.

EFFECTS OF AFFERENT STIMULATION AND OF LONG TERM

DEAFFERENTATION ON THE CRAB VENTILATORY MOTOR PATTERN GENERATOR (CPG). J.L.Wilkens, Biological Sciences, University of Calgary, Calgary, AB T2N 1N4, Canada Acutely deafferented CPGs produce coordinated rhythmic bursts of motoneuron spikes typical of the output in intact animals but at much reduced rates (120 vs > 400 bpm, resp.). Stimulating the mixed sensory/motor levator pages (110) increases hurst pages to intact levalor and can nerve (LN) increases burst rates to intact levels and can activate silent CPGs. LN stimulation also eliminates some motor units from both levator and depressor bursts.

Trains of stimuli reset and can entrain the CPG rhythm. Stimulation of the purely motor depressor nerve has no

effect on the rhythm.

The ability of LN stimulation to enhance burst rate decreases as afferent axons degenerate following gill bailer ablation. Five d after ablation LN effectiveness is reduced 50%; at 22 d there is no increase. At 60 d LN stimulation inhibits the rhythm and phase resetting by train stimuli is largely lost. After 6 mo the motoneuron collateral arborizations are reduced by half while the

Afferent input has both phasic and tonic influences on this CPG; however, this input is not necessary for long term stability of the motor program. Supported by NSERC of Canada.

MODELING THE PYLORIC RHYTHM OF THE STOMATOGASTRIC GANGLION. L. Abbott, T. Kepler, E. Marder and S. Hooper. Center for Complex Systems, Brandeis Univ., Waltham MA; Center for Neurobiology and Behavior, Columbia Univ., NY.

The pyloric network of the crustacean stomatogastric ganglion produces a three-component rhythm with approximately constant phase relationships over a wide range of frequency. In the network, the anterior burster (AB) cell, which acts as a pacemaker for the rhythm, exhibits a constant duty cycle (burst duration proportional to oscillation period) when its frequency is manipulated by external current injection. However, when current is injected into an AB cell which is isolated from the rest of the network, the AB bursts show constant duration (nonconstant duty cycle) as the frequency varies. Modeling studies are revealing the mechanisms by which network interactions are able to produce this modification of behavior which is vital for proper network function. REAL-TIME DISCREPANCIES IN THE CONTROL OF SLOW LOCOMOTOR ACTIVITY BY A CENTRAL PATTERN GENERATOR, Jeffery Lee Johnson, Dept. of Phys/Pharm., USD School of Medicine, Vermillion, SD 57069

Slow crawling movements in segmented vertebrates are regulated by a central network of interneurons which control the activity in small motoneurons which distribute to the body wall musculature. In order to understand how such a neuromuscular system operates, it becomes necessary to discern how the discharge rate initiated in the motoneuron by the central pattern generator(s) can be correlated with the slow contractile response. In this study it was learned that the slow contractile response in the longitudinal muscle of the earthworm over time could be described by a parabolic equation. Most importantly, the slope of the parabolic equation describing the end organ response could be precisely indexed to the amount of interneuronal tract fibers that were activated as well as the motoneuron discharge rate. The slope for the parabolic contraction curve displayed a 23X variation between the weakest and strongest response. Thus, the central network of interneurons may primarily fuction to control the place of the parabolic contraction graph in the and coron the slope of the parabolic contraction curve in the end organ merely by inducing slight changes in the motoneuron discharge rate. In addition, each given slope value for contraction finally attained a stable plateau level of tone which may be associated with a specifically indexed modifiction of the central pattern generator. THE HELISOMA "CYBERCHRON" NETWORK: IS IT PART OF THE FEEDING PATTERN GENERATOR? A. D. Murphy. Dept. of Biol. Sci., University of Illinois at Chicago, Chicago, IL 60607

A network of premotor neurons called the cyberchron and thought to drive and time the rhythmic activity of feeding motoneurons was described by Kater and colleagues. The cyberchron was supposed to excite retractor neurons and inhibit protractor neurons which then fired due to post-inhibitory rebound. There are three phases of activity in the standard buccal pattern and three pattern generator subunits (S1, S2, & S3) provide excitation to motoneurons active during each phase. S1 and S3 interneurons have been identified but not S2. S2 PSPs in motoneurons were attributed to cyberchron activity. However, rhythmically active cyberchron neurons may sustain rhythmic activity in the pattern generator without phase linkage to it and neuromodulators that activate the pattern generator do not activate monitored cyberchron neurons. I suggest that the "cyberchron" is an electrically coupled network of sensory neurons or modulatory interneurons that can trigger and sustain rhythmic activity in the buccal pattern generator. (Supported by NIH grant NS26145).

COMPUTER MODELING OF THE RESPIRATORY CENTRAL PATTERN GENERATOR (CPG) OF LYMNAEA USING HODGKIN-HUXLEY EQUATIONS. P.J. Kruk, N.I. Syed and A.G.M. Bulloch. Dept. of Medical Physiology, University of Calgary, Calgary, Alberta, Canada, T2N 4N1.

In vitro reconstruction of the respiratory central pattern generator (CPG) of <u>Lymnaea</u> was recently reported (Syed et al., 1989, Soc. Neurosci. Abstr. 15: 1047). This CPG is comprised of three identified interneurons: R.Pe.D1, Ip.3.I and V.D4. Inis CPG is comprised of three identified interneurons: R.Pe.DI, Ip.3.1 and V.D3. In the present study, using Hodgkin-Huxley-like equations we modeled the electrical activities of this network. When interconnected, the electrical stimulation of R.Pe.D1 elicits a series of alternating bursts of action potential in previously quiescent Ip.3.1 and V.D4. When cultured as single cells, both Ip.3.1 and V.D4 which are conditional bursters produced only a single burst of APs upon their electrical stimulation and no repetitive bursts were observed. R.Pe.D1, on the electrical stimulation and no repetitive bursts were observed. R.Pe.D.1, on the other hand is a low frequency pacemaker and the injection of depolarizing currents increases its firing rate. These intrinsic properties of identified neurons were modeled in the present study using three voltage-dependent membrane currents: (1) sodium, (2) potassium, and (3) a low-voltage-activated (LVA) Ca^{2r} current. In our model system Ca^{2r} current is relatively low, yet allows one AP to evoke another thus producing a burst. Channel inactivation leads to stepwise attenuation of this Ca^{2r} current with each AP, and eventually terminates the burst. Excitation is transmitted within this network by two mechanisms: (1) depolarization of the postsynaptic cell, and (2) postinhibitory rebound. Both mechanisms are simulated by the same set of differential equations. This suggests that just three currents (Na², K² and LVA Ca^{2r}) can account for some aspects of CPG activity. NEURONAL NETWORK GENERATING LAMPREY LOCOMOTION
- EXPERIMENTS AND SIMULATIONS - SUPRASPINAL, INTERSEGMENTAL, SEGMENTAL AND SENSORY MECHANISMS. S. Grillner, P. Wallén, L. Brodin, A. Lansner, Ö. Ekeberg and H. Traven, T. Matsushima and J. Christensson, Nobel Institute of Neurophysiology, Karolinska Institute and Computer Science Department at Royal Institute of Technology, Stockholm, Sweden The isolated nervous system of the lamprey, a lower vertebrate, can

produce the motor pattern underlying locomotion. Ventral root bursts alternate between left and right side in a range between 0.2-10 Hz in each segment (Wallén and Williams 1984, Brodin et al 1985). Along the spinal cord the segments are coordinated with a constant phase lag around 1% of the cycle duration (Grillner 1974) generating a rostro-caudal travelling wave. The motor pattern is elicited by reticulospinal projections (McClellan and Grillner 1984), and it is modulated by sensory input (Viana di Prisco et al 1989). A neuronal network of supraspinal, sensory and segmental neurones have been described in terms of connectivity, membrane properties and transmitters (Buchanan and Grillner 1987, Ohta and Grillner 1989, Viana di Prisco 1989, Wallén and Grillner 1987, Dubuc et al 1989, Alford et al 1989). It is shown by realistic simulation that the experimentally established network can account for the locomotor behaviour in the entire physiological range including the initiation, sensory modulation and the intersegmental coordination (see also Grillner et al 1988,1989). The connectivity can create a constant excitability gradient between adjacent segmental oscillator networks from a leading segment anywhere in the spinal cord. The significance of the different neuronal mechanisms for the operation of the network is evaluated.

Optical techniques can be used to identify neurons and their patterns of activity during rhythmic motor programs in the buccal ganglion of Aplysia. D. W. Morton, H. J. Chiel, J.-Y. Wu, and L. B. Cohen, Depts. of Biology and Neuroscience. Case Western Reserve University. Cleveland. OH 44106. Dept. of Physiology, Yale Univer. Sch. of Med., New Haven CT. 06510. and Marine Biological Lab., Woods Hole MA 02543. We have used optical techniques to observe the activity of buccal ganglion neurons.

rons in Aphysia californica during patterned activity induced by stimulating the esophageal nerve. Ganglia were stained with a voltage-sensitive absorbance dye. JPW 124 (2 mg/ml) dissolved in Aphysia L15. Extracellular activity from all six buccal neurons projecting from one side of the ganglion was measured while optical data were obtained from an array of 124 photodiodes (recording time: 16 seconds). Data were obtained from 6 different ganglia. Ganglia were then photographed in place to aid in cell identification Of these ganglia, one was selected for detailed analysis because its rhythmic pattern of activity most closely resembled that observed in isolated buccal ganglia not exposed to the dye. Action potentials were grouped using a template matching technique, and a total of 48 distinct neurons showing different patterns of activation were identified from the optical data. In order to identify projection neurons, extracellular action potentials on buccal nerves were grouped using the template matching technique. In each group, the time of occurrence of each extracellular action potential was used to search the optical time of occurrence of each extracellular action potential was used to search the optical record for the locations in the ganglion displaying action potentials. Using this technique it was possible to reliably associate intracellular optical activity with extracellular action potentials for several neurons (2 on buccal nerve 1. 6 on buccal nerve 2. 3 on buccal nerve 3. 1 on the cerebral-buccal connective). Furthermore, neurons with similar patterns of activity were found in similar locations in two other ganglia. Analysis of other nerves was complicated by the high level of activity on the extracellular record. We also determined the location of 19 neurons showing intracellular activity during the rhythmic pattern, but showing no obvious correspondence to the neural activity during the rhytimize pattern, but showing no obvious correspondence to the neural activity on the extracellular record. We conclude that, if a neuron has a large or distinctive action potential, and the extracellular record is not overly complex, optical techniques can be utilized to identify putative projection neurons and their dynamic pattern of activity during rhythmic motor programs. IN VITRO STUDIES ON THE INTRINSIC PROPERTIES OF RESPIRATORY CENTRAL PATTERN GENERATING (CPG) NEURONS OF LYMNAFA STAGNALIS.
K. Lukowiak, N.J. Sved, R.L. Ridgway and A.G.M. Bulloch. Department of

Medical Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

We recently reconstructed the respiratory CPG of Lymnaea in culture and described the network properties of this neural ensemble. In the present study we explore the intrinsic properties of these respiratory interneurons. The network that comprises the respiratory CPG of Lymnaea is composed of three interneurons: Ip.3.I, V.D4 and R.Pe.D1. Interneurons Ip.3.I and V.D4 contain FMRFamide, whereas R.Pe.D1 is dopaminergic. Ip.3.I and V.D4 are conditional bursters and have reciprocal inhibitory connections with each other. Weak mutual inhibitory connections also exist between R.Pe.D1 and V.D4. The dopamine cell inhibitory connections also exist between R.Pe.D1 and V.D4. The dopamine cell R.Re.D1 can initiate the respiratory rhythm by postinhibitory rebound excitation (PIR) of Ip.3.I. In turn Ip.3.I, in the presence of R.Pe.D1 activity, excites V.D4 by PIR and the cycle is repeated. Ip.3.I and V.D4 were cultured in vitro as single cells and their intrinsic properties were examined. Upon release from hyperpolarizing currents, both Ip.3.I and V.D4 fired only one burst of action potentials before becoming quiescent. Further trials with hyperpolarizing currents of even higher intensity failed to evoke the PIR in most cells tested. However, the presence of exogenous dopamine (applied via pressure pulses) decreased the threshold for PIR. Phasic application of dopamine evoked PIR in Ip.3.I, but not in V.D4. Similarly, phasic application of FMRFamide on V.D4 did not cause PIR in this cell. However, when both dopamine and FMRFamide were applied simultaneously at short intervals, V.D4 exhibited PIR. These results suggest that PIR plays an important role in this neural network and that both dopamine and FMRFamide are critically required for rhythm generation.

EXTRACELLULAR RECORDINGS FROM THE MOTORNERVOUS SYSTEM OF THE NEMATODE <u>ASCARIS</u>. <u>R.E. Davis and A.O.W. Stretton</u>. Department of Zoology and Neuroscience Training Program, Univ. of Wisconsin - Madison. Madison, WI 53706.

Previous intracellular recordings from <u>Ascaris</u> motorneurons and some interneurons revealed that these cells do not show the classical voltage-sensitive action potentials characteristic of other nervous systems (Davis, R.E. and A.O.W. Stretton, J. Neurosci., 9:415, 1989; Angstadt, J.D. et al., J. Comp. Neurol., 284:374, 1989). The existence of discrete EPSPs and IPSPs in some classes of motorneurons, however, suggests that spikes are probably being generated in presynaptic interneurons.

Extracellular suction electrode recordings made over the nerve cords and over muscle cells have revealed fast spike activity. There are two general categories of spikes associated with the ventral nerve cord of <u>Ascaris</u>: (1) small amplitude, short duration, relatively simple biphasic spikes and (2) larger amplitude, longer duration, typically complex multiphasic spikes. The small spike population can show a variety of patterns of firing activity, has been correlated with motorneuron PSPs, and is not correlated with intracellularly recorded ventral muscle events. It is likely that this population of signals originates in interneurons responsible for the motorneuron PSPs. The large spike population is correlated with intracellularly recorded muscle events and can be manipulated by polarizations of presynaptic motorneurons as would be expected if this population originates in muscle. Pharmacological experiments indicate that the spikes are Ca⁺⁺ based signals. We are in the process of further characterizing these various spike events and assessing their role in motory behavior

DEVELOPMENT OF SEROTONERGIC PROJECTIONS AND SEROTONIN-

DEVELOPMENT OF SEROTONERGIC PROJECTIONS AND SEROTONIN-INDUCED DEPOLARIZATIONS IN THE SPINAL CORD OF RAT EMBRYOS. L. Ziskind-Conhaim. and P.D. Newcomer*. Department of Physiology, University of Wisconsin, Madison, WI 53706. Development of serotonergic projections and motoneuron responses to serotonin (5-HT) were studied in isolated lumbar segments of the spinal cord of rat embryos. We determined the increase in 5-HT innervation using intracellular recordings and immunocytochemistry. 5-HT projections were first detected in the lateral and ventral functions. tions were first detected in the lateral and ventral funculi at 16-17 days of gestation. By Day 18, 5-HT fibers invaded the ventral horn and the intermedio-lateral column. At this stage, 5-HT application (10-50 μ M) induced membrane depolarizations <10 mV and spontaneous sub-threshold potentials. After birth, the number of 5-HT projections significantly increased around motoneurons, and 5-HT application generated membrane depolarizations >10 mV and high frequency spontaneous action potentials. These depolarizations were blocked by methysergide (20-50 μ M). In the continuous presence of 5-HT, the frequency of the spontaneous potentials was gradually reduced. 5-HT induced membrane depolarization was associated with either a small decrease (< 25%) or no measureable change in membrane conductance. Depolarizations evoked by 5-HT were unaffected by blocking presynaptic activity with high Mg²/low Ca² or TTX, which suggests that 5-HT acts on motoneuron membranes. Supported by NIH Grants NS23808 and NS01314.

BRAINSTEM GLUTAMATE RECEPTORS CONTROLLING

MUSCLE ATONIA AND LOCOMOTION.

Siegel. UCLA and VAMC, Sepulveda, CA 91343.

We have demonstrated previously that L-glutamate (Glut) participated in muscle atonia. We also found that electrical stimulation in rostral brainstem produced not only atonia but also locomotion. In the present study, we examined the effect of different Glut agonists on muscle activity in the decerebrate cat. NMDA and non-NMDA agonists microinjected into the same points within the inhibitory area of the pons and nucleus magnocellularis (NMC) produced opposite effect. Non-NMDA agonists produced muscle tone suppression, while NMDA produced muscle excitation and locomotion. This chemical effect was consistent throughout the survival period. In contrast, electrical and mechanical (by needle insertion) stimulation of these same points produced only atonia when administered within 10 h of decerebration, but produced atonia followed by locomotion when administered > 10 h after decerebration. We hypothesize that 1) non-NMDA receptors mediate muscle suppression, and that NMDA receptors participate in locomotion and muscle facilitation, 2) degeneration of axons severed by decerebration removes a net inhibition of the brainstem locomotor control system. Pathological dysfunction of these descending motor systems in the REM sleep behavior disorders may similarly disinhibit brainstem locomotor systems, and produce motor activity in response to the glutamate release of REM sleep.

302.5

BURSTING PATTERNS, IN VITRO, IN NEURONS WITHIN THE SWALLOWING AREA OF THE NUCLEUS TRACTUS **SOLITARII: ROLE OF ENDOGENOUS PROPERTIES. A. JEAN** and F. TELL*. Laboratoire de Neurobiologie fonctionnelle. CNRS URA 205. Faculté Saint-Jérôme 13397 Marseille Cedex 13. France.

The activity of nucleus tractus solitarii (NTS) neurons was recorded on rat brainstem slices within the swallowing area. Extracellular recordings showed that repetitive stimulation of afferent fibers, in tractus solitarius, elicited in some neurons a synaptic response followed by a burst of spikes (350-450 ms; 16-35 Hz). Under bath application of NMDA (30-120 µM), these neurons exhibited a pattern of rhythmic bursting characterized by trains of action potentials (400-450 ms; 30-35 Hz) occuring at a regular frequency (0.5-1.5 Hz). Intracellular recordings indicated that these rhythmic activities were subtended by endogenous properties : NMDA elicited TTX-resistant membrane potential oscillations with a voltage-dependent frequency. These findings suggest that some NTS neurons might have conditional pacemaker properties. The patterns of these bursting activities in vitro being very similar to those of swallowing neurons, it may be suggested that the endogenous properties of NTS neurons are involved in the generation of the swallowing motor activity.

MODULATION BY GLYCINE AGONISTS AND ANTAGONISTS OF THE EFFECTS OF NMDA AND L-HOMOCYSTEIC ACID IN THE HEMISECTED RAT SPINAL CORD PREPARATION F.Bruqqer*, M.F. Pozza*, U. Wicki*, H.-R. C G.E. Fagg. Res. and Dev. Dept., Pharm. Div. CIBA-GEIGY Ltd., CH-4002 BASEL/Switzerland.

The NMDA receptor is a multiple domain transmitter-gated neuronal membrane channel. The most potent antagonists currently defined for this repotent antagonists currently defined for this receptor are CGP 37849 (competitive), MK-801 (channel blocker), 7-chlorokynurenic acid (7CKA) and HA-966 (allosteric modulators), with K, values of about 35nM, 5nM, 0,2µM and 3µM as determined using receptor binding techniques. We have compared the actions of these substances on NMDA-and L-homocysteic (L-HCA) acid-evoked responses on the hemisected spinal cord preparation of the rat (extracellular root recordings). NMDA and Lrat (extracellular root recordings). NMDA and L-HCA evoked depolarizations of the ventral roots which could be potentiated by the addition of D-serine (a glycine like agonist). 7CKA ($10\mu\text{M}$), HA-966 ($100\mu\text{M}$) and CGP 37849 ($1\mu\text{M}$) antagonized the effects of NMDA and L-HCA (CGP 37348 > 7CKA > HA-966). Unlike CGP 37849, the antagonistic effect of 7CKA and HA-966 could be overcome by the addition of D-serine. Our results indicate that L-HCA induces its major effects in the spinal cord via an action at the NMDA receptor.

THE IDENTIFICATION OF GABAergic TRIGEMINAL PREMOTONEURONS. J.E. Turman. 1r.. S.H. Chandler and R.S. Fisher. Dept. of Kinesiology, Anatomy/Psychiatry and the Brain Research Institute, UCLA, L.A., CA. 90024.

A GABAergic innervation of the trigeminal motor nucleus is suggested from physiological studies which investigated the inhibition of masseter motoneurons

following peripheral and cortical stimulation. Following stimulation of the inferior alveolar, hypoglossal and masseter nerves an early and late hyperpolarization is observed in masseter motoneurons. The late hyperpolarization is blocked by a systemic application of picrotoxin suggesting that the hyperpolarization is due to GABA (Nakamura, Y. et al., <u>Brain Res.</u>, 57:29, 1973). Following repetitive stimulation of the masticatory cortex, rhythmical jaw movements are observed. Most of the hyperpolarization seen in the masseter motor neurons is blocked by strychnine, yet a residual component persists which is strychnine resistant (Enomoto, S. et al., Neurosci. Res., 4:396, 1987). This latter component is possibly GABAergic.

Neurosci, Res., 4:396, 1987). In slatter component is possibly GAAAergic. We initiated a series of experiments to identify GABAergic inputs to the trigeminal motor nucleus. A retrograde tracer, colloidal-gold bound WGA-HRP (gWGA-HRP) was injected into the trigeminal motor nucleus of male albino guinea pigs. Following a 72 hour survival time, the animals were transcardially perfused with 4% paraformaldehyde and 0.1% glutaraldehyde. GABA and GAD immunohistochemistry was performed using polyclonal antibodies. ABC histochemistry with DAB as a chromagen was used to label the immunoreactive complex. Neurons which contained the retrograde tracer and displayed a positive immunoreactivity were identified in the parvocellular reticular formation restrictional region surprefregational regions are given to mind trigenal projects. formation, peritrigeminal region, supratrigeminal region and spinal trigeminal nucleus oralis. Immunoreactive GABA and GAD cells, not containing the retrograde marker, were identified in the superior olive, nucleus of the lateral lemniscus, dorsal cochlear nucleus, trapezoid body, nucleus gigantocellularis, lateral reticular formation and spinal trigeminal nucleus interpolaris. We are providing anatomical evidence for the existence of GABAergic inhibitory trigeminal premotoneurons which contribute to jaw closure motoneuron hyperpolarization during reflex and centrally produced jaw movements. Funded by NIH-NIDR grant DE01693.

MODULATION OF THE ACOUSTIC STARTLE REFLEX AFTER DIETARY FALSE CHOLINE PRECURSOR NADE. M.-F. Wu, D. J. Jenden, M. D. Fairchild, R. S. Szymusiak, D. J. McGinty, and J. M. Siegel. Neurobiol. Res., VAMC, Sepulveda, CA 91343 & Depts. Psychiat., Psychol., & Pharmacol., UCLA, Los Angeles, CA 90024.

The role cholinergic systems play in modulating the startle reflex mechanism is unclear (Davis, M., Neurosci. Biobehav. Rev., 4:241, 1980). It was recently reported that rats treated with chronic diet of cholinergic false precursor N-amino-N,N dimethylaminoethanol (N-aminodeanol, NADe), which replaced 65-75% of the endogenous acetylcholine in certain brain regions, showed enhanced startle reflex (e.g., Newton, M. W., Crosland, R. D., & Jenden, D. J., Brain Res., 373:197, 1985). In the present study the acoustic startle reflex and its modulation by a preliminary stimulus (prepulse inhibition) was examined in the choline deficient NADe rats.

Veanling rats were fed ad libitum a choline free basic diet in pellet form. Either NADe chloride (experimental group, n=7) or choline chloride (control group, n=6) at a concentration of 35.8 mmol/kg was added to the diet. Startle tests were performed following 100-120 days of diet. The basal startle level was determined with a 20 msec noise pulse of either 115 or 100 dB (SPL). In half of the trials a 65 db noise pulse was presented 100 msec before the eliciting stimulus (prepulse trials). Basal startle level was facilitated by 160-200% in the NADe rats as compared to the choline controls Prepulse inhibition was greatly reduced in the NADe rats (12% reduction of basal startle level) as compared to the controls (75%). Reducing the intensity of the eliciti stimulus to 100 dB decreased the basal startle level of the NADe rats to about that of the controls with $115\ \mathrm{dB}$ but did not change the deficit in prepulse inhibition. It is concluded that cholinergic systems not only modulate the elicitation of the startle reflex but also play a role in prepulse inhibition of the startle reflex . (Supported by PHS grants MH17691 & MH43811 and the Medical Research Service of the Veterans Administration)

LOCOMOTION IN THE <u>IN-VITRO</u> MUDPUPPY (NECTURUS MACULATUS). <u>M. Wheatley*, M. Edamura*, R.B. Stein.</u> Division of Neuroscience, University of Alberta, Edmonton, Alberta, Canada,

Previous investigations have demonstrated the viability of the Mudpuppy as a suitable in-vitro model of vertebrate locomotion (Wheatley and Stein, Can. J. Physiol. Pharm. 67, 1989). Locomotion in which the in-vitro preparation is initiated by bath application of the excitatory amino acid N-methyl aspartate (NMA 100 μM). Further investigations on this isolated brainstem - spinal cord - forelimb preparation have shown that the locomotion in-vitro requires the presence of Mg²⁺ in the solution. The locomotor rhythm appears to require a basal level of glycine in the media and is potentiated by 1 µM glycine.

The mudpuppy shows many of the reflex responses commonly seen in higher vertebrates. In particular we have investigated the cutaneous reflex elicited with an electrical stimulus to the dorsal aspect of the foot. This reflex is modulated throughout the step cycle in both cats (Forssberg, J. Neurophysiol. 42:963-953) and humans (Yang and Stein, Soc. Neurosci. Abstr., 14:1303, 1988). The mudpuppy shows a similar reflex modulation. The most consistent response seen is an excitation of the elbow flexor muscle (Brachialis) during the swing phase and no response in the Brachialis during the stance phase. The response seen in the elbow extensor muscle (Extensor Ulnae) is less consistent but is also modulated. (M.W. is an AHFMR student, M.E. is an Alberta Parapelegic Foundation fellow, Research is supported by MRC of Canada.)

NMDA RECEPTOR ANTAGONISTS BLOCK BRAINSTEM-EVOKED LOCOMOTION IN DECEREBRATE CATS. J.R. Douglas*, X. Dai*, B.R. Noga and L.M. Jordan. Dept. of Physiology, Univ. of Manitoba, Winnipeg,

Noga and L.M. Jordan. Dept. of Physiology, Univ. of Manitoba, Winnipeg, Man. R3E 0W3.

The excitatory amino acid agonist NMDA has been implicated in the generation of locomotion in the frog embryo (Dale, N. and Roberts, A., J. Physiol. 348:527 (1984)), lamprey (Grillner, S. et al, TINS 10:34 (1987)) and newborn rat in vitro (Smith, J.C. et al, FASEB J. 2:2283 (1988)). The present study was designed to extend these findings to an adult mammalian preparation. Pre-collicular, post-mammillary decerebrations were performed on adult cats. An intrathecal cannula was inserted at the seventh lumbar segment and advanced rostrally under the dorsal roots for 2-3 segments. A string was tied around the twelfth thoracic segment securely enough to occlude the subarachnoid space. The mesencephalic locomotor region (MLR) was electrically stimulated (less than 200 µA) to produce locomotion as monitored by electromyograms in treadmill locomotion experiments or electroneurograms in fictive locomotion experiments.

The amplitude of hindlimb steps began to decrease within 20 minutes of intrathecal administration of the specific NMDA antagonist 2-amino-5-phosphono-valeric acid (APV) to the lumbar region of the spinal cord, with no changes in forelimb locomotion gradually rose in the first hour, until no hindlimb movements were seen even at high stimulation strengths. Full recovery was possible within 2 hours of APV administration. These results are consistent with previous findings that NMDA receptors play a role in locomotion. However, they do not indicate the mechanism of their involvement. Possible sites of action of NMDA include interneurons involved in the pattern generation circuitry, the last order interneurons which produce locomotor drive potentials in motoneurons, or the motoneurons themselves. (Supported by the Medical Research Council of Canada)

TRH AUGMENTS THE FREQUENCY OF RAT RESPIRATION IN VITRO IN BRAINSTEM - SPINAL CORD PREPARATIONS FROM NEONATES. D.F. Russell and M. Takenoshita*. Dept. of Anesthesiology, Washington Univ. Med. School, St. Louis, MO 63110.

The site of action of thyrotropin-releasing hormone (TRH) on the breathing rhythm is controversial. Modulation of respiratory rhythms by TRH was characterized using in vitro preparations from 0-2 d old Long-Evans rats that included the medulla and cervical spinal cord (MC), usually with the pons (PMC), or sometimes with the hypothalamus (HPMC). Fictive respiratory discharges were recorded from a phrenic nerve. The bath was always partitioned near $C_{2,3}$ for selective bath application of ~100 nM TRH and other agents to the brainstem. The action of TRH depended on the rhythm pattern. If it had stopped or consisted of single bursts at 8-20 s intervals, TRH restarted rhythmic bursting or accelerated its frequency in a marked tachypnea. Conflicting results came from fresh active preparations in which the rhythm pattern was episodic, consisting of 2-23 bursts at ~ 1 Hz with ~ 10 s apneas between episodes; TRH tended to slow the average burst frequency and convert the pattern to regular single bursts, in a seemingly "inhibitory" manner. This may be due to a performance ceiling of the in vitro preparation. To illustrate the inverse relation between TRH stimulation and the basal rhythm rate, 60-500 µM GABA or glycine was applied to the brainstem to experimentally slow the rhythm. Simultaneous application of TRH then consistently evoked 2-3x tachypnea in PMC preparations. Transection at the level of n.VI yielded MC preparations, which also showed tachypnea under 100-500 nM TRH. Removal of the cerebrum and transection at the optic chiasm left the hypothalamus attached; the effects of 100 nM TRH were not statistically different from those in PMC preparations. In sum, we obtained no evidence for a rostral tachypneic site of TRH action, but did confirm that TRH can augment the respiratory rhythm frequency at the level of the medulla. EXCITATORY AMINO ACID-MEDIATED RESPONSES IN THE PONTINE RETICULAR FORMATION OF THE RAT. D.R. Stevens. R.W. McCarley, and R.W. Greene. Dept. of Psychiatry, Harvard Medical School/VAMC, Brockton, Mass 02401.

The medial pontine reticular formation has been implicated as a site important in the induction of REM sleep and other behavioral processes. As a prelude to studies of the role of excitatory amino acids in synaptic transmission in the pontine reticular formation, we have examined the actions of excitatory amino acid receptor agonists on neurons in brain slices containing the pontine reticular formation.

Application of glutamate or more selective agonists led to depolarizations associated with inward current in 95% of the reticular neurons examined. Glutamate and N-methyl-D-aspartate (NMDA) treatment resulted in mixed conductance changes while kainate and quisqualate receptor agonists caused clear conductance increases. NMDA currents were voltage-dependent and were depressed in physiological concentrations (1.3 mM) of magnesium. Currents evoked by NMDA were blocked by the NMDA antagonist 2-amino-5-phosphonopentanoic acid (AP5, 40 uM). Currents activated by kainate and amino-3-hydroxy-5-methyl-4-isoxazoleproprionic acid, a quisqualate agonist, were voltage-insensitive and were blocked by kynurenic acid.

These results demonstrate the presence of the three subtypes of excitatory amino acid receptors on neurons of the pontine reticular formation. The responses associated with the actions of NMDA and non-NMDA agonists are similar to those reported for these agents in mammalian cortical and spinal neurons.

PHENTOLAMINE REDUCES MOTONEURON DEPOLARIZING RESPONSES TO LOCUS COERULEUS STIMULATION AND IONTOPHORETICALLY RELEASED NOREPINEPHRINE. S.J. Fung, I.Y.H. Chan, D. Manzoni and C.D. Barnes. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

It has previously been shown that synaptically (via electrical stimulation of the locus coeruleus, LC) and iontophoretically released norepinephrine (NE) induced spinal cord motoneuron (MN) depolarizations accompanied by enhanced excitabilities in cats. present work was aimed at determining an a-adrenergic role of NE-LC actions on spinal MNs of decerebrate cats. Placements of a stimulating electrode in the LC, with subsequent histological verifications, were aided by exploring the low-threshold sites for inducing EPSPs from antidromically identified lumbar MNs. Low intensity (15-150 µA) cathodal train stimuli (4-34 pulses at 500 Hz) were delivered to the LC while intracellular recordings plus extracellular iontophoresis of NE and phentolamine were made from MNs. In MNs with antidromic spike height above 60 mV, phentolamine (15-40 nA, 2-5 min) was found to significantly reduce the NE- (45-60 nA, 1-2 min) and LC-induced membrane depolarizations. Multiple discharges of MNs in response to LC stimuli, and NE in combination with subthreshold current injections, were both inhibited by concurrent phentolamine application. data indicate the involvement of α -adrenoceptor-mediated NE and LC activations of ventral horn MNs in cats. Supported by NIH grant NS 24388.

302.12

GABA-MEDIATED DEGLUTITIVE MECHANISMS IN THE RAT NUCLEUS TRACTUS SOLITARII (NTS). D. Bieger and Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland A1B 3V6

The role of central GABA neurons in swallowing is still poorly defined despite suggestive clinical evidence. In the present study, the GABA receptor antagonist, bicuculline (BIC) was used as a tool to characterize the role of solitarial GABA synapses in deglutitive control.

When applied to the NTS surface in urethane-anaesthetized rats BIC (5-200 picomol) evoked robust dose-dependent rhythmic complete swallows. Pressure ejection of BIC at solitarial sglutamate responsive loci in the subnuclei intermedialis and centralis gave rise to buccopharyngeal and oesophageal peristalsis, respectively, accompanied by an enhancement of glutamate-evoked responses. Furthermore, subthreshold BIC doses injected into the subnucleus centralis caused a transient disinhibition of primary deglutitive peristalsis of the esophagus, evident when buccopharyngeal swallowing was elicited by chemical (kainic acid or noradrenaline) or electrical stimulation of the NTS

We conclude that solitarial GABA neurons exert a tonic inhibition of the medullary deglutitive pattern generator and control buccopharyngeal - esophageal coupling.
Supported by MRC (Canada) ANATOMICAL EVIDENCE FOR AXON COLLATERALS OF BRAINSTEM NEURONS PROJECTING BILATERALLY TO AREAS IN AND AROUND THE TRIGEMINAL MOTOR NUCLEUS IN GUINEA PIGS. D.M. Phillips*, J.E. Turman, Jr., M.C. Woo*, T.V. Trank*, L.J. Goldberg and S.H. Chandler. Dept. of Kinesiology, School of Dentistry, and The Brain Research Institute, UCLA, L.A., CA 90024.

Previous anatomical and electrophysiological experiments from our lab suggest that trigeminal pre-motoneurons are distributed throughout the lateral reticular formation in the guinea pig brainstem. The present study was undertaken to determine if brainstem reticular neurons have axon collaterals projecting bilaterally to the trigeminal motor nucleus or areas adjacent to the motor nucleus. Retrograde fluorescent tracers were injected into the right and left trigeminal motor nucleus with either a Hamilton syringe or with a glass pipette via pressure. Red beads were injected into the left side, while either a 3% solution of fluorogold in saline or green beads were injected into the right side. Following a transcardial perfusion of 4% paraformaldehyde and post fixation in 4% paraformaldehyde and solutions of increasing concentrations of sucrose, the brainstem was cut from the obex through increasing concentrations of sucrose, the oranistem was cut from the obex infrough the inferior colliculus into 30µm sections using a freezing microtome. Labeled neurons were observed using an epifluorescent unit on a Nikon Optiphot microscope. Neurons containing red beads were found in clusters with neurons containing the other retrograde fluorescent tracer. These bilateral clusters were best observed in the parvocellular reticular formation, particularly in that portion around the caudal 1/3 of the facial motor nucleus and around the descending branch of the facial nerve. Occasional double labeled neurons were observed in these clusters of singly labeled cells. The clusters of singly labeled reticular formation neurons suggest that projections to areas in and around the trigeminal motor nucleus are primarily unilateral and allow for independent control of jaw musculature on the left and right sides. The double labeled neurons may be used in bilateral coordination of synchronous jaw movements, such as occurs in jaw opener muscles during reflex jaw opening, mastication or vocalization. Funded by NIH-NIDR grants DE 06193 and DE 04166.

NUCLEUS PREPOSITUS HYPOGLOSSI PROJECTS TO THE DORSOLATERAL PERIAQUEDUCTAL GRÂY (PAG): A LINK BETWEEN VISUOMOTOR AND LIMBIC SYSTEMS. G. Holstege¹, R.J. Cowie² and P.O. Gerrits^{1*} Depts. of ¹Anatomy Groningen, The Netherlands, and ²Howard University, Washington D.C.

The PAG forms part of the limbic system. Stimulation in the PAG elicits behavioral patterns used for defense in situations which represent a threat to the animals' survival (such as antinociception, postural and vocal signals and cardiopulmonary responses). Many neurons in the PAG project to the caudal brainstem and receive profuse afferent connections from various limbic structures. However, this is not true for the neurons in the dorsolateral wedge-shaped portion of the PAG (PAGdI). In order to clarify the role of this part of the PAG, it was injected with WGA-HRP in 4 cats to identify its connections. The injection-sites extended into the adjacent superior colliculus (SC). In all 4 cases, a specific group of labeled neurons was found in the contralateral prepositus hypoglossi nucleus (PPH) and ventrally adjacent reticular formation. To determine the exact dorsal midbrain target of these medullary neurons, 3H-leucine was injected into the PPH and adjoining areas in 3 additional cats. In these cases, a pronounced termination of labeled fibers was observed in the contralateral PAGdI, while other parts of the contralateral PAG were devoid of label. Only sparse labeling was found in the intermediate layer of the contralateral SC.

It has been shown that the PAGdI receives afferents from the deeper layers of SC, substantia nigra and various parts of the prefrontal cortex. However this specific PPH projection to the PAGdI has never been demonstrated. The PPH is known to be involved in control and adaptation of eve- and headmovements. The present results show that the PPH not only projects to visuomotor structures, but also to the PAG. This PPH-PAG connection may play a role in informing the limbic system about ongoing visuomotor activity.

FOS PROTEIN-LIKE IMMUNOREACTIVITY IN RAT AND CAT SPINAL NEURONES EVOKED BY PERIPHERAL ELECTRICAL STIMULATION.

Baralon*, H. Hultborn* and J.-P. Gossard. Dept. Neurophysiology, Univ. Copenhagen, DK-2200 Copenhagen, Denmark.
 The intracellular level of the translational product of the fos protooncogene may be enhanced by direct or synaptic activation of neurones. After electrical stimulation of peripheral nerves and spinal roots we evaluated the expression of fos-like immunoreactivity in the

roots we evaluated the expression of fos-like immunoreactivity in the dorsal and ventral horn of rat and cat spinal cord. Cambridge polyclonal primary antibody 0A-11-823 'fos-family' was used in both species.

Stimulation including both noxious and non-noxious afferents (20-50 xT at 10 Hz for 1 hour) gave rise to a fos nuclear labelling more densely distributed in the superficial layers and deeper regions of the dorsal horn, but to a lesser extent present also in the ventral horn and controlateral grey matter. These data support the results reported in the rat after other kinds of peripheral sensory stimulations. (Hunt, S.P., Nature, 328:632, 1987. Menetrey, D., J. Comp. Neurol., 285:177, 1989).

When we attempted a more selective activation of subsets of neurones in the intermediate zone and vertal horn (in stimulation of muscle group.)

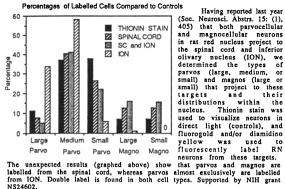

when we attempted a more selective activation or studeses or neurons in the intermediate zone and ventral horn (by stimulation of muscle group I afferents, by antidromic volleys in motor axons and by activating the long-latency long lasting flexor reflexes following i.v. administration of DOPA to acute spinal cats) the labelling of neurones in the intermediate zone and in the ventral horn was still present, while much fewer positive cells were seen in the dorsal horn (despite that the initial surgery must

cells were seen in the obtain north (despite that the initial surgery must have activated pain afferents).

These preliminary results show the possibility to extend the use of fos immunohistochemistry to the CNS of the cat. Furthermore they suggest the use of this technique as a tool in the investigation of cells not only involved in sensory pathways but also of neurones that are more directly part of the network underlying motor behaviour.

RE-DEFINING RAT RED NUCLEUS: CYTOARCHITECTURAL ANALYSIS OF RED NUCLEUS NEURONS SINGLY AND DOUBLY LABELLED FROM SPINAL CORD AND INFERIOR OLIVARY NUCLEUS.

C. L. Tucker* and P. R. Kennedy. Neuroscience Laboratory, Georgia Institute of Technology, Atlanta, GA 30332.

(Soc. Neurosci. Abstrs. 15: (1), 405) that both parvocellular and magnocellular neurons in rat red nucleus project to the spinal cord and inferior olivary nucleus (10N), we determined the types of parvos (large, medium, or small) and magnos (large or small) and magnos their distributions within the nucleus. Thionin stain was used to visualize neurons in direct light (controls), and

TELENCEPHALIC EFFERENT PROJECTIONS IN BUDGERIGARS. D.M.S. Webster. School of Rehabilitation Medicine, University of British Columbia (UBC), Vancouver, B.C., V6T 2B5.

Previous retrograde tracing studies have shown no differences in

British Columbia (UBC), Vancouver, B.C., - V6T 2B5.

Previous retrograde tracing studies have shown no differences in the origins of descending brainstem-spinal pathways, or supraspinal afferents to the medullary reticular formation in prehensile (parrots) compared to non-prehensile (duck, goose) birds that could account for the pedal dexterity of parrots. The purpose of this study is to extend those findings using anterograde tracers in other members of the parrot family, the budgerigar (Melopsittacus undulatus). Fluorescent anterograde axonal tracers fluorescein-conjugated dextran-amines (FDA) or rhodamine- conjugated dextran-amines (RDA) were injected (0.05-0.1 µL) into the intermediate archistriatum. Dense labelling of fibres and terminals was found in the diencephalon, tectum, nucleus intercollicularis, lateral mesencephalic reticular formation, locus coeruleus, dorsal and ventral subcoeruleus and caudal pontine reticular formation. In the medulla, labelling was largely confined to the parvocellular reticular nucleus, subtrigeminal nucleus and dorsal column nuclei. There was little or no labelling within the medial medullary reticular formation. At the level of the spinomedullary junction, labelling in the descending nuceus and tract of the trigeminal nerve and dorsal column was equivocal; there was no clear evidence of a fibre tract emanating from the archistriatum that descended into the spinal cord. These results confirm that there are little or no differences in the efferent projections onto brainstem reticular formation neurones the efferent projections onto brainstem reticular formation neurones in parrots, compared to previous reports in non-prehensile birds. Confirmation of other efferent projections from the hyperstriatum are being investigated. Supported by NSERC of Canada.

TERMINATION OF CORTICOSPINAL EFFERENTS WITHIN THE CERVICAL CORD OF NEW WORLD PRIMATES. G.A. Bortoff and P.L. Strick. VA Med. Ctr. and Depts. of Neurosurg. & Physiol., SUNY-HSC @ Syracuse, Syracuse NY, 13210.

Anterograde transport of 2-10% wheat germ agglutinin conjugated to horseradish peroxidase was used to examine the pattern of termination of efferents from the primary motor cortex within cervical segments of the spinal cord in cebus (Cobus acquired Cobus acquired Spinal Cord in cebus Cobus acquired Spinal Cord in Cobus Cobus acquired Spinal Cord in Cobus (Cebus apella) and squirrel (Saimiri sciureus) monkeys. We have compared the termination patterns in these monkeys because of marked differences in their manipulative abilities. Both primates have pseudo-opposable thumbs; however, only cebus monkeys use independent finger movements to pick up small objects. We found that cebus and squirrel monkeys differ in the extent of corticospinal terminations within the ventral horn. As others have noted, efferents from the primary motor cortex of squirrel monkeys terminate densely within the intermediate zone of the spinal cord and have, at best, only sparse terminations within the ventral horn. In contrast, our results show that efferents from the primary motor cortex of cebus monkeys have dense terminations within both the intermediate zone and the ventral The projection to the ventral horn in these monkeys is particularly dense at C8-T1 segments, where terminations form a 'ring' which encircles the lateral motoneuronal cell group. These observations provide further evidence for the concept that cortical projections to the ventral horn provide the neural substrate for independent movements of the fingers. Support: VA Med. Res. Serv. and Rehab. R&D; USPHS 2957, 24328.

PRIMARY AFFERENT PROJECTIONS FROM INTRINISIC HAND MUSCLES TO THE SPINAL CORD AND BRAINSTEM OF THE MONKEY.

D. L. Schulmann, C. L. Martin-Clinis* and C. J. Vierck.

Dept. of Neuroscience, University of Florida, College of Medicine, Gainesvile, Fl 32610.

The most severe and enduring sensorimotor deficit associated with dorsal column lesions is an inability to perform fine, coordinated finger movements. The intrinsic hand muscles, including the lumbricals, play an important role in these movements. We used WGA-HRP and free HRP placed into selected lumbrical muscles to study the organization of primary afferent terminations specific to these muscles. In one animal, tracer injection of a single lumbrical labeled terminals in a discrete column in lamina 9 of segments C7, C8 and T1 of the spinal cord gray matter, while more superficial ventral horn laminae and intermediate gray contained a diffuse pattern of labeling. In the brainstem, terminal patchy labeling was located within the main cuneate nucleus, but not the external cuneate. Unilateral injection of two separate lumbrical muscles in another animal resulted in two distinct patches of terminal labeling in the main cuneate. Supported by NS-17474 and NS-07261. free HRP placed into selected lumbrical muscles

THREE-DIMENSIONAL ANALYSIS OF DENDRITE DEVELOPMENT IN PHRENIC MOTONEURONS. W.E. Cameron, He F., P. Kalipatnapu and R.D. Guthrie. Department of Pediatrics, Magee-Womens Hospital and Center for Neuroscience, Univ. of Pittsburgh, PA 15213.

Fifteen kitten phrenic motoneurons labeled by intracellular injection of HRP were reconstructed using a personal computer and the Eutectic Neuron Tracing System. Five cells were analyzed in each of three postnatal age groups: 2 wks, 1 and 2 mos. We found no change in mean total surface area of phrenic motoneurons between 2 wks (68,224±10,135um²) and 1 mo area of phrenic motoneurous between 2 was (66,2851±11,373um²) while the surface area at 2 mos (123,879±22,487um²) was twice the area found at 1 mo. In contrast, the area of influence (defined by the surface covering the distalmost points of the terminal dendrites) increased throughout postnatal development. At 1 mo, the expansion of the dendritic field without a concomitant increase in total membrane surface area was achieved by an elongation of the dendrites and a reduction in the complexity of the dendritic tree. There was an increase in segment length of 4-6th order with a loss of most 7th and all 8th order dendrites at 1 mo when compared to 2 wks. Subsequent development (between 1 and 2 mos) was characterized by an increase in the numbers and lengths of the more distal segments (7-9th order dendrites). The mean dendritic diameter which had remained constant in early development was found to have increased in all segments of the dendritic tree between 1 and 2 mos. Analysis of the distribution of dendrites in three-dimensional space revealed an increase in the proportion of terminal branches found in the rostral and caudal hexants with age.

NUCLEUS RETICULARIS INTERMEDIALIS (NIR) CHOLINERGIC SOURCE SUBSERVING OESOPHAGEAL PERISTALSIS IN THE RAT. D. Vyas, Y.T. Wang and D. Bieger, Faculty of Medicine, Memorial University of Newfoundland, St. John's, NF A1B 3V6

Cholinergic mechanisms in the rat brainstem play a crucial role in the control of oesophageal peristalsis at the levels of both premotoneurons in the subnucleus centralis of solitary complex (NTS₂) and motoneurons in the compact formation of the nucleus ambiguus (AMB_e). In this study, the origin of cholinergic afferents to those neurons was investigated by the combination of retrograde tracing and ChAT-immunocytochemistry. Deposits of fluorogold into glutamate-responsive oesophageal loci in NTS, resulted in bilateral labelling of a discrete population of cells extending 200-300 µm medial and up to 600 µm rostral to AMB and corresponding to the nucleus intermedialis reticularis of the medulla. Most of the fluorogold-labelled cells were ChATimmunopositive. Smaller numbers of double-labelled cells were also revealed in the NIR after injection of fluorogold into the AMB_c. The present study implicates the NIR as a major cholinergic afferent input to the brainstem pattern generator for oesophageal peristalsis.

Supported by MRC (Canada)

ORGANIZATION OF THE MOTORPOOLS INNERVATING EPAXIAL MUSCULATURE IN THE MACAQUE. M. Kramer and T.W. Deacon. Biological Anthropology, Harvard University, Cambridge, MA 02138. Although much is known about the organization of the motorpools that innervate appendicular muscles, little is known about the innervation of axial musculature. Previous studies indicate interspecific differences in the organization of the motorpools that innervate dorsal neck muscles in the cat and the rat (Richmond et al., JCN. 181-451,1978; Abrahams & Keane, JCN, 223:448,1984; Callister et al., JCN, 255:369,1987). In this study the organization of the motorpools that innervate individual epaxial muscles in the macaque (M. fascicularis) is described. Approximately 2 µl of WGA-HRP was injected into five epaxial muscles: the ilicocatalis, the longissimus, and the transversospinalis (at thoracic and lumbar levels); as well as two tail muscles, the extensor caudae lateralis and medialis (ECL and ECM). The spinal cords were serially sectioned and the tissue was processed with TMB. For each injection a single composite diagram illustrating the locations in the ventral horn (VH) of all the HRP-labelled motoneurons was constructed.

Motoneurons that innervate the individual epaxial muscles are found in localized regions within the ipsilateral VH. The transversospinalis motorpool is confined to the extreme medial border of the VH. The longissimus motorpool is centrally located in the ventral third of the VH and extensions that increase the language of the contraction of the ventral third of the VH.

motopool is confined to the extreme medial border of the VH. The longissimus motorpool is centrally located in the ventral third of the VH and extends into the tip of the VH. Motoneurons that innervate the iliocostalis are found along the lateral border of the ventromedial nucleus. The motorpools of the longissimus and iliocostalis muscles exhibit a small amount of overlap. The motorpools that innervate the tail muscles, ECL and ECM, are the direct caudal continuations of the motorpools that innervate the longissimus and transversospinalis, respectively. These results in the macaque are similar to those reported in the rat (Brink et al., Brain Res., 170:23,1979; Smith & Hollyday, JCN, 220:16,1983).

FLUORESCENT DYE LABELLING OF NEURONS IN THE MESENCEPHALIC NUCLEUS IN PIGS AND FERRETS. R. E. Druzinsky, S. W. Herring, T. J. Drolsum, and E. H. Polley. Depts. of Oral Anatomy, and Anatomy and Cell Biology, Univ. of Illinois, Chicago, IL 60612.

The cell bodies of primary and secondary afferents from spindles of the jaw adductor muscles are found in the mesencephalic nucleus of the fifth nerve (Mes V). In order to map the positions of cell bodies in preparation for electrophysiological studies in the Mes V and trigeminal motor nucleus, dyes were injected into the masseter muscle in pigs (Sus scrofa) and ferrets (Mustela putorius furo). Although Fast Blue (Sigma F-5756, 2.5% sol.) and TRITC (Sigma T-2018, 2.5% sol.) were tried, the most consistent labelling was obtained using Fluoro-Gold (2-5% sol.). In both species cells were labelled throughout the entire rostro-caudal length of the Mes V. The labelled cells exhibited a variety of cell types, including some which are clearly multipolar. Our results are consistent with the findings reported in other recent studies of the Mes V (e.g., Gottlieb, et al., J. Comp. Neurol., 228:273-283, 1984, in cats) and demonstrate that the topological arrangement of primary afferents from the masseter in two members of the Carnivora studied (cats and ferrets) is similar to the arrangement found in the pig, a member of the Ungulata. Supported by NIDR NRSA DE05562 to R.E. Druzinsky.

HETEROGENEITY OF THE MORPHOLOGY OF SINGLE VESTIBULOSPINAL COLLATERALS IN THE UPPER CERVICAL SPINAL CORD OF THE CAT.

A. Donevan, S. Vohra* and P.K. Rose, Department of Physiology, Queen's University, Canada, K7L 3N6.

Recent studies using the anterograde tracer PHA-L have demonstrated that the funicular paths and terminations of vestibulospinal axons projecting to the upper cervical cord are more extensive than had been appreciated using classical neuroanatomical techniques. Following PHA-L injections into regions of the medial and descending vestibular nuclei, boutons were observed bilaterally in lamina II through IX. The goal of the present study was to determine the contribution of individual collaterals to this widespread projection.

The structure and bouton distribution of single PHA-L labelled collaterals arising from axons travelling in the reconstructions. Some collaterals had one termination zone in a small region of the ventral horn or intermediate zone. Although the termination zones of some of these collaterals overlapped, no two were identical. Other collaterals projected to several discrete sites. sites included small regions as dorsal as lamina IV and as ventral as lamina IX. The unexpected structural diversity of vestibulospinal collaterals suggests that vestibulospinal cells, even those whose axons travel in the same funiculi, may serve different functions. (Supported by MRC).

IS THE ROLE OF THE TECTOSPINAL TRACT IN THE CONTROL OF HEAD MOVEMENT OVERRATED? P.K. Rose, J. MacDonald* and V.C. Abrahams, Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

The tectospinal tract (TST) together with the

The tectospinal tract (TST) together with the tectoreticular spinal system provide two routes by which the superior colliculus can influence the activity of neurons in the upper cervical spinal cord and hence, play a role in the control of head movement. In the present experiments we re-examined the projections of TST neurons using the anterograde tracer PHA-L. Despite the proven sensitivity of this technique, PHA-L labelled axons and collaterals in the upper cervical spinal cord were sparse following two or more injections of PHA-L in the superior colliculus. All labelled axons and collaterals found were contralateral to the site of injection. In agreement with previous studies, boutons were found in the lateral part of laminae VI and VII. Unexpectedly, boutons were also found in the medial part of laminae VII and VIII with most in lamina VII. Boutons belonging to single collaterals were usually clustered in a small zone and thus, only occupied a small fraction of the grey matter receiving TST projections as a whole. These results suggest that the TST plays little or no direct role in the control of head movement, but may influence the activity of neck motoneurons via a selective action on a small number of segmental interneurons. (Supported by MDAC).

EXTENSIVE AXON COLLATERALS REVEALED BY INTRACELLULAR NEUROBIOTIN OR HRP SUGGEST SPINAL INTERNEURONAL FUNCTIONS FOR SACRAL PGN.

C.W. Morgan, W.C. deGroat, S.J. Zhang*, and
L.A. Felkins* Depts.Anatomy and Neurobiology, and
Urology, Eastern Virginia Med. School, Norfolk, VA 23501.

The morphology of sacral preganglionic neurons (PGN) in the cat was examined using intracellular injections of neurobiotin or HRP. Among 21 filled PGN extensive axon collaterals from parent axons were identified in laminae I, V, VII, VIII, X, and the lateral funiculus bilaterally and in lamina IX ipsilaterally. Labeled boutons were located in proximity to: (1) areas of visceral primary afferent termination, (2) the soma and dendrites of PGN, (3) interneurons near the central canal, (4) motoneurons and interneurons in the ventral horn, and (5) descending axons in the lateral funiculus. Patterns and locations of boutons suggested that a single PGN could directly contact as many as 40 neurons in the cord. These results indicate that PGN have integrative, interneuronal functions in the central nervous system in addition to their traditional efferent role of conveying information to ganglion cells in the peripheral nervous system. SOURCES OF NORADRENERGIC AFFERENTS TO THE HYPOGLOSSAL NUCLEUS IN THE RAT. <u>L.D. Aldes</u>, Department of Structural and Cellular Biology, University of South Alabama, College of Medicine, Mobile, AL 36688

The hypoglossal nucleus (XII) in rat receives a topographically organized noradrenergic (NE) projection that terminates preferentially among protrusor motoneurons in the caudoventromedial quadrant (Aldes et al., Brain Res. Bullet., 21:305-312, 1988). The present study investigated the source(s) of this innervation with double-labeling histochemical/immunocytochemical and lesion/degeneration methods. Following injection of WGA-HRP into XII, sections through the rostral pons (RP) were reacted with tetramethylbenzidine (Mesulam, J. Histochem. Cytochem., 26:106-117, 1978), stabilized with DAB-CoCl₂ (Rye et al., J. Histochem. Cytochem., 32:1145-1153, 1984), and incubated in antisera to tyrosine hydroxylase (TH-Aldes et al., Brain Res. Bullet., 21:305-312, 1988). Double labeled-neurons (HRP+/TH+) were found in the nucleus subceruleus (nSC-63%) and A7 (24.6%) and A5 (12.3%) cell groups (N=68 neurons). The projections were mainly ipsilateral. Confirmation of these data and identification of the course taken by descending NE-XII projections was accomplished by placing lesions in the RP or in the medullary catecholamine bundle (MB). After 6-18 days survival, a marked decrease in TH immunoreactivity was observed ipsilaterally in XII that was most pronounced caudoventromedially. These results demonstrate that NE-XII afferents are derived from multiple cell groups in the RP, descend the brainstem in the MB and terminate topographically in XII. That the nSC provides a substantial NE innervation to XII is consistent with a recent report that the nSC projects to XII and terminates in the same pattern as NE (Aldes, J. Comp. Neurol., in press). On the basis of these data, coupled with findings in other cranial nerve nuclei (Grzanna et al., J. Comp. Neurol., 263:76-91, 1987), it is proposed that NE cell groups in the RP comprise part of an integrative network involved in controlling oral motor behavior. Supported by NIH grant NS-22686.

PROJECTIONS FROM THE LATERAL VESTIBULAR NUCLEUS TO THE UPPER CERVICAL SPINAL CORD OF THE CAT - AN ANTEROGRADE TRACING STUDY USING PHA-L. K. Wainwright*, M. Neuber-Hess* and P.K. Rose, Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.
Use of the sensitive anterograde tracer PHA-L has

Use of the sensitive anterograde tracer PHA-L has recently shown that spinal projections originating from the medial and descending vestibular nuclei terminate in regions of the spinal cord previously not thought to receive direct vestibulospinal input. In the present experiments, we have extended these studies to include the spinal projections from the lateral vestibular nucleus (LVN). Injections of PHA-L in the LVN labelled similar number of axons in the medial vestibulospinal tract (MVST, bilateral) and lateral vestibulospinal tract (LVST, ipsilateral) at the Cl/C2 junction. Many boutons were found in laminae VIII and IX and the ventral part of lamina VII ipsilateral to the injection site. Contralateral projections were sparse and the boutons were widely scattered in laminae V through IX. More caudally (C3/C4 junction), few boutons and axons were found contralaterally. Ipsilaterally, the number of axons travelling in the MVST was smaller, the frequency of axons in the LVST was unchanged, and the number of boutons decreased. These results indicate that descending axons from the LVN take a variety of routes in the upper cervical spinal cord, but the major termination zone is in the ipsilateral ventral horn of Cl and C2. (Supported by MRC).

AFFERENT CONNECTIONS OF THE PARVICELLULAR RETICULAR FORMATION, STUDIED IN THE RAT BY ANTERGGRADE AND RETROGRADE TRANSPORT METHODS. S.J.Shammah-Lagnado*,M.S.M.O. Costa*,S. Nicastri* and J.A.Ricardo. Dept. of Physiology, Inst. Biomed. Sci.,Univ. of São Paulo,01000 São Paulo, SP,Brazil.

The afferent connections of the parvicellular reticular formation (RFp) were studied in the rat with either HRP or WGA-HRP tracer techniques; tetramethylbenzidine was the chromogen. Injections of the tracers into the RFp led to retrograde labeling in several structures that included the primary somatosensory and motor cortical areas, the granular insular cortex, the central amygdaloid nucleus, hypothalamic districts, the field H₂ of Forel, the superior colliculus, the central gray substance, the red nucleus, mesencephalic and magnocellular pontomedullary reticular structures, the contralateral RFp, the lateral, 'dorsolateral hump' and medial cerebellar nuclei, the supratrigeminal region, the vestibular complex, the nucleus of the solitary tract and the spinal cord. Deposits of WGA-HRP in several territories, that included the above-mentioned cortical and cerebellar structures, the central amygdaloid nucleus, several reticular districts, and the principal and spinal trigeminal nuclei, gave rise to anterograde labeling in the RFp. The present results may contribute to the elucidation of the anatomical substrate of the functionally demonstrated involvement of the RFp in several domains that conspicuously include forms of oral behavior. (Supported by FAPESP, FINEP and CNPq grants.)

AFFERENTS AND EFFERENTS OF A HEAD MOVEMENT AREA IN THE PONTOMEDULLARY RETICULAR FORMATION OF THE MACAQUE. R. J. Cowie, D. L. Robinson, G. B. Stanton, and M. K. Smith.* Department of Anatomy, Howard University, Washington, D.C. and Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Little is known about the supraspinal centers for the control of head movements and the interconnections of such areas. We investigated the organization of head movements by electrically evoking them in awake monkeys and then injecting WGA-HRP into physiologically defined areas. Three monkeys were studied. We identified a region within the medial pontomedullary reticular formation where stimulation with currents of less than 40 µA would reliably evoke head movements. Horizontal, vertical, as well as tilting movements were elicited. This region was bounded by tissue where stimulation evoked ear, mouth, snout, shoulder, and arm movements. The head movements were saccade-like. The amplitude of head movements was dependent on the initial starting position as well as current intensity.

At physiologically identified head movement sites, we microinjected WGA-HRP. Retrogradely-labeled cells were located in the head and face regions of frontal cortical areas 4 and 6, the deeper layers of the superior colliculus, and the cervical spinal cord. Orthograde transport was found in the spinal cord, rostral interstitial nucleus of the medial longitudinal fasciculus, and interstitial nucleus of Cajal.

We conclude from these experiments that signals which originate within the deeper layers of the superior colliculus and motor cortices impinge on this head movement center. After integration within this area, such signals are transmitted to neck motoneurons as well as other premotor centers for the generation of ballistic head movements.

AN OPEN FIELD ACTIVITY ANALYSIS OF UNILATERALLY LABVRINTHECTOMIZED RATS. J.D. Porter, S.M. Pellis, M.E. Meyer. Dept. of Psy., Univ. of FL, Gainesville, FL 32611. Classification of the neural deficits such

Classification of the neural deficits such as vestibulo-ocular and vestibulo-motor deficits following destruction of one of the labyrinths is a common experimental theme. This study provides a detailed analysis of the behavior of unilaterally labyrinthectomized rats. Labyrinthectomies were performed by injecting sodium arsanilate (Abott, 100 mg/ml 0.9% saline) intratympanically into the middle ear cavity of 20 animals (10 left, 10 right). Two days following surgery the animals were placed into a Digiscan Activity Monitor where their behaviors were automatically scored and placed into twelve individual categories. Compared to control, the labyrinthectomized animals spent a significantly greater amount of time in motion and in repetitive behavior. The hyperactivity and stereotypy of the labyrinthectomized animals appears to reflect their inability to adequately explore the novel environment.

DYNAMIC POLARIZATION VECTOR OF OTOLITH NEURONS. D.E. Angelaki. Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455.

The study of the dynamic properties of otolith vestibular neurons has been difficult previously because of the differing response sensitivities of individual fibers to specific stimulus directions. A method for estimating both the spatial and temporal properties of neurons like the otolith afferents that are spatially tuned to different stimulus directions is presented. At each stimulus frequency, a response ellipsoid can be constructed from the neural responses elicited by stimulation along three linear independent axes. The response ellipsoid then predicts the gain and phase properties of a neuron at the same frequency along any other direction in the three dimensional space. The gain of the neuron for stimulation along any axis is represented by the intersection of that axis with the surface of the ellipsoid. The phase during stimulation along that axis can also be estimated from the parametric equations of the ellipsoid. Further, the major axis of the ellipsoid will specify the direction of maximum sensitivity (polarization vector) of the neuron, while the minor axes will provide the neural sensitivity in the perpendicular (null) directions. The predictions of the method for non-zero lengths of the minor axes (i.e., broadly tuned neurons) is qualitatively the same with the experimentally observed dependance of response phase on stimulus orientation (Baker et al., Brain Res., 294:138, 1984; Bush and Perachio, Soc. Neurosci. Abstr., 14:330, 1988). Supported in part by Shevlin and A.P.Anderson fellowships, Univ. of Minnesota.

GLUTAMATE-LIKE IMMUNOREACTIVITY IN VESTIBULO-OCULAR CELLS IN GERBILS, G.A. Kevetter, R.D. Hoffman*, Dept. Otolaryngology and Anatomy and Neurosciences, Univ. TX. Med. Br., Galveston, TX 77550.

Med. Br., Galveston, TX 77550.

Cells in the vestibular nuclei that project to the oculomotor nuclear complex and also stain for the excitatory amino acid neurotransmitter, glutamate, were studied. Gerbils were anesthetized with pentobarbital and ketamine. HRP was injected stereotaxically into the oculomotor nuclear complex. After 48 hours, the gerbils were reanesthetized and perfused. Sections, 30 μm thick, were reacted with an intensified nickel acetate diaminobenzidine procedure that stained retrogradely transported HRP black. The sections were then incubated with rabbit antiglutamate (Chemicon 1:200; 1.500; Arnel 1:10,000) antibodies for twenty-four hours. The sections were then incubated using an avidin-biotin-peroxidase procedure, and reacted with diaminobenzi-dine producing a brown product. Retrogradely labeled cells were found in the medial (M) and superior (S) vestibular nuclei and cell group Y. Cells labeled with glutamate-like immunoreactivity (GLU-lir) were found in all major vestibular nuclei. Cells labeled with both HRP and GLU-lir were found in M, S, and cell group Y. More than half of the HRP labeled cells in the M contralateral to the injection site were also GLU-lir. Less than half of the retrogradely labeled cells in the S ipsilateral to the injection site were stained with GLU-lir. (Supported by a John Sealy and Deafness Research Foundation grant).

SEMICIRCULAR CANAL HAIR CELL RESPONSE TO ACh A. Ricci*, C. Norris, P. Guth. Departments of Otolaryn-gology, Pharmacology, and the Neuroscience Training Program, Tulane University, New Orleans, LA 70112-2699 Acetylcholine (ACh), the major efferent transmitter of the vestibular end organ, elicits a biphasic response from hair cells as measured in the afferent nerve endings of an isolated semicircular canal preparation. The calcium dependency and voltage dependency of the response were studied. In one set of experiments calcium was replaced by magnesium, in another calcium channels were blocked with diltiazem, Cd or Co respectively. The ACh response was not affected by any of these manipulations indicating that ACh can cause the release of intracellular stores of calcium. A constant DC field was used to demonstrate the lack of voltage dependence of this ACh response, supporting the hypothesis of intracellular release of calcium. Other experiments have shown ACh to preferentially increase spontaneous afferent firing over mechanically evoked firing. It is therefore suggested that the regulation of free intracellular calcium is critical in determining the level of afferent nerve firing. The mechanisms involved in regulating this concentration vary for spontaneous, mechanically evoked and ACh induced afferent nerve firing. (This work was supported by grant USPHS-DC 00303.)

304.4

DYNAMIC RESPONSES OF MEDIAL VESTIBULAR NUCLEUS NEURONS TO HEAD ROTATION AND TRANSLATIONAL MOTION. G.A. Bush, A.A. Perachio, Depts. of Otolaryngology and Physiology & Biophysics, Univ. TX Med. Br., Galveston, TX 77550. We have previously demonstrated that type I and type II medial

vestibular nucleus (MVN) cells may also exhibit responses to timevarying translational head acceleration. In those studies, responses to horizontal head rotation were only qualitatively described. We have now characterized, quantitatively, the dynamic responses of both types of MVN neurons in decerebrated rats to single harmonic frequency head acceleration in the form of rotations in the plane of the horizontal semicircular canals and to purely linear accelerations in the same head plane or off-vertical axis constant velocity rotation. Horizontal canal-related MVN neurons were identified by their responses to electrical stimulation of the ipsilateral vestibular nerve and to horizontal head rotation at 0.05, 0.1, 0.5, 1.0 and 2.0 Hz (50 deg/sec peak velocity). Linear head acceleration was applied in different vectors spaced at 30° intervals across the horizontal head plane and at single frequencies ranging from 0.2 to 1.4 Hz, peak acceleration 0.1g. For type I neurons that responded to linear acceleration, responses to head rotation were characterized by decreasing gains and increasing phase lags re velocity with increasing frequency (0.1 to 1.0 Hz mean gain difference = -6.0 dB, mean phase at $1.0 \text{ Hz} = -32.2^{\circ}$). For cells without otolith input, over the same rotation frequency range, gains increased (mean gain difference = +3.6 dB) and phase leads decreased (mean phase angle at 1.0 Hz = -9.2°). Though the sample size is at present small for type II cells, the same frequency dependent effects were not observed. (Support by NIH DC00385, NASA NAG 2-26 and NGT-50165).

PHYSIOLOGY AND BRAINSTEM MORPHOLOGY OF SINGLE HORIZONTAL SEMICIRCULAR CANAL AFFERENTS IN THE TOADFISH, OPSANUS TAU: A BIOTIN DYE STUDY <u>I.P. Carey and S.M. Highstein</u>. Wash. U. Sch. Med., Dept. Oto., St. Louis. MO 63110.

Individual horizontal semicircular canal afferents were impaled with glass microelectrodes filled with Biocytin or Neurobiotin to study their morphology and physiology. Responses to sinusoidal rotations were classified as low-gain, velocity-sensitive (LG); high-gain, velocity-sensitive (HG); or acceleration-sensitive (AC) (Boyle and Highstein, 1990). Fibers were then injected, and their morphology characterized with light microscopy. Brainstem projections of these three classes differ. AC and HG fibers project to ventral n. anterior octavus (AO), all parts of n. descending octavus (DO), n. magnocellularis (M), n. tangentialis (T), and emenentia granularis (EG, the vestibulocerebellum). In contrast, LG fibers project heavily to ventral DO, lightly to M and T, but not to AO or EG. Afferent distributions in the horizontal canal crista corroborate previous findings (Boyle and Highstein, 1986), namely, AC and HG fibers occupy the middle 2/3 of the crista, with AC fibers more central, and LG fibers are confined to the distal 1/6. Microinjections of HRP into the distal 1/6 of the crista confirmed the restricted central distribution of LG fibers found with biotinylated dyes. Thus, peripheral parcellation of velocity and acceleration information is partly maintained centrally. Differential central projections may be the first stage of anatomic separation of information underlying the functional diversity of vestibular actions. (Supported by NIH NS21055 and AHA MA/MD Fellowship.)

VELOCITY STORAGE AND THE OCULAR RESPONSE TO MICROSTIMULATION OF VESTIBULAR NUCLEI IN ALERT MONKEY J. Yokota, H. Reisine, B. Cohen Depts. of Neurol. and Physiol. & Biophys., Mount Sinai Sch of Med New York NY 10029

Velocity storage holds activity that produces slow phase eye velocity during vestibular nystagmus, OKN and OKAN. The neuronal circuits underlying this mechanism are still unknown. Functions attributable to velocity storage are lost after lesion of the medial part of the medial vestibular nucleus (MVN; Uemura & midline section of vestibular commissural connections Cohen,1973) and caudal to the abducens nucleus (Katz et al.,1989). Thus, the velocity storage integrator appears to be represented in the vestibular nuclei. In this study we electrically stimulated the vestibular nuclei of the cynomolgus monkey to determine whether eye movements could be evoked, and if the characteristics of the nystagmus were related to vestibular nystagmus. OKN and OKAN. Eye movements were monitored with search coils. In darkness currents less than 40 uA evoked horizontal or rotatory nystagmus with contralateral slow phases, followed by after-nystagmus in the same direction. The rising time course of the slow phase velocity was similar to the slow rise in OKN. The maximum velocity of the steady state nystagmus was almost same as that of OKAN, and the falling time course of the after-nystagmus corresponded to that of OKAN and per- or post-rotatory nystagmus. In some tracks, the time course of rise and fall was shorter, and the peak velocity was higher. Positive stimulus sites for inducing nystagmus were located in or near the boundary between MVN, LVN and rostral DVN, just caudal to the abducens nuclei and 3-4mm from the midline and in the white matter lateral and dorsal to the vestibular nuclei. These data suggest that the contribution of velocity storage to the VOR,OKN and OKAN can be elicited by stimulation of the vestibular nuclei in the alert monkey. Supported by NS00294, EY01867.

EYE AND HEAD MOVEMENT-RELATED DISCHARGE OF SECONDARY ESTIBULOSPINAL NEURONS IN THE ALERT SQUIRREL MONKEY

R. Boyle. Depts. Oto. & Physiol., Oregon Health Sci. Univ., Portland, OR 97201.

In the vestibular nuclei of the alert squirrel monkey, spinal-projecting neurons were identified by their antidromic response to pulses applied to wires implanted in the ventromedial funiculi at C1; each cell's short-latency input from the ipsilateral VIIIth nerve (Vi) was determined by shocks applied to middle ear wires. The cell's discharge was examined during spontaneous eye movements, pursuit tracking of visual targets, optokinetic stimuli, and to sinusoidal head person tracking of visual ragies, opportunite similar, and to sindesteal recall movement in the dark and during suppression of compensatory eye movements. Using a paradigm of Minor and Goldberg (1986), 100μ A anodal (inhibitory) current was applied to Vi during head rotation in some cases to assess the possible contribution from low threshold (irregular) afferents to the secondary cell's response modulation. Of the 143 neurons studied in one monkey, 19 were vestibulospinal (10 monosynaptically related to Vi). Cells encountered were: type I only (1), type I + eye position (2), type I + pursuit velocity with or without eye position (5), type II only (5), type II + pursuit velocity + eye position (2), and 4 were related to vertical head/eye movements. The discharge of 60% of the vestibulospinal cells related to horizontal head movement was modulated by the position and/or movement of the eyes in orbit and, most frequently, the head and eye velocity component of the individual responses were in the same (anticompensatory) direction. Curiously, none of the horizontal PVP (11), the vestibular-pause (12) or -burst (5) cells recorded were C1-activated in this study

These results show that i) vestibular neurons carry varied gaze signals to the spinal cord and ii) the position/movement of the eye in orbit can strongly influence the cell's head velocity modulation; and suggest that vestibulospinal neurons may participate in different operations of gaze control.

PHYSIOLOGICAL PROPERTIES OF VESTIBULAR AFFERENTS PARTICIPATING IN THE PLASTICITY OF THE VESTIBULO-OCULAR

PARTICIPATING IN THE PLASTICITY OF THE VESTIBULO-OCULAR REFLEX. H.M. Bronths-Stewart and S. G. Lisberger. Dept. of Physiology UCSF, San Francisco, CA 94143.

Our goal is to determine the role of different classes of vestibular afferents in the plasticity of the vestibulo-ocular reflex (VOR). We use an electrical method of stimulating the VOR with an electrode implanted in the superior semicircular canal. Single electrical pulses elicit at which of eye velocity, the amplitude of which increases with increasing current intensity and plateaus at high currents. There is a relationship between the electrical activation of afference and their observations proportice. Afference with activation of afferents and their physiological properties. Afferents with irregular spontaneous discharge are recruited at low currents that elicit little irregular spontaneous discharge are recruited at low currents that elicit little eye movement. Afferents with a more regular firing pattern are recruited over a wider range of current intensity. As the current is increased those with a higher coefficient of variation (CV) and greater sensitivity to head turns are recruited first. Afferents with very low values of CV are activated only at current values beyond the saturation of eye velocity. We tested the role of different afferents in plasticity by examining the eye velocity elicited by 200Hz trains of electrical pulses at different current intensities. We compared the responses before, during and after plasticity achieved with magnifying and miniaturizing spectacles. At low currents, trains evoke an eye velocity that does not vary with plasticity. As the more regularly firing afferents are recruited, the eye velocity evoked by trains varies with plasticity, concordant with the variation seen using natural vestibular stimuli. At higher currents the evoked eye velocity shows no further change with plasticity even though the most regular afferents have not been activated yet. It appears that plasticity in the VOR is driven largely by a group of afferents with physiological properties in the intermediate range of discharge regularity and sensitivity to head turns. (Supported by NiH grants K11 EY00302 and RO1 EY03878).

RESPONSES OF NEURONS IN THE RAT VESTIBULAR NUCLEI TO STATIC TILT AND AFFERENT ELECTRICAL STIMULATION. Y. Wada'*, T. Matsunaga'*, and T. Tsumoto² ¹Dept. Otolaryngol., Nara Medical College, Nara, 634 Japan and ²Dept. Neurophysiol., Osaka Univ. Med. Sch., Osaka, 530 Japan

To elucidate central information processing of the otolith system, extracellular single unit recordings were made from the medial, lateral and superior vestibular nuclei of the urethane-anaesthetized rat. Responses to anteroposterior static tilt and to electrical stimulation the ipsi- and contralateral vestibular nerve analysed in 72 neurons. Thirty-two neurons showed sustained changes in their activity in response to tilt. Nineteen of the 32 cells (59 %) displayed reciprocal responses to anteroposterior tilt, i.e., excitation to nose-down tilt and inhibition to nose-up tilt and vice versa. A and inhibition to nose-up tilt and vice versa. A difference in resting discharge was seen between tiltresponsive cells (n=32) and non-responsive cells (n=26). The frequency of resting discharge of the former cells was significantly lower (mean±standard deviation, 19.1±11.8 Hz) and more irregular than that of the latters (37.3±17.2 Hz). All the cells responded with short latency to ipsilateral vestibular nerve stimulation, and about 20 % of them responded also to contralateral stimulation. A possible relationship between the excitatory convergence from both sides and responsiveness to tilt is discussed.

COMPARATIVE TRANSDUCTION MECHANISMS OF HAIR CELLS IN THE BULLFROG UTRICLE. R.A. Baird, R.S. Dow Neurological Sci. Inst., 1120 NW 20th Ave., Portland, OR 97209.

Previous studies have shown that the response dynamics of utricular afferents are correlated with both the epithelial location and hair bundle morphology of their innervated hair cells. To clarify the contribution of hair cell transduction mechanisms to the response properties of utricular afferents, we measured the responses of hair cells to intracellular current and mechanical stimulation to determine their membrane properties and response dynamics, including the extent and time course of adaption to long-duration stimuli and the contribution, if any, of an electrical resonance in the hair cell membrane.

Hair cells in the extrastriola have similar hair bundle morphology, exhibit little or no active currents following current steps, adapt to neither intracellular current nor mechanical stimulation, and respond only to low (< 5Hz) frequencies. Striolar hair cells, while differing in hair bundle morphology, display active currents to both depolarizing and hyperpolarizing steps, rapidly adapt to step displacements of their hair bundles, and respond to much higher (>50 Hz) frequencies. An electrical resonance, similar to that observed in bullfrog saccular hair cells, is seen in striolar hair cells with bulbed kinocilia. With the exception of this resonant behavior, the response dynamics of utricular hair cells correlate with their epithelial location rather than their hair bundle morphology and probably reflect the kinetics of voltage- and ion-sensitive conductances in the hair cell membrane. supported by NIDCD 00355, NASA NCC 2-651, & OLSHF.

HORIZONTAL AND VERTICAL VOR LATENCY BEFORE AND AFTER CROSS-AXIS VOR PLASTICITY. T.T. Khater. B.W. Peterson. K.D. Powell, K.J. Ouinn, and J.F. Baker. Northwesterm Univ. Medical School, Chicago, IL. 60611.

When a monkey wears magnifying lenses for a few days, his VOR adapts to minimize the lens-induced retinal slip. The adaptive component of the VOR has a latency as short as 19 msec (Lisberger, Science 242:771), suggesting a relatively direct pathway is responsible for the learned response. To measure comparable latencies for plastic changes in VOR direction, we recorded eye movements evoked by random velocity transitions between ±19°/sec earth-horizontal whole body rotation (HWBR) in total darkness with a CNC eye coil system in 4 cats before and after "cross-axis" training. Training consisted of 2 hrs of HWBR coupled with vertical pitch rotation of a projected random dot pattern with identical phase and 1.5X the amplitude. HWBR was done with the cat in the prone position, or lying on its left side (onside adaptation).

VOR latencies to ±19°/sec transitions in the plane of the HWBR were 8-11 msec both before and after adaptation to a orthogonal optokinetic

VOR latencies to ±19°/sec transitions in the plane of the HWBR were 8-11 msec both before and after adaptation to a orthogonal optokinetic stimulus. Orthogonal (vertical) responses (OVOR), which were absent before the training, usually had a latency of 35-45 msec. In 5 of 18 cases, however, two cats produced responses in the 17-21 msec range. Furthermore, a second eye velocity step (increasing velocity) often occurred at 100-120 msec latency in the adapted OVOR trace. Similar latencies were found in our onside cases. Our short (20 msec) latencies suggest a direct (intra-brainstem) pathway similar to that proposed by Lisberger. Latencies of ~ 40 msec are long enough for more complex (eg. trans-cerebellar) pathways to be involved. We believe that the most rapid learning occurs in these pathways. Short latency OVOR would appear only when significant learning occurred in longer time constant brainstem pathways within our 2 hr training period. Supported by EY05289, EY06485, and EY07342.

FUNCTIONAL CONSIDERATIONS IN MODELING VOR PLASTICITY. K.J. Quinn, N. Schmajuk, S.A. Rude, T.T. Khater, J.F. Baker and B.W. Peterson. Northwestern University Medical School, Chicago, IL 60611

School, Chicago, IL 60611

We are developing a model of the vestibuloocular reflex (VOR) using neural network techniques. Structure of the model is constrained by known anatomy and physiology of the reflex. Initial efforts concentrate on computational capabilities of the basic 3 neuron arc. Activation levels of individual model elements are calculated in a way similar to that described by Grossberg (Stud.Appl.Math.,52,p213). Semicircular canal input is modeled as a head velocity (HV) signal and eye/muscle plant activation is based on the laplace transform described by Robinson (Ann.Rev.Neuro.,4,p463). The current model contains a total of 14 nuits and simulates a perfectly compensatory horizontal VOR at fixed

(Ann.Rev.Neuro.,4,p463). The current model contains a total of 14 units and simulates a perfectly compensatory horizontal VOR at fixed frequencies (0.5 & 1.0 Hz). Frequency response analysis indicates that the model is much more narrowly tuned than the normal VOR, suggesting that units simulating a neural integrator producing an eye position (EP) signal (Arnold & Robinson, Soc. Neuro. Abstr,416.20) may be required to match normal VOR behavior.

A signal related to retinal image slip velocity (RSV) is thought to be the principal means by which the CNS detects errors in the VOR. How can reflex adaptation correct errors in gain andor phase if only a RSV signal is provided? It can be demonstrated that the product RSV*HV is differentially sensitive to gain errors while RSV*EP is differentially sensitive to phase errors. Modeling a multiplicative learning process at sites where these signals converge (vestibular and prepositus nuclei?) may therefore simulate adaptive performance of the VOR. Supported by EY05289, EY06485, EY07342, NS07223.

304.14

VESTIBULO-OCULAR REFLEX (VOR) DIRECTION ADAPTATION TO MULTIFREQUENCY AND SINGLE FREQUENCY STIMULI. K.D. Powell. K.J. Quinn. S.A. Rude. B.W. Peterson. J.F. Baker. Dept. of Physiology, Northwestern Univ., Chicago, IL 60611.

Coupling horizontal vestibular rotation (HVR) with vertical optokinetic pattern rotation (VOKR) causes the VOR to acquire an adaptive vertical component (AVOR). When HVR and VOKR are .25Hz sinusoids, the AVOR is maximal at .25Hz with smaller, phase advanced responses at lower frequencies. Here we examine how this tuned frequency response depends on the frequency(ies) in the training stimulus. Two classes of cross axis adaptations were performed in 4 cats. Vertical and horizontal VOR at .02-2.5Hz were measured with EOGs in the dark before and after training. EOGs in the dark before and after training.

1) Single frequency adaptation (SFA): Whole body HVR at .05, .1, .25, .5, or 1Hz was coupled to VOKR for 2hr.
2) Multifrequency adaptation (MFA): A multifrequency stimulus containing .2, .3, .5, .7, 1.1, 1.7Hz was used in synchrony for the HVR and VOKR for 2hr.

After 2hr. of MFA, vertical VOR gain during horizontal rotation was increased to .1-.2 across the training frequencies with no preferred frequency and little or no phase shift at low frequencies. This broad frequency and little or no phase shift at low frequencies. This broad band adaptation in MFA contrasts with the frequency tuning seen in SFA after which adaptive vertical VOR consistently showed bandpass characteristics tuned near the adaptation frequency. Preliminary results from 1Hz SFA and adaptation to a combination of .25Hz & 1Hz suggest the presence of a high frequency stimulus decreases the phase advance at low frequencies. Supported by EY05289, EY06485, EY07342.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: VESTIBULAR SYSTEM II

AN IN VITRO BRAINSTEM-CEREBELLUM PREPARATION TO STUDY VESTIBULOCEREBELLAR INTERACTIONS.

LL. Larson-Prior and N.T. Slater. Department of Physiology, Northwestern University Medical School, Chicago, IL 60611.

Vestibulo-cerebellar interactions regulate reflexes which are involved in the maintenance of posture, balance, and gaze, and have been implicated in the development of reflex plasticity. To better understand the cellular basis of these interactions, we have utilized an in vitro preparation of the turtle brainstem-cerebellum [1,2]. This preparation takes advantage of the extreme anoxia resistance of turtle brain, and the similarity of the reptile vestibulocerebellar system to that of mammals. The preparation included the intact cerebellum, one-half of the metencephalic tegmentum and the ipsilateral eighth nerve (nVIII). This insured that all stimuli were carried through a single cerebellar peduncle. nVIII was stimulated by a suction electrode placed either on the anterior or posterior branch of the nerve. The vestibular nuclear complex (VNC) was stimulated via a bipolar concentric electrode placed just lateral to the sulcus limitans at the level of nVIII entry.

vestibular nuclear complex (VNC) was stimulated via a bipolar concentric electrode placed just lateral to the sulcus limitans at the level of nVIII entry.

In turtle, the auricular lobe of the cerebellum is reciprocally connected to the vestibular system and constitutes the "vestibulocerebellum". Consistent with a projection to the granule cell layer of the auricle, VNC stimulation produced espips sequences at latencies of 5-7 msec in intracellularly recorded auricular Purkinje cells. Higher stimulation intensities frequently evoked complex spike activation. Somewhat unexpectedly, stimulation of either branch of nVIII evoked short latency (<0.5 msec) action potentials, consistent with antidromic activation. Such responses (CO.5 misec) action potentials, consistent with annual mutual activation. Such responses followed stimulus presentations at frequencies of up to 100 Hz, and increased intensity of stimulation did not result in an increased number of simple spikes. It therefore appears that in turtle, as in frog [3], auricular Purkinje cells send direct afferents through nVIII to the vestibular apparatus. Supported by NS 17489 and NS

SOURCES OF CHOLINERGIC INNERVATION OF THE VESTIBULAR NUCLEI IN THE RAT R.W. Sikes, B. Litofsky*, P.A. Ullucci*, Department of Physical Therapy, Northeastern

University, Boston, MA 02115.

Histological, neurochemical and physiological studies have established that the vestibular nuclei (VN) receive a prominent extrinsic cholinergic input. Although cholinergic afferents are thought to be important in vestibular compensation following uni-lateral labyrinthectomy, the source of this input has not been identified. By combining sensitive immunohistological and retrograde tracing methodologies, this study

identifies several putative cholinergic inputs to VN.
Injections of transportable fluorescent dyes were made into the VN in anesthetized rats using standard stereotaxic procedures. Sections from the brains of these animals were processed to show the location of neurons containing choline acetyltransferase-like immunoreactivity (ChAT-L) using a fluorescent tag. location of tracer dye, ChAT-L and double-labeled neurons were charted.

Overlapping populations of ChAT-L positive cells and vestibular projecting cells were observed in the prepositus nucleus, cervical spinal cord and medial medullary reticular formation. Thus, these regions may play a key role in vestibular compensation.

RESPONSES OF BILATERAL VESTIBULAR NUCLEAR NEURONS OF ACUTE HEMILABYRINTHECTOMIZED CATS TO OFF-VERTICAL AXIS ROTATIONS. Y.S. Chan, Y.M. Cheung and C.W. Chen*. Department of Physiology, Faculty of Medicine, University of Hong Kong, Sassoon Road, Hong Kong.

To explore whether vestibular nuclear neurons on the lesioned side and the labyrinth-intact sides of acute hemilabyrinthectomized cats can encode spatial orientation during 360° off-vertical axis rotations (OVAR), responses of these units were studied in decerebrate cats during constant velocity OVAR in the clockwise (CW) and counterclockwise (CCW) directions. On both the lesioned and the labyrinth-intact sides, some units showed position-dependent discharge modulation only to OVAR of one direction but not to both. Such asymmetric response was not observed in animals with intact bilateral labyrinths (Chan et al., 1988). On both the lesioned and labyrinth-intact sides, other units were found to respond to OVAR in both directions with comparable response gain. For each side, the averaged position of the CW/CCW discharge maxima of each of these units was plotted in a map to show the orientations of the best response. For units showing best response along the transverse plane, there was a predonderance of type α over type β units on both the lesioned and labyrinth-intact sides, suggesting the existence of a predominant crossed otolith contribution from type $\boldsymbol{\beta}$ units. For units showing best response along the antero-posterior plane, a greater proportion of units showed type 2 than type 1 response on both the lesioned and labyrinth-intact sides; a reverse pattern was observed in cats with intact bilateral labyrinths. These results suggest that inputs from the intact otoliths in acute hemilabyrinthectomized cats are operative at the level of the vestibular nuclei bilaterally to encode spatial orientation of the head

SEMICIRCULAR CANAL AFFERENT RESPONSE TO EFFERENT STIMULATION. J.D. Dickman and M.J. Correia. Depts. of Surgery and Anatomy, Univ. of Mississippi Medical Center, Jackson, MS 39216; Depts. of Otolaryngology and Physiology & Biophysics, Univ. of Texas Medical Branch, Galveston, Texas 77550.

We recorded extracellular single fiber responses from horizontal

semicircular canal afferent (HCA) fibers in pigeons elicited by stimulation of the contralateral horizontal semicircular membranous duct using a mechanical micropusher (Dickman & Correia, J. Neurophysiol., 1989, 62, 1090-1101). Step displacements (±10 micron) of the exposed contralateral membranous duct were delivered in order to stimulate efferent fibers projecting to the ipsilateral horizontal canal neuro-epithelium. Experiments were conducted in awake, decerebrate animals that were paralyzed (Flaxedil) and ventilated (250 ml/min O₂/CO₂). To date, complete protocols have been recorded in 19 HCA fibers. Of these, 53% (10/19) responded with clear decreases in the firing rate below the resting discharge level as step displacements of the contralateral membranous duct were delivered, followed by increases in firing rate above the resting discharge level at the cessa tion of the step displacement. This response pattern is opposite to that observed with ipsilateral membranous duct mechanical stimulation. The magnitude of the elicited unit responses (ranging 4 - 30 spikes/sec, n = 6) appeared to vary with the spontaneous firing rate and the coefficient of variation (CV) of the individual neuron. The largest responses were elicited in HCA fibers with high CV values. Several HCA fibers were rectified with contralateral stimulation. Supported in part by NIH grant 2507RR05386 and ONR grant N00014-88-K-0015

VESTIBULAR PRIMARY AFFERENT AND VESTIBULOOCULAR CHANGES IN RHESUS MONKEY FOLLOWING 14 DAYS OF MICROGRAVITY. M. J. Correia, A. A. Perachio, J. D.Dickman, I. B. Kozlovskaya*, M. G. Sirota*, S. B. Yakushin* & I. N. Beloozerova*. Depts. of Otolaryng. & Physiol. & Biophys., UTMB, Galveston TX, 77550, ^Dept. of Surg., Univ. of Miss. Med. Sch., Jackson MS, 39216, & *Inst. of Biomed. Prob., Moscow, U.S.S.R.

Two Rhesus monkeys (782 & 2483) were tested before, during and after (14.5 hrs-9 days) they orbited the earth for 14 days on Cosmos Biosatellite 2044. Seven control monkeys were also tested. Nystagmus was recorded using indwelling corneo-retinal potential electrodes and single unit extracellular action potentials were recorded from the vestibular nerve in the alert animals. During pre-flight studies, 27 units were recorded from five monkeys, including 8 from the flight animals. During post-flight studies, 102 units were recorded from 4 monkeys including 41 from the flight animals. We report that during yaw pulse rotations (± 60 deg/s for 30 s) of both the flight monkeys on post-flight day 1, the mean (+SEM) horizontal semicircular canal primary afferent excitatory time constant, $\tau_e = 3.3 \pm 0.5$ s, and inhibitory time constant, $\tau_1 = 3.5\pm0.6$ s were shorter than during pre-flight and control monkey tests ($\tau_e = 6.0\pm0.4$ s, $\tau_i = 4.8\pm0.6$ s). The gains were also greater (Ge = 0.83*±0.12, Gi = 0.85*±0.10) during post-flight day 1 compared with preflight and control monkey tests ($G_e = 0.49\pm0.05$, $G_i = 0.39\pm0.03$), (* = p<0.01, ANOVA, d.f. = 1,41; 1,41 & 1,30, respectively). Yaw pulse rotations (± 60deg/s for 60 s) produced horizontal slow phase eye velocity of longer duration (1.6 times) on post-flight day 1 in both flight monkeys when the plane of their horizontal semicircular canals was pitched down 45 deg relative to a vertical axis of rotation. No difference was noted when this plane was not pitched or pitched up 45 deg. This work was supported in part by a NASA grant, NAG-2-446.

SYNAPTIC INPUTS TO BEHAVIORALLY CHARACTERIZED NEURONS IN THE MACAQUE VESTIBULAR NUCLEI. D. M. Broussard and S. G. Lisberger. Dept. of Physiology, UCSF, San Francisco, CA 94143.

The brainstem neurons mediating the vestibulo-ocular reflex show a variety of discharge patterns during head turns, but little is known about the relationship between a neuron's discharge pattern and the synaptic inputs it receives. We tested central vestibular neurons using standard behavioral paradigms in alert, trained rhesus monkeys. We then applied single, brief current pulses via chronically implanted stimulating electrodes in the flocculus and in the ipsilateral and contralateral labyrinths. Initially we have focused on flocculus target neurons (FTNs) and tonic-vestibular-pause neurons (TVPs). Horizontal TVPs paused during saccades, carried ipsilateral head velocity and contralateral eye velocity signals, and were not inhibited from the flocculus. Horizontal FTNs were defined as neurons which are strongly inhibited, within 2 msec, by stimulation of the flocculus; they usually were contralateral eye movement cells. Following stimulation of the ipsilateral vestibular labyrinth, both TVPs and FTNs were strongly excited, usually at monosynaptic latencies. When the contralateral labyrinth was stimulated, FTNs received an excitatory input, followed by inhibition. We expected TVPs to be inhibited via the vestibular commissure, and some were; however, in other TVPs, the crossed input was purely excitatory. In one animal whose ipsilateral horizontal canal was blocked, TVPs apparently lost their head velocity signals, suggesting that the commissural input to TVPs may not be related to head turns. Supported by NIH grant EY03878.

TWO SUBCLASSES OF BOUTON-TYPE VESTIBULAR PRIMARY

TWO SUBCLASSES OF BOUTON-TYPE VESTIBULAR PRIMARY AFFERENTS IN A TURTLE, Pseudemy scripta. A. M. Brichta and E. H. Peterson. Neurobiology Program, Ohio University, Athens, OH 45701. Classical descriptions divide vestibular primary afferents into three morphological classes. One class, the bouton-type afferent, is found in all vertebrate groups. We conducted a quantitative analysis of 69 bouton afferents supplying the posterior semicircular canal that had been filled with HRP and reconstructed from serial sections. Our analysis suggests that there may be two subclasses of bouton afferents in this species.

Compared with other (a) bouton afferents, beta (β) bouton afferents have large diameter somata and axons, and large varicosities spread over extensive collecting areas. They comprise 12% of bouton afferents in our sample. Multivariate statistical analyses reveal that the structure of these β primaries is significantly different from that of α bouton afferents at the same location. Alpha and beta afferents also differ in spatial distribution. same location. Alpha and beta afferents also differ in spatial distribution. Alpha afferents are homogeneously distributed over the surface of the hemicrista, but the density of β primaries is greatest near the center of the canal and decreases toward the canal wall. This gradient parallels the gradient of structural features observed previously for total bouton afferents and for vestibular hair cells in this species (Brichta et al., 1989 and Peterson et al., 1989, Soc. Nsci. Abs. 15: 517). It provides further evidence that bouton afferents in this species are organized around a canal-centered coordinate frame. coordinate frame.

Our data suggest that bouton afferents in <u>Pseudemys</u> may be divisible into two subclasses that differ in both structure and spatial organization, and they extend our earlier findings of spatial heterogeneity within the vestibular neuroepithelium. Supported by NIH-NINCDS (NS23498), NIH-NINCD (DC00618), and the College of Osteopathic Medicine.

CHARACTERIZATION OF THE THREE DIMENSIONAL STRUCTURE OF VELOCITY STORAGE IN THE MONKEY. M.J. Dai*, T. Raphan, D. Sturm, B. Cohen. Dept. of Computer & Inf. Sci., Brooklyn College, CUNY, N.Y., & Dept. of Neurol. Mt. Sinai Sch. of Med., N.Y.

When subjects are tilted, OKN slow phase velocity along the subject's yaw axis generates SP Vel along the pitch or roll axis during OKAN. This "cross coupling" has pitch or roll axis during OKAN. This "cross coupling" has been related to the 3-D characteristics of velocity storage in terms of the eigenvalues and eigenvectors of the system matrix re gravity. The eigenvalues and eigenvectors of OKAN around yaw and pitch axes were determined for 4 monkeys as a function of head roll-tilts (0-150 deg) using a modified Marquardt algorithm. For cross coupling that produced upward SP Vel the yaw axis eigenvector changed from -10.3 deg to 23.8 deg (mean) re the spatial vertical, showing Muller & Aubert-like effects. Eigenvalues (the inverse of the Tc) associated with the yaw axis increased from .051-.135/s, and pitch axis eigenvalues decreased from .23-.056/s. They were about the same whether cross coupling or pure pitch OKN stimulation was given (p<0.34, mean). For oblique stimulation along the eigenvector, the direction of the OKAN remained along the eigenvector as predicted. Under all conditions the pitch axis eigenvector rotated with the head. Thus, the upward yaw axis eigenvector associated with the valority storage. head. Thus, the upward yaw axis eigenvector associated with velocity storage is closely linked to gravity. EFFERENT MODULATION OF SYNAPTIC NOISE IN LAGENAR AFFERENTS OF THE TOADFISH R.E. Locke, S.M. Highstein. Dept Oto. Washington Univ. Sch. Med., St. Louis. MO 63110

Glass microelectrodes were visually guided into primary afferents of the labrynthine lagena in anesthetized toadfish. Spontaneous miniature EPSPs (mEPSPs) of hair cell origin were recorded before and during electric pulse train stimulation of the efferent vestibular nucleus (EVN) in the floor of the IV ventricle. Control unitary mEPSPs ranged from 0.3-8.5 mV with an amplitude distribution that was skewed to the left (mode 0.375 mV). Time to peak of mEPSPs ranged from 0.12-2.06ms (mode 0.28ms). EVN stimulation shifted the amplitude histogram to the left, eliminating the largest EPSPs. The shape of the amplitude distribution did not change, but the average time to peak was shortened such that fewer medium and long duration (>.56ms) EPSPs were seen. This reduction of synaptic noise from hair cells is correlated with a reduction in firing rate. In some afferents single, double, triple, etc. pulse stimulation of the EVN evoked large (ca. 10mV) monosynpatic EPSPs which summated. Thus the EVN exerts a dual control over lagenar afferents via efferent innervation of both hair cells and afferents. We propose that the axo-axonic synapses are responsible for increased firing rates while the axo-somatic synapses on hair cells may be responsible for reducing spontaneous EPSPs and evoked firing rates. STRUCTURAL AND SPATIAL DIVERSITY OF TYPE I AND TYPE II HAIR CELLS FROM THE VESTIBULAR EPITHELIUM OF A TURTLE, Pseudemys scripta. L. L. DiCaprio, A. M Brichta and E. H. Peterson. Neurobiology Program, Ohio University, Athens, OH 45701. To understand vestibular control of head movement in P. scripta we are characterizing the organization of its vestibular neuroepithelium. We distinguished between Type I and II hair cells by differential interference contract invaring of scripted griters that had registered gritered griters that had registered by the contract invaring of scripted gritered griters that had registered gritered griters.

contrast imaging of sectioned cristae that had previously been loaded with HRP to visualize calyx endings around Type I hair cells, and we compared these images with scanning electron micrographs of sonicated and unsonicated cristae.

unsonicated cristae.

Type I hair cells are sequestered in a central region of the epithelium that occupies approximately 35% of its total surface. They typically are housed in complex calyces that bear 4-5 hair cells. Type II cells are densely packed in a peripheral limbus, and they are larger and less numerous in the central region. The ratio of Type I to Type II cells is 5:1 or higher in the center of the epithelium. Apical profiles of peripheral (Type II) hair cells vary in size and shape, from small and elliptical near the wall of the canal to large and round near the torus. All bear a cluster of approximately 20-40 stereocilia near the kinocilial end of the apical surface. Apical profiles in the central region (Types I and II) are larger and structurally more diverse, including (1) elliptical profiles with as few as 30 stereocilia clustered near the kinocilium, (2) large round profiles with 60-100 stereocilia covering most of the apical surface, and (3) yers wall profiles that appear to be erupting from the (2) large round profiles with 60-100 stereocilia covering most of the apical surface, and (3) very small profiles that appear to be erupting from the epithelium. The ratio of the first two varieties is approximately 5:1 in the middle of the central region and decreases toward the periphery.

Our data suggest that Type I and II hair cells in Pseudemys differ in ciliary bundle morphology and that they are organized around distinctive spatial coordinate frames. Supported by NIH-NINCDS (NS23498), NIH-NINCD (DC00618), and the College of Osteopathic Medicine.

HORIZONTAL AND VERTICAL VESTIBULAR AND EYE MOVEMENT SENSITIVITY OF VESTIBULAR NUCLEAR NEURONS. J.O. Phillips and A.F. Fuchs. Regional Primate Research Center and Depts. of Psychology and Physiology and Biophysics, University of Washington, Seattle, WA,98195 Cells of the vestibular nuclei are known to carry both vestibular

and eye movement signals. It is not known, however, to what extent individual primate vestibular neurons carry signals related to both vertical and horizontal vestibular stimulation and/or vertical and horizontal eye movements. To address this question, we recorded the activity of vestibular neurons (located primarily in the medial and lateral vestibular nuclei) that responded to a horizontal search stimulus (i.e.,the animal tracked a spot of light that moved in counterphase to a yaw rotation). We then tested the responsive units with a velocity series of horizontal and vertical rotations, and during horizontal and/or vertical smooth pursuit.

Preliminary analysis of 39 such units shows that most horizontally sensitive vestibular neurons (24/33) also responded to vertical vestibular stimulation. The vast majority of horizontally sensitive Type II neurons (17/21) responded to vertical stimulation, with many of the vertical responses meeting or exceeding the response to horizontal stimulation. In contrast, Type I neurons responded weakly (7/12), or not at all (5/12), to vertical stimulation. In addition, cells were observed with eye (5/12), to vertical stimulation. In addition, cells were observed with eye movement sensitivities orthogonal to a given vestibular sensitivity. These data suggest that one should exercise caution in suggesting a role for the Type II neuron in horizontal vestibular responses.

VERGENCE RESPONSES DURING NASO-OCCIPITAL LINEAR NASA Ames Res. Center, Moffett Field, CA 94035
Horizontal and vertical eye movements were

recorded binocularly (scleral search coil technique) from squirrel monkeys during naso-occipital (NO) linear oscillations (5.0 Hz, ±0.354 g peak). Vergence was also measured by subtracting the right from the left horizontal eye position signals. Responses were measured in the dark (LVOR) or while viewing a head-fixed visual sur round (VSLVOR) with target distances of 9 and 22 round (VSLVOR) with target distances of 9 and 2 cm. Vergence responses were observed during both LVOR and VSLVOR trials in the two animals tested. Vergence responses (8) were time-locked to the 5 Hz stimulus with near 0° phase. Their amplitudes depended on the point of binocular fixation (vergence) independently of visual insurance and were adequately characterized by:

fixation (vergence) independently of visual input, and were adequately characterized by: $\theta = \arctan{(PD/F_0 + H_\chi)}$ where PD is the interpupillary distance, F_0 is the initial fixation distance (l/vergence), and H_χ is the linear displacement along the naso-occipital axis. These responses are consistent with the kinematics required of a compensatory vergence LVOR.

EFFECT OF ROLL TILT ON EYE MOVEMENTS DURING 5 HZ
INTERAURAL LINEAR OSCILLATION. J.Clifford*, G.D.
Paige, D.L.Tomko (SPON:C.Somps) Vest. Res. Fac.,
NASA Ames Res. Ctr., Moffett Field, CA 94035.
Interaural (IA) or dorsoventral (DV) linear
oscillations produce visually compensatory hori-

zontal (IA) or vertical (DV) eye movements, the linear VOR. During Earth-horizontal (E-H) oscil-lations in the frontal plane, these two LVORs should add to produce behaviorally appropriate should add to produce behaviorally appropriate eye movements (parallel to motion axis) when the head is reoriented relative to oscillation by statically rolling it from upright. Eye movements were recorded (coil technique) in three squirrel monkeys during E-H oscillatory motion (5 Hz, 0.36g pk) along the IA axis, or rolled by 10, 20, or 30°. Continuous records of digitally sampled (200 Hz) eye position in the frontal plane were plotted. Oscillatory eye movement plane were plotted. Oscillatory eye movement orientation in 2-D was calculated from these plots. In upright IA oscillation, E-H eye movements occurred; When rolled 10° to either side, eye movements were also parallel to the motion axis, i.e., tilted appropriately relative to the head. For 20 and 30° tilts in either direction, eye oscillations were 27 and 39°, respectively, indicating over-compensation. Support: NASA Space Med. Tsk 199-16-12-02 & -03.

HIPPOCAMPUS AND AMYGDALA: NEUROPHYSIOLOGY I

306.1

GABA BLOCKADE IN THE REGION OF THE ANTERIOR BASO-LATERAL AMYGDALA ELICITS A DEFENSE REACTION. S.K. Sanders and A. Shekhar. Dept. of Psychiatry and Program in Med. Neuro-biology, Indiana Univ. Med. Ctr., Indianapolis, IN 46202. Although electrical stimulation of the amygdala has been

known to elicit cardiovascular and behavioral changes suggesting a "fight-or-flight" reaction, the specific neurotransmitters involved in this response have not been studied in detail. The present study was conducted to determine the effects of microinjecting GABA antagonists into the different regions of the amygdala in awake and freely moving rats and measuring the changes in heart rate (HR) and blood pressure (BP). Male Sprague-Dawley rats with arterial and venous catheters placed for physiological measurements were implanted with chronic microinjection cannula in the anterior baso-lateral nucleus of the amygdala (ABL) under pentobarb anesthesia. After recovering rats were injected bilaterally with saline and bicuculline methiodide (BMI, 25 ng/250 nl) which gave the following results:

Treatment n Incr. in HR (bts/min) Incr. in BP (mm/Hg) Saline 4 6 \pm 5 1 \pm 3 BMI 4 76 \pm 13* 24 \pm 4* (Significantly different from saline, *P 0.05) Locomotor activation was also observed with BMI. These results suggest that GABA blockade in the region of ABL elicits changes suggesting a defense reaction in rats. (Supported by R29 MH 45362-01).

SELECTIVE SEROTONERGIC INNERVATION OF A SPECIALIZED TYPE OF GABAERGIC INTERNEURON IN THE RAT HIPPOCAMPUS. T.F.Freundl, A.I.Gulyás¹,L.Acsádi¹,T.Görcs¹,R.G.Bickford²,K.Tóth¹. ¹Inst.Exp.Med.Budapest,H-1450, ²Dept.Neurosci.,UCSD,La Jolla, CA. Serotonergic axons were identified in the hippocampal

formation by anterograde transport of Phaseolus vulgaris leucoagglutinin (PHAL) following median raphe injections. and by immunostaining for serotonin. Different types of interneurons were visualized in the same material by immunostaining alternate sections for calbindin D28K, parvalbumin, CCK and somatostatin. The relative distribution of serotonergic afferents was identical in the PHAL transport and the serotonin immunocytochemical experiments, they were most numerous in str.radiatum and lacunosum moleculare of the CA1-CA3 regions. In the double-stained sections the calbin-din-containing interneurons of these strata received multi-ple contacts from the serotonergic axons, whereas other types of interneurons were largely avoided. The serotoninimmunoreactive varicosities established symmetrical synap-Immunicactive varicosities established symmetrical synaptic contacts with dendritic shafts some of which were GABA-ergic, as shown by postembedding immunogold staining of serial ultrathin sections for GABA. The calbindin-containing interneurons in stratum radiatum terminate in the dendritic region of pyramidal cells, and are suggested to participate in GABA-B receptor-mediated feed-forward inhibition. Thus, the serotonergic afferents can - via these interneurons - selectively modulate a specialized inhibitory circuit in selectively modulate a specialized inhibitory circuit in the hippocampus.

DIRECTION AND LOCATION CORRELATES OF CELL FIRING IN THE RAT SUBICULUM, P. E. Sharp, J. B. Ranck, Jr., R.U. Muller, SUNY Health Sciences Center, Brooklyn, N.Y. 11215

Firing patterns of cells in each hippocampal formation region studied so far show distinctive spatial correlates. Cells in both entorhinal cortex and hippocampus show location specific firing, with that in entorhinal cortex being less crisp (Muller et al., J. Neurosci., 7,1987; Quirk & Ranck, Soc. Neurosci. Abstr., 12,1986). In contrast, cells in postsubiculum fire as a function of head direction, regardless of location (Taube et al., J.Neurosci., 10,1990). We here present data on spatial correlates of cells in subiculum. As in earlier studies, activity was examined while rats performed a pellet-chasing task in a cylindrical apparatus with a white card on the wall. A headstage with two light-emitting diodes allowed continuous monitoring of head direction and location.

The 14 cells fell into three categories; 1) 8 cells fired as a function of both place and head direction. They had well-defined location-specific fields like those in the hippocampus, but firing within the field was strongly modulated by head direction, unlike that observed for hippocampal cells in this environment (Bostock et al., Soc. Neurosci. Abstr., 14, 1988). 2) 4 cells fired strictly as a function of head direction, regardless of location. 3) One cell had a sloppy place field, apparently not modulated by head direction. Probe sessions showed that these cells were similar to hippocampal

place cells in that their spatial firing properties rotated along with rotations of the cue card, yet were maintained if the card was completely removed.

Thus, spatial signals in subiculum are from a heterogeneous population and provide both locational and directional information.

SIMULATION OF NMDA RECEPTOR-MEDIATED DENDRITIC ACTIVITY IN CA1 HIPPOCAMPAL PYRAMIDAL NEURONS. G.M. Shepherd, N.P. Poolos, F. Pongracz* and J.D. Kocsis. Sect. of Neuroanatomy and Dept. of Neurology, Yale Univ. Sch. of Med., New Haven, CT. 06510.

We have constructed a compartmental model in SABER of the rat CA1 We have constructed a compartmental model in SABER of the rat CA1 pyramidal neuron and its responses to repetitive synaptic activation. The model represented apical and basal dendritic trees, and included g_{Na} , g_{K} , g_{Ca} and $g_{K}(Ca)$; excitatory glutamatergic (NMDA and nonNMDA) and inhibitory (g_{Cl} and g_{K}) synaptic conductances; and changes in [K+]o in a restricted extracellular space.

The model reproduced intradendritic and intrasomatic responses to single excitatory inputs. Brief repetitive inputs elicited NMDA-mediated potentiation of successive EPSPs. Maximal depolarizing charge in the dendrites occurred with 10-100 Hz. The results suggest that the Ca²⁺ component of the NMDA-mediated synaptic suggest that the Ca** component of the MMDA-mediated synaptic current can be a significant factor in increasing [Ca²+]i at postsynaptic sites. Elevation of [K+]o depolarized the membrane during repetitive activity and enhanced NMDA-mediated responses, leading to increased neuronal excitability and increased [Ca²+]i at postsynaptic sites. Large increases in [K+]o led to excessive postsyraptic sites. Large increases in [N]o led to excessive depolarization and repetitive discharge resembling convulsive activity, which was prolonged by the NMDA-mediated synaptic conductance. Blockade of dendritic $g_{K(Ca)}$ increased the EPSP amplitude, leading to slow depolarization and facilitation of impulse activity. The results support the notion that the NMDA conductance functions as an amplifying component underlying short-term potentiation of responsiveness of CA1 pyramidal neurons to repetitive synaptic activation. Supported by ONR and NIDCD.

SPECTRAL ANALYSIS OF CORTICAL EEG ACTIVITY DURING AN AUDITORY ATTENTION TASK. L.C. Oatman. U.S. Army Human Engineering Lab., Aberdeen PG, MD 21005.
Hippocampal theta during behavioral immobility was significantly larger during visual attention than non-attention (Oatman, L.C., Physiol, Psych., 10:336, 1982). Since sensory stimulation can also elicit hippocampal theta, perhaps the increase in theta was the result of increased sensory stimulation rather than attention mechanisms. This study determined whether an increase in hippocampal theta occurred during auditory attention and/or during increased irrelevant sensory stimulation. Four chronically implanted cats learned an auditory

attention task consisting of two tones (S1, 1000 Hz and S2, 800 Hz) presented successively using food reward. Auditory clicks (irrelevant stimuli) were presented at 1/sec at each 10-dB step from 35 to 125 dB SPL as background before, during, and after the presentation of the S1-S2 task. Sample epochs of cortical EEG activity from attention and nonattention periods were subjected to the fast Fourier transform. Theta (4-8 Hz) was significantly greater when the cats' attention was focused on the auditory attention task than when they were nonattentive. The increased intensity of the irrelevant auditory clicks had no systematic effect on theta (4-8 Hz). The results suggest that increased auditory stimulation had no increased arousal or alerting effect on the hippocampal theta, and significant amounts of hippocampal theta were produced only during auditory attention.

306.4

RAPHE STIMULATION: THE ROLE OF SEROTONIN AND ACETYLCHOLINE IN NEOCORTICAL ACTIVATION AND IN HIPPOCAMPAL ACTIVATION AND SUPPRESSION. B.K. Peck* and C.H. Vanderwolf. Dept. of Psychology, Univ. of Western Ontario, London, Ont., Canada, N6A 5C2. In chronically prepared rats, electrical stimulation (100 Hz, 0.1 ms pulses) of the dorsal raphe nucleus, some sites in the median raphe nucleus (MR), and adjoining regions of the midbrain produced locomotion accompanied by hippocampal rhythmical slow activity (RSA) and neocortical low voltage fast activity (LVFA). Both the behaviour and the cerebral waveforms persisted after injection of scopolamine HBr (Smg/kg, s.c.). MR stimulation in 14 rats produced behavioural freezing or an unnatural forced movement accompanied by RSA and LVFA. However, after scopolamine treatment, stimulation produced low amplitude, irregular (suppressed) hippocampal activity but did not alter the behavioural response or the LVFA. P-Chlorophenylalanine (PCPA, 500mg/kg/day x 3, ip.) reduced the RSA and LVFA normally present after scopolamine but did not reduce the hippocampal suppression produced by MR did not reduce the hippocampal suppression produced by MR stimulation in scopolamine-treated rats. Hippocampal suppression and LVFA in response to MR stimulation were also present in urethane (1.0-1.5g/kg, i.p.) anesthetized rats, whether pretreated with PCPA or not. Stimulation at most other midbrain sites produced RSA and LVFA in the urethane condition. RSA was abolished in the

urethane+scopolamine condition. RSA was appressed in the urethane+scopolamine condition.

The data support the view that scopolamine-resistant RSA and LVFA are dependent on serotonergic projections. The hippocampal suppression produced by MR stimulation may be dependent on nonserotonergic neurotransmission.

INTRADENDRITIC RECORDINGS OF NMDA RECEPTOR-MEDIATED POTENTIALS IN CA1 HIPPOCAMPAL PYRAMIDAL CELLS. N.P. Poolos, J.D. Kocsis, F. Pongracz*, and G.M. Shepherd, Dept. of Neurology and Section of Neuroanatomy, Yale University, New Haven, CT 06510.

Intracellullar recordings in the distal dendrites of rat hippocampal CA1 pyramidal neurons were obtained in order to study N-methyl-D-aspartate (NMDA) receptor-mediated potentials during repetitive synaptic stimulation. CA1 pyramidal cells in the hippocampal slice preparation were impaled in the distal stratum radiatum using high impedance (120-250 Mohm) glass microelectrodes. Intradendritic recordings disclosed features of the dendritic response to synaptic stimulation which were not observed in standard intrasomatic recordings. The dendritic response to a single stimulus consisted of up to 45 mV EPSPs on which were superimposed multiple fast Na-mediated action potentials of varying amplitudes. These action potentials could summate to form larger composite spikes of graded amplitude. Brief periods of repetitive stimulation (2-10 stimuli at 2-100 Hz) produced robust short-term potentiation of the dendritic EPSP, and elicited an increase in dendritic spike activity. Much of this increased postsynaptic response was mediated by NMDA receptors, as shown by application of NMDA receptor antagonists. The magnitude of NMDA receptor-mediated activity increased with increasing number of stimuli, and was maximal at frequencies around 10-20 Hz. Further, dendritic NMDA receptor-mediated activity was greatly augmented by small changes in extracellular K concentration, or by partial blockade of K conductances with low concentrations of TEA. Under these conditions, repetitive stimulation led to NMDA receptor-mediated burst firing as well as activation of intrinsic Ca spikes.

These results demonstrate that NMDA receptors in CA1 hippocampus contribute to the postsynaptic response and short-term synaptic plasticity in hippocampal pyramidal cells at a broad range of afterent stimulus frequ

be distinct from that seen at the cell body of highly arborized neurons.

BICUCULLINE- AND PHACLOFEN-RESISTANT HYPERPOLARIZATIONS EVOKED BY GLUTAMATE APPLICATIONS TO STRATUM LACUNOSUM-MOLECULARE IN CAI PYRAMIDAL CELLS OF THE HIPPOCAMPUS IN VITRO. S. Williams and J.-C. Lacaille. Centre de recherche en sciences neurologiques, département de physiologie, Université de Montréal, Montréal, Québec, Canada, H3C 317. In the hippocampus, different types of interneurons may mediate distinct GABA responses, i.e. early and late inhibitory postsynaptic potentials (IPSPs). To verify this hypothesis, intracellular recordings were obtained from CAI pyramidal cells (n=57) in rat hippocampal slices. Glutamate (ImM) was locally ejected in str. lacunosum-moleculare (L-M) to active interneurons in this region. Hyperpolarizations induced with glutamate (glutamate IPSPs) were characterized and compared to the early and late IPSP elicited by str. radiatum electrical stimulation. Several characteristics of the glutamate IPSPs were similar to the late IPSP: their amplitude was small (-3.4 vs -4.9 mV, respectively), each was associated with a small conductance increase (5.0 vs 9.3 nS), their peak latency was slow (124.4 vs 129.8 ms) and in the majority of cells, each displayed little response reversal. However, the equilibrium potential of the glutamate was slow (124.4 vs 129.8 ms) and in the majority of cells, each displayed little response reversal. However, the equilibrium potential of the glutamate IPSP (-76.5 mV) was similar to that of the early IPSP (-73.8 mV). Perfusion with a low Ca**(0.5 mM)/high Mg**(8 mM) medium that blocked synaptic transmission also reduced the glutamate IPSP. Therefore the glutamate IPSP may be mediated indirectly by inhibitory interneurons. The GABA_A antagonist bicuculline (10µM) blocked the early IPSP but not the glutamate IPSP. The GABA_A intagonist phaclofen (1mM) reduced the late IPSP but not the glutamate IPSP. In conclusion, glutamate stimulation of interneurons in str. L-M evoke a slow IPSP different from the early (GABA_A) or late (GABA_B) IPSPs in CA1 pyramidal cells of hippocampus. pyramidal cells of hippocampus.

SYNAPTIC POTENTIALS IN NONPYRAMIDAL CELLS OF STR PYRAMIDALE OF THE CA1 REGION OF RAT HIPPOCAMPUS IN VITRO J.-C. Lacaille. Centre de recherche en sciences neurologiques, département de physiologie, Université de Montréal, Montréal, Québec, Canada, H3C 3J7.

Synaptic responses of nonpyramidal cells were studied with intracellular recordings in the str. pyramidale region of hippocampal slices. Nonpyramidal cells (n=27) were impaled and identified by their characteristic electrophysiological properties: short duration action potential (≤ 1.0 ms at base), presence of a fAHP after an action potential, and little spike frequency adaptation during depolarizing pulses. Synaptic responses were evoked by electrical stimulation of str. radiatum. In most cells, stimulation evoked a short latency EPSP followed by a biphasic IPSP. The amplitude of the fast EPSP increased with membrane hyperpolarization (n=7 cells). The IPSPs consisted of early (mean latency 19.8 ms; 9/12 cells) and late (mean latency 145.7 ms; 12/12 cells) components. The early IPSP was associated with a 16.4 nS conductance increase (n=8), an equilibrium potential of -68.9 mV (n=9), and was blocked by bicuculline (2/2 cells). The late IPSP was accompanied by a 2.6 nS conductance increase (n=7) and its equilibrium potential was -116 mV (n=7). In some cells (6/12), a longer latency (30-80 ms) EPSP appeared at increased stimulation intensities.

The balance of excitation-inhibition resulted in the production of a single action potential in 50% of cells (6/12) or of bursts (\geq 2 action potentials) in the other 50%.

COMPUTATION OF UNOBSERVED HIPPOCAMPAL ELEMENTS R.J.Sclabassi, T.Biedka*, J.Solomon*, D.Krieger, G.Barrionuevo, and T.W.Berger. Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15213.

The nonlinear input/output properties of major nodes within the hippocam-pus can be characterized experimentally by recording electrophysiological responses to random impulse train stimulation and by expressing the relationship between the input and output activity as the kernels of an orthogonalized functional power series, which may be interpreted as n^{th} order impulse responses. In the hippocampal formation, there are elements which cannot be isolated and whose input/output properties cannot be measured directly. The transformational properties of these elements must be inferred from their effect on the other directly observable groups of neurons. To accomplish this the n^{th} order Laplace transforms of the impulse responses are computed and algebraically manipulated. Models of the observable and unobservable subsystems, as well as the entire system, may thus be computed in terms of nth order convolution operators.

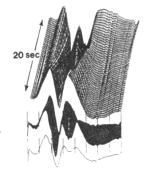

An example is presented utilizing data from three preparations: the intact hippocampal formation, with the dentate granule cell layer considered as a feed-forward element, and the remainder of the ipsilateral hippocampus as a feedback element; a partially closed-loop system, where the contralateral hippocampus has been removed; and an open-loop system, where the contralateral hippocampus has been removed, and an open-noop system, where the contralateral improcampus has been removed, the ipsilateral trisynaptic pathway is open, and the local GABAergic pathways have been blocked. Three results are presented: (1) the n^{th} order Laplace transforms; (2) the results of the algebraic manipulation of the nth order transforms used to calculate the unobservable elements; and (3) the results of simulations used to verify the estimated kernels. The solutions allow computation of the kernels for both the GABAergic pathways and the contralateral hippocampus, neither of which is available by direct measurement. CHARACTERIZATON OF TIME-VARYING BEHAVIOR IN NON-LINEAR SYSTEMS. D Krieger¹, T Berger², D Weisz^{1,2}, and RJ Sclabassi^{1,2}. Dept's. of Neurosurgery¹ & Beh'l Neuroscience², U. Pittsburgh, PA 15213.

A nonlinear system may be completely characterized (Wiener, Wiley & Sons. 1958) using functional power series (FPS). A technique is reported for identification of time-varying FPS from stimulus evoked neural activity. For each point in a FPS, regression on a closed form function of time expands the FPS to capture time-varying behavior. Evaluation of these functions at a specified time point produces an instantaneous system characterization.

Demonstration of the Technique. Potentiation was induced in the granule cell layer of the dentate gyrus by a stimulus train to the perforant path. (A) The averaged response is shown at the bottom. There is a negative going population spike (PS) at 7.0 msec poststimulus. 2nd order polynomials were used to capture time-varying behavior. Two views of the instantaneous characterization are shown: (B) superimposed - center, and (C) isometric projection top. The latency and amplitude of the PS changes over the 20 sec course of stimulation. A 2nd PS appears beginning 5 sec following the onset of the first stimulus. Timing marks = 3.0 msec

SYNAPTIC CONNECTIONS DETERMINED BY SIMULTANEOUS INTRACELL-ULAR RECORDINGS OF DENTATE GRANULE CELLS AND HILAR NEURONS, OR INTRACELLULAR DYE INJECTION, IN RAT HIPPOCAMPAL SLICES. H.E. Scharfman, D.D. Kunkel, and P.A. Schwartzkroin. Dept. Neurological Surg., Univ. of Washington, Seattle, WA 98195

To examine the circuitry of the fascia dentata, paired intracellular recordings were made from granule cells and non-granule cells in transverse and longitudinally cut hippocampal slices. Many of the non-granule cells were identified morphologically by recording with dye-filled electrodes. Other non-granule cells were identified by their electrophysiological properties.

Granule cells strongly excited spiny hilar "mossy" cells; a single action potential (AP) of a granule cell elicited by brief intracellular current injection, could evoke more than one AP in a mossy cell. Granule cells also excited aspiny cells, located in the hilus or granule cell layer. Very few connections were observed between aspiny cells and other neurons; those that were found were inhibitory and prone to fatigue. Electron microscopy of dyefilled mossy cells showed that mossy cells made synapses on aspiny dendrites in the hilus, but no clear effect of mossy cells has yet been found in any of the paired recordings. These studies are fundamental steps in unraveling the complex circuitry of the dentate region. INTRACELLULAR ANALYSIS OF THE NONLINEAR RESPONSE PROPERTIES OF HIPPOCAMPAL DENTATE GRANULE CELLS. T.P. Harty, X. Xie, R.J. Sclabassi, T.W. Berger and G. Barrionuevo. Departments of Behavioral Neuroscience, Neurological Surgery and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

We have used nonlinear systems analytic techniques to compare the interval of the principal of the princi

We have used nonlinear systems analytic techniques to compare the input/output dynamics of single cell and population responses of hippocampal dentate granule cells. Intracellularly recorded action potentials and extracellularly recorded population spike responses evoked by perforant path input were recorded simultaneously from sites less than 1 mm apart in the granule cell body layer of rabbit hippocampal slice preparations. The perforant path was stimulated with a train of 4064 electrical impulses having randomly distributed inter-impulse intervals (A's). First, second and third code learners. having randomly distributed inter-impulse intervals (Δ 's). First, second and third order kernels were computed to characterize the relationship between Δ 's in the stimulus train and either population spike amplitudes or action potential probabilities. Results revealed that the nonlinear response properties of granule cells expressed at the population and single cell levels were highly similar. With respect to second order nonlinearities, both population spike amplitude and action potential probability were strongly facilitated for $\Delta < 100$ ms. In addition, both measures revealed that granule cell responses were suppressed when $\Delta = 100-600$ ms. Third order nonlinearities showed that both population spike amplitude and the probability of single cell discharge were decreased markedly when the intervals associated with two preceding reponses (Δ , and Δ ₂) were less than 200 ms. This research was supported by AFOSR, ONR, MH00343 and NS01196.

ALPHAXALONE-ENHANCED IPSPs ALTER NONLINEARITIES OF HIPPOCAMPAL DENTATE GRANULE CELLS. X. Xie, T.P. Harty, R.J. Sclabassi, T.W. Berger and G. Barrionuevo. Depts. of Behavioral Neurosci, Neurological Surgery, and Psychiatry, Univ. of Pittsburgh, Pgh., 1866.

Second order nonlinearities of hippocampal dentate granule cells to perforant path input in vitro are characterized by facilitation of population spike amplitude in response to interstimulus intervals (ISIs) of 10-50 ms. In contrast, suppression of spike amplitude is observed in vivo to the same In contrast, suppression of spike amplitude is observed in vivo to the same ISIs. This difference between the in vivo and in vitro preparations suggests that basket cell inhibition is reduced in the slice, an hypothesis supported by the finding that the GABA_A allosteric agonist, alphaxalone, selectively induced suppression of spike amplitude for ISIs <100 ms. In the present study, we used intracellular recordings obtained from rabbit dentate granule cells maintained in vitro to study alphaxalone-induced changes in input resistance, ortho- and antidromic IPSP amplitude (avoked by stimulation of the preferent neth and record from

(evoked by stimulation of the perforant path and mossy fibers, respectively). In addition, we have characterized the resulting changes in respectively). In adminin, we have characterized the resulting changes in political response to perforant path stimulation. Bath applied alphaxalone at 2, 3, 4 and 6 μM, produced similar reductions in input resistance (23.6%, n=7). At these same concentrations, alphaxalone increased IPSP amplitudes on average by 102% (orthodromic IPSPs, n=5); and 197% (antidromic IPSPs, n=5). Second order kernels revealed that alphaxalone produced a suppression in action potential discharge in response to ISIs <100 ms. These results indicate that GABA-mediated inhibition plays a major role in determining the dynamic response characteristics of dentate granule cells. Supported by AFOSR, ONR, MH00343 and NS01196.

NONLINEAR RESPONSE PROPERTIES OF HIPPOCAMPAL DENTATE GRANULE CELLS: DUAL INPUT STIMULATION OF MEDIAL PERFORANT PATH AND COMMISSURAL AFFERENTS.

MEDIAL PERFORANT PATH AND COMMISSURAL AFFERENTS. T.W. Berger. C.L. Weikart* and R.J. Sclabassi. Depts. of Behavioral Neuroscience, and Neurol. Surgery, Univ. of Pittsburgh, Pgh., PA 15260.

We have investigated functional interactions between medial perforant path (mpp) and commissural (comm) inputs to the hippocampal dentate gyrus using nonlinear systems analytic methods. The mpp was stimulated electrically with a series of 4064 impulses; interstimulus intervals (as) were determined by a Poisson distribution with a mean of 2.0 Hz. This sequence then was repeated, and comm afferents (contralateral hilus) were stimulated at a constant frequency of 2.0 Hz. Amplitude of the propulation stile severed to constant frequency of 2.0 Hz. Amplitude of the population spike evoked to each mpp stimulus was measured. First, second, and third order kernels for

constant requency of 2.0 Hz. Amplitude of the population spike evoked to each mpp stimulus was measured. First, second, and third order kernels for mpp input were calculated using cross correlation techniques.

When the mpp was stimulated alone, the average population spike amplitude to all 4064 impulses (first order kernel) was approximately 1.3 mV; the influence of any preceding impulse (second order kernel) was inhibitory when Δ =100-400 ms. Simultaneous stimulation of comm input decreased the first order kernel, consistent with previous reports of an inhibitory effect of comm afferents on mpp input to granule cells. In addition, however, second order kernel facilitation for Δ =100-400 ms was decreased markedly; second order kernel inhibition was reduced to a lesser degree, occurring in response to a smaller range of Δ s. Simultaneous stimulation of comm afferents did not affect second order kernel values for any other Δ s. These results are the virtual complement of the effects of unilateral hippocampectomy: an increase in the first order kernel average, a small increase in second order inhibition, and a robust increase in second order facilitation. Thus, inhibitory comm input to the dentate primarily modulates facilitation of granule cell response to mpp input. Supported by AFOSR, ONR, and NIMH (MH00343).

TWO-LEVEL FIELD THEORY INTERPRETATION OF HIPPOCAMPAL EXTRACELLULAR FIELD POTENTIALS.

HIPPOCAMPAL EXTRACELLULAR FIELD POTENTIALS.

G. Chauvet and T.W. Berget. Lab. of Theoretical Biology, School of Medicine, Angers, France, and Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pgh., PA 15260.

From a model based on a two-level field theory, an interpretation is given for extracellular field potentials generated by the action potential firing of hippocampal dentate granule cells, as a function of the magnitude of perforant path input. It is shown that this input/output (I/O) relationship depends on: (i) the anatomical structure, as defined by the densities of input fibers, and the synaptic density-connectivity of postsynaptic neurons; (ii) the dynamics of the neural network, which is determined by six physiological parameters:

One parameter, the source term in the field equations, plays a major role in firing, and imposes the latency onset. It depends on the internal biochemical state of the stimulated neuron that becomes active.

Three parameters describe the dynamics of firing, i.e., the time evolution of

Three parameters describe the dynamics of firing, i.e., the time evolution of firing as determined by the dynamics of the entire synapse-cell body system.

This dependence is represented accurately by a linear function.

Two parameters describe the influence of synaptic activation upon the generation of extracellular potentials when cells are not active. This resting state depends on stimulation intensity according to a function that can be estimated with experimentally determined I/O curves.

Finally, the mathematical model can be simulated with a computer. In the

Finally, the mathematical model can be simulated with a computer. In respectific case of the hippocampus, a geometrical model describes the interaction between the set of active perforant path afferents assumed to be a cylinder with a diameter depending on stimulation intensity, and a conical shape of the granule cell dendritic tree. An assumed topographical distribution of en passage synapses should permit calculation of the number of stimulated and activated granule cells according to the values of the above parameters. BRAIN METABOLISM AND BLOOD FLOW: EXOGENOUS FACTORS

307.1

BLOOD FLOW TO CHOROID PLEXUS DURING HYPERCAPNIA. <u>John L.</u>
<u>Williams, S.C. Jones, and Robert M. Bryan, Jr.</u> Cleveland
<u>Clinic Foundation, Cleveland, OH 44195 and Milton S. Hershey</u>

Medical Center, Univ. of Pennsylvania, Hershey, PA 17033.
The response of choroid plexus blood flow (CPBF) during hypercapnia is controversial. In this study, we examined effects of hypercapnia on CPBF in unanesthetized, Long-Evans rats and in rats pretreated with phentolamine, an al-pha-adrenergic antagonist. Rats were first prepared surgi-cally during nitrous oxide-halothane anesthesia. After recovery, unanesthetized rats breathed air or a 5-8% $\rm CO_2$ -air mixture. CPBF was measured with [14C]isopropyliodoamphetamine and quantitative autoradiography. CPBF in hyper-capnic rats (PaCO₂ = 61.6±1.6 mmHg, mean±SE) was similar to CPBF in normocapnic, control rats $(525\pm39~\text{ml}\cdot\text{min}^{-1}\cdot100\text{g}^{-1};$ PaCO₂ =42.7 \pm 0.6 mmHg; n = 7). In contrast, blood flow to cerebral cortex increased 67% during hypercapnia (P<0.01). CPBF in normocapnic rats that were treated with phentolamine (n = 7) was similar to untreated normocapnic and hypercapnic rats. However, during hypercapnia, CPBF in phentolamine-treated rats (n = 6) increased 29% (P<0.001).

Our findings indicate that hypercapnia has no effect on CPBF when alpha-adrenergic receptors are intact. In contrast, after blockade of alpha-adrenergic receptors, hypercapnia increases CPBF. These findings suggest that, during hypercapnia, catecholamines are released and prevent increases in CPBF.

CEREBRAL VASODILATORY FUNCTION IN THE STREPTOZOTOCIN (STZ) DIABETIC RAT. <u>D.A. Pelligrino and A.J. Sharp*</u>. Dept. of Anesthesiology, Univ. of Illinois/Michael Reese Hosp., Chicago, IL

thesiology, Univ. of Illinois/Michael Reese Hosp., Chicago, IL 60616.

It has been suggested that a cerebral microangiopathy develops in the diabetic (D) to the extent that cerebral vasodilatory function may be impaired. To investigate this, we measured in the chronically hyperglycemic D rat (-6 mo. post-STZ), compared to agematched non-diabetic (ND) controls, the regional cerebral blood flow (rCBF) changes accompanying hypoglycemia (HG), hypoxia (HK), or hypercapnia (HC). For surgical preparation, rats were maintained on 0.7% halothane/70% N₂0/30%O₂, paralysis, artificial ventilation, and local anesthesia. For study, the halothane only was discontinued (>1 h). rCBF was measured, via radiolabeled microspheres, in the cortex (CX), subcortex (SC), brainstem (BS), and cerebellum (CE). In all rats, initial rCBF determinations were made at a normal P₂O₂ (35-40 mmHg) and P₂O₂ (>90 mmHg). For HG studies, rCBF was measured prior to i.v. insulin and at a plasma glucose -1.8mM. For HX, a second rCBF evaluation was made with P₂O₂-30-40 mmHg (normal P₂O₂). With HC experiments, a second rCBF measurement was performed at a P₂O₂-70-80 mmHg (P₂O₃ normal). When comparing D to ND rats, the cerebral hyperemic response to HG was lost in 3 of 4 regions (CX, SC, CE), but no changes were observed in the responses to HK or HC. These results might be a result of a diminished cerebrovascular 8-adrenergic (8-ad) receptor density in D rats and that 8-ad influences play a far greater role in the hyperemia associated with HG, as opposed to HX or HC.

307.2

CEREBRAL BLOOD FLOW (CBF) DURING HYPOGLYCEMIA IN REGIONS WITH AND WITHOUT A BLOOD-BRAIN BARRIER (BBB). R.M. Bryan.

Jr. J.C. Reichert, S.C. Jones, and J.L. Williams. Dept. of Surgery, Hershey Medical Center, Hershey, PA 17033.

CBF was measured in rats during mild hypoglycemia in order to compare CBF in regions with and without a BBB. Male Long-Evans rats were fasted overnight and surgically prepared with halothane/nitrous oxide. The hindquarters of each rat was immobilized with a plaster cast and the rats were allowed to recover from the anesthesia. GBF was measured using C-isopropyliodoamphetamine after iv saline injection in controls or iv insulin injection (15 units/kg) in experimental rats. Plasma glucose was 8.2 umol/ml (148 mg/dl) in normoglycemic control rats and 1.7 umol/ml (31 mg/dl) in hypoglycemic rats. In general brain regions lying behind the BBB showed significant increases in CBF during hypoglycemia. The increase ranged from 19% to 120% with the mean increase of 22 regions being 70%. Regions not lying behind the BBB (median eminence, neural lobe, chloride plexus, and pineal) had higher resting flows than most other brain regions and showed no tendency to increase their flow during hypoglycemia; in fact, there was a tendency for some of these regions to decrease their rates of blood flow. We conclude that the presence or the absence of the BBB for a given region is an important factor in the regulation of blood flow during hypoglycemia. The fact that CBF did not increase in regions without a BBB may be due to their ability use substrates other than glucose.

307.4

SOMAN INDUCES UNCOUPLING OF CEREBRAL BLOOD FLOW AND META-BOLISM IN CEREBRAL CORTEX. O.U. Scremin, T. Shih and K.D. Corcoran* V.A. Medical Center, Albuquerque, NM 87108 and USAMRICD, Aberdeen Proving Ground, MD 21010-5425.

Regional cerebral blood flow (rCBF) and glucose utilization (rCGU) were studied in conscious rats with a quanti-tative, double label, autoradiographic technique. Animals were treated with saline or soman (33-55 ug/kg) by subcutaneous route and rCBF/rCGU measurements were performed 1 hr later. Animals showing signs of toxicity were excluded. No change in mean arterial blood pressure was induced by soman with the doses used (before drug=112(1.7) after drug=105(3.9), n=7). A significant increase in rCBF was observed in motor, somatosensory, temporal, occipital, olfactory and cingulate cortex of soman treated animals but no changes were observed in rCGU in these same regions. A similar phenomenon was recorded in claustrum and anterior thalamus. In contrast, no changes in rCBF or rCGU were observed in posterior thalamus, hippocampus, striatum, preoptic area, hypothalamus or brain stem. A parallel increase in rCBF and rCGU was only observed in the superior colliculus. In conclusion, in the absence of signs of toxicity, soman uncouples blood flow and metabolism in select areas of the brain that show significant hyperemia.

EFFECTS OF HEMIBRAIN X-IRRADIATION ON CEREBROVAS-CULAR AND METABOLIC FUNCTION. E. H. Lo, D. M. Kunis, G. K. Steinberg, K. A. Frankel*, R. L. DeLaPaz*, A. Poljak*, N. B. Manley and J. I. Fabrikant*. Department of Biophysics, Univ. California, Berkeley, CA94720; Stanford University School of Medicine,

It has been demonstrated that the rabbit brain is a suitable experi-It has been demonstrated that the rabbit brain is a suitable experimental model for investigating the delayed reaction to radiation injury in the brain (Lo, E. H.; Brain Res., 504:168-172, 1989). In this study, alterations in blood-brain barrier (BBB), regional cerebral blood flow (rCBF), and metabolic function were examined following high-dose (60 Gy, 225 keV X-rays) irradiation to the left hemisphere of the rabbit brain. GdDTPA-enhanced magnetic resonance imaging (MRI) demonstrated focal regions of BBB disruption in irradiated brain 2.5 mo post-irradiation. These BBB disruptions were primarily limited to the corona radiata, hippocampus, and fimbria. There were no changes in T1-weighted or T2-weighted scans. Radioactive microsphere flow studies were conducted to measure radiation-induced alterations in rCBF. At 2.5 mo post-irradiation, significant decreases in rCBF were demonstrated in the irradiated hemisphere (p<0.05). Alterations in cerebral metabolism were measured *in vivo* using positron emission tomography (PET). Initial results suggest that profound alterations in cerebrovascular and metabolic function occur following high-dose irradiation to the rabbit brain. These alterations may play important roles in the potentiation and development of delayed radiation injury in the brain. RETINAL AND CEREBRAL BLOOD FLOW DURING GENERAL ANESTHESIA. S. Roth.* A.P. Crittenden.* and S. Glusman. Department of

ANESTHESIA. S. Roth,* A.P. Crittenden.* and S. Glusman. Department of Anesthesia and Critical Care, University of Chicago, Chicago, IL 60637 We have previously shown that enflurane anesthesia increases retinal blood flow (ARVO, 3282, 1990). We performed this study to test the hypothesis that cerebral (CBF) and retinal blood flow (RetBF) are autoregulated in a similar manner during general anesthesia. With approval of our Animal Care Committee, we studied 13 adult cats anesthetized with enflurane, air, and oxygen. We placed bilateral femoral artery and venous catheters, a left atrial catheter (via a thoracotomy), and bilateral intraocular pressure cannulae. The Peo₂ was controlled between 25 and 30 mmHg (normocarbia). Cats were anesthetized with three different concentrations of enflurane (0.5, 1.0, and 15 MAC) a standard anesthetic measurement) administered in a random Cats were anesthetized with three different concentrations of entitiating (0.5, 1.0, and 1.5 MAC; MAC = a standard anesthetic measurement) administered in a random sequence. Blood flows were measured by injection of radiolabelled microspheres into the left atrium. After completion of the experiment, cats were killed and tissues counted for radioactivity using standard methods.

RetBF and CBF (ml/100gm/min) increased significantly during enflurane anesthesia Figure) despite significant decreases in perfusion pressure. The percent of change in RetBF vs CBF was significantly greater at 1.5 MAC than at 0.5 MAC. Both RetBF and CBF are increased in a dose-dependent manner by enflurane although the effect on RetBF is more pronounced.

* = p < .05 vs 0.5 MAC

LARGE REVERSIBLE HYPOXIA-INDUCED DECREASES IN PHOSPHOCREATINE IN THE DEVELOPING BRAIN. D. Holtzman, M. Offutt, F. Jensen, L. J. Neuringer. Dept. of Neurology, The Children's Hospital, Boston, MA 02115 and the F. Bitter National Magnet Laboratory, MIT, Cambridge, MA 02139.

Reversible hypoxia in the mature rodent brain produces up to a 30% decrease in brain phosphocreatine (PC) concentration, a doubling of inorgan decrease in oran prosprocreame (PC) concentration, a doubting of inorganic phosphate (P₁), and no change in ATP. Using ³¹P nuclear magnetic resonance spectroscopy, similar studies have been carried out in immature rats made hypoxic with either intraperitoneal cyanide (KCN) or hypoxic gas mixtures (3 or 4% O₂). with either intraperitoneal cyanide (KCN) or hypoxic gas mixtures (3 or 4% 0₂). Hypoxia in 10-12 day-old animals produced up to a 90% decrease in PC concentration and much larger increases in P₁ concentration than seen in the adult. The brain ATP concentration, measured by the change in nucleoside triphosphate signal, decreased up to 20%. These changes in NMR spectra were associated with electrocortical seizure activity, which occurs during acute hypoxia in 100% of rodent pups at this age (F. Jensen, Neuroscience Abstracts, 1989). All the spectral changes were reversible within minutes of returning the animals to a normoxic gas mixture. The legal decrease in high energy placeholds concentrations in the changes were reversible within minutes of returning the animals to a normoxic gas mixture. The large decrease in high energy phosphate concentrations in the hypoxic immature brain may be due to the seizure activity, which is not seen in the mature animal. The limited capacity for increased ATP synthesis during states of high energy demand in the immature brain also may contribute to the large decreases in brain PC concentration. These animal studies are relevant to the pathogenesis of neurologic sequelae of prematurity and of conditions such as cardiopulmonary bypass in the neonate. [Supported by a Mental Retardation Center Grant from NICHD (P30-HD 18655), an NIH Resource Center Grant (RR-00995), a grant from NICHD (HD 00807), the Kaplan Foundation, and the Cardiovascular Surgery Research Fund of the Children's Hospital).

OUTCOME FOLLOWING COOLING TO NEAR THE FREEZING POINT IN TOTALLY BLOOD-SUSSTITUTED DOGS. M.L.Leavitt*, J.E.Bailes*, T.Shih*, A.M.Elrifai*, E.Teeple*, W.E.Hoffman, J.C.Maroon*. Allegheny-Singer Research Inst., Pittsburgh, PA 15212.

A new technique to maximally suppress metabolism by combining total blood substitution with whole body perfusion at near the freezing point was tested in 11 beagles. At 23°C esophageal temp. (E) the heart was stopped with a cardioplegic blood substitute. Whole body perfusion of K15 aqueous blood substitute (Cryomedical Sciences, Inc.) was continued at a mean blood press. of 30mmHg for the next 155 min. with E < 10°C and a hematocrit of < 1%. The fell to 2°C or less for 1 hr. Upon rewarming to 10°C replacement of the perfusate with whole blood began. Mean duration of cardiac arrest was 169 min. Two dogs died due to technical errors during cardiac defibrillation. Of the 9 survivors, one died at 3 days and the other at 10 days post-op of hepato-renal failure. Creatinine, BUN, SGOT, SGPT, LDH, and alkaline phosphatase were elevated in the first post-op week but returned to normal by the second. Transient hind limb weakness occurred in half the dogs and transient circling in one dog. Two experiments are currently ongoing; all of the other 5 long term survivors behaved normally upon sacrifice at 32 to 51 days post-op. All visceral organs, the visual system and samples from the cranial and peripheral nerves, the spinal cord and 7 brain regions were microscopically normal. These results suggest that near freezing point temperatures can be tolerated in the bloodless state for prolonged periods of time.

BIPHASIC EFFECT OF CP 55,940, A THC ANALOG, ON METABOLIC ACTIVITY IN RAT BRAIN. J. E. Margulies, L. S. Melvin, M. R. Johnson and R. P. Hammer, Jr. Dept. of Anatomy & Reproductive Biology, Univ. of Hawaii, Honolulu, HI 96822 and Central Research, Pfizer Inc., Groton, CT 06340.

Reproductive Biology, Univ. of Hawaii, Honolulu, HI 96822 and Central Research, Pfizer Inc., Groton, CT 06340.

CP 55,940, a synthetic cannabinoid with high enantioselectivity and potency, has recently been used to identify, characterize and localize a cannabinoid receptor. In this study, regional metabolic activity was measured in male Sprague-Dawley rats following acute treatment with CP 55,940 using the quantitative 2-[14C]deoxy-D-glucose (2DG) autoradiographic method. CP 55,940 (0, 0.02, 0.05, 0.1 and 1.0 mg/kg, i.p.), solubilized in 5% propylene glycol and 0.5% Tween 80, was administered 1 hour before 2DG injection. Timed arterial blood samples were collected, and local cerebral glucose utilization (ICGU) was determined. CP 55,940 altered ICGU in a biphasic, dose-dependent manner in hippocampus and cortical regions. Low doses (0.02 and 0.05 mg/kg) significantly increased ICGU in selected brain regions, while higher doses (0.1 and 1.0 mg/kg) produced a generalized decrease of metabolic activity relative to vehicle treatment. In particular, low CP 55,940 doses increased ICGU (33-65%) in motor, somatosensory, cingulate, auditory, visual and entorhinal cortices. All layers of hippocampal region CA1 showed increased ICGU (35-74%) following 0.02 mg/kg however, CA3 was relatively less affected. In contrast, ICGU was unaffected in thalamic regions. This biphasic response is consistent with the metabolic effects of acute delta-9-THC (Margulies and Hammer, Brain Res., submitted) wherein maximal effects are observed in brain regions known to contain high densities of cannabioniod recenters. (Supported by ISPHS Awards DAO4081 and NSO1161) observed in brain regions known to contain high densities of cannabinoid receptors. (Supported by USPHS Awards DAO4081 and NSO1161.)

BRAIN VASOACTIVE EFFECTS OF PHENOBARBITAL DURING HYPERTENSION AND HYPOXIA IN NEWBORN PIGLETS. J. Goddard-Finegold and L.H. Michael.* Depts. of Pediatrics (Neurol.), Physiol., and Med., Baylo College of Medicine, Houston, Tx. 77030.

Phenobarbital (PBS) at anti-convulsant levels lowers cerebral blood flow (CBF) during hypertension (HT) in newborn dogs (in press). We proposed that hypoxic dilatation of brain vessels might that hypoxic dilatation of brain vessels might overcome this effect. 12 control and 8 PBS-treated piglets (1-3 days postnatal) had microsphere determinations of CBFs during (1) steadystate (SS), (2) phenylephrine-induced HT, and (3) HT plus 5 mins. of hypoxia (HTHY). PBS was infused after SS in 1 ml. volume (20mg/kg); levels were 27.5+10ug/ml. pO2s were reduced significant ly from SS during hypoxia, and pCO2s ranged from 30 to 37 mm Hg (n.s. within or between groups). SS CBFs were 37+16(C) and 40+20(PBS) ml/min/100q. During HT CBFs were 61+21(C)[p=.006 comp. to SS] During HT CBFs were 61±21(C)[p=.006 comp. to SS] and 49±14(PBS)[n.s. comp. to SS]. During HTHY, CBFs were not signif. different from those during HT. We conclude that (1) in the newborn piglet, as in the newborn puppy, PBS attenuates CBF during HT, and (2) this PBS effect persists during HT plus five minutes of hypoxia without hypercarbia. In addition, hypoxia does not increase CBF further during HT. (Supp. by NS28388 to JGF).

CHANGES IN MEMBRANE PROPERTIES AND SURVIVAL STRATE-GIES FOR TURTLE BRAIN DURING ANOXIA. M. Pérez-Pinzón, C. Chan*, M. Rosenthal and T. Sick. Dept Neurology, Univ Miami Med Sch, Miami, FL 33101, *Dept Physiology, CUNY Med Sch, NYC 10031

Turtle brain survives prolonged anoxia during which ion homeostasis and ATP levels are maintained. A key to such survival may be decreased energy consumption from depression of electrical activity, and changes in membrane physiology which decrease reliance on ion transport. To examine these suggestions, it was necessary: a) to determine if an in vitro preparation of turtle brain survived anoxia; and b) by intracellular recording, to define changes in synaptic transmission, spike activity and resting membrane properties during anoxia. In cerebellum isolated from freshwater turtles, extracellular potassium ion activity (K+)o was maintained for at least six hours of anoxia when superfused with 20 mM glucose. Anoxia exacerbated oscillations in transmembrane potentials (TMP) with a general pattern being that TMP became relatively more depolarized in most Purkinie cells. However, TMP was never depolarized to levels associated with energy failure. Sodium (and likely calcium) spike thresholds were increased, postsynaptic responses from the major afferent input pathways to Purkinje cells were depressed but input resistance underwent no consistent pattern of change among cells. Although preliminary, this latter finding suggests that maintenance of ion homeostasis remains linked to ion transport rather than to changes in membrane conductances. We conclude that during anoxia, synaptic depression and spike threshold increases occur which likely contribute to the sparing of energy for ion transport and perhaps other functions which may be more directly related to cell survival.

307.13

BRAIN CAPILLARY PERFUSION AND BLOOD VOLUME DURING ACUTE HYPOXIA, HYPERCAPNIA OR PENTOBARBITAL ANESTHESIA. Robinson, N. Villacreses*, S. Rapoport and Q. R. Smith, Lab. of Neurosciences, NIA, NIH, Bethesda, MD 20892. Several studies have reported that only a fraction of

brain capillaries are perfused under normal conditions and that the fraction varies with cerebral blood flow (CBF), metabolism and physiologic state. To determine whether changes in blood flow result in measurable changes in perfused brain capillary surface area or blood volume, regional blood-brain barrier permeability-surface area (PA) products for [14C]sucrose and [14C]urea, and brain "blood" volumes to [14C]inulin and [3H]dextran were measured in normal awake rats, in rats made acutely (10 min) hypercapnic (10% CO₂) or hypoxic (6% O₂), and in rats anesthetized with sodium pentobarbital (50 mg/kg, i.p.). CBF was quantitated using [14C]IAP. As expected, CBF increased markedly (2-3 fold) during acute hypoxia or hypercapnia and decreased 30-50% with pentobarbital anesthesia. However, there were no statistically significant changes among groups in PA or "blood" volume for any of The results indicate that, if capillary recruitment does occur in brain, it may not be through the addition of previously unperfused, collapsed capillaries, and that small tracer penetration into unperfused capillaries is "blood" volumes between large and small tracers.

CEREBROVASCULAR RESPONSIVENESS TO HYPEROXIC-HYPERCAPNIA AFTER BRAIN MISSILE WOUNDING (BMW) IN PENTOBARBITAL ANESTHETIZED CATS. D. Torbati M.E. Care‡ and J.F. Davidson*
Dept. Neurosurg. LSU Med. Ctr., New Orleans, LA 70112.

We have previously studied the regional cerebral blood flcw (rCBF; responsiveness to normoxic-hypercapnia (5% CO₂) and hyperoxic-normocapnia (100% O₂) in pentobarbitāl anesthetized ventilated cats subjected to BMW. After BMW the vasodilatory effect of hypercapnia was entirely abolished and the vasoconstrictive effect of hyperoxia was enhanced in all structures. Since these conditions may enhanced in all structures. Since these conditions may prevent adequate brain oxygenation, we tested the hypothesis that a hyperoxic-hypercapnic mixture may ameliorate the enhanced vasoconstrictive effect of hyperoxia after wounding. The rCBF responsiveness to 95% O₂ + 5% CO₂ breathing was determined before and after BMM, inflicted by a 2mm steel sphere penetrating fronto occipitally through an intact cranium. Our preliminary results (n=3), as compared with previous data, indicate that before BMW the vasodilatory effect of hypercapnia predominated the vasoconstrictive effect of hyperoxia. After BMW however, the vasodilatory effect of hypercapnia was completely abolished, whereas the vasoconstrictive effect of hyperoxia was ameliorated in all brain areas except in the damaged tissues. Thus, brain tissue oxygenation after wounding in undamaged tissues may be improved by a hyperoxic-hypercapnic mixture rather than by hyperoxia alone. Supported by contract No. DAMD17-86-C-6098 LAIR, USMRDC.

HORMONAL CONTROL OF BEHAVIOR II

CHRONIC FIGHTING IS FOLLOWED BY INCREASES IN PLASMA PITUITARY-ADRENOCORTICAL HORMONES AND DECREASES IN TESTOSTERONE AND IMMUNE RESPONSIVENESS IN SUBMISSIVE MALE HAMSTERS. K.L. Huhman, T.O. Moore, C.F. Ferris',
E.H. Mouqey, E.W. Bernton*, & J.L. Meyerhoff. Dept.
Medical Neurosci., Walter Reed Army Institute of
Research, Washington, D. C. 20307-5100; Dept. Physiol., U. Mass. Med. School, Worcester, MA 01605.

This experiment was designed to examine the hormonal and immune responsiveness of dominant and submissive male hamsters following chronic exposure to social conflict. Hamsters were housed in double cages divided by mesh guillotine doors which allowed the animals constant visual, olfactory, and auditory communication with one another. The animals were paired (guillotine doors lifted) twice a day for 15 minutes on five consecutive days. Two observers rated the animals as dominant or submissive. Following the final we measured plasma adrenocorticotropin (ACTH), cortisol, and testosterone. We also examined splenic lymphocyte proliferation in vitro following mitogenic challenge.

Submissive, but not dominant, hamsters exhibited increases in plasma ACTH and cortisol and a decrease in plasma testosterone. Lymphocyte proliferation following challenge with Concanavalin-A was decreased in submissive hamsters. Further study of immune responsiveness following fighting is planned.

CHANGES IN DISTRIBUTION OF LUTEINIZING HORMONE RELEASING HORMONE (LHRH)-LIKE **IMMUNOREACTIVITY FOLLOWING SEXUAL ACTIVITY** IN DOVES. C. Ramos and R. Silver. Barnard College of Columbia Univ., New York, NY 10027

LHRH immunoreactivity was examined throughout the brain of ring doves using LR-1 (gift of R. Benoit). Immunoreactive perikarya and/or fibers were consistently observed in the following regions: lining the ependymal wall, medial to the ventriculus olfactorius (VO), medial to the ventriculus lateralis (VL), nucleus septalis lateralis (SL), nucleus preopticus anterior (POA), nucleus preopticus medialis (POM), bed nucleus pallial commissure (nCPa), nucleus septalis medialis (SM), lateral hypothalamic area (LHy),in the midline region coursing towards the decussatio supraoptica (DS), dorsal to DS, nucleus dorsomedialis anterior thalami (DMA), nucleus dorsomedialis posterior thalami (DMP), median eminence (ME), and central gray (GCt). All immunoreactivity was adsorped with mammalian LHRH.

In contrast to isolated doves, birds which had been paired with a novel partner for two hours prior to sacrifice expressed LHRH-like immunoreactivity in the lateral habenula (HL) and in the right hemisphere of a localized region of Field L (FL). Immunoreact i vity in the lateral habenula was adsorped with both cGNRHI and cGNRHII (gift of R.Millar) but not with mammalian LHRH. (Supported by NIMH 029380-14).

SEXUAL CYCLICITY IN MONOGAMOUS PRIMATES. B. Ingelett*, J. French*, and S. Hendricks. Department of Psychology, University of Nebraska at Omaha, Omaha, NE 68182

The distribution of sexual behavior across the ovulatory cycle was examined in adult heterosexual pairs of golden lion tamarins (Leotopithecus r. rosalia). Urinary estrogen and luteinizing hormone were assayed in urine samples obtained from females (N=6) to monitor the ovarian cycle throughout the study. Behavioral interactions between males and females were recorded using a pair test paradigm. Thirty pair tests were conducted in each of the following conditions: 1) partners were randomly assigned immediately prior to each test; 2) partners were specifically assigned but had no interaction outside of the pair tests; and 3) partners were permanently housed together but could not interact sexually except during pair tests. Affiliative behaviors such as remaining in close proximity, sniffing, allo-grooming, and huddling were higher in Conditions 2 and 3 compared to Condition 1. However, sexual behavior (female solicits, sexual mounts, and intromissions) occurred more often between partners in Conditions 2 and 3 than between partners in Condition 1. Sexual behavior was differentially distributed across the ovulatory cycle in each of these conditions. The patterns of social sexual activity will be discussed with regard to sexual cyclicity and monogamous mating systems.

308.5

EFFECTS OF CHRONIC STRESS ON SEXUAL BEHAVIOR IN OLFACTORY BULBECTOMIZED FEMALE RATS. G.W. Williams*, M.Y. McGinnis and A.R. Lumia*. Biopsychology Prog., Skidmore College, Saratoga Springs, NY 12866 and Dept.Cell Biology/Anatomy Mt. Sinai Sch. Med., CUNY, New York, NY 10029. Chronic stress activates the hypothalamopituitary-adrenal system and alters serum glucocorticoids. Chronic stress also alters ovarian cyclicity suggesting it may affect sexual behavior. Because bilaterally olfactory bulbectomized (BOB) rats are commonly used as a model for studying stress, and show behavioral extrasensitivity to estrogen (E2), we examined the effects of a subthreshold E2 dose on chronically stressed, BOB females. Ovariectomized Long-Evans rats received either BOB or sham surgery. Beginning a week later, half the rats in each group received 21 days of predictable chronic stress (strobe light and siren). On day 22 all rats received a 5 mm E2-filled Silastic capsule for 4h. The next day 500ug progesterone was given and rats were tested for sexual behavior. Chronic stress significantly increased both lordosis and proceptivity regardless of surgical condition. Results suggest that predictable chronic stress induces hypersexuality in both BOB and sham operated female rats.

DEVELOPMENTAL CHANGES IN THE SPONTANEOUS LOCOMOTOR ACTIVITY OF JUVENILE MALE AND FEMALE MEADOW VOLES. M. Kavaliers. D.M. Tysdale*. E.L. Hargreaves. K.-P. Ossenkopp and R.R. Shivers. Div. Oral Biology and Dept. Psychology, Univ. Western Ontario, London, Ontario, CANADA N6A 5B7.

Psychology, Univ. Western Ontario, London, Ontario, CANADA N6A 5B7.

Results of both field and laboratory studies have revealed sex differences in the locomotor activity of adult meadow voles, Microtus pennsylvanicus. Adult males of this polygynous microtine rodent have been shown to have greater levels and patterns of activity than adult female voles. Little is known, however, about the development of these sex differences and the emergence of the adult patterns of activity. In the present study developmental changes in the locomotor behavior of juvenile (7-36 days of age) male and female meadow voles were examined in the laboratory through a multivariate measurement of spontaneous activity with a Digiscan Animal Activity Monitor. The locomotor activity variables that were measured over 0.5-1.0 hour periods included: total distance travelled (TD), average distance travelled (AD), average speed (AS), number of movements (NM) and time in movement (MT). It was found that the spontaneous activity of the juvenile meadow voles differed from that of the adults. The juvenile voles showed no evident sex differences in their spontaneous activity, as well as, no consistent levels or patterns of activity through early (7-21 days of age) juvenile development. These findings indicate that male-female differences in activity are not present during early development in juvenile meadow voles. (Supported by Grants from NSERC to M.K. and K.P.O)

308.4

HORMONAL BASIS OF FEMALE AGGRESSION AND MALE PARENTAL CARE IN SEX-ROLE REVERSED BIRDS. A.J. FIVIZZANI and L.W. ORING* Biology Dept., Univ. of North Dakota, Grand Forks, ND 58202.

of North Dakota, Grand Forks, ND 58202.

A few avian species such as the spotted sandpiper and Wilson's phalarope display reversed sex roles, i.e., females aggressively compete for mates and primarily males incubate eggs and care for chicks. Plasma levels of prolactin, the hormone associated with parental care in birds, is also reversed being greater in concentration in incubating males than in females. The aggressiveness of females in competing for mates, however, is not based upon a reversal of the typical avian pattern of gonadal steroid hormones. Testosterone levels are 6 to 10-fold greater in males than in females, whereas estradiol levels are greater in females, Female phalarope aggression is not based upon atypical brain steroid conversion enzymes as hypothalamic/preoptic aromatase activity was greater in males than in females and reductase activity was equivalent. Female aggressiveness may be dependent upon unusual densities of steroid hormone receptors in adult neural tissue or upon exposure of embryonic brain tissue to atypical hormone profiles. Supported by NSF Grant DCB 8608162.

SEX DIFFERENCES IN THE SPONTANEOUS LOCOMOTOR ACTIVITY OF THE MEADOW VOLE (MICROTINAE): REVERSAL OF THE USUAL LABORATORY RODENT PATTERN. D.M. Tysdale*. E.L. Hargreaves. M. Kavaliers. K.-P. Ossenkopp. and D.P. Cain. Div. Oral Biology and Dept. Psychology, Univ. Western Ontario, London, Ontario, CANADA N6A 5B7.

The locomotor behavior of a polygynous microtine rodent, the

The locomotor behavior of a polygynous microtine rodent, the meadow vole, Microtus pennsylvanicus, was examined in the laboratory through a multivariate measurment of spontaneous activity with a Digiscan Animal Activity Monitor. The locomotor activity variables that were measured over 0.5-1.0 hour periods included: total distance travelled (TD), average distance (AD), average speed (AS), number of movements (NM), and time in movement (MT). Significant sex differences in activity were observed, with adult male voles exhibiting greater levels and amounts of activity than adult female voles. These sex differences in activity were present in both wild and laboratory bred voles and were evident across recording sessions and breeding conditions. These sex differences in the spontaneous activity of meadow voles are the reverse of what has been reported for laboratory rats, whereby females are indicated to be more active than males. The present male-female differences in the laboratory activity of meadow voles do, however, agree with the sex differences in activity that have been observed in field studies and are consistent with the ecology of meadow voles. (Supported by Grants from NSERC to M.K., K.P.O. and D.P.C.)

SEX DIFFERENCES IN THE SPONTANEOUS LOCOMOTOR ACTIVITY OF THE LABORATORY RAT: MULTIVARIATE AND TEMPORAL PATTERNS. E.L. Hargreaves, D.M. Tysdale*, D.P. Cain, K.-P. Ossenkopp, and M. Kavaliers. Dept. Psychology and Div. Oral Biology, Univ. Western Ontario, London, Ontario, CANADA N6A 5C2.

The locomotor behavior of the laboratory rat (Royal Victorian Hooded), Rattus norvegicus, was examined in the laboratory through a multivariate measurment of spontaneous activity with a Digiscan Animal Activity Monitor. Three samples were collected per session with sessions run serially on 4 consecutive days. In one experiment the session had a duration of 0.5 hours, in another, the duration was only .15 hours. Variables examined included: total distance travelled (TD), average seamined included: total distance travelled (TD), average speed (AS), number of movements (NM), time in movement (TM), number of vertical movements (YM) and time in vertical movement (VT). The 0.15 hour sessions revealed significant sex differences on the following variables: TD, AD, AS, and VT, with the female rats exhibiting higher levels of activity. A similar, but not identical pattern of sex differences was seen during the 0.5 hour sessions, where differences were observed on TD, AD, and AS. Within a session across the three samples activity declined for both sexes, with the activity of the females declining faster than that of the males. The only exception to this was observed during the 0.15 hour sessions where NM actually increased across the three samples. The observed sex differences and within session trends were consistent across days. These results support and expand previous findings from wheel running and open-field studies. (Supported by Grants from NSERC to D.P.C., K.P.O. and M.K.)

MULTIVARIATE ANALYSES OF SPONTANEOUS LOCOMOTOR ACTIVITY OF THE LABORATORY RAT ACROSS THE ESTROUS CYCLE: A PRELIMINARY REPORT. D. Sauvé*, E.L. Hargreaves, D.J. Stewart and D.P. Cain. Dept. Psychology, Univ. Western Ontario, London, Ontario, CANADA N6A 5C2.

The spontaneous locomotor behavior of the laboratory rat (Royal Victorian Hooded), <u>Rattus norvegicus</u>, was monitored across the estrous cycle through multivariate measurement of activity with a Digiscan Animal Activity Monitor. Three samples activity with a Digiscan Animal Activity Monitor. I have samples were collected per session with each session having a duration of 0.15 hours. Activity sessions were run invariantly between 17:30-18:30 approximately 3 hours prior to the onset of the dark phase. Weights and vaginal smears were taken immediately after each session. The experiment was run for 40 days with a minimum of 5 cycles collected from each animal. Males were simultaneously run to account for non-hormonal influences on spontaneous activity. Variables examined were selected for their past ability to show sex differences. For similar reasons only data from the first sample of the session were analysed. Results indicate that spontaneous locomotor activity across all testing days was higher for females, but failed to indicate consistent changes across the for females, but failed to indicate consistent changes across the estrous cycle. However, similar analyses of body weight across the cycle indicated that it was lowest at estrous and highest at diestrous. These results concur with previous findings of weight changes and sex differences, but fail to replicate those of activity across the estrous cycle. Analyses continue on the remaining samples and unexamined variables. (Supported by Grants from NSERC to D.P.C.)

PERIPHERAL SEXUAL DIMORPHISM WITHOUT CORRESPONDING CNS DIMORPHISM IN A HORMONE-SENSITIVE NEUROMUSCULAR SYSTEM. M. Seiwert and E. Adkins-Regan Department of Psychology, Cornell

C.M. Sciwert and E. Adkins-Regan Department of Psychology, Cornell University, Ithaca, NY, 14853.

The foam gland complex (FGC) of Japanese quail (Coturnix japonica) is a large sexually dimorphic structure located in the dorsal cloaca. The FGC consists of an aggregate gland whose units are interdigitated with fibers of the sphincter cloacae muscle (mSC). The gland secretes a fluid that is whipped into a stiff foam, possibly by the undulation of mSC (Klemm et al., 1973), which is transferred to the female during copulation. Although the FGC is present and androgen-sensitive in both sexes, in females it is much smaller and no foam is produced (Nagra et al., 1959). To investigate possible neural correlates of this peripheral set difference. 1959). To investigate possible neural correlates of this peripheral sex difference, the dendritic field of mSC motor neurons was characterized in male and female Japanese quail. 0.5µl of 0.2% cholera-toxin conjugated horseradish peroxidase (CT-HRP) was injected into the dorsal midline of mSC and the FGC was measure externally. Because it was not possible to assign arbor to specific neurons, the externally. Because it was not possible to assign above a special content, and dendritic field of the entire population of neurons was measured. Analyses in the medial-lateral and rostral-caudal planes revealed no evidence of sex differences in the mean, minimum, or maximum length or width of the dendritic field [length; mean, μ] me mSC motor neurons, are in striking contrast to the large sex difference in FGC area (males: x±sem=165±15mm²; females: x±sem=49±6mm²; t(14)=7.18, p<.0005]. Future work will address the possibility of a sex difference in the number of motor neurons innervating mSC and will further characterize the dimorphim in mSC itself. INFLUENCE OF THE VASOPRESSIN-DEFICIENCY OF BRATTLEBORO (BB) RATS ON A SEXUALLY DIMORPHIC BEHAVIOR. M.D. Brot, I.L. Bernstein, and D.M. Dorsa. Depts. of Psychology, Pharmacology, and Medicine, Univ. of WA, and GRECC, VA Medical Center, Seattle, WA 98195

We have examined the interaction of gender with vasopressin (VP)-deficiency using a conditioned taste aversion (CTA) paradigm. The extinction of CTAs has been shown to be steroid-dependent such that male rats retain a taste aversion longer than females. VP induces a long-term inhibition of extinction of an avoidance response whereas long-term inhibition of extinction of an avoidance response whereas VP-deficient BB rats are not able to retain such a response. The expression of the VP gene and VP immunoreactivity in the brain is also steroid-dependent. We reasoned that gonadal steroids might influence the retention of a CTA by acting on the VP system and that homozygous BB rats therefore would not exhibit sex differences in a CTA. Three rat strains were used: BB homozygous (BB-HO), heterozygous (BB-HET), and Long-Evans (LE). Male and female LE and BB-HO and males of BB-HET strains were given 10% sucrose to drink, then injected with LiCl to create a taste aversion to the sucrose. Rats that developed aversions were given ad his access to water and sucrose solution for 3

aversions were given ad lib access to water and sucrose solution for 3 weeks and their fluid intake was monitored.

Overall, the strain comparison showed that BB males extinguished faster than LE males with the BB-HETs showing intermediate retention. The gender comparison indicated a reverse pattern of extinction. While LE females extinguished quickly, BB-HO females maintained their aversions for much longer. The results of these preliminary studies suggest that expression of the sexually dimorphic retention of CTA is dependent on an intact VP system.

INTRACRANIAL ANDROGENIC AND ESTROGENIC STIMULATION OF MALE-TYPICAL BEHAVIORS IN HOUSE MICE. John Nyby 1, John Matochik 2 & Ronald Barfield². ¹Dept. of Psychology, Lehigh University, Bethlehem, PA, 18015, ²Dept. of Biological Sciences, Rutgers University, New Brunswick, NJ,

Two experiments were conducted to examine the neural sites of action of steroid hormones in the activation of male-typical behaviors. Male mice were castrated and randomly assigned to 6 treatment conditions. In Experiment 1, four groups

randomly assigned to 6 treatment conditions. In Experiment 1, four groups bilaterally received 27 ga. cannulae containing testosterone (T) into either the SEPTUM (N=9), MPO (N=9), AHA (N=8), or VMH (N=7). The two control groups received silastic capsules of T (TSIL, N=7) or empty silastic capsules (ESIL, N=7). The TSIL males performed all behaviors at male-typical levels while the ESIL were unresponsive. MPO males emitted ultrasonic mating vocalizations at high levels while few vocalizations were seen in the other groups. The VMH and MPO males urine-marked at higher levels than the ESIL but did not exhibit the high levels of the TSIL. Aggression and mounting were rare in males from any of the brain

of the ISIL. Aggression and mountaing were rate in males from any or the stream implant groups.

In the second experiment, the hormone activity of the implants was increased by using testosterone propionate (TP) or a 50% mixture of estradiol (E2) and cholesterol. The six groups were: SEPTUM TP (N=9), SEPTUM E2 (N=9), MPO TP (N=10), MPO E2 (N=10), TPSIL (N=9), and ESIL (N=9). TP was effective at restoring vocalizations and urine marking only when placed in the MPO, however E2 was effective at both sites. Again aggression and mounting were rare in the implant

In conclusion, implants of T and TP were effective in restoring ultrasonic mating vocalizations and urine marking when placed into the MPO. The restorative effects of E2 were less localized which is probably related to the greater hormonal activity of

(Supported by a sabbatical grant from Lehigh and NIH grant HD-04484.)

DETERMINATION OF AROMATASE ACTIVITY AND ESTROGEN RECEPTOR LEVELS IN DISCRETE BRAIN REGIONS FROM INTACT AND CASTRATED HYBRID B6D2F1 MALE HOUSE MICE THAT COPULATE AND THOSE THAT DO NOT. Sinchak, K.', C.E. Roselli² and L.G. Clemens¹, ¹Dept. Zoology, Michigan State Univ., E. Lansing, MI 48824. ²Dept. of Physiology, Oregon Health Sciences Univ., Portland, OR 97201.

After castration, most males of the B6D2F1 hybrid strain of house mouse (Mus musculus) continue to exhibit an ejaculatory reflex (continuers) for six to twelve months while others do not (noncontinuers). Retention of the ejaculatory reflex in castrated B6D2F1 continuer males appears to be estrogen dependent. In the present study we wished to determine if neural aromatase activity and estrogen receptor levels were different between castrated continuer and noncontinuer and intact B6D2F1 males. Discrete brain regions, preoptic area (POA), hypothalamus (HYP) and amygdala (AM), were microdisceted out and radioassayed to measure aromatase acitivity (AA) and estrogen receptors levels. In general, aromatase activity and estrogen receptors were the same in both castrated continuers and noncontinuers. castration significantly reduced without abolishing aromatase activity in the POA and HYP (p < 0.01). The AM was not affected when compared to intacts. Compared to intact males castration did not affect nuclear estrogen receptors (nER)(fmol/mg DNA) in the POA and HYP, but reduced AM nER. Cytosolic and total estrogen receptors (fmol/mg DNA) increased after castration in all three brain areas with significant increases in the POA and AM (p < 0.05). In conclusion, although estrogen is important for the expression and maintenance of the ejaculatory reflex after castration, we cannot distinguish between castrated continuer and noncontinuer B6D2F1 male mice based on levels of aromatase activity or estrogen receptors in the POA, HYP, and AM.

INSULIN-INDUCED ANESTRUS IN SYRIAN HAMSTERS. J. E. Schneider and G. N. Wade. Dept. of Psychology and Neuroscience and Behavior Program, Univ. of Massachusetts, Amherst, MA 01003. In previous experiments manipulations that decreased the availability

of metabolic fuels interrupted estrous cycles in Syrian hamsters. Low body fat content, food deprivation, pharmacological inhibition of both glucose and fatty acid utilization, and housing at cold ambient tempera-tures all increased the incidence of anestrus. If estrous cycles are tures an increased the incenter of anestius. If estimate years are sensitive to the general availability of metabolic fuels it would be predicted that anestrus would result from enhanced energy storage. In protect that assists would result from tenantic energy storage. In the present experiment, energy storage was promoted by treatment with protamine zinc insulin (PZI, 5U every 12 hr starting on day 1 of the estrous cycle). PZI hamsters fed ad libitum increased food intake, body estrous cycle). PZI hamsters fed ad libitum increased food intake, body weight and body fat levels, however, there were no effects on estrous cycles. PZI hamsters limited to 110% of their pretreatment food intake also increased body weight and fat content and showed decreased plasma glucose levels but, in contrast to ad lib-fed hamsters, showed a significant increase in the incidence of anestrus. We suggest that in the absence of hyperphagia, PZI-enhanced energy storage leads to a shortage of oxidizable metabolic fuels with the result that reproduction is inhibited in favor of processes critical for survival such as cellular maintenance, thermoregulation, or foraging. It is unlikely that anestrus was due to a pharmacological action of PZI unrelated to its effects on metabolic fuel partitioning, since PZI had no effect on estrous cycles in the ad lib-fed hamsters. These findings also raise the possibility that infertility associated with some types of obesity could be due in part to a disorder of macronutrient partitioning. LUTEINIZING HORMONE (LH) RELEASE IS ATTENUATED LUTEINIZING HORMONE (LH) RELEASE IS ATTENUATED IN PRENATALLY-STRESSED (P-S) MALE RATS EXPOSED TO SEXUALLY-RECEPTIVE FEMALES. C.H. Kinsley', P.E. Mann & R.S. Bridges Dept. Psychol., Univ. of Richmond, VA 23173 and LHRRB, Harvard Medical School, Boston, MA 02215.

P-S males show reductions in male sexual behavior, medial preoptic area volume and levels of given by the sexual transfer of th

of circulating testosterone. We examined the LH response to sexually receptive females, a known index of arousal. Adult male offspring from mothers stressed on days 15-22 of pregnancy (thrice-daily exposures to heat, light and restaint) were implanted with an intra-atrial catheter. 48 hours later they were placed into test chambers divided by a wire mesh partition; the catheter was extended outside the chamber 30 min later a baseline blood sample (time 0') was taken. Then a sexually-receptive female was was taken. Then a sexually-receptive female was placed on the side of the partition opposite the male. Blood was taken at 5, 10, 15, 30, 60 min and 24 h after introduction of the female. With the exception of the 0' sample, P-S males exhibited significantly reduced LH levels in response to the female. These data suggest that attenuations in LH release may account, in part, for the marked reductions in male sexual behavior characteristic of the P-S male.

308.17

SEXUAL RESPONSIVENESS OF OLD AND YOUNG FEMALE RATS TO ESTRADIOL. K.C. Chambers, D.L. Yuan, and E.A. Brownson. Depts. of Psychology and Neurobiology, Univ. So. Cal., Los Angeles, CA 90089.

This study was designed to determine whether there are age-related changes in behavioral sensitivity to estradiol (E) in gonadectomized female rats. The 18 old (25.5-27.5 mo) and 23 young (2.5 mo) Fischer 344 rats were given tests of sexual behavior after injections of 3 different doses of estradiol benzoate (EB; 0.1, 1.0, or 10.0 ug/250 g of bodyweight) and 1 dose of progesterone (P; 0.5 mg/250 g of body weight). The frequencies of 3 different intensity levels of a receptive behavior (lordosis in response to a mount) and a proceptive behavior (crouch) were measured. There were no differences in the total frequencies (all intensity levels combined) of the lordosis and crouch responses shown by the old and young females after injections of each dose of EB. However, young females exhibited higher frequencies of the most intense level of the lordosis responses after injections of each dose of EB and higher frequencies of the 2 most intense levels of the crouch responses after injections of the 10 ug dose of EB. These data indicate that age-related deficits in the display of these receptive and proceptive behaviors are a function of the intensity of the response rather than the frequency. Factors other than decreased sensitivity to E most likely account for deficits in intensity of response. HD 20970

308.19

AGE-RELATED DEFICITS IN BRAIN ESTROGEN RECEPTORS AND SEXUAL BEHAVIOR OF MALE RATS. C.E.Roselli, J.E.Thornton and K.C.

Chambers. Physiology Dept., OHSU, Portland, OR 97201 and Psychology Dept., USC, Los Angeles, CA 90089.

Neural estrogen receptors and sexual behavior were measured in young (5 mo) and old (24.5 mo) Fischer 344 male rats that were gonadally intact (I), gonadectomized (GX), or GX and testosterone-treated (GX-T). After behavioral testing, rats were anesthetized, perfused with 10% DMSO and their brains removed and frozen (4 days). The levels of cytosolic (ERc) and nuclear (ERn) estrogen receptors were measured in the preoptic area (POA), hypothalamus (HYP), and amygdala (AMG). Whereas all of the young I males ejaculated during sexual behavior tests, none of the old I did and their mean ERn levels in POA and AMG were ~50% lower than levels in young I males. Gonadectomy eliminated ejaculatory behavior and reduced ERn levels in both old and young males. After treatment, only 33% of the old GX-T males ejaculated while 86% of the young GX-T males ejaculated. ERn levels in old GX-T males were 30-60% lower than levels in young GX-T males, however, they were comparable to young I levels. These data suggest that there is an association between aging and decreased neural ERn levels. Since testosterone treatment increased ERn levels but not the sexual performance levels of old males to those found in young males, the age-related deficits in behavior probably not due to changes in ERn. (Supported by HD23293 and HD20970.)

CORTISOL MICROINJECTIONS IN THE ANTERIOR HYPOTHALAMUS (AH) EXERT DOSE- AND STERDID-SPECIFIC EFFECTS ON THE AGONISTIC BEHAVIORS OF MALE SYRIAN HAMSTERS. D.M. Hayden-Hixson and C.F. Ferris. Dept. of Physiol., U. Mass. Med. Sch., Worcester, MA 01655.

Previous studies have shown that cortisol (F) implants in

AH have site- and context-dependent effects on the agonist ic behaviors of male Syrian hamsters. To determine whether these effects were dose- and steroid-specific, male hamthese effects were dose- and steroid-specific, male hamsters (N=8/ treatment) received 100nL injections of (a)1 of 6 doses of f ($10^{-8}M$, $10^{-7}M$, $10^{-6}M$, $10^{-5}M$, $10^{-2}M$, $10^{-2}M$, $10^{-6}M$); or (b)1 of 2 doses ($10^{-6}M$, $10^{-3}M$) of 1 of 6 steroids (testosterone/1; B-estradiol/BE2; dihydrotestosterone/DH1; progesterone/P4; deoxycorticosterone; F). Experimentals were tested a) for dominant/subordinate responses (D/S test) 5min postinjection in paired encounters with vehicleinjected Controls; b) for odor-induced flank marking (01-FM tests) 20min & 24hr postinjection

injected Controls; b)for odor-induced flank marking (OI-tests) 20min & 24hr postinjection. Significant (P<.05) effects of F, P₄ and DOCA were observed in D/S-tests (10^{-6} M: F induced aggression, P₄ submission; 10^{-3} M: F induced submission, DOCA aggression); of BE₂ and DHT in 20min & 24hr OI-FM tests (10^{-6} M BE₂ stimulated; 10^{-6} & 10^{-3} M DHT inhibited flank marking). These results independ that is a 10-3 of 10-3 o marking). These results suggest that in AH, F and P4 act to promote aggression and submission, respectively; while T-aromatization stimulates and T-reduction inhibits flank marking in response to the odors of conspecifics. (Work supported by NIH grant #NS23557).

SIMILAR BEHAVIOURAL EFFECTS OF ADRENALECTUMY HYPOTHYROIDISM AND FOOD DEPRIVATION IN THE PORSOLT SWIM TEST D Jefferys and J W Funder Medical Research Centre, Prince Henry's Hospital Melbourne, Australia 3004

Medical Research Centre, Prince Henry's Hospital Melbourne, Australia 3004 In the Porsolt swimming test intact animals become progressively immobile over a 15 min test period. On retest 24h later, they remain immobile for $\sim 70\%$ of the 5 min test period. Adrenalectomy (ADRX) blocks retention of the response, which is restored by dexamethasone (IM) or ketocyclazocine (KCZ), given at test but not retest. Propylthiouracil (PTU) treated, hypothyroid rats neither acquire or retain the response, both of which are reversed by thyroxine (T₂) given at test. The present studies show that (a) the behavioural effect of ADRX (surgical, or with peripheral receptor antagonists MR2266 and RU486) is reversed by T₄; (b) the effect of PTU is reversed by IM, ADRX or to a lesser extent KCZ; (c) rats food-deprived for 24h acquire but do not retain the response, an effect reversed by DM, KCZ, T₄ or ADRX; and (d) rats food-deprived for 48h acquire and refain the response, which is blocked by ADRX. We interpret these counterintuitive findings as suggesting (1) possible physiological equivalents of the commonly described pharmacological U-shaped dose response curves; (ii) and important regulatory role for metabolic state in the acquisition and retention of the immobile response; and (iii) a complex effector interaction between glucocorticoids and thyroid hormones, at either the receptor or post-receptor level.

COCAINE INDUCES RAPID EXPRESSION OF C-FOS AND ZIF/268 IN RAT BRAIN. B. M. Cohen. T. Van Nguyen*, S. M. Babb*, S. E. Hyman, Mailman Research Center, McLean Hospital, 115 Mill St., Belmont, MA 02178 and Molecular Neurobiology Lab., MGH, Boston, MA 02114.

The precise mechanisms contributing to the development of

dependence on drugs of abuse remain unknown, but are likely to involve long-term changes in neural functioning. We have been studying early neural events that occur in response to cocaine administration that may contribute to long-term plastic changes in the brain. We have studied the regulation of immediate early gene expression in rat brain after single doses (3 mg or 10 mg) of cocaine given IV. Robust and dose-dependent induction of c-fos mRNA is observed 45 minutes after cocaine administration in frontal and occipital cerebral cortex, cerebellum, amygdala, hippocampus, and striatum. By 75 minutes c-fos mRNA has returned to basal levels. Another immediate early gene, Zif/268 is induced in frontal, parietal, and occipital cortex, amygdala, and hippocampus in dose dependent fashion. Induction of zif/268 is observed 45 minutes after cocaine administration and, in contrast to c-fos, is still observed 75 minutes after administration. Studies of immediate early gene expression permit us to map cells which are activated by cocaine. In addition, since many immediate early genes have been shown to function as transcription factors, their repeated activation with multiple doses of cocaine may lead to alterations in expression of genes involved in neuronal signaling, with important functional consequences. Studies of gene expression following repeated dosing are in progress.

309.3

ENHANCED D2 RECEPTOR BINDING FOLLOWING CHRONIC

ENHANCED D₂ RECEPTOR BINDING FOLLOWING CHRONIC COCAINE TREATMENT IS REVERSED BY BROMOCRIPTINE. D.W. Clow and R.P. Hammer, Jr. Dept. Anatomy & Reprod. Biol., Univ. Hawaii Sch. Med., Honolulu, HI 96822.

Cocaine blocks neuronal uptake of dopamine which in turn alters the post-synaptic response to this neurotransmitter. During abstinence following chronic occaine treatment regional cerebral metabolism is selectively reduced in dopaminergic regions and this can be reversed by bromocriptine (BROM) treatment (Clow and Hammer, Neuropsychopharmacology, in press). In the present study, we investigated the effect of BROM during abstinence following chronic occaine treatment on D₂ receptor binding Male Sprague-Dawley rats were given 14 daily ip, injections of cocaine HCl (Id mg/kg/ml) or saline followed by 3 daily injections of BROM (10 mg/kg/ml) or vehicle. Animals were then prepared for quantitative 2-[¹⁴C]deoxyglucose autoradiography, and the same brains were subsequently prepared for autoradiographic analysis of [³H]spiroperidol binding. D₂ receptor binding was significantly increased relative to control during abstinence following chronic occaine administration, in the rostral but not the caudal portion of nucleus accumbens (NAc) (+48.76%), and in olfactory tubercle (+51.04%), caudatoputamen (+44.43%), and substantia nigra pars compacta (+125.25%). The effect was significantly reversed in these regions by BROM administration. The increased binding in rostral NAc correlates well with the reduced metabolic activity observed in adjacent sections from the same brain region (r=-0.8612, p≤0.05). These results indicate that chronic cocaine administration results in a sustained increase in D₂ binding which is rapidly reversed by bromocriptine intervention. increase in D_2 binding which is rapidly reversed by bromocriptine intervention. Cocaine abstinence-induced D_2 alterations in NAc may represent a regional substrate for bromocriptine-induced metabolic recovery in this region. (Supported by USPHS Awards DA04081 and NS01161)

IN VIVO BINDING, INTERNALIZATION, AND DOPAMINE-RELEASING EFFECTS OF [H-3]-CFT (WIN 35,428): A POTENTIAL BRAIN IMAGING LIGAND FOR DOPAMINE TRANSPORTER OR COCAINE RECEPTOR SITES. J.J. Chen*, J.L. Neumeyer, R.A. Milius, R.M. Brown, and C.C. Chiueh, NIMH & NIDA, Bethesda, MD 20892 and RBI, Natick, MA 01760.

CFT (WIN 35,428) has been shown to exhibit a high affinity for cocaine receptors in vivo and in vitro. In

CFT (WIN 35,428) has been shown to exhibit a high affinity for cocaine receptors in vivo and in vitro. In the present study, $^{9}\text{H-CFT}$ (5 μCi) was injected into striatum 10 min prior to the initiation of an intrastriatal microdialysis procedure (1 $\mu\text{I/min}$) in anesthetized rats. (-)-Cocaine and its tropanyl analogs, CFT, diphenylethylenetropane, and benztropine were added to Ringer solution and perfused for 5 min into the brain through the probe. Dialysates were assayed for tritium overflow or dopamine efflux by HPLC. The resting efflux of newly bound $^{9}\text{H-CFT}$ from striatum was enhanced 2-3 fold by MPP (a non-tropanyl dopamine uptake blocker and a metabolite of MPTP) or cold CFT. Similar to but not identical to MPP, all tested tropanyl compounds produced a calcium-dependent exocytosis of striatal dopamine. ED of CFT and cocaine for releasing endogenous dopamine

of CFT and cocaine for releasing endogenous dopamine were 0.3 and 12 nmol, respectively. It appears that after binding to the dopamine transporter or the cocaine receptor, CFT can be internalized, and be subsequently released from brain dopaminergic terminals $\underline{\text{in}} \underline{\text{vivo}}$.

IDENTIFICATION OF COCAINE-REGULATED PROTEINS IN RAT NUCLEUS IDENTIFICATION OF COCAINE-REGULATED PROTEINS IN RAT NUCLEUS ACCUMBENS BY SUBTRACTION HYBRIDIZATION. K.A. Sevarino, J.R. Walker, R.S. Duman, and E.J. Nestler, Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

The mesolimbic dopamine pathway from the ventral tegmental

area to the nucleus accumbens (NAc) plays a major role in the reinforcement of addictive behavior. In the NAc, behavioral, electro-physiological, and neurochemical studies indicate that chronic exposure to the powerfully addicting drug cocaine results in sensitization to the effects of the drug. To define the biochemical changes that underlie this sensitization we have set out to identify mRNA species regulated in the NAc by chronic cocaine treatment. (Parallel studies on cocaine regulation of second messengers and protein phosphorylation in the NAc are presented herein by Beitner et al. and Nestler et al.)

We isolated mRNA from the NAc of control rats and rats treated

chronically with cocaine. In vitro translation experiments detected a number of mRNA species regulated by chronic cocaine treatment. From the control and treated mRNA pools we synthesized cDNA libraries of 106 recombinants each. The libraries were screened with subtracted probes generated by hybridizing cDNA from control rats with an excess of biotinylated mRNA from treated rats, and vice versa, to isolate downand up-regulated mRNAs, respectively. We are using Northern blot analysis and sequencing studies to examine positive clones.

Characterization of proteins in the NAc that are regulated by chronic cocaine exposure will provide important information recognities the molecular basis of true addiction.

regarding the molecular basis of drug addiction.

309.4

A RAPID BINDING ASSAY FOR SOLUBLE DOPAMINE TRANSPORTERS. R.A. Vaughan*, R. Simantov, R. Lew, E. Webster and M.J. Kuhar. Neuroscience Branch, NIDA Addiction Research Center, Baltimore, MD 21224.

Presynaptic dopamine transporters have been implicated as sites of cocaine action in membrane binding and synaptasomal uptake experiments. A binding assay for solubilized transporters has previously been developed using ³H-GBR 12935. However, this method is limited by the number of samples that can be processed at one time. We have subsequently developed a charcoal binding assay using the cocaine derivative ³H-WIN 35,428 with which

using the cocaine derivative $^{3}H-WIN$ 35,428 with which hundreds of samples can be rapidly processed. Dopamine transporters from dog caudate nucleus were solubilized with 1% digitonin. Binding activity was measured using $^{3}H-WIN$ 35,428 with mazindol (30 μ M) to define non-specific binding. Specific binding was observed in caudate but not in cerebellum and was linear with tissue concentration (20-200 mg/ml original wet with tissue concentration (20-200 mg/ml original wet weight). Binding was saturable ($B_{max}=0.1$ pmole/mg protein) and of high affinity ($K_{d}=4$ nM). Soluble binding was inhibited by mazindol, GBR 12909, (-)cocaine, in a manner typical for binding to the dopamine transporter. Binding was also stereospecific with (+)cocaine being 100-fold less potent than (-)cocaine. Finally citalopram and desipramine exhibited low affinity for 3 B-WIN 35,428 binding, thus binding was neither to serotonergic nor noradrenergic transport sites. serotonergic nor noradrenergic transport sites.

309.6

COMPARISON OF $[^3H]$ CFT AND $[^3H]$ MAZINDOL BINDING IN MOUSE

COMPARISON OF ['H]GFT AND ['H]MAZINDOL BINDING IN MOUSE STRIATUM. M.E.A. Reith and G. Selmeci*. Center for Neurochemistry, NKI, Ward's Island, New York, NY 10035.

Dopamine uptake sites can be labeled with various tritiated ligands such as GBR 12935, methylphenidate, nomifensin, mazindol (MZ), cocaine and WIN 35428 (CFT), but it still under debate whether a common binding site is involved. In the present study ['H]CFT and ['H]MZ binding was compared in the same preparation (fresh mouse striatal P_membranes) under identical conditions (25 mM phosphate, 48 mM Na, pH 7.7: 0°C for 2.h). One-site kinetics were observed for both in the same preparation (fresh mouse striatal r membranes) under identical conditions (25 mm phosphate, 48 mm Na¹, pH 7.7; O°C for 2 h). One-site kinetics were observed for both [3H]CFT and [3H]MZ. Three lipes of evidence support a common binding site. First, [3H]CFT binding was competitively inhibited by 15 nM MZ (K, increased from 9 nM in the absence to 28 nM in the presence of MZ, without a change in B 2, 4.4 pmol/mg prot.). Vice-versa, [3H]MZ binding was competitively inhibited by 10 nM CFT (K, from 9 to 23 nM, unchanged, 3max of 5.0 pmol/mg). Second, the dissociation rate of [3H]CFT or [3H]MZ binding (k, 0.34 and 0.36 min-1) was not affected by the presence of 1 uM MZ or CFT. Third, pretreatment of membranes with N-ethylmaleimide affected [3H]CFT and [3H]MZ binding equally. Conditions used by others for [3H]CFT (frozen tissue, high-speed centrifugation, Tris-Na¹) produced an additional low-affinity binding component. Inhibition of [3H]CBR 12935 binding by CFT under our conditions involved a reduction in Bmax. The present results are consonant with the existence of a common binding site for CFT and MZ, probably distinct from the GBR 12939 site. (Supp.NIDA 03025)

309 7

AUTORADIOGRAPHIC LOCALIZATION OF [3H]CFT BINDING SITES IN SQUIRREL MONKEY BRAIN. M.J. Kaufman, R.D. Spealman and B.K. Madras. Harvard Medical School, New England

Regional Primate Research Ctr., Southborough, MA 01772.
The high affinity cocaine analog [3H]CFT (WIN 35,428;
2β-carbomethoxy-3β-(4-fluorophenyl)-tropane) was used to map cocaine binding sites in squirrel monkey brain. Tissue sections (20 μ m) were incubated with 5 nM [3 H]CFT alone or in the presence of 30 μ M (-)-cocaine to define total and nonspecific binding, respectively. The highest densities of [3H]CFT binding were observed in caudate nucleus, putamen, nucleus accumbens, and olfactory tubercle. In these regions, approximately 97% of the total binding was specific. Moderate binding densities were found in the substantia nigra, amygdala, the stria terminalis, zona incerta and hypothalamus. Little or no binding was observed in cortical regions, the globus pallidus, and cerebellum. Previous studies indicate that [3H]CFT binding sites in striatum are associated with the dopamine uptake system and may play a role in the behavioral effects and abuse liability of cocaine. The functional significance of [3H]CFT binding sites in other brain regions and the relevance of these sites to the behavioral effects of cocaine is not yet known. (Supported by USPHS grants DA00088, DA00499, DA06303 and RR00168.)

PROBES FOR PHOTOAFFINITY NEW PHOTOAFFINITY PROBES FOR THE RECEPTOR. R. Lew, J.W. Boja, R. Simantov, F.I. THE COCAINE

Carroll*, A. Lewin* and M.J. Kuhar. NIDA Addiction Research Ctr, Baltimore, MD 21224 and RTI, Research Triangle Park, NC 27709.

The cocaine binding site located on the dopamine transporter has been studied with a variety of compounds including two photoreactive compounds based upon GBR 12935. However, GBR compounds based upon GBR 12935. However, GBR 12935 has been reported to recognize a single affinity site, whereas cocaine and its congeners recognize both a high and low affinity site. Two novel photoaffinity probes for the cocaine receptor have been developed that are analogs of cocaine and WIN 35,065-2. p-Azidobenzoylecgonine methyl ester tartrate (AZIDO-COC) and 3 -[4-azido-phenyl]-tropan-2 -carboxylic acid methyl ester tartrate (AZIDO-WIN) both displace specifically bound [HIWIN 35,428 with high azido-phenyl]-tropan-2 -carboxylic acid methyl ester tartrate (AZIDO-WIN) both displace specifically bound [3H]WIN 35,428 with high affinity (IC₅₀ = 748 nM and 1.21 nM). Exposure to UV light resulted in irreversible covalent attachment to a protein located within the dopamine transporter as evidenced by continued inhibition of [3H]WIN 35,428 binding following 3 washes with buffer. Futhermore, AZIDO-WIN significantly inhibited 12J-1-[2-(diphenyl-methoxy)ethyl]-4-[2-(azido-3-iodophenyl)ethyl] piperazine binding to the dopamine transporter. piperazine binding to the dopamine transporter.

309.11

PRELIMINARY EVIDENCE THAT THE HIGH AFFINITY DOPAMINE REUPTAKE INHIBITOR, GBR12909, ANTAGONIZES THE ABILITY OF COCAINE TO ELEVATE EXTRACELLULAR LEVELS OF DOPAMINE. R. B. Rothman¹, A. Mele², A. A. Reid³, H. C. Akunne¹, N. Greid⁴, A. Thurkauf³, B. B. de Costa³, K. C. Rice³ and A. Perl². Unit on Receptor Studies, LCS, NIMH; 2Biological Psychiatry Branch, NIMH; 3Laboratory of Medicinal Chemistry, NIDDK; 4Laboratory of Neurosciences, NIA; Bethesda, MD

Systemic administration of GBR12909 (10, 20, 40 and 100 mg/kg) to rats resulted in a dose-dependent inhibition of [3H]cocaine, and a dosedependent decrease in the Bmax of [3H]GBR12935 binding sites in striatal membranes prepared 60 min after drug administration, consistent with a persistent occupation of the dopamine (DA) transporter by this high affinity inhibitor of DA reuptake. In *in vivo* microdialysis studies, anesthetized rats were administered either GBR12909 (25 mg/kg) or saline, and the levels of extracellular DA (ECDA) measured. GBR12909 did not produce a statistically significant increase in ECDA levels. Administration of cocaine (0.1, 1.0 and 10 mM) through the microdialysis probe increased ECDA levels by 467, 686, and 2101 % in saline-treated animals, and 174, 248 and 732 % in GBR12909-treated animals. These data demonstrate that doses of GBR12909 sufficient to persistently occupy the DA transporter also attenuate the ability of cocaine to raise ECDA levels.

3H/11C-WIN-35,428 LABELS THE COCAINE RECEPTOR IN VIVO. U. Scheffel*, R.F. Dannals*, A.A. Wilson*, H.T. Ravert*,
J.W. Boja, M. Stathis* and M.J. Kuhar. Department of
Radiology, Johns Hopkins Medical Institutions and
Neuroscience Branch, NIDA Addiction Research Center,

Baltimore, MD. $^{3}\text{H-WIN-35,428}$ has recently been identified as a useful radioligand for in vivo labeling of the cocaine receptor located on the dopamine transporter (Synapse 4:390, 1989). With a view toward developing a PET ligand for imaging cocaine receptors in the living human brain, we

imaging cocaine receptors in the living human brain, we have further evaluated the in vivo binding characteristics of ³H-WIN-35,428 and have synthesized ¹¹C-WIN-35,428 and studied its biodistribution in mice. For ³H-WIN-35,428 the highest striatal/cerebellar (Str/Cb) ratio in the mouse was 4.0:1 at 60 min after intravenous injection. In vivo ³H-WIN-35,428 binding was saturable and was inhibited by (-)cocaine and dopamine

saturable and was inhibited by (-)cocaine and dopamine uptake blockers (mazindol, GBR-12909, nomifensine), but not by drugs with different sites of action.

11c-WIN-35,428 was prepared from nor-WIN-35,428. After i.v. injection, 11c-WIN-35,428 accumulated mainly in the striatum. The Str/Cb ratio reached 7.2:1 at 60 min and 9.4:1 at 90 min. 11c-WIN-35,428 in vivo binding was found to be saturable and was blocked by (-)cocaine.

These results indicate that 3H- and 11c-WIN-35,428 are potent and selective in vivo labels of cocaine receptors.

11c-WIN-35,428 should be an excellent PET ligand for studying cocaine receptors in humans.

studying cocaine receptors in humans.

HIGH AFFINITY INHIBITION OF THE COCAINE BINDING SITE BY NOVEL COCAINE ANALOGS. J.W. Boja, T. Kopajtic*, F.I. Carroll*, A. Lewin* and M.J. Kuhar. Neuroscience Branch, NIDA Addiction Research Ctr, Baltimore, MD 21224 and Research Triangle Institute, Research Triangle Park, NC

Several structural congeners of cocaine were prepared and tested for their ability to inhibit specific [³H]WIN 35,428 binding and [³H]dopamine (DA) uptake. Previous studies have demonstrated the addition of fluorine to the para position of the phenyl ring of WIN 35,065-2 (WIN 35,428) increases its potency. Azido-, methyl-, chloroand bromo-substitutions in the para positions of WIN 35,065-2 resulted in increased potency to inhibit both [³H]WIN 35,428 binding and [³H]DA uptake. These compounds are the most potent Several structural congeners of cocaine were uptake. These compounds are the most potent cocaine analogs that have been reported to date.

Compound	Binding IC ₅₀	DA Uptake IC ₅₀
Cocaine	102.0 (nM)	5.05 (μM)
WIN 35,065-2	23.0	0.96
WIN 35,428	15.7	0.51
Azido-WIN	2.1	0.20
Methyl-WIN	1.7	0.11
Chloro-WIN	1.2	0.03
Bromo-WIN	1.2	0.03

SUBSTITUTED 3-PHENYLCARRAMATE ECGONINE ANALOGUES: SYNTHESIS AND ACTIVITY AS INHIBITORS OF COCAINE BINDING AND DOPAMINE UPTAKE. R.H. Kline, Jr., J. Wright, A.J. Eshleman, K.M. Fox, M.E. Eldefrawi and A.T. Eldefrawi. Dept. of Biomedicinal Chem. and Dept. of Pharmacology and Experimental Therapeutics, Univ. of Maryland, Baltimers, MD 23226. Maryland, Baltimore, MD 21201.

Substituted 3-phenylcarbamate ecgonine analogues were synthesized and characterized by ¹H and ¹³C NMR, IR and MS. The compounds were synthesized as (·)-stereoisomers from (·)-cocaine. These analogues were assessed for their ability to inhibit [3H]-cocaine binding to rat striatal tissue and to inhibit [³H]-dopamine uptake into synaptosomes prepared from the same tissue. The most potent of the analogues towards inhibition of [³H]- cocaine binding was methyl (1RS-2-exo-3-exo)-3-(3trifluoromethylphenylcarbamate)-8-methyl-8-azabicyclo[3.2.1]octane-2-carboxylate which showed an IC50 value of approximately 140nM. (1RS-2-exo-3-exo)-3-(3-nitrophenylcarbamate)-8-methyl-8azabicyclo[3.2.1]octane-2-carboxylate was most potent in blocking dopamine uptake with an IC50 value of approximately 120nM. The least potent compound was methyl (1RS-2-exo-3-exo)-3-(4-trifluoromethylphenylcarbamate)-8-methyl-8-azabicyclo[3.2.1]octane-2-carboxylate which showed approximate IC50 values of $6.3\mu M$ and $30\mu M$ with inhibition of cocaine binding and dopamine uptake, respectively. Funded in part by a grant from NIDA (DA03680).

REGULATION OF RELEASE-MODULATING TERMINAL DOPAMINE AUTORECEPTORS: EFFECT OF CHRONIC COCAINE TREATMENT, S.-J. Yi and K.M. Johnson. Dept. of Pharmacol., Univ. of Texas, Galveston, TX 77550

The D_2 receptor agonist, N-0437, caused a significant sulpiride reversible inhibition of Ca^{2+} -evoked 3 H-DA release from synaptosomes prepared from the striatum and the nucleus accumbens. Chronic cocaine administration abolished the effect of N-0437 in both areas. This suggests a subsensitivity of releasemodulating terminal DA autoreceptors as a consequence of repeated cocaine administration. This study is primarily concerned with determining the

administration. This study is primarily concerned with determining the mechanisms underlying autoregulation of DA release.

The voltage-sensitive Ca²⁺ channel antagonists, verapamil (10 µM), nimodipine (1 µM) and w-conotoxin (60 nM and 1 µM), resulted in a significant reduction of Ca²⁺-evoked DA release (49 %, 20 %, 47 % and 60 %, respectively). Furthermore, the inhibition of Ca²⁺-evoked DA release produced by verapamil or nimodipine was not additive with the effect of N-0437, indicating that Ca²⁺ nimoupine was not additive with the effect of N-0437, indicating that Carchannel antagonists and N-0437 may produce their inhibitory actions through mechanisms in which the same Ca²⁺ channels are involved. However, we also found that the K⁺ channel blockers, TEA (5mM) and 4-aminopyridine (0.1 mM), prevented or significantly reduced the inhibitory effect of N-0437. These data are in agreement with Bowyer and Weiner, and indicate that D₂ autoreceptors activate a hyperpolarizing K⁺ conductance, resulting in a reduction of Ca²⁺ influx through voltage-sensitive Ca²⁺ channels and DA release. Pertussis toxin (2.5 µg, involved in D₂ receptor-mediated modulation of Ca²⁺-evoked ³H-DA release.

Thus, we suggest that chronic cocaine-induced down regulation of DA

autoreceptors may invove changes in autoreceptor density or affinity or in transduction mechanisms such as number or fuctionality of K⁺ ion channels associated with these receptors. Supported by DA-05159.

EFFECTS OF PERINATAL COCAINE EXPOSURE ON CENTRAL

CATECHOLAMINES AND NORADRENERGIC RECEPTORS IN RATS. M.A. Kosek, G.A. Ordway, P.S. Widdowson*, B. Yamamoto and R.M. Kleigman. Dept. of Pediatrics, Rainbow Babies and Childrens Hosp. and Dept. of Psychiatry, MetroHealth Med. Ctr., Case Western Reserve Uni., Cleveland, OH 44106. Cocaine abuse during pregnancy has reached epidemic proportions and is implicated in neurobehavioral changes in children. The effects of cocaine exposure during development on brain catecholamines are poorly understood. We investigated whether there are changes in brain catecholamines and noradrenergic receptors Sprain categorism shall cocaine exposure in rats. Pregnant Sprague Dawley rats were given saline, no treatment, or cocaine HCl (25 mg/kg/twice daily i.p.) from post-conception day 11 to birth. Animals were pair-fed and housed under identical conditions. At birth some pups from each group were sacrificed while the remainder were continued for 30 days on the same regimen as above and sacrificed at post-natal day 31. Catecholamine concentrations were estimated using HPLC-EC while noradrenergic receptors were measured by quantitative autoradiography. Perinatal cocaine exposure did not alter catecholamine concentrations at birth or at age 31 days. There was no change in the binding of [125] illiodopindolol to beta-1 or beta-2 adrenoceptors or in the binding of [125] illiodoclonidine to alpha-2 adrenoceptors in the 31 day old rats.

309.17

ISRADIPINE INHIBITION OF COCAINE CONDITIONED PLACE PREFERENCE. L. Panix, A. Kuzmin*, M.C. Martellotta*, G.L. Gessa* and W. Fratta.

"B.B. Brodie" Department of Neuroscience, University of Cagliari, 09124 CAGLIARI, ITALY.

The rewarding effects of cocaine are known to be associated with its ability to block reuptake of dopamine (DA) from nerve terminals. It has been shown that cocaine increases DA release via calcium dependent mechanism (Di Chiara G. and Imperato A., Proc. Natl. Acad. Sci. USA 85, 5274, 1988). Furthermore we showed that only calcium antagonists of dihydropiridine (DHP) class were able to inhibit cocaine-induced DA release and locomotor activity. The aim of the present work was to clarify if blockade of DA release by Isradipine, the most potent among the DHP compounds tested, will also inhibit cocaine induced rewarding effects in rats. The results ontropounds tested, will also inhibit cocaine induced rewarding effects in rats. The results obtained indicate that Isradipine inhibits cocaine reinforcing properties in a conditioned place preference paradigm at doses (< 2.5 mg/Kg s.c.) which did not cause any sedative effects.
The present results suggest the possibility that
Isradipine might be a useful treatment of
cocaine related disordes.

309.14

EFFECTS OF CALCIUM AND TETRODOTOXIN ON PHENCYCLIDINE INDUCED DOPAMINE INCREASE IN THE NEOSTRIATUM OF THE RAT D. Chapman* and S. Howard. MRRC, BRI, and Dept. of Pharmacology, UCLA, Los Angeles, CA 90024.

Phencyclidine (PCP) is a drug of abuse which is known to increase extracellular dopamine (DA) levels in the neostriatum of the rat. We examined the effects of reduced calcium (Ca⁺⁺) or the addition of tetrodotoxin (TTX,10⁻⁵M) on PCP induced DA increase. Rats were given PCP either systemically (20 mg/kg) or locally (5 µl of 100 µM over one minute) through the microdialysis probe. In vivo microdialysis samples were collected every ten minutes and analyzed for DA, DOPAC, and HVA using HPLC-EC. Removal of Ca⁺⁺ from the perfusate decreased baseline extracellular DA, DOPAC, and HVA as well as reduce the PCP induced increase in DA. Addition of TTX to the perfusate also decreased baseline extracellular DA, DOPAC, and HVA as well as reduce the PCP induced DA increase. Ca++ and TTX produced similar effects on PCP induced DA increase when PCP was given systemically or locally. PCP increases extracellular DA in the neostriatum by a Ca⁺⁺ dependent and TTX sensitive process. Since Ca⁺⁺ and TTX perturbations were applied to the neostriatum through the microdialysis probe and since systemic and local applications of PCP showed similar results, the effects of PCP on areas outside of the neostriatum did not influence this process. USPHS Grant DA03020.

LACK OF PERSISTENT EFFECTS FROM POSTNATAL COCAINE EXPOSURE IN THE DEVELOPING RAT. T. B. Sonderegger, E. Y. Fung, H.E. Grotjan Jr.* R.J. Krueger.* & J.A. Weinberg^, Univ.of Nebraska-Lincoln, Lincoln, NE 68588; "University of British Columbia, Vancouver, British Columbia.

Litters from 12 Charles Rivers CD albino rats were sized to 9 pups on postnatal day 2; two female and one male pup from each litter were treated with cocaine [45 mg/kg 0.9% saline vehicle once daily] on days 5-12, a brain growth spurt period in the rat; same sex controls received comparable volumes of saline or were merely handled. Body weights of treated animals and controls were comparable at time of weaning on day 21. Three litters served as unhandled controls. Animals were tested in the open field on day 90 for 5-min trials over four consecutive days. Females were significantly more active than males but treatment groups did not differ in activity. Females were bred with nondrug treated males on day 100. (Data are reported elsewhere). When approximately 180 days-old, blood samples were obtained through cardiac puncture immediately upon removal from the home cage and after a 30-min stress period due to placement in a novel cage. Plasma samples were analyzed for levels of b-corticosterone. Neither basal levels nor the significantly elevated 30-min stress levels differed for the treatment groups. Animals were then sacrificed. The corpus striatum from 5 cocaine-exposed males and 5 cocaine-exposed females and a comparable number of saline controls were analyzed for dopamine receptor binding. No significant differences were found. Cells from the adrenal glands from these animals were cultured and dose-response curves of glucocorticoid production obtained; although the rate of production was less in the cocaine-treated males, differences were not significant. Pituitary glands were removed from 15 cocaine-treated females and 10 cocaine-treated males and a comparable number of saline controls and analyzed for Lutelnizing Hormone using radioimmunoassay. Comparable levels of LH were found in the treated groups and their controls. Other behavioral data will be presented.

DIFFERENCES IN THE PRE-REINFORCED BEHAVIOR OF RATS RUNNING AN ALLEY FOR INTRAVENOUS COCAINE & HEROIN REWARD.

A.Ettenberg and T.D.Geist. Dept Psychol. Univ. of Calif., Santa Barbara, CA. 93106

Rats were trained to traverse an alley for five I.V. injections of either cocaine (0.75mg/kg/inj) or heroin (0.06 mg/kg/inj). Testing consisted of single daily trials over 15 days during which the following measures were recorded: 1) time to initiate running; 2) time required to traverse the alley; 3) number (and location) of retreats occurring within the alley (a stop in forward locomotion with a return back toward the start box). Cocaine and heroin reinforced rats exhibited extremely different patterns of pre-reinforced (i.e. runway) behavior. While cocaine start latencies remained relatively stable over days, heroin rats initiated slowly at first and then improved as testing continued. Heroin Ss also traversed the alley with progressively faster running speeds while cocaine-reinforced Ss took progressively longer to enter the goal box. These differences in running behavior were directly related to the frequency of retreats observed in the two groups. Cocaine, but not heroin, animals exhibited a greater and greater "reluctance" to enter the goal box over trials. Such results suggest that chronic cocaine self-administration induces a state of conflict that is not observed in animals working for I.V. heroin reward.

310.3

TOLERANCE OR SENSITIZATION TO COCAINE'S REINFORCING EFFECTS? A STRUCTURAL ANALYSIS OF COCAINE SELF-ADMINISTRATION PATTERNS IN RATS DURING 3-48 HOUR COCAINE BINGES. A. Markou, M.P. Paulus, and G.F. Koob, Dept of Neuropharmacology, Research Institute of Scripps Clinic, La Jolla, CA 92037 and Lab. of Biological Dynamics and Theoretical Medicine, La Jolla CA 92093.

It has been hypothesized that the increase in cocaine dose selfadministered by humans during a binge is due to the development of tolerance to cocaine's euphorigenic effects. The present studies investigated this hypothesis in two animal models of cocaine's reinforcing effects: intracranial self-stimulation and cocaine self-administration. Acute cocaine administration (5-10 mg/kg, IP) lowered self-stimulation current thresholds. Chronic cocaine administration (10 mg/kg daily for 10 days) did not produce tolerance or sensitization to cocaine's lowering effects on thresholds. In a third experiment, rats were allowed to self-administer cocaine for 3, 6, 12, 24, 48 hr continuously. Rats consumed a constant dose of cocaine per unit time (5 mg/kg per hr), even during a 24 or 48 hr binge, suggesting a lack of tolerance or sensitization to cocaine's effects. However, a structural analysis of the cocaine interinjection intervals indicated that the patterns of self-administration were changing over time. The first 200 injections occurred at very regular time intervals characteristic for each rat. During subsequent injections, rats started alternating short with long interinjection intervals while still consuming the same amount of cocaine per unit time. The structural changes in the interinjection intervals might reflect an attempt by the animal to avoid the development of tolerance to cocaine's reinforcing effects.

310.5

THE EFFECTS OF COCAINE ON DIFFERENT RESPONSE RATES MAINTAINED BY EQUAL RATES OF REINFORCEMENT Frans van Haaren Dept. of Psychology, Univ. of Florida, Gainesville, FL 32611.

Small doses of cocaine increase low response rates and decrease high response rates. The 'rate-dependent' effects of cocaine might be accounted for by differences in reinforcement rates between schedules which generate high and low rates of responding. Three White Carneaux pigeons were trained in a two-component multiple schedule. Keypecking was maintained on a tandem RI 45 s - DRH 0.2 s schedule in one of the components, and on a tandem RI 45 s - DRL 3.0 s schedule in the other. Subjects were then i.m. injected with 0.3, 1.0, 1.7, 3.0, 5.6, and 10.0 mg/kg of cocaine. Small doses of cocaine (0.3 and 1.0) did not affect high rates and increased low rates in 2 of 3 pigeons. Larger doses (3.0 and 5.6) decreased high and low rates, but the decrease was more pronounced on the schedule maintaining high rates. Cocaine's behavioral effects in pigeons thus seem to be a function of the respone rates maintained in the absence of the drug.

310.2

COCAINE-INDUCED PLACE PREFERENCES: EFFECTS OF ALTERATIONS IN LENGTH OF NEUTRAL ZONE ON TEST DAY. T.D. Geist and A. Ettenberg. Dept Psychol. Univ. of Calif., Santa Barbara, CA. 93106

Animals readily exhibit conditioned place preferences (CPP) for environments previously paired with injections of cocaine. However, we have shown using an operant runway paradigm, that in addition to the rewarding properties of cocaine there exists strong anxiogenic effects of the drug. We hypothesized that the runway paradigm is particularly sensitive to such effects since it provides a long "neutral" zone between the start and goal boxes during which "conflict" behavior can be manifested. To determine whether the CPP test might also be sensitive to cocaine's anxiogenic actions, we examined whether CPPs would be reduced in magnitude for tests conducted in a preference apparatus with a long (vs short) neutral zone (between the saline- and cocaine-paired environments). CPPs were induced for one of two distinct environments by pairing it with IV injections of 0.75mg/kg/inj of cocaine. Ss received IV saline injections while in the non-drug environment. On each test day, the Ss were provided a choice between the two conditioned boxes separated by either a long (240cm) or short (40cm) neutral zone (alley). The color of the drug environment and the order of testing was counterbalanced between Ss. Results confirmed our hypothesis that the size of the resulting CPPs would diminish when Ss were tested in the long alley relative to the short alley.

COCAINE-INDUCED TASTE AVERSIONS: A COMPARISION OF INTRAPERITONEAL AND SUBCUTANEOUS INJECTIONS. C.M. Ferrari, D.A. O'Connor*and A.L. Riley. The American University, Washington, D.C. 20016.

Although a range of pharmacological agents condition taste aversions, aversions induced by cocaine HCl are generally weak. Although the basis for these weak aversions is unclear, one possibility is the route of administration. Reports assessing the ability of cocaine to induce aversions have administered cocaine intraperitoneally (IP). The single paper reporting a robust aversion injected cocaine subcutaneously (SC) (Gale, K., NIDA Research Monograph Series, 54:323-332, 1984). To address the role of route of administration in cocaine-induced aversions, rats were given 20-min access to saccharin followed immediately by an IP or SC injection of 0, 18, 32 or 50 mg/kg cocaine. This procedure was repeated every fourth day for five trials. On intervening days, subjects were given water. Subjects receiving the IP injections displayed weak and non dose-dependent aversions. On the final saccharin exposure, these subjects had decreased consumption by only 35%. Although subjects in Group SC 18 decreased saccharin consumption by only 35%, subjects in Groups SC 32 and SC 50 decreased consumption by approximately 95 and 98%, respectively. It is clear that route may play an important role in the behavioral toxicity of cocaine (Dow-Edwards et al., Pharmac., Biochem. & Behav., 33:167-173, 1989)

310.6

EFFECTS OF COCAINE ON SLEEP IN RATS. M. Radulovacki, S.D. O'Connor, S. Ticho, C. Vugrincie*, M. Lekovic*. Dept. of Pharmacology, University of Illinois, Chicago, IL 60612

Hill et al (Psychopharm., 51: 125-125, 1977) showed that acute administration of cocaine to rats resulted in decreased sleep time, with suppression of both deep sleep (SWS2) and REM. We examined in rats the effects of chronic administration of cocaine and cocaine withdrawal on sleep. The left carotid artery was cannulated in rats and connected to an Alzet mini-osmotic pump to deliver cocaine for a period of 7 days. Sleep was measured during cocaine administration and the following 7 days of cocaine withdrawal. Continuous infusion of 100mg/kg/day cocaine resulted in a decrease in total sleep (p<0.05). Light sleep (SWS1) also decreased (p<0.05), while deep sleep (SWS2) and REM initially decreased but returned to control levels by end of the cocaine infusion. During the cocaine withdrawal, wakefulness was reduced for the first 72 hrs (p<0.05). SWS2 rebounded at the fifth day of withdrawal (p<0.05). These preliminary results (N=4) show that chronic administration of cocaine suppresses sleep, but are inconclusive in regard to the total sleep rebound during withdrawal.

MICROINJECTIONS OF COCAINE, BUPROPION, AND PIPRADROL INTO THE NUCLEUS ACCUMBENS ENHANCE LOCOMOTOR ACTIVITY AND POTENTIATE RESPONDING FOR A CONDITIONED REINFORCER. S. Rosenzweig-Lipson. B. Chu*, J. M. Delfs. and A. E. Kelley. Dept. of Psychology, Harvard University, Cambridge, MA 02138

Many psychomotor stimulant drugs function as indirect dopamine agonists. These drugs can either expense release of description into

agonists. These drugs can either enhance release of dopamine into the synapse, or they can block the reuptake of dopamine from the synaptic cleft. Psychomotor stimulants have been shown to increase motor activity as well as enhance responding for a conditioned reinforcer. The nucleus accumbens has been implicated as a site of reinforcer. The nucleus accumbens has been implicated as a site of action for the reinforcing and rewarding effects of these drugs. In the studies of motor activity, rats were placed into cages equipped with infrared photocell beams linked to a microprocessor that measured locomotor activity and rearing. In the conditioned reinforcement studies, hungry rats were trained to associate a compound stimulus (light/click) with the delivery of a food pellet. During the test phase, a lever was introduced into the box and lever pressing was reinforced by the stimulus alone. In these studies, the monoamine uptake by the stimulus alone. In these studies, the monoamine uptake inhibitors cocaine (1-60 μg) and bupropion (10-60 μg), as well as the monoamine releaser pipradrol (2-20 μg) were infused bilaterally into the nucleus accumbens. All three drugs increased total activity and rearing in a dose-dependent manner. In conditioned reinforcement experiments, all three drugs dose-dependently enhanced responding for a conditioned reinforcer. It is hypothesized that these compounds may affect reward-related processes when infused into the nucleus accumbens.

INDIVIDUAL DIFFERENCES TO SYSTEMIC AND INTRACRANIAL COCAINE. A.D. Smith, M.S. Hooks, H.O. Pettit, I.B. Justice, Ir. Dept. of Chem., Emory Univ., Atlanta, GA 30322.

The purpose of this study was to determine if rats show individual differences to cocaine, both peripherally and intracranially. Rats from the same strain have shown different become resease to a posel and interaction.

shown different locomotor response to a novel environment (Piazza, Science, 245, 1989). This response to a novel environment was used to predict how rats would respond to cocaine.

respond to cocaine.

Animals were placed in a photocell cage where their locomotor activity (IA) was monitored. Based on their IA to the novel environment animals were classified into groups. Animals showing IA above the median for the initial hour in the test cages were classified as high responders (IR), while those showing a IA below the median for the initial hour were classified as low responders (IR). Two days after the response to the novel environment animals were placed back into the test cages for a 90 minute habituation period. Animals were given an intraperitoneal (IP) dose of cocaine (0.0, 2.5, 5.0, or 10.0 mg/kg) and their IA was required for 1 hour effort from the content of the company of the content monitored for 1 hour after drug injection. This same procedure was repeated in the animals who received intracranial injections of cocaine. Animals were injected

bilaterally into the CA3 region of the hippocampus at a dose of 27.2 ug per side. There was a significant difference in LA between HR and LR who received IP There was a significant difference in LA between HR and LR who received IP cocaine (p<.02). These animals also showed an interaction between response to novelty, dose of cocaine, and the time course of the LA (p<.02). HR showed a significant increase (p<.01) in their LA with increasing doses of cocaine, while LR exhibited no significant increase in LA with increasing cocaine dose. A significant difference between HR and LR animals that received intracrantal cocaine (p<.01) was also observed. Moreover, this interaction was significant over the entire time course (p<.05) of LA. The finding that individual differences are observed following both peripheral and central administration indicates that individual differences to cocaine may be mediated by central mechanisms.

310.11

COCAETHYLENE IS A PHARMACOLOGICALLY ACTIVE METABOLITE OF COCAINE FORMED AFTER COMBINED INTAKE OF COCAINE AND ETHANOL. J.D. Elsworth. C.W. Bradberry. J.R. Taylor. J.R. Walker*. W.L. Hearn*. P. Jatlow* and R.H. Roth. Depts Pharmacology, Psychiatry and Laboratory Medicine, Yale University of Medicine, New Haven, CT 06510 and Dade County Medical Examiners Dept, Miami, FL.

Cocaethylene (ethylbenzoylecgonine) has been found in high concentrations in plasma (up to 850 ng/ml) of fatalities that were associated with combined use of cocaine and ethanol (1). Since many cocaine users prefer to take ethanol with cocaine, we have examined whether cocaethylene has cocaine-like effects.

Cocaethylene inhibited binding of the dopamine uptake blocker, [3H]GBR (2nM), to rat striatal membranes as effectively as cocaine (IC₅₀ 300nM). In addition, cocaethylene and cocaine were equipotent (IC₅₀ 250nM) at inhibiting [3H]dopamine uptake (40nM) into synaptosomes prepared from either striatum or nucleus accumbens of rats. Systemic administration of cocaethylene (1 mg/kg i.v.) to rats resulted in a 3 to 5 fold increase in extracellular dopamine concentration in nucleus accumbens, measured by microdialysis; similar effects were observed after injection of the same dose of cocaine. Locomotor activity and rearing in rats treated with 10 mg/kg i.p. of either cocaethylene or cocaine was markedly increased.

Thus, unlike other cocaine metabolites, cocaethylene possesses biochemical and behavioral effects similar to cocaine. This indicates that cocaethylene may play a role in the behavioral effects that occur after concurrent use of cocaine and ethanol. Support: DA05119 & DA04050.

A COMPARISON OF COCAINE-INDUCED ACTIVITY PATTERNS FOLLOWING SINGLE OR CUMULATIVE DOSING REGIMENS. P. Terry. Psychobiology Lab., NIDA Addiction Res. Ctr., P. O.

Box 5180, Baltimore, MD 21224 Locomotor activity and stereotyped behaviors were measured in male Swiss-Webster mice receiving i.p. cocaine measured in lare swiss-webster mice receiving 1.5. Cocarne at 5, 10, 20 or 40 mg/kg. Mice in the cumulatively-dosed condition were injected first with saline and then with 5, 5, 10, and 20 mg/kg at 10 minute intervals. In the single-dose/multiple-injection condition, independent groups of mice received a single dose of cocaine at the appropriate time point, with saline injections at other times. all mice received five injections per session. In Thus In the single-dose/single-injection condition, the saline injections were omitted and one injection of cocaine was administered at the appropriate time. Scores were taken at each 10 minute interval. All mice were retested six weeks later and one day after that. Dose-response curves were similar for all three conditions on first test, but diverged markedly on subsequent tests. Despite the long inter-test interval, significant locomotor sensitization was evident at the higher doses on second test, but only in the two single-dose conditions. On third test, convulsions occurred at 40 mg/kg, but only in the singledose conditions. The results demonstrate how certain injection parameters can chronically affect both the behavioral and toxic effects cocaine.

COCAINE PHARMACOKINETICS IN COCAINE EXPERIENCED AND NAIVE RATS AND ITS APPLICATION IN SELF ADMINISTRATION BEHAVIOUR

Stanley Menacherry, Hwai-Tzong Pan, Hugh Pettit and J. B. Justice, Jr. Emory University, Department of Chemistry, Atlanta, GA 30322

Blood and extracellular brain concentrations of cocaine are significantly enhanced in rats that are exposed to repeat administration of cocaine for 10 days prior to an i.p. challenge dose (Pettit et al., J. Neurochem. 1990, in press). The source of this enhancement was traced to a change in the absorption process from the peritoneal cavity into the blood stream. This is evidenced by the result that i.v. administration of cocaine did not produce a significant difference between cocaine experienced subjects and the control group. Nonlinear regression with global optimization was performed on the i.v. and i.p. data using a two compartment open model to determine rate constants for blood/brain transfer, elimination by metabolism and excretion and absorption from the body cavity. The absorption rate constant was found to be higher by 150% in experienced animals over naive animals (0.025 vs 0.016 min⁻¹), whereas the other rate constants were not substantially different constants. ferent. Robust estimates of the rate constants was obtained from the entire data set (rate constants for blood to brain transfer, brain to blood transfer and elimination of drug from the system were 0.35, 0.22 & 0.45 respectively). These rate constants were used to compute the blood and extracellular brain profiles of cocaine that would be obtained for the self administration behaviour reported by Petit et al. 1989 (Pharmacol. Blochem. Behav. 34, 899-904). Individual preferences for drug intake across doses are noticed. Analysis of minimum levels in blood and brain indicate a tighter regulation of brain concentrations.

310.12

GENERALIZATION TESTS OF LOCAL ANESTHETICS AND STIMULANTS IN RATS TRAINED TO DISCRIMINATE

GEMERALIZATION TESTS OF LOCAL ANESTHETICS AND STIMULANTS IN RATS TRAINED TO DISCRIMINATE COCAINE OR PROCAINE FROM SALINE. P.B. Silverman. Dept. of Psychiatry and Behavioral Sciences, Univ. of Texas Medical School, Houston, TX 77030. Rats were trained to discriminate cocaine (10 mg/kg; 29 umol/kg) or procaine (54 mg/kg; 200 umol/kg) from saline in a two-lever, food-reinforced operant task. The stimulants amfonelic acid, amphetamine and methylphenidate all generalized completely to the cocaine stimulus but not to the procaine stimulus. The local anesthetics, bupivacaine, chloroprocaine and mepivacaine generalized completely to procaine while lidocaine, piperocaine and tetracaine did not. Most of the local anesthetics generalized, at most, only partially to cocaine, but dimethocaine, recently shown to exhibit frank stimulant activity as well as high affinity binding at dopamine uptake sites, generalized completely to cocaine and nearly completely to procaine. (+)-Cocaine did not generalize to either cocaine or procaine. Pseudococaine was tested only in cocaine animals, it did not generalize to cocaine. Apomorphine and caffeine generalized partially to both it did not generalize to cocaine. Apomorphine and caffeine generalized partially to both training compounds. [Supported by NIDA grant DA04423.]

GESTATIONAL EXPOSURE TO COCAINE INDUCED DEFICITS IN SENSORY PRECONDITIONING IN INFANT RAT PUPS. C.J. Heyser, W. Chen*, J. Miller*, N.E. Spear*, and L.P. Spear*. Center for Developmental Psychobiology, Dept. of Psychology, SUNY, Binghamton, NY 13901.

Offspring derived from gravid Sprague Dawley dams that received daily subcutaneous injections of 40 mg/kg cocaine hydrochloride (C40) or saline (LC) from gestational days 8-20 were tested for first order Pavlovian conditioning and sensory preconditioning at postnatal days 8 (P8), P12, and P21. Sensory preconditioning consisted of the simultaneous exposure to 2 odors (A and B), followed by the pairing of one cdor (A) with footshock. A preference test for location was conducted between the cdor previously not paired with footshock (B) and a novel cdor. Although the onset cocaine treatment reduced food and water intake for 2-5 days, no significant differences were observed between the prenatal treatment groups in duration of pregnancy, absorption rates, litter size, or pup body weights. C40 pups did not display sensory preconditioning at any of the tested ages, whereas significant conditioning was observed in IC controls at 8 and 12 days of age. In addition, C40 pups exhibited a deficit in first order conditioning at P8. Taken together these results may indicate a more general deficit in cognitive functioning rather than a delay in cognitive development.

THE ONTOGENY OF BEHAVIORAL SENSITIZATION TO PCP OR COCAINE. F.M. Scalzo and R.R. Holson, Div. of Reprod. & Develop. Tox., National Center for Toxicological Research, Jefferson, AR 72079.

Repeated exposure to PCP or cocaine can induce

Repeated exposure to PCP or cocaine can induce sensitization to later exposures in adults. We assessed developmental exposure effects of these compounds on later psychopharmacological responsiveness to determine the age at which sensitization occurs. Rat pups were injected for 9 days beginning on postnatal days (PNDs) 1, 12, 20 or 37 with saline, 10 mg/kg PCP or 20 mg/kg cocaine. Ten days following the last injection, rats were challenged with either saline, 10 mg/kg PCP or 20 mg/kg cocaine and activity, stereotypies and ataxia were measured. Pups treated on PNDs 1-9 appeared less sensitive to the effects of PCP when challenged on PND 19 compared to PCP-challenged saline-treated controls. In contrast, all other age groups exhibited an increased sensitivity to the PCP challenge. Regardless of age during subchronic treatment, there was no evidence of behavioral sensitization or tolerance to cocaine as measured by activity and stereotypy scores. It thus appears that subchronic PCP exposure has age-dependent effects on PCP sensitivity, while altered behavioral responsiveness to cocaine following subchronic administration does not occur in young animals using this testing paradigm.

310.17

CATECHOLAMINE AND BEHAVIORAL EFFECTS OF PRENATAL COCAINE EXPOSURE IN HUMAN NEONATES. J. Meyer, M. Mirochnick*, J. Cole*, and B. Zuckerman*. Univ. of Massachusetts, Amherst, MA 01003, and Boston City Hospital, Boston, MA 02118. Although previous studies have reported intrauterine

Although previous studies have reported intrauterine growth retardation and behavioral abnormalities in infants exposed to cocaine prenatally, there has been relatively little research on the physiological consequences of such exposure. We now report initial findings from an ongoing study of catecholamine and behavioral responses in cocaine-exposed neonates. The subjects were 12 infants who were positive for cocaine by maternal history or urine drug screen, and/or infant urine or meconium screen, and 8 infants who were drug negative by maternal history and infant meconium screen. Physical measurements, Neonatal Behavioral Assessment Scale (NBAS) testing, and blood drawing were performed between 24 and 48 h post-partum. Serum samples were assayed for norepinephrine (NE), dopamine (DA), and dihydroxyphenylalanine (DOPA) by HPLC. Compared to controls, cocaine-exposed infants exhibited decreased body weight, head circumference, and height. Serum DOPA levels, but not NE or DA, were elevated in the cocaine infants. However, there was a highly significant negative correlation between NE and NBAS orientation cluster scores within the cocaine group. These results suggest that behavioral abnormalities found in prenatally cocaine-exposed neonates may be accompanied by alterations in peripheral catecholaminergic functioning.

DAILY COCAINE TREATMENT DIFFERENTIALLY AFFECTS ENRICHED- AND ISOLATION-REARED RATS' ACQUISITION AND PERFORMANCE OF AN OPERANT TASK. J.M. Chase and S.C. Fowler. Depts. of Psychol. and Pharm., Univ. of Miss., University, MS 38677

Male rats were reared in either enrichment

Male rats were reared in either enrichment cages (EC) or individual cages (IC) and were then exposed to a nose-poke operant task to assess the effects of cocaine (0.0, 2.5, or 10.0 mg/kg, ip. 10 min pre-session) during 11 15-min sessions of task acquisition. A rat's insertion of its head into a tube produced a light cue; further extension of the snout to break a photobeam resulted in immediate presentation of a dipper of milk below the rat's mouth. In the first session of exposure to the contingencies, 11 of 22 EC rats produced 10 or more reinforced responses, whereas only 4 of 23 ICs did this well. Over the 11 sessions, EC groups spent more of the total session with their head inside the tube, entered/exited fewer times, and maintained individual entries for a greater amount of time than IC rats. 10 mg/kg cocaine retarded task acquisition, and the drug treatment interacted with both rearing condition and training days. Supported by DA 05310.

COCAINE IN PREGNANCY AND DEVELOPMENT. E.W. HALLER, R.G.HOFFMAN', R.M.EISENBERG', A. VAINIO' SCH. MED., U. MINN., DULUTH, MN. 55812. The effect of 20 mg/kg cocaine exposure was investigated on maternal-pup interaction, pup growth rate and pup activity. Eight virgin female Sprague-Dawley-derived rats were synchronously mated with randomly selected males of the same strain. Following the onset of pregnancy, two dams were randomly selected and injected daily with 20 mg/kg cocaine sc from day 0 to day 21 of pregnancy. Cocaine-treated animals were matched with saline controls injected on the same schedule. Following delivery, the litters were reduced to 6 pups each and cross-nurtured. At seven days of age postnatally, serial observations of maternal-pup interaction were made at two-day intervals until post-natal day 17. The pups were weaned from the dams at post-natal day 28 and activity measurements and daily weights were taken on individual pups at two-day intervals for the next 40 days. During each observation period, after a 10-minute separation from the pups, dams treated with cocaine during pregnancy took significantly longer to identify their pups, with a (mean time 90.6 sec vs.16.9 sec for control, paired t-test, p<.05). Experimental dams were significantly less likely to nest build or to gather their pups into a nest during the observation period (p<.01, Fisher's Exact Test). Although there were no differences in initial litter weights, following weaning female pups born to cocaine-treated dams were significantly less active than female pups born to vehicle treated dams (p<.05, ANOVA), both in terms of overall activity and stereotypic activity. The principal differences due to prenatal cocaine occur in growth rate and activity in females rather than in male pups, and the greatest effects appear to be confined to the period between attainment of puberty and adulthood. ADMINISTRATION OF COCAINE TO RATS IN DRINKING WATER. A.B. Kelly, S.K. Overman* and D.G. Morgan, School of Gerontology, Univ. of Southern Cal., Los Angeles, CA 90089-0191

Rats were administered cocaine in their drinking water to develop a method for long term cocaine administration which avoids the stress of multiple daily injections, or surgery. In an obligatory drinking regimen, rats were presented with a single water bottle ad libitum in which cocaine doses were increased at 4 day intervals. At doses of 0.2, 0.3 and 0.5 mg/ml rats consumed the same amount of water as they did prior to receiving cocaine, or control rats receiving water alone. At 0.7, 1.0 and 1.2 mg/ml rats initially decreased their water consumption on the first day, followed by a slight return towards baseline on subsequent days. 0.5 mg/ml produced doses of 45 mg/kg/d while 1.2 mg/ml produced 73 mg/ml due to decreased consumption. No changes in body weight were observed at any dose.

In a two bottle choice paradigm, where the cocaine dose was paired with 0.02% saccharin, rats initially consumed 8-32 mg/kg/d at a dose of 0.77 mg/ml. This decreased to 2-12 mg/kg/d at 1.2 mg/ml. When the cocaine concentration was decreased to 0.2 mg/ml, some rats increased water consumption to maintain 5-10 mg/kg/d, while others continued to drink little of the saccharin+cocaine water. Consumption in the choice paradigm is idiosyncratic with some rats titrating their cocaine dose according to cocaine concentration, and other not drinking much of the cocaine solution at any concentration. Supported by the Greenwall Award from Amer. Fdn. for Aging Res., and an Established Investigator Award from Amer. Heart Assn. (DGM) and NIA training grant AGO0093-08.

ESTRADIOL (E₂) ENHANCES BEHAVIORAL SENSITIZATION TO COCAINE. J.W. Simpkins, J. Peris, N. Decambre* and M. Coleman*, Dept. of Pharmacodynamics, Univ. of FL, Gainesville, FL 32610. Studies were undertaken to determine the effects of ovarian steroids

on sensitization of the locomotor and stereotypic behavioral responses to repeated cocaine injections. Young female adult rats were ovariectomized and 2 weeks later were implanted with one of the following chronic release forms of ovarian steroids in 5 mm silastic tubes: (i) sham (cholesterol); (ii) E₂ (diluted 1:1 with cholesterol); (iii) progesterone (P₄; diluted 3:1 with cholesterol) or (iv) E₂ plus P₄. Behavior was then rated using a 4 point scale (Ernst, <u>Psychopharmacol.</u> 10:316, 1967) after an initial injection of either saline or cocaine (10 mg/kg, i.p.) and after the 8th daily injection of saline or cocaine (n = 6). A significant increase in both locomotor and stereotypic behaviors was seen in all groups after the first cocaine injection compared to saline. Steroid-treatment did not influence the initial cocaine response, although each of the three steroid treatments slightly increased the incidence of locomotor activity after the first saline injection. Repeated injections of cocaine caused sensitization in all treatment groups, i.e. an increase in stereotypic and locomotor behavior over days with no change occurring in saline-treated groups over days. E₂-treatment significantly increased the magnitude of cocaine sensitization compared to the sham-treated controls. When striatal ³Hdopamine release was measured 1 day after the 8th injection, both amphetamine and electrically stimulated release was decreased in $\rm E_2$ -treated animals regardless of saline or cocaine treatment. Collectively these data indicate that $\rm E_2$ enhances behavioral sensitization to cocaine although more studies on the neurochemical substrate of this effect are warranted (Supported by AG 02021 and AA 08262).

ENHANCEMENT OF BEHAVIORAL EFFECTS OF COCAINE BY INHIBITORS OF MONOAMINE UPTAKE. R.D. Spealman. Harvard Medical School, N.E.R.P.R.C., Southborough, MA 01772.

The behavioral effects of cocaine were determined alone

and after pretreatment with various monoamine uptake inhibitors that differ in selectivity for dopamine, norepinephrine, and serotonin: GBR 12909, talsupram, citalopram, and Lu 19005. When given alone, cocaine (.03-1.0 mg/kg) produced dose-related increases in responding by squirrel monkeys under a fixed-interval schedule of stimulus-shock termination. With the exception of citalogram, all uptake inhibitors produced leftward shifts in the cocaine dose-response curves and sometimes increased the peak response rates produced by cocaine. The order of potency was: Lu 19005> GBR 12909> talsupram. This potency order corresponds to that reported for in vitro inhibition of dopamine uptake and [3H]cocaine or [3H]CFT binding, but not for inhibition of uptake of either norepinephrine or serotonin. results support the view that cocaine recognition sites associated with the dopamine uptake system play a principal role in mediating the stimulant effects of cocaine on behavior. Although citalopram did not produce an overall leftward shift of the cocaine dose-response curve, it sometimes decreased response rates when combined with cocaine doses 2 l.0 mg/kg, suggesting that inhibition of serotonin uptake may be involved in some high-dose effects of cocaine. EFFECTS OF DOPAMINE RECEPTOR BLOCKADE IN NUCLEUS

EFFECTS OF DOPAMINE RECEPTOR BLOCKADE IN NUCLEUS ACCUMBENS AND CAUDATE ON FEEDING INDUCED BY INTRA-RAPHE 8-OH-DPAT. P.J. Fletcher. Biopsychology, Clarke Inst. Psychiatry, 250 College St., Toronto, Ontario, Canada M5T 1R8.

The 5-HT_{1A} receptor agonist 8-OH-DPAT (DPAT) elicits a variety of behaviours including feeding. The effect on feeding appears to be due to reduced 5-HT neurotransmission resulting from activation of 5-HT somatodendritic autoreceptors in the raphe nuclei. Some behavioural effects of 5-HT_{1A} agonists are blocked by DA receptor antagonists suggesting that a facilitation of DA activity, secondary to reduced 5-HT function, may mediate the effects of these compounds. Experiments explored the importance of several DA-rich terminal regions in mediating feeding induced by intra-raphe DPAT. Adult male rats were used, and all drugs were injected directly into the brain via chronically dwelling guide cannulae; food intakes were measured 1h after injection. Dose-dependent increases in feeding were observed when DPAT (0.125-2ug) was injected separately into the dorsal raphe (DR) or median raphe (MR). Feeding elicited by DPAT from both DR (1ug) and MR (0.5ug) was attenuated by the DA antagonist alpha-flupenthixol (FLU; 1.25 and 2.5ug) injected into the nucleus accumbens. The effect of DR-injected DPAT was completely blocked by injection of FLU into dorsolateral and ventrolateral regions of the caudate. In contrast FLU injected into these sites failed to modify the effect of MR-injected DPAT. None of the effects of FLU can be explained in terms of non-specific motor impairments. The results confirm that DA is involved in DPAT induced feeding and show that DR and MR induced feeding have separate but overlapping substrates. Thus, while nucleus accumbens DA is involved in bOth effects, DA in the caudate is involved only in feeding induced by DPAT injected in the DR.

EFFECTS OF CONDITIONED TASTE AVERSION (CTA) ON SEROTONIN RELEASE IN THE LATERAL HYPOTHALAMUS AND HIPPOCAMPUS. H. L. West, G. P. Mark & B. G. Hoebel. Dept. Psychology, Princeton Univ., Princeton, NJ 08544

Previous data from this laboratory demonstrated that dopamine release in the nucleus accumbens could be attenuated by presentation of a taste stimulus which had previously been paired with LiCl-induced malaise (Mark et al., Soc. Neurosci. Abstr., 1989). Our next question concerned the effect of learned aversion on serotonin (5-HT) output in the perifornical lateral hypothalamus (PLH). Eighteen male, Sprague-Dawley rats were implanted with intriaoral catheters and stainless steel guide cannulas ending 5 mm dorsal to the PLH. Prior to testing, subjects were given two conditioning trials in which the taste of Na saccharin (2.5 mM, the CS) was paired with LiCl-induced malaise (the US). Thirty-six hr after the final LiCl injection, microdialysis probes were inserted into the PLH (200 µm diam., 3 mm fiber). Following a 12 hr delay, dialysates were collected every 20 min for 1 hr prior to and 2 hr after oral infusion of the CS. Serotonin concentrations were determined using HPLC-EC. Results showed a 48% increase in 5-HT levels during the 20 min CS infusion (p<-0.5). This effect was absent in unconditioned control subjects and attenuated in pseudo-conditioned (US only) subjects. To explore the possibility that this effect would occur in a 5-HT terminal region not directly implicated in taste aversion learning, the experiment was repeated with 18 animals in which probes (4 mm) were placed in the Previous data from this laboratory demonstrated that dopamine release in the terminal region not directly implicated in taste aversion learning, the experiment was repeated with 18 animals in which probes (4 mm) were placed in the hippocampus. At this site, 5-HT output was not uniquely affected by oral infusions of saccharin in subjects which had developed a CTA but rather was increased 18-25% in all groups, suggesting that hippocampal 5-HT is related to arousal. These results are consistent with the hypothesis that serotonin transmission in the LH plays a role in the inhibition of ingestion during expression of a CTA that may not be entirely attributable to a global enhancement of the serotonergic system accompanying arousal.

STUDIES OF THE AFFERENT CONTROL OF THE DORSAL RAPHE NUCLEUS IN THE AWAKE CAT. E. S. Levine, R. N. Holdefer, D. A. Morilak, and B. L. Jacobs. Program in Neuroscience, Dept. of Psychology, Princeton Univ., Princeton, NJ 08544.

These studies investigated the neurochemical control of dorsal raphe nucleus (DRN) serotonergic neurons under physiological conditions by recording neuronal activity in conjunction with microiontophoresis in the awake head-restrained cat. Serotonergic neurons in the DRN were identified on-line by their slow, regular firing rate during quiet waking, long duration action potential, and inhibition by iontophoretically applied 5HT-1, agonists. When applied iontophoretically, GABA inhibited the activity of DRN serotonergic neurons in the awake cat, and this effect was reversed by the iontophoretic application of bicuculline, a GABA-A receptor antagonist. During quiet waking, the spontaneous activity of DRN cells was not significantly increased by application of bicuculline alone (baseline firing rate = 2.4 ± 0.4 spikes/sec; firing rate during bicuculline = 2.6 ± 0.4 spikes/sec), suggesting that these neurons do not receive a tonic GABAergic Input during this state. However, preliminary data indicate that iontophoretic application of bicuculline activates these neurons during rapid eye movement (REM) sleep, when serotonergic neurons are otherwise silent. This suggests a role for GABA in mediating the inhibition of DRN serotonergic neurons during REM sleep. Additional studies are examining the roles of other neurotransmitter inputs in the afferent control of DRN neuronal activity. (Supported by AFOSR grant 87-0301).

A SEROTONIN DEPLETING REGIMEN OF (+/-)-3,4-METHYLENEDIOXYMETHAMPHETAMINE DECREASES THE BEHAVIORAL EFFECTS OF SEROTONERGIC AGONISTS IN RATS Dept. of Pharmacol. and Physiol., University of Chicago, Chicago, Illinois. 60637. PERFORMING ON AN OPERANT SCHEDULE. D. Jolly and L. S. Seiden.

Bats performing on a Differential Reinforcement of Low Rate (DRL) schedule of water reinforcement respond in a characteristic fashion to serotonergic agonists. Administration of either 8-hydroxy-2-(din-propylamino)tetralin (DPAT) or 5-hydroxytryptophan (5-HTP) increases reinforcement (RI) rate and decreases response (Rs) rate. This report describes the decreased DRL effects of DPAT and 5-HTP observed after partial depletion of brain 5-HT in the rat. One group of 9 rats received 20 mg/Kg (+/-)-3,4-methylenedioxymethamphetamine HCl every 12 hours for 4 days (MDMA). A control group of 6 rats received an identical regimen of vehicle (SAL). Fifteen weeks later, the DRL effects of DPAT and of 5-HTP were determined. Both DPAT and 5-HTP increased Rt rate and decreased Rs rate in both groups. These effects were greater in the SAL group than in the MDMA group. Neurotransmitter levels were assayed 22 weeks after the repeated injections of MDMA. These assay results showed that in the MDMA group, there were widespread depletions of 5-HT. These results suggest that an intact 5-HT system is necessary for the expression of characteristic DRL effects of 5-HTP or DPAT.

THE 5-HT SYNDROME INDUCED BY 5-HTP IN NEONATAL, WEANING AND POSTWEANING RATS. S.A. Sullivan, B.J. Winterson and D.J. Mokler. Depts. Pharmacol. & Physiol., Univ. New England, Biddeford, ME 04005.

There are similarities between the 5-HT behavioral syndrome in adult rats and behaviors in neonates. We observed the 5-HT syndrome in rats at various during various developmental stages. The 5-HT precursor, 5-hydroxytryptophan (5-HTP) was administered ip or sc (dose: 200 mg/kg). Rats were monitored for 2 hours after injection. Behaviors were similar in adult, 4 and 2 wk old rats and consisted of hindlimb abduction, forepaw treading, resting tremors, and circling (5-HT1 mediated), and headshakes (5-HT2 mediated). The 5-HT1 mediated behaviors emerged at similar times in these groups, except circling was absent in 4 wk rats. In contrast, headshakes began 40 min post-injection in adults, 26 min in 4 wk rats and 16 min in 2 wk rats. Four wk rats showed fewer of all behaviors and more grooming. Neonates (1-2 d) showed a different pattern of behavior. Although 5-HT1 mediated behaviors emerged at a time similar to older rats, these were followed by rolling over, limb extension, and ventroflexion. Distress vocalization was present throughout observations suggest that behaviors related to posture and locomotion (5-HT1 mediated) are present at birth and developmental changes are quantitative. However, headshakes (5-HT2 mediated) do show developmental differentiation. Supported by AOA grant #88-11-290.

LEARNED HELPLESSNESS AND SEROTONIN: IN VIVO MICRODIALYSIS. F. Petty, G.L. Kramer*, T.R. Phillips*, L.A. Speece* and D. Dunnam*. DVAMC and Dept. Psychiat., Univ. Texas Southwest. Med. Sch., Dallas, TX

Learned helplessness is a maladaptive behavior caused by exposure to uncontrollable stress. Previous research had shown serotonin to reverse helpless behavior when microinjected into frontal neocortex. Also, serotonin released from tissue slices of frontal cortex and septum was found to be low in helpless rats with this deficit which normalized by chronic administration of tricyclic antidepressants. Other laboratories, however, have shown that serotonin depletion prevents the development of learned helplessness and that serotonin receptor blockade does not influence tricyclic activity in this model. We, therefore, examined serotonin release in frontal neocortex using in vivo microdialysis in four experiments. In the first study, basal serotonin release was measured before exposure to inescapable stress and again before testing for helpless behavior and a significant increase was observed in rats which became helpless. In the second experiment, 60 mM K + was perfused prior to behavioral testing: this resulted in a "cure" of helpless behavior but no correlation was observed between serotonin release and helplessness. In the third experiment, rats were perfused during stress re-exposure and no correlation was found between stress-induced serotonin release and subsequent behavioral activity. Finally, animals were administered diazepam (once), imipramine (7 days) or training in escape behavior. All three interventions prior to exposure to inescapable stress prevented the development of behavioral helplessness, confirming prior research. None, however, demonstrated a significant correlation between +-induced serotonin released 24 hours after testing and degree of learned helplessness. Taken together, these results suggest that higher basal release of serotonin prior to stress exposure accompanies the development of learned helplessness, but that learned helpless behavior once established is not related to the functional releaseable serotonin pool.

311.9

AGE-RELATED VARIATIONS OF CENTRAL AMINES FOLLOWING ACUTE STRESS IN MICE. N. Shanks. S. Zalcman, A. Minkiewicz-Janda* and H. Anisman, Dept. of Psychology, Carleton University, Ottawa, Ontario, K1S 5B6, Canada.

Exposure to footshock reduced the levels and increased utilization of norepinephrine (NE), dopamine (DA) and serotonin (5-HT) in some brain regions of CD-1 mice. Transmitter levels and turnover varied with age (3 vs. 9 months) of the organism. Moreover, stressor exposure provoked more pronounced and persistent amine variations in the older animals, at least insofar as some amines were concerned. Hypothalamic NE, for instance, was more readily reduced in 9- than in 3-month old mice, even though the MHPG accumulation was greater in the younger animals. It is likely that in younger animals the increased utilization is more readily met with increased synthesis. In contrast, the accumulation of 5-HIAA was more pronounced in the older animals, and 5-HT levels were still reduced as long as 24 hr after stressor exposure. Finally, mesocorticolimbic DOPAC alterations were initially more marked in older mice, but were more persistent in the younger animals. The data are related to stressor-induced behavioral changes.

311.6

COMPARISONS OF BEHAVIORAL EFFECTS OF 5-HT1B AGONISTS VERSUS MDMA IN RATS. N. L. Rempel* and M. A. Geyer. Departments of Neurosciences and Psychiatry, Univ. of California at San Diego, La Jolla, CA 92093.

Hyperlocomotion induced by methylenedioxymethamphetamine (MDMA) in rats appears to be due to the serotonin (5-HT) releasing properties of the drug. Unlike amphetamine, the behavioral effects of MDMA are blocked by the 5-HT uptake inhibitor fluoxetine or the 5-HT synthesis inhibitor PCPA. Locomotor hyperactivity induced by 5-HT releasing agents is not consistent with the effects of 5-HT1A or 5 HT2 agonists. In the same behavioral paradigm used in the studies of MDMA, 5-HT1A agonists decrease locomotor activity. 5-HT2 agonists similarly decrease activity, especially in a novel environment. The present experiments were designed to determine if 5-HT1B agonists induce hyperlocomotion qualitatively similar to that induced by MDMA. Activity was examined using the Behavioral Pattern Monitor (BPM) system to provide detailed information regarding the amount and qualitative patterning of locomotor activity and investigatory responses. Six groups of rats were injected with various doses of CGS 12066B (0.003 to 0.3 mg/kg) 10 min prior to placement in the BPM chambers. No differences in locomotion, holepokes, or rear-ings were evident for any dose compared to the saline-injected control group. The behavioral effects of trifluoromethylphenylpiperazine (TFMPP; 0.625 to 10.0 mg/kg) were examined in the same paradigm. Decreases in locomotion, holepokes, and rearings were observed only at the highest dose. However, CGS 12066B is reportedly less active *in vivo* than *in vitro* and TFMPP has relatively high affinities for the 5-HT1A and 5-HT2 sites, as well as 5-HT1B. The behavioral effects of RU 24969, a more selective 5-HT1B agonist reported to induce hyperlocomotion in other paradigms, remain to be examined in the BPM system. A qualitative comparison of the effects of MDMA and RU 24969 will be important in understanding the stimulantlike effects of increased 5-HT release. (Supported by DA02925)

ZACOPRIDE IN SCHIZOPHRENIA: A SINGLE-BLIND 5-HT3
ANTAGONIST TRIAL. J.W. Newcomer*, W.O. Faustman, B. Roth,
R.A. Bierley*, J.A. Moses, Jr.*, J.G. Csernansky. Palo Alto VA Med.
Center, Stanford Univ. Sch. of Med., Palo Alto, CA 94304
Zacopride inhibits locomotion associated with mesolimbic dopa-

Zacopride inhibits locomotion associated with mesolimbic dopaminergic hyperactivity in the rat, without rebound hyperlocomotion, CNS depression, or the prolactin elevation seen with neuroleptics. In other animal models and in humans, it is anxiolytic. In animals, it may facilitate learning. It has been hypothesized that zacopride might have efficacy for the treatment of schizophrenic symptoms, without the motor side-effects associated with conventional neuroleptics.

Six severely ill male inpatients with schizophrenia (initial BPRS

Six severely ill male inpatients with schizophrenia (initial BPRS total score > 50 in 5 subjects) received zacopride in a single-blind trial: no psychotherapeutic medications (except chloral hydrate) for 2 weeks, followed by 1 week of placebo, and 4 successive weeks of zacopride treatment at 0.2 mg, 0.4 mg, 08 mg, and 1.6 mg per day.

Two patients experienced a mild anxiolytic effect without sedation, most pronounced at lower doses of zacopride. A reduction in the distress associated with psychotic symptoms was clinically observed in a third patient. Core positive symptoms showed little change in any patient. Memory function, before and during treatment, revealed no changes.

No adverse motor effects were seen. The only subject who started the trial with a moderate degree of tardive dyskinesia, showed a decrease in abnormal movements in the first week of treatment. Withdrawal of zacopride resulted in a return of abnormal movements. CSF/plasma neurochemistry measures from the subjects will also be presented. Supported by MH30854 from the NIMH.

DIFFERENTIAL EFFECTS OF 5HT1A AGONISTS 80HDPAT, BUSPIRONE, GEPIRONE, IPSAPIRONE AND 5MEODMT ON A DRL 72 SEC SCHEDULE OF REINFORCEMENT. J.B Richards. K.E. Sabol, D.C.Jolly, and L.S. Seiden, Dept. Pharmacol. Physiol. Sci., Univ. Chicago, Chicago, IL 60637

Previous work from our lab has shown that 5HT1A agonists have antidepressant like effects on the DRL 72 sec schedule of reinforcement (increased reinforcement rate). Here we report that although 5HT1A agonists increase reinforcement rate they affect the pattern of DRL 72 responding differently. The DRL 72 sec schedule of reinforcement produces a typical pattern of responding which is reflected in the distribution of interresponse times (IRTs). Rats performing on the DRL 72 sec schedule have a peaked IRT distribution. The peak usually occurs before the 72 sec point. We have previously reported that antidepressant drugs which increase reinforcements shift this peak to the right - toward the 72 second point. If responses on the DRL 72 sec schedule were randomly spaced in time the distribution of IRTs would form a negative exponential curve and would not be peaked. We compared the obtained IRT distributions of drugged animals with the predictions of random performance. At doses which increased reinforcements, buspirone, gepirone and ipsapirone altered the IRT distribution so that it was more similar to the prediction of random performance. Conversely, doses of 8OHDPAT and 5MeODMT which increased reinforcements, did not cause the IRT distribution to become more similar to random performance. In addition, 5MeODMT caused a significant peak shift to the right. This work was supported by: MH-11191; RSA-10562 (L.Seiden).

SEXUAL BEHAVIOR OF MALE RATS FOLLOWING 5,7-DHT TREATMENT MAY BE RELATED TO PRESENCE OF SEROTONERGIC FIBERS LOCATED IN ASEXUALLY DIMORPHIC NUCLEUS IN THE SPINAL CORD. N.L. Brackett and V.R. Holets. The Miami Project, Dept. of Neurological Surgery, University of Miami, Miami, FL 33136.

Sexually experienced male rate received on intertheol injection of Sexually experienced male rate received on intertheol injection of

Sexually experienced male rats received an intrathecal injection of 5,7-dihydroxytryptamine (5,7-DHT) or its vehicle. Each male was

5,7-dihydroxytryptamine (5,7-DHT) or its vehicle. Each male was given four mating behavior tests with a receptive female for up to two months after surgery. Males were then sacrificed and their spinal cords were processed for immunohistochemistry.

Measures of mating behavior were not different between the two groups. Cross sections of spinal cord taken from lumbar and sacral segments were examined for 5-hydroxytryptamine (5-HT) immunoreactive fibers. In 5,7-DHT treated males, there was an overall reduction in the number of 5-HT fibers in the gray matter with the exception of the dorsolateral motor nucleus (DLN) located in the ventral horn of lumbar segments. In both vehicle and 5,7-DHT injected males, comparable numbers and densities of 5-HT fibers were injected males, comparable numbers and densities of 5-HT fibers were observed surrounding motoneurons in the DLN. The DLN is a sexually dimorphic nucleus in adult rats with males exhibiting more motoneurons in the DLN than females (Jordan, et al., Br. Res. 249:309,1982). These motoneurons innervate the ischiocavernosus muscle which lies at the base of the penis (Breedlove and Arnold, Science, 210:564,1980). We hypothesize that serotonergic action on the motoneurons in the DLN is responsible in part for mating behavior in 5,7-DHT treated males. The existence of intrinsic sources of 5-HT within the spinal cord (Newton, et al. Br. Res., 376:155,1986) may account for the 5-HT fibers in the DLN following 5,7-DHT treatment. (Funded by The Mismi Project and the Daniel Heumann Fund.) (Funded by The Miami Project and the Daniel Heumann Fund).

311.13

DEPLETION OF NOREPINEPHRINE IN EITHER THE VENTROMEDIAL NUCLEUS OR THE MEDIAL PREOPTIC NUCLEUS FAILS TO ALTER LORDOSIS IN RATS. B.L.Davis¹, J.Manzanares², K.J.Lookingland², K.E.Moore², L.G.Clemens¹. Neuroscience Prog., Dept. Zoology¹ and Dept. Pharmacol/Toxicol², Michigan State Univ., E. Lansing, MI 48824

Norepinephrine (NE) has been implicated as being important in mediating lordosis in estrogen-primed female rats. Lesions in the ventral noradrenergic bundle (VNAB) deplete NE in the whole hypothalamus and inhibit lordosis (Hansen, 1981), but little is known regarding the role of NE in specific hypothalamic nuclei in mediating this behavior. The present study examined the effects of depletion of NE in either the ventromedial nucleus (VMN) or the medial preoptic nucleus (MPN), two areas thought to be important for the control of lordosis. In separate experiments, anesthetized, ovariectomized (OVX), female rats received microinjections of the selective NE neurotoxin, 5amino-2,4-dehydroxy- α -methylphenylethylamine (5-ADMP), in either the VNAB (8 μ g/0.3 μ l, bilateral), the VMN (2 μ g/0.3 μ l, bilateral), or the MPN (4µg/0.6µl, bilateral). Females were hormonally-primed and tested for sexual receptivity one week after neurotoxin administration. VNAB lesions depleted NE (VMN: 65%, MPN: 70%), but not dopamine or 5-hydroxytryptamine, and significantly reduced lordosis. In contrast, depletion of NE in either the VMN (83%) or MPN (83%) failed to alter lordosis. These results indicate that the medullary NE input into the VMN or MPN is not required for lordosis in hormonally-primed OVX rats. This work is supported by PHS Grant No. HD 06760.

CONCURRENT BRAIN GLUCOSE UTILIZATION AND BIOGENIC MONOAMINE NEUROTRANSMITTER TURNOVER RATES WITH VTA BRAIN STIMULATION REINFORCEMENT J.E. Smith, S.I. Dworkin, C. Co* and L.J. Porrino, Dept. Physiol.& Pharmacol., Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, NC 27103 and Unit on Brain Imaging, NINDS.

Glucose utilization and biogenic monoamine turnover rates were

concurrently measured in discrete brain regions of rats receiving either contingent or non-contingent electrical stimulation of the ventral tegmental area and nonstimulated controls. This combination of procedures was employed to not only identify brain regions with altered glucose utilization, but in addition to determine whether the indicated changes in metabolic activity were also related to biogenic monoamine neurotransmitter turnover. [14C]-2-deoxyglucose and [3H] tyrosine and tryptophan were intravenously administered to 12 rats in each of these three nt conditions. Significant changes in the turnover rates for dopamine (DA), norepinephrine (NE) and serotonin (5-HT) resulted from non-contingent stimulation in the nucleus accumbens (NA), frontal cortex, medial prefrontal cortex (MPC), substantia nigra, ventral tegmental area, amygdala (AMY) and caudate-putamen (CP). Changes specific to contingent electrical stimulation included an increase in DA and decrease in 5-HT turnover in the contralateral NA and ipsilateral increases in DA and NE in the CP and 5-HT in the AMY. These procedures permit the simultaneous identification of the brain regions showing increased glucose utilization and changes in the activity of specific innervations of these regions in the same animals. The changes in turnover rates are consistent with the alterations in glucose utilization seen in the NA, AMY and MPC in the self-stimulating animals and suggest an important role for 5-HT, NE and DA in the neuronal events underlying electrical brain stimulation reinforcement. 5,7-DIHYDROXYTRYPTAMINE AND CASTRATION INCREASE DENDRITIC SPINE DENSITY ON VENTROMEDIAL HYPOTHALAMIC NEURONS. Maya Frankfurt. Neuroendocrinology Lab., Rockefeller University, New York, 10021

It has been demonstrated that lordosis facilitation in both female and male rats occurs after intrahypothalamic injection of the serotonin (5-HT) neurotoxin, 5.7-dihydroxytryptamine (5.7-DHT) and that this correlates with 5-HT levels in the ventromedial hypothalamic nucleus (VMN) (Frankfurt, M., Brain Res., 340: 127, 1985). Using Golgiimpregnation we have recently shown that ovariectomy causes a decrease in dendritic spine density on VMN neurons and that this effect is reversed by estrogen (E) (Frankfurt, M., Neuroendocrinology, in press).

In the present study the effect of intrahypothalamic injection of 5,7-DHT in both sexes and castration in the male vas studied. In the VMN of intact females, 5,7-DHT injection increased the density of dendritic spines on VMN neurons four-fold as compared to sham. In intact males, 5,7-DHT increased spine density two-fold as compared to sham- injected rats. Castration in males had the opposite effect of ovariectomy in that it increased dendritic spines as compared to intact. E given to castrated males reversed the increase in dendritic spines. These results suggest that 5,7-DHT and E have the same effect in the female; to increase spine density on VMN neurons. Whether this also reflects increased synaptic density must be seen. Supported by NS07080.

NEUROCHEMICAL DIFFERENCES IN STEROID-SENSITIVE AREAS MEDIATING REPRODUCTIVE BEHAVIORS IN QUAIL. A. Foidart, (Surlemont*, G.F. Ball and J. Balthazart, Lab. Biochemistry, Univ. Liège, B-4020 Liège, Belgium and Dept. Psychology, Boston Coll., Boston MA 02167. The steroid-sensitive nuclei underlying different reproductive behaviors show a

diversity of biochemical mechanisms in generating the steroid-dependent resp Their comparison could reveal essential principles of brain functioning without the possible confounding effects that are inevitable when comparison across species are attempted. We have analyzed steroid actions on the neurochemistry of two regions in the quail brain: the medial preoptic nucleus (POM) which is critically implicated in the activation by testosterone (T) of copulation and the nucleus intercollicularis (ICo) which presumably controls T-dependent vocalizations. In both nuclei, T metabolism (aromatization, 5α-and 5β-reduction) was quantified by radioenzyme assays, aromatase and estrogen receptors were studied by immunocytochemistry, catecholamines and their turnover were assessed by HPLC and α 1 and α 2-adrenergic and muscarinic cholinergic receptors were determined by quantitative autoradiography. Although both nuclei control androgen-dependent behaviors and contain androgen and estrogen receptors, they show major neurochemical differences In particular, aromatase activity and aromatase-immunoreactive neurons are present in POM but not in ICo. Norepinephrine levels are higher in the POM and ICo of females compared to males and this difference does not disappear after gonadectomy followed or not by a treatment with T. Dopamine turnover is higher in male than in female POM but not in Ico, $\alpha 2$ -adrenergic and muscarinic cholinergic receptors are also modulated by T specifically in sub-regions of ICo but not in POM. These neurochemical differences may provide insight into a general theory of how T acts biochemically to activate behavior. Supported by NIH HD22064, FNRS and EEC (SC1-0230-C/TT) to JB.

THE ROLE OF PEDUNCULOPONTINE NUCLEUS IN LOCOMOTOR ACTIVITY. G.J. Mogenson, M. Wu* & S.M. Brudzynski. Dept. Physiology & Dept. of Clinical Neurological Sciences of Western Ontario, London, Ontario, Canada N6A 5Cl.

It has been reported that nucleus accumbens-subpallidal-

pedunculopontine nucleus (PPN) projections contribute to locomotor activity (Mogenson, Swanson and Wu, Brain Res., 334: 65-76, 1985; Mogenson and Wu, Brain Res. Bull., 20: 241-246, 1988). However, it is not clear whether these projections from accumbens and subpallidal region pass through or terminate in the PPN. Since cobalt chloride is a reversible blocker of synaptic transmission by blocking the release of neurotransmitters (Lee and Malpeli, Brain Res., 364: 396-399, 1986), the present study was undertaken to determine whether the PPN and not just the fibres of passage, mediate locomotor activity.

Locomotor activity measured in an open-field chamber was elicited by unilateral injections of dopamine (DA) into was electived by unitateral injections of picrotoxin (PTX) into subpallidal region of rats. The ipsilateral administration of cobalt chloride (4mM, 0.2 µl) into PPN reduced locomotor activity elicited either by DA injections into accumbens or by PTX injections into subpallidal region while the ipsilateral administration of saline into PPN had little or no effect.

These results provide additional evidence that the PPN has a role in initiating locomotor activity. (Supported by NSERC of Canada)

DEFICITS IN SENSORIMOTOR GATING OF ACOUSTIC STARTLE FOLLOWING CARBACHOL INFUSION INTO THE HIPPOCAMPUS N.R. Swerdlow, S.B. Caine and M.A. Geyer. Department of Neuroscience, UCSD, La Jolla, CA 92093.

"Prepulse inhibition" (PPI) occurs when the startle reaction to a startling sensory stimulus is reduced by the prior presentation of a weak stimulus. PPI is a measure of sensorimotor gating and is decreased significantly in rats following dopamine (DA) activation of the nucleus accumbens (NAC). In the present study, we ared PPI after chemical stimulation of NAC afferents originating in the dentate gyrus of the hippocampus (HP). Male Sprague-Dawley rats were surgically equipped with bilateral steel cannulae aimed above the HP, and starting one week later, they were tested during three sessions with four days separating each session Prior to each session, rats received intra-HP infusions of carbachol (CBC) (0, 0.2 or 0.4 ug/side, n=9; 0, 0.8 or 1.6 ug/side, n=8) and startle amplitude was then measured following 50 presentations of a startle pulse (118 dB [A]) either alone or preceded 60, 120 or 500 msec earlier by a weak prepulse (80 dB [A]). The normal inhibition of startle amplitude by the prepulse was reversed by intra-HP CBC in a dose-dependent manner. Higher doses of CBC significantly depressed pulse-alone startle amplitude. In a separate experiment, the CBC-induced loss of PPI was not completely reversed by systemic pretreatment with the D2 DA antagonist spiperone at a dose (0.1 mg/kg sc) that completely reversed the loss of PPI caused by the DA agonist apomorphine. These findings suggest that HP-NAC circuitry is a neural substrate of PPI; activation of the HP-NAC projection may modify PPI through changes at the NAC that are partly or entirely independent of NAC D2 receptors.

AN INEXPENSIVE AUTOMATED SYSTEM FOR THE QUANTIFICATION OF ROTATIONAL BEHAVIOR IN SMALL ANIMALS. D.K. McFarlane, B.J. Martonyi*, J.B. Becker,

ANIMALS. D.K. McFarlane, B.J. Martonyl*, J.B. Becker, and T.E. Robinson. Dept. Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48104-1687.

The quantification of turning behavior in small animals is a useful tool for assessing the results of unilateral brain lesions, surgery and drug regimens. We describe here a new inexpensive and reliable system for the automated measurement of rotational behavior.

The system uses a single computer (Compared SA) to counter the program of the system uses a single computer (Compared SA) to counter the system uses a single computer (Compared SA) to counter the system uses a single computer (Compared SA) to counter the system uses a single compared SA) to counter the system uses a single computer (Compared SA) to counter the system uses a single computer (Compared SA) to counter the system uses a single computer (Compared SA) to counter the system uses a single compared to the system uses a single computer (Compared SA) to counter the system uses a single compared to t

The system uses a single computer (Commodore 64) to count quarter and full turns from up to ten subjects at once. The essential counting routine is written in machine code. The remaining program is written in BASIC. Input to the computer is memory mapped through a simple, inexpensive and commercially available digital I/O board providing 40 lines. For each subject, two combination LED/photocells and a bisected reflective disk are used to provide a continuous two-bit signal indicating which quadrant the subject is in. The photocells and disk are housed in a small box which can be suspended over any appropriate testing chamber. The subject is attached to the disk by means of an elastic harness and flexible

Multiple counting periods can be designated by the user before the start of an experiment. At the conclusion of an experiment, data that has been gathered can be printed out, stored to disk or transmitted over a standard RS-232 serial line to a Macintosh or other computer for further analysis. The total cost of the system with 10 test sites is approximately \$1000.

POST-TRAINING EFFECTS OF ETHANOL AND ENVIRONMENT ON APPETITIVE TASK MEMORY. M. Babbini*, M. Bejanian, and R.L. Alkana. Alcohol and Brain Research Lab., Sch. of Pharmacy, Univ. of South. Calif, Los Angeles, CA 90033

Colbern et al. found that ethanol's (E) post-training facilitatory effect on aversive memory in mice disappeared if animals were isolated after training suggesting that E and group housing combined to improve retention by adding aversive information to training. To test this hypothesis, we studied the effects of E on appetitive memory. During individual training, C57BL/6 mice were allowed to find a cheese pellet in the corner of an open field. Then, the mice were injected i.p. with E (2.0 g/kg) or saline (S), returned to their home cage and tested 24 hours later for retention [latency to begin eating on day 1 (L1) vs the latency on day 2 (L2)]. L2 was shorter than L1 in both Eand Smice grouped 4 per cage before and after training. When mice were isolated the day before training and housed with 5 new mice for 2 hours after training, L2 was significantly longer than L1 in both S and E groups. When put with a single mouse after training, L2 was shorter than L1 in S mice, but was longer than L1 in E mice. The results support Izquierdo's hypothesis that E's post-training facilitory effects on aversive memory may reflect post-training addition to the stimulus complex, rather than or in addition to enhanced consolidation of memory traces. (Supported by NIAAA grant AA03972).

312.3

EFFECT OF MORPHINE ON ETHANOL-REINFORCED RESPONDING IN NONDEPRIVED RATS. K.S. Schwarz-Stevens and H.H. Samson. Alcohol and Drug Abuse Institute, University of Washington, Seattle, WA 98118.

It has been reported that morphine increases home cage ethanol (EtOH) drinking. The present studies assessed morphine's effect on oral EtOHtraining. The present studies assessed morphine's effect on that EUOT-reinforced responding. Nondeprived rats were trained to respond using the sucrose-fading EtOH initiation procedure. In one study, rats responded on a single lever on an FR4 schedule with either 10% EtOH (n=3) or 10% EtOH mixed with 2% sucrose (n=3) reinforcement. In the second study, rats (n=7) responded under a concurrent FR4FR4 schedule with EtOH (10%) and water as the reinforcers. Daily sessions lasted 30 min. Morphine (0.1, 0.3, 1.0 and 3.0 mg/kg, s.c.) was injected 15 min before selected sessions. Each dose was

At the three lower doses, morphine slightly decreased responding independent of reinforcer. In the single-lever experiment, the pattern of responding with 10% EtOH reinforcement suggested that morphine may increase the number of drinking bouts per session. Response patterns with the EtOH-sucrose mix were not changed. In the concurrent study, the .3 and 1.0 mg/kg doses slowed response rates for EtOH reinforcement. At the 3.0 mg/kg dose, all rats' responding was suppressed to near zero.

These results suggest that morphine does not enhance drug-seeking behavior nor increase EtOH intake to excessive amounts in this situation. Also, water-reinforced responding was suppressed in a manner similar to

POST-TRIAL ADMINISTRATION OF ETHANOL FACILITATES RECALL OF PROSE BUT NOT UNRELATED LISTS OF WORDS.

G. Lamberty*, B. E. Beckwith, T. V. Petros, and A. R. Ross*. Psychol. Dept., Univ. of North Dakota, Box 7187, Grand Forks, ND 58202.

Although many studies have documented the detrimental effect of pre-trial treatment with ethanol on human memory, few studies (Kalin, 1964; Parker et al., 1980; 1981) have explored the post-trial facilitation of ethanol on human memory. In the present study, either lists of unrelated words or narrative prose passages were presented to young adult males who reported being in good health and reported being moderate users of alcohol. Immediately after encoding these materials, subjects were given either 1.0 ml/kg of absolute ethanol or the masking solution in a double-blind design. After 24 hours, the subjects returned to the lab and were asked to recall the materials they learned earlier. Ethanol significantly enhanced recall of the prose passages, but had no effect on the recall of the lists of words. It appears that the post-trial facilitation effect is specific for some materials, highly organized and elaborated text, but not others, unrelated lists or words that are rote memorized.

ETHANOL-INDUCED HYPERGLYCEMIA AND CONDITIONED TASTE AVERSION IN C57 AND DBA MICE. F.O. Risinger, C.L. Cunningham and S.I. Lawley. Oregon Health Sciences University, Portland, OR 97201

Acute exposure to ethanol produces an elevation of blood glucose level. In these experiments the genetic basis for the glycemic response to ethanol and its possible role in development of conditioned taste aversion were examined. Adult male C57Bl/6J and DBA/2J were acutely exposed to ethanol (0-6 g/kg, I.P.) and blood glucose levels determined over 4 hours. C57 mice demonstrated profound dose-related elevations in blood glucose levels while DBA mice were relatively unresponsive. Fasting for a 24-h period prior to ethanol exposure reduced the magnitude of the hyperglycemic response in the C57 mice. A water restriction schedule (2 h water/day) resulted in a significant lowering of basal blood glucose level. Water restricted DBA mice showed significant hypoglycemia following ethanol exposure while C57 mice were unresponsive. In a conditioned taste aversion procedure, C57 mice showed less aversion development to an ethanol paired flavor while DBA mice demonstrated greater dose-dependan aversion. Manipulation of blood glucose levels after ethanol exposure using insulin resulted in potentiation of the ethanol-induced conditioned taste aversion in DBA mice, but not in C57 mice. Profound hypoglycemia was noted in both strains. These results indicate a genetic component for the glycemic response to ethanol and provide further evidence for a genetic component determining the hedonic value of ethanol. There appears to be an inverse correlation between glycemic responsiveness to ethanol and the development of ethanol-induced taste aversion, although the mechanisms underlying this relationship have yet to be determined. (Supported by AA07702 and AA07468 from NIAAA)

TASTE REACTIVITY FAILS TO PREDICT ALCOHOL CONSUMPTION DURING RESTRICTED FLUID ACCESS TESTS IN RATS. P.J. B and S.W. Kiefer. Department of Psychology, Kansas State University, Manhattan, Kansas 66506-5302.

Taste reactivity tests were used to examine the palatability of 0.5%, 3%, 6%, 9%, 12%, and 15% (v/v) alcohol. Rats were then given the same concentrations, one solution per day, during restricted fluid access tests with a single bottle. Results from the reactivity tests showed that rats displayed little aversive responding across the alcohol concentrations; there was a nonsignificant increase in gapes as the alcohol concentration increased. Ingestive responses (tongue protrusions, lateral tongue protrusions) did not vary despite the relatively large range of concentrations. Mouth movements were consistent up to 6% alcohol and then showed an abrupt increase for the 9% and higher concentrations. Consumption during the restricted access tests showed a similar break between 6% and 9% with consumption significantly decreasing at 9% and remaining low. Correlations between reactivity responses and subsequent consumption were consistently nonsignificant. The data indicate that alcohol consumption, even during relatively short periods of access, is dependent on factors beyond those of simply (Supported by NIAAA grant AA07185)

ETHANOL-INDUCED CONDITIONED PLACE PREFERENCE IN MICE: ROLE OF CONDITIONING TRIAL DURATION. C.L. Cunningham and L.K. Prather*. Department of Medical Psychology, School of Medicine, Oregon Health Sciences University, Portland, OR 97201.

Recent studies in this lab suggest that the place conditioning paradigm offers a sensitive model for assessing EtOH's rewarding effects in mice. These studies show a conditioned preference (CP) for EtOH-paired cues that is influenced by dose and genotype. The purpose of the present experiments was to determine the effect of conditioning trial duration on strength of EtOH-induced CP. In a counterbalanced, differential conditioning procedure, DBA/2J mice received four pairings of a distinctive floor stimulus with injection of EtOH (2 g/kg); a different floor stimulus was paired with saline. Different groups were exposed to the floor stimuli for 5, 15 or 30 min after injection. CP was inversely related to trial duration, with mice in the 5, 15 and 30-min groups spending 83, 74 and 66% of their time, respectively, on the EtOH-paired floor during a choice test. This outcome was replicated in a second study which showed that part of the difference between 5 and 30-min groups is due to a difference in total duration of exposure to the apparatus. In general, these findings support the notion that EtOH produces an initial, short-lived excitatory (rewarding) effect that is replaced by a longer-lasting inhibitory (aversive) effect.

SPIROXATRINE ANTAGONIZES THE HYPOTHERMIC EFFECT OF ETHANOL In MICE. M.K. Menon and R.L. Lloyd. Psychopharmacol. Res. Lab., V.A. Med. Ctr., Sepulveda, CA 91343 and Dept. Psychiat. UCLA Sch. Med., Los Angeles, CA 90024.

Male Swiss-Webster mice (Hilltop) were used and, if not stated otherwise, all injections were made i.p. Rectal

stated otherwise, all injections were made 1.p. Rectal temperature was measured using a telethermometer. In the animals, spiroxatrine (0.1-1.0 mg/kg), BMY 7378 (1.0-3.0 mg/kg) and pindolol (3-10 mg/kg s.c.) injected 10 min before, blocked the hypothermic effect of the 5-HT_{1A} agonist 8-OHDPAT (1.0 mg/kg., s.c.) in a dose-dependent manner. It was concluded that three drugs act as 5-HT_{1A} the showe does range only antagonists in mice. In the above dose range, only spiroxatrine blocked the hypothermic effect of ethanol (2.4 g/kg, i.p.). It was inferred that the blockade of this g/kg, 1.p.). It was interred that the blockade of this response to ethanol by spiroxatrine does not depend upon the 5-HT_{1A} antagonistic effect. Further studies indicated that the interaction between spiroxatrine and ethanol did not take place at the dopamine, opioid or α_2 adrenergic binding sites. Spiroxatrine did not block the hypnotic effect of others (3.9, 2/4g). It appears that effect of ethanol (3.9 g/kg). It appears that neurochemical studies between ethanol and spiroxatrine could provide information on the mechanism by which ethanol produces hypothermia. (Supported by the U.S. Veterans Administration).

312.6

ANXIOGENIC BEHAVIOR DURING ETHANOL WITHDRAWAL: REVERSAL BY BUSPIRONE AS EVALUATED IN THE ELEVATED PLUS MAZE. S.M. Rezazadeh. P.L. Prather and H. Lal. Department of Pharmacology, Texas College of Osteopathic Medicine, Ft. Worth, TX 76107

Ethanol withdrawal in rats produces behaviors indicative of an anxiety state (J. Pharmacol. Exp. Ther., 247:508, 1989). This study investigated the effects of buspirone, a 5-HT_{1A} receptor agonist with anxiolytic action, in ethanol withdrawn rats. Using the elevated plus-maze, two parameters were measured: percent open-arm entries (%OAE), and percent time spent in the open arms (%OAT). In an anxiety state, rats spend less time and make fewer entries onto the open-arms. The total number of arm entries is an index of locomotor activity. Long-Evans hooded-rats were fed, for 5 days, a liquid diet which was nutritionally complete and contained 4.5% ethanol. Twelve hours after the last ethanol dose, the rats were injected with buspirone (0, 0.32, 0.64, or 1.25 mg/kg). Fifteen min later, the rats were placed in the center of the maze and observed for 5 min. In rats fed with ethanol-free diet, buspirone caused a reduction in both %OAE and %OAT, with no change in the total arm entries. However, in ethanol withdrawn rats, buspirone dose-dependently increased the %OAE and %OAT. In the ethanol withdrawn animals injected with saline, both %OAE and %OAT were significantly reduced. Thus, the re-duction in open-arm activity, suggestive of anxiogenic-like effects, was shown to occur during ethanol withdrawal and this response was reversed by buspirone. The paradoxical anxiogenic-like effect of buspirone observed in rats given ethanol-free diet may be attributed effect of obspirone observed in rais given emanoi-free diet may be attributed to the partial agonistic action at postsynaptic 5-HT receptors. In conclusion, pharmacotherapy with selective 5-HT_{1A} agonists may be beneficial in alleviation of anxiety occurring during ethanol withdrawal. (Supported by NIAAA grant AA06890).

312.8

EARLY HANDLING MODIFIES HYPOTHERMIC RESPONSES OF RATS EXPOSED TO ETHANOL IN UTERO. J. Weinberg, Dept. of Anatomy, Faculty of Medicine, The University of British Columbia, Vancouver, B.C., Canada V6T IMS Animals handled daily during the preweaning period are less emotional and show more adaptive responses to stress than nonhandled animals. Previous data have shown that early handling may interact with prenatal ethanol exposure to modulate pituitary-adrenal activity and responsiveness. The present experiment examined effects of early handling on ethanol-induced hypothermia in adult animals exposed to ethanol in utero. Ethanol (A) was administered to pregnant Sprague-Dawley rats in liquid diets, gestation days 1-22; pair-fed (PF) and ad libitum fed (C) control groups were included. From birth to 15 days of age, half the litters in each condition were handled for 3 min daily; the rest were undisturbed until weaning. In adulthood, male and female offspring were tested for hypothermic responses to a challenge dose of ethanol (2 g/kg, ip). For nonhandled males, the hypothermic response to ethanol was greater in A and PF then in C animals; early handling eliminated the differences among groups. Group differences were not significant for females. These data indicate that early handling can modulate physiological responsiveness in animals prenatally exposed to ethanol, and that males and females may be differentially affected. be differentially affected Supported by grant #AA07789 from NIAAA.

312.10

FAT-PREFERRING RATS CONSUME MORE ALCOHOL THAN CARBO-HYDRATE-PREFERRING RATS. D.D. Krahn, B.A. Gosnell and M.J

Maichrzak. Dept. of Psychiatry, University of Michigan, Ann Arbor, MI 48109.

Rats with a genetic preference for alcohol (ETOH) have been found to consume more dietary fat than ETOH non-preferring rats. We therefore hypothesized that rats selected on the basis of fat and carbohydrate (CHO) preferences would differ in ETOH intake. Patterns of macronutrient self-selection were determined by allowing rats to self-select their diets from separate sources of CHO, fat and protein. From measurements of daily intakes, fat-preferring and CHO-preferring groups were formed (n=8/group). All rats were then returned to a standard lab chow diet, and placed on a schedule in which chow was available for 4 hrs/day (1 hr in testing cages, 3 hrs in home cages). In the 1 hr drinking session, 4% ETOH was available as the only fluid; water was available ad lib at all other times. The ETOH concentration was increased by 4%/week to 12%; after 7 sessions with 12% ETOH, the food deprivation schedule was discontinued. Food was then available ad lib except during daily 1 hr drinking sessions. For 22 additional days, rats were given daily 1 hr drinking sessions (12% ETOH). After 2 days on which only water was presented in the daily sessions, water and 8% ETOH were alternated daily (for 6 days) as the only available fluid in the session. Intakes wer averaged for the final 3 water sessions and the three 8% ETOH sessions and compared with repeated measures t-tests. Fat-preferring rats consumed significantly more 8% ETOH than water (3.0 \pm 0.5 vs 1.9 \pm 0.2 mls, p<.01); CHO-preferring rats consumed approximately equal volumes of ETOH and water (1.5±0.4 vs 1.2±0.5 tents and water (p < 0.5). Furthermore, fat-preferring rats consumed more ETOH than CHO-preferring rats (p < 0.5). This study suggests a positive relationship between fat preference and oral intake of ETOH. This effect appears to be due to differences in diet preference rather than to actual intake, because both groups were maintained on standard lab chow during testing. (Supported by NIDA Grant DA05471)

A Comparison of Three Inverse Benzodiazepine Agonists on Ethanol Stimulant Effects. L.H.Hicks,H.L.June,T.O.Moore and M.J.Lewis. Howard Univ.,Washington, DC 20059

number of reports suggest that GABA-BDZ mechanisms may mediate the behavioral effects of ethanol (E). We previously showed that both the locomotor stimulant and depressant effects of E could be altered by Rol5-4513 (RO) an imidazobenzodiazepine inverse agonist.

The present research compared the actions of RO, BCCE and FG 7142 (two other inverse agonist) and Rol5-1788 (a CNS BDZ antagonist) on the stimulatory effects of E in rats habituated to an open field. To specifically investigate these effects, three components of activity were assessed: horizontal activity, vertical activity and total distance (# of inches travelled). The results showed that E (.12-1.0 g/kg) alone stimulated all components of locomotor activity. All inverse agonists appeared to attenuate E effects on each of the three measures. The antagonistic actions of Ro15-1788 was, however, apparent only in animals pretreated with RO and E. Rol5-1788 given alone, however, enhanced all locomotor activity measures above control levels. These results suggest that some of the antagonistic actions of E may be shared by various inverse agonist compounds.

312.13

PERFORMANCE ON THE PLUS-MAZE TEST OF ANXIETY IN WISTAR, ALCOHOL-PREFERRING (P) AND -NONPREFERRING (NP) LINES OF RATS: EFFECTS OF ETHANOL AND CHLORDIAZEPOXIDE (CDP) RB Stewart, JM Murphy, L Lumeng* and T-K Li* Pyschiat Res & Regenstrief Insts, Indiana Univ Sch Med, & Psy Dept, Purdue Sch Science, Indianapolis, IN 46202

The plus-maze test of anxiety was used to assess the effects of selective breeding for ethanol preference in alcohol-naive P, NP and Wistar rats. In this test, the degree of anxiety is assumed to be inversely proportional to length of time spent on the open arms of the maze. Number of arm entries is used to measure activity. In Expt 1, Wistar rats (n = 7-9/dose) received ip injecspent in open arms and activity were unchanged by all doses of ethanol. In Expt 2, P and NP rats (n = 8-11/ line/dose) received saline, 0.5 or 1.0 g ethanol/kg BW or 7.5 mg CDP/kg BW. CDP produced a similar increase in time spent on the open arms for both lines (p<0.001), while ethanol had no effect. However, compared with NP rats, P rats spent less time on the open arms under all conditions (p<0.003). No line differences in activity were observed, except that 1.0 g ethanol/kg BW reduced activity only in NP rats (p<0.001). The findings indicate that selective breeding for ethanol preference is associated with increased levels of anxiety in rats of the P line, but ethanol is an ineffective anxiolytic compared with CDP. (AA03243, AA07611)

312.15

ALCOHOL AND RELAXATION EFFECTS ON LOW FREQUENCY EEG VARIABILITY. L. T. Crow, Y. G. Quevedo*, and P. J. McKinley*, Dept. of Psychology, Western Washington University, Bellingham, WA 98225.

Parietal electroencephalograms (P3 and P4) were taken from college students after a 30-min. ingestion period of 0.4 g/kg ethanol in table wine. FFTs of AD samples were taken at three intervals during a postdrinking relaxation period in which subjects reclined in a dark room

While variance measures of frequency magnitudes between 4 and 16 Hz indicated significant alcohol effects for the first [F(7,12)=7.31] and third [F(7,12)=3.59] readings, coefficients of variation (100 x S.D./mean) did not. There were no significant differences in either mean magnitudes [F(1,19)=0.31] or coefficients of variation [F(1,19)=.028] between alcohol and control groups.

Coefficients of variation did, however, indicate significant increases in EEG variability over relaxation time [F(2,42)=6.68]. The results are believed to support a general theory of "environmental tolerance" and behavioral variability (Crow, L. T., Psych. Rec., 27:783, 1977) and to bear on the heuristic aspects of drug effects on EEG variability.

FEMALE SEX STEROIDS AND ETHANOL: A PROFILE OF ACETALDEHYDE LEVELS, WHEEL RUNNING AND SLEEP IN SPAYED FEMALE RATS. A. Torres and F.A. Holloway, Department of Psychology, University of Alabama at Birmingham, Birmingham, Al 35294, and Department of Psychiatry and Behavioral Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK. The effects of the female sex steroids estradiol-178 (E₂) and progesterone (P₄) on responses to acute ethanol administration were evaluated by comparing responses in four groups of spayed female rats: OVX, E2, P4, E2P4. Estrogen administration resulted in higher acetaldehyde levels (e.g., 8.6-9.3 ng/ml versus 4.9-6.0 ng/ml) although no differences in peak ethanol level were found for 0.4, 1.2, 3.2 g/kg EtOH. Running wheel activity was monitored for one hour in 15-minute sessions at 0.4, 0.8 and 1.2 g/kg EtOH. A significant depression in cumulative running activity was produced by ethanol in groups with P₄ implants. When evaluating wheel running for the 15-minute sessions, increases above saline rates were found in groups with E₂ implants. increases above saline rates were found in groups with E_2 implants. Finally, progesterone was associated with an increase in sleep onset time to 4.0 g/kg EtOH. This research deomonstrates that ethanol produces differential effects in rats with different steroid backgrounds.

COCAINE POTENTIATES ETHANOL'S THRESHOLD LOWERING EFFECT ON BRAIN-STIMULATION REWARD. M. Moolten and C. Kornetsky. Laboratory of Behavioral Pharmacology, Boston Univ. Sch. of Med., Boston, MA 02118.

We have found that ethanol will, as do other abused substances, lower the threshold for rewarding brain stimulation. In addition, abused drugs that increase an animal's sensitivity to brain stimulation reward (BSR), such as morphine or cocaine, will have synergistic effects on BSR, when co-administered. Because cocaine and ethanol are often used together, the present experiment was designed to determine whether cocaine would potentiate the threshold lowering effects of ethanol. Dose effect curves for ethanol's action on BSR were determined in Lewis rats with stimulating electrodes in the medial forebrain bundle, with and without the co-administration of an ineffective dose of cocaine (0.5 mg/kg ip, or less). The addition of the cocaine significantly increased the potency of the ethanol, shifting the dose-effect curve to the left. These results support the hypothesis that ethanol's rewarding effects are mediated, in part, by similar neuronal systems as other abused substances

(Supported by NIAAA grant AA05950 and Research Scientist Award DA00099 to CK).

R.H. Bradley, D.O., Ph.D., S. Meiners, Ph.D.*, E.Dunlap, M.T.*, P. Fraker, Ph.D.*, & P. Bradley, R.N., B.S.N.* Neuroimmunocytochemistry Lab/Psychiatry and Dept of Biochemistry, Michigan State University, East Lansing, MI. 48824-1316. The use, abuse and dependency of psychoactive drugs (as DSM-III-R defined) in the U.S.A. is an at an all time high. The psychoactive drugs are seriously affecting the working population between the ages of 20-40 years of age. In this study, we have examined 40 psychoactive drug using adults [PDUA](mean age for both=30) and 20 aged matched sex control adults. The majority of the reports on alcoholism indicate that it is a behavioral problem. This study shows that 50% of the PDUA have a clear genetic linkage via the peripheral immune system via conservation of the genome. We have examined their psychosocial, psychiatric, SMAC-21, HbA/HbB&non HbA/B, HTL-IIIAb and a series of immunological functions(all examined at the same time of day 8-11 a.m.). Exclusion criteria were strictly upheld. This study revealed that the PDUA had no Axis I diagnosis of any major psychiatric magnitude but we did find 50% of the PDUA to possess an Axis II diagnosis: cluster B.
The CD-8 genetic marker (U.S.A. Patent Pending-Test Kit for inherited substance abuse dependency) is 2 (two) standard deviations from the control CD-8 (T-Suppressor/Cytotoxic) absolute total number Human Lymphocyte. Profound meanings can be derived from PDUA CD-8 deviation.

NEUROETHOLOGY: INVERTEBRATES

THE CRAWLING BEHAVIOR OF THE LEECH, Hirudo medicinalis: PROPERTIES AND CONNECTIONS OF CIRCULAR MOTOR NEURONS. A. Baader and W. B. Kristan, Jr., Deptartment of Biology, University of California at San Diego, La Jolla, CA 92093-0322.

A starving leech can either swim or walk to a prey to satisfy its appetite. How does it decide between the one or the other behavior? In contrast to swimming, little is known about crawling. As a first step, we have analyzed candidate neurons for crawling behavior on three different

1) In behaving animals. A leech walks on a ball and a movable stage in a water filled tank with two segments of its midbody suspended in a holder and a ventral ganglion was exposed to allow intracellular recordings. 2) In ganglia with an attached piece of body wall. Interneurons and motor neurons of circular muscles were stimulated to determine their output effects. 3) In an isolated chain of ganglia. We recorded from motor neurons of the circular muscles which are active during craying but not during explains.

during crawling but not during swimming.

Dorsal circular muscles are innervated by at least three pairs of motor neurons: CV, 112 and 152. CV neurons are excited by cell 152 and inhibited by cell 157 stimulation. Cell 208, a swim interneuron, produces inhibited by ceil 157 stimulation. Cell 208, a swim interneuron, produces circular contraction of the skin when stimulated, and excites cell 152. Other identified interneurons (e.g. 204 or S) have no effect on the CV cells. CV cells receive strong mechanosensory inputs from P cells and weaker input from T and N cells. The results provide the basis for studying the circular motor output in a tethered walking animal and finding interneurons involved in either swimming and/or walking. Supported by a USPHS research grant, MH 43396 to WBK.

313.3

ORIENTATION TO WATER-FLOW IN TRITONIA: NEURAL BASIS OF RHEOTAXIS. J.A. Murray* and A.O.D. Willows. Friday Harbor Laboratories, Friday Harbor, WA 98250.

The nudibranch gastropod *Tritonia diomedea* orients to and moves toward water-currents in the lab and in nature. Field observations indicate that tidal flow threatens to pull the animal off the substrate and away from that tidal flow threatens to pull the animal off the substrate and away from food and potential mates. Additionally, flow-tank experiments show that orientation to current reduces hydrodynamic drag. We examined the neural basis of this rheotaxis behavior by recording intracellularly from the brain, in a semi-intact animal preparation. Neurons of the pedal and cerebral ganglia respond to water-flow directed to the oral veil and rhinophore sheaths with bursts of EPSPs and action-potentials.

We identify 14 neuron pairs of the pedal ganglia that respond tonically and/or phasically to water flow directed at the rhinophore sheaths and oral veil tips. Most respond equally to inputs from either side of the body, but 5 respond with greater Intensity to stimuli originating ipsilaterally. When

stimulated intracellularly, 5 pairs of these neurons drive ipsilateral movements that turn the animal in the direction of the stimulus. Further, 6 movements that turn the animal in the direction of the stimulus. Further, 6 of these pairs of neurons make polysynaptic, excitatory connections to another pedal neuron (Pd5), previously shown to be sensitive to changes in earth-strength magnetic fields. Pedal neurons like those we found that respond more strongly to ipsilateral water-flow, affect ipsilateral turns, and don't fully adapt to the water-flow stimulus (eg Pd3) after a minute are likely to play a key role in rheotaxis. Pd3 is also thought to contribute to escape swimming (Willows et al., <u>J. Neurobiol</u>, 4:255, 1973). These observations are consistent with the hypothesis that current-sensitive neurons contribute to previously described behavioral orientation to water currents and to the lunar-modulated magnetic heading preference of *T. diomedea*. NEURONAL PATHWAYS INVOLVED IN THE EXPRESSION OF EGG LAYING BEHAVIORS IN THE POND SNAIL LYMNAEA STAGNALIS. R.F. Jansen. G.P. Ferguson*, A.W. Pieneman* and A. Ter Maat. Dept of Biology. Vrije Universiteit, De Boelelaan 1087, 1081HV Amsterdam, The Netherlands, *Stazione Zoologica, Naples, Italy. The egg laying behavior of the pond snail consists of three consecutive phases: Resting, Turning and Oviposition, each named after the activity of the animal during these phases. The patterns of motor activity characteristic of overt egg laying behaviors (locomotion, turning, and rasping) are caused by the coordinated action of sensory feedback from the ovotestis and several neuropeptides. These neuropeptides are released during a synchronous burst of spiking activity in the neurosecretory caudodorsal cells (CDCs) that precedes egg laying.

The pathways via which sensory feedback from the genital tract reaches the central ganglia ring to activate motor circuits of egg laying behavior were identified in a lesion study. Of the visceral nerves, the intestinal nerve is both necessary and sufficient for the full expression of the high rasping activity by the buccal mass during Turning and Oviposition. For the activation of shell turning the intestinal nerve is necessary, but not sufficient. In vivo recordings were made from the intestinal nerve in freely behaving animals during egg laying. Using a spike separating algorithm we were able to show that during egg laying a specific change occurs in most of the individual units contained in this nerve. The ways in which the individual units contained in this nerve. The ways in which the individual units contained in this nerve. The ways in which the individual units contained in this nerve. ODOR-MEDIATED UPWIND FLIGHT BEHAVIOR OF THE TOBACCO HORNWORM MOTH, Manduca sexta. M.A. Willis and E.A. Arbas. ARL Div. of Neurobiol., Univ. of Arizona, Tucson, AZ 85721.

The upwind flight response of male moths to sex-pheromone released by conspecific females has long been used as a model for study of long-distance orientation to odors by insects. A primary mechanism mediating this response is an odor-triggered, visually guided anemotaxis.

We studied the odor-mediated upwind flight response of freely flying males and females of *M. sexta* in a laboratory wind tunnel. We presented appropriate odors to males and females in flight, removed the odor while the moths were still in flight, and varied the wind velocities while video-recording the flight responses. The track of each moth was digitized, and velocity and steering manoeuvers were measured every 0.03 seconds.

Males and females responded to their appropriate odors (females, host-plant odor; males, pheromone) with zigzagging upwind flight. The loss of odor causes a rapid change in steering and flight speed, resulting in the arrestment of upwind progress and widening of the cross-wind component of the flight path. When confronted with varying wind velocities, males flying toward sources of female pheromone make compensatory changes in their visually guided steering and flight speed. Of particular interest is the temporal regularity of the crosswind counterturns. Both males and females exhibited turns at similar wind counterturns.

Both males and temales exhibites utilis at similar frequencies, ca. 2 Hz. This turning frequency remained similar at all wind velocities tested, even though flight speed and steering changed significantly. Upon loss of odor, the frequency of counterturning decreased significantly until it eventually ceased. This temporal regularity suggests the presence of a stereotyped program of counterturning, triggered by olfactory stimuli, that combines with the motor program for wing beating to enable successful odor source location. [Supported by NIH grants NS-23405 and NS-07309.]

OLFACTORY AND VISUAL INFLUENCES ON FICTIVE FLIGHT IN MANDUCA SEXTA. R. Kanzaki and E.A. Arbas ARL Div. of Neurobiology, Univ. of Arizona, Tucson, AZ 85721.

Male sphinx moths Manduca sexta respond with oriented flight when they are stimulated with the sex-attractant pheromone blend released by a receptive female. Multimodal inputs (olfactory, visual, mechanosensory etc.) coordinate this flight and guide the male to the female. To study the influences of these inputs, we have developed techniques to elicit fictive flight (herein called "flight") from intact or dissected Manduca, and apparatus to provide multimodal stimuli. To elicit flight we injected chlordimeform [N-(2-methyl-4-chlorophenyl)-N',N'-dimethylformamidine, $10^{-9} - 10^{-7}$ moles/insect dissolved in acetone and diluted in saline] and provided sensory stimuli of different modalities. A continuous current of filtered air was delivered via a small wind tunnel equipped with ports into which pulsed odor stimuli were injected. The mouth of the wind tunnel was surrounded by an array of >125 green LEDs controlled by a computer to simulate the visual flow fields for forward, backward, or turning movements. All tethered moths (n>20) so stimulated flew robustly with wingbeat frequencies (measured with EMG) of 15-25 Hz and attempted to steer when turns were simulated. Stimulation with pheromone blend alone elicited flight in fewer preparations than did visual stimuli alone. After all of their peripheral nerves had been cut, and during presentation of visual stimuli, thoracic ganglia produced antiphasic activity in depressor and elevator motorneurons (Mns) at burst frequencies of 8-10 Hz. If neck connectives were cut during ongoing activity, bursting continued for 15-30 sec before stopping. In a small number of preparations tested with connectives intact, stimulation with pheromone blend alone caused increased motor outflow in elevator and depressor Mns but not, as yet, in the pattern of flight. [Supported by NIH grants NS-23405 & NS-07309].

THE GIANT FIBER PATHWAY IN HAWAIIAN DROSOPHILA (INSECTA: DIPTERA). D. G. King, Dept. of Anatomy and Dept. of Zoology, Southern Illinois Univ., Carbondale, IL 62901.

Evolution in the Hawaiian islands has produced many diverse species of *Drosophila*. Axons of the giant fiber pathway were recognizable in each of six such species, using the same criteria that identify homologous axons in *D. melanogaster* and other flies (King & Valentino, <u>J. Comp. Neurol.</u> 219:1, 1983). Body size of each species was larger than that of *D. melanogaster*, and axons in the pathway were correspondingly more conspicuous. These observations are unsurprising since such closely related species might be expected to share similar structures, even though giant axons are known to vary tremendously among flies generally (King, <u>J. Morph.</u> 175:27, 1983; Benson & King, <u>Soc. Neurosci. Abstr.</u> 10:51, 1984).

However, the putative escape behavior controlled by the giant fiber pathway appears weaker in these Hawaiian drosophilids than in *D. melanogaster*. Unlike many more familiar species, these flies can be caught easily by hand, suggesting that evolution may have altered neuronal functions associated with the pathway. Comparative physiology of this pathway might prove interesting.

(Specimens were provided by K. Kaneshiro, Hawaiian Evolutionary Biology Program, University of Hawaii.)

REGULATION OF PHONOTAXIS BY FEMALE CRICKETS THROUGH JUVENILE HORMONE III CONTROL OF AN IDENTIFIED AUDITORY INTERNEURON. J. Stout. D. Zacharias* V. Rochette*, and G. Atkins. Dept. of Biol., Andrews Univ., Berrien Springs, MI 49104.

Removal of the corpora allata from sexually responsive female crickets (Acheta domestica) eliminates their phonotactic response to the calling song of conspecific males. Treatment of these allatectomized females with Juvenile Hormone III (JHIII) restores phonotaxis. Females normally become phonotactically responsive on the third or fourth day following the imaginal molt, at a time when production of JHIII is maximal. However females do not suddenly become phonotactically responsive on days 3 or 4. Rather the behavioral threshold for the female's response to the intensity of the male's call drops progressively between days 2 and 4, while JHIII production is increasing.

The L1 auditory interneuron is tuned to the carrier frequency of the male's calling song and encodes its temporal pattern. Activity of this neuron is necessary for the female's phonotactic response to model calling songs with an intensity below 70 dB. The threshold for the L1 neuron's response to model calling songs drops in females 2 to 4 days of age in parallel with the decrease in the female's behavioral threshold for phonotaxis. Treatment of a one day old female with JHIII causes the female's phonotactic threshold to drop 20 to 30 dB over the next 12 hours. The threshold of the L1 neuron also drops 25 to 35 dB, 12 hours following treatment with JHIII.

The effect of JHIII on the female's phonotactic threshold can be blocked by simultaneous injection of α -amanatin (a transcription blocker) or emetine (a translation blocker). These results suggest that JHIII might regulate the sensitivity of the female to the male's call by genetically regulating the sensitivity of the L1 neuron to the calling song.

313.6

STATE-DEPENDENT ACTIVITY CHANGES IN DESCENDING NEURONS IN OLFACTORY PATHWAYS OF *Manduca sexta*. E.A. Arbas, R. Kanzaki, and J.G. Hildebrand ARL Div. of Neurobiology, Univ of Arizona, Tucson, AZ 85721.

Our aim is to understand how the sex-attractant pheromones released by female moths activate and influence the oriented nuptial flight of male moths. We have used intracellular recording and staining with Lucifer Yellow followed by reconstruction from serial sections to characterize higher-order pheromone-responsive olfactory interneurons in the brains of male spinx moths, *M. sexta* including neurons whose axons descend in the ventral nerve cord [Soc. Neurosci. Abstr. 14: 379 (1988)]. Descending neurons that were excited by pheromonal stimuli were usually also excited by visual stimuli (lights on/off; movement) and sometimes by non-pheromonal olfactory stimuli as well. Excitatory responses to pheromone blends were of two general types: (a) brief increases in firing that recovered to background in <1 sec after the stimulus, and (b) long-lasting excitation (LLE) that outlasted the stimulus by >1 sec and, in some cases, as long as minutes. Neurons showing LLE also exhibited additional, state-dependent responses to sensory stimuli. For example, neurons firing at rates near 8 Hz responded to pheromone blend with acceleration of firing to persistent levels near 20 Hz (i.e. LLE was elicited). When similar stimuli were reapplied, firing was reduced to 8-12 Hz for up to 5 sec and then gradually increased to the initial high level. Thus, identical pheromone blend stimuli: (a) accelerated firing when the neurons were in a state of high background firing, and (b) decelerated firing when the neurons were in a state of high background firing, Individual pheromone components were ineffective. Visual stimuli (lights on/off) niteracted with olfactory stimuli to produce other state-dependent responses. [Supported by NIH grants NS-23405 & NS-07309].

PLASTICITY OF THE CRICKET RIVALRY SONG DURING AGGRESSIVE ENCOUNTERS. T.G. Nolen and C. Lam. Dept. of Biology, University of Miami, P.O. Box 249118, Coral Gables, FL 33124.

Male crickets employ acoustic signals to establish and defend their territories. As a prelude to neuroethological studies of aggressive behavior we have found that the probability of singing the RIVALRY SONG depends on the experience of the combatants; and that the RIVALRY SONG generally is necessary (but not sufficient) for territorial success. Adult males (Acheta domesticus), matched for size, were introduced into an arena and their aggressive interactions and acoustic behavior recorded over a ten minute observation period (sufficient for one male to gain control of the territory).

The territory holder at the end of ten minutes had won >90%, and initiated >70% of the encounters, and was the first to sing (88% of encounters), [all p<0.005; 25 pairs, 340 encounters]. Moreover, while the probability that either male would sing was about 50% initially, by the end of the observation period, the winner sang in >80% of the encounters (vs <20% for the losser). Muted males were less likely to getablish control of the territory in encounters with a yocal male [p<0.01, compared to vocal controls, n=17 & 12 pairs respectively]; and were less likely to maintain control of the territory [85% won BEFORE, vs 35% AFTER muting; p<0.0001, compared to sham control groups]. Nevertheless, some muted males retained their territory and some vocal males could not establish control in encounters with a muted male.

Pilot studies suggest that the RIVALRY SONG could play two roles in aggressive interactions: (1) a conditioning role in establishing male-male relationships, and, (2) a conventional communication (signalling) role involved in maintenance of the territory. Current experiments involve manipulation of the individuals' acoustic experience, the analysis of changes in the song during encounters and the plasticity of auditory neurons in response to RIVALRY SONG. (Supported by NSF & the UM Biol. Dept. Alumni Fund.)

313.10

A NEURAL CORRELATE FOR CONTROL OF SYLLABLE PERIOD SELECTIVE PHONOTAXIS IN THE CRICKET ACHETA DOMESTICA BY JUVENILE HORMONE III. G. Alkins. J. Henley* and J. Stout. Dept. of Biol., Andrews Univ., Berrien Springs, MI 49104.

Phonotaxis of female Acheta domestica is dependent on the syllable period (SP) of the calling song. This SP selective response is age-related. Young females (4-5 days following the imaginal molt) respond to a narrow range of SPs (50-70 ms), while old females (14-21 days) respond to a wide range of SPs (30-100 ms). This decreasing selectivity is inversely correlated with Juvenile Hormone III (JH3) synthesis which peaks in 3 to 5-day-old adult females and is relatively lower in older females. Addition of JH3 to old, unselective females resulted in these females becoming more selective 4 days following application. They became as selective as 5-day-old crickets.

A pair of auditory interneurons in the prothoracic ganglion of females known to be involved in phonotaxis (L3), has been shown to exhibit SP specific responses to calling songs (Atkins et al. <u>J. Comp Physiol</u> 165:827. 1989). In intracellular recordings L3 shows a decrementing response to successive syllables of a chirp having ideal SPs (50-70 ms) which is less apparent in reponse to increasing or decreasing SPs. We now report that this response in L3 is related to the age of the females and parallels the changing behavioral selectivity to SP. In 4-day-old females, L3 shows maximal decrement to ideal SPs whereas in 21-day-old females, L3 does not decrement at any SP and thus is unselective. Application of JH3 to old females (21 days) results in L3s which exhibit a strong decrementing response to ideal SPs similar to that of L3s in young females. Further, the effect of JH3 on L3 is maximal 3 - 4 days following application which parallels the time course of the behavioral effect of JH3.

THE "PRECEDENCE EFFECT" AND "ECHO SUPPRESSION" IN NEGATIVE PHONOTAXIS OF THE CRICKET TELEOGRYLLUS OCEANICUS.
R.A. Wyttenbach and R.R. Hoy. Section of Neurobiology and Behavior,
Cornell University, Ithaca, NY 14853.

Cornell University, Itaaca, NY 14853.

Tethered flying crickets make steering movements away from pulses of ultrasound. These movements include forewing tilt, abdomen swing, and metathoracic leg swing, all of which are lateralized relative to the sound source. A bilateral pair of ascending prothoracic auditory interneurons (int-1) has been shown necessary and sufficient to elicit these responses: stimulation of an int-1 (electrically or by ipsilateral ultrasound) causes steering to the contralateral side, while hyperpolarization prevents steering in response to sound. To correctly localize a sound source in the presence of echoes, directional information must be taken only from the first-arriving wavefront (precedence effect) and subsequent wavefronts cannot be treated as coming from additional sources (echo suppression).

We simulated a sound and its echo by presenting equal-intensity pulses from the right and left of a cricket with a variable delay between pulses. For delays of 4 to 75 ms, a single turn away from the first pulse is made. With smaller delays, a single turn in an arbitrary direction is made, while greater delays give rise to separate turns in response to each pulse. Thus the precedence effect occurs at delays greater than 4 ms and echo suppression occurs at delays less than 75 ms. In these experiments, abdomen swing, forewing tilt, or EMG of metathoracic leg abductors was monitored as an indicator of turning.

as an indicator of turning.

Investigation of the neural basis of this response has begun with extracellular recordings from both int-1s. When two pulses are presented as above, there is no difference between the two int-1s in spike number and only a small difference in maximum spike frequency at delays of 4 to75 ms. This difference probably cannot account for the clear single turns, and there are no int-1 differences that could account for the arbitrary turns at 0 to 2 ms delay. Work on suppression of the response to the delayed pulse is continuing with intracellular recording from int-1 and consideration of other auditory cells.

NEURAL ACTIVITIES OF HIGHER BRAIN CENTERS OF FREELY-MOVING COCKROACHES. M. Mizunami and N. J. Strausfeld. Arizona Research Labs, Div. of Neurobiology, Univ. of Arizona, Tucson AZ 85712

Two areas of the insect brain, the mushroom bodies and the central complex, have been implicated in memory and behavioral control (Huber F., Z. Vergl. Physiol. 44:60, 1960), but their respective functional organization is less understood. We have established methods for recording units in higher brain centers from freely behaving cockroaches. Enamel-coated copper or nichrome wires (20 µm in diameter) were implanted chronically into the brain of cockroaches. Unit activity was recorded while the cockroaches move freely in an arena. The site of recording was detected by copper or nickel sulfide precipitation followed by silver intensification. This procedure also revealed the profile of single identifiable neurons which could be matched to the morphology of cobalt-silver or Golgi impregnated elements. Units of higher centers could be classified into several types from their sensory and behavioral correlates. Possible participation of the mushroom bodies in cognition of environmental space and possible participation of the central complex in the control of behavior will be discussed. A COMPUTER MODEL FOR ESCAPE IN THE COCKROACH. R.D. Beer, G.J. Kacmarcik, R.E. Ritzmann and H.J. Chiel. Dept. of Comp. Eng. and Sci. and Dept. of Biology, Case Western Reserve University, Cleveland, OH 44106.

We have begun a long term project designed to simulate the cockroach escape system. This system represents a relatively complex distributed decision making and motor control circuit that is amenable to detailed cellular analysis. The model is based upon biological data that has been collected over several years both in our laboratory and in those of others. In response to gentle wind puffs, the cockroach rapidly turns away from the wind source and runs. The circuit that controls this behavior involves sensory neurons located on the cerci (two antennae-like appendages located on the rear of the animal's abdomen) which excite a population of 4 pairs of ventral giant interneurons (the vGls). The vGls in turn excite a population of approximately 100 interneurons in the three thoracic ganglia. Finally, the thoracic interneurons connect to motor neurons and local interneurons which control movements of each individual leg.

A three-dimensional kinematic model of the cockroach was constructed which accurately represents all leg segments and joint angles, and we have begun to incorporate actual neural circuitry into that model. We have simulated the wind responses of the nine most prominent columns of cercal hairs and their connections to vGls. We have reproduced the wind fields for each vGl. Moreover, we found that the specific shape used for the sensory response has significant effects on the simulated wind fields of the individual vGls. We are currently in the process of simulating the connections from the vGls to the thoracic interneurons. The model will allow for experimental interaction to assist in predicting and planning future neurobiological experimentation, which will in turn be used to improve the model. KINEMATICS AND PHYSIOLOGY OF THE ULTRASOUND-INDUCED LEG SWING OF FLYING CRICKETS. C.I. Miles. M.L. May and R.R. Hoy.

Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

In tethered flying crickets, *Teleogryllus oceanicus*, ultrasound (20kHz) induces a rapid swing of the metathoracic leg into the sweep of the hindwing contralateral to the sound source. This movement directly impedes the downstroke, and exerts a pronounced aerodynamic effect, assisting in a rapid turn away from the sound. This reaction is believed to be mechanism for evading hunting bats. We analyzed the kinematics of the leg's movement and recorded electromyograms from a muscle involved in producing it.

kinematics of the leg's movement and recorded electromyograms from a muscle involved in producing it.

The leg movement involves both abduction and elevation, and the extent of these movements is linearly related to the intensity of the sound. Abduction and elevation increase from about 4° and 3°, respectively, at threshold intensity (72dB) to 18° and 10°, respectively at 97dB. The duration of the leg's swing is also linearly related to stimulus intensity, ranging from 136ms at 72dB to 204ms at 97dB, in either case being long enough to impede the wing for several wingbeats. The latency of the leg swing decreases exponentially with increasing stimulus intensity, from about 72ms at 72dB to 35ms at 97dB. The shortest latency we recorded was 29ms.

being long enough to impede the wing for several wingbeats. The latency of the leg swing decreases exponentially with increasing stimulus intensity, from about 72ms at 72dB to 35ms at 97dB. The shortest latency we recorded was 29ms.

The metathoracic leg abductor (muscle 126) responds to ultrasound with a burst of spikes followed by activity that is in phase with the flight motor pattern. The response also showed linear increases in response and duration, and a linear decrease in latency with increasing stimulus strength. The mean response increases from about 1 spike/stimulus at 68dB to 16 spike/stimulus at 98dB, similar to the durations measured for the leg's swing. Latency to the first muscle spike declines from 63ms at 68dB to 36ms at 98dB. The shortest latency measured was 24ms.

duration increases from 105ms at 72dB to 218ms at 98dB, similar to the durations measured for the leg's swing. Latency to the first muscle spike declines from 63ms at 68dB to 36ms at 98dB. The shortest latency measured was 24ms.

The metathoracic leg swing has the shortest latency of any aspect of negative phonotaxis described so far. It is a simple yet effective component of this behavior, and provides a favorable system for further neurophysiological studies. We have identified the motoneuron for 126, and its role in the behavior is under investigation.

313.14

VIDEOTAPE MOTION ANALYSIS OF LEG JOINT ANGLES DURING ESCAPE TURNS OF THE COCKROACH. <u>S.W. Nye and R.E. Ritzmann.</u> Dept. of Biology, Case Western Reserve University, Cleveland, OH 44106.

The cockroach, <u>Periplaneta americana</u>, escapes from wind puffs by making a rapid and directional turn away from the wind source followed by a more random run. To achieve our goal of relating neural activity to the turning movements, we require a detailed understanding of the changes in each joint angle for all of the six legs. We have employed a high speed videotape recording system (200 frames/second) and motion analysis software to analyze each joint angle of tethered cockroaches responding to wind stimulation presented at 45, 60, 90, and 120 degrees relative to the rear of the insect.

Our data indicate that the legs of each segment play very different roles during the turn. For example, the mesothoracic legs provide direction for the turn, whereas the metathoracic legs provide more power than direction. Directionality arises in the mesothoracic legs by changes in the femoro-tibial (F-T) joint angles. In the mesothoracic leg ipsilateral to the wind, the F-T joint angle increased, while in the contralateral mesothoracic leg the F-T joint angle decreased. This caused both mesothoracic legs to move toward the wind source providing a force that would turn the animal away from the wind. In contrast, winds from the rear caused the C-F joints of both metathoracic legs to increase in angle driving the legs backward. Unlike the mesothoracic legs, the changes in the F-T joints of the metathoracic legs were approximately equal to changes at the C-F joint of the same leg. As a result, the force vector produced by these legs remained parallel to the long axis of the animal's body.

Presently we are obtaining electromyographic recordings that will relate changes in leg joint angle to the activity of individual muscles. This work was supported by NIH grant NS 17411 to R.E.R.

FUNCTION OF FEEDBACK LOOPS BETWEEN THE GIANT INTERNEURONS AND THE FLIGHT CUIRCUITRY OF THE COCKROACH. F. Liberset, M. Kiflawi* and J.M. Cambi, Dept. of Zoology, Hebrew University, Jerusalem, Israel

JM. Camhi, Dept. of Zoology, Hebrew University, Jerusalem, Israel.

In the flying cockroach, a small population of neurons located in the thoracic locomotory centers produces a copy of the central flight rhythm (an efference copy) and conducts this to the last abdominal ganglion. There, this rhythm modulates two groups of giant interneurons (GIs), the dorsals (dGIs) and the ventral (vGIs) (Libersat et al., <u>J. Comp. Phys.</u> 165: 651-668). The dGIs are a command system for flying behavior and the vGIs for running escape behavior of the insect on the ground. In this report, we exemine the behavioral functions of the efference copy and of its influences on the GIs.

Intracellular rhythmic stimulation of a single dGI (burst of 25ms at 400/sec, burst repetition rate: 25/sec) during flight resulted in a prolongation of flight sequences and an increase of the wingbeat frequency. A single short train (20 to 50ms, 400/sec) in a dGI has complex effects including a change of the next wingbeat cycles duration. Cutting one abdominal connective, thereby removing 50% of the dGI rhythm, reduces both the flight frequency and duration. Cutting both connectives further reduces both these parameters. Theses results suggest that the rhythmic activation of the dGIs during flight participates at least in the control of the wingbeat frequency and the flight duration.

In contrast to the dGIs, stimulation (400/sec for 50ms) of one of the vGIs, GI1, evokes immediate cessation of flight. So far, stimulations of GIs 2 and 3 do not have this effect on flight.

In summary, the dois and volls have antagonists effects on flight, the former excitatory and the latter inhibitory. (Supported by NINDS grant RO1 NS20923)

GETTING IT TOGETHER: COORDINATING A MULTI-GANGLIONIC DECISION. J. M. Camhi, P. Levi*, A. Neville* and H. Sassoon*. Dept. Zoology, Hebrew U., Jerusalem, Israel Cockroaches turn away from wind puffs. Posterior wind receptors activate ventral giant interneurons (vGl's). These excite, in all 3 thoracic ganglia, thoracic interneurons (TI's) that activate local interneurons (LN's) and leg motoneurons (LMN's) of their own ganglion. Ti's also send axons to the other thoracic ganglia

How does the thoracic network read the v6! code for wind direction? (1) A midline saggital cut of any one thoracic ganglion severs, the decussating axons of all of this ganglion's Ti's known to receive vGI input, but does not sever the vGI's, LI's, or LMN's. After one week, the TI axons in the connectives have degenerated, yet turn directions are normal. (2) After cutting the left abdominal connective (and thus all left vGl's), left winds result in 100% left ("wrong") turns. (3) As a control, cutting the left neck connective did not bias turn direction. (4) Cutting the left connective between thoracic ganglia 2 and 3 (T2-3) severs the left vGl's and the left ascending axons of Tl's of ganglion T3. These vGl's all respond most strongly to left winds, whereas these Tis are of mixed directional response. This cut resulted in 100% left (wrong) turns to left wind. (The front and middle legs dominated in effecting the turn.) (5) Cutting the left TI-2 connective causes the TI (front) legs to turn the body toward the left in response to left winds. The above results suggest that the vGI's, and not TI's, instruct each ganglion which way to turn, and that each ganglion separately reads out the vGI code. (6) Following the left TI-2 cut, in response to left wind, the vGI's should instruct ganglia T2 and T3 (behind the cut) to effect a right turn with their mid- and hindlegs, but should instruct ganglion T1 (beyond the cut) to effect a left turn with the front legs. Surprisingly, the front, middle (and possibly hind) legs all turned left. This suggests that although each ganglion separately reads the v61 code, if the ganglia disagree, T1 decides for all. (7) Fluorescence photoablation of single vGI's and TI's so far confirms the above results Supported by grant 86/152 from the US-Israel Binational Research Foundation.

LEARNING AND MEMORY: PHYSIOLOGY IV

UNIT ACTIVITY IN CINGULATE CORTICAL LAYERS AND ANTERIOR THALAMIC SUBNUCLEI DURING IN RABBITS. M. Gabriel, A. Poremba, Y. Kubota, E. Kang and B.A. Vogt. Dept. of Psychol. and Beckman Institute, Univ. of Illinois, Urbana IL 61801; bept. Pharmachol, Boston Univ. Sch. of Med., Boston MA.

Past studies implicate cingulate cortex and limbic thalamus in mediation of disciminative avoidance learning, wherein stepping in an activity wheel to a tone CS+ prevents a footshock US 5 seconds after CS+ onset. This experiment documents learning-relevant neurophysiological plasticity (NF) related to recently demonstrated training-induced up-regulation of M2 cholinergic receptors in posterior cingulate area 29 and the AV thalamic nucleus (AVN, Vogt, B.A., et al., Neurosci. Abst., 1990). The NP took the form of greater multi-unit discharges in response to the CS+ than to a CS-, a tone that did not predict the US. The present results showed: a) NP acquisition in early stages of training in layers I-III, V and in parvocellular AVN, b) NP acquisition in late stages of training in layers IV, VI and magnocellular AVN. These distinct patterns of M2 receptor changes in these areas, suggesting a causal relationship. These data provide the first localized correlation of NP with receptor regulation in mammalian learning-relevant brain circuitry. (Supported by AFOSR grant 89-0046 and NIH grant NS26736 to MG).

LOW FREQUENCY OSCILLATORY ACTIVITY OF SINGLE NEURONS IN THE TEMPORAL POLE OF THE RHESUS MONKEY. K. Nakamura*, A. Mikami and K. Kubota. Dept. of Neurophysiol., Primate Res. Inst., Inuyama, Aichi, 484, Japan.

To examine roles of the temporal pole (TP) in visual recognition and short-term memory, we recorded the single neuron activity from the TP of the monkey (Macaca mulatta) during a sequential visual discrimination task with a time delay. On pressing a lever, a stimulus selected from 600 colored photographs (human face, monkey, primate chair, etc.) was presented on TV monitor several times for 0.5-1.0 s with 1.0-5.0 s delay interval. When a new stimulus was presented after a varied number of presentation, the monkey released the lever and was rewarded. Thirteen neurons showed a regular oscillatory activity of 5-8 Hz with average peak discharge rate of 98 sp/s. Twelve neurons showed a sustained activity during delay (average, 14 sp/s). Mean latency from the stimulus onset was 157 ms. Most of these neurons showed statistically significant responses only to particular stimuli. The oscillatory activity might be co-active with the hippocampus known for its theta activity and connectivity to sharpen responses to some aspects of a particular visual stimulus. Sustained activity during delay might be storing visual information during delay period.

314.2

TEMPORAL FIRING PATTERNS OF INFEROTEMPORAL NEURONS IN A VISUAL MEMORY TASK. <u>A.E.P. Villa and I.M. Fuster</u>, Dept. of Psychiatry and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024

Single units from the inferotemporal (IT) cortex of monkeys performing a color delayed-matching task (Fuster and Jervey, <u>I. Neurosci.</u> 2:361, 1982) were studied by means of time series analyses of the spike train (Abeles, <u>I. Neurosci.</u> 3:361, 1982). A task-trial consisted of the following: (I) sample color; (2) 10-20 seconds of delay (retention period); and (3) choice of the color (among 2 or 4) that matched the sample. Eighty-eight units that were activated during the delay were selected for the analysis; in 19 of them the firing activation was significantly higher after one particular sample color (preferred color of the unit). Discharge during delay periods was compared with discharge during intertrial periods. The spontaneous (intertrial) activity of 20 units was tonic and that of the 68 others exhibited bursts with intermingled and isolated spikes. The autocorrelogram of 32% of the units was significantly changed during the delay, independently of level of spontaneous firing. Most of these cells (20/28) showed during the delay a tendency to decreased bursting activity; furthermore, the average intraburst frequency stayed unchanged or decreased. Retention of the cue affected the firing pattern of a much larger proportion of color-selective units (63%) than of non-selective units (23%). In 5 color-selective units the autocorrelogram was only modified after the preferred color. These results show that some IT units that are selectively activated during the retention of the visual cue also exhibit a change in their temporal pattern of discharge (mostly in the form of decreased bursting). This indicates that the temporal structure of the spike train is an important feature of the changes that IT neurons undergo in visual short-term memory.

NEURONAL ACTIVITY IN HUMAN TEMPORAL LOBE WITH MULTIPLE MEMORY RETRIEVALS. MM Haghind. G Olemann. D Cawthon, and E Lettich. Dept. Neurological Surgery, Univ. Washington, Seattle, WA 98195 Extracellular microelectrode (me) recordings were obtained from left lateral neocortex that was subsequently resected in patients undergoing craniotomies for treatment of medically intractable epilepsy. During me recordings, the patient performed four trials of a visually presented short term weeklal memory task that entailed multiple/3 memory task the entailed multiple/3 memory task that the entailed multiple/3 memory task that th recordings, the patient periormed four trials of a visually presented short term verbal memory task that entailed multiple(3) memory retrievals of an initially overtly named memory input. The multiple memory retrievals were separated by overtly named distractors and blank slides which served as controls. Previous studies from our laboratory showed lateral temporal lobe neurons with sustained increases in activity during both memory input and the first retrieval compared to controls (Brain 111:1393,1988). The present study was to determine how this activity changed with later retrievals of the same item, i.e. as part of the process of learning.

determine how this activity changed with later retrievals of the same item, i.e. as part of the process of learning.

Technically satisfactory me recordings were obtained in 12 patients, 8 of which performed the 4 trials of the multiple memory retrieval tasks with no or one mistake. From these patients 19 neuronal populations(1-few units) were recorded. 16 of 19 neuronal populations showed significant changes in activity between controls and retrieval #1 and 3, while 10 demonstrated "sharpening". "Sharpening" or fine tuning of neuronal activity was defined as a reduction in the number of 500 msec bins showing increases in avg. firing frequency. These increased periods of neuronal activity flanked by decreases did not result in an overall change in the firing frequency during the 4 sec task. In addition to providing further evidence of a lateral temporal neocortical role in recent verbal memory, these findings suggest that neural activity becomes more compact with multiple retrievals of an item. Some neurons presumably in the periphery become inhibited while those more central in the pool become sharpened. (supptid. by AES fellowship-MH;NIH NS21724,17111 20482-GO)

A PHYSIOLOGICAL CORRELATE OF SITUATIONALLY DEPENDENT LTP IN PIRIFORM CORTEX. <u>U. Staubli, T. Le^a and G. Lynch.</u> CNLM, University of California, Irvine, CA 92717.

Previous work in freely moving rats has established that induction of LTP in the lateral olfactory tract synapses in piriform cortex is dependent on the past experience of the animal and the use of electrical stimulation as a discriminative cue in a two-odor discrimination task (Roman et al., <u>Brain Res.</u>, 1987, 418). In the present experiments we tested if the post-synaptic responses to bursts of stimulation pulses differed according to the behavioral situation. A single high-frequency burst (4 pulses at 100 Hz) is followed by a positive afterpotential lasting about 60msec in naive animals (n=4) and in rats (n=7) tested in an olfactory discrimination task in which they had been extensively trained. This afterpositivity was also present on subsequent bursts in a theta pattern (i.e., successive bursts delivered at 200msec intervals) in naive rats but was significantly reduced on subsequent bursts when the stimulation served as a discriminative cue to the experienced animals. The suppression of the afterpositivity was obtained when 150-200msec between burst intervals were used but not with 1-2 sec intervals. These findings suggest that the effect in piriform cortex may represent a situationally dependent variant of the IPSP blocking effect known to occur in hippocampus when LTP is induced with theta burst stimulation (Larson & Lynch, <u>Brain Res.</u>, 1988, 441). Work in progress will examine if these observations in piriform cortex and the phenomenon of IPSP suppression ('priming') in hippocampus have mechanisms in common. The results could provide new insights in how attention and past experience influence synaptic plasticity. (Supported by NSF grant BNS 8809316 to U.S. and ONR grant N00014-89-J-1255 to G.L.)

INTRACELLULAR RECORDINGS FROM THE FRONTAL CORTEX OF CONSCIOUS, LICKING RATS. M.P. Kristensen and C.D. Woody. UCLA Med.Ctr., Los Angeles, CA 90024.

Intracellular records were obtained from 67 neurons of the frontal cortex of conscious rats, so that their properties might be compared with those observed by other investigators in vitro. Spontaneous activity and responses to a 1 nA depolarizing current pulse were analyzed in 54 units, of which five showed bursting (spiking activity > 100 hz) in response to depolarization. The majority fired at a slower rate spontane-ously as well as during depolarization. Input resis-tances were determined for 21 cells and found to be 11 $M\Omega$, with a resting membrane potential of -56 mV.

Cells exhibiting afterhyperpolarizations, delayed spike repolarizations, low threshold spikes, multiple spikes, adaptation, bursting with inactivation, and spontaneous, oscillatory membrane-depolarizations

supporting spiking were seen.

The setup enabled intracellular recording of electrical activity for as long as 5 minutes while the animal was licking. Intracellular records were obtained from 6 cells, of which 2 showed increased spike discharge correlated with the behavior, as did 1 extracellularly studied unit. (Supported by HD05958)

DIFFERENTIAL EFFECTS OF ASSOCIATIVE LEARNING ON RECEPTIVE FIELDS IN THE SUBDIVISIONS OF THE GUINEA PIG MEDIAL GENICULATE BOOY. <u>Jean-Marc Edeline¹ and Norman M. Weinbergen^{1,2} Cntr. Neurobiol. Learn. Mem. ¹& Dept. Psychobio. Univ. California^{1,2} Irvine, Ca. 92717.</u>

CS-specific frequency receptive field (RF) plasticity was previously found several areas of the auditory cortex (Diamond & Weinberger, Br.Res., 372:357, 1986; Bakin et al. Soc. for Neurosci. 14:862, 1988), and in the dorsal division (MGd) of the medial geniculate body (MGB) (Edeline & Weinberger, Soc. for Neurosci., 15:81, 1989). We investigated the degree of generality of this phenomenon at the thalamic level by determining the RF of clusters or single neurons in the ventral (MGv) and the medial (MGm) divisions of the MGB in the adult guinea pig before, after, and 1 hour after classical conditioning (CS=a non-best frequency tone, 6 sec.; US=250 msec footshock at CS offset; CR=conditioned bradycardia, which developed in all subjects). RF were determined by presenting ranges of pure tone frequencies (50 ms,1/sec) at different intensities (20-80dB) via a calibrated system to the contralateral ear. General changes in the RF (increases or decreases), with no shift of best frequency, were commonly found in the MGv (11/15, 73%) both immediately and 1 hour post conditioning. General changes were also observed in 6/13 cases (46%) of recordings in the MGm. These effects contrast with the lower proportion (31%) of general effects and the high proportion of CS-specific effects found in the MGd (21/38, 55%), including maximal increased response to the CS frequency and shift of tuning to this frequency. The present findings suggest different functional roles for the MGB subdivisions, and possibly, a different ement in information processing during learning. CODING OF SPACE IN THE DORSOLATERAL PREFRONTAL CORTEX OF MONKEY PERFORMING A DELAYED ALTERNATION TASK. S.Carlson, H.Tanila, A.Pertovaara, I.Linnankoski and A.Lähteenmäki Dept.Physiology,Univ. Helsinki, Helsinki, Finland.

The aim was to study neuronal activity in and around sulcus principalis during the upward performance of a delayed alternation task (DA) and compare it with the firing pattern of the right left directed performances. Electrophysioloand left directed performances. Electrophysiolo-gical response properties of single neurons were recorded conventionally in a monkey performing a DA task in three directions; to the right, left and upwards. Of the 154 neurons recorded in all three directions 72 % were task related neu-rons. 68 % of the task related neurons were spa-tially selective. Of the task related neurons 14 % were selective upwards, 14 % either to the right or to the left, 59 % in two directions and 13 % in all three directions. Functional properties of part of the neurons are reported, too. The results support the earlier suggestion (by Funahashi et al., J.Neurophysiol.1989.61.331) that there is a spatial memory map in the prefrontal cortex and indicate that spatial selectivity is a common feature in the task related neurons.

BASAL FOREBRAIN NEURON RESPONSES DURING RIGHT EYE VS. LEFT EYE LIGHT DISCRIMINATION. J.H. Pirch. Department of Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX 79430. Extracellular recordings were obtained from single units in the basal forebrain of rats during associative conditioning using light stimuli. Medial forebrain bundle (MFB) stimulation was paired with a 2-second light stimulus (CS+) to one eye, or a similar light stimulus (CS+) to one eye, or a similar light stimulus (CS+) was presented to the other eye without MFB stimulation. Event-related slow potentials were recorded from the frontal MFB stimulation. Event-related slow potentials were recorded from the frontal cortex to monitor the development and maintenance of discrimination between CS+ and CS-. Recordings were obtained while the animals were anesthetized with urethane (1.5 g/kg with supplementation). Previous studies demonstrated that differential slow potential and cortical single unit responses to reinforced and non-reinforced tone stimuli can be recorded in urethane-anesthetized rats (Rucker, Corbus and Pirch, Brain Res. 376: 368, 1986). Some animals had permanently implanted stimulating electrodes and were trained to associate light with MFB stimulation prior to the recording session; others had no prior

training.

Recordings were obtained from 21 basal forebrain units which demonstrated discrimination between CS+ and CS-. Six of the units were located in the globus pallidus and 15 were in the substantia innominata area. Of the 10 units that responded to right-eye CS+, 7 were excited and 3 were inhibited. Left-eye CS+ excited 9 units and inhibited 2 units. A few additional units responded with excitation or inhibition, but failed to discriminate between CS+ and CS-. Single units in the frontal cortex demonstrated differential responses in this light discrimination paradigm, as well as during tone discrimination. These results provide further evidence that basal forebrain neurons respond selectively to conditioned stimuli, and that these neurons may play a role in modulation of cortical cell activity during associative conditioning. Supported by NINDS NS22408.

SENSITIZATION PRODUCES NON-SPECIFIC INCREASED RESPONSES OF RECEPTIVE FIELDS IN GUINEA PIG AUDITORY CORTEX. Jonathan S. Bakin and Norman M. Weinberger, Centr. Neurobiol. Learning and Memory and Dept. Psychobiol., Univ. of California, Irvine, Ca. 92717

Previously we reported that classical conditioning produces frequency-

specific receptive field (RF) plasticity in the auditory cortex of the guinea pig (Bakin, Condon and Weinberger, <u>Soc. Weurosci.</u>, 14:862,1988). Following tone-shock pairing until development of behavioral conditioned responses (CR), 70% of single neurons or neuronal clusters showed maximal increased responses to the CS frequency, while responses to the pretraining best-frequency (BF) and other frequencies exhibited decreased responses. These effects were observed immediately and at the longest postconditioning interval tested, 24 hours. The present experiment determined the effects of sensitization training on receptive fields. Training consisted of unpaired presentation of 30 trials in which a non-best frequency tone (10 sec) and footshock (2 sec) were presented with the same density as during conditioning. RF were obtained prior to training and immediately, 1 hour and 24 hours following training. Sensitization training produced no behavioral CRs and a general increased response across the RF, with no specificity to the CS frequency. Such non-specific RF plasticity was present immediately and for as long as 24 hours post-training. These results indicate that sensitization can produce a long-lasting general facilitation of acoustic processing in distinction to classical conditioning which produces a highly CS-specific modification of frequency receptive fields. Supported by Chancellor's Fellowship (JSB) and ONR #00014-87-K-0433 and the Monsanto Co. (NMW)

CLASSICAL CONDITIONING SELECTIVELY ALTERS THRESHOLDS IN THE AUDITORY CORTEX OF THE GUINEA PIG. <u>David A. South, Scott J. Cruickshank, Duc o. Pham and Norman M. Weinberger</u>, Centr. Neurobiol. Learning and Memory and Dept. Psychobiol., Univ. California, Irvine, Ca. 92717

Classical conditioning produces frequency-specific plasticity in the auditory cortex. Specifically, responses to the frequency of the conditioned stimulus (CS) are increased while responses to other frequencies. including that of the pre-training best frequency (BF), are reduced (Bakin, Condon and Weinberger, Soc. Neurosci., 14:862, 1988). The purpose of this experiment was to determine whether classical conditioning alters thresholds. Conditioning consisted of presentation of a tone (6 sec.) and footshock (0.3 sec.) unpaired (sensitization control) or paired (conditioning) during the development of the cardiac deceleration conditioned response. Thresholds were determined before and after training (immediate, 1 hour and 24 hours) at the frequency of the conditioned stimulus and the frequency of the pre-training characteristic frequency (frequency with lowest threshold, CF), Following training, thresholds were changed, with the dominant effect consisting of a relative change between the frequency of the CS and the CF such that thresholds to the former were lowered relative to the latter. These findings indicate that classical conditioning produces a relative decrease in threshold for a stimulus that has acquired behavioral significance and produces a relative increase for a potent stimulus that is not involved in training. Thus, learning alters thresholds as well as response magnitudes of neurons within the auditory cortex. Supported by ONR #00014-87-K-0433 and the Monsanto Co. (NMW)

EVIDENCE FOR DIFFERENCES IN AUDITORY TRANSIENT AND SUSTAINED STIMULUS PROCESSING USING THE STARTLE PARADIGM. E.J. Schicatano and T.D. Blumenthal. Dept. of Psychology, Wake Forest University Winston, Salem NC. 27109

Wake Forest University, Winston-Salem, NC. 27109.

Two distinct neurophysiological systems underlie acoustic reflex behavior, a transient system which possesses neurons sensitive to brief acoustic stimuli, and a sustained system in which neurons are sensitive to stimuli with prolonged durations. The startle reflex provides a noninvasive means for separately assessing auditory transient and sustained system activity. The present study examined startle reflex habituation in the transient and sustained systems. Thirty-six undergraduate students were exposed to 30 presentations of 85 dB broadband noise stimuli (.1 ms rise time) with the ISI randomly varied from 25-35 s. Two types of stimuli were presented: single acoustic pulses with durations of 6, 20, and 50 ms, or a pair of 3 ms acoustic pulses with pulse onsets separated by 6, 20, or 50 ms. While females exhibited habituation only to stimuli activating the sustained system (single pulse), males habituated to stimuli activating both the transient (pulse pairs) and sustained systems. Furthermore, sustained system activity habituated more and faster in females than in males. Habituation was more pronounced for single than for paired stimuli, possibly due to larger initial responses to single stimuli, for both sexes. These results suggest that neuronal plasticity (startle habituation) in auditory sensory processing differs in males and females based on the type of stimulus presented. Also, sustained systems may be more appropriate than transient systems in habituation research.

CEREBELLAR MOTOR LEARNING: QUANTITATION OF MOVEMENT ADAPTATION AND PERFORMANCE IN RHESUS MONKEYS AND HUMANS IMPLICATES CORTEX AS THE SITE OF ADAPTATION. J.G. Keating, and W.T. Thach. Dept. of Anatomy and IWJ Rehab. Institute, Washington Univ. Sch. Med., St. Louis, MO 63110.

Rhesus monkeys and humans placed their hand in a manipulandum which controlled the position of a cursor on a screen in front of them. The subject held in a target zone and stepped to a new target zone by flexing or extending the wrist in one quick movement. After a series of control trials, the gain was altered such that the hand/cursor relationship appeared unchanged during the initial hold, but the previously performed movement was no longer of the right magnitude to place the cursor in the target zone. Over several trials the movement magnitude changed to produce the proper ranging. The endpoints of the initial ballistic movement from a series of trials were fit by regression to an equation of the form: $f(x) = A + B *e(^{-X}/C)$. Residuals were trial-invariant and had normal distrubutions. C, analogous to a time constant, was used as a measure of the rate of adaptation. Performance was measured as the standard deviation of regression of the curve fit, and was independant of adaptation.

Purkinje cells recorded from a Rhesus monkey during adaptation showed a increase in peri-movement complex spike activity during the period of adaptation and a clear decrease in periods spike spike spike activity which was maintained after adaptation.

and a slow decrease in simple spike activity which was maintained after adaptation.

A right handed patient of 61 yrs. who suffered a right cerebellar cortex infarct, adapted behavior with his right hand one third as fast as with his left. Both hands of a control subject showed the same rate of adaptation as the patient's left hand.

Changes in Purkinje cell discharge similar to that seen by Gilbert and Thach (1977) and Watanabe (1984) and a specific loss in adaptation on damage to cerebellar cortex support the Marr-Albus theory of motor learning. (NIH grants NS12777 and NS15070).

TREQUENCY-SPECIFIC RECEPTIVE FIELD PLASTICITY IN AUDITORY CORTEX DURING HABITUATION. <u>C.D. Condon</u> and <u>N.M. Weinberger</u>², ¹Neuroscience Program, Univ. Illinois, Champaign-Urbana, IL. ²Dept. Psychobiology and Center Neurobiology Learning & Memory, Univ. Calif., Irvine, CA.

Associative processes during classical conditioning induce CS-specific receptive field (RF) plasticity in the auditory cortex (Diamond & Weinberger, Br. Res., 372:357, 1986: Bakin, Condon and Weinberger, Soc. Neurosci. Abst., 14:862, 1988). This experiment asked whether frequency-specific RF plasticity also characterizes a non-associative form of learning, habituation. Neuronal discharges were recorded in the auditory cortex of waking guinea pigs. First, at least two frequency RF were determined (15min. interval) followed by repetition of a single non-best frequency (REP: 1.25/sec.), followed by one or more additional RF. Discharges analyzed were typically onset responses (10-30 ms latency). RF were stable prior to REP. Thereafter they exhibited a specific decrease at the REP frequency (72% of sessions), which averaged 74% below control values. This decrease was highly selective as responses to frequencies +/-1/8 octave showed only a 10-15% reduction. During REP, responses declined, reaching asymptote after 108 stimuli, and either remained depressed (n=14) or recovered to near control levels despite continued presentation of tones (n=8). Both types of REP effect were associated with the same magnitude and degree of selectivity of RF decreased responses. Therefore, a depressed response at the end of the REP is not necessary for the RF effect. Further, the RF decrease at the REP frequency could develop over time (n=8), not reaching maximal depression for several minutes. These characteristics rule out sensory adaptation or fatigue and indicate that habituation induces stimulus-specific RF plasticity. Accordingly, frequency-specific RF plasticity in the auditory cortex characterizes habituation as well as classical conditioning. COMPARISON OF CROSS-MODAL TRANSFER EFFECTS ON BEHAVIORAL RECOVERY AFTER EITHER AUDITORY OR VISUAL CORTEX LESIONS IN RATS. E. R. Delay and T. M. Rudolph*. Department of Psychology, Regis College, Denver, CO 80221.

Cross-modality training (CMT) with noise intensity

Cross-modality training (CMT) with noise intensity cues enhances recovery of a brightness discrimination more than within-modality training (WMT) after visual decortication in rats (Delay, E.R., Neuropsychologia, 26:667, 1988). To extend these findings, this study examined the effects of CMT and WMT on behavioral recovery after either auditory or visual cortex lesions. One group of rats was trained with a high intensity light cue 24 hours before visual cortex ablations were made under Nembutal anesthesia. Another group was trained with a high intensity noise cue 24 hours before auditory cortex lesions. Six days later, 6 rats from each lesion group were given brief training in one of five conditions: 1) WMT with the preop cue, 2) reversal WMT with a low intensity cue, 3) CMT with a high intensity cue, 4) reversal CMT with a low intensity cue, or 5) no training. The next day all rats were retrained on the preop task. Both lesions produced relearning deficits. CMT reduced behavioral deficits more than WMT after both lesions. Transfer of CMT appears to occur through common multisensory structures and to have general facilitative effects on behavioral recovery after brain injury.

SINGLE UNIT RESPONSES FROM THE CEREBELLAR CORTEX OF NAIVE RABBITS. D.J. Krupa, J. Tracy, C. Weiss and R.F. Thompson, Neurosciences Program, Univ. Southern Cal., Los Angeles, Ca. 90089-2520.

The cerebellum has been identified as the most likely site to contain the associative elements which mediate eyeblink conditioning in the intact rabbit. To further investigate the underlying mechanisms we have been recording the activity of single units in response to unpaired stimuli typically used in conditioning paradigms i.e., tones, white noise & airpuffs. Thus far we have recorded 61 single units from seven New Zealand white rabbits. Of these, 29 were identified as Purkinje cells (based on the presence of complex spikes). Most were from the HVI lobule. We found that the responsive cells (n=15) were often grouped together and responded preferentially to the airpuff (14/15) with both complex and simple spike activity. Airpuff responsive cells showed various patterns of simple spike excitation and inhibition, but almost always responded by firing a complex spike as well. Interestingly, most of the responsive non-Purkinje cells were excited about equally by airpuff (n=8) and auditory stimuli (n=5). These cells tended to be preferentially located nearby the responsive Purkinje cells. Nonresponsive cells (Purkinje and non-Purkinje cells) also tended to be located nearby each other. These data will form a foundation for comparisons with data that are to be collected from rabbits acquiring a classically conditioned eyeblink. Supported by: ONR N00014-88-K-0112, BNS 8718300 and McKnight Foundation.

CEREBELLAR INTERPOSITUS NUCLEUS LESIONS AND LIMBIC SYSTEM ACTIVITY DURING CLASSICAL EYELID CONDITIONING IN RABBITS. J.L. Stotler. D.P. Miller, and J.E. Steinmetz. Program in Neural Science & Department of Psychology, Indiana University, Bloomington, IN 47405

Recent evidence showed that the interpositus nucleus was necessary for acquisition and maintenance of classically conditioned responses and training-related activity in the and maintenance of classically conditioned responses and training-related activity in hippocampus (Clark et al., Brain Research, 326, 1984; Sears & Steinmetz, Behav, Neurosci., in press). It has been suggested that the hippocampus is important when conditioning with relatively long interstimulus intervals (ISIs) or when trace procedures are used (Port et al, Behav, Neurosci., 92, 1985; Port et al, Behav, Neurosci., 100, 1986). The present experiments were conducted to determine the effects of interpositus lesions on hippocampal activity during conditioning with long ISIs and trace intervals and also on activity in the septal region, a region closely associated with the hippocampus.

associated with use inflocations.

In the first experiment, the nictitating membrane (NM)/eyelid responses of rabbits with unilateral interpositus lesions were either trained with a relatively long ISI (700 ms) or trace conditioned (250 ms CS, 450 ms trace period) using a tone CS and an air puff US. Multiple-unit activity was recorded bilaterally from the hippocampus throughout training. The interpositus nucleus lesions disrupted conditioning on the ipsilateral eye and bilaterally disrupted hippocampal plasticity during training at long ISI's. Similar results were found for trace conditioning. In the second experiment, multiple unit activity was recorded from the medial and lateral septal nuclei during NM multiple timit activity was recorded from the mediat and lateral septian nuclei utimity conditioning that followed a unilateral lesion of the interpositus nucleus (tone CS, air puff US, 250 ms 181). Interpositus lesions abolished conditioned responses during training on the ipsilateral eye but did not abolish stimulus-related activity in the nedial septum. Training-related activity in the lateral septum was blocked by the cerebellar lesion. These data suggest that the hippocampus continues to receive stimulus-related information from the medial septum following interpositus nucleus lesions but that the interpositus nucleus is necessary for the formation of training-related activity in the hippocampus and one of its efferents, the lateral septum. UNCONDITIONED STIMULUS-EVOKED ACTIVITY IN THE DORSAL ACCESSORY INFERIOR OLIVE DIMINISHES WITH ACQUISITION OF THE CLASSICALLY CONDITIONED EYELID RESPONSE. L. L. Sears and J.E. Steinmetz. Program in Neural Science and Department of Psychology, Indiana University, Bloomington, IN 47405.

The cerebellum exhibits learning-related plasticity and is essential for execution of the rabbit classically conditioned eyelid/nictitationg membrane (NM) response. Evidence suggests that information about the unconditioned stimulus (US) is projected to the cerebellum along climbing fibers that arise from the dorsal accessory inferior olive (DAO) (e.g., Steinmetz et al., Synapse, 3:225, 1989).

In the present study, multiple-unit DAO recordings from eight rabbits revealed significant US-evoked neural activity during initial paired presentations of a tone CS and air puff US. Across five training sessions, however, as percent conditioned responses (CR) increased, there was a significant decrease in DAO activity on paired CS-US trials. In contrast, no across-session decrease in DAO activity was observed on US-alone trials given at the end of each paired training session. These results are similar to findings of diminished inferior olive activity in response to "expected" cutaneous stimuli (Gellman et al., J. Neurophysiol., 54:40, 1985) and demonstrate that the "reinforcement" nature of DAO input to the cerebellum may

RABBIT CEREBELLAR ACTIVITY EVOKED BY PONTINE NUCLEI OR INFERIOR OLIVE STIMULATION -- POTENTIAL REGIONS OF CS-US CONVERGENCE DURING EVELID CONDITIONING. T.J. Gould, L.L. Sears, and J.E. Steinmetz. Program in Neural Science and Department of Psychology, Indiana University, Bloomington, IN 47405.

Neural responses recorded in the cerebellar and deep nuclei are related to the learning of a conditioned response (McCormick & Thompson, J. Neurosci, 4:2811, 1984). These recording data suggest that the cerebellar cortex and deep nuclei may be areas

that code plasticity associated with performance of the learned response. Also, some studies indicate that CS information may be relayed from the pontine nuclei to the cerebellum via mossy fibers and US information may be relayed from the inferior olive to the cerebellum via climbing fibers (Steinmetz et al., Synapse, 3:225, 1989)

In an initial attempt to locate and characterize cerebellar neuronal responses associated with activating the pontine nuclei and inferior olive, both single units population potentials evoked by electrical stimulation were recorded. In acute, untrained, anesthetized rabbits, stimulating electrodes were placed in the pontine nuclei or inferior olive. Recording electrodes were then systematically lowered through the cerebellar cortex, dentate nucleus, and interpositus nucleus and activity evoked by single pulse stimulation was recorded. Both pontine-evoked single unit activity and pontine-evoked population potentials recorded in cerebellar cortex (e.g., Larsell's HVI) demonstrated activation of granule cells and Purkinje cells. Pontine-evoked single unit activity and population potentials recorded in the interpositus and dentate nuclei showed an initial phase of excitation (1 msec latency, presumably reflecting direct mossy fiber activation) followed by a later phase of inhibition (presumably from cortical inputs). Similar patters of cerebellar activation (in the same regions of cortex and deep nuclei that were mapped for pontine inputs) were same regions of correx and deep nuclei that were mapped for pontine inputs) were observed when olivary stimulation was used. These data support anatomical evidence that inputs from the pontine nuclei and the inferior olive converge in the cerebellar cortex and deep nuclei (Steinmetz & Sengelaub, Neurosci Abstr., 14, 782, 1988) and suggest possible cerebellar regions that may receive both CS and US information. This research was supported by NIMH Grant MH44052 to JES.

CONDITIONED RESPONSE LEARNING IN THE IN VITRO

CONDITIONED RESPONSE LEARNING IN THE IN VITRO TURTLE BRAINSTEM-CEREBELLUM. J. Keifer and J.C. Houk. Dept. of Physiology, Northwestern Univ. Medical Center, Chicago, IL 60611.

The eye-blink reflex has been widely adopted for physiological studies of the mechanisms of conditioned response learning. In behaving animals, a typical approach is to pair an auditory conditioned stimulus (CS) with a corneal air puff unconditioned stimulus (US), which results in a conditioned reflex response (CR) after a few training sessions. Recently, we developed an in vitro preparation from the training and processors are recommended to the corpolations of the corpolations of the corpolations of the corpolations of the corpolations. after a rew training sessions. Recently, we developed an *in vitro* preparation from the turtle to study mechanisms of motor program generation in the cerebellorubral circuit (Neurosci. Letters 97: 123, 1989). Studies indicate an essential role of the cerebellorubral circuit in the conditioned eye blink response. To examine how motor programs produced by this circuit are modified by learning, we have obtained the neural correlate of the conditioned eye blink response generated entirely in the *in vitro*

Neural activity characteristic of the blink reflex is evoked by electrical stimulation applied to nV (US), which contains afferents from the eye, while recording from nVI, which contains efferent fibers that normally project to retractor muscles of the eyelid. The reflex consists of a nVI burst discharge having a latency of 10-15 ms and a duration of several tens of ms to many seconds. The CS is applied electrically to the posterior root of nVIII, which contains predominantly auditory afferents. Paired CS-US presentations of a 100 Hz, 1 s train stimulus to nVIII (CS) immediately preceded a single shock to nV (US) and both stimuli terminated simultaneously. Intertrial intervals were 30 s. Fifty paired stimuli were interspersed by a 30 min rest period. The results show that after about the third training session, nVI activity is recorded during the end of the CS and preceding the US. With further training, the response to the CS shifts into earlier stages of the CS presentation until a nVI burst discharge occurs at ~150 ms following the CS onset. This conditioned response can be recorded without further pairing for at least 5 hours but not longer than 12 hours. These data show that it is possible to produce conditioned response learning in vertebrate reflex pathways in vitro. This will allow studies of the mechanisms for generating conditioned responses at both cellular and circuit levels.

HORMONAL CONTROL OF BEHAVIOR III

COMPARISON OF [1251]ESTROGEN UPTAKE IN MALE AND FEMALE MOUSE BRAIN. M. J. Walters. R. B. Hochberg* and N. J. MacLusky. Div. of Reproductive Science, Toronto General Hospital, Toronto, Ontario M5G 1L7, and Dept. Obstetrics and Gynecology, Yale University Sch. of Med., New Haven, CT 06510.

Sex differences in gonadotropin secretion and sexual behavior are presumed to result from functional differences within the central nervous system. In the present study, quantitative autoradiography was used to assess sex differences in estrogen uptake in the adult mouse brain. Gonadectomized male and female mice were injected i.v. with a saturating dose (2 μg/kg b.w.) of 1251-labelled 11β-methoxy- 16α -iodoestradiol (MIE₂), a synthetic analog of estradiol. Control animals were injected with 5 μg DES 5 min prior to [125I]MIE₂ injection. Thin frozen sections (10 µm) were then cut through the hypothalamus and preoptic area and exposed to high-resolution Hyperfilm for 8 days. No sex difference in silver grain density was observed in the arcuate-median eminance region, the bed nucleus of the stria terminalis, or amygdala. However, [125] jestrogen uptake in the medial preoptic area and ventromedial hypothalamic nucleus was significantly greater in females than in males. These findings suggest that sexually dimorphic patterns of sexual behavior and gonadotropin secretion in this species may be due to sex differences in estrogenbinding capacity in specific regions of the hypothalamus-preoptic

BEHAVIORALLY-EFFECTIVE ESTRADIOL PULSES INDUCE PROGESTIN RECEPTORS SELECTIVELY IN SUBSTANCE F CONTAINING CELLS IN THE VENTROLATERAL HYPOTHALAMUS OF FEMALE GUINEA PIGS. D.H. Olster and J.D. Blaustein. Psychology Department and Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Substance P (SP), which may mediate steroid-induced lordosis in rodents, is found in the ventrolateral hypothalamus (VLH), a site at which estradiol (E₂) primes ovariectomized (OVX) guinea pigs to display progesterone-facilitated lordosis. In OVX guinea pigs implanted with E₂ capsules, many progestin receptor-immunoreactive (PR-IR) VLH cells also contain SP-IR (Nielsen and Blaustein, 1990, in press). Low doses of E2, administered as pulses, prime OVX females to respond behaviorally to progesterone as effectively as much higher doses of E₂. In the current experiment we compared the degree of cellular colocalization of SP-IR and PR-IR following E₂ capsules (20 mm for 40 h) and pulses (2 injections of 2 µg, 28 h apart) in the VLH of OVX guinea pigs (after intracerebroventricular colchicine injection). The total number of PR-IR cells in the VLH and SP-IR cells in the VLH/ventromedial nucleus did not differ between treatment groups. However, in the VLH of E_2 pulse-treated animals, 50% more PR-IR cells contained SP-IR than in the E_2 capsule-treated animals (52% \pm 1 vs. 36% ± 4, respectively). Thus, behaviorally-effective E2 pulses induce PR-IR selectively in SP-IR cells in the VI-H. These data are consistent with the hypothesis that SP cells in this region play a role in steroid induction of lordosis in guinea pigs. (Supported by NIH grants HD 23483, NS 00970 and NS 19327.)

PROGESTERONE IMMOBILIZED ON BSA IMPLANTED IN THE VTA BUT NOT THE HYPOTHALAMUS FACILITATES SEXUAL RECEPTIVITY IN HAMSTERS. C.A. Frye, P.G. Mermelstein* and J.F. DeBold. Dept. Psychology, Tufts University, Medford, MA 02155.

Progestogenic stimulation of both the ventromedial nucleus of the hypothalamus (VMH) and the ventral tegmental area (VTA) is critical for normal receptivity in estrogen-primed hamsters. However, anatomical and biochemical studies have identified very few estrogen-induced progestin receptors in rodent ventral midbrain. To determine whether progesterone might be working on the membrane of neurons in the VTA, progesterone 3-CMO BSA (P-3-BSA) was applied intracranially. The size of P-3-BSA makes it relatively impermeable to the cell membrane.

might be working on the membrane of neurons in the VTA, progesterone 3-CMO BSA (P-3-BSA) was applied intracranially. The size of P-3-BSA makes it relatively impermeable to the cell membrane.

Ovariectomized hamsters were implanted with 2 chronic cannulae, one aimed at the VMH and the other at the contralateral VTA. These animals were then estrogen-primed and tested for sexual receptivity after progesterone containing tubes were inserted just dorsal to the VMH and P-3-BSA inserts were applied above the VTA. The following week the hamsters were again tested with the contents of the inserts reversed. Animals with progestogenic stimulation to the VMH and P-3-BSA to the VTA were significantly more receptive than those with P-3-BSA to the hypothalamus and progesterone to the VTA. Facilitation of receptivity also occurred when progesterone was applied to other sites within the hypothalamus concurrent with P-3-BSA stimulation to the VTA. When P-3-BSA was applied to the VTA alone or in conjunction with extra-hypothalamic progesterone simulation the animals were less receptive. These data suggest that progesterone is capable of facilitating sexual receptivity within the VTA by actions on the cell membrane. The non-genomic effects in the VTA may require concurrent genomic activation by progesterone within the hypothalamus.

MALE ACTIVATION OF SEXUAL RECEPTIVITY IN OVARIECTOMIZED ESTROGEN-PRIMED RATS: ROLE OF THE VENTROMEDIAL NUCLEUS OF HYPOTHALAMUS. <u>G.Rajendren*</u>, C.A.Dudley and R.L.Moss, Dept. of Physiology, Univ. of Texas Southwestern Med. Ctr., Dallas, TX 75235-9040.

The role of the ventromedial nucleus of hypothalamus (VMH) on the mating-induced enhancement of sexual receptivity in ovariectomized estrogen-primed rats was investigated. In the first experiment, the females were subjected to bilateral VMH lesion or sham-operation. Forty eight hours after priming with 2 u g of estradiol benzoate, they were tested repeatedly for sexual receptivity. The sham-operated females exhibited a gradual increase in lordosis quotient (LQ) during the 5 hr testing period. However, the VMH-lesioned rats did not show any sign of lordosis.

In the second experiment, ovariectomized rats were bilaterally implanted with estradiol (E) at various sites in the hypothalamus. Females with bilateral E implant in the VMH exhibited a gradual increase of LQ over time. Those with bilateral E implant in other hypothalamic areas lying close to the VMH did not exhibit lordosis. To further exclude the possibility of the spread of E to areas lying outside the VMH, plasma luteinizing hormone (LH) was measured in the females. Castration-induced elevation of LH was not suppressed in females bearing bilateral E implant in the VMH. Since the median eminence, which lies close to the VMH, is one of the important neural sites where estrogen exerts its negative feedback on gonadotrophin release, the results further support the conclusion that in the present studies the effects of E on sexual receptivity are due to its local action within the VMH.

Together, the experiments described above suggest that an intact VMH is necessary for the male-induced enhancement of LQ in ovariectomized rats and that selective priming of the VMH with E is sufficient for the activation of sexual receptivity following mating. Supported by NIH grants HD 09988 and MH 41784.

CHRONIC FREE TESTOSTERONE (T) IN FEMALE RATS DURING 15-30 DAYS OF AGE: MASCULINIZATION OF OVARIAN AND BEHAVIORAL FUNCTION IN ADULT-HOOD. S.D. Gale, S. Kurth, and G.J. Bloch, Dep't of Psychology, Brigham Young U, Provo, UT, 84602. Lordosis behavior is markedly stimulated in adult-

Lordosis behavior is markedly stimulated in adultgonadectomized (Gxd), estrogen(E)-primed male rats given medial preoptic CCK (Bloch et al, Physiol Behav 46, '89), and adult-Gxd males can be made highly sensitive to the lordosis-stimulating effects of progesterone (P) after pulse administration of E (Sodersten et al, Endoc 112 '83 Olster et al, Horm.Behav 6, '88). To further study sex reversal during periods beyond the perinatal period, Silastic capsules containing 7 mm T or nothing (blank) were implanted s.c. in 15-day-old females that were either Gxd or not Gxd (intact) at this time, and the capsules were removed 15 days later (30 days old). Blank-implanted rats showed vaginal cycles, normal ovaries, and a high level of proceptive behavior after sequential E and P treatment at 100 days of age. In contrast, T-implanted rats showed persistent vaginal estrus starting at vaginal opening, polyfollicular and smaller ovaries, and virtually no proceptive behavior. Thus, chronic androgen during the prepubertal period can markedly masculinize reproductive function. Supported by BYU research funds.

LOCALIZATION OF CELLS CONTAINING ESTROGEN RECEPTOR-LIKE IMMUNOREACTIVITY IN THE BRAZILIAN OPOSSUM FOREBRAIN. C. A Fox, L. R. Ross', and C. D. Jacobson. Department of Veterinary Anatomy, lowa State University, Ames, IA 50011

The Brazilian opossum (Monodelphis domestica) is a small, pouchless

The Brazilian opossum (Monodelphis domestica) is a small, pouchless marsupial whose young are born in an immature, sexually undifferentiated state. Etgen and Fadem (Gen. Comp. Endo. 66: 441), and Handa et al. (Soc. Neurosci. Abst. 15: 1099) have biochemically detected and characterized estrogen receptors in the forebrain of the Brazilian opossum. In this study, we have examined the distribution of estrogen receptor-like immunoreactive (ER-LI) cells in the forebrain of six gonadectomized (three male and three female) Brazilian opossums using Abbott H222 rat monoclonal estrogen receptor antibody (H222 is a gift of Abbott labs). An indirect immunohistochemical procedure employing the Vectastain Elite system and a nickel-enhanced DAB chromogen was used. A large number of ER-LI cell nuclei were seen in the medial preoptic area, ventral septal nucleus and intermediate septal nucleus, lateral part of the ventromedial hypothalamus, arcuate nucleus, and the periventricular hypothalamic nucleus. Lower numbers of ER-LI cell nuclei were observed in bed nucleus of the stria termimalis and the anterior and medial amygdaloid nuclei. The anatomical distribution of ER-LI in the Brazilian opossum brain is similar to that which has been reported for estrogen binding sites following biochemical analysis. The results presented here provide evidence for the cellular localization of estrogen receptors in the Brazilian opossum brain. In addition, these results support the use of this animal model in studies on the organizational effects of estrogen on the developing central nervous system. Supported by Iowa State University, NSF grant BNS 8909751 and USDA Formula Funds Section 1433.

SEX DIFFERENCE IN ESTRADIOL(E2)-CONCENTRATING CELLS WITHIN SPECIFIC COMPONENTS OF THE RAT MEDIAL PREOPTIC AREA (MPOA). S. Kurth¹, T.R. Akesson², P.E Micevych³, and G. J. Bloch¹ ¹ Brigham Young U., Provo, UT; ²VCAPP, Wash State U Pullman; ³Anatomy, UCLA Sch Medicine.

Several studies show that MPOA cells accumulate and bind more estrogen (E) in the adult female than in the male, but other studies do not document these differences. A reason for the discrepancy may be differences in methods used to assess E binding (see Breedlove, Trends in Neurosci 6, '83; Brown et al, Endoc 123, '88). Using autoradiography as outlined separately by Pfaff and Stumpf (Science 161, 162, '68) and cytoarchitecture as described by Simerly et al and Bloch et al (J. Comp. Neurol 225, 272, '84, '88), the density (# cells/mm2X10-2) of E-concentrating cells was determined within the medial preoptic nucleus (MPN) and its medial lateral, and central components (MPNm, MPNI, & MPNc), as well as the anteroventral and periventricular preoptic nuclei (AVPV and PVPO). All of these areas had a significantly greater density of E2-concentrating cells in the female than in the male (range: 3.28 to 5.73X greater). These data suggest a large sex difference in E cells within discrete components of the MPOA.

315.8

GALANIN (GAL) MICROINJECTED INTO THE MEDIAL PREOPTIC AREA (MPOA) FACILITATES COPULATORY BEHAVIOR IN THE MALE. P. Butler*, R. Hammond*, S. Kurth, B. Padgett*, C. Lowry*, J. G. Kohlert, R. Mills*, and G. J. Bloch, Dep't of Psychology, Brigham Young U, Provo, UT, 84602.

Because steroid-sensitive, sexually dimorphic regions of the male rat MPOA appear to contain relatively large amounts of GAL (Bloch et al, Neurosci Abst 15, 89 and unpublished), copulatory behavior was assessed in sexually experienced animals that were gonadectomized in adulthood, then implanted with 2mm testosterone capsules in order to maintain behavior at low levels. 0.3 ul microinjection of 50ng or 500ng GAL into the MPOA of these males significantly increased the percentage of animals that mounted or ejaculated when compared to vehicle-injected controls, and also significantly increased the percentage of animals showing intromission behavior within the first 2 minutes (i.e., a short intrommission latency). General body movement measured in an openfield apparatus (number of line crossings, rears) was unaffected by GAL microinjection. These data suggest that GAL within the MPOA may play a specific role in the maintenance of copulatory behavior in the male. Supported by BYU research funds.

BRAIN ANTIESTROGEN BINDING SITES. J.M.Gray and L.Ziemian* Program in Biopsychology, Vassar College, Poughkeepsie, NY

Antiestrogens (AE; e.g., tamoxifen, TAM) are synthetic substances which antagonize many of the reproductive actions of estradiol (E) while mimicking many of the anorections of estration (c) while ministring many of the anorectic and metabolic effects of E. AE may exert many of their effects by competing with E for the estrogen binding site (EBS) in peripheral reproductive and metabolic, as well as central neural tissues. Recent studies have also demonstrated the presence of microsomal sites in reproductive tissues which bind AE, but not E (antiestrogen binding sites, AEBS). We are reporting the presence and characteristics of AEBS in several areas of the brain and pituitary in ovariectomized rats.

Single point binding assays with 2 nM 3H-TAM (+ 1 uM TAM) in the presence of saturating amounts (2 uM) E indicated the existence of specific binding to AEBS throughout the brain and pituitary. In most areas of the brain and pituitary, Scatchard analyses revealed the presence of a single AEBS with a dissociation constant ($K_d=1-4 \times 10^{-9}M$) similar to that previously reported for other tissues. However, in both hypothalamus and preoptic area, an additional, higher affinity site (K_d =6-9 x 10⁻¹¹M) was found. Ongoing competetive inhibition studies using a variety

of neurotransmitter agonists and antagonists are exploring the specificity of $^{3}\mathrm{H-TAM}$ binding to the two AEBS.

315.11

DISTRIBUTION OF ESTROGEN RECEPTORS IN THE BRAIN OF THE FEMALE MUSK SHREW: AN IMAMOCYTOCHEMICAL STUDY. T.L. Dellovade, J.D.Blaustein and E.F. Rissman. Dept. of Psychology, Univ. of Virginia, Charlottesville, VA 22901 and Neuroscience & Behavior Program and Dept. of Psychology, Univ. of Mass., Amherst, MA 01003

Neural aromatization of testosterone to estradiol is essential for the regulation of sexual behavior in the female musk shrew (Rissman, et al. Neuroendo 51:468, 1990). One step toward better understanding the neural mechanisms involved with this process, is to localize the distribution of the cells containing estrogen receptors (ER). In this study, we used immunocytochemistry for the localization of ER. We used a multi-bridging peroxidase-anti-peroxidase technique with a monoclonal antibody. H222 (a gift of Abbott Laboratories, Blaustein and Turcotte, Brain Research 49:75, 1989).

ER-immunoreactive cells were found in the preoptic-hypothalamic and limbic regions of the brain. Relatively dense staining was seen in the anterior medial, arcuate and ventromedial nuclei of the hypothalamus. Cells in the medial and lateral preoptic, lateral hypothalamus, and the ventral premammillary nuclei also contained ER staining. Limbic regions containing ER-immunoreactivity included the bed nucleus, lateral septum and the central and cortical nuclei of the amygdala. ER-immunoreactivity was primarily nuclear in appearance, with an occasional process lightly stained. As compared with similar studies in other species, these results

suggest that the location of ER in the brain is highly conserved.

BEHAVIORAL EFFECTS OF ANDROGENS AND ESTROGENS IN THE QUAIL PREOPTIC AREA <u>C. Surlemont*</u>, A. Vockel, A. Foidart and J. Balthazart, Laboratory of General and Comparative Biochemistry, University of Liège (BAT L1), B-4020 Liège, Belgium.

ereotaxic implantation of hormones, antihormones and metabolism inhibitors was used to study the sites of androgen and estrogen action on sexual behavior in the preoptic area of castrated male Japanese quail. Bilateral implantation of the aromatase inhibitor, androstatrienedione (ATD) in the sexually dimorphic nucleus (POM) of the preoptic area completely suppressed the behavioral activation produced by a systemic treatment with testosterone (T). The effects of ATD were only observed if the implants were located in the POM. In a second experiment, implants of the synthetic estrogen, diethylstilbestrol in the POM restored copulatory behavior in castrated males while implants of the synthetic non-aromatizable androgen, methyltrienolone (R1881) were almost ineffective. During a third experiment, the activating effects of a systemic treatment with T were blocked by stereotaxic implants in the POM of the antiestrogen, tamoxifen or the antiandrogen, fluta The effects of tamoxifen were more pronounced than those of flutamide. In addition, tamoxifen was active in all parts of the POM while a behavioral inhibition was observed only for flutamide implants which were located in the caudal part of the nucleus. Taken together, these results demonstrate that the sexually dimorphic POM is the area where the behaviorally active estrogenic metabolites of T have to be produced. The estradiol derived from T aromatization in the POM presumably acts within the nucleus to activate copulation as demonstrated by the effectiveness of DES implanted in this region. Androgens might also have a direct action on sexual behavior as suggested by the partial inhibition observed in flutamide-treated birds. It is however possible that androgens and estrogens do not act in the same brain area to activate behavior. Supported by NIH HD22064, FNRS and EEC (SC1-0230-C/IT)

COMPARISON OF THE DISTRIBUTIONS OF ESTROGEN TARGET NEURONS IN THE BRAINS OF ADULT MALE AND FEMALE MACAQUES. R.P. Michael, H.D. Rees and R.W. Bonsall, Department of Psychiatry, Emory University School of Medicine, Atlanta, Georgia 30322 and the Georgia Mental Health Institute, Atlanta, Georgia 30306.

To compare the uptake of estradiol by the brains of male and female

monkeys, 2 adult female and 4 adult male Macaca mulatta were gonadectomized and 3-5 days later administered ³H-estradiol i.v. (males 0.47 mCi/kg; females 0.15 mCi/kg). After 60 min, brains were rapidly removed and frozen for autoradioagraphy. Sections were cut in a cryostat at 4 μ m and thaw-mounted on emulsion-coated slides. After 140-days exposure, slides were developed and stained. A total of 6,600 neurons in 11 regions of the hypothalamus, preoptic area, amygdala and septum were examined using a rigorous procedure based on the Poisson distribution. There were significant differences in the percentages of labeled neurons (P<0.001) in the 11 regions. In both males and females, highest percentages (59%-84%) occurred in the ventromedial and arcuate hypothalamic nuclei and in the cortical and basal accessory amygdaloid nuclei. Moderate percentages of labeled neurons (45%-59%) occurred in the anterior hypothalamic area, bed nucleus of stria terminalis and medial preoptic nucleus. Lower percentages (20-29%) occurred in the lateral septal and medial amygdaloid nuclei and lowest percentages (<55%) occurred in the premammillary and intercalated mammillary nuclei. No significant differences between males and females were found either in the regional distribution of labeled neurons or in the intensity with which the neurons were labeled. Results suggested that the distribution of estrogen-target neurons in the adult primate brain is not sexually dimorphic.

NOVEL STEROID-BINDING SITE ON SYNAPTIC MEMBRANES MAY MEDIATE STRESS-INDUCED INHIBITION OF SEXUAL BEHAVIORS. M. Orchinik, T.F. Murray and FL. Moore. Oregon State Univ., Corvallis, OR 97331. Short-term stress inhibits sexual behaviors of male amphibians (*Taricha granulosa*) through a mechanism that involves corticosterone (CS), and injection of low doses of CS inhibits the behavior within 10 min (Moore and Miller, *Horm.Beh.*, 18:400, 1984). This response is too rapid to be mediated through classical intracellular receptors. To determine if there are high-affinity membrane-bound steroid receptors that could mediate this rapid response, we have partially characterized the binding of ⁵H-CS to brain membranes from *Taricha.* ³H-CS binding to a crude synaptosomal preparation was specific, saturable and reversible. The binding site had high affinity (Kd=5.0SX10⁻¹⁰M) for CS and the density of binding sites was 143 fmol/mg protein. We examined ³H-CS binding to more purified subcellular fractions obtained from sucrose gradient centrifugation and found specific binding of ³H-CS most enriched (>11x) in the synaptosomal fraction. The enrichment of ³H-CS minding in the synaptosomal fraction precisely paralleled the enrichment of ³H-quinuclidiny benzilate binding (a muscarinic cholinergic antagonist), used as a positive control for neuronal membranes.

Competition experiments indicated that the membrane-bound binding site was highly specific for corticosteroids, and the specificity differed from both Type I and Type II intracellular receptors. In behavior experiments, the potency to inhibit ³H-CS binding. Our results suggest that rapid behavioral responses to corticosteroids may be emediated by this previously undescribed high-affinity, steroid-binding site on amphibian brain synaptic membranes. EFFECTS OF ANDROGEN ON SEXUAL DIFFERENTIATION OF THE ZEBRA FINCH SONG SYSTEM. B.A. Schlinger and A.P. Arnold. Laboratory of Neuroendocrinology, Brain Research Institute and Department of Psychology, University of California, Los Angeles, CA

Although estradiol is generally considered the hormone responsible for masculinization of the zebra finch song system, studies of Gurney (1981, 1982) suggest that the non-aromatizable androgen 5\(\alpha\)-dihydrotestosterone (DHT) has limited effects, most notably masculinizing cell number in nucleus RA. To replicate and extend this work, hatchling (day 1) male and female zebra finches were treated with Silastic pellets containing 0, 50 or 200 ug crystalline DHT. Birds were sacrificed as adults (day 90) and their brains were sectioned at 30 um and stained with thionin. Treatment of hatchlings with DHT had small effects on volumes of several song control nuclei and the direction of these effects was opposite in males and females. In females, 50 or 200ug DHT increased RA volume by 35% and 37% and in males decreased RA volume by 4% and 22%. Similar changes were observed in volumes of female and male HVc, but these were not significant. These divergent effects were most obvious in Area X where 200ug DHT made Area X recognizable in 4 of 9 females and significantly reduced the volume of Area X in males by 34%. Although treatment of females with either 50 or 200ug DHT increased neuron number in RA 1.9- and 1.3-fold, these increases were not significant. In addition, 200ug DHT significantly increased soma size in RA by 1.6-fold. These data suggest that androgens have diverse effects on development of the zebra finch song system. ANALYSIS OF THE CANARY ANDROGEN RECEPTOR. K.L. Nastiuk and D.F. Clayton. Lab. of Animal Behavior, Rockefeller Univ., New York, NY

In order to investigate the mechanisms by which gonadal steroids regulate the highly plastic song circuit in the brains of canaries, we have cloned the canary androgen receptor and have begun experiments to examine its regulation. We used the polymerase chain reaction to amplify canary androgen receptor mRNA from testes in sufficient quantities to clone and sequence. Analysis reveals that the DNA binding domain is almost identical to the rat and human domains, whereas the hinge has fifty percent identity and many conservative substitutions. Preliminary analysis indicates that the steroid binding region has an intermediate level of homology. This suggests that, unlike currently available antibodies, cDNA probes will make possible the analysis of seasonal regulation and localization of the receptor in the canary and other songbirds.

EFFECTS OF FLUID DEPRIVATION ON TESTOSTERONE SENSITIVITY AND EXTINCTION OF A CONDITIONED TASTE AVERSION. E.A. Brownson, C.B.Sengstake* and K.C. Chambers. Depts. of Neurobiology and Psychology, Univ. of So. Cal., Los Angeles, CA 90089 and Dept. of Psychology, Portland State

Univ., Portland, OR 97207.

Fluid deprivation reduces behavioral sensitivity to testosterone (T). The amount of T required to prolong extinction of a conditioned taste aversion (CTA) is greater in fluid deprived than nondeprived male rats. In Trequired to prolong extinction in fluid deprived to Sprague-Dawley (SD) male rats is not sufficient in Fischer 344 (F344) males. To determine whether this is due to a greater effect of fluid deprivation on F344 males, 40 F344 and 40 SD male rats were either fluid deprived (1 hr/day access to fluid) or nondeprived (24 hr access to fluid). Following the first presentation of a 10% sucrose solution, a CTA was induced by injection of 0.15 M LiCl (10 ml/kg). Daily extinction trials began 2 days later and continued until criterion for extinction (100% of first day consumption) was reached. The fluid deprived F344 and SD rats extinguished faster than the nondeprived rats. However, the percentage increase in the extinction rates of the deprived F344 was 2-fold greater than that of the SD. These results suggest that F344 are affected more strongly by fluid deprivation and have a greater reduction in sensitivity to T. ONR NO014-J-1296

EFFECTS OF AMBIENT TEMPERATURE ON BAG-CELL ACTIVITY AND EGG LAYING IN APLYSIA CALIFORNICA. N.L. Wayne and G.D. Block. Dept. of Biology, Univ. of Virginia, Charlottesville, VA 22901.

Aplysia are seasonal breeders, and previous studies suggest that water temperature is an important environmental signal which regulates the timing of reproduction in this marine mollusc. Specifically, cold water inhibits while warm water can stimulate egg laying. The purpose water infinitis while wain water can similitate egg laying. The pulpose of the present studies was to investigate the effects of temperature on activity of the neuroendocrine bag cells controlling egg laying. Reproductively mature animals were maintained either in warm (20°C, n=8) or cold (15°C; n=7) water. Aplysia were fitted with a stimulating/recording electrode at the bag-cell neurites. Following electrical stimulation of the bag cells, 8 of 8 warm Aplysia layed eggs but only 1 of 7 cold Aplysia layed eggs (subsequently all animals but only 1 of 7 cold Aphysia layed eggs (subsequently, all animals layed eggs in response to hormonal stimulation of the ovotestis documenting that they were capable of showing this behavior following surgery). This difference in electrically-stimulated egg laying could not be accounted for by differences in duration of bag-cell afterdischarge, in number of impulses during afterdischarge, or in bag-cell content of bioactive egg laying hormone (ELH). Further, there was no significant difference between cold and warm animals in the sensitivity of the ovotestis (egg laying response) to varying doses of atrial-gland extract. These results suggest that cold temperatures inhibit some process between bag-cell afterdischarge and ovotesticular response to ELH. We are currently investigating whether cold temperature inhibits egg laying by suppressing bag-cell secretion of ELH. Supported by NIH grants NS-08725 to NLW and NS-15264 to GDB.

LEARNING AND MEMORY-PHARMACOLOGY: EXCITATORY AMINO ACIDS

MK-801 IMPAIRS LEARNING IN AVERSIVELY-MOTIVATED COMPLEX MAZE TASKS IN RATS. E. Spangler*, P. Garofalo*, E. Bresnahan, N. Muthr*, J. Long, D. Ingram. Gerontol. Res. Ctr., NIA, NIH, Baltimore, MD 21224; Essex Community College, Baltimore, MD 21237.

We evaluated NMDA receptor blockade by MK-801 in male F-344 rats in a 14-unit T-maze (Ingram D., Neurobiol. Aging, 9:475, 1988) and in a 3-unit testit (1) acre (Perceptor Exercise).

detour (D) maze (Bresnahan E., et al., Soc. Neurosci. Abst., 15:1382, 1989). For the T-maze, 3-mo old rats were pretrained in 1-way active avoidance to criterion (8 avoidances/10 trials), and 24 hr later received s.c. injections of either saline (SAL, n=15) or MK-801 (ns=8) in doses of 0.025, 0.05, or 0.1 mg/kg 20 min before T-maze training (15 trials). Rats had to locomote toward goalbox via 5 segments each within 10 sec to avoid footshock (0.8 mA). SAL-treated rats received 1 wk later either 0.05 mg/kg MK-801 (n=5) or SAL (n=5) s.c. 20 min before a 10-trial retention test. During acquisition significant (ps<.01) drug effects appeared in all measures (errors, alternation errors, runtime, shock frequency and duration) with 0.1 mg/kg MK-801, but 0.05 mg/kg MK-801 impaired cognitive performance (errors, alternation errors) only. No MK-801 effect was observed in retention. After extensive D-maze pretraining, 1-yr old rats (n=7) received 4 sessions with 4 problems each in which they ran to a goal through a path containing pairs of U-shaped Ds deviating bilaterally at 3 locations. Each problem involved 2 forced runs with entrance to 1 side of a D pair blocked at 2 locations followed by choice runs with D entrances opened. To avoid footshock (0.4 mA), the rat had to run to goal without stopping. During counterbalanced sessions 2-3, rats received either 0.025 or 0.05 mg/kg MK-801 s.c. 20 min before testing, and SAL during sessions 1,4. Relative to SAL sessions, 0.05 but not 0.025 mg/kg MK-801 significantly (p<0.05) increased errors. Thus, alterations in NMDA receptors might underlie age-related performance declines in these tasks.

REPEATED ACQUISITION OF THREE-LEVER SEQUENCES: DIFFERENT BEHAVIORAL MECHANISMS OF SCOPOLAMINE AND MK-801. J. Cohn* and D.A. Cory-Slechta. Environmental Health Sciences Center, Univ. Rochester School of Medicine & Dentistry, Rochester, NY 14642.

Several different neurotransmitter systems have been implicated as biological substrates for learning processes, particularly the cholinergic and glutaminergic (NMDA) systems. Analyses of behavioral mechanisms by which such drugs impact learning should result in a greater understanding of the differential roles of these neurotransmitter systems. In this study, a simplified repeated acquisition procedure was used to compare the effects of scopolamine, a cholinergic antagonist, and MK801, an NMDA-receptor antagonist, on response sequence learning. Rats were required to learn a different 3-response sequence elarning. Rats were required to learn a different 3-response sequence each session (e.g. Left (L), Right (R), Center (C)) for food reinforcement. Perseverative sequences, e.g. LLR were excluded. Presentation of sequences was ordered such that each member of the response sequence always differed in its position from the previous session's sequence. Errors produced a 2 sec timeout period, and an increase in the ratio of correct sequences for food presentation (FR1 to FR2). An error also required the rats to begin the sequence anew. A tone stimulus followed each correct response.

Both scopolamine and MK-801 significantly increased error rates in a dose-dependent manner. However, microanalysis of error patterns revealed that this effect was produced through different behavioral mechanisms. Following administration of scopolamine, rats tended to proceed directly from the first to the third member of the sequence, suggesting a loss of control of the reinforcement contingencies over behavior. MK-801 produced perseverative responses on the first sequence member, an effect similar to that observed following administration of d-amphetamine. Both scopolamine and MK-801 produced a

EFFECTS OF MK801 ON LEARNING AND MEMORY AS ASSESSED USING A NOVEL WATER MAZE. G.J. Kant, C.P. D'Angelo*, T. N. Robinson III*, W. L. Wright*, C.P. Wingfield* and D.D. Rigamonti. Dept. of Medical Neurosciences, Walter Reed Army Institute of Research, Washington DC 20307.

We have recently reported on the usefulness of a novel water maze for the assessment of learning and memory [Kant et al., Pharmacol. Biochem. Behav., 31: 487,1988; Przybelski et al., Biomat. Art. Cells Art. Org., 17: 583-596, 1989; Neurosci. Abs. 15: 1771. 1170]. In the present study we investigated the effects of MK801, an NMDA receptor antagonist reported to have beneficial effects both as an anticonvulsant and neural protectant as well as adverse effects on cognition and neuronal morphology. Groups of rats (n=12/group) were injected with saline or MK801 (0.1 mg/kg) 15 (n=12/group) were injected with saline or MNOVI (0.1 mg/sg/) min prior to daily water maze testing. Rats learned to swim a path through an alley maze set inside a 5 ft diameter pool to an exit platform. Both time to completion (300 sec maximum) and errors (entries through incorrect doors) were recorded. Testing was conducted daily (1 trial/day) in 3 phases. In phase 1 (24 trials), rats were tested on one maze configuration. After rats had learned this first maze, six of each group continued to get saline or MK801 prior to daily testing and the other six rats in each group received the alternate treatment (phase 2: memory testing, 9 trials). Drug treatment remained as in phase 2 testing for phase 3 which consisted of 8 trials on a new maze configuration. MK801 retarded learning in both phase 1 and 3 as shown by increased swim times and increased numbers of errors made, but did not significantly impair memory in phase 2.

316.5

LONG-TERM CHANGES IN RESPONSIVENESS OF ACOUSTIC STARTLE CAN DEVELOP UNDER KETAMINE ANESTHESIA. S.

STARTLE CAN DEVELOP UNDER RETAMINE ANEST HESTA. S A. Rabchenuk*, B. J. Young, and R. N. Leaton. Dept. of Psychology, Dartmouth College, Hanover, NH 03755 Edeline and Neuenschwander-El Massioui recently showed (<u>Brain</u> <u>Research</u>, 1988, 457, 274-280) that Pavlovian conditioning can occur under ketamine anesthesia. Since ketamine anesthesia may allow the processing of sensory information, we asked if rats can develop long-term habituation of acoustic startle under ketamine anesthesia. Male hooded rats, 70 days old, were trained under ketamine anesthesia and tested undrugged. Animals in Group E (n = 7), received 20, 115-dB, 100-ms, white noise startle stimuli on a 30-sec interstimulus interval in one 10-min session. Animals in Group C (n = 8), were placed in the startle chamber for 10 min but without stimulus presentations. Anesthesia was induced in both groups with an initial injection of 170 mg/kg ketamine hydrochloride, i.p., supplemented as necessary to eliminate any response to tail pinch before training. Responsiveness of both groups to the initial startle stimulus was tested without drug injections 48 hours later and again 24 hours later. On the first trial of Test Day 1 Group E was more responsive than Group C. This pattern reversed for the first trial of Test Day 2. Statistical analysis yielded a significant group x trial interaction (p < .05). There were no detectable responses to the startle stimuli during the training session. The results indicate that long-term changes in responsiveness can develop under ketamine anesthesia which is adequate to suppress detectable responses. However, the outcome was complex, suggesting that both long-term sensitization and habituation can occur under ketamine anesthesia.

INTRA-AMYGDALA INJECTION OF N-METHYL-D-ASPARTATE RECEPTOR ANTAGONISTS IMPAIRS MEMORY IN AN INHIBITORY AVOIDANCE TASK. K.C. Liang & M. Davis, Dept. of Psychology, Natl' Taiwan Univ., Taipei, Taiwan 10764, R.O.C. & Dept. of Psychiatry, Yale Univ., Sch. of Med., New Haven, CT 06508, U.S.A.

N-methyl-D-aspartate (NMDA) receptors have been implicated in neural plasticity. Previous findings indicate that central administration of NMDA antagonists such as dl-2-amino-5-phosphonopentanoic acid (AP5) affects acquisition and/or retention in several learning tasks. A recent study reports that pretraining injections of AP5 into the basolateral nucleus of the amygdala impair acquisition of fear conditioning in a fear-potentiation of startle paradigm. The present study examined the generality of this effect by investigating the influences of pre- and posttraining intra-amygdala injections of APS on retention in an inhibitory avoidance task.

Male Sprague-Dawley rats were implanted with cannulae aiming at the basolateral

Male Sprague-Dawley rats were implanted with cannulae aiming at the basolateral amygdala. In the first experiment, four groups of rats received bilateral intra-amygdala injections of buffered vehicle, 1.25, 2.5 or 5.0 ug of AP5 (0.5 ul/side). Five minutes after the injection, rats were trained on a one-trial step-through inhibitory avoidance task with 1.6 mA/1 s footshock. Retention tested 24 hrs later indicated that pretraining intra-amygdala injections of AP5 produced a dose-dependent retention deficit. S.0 ug inuced a profound effect but 1.25 ug had no significant effect. The second experiment examined the effect of posttraining injections of AP5 on retention to determine whether the retention deficit could be due to AP5 influencing retention to determine whether the retention deficit could be due to AP5 influencing performance factors other than memory processing. Three groups of rats were trained and tested on the task described above. Immediately following training, two groups received intra-amygdala injections of vehicle or 5.0 ug of AP5, while the third group received a delayed injection of AP5 5 hrs after training. Results indicated that while immediate posttraining intra-amygdala injections of AP5 significantly impaired retention performance, delayed injections of AP5 did not produce a significant effect. These findings suggest that amygdala NMDA receptors may be normally activated by certain learning experiences and involved in memory formation processing.

316 4

EFFECTS OF POSTNATAL NMDA ANTAGONISTS AND ENVIRONMENTAL STIMULATION ON SPATIAL MEMORY IN THE ADULT RAT. N. Venable*, P.H. Kelly. Preclinical Research, Sandoz AG, CH-4002 Basel, Switzerland.
Blockade of NMDA receptors in adult animals disrupts

memory formation, whereas environmental enrichment increases learning abilities. The present study examined the separate and combined effects of postnatal NMDA antagonists and environmental enrichment on adult learning. At 3 days of age Sprague-Dawley littermates learning. At 3 days of age Sprague-Dawley littermates were redistributed into 8 groups (n=8) to form a 3-factor design (drug x environment x sex). From days 10 to 24 pups received $300\mu g/kg$ MK-801 or saline s.c. ≥ 1 hr after the last of 4 daily 30-min enrichment sessions. Environmental controls remained in social conditions. similar experiment was carried out using (\pm)-CPP (10-20 mg/kg s.c.). At 6-8 months, drug-treated animals showed significant deficits in several indicators of learning in a water maze and in a delayed alternation task. Enrichment significantly facilitated the alternation task in the MK-801 and CPP experiments and the water maze task in the CPP experiment, and partially reversed some drug effects. Sex differences were also observed. It is concluded that 15 days of MK-801 or CPP treatment during early development produces a long-term deficit in spatial memory.

316.6

EXCITATORY AMINO ACID ANTAGONISTS INFUSED INTO THE AMYGDALA BLOCK EXTINCTION OF FEAR-POTENTIATED STARTLE. W.A. Falls. M.J.D. Miserendino & M. Davis. Psychology & Psychiatry Dept., Yale Univ. Med Sch., 34 Park st., New Haven, CT. 06508

Paired presentation of a neutral stimulus, such as a light, and an aversive stimulus. such as a shock, allows the light to now potentiate the startle response. Presentation of the same light, in the absence of shock, leads to a disappearance of this potentiation. These results are generally attributed to the acquisition and extinction, respectively, of conditioned fear of the light. The amygdala is known to be important for the acquisition of conditioned fear, however, relatively little is known about its role in extinction. Recently it has been shown that activation of N-methyl-D-aspartate (NMDA) receptors in the amygdala is necessary for the acquisition of potentiated startle (Miserendino, M.J.D., et al., Nature, in press). We therefore examined whether blockade of NMDA receptors in the amygdala would affect extinction of fear-potentiated startle.

Rats were implanted with bilateral cannulae aimed at the basolateral nucleus of the amygdala. One week later, the rats underwent training in which a light was paired with footshock (0.6 mA). Five days after training, the initial level of fear-potentiated startle was assessed by measuring the amplitude of noise-elicited startle in the presence or absence of the light. One day later, the rats were infused with either the non-selective excitatory amino acid (EAA) receptor antagonist γ-D-Glutamylglycine (DGG; 10μg), the NMDA receptor antagonist DL-2-amino-5-phosphono-valeric acid (AP5; 10µg) or vehicle immediately prior to receiving 30 light alone extinction trials. One day later, the level of fear-potentiated startle was again assessed but without drug infusion.

Rats that received vehicle during light-alone trials did not exhibit potentiated startle relative to their initial levels (i.e., extinction). Rats receiving DGG or AP5 exhibited potentiated startle equivalant to their initial levels (i.e., no extinction).

These data suggest that activation of NMDA receptors in the amygdala are importantly involved in extinction of conditioned fear.

316.8

MICROINFUSION OF AN N-METHYL-D-ASPARTATE ANTAGONIST INTO THE AMYGDALA IMPAIRS AVOIDANCE LEARNING IN RATS. M.Kim* and J.L.McGaugh. Center for the Neurobiology of Learning and Memory and Department of Psychobiology, University of California, Irvine, CA 92717.

Extensive evidence indicates the importance of the amygdala (AM) in avoidance learning. However, whether memory storage occurs in the AM is not clear. Recently, long-term potentiation (LTP) was demonstrated in the AM (Clugnet et al., 1989). Assuming that LTP serves as a basis of learning, interfering with LTP may impair learning and retention if the AM is a locus of neuronal change underlying avoidance learning. Since LTP induction depends on activation of the NMDA receptors, we examined the effects on learning and memory, of an NMDA antagonist D,L-2-amino-5-phosphono-valeric acid (AP5) injected into the AM.

Sprague-Dawley rats were implanted with bilateral cannulae aimed at the AM, and trained with continuous multiple-trial inhibitory avoidance (CMIA) and one-way active avoidance (AA) tasks. In CMIA, whenever a rat entered dark compartment, a footshock was given until the rat escaped to the starting compartment. The number of trials required before the rat remained in the starting compartment for 100 sec in one trial was recorded. Step-through latency was measured in a retention test 48 hours later. Vehicle or AP5 (1, 3, or 10 ug/0.5 ul)

was injected into the amygdala 3 min before training in both tasks.

10 ug AP5 impaired acquisition and retention in CMIA and AA as compared to vehicle. 3 ug AP5 did not affect acquisition but impaired retention in CMIA, and impaired both in AA. The effects of AP5 were not due to state-dependency or altered sensitivity to footshock. These findings are consistent with other evidence (Miserendino et al., 1989), suggesting that learning and retention of aversively-motivated tasks may be mediated by changes involving activation of NMDA receptors. MH12526 from NIMH/NIDA and ONR N00014-87- K-0518.

BLOCKING NMDA RECEPTORS IN TURTLES BY MK-801 PREVENTS MAZE ACQUISITION. M. Avigan* and A. S. Powers. Psychology, St. John's University, Jamaica, NY 11439.

The dorsal cortex of turtles has been shown to be involved in learning and memory. This cortex contains NMDA receptors and, in lizards, it shows long-term potentiation. The present study investigated whether blockade of NMDA receptors by systemic injections of the NMDA antagonist MK-801 would affect maze learning.

Fifteen turtles were first trained on a T-maze for food reward to determine whether they were capable of learning a maze. They were then divided into three groups: Group I was given sham lesions or injected with saline daily (n=5), Group 2 was given lesions of the dorsal cortex (n=5) and Group 3 was given daily subcutaneous injections of MK-801 (dose: .05 mg/kg) 20 min before running. All three groups were trained on an X-maze for food reward. Three trials per day were given, and the turtles were run until they had reached a criterion of learning or until they had had 40 days of training.

The results showed that acquisition of the maze was significantly impaired both for the subjects that were given dorsal cortex lesions and for those that were given MK-801. This finding is consistent with the possibility that NMDA receptors in the dorsal cortex may be involved in learning in turtles.

316.11

EFFECT OF THE NMDA ANTAGONIST MK-801 ON CLASSICAL CONDITIONING OF THE RABBIT NICTITATING MEMBRANE RESPONSE.

J.H. Stillwell* and G. B. Robinson. University of New
Brunswick, Fredericton, New Brunswick, Canada, E3B 6E4.

Several lines of investigation suggest that hippocampal long-term potentiation (LTP) or potentiation-like effects are involved in acquisition of the classically conditioned rabbit nictitating membrane (NM) response (Berger et al., 1986; Robinson et al., 1989). If LTP is a neural substrate of associative learning then manipulations which reduce or abolish LTP should have similar effects on learning. The noncompetitive NMDA receptor antagonist MK-801 is known to reduce or abolish hippocampal LTP. The present study examined the effects of MK-801 on acquisition of the conditioned NM response of the rabbit.

Male New Zealand rabbits were administered MK-801 1.5

hrs. prior to each daily conditioning session. Dosages ranged from 0.0 - 0.5 mg/kg. Each session consisted of 12 blocks of 9 trials (8 CS-US pairings and 1 CS alone test trial). A tone (1 KHz, 82 db, 400 ms) served as the CS and coterminated with a corneal airpuff US (5 psi, 100 ms duration). Administration of MK-801 prior to each session resulted in a dose-dependent decrease in acquisition rates that did not appear to result from changes in CS or US sensitivity. We are currently examining the effects of MK-801 on the development of enhanced hippocampal neural activity that occurs during acquisition of the NM CR. Supported by MRC and NSERC.

316.13

EFFECT OF PHOSPHATIDYLSERINE TREATMENT ON SPATIAL MEMORY AND HIPPOCAMPAL SYNAPTIC PLASTICITY IN AGED RATS. D. Guidolin*, L. Petrelli*, A. Zanotti*, M.G. Nunzi and G. Toffano. Fidia Research Laboratories, 35031 Abano Terme (PD), Italy.

It has been shown that chronic oral administration of phosphatidylserine, significantly improves spatial memory in aged rats with a severe place-navigation deficit (Zanotti et al., 1989, Psychopharmacol., 99:316). In aged rats, loss of axospinous perforated Sy:316). In aged rats, loss or axospinous perforated synapses in the dentate gyrus is regarded as one of the structural substrates of this memory deficit (Geinisman et al., 1986, Brain Res. 398:266). We evaluated the number of perforated and nonperforated axospinous synapses per granule cell in the middle molecular layer of the dentate gyrus from behaviorally characterized rats: young adults (5 mo); and aged-(27 mo) nonimpaired and invited available the latter untrated or trated and impaired animals, the latter untreated or treated with BC-PS 50mg/kg/d for 12 weeks. The total number of axospinous synapses per neuron decreased significantly in control aged-impaired and nonimpaired rats relative to young adults. However, the percentage of perforated synapses was significantly lower only in the synapses was significantly lower only in the aged-impaired rats. BC-PS restored both the number of axospinous synapses and the incidence of perforated synapses to normal values. Enhancement by BC-PS of synaptic plasticity may well relate to its effects on neurotransmission and cognitive function in the aged.

316.10

NMDA RECEPTORS MEDIATE ACQUISITION BUT NOT EXPRESSION OF PAVLOVIAN FEAR CONDITIONING. J. J. Kim, J. Landeira-Fernandez*, J. P. DeCola* and M. S. Fanselow. Dept. of Psychology, UCLA, Los Angeles, CA 90024.

The role of N-methyl-D-aspartate (NMDA) receptors in Pavlovian fear conditioning was examined using a specific NMDA antagonist DL-2-amino-5-phosphonovaleric acid (APV). A 2 x 2 factorial design was employed in which APV (5ug) or saline was administered icv before the training and/or testing phases. APV completely blocked acquisition but not expression of fear conditioning. To separate encoding from consolidation process, APV was administered either before or immediately after the footshock unconditional stimulus during the training phase. The results indicate that APV must be present during the unconditional stimulus to produce its effect on fear conditioning. In addition, our findings suggest that there may be both long-term and short-term associative memories for learned fear.

These effects on fear conditioning offer a striking parallel with APV's in vitro effects on the acquisition but not expression of longterm potentiation (LTP) and suggest that endogenously generated NMDA-dependent LTP participates in the neural plasticity underlying fear conditioning.

NETWORK LEARNING: PHARMACOLOGICALLY-INDUCED LONG-

NETWORK LEARNING: PHARMACOLOGICALLY-INDUCED LONG-LASTING CHANGES OF ACTIVITY STATES IN CULTURED MONOLAYER NETWORKS. M.B. Gordon and G.W. Gross. Dept. of Biological Sciences and Center for Network Neuroscience, Univ. of North Texas, Denton, TX 76203

This study was undertaken to explore a possible role of NMDA receptor-dependent long-term potentiaion (LTP) mechanisms in the development of enduring changes in network activity states. The network states are determined by the long-term monitoring of spatio-temporal patterns within a 1mm diameter monolayer network cultured on 64 photoetched microelectrodes. Both mouse spinal cord and olfactory bulb cultures are being investigated. The cultures are pretreated with norepinephrine (NE) in 5 separate 5 min pulses one hr before addition of NMDA and glutamate. The pretreatment with NE elevates c-AMP levels which cause transient increases in spike and burst frequencies but with a return to the original activity 1 min after washout. After pretreatment the networks are exposed to a 2 min pulse of NMDA to which glutamate is added during the last min. This regimen is meant to activate the NMDA recents described to the procedure of the procedure receptor-dependent LTP mechanisms.

receptor-dependent L1r mechanisms. Our preliminary results show long-lasting changes in network activity states (spike and burst patterns) which persist for 60-90 minutes and decay slowly over 3-4 hrs to the original activity. We suggest that this behavior could be a reflection of LTP-dependent storage mechanisms expressed on the network level. Supported by the State of Texas Advanced Research Program and the Hillcrest Foundation of Dallas, TX, founded by Mrs. W.W. Caruth, Sr.

IMPLICATION OF HIPPOCAMPAL PROTEIN KINASE C (PKC) IN MOLECULAR MECHANISMS INVOLVED IN LEARNING AND MEMORY PROCESSES: PHARMACOLOGICAL AND BIOCHEMICAL DATA.

X. Nogues*, J. Micheau* and R. Jaffard., Laboratoire de Psychophysiologie, URA CNRS 339, Univ. Bordeaux I, avenue des Facultés 33405 Talence Cedex France.

Recent evidences have suggested that PKC may be a critical intracellular second messenger in learning and memory processes. 1) The involvement of PKC in long term potentiation (LTP) that is proposed as a cellular model of learning and memory, is suggested by studies showing correlations between PKC activation and LTP. 2) Classical conditioning of the rabbit nictitating membrane produces translocation of PKC activity from the cytosolic to the membrane compartments in the CA1 hippocampal region (BANK et al., Proc. Natl Acad. Sci., 1988, 85, 1988 1992). In the following experiments we have investigated the contribution of PKC activity to learning and memory processes. The first set of experiments was aimed at studying the effects of intrahippocampal administration of phorbol-12-myristate-13 studying the effects of intrahtippocampial administration of phorbol-12-myristate-13 accutate (TPA: a PKC activator; 1.6 mM in 0.2 µl/hippocampius) on the acquisition and the 24 hr delayed retention of a bar pressing task on a CRF schedule. TPA administration 5 min before the fetention session produced an improvement of learning at the beginning of the session while the other treatment conditions had no effect on this task. In the second set of experiments, we measured PKC activity in membrane and cytosol compartments of the hippocampius at different delays (5 min, 1 hr 24 hr 25 feet of the second set of the programming at different delays (5 min, 1 hr 24 hr 25 feet of the second set of the programming at different delays (5 min, 1 hr 24 hr 25 feet of the second set of the programming the programming the second set of the programming membrane and cytosol compartments of the hippocampus at different delays (5 min, 1hr, 24 hr) after a spatial concurrent discrimination task performed in a 8-am radial maze. The results showed a decrease of PKC activity in the cytosolic fraction at the 3 delays (p < 0,01; Dunnett t-test) and an increase at the 1 hr delay of the percentage of PKC activity in the membrane fraction on the total PKC activity (p < 0.05). Together, these data support the hypothesis of the implication of PKC in the molecular mechanisms by which the hippocampus may exert its influence on information processing. Morroover, since we observed changes in PKC activity 5 min after the learning task, these results may suggest an early involvement of PKC in the hippocampus depares indeed by learning represented. biochemical changes induced by learning processes.

SELECTED PKC INHIBITORS DISRUPT LONG-TERM MEMORY FORMATION IN THE 2-DAY-OLD CHICK FOR A PECK-AVERSION TASK; FORSKOLIN ATTENUATES THE AMNESIA. P.A.Serrano, M.G. Oxonian*, E.L.Bennett and M.R. Rosenzweig. Dept. of Psychology, University of California Berkeley. CA 94720

R.A. Serrano, M.G. Oxonian*, E.L. Bennett and M.R. Rosenzweig. Dept. of Psychology, University of California, Berkeley, CA 94720.

Dose response functions were determined for melittin (MT), H-7, H-8, H-9, H-A and polymyxin-B. All agents were injected 5 min pre-training into the area of the medial hyperstriatum ventrale (MHV) (10ul/hemisphere). All agents except polymyxin-B were effective in producing significant amnesia as compared to saline injected controls (p<.01). MT (.04 mg/ml) and H-7 (4.0 mg/ml) were found to produce amnesia beginning 45 min and 60 min posttraining, respectively. These time courses for the appearance of amnesia suggest that these agents inhibit formation of long-term memory. There was no evidence of inhibition for short-term and intermediate-term stages of memory formation.

intermediate-term stages of memory formation.

At a 24 hr test, chicks injected with both MT (.04mg/ml) and forskolin (.25mg/ml), an adenylate cyclase activator, showed attenuation of the memory impairment induced by MT. These results suggest that PKC and adenylate cyclase activation are involved in long-term memory formation. Supported by NSF grant BNS-88-10528.

SEASONAL VARIATION IN THE PERFORMANCE OF CHICKS IN A 1-TRIAL PECK AVOIDANCE TASK. M.R. Rosenzweig. D.W. Lee, G.G. Murphy'. & E.L. Bennett. Dept. of Psychology, Univ. of CA, Berkeley, CA 94720. Upon presentation of a small metal bead dipped in methylanthranilate

Upon presentation of a small metal bead dipped in methylanthranilate (MeA, an aversive liquid) chicks will peck the bead, show disgust, then subsequently avoid a similar but dry bead presented at test.

Five minutes pretraining, neonate chicks were given bilateral i.c. injections of 10 µl saline into the region of the intermediate-medial hyperstriatum ventrale. They were then trained with a target bead dipped in either 5%, 10%, or 100% MeA. Testing occurred at times from 10 s up to 24 hr posttraining. Runs were conducted either during the summer (Jun-Aug) or winter (Nov-Jan). At every test time, groups of chicks trained with 100% MeA showed greater avoidance than those trained with 10% or 5% MeA indicating that diluted MeA results in weaker training and retention.

Winter runs resulted in lower % avoidance scores, shorter test latencies, greater numbers of pecks at test, and longer training latencies than summer runs. Measures of variability -- standard deviations & ranges -- were greater for almost all winter data. In the winter, chicks were more difficult to train (longer training latencies & greater number of discarded data due to lack of training) and showed less retention (lower % avoidance scores & shorter test latencies). Data obtained from chicks given weak training (5% & 10% MeA) showed particularly strong seasonal differences. Data from chicks receiving strong training (100% MeA) showed differences due to season but not to the same extent as those seen with weak training. Supported by NSF grant BNS-88-10528 & NIDA grant DA04795.

EFFECTS OF GLUTAMATE, OUABAIN & ANISOMYCIN ON MEMORY FOR WEAK TRAINING IN CHICKS. <u>D.W.Lee. G.G.Murphy*. F.L.Bennett & M.R.Rosenzweig</u>. Dept. of Psychology, Univ. of CA, Berkeley, CA 94720

Memory for 1-trial peck avoidance using strong training (100% methylanthranilate (MeA, a strong liquid aversant) is impaired by glutamate (GLUT, an STM inhibitor), ouabain (OUAB, an iTM inhibitor) and anisomycin (ANI, an LTM inhibitor). The present study investigated the effect of these agents using weak training (10% MeA).

investigated the effect of these agents using weak training (10% MeA). Bilateral i.c. injections (10 µl/hemisphere) were made into the region of the intermediate-medial hyperstriatum ventrale 5 min pretraining using one of the following: saline; 25, 50 or 75 mM GLUT; .01, .03 or .05 mM OUAB; or 7.5, 11.3 or 15.0 mM ANI. When tested at 24 hr, memory for weak training is impaired by GLUT and ANI. The effective doses for GLUT (50 & 75 mM) and ANI (11.3 mM) are the same as those that impair memory for strong training. OUAB did not significantly impair weak memory formation. Further studies will extend the dose range for OUAB and determine if other ITM inhibitors impair weak memory formation.

impair weak memory formation.

To determine the time courses of amnesia following weak training, chicks were tested at times from 10 s up to 24 hr after training. Using strong training, GLUT results in amnesia between 5 & 10 min posttraining. With weak training, GLUT also results in amnesia between 5 & 10 min posttraining and, therefore, inhibits STM for weak training as well as strong training. Work is in progress with ANI and other drugs.

HALOTHANE ANESTHESIA INDUCES STATE DEPENDENT ANTEROGRADE BUT NOT RETROGRADE AMNESIA FOR INHIBITORY AVOIDANCE LEARNING Edwin Rosman MD', David Quartermain PhD, Herman Turndorf MD' Departments of Anesthesiology and Neurology, New York University Medical Center, New York, NY 10016

Memory for a single brief foot shock administered for

Memory for a single brief foot shock administered for entering the dark side of a two compartment chamber was tested by measuring latency to enter the dark compartment 24 hours after training. Mice were exposed to 2% halothane in oxygen with a flow rate of 6 L/min in a 5 liter acrylic chamber. Retrograde amnesia was studied by exposing mice to halothane immediately after the training trial and anterograde amnesia was investigated by training animals following recovery from halothane. Animals trained 15 mins after exposure exhibited normal activity levels and had a normal response to foot shock. Results showed (1) exposing mice to halothane for 15, 30 or 60 min immediately after training failed to produce retrograde amnesia. (2) Mice trained 15 mins after recovery from 30 mins of anesthesia exhibited significant memory loss when tested 24 hrs after training. (3) The anterograde amnesia was temporally graded, i.e. mice were trained up to 2 hrs after recovery were amnestic, but mice trained 4 hrs or longer after recovery were not. (4) The anterograde amnesia resulted from state dependent retrieval failure since mice re-exposed to halothane before testing showed restoration of memory while mice untreated before training but exposed to halothane prior to testing exhibited memory loss.

CIRCADIAN RHYTHMS RESTORED USING GRAFTS OF CULTURED SUPRACHIASMATIC CELLS. M. R. Ralph and E. R. Torre. Dept. of Psychology, Univ. Toronto, Toronto, Canada, MSS 1A1; Dept. of Neuroscience, Univ. Virginia, Charlottesville, VA 22908.

Circadian rhythmicity can be restored to arrhythmic hamsters with suprachiasmatic lesions using neural grafts from the embryonic suprachiasmatic region. The rhythm produced is specific to the donor cells. In an attempt to isolate the types of cells required for successful restoration, we have asked whether cultured cells retain the ability to produce overt rhythms following implantation, and if particular populations are required.

rhythms following implantation, and if particular populations are required. Tissue from wild type litters was harvested on embryonic day 13, dissociated and maintained in cell culture conditions that restricted survival and growth to defined subpopulations of cells. Under these conditions, we can produce from the same harvest, cultures of neurons only, glia only and a neuron-glial mixed population. Identification of basic cell types was based upon morphology and immunocytochemical characteristics.

After 8-days in culture, the cells were collected and implanted into the 3rd ventricle of arrhythmic hosts. Animals that were heterozygous for a period mutation (tau) were used as hosts to help distinguish restored rhythms. Circadian rhythmicity in the wild type range was restored to animals given implants of the neuron-glia culture. As yet, we have not seen an effect of the neuron only or glia only implants.

The results indicate that suprachiasmatic cells can be maintained in

The results indicate that suprachiasmatic cells can be maintained in culture while retaining their pacemaker capability. By reducing the number of cell types in the cultures, it may be possible to identify those that are required for the production and expression of rhythmicity. Supported by an NSERC operating grant to M. Ralph.

AGE OF DONOR INFLUENCES SURVIVAL OF SCN GRAFTS IN HAMSTERS. M.-T. Romero¹, M. N. Lehman², A. Philipot-DeBernardo¹ and R. Silver¹. Barnard College of Columbia University¹, N.Y., N.Y. 10027 and Dept. of Anat. & Cell Bio., U. of Cincinnati College of Medicine², Cincinnati, OH 45267.

Hypothalamic grafts of embryonic day 15 (E15) fetuses develop fully and promote behavioral recovery when implanted in the 3rd ventricle of SCN-lesioned (SCN-X), arrhythmic hamsters (Lehman et al., J.Neurosci., 7:1626, 1987).

In the present experiment hypothalamic tissue, taken from donors at ages E13 to postnatal day 10 (P10) was implanted into the 3rd ventricle of SCN-X hamsters. Immunocytochemical staining for vasoactive intestinal polypeptide (VIP) and neurophysin II (NP) of serial sections of the implanted brains was performed at least 40 days following transplantation. Results indicate that hypothalami taken from E13 to P1 readily develop and express nonoverlapping clusters of VIP and NP cells in a pattern characteristic of the SCN. In grafts taken from older donors, P3 to P10, necrotic tissue is often observed and the size of the graft is decreased. Clusters of VIP and NP cells were less frequent in older tissue, although immunoreactive fiber plexi were still observed in some grafts. Recovery of circadian locomotor rhythms in SCN-X arrhythmic hosts bearing grafts of ages E13-P10 will be analysed. (Supported by NIH grant NS 08518 to MTR and NS 24292 to RS & ML)

TRIAZOLAM FAILS TO PHASE ADVANCE CIRCADIAN LOCOMOTOR ACTIVITY IN SCN-LESIONED HAMSTERS WITH FETAL SCN

TRANSPLANTS. R. Silver, M.-T.Romero and R. S. Canbeyli. Barnard College of Columbia University, NY, NY 10027.

A single ip injection of the short-acting benzodiazepine, triazolam (Tz), at CT6 produces a permanent phase shift of about 1.5 hrs in the circadian locomotor activity of the golden hamster (Turek and Losee-Olson, Nature, 1986). It is not known whether Tz acts directly on the SCN or on other target sites that communicate with the SCN.

The present study investigated the effect of Tz in SCN-lesioned (SCN-X) hamsters bearing fetal SCN grafts in the 3rd ventricle, on the assumption that the grafted SCN lacks normal afferent connections. Tz (2.5 mg/0.1 or 0.5 ml DMSO ip) was administered to hamsters housed in DD once they had regained circadian locomotor rhythmicity. While 5/8 intact controls (8 injections) phase advanced when injected with Tz at CT6, 0/7 SCN-X grafted animals (11 injections) showed a permanent phase shift. Immunohistochemical staining for VIP, NP and NPY indicated that 4 of the grafted animals (6 injections) had complete SCN-X. The results suggest that Tz does not act directly on the SCN. This is consistent with reports that lesions of the intergeniculate leaflet blocked Tz effects (Johnson et al., PNAS, 1988), though it is possible that the phase response curve or the dose-response curve of the SCN-grafted animals may differ from that of intact animals. (Supported by NS 24292 to RS).

CHARACTERIZATION OF PROTEIN KINASE A SUBSTRATES IN THE RAT SUPRACHIASMATIC NUCLEUS. L. Faiman* and M.U. Gillette. Dept. of Physiol. & Biophys. and Neuroscience Program, Univ. of Illinois, Urbana, IL 61801.

Specific stimulation of cAMP-dependent pathways induces a 4-5 hr advance in the phase of the circadian rhythm of neuronal activity of the suprachiasmatic nucleus (SCN) in vitro. Sensitivity is limited to the subjective day of the SCN circadian pacemaker. This suggests that stimulation of protein kinase A (PKA)-mediated phosphorylation is important to the mechanism underlying phase-shifting. Therefore, we are characterizing PKA substrates in rat SCN.

Protein phosphorylation was examined in an *in vitro* system consisting of tissue punches of SCN collected from brain slices at CT 5.0 \pm 0.5, a time in the circadian cycle most sensitive to cAMP stimulation. Phosphorylatable substrates in single SCN (~6 μ g protein) were identified by SDS-PAGE. We have found that 1) 10-100 μ M exogenous cAMP uniformly increases the phosphorylation level of specific protein bands, 2) the PKA catalytic subunit phosphorylates specific substrates in a sonicated extract subjected to heat, and 3) a specific inhibitor of PKA prevents phosphorylation. We are comparing the pattern of PKA substrates at CT 5.0 with that at points in the circadian cycle when the SCN is insensitive to cAMP stimulation. (Supported by NINDS Grant NS22155.)

PERTUSSIS TOXIN BLOCKS MELATONIN'S ABILITY TO RESET THE SUPRACHIASMATIC CIRCADIAN CLOCK IN VITRO. A.I. McArthur and M.U. Gillette. Dept. of Physiol. & Biophys., Univ. of Illinois, Urbana-Champaign, IL 61801.

Melatonin (MEL) acts directly on the SCN in vitro, phase

Melatonin (MEL) acts directly on the SCN in vitro, phase advancing (ϕ_A) the time-of-peak neuronal activity nearly 4hr when applied at the subjective day-night transition. Other systems have indicated that MEL can act through a G_i protein. To further elucidate the transduction mechanism by which MEL affects the SCN clock, a long-term pertussis toxin (PTX) incubation prior to a short MEL+ PTX treatment at circadian time (CT) 10 was used.

SCN clock, a long-term pertussis toxin (F1X) incubation prior to a short MEL+ PTX treatment at circadian time (CT) 10 was used. Coronal hypothalamic slices containing the SCN were prepared from 8 wk old male Long Evans rats housed in a 12L:12D cycle. The media in the brain slice chamber was replaced with fresh media containing PTX (1.0µg/ ml) for 6hr. At CT 10 this treatment was replaced with media containing both PTX and 10.9M MEL for 10min. All measurements of phase were made on day 2 by monitoring firing rates and determining the time-of-peak in the ensemble neuronal activity in vitro.

Whereas 10 min exposure to MEL alone induces $\phi_A > 3$ hr, long-term exposure to PTX blocks the MEL-induced phase advance. The time-of-peak in these experiments (CT $6.6 \pm .1$, n = 4) does not deviate significantly from that seen in PTX controls (CT $6.8 \pm .2$, n = 3). These results suggest that MEL may regulate the SCN pacemaker during late subjective day through PTX-sensitive pathways. (Supported by NINDS grant NS22155).

TRACING SCN GRAFT EFFERENTS WITH THE CARBOCYANINE DYE DII. R.S. Canbevii M. Lehman and R. Silver Barnard College of Columbia University NY, NY.10027; Univ. Cincinnati², Med. Coll., Cincinnati, OH 45267. SCN lesioned hamsters recover circadian locomotor rhythmicity

SCN lesioned hamsters recover circadian locomotor rhythmicity following implantation of embryonic day 15 donor SCN irrespective of attachment site of whole tissue grafts in 3rd V. (Lehman et al., J. Neurosci. 7:1626, 1987). Furthermore, adult hamsters bearing an SCN island retain locomotor rhythmicity (Hakim and Silver, Soc. Neurosci. Abstr.14: 51,1988), thus raising the question of functional role of SCN efferents.

This study was undertaken to evaluate efferent connections of SCN states with the state of
This study was undertaken to evaluate efferent connections of SCN grafts using Dil. Hamsters were sacrificed 40 days after implantation of fetal SCN into the 3rd V. Dil crystals were placed on implants in paraformaldehyde fixed brains. Following incubation for 4 weeks, brains were sectioned, photographed and stained for VIP- and NP-like immunoreactivity (to locate the SCN). Histological analysis revealed that ventricular wall surrounding the graft was largely intact. Graft efferents entered the host brain at sites where the ependymal cell boundary of the 3rd V was absent and projected only a small distance into the host brain. Even at sites where the graft and host seemed to merge, most labelled fibers remained within the graft. The few fibers that entered host tissue did not travel far regardless of whether the SCN was present in the graft or not. The observation of limited connectivity between the transplanted SCN and the host is consistent with immunocytochemical evidence in SCN implanted NP-deficient Brattleboro rats (Wiegand, Bestor. Neurol. Neurosci. Suppl. 1: 17,1989). (NIH Grant 24292 to RS & ML).

317.6

ELECTRICAL CHARACTERIZATION OF VENTROLATERAL AND DORSOMEDIAL REGIONS OF THE SUPRACHIASMATIC NUCLEUS. T.K. Tcheng and M.U. Gillette. Neuroscience Program and Department of Physiology & Biophysics, University of Illinois, Urbana, IL 61801.

The rat suprachiasmatic nuclei (SCN) contain a circadian pacemaker that is expressed in the brain slice as a 24-hr oscillation in ensemble neuronal firing rate. We are studying neuronal firing patterns within the dorsomedial (DM) and ventrolateral (VL) SCN, the two major anatomical subdivisions, to further characterize the circadian pacemaker.

We have shown previously that hemisection of the SCN into DM and VL halves results in an unperturbed electrical circadian rhythm (ECR) in the VL-SCN and the possible loss of an ECR in the DM-SCN. Our current work elaborates upon this finding. In this study, the SCN are unequally divided, leaving less SCN in either the DM-SCN (DM-biased) or VL-SCN (VL-biased). Preliminary results suggest that after DM-biased hemisection the ECR in the DM-SCN is completely abolished (N=5). The effect of VL-biased hemisection on the ECR in the DM and VL regions is presently being examined. Additionally, we have observed that firing patterns of individual neurons change after hemisection. Firing patterns from control SCN and isolated VL and DM regions will be compared in order to identify firing patterns contributing to the ECR.

317.8

ENDOGENOUS CIRCADIAN CHANGES IN cGMP LEVELS IN THE RAT SUPRACHIASMATIC NUCLEUS. E.T. Weber and M.U. Gillette. Dept. of Physiology & Biophysics, Univ. of Illinois, Urbana, IL 61801.

Biophysics, Univ. of Illinois, Urbana, IL 61801.
Stimulating the SCN with cGMP analogs induces a nearly immediate, large advance in the phase of the circadian rhythm of SCN neuronal activity. The sensitive period is limited to subjective night and is in antiphase to SCN sensitivity to cAMP analogs. We questioned whether changes in endogenous cGMP levels might occur within the SCN over the circadian cycle.

levels might occur within the SCN over the circadian cycle.

Brain slices were made from 8-wk-old Long-Evans rats reared on a 12L:12D cycle. Tissue punches of SCN and of hypothalamus were obtained from 500 μm brain slices quick-frozen at the desired time-of-day. Six time points at 4-hr intervals were sampled. Levels of endogenous cGMP were

measured by radioimmunoassay (NEN).

Preliminary results suggest that cGMP levels in the SCN change over the course of the day, possibly with a 24-hr period. Levels in the SCN ranged from 0.02 to 0.60 pmol/mg protein, peaking late in the subjective night. Levels in the hypothalamus ranged from 0.02 to 0.35 pmol/mg protein, consistent with other reports. This cyclicity, in addition to the phase-shifting effects of cGMP, suggests a central role for cGMP in regulating the SCN circadian system during the night. (Supported by NINDS Grant NS22155.)

SEROTONIN PHASE SHIFTS THE CIRCADIAN RHYTHM OF ELECTRICAL ACTIVITY IN THE RAT SCN IN VITRO.

M. Medanic and M.U. Gillette, Dept. of Physiol. & Biophys. and Neuroscience Program, Univ. of Illinois, Urbana, IL 61801. Ventrolateral (VL) regions of the suprachiasmatic nuclei (SCN)

receive serotonergic projections from the raphe nuclei. We investigated the possible role of serotonin (5-HT) in the mammalian circadian system by examining its effect on the rhythm of electrical activity in the rat SCN *in vitro*.

Eight week old, male Long-Evans rats from our inbred colony, raised on 12L:12D schedule, were used. Hypothalamic brain slices containing the paired SCN were made during the day, and maintained in vitro for two days. A 30 fl drop of 10⁶M 5-HT was applied for 5 minutes to the VL region of one of the SCN at CT 7 (n=3), 13 (n=3) or 19 (n=4). The time of peak in the

rhythm of neuronal activity was determined on the following day.

Exposure of the VL-SCN to 5-HT treatment during the subjective night (CT 13 and 19) did not significantly alter time-of-peak compared to untreated slices. However, treatment during the subjective day (CT 7) resulted in a 6.9±0.1 hr advance in the time-of-peak of neuronal activity in the next cycle. This suggests that the SCN are sensitive to 5-HT during the subjective daytime and respond with a phase advance in the circadian clock. (Supported by AFORS grant 90-0205.)

317.11

CIRCADIAN RHYTHM IN C-FOS-LIKE IMMUNOREACTIVITY IN THE RAT BRAIN. J. Kononen^{1*}, H. Alho¹ & J. Koistinaho²

Dept. of Biomedical Science, Dept. of Public Health, University of Tampere, P.O. Box 607, SF-33101 Tampere, Finland.

The proto-oncogene c-fos encodes a nuclear phosphoprotein (Fos), which has been suggested to act as a transcriptional regulatory protein for a specific set of genes. It has been demonstrated that various types of stimulation induces activation of c-fos gene expression in specific neuron populations. However, little attention has been paid to the possible diurnal variation of c-fos expression in the brain. Therefore we studied immuno-histochemically the basal c-fos expression in the rat brain at different times of the day.

Sprague-Dawley rats were maintained on a 12/12 h light/dark schedule. The animals were killed at every four hours starting at 24.00 h. Sections were stained for Fos with standard ABC-immunohistochemical technique. We observed that in certain brain areas, such as the cortex, hippocampus and amygdala, the number of c-fos immunoreactive nuclei was considerabl higher at 24.00 h than that at 12.00. In many other areas, such as in periventricular, paraventricular, septal and supraoptic nuclei no changes were observed, between the same time points. The variation of Fos protein induction at different times of the day indicates diurnal variation of Fos activation and should be considered when planning Fos related studies.

317.13

EFFECT OF OPTIC NERVE STIMULATION ON PEPTIDE RELEASE AND mRNA LEVELS EXPRESSED BY CULTURED SUPRACHIASMATIC EXPLANTS. D.J. Earnest. M. Gallagher. C. Yagil and C.D. Sladek. Dept. of Neurobiology/Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642

Since visual inputs to the light-entrainable circadian pacemaker in the suprachiasmatic nucleus (SCN) presumably trigger a cascade of cellular events locally, the present study was conducted to examine the photic regulation of cellular activity within the SCN. Experiments examined the effect of optic nerve stimulation on peptide release and mRNA levels expressed by perifused SCN explants. Preliminary embasis was placed on studying the distinct ropulations explants. Preliminary emphasis was placed on studying the distinct populations of SCN neurons containing vasoactive intestinal polypeptide (VIP) or vasopressin (VP) since these neurons receive visual input and/or maintain local

vasopiessin (V) since these herrors receive visual input autoof infantian local connections.

Individual rat SCN explants were maintained in a perifusion culture system and after equilibration, electrical stimuli were delivered to the optic nerves via cuff electrodes. Peptide levels in the perifusate and mRNA levels in the explants were analyzed in parallel at regular intervals before and after stimulation. Stimulation of the optic nerves during the early subjective night evoked acute increases in the release of VP, but not VIP. VP output during optic nerve stimulation was 2-5 times greater than that observed during the preceding control interval. Immediately after stimulation, VP release declined to pre-treatment levels. In accord with its acute effect on VP release, optic nerve stimulation also induced a 2-fold increase in the levels of VP mRNA in SCN explants. The present results suggest that VP neurons in the SCN, although devoid of retinal innervation, may be responsive to photic stimulation. Further analysis of the effect optic nerve stimulation at different circadian times and using different parameters is necessary to complement these observations, but the present approach may provide a basis for examining the light responsiveness of different cell types within the SCN. Supported by AFSC Grant #90-0182 (D.E.).

TIME-BASED CHANGES IN THE PHOTOINDUCTION OF FOS EXPRESSION IN THE SUPRACHIASMATIC NUCLEUS. S. Ouyang, L.A. Trojanczyk, J.A. Olschowka, and D.J. Earnest Dept. of Neurobiology/Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY

Induction of the c-fos proto-oncogene in neurons within the brain occurs in response to various extracellular stimuli. Consistent with this observation, we have reported that light exposure causes an increase in the immunohistochemical expression of c-fos protein (Fos) within the ventrolateral subfield of the suprachiasmatic nucleus (SCN). Since the light-entrainable circadian pacemaker located in the SCN exhibits rhythmic changes in its sensitivity to light, the present study was conducted to determine whether the photoinduction of Fos expression within the ventrolateral SCN is similarly time-dependent.

During exposure to constant light, Long-Evans rats (N=13) were sacrificed and perfused at 4-hour intervals over a period of 24-hours. Brain sections were processed for the immunohistochemical localization of Fos protein(s) along with neuropeptide Y (NPY) in the SCN.

In all animals, most of the cells in the SCN with Fos-positive nuclei were

neuropeptide Y (NPY) in the SCN.

In all animals, most of the cells in the SCN with Fos-positive nuclei were segregated in an area that was coextensive with the NPY-immunopositive fibers found in the ventrolateral subfield. Moreover, temporal variation in the expression of Fos was evident within the ventrolateral SCN, such that the density of immunopositive cells during the subjective night was 2-3 times greater than that observed during the subjective day. These results demonstrate that the inductive effect of light on Fos expression in the ventrolateral SCN oscillates over time. Furthermore, the observation that the photoinduction of Fos expression in the SCN was greatest at times when light is known to phase shift circadian rhythms serves to further implicate the c-fos proto-oncogene in the processing of photoentrainment information within the mammalian circadian system. Supported by AFSC Grant #90-0182 (D.E.).

PHASE-SPECIFIC DISTRIBUTION OF LIGHT-INDUCED FOS IMMUNOREACTIVITY IN THE SCN M.A. Rea and A.M. Michel*
Neuroscience Laboratory, Aerospace Research Branch, USAF
School of Aerospace Medicine, Brooks AFB, Tx 78235
Male, Syrian hamsters were housed individually in activity

cages and maintained under constant darkness for at least 10 days. Hamsters were exposed to 15 min of white light (33 lux) at either circadian time (CT)6, CT13 or CT18. Light exposure at these times resulted in phase shifts of the free running activity these times resulted in phase shifts of the free running activity rhythm of -0.12 ± 0.12 hrs (no shift), -1.0 ± 0.2 hrs (phase delay) and +1.9 ± 0.8 hrs (phase advance), respectively. Two hours after stimulation, groups of hamsters (n=8) were anesthetized and perfused with 4% paraformaldehyde. Serial 70 micronthick sections containing the SCN were immunostained for c-fos protein (FOS) using antiserum provided by Dr M. Iadarola (NIDR). Light exposure at both CT13 and CT18 resulted in the appearance of FOS-immunoreactive (FOS-ir) cell nuclei in the suprachiasmatic hypothalamus. In CT13 animals, FOS-ir cells were confined to the SCN and concentrated within the ventraleteral

confined to the SCN and concentrated within the ventrolateral aspect of the nucleus. In contrast, FOS immunostaining was more aspect of the nucleus. In contrast, FOS immunostating was more widespread in CT18 animals, with FOS-ir cells present throughout the SCN and extending dorsally into the surrounding hypothalamus. Stimulation at CT6 did not increase FOS-ir in the SCN. These data indicate that (1) c-fos expression in the SCN occurs in association with light-induced alterations in pacemaker activity, and (2) different populations of cells in the suprachiasmatic hypothalamus are activated by retinal illumination at phase delay and phase advance times. Supported by AFOSR 2312W6 (MAR)

CHANGE IN CIRCADIAN PATTERNS OF RUNNING ACTIVITY IN RATS AS A FUNCTION OF VASOPRESSIN ANTAGONISM IN THE SUPRACHIASMATIC NUCLEUS. J. R. Prather, M. Shuck, M. Mims, and E. Quinton. Lab. of Psychobiology, Univ. of Louisville, Louisville, KY 40292.

Vasopressin (VP) has been implicated as a possible CNS neuromodulator for circadian cycles. The major locus of control for circadian rhythms is believed to be the Suprachiasmatic rhythms is believed to be the Suprachiasmatic Nucleus (SCN) in the hypothalamus. VP in the SCN has been shown to be depleted in aged rats, and as rats age, their circadian cycles tend to be disrupted, becoming shorter and occurring with higher frequency. In this study, the relationship between the blockade of VP and circadian cycles was examined. Vasopressin antagonist (VPA) was administered chronically over an eight day period from a mini osmotic over an eight day period from a mini osmotic pump into the SCN of three month old rats via a cannula tube. This infusion should produce daily cycles similar to the cycles found in older rats with no change in the mean level of activity. Results indicate that the chronic administration of VPA produces disrupted circadian cycles which are higher in frequency than controls without changing the total level of activity, a pattern which resembles those found in old rats .

VASOACTIVE INTESTINAL PEPTIDE (VIP), PEPTIDE HISTIDINE ISOLEUCINE (PHI) AND GASTRIN RELEASING PEPTIDE (GRP) INTERACT WITHIN THE SUPRACHIASMATIC NUCLEUS (SCN) IN A DOSE-DEPENDENT MANNER TO MIMIC THE PHASE DELAYING EFFECTS OF LIGHT. H.E. Albers, E.G. Stopa & R.T. Zoeller. Lab. Neuroendocrinol. & Behav., Depts. Biol. & Psychol., Georgia State Univ., Atlanta, GA 30303; SUNY Health Sci. Ctr., Syracuse, NY 13210; Dept. Anat., Univ. Missouri Med. Sch., Columbia, MO 65212.

VIP, PHI and GRP are co-localized in neurons found in the terminal field of SCN photic afferents. To determine whether VIP, PHI and GRP interact within the SCN in a dose-dependent manner male hamsters were implanted with guide cannula aimed at the SCN and microinjected with a cocktail containing equimolar concentrations of

cannula aimed at the SCN and microinjected with a cocktail containing equimolar concentrations of VIP, PHI and GRP at either 0.3 (N=6), 3 (N=7), 30 (N=5), 300 (N=10) or 3000 (N=7) µM during the 3 hrs following activity onset. Phase delays were observed at all doses, but the magnitude of the delay differed significantly (P<0.05). The smallest delays (i.e. 0.57±0.21) were produced by 0.3 µM and the largest (i.e. 1.92±0.22) by 3000 µM. These data support the hypothesis that the interaction of VIP, PHI and GRP within the SCN is necessary for light-dark cycle entrainment. (Supported by ONR Grant N00014-89-J-1640)

OF MELATONIN ON THE NEUROCHEMISTRY OF SUPRACHIASMATIC HYPOTHALAMUS. S.A. Ferreira*, W.W.
Randolph*, M.A. Rea¹ and J.D. Glass. Dept. Biological
Sciences, Kent State Univ., Kent, OH 44242 ¹U.S.A.F. School
of Aerospace Med., Brooks A.F.B., TX 78235.
In vivo microdialysis was used to determine the effect

of melatonin on serotonergic and amino acid activities in the area of the SCN. Adult male Djungarian hamsters under L:D 16:8 (n=4) received a microdialysis probe $(1.0 \times 0.2 \text{ mm})$ tip size) stereotaxically placed in or near the SCN. Samples were collected every 20 min for 120 min prior to and 120 min following s.c. injection of 100 ug melatonin or vehicle at 1900 h (4 h prior to lights-off). 5-hydroxyindoleacetic acid (5-HIAA) and amino acids were measured by HPLC. The nature of release of neurotransmitters and metabolites to the dialysis probe has been validated in previous experiments. increased the concentrations of 5-HIAA dialysate by $26.6\pm5.9\%$ compared to preinjection levels (p<0.05); vehicle did not increase 5-HIAA. Glutamate was increased by $70.8\pm22.1\%$ (p<0.05). The maximal effect of melatonin on 5-HIAA occurred 40-80 min post-injection, but the rise in glutamate was more prolonged with peak levels occurring ≥ 100 min. CHARACTERIZATION AND DEVELOPMENT OF [1251]IGF-I BINDING SITES IN THE SUPRACHIASMATIC NUCLEUS OF THE RAT HYPOTHALAMUS. K.M. Michels and J.M. Saavedra. LCS, NIMH, Bethesda, MD 20892.

Although insulin-like growth factor-I (IGF-

Although insulin-like growth factor-I (IGF-I) is involved in the growth and differentiation of a variety of neural and non-neural tissues specific receptors for IGF-I have also been demonstrated in the brain of the adult rat. One of the brain regions shown to exhibit [125]IGF-I binding is the suprachiasmatic nucleus (SCN) of the rat hypothalamus. In the present study we used quantitative autoradiography to characterize the specific binding of [125]IIGF-I used quantitative autoradiography to characterize the specific binding of [125 I]IGF-I within the SCN in vitro at equilibrium conditions. Saturation binding of [125 I]IGF-I at 0 °C revealed a single class of sites with a K₀ of 0.21 nM and a B_{max} of 82 fmoles/mg protein. Binding sites for [125 I]IGF-I were already

present at near-adult levels in the rat SCN at present at near-adult levels in the rat SCN at embryonic day 18. The receptor density doubled by postnatal day 1 then decreased precipitously to day 7, attaining near-adult levels by day 12 which remained constant thereafter. These results suggest that IGF-I may play a role particularly in the postnatal development of the SCN but also may have some role in regulating function of the adult SCN.

APPLICATION OF MK-801 INTO THE SUPRACHIASMATIC REGION ATTENUATES THE PHASE-SHIFTING EFFECTS OF LIGHT ON THE CIRCADIAN ACTIVITY RHYTHM OF THE HAMSTER. ALFRED B. LORD, FRED W. TUREK AND JOSEPH S. TAKAHASHI. Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Entrainment of mammalian circadian rhythms to environmental light cycles is

dependent on a branch of the optic nerve known as the retino-hypothalamic tract (RHT). Data implicating an excitatory amino acid neurotransmitter (EAA) in mediating the effects of light on the circadian clock in the suprachiasmatic nucleus (SCN) of the hamster have been presented (Colwell et al., Society for Research on Biological Rhythms Abstract #22, 1990). Although systemically applied antagonists of EAAs can block light-induced phase-shifting in hamsters, the site of action of MK-801 is not clear. For example, this effect could have its basis in the retina, known to utilize EAAs, or in a polysynaptic effect at or near the SCN. In order to test whether MK-801 acts in the SCN region, microinjections of the NMDA blocker were applied to the SCN region. were applied to the SCN region. Hamsters were implanted with a guide cannula in the SCN region and allowed to free-run in constant darkness. Light pulses were given at circadian time (CT) 19 at an intensity and duration to yield 70-80% of maximal phase shifts in the activity rhythm. MK-801 or vehicle were injected 10 minutes before the light pulse was presented. A second control group consisted of animals receiving only MK-801 at the appropriate CT. Each animal (n = 18) received all three treatments, but in different orders. Hamsters receiving the vehicle showed all three treatments, but in different orders. Hamsters receiving the vehicle showed the expected phase advances of approximately 120 min. in response to the light pulse. Those animals that received MK-801 before the light pulse showed a significantly decreased phase shift (p< .05) with a mean of about 60 min. MK-801 alone caused no significant phase shift. These results show that MK-801 application atome caused in signmean place saint. These results show that introduced application into the SCN region can attenuate light-induced phase shifts and are consistent with the hypothesis that an EAA transmitter in the region of the SCN is involved in lightinduced phase shifts in the circadian clock.

EFFECTS OF EXOGENOUS MELATONIN ON CIRCADIAN TIMING IN A NON-HUMAN PRIMATE. T. M. Hoban-Higgins* and C. A. Fuller. Dept. of Animal Physiology and California Primate Research Center, University of California, Davis, CA 95616. Melatonin administration has been shown to affect the circadian timing system of a variety of species. This study was designed to

examine the effect of daily melatonin administration on the circadian system of a non-human primate. Six individually housed, adult male squirrel monkeys were maintained in a constant environment (LL=30 lx). Drinking data were collected in half-hour bins. After a 50 day free-run to establish a baseline circadian pattern, a daily timed dose of melatonin was administered for 140 days (5 mg/kg D 51-77; 10 mg/kg D 78-191). As a control, the animals were given vehicle alone from day 191 to 214. Administration at this dose level was unable to produce consistent entrainment to the 24-h period of melatonin produce consistent entrainment to the 24-n period of melatonin presentation. However, a beating pattern in the rhythm period, analogous to relative coordination, is evident in the data. All six animals increased free-running period when melatonin was administered during their late subjective day-early subjective night and administered during their late subjective day-early subjective night and five of six shortened free-running period when administration coincided with late subjective night. This would occur if the melatonin produced phase delays in the early subjective night and phase advances late in the subjective night. It could not be determined if this beating pattern continued during the control portion of the experiment. Our results suggest that melatonin does have an effect on the circadian timing system of this diurnal primate. EVIDENCE FOR CENTRAL SITES OF MELATONIN ACTION. L.L. Badura & B.D. Goldman, Dept. Physiol. & Neurobiol., Univ. of Connecticut, Storrs, CT

The suprachiasmatic nuclei (SCN) of the hypothalamus are putative sites for central melatonin (MEL) action. In the Siberian hamster, the SCN are MEL binding sites, and lesions of this region render the animals unresponsive to the effects of exogenous MEL on the reproductive system. In this study, the effects of central MEL administration on testicular maturation were assessed in juvenile Siberian hamsters.

Hamsters were implanted with central microdialysis probes and were infused with one of two doses of MEL (0.75 ng or 0.075 ng/infusion) or saline for 12 days under long days (16L), with 5 hr infusions commencing 3 hr before lights out, or constant light (LL) with either 5 or 10 hr infusions. On day 13, all animals were anesthetized, perfused transcardially, the testes weighed, and the brains prepared for histological evaluation of the infusion site.

Animals housed in LL receiving either dose of MEL for 10 hr in the SCN region

had smaller testes weights than animals infused for only 5 hr, or animals infused with saline. The 5 hr infusions in 16L also delayed gonadal maturation at both doses. However, for the lower dose, infusions were effective only if centered in the SCN area, whereas the higher dose delayed maturation at slightly more dorsal levels if the third ventricle was also involved. Infusions in other periventricular regions were not effective unless there was substantial damage to the ventricle. Probes centered in the lateral hypothalamus had no effect on gonadal size. These results suggest that the SCN may play an important role in the central mediation of MEL-dependent physiological responses. However, it will be important to evaluate the effects of MEL administered at other sites near the SCN and other sites reported to exhibit uptake of labeled MEL.

AUTORADIOGRAPHIC LOCALIZATION OF 2-[125] IODOMELATONIN BINDING SITES IN THE BRAIN OF GROUND SQUIRRELS (CITELLUS BINDING SITES IN THE BRAIN OF GROUND SQUIRRELS (CITELLUS LATERALIS). Stanton, T.L., J.A. Siuciak¹, D.N. Krause² and M.L. Dubocovich¹. Dept. of Physiology, CSU, Long Beach, CA 90840; Depts. of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611 and ²UCI, Sch. of Med., Irvine, CA 92717. Melatonin (mel) may play a role in the modulation of brain arousal level. In earlier studies, using the hibernating ground squirrel as a model system, we demonstrated

significant variations in pineal mel level throughout the hibernation bout cycle. A direct correlation between mel level and the duration of individual bouts of hibernation suggested that mel availability might be one of the factors that determines bout duration. Subsequent work showed that ICV infusion of mel during hibernation could prolong the bout. The present study was undertaken to investigate possible CNS sites of mel action by determining the distribution of specific 2-iodomelatonin binding sites in the

brain of the golden-mantled ground squirrel.

Quantitative autoradiography was employed using 72-123pM 2-[125] iodomelatonin and 20u coronal brain sections of hibernating and awake animals. Non-specific binding was defined using 3uM mel. Initial results indicate discrete localization of specific binding in the region of the pars tuberalis that is significantly greater in awake compared to hibernating brain. The results are consistent with mel's ability to induce gonadal regression, a prerequisite for successful hibernation in ground squirrels. DEVELOPMENTAL APPEARANCE OF SPECIFIC BINDING SITES FOR 2-[1251]-IODOMELATONIN IN THE SYRIAN HAMSTER BRAIN AND PITUITARY. M.J. Duncan, K. Jaeck*, and F.C. Davis.
Dept. of Anatomy & Neurobiology, Univ. of Missouri Medical School, Columbia, MO 65212; Dept. of Biology, Northeastern Univ., Boston, MA 02115.

In Syrian hamsters, melatonin administration exerts both circadian and reproductive effects which are prevalent at different developmental stages and have different anatomical substrates. The circadian effects are most the suprachiasmatic nuclei (SCN); the reproductive effects occur during adulthood and do not require the SCN. In order to elucidated the basis for these effects of melatonin, the present studies investigated the regional distribution of specific 2-[125I]-iodomelatonin (IMEL) binding sites in the brain and pituitary of hamsters sacrificed at different ages (days relative to birth): sacrificed at different ages (days relative to birth): fetal (-2), neonatal (+2), prepubertal (+25) or adult (+119). Slide-mounted coronal sections through the diencephalon were incubated with IMEL (400 pM), washed and processed for autoradiography (Duncan et al, Endocrinol. 125:1011, 1989). Specific IMEL labelling was identified in the pars tuberalis and lateral habenular nucleus at all ages and in the SCN of fetuses and neonates but not older hamsters. These results suggest that specific IMEL binding sites are present by late gestation and that their density, at least in the SCN, may decrease during development.
