DESENSITISATION OF GABAA RECEPTOR CHANNELS IN PATCHES OF MEMBRANE EXCISED FROM CULTURED SPINAL CORD NEURONS. D.A. Mathers and Y. Wang. Physiology Department, University of British Columbia, Vancouver, B.C. V6T 1W5 Canada. Recent studies have shown that elevated intracellular Ca²⁺, [Ca²⁺]_i decreases the sensitivity of rat hippocampal neurons to externally applied y-aminobutyric acid (GABA) (Stetzler et al., Science, 242:339, 1988). In this study, we have examined the effect of intracellular calcium ions on the kinetic properties of GABAA receptor channels. properties of GABAA receptor channels. Embryonic mouse spinal cord neurons were removed at day E13 and maintained in Minimum removed at day E13 and maintained in Minimum Essential Medium for 14-21 days prior to use. Outside-out patches were bathed on both faces in solutions containing 145 mM chloride. [Ca²⁺]₀ was 1 mM, while [Ca²⁺]₁ was varied from 0.1 nM to 10 μ M using Ca-EGTA buffers. 5 μ M GABA induced a response which showed desensitisation at all [Ca²⁺]₁ levels tested. The open times of GABA induced single channel currents were fit by the sum of multiple exponentials. At high [Ca²⁺]₁ (1 μ M), the mean open time of GABA induced channels was significantly reduced when compared to values obtained in the presence of low [Ca²⁺]₁.

EFFECTS OF PROGESTERONE AND 3α -OH-DHP ON β -ALANINE-INDUCED CURRENTS IN CULTURED NEURONS. <u>F.-S. Wu. T.T.</u> Gibbs. and D.H. Farb. Dept. of Anatomy and Cell Biology, SUNY Health

Gibbs, and D.H. Farb. Dept. of Anatomy and Cell Biology, SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203.

We have previously shown that progesterone enhances GABA-induced choride currents and antagonizes those induced by glycine, and that its reduced metabolite 5α-pregnan-3α-ol-20-one (3α-OH-DHP) dramatically potentiates GABA-induced currents, but produces little effect on glycine responses. Here we examine the effects of these two steroids on currents induced by β-alanine in cultures of chick spinal cord neurons. Using whole-cell recording methods cells were voltage-clamped at -70 mV. Drug solutions were applied to single neurons by pressure ejection from 7-barrel pipettes. While pressure application of progesterone (100 μM) rapidly and reversibly reduced (by 31 ± 2.0%, in 6 cells) responses to 200 μM β-alanine, application of 3α-OH-DHP (1 μM) potentiated (by 116 ± 18%, in 6 cells) β-alanine responses. In the presence of 1 μM strychnine, a selective glycine receptor antagonist, both progesteron and 3α-OH-DHP potentiated β-alanine-induced currents. In 6 cells, the average potentiation produced by progesterone and 3α-OH-DHP was 264 ± 46% and 1621 ± 277%, respectively. In contrast, in the presence of 100 μM SR-95531, a selective GABAA receptor antagonist, inhibition of β-alanine-induced currents by progesterone was increased to 54 ± of β -alanine-induced currents by progesterone was increased to $54\pm4.6\%$ (in 6 cells) and 3α -OH-DHP produced a small inhibitory effect (10 $\pm2.8\%$, in 5 cells) on β -alanine responses. These results suggest that β -alanine activates both the glycine receptor and the GABA γ receptor.

REGULATION OF CATECHOLAMINE RECEPTORS

163.1

ACTIVATION OF DIACYLGLYCEROL-PHOSPHOINOSITOL PATHWAY BY DOPAMINE D2B RECEPTORS R.D. Todd, J. Hickock, and K. O'Mallev. Depts. Psychiatry, Genet. & Anat. & Neurobiol., Washington Univ. Sch. Med., St. Louis, MO 63110.

The intercellular signal dopamine interacts with two pharmacologically distinct types of neural receptors termed D1 and D2. The D1 receptor has been linked to activation of the cyclic AMP second messenger system. Contradictory reports have appeared about the inhibitory effects of D2 receptor on the cyclic AMP and the diacylglycerol-phospoinositol (DAG-PI) second messenger pathways. Bunzow et al. (Nature 336:783-787, 1988) reported the cloning of a cDNA for a rat D2 receptor which is a member of the G-protein coupled receptor gene family. This receptor, called here D2,, is capable of interacting with G-proteins and inhibiting adenylate cyclase activity. We recently reported on the isolation of a transfected cell line, DA10-4, which expresses a rat D2 receptor (Todd et al., PNAS 86:10134-10138, 1989) distinct from that found by Bunzow et al. Here, we report association of this novel D2 receptor (called D2₂) with activation of the DAG-P1 second messenger systems. Stimulation of D2₈ receptors with either PPHT or bromocriptine results in increases in intracellular calcium in DA10-4 cells. This increase can be blocked or reversed by application of D2 antagonists or increase can be blocked or reversed by application of D2 antagonists or increases. cells. This increase can be blocked or reversed by application of D2 antagonists or inorganic calcium blockers (Todd et al, 1989). Growth of DA10-4 cells for up to 12 hours in 0-0.5 μ g/ml pertussis toxin or 0-1.0 μ g/ml cholera toxin had no effect on calcium level changes, suggesting that the expressed receptors are not linked to Go, Gi, or Gs proteins. In contrast, the calcium increases were blocked in a dose dependent fashion by the protein kinase C inhibitor sphingosine $(E.C._{50} = 1 \, \mu M)$. PPHT stimulation also resulted in increases in free inositol-phosphate levels (IPI, IP2, and IP3) with the same time course as the calcium level changes. These results suggest that D2₈ receptors can activate the DAG-PI second messenger systems.

163.2

DOPAMINE D-2 RECEPTOR REGULATION BY Na⁺ AND H⁺ B. Tester and K.A. Neve. VA Medical Center and Oregon Health Sciences University, Portland, OR 97207. Regulation of ligand binding to dopamine D-2 receptors by Na⁺ may be due to sodium-dependent isomerization of D-2 receptors. We now describe selective regulation of ligand binding by H⁺. As shown in the table below, [H⁺] had little effect on the binding of the antagonists spinerone and buttedpart to D-2 by H⁺. As shown in the table below, [H⁺] had little effect on the binding of the antagonists spiperone and butaclamol to D-2 receptors. In contrast, K_f values for inhibition of the binding of [³H]spiperone by sulpiride and epidepride varied widely according to the pH of the binding assay. The affinity of agonists for D-2 receptors was also decreased by increasing [H⁺]. Binding of dopamine to D-1 receptors was not altered by changing pH from 6.5 to 8. Two lines of evidence suggest that effects of Na⁺ and H⁺ on D-2 receptors are related. First, greater pH-induced shifts in affinity were observed in the absence of Na⁺ than in the presence of 50 mM Na⁺. Second, the most pronounced changes in affinity induced by high [H⁺] were for drugs sensitive to Na⁺, such as substituted benzamides and agonists. such as substituted benzamides and agonists.

EFFECTS OF ADRENALECTOMY AND GLUCOCORTICOIDS ON RAT BRAIN DOPAMINE RECEPTORS. D.Biron*, T.Di Paolo, School of

BRAIN DOPAMINE RECEPTORS. <u>D.Biron*T.Di Paolo.</u> School of Pharmacy, Laval University and Dept. of Molecular Endocrinology, CHUL, Québec, Canada GIV 4G2

The behavioural responses to dopamine (DA) agonists has been shown to be influenced by adrenalectomy (ADX) (Eur.J. Pharmacol.152:255-261,1988). In order to investigate the possible mechanism of this response, we studied the effects of adrenalectomy (ADX) (28 days) and Dexamethasone (DEX) on the amount of D1 and D2 DA receptors by autoradiography using the D1 and D2 DA receptors by autoradiography using the D1 and D2 antagonists(3H-SCH 23390 and 3Husing the D1 and D2 antagonists (3H-8CH 23390 and 3H-Spiperone) in regions of the nigrostriatal and mesolimbocortical pathways. D1 and D2 receptors decreased in anterior striatum (AS) by 6% and 17% (P< 0.05 and 0.01), in median striatum (MS) by 10% (D2,P< 0.01) and of 31% (D1,P< 0.01) in substancia nigra (SN) in ADX rats vs control ovariectomized rats (OVX). DEX treatment (1mg/kg/d,I.M.,10 days) reversed these effects in AS (D1,D2,P< 0.01) in MS (D2,P< 0.01) and of SN (D1,P< 0.01) and SN (D1,P< 0.01) and SN (D2,P< 0.01) in MS (D2,P< 0.01) in MS (D2,P< 0.01) in MS (D2,P< 0.01) and SN (D1,P< 0.01) and SN (D1,P< 0.01) and SN (D2,P< 0.01) and 0.01) and in SN (D1,P< 0.05) vs ADX rats. DEX also increased the amount of D1 receptors in accumbens and MS by 10% (P< 0.01) vs OVX rats.It is known that ADX elevates and DEX decreases ACTH levels. However, our findings are unlikely due to ACTH ACTH levels. However, our lindings are unlikely due to ACTH since our results in striatal homogenates of rats treated with ACTH and corticosterone showed increased amount of D1 receptors such as following DEX treatment. Our results suggest a role of the adrenals in the modulation of DA activity in the rat brain that could be implicated in the behavioural changes occuring in stress . (Supported by the MRC of Canada)

DOPAMINE D1 AND D2 RECEPTORS IN RAT CORTEX: AUTORADIOGRAPHIC LOCALIZATION FOLLOWING NEUROTOXIC LESIONS. S. Giddings, M. Al-Tikriti, R. Kessler, R.H. Roth, and R.B. Innis. Dept. Psychiatry, VA Medical Center and Yale University, West Haven, CT 06516.

Relative to the dopaminergic (DA) innervation of cortex, the dopamine D1 and D2 receptors may be located "presynaptically" on DA terminals and/or "postsynaptically" on neurons intrinsic to cortex. To examine the relative neuronal distribution of these sites, we performed quantitative in vitro receptor autoradiography following a "presynaptic" lesion of DA terminals (with 6-hydroxydopamine (6-OHDA) injected into the medial forebrain bundle) or a "postsynaptic" lesion in cingulate and medial prefrontal (MP) cortex (with local injection of ibotenic acid).

Groups of male Sprague-Dawley rats received injections of 6-OHDA (pretreated with designamine for relative sparing of noradrenergic innervation); ibotenic acid; or vehicle. Approximately 10 days after injection, animals were killed, the brains removed, and 1 mm coronal tissue slabs cut in a brain mold. Cryostat sections (20 μ m) were used for quantitative receptor autoradiography with ¹²⁵I-epidepride (D2 ligand) and ³H-SCH23390 (D1 ligand). In a parallel group of animals, the cingulate and MP cortical areas were dissected from the 1 mm slabs for measurement of DA and DOPAC as a neurochemical characterization of the lesions. Results with D1 receptor autoradiography are pending.

D2 receptors are concentrated in cortical layers V and VI of cingulate and MP

cortex. Local injection of ibotenic acid caused a reduction of at least 70%, although the concentrations of DA and DOPAC were not significantly changed. In contrast, injection of 6-OHDA into the medial forebrain bundle caused no significant change in D2 receptor binding, but was associated with a 60% decrease of DA and a 40% decrease of DOPAC in cingulum.

These results suggest that the vast majority of D2 receptors in cingulate and MP cortex are not located on dopaminergic terminals, but rather "postsynaptically" to these terminals on neurons whose cell bodies are intrinsic to the cortex.

163.7

BOTH ISOFORMS OF THE D2 DOPAMINE RECEPTOR COUPLE TO A G PROTEIN-ACTIVATED K+ CHANNEL WHEN EXPRESSED IN GH₄ CELLS. L.C. Einhorn, P. Falardeau¹, M. Caron¹, O. Civelli² and G.S. Oxford. The Neurobiology Curriculum, University of North Carolina, Chapel Hill, NC 27599, ¹Dept. of Cell Biology, Duke University, Durham, NC 27710, and ²Vollum Institute, Portland, OR 97201.

Recent evidence suggests that the D2 dopamine (DA) receptor gene encodes two receptor isoforms (415 vs. 444 amino acids). The 444 a.a. splice variant differs from the short variant by an additional 29 a.a. insert in a variant differs from the short variant by an addutional 29 a.a. insert in a region thought to couple to G-proteins. In pituitary lactotrophs, D2 receptors activate K channels via a PTX-sensitive G-protein. To examine whether the two receptor isoforms differentially regulate such an effector mechanism, cDNA encoding either receptor isoform was transfected into prolactin-secreting GH₄ cells which lack D2 receptors. Receptor density was assayed by ³H-spiroperidol binding and two clones with equivalent levels of each isoform (2.0 pmol/mg protein) were used for patch clamp studies. Application of DA to cells expressing either receptor isoform results in a rapid membrane hyperpolarization (5-10mV) halting spontaneous spiking activity. Under voltage clamp, D2 agonists activate a current which reverses near $E_{\rm K}$ and voltage clamp, D2 agonisis activate a current which reverses hear Eg and shifts with extracellular [K+]. The K current response to DA was independent of [Ca++] or intracellular cAMP. DA responses were never observed in non-transfected cells, although similar K currents could be induced by somatostatin (SRIF). The DA response was slightly greater in cells expressing somatosatin (SKIF). The DA response was signify greater in tens expressing the long rather than the short isoform, however K current responses to SRIF differed similarly. Both the SRIF- and DA-activated K currents are sensitive to blockade by [TEA]_O and are abolished by PTX pretreatment. We suggest that both forms of the D2 receptor can functionally couple to K channels, and share a common signal transduction pathway with SRIF receptors.

163.4

STIMULATION OF PHOSPHATIDYLINOSITOL TURNOVER BY DOPAMINE D2 RECEPTORS IN RAT STRIATUM. S. Kito, R. Miyoshi and T. Nomoto*. Division of Health Sci., Univ. of the Air, Chiba 260 and Dept. of Pharmacology, Tokyo Women's Medical College, Tokyo 162, Japan.

Dopamine receptors are classified into D1 and D2 subtypes on the basis of their pharmacological and biochemical characteristics. The intracellular signalling system of D2 receptors has not been determined conclusively. It has been described that as well as the inhibition of adenylate cyclase, D2 receptors are linked to other signalling system. The authors investigated effects of dopamine on phosphatidylinositol (PI) turnover in the rat striatum. Overall agonists of DI and D2 receptors, both dopamine and apomorphine, caused stimulation of PI turnover. The effect of dopamine was dose-dependent. The dopamine effect was prevented by the D2 receptor antagonist, spiperone, while it was not by the D1 receptor antagonist, SCH23390. Pretreatment of striatal slices with islet-activating protein (IAP) caused a partial inhibition of the effect of dopamine. Neither forskolin nor tetrodotoxin affected stimulation of PI turnover elicited by dopamine. Above-mentioned results suggest that D2 receptors activate PI turnover in the rat striatum through an IAP-sensitive GTP binding protein. The second messenger system of D2 receptors is more complicated than previously thought.

163.6

QUANTITATION OF ISOTYPES OF D2 RECEPTORS USING SOLUTION HYBRIDIZATION. R.P. Artymyshyn, R.R. Luedtke, B.R. Monks, J.L. Neisewander, and P.B. Molinoff. Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Solution hybridization was used to quantitate the expression of two isotypes of the D2 receptor. Sequences corresponding to 450 bases of the coding region of the long form of the third intracellular loop (33) and full-length coding sequences of both the long and short forms of the D2 receptor were amplified using PCR, cloned into a Bluescribe (pBS+) plasmid vector, and sequenced. T3 RNA polymerase was used to synthesize a radiolabelled antisense riboprobe using the sequence of the long form of the third intracellular loop as a template. Sense RNA synthesized using the full-length coding sequence of the long and short isotypes of the D2 receptor was used to define specific hybridization. Hybridization was carried out overnight using one of the sense control RNA templates or total RNA isolated from tissue or cells. After hybridization with nucleases, hybridization products were size-fractionated on a urea/acrylamide sequencing gel. Autoradiographs of gels containing control RNA as template demonstrated distinct banding patterns. The i3 probe hybridized to the long-form sense RNA to reveal a single band of 410 bases. When the same probe was hybridized to the short-form sense RNA the probe was split into two bands, one of 290 bases and one of 68 bases. The pattern seen when total RNA from tissue was hybridized with the i3 probe revealed two major bands: one band corresponding to the long form of the receptor and the other corresponding to the hong form of the receptor and the other corresponding to the long form of the receptor and the other corresponding to the long form of the receptor and the other corresponding to the long form more thands. The long form probe form greater degree (>10:10). The development of this technique allows us to accurately measure the individual isotypes of mRNA co

NON-STEADY-STATE MEASUREMENT OF IN VIVO RECEPTOR BINDING WITH POSITRON EMISSION TOMOGRAPHY: SPECIFICITY ANALYSIS. J. S. Perlmutter, S. Moerlein, D-R. Hwang* and R. Todd. Departments of Neurology, Radiology, Psychiatry and Genetics, Washington Univ. Sch. of Med., St. Louis, MO 63110.

The purpose of this study is to determine the specificity of our nonsteady-state method for in vivo measurement of radioligand binding in brain with positron emission tomography (PET) and ¹⁸ F-spiperone (¹⁸ F-SP). Three to 6 studies were performed in each of 4 male baboons. Animals w pretreated with either ketanserin (S₂), eticlopride (D₂) or unlabeled SP to compete with ¹⁸F-SP for specific binding sites. We measured regional blood flow, blood volume and total binding in blood of ¹⁸F-SP. After i.v. injection of ¹⁸F-SP, sequential PET scans and arterial-blood samples were collected for 3 hrs. Data were analyzed with a 3-compartment model that considered the accumulation of radiolabeled metabolites in arterial blood. Four baboons were sacrificed and SP binding was measured with in vitro homogenate techniques. There was no detectable in vitro or in vivo specific binding of SP in cerebellum. In vitro specific binding of SP in specific bilding of 3r in cerebellatin. In who specific bilding of 3r in striatal tissue was 76% to D₂ sites and 24% to S₂ sites, whereas, about 34% of apparent in vivo specific binding in striatum could be blocked by ketanserin and 70% blocked by eticlopride. The close relationship between in vitro and in vivo findings further validates this PET method although the modest differences may result from the relatively poor resolution of PET.

DOPAMINE-STIMULATED LOW K_M GTPASE ACTIVITY IN RAT AMYGDALOID COMPLEX. J.E. Lachowicz, S.E. Eldon and C.D. <u>Kilts</u>. Dept. of Pharmacology, Duke Univ. Med. Ctr., Durham. N.C. 27710.

Striatal D_1 and D_2 dopamine receptors are functionally classified by their ability to stimulate and inhibit adenylate cyclase activity via interaction with the guanyl nucleotide binding proteins, $\mathbf{G_S}$ and $\mathbf{G_i}$, respectively. We have demonstrated that in the amygdaloid complex, neither D_1 nor D_2 receptors influence adenylate cyclase activity. To determine whether amygdaloid dopamine receptors are coupled to G-proteins despite their apparent non-coupling with adenylate cyclase, the effects of dopamine on low $K_{\rm m}$ GTPase activity were assessed. Dopamine (100 uM) stimulates GTPase activity in the amygdala to the same degree as in the striatum. The \$\delta\$-opiate agonist D-pen,D-pen enkephalin (10 uM) and the muscarinic cholinergic agonist carbachol (1 mM) also increase low

These results suggest that amygdaloid dopamine receptors regulate the activity of G-proteins coupled to effectors other than adenylate cyclase. Character-ization of the pharmacology of the dopamine receptor and G-protein subtypes involved will be presented. (Supported by NIGM-5T32GM07105 and MH-39967).

REGULATION OF D, DOPAMINE RECEPTOR FUNCTION IN NS20Y CELLS: ROLE OF G-PROTEINS.

T.W. Lovenberg¹, D.E. Nichols³, E.J. Nestler⁴, R.H. Roth⁴, R.B. Mailman¹¹² Pharmacology¹ and Psychiatry², Univ. North Carolina, Chapel Hill, NC 27599; Med. Chem. and Pharmacology and Psychiatry⁴, Yale Univ., New Haven, CT 06510.

NS20Y neuroblastoma cells possess D, receptors and muscarinic receptors that are linked to the stimulation and inhibition of adenylate cyclase, respectively. To study these processes, cyclic AMP was measured in intact cells following either cholera or pertussis toxin treatment. Pretreatment with pertussis toxin (100 ng/ml), which ribosylated >95% of G, caused the complete loss of muscarinic induced inhibition. Dihydrexidine (a D₁ agonist) on forskolin (a direct activator) stimulated cAMP accumulation were unaffected. Conversely, cholera toxin dose-dependently induced large accumulations of cAMP. At low cholera toxin concentrations, dihydrexidine (300 nM) was an effective stimulus. However, when cholera toxin was >100 ng/ml, dihydrexidine was ineffective, whereas forskolin (1 µM) could still enhance cAMP accumulation. These data suggest that adenylate cyclase in NS20Y cells is linked to regulated by both stimulatory and inhibitory G-proteins linked to whereas forskolin (1 μ M) could still enhance cAMP accumulation. These data suggest that adenylate cyclase in NS20Y cells is regulated by both stimulatory and inhibitory G-proteins linked to D, and muscarinic receptors, respectively. Interestingly, dihydrexidine-stimulated cAMP accumulation was additive with forskolin-stimulated cAMP accumulation at low forskolin concentrations (10 nM-3 μ M), but synergistic at high forskolin (3-100 μ M) concentrations, suggesting possible interactions between activated G₈ and the catalytic unit of adenylate cyclase in this cell type.

163.10

HETEROLOGOUS DESENSITIZATION OF D1 DOPAMINE RECEPTOR-COUPLED ADENYLYL CYCLASE ACTIVITY IN NS20Y NEUROBLASTOMA CELLS. Anne C. Barton. Lauren E. Black, and David R. Sibley. Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

8-(4-chlorophenylthio)-adenosine-3':5'-cyclic monophosphate (CPT-

cAMP), a membrane permeable analogue of cAMP, induced heterologous desensitization of D₁ receptor-coupled adenylyl cyclase (AC) activity in NS20Y neuroblastoma cells. Membranes prepared from these cells showed a 55-75% reduction in maximal DA-induced stimulation of cAMP production responsiveness to adenosine was also decreased by 60%, while AC responsiveness to PGE₂, sodium fluoride and forskolin was decreased 15-20%. Desensitization of D₁ receptor-coupled AC activity by CPT-cAMP was time-dependent, exhibiting a maximal effect by 20 hr and an approximate t_{1/2} of 6 hr. CPT-cAMP treatment also induced down-regulation of D₁ receptor binding activity, the time course and extent of which matched AC inactivation. Saturation analysis with ³H-SCH-23390 after 24 hr CPT-cAMP treatment indicated that the loss of binding activity was predominantly due to a decrease in the B_{max}. Similarly, following 24 hr CPT-cAMP treatment, DA dose response curves for stimulation of cAMP production indicated that the predominant desensitizing effect is a reduction in the maximal responsivesness of the enzyme to DA. In addition, agonist/³H-SCH-23390 competition curves following CPT-cAMP treatment demonstrated a loss in competition curves following. The effect of CPT-cAMP on D₁ dopamine receptor coupled AC activity and binding was dose-dependent, exhibiting an IC_{50} of = 50 μ M, and was specific for cAMP as 8-bromo-AMP produced negligible effects on both AC activity and binding. These data suggest that cAMP mediates a heterologous form of desensitization of the D₁ receptor involving functional uncoupling and receptor downregulation.

CELL BIOLOGY OF CATECHOLAMINE RECEPTORS

164.1

DEVELOPMENTAL EXPRESSION AND REGIONAL DISTRIBUTION DEFAULT ALL LANGE AND REDIGINAL DISTRIBUTION OF A FAMILY OF ALPHA ADRENERGIC RECEPTORS IN THE RAT BRAIN. Susan K. McCune and Mark M. Voigt. Lab. of Developmental Neurobiology, NICHD, and Lab. of Mol. Biol., NINDS, NIH, Bethesda,

Multiple subtypes of adrenergic receptors have been identified by a combination of molecular biological and pharmacologic techniques. However, it has been difficult to differentiate various subtypes of these receptors in tissues based on rank-order potencies of agonists and antagonists. In order to examine the regional and developmental expression of multiple alpha adrenergic receptor subtypes in the brain, we have isolated clones from a rat brain cDNA library for the alB, a2A, and

AZD adrenergic receptors.

Northern blots of mRNA from various brain regions in the adult rat were probed with random-primed DNA derived from each of the subtypes. These blots indicated that all three subtypes are present in the subtypes. cortex, hippocampus, hypothalamus, midbrain, brainstem and cerebellum. The α 2D receptor message was strongest in the cortex, hippocampus, hypothalamus and cerebellum and weakest in the midbrain and brainstem. The mRNA transcript for the α 2A receptor was most abundant in the hypothalamus with an equivalent but lower representation in the other areas. The $\alpha 1B$ receptor message showed a fairly uniform distribution throughout the brain regions examined. The ontogenic expression of these receptors was also studied using these three probes. The mRNA transcripts for the α 2D and α 1B clones showed an increase in abundance from embryonic day 18 through adult while the transcript for the α 2A

remained constant prenatally and then declined into adulthood.

These results document a unique regional and developmental expression for three subtypes of adrenergic receptors. This receptor diversity may play an important role in modulating the physiologic responses to catecholamines

GENERATION OF A DNA PROBE FOR THE ALPHA₂-ADRENERGIC RECEPTOR IN AN OPOSSUM KIDNEY CELL LINE (OK). <u>H.S. Blaxall and D.B. Bylund.</u> Department of Pharmacology, University of Nebraska Medical Center, Omaha, NE 68198-6260.

Previous studies from our laboratory have characterized an alpha₂-adrenergic receptor in the OK cell (Murphy, T.J. and Bylund, D.B., <u>J. Pharmacol. Exp. Ther.</u>, 244:571-578, 1988). As a preliminary step in cloning the receptor, the polymerase chain reaction (PCR) was utilized to generate a probe for this receptor. Using the published sequences of the human α₂ receptors C₄ and C₁₀, oligonucleotide primers were developed to transmembrane regions I and VII. RNA was isolated from OK cells using an Applied Biosystems nucleic acid extractor. Between 1.5-2 μg of this RNA was reverse transcriptase. The resulting cDNA's subjected to 30 cycles of PCR with the above primers, yielding a product of the expected size of approximately 1 kb. PCR was also used on HPα2GEN (a plasmid containing alpha₂ C₁₀ to produce a 0.6 kb fragment labeled by the random primer method hybridized strongly to the 1 kb PCR product from the OK cDNA. This 1 kb product is currently being used as a probe in a lambda gt11 OK cell cDNA library (Supported by NIH grant GM 40784).

NORADRENERGIC AND NON-NORADRENERGIC RECEPTOR BINDING OF [1251] IODOCIONIDINE (ICLO) IN HUMAN TISSUE. J.E. Piletz and G.A. Ordway, Depts. Psychiatry, Neuroscience & Pharmacology, Case Western Reserve Univ. Cleveland. 04 44109.

acology, Case Western Reserve Univ. Cleveland, OH 44109.

LIGAND computer analysis revealed two high affinity sites for ICLO in normal human platelet purified plasma membranes and in frontal cortex lysates. The two sites were highly comparable between tissues: in platelets KD1=.09 nM(±1.05 SD) & Bmax1= 55 fmol/mg prot.(±23 SD), while KD2=1.9 nM(±1.7 SD) & Bmax2= 200 fmol/mg (±54 SD) (n=3). In frontal cortex, KD1=.12 nM(±0.7 SD) and Bmax1=56 fmol/mg(±38 SD) while KD2=1.7 nM(±1.1SD) & Bmax2=191 fmol/mg(±57 SD) (n=7). Both sites were GTP sensitive. Sitel was displaced at high affinity by (-)norepinephrine (NE),clonidine(CLO),and yohimbine(YOH). However,site2 was not significantly displaced by NE even at 10uM; apparently an imidazoline-preferring (IZP) site. Expressed as percent of specific 0.3nM ICLO binding (± 10uM YOH), 10uM NE displaced only 60% (=A2 adrenoceptors), but 10uM CLO or YOH displaced the additional 40% (=IZP sites) in cortex and platelets. Autoradiography at 0.3nM ICLO revealed the same in entorhinal cortex (EC) layer 1. However, in EC layers 2-4,and 5 & 6, IZP sites predominated (>80%). In dentate gyrus and hippocampal layer CA4, ICLO was displaced equally by 10 uM of NE, CLO or YOH (100% adrenoceptors). In pyramidal and molecular CA1 layers ICLO was about 80% displaceable by NE and CLO (80% adrenoceptors,no IZP sites) but 20% more was displaced by YOH. Relevance is to the design of ICLO binding studies in pathological states.

IDAZOXAN BINDS "IMIDAZOLINE-PREFERRING" SITES AND ALPHA2 NORADREMERGIC RECEPTORS IN HYPOTHALAMUS. P. A. VINCENT, C. P. REBULLEAU* AND H. H. FEDER Biol. Sci. Rutgers University, Newark, NJ 07102

The imidazoline clonidine, an alpha2 noradrenergic (NA) receptor agonist, has been used to study reproductive behavior in rodents. We have shown that another imidazoline idazovan a mitative

The imidazoline clonidine, an alpha₂ noradrenergic (NA) receptor agonist, has been used to study reproductive behavior in rodents. We have shown that another imidazoline, idazoxan, a putative alpha₂ NA receptor antagonist, blocks steroid-dependent female reproductive behavior in guinea pigs. In the present work, we investigated the binding properties of idazoxan and the alpha₂ NA antagonist yohimbine in guinea pig hypothalamus. We demonstrated that: 1) A number of alpha₁ and beta NA selective drugs compete with only low affinity for idazoxan binding sites. 2) Yohimbine, epinephrine and norepinephrine displace idazoxan poorly (IC₅₀ = 5.5 x 10⁻⁶ M, 2.5 x 10⁻³ M and 7.5 x 10⁻³ M, respectively). 3) Imidazolines such as cluaneber displace idazoxan with high affinity. This evidence suggests that idazoxan and other imidazolines bind to hypothalamic alpha₂ NA sites as well as non-alpha₂ NA sites. Brain "imidazoline-preferring" sites are probably involved in the central regulation of blood pressure and may also be involved in modulation of steroid-dependent reproductive behavior.

⁸H-ATIPAMEZOLE, A NEW a_2 -ADRENOCEPTOR RADIOLIGAND FOR RECEPTOR BINDING STUDIES T. Miettinen, R. Voutilainen, J-M. Savola, B. Sjöholm, L. Ahtee, M. Scheinin, Dept. of Pharmacol, Univ. of Turku, SF-20520 Turku, 'Farmos-Group Ltd., Turku, ²Dept. of Pharmacy, Univ. of Helsinki, Finland

Atipamezole (ATI, 4-(2-ethyl-2,3-dihydro-1H-inden-2-yl)-1H-imidazole) is a novel potent, specific α_s -adrenoceptor antagonist with a high α_s/α_τ -selectivity ratio. We have now carried out a preliminary investigation of the suitability of ³H-ATI (65 Ci/mmol, NEN) as a radioligand for in vitro receptor binding studies, performed essentially as described by Bylund (JPET 245:600, 1988). ³H-ATI, and for comparison, ³H-rauwolscine (RAU) (both at 0.02-4.0 nM), were incubated with the membranes in the absence and presence of phentolamine (PHEN, 10 uM) or norepinephrine (NE, 50 uM) to determine the specificity of the observed binding, ³H-ATI binding equilibrated rapidly, and was also readily reversible upon addition of competing drugs. Scatchard analysis indicated that ³H-ATI labelled one population of sites, with Hill coefficients near unity. Compared to ³H-RAU, ³H-ATI labelled significantly more PHEN-defined sites in rat brain cortical (B_{max} 460 vs. 80 fmol/mg prot) and neonatal rat lung membranes (230 vs. 100), whereas in human blood platelets the number of binding sites detected was in closer agreement (250 vs. 190). With NE, both radioligands yielded approximately equal B_{max} values. The affinity of ³H-ATI was somewhat higher than that of ³H-RAU (K_D 0.1-0.8 vs. 0.4-0.8 nM), particularly in rat brain cortex. ³H-ATI thus appears to possess promising potential as an α_z -adrenoceptor radioligand, but further validation with competing drugs is required before its introduction into routine use. The higher PHEN-defined B_{max} values compared to ³H-RAU in some tissues probably reflect binding to imidazole-preferring sites.

Subnuclear Distribution of Alpha₂-Binding Sites in the Rat Parabrachial Nucleus. <u>H.Herbert¹, G.Flügge², and E.Fuchs²;</u> ¹Univ. of Tübingen, Dept. Animal Physiol., Morgenstelle 28, 7400 Tübingen, FRG; and ²German Primate Center, Kellnerweg 4, 3400 Göttingen, FRG.

The parabrachial nucleus (PB) is composed of several subnuclei which have distinct cyto- and chemoarchitectonic properties and specific sets of afferent and efferent connections. We investigated the distribution of ³H-rauwolscine (³H-RAUW) binding sites to elucidate whether the anatomical diversity of PB subnuclei is also reflected by a differential distribution of alpha₂-adrenocentors.

Five different areas of the PB complex were analyzed: the Kölliker-Fuse nucleus (KF), the medial (m)PB, the lateral (l)PB, the external lateral (el)PB, and the 'waist area". The largest number of binding sites were found in the elPB (B_{max}:280 fmol/mg), and in the 'waist area' (220 fmol/mg), followed by the IPB (180 fmol/mg). The mPB (150 fmol/mg) and the KF (130 fmol/mg) exhibited only few binding sites for ³H-RAUW. Scatchard analyses revealed that the binding sites in different PB subnuclei also have different affinities for the ligand. K_D-values were lowest in the elPB, the IPB and the "waist area" with K_D:6.8mM, 7.3nM, and 10.6nM, respectively. Fairly high K_D-values were found in the mPB and the KF (K_D:15.7nM and 16.1nM, respectively), indicating a low affinity for the ligand.

the ligand.

To summarize, ³H-RAUW binding demonstrates that each subnucleus in the PB exhibits a distinct pattern of alpha₂-adrenoceptors. The highest B_{max}-values were found in those PB subnuclei that receive catecholaminergic afferents from the medial nucleus of the solitary tract. Experiments are currently performed to examine the response of alpha₂-binding sites to different types of deafferentiation such as the selective depletion of the noradrenergic innervation.

DETECTION OF α_2 -ADRENOCEPTOR SUBTYPE GENE EXPRESSION IN CULTURED MAMMALIAN CELLS M. Scheinin, A. Marjamāki, M. Perālā, R. Voutilainen, B. Sjöholm, J.W. Regan'. Dept. of Pharmacol., Univ. of Turku, SF-20520 Turku, Finland, and 'Dept. of Pharmacol. & Toxicol., College of Pharmacy, Univ. of Arizona, Tucson, AZ 85721 (SPON: European Neuroscience Association)

Chinese hamster lung fibroblasts, transfected with the dexamethasone-inducible mammalian expression vector pMAMneo, have been used to express human platelet (a_2 –C10) and human kidney-type (a_2 –C4) a_2 -adrenergic receptors. Expression levels in the resulting cell lines were quantitated by two different assays. Ligand binding studies with ${}^3\text{H}$ -atipamezole (0.03–4 nM), a novel subtype-nonselective a_2 -antagonist, showed 4 to 5-fold increases in receptor density in crude membrane preparations from dexamethasone-treated cells. Parallel increases in receptor subtype gene expression were also seen in Northern blot analysis of both total and poly–A'–RNA. With the full length a_2 –C4 and a_2 –C10 cDNAs as probes, subtype–specific mRNA species of about 4.5 kb and 3.5 kb were recognized. Recombinant DNA techniques are increasingly used to express neurotransmitter and drug receptors in cell cultures for studies on the molecular

Recombinant DNA techniques are increasingly used to express neurotransmitter and drug receptors in cell cultures for studies on the molecular mechanisms of drug action. This approach necessitates the development of practical and sensitive detection methods for receptor subtype gene expression in small samples.

ALPHA2-ADRENERGIC INHIBITION OF NEURALLY-MEDIATED SECRETION IN PORCINE DISTAL JEJUNUM (PDJ). Keith R. Hildebrand and David R. Brown. Dept of Vet Biol, U of Minnesota, St Paul, MN 55108

Electrical transmural stimulation (ETS) delivered to muscle-stripped

Electrical transmural stimulation (ETS) delivered to muscle-stripped PDJ mucosa mounted in Ussing chambers evokes a neurally-mediated increase in short-circuit current (Isc) attributable to active anion secretion. In this study we examined the effects of norepinephrine (NE) on the ETS-evoked increases in Isc. Serosal NE inhibited ETS-evoked increases in Isc with an EC50 of 23 nM and complete inhibition at 10 μ M. The secretory actions of carbachol which acts directly on epithelial cells remained unaffected by NE. The cardenergic antagonists, phentolamine and yohimbine, at 1 μ M produced respective 8 and 38-fold decreases in NE potency. Propranolol and prazosin, β and α_1 -adrenergic antagonists respectively, at 1 μ M did not after the NE potency. Desipramine (10 μ M), a blocker of neuronal NE reuptake, enhanced NE potency by 1000-fold. In the presence of desipramine, the α_2 -adrenergic agonist p-aminoclonidine was extremely potent (EC50 = 5 pM) in inhibiting ETS responses relative to the α_1 -adrenergic agonist phenylephrine (EC50 = 40 nM). Dopamine and isoproterenol, a β -agonist, were weak agonists with EC50's > 10 μ M. Tyramine, a releaser of endogenous NE, like NE produced a concentration-dependent inhibition of ETS-evoked responses which was antagonized by phentolamine (1 μ M). These results suggest that (i) NE inhibits electrically-evoked anion secretion by acting at α_2 -adrenergic receptors located on submucosal neurons, and (ii) PDJ submucosal neurons receive functional NE inputs.

MULTIPLE MECHANISMS OF CATECHOLAMINE INDUCED GLYCOGENOLYSIS IN BRAIN TISSUE: INVOLVEMENT OF a1-ADRENORECEPTORS. T.T. Ouach, M. Dam*, F. Brion*, C. Rose* and A.M. Duchemin. INSERM U109, 2ter Rue d'Alesia. Paris 75014. France.

We have previously shown that noradrenaline stimulated the hydrolysis of 3H-glycogen in mouse brain slices. This effect is selectively mediated by \$1receptors. However, in the liver, the glycogenolytic effect of catecholamine can be mediated either by the B-adrenergic receptor or by a typical cAMP-independant a1-adrenergic receptor. Based on these findings, we propose to examine whether similar plasticity can be observed in brain tissue. To eliminate the β 1-adrenergic receptor component, adrenergic drugs selective for α receptors were used to explore the particitation of the α -adrenoreceptors. Addition of phenylephrine and methoxamine, two relatively potent a1adrenoreceptor agonists produced a clear concentration-dependent hydrolysis of newly synthetized 3H-glycogen. Their apparent Ka values were 2.04.0.1 µM and 15±0.1 µM respectively. This effect was selectively inhibited by a1-receptor antagonists, such as WB401, prazocin and phentolamine. A selective a2-adrenoreceptor agonist, clonidine, 0.1 μ M, did not produce any significant glycogenolytic response. The glycogenolytic response to α 1-adrenoreceptor agonists was markedly reduced when the extracellular calcium ion was lowered to 0.3 µM. Thus, the glycogenolytic response to a1 receptor agonists could involve calcium as a second messenger as other responses mediated by a1 adrenoreceptors.

HUMAN CEREBRAL MICROVASCULAR ENDOTHELIUM ANALYSIS OF ADRENERGIC RECEPTORS LINKED TO ADENYLATE CYCLASE. F. Bacic*, Uematsu*, R. McCarron* and M. Spatz. LNNS, NINDS, NIH, Bethesda, MD 20892 and Johns Hopkins Hospital, Baltimore, MD.

Receptors for neurohormones coupled to quanine nucleotide regulatory protein were detected in cultured endothelial cells (EC) derived from three fractions of human cerebral microvessels (Spatz, derived from three fractions of numan cerebral microvessels (Spatz, 1989). This report characterizes adrenergic receptors linked to adenylate cyclase (AC) activity in cultured EC dissociated from capillaries (CA) small [SM (< 50 μ M)] and large [LM (> 50 μ M)] arterioles and venules. Catecholamines and their analogues dosedependently increased endothelial production of cAMP in all cultures. The specific antagonists for β_1/β_2 (propranolol), β_2 (butoxamine), β_1 (atenolol), α_1 (prazosin) and $\alpha_2\text{-agonist}$ (clonidine) dosedependently blocked the stimulatory effect of isoproterenol. EC50 for isoproterenol was 5.27 x 10⁻⁸ M, 3.16 x 10⁻⁸ M and 1.9 x 10⁻⁹ M for EC derived from CA, SM and LM, respectively. The β_1/β_2 , β_2 - and $\beta_1\text{-type}$ antagonists inhibited the isoproterenol AC stimulation with IC_{50} for propranolol 9.1 x 10⁻¹¹ M (CA), 2.4 x 10⁻¹¹ M (SM) and 1.9 x 10⁻¹¹ M (LM); for butoxamine 1.8 x 10⁻¹³ M (CA), 1.1 x 10⁻¹¹ M (SM) and for atenolol 5.8 x 10⁻¹¹ M (CA) and 1.1 x 10⁻¹¹ M (SM). Endothelial AC responsiveness to adrenergic agonists and antagonists is segmental in nature. Only endothelial β_2 - and α_2 -adrenergic receptors linked to AC activity were reported in cultured brain EC. This is the first demonstration of β_1 - and α_1 -adrenergic receptors coupled to AC activity in microvascular EC of human brain.

DIURNAL AND GLUCOCORTICOID REGULATION OF BETA ADRENERGIC RECEPTORS IN THE RAT HIPPOCAMPUS. H.M.Chao, H.Coirini, T.T.Silverstein* and B.S.

H.M.Chao, H.Coirini, T.T.Silverstein* and B.S. McEwen. Rockefeller University, N.Y., N.Y. 10021.

In the hippocampus, which is highly sensitive to diurnal changes in serum McEwen. Rockefeller University, N.Y., N.Y.10021.

In the hippocampus, which is highly sensitive to diurnal changes in serum glucocorticoids, there is a circadian rhythm to glucocorticoids, there is a circadian rhythm to the noradrenaline stimulated cAMP accumulation that is abolished by adrenalectomy (ADX). We investigated the hypothesis that the diurnal rhythm in cAMP is mediated by glucocorticoid regulation of the β adrenergic receptors in the hippocampus. The expression of the $\beta 1$ and the $\beta 2$ adrenergic receptor ($\beta 1AR$ and $\beta 2AR$) in the hippocampus was determined by receptor autoradiography (to assess receptor binding levels) and by in situ hybridization (to assess receptor mRNA levels). Animals were intact or ADX and were sacrificed at intervals throughout receptor mRNA levels). Animals were intact or ADX and were sacrificed at intervals throughout the light/dark cycle. There was less $\beta 2AR$ binding in the hippocampus than $\beta 1AR$ binding and this was mirrored in the expression of the respective receptor mRNAs. The levels of $\beta 2AR$ binding and mRNA were not affected by the time of day or by ADX. However there was a diurnal rhythm in the expression of the $\beta 1AR$, both in receptor binding and in mRNA levels, that was altered by ADX. (Supported by MH41256.)

SITE-DIRECTED MUTAGENESIS OF HUMAN ALPHA_{2A}-ADRENERGIC RECEPTORS IDENTIFIES AMINO ACID RESIDUES INVOLVED IN LIGAND BINDING AND AGONIST ACTIVATION. Cheng-Dian Wang*, Melissa A. Buck* and Claire M. Fraser. Section on Mol. Neurobiology, LPPS, NIAAA, Rockville, MD 20852.

The functional significance of conserved aspartic acid (Asp) and serine (Ser) residues in transmembrane domains (TMD) of human α_{2A} -adrenergic receptors (α -AR) was examined by sitedirected mutagenesis and permanent expression of mutant receptor genes in CHO cells. Substitution of Asp⁷⁹ with Asn had no effect on antagonist or imidazoline agonist binding but increased α -AR affinity for β -phenethylamine agonists. Asn⁷⁹ mutant α -AR were unable to mediate agonist-induced changes in forskolin-stimulated cAMP levels. Substitution of Asp¹¹³ with Asn eliminated the ability of mutant α-AR to bind [3H]with Ash eliminated the ability of mutant α-AR to bind [4]-yohimbine, consistent with previous findings on the role of this Asp in ligand binding to β-AR and muscarinic receptors. Replacement of Asp¹³⁰ with Ash had no effect on ligand binding but altered cellular responses to epinephrine. Wild type α-AR expressed in CHO cells mediate both inhibition and type α -AR expressed in CHO cells mediate both inhibition and potentiation of forskolin-stimulated cAMP accumulation; Asn¹³⁰ mutant α -AR only inhibit cAMP production in response to agonist. Ser²⁰⁰ in the 5th TMD appears to be involved in interaction with the *meta*-hydroxyl group of catecholamines. These data together with our previous work indicate differences in ligand binding to α -AR and β -AR, but suggest common mechanisms of receptor activation.

BIOCHEMICAL STUDIES OF BETA ADRENOCEPTOR FUNCTION IN VIVO IN THE RAT CEREBRAL CORTEX. E.A. Stone and S.M. John*, Dept. Psychiatry, New York University Sch. Med., New York, NY 10016.

Previous research in brain slices has shown that the cAMP response to beta receptor activation in the rat cortex is mediated primarily by beta-l receptors and appears to occur largely in glial cells. Whether these findings hold for the brain in vivo is not known. To examine this question we have employed a newly devised method for studying beta receptor function in vivo which involves microdialysis measurement of extracellular brain cAMP. Rats implanted with microdialysis probes in the prefrontal cortex were infused with norepinephrine in the presence or absence of a beta-1 antagonist (ICI 89,406), a beta-2 antagonist (ICI 118,551) or a selective glial metabolic inhibitor, fluorocitrate (FC). It was found, in preliminary experiments, that the beta-l blocker was more effective than the beta-2 in attenuating the cAMP response to NE. FC, however, had equivocal effects, producing a significant reduction when given alone but not when given with a NMDA receptor blocker (aminophosphonovaleric acid) to inhibit FC-induced convulsions. The results suggest that the in vitro finding of beta-l predominance for the cAMP response in the cortex holds for in vivo conditions but the role of the glia in the in vivo response is as yet unclear Supported in part by grants AFOSR 89-0208 and MH45265.

CHRONIC EXPOSURE OF RAT GLIOMA C, CELLS TO OXAPROTILINE REDUCES THE DENSITY OF BETA ADRENOCEPTORS. D.H. Manier*, Vanderbilt Univ. Sch. of Med., Nashville, TN 37232

The (+)-enantiomer of oxaprotiline (O) blocks the neuronal uptake of norepinephrine (NE), down-regulates the density of beta adrenoceptors (BAC) in brain and de amplifies the NE signal while the (-)-enantiomer is devoid of these pharmacological properties. In cultured rat glicma C₆ cells (C₆), both enanticmers of O reduce the B_{max} value of BACs with equal potency without a change in B value of BACs with equal powers, which is a compe-walues. Since nonlinear regression analysis of compe-tition binding curves revealed that the bulk of BACs in in C displays high nanomolar affinity for isoproterenol (I), a deamplification of the BAC signal following both enantiomers is implied. While the down-regulation by I occurs rapidly with a significant effect at 15 minutes and a maximal effect at 2 hours, at least 48 hours are required for the enantiomers of O to elicit a significant reduction in BAC density. I still elicits the same degree of down-regulation of BACs in (-)-O treated cells as in control preparations and is blocked by co-incubation with propranolol. Though the beta antagonist seems not to affect the (-)-O induced down-regulation of BACs, drug interactions preclude an unequivocal interpretation of the data. The results with (-)-O suggest a novel BAC deamplification that is independent of an agonist receptor interaction (Supported by USPHS Grant MH-29228).

PERIPHERAL ADRENERGIC RECEPTOR FUNCTION IN DEPRESSED PATIENTS E.S. Werstiuk, M. Coote*, and M. Steiner. Departments of Biomedical Sciences and Psychiatry, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Alterations in adrenergic receptor function have been implicated in depression, and modulation of receptor sensitivity is thought to be the mechanism of action of effective antidepressant treatments. The present study was undertaken to evaluate platelet α_2 - and leukocyte, B_2 -adrenergic receptors in depressed patients and to assess the effect of ECT treatment on these parameters. Subjects were 13 acutely depressed patients, treated with ECT, and 18 subjects served as controls. We measured adrenergic receptors binding parameters (Bmax and Kd) in intact platelets (*H-Yohimbine) and in intact leukocytes (125I-Cyanopindolol) and receptor function, 8-agonist stimulated, and α_2 -agonist inhibited cAMP levels in leukocytes and platelets respectively. All parameters were determined pretreatment and 14 days after the last ECT. Bmax of 3H-Yohimbine binding was significantly elevated in untreated patients compared to controls (p<0.05). We found no patient/control differences in any other parameters measured. Treatment with ECT led to enhanced receptormediated cAMP levels in both platelets, and leukocytes, but this did not reach statistical significance. Binding affinity for ³H-Yohimbine increased in platelets of ECT treated patients and was significantly different from those of controls (p<0.01). Our findings support the hypothesis that in depressed patients platelet a2-receptor densities are elevated. The effects of ECT, however will require further clarification. Supported by the Ontario Mental Health Foundation.

CO-DISTRIBUTION OF D₁ RECEPTOR mRNA AND D₁ RECEPTOR BINDING IN THE RAT BRAIN: AN <u>IN SITU</u> HYBRIDIZATION RECEPTOR AUTORADIOGRAPHIC ANALYSIS. A. Mansour J.H. Meador-Woodruff, Q.Y. Zhou *, O. Civelli*, H. Akil, and S.J. Watson Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0702; Vollum Institute for Advanced Biomedical Research, The Oregon Health Sciences University, Portland, OR 97201

The Oregon Health Sciences University, Portland, OR 97201
The recent cloning of the D₁ dopamine receptor (Zhou et al, Nature, submitted) suggests that it is structually similar to the D₂ receptor and is a member of the G-protein-coupled seven transmembrane receptor family. This study examines the co-distribution of D₁ receptor mRNA in relation to D₁ binding sites in rat brain using a combination of in situ hybridization and receptor autoradiographic techniques. Adjacent slide-mounted brain sections were examined for D₁ receptor binding using [³H] SCH23390 (in the presence of 1 µM Ketanserin) and D₁ mRNA was visualized with a 530 bp riboprobe corresponding to a region between the third and sixth transmembrane domain of the D₁ receptor. D₁ receptor-mRNA and binding sites appear to be co-distributed in the caudate-putamen, nucleus accumbens, olfactory tubercle, hippocampus, and cerebellum. Regions demonstrating a lack of correspondence include the substantia nigra and suprachiasmatic nucleus where high levels of D₁ binding are observed in conjunction with no D₁ mRNA. These results suggest that the binding observed in these latter regions is localized on terminals arising from distant somata. This is supported by the finding that unilateral ibotenic lesions of the caudate-putamen produce a marked loss of D₁ receptor binding in the ipsilateral substania nigra, pars reticulata. These studies were supported by MH00818, DA02265, MH422251, and MH45614.

CLONING AND EXPRESSION OF A HUMAN AND A RAT D1 DOPAMINE RECEPTOR. O.Y.Zhou, D.K.Grandy, L.Thambi, J.Kushner, H.H.M.Van Tol, J.Salon, J.R.Bunxow and O.Civelli.

Vollum Inst., OHSU, Portland, OR 97210.

The importance of the dopaminergic system in brain function has been emphasized by its association with neurological and psychiatric disorders such as Parkinson's disease and schizophrenia. Based on their biochemical and pharmacological characteristics, dopamine receptors are classified into D1 and D2 subtypes. As the most abundant dopamine receptor in the central nervous system, D1 receptors appear to mediate some behavioral responses; modulate activity of D2 dopamine receptors; and regulate neuron growth and differentiation. The D2 dopamine receptor has been cloned by low stringency screening. We report here the cloning of human and rat D1 dopamine receptors by applying an approach based on the polymerase chain reaction. The cloned human D1 dopamine receptor has been characterized on the basis of four criteria: the deduced amino-acid sequence which reveals that it is a G-protein-coupled receptor; the tissue distribution of its messenger RNA which is compatible with that of the D1 dopamine receptor; its pharmacological profile when transfected into COS-7 cells; and its ability to stimulate cAMP accumulation in human 293 cells.

SPECT IMAGING OF THE DOPAMINE D2 RECEPTOR IN HUMAN AND MONKEY BRAIN. M. Al-Tikriti, S.W. Woods, S. Zoghbi, J. Seibyl, R.H. Roth, D.S. Charney, G.R. Heninger, A. Alavit, P.B. Hoffer, H.F. Kungt, and R.B. Innis. Dept. Psychiatry, VA Medical Center and Yale Univ., West Haven, CT and tUniversity of Penn. Philadelphia, PA.

†University of Penn., Philadelphia, PA.

The brain uptake of the specific dopamine D2 receptor probe ¹²³I-IBZM (iodobenzamide) was studied with SPECT (Single Photon Emission Computed Tomography). A series of twenty scans were performed on 10kg female baboons (Papio anubis) injected with 2-16 mCi of ¹²³I-IBZM and five healthy human subjects with 5 mCi injection. The uptake of radioactivity measured in the Strichman 810X Brain Imager was very similar in humans and monkeys. "Specific" uptake (defined as the concentration of radioactivity overlying striatum minus that in a posterior cortical area) was concentrated in the striata, reached maximal levels in 45-90 min, and was relatively stable for the following 60-100 min. Pharmacological specificity was demonstrated in monkeys by displacement of radioactivity with haloperiod (20 µg/kg i.v.), which caused 65-90% decrease of specifically bound radioligand in 30-60 min.

HPLC analysis of arterial blood samples in humans and monkeys showed that 1231-IBZM was metabolized rapidly (more than 50% within 10 min) into two less lipophilic compounds. Levels of non-protein bound 1231-IBZM reached a stable concentration at the same time as the "Specific" brain uptake measured with SPECT.

Endogenous dopamine appears capable of displacing IBZM binding. D-amphetamine (1.0 mg/kg i.v.) caused 75% decrease of "Specific" uptake. The effect of d-amphetamine (but not that of haloperidol) could be blocked by pretreatment of the animal with reserpine. Quantitative ex vivo autoradiography following injection of 1231-IBZM into monkeys confirmed the concentration of radioligand in caudate and putamen with low levels in globus pallidus. However, autoradiograms also showed receptor binding in substantia nigra, an area presumably too small to be seen in the SPECT image.

164.18

DISTRIBUTION OF D₁ AND D₂ DOPAMINE RECEPTOR mRNAs IN THE RAT BRAIN: AN IN SITU HYBRIDIZATION STUDY. I. H. Meador-Woodruff, A. Mansour, O.Y. Zhou*, I.R. Bunzow*, O. Civelli*, and S. I. Watson Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720; Vollum Institute for Advanced Biomedical Research, The Oregon Health Sciences University, Portland, OR 97201

The dopamine receptor has been resolved into at least two distinct subtypes, D₁ and D₂. Neuroanatomical localization of these subtypes, until quite recently, has been limited to visualization of the binding sites by the use of radiolabelled pharmacological ligands. The recent cloning of the D₁ and D₂ receptors now allows the direct visualization of the mRNAs that code for these dopamine receptors. We have mapped these mRNAs in the rat brain with in situ hybridization, using a 530 base riboprobe complementary to rat D₁ mRNA, and a 495 base riboprobe that recognizes both D₂\(\text{a}\) and D₂\(\text{B}\) mRNA. The distribution of D₁ and D₂ mRNAs was fairly similar in most traditional dopaminoceptive regions of brain, with high levels of both visualized in the caudate-putamen, nucleus accumbens, and olfactory tubercle, with distinct labelling in the septum and limbic cortex. Some regions had markedly different patterns of distribution of these mRNAs, such as in the hippocampal formation. D₂ mRNA could be visualized in dopamine-containing regions as well, most notably in the substantian nigra, ventral tegmental area, and zona incerta; D₁ mRNA was not appreciated in any of these structures, suggesting that the autoreceptors in these areas are exclusively D₂. Detailed comparisons of these mRNAs will be presented for various brain levels. This work was supported by MH00818, DA02265, MH422251, and MH45614.

CHOLINERGIC MODULATION OF ORAL MOVEMENTS INDUCED BY DIFFERENT CHRONIC NEUROLEPTIC ADMINISTRATION

BY DIFFERENT CHRONIC NEUROLEFTIC ADMINISTRATION REGIMENS G. D. Ellison, A. S. Keys*, and Y. Bohn*. Department of Psychology, UCLA, 405 Hilgard Ave., Los Angeles, CA 90024 Oral movements (OMs) of rats given chronic haloperidol (HAL) pretreatment using either weekly HAL injections (HI), pillow implants of HAL (HP), or a combination of HI and HP (IP) were measured in a computerized video analysis were measured in a computerized video analysis system following acute injections of several doses of physostigmine (PHY), scopolamine (SCO), or saline. Previous findings of different behavioral syndromes induced by the two HAL regimens were replicated. PHY treatment resulted in an augmentation of OMs across all regimens, but especially in HI animals. SCO had different but especially in HI animals. SCO had different effects depending upon HAL regimen, with large, steep-sloped OMs increased in control & HI animals but attenuated in HP & IP animals. Surprisingly, IP rats were quite similar to the HP group and in fact showed the least severe syndrome. The results confirm the importance of drug regimen effects and the need for a multivariate approach in the study of multivariate approach in the study of neuroleptic induced OMs.

BEHAVIORAL EFFECTS OF IC ADMINISTRATION OF THE NICOTINE ANALOGUE CYTISINE IN RATS. <u>E.J. Cline and C. Ksir</u>, Department of Psychology, University of Wyoming,

NICOTINE ANALOGUE CYTISINE IN RATS. E.J. Cline and C. Ksir. Department of Psychology, University of Wyoming, Laramie, WY, 82071.

Different investigators have suggested that the locomotor activation caused by nicotine may be mediated by mesolimbic dopamine projections. Other studies have shown that the nicotinic agonist cytisine can also produce increases in behavioral activity when infused into the VTA. Previous studies have reported sensitization to the locomotor effects of repeated nicotine injections. One purpose of this study was to determine whether nicotine pre exposure would alter the behavioral response to cytisine. VTA cannulas were implanted in 24 rats. 12 received 0.2mg/kg nicotine and 12 received saline S.C. for 7 days. On day 8 rats were tested for behavioral activity after bilateral IC infusion of 1 ul cytisine (3.10, or 30 nm/2ul) or saline. Drugs were given in a counterbalanced order over 4 days. Each rat was put in a plexiglass chamber divided into quadrants, and number of quadrant crossings was counted for 20 min. On day 12, 1/2 the rats were injected with 0.2mg nicotine and their behavior monitored. Only the 30 nm dose of cytisine significantly increased quadrant crossings. There was no effect of pretreatment with nicotine on the subsequent response to cytisine. There was, however, a significant effect of lately nicotine injections on the subsequent response to daily nicotine injections on the subsequent response to nicotine in these animals. These results show that 30nm cytisine can cause increases in locomotor activity. Results suggest that locomotor sensitization to nicotine after repeated exposure is a separate phenomenon from mesolimbic DA involvement in the acute effects of nicotine.

165.5

DOSE DEPENDENT BEHAVIORAL CHANGES INDUCED IN SELECTED MEMBERS OF A PRIMATE SOCIAL COLONY BY ACUTE ADMINISTRATION OF THE 5-HT, AGONIST 8-HYDROXY-2-(DI-N-PROPYLAMINO) TETRALIN (8-OHDPAT). R.F. Schiemmer, Jr. J.E. Young*, and J.M. Davis. Dept. of Pharmacodynamics, University of Illinois at Chicago and Research Dept., Illinois State Psychiatric Institute, Chicago, IL 60612.

This study sought to determine the behavioral effects induced in socially housed monkeys by 8-OHDPAT, a highly selective agonist at the 5-HT_{1A} receptor. The study was conducted using a stable social colony of 3 adult stumptail macaques (Macaca arctoides). Following observation of baseline colony behavior, 6 acute doses of (±)8-OHDPAT HBr, 0.005-0.30 mg(base)/kg, were administered to the 4 females of the group in a crossover design. The dominant male remained untreated Only 2 monkeys received drug treatment per day and at least 72 hr. separated drug treatment to the same animal. Each monkey received an i.m. injection of drug or normal saline 15 min. prior to the start of each observation. Each day of the study, a 60 min. observation session was conducted by a "blind" observer who recorded the behavior of the colony from a checklist of over 40 social, solitary and drug-induced behaviors. 8-OHDPAT reduced initiated social activity, including social grooming, at doses ≥ 0.05 mg/kg. Although checking (visual scanning) was intrificantly increased are time (aves constructions). at doses ≥ 0.05 mg/kg. Although checking (visual scanning) was significantly increased, resting (eyes open) was increased and self grooming and feeding were decreased. Interestingly, 8-OHDPAT, 0.1-0.3 mg/kg, induced movement abnormalities similar to those induced by 0.3 mg/kg, induced intovening ability in a mark to those induced intovening neuroleptic drugs (tremor, bradykinesia, rigidity, posturing). Conversely, 8-OHDPAT failed to induce limb jerks (myoclonus) and body shakes as do hallucinogens in this species. The results of this study implicate 5-HT_{IA} receptors in the mediation of important social and solitary behaviors in primates.

ACUTE SYSTEMIC ADMINISTRATION OF CHOLINERGIC AGONISTS AND ANTAGONISTS PRODUCE UNIQUE PATTERNS OF ORAL ACTIVITY IN RATS. Mary Ann Chapman and Ronald E. See, Department of Psychology, Washington State University, Pullman, WA, 99164-4820.

Cholinergic manipulation of oral movements in rodents has been extensively utilized in attempts to model various types of oral dyskinesias, including dystonia and tardive dyskinesia. Groups of female, Sprague-Dawley rats (N=6-8) were habituated to being placed in Plexiglas tubes and jaw movements monitored by a computerized video detection system. Each group was tested with a single cholinergic agonist, antagonist at 3 different doses. Drugs used (dose range in mg/kg) included the cholinergic agonists pilocarpine (.50, 1.0, 2.0), oxotremorine (.10, .50, 1.0), and physostigmine (.05, .20, .50) and the cholinergic antagonists scopolamine (.01, .05, .10) and trihexyphenidyl (.50, 1.0, 2.0. Oral movements were automatically recorded and analyzed according to amplitude and slope. Fast fourier analysis was also used to determine percentage of power at various frequencies.

Each agonist tested produced a unique profile of increased oral activity. Oxotremorine increased small-amplitude oral movements and increased the percentage of oral movements at higher frequencies (9-11 Hz). Pilocarpine increased middle-amplitude oral movements and increased the percentage of oral movements in the middle frequency range (5-9 Hz). Physostigmine increased oral movements at all amplitudes measured, and showed a shift in the frequency spectrum similar to pilocarpine. In contrast, the antagonists did not potently enhance oral activity but did produce unique changes in oral movements. Concurrent administration of scopolamine completely blocked the pilocarpine-induced oral movements. The relationship of these data to cholinergic mechanisms mediating oral activity will be discussed.

DRUG-INDUCED EMOTION: BEHAVIORAL VERSUS INTERO-CEPTIVE EFFECTS OF NICOTINE (NIC) AND PENTYLENE-TETRAZOL (PT2). C.M. Harris, Dept. Pharmacol., NY Col. Osteo. Med., Old Westbury, NY, 11568.

NIC substitutes in a systematic manner for the

NIC substitutes in a systematic manner for the anxiety-like discriminative stimulus produced by PTZ (Harris et al., Psychopharmacol. 98:460-464, 1989). NIC also produces a pattern of emotional behaviors identical to that of PTZ: in 27 drug naive rats, both NIC, 0.64 mg/kg and PTZ, 20 mg/kg increased incidence of defecation (29% and 79% respectively), increased urination (45% and 62%), decreased food consumption (29% and 45%), and both failed to increase vocalization or escape attempts in response to handling. In 24 rats trained to discriminate PTZ, 20 mg/kg from saline, 1 ml/kg, in a two-lever choice task with food reward, the visceral responses to PTZ, as well as a decreased rate of lever pressing for food reward, continued with no sign of tolerance or sensitization for 70 pairs of PTZ and saline or sensitization for 70 pairs of PTZ and saline sessions, and NIC also produced these visceral and rate-suppressant effects. However, although both overt and interoceptive effects of NIC and PTZ were dose-dependent, occurrence of the overt behaviors did not reliably predict detection of the drugs' interoceptive effects. the drugs' Supported by AOA 89-07-301

CENTRAL ADMINISTRATION OF 8-OH-DPAT OR MIDAZOLAM INTO THE ARCHISTRIATUM DIFFERENTIALLY EFFECTS RESPONDING UNDER A ANTICONFLICT PROCEDURE IN PIGEONS S.T. Ahlers & J.E. Barrett. Environmental Medicine Dept., Naval Medical Res. Inst. & Dept of Psychiatry, Uniformed Services Univ. of the Health Sciences, Bethesda, MD 20814

Psychiatry, Uniformed Services Univ. of the Health Sciences, Bethesda, MD 20814

Key pecking of pigeons was maintained under a two-component multiple schedule in which every 30th response produced food. During one component, correlated with a red keylight, every 30th response also produced an electric shock that suppressed responding during this component. Administration of 8-OH-DPAT (lo.3-0.3 mg/kg, IM), or administration of 0.1-30.0 μg 8-OH-DPAT injected into the archistriatum, increased responding in the punishment component. In general, increases in punished responding with 8-OH-DPAT injected into the archistriatum were as high as those observed with systemic administration. Higher doses (1.0-3.0 mg/kg given IM tended to decrease responding in both components whereas nonspecific decreases in response rate were not observed when 8-OH-DPAT was administered into the archistriatum. Relative to 8-OH-DPAT, the short acting benzodiazepine midazolam increased punished responding over a fairly narrow dose range from 0.1-1.0 mg/kg when given IM, and also decreased unpunished responding at higher doses. In most, but not all animals, the magnitude of increased punished responding seen with systemic administration of midazolam (0.1-10 μg/3μl) into the archistriatum were comparable to those observed with 8-OH-DPAT. In contrast, administration of midazolam (0.1-10 μg/3μl) into the archistriatum produced marginal increases in punished responding but and did not systematically affect unpunished responding. These data suggest that the archistriatum may be one of several discrete structures mediating 5HT, a anticonflict behavior in the pigeon. Supported by PHS Grant DA-02873.

ACUTE EFFECTS OF FENFLURAMINE AND PARA-CHLOROAMPHETAMINE ON COPULATORY PERFORMANCE OF MALE RATS. M. M. FOREMAN, R. L. LOVE* AND J. L. HALL*, The Lilly Research Laboratories, Eli Lilly and

Company, Lilly Corporate Center, Indianapolis, IN, 46285.

The augmentation of serotonergic neuron activity has a variety of effects on components of sexual response. Experimental treatments that increase serotonergic receptor activity suppress the expression of sexual behavior but can also induce erection and ejaculation in the male rat. The present studies have evaluated the effects of 0.1-3 male rat. The present studies have evaluated the effects of 0.1-3 mg/kg fenfluramine and 0.01-1 mg/kg para-chloroamphetamine (pCA) on copulatory rate (CR), copulatory efficiency (CE) and ejaculatory latency (EL) of male rats of the Sprague-Dawley strain. These test compounds were dissolved in a vehicle containing 1 mM ascorbic acid and 1 mM acetic acid and given by s.c. injection 30 minutes prior to testing. Both compounds produced significant, dose related decreases in CR and CE and significant, dose-related increases in EL. The administration of 3 mg/kg fenfluramine or 1 mg/kg pCA suppressed the capacity of approximately 80 % of the rats to achieve ejaculation. In all of these responses, pCA appeared to be 3 times more potent than fenfluramine. The effects of these 5-HT releasing agents were blocked by pretreatment with LY53857, a 5-HT₂ antagonist. These data are suggestive that the augmentation of 5-HT release suppressed the sexual drive (e.g. decreased CR) and decreased the capacity to achieve erection (e.g. decreased CE) and ejaculation (e.g. increased EL) of male rats. The antagonism of the responses to fenfluramine and pCA by pretreatment with LY53857 is indicative of an involvement of 5-HT2 receptors in the endogenous control of sexual response.

A DOSE-RESPONSE FOR ISOPROTERENOL AND BEHAVIORAL

A DOSE-RESPONSE FOR ISOPROTERENOL AND BEHAVIORAL THERMOREGULATION IN RATS.

C. Chancellor-Freeland* and H.J. Carlisle. Department of Psychology, University of California, Santa Barbara, CA 93106.

The present experiment examines the effects of pharmacological augmentation of nonshivering thermogenesis (NST) on behavioral thermoregulation in rats. Peripheral administration of the beta agonist, isoproterenol(isotonic saline, 20ug/kg, 65ug/kg, 100ug/kg) was used to stimulate NST. The effects of the different drug doses on an operantly-conditioned response were examined. Contrary to predictions, isoproterenol did not enhance NST, but rather impaired heat production in a cold environment. Behavioral heat intake increased with isoproterenol treatments, while core temperature continued to drop in a dose-dependent manner. These results suggest that the use of manner. These results suggest that the use of isoproterenol as a thermogenic agent should be reconsidered.

UNCONTROLLABLE BUT NOT CONTROLLABLE STRESS PRODUCES ENDURING ANXIETY IN RATS DESPITE ONLY TRANSIENT BENZODIAZEPINE RECEPTOR INVOLVEMENT. K. R. Short and S. F. Maier. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309.

Anxiety was measured by changes in social interaction (File & Hyde, 1978) independent of locomotion changes 24 hrs after 100 escapable or inescapable shocks or restraint. Subjects with no control over the stressor exhibited significantly higher anxiety than either non-shocked subjects or subjects that maintained control over stressor termination, which did not differ from one another. The anxiety increases could be prevented by treatment with the benzodiazepine (BZ) receptor antagonist Ro15-1788 prior to shock treatment, but could not be reversed by antagonist treatment prior to interaction testing. A similar pattern of decreased interaction could be produced by treating restrained rats with the anxiogenic BZ receptor inverse agonist FG-7142 24 hrs prior to interaction. These results are consistent with the hypothesis that anxiogenic rather than anxiolytic endogenous BZ receptor ligands (Ferrero et al., 1984) are involved in some anxious behavior. The results also provide evidence for separate receptor systems involved in the generation, maintenance, and/or expression of anxiety. BNS 8808840 anxiety than either non-shocked subjects or subjects that

TOOTH PULP-EVOKED JAW-OPENING REFLEX IN CAT IS SUPPRESSED TOOTH PULP-EVOKED JAW-OPENING REFLEX IN CAT IS SUPPRESSED BY MEDETOMIDINE, AN ALPHA-2-ADRENORECEPTOR AGONIST, BUT NOT BY COCAINE. P. Kemppainen*, A. Pertovaara and T. Kauppila* (SPON: European Neuroscience Association). Dept. of Physiology, Univ. of Helsinki, Helsinki, Finland. The effects of medetomidine, an alpha-2-adrenoreceptor

agonist, and cocaine on tooth pulp-elicited jaw-opening reflex was studied in pentobarbitone-anaesthetized cat. The threshold of the jaw-opening reflex was determined by constant current pulses (duration: 2 ms) applied at a frequency of 0.25 Hz. Medetomidine elevated the threshold in a dose-dependent way (30-100 µg/kg, i.p.), and this elevation was significantly reduced by atipametzole (1 mg/kg, i.p.), an alpha-2-adrenoreceptor antagonist. The inhibii.p.), an alpha-2-adrenoreceptor antagonist. The inhibitory interaction between two successive dental stimuli (in-field inhibition) was suppressed by a lower dose of medetomidine (30 µg/kg) than the threshold to single electric pulses (55 µg/kg). Only the highest dose of medetomidine (100 µg/kg) reduced significantly the temporally facilitated (in-field facilitation) response. In comparison, cocaine (1-25 mg/kg, i.p.), a non-specific monoaminergic agent, had no marked effect on the tooth pulp-evoked jaw-opening reflex. It is concluded that systemic medetomidine, through an action on alpha-2-adrenoreceptors, can suppress a predminantly nociceptive trigeminal reflex in suppress a predominantly nociceptive trigeminal reflex in anaesthetized cats. In-field inhibition and in-field facilitation display different sensitivities to medetomidine effects.

NOVELTY STRESS THE EFFECTS OF NOVELTY STRESS OF DISCRIMINATIVE CONTROL BY LOW DOSES OF CHLORDIAZEPOXIDE IN PIGEONS. P.L. Shultz and A. Tomie*. Rutgers University, New Brunswick,

N.J. 08903.

To examine the effects of novelty stress on To examine the effects of novelty stress on chlordiazepoxide (CDP) discrimination, 12 homing pigeons previously tested on CDP (4.0, 2.8, 2.0, 1.4, 1.0, .7 and .5mg/kg) vs. saline discrimination were given ten minutes of novelty stress followed immediately by administration of either a CDP test solution (1.4, 1.0, .7 or .5mg/kg) or saline. One hour post-injection, the pigeons were placed in a two key operant chamber and the drug discrimination procedure was initiated. Results revealed that novelty stress increased the mean percent of drug appropriate choices the mean percent of drug appropriate choices for all four test doses by 15-20% above levels of discriminative control observed in the nonor discriminative control observed in the non-stress condition. This effect occurred rapidly and was very durable. These results are not inconsistent with present neurophamacological findings (Paul, 1988) which show a stress-induced increase in benzodiazepine receptor number.

CONFLICT TESTING FOR EFFECTS ON MEMORY AND ANXIETY IN AN APPROACH-AVOIDANCE TEST DEMON-STRATES SELECTIVE ADVANTAGES OF BUSPIRONE AND STRATES SELECTIVE ADVANTAGES OF BUSPIRONE AND GEPIRONE OVER DIAZEPAM AND LORAZEPAM.
Martin E. Judge, Novo Nordisk, Ferrosan CNS Division, Sydmarken 5, DK-2860 Soeborg, Denmark.
Conflict testing is widely used to demonstrate the cognitive effects of anxiolytic drugs. Anxio-

lytic effects are frequently inferred from increased tolerance to shock in a drinking conflict test, while a decreased latency to enter an area where shock was previously received is interpreted as indicating amnesia.

In an approach-avoidance system (Judge and Quartermain, Neuroscience Letters; 24: 313-317, 1981) using thirsty mice and a water-shock (0.33 mA) motivated two session conflict test, it was possible to demonstrate both the anxiolytic and the amnesic effects of clinically efficacious minor tranquilizers given i.p. 30 min. before the first session. There were clear differences between the benzodiazepines diazepam and lorazepam, which gave only a weak "anxiolytic" effect but potent amnesic effects, while buspirone and gepirone gave clear anxiolytic effects (100%) increase in day 1 shocks) as well as a signifi-cant amnesia, but with a much greater separation of anxiolytic and amnesic effects.

LOW-DOSE INTERACTIONS OF THE IMIDAZOBENZODIAZEPINE RO 15-4513 WITH ETHANOL ON WHEEL-RUNNING BEHAVIOR IN THE RAT. M.A. Bixler, R. Hughes and M.J. Lewis Department of Psychology, Howard University, Washington, D.C. 20059. Previous work has demonstrated that Ro 15-4513 (3.0

mg/kg, ip) pretreatment can augment et anol-induced (0.75 g/kg, ip) suppression of wheel-running behavior in the rat (Bixler,M.A. and Lewis,M.J.,Drug Dev. Res., in press). Moreover, Ro 15-4513 administration alone suppresses spontaneous locomotor activity, as assessed via wheelrunning behavior. At doses as low as 0.078 mg/kg Ro 15-4513 **su**ppresses wheel-running in rats. In the present study, subjects were maintained on a 12:12hr light/dark cycle, and allowed 10 minute daily access to a running wheel during the dark phase. To examine its interaction with ethanol, Ro 15-4513 was administered in an ascending dose series according to an A-B-A repeated measures design. Relatively low doses of Ro 15-4513(0.078 to 0.312 mg/kg) were found to antagonize ethanol-induced suppression of wheel-running in a dose-dependent manner, and independently suppress wheel-running when administered alone. This suggests a possible biphasic action of Ro 15-4513 with respect to its antagonism of the motorincapacitating effects of ethanol.

TOLERANCE AND BEHAVIOURAL DEPENDENCE STUDIES IN RATS WITH BUSPIRONE AND IPSAPIRONE. A.J.GOUDIE and M.J. LEATHLEY*.
Psychology Dept., Liverpool Univ., Liverpool, L69 3BX, U.K.
Chronic effects of buspirone (4 mg/kg. b.i.d) and

ipsapirone (15 mg/kg b.i.d), and of withdrawal, were studied in rats run for 2 operant sessions/day on a DRL 15 sec schedule. When administered pre-session, both drugs suppressed responding by c. 50%. During 22 days of treatment (b.i.d) full tolerance developed to both drugs. withdrawal, subjects treated pre-session with buspirone and ipsapirone showed significant (c. 50%) increases in response rates, which were highest on the first withdrawal day and then decreased to baseline over 4 further days. However, subjects which had always received ipsapirone (15 mg/kg b.i.d) after operant sessions showed no withdrawalinduced increases in responding. The withdrawal effects observed cannot have been due to physical dependence, as they were only seen in subjects receiving chronic presession treatment. The withdrawal effects recorded were due presumably to state-dependent learning induced by chronic pre-session administration of behaviourally disruptive drug doses. These data indicate that tolerance develops to effects of buspirone and ipsapirone on DRL responding when the drugs are administered at high doses twice daily. The also suggest that state dependent learning may be of critical importance in behavioural dependence procedures when such procedures are used to assess withdrawal effects.

SHIFTS IN NONDRUG BASELINE FOLLOWING ACQUISITION OF DIAZEPAM-PENTYLENETETRAZOL DISCRIMINATION REFLECT ADAPTIVE PROCESSES. R.L. Smith and R.J. Barrett*. Dept of Psychology, Vanderbilt University and VA Medical Center, Nashville, TN 37203

Rats were trained to discriminate diazepam (DZ) (0.3 mg/kg) from pentylenetetrazol (PTZ) (10-20~mg/kg). Training doses of the drugs were adjusted such that when animals were tested on saline 48 h after the last acquisition session they made 50% of their responses on each lever. Similar tests at subsequent intervals (7, 27 and 90 days) indicated a drift in the nondrug baseline from 50% DZ lever choice to 48%, 34% and 22% for the 7, 27 and 90 day intervals, respectively. If the drift in the nondrug baseline reflects the gradual dissipation of adaptive changes induced by chronic injection of the training drugs, then it should be possible to reinstate the original nondrug baseline (50%) by simply administering chronic injections of the training drugs. Animals were assigned to one of three groups and received either DZ-PTZ discrimination training, DZ-PTZ injections but no training, or saline injections for 14 days. Tests 48 h after the final treatment indicated that in addition to retraining, injections alone are effective in minutains. injections alone were effective in reinstating the original nondrug baseline. These results support the explanation that the instability in the nondrug baseline reflects the gradual dissipation of adaptive processes.

DRUG DISCRIMINATION IN BABOONS TRAINED TO DISCRIMINATE &-CARBOLINE-3-CARBOXYLIC ACID ETHYL ESTER (&-CCE) OR PENTYLENETETRAZOLE (PTZ) N.A. Ator and R.R. Griffiths*

Johns Hopkins Univ. Sch. of Med. Baltimore, MD 21205. B-CCE and PTZ both act through the benzodiazepine/ B-CCE and PTZ both act through the benzodiazepine/y - aminobutyric-acid (BZ/GABA) receptor complex but through different sites: B-CCE through the BZ receptor and PTZ through the picrotoxinin site. Both have subjective effects characterized as anxiogenic in humans. Baboons were trained to discriminate either β-CCE (0.18 mg/kg i.m.) or PTZ (10 mg/kg i.m.) from the no-drug condition. Both discriminations were acquired relatively slowly compared to such training with sedative/anxiolytics in this species. In previous work the PTZ response was occasioned by β-CCE and by the novel anxiolytic buspirone (a drug having little effect in the BZ/GABA complex). In the present study the β-CCE response was occasioned by PTZ and buspirone suggesting overlap in the stimulus generalization profiles of PTZ and β-CCE. Yohimbine, a drug with high Ø-2 adrenergic activity, has been drug with high A-2 adrenergic activity, has been reported to have anxiogenic effects but did not occasion drug lever responding reliably in either training group. The discriminative stimulus effects of B-CCE but not PTZ The discriminative stimulus effects of \$A-CCE but not PT were blocked by the BZ-receptor antagonist flumazenil (flumazenil alone, up to 18 mg/kg p.o., had no effect). Neither phenytoin nor valproic acid blocked the PTZ discriminative stimulus. To date neither a putative anxiogenic effect nor a particular molecular mechanism appears to account for commonalities in discriminative stimulus effects of PTZ and \$B-CCE. (NIDA Grant DA04133)

RO 15-1788 REVERSES PHARMACOLOGIC TOLERANCE, BUT NOT CONTINGENT TOLERANCE, TO DIAZEPAM'S ANTICONVULSANT

RO 15-1788 REVERSES PHARMACOLOGIC TOLERANCE, BUT NOT CONTINGENT TOLERANCE, TO DIAZEPAM'S ANTICONVULSANT EFFECT. Michael J. Mana and John P.J. Pinel. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C., Canada. V6T 1Y7.

The development of tolerance to the anticonvulsant effect of diazepam (DZP; 2 mg/kg, IP) administered once every 48 hr for 20 days is contingent upon amygdaloid kindled rats receiving a convulsive stimulation 1 hr after each drug injection; accordingly, we refer to this as contingent tolerance. Tolerance to DZP's anticonvulsant effect also develops when the same dose is administered every 8 hr over a 10-day period, even though the rats are not stimulated during this time; we refer to this as pharmacologic tolerance because its development is a function of drug exposure. The present experiment examined the effect of the benzodiazepine antagonist RO 15-1788 (Flumazenil) on the retention of contingent and pharmacologic tolerance to DZP's anticonvulsant effect. On the tolerance-test trial that followed each tolerance-development regimen, when each rat received DZP 1 hr prior to a stimulation, the mean forelimb clonus duration (FLC) was not significantly different for the two groups (42 sec for the Contingent-Tolerance Group and 51 sec for the Pharmacologic-Tolerance Group (FLC = 24.6 sec.) but not in the Contingent-Tolerance Group (FLC = 24.6 sec.) but not in the Contingent-Tolerance Group (FLC = 24.6 sec.) but not in the Contingent-Tolerance Group (FLC = 34.6 sec.) but not in the Contingent-Tolerance Group (FLC = 34.6 sec.) but not in the Contingent-Tolerance Group (FLC = 34.6 sec.) but not in the Contingent-Tolerance Group (FLC = 34.6 sec.) but not in the Contingent-Tolerance Group (FLC = 34.6 sec.) but not in the Contingent-Tolerance Group (FLC = 34.6 sec.) but not in the Contingent-Tolerance Group (FLC = 34.6 sec.) But not in the Contingent-Tolerance Group (FLC = 34.6 sec.) But not in the Contingent-Tolerance Group (FLC = 34.6 sec.) But not in the Contingent-Tolerance Group (FLC = 34

DIAZEPAM-INDUCED AMNESIA IN A DELAYED NONMATCHING-TO-SAMPLE TASK MAY BE THE RESULT OF SEDATION RATHER THAN MEMORY LOSS. <u>L.E. Kalynchuk* and C.H.M. Beck</u>. Psychology, University of Alberta, Edmonton, AB, Canada T6G 2E9. Acute administration of benzodiazepines to rats

impairs acquisition of avoidance tasks. It is not clear whether this represents an amnesic effect generalizable in a delay-dependent fashion to nonaversive tasks, nor whether the effect would be observable in chronically treated animals. To explore these issues we examined the effects of diazepam (2.0 mg/kg,ip) administered acutely or chronically (x6) on the performance of rats on a food-reinforced delayed nonmatching-to-sample task (DNMTS) with nonrepeating objects. Compared to saline controls, acutely treated rats made more errors but this deficit was delay-independent. Chronically treated rats did not differ from controls in the number of errors but did use a different strategy. Whereas control animals ran to the test object, examined it, switched to the other object, and displaced the object, the chronic rats paused in front of the objects, looked at both, moved to one and displaced it. These rats were generally less active than the control rats. Mobility was reduced even further in acutely treated rats and errors were related to a tendency to proceed directly to the nearest object and to increasing immobility throughout the session. In conclusion, diazepam-induced impairment in performance of DNMTS may be a consequence of sedation rather than amnesia.

sedative effects of BZs.

REPEATED ADMINISTRATION OF DIAZEPAM BUT NOT OF CLONAZEPAM REDUCES 3H-RO 5-4864 BINDING IN THE MITOCHONDRIAL FRACTION OF RAT CEREBRAL CORTEX. G.Diana* and M.Massotti. Laboratorio di Farmacologia, Istituto

We previously reported that rapid tolerance to the EEG

Superiore di Sanità, 00161, Roma, Italy.

synchronization and behavioral sedation can occur after large doses of diazepam (DIAZ) but not of clonazepam (CLN). The effect of DIAZ is abolished when the drug is coadministered on a chronic basis with PK 11195. The effects of CLN undergo to tolerance when the drug is coadministered on a chronic basis with Ro 5-4864 (Ph Bioch Beh 35,933,1990). These data suggest that the peripheral benzodiazepine (BZ) receptor can modulate the occurrence of rapid tolerance to the

To verify this possibility, 3H-Ro 5-4864 binding was determined in the mitochondrial fraction of cerebral cortex of rats treated for 5 days (once a day) with DIAZ (10 mg/kg iv), CLN (2.5 mg/kg iv) or Ro 5-4864 (4 mg/kg iv). In naive rats, Kd and Bmax of 3H-Ro 5-4864 were 3.2 nM and 0.82 pmol/mg prot, respectively. No change was observed after single injection of all these drugs. After 5 days of treatment, a decrease of the Bmax was obtained in rats receiving DIAZ (-48%) and Ro 5-4864 (-74%), but not CLN or vehicle

These data are consistent with the hypothesis that a down regulation of peripheral BZ receptor may play an important role in the development of rapid tolerance to the sedative effect of BZs.

ISOLATION SUPRESSES BOTH IMMUNE AND NEUROENDOCRINE FUNCTIONING AND DECREASES THE LOCOMOTOR ACTIVITY OF NORMAL AND IMMUNOSUPPRESSED C3H/HeN MICE. D.L. Collins, S.J. Cohen*, D.E. Gruber*, M.M. D'Alesandro*, and D.A. Mickley. Armed Forces Radiobiology Research Institute, Bethesda, MD 20814-5145.

Environmental variables can dramatically influence behavioral, neuroendocrine, and immune system parameters.
We examined the effects of housing on locomotion,
circulating lymphocytes, and catecholamines (i.e., We examined the effects of housing on locomotion, circulating lymphocytes, and catecholamines (i.e., Norepinephrine [NE] of 12-week-old female C3H/HeN mice. Mice (10/group) were either immunocompromised (following 0.5 or 4.5 Gy 60Co irradiation) or normal (shamirradiated) and were housed in isolation or groups (10/cage) for 25 days following radiation exposure. Individual spontaneous locomotion measures and blood samples were obtained 25 days following the radiation and powering manipulations. Blood samples showed that the housing manipulations. housing manipulations. Blood samples showed that the catecholamines of isolated mice were more divergent (i.e., NE=73% and EPI=81%) from normal values than were the catecholamines of group-housed mice (i.e., NE=38% and EPI=62%). Across doses, mice housed in isolation had 50% less circulating EPI and 43% less circulating NE than did group-housed mice. This study suggests that the regulations of the control of group-housed mice. This study suggests that the regulatory processes of the neuroendocrine system are influenced not only by exposure to immunosuppressive radiation but also by environmental factors, such as different housing conditions.

PEPTIDES: BIOSYNTHESIS AND METABOLISM I

166.1

EFFECT OF COLCHICINE ON RAT HYPOTHALAMIC VASO-PRESSIN, OXYTOCIN AND SOMATOSTATIN BIOSYNTHESIS

PRESSIN, OXYTOCIN AND SOMATOSTATIN BIOSYNTHESIS IN VIVO. B.Liu*. R.P.S.Kwok, and J.D.Fernstrom. Neuroendocrine Program, Dept. Psychiatry, Univ. of Pittsburgh, Pittsburgh PA 15213.

Colchicine (COL) blocks axonal transport and causes peptides to accumulate in their neuronal cell bodies of origin. This accumulation has recently been used to estimate vasopressin (AVP) synthesis rate in hypothalamus (Am.J.Physiol. 257 :R109,1989). We have examined this method for possible use in estimating somatostatin (SRIF) synthesis as well. Groups of rats received COL (8 µg, third ventricle), and were killed 10 or 24 hr later. Whole hypothalamus, or hypothalamic regions and posterior pitultary were assayed for immunoreactive (IR) AVP and/or SRIF. COL treatment clearly increased IR-AVP levels at 10 and 24 hr, in whole hypothalamus and supraoptic and para/periventricular nuclei, as previously shown. However, no changes were noted in IR-SRIF content, in whole hypothalamus, para/periventricular nucleus or median eminence. Synthesis of AVP and SRIF peptides (SRIF-14 and SRIF-28) was also estimated in vivo in hypothalamus 4 hr after third ventricular 3°S-cysteine injection, administered 6hr and 20 hr after COL. 3°S-AVP, 3°S-SRIF-14 and 3°S-SRIF-28 were isolated on HPLC; the accumulation of label in each peptide 6-10 hr after COL was increased over control, while at 20-24 hr, peptide labeling was SRIF28 were isolated on HPLC; the accumulation of label in each peptide 6-10 hr after COL was increased over control, while at 20-24 hr, peptide labeling was clearly reduced. At this latter timepoint, no alteration in the mRNA level for proSRIF or proAVP was apparent. The results suggest that COL treatment coupled with IR-SRIF measurements is *not* a useful method for estimating SRIF synthesis in hypothalamus. In addition, they show that COL can suppress SRIF and AVP labeling within 24 hr, indicating either that the build-up of peptide in the cell body ultimately inhibits synthesis, or that COL lowers synthesis by some other mechanism. The effect is presumed to be post-transcriptional, since the mRNA levels were unaltered. Because of the COL-induced changes in labeled AVP synthesis, care must be taken in the use of the COL method for estimatling AVP synthesis.

LOCALIZATION OF OXYTOCIN mRNA IN AXONS OF THE HYPOTHALAMO-NEUROHYPOPHYSIAL TRACT. G.F. Jirikowski, P.P. Sanna and F.E. Bloom, Dept. of Neuropharm. Scripps Clinic and Res. Fnd., La Jolla, CA 92037

With in situ hybridization, using 5'bromo-2'deoxyuridine (BRDU)labelled oligoprobes complementary to oxytocin (OT) mRNA, we found hybridization in some of the Herring bodies in the median eminence and the posterior lobe of 6 days lactating rats. In lactating rats, whose pups had been removed 5 hours before sacrifice, we observed hybridization in axons in the lateral hypothalamus and increased hybridization in both the median eminence and the posterior lobe, while hybridization in the magnocellular perikarya seemed to be reduced. With electron microscopy we could demonstrate that the axonal hybridization signal was present in secretory vesicles. Several hypothetical explanations are under functional evaluation: The shift of mRNA into the axonal compartment could represent a mechanism for rapid downregulation of synthetic activity. Since neurons are generally thought to have low RNAase activity, it also seems possible that neurons are capable of reducing mRNA levels by terminal release. RNA might also be stored in axons and transported retrogradely to reinitiate translation upon certain stimuli without de novo transcripiton. Preliminary experiments seem to provide evidence that certain target neurons can take up mRNA to translate the respective message, thus representing an novel principle of interneuronal communcation.

MODULATION OF STRIATAL PREPROENKEPHALIN MRNA LEVELS BY SCOPOLAMINE. A.E. Pollack and G.F. Wooten. Dept. of Neurology, University of Virginia, Charlottesville, Va. 22908.

Eight days post lesion (dpl) preproenkephalin (PPE) mRNA levels increased 2.5-fold in the striatum ipsilateral to a 6-hydroxydopamine (6-OHDA) lesion of the substantia nigra pars compacta. Administration of the D2 agonist, quinpirole, or the D1 agonist, SKF 38393, for 7 d following a 6-OHDA lesion attenuated the increase in striatal PPE mRNA by 30% and 15% respectively as compared to the ipsilateral striatum of 8 dpl control rats (Pollack and Wooten, Soc. Neurosci. Abst., <u>15</u>:368, 1989). In striatal slices, application of a D2 dopamine agonist decreased the K'-induced release of acetylcholine (Stoof et al., Eur. J. Pharm., <u>84</u>:211, 1982) suggesting that dopamine agonists could regulate striatal PPE mRNA levels indirectly via effects on cholinergic interneurons. In this study we examined the effects of effects on cholinergic interneurons. In this study we examined the effects of scopolamine (a muscarinic cholinergic antagonist) treatment on striatal PPE mRNA following a 6-0HDA lesion. Rats received a unilateral stereotaxic injection of 6-0HDA (2 µl, 4 mg/ml) and their striata were processed separately for RNA extraction. PPE mRNA of the ipsl- and contralateral striata were compared by dot blot hybridization using a ³²P-labeled 30mer oligonucleotide probe complementary to PPE mRNA. Administration of scopolamine (10 mg/kg/3xd, s.c.) to intact rats for 14 d resulted in a 25% reduction of striatal PPE mRNA compared to control animals (p<0.01), whereas a 7 d course of treatment was without effect. Administration of scopolamine (10 and 50 mg/kg/3xd, s.c.) for 7 d following a 6-0HDA lesion attenuated the increase of PPE mRNA in the striatum ipsilateral to a nigral lesion by 40% (p<0.05). In contrast, scopolamine administration did not alter PPE mRNA in the contralateral striatum. Thus, dopamine may, at least in part, regulate PPE mRNA expression via effects on striatal cholinergic intermeurons.

EXPRESSION AND PROCESSING OF PRO-OPIOMELANOCORTIN IN A NEURONAL CELL LINE. N. C. Day, J. E. Dixon# and H. Akil. Mental Health Res. Inst., University of Michigan, Ann Arbor, MI 48109 and #Dept. of Biochemistry, University of Purdue, West Lafayette, IN 47907.

We examined the expression and processing of monkey pro-opiomelanocortin (POMC) following transfection into a mouse neuronal cell line, Neuro 2A (N2A). Two POMC vectors were compared for their level of expression and pattern of peptide processing: one which employed the Zn2+-inducible metallothionein promoter (Mtneo-POMC) and another which employed the cytomegalovirus immediate early gene promoter (CMV-POMC). It was found that POMC expression, as assessed by total β -Endorphin levels, was markedly higher in cells transfected with CMV-POMC than with Mtneo-POMC. Molecular sieving of cells transfected with either vector revealed that the precursor was processed at the correct sites to give β -Lipotropin and β -Endorphin. While both cell lines produced ACTH and α -melanocyte-stimulating hormone (α -MSH, ie. ACTH₁₋₁₃),

ACTH and α -melanocyte-stimulating hormone (α -MSH, ie. ACTH₁₋₁₃), the levels of fully processed peptides were much lower than those found in tissues which normally produce POMC, such as the pituitary. We also investigated the structural parameters dictating processing of the mid-ACTH cleavage site (sequence; -lys-lys-arg-arg-). A series of mutants of this region were subcloned into the Mtneo vector, transfected into N2A cells, and α -MSH production measured. Preliminary data suggest that one of the mutant vectors (cleavage site sequence; -lys-lys-arg-gly-) produces higher levels of α -MSH in N2A cells than the wild-type vector. This implies that the arg in position 4 of the wild-type cleavage site sequence may prevent cleavage by the N2A protease. (Supported by NIDA DA02265 and the Lucille P. Markey Charitable Trust). and the Lucille P. Markey Charitable Trust).

DECREASED EXTRACELLULAR CONCENTRATION OF GLUTAMATE AND ELEVATED TISSUE CONTENT OF DYNORPHIN IN THE HIPPOCAMPUS OF AGED RATS. W. Zhang, L. Thai, W. Mundy, M. Gallagher, H. Tilson and J. S. Hong. LMIN, NIEHS/NIH, Research Triangle Park, NC and Dept. of Psychology, Univ. of North Carolina, Chapel Hill, NC.

The purpose of this study was to examine the effects of aging on extracellular glutamate and tissue dynorphin A(1-8)(DYN) contents in the hippocampal formation of Fischer-344 rats. Data collected for glutamate using an

Fischer-344 rats. Data collected for glutamate using an in vivo microdialysis perfusion method were compared to DYN tissue content in the same brains. The present investigation showed a selective reduction (40%) of extracellular, but not tissue, concentration of gluta-mate in aged (24 mo) rats compared to young (3 mo) rats. Furthermore, the decrease in extracellular glutamate was inversely correlated with an elevated hippocampal content of DVN. This study extends the earlier finding of elevated dynorphin in the aged hippocampus to another rat strain. In addition, the results suggest that the dysregulation of dynorphin occurs in conjunction with reduced excitatory transmission within the hippocampal formation. This interpretation is also consistent with our observation that glutamate antagonist administration prevents a decrease in hippocampal dynorphin content induced by perforant path stimulation in the young adult rat. PROTEOLYTIC ACTIVITY IN BOVINE ADRENAL CHROMAFFIN
GRANULES USING (\$^{35}s)-METHIONINE LABELLED PROENKEPHALIN
COPOLYMERIZED INTO SDS-PAGE. S.F. Roberts*, J.W. Irvine*,
and I. Lindberg. Dept. of Biochem. and Mol. Biol. LSU
Medical Center, 1901 Perdido St., New Orleans, LA 70112.
A novel method was used to characterize proenkephalin
cleaving activities in subcellular fractions. Purified

[35s]-methionine labelled recombinant proenkephalin was

cleaving activities in subcellular fractions. Purified (135s)-methionine labelled recombinant proenkephalin was added to SDS polyacrylamide gels prior to polymerization. Samples were applied to polymerized gels which were run on ice, washed with 2.5% Triton X-100 to remove SDS, and then incubated at 37 C to allow renatured enzymes to cleave in situ proenkephalin into diffusible peptides. Enzymatic activity was revealed as clear bands against a dark background by autoradiography of dried gels.

A 1 M NaCl extract of membranes pelleted from freeze/thawed crude (P2) chromaffin granules contained two dominant bands of activity at pH 8.2, a 75 kDa and a calcium-dependent 60 kDa. A 30 kDa band could be discerned as a minor component.

Sucrose gradient fractionation of P2 granules assayed at pH 8.2 showed the 75 kDa enzyme in granule and lysosomal fractions while the 60 kDa enzyme was concentrated in the lysosomal and mitochondrial fractions. Neither of these bands were inhibited by DFP or E-64. At pH 5.0 a 66 kDa band was evident that is possibly lysosomal. A 30 kDa activity may be granule-associated but is at the limit of detection. Preliminary results also indicate that a 46 kDa enzyme may be associated with both chromaffin granules and anterior pituitary secretory granules. pituitary secretory granules.

DETERMINATION OF THE DISTRIBUTION OF LEUCINE-ENKEPHALIN IN BRAIN REGIONS OF THE TWO-DAY-OLD CHICK BY RADIOIMMUNOASSAY. E.L. Bennett, P.J. Colombo, J.Y. Sun*, G. Schulteis, M.R. Rosenzweig, and J.L. Martinez Jr. Dept. of Psychology, Univ. of California, Berkeley,

The brain of the two-day-old chick was dissected into the following regions: the cerebellum, optic tectum, brain stem, and dorsal and ventral aspects of the forebrain. The forebrain was dissected at the level of the lamina medullaris dorsalis such that the dorsal portion contained the visual wulst, neostriatum, and ectostriatum. The ventral forebrain contained the lobus parolfactorius and paleostriatum augmentatum. Tissue samples were immediately homogenized and prepared for radioimmunoassay of leucine-enkephalin (LE). radioimmunoassay of leucine-enkephalin (LE). Preliminary values of pmol LE-like immunoreactivity/mg protein in the regions tested, based on 13 individual samples, were as follows: cerebellum = 0.042 ± 0.033, dorsal forebrain = 0.437 \pm 0.188, optic tectum = 1.234 \pm 0.290, brain stem = 2.699 \pm 0.916, and ventral forebrain = 4.836 \pm 1.169.

STORAGE AND PROCESSING OF PROENKEPHALIN IN ADRENAL CHROMAFFIN CELLS. <u>S.P. Wilson</u>. Dept. of Pharmacology, Univ. of South Carolina Sch. of Med., Columbia, SC 29208

The relationship between proenkephalin (PE) storage and processing was examined in primary cultures of boyine adrenal medullary chromaffin cells (purity >95%). Cultures were labeled with [35S]methionine with or without prior exposure to secretagogues to enhance PE synthesis. A crude chromatfin vesicle (CV) fraction obtained by differential centrifugation of cell homogenates was subjected to density gradient centrifugation. [35S]Met5-enkephalin sequences in gradient fractions were quantitated following digestion with trypsin + carboxypeptidase B and reversed-phase high performance liquid chromatography (RPHPLC). Within 1 h after labeling all PE-derived peptides were incorporated into structures with properties of newly synthesized CV. These vesicles required 9-12 h to achieve the buoyant density of mature CV. The processing of PE was examined in whole cell extracts by first separating the major PE-derived peptides by RPHPLC with subsequent analysis of [3⁵S]Met⁵-enkephalin content. Maximum formation of free pentapeptide occurred within 2-4 h after labeling, with a corresponding loss of [3⁵S]Met⁵-enkephalin from PE-derived peptides of ≥15 kD. No appreciable processing of other PE-derived peptides, including species of 3-10 kD, was observed over 24 h. The results show that PE is rapidly packaged into CV and that PE processing is complete before CV maturation. These studies also suggest that many of the PE-derived peptides found in the adrenal medulla are final secretory products. This research was supported by NSF grant BNS-8719149.

[LEU]ENKEPHALIN HYDROLYSIS IN CRUDE MEMBRANE FRACTIONS OF [LEU]ENKEPHALIN HYDROLYSIS IN CRUDE MEMBRANE FRACTIONS OF CHICK BRAIN. G. Schulteis', S. Shibanoki*, D. Beniston*, K. Ishikawa*, E.L. Bennett', M.R. Rosenzweig', & J.L. Martinez, Jr.'. 'Dept. Psych., Univ. Calif., Berkeley, CA, 94720, & *Dept. Pharm., Sch. Med., Nihon Univ., Tokyo, Japan. Hydrolysis of [leu]enkephalin (LE) in crude (P2) membrane fractions of selected chick brain regions was examined using HPLC/electrochemical detection. LE (32.4 µM) was added to P2 from ventral (V) or dorsal (D) forebrain, tectum (T), brainstem (B), or cerebellum (C). The only detectable products of LE hydrolysis were free Tyr and Tyr-Gly-Gly (YGG). Tyr formation did not differ markedly among brain products of LE hydrolysis were free Tyr and Tyr-Gly-Gly (YGG). Tyr formation did not differ markedly among brain regions; differences in YGG formation were noted, however, with V > T > D=B > C. A somewhat similar profile was noted for LE concentrations in these regions (Bennett et al., this volume). In P2 of whole forebrain, bestatin (IC50=2μM) and puromycin (IC50=6μM), aminopeptidase inhibitors, inhibited Tyr formation; in combination with earlier reports of bestatin and puromycin affinity for aminopeptidases M and MII (Molec Pharmacol, 29:281, 1986), our data suggest that MII activity is predominant in chick forebrain. formation was potently inhibited by captopril (IC50= 0.003µM), an angiotensin converting enzyme (ACE) inhibitor, but poorly inhibited by thiorphan (TC50=0.6µM), an 'enkephalinase' inhibitor, suggesting that ACE activity accounts for most YGG formation in chick forebrain. This contrasts with data from rat forebrain or striatum, in which thiorphan is considerably more potent than captopril. (Supported by PHS grants DA04795, DA04195, DA05334, from NIDA).

RECIPROCAL EFFECTS OF CENTRAL AND PERIPHERAL AXOTOMY ON RECIPROCAL EFFECTS OF CENTRAL AND FERTIFIERAL ANDOIST OF CALCITONIN GENE-RELATED PEPTIDE CONTENTS IN RAT DORSAL ROOT GANGLION CELLS. Y. Kashihara*, Y. Inaishi* and M. Sakaguchi* and M. Kuno. National Institute for Physiol. Sciences, Okazaki 444, Japan.

The synthesis of calcitonin gene-related peptide (CGRP) in cultures of adult rat dorsal root ganglion (DRG) cells is known to be up-regulated by nerve growth factor (NGF; Lindsay et al., Neurosci. 33:53, 1989). We measured the CGRP content in the rat lumbar DRG $in\ vivo$ by a two-site enzyme immunoassay 9 days after rhizotomy or peripheral nerve section. Section of the sciatic nerve (peripheral axotomy) on one side reduced slightly (by 15%) but significantly the CGRP content in the lumbar DRG compared with the control side. In contrast, section of the lumbar dorsal roots (central axotomy) caused a 2.7-fold increase in the CGRP content of the lumbar DRG. In order to test the possible effects of cut motor fibers associated with section of the sciatic nerve, the lumbar ventral roots were transected. Unexpectedly, this procedure caused a 1.7-fold increase in the CGRP content of the lumbar DRG. This was not attributed to section of ventral root afferent was not attributed to section of the 4th lumbar ventral root increased the CGRP content in the 5th lumbar DRG as well as in the 4th lumbar DRG. It is concluded that, in addition to NGF, at least two other factors are involved in regulation of the synthesis of CGRP in sensory neurons.

Somatostatin mRNA during development of the Rat

DM Ferriero, <u>VA Head*</u>, RH Edwards, SM Sagar
We have previously shown marked developmental
regulation of somatostatin(SS) concentrations
during retinal development. SS appears as early as embryonic day 16(E16) in high quantities and decreases to barely detectable levels at an early postnatal age, gradually returning to adult levels after eye opening. To determine whether these variations in retinal SS content reflect variations in synthesis, we determined SS mRNA levels using Northern blot hybridization as a measure of the regulation of SS transcription accumulation. SS RNA probe was prepared from a SS cDNA clone in SP65. When relative SS mRNA hybridizing signal is plotted as a function of age, the pattern of gene expression in the developing retina paralleled the peptide concentration throughout development, both showing higher concentrations prenatally than postnatally. There appears to be only one species of SS mRNA present throughout development. These data suggest that there is control of SS peptide expression throughout development at the level of SS mRNA; the early appearance of message and peptide suggest a role for SS in the developing retina.

VASOPRESSIN AND ANGIOTENSIN II DISAPPEAR AND REAPPEAR IN POST-MITOTIC SOLITARY HYPOTHALAMIC CELLS OF THE HOMOZYGOUS BRATTLEBORO RAT. F.W. van Leeuwen, E.M. v.d. Beek, *H. Imboden and *D. Felix Neth. Inst. Brain Res. Amsterdam, The Netherlands; *Univ. Berne, Switzerland.

Neth. Inst. Brain Res. Amsterdam, The Netherlands; *Univ. Berne, Switzerland.

The mutation of the homozygous Brattleboro rat is due to a single base deletion in exon B resulting in a completely different C-terminus of the vasopressin (VP) precursor. This altered precursor cannot be transported from the endoplasmic reticulum towards the Golgi apparatus and is therefore not packaged in granules. For this reason the axonal transport of VP granules is blocked. The expression in VP cells of two co-existing peptides, Angiotensin II (Ang II) and dynorphin (DYN), is, respectively, totally disturbed and not affected. Paradoxically, a small number of solitary hypothalamic neurons of di/di rats synthesize the wild-type VP precursor (i.e. VP, neurophysin and glycopeptide) (Van Leeuwen et al., PNAS, 86:6417, 1989). During life an increasing number of these somatic post-mitotic neurons (up to 3% of the VP cells) undergoes a switch to a genuine heterozygous phenotype (i.e. exhibiting both the wild-type and mutated VP precursors). Here we report the coexistence of Ang II and glycopeptide in these heterozygous cells indicating that for the expression of Ang II a normal VP precursor is necessary. It is hypothesized that in the Golgi apparatus the various neuropeptides present in VP cells, and in the same granule, are packaged in the following order: first DYN, followed by VP and Ang II. Alternatively, protein sorting in the trans-Golgi network is possible. Alternatively, protein sorting in the trans-Golgi network is possible.

PARTIAL PURIFICATION OF A CCK CLEAVING ENDOPROTEASE FROM RAT BRAIN SYNAPTOSOMES. <u>J.C.Viereck and M.C.Beinfeld.</u> Dept. of Pharmacology, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

An endoproteolytic activity which specifically cleaves CCK-33 to produce CCK-8 has been partially purified from a rat brain synaptosome preparation. This activity was assayed by incubating with substrate and separating the product on DEAE Sephadex ion exchanger. The assay product co-eluted with authentic CCK-8 on reverse phase HPLC. Both soluble and membrane bound activities were present in synaptosomes. A two step purification of the soluble activity involved anion exchange chromatography over DEAE Sephacel, followed by gel filtration on a G-150 Sephadex column. These steps resulted in a 320 fold enrichment of activity relative to the original brain homogenate. Because the CCK-33 cleaving activity of the crude preparation was marginally inhibited by aprotinin (25 μ g/ml), kallikrein activity as assayed by the fluorogenic substrate Pro-Phe-Arg-AMC was followed through the purification. The two activities were separated by the procedure. The CCK-33 cleaving activity was not inhibited by PMSF (5 mM), soybean trypsin inhibiter (200 µg/ml), pCMB (5 mM) or EDTA (2mM). The activity would not cleave CCK-12 desulfate. Because of its subcellular localization, this non-trypsin, non-kallikrein activity is a good candidate for a CCK converting enzyme. Supported by NIH Grant NS18667

CORRELATION OF ANGIOTENSIN II BINDING AND METABOLISM IN RAT BRAINS. A.L. Dewey and J.W. Harding. Pharmacology/Toxicology Program, Washington State University, Pullman, WA 99164-6510.

We are using the micropunch technique to investigate the correlation of angiotensin II (AII) binding and metabolism of AII to angiotensin III in Wistar-Kyoto (WKY) and Sprague-Dawley (SD) rats. Using a 1-2 mm thick midsagittal slice, we are punching out 5 areas known to bind AII (nucleus of the solitary tract, paraventricular nucleus, subfornical organ, suprachiasmatic nucleus and the cortex of the superior colliculi) and 3 areas as negative controls (the frontal region of the cortex, the posterior region of the cerebellum, and the ventromedial nucleus of the region of the cerebellum, and the ventromedial nucleus of the hypothalamus). We are also including the adrenal cortex as a positive control for binding. Tissue punches from several animals are pooled and divided into aliquots for binding and metabolism. Binding studies are a single point determination using ¹²⁵I (Sarcosine¹) (Isoleucine⁵) AII to quantitate binding. Metabolism studies are done with ¹²⁵I-AII, and use HPLC to separate ¹²⁵I-AII and its metabolites. Detection and quantification are done with radioligand detection. Preliminary binding data agrees with the distribution of AII receptors in brain regions.

166.14

METABOLISM OF CCK-8 AND ITS ANALOGUE BY BRAIN SLICES OF FRONTAL CORTEX AND HIPPOCAMPUS. P.N.M. Konings, T. J. Gillespie*, D. Spall*, S. Fang*, V.J. Hruby* and T.P. Davis. Dept. of Pharmacology, and Dept. of Chemistry, Univ. of Arizona Health Sci. Center, Tucson, Arizona 85724.

Cholecystokinin-8 (CCK-8) is widely distributed throughout the brain and is involved in the neural control of several biological processes. The role which CCK-8 plays is linked to the mechanisms which regulate biosynthesis and metabolism. Brain slices from frontal cortex and hippocampus, rich in CCK-8, were incubated with CCK-8 or an analogue of CCK-8, SNF-8702 (Asp-Tyr-[N-Me]Nle-Gly-Trp-[N-Me]Nle-Asp-Phe-NH2), to study extracellular metabolism by membrane bound peptidases. Rats were ether anesthetized and perfused with cold buffer. Brains were removed and placed into a rat brain matrix. A 2 mm coronal slab was taken at Bregma 4.20 - 2.20 mm and 2 mm punches were taken from frontal cortex. A 2 mm coronal slab was taken at Bregma -4.16 mm - -6.30 mm and punches were taken from the CA3 region. Brain slices (240 μ m) were washed in O2/CO2 (95:5%) buffer at 4°C to remove soluble enzymes. 4 Slices per tube were time-course incubated with 50 µM CCK-8 or SNF-8702 at 37.5°C. CCK-8 was metabolized at a high rate with a half-life of 60 min for both cortex and CA3. Fragments were identified as formed by several proteases. SNF-8702 was stable to metabolism with a t1/2 of > 400 min. This peptidase resistant, biologically active analogue, containing modifications of Met³ and Met⁶ was not recognized by serine proteases or metalloendopeptidase 3.4.24.15. Neutral endopeptidase-24.11 cleavage at Gly⁴-Trp⁵ and Asp⁷-Phe⁸ appears to be inhibited by [N-Me]Nle modifications at the 3 and 6 positions of CCK-8. These data provide information concerning structural requirements for CCK-8 metabolism by specific proteases. (Supp. by NIH DA 06284, DK 36289 and MH 42600)

AUTOCRINE REGULATION OF SELECTED PITUITARY GONADOTROPE FUNCTIONS BY ACTIVIN. A. Corrigan, L. Bilezikian, J. Yaughan, L. Bald*, C. Schmelzer*, B. Sendly*, A. Mason*, R. Schwall* and W. Vale. The Salk Institute, La Jolla, CA; *Genentech Inc, So. San Francisco, CA Inhibins are gonadal dimeric proteins comprising an α and one of two β (β A or β B) subunits, that suppress FSH secretion by the anterior pituitary. Potent FSH-releasing proteins, activins, have been purified from gonadal fluids and characterized to be dimers of the inhibin β subunits. We have shown previously that inhibin/activin α and β B subunit mRNA's are expressed in the anterior pituitary and that the two proteins can be localized by immunohistochemistry to the gonadotropes which produce both LH and FSH. We report here that α and β B subunit proteins were immunoprecipitated and resolved on SDS-PAGE from 35 S-cysteine labeled lysates of cultured rat anterior pituitary cells. We have considered that the pituitary gonadotrope might produce either inhibin B $(\alpha\beta B)$ or activin B $(\beta\beta B)$ and have explored their possible autocrine roles within primary rat anterior pituitary cultures by using antibodies that neutralize either dimer. The addition of mouse monoclonal antibodies against $\beta\beta\beta B$ (MAb- βB) that neutralize the effects of activin B strongly suppressed the spontaneous secretion of FSH while not influencing the release of LH. The inhibition of FSH secretion by MAb- βB was dose and time dependent. Treatment of cells with Mab- βB sensitized cells to activin A $(\beta A\beta A)$, which is not bound by this antibody, while the response to hypothalamic gonadotropin releasing factor was attenuated. The addition of affinity purified rabbit antibodies directed towards the inhibin α subunit (rAb- α) that neutralize the biological activity of inhibins had no effect on basal or GnRH stimulated FSH or LH. We propose that the pituitary gonadotropes produce activin B which selectively enhances the secretion of one of the cells' products, FS

167.3

INHIBIN, ESTROGEN AND PROGESTERONE EFFECT IN OVINE PITUITARY CULTURE ON GNRH RECEPTOR mRNA ACTIVITY. UITARY CULTURE ON GNRH RECEPTION HIGHER Sealfon, J.C. Wu*, S.C. Laws*, B. Gillo, W.L. Miller*. Dept. of Neurology and Fishberg Center in Neurobiology. Mount Sinai Medical School. New York, N.Y. 10029 and Dept. of Biochemistry. North Carolina State University, Raleigh, N.C.

Biochemistry. North Carolina State University, Raleigh, N.C. A Xenopus oocyte expression assay was used to study the effect of hormonal treatment on GnRH receptor mRNA activity in primary ovine pituitary cultures. Cultures were treated for 48 hours with drugs or vehicle and RNA was isolated. Xenopus oocytes, when injected with RNA isolated from cells expressing the GnRH receptor, develop an electrophysiological response to GnRH. The size of the response obtained was used to assay the GnRH receptor mRNA activity in the samples. Oocytes were each injected with 250 ng of total RNA. Two days later, using standard two-electrode voltage clamp, the maximum clamp-current in response to 2 x 10-7 M GnRH was measured. RNA injection from control cultures led to a mean response to GnRH of 8 response to 2 x 10⁻⁷ M GnRH was measured. RNA injection from control cultures led to a mean response to GnRH of 8 nA(n=5). The response obtained after the following treatments were: 10 ug/ml crude inhibin, 90±18 nA(n=5); 10 nM estradiol, 63±32 nA(n=3); inhibin + estradiol, 334±88 nA(n=5); inhibin + 100 nM progesterone, 30±15nA(n=5). These data suggest that estrogen and inhibin have a complementary effect in increasing GnRH receptor mRNA activity and progesterone prevents the inhibin induced increase. (Supported by NIH Grant K11 DK01854 and USDA Grant 86-CRCR-1-2181.)

167.5

Possible role of tubulin in GnRH receptor-G protein coupling in the rat anterior pituitary lobe. R. Ravindra and R.S. Aronstam, Department of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912.

We have recently demonstrated that a GnRH agonist stimulated G

protein GTPase activity in the rat anterior pituitary in a concentrationdependent manner; moreover, this stimulation was blocked by a GnRH antagonist (J. Neuroendocrinology, in press). Colchicine and taxol, which are known to stimulate tubulin-induced GTPase activity, were used in the present study to delineate the possible role of tubulin in signal transduction in the anterior pituitary lobe. Plasma membranes from anterior pituitary lobes obtained from adult male rats were prepared by a discontinuous sucrose gradient method and stored at -80°C. Colchicine and taxol stimulated the G protein GTPase activity in the pituitary membranes in a concentration-dependent manner. For example, 100 nM of colchicine and taxol stimulated the GTPase activity by up to 80% and 70%, respectively. Although these results suggest that these drugs interact with tubulin present in association with the pituitary membranes, the possibility of a direct action on G proteins can not be ruled out. In another experiment, GnRH agonist (100 nM) stimulated the GTPase activity by up to 70%; in the presence of 100 nM of either colchicine or taxol, the ability of GnRH agonist to stimulate the GTPase activity was completely abolished. These drugs may 1) inhibit the GnRH binding to its receptor, or 2) disrupt GnRH receptor-G protein coupling. Studies are in progress to evaluate these two possibilities. (Supported by GM-37948 and AA-07698).

167.2

TRANSFORMING GROWTH FACTOR- β : A POTENT INHIBITOR OF PROLACTIN SECRETION AND LACTOTROPIC GROWTH IN PRIMARY CULTURES OF RAT ANTERIOR PITUITARY CELLS. D.K. Sarkar and S. Minami*. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Transforming growth factor- β (TGF- β) has been shown to be an important regulator of growth and differentiation of various normal probability of the state of the st

epithelial cell types. We report here, for the first time, that this growth factor inhibits both the secretion and growth of anterior pituitary (AP) lactotropes in primary cultures.

Enriched populations of rat AP cells were obtained from estradiol

(E₂)-treated ovariectomized female rats and grown in culture, in serum-free Macoy-5A media for the secretion studies or grown in Macoy-5A media containing 2.5% fetal calf serum for the growth studies. Acute treatment (4 h) of TGF- β (0.002-20 ng/ml) dose dependently inhibited the secretion of basal and TRH-induced prolactin release. The basal secretion of other AP hormones was not affected by similar treatment. Furthermore, 2.0 ng/ml of TGFpotentiated the inhibitory action of 1 μ M but not 10 and 100 μ M of dopamine on prolactin secretion. Long-term treatment (1-6 days) with 2.0 ng/ml of TGF- β completely suppressed the basal and E₂with 2.0 ng/ml of 1GF-\$ completely suppressed the basal and E₂induced growth of lactotropes in culture, as assessed by counting
viable cell numbers and ³H-thymidine incorporation into cellular
DNA. The growth-inhibiting action of the growth factor was
prevented by a monoclonal antibody to TGF-\$. These results suggest that TGF-\$\beta\$ may be important in controlling pituitary lactotrope growth and function.

GnRH DECREASES GnRH RECEPTOR mRNA ACTIVITY IN A RODENT

GnRH DECREASES GnRH RECEPTOR mRNA ACTIVITY IN A RODENT PITUITARY CELL LINE. M. Tsutsumi. P.L. Mellon. J.L. Roberts, and S.C. Sealfon. Fishberg Center in Neurobiology, The Mount Sinai School of Medicine, New York, NY 10029 and Regulatory Biology Laboratory (P.L.M.), The Salk Institute, San Diego, CA 92138.

Gonadotropin releasing hormone (GnRH) is a hypothalamic decapeptide that stimulates luteinizing hormone and follicle-stimulating hormone secretion from the anterior pituitary gland. Activation of pituitary gonadotrophs by GnRH is dependent on the level of GnRH as well as the responsiveness of GnRH receptors to GnRH and other agonists. GnRH receptor expression in Xenopus oocytes injected with RNA isolated from alpha-T3 cells, a gonadotrope cell limederived from a transgenic mouse, has been demonstrated (Mol. Endocrinol. 4: 119, 1990). Using Xanopus oocyte as a bioassay, GnRH receptor mRNA activity levels from alpha-T3 cells treated with GnRH, inhibin, testosterone, progesterone, and estrogen were examined. No apparent change was found in GnRH receptor mRNA activity from alpha-T3 cells treated with inhibin, estrogen, progesterone, and testosterone for 48 hours. Exposure to GnRH, however, led to a decline in GnRH receptor mRNA activity, similar to that seen in the thyrotropin releasing hormone receptor regulation in GH3 rat pitulitary cells by thyrotropin releasing hormone (Science 238: 1406, 1987). A 40 % decrease was observed in mRNA activity isolated from alpha-T3 cells treated with 1 uM GnRH for 48 hours. These data suggest GnRH receptor regulation by altered biosynthesis in response to continuous exposure to GnRH in alpha-T3 cells.

MODULATION OF NEURAL OXYTOCIN mRNA BY GONADAL STEROIDS DURING SEXUAL MATURATION. R. Chibbar*, J. Toma*, B.F. Mitchell*, F.D. Miller. Depts. of Anatomy & Cell Biology, & Obstetrics & Gynecology, Univ. of Alberta, Edmonton, Alberta. CANADA
We have previously demonstrated (Miller, F.D. et al P.N.A.S. 86;2468) that in female rats, oxytocin (OT) mRNA increases during puberty and is decreased in adult females following ovariectomy. We have investigated the factors that regulate neural oxytocin mRNA in the male and female rat brains during puberty. Prepulpertal male and female rats were sprained for miles. neural oxytocin mkNA in the male and temale rat brains during puberty. Prepubertal male and female rats were gonadectomized and replaced with estradiol and testosterone. Forty days later animals were sacrificed and total cytoplasmic RNA preparations from the brain were analyzed on Northern blots using 32P labelled oxytocin riboprobes. These experiments indicate that the pubertal increase in OT mRNA is partially inhibited by gonadectomy. This inhibition is completely reversed by administration of exogenous steroids. Estadiol had greater effects on OT gene expression than testosterone in both male and female rats. To determine whether oxytocinergic neurons were equally responsive to steroid hormones at all developmental stages, 10 day old male and female rats were treated with estradiol, testosterone or dihydrotestosterone for 10 days. Steroids had no effect on the expression of OT mRNA in the prepubescent rats suggesting that neuronal maturation is a requisite for sensitivity to gonadal steroids. We also determined levels of OT mRNA during the estrus cycle in mature female rats: OT mRNA was approximately two-fold higher during proestrus versus metestrus or diestrus. These studies suggest levels of circulating gonadal steroids regulate neural OT mRNA but that additional factor(s) also play a role in the observed developmental increase.

OXYTOCINMEDIATES THE ANGIOTENSIN-INDUCED RELEASE OF L.H. <u>C. A. Johnston, J. B. Gelineau-van Waes* and M. V. Templin*</u>. College of Pharmacy, Wash. State Univ., Pullman, WA 99164-6510.

Recent evidence from our laboratory using the cycling female rat has demonstrated a physiologically important stimulatory role for central oxytocin (OXY) neurons in regulating the preovulatory release of luteinizing hormone (LH). This effect requires the presence of physiologically high levels of plasma estradiol (E2). Central injection of angiotensin II (ANG II) also stimulates LH release by an E2-sensitive mechanism (Steele et al., Endo. 111:722, 1982). To determine whether the influence of ANG II on LH secretion was mediated by OXY neurons, the ability of intracerebroventricular (icv) injection of ANG II (10 ng) to affect plasma LH was examined on both proestrus (when plasma E2 is high) and on metestrus (when plasma E2 is low) in rats pretreated with either saline or an OXY antagonist, [1-(β-mercapto-β, β-cyclopentamethylene propanoic acid) 2-0-methytryosine, 8-orni-thinel vasotocin (45 ug/kg BW, iv) 50 min prior to the icv injection. ANG II or vehicle was administered at 15:00 h on proestrus or metestrus and plasma samples were obtained via chronic jugular cannulae from the unanesthetized, freely moving rats at 10 min before and 5, 15, 30 and 60 min after the icv injections. ANG II increased plasma LH on proestrus and tended to decrease LH on metestrus. The OXY antagonist blocked the increase in LH caused by ANG II on proestrus, and ex-erted a slight stimulatory influence on plasma LH on metestrus. The data demonstrate that the ANG II-induced effects on plasma LH may be mediated by OXY neurons, and that the influence of OXY neurons on LH may switch from inhibitory to stimulatory under the influence of E2.

167.9

SEXUALLY DIMORPHIC DISTRIBUTION OF NEUROTENSIN mRNA IN THE MEDIAL PREOPTIC REGION OF THE RAT. M.J. Alexander, Z.J. Kiraly*, and S.E. Leeman, Univ. of Mass. Med. Ctr., Worcester, MA 01655.

We have previously reported that estrogen induces neurotensin (NT) mRNA in the

terior medial preoptic nucleus (AMPN) (Endocrinology 125:2111, 1989), a cell group essential for the preovulatory surge of luteinizing hormone in the rat. To investigate the possibility of sexually dimorphic expression of the NT gene in this region, we used in situ hybridization histochemistry with a 35S-labeled cRNA probe to detect NT mRNA in adult male (n = 6) and female (n = 12) rats. Brains were obtained from female rats at diestrus 1 (n = 6) and proestrus (n = 6), the estrous cycle stages during which circulating estradiol levels are at a minimum and maximum, respectively. In both males and females, labeled cells were present in a continuum beginning in, or immediately lateral to, the AMPN and extending caudally through the medial preoptic nucleus (MPN). However, a marked sex difference in the distribution of NT mRNA was observed. A single coronal section (20 µm) through the caudal AMPN of each rat was examined by an investigator blinded to the rat's sex, and bilateral cell totals were obtained. The AMPN cross section from proestrous rats contained four times (36 \pm 3) as many labeled cells as did that of male rats (9 \pm 1). Cell totals for diestrous rats were intermediate and more variable (18 \pm 5) but were nevertheless significantly different from the proestrous totals. There was also a sex difference in the distribution of NT mRNA in the rostral portion of the medial subdivision of the MPN, where labeled cells in the female were located closer to the midline than those of the male. These results i) provide evidence of sexually dimorphic expression of the NT gene in the rat preoptic region, ii) indicate that NT mRNA abundance in the AMPN varies across the estrous cycle in parallel with the circulating estradiol level, and iii) are consistent with the view that NT neurons in the AMPN are involved in the neural regulation of the preovulatory surge of luteinizing hormone.

SERUM LH AS INFLUENCED BY NEUROPEPTIDE Y (NPY) IN SHEEP.

T. M. McShane', J. L. Miner, D. K. Keisler' and J. A.

Paterson', Dept. Anim. Sci., Univ. of Missouri, Columbia,
MO 65211.

In experiment 1, the effect of centrally administered NPY on tonic secretion of LH was investigated. Six yearling ewes were fitted with lateral cerebroventricular (LCV) and indwelling jugular cannulas. Ewes were synchronized using progestagen sc implants. Twenty-two hours after implant removal, feed was removed and blood was collected every 15 min for 6 h for LH and estradiol 17-8 (E) analysis. At 26 h after implant removal, ewes were injected LCV with either 13 µg of NPY (NPY, n=3) or .9% saline (SAL, n=3). Feed intake between 2 and 3 h post treatment was greater (P<.02) in NPY (483.3 g) vs SAL (176.7 g). Serum conc. of E (pg/ml) did not differ between NPY (4.12) and SAL (3.96). All ewes exhibited episodic secretion of LH prior to LCV injection, whereas during 2 h post-treatment, 3/3 SAL and 0/3 NPY exhibited a pulse of LH. In exp. 2, 30 days following exp. 1, ewes were renadomized and treated as in exp. 1. Fifteen min following LCV treatment, 50 µg GnRH was given iv to each ewe. Blood samples were obtained every 15 min, from immediately prior to until 2 h after LCV treatment. Concentrations of LH did not differ between NPY and SAL over time. In summary, NPY may act to suppress tonic secretion of LH in the presence of E (ranging in serum conc. from 2.50 to 5.33 pg/ml), but does not influence GnRH-induced LH secretion.

167.8

HIGH LEVELS OF BRAIN ANGIOTENSIN PRECEDE THE LUTEINIZING HORMONE SURGE IN FEMALE RATS. I. Phillips, B. Kimura*, P. Borra*, M. Rejtman*, S.P. Kalra and P. Kalra. Dept. of Physiology, University of Florida, Gainesville, FL 32610.

Brain angiotensin (b Ang II) has several functions in fluid balance and has been implicated in reproductive function. To test if brain ang II is elevated during the reproductive cycle, 3 experiments were carried out in rats. 1) Normal, cycling in female rats was tested by vaginal smears and brain tissue removed at metestrus, diestrus, proestrus and estrus. The results showed occasional but inconsistent high levels of b Ang II during the proestrus phase. 2) Female rats were ovariectomized and given replacement estrogen. On the day of testing, rats were injected with progesterone at 10 a.m.. This results in an LH peak at 3 p.m. At 10 minute intervals from 12 a.m. to 3 p.m., rats were escrificed and brain Ang II measured by RIA and HPLC. Brain Ang II in the hypothalamus is normally 100 pg/gm tissue. Between 1:20 p.m. and 1:45 p.m., 4 rats had levels of b Ang II in the ug or ng range in the hypothalamus. These high increases in b Ang II occurred prior to the LH peak. Plasma Ang II levels did not rise. 3) Female rats treated the same as in Exp. 2, were anesthetized and CSF collected through an intraventricular push-pull perfusion technique. Samples of CSF were collected every 15 minutes, 2 hours after progesterone injection. A peak of Ang II in CSF was found 3.5 hr. after progesterone. The results indicate that b Ang II peaks in high quantity before the LH release and may contribute to the beginning of the LHRH-LH surge. These are the highest levels of Ang II we have ever detected in the brain.

167.10

INTRAVENTRICULAR ADMINISTRATION OF NEUROPEPTIDE Y (NPY) INHIBITS LH RELEASE IN OVARIECTOMIZED SHEEP.

P. V. Malven, S. A. Haglof* and H. DeGroot*. Dept. Animal Sciences, Purdue Univ., West Lafayette, IN 47907.

We investigated whether the elevated secretion of pituitary LH in

We investigated whether the elevated secretion of pituitary LH in ovariectomized ewes could be suppressed by intracerebral infusion of NPY via permanently implanted guide cannula. Human NPY in dosages of 20 μ g peptide/infusion (20 μ l volume and 20 sec duration) was infused unilaterally into the brain of 9 ewes (13 different sites) on 46 days. Equal volumes of saline were infused 1 day before or after NPY. Each daily infusion occurred after 90 min of blood sampling at 10 min intervals, and this sampling continued for an additional 100-190 min. Concentrations of serum LH were quantified by radioimuunoassay and were presumed to reflect LHRH secretion. To infer that exogenous NPY suppressed LHRH, post-NPY concentrations of LH had to be lower than (1) pre-NPY levels as well as (2) post-saline levels for all trials at a particular site. These criteria were satisfied in 13 NPY trials representing 5 cannula sites. Four of these five sites were in or near the ventricular system. Two sites were in the anteroventral portion of one lateral ventricle while two other effective sites were in the rostral part of the 3rd ventricle. The fifth effective site was within the tissue of the hypothalamic ventromedial nucleus. Ineffective sites of NPY infusion included posterior hypothalamus and the lateral and dorsolateral parts of anterior hypothalamic area. Although the site of NPY action cannot be precisely localized after intraventricular infusion, these results suggest that NPY may suppress LHRH by acting on circumventricular tissues in and around the medial parts of the rostral hypothalamus. In summary, intracerebral administration of NPY suppressed release of LHRH/LH in ovariectomized ewes, and this effect is consistent with published observations in ovariectomized rats and rabbits. Supported in part by USDA grant 87-CRCR-1-2538.

NALOXONE ENHANCES LHRH RELEASE FROM THE ISOLATED HYPOTHALAMUS OF OVARIECTOMIZED, ESTROGEN-PRIMED, MIDDLE-AGED RATS. B.S.Rubin, J.C.King and R.A.Strauss. Department of Anatomy and Cellular Biology, Tufts Health Science Schools, Boston, MA 02111.

Endogenous opiates are important for the maintenance of regular estrous cyclicity, and changes in opiate tone on proestrus may be integral to the preovulatory LH surge. Experimental evidence suggests that opiate neuronal activity may change with age. Such changes could contribute to the eventual loss of spontaneous LH surges in female rats. The present study tests the ability of an opiate receptor blocker to influence LHRH release from hypothalamic fragments from ovariectomized, estrogen-primed, middle-aged (MA) female rats. Young and MA animals received 3 days of estrogen priming, and were sacrificed prior to the expected afternoon LH surge. Brains were removed and the MBH was dissected and placed into 0.5 ml chambers for in vitro perifusion. Fragments were oxygenated, maintained at 37° C, and effluents collected continuously at 10 minute intervals. After an initial 2 hour period, tissues were stimulated sequentially at hourly intervals with pulses of naloxone (0.4 mg/ml), norepinephrine (600 uM), and potassium chloride (Il0 mM). LHRH output from hypothalamic fragments from all of the MA females was enhanced by at least 50% after exposure to naloxone. Naloxone enhanced LHRH output from 4 of the 6 hypothalami taken from young females. These data suggest that endogenous opiates continue to exert an inhibitory influence on LHRH release in aging females prior to an expected LH surge. The possibility that opiate influence remains elevated in MA females and contributes to age-related alterations in the LH surge is being examined in vivo. Supported by NIH HD 19174.

NALOXONE AUGMENTS LH PULSE FREQUENCY IN GONADECTOMIZED MALE AND FEMALE FERRETS BEFORE, BUT NOT AFTER, ESTRADIOL REPLACEMENT. G.M. Lambert, M.S. Erskine, and M.J. Baum. Dept. of Biology, Boston University, Boston, MA 02215.

Male and female ferrets were purchased in breeding condition and gonadectomized. Ten days later, subjects were implanted with double intrajugular catheters. Blood samples were collected every 5 minutes from each subject via one catheter tube, while saline or the opioid receptor antagonist, naloxone (600 µg/kg/hr) was continuously infused for 2 hours via the other catheter. Intravenous infusions of naloxone caused a significant rise in LH pulse frequency in males and females, while mean LH concentrations and LH pulse amplitudes were not affected. Gonadectomized ferrets were then given 2 daily injections of a low dose of estradiol (1.25 µg/kg) for one week which produced plasma levels of estradiol similar to those of intact estrous females. Naloxone failed to stimulate LH pulse frequency, or other LH parameters in gonadectomized ferrets of either sex after they received estradiol. Our results for the ferret resemble those previously obtained by other investigators in another induced ovulator, the rabbit. They contrast, however, with the results of numerous studies using spontaneously ovulating species in which gonadal steroids, if anything, facilitate the ability of naloxone to stimulate LH secretion.

CHANGES IN OPIOID INHIBITION OF LUTEINIZING HORMONE (LH) SECRETION IN PREPUBERTAL EWES. C.S. Whisnant, R.L. Havern and D.J. Tortonese. Department of Physiology, West Virginia University, Morgantown, WV 26506

Previous research indicates that opioid antagonists increase LH secre-

Previous research indicates that opioid aniagonists increase Lri secretion in prepubertal ewes. We have found that the LH response to a single dose of the opioid antagonist WIN44,441-3 (WIN) decreased with age prior to puberty. The purpose of the current study was to determine: 1) a more complete dose-response curve for WIN at various ages and 2) pituitary response to gonadotropin-releasing hormone (GnRH). Prepubertal ewes were given 0, .0625, .125 or .25 mg WIN/kg body weight, (n=6/group) at 16, 22, and 28 weeks of age. Blood samples were taken at 15 min intervals for 3 h before and after WIN injection (iv). Ewes were then given 5 ng/kg body weight of GnRH (iv) and blood samples taken for 1 h. At 16 weeks of age only the .25 mg/kg dose increased LH secretion. In contrast, in 22 week old lambs both the .125 and .25 mg/kg doses were effective in increasing LH pulse frequency. At 28 weeks, there was no LH response to any dose. Pituitary response to GnRH was greater (P < .05) at 22 weeks than at other ages. Experiment 2 was conducted to determine if a diurnal variation existed in response to WIN at these ages. Lambs on a natural photoperiod were injected with .25 mg/kg WIN at either 0900, 1200 or 1500 h. Blood samples were taken at 15 min intervals for 1 h before and 5 h after WIN injection. Half of the ewes (n=8) at each time received dextrose as a vehicle. At 16 and 22 weeks of age, lambs in the 0900 and 1500 h groups had increased LH pulse frequency (P < .01) following WIN injection. However there was no response in the 1200 h group. At 28 weeks there was no effect of WIN at any time. These results suggest a decrease in opioid inhibition of LH secretion as lambs mature. Further it appears that at 16 and 22 weeks of age inhibitory opioid tone varies during the day.

167.17

AN INCREASE IN 8-ENDORPHIN IN ARCUATE NEURONS IS CORRELATED WITH REPRODUCTIVE MATURATION IN MALE FERRETS. Y.P. Tang and C.L. Sisk. Neuroscience Program and Dept. of Psychology, Michigan State University, East Lansing, MI 48824.

Steroid negative feedback on luteinizing hormone (LH) secretion is mediated in part via endogenous opiate inhibition of LH-releasing hormone. In male ferrets, the low circulating levels of LH observed prepubertally are solely due to gonadal steroid inhibition, and a decrease in responsiveness to steroid permits the pubertal rise in pulsatile LH release. We tested whether production of the endogenous opiate \(\textit{B}\)-endorphin is greater in prepubertal than in postpubertal ferrets. \(\textit{B}\)-endorphin-producing neurons of the arcuate nucleus were identified immunocytochemically in sexually immature (n=4) and mature (n=4) male ferrets. Two animals in each group received a cerebroventricular injection of 200 \(\textit{µg}\) colchicine in 2 \(\textit{µl}\) at ricical CSF; the other 2 ferrets in each group received vehicle injections. Ferrets were anesthetized and perfused with Zamboni's fix 24 hr later. Coronal sections (40 \(\textit{µm}\)) were processed for immunocytochemical visualization of \(\textit{B}\)-endorphin using R. Benoit's \(\textit{B}\)endor-2 as first antibody, Vecastain ABC-Elite Kit reagents, and diaminobenzidine as chromagen. In both groups, the number of labelled cell bodies was increased by colchicine pretreatment. The number of immunopositive arcuate neurons was 15-fold higher in colchicine treated adults compared to colchicine treated prepubertal ferrets. These results do not suggest that a decrease in production of \(\textit{B}\)-endorphin mediates the pubertal decrease in responsiveness to steroid negative feedback, but indicate an alternative role for this neuropeptide during reproductive maturation. Supported by HD26483.

B-ENDORPHIN REGULATION OF LHRH RELEASE IN EWES: IMMUNO-CYTOCHEMISTRY, TISSUE CONTENT AND IN VIVO ANALYSIS. C.D. Conover*, R.O. Kuliis, D.K. Sarkar and J.P. Advis. Dept Animal Sci, Rutgers Univ, New Brunswick, NJ 08903, VCAPP, Washington State Univ, Pullman, WA 99164 and Dept Neurol, Univ Iowa Coll Med, Iowa City, IA 52242.

Pullman, WA 99164 and Dept Neurol, Univ Iowa Coll Med, Iowa City, IA 52242.

B-endorphin (βE) and other endogenous opioids have been implicated in the neuroendocrine control of LHRH release. We analyzed: a) the distribution of both peptides immunocytochemically; b) their tissue content in median eminence (ME) and immediately adjacent hypothalamic areas, and c) their in vivo release from ME by push-pull cannula (PPC) sampling during the estrous cycle of the ewe. BE containing perikarya are located in and around the arcuate nucleus and fibers are present in the diagonal band, medial septal nucleus, and medial and lateral hypothalamic areas, including the preoptic region and the posterior ME. LHRH-containing perikarya located in the preoptic area project also to the ME, providing opportunities for synaptic interactions between βE- and LHRH-containing axons at this level. In vivo release of βE from the postero-lateral ME in the same ewes (n=5) was higher in late luteal (day 16) than in mid-luteal (day 11) stages of their estrous cycle (30±8 vs 139±30, mean ± sem, pg/200 μ PPC perfusate/20 min). In vivo LHRH content in these same PPC samples also increased from day 11 through16 of the estrous cycle (16±5 vs 76±20 pg/200 μ PPC perfusate/20 min). Administration of βE through the PPC (5 μg/ 200 μ PPC perfusate) decreased in vivo LHRH release in late luteal (P<0.01) but not in mid-luteal ewes. Changes in βE tissue content were observed in ewes killed during these reproductive stages (58% reduction in ME-stalk: 45±7 vs 26±6 pg/μgP and 500% increase in infundibulum/ arcuate: 5±3 vs 25±6 pg/μgP, n=12, mid-luteal vs late luteal, respectively). These results indicate that βE might effect an increasing tonic inhibition on LHRH release until the onset of the preovulatory surge of LHRH (Supported by NJES-Hatch 06108 and USDA 89-37240-4587 to JP Advis).

167.16

EFFECT OF ESTRADIOL (E₂) ON LHRH AND POMC mRNA LEVELS DEPENDS UPON THE INTERVAL BETWEEN OVARIECTOMY AND HORMONE REPLACEMENT. <u>S.L. Petersen</u>, S. <u>Shores* and S. McCrone*</u>. Dept. of Anat. & Neurobiol, Univ. Missouri Med. Sch., Columbia, MO 65212.

Estradiol (E₂) exerts both negative and positive feedback effects on LH release, in part, by altering LHRH neuronal activity. β-endorphin (synthesized from proopiomelanocortin mRNA; POMC) has been implicated as a negative modulator in the transduction of E₂ signals into the LHRH system. We have shown previously that in ovariectomized (OVX) animals, positive feedback effects of E₂ on LH release are temporally associated with changes in LHRH mRNA and POMC mRNA levels which, in turn, appear to reflect changes in neuronal activity. In the present studies we tested the hypothesis that negative feedback effects of E₂ on LH release are also reflected in changes in LHRH and POMC mRNA levels. We used in situ hybridization histochemistery to measure mRNA changes resulting from E₂ treatment in long-term (LT) versus short-term (ST) OVX females, models exhibiting different levels of negative feedback. Rats were OVX and implanted s.c. either immediately (ST), or after 4 weeks (LT) with E₂. Three days after implantation, animals were sacrificed between 0800 and 0900 H. POMC mRNA levels were markedly decreased in LT OVX rats compared with E₂-treated LT OVX rats. Surprisingly, LHRH mRNA levels were also markedly decreased in the LT OVX rats, E₂ decreased LHRH mRNA levels, but did not alter POMC mRNA levels. These results suggest that the activity of neurons encoding LHRH and β-endorphin may be decreased in LT OVX rats and that previously-reported differences in the effect of E₂ on LHRH mRNA levels may be a result of differences in animal models.

167.18

AGE-RELATED CHANGES IN PROOPIOMELANOCORTIN (POMC) GENE EXPRESSION IN THE ARCUATE NUCLEUS OF OVARIECTOMIZED RATS ARE INDEPENDENT OF REPRODUCTIVE STATUS. J.M. Lloyd* and P.M.Wise. Dept. Physiology, U. Maryland, Baltimore, MD 21201

The transition to reproductive acyclicity in the rat is associated with altered hypothalamic function. This results in subtle changes in the pattern of pulsatile LH secretion. Diate peptides are thought to play a role in maintaining normal patterns of LH secretion; however, it is unknown whether they are involved in age-related reproductive decline. The present study was designed to assess whether POMC gene expression changes with age, and whether any changes are related to the reproductive status of the animal. Seven groups of animals were used: young (3-4 mo) regularly cycling; middle-aged (10-12 mo) regularly cycling, irregularly cycling; and constant estrus; and, old (17-19 mo) regularly cycling, constant estrus and persistent diestrus. Three weeks after bilateral ovariectomy (OVX) animals were sacrificed at 1000 h and the brains rapidly removed and stored at -70°C. Brain sections (8µm) were taken through the arcuate nucleus and prepared for *in situ* hybridization with a ³⁸S-labelled POMC riboprobe. Slides were exposed to film and POMC mRNA levels were highest in the young animals and were decreased in the middle-aged group. No further decline was noted in old animals. This age-related decline in POMC mRNA aveils windependent of the reproductive status of the animals before OVX. These data suggest that hypothalamic POMC mRNA levels decline by the time animals are middle-aged and may contribute to reproductive decline. (NIH AG 02224).

MEDIAL PREOPTIC 4-OPIATE RECEPTOR DENSITY BEFORE AND AFTER PARTURITION IN RATS, A.R. Mateo*, R.P. Hammer, P.M. Ronsheim*, and R.S. Bridges. Dept. Anat. & Reprod. Biol., Univ. Hawaii, Honolulu, H 96822 and Dept. Anat. & Cell. Biol., Harvard Med School, Boston, MA 02115.

Activation of μ-opiate receptors disrupts maternal behavior in rats (Bridges & Grimm, 1982). μ-Receptor density in the medial preoptic area (MPOA) is elevated during pregnancy and reduced during lactation (Hammer & Bridges, 1987). Moreover, the density of MPOA μ -receptors is cyclical and gonadal steroid hormone-dependent (Hammer, 1990). The present study examined MPOA μ -receptor density during the periparturitional period. Brains were removed from ovariectomized or timed-pregnant Sprague-Dawley rats on days 18, 20 or 22 of pregnancy, and 1 hr or 1 day postpartum. Cryosections were prepared, preincubated for 30 min at 4°C in buffer, incubated for 60 min at 25°C in 50 mM Tris HCl, 3 mM MnAc, 0.1% BSA and 2 nm [3H]DAGO, rinsed, dried and exposed to X-ray film. Density of MPOA μ receptors was then determined using quantitative autoradiography. Receptor density was greatest on day 18 of pregnancy, when it was significantly higher than after ovariectomy (p < 0.01). Thereafter, receptor density declined gradually. There was, however, no abrupt change in density after parturition. It would appear that µ-receptor density decreases gradually following parturition, and that this decrease is not directly affected by the prepartum decline in plasma progesterone. Rather, receptor level may decline over time due to receptor turnover in the absence of sufficient hormonal stimulus promoting continued receptor expression. The subsequent reduction of MPOA µ-receptor level later during lactation may facilitate continued expression of maternal behavior. Supported by USPHS Awards DA04291 and MH00536 to RSB and NS01161 and RR03061to RPH.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: GnRH

168.1

DIM LIGHT DURING THE NIGHT DECREASES HYPOTHALAMIC LHRH CONTENT OF RATS. T.Porkka-Heiskanen, M-L.Laakso*, D.Stenberg. Institute of Physiology, University of Helsinki, Finland We have previously reported that the hypothalamic LHRH content of rats decreases under constant light (Porkka-Heiskanen, Acta Physiol Scand 1990, 138:187-192). The melatonin synthesis of the rat is known to be inhibited in such conditions. In the present experiment we studied the effect of dim night light on the hypothalamic LHRH and princal melatonin contents of rats. The ratis known to be limited in such containts. In the present experiment we studied the effect of dim night light on the hypothalamic LHRH and pineal melatonin contents of rats. The rats were kept under 12/12 illuminance schedule, where during the day the illuminance was 300 lx and during the night for the experimental group 1 lx and for the control group complete darkness. After one week the rats were decapitated in groups of 10 animals during 24 hours every three hours beginning at 1000 h. In the night light group the nocturnal pineal melatonin was significantly decreased (2-way ANOVA, p < 0.0001), but not to the daytime levels, the peak appeared at 0400 h in both the control and the night light groups. The hypothalamic LHRH content was significantly decreased in the night light group (2-way ANOVA, p < 0.0001) throughout the day. We conclude that the decrease of hypothalamic LHRH content is as sensitive to illuminance as the pineal melatonin synthesis. The decrease appears also in periodically altering light (300 vs. 1 lx) and thus seems to be dependent on the intensity of the night illuminance rather than on the lack of periodicity under constant light.

EVIDENCE THAT CAESARIAN-SECTION-INDUCED OVULATION IN THE RAT IS MEDIATED BY THE PELVIC AND HYPOGASTRIC NERVES.

S.T. CUNNINGHAM, J.S. ROSENBLATT* AND B.R. KOMISARUK

Inst. Animal Behavior, Rutgers Univ., Newark, NJ 07102

In the rat, a spontaneous ovulator, mating can induce ovulation reflexively (Endoc. 79:1130, '66). Furthermore, reflexive ovulation in rats in response to afferent stimulation of the reproductive tract is indicated by or the reproductive tract is indicated by findings that Caesarian section (CS) induces early ovulation (latency approx. 18h) that is blocked by uterine ligation (N.P. Johnson, <u>Diss. Abst.</u>, '72). To test whether the innervation of the reproductive tract mediates CS-induced ovulation, tubal over and hemorrhagic ovarian follicles were counted 24h after bilateral transection of the pelvic (PX) and/or hypogastric (HX) nerves or sham neurectomy, performed on gestation day 22 (8-11 AM). Immediately upon completion of this procedure, all rats received CS. Results: (Mean and [range] #ova, and whemorrhagic follicles, resp.): Sham group, n=8: 4.5 [1-11], 3.5 [1-5]; FX, n=7: 0 [0-2], 0 [0-9]; HX, n=5: 0 [0], 0 [0]; PX+HX, n=5: 0 [0], 0 [0]. All nerve transection groups were significantly lower in both measures than the sham group (Mann-Whitney U-tests, p's <0.01-0.05). These findings suggest that CS activates the pelvic and hypogastric nerves to trigger ovulation, implying that normally the afferent stimulation produced during parturition may reflexively stimulate ovulation. HYPOTHALAMIC GONADOTROPIN-RELEASING HORMONE (GnRH) GENE EXPRESSION IN LACTATING RATS. O.-K. Park, S. Gugneja*, and K. E. Mayo*. Department of Biochemistry, Molecular Biology and Cell Biology, Northwesterm University, Evanston, IL 60208.

Suppression of LH secretion in lactating rats is thought to occur by a decrease in hypothalamic GnRH secretion. To address the question of whether a suckling stimulus plays a role in regulating the hypothalamic GnRH system, we examined GnRH gene expression utilizing in situ hybridization. Pregnant rats were housed individually with a standard photoperiod (14L:10D). Four groups of animals were included in this study: intact with or without pups, and ovariectomized (OVX) with or without pups. The day of delivery was designated day 0. On day 2, bilateral OVX was performed and litter size was adjusted to 9. On day 8, pups were removed from appropriate groups. At 1000-1100 h on day 10, rats were sacrificed, brains were rapidly frozen for in situ hybridization and trunk blood was collected for gonadotropin RIAs. 20 µm coronal sections of the brain in a region encompassing the diagonal band of Broca (DBB), the septal area, the organum vasculosum of the lamina terminalis (OVLT), and the preoptic area (POA) were hybridized to an ³⁵S-UTP-labeled antisense RNA probe synthesized from a full-length rat GnRH cDNA. The number of GnRH mRNA-expressing cells in the OVLT-POA in both intact and OVX rats with pups was decreased to 68.6 ± 6.7 % and 69.6 ± 5.3 % of control values, respectively. In these animals, serum LH levels were significantly decreased while serum FSH levels remained unchanged. No significant changes in the number of GnRH mRNA-expressing cells were noticed in the DBB and the septal area, suggesting that GnRH gene expression in subsets of GnRH neurons located in the OVLT-POA area is inhibited by the suckling stimulus. No noticeable differences were found between intact and OVX groups, indicating that the effect of suckling does not require ovarian steroids. Our results suggest t

EFFECTS OF SHORT-TERM CASTRATION ON LHRH PATTERNS IN INTRA-HYPOPHYSIAL MICRODIALYSATES. J.E. Levine and J.M. Meredith. Dept. Neurobiol & Physiol., Northwestern Univ., Evanston, IL 60208

In a recent study using push-pull perfusion of the hypothalamus, we demonstrated that frequency of pulsatile luteinizing hormone-releasing hormone (LHRH) release is increased in short-term castrate rats. It was proposed that hypothalamic feedback actions of testicular hormones are increased in short-term castrate rats. It was proposed that hypothalamic feedback actions of testicular hormones are manifest primarily through retardation of the activity of the LHRH pulse generator. We sought to confirm this hypothesis by measuring LHRH in the extra-cellular fluid of the anterior pituitary. Rats received guide cannulae implants with stylettes extending into the adenohypophysis. Animals underwent intra-hypophysial microdialysis procedures on day 4 following castration or sham-surgery. Analysis of microdialysate LHRH levels revealed that patterns in both groups were pulsatile, with mean pulse frequency being moderately higher (p<.05) in castrates (1.30±0.26 pulses/h, n=0) vs. sham-castrates (0.87±0.06 pulses/h, n=11). Castration produced no significant effect on LHRH pulse amplitude and mean LHRH levels. Our results using intrahypophysial microdialysis are strikingly similar to those previously obtained in hypothalamic push-pull perfusion experiments. Moreover, they are entirely consistent with the hypothesis that rapid responses (<24h) to castration arise primarily from disinhibition of pituitary responsiveness, while more slowly-developing changes in LHRH pulse generator activity, such as those observed in this study, underlie the continued post-castration rise in LH secretion. (NIH RO1-HD20677, PO1-HD21921, and KO4-HD00879)

DYNAMIC CHANGES IN PROGNRH AND GNRH DURING PROESTRUS IN THE FEMALE RAT. Y.J. Ma. M.J. Kelly and O.K. Ronnekleiv. Dept. of Physiology, OHSU, Portland and ORPRC, Beaverton, 0R 97201.

The contents of proGnRH and GnRH in preoptic area (POA) and basal hypothalamus (BH) were measured by RIA using ARK2 and EL14 antisera, respectively. Plasma levels of LH, estrogen and progesterone were also determined. Female rats on a 12:12 light:dark schedule, lights off at 1630 h, were sacrificed at hourly intervals during proestrus (0830-1730 h). ProGnRH was significantly (P < 0.01) elevated in the POA (mean peak value: 150 \pm 20 fmoles/POA, N-6), but not in the BH (mean value: 22 \pm 2 fmoles/BH, N-6, 6-7 h before lights off. GnRH was significantly (P < 0.01) elevated in the BH (mean peak value: 2160 \pm 110 fmoles/BH, N=6), but not in the BH (mean value: 22 to 2 fmoles/BH, Pfonces/POA, N=6), 3 h before lights off and immediately preceding the proestrous surge of LH h. Plasma levels of estrogen were elevated during the morning and declined at the time of the LH surge. Plasma levels of progesterone were low during the morning, and increased at the time of the LH surge. These data indicate that there is an increase in synthesis of proGnRH in the POA and increase in processing to GnRH during transport to the median eminence prior to the LH surge during proestrus. The mechanisms by which these changes occur are presently being investigated. (PHS HD 16793, P30 HD 18185).

EFFECTS OF INCUBATION TEMPERATURE ON THE IN VITRO SECRETION OF TRH, CRH, GnRH. G. Cizza* 1 2, A.E. Calogaro* 1 2, G. P. Chrousos 2, P. W. Gold* 1, and M. A. Kling 1. CNE NIMH 1, and DEB NICHD 2, National Institutes of Health (NIH) Bethesda, M. D. 20895

A. G. P. Chrousos 2, P. W. Gold* 1, and M. A. Kling 1. CNE Betheda, M. D. 20895

The hypothalamus has a major role in the control of temperature. On the other hand, several hypothalamic hormones can affect body temperature directly affects the secretion of themoregulatory peptides. Hypothalami explanted from 8-10 week old S-D male rats and incubated in medium M 199 in a 48-well plate were exposed to plain medium first, then to 80 mM KCl at temperatures ranging from 0° to 42°. We measured directly, by RIA, the amount of TRH, CRH, GRRI released in the medium.

TRH: spontaneous release remained quite stable; KCl-stimulated release showed a plateau between 22° and 37°, a decrease at higher temperatures. At temperature above 0° there was a significant stimulation by KCl (Bassl 0° 18.6±1.6; 22° 14.1±1.4; 28° 22.3±4.0; 32° 13.6±0.7; 37° 14.0±0.6; 39° 9.8±0.9; 42° 13.9±1.0. KCl: 0° 16.9±1.5; 22° 28.1±2.2; 28° 32.9±3.7; 32° 32.5±3.6:37° 30.1±1.5; 39° 21.2±2.0, 42° 23.1±2.1).

CRH: Showed a pattern similar to TRH (Bassl 0° 8.8±1.2; 28° 39° 37.1±0.1; 42° 4.2±0.1. KCl: 0° 4.6±0.4; 28° 67.5±7.1; 32° 51.8±20.8; 37° 68.5±9.9; 39° 37.1±0.1; 42° 4.2±0.1. GRH with the similar to TRH (Bassl 0° 8.9±1.2; 28° 30.937.1±0.1; 32° 51.8±20.8; 37° 68.5±9.9; 39° 37.1±0.2; 37° 1.1±0.2; 37

LOCUS COERULEUS-PERIVENTRICULAR GRAY SUBSTANCE COMMUNICATION PARTICIPATES IN THE CONTROL OF THE ESTROUS CYCLE IN THE RAT. L.P. Solano-Flores, M. P. Rosas-Arellano* and R. Guevara-Guzmán. Dep. Fisiología, Fac. Medicina. U.N.A.M. Ap. Postal 70250, 04510-México, D.F. México.

We have shown that electrolytic damage of locus coeruleus (LC) causes a transient cessation of the estrous cycle and experimentally-induced persistent estrous in the naive female rat. Simultaneous damage of the periventricular gray substance (PVG) adjacent to the LC prevented those suppression effects. Histological evidences indicate a LC-PVG communication. These facts suggest a physiological role of LC-PVG communication in the modulation of neuroendocrine events for ovarian function control. To assess whether the LC-PVG communication participates in the modulatory systems for gonadotropic activity, the LC was anatomically separated from the PVG by means of knife cuts. Done that, the estrous cycling was totally suppressed during 10-13 days, then, 3-6 irregular cycles were observed. The regular cycling was reestablished 30-40 days after the cuts. These data suggest that the LC-PVG communication is part of a modulatory circuit for the gonadotropic neuroendocrine mechanisms. CONACyT Fortalecimiento al Posgrado N° 121.

PHORBOL MYRISTATE ACETATE-INDUCED LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) RELEASE FROM PREOPTIC AREA-MEDIOBASAL HYPOTHALAMIC EXPLANT CULTURES: A ROLE FOR PROTEIN KINASE C IN LHRH NEURON ACTIVATION. Richard W. Clough, Dept. of Anatomy, Southern Illinois University School of Medicine-Carbondale, Carbondale, IL. 62901

Phasic gonadotropin secretion in female rats is controlled by preoptic area neurons which project to and release LHRH into the vasculature of the median eminence ultimately to gain access to the gonadotrophs of the anterior pituitary gland. Although stimulation of LHRH release by a cAMP dependent mechanism (Hartter et al., Neuroendo, 40, 1985) and a calmodulin (CaM) dependent mechanism brouva et al., Neuroendo, 38, 1984) have been described, and, a preliminary report of phorbol ester induced LHRH release has been offered (King et al., SON ABST 15:258.14, 1989), characterization of intracellular signaling mediating LHRH release remains ill-defined. The present study has evaluated LHRH release in vitro using explants comprised of preoptic area-mediobasal hypothalamus as previously described (Clough, et al. Brain Res 446 1988). Explants were removed from decapitated rats and placed into a perifusion tissue culture apparatus and subsequently perifused at a flow rate of 25 ul/min with an F12 culture media. Following 2 hours of equilibration, explants were sequentially exposed to PMA (10 -4 M) in dimethylsulfoxide (DMSO), DMSO alone and a final challenge with potassium chloride (KCl). Fractions of effluent were collected every 15 minutes, frozen and subsequently assayed for LHRH by radioimmunoassay PMA, which is a potent stimulant of Protein Kinase C resulted in a dramatic and prolonged increase in the release of LHRH (p<0.05). Subsequent experiments evaluating the calciumindependant mechanism operative in LHRH neurons. Taken together, these studies demonstrate that, in addition to the previously described LHRH release in response to diburyl cyclic AMP, there are alternate second messenger sytems with the capability to mediate LHRH release. LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) AND GONADOTROPIN-RELEASING HORMONE ASSOCIATED PEPTIDE (GAP) AND THE APPEARANCE OF LUTEINIZING HORMONE (LH) AND FOLLICLE-STIMULATING HORMONE (FSH) IMMUNOREACTIVITY IN THE RAT ANTERIOR PITUITARY GLAND (APG). C.A. Blake, G.T. Campbell*, F. Mascagni*, M.D. Culler* and A. Negro-Vilar*. Dept. of Anatomy, USC Sch. of Med., Columbia, SC 29208; Reproductive Neuroendocrinology Section, Lab. of Molecular and Integrative Neuroscience, NIEHS, NIH, Research Triangle Park, NC 27709.

We investigated the effects of anti (A)-LHRH serum or A-GAP serum on the development of gonadotrophs in the APG. Non-immune serum or A-LHRH, A-LHRH/GAP (which bound LHRH and GAP), or A-GAP serum were injected sc into neonatal female and male rats on days 1,3,5 and 7 after birth. Pups were killed on day 9. A-GAP had no effects on the parameters measured. A-LHRH and A-LHRH/GAP had similar effects. In both sexes, they reduced the percentage of APG cells immunoreactive for LH or FSH. In females, immunoneutralization of LHRH decreased the size of LH and FSH cells. No treatment had any significant effect on the size of LH or FSH cells in males. LH and FSH cells were of similar size within each group. The results suggest that LHRH but not GAP plays a role in the development of the number of LH and FSH cells in the APG of female and male rats and the size of gonadotrophs in female rats. Supported by a grant from the NIH (HD 22687).

168.10 CHANGES IN GONADOTROPIN-RELEASING HORMONE DURING

METAMORPHOSIS AND FINAL MATURATION IN SEA LAMPREY. S.A. Sower, T.G. Bolduc*, and Y.H. Youson*. Dept. of Zoology, Univ. of New Hampshire, Durham, NH 03824 and Dept. of Zoology, Univ. of Toronto, Toronto, Ont. Gonadotropin-releasing hormone (GnRH) concentrations were measured in brains of sea lampreys during metamorphosis (early developmental) and the final reproductive period with a homologous radioimmunoassay using lamprey GnRH antiserum (JAK 1467). Larval lampreys were collected in May and were sacrificed between July and November during the seven stages of metamorphosis. One of the four larval samples showed detectable levels of lamprey GnRH, but consistent levels were not detected until stage 6, and reached highest concentrations at stage 7. A second GnRH-like molecule was detected and occurred at stage 4, and persisted in small concentrations to the end of metamorphosis. time of appearance of GnRH within the brain is consistent with the time in which the gonads of lampreys enter a rapid period of growth. In adult female lampreys, there were significant increases in brain GuRH (1989) and plasma estradiol (1988, 1989) through time during the final maturational period. Changes in brain GnRH and estradiol covaried through time. These data provide further evidence for an association between GnRH and estradiol during reproduction. Supported by NSF DCB-8808946 and DCB-8904919 (SAS) and NSERC (JHY).

CHANGES IN LHRH NEURONAL POPULATIONS ASSOCIATED WITH THE LH SURGE IN YOUNG AND MIDDLE-AGED FEMALE RATS. <u>I.C.King, B.S.Rubin and P.Yao</u>. Dept. of Anatomy and Cellular Biology, Tufts Health Science Schools, Boston, MA 02111.

LHRH neurons were examined at two time points on proestrus in middle-aged and young cycling female rats in an attempt to reveal dynamic changes associated with the preovulatory surge of LH. In addition, it was anticipated that these studies might yield insight into the nature of the deficit that leads to disruption of LH surges in aging females. Immunocytochemistry was performed using 2 different antisera to LHRH, 419 (A. Arimura) and 1076 (R. Millar). These antisera have been used extensively in the laboratory and have consistently revealed a difference of approximately 20% in the number of immunoreactive [+] perikarya detected on the morning of each day of the estrous cycle. The data obtained thus far reveals larger numbers of + cell bodies in animals sampled on the evening of proestrus compared to those sampled prior to the LH surge. This increase was observed with each antiserum, but not with either antiserum in aging females. If an increase in LHRH+ neurons on proestrus evening is indicative of secretion-synthesis coupling, then perhaps the absence of an increase in detectable LHRH perikarya in aging females suggests a disruption of this regulation. Comparison of cell counts of LHRH+ perikarya from each animal with the two LHRH antisera revealed the expected relationship in young females, but not in middle-aged animals. We hypothesize that the differences in cell number detected with these two antisera reflect different rates of processing of prohormone. These data suggest that the dynamic biosynthesis/ processing activities associated with the LH surge in young animals are not as rapid or as robust in aging females. NSF DCB8702388; NIH HD19174.

SEX DIFFERENCES IN SPINE DENSITY IN VMN NEURONS OF PERIPUBERTAL RATS. Annabell C. Segarra and Bruce S. McEwen. The Rockefeller University, 1230 York Ave., N.Y., N.Y. 10021.

The ventromedial nucleus of the hypothalamus (VMN) is one of the main regulatory sites of female sexual behavior. Using the single-section Golgi impregnation technique, sex differences in VMN neurons in gonadectomized juvenile and peripubertal rats were assessed. The effect of estrogen treatment on VMN neurons was also investigated. Juvenile rats were gonadectomized at 16 and peripubertal rats at 36 days of age. At day 5 post-surgery rats were injected with estradiol benzoate (EB) (20 ug/kg) or oil for 2 days after which they were perfused and the brains processed for Golgi staining. EB treatment significantly increased dendritic and soma spine density in juvenile and peripubertal male and female rats. A sex difference was observed in oil and in EB treated rats, with females exhibiting higher dendritic spine density. Moreover, dendritic and soma spine density was significantly higher in juvenile vs peripubertal rats. It is possible that the sex differences observed in dendritic and soma spine density and in the response to EB treatment is due to an organizational effect of sex steroids. During this critical period, sex steroids might bias synaptogenesis of select steroid sensitive cells and ultimately affect neuronal circuitry.

SYNAPTIC ARRANGEMENTS OF GONADOTROPIN-RELEASING HORMONE (GriRH) NEURONS IN BREEDING SEASON SHEEP: REGIONAL COMPARISONS. J.J. Xiong* and M.N. Lehman. Dept. Anat. & Cell Biol., Univ. Cincinnati Coll. Med., Cincinnati, OH, 45267.

GnRH neurons and their projections play a pivotal role in the control of seasonal reproduction in the Suffolk ewe. We previously described seasonal changes in the density of synaptic input onto preoptic GnRH neurons in intact ewes (Karsch et al., Neurosci. Abstr., 13: 1527). We now compare the synaptic arrangements of GnRH neurons located in different brain regions in intact (n=5) and ovariectomized estradiol-implanted ewes (OVX+E) (n=5) perfused during the breeding season. Brains were processed for EM immunocytochemistry using LR-1 antiserum (gift of Dr. R. Benoit) and an avidin-botin-HRP procedure. GnRH neurons were analyzed from the medial preoptic area (POA), medial septum-dorsal preoptic area (MS), and anterior hypothalamic area (AHA). No significant regional differences, nor differences between intact and OVX+E ewes, were observed in the density of innervation among GnRH neurons, although GnRH cells in all regions received significantly fewer inputs than adjacent non-identified cells. Previously unreported observations from these animals include the presence of immunoreactive GnRH axon terminals in the POA and AHA, one example of direct contact between 2 GnRH somata in the MS, and what appears to be an autosynapse emanating from a GnRH cell. Comparison of this data with that from ewes perfused during anestrus will reveal whether seasonal alterations in GnRH ultrastructure are due to changing photoperiodic or hormonal signals. [Supported by NIH HD21968 (MNL)]

PRO-GnRH mRNA AND PEPTIDE IN AGED AND YOUNG FEMALE RATS O.K. Ronnekleiv, J.E. Thornton and K.C. Chambers. Dept. of Physiology, OHSU, Portland and ORPRC, Beaverton, OR 97201 and Dept of Psychology, USC, Los Angeles, CA.

The distribution and number of neurons containing

The distribution and number of neurons containing proGnRH mRNA, proGnRH and GnRH were investigated in aged (20-21 months) and young (4-5 months) Fischer 344 female rats. Aged (N-4) and young (N-5) animals were perfused during estrus with 4% paraformaldehyde, the brains sectioned at 50 μ m and reacted for proGnRH (ARK-2) and GnRH (EL14). Aged (N-5) and young rats (N-5) were prepared during estrus for in situ hybridization using a 42-mer oligonucleotide cDNA probe to detect proGnRH mRNA as described (Ronnekleiv and Resko, Endocrinology, 126:498, 1990). The number of neurons that contained GnRH was lower in the aged as compared to young animals (P-0.053). The intensity of cell stain as well as the GnRH fiber stain in the median eminence, were similar between the two groups. The number of neurons containing proGnRH was significantly decreased (P<0.02) and the intensity of the stain was highly reduced in the old compared to young rats. The number of neurons containing proGnRH mRNA in 10- μ m sections (N-20) through the POA was not different between the old and young rats (149 \pm 56 and 184 \pm 32, respectively). These results suggest that proGnRH synthesis is reduced in the aged female rat. (PHS HD 16793, HD 20970).

IMMUNOCYTOCHEMICAL DEMONSTRATION OF NEURAL CELL ADHESION MOLECULE (NCAM) ALONG THE MIGRATION ROUTE OF LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) NEURONS IMICE. M. Schwarzel-Fukuda, S. Abraham, K. L. Crossin, G. M. Edelman and D. W. Pfaff. Rockefeller University, New York, New York 10021.

and D. W. Pfaff. Rockefeller University, New York, New York 10021.

Neural cell adhesion molecule (NCAM) is a cell surface glycoprotein produced by all nerve cells early in development. An integral membrane protein, it mediates cell-to-cell adhesion and is present on the cell body, neurites and on the tips of growing axons (Edelman, Ann.Rev. Cell Biol., 2:81-116, '86). Examination of Bouin's-fixed, paraffin-embedded serial sections of fetal mice, with amtisera to NCAM and LHRH, using a double-label procedure, showed 1) by day 11 NCAM-immunoreactive fibers form a "scaffolding", either side of midline, appearing to anchor the tip of the rostral forebrain to the epithelium of the olfactory placode and 2) shortly thereafter, LHRH-immunoreactive neurons, which originate in the medial offactory placode (Schwanzel-Fukuda and Pfaff, Soc. Neurosci. Abstr. p. 984, '88; Nature, 338:161-164, '89; Wray et al., Devel.Brain Res., 46:309-318, '89), migrate out of the placode, cross the nasal septum and enter the forebrain, along and within the NCAM-immunoreactive fascicles that also arise from the medial part of the placode. These fascicles appear to be central projections of the terminalis and vomeronasal nerves, and often surround a cord of migrating LHRH neurons. Antisera to cytotactin, CTB proteoglycan, fibronectin or laminin, used on adjacent sections, showed no immunoreactive cells or fibers within the migration route. Since no migrating LHRH cells were seen independent of the NCAM-immunoreactive fascicles, we raise the possibility that an NCAM scaffold provides a guide for migration of LHRH cells into the brain. HYDROCEPHALUS RESULTS IN PERSISTENT DISRUPTION OF THE ESTROUS CYCLE IN THE HAMSTER (Mesocricetus auratus). S. D. Ham*, A. I. Canady*, R. Johnson* and J. A. Mitchell. Departments of Neurosurgery and Anatomy & Cell Biology, Wayne State University School of Medicine, Detroit, MI 48201

Hydrocephalus (HC) is a major neurological disorder in children and often results in diverse endocrinopathies including altered hypothalamic-pituitary-ovarian function. The effects of HC on the estrous cycle in hamsters maintained in a photoperiod of 12 h light/12 h dark were determined. Regularly cycling animals were assigned to control (C) (saline injected) and kaolin treated (K) groups. Injections of 0.03ml sterile kaolin in saline (250mg/ml) or vehicle were made into the cisterna magna. Body weight, food and water intake and estrous cycles were monitored daily. At selected intervals, animals were anesthetized and perfused with fixative: brains were examined, ovaries and uteri were weighed. Ventricular distention was apparent by 3 days, maximal by 21 days and persisted beyond 50 days post-K. Relative to controls, K animals experienced acute reductions in body weight, and food and water intake but were equivalent to controls by 50 days. Alterations in the estrous cycle were immediate and persistent; % C vs. K: normal = 80% vs. 30%; irregular = 20% vs. 40%; persistent diestrus = 0% vs. 30%; persistent estrus = 0% vs. 0%. Mean ovarian weights did not differ in K vs. C animals. However, some uteri were atrophic and others within normal range. Studies are in progress to determine the anatomical correlates of HC induced disruption of normal ovarian function. (Supported by a grant from the Children's Hospital of Michigan).

EVIDENCE THAT THE SUPPRESSION OF HYPOTHALAMIC-PITUITARY-GONADAL AXIS ACTIVITY DURING FASTING RESULTS FROM A NUTRITIONAL SIGNAL AND NOT THE PSYCHOLOGICAL STRESS OF FOOD DEPRIVATION. D.A. Schreihofer, D.B. Parfiut, and J.L. Cameron. Depts. of Behavioral Neuroscience, Psychiatry, Physiology, and the Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260. We have previously shown that short periods of fasting (1-2 days) significantly suppress the frequency of pulsatile LH secretion in male rhesus monkeys, and that this appears to result from a decrease in GnRH stimulation of the pituitary. Refeeding a normal meal rapidly recrease in the properties of the pituitary. Refeeding a normal meal rapidly recrease in the properties of the pituitary.

restores pulsatile LH secretion. We have hypothesized that restricting food intake may suppress the central drive to the reproductive axis via "metabolic signals" resulting from the suppress the central drive to the reproductive axis via metabolic signals resulting from the psychological stress of food deprivation. To differentiate between these two possible types of signals we have examined whether feeding through an indwelling gastric catheter can restore pulsatile LH secretion in fasting monkeys. We reason that this type of refeeding would relieve the undernutrition without relieving psychological stress. Adult male rhesus monkeys with indwelling gastric and venous catheters were fasted for one day and on the following day they received an and venous catheters were fasted for one day, and on the following day they received a a liquid nutrient infusion (equal in caloric content and macronutrient composition to a normal inquo inducent musion (equal in carolic content and inactionative) to emposition to a normal meal) at the time they are normally fed (11:00 AM). Blood samples were collected for 5 h prior to infusion and 13 h after infusion at 20 min intervals. Nutrient infusion caused a rapid increase in pulsatile LH secretion, and therefore mean LH, similar to that caused by refeeding a normal meal of 30 Purina monkey chow pellets, as shown in the figure. In contrast, a saline infusion of equal volume did 30

onu asi, a saline infusion of equal volume did not restore pulsatile LH secretion in a pilot study with a single monkey. These results indicate that prelieving undernutrition caused by fasting. without relieving the psychological stress of # 10. food deprivation, can restore the activity of the HPG axis. These findings support the hypothesis that "metabolic signals" occurring in undermourished states cause the suppression of the central drive to the reproductive axis.

DECREASED AVAILABILITY OF METABOLIC FUELS OR FOOD DEPRIVATION ATTENUATES THE PREOVULATORY LH SURGE IN SYRIAN HAMSTERS R. W. Dickerman, J. E. Schneider*, and G. N. Wade Neuroscience and Behavior Program. Dept. of Psychology, University of Massachusetts, Amherst, MA 01003.

recuroscience and Behavior Program. Dept. of Psychology, University of Massachusetts, Amherst, MA 01003.

Food deprivation or treatment with the metabolic inhibitors 2-deoxy-D-glucose (2DG) plus methyl palmoxirate (MP) reduces the rate of ovulation and estrous behavior in female hamsters (Schneider, J.E. and Wade, G.N., Science 244:1326,1989). 2DG and MP inhibit utilization of glucose and fatty acids respectively. We examined the effect of either food deprivation or 2DG+MP on plasma levels of LH, E₂, and FSH in hamsters. On days 1 and 2 of the estrous cycle, hamsters were either food deprived, given food and treated with 2DG+MP in vehicle (2DG+MP), or given food and treated with vehicle alone (controls). Serum was collected at -10 and -4 hours before lights out. The expected time of the precovulatory LH surge is at -4 hours before lights out.

In controls serum LH was elevated (p<0.01) at -4 compared to -10 hrs (3.2±0.8 vs 0.8±0.2ng/ml). In food deprived hamsters LH levels were not different at -4 compared to -10 hrs (1.1±0.5 vs 0.8±0.1ng/ml). In 2DG+MP treated animals, serum LH was higher (p<0.05) at -4 compared to -10 hrs (1.4±0.4 vs 0.6±0.1ng/ml), but the levels at -4 hrs were less than in controls. Levels of E₂ did not change in any group over time. However, serum E₂ concentrations in controls were higher (p<0.01) than in 2DG+MP or food deprived animals. Significant fluctuations in serum FSH concentrations were not detected.

These data indicate that similar to food deprivation, reduced availability of metabolic fuels is associated with an attenuated LH surge. Reduced availability of metabolic fuels may act to reduce LH by a peripheral action or through a

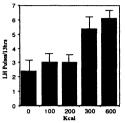

direct central effect.

FASTING-INDUCED SUPPRESSION OF PULSATILE LH SECRETION IS RAPIDLY REVERSED BY REFEEDING IN RHESUS MONKEYS (Macaca mulatta). B.B. Parfitt*, K.R. Church*, and J.L. Cameron. Depts. of Behavioral Neuroscience, Psychiatry, Physiology, and Ctr. for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

We have previously shown that brief periods of fasting (1-2 days) cause a slowing of pulsatile LH secretion in adult male rhesus monkeys that appears to result from a decrease in GnRH stimulation of the pituitary. The present study was designed to investigate how rapidly this effect of fasting can be reversed and whether a correlation exists between the amount of food provided during refeeding and the rate of restoration of pulsatile LH secretion. Adult male rhesus monkeys (5-7/group) were fasted for one day and the next day they were refed different amounts of food (0-600 kcal of Purina monkey chow) at the normal time of feeding (11:00 am). Blood samples were collected from 8:00am to 12:00 midnight at 20 min intervals. Refeeding the monkey's standard meal (600 kcal) resulted in the immediate stimulation of LH pulse frequency (6.14 ± .55 pulses/ 13 h). Moreover, the degree of restoration of LH pulse frequency was directly correlated with the amount of food provided in the refeeding meal, as shown in the figure below. These results indicate that the suppression of the central drive to the reproductive axis can be immediately for the pulse frequency (1.4 ± .55 pulses/ 13 h) the central drive to the reproductive axis can be immediately for the pulse frequency (1.4 ± .55 pulses/ 13 h) the central drive to the reproductive axis can be immediately for the pulse frequency (1.4 ± .55 pulses/ 13 h) the central drive to the reproductive axis can be immediately for the pulse frequency (1.4 ± .55 pulses/ 13 h) the central drive to the reproductive axis can be immediately for the pulse frequency (1.4 ± .55 pulses/ 13 h) the pulse frequency (1.4 ± .55 pulses/ 13 h) the pulse frequency (1.4 ± .55 pulses/ 13 h) the pulse freque

suppression of the central drive to the reproductive axis can be immediately relieved by refeeding a normal meal and that the restoration of pulsatile LH secretion is dependent on the amount of food consumed. These findings suggest that a "metabolic signal" related to the degree of undernutrition of the body modulates the central drive to the reproductive axis.

SUPPRESSION OF PUBERTY BY PROLONGED EXERCISE IN FEMALE RATS EFFECTS ON HORMONE LEVELS, AND RECOVERY ON REPRODUCTIVE FUNCTION WITH CONADOTROPIN-RELEASING HORMONE (CORH) J.M. Manning and F.H. Bronson. Dept. of Zoology, University of Texas, Austin, TX 78712.

Loss of menstrual cyclicity is common in athletes engaged in endurance training. In an effort to better understand the relationship between prolonged exercise and ovulation, we made a variety of comparisons between female rats in two treatment groups: 1) Prolonged Exercise, in which growth and reproductive development were arrested at a peripubertal stage be requiring rats to run for prolonged periods of time in order to obtain food, vs. 2) Voluntary Exercise, in which same-aged control rats were fed <u>ad lib</u> and given free access to a running wheel. The pulsatile secretion of luteinizing hormone (LH) was completely suppressed by the Prolonged Exercise treatment, but FSH levels were unaffected. Rats in the Prolonged Exercise regime exhibited elevated corticosterone titers, and the circadian secretory pattern of this steroid was shifted out of phase with running activity. GnRH levels in the hypothalamus and LH levels in the pituitary were enhanced, not suppressed, by prolonged exercise. Most importantly, rats subjected to the Prolonged Exercise treatment achieved normal pubertal development when given pulsatile infusions of GnRH, despite a total lack of body growth. The results of this study clearly show that the suppressive effects of prolonged exercise occur at or above the level of the hypothalamic GnRH pulse generator.

INVERTEBRATE SENSORY SYSTEMS

5-HT MODULATES ACCOMMODATION/ADAPTATION IN STATOCYST HAIR CELLS OF HERMISSENDA. T. Crow. Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, Tx. 77030.

Serotonin (5-HT) alters the excitability of identified photoreceptors within the eyes of *Hermissenda* and has been proposed to contribute to cellular plasticity associated with *in vivo* conditioning (Crow, 1988; Forrester and Crow, 1989). Immunohistochemical studies have identified serotonergic neurons in the cerebropleural ganglia and immunoreactive fibers and varicosities in the region of the neuropil near photoreceptor and statocyst hair cell synaptic terminals (Land and Crow, 1985). In order to further characterize the role of 5-HT as a modulator in Hermissenda, its effects upon statocyst hair cell accommodation

5-HT (10⁻⁴M) produces a slow depolarization of hair cells accompanied by an increase in input resistance and an increase in the amplitude and frequency of hair cell noise. Hair cell excitability is enhanced by 5-HT as expressed by larger amplitude responses produced by extrinsic constant current depolarizing pulses and less apparent spike frequency adaptation. In order to rule out the influence of synaptic input from photoreceptors contributing to the effects of 5-HT on accommodation, hair cells were either surgically isolated from all synaptic input or photoreceptors were surgically eliminated. After elimination of synaptic input from the visual system, 5-HT still produced less accommodation in hair cells to the same depolarizing current pulse. In surgically isolated hair cells, 5-HT resulted in an increase in the amplitude of electrotonic potentials evoked by hyperpolarizing and depolarizing current pulses.5-HT produced an enhancement of multiple regenerative events evoked by depolarizing current pulses. The multiple regenerative events are TTX insensitive, and are blocked or reduced in amplitude by 15mM Ni²⁺ 5-HT may affect hair cell accommodation by decreasing an outward K⁺ current or enhancing an inward Ca²⁺ current.

RECEPTIVE FIELDS AND PROPERTIES OF A NEW CLUSTER OF MECHANORECEPTOR NEURONS INNERVATING THE MANTLE REGION AND THE BRANCHIAL CAVITY OF THE MARINE MOLLUSK APLYSIA CALIFORNICA.

V.F. Castellucci. Lab. de Neurobiologie, Institut de Recherches
Cliniques de Montréal, Montréal, (Québec), Canada. H2W 1R7.

The rostral LE cluster (rLE) is a new set of mechanoreceptor

neurons innervating the mantle area, the branchial cavity, the gill and the siphon of the marine mollusk Aplysia californica. We have compared the organization of their receptive fields with those of LE, RE and RF sensory neurons of the abdominal ganglion which have been reanalyzed.

There is extensive receptive field overlap among the four populations of sensory cells; the most exposed areas of the mantle are the most densely innervated. The sensory threshold is similar for all groups. The neurons of the LE and rLE clusters have common physiological properties. Their actions potentials are broadened by serotonin and SCP peptides and narrowed by dopamine and FMRFamide. Their synaptic outputs undergo synaptic depression, homosynaptic and heterosynaptic facilitation.

More than one hundred mechanoreceptor neurons innervate the entire mantle and siphon skin, branchial cavity and gill of Aphysia. The degree of their divergence to various interneurons and motor neurons mediating the gill and siphon withdrawal reflex and other reflexes is under investigation. (Supported by MRC grant MA10047 and Strauss Canada Foundation).

PERIPHERAL AND CENTRAL RESPONSES OF THE LATERAL LINE ANALOGUE OF THE CUTTLEFISH SEPIA TO LOCAL WATER MOVEMENTS. B.U. Budelmann', H. Bleckmann' and T.H. Bullock'. 'Marine Biomed. Inst., Univ. Texas. Med. Branch, Galveston, TX 77550, 'Div. Biol. Univ. Bielefeld, D-8400 Bielefeld, FRG and 'Neurobiol. Unit, A-001, SIO, UCSD, La Jolla, CA 92093.

The epidermal head lines of Sepia and other cephalopods are

The epidermal head lines of Sepia and other cephalopods are composed of rows of hair cells. They respond to local water movements in a way similar to the amphibian and fish lateral lines (Budelmann, B.U. & Bleckmann, H., J. Comp. Physiol. A, 165:1, 1988).

The response of the lines to stimulation with sinusoidal water waves has three components: (i) a large phasic ON-response, (ii) a tonic microphonic response, frequency-doubling within a wide frequency areas and (iii) a story OPE wave. Slowly triping and fulling stimulation. range, and (iii) a slow OFF-wave. Slowly rising and falling stimuli lack the ON and OFF components. The amplitudes of the receptor potentials increase nonlinearly with stimulus amplitude (tested at 6-100 Hz) and finally reach saturation. Best displacement frequency is about 100 Hz main reach saturation. Best displacement frequency is about 100 Hz and lowest threshold recorded was 0.06 μ m peak-to-peak water displacement (18.8 μ m/s as velocity), calculated at the skin surface. Abrupt modulation of stimulus frequency or amplitude elicits large responses at the onset and offset of modulation and marked changes in the tonic microphonic response. Change of stimulus direction relative to the course of the line has only little effect on the summed response, perhaps due to the four directions of polarization of the hair cells in each line. Preliminary recordings from subesophageal brain areas show only little change of the, presumably first-order, afferent signals of the epidermal lines. [Support: NIH, DFG and NSF grants]

BRANCHING PATTERNS OF SINGLE OLFACTORY AFFERENTS IN THE CRAYFISH BRAIN. DeF. Mellon, V. Alones, & M. Riddick. Dept. of Biology, Univ. of Virginia Charlottesville, Virginia 22903.

In crustaceans primary olfactory afferents are associated with batteries of unique antennular sensilla called aesthetascs. Each sensillum houses the

In crustaceans primary olfactory afferents are associated with batteries of unique antennular sensilla called aesthetases. Each sensillum houses the ciliary dendrites of several hundred bipolar sensory neurons, many of which are narrowly tuned to specific odorants. A current hypothesis regarding the central organization of olfactory input regards each olfactory glomerulus as a functionally unique subunit, within which information about specific odorants is refined and amplified. We have suggested previously that primary olfactory afferent projections to the brain in crayfishes are not spatiotopically distributed; instead afferent fibers from each antennular olfactory sensillum distribute themselves among all glomeruli in the ipsilateral olfactory lobe. We speculate that afferent fibers having similar odorant sensitivities terminate in the same glomeruli. These conclusions are valid, however, only if each afferent fiber terminates in just one glomerulus. We have now obtained evidence from Golg preparations for a univalent pattern of terminal distribution in the deutocerebrum of the crayfish, Procambarus. Observations in numerous preparations suggest that primary fibers approach the olfactory lobe without branching and that each penetrates only a single glomerulus, within which each fiber typically subdivides into four or five filaments that terminate at the central apex of the glomerular column. Varicosities which we interpret as presynaptic sites are a prevalent feature of the columnar terminals and occur as well as in the peripheral cap region of each glomerulus. These findings are not inconsistent with our recent observations that the glomerular columns are sites of contact between unidentified presynaptic neurons and Biocytin filled olfactory-globular tract interneurons. THE AFFERENT PROJECTION PATTERN OF CERCAL BRISTLE HAIRS IN THE COCKROACH. Darryl I. Daley. Department of Physiology, National College of Chiropractic, Lombard, II 60148.

The projection pattern of the largest bristle hairs (BH's) located on the ventral surfaces of the cerci of adult cockroaches (Periplaneta americana) was examined by bringing the broken off end of a BH in contact with a 200 mM cobaltic hexamine chloride solution for 18-24 hours at 5° C. The cobalt was then precipitated as a sulfide and silver intensified.

The largest BH's appear to be singly innervated since only one axon is stained by the above method. The sensory neurons innervating BH's project to a broad region of neuropil and show some overlap with the projection area of filliform hairs (Daley, D. L., <u>Soc. Neurosci. Abst., 15, 1287, 1989</u>). Those BH afferents from proximal cercal segments tend to have smaller arbors and terminate more posteriorly. The arbors of BH afferents located more distally on the cerci are more extensive and project more anteriorly when compared to BH afferents. project more anteriorly when compared to BH afferents more proximally located. When small groups of neighboring BH afferents were stained they all arborize in the same region of neuropil. Thus the afferent projection of the BH's is somatotopic.

ARE THERE CHOLINERGIC PRIMARY AFFERENT SYNAPSES ON CRAYFISH LATERAL GIANTS? E. T. Vu, M. W. Miller, and F. B. Krasne. Dept. of Psychology and Brain Res. Inst., University of California, Los Angeles, CA, 90024.

Primary afferents (PAs) of the crayfish lateral giant (LG) circuit make choliners.

lateral giant (LG) circuit make cholinergic synapses having nicotinic ganglionic pharmacology on sensory interneurons. The PAs also monosynaptically innervate the LGs via junctions that are thought from latency and following ability to be electrical. However, the monosynaptic EFSPs are diminished by LG depolarization and increased by hyperpolarization. This could result from (1) a chemical component to transmission, (2) spread of polarizing current into PA terminals, or (3) biassing of rectifying electrical junctions (see Edwards et al., Neurosci. Abstr., 14:999, 1988). A similar observation on monosynaptic inputs to the medial giants (Glantz & Viancour, J. Neurophys., 50:1122, 1983) has been explained by mechanism (1). We find that the LGs have cholinergic receptors that are pharmacologically similar to receptors that are pharmacologically similar to those of sensory interneurons, also encouraging interpretation (1). However, mecamylamine, which blocks those receptors, has no effect on monosynaptic EPSPs. (USPHS grant NSO8108).

AFFERENT PROJECTIONS TO THE MIDBRAIN OF THE SPINY LOBSTER REVEALED BY BIOCYTIN. M. SCHMIDT*. B.W. ACHE. Whitney Lab. and Depts. of Zoology and Neuroscience, Univ. of Florida, St. Augustine, FL 32086.

The projection of afferent fibers in the antennular nerve to the midbrain (deutocerebrum) of the Caribbean spiny lobster, Panulinus argus, was characterized by applying the recently introduced intracellular marker, biocytin (J. Neurosci. Meth. 25: 1-11, 1988), to cut nerve bundles as an anterograde tracer. Three deutocerebral neuropils receive input from the antennular nerve. Numerous fibers (0.3 - 2 μ m diam.) project to the olfactory lobe (OL), surround it, and penetrate its column-like glomeruli. The fibers extend into the base of the glomeruli where they terminate in small boutons (1 - 2 μ m diam.), presumably representing presynaptic sites. Typically, the thicker fibers branch outside the OL and project into several glomeruli. In contrast, the thinner fibers only innervate single glomeruli. A second, very heterogeneous population of afferent fibers (0.3 - 8 µm diam.) projects into both lobes of the lateral antennular neuropile. The thickest of these fibers also branch to the medial antennular neuropile where they terminate in large boutons (5 μ m diam.). (Supported by DFG award Schm 738/1-1 and NSF award # 88-10261).

169.8

A MISSING LINK IN INSECT AUDITION.S.R. Shaw, Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada. When a spine on a cockroach leg is deflected by an amount subthreshold for its own mechanoreceptor neuron, a vibrationally evoked potential (VEP) is still recorded from the leg nerve. If the leg is pulsed with airborne sound, a damped oscillatory acoustic EP results (AEP), consisting of initially coherent volleys of impulses at a fixed frequency around 300 Hz, regardless of tone frequency or intensity, implying resonant or electrical tuning. The AEP originates from an internal organ, not external hairs, since covering the leg with Vaseline fails to abolish it. Local cooling or cautery pinpoint its origin in the tibia below the knee, the site the subgenual organ (SGO), previously identified as a sensitive mechanoreceptor tuned to surprisingly high vibrational frequencies (H. Schnorbus, 1971, Z. vergl. Physiol. 71: 14). Local SGO ablation abolishes both VEP and AEP, and cross-modal adaptation is highly effective, indicating that VEP and AEP both originate in the same receptors. Threshold acoustic tuning curves (CF 1.8-2.2KHz) sometimes peak below 50dB SPL, a sensitivity commensurate with bona fide insect ears. Threshold activation energy is 4×10^5 greater for VEP than AEP, suggesting that these SGOs are specialized for audition. Thus the tibial ears of crickets may have evolved from SGOs that were not just pure vibration detectors, as previously supposed, but from SGOs that already possessed high acoustic sensitivity, like the SGOs in cockroach legs. (Supported by NSERC A9593, Canada)

QUANTITATIVE ANALYSIS OF TOPOGRAPHIC MAPPING IN THE CRICKET CERCAL SENSORY SYSTEM. G.A.Jacobs and N.S.J.Poy*. Dept. of Molecular and Cell Biology, Univ. of CA, Berkeley, CA 94720

Wind sensitive mechanosensory afferents form a topographic map of wind direction in the cricket cercal glomerulus. We have analyzed this sensory map by staining sensory neurons with cobalt and reconstructing their terminal arbors in 3-D using a computer-based reconstruction system. Filiform hairs have been shown to be segregated into seven principle directional sensitivity classes. At least five afferents from each class were reconstructed for the map. The location and volume of neuropil filled by the afferent arbors were measured and scaled to a "mean" standard ganglion. A computer atlas of the positions of the afferents' terminal varicosities was constructed by dividing the cercal glomerulus into cubical volume elements, o "voxels", and calculating the density of varicosities of each type of afferent within each voxel. The resolution the atlas could be varied by changing the dimensions of the voxels. Afferents with directional sensitivities separated by at least 90° showed very little overlap, whereas those separated by 45° or less showed significant overlap. The variability in the density distribution of varicosities from different afferents of the same identified type was also assessed. These results will be discussed in terms of possible substructure in the map.

INFORMATION THEORETIC CALCULATION OF DIRECTIONAL RESOLUTION AND OPTIMAL WIDTH OF TUNING CURVES OF FOUR PRIMARY INTERNEURONS IN THE CRICKET CERCAL SYSTEM.

F.E. Theunissen* and J. P. Miller, Dept. of Molecular and Cell Richary Unit of California Berkeley, CA 94720

Biology, Uni. of California, Berkeley, CA 94720.

The activity patterns of primary sensory interneurons in the cricket cercal sensory system encode information about the direction of air current stimuli in the animal's immediate environment. In previous studies, we have characterized the directional sensitivity of several types of these interneurons. On the basis of this data, principles of information theory were used to calculate the maximum directional resolution attainable by the sub-system consisting of four low velocity threshold interneurons. This analysis was limited to a consideration of the mean independent firing rates of the interneurons. These interneurons had broad symmetrical directional sensitivity curves that could be accurately represented as truncated sine waves. We have demonstrated that the system could achieve a directional resolution of 4.25 bits. The directional resolution was also calculated for hypothetical situations in which the widths of the tuning curves were varied from the observed values. These simulations showed that the width of the tuning curves were close to optimal, and that this resolution was robust to changes in the relative spacing of the tuning curves. Analyses incorporating information available in the higher order statistics and covariance of activity in different cells allow for even greater resolution.

169.13

NEURAL CORRELATES OF DIRECTIONAL SELECTIVITY IN THE VISUAL SYSTEM OF THE FLY.
H. Öğmen. Dept. of Elect. Eng., University of Houston, Houston, TX 77204.

Recent efforts in the understanding of neural correlates of motion detection and directional selectivity in the visual system of the fly includes electrophysiological studies using single photoreceptor stimulations (Riehle & Franceschini, Exp. Brain Res., 54:390-394, 1984) and a combination of electrophysiology and neuropharmacology (Schmid & Bülthoff, Biol. Cybern., 59:71-80, 1988). Results of the former have been interpreted in favor of facilitatory models while results of the latter in favor of inhibitory models thus creating an apparent conflict. Predictions of a neural network model proposed for directionally selective cells in the visual system of the fly (Öğmen & Gagné, Neural Networks, 1990) for single photoreceptor stimuli as well as for neuropharmacological manipulations offer a possible resolution to the paradox and suggest that motion detection and directional selectivity should not be confined into a single synaptic interaction.

169.10

CODING AND DECODING IN THE CERCAL FILIFORM HAIR RECEPTORS OF THE CRICKET. <u>David Warland*</u> †. <u>Michael A. Landolfa*</u>, <u>John P. Miller, William Bialek*</u> †, and <u>Robert M. Olberg</u>. Department of Physics †, and Department of Molecular and Cell Biology. University of California at Berkeley, Berkeley, California 94720

The cercal filiform hair receptors of the cricket Acheta domesticus encode information about near-field air current stimuli. Behavioral studies have shown that crickets can discriminate among different kinds of air-current stimuli within 100 msec, based on information obtained from the deflection of filiform hairs. Traditional approaches to the study of neural coding attempt to predict average neural response to particular stimuli. The cricket, however, faces nearly the opposite task; based on a limited number of spikes, the cricket must make real-time estimates of air movement. Here we present the results of a study which allows the generation of realtime estimates of filiform hair motion based on observations of the spike train from single sensory cells. The analysis yields a characterization of an equivalent noise spectrum. It is ultimately the uncertainties in the estimate of hair movement that limit the resolution with which the cricket can distinguish features of air current stimuli. We calculate the threshold for reliable detection of movement in a real-time estimation task and the information coded by a single afferent.

169.12

SENSORY AFFERENTS AND INTERNEURONS DEFINE DISCRETE SYNAPTIC NEUROPILS IN THE LEG NEUROMERES OF *Drosophila* R. Naresh Singh¹, Shubha R. Shanbhag⁴¹, and Nicholas J. Strausfeld². ¹Molecular Biology Unit, Tata Institute for Fundamental Research, Hombaha Road, Bombay 400 005, India and ²ARL Division of Neurobiology, and Center for Insect Science, Univ. of Arizona, Tucson AZ 85721

Golgi- and Cobalt-silver staining demonstrates the neuroarchitecture and cellular organization of thoracic neuropils receiving sensory afferents from, and giving rise to motor neurons to the legs of *Drosophila melanogaster*. Selective uptake of HRP containing sucrose or KCl (or NaCL) has resolved specific chemosensory afferents into leg neuromeres. Sensory terminals occupy specific zones of the leg neuromere, where they terminate in laminar or glomeruli-like domains arranged concentrically around coarse core neuropil. Specific domains of terminals are visited by the dendritic trees of inter- and intrasegmental interneurons. The neuroanatomy suggests that motor neurons supplying leg muscles receive the great majority of their sensory afferents from the leg of the same side and segment. The same motor neurons are richly supplied by local and interganglionic interneurons. Interganglionic connections are also provided by certain sensory afferent which extend between leg neuromeres. However, unlike the direct primary afferent supply to the brain from the wings, the passage of sensory information from the legs to the brain may be mediated by interneurons with segmentally repeated dendritic trees, the axons of which ascend to the descending neuron dendrites originating in the dorsolateral deutocerebrum. The organization of leg neuromeres is compared to their segmental homologues in the brain; chemosensory antennal lobes and antennal mechanosensory neuropils of, respectively, the ventral and dorsolateral deutocerebrum. ANALYSIS OF ADJACENCY AMONG NEURONS IN THE FLY OPTIC LOBE. A. Fröhlich. Biol. Dept., MSVU, Halifax, NS, Canada B3M 2J6.

The relationship between the architecture of a neuropile and the synapse classes found therein was analyzed from serial EM-sections of the first optic neuropile, or lamina, of the fly Musca domestica. As many profiles of cell processes as Possible were identified uniquely within a defined proximal area of the lamina. Then the frequency was scored with which profiles of certain cells are direct neighbours to profiles of other cells. Results show that at least half of all processes directly adjacent to neuronal processes are those of epithelial glial cells. Adjacency between neurons is most frequent between profiles of those neurons that occur together at synapses, be it as pre- and postsynaptic partners, or as postsynaptic processes opposite a shared presynaptic site of a multiple-contact synapse. Adjacency is least frequent between profiles of the same cell or cell type. Self-avoidance is absolute in processes of neurons L1 and L2. Some contact (<5%) occurs between axons of different photoreceptors, alpha processes of amacrine cells and beta processes of T1 cells. The results imply that the contact preferences of cells that determine the architecture of the lamina influence the composition of its synapses as well.

SINGLE UNIT ANALYSIS OF VISUAL INTERNEURONS
IN THE MESOPELAGIC MYSID, Gnathophausia
ingens. J.F. Moeller and J.F. Case*. Univ.
of Calif., Santa Barbara, CA, 93106.
Gnathophausia ingens inhabits a daytime
depth of 600 m, dispersing between 400 and
1000 m at night. To determine visual
capabilities of this deep-sea mysid, sensory
neurons traversing the optic stalk were
examined electrophysiologically with
tungsten electrodes. Based upon their examined electrophysiologically with tungsten electrodes. Based upon their response to a single monochromatic light flash (10-1000 msec duration), interneurons were classified into two types. One class resembled sustaining fibers common to most crustaceans; the other class exhibited a unique "on" response without sustained firing. Both classes showed a 150 msec firing. Both classes showed a 150 msec delay between stimulus and onset of spikes. Latency was inversely proportional to stimulus intensity. Response characteristics of these neurons may be indicative of a sensory system optimized for photon capture. Light levels of 10⁴ photons sec⁻¹ cm⁻² could elicit a response.

169.17

DIFFERENTIATION OF PHOTORECEPTOR CELLS IN

MANDUCA SEXTA. R.H.White and R.R.Bennett. Dept. of Biol., Univ. of Mass./Boston, Boston, MA 02125.

We are studying the differentiation of photoreceptor microvilli (rhabdomere) and smooth endoplasmic reticulum (SER) in relation to rhodopsin synthesis and the availability of the chromophore, 11-<u>cis</u> 3-hydroxy retinal (R3), in the pupal tobacco hornworm moth. The initiation of microvillus formation at the center of the clustered retinula cells, early in formation at the center of the clustered retinula cells, early in the pupal instar, is accompanied by the elaboration of adjacent tubular SER oriented parallel to the axes of the microvilli. Although SER is intimately associated with with the microvilli throughout their development - fingers of SER later extend deep into the growing microvilli - SER does not appear to contribute directly to microvillus formation by membrane flow. SER proliferates and becomes organized in myeloid bodies as development proceeds into the late pupa. The synthesis of opsin is regulated by the availability of R3. Normal rhodopsin levels are not required for microvillus differentiation; microvillus P-face particle density is reduced in R3 deficient moths at all stages of development. In the transition to the adult, SER fingers withdraw from the microvilli leaving a more limited system of subrhabdomeric cisternae, and much of the extensive pupal SER is degraded. In R3 deficiency, fingers and myeloid bodies remain. Thus R3 and/or rhodopsin deficiency affects the maturation of the SER, probably in relation to chromophore metabolism or transfer of rhodopsin from endomembrane to photoreceptor membrane. Supported by NSF grant BNS-8510087.

AN INTERSTITIAL MATRIX BELT: ACTIN NETWORK FOR TUNING OPTICS IN NEURAL SUPERPOSION EYES.

M. Järvilehto, R. Harjula*, and M. Weckström*.
Dept. of Zoology, Univ. of Oulu, Linnanmaa, 90570 Oulu, Finland.

The innerommatidial space (IOS) connecting the rhabdomeres of one ommatidium in the compound eye of the blowfly contains actin filaments (Järvilehto, M. et al. <u>Soc. Neurosci Abstr.</u>, Vol. 15, Part 2, p.1292, 1989). The optical axes of the photoreceptors in seven different ommatidia of the photoreceptors in seven different ommatidia feeding the same second order neuron are precisely aligned. Changes in deep pseudopupil (DPP), an indicator for the parallelity of the optical axes, were recorded in white mutant blowflies with low aperture optics using a video recorder. Actin was localized in EM by immunocryo-techniques (PAG). In detail we have located actin to a narrow region in the distal part of the IOS. Filaments are frequently found connecting R(3,4) and R(7) receptor cells. We dis rupted actin filaments by allowing weak (1-0.01 M) KI in Ringer solution diffuse into retina via small corneal hole. The DPP disappeared in a few minutes depending on concentration. Thus the actin network in distal IOS seems to play an important role in maintaining the optical alignment of the neuro-ommatidium.

PHYSIOLOGY AND MORPHOLOGY OF GUSTATORY INTERNEURONS IN THE SUBESOPHAGEAL GANGLION OF THE FLESHFLY SARCOPHAGA BULLATA. B.K. Mitchell* and H. Itagaki. ARL, Div. of Neurobiology, Univ. of Arizona, Tucson, AZ 85721.

The peripheral coding of gustatory information and the behaviors resulting from gustatory stimulation have been particularly well-documented in some Cyclorrhaphous Diptera by numerous investigators. Each gustatory sensillum on the labellum of the mouthparts is innervated by four chemosensory neurons. Three of these have been well-characterized, with one neuron preferentially sensitive to sugars and some amino acids, a second to cations, and the third to water. Despite the wide interest in the peripheral taste system and feeding behavior of these insects, the central processing of gustatory information leading to the control of feeding has not been directly studied. To address this, we have begun to record intracellularly from gustatory interneurons in the subesophageal ganglion of the fleshfly while stimulating the labellar sensilla with water and solutions of sucrose and of KCI. Since prohing is known about water and solutions of sucrose and of KCl. Since nothing is known about specific connections between the gustatory afferents and central cells, the first requirement is a catalogue of central cell types involved. So far, we have evidence for cells 1) stimulated by sucrose, but not KCl 2) stimulated by sucrose and inhibited by KCl 3) inhibited by sucrose. We hope to describe the morphology of these cell types, and others that respond to different taste stimuli using fluorescent dye techniques.

MODELLING THE SALAMANDER OLFACTORY BULB: SINGLE CELL AND NETWORK INTERACTIONS. J. White, S.N. Neff*, A. Cinelli, and J.S. Kauer. Neurosci. Program, Tufts/NEMC, Boston, MA 02111.

Boston, MA 02111.

Anatomical, physiological, and behavioral data obtained in the tiger salamander now allow modelling of odor encoding properties of the peripheral olfactory system: the olfactory epithelium (OE) and bulb (OB). Available data include single receptor and bulbar cell responses, topography of OE and OB connections, OE and OB response distributions using voltage-sensitive dyes (VSD), and behavioral odor responses. We have used two different modelling approaches that incorporate these data. The first models the temporal and spatial response properties of single OB cells. Cell responses are calculated with a series of linked differential equations representing activity and connectivity of various OE and OB cell types. The model computes the output in each cell type after simulated odor or electrical stimulation. Outputs computed for mitral/tufted cells compare very well with those observed in intracellular and VSD recordings. The well with those observed in intracellular and VSD recordings. well with those observed in intracellular and VSD recordings. The second model uses a back propagation neural network algorithm from McClelland and Rummelhart (1988) to relate receptor cell loci with activity in their OB projection sites. The model is trained with OE to OB electrical mapping data and then uses known patterns of OE odor sensitivities to calculate OB odor response distributions. Computed patterns compare well with OB responses seen in VSD recordings.

GABAERGIC CIRCUITS OF DISSOCIATED MOUSE OLFACTORY BULB

CELL CULTURES <u>I. Weil and S.P. Fracek</u>, <u>Ir</u>, Department of Biological Sciences and Center for Network Neuroscience, University of North Texas, Denton, TX 76203 The effects of g-amino butyric acid (GABA) and the GABA antagonist, bicuculline (BIC), on the dynamics of neural networks of mouse olfactory bulb monolayer The effects of g-amino butyric acid (GABA) and the GABA antagonist, bicuculline (BIC), on the dynamics of neural networks of mouse olfactory bulb monolayer cultures are examined. The cells are grown on multimicroelectrode plates that have 64 extracellular electrodes in a 16x4 array; within two weeks these cultures form networks that spontaneously generate bursting activity. Fast Fourier Transforms (FFTs) of single-unit baseline data show a broad peak between 1 and 3 Hertz (Hz). Phase-space reconstructions (PSR) are a method of determining the degree of order in a time series. PSRs of various parameters (e.g. burst duration) do not show any apparent patterns. GABA (≥ 25 μM) consistently inhibits the spontaneous bursting; GABA (< 25 μM) causes either short term pauses (lasting only a few minutes), or decreases the bursting frequency. BIC (≥ 5 μM) consistently generates a simple periodic pattern, the bicuculline pattern. FFTs of these data indicate a peak frequency of approximately 0.5 Hz. PSRs show a simple lobe pattern indicative of periodicity. At 5 μM BIC, this pattern can be changed back to the baseline state with several washings. At 100 μM BIC, this pattern persists through subsequent washes and within an hour decays to another, more complex state, that is similar to the original baseline state. These cultures are sensitive to the sequential order and concentration of both these compounds. Bursting activity is inhibited or becomes periodic if the sequence addition starts with GABA or 5 μM BIC, respectively. Addition of 100 μM BIC first and subsequent additions of GABA (up to 100 μM) show no inhibition of the bicuculline pattern. However, PSRs of these data indicate that subsequent GABA addition causes the system to enter a higher periodic state.

ANALYSIS OF CALCIUM INVOLVEMENT IN OPTICAL SIGNALS FROM THE IN VITRO SALAMANDER OLFACTORY BULB. A.R. Cinelli and J.S. Kauer. Neuroscience Program, Tufts/NEMC, Boston, MA 02111.

The long-lasting depolarizations previously seen in subglomerular levels of the olfactory bulb (OB) after ortho-(OD) and antidromic(AD) electrical stimulation have been attributed to Ca++ currents (Cinelli electrical stimulation have been attributed to Ca++ currents (Cinelli and Salzberg, Nrsci. Abst., 1988). In the present study these slow components were recorded in OB slices from waterphase Ambystoma tigrinum using the voltage-sensitive dyes RH414 and RH795. Videorate imaging was used to evaluate the spatial properties of the signals and to examine effects of manipulating Na+ and Ca++ currents. Electrical stimuli applied locally to the glomerular layer elicit these signals in 10uM TTX or low [Na+] medium, while OD or AD stimuli do not, but lateral and central spread of the signals were reduced and the time courses of depolarization and suppression were increased the time courses of depolarization and suppression were increased. Since signals were still observed after 3.0 mM Ba++, it appears they did not arise from glia. These data suggest that these depolarizing signals are Ca++ current related and that Na+ affects their spatial distribution. These signals are presently being investigated using fluorescent calcium indicators.

EXCITATORY ACTIONS OF GABA IN THE RAT OLFACTORY BULB. B. K. Rhoades and W. J. Freeman. Department of Molecular and Cell Biology, Univ. of Cal. at Berkeley, Berkeley, CA 94720.

GABA is an intrinsic neurotransmitter of the vertebrate olfactory bulb, released primarily by the superficial periglomerular (PG) cells and the deeper granule cells. GABAergic actions of granule cells are inhibitory, at A-type receptors of reciprocal dendrodendrite synapses with mitral and tufted projection neurons. GABAergic periglomerular cells are also generally considered to have inhibitory actions at both A- and B-type receptors. However, electrophysiological evidence, and subsequent ensemble- level modelling, from our laboratory strongly indicates that periglomerular cells are mutually excitatory and excite mitral and tufted cells.

GABA actions in the rat olfactory bulb were investigated in barbiturate anesthetized animals with a unilaterally exposed main olfactory bulb, primary olfactory nerve (PON), and lateral olfactory tract (LOT). Averaged evoked potential (AEP), spike post-stimulus time histogram (PSTH), transbulbar DC potential, and ongoing surface EEG responses to local and regional application of GABAactive neurochemicals were recorded.

GABA and baclofen (B-agonist) increased the slow negative PON-induced AEP component and LOT-induced AEP frequency; both indicative of increased PG cell activity levels and excitation of mitral/tufted cells. Picrotoxin (Cl- channel uncounler) and 5-aminovaleric acid (B-antagonist) had opposite AEP effects; indicative of decreased periglomerular excitation. Muscimol (A-agonist) and bicuculline (A-antagonist) had effects attributed to action at granule cell synapses. results were confirmed by DC recording and periglomerular and mitral cell PSTHs.

Ongoing EEG was altered by regional, but not local, neurochemical applications. Established neuropharmacology suggests disinhibition, but these electrophysiological results indicate direct GABAergic excitation by PG cells. Research supported by NIMH grant MH06686.

IMMUNOCYTOCHEMISTRY OF DISSOCIATED MOUSE OLFACTORY BULB CELL CULTURES L. Guo*, T. Thomas*, R. Schafer and S.P. Fracek, Jr.
Department of Biological Sciences and Center for Network Neuroscience, University of North Texas, Denton, TX 76203 USA.

The morphology and immunocytochemistry of intact murine olfactory bulbs (adult

The morphology and immunocytochemistry of intact murine olfactory bulbs (adult and embryos) was compared to that of dissociated mouse olfactory bulb cell cultures using antibodies to microtubule associated protein 2 (MAP2), tau protein (Tau), neurofilament 200 (NF200), and glial fribrillary acidic protein (GFAP). These analyses were carried out using both light microscopy (LM) and transmission electron microscopy (TEM). For LM, the streptavidin-biotin method (ABC) and 3.3-diaminobenzidine was used to visualize the antibodies; for TEM, the streptavidin-biotin immuno-gold labelling technique was used. Cultured murine bulb cells were essentially similar to those found in intact bulbs, as judged by

cells were essentially similar to those found in intact bulbs, as judged by morphology and expressed proteins.

MAP2 antibodies heavily stained cultured nerve cell bodies and their thick, dendrite-like processes, when viewed with LM. At the TEM level, immuno-gold particles were found adjacent to microtubules in the soma and the dendritic-like processes. Non-specific gold staining of the background and glial cells was far lower than that associated with neurons. LM revealed that Tau antibodies lightly stained the soma. Some thick fascicles of cell processes were also lightly stained. TEM revealed Tau staining nerve cell soma, but always much less than MAP2. Some axon-like processes within thick fascicles had lightly stained regions adjacent to microtubules. NF200 heavily stained the cultured neurons, especially the soma and fascicles. GFAP, as expected, was found in glial cells only.

EVOKED NEURAL ACTIVITY IN THE SALAMANDER OLFACTORY BULB MONITORED WITH CALCIUM, pH, AND VOLTAGE-SENSITIVE PROBES. D.M. Senseman, J.-Y. Wu, and L.B. Cohen. Division of Life Sciences, University of Texas at San Antonio, San Antonio, TX, 78285 and Department of Physiology, Yale

University School of Medicine, New Haven, CT, 06510,.

In the Tiger salamander (Ambystoma tigrinum) brief electrical stimulation of the olfactory nerve evokes a prolonged activation (>1000 ms) of the in vitro olfactory bulb and more central cortical structures that can be monitored optically with millisecond temporal resolution using voltage-sensitive probes in conjunction with a 124-element photodiode array. We recently found that evoked neural activity in this preparation can also be monitored optically using probes that are selective for changes in intracellular calcium (rhod-2 AM), extracellular calcium (murexide) and pH (phenol red). Nerve stimulation produced a transient increase in resting fluorescence after loading the in vitro preparation with the membrane permean calcium indicator rhod-2 AM for 70 min. The fluorescent increase continued for 300 ms followed by a slow decay to base-line lasting several seconds. Significant differences in waveform were observed between the olfactory nerve, glomerular and granular layers. Qualitatively similar waveforms, but opposite in sign, were recorded with transmitted light when the preparation was bathed in saline containing the extracellular calcium indicator murexide (0.75 mg/ml). These data suggest that neural activity in the olfactory bulb is associated with a rise in intracellular calcium that is derived in part from extracellular sources. Nerve stimulation was also found to generate a transient decrease in light intensity when the preparation was bathed in unbuffered saline containing the pH indicator, phenol red (1 mg/ml). Unlike the 'calcium signals' which were monophasic, the initial decrease in light intensity was followed by a transient increase. In addition to voltage-sensitive dyes, calcium and pH probes may also prove useful for monitoring activity in the mammalian cortex. PARABRACHIAL GUSTATORY RESPONSES IN AWAKE RATS: AN EXTENDED STIMULUS ARRAY. H. Nishijo* and R. Norgren Dept. Physiol, Fac. Medicine, Toyama Med. Pharm. Univ., Toyama 930-01 JAPAN and Dept. Beh. Science, Col. Medicine, The Pennsylvania State University, Hershey, PA 17033.

Previously we reported that parabrachial (PBN) gustatory responses to 4 standard stimuli were equivalent whether the fluids were delivered via intraoral infusion or by licking (Neurosci. Abst. 15: 930, 1989). In the present study, a total of 74 single PBN neurons were tested with up to 15 sapid chemicals delivered by intraoral cannula. Of these, 70 responded differentially to one or more of the stimuli; the remaining 4 responded similarly to both water and tastants. Of the 70 taste neurons, 44 were tested with all 15 chemicals. Cluster analysis revealed 5 stimulus groups with mean intergroup correlations of less than 0.4. These groups consisted of the 3 Na-salts, the 3 Cl-salts, the 3 acids, quinine HCl, and 5 normally preferred chemicals. In this last group, polycose had an average correlation of 0.61 with 4 'sweet' chemicals. Factor analysis of the same data produced 4 factors that accounted for 85.6% of the variance. With the exception of QHCl, the individual factors grouped the stimuli as did the cluster analysis. The lowest loading for a chemical within a group was 0.75. Excluding quinine, the highest loading for a chemical outside a group was 0.39. Quinine had loadings of 0.52 and 0.43 in the factors that contained the high Cl-salt loadings and the high acid loadings, respectively. Supported by PHS grants NS 00240, MH 43787, and MH 00653.

PROJECTIONS OF ELECTROPHYSIOLOGICALLY-IDENTIFIED LOCI IN THE ORALLY-RESPONSIVE SOLITARY NUCLEUS <u>D. Becker* and S. Travers.</u> Depts. of Psychology and Oral Biology, The Ohio State University, Columbus, OH 43210.

Psychology and Oral Biology, The Ohio State University, Columbus, OH 43210.

The nucleus of the solitary tract (NST) receives primary afferent terminations from gustatory and somatosensory afferents innervating the oral cavity. Recent neurophysiological experiments in this laboratory have demonstrated that NST neurons are organized as a function of modality and receptive field location (Travers and Norgren, '88). The present experiments examined efferent projections of small regions of NST that responded to specific stimulations of the oral cavity. Iontophoretic injections of horseradish peroxidase (HRP) or Phaseolus vulgaris leucoagglutinin (PHAL) were made through one side of a double-barrelled pipette (Dia=15u), whose second barrel was used for recording. When injections were made into regions of the NST that responded to gustatory or mechanical stimulation of the foliate and/or circumvallate papillae, a distinct pattern of label was seen in the reticular formation and NST. Terminal labelling was observed in the reticular formation directly subjacent to the NST, both rostral and caudal to the injection site. Terminal labelling was also present in the NST and was prominent caudal to the injection site in the medial and ventral subnuclei but not in the central subnucleus. The intrasolitary projections include regions implicated in processing visceral afferent signals (e.g., Hamilton and Norgren, '83) and in triggering the pharyngeal phase of swallowing (Hashim et al., '89). These projections provide an anatomical basis for the interaction of oral afferent information with visceral afferent signals and ingestion. Supported by NIH R29 DC00416.

THETA STIMULATION AND LONG-TERM POTENTIATION IN THE PIRIFORM CORTEX. J. S. Stripling, M. Paz Galupo*, and D. K. Patneau. Department of Psychology, University of Arkansas, Fayetteville, AR 72701.

Stimulation of association fibers in the piriform cortex (PC) using 10-pulse trains repeated at 10 sec intervals produces a selective long-term potentiation (LTP) of period 2 in PC evoked potentials (Stripling and Patneau, Soc. Neurosci. Abstr. 14: 1189, 1988). In contrast, stimulation with 4-pulse trains repeated at theta frequency potentiates transmission at either lateral olfactory tract (LOT) theta rrequency potentiates transmission at either lateral olfactory tract (LOT) or association fiber synapses in the PC slice (Kanter and Haberly, <u>Soc. Neurosci. Abstr.</u> 15: 929, 1989), or, when applied to the LOT and used as a discriminative cue in intact animals, produces LTP of the A₁ component of the evoked potential, signifying increased transmission at LOT synapses (Roman, Staubli, and Lynch, <u>Brain Res.</u> 418: 221-226, 1987). The present experiment compared the effects of theta vs. spaced stimulation applied to the LOT or PC association

fibers in intact animals in the absence of a learning task.

Male Long-Evans rats were stimulated in the LOT or layer lb of the PC using 4-pulse 100 Hz trains. Layer Ib stimulation at theta frequency (200 ms intertrain interval) produced LTP of period 2 with no change in A1. Stimulation of the LOT at theta frequency or layer Ib with trains at 2 sec intervals had no effect. Theta stimulation was more effective than spaced stimulation in triggering an afterdischarge, but this also had no effect on A₁. These results indicate that theta stimulation by itself is relatively ineffective in altering LOT transmission in intact animals, but can potentiate period 2 if cortical association fibers are activated.

GUSTATORY RESPONSES FROM THE NUCLEUS OF THE SOLITARY TRACT IN AWAKE RATS. K. Nakamura and R. Norgren Dept. Behavioral Science, College of Medicine,

The Pennsylvania State University, Hershey, PA 17033. Single neurons were isolated from the nucleus of the solitary tract of alert rats using previously described techniques (Nishijo & Norgren, J Neurophys. 63: 707, 1990). Fluid stimuli consisted of 50 ul samples of water, sucrose, NaCl, citric acid (CA), and quinine HCl (QHCl) delivered via intraoral cannulae. From a total of 78 neurons, 70 responded significantly to at least one of the sapid stimuli. The mean spontaneous rate of the taste neurons was 4.0 ± 5.9 (SD) spikes/sec; the mean response to water (above spont rate), 3.7 ± 5.4 spikes/sec. Gustatory responses were considered significant if the activity elicited by a sapid chemical differed from the mean, uncorrected water response for each neuron by 2.5 SD. Based upon their largest response, taste neuron by classified as follows: 29 sucrose-best, 21 acid-best, 17 NaCl-best and 3 QHCl-best. Fifty percent of the neurons (35/70) responded significantly to only one of the four sapid stimuli, but the degree of specificity varied with best-stimulus category. Of the 21 acid-best neurons, 19 (90%) responded only to CA. For sucrose-best cells, specific sensitivity was less common (45%, 13/29), and for NaCl-best neurons, it was relatively uncommon (18%, 3/17). None of the QHCl-best neurons was specific. In general, gustatory neurons in the NST of awake rats resemble acutely recorded, peripheral taste cells more than chronically recorded parabrachial ones. Supported by PHS grants NS 00240, MH 43787, and MH 00653.

107.10

SIMULATION OF THE MEMBRANE CURRENTS REVEALED BY CURRENT SOURCE DENSITY ANALYSIS IN PIRIFORM CORTEX PROVIDES INSIGHT INTO THE DYNAMICS OF PROPAGATION IN EXCITATORY FIBER SYSTEMS. K.L.Ketchum and L.B.Haberiy. Dept. of Anatomy, Univ. of Wisc., Madison, WI 53706.

The membrane currents in a model of piriform cortex (PC) replicated those revealed by current source density analysis of the response to stimulation of afferent fibers in the lateral olfactory tract (LOT) in vivo. The model reproduced the timecourses of membrane currents by incorporating known excitatory and inhibitory synaptic inputs and with voltage dependent conductances. As a consequence of distributed conduction velocities and the large number of axons, activity in excitatory fiber systems was described as a continuous wavefront that disperses as it propagates. The timecourse of synaptic input was calculated by convolution of this dispersive wavefront and a synaptic conductance waveform. The resulting input waveforms were appropriately distributed in depth over a discrete cable of variable caliber that simulated the predominate pyramidal cell population. This reproduced capacitative effects on the timecourses and spatial distributions of membrane currents. It was found that the wavefront evoked by the afferent fiber volley could be described by a single dispersive wave originating at the caudal end of the LOT. This suggests that the wavefront remains coherent as it propagates in the LOT but disperses as it travels in slower LOT collaterals. It was found that the response component mediated by association fibers that originate in anterior PC could be described by a sum of dispersive wavefronts originating across the rostral to caudal extent of anterior PC. As a further validation of the model, the same parameters used to generate the afferent and association waveforms at the initial site successfully predicted changes in the waveforms at different recording sites. It is propogate that dispersive propagation within excitatory fiber systems provides a m

PHOTORECEPTOR INNER AND OUTER SEGMENTS IN TRANSPLANTED RETINA. Y. Liu*, M.S. Silverman and S.E. Hughes. Central Institute for the Deaf and Department of Ophthalmology and Visual Science, Washington University School of Medicine, St. Louis, MO 63110.

Previously we reported transplantation of the outer nuclear layer (ONL) from the developing and mature rat retina as well as the ONL from mature human retina to adult albino rats with light-induced loss of photoreceptors (Silverman and Hughes, IVOS 30:1684; PCBR 314:687, 1989). While the transplanted photoreceptors stained positive for opsin and formed synapses with host retina (Hughes, Valentino & Silverman, IVOS 31:594 Suppl., 1990) inner segments (IS) and outer segments (OS) were rare and were primarily seen within rosettes that formed in areas where the organization of the transplanted ONL was disrupted.

To investigate the role of inner retina and developmental constraints on the expression of IS and OS we transplanted sheets of 1) mature rat retina, 2) mature retina in which the ganglion cell layer was removed by vibratoming, 3) immature retina (8 day old) or 4) immature retina minus ganglion cells to the subretinal space of

mature light-damaged rats using a transcorneal approach (IVOS, 30:1684).

Two weeks following transplantation we found that in each group the transplant showed photoreceptors with a complement of IS and OS that were apposed to the underlying pigment epithelium. The degree of ONL, IS and OS organization as well as the amount of segment expression seen in these groups was different, with mature transplanted retina approximating normal retina > immature retina > mature retina minus ganglion cells > immature retina minus ganglion cells.

These results show that transplanted photoreceptors can express a comparatively normal complement of IS and OS. The degree of organization of the ONL and the expression of photoreceptor IS and OS is strongly influenced by inner retinal components as well as the developmental maturity of the transplant.

IN SEARCH OF A RECEPTOR FOR OUTER SEGMENTS IN RAT RETINAL PIGMENTED EPITHELIUM. L. Tien and N.G.F. Cooper. Dept. of Anatomy and Neurobiology, Univ. of Tenn, Memphis, TN 38163

The phagocytosis of photoreceptor outer segments is thought to be a receptor-mediated process. A procedure has been developed to study membrane-associated glycoproteins been developed to study membrane-associated glycoproteins of pigment epithelial cells to look for receptors of photoreceptor outer segments. The method involves the oxidation of the carbohydrate moieties of the RPE apical membrane glycoproteins. The resultant aldehyde groups are then labeled with biotin hydrazide. Biotinylated glycoproteins are then demonstrable through interaction with an avidin-based enzyme or avidin-based FITC probe. Three biotinylated glycoproteins with the MWs of 175 kD, 150 kD and 130 kD are detected with peroxidase linked streptavidin in Western blots. At the electron microscope level, the biotinylation sites are distributed on the microvilli of the RPE. The biotinylated RPE distributed on the microvilli of the RPE. The biotinylated RPE distributed on the microvilli of the RPE. The biotinylated RPE protein mixture was incubated with the neural retina and binding was detected through the use of streptavidin-FITC. The tips of the outer segments (OS) of the retina are fluorescently labeled and the inner retina is not labeled. Control sections which were not pretreated with the biotinylated RPE-proteins do not show any fluorescent labeling. Our results suggest that at least one of the three biotinylated RPE apical membrane glycoproteins seen in our blots can bind to the outer segments in tissue sections and blots can bind to the outer segments in tissue sections and they are therefore candidates for outer segment receptors.

171.5

ULTRASTRUCTURE AND TRANSDUCTION IN THE CAUDAL PHOTORECEPTOR OF CRAYFISH. B. Kruszewska and J.L. Larimer.

Zoology Dept., University of Texas, Austin, TX 78712

The well-known caudal photoreceptor (CPR) of crayfish (Prosser, <u>I.Cell.</u> Comp. Phys. 4:363,1934) has recently been assigned a command role for a particular behavior (Edwards, IEB 109:291,1984). Little is known, however, regarding its ultrastructure or the molecular basis of its transduction of light. regarding its unastructure of the moterature basis of its transduction of light Recording and injection techniques were combined with electron microscopy to determine whether the cell is a primary photoreceptor and to elucidate the transductive mechanism. The cell was impaled and pressure injected with $100 \, \mu \text{M}$ inositol(1,4,5,)trisphosphate (IP3). IP3 is known to play a role in signal transduction by stimulating release of internal calcium stores. Injection of IP3 into the soma or dendrites mimicked the response to light, resulting in depolarization and increasing the firing frequency in proportion to the strength of injection. The effect was reversible and the cell continued to be light-sensitive between injections. Injection of 2mM CaCl₂ had the same effect. Control injections of IP1, cGMP and KCl were sometimes accompanied by a change in membrane potential, but had no effect on firing rate. Control injection of IP3 into other (non-CPR) cells showed no effect on firing rate in approximately 87% of cells impaled. The number of cells responding to CaCl₂ was higher.

The ultrastructure of the cell was also examined with the goal of determining

The uttrastructure of the cell was also examined with the goal of determining whether it contained any phototransductive organelles. The cell was labeled by pressure injection with 0.01% 2nm colloidal gold particles and processed using standard electron microscopy techniques. Several processes of the labeled cell contained structures composed of layers of concentric membrane, structures that would be useful for maximization of photon capture by visual pigments. These structures, together with the clear response to injection of IP3, suggest that the CPR is a primary photoreceptor and that transduction takes place by means of a second messenger system. (Supported by NIH NS05423)

TRANSPLANTED PHOTORECEPTORS FORM SYNAPSES IN RECONSTRUCTED RCS RAT RETINA. T.L. Valentino*, S.E. Hughes, and M.S. Silverman. Sensory Neuroscience Laboratory, Central Institute for the Deaf, St. Louis, MO 63110.

Inherited retinal degeneration afflicts a variety of animals, including humans. Several animal models exist for inherited retinal dystrophy, including the RCS rat. By three months of age the RCS retina is devoid of photoreceptors, presumably due to a deficit in the retinal pigment epithelium. We have previously shown that it is possible to isolate the immature outer nuclear layer from 8 day old nondystrophic congenic rats and transplant the resulting photoreceptor layer to the subretinal space of adult dystrophic animals (Hughes and Silverman, Soc. Neurosci. Abstr. 14: 1277, 1988; Silverman and Hughes, PCBR 314: 687, 1989). The transplanted photoreceptors integrate with the host retina, forming a new outer nuclear layer

In a recent study involving transplantation of photoreceptors to light-damaged retina, we have shown that a new outer plexiform layer forms between the transplanted photoreceptors and the host inner nuclear layer (Hughes et al., Invest. Ophthalmol. Vis. Sci. 31 (Suppl): 594). The new outer plexiform layer contains ribbon synapses characteristic of photoreceptor synapses. We thus sought to determine whether similar events occur in the reconstructed RCS retina.

In transplants to the dystrophic RCS retina, a new outer plexiform layer is visible at the interface of the transplanted outer nuclear layer and the host inner nuclear layer. Ribbon synapses are frequently seen within this outer plexiform layer. These synapses are characteristic of rod spherules, with an electron dense ribbon surrounded by a cluster of vesicles. These synapses persist for at least three months. Ribbon synapses are extremely rare in control dystrophic retina.

These results indicate that transplanted photoreceptors form connections with elements of the host inner nuclear layer and may be used to reconstruct the dystrophic RCS retina.

171.4

ULTRASTRUCTURAL LOCALIZATION OF RPE EPITOPES IN IN SITU AND CULTURED RPE CELLS AND THEIR EXPRESSION IN FIBROBLASTS IN VITREOUS CULTURE. S.A.Vinores,P.A.Campochiaro*,W.Orman*, J.J.Hooks*,and B.Detrick*,Dept.Ophthalmol.,Univ.Virginia Sch.Med.,Charlottesville,VA and NEI,NIAID,NIH,Bethesda,MD.

Two distinct monoclonal antibodies (MAbs) against human retinal pigment epithelial (RPE) cells specifically stained RPE cells <u>in situ</u> by light microscopic immunohistochemistry. By electron microscopic immunocytochemistry, the labelling patterns of both MAbs were indistinguishable. In normal human RPE, the MAbs labelled the cytoplasm and surface and intracellular membranes. Other retinal and choroidal cells were negative. In vitro studies were performed to evaluate the effect of vitreous fluids on cell phenotype. Human RPE cells cultured on irradiated bovine vitreous demonstrated prominent staining on filaments of processes and on ribosomes in addition to cytoplasmic and membrane positivity. Human fibroblasts, which were normally negative, reacted with the RPE MAbs in the same pattern as RPE cells when maintained in vitreous culture. Unrelated MAbs failed to label RPE cells or fibroblasts. The induction of the two RPE-associated epitopes in fibroblasts suggests that their expression is related to metabolic or structural differexpression is related to metabolic or structural differences regulated by a component of bovine vitreous. These studies determine the cellular locations of specific RPE cell epitopes and demonstrate the effect of the vitreous environment on fibroblasts and RPE cells. These vitreousinduced alterations may also occur in ocular disorders such as proliferative vitreoretinopathy.

LICHT-REGULATED PROTEIN PHOSPHATASE ACTIVITY IN <u>LIMULUS</u>
VENTRAL PHOTORECEPTORS. <u>S.C. Edwards.</u> Dept. of Biology,

Univ. of South Florida, Tampa, FL 33620.

Exposure of dark-adapted (DA) Limulus ventral photoreceptors to an adapting light flash stimulates the phosphorylation of a 46 kD protein (46A), a major substrate for phorylation of a 46 kb protein (46A), a major substrate for a calcium(calmodulin dependent protein kinase (CaCAM PK). Okadaic acid (0KA), a potent inhibitor of protein phospha-tases 1 and 2A (PrP 1; PrP 2A), blocks the subsequent 46A dephosphorylation that normally occurs following the flash. This suggests that light increases the activities of both the kinase (presumably CaCAM PK) and the protein phospha-tase that catalyzes 46A dephosphorylation (46A PrP), but with a latency of activation compared to the kinase. The level of phosphorylation of 46A in long term light adapted (IA) and DA cells is the same even though Ca; in IA cells is elevated sufficiently to increase CaCAM PK activity. Addition of OKA to these preparations results in the selective increase in the level of 46A phosphorylation in IA, but not DA cells suggesting that the activities of both 46A PrP and CaCAM PK are elevated in IA cells. The identity of 4GA PrP and how it is activated by light are presently unknown. While it is possible that it is either PrP 1 or PrP 2A since the concentration of OKA utilized so far in this study was 1 uM, a concentration sufficient to activate either enzyme, the narrow specificity for 46A is not characteristic of either enzyme. (Supported by NIH EY08765.)

DOES SEAWATER CAUSE STRUCTURAL LIGHT ADAPTATION IN LIMULUS VENTRAL PHOTORECEPTORS IN VITRO? - A STUDY OF ORGAN CULTURE VS. SEAWATER INCUBATION. Robert N. Jinks* and Steven C. <u>Chamberlain.</u> Department of Bioengineering and Institute for Sensory Research, Syracuse University, Syracuse, NY 13244-1240.

Although most studies have utilized excised ventral photoreceptors maintained in scawater, Bayer and Barlow (J. Gen. Physiol. 72:539) showed that excised photoreceptors maintained in organ culture retain functional properties more characteristic of the intact state. For example, they possess a greater dynamic range with better threshold sensitivity than those maintained in seawater. To examine possible structural bases for this difference, ventral optic nerves of four animals were dissected in light and then maintained at 4° C in vitro in darkness for 5 hrs before fixation. One nerve of each animal was incubated in seawater; the other was incubated in organ culture. Preparation for examination with TEM followed our standard procedures (J. Gen. Physiol. 80:839).

Contrary to our expectations we observed no consistent differences in the overall size or organization of the light-sensitive rhabdomere; however, we found a consistent and significant ultrastructural difference in its microvilli. In organ culture, as in vivo, adjacent microvilli of dark adapted cells were joined by fused, quintuple-layered membrane. By contrast, in seawater, these quintuple-layered junctions had disappeared and all microvillar profiles were completely surrounded by extracellular space, both in the external and internal rhabdom.

Similar breakdown of the fused contacts between adjacent microvilli occurs late in the afternoon in the lateral eye of intact animals (J. Neurosci. 4:2792), suggesting that loss of fused junctions correlates with extensive light adaptation. Perhaps changes to the microvillar organization in ventral photoreceptors maintained in seawater underlie functional changes observed under these experimental conditions.

EVIDENCE THAT HYPERPOLARIZATION DESENSITIZES TURTLE CONES BY REDUCING INPUT IMPEDANCE David Schneeweis & Daniel G. Green

University of Michigan, Ann Arbor, MI 48109 Previous experiments using the eyecup preparation have shown that adaptation may spread laterally between cones in the turtle retina (Copenhagen & Green, 1987; Itzhaki & Perlman, 1987). Using an isolated turtle retina preparation and pairs of microelectrodes we now show that the sensitivity of a cone may be reduced when it is hyperpolarized indirectly by current that is injected into a neighboring cone. The same result holds if current is injected directly into the cone itself.

In order to better understand the effects of directly applied current we used 50pA test pulses to measure cone input impedance in the presence and absence of direct, steady hyperpolarizing current. Under both conditions the voltage response was high-pass in nature, indicating the presence of a voltage-sensitive conductance not noted by others using a dark adapted eyecup preparation. Furthermore, hyperpolarizing current caused a decrease in both the peak and steady state resistance, suggesting that hyperpolarization-induced desensitization to light is a reflection of lower input impedance rather than a decreased photocurrent response. (Supported by NEI grant 00379.)

RESPONSES OF CULTURED CHICK EMBRYO PHOTORECEPTOR CELLS TO LIGHT: A ROLE FOR NEUROMODULATORS. D. Stenkamp*, E. Adler-Graschinsky and R. Adler. Depts. of Neuroscience and Ophthalmology, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

We are investigating possible regulatory and developmental roles of light using cultures of chick embryo retinal cells which differentiate in vitro embryo retinal cells which differentiate in vitro into neurons and photoreceptors (PhR). Cells grown in the absence of pigment epithelial and glial cells, with minimal intercellular contacts, were maintained from the time of seeding on a 12 hr light cycle (80 lux, from a tungsten or fluorescent source). Over 50% of the PhR contracted during the dark period and elongated during the light period. PhR elongation was accompanied by myoid constriction, resembling photomechanical movements in vivo. Some of the neuromodulators and second messenger systems known to neuromodulators and second messenger systems known to affect photomechanical responses in vivo are also present in our cultures, and are now under investigation for possible regulatory roles in vitro. Ongoing studies show inhibitory effects of melatonin (10 μ M) upon light-dependent elongation, and suggest that dopamine and cyclic nucleotides may also play a role. Supported by USFHS grant EY04859, and an NSF graduate fellowship.

DO DOUBLE CONES MEDIATE VERTEBRATE POLARIZATION SENSITIVITY? D.A. Cameron', M. Rowe', N. Engheta' & E.N. Pugh, Jr. Inst. of Neurological Sciences, and Depts. of Electrical Engineering & Psychology, Univ. of Pennsylvania, Philadelphia, PA 19104.

Light-adapted green sunfish (Lepomis cyanellus) sensitivity to light linearly polarized at different angles (Θ) was measured in a Maxwellian-view optical apparatus with a classical conditioning paradigm (heart rate suppression). Threshold sensitivity was a W-shaped function of Θ with maxima at 0° (vertical) and 90° (horizontal), and up to 0.8 log units less-sensitive at oblique angles. A dielectric waveguide model of the sunfish double cone has been developed, and shows promise in accounting for the threshold data. The propagation characteristics of optical waves inside this guide for electric field vectors oriented parallel to either the long or short axis of the waveguide cross-section have been analyzed numerically. Preliminary results reveal a dependence of mode propagation on the optical wave polarization in the model. We hypothesize that (1) the individual double cone acts as a polarization analyzer, and (2) the orthogonal, tetradic arrangement of the double cone mosaic determines the polarization-sensitivity curve in this vertebrate. Anatomical work in progress is examining the prediction that the double cone tetrads under the Maxwellian image are aligned along the axes (0° and 90°) of maximum polarization sensitivity. Theoretical work is aimed at demonstrating that the severe drop in sensitivity at oblique angles requires a neural polarization-opponent mechanism. Supported by NIH grant EY-08260

MODULATION OF CALCIUM-ACTIVATED CHLORIDE CURRENT IN CONE PHOTORECEPTORS WITH CHANGES OF EXTERNAL pH. Steven Barnes and Quvnh Bui*. Department of Medical Physiology, University of Calgary Faculty of Medicine, Calgary, Alberta, Canada T2N 4N1.

Isolated larval tiger salamander cone photoreceptors exhibit robust Ca2+ activated CI⁻ tail currents following step depolarizations under whole-cell voltage-clamp when bathed in 10 mM HEPES-buffered media at pH 7.4 with 90 mM NaCl, 2.5 mM KCl, 3 mM CaCl₂ and 8 mM glucose (patch pipette: 100 mM cScl, 3.5 mM MgCl₂, 1.5 mM Na₂ATP, 10 mM NaHEPES and 1 mM EGTA at pH 7.4). Decreasing bath pH (7.0) reduces Cl⁻ tail currents to nil, while increasing pH (7.8) leads to larger, sustained tail currents. Peak Ba²⁺ currents (20 mM Ba²⁺) are reduced by decreasing pH (33% reduction, pH 6.8) and are enhanced by increasing external pH (25% increase, pH 7.8). The Ba²⁺ current activation range is also shifted positive 9 mV at pH 6.8 and negative 4 mV at pH 7.8, however neither the change in peak current nor activation shift accounts for the modulation of CI current with pH.

Long depolarizations or repeated depolarizations in control solutions (pH 7.4) give slow Cl⁻ tail current decays similar to those in basic media (pH 7.4) give slow 1 tail current decays similar to those in basic media (phr 7.5-7.8) suggesting that the enhancement of tail currents occurs as a result of an intracellular [Ca²+] increase. However, EGTA's ability to buffer Ca²+ is reduced by decreasing pH, opposite to the reduction in Ca²+ activated tail current seen with decreasing pH. Also, the Na*/Ca²+/K+ exchanger of photoreceptors is probably not involved as block of exchange by internal Cs+ has no effect on the pH dependence of tail current timecourse. Gating mechanisms intrinsic to the channel may be modified at different pH's

ADDITIONAL EVIDENCE SUPPORTING THE PRESENCE OF D2-LIKE RECEPTORS ON PHOTORECEPTORS OF THE MOUSE RETINA. A.I.Cohen. Dept. of Ophthal. and Visual Sciences, Washington University Sch. of Med., St. Louis, MO 63110.

Dark adapted (DA) mouse retinas isolated in dim red light and quick-frozen possessed about 60% more cAMP than did light adapted (LA) quick-frozen retinas. A similar disparity in cAMP and the ability of light to reduce the cAMP of dark incubated (DI) retinas were only preserved if retinas were incubated in media containing 1 mM IBMX or 5 mM Co⁺⁺. That a substantial part of the calls in if retinas were incubated in media containing 1 mM IBMX or 5 mM Co⁺⁺. That a substantial part of the cAMP is located in DA mouse photoreceptors follows from the ability of light to reduce cAMP in DA-DI retinas in media containing 5 mM Co⁺⁺ plus 10 mM glutamate or 1 mM IBMX plus either Co⁺⁺ or 10 mM glutamate or aspartate or 50 µM kainate or 50 µM APB plus 6 mM PDA, agents said to confine the effects of light to photoreceptors. This pool was eliminated in DA-DI retinas if the medium contained either 0.1 µM dopamine (in the presence of 10 µM SCH 23390, a DI blocker), or synthetic D2 agonists, e.g. 1 µM LY171555 (an ergoline), 1 µM (+)N-0437 (an aminotetralin) or 100 µM (+)-3-PPP (a phenylpropylpiperidine). Similar results were observed if cAMP had been further increased by high K⁺ in Cl⁻ free medium. The agonists had no action on the cAMP of LA-LI retinas in IBMX medium. Agonist actions were reversed by spiperone (in the presence of ketanserin) but not by substituted benzamides.

DIFFERENTIAL INCORPORATION OF DOCOSAHEXAENOYL (22:6)-PHOSPHOLIPIDS IN ROD AND CONE PHOTORECEPTOR CELLS OF THE FROG RETINA. N.G. Bazan, W.C. Gordon, B.D. Shivers and E.B. Rodriguez

de Turco.* LSU Eye Center and Neuroscience Center, New Orleans, LA 70112.

Docosahexaenoic acid (22:6) is avidly taken up by photoreceptors, cells that continually renew their membranes. When 3H-22:6 is delivered to the retina by way of the circulatory system, the outer segments soon acquire an overall diffuse label. A highly labeled region at the base of the outer segment also forms, and gradually accumulates until this dense label reaches the photoreceptor tip about 28 d later (J. Neurosci., July, 1990). When H-leucine (protein marker) is used, a dark band corresponding to newly synthesized disc membranes forms. This marker also migrates to the receptor tip, arriving in about 28 d. Measurements of migration rates of the 22:6 dense region and the leucine-labeled opsin suggest that these 2 membrane components are linked. However, isolation and counting of outer segment protein reveal no activity, demonstrating that the association is noncovalent. This suggests a functional role for 22:6 in the disc membrane in the region adjacent to the opsin molecule. This autoradiographic and biochemical study investigated the uptake pattern of 22:6 by isolated retinas over very short time periods. Some 22:6 diffusely labeled the outer segments within 15-30 min, however inner segments only began to label in the ER- and Golgi-rich region of the myoid after 30 min. 22:6 accumulated and migrated distally into the ellipsoid region just below the region of disc morphogenesis of the outer segment, where it continued to collect. The basal region of the outer segment began to label after 6-10 h incubation. Grain counts of these regions in autoradiographs revealed that the 435-rods accumulated 2-4 times as much 22:6 as the 502-rods, and cone cells only diffusely labeled. This differential uptake suggests either that photoreceptor types have different metabolic rates, or that the 22:6-containing phospholipid-visual pigment association differs for each type of opsin. NIH grant EY04428.

VISININ: A NOVEL CALCIUM BINDING PROTEIN EX-PRESSED IN RETINAL CONE CELLS. K.Yamagata*, K.Goto, C-H.Kuo and H.Kondo and N.Miki*. Dept. of Pharmacol., Osaka Univ. Sch. of Med., Osaka 530,

Visinin (24kDa) is a retinal cone cell-specific protein. Visinin cDNA was isolated from a chick retinal λ gtl1 cDNA library, using anti-visinin serum. The β -galactosidase-visinin fusion protein was used for purifying epitope-selected antibody. The purified visinin antibody reacted only with a 24 kd protein in retinal cone cells. Visinin mRNA was expressed only in the retinal photoreceptor layer. The nucleotide sequence of the cDNA revealed that visinin has three E-F hand structures and is a Ca²+ binding protein. Visinin protein expressed in E.coli exhibited Ca²+ binding activity. Visinin was also found in chicken pineal body by immunohistochemistry. Northern blot analysis showed that pineal visinin mRNA was the same as retinal visinin mRNA. When hatched chicks were fed in the light or dark for three days, increased numbers of visinin-positive cells in the pineal body from illuminated chicks were observed. These results suggest that visinin is a photoreceptor-specific Ca²+ binding protein and may be involved in phototransduction in Visinin (24kDa) is a retinal cone cell-specific and may be involved in phototransduction in retinal and pineal cone-type photoreceptors.

GAP JUNCTIONS BETWEEN PEDICLES OF MACAQUE FOVEAL CONES. GAP JUNCTIONS BETWEEN PEDICLES OF MACAQUE FOVEAL CONES.
Y. Tsukamoto*, P. Masarachia*, S.J. Schein, and P.
Sterling. Hyogo Coll. Med., Hyogo; Harvard Med., Boston;
U. Penn Med., Phila. PA 19104
Electrical coupling of cone pedicles by gap junctions is universal in vertebrate retinas. Such junctions have

been reported between cones in primate fovea, but this claim has been disputed. We reinvestigated the issue by reconstructing a patch of 80 cone pedicles from electron micrographs of serial sections near 1.5° eccentricity.

A glial curtain isolates each pedicle. However, the curtain occasionally parts, exposing each pedicle at 4 ± 1 sites to its neighbors. Each site bears a desmosomelike, adherent junction (en face, roughly elliptical, $\simeq 0.2~\mu\text{m}^2$). Sections through the adherent junction (tilted appropriately) show several gap junctions. vary in size, shape, and in their number/adherent junction. Via such clusters of small gap junctions every pedicle connects, with no selectivity, to at least 2 neighbors. The mean gap junction area/pedicle X the density of connexons (estimated from freeze-fractured material, Raviola and Gilula, '74) suggests on the order of 100 connexons per pedicle. Assuming 100pS/connexon, the total coupling conductance of a pedicle might be 10^4

Such coupling would tend to degrade spatial acuity but would improve contrast sensitivity to middle spatial frequencies. (EY08124).

APOF-MEDIATED DELIVERY OF DOCOSAHEXAENOVI-PHOSPHOLIPIDS INTO NEURAL RETINA AND PHOTORECEPTOR CELLS (PRC). F. Cai,* M.P. Mims, * and E.B. Rodriguez de Turco, * D. Webster and N.G. Bazan. ISU Eye Center and Neuroscience Center, New Orleans, LA 70112; ADepartment of Medicine, Baylor College of Medicine, Houston, TX.

ApoE is a plasma apolipoprotein synthesized and secreted by the liver and

extrahepatic tissues, including the nervous system. It participates in receptormediated transport and delivery of cholesterol and other lipids between cells. We have evaluated the involvement of ApoE in the transport and transfer of lipids containing 22:6 fatty acids to PRC and retinal cells using retinas from 10-day-old mouse pups as a model of CNS. At this point of development, PRC are actively building new membranes enriched in 22:6. By incubating retinas with ¹²⁵I-ApoE/DMPC in the presence or absence of unlabeled ApoE/DMPC, we found specific binding and internalization of ¹²⁵I-ApoE/DMPC by developing retinal photoreceptor cells. Further studies indicated that binding and internalization were saturable, and that unlabeled ApoE/DMPC specifically competed for binding and internalization. H-22:6 labeled phospholipids were assembled into the ApoE/DMPC disk and incubated with the retina. After isolation of retinal photoreceptor cells, lipids were extracted and the uptake of labeled phospholipids determined by scintillation counting. Results indicated that 22:6 was also specifically bound and internalized by retinal photoreceptor cells when combined with ApoE. The ApoE-receptor-mediated uptake of phospholipids and/or cholesterol may be an important mechanism for support of photoreceptor cell membrane biogenesis and synaptogenesis. Supported by NIH grant EY04428.

CALCULATED COLORS OF VERTEBRATE RODS AND CONES: THE HUMAN FOVEA Abner B. Lall. ** Steven Park* and Richard A. Cone* 'Howard University, Washington DC. 20059 and 'The Johns Hopkins University, Baltimore, MD. 21218

The colors of most photoreceptors have yet to be seen since their

visual pigments bleach too rapidly when viewed in a microscope. We have calculated the colors of vertebrate photoreceptors as they would appear if they did not bleach. Transmission spectra for the pigments were obtained from a computer program based on the polynomial expression of Dawis (1981) for the Ebrey-Honig nomogram. At each wavelength, the transmission for a given axial density value was multiplied by the tristimulus functions for human color vision and the product was integrated to obtain the corresponding tristimulus values. These values were used to construct two nomograms for vitamin A_1 and A_2 pigments. The nomograms are plotted on the C.I.E. 1931 chromaticity chart, and can be used for all vertebrate photoreceptors with visual pigments with max between 425-650 nm, and for axial densities between 0.5-1.5. To test our calculations, we obtained the Munsel color chips that correspond most closely to the calculated chromaticity coordinates for frog rhodopsin rods, and these chips were visually compared to the color of fresh dark-adapted frog retinas (N=6) viewed under a calibrated light source. The colors closely matched, confirming the calculations. Munsel chips corresponding to human rods and cones were then used to create a color montage of the human fovea. These Munsel colors were applied to an enlargement of a detailed micrograph of the human fovea published by Ahnelt, Kolb, and Pflug (1987) to depict, as accurately as possible, the actual colors of the human fovea.

AN UNEXPECTED CONE SPECIALIZATION AROUND THE RIM OF THE HUMAN RETINA. Robert W. Williams, University of Tennessee, School of Medicine, Memphis, TN 38163
Retinas from 5 adult humans were flattened in glycerin and studied at high magnification using video-enhanced Nomarski optics. It is hard to get good images from the edge of the retina. Pigment often obscures the mosaic. Furthermore, the retina is often not flat at the ora serrata and oil immersion objectives typical do not have enough working distance to focus on the photoreceptor mosaic. My solution was to transilluminate the retina with a bright monochromatic light source and use a 63x 1.25 NA Zeiss fluorite objective with a working distance of 500 µm. High contrast images of inner segments were quantified using a video overlay system at a focal plane just beyond the outer limiting membrane (Wikler et al. '90; Curcio et al. '90).

Cone inner segments at the extreme periphery have conventional morphology and can be clearly identified and easily distinguished from rods at all sites. In each retina I found a thin belt at the extreme periphery that is heavily populated by cones. This cone-enriched belt varies from 50 to 500 µm in width and is found around the entire rim, including the temporal quadrant. Cone densities increase rapidly and rod densities decrease rapidly moving outward within the belt. This gradient is as precipitous as that at the foveal rim, but of course, opposite in direction. At the edge of the retina many fields are almost entirely covered by a tight mosaic of cones (greater than 90% cone coverage). Here cone densities peak between 10,000 and 15,000/mm². This is 3 to 5 times higher than cone densities 1 mm from the edge of the retina. Conversely, rod densities plummet at the edge, dropping from more than 20,000 to about 5,000/mm².

The cone-enriched retinal rim may function as an alert field under conditions of bright illumination.

conditions of bright illumination. Supported by EY06627.

Monkey Cone ERG: Analysis by PDA, KYN, CNOX, APB, ASP, Co. PA Sieving, K Murayama, F Naarendorp. U Mich. Ann Arbor.
Light-adapted Rhesus ERGs were evoked by 200 ms flashes
on 3.3 log Td rod saturating backgrounds. ON- and OFFpathway agents were studied by intravitreal injections.
APB suppressed the Bwave, and the normally negative

"sustained plateau" became more negative. The normal "sustained plateau" became more negative. The normal Dwave, at stimulus off, has a positive face, with a slow phase (which we called d_1) and a second phase with steeper slope (d_2) , followed by the negative-going face (d_1) . APB did not change d_1 , but d_2 was larger and d_1 smaller. PDA, KYN and CNOX doubled the Bwave positive face (b_1) , but the Bwave negative face (b_2) was nearly absent because

the sustained plateau was elevated far above baseline; d₁ remained, but d₂ was gone; d₂ amplitude was unchanged.

ASP & Co⁺⁺ abolished the Bwave; the sustained plateau stayed negative; d₁ remained, but d₂ and d₂ were missing. This suggests that the Dwave reflects both cone and

post-photoreceptor activity; and both Bwave and Dwave are controlled by both hyper- and depolarizing cells. In this scheme, the cones contribute the light-adapted Awave and scheme, the cones contribute the light-adapted Awave and d₁ (initial part of Dwave only); depolarizing cells give b₁ and d₂; hyperpolarizing cells give b₂ and d₃, either directly or via control of depolarizing cells; b₄ and the sustained plateau comes from cones dz/d_ plus the sustained net contribution of hyper-and depolarizing cells. R01-EY06094 and Retinitis Pigmentosa Fndn, Baltimore, MD. plateau

RETINAL ARTERY OCCLUSION FOLLOWING INTRANASAL INJECTION OF CORTICOSTEROID AND SUBSEQUENT EFFECTS ON THE PATTERN ERG.

J. Mishra, R. A. Tang* and T. C. Prager*.

Dept. of Ophthalmology, University of Texas Medical Center., Houston, TX 77030.

The Pattern Electroretinogram (PERG) is thought to reflect the electrical activity of the inner retina to patterned stimuli. We report two cases of optic atrophy following intranasal injection of methylprednisone into the left turbinate and subsequent effects on the PERG. Intranasal injection of corticosteroids is given as a treatment of chronic sinusitis. Vascular anastomoses between the nasal and retinal circulations are present as branches of the ophthalmic artery reach the anterior and posterior ethmoidal arteries which supply the nasal mucosa. Corticosteroids injected intranasally under pressure can make their way into the ethmoidal artery, and by retrograde flow, to the ophthalmic artery and occlude retinal artery. As a result of emboli of injected material, visual complications, such as blurring or permanent loss of vision have been reported. A reduction in the amplitude of the pattern ERG was found in both of these patients, indicating damage to the inner retinal layers(e.g., ganglion cells) either from the extensive retinal edema at the time of occlusion ,or from a retrograde degeneration of optic nerve fibers.

171.23

ACCUMULATION OF AMINO-ACIDS AND HYDROXYL FREE RADICALS IN BRAIN AND RETINA OF GERBIL AFTER TRANSIENT ISCHEMIA.

B. Delbarre, G. Delbarre, F. Calinon* and A. Ferger*.
Faculté de médecine, 37032 Tours, FRANCE.

Mongolian gerbils (Meriones Unguiculatus) have been widely accepted as model of cerebral ischemia because of its incomplete circle of WILLIS (40 to 60 %). Delbarre et al. (Delbarre, G., Stroke, 19:126, 1988) selected sensitive gerbils by examination of the fundus. Two groups of adult gerbils were used. One control group was sham operated and in the second ischemic group, left carotid was ligated during 30 min. Only sensitive ischemic gerbils were used for this study. 60 min. after release of the clip, left brain and left retina were removed and amino-acids (glutamate, aspartate and GABA. XU, X, J. Liquid Chromotog., 9: 2253, 1986) and hydroxyl free radicals (Floyd, R.A., J. Free Radic. Biol. & Med., 2:13, 1986) were determined using HPLC method.

In ischemic brain and retina, amino-acids (> 122 %) and free radicals (> 385 %) were significantly increased. These results show that simultaneous determination of amino-acids and hydroxyl free radicals is a good index to study cerebral ischemia after reperfusion.

171.20

CIRCADIAN ROD OUTER SEGMENT DISC SHEDDING IN RABBITS IS ASSOCIATED WITH DECREASED PHOTORECEPTOR SENSITIVITY, AS MEASURED IN THE ISOLATED A-WAVE OF THE ELECTRORETINOGRAM. M.P. White,D.M. Impelman, and P.A. Hock, Ophthalmology Sect. Veterans Admin. Medical Ctr, Palo Alto, CA 94304 In rabbits a decrease in retinal sensitivity, measured

in the b-wave of the AC-ERG, is temporally correlated with the increase in phagosomes in retinal pigment epithelium that defines circadian rod outer segment disc shedding (White, et al, Vision Res. 27:357, 1987). If shedding of photopigment-containing membrane by photoreceptor cells causes the observed decrease in retinal b-wave sensitivity, it is predicted that the a-wave of the ERG, the component produced directly by the photoreceptor cells, will also decrease in amplitude. Normally, the onset of the positivegoing b-wave masks the full expression of the negativegoing a-wave. However, by pharmacologically removing the postsynaptic input to the ERG with sodium aspartate, the a-wave can be observed in isolation. We measured isolated scotopic a-waves in 44 albino and pigmented rabbit retinas after intravitreal sodium aspartate (60-150uM). A decrease in a-wave amplitude reliably occurs at the same time as the decrement previously measured in the b-wave, showing that rod sensitivity decreases at approximately 30 min after the usual time of light onset in photoentrained animals. In constant dark the a-wave decrease phase advances, also re-sembling b-wave measurements. These data fit a model of disc shedding based on removal of photosensitive membrane.

171.22

ELECTRORETINOGRAM OF GERBIL AFTER TRANSIENT ISCHEMIA

Faculté de médecine, 37032 Tours, FRANCE.

Mongolian gerbils (Meriones Unguiculatus) were selected by Delbarre method (Delbarre, G., Stroke, 19:26,1988).

Adult gerbils were used. Left carotid was ligated during 30 min. Sensitive and non sensitive ischemic gerbils were used for study electroretinogram (E.R.G.). E.R.G. was recorded with a silver electrode placed against the left cornea of anesthetized animals (sodium pentobarbital, 60 mg.kg-1 I.P.). The flash stimulus (intensity:3 Joule, 1 flash per sec.) triggered the averager. E.R.G. was measured before ligation, 5 min. after ligation and again 5 min., 1, 2 and 24 hours after release of the clip. Two waves were studied: the a negative wave (photopic vision) and the most important positive b wave (scotopic vision). 5 min after ligation, the b wave disappeared in sensitive gerbil while this wave persisted in non sensitive gerbil. After reperfusion, latencies and amplitudes of sensitive gerbils were significantly decreased for b wave. Latencies and amplitudes of the a wave were significantly decreased only in sensitive gerbil 5 min after ligation. It is known that a wave has a high resistance to anoxia caused by circulatory blocage while b wave is abolished by clamping the retinal circulation (Brown, K.T., NATURE, 193:958, 1962).

These results show that gerbil is a suitable model to stu-

dy drugs protecting neural retina in ischemia.

SYNERGISTIC ACTIONS OF SPINAL DELTA BUT NOT MU OPIOID AGONIST WITH SEROTONIN.

K. Nakatani, Y. Harada, L.M. Kitahata, J.G. Collins. Dept. of Anes., Yale Univ. Sch. of Med., New Haven, CT 06510

It has been demonstrated that intrathecally administered opioids and serotonin have antinociceptive effects. This study is part of a series of experiments aimed at determining optimum drug combinations that produce maximal deppression of noxiously evoked activity at the level of the spinal cord. The present study examined interactions between mu and delta opiate subtypes and serotonin.

This protocol was approved by the Yale Animal Care and Use Committe. Noxious activity evoked by radiant heat was recorded from single discriminated wide dynamic range (WDR) neurons in decerebrate, spinally transected cats. Following baseline determination, lug of DAGO(mu selective opioid agonist) or 30ug of DPDPE(delta selective opioid agonist) was combined with 250ug of serotonin and neuronal activity was recorded for 30 minutes. At 31 minutes 0.1mg of naloxone was administered intravenously. The dose of each drug administered alone intrathecally produced no suppression of WDR neuron activity evoked by radiant heating (51°C for 8sec). Although the combination of DAGO and serotonin produced no significant suppression of noxiously evoked activity, DPDPE and serotonin produced significant suppression(to $72.8 \pm 8.0\%$ (mean \pm S.E.) of control values (p<0.05). 0.1 mg of intravenously administered naloxone reversed the suppression produced by the DPDPEserotonin combination.

The results of the present study suggest that combinations of serotonin with delta selective opiate agonists may be more effective in suppressing noxiously evoked activity than combinations with mu selective opiates.

(This study was supported by NIH Grant NS-09871.)

MODULATION OF NOCICEPTIVE AND 'COLD' INPUTS IN THE MEDULLARY DORSAL HORN: THE ROLE OF KAPPA OPIOID RECEPTORS. S. S. Mokha, Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

It has previously been reported (Mokha, S.S., Soc. Neurosci, Abs., 15, 372p) that dynorphin, an endogenous ligand for the kappa opioid receptor, 372p) that dynorphin, an endogenous ligand for the kappa opioid receptor, produces a widespread influence on somatosensory information from the face. The present study investigated the effects of U-50,488H, highly selective agonist for the kappa opioid receptor, on the responses of neurones in the superficial and deeper layers of the dorsal horn of the medulla (trigeminal nucleus caudalis). Extracellular single unit recordings were made in rats anesthetized with halothane. Nociceptive neurones were activated by thermal stimuli. The effects of intravenously administered U-60.488H. activated by thermal stimuli. The effects of intravenously administered U-50,488H (1-2 mg/kg) were tested on the thermal stimuli evoked responses of nociceptive neurones and on the activity of cold receptive neurones. The responses of selectively nocirceptive neurones in the superficial laminae of the dorsal horn were reduced by U-50,488H. However, the responses of multireceptive neurones in the deeper dorsal horn were either reduced or enhanced. A similar action was observed on the activity of cold receptive neurones. These actions of U-50,488H were similar to those observed previously with dynorphin. It is concluded that kappa opioid receptors play an important role in modulating somatosensory information from the face.

INTRATHECAL DOSE RESPONSE CURVES FOR MORPHINE (MOR) AND SUFENTANIL (SUF): ROLE OF DRUG EFFICACY IN THE RIGHT SHIFTS PRODUCED BY INCREASING STIMULUS INTENSITY. T.L. Yaksh. Dept. of Anesthes., UCSD, La Jolla, CA 92093.

Yaksh. Dept. of Anesthes., UCSD, La Jolla, CA 92093.

Agonists with high efficacy by definition are able to produce their effects by occupying a small fraction of the available receptors while low efficacy agonists must show a higher fractional receptor occupancy (FRO). If the intensity of the stimulus is increased, it follows that a larger number of the available receptors will require occupancy to produce a given effect. It can be shown that for any required increase in effect, agents with high FRO's will show a greater right shift than agents with low FRO's. We have shown in studies with the irreversible mu antagonist B-funaltrevamine that the degree of shift in the respective intrathecal dose response curves is: MOR>-SUF, suggesting that relative to SUF, MOR is a lower efficacy agonist. To assess the prediction made above that lower efficacy agonists may show a greater shift in their dose response curves for a given increase in required effect, dose response curves for intrathecal MOR and SUF were assessed in rats with chronic lumbar intrathecal catheters using the 48°C, 52.5°C and 60°C hot plate. Both agents showed a rightward shift in their respective dose response curves with increasing stimulus intensity. response curves with increasing stimulus intensity.

COMPARISON OF THE ANTINOCICEPTIVE AND MOTOR EFFECTS OF INTRATHECAL OPIOID AGONISTS IN THE RAT. C. Miaskowski K.A. Sutters, Y.O. Taiwo, and J.D. Levine.* Neuroscie University of California, San Francisco, CA 94143.

The purpose of this study was to compare the antinociceptive and motor effects produced by the intrathecal (IT) administration of selective mu- (DAMGO; o.5 ng - 5 ug) delta- (DPDPE; 0.5 ng - 5 ug), and kappa- (U50,488H; 5 ng - 50 ug) agonists. IT catheters were inserted one week prior to the experiments. The Randall Selitto paw-withdrawal test was used to measure changes in mechanical nociceptive threshold. The rat's motor coordination was tested using an accelerating Rota-Rod treadmill (Ugo Basile). The effect of each of the agonists on nociceptive threshold and motor coordination was calculated as a percentage change from baseline threshold. Each agonist produced a statistically significant dose-dependent increase in nociceptive threshold as measured by one-way ANOVA. At the two highest doses tested (500 ng and 5 ug), the selective mu-agonist, DAMGO, produced marked decreases in motor coordination. In contrast, lower doses of DAMGO and the selective kappa- (U50,488H) agonist, over the full range of doses tested, produced smaller decreases in motor coordination. The results suggest that motor side effects need to be considered when interpreting the results of analgesic tests that are dependent on a normally functioning motor system.

172.4

EPIDURAL AND INTRATHECAL ADMINISTRATION OF SUFENTANIL, ALFENTANIL AND MORPHINE IN THE DOG; A COMPARISON OF ANALGESIC EFFECTS AND THE DEVELOPMENT OF TOLERANCE. Paul J. Tiseo, Marc B. Sabbe * and Tony L. Yaksh U. C. San Diego, Dept. of Anesthesiology, La Jolla, CA 92093

Sufentanil (Suf), alfentanil (Alf) and morphine (Mor) are mu receptor agonists with different receptor affinities, intrinsic efficacies, and lipid solubilities. There is clinical interest in the anilinopiperidines because of their higher liposolubility, and a decreased risk of delayed respiratory depression secondary to bulk redistribution in the CSF. The purpose of this study was to evaluate the analgesic effects and the development of tolerance to these drugs following 14 day EP or 28 day IT administration. Beagles (-10 kg) were implanted with EP and IT catheters (PE-50) mg) and IT Mor (0.5, 5 mg). In all cases the analgosic response was dose-related and produced 100% MPE at the higher doses. The development of tolerance was quantified produced 100% MPE at the higher doses. The development of tolerance was quantified by comparing the extent and the duration of the analgesic effect produced on Day I with that observed on the final day (Day-F) of the study. Results are expressed as a ratio of the AUC on Day-I/AUC on Day-F, where AUC = %MPE vs Time. The magnitude of tolerance observed for a given agent was similar regardless of the route of administration. Mor produced the greatest degree of tolerance over time with a ratio of 25. Alf and Suf demonstrated significantly less tolerance over time with ratios of 2 and 3 respectively. Such differences in the magnitude of tolerance may result from different drug kinetics or possible differences in drug pharmacodynamics. These results suggest that although the duration of action of Alf and Suf is significantly shorter than that of Mor, the more liposoluble and receptor specific anilinopiperidines produce a slower tolerance development which is of significance in the treatment of opioid-sensitive chronic pain. sensitive chronic pain.

MORPHINE MICROINJECTED INTO THE MEDULLARY DORSAL HORN PRODUCES NALOXONE-REVERSIBLE FACIAL SCRATCHING IN THE MONKEY. D.A. Thomas*, K. Iwata, Dubner, R. and D.R. Kenshalo, Jr., Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892

A frequently observed side effect of spinal opiates in humans is itch and scratching, especially on the face.
examined the effects on facial scratching behavior of
morphine sulfate microinjected unilaterally into the medullary dorsal horn (MDH) of a rhesus monkey. monkey was seated in a primate chair and the number of scratches in five-min blocks were recorded by two raters independently. The location of the scratches in the trigeminal nerve divisions were determined. Morphine (Morphine (1.0, 2.5, 5.0 µg/0.2µl saline) produced a dose-dependent increase in scratching behavior. Scratching increased on both sides of the face and occurred about twice as frequently on the side of the face ipsilateral to the injection. Increases in scratching were observed 10-15 min postinjection with a peak (M = 253.0 tacial scratches/5 min) occurring at 70 min. Scratching increased in all three trigeminal areas, with the greatest increases observed in the ophthalmic and maxillary areas. Naloxone (0.5 and 2.0 mg/kg; IM) administered 50 min after morphine (5.0 µg) completely reversed the effects of morphine on facial scratching behavior. These data demonstrate that MDH-administered morphine can produce a dose-dependent, receptor-specific increase in facial-scratching behavior in the monkey.

CROSS-DESENSITIZATION BETWEEN MORPHINE AND NOREPINEPHRINE ON THE INHIBITION OF SUBSTANCE P RELEASE FROM RAT SPINAL CORD SLICES. M.R. VASKO, P.M. DULBERGER* AND M.N. PAYNE*. Departments of Pharmacology and Toxicology and Anesthesia, Indiana Univ. School of Medicine, Indianapolis, IN 46202.

Since morphine (M) and norepinephrine (NE) inhibit the release of substance P (SP) from sensory neurons, we studied whether these inhibitory effects could desensitize with chronic exposure of the spinal cord to M.

Rats were implanted with thecal cannulae attached to Alzet miniosmotic pumps containing either saline or 20 nmol M. The pumps delivered lul/hr of solution for 7 days. On day 7 after implantation, rats were decapitated and SP release from a segment of the dorsal lumbosacral spinal cord was measured using an in vitro perfusion technique. Release of SP was evoked by exposing the tissue to 50mM KCl in the presence or absence of drug.

Exposure of dorsal spinal cord tissue from control rats to 50mM KCl produces an increase in the release of SP from a basal level of 0.16±0.04 to 0.78±0.11 pg/mg/min. tissues from rats implanted with pumps containing saline, exposure of cord slices to M or NE (10^{-5}M) results in a significant inhibition in the stimulated release of SP. In contrast, evoked release of SP is not significantly inhibited by either M or NE (10-5M) in cord slices from rats exposed to M for seven days. Thus, desensitization develops to both M and NE-induced inhibition of SP from the dorsal spinal cord after chronic exposure of the spinal cord to the opioid. (Supported by NS 21697)

CHOLECYSTOKININ OCTAPEPTIDE ATTENUATES MORPHINE-INDUCED INHIBITION OF C-FIBER EVOKED DISCHARGES OF SPINAL CORD NOCICEPTIVE NEURONS. D.E. Kellstein¹, D.D. Price², and D.J. Mayer¹. Depts. of ¹Physiology and ²Anesthesiology, Medical College of Virginia, Richmond, VA

Previous studies suggest that cholecystokinin octapeptide (CCK), a putative CNS neurotransmitter or neuromodulator, may function as a selective antagonist of opioid-induced analgesia. Using extracellular electrophysiological recording, the present study investigated the effects of CCK and the CCK antagonist lorglumide (LGM) on 1) A- and C-fiber evoked firing of dorsal horn nociceptive neurons, and 2) the inhibition of C-evoked firing induced by morphine sulfate (MS).

Male Sprague-Dawley rats (450-520 g) were anesthetized with urethane (1.3 g/kg).

A laminectomy was performed at spinal segments L4 and L5, and the dura was retracted. Single unit recordings were made from wide dynamic range and nociceptive specific neurons of the dorsal horn (laminae 2 to 7) during controlled repetitive electrical stimulation of the ipsilateral hindpaw. Stimulation consisted of a train of six pulses (3 mA; supramaximal for C-fiber activation) delivered at 2 sec intervals. Following determination of control responses, CCK (6.4 pmol to 20 nmol) or LGM (0.145 to 145 pmol) was superfused onto the spinal cord in a volume of 10 μ l, and evoked discharges were quantified at 1, 5, and 10 min after each dose. Eleven min after the last dose of either drug, MS (4, 20, and 100 nmol) was applied and evoked discharges were again counted. Neither CCK nor LGM administered alone significantly altered either spontaneous, A-evoked, or C-evoked firing. CCK pretreatment, however, significantly attenuated, whereas LGM pretreatment significantly enhanced, MS-induced inhibition of C-evoked firing. Consistent with the results of behavioral studies, these findings suggest that CCK is not a neurotransmitter or neuromodulator of nociception, but rather an antagonist of opioid-induced anti-nociception. Supported by PHS awards NS 24009-1A2, DA 00576, and FIDIA.

DIFFERENTIAL DOSE-DEPENDENT EFFECTS OF MORPHINE ON

DIFFERENTIAL DOSE-DEPENDENT EFFECTS OF MORPHINE ON THE VENTRAL ROOT POTENTIAL. R.A. Jaffe, M.D., Ph.D. Dept. of Anesthesia, Stanford Univ. Sch. of Med., Stanford, CA 94305.

The ventral root potential (VRP) evoked by stimulation of the corresponding ipsilateral dorsal root (DR) typically consists of three distinct components: two early low-threshold components representing A-fiber mediated activity in monosynaptic and in polysynaptic pathways respec tively, and a late high-threshold component representing C-fiber mediated activity related to nociception. An objective of this study was to examine the VRP as a measure of nociceptive processing in the spinal cord. Adult male SD rats were decerebrated under inhalational anesthesia, and a laminectomy extending from T13 thru L5 was performed. Ipsilateral L5-6 dorsal and ventral roots were isolated for subsequent stimulation and recording with suction electrodes. Rats were mounted in a spinal frame, paralyzed with pancuronium and mechanically ventilated. End-tidal CO₂ and rectal temperature were maintained in a normal physiologic range. A pool was formed directly above the exposed spinal physiologic range. A pool was formed directly above the exposed spinal cord by removing overlying agar used to stabilize the preparation. All drugs were dissolved in physiologic saline bathing the exposed spinal cord. Analysis of the VRP evoked by DR stimulation suprathreshold for C-fibers revealed that morphine sulfate (MS) 15uM or 150uM eliminated the C-fiber component of the VRP within 30-45 minutes. The C-VRP gradually returned to control levels over a 2-4 hour period following removal of the MS containing medium. This C-VRP effect was completely experience of the VRP were component of the VRP were pletely reversible by naloxone. The early components of the VRP were minimally affected at 15uM MS but clearly enhanced at 150uM MS. This augmentation of A-fiber evoked VR activity may be related to previou observations of MS-induced increased activity in some dorsal horn neurons and with the behavioral observations suggesting hyperalgesia with large intrathecal MS doses. Supported in part by NIH BRSG RR05353.

THE EFFECTS OF SULFATED CHOLECYSTOKININ TAPEPTIDE ON ANTINOCICEPTION INDUCED BY DIFFERENT OPIOID AGONISTS. Leon F, Tseng and Keith A. Collins Department of Pharmacology and Toxicology, Medical College of Wisconsin and Research Service, C. J. Zablocki VA Medical Center, Milwaukee, WI

The effects of sulfated cholecystokinin octapeptide (CCK8s) given Ine effects of sulfated cholecystokinin octapeptide (CCK8s) given intrathecally (i.t.) or intracerebroventricularly (i.c.v.) on inhibitions of the tail-flick (TF) and hot-plate (HP) responses induced by epsilon (β-endorphin), mu (morphine and DAMGO) and delta (DPDPE) opioid agonists given i.t. or i.c.v. were studied in male ICR mice. CCK8s (1 nξ) given i.t. effectively antagonized TF inhibition induced by β-endorphin (2 μg) and DPDPE (10 μg) but not morphine (4 μg) and DAMGO (0.02 μg). However, CCK8s given i.t. did not affect HP inhibition induced by any of the opioid agonists given i.c.v.. CCK8s (2.40 ng) in complication with β-endorphin (2 μg) or morphine (4 μg). inhibition induced by any of the opioid agonists given i.e.v.. CCK8s (0.2-40 ng) in combination with β -endorphin (2 μ g) or morphine (4 μ g) given i.e.v. did not affect β -endorphin- or morphine-induced TF and HP inhibitions. Intrathecal administration of CCK8s (1 ng) significantly attenuated the TF inhibition induced by i.t. β -endorphin (0.5-1 μ g) and DPDFE (5 μ g) but not morphine (0.5-1 μ g), DAMGO (5 ng), ncrepinephrine (5 ng) or serotonin (16 μ g). The HP inhibitions induced by i.t. administration of these agonists were not affect by i.t. CCK8s. The results indicate that CCK8s selectively attenuates the TF inhibition by inhibiting the descending pain control system activated by β -endorphin and inhibiting the descending pain control system activated by β-endorphin and DI-DPE but not morphine and DAMGO given supraspinally (Supported by NIDA Grant DA 03811).

PAIN MODULATION: PHARMACOLOGY I

173.1

THE ROLE OF VAGAL AFFERENTS IN ANTINOCICEPTION PRODUCED BY THE ROLE OF VAGAL AFFERENTS IN ANTINOCICEPTION PRODUCED BY IV MORPHINE. A. Randich, C. L. Thurston, P. S. Ludwig*, M. R. Timmerman*, and G. F. Gebhart. Departments of Psychology and Pharmacology, The University of Iowa, Iowa City, IA 52242.

This experiment evaluated the role of cervical vagal afferents in the antinociception produced by IV administration of morphine sulphate. Rats were maintained

administration of morphine sulphate. Rats were maintained in a lightly-anesthetized state with pentobarbital sodium. Control rats (N=8/group) received IV bolus administration of 0.1, 0.5, 1.0, or 2.5 mg/kg of morphine sulphate followed by tail-flick test trials at 0.16-, 1-, 2-, 3-, 4-, 5-, 10-, 15-, and 20-min. Significant inhibition of the nociceptive tail-flick reflex was observed in the 0.5, 1.0, and 2.5 mg/kg conditions. Experimental rats (N=8/group) receiving prior bilateral resection of the cervical vagi showed significantly less antinociception across all test trials in the 0.5 and 1.0 mg/kg conditions and during the initial test trials in the 2.5 mg/kg condition. Intact rats (N=8/group) receiving prior IV administration of 5.0 mg/kg of naloxone methobromide and tested in either the 0.5 or 2.5 mg/kg conditions showed significant attenuation of mg/kg of naloxone methobromide and tested in either the 0.5 or 2.5 mg/kg conditions showed significant attenuation of antinociception statistically equivalent to that produced by bilateral cervical vagotomy. The antinociception produced by 0.5 mg/kg of IV morphine was significantly attenuated by intrathecal administration of 1 ug of naloxone, but not by IV administration of 1 ug of naloxone. However, intrathecal administration of 1 ug of naloxone also attenuated cardiovascular responses produced by IV morphine suggesting the possibility of rostrad spread of the receptor antagonist. Supported by NS24958.

173.2

ANALGESIC EFFECTS OF INTRANIGRAL INJECTION OF SELECTIVE A.A. Baumeister, Psychology Department, Louisiana State University, Baton Rouge, LA 70803.

Intranigral morphine suppresses pain-related behavior on the tail flick and hot plate tests (Baumeister et al., Brain Research, in press). However, the nigra is less sensitive to this effect of morphine than other sites. A possible explanation for such differences in potency is that analgesic effects in different sites are mediated by different receptor subtypes. To determine the types of nigral opioid receptors involved in analgesia, studies with selective agonists were conducted. As can be seen from the table below, among the most selective agonists (i.e., DAGO, DPDPE, & U50-488H) only DAGO produced analgesia, implicating the mu receptor. DTLET, a mixed delta/mu agonist, also had potent analgesic effects, suggesting that a mu/delta receptor complex within the nigra may mediate analgesia.

Minimum Effective Intranigral Dose (nM/0.5 ul)

	.		
Agonist	Preferred Receptor	Tail Flick	. Hot Plate
Morphine DAGO DTLET DPDPE U50-488H	mu mu delta delta kappa	10.0 0.3 1.0 No Effect No Effect	15.0 0.1 1.0 No Effect No Effect

INTERACTION OF TRICYCLIC ANTIDEPRESSANTS WITH MORPHINE ON C FIBRE-EVOKED ACTIVITY IN RAT THALAMUS. LJuma, R. Hecht* and T.L. Yaksh. Dept. of Pharmacology, University of the Saarland, D-6650, Homburg/Saar, FRG and Dept. of Anesth., University of California, San Diego, La Jolla, CA 92093 Activity evoked in the rat thalamus (VDM) evoked by afferent C fibre stimulation was examined when amitriptyline (AMI), imipramine (IMI), and desipramine (DES) were given alone or in combination with morphine. IMI and DES dose-dependently reduced C fibre-evoked activity in the thalamus (ED50: 3.1 mg/kg and 4.1 mg/kg). AMI was ineffective at doses of 10 and 20 mg/kg. At low doses it significantly depressed the activity; the dose-response curve was bell-shaped, 1 and 5 mg/kg being less effective than 2.5 mg/kg. Morphine produced a depression that was significant only 5 min. after the injections. When morphine was given in combination with IMI 2.5 mg/kg on DES 2.5 mg/kg, the depression of evoked activity was enhanced in magnitude and duration beyond the effects caused by each drug alone. A combination of AMI 10 mg/kg with morphine resulted in a long-lasting depression of evoked activity, while combinations of lower doses of AMI with morphine showed reduced depression. The facilitating effect was observed in unanesthetized rats. Small doses (1 mg/kg on 52°C to plate) of DES and IMI will produce small effects (2x baseline) in unanesthetized rats. Administered concurrently, there is a 5.1 and 7.2 fold shift in the morphine dose response curves. Thus, certain TCAs tested, depressed nociceptive activity in the thalamus and enhanced the antireflexive effects of morphine.

POTENTIATION OF OPIOID ANTINOCICEPTION FOLLOWING POTENTIATION OF OPIOID ANTINOCICEPTION FOLLOWING COADMINISTRATION OF AN INHIBITOR OF ENDOPEPTI-DASE 24.15. B. Kest, M. Orlowski*, C.J. Molineaux and R.J. Bodnar. Dept. of Psychology, Queens Col., CUNY, NY, NY 11367 and Dept. of Pharmacology, Mt. Sinai Sch. of Med., NY, NY. The duration of opioid antinociception is limited by peptidase degradation. Endopeptidase (EP) 24.15 and EP24.11 respectively degrade pro-dynorphin and pro-enkephalin derived pertides.

orphin and pro-enkephalin derived peptides. Inhibitors of either EP24.15 or 24.11 produce naloxone-reversible antinociception after 5-7 h; EP 24.11 inhibitors potentiate pro-enkephalin antinociception. The present study compared EP24.15 and 24.11 inhibitors to produce or augment antinociception in rats following central co-administrationwith either dynorphin A(1-8:DYN), met-enkephalin (Arg-Gly-Leu:MERGL) or opioid-media-ted swims (OMS) on the tail-flick and jump tests, Neither DYN nor either EP inhibitor altered pain thresholds, whereas MERGL and OMS were antinociceptive. The EP24.15 inhibitor produced naloxone reversible antinociception when paired with DYN, and potentiated both MERGL (33%) and OMS (29%) antinociception. In contrast, the EP24.11 inhibitor produced smaller and less consistent effects. Endopeptidase 24.15 appears to exert a modulatory release to exert a modulatory role upon opioid antinociception.

173.7

A-3508: A µ OPIATE AGONIST/µ ANTAGONIST?

C.A. Taylor, J.R. Bagley, S. Harris, G. Lysko, R.
Lozito, J. Green, P. Lloyd, E. Messineo, S. Bielen,
T.P. Jerussi, and M.H. Ossipov. Anaquest/BOC Health Care,
Murray Hill, NJ 07974, USA.

A-3508 [N-(2-pyraziny1)-N-(1-phenethy1-4-piperidiny1)-2-A-3308 [N-(2-pyraziny1)-N-(1-pnenetny1-4-piperidiny1)-2-furamide] is a novel opioid analgesic with a unique pharmacologic profile. Its IC₅₀ in guinea pig brain homogenates is 27 nM against [H³]-DAGO, 262 nM against [H³]-DPDPE, and >10 µM against EKC. Antinociception was measured in the rat tail flick (TF) and hot plate tests. Respiratory (PaO₂ and PaCO₂) and cardiovascular parameters (artefial pressure and heart rate) were measured in conscious freely moving rate. CI motility was measured in conscious, freely moving rats. GI motility was measured in mice by the charcoal meal test. A-3508 produced dose-dependent antinociception after i.v. (TF ED₅₀ = 0.078 mg/kg) and i.t. (TF ED₅₀ = 8 ug) dosing. Naloxone reversed the antinociceptive effect of a-3508. Doses of up to 24 times the lowest maximally effective analgesic dose of A-3508 produced no significant changes in PaCO, or PaO, in rats. A-3508 reversed fentanyl-induced respiratory depression in rats, reduced morphine-induced inhibition of GI transit and also precipitated withdrawal in morphine tolerant mice, whereas the antinociceptive effect of combinations of A-3508 with fentanyl or morphine was additive. This pharmacologic profile is consistent with an agonistic activity at the proposed μ_1 and antagonism at the μ_2 opiate receptor.

INHIBITION OF MORPHINE ANALGESIA BY ETHYLKETOCY-CLAZOCINE PRETREATMENT IN RAT PERIAQUEDUCTAL GRAY AND LOCUS COERULEUS. R.J. Bodnar, D. Paul and G.W. Pasternak. Dept. of Psychology, Queens Col., CUNY, Flushing, NY 11367 and Dept. of Pharmacology, Memorial Sloan-Kettering Cancer Ctr., NY, NY 10021.

Analagesia elicited by morphine following mic-roinjection into the periaqueductal gray (PAG) and locus coeruleus (LC) in rats appears depend-ent upon the mu₁ opioid receptor subtype. The present study examined the analgesic properties of ethylketocyclazocine (EKC) and U50488H in the of ethylketocyclazocine (EKC) and U50488H in the PAG and LC alone and in conjunction with morphine. Neither EKC nor U50488H (30 ug) produced analgesia in PAG or LC loci which supported morphine analgesia. EKC (50 ug, ICV) produced analgesia which was reversed by the mul antagonist, naloxonazine. Coadministration of EKC, but not U50488H with morphine reduced morphine analgesia in the PAG and LC in a dose-dependent manner.Co-administration of EKC into both the PAG and LC produced naloxonazine-reversible analgesia. The data indicate that the actions of EKC in inhibit ing morphine analgesia in the PAG and LC are probably due to weak mu_1 agonist actions and not due to antagonistic interactions between mu and kappa receptors.

173.6

SITE-SPECIFIC POTENTIATIONS AND REDUCTIONS IN OPIATE AND NONOPIOID ANALGESIA FOLLOWING MESEN-CEPHALIC MICROINJECTIONS OF THYROTROPIN RELEASING HORMONE. J.A. Robertson and R.J. Bodnar. Dept. of Psychology, Queens Col., CUNY, Flushing, NY 11367. Thyrotropin-releasing hormone (TRH) modulates

rnyrotropin-releasing hormone (TRH) modulates opioid and nonopioid analgesia as a function of route; ventricular TRH potentiates nonopioid footshock and continuous cold water swim (CCWS: 2°C, 3.5 min) analgesia. Ventricular and systemic TRH failed to alter morphine (MOR) analgesia but intrathecal TRH produces a U-shaped function. The present study mapped mesencephalic losi acceptance. present study mapped mesencephalic loci associated with pain inhibition to determine whether central MOR and CCWS analgesia were differentially tral MOR and CCWS analgesia were differentially modulated by microinjections (33 g cannula) of TRH as measured by tail-flick latencies and jump thresholds in rats. TRH (10 ug) transiently (5-15 min) produced analgesia but failed to exert effects thereafter. TRH given 20 min prior to CCWS reduced analgesia (48-60%) in III cranial nerve placements, and increased analgesia (23-34%) in dorsal raphe nucleus (DRN) placements. MOR analgesia (1-2 5 ug) was more potent in DRN as comalgesia (1-2.5 ug) was more potent in DRN as compared to III N placements. However the same TRH regimen potentiated MOR analgesia following coadministration into the III N (58-435%) and the DRN (15-36%).

173.8

PHARMACOLOGICAL CHARACTERIZATION OF THE MU-SELECTIVE DRUG, TRIMU-5. L.A. Tive D. Paul, G.A. Gacel, B.P. Roques & G.W. Pasternak, Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Depts. of Neurology and Pharmacology, Cornell University Medical Center, 1275 York Avenue, New York, NY, 10021, U.S.A., and U266 INSERM, UA 498 CNRS, Laboratoire de Chimie Organique, Faculte de Pharmacie, 4 av. de l'Observatoire, 75006 Paris,

FRANCE.

In binding studies, the novel opiate Tyr-D-Ala-Gly-NH-CH₂-CH₂-CH₂-CH(CH₃)₂ (TRIMU-5) is 200-fold more potent when competing for mu sites than for delta or kappa sites. Accordingly, we assessed the analgesic activity of TRIMU-5 using the tail-flick assay. In rats, intracerebroventricular (i.c.v.) injections of TRIMU-5 produced naloxone- and naloxonazine-sensitive analgesia at doses as low as 10 ug implying a mu_1 mechanism of action. However, TRIMU-5 injected into the periaqueductal gray (PAG) did not produce analgesia, and blocked morphine analgesia when both drugs were given to the PAG suggesting that it is only a partial mu₁ agonist. In mice, TRIMU-5 injected intrathecally was 100-fold more potent than when injected i.c.v. TRIMU-5 analgesia following i.c.v. injection was naloxonazine-sensitive (mu_1) whereas i.t. was not (mu_2) . Therefore, the present results suggest that TRIMU-5 is a potent mu_2 agonist and a partial agonist at mu_1 receptors.

EFFECTS OF LEU-ENKEPHALIN MICROPRESSURE APPLICATION ONTO RAT NUCLEUS SUBMEDIUS NEURONS. J.A. Coffield and V. Miletic, Dept. Comp. Biosci., University of Wisconsin, Madison, Wi, 53706.

Animals were anesthetized with pentobarbital (60mg/kg i.p.) and maintained with ketamine (40mg/kg i.p.). Extracellular recordings were used to examine the effects of leu-enkephalin (50mM), applied with micropressure (10-12psi), on the spontaneous firing rate of 20 SM neurons. Thirteen of these units had cutaneous receptive fields (RFs), and could be classified as low-threshold mechanoreceptive (LTM), nociceptive-specific (NS), or wide-dynamic-range (WDR). The following table summarizes the results.

Туре	No.	Response to L-enkephalin					
		Inhibited	Excited	Biphasic	No Effect		
LTM	3	1	1	-	1		
NS	5	2	1	2	-		
WDR	5	4	1	-	-		
Total	13	7	3	2	1		

Enkephalin effects appear correlated with RF properties. Units with confined RFs responded to the opioid with an inhibition in their spontaneous firing. Neurons with complex RFs (whole body or multiple sites) demonstrated

Neurons with complex Hrs (whole body or multiple sites) demonstrated complex responses (bliphasic or excitation). Naloxone (50mM, 10-12psi) reversed the enkephalin effects in some, but not all cases.

These data suggest that submedius neurons respond to enkephalin differently depending on their physiologic type (nociceptive vs. non-nociceptive) and RF characteristics. (Supported by NIH NS26850).

MORPHINE BLOCKS THE INCREASED GLUCOSE METABOLISM IN THE DORSAL RAPHE AND LATERAL HABENULA CAUSED BY NOCICEPTIVE BRAIN STIMULATION. D. Huston-Lyons[†], L.J. Porrino[§], and C. Kornetsky[†] . [†]Boston Univ. Sch. of Med., Boston, MA, § NINCDS, Bethesda, MD.

The present study investigated the effects of morphine (4) mg/kg sc) on local cerebral metabolic rates for glucose (LCMR $_{\rm g1u}$) in animals working to escape nociceptive electrical brain stimulation to the mesencephalic reticular formation (MRF). In this supraspinal pain model, morphine as well as other opiate analgesics decrease the sensitivity of animals to this stimulation. Results of this experiment indicate that MRF stimulation alone increased LCMR_{glu} in a number of structures associated with pain such as the periaqueductal gray and raphe nuclei, as well as limbic system structures, e.g., the habenula and ventral tegmental area. Although morphine alone had no effect in any of these structures, it reversed the effect of stimulation in the dorsal raphe and lateral habenula. These data suggest that, although nociceptive MRF stimulation activates various sites, these two structures play an important role in morphine-induced antinociception. (Supported by NIDA grant DA02326 and Research Scientist Award DA00099 to CK).

OPIOIDS BUT NOT INDOMETHACIN OR ASPIRIN ABOLISH RESPONSES TO NOXIOUS COLORECTAL DISTENSION. V. Kumar*, T.J.Ness and G.F.Gebhart. Depts. Anesthes. and Pharmacol., College of Medicine, Univ. Iowa, Iowa City, IA 52242

College of Medicine, Univ. Iowa, Iowa City, IA 52242 Male Sprague-Dawley rats were surgically implanted with chronic femoral venous and arterial catheters. Three or more days later experiments were performed in awake, unrestrained rats using colorectal distension (CRD, 7 cm balloon; 0-80 mm Hg) as a noxious visceral stimulus. The effects of i.v. normal saline, morphine (1-16 mg/kg), fentanyl (5-20 μ g/kg), alfentanyl (50-200 μ g/kg) or sufentanyl (1-8 μ g/kg) or i.p. vehicle, indomethacin (1-10 mg/kg) or aspirin (1-10 mg/kg) on the cardiovascular (pressor/tachycardia) and visceromotor (abdominal contraction) responses to CRD were examined. (abdominal contraction) responses to CRD were examined

Opioids produced a dose-dependent, naloxone-reversible inhibition of the cardiovascular and visceromotor responses to CRD in a rank order of potency identical to their clinical analgetic potency (sufentanyl > fentanyl > alfentanyl > morphine). At the highest doses of opioids, all responses to CRD were abolished. Indomethacin and aspirin when administered alone had little effect on the

visceromotor or cardiovascular responses to CRD, but significantly potentiated the effects of morphine.

The effects of opioids, indomethacin and aspirin on this model of visceral pain is similar to their clinical effects, supporting use of this model for examining the effects of analgesics and their interactions with other agents.

173.10

DEVELOPMENT OF FORMALIN PAIN AND MORPHINE AND AMPHETAMINE ANALGESIA IN INFANT RATS. F. V. Abbott and E. Guy, of Nursing & Dept. Psychiatry, McGill Univ.,

In rats opioid-induced suppression of defensive reflex responses to noxious stimulation matures at 7-14 days of age but little is known about the development of responses to injury. The present study investigated the maturation of the behavioral response to formalin-induced pain and the analgesic effects of morphine and amphetamine. Formalin was injected sc into the ventral surface of a rear paw of 1 to 20 day old pups. One day old pups responded to 10 ul of 1% formalin by elevating the paw, responded to 10 ul of 1% formalin by elevating the paw, flexing the limb and occasionally making oral contact to lick the paw, as do adults. General activity was increased by pain and was characterized by swimming movements. As pups matured, the response to 1% formalin decreased so that by 20 days it 2.5% formalin was necessary to obtain a pain response reliably. Morphine (1-2 mg/kg) decreased pain and activity levels at all Pentobarbital (10 mg/kg) decreased activity without decreasing pain. Amphetamine (0.5 - 2 mg/kg) reduced pain and increased activity in pups 10 days and older. The data indicate that the behavioral responses to pain in injured tissue are present from birth. The analgesic effects of morphine involve two mechanisms, one that is present at birth and independent of dopamine systems and a later maturing one that is dependant on dopamine.

173.12

COMPARISON OF VOCALIZATION AND TAIL FLICK THRESHOLDS FOLLOWING MORPHINE TREATMENT IN THE RAT: ASSESSMENT OF SENSORY AND PERFORMANCE VARIABLES, G.S. Borszcz and C.A. Pelletier*. Department of Psychology, Dartmouth College, Hanover, NH 03755.

The relative hypoalgesic influence of morphine on tail flick and vocalization thresholds in the rat was examined. Responses were generated by applying graded electric current to the tail. Vocalizations were recorded during the shock epoch (VDS) and for the 1 sec interval following shock termination (VAD). Performance (i.e., latency and amplitude) of all three responses was recorded in order to determine whether increases in response thresholds were confounded by motor deficits.

A dose-response analysis (1-16 mg/kg) of systemic morphine treatment revealed that thresholds of VAD were most readily increased, followed by those of VDS and tail flick. Analysis of performance revealed that morphine treatment more readily disrupted VAD, followed by VDS and tail flick. Nevertheless, across the dose range (1-7 mg/kg) of morphine that did not disrupt performance of any of the responses, the order of susceptibility to increases in response thresholds remained VAD, VDS and tail flick. Results are discussed in terms of the relative influence of systemic morphine on response organized at different levels of the neural axis.

PEPTIDE AND GLUTAMATE NMDA RECEPTORS MEDIATE A NOCICEPTIVE REFLEX IN NEONATAL RAT SPINAL CORD. S. J. Woodley and J. J. Kendig, Department of Anesthesia, Stanford

University School of Medicine, Stanford, CA 94305-5117.
Substance P' and glutamate actions have separately been implicated in the generation of a slow ventral root potential (slow VRP) in neonatal rat spinal cord, which has been linked to nociception. We report that the slow has been inked to nociception. We report that the slow VRP is dependent on both neurotransmitters. Spinal cords were isolated from 1-5 day old Sprague-Dawley rats and superfused with oxygenated artificial cerebrospinal fluid (ACSF) at 27-28°C, pH 7.3. Slow VRP's of 10-40 s duration were evoked by electrically stimulating a lumbar dorsal root and recorded at the corresponding ipsilateral ventral root. The NMDA receptor antagonist APV (5-20 μ M) and the substance P antagonist spantide (10-20 μ M) both reversibly depressed the slow VRP; spantide and APV applied together nearly abolished it. Spantide-sensitive and APV-sensitive components overlapped, although an APV-sensitive component was more prominent earlier. A slow VRP could be elicited by brief (0.1-1.0 s) applications of either substance P (2-20 μ M) or NMDA (10 μ M). Both excitatory amino acids, acting on an NMDA receptor, and substance P thus appear to be involved in generating this nociceptive reflex.

OPIOID AND EXCITATORY AMINO ACID ACTIVITY IN THE DORSAL HORN IN VITRO. D. S. K. Magnuson and A. H. Dickenson*. Department. of Pharmacology, University College London, U.K. WC1E 6BT

In order to compare the responses of substantia gelatinosa (SG) neurones with those of deeper dorsal horn neurones we have made intracellular and extracellular recordings in sagittal slices of spinal cord from 21 day old rats. Electrical stimulation of the dorsal root zone elicits depolarizations and spiking activity lasting several hundred msec. These responses can be separated into early and late phases on the basis of stimulus threshold and the effects of elevated Mg2+ (which selectively reduces the late phase) and kynurenate (which reduces both phases). Responses of SG and deeper dorsal horn neurones were similar in their sensitivity to Mg2+ and kynurenate.

Intracellular recordings made from SG neurones show that the μ opioid agonist morphine, and the GABA antagonist bicuculline cause depolarizations and increases in membrane input resistance, as does a high Mg2+/low Ca2+ superfusate (which blocks synaptic transmission). In contrast, GABA and the opioid antagonist naloxone cause decreases in the membrane input resistance of most SG neurones. This action of naloxone is absent when synaptic activity is blocked. These data suggest that in sagittal slices of spinal cord the activity of SG neurones may be under the control of a GABAergic interneurone which is in turn sensitive to both exogenous and endogenous opioids. Opioid enhanced responses may therefore involve a GABAergic disinhibitory mechanism present in the substantia gelatinosa, similar to that found in the hippocampus.

Application of Whole-Cell Patch Clamp Techniques to Dorsal Horn Neurones of the Hemisected Rat Spinal Cord. S. Alford*, G.L. Collingridge* and R.H. Evans*, (SPON: Brain Research Association). Dept. Pharmacology, School of Medical Sciences, University of Bristol, University Walk, Bristol BS8 1TD UK.

We have made whole-cell patch clamp recordings (Blanton et al., 1989; J. Neurosci. Methods 30;203) from dorsal horn neurones (DHN) in hemisected spinal cord preparations from 3-5 day rats. DHN patch clamped with pipettes containing KmeSO4 as the principal ionic constituent had impedances ranging from 300-400 Mohms and resting membrane potentials of -60 +/- 1mV sem. Stable, low noise (<1.0 pA rms), recordings were maintained for 2-3 hrs. DHN were characterised by their regenerative response to a 15 to 20mV step and the presence of both spontaneous and dorsal root evoked E- and IPSCs. Spontaneous and later components (>80ms) of dorsal root-evoked EPSCs were sensitive to the NMDA receptor antagonist (+/-) 2-AP5 (10uM). Short latency (to 80 ms) components of dorsal root-evoked EPSCs were resistant to AP5 (400uM). At a holding potential of -60mV unitary monosynaptic EPSCs with amplitudes of approximately 20pA were evoked by stimulation of the dorsal root at near threshold intensity. This demonstrates the suitability of the patch clamp technique for the study of primary afferent input to an intact spinal preparation.

174.2

EFFECTS OF STIMULATION AND LESIONS OF PRIMARY AFFERENTS ON DORSAL HORN TRANSMITTERS. G. Li Volsi. R.J. Weinberg and A. Rustioni. Dept. of Cell Biology and Anatomy, University of North Carolina, Chapel Hill, NC 27599.
Rats were perfused after 20'-30' of repetitive sciatic nerve stimulation. L4 and L5 spinal segments were removed

and immunocytochemically processed for three dorsal horn transmitters: substance P (SP), glutamate (Glu) and GABA. Staining in superficial laminae was analyzed densitometrically with a video microscopic system. SP was reduced, on the average, by 6.5% from control values after stimulation at C fiber strength, whereas Glu levels increased 11% after C fiber stimulation. Stimulation of A- α fibers had on effect on staining for these substances, but increased GABA staining by 5%. Fourteen days after sciatic nerve ligation or lumbar dorsal rhizotomy, similar decreases were seen in SP (118-13%) and similar increases in Glu (9%-14%) and GABA (2%-7%). SP reduction, expected on the depletion in terminals. Staining for Glu was generally more variable than for SP and its higher density on the experimental side was observed in both neuropil and cells. Since Glu increased with all experimental paradigms, including rhizotomy, it is unlikely that the effects are related to metabolic changes. Further experiments are underway to establish the mechanisms by which reciprocal effects on SP and Glu are elicited by these three different experimental manipulations.

EFFECTS OF EXCITATORY AMINO ACID AGONISTS AND ANTA-GONISTS ON NOCICEPTIVE AND NON-NOCICEPTIVE RESPONSES OF DORSAL HORN NEURONES IN THE CAT SPINAL CORD; AN EXTRACELLULAR AND INTRACELLULAR STUDY IN VIVO. V. Radhakrishnan, Y. De Koninck and J.L. Henry, Depts. of Physiology, Anaesthesia Research and Psychiatry, McGill Univ., Montréal, Qué. H3G 1Y6.

We investigated the effects of several excitatory amino acid agonists and antagonists on the responses of dorsal horn neurone responses to noxious and non-noxious cutaneous stimulation in cats anaesthetized with α -chloralose. Extracellular recording and iontophoresis were done using multibarrelled micropipettes. Single micropipettes (KCl, KCH₃SO₄) glued to multibarrelled micropipettes were used for intracellular recording and extracellular iontophoresis. Iontophoretic barrels were filled with: glutamate (1M), quisqualic acid (2.5mM), domoic acid (1mM), N-acetyl-Asp-Glu (NAAG; 10mM), kynurenic acid (1mM), 2-amino-phosphonovalerate (APV; 1mM). Hair stimulation-induced EPSPs were reversibly and repeatably blocked by iontophoretic application of kynurenic acid in two cells. Iontophoretic application of APV and kynurenic acid as well as i.v. administration of ketamine (5 mg/kg) blocked the response to non-noxious thermal stimulation, but, with 4 cells, failed to alter the noxious thermal response. Quisqualate and glutamate potentiated the afterdischarge upon noxious mechanical stimulation (n=5); these cells were unresponsive to domoic acid. Domoic acid produced a prolonged discharge in two non-nociceptive neurones. NAAG had no effect on any cell (n=13). Supported by the Canadian MRC and the NIH. YDK was funded by the FRSQ.

174.6

GLYCINE AND GARA-MEDIATED IPSPS IN BAT SUBSTANTIA GELATINOSA EVOKED BY PRIMARY AFFERENT STIMULATION. T. M. Jessell & M. Yoshimura, Center for Neurobiology and Howard Hughes Medical Institute. Columbia University. New York, NY. 10032

To provide further information on mechanisms involved in the regulation of

pain transmission at primary afferent synapses we have examined the properties of inhibitory synaptic responses (ipsps) evoked by A-delta afferent fibers. Intracellular and whole cell voltage clamp recordings were obtained from substantia gelatinosa (s.g) neurons in an adult rat spinal cord slice preparation which retains an attached dorsal root.

The ipsps were divided into two groups, based on their duration and sensitivity to glycine and GABA receptor antagonists. Fast ipsps were observed in more than 60 % of s.g. neurons and had a duration of 30-60 ms and were blocked by glycine receptor antagonist strychnine. Slow ipsps were observed in about 30 % of s.g. neurons, and had a much longer time course (80-300 ms) and were blocked by the GABA_A receptor antagonist bicuculline. A subset of s.g neurons exhibited both fast and slow ipsps. The excitatory amino acid receptor antagonist CNQX blocked afferent-evoked fast and slow ipsps as well as the monosynaptic afferent evoked epsp. Spontaneous ipsps were observed in 50 % of s.g neurons and were blocked by either strychnine and bicuculline but not by CNQX. Afferent evoked ipsps are likely to be di- or polysynaptic. The fast and slow ipsps were reduced in amplitude with membrane hyperpolarization and reversed in polarity at around -75 mV.

These findings provide evidence that A-delta fibers activate local interneurons which release glycine or GABA as transmitters on subset of s.g. neurons. This inhibitory network may play a role in modulating nociceptive transmission in the substantia gelatinosa.

CHARACTERIZATION OF INHIBITORY MECHANISMS IN RESPONSE TO LOW-THRESHOLD MECHANICAL STIMULATION; AN IN 170 INTRA-CELLULAR STUDY USING INPUT FROM SINGLE PRIMARY AFFERENTS TO SINGLE DORSAL HORN NEURONES IN THE CAT SPINAL CORD. Y. De Koninck and J.L. Henry. Depts. of Physiology, Anaesthesia Research and Psychiatry McGill Univ., Montréal, Qué. H3G 1Y6.

The present study focuses on inhibitory responses following input from low-

threshold afferents to functionally identified single dorsal horn neurones. Extracellular multibarrelled micropipettes and intracellular single micropipettes (KCl or K-CH₃SO₄) were used to record responses in dorsal horn neurones to low threshold stimulation of the receptive field and to intracellular activation of single primary afferents. Cats were anaesthetized with α -chloralose or decerebrated. Spinal segments L_5 - L_7 were exposed for recording of dorsal horn neurones and ganglia L_5 - S_1 for intracellular recording and stimulation of single DRG neurones. An automatically controlled mechanical stimulator was used for low threshold mechanical stimulation of the receptive field. Single mechanical pulses outside the receptive field of the dorsal horn neurone induced a large bicuculline-sensitive IPSP (0.3-1.0mg/kg i.v.) in some of these neurones. This IPSP was depressed upon repetitive stimulation at interstimulus intervals of less than 2s. A similar IPSP and depression of the second of paired IPSPs was observed upon stimulation of a single hair-afferent arising from the inhibitory receptive field of the dorsal horn neurone. single hair afferent input from the excitatory receptive field produced excitatory responses; the second of paired EPSPs followed the same type of depression as the 2 IPSPs. The time course of the depression of the second of these pairs of responses matched that of primary afferent depolarization (PAD). Bicuculline attenuated both PAD and the depression of the second EPSP. These results suggest that both inhibitory and excitatory responses from low threshold afferent stimulation are affected similarly by repetitive stimulation and are subject to similar regulatory mechanisms. (Supported by the MRC, YDK is funded by the FRSQ.)

Univ. Zurich, Switzerland; ⁴MRC Anat Neuropharmacol. Unit, Oxford, U.K.

The coexistence of calcium binding proteins (parvalbumin and calbindin-D 28k) with GABA and the uptake of ³H-Asp was studied in laminae I-IV of the dorsal horn of the rat spinal cord. After injecting ³H-D-Asp into the dorsal horn, perikarya selectively accumulating ³H-D-Asp were detected in analytic embedded semithin sections by autoradiography. Consecutive semithin sections were reacted to reveal parvalbumin (PV), calbindin (CaBP) or GABA by postembedding immunocytochemistry.

Nearly 70% of the total population of PV-immunoreactive cells were also GABA-positive in laminae II and III, but only one fourth of them proved to be GABA-immungreactive in lamina IV. PV was never detected in neurons accumulating ³H-D-Asp.

Most of the cells accumulating ³H-D-Asp were in lamina II where 16% of them displayed CaBP-immunoreactivity. On the other hand, 99% of CaBP-immunoreactive perikarya were GABA-negative. A significant proportion of the GABA-negative but PV-immunoreactive neurons showed CaBPimmunoreactivity as well.

The results show that interneurons using putative inhibitory and excitatory amino acid transmitters differ in their calcium binding proteins.

CAFFEINE BLOCKS THE ADRENAL-MEDIATED, NALOXONE-REVERSIBLE INCREASE IN REACTION TIME IN THE TAIL-FLICK TEST FOLLOWING INTRATHECAL ADMINISTRATION OF SUBSTANCE P AT THE LOWER THORACIC SPINAL LEVEL IN THE RAT. K. Yashpal and J.L. Henry, Depts. of Physiol. and Psychiat., McGill Univ., Montréal, Oué.

We have previously shown that intrathecal administration of substance P (SP) in the awake Sprague Dawley rat increases reaction time in the tail-flick test and this increase is blocked by adrenalectomy and by naloxone but not by phentolamine or by morphine antagonists which do not cross the blood-brain barrier (Cridland & Henry, Neuroscience 26: 243, 1988); the suggestion was made that SP activated sympathetic neurons to the adrenal medullae, caused the release of an opioid into the blood and this opioid acts in the central nervous system to depress the tail flick reflex. As adenosine has been proposed nervous system to depress the tail linck retirex. As adenosine has been proposed to mediate the spinal antinociceptive effects of morphine in the tail-flick test (Jurna, N.S. Arch Pharmacol. 327:23, 1984), the present study was done to determine whether adenosine might also mediate the antinociceptive effects of the adrenal opioid. In control rats, pretreated with 0.5 mL saline i.p., intrathecal administration of 6.5 mmols of SP produced an increase in reaction time of 15-20% which lasted 15-20 min (n=12). Pretreatment with 30 mg/kg of the adenosine antagonist, caffeine, had no effect on reaction time; however, subsequent administration of 6.5 nmols of SP decreased reaction time by about 70% and produced behavioural effects suggesting the animals perceived a noxious stimulus. These results indicate that the adrenal-induced analgesia observed earlier may be mediated by a purine mechanism. (Supported by Canadian MRC)

IONIC MECHANISMS OF THE PROLONGED SYNAPTIC EXCITATION OF RAT SPINAL CORD NEURONS. R. Cerne, G. Gerber*, M. Jiang Y. Parpura and M. Randic. Dept. of Vet. Physiol. and Pharmacol., Iowa State University, Ames, IA, 50011.

Pharmacol., Iowa State University, Ames, IA, 50011.

Slow excitatory postsynaptic potential (EPSP) evoked in deep dorsal horn neurons by single or repetitive stimulation of dorsal roots has two components, an initial transient component that requires activation of excitatory amino acid receptors and a late longer-lasting probably peptidergic component (Neurosci, Lett. 106: 220-228). Since the ionic mechanism of the slow EPSP has not been characterized, we used spinal slice preparation and current- and voltage-clamp techniques to examine the effects of: 1) changes in ionic microenvironment and, 2) agents that interfere with influx, release and/or storage of Ca²⁺. We found that at least two ionic mechanisms are required to explain the generation of the slow EPSP, a conductance decrease of a voltage-dependent K* current and a conductance increase possibly to Na* and/or Ca²⁺. Furthermore, amplitude and especially duration of the late component of the slow EPSP was increased after bathapplied caffeine (5-10 µM) or intracellular iontophoresis of BAPTA (20 mM). In some of the caffeine-sensitive cells the slow depolarization was suppressed by LaCl₃ (10-100 µM) and nifedipine (1-10 µM). Whereas dantrolene (20 µM) depressed the late depolarizing component, both depression and potentiation was observed with ryanodine (1-100 µM). The initial component of the slow EPSP was not significantly modified by any of the agents used. These results suggest that the increase in Ca²⁺ influx and the changes in intracellular free Ca²⁺ are important during the late phase of the slow depolarizing response of the rat dorsal horn neurons. Supported by NIH and NSF.

ELECTROPHYSIOLOGICAL PROPERTIES OF FROG SPINAL DORSAL HORN NEURONS AND THEIR RESPONSES TO SEROTONIN: AN INTRACELLULAR STUDY IN THE ISOLATED HEMISECTED SPINAL CORD. H. Tan and V. Miletic. Dept. Comp. Biosci., Sch. Vet. Med., Univ. of Wisconsin, Madison, WI 53706.

Wisconsin, Madison, WI 53706. In the present study we have used intracellular recordings to examine the electrophysiological properties of frog (R. Pipiens) dorsal horn neurons and their responses to serotonin (5HT). We found that the average resting membrane potential and amplitude of action potentials were 63.2±1.8 mV and 57.5±6.3 mV (mean ±50, n=30) respectively. The membrane input resistance ranged from 49 to 240 MΩ (83.7±5.4, n=9). Spontaneous EPSPs and IPSPs were also observed. About 39% of tested neurons (14/36) exhibited spontaneous action potentials at rest. The majority of tested cells (11/14) fired single spikes, while a few (3/14) exhibited burst discharges. Stimulation of dorsal roots with single shocks ellcited postsynaptic potentials with different latencies and amplitudes in all of the 17 tested neurons, suggesting the activation of different sizes of afferent fibers. The current-voltage relationship of a few tested cells was found to be linear.

Bath application of 5HT (10-50 μM) increased the excitability and caused

of a few tested cells was found to be linear. Bath application of 5HT (10-50 μ M) increased the excitability and caused membrane depolarizations in 50% of tested neurons (7/14). 5HT also inhibited 4/14 dorsal horn cells by hyperpolarizing the membrane and suppressing the spontaneous activity. Biphasic response to 5HT were seen in 2/14 cells. These data indicate that the basic membrane properties of frog dorsal horn neurons are comparable with those in mammalian spinal cord slice preparations, and the multiple effects of 5HT may be mediated through different 5HT receptor subtypes. (Supported by NIH NS21278).

GALLAMINE RESPONSES OF SPINAL NEURONAL NETWORKS IN CULTURE T.K.Baumann¹ and G.W.Gross², ¹Div. of Neurosurgery and Dept. of Pharmacology, OHSU, Portland, OR 97201 and ²Dept. of Biological Sciences and Center for Network Neuroscience, Univ. of North Texas, Denton, TX 76203

The effects of the neuromuscular blocker gallamine triethiodide (G) were examined in monolayer cultures of fetal mouse spinal cord and DRG neurons grown on glass plates with 64

and DRG neurons grown on glass plates with 64 photoetched microelectrodes. Under control photoetched microelectrodes. Under control conditions (in conditioned medium), most cultures (7/8) showed spontaneous activity by random bursts of action potentials (APs). The addition of G to the bath (100 µg/ml) disrupted the discharge pattern; it lead to approx. 10 states of the discharge pattern; it leads to approx. of high frequency, tonic AP discharge, followed by a gradual decline in firing to near zero. Minutes later, AP discharge gradually returned, in the form of regularly occurring brief bursts, and was maintained for minutes. Lower doses of G (10 µg/ml) had less pronounced effects. Higher doses of G (1 mg/ml) resulted in a more prolonged period of inactivity. This was reversible upon washing with conditioned medium. Supported by NIH BRSG S07 RR05412, The Johns Hopkins Univ. CAAT, and the Hillcrest Foundation

of Dallas, TX, founded by Mrs. W.W.Caruth, Sr..

ANTINOCICEPTIVE AND BLOOD PRESSURE EFFECTS OF INTRATHECAL GUANABENZ AND CLONIDINE. Kishikawa, Y. Harada*, M. Aoki* and A. Namiki*

Dept. of Anesthesiology. Sapporo Medical College. Sapporo 060, JAPAN. Guanabenz Acetate (GA), an alpha-2 agonist, possesses a higher affinity for alpha-2 receptors than clonidine (CL) (Pharmacol Rev 337,1980). GA suppresses opioid withdrawal with less side effects than CL (Drug Intell Clin Pharm 32,1985). GA may have antinociceptive effects like CL. However, intrathecally administered GA has not been extensively evaluated. The present study was undertaken to assess the antinociceptive and blood pressure effects of spinal GA and CL in rats implanted with chronic intrathecal (i.t.) catheters. Following i.t. administration of drugs, antinociceptive effects were assayed using the hot-plate test, and mean arterial pressure (MAP) was measured via femoral artery during halothane (0.6 %) and oxygen anesthesia. GA (25, 50, 100 µg), CL (5, 10, 25 µg) and yohimbine (10 µg) were administered. GA (100 µg) and CL (25 µg) showed significant elevations of nociceptive threshold. All doses of GA elicited decreases in MAP, but a dosedependent effect was not observed. CL (25 μ g) produced a transient elevation of MAP followed by hypotension, whereas CL (5 and 25 μ g) elicited only hypotensive effects. I.t. yohimbine alone caused no significant effects on the resting MAP, and yohimbine pretreatment significant nificantly attenuated the hypotensive effects of GA and CL. Our study demonstrates that i.t. GA has an antinociceptive effect on the hot-plate test, as was shown for CL. However, GA produced different blood pressure effects than CL. Further studies of the antinociceptive actions of GA should be conducted.

EXPRESSION OF GAD AND GABA BY MOTONEURONS OF THE CHICK SPINAL CORD: IMMUNOCYTOCHEMICAL AND RADIOAUTOGRAPHIC APPROACH. F. GAULIN*, F. PHILIPPE and G. AUDET, Neurobiology Res. Center and Laval University, 1401,18e rue, Quebec - CANADA.

Among the phenotypes normally expressed by vertebrate spinal motoneurons, it is well accepted that acetylcholine is the classical excitatory neurotransmitter of the neuromuscular junction.

However, by means of immunocytochemical procedures (according to the peroxidase antiperoxidase method), it has recently been shown that the motoneurons of the chick spinal cord also express a classical inhibitory neurotransmitter: GABA (gamma aminobutyric acid) (Philippe et al., 1990).

In order to establish a better understanding of the presence of

GABA in motoneurons and their related neuromuscular junctions, it seems important to determine whether the presence of GABA is due to the action of the biosynthetic enzyme GAD (glutamic acid decarboxylase) or to the result of a high affinity uptake of this

inhibitory amino acid.

According to the colocalization of GAD and GABA within chick spinal motoneurons, we could suggest that GABA is synthesized within the perikaryon of these motoneurons. However, these results do not exclude the possibility of a high affinity uptake of GABA by chick spinal motoneurons. (Supported by grants of C.R.M. and F.R.S.Q.)

SOMATIC AND VISCERAL AFFERENTS I

EXCITATION AND SENSITIZATION OF NOCICEPTORS BY ACID PH IN RAT SKIN, IN VITRO. H.O. Handwerker, K.H. Steen* Reeh*. Dept. Physiology and Biocybernetics, University Erlangen-Nürnberg, Universitätsstraße 17, D-8520 Erlangen, F.R.G.

Primary afferent responsiveness to pathologically relevant pH levels was studied in a rat skin-nerve preparation, in vitro. Receptive fields were superfused at the corium side (5 min at 10 min intervals) with CO₂ saturated "synthetic interstitial fluid" (SIF at pH 6.1) and with phosphate buffered SIF at varying pH (7.0-4.3). Mechanosensitive A-beta and Adelta fibers were not excited by such superfusions; in 28 of all nociceptor type C and A-delta fibers (n=84) low frequency ongoing discharge was induced. In contrast, 40% of the mechano-heat sensitive C and Adelta nociceptors (CMH and AMH) showed dose and duration dependent responses with a mean maximum discharge at pH 5.2 and thresholds between pH 6.9 and 6.1. Prolonged application (30 min) evoked non-adapting activity around 5 spikes per s. Phosphate buffered SIF at pH 6.1 was as effective in exciting as CO₂ saturated SIF but showed significantly longer latencies. The carboanhydrase blocker acetazolamide markedly delayed and reduced the CO₂ responses. Prolonged or repeated application of acid pH induced a marked and long lasting decrease of the von Frey thresholds in almost all CMH fibers tested (from 35 to 16 mN on average, p = 0.001 Wilcoxon test). This is remarkable, since previously even an extensive combination of inflammatory mediators had only induced sensitization to heat, but never an increase to mechanical sensitivity in this skin-nerve preparation.

Supported by the DFG, grant Re704/1-6.

175.2

CHEMOSENSITIVITY AND SENSITIZATION OF MECHANICALLY INSENSITIVE AFFERENTS IN THE PRIMATE. K.D. Davis, R.A. Meyer, R.D. Treede, R.H. Cohen and J.N. Campbell. Dept. of Neurosurgery, The Johns Hopkins University, Baltimore, MD 21205.

We recently described a group of A- and C-fiber afferents that are either not sensitive to mechanical stimuli or have very high mechanical thresholds. To explore the role of these mechanically insensitive afferents (MIAs) in the pain and hyperalgesia that accompany injury, we examined the effects of intradermal injection of algesic/inflammatory chemicals.

Standard teased fiber techniques were used to record from 14 A. and 9 C-fiber MIAs in cutaneous nerves of monkeys (Macaca fascicularis). The fiber's presumed receptive field (RF) was located with an electrocutaneous search technique. Sensitivity to mechanical and heat stimuli was determined with calibrated von Frey filaments and a CO₂ laser stimuli was determined with calibrated von Frey hiaments and a CO₂ laser before and after intradermal injection of a chemical soup into the fiber's RF. The soup consisted of bradykinin, histamine, 5-HT (10^{-8} moles) and PGE1 (10^{-10} moles) in 10_{μ} I saline. Nine A- and five C-fiber MIAs responded to the soup either immediately upon injection or after a 1.5-4 min delay. Evoked responses lasted for 3 to >20 min and the peak discharge frequency varied from 1-60 spikes/5s. Six MIAs (3As, 3Cs) became sensitized to mechanical stimuli following soup injection, and in two cases there was an accompanying expansion of RF. Three MIAs

were sensitized to heat stimuli.

These data suggest that some MIAs play a role in the pain and/or hyperalgesia induced by certain injuries.

PROSTAGLANDIN E, SENSITIZES CUTANEOUS NOCICEPTORS IN MONKEY. S.N. Raja, E.L. Mitzel*, J.N.Campbell, Depts. of Anesthesiology and Neurosurgery, The Johns Hopkins Univ., Baltimore, MD 21205.

Prostaglandin E (PGE), a product of the cyclo-oxygenase arachidonic acid pathway, is considered to be a mediator of inflammatory pain and hyperalgesia. In this study, we determined the effects of PGE, on the response properties of C- and A- fiber nociceptors responsive to mechanical and heat stimuli (CMHs & AMHs). Standard teased-fiber techniques were used to record from single CMHs and AMHs that innervated hairy skin of pentobarbital-anesthetized monkey (Macaca fasicularis). Responses to a sequence of heat stimuli (laser heat stimulator, 39°-49° C) and mechanical thresholds (von Frey probes) were compared before and after PGE₁ (3x 10⁻¹⁰ moles in 10 µl) injection into the receptive field of the nociceptors. The injection of PGE₁ resulted in evoked responses in 7 of 12 CMHs and 2 of 4 AMHs. PGE₁-induced sensitization of CMHs was characterized by a decrease in heat threshold (pre= 42.9 ± 0.8 , post= 40.8 ± 0.6 , p<0.01, t-test) and an increase in response to suprathreshold stimuli. The total evoked response of CMHs to the heat sequence increased by 80 ± 30 % after PGE, injection (p<0.01). Sensitization to heat was also observed in the AMHs studied. The heat threshold decreased from $>49^{\circ}$ C before PGE, injection to 47.5 \pm 0.7 after the injection. A decrease in mechanical threshold after PGE, injection was observed in 3 of 10 CMHs, and 2 of 4 AMHs tested . The results indicate that PGE, sensitizes both cutaneous CMHs and AMHs to heat stimuli. The mechanical threshold was, however, decreased only in a proportion of the nociceptors. These data provide additional evidence for a role of PGE in the hyperalgesia associated with inflammation. STIMULUS HISTORY AFFECTS THE HEAT RESPONSE OF

C-NOCICEPTORS. <u>D.B.Oakland, R.A.Meyer, and J.N.Campbell,</u>
Johns Hopkins University, Baltimore, MD 21205.
To develop a kinetic model which accounts for the heat response properties of C-fiber nociceptors, we studied the effects of stimulus history on responses to heat stimuli.
Single C-fiber nociceptors sensitive to mechanical and heat stimuli (CMHs) were studied in the anesthetized monkey (<u>Macaca fasicularis</u>). A Peltier device was used to deliver heat stimuli at interstimulus intervals (ISI) of 10, 30, 60, 120, 300, or 600 s at stimulus rise rates of 1°C/s and 60, 120, 300, or 600 s at stimulus rise rates of 1°C/s and 10°C/s. CMHs exhibited a marked suppression of response as the ISI decreased or the intensity of the preceding stimulus increased. This suppression was manifest in three ways: (1) an increase in latency to the first action potential; (2) a decrease in peak discharge frequency; (3) a decrease in total evoked response. The increase in latency was significantly greater for the slow ramps than the fast ramps. This is likely explained by a transfer the fast ramps. This is likely explained by a transient increase in the heat threshold of the receptor. The decrease in peak discharge frequency was significantly greater for the fast ramps. This suggests that the phasic part of the suprathreshold response is more susceptible to suppression. We have recently shown that the apparent heat threshold of a CMH is also dependent on stimulus parameters. These results will be used in a model of the heat response of CMHs that incorporates heat transmission, transduction, action potential initiation and conduction.

THE APPARENT HEAT THRESHOLD OF A C-FIBER NOCICEPTOR IS DEPENDENT ON STIMULUS PARAMETERS. R.-D.Treede* D.B.Oakland, R.A.Meyer, and J.N.Campbell, Johns Hopkins Univ., Baltimore, MD 21205.

The skin surface temperature necessary to activate a cutaneous nociceptive receptor is determined not only by the response properties of the neural transducer, but also by the thermal properties and thickness of the overlying skin. To examine the influence of stimulus parameters on heat threshold, we recorded the responses of single C-fiber nociceptors that innervated the hairy skin of anesthetized monkey (Macaca fascicularis). Heat stimuli were delivered by a laser thermal stimulator or a Peltier device. In the first set of experiments, the heat stimulus consisted of a stepped increase in surface temperature. Thresholds were significantly lower when stimulus duration was 30 s as opposed to 1 s. Similarly, thresholds for a 1 s duration stimulus from a 38°C base were significantly lower than those from a 35°C base. In the second set of experiments, the heat stimulus consisted of a linear increase in surface temperature at a rate that ranged from 10 to 0.1°C/s. The heat threshold increased with faster ramp rates. These results indicate that the heat threshold of C-fiber nociceptors depends primarily on the temperature rather than rate of temperature change at the depth of the neural transducer. Differences in threshold as a function of base temperature, stimulus duration, and ramp rate are likely due to the thermal transmission properties of skin.

ARE EXCITABILITY AND CONDUCTION PROPERTIES SUFFICIENT TO IDENTIFY MODALITY OF MAMMALIAN CUTANEOUS AFFERENTS? Frederique Popitz-Bergez, Johann G. Thalhammer, G. R. Strichartz and Stephen A. Raymond. Anesthesia Research Laboratories, Brigham & Women's Hospital, Harvard Medical School, Boston, MA. 02115.

Functional identification of cutaneous afferents requires testing the response to natural stimulation of the receptive field as well as determination of the fibre's conduction velocity (CV). Recognizing that resting CV cannot establish modality because of overlap in resting CV among modalities, we have investigated dynamic shifts in excitability and CV during repetitive electrical stimulation of fibres of known modality to learn if such measures could serve as a tool for distinguishing fibre modality even in the absence of the receptive field.

Response latencies to repeated electrical stimulation (1-50 Hz, .2/.5 ms, .20s) were monitored in 18 C fibres, .2m/s (7cold, .11 nociceptors) and .13 A δ fibres, .4 10 m/s (5 cold, 8 nociceptors) from the sciatic nerve in fully anesthetized rats. As excitability decreased, latency increased in any given fibre. In A6 and C cold fibres the latency increased initially then stabilized, recovering within a few seconds when stimulation ended. In contrast, the latency in $A\delta$ and C nociceptors increased to a much greater degree than in cold fibres throughout the stimulation period and did not fully recover for up to several minutes afterwards. The magnitude of slowing increased with frequency, but at any given discharge rate the latency changes were tightly clustered among all cold fibres whereas in nociceptors there was a wide range (3-80%). In addition, nociceptors tended to show conduction failure at lower frequencies than the cold fibres.

For the types of fibres studied here, the profile of shift in latency and excitability is a signature of the fibre function. This suggests that measurement of excitability and CV during impulse activity may suffice to characterize the modality of a cutaneous afferent

DRG ACTION POTENTIAL DECOMPOSITION DUE TO HIGH FREQUENCY STIMULATION VARIES WITH PERIPHERAL RECEPTOR SUPPLIED.

RD Rose. Biological Sciences, Duquesne University, Pgh PA 15282 and Neurobiology & Behavior, SUNY Stony Brook NY 11794

Several spike (AP) components can be resolved via decomposition of APs recorded from DRG somata following high frequency orthodromic stimulation. Brock et al (IP '53) suggested that in motorneurons similar results were indicative of partial AP transmission block occuring at morphological junctures along the conduction path. Ito (Jap IP '57) termed the DRG AP components Can be resolved using high frequency stimulation (Strauss & Duda [Brat lek Listy '82], Harper & Lawson [JP '85]). The present work examines organization of frequency dependent conduction failure in identified DRG neurons.

In lumbosacral DRGs of anesthetized cats, 41 muscle and 32 skin units were examined. Of these 43 followed at frequencies of IkHz at least briefly (up to 3s) with only minor deterioration in AP configuration that consisted of a slight (<20 mV) decrease in AP amplitude, decreased (or disappearing) afterhyperpolarization amplitude, and increase in baseline AP duration. 30 units failed at frequencies of 40 Hz up. Typically both muscle and skin units with A-alpha/beta conduction velocities followed at frequencies associated with particular afferent types was often broad (from 250 to >1000 Hz for Ias) with no apparent correlation with conduction velocity. APs of units supplying similar peripheral receptors (e.g. Ias, touch domes or high threshold mechanoreceptors [HTMRs]) decomposed in similar and characteristic fashions. For example, in touch dome, HTMR and deep pressure muscle units, spike duration increased due to a delay in the S-component. A concave-up inflexion (termed N2 by Ito) on the rising phase became apparent and then pronounced. N2 however was neither apparent nor pronounced in successive spikes of muscle stretch of hair afferents. Several other AP characteristics, including augmentation of th

CHARACTERIZATION OF ACTIVITY-DEPENDENT MODULATION OF EXCITABILITY IN SINGLE AB, AB, AND C FIBERS OF RAT SCIATIC NERVE. Hyung-Cheul Shin & Stephen A. Raymond. Anesthesia Research Labs, Brigham & Womens' Hospital, Harvard Medical School, Boston, MA 02115.

The excitability of axon membrane changes after transmission of impulses, making it possible for the axon to serve as a memory element. Theories for the role of axon memory in neuronal information handling rely on properties of activity-dependence in axons of A and C fibers. However, there has been no comprehensive description of activity-dependence for mammalian fibers. Here we report on comparative studies of aftereffects of impulse discharge on the excitability of rat sciatic nerve

fibers with resting conduction velocities ranging from 0.5-29 m/s (0.5 Hz).

Across the fiber spectrum there were 4 principal phases: refractoriness, superexcitability (S), hypoexcitability (H1), and depression (H2). After a conditioning impulse (CP), S peaked at 6 ms in $A\beta$ fibers (CV=16-29 m/s) and at 9 ms in the $A\delta$ fibers (CV=2.5-13.0 m/s). Threshold re-crossed the resting level within 25 ms. With more CP's (2 to 4 CP's, 10 ms interval) S diminished, and became briefer in A fibers, and with 8 CP's or more only a "relative" S phase appeared where threshold never descended below the resting level. In C fibers (CV=0.5-2.0 m/s) the S phase was relative even after 1 CP, and appeared only when tonic excitability had been depressed by prior activity. With 1 CP, H1 was observed after S in all A fibers. H1 appeared in only 4 of 9 C fibers, but was more intense in them $(A\beta: 10\%, A\delta: 15\%, C: 30\%, 1$ CP). H1 peaked earlier in A fibers $(A\beta: 48 \text{ ms}, A\delta: 60 \text{ ms})$ than in C fibers (87 ms), and threshold returned to baseline in ~ 100 ms in A fibers vs $^{-}$ 200 ms in C fibers. H2 appeared, but with wide variation in degree, in all fibers given repeated bursts of CP's. It generally required more CP's at higher rates to produce significant H2 (>20% rise in threshold) in A β fibers.

These results show that excitability in rat fibers depends on impulse activity and that the after-oscillations in threshold differ in phase and magnitude among $A\beta$, $A\delta$ and C-fibers. They predict fiber-specific patterns of impulse discharge.

175.8

NERVE IMPULSE PATTERNS DEPEND ON ENDOGENOUS OSCILLA-TIONS IN MEMBRANE EXCITABILITY. Johann G. Thalhammer, Hyung Cheul Shin, Frederique Popitz-Bergez and Stephen A. Raymond. Anesthesia Research, Brigham & Women's Hosp., Harvard Med. Sch., Boston, MA 02115 Intermittent conduction, which is characterized by "on" phases where all

impulses conduct or all stimuli succeed and "off" phases where none do, is a common bursting pattern. Here we report a progression in intermittent conduction seen in rat sciatic fibers stimulated at various frequencies with trains of current pulses at intensities ranging from 10-30% above the resting threshold. When the train begins, the alternation between on and off is rapid (0.2-0.5 s), but as the stimulation is sustained the periodicity becomes both slower and more consistent with on and off phases lasting several seconds. Measurements of threshold and conduction latency following bursts of above-threshold conditioning stimuli account for this progression as follows. When stimuli begin, the first discharges each produce superexcitability lasting as long as 50 msec, which favors successive firing. After several spikes, superexcitability declines and a phase of transient hypoexcitability (H1) grows, elevating the threshold by 20-40 % at delays of 20-100 ms after each impulse. This increases the likelihood of failure of a spike. After a failure, H1 decays over several hundred ms yielding a brief off phase where several spikes in sequence are likely to fail. As the intermittent firing proceeds with rapid periodicity for several seconds, the threshold builds up as the "depression" phase (H2) develops. Depending on the intensity of the stimulus pulses it may take 10 or more seconds before the combined effects of depression and H1 are great enough to elevate the threshold above the stimulus to cause a failure. Recovery of the threshold is quick for the H1 component, but as may last as long as a minute for H2, which is consistent with the prolonged off periods that appear when stimulation has been sustained for over a minute.

Rapid intermittent conduction, characteristic of mammalian fibers, may reflect the presence of the H1 phase in these fibers.

175.10

UTERINE PAIN: THE ROLE OF ISCHEMIA AND THE HYPQGASTRIC NERVE. K. J. Berkley, S. Scofield*, and E. Wood* Dept. of Psychology, Florida St. Univ., Tallahassee, FL

Sensory fibers in the hypogastric nerve of adult, virgin, anesthetized rats respond to mechanical stimulation of the uterus usually only when the stimuli are noxious. For example, distension of the uterus normally activates fibers only at intensities which produce ischemia (i.e., occlude the blood supply) and which are much greater than those produced by uterine contractions. In order to examine the relation between this neural response and sensation, inflatable balloons were implanted in the uterine horns of rats previously trained to perform an operant escape response to terminate a painful somatic stimulus (tail pinch). The rats' escape responses to tail pinch and to various levels of uterine distension were then assessed before and after bilateral hypogastric neurectomies. Their ability simply to detect different intensities of uterine stimulation was also assessed. Rats escaped and were able to detect uterine stimulation only at distension levels which produced ischemia. Whereas hypogastric neurectomy had no effect on responses to tail pinch, it significantly reduced, and sometimes eliminated both detection and escape responses to uterine distension. These results indicate that, in nulliparous rats, uterine stimulation is consciously appreciated only at levels which produce ischemia and then probably only as pain. In addition, the results suggest that this function is subserved at least in part by the activity of fibers in the

hypogastric nerve. Supported by NIH grant 1RO1 NS 11892.

SYNAPTIC INTERCONNECTIONS BETWEEN PYRAMIDAL TRACT CELLS AND CORTICOSTRIATAL NEURONS IN RATS. R. L. Cowan and C. J. Wilson. Dept. of Anat. & Neurobiol., U. T. Memphis, Memphis, TN. 2012. U.S.

Ipsilateral pyramidal tract (PT) and contralaterally projecting (crossed) corticostriatal neurons were antidromically identified and their synaptic responses to contralateral neostriatal and ipsilateral PT stimulation were examined using intracellular recording in vivo. Stimulation of either pathway produced short latency EPSPs in both types of neurons, but these responses overlapped with a much stronger inhibitory response. Intracellular staining revealed that both types of neurons had axon collateral projections to the ipsilateral neostriatum, and extensive intracortical axonal arborizations.

Both types of neurons showed late responses to contralateral striatal stimulation. Late responses to PT stimulation were usually absent in PT neurons, but present in crossed corticostriatal neurons. The late responses to contralateral striatal stimulation and PT stimulation consisted of a prolonged («150 ms) period of membrane polarization and an absence of background synaptic noise, followed by a period of depolarization and increased synaptic noise. The latency and duration of the late depolarization were variable. Both components of the delayed response resembled spontaneously occurring but less predictablefluctuations in the membrane potential.

The excitatory EPSPs evoked in corticostriatal neurons and in PT neurons by antidromic activation of their axons suggest that these two kinds of striatal-projecting neurons make direct mutually excitatory synaptic contacts. The powerful IPSPs, which predominate in the response to strong stimulation, indicate the existence of an interneuron pool contacted by the axons of both types of pyramidal cells.

176.3

CURRENT TO FREQUENCY TRANSDUCTION IN NEOSTRIATAL NEURONS. J.Bargas, E.Galarraga, M.Cristancho*, J.C.Pineda* and J.Aceves. Depto. de Fisiología, CINVESTAV. I.P.N. Ap. Post. 14-740, México, D.F. 07000, MEXICO.

Intracellular recordings were obtained from in vitro brain slice preparations of the rat neostriatum. Intensity-frequency (I-f) and frequency-time (f-t) relationships using direct current injections (>1.5 s) were analyzed. The firing pattern was tonic with relatively little adaptation. Adaptation was present only with the stronger stimuli. I-f overall slopes were: 8748 (Hz/nA) for initial frequencies and 50½8 (Hz/nA) for final frequencies (n = 14, mean±SEM, 29 $^{\circ}$ C). In many cases the I-f plot presented a greater slope for weaker than for stronger stimuli. I-f relationships were similar for the first and for the last interspike intervals. Most adaptation was reached within the beginning of the stimulus ($\tau \simeq 300-600$ ms). Cd $^{2+}(50, 100~\mu\text{M})$ increased the slope of the I-f function, but it did not change the general shape of this relationship. Neurons could still adapt in the presence of Cd $^{2-}$ Ni $^{2-}$ (100 μM) had no effects on the same parameters. Apamin also (1 μM) increased the slope of the I-f relationship. 176.5

CONTRIBUTION OF EXCITATORY AMINO ACIDS TO SPONTANEOUS SYNAPTIC ACTIVITY IN CAUDATE NEURONS. <u>C. Cepeda</u>, <u>C. Meier, N.A. Buchwald and P.L. Herrling.</u> Mental Retardation Research Center, UCLA, Los Angeles, CA 90024 (USA) and Sandoz Research Institute, CH-3000, Bern, Switzerland.

The present study assessed spontaneous postsynaptic potentials in caudate (Cd) neurons using <u>in vivo</u> and <u>in vitro</u> preparations. Cd neurons are generally silent. However, <u>in vivo</u> intracellular recordings reveal the presence of a barrage of spontaneous depolarizations (5-15 mV) that rarely produce action potentials. In <u>in vitro</u> recordings spontaneous depolarizations occur infrequently suggesting that they are generated by extrinsic afferents. A major source of excitatory input to the Cd is the cortex. The likely transmitter of this input is an excitatory amino acid. <u>In vitro</u> experiments in rat Cd slices combined iontophoretic application of NMDA with intracellular recordings. Electrode tips were 100-200 μm apart. Ejection of NMDA with low currents (-10 to -30 nA) which were insufficient to induce action potentials, consistently produced a depolarizing shift (about 10 mV). Superimposed on this depolarization a series of smaller depolarizations (1-5 mV) occurred. Higher ejection currents (>-30 nA) produced rapid large depolarizations accompanied by bursts of action potentials. Most of these responses were blocked with the NMDA receptor antagonist (D)AP-7 failed to block spontaneous depolarizations. CNQX, a non-NMDA receptor preferring antagonist, and kynurenic acid reduced the frequency of spontaneous synaptic activity but were not able to completely eliminate it. Assuming that at least part of the spontaneous activity is of cortical origin, the <u>in vivo</u> observations imply that Cd spontaneous depolarizations appear to be preferentially mediated through non-NMDA receptors. Supported by USPHS HD 5958.

176.2

TWO TYPES OF NEURON AND THEIR SYNAPTIC INPUTS IN RAT NEOSTRIATUM. Z.G. Jiang and R.A. North. Vollum Institute, Oregon Health Sciences Univ., Portland, OR 97201.

Rat brain slices were used for intracellular recording from dorsal striatum neurons (n=338). Two types of cell were distinguished. Principal cells (96%) had very negative resting potentials (-90 mV), low input resistances (40 MD), and showed quickly developing (ms) inward rectification (conductance 10 nS at -65 mV, 99 nS at -120 mV). Secondary cells (4%) were less polarized (-60 mV), had higher input resistances (120 MD), and hyperpolarization caused a slower increase in conductance with properties of H-current. Intracellular labeling (biocytin-avidin-HRP) showed that principal cells had a medium sized soma (10-18 µm), dendritic trees densely studded with spines and, sometimes, a main axon extending toward globus pallidus. Focal stimulation of the globus pallidus evoked an antidromic action potential in 54 of 85 principal neurons. Stimulation of the corticostriate fibers evoked a depolarizing postsynaptic potential in 78 of 91 principal cells, which was reversibly blocked by CNQX and APV, but unaffected by bicuculline. Focal stimulation within the striatum evoked a synaptic potential that was partially blocked by CNQX and APV, but completely blocked by adding bicuculline and/or picrotoxin. Conclusion: the principal striatal neurons are projection cells receiving glutamate synaptic inputs from cerebral cortex and GABA inputs from intrinsic cells. The minority of cells seem to be interneurons but also receive glutamate and GABA inputs.

176.4

CARBACHOL DELAYS ACTION POTENTIAL REPOLARIZATION AND DECREASES THE AFTERHYPERPOLARIZATION IN NEOSTRIATAL NEURONS. J.C.Pineda*, E.Galarraga, J.Bargas and J.Aceves. Depto. de Fisiología. CINVESTAV. I.P.N. Ap. Post. 14-740, México, D.F. 07000, MEXICO.

Intracellular recordings were obtained from in vitro brain slice preparations of the rat neostriatum. Ionic substitution experiments showed that Cd^{2+} (50, 100 $\mu\mathrm{M}$), but not Ni $^{+}$ (100 $\mu\mathrm{M}$), increased action potential (AP) duration, decreased the repolarizing $\partial\mathrm{V}/\partial t$ and reduced both phases (fast and slow) of the afterhyperpolarization (AHP). Apamin (1 $\mu\mathrm{M}$) only reduced the slow AHP. These results suggest that Ca^{2+} -activated components of the outward current, are present in both repolarization and AHP. The Ca^{2+} current involved may be high-voltage activated and Cd-sensitive. Carbachol (10 $\mu\mathrm{M}$) also reduced the slow AHP and delayed AP repolarization. These results suggest that carbachol might modulate the Ca $^{2+}$ or K $^+$ conductances involved in the AP and AHP generating mechanisms of these neurons. Supported by CONACyT grants P228CCOX891576 to E.G. and P228CCOX891559 to J.B.

INTRACELLULAR RESPONSES OF HUMAN CAUDATE AND NEOCORTICAL NEURONS IN CHILDREN: EFFECTS OF NMDA AND DOPAMINE. N.A. Buchwald, C. Cepeda and M.S. Levine. Mental Retardation Research Center, UCLA, Los Angeles, CA 90024.

Studies of caudate and cortical neurons were made on brain slices obtained

Studies of caudate and cortical neurons were made on brain slices obtained surgically during the course of treatment for intractable pediatric epilepsy. The patients were 9 children (4 mo - 9 yrs of age). 15 neocortical and 6 caudate neurons were studied.

Intracellular recordings were combined with iontophoretic application of excitatory amino acids and dopamine (DA). In all cells, resting membrane potential exceeded -60mV and action potential amplitude exceeded 65 mV. Iontophoretic application of NMDA (-25 to -250 nA) onto neocortical cells induced sustained depolarizations accompanied by continuous firing. In contrast, in caudate cells NMDA induced rhythmic oscillatory depolarizations with bursts of action potentials occurring at the peak of the depolarizations. Each oscillation was followed by a pronounced after-hyperpolarization. Both cortical and caudate cells were blocked by AP-5, a specific NMDA antagonist. Concurrent iontophoretic or bath application of DA did not inhibit NMDA responses but in several neurons in both sites, DA potentiated responses. These experiments indicate that the role of NMDA receptors may differ in human cortical and caudate neurons and that DA is capable of modulating some of these responses. Supported by USPHS Grant HD05958.

PROPERTIES OF A VOLTAGE-DEPENDENT CHLORIDE CURRENT IN RAT NEOSTRIATAL NEURONS. A. Stefani, D.J. Surmeier and S.T. Kitai, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.

Neostriatal cells manifest an inward rectification commonly attributed to a Ba-sensitive K-current. We tested the hypothesis that a chloride current can contribute to the inward relaxation present at negative potentials using whole-cell voltage-clamp techniques

Whole cell voltage-clamp recordings were made from embryonically-dissociated neostriatal cultures and acutely-dissociated adult neostriatal neurons using standard techniques at room temperature. The usual composition of the pipette solution was (in mM): KFI 100-120, KCl 0-20, CaCl 1, MgCl 2, EGTA 11, Hepes 10, ATP 2, GTP 0.2. The external solution contained in (mM): 130 NaCl, 2-5 KCl, 2 CaCl2, 1 MgCl2, 10 Na-HEPES, 8-12 glucose, 0.001 TTX, 0.2 CdCl2, 0.2 BaCl2, pH=7.3. A multi-barrel superfusion stem allowed fast exchange of the external baths in such a way that

Na-isethionate could replace the NaCl solutions.

In response to hyperpolarizing commands, a Ba-insensitive slow inward relaxation was observed. This current was not eliminated by the inclusion of 150 mM TEA-Cl in the bath or 120 mM Cs in the patch pipette, suggesting that chloride, and not potassium, was the primary charge carrier. Although active over a broad range of potentials (-20 mV to -150 mV), the steady-state current-voltage relation displayed a clear inward rectification. At negative potentials, the current activated slowly and did not appear to inactivate. The current was not blocked by external Cd at concentrations sufficient to block all Ca currents. This work was supported by NINDS grants NS 20702 and NS 26473.

PARTICIPATION OF DOPAMINE RECEPTOR SUBTYPES ON CORTICO-STRIATAL TERMINAL EXCITABILITY. M. Garcia-Munoz. S.J. Young and P.M. Groves. School of Medicine, University of California, San Diego, La Jolla, CA 92093.

We previously found that amphetamine- or stimulation-induced increases in dopamine

We previously found that amphetamine- or stimulation-induced increases in dopamine release decrease the electrical excitability of corticostriatal terminals possibly by activation of presynaptic receptors on the terminals. In this study, we examined the effects of D1 and D2 specific agents on corticostriatal excitability in dopamine depleted rats. Experiments were performed on urethane anesthetised male Sprague-Dawley rats pretreated with alphamethylparatyrosine (250 mg/Kg, i,p.) and reserpine (25 mg/Kg, i,p.) and 2 hrs before the recording session. Extracellular action potentials were recorded from the contralateral pretrontal cortex. Bipolar stimulating electrodes for antidromic activation of the cortical terminal field and canulae for local administration of drugs were placed in the contralateral stratum. All drugs were infused in a 300nl volume over 5 min. Excitability was assessed by determining the threshold current required for antidromic activation before and immediately after drug intestin. Local administration of the mixed agonist apmorphips (10), significantly. the threshold current required for antidromic activation before and immediately after drug influsion. Local administration of the mixed agonist, apomorphine ($10\mu M$), significantly decreased excitability ($10.2\pm1.6\%$, n=4). The D2 agonist, quinprine ($10\mu M$), n=6) did not affect excitability. The D1 agonist SKF38393 (SKF, $2.5\mu M$) was also without effect in 5 cases and decreased excitability be 6.9 ± 1 % in one case. However, following simultaneous administration of quinprine and SKF (0.48KF, n=22) excitability decreased in 13 cases ($17.3\pm2\%$, n=13), increased in 6 of the cells ($8.6\pm1\%$) and on 3 occasions no change occurred. Following a decrease in excitability to SKF+Q, apomorpine ($10\mu M$) further reduced excitability ($8.7\pm1\%$, n=10). The D2 antagonist L-sulpride (10mM) partially reversed the decrease in excitability to SKF+Q, while the D1 antagonist, SCH 23390 ($10\mu M$) reversed this effect in only 4 of 16 cases and was ineffective in 12. These results suggest that dopamine effects on 4 of to cases and was interlecture in 12. These results suggest that oppamine enects on conficional terminal excitability may involve the participation of dopamine receptors which differ from the D1 and D2 subtypes or that, since sulpiride and not SCH 23390 reversed the decrease in excitability to the combined administration of D1 and D2 agonists, excitability changes are mainly mediated by the D2 receptor which requires stimulation of D1 receptors for the full expression of its function. ELECTROPHYSIOLOGICAL ACTIONS OF SOMATOSTATIN ON STRIATAL NEURONS. <u>T.W.J.Watson</u>, Neuroscience Research Group, University of Calgary, Calgary Canada T2N4N1. Somatostatin (SS) is localized within the medium aspiny striatal

interneurons. The physiological role of SS in this brain region is uncertain but reports of the effect of intrastriatal injection of SS in vivo suggest that it exerts a potent influence on striatal function. The mechanism underlying these effects is unknown and may simply represent an indirect action secondary to previously demonstrated SS induced release of dopamine (Chesselet and Reisine, J. Neurosci. 3:232-36). Using the in vitro rat striatal slice we tested the hypothesis that SS exerts direct electrophsiological effects on striatal neurons. Parasagital slices were submerged and constantly perfused with buffered-oxygenated artificial CSF. Intracellular voltage recordings were obtained using conventional techniques and drugs were applied through the bath. At concentrations in the µM range SS caused a 3-10 mV membrane hyperpolarization associated with an increase in membrane conductance in 70% of the cells examined. This was accompanied by a suppression of spontaneous firing and anode break spikes. The hyperpolarization was seen with KCl filled electrodes and persists in the presence of 500 μ M CdCl₂. Thus SS exerts a direct inhibitory action on striatal neurons which appears to involve activation of a membrane K+ conductance. This direct action on striatal neurons may explain the effects of SS on striatal function noted in vivo.

DOPAMINERGIC MODULATION OF VOLTAGE-DEPENDENT POTASSIUM CONDUCTANCES IN RAT NEOSTRIATAL NEURONS. S.T. Kitai, D.J. Surmeier and A. Stefani, Dept. of Anatomy and Neurobiology,
College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.
The dopaminergic innervation of the neostriatum by the substantia nigra is

of broad clinical and functional importance. However, the neuromodulatory role of dopamine in the neostriatum is unclear. We have used whole-cell and patch voltage-clamp techniques to examine the effects of dopaminergic agonists on the biophysical properties of potassium conductances in acutely-dissociated and cultured neostriatal neurons.

Adult and iuvenile neostriatal neurons were acutely dissociated using a procedure similar to that described by Mody et al. (Neurosci.Lett., 96:70,1989). Embryonic neurons were cultured as previously described (Surmeier et al., Dev. Brain Res., 42:265,1988). Whole-cell and cell-attached patch voltage-clamp studies employed standard techniques to isolate K currents (e.g. Surmeier et al. Neurosci, Lett., 103:331,1989). Dopaminergic agonists and antagonists were applied with a multi-barrel pipette positioned within a few hundred microns of the recorded cell.

Preliminary experiments suggest that dopamine (10-50 µM) reversibly decreases a low-threshold, slowly-inactivating potassium current activated by depolarization. This D-like potassium current exhibits steady-state half-activation and half-inactivation voltages that are 10-30 mV more negative than the A-current. The modulation of this current may underlie dopamine's ability to control first spike latency and discharge frequency. (Supported by NINDS grants NS 20702 and NS 26473).

CALCIUM INFLUENCES ON FIRING PATTERN OF DOPAMINE NEURONS IN THE SUBSTANTIA NIGRA PARS COMPACTA. M.A. Häusser* and W.H. Yung* (SPON: Brain Research Association).
University Lab. of Physiology, Parks Rd., OXFORD OX1 3PT, U.K.

We have studied immunohistochemically-identified dopamine neurons in an in vitro slice preparation of the guinea-pig substantia nigra pars compacta (SNC), and have found that their electrophysiological properties are strongly influenced by the entry of extracellular Ca and the resting intracellular Ca level. Rythmic oscillations were found to underlie the spontaneous pacemaker firing of these neurons. These oscillations were blocked by extracellular Co or Ni, and their pharmacology and voltage-dependence indicate that a T-type Ca channel plays a necessary role. The oscillations appeared to be related to the low-threshold spike (LTS), which was also Co- and Ni-sensitive. Under voltage clamp, the current underlying the late afterhyperpolarization (AHP) following a fast spike was found to be apamin-sensitive. This late AHP was blocked by Co, which also shortened spike width. Blocking the late AHP caused a large increase in the slope of the frequency-current relation and increased resting firing rate and accommodation. Intracellular EGTA also blocked the late AHP and increased resting firing rate. Prolonged ionophoresis of EGTA allowed the expression of "burst" responses, which were not observed in control neurons. We speculate that neurotransmitters which modulate Ca and Ca-dependent channels or intracellular Ca levels may help regulate the transition between pacemaker and burst firing observed in SNC dopamine neurons in vivo.

EFFECTS OF ENHANCING GABAergic INPUT ON THE

EFFECTS OF ENHANCING GABAergic INPUT ON THE INTRACELLULAR RESPONSES OF STRIATAL NEURONS TO STIMULATION OF CORTICAL AFFERENTS IN VITRO.

E.S. Nisenbaum. T.W. Berger, and A.A. Grace. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260. We have demonstrated previously using an in vitro corticostriatal slice preparation that paired impulse stimulation of cortical afferents elicits a facilitation in probability of striatal cell spike discharge for interstimulus intervals (ISI) of 10-250 ms. When the allosteric receptor agonist, pregnanolone, is used to potentiate the effects of endogenously released GABA, then spike discharge is selectively inhibited in response to short ISIs of 10-30 ms. The present experiments have investigated the synaptic responses which underlie this inhibition of spike discharge.

Intracellular recordings from striatal neurons in vitro revealed that paired impulse facilitation of spike discharge in response to ISIs of 10-250 ms was

Intracellular recordings from striatal neurons in vitro revealed that paired impulse facilitation of spike discharge in response to ISIs of 10-250 ms was mediated by a facilitation of EPSP amplitude to the second impulse of these ISIs. Pregnanolone (5.0-7.5 μM) selectively inhibited spike discharge and decreased EPSP amplitude to the second impulse of ISIs of 10-30 ms. These inhibitory effects were antagonized by bicuculline (20 μΜ). When paired impulse stimulation was applied directly using intracellular current injections, a similar facilitation of spike discharge was found to ISIs of 10-250 ms. However, the magnitude of this facilitation was less than that observed in response to afferent stimulation. Moreover, the facilitatory responses to direct current injection were not altered by pregnanolone. These results demonstrate that potentiation of GABAergic input in vitro selectively inhibits cell discharge to short ISIs, thereby restoring the response pattern characteristic of Type II neurons in vivo. These data also indicate that this inhibition results from a shunting of cortically evoked EPSPs by activation of afferent GABAergic neurons. (Support: NS19608, MH00343, MH09717, MH42217, Tourette's Syndrome Association, NARSAD).

INVOLVEMENT OF CHLORIDE CONDUCTANCES IN THE RESPONSE PATTERNS OF STRIATAL NEURONS TO CORTICAL STIMULATION. 5-P. Onn, T.W. Berger & A.A. Grace, Depts. of Behavioral Neurosci. & Psychiatry, Univ. of Pittsburgh, Pgh, PA 15260

We have used intracellular recordings from rat striatal neurons in vivo to characterize the response patterns to paired impulse stimulation of cortical afferents. Two types of responses were observed: 1) 29% (7/24) neurons displayed facilitation to the second stimulus when the interstimulus interval (ISI) was 10-20 ms and inhibition when ISI=100ms (Type I response pattern) whereas 2) the majority (71%; 17/24) of the recorded cells exhibited facilitation when the ISI was 100 ms (the Type II response pattern). Of the 17 Type II neurons, 7 also showed inhibition when ISI=10-20 ms with the remaining 10 neurons exhibiting facilitation at this interval. Using Lucifer-yellow (in 0.1M LiCI) filled electrodes, similar proportions of Type I and Type II neurons have been observed: 35% (17/48) showed the Type I response pattern and 65% (31/48) exhibited the Type II response pattern. However, of the 31 cells with the Type II response pattern, none showed short-interval inhibition. Since the LY electrodes contained chloride ions, we determined if altering intracellular chloride or changing the membrane potential could account for these differences. Recordings with intracellular KCI-filled microelectrodes to date revealed similar proportions of Type I (25%; 3/12) and Type II (75%,9/12) responses with none of Type II neurons showing short-interval inhibition. This result suggests that the failure to observe the short-interval inhibition in Type II neurons when recording with dye filled electrodes is due to reversal of the electrochemical gradient to chloride ions. The membrane potential does not seem to alter the paired-impulse response pattern. This evidence supports a role for a GABA-mediated chloride conductance in the short-interval inhibition of the Type II response pattern.

RESPONSES OF SPINY NEURONS IN RAT STRIATAL GRAFTS TO CORTICAL AND THALAMIC STIMULATION. Z.C. Xu, C.J. Wilson and P.C. Emson Department of Anatomy and Neurobiology, University of Tennessee, Memphis. U.S.A. and AFRC Institute of Animal Physiology and Genetics Research, Cambridge, U.K.

Two months after implantation of striatal primodia into the neostriatum of adult rats, intracellular recording was performed in vivo to study the responses of graft neurons to the cortical and thalamic stimulation.

The initial responses of most of the graft neurons to cortical or thalamic stimuli were predominant inhibitory postsynaptic potentials (IPSPs), which could be reversed by intracellular injection of Cl-. Several minutes after impaling the cell, the amplitude of IPSPs became increasingly smaller. Eventually the IPSPs could not be detected. The same stimuli elicited excitatory postsynaptic potentials (EPSPs). Many EPSPs elicited in grafts were monosynaptic. Polysynaptic EPSPs were also observed in some graft neurons. Unlike the spiny neurons in the intact neostriatum, no long lasting hyperpolarization followed the initial EPSP and no rebound excitation was observed in grafts. Using higher stimulus intensity, a burst was evoked in some graft neurons. The onset and duration of the bursts varied even when the stimulus intensity was constant. The neurons were labeled intracellularly with biocytin. Ninty-five percent of the cells labeled in grafts were spiny neurons.

176.17

EFFECTS OF SYSTEMIC ETHANOL AND BEHAVIORAL CONTEXT ON MANY-NEURON ACTIVITY IN RAT NEOSTRIATUM AND NUCLEUS ACCUMBENS DURING LONG-TERM ON-OFF TREADMILL LOCOMOTOR BEHAVIOR. R.-S. Lee, B.N. Maddux and D.J. Woodward. Dept. of Cell Biol. and Neurosci., Univ. of Texas Southwestern Med. Ctr., Dallas, TX 75235.

The objective of this study was to clarify the effects of ethanol on the firing rate of neurons in neostriatum and nucleus accumbens (NAc) at different stages of the experience of treadmill (TM)-induced locomotion. Long-Evans rats were prepared for chronic recording with 20 microwires (25-60µ), implanted into neostriatum and NAc. Rats were trained to walk on a treadmill (30 sec on/30 sec off). The spontaneous activity of single units (on 2-6 separate wires) in neostriatum and NAc neurons was recorded extracellularly separate wires) in neostratum and NAC neurons was recorded extracentary 2-4 hours daily up to 10 sessions for 2-7 weeks from the same microwires. Ethanol (0.8-1.4 g/kg, i.p.) was administered 3-4 times for the same rat (n=8) throughout the recording period. Our results demonstrate that: (1) In simultaneously recorded neostratal neurons, heterogeneous responses to ethanol occur. The firing rate of some cells was unaffected, increased, or decreased. Furthermore, the firing rate or pattern of neostriatal neuronal activity of TM-trained rats often exhibited abrupt changes over several 30 sec on-off intervals during TM exercise after ethanol: a "mode switch" between contexts of neuronal firing (Lee, et. al., 1989, Soc. Neurosci. Abstr., 15: 286). (2) Preliminary observations demonstrate that the "mode switch" property also exists in the region of NAc of TM-trained rat. Our conclusion is that systemic ethanol causes the emergence of context dependent states which determine the dynamic and phasic responses of neurons in neostriatum and NAc to behavioral and pharmacological challenges. HALOPERIDOL-INDUCED SYNAPTIC CHANGES IN RAT CAUDATE NUCLEUS ARE PREVENTED BY PRIOR TREATMENT WITH MK-801 OR LESIONING OF THE THALAMUS. C.K. Meshul, A. Janowsky*, D.E. Casey*, and R.K. Stallbaumer*, V.A. Medical Center and Oregon Health Sciences University, Portland, Or. 97201

We have previously shown that 14d treatment with haloperidol (0.5)

mg/kg/d) causes a 50% increase in the density of "perforated" synapses mg/kg/d) causes a 50% increase in the density of "perforated" synapses within the caudate nucleus (Meshul and Casey, 1989). The nerve terminals undergoing the changes, which have twice the diameter of dopamine terminals, were hypothesized to originate in motor cortex and to release glutamate. Blockade of dopamine receptors by haloperidol may also block the inhibitory pathway from globus pallidus to VAVL of thalamus. This could activate the thalamocortical and corticostriatal pathways, leading to an increase in the density of perforated synapses. To determine if glutamate receptors are associated with this increased synapse density, the NMDA channel blocker, MK-801 (0.3 mg/kg/d), was given in conjunction with haloperidol to rats for 14d. To test the importance of the thalamocortical pathway in the effect of haloperidol, VA/VL of thalamus was lesioned with kainic acid and 10d later, haloperidol was given for 14d. Both MK-801 treatment and thalamic latioperido was given to 144. South in the state of the lesioning prevented the increase in perforated synapses due to haloperidol. In addition, WGA-HRP injections into motor cortex labelled numerous perforated synapses in the caudate nucleus. We conclude that glutamate transmission and VA/VL of thalamus may be important in controlling the haloperidol-induced changes in the density of perforated synapses and some of these synapses originate in motor cortex. Supported by the Dept. of Veteran Affairs and NIMH.

ACTIVITY OF NEURONS IN THE STRIATUM DURING WISUALLY-TRIGGERED, SELF-PACED AND MEMORY-GUIDED MODE OF MOVEMENT IN THE MONKEY. M. Kimura, T. Aosaki, Y. Hu, and K. Watanabe Department of Physiology, Jichi Medical School, Minamikawachimachi, Kawachi-gun, Tochigi 329-04, Japan.

Single neuron activity in the putamen (n=171) and caudate nucleus (n=120) was examined during learned arm movements initiated in 3 different behavioral contexts: A monkey depressed 3 push buttons laid out in a triangular form (side length 9 cm) on a panel in an instructed sequence using its arm in 1)visually-triggered, 2) self-paced and 3) memory-guided modes. The pattern of muscle activity were not significantly different during the 3 modes of movements. Fortynine out of 68 task-related putamen ceils showed movement-related activity, while 38 out of 50 caudate cells showed tonic activity during an instructed delay period or activity related to the reward. In 98 cells in which neuron activity was examined in more than 2 modes, a majority of cells (57% in the putamen, 55% in the caudate nucleus) were selectively activated during either visually-triggered or self-paced or memory-guided mode of movement. These results suggested a role of the striatum in retrieving a learned movement in a particular behavioral context.

ACTIVATION HISTORY AND FORCE HYSTERESIS IN HUMAN MUSCLE. C.L. Rice*, F. Furbush*, and B. Bigland-Ritchie. J. B. Pierce Foundation Laboratory, New Haven, CT 06519

Muscle force is generally greater for a given stimulus frequency when preceded by higher, rather than lower rates. Cat motor unit studies suggest this strategy may be used during voluntary contractions (Binder-Macleod & Clamann, J. Neurophysiol. 61:208, 1989). We compared the force-frequency values from adductor pollicis during different patterns of stimulation when stimulus rates were increased continuously from 4 to 80Hz, held for 0.5s, then reduced to 4Hz at the same rate (total duration 6.6s). The forces for rates <60Hz were 5 to 30% greater during the descending compared with the ascending sequence. The largest differences generally occurred at rates <20Hz. However, descending sequence values were similar to those seen when each rate was applied separately (steps). Step values were often slightly lower at rates <15Hz, but increased to match the descending sequence values after pre-potentiation by a brief 50Hz burst. When steady state stimulation was preceded by frequencies initially descending from 50Hz, the force was elevated above the step value, but for only 2-5 pulses. This force increment was similar to that seen when a step train started with only a single short (10ms) interval. Thus, most of the hysteresis seen when frequencies changed continuously can be attributed to a lag in the rate of force development or decay, and post-tetanic potentiation. NORMALIZED ELECTROMYOGRAPHIC ACTIVITY PATTERNS IN HUMAN EXTENSOR CARPI RADIALIS LONGUS AND FLEXOR CARPI RADIALIS MUSCLES: DIFFERENTIAL AND TOTAL ACTIVITY. S. Wolf, P. Catlin*, R. Segal, A. English, T. McMahon*, T. Craft*, L. Mason*, T. Pianta*, L. Couch*. Dept. Rehabilitation Medicine, Division of Physical Therapy and Department of Anatomy and Cell Biology, Emory University School of Medicine, Atlanta, Georgia.

Medicine, Atlanta, Georgía.

This study examined the relationship of normalized EMG activity from specific locations in extensor carpi radialis longus (ECRL) and flexor carpi radialis longus (FCR) muscles during twelve movements in an effort to gain insight into the possibility of task-specific muscle partitioning in human subjects. Two sets of bipolar fine wire electrodes were inserted into both the ECRL and FCR muscles of twenty normal individuals (nine men, eleven women). Significant (p .05) differences in normalized EMG between proximal and distal sites in the ECRL were found for most movements with the exception of prehension and unsupported wrist extension. The ECRL increased its activity compared to FCR in unsupported wrist movements. Results indicate: 1) portions of the same muscle can be recruited differentially; 2) these portions of muscles may have distinct functional roles; and 3) the central nervous system may both coactivate and reciprocally inhibit muscles lying about the same joint. To more efficiently reeducate dysfunctional muscle, therapeutic exercise may need to include retraining of muscle portions for particular functional tasks.

FATIGUE EFFECTS ON FORCE AND EMG POTENTIATION. T. Hortobágyi and N.J. Lambert. Dept. of Sport Sciences/Biology, Univ. of Denver, Denver, CO 80208

The effects of 4 fatigue protocols on stretch-evoked forces and EMG of the right thigh musculature were evaluated in 12 distance runners (48 mi-wk⁻¹) and 12 power athletes (10 tons-wk⁻¹). Power athletes had 1.33 1 larger estimated thigh muscle volume (p < .05). On each of 3 days, muscular fatigue was induced with 49 reps of isometric (1, 5-s MVC), shortening (S), and lengthening (L, 0.85 rad-s⁻¹) knee extension and, on the 4th day, with a 1-min stretch-shortening jumping exercise (J). Pre- and post-fatigue, a 1-s ramp stretch at 0.30 rad-s⁻¹ was superimposed on a 2-s MVC at 145° knee angle. Peak integrated EMG was monitored on the surface of mm. vastus lateralis and biceps femoris. Potentiation was calculated as the difference between the initial 2-s MVC and its EMG and the ensuing peak stretch force and EMG, respectively. There were no significant changes in the EMG of the m. biceps femoris (p > .05). Force and EMG fatigue averaged 39N (5%) and 9 μ V·s (6%) in the runners (p > .05) and 218N (23%) and 19 μ V·s (14%) in the power athletes (p < .05). With fatigue, the net change in force potentiation was -27N (-29%, I), -9N (-8%, S), 14N (12%, L), and 7N (8%, J) and the uniform decrease in EMG potentiation averaged 25 μ V·s (14%) in the runners. In power athletes, the net change in force potentiation was 30N (18%, I), -36N (-23%, S), 49N (32%, L), and 16N (10%, I) and the uniform decrease in EMG potentiation averaged 38 μ V·s (98%, p < .05). These data suggest a differential stretch response to fatigue across contraction modes and training history of athletes compared to the prediction of the force feedback hypothesis.

177.2

COMPARISON OF MUSCLE FIBER CONDUCTION VELOCITY AND EMG CHARACTERISTICS BETWEEN THE RIGHT AND LEFT BICEPS BRACHII OF NORMAL SUBJECTS. M. J. Blaschak and K. Keesey* Dept. of Phys. Ther., Boston Univ., Boston, MA 02215.

Comparisons between the normal and involved limbs of patients with unilateral brain lesions is common, made under the assumption that the limbs were comparable prior to injury. The purpose of this study was to determine if such an assumption is valid regarding muscle fiber conduction velocity and surface EMG characteristics. To date, conduction velocity and EMG characteristics have been recorded from the right and left biceps brachii in 9 normal subjects, with data analysis complete in 4. Muscle fiber conduction velocity was recorded during 5 5-sec. stimulated contractions(stimulated at 20 Hz. and averaged over 1 sec. epochs). Surface EMG was recorded during 2 sec. voluntary constant force isometric contractions at each of 3 trials of 7 different force levels. The EMG was recorded in 500 msec. epochs at a rate of 1024 Hz. Comparisons were then made using matched case t-tests between the right and left conduction velocity and the EMC characteristics of median and mean power frequency, the average rectified value and the RMS value.

Preliminary results from 4 subjects indicate that there are no statistical differences between the two limbs for any of the characteristics, providing initial support that for these measures, the limbs are comparable.

177.4

PATTERNS OF ELECTROMYOGRAPHIC ACTIVITY IN THE HUMAN LATERAL GASTROCNEMIUS MUSCLE DURING WEIGHTBEARING AND NON-WEIGHTBEARING TASKS. A. English, S. Wolf, P. Catlin*, R. Segal, C. Richardson-Bond*, L. Coratti*, A. Mast*. Dept. Rehabilitation Medicine, Division of Physical Therapy and Department of Anatomy and Cell Biology, Emory University School of Medicine, Atlanta, GA.

This study compared normalized EMG activity from four previously determined locations within the human lateral gastrocnemius, LG, (N=20), during performance of 5 non-weightbearing and 3 weightbearing tasks to determine if muscle compartmentalization observed in cats might also apply to human muscle.

A similar pattern of normalized EMG activity was found at all recording sites when comparing knee flexion in stance to knee flexion in prone. Each distal location had significantly greater activity compared to the proximal lateral location. Normalized data revealed that plantarflexion in stance consistently exhibited significantly greater amounts of activity at all four locations.

The greatest LG activity was observed across locations during plantarflexion in stance. Activity patterns appeared greater when LG was functioning at one joint or stabilizing the ankle rather than acting about two joints. These data lend support to differential activity within loci of LG during specific tasks. Further explorations into muscle compartments may ultimately produce more anatomically-specific exercise applications.

177.6

ELECTRICAL RESPONSE OF HUMAN ANKLE DORSIFLEXORS AND PLANTARFLEXORS DURING FATIGUE. V.Galea and A.J.McComas. Dept. of Biomed. Sci.,McMaster University, Hamilton, ON, Canada L8N 325.

The rate of fatigue in human skeletal muscle depends on the

The rate of fatigue in human skeletal muscle depends on the frequency of excitation and on the number of stimuli delivered (Garland, ét.al. J.Appl.Physiol. 362:205-213,1988). We have extended these findings by using a wide range of stimulating frequencies (0 - 30Hz) and by comparing fatigue in Tibialis Anterior (TA;ankle dorsiflexor) and Soleus (SOL;plantarflexor) muscles; the effect of ischemia was also studied, as was recovery from fatigue. Ten subjects (out of a total of fifteen) successfully completed the six experiments, five out of those ten also volunteered for the SOL experiments. At least one week rest was allowed between each fatigueing protocol. As anticipated, stimulation at the highest frequencies induced the greatest change in the M-wave (muscle compound action potential; p<.01), but the decrement in area was always less than that in peak-to-peak amplitude. No significant differences emerged in M-wave changes between TA and SOL. Ischemia accelerated the decline in the M-wave (TA; p<.01). Recovery of the M-wave was limited when tetanic stimulation ceased but progressed rapidly after the circulation was restored. M-wave failure occurred at firing rates not normally associated with neuromuscular junction blockade, implicating propagation failure along the sarcolemmal membrane.

MEDIAN FREQUENCY OF THE MYOELECTRIC SIGNAL IN ANTERIOR AND POSTERIOR NECK MUSCLES. M. A. SABRAHI, P.P. GOGIA*. Texas Moman's University, School of Physical Therapy, Houston, TX 77030.

Characteristics of median frequency (MF) of myoelectric signal, a

measurement of localized muscle fatigue, has been used as objective measurement or localized muscle ratigue, has been used as objective indicator of muscle function. The purpose of this study was to characterize changes in anterior cervical muscles (ACM) and posterior cervical muscles (PCM) during isometric contractions. Twenty-eight normal subjects between the ages of 22 and 43 (31.7 + 5.7) with normal head/neck posture participated in the study. The subjects were equally divided into two groups. EMG of the ACM and PCM was recorded bilaterally during attempted isometric pack forward bond (PCM) and backward (PR) in Croup A. and during isometric neck forward bend (FB) and backward (BB) in Group A, and during neck right and left side bend (RSB and LSB) in Group B. Subjects were restrained in sitting position in a specially designed force apparatus and performed constant isometric contractions at 20%, 50%, 80% and 100% of maximum voluntary contractions (MCV) in either FB/BB or RSB/LSB. Frequency spectrum of the EMG signal was analyzed through 0.5 sec. windows and the two parameters measured were initial median frequency (IMF) and the MF slope during sustained isometric 10 sec contraction.

Results showed consistently higher IMF as well as MF slope values for the ADM as compared to PCM in FB/BB AND RSB/LSB. Contrary to PCM, the IMF values increased with increasing force levels in ADM. The MF slope values increased with increasing force levels of contraction, however, the slopes were steeper in ACM. These results indicate that ACM and PCM have different fatigue characteristics i.e., the PCM are more fatigue resistant than ACM.

177.9

HIGH ENERGY METABOLISM IN SEVERELY ATROPHIC MUSCLE FIBERS IN DERMATOMYOSITIS. S. Sesodia. P.M. Nemeth, R.M. Choksi*, A. Pestronk. Depts. of Neurology, Anatomy and Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

The metabolic changes associated with physical weakness and muscle pathology in dermatomyositis were investigated in individual muscle fibers. Dermatomyositis is characterized histologically by severe perifascicular atrophy of muscle fibers having normal differential staining for three fiber types by myosin ATPase histochemistry. Using highly sensitive microfluorometric enzyme assays, we assessed the activities of 2 energy related enzymes, lactate dehydrogenase (LDH) and adenylokimase sensitive microfluorometric enzyme assays, we assessed the activities of 2 energy related enzymes, lactate dehydrogenase (LDH) and adenylokinase (AK), in atrophic and normal-sized fibers dissected from transverse sections of muscle. These 2 enzymes metabolically separate human muscle fibers into 3 types corresponding to myosin ATPase types 1, IIA and IIB. We found that the non-atrophic fibers had AK and LDH values in the same range as fibers from control human muscle and that their AK/LDH ratios were appropriate to their histochemical type. The atrophic fibers had increased AK or LDH values depending on fiber type. The AK values of the atrophic type I and IIA fibers were, on average, 2-fold above normal and their LDH values were normal. Atrophic IIB fibers had elevated LDH values and normal AK. In contrast, considerable numbers of muscle fibers from Duchenne musclar dystrophy (DMD) nate levated Dry values and ioninal AK. In contrast, considerable numbers of muscle fibers from Duchenne muscular dystrophy (DMD) have extremely low energy-generating enzyme levels (Chi et al., Metabolism, 1987). We conclude that, unlike a genetic dystrophy (DMD), fibers from dermatomyositis show a normal, or even high, capacity for energy generation

EFFECTS OF IMMOBILIZATION ON MOTOR FUNCTION IN A HUMAN HAND MUSCLE. A.J. Fuglevand and R.M. Enoka. Depts. of Exercise & Sport Sciences and Physiology, Univ. of Arizona, Tucson, AZ 85721

Immobilization is known to cause alterations in muscle and in motor neuron properties (Mayer et al., Neurosci., 6:725-729, 1981). Little is known, however, about the functional consequences of these immobilization-induced adaptations on motor function. The purpose of this study was to examine the effect of immobilization on the ability to generate and sustain force in first dorsal interosseus (FDI) muscle. Nine subjects volunteered to have the index finger and thumb of their non-dominant hand immobilized in a cast for three weeks. Each subject participated in five experimental sessions: one prior to immobilization, at one and three weeks of immobilization, and at one and three weeks post-immobilization. In each session, abduction force, FDI surface EMG, and single motor unit action potentials of FDI were recorded while subjects performed several isometric abduction tasks. These included: maximum voluntary contractions (MVCs), slow ramp-and-hold contractions, and a sustained contraction to exhaustion at a target level of 35% of MVC. EMG responses in FDI to supramaximal stimulation of ulnar nerve (M-waves) were responses in Folia Supraintation of the fatigue task. Despite the constraint in FDI usage imposed by the cast, MVC force was unchanged following immobilization. Motor unit discharge, however, became more variable with immobilization. Surprisingly, endurance time of the fatigue task was 16% longer and M-wave amplitude after the fatigue test was less reduced in immobilized FDI as compared to the pre-immobilized control values. These findings are consistent with decreased fatiguability observed in cat hindlimb motor units following short-term immobilization (Robinson et al., <u>Muscle & Nerve</u>, in press). Supported by USPHS grants NS 07309 and NS 20544.

MOTOR CORTEX OUTPUT AND MOTOR UNIT RECRUITMENT IN MOTOR INITIATION. E.B. Montgomery, S. Sahrman, M. Clare, S. Buchholz*, W.M. Landau. Dept. of Neurol. and Neurosurg. (Neurol.) Wash. Univ. Sch. Med., St. Louis, MO. 63110
Whether motor cortex neuronal output activity codes for the patterns of motor unit recruitment or some less

specific command was studied using analyses based upon temporal consistencies between neuronal activity changes and behavioral events within a single task. Output neurons were identified as those whose activity changes preceded their best related behavioral event. 37 neurons related to an isometric ankle force task and 46 neurons to a wrist flexion and extension task were studed. Of 73 occasions where activity changes indicated output functions, 66 (90.4%) were best related to force or movement onset while only 7 (9.6%) were best related to agonist or antagonist EMG changes. There was variability between onset time of agonist EMG and onset of force or movement. There was also variabililty in the amount of EMG during this time period, but there was a precise correlation between the amount of EMG and the timing. These findings indicate that different patterns of motor unit recruitment are put forth to accomplish the same task. Poorly synchronized motor unit patterns are less efficient in producing force or movement onset but are recruited earlier.

CORTICAL NEURAL NETWORK FOR SENSORIMOTOR INFORMATION PROCESSING. <u>Jean Requin</u>, <u>Alexa Riehle</u>, <u>John Seal</u>, Cognitive Neuroscience Unit, CNRS-LNF1, 31 ch. J. Aiguier, 13402 Marseille Cedex 9, France.

Single neuron activity was recorded in the primary motor, premotor and superior parietal cortex of the monkey during the performance of simple, choice and precued-response reaction time tasks. The results obtained can be similarly described in terms of three neuronal populations differentiated on the basis of the temporal relationship between changes in neuronal activity and behavioral events: the first population modified its activity with respect to the sensory cue ("input neuron"), the second with respect to the motor act ("output neuron"), and the third with respect to both these events ("interfacing neuron"). The observation that these three populations were found, although with different proportions, in several cortical areas suggests that they may represent a basic modular mechanism of cortical functioning by which the informational content of sensory cues is processed and used to shape adapted behavioral responses. The results provide a basis for our view that the plan for a sensorimotor act is formulated within a large neuronal network of basic modular units that spans the macroanatomical divisions of the neocortex. To elaborate this model further we need: 1) to determine whether all the neurons within a module are members of either a single class whose role in the module is more probabilistic than discrete or, as suggested here, members of several distinct classes are each characterized by their specific role within the module; 2) to describe the functional cooperation among neurons in a module by deciphering their interconnectivity; 3) to discover whether the differences in function of the cortical areas involved in motor planning are qualitative or quantitative; and, 4) to understand how the cognitive processes underlying sensorimotor information processing are implemented, whether continuous or in sequence, by the proposed functional organization of the neocortex. (Supported by ONR grant N00014-89-J1557)

NEURONAL PREPARATORY ACTIVITY: PREDICTIVE VALUE FOR PERFORMANCE SPEED. <u>Alexa Riehle</u>, <u>Jean Requin</u>, Cognitive Neuroscience Unit, CNRS-LNF1, 31 ch. J. Aiguier, 13402 Marseille Cedex 9, France.

In the preparation paradigm, a trial consists of the successive presentation of two signals. The second signal (S2) identifies the response to be made; the first signal (S1) may provide complete, partial, or no prior information about parameters of that response. Depending on the information in S1, the subject may prepare completely, partially, or not at all for the upcoming response movement. The reaction time (RT) for that response will decrease as a function of the degree of preparation. Preparatory mechanisms are elucidated by an analysis of the changes in neuronal activity occurring during the preparatory SI-S2 interval. Our behavioral task consisted of a wrist flexion and extension to targets which varied in two directions (left/right) and two distances (near/far). We recorded the activity of 499 neurons in the primary motor (MI) cortex and the premotor (PM) cortex of three macaque monkeys. Significant (p < 0.05) trial-by-trial correlations were obtained between RT and the neuronal discharge frequency during the S1-S2 interval for 38.2% (178/466) of the task-related neurons in at least one condition of prior information: when direction was precued, 34.8% of the neurons (162/466) had number dropped to 10.7% (50/466). The correlation was spread to the rections (162/466) and no parameter, was precued, this number dropped to 10.7% (50/466). The correlation was significantly (t = 7.9, p < 0.001) stronger in conditions of information about direction than in conditions of information about extent and no information. No significant difference in correlation was found between MI and PM (chi-square = 2.07, p > 0.1), but correlation was found between M1 and FM (chi-square = 2.0.7, p > 0.1), but significant differences (chi-square = 24.76, p < 0.001) were found between purely preparation-related neurons (16/52, 30.8%), preparation- and execution-related neurons (116/236, 49%), and purely execution-related neurons (46/178, 25.8%). Correlations were negative when 51.52 activity increased, and positive when activity decreased. (Supported by ONR grant N00014-89-J1557)

PREPARATORY ACTIVITY IN AREA 7A RELATED TO MOVEMENT DIRECTION OR EXTENT. William A. MacKay and Alexa Riehle. Dept. of Physiology, University of Toronto, Toronto M5S 1A8, Canada and CNRS-LNF1, 13402 Marseille, France.

Cortical area 7a is known to be involved in directing arm movements to targets in extrapersonal space. The hypothesis that it may code information about direction and extent of an intended reach to a visual target was tested in one cynomolgus monkey trained to reach to two sequentially occurring target positions displayed on a touch sensitive videomonitor. The right hand was held at one of four target positions while the second target was indicated as an open square 11 or 22 cm to the right or left. After 1 s (preparatory period) the square filled in and the monkey then reached toward it. For one movement direction, movements of the same extent could be started from two positions. Of 160 neurons recorded in the left area 7a, 39 changed their activity during the preparatory period in relation to movement direction and 15 in relation to movement extent regardless of starting position (including 9 which were related to both direction and extent). Activity changes were usually phasic in response to appearance of the second target (latency 50-100 ms) but some were sustained over the 1 s delay. Only 6/39 direction-related cells preferred leftward targets to rightward, and 12/15 extent-related cells preferred small movements to large. For 5 of these extent cells, the specificity for small movements was maintained in both directions. The results suggest that some area 7a neurons code visual signals in terms of arm movement parameters and that parameters such as direction and extent are partially specified by independent mechanisms.

NMDA ANTAGONIST (MK-801) BLOCKS PLASTICITY OF MOTOR CORTEX MAPS INDUCED BY PASSIVE LIMB MOVEMENT.

X.Q. Qiu*, D.L. O'Donoghue and D.R. Humphrey, Lab. Neurophysiology, Emory Sch. Med., Atlanta, GA 30322.

Two hours of forelimb movement in the ketamine-sedated rat can induce expansion of the motor cortical area from which forelimb movements are evoked with intracortical microstimulation (ICMS). We believe that such expansion results from input-induced changes in the excitability of extant synapses. In this study, we tested the contributions of N-methyl-D-aspartate (NMDA) mediated activities to such putative changes in synaptic efficiency. Two ICMS mappings of the motor cortex forelimbvibrissae border zone were performed in each of 13 ketamine-sedated rats: one before and one after two hours of passive flexion-extension movements of the contralateral elbow. During these movements, the exposed cortex was perfused with either artificial cerebrospinal fluid (CSF) (N=5 animals), CSF containing 3 uM concentration of MK-801 (N=3), or CSF with 300 uM MK-801 Expansions of the forelimb zone occurred in the first two groups. In contrast, significant shrinkage of the forelimb zone occurred in the 300 uM MK-801 group. The shrinkage was not accompanied by an increase in the range of threshold currents, indicating that it was not due to a general decrease in cortical excitability. The results are therefore consistent with the hypothesis posed (Supported by NIH Grant NS 20146 to DRH).

CORTICAL MECHANISMS OF STIMULUS-RESPONSE ASSOCIATION IN THE MONKEY, J. Seal, T. Hasbrouce*, I. Mouret* and S. Kornblum*¹. Cognitive Neuroscience Unit, C.N.R.S., 31 ch. J. Aiguier, 13402 Marseille Cedex 9, France and ¹Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720, U.S.A.

The aim of this study was to investigate the mechanisms by which the sensory response to a cue for movement becomes linked to the motor activity necessary for the execution of that movement. In a first series of experiments, a Rhesus monkey was trained in a choice reaction time task in which the stimulus was a brief vibration delivered to either the fingers or the thumb and the response was a press with the stimulated digit/digits. Single neuron recordings were made in S1, and areas 5, 6 and 4. The hand region of S1 was localized using N.M.R. imaging, which accounts for the high percentage of task-related activity observed (101/116 neurons). Trial by trial data analysis showed a temporal ordering of the changes in neuronal activity that was: S1 < A5 < A6 < A4. The same sequential organization was observed when we constructed a sensory to motor gradient based on the degree to which a change in neuronal activity was related to the stimulus and the movement. Within-burst analysis showed that A6 neurons displayed several changes in activity, some related to stimulus onset, others to movement parameters. However, all these changes occurred prior to the onset of movement which suggests that such neurons may be involved in the mechanism of associating context-related, sensory input with motor commands. We conclude that the cortical areas studied may contain a neuronal mechanism for sensory to motor transformation. (Supported by O.N.R. grant N00014-89-I1557)

CHANGES IN FORELIMB MOTOR REPRESENTATION IN RODENT CORTEX INDUCED BY PASSIVE MOVEMENTS. D.R. Humphrey, X.O. Qiu*, P. Clavel* and D.L. O'Donoqhue. Lab. I physiology, Emory Sch. Medicine, Atlanta, GA 30322.

To test the hypothesis that motor cortical representations are shaped by sensory experience, intracortical microstimulation (ICMS) was used to map the forelimb representation in the motor cortex of Ketamine-sedated adult rats, before and after 90-120 min of passive movements (100/min) of the contralateral forelimb (elbow flexion-extension, N=10), the vibrissae (N=5), the forelimb and vibrissae (N=4), the hindlimb (N=4), or after no movement (N=8). ICMS (0.2 msec cathodal pulses, 330 pps, 400 msec train) was delivered at a depth of 1.7 mm (in lamina V), using glass micropipettes (3.6 M NaCl) and a map-grid spacing of 0.25 mm.

Consistent expansion of the forelimb zone was seen

after passive movements about the elbow. No such increase in the forelimb zone occurred in the other movement conditions. However, a slight shrinkage occurred after vibrissae movements, due to expansion of the adjacent vibrissae zone. We interpret this movementinduced expansion to be due to changes in the synaptic strengths of afferent pathways which converge onto forelimb motor control cells at the periphery of the zone, produced by the period of sustained sensory input and now more effectively excited by ICMS. (Supported by NIH Grant NS 20146 to DRH).

MOTOR CORTEX REPRESENTATION PATTERNS REORGANIZE WITH MAINTAINED FORELIMB POSITION. J. N. Sanes, J. Wang, R. Kim*, and J. P. Donoghue, Center for Neural Science, Brown University, Providence, RI 02912

Donoghue, Center for Neural Science, Brown University, Providence, RI 02912
In previous experiments, we demonstrated that output representation patterns of the primary motor cortex (MI) are flexible. After a motor nerve injury in adult rats, forelimb (FL) EMG can be evoked with intracortical electrical stimulation in regions that before the nerve injury were unrelated to the FL. This effect may occur within 45 min of the nerve transection and endures for at least four months.

To test whether changes in afferent input reorganize MI output, we studied MI in 5 ketamine anesthetized rats with intracortical electrical stimulation while recording ketamine anesthetized rats with intracortical electrical stimulation while recording biceps and wrist extensor EMG. After initial mapping of the MI FL-vibrissa (VIB) border, a linear array of 4 electrodes (250 µm separation) was placed across the two zones. The FL contralateral to the stimulated MI was first maintained in an elbow-flexed, wrist-extended position (EfWe) and then in an elbow-extended, wrist-flexed position (EeWf), each for 30-150 min. EfWe shortens and EeWf lengthens muscles commonly activated by MI stimulation. The sample data set included biceps and wrist extensor EMG evoked from each of 20 stimulating electrodes (total of 40 data points). In EfWe, MI stimulation evoked weak FL EMG only from the most lateral electrodes and none from the medial electrodes. Immediately after FL repositioning to EeWf, the size of evoked EMG increased for 9 MI samples (position effect). After an additional 15-150 min of EeWf maintenance, FL EMG appeared for 12 samples within the VIB area where no EMG was previously evoked (reorganization effect) and evoked EMG increased in amplitude for 3 samples (strengthening effect).

the VIB area where no EMG was previously evoked (<u>reorganization</u> effect) and evoked <u>EMG</u> increased in amplitude for 3 samples (<u>strengthening</u> effect).

These results indicate that maintenance of limb position reveals *new* or *strengthens* existing synaptic relationships between MI and FL motor neurons. Further, changes in FL position can alter MI output immediately. Thus, the effect of an MI output volley on FL motoneurons, in rats, is position dependent. This suggests that limb position feedback influences MI map organization and that the amount of cortex controlling a set of muscles is regulated by competitive dynamic processes.

MICROSTIMULATION OF MOTOR CORTEX IN MONKEYS: FORCE FIELD ANALYSIS. D. Minciacchi, F. A. Mussa-Ivaldi*, S. Giszter and E. Bizzi. Dept. Brain and Cognitive Sciences, M. I. T., Cambridge, MA 02139.

We have examined the relationship between focal activation of cells in the motor cortex and the consequent multi-joint motor output. Recent work by Georgopoulos and coworkers based on single recordings in trained alert monkeys have suggested that individual cortical neurons encode for directions of hand movements, independently of the initial arm configuration. According to this interpretation, focal stimulation of a cortical site should result in the same end-point response regardless of the initial arm location. We addressed this by monitoring the total forces produced at the level of the wrist by focal cortical microstimulation in untrained tranquilized monkeys. Animals sat in a primate chair with the arm supported in the horizontal plane and the wrist attached to a six-axes force transducer. A stimulating electrode was inserted in the arm-related area of the precentral motor cortex. We placed the wrist at different workspace locations in the horizontal plane while keeping the electrode in one cortical site. For each arm location, we measured the force vectors elicited at the wrist by stimulation of this single cortical site (stimulation parameters: 7-15 µA, 100-150 msec, 50-150 Hz). Our data show that: (a) the force elicited by the stimulation of a cortical site varied in magnitude and direction at different workspace locations, and (b) for most stimulation sites, the pattern of wrist forces converged to a single equilibrium point. If we assume that the motor cortex of untrained tranquilized animals is functionally equivalent to the cortex of the trained alert preparation, then our results are not consistent with the hypothesis that neurons in the motor cortex encode an invariant direction of hand movement

COMPARISON OF NEURAL SIGNALS AND ARM TRAJECTORY DURING DRAWING MOVEMENTS. James L. Adams and Andrew B. Schwartz. Barrow Neurological Institute, 350 W. Thomas Road, Phoenix, AZ 85013.

Our prior research has shown that the population of proximal arm segment motor cortical neurons codes for direction of fingertip movement. The current study examines the motion of the limbs controlled by the proximal arm muscles during performance of the same and additional drawing tasks.

Two Rhesus monkeys (Macaca mulatta) were used in this study. Fingertip positions were recorded while each monkey traced figures with its index finger on a computer touch screen. Instantaneous wrist, elbow, and shoulder positions were captured via an OPTOTRAK system with four infrared emitting diodes affixed to a two-piece sleeve strapped to the monkey's arm and forearm. The OPTOTRAK data show the wrist trajectory resembles the fingertip trajectory. The elbow and upper arm trajectories are much less similar to those of the distal joints.

The population model is based on the activity of

distal joints.

The population model is based on the activity of cells identified by passive manipulation of the shoulder and elbow. Population vectors were generated from vector sums of firing rates and preferred directions of more than 200 such cells active during drawing movements. The trajectory model derived from these data closely resembled that of the distal (wrist and finger) trajectories.

MOTOR AND PREMOTOR CORTEX ACTIVITY DURING ARM MOVEMENT SEQUENCES IN MONKEY. I. RESPONSE PROFILES. J.K. Marcario and R.E. Kettner. Dept. Psych, Prog. Neural Science, Indiana University, Bloomington, IN 47405.

Single unit activity was recorded from the motor and premotor cortices of a thesus monkey performing a movement-sequence delay task. The monkey initiated each trial by depressing a central button when a small LED was lit. Two of four target lights indicating the sequence for subsequent forelimb movement were then randomly illuminated for 500 ms each, followed by a variable delay period (2.5-3.5 s) which terminated when the LED dimmed. The monkey then pressed the previously illuminated target buttons in the proper sequence to obtain a liquid reward. Fixation was maintained for the final 2.0 s of the delay period before the movement sequence was initiated. This task allows the separation of initiation, sensory, delay, and movement responses. At this point 253 single units from both hemispheres have been analyzed. PST histograms were constructed for each neuron and the types of response profiles were categorized on the basis of activity in the four main periods of the task. Plots of response rates in one period versus another were used in the analysis of response categories. Often quite different response profiles were observed within the same penetration for both motor and premotor areas. Further, both similar and different responses could be observed from nearby neurons including pairs of neurons simultaneously recorded from the same electrode tip. One of the most striking findings was that of complementary (e.g. motor/sensory-delay) responses in simultaneously recorded unit pairs. The diversity of response types observed suggests some complexity in local processing. Possibilities include: the activation of different muscle groups; the integration of sensory, mnemonic, and motor activity; interactions between interneurons and output neurons; and combinations of the above. DIRECTION AND VELOCITY CODING IN MOTOR CORTICAL CELLS.
Andrew B. Schwartz and Bryan J. Anderson. Barrow
Neurological Inst., 350 W. Thomas Rd., Phoenix, Az 85013
Unitary activity from cells located in the
proximal-arm area of primary motor cortex was recorded as
monkeys performed two drawing tasks. The animal initially
moved its finger in eight radial directions from a center
start position after a cell was isolated. Sinusoids of
different amplitudes and spatial frequencies were then
traced on the same touch-screen. Regression analysis of
the data from the first task showed that many cells
possessed discharge rates that were correlated to the
direction of movement (r² > .7). Each sinusoid was
represented as a vector based on that cell's preferred
direction (fixed) and its rate of discharge in that part
of the sinusoidal trajectory. These vectors were summed
across all the directionally-tuned cells in the
population (n= 238). This resulted in 100 "population"
vectors for each sinusoidal trajectory. The direction of
each population vector matched that in the corresponding
part of the trajectory with a time difference of about
150 msec. In addition, the length of each population
vector closely matched the speed of that part of the
trajectory. Regression analysis of each cell's activity
shows that although it is poorly correlated to speed, the
relation is non-random. The relation between speed and
discharge is more clear when data form the entire
population may be weakly represented in individual
discharge patterns and only evident when considering
large populations. Supported by NIH- NS26375.

CORTICAL NEURONAL ACTIVITY RECORDED IN A DELAY TASK THAT DISSOCIATES LOCATION OF CUE STIMULUS AND MOVEMENT ENDPOINT. J.F. Kalaska and D.J. Crammond. CRSN, Département de physiologie, Université de Montréal, Montréal, Canada, H3C 3J7.

Monkeys were trained to make arm movements to 8 peripheral targets arranged in a circle around a central starting position. In Direct-Delay (DD) trials, a green LED (CUE stimulus) at a peripheral target signalled intended movements to be made directly toward the stimulus location. In Reverse-Delay (RD) trials a yellow LED at a peripheral target signalled intended movements to be made in the opposite direction away from the stimulus location. The monkey withheld its response during the delay period (mean 2 sec) until a red LED (GG) signal) was illuminated. DD and RD trials were randomly interspersed. When the RD delay period was short the monkey often erroneously moved in the direction of the yellow LED when the GO signal appeared. Such directional errors were rarely observed in DD trials. This suggests that a period of time is required after the CUE signal is illuminated in RD trials to correctly make the dissociation between stimulus location and the intended movement direction.

CUE signal is illuminated in RD trials to correctly make the dissociation between stimulus location and the intended movement direction.

All cells recorded in this task in both premotor area 6 and posterior parietal area 5 were directionally tuned during the delay period of DD trials. The initial delay period response to the CUE stimulus in RD trials usually resembled that to CUE stimuli in the same location in DD trials. The RD delay period activity then gradually changed over several hundred mise to resemble that recorded in DD trials for movements intended in the opposite direction. Thus the initial cortical response to a CUE stimulus in RD trials resembled that for the motor response of highest stimulus-response compatibility (move to the stimulus) and may be the neuronal correlate of the directional errors seen in RD trials with short delay periods. Further neuronal processing was required in RD trials with short delay periods. Further neuronal processing was required in RD trials before neuronal correlates of the appropriate motor response were observed in both cortical areas. (Supported by MRC Group Grant in neurological sciences)

MOTOR AND PREMOTOR CORTEX ACTIVITY DURING ARM MOVEMENT SEQUENCES IN MONKEY. II. DIFFERENTIAL RESPONSES. R.E. Kettner and J.K. Marcario. Dept. Psych, Prog. Neural Science, Indiana University, Bloomington, IN 47405.

Variation in single-unit activity was studied during the 12 different movements in the movement-sequence task described in the first abstract. Statistically significant differences were determined using ANOVA tests and, if present, regression techniques were used to determine whether there were systematic variations in response rate relative to either sensory or movement direction. Delay period activity was analyzed relative to both sensory and motor events. Initial results indicate that most units show differential responses during at least one of the initial (0%), sensory (16%), delay (18%), or movement (59%) periods although some neurons had statistically similar response profiles across trial types. Sensory related differences were 3 times more common in anterior penetrations. Differences during one light did not generally predict differences to the other. During the final 2 s of the delay period both eye and arm position were stable. This final period was divided into two 1 s intervals for analysis. Delay period differences were twice as common in anterior penetrations and were also more common during the final delay interval suggesting a similarity to motor set responses that have been reported elsewhere. Movement period analyses were based upon intervals corresponding to the separate task movements. Differences during movement were present in both anterior and posterior penetrations. Significant regression fits generally followed the above trends. These results suggest that information about specific movements may be encoded in the firing patterns of both motor and premotor neurons during the sensory and delay periods of this task as well as during movement. (Supported by NSF grant BNS-8919867)

EFFICIENCY OF CORTICO-MOTONEURONAL (CM) FACILITATION OF MONKEY HAND MUSCLES R.N. Lemon, K.M. Bennett* and Flament. Anatomy Dept., Cambridge University, England.

There is good evidence that the post-spike facilitation (PSF) of EMG activity in hand muscles produced by monkey corticospinal cells is mediated by the monosynaptic CM pathway. Factors which might influence the efficiency of the CM synapse were studied in 3 <u>M. nemestrina</u> monkeys performing a precision grip. CM cells were identified by spike-triggered averaging of EMG and by cross-correlation with motor units. 1) **CM** cell firing pattern. At movement onset, short-interspike intervals (<20ms) produced large PSF, due to temporal facilitation and summation of post-spike effects. But long intervals (>40ms) were also effective, especially during precise maintenance of grip force. 2) Level of EMG activity did not appear to influence the amplitude of PSF relative to background EMG. Some CM cells produced similar facilitation of both the lowest threshold motor units (active at grip forces <0.4N) and of higher threshold units. 3) **Task**. One monkey performed two tasks: a precision pincer grip and a rotation task, both involving thumb and index finger. Intrinsic hand muscles were active during both tasks. For 15 CM cells we found dramatic differences in the amplitude of PSF produced by the same CM cell during the two tasks. These changes may be related to the pattern of activity required in the different target muscles, which could be varied by using CM cells with different muscle fields. Supported by MRC and Action Research.

MODULATION OF MOTOR CORTICAL ACTIVITY BY THE WEIGHT AND TEXTURE OF A GRASPED OBJECT. Nathalie Picard, Claude Dugas and Allan M. Smith, C.R.S.N., Université de Montréal, Québec, Canada. A macaca fascicularis was trained to grasp, lift and hold an object of varying weight and texture within a narrow position window. Weights of 15, 65 and 115 g and textures of smooth metal, fine and coarse grain sandpaper were used. The monkey scaled the grip and lifting forces appropriately for the object weight and texture. Unit activity was recorded in the hand representation area of the primary motor cortex, where low threshold intracortical microstimulation (< 30 μ A) elicited discrete wrist or digit movements. Receptive fields of the neurons were defined by stroking the skin and passive joint manipulation. In contrast to were defined by stroking the skin and passive joint manipulation. In contrast to cerebellar cortex, a greater proportion of motor cortical cells had cutaneous receptive fields and stronger responses to object texture. 93 cells related to the task were tested with weights and 47 of them with more than one texture. 45% of the cells showed a significant activity modulation with texture and 24% with weight. Of the proprioceptive units, 40% were modulated by weight and 33% were modulated by texture. In contrast the units with cutaneous receptive fields were more responsive to texture (58%) than to weight (11%). Alternatively, considering cells modulated by weight, 71% had proprioceptive receptive fields compared to only 25% which had cutaneous fields. Likewise, 74% of cells modulated by object texture had cutaneous fields compared to only 29% with proprioceptive fields. The responses to object texture occurred during dynamic proprioceptive fields. The responses to object texture occurred during dynamic grasping after contact with the object, but before either the force peak or the point at which texture causes a divergence in the rate of grip force application.

Cutaneous afferents provide the motor cortex with information about friction and slip needed to adjust the grip force and proprioceptive afferents carry information about the loads transported by hand muscles. The weight and texture of a grasped object appear to be encoded by separate but partially overlapping neural populations receiving proprioceptive and cutaneous input. Supported by MRC and NSERC of Canada and le Fonds FCAR du Québec.

ACTIVATION OF MOTOR CRANIAL NERVES BY ELECTRICAL AND MAGNETIC STIMULATION OF THE MOTOR CORTEX IN THE DOG. S.S. Haghighi, and S.A. Estrem*. Divisions of Neurosurgery and Otolaryngology, Univ. of Missouri. Sch. of Med., Columbia, MO 65202.

Transcranial electrical and magnetic stimulation are now widely used for the functional assessment of the corticospinal tract in man. Central delay time (CD) has been estimated for activation of limb muscles by subtracting the peripheral conduction time, estimated by stimulation of the ventral roots of the cervical spine, and recording peripherally from the same muscle group. In the present investigation, we used surface electrical stimulation of the motor cortex to produce evoked compound muscle action potential (CMAP) from ipsilateral and contralateral muscles innervated by motor cranial nerves (5,7,10,11,12). Monopolar electrical stimulation of the nerves at the cerebello-pontine angle (CPA) yielded CMAP activation of ipsilateral corresponding muscles. These latencies when subtracted from those obtained by direct cortical stimulation established CD for activation of the nerves. Our preliminary data with single pulse magnetic stimulation at high stimulation strengths (>80%) revealed ipsilateral CMAP with onset latencies similar to the direct nerve stimulation at the CPA for all innervated muscles suggesting intracisternal activation of cranial nerves with magnetic stimulation.

ANTICIPATED AND LONG-LATENCY REFLEX RESPONSES TO PERTURBATION OF PREHENSION IN MOTOR CORTEX. Alian M. Smith, Nathalie Picard and Claude Dugas, C.R.S.N., Université de Montréal, Québec. Extracellular unit activity was recorded from the hand representation area of the primary motor cortex of a macaca fascicularis trained to lift and hold an object within a narrow position window for one second. Neural activity related to the task recorded during control unperturbed trial-livelys was compared to object within a narrow position window for one second. Neural activity related to the task recorded during control, unperturbed trial-blocks was compared to the activity evoked during trials when a predictable perturbation was applied during the holding phase. Two types of grip force responses were observed; a long latency increase that occurred within 100 ms of the stimulus and anticipatory response which appeared prior to the onset of the perturbation. The slip of the object induced by the perturbation was accompanied by a long-latency reflex response in 50% of the cells tested. The latency of the cortical responses ranged from 20 to 105 ms (x= 47.8 ± 21.8). The wide range of observed latencies presumably reflected the diversity of input pathways to motor cortax. The proportion of cells sensitive to the perturbation did not vary. observed latencies presumably reflected the diversity of input pathways to motor cortex. The proportion of cells sensitive to the perturbation did not vary significantly between those receiving cutaneous input (63%) tested by stroking the skin and proprioceptive afferents (60%) assessed by passive joint manipulation. Furthermore, no significant difference existed between the mean latency of neurons with cutaneous (x= 45.0 ms ± 20.2) or proprioceptive (x= 45.3 ms ± 25.4) receptive fields, indicating that both types of afferents participate equally in long-loop servo control mechanisms. Twelve of the 124 neurons tested (10%) showed an anticipatory increase in discharge frequency prior to the perturbation. In addition, a significantly higher proportion of cerebellar cortical neurons tested in the same manner demonstrated anticipatory cerebellar cortical neurons tested in the same manner demonstrated anticipatory responses (29/104, 27%, p < .001). However, the incidence of reflex responses to the perturbation and the mean latencies were equal. This may represent an important difference in the respective contribution of motor cortex and cerebellium to the control of prehension. Supported by the MRC and NSERC of Canada and le Fonds FCAR du Québec.

ROLE OF MOTOR CORTEX IN ACCURACY AND COORDINATION OF PREHENSION IN THE CAT. <u>J.H. Martin, O. Priceman*, & C. Ghez.</u> Ctr. for Neurobiol & Behav, Columbia Univ & NYS Psych Inst, New York, NY 10032.

The present study compares the effects of reversible lesion of different portions of the forelimb representation in the motor cortex on prehension. Cats reached to a baited target well, whose position could be changed, to grasp a morsel of food. Pre- and postcruciate areas of the distal forelimb representation were inactivated by microinjection of muscimol. Changes in limb kinematics due to the inactivation were assessed before and up to 30

limb kinematics due to the inactivation were assessed before and up to 30 min after drug injection. Drug spread was monitored autoradiographically. Prior to injection, prehension and subsequent food retrieval from the target well was accomplished in a coordinated sequence of response components. Following injections in the precruciate distal forelimb representation, aiming of responses to the target became inaccurate. Movements showed consistent directional biases due to defective control of both proximal and distal forelimb segments. Multiple attempts were required to place the paw in the target well and corrections were erratic. required to place the paw in the target well and corrections were erratic. Grasping, supination, and limb retraction, required for food retrieval, became ineffective after injections due to impaired coordination of response fragments rather than to their loss. Animals failed to use somatic sensory information for the fine control of paw movements and often neglected food sucessfully grasped. Injections in the postcruciate distal forelimb representation produced signs of limb weakness but not incoordination. Our results suggest that the distal limb representation of cat motor cortex plays a role in the spatial and temporal coordination of distal and proximal muscles in multijoint movements. The presence of coordination detects and impaired accuracy following inactivation of the pre- but not the postcruciate region supports the hypothesis that there is a dual functional representation of the forelimb in cat motor cortex. PREMOTOR CORTICAL REPRESENTATION OF MOVEMENT DIRECTION. R. Caminiti, P.B. Johnson, C. Galli*, S. Ferraina*, Y. Burnod* and A. Urbano*. Inst. of Physiology, Univ. of Rome, Italy, and Inst. of Neurosciences, Univ. Paris VI, France

The activity of 156 cells was recorded in while monkeys made arm movements of similar directions within different parts of space. In this premotor area, 152/156 (97.4%) cells were directional. As movements traveling along parallel paths were made across the work-space, the preferred directions (PDs) of these cells shifted their orientation in a way which followed the orientation of the arm in space. This suggests that premotor cortical neurons combine information relative to both direction of movement and arm orientation in space. This invariance between cell PD and arm orientation has been observed also in the primary motor cortex. Neuronal movement population vectors, differently from individual cells upon which they are based, did not change their spatial orientation across the work-space, suggesting that they remain good predictors of movement direction regardless of the region of space where movements are made. These results are similar to those obtained in the motor cortex. The use of common mechanisms may facilitate the transformation of information between these areas and suggests a coding of arm movement direction within a coordinate system centered on the shoulder joint.

THE DISTRIBUTION OF PALLIDOTHALAMIC AND NIGROTHALAMIC PROJECTIONS IN THE DOG. B.A. Hannah and S.T. Sakai. Dept. of Anatomy, Michigan State University, East Lansing, MI 48824.

Based on our previous autoradiographic (ARG) tracing studies, the pallidothalamic and nigrothalamic projections appear to distribute to partially overlapping regions of the ventral thalamus in the dog. The purpose of the present study was to determine the extent of anatomical convergence of the pallidothalamic and nigrothalamic projections utilizing a double labeling paradigm. Tritiated amino acid injections were made into the entopeduncular nucleus (EP) at the same time, lectin conjugated horseradish peroxidase injections (WGA-HRP) were made into the substantia peroxidase injections (WGA-HIK?) were made into the substantial nigra pars reticulata (SNr) in the anesthetized dog. The tissue was processed for both ARG and HRP histochemistry using tetramethyl benzidine as the chromogen. The pallidothalamic ARG label was observed in the ventral anterior (VA), ventral medial (VM), parafascicular (Pf) and lateral habenula (LHb) nuclei whereas nigrothalamic HRP label was primarily observed in VA, VM, mediodorsal (MD) nucleus and Pf. The anterograde HRP label was observed in close apposition to the ARG silver grains within portions of VA and in VM and Pf. Although these latter observations suggest that a portion of thalamus may receive converging afterents originating from EP and SNr while other thalamic regions appear to receive separate and parallel inputs from these basal ganglia sources, the possibility of anatomical convergence within the canine thalamus awaits electron microscopic verification. (Supported by NIH Grant 18551).

OF THALAMIC INPUTS TO THE REPRESENTATION IN THE PRIMARY MOTOR CORTEX. LW.
Holsapple, J.B. Preston and P.L. Strick. VA Med. Ctr. and
Depts of Neurosurg. & Physiol., SUNY-HSC @ Syracuse, Syr., NÝ, 13210.

Recently there has been considerable controversy about the origin of thalamic input to the primary motor cortex. There is general agreement that the nucleus ventralis posterior lateralis pars oralis (VPLo), a target of cerebellar efferents, has substantial projections to the arm area of the primary motor cortex. The extent of projections from the nucleus ventralis lateralis pars oralis (VLo), a target of pallidal efferents, has been unclear. To begin to resolve this controversy we made tracer injections into the forelimb representation of the primary motor cortex of macaques (Macaca nemestrina). When injection sites were placed in the central sulcus, at sites where stimulation evoked hand movements, over 60% of the input from the ventrolateral thalamus originated from VLo. In contrast, when injection sites were placed on the crest of the precentral gyrus over 65% of the input originated from VPLo. These observations indicate that both the basal ganglia and the cerebellum 'directly' influence the forelimb area of primary motor cortex. Furthermore, our observations suggest that the basal ganglia has a significant input to the hand representation in the central sulcus. origin of thalamic input to the primary motor cortex. in the central sulcus. EVIDENCE FOR SOMATOTOPIC ORGANIZATION WITHIN THALAMIC NUCLEUS VLo (VENTRALIS LATERALIS PARS ORALIS) <u>I.Ashe</u>,

NUCLEUS VI.0 (VENTRALIS LATERALIS PARS ORALIS) IAShe, J.L. Vitek, M.R. DeLong, G.E. Alexander Dept. of Neurology, The Johns Hopkins Hospital, Baltimore, MD., 21205, USA The thalamic nucleus (VI.0) which receives direct output from globus pallidus is part of the basal ganglia "motor" circuit. While there has been direct demonstration of somatotopic organization at the cortical, striatal, and pallidal stages of the circuit, a somatotopy within VLo has merely been inferred on the basis of the strong topographic nature of the pallidal-thalamic projection. In an effort to determine directly whether VLo is somatotopically organized we did the folowing study. African Green monkeys were conditioned to permit a detailed following study. African Green monkeys were conditioned to permit a detailed sensorimotor exam that included passive joint rotation, muscle palpation, tactile stimulation, and the elicitation of active movements of the limbs and orofacial structures. Electrode penetrations were made in parasagittal planes by an anterior oblique approach and neuronal activity was sampled throughout each penetration. We demonstrated clear evidence for a somatotopic arrangement within VLo in the mediolateral plane, with the arm more medial and the leg lateral. These data show that a strict somatotopic organization is maintained throughout the "motor" circuit. Following induction of experimental parkinsonism with MPTP, the somatotopy within VLo was difficult to discern. This appeared to be the result of substantial changes in the somatosensory response properties of VLo neurons (see companion poster:Vitek el al.)

RETROGRADE AND ANTEROGRADE TRANSNEURONAL TRANSPORT OF HSV1 IN THE PRIMATE MOTOR SYSTEM. M.C.Zemanick and P.L.Strick. V.A. Med. Ctr. and Depts. of Neurosurg. and Physiol., SUNY-HSC @ Syracuse, Syr., NY, 13210.

We have examined the transneuronal transport of 2 strains of Herpes Simplex Virus, Type 1 (HSV1) after their injection into the 'arm area' of the primary motor cortex of cebus monkeys (Cebus apella). The McIntyre-B strain was transported transneuronally in the retrograde direction. Injections of this virus strain resulted in labeled neurons at sites known to project to the arm area of the primary motor cortex (e.g., ventrolateral thalamus, nucleus basalis). In addition, 'second order' neurons were labeled in the deep cerebellar nuclei (dentate and interpositus) and in the globus pallidus (internal segment). These observations support recent suggestions that from both the cerebellum and basal ganglia. In contrast, the H129 strain was transported transneuronally in the anterograde direction. Injections of this virus strain resulted in labeled neurons at sites known to receive input from the arm area of the primary motor cortex (e.g., putamen, pontine nuclei, spinal cord). In addition, 'third order' neurons were labeled in the cord). In addition, furd order neurons were labeled in the globus pallidus (largely external segment) and cerebellar cortex (Granule and Golgi cells). Taken together, these results suggest that the direction of transneuronal transport of HSV1 is strain dependent. We plan to exploit these strain differences to examine cerebellar and basal ganglia loops with cerebral cortex. Support: VA Med. Res. Serv.; USPHS 2957, 24328, 870501.

ALTERED SOMATOSENSORY RESPONSE PROPERTIES OF NEURONS IN THE "MOTOR" THALAMUS OF MPTP TREATED PARKINSONIAN MONKEYS. J.L. Vitek, J. Ashe, M.R. DeLong, G.E. Alexander, Dept. of Neurology, The Johns Hopkins Hospital, Baltimore, M.D., USA. Previous studies in monkeys rendered parkinsonian by injections of the neurotoxin MPTP have found that neurons in the globus pallidus pars interna

neurotoxin MPTP have found that neurons in the globus pallidus pars interna (GPi) show increased sensitivity and decreased specificity of somatosensory responses. The present study was carried out to determine whether similar alterations in neuronal response properties are seen in the thalamic subnucleus VLo (ventralis lateralis pars oralis) which receives direct projections from GPi. African Green monkeys were conditioned to permit detailed sensorimotor examinations including passive joint rotation, muscle palpation, tactile stimulation and the elicitation of active movements of the limbs and oralfacial structures. Using the same microelectrode to map the sensorimotor response properties of VLo neurons both before and after MPTP treatment, it was possible to keep the resulting sets of physiologic maps in precise register. was possible to keep the resulting sets of physiologic maps in precise register. Treatment with MPTP (0.5mg/kg/day x 3 days, i.m.) resulted in severe parkinsonian signs, including bradykinesia, akinesia, rigidity, tremor and postural instability. Prior to MPTP treatment the great majority of VLo neurons responded only to active movement; those few which did respond to somatosensory stimulation did so only to muscle palpation or passive movements about a single joint of the contralateral limb. After systemic MPTP treatment, neuronal somatosensory responses in VLo were far more frequent, more pronounced, and less specific. It was now common to find extremely broad somatosensory fields extending over multiple joints and frequently involving more than one limb. Even ipsilateral responses, which were never seen under normal conditions, were now seen with some regularity. Altered sensorimotor integration in the basal ganglia-thalamocortical "motor" circuit may play a significant role in the pathogenesis of parkinsonian signs. circuit may play a significant role in the pathogenesis of parkinsonian signs.

POSTSPIKE FACILITATION (PSpF) OF EMG ACTIVITY FROM NEURONS IN PRIMATE MOTOR THALAMUS.

K. Mewes and P.D. Cheney. Dept. of Physiol. and R.L. Smith Research Center, University of Kansas Medical Ctr., Kansas City, KS 66103.

In previous work we showed that spike-triggered averaging of EMG activity in the awake monkey can reveal the target muscles of corticospinal and rubrospinal the awake monkey can reveal the target muscles of corticospinal and rubrospinal neurons. Onset latency data coupled with the fact that multiple synapses should diminish cross-correlation peaks, suggest that most postspike facilitations (PSpFs) are mediated by monosynaptic linkages to motoneurons. However, Kasser and Cheney (*I. Neurophysiol*, 53: 959, 1985) showed that postspike suppression (PSpS) is also readily detectable with spike-triggered averaging. PSpS is longer in latency and weaker than PSpF - consistent with mediation by a minimal disynaptic linkage. The purpose of this study, therefore, was to test the extent to which spike-triggered averaging. The purpose of this study, therefore, was to test the extent to which spike-triggered averaging of EMG activity might be effective in detecting non-monosynaptic excitatory linkages to motoneurons. Neurons in motor thalamus were selected for study because they are known to make monosynaptic connections with fast and slow conducting corticospinal neurons; that is, the minimum linkage to motoneurons is disynaptic (Deschenes, M, et al., Meurosci. 7: 2149, 1982). Of 116 neurons recorded in motor thalamus, 12 neurons (10%) showed significant PSpF of rectified EMG activity. The magnitude of thalamic PSpF expressed as %-increase above baseline activity was 4.6±3.2. This compares to 7.0±6.6 for CM and 4.1±1.95 for rubromotoneuronal (RM) cells. The mean onset latency of thalamic PSpF was 6.3±2.1 ms. This compares to 6.3±1.6 ms for CM cells and 5.6±1.9 ms for RM cells. Stimulus-triggered averages computed at the sites of thalamo-motor cells produced poststimulus facilitation in the same muscles showing PSpF from the recorded cell at that site. We conclude that spike-triggered averaging of EMG activity is not limited to the detection of monosynaptic connections. The results of this study show that the method can be effective in identifying less direct synaptic linkages to motoneurons and this will extend its application to the analysis of more central brain structures involved in the control of movement. Supported by NIH grant NS25646.

PLASTICITY IN THE THALAMUS AFTER LESIONS IN THE BASAL GANGLIA. T. De Boom.* K. Kultas-Ilinsky and I, Ilinsky. Department of Anatomy, University of Iowa College of Medicine, Iowa City, IA 52242

We have demonstrated recently (Kultas-Ilinsky et al., 1990, <u>Brain Res.</u>, 511:197-208) that unilateral elimination of the substantia nigra pars reticularis (SNr) and entopeduncular nucleus (EPN - the feline homologue of the medial globus pallidus) induces a several fold increase in the number of [3H]-muscimol binding sites in the area of overlap of nigro- and pallidothalamic projections in the cat thalamus (VA). This increase develops gradually over a period of time (1 year) and may be associated with lesion-induced remodeling of GABAergic systems in the thalamus. In this study we used quantitative morphometry to analyze ultrastructural changes in the same thalamic region after similar lesions at short-term (4 days) and long-term (1 year) survival times with the goal of identification of anatomical substrate of neurochemical changes detected earlier. The results demonstrate that combined SNr and EPN lesions induce synaptic reorganization in the VA that involves proximal parts of dendritic arbors of thalamocortical projection neurons. At 1 year post-lesion, the remarkable changes at secondary dendrites include a 4-fold decrease in the density of large size boutons with symmetric contacts; i.e., typical terminals of basal ganglia afferents, and a 4-fold increase in the number of dendro-dendritic synapses accompanied by an increase in the appositional length of LCN dendrites and the noticeable presence of unusual-looking boutons of unknown origin. Such boutons are also found on primary dendrites, however, in contrast to secondary dendrites, the 3-fold decrease in the density of boutons of basal ganglia origin is not accompanied by increased LCN apposition or an increased number of dendro-dendritic synapses on primary dendrites. The findings suggest a lesion-induced process of synaptic remodeling with involvement of GABAergic local circuit neurons that attempt to replace inhibitory basal ganglia input on secondary dendrites of projection neurons. PARALLEL ARRANGEMENT OF FOREBRAIN CIRCUITS IN THE RAT. 2. VENTRAL STRIATUM, VENTRAL PALLIDUM, AND MEDIODORSAL THALAMIC NUCLEUS. HJ.Groenewegen and H.W.Berendse*. Dept. Anatomy and Embryology, Vrije Universiteit, Amsterdam, The Netherlands.

In the rat a number of parallel systems can be distinguished within the corticostriatal projections from the prefrontal cortex (PFC) to the ventral striatum (VStr) and the projections from the midline (ML) and intralaminar (IL) thalamic nuclei to the PFC and the VStr (see companion abstract: Berendse and Groenewegen). The aim of the present study is to investigate whether the topography in the ventral striato-pallido-thalamic projections is in register with this parallel arrangement. Injections of anterograde (PHA-L) and retrograde (cholera toxin B) tracers were placed in various parts of the VStr and the ventral pallidami (VP). Both the ventral striatopallidal and the ventral pallidamic pathways, the latter primarily directed at the mediodorsal thalamic nucleus (MD), are topographically organized. In the reciprocal ventral striatopallidal projections medial-to-lateral and dorsal-to-ventral coordinates are maintained. The present experiments confirm the previously described topograpy in the projections from the VP to the MD (Groenewegen, 1988, Neuroscience 24:379). The point-to-point relationship in the mentioned projections and in the repriorcal MD-PFC connections is such that, in conjunction with the results discussed in the companion abstract, a number of distinct parallel circuits can be composed that each involve different parts of the PFC, the VStr, the VP, and the MD. Moreover, the topographical organization of the thalamoctrical projections originating from the ML and IL nuclei is in register with these parallel circuits. The present data in the rat validate and add to the previously formulated concept of parallel basal ganglia-thalamocortical loops in the primate (Alexander et al., 1986). AN ELECTRON MICROSCOPIC STUDY OF RETROGRADELY LABELED PROJECTION NEURONS AND THEIR RELATION TO THE EPENDYMAL LAYER OF THE THALAMIC PARAVENTRICULAR NUCLEUS. G Balercia*, M. Bentivoglio and L. Kruger. University of Verona, Italy and UCLA Medical Center, Los Angeles, CA. Neurons of the thalamic paraventricular complex, retrogradely labeled by fluorescent dyes from the amygdala, extend numerous dendrites towards the ventricular sur-In order to determine the relation of these processes to the cerebrospinal fluid, they were labeled retrogradely with horseradish peroxidase (HRP) and visualrized by a reaction product suitable for electron microscopy. The glial variants of this region are less diverse than those in the basal III ventricle, revealing a fairly uniform ependymal layer and a few "dark" ependymocytes lacking descending tanycyte processes. The subependymal layer contains scattered typical oligodendrocytes and astrocytes, the latter generally forming a thin boundary between labeled dendrites and ependyma ependyma. Subependymal HRP-labeled dendrites containing lipid and lysosome-like dense bodies are often surrounded by membranous whorls of reactive astrocytes. Neurons and their neurites are isolated from the surface by glial and ependymal elements exhibiting a variety of interdigitating and junctional membrane characteristics including sinuous sheet-like astrocyte processes and basal ependymocyte caveolar zones. AN ANALYSIS OF TRANSIENT STRIATOTHALAMIC PROJECTION IN THE RAT. T. Kono, M. Takada and S. T. Kitai. Department of Anatomy and Neurobiology, College of Medicine, The University of Tennessee, Memphis, Memphis, TN 38163.

These studies further characterize the striatothalamic (ST) projection reported to exist only during early postnatal period (Hattori et al., Dev. Brain Res. in press). Its development was examined by injecting Fluoro-gold (FG) into the thalamus at various developmental stages (E17, 19, P0, P3, P6) and animals were perfused one day after each injection. Results indicated ST projection emerges by E17 and disappears by P7. Bromodeoxyuridine immunocytochemistry combined with FG tracing revealed that ST cells undergo the final mitosis as ealy as E15. Immunocytochemical analyses on P0 injection/P1 sacrifice showed that ST cells express GABA and leu-enkephalin but not substance P, and are organized in a discrete patch-like manner. A retrograde double labeling using True blue and Diamidino yellow also demonstrated that some of ST cells issue axon collaterals to the substantia nigra. Their distribution also matches well with tyrosine hydroxylase- and substance P-immunoreactive zones in the striatum. We infer from these data that transient ST projection might play a crucial role in the compartmentalization in the striatum.

might play a crucial role in the compartmentalization in the striatum. The retrograde studies of ST cells after short term (P0/P1 and P6/P7) and long term (P0/P7) survivals showed that ST cells are no longer present at short term survival of P6/P7 but can still be present though less in number at long term survival of P0/P7. These results indicate that both cell death and collateral retraction are occurring development of ST projection. (Supported by NIH grants NS 20702 and NS 23886 to S. T. Kitai).

PARALLEL ARRANGEMENT OF FOREBRAIN CIRCUITS IN THE RAT. 1. PREFRONTAL CORTEX, MIDLINE AND INTRALAMINAR THALAMIC NUCLEI, AND VENTRAL STRIATUM. H.W.Berendse* and H.J.Groenewegen (SPON: European Neuroscience Association). Dept. Anatomy and Embryology, Vrije Universiteit, Amsterdam, The Netherlands.

On the basis of anatomical and physiological data in the primate, Alexander et al. (Ann.Rev.Neurosci. 9:357, 1986) have distinguished a number of parallel, functionally different basal ganglia-thalamocortical circuits. The objective of the present study is to unravel the forebrain circuitry that involves the limbic lobe-innervated parts of the basal ganglia in the rat. The corticostriatal projections from the prefrontal cortex (PFC) to the ventral striatum (VStr) and the projections from the midline (ML) and intralaminar (IL) thalamic nuclei to the VStr and the PFC were studied by means of anterograde (PHA-L) and retrograde (cholera toxin B) tracing techniques. The projections originating from cytoarchitectonically and presumably functionally different regions of the PFC to the VStr are topographically organized, such that dorsal-to-ventral and medial-to-lateral coordinates are maintained. A similar topography characterizes the ML and IL thalamostriatal projections (Berendse and Groenewegen, 1990, J.Comp.Neurol., in press). Furthermore, each of the ML and IL nuclei projecting to the VStr has a restricted terminal field in the PFC. A comparison of the organization of the different pathways reveals that in the VStr the projections of individual ML and IL nuclei converge with those of their PFC target areas. Thus, a number of parallel systems can be identified that each comprise distinct parts of the PFC, the ML and IL thalamic nuclear complex, and the VStr. In a companion abstract (Groenewegen and Berendse) the organization of the ventral striatopallidofugal pathways is discussed in relation to this parallel

EFFECT OF THALAMIC MICROINJECTIONS OF APOMORPHINE AND MUSCIMOL ON THE ACOUSTIC STARTLE STARTLE RESPONSE AND OTHER BEHAVIORS. K.A. Young¹. P.K. Randall² and R.E. Wilcox². ¹Dept. of Pharmacology, Texas A&M College of Medicine, Temple, TX, 76508 and ²Dept. of Pharmacology, Univ. of Texas, Austin, TX 78712.

The role of DA neurotransmission in the rodent thalamus has not been systematically studied. Rats were administered apomorphine (400 ng), vehicle or muscimol (50 ng) through indwelling cannulae. Catalepsy, sensory asymmetries, and acoustic startle response with prepulse inhibition were measured following drug administration. Bilateral microinjections of apomorphine (APO) into the ventromedial (VM) thalamus caused a loss of prepulse inhibition of

Bilateral microinjections of apomorphine (APO) into the ventromedial (VM) thalamus caused a loss of prepulse inhibition of the acoustic startle response, while unilateral APO microinjections into the mediodorsal and posterior thalamus increased the amplitude of startle responses without producing a loss of prepulse inhibition. Loss of prepulse inhibition after APO microinjection was site specific to the VM nucleus and occurred 10-15 minutes postinjection, but not at later testing periods (30-35, 50-55, 70-75 min). Counterbalanced injections of vehicle produced no effect on startle or other behaviors. The profound catalepsy produced by VM microinjections of muscimol did not interfere with the expression of normal startle behavior. These findings are consistent with the observed pattern of prepulse inhibition loss after systemic APO administration. Thus, our data suggest a role for thalamic DA neurotransmission in the modulation of the acoustic startle response.

CONVERGENCE OF PRELIMBIC AND MOTOR CORTICAL INFORMATION IN THE GLOBUS PALLIPUS AND SUBTHALAMUS OF RATS. Lawrence J. Ryan and Kevin B. Clark., Dept. Psychology, Oregon State University, Corvallis, OR 97331-5303.

Do projections from the neostriatal striosomes and matrix converge? Since

both matrix and striosomes possess neurons that project to the globus pallidus, information from these systems may converge directly there or indirectly via pallidal-subthalamic-pallidal connections. Our evidence suggests both types of convergence may occur.

palidad-subthalamic-palidal connections. Our evidence suggests both types of convergence may occur.

Prelimbic cortex, which projects primarily to striosomes, (PL; Cg3 of Paxinos and Watson, 1986) and frontal agranular cortex (FRI and FRII, primarily to matrix) were stimulated with bipolar stainless steel electrodes (0.3 and 0.7 mA, 0.2 ms monopolar pulses) while single neurons were recorded in globus pallidus (GP) or subthalamus (ST). GP neurons responded with various patterns of inhibition and excitation of firing after cortical stimulation: 38.5% (15 of 39) responded to FRI, 77.2% (44/59) to FRII, and 29.3% (22/75) to PL. Convergence: 19.0% (4/21) for FRI-FRII, 5.1% (2/39) for FRI-PL, and 26.3% (15/57) for FRII-PL. 9.5% (2/21) responded to all three.

Subthalamic lesion (kainic acid) 1) increased the duration of induced inhibition (e.g. to FRI: 18.24 vs 49-9ms, 1(24) =2.59, p<0.02), and 2) generally reduced excitatory responses, completely eliminating all late (13+ms) excitation not preceded by inhibition. These late responses may reflect reciprocal GP-ST interactions since ST cells show inhibition and excitation that follows GP excitation and inhibition by several ms. GP firing rate was not reduced by ST lesion (24.95 vs 21.71 Hz, t(105) = 1.33, ns). Antidromically identified (from GP) ST neurons (N=29) responded to FRI (65.5%, 19 of 29), to FRII (62.1%) and to PL (10.3%). Responses to PL were always slow (>22ms). The responses to PL (10.3%). Responses to PL were always slow (>22ms). The responses revealed convergence from the cortex: FRI-FRII (44.8%), FRI-PL (10.3%), FRII-PL (10.3%), and all three (10.3%). Thus information from the striosomes and matrix may converge in the globus pallidus and in the subthalamus.

THE STRIATO-PALLIDO-STRIATE PATHWAY IN THE RAT BRAIN. DEMONSTRATION OF RECIPROCAL MONOSYNAPTIC CONNECTIONS. M.N. Williams* and R.L.M. Faull.

Department of Anatomy, University of Auckland, New Zealand.

Procedures utilizing combined light microscopic (LM) and electron microscopic (EM) techniques were used to demonstrate direct monosynaptic connections between neuronal pathways in the basal ganglia of the rat brain. The horseradish peroxidase technique was used singly or in combination with the anterograde axonal degeneration technique to investigate the synaptic organization of the pathways interconnecting the striatum and globus pallidus. Small (5-10 nl) injections of 2% HRP-cholera toxin or 5% HRP-lectin dissolved in 1% kainic acid (a neurocytotoxin known to destroy neurons and spare fibres of passage), were injected into the right striatum or globus pallidus. Two days later the animals were killed by transcardiac perfusion of fixative. Serial sections through the striatum and globus pallidus were processed for HRP cytochemistry and embedded in Epon. Blocks taken from regions containing labelled striatal or pallidal neurons were reembedded, thin sectioned and examined in the electron microscope. The results showed that after combined injections of neurocytotoxin and HRP-lectin into the striatum, degenerating injections of reerrocytotoxin and HHP-lectin into the stratum, degenerating boutons in the globus pallidus formed synapses on the soma and dendrites of HRP-labelled pallidostriate neurons. Also, after injections of HRP-cholera toxin into the globus pallidus, HRP-labelled boutons in the striatum made synaptic contact with small spinous HRP-labelled dendrites. These findings demonstrate the existence of two monosynaptic links: one in the globus pallidus between striatopallidal axon terminals and pallidostriate neurons and the other in the striatum between pallidostriate axon terminals and striatopallidal neurons.

EVIDENCE FOR A PROJECTION FROM THE GLOBUS PALLIDUS TO THE ENTOPEDUNCULAR NUCLEUS IN THE RAT. A.E. Kincaid, S.W. Newman, A.B. Young and J.B. Penney Jr., Dept. of Anatomy and Cell Biology and Dept. of Neurology, University of Michigan, Ann Arbor MI 48109.

The entopeduncular nucleus (EP) of the rat is considered to be one of the major

re entoperuncular nucleus (EP) of the rat is considered to be one of the major sources of outflow from the basal ganglia. It projects to the ventroanterior and ventrolateral complex and the parafascicular nuclei of the thalamus, the habenula and the pedunculopontine tegmental nucleus (PPT). Afferents to the EP include the striatum (CP), the subthalamic nucleus (STN) and the PPT. We present evidence from both retrograde and anterograde tract tracing studies that the rat globus pallidus (GP) sends a substantial, topographic projection to the EP. Fluoro-gold (FG), a fluorescent retrograde tracer, was iontophoretically injected into the EP of 11 adult Sprague-Dawley rats and *Phaseolus vulgaris*leucoagglutinin (PHAL), an anterograde tracer, was injected into the GP of 5 Sprague-Dawley adult rats. Following a 4-10 day survival period the animals were transcardially perfused with 4% paraformaldehyde and 40 um coronal and sagittal brain sections were cut on a freezing microtome. The FG sections were mounted, dehydrated, coverslipped with DPX and viewed on a epifluorescence microscope under a UV filter. The PHAL sections were immunohistochemically processed using the Vectastain ABC Elite Kit and viewed under brightfield and darkfield using the Vectastan ABC Elite Kit and viewed under brightfield and darkfield conditions. All FG injection sites that included some part of the EP resulted in retrogradely labeled neurons in GP. PHAL injection sites restricted to GP resulted in anterogradely labeled fibers, boutons en passant and apparent terminals in EP. The projection from GP to EP appears to be topographically organized with dorsal parts of GP projecting to dorsal EP and medial GP projecting to medial EP. This projection may need to be incorporated into models of how the basal ganglia influence behavior. Supported by NIH NS20629 to SWN and NIH NS20629 to APM cod JIPS. and NIH NS19613 to ABY and JBP.

MOTOR EFFECTS FOLLOWING ELECTRICAL STIMULATION OF THE GLOBUS PALLIDUS IN RATS. Y.E. Anagnostakis*, E. Miliaressis and C. Spyraki, Lab. of Pharmacology, Medical School, University of Crete, 71409 Iraklion, Greece.

Although the globus pallidus is believed to play an important role in the expression of molary behaviors.

tor behaviors, a systematic mapping investigation of this area has not yet been performed in the rat. In this study we present a summary of behavioral reactions obtained by electrical intrapallidal stimulation using moveable electrodes (Kinetrods, model SME-01, Ottawa) in 11 freely moving rats. The electrode was lowered by single steps of 0.2 mm, from the dorsal to the ventral pallidus, at lateral coordinates varying from 2.4 to 3.2 mm from the midline. Each brain site was to 3.2 mm from the midline. Each brain site was stimulated with single trains (0.4 sec duration) of cathodal rectangular pulses of fixed intensity (200 μ A) and width (0.1 msec). The effects of the stimulation were noted at each brain site for pulse frequencies varying from 5 to 50 pulses/train. The following reactions were observed, depending on the vertical and lateral coordination with the standard contraction to the standard coordination. tes: head turning, forelimb retraction, vibris-sae movement and behavioral inhibition. Direc-tional reactions were always contralateral to the stimulated side.

EFFECT OF SUBTHALAMIC NUCLEUS ABLATION ON GLOBUS PALLIDAL CELLS AGAINST KAINIC ACID NEUROTOXICITY. M. Takada, T. Kono and S. T. Kitai.
Department of Anatomy and Neurobiology, College of Medicine, The
University of Tennessee, Memphis, Memphis, TN 38163.

University of Tennessee, Memphis, Memphis, TN 38163.

Recent anatomical and physiological evidence has indicated that subthalamic nucleus (STN) cells are excitatory to their targets and glutamate is considered to be a likely neurotransmitter involved. We have tested this hypothesis by examining the kainic acid (KA)-induced cell loss in the globus pallidus (GP) after STN ablation.

Adult male albino rats (Wistar, 250-300 g) were used. STN lesions were made by injecting KA (5 mmol) unilaterally into the nucleus.

One, four, or twelve weeks later, the animals received KA (5 nmol) injections bilaterally into the GP. After a survival of 3-4 days, formalin-fixed brains were stained with cresyl violet. On the control formalin-fixed brains were stained with cresyl violet. On the control side where the STN was intact, GP cells were almost completely depleted with KA. In contrast, KA-induced GP cell loss was limited to only 20% (i.e. 80% spared) on the side where the STN was lesioned. These findings were consistently observed regardless of time intervals between STN and GP lesioning. On the other hand, decortication resulted in 60% (i.e. 40% spared) of GP cell loss. A combination of STN lesioning and decortication did not change the KA-induced GP cell loss with STN lesioning alone. These observations were interpreted to indicate that glutamatergic inputs to the GP are derived predominantly from the STN and cortical afferents to the GP share glutamatergic receptors with STN afferents. to the GP share glutamatergic receptors with STN afferents.

INTRACELLULAR RESPONSES RECORDED IN THE GLOBUS

INTRACELLUIAR RESPONSES RECORDED IN THE GLOBUS PALLIDUS AFTER STIMULATION OF THE FRONTAL CORTEX (CX). THE NEOSTRIATUM (Str). THE SUBSTHALAMIC NUCLEUS (STH) AND THE SUBSTANTIA NIGRA (SN). H. Kita. Dept. of Anatomy and Neurobiology. College of Medicine, Univ. of Tennessee Memphis, Memphis, TN 38163.

Responses of GP neurons to stimulation of the CX, the Str, the STH, and the SN were intracellularly recorded in rats anesthetized with urethane (1.2 g/Kg, 1.p.) supplemented with a Ketamine/Zylazine mixture. In some experiments, animals were immobilized by gallamine. Stimulus electrodes were bipolar stainless steel pins separated by 0.8 mm and insulated (on all but their tips) with epoxy. The stimulus current was less than 0.3 mA. Recording glass microelectrodes were filled with 0.5 M KCH_3SO4 or KCl and 4% HRP in 0.05 M Tris buffer (pH 7.6). Neurons with membrane potential greater than 40 mV and spike amplitude greater than 50 mV were analyzed. Most of the GP neurons recorded were antidromically activated by STH and SN stimulation. Approximately one half of the GP neurons were also antidromically activated by STH stimulation. Results suggest that GP neurons send axons to multiple targets. Stimulation of the CX or Str evoked a sequence of orthodromic responses consisting of initial short duration EPSPs, short duration IPSPs, and late EPSPs. Stimulation of the STH and the SN evoked EPSPs which overlapped IPSPs. All of the IPSPs were decreased in amplitude by intracellular injection of Cl ions and blocked by systemic application of picrotoxin. Chronic decortication was made in some animals 5 days prior to the recording. In these animals, Str stimulation evoked small short latency IPSPs, and late EPSPs. The responses of GP neurons to STH and SN Stimulation in decorticated rats were very stimilar to those seen in intact ones. (Supported by NIH grant NS- 25783)

CONTEXTUALLY DEPENDENT ACTIVITY IN GLOBUS PALLIDUS. P Brotchie, R. Iansek and M.K. Horne, Department of Clinical Neurophysiology, Alfred Hospital, Prahran, 3181, Australia.

Single cell activity was recorded from the globus pallidus of awake behaving monkeys. Pallidal neurons were found to increase or decrease their background discharge phasically in relation to wrist movements. In approximately half the pallidal neurons which displayed movement related activity, the magnitude of the response was dependent on the contextual setting of the task. If the animal was unaware of the direction of the upcoming motor response, the phasic movement related discharge was diminished in these cells.

Phasic activity was also recorded at the end of the movement task in approximately one third of pallidal neurons. We called this neuronal response "delayed activity" because it occured well after the movement. During the performance of a task containing two ballistic movements in sequence, many cells displayed delayed activity well after the first movement, immediately prior to the cue for the second movement. This activity was often present in a cell, only when the second target movement was expected to occur in a particular direction. Therefore, as with the phasic movement related activity, delayed activity was dependent on the contextual setting of a task for its expression.

We hypothesize that the contextually dependent phasic

activity of pallidal cells represents internal cues which assist in the switching between motor programs in sequential tasks.

BEHAVIORAL AND NEURONAL EFFECTS OF GABA AGONIST AND ANTAGONIST INJECTED LOCALLY IN THE GLOBUS

NOTATIONS INTECTED LOCALLY IN THE GLOBUS
PALLIDUS OF INTACT MONKEYS. L. Tremblay and M. Filion.
Neurobiology Res. Ctr, Laval Univ., Québec, Qué., Canada.
We have shown previously that akinesia and muscular rigidity, induced in monkeys by the neurotoxin MPTP, are correlated with an induced in monkeys by the neurotoxin MPTP, are correlated with an increased neuronal activity in the internal segment of the globus pallidus (GPi) but with a decrease in the external segment (GPe). Apomorphine suppressed the signs of parkinsonism and induced dyskinesia (repetitive movements of choreic type), which were correlated inversely with abnormally low GPi and high GPe activities. The objective of the present work was to reproduce those behavioral and neuronal alterations in intact monkeys by means of injections of the GABA agonist muscimol and antagonist bicuculline locally within the GP. Bicuculline (30 mmol, 0.5-2 μ L) greatly increased the activity of GPe neurons near (0.3-2 mm) the injection site and induced contralaterally localized dyskinesia with thresholds lowest in the caudal GPe. Simultaneously. dyskinesia, with thresholds lowest in the caudal GPe. Simultaneously, in the ipsilateral GPi, neurons with abnormally low activity were surrounded by others with abnormally high activity. Consecutive injections of muscimol (10 mmol, 1 µL) in these area of low GPi activity induced similarly localized dyskinesia, whereas the localizations were different when muscimol was injected in the surrounding area of high GPi activity. The dyskinesia induced by bicuculline in the GPe could be suppressed and replaced by contralateral akinesia following injection of muscimol at the same site. And then, GPi neurons that had been hypoactive during dyskinesia, became hyperactive during akinesia. (Supported by the FRSQ and MRC of Canada).

ELECTROPHYSIOLOGY OF THE GLOBUS PALLIDUS NEURONS: AN IN VITRO STUDY IN GUINEA PIG BRAIN SLICES A. Nambu and R. Llinás. Dept. of Physiology and Biophysics, New York Univ. Med. Ctr., New York, NY 10016.

In vivo, globus pallidal (CP) neurons are known to discharge at a high frequency and to change their firing rate in relation to limb and facial movements (DeLong et al, J. Neurophysiol. 53: 530, 1985); little is known, however, about the ionic mechanism responsible for this behavior. Intracellular recordings were obtained from GP in brain slices from adult guinea-pig. Two classes of neurons were identified on the basis of their membrane properties. The first type, which includes the majority of neurons recorded, generated a slow rising, all-or-none low threshold response upon direct depolarization from a hyperpolarized membrane potential. This response could trigger a short spike burst and a rebound depolarization that would generate another spike such that the cell could fire at 4-6Hz. The low threshold response was inactivated by membrane depolarizations, was TTX insensitive, and was blocked by CoCl₂, suggesting that it is generated by activation of a low threshold calcium conductance (Llinás and Yarom, J. Physiol. 315: 549, 1981). Prolonged (300ms) direct depolarization elicited rhythmic repetitive firing which often exhibited a prominent accommodation. These neurons had a fast, transient K^* -dependent current (A-current) and input resistances $\geq 50~M\Omega$. The second type of neuron also demonstrated a fast, input resistances $\geq 50~M\Omega$. The second type of neuron also demonstrated a fast, transient K*-current but was characterized by a low input resistance ($\leq 50~M\Omega$), and showed neither low threshold calcium spikes nor accommodation. The 4-6 Hz oscillatory firing seen in the first type of cell may be related to the burst activity which has been reported in the GP of monkeys with Parkinsonism induced by MPTP (Miller and DeLong, *Adv. Beh. Biol.* 32: 415, 1987). Supported by grant 13742 from NINDS and the Naito Foundation.

IMMUNOHISTOCHEMICAL STUDY OF THE PALLIDAL COMPLEX IN SYMPTOMATIC AND ASYMPTOMATIC MPTP-TREATED MONKEYS, NORMAL HUMANS, AND PARKINSON'S DISEASE PATIENTS. S. Dacko, M.G. Smith* and J.S. Schneider. Dept. of Neurology, Hahnemann University
School of Medicine, Philadelphia, PA. 19102.
The globus pallidus in the normal macaque monkey as well as in the normal

human contains many tyrosine hydroxylase (TH) immunoreactive fibers. Met-enkephalin, substance P and serotonin, are also localized to the pallidum, as enterplanti, substance r and sectionality, are also recarried to the particular, as previously described by others. The present study examines the extent to which these different neurochemical innervations of the pallidal region might differ between symptomatic and asymptomatic and symptomatic participations of the pattern of these pallidal Parkinson's disease (PD) panents and whether the pattern of these pathean innervations differs in monkeys vs. humans. Four monkeys received low dose MPTP over several months, sustained extensive damage to the ventral mesencephalon, had large striatal dopamine depletions, yet remained asymptomatic for a significant motor disorder. These animals had relative sparing of GPi TH immunoreactivity with significant loss of GPe and striatal TH staining. Animals given large doses of MPTP over a short period of time also had large striatal given large doses of MPTP over a short period of time also had large striatal dopamine depletions and loss of mesencephalic dopamine neurons, but were severely parkinsonian. These animals had some loss of GPI TH immunoreactivity but a relative sparing of this innervation compared to the more extensive loss of GPe and striatal TH staining. In contrast, humans with PD had extensive loss of TH immunoreactivity throughout pallidal and striatal regions. The possibility exists that the relative sparing of the dopamine innervation of the GPI in MPTP-exposed monkeys may at least partially contribute to either recovery from the effects of MPTP or the ability to remain motor asymptomatic despite severe damage to the nigrostriatal dopamine system. These results also suggest a major difference in the neuropathology of MPTP-induced parkinsonism in the monkey and PD in man. Changes (or lack thereof) in the other neurochemical systems innervating the pallidal region will also be discussed. region will also be discussed.

HIPPOCAMPUS AND AMYGDALA: NEUROCYTOLOGY

181.1

SELECTIVE REGULATION OF DYNORPHIN LEVEL IN RAT HIPPOCAMPUS BY GLUCOCORTICOIDS. P. H. K. Lee, L. T and J. S. Hong. LMIN, NIEHS/NIH, Research Triangle L. Thai, and J. S. Hong. Park, NC 27709.

The hippocampus, a brain region involved in learning, memory and a number of neurological diseases, is a target of adrenal hormones and it may also play a role in the regulation of the endocrine functions of the hypothalamic-pituitary-adrenal axis. In this study, we examined the effects of adrenocorticoids in the regulaexamined the effects of adrenocorticoids in the regulation of the opioid system in rat hippocampus. Male Fischer-344 rats were either bilateral adrenalectomized or sham-operated under light methoxyflurane anesthesia. Hippocampal dynorphin A(1-8) immunoreactivity (DYN-IR), determined by radioimmunoassay, remained unchanged 24 hr after adrenalectomy (ADX), but it was significantly reduced by 19% 1 week post ADX. A gradual and further reduction of hippocampal DYN-IR was observed in ADX rats, decreased by 43% and 58% at 1- and 2-month post ADX, respectively. Immunohistological study revealed a marked decrease of DYN-IR in the mossy fiber. These decreased DYN-IR were restored by dexamethasone These decreased DYN-IR were restored by dexamethasone treatment, suggesting glucocorticoids play an important role in modulating the dynorphin level in the hippocampus. No changes in hippocampal Met-enkephalin immuno-reactivity were detected in ADX animals, suggesting that glucocorticoids are essential and selectively regulated. late the dynorphinergic system in rat hippocampus.

NORADRENERGIC (NA) ENHANCEMENT ON HIPPOCAMPAL NORADRENERGIC (NA) ENHANCEMENT ON HIPPOCAMPAL SYNAPSES AFTER NEONATAL ADMINISTRATION OF 6-HYDROXYDOPAMINE (6-OHDA) IS DUE TO AN INCREASE OF \$2-ADRENERGIC RECEPTOR NUMBER. H.-M. Hwang, W.-H. Tsai, Y.-P. Lee, and T. H. Chiu*. Depts. of Anatomy & Physiology, National Yang-Ming Medical College, and IBMS Academia Sinica, Taipei, Taiwan, R.O.C.

In order to examine the NA modulation on the hippocampal function, synaptic efficacy was studied on the hippocampal slices of animals with NA depletion. Rats were injected s.c. with mg/kg of 6-OHDA dissolved in 0.9% saline containing 0.04% L-ascorbic acid for 4 days starting from the day of birth, while the control animals received an equal volume/weight of vehicle. Experiments were performed at the postnatal 120-150 days. \$2-adrenergic receptor immunohistochemistry revealed an increase of receptor number, while Dopamine-\$-hydroxylase immunohistochemistry indicated 90% reduction of immunonistochemistry indicated 90% reduction of NA innervation. Electrophysiology showed a faster decay of potentiation on CA1 pyramidal cells after NE depletion, but greater response to \$\mathbb{G}\$-adrenergic agonist. Study on expression of \$\mathbb{S}\$-adrenergic receptors related to NA modulation on hippocampus is in progress. (supported by NSC79-0412-B010-19 R.O.C.)

INTRACELLULAR pH REGULATION IN SINGLE MAMMALIAN HIPPO-CAMPAL CA1 NEURONS. G. Boyarsky, T.R. Cummins*, G.G. Haddad, and W.F. Boron*, Depts. of Cell. and Molec. Physiol. and Pediatrics, Yale U. Sch. of Med., New Haven, CT 06510.

Intracellular pH (pH;) was measured in single dissociated rat hippocampal cells (CA1) using a microscope-based fluorimetric technique and the pH-sensitive dye BCECF. In the nominal absence of CO₂/HCO₂, two distinct patterns of pH_i regulation were observed. In six "high-pH_i cells", the initial pH_i was 7.47 ± 0.05 and the cells recovered very rapidly from an NH₄*-induced acid load (dpH_i/dt of $57.5 \pm 13.3 \times 10^{-4} \text{ pH/sec}$ at pH_i 7.2). In ten "low-pH_i cells", the initial pH_i was 6.83 ± 0.06 and the cells recovered very slowly from an NH₄+-induced acid load $(dpH_{i}/dt \text{ of } 9.1 \pm 2.2 \text{ x } 10^{-4} \text{ pH/sec at } pH_{i} \text{ of } 6.4 \text{ and } 5.5 \pm 2.8 \text{ x } 10^{-4} \text{ pH/sec at}$ pH; of 6.8). Similar results were obtained for cells isolated from 7-, 11-, 12-, 25-, and 26-day rats. In nine experiments, cells were acidified by removal of Na⁺ (replaced by N-methyl-D-glucammonium). In seven of the nine cells, from both "high-p \mathbf{H}_{i} " and "low-p \mathbf{H}_{i} " groups, p \mathbf{H}_{i} spontaneously recovered in the continued absence of Na⁺, over a period of ~3 to 15 minutes. The "high-pH; cells" probably possess a potent acid extrusion mechanism, whereas the "low-pH; cells" have only a moderate capacity for acid extrusion. The pH, recovery in the absence of $\mathrm{Na^+}$, which occured in both "high-pH $_i$ " and "low-pH $_i$ " cells, has been observed previously in rabbit S3 proximal tubules and may be due to a H+-pump. This Na+-independent mechanism may play an important role in pH; regulation in neurons, and be a more general phenomenon than previously thought.

IDENTIFICATION OF DYNORPHIN-POSITIVE CELLS IN HIPPOCAMPAL CELL CULTURES. X. He*, P. Lee, R. Tuom
L. Thai, B.Culver, E. Mar*, W. Zhang* and J. Hong.
LMIN, NIEHS/NIH, Research Triangle Park, NC 27709.
The purpose of this study was to examine dentate

The purpose of this study was to examine dentate gyrus (DG) cell cultures as a model system to study dynorphin (DYN) regulation. The hippocampus (HC) was removed from rat pups between 1-12 days of age, the DG was dissected free from HC, and cells from these areas were dissociated and cultured. Localization of DYN and mRNA encoding the peptide were studied using, respectively, immunocytochemical and in situ hydridization

Results from studies of different culture conditions showed that DG provided more DYN+ cells than the rest of the HC and that these cells were most prominent after 2 wks in culture. Cultures from 7 day old pups yielded more DYN+ cells than those from younger or older rats. Also, the optimal concentration of corticosterone for supporting DYN+ cells was 1 pmol, and 2% fetal bovine serum was more effective in maintaining these cells than serum-free media. Ara-C suppressed glial cell growthe but also decreased DYN+ cells. Together these studies demonstrate DYN is localized in cells cultured from DG and that they exhibit mRNA encoding DYN, indicating the ability to synthesize this peptide. It seems reasonable to propose that most of these DYN+ cells are derived It seems reasonable from DG granule cells.

INTRAHIPPOCAMPAL ADMINISTRATION OF NMDA ALTERS OPIOID PEPTIDE AND C-FOS LEVELS IN THE RAT I.E. Helton and J.F.McGinty. Dept. of Anatomy and Cell Biology. East Carolina University School of Medicine, Greenville.NC 27858.
This study examined the effects of N-Methyl-D-aspartate (NMDA)

on enkephalin, dynorphin and c-fos expression in the hippocampus. Rats were implanted with a 24 g stainless steel guide cannula (AP -5.2, ML -5.6, DV -2.5, <2°) and handled daily for 1-2 wk. received at least 2 saline injections prior to the day of the experiment to habituate them to restraint during injection. was necessary to reduce non-specific induction of fos. On the day of the experiment rats received 0.9% saline or 120 nmols NMDA in 0.5 μ 1 into the ventral hippocampus. NMDA treated rats exhibited wet dog shakes, forelimb clonus, hypersalivation and hyperactivity which lasted for 1 to 2 hours after injection. Rats were perfused with buffered 4% paraformaldehyde 1,3,8, or 24 hr after injection. Frozen sections were cut at 50 µm and collected for immunocytochemistry. At 1h a significant rise in fosimmunoreactivity (IR) in the dentate granule cells (DGC) was observed while pyramidal cells in the CA3 and CA1 fields showed little staining. By 3h fos-IR in the DGC and the CA3 and CA1 pyramidal cells was high. The entorhinal and piriform cortices, amygdala, hypothalamic and thalamic nuclei also exhibited a significant rise in for IR. At 8h and 24h, for IR remained significantly elevated in NMDA treated rats vs. control rats. NMDA-induced elevation of for preceded the decrease in opioid peptide IR levels in the hippocampus. Accompaning changes in mRNA levels are being investigated. Supported by DA03982.

MODULATION OF SYNAPTIC EFFICACY IN FIELD CA1 OF THE RAT HIPPOCAMPUS BY FORSKOLIN.

L. E. Chavez-Noriega and C. F. Stevens. The Salk Institute, Howard Hughes Medical Institute, La Jolla, CA 92037.

An increase in intracellular cyclic AMP levels has been reported to enhance synaptic excitation and reduce the threshold for the induction of long-term potentiation (LTP) in the dentate gyrus and field CA3 of the hippocampus (Stanton and Sarvey, 1985, Brain Res., 361:276; Hopkins and Johnston, 1988, J.Neurophysiol., 59:667).

We have studied the effect of the direct activator of adenylate cyclase forskolin, on field potentials evoked in area.

adenylate cyclase, forskolin, on field potentials evoked in area CA1 by stimulation of Schaffer/commissural fibres. Transverse hippocampal slices were prepared and incubated using standard procedures.

standard procedures.
Forskolin (10-50 uM) produced a dose-dependent increase in the early field EPSP slope (50 uM: mean +/- SEM: +22 +/- 10%, n=7) and population spike amplitude (+88 +/- 19%). These effects were potentiated in the presence of IBMX, a phosphodiesterase antagonist and adenosine receptor blocker (50 uM; EPSP: +40 +/- 7%; population spike: +142 +/- 37%, n=5). The inactive analogue 1,9 dideoxy forskolin (50 uM, n=3) did not affect the EPSP slope (-3 +/- 3%) nor the PS amplitude (0 +/- 0%).
These results suggest that activation of adenylate cyclase may modulate synaptic efficacy in CA3 - CA1 synapses

cyclase may modulate synaptic efficacy in CA3 - CA1 synapses of the hippocampus.

COMMISSURALLY-PROJECTING HIPPOCAMPAL

COMMISSURALLY-PROJECTING HIPPOCAMPAL DENTATE BASKET CELLS ARE A SUBPOPULATION OF GABA NEURONS IMMUNOREACTIVE FOR PARVALBUMIN J.H. Goodman and R.S. Sloviter, Helen Hayes Hosp., W. Haverstraw, NY 10993 and Columbia Univ., New York, NY 10032 Fluorogold (FG) was used to identify commissurally-projecting dentate neurons. Injections (0.05-0.3ul, 4%) were made in the dentate of 15 male Sprague-Dawley rats. Contralateral FG fluorescence was examined in 30u-thick Vibratome fluorescence was examined in 30µ-thick Vibratome sections. Consistent with previous studies, we noted FG in many hilar neurons and CA3 pyramidal cells. FG was unexpectedly seen in neurons with the morphology of pyramidal-shaped basket cells of the granule cell layer. Each section was photographed and then sequentially stained immuno-cytochemically for parvalbumin (PV) and GABA. Virtually all FG-labeled basket cells contained Virtually all FG-labeled basket cells contained PV and GABA. Conversely, many PV cells, particularly those in the upper granule cell and molecular layers, did not exhibit FG fluorescence. Nor did all GABA neurons contain PV. These results identify a previously undescribed subpopulation of GABA-immunoreactive dentate basket cells that have commissural connections. The association between the expression of PV and those dentate basket cells that have commissural projections is intriguing. Supported by NSI8201. projections is intriguing. Supported by NS18201.

NEUROTOXICITY OF INTRAHIPPOCAMPAL INJECTIONS OF EXCITATORY AMINO ACIDS: PROTECTIVE EFFECTS OF CPP. L.E. Jarrard and B.S. Meldrum, Dept. Psychol., Washington and Lee Univ., Lexington, VA 24450, and Inst. of Psych., London, SE5 8AF. The pattern of cell loss and neuronal degeneration

resulting from focal injections of excitatory amino acids into hippocampus was studied, together with the protection provided by $3-((\frac{1}{2})-2-carboxypiperazin-4-y1)propyl-1$ phosphonate (CPP). Rats received bilateral injections mM), quisqualate (QUIS; 120 mM), kainic acid (KA; 4.7 mM) or ibotenic acid (IBO; 63 mM) at 13 sites in the hippocamor incentic acid (180; 63 mm) at 13 sites in the hippocampus (see Jarrard, Neurosci. Methods, 29:251, 1989). Half of the animals in each group were given i.p. injections of CPP (20 mg/kg) immediately before the operations, and again after 3 hr. The rats were sacrificed after 7 days, and the brains were stained with cell and silver stains. Within the hippocampus all cell fields including dentate gyrus were destroyed following injections of NMDA and IBO. After QUIS and KA severe damage was limited to hilar and CA3 cells, with partial loss of CA1 cells. CPP injections blocked most of the hippocampal damage due to NMDA and IBO while in QUIS and KA animals the protection was limited to CAl cells. NMDA and IBO resulted in minimal extrahippocampal damage. QUIS and KA caused extensive secondary damage to olfactory areas, amygdala, ventral neocortex (layers V and VI), and thalamus; this extrahippocampal damage was partially or completely blocked by CPP.

LOCALIZATION OF SEROTONINERGIC FIBER PLEXUS. 5-HT UPTAKE SITES AND 5-HT1A RECEPTORS IN THE HIPPOCAMPUS OF NORMAL AND PRENATALLY PROTEIN MALNOURISHED RATS. G. J. Blatt. D. L. Rosene, A. Virga, and K. J. Rhodes. Dept. Anat., Boston Univ. Sch. Med., Boston, MA 02118.

Prenatally protein malnourished rats born to dams on a 6% casein diet during Prenatally protein malnourished rats born to dams on a 6% casein diet during pregnancy and then cross-fostered at birth to females on a 25% diet show adult alterations in vigilance state activity, kindling and behavior that suggest hippocampal (HF) dysfunction and neurochemical studies have shown an elevation of brain serotonin. To investigate this an antibody to serotonin (5-HT) was used to assess the density and distribution of 5-HT fiber plexus in the HF in four pairs of normal (25/25) and malnourished (6/25) adult (day 220) rats. In normal rats, 5-HT fiber plexus in the HF was very dense in the molecular layer of the dentate gyrus, stratum oriens and radiatum of CA3 and in stratum moleculare in CA1, prosubiculum and subiculum. In contrast, in malnourished rats, athough there was a similar laminar distribution of 5-HT fibers there was a marked decrease in the density in all subfields and levels of the contrast, in mainourisited rats, autologic uncer was a similar admired austroaction of HT fibers there was a marked decrease in the density in all subfields and levels of the HF, especially in the dentate gyrus. To examine this system further we utilized on the slide in vitro ligand binding techniques to assay both 5-HT uptake sites localized to 5-HT afferents using ³H-citalopram and 5-HT_{1A} receptors using ³H-8-OH-DPAT in three pairs of 25/25 and 6/25 rats. In normal rats, the density and distribution of 5-HT uptake sites was generally similar to the pattern demonstrated immunocytochemically. The only difference was in CAI where there was a moderate density of 5-HT uptake sites where only small caliber lightly stained 5-HT fibers were seen immunocytochemically. In malnourished rats, there was a small decrease in the density of 5-HT uptake sites in all subfields of the HF except in the molecular layer of the dentate gyrus where there was a 20-25% decrease (measured densitometrically). This confirms the immunocytochemical observation but suggests that the effect is greatest in the dentate gyrus. In the same rats 5-HT1A receptors were most dense in the molecular layer of the dentate gyrus, stratum oriens of CA3 and in stratum oriens, radiatum and moleculare of CA1 but there was no difference between the normals and malnourished. "Supported by NIH HD22539".

PHYSICAL ACTIVITY EFFECTS ON HIPPOCAMPAL CHOLINERGIC FUNCTION AND SPATIAL MEMORY. D.E. Fordyce and R.P. Farrar. Institute of Neuroscience, The University of Texas at Austin, Austin, TX 78712

In the present study, specific markers of hippocampal cholinergic function, high affinity choline uptake (HACU) and muscarinic quinuclidinylbenzilate (QNB) binding, were and muscarinic quinuclidinylbenzilate (QNB) binding, were shown to be altered by endurance training (6 months of treadmill running, 5 day/week, 30 min/day). HACU and QNB binding were determined in synaptosomes of endurance trained F344 rats and their age matched sedentary controls. Endurance trained rats (trained from 6 months to 12 months of age) showed a reduction in HACU (10.85±0.55 vs. 15.28 pmoles/mg, p<0.02) and an increase in QNB binding (4027± 155 vs. 3522 fmoles/mg, p<0.05) compared to their age—matched sedentary controls. As cholinergic function has been implicated in spatial memory, it was of interest to determine if the cholinergic changes in the hippocampus of run rats would be accompanied by altered performance in run rats would be accompanied by altered performance in spatial memory. Using a modified version of the place learning set procedure described by Whishaw (1985), endurance trained rats showed significantly enhanced performance compared to controls with regard to latency of acquisition (blocks of four trials from fifth to fourteenth day of training, second trials, 4.9 ± 0.25 (N=6) vs. 9.1 ± 0.28 seconds (N=6) and retention (after 4 days of rest from spatial testing, blocks of four, second trial, 4.1 vs. 9.1 seconds)

181.13

QUANTITATIVE AUTORADIOGRAPHY OF MUSCARINIC BINDING IN HUMAN AMYGDALA. H.R. Brashear, C.A. Levesque, S.S. Wolf* and G.F. Wooten. Department of Neurology, University of Virginia, Charlottesville, VA 22908.

Quantitative autoradiography with [³H]quinuclidinyl benzilate ([³H]QNB) was used to define the subnuclear organization of muscarinic cholinergic receptors in the human amygdala. Series of 10 µm sections at 700 µm intervals through normal human amygdala were incubated with 0.1-10.0 nM concentrations of [³H]QNB. Nonspecific binding in the presence of 1 µM atropine was less than 5% of total. Autoradiographs presence of 1 _sM atropine was less than 5% of total. Autoradiographs were compared to adjacent sections stained for acetylcholinesterase and Nissl substance. Muscarinic binding was not uniform and differentiated amygdaloid subnuclei well. Anatomical localization was comparable to binding in the rat. Binding correlated with acetylcholinesterase activity in most regions. Specific binding was highest in the magnocellular basolateral nucleus, followed by basomedial, cortical, central and lateral nuclei, and was lowest in the anterior amygdaloid area. Optimal binding occurred at concentrations of 0.5-1.0 nM, consistent with data on rat and human putamen from this laboratory. These data suggest that muscarinic cholinergic receptors are differentially distributed among subnuclei of the human amyodala. subnuclei of the human amygdala.

THEREASE IN HIPPOCAMPAL NOREPTHEPHRINE (NE) AND DOPAMINE (DA) AFTER BLOCKADE OF α_2 -ADRENOCEPTORS.

DOPAMINE (DA) AFTER BLOCKADE OF α_2 -ADRENOCEPTORS, K.Xu, K.Frerichs, J.Hallenbeck, G.Feuerstein, J.N.Davis, and A.-L.Sirén, Dept of Neurology, USUHS, Bethesda, MD, Dept of Pharmacology, SmithKline Beecham, King of Prussia, PA, VA Medical Center, Duke University, Durham, NC. The effect of SK&F 86466 (6-chloro-2,3,4,5-tetrahydro-3-methyl-1-H-3-benzazepine), a potent and selective α_2 -adrenoceptor antagonist, was investigated on hippocampal release of NE, DA and serotonin (5-HT) in awake rats (n=17). Microdialysis samples (30-min) were collected and immediately injected (20 μ l) into an HPLC with immediately injected (20µ1) into an HPLC with electrochemical detection. The basal release of NE was 4±0.4pg. Administration (i.v.) of 5mg/kg and 10mg/kg of SK&F 86466, increased NE two-fold (11±1pg, p<0.05) and nine-fold (39±3pg, p<0.01), respectively, while the 1mg/kg dose had no effect. DA was not detected at baseline, but after administration of 5mg/kg and 10mg/kg of SK&F 86466, a peak with the retention time of DA was detected (4±0.3pg and 6±1pg, respectively). SK&F 86466 had no effect on 5-HT release (baseline 17±3pg).

The results show that blockade of α_2 -adrenoceptors modulates NE and probably DA release in the hippocampus. (Supported by VA and DoD).

ARGININE VASOPRESSIN-INDUCED MOTOR DISTURBANCES: LOCALIZATION OF A SENSITIVE SITE IN THE MEDIAL AMYGDALA. B.J. Willcox, P. Poulin, O.J. Pittman and W.L. Veale. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1. Arginine vasopressin (AVP) can produce motor disturbances when injected intracerebroventricularly (i.c.v.) or when injected into the ventral septal area of the rat brain. These AVP-induced motor disturbances result from an interaction of AVP with the V1-type of AVP receptor and involve a sensitization process, whereby an initial injection of AVP may cause minor motor disturbances such as ataxia, whereas subsequent AVP injections one to four days later cause severe motor. an initial injection of AVP injections one to four days later cause sever antior disturbances, such as barrel rotations and myoclonic/myotonic convulsions. Since AVP-like immunoreactivity as well as AVP receptors have been shown to exist in the amygdala and since the amygdala is a well known locus for kindling of a variety of motor disturbances including myoclonic/myotonic convulsions, experiments were undertaken to determine if AVP would cause motor disturbances following migratifying into the anyundule.

internation into the amygdala.

Twelve male Sprague-Dawley rats were implanted stereotaxically with bilateral cannulae directed towards the medial amygdala. Following a 7 day recovery period bilateral microinfusion of AVP (40 ng) was given into the medial amygdala on two consecutive days. The severity of motor disturbances was scored (over 10 min) according to a predetermined behavioral code. The results indicated that the initial AVP infusion caused minor motor disturbances while the subsequent infusion 1 day later caused severe motor disturbances including barrel rotations and myoclonic/myotonic convulsions. These results suggest that the amygdala is a sensitive site for AVP-induced motor disturbances and that these motor disturbances undergo a sensitization process after an initial exposure to AVP. LOCALIZATION OF CORTICOTROPIN-RELEASING FACTOR (CRF)-LIKE IMMUNOREACTIVITY IN MONKEY AMYGDALA. J.L. Bassett and S.L. Foote. Dept. of Psychiatry (M-003) UCSD, La Jolla CA 92093. Previous investigations of the distribution of CRF-like

immunoreactivity in rat brain have reported the presence of this peptide within the amygdala. Most notably, the highest concentrations of both CRF-positive cells and fibers have been observed in the rat central nucleus, consistent with the putative role of this peptide in autonomic and endocrine responses. In addition, moderate to low densities of CRFpositive somata and processes have been noted in other nuclei of the rat amygdala. However, the distribution of CRF-like immunoreactivity in primate amygdala has not been described.

In the present study, sections through the amygdala of non-colchicine treated monkeys (Saimiri sciureus) were processed for immunohistochemistry using a polyclonal antiserum directed against the human form of CRF (donated by J. Rivier & W. Vale). Within the amygdaloid complex, large numbers of CRF-positive cells were seen within the lateral and basal nuclei. Lower numbers of immunoreactive somata also were seen in the nucleus of the lateral olfactory tract, periamygdaloid cortex, anterior cortical and central nuclei. Dense networks of CRF-positive fibers and varicosities were seen within the lateral and central nuclei; moderate densities were evident in the medial nucleus, anterior amygdaloid area, layer Ia of the periamygdaloid cortex, anterior and posterior cortical nuclei. Thus, striking differences are evident between the distributions of CRF-like immunoreactivity in the rat and monkey amygdala.

CALCIUM BINDING PROTEIN CONTAINING NEURONS OF BASOLATERAL AMYGDALA ALSO EXHIBIT GABA AND CYTOCHROME OXIDASE IMMUNOREACTIVITY. A.J. McDonald and K.G. Baimbridge. Dept. of Anatomy, Univ. of South Carolina Sch. of Med., Columbia, S.C. 29208 and Dept. of Physiol., Univ. of British Columbia, Vancouver, Canada VGT 1W5.

The calcium binding proteins parvalbumin (PV) and calbindin (CB) are thought to sequester calcium in neurons with high firing rates. This investigation used two-color immunoperoxidase and adjacent section techniques to characterize PV-ir and CB-ir neurons of the rat basolateral amygdala (BLA) and to determine whether these neurons also contain GABA or cytochrome oxidase (CO) immunoreactivity. Intense PV-ir and CB-ir was observed in nonpyramidal (local circuit) neurons and in small puncta surrounding pyramidal perikarya. The great majority of PV-ir neurons also exhibited CB-ir (comprising about one-half of all CB-ir neurons). Virtually all PV-ir and CB-ir neurons were also GABA-ir (CB-ir neurons comprised more than one-half of all GABAir cells). The majority of PV-ir and CB-ir neurons also ir cells). The majority of PV-ir and CB-ir neurons also exhibited high levels of CO-ir. These cells, which may correspond to the bursting neurons noted in electrophysiological studies of BLA, may utilize PV and/or CB to buffer the calcium ion influx associated with high firing rates. Since these active cells appear to be CABAergic local circuit neurons, they may mediate the profound inhibition that characterizes BLA. (NS19733)

CHARACTERIZATION OF VICIA VILLOSA AGGLUTININ POSITIVE CELLS IN THE HIPPOCAMPAL REGION C. Drake, K. Mulligan, T. Wimpey, A. Hendrickson, and C. Chavkin. Depts of Pharmacology and

POSITIVE CELLS IN THE HIPPOCAMPAL REGION C. Drake, K. Mulligan, T. Wimpey, A. Hendrickson, and C. Chavkin. Depts of Pharmacology and Biological Structure, University of Washington, Seattle WA 98195.

The lectin from Vicia villosa (VVA) has been shown to label a subset of cortical GABAergic cells in several species. We have examined the regional distribution, morphology, and intracellular characteristics of VVA-positive cells in the hippocampal formation. The brains of perfusion-fixed adult male Sprague-Dawley rats were cut coronally or sagittally into 25-micron sections. Visualizing the binding of horseradish peroxidase- or biotin-conjugated VVA with the chromagen diaminobenzidine revealed heavily stained neurons in the subiculum and lightly-stained dispersed neurons in hippocampal strata pyramidale, oriens, and alveus. The morphology of VVA-positive cells was diverse. In the hippocampus proper, vertically-oriented cells predominated in stratum pyramidale, and bipolar and multipolar shapes were most common in stratum alveus and stratum oriens, respectively. The subiculum contained large multi- and bipolar neurons. Consistent with descriptions of VVA binding in other brain areas, VVA labeled the peripheral surface of somata and proximal dendrites in a punctate fashion. Labeling was abolished by preadsorbing HRP- or biotin-conjugated lectin to GalNAc. The extent to which expression of VVA binding sites colocalized with intracellular markers was examined in detail. All of the subicular VVA-positive cells contained parvalbumin, none colocalized with calbindin and about 85% were GABA-positive. Taken together, the data from these experiments suggested that these cells are GABAergic interneurons and that VVA might be a useful marker for physiological studies of this population. Accordingly, acutely dissociated subicular neurons were dableded in vitro with VVA coupled to small magnetic beads. The viability of labeled dissociated cells was confirmed and identified cells were characterized physiologically using whole-cel using whole-cell voltage clamp recording. The cells exhibited characteristic transient and slowly inactivating potassium conductances. Supported by DA04123.

LOCALIZATION OF PRESYNAPTIC CHOLINERGIC MARKERS AND MUSCARINIC RECEPTORS IN THE HIPPOCAMPAL FORMATION OF THE RHESUS MONKEY K.J. Rhodes, D.L. Rosene, and M.B. Moss. Dept. of Anatomy, Boston Univ. Sch. Med., Boston, MA 02118.

The aim of this study was to localize cholinergic afferents and muscarinic receptors to intrinsic neurons or specific populations of afferent axons in the hippocampal to ministe inclinits of spectra populations of arterial axions in the impression formation (HF) of the rhesus monkey. The distribution of presynaptic cholinergic markers, (high affinity choline uptake sites [HACU] and acetylcholinesterase [AChE]), and muscarinic receptors (M1 and M2) was examined in monkeys in which the fornix (n=2) or entorhinal cortex (n=1) were ablated unilaterally to deafferent the the fornix (n=2) or entorhinal cortex (n=1) were ablated unilaterally to deafferent the hippocampus of basal forebrain and perforant path inputs, respectively, in monkeys in which the hippocampus was bisected unilaterally (n=2) to transect longitudinally directed intrahippocampal association projections, and in monkeys in which discrete (1µ1) intrahippocampal injections of ibotenic acid (10µg/µ1) were made to destroy intrinsic neurons while sparing afferent fibers (n=5). After 14 to 21 days post lesion the animals were sacrificed, their brains immediately frozen and cut into 15µm thick serial sections. AChE was localized histochemically, and HACU sites, M1 and M2 receptors were localized using in vitro ligand binding and autoradiography. Quantitative analysis of the histochemically stained sections and autcradiograms revealed the following major changes: 1) both HACU sites and AChE are associated with cholinergic afferents since the density of both markers was significantly reduced following fornix transection. However, in the dentate gyrus (DG) 80% of the AChE in the inner third of stratum moleculare remained after a fornix transection but only 25% remained after hippocampal bisection, indicating that a significant proportion of so the inner turu or stratum moleculare remained after a formix transection but only 25% remained after hippocampal bisection, indicating that a significant proportion of this AChE is associated with the dentate gyrus association pathway. 2) M1 sites are located on the somata and dendrites of intrinsic neurons in the DG, CA3, CA2 and CA1 subfields since ibotenic acid lesions in these areas reduced the density of M1 sites; 3) M2 sites are located on CA1 afferents in the subiculum since only ibotenic sacid lesions within CA1 reduced the high density of M2 binding in this subfield while other deafferenting lesions and even ibotenic acid injections within the subiculum left it intact. "Supported by NIH 16841, 19416, and 04321"

181.16

LOCALIZATION OF INSULIN AND INSULIN-LIKE GROWTH FACTOR (IGF) RECEPTORS IN RAT HIPPOCAMPUS FOLLOWING KAINATE AND ISCHEMIC LESIONS. M.G. King, J.E. Franck, and D.G. Baskin. Depts. Biological Structure, Neurological Surgery, and Medicine, University of Washington, Seattle, WA 98195, and V.A. Med. Center, Seattle, WA 98108.

Insulin, IGF-I, and IGF-II binding sites have previously been localized in the hippocampus with quantitative autoradiography (QAR). To test the hypotheses that insulin receptors are on CA1 pyramidal cell dendrites, nyportnesses that insulin receptors are on CA1 pyramidal cell dendrites, IGF-I receptors are on CA3 pyramidal cell dendrites, and IGF-II receptors are on CA1 and CA3 pyramidal cell bodies, we examined the effect of hippocampal lesions on the localization of these binding sites with QAR using Hyperfilm β-max. Frozen sections (20 μm), from Wistar rats which had recovered for 7 days after either kainate (10 min bilateral intraventricular infusion at 0.5 µg/µl saline) or ischemic (4 vessel occlusion) lesions, were incubated in either ¹²⁵I-insulin, ¹²⁵I-IGF-I, or ¹²⁵I-IGF-II at 0.05 nM (16h, 5°C) alone or with 50 nM unlabeled peptide. Autoradiographs were analyzed by computer densitometry. Kainate reduced insulin and IGF-I binding in both the CA3 s. oriens and s. radiatum by 85% and 50%, respectively, and IGF-II binding in the CA3 s. pyramidale by 75%. Kainate also reduced insulin binding in the CA1 s. oriens by 30% and s. radiatum by 65%. Ischemia reduced insulin binding in the CA1 s. oriens by 25% and s. radiatum by 60% but did not affect IGF-I binding in either region. These results suggest: (a) insulin receptors are on CA1 pyramidal cell dendrites and possibly Schaffer collaterals of CA3 pyramidal cells; (b) IGF-I receptors are on CA3 pyramidal cell dendrites; and (c) IGF-II receptors are on CA1 and CA3 pyramidal cell bodies. (Supported by NIH Grant NS 24809 and the Veterans Administration.).

SOMATOSTATIN, SUBSTANCE P AND HIPPOCAMPAL INNERVATION OF THE RAT LATERAL SEPTAL AREA SOMATOSPINY" NEURONS; HIPPOCAMPAL INPUT ONTO SEPTAL SUBSTANCE P-IMMUNOREACTIVE CELLS. R.L. Jakab¹ and C. Leranth¹.² Dept. of Obstetrics and Gynecology¹ and Section of Neuroanatomy², Yale University, School of Medicine, New House CT 06510 Haven, CT. 06510

"Somatospiny" neurons of the lateral septal area (LSA) are targets of Somatospiny neurons of the lateral septal area (LSA) are targets of hippocampal afferents, and GABA, monoamine- acetylcholine, and vasopressin-containing fibers of various origin. The overlapping distribution pattern of the somatospiny neurons and the somatostatin-(SS) and substance P- (SP) immunoreactive (IR) pericellular baskets in the mediolateral part of the LSA suggests further peptidergic afferents of these cells. To test this hypothesis, electron microscopic immunocytochemistry using antisera against SS or SP was performed on rats two days following fimbria-fornix transection. Asymmetric synapses of degenerated hippocampo-septal axon terminals, and symmetric synaptic contacts of SS- or SP-IR boutons were observed on the same somatospiny neurons

In addition, following fimbria-fornix transection of colchicine treated rats (80µg in 20µl saline), we demonstrated that SP-IR neurons in the lateral border of the medial septum form synaptic contacts with degenerated hippocampo-septal axon terminals. SP-containing neurons of this area were reported to project to the hippocampus (Surlow and Peterson '89). This synaptic arrangement indicates a direct "short circuit", reciprocal interaction between the septum and hippocampus. Supported by NIH grant NS 26068.

THE LAMINAR DISTRIBUTION OF MUSCARINIC AND 5-HT_{1A} RECEPTORS IN THE POSTERIOR PARAHIPPOCAMPAL GYRUS OF THE RHESUS MONKEY. D. L. Rosene. K. J. Rhodes. G. J. Blatt. and M. B. Moss. Dept. of Anatomy, Boston Univ. Sch. Med., Boston, MA 02118. The posterior parahippocampal gyrus (PPHG), comprising cytoarchitectonic areas TH, TL, and TF, forms a critical structural and connectional link between unimodal and the contractions of the contraction of the c

and multimodal sensory association cortices and the medial temporal lobe limbic system. We examined the distribution of muscarinic cholinergic (M1 and M2) and serotonergic (5-HT1A) receptors within each subdivision of the PPHG in five young serotonergic (5-HT_{1A}) receptors within each subdivision of the PPHG in tive young adult rhesus monkeys. At the time of sacrifice the brains were immediately frozen and cut into 15µm thick serial coronal sections. Muscarnic M1 and M2 receptors were labeled in vitro with [3H]-pirenzepine and [3H]-oxotremorine, respectively, and 5-HT_{1A} sites were labeled with [3H]8-OH-DPAT, and all were visualized by autoradiography. The distribution of M1 receptors was similar in all three architectonic subdivisions of the PPHG, with a higher density in supragranular and a lower density in the infragranular layers. However, there was a higher density of M1 sites in TF than in TH or TL. In contrast, the distribution of M2 and 5-HT_{1A} recentors was distinct in each subdivision of the PPHG and the changes corresponded receptors was distinct in each subdivision of the PPHG and the changes corresponded to cytoarchitectural borders. In general, the laminar distribution of M2 and 5-HT $_{1A}$ receptors was less differentiated in the medial proisocortical areas TH and TL than in receptors was less differentiated in the medial proisocortical areas TH and TL than in the lateral isocortical area TF and adjacent inferotemporal cortex (area TE). This trend was particularly obvious in TF where the distribution of M2 sites was clearly multilaminar with a high density in the deep third of layer III, a low density in layer IV, and a high density in layer V. Similarly, from TH to TF there was a clear stepwise change in the distribution 5-HT1_A sites, with a steady decrease in the density of these receptors in layers V and VI. Together these findings complement our recent anatomical observations of differential cortical connections of these subdivisions of the PPHG and suggest that there are unique associations between receptor types and particular afferent inputs in each cytoarchitectonic subdivision. "Supported by NIH grants NS16841 and 19416"

ROLE OF THE AMYGDALA IN STRESS-INDUCED INCREASES IN PLASMA CORTICOSTERONE AND RENIN. T.S. Gray, R. Piechowski*, P. Rittenhouse, and L.Van de Kar, Dept. of Cell Biology, Neurobiology and Anatomy, and Dept. of Pharmacology, Loyola University Stritch Sch. of Med, Maywood, II. 60153

Med, Maywood, II. 60153

The effects of amygdaloid lesions upon stress induced increases in plasma corticosterone (CORT) and renin was tested using immobilization or conditioned emotional responses (CER) paradigms. Amygdaloid lesions were made using bilateral injections of ibotenic acid (1.5µg in 0.1µl of solution). Two weeks later, the rats were stressed using immobilization or a

Rats with lesions in the central amygdala showed attenuated corticosterone responses in both the immobilization and CER tests. Lesions in the central amygdala reduced the renin response in the CER paradigm, but not in the immobilization stress test. Damage to the lateral amygdala or regions adjacent to the amygdala had no effect upon CORT or renin responses to either stress procedures.

Thus, amygdaloid lesions blunt corticosterone and renin responses to CER stress, but only corticosterone levels are attenuated in the immobilization stress test. The data indicate that the amygdala is an important part of the neural circuitry for expression of corticosterone and renin responses to "psychological" stress as measured by the CER paradigm. Supported by ONR N000-14-88-k-0010.

STIMULATION OF THE BED NUCLEUS OF THE STRIA TERMINALIS PRODUCES STRESS RELATED BEHAVIOR.

Dafny. Dept. Neurobiol. and Anat., The University of Texas Medical School at Houston, TX 77225.

The amygdala is involved with the modulation of both stress-related neuroendocrine function and affective behavior. The pathway by which the amygdala modulates corticosteroid secretion has been suggested to include the bed nucleus of the stria terminalis (BNST). The present experiment was designed to determine if stress related behaviors could also be produced by BNST stimulation and to determine the similarities and differences between the behaviors produced by restraint, BNST stimulation, and a combination of restraint and stimulation. Eight male Sprague Dawley rats (180-250 gm) were anesthetized with 50 mg/kg pentobarbital and permanently implanted with bipolar stimulating electrodes in the BNST and, after 7-8 days of recovery, were given each of the following four treatments on consecutive days: control unhandled, restraint for four hours, BNST stimulation for four hours, and restraint with BNST stimulation for four hours. Eight behavioral measurements were made over the four hours immediately following each treatment using a Digiscan Model RXYZCM(16)DVA animal activity monitor. During the first hour after treatment, all treatments increased horizontal activity, total distance travelled, movement time, low vertical rearings, high vertical rearings, and center time over control values. The effects of BNST stimulation. Thus, the behavioral effects of BNST stimulation. Thus, the behavioral effects of BNST stimulation. Thus, the behavioral effects of SNST stimulation are qualitatively similar to the effects of stress but differ in time course.

STIMULUS CONTROL OF NEUROENDOCRINE RESPONSES IN A CER PARA-DIGM. M.A. Hebert*, D.F. Rice*, S.J. Chee, B.N. Bunnell, E.H. Mougey and J.L. Meyerhoff. Dept. of Psychology, Univ. of Georgia, Athens, GA 30602 and Dept. Med. Neurosciences, Walter Reed Army Inst. Research, Washington, DC 20307.

In psychological stress experiments, rats returned to the place where they have been exposed to a physical stressor exhibit a pattern of neuroendocrine responses similar to that produced by the stressor itself. However, it has been difficult to show that this is due to associative processes rather than sensitization. In this study, two groups of nine rats received CER training in which the conditioned stimulus (CS), an illumination change, was paired with 5 sec of 1 ma footshock (US) for 20 trials per day. Seven extinction days, on which the rats received neither the CS nor the US, were randomly interposed among the 13 conditioning days to make the CS discriminable from other situational cues. On the 21st day, the experimental group received only the CS while the other group got another extinction day. Two groups of six rats received noncontingent CS and US presentations on the same schedule as the conditioning groups, another group got only the CS and a sixth group served as a handling control. After the last session, rats were decapitated and plasma was assayed for prolactin, ACTH and corticosterone. Prior exposure to footshock elevated levels of all three hormones, but only pro-lactin showed evidence of being conditioned to the CS. Re-sults are discussed in terms of the different mechanisms governing the release of these hormones.

182.2

BEHAVIOR AND TELEMETERED AUTONOMIC RESPONSES TO CLONIDINE, DIAZEPAM AND SOCIAL STRESS. W. Tomatzky and K.A. Miczek. Dept. Psychology, Tufts Univ, MA 02155

Increased cardiovascular and pituitary-adrenal activity as well as defensive and submissive behavior including vocalizations are reactions to threats and attacks by an opponent. We examined how diazepam and clonidine differentially modulate these responses. During a 1-h exposure to the threats by a dominant opponent the heart-rate (HR) and core temperature (T_c) of the experimental intruder rat is monitored by telemetry (Mini-Mitter Dataquest III), and the behavior and ultrasounds (US) were recorded. Neither clonidine (0.01-0.1 mg/kg IP) nor diazepam (1-10 mg/kg IP) affected salient defensive behavior in reaction to the intense initial threats by the resident. Locomotor activity, by contrast, was substantially decreased by both compounds. As the intensity and the variability of the social interaction decreases towards the end of the 1-h threat period neither locomotor nor social behavior were suppressed by diazepam. Clonidine decreases dose-dependently locomotion and also defensive behavior (at 0.1 mg/kg). Neither clonidine nor diazepam decreases rate or duration of 22-30 kHz US. The HR and $T_{\rm c}$ during the 1 h encounter are elevated above dark cycle mean values (+100 b/min for HR and +1.6 °C for $T_{\rm c}$) and return to baseline within 3 to 4 h in the homecage of the animal. No significant adaptation of the animals $T_{\rm c}$ response to this relevant stressoris observed over a three month period. During the threat period clonidine decreases the tachycardia and hyperthermia dose-dependently. The increase in $T_{\rm C}$, but not the tachycardia, is attenuated by diazepam. The massive autonomic and behavioral reactions to a social stress appear to be modulated differentially by adrenergic and benzodiazepine receptors.

182.4 EFFECTS OF β-CARBOLINE (β-CCE) ON DEFENSIVE BEHAVIORS AND STRESS-RELATED HORMONAL CHANGES IN INFANT RHESUS MONKEYS. N.H. Kalin and S.E. Shelton*. VA Hospital and Department of Psychiatry, University of Wisconsin, Madison, WI 53705. We have established a paradigm in infant rhesus monkeys that elicits specific defensive behaviors in response to changing parameters of threat. Rhesus infants separated from their mothers (A) emit frequent "coos." The presence of a human not engaging the infant in eye contact (NEC) induces freezing; staring (ST) induces barking and hostility. Morphine decreases and naloxone increases the number of coos but has no effect on freezing, barking, and hostility but does not affect cooing. To investigate how benzodiazepine systems mediate defensive responses and hormonal changes, we gave the inverse agonist β-CCE (0, 125, 250, 500 μg/kg) to 12 infant monkeys. ST significantly increased cooing, barking, lip smacking, teeth grinding, and hostility toward the intruder. NEC significantly increased freezing. Across all test conditions, β-CCE significantly decreased cooing and self mouthing and increased freezing and orientation toward the intruder. The effects of β-CCE were notable because of the significant test condition × dose interaction characterized by a dose-dependent increase in NEC-induced freezing. These results confirm the anxiogenic effects of β-CCE and support our findings that benzodiazepine systems are important mediators of threat-induced freezing in primates.

PRENATAL STRESS AFFECTS SENSITIVITY TO DIAZEPAM.
L.A. Pohorecky and R. Roberts*. Center of Alcohol Studies, Rutgers University, Piscataway,
New Jersey 08855-0969.
We examined the effect of prenatal stress exposure on sensitivity to diazepam. Stress expo-

sure consisted of handling pregnant rats 5 min/ sure consisted of nandling pregnant rats 3 mill/day from day 14 to 21 of gestation. Male off-spring were tested when 60 days of age in a modified open field apparatus after injection with diazepam (0, 1, 5 mg/kg). The 5 mg/kg dose of diazepam depressed the frequency and duration of crossover, rearing, headpoke and corner activities. Rearing was not affected by the 1 mg/kg dose of diazepam. Defecation was increased by the 1 mg/kg dose, but was decreased by 5 mg/kg of diazepam. Prenagal stress exposure altered responsiveness to diazepam on only crossover activity and defecation. Compared to control, prenatally stressed animals exhibited an increase in crossover at the low dose of diazepam. Also, there were more boli in prenatally stressed rats treated with 1 mg/kg diazepam, while the 5 mg/kg dose of the drug decreased the number of boli. These results indicate that prenatal stress has very specific effects on the sensitivity of adult offspring to diazepam. (Supported by RO1 AA07071.)

TIME-DEPENDENT EFFECTS OF PRIOR STRESS CAN EITHER INCREASE OR DECREASE SUBSEQUENT RESPONSIVENESS TO HALOPERIDOL. S.M. Antelman.* A.R. Caggiula, D. Kocan.* S.Knopf.* and D. Edwards. Depts. of Psychiatry and Psychology, Univ. of Pittsburgh, Pittsburgh, PA, 15213

We have shown that prior stress can increase responsiveness to pharmacological and nonpharmacological stressors in a time dependent fashion, a phenomonon that we have termed time-dependent sensitization (TDS). But we also have observed time-dependent decrements in responsiveness. Here we identify one factor that determines which time-dependent effect is manifest. Male rats were subjected to a single exposure to stressors of either higher or lower intensity, as indexed by blood corticosterone levels. No effect was observed on haloperidol (HALO)-induced catalepsy when either stressor preceded HALO by only 1 hour. By contrast, when the interval was 2 weeks, the lower intensity stressor increased HALO-catalepsy whereas the higher intensity stressor increased the same response. These results demonstrate that the time-dependent process can act on both sensitizing and decrementing phenomena and suggest that the effective intensity of early stressful experiences may be a key in whether an individual is made more vulnerable to or protected from stress in the future. These findings also suggest that individual differences in prior stressful experiences can influence current drug responsiveness in such a way as to contribute to drug variability.

182.9

ALARM PHEROMONE IN THE FORCED SWIMMING TEST. P. Bilitzke and E.L. Abel. Department of Obstetrics and Gynecology and the Fetal Alcohol Research Center, Wayne State Univ., Detroit, 48201.

Male rats (2 months old) were tested in the forced swimming paradigm. Immediately after an initial 10 minute test, the animal was placed in a holding cage for 10 minutes and was returnin a holding cage for 10 minutes and was returned to the cylinder and immobility was again observed. For half the animals, the water was not changed. For the other half, the water was replaced with clean water. Animals that swam in clean water were immobile for 15% of the test period whereas animals placed in the previously swum water were immobile for 0%.

In the next study, animals were tested in clean water versus water containing feces from nonstressed animals. Animals placed back into this feces-contaminated water swam the same amount of time as when placed in clean water whereas animals tested in previously swum water (unchanged) again exhibited almost no immobility.

These data suggest that male rats produce an "alarm pheromone" during the forced swimming test which causes animals to be less immobile (i.e., more frightened).

REPEATED EXPOSURE TO A STRESSOR CAN ELICIT HYPER-REPEATED EXPOSURE TO A STRESSOR CAN ELICIT HYPER-RESPONSIVENESS OF PLASMA OXYTOCIN IN THE RAT. T.E. Orr* B.N. Bunnell E.H. Mougey, G.P. Chrousos, K.T. Kalogeras* E.O. Johnson and J.L. Meyerhoff. Dept. Med. Neurosci., Walter Reed Army Inst. of Research, Wash., D.C. 20307-5100; Dept. of Psychology, Univ. of Georgia, Athens, GA 30602 and Devel. Endo. Br., NICHHD, NIH, Bethesda, MD 20892.

Plasma oxytocin (OXY) was previously shown to increase in response to immobilization (IMO) stress. Using 15 min of tailshock (TS) in male rats as a day 1 priming stressor, we found that TS presented on the second (test) day enhanced plasma OXY response. Rats were decapitated immediately after exposure to stressor or control conditions, and trunk blood was collected, centrifuged at 4°C and the plasma frozen pending RIA. When IMO was used as both the priming and the testing stressor, the OXY response was diminished to the repeat IMO. But, whenever tailshock was administered on day 2, hyperresponsiveness of OXY was elicited, compared to response to single TS. ACTH and corticosterone (CS) responses were also enhanced after repeat TS. OXY has been reported to amplify the ACTH response to CRH, and the increase in plasma levels of OXY is one of several mechanisms which might contribute to hyperresponsiveness of ACTH and CS. Reports vary as to whether OXY releases prolactin (PRL). In the present study, PRL response to stressors was not enhanced, despite the hyperresponse of OXY.

182.8

CHRONIC STRESS IN RATS: 3 DAYS ARE SUFFICIENT TO PRODUCE ADRENOCORTICAL AND BEHAVIORAL ALTERATIONS. R.J.Servatius, B.H.Natelson, S.D.Drastal*, M.T.Bergen*, T.A.Pritzel*, W.N.Tapp, & J.E.Ottenweller*. University of Medicine and Dentistry of New Jersey, Neurobehavioral Unit (127A), V.A.Medical Center, E.Orange, N.J. 07019. Recently we reported on an animal model of chronic stress which

exhibited elevated basal corticosterone levels, coupled with behavioral alterations, that persisted for days after the last stress session. To further define the stress parameters which produce the chronic stress state, we compared Sprague-Dawley rats subjected to either 10, 7, 4, or 3 days of tail-shock (2-hr sessions) with nonshocked controls. Shocked rats lost weight in relation to the number of days of stress. Control rats rats lost weight in relation to the number of days of stress. Control rats exhibited normal growth rates. Basal corticosterone levels were elevated in shocked rats (4.64 \pm 0.33 $\mu g/dl)$ compared to nonshocked controls (0.52 \pm 0.10 $\mu g/dl)$ for three days post-stress. Corticosterone values for the 4 shocked groups were equivalent. On the first day post-stress the latencies to drop from a hanging wire for the chronically stressed rats were equivalent and were significantly longer than controls. Subsequently, all rats exhibited equivalent latencies. The present results are consistent with earlier reports that chronic stress produces visceral arousal that lasts beyond the period of stress, as well as behavioral alterations. Since 3 days of tailshock produced equivalent elevations of basal corticosterone and hanging wire latencies as 10 days, the present results indicate that 3 days of this tail-shock paradigm are sufficient to induce chronic stress. Due to the rapid decrease in hanging wire latencies over days for the chronically stressed rats, we are currently looking for a more robust measure of behavioral disruption. Supported looking for a more robust measure of behavioral disruption. Supported by V.A. Medical Research Funds.

EXPOSURE TO INESCAPABLE SHOCK RESULTS IN INCREASED SYNTHESIS OF A SPECIFIC POLYPEPTIDE IN RAT HIPPOCAMPUS. Uenishi, T.J. Shors, N.R. Nichols, C.E. Finch R.F. Thompson. Neurosciences Program, Univ. of Southern Calif., IA CA 90089.

The effect of inescapable and unpredictable stress

on protein synthetic patterns was examined in the rat hippocampal slice preparation. One group of rats (n=5) was restrained and exposed to acute tail-shock (1mA, 1 sec, 1/min for 30 min.), while another group served as unstressed controls. Immediately following treatment, hippocampal slices were prepared and equilibrated for 1 hour. Slices were labeled with [358]methionine for 2 hours and analyzed by 2-dimensional electrophoresis and fluorography. A consistent increase (5/5, 3.9-fold) in a 35kD polypeptide with an isoelectric point of 6.4 was found in stressed rats compared to controls. This 35kD polypeptide may not be the same as glucocorticoid- and stress-responsive glycerol phosphate dehydrogenase (GPDH) since it was found in the 20,000xg precipitate rather than in the supernatant. These results suggest that there is a stress-specific protein synthesized in the hippocampus following exposure to uncontrollable stress. LESIONS OF THE PARAVENTRICULAR NUCLEUS ATTENUATE STRESS-INDUCED INCREASES IN PLASMA OXYTOCIN LEVELS IN THE RAT. J.L. Meverhoff, E.H. Mougey, G.J. Kant, G.P. Chrousos and K.T. Kalogeras*1. Dept. Med. Neurosci., Walter Reed Army Inst. Res., Wash., D.C. 20307-5100 and Devel. Endo. Br., NICHHD, NIH, Bethesda, MD 20892

Oxytocin (OXY) has been demonstrated in neurons in the paraventricular nucleus (PVN) which may project to the external lamina of the median eminence or to the neural lobe of the pituitary. Plasma levels of OXY have been shown to increase in rats exposed to stressors. We have examined the effect of PVN lesions on the stress-induced increases in plasma levels of OXY. Bilateral radiofrequency lesions were placed in the PVN of anesthetized male rats. One week later, lesioned and sham-operated rats were decapitated immediately after exposure to 15 min of unavoidable, 1.6 mA footshock (FS). Trunk blood was collected, centrifuged at 4°C and the plasma frozen pending RIA. Unstressed control groups of lesioned and sham-operated rats were decapitated immediately upon removal from home cages. FS elicited a nearly fivefold increase in plasma OXY. This response was attenuated by 40% in the PVN-lesioned rats. Stress-induced increases in ACTH and prolactin (PRL) were attenuated 60% in the lesion group. OXY has been reported to enhance the response of ACTH to CRH. Reports vary on the ability of OXY to release PRL. Effects on circulating OXY levels should be considered when assessing the role of the PVN in neuroendocrine regulation.

THE INVOLVEMENT OF CENTRAL NORADRENERGIC SYSTEMS AND CORTICOTROPIN-RELEASING FACTOR IN DEFENSIVE-WITHDRAWAL IN RATS. X. M. Yang* & A. J. Dunn Dept. of Pharmacology & Therapeutics, LSU-MC, Shreveport, LA 71130-3932

Therapeutics, LSU-MC, Shreveport, LA 71130-3932

The role of the central noradrenergic systems and corticotropin-releasing factor (CRF) in modulating defensive withdrawal (Takahashi, et al., *Behav. Neurosci.* 3:648, 1989) was studied in rats. When rats were unfamiliar with apparatus, i.p. administration of clonidine (0.03 mg/kg), *I*-propranolol (2.5 mg/kg), prazosin (0.1 mg/kg) or chlordiazepoxide (CDP, 5 mg/kg) each significantly decreased the latency to emerge from a small chamber and the proportion of time spent in the chamber (TIC). When rats were familiar with the annaratus tom a small chamber and the proportion of time spent in the chamber (TIC). When rats were familiar with the apparatus, prior restraint for 20 min significantly increased the latency and TIC. Prazosin, clonidine, CDP, or *l*-propranolol reversed the restraint-induced defensive withdrawal. CRF (10-100 ng, i.c.v.) dose-dependently induced defensive withdrawal in rats familiar with the apparatus. *dl*-Propranolol (5 mg/kg) or CDP blocked the CRF-induced changes in the latency and the TIC; but clonidine and prazosin had no statistically significant effects on these measures. Phenylephrine (PE, 25-200 ng, i.c.v.) dose-dependently induced defensive withdrawal. This effect of PE (200 ng) was significantly antagonized by prazosin or the CRF antagonist, ahCRF (25 or 50 µg i.c.v.), but not by CDP. Our results suggest that the hyperactivity of central noradrenergic systems in the novel environment stimulates the release of CRF, which in turn induces defensive withdrawal in rats. MICROINIECTIONS OF CGRP WITHIN THE MEDULLARY DORSAL HORN: EFFECTS ON ADRENAL AND AUTONOMIC FUNCTION AND INTERACTION WITH SUBSTANCE P. D.A.Bereiter and A.P.Benetti* Sect. of Neurobiol. & Dept. of Surgery, Brown Univ./R.I.Hospital, Providence, RI 02903. The role of putative neuropeptides within trigeminal subnucleus caudalis (Vc) in mediating the reflex autonomic responses that often accompany nociception was

in mediating the reflex autonomic responses that often accompany nociception was assessed in chloralose-anesthetized cats. CGRP (2-5pmol in 40-100nl CSF) was injected alone or coincidently with Substance P (SP, 13pmol) via micropipettes into different laminae of Vc. CGRP injections into laminae I-II evoked prompt dose-related increases in the adrenal secretion of catecholamines (CA, P<0.01), adrenal blood flow (P<0.05), plasma ACTH (P<0.01), mean arterial pressure (MAP, P<0.05) and heart rate (HR, P<0.001), whereas injections into deeper laminae of Vc had no consistent effects. These data were similar qualitatively to laminae of Vc had no consistent effects. These data were similar qualitatively to those seen previously after injections of SP alone (Brain Res 490: 307,1989). To determine if CGRP and SP interact within Vc to control adrenal and autonomic function, subthreshold doses of CGRP (3pmol) and SP (13pmol) were injected simultaneously into Vc. The adrenal secretion of CA, adrenal blood flow or plasma ACTH was not affected regardless of the laminar site of injection, whereas coincident injections of CGRP and SP into laminae I-II or V-VI evoked increases coincident injections of CGRP and SP into laminae I-II or V-VI evoked increases MAP (P<0.01) and in HR (P<0.01) that could not have been predicted from the response to either injection alone. Summary: CGRP and SP act separately within laminae I-II of Vc to evoke dose-related increases in the adrenal secretion of CA, in adrenal blood flow, and in plasma ACTH. In contrast, CGRP and SP interact functionally within laminae I-II and V-VI of Vc in control of MAP and of HR. Thus, the co-release of CGRP and SP within the laminae of Vc that process nociceptive input likely interacts to alter specific reflex functions rather than having a generalized effect on the adrenal and autonomic responses often associated with nociception. DRUGS OF ABUSE, ALCOHOL III

183.1

EFFECT OF HIGH DOSE ETHANOL ON THE EEG OF ALCOHOL-PRE-FERRING (P) AND -NONPREFERRING (NP) RATS. S. Morzorati,
L. Lumeng* and T.-K. Li*. Depts. Psych. & Med., Psych. Res.
& Regenstrief Insts., Indiana Univ. Sch. Med. & VAMC, Indianapolis, IN 46202.

We have shown that P rats are behaviorally less affected than NP rats by high dose ethanol. In the present study, we examined if high dose ethanol differentially affects the EEG of P and NP rats. Adult male rats were implanted with EEG electrodes in the frontal cortex and dorsal hippocampus. Ethanol (3g/kg) was infused intragastri-cally via an indwelling cannula. The EEG was subjected to power spectral analysis and the spectra were sorted accor-ding to behavior (non-REM and REM sleep, awake/immobile and moving). Prior to ethanol, P and NP rats differed with respect to hippocampal theta peak frequency during REM sleep. After ethanol, both P and NP rats exhibited (a) a decrease in hippocampal and cortical spectral power, es pecially in higher frequencies, during all behaviors; (b) a predominant theta frequency in the hippocampal signal during awake immobility; (c) a lowering of the hippocampal theta peak frequency during REM sleep. Thus, high dose ethanol is a depressant in P and NP rats. The mechanisms which generate hippocampal theta may be different in the 2 groups; however, high dose ethanol has a similar effect on these mechanisms. The neuronal substrates that produce a differential behavioral sensitivity to ethanol are not reflected in the cortical and hippocampal EEG.

183.3

DENSITEES OF OPTOTO RECEPTORS IN THE CNS OF ALCOHOL-PRE-FERRING (P) AND -NONPREFERRING (NP) LINES OF RATS. W.J. McBride, E. Chernet*, X.-M. Guan, L. Lumeng*, T.-K. Li*.
Psychiatric Res. & Regenstrief Insts., Indiana Univ. Sch.
Med. & VAMC, Indianapolis, IN 46202.

The densities of delta and mu opioid receptors in the

The densities of delta and mu opioid receptors in the CNS of alcohol-naive, adult male P and NP rats (n=3 each) were determined with quantitative autoradiography. Coronal cryostat sections (20 um) were prepared from frozen brains, mounted onto subbed slides and dried. Sections were then incubated with (a) 5 nM [3 H]- 3 H]- 3 Habel Dala D-Leu enkephalin (DADL) in the presence of 1 uM D-AlaMe-PheGlycol enkephalin (DADL) to label delta sites; or (b) 5 nM [3 H] DAGO to label mu sites. Compared with the NP animals, the following differences were found for the P rats: (a) 25-30% lower amounts (p<0.01) of delta sites in layers I and II of the frontal cortex (87 \pm 4 \pm 9.65 \pm 1 fmol/mg prot) and the posterior cinculate cortex (62 \pm 5 fmol/mg prot) and the posterior cingulate cortex (62 \pm 5 vs 44 \pm 1); (b) 20% lower densities (p<0.05) of delta sites in the caudate-putamen (139 \pm 10 vs 116 \pm 4) and medial nucleus accumbens (ACC; 108 \pm 2 vs 88 \pm 7); and (c) a 40% higher value (p< 0.05) for the mu site in the lateral ACC (510 \pm 17 vs 367 \pm 3 fmol/mg prot). The data suggest that innate differences exist between the P and NP lines in the delta and mu opioid receptors in the ACC, a limbic region considered to be involved in mediating the actions of various drugs of abuse, including alcohol. OPERANT RESPONSE SUPPRESSION BY THE 5HT, AGONIST DOI IN J.N. Hington. Psychololgy Dept., Purdue Sch. Science; Psychiatric Research & Regenstrief Insts., Depts. Biochem. & Psychiatry, Indiana Univ. Sch. Medicine & VAMC, Indianapolis, IN 46205.

P and NP rats differ in several facets of CNS

rotonin (5HT) systems (McBride et al., Alcohol 7:199, 1990). To test for a functional difference in 5HT₂ receptors, P and NP rats were compared in an operant task for the suppression of responding following IP injection of the 5HT₂ agonist DI. Adult male P (n=9) and NP (n=7) rats were kept at 80% of their free-feeding body weights and trained to bar press for sweetened milk on a VI 1 min reinforcement schedule in three 90 min sessions each week. After stable responding was established, one weekly session served as baseline after IP injections of saline. In the next session, the rats were injected with DOI (0.125, 0.25 or 0.5 mg/kg). The baseline responses/session of the P rats were significantly higher than for NP rats (p<0.03; 521 ± 66 vs significantly higher than for NP rats (pt0.03; 521±66 vs 292±52). Response suppression (min) following DOI was significantly longer for the P than the NP rats at the 0.5 mg/kg dose (p<0.007; 46±12 vs 2±1 min). Compared with NP rats, the P rats are behaviorally more active in this task and may have enhanced functional sensitivity of $5\mathrm{HT}_2$ receptors. (AA03243 & AA07611)

183.4

PASSIVE AVOIDANCE BEHAVIOR IN ALCOHOL-PREFERRING AND

PASSIVE AVOIDANCE BEHAVIOR IN ALCOHOL-PREFERRING AND -NOMPREFERRING LINES OF RATES, G.J. Gatto, J.M. Murphy, R.B. Stewart*, W.J. McBride, Inst. Psychiat. Res., Med. Neurobiol. Prog., Indiana Univ. Sch. Med., & Psychol. Dept., Purdue Sch. Science, Indianapolis, IN 46202. Alcohol-preferring (P) and -nonpreferring (NP) lines of rats were compared on acquisition and retention of a one-trial passive-avoidance task. Adult male rats were randomly divided into 4 groups (n=9/group/line). One group/line received a 3-sec. 0.25 mA shock after stepning off a platform to a grid floor: the other two groups were given a 0.5 mA shock. There were no dif-rences between the lines in acquisition step-down latencies, but emotional reactivity may be less in P rats as indicated by almost no fecal boli compared with a mean of nearly two for NP rats (p<0.05). When retested on the platform 24 hr later, there was no significant difference in median step-down retention latencies between the P and NP groups trained at the 0.25 mA shock. However, for groups trained at 0.5 mA, P rats stayed on the platform significantly longer than NP rats (p<0.05; 532 vs 87 sec) and tended to be more active while on the platform (photobeam crossings/min; p<0.05, one-tail). Relative to NP rats, the P rats show greater retention of this passive avoidance task. Factors that could account for this difference include learning abilities, shock sensitivity and emotionality. (AA03243, AA07462 & AA07611)

EFFECTS OF ETHANOL ON ELICITATION AND RETENTION OF UNCONDITIONED AND CONDITIONED HEART RATE RESPONSES In THE DEVELOPING RAT. J. A. Saiers* B. A. Campbell* and D. J. Knapp* 1 Dept. Psych., Princeton Univ., Princeton, NJ 08544; Ctr. Alcohol Studies, Rutgers Univ., New Brunswick, NJ 08903

The effects of ethanol on elicitation and retention of unconditioned and

The effects of ethanol on elicitation and retention of unconditioned and conditioned heart rate (HR) responses to an 80 dB auditory stimulus in preweanling, periadolescent, and adult rats were assessed in this research. In Experiment 1, ethanol dose-dependently reduced the magnitude of the (unconditioned) heart rate orienting response (HR OR) equally in all 3 ages. In the second experiment, periadolescent animals exhibited long-term retention of habituation of the orienting response even though alcohol prevented initial elicitation of the cardiac OR. In contrast, adult rats in which initial elicitation of the OR was prevented by ethanol did not exhibit long-term retention of habituation of the OR. These results indicate that periadolescent rats are less susceptible than adult rats to ethanol-induced impairment in nonassociative learning.

Experiments 3 and 4 investigated the effect of ethanol on acquisition of a conditioned bradycardic heart rate response, established by pairing the 80 dB tone with a burst of white noise, in the developing animal. Ethanol dose-dependently impaired both acquisition and retention of the conditioned HR response. Ethanol did not affect acquisition or retention of the conditioned HR response differentially as a function of age, a result that contrasts with ethanol's effects on nonassociative learning.

Previous data collected by the present investigators indicate that periadolescent animals are less susceptible to ethanol-induced motor impairment than either preweanling or young adult animals. These motor data complement results obtained in Experiment 2, in which periadolescents, but not adults, were demonstrated to be more resistant to ethanol-induced impairment in nonassociative learning.

BODY TEMPERATURE AND ETHANOL TOLERANCE IN C57, LS AND SS MICE. D.A. Finn, B.L. Jones*, L.S. Kobayashi*, P.J. Syapin and R.L. Alkana, Univ. So. Calif. Sch. Pharm., L.A., CA 90033.

Acute sensitivity to ethanol-induced loss of righting reflex (LORR) increases in SS and C57 mice and decreases in LS mice, as body temperature during intoxication is increased. Adaptation based theories of tolerance predict that the degree of tolerance development is proportional to the magnitude of the disturbance. The present study tested the hypothesis that increasing body temperature during intoxication should increase tolerance to LORR in SS and C57 mice and decrease tolerance to LORR in LS mice. Drug-naive C57, LS and SS mice were injected with a hypnotic dose of ethanol and exposed to either 22 or 34°C for 6 hours for 7 days. On day 8 the mice were injected with ethanol and exposed to 22°C. LORR was measured on days 1 and 8. The results suggest that a greater degree of tolerance to LORR developed in the 34°C versus the 22°C exposed C57 mice, but not in LS mice. Although tolerance to LORR developed in the 22°C exposed SS mice, the 34°C environment was lethal to all SS mice. Studies are underway to investigate the role of ethanol concentration and other body temperatures in the development of tolerance to LORR. Overall, the results in C57 and LS mice suggest that differences exist in the effects of body temperature manipulation on acute and chronic sensitivity to ethanol. (NIAAA grant R01 AA05234)

Rol5-4513 Antagonizes Ethanol-Induced Stimulant Effects on

Measures of Exploration in Rats. T.O.Moore, N.L.June, M.J. Levis. Howard Univ., Washington, DC 20059.

Several reports have implicated GABA-BDZ mechanisms in mediating ethanol (E) effects in both locomotor activity and exploration. The effect of Rol5-4513 (RO), an imidazobenzodiazepine inverse agonist, on E-induced changes in locomotor activity varies depending on the type of activity observed. It has been found that RO blocks E-induced stimulation of holeboard activity in mice (Lister, R.C., Pharm, Bio, Behav., 28:75, 1987). The present study further investigated BDZ compounds in E-effects on holeboard activity in rats. RO and Rol5-1788 (BDZ antagonist) alone and in combination with low doses of E were examined. RO but not Rol5-1788 attenuated E-induced increases in exploration. Rol 1788 blocked RO's attenuation of E-induced exploration. RO alone did not effect holeboard activity; however, Rol5-1788 alone produced substantial increase in exploratory behavior. These data suggest that GABA-BDZ mechanisms play a significant role in E stimulation of holeboard Moreover, they suggest further that Rol5-1788 may possess intrinsic behavioral effects of its own.

SENSITIVITY OF HOT AND COLD MICE TO THE HYPOTHERMIC EFFECT OF ETHANOL, SEDATIVE-HYPNOTICS AND TRANSMITTER SPECIFIC

OF ETHANOL, SEDATIVE-HYPNOTICS AND THANSMITTER SPECIFIC DRUGS. DJ. Feller and J.C. Crabbe. Veterans Administration Medical Center and Oregon Health Sciences University, Portland, OR 97201. Mouse lines are being genetically selected which are sensitive (COLD) and resistant (HOT) to ethanol induced hypothermia. HOT/COLD mice from selected generations 7-9 (S7-9) and 11-12 (S11-12) were tested for their sensitivity to ethanol, longer chain alcohols and other hypnotics. Mice were administered 4 doses of each drug, and body temperatures measured using a rectal probe. There were dose-dependent decreases in temperatures after all drug treatments. COLD mice were more sensitive than HOT mice. The ratio of ethanol's ED-20C value for HOT versus COLD mice from S7-9 was 1.58. This ratio was 48% higher in mice from S11-12 compared to S₇₋₉. We also observed an increase in the ratios for the other alcohols in S₁₁₋₁₂ mice. The increased line difference in hypothermic response after continued selection was also found for the sedative drugs, diazepam and methyprylon. While HOT/COLD mice from S7-g were equally sensitive to the hypothermic effect of hydralazine, a peripheral vasodilator, after 5 more generations COLD mice were more sensitive than HOT mice.

Among the neurotransmitter specific drugs tested, only morphine and Among the neurotransmitter specific drugs tested, only morphine and levorphanol, µ-opiate agonists, were more potent at lowering the body temperature of COLD mice compared to HOT mice. These data demonstrate that with further genetic selection the HOT/COLD lines have continued to diverge in response to ethanol and some hypnotics. This may be partially due to changes in vascular mechanisms. Finally, the opiate data suggest that opiate and ethanol sensitivity may share some common genetic basis. These studies were supported by Grants AA05828, AA06243, AA06498, NIDA Contract 271-87-8120 and AA06548.

183.8

BEHAVIORAL AND NEUROANATOMICAL EFFECTS OF DAILY PEAK BEC RESULTING FROM EARLY POSTNATAL EXPOSURE TO ETHANOL P. L. Amsel. Department Greene, J. L. Diaz-Granados & A. Amsel. Department of Psychology and Institute for Neuroscience, University of Texas, Austin, Texas, 78712]

Electrolytic hippocampal lesions at 10-11 days of Electrolytic hippocampal lesions at 10-11 days of age (P10-11) significantly retard the acquisition of patterned (single) alternation (PA) with 60-s but not 8-, 15- or 30-s intertrial interval (ITI) in rat pups tested on P17-18 (Lobaugh et al., <u>Behav. Neurosci.</u>, 103:1159, 1989). Chronic prenatal exposure to ethanol (EtOH) does not disrupt PA in infant rats tested at P17-18 with either 8- (Wigal et al., <u>Behav, Neurosci.</u>, 102:43, 1988) or 60-s ITI (Greene et al., unpublished). We examined the effects on PA at P17-18 of postnatal exposure to EtOH with high (H) and low (L) peak blood ethanol concentration (BEC). Artificially-reared pups in the H condition were fed a 10.2% EtOH-adulterated diet (control pups received an isocaloric control diet) on 4 consecutive feedings in a 4-h period each day and unadulterated diet for the remaining 20 feedings. L pups received a 1.7% EtOH-adulterated diet on all 24 feedings. H pups at P17-18 were impaired in PA relative to L and control pups with a 60- but not a 30-s ITI.

This result mirrors the earlier lesion results. Neuroanatomical nns result mirrors the earlier lesion results. Neuroanatomical measures were significantly affected in Group H relative to Group L and controls. That H exposure produces more severe neurological damage than L exposure to comparable daily doses of ethanol confirms the findings of other investigators (Bonthius et al., Alc. 5:209, 1988). Supported by NIAAA grant AA07052.

183.10

Failure of Ro15-4513 to Alter Ethanol-Induced CTA in Rats. H.L.June, T.O.Moore, K.R.Domague, M.J.Lewis. Howard Univ. Wahsington, DC 20059.

Previous research (Amit, Z., Pharm. Bio. Behav., 42:26, 1989) suggests that Rol5-4513 (RO), an inverse benzodiazepine agonist attenuates an ethanol-induced conditioned taste aversion (CTA). To further investigate this possibility, the present study examined the effects of RO (3 mg/kg) on rats fluid consumption in both a traditional and a preexposure CTA paradigm. In an attempt to obtain maximal preexposure and unconditioned stimulus effects 2 g/kg of ethanol (20%v/v) was used in the present study. As previously reported (Cannon, et al., Anim.Behav.Proces. 41:26, 1975) animals given ethanol following 30 min access to saccharin established moderate aversions. RO failed to alter the aversion established under pretreatment or nonpretreatment conditions. These results suggest that GABA-BDZ mechanisms do not mediate an ethanolinduced CTA.

DOES FLUMAZENIL ANTAGONIZE OR POTENTIATE THE BEHAVIORAL EFFECTS OF ETHANOL IN SQUIRREL MONKEYS? DOES FLUMAZENIL E.M. Weerts and K.A. Miczek. Dept. Psychology, Tufts University, Medford, MA 02155.

Compounds acting at the Benzodiazepine receptor (BZR) are useful tools to determine the mechanism of action for some of the behavioral and physiological effects of ethanol (ETOH). However, the currently available BZR "antagonists", flumazenil and ZK 93426, possess intrinsic activities more similar to weak agonists and inverse agonists than pure neutral antagonists. Quantitative ethological studies in socially housed primates are particularly sensitive for detection of subtle drug effects and distinct changes in the behavioral repertoire. During the breeding season, socially housed dominant male squirrel monkeys show an increase in agonistic behavior. Low doses of ETOH (0.1, 0.3 g/kg) further enhanced aggressive behavior in dominant male monkeys. Higher ETOH doses (1.0, 1.5 g/kg) reduced these behaviors, and produce marked motor incoordination. In a similar manner as ZK 93426, pretreatment with flumazenil (10 mg/kg) effectively reduced the pro-aggressive effects of ETOH, but flumazenil potentiated the sedative and motor-incoordinating effects. Subordinate rlumazenii potentiated the sedative and motor-incoordinating effects. Subordinate males were threatened and attacked more frequently when administered flumazenil and ETOH, when compared to ETOH alone. These effects may be due to the mild agonistic properties of flumazenil. When administered alone, flumazenil, but not ZK 93426, increased the durations of foraging and feeding. It appears flumazenil pretreatment shifts the ETOH dose response curve to the right as evidenced by increased ETOH-induced staggering and duration of inactivity. The "antagonism" of the pro-aggressive effects of ETOH by flumazenil are more likely a potentiation towards the aggression-reducing properties of ETOH.

183.13

COMBINED EFFECTS OF ETHANOL AND MK 801 ON LOCOMOTOR ACTIVITY IN RATS. P. Robledo, W. Tanaka* and C. Ehlers. Department of Neuropharmacology, Research Institute of Scripps Clinic, 10666 North Torrey Pines Rd. La Jolla, CA. 92037.

Some of the actions of ethanol have been suggested to involve an interaction with the NMDA receptor complex. For instance, the non-competitive NMDA antagonist MK 801 has been found to potentiate the anticonvulsant effects of ethanol in rats. However, little data is available regarding the interaction of ethanol and MK 801 using other behavioral measures. The present study examined the effects of these two compounds on locomotor activity in rats. Sixteen rats were these two compounds on locomotor activity in rats. Sixteen rats were reated with saline only, MK 801 plus saline, saline plus ethanol, and MK 801 plus ethanol. Locomotor activity was quantified by placing rats in automated photocell activity cages for a period of 12 hours overnight. Ethanol (10%) was administered i.p. at the dose of 0.75 g/kg, and MK 801 s.c. at the dose of 0.1 mg/kg. Ethanol was found to reduce locomotor activity during the first three hours (F=13.5, df=1, p<.002), while MK 801 increased it (F=17.4, df=1, p<.001). Ethanol and MK 801 appeared to antagonize each others effects during this first and MK 801 appeared to antagonize each others effects during fins first three hour period. Three to six hours post-drug, ethanol was observed to augment (F=6.35 df=1, p<.02), and MK 801 to reduce (F=13.5, df=1, p<.002) locomotor activity, but ethanol did not antagonize MK 801's effect during this time period. These results demonstrate that ethanol and MK 801 have opposite effects on locomotor activity in contrast to what has been observed for other behavioral parameters (expopered by NIA A 0.6050) (supported by NIAAA 06059).

183.12

HYPERBARIC EXPOSURE ANTAGONIZES ETHANOL-INDUCED DEPRESSION OF LOCOMOTOR ACTIVITY IN MICE: DOSE RESPONSE. R.L. Alkana, D.A. Finn, B.L. Jones*, M. Babbini*, and P.J. Syapin. Alcohol and Brain Research Lab., School of Pharmacy, Univ. of So. Cal., Los Angeles, CA 90033.

Previous studies found that exposure to 12 atmospheres absolute (ATA) helium-oxygen (heliox) antagonized the acute and chronic behavioral effects of ethanol in mice. The present study characterized the effects of hyperbaric exposure on the dose-response curve for ethanol-induced depression of locomotor activity. Drug-naive, male C57BL/6 mice were injected with saline, 1.5, 2.0, 2.5 or 3.0 g/kg ethanol i.p., and were exposed to 1 ATA air, 1 ATA heliox or 12 ATA heliox at temperatures which offset the hypothermic effects of ethanol and helium. Locomotor activity was measured 15 to 45 minutes postinjection. Preliminary analysis indicates that ethanol caused a significant, dose-dependent reduction in activity beginning at 2.0 g/kg. Exposure to 12 ATA heliox completely antagonized ethanol's depressant effect on activity at 2.0 and 2.5 g/kg and partially blocked its effect at 3.0 g/kg. Activity in mice given 1.5 g/kg ethanol was not significantly affected in 1 ATA air, but was significantly activated in 12 ATA heliox. These results suggest that pressure shifts the ethanol dose response curve to the right and that pressure may unmask an activating effect of low dose ethanol on C57 mice. (NIAAA grant AA03972)

183.14

MK801 AND ETHANOL, EFFECTS ON THE EEG AND ERPS IN RATS. C.L. Ehlers, W. Kaneko*, T. Wall, and R. Ian Chaplin*. Department of Neuropharmacology, Inst. of the Scripps Clinic, La Jolla, CA 92037.

Recent neurophysiological data have suggested an interaction of ethanol with the glutamate-NMDA receptor complex. For instance, low levels of alcohol have been found to inhibit the ion current activated by NMDA in in-vitro preparations. The present study extends these paradigms in order to evaluate the electrophysiological effects of ethanol and the nonspecific NMDA receptor antagonist, MK801 in awake, behaving ethanol and the nonspecific NMDA receptor antagonist, MK801 in awake, behaving rats. Twenty Wistar rats were sterectaxically implanted with electrodes aimed at dorsal hippocampus (DHPC), amygdala (AMYG), nucleus accumbens (NAC), and frontal cortex (CTX). Rats received the following drug regimes: saline SC, 0.01 and 0.1 mg/kg MK801; EtOH, 0.75 g/kg IP; 0.75 kg EtOH plus 0.01 mg/kg MK801; 0.75 g/kg EtOH plus 0.01 mg/kg MK801. At least two weeks elapsed between drug doses. Five minutes of EEG was collected and event related potentials (ERPs) recorded in response to an auditory "oddball" paradigm between 30 and 40 minutes post drug. Spectral analysis revealed that MK801 (0.1 m/kg) produced significant increases in low frequency EEG components at all sites (1.6 Hz) and decreases in higher frequencies (18.32 Hz). Ethanol (7.5 n/kn) produced decreases in power in all frequency bands (16-32 Hz) Ethanol (0.75 g/kg) produced decreases in power in all frequency bands. Whereas the combined administration of EtOH and MK801 produced antagonistic EEG effects at low frequencies and additive effects in the higher frequency ranges. Evaluation of ERPs revealed that MK801 (0.1 mg/kg) produced significant decreases in the amplitude of the N1 and P2 components in cortex, decreases in the P1 and N2 in NAC and decreases in the P3 components in DHPC and AMYG. Ethanol was also found to produce decreases in the N1 in cortex and P3 in AMYG. The combined effects of MK801 and ethanol on ERPs were primarily additive. These studies suggest the antagonism of the NMDA receptor may produce some effects similar to ethanol, especially in response to sensory events. (Supported by AA 00098, 05069)

MONAMINES AND BEHAVIOR III

ROLE OF D, AND D, SUBTYPES OF DOPAMINE RECEPTORS IN NOVELTY-INDUCED PLACE PREFERENCE. M. T. Bardo, S. L. Bowling* and B. A. Mattingly. Dept. Psychology, Univ. Kentucky, Lexington, KY 40506 and Morehead St. Univ., Morehead, KY 40351.

Previous research has shown that the rewarding effect of novelty is blocked by the dopamine antagonist haloperidol (Bardo et al., <u>Pharmacol. Biochem. Behav.</u> 1989, 32:683-689). The present experiment examined the 1989, 32:683-689). The present experiment examined the ability of the D, antagonist SCH-23390 and the $\rm D_2$ antagonist sulpiride to block the rewarding effect of novelty. Adult male rats were exposed to one distinct environment for 30 min per day on eight consecutive days. On the ninth day, rats were injected with either SCH-23390 (0, 0.3, 0.1 or 0.3 mg/kg) or sulpiride (0, 25, 30, 50, 100 or 200 mg/kg). Thirty min after injection, rats were allowed free-choice access to the familiar environment and a novel environment for 15 min.

As expected, saline-injected control rats spent significantly more time in the novel environment than in the familiar environment. This novelty-induced place preference was blocked by SCH-23390 in a dose-dependent However, sulpiride was without effect except for the highest dose tested (200 mg/kg). These results suggest that the rewarding effect of novelty involves primarily a D, receptor system.

STRIATAL D1 AND D2 INTERACTIONS IN THE CONTROL OF SENSORIMOTOR BEHAVIOR IN RATS DEPLETED OF DOPAMINE AS NEONATES. B.J. Johnson and J.P. Bruno. Dept. of Psychology, Ohio State University. Columbus, Ohio 43210.

Rats depleted of dopamine (DA) as neonates are spared from the sensorimotor deficits seen in comparably damaged

adults. Recent studies suggest that striatal DA neurons mediate the expression of these behaviors in adults depleted as neonates. Our studies directly tested this hypothesis by determining the sensorimotor effects of intrastriatal injections of DA antagonists in these animals. Male rats received intraventricular injections of 6-HDA (100 μ g) or its vehicle on postnatal Day 3. Adult animals were tested for akinesia, catalepsy, and Adult animals were tested for akinesia, catalepsy, and somatosensory neglect immediately before and after intrastriatal injections (.5 µl) of the Dl antagonist SCH 23390 (1 µg), the D2 antagonist clebopride (2 µg), or both drugs. Vehicle-treated controls exhibited sensorimotor deficits after injections of D1, D2, or D1 + D2 antagonists. DA depleted animals were insensitive to the individual antagonists, but exhibited sensorimotor impairments after combined D1 and D2 blockade. Thus, activity within striatal DA neurons is necessary for sensorimotor function in normal animals and rats depleted of DA as neonates. The data also suggest lesion-induced differences in striatal D1 and D2 control of sensorimotor function.

COMPARISON OF THE EFFECTS OF SELF-STIMULATION ON DOPAMINE RELEASE AND METABOLISM IN THE RAT MEDIAL FRONTAL CORTEX, NUCLEUS ACCUMBENS AND STRIATUM STUDIED BY IN VIVO MICRODIALYSIS D. Nakahara*, N. Ozaki*2, K. Yoshida³ and T. Nagatsu*4. Departments of Psychology¹, Psychiatry² and Biochemistry⁴, Nagoya University, Nagoya 461, Japan and Department of Psychology³, Fukui Medical School, Fukui 1001.

Changes in dopamine (DA) release and its metabolism in the dopaminergic terminal regions, the medial frontal cortex (MFC), nucleus accumbens (NAC), and striatum (STR), were measured by a microdialysis during self-stimulation (SS) of the medial forebrain bundle (MFB) in rats pretreated with the dopamine (DA) uptake inhibitor, nomifensine (1 mg/kg, i.p.). SS of the MFB caused in-creased releases of DA in the MFC, NAC and STR. Despite blockade of DA uptake by nomifensine, the extracellular concentrations of the main DA metabolites, 3, 4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA), were also increased in these brain regions. However, there were clear regional differences in the neurochemical changes with the STR showing smaller extracellular levels of DA, DOPAC and HVA than either the MFC or the NAC. The results indicate that SS of the MFB mainly activates the mesocortical-mesolimbic DA systems, thereby increases in release and uptake as well as in intraneuronal metabolism of DA being produced in the dopaminergic terminal regions, the MFC and NAC.

ENHANCEMENT OF CONDITIONED REINFORCEMENT BY MECHANISMS OF DOPAMINE-DEPENDENT STRIATUM:INTERACTION WITH CHOLECYSTOKININ AND GLUTAMATE. B.J. Everitt. L. Burns*, G. Wolterink*, J. Le Noury*, I. Wolterink*, T.W.Robbins. Depts. of Anatomy and Experimental Psychology, Univ. of Cambridge, Cambridge CB2 3EB, U.K.

These studies examined the modulation of the enhancement of conditioned reinforcement (CR) with intra-accumbens d-amphetamine by simultaneous application of either the co-existing neuropeptide in dopamine neurons, cholecystokinin (CCK8 sulphated), or agonists and antagonists at excitatory amino-acid receptors, in order to modulate limbic and cortical glutamatergic inputs to the ventral striatum. Rats were trained to associate a light/noise compound stimulus with reward and the efficacy of the resulting conditioned reinforcer was tested using an acquisition of new response procedure. Intra-accumbens CCK dosean acquisition of new response procedure. Intra-accumbens CCK dose-dependently (1,3 and 10ng/1 ul) increased responding with CR, both by itself and in combination with intra-accumbens d-amphetamine (5ug/1ul). In contrast, quisqualate (0.3nmol/1ul) failed to affect responding with CR, either alone or with amphetamine, and NMDA (0.3 nmol/1ul) had only decremental effects. These results are discussed in terms of the regulation of mesolimbic DA neuron activity in reward-related situations and functional interactions between the limbic system and the ventral striatum.

HIGH-SPEED CHRONOAMPEROMETRIC MONITORING OF STRESS-ELICITED DOPAMINE RELEASE IN FREELY MOVING RATS. <u>A. Gratton</u> and M. D. Doherty, Douglas Hosp. Res. Ctr, McGill Univ., Montréal, CANADA, H4H 1R3.

and M. D. Doherty, Douglas Hosp. Res. Ctr, McGill Univ., Montréal, CANADA, H4H 1R3.

The effects of two stressors, tail pinch and immobilization, on dopamine (DA) release were studied in the nucleus accumbens, the striatum and the medial prefrontal cortex of freely-moving animals using high-speed chronoamperometry in combination with moveable electrochemical electrode assemblies. Male rats were each fitted with a stainless steel pedestal onto which could be attached a microdrive containing an electrochemical electrode assembly made of 3 glass-insulated, Nation-coated, 30 um diameter carbon fibers. Electrochemical recordings were obtained by applying to the electrochemical electrode, at a rate of 5 Hz, a +0.5V pulse relative to a Ag/AgCI reference electrode. The microdrive allowed several sites in the same animal to be tested for the effects of tail pinch and immobilization. Tail pinch stress was reliably associated with gradual increases in oxidation current in all three regions studied while immobilization stress produced similar but far less consistent results. The magnitude of the reduction current associated with the stress effects suggested that DA as well as DOPAC were the main contributors to the electrochemical signals. Typically, tail pinch-elicited signals reached peak amplitude (100-500 nM) 2 to 5 min after stimulus onset and decayed over a period of 5-20 min following stimulus offset. While the magnitude of the signals varied with recording site, these variations were not correlated with any obvious anatomical division. Furthermore, there was a tendency for the signals at the initial recording site to increase in size with repeated daily application of tail pinch stress. The present study provides a fine grain temporal characterization of stress effects on DA release in the freely moving animal and suggests that tail pinch can activate limbic, striatal and cortical dopaminergic systems. NUCLEUS ACCUMBENS DOPAMINE AND ANTICIPATORY BEHAVIOR. G.H. Jones, D.B. Neill, and J.B. Justice, Jr. Departments of Chemistry and Psychology, Emory University,

BEHAVIOR. G.H. Jones, D.B. Neill, and J.B. Justice, Jr. Departments of Chemistry and Psychology, Emory University, Atlanta, GA 30322.

Food-deprived rats placed on a scheduled food delivery regimen develop an anticipatory locomotor response which has been suggested to be due to the action of incentive stimuli. The proposed involvement of mesolimbic dopamine in incentive motivational processes and locomotor activity conditioned to drug presentation implicates this pathway in a general anticipatory state. This experiment examined the role of nucleus accumbens (NACC) dopamine in locomotor activity conditioned to food presentation using intracerebral microdialysis.

Rats were housed permanently in individual activity cages and their locomotor activity monitored daily between 09:00 and 17:00. Subjects were gradually reduced to 85% of their free-feeding weight and maintained at this reduced weight for the duration of the experiment. All rats were fed daily at 14:00. For one group of animals a stimulus light was illuminated for the 30 min period prior foeding (CUED). For another group of rats the light was turned on for a 30 min period which varied daily on a pseudo-random schedule (NON-CUED). Thus, for this latter group of animals there were no external cues for food delivery.

Both groups of rats demonstrated a marked anticipatory response, with locomotor activity increasing prior to food presentation. This response developed to a much greater extent in the NON-CUED group. Extracellular dopamine levels in the NACC, measured by microdialysis, increased in the NON-CUED group prior to feeding. Furthermore, this dopaminergic response did not correlate with the absolute level of locomotor activity.

These results indicate the involvement of mesolimbic dopamine in anticipatory behavior.

in anticipatory behavior.

EATING BEHAVIOR IS ACCOMPANIED BY DOPAMINE RELEASE IN RAT MEDIAL STRIATUM. G.M. Rose¹ and A. Gratton². ¹Medical Research Service, VAMC & Dept. of Pharmacology, UCHSC, Denver, CO 80262 USA and ²Douglas Hospital Research Center, McGill University, Montreal, Québec, Canada H4H 1R3

We recently began an investigation of the behavioral correlates of dopamine function in rat caudate nucleus, using in vivo electrochemical methods. Chronoamperometric recordings were made using a 2-electrode system (IVEC-5, Medical Systems Corp.) which was modified so that a miniaturized headstage amplifier plugged directly into a connector cemented on the rat's skull. The reference electrode consisted of a chlorided silver wire; the working electrode was a glass-insulated bundle of 3 carbon fibers (O.D. = 100 μ). Working electrodes were coated with Nafion and calibrated before being lowered into the caudate nucleus using a small microdrive.

The animals were observed during a number of natural behaviors. Of these, only eating and, under certain circumstances, sniffing, evoked a reliable increase in the electrochemical signal. The amplitude of eating-induced changes varied from 50->500 nM, and was proportional to the duration of the eating episode. Measurements of reverse current indicated that the signals consisted of a mixture of dopamine and DOPAC. Eating related signals occurred in response to a variety of food items; by contrast, drinking either plain or sugared water produced no reliable changes. In addition, gross or fine motor movements were not accompanied by reliable changes in signal amplitudes. (Supported by NIMH Grant P50 MH442212-01, the VAMRS, and NSERC of Canada.)

SEXUALLY RELEVANT STIMULI MESOLIMBIC DOPAMINE SYSTEM: M SEXUALLY RELEVANT STIMULI ACTIVATE THE MESOLIMBIC DOPAMINE SYSTEM; MEASUREMENT USING HIGH SPEED CHRONOAMPEROMMETRY IN FREELY MOVING

J. B. Mitchell and A. Gratton, Douglas Hosp. Res. Ctr., McGill Univ., Montréal, Québec, H4H 1R3 CANADA.

Quebec, H4H 1R3 CANADA.

Evidence from a variety of sources suggests that common neural mechanisms may underlie at least some aspects of all appetitively motivated behaviors. Exploration, feeding, drinking and sexual behaviors can all be elicited or facilitated by manipulations that activate the mesolimbic dopamine (DA) system. In order to assess the effects of sexually relevant stimuli, without copulation itself, on activity within the mesolimbic DA system, sexually experienced male rats were exposed bedding from cages that housed conspecific males, ovariectomized females, or estradiol- progesterone-primed females. Electrochemical recordings were obtained as the progester of the progesterone captor files electroche lowered weins a microdium to them. using a Nafion-coated carbon fiber electrode lowered, using a microdrive, to three different sites within the ventral striatum and nucleus Accumbens (nAcc). At each officient stress within the ventral striatum and nucleus Accuments (nAcc). At each site, the male rat was exposed to the three different stimuli. Electrochemical measurements were obtained by applying to the electrochemical electrode a +0.5 V pulse, relative to a Ag/AgCl reference electrode at a rate of 5 Hz. Olfactory stimuli associated with sexually receptive females elicited an increase in the oxidative current at all three sites; the largest increase, however, was obtained from the nAcc. Bedding from cages that housed other males elicited a small increase in oxidative Bedding from cages that housed other males elicited a small increase in oxidative current, but was consistently less potent than the bedding from the cages of sexually receptive female rats. Exposure to bedding from cages that housed ovariectomized, untreated females did not reliably increase oxidative current at any site tested. The reversibility of the oxidation current indicated that DA and DOPAC were the primary contributors to the electrochemical signal. Preliminary data suggest that opioid receptor blockade attenuates this activation. In conclusion, the present data indicate that sexually relevant stimuli potently activate the mesolimbic DA system, without the occurrence of copulation.

INDIVIDUAL DIFFERENCES IN THE BEHAVIORAL EFFECTS OF STRESSORS ATTRIBUTABLE TO LATERALIZED DIFFERENCES IN MESOCORTICAL DOPAMINE SYSTEMS. J.N. Carlson, R.W. Keller, S.D. Glick. Dept. of Pharmacology & Toxicology, Albany Medical College, Albany, NY 12208

Rats exposed to uncontrollable (YOK) but not controllable (ESC) footshock develop a transient behavioral deficit upon later shock escape testing. We have previously shown that exposure to YOK footshock stressors induces a change in the direction of rotational behavior and that effects of lack of stressor control are associated with changes in dopamine (DA) activity on the right side of the mesocortical DA system. It was thus of interest to assess possible differences among rats of differing lateral bias in their response to lack of stressor control. Male Zivic-Miller Sprague-Dawley rats were subjected in matched pairs to ESC or YOK footshock and were tested for footshock escape behavior on the next day. Left and right biased YOK rats differed in their escape performance; while right sided rats showed a large deficit, left biased rats performed better than comparable ESC animals. Similar effects of varying magnitude were seen in rats from a different stock (Taconic) and in rats from a different strain (Long-Evans). Neurochemical findings implicated lateralized differences in the mesocortical DA system as a substrate for these differences. These observed differences may have relevance for accounts of human depression that are based upon differences in cerebral laterality. (Supported by ES 04032)

DOSE AND TIME RESPONSE ANALYSIS OF APOMORPHINE EFFECT ON PREPULSE INHIBITION OF ACOUSTIC STARTLE. R.E. Wilcox¹. P.K. Randall¹ and ACOUSTIC STARTLE. R.E. Wilcox¹ P.K. Randall¹ and K.A. Young². ¹Dept. of Pharmacology, Univ. of Texas, Austin, TX 78712 and ²Dept. of Pharmacology, Texas A&M College of Medicine, Temple, TX, 76508

Temple, TX, 76508.

Previous studies have suggested a dopaminergic modulation of the acoustic startle response. Acoustic startle responses of rats during a short (25 min) or extended (85 min) session were observed after systemic injections of the DA agonist apomorphine (APO). Using a 73 dB tone as a prestimulus to 100 dB white noise (PP trials), and 100 dB white noise alone (WN trials), we found that IP injections of APO preferentially elevated PP means to levels statistically indistinguishable from WN means. This result confirms that APO disputs prepulse inhibition of the acoustic startle response under APO disrupts prepulse inhibition of the acoustic startle response unde appropriate conditions.

During the extended session, 5 min blocks of trials were interspersed between 20 min blocks when no stimuli were presented. This pattern of presentation produced increased responses in vehicle controls consistent with phesentation produced inclusate responses in volucie controls controls controls that the concept of sensitization. Sensitization was not observed in rats injected with a high (3.2 mg/kg) dose of APO. After an initial amplitude elevation compared to controls during the first 25 minutes, amplitudes of WN and PP startle responses for the high dose group decreased to levels lower than controls 65 and 85 minutes postinjection. WN trial amplitudes were not significantly different from PP trials during the 85 min session for this group. These results suggest that besides disrupting prepulse inhibition, APO also interferes with sensitization of the acoustic startle response. Since prepulse inhibition is disrupted in schizophrenics, APO-induced loss of prepulse inhibition in rats may represent a model of sensorimotor deficits of schizophrenia.

STRIATAL DOPAMINE D₂ RECEPTOR ASYMMETRY IN A
TRANSGENIC CIRCLING MOUSE. K.J. Miller, L.W. Fitzgerald, M.
Teitler, S.D. Glick, A.K. Ratty^a, and K.W. Gross^a. Dept. of
Pharmacology, Albany Medical College, Albany, NY and ^aDept. of
Molecular & Cellular Biology, Roswell Park Cancer Inst., Buffalo, NY.
We recently described the discovery of transgenically-derived

circling mice whose pooled striata showed elevated dopamine (DA) D₂ receptors without changes in the levels of DA and its metabolites (Ratty et al., Neurosci. Abstr.,1990). Since circling behavior has been associated with asymmetric striatal DA function, we assayed D₂ binding in homogenates of individual striata using ³H-N-methylspiperone (1.0 nM). The % asymmetry between left and right striata of homozygous circling mice averaged 47% while the % asymmetry in heterozygous normal mice averaged 17%. Similar asymmetries were also observed using receptor autoradiography with ¹²⁵I-IBZM (0.5 nM); the enhanced asymmetry in the circling mice was observed at several anterior-posterior levels of the striatum and was more apparent laterally than medially. We also studied the development of several behaviors in the these mice. Circling mice displayed a characteristic hyperactivity at postnatal day 16 which persisted though day 20. Exaggerated circling behavior by the mutant was present by day 14. These mice also showed less grooming and almost no rearing compared to normal mice. Relationships between the D₂ receptor asymmetries and the observed behavioral abnormalities are currently being investigated.

PERIODIC FOOD PRESENTATION INCREASES EXTRACELLULAR DOPAMINE AND METABOLITES IN NUCLEUS ACCUMBENS DIALYSIS PERFUSATES. L.D. McCullough, D. Singer*, and J. D. Salamone. Dept. of Psychology, Univ. of CT, Storrs, CT

Dopamine (DA) systems have been implicated in motor functions that are important for responding to motivationally-relevant stimuli. In vivo microdialysis was used to measure DA and its metabolites, homovanillic acid (HVA) and 3,4-dihydroxyphenylacetic acid (DOPAC), in unanesthetized rats subjected to periodic food presentation (PFP). different groups were studied: high rate of PFP (1 45 mg food pellet per 45 s), low rate of PFP (1 pellet per 4 min), mass feeding (15-18 g food), and unfed food-deprived controls. Although feeding on large numbers of pellets generated little locomotor activity, PFP induced substantial increases in locomotion comparable to those produced by low doses of amphetamine. PFP also produced large increases (20-50%) in DA release and metabolism in the nucleus accumbens. These data are consistent with the idea that the nucleus accumbens is involved in both locomotion and the response to motivationally-relevant stimuli.

184.12

CROSS-SENSITIZATION BETWEEN THE LOCOMOTOR-ACTIVATING EFFECTS OF THE DOPAMINE (DA) D2 AGONISTS BROMOCRIPTINE AND QUINPIROLE. D.C.

Hoffman and R.A. Wise.. Center for Studies in Behavioral Neurobiology, Dept. Psychol., Concordia U., Montreal, Canada. We recently discovered that the locomotor-activating effects of the dopamine (DA) D2 receptor agonist bromocriptine show environment-specific sensitization. To further explore this effect, tests for crossspecific sensitization. To further explore this effect, tests for cross-sensitization between bromocriptine and another D2 receptor agonist were conducted. Three groups of Long-Evans rats were used. The Paired group received 5.0 mg/kg bromocriptine prior to placement in an activity box for 3 h; following the session, vehicle was administered. The Unpaired group was given vehicle prior to testing and bromocriptine in the home cage following the session. The Vehicle group received vehicle injections in the activity box and home cage. Following eight alternate-day pairing sessions, each group was tested with 0.1 mg/kg quinpirole on six separate occasions. When tested with quinpirole, the Paired group showed significantly more activity than the Unpaired and Vehicle groups on the first test day. Thus, prior history with bromocriptine in the activity box altered the behavioral response to authorized indicating the development of environment specific cross quinpirole, indicating the development of environment-specific cross-sensitization. This suggests that a common synaptic or intraneuronal modification may underlie the development of drug-induced behavioral sensitization.

184.14

GUSTATORY NEOPHOBIA AND PERFORMANCE ON A LEARNED TASK ARE AFFECTED BY HIPPOCAMPAL SYMPATHETIC INGROWTH. Y. Avyagari and L.E. Harrell. Departments of Neurology and Psychology, Veterans Administration Medical Center and University of Alabama, Birmingham, Al. 35294.

After lesions of the medial septum, hippocampal NE levels increase as cholinergic input to the hippocampus is replaced by sympathetic ingrowth (HSI) from the superior cervical ganglion. Certain age related changes in inhibitory avoidance have been attributed to changes in brain NE. To assess whether increased NE levels due to HSI produce behavioral changes, we looked at gustatory neophobia, a passive avoidance task and open field activity in 33 adult male rats. Animals underwent 1 of 4 surgical procedures: sham surgery (CON), MS lesions (MS), Ganglionectomy (GX), or MS+GX. Four weeks after surgery, rats were trained on passive avoidance, and tested 24 hours later for retention. Open field activity (5 min) was recorded and 23-hr water/food deprived rats were given a choice of either tap water or 0.1% saccharin solution. Freliminary results indicated that MS animals (increased brain NE) preferred saccharin to water, as did GX, while CON and MSGX rats showed gustatory neophobia. MS animals were more active on open field and took longer to acquire and did not retain the inhibitory avoidance task. There were no differences in learning, retention or activity in the other groups. While the results from the drinking experiments support the NE hypothesis of age related changes, the results from the memory task need further exploration.

EFFECTS OF SOME ADRENOCEPTOR-SELECTIVE DRUGS ON AUDIOGENIC SEIZURE ACTIVITY IN DBA MICE. C.E.Lints, B.W.Santi* and D.Capruso*. Department of Psychology, Northern Illinois University, DeKalb, IL 60115.

Vehicle control and drugged (i.p.) DBA mice were exposed to a white noise stimulus of 110 dB (SPL) at their age of peak audiogenic seizure (AGS) susceptibility. This intensity stimulus produced intermediate levels of AGS incidence and latency from which either increases or decreases in AGS severity could be measured. The alpha-1 and beta-1 antagonists, corynanthine and metoprolol, respectively, produced significant dose-dependent protection from AGS. The nonselective beta agonist, isoproterenol, produced dose-dependent proconvulsant effects. The alpha-l agonist, methoxamine, was without effect by itself (possibly due to poor CNS penetration), but potentiated the proconvulsant effects of a subthreshold dose of isoproterenol. Subthreshold doses of corynanthine plus metoprolol interacted to produce complete protection from AGS activity, as did a maximally protective dose of metoprolol followed by a proconvulsant dose of isoproterenol.

These results are consistent with the midbrain adreno-ceptor hypothesis of AGS activity in DBA mice, which posits that excess proconvulsant alpha-l and beta-l adrenoceptors in auditory centers of the DBA midbrain modulate seizure severity in these animals.

NA NEURONS ARE REQUIRED FOR POSTSYNAPTIC α_2 -ADRENOCEPTOR DOWN-REGULATION BY DMI, BUT NOT ECS. D.J. HEAL AND W.R. BUCKETT. (SPON: Brain Research Association) Boots Pharmaceuticals Research Dept, Nottingham NG2 3AA, UK. While intact noradrenaline (NA) neurones are essential

for the 8-adrenoceptor desensitization by desipramine (DMI), this is not so for the electroconvulsive shock (ECS) effect. Recently, we reported that DMI and ECS down-regulated postsynaptic α_2 -adrenoceptors assessed by clonidine mydriasis (Heal, D.J. et al Br. J. Pharm., 99, 74P, 1990). We have now studied the effect of NA treated C57/B1/6 mice were given DSP-4 (100 mg/kg) twice, 7 days apart. Lesioning was initially confirmed by days apart. Lesioning was initially contirmed by abolition of methamphetamine (0.5 mg/kg) mydriasis; ultimately by HPLC-ECD. We gave DMI (10 mg/kg) for 14 days; ECS (200 V, 2s) to anaesthetised mice 5 times over 10 days. Clonidine (0.1 mg/kg) mydriasis was measured 24h later. DMI and ECS decreased clonidine mydriasis by 24h later. Den and the decreased cloud the mydriasis 32% (P<0.001) and 41% (P<0.001), respectively. DSP-4 abolished mydriasis to methamphetamine (98%, P<0.001) but did not alter the response to clonidine. The lesion decreased brain NA by 64% (P<0.001), but did not alter 5-HT or dopamine levels. DSP-4 abolished the effect of DMI on mydriasis, but did not prevent the attenuation by ECS (24%, P<0.05). Hence, like 8-adrenoceptor down-regulation, the ECS effect is independent of an NA input, whereas this is essential for the action of DMI.

EARLY POSTNATAL HANDLING OR MATERNAL SEPARATION IN RATS: EFFECTS ON BEHAVIOR AND BRAIN BETA-ADRENOCEPTORS. L.A.

Hilakivi-Clarke, J. Turkka*, R.G. Lister and M. Linnoila.
Lab. of Clin. Stud., NIAAA, Bethesda, MD 20892.
This study investigated the effects of early postnatal handling or temporary maternal isolation on various behaviors and beta-adrenoceptor binding. From the 5th to the 20th postnatal days, male Wistar rat pups were either The 20th postnatal days, male wistar rat pups were either 1) handled daily for 3 min, 2) isolated from their nursing mother for 1 hr daily, 3) non-handled but housed with handled or isolated rat pups, or 4) non-handled and housed in cages which were left undisturbed. Eight to sixteen weeks later, it was found that the time spent immobile in Porsolt's swim test was shortened (p<.01) in the handled rats, as compared with all other groups. Voluntary alcohol consumption, assessed using a procedure in which the rats were allowed a choice between tap water and a 5% (v/v) alcohol solution, was also reduced in the handled rats (p.01). No differences in the measure of anxiety - food consumed in a novel environment - or the time spent in social, aggressive and defensive behaviors in resident-intruder paradigm, were noted. Neither di Neither did the density or affinity of beta-adrenoceptors in the frontal cortex or hippocampus differ significantly between the groups. The results indicate that short-lasting maternal separation does not cause sustained effects on a number of behaviors in the rat. Early postnatal handling, however, leads to shortened immobility in the swim test and reduced voluntary alcohol consumption.

184.16

THE EFFECTS OF NORADRENERGIC AGONISTS ON THE DRL 72-S SCHEDULE. R. Dunn. D. Jolly and L. Seiden. Dept. of Pharmacological and Physiological Sciences, Univ. of Chicago, Chicago, IL 60637.

Antidepressants, including the norepinephrine reuptake inhibitors desipramine and protriptyline, increase the reinforcement rate and decrease the response rate of rats performing on a differential-reinforcement-of-low rate 72-second (DRL 72-S) operant schedule (Seiden et al, Psychopharmacol. 86:55, 1985). The present work examined further the effects of noradrenergic agents on this antidepressant screen. Maprotiline, a tetracyclic antidepressant, and nisoxetine, a non-tricyclic norepinephrine reuptake inhibitor, produced antidepressant-like effects on the DRL 72-S schedule. Neither the $\alpha\text{-1}$ agonist phenylephrine nor the $\alpha\text{-2}$ agonist clonidine produced the same effects as antidepressants. However, isoproterenol, a β agonist, and the $\beta\text{-}2$ agonists salbutamol and clenbuterol did elicit antidepressant-like effects. Thus, β receptors mediate the noradrenergic component of antidepressant-like effects on the DRL 72-S schedule. This research was supported by PHS MH-11191; RSA MH-10562 (L.Seiden).

EFFECTS OF VACOTOMY ON HIPPOCAMPAL LESION-INDUCED BEHAVIOR AFTER PERIPHERAL INTERVENTION: OPEN FIELD ACTIVITY AND NOVELTY RESPONSE. D.L.

Maier and R.L. Isaacson. Dept of Psychology, SUNY, Birghanton, NY 13901.

Peripheral pharmacologic interventions attenuate hippocampal lesioninduced deficits in both spatially based behavioral tasks and open field locomotion (Maier, Ryan, and Isaacson, 1990). This report examines the possible role of visceral afferents in the vagus nerve on behavioral alterations produced by peripheral sympathetic intervention in the open field (OF) and response to novelty. Male Long-Evans rats received a bilateral subdiaphragmatic vagotomy or sham surgery. These groups were divided into groups receiving bilateral hippocampal lesions (H) or sham operations. Subsequently, drug treatments consisted of repeated peripheral administration of bretylium (5 mg/kg) for seven days, and norepinephrine (4 µg/kg, ip) or saline vehicle before each test. Locomotor activity and response to novelty were tested sequentially starting 35 days after surgery. In the novelty test, a fourth novel arm was added to a T-maze, making it into a cross-maze. All rats had previous repeated experience with the T-maze. The locomotor hyperactivity of H rats was reduced by prior vagotomy (p 4.001). There was no drug treatment effect. The results of novelty testing indicated that all groups entered the "novel arm" more frequently than the three familiar arms (p 4.01), although the sham-vagotomized, saline-treated H group did this least and entered all maze arms more frequently than any other group (p 4.01). The triple interaction of lesion, treatment and vagotany measured in time spent in the novel arm (p \pounds 0.1) will be interpreted and discussed with relevance to possible beneficial effects of pharmacologic intervention found in specific surgical groups.

d-AMPHETAMINE EFFECTS ON LANGUAGE AND MOTOR REHAVIORS IN A CHRONIC STROKE PATIENT. R. Homan, J. Panksepp, J. McSweeny*, P. Badia, F. Borroughs*, L. Chapman* and R. Conner*, Medical College of Ohio at Toledo, Toledo, OH 43699 and Bowling Green State Univ., Bowling Green, OH. Presently no established pharmacological maneuvers exist which can

facilitate recovery in long-term stroke patients. Because of promising preclinical data, we evaluated the effects of 15 mg oral d-amphetamine (DEA) and placebo using a single-subject double-blind ABAB design, followed by a chronic phase of 6 consecutive daily doses of 15 mg DEA or placebo. A standard test series evaluated motor, speech and cerebral functions. The subject, a 53 year-old male was hemiplegic with transcortical motor aphasia 1.5 years after an remergency left internal carotid endarterectomy. SPECT scans demonstrated markedly diminished blood flow in frontal and parietal areas of the left cortex.

Within 5 hrs following drug administration, the subject underwent 5 testing stages: saggital gait analysis, a simulated driving test, an abbreviated neuropyschological battery, language evaluation, and a performance assessment battery accompanied by EEG/ERP analysis at frontal central and posterior sites on each hemisphere. The largest improvements following DEA were observed on the simulated driving test, measures of language performance (including naming, morphemes per second, onset pauses, pauses/utterance). DEA also increased cerebral blood flow, signal detection on a continuous performance task, with decrerases in both errors of commission and omission. The power in the EEG was shifted away from slow potentials in the afflicted hemisphere There were speech, motor, and IQ improvements as a result of testing, with the best performance being achieved at the end of the chronic DEA phase Benefits were not sustained, but they were of sufficient magnitude that a therapeutic phase will be conducted (using a titration schedule of DEA) to determine whether improvements can be consolidated into a permanent store.

CALORIC RESTRICTION PREVENTS AGE-ASSOCIATED IMPAIRMENTS IN LEARNING OF A MAZE STRATEGY BY AUTOIMMUNE MICE. E.N. Ahanotu, H. Lal. P. L. Prather, and M.J. Forster, Dept. of Pharmacology,

Texas College of Osteopathic Medicine, Fort Worth, Texas 76107-2690
When present in the MRL/MpJ++ background , the "accelerator "gene ipr
(lymphoproliferation) results in rapid development of autoimmune disease and death by 8 months of age. Concurrently, these mice (MRL/MpJ-lpr) show evidence of rapid cognitive decline (Forster et al., Behav. Neural Biol., 49:139, 1988). In this experiment we tested the prediction that cognitive decline associated with autoimmunity would be retarded by caloric restriction, an experimental procedure known to decelerate immunologic consequences of "lpr" MRL/MpJ-lpr and MRL-MpJ-+ mice were maintained on either ad libitum feeding or 40% caloric restriction beginning at weaning and were subsequently compared for learning and memory according to a delayed reversal paradigm (Lal et al., Soc. Neurosci Abstr., 16 [this volume]) when 2.5, 3.5, or 6.5 months old. In order to differentiate short- and long-term effects of the diet conditions, half of the mice under each diet condition were switched to the opposite condition 5 weeks before testing at 6.5 months. The 6.5-month-old MRL/MpJ-/pr mice learned the maze reversal strategy more slowly and showed more rapid forgetting when compared with younger MRL/MpJ-/pr mice. Caloric restriction completely prevented the age-associated decline in ability to acquire the learning strategy in MRL/MpJ-lpr, but was only partially effective in preventing decline of memory capacity. These results suggest that the gene "lpr" leads to acceleration of age-associated learning and memory dysfunctions, whereas restriction of calories acts in an opposite fashion. Analysis of the neurological functions influenced by caloric restriction and the *lpr* gene might reveal important neuroimmunologic processes involved in autoimmuneassociated cognitive decline. A DELAYED REVERSAL PARADIGM FOR ASSESSMENT OF AGE-ASSOCIATED DECLINE IN MEMORY CAPACITY OF INDIVIDUAL MICE. H. Lai, M. Flores, and M.J. Forster, Dept. of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, Texas 76107-2690 To estimate age differences in memory capacity or rate of "forgetting", it is

often necessary to employ several different groups of a given age, each tested under a different retention parameter. In the current experiment, we tested the effect of age on memory using a paradigm which permitted retesting of the same subject under a variety of retention parameters. Mice aged 8, 14, or 27 months were initially trained for discriminated shock avoidance in a T-maze and, subsequently, the mice received daily "reversal" training in which the correct goal arm on all trials (intertrial interval of 1 minute) for that session was the one opposite that selected on the first trial. All mice eventually developed a reliable strategy of reversing arm choices between the first and second trials on each day. During the memory-testing phase, a delay of 7, 15, 30, 60, or 120 minutes was introduced between the first and second trial, and memory capacity was considered to be inversely proportional to the decline in performance as a function of delay. The delays were presented in an alternating ascending and descending sequence until each delay had been presented four times. The stability of the reversal strategy was verified between each series of 5 delays. Although the 27-month-old mice learned the discrimination and avoidance components more slowly than the younger mice, all mice acquired the reversal strategy within a similar number of sessions. In contrast, time-dependent decay of memory performance (i.e, forgetting) became more rapid as a function of age. These findings indicate that delayed reversal provides an "individual" estimate of memory capacity for mice, which would have a variety of applications in gerontology, pharmacology and toxicology. [Supported by NIH grants AG06182 (MJF) and AG07695 (HL)].

ENDURANCE TRAINING IN AGED F-344 RATS: FAILURE TO MODIFY SPATIAL MEMORY, BRAIN AUTOIMMUNITY, AND HUMORAL IMMUNE RESPONSE. M. J. Forster. C. A. Barnes, M. Fleshner, E. N. Ahanotu, M. L. Laudenslager, R. S. Mazzeo, S. F. Maier, and H. Laj. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107; Departments of Psychology and Kinesiology, University of Colorado, Boulder, CO 80309; and Behavioral Immunology Laboratory, University of Colorado, Boulder, CO 80309; and Sensor No. 100, 20004.

Colorado, Boulder, CO 80309; and Behavioral Immunology Laboratory, University of Colorado, Boulder, CO 80309; and Behavioral Immunology Laboratory, University of Colorado Health Sciences Center, Deriver CO, 80204.

The current studies addressed the possibility that impaired immune and central nervous functions of old individuals could be modified by physical exercise. After ten weeks of exercise training employing a motorized treadmill (Mazzeo et al., J. Appl. Physiol. 57:1369, 1984) old F-344 rats (24-27 months) showed increases in several indicators of physical endurance (e.g., oxygen consumption and reductions in the respiratory exchange ratio). However, exercise failed to improve antibody response to keyhole impet hemocyarin (Laudenslager et al., Br. Behav. Immun. 2:1, 1989) or to alter the frequency of serum antibodies recognizing 64- and 45-kl Drain cell membrane antigens (Ahanotu et al., FASEB J. 3:4571, 1989). Spatial memory performance on a circular platform task (Barnes, JCPP 93:74, 1979) was also unaltered following this exercise training. There was, however, a significant relationship between behavioral performance on the circular platform and the presence of brain-reactive antibodies in the old rats, regardless of training group. Overall, these results suggest that some immunological and neurological functions may be insensitive to modification by endurance training which is initiated relatively late in life. The data also suggest that individual differences in cognitive performance of old rats can be predicted by the presence or absence of brain-reactive antibodies. Although the significance of this relationship is not yet dear, it is possible that these antibodies could play a role in central nervous system changes that lead to that these antibodies could play a role in central nervous system changes that lead to compromised memory function in old animals. MEMORY SCORES IN MIDDLE-AGED RATS PREDICT LATER DEFICITS IN MEMORY, PARADOXICAL SLEEP AND BLOOD GLUCOSE REGULATION IN OLD AGE. W.S. STONE and P.E. GOLD. Dept. Psychol., U. Virginia, Charlottesville, VA 22903.
Paradoxical sleep measures and blood glucose regulation

Paradoxical sleep measures and blood glucose regulation are significantly correlated with memory in old rats. Here, using a longitudinal design, we determined whether measures of sleep or glucose regulation in middle-aged rats would predict individual differences in memory when the rats were old. Sleep (3-hr records via cortical electrodes), blood glucose regulation (tail nicks after 500 mg/kg glucose injection, IP), and memory (spontaneous alternation, 20 trials, 1 min ITI) were assessed in male Sprague-Dawley rats every 2-3 months from 12 to 24 months of age. The 10/23 rats which completed the protocol were then trained in an inhibitory avoidance task (1 ma, 1 s FS) and tested for retention 24 hr later. 1 s FS) and tested for retention 24 hr later.

The major finding of the study was unexpected. Rather than finding biological measures in middle-age (e.g. poor glucose tolerance) which predicted poor memory in old age, memory in middle age predicted deficits in both behavioral (inhibitory avoidance) and biological (glucose tolerance and paradoxical sleep) measures in old age. These findings indicate that behavioral measures of memory may be useful markers of biological aspects of aging. They also provide additional evidence that levels of glucose regulation and paradoxical sleep are correlated with measures of memory. (Supported by AG 07648, ONR N0001489-J-1216 and NRSA AG 05408).

SENESCENCE ACCELERATED MOUSE (SAM):

SENESCENCE ACCELERATED MOUSE (SAM): ANIMAL MODEL FOR AGE-RELATED EMOTIONAL DISORDER AND MEMORY IMPAIRMENT. M. Miyamoto, Y. Kiyota,* M. Nishiyama* and A. Nagaoka* Research and Development Devision, Takeda Chem. Ind., Osaka 532, Japan.

We have demonstrated that a substrain of senescence accelerated mouse (SAM), SAM-P/8 mice showing accelerated aging, exert marked deficits in learning and memory compared to SAM-R/1 mice showing normal aging (Physiol. Behav. 38, 399, 1986). Age-related changes in emotional behavior and in learning ability in P/8 and R/1 mice were studied. P/8 mice showed significant deficits in passive avoidance and water maze tasks compared to R/1 mice, which became obvious with aging. The impairments in the P/8 strain were derived from reduced ability in acquisition and retention. SAM-P/8 mice showed age-related acquisition and retention. SAM-P/8 mice showed age-related acquisition and retention. SAM-P/8 mice showed age-related decrease in latency to eat novel food in a neophobia test. In an elevated plus-maze, P/8 mice exhibited apparent increases in the number of entries into open arms and time spent on open arms, implying age-related reduced anxiety in the P/8 strain. Aged R/1 mice, 20 months old, showed low anxiety-like behavior such as was seen in the P/8 strain. These findings indicate that the P/8 strain shows age-related low anxiety-like behavior which may be related to deficits in learning and memory in the strain, and suggest that P/8 mice may be a valid animal model for studying emotional disorders and related memory impairment in dementia. impairment in dementia.

AGE-RELATED DECREASE IN HIPPOCAMPAL RESPONSIVENESS TO THE GUTAMATE SYNAPTIC RECEPTOR AGONIST AMPA. G. Rao. C. A. Barnes and B. L. McNaughton. Department of Psychology, University of Colorado, Boulder, CO 80309

We previously reported that CA1, CA3 or FD unit responsiveness to glutamate applied near the soma by iontophoresis was unchanged across a range of ages from 5-28 months in F-344 rats. However, the effects of exogenous glutamate may be extrasynaptic in origin, as they are not blocked by the quisqualate receptor antagonist CNCIX. In this study, possible changes in hippocampal synaptic function with senescence were assessed using AMPA, a specific and potent quisqualate receptor agonist. Hippocampal slices were prepared from rats at ages 5,9.24, and 27 mo (n=4 per group). In both CA1 and the FD, a stimulating electrode was positioned in the apical synaptic zone, and two ringer-filled recording pipettes were placed on either side about 1 mm apart. Stimulus intensity was set to evoke a field epsp of about 2 mV at each location. After collecting baseline responses at 1.1 Hz, an AMPA (.1 M) pipette was touched to the slice surface within 100 μm of one recording site, -100 nA (7 sec on, 3 sec off) was applied for 2 minutes, and the AMPA pipette was withdrawn. In all age groups, application of AMPA produced an attenuation of the field epsp within 5 minutes, without significantly affecting the control response 1 mm distant. The magnitude of the AMPA response was substantially reduced in the old animals in CA1, but there was no age effect in FD. These results were confirmed in a second study with 5 mo old (n=3) and 27 mo old (n=4) rats in which AMPA was applied for one recording location and glutamate was applied at the other. In this study also, there was no age-related change in responsiveness to glutamate (see below). We conclude that there is a region specific, age-dependent alteration in postsynaptic sensitivity that is localized to the sites (probably synaptic) which are accessible to exogenous AMPA but not t

QUANTAL ANALYSIS OF PERFORANT PATH TO DENTATE GRANULE CELL SYNAPTIC STRENGTH IN OLD AND YOUNG RATS. T. C. Foster. C. A. Barnes, and B. McNaughton. Department of Psychology, University of Colorado, Boulder, CO, 80309-

In rats, a decrease in spatial memory and a loss of perforant path to dentate granule cell synaptic contacts are observed with aging. However, the efficacy of remaining synapses appears to increase, as assessed indirectly by the EPSP to presynaptic fiber potential ratio *in vitro* (Barnes & McNaughton, <u>J.Physiol</u>, 1980). To examine this in more detail, we compared quantal parameters of perforant path synapses in 5 (n=13), 9 (n=14) and 24 (n=13) month old F344 rats using minimal electrical stimulation to (1=14) and 24 (in 15) influit of 0.544 rats using influintal electrical simulation to distribute activate single perforant path fibers, while recording intracellularly from granule cells (McNaughton, Barnes, and Andersen, J. Neurophysiol, 1981). The average EPSP amplitudes were related to the product "m" (mean number of transmitter quanta released per impulse) and "q" (the size of the individual quantal components of the EPSP). These estimates were obtained using both the method of failures and by a noise deconvolution algorithm. A positive correlation (p < 0.05) of q with age was observed. These results suggest that average quantal size in the perforant path may increase over the lifespan and thus account for the apparent increase in efficacy of surviving synapses in old rats. This is particularly interesting in light of the fact that Foster and McNaughton have recently shown that **q** also increases after the induction of long-term enhancement (LTE/LTP) is obtained by Schaffer-collateral-CA1 synapses. THE CONTRIBUTION OF PROXIMAL AND DISTAL VISUAL COMPLEXITY TO THE DISCHARGE CORRELATES OF HIPPOCAMPAL 'PLACE' CELLS. B. W. Leonard. B. L. McNaughton. C. A. Barnes, and M. Marquis'. Department of Psychology, University of Colorado, Boulder 80309.

B. L. McNaughton, C. A. Barnes, and M. Marquis*. Department of Psychology, University of Colorado, Boulder 80309.

To assess the contribution of visual complex-spike cells, we recorded cells in two specific discharge of hippocampal complex-spike cells, we recorded cells in two environments differing only in the number and complexity of visual cues and in which the behavioral demands placed on the animals were identical. Three F-344 rats were trained to retrieve food pellets in a cylindrical apparatus which had a single white card on the wall, subtending 100° of arc. Cells were recorded first in this simple-oue condition. Different CS cells were recorded in the same apparatus whith more complex visual cues on the wall, lead direction and spatial location were monitored by tracking two points on the rats' headstage. For analysis, the cylinder floor was divided into 32 locations. For each visit, firing rates were calculated as a function of head direction (8 intervals). These rates were analyzed by multiple regression to assess the relative contributions of location and orientation to the overall firing variance.

For 75 CS cells, the amount of variance explained by location did not differ between the explained variance due to head direction. Thus, place cells are more directionally dependent in visually rich environments. Interestingly, however, the explained variance in either environment was considerably lower than that observed in different experiments in which the recording was carried out on an open radial maze. Thus, while proximal visual complexity contributes to direction-dependency of spatial firing, it also appears that in high-walled environments hippocampal CS cells send a rather unreliable signal to their efferent targets. This may indicate that remote visual cues play a dominant role in controlling hippocampal output. (Supported by AG03376 and NS20331)

HEAD DIRECTION CELLS IN THE DORSAL PRESUBICULUM INTEGRATE BOTH VISUAL AND ANGULAR VELOCITY INFORMATION. E. J. Markus. B. L. McNauchton. C.A. Barnes. J. C. Green'. and J. Melizer. Dept. Psych., Univ. Colo., Boulder, CO 80309. Cells that fire selectively when a rat is facing a certain direction, independent of its location in space, have recently been found in the dorsal presubiculum (Taube et al., J. Meurosci, 1990). In the present experiment, over 200 cells in total were recorded in this general region (including a few penetrations in subiculum and retrosplenial cortex), from 4 F-344 rats, using a modified version of the stereotrode method (McNaughton et al., J. Neurosci Meth. 1983) that permitted multiple penetrations per hemisphere. Of these, approximately 15% exhibited noticeable unimodal directional selectivity, and were subjected to systematic analysis under two environmental conditions. Directional and angular movement effects were first examined in a large room filled with complex sensory stimuli. Next the same measurements were conducted in a controlled-cue room whose main visual stimulus came from a brightly illuminated white panel on one of the surrounding black curtains. Measurements were repeated in the same room in total darkness, again with the lights on, and again following a 90' shift in the white panel. A final measurement was taken in the original environment. Most of the recorded cells exhibited a lesser degree of directional uning than reported by Taube et al., an effect which may result either from the present use of albino rats or from differences in recording location. The average arage of directional specificity was 101'. About 80% of the cells exhibited a pronounced sensitivity to movement, and about 25% were selective for the direction of angular movement. All cells rotated their directional preferences according to the shift in the wall panel, and in all but 1 cell, directional preferences according to the shift in the wall panel, and in all but 1 cell recorded in the dark. In a diffe

ACTIVATION OF TRANSCRIPTION FACTOR GENES IN HIPPOCAMPUS OF ACTIVATION OF TRANSCRIPTION FACTOR GENES IN HIPPOCAMPUS OF CHRONICALLY-PREPARED RATS FOLLOWING INDUCTION OF LONG-TERM SYNAPTIC ENHANCEMENT. C. A. Barnes, B. L. McNaughton, B. Christy', A. J. Cole, J. M. Baraban, and P. F. Worley. Dept. of Psychology, Univ. Colorado, Boulder, CO 80309; Depts. Neuroscience and Molecular Biology, Johns Hopkins Univ., Baltimore, MD

21205.

Programs of gene activation appear important in long-term cellular responses to transmitters and growth factors. In a previous study, we found that synaptic stimulation of the perforant pathway that elicits LTE/LTP in hippocampus of anesthetized rats in vivo, activates zii/266, a putative transcription factor (TF) gene, in hippocampal granule cells (Nature 340:474, 1989). With the ultimate goal of studying the time course characteristics in the absence of secondary effects of surgery or amesthesia, we have initiated studies using rats with chronically indvelling electrodes.

After electrode implantation, rats were permitted to recover for a minimum of 2 weeks.

After electrode implantation, rats were permitted to recover for a minimum of 2 weeks. In initial studies, we ascertained that chronically-implanted electrodes do not alter levels of zi/288 mRNA in the hippocampus relative to naive controls (n=4). To examine TF responses to synaptic stimuli, animals received high-frequency stimulation (400 Hz) and were sacrificed 30 or 60 min after the initiation of this stimulation. As observed in anesthetized rats, zi/z88 mRNA is markedly increased in granule cells by high-frequency (HF) stimuli that induce LTE but not afterdischarges (n=8 of 8 preparations). In contrast to findings in anesthetized rats, preliminary data suggest that jun-8, but not c-jun or c-fos, is also reliably induced by stimuli that produce LTE in awake animals. Increases in zi/288 or jun-8 mRNA are blocked by the NMDA receptor antagonist MK-801 (1.0 mg/kg). Furthermore, zi/1288-like immunoreactivity is markedly increased in nuclei of granule cells 30 min following HF stimulation. Our results indicate that the chronic preparation may be useful for studies aimed at understanding the relationship between genomic activation and the long-term maintenance of LTE. between genomic activation and the long-term maintenance of LTE.

HEAD-DIRECTIONAL AND BEHAVIORAL CORRELATES OF POSTERIOR CINGULATE AND MEDIAL PRESTRIATE CORTEX NEURONS IN FREELY-MOVING RAT L. L. Chen, B. L. McNaughton, C. A. Barnes, and E. R. Ortiz*, Dept. Psychol., Univ. of

Colorado, Boulder, CO 80309
Posterior cingulate and medial prestriate cortex form a bridge between parietal/visual Posterior cingulate and medial prestriate cortex form a bridge between parietal/visua cortex, and postsubiculum (Vogt and Miller,1983; Vastola, 1982). Recently, Taube et al. (1990) have shown that cells in postsubiculum code for head direction, independently of spatial location or behavior. It is thus of interest to analyze the directional and behavioral correlates of cells in regions which may project to postsubiculum in order to elucidate how the head-orientation cells may be constructed from simpler sensory and/or motor input. To quantify head-directional and behavioral correlates, a dual-LED recording headstage was mounted on the heads of freely-moving rats so that position and head-direction were obtained simultaneously with single unit activity recorded using the stereotrode technique. Data were analyzed in terms of unit firing relationships to head orientation, visual stimuli, and angular and linear motion on the maze.

A substantial number of cells (about 10%) were recorded that showed significant directional firing bias in the standard maze configuration. Most but not all of these cells changed their orientation bias following rotations of the major salient visual stimuli. A few cells were resistant to rotations of visual stimuli, and maintained a directional bias in total darkness. Most cells exhibited at least a general sensitivity to state of motion, with many

cells were resistant to rotations or visual stimuli, and malaritane a directorial bals in total darkness. Most cells exhibited at least a general sensitivity to state of motion, with many (over 20%) being selective for particular motions (e.g. right turns). A few cells exhibited an interaction between head orientation and specific motion. These overall behavioral correlates could subserve the expression of purely directional correlates in target structures (McNaughton, these abstracts). (Supported by NS20331.)

AN "ASSOCIATIVE" NETWORK MODEL FOR THE GENERATION OF HEAD-ORIENTATION SPECIFIC NEURONAL FIRING FROM ANGULAR VELOCITY INFORMATION. B.L. McNaughton. Department of Psychology, University of Colorado, Boulder CO, 80309

ny cells in the rat postsubiculum (dorsal presubiculum) are selectively active over a Many cells in the rat postsubculum (dorsal presubiculum) are selectively active over a limited range of the animal's head orientation (h), apparently independent of either spatial location or behavior, and, although they can be controlled by specific visual stimuli, they retain orientation tuning (sometimes with directional shifts) when these stimuli are absent (Taube et al., Neurosci, 1990). A number of cells in the postsubucular region (Markus et al. these abstracts) as well as its cortical afferent structures (Chen et al. these abstracts, McNaughton et al. Psychobiology, 1989) exhibit sensitivity to head rotation (h') or to the interaction of h and h'. McNaughton et al. 39 presented a simple associative network model which could recall representations of spatial location using input from a system cortifor for the interaction of forction and movement (both lines and relational). system coding for the interaction of location and movement (both linear and rotational). For example, in that model, the compound input configuration left turn in location A provided a unique cue for the recall of the representation of location B. In the same manner, the nh' interaction could be used to "recall" the resulting h, e.g., an angular velocity input of 20 "/time-step in conjunction with an initial heading angle of 70" can "recall" a head angle representation of 90° in the absence of visual stimuli. This need not be recall in The advantage representation of some analysis of the traditional sense, as the transform is so simple and reliable that the necessary connection weights might be hardwired developmentally with no actual learning. A modifiable input from the visual system could allow superimposed associations between sets of visual inputs, and the corresponding head orientation representations. This would be necessary, for example, to allow the h representation to be updated during very slow rotations, or to allow visual stimuli to set the reference direction in familiar places.

It is interesting to note that the same network organization would appear to fulfill some of the requirements of the hypothetical neural "integrator" in the oculomotor/vestibular system, which is presumed to derive eye position signals from eye velocity (Robinson, Science, 1968), but with no actual temporal integration. SIMULATION OF PERFORANT-PATH EVOKED SYNAPTIC AND POSTSYNAPTIC FIELD POTENTIALS IN THE DENTATE GYRUS OF THE RAT. W.E. Skagos and B. L. McNaughton. Department of Psychology, University of Colorado, Boulder CO, 80309 Field potentials are the best if not the only available tool for studying experience-dependent changes in synaptic efficacy in the CNS of conscious mammals. However, interpretation of extracellular fields is difficult because they reflect the summed influences of large pools of cells, and are caused by spatial segregation of inward and outward currents within dendritic trees. We have developed a computational simulation of the fascia dentata (FD) of the rat hippocampus, with the aim of modeling field potentials evoked by stimulation of the perforant path. The ultimate goal of the model is to aid in the interpretation of spontaneous and electrically induced changes in synaptic efficacy and postsynaptic excitability in this system. Our initial goal has been to capture the postsynaptic excitability in this system. Our initial goal has been to capture the fundamental dynamics of evoked responses, especially their dependence upon location of recording electrodes, location of afferents on the dendritic trees of granule cells,

recording electrodes, location of anterents of the defrontic trees of granule cells, intensity of stimulation, and repetition of stimulation.

The model simulation FD as a collection of many copies of a small pool of cells, arranged to approximate the curvature of FD in the transverse plane. The pool contains 100 granule cells, and 20 interneurons of two classes, which provide feed-forward and feedback cells, and 20 interneurons or two casses, which provide reductionward and recoulable inhibition via fast Cr and slow Kr channels. Each granule cell consists of a spherical soma, an axon initial segment, and a cylindrical dendrite divided into six compartments. Excitatory and inhibitory synapses, modeled as variable conductances within equivalent circuits, are distributed over the compartments. Spiking activity is generated by modified

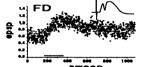

Hodgkin-Huxley Na* and K* channels.

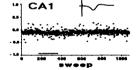

The simulation reproduces observed field potentials with considerable accuracy. We will discuss several insights the model provides into factors that may underlie specifi aspects of the evoked response. Of particular interest has been the need for careful aspects of the eventual responses. To planticular interest has been the freed in Cateful regulation of the timing and extent of feed-forward inhibition in reproducing the detailed behavior of the population spike with stimuli of varying intensity, as well as the possible role of GABAB mediated dendritic inhibition in shaping the late phase of the population e.p.s.p. (Supported by NSF and the A.E. Sloan Foundation.)

REGIONAL VARIATION IN THE PROPENSITY FOR EXPLORATION INDUCED SYNAPTIC ENHANCEMENT IN THE RAT HIPPOCAMPUS, J. Meltzer, C. A. Barnes, and B. L. McNaughton, Department of Psychology, University of Colorado, Boulder CO 80309. An important function of the hippocampal formation is believed to be its involvement in

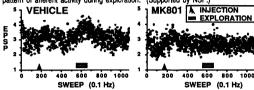

spatial learning. One line of evidence for this possible role in learning is electrically induced enhancement of synaptic transmission (LTE/LTP) in the hippocampus. In addition, exploratory behavior is accompanied by a considerable increase in perforant path-evoked dentate granule cell population synaptic responses (Sharp et al., <u>Psychobiology</u>, 1989). These changes do not result from motor activity per se, nor from the accompanying EEG theta activity (Green et al., J. Neuroscience, 1990). This experiment addressed the question of activity (Green et al., <u>IN Neurosapiroa</u>, 1990). This experiment adoressed in et question whether similar synaptic plasticity occurs in area CA1 of the hippocampus. Rats were prepared for chronic recordings of perforant path-evoked FD granule cell responses in one hemisphere and CA3 stimulated CA1 responses in the other. After a period of adaptation to the recording situation, the effects of exploration were assessed under two different conditions. In one, the animal ran on a radial 8-arm maze, in either a cue-rich or a cue-poor contitions. In the other, the animals explored on an open triangular platform on which food reinforcement could be found. During the exploratory period, there was a gradual growth of the synaptic response in both regions. However, in the three animals studied to date, the change in the CA1 response was less than half that of the simultaneously recorded response in FD. It thus appears that there exist marked regional differences in the propensity for this exploration-induced enhancement of synaptic efficacy. (Supported by NSF.)

EXPLORATION-DEPENDENT ENHANCEMENT OF SYNAPTIC RESPONSES IN RAT FASCIA DENTATA IS BLOCKED BY MK801. <u>C. A. Erickson. B. L. McNauchtion. and C. A. Barnes.</u> Department of Psychology, University of Colorado, Boulder CO 60309. Exploratory behavior results in robust growth of perforant path evoked synaptic re-

Exploratory behavior results in robust growth of perforant path evoked synaptic responses in fascia deniata (Sharp et al., <u>Psychobiol</u>, 1999, Green et al., <u>Psychobiol</u>, 1990, These changes are due neither to handling nor to low-frequency stimulation, and are related to the integral of the recent history of exploration rather than to instantaneous behavior per se. The effects are dissociable from the EEG theta rhythm that accompanies exploration because reversible septal inactivation or septal lesions (which abolished theta) had no effect on the EPSP enhancement. Moreover, forced locomotion on a treadmill did not produce the effect, suggesting that the determining factor was the change in sensory input rather than locomotion per se. Biockade of NMDA-type glutamate receptors by the noncompetitive antagonist, MK801, impairs acquisition of spatial memory tasks (Robinson, et al., <u>Psychobiol</u>, 1999) and blocks long-term enhancement (LTE/LTP) of synaptic transmission (Abraham & Mason, <u>Brain Res</u>, 1988), a possible physiological substrate for memory. In the present experiment, exploration-dependent changes in the field EPSP were blocked by MK801 (0.3 mg/kti p.). supposition that the exploration-induced increase were blocked by MK801 (0.3 mg/kg i.p.), suggesting that the exploration-induced increase in synaptic efficacy and artificially-induced LTE may be mediated by the same NMDA receptors. It remains to be determined whether the blockade is due to direct actions of MK801 on the induction mechanism or whether the effect occurs indirectly by altering the pattern of afferent activity during exploration. EFFECTS OF MEDIAL SEPTAL INACTIVATION ON MULTIPLE UNIT ACTIVITY IN THE SUBICULUM AND ENTORHINAL CORTEX OF ANESTHETIZED RATS. G. M. Perez. C. A. Barnes, and B. L. McNaughton. Department of Psychology, University of Colorado,

Boulder, CO 80309.

Mizumori, et.al., (Brain Res. 1989, J. Neurosci., 1989) showed that reversible inactivation of the medial septum with local anaesthetic reduced the output of CA3 pyramidal cells in both acute (anesthetized) and chronic preparations, while leaving CA1 pyramidal cell output relatively intact. In the awake animals spatial selectivity of CA3 cells as well as spatial memory were disrupted, whereas CA1 cells continued to fire with normal

Preservation of normal place specific firing in CA1 following septal inactivation raised the question of why spatial memory impairment was observed. Because the medial septum projects to the output structures of the hippocampus (i.e., subiculum and entorhinal cortex), it is possible that the behavioral deficit was due to the blockade of hippo output "downstream" of CA1.

To address this hypothesis, preliminary studies involved recording multiple unit activity in hippocampal output structures following reversible septal inactivation with tetracaine (2%) in 7 rats anaesthetized with sodium pentobarbital. Multiple unit activity was recorded simultaneously from the subiculum and entorhinal cortex for a 15 minute baseline period followed by injection of .5 µl of tetracaine into the medial septum. A 30% decrease in multiple unit activity was observed in both the subiculum and entorhinal cortex ely following septal inactivation and generally recovered within about 20 min. These data suggest that septal activity does maintain the general levels of excitability in these areas. Further studies, however, are needed to resolve how different cell types are affected, and whether these effects occur in the behaving animal. (Supported by an NSF fellowship to GMP, AG03376, and NS20331).

NEUROPEPTIDES AND BEHAVIOR II

186.1

PLASMA PROOPIOMELANOCORTIN PEPTIDES IN AUTISTIC AND SELF-INJURIOUS CHILDREN: RELATIONSHIP TO COGNITIVE AND SOCIAL FUNCTIONING. B.H. Herman, P. Papero*, J. Hartzler*, E. Porter*, Chatoor*, J. Egan*, V. Der-Minassian* and A. Arthur-Smith. Brain Res Cen and Dept Psychiat, Children's Natl Med Cen, Wash, DC 20010 and Dept Psychiat, George Wash Univ Sch Med, Wash, DC.

We have proposed that autistic and self-injurious behavior (SIB) individuals may have a dysregulation in proopiomelanocortin (POMC) systems of the HPA axis. Here we measured plasma concentrations of immunoreactive (ir)B-endorphin(B-E, pmol/L), cortisol (nmol/ L) and irACTH(pmol/L) in 10 nonSIB autistic children (Aut Grp) and 7 children with severe SIB(SIB Grp). The relationship between plasma POMC and cognitive functioning as well as social functioning was also evaluated.

Plasma POMC peptide concentrations (M±SEM) were: Aut Grp, irBE(7.17±0.83), cortisol(316±46), and irACTH(7.62±1.19); SIB Grp, irB-E(4.63±0.34), cortisol(419±47), irACTH(5.25± 0.90). (Normal concentrations of irB-E are about 7 pmol/L). the Aut Grp, no significant differences were found between MR (IQ<70) and NMR subjects for either irB-E or irACTH. In the SIB Grp, 6/7 subjects had IQ's in the MR range.

Thus, these data suggest that the reduced plasma concentrations of irB-E and irACTH of SIB children versus autistic and normal children do not appear to be a function of cognitive differences. Supported by FDA OD, NICHD HD23330 and March of Dimes(BHH).

EARLY SOCIAL RESTRICTION OF RHESUS MONKEYS ALTERS CHEMOARCHITECTURE IN THE STRIATUM BUT NOT IN THE BED NUCLEUS-AMYGDALA COMPLEX. L.C. Cork, L.J. Martin, M.H. Lewis, and J.P.Gluck*. Neuropathology Lab., Johns Hopkins Univ., Baltimore, MD 21205

Permanent behavioral disturbances (e.g., stereotypic movements and psychosocial anomalies) can result from early isolation rearing of rhesus monkeys (Macaca mulatta). We have shown that compartments of the neostriatal mosaic (patch-matrix) are abnormal in isolation reared monkeys [based on patterns of immunoreactivity for tyrosine hydroxylase (TH), substance P (SP), and leucine-enkephalin (LENK); Martin et al, 1990]. However, it is uncertain whether chemoarchitectonic changes are specific for the striatum or if they are present in other subcortical telencephalic locations. We examined patterns of immunoreactivity for TH, SP, LENK, and somatostatin (SOM) in the striatum and the bed nucleus-amygdala continuum in isolation- and sociallyreared monkeys. In isolates, TH-immunoreactive fibers and terminals were lost in striatal matrix; striatal patches (particularly in the caudate) were reduced in neuronal cell bodies and processes immunoreactive for SP and LENK, but not for SOM. In contrast, patterns of immunoreactivity for TH, SP, LENK, and SOM in the bed nucleus-amygdala continuum of isolates and social controls were similar. These results suggest that monoaminergic and some peptidergic systems of the striatum are selectively at risk in infant monkeys reared in social isolation.

ALPHA-MSH ENHANCED ATTENTION IN A CUED DISCRIMINATION TASK.

C.W. SIMPSON AND G.E. RESCH. School of Basic Life Sciences, Univ. Missouri-Kansas City, Kansas City, MO 64108. Early studies using avoidance and stretch-yawn indices showed that icv or peripheral alpha-melanocyte stimulating hormone (α -MSH) altered attention; however, no brain sites of action were identified. Data in the present work show changes in attention behavior following microinjection of α -MSH into specific brain tissue sites. Changes in attention were described by differential changes between responses similar to attention behavior criteria in the literature. Female Sprague Dawley rats 200-250 gm were implanted with guide tubes in the medial anterior hypothalamus preoptic area (MAHPOA) and trained to an 80 to 85% correct barpress response in a visual cued discrimination task for infra-red heat reinforcement, as previously reported. discrimination task for infra-red heat reinforcement, as previously reported. A significant (P<.001) improvement in task performance occurred following the microinjection of α-MSH into previously identified PGE₂-sensitive sites of the MAHPOA. The improvement in performance occurred due to a decrease in error rate following α-MSH. No significant effect was elicited by α-MSH on correct scores in the cued discrimination task. Comparison of barpress rates (strikes/min) show a mean decrease of 54% of incorrect responding vs correct responding following the microinjection of α-MSH. α-MSH elicited responses between 10[-6] and 10[-12] gm but not at lower values tested. Three of 12 animals injected into PGE₂ responsive heat gain sites showed a Tc response but did not show behavioral changes to α-MSH. Nine of 12 animals showed improved task performance correlated with criterion Tc Tc response but did not show behavioral changes to α -MSH. Nine of 12 animals showed improved task performance correlated with criterion Tc (0.5°C) increases. These data suggest differentiation between site functions. Task performance improved following α -MSH due to a decrease in error rate. The doses of α -MSH eliciting responses were in the nanogram to picogram range. The data also show α -MSH discrimination between two kinds of sites, one showing only a Tc response and the other both Tc and behavior changes. The data show specific MAHPOA sites from which α -MSH elicits changes in both Tc and attention behavior. Supported by AFOSR 87-6297.

RECOVERY FROM CYSTEAMINE - INDUCED COMMITS OF SOME SOME CONTRACTOR OF STREET CENTRAL SOMATOSTATIN DEPLETION: RADIAL MAZE
ACQUISITION. G.R. Sessions, E. Demetriades*,
L.L. Leber* and G.F. Koob. Walter Reed Army
Inst. Res., Wash, D.C. 20307, U.S. Air Force
Acad., Colorado Springs, CO 80840 and Scripps
Clinic & Res. Found., La Jolla, CA 92037.
Cysteamine HCl temporarily depletes brain
somatostatin (Bakhit, et al., 1983, Reg. Peptides, 6:169) and produces deficits in eightarm radial maze performance in rats injected

arm radial maze performance in rats injected after they learn the task (Sessions, et al., 1989, Neurosci. Abstr., 15:712). The present study investigated the acquisition of a radial maze memory task in rats following recovery from cysteamine-induced somatostatin depletions. Groups of animals received four daily ICV injections of cysteamine (250 or 350 μ g in $2~\mu l)$ or buffered saline, then were allowed 4 to 5 weeks to recover from the effects of the drug before receiving training to obtain food pellets in an eight arm maze. Results showed no differences in latency or error measures during acquisition. Apparent memory deficits associated with acute central somatostatin depletion are not evident in subsequent acquisition of a memory task in recovered animals.

OPIOID SUPPRESSION OF DISTRESS ULTRASOUNDS AFTER SOCIAL DEFEAT IN RATS. <u>I.A. Vivian and K.A. Miczek</u>. Dept. of Psychology, Tufts Univ., Medford, MA 02155.

Ultrasounds (US) in adult rats occur in highly significant social situations, such as mating, maternal and agonistic behavior and may serve as communicative signals of affective expressions. In this experiment, US were studied in Long-Evans rats (Rattus norvegicus) (1) with three exposures to attacks and threats by a resident opponent while displaying defensive and submissive responses (2) with three exposures to the threat of attack (no physical contact) by a resident opponent. The attack and threat situation consisted of brief agonistic interactions until the intruder rat displayed a submissive posture (crouch, supine) for five s; subsequently, the intruder was exposed for 25 min to threats by the opponent while being protected from physical contact by a wire mesh. Immediately prior to each physical encounter, the intruder was administered morphine or ethylketocyclazocine (EKC); to determine opioid specificity, naltrexone was administered 30 min prior to the first physical encounter followed by morphine. During the physical encounter, intruders received ca. 7 bites in 40 s, prompting frequent US. During the protected encounter, morphine (0-6 mg/kg SC) and EKC (0-1.0 mg/kg SC) dose dependently decreased the rate and duration of US which correlated well with their analgesic effect and was antagonized by naltrexone (0.1 mg/kg IP: 4-6 fold rightward shift). Sonographic analysis revealed no change in modal frequency after administration of either opiate. By itself, naltrexone had no effects on the rate, duration or frequency of US. Morphine and EKC decreased motor activity which was reversed by naltrexone. Naltrexone increased motor activity when administered alone. The potent suppression of US by threatened intruders may reflect opioid actions on affective components of social stress reactions.

MICROINJECTION OF DYNORPHIN INTO THE HIPPOCAMPUS IMPAIRS SPATIAL LEARNING IN RATS. K.L. McDaniel*, W.R. Mundy and H.A. Tilson. Curriculum in Toxicology, North Carolina State University, Raleigh, NC and Neurotoxicology Division, US Environmental Protection Agency, Research Triangle Park, NC 27711.

The effect of hippocampal dynorphin administration on learning and memory was examined in spatial and nonspatial tasks. Bilateral infusion of dynorphin A(1-8)(DYN; 10 or 20 ug in one ul) into the dorsal hippocampus resulted in a dose-related impairment of spatial working memory in a radial maze win-stay task. Subsequent experiments found that acquisition of a reference memory task in the water maze was impaired by DYN injections (20 ug/ul) in the dorsal, but not ventral hippocampus. This impairment was blocked by naloxone (3 mg/kg). In a nonspatial task, post-training DYN injections (20 ug) in the dorsal hippocampus had no effect on retention of a step-through passive avoidance task. These results suggest that DYN interferes specifically with spatial learning and memory, and that this effect is mediated by opioid receptors in the hippocampus.

OXYTOCIN RECEPTOR DISTRIBUTION REFLECTS SPECIES-TYPICAL PATTERNS OF SOCIAL BEHAVIOR. L. E. Shapiro. R. E. Gelhard* and T. R. Insel., LCS, NIMH, Poolesville, MD 20837.

Rodents of the genus Microius are a group of phylogenetically related species that display a diverse range of social and reproductive behaviors. The comparative analysis of such naturally occurring species provides a unique opportunity for the study of brain/behavior relationships. Prairie voles are monogamous, highly social, and intensely parental. In contrast, montane voles have a polygamous mating system, are asocial, and display relatively low levels of parental care. Previous research has indicated that the nonaeptide oxytocin (OT) is involved in the onset of maternal behavior following parturition and may be important for affiliative processes in general. In this study we describe the distribution of OT receptors in these two species and evaluate the role of this peptide in the species-typical expression of social and parental behaviors. The distribution of OT receptors was evaluated using in vitro receptor autoradiography with the potent OT receptor anatgonist, 1251-d(CH)5[Tyr(Me)², Thr⁴, Tyr-NH2⁹]OVT (1251-OTA). Relative to montane voles, 1251-OTA binding was increased 2.4 fold in several discrete regions of the prairie vole brain, including the lateral bed nucleus of the stria terminalis, anterior cingulate cortex, nucleus accumbens, olfactory tubercle, and putamen. There were no within-species gender differences in any of these brain regions. However, 1244-OTA binding was increased in the lateral septum of female prairie voles relative to male prairie voles; the converse was true for montane voles with males displaying higher binding levels than conspectific females. We have also mapped 1251-OTA binding in two additional species of Microtus, the monogamous and highly parental pine vole, and the polygamous and asocial meadow vole. The identical sexually dimorphic pattern of binding observed in the lateral septum of prairie and mont

VASOPRESSIN INNERVATION OF LATERAL SEPTUM IN TWO LINES OF MICE SELECTED FOR AGGRESSION. J.C. Compaan¹, R.M. Buils², C. Pool², J.M. Koolhaas¹, A.J.H. de Ruiter¹, G.A. van Cortmerrsen¹, B.Bohus¹, (SPON: European Brain and Behaviour Society), Univ. of Groningen, Dept. of Animal Physiol., P.O.Box 14, 9750 AA Haren, The Netherlands, Netherlands Instit. for Brain Paganage. Netherlands Instit. for Brain Research, Meibergdreef 33, 1105 AZ Amsterdam, The Netherlands.

In the adult rat brain the vasopressinergic (AVP) innervation of the lateral septum (LS) is testosterone (T) dependent. It is unknown, to what extent this system is involved in the differentiation in social behaviour within the male sex. In this study we used male mice (Mus Musculus Domesticus), genetically selected for aggressi-on. Mice with a Short Attack Latency (SAL) possess a higher plasma T level compared to males with a Long Attack Latency (LAL). Neonatally, however, a higher T-production occurs in the non-aggressive LAL males than in SAL males. We found that adult LAL-males posses a higher density of AVP immunoreactive (AVP-i) fibers especially in the posterior part of the LS. This difference is consistent with the differences in meonatal T-production.
Neonatally high T perhaps permanently organizes AVP neurons which might be involved in the differentiation in social behaviour of these selection lines.

The investigations were supported by the Foundation

for Biological Research (BION), which is subsidized by the Netherlands Organization for Scientific Research.

STRAIN DIFFERENCES IN THE BEHAVIORAL EFFECTS OF CRF AND AN ANTAGONIST, CRF 9-41 IN MICE, L.H. Conti, D.G. Costello*, L.A. Martin* M.F. White* and M.E. Abreu. Nova Pharmaceutical Corp. 6200 Freeport Centre, Baltimore, MD 21224.

Corticotropin releasing factor (CRF), a hypothalamic peptide also found in other brain regions, has behavioral effects independent of its rituitary/adrenal effects and acts as an anxiogenic following intracerebroventricular (icv) administration (Dunn and File, Horm Behav, 21, 193). A CRF antagonist, CRF on attenuates behavioral, physiological and immunological effects of CRF and exhibits anxiolytic activity in the fear potentiated startle paradigm (Swederlow et al., Neuropsychopharm, 2, 285).

In the present experiments, the effects of CRF ₉₋₄₁ (25 and 50 ug,icv) were examined in different strains of mice (CF-1 derived, CD and BALB/C, Harlan Sprague Dawley) in the elevated plus-maze anxiolytic test. CRF ₉₋₄₁ significantly increased percent open arm activity in BALB/C mice only. Diazepam (1 - 4 mg/kg, ip) increased open arm activity in all strains

activity in all strains.

In a second set of experiments, locomotor activity of each strain was assessed in a 30 min session following icv administration of one of 5 doses of CRF (.1 - 1.0 ug). Locomotor suppression by CRF was seen in all mouse strains. However, CRF was more potent and its effects more sustained in BALB/C mice than in CF-1 or CD mice. Behavioral differences cannot be readily explained on the basis of differential binding of CRF to cortical receptor sites in the three strains.

These data suggest that the BALB/C mouse is more sensitive to the behavioral effects of CRF and its antagonist, CRF 941, than either the CD or CF-1 derived strain.

CD or CF-1 derived strain.

 $\mbox{D-ALA}^2\mbox{-MET}^5\mbox{-ENKEPHALINAMIDE ATTENUATES STRESSOR INDUCED ALTERATIONS IN INTRACRANIAL SELF-STIMULATION$ FROM THE DORSOLATERAL VENTRAL TEGMENTUM. Cindy L. Wolfe and Robert M. Zacharko, Department of Psychology,

Wolfe and Robert M. Zacharko, Department of Psychology, Carleton University, Ottawa, Ontario, Canada.

A decline in responding for previously rewarding intracranial self-stimulation (ICSS) following uncontrollable stressor exposure is evident from a number of mesocorticolimbic sites. It has been suggested that these stressor induced disruptions of ICSS may be mediated by region specific alterations in dopaminergic (DA) activity. Current research has demonstrated that a number of neuropeptides, particularly enkephalin, interact with DA within the ventral tegmental area (VTA), the point of origin of the mesocorticolimbic system. This raises the possibility that enkephalin may play an interactive role with DA in the mediation of stressor related ICSS deficits observed from the VTA. In the present study, uncontrollable footshock induced response deficits in ICSS from the dorsolateral aspects of the VTA. Administration of D-Ala²-Met⁵-Enkephalinamide (DALA) VTA. Administration of D-Ala²-Met⁵-Enkephalinamide (DALA) VTA. Administration of D-Ala²-Met³-Enkephalinamide (DALA) into the lateral ventricles following stressor exposure led to a transient reveral of the footshock induced disruption of ICSS. Administration of DALA prior to stressor exposure blunted the initial impact of footshock on ICSS and attenuated decreases in ICSS both 24 and 168 hours post stressor. These results are discussed with respect to the possible mechanisms by which DALA interacts with DA neurons within the VTA to attenuate the impact of stressor exposure on ICSS. the impact of stressor exposure on ICSS.

REGULATION OF TYROSINE HYDROXYLASE (TH) IN THE LOCUS COERULEUS (LC) BY CORTICOTROPIN-RELEASING FACTOR (CRF): RELATION TO STRESS AND DEPRESSION. K.R. Melia. E.J. Nestler. J. Haycock, and R.S. Duman, Laboratory of Molecular Psychiatry, Yale University School of Medicine, New Haven, CT 06058.

Electrophysiological, biochemical, and behavioral studies suggest that both the producersic and CEE intermental plays and in stress and depression. Stress

noradrenergic and CRF systems may play a role in stress and depression. Stress increases levels of CRF and TH in LC (see Duman et al., this volume) and increased levels of CRF and norepinephrine have been found in some depressed patients. Moreover, CRF increases LC neuronal activity and CRF antagonists block stress-

Moreover, CRF increases LC neuronal activity and CRF antagonists block stress-induced increases in LC firing rates. The present studies investigated the possibility that CRF may mediate the stress-induced changes in TH in the LC. In the first study, levels of TH were determined by Western blot analysis in animals infused (ICV) for 6 days, twice daily (am,pm), with either CRF (Sug) or vehicle (Sul at 0.Sul/min). Chronic CRF increased TH levels in the LC by 74% relative to chronic vehicle treatment. We next infused either 10µg of a-helical CRF (in 1.0µl) or vehicle unilaterally into the LC twice a day for four days. Five minutes after infusions animals received 10 1.0mA footshock (am) or 1/hr noise stress (pm). On day five, animals were sacrificed and each LC was dissected and analyzed separately. A 58% decrease in TH levels was found in the LC infused with alpha-helical CRF relative to its contralateral control. In contrast, only a 15% decrease was found in TH in the LC infused with wehicle relative to its control. Finally, the ability of antidepressants to modulate stress-induced changes in TH was examined.

Administration of imipramine (15mg/kg) or tranylcypromine (7.5mg/kg) for two weeks attenuated the increase in TH in the LC elicited by 5 days of cold stress. Thus, chronic manipulation of the CRF system modulates the noradrenergic system

weeks attenuated the increase in 1H in the LC elicited by 5 days or cold stress. Thus, chronic manipulation of the CRF system modulates the noradrenergic system by actions at CRF receptors nearby or in the LC. Furthermore, the CRF antagonist and chronic antidepressant administration share the ability to decrease stress-induced changes in TH in the LC. As the therapeutic actions of antidepressants may be mediated in part through the regulation of TH, inhibition of CRF might be an effective form of treatment for depression and other stress-related disorders.

REINFORCING AND MEMORY PROMOTING EFFECTS OF THE NEUROTACHY-KININ SUBSTANCE P AND ITS FRACMENTS. J.P. Huston, R. U. Hasen-öhrl*, P. Gerhardt* and P. Krappmann*. Inst. Physiol. Psycho-logy, Univ. Düsseldorf, D-4000 Düsseldorf, F.R.G.

Several studies have shown that the posttrial administra-tion of the neurotachykinin substance P (SP) can promote learning. A theory linking memory and reinforcement explains the action of reinforcers by their strenghtening effects on memory traces. Based on this theory we hypothesized SP to have reinforcing effects as well. For evaluating reinforcing properties of SP in rats, a place preference task was used. SP displayed reinforcing effects where the injection of the peptide had facilitated learning: in the lateral hypothala-mus, the n.basalis magnocellularis and in the periphery.Further evidence for a reinforcing action of SP was provided by a self-injection technique, showing that rats self-admin-istered ng-amounts of SP into the ventral neostriatum. In order to determine the active amino-acid sequence encoding the reinforcing and mnemonic properties of peripherally applied SP, we examined its N-terminal fragment SP1-7 and applied or, we examined its N-terminal ragment sir-/ and the C-terminal fragment analogs DIME-C7 and pGlu⁶-SP6-11. A different structure-activity relationship was obtained for the effects of the fragments on place conditioning and avoidance learning: while the C-terminal fragment analogs mediated the reinforcing properties, the N-terminus encoded the memory promoting effects of SP. It remains to be determined, whether this behavioral dissociation also occurs when the SP-fragments are injected into the CNS directly.

186.12

CHRONIC STRESS OR ANTIDEPRESSANT TREATMENTS DIFFERENTIALLY REGULATE THE CYCLIC AMP SYSTEM IN RAT LOCUS COERULEUS (LC). R.S. Duman, K.R. Melia, R.Z. Terwilliger*, and E.J. Nestler. Lab. of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School of Med., New Haven, CT 06508.

Recent studies have demonstrated that chronic stress or Recent studies have demonstrated that chronic stress or antidepressants differentially regulate neuronal activity and expression of tyrosine hydroxylase (TH) in LC neurons (see Melia et al., this volume). In the present study we extend these studies by examining the effects of stress or antidepressant treatments on the cyclic AMP second messenger system in this brain region.

Levels of both adenylate cyclase (AC) and cyclic AMP-dependent protein kinase (cA-K) were determined in the same samples of LC isolated, from the complete of the cycles of the complete of the cycles.

isolated from rats administered either cold stress (5 D) or imipramine (18 D). Cold stress was found to significantly increase levels of AC and soluble cA-K by 25 to 30 percent; levels of kinase in particulate fractions were not significantly altered. Adminstration of ACTH (7 D) or bilateral adrenalectomy (7 D) had similar results, suggesting that ACTH, not corlicosterone, positively regulates the cyclic AMP system in LC. In contrast, chronic imipramine treatment decreased levels of cA-K in soluble fractions of LC; levels of AC were

not altered by antidepressant treatment.

These findings demonstrate that 1) the activity of LC neurons, 2) the levels of TH, and 3) the activity of the cyclic AMP system are either up- or down-regulated in parallel by stress or antidepressants, respectively. Moreover, these findings raise the possibility that adaptations of this second messenger system contribute to the long-term effects of stress and the therapeutic actions of antidepressant treatments on LC neuronal function.

THE EFFECT OF THE CCK ANTAGONISTS L-364,718 and

THE EFFECT OF THE CCK ANTAGONISTS L-364,718 and L-365,260 ON THE ACQUISITION OF A DISCRIMINATED ACTIVE AVOIDANCE TASK IN C57BL/6J MICE. J. Rodenhiser and E. Quinton. Lab of Psychobiology, University of Louisville, Louisville, KY. 40292.

The octapeptide fragment of cholecystokinin (CCK-8) seems to modulate a wide range of behaviors, but the data are inconsistent. We have previously shown that CCK facilitates acquisition of active avoidance in a multi-trial discrimination task. The present study seeks to determine whether two CCK antagonists, selective for the CCK, and CCK, receptors, affect acquisition in the same task. C57BL/6J mice were given injections of either vehicle control, 200ug/kg L-365,260 SC before each daily session (7 trials/session, 8 sessions). The task required 120ug/kg L-365,260 SC before each daily session (7 trials/session, 8 sessions). The task required the animal to discriminate an illuminated door from among 5 doors, and to exit through that door to escape/avoid shock (.2mA). Attempts to exit through incorrect doors were counted as errors. Contrary to expectation, the two antagonists made fewer errors over sessions than did the CCK or control groups; the L365,260 group made the fewest errors. It seems possible that the high doses of antagonists used in this study may doses of antagonists used in this study may interact with other systems.

CCK-8 MODULATION OF TOLERANCE TO STRESS-INDUCED

CCK-8 MODULATION OF TOLERANCE TO STRESS-INDUCED ANALGESIA. M.Mims, M. Shuck, J. Prather, and E.E. Quinton. Lab. of Psychobiology, University of Louisville, Louisville, KY 40292.

Research suggests that CCK-8 is a modulator of opioid-induced analgesia. Other research has suggested that CCK-8 may facilitate the development of tolerance to opioid-induced analgesia. The present study was performed to determine whether CCK is involved in the development of tolerance to stress-induced analgesia. Male Sprague-Dawley rats were injected into the PAG with antibodies to CCK-8 (ACCK) five minutes before receiving 90s of footshock at 1 mA on two consequtive days. The animals were tested for analgesia on a hot-plate test two minutes later. On the first day there was a significant increase in analgesia in the was a significant increase in analgesia in the ACCK and control groups, with the level of analgesia somewhat greater in the ACCK group. On the second day there was a significant reduction the second day there was a significant reduction in analgesia in both groups and this reduction was greater in the ACCK group. The data from this study suggests that CCK-8 may not modulate the development of tolerance to stress-induced analgesia. It seems possible that tolerance to morphine-induced analgesia and tolerance to stress-induced analgesia may be mediated through seperate systems.

186.16

INTERACTION OF CCK-8, MORPHINE, AND CCK ANTAGONISTS ON ANALGESIA ON THE HOT-PLATE TEST IN MICE. E.E. Ouinton. Lab. of Psychobiology, University of Louisville.

The results of numerous studies employing different methodologies and response systems

different methodologies and response systems suggest that CCK modulates pain systems and interacts with morphine. However, the mechanisms underlying the modulation and interaction are unclear. This study seeks to determine whether CCK-induced analgesia is mediated through the CCK, or CCK, receptors; and whether antagonists of these receptors would affect morphine induced of these receptors would affect morphine induced analgesia in the C57BL/6j mouse. CCK-8s (400µg/kg,SC) was injected 15 min after an injection of L365,260 (120µg/kg, SC), L364,718 (120µg/kg, SC), saline, or proglumide (40mg/kg,SC). The mice were tested on the hot-plate (55°C) 10, 15, 20, 30, 45, 60,75, or 90 min after the CCK injection. All three drugs reduced CCK-induced analgesia with L364,718 and proglumide most effective. The same drugs and CCK-8s were tested with morphine (10µg/kg, SC). Only L364,718 antagonized morphine analgesia, and CCK-8s increased the duration of morphine analgesia. These preliminary data suggest that CCK modulates the pain systems and interacts with morphine through the CCK receptors. through the CCK receptors.

NEUROTOXICITY: METALS

The Effects of Low-Level Lead Exposure During Different Developmental Periods on Growth, Behavioral Activity, and Spatial Discrimination in Male Binghamton Heterogeneous Stock Mice. D.A. Rasile*, P.J. Donovick and R.G. Burright*. Environmental Neuropsychology Laboratory, Dept. of Psychology, SUNY Binghamton, Binghamton, N.Y. 13901.

In the past two decades, numerous experimental studies have established the teratogenic effects of low-level lead exposure on development, behavioral activity and learning. It has also been established from such studies that the effects of such exposure can differ widely in their nature and severity depending, in part, on the developmental stage of the organism when exposed as well as the duration of exposure. The present study addresses such issues and attempts to determine the impact of low-level lead exposure administered during different developmental periods on body weight, running wheel activity, and water maze spatial reversal learning. Four experimental groups are employed: a distilled water control group (WW); a group of mice exposed to lead from gestation to weaning—age 21 days and then switched to distilled water (LW); mice exposed to lead from age of weaning to early adulthood (WL); and mice exposed to lead from gestation and continuing through adulthood (LL).

EFFECTS OF INORGANIC AND TRIETHYL LEAD AND INORGANIC MERCURY ON THE VOLTAGE ACTIVATED CALCIUM CHANNEL OF APLYSIA NEURONS. D. Büsselberg, M.L. Evans, H. Rahmann* and D.O. Carpenter. Wadsworth Labs and School of Public Health, Albany, NY 12201-0509 USA, and Universität Mainz, FRG.

Using conventional two-electrode voltage-clamp techniques we have studied the effects of Pb²⁺, triethyl lead (TEL) and Hg²⁺ on voltageactivated calcium channels of Aplysia neurons and found that all three are potent inhibitors at micromolar concentrations. However the time course of reduction and reversibility of blockade are very different when comparing Pb²⁺ with TEL and Hg²⁺. With application of Pb²⁺ the comparing Po⁺ with TEL and rig⁻. With application of Po⁺ with a time calcium current decreases immediately; a steady state is reached within three to seven minutes, depending upon the concentration of Po²⁺. The blockade is easily reversed upon washout of Pb²⁺ with a time course similar to that of onset. Perfusion with either TEL or Hg²⁺ resulted only in a small reduction of the current when the substances reached the cell membrane but the decrease continued at about the same speed for the total duration of the application. Upon washing there was no recovery of the response. At the onset of washing the rate of current decline stopped for several minutes, but then the current continued to decline a slower rate in the absence of toxin. Our data suggest that Pb^{2+} acts by a direct and reversible blockade of the calcium channel. In contrast TEL and Hg^{2+} act slowly and irreversibly to block calcium channels at concentrations that do not greatly affect membrane potential or resistance. In spite of the slow time course these substances are probably acting directly on the channel.

NEUROTOXICITY OF METHYLMERCURY: NEUROTRANSMITTER RELEASE AND GLUTATHIONE STATUS IN THE CEREBELLUM. B.E. Kalisch*, W.J. Racz* and C. Romero-Sierra. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Chronic methylmercury (MeHg) exposure in man and animals is known to selectively damage the cerebellum. Presently, there is no satisfactory explanation for this selective toxicity. Recent studies have shown that MeHg may interfere with neurotransmission. In addition, glutathione (GSH), which protects membranes from oxidative damage, has been shown to decrease following exposure to MeHg. The present study investigates the effects of chronic high levels of MeHg on GSH status and amino acid release from mouse cerebellar tissue and correlates these with the symptoms associated with MeHg intoxication.

Mice were dosed for 6 weeks with 10 mg/kg/week MeHg and subsequently oxidized and reduced GSH levels and amino acid release were measured 24, 48, 72 hours and 7 days after the last treatment. Tissue amino acid content was not significantly different from control in any of the treatment groups. The 35 mM K⁺-stimulated release of glutamate was significantly higher in mice exhibiting severe symptoms of toxicity when compared to control at 24 and 48 hours after the last dose of MeHg, but by day 7 had returned to control. K+-stimulated release of aspartate and gamma-aminobutyric acid (GABA) were not different from control.

GSH content in the MeHg-treated mice was elevated 24 hours after the last dose of the toxicant and paralleled the increase in glutamate release. This increase may be a rebound effect due to GSH depletion. The role of GSH depletion during MeHg intoxication is currently under investigation. (Supported by NSERC)

DIFFERENTIAL EFFECTS OF MERCURIALS ON SYNAPTOSOMAL PLASMA & MITOCHONDRIAL MEMBRANE POTENTIALS. M.F. Hare and W.D. Atchison. Dept. Pharm./Tox. & Neurosc. Prgm, Mich. State Univ., E. Lansing, Mil 48824. Both methylmercury (MeHgʻ) and inorganic divalent mercury (Hgʻ) alter the

Both methylmercury (MeHg') and inorganic divalent mercury (Hg'') alter the flux of ions and small molecules across nerve terminal membranes by mechanisms that may involve membrane depolarization. We examined the effects of MeHg' and Hg'* on nerve terminal membrane potential in synaptosomes using the potentiometric carbocyanine dye [DIS-C₂(6)]. Compounds known to depolarize synaptosomes (e.g., ouabain, high [K'], and gramicidin) increased dye fluorescence. Depolarization of the mitochondrial membrane by cyanide and oligomycin increased dye fluorescence by 49%. Subsequent addition of valinomycin produced no further fluorescence increased. gramicidiny increased dye fluorescence. Depolarization of the mitochondrial membrane by cyanide and oligomycin increased dye fluorescence by 49%. Subsequent addition of valinomycin produced no further fluorescence increase indicating that intrasynaptosomal mitochondria were totally depolarized. Increased fluorescence consequent to a pulse of high K' decreased as the resting membrane potential became more positive. There was no significant difference between control and cyanide/oligomycin-treated synaptosomes in this response, which suggests that these agents did not alter the resting plasma membrane potential. Azide substitution for cyanide caused a 64% increase in fluorescence. Azide also depolarized the plasma membrane potential by 18 mV. Five min exposures to either MeHg' of Hg'* produced concentration-dependent increases in dye fluorescence. Prior depolarization of the mitochondrial membrane reduced the 10 μ M MeHg' induced depolarization by 67% but did not alter the 10 μ M MeHg' induced depolarization. The fluorescence response to a subsequent depolarization was decreased 32% after 10 μ M MeHg' and was abolished totally by 10 μ M Hg'. These effects of MeHg' and Wes abolished totally by 10 μ M Hg'. These effects of MeHg' and Hg' were unaltered by retrodotoxin or Cg'. In addition, MeHg'-induced depolarizations were not altered by removal of Cg² and Na' from the media. In summary, 10 μ M MeHg' depolarized mitochondria and decreased plasma membrane potential by 16 mV. Hg'*, on the other hand, totally abolished the plasma membrane potential with minimal effects on the mitochondrial membrane potential. Supported by NIEHS grant ES03299.

ACRYLAMIDE OR METHYLMERCURY EXPOSURE INCREASE GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) IN THE PIGEON BRAIN. H. L. EVANS, H.A.N. EL-FAWAL* AND F. R. MOON*. INST. OF ENVIRON. MED., N.Y.U. MED. CTR., N.Y., N.Y. 10016

Acrylamide (ACR) and methylmercury (MeHg) provide models of neurotoxicant induced, central-peripheral axonopathy. It is not known whether these toxicants alter the gliotypic protein GFAP in the CNS. We used the radio immuno assay (RIA) to quantify the astrocyte reaction to ACR or MeHg. Female pigeons were given doses known to cause overt neuropathy [ACR (45 mg/Kg/day for 5 day, p.o.) or MeHg (2.0 mg/Kg/day for 5 day, p.o.)]. Vehicle (H₂O) treated pigeons acted as controls. Brains were immediately removed and snap frozen. On the day of assay the cerebrum (C), cerebellum (CR) and medulla (M) were dissected, weighed and sonicated in SDS and the RIA was performed with GFAP polyclonal antibody and 123 I protein A. GFAP was evaluated after 1,3 and 5 weeks of exposure (for ACR) and 1,3,5 and 7 weeks (for MeHg). ACR increased GFAP only at 3 weeks and only in C(136%) and M(150%). GFAP increased in C (150%) at 3 weeks and in the CR (255%) at 3 and 5 weeks of MeHg exposure. These results suggest that the astrocytic response is biphasic, which may indicate initial hypertrophy followed by degeneration. Supported by ES-00260, ES-08945.

CORRELATION BETWEEN ALUMINUM DOSE, CLINICOPATHOLOGICAL CHANGES AND NEUROFILAMENT MRNA EXPRESSION IN ALUMINUM NEUROTOXICITY. V.R. Nerurkar*, M.J. Strong, I. Wakayama*, R. Yanagihara* and R.M. Garruto. Laboratory of Central Nervous System Studies, NIH, Bethesda, MD 20892.

We investigated the relationship between the clinicopathological changes, neurofilament (NF) accumulation and NF subunit protein mRNA expression in 6 week old New Zealand white rabbits 48 hrs after intracisternal inoculation with varying doses of $AlCl_3$ (100, 250, 500, 750 or 1000 ug) or with 0.9% NaCl. Sections of cerebral hemisphere, cerebellum, cervical and lumbar spinal cord were silver stained (Bielchowsky) and immunostained using a monoclonal antibody directed against NF-M and NF-H. Northern blots using ³²P-labelled cDNA probes encoding NF-L, NF-M and NF-H subunit protein mRNA were performed for each region.

We observed (i) no clinically differentiating features amongst the 5 dosage groups, (ii) a positive correlation between increasing $AlCl_3$ dosage, topographic localization and extent of neuropathologic changes, (iii) a negative correlation between AlCl₃ dose and NF mRNA expression, and (iv) sibship-dependent neuropathological variability. In contrast to previously reported studies, our data support AlCl₃ and alterations in NF subunit protein mRNA

ACUTE EFFECTS OF ALUMINUM IN THE STRIATUM. T.I. Lidsky, S.P. Banerjee, H.M. Wisniewski. NYS Inst. for Basic Research, Staten Island, NY.
Aluminum (Al) is, under certain conditions, neurotoxic and has been implicated in several neurodegenerative diseases (e.g. dialysis dementia). In this context, there has been considerable work concerning the neural effects of long term exposure to Al. There is, however, little known concerning acute effects. The present study was addressed to the latter.
Somatosensory field potentials were recorded in the

to the latter.

Somatosensory field potentials were recorded in the cortex and striatum of urethane anesthetized rats. Intravenous aluminum chloride (0.125 - 2 mg/kg) transiently attenuated striatal potentials at a latency of about 30 seconds with recovery within several minutes. Striatal potentials from cortical stimulation were similarly affected while somatosensory cortical potentials were not attenuated. Thus, Al effects occurred in the striatum rather than presynaptically.

Ongoing work is investigating the pharmacological bases of these acute Al effects. GABA and glutamate, because of their importance in striatal functioning and the well established influences of Al, are presently the focus of these investigations.

ALTERED LOCOMOTION AND NEUROMUSCULAR FUNCTION CHRONIC EXPOSURE TO ACRYLAMIDE (ACR) OR METHYLMERCURY (MeHg) IN THE PIGEON. H.A.N. EL-FAWAL*, F.R. MOON*, S. DANIEL* AND H. L. EVANS. INST. ENVIRON. MED, NYU MED. CTR., N. Y., N.Y. 10016.

ACR and MeHg cause peripheral neuropathy including behavioral deficits. We studied physiological mechanisms in these changes. Pigeons received ACR (45 mg/Kg/day, 5 days/week) or MeHg (2 mg/Kg/day, 5 days/week). Pecking accuracy and gait indicated gradual impairment of locomotion. Early physiological changes occurred in anatomical correlates of the locomotor deficits, the biventer cervicis nerve-muscle (BC) and sciatic-gastrocnemius (SG) muscle preparations in vitro. Strength-duration relationships in response to electrical stimulation of BC indicated an increase in excitability threshold within 1 week of exposure to either ACR or MeHg. Rheobase (volts) and chronaxie (msec) were higher and longer, respectively than controls with ACR. Rheobase and chronaxie following MeHg were higher and shorter, respectively. Responses of both BC and SG to ACh were potentiated beginning 3 weeks of ACR and 1 week of MeHg. Pecking accuracy and gait changed at 3 weeks of ACR exposure and did not change for the duration of MeHg exposure. Eletrophysiological changes precede behavioral deficits with ACR or MeHg exposure. Supported by ES-00260 and ES-08945.

TOPOGRAPHIC DIFFERENCES IN NEUROPATHOLOGIC CHANGES REFLECT NEURON-SPECIFIC THRESHOLDS OF ALUMINUM TOXICITY M.J. Strong^a and R. M. Garruto. Laboratory of Central Nervous System Studies, NIH, Bethesda, MD 20892

We exposed mature dissociated motor neuron-enriched and hippocampal neuron cultures derived from fetal New Zealand white rabbits to 1, 10, 25, 50 or 100 uM $AlCl_3$ in a chemically-defined medium to determine whether the observed disparity in sensitivity between motor and hippocampal neurons to intracisternally inoculated AlCl₃ is a neuron-specific phenomenon. Following 14 days of exposure to 1 uM or 10 uM AlCl₃, motor neuron-enriched cultures developed perikaryal and neuritic neurofilament inclusions. In cultures exposed to 25 uM or 50 uM AlCl $_{3}$, the neurons developed inclusions but did not survive beyond 10 days. 100 uM exposure induced cell death within 4 days without the development of inclusions. By contrast, hippocampal neurons exposed to 1, 10, or 25 uM AlCl₃ for 14 days did not show morphological changes. Cultures exposed to 50 or 100 uM remained viable but developed perinuclear and proximal neuritic inclusions We interpret this 10 fold greater threshold sensitivity to aluminum in spinal motor neurons compared to hippocampal neurons as evidence for neuron-specific differences in the regulatory mechanisms of neurofilament metabolism amongst distinct neuronal cell populations, supporting our earlier in vivo observations.

Aluminum (Al) administration has been shown to induce neurofibrillary tangles in brains of experimental animals. However, the role of Al in Alzheimer's disease has not been resolved. Some reports suggest that chronic Al treatment significantly reduces choline acetyltransferase (ChAT) activity, but a negative result has been reported. While Al has been administrated by several different routes, Al has not been shown to cross the blood brain barrier. To gain further insight into Al neurotoxicity, Al was injected via the femoral vein (1 mg/kg) and was elevated in the cerebrospinal fluid, reaching a peak $(41.6 \pm 21.2 \text{ ng/ml})$ 2 hr following injection. Therefore, the cholinergic neurotoxicity of Al at this stage was further investigated. ChAT and acetylcholinesterase (AChE) activities were measured radiochemically in homogenates prepared from different brain areas. ChAT activities in the basal forebrain, frontal cortex, and hippocampus were reduced 30, 29, and 24%, respectively, while no change was observed in the caudate nuclei. On the other hand, AChE activity was increased 38.5% in caudate nuclei while little change was observed in other brain areas. These data suggest that the Al cholinergic neurotoxicity could be an initial event in neurofibrillary degeneration.

ALUMINUM SILICATE TOXICITY IN PRIMARY NEURONAL CULTURES E.J. Murphy*, E. Roberts, D.K. Anderson and L.A. Horrocks. The Ohio State University, Department of Physiological Chemistry, Columbus, OH 43210 Aluminum silicates are often found in the plaques of Alzheimer's disease (AD) brains so the toxicity of

Aluminum silicates are often found in the plaques of Alzheimer's disease (AD) brains so the toxicity of aluminum silicates towards mixed primary neuronal cultures was examined. Three common aluminum silicate containing clays, erionite, montmorillonite and bentonite, were used. The clays were added in a suspension to the cells at concentration of 0.1 mg/ml. Previous studies with primary cultures of human umbilical vein endothelial (HUVE) cells indicated that this concentration was toxic to the cells. With bentonite, there was some lysis of astrocytes at 5 min of incubation. At 15 min there was a greater degree of lysis of both astrocytes and neurons and following 60 min of incubation the cells were completely lysed. Montmorillonite had the same effect as bentonite although montmorillonite affected primarily astrocytes for the first 15 mins of incubation. After 60 min of incubation there was lysis of astrocytes and to a lesser degree neurons. Erionite had no effect on the cells at any time point. The order of toxicity was bentonite > montmorillonite >> erionite. Unlike the mixed neuronal cultures, lysis of HUVE cells occurred between 6 and 24 h of incubation. This indicates two different lytic mechanisms may be occurring. Supported in part by a grant given to Eugene Roberts by the G. Harold and Lily Y. Mathers Charitable Foundation and by NIH NS-10165.

THE COUPLED FREE RADICAL FORMATION IN THE NEUROTOXIC EFFECT OF MANGANESE. A.Y.Sun, D.L.Cowan* and F.F.Ahmad. Dept. Pharmacology and Dept. Physics*, Univ. of Missouri, Columbia, MO 65212.

Manganese poisoning has caused extra pyramidal disorder similar to the behavioral abnormality of Parkinson's disease (PD). Since free radical damage was suggested to be involved in the etiology of PD, we used electron spin resonance (ESR) spectroscopy and spin trapping technique to detect the involvement of free radical in Mn* toxicity. The spin adduct of 1,1-dimethyl pyrrolidine-N-oxide (DMPO) of the hydroxyl radicals were detected when 0.14 mm of Mn* was added to a K-PO, buffered system (pH 7.4) containing 0.04% H₂O₂. A Fenton-type reaction similar to that catalyzed by Fe* may be operated in this system. Interestingly, a hydroxyethyl free radical signal was detected when ethanol was added to the above system and the amount of hydroxyethyl free radical was much enhanced if vitamin C was also added into the system. It is possible that the elevated Mn* in basal ganglia may catalyze the free radical formation by coupling to some redox reactions, leading to the symptoms of PD. Since hydroxyethyl free radicals are much longer lived radical species than hydroxyl radical and may cause more damage to the cell, alcohol administration under those conditions may potentiate the harmful effect of Mn* in causing tissue injury and neuronal death. (Supported by AAO2054.)

PC12 (pheocromocytoma cells) as a model of manganese Dopomine-mediated toxicity. A. Vescovi. A. Nespolo. A. Zaffaroni. M.Clini. A. Colangelo. A. Gritti, and E.A. Parati. Lab Neuropharmacology, Natl. Neurol. Inst. C. Besta, Via Celoria 11, Milan, Italy.
High environmental manganese (Mn) concentrations induce in human

High environmental manganese (Mn) concentrations induce in human an irreversible parkinson-like syndrome. Since an increase in the rate of dopamine (DA) oxidation has been suggested to play a major role in Mn neurotoxicity, we studied the effects of this metal on DA turnover in PC12. We demonstrated that Mn is toxic to PC12, inducing a time dependent decrease in DA intracellular levels,

strictly related to an increase in lactate dehydrogenase activity released in the medium (an index of cell safety). The specifity of the effect was assessed by comparing Mn to equimolar zinc (Zn) concentrations. Briefly: 1) Mn induced a complete disappearance of DA in the medium where Zn did not, ii) the DA lack in the medium was due to both an increased oxidation rate and a release blockade where Zn induced an increased release. The Mn-mediated release impairment was not prevented by ascorbic acid alone or in combination with catalase and superoxidedismutase. The data suggest that not only oxidative phenomena occour in Mn neurotoxicity early stages.

EPILEPSY: HUMAN STUDIES

MODULATION OF EXTRACELLULAR ASPARTATE LEVEL DURING EPILEPTIFORM EVENTS IN PRIMARY EPILEPTOGENIC AREA OF PATIENTS. K.O.Do. L. H.G.Wieser 2. H.Perschak 2 and M.Cuénod 1. Brain Research Institute, University of Zürich, Department of Neurology, University Hospital, Zürich Switzerland.

Numerous associations have been made between perturbations in inhibitory and/or in excitatory systems and epilepsy. However, the investigation in human epilepsy are generally limited to the biochemical measurement of transmitter either in plasma or CSF or in biopsied or autopsied pathological brain tissue. In the course of presurgical Stereo-EEG evaluation of candidates for epilepsy surgery, we investigated the pattern of the amino acids (aa) efflux in the primary epileptogenic area during spontaneous or electrically induced epileptic discharges. A push-pull cannula was introduced into the lumen of a standard hollow-core multicontact depht electrode placed in the hippocampus. Sterilized Gey's balanced salt solution was perfused (20 ul/min)through the push-pull cannula and one minute fractions were collected over a period of one hour in patients under general anaesthesia. The perfusate was analyzed by on-line ophtalaldehyde precolumn derivatization HPLC to quantify aa at the femtomole level. A computer-assisted analysis of the background depht-EEG and of spontaneous and electrically provoked epileptiform events were performed and the results were correlated with the biochemical measurements. In three out of four patients, an increase in aspartate level was observed in correlation with the epileptiform EEG events. Their correlation with changes with glutamate concentration was less clear, although there is possibly an elevation related to afterdischarges. Non-transmitter aa levels remained constant and unaffected by the epileptic discharges. These preliminary observations suggest that the excitatory aa aspartate could be involved in pathophysiological mechanisms of human epilepsy and particularly within an epileptic focus.

ALTERATIONS IN THM RECEPTORS IN DISCREET REGIONS OF THE HIPPOCAMPUS IN TEMPORAL LOBE EPILEPSY, N. Lexow, J. Phillips, M. Dichter, M. O'Connor, & A. Winokur. Depts. of Psychiatry & Pharmacology, U. of PA, Depts. of Neurology & Neurosurgery, Graduate Hospital, Philadelphia, PA.

The role of thyrotropin-releasing hormone (TRH) in the seizure process has recently received considerable interest. Animal models of limbic seizure phenomen have demonstrated consistent increases (2 to 17 fold) in TRH content in limbic regions as a result of the increased CNS activity associated with seizures (Kubeck et al '94; Walczak et al '83; Kreider et al '90). Moreover, chronic administration of TRH or TRH analogs in rats results in 20-50% reduction in receptor density in the hippocampus, amygdala and hypothalamus (Sharif '87).

Our studies in human postnortem tissue have demonstrated a discreet localization of TRH receptors at points of origin and termination of preferential pathways of seizure propagation. In this study we utilized quantitative autoradiography to examine the density and distribution of TRH receptors in surgically resected hippocampal tissue from 12 patients undergoing temporal lobectomy for intractable seizures. In this tissue the density of binding sites for [3H]MeTRH in the molecular layer of the dentate gyrus was reduced by 46%~(p<0.001) when compared to postmortem tissue. It is unlikely that these alterations are due to cell loss as adjacent stained sections do not demonstrate a loss of dentate gyrus cells. We propose that this dramatic decrease in the density of TRH receptors in the molecular layer of the dentate gyrus is due to a compensatory down-regulation of receptors in response to an excess of neurotransmitter in this region as a result of seizures. These observations suggest a role for TRH in the neurochemical dysfunction of temporal lobe epilepsy.

ALTERED GABA-A/BENZODIAZEPINE RECEPTOR DISTRIBUTION IN HUMAN TEMPORAL LOBE EPILEPSY. R.W. Olsen, C.R. Houser, A.V. Delgado-Escueta, J.G. Richards and H. Möhler*. Brain Res. Inst., UCLA, Los Angeles, CA 90024; VA Medical Center, W. Los Angeles; Hoffman La-Roche, Basel, Switzerland. Distribution of the α -subunit of the GABA-A/benzodiaze-

Distribution of the α -subunit of the GABA-A/benzodiazepine receptor (GABA-R) has been determined immunocytochemically in surgical specimens from the hippocampal formation of patients with temporal lobe epilepsy (TLE) using a monoclonal antibody (bd-24) to the receptor complex (Schoch et al., Nature 314:168, 1985). In epilepsy specimens, regions of marked cell loss, such of the CAl field, showed concomitant decreases in the density of GABA-Rs, although isolated neurons remaining within these regions frequently had high densities of receptor labeling on their surfaces. Alterations in GABA-R distributions within the molecular layer of the dentate gyrus were also observed. In control autopsy specimens, dense staining was present throughout the molecular layer with slightly heavier staining in the inner zone. However, in a subpopulation of epilepsy specimens, there was decreased density of labeling in the inner one-third to one half of the molecular layer, with increasing densities in the mid to outer regions of the layer. These changes in receptor distribution may be related to reorganization of other inputs to the molecular layer in severe TLE. Supported by NIH grants NS21908, NS22071 and VA Medical Research Funds.

ABNORMAL ASTROCYTE PROCESSES IN THE CEREBRAL CORTEX OF AN EPILEPTIC INFANT. W.A. Schreier, J. de Vellis, H.V. Vinters*, and R.S. Fisher. UCLA School of Medicine, Los Angeles, CA 90024.

Surgical specimens of the cingulate cortex were obtained from a 13 month-old, white male with severe epilepsy. Astrocytes were examined using glial fibrillary acidic protein (GFAP) immunohistochemistry. Reactive astrocyte-like cells were found in layer I of the cortex and in the subcortical white matter. These cells project long thick processes which frequently appear to traverse the entire width of the cortex (greater than 1 mm). Some of these processes are completely straight and smooth, however, most processes have a spiral-like appearance and contain numerous varicosities. Spiraling processes leaving the white matter frequently extend 0.2-0.5 mm toward the cortical surface before giving off right angle branches. We speculate that these

cells may be radial glia which have failed to mature properly.

IMMATURE HUMAN NEOCORTICAL NEURONS HAVE LOW-THRESHOLD CA²⁺ SPIKES BUT DO NOT GENERATE INTRINSIC BURSTS. J.G. Tasker, N.W. Hoffman, R.S. Fisher, Y.I. Kim, W.J. Peacock*, and F.E. Dudek. Mental Retardation Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024.

Pyramidal neurons showing intrinsic bursting properties have been described in infragranular layers of guinea pig and mouse somatosensory cortex (Connors, B.A., Gutnick, M.J. and Prince, D.A., J. Neurophysiol. 48:1302, 1982; Agmon, A. and Connors, B.A., Neurosci. Lett. 99:137, 1989). It was proposed that bursting neurons were possible pacemaker cells responsible for the synchronization of neocortical neurons during epileptiform bursting (Connors, B.A., Nature 310:685, 1984). We performed intracellular recordings and biocytin injections in slices of human neocortex removed from children, ages 4 mo - 15 yr, for the treatment of intractable epilepsy. A total of 145 cells were recorded throughout layers IIV II in frontal (n=39), parietal (n=39), temporal (n=53) and occipital lobes (n=14) from 33 patients. Although human neocortical neurons were electrophysiologically similar to neocortical neurons recorded in other species, we never observed intrinsic bursting characteristics of the type described in animal models. Of 39 neurons injected with biocytin, 20 were situated in layers IV (n=5), V (n=9) and VI (n=6). However, evidence of putative low-threshold Ca²⁺ potentials or currents, capable of generating one or two action potentials, was seen in approximately 60% of recorded cells. These potentials were insensitive to tetrodotoxin (1-3 µM, n=2) but were reduced or blocked by a solution containing low [Ca²⁺] (0.2 mM) and Cd²⁺ (0.25 mM, n=4). Our results suggest that intrinsically bursting neurons are not necessary for the generation of epileptiform activity, but that low-threshold Ca²⁺ spikes may contribute to burst generation in immature human neocortex. Supported by NS 16683.

188.4

SYNAPTIC MORPHOMETRY OF GRANULAR NEURONS IN INTRACTABLE TEMPORAL LOBE EPILEPSY. M.Y. SHEN*. J.H. KIM, P.O. GUIMARAES*, N.C. de LANEROLLE and D. D. SPENCER. Sections of Neuropathology and Neurosurgery, Yale Univ. School of Medicine, New Haven, CT 06510

Granular neurons of the dentate fascia, as part of the tri-synaptic hippocampal loop (entorhinal cortex-dentate fascia-CA3-CA1), may play an important role in the pathogenesis of temporal lobe epilepsy. We conducted an ultrastructural morphometric study on the synaptic structures of the stratum granulosum in hippocampi surgically removed from 6 tumor associated epilepsy (TAE) and 8 non-tumor epilepsy (NTE) cases. With a computer assisted scanning device, the following synaptic parameters were investigated in both pre- and postsynaptic profiles of symmetric and asymmetric synapses: the perimeter and area of the synaptic profile, and the length of the synaptic terminals were inversely correlated with the granule cell density (mean cell number/mm3) in both asymmetric (R=0.682 and 0.681, respectively) and symmetric (R=0.630 and 0.605, respectively) synapses, but showed no correlation with the length (years) of seizure history. Compared with TAE, NTE showed a statistically significant increase in the perimeter length and area size of presynaptic terminals (p=0.0126 and 0.0165 respectively for symmetric synapses, and 0.0436 and 0.0438 for asymmetric ones). Excessive neuronal activities may have caused an enlargement of presynaptic terminals in NTF.

INTRACELLULAR NEURONAL RESPONSES IN HIPPOCAMPUS AND DENTATE GYRUS OF EPILEPSY PATIENTS STUDIED IN <u>IN VITRO</u> BRAIN SLICES.

L. M. Masukawa, M. Higashima*, D. D. Spencer and M. J. O'Connor*.
Depts. of Neurology and Surgery, Graduate Hospital, Philadelphia,
PA, 19146 and Sections of Neuroanatomy and Neurosurgery, Yale
University Medical School, New Haven, CT, 01610.

Previously, we showed that hippocampal brain slices from temporal lobe epilepsy patients exhibit abnormal field discharges in the dentate gyrus in response to either single or trains of low frequency stimuli presented to the perforant path (Masukawa, L.M. et al, Brain Res., 492:168, 1989). Intracellular recordings from neurons in CA fields and dentate gyrus demonstrate that cells in in vitro brain slices of surgically removed tissue: 1) generate action potentials which are 80-90 mV in amplitude, 2) have resting membrane potentials which are 80-90 mV in amplitude, 2) have resting membrane potentials in excess of -50 mV, 3) have input resistances of at least 30 Mohms at -60 mV, and 4) exhibit repetitive action potentials during depolarizing current steps. Functional inhibition was demonstrated in individual neurons by the presence of ipsps which could interrupt trains of action potentials. Orthodromically driven intracellular responses are correlated with the field responses in the dentate. Such observations indicate that field responses that we recorded previously originated from dentate granule cells. Thus, we suggest that the electrical characteristics of neurons in in vitro hippocampal slices from temporal lobe epilepsy patients are comparable to those in normal rodent tissue under identical slice conditions. Supported by NIH grants NS-23077 to LMM and NS-06208 to DDS.

INTRACELLULAR RECORDING IN NEOCORTICAL SLICES FROM PATIENTS WITH INTRACTABLE PEDIATRIC EPILEPSY: CHOLINERGIC MODULATION J.P. Walsh, C. Cepeda, N.A. Buchwald, Mental Retardation Research Center, UCLA, Los Angeles, CA 90024.

These experiments assessed the mechanism and pharmacological basis of cholinergic modulation in neurons recorded from neocortical slices from patients with intractable pediatric epilepsy. Thirteen cells were characterized for their response to cholinergic drugs from subjects ranging from 8 months to 13 years of age. All cells were equally responsive to ACh. Each cell that responded also generated low-threshold ${\bf Ca}^{4+}$ spikes (LTS cells). ACh (10-100 μ m) produced a depolarization associated with increased input resistance and cell excitability. Two lines of evidence indicated that a reduction of K⁺ current produced this response. First, ACh decreased after-hyperpolarizations generated by trains of action potentials. Second, voltage clamp analysis showed that ACh reduced the current elicited by hyperpolarizing steps from depolarizing holding potentials ("m-current"). Separate from these effects, ACh consistently reduced the amplitude of postsynaptic potentials. Combined application of ACh and the nicotinic receptor antagonist, hexamethonium (200 μ m), had no effect on the ACh response. Application of the muscarinic receptor antagonist, atropine (10 μ m), completely blocked the ACh effects. All aspects of the ACh response were mimicked by the muscarinic receptor antagonist, carbachol (2-10 μ m). These studies indicate that ACh modulates human neocortical neurons by acting on muscarinic receptors.

CONSTRUCTION AND TESTING OF AN NSE PROMOTER-MAO-B EXPRESSION VECTOR FOR USE IN CREATING TRANSGENIC MICE THAT OVEREXPRESS MAO-B NEUR-ONALLY. J.K. Andersen, K. Herrup, and X.O. Breakefield, Mol. Neurogenetics Unit, Mass. General Hosp., Charlestown, MA; Dev. Neurobiology Div., E.K. Shriver Ctr., Waltham, MA; Neuroscience Prog., Harvard Med. Sch., Boston, MA., 02115.

Studies are underway to evaluate the effects of abnormally high peuronal MAO-R activity on development and MPCIP sensitivity in

Prog., Harvard Med. Sch., Boston, MA., 02115.

Studies are underway to evaluate the effects of abnormally high neuronal MAO-B activity on development and MPTP sensitivity in transgenic mouse lines. Normal humans inherit 50-fold variations in platelet MAO-B activities; this enzyme converts substances like MPTP to neurotoxins, leading to a Parkinsonian syndrome. Individuals with higher levels of MAO-B activity may be more susceptible to the actions of MPTP. An MAO-B cDNA has been generated from human liver mRNA by first strand synthesis, followed by PCR amplification using oligonucleotide primers that encompass the MAO-B coding region, defined previously (Bach et al, 1989). The resulting 1.7 kb fragment was subcloned into a Bluescript (Stratagene) vector for amplification, then into a eukaryotic expression vector containing the neuronal specific enolase (NSE) promoter (kindly provided by Drs. S. Forss-Petter and G. Sutcliffe). This vector construct is being evaluated for its ability to confer high MAO-B activity onto a mouse neuroblasoma cell line with no MAO activity. After MAO-B overexpression is confirmed in cultured cells, the linearized pNSE-MAO-B construct will be injected into early mouse embryos to create transgenics which overexpress MAO-B in neurons. [Funding was provided by NINDS NRSA (JKA) and United Parkinson Fdn. (XOB).]

SELECTIVE KILLING OF RAT C6 GLIOMA CELLS FOLLOWING RETROVIRUS-MEDIATED TRANSFER OF THE HERPES SIMPLEX VIRUS THYMIDINE KINASE GENE. Z.D. Ezzedine. D. Piditika, R.I., Martuza & X.O. Breakefield. Molec Neurogenet. Unit, Neurol. and Neurosurg. Services, Mass. General Hosp. & Neurosci. Prog., Harvard Med. Sch., Boston, MA 02114 & 02115

The herpes simplex type I virus (HSV-1) thymidine kinase (TK) gene has been inserted into a retroviral vector derived from MoMLV and MoMSV (obtained from M. Rosenberg). The HSV-1-TK gene is under the transcriptional control of the retroviral LTR promoter, upstream from a neomycin resistance gene, itself under the transcriptional control of a Rous sarcoma virus promoter. Vector DNA was transfected into an ecotropic packaging cell line (psi-2), and replication-defective viral particles were produced and used to infect several C6 rat gliomaderived cell lines in cultrue. Recipient cells included C6-BU1-TK-, a line lacking endogenous thymidine kinase activity, and a derivative of it, C6-BU1-TK-BAG, expressing bacterial β-galactosidase from a recombinant retrovirus stably integrated into the cell genome following infection with the BAG vector (obtained from C. Cepko). The dosedependent sensitivity of cells with and without the HSV-1-TK gene to the toxic effects of ganciclovir was evaluated. (The HSV-1-TK enzyme has a greater affinity than its mammalian homolog for this nucleoside analog.) The dose of ganciclovir necessary to kill all cells was found to be approximately tenfold higher for uninfected cells compared to those infected with the HSV-1-TK retrovirus. An *in vivo* model for the selective killing of HSV-1-TK-expressing glioma cells by administration of ganciclovir is being tested in rats. This work paves the way for the use of retroviral vectors to selectively kill tumor cells in the CNS.

NIEMANN-PICK TYPE C MOUSE- ULTRASTRUCTURAL AND IMMUNOCYTOCHEMICAL STUDIES Y. Higashi*, S. Murayama, C.E. Argoff*, P.G. Pentchev*, K. Suzuki, K. Suzuki, School of Medicine, Univ. of North Carolina, Chapel Hill, NC and Developmental and Metabolic Neurology Branch, NINDS, Bethesda, MD

An inborn cholesterol storage disorder in BALB/c mouse is considered to be an animal model of Niemann-Pick disease type C (Pentchev et al 1986). Neuronal storage, axonal spheroids and myelin abnormalities are prominent neuropathological features. To elucidate relationship of neuronal, axonal and myelin pathologies, ultrastructural and immunocytochemical studies were conducted. Neuronal storage was most prominent in deep cerebral cortex and in the CA3 and CA4 regions of the hippocampus, whereas axonal spheroids were mostly in projection fibers, subcortical relay nuclei and spinal white matter. Spheroids were detected by a monoclonal antibody 03-44 (Sternberger) that recognizes weakly phosphorylated epitope of neurofilament and by DF2, the monoclonal antibody against ubiquitin (Mori, 1987). Degeneration of myelin was observed in the cerebellar white matter, pencil fibers in the striatum and sciatic nerves. Corpus callosum, however, revealed a marked paucity of myelin without apparent myelin degeneration. These morphological differences may reflect regional and/or cellular difference in the cholesterol metabolism in this mutant mouse.

DIRECT INFECTION OF RAT C6 GLIOMA CELLS IN THE BRAIN BY GRAFTING OF A RETROVIRUS PACKAGING LINE. M. P. Short, J-K. Lee, B. Choi, A. Malick, X.O. Breakefield and R. Martuza. Mol. Neurogenetic Unit, Neurol. and Neurosurg. Services, Mass. General Hosp., and Neurosci. Prog., Harvard Med. Sch., Boston, MA 02115 Retroviral vectors only integrate into the genome of dividing cells and can thus be used to selectively infect tumor cells in the adult rat brain part of the RAC vector. Gripe et al.

Retroviral vectors only integrate into the genome of dividing cells and can thus be used to selectively infect tumor cells in the adult rat brain. Retroviral gene delivery was assessed using the BAG vector (Price et al. PNAS., 84:156, 1987) which bears the lacZ gene under the MoMLV LTR promoter-enhancer element, and histochemical staining for beta-galactosidase. Direct injection of this vector (900 cfu) into the adult rat brain, with or without prior inoculation of C6 glioma cells (2 X 10⁵cells) resulted in labelling of only a few cells as assessed one week later. When the psi-2 BAG packaging line was grafted into the brain, labelled psi-2 cells could be found up to five-seven days post grafting; however no labelled cells were seen at two weeks post grafting, suggesting that the grafted cells had been rejected and no endogenous cells had integrated released vector. In contrast, when the psi-2 BAG packaging line was grafted into the brain region which had been previously seeded with rat C6 glioma cells (2 X 10⁵ cells), extensive labelling of these tumor cells could be demonstrated ten days later. Thus grafting of retrovirus packaging lines into adult brain provides a mean to efficiently infect tumor cells in vivo. Presumably the grafted cells continue to release retroviral particles for an extended period, thus infecting more cells at the stage of division appropriate for viral integration. This approach can be used to selectively deliver "killer" or "suppressor" genes to tumor cells in the brain to curtail their growth.

189.4

LOCALIZATION OF HPRT mRNA IN THE MAMMALIAN BRAIN BY IN SITU HYBRIDIZATION. H.A. Jinnah, E.J. Hess, M.C. Wilson, F.H. Gage, and T. Friedmann*. Depts. of Neurosciences and Pediatrics, UCSD; Dept. of Neuropharmacology, Reasearch Institute of Scripps Clinic, La Jolla, CA 92093.

Hypoxanthine-guanine phosphoribosyltransferase (HPRT) is a housekeeping enzyme involved in the recycling pathway for the purines. Congenital deficiency of HPRT in humans results in the Lesch-Nyhan syndrome, characterized by choreoathetosis, spasticity, self-injurious behavior, and hyperuricemia. Although the mechanism by which HPRT-deficiency leads to the neurological abnormalities remains unknown, a dysfunction of dopamine systems in the striatum is thought to play a role. In order to determine if the expression of HPRT correlates with known dopaminergic pathways or with the targets of dopaminergic pathways, we have examined the regional distribution of HPRT mRNA by in situ hybridization in the mouse brain. An HPRT-deficient transgenic mouse which does not express the HPRT mRNA served as a negative control. As might be expected for a housekeeping enzyme, HPRT was detected in most brain regions. However, the distribution of HPRT was not homogenous, but varied greatly among different brain regions. The highest levels of HPRT mRNA were observed in locus coeruleus, pons, hypothalamus, and hippocampus. Intermediate levels were detected in cortex, thalamus, substantia nigra, and cerebellum. The lowest levels were observed in the striatum, thalamus, tectum, and most of the brainstem. White matter had nondetectable levels of HPRT mRNA. This distribution suggests no strict correlation with the dopamine system or any other classical neurotransmitter system in the mouse brain. These in situ hybridization results are not consistent with previous biochemical studies indicating that the highest levels of HPRT activity in the primate brain occur in the striatum. This difference may reflect species differences or transport of HPRT protein from the sites of transcription. Studies involving the localization of HPRT mRNA in the primate brain are currently in progress.

189.6

EXCITATORY AMINO ACID RECEPTORS IN THE SPASTIC HANWISTAR RAT: NEUROPHYSIOLOGICAL ANALYSIS USING THE XENOPUS OOCYTE ASSAY. R.W. Cohen, C.D. Hull, A.T. Campagnoni, N.A. Buchwald, and M.S. Levine. M.R.R.C., UCLA, Los Angeles, CA 90024.

A strain of Han-Wistar rat carries an autosomal recessive gene that produces spastic paresis characterized by ataxia, tremor and limb rigidity. Previously, our results suggested that a disturbance in glutamate transmission was found the caudal brain (cerebellum and brain stem) of these rats. The present study utilized the Xenopus oocyte assay to search for the glutamate receptor subtype involved in this brain dysfunction. Brains of unaffected or affected rats were bisected into rostral and caudal halves and mRNA was isolated and injected into oocytes. The oocytes were voltage-clamped at -60 mV and exposed to 1 mM L-glutamate, 500 μ M kainate, 200 μ M NMDA or 1 mM GABA. Oocytes injected with unaffected-rostral (33.7 \pm 5.7 nA; n=6) or affected-rostral (36.3±6.6 nA; n=10) mRNA showed similar current responses to glutamate; oocytes injected with unaffected-caudal (42.8±4.8 nA; n=8) or affected-caudal (103.7±8.5 nA; n=11) brain mRNA had statistically different (p<0.001) responses. Values in parentheses are average peak inward current amplitudes ±S.E.M and sample size. The inward current amplitudes were significantly larger in affected-caudal oocytes (p<0.0001) when kainate was applied: Unaffected-rostral= $46.0\pm11.5\,\text{nA}$ (n=4); affected-rostral= $62.2\pm14.4\,\text{nA}$ (n=4); unaffected-caudal=24.0±4.7 nA (n=5); affected-caudal=167.5±10.0 nA (n=11). We verified presence of caudal brain kainate receptors by establishing that the reversal potential for kainate was 0 mV and by applying a kainate antagonist CNQX which blocked 90% of the kainate response. There were no differences in responses of oocytes to NMDA or GABA. The results indicate a genetic disturbance in the kainate excitatory amino acid receptor subtype in the caudal brain of these mutant rats. Supported by USPHS HD05958.

LOWER HYPERTHERMIC EFFECT OF MK-801 IN SELECTIVELY BRED HYPERCHOLINERGIC THAN IN NORMOCHOLINERGIC RATS. O.Pucilowski*, W.Danysz*, D.H.Overstreet, A.H.Rezvani*, B.Eichelman and D.H.Janowsky. Ctr. for Alcohol Studies and Dept. of Psychiatry, Univ. o

NC, Chapel Hill, NC 27599.
Flinders Sensitive Line (FSL) of rats has been selectively bred for increased sensitivity to cholinergic agonists. Typically FSL rats react with twice as high temperature drop as the similarly bred Flinders Resistant Line (FRL) not only to the muscarinic agonist oxotremorine but also to other hypothermic agents, e.g. apomorphine, buspirone and ethanol. This suggests that selective breeding altered the activity of many interacting transmitter systems. This study compared the FSL and FRL rats in terms of their hyperthermic response to the PCP receptor agonist MK-801. MK-801 binding characteristics were also compared. After establishing a temperature baseline the rats were injected ip with saline or 0.2 mg/kg of MK-801 and the colonic temperature was measured every 30 min for 240 min. We have found FSL rats to react with a delayed hyperthermia having a significantly lower hyperthermia for the first 120 min. Thereafter the response did not differ in FRL and FSL rats. Both groups also had similar affinity and number of [³H]MK-801 labelled PCP receptors. These findings suggest the genetically developed cholinergic supersensitivity attenuated the secondary mechanisms involved in the PCP receptor-mediated hyperthermic response.

LEARNING IN NZB MICE AND THE EFFECTS OF ENVIRONMENTAL ENRICHMENT. L. M. Schrott. N. S. Waters. G. F. Sherman. G. D. Rosen. A. M. Galaburda. and V. H. Denenberg. Biobehavioral Sciences Graduate Program, Univ of CT, Storrs. CT. 06269; and Beth Israel Hospital and Harvard Medical School, Boston, MA 02215

NZB mice are known to perform poorly in active and passive avoidance learning. However, NZBs, as well as BXSB mice, are able to learn a simple spatial water escape task (Denenberg et al., Neurosci. Abstr., 1990). This implies that the NZB does not have a generalized learning deficit. The purpose of this study was to (1) examine NZB learning in a variety of tasks, (2) determine if rearing in an enriched environment facilitated learning, and (3) investigate the effects of cortical ectopias (typically present in 20-40% of NZB mice) upon learning. Twenty male NZB/BINJ mice were placed in enriched environments at 6-7 weeks of age and remained there throughout the course of behavior testing; 18 other male NZBs were group reared in standard laboratory cages. Testing started at 7-8 weeks and included water escape, discrimination learning, Morris maze learning, and two-way active avoidance. They were perfused at 18-19 weeks and their brains examined for ectopias. All mice performed poorly in avoidance learning. They had a weak learning curve in water escape, and learned well in the discrimination apparatus and the Morris maze. The Enriched group learned faster on the latter two tests (pc.01 in both cases). In addition, Enriched mice without ectopias had the best percent correct in discrimination learning (pc.04). Conclusions: (1) NZBs can effectively learn both spatial and non-spatial associative tasks; therefore, they do not have a generalized learning deficit; (2) learning speed of both normal and mice with ectopias can be improved by Environmental Enrichment; however (3). Enrichment was not able to increase the percent of correct discriminations of mice with ectopias.

SELECTIVE BREEDING FOR DISTINCT STIMULUS FILTERING/
SELECTIVE ATTENTION BEHAVIORAL PHENOTYPES. C. Kilts, R. Scibilia, L. Dunn. Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, N.C. 27710.

The maintenance of a flexible and efficient information processing strategy represents a primary defect in schizophrenia. We sought to develop via the selective breeding of rats under standardized environmental conditions a homogeneous population of subjects exhibiting an analogous deficit in stimulus filtering/ selective attentional functioning, using a latent inhibition (LI) paradigm as an index of behavioral phenotype. The LI performance of a population of outbred rats exhibited a large variance. The generation of successive filial generations by the selective intra-litter breeding of subjects exhibiting maximal and negligible LI resulted in both F₂ and F₃ progeny which exhibit statistically significant differences in the LI of a conditioned response. These results indicate that behavioral genetics represents a promising means of developing animal models for schizophrenia research. (Supported by Scottish Rite Foundation)

SPATIAL LEARNING, PAW PREFERENCE, AND BRAIN ECTOPIAS IN NZB AND BXSB MICE. <u>V. H. Denenberg</u>, <u>G. F. Sherman</u>, <u>G. D. Rosen, and A. M. Galaburda</u>. Biobehavioral Sciences Graduate Degree Program, Univ of CT, Storrs, CT., 06269; and Beth Israel Hospital and Harvard Medical School, Boston, MA 02215

Cortical ectopias have been found in some mouse strains that have

Cortical ectopias have been found in some mouse strains that have autoimmune diseases, but the functional implications of the ectopias are not well understood. We previously found that ectopias and paw preference jointly affected discrimination learning in BXSB mice (Denenberg et al., Neurosci. Abstr., 1988). We now report on the effects of these variables upon spatial learning. Sixty-two NZB and 67 BXSB 6-week old mice were given the Collins paw preference test. At 8 weeks they were tested for water escape, a task requiring test. At 8 weeks they were tested for water escape, a submerged platform test. At 8 weeks they were tested for water escape, a task requiring the animal to use spatial information to locate a submerged platform. At 12 weeks they were perfused and their brains examined for cortical ectopias. Mice were classified by sex, paw (left/right) and ectopia (yes/no), and their swimming speed over 5 trials was evaluated. Within the NZB strain there was a Paw x Ectopia interaction (p<.02). Within the Ectopic groups left pawed mice had the fastest swimming time while right pawed ones were the slowest. The right and left pawed Non-Ectopic mice did not differ. The identical profile was also significant in the BXSB strain except that it was restricted to male mice. In both strains there was a Sex x Trials interaction: both groups of females were slower on Trial 1 and faster thereafter. Thus, cortical ectopias are associated with simple spatial learning for left pawed males of both strains and also left pawed NZB females.

Separation of Nature and Nurture in an Animal Model of Affect L. Fochtmann, E. Edwards, and F.A. Henn. Dept of Psychiatry, SUNY at Stony Brook, NY 11794.

The learned helplessness model of depression and/or anxiety developed by Seligman has proven to be an excellent model for looking at such diverse issues as the pharmacology of anti-depressants and the role of control in shaping behavior. In this model an animal is exposed to random uncontrollable aversive stimuli for a period and then develops a behavioral deficit when subsequently exposed to aversive stimuli. We have developed this model in rodents and using a design with a yoked control have duplicated the finding that the development of escape deficient behavior is dependant on the lack of control over the aversive stimuli, not the stimuli itself. In addition, we have shown that the development of "helpless" behavior is correlated with long term receptor changes in specific brain regions suggesting that psychological inputs can alter brain structure and behavior in parallel. This demonstrates the effect of nurture on behavior. We now report that the susceptibility to develop helpless behavior in The learned helplessness model of depression and/or anxiety parallel. This demonstrates the effect of nurture on behavior. We now report that the susceptibility to develop helpless behavior in rats can be enhanced by selective breeding. We will report on the development of two strains of rats by selective breeding. The first, after twenty generations, is essentially spontaneously hapless while the second is resistant to the development of helplessness. We will also present quantitative autoradiographic assessments of $\boldsymbol{\beta}$ and 5-HT_{1p} receptor binding in these two strains, as well as several behavioral parameters which distinguish between them.

AMYLOID PRECURSOR PROTEIN EXPRESSION IN RAT BRAIN. G.S. Huber. J. Löffler*, A. Schuler* and W.E. Haefety. Pharmaceutical Research Department, F.Hoffmann-La Roche Ltd, 4002 Basel, Switzerland.

The deposited B-amyloid protein in senile plaques of Alzheimer's disease presumably derives from one or more precursor proteins (APPs) by aberrant presumably derives from one of more precursor proteins (AFFS) by aberrain proteolytic processing. A family of three different APPs have been identified so far. We have raised a series of monoclonal antibodies against synthetic peptide domains of APPs in order to differentiate between the individual forms and also to examine their expression in rat brain. We use Western blotting to characterize different molecular forms of APP in soluble and particulate fractions of brain homogenates. We find most of the immunoreactive proteins present in homogenates and soluble brain fractions containing 0.15 M NaCl. In the adult rat brain, the most abundant N-terminal-immunoreactive forms are of M_r 135 kD, 100 kD and 75 kD (an additional 50 kD form is recognized by one of the antibodies). In contrast, the major Kunitz inhibitor containing form in the soluble fraction has a M_f of 75 KD accompanied by less abundant forms of 135 kD, 100 kD and 50 kD. The presence of these proteins in our soluble brain fraction in the absence of detergents suggests a rather loose association of these proteins with cellular membranes.

QUANTITATIVE CHARACTERIZATION OF THE AMYLOID PROTEIN PRECURSOR (APP) EXPRESSION IN RAT BRAIN PRIMARY CULTURES. P.I.Woloshin, A.Parent, F.P. Eckenstein, Dept. of Cell Biology and Anatomy, Oregon Health Sci. Univ., Portland, OR 97201 The cellular sources of APP in the brain have not been well determined and

analyses of the changes in the relative expression levels of the various transcripts has produced conflicting results. We have focussed on a defined cellular population and have quantitatively analyzed the relative levels of expression of the three most abundant APP mRNA species, APP695, 751 and 770, under various conditions. Changes in the relative levels of these transcripts in the brain may be a contributing factor to the deposition of the amyloid peptide, a component of senile plaques. Over 90% pure populations of Type 1 and Type 2 astrocytes, neurons and meningeal fibroblasts were obtained from neonate rats and were grown in a serum-free defined medium. The cells were then stimulated with one of

grown in a serum-free defined medium. The cells were then stimulated with one of the following factors: basic fibroblast growth factor, platelet derived growth factor, interleukin-1, fetal calf serum or dibutyryl cAMP.

Total RNA was extracted from these cells and analyzed with Polymerase Chain Reaction (PCR), Northern Blot and Solution Hybridization. High specific activity cRNA probes were synthesized which are complementary to a part of the APP 695 coding sequence. For PCR, oligonucleotides were synthesized which flank the Kunitz inhibitor domain and were found to produce different length reaction products depending on which APP transcript is present. Preliminary results indicate that cultured Type 1 astrocytes produce relatively higher levels of APP 751 and APP 770 than whole cortex and that fetal calf serum stimulates the overall level of APP mRNA in Type 1 astrocytes over that found in cells grown serum-free. It is interesting to speculate that these changes may be analogous to the reactive gliosis which occurs in Alzheimer's disease.

PARTIAL CHARACTERIZATION OF RAT cDNA CLONES SIMILAR TO A HUMAN AMYLOID PRECURSOR-RELATED PROTEIN mRNA. C. E. Byrne, C.J. Smith-Maxwell, V.H. Mah, C.A. Sherman, R.L. Neve² and G.A. Higgins. Univ. of Rochester Med. Ctr., Rochester, NY 14642; Gerontology Res. Ctr., NIA/NIH, Baltimore, MD 21224; and 2 Univ. California, Irvine CA 92127.

Increased expression of amyloid precursor protein (APP) mRNAs has been associated with amyloid deposition in Alzheimer's disease. Recent work suggests that forms of APP mRNA which contain a Kunitz protease inhibitor (KPI) motif are increased in pathologically-vulnerable brain regions in AD. Another amyloid precursor-related protein (APRP) of approximately 563 amino acids, which lacks the \(\beta/A4\) protein sequence, but contains the KPI motif, has also been isolated (de Sauvage, F. and Octave, J-N., <u>Science</u> 245:651-653 (1989)). Preliminary northern analysis using a probe for human APRP-563 shows that several related transcripts of 1-2 kb in length are expressed in the rat CNS. In order to further characterize rat APRP mRNAs, we used RT-PCR to isolate several different rat cDNAs. Partial sequencing shows that several rat brain mRNAs share partial identity with human APRP-563. Further studies are aimed at a more complete characterization of these rodent transcripts.

THE NEUROTOXIC CARBOXYTERMINAL FRAGMENT OF THE ALZHEIMER AMYLOID PRECURSOR PROTEIN MAY INTERFERE WITH CELL ADHESION. L.R. Dawes, S.F. Fidel, M.R. Kozlowski, A. Spanoyannis*, R.L. Neve. Dept. of Psychobiology, U. of Calif., Irvine, CA 92717 and Bristol-Myers Squibb, Wallingford, CT 06492. We previously reported that the carboxyterminal 105 amino acids of the Alzheimer amyloid precursor protein (ADI) is taxis credifically the course of Science 245, 417

(ABI) is toxic specifically to neurons (Science 245: 417, 1989). Addition of conditioned medium (CM) from ABI-transfected cells to primary rat hippocampal cultures leads to death of the neurons in these cultures within 4 days. We demonstrate that there are characteristic morphological features of this AB1 neurotoxicity. Freshly plated E18 hippocampal cultures demonstrate an initial burst of process outgrowth when exposed to AB1 CM. However, after several days the cultures treated with AB1 CM display clumping of neurons and increased fasciculation of their processes. A significant number of neurons have abnormally processes. A significant number of neurons have abnormally short processes with enhanced arborization relative to controls. These morphological features suggest that AB1-treated neurons possess a decreased affinity for substrate compared to controls. We hypothesize that AB1 may alter cell surface protein processing and thereby influence neuron-substrate interactions. To determine whether AB1 interacts with a cell surface molecule, we synthesized radiolabeled AB1 in an <u>in vitro</u> transcription/translation system, and showed that it binds to the surface of PC12 cells. This binding was partially displaceable by unlabeled AB1. unlabeled AB1.

190.4

THE AMYLOID PRECURSOR-RELATED TRANSCRIPT LACKING THE B/A4 SEQUENCE IS INCREASED IN ALZHEIMER DISEASE BRAIN. G.A. Higgins¹, J. Rogers² and R.L. Neve³. ¹Gerontology Res. Ctr., NIA/NIH, Baltimore, MD 21224, ²Inst. for Biogerontology Res., Sun City, AZ 85351, and ³Univ. Calif., Irvine, CA 92717.

We have used a combination of RNA blotting, RT-PCR, and in situ hybridization to study the differential expression of APP-695, APP-751, and APP-770 mRNAs in Alzheimer's disease (AD). We have also examined the expression of the amyloid precursor-related protein (APRP) transcript that encodes a 563 amino acid protein which lacks the $\beta/A4$ protein but contains the Kunitz-type protease inhibitor (KPI) sequence. Six brain regions were examined in AD patients and normal aged controls, using a combination of these methods within the same brains. KPI-containing forms of APP were elevated relative to APP-695 in AD. Dramatic increases in APRP-563 mRNA were observed in the nucleus basalis, parahippocampal gyrus and occipitotemporal cortex in AD, but not in the striatum, primary visual cortex, or hippocampal formation. These studies suggest that a secreted form of APP (APRP-563) may play a role in amyloid pathogenesis.

DIFFERENTIAL EXPRESSION OF AMYLOID PRECURSOR PROTEIN TRANSCRIPTS IN THE DEVELOPING RAT CNS. C.A. Sherman, S. Koh and G.A. Higgins. Univ. Rochester, Rochester, NY 14642 and Gerontology Res. Ctr., NIA/NIH, Baltimore, MD 21224.

Recent evidence suggests that the amyloid precursor protein (APP) may regulate cell growth. In order to study the contribution of different APP variants on neuronal growth in the developing CNS, we used the reverse transcription - polymerase chain reaction (RT-PCR) to examine differential APP gene expression in postnatal rat brain. Multiple species of APP mRNA were detected in the rat CNS, including APP-695, APP-714, APP-751 and APP-770. To quantify the relative amounts of different APP transcripts at postnatal days (PD) 1, 5, 10, 15, 22, 30 and in the adult, we used competitive RT-PCR analysis (Wang, A.M. et al, PNAS, 86:9717, 1989). APP-695 accounts for more than 75% of total APP mRNA at all developmental stages. APP-695 mRNA also showed the greatest variation in abundance during development, reaching a peak of expression at PD 15 - 22, the period of maximal NGF-responsiveness in the rat forebrain. These results suggest the possibility of an interaction between growth factor responsivity and APP gene expression in the developing CNS.

STUDIES ON THE EXPRESSION AND SUBCELLULAR ORGANIZATION OF THE ALZHEIMER'S AMYLOID PRECURSOR PROTEIN IN GLIA. Inc. ALGARIAGE'S AMILOTO PROCUSOR PROTEIN IN GITA.

Mt. Sinai Medical Center, New York, N.Y. 10029.

Neuritic plaques are a histopathological hall mark of Alzheimer's disease. However, the source of the B-peptide comprising the plaque amyloid core remains unknown. Much work has focused on a neuronal source of the B-peptide. We are currently testing the hypothesis that glia are a B-pep tide source.Northern and Western analysis of rat primary, cortical glia indicated that BAPP 695 is the predominant form expressed, while KPI forms are not dectable.In contrast the rat glioma C6 expresses high levels of KPI containing BAPP.Immunocytochemical examination of primary glia revealed that BAPP expression was limited to Type I astrocytes and neither oligodendrocytes nor A2B5 progenitors expressed detectable levels of BAPP. Immunolocalization indicated that the subcellular organization of BAPP was similar to the fib rillar pattern observed for GFAP, suggesting a cytoskeletal association for BAPP.Detergent extraction of C6 cultures futher support the notion of a cytoskeletal association for BAPP.Experiments designed to study "factors" modulating BAPP expression in glia have found that both II-l and bFGF increase BAPP several fold, while both 8-bromo cAMP and NGF were found to have no effect.

AMYLOID PRECURSOR PROTEIN AND NEURONAL CELL SUR-VIVAL AS STUDIED BY ANTISENSE TRANSFECTION.

A. LeBlanc,* D. Kovacs, F. Villare, M. Tykocinski, L. Autilio-Gambetti and P. Gambetti. Div. of Neuropathol, CWRU, Cleveland OH 44106.

The function of the amyloid precursor protein (APP) was investigated in the neuroblastoma cell line, LaN-1 using antisense RNA to inhibit translation of all forms of APP. Lipofectin-mediated transfection of translation of all folia of AFF. Exporectin-inediated transfection of LaN-1 was achieved with a replicating episomal vector containing a IKb fragment of APP₆₉₅ in antisense orientation. APP mRNA as well as cellular and secreted APP proteins were reduced by 75-90% in antisense amyloid transfected (ASAT) LaN1 relative to that of normal tisense amyloid transfected (ASAT) LaN1 relative to that of normal LaN-1. ASAT cells grew slowly compared with normal and RepIII-transfected cells, and exibited a high rate of cell death. These conditions were partially reversed by the addition of normal LaN-1 conditioned media (CM). To determine if the addition of CM increased cell division, ³H-thymidine was added to normal, ASAT and RepIII transfected LaN-1 at 1,2,3 and 4 days of culture in the presence(+) or absence(-) of CM. The percentage of ASAT cells synthesizing DNA was lower (~30%) than normal LaN-1 (~50%) or RepIII transfected LaN-1 (~46%) in CM- and this difference did not change with time. A higher number of normal LaN-1, RepIII-transfected and ASAT cells in CM+ incorporated ³H-thymidine at day 1 of culture but then decreased to the level found in CM- by day 2 and thereafter. Despite the lack of significant difference in DNA synthesis by ASAT cells in CM+ or CM-, at day 4 the cells grown in CM- were less abundant and appeared to undergo degeneration. These results indicate that APP affects cell surundergo degeneration. These results indicate that APP affects cell survival rather than cell proliferation of LaN-1. Supported by NIH Merit Award AG08155 and the Britton Fund.

CELLS TRANSFECTED WITH AMYLOID PRECURSOR PROTEIN DNA FRAGMENT AB-1 PRODUCE MEDIUM TOXIC TO DIFFERENTIATED PC12 CELLS. T.L. Martin & E.E. Baetge. Bristol-Myers Squibb Pharm. Res. Inst., CNS Biology Wallingford, Ct. 06492

Amyloid deposits in cortex and hippocampus comprise one of the two pathological hallmarks of Alzheimer's Disease. Amyloid precursor proteins (APP) are present in normal brain and have been shown to be synthesized in neurons and glial cells by alternative splicing of a single gene. We report here on data corroborating the findings of Yankner et al., Science 245: 417-420, 1989 who demonstrated that a portion of the APP gene (AB-1) is toxic to postmitotic neurons and differentiated PC12 cells. PC12 cells were transfected with an SV40-neo

selection/expression vector containing the Bgl II-Xmn I fragment of the human APP gene (AB-1 as defined by Yankner et al.). G418 resistant clones were isolated and RNA extracts probed for expression of the foreign fusion mRNA. The 600 bp Bgl II-Xmn I APP fragment hybridized to two bands, the lower molecular weight form being unique to the AB-1 transfected cell lines. Medium conditioned by AB-1 or control transfected cell lines was tested for toxicity in NGF differentiated PC12 cells. Viability was spectrophotometrically quantitated with the vital dye MTT revealing up to 90% death of cells exposed to AB-1 conditioned medium. Our results indicate that the protein(s) secreted from AB-1 transfected cells is toxic to differentiated PC12 cells. These findings further suggest the possibility that an APP fragment may play a role in the cell death characteristic of the Alzheimer's diseased brain.

A HIGH RESOLUTION ELECTRON MICROSCOPIC STUDY OF ALZHEIMER NEUROFIBRILLARY TANGLES AND SENILE PLAQUE CORE AMYLOID. K. Iqbal, G.C. Ruben*, H.M. Wisniewski* and J.E. Johnson Jr. Inst. Basic Res. Staten Island, NY, Dept. Biol. Sci., Dartmouth Coll., Hanover, NH, Dept. Neurosci., Stanford Res. Inst., Menlo Park, CA.

Tangles and plaque cores were isolated, using non-denaturing conditions, from frozen autopsied brains of patients with Alzheimer disease, were freezedried and vertically replicated (FDVR) and the replicas were examined by electron microscopy. Tangles contained paired helical filaments (PHF) and 2.1±0.2 nm filaments in different proportions. The PHF were generally righthanded helices with a twist period (L) averaging 79.3±5.9 nm and a maximum filament width (W) averaging 14.9±1.0 nm. The regions of minimum width (T) showed three size averages of 2.4±0.3 nm, 4.9±0.6 nm and 9.6±1.4 nm. These measurements are very similar to previous negative stain measurements and when averaged together produce L=74.4 \pm 8.0 nm, W=16.2 \pm 2.7 nm, and T=5.2 \pm 2.6 nm. The average PHF reported from thin sectioned Alzheimer tissue indicate that the PHF widths have been increased by a positive stain deposition of 9.4 nm. The concept of PHF twisting around each other longitudinally is not supported by the FDVR images or by the measurements from negative staining and FDVR. Images of plaque cores showed that amyloid has a more solid appearance than the tangles and was constructed of 6.8-19.5 nm filaments which are unlike any of those found in tangles. Since the term PHF incorrectly describes the filament structure we suggest that a more accurate term would be Alzheimer helical filaments

SYMPOSITIM

SYMPOSIUM. BRAIN MODULATION OF SENSORY SIGNALS. R. B. Barlow, Jr., Syracuse University, (Chairperson); J. Art*, University of Chicago; S. M. Highstein, Washington University School of Medicine; R. Dubner, NIH-NIDR; E. Kaplan, Rockefeller University.

Sensory pathways are two-way channels that allow the brain to modulate the sensory information it receives. The brain's output may tune the signals of a sensory organ to specific stimuli, shape sensory signals to current or anticipated environmental conditions, modulate the metabolic activity of a sensory organ, or influence other properties such as neuronal development.

The symposium will address the following questions: - What controls the brain's output?

- What effect does the brain's output have on sensory signals?
 What cellular mechanisms underlie the brain's modulation
- of sensory signals?

Answers to such questions are far from complete. However, numerous studies show that efferent modulation of sensory signals is a fundamental aspect of brain function. Clear examples will be presented for the auditory, pain, vestibular and visual systems. Knowledge of the central modulation of sensory signals should provide a better understanding of the functional organization of the brain and of the neural mechanisms underlying behavior.

EXPRESSION OF C-FOS IN CRH NEURONS OF THE FETAL HYPOTHALAMUS DURING PARTURITION IN THE SHEEP.

G.E. Hoffman, T.J. McDonald • and P.W. Nathanielsz. Dept. Physiology, Univ. Pittsburgh, School of Med., Pittsburgh, PA 15261

Physiology, Univ. Pittsburgh, School of Med., Pittsburgh, PA 15261 and Laboratory for Pregnancy and Newborn Research, Dept. of Physiology Cornell Univ., Ithaca, NY 14853.

The fetal pituitary adrenal axis plays an important role in parturition. Fetal corticotrophin releasing hormone (CRH) neurons in the paraventricular hypothalamus undergo changes in immunoreactivity (IR) late in gestation suggestive of cellular extensive horses after the parameters of CRH. immunoreactivity (IR) late in gestation suggestive of ceilular activation; however, direct evidence for stimulation of CRH neurons at time of parturition is lacking. The present study tested the hypothesis that activation of the fetal hypothalamic CRH system, evidenced by expression of the oncogene product c-fos, accompanies labor in sheep. Monitoring of uterine EMG activity determined the onset of labor. The brains of six fetuses (removed by caesarian section under anesthesia) and five newborn sheep were caesanan section under anestnesia) and live newborn sneep were perfused and stained for c-fos and CRH. c-fos was detected with an N-terminal directed antibody (Cambridge Research OA 11-821, 1:44,000); an anti-CRH serum (Dr. A.-J. Silverman, 1:50,000) detected comparable numbers of CRH neurons in all animals. Prior to labor, less than 5% of CRH neurons expressed c-fos. At the time uterine contractions were first detected, 70% of CRH neurons expressed c-fos, and c-fos IR persisted until just after birth. c-Fos staining declined rapidly reaching pre-labor levels by 2-3 hrs after birth.

These data are consistent with the hypothesis that fetal CRH neurons are stimulated during labor, and that termination of stimulation probably occurs rapidly after delivery. Supported by NIH PO1 HD 21350 and RO1 NS 23858.

ALTERATIONS TO FLUID HOMEOSTASIS IN THE RAT LEADS TO CHANGES IN PEPTIDE GENE EXPRESSION IN DISCRETE REGIONS OF THE LATERAL HYPOTHALAMUS. by Alan G. Watts. NSL, The Salk Institute, La Jolla, CA 92037. Fluid homeostasis in the mammal is achieved by the complex interaction of cellular, hormonal and behavioral mechanisms. Dehydration initiates a series of responses aimed at restoring normal hydration. A number of studies have shown that forced dehydration or increased ingestion of sodium both lead to increased synthesis of vasopressin and oxytocin within the magnocellular population of the hypothalamic paraventricular (PVH) and supraoptic (SON) nuclei. Additionally, changes in gene expression have also been reported for corticotropin-releasing hormone (CRH) within the PVH and SON after both treatments. In the present study, in situ hybridization (ISH) using a number of different peptide mRNAs was used to investigate possible changes in other regions of the hypothalamus known to be involved in the response to osmotic stimulation.

Male Sprague-Dawley rats (275-400g BW; maintained on a 12:12 light dark schedule) were given 2.5% saline to drink for 3 days or allowed unrestricted access to water. At the end of the treatment all animals were deeply anesthetized and perfused (between 13.00h and 15.00h) with loc-cold 4% paraformaldehyde in 0.1M borate buffer at pH9.5. After 24h post-fixation 15x; coronal sections through the hypothalamus were cut and mounted on polyt-Lysine coated sikes. Sections were pre-hybed, hybridized and post-hybed as previously described (J.Histotech 12:169). Hybridized sections were exposed to Cronex-4 X-ray film for an appropriate period, and then dipped in Kodak NTB-2 emulsion and developed accordingly. cRNA probes for a number of different peptide mRNAs were used including prepro-CRH (ppCRH), prepro-enkephalin A (ppENKA) and prepro-neurotensin/neuromedin N (ppNT/NMN). Examination of the exposed material showed that ppENKA and ppNT/NMN mRNAs were found in a number of regions of the hypothalamus

IMPAIRMENT AND RECOVERY OF THE ACTH RESPONSE TO A SECOND STRESSOR IN 10 DAY-OLD RATS: IS STEROID FAST FEEDBACK INVOLVED? C.-D. Walker*, K. Scribner*, M.J. Meaney and M.F. Dallman*. Dept of Physiology, UCSF, San Francisco, CA 94143 and Dept of Psychiatry, McGill University, Montreal H4H 1R3, Canada. From days 3 to 14 of age, it is recognized that pituitary-adrenocortical activity is low in rat pups as assessed by a lack of ACTH and corticosterone (B) secretion at specific times after exposure to stress. In this study, we determined the time course of ACTH and B responses to a single or a double 3 min-exposure to ether vapor at 5, 60 and 240 min after the initial stressor in intact or adrenalectomized (ADX, 5d previously) 10 day-old rats. Plasma ACTH levels in intact pups are shown in the figure. In ADX pups no rapid decline in ACTH levels was observed at 10min (cont=1489±222 pg/ml, 5min =2125±203, 10min=2347±323) and baseline values were restored 30min post stress. Further ACTH and B increases after a second stressor were abolished when ether was given 5min after the first exposure but were normal if the 2nd exposure occured at 1h or 4h. We suggest that: 1) a normal adult-like response to one or two stresses is observed in 10

response to one or two stresses is observed in 10 day-old pups if the interval between the two stressors is greater than 5min and 2) depletion of readily releasable ACTH pools or fast B inhibition of ACTH release at 10 min after ether stress might explain the lack of pituitary responses to ether stress described

earlier.

c-fos mrna, fos and fos-related antigens induced by hypertonic saline and stress: an in situ hybridization AND IMMUNOCYTOCHEMICAL STUDY. Frank R. Sharp and Stephen M. Sagar, Depts. Neurology and Physiology, Univ. Cal and VA Medical Center, San Francisco, CA. 94121 Hypertonic saline (HS) induced c-fos mRNA magnocellular (PVNm) and parvocellular (PVNm)

magnocellular (PVNm) and parvocellular (PVNp), supraoptic n. (SON), and lamina terminalis (LMT). This occurred within 5', was maximal at 30-60', and disappeared by 180'. Fos protein, detected using a monoclonal antibody, was maximal at 1-2h, and disappeared 4-5h after hypertonic saline.

In contrast, Fos-like immunoreactivity (FLI) was detected in PVNm, PVNp, SON, and LMT at lh, 4h, 24h, 3d, and 7d following administration of HS. This and other data suggests that FLI at >4h represents FRAs, proteins immunologically and functionally related to Fos.

Induction of c-fos mRNA due to "stress" of injections was assessed by comparing isotonic saline (IS) injected subjects to untouched controls. IS induced c-fos mRNA PVNp, hypothalamus, suprachiasmatic n., cingulate in PVNp, hypothalamus, suprachiasmatic n., cingulate cortex, neocortex, ventral lateral septal n., piriform cortex, hippocampal pyramidal neurons, dentate gyrus granule cells, certain thalamic n., bed n. of stria terminalis, the amygdaloid n. and other structures.

Osmotic and stressful stimuli both induce the

transient c-fos (0-4h) and longer duration fra (0-7d) genes which in turn regulate target gene expression.

CONTRIBUTION OF ARACHIDONIC ACID METABOLITES TO BASAL AND INTERLEUKIN 1-INDUCED CRF SECRETION. E. Redei, B.J. Branch*, R.E. McGinnis* and A.N. Taylor. Dept. of Psychiatry, Univ. of Pennsylvania, Philadelphia, PA 19104 and Dept. of Anatomy, UCLA, Los Angeles, CA 90024.

The contribution of arachidonic acid (AA) metabolites

to basal and Interleukin 1 beta (IL-1) induced release of CRF was studied using superfusion of hypothalamic blocks from male rats. Inhibition of both lipoxygenase and cyclooxygenase pathways by 500 uM indomethacin (INDO) increased CRF secretion significantly (167.3+35.0 vs. 58.7+3.3 pg/ml CRF). Of the AA metabolites tested only 15-HETE increased in response to INDO (814.1+32.3 vs. 336.1+19.3 pg/ml 15-HETE) with kinetics identical to that found in the CRF response. Nordihydroquaiaretic acid (NDGA, 10 uM), a lipoxygenase inhibitor, produced a moderate CRF response with 4-6 min latency, 15-HETE again showing the same kinetics and percentage increase.

Addition of IL-1 (50 U/ml) resulted in marked increases of CRF with simultaneous 15-HETE secretion over basal release (CRF: 93.7+17.6%; 15-HETE: 120.7+25.8%). response was not altered by NDGA.

In conclusion: INDO. NDGA and IL-1 increased CRF and

15-HETE secretion with a constant ratio despite very different degrees of stimulation by these secretagogues. This suggests that CRF and 15-HETE secretion are intimately connected, possibly consequtive because 15-HETE serves as a second messenger for CRF secretion.

HEMORRHAGE-INDUCED POTENTIATION OF PITUTARY-ADRENOCORTICAL RESPONSES IN AWAKE RATS. K.V. Thrivikraman and P.M. Plotsky. The Clayton Fndn. Laboratories. for Peptide Biol., The Salk Institute, La Jolla, CA 92037.

Potentiation of pituitary-adrenal responsiveness to a second stimulus in the face of glucocorticoid negative feedback occurs in many species. A model of pituitaryadrenocortical potentiation in response to paired hemorrhages (HEM) has been developed in awake, male rats (Sprague-Dawley, 450-500 g). All experiments were performed between 0900-1330 h in preinstrumented (3-4 da) rats habituated to the test chamber. Systemic blood samples (300 μ l) were collected at -5, 0, 3, 6, 9, and 18 min with respect to HEM. Volumes were replaced by saline. HEM was performed by removal of 14 ml blood/kgBW (estimated 20% of blood volume) over 3 min via jugular cannula, with-holding blood for 7 min, then reinfusing over 3 min. All rats sustaining blood loss exhibited increases in plasma ACTH (ANOVA, p<0.01) and corticosterone (B; p<0.01). ACTH returned towards prestimulus levels after retransfusion. In group A rats, HEM1 and HEM2 were separated by 90 min. A significant enhancement of the peak change in ACTH at +9 min was observed in HEM2 vs HEM1 (929±292 vs 730±269 pg/ml), with the integrated response of HEM2 significantly greater (paired t, p<0.05) than that of HEM1 (1726±541 vs 1272±439 pg). Prehemorrhage B levels were 16±1 ng/ml (HEM1) and 18±2 ng/ml (HEM2). A significant (p<0.01) elevation in B was evident by +9 min during HEM1 (95±36 ng/ml) and HEM2 (129±55 ng/ml); 4 of the 5 rats exhibited larger, significant (p<0.05) total increases in B during HEM2 vs HEM1 (386±111 vs 248±83 ng). Rats receiving only 1 HEM episode corresponding to the time of HEM2 (group B) exhibited ACTH secretory responses equivalent to those measured during HEM1 of group A (525±172 vs 730±269 pg/ml; p>0.05). These data suggest that pituitary-adrenocortical responsiveness to HEM is potentiated by a prior HEM in awake rats. Underlying mechanisms are currently under investigation.

ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL EVIDENCE FOR ADRENOCEPTOR SPECIFICITY IN THE HYPOTHALAMIC REGULATION OF ADRENOCORTICAL SECRETION. D. Saphier Department of Pharmacology, LSU Medical Center, Shreveport, LA 71130.

Noradrenergic projections to the hypothalamic paraventricular nucleus (PVN) play a primary role in the regulation of the activity of corticotropin-releasing factor (CRF) neurones. Thus, electrical stimulation of the ventral noradrenergic ascending bundle (VNAB) causes increased adrenocortical secretion. Using rats bearing cannulae implanted above the PVN for administration of adrenergic agonist and antagonist agents, we have demonstrated that these effects are mediated by both $\alpha 1$ - and $\alpha 2$ -adrenoceptors. In parallel electrophysiological experiments, iontophoretic application of the $\alpha 1$ -antagonist ergotamine, prevented the excitation of antidromically identified putative CRF-secreting PVN neurones elicited by low frequency VNAB stimulation. Iontophoretic application of the $\alpha 1$ -agonist, I-phenylephrine excited such cells. Responses to application of the $\alpha 2$ -agonist, clonidine produced an initial excitation of the majority of cells tested but the $\alpha 2$ -antagonist, tolacoline had less clearly defined effects upon responses evoked following VNAB stimulation. There is some evidence for an inhibitory role for β -adrenoceptors in the regulation of adrenocortical secretion and iontophoresis of the β -antagonist, propranolol caused almost ubiquitous excitatory responses, supporting the concept of an inhibitory role for β -adrenoceptors. In addition, application of propranolol was found to block the inhibitory responses of putative CRF-secreting PVN neurones following high frequency stimulation of the VNAB.

TIME-COURSE OF ACTION OF THE 5-HT, AGONIST, DOB, ON THE DOWN-REGULATION OF CRF AND 5-HT, RECEPTORS DURING CHRONIC INFUSION. D.L. Knight, M.J. Owens, J.C. Ritchie and C.B. Nemeroff. Depts. Psychiatry & Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710.

We have previously found that 7 day infusion of the 5-HT₂ agonist, DOB, resulted in tolerance to the stimulatory actions of the drug on the HPA axis. These rats also exhibit decreased anterior pituitary CRF and cortical 5-HT₂ receptor binding. In order to further examine these drug-induced changes, a series of experiments was performed to scrutinize the time-course of these alterations. Administration of DOB (0.35 mg/kg/day) via osmotic

Administration of DOB (0.35 mg/kg/day) via osmotic minipumps resulted in increases in plasma corticosterone which returned to baseline by 48 hours post-implantation. This was apparently associated with desensitization of the 5-HT₂ receptor because high affinity cortical H-DOB and hypothalamic 1251-DOI binding was decreased 48 hours post-implantation. Median eminence CRF content was unchanged at all time points; anterior pituitary CRF receptor binding was significantly decreased 7 days post-implantation. These results suggest that tolerance of the HPA axis to the stimulatory actions of DOB, as evidenced by plasma corticosterone, initially results from down regulation of 5-HT₂ receptors. Additionally, by 7 days post-implantation, down-regulation of anterior pituitary CRF receptors may also contribute to the observed tolerance. (Supported by NIMH MH-42088)

ELEVATED CEREBROSPINAL FLUID CORTICOTROPIN-RELEASING HORMONE AND ARGININE VASOPRESSIN IN DEPRESSED PATIENTS WITH DEXAMETHASONE NON-SUPPRESSION. AF Pitts. RG Kathol, TL Gehris*, SD Samuelson, BT Carroll, WH Meller*, J Carter*, CB Nemeroff, and G Bissette, The University of Iowa College of Medicine, Iowa City, IA 52242.

G Bissette. The University of Iowa College of Medicine, Iowa City, IA 52242.

Dysfunction of the hypothalamic-pititary-adrenal (HPA) axis is one of the best documented findings in major depressive disorder (MDD). Recent evidence, including elevated cerebrospinal fluid (CSF) corticotropin-releasing hypersecretion of CRH as a likely gauge.

hormone (CRH), suggest hypersecretion of CRH as a likely cause.

CSF was obtained by lumbar puncture at 1600 hours on 19 Inpatients with MDD and 18 healthy normal controls. We found no significant difference in CSF CRH levels between the MDD (mean ± S.D.: 38.59 ± 8.14pg/ml) and control (43.28 ± 9.97pg/ml) groups. Similarly, no significant differences were found on measures of CSF arginine vasopressin (AVP) or CSF oxytocin (OT). When subdivided by dexamethasone suppression test (DST) status, MDD nonsuppressors (MDD-NS) (n=5) had the highest CSF CRH levels (45.92 ± 7.94pg/ml) and the MDD suppressors (MDD-S) (n=14) demonstrated the lowest (35.98 ± 9.50pg/ml) (F=3.51; df=2,33; p=0.04). CSF AVP and CSF OT measurements, though not significantly different, followed the same pattern. There was a significant positive correlation of CSF CRH with CSF AVP (r=0.536; p=.0006) for all subjects.

We conclude that CSF CRH is higher in depressed DST non-suppressors. Furthermore, AVP, which has been documented to be an ACTH cosecretogogue with CRH, also tends to be higher in the same depressive supporting and may also be hypersecreted in this group. Lastly, a strong positive correlation between CSF CRH and CSF AVP provides support for their conserted action in enhancing ACTH release.

195.8

ACUTE AND CHRONIC EFFECTS OF THE 5-HT₂ AGONIST, (±)-1-(2,5-DIMETHOXY-4-BROMOPHENYL)-2-AMINOPROPANE (DOB) ON HPA AXIS ACTIVITY. M.J. Owens, J.C. Ritchie, D.L. Knight and C.B. Nemeroff. Depts. Psychiatry & Pharmacology, Duke Univ. Med. Ctr., Durham, NC 27710.

In vitro studies have suggested that hypothalamic CRF secretion is under stimulatory 5-HT, recentor control

<u>In vitro</u> studies have suggested that hypothalamic CRF secretion is under stimulatory 5-HT₂ receptor control. We examined the acute and chronic effects of the highly potent and selective 5-HT₂ agonist, DOB, on a number of indices of HPA axis activity <u>in vivo</u>.

DOB dose-dependently increased plasma ACTH and

DOB dose-dependently increased plasma ACTH and corticosterone concentrations at doses greater than 0.1 mg/kg. Peak effects occurred by 30 minutes and returned to basal values by 4 hours. This was hypothesized to be due to release of hypothalamic CRF because pretreatment with the CRF antagonist, α -helical CRF9_41 (0.4 μ mol/kg), resulted in a blunted ACTH response to DOB. Median eminence CRF content was also decreased following DOB administration in the prescence of cycloheximide. Seven day administration of DOB via osmotic minipump resulted in down regulation of both anterior pituitary CRF receptors and brain 5-HT_2 receptors. These receptor changes were physiologically significant as challenge doses of DOB or CRF resulted in blunted ACTH responses. Neither acute nor chronic DOB administration altered CRF concentrations in any of 14 extrahypothalamic brain regions studied. These results support a stimulatory role for 5-HT_2 receptors on hypothalamic CRF secretion.

195.10

BLUNTED ACTH RESPONSE TO PHYSIOLOGIC STRESS IN DEPRESSED PATIENTS BUT NOT PATIENTS WITH SCHIZOPHRENIA. RG Kathol. TL Gehris*, BT Carroll, SD Samuelson, AF Pitts, WH Meller*, J Carter*. The University of Iowa College of Medicine, Iowa City, IA 52242.

In this study seven hospitalized patients with major depression (MD), five

In this study seven hospitalized patients with major depression (MD), five hospitalized patients with schizophrenia (S), and 13 control subjects (C) were administered 0.15 units regular insulin/kg at 1600 hours by intravenous bolus infusion. ACTH, cortisol, and glucose levels were measured intermittently for two hours following infusion. Baseline ACTH, cortisol, and glucose levels were similar in Cs, MDs, and Ss. The mean glucose nadir was 23.6 mg/dl for Cs, 28.4 mg/dl for MDs, and 21.0 mg/dl for Ss (F=1.44; df=2,22; p=.258). The MDs had a blunted ACTH response to hypoglycemia when compared to Cs and Ss (F=3.28; df=12,126; p=.0004). They also had an appropriate decreased cortisol response (F=4.20; df=12,132; p=.0001). This was observed despite the Ss having Carroll Depression Scale scores (23) similar to MDs (30) and significantly different than Cs (1.4) (F=55.2; df=2,22; p=.0001). When MDs (28 mg/dl) were matched with Cs (27 mg/dl) for glucose nadir, significant differences between the two remained (F=4.51; df=6,72; p=.0006).

This study replicates in a new cohort a previously reported comparison of controls and patients with MD by showing blunting of the ACTH response to hypoglycemia and extends the original findings by demonstrating that patients with schizophrenia do not show similar changes. This suggests that patients with MD show different ACTH responses to physiologic stress which are not explained by the negative feedback of baseline ACTH or cortisol. Furthermore, the presence of depressive symptoms alone do not appear to influence the development of a blunted ACTH response but that the underlying state of primary major depression is more important.

195.12

DYNAMICS OF IN VIVO SECRETION OF ACTH IN MEN AFTER INSULIN-INDUCED HYPOGLYCEMIA. A Iranmanesh*, G. Lizarralde* and J.D. Veldhuis. Divisions of Endocrinology, VA Medical Center, Salem, VA 24153 and University of Virginia, Charlottesville, VA 22908.

Endocrinology, VA Medical Center, Salem, VA 24153 and University of Virginia, Charlottesville, VA 22908. The kinetic responses of the corticotropin axis to insulin-induced hypoglycemia were investigated by deconvolution analysis of plasma concentrations of ACTH measured by IRMA in blood samples collected at 10 min intervals for a period of 3 hrs in 7 normal men after iv administration of insulin. Plasma concentrations of glucose deceased to a mean of 34 \pm 3 (SE) mg/dl, 36 \pm 2.4 min after insulin. Concomitantly plasma concentrations of ACTH increased from 18 \pm 3 (baseline) to 347 \pm 66 pg/ml (maximum) occurring at min 54 \pm 2. Deconvolution analysis revealed significant increases in the mean rate (5.2 \pm 0.9 vs 1.0 \pm 0.1 pg/ml/min; p=0.03), maximal rate (29 \pm 6 vs 1.5 \pm 0.2 pg/ml/min; p=0.003) and mass (936 \pm 170 vs 173 \pm 23 pg/ml; p=0.03) of ACTH secreted. Maximal ACTH secretory rate occurred 8 \pm 2 min after maximal hypoglycemia. We conclude that acute insulin-induced hypoglycemia causes marked increases in ACTH secretion rates and mass, and consequently its plasma concentration. By coupling, additional measurements of POMC-related products such as B-endorphin with deconvolution analysis, the exact kinetic of coordinate activation of the adrenocorticotropin axis can be evaluated quantitatively in vivo.

RAPID DIFFUSIVE LINKS IN NEURAL DEVELOPMENT AND

RAPID DIFFUSIVE LINKS IN NEURAL DEVELOPMENT AND FUNCTION. P.R. Montague. J.A. Gally*, and G.M. Edelman. The Neurosciences Institute, 1230 York Ave., New York, NY 10021.

The segregation and refinement of axonal projections in the vertebrate central nervous system depend critically on the correlation of presynaptic firing and postsynaptic depolarization as well as on NMDA receptor activation. To account for these activity-dependent phenomena, we have proposed that a short-lived diffusible signal is released from postsynaptic sites in a calcium-dependent fashion, diffuses to both presynaptic and postsynaptic sites nearby, and affects afferent branching and synaptic stabilization in a restricted volume of neural tissue (PNAS 87, 3547). This diffusive signal labels a small volume of neural tissue as being previously active. Those afferents whose firing is correlated with transiently increased levels of the substance are induced to branch through transient stabilization of their growth cones either by synapse formation or by slowing neurite extension.

We have modeled these mechanisms by simulating the growth of afferent We have modeled these mechanisms by simulating the growth of afferent axons into a 3-dimensional region containing neurons with explicit dendritic geometry. Synaptogenesis and axonal branching occur according to the mechanisms hypothesized above. Two kinds of neuroanatomy are considered: 1) regions that have both local and longer range excitatory connections and 2) regions that lack local excitatory connections. Both cases contain inhibitory neurons and their role in shaping the segregation of the terminals has been explored. The simulations show that a rapid diffusive signal, for example nitric oxide (PNAS 87, 3547), can account for known features of axonal segregation in the thalamus and cortex. The overall model demonstrates the sensitive dependence of developmental anatomy on the history of afferent correlations and reveals the effects of diffusive links in a network with fixed anatomy. LOCAL APPLICATION OF BASIC FIBROBLAST GROWTH FACTOR INDUCES POSTSYNAPTIC DEVELOPMENT IN MUSCLE CELLS. H. B. Peng and L. P. Baker. Dept. of Cell Biology & Anatomy and Curr. in Neurobiology, Univ. of North Carolina, Chapel Hill, NC 27599.

Peptide growth factors are universally used by cells for signaling proliferation and differentiation. Little is known about their role in synaptic induction. In this study,

we examined the effect of basic fibroblast growth factor (bFGF) in signaling postsynaptic differentiation in cultured muscle cells, since previous studies have shown the importance of this protein in myogenesis. To mimic the local cellular interaction at nerve-muscle contact, we applied bFGF to cultured Xenopus muscle cells via coated latex beads. After an incubation period of 12-24hr, we observed that acetylcholine receptor (AChR) clusters appeared at the bead-muscle contacts. The size of the clusters conformed to the size of beads applied and their number was proportional to the number of bead-muscle contacts. In addition to cluster induction, a dispersal of preexisting AChR clusters (hot spots) was also elicited by the treatment of bFGF beads. Ultrastructural studies showed that the bFGF beadinduced clusters were associated with membrane infolding and basal lamina. Beads coated with bovine serum albumin or acidic FGF were ineffective in inducing AChR clustering. Heat-denatured or reduced bFGF was also ineffective. Suramin, a polyanionic molecule that interferes with the binding of growth factors to their receptors, abolished bFGF bead-induced AChR clustering. bFGF receptor, similar receptors, abolished bFGF bead-induced AChR clustering, bFGF receptor, similar to many other receptors for growth factors, has an tyrosine kinase domain on its cytoplasmic tail. When the cells were incubated with tyrphostin RG50864, a tyrosine kinase inhibitor, the bFGF bead-induced AChR clustering was reversibly blocked. These results show that local application of bFGF can induce the postsynaptic development in Xenopus and this induction may be mediated by tyrosine kinase activity of bFGF receptors. AGRIN-LIKE MOLECULES ARE INVOLVED IN THE MOTOR NEURON-INDUCED AGGREGATION OF AChR'S AT DEVELOPING NEUROMUSCULAR JUNCTIONS. Noreen E. Reist and U.J. McMahan. Dept. of Neurobiology, Stanford University, Stanford, CA 94305.

According to the agrin hypothesis, agrin, or a molecule similar to it, is synthesized by motor neurons, transported to the neuromuscular junction and released from nerve terminals into the synaptic cleft, where it directs the formation of acetylcholine receptor (AChR) aggregates on formation of acetylcholine receptor (AChR) aggregates on developing muscle fibers. In order to test the involvement of agrin in directing the formation of this postsynaptic specialization, we generated polyclonal antisera against purified agrin from Torpedo electric organ extracts and tested the sera for the ability to inhibit the formation of neurally-induced AChR aggregates on cultured myotubes. Dissociated chick motor neurons grown in culture with chick myotubes normally induce a dramatic increase in the number of AChRaggregates on the myotube surface at or near the point of contact with neurites. IgG's purified from anti-agrin serum markedly inhibited the motor neuron-induced aggregation of AChR's in cocultures of chick motor neurons and myotubes, while IgG's purified from the preimmune serum had little effect. This is the most direct evidence to date that agrin plays a role in the formation of the postsynaptic apparatus at the neuromuscular junction.

MODULATION OF PRESYNAPTIC TRANSMITTER RELEASE BY POSTSYNAPTIC DEPOLARIZATION AT DEVELOPMING NEUROMUSCULAR SYNAPSE. Y.J. Lo, D. Sanes , and M. Poo. Dept. Biological Sciences, Columbia Univ., N.Y., NY 10021, and Depts. Otolaryngology and Physiol. & Biophys., NYU Med. Ctr., NY NY 10016 N.Y., NY 10016.

The development and stability of early nerve connections are affected by the synaptic activity. We have examined the effects of postsynaptic depolarization on the efficacy of synaptic transmission at developing Xenopus neuromuscular synapses in culture.

Spontaneous synaptic currents were recorded in single innervated muscle cells by whole-cell patch recording method under voltageclamp condition. The recordings were interrupted for brief (15 to 30 min) episodes of pulsatile current injections (in current-clamp mode) which resulted in repetitive depolarizations of the muscle membrane (70-100 mV amplitude, 5-20 ms duration, 4-8 Hz). In 17 out of 25 (70-100 mV amplitude, 5-20 ms duration, 4-8 Hz). In 17 out of 25 cases we found that the frequency of the spontaneous synaptic currents (SSCs) were significantly reduced (range: 21 to 87%). Similar episodes of hyperpolarization did not induce this change. The effect of repetitive depolarizations was significantly diminished in the presence of constant local perfusion of the synaptic site with fresh culture medium, suggesting involvement of diffusible factor(s) in the observed depolarization dependent modulation of presynaptic transmitter release. Since presynaptic neurons in this culture rarely fire action potential spontaneously, the present result is consistent with the notion that postsynaptic activity de-stablizes synapses that are not concurrently releasing transmitter. are not concurrently releasing transmitter.

Motor neurons contain an mRNA that codes for an agrin-like molecule. C. Maoill-Solc. R. H. Scheller & U. J. McMahan. Dept. of Neurobiology and Dept. of Biological Sciences, Stanford

University, Stanford, CA 94305.

Several lines of evidence indicate that agrin or a molecule very similar to it mediates the motor neuron-induced aggregation of acetylcholine receptors and acetylcholinesterase at the neuromuscular junction. In the study described here we tested this hypothesis by seeking to determine whether the cell bodies of motor neurons contain an mRNA that encodes agrin-like proteins, which would be expected if motor neurons synthesized such

which would be expected if motor neurons symmestized social proteins.

32P-labelled RNA probes were generated from a cDNA that codes for an agrin-like protein in the marine ray *D. ommata* and were used to probe Northern blots of poly (A)* mRNA from various *D. ommata* tissues. The probe hybridized to two prominant mRNA species, 9.5 kb and 7 kb in CNS tissues. A relatively small amount of the 9.5 kb mRNA only was detected in muscle, electric organ and liver. *In situ* hybridizations using ³⁵S-labelled RNA probes demonstrated that the mRNA is concentrated in motor neurons of the D. ommata electric lobe and spinal cord, although it appears to be expressed at a low level throughout the CNS.

AGRIN INDUCES THE REDISTRIBUTION OF ACh RECEPTORS AND Na CHANNELS ON ADULT SKELETAL MUSCLE FIBERS IN CULTURE. M.T. Lupa* and J.H. Caldwell. Department of Cellular and Structural Biology, Univ of Colorado, Denver, CO 80262. It has been shown that acetylcholine receptors (AChR)

and Na channels (NaCh) are both highly concentrated at the neuromuscular junction (NMJ). The nerve is believed to influence the formation of the AChR patch, possibly through the action of agrin, which is a basal lamina protein that induces the formation of AChR clusters on myotubes in vitro. We have applied agrin (kindly supplied by J. Fallon) to adult muscle fibers in culture in order to test whether agrin can play a role in the formation of NaCh clusters on muscle fibers. Enzymatically-dissociated adult rodent FDB muscle fibers were used because these have a higher density of NaCh than embryonic myotubes. Rhoda mine-a-bungarotoxin was used to visualize AChR patches, and the loose patch voltage-clamp was employed to map NaCh densities on the muscle fiber. Agrin increased the number of AChR clusters about 4X within 24 hr on 5-10 d denervated muscle fibers. 55% of the AChR aggregates had NaCh densities more than twice the average extra-cluster density, a figure similar to naturally-occurring AChR clusters. Some NaCh 'hot spots' were found in areas devoid of AChR clusters, both in the presence and absence of agrin. conclude from these results that 1) agrin can induce new clusters of AChR and NaCh on adult muscle fibers in culture, and 2) though often co-localized, the distributions of AChR and NaCh are not closely co-regulated.

THE BINDING OF TORPEDO AGRIN TO THE MUSCLE CELL SURFACE IS CALCIUM DEPENDENT, J. R. Fallon and E Lieth, Worcester Fdn. for Exper. Biol., Shrewsbury, MA. 01545

Agrin is likely to play a central role in directing the differentiation the postsynaptic apparatus during development and regeneration of the neuromuscular junction. Our current studies are aimed at characterizing the muscle cell surface receptor for the agrin molecule. The binding of Torpedo agrin to the muscle cell surface detected by immunofluorescence microscopy is saturable and does not require the presence of serum or embryo extract. When myotubes are incubated with agrin at 37°C, agrin binding sites become concentrated at the induced AChR clusters. This redistribution of agrin binding sites is unaffected by 5mM Na azide or 100µg/ml cycloheximide. No binding of agrin to the myotube surface is detected when Ca2+ is omitted from the incubation medium or specifically chelated with EGTA. Mg²⁺ or Mn²⁺ are not required for binding nor do they substitute for Ca²⁺. The omission of Ca²⁺ does not irreversibly alter either the ligand or receptor since pre-incubation of either the cells or the agrin with EGTA did not affect their subsequent binding in the restored presence of Ca²⁺. Moreover, even after overnight incubation at 37°C, <u>Torpedo</u> agrin can be dissociated from its binding site by brief incubation in EGTA. These results indicate that both the formation and maintenance of agrin-receptor complexes is dependent upon the presence of extracellular Ca2+.

AN IN VITRO ANALYSIS OF THE ONSET OF SYNAPTIC TRANSMISSION

AN IN VITRO ANALYSIS OF THE ONSET OF SYNAPTIC TRANSMISSION BETWEEN CHICK AUTONOMIC NEURONS. James J. Walker and Richard I. Hume. Department of Biology, University of Michigan, Ann Arbor, MI 48109.

In the developing neuromuscular system there is an almost instantaneous onset of synaptic transmission following growth cone-muscle contact, due to the high degree of maturity of both the pre- and postsynaptic elements. We were interested in whether synaptogenesis occurred over a comparable time course in a neural system. We have examined the initial interactions between developing chick preganglionic sympathetic neurons and their target ganglion cells in vitro. Preganglionic neurons were retrogradely labeled with Dil, dissociated into single cells and plated on a laminin substrate. Several hours later sympathetic ganglion cells were manipulated onto the growth cones or neurites of the established preganglionic neurons. To test for synaptic function we monitored the spontaneous and evoked whole cell currents in the ganglion cells. Our major finding is that within the first two hours of recording, no synaptic currents were detected in ganglion cells in contact with preganglionic neurons. This failure to observe synaptic interactions was not a consequence of the recording methods, since when similar methods were used to examine the interaction between ciliary ganglion neurons and spherical myoballs, synaptic interactions were commonly observed within minutes of contact.

Further experiments explored why no synaptic currents were detected. Immaturity of the postsynaptic neurons was indicated by the observation that the responses of sympathetic ganglion neurons to application of 50 µM acetylcholine (ACh) were very small. The average ACh receptor density was estimated to be less than 1 receptor per µm². Immaturity of the presynaptic cell was indicated by the observation that no synaptic currents were recorded from myoballs placed onto preganglionic growth cones. Since evoked ACh release from ciliary ganglion neurons was d

TARGET CONTACT REGULATES THE CALCIUM SENSITIVITY OF SECRETORY MACHINERY DURING SYNAPTOGENESIS. M. J. Zoran, R. T. Doyle, and P. G. Haydon, Department of Zoology, Iowa State University, Ames, lowa 50011

Buccal neuron 19, isolated from the pond snail Helisoma trivolvis and

plated into cell culture, requires sustained periods of muscle-specific contact to induce the acquisition of functional excitation-secretion machinery. The contact-dependent transformation of this motoneuron's terminal into a secretory state requires protein synthesis (Doyle et al., 1990; <u>Soc. Neurosci. Abst.</u>). In this study, we determined whether contact regulates synaptogenesis through presynaptic actions involving increased density of

synaptogenesis through presynaptic actions involving increased density of calcium currents or the ability of calcium to promote exocytosis. Giant somatic synapses of B19, with appropriate buccal muscle contact but not novel neuronal contact, develop functional excitation-secretion machinery in cell culture. This preparation provides direct access to secretory membrane for studies of mechanisms underlying synaptogenesis. The types and density of calcium currents in B19 somata cultured alone, in contact with inappropriate neuronal targets, or in contact with appropriate muscle targets were not significantly different. Since calcium current densities were not different between these groups, the contact-dependent induction of secretory capabilities at the nerve terminal of B19 must involve a component of the secretory apparatus distal to the influx of calcium on component of the secretory apparatus distal to the influx of calcium ions. This idea was supported by experimental manipulations of intracellular calcium levels in presynaptic cells with the photolabile calcium cage, DM-nitrophen. Photolytic release of calcium increased presynaptic free calcium levels, as indicated by the co-injected calcium fluorophore Fluo-3, and evoked the release of neurotransmitter at somatic synapses only following sustained periods of appropriate muscle contact.

LOSS OF SYNAPTIC SITES DURING COMPETITIVE SYNAPSE ELIMINATION IS BOTH RAPID AND SALTATORY. R.J. Balice-Gordon & J.W. Lichtman, Dept. Anatomy & Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Univ. School of Medicine, St. Louis, MO 63110.

We are studying the competitive interactions between motor axons vying for capture of the same muscle fibers by following neuromuscular junctions innervated by two axons over time in the sternomastoid muscle of living mice. At transiently multiply innervated junctions, loss of ACh receptors precedes loss of overlying motor nerve terminals and retraction of the parent motor axon. Studies in which we labeled the two competing axons converging at the same junctions with different lipophilic dyes (see Chua et al., this volume) suggest a surprising stepwise elimination of terminals belonging to one axon. Consistent with this is the observation that although each axon initially occupies roughly equal synaptic territories, only 1-2 very small regions per junction lose motor nerve terminals (and ACh receptors) at any one time. Moreover, because fluorescent albab bungarotoxin labeled junctions containing motor nerve terminals (and ACh receptors) at any one time. Moreover, because fluorescent alpha bungarotoxin labeled junctions containing faint ACh receptor regions (in the process of being eliminated) are infrequently observed, we calculate that any one synaptic site may be eliminated in as few as 2-3 hours. Observations of multiply innervated junctions in living animals confirm that the loss of synaptic sites is indeed rapid. Because each axon occupies roughly 6-8 synaptic sites, the rapid loss of each site means that all of the synaptic sites occupied by the retracting axon may require a total of 18 hours to be eliminated. At some junctions, however, multiple innervation persists for several days even though synaptic sites are being lost, suggesting that these 18 hours might not be contiguous. We are studying the possibility that the rapid loss of an individual synaptic site may be followed by a period of relative quiescence before the next site is eliminated. These studies suggest that synaptic competition may occur locally, site-by-site, rather than on an all-or-none basis.

CELL INTERACTIONS REGULATE DENDRITIC MORPHOLOGY AND RESPONSES TO NEUROTRANSMITTERS IN EMBRYONIC CHICK PREGANGLIONIC NEURONS IN VITRO. B. Clendening and R. I. Hume.

Dept. of Biology, University of Michigan, Ann Arbor, MI 48109.

We studied the influence of non-neuronal cells and interneurons on the morphological development of chick sympathetic preganglionic neurons (SPN) and on the responsiveness of these neurons to the neurotransmitters, GABA, glycine and glutamate. SPN were retrogradely labeled with the fluorescent dyes, dil and diO, and glutaniate. STIN were retrogrately labeled with the fluorescent types, did and did, and then separated from spinal cord non-neuronal cells and interneurons by fluorescence-activated cell sorting. SPN were grown in culture either alone, or in co-culture with non-neuronal cells, with interneurons, or with both of these cell types (control cultures). The responsiveness of SPN to neurotransmitters was assessed by whole cell recording, while cell morphology was assessed after intracellular staining with 6-

cen recording, while cen into priorby was assessed and inducentual standing while carboxyfluorescein.

Cell size and morphology were affected by non-neuronal cells. In the absence of non-neuronal cells, SPN had smaller cell bodies and fewer major processes, whether or not interneurons were present. In contrast, responses to the three neurotransmitters were affected by both non-neuronal cells and interneurons but in different ways. In the absence of both non-neuronal cells and interneurons, responses to all three transmitters were much smaller than in control cultures. Responses to glutamate were most profoundly affected. The addition of non-neuronal cells or interneurons alone had no significant effect on the responses of SPN to GABA. The addition of either non-neuronal cells or interneurons significantly increased the addition of either non-neuronal cells or interneurons significantly increased the amplitude of SPN responses to glutamate, but the level of responsiveness was still much lower than those of SPN grown in the presence of both cell types. Finally, the addition of either non-neuronal cells or interneurons to SPN cultures brought responses to glycine back to control levels. These experiments demonstrate that although interneurons can have a powerful inductive effect on the responses of SPN to the neurotransmitters, not all of the changes in neurotransmitter responsiveness can be related to the formation of functional synapses.

196.12

REQUIREMENT FOR CONTACT-DEPENDENT PROTEIN SYNTHESIS FOR SYNAPTIC SPECIFICITY R.T. Doyle, M.J. Zoran and P.G. Haydon Department of Zoology, Iowa State University, Ames IA 50011. Cholinergic neuron B5 of *Helisoma* is indiscriminate in synaptogenesis since

it readily forms chemical synapses with novel cholinoceptive targets. By contrast, cholinergic neuron B19 is restricted and forms functional chemical connections with appropriate muscle targets only. It has been shown that neuron B5 forms its functional chemical connections with novel target cells within seconds of contact (Haydon and Zoran, Neuron 2:1483, 1989). By contrast, functional chemical connections were never detected within the first 30 minutes of specific target (supralateral radula tensor (SLT) muscle) contact with neuron B19 (Zoran et. al. <u>Dev. Biol.</u> 138:202,1990).

We determined whether protein synthesis is required following target contact for the formation of both novel and appropriate functional chemical connections. Neurons B5 and B19 were plated into culture where they extended neurites. After 2-3 days, future presynaptic neurons were challanged with target cells in the presence of the protein synthesis inhibitor, anisomycin (20µM).

indiscriminate neuron B5 reliably formed functional chemical connections in the presence of anisomycin. By contrast selective neuron B19 was unable to form a functional synapse with its appropriate target cell when protein synthesis was inhibited.

Thus, indiscriminate neuron B5 synthesizes presynaptic macherinery before target contact and can form novel chemical connections. Neuron B19, in contrast, requires target specific contact-dependent protein synthesis to complete the functional assembly of its presynaptic machinery. Supported by NiH grant NS24233.

ELECTRICAL COUPLING BETWEEN APLYSIA SENSORY CELLS IN CULTURE DISRUPTS THE SPATIAL SEGREGATION OF THEIR VARICOSITIES ON A POSTSYNAPTIC TARGET. M. Bank and S. Schacher. Ctr. for Neurobiol. and Behav., Columbia University CPS and NYS Psych. Inst., New York, NY 10032.

Sensory cells of *Aplysia* form chemical synapses with the motor neuron L7 in culture. Sites of synaptic interaction between these cells are typically found at varicosities of sensory cell processes overly-ing the main axons of L7, since these structures have been shown ultrastructurallly to contain active zones (Glanzman et al., Neuron 3:441, 1989). Using flourescent dye injection and video microscopy, we have investigated a) whether varicosities contributed by two different sensory cells segregate or intermingle on the main axons of L7, and b) how conditions such as electrical coupling between the sensory cells affects this pattern. At early times after plating (day 2), varicosities from different non-electrically coupled sensory cells can be seen to intermingle on the main axons of L7 (6 of 8 cocultures). At later times (day 4), varicosities from different non-electrically coupled sensory cells always segregate to separate areas of the motor axons (7 cocultures). In contrast, sensory cells which are electrically coupled (coupling coefficient of 0.05 to 0.10) do not segregate their varicosities on day 4 (4 of 5 cocultures). These observations suggest that the mature segregated pattern of varicosity distribution from non-electrically coupled sensory cells may arise through a process of rearrangement from an immature intermingled pattern. This process may be disrupted when sensory cells are electrically coupled

CALCIUM HOMEOSTASIS IN AN IDENTIFIED NEURONAL GROWTH CONE.

CALCIUM HOMEOSTASIS IN AN IDENTIFIED NEURONAL GROWTH CONE. Vincent Rehder, John R., Jensen, Ping Dou, Stanley B., Kater. Dept. of Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523, USA Calcium homeostasis was investigated in growth cones of identified neurons from the snail Helisoma trivolvis. The intracellular calcium concentration ([Ca]i) was experimentally altered by increasing the calcium flux into the cytoplasm, and resulting changes in [Ca]i were measured with the fluorescent calcium-indicator Fura-2 (K-salt). changes in [Ca]i were measured with the Huorescent calcium-indicator Fura-2 (K-salt). Sustained elevation of calcium influx was achieved by addition of the calcium ionophore 4-bromo A23187. The [Ca]i reached its peak value of 910nM 5min after the application. Most interestingly the growth cones gradually restored their [Ca]i back towards pretreatment levels despite the continuous presence of the ionophore. Two candidate mechanisms for lowering [Ca]i are the mitochondria and the Na/Ca exchanger. We tested their involvement in the restoration process by blocking these mechanisms, singly or in combination, and then compared the restoration in the presence of an increased calcium influx to the unblocked situation.

presence of an increased calcium influx to the unblocked situation. The mitochondria were rendered dysfunctional by use of FCCP which dissipates the proton gradient across the mitochondrial membranes and prevents calcium reuptake. Subsequently 4-bromo A23187 was applied to continuously increase calcium influx. Under this condition the growth cones were still able to restofe their [Ca]i. To test for the possible contribution of the Na/Ca exchanger, this system was blocked by reducing the extracellular [Na]. Upon increased calcium influx growth cones were again able to restore their [Ca]i. However, one could envision a situation where the inactivation of one mechanism could be compensated for by another, and vice versa. When both the mitochondria and the Na/Ca exchanger were blocked simultaneously, and growth cones subsequently challenged with increased calcium influx, the ability to control the [Ca]i was lost immediately, and neurons died within minutes. These results demonstrate a powerful calcium homeostatic capability within growth cones, based on an overlapping system of mechanisms controlling [Ca]i.

CALCIUM HOMEOSTATIC CAPACITY IS REGULATED BY PATTERNED ELECTRICAL ACTIVITY IN GROWTH CONES OF MOUSE DRG NEURONS. R.D. Fields¹, P.B. Guthrie², P.G. Nelson¹, and S.B. Kater². Lab. Developmental Neurobiology, NICHD, NIH, Bethesda MD 20892¹, and Dept. Anatomy and Neurobiology, Colorado State Univ., Fort Collins, CO 80523².

We have previously shown that electrical stimulation causes growth cones of several types of neurons to collapse. This collapse is due to an influx of calcium into the growth cone. Interestingly, following prolonged stimulation of mouse DRG neurons (>24 hrs.), motile growth cones are once again observed. This adaptation to electrical stimulation could be due in part to restoration of normal intracellular calcium concentration ($[{\rm Ca}^{2+}]_i$). We tested this hypothesis directly using dissociated DRG neurons grown in a three-compartment culture chamber.

We stimulated neurons crossing from a side compartment into the center compartment. Calcium levels were monitored with fura-2. Electrical stimulation resulted in a large increase in [Ca²⁺], and growth cone collapse. With continued stimulation calcium levels decreased substantially, but never returned to control levels. Immediately after cessation of chronic (>24 hrs.) stimulation, [Ca²⁺]_i fell significantly below control levels, suggesting additional calcium removal capacity activated by chronic electrical stimulation. Activity-dependent regulation of calcium homeostatic capacity could have a major influence on neurite outgrowth and interact with a range of other calcium-dependent developmental processes.

197.3

AMITRIPTYLINE TREATMENT DECREASES CAMP LEVEL IN EMBRYONIC CHICK EXPLANTS, AND INTERFERES WITH NEURAL DEVELOPMENT IN VIVO. K. L. WONG*, R. C. BRUCH* AND A. I. FARBMAN. Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Our laboratory has shown that amitriptyline (AMI), a typical tricyclic antidepressant, has potent effects in inhibiting neurite outgrowth from chick embryonic cerebral and olfactory explants [Brain Res. (1988) 457:281], and that dibutyryl cAMP can partially reverse the inhibitory effects of AMI [Soc. Neurosci. Abstr. (1989) 875]. These data suggest the possibilty that AMI may inhibit neurite outgrowth via the alteration of intracellular cAMP level.

In 8-day chick embryonic cerebral explants exposed to 8 µM of AMI, there is a significant 43% decrease in cAMP level (t=4.03, df=7, p<0.005). Interestingly, there is a significant correlation between the level of cAMP and the degree of neurite outgrowth (r=0.56, df=20, p<0.01).

Furthermore, we have studied the physiological and biochemical effects of AMI on brain development in vivo. Six day treatment of AMI (single daily injections of 48-172 μg) results in a significant 14% decrease in the weights of chick forebrains (t=4.18, df=8, p<0.005). The body weights, on the other hand, show a non significant 12% decrease. In addition, immunoblots and densitometric scans have shown a selective decrease in the level of a 93.6 K Da protein (-24%), β-tubulin (-18%), and actin (-20%). Several other proteins are not affected. Both flourescent and spectrophotometric DNA assays have shown that DNA:protein ratio in the AMI-treated and the control groups are the same, thus strongly suggesting that the reduction in forebrain weights may be due to a lower number of developing neurons, as well as an arrest of neurite outgrowth.

197.4

THE IN VITRO FORMATION OF PUTATIVE PEPTIDE RELEASE SITES USING A PHORBOL ESTER AND CYCLIC AMP R.J. Knox, E.A. Quattrocki, J.A. Connor and L.K. Kaczmarek, Dept. Pharmacology, Yale University, New Haven, CT 06510 and Roche Inst. Mol. Biology, Nutley, NJ 07110.

We have investigated the effects of a phorbol ester (TPA) and agents that elevate cAMP levels on morphology and calcium influx in the growth copies of hag cell neurons from Antwise by

influx in the growth cones of bag cell neurons from Aplysia by ratio imaging fluorescence of microinjected fura-2 and by DIC microscopy. In control cells in an arrested state of outgrowth, action potential driven Ca influx in the growth cones occurred in the central regions of the structures but did not appear at the leading edges of the lamellapodia. Bath application of TPA (20 nM), but not inactive analogs, triggered a thickening of the central region of the growth cone and extension of the lamellipodium. Electrically driven calcium influx now occurred at leading edges of the lamellae as well as the more central regions. The change in influx pattern may reflect the rapid recruitment of previously inactive Ca channels into the lamellae (Strong et al., 1987). There was no significant difference in resting Ca levels of the growth cones when effects of increased excitability were nulled out. Cotreatment with cAMP analogs or with forskolin promoted the movement of organelles into the newly extended lamellae but appeared not to alter the redistribution of the voltage gated Ca channel activity. Our findings suggest that activation of protein kinases produces morphological specializations in which secretory granules move to sites where calcium channels have been newly recruited.

TUBULIN IS PHOSPHORYLATED BY PP60C-SRC IN NERVE GROWTH CONE MEMBRANES. P. Maness and W. T. Matten. Department of Biochemistry, University of North Carolina School of Medicine, Chapel Hill, NC 27599.

pp60^{C-STC} is enriched in a subcellular fraction from

fetal rat brain containing membranes of the nerve growth cone. Tubulin was the major phosphotyrosine-containing protein in growth cone membranes in vivo, as detected by immunoblot with anti-phosphotyrosine (Ptyr) antibodies. Ptyr immunoblots of growth cone membranes showed that α and β -tubulin comigrated with the most prominent Ptyrmodified proteins on one-dimensional gels, and that they were highly enriched in the growth cone fraction. lpha- and $\ensuremath{\mbox{$\mathfrak{B}$-Tubulin}}$ were the most prominent proteins phosphorylated at tyrosine in in vitro protein kinase ractions with growth cone membranes (0.12 mol $[^{32}\mathrm{P}]$ -Ptyr/mol tubulin dimer. Ptyr antibodies immunoprecipitated tubulin from growth cone membranes. Tyrosyl residues in a subset of α -and 3-tubulin isoforms were phosphorylated in $[^{32}{\rm P}]^$ labele_ cultures of rat cortical neurons. pp60c-src, either in growth cone membranes or in immune complexes, phosphorylated purified brain tubulin $in\ vitro$. The consequence of tyrosine phosphorylation was to inhibit polymerization of α -tubulin isoforms into microtubules. These results suggest a model in which tyrosine phosphorylation of tubulin by $pp60^{C-SIC}$ at the growth cone membrane could regulate neurite extension by inhibiting microtubule assembly and destabilizing local adhesive contacts.

197.7

NGF-REGULATED PHOSPHORYLATION OF TYPE III β-TUBULIN DURING NEURITOGENESIS IN RAT PC12 CELLS. J.M. Aletta and L.A. Greene*. Dept. of Pathology, Columbia University, N.Y.C., N.Y. 10032.

Phospho-β-tubulin (PβT) has previously been identified as an NGFregulated phosphoprotein which undergoes increased phosphorylation in temporal correlation with PC12 cell neurite formation. The present work establishes that this increase occurs on neuronal-specific isotype III β -tubulin, but not on isotypes II or IV. Little, if any, β -tubulin is phosphorylated before NGF-treatment as determined by immunoprecipitation with both isotype-specific and general β -tubulin reagents. P β T is associated predominantly with Ca²⁺-/cold-sensitive microtubules, but taxol-driven assembly does not produce phosphorylation equivalent to long-term NGF-treatment, nor does it enhance that obtained by NGF. NGF is necessary, but not sufficient, for maximal phosphorylation. Cells grown with NGF for 1-2 w, either in suspension or on a substrate with colchicine, are neurite-less and contain less than 10% of the PBT of control neurite-bearing cultures. When the cells are replated on a substrate or the colchicine is removed, they rapidly extend long processes and attain levels of $P\beta T$ comparable to those in matched controls. Finally micro-excision experiments revealed that P β T is enriched in neurites relative to that in their corresponding cell bodies (2.9-fold±0.7; n=10), despite comparable total β -tubulin levels in the two regions. The rapid phosphate turnover on neuronal β -tubulin, its association with Ca²⁺-/cold-sensitive microtubules and its enrichment in neurites suggest some functional role in dynamic events related to polymerized microtubules in the specialized neuritic compartment of the cell.

ENDOGENOUS FATTY ACIDS OF PHOSPHOLIPIDS IN GROWTH CONES: INCORPORATION AND METABOLISM OF DOCOSAHEXAENOIC ACID (22:6) DURING DEVELOPMENT. R.E. Martin,* D. Kline and N.G. Bazan, LSU

Eye Center and Neuroscience Center, New Orleans, LA 70112.

Nerve growth cones are the dynamic endings of neurites that are actively growing, regenerating and undergoing plasticity changes. They represent a site of rapid membrane expansion and are the developmental precursors of synapses. Docosahexaenoic acid (22:6), an essential polyunsaturated fatty acid, is enriched in synaptic membranes and photoreceptors. We isolated nerve growth cone particles from mouse cerebrum and examined a) their endogenous fatty acid content as a function of development and b) the metabolism of 22:6 in phospholipids. Our results indicate marked changes in fatty acid composition of growth cones during development. In the homogenates, total nmol fatty acid per μg lipid P remains relatively constant during the first 15 d of life, whereas in growth cones these values decrease. Arachidonic and other fatty acids followed this pattern; however, 22:6 increased in the homogenate and decreased in the cone fraction. Expressed as mole percent fatty acid, 22:6 increased in both the cone fraction and the homogenate. At 5 d after intraperitoneal injection of ³H-22:6 into 5-day-old pups, more than 98% of the label in brain remained as 22:6. The 22:6 was incorporated in phosphatidylethanolamine (PE), phosphatidylcholine (PC) and phosphatidylserine (PS) in all cell fractions. The growth cone fraction was unique because it contained high concentrations of 3H-22:6 in ethanolamine-containing and neutral lipids. This correlated well with endogenous fatty acid content of phospholipids in that most of the 22:6 was seen in PE. Collectively these data indicate that growth cones are sites of active phospholipid metabolism and are different from other subcellular fractions. How these lipids are engaged in cell signaling, pathfinding and synapse formation are questions being addressed. NIH grant NS23002.

TURNING RESPONSE OF NERVE GROWTH CONES IN PULSATILE GRADIENTS OF DIBUTYRYL CYCLIC ADENOSINE MONOPHOSPHATE. M. Quillan* and M-m. Poo, Department of Biological Sciences, Columbia University, New York, NY 10027.

The directionality of neurite outgrowth is controlled by subcellular processes which are poorly understood. These processes may involve signal transduction which transmit information from the surrounding environment via second messengers. Cyclic nucleotides are known to serve second messengers in a number of systems. We thus tested directly the effect of membrane permeable cyclic nucleotides in influencing directionality of nerve growth, bypassing the action of the primary extracellular signal. A periodic pulsatile gradient of cyclic nucleotides was created near the growth cone of Xenopus spinal cord neurons in culture by using a picospritzer. In a restriction of the control of the co has and requesticy of 0.5 11 C₂ and a 12 C₂ mm opening) was positioned at 100 μ m from the center of the growth cone, at a 45° angle with respect to the direction of neurite extension, and the turning response was determined after 2 hrs in the presence of pulsatile chemical gradient by measuring any change in direction of neurite extension. We found gradients of dibutyryl cyclic adenosine monophosphate (dB-cAMP) caused significant turning of the growth cone toward the source of the chemical (average angle of turning $24.1 \pm 4.7^{\circ}$, n=16), while no effect was observed for gradients of sucrose ($6.4 \pm 7.8^{\circ}$, n=12) and dB-cGMP ($2.1 \pm 12.4^{\circ}$, n=7). The result is consistent with the notion that concentration gradients of cytoplasmic second messenger, cAMP in particular, may underlie cellular mechanisms involved in the turning of growth cones in response to environmental cues.

GROWTH AND DEGENERATION OF RAT SYMPATHETIC NERVE FIBERS IN COMPARTMENTED CULTURES: EFFECTS OF SPHINGOSINE, PHORBOL ESTER, AND THE MECHANISM OF NGF ACTION. B. B. Campenot. A. Walji* and D. D. Draker*, Dept. of Anatomy and Cell Biology, Faculty of Medicine, Univ. of Alberta, Edmonton, Alta., Canada T6G 2H7.

Local application of 8 or 10 µM sphingosine to distal neurites of NGF-treated rat sympathetic neurons in compartmented cultures caused their degeneration within 24 hrs, but sphingosine applied to cell bodies and/or proximal neurites caused no apparent damage, and the distal neurites continued to grow. Interference with the action of NGF was not the

cause since anti-NGF produced no similar effect. Treatment for 24 hrs with 2 μM of the phorbol ester, TPA, was used to down regulate protein kinase C activity (Matthies et al., <u>J. Neurosci.</u> 7, 1198-1206, 1987; Reinhold & Neet, <u>J. Biol. Chem.</u> 264, 3538-3544, 1989), but this neither destroyed distal neurites nor blocked the effect of sphingosine. Thus, protein kinase C appears not to mediate the degeneration of distal neurites by sphingosine.

Although TPA treatment caused a 50% reduction in the rate of neurite extension, the TPA-resistant component of neurite growth was completely blocked by anti-NGF. Thus, as with PC12 cells (Reinhold & Neet, 1989), protein kinase C does not appear to play an essential role in the mechanism by which NGF promotes neurite growth. The selective degeneration of distal nerve fibers by sphingosine may reflect the existence of a ligand-actuated system, not involving NGF or protein kinase C, that can trigger the degeneration of nerve endings and which may be important in synapse and collateral elimination, synaptic competition, and growth cone

197.10

CAP50, A CORTICAL CYTOSKELETON-ASSOCIATED PROTEIN OF DEVELOPING TISSUES AND NEURONS WITH PROPERTIES SIMILAR TO THE ONES OF GAP43. P. Caroni and F. Widmer. Friedrich Miescher Institute, P.O. Box 2543, 402-Basel, Switzerland. The subcellular distribution and expression pattern of GAP43 indicate that this protein might play an important role in axonal growth. The lack of both significant similarities between GAP43 and known proteins and of cell biological correlates of axonal growth has hindered the formulation of testable hypotheses concerning the function of GAP43.

formulation of testable hypotheses concerning the function of GAP43.

We have searched for proteins with physical properties and subcellular locations similar to those of GAP43 and report here on primary structure, distribution, and aspects of the expression of one such protein, CAP50, a novel cell membrane and cortical cytoskeleton-associated protein of developing tissues and of neurons in the chick and the rat. Properties shared by CAP50 and GAP43 also included deduced amino acid composition, phosphorylation by protein kinase c, approximate abundancy in the developing nervous system, and characteristic immunofluorescence labeling pattern in neurites and in growth cones. A similar patchy subplasmalemmal labeling pattern was also observed for CAP50 in non-neuronal cells. CAP50 was a ubiquitous protein in E2 chick embryos. Subsequently, the protein and its mRNA became restricted to an increasingly narrow range of tissues and cell types. In the nervous system CAP50 levels displayed marked regional and quantitative variations during development. Overall, CAP50 levels were highest and most persistent in the nervous system, where the protein was not restricted to neurons. CAP50 and GAP43 might belong to a class of extremely hydrophilic small components of the subplasmalemmal domain, whose presence is linked to specialized cellular functions.

PIEZOELECTRIC POLYMER SUBSTRATES ENHANCE MOUSE NEUROBLASTOMA NEURITE OUTGROWTH IN VITRO. R.F. Valentini, R. Bellamkonda*, E.G. Fine* and P. Aebischer ection for Artificial Organs, Biomaterials and Cellular Technology,

Section for Artificial Organs, Biomaterials and Cellular Technology, Brown University, Providence, RI 02912

Bioelectric fields may play an important role in neuronal development, plasticity and regeneration. Polymer films of polyvinylidene fluoride (PVDF) may be rendered piezoelectric by electrical poling in a high intensity electric field, which permanently aligns molecular dipoles. Displacement of the oriented dipoles by mechanical stress results in a transient charge on the PVDF surface. No external power source or electrodes are required. Mouse neuroblastoma (Nb2a) cells were cultured directly on transparent films of electrically (Nb2a) cells were cultured directly on transparent films of electrically poled (i.e. piezoelectric) or unpoled (i.e. non-piezoelectric) PVDF. Poled and unpoled PVDF feature identical chemical surfaces as ascertained by electron spectroscopy for chemical analysis. Neurite outgrowth and length in serum-containing or serum-free media was assessed at 24, 48, 72 and 96 hr. Poled PVDF film placed in a standard tissue culture incubator showed a voltage output of 3-4 mV at 1200 Hz, the vibrational frequency of the incubator shelf. Unpoled PVDF showed no output. At all time periods and under both media conditions, a significantly greater percentage of Nb2a cells cultured on poled vs. unpoled PVDF films displayed neurite outgrowth. Nb2a cells grown on poled PVDF also extended longer neurites. These results suggest that biologically relevant electrical fields produced by piezoelectric polymers enhance neuronal differentiation and neurite extension. PVDF and related materials may provide novel techniques to evaluate the influence of bioelectrical fields on neuronal development and regeneration.

CHOLECYSTOKININ OCTAPEPTIDE INCREASES THE EXCITATORY EFFECT OF ETHANOL ON NEURONS OF THE VENTRAL TEGMENTAL AREA RECORDED IN VITRO. Mark S. Brodie, Abbott Laboratories, Abbott Park, IL 60064
Cholecystokinin octapeptide (CCK8) is co-localized with dopamine in some neurons

of the ventral tegmental area of Tsai (VTA). Dopamine-containing neurons of the VTA have been implicated in the rewarding properties of drugs of abuse. We have demonstrated in earlier studies that CCK8 potentiates the inhibitory effect of dopamine on VTA firing studied with extracellular recording from putative dopamine-containing neurons in a brain slice preparation (Brodie and Dunwiddie, *Brain Res.* 425:106, 1987). In addition, ethanol has been shown to excite VTA neurons, both *in vivo* (Gessa et al., Brain Res. 348:201, 1985) and in vitro (Brodie, et al., Brain Res. 508:65, 1990). In the present study, the effects of CCK8 on ethanol-induced excitation of putative dopamine neurons of the VTA was examined. Coronal brain slices containing the VTA were prepared from Sprague-Dawley rats (75-150 gm), as previously described. Drugs were applied to the brain slices by addition to the superfusate via calibrated syringe pumps. applied to the prain slices by addition to the superfusate via calibrated syringe pumper. Extracellular recording of single unit activity was performed using glass microelectrodes (6-10 Ma, 0.9% NaCl). Only units conforming to characteristics of putative dopamine neurons were studied; these characteristics included slow firing rate (0.5-5 Hz), and long duration action potential (>2.5 msec). In addition, cells selected for study were iong duration action potential (>2.5 misec). In addition, cells selected for study were excited by ethanol in concentrations from 20 to 160 mMt, this concentration range is behaviorally relevant for rats. Sixty percent of these cells exhibited a CCK8-induced potentiation of ethanol-induced excitation, the mean enhancement of the ethanol response by 10 nM CCK8 was 55% ± 19%. This enhancement seemed to persist in some recordings for more than one hour after cessation of CCK8 infusion. These data indicate that ethanol-induced excitation of dopaminergic VTA neurons is potentiated by CCK8. This long-duration enhancement of the response to ethanol may provide important information about the action of ethanol on VTA neurons, as well as to the role of CCK8 in dopaminergic neurotransmission in the central nervous system

198.3

STRESS RESPONSES IN RAT LINES SELECTED DIFFERENTIAL ETHANOL-INDUCED MOTOR IMPAIRMENT.

E.R. Korpi and K. Tuominen*. Res. Labs, Alko
Ltd., P.O.B. 350, SF-00101 Helsinki, Finland.

Alcohol non-tolerant (ANT) and alcohol-tolerant (AT) rats, developed by selective outbreeding for high and low sensitivity to ethanol-induced motor impairment on the tilting plane test, were measured for ethanol sensitivity with the tilting plane (2 g/kg IP) and sleep time with the tilting plane (2 g/kg IP) and sleep time (3.5 g/kg IP) tests and for non-intoxicated behavior in the plus-maze test. The lines differed on each of these tests. Daily handling of half of the animals for 2 weeks prior to testing had no significant effects in either rat line. Following the behavioral tests, the rats were decapitated after a 10-min swim at 25 °C. This stress increased the adrenal dopamine concentration and the hypothalamic MHPG/norepinephrine ratio more in the AT than ANT rats. Plasma and adrenal corticosterone was also higher in the stressed AT than ANT rats.

The results indicate that the AT rats have

more intense stress reactions without ethanol than the ANT rats, which may at least partly account for their apparent insensitivity to difference This appears occur irrespective of any handling habituation.

ETHANOL-INDUCED CHANGES IN NEURONAL FUNCTION AND NOREPINEPHRINE SYNAPTIC OVERFLOW IN LOCUS COERULEUS GRAFTS IN OCULO: IN VIVO ELECTROCHEMISTRY AND ELECTROPHYSIOLOGY. M.R. Palmer¹, A.-Ch. Granholm³ and G.A. Gerhard¹¹². Depts. of Pharmacology¹ and Psychiatry², Univ. of Colorado Health Sciences Center, Denver, CO 80262 and Dept. of Cell Biology³, Univ. of Linköping,

In the present study, fetal Sprague-Dawley locus coeruleus (LC) brain grafts were transplanted into the anterior eye chamber of adult host rats and allowed to mature 4 - 8 months. High-speed in vivo electrochemical measurements were used in urchane-anesthetized rats to characterize the ethanol-induced alterations of potassium-evoked synaptic overflow from norepinephrine (NE)-containing cells in these brain grafts in oculo. Ethanol, when superfused over LC grafts consistently attenuated potassium-evoked synaptic overflow of NE at doses between 3 - 10 mM. attenuated potassium-evoked synaptic overflow of NE at doses between 3 - 10 mM. Furthermore, in preliminary experiments, these responses appeared to be augmented by 30 mM ethanol. Electrophysiologically, the neuronal firing rates in LC grafts were depressed by the superfusion of 1 - 30 mM ethanol. Ethanol, when superfused over sequential co-grafts of LC with either hippocampus or cerebellum caused excitations of hippocampal and cerebellar neuronal activity at doses between 1-10 mM. These ethanol-induced excitations in the double grafts could be prevented by depressing the activity of LC graft neurons before and during ethanol exposure with a co-superfusion of 0.5 - 1.0 µM clonidine. Clonidine caused similar excitations of neuronal activity, but was ineffective in single grafts of either hippocampus or cerebellum. Thus, the ethanol-induced excitations in the hippocampal and cerebellar co-grafts appear to be disinhibitions mediated by a reduction in the release of NE from LC nerve terminals in the target grafts caused by ethanol-induced depressions of the LC neurons. REGIONAL CHANGES IN FUNCTIONAL BRAIN ACTIVITY WITH ETHANOL STIMULANT AND DEPRESSANT EFFECTS. M.J.Lewis,L.B.Perry,H.L. June,M.L.Garnett*and L.J.Porrino*. Howard Univ.,Washington, DC 20059 and *NINDS, NIH, MD 20892.

Increases in open field activity and enhanced brain stim-

ulation reward have been found within the first 30 min after intraperitoneal(IP) injection of low doses of ethanol (E). These effects occur during ascending concentrations of the blood alcohol curve(BAC), but not during the descending portion. To determine the brain systems involved in these effects, the quantitative $2-[1^4C]$ -deoxyglucose(2-DG) method was used to map the distribution of changes in local rates of cerebral glucose that accompany E administration. Rats were injected with E(0.50g/kg,IP) and then tested in an open field 0-10 or 30-40 min after administration. For measurement of functional brain activity, rats were implanted with arterial and venous catheters on the day of experimentation and injected with 2-DG 10 or 40 min after E. Activation was found 0-10 min and depression or no effect was found at 30-40 min after E injection. Quantitative autoradiography showed increases in functional activity at both 10 and 40 min in the nuc acc, sub nigra, b-1 amyg and caud-put. Increased functional activity in the olfactory tubercle(OT), however, occurred only at 10 min(ascending BAC). This selectivity suggests that the OT may play a significant role in the activation and reward properties of E.

ELEVATED PLASMA ANGIOTENSIN II: AN EARLY MANIFESTATION OF CHRONIC ALCOHOL INTAKE. KB Brosnihan, GB Collins*, JL Joyce*, RA Zuti*. Departments of Brain and Vascular Research and Psychiatry. Cleveland Clinic Foundation, Cleveland, OH 44195.

Recent studies have suggested relationships among alcohol intake, the renin-angiotensin system (RAS), and hypertension. We have developed a chronic alcoholic animal model to examine blood pressure and plasma and cerebrospinal fluid (CSF) levels of RAS, pressure and plasma and cereorospinal find (CSr) levels of RAS, vasopressin (AVP), and catecholamines. Conscious, trained dogs (n = 9) were given ethanol (4 g/kg/day, 50% v/v) or saline (n = 5) intragastrically for 4 weeks. Plasma Ang II increased from baseline (21.1 \pm 9.7 vs 7.1 \pm 1.5 pg/ml, p = 0.05) and PRA tended to increase after one week of ethanol intake. Both plasma Ang II and PRA were significantly correlated with plasma ethanol (p < 0.0001) over the treatment period. In contrast, CSF Ang II did not change and was not correlated with ethanol. Likewise, no significant changes in blood pressure, plasma aldosterone, or CSF and plasma catecholamines were found. A significant reduction in plasma AVP was only observed after 4 weeks of treatment. In summary, our study suggests that plasma Ang II may be an early manifestation of alcoholism. In addition, we have demonstrated for the first time that elevations in plasma Ang II are not mirrored in CSF under conditions of chronic ethanol intake. MECHANISM FOR INDUCTION OF ALCOHOLISM: A NEW HYPOTHESIS. <u>B. A. McMillen and R. D. Myers</u>, Dept. of Pharmacol., Sch. of Medicine, East Carolina Univ., Greenville, NC 27858.

Formation of alkaloidal products from aldehyde condensation reactions occurs in mammalian brain. Injections of ng amounts of tetrahydropapaveroline (THP) or related or ng amounts or tetranydropapaveroline (inr) or related alkaloids i.c.v. or into specific brain areas enhance alcohol (EtOH) preference in rats. Increased EtOH consumption persists long after the injections, which suggests a permanent change in neural function. Radio-ligand assays were used to determine THP affinity for several process. eral transmitter receptor sites. THP had uM affinity for alpha, beta, Dl, D2 and sigma receptors and no affinity for 5HTla or 5HT2 receptors. It is hypothesized that taste and other aversive aspects of EtOH limit daily intake by normal rats to 1.0 gm/kg/day or less. THP injections produce a stimulus that is not perceived at this low level of drinking, 'primes' the animal to recognize the reward component of EtOH and causes increased consumption of EtOH in order to maintain a desired reinforcing level of formation of THP and related compounds. In an EtOH preferring individual, either increased formation of rewarding alkaloids or decreased aversion to EtOH will result in increased EtOH consumption. Thus, the decreas-ed level of 5HT function in the P line of rats and Type II alcoholics may result in less aversion to EtOH and re-(DA 04895 and AA 04200) lease EtOH drinking.

CLASSICAL GENETIC ANALYSES OF SENSITIVITIES TO ALCOHOL AND NICOTINE IN CROSSES DERIVED FROM LONG-SLEEP AND SHORT-SLEEP MICE. C. M. de Fiebre and A. C. Collins. Institute for Behavioral Genetics, Univ. of Colorado, Boulder, CO 80309.

Alcohol and nicotine, two of the most commonly used drugs by humans, are often used simultaneously. In an attempt to ascertain whether common genes regulate responsiveness to these two drugs, sensitivities to these compounds were assessed in mice derived from a classical (Mendelian) cross of the long-sleep (LS) and short-sleep (SS) mouse lines which were selectively bred for differential "sleep-time" following ethanol. Analysis of the isogenic generations (LS, SS, Fl) and segregating generations (F2, F1XLS, F1XSS) revealed that the inheritance of sensitivities to both of these drugs is primarily additive; however, evidence of epistatic interaction was also found. While the segregation patterns for these two drugs were similar, they were not identical. The segregation patterns for sensitivity to nicotine-induced hypothermia and nicotine-induced seizures more closely resembled the segregation pattern for ethanol "sleep-time" than the other nicotine tests. Previous evidence has indicated that these two nicotine responses may be regulated by the sites which bind (3H)nicotine and α-(1251)bungarotoxin, respectively. These data are consistent with the hypothesis that these two drugs may be regulated, in part, by common genesic control, these two drugs may act, in part, on nicotinic cholinergic systems. cholinergic systems.

MODIFICATIONS REHAVIORAL INDUCED CHRONIC RY ADMINISTRATION OF ETHANOL IN RATS. F.Drago, A.A. Genazzani, G.M.Fontana, F. Spadaro and M.Grassi . Institute of Pharmacology, University of Catania Medical G.M.Fontana, F.

Chronic administration of ethanol induces changes in social and motor behavior. We studied the possibility that different doses of ethanol exert opposite effects on the behavior of male rats. Ethanol (0.01, 0.25, 6.25 ml/kg/die) was dissolved in the drinking water and made available ad libitum. Control animals received tip water with the same procedure. The total volume of the solution drunk daily was recorded up to 56 days. Results showed that higher doses of ethanol induced the development of tolerance increasing significantly the consumption after That remained elevated for 35 Interestingly, animals administered with 0.01 ml/kg of ethanol did not develop any tolerance and they showed a decrease in drinking compared to controls. Animals tested in the hot plate showed that chronic administration of ethanol reduced pain sensitivity and the effect was dose-dependent. Chronic administration of ethanol was also followed by an increase in locomotor activity.

ALZHEIMER'S DISEASE: NEUROPATHOLOGY I

199.1

DISTRIBUTION OF NEUROFIBRILLARY TANGLES AND NEURITIC PLAQUES IN THE CEREBRAL CORTEX IN ALZHEIMER'S DISEASE. S.E. Arnold*, J.E. Flory*, B.T. Hyman, A.R. Damasio and G.W. Van Hoesen. Depts. of Neurology and Anatomy, Univ. of Iowa, Iowa City, IA 52242.

The distribution of neurofibrillary tangles (NFTs) and neuritic plaques (NPs) was mapped in 35 cortical areas in 11 cases with dementia and Alzheimer's disease. Whole hemisphere blocks were embedded in polyethylene glycol, sectioned coronally and stained with thioflavin S and thionin. Some were immunolabeled with Alz-50. The density of NFTs and NPs was assessed using a semi-quantitative scale for each of 577 observations. Analysis of variance yielded highly significant differences between types of cortex for quantitative scale for each of 577 observations. Analysis of variance yielded highly significant differences between types of cortex for NFT densities (F=44.959, p<.0001). Limbic periallocortex (area 28) was the most densely invested with NFTs, significantly more than any other type of cortex. It was also the most invariantly affected cortical area analyzed. Descending order of density of NFTs was: limbic periallocortex > limbic proisocortex (areas 11, 12, 24, 23, anterior insula, 38, 35) > nonprimary association cortex (areas 32, 46, superior temporal sulcus, 40, 39, posterior parahippocampal cortex, 37, 36) > primary association cortex (areas 7, 18, 19, 22, 21, 20) > agranular cortex (areas 44, 45, 8, 6, 4) > primary sensory cortex (areas 41, 42, 3, 1, 2, 17). NPs were distributed more homogeneously throughout the cortex. There were no differences in the densities of NPs between types of cortex with the exception of limbic periallocortex (area 28) which had significantly fewer NPs than any other cortical area. No significant left-right differences were found. (Supported by: AG 08487, NS 14944, PO NS 19632.)

LESIONS OF ANTERIOR THALAMUS IN ALZHEIMER'S H.Braak and E.Braak. Dept. Anatomy, ne University, 6000 Frankfurt 70, J.W. Goethe University, Fed. Rep. Germany.

Sensitive silver methods for amyloid and neurofibrillary changes were employed to examine the pathological changes of the anterior thalamus in Alzheimer`s disease. Large numbers of amyloid deposits occurred in the antero-ventral, antero-medial and antero-dorsal nucleus while portions of the nuclear grays situated close to the ventricular surface were virtually devoid of amyloid. Neurofibrillary changes were found in all nuclei of the anterior complex. The antero-dorsal the anterior complex. nucleus showed the most severe affection with very large numbers of neurofibrillary tangles and neuropil threads. Many ghost tangles were present reflecting a considerable loss of nerve cells. It is concluded that the circumscribed and thoroughgoing changes revealed by the limbic thalamic nuclei hamper the trans-port of information from the hippocampal forport of information from the hippocampai formation to the cingulate cortex, in particular to the retrosplenial region. Such impairments of the Papez circuit may contribute to the development of dementia (Supported by the Deutsche Forschungsgemeinschaft)

A QUANTITATIVE COMPARISON OF ALZHEIMER NEUROPATHOLOGY AS DETECTED BY A128. ALZ-50. TAU-1 AND TAU-2 IMMUNOLABELLING AND BIELSCHOWSKI SILVER STAINING TECHNIQUES. M-C. de Lacoste, D.R. Sparkman, K.S. Pollan*, C.L. White III*, Depts. Cell Biology and Neuroscience and Pathology, U.T. Southwestern Med. Sch., Dallas, TX 75235

The aim of this study was to obtain comparative quantitative data on the

relative reliability of various histological techniques for identifying neuritic plaques (NP), neurofibrillary tangles (NFT) and dystrophic neurites (DN) in cases with neuropathologically confirmed Alzheimer disease (AD).

Formalin-fixed tissue blocks of the hippocampal formation were sectioned

at 50 µm on a freezing microtome. NP, NFT, and DN were immunolabelled in a series of adjacent sections using the avidin-biotin immunoperoxidase method and four different antisera including the polyclonal A128 antibody to paired helical filaments, monoclonal TAU antibodies TAU-1 and TAU-2, and the ALZ-50 monoclonal antibody. Sections in the same series were processed with a modified Bielschowski silver stain. CARP software (Computer Assisted Reconstruction Package) was utilized for semiautomated counts of NP, NFT

and DN in a representative series of sections.

The results suggest that there is significant variation in the total counts of NP, NFT and DN depending on the labelling technique. Quantitative studies of AD-related neuropathology should take into account the variation in the sensitivity of available techniques.

ALZ-50 antiserum was kindly provided by Dr. P. Davies. TAU-1 and TAU-2 antibodies were a gift from Dr. L.I. Binder. Supported by UT ADRC NIH-Ag-08013 (MCL, DRS, CLW) and NIH-HD21711 (MCL).

NASAL EPITHELIUM IN AGED RHESUS MONKEYS DOES NOT SHOW FEATURES OF HUMAN ALZHEIMER'S DISEASE. B.R. Talamo, W.H. Feng., L. Cork. and J.S. Kauer. Tufts Medical School, Boston, MA 02111; Johns Hopkins Med. School, Baltimore, MD 21205.

Nasal epithelium taken at autopsy from 13 rhesus monkeys ranging in age from 8 to 30 years was immunohistochemically examined for cytoskeletal components that have been seen in olfactory epithelium of Alzheimer's (AD) patients. Monkeys older than 20 years were mildly impaired behaviorally. All monkeys had extensive areas of sensory olfactory epithelium with MAP 5 (Sigma; D. Asai) immunoreactivity (ir). Receptor cells also showed variable OMP-ir but no neurofilament-ir. Similar to human tissue, monkey sensory epithelium was patchy, interspersed with non-sensory regions. Some areas of the epithelium were invaginated into sac-like structures which contained variable numbers of sensory cells. Occasionally neurons were tau-ir (tau 14, V. Lee); staining in olfactory axon bundles was bright, but heterogeneous, suggesting that only a subset of neurons reacted with this antibody. Unlike human and rat, there were abundant fine beaded fibers in non-sensory epithelium and in the lamina propria. These fibers were MAP5-ir, and sometimes tau-ir, but did not stain for neurofilaments, including peripherin. Other smooth, thick fibers that were ir for neurofilament protein and/or peripherin paralleled the basement membrane and occasionally projected into the epithelium, primarily in non-sensory areas, but these did not resemble the masses of neurites seen in AD cases. These findings suggest that the neuritic accumulation in olfactory epithelium of AD patients (Talamo et al, Nature 337:736,1989) is not a normal concommitant of aging in non-human primates. (Supported by the Pew Charitable Trusts and ADRDA grant IIRG-89-041).

DENDRITIC NEURITES ARE HISTOCHEMICALLY AND
MORPHOLOGICALLY DISTINCT FROM AXONAL NEURITES IN
ALZHEIMER'S DISEASE. A.C. McKee. K.S. Kosik. and N.W. Kowall. Dept.
of Neuropathology & Neurology, Harvard Medical School, Boston, MA 02114
The origin of tau immunoreactive (timr) argyrophilic neurites in Alzheimer's
disease (AD) is not known. Using monoclonal antibodies against tyrosylated &
acetylated tubulin, tau, AL 25 0, MAP2, phosphorylated (SMI 31) & nonphosphorylated neurofilament (SMI 32), we compared the hippocampal
distribution of these axonal & dendritic markers in normal elderly and AD
natients In AD, granular & spindle shaped Alz 50 imr dystroptic neurites (DN) distribution of these axonal & dendritic markers in normal elderly and AD patients. In AD, granular & spindle shaped Alz 50 imr dystrophic neurites (DN) were found in the white matter, outer dentate molecular layer, & molecular layer & stratum oriens of Ammons horn. Similar Alz 50 imr DN were found in senile plaques (SP). Tau imr DN were filiform fibers often with spike-like projections. This type of neurite was infrequently Alz 50 imr. Their density paralleled that of Alz 50 in Ammon's horn, but they were rare in the dentate molecular layer. Tau imr DN of SPs were both filiform & spheroidal. The axon specific antibody SMI 31 largely retained its axonal location in AD. Numerous spheroids with axonal tails were found in the white matter & within SPs. Small granular DN, similar to those found with Alz 50 were seen in the white matter & stratum oriens. The distribution of tau imr DN in the molecular layer of Ammon's horn. oriens. The distribution of tau imr DN in the molecular layer of Ammon's horn was co-extensive with a dense network of tyrosylated tubulin imr distal dendritic was co-extensive with a dense network of tyrosylated tubulin imr distal dendritic branches. This same pleasus was imr for the dendritic specific markers, MAP2 & SMI 32. In contrast, acetylated tubulin imr was confined to proximal axons & dendrites. DN were not imr for MAP2, SMI 32, or the tubulins. We show that DN are both axonal & dendritic in origin. Tau antibodies preferentially demonstrate dendritic DN, whereas AIz 50 & SMI 31 DN are largely axonal. Axonal DN have a typical spheroidal & spindled shape; dendritic DN arise in association with unstable forms of tubulin & are filiform. AIz 50, a marker of early neuronal degeneration in AD, clearly demonstrates axonal pathology which may suggest that the initial focus of injury in AD is the axon. may suggest that the initial focus of injury in AD is the axon.

199.4

OLFACTORY BULB PATHOLOGY IN ALZHEIMER DISEASE. R.G. Struble and H.B. Clark. Depts of Psychiatry, Pathology and Laboratory Medicine. Southern Illinois University School of Medicine and Memorial Medical Center, Springfield IL 62704

Deficits in olfactory function are an early abnormality in Alzheimer disease (AD). However, several previous reports have not found the hallmarks of AD, senile plaques and neurofibrillary tangles, in the main olfactory bulb (MOB) suggesting that the MOB is relatively free of We have confirmed the general absence of NFT and SP but, in addition, we find marked loss of mitral and tufted neurons in the MOB from AD cases. Further, there is a spectrum of abnormalities of glomeruli. In some cases there is a severe depletion of glomeruli. In other cases there is an apparent 'hypertrophy' of glomeruli, associated with glomerular invasion of the external plexiform layer. These observations suggest that an early manifestation of AD is the loss of mitral and tufted neurons followed by aberrant regrowth of olfactory nerve. These observations also suggest that the loss of mitral and tufted neurons may underlie the olfactory deficit characteristic of AD.

CONTINUOUS CULTURE OF HUMAN OLFACTORY EPITHELIAL NEUROBLASTS. B.L. Wolozin, T. Sunderland*, B. Zheng*, I. Resau*, R.D. Swerdlow* and H.G. Coon* Lab. of Clinical Science, NIMH and Lab. of Genetics, NCI, Bethesda, MD 20892

The primary sensory neurons of the olfactory epithelium are the

only neurons in mammals that have been shown to maintain the capability to regenerate throughout life. Recent reports show that neuroblasts can be grown in culture from explants of neonatal rat olfactory epithelium (Coon et al, PNAS 86:1703-7, 1989). Using similar methods, we have been able to generate cell lines of neuroblasts from explants of adult human olfactory epithelium taken at autopsy. The cells have a robust odorant response, yielding a doubling of basal cAMP in response to odorant challenges in a dose dependent fashion. Using Western blot and immunohistochemical methods, the cells have been shown to exhibit many of the antigens methods, the cells have been shown to exhibit hany of the antigens of olfactory neurons in vivo, including: neuron specific enolase, tau protein, MAP 2, 68 and 200 KD neurofilaments, neuron specific calcium binding protein, olfactory marker protein and calcitonin gene related peptide. When allowed to grow in a collagen-laminin gel, many of the cells appear to develop into mature olfactory neurons exhibiting short dendrites with apical olfactory vesicles having cilia and basal axons. We are currently growing cells from two individuals who died from Alzheimer's disease and plan to study these cells to determine if any disease related pathophysiology exists. The ability to create cell lines of differentiating neuroblasts from individuals with neuropsychiatric disorders may prove to be very useful in the study of these illnesses.

LAMININ IMMUNOREACTIVITY IS INCREASED IN ALZHEIMER DISEASE HIPPOCAMPUS. N.W. Kowall and A.C. McKee. Dept. of Neurology and Pathology, Mass. General Hospital, Boston MA 02114.

Laminin, a major glycoprotein component of the basal lamina, is a potent promoter of neurite outgrowth and the principal factor produced by cells promoting neurite extension in culture. It allows nerve growth factor (NGF)-dependent cell lines to survive temporarily without NGF and plays a role in regeneration following injury. Laminin was initially thought to be confined to the basement membranes of blood vessels in the central nervous system (CNS). Subsequent studies showed laminin immunoreactivity in non-neuronal cells in the CNS studies showed laminin immunoreactivity in non-neuronal cells in the CNS. Recently, laminin mRNA has been localized to neurons in rodent brain and laminin immunoreactive neurons have been found in several forebrain structures of the human brain, including the hippocampus. We used 2 monoclonal anti laminin antibodies to study the distribution of laminin immunoreactivity in normal elderly and Alzheimer's disease (AD) brain. One antibody (MAB 1975, Chemicon) was raised against murine laminin and recognizes a conformational epitope on the B1 and B2 heterodimer and P1 fragment of laminin. This antibody does not inhibit laminin mediated adhesion. The second antibody (LAM-1, ICN) stains basement membranes and smooth muscle in a wide variety of organs in both mouse and human. MAB 1975 stained the basement membrane surrounding blood vessels in both control and AD hippocampus. No cellular or other localized immunoreactivity was visible. Perivascular staining with LAM-1 was present, although weaker, in all cases. In control brains scattered pyramidal neurons and occasional astrocytes were weakly immunoreactive with LAM-1. In AD, and occasional succycles were wearly immunopositive in the CA fields and subiculum. Astrocytes were more frequently immunopositive in the CA fields and subiculum. Astrocytes were occasionally seen. Senile plaque cores were often laminin immunoreactive. Increased expression of laminin or laminin-like peptides in AD may play a primary role in neuritic proliferation in the neuropil and around senile plaques. Alternatively laminin synthesis may be increased in response to neuronal injury and degeneration in AD.

ACETYLCHOLINESTERASE, BUTYRYLCHOLINESTERASE AND NON-SPECIFIC ESTERASE OF CEREBRAL CORTEX AND MICROVESSELS IN ALEMENTS DISEASE. R. N. Kalaria and I. G. Grahovac*. Departments of Neurology and Neuroscience, Case Western Reserve University, Cleveland, OH 44106, USA
Previous investigators have shown the consistent presence of acetylcholinesterase (AChE) and butyryl-

Previous investigators have shown the consistent presence of acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) in amyloidotic lesions of Alzheimer's disease (AD). We similarly used histochemical methods to confirm AChE and BChE activities in amyloid deposits and vessels in tissue sections of necoortex and hippocampus from subjects with AD and other related disorders. We also stained for non-specific esterase (NSE) for comparison. Like AChE and BChE, NSE activity was evident in plaques.

It has been suggested by others and us that ACHE and BCHE bind to the heparan sulphate proteoglycan-type of molecules (HSPG) described to be present in these lesions and in cerebral vessels. Thus, we investigated the activities and inhibitory properties of these enzymes in cerebral microvessels (CMV) and plaque fractions isolated from AD subjects. Activities of both ACHE and BCHE were significantly decreased in CMV from AD subjects compared to age-matched controls. The inhibition of ACHE and BCHE by diisopropylflourophosphate and other specific inhibitors was markedly reduced in AD whereas EDTA and other antiproteases had no apparent effect. Our results imply that co-localization of CHES with HSPG-type of molecules may affect their inherent properties. Supported by the ADEDA.

MEASUREMENT OF ALZHEIMER'S DISEASE ASSOCIATED PROTEIN (ADAP) WITH A SANDWICH ENZYME IMMUNOASSAY INCORPORATING ALZ-50. Ga Bissette W. Smith, K. Dole, H. Ghanbari, B. Miller, B. Crain and C.B. Nemeroff! Depts. of Psychiatry and Pathology, Duke Univ. Med. Ctr., Durham, NC and Abbott Labs., North Chicago, IL.

Using a 2 antisera sandwich enzyme-linked immunoassay for Alzheimer's disease (AD) associated protein (ADAP) that employes the Alz-50 antibody but excludes such non-Alzheimer specific antigens such as tau or microtubule-associated protein, we measured ADAP concentrations in micro-punched post-mortem samples of frozen temporal and frontal cortex from 91 cases of histologically confirmed AD compared to 27 non-AD controls with and without a clinical history of dementia. Both temporal and frontal cortex samples from AD patients were significantly higher in ADAP concentration than the non-AD controls. Only 10 of the 91 AD patients had ADAP concentrations below the mean control concentration in both temporal and frontal cortex. ADAP concentration correlated with numbers of both plaques and tangles. Several of the non-AD controls had high levels of ADAP that were shown to represent authentic ADAP antigen by Western blot analysis. This assay has the potential as an adjunct in early diagnosis in biopsy samples and, perhaps with refinement of the assay, in cerebrospinal fluid. (Supported by NIMH MH-40524 and NIA AG-05128.)

199.10

ANTIBODY IN THE CEREBROSPINAL FLUID OF ALZHEIMER'S DISEASE PATIENTS RECOGNIZES AMOEBOID MICROGLIAL CELLS: ANOTHER LINK TO IMMUNOLOGICAL INVOLVEMENT IN THIS NEURODEGENE-RATIVE DISEASE. A. Dahlström¹, E.A. Ling*², R. Polinsky*³, A. Wigander*¹, K. Lundmark.*¹ and A. McRae¹. University of Göteborg, Dept. of Histology, PO 33031, S-400 33 Göteborg Sweden¹, National University of Singapore, Dept of Anatomy ², NINDS Bethesda, MD, USA³

Previous investigations showing the presence of antibodies in cerebrospinal fluid (CSF) from Alzheimer's disease (AD) patients support a pathogenetic role for immunological abberations in this disorder. Paraformaldehyde (PF) fixed 2 weeks old cultures, prepared from dissociated cells from the medial septum of 18 day (E18) fetal rats, were incubated with CSF from 12 AD patients and 22 non-demented healthy controls. The cultures were processed for immunocytochemical observations with the avidin-biotin complex method. Only AD-CSF recognized neuronal like cells and microglia in culture. The study was extended to developing central nervous system (CNS) by using rats ranging in age from E18 through postnatal day 5. After PF fixation frozen brain sections (20µm) were incubated with CSF samples. The AD-CSF antibody recognized diverse morphological forms of amoeboid microglial cells, located mainly in the cavum septum pellucidum and corpus callosum. Electron microscopy revealed that the AD-CSF antibody recognizes specific membrane receptors in the macrophagic microglia. The unexpected recognition of amoeboid microglia by AD-CSF is particularly significant since these cells proliferate in response to nervous system disease and also engulf debris. These results add further support to the concept that inflammation and similar immune mechanisms may contribute to AD pathogenesis.

199.12

NON-HEME IRON IS INCREASED AND ASCORBATE-STIMULATED LIPID PEROXIDATION IS REDUCED IN POSTMORTEM PREFRONTAL CORTEX IN ALZHEIMER'S DISEASE (AD): A COMPARISON OF FINDINGS IN AD AND NORMAL AGE MATCHED CONTROLS. A.C. Andorn, R.S. Britton*, B.R. Bacon*, M. Franko*, N. Hamazaki* and R.N. Kalaria. Depts. of Psychiatry, Pharmacology and Medicine, LSU Med. Cntr., Shreveport, LA, 71130 and Dept. of Neurology, Case Western Reserve Univ., Cleveland, Ohio 44106.

Some etiologic theories about AD have been based on the hypothesis that lipid peroxidation (LP) occurs to a greater extent in AD brain in vivo than in normal controls. If a difference in LP does occur between AD and age-matched controls, such a difference could be due to differences in the concentrations of total iron, antioxidants, or oxygen radical scavenging enzymes. In the studies reported here, we determined ascorbate-stimulated (0.1 mM) LP and non-heme iron in particulate membrane fragments from AD (diagnosed by NIH consensus criteria), and normal age-matched controls. The membrane preparations and ascorbate-stimulated LP (measured by malondialdehyde [MDA]) were done as previously described (Andorn, et al., Mol. Pharmacol., 33:155, 1988). Total non-heme iron was determined by spectrophotometric assay. A total of 16 AD brains and 8 age-matched controls were used (both studies were not done on all brains).

BRAIN TYPE	MDA (nmoles/mg)	Fe (μg/mg)
ALZHEIMER'S	11.3 ± 2.3*	0.43 ± 0.11**
CONTROL	20.8 ± 6.1	0.31 ± 0.11

Values are mean: S.D. per mg protein. Significantly different as determined by Student's t-test at p = 0.01 (*) and p = 0.027 (**). The differences in LP in AD could be due to changes in lipid composition, antioxidant balance and/or increased ante-mortem LP.

EXCITATORY AMINO ACIDS: PHARMACOLOGY II

BEHAVIOURAL PROPERTIES OF ANTAGONISTS ACTING AT THE GLYCINE MODULATORY SITE ON THE NMDA RECEPTOR/ION CHANNEL COMPLEX. M.D. Tricklebank and K. Saywell. Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex CM20 2QR, U.K.

Non-competitive NMDA receptor antagonists are anticonvulsant and induce in rodents a motor syndrome of head weaving and ataxia. We have examined the behavioural effects of antagonists acting via the glycine modulatory site on the NMDA receptor, viz: 5,7-dichlorokynurenic acid (5,7-DCK), (+)-HA-966 and D-cycloserine (D-CS). The results in units of µmol/mouse, icv, are summarised in the table.

	Audiogenic	Electrogenic	Rotarod	Head
	seizures (ED50)	seizures (ED50)	(MED)	weaving (MED)
5,7-DCK	0.01	0.05	0.04	0.01
(+)-HA-966	0.01	1.00	0.90	0.90
D-CS	0.20	>2.90	>2.90	1.00

All compounds antagonised seizures induced by sound in DBA/2 mice, but D-CS was inactive against electroshock in Swiss Webster mice. Ataxia (measured by rotarod performance in Swiss Webster mice) was induced by 5,7-DCK and (+)-HA-966 at doses similar to those protecting against electroshock. D-CS did not induce ataxia at the doses tested. All compounds induced head weaving, but the peak intensity of the response was never more than 12% of that seen with the non-competitive NMDA receptor antagonist, MK-801 (0.03 µmol/mouse). Thus, glycine receptor antagonists are anticonvulsant, but differ from NMDA ion channel blockers by their reduced propensity to induce head weaving. The greater separation between ataxic and audiogenic anticonvulsant doses of (+)-HA-966 and D-CS may reflect their partial agonist properties.

SPERMIDINE REVERSES ARCAINE'S INHIBITION OF NMDA-INDUCED HIPPOCAMPAL [³H]NE RELEASE. A. I. Sacaan and K. M. Johnson. Department of Pharmacology, Univ. of Texas Med. Br., Galveston, TX 77550.

Arcaine, a putative polyamine antagonist (Reynolds, 1990) completely inhibited

[3 H]NE released from hippocampal slices in the presence of 1 00 μ M NMDA. The IC $_{50}$ value was 1 02 μ M, a value about 10-fold higher than its K $_{\rm B}$ calculated from binding studies (see Johnson and Sacaan, this meeting). Arcaine's inhibition was noncompetitive with respect to NMDA. Arcaine (100 µM) had no effect on release induced by either 300 μ M kainic acid or 15 mM K⁺, suggesting specificity for the NMDA receptor ionophore complex. To address the question of whether arcaine's inhibition was mediated through the polyamine site, we unsuccessfully tried to reverse the effect of 30 µM arcaine with 1mM spermidine. When the release experiments were conducted in buffer containing 5% DMSO spermidine had no effect alone at either 1 or 3mM, but was able to completely reverse the inhibitory effect of 100 µM arcaine in a concentration-dependent manner. We speculate that DMSO increased membrane permeability, thus allowing spermidine access to its putative intracellular site, resulting in reversal of arcaine's inhibition. Why arcaine was equipotent in physiologic and DMSO containing buffer is unknown. Interestingly, putrescine (a noncompetitive antagonist of spermidine-induced [3H]TCP binding) also inhibited NMDAinduced [3H]NE release in DMSO containing buffer. Unexpectedly, this inhibition was also reversible by spermidine, perhaps suggesting a metabolic conversion of putrescine to a competitive inhibitor. Supporting this possibility is the observation that putrescine can be metabolized in invertebrates to arcaine by two successive transamidination reactions (Robin et al., 1967). These data suggest that polyamines play an important, perhaps obligatory role in the function of the NMDA receptor ionophore complex. Supported by DA-02073.

THE STIMULATORY, BUT NOT INHIBITORY, EFFECTS OF SPERMIDINE AND MAGNESIUM ON 13HITCP BINDING TO THE NMDA IONOPHORE ARE MEDIATED BY THE SAME SITE. K. M. Johnson and A. I. Sacaan

Department of Pharmacology, Univ. of Texas Med. Br., Galveston, TX 77550.

Spermidine and magnesium stimulate the binding of [³H]TCP to well washed buffy coat (BC) membranes with EC₅₀ values of about 25 and 250 µM, respectively. The maximal effect after 2 hrs incubation is about 10-fold for spermidine and 5-fold for magnesium. At higher concentrations, the dose effect curve turns downward, bringing binding back to control with IC 50 values of 13 and 9mM, respectively. Arcaine (30 μ M) produced a four-fold, parallel, rightward shift in the concentration-response curve for both spermidine and magnesium, confirming that arcaine is a competitive spermidine antagonist (Reynolds, 1990) and suggesting that magnesium is a partial agonist at this site. This was confirmed by redetermining the spermidine concentration-response in the presence of $MgCl_2$. Magnesium (0.1mM) had little effect while 3mM completely blocked the stimulatory effect of spermidine. The inhibitory effects conspirely shock the samulatory letter to springer the springer of spermidine and MgCl₂ were studied in the presence and absence of different activators. MgCl₂ right shifted the IC₅₀ value for spermidine from 13 to 27mM, while spermidine left shifted the IC₅₀ value for MgCl₂ from 8 to 2.5mM, implying distinct inhibitory sites. This distinction was further amplified by 10μ M glutamate which left shifted the IC₅₀ value for MgCl₂ 2-fold, but shifted that for spermidine 13-fold and reduced its maximal inhibition by about 50%. that for spermidine 13-fold and reduced its maximal inhibition by about 50%. We speculate that the spermidine site is distinct, but overlaps that for M_2^{*2} and that glutamate induces a conformational change in the NMDA ionophore that uncouples the spermidine site from the inhibitory M_2^{*2} site. On the other hand spermidine and M_2^{*2} stimulate [3 H]TCP binding via activation of the same site, which is distinct from the lability of the specific of the same site. same site, which is distinct from the inhibitory site. Supported by DA-02073.

NMDA-, QUISQUALATE- AND KAINATE-DEPENDENT INCREASES IN CEREBELLAR cGMP IN VIVO; MEDIATION BY NITRIC OXIDE. P.L. Wood. Department of Biological Research, Hoechst-Roussel Pharmaceuticals Inc., Somerville, NJ 08876.

The excitatory amino acid agonists N-methyl-D-aspartate (NMDA), quisqualate and kainate all dose-dependently increased mouse cerebellar cGMP after direct intracerebellar injection, in vivo. These actions were time dependent, with NMDA-dependent responses being selectively antagonized by the noncompetitive NMDA antagonist, dizocilipine and the competitive antagonist of the NMDA-associated glycine site, 1-hydroxy-3-aminopyrrolidone-2 (HA-966). Quisqualate responses were blocked by the nonselective antagonist, 6,7-dinitroquinoxaline-2,3-dione (DNQX).

To examine possible mediation of these excitatory amino acid responses by nithe oxide, an inhibitor of nitric oxide synthase, Nmonomethyl-L-arginine, was used. This enzyme inhibitor was found to antagonize the responses of all 3 receptor agonists; with this inhibition being reversed by coadministration of a molar excess of the competitive enzyme substrate, L-arginine. These data are all consistent with modulation of cerebellar cGMP by all 3 major excitatory amino acid receptor subtypes and mediation of these responses by the intercellular messenger molecule, nitric oxide.

GABAB RECEPTOR-MEDIATED INHIBITION OF THE NMDA COMPONENT OF SYNAPTIC TRANSMISSION. R.A.Morrisett, D.D.Mott, H.S.Swartzwelder, D.V.Lewis, and W.A.Wilson. Depts. of Med. (Neurol.), Pharmacol. and Pediatr. (Neurol.), Duke University and the VA Med. Ctrs., Durham, NC 27710.

Recent developments in excitatory amino acid pharmacology have allowed the demonstration of a GABAB-receptor mediated monosynaptic IPSP in the rat hippocampal slice preparation (Davies and Collingridge, SON Abstr. 15:529, 1989). This demonstration has led us to hypothesize that this post-synaptic action of GABAB receptors may promote the voltage-dependent block of the NMDA channel by Mg⁺⁺.

We now report the direct demonstration of GABAB receptor-mediated inhibition of the NMDA component of synaptic transmission. In order to prevent complications of other excitatory and inhibitory amino acid receptors, we utilized the non-NMDA receptor antagonist, DNQX (10 uM) and the GABA_A channel antagonist, picrotoxin (10 uM). Under these conditions large, long-lasting NMDA EPSPs were recorded from s. radiatum of area CA₁ upon stimulation of the Schaffer collaterals. NMDA EPSPs were sensitive to competitive and non-competitive NMDA antagonists. When NMDA EPSPs were paired at interstimulus intervals between 100-400 msec, we observed an almost complete block of the second response. The paired pulse inhibition was completely reversed by GABAB receptor antagonists. Intracellular recordings revealed a late phaclofensensitive IPSP which correlated in time with the period of inhibition. Non-Sensitive 17-37 which correlated in time with the period of inhibition. Non-NMDA EPSPs showed no such inhibition suggesting that the relevant GABAB receptors were located post-synaptically. These data suggest that GABAB receptors may play a significant role in regulating NMDA-dependent processes. (NS #17701, MH #15177-13 and Vet. Admin).

IN VIVO INTERACTION OF A POLYAMINE WITH THE NMDA RECEPTOR.

L Singh*, R J Oles and G N Woodruff
Parke-Davis Research Unit, Cambridge, England Parke-Davis Research Unit, Cambridge, England Polyamines in vitro potentiate the specific binding of radioligands that interact with the ion channel of the NMDA receptor complex. It not clear whether this interaction would have any physiological consequences in vivo. We have investigated the ability of the polyamine spermidine to modulate NMDLA-induced tonic It is seizures in mice.

The s.c. administration of NMDLA (25-300 mg/kg) and pentylenetetrazol (PTZ 40-120 mg/kg) dose-dependently induced tonic-seizures. Spermidine administered i.c.v. 15 min before the convulsant dose-dependently (0.5-2.0µmols) potentiated NMDLA-induced seizures, decreasing the dose of NMDLA required to induce seizure stignty in 500 of mics (PD) by more than activity in 50% of mice (ED₅₀) by more than 3 fold. However, spermidine (2.0µmols, i.c.v.) decreased the PTZ ED₅₀ by only 14%.

These results suggest that polyamines may

interact with the NMDA receptor in vivo and the polyamine modulatory site under normal circumstances may not be fully activated.

GABAR RECEPTOR STIMULATION AND EXCITATORY AMINO ACID-CED PHOSPHATIDYLINOSITOL TURNOVER IN RAT CEREBEL-LUM. Sheryl S. Smith and B.-K. Jin, Dept. of Anatomy, Hahnemann Univ., Phila.,

Excitatory amino acid (EAA) effects on turnover of phosphatidylinositol (PI) were assessed under different conditions as a possible mechanism for their observed actions on synaptic development. PI hydrolysis was measured in 160 x 160 µ minces of cerebellar tissue from 7-10 day old female Long-Evans rats using [³H] μ minces of cerebellar tissue from 7-10 day old female Long-Evans rats using [3 H] myo-inositol. Inositol phosphates (IP's) were separated by chloroform/MeOH extraction and anion exchange chromatography, and the PI turnover rate assessed as a percentage of basal under varying conditions. Addition of NMDA (10 4 M) enhanced the ability of QUIS (10 4 M) to increase PI turnover by 71 ± 3.5% (P <0.05) in the presence of the GABAB agonist baclofen at a dose of 50 μ M (n = 10). A lower dose of baclofen (1 μ M) exerted permissive effects on the ability of NMDA to stimulate PI turnover (n = 10), an effect not diminished by the addition of 500 nM tetrodotoxin. Normally inhibitory to this parameter, NMDA increased IP formation by 47 ± 2.6% above basal levels (P < 0.01, a 25 ± 1.2% increase above QUIS-stimulated values) in the presence of the lower dose of baclofen. Under these conditions, combined administration of QUIS and NMDA resulted in levels of PI turnover internediate between those obtained with either resulted in levels of PI turnover intermediate between those obtained with either EAA alone. At neither dose of baclofen were effects on basal or QUIS-stimulated EAA alone. At neither dose of baclofen were effects on basal or QUIS-stimulated PI turnover observed. These effects of the GABAA agonist were specific for this receptor subtype as stimulation of the GABAA receptor with isoguvacine (50 µM) did not result in any significant change in EAA agonist stimulated levels of PI turnover. In addition, both phaclofen (10² M) and APV (5 mM) completely blocked the permissive effect of baclofen on NMDA and OUIS/NMDA induced production of IP's, suggesting that functional GABAB and NMDA receptors are both required for the observed interaction of these amino acids on stimulation of PI turnover. These results are consistent with the hypothesis that interactions of amino acids may play a role in development of the cerebellum. (Supported by NS 25809 to SSS.)

PDI17302 ATTENUATES GLUTAMATE NEUROTOXICITY IN VITRO. M. A. DeCoster, J. C. Hunter¹, J. Hughes¹, and F. C. Tortella. Neuropharmacology Br., Dept. Med. Neurosciences, Walter Reed Army Inst. of Research, Washington, DC 20307-5100 and Parke-Davis Res. Unit, Addenbrookes Hospital Site, Cambridge, CB2 2QB, England.

Anticonvulsant and N-methyl-D-aspartate (NMDA) antagonist

Anticonvulsant and N-methyl-D-aspartate (NMDA) antagonist effects of the selective kappa opioid PD117302 have recently been described (Tortella et al., Life Sci., 46: 1990). Here we report that PD117302 protects cultured rat neurons from glutamate (glu) toxicity. Fetal neurons from E-14 cortex were cultured for 2 weeks, exposed for 1 hour to 50 um glu in Locke's solution (Locke's) without Mg*+ and, 20 hours later, the degree of neuronal injury was assessed by measuring lactate dehydrogenase (ldh) release. Cells treated with 50 um glu released 193.8 + 10.9 units/ml of ldh; those treated with Locke's alone released 76.1 + 30.2. Treatment with 25 nm PD117302 or 25 nm MK801 resulted in 32.6% (155.4 + 13.5) or 74.6% (105.9 + 8.0) protection, respectively. Doses of 50 nm PD117302 and MK801 protected against 100 um glu to the extent of 95.9% and 100%, respectively. PD117302 or MK801 alone had no significant effect on ldh release when compared to cells receiving only Locke's. Anticonvulsant and N-methyl-D-aspartate (NMDA) antagonist on ldh release when compared to cells receiving only Locke's. These results indicate that in addition to its anticonvulsant and NMDA antagonist properties in vivo, PD117302 protects cultured rat neurons from glutamate-induced cell death, raising the possibility that this drug, or related compounds, may have therapeutic utility as a neuroprotective agent.

TRANSIENT DEPRESSION OF THE ELECTROGRAPHIC ACTIVITY OF THE RAT SENSORIMOTOR CORTEX FOLLOWING LOCAL MICROPERFUSION OF N-METHYL-D-ASPARTATE, IN VIVO. N. Ludvig, P.K. Mishra, R.L. Burger, S.M. Lasley, J.W. Dailey and P.C. Jobe. Dept. of Basic Sciences, University of Illinois College of Medicine at Peoria, Peoria, IL 61656.

This study was designed to obtain insight into the role of N-Methyl-D-aspartate (NMDA) receptors in the cerebral cortex in physiological conditions. Intracerebral microdialysis was utilized to perfuse NMDA (2 ul/min, 15 min duration) in the sensorimotor cortex of freely moving Sprague-Dawley rats. Before, during and after the drug microper-fusions the behavior of the rats was videotaped, and the local electro-graphic activity was analyzed on-line with a Cadwell 8400 system. The microdialysates were collected for subsequent HPLC analyses.

Control aspartate and glutamate concentrations in the extracellu-

Control asparate and glutamate concentrations in the extracellu-lar space were in the range of 0.2-2.0 µM and approximately 60 % of the perfused NMDA entered in the tissue. Dialysis with 1.0 mM NMDA did not cause significant behavioral or electrographic effects. However, 10 mM NMDA induced a marked depression of the electrographic activity. This was reflected in a 74.3+8.1 % decrease of the spectral power of the high frequency EEG bands and the concomitant decrease of EEG amplitude. The depressant effect of NMDA was transient: 2 hours after the drug perfusions the electrographic activity returned to normal. Remarkably neither behavioral nor electrographic selzures were observed.

These data may indicate that in the cerebral cortex the NMDA receptor-linked excitatory, potentially epileptogenic, effects are controlled by powerful regulatory mechanisms of which activation can lead to depression.

200.11

DUAL REGULATION OF KYNURENIC ACID PRODUCTION IN RAT HIPPOCAMPUS IN VIVO. H.-Q. Wu and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD 21228.

Kynurenic acid (KYNA), an unspecific and competitive

excitatory amino acid receptor antagonist, can be synthesized from its immediate bioprecursor L-kynurenine (KYN) in the brain <u>in vitro</u> and <u>in vivo</u> (J. Neurochem., 52: 1629, 1989; Neurosci. Lett., in press). We have now examined the regulation of extracellular KYNA levels in the rat hippocampus by microdialysis in unanesthetized rats. KYN (500 μ M) and all drugs were applied through the dialysis probe (2 mm) which was positioned in the dorsal hippocampus. Drugs were applied after 3 hours of KYN perfusion (at steady-state KYNA levels). 300 μ M aminooxyacetic acid (AOAA), an inhibitor of kynurenine aminotransferase decreased KYNA levels by 80%. After discontinuation of AOAA, no return to basal levels was seen for at least 3 h. Veratridine (50 μ M) caused a KYNA decrease of 50%, and levels recovered completely within 1 hour of discontinuation. KYNA production was doubled one week after injection of quinolinic acid (20 μ g/l μ l). The lesion blocked the effect of veratridine but did not prevent the inhibitory action of AOAA. Tetrodotoxin (5 μ M) abolished the

effect of veratridine but not that of AOAA.

These data suggest that KYNA function in the brain in vivo can be influenced both by a direct block of its biosynthetic enzyme and by neuronal depolarization.

Supported by USPHS grant NS 16102.

CLOZAPINE ATTENUATES EVENTS MEDIATED BY N-METHYL-D-ASPARTATE (NMDA) RECEPTOR COMPLEX: FUNCTIONAL EVIDENCE FOR AN ADRENERGIC MODULATION OF CEREBELLAR PURKINJE CELL ACTIVITY IN VIVO. T. S. Rao, P. C. Contreras, J. A. Cler, M. R. Emmett, S. J. Mick, S. Lyengar and P. L. Wood. G. D. Searle-Monsanto, St. Louis, MO 63198.

Due to the putative role for dopamine (DA) and noradrenaline (NE) in the etiology of ischemia-induced neuronal cell death, the modulation by clozapine, an atypical anti-psychotic agent that interacts with NE receptors of NMDA receptor complex-mediated events were studied by examining its effects on mouse cerebellar cGMP levels. Clozapine decreased basal cerebellar CGMP levels and antagonized harmaline-, methamphetamine (MA)-pentylenetetrazol (PTZ)- and D-serine-induced CGMP levels with Ab5,0 values of 3.9, 2.36, 2.13 and 2.1 mg/kg (ip), but did not affect quisqualate-response. Antagonists of DA (D,) and serotonin did not reverse the harmaline response. However, WB-4101, an α,-adrenergic antagonist, reversed harmaline-, D-serine-, PTZ-and MA-induced CGMP levels indicating an adrenergic modulation of the NMDA receptor complex's response. These results indicate an adrenergic modulation of

REDOX PHENOMENA MODULATE FUNCTION OF THE NMDA RECEPTOR,

M.D. Majewska. J.A. Bell. and E.D. London, Neuropharmacology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224. Redox phenomena play a vital role in the function of proteins, including some receptors (Karlin, A. and Winnik, M., Proc. Natl. Acad. Sci., 60:668, 1968). Ascorbic acid (AA) and glutathione (GSH), are prominent biological reductants, present in the CNS at millimolar concentrations. Previously we showed that AA and GSH inhibit the binding of [3H]glutamate and [3H]thienylcyclohexylpiperidine ([3H]TCP) to the N-methyl-D-aspartate (NMDA) receptor, and block NMDA-gated currents in neurons (Majewska, M.D. et al., Soc. Neurosci. Abstr., 15:1167, 1989). To determine if redox phenomena regulate the function of the NMDA receptor, we subsequently examined interactions of other reductants with this receptor. Hydroquinone (mM) behaved as AA or GSH, inhibiting TCP binding and reversibly reducing NMDA-gated currents in cultured rat cerebral cortical neurons. However, dithiothreitol (10 μ M - 1 mM), which cleaves disulfide bonds in protein cystine residues, and which was almost inactive in altering [3H]glutamate and [3H]TCP binding, markedly and reversibly potentiated NMDA-gated currents. Mercaptoethanol had a circles of the state of the contraction of th similar effect. Effects of the reductants were rapidly decreased or abolished by addition of an oxidizing agent. Our data suggest that redox phenomena play a complex role in regulating the function of the NMDA receptor.

PYRAZINAMIDE STIMULATES 3-HYDROXYANTHRANILATE PRODUCTION FROM ANTHRANILATE IN RAT BRAIN AND SPLEEN SLICES. H. Baran and R. Schwarcz. Maryland Psychiatric Research Center, Baltimore, MD 21228.

Upon systemic administration to rats, the anti-tuberculosis agent pyrazinamide (Pyr) substantially raises serum and urine concentrations of the endogenous excitotoxin quinolinic acid (QUIN). The mechanism of action has been suggested to involve a block of aminocarboxymuconatesemialdehyde decarboxylase, resulting in a dysfunctional glutarate pathway and a concomitant shift towards enhanced QUIN production (BBA, 677:109, 1981). We have now tested the ability of Pyr to affect anthranilate 3-hydroxylase, an enzyme which may be preferentially involved in QUIN production in the brain (Baran and Schwarcz, J. Neurochem., in press)

In the presence of 100 μ M anthranilic acid and an inhibitor of 3-hydroxyanthranilic acid (3HANA) degradation, rat tissue slices (base: 1 x 1mm) were incubated in Ringer buffer for 2 h at 37°C. In brain and spleen, 1 mM Pyr stimulated 3HANA production (2.3 and 2.8-fold, respecstimulated shawa production (2.3- and 2.6-fold, respec-tively). In brain slices, Pyr effects were linear up to 1 mM. Incubation for 5 min yielded 56% of that seen after 2 h. Notably, Pyr was without effect on 3HANA production from 3-hydroxykynurenine in both brain and spleen slices.

Stimulation of anthranilate 3-hydroxylase may be responsible for the effect of Pyr on QUIN production in mammalian cells. (Supported by USPHS grant NS 28236).

CALCIUM FEEDBACK AND SENSITIVITY REGULATION IN PRIMATE RODS. K. Nakatani, T. Tamura* and K.-W. Yau. Howard Hughes Medical Institute and Dept. Neuroscience, Johns Hopkins School of Medicine, Baltimore, MD 21205.

We and others have previously shown in amphibians that when retinal rods are illuminated there is a net efflux of Ca⁺⁺ from the cells via a Na⁺-Ca⁺⁺ exchange mechanism. This Ca⁺⁺ efflux leads to a decrease in free calcium in the rod outer segment, which in turn feeds back negatively on the phototransduction process to regulate the light sensitivity of the cells. We now report a similar mechanism in primate rods. Using a suction pipet to record membrane current from an isolated primate rod, we examined the kinetics of the electrogenic Na⁺-dependent Ca⁺⁺ efflux during illumination after dark-loading the cell with Ca⁺⁺ (by either removing Na⁺ from around the outer segment or exposing it to IBMX). We found that the rate of this efflux, which reflects the internal free Ca⁺⁺ concentration, declined with a time constant of about 100 msec. In separate experiments involving the removal of this Ca⁺⁺ efflux (and hence the negative feedback) with a ONa⁺ - OCa⁺⁺ external solution, the response of a primate rod to a dim flash was found to increase by 2-3 fold, accompanied by an increase in the time-to-peak of the response. These changes can be broadly reproduced by a quantitative model of phototransduction that has the Ca⁺⁺ feedback as one of its features. Finally, the adaptation to background light that we have observed in these cells most likely also arises from the Ca⁺⁺ feedback.

201.3

EVIDENCE FOR ELETROGENIC TRANSPORT OF GABA INTO CONE-DRIVEN HORIZONTAL CELLS OF THE CATFISH RETINA. R.P. Malchow, H. Oian*, and H. Ripps, Depts. Ophthalmology and Anatomy & Cell Biology, Univ. Illinois College of Medicine, Chicago, II. 60612.

Recently we reported that GABA induces an inward current in rod-driven horizontal cells of the skate retina (Biol. Bul. 177: 324, 1989); the current appeared to result from the electrogenic transport of this compound into the cells. We now find that GABA induces a current with similar properties in conedriven, but not rod-driven, horizontal cells of the catfish retina.

Current responses from enzymatically-isolated catfish horizontal cells were obtained using the whole-cell voltage-clamp technique. With the membrane held at -70 mV, application of 100 uM GABA to cone-driven horizontal cells elicited an inward current. The magnitude of the current decreased with progressive depolarization, becoming undetectable at +30 to +50 mV, but it was never seen to reverse into an outward current. At 100 uM, neither the GABAa agonist muscimol nor the GABAb agonist (-) baclofen were capable of mimicking the GABA response. The current was not significantly reduced by superfusion of 100 uM picrotoxin, a GABAa antagonist, or by 100 uM of the GABAb antagonist phaclofen. However, replacement of external sodium with either choline or lithium markedly reduced the GABA-induced current.

100 uM GABA had no effect on rod horizontal cells of the catfish. Interestingly, autoradiographic experiments have shown that cone horizontal cells, but not rod horizontal cells, take up tritiated GABA (Lam, D. M. K., Lasater, E. M., and Naka, K.-I. <u>PNAS 75</u>: 6310, 1978). In sum, our results are consistent with the hypothesis that the GABA-induced current in catfish cone horizontal cells reflects the activity of an electrogenic transport system. Supported by N.E.I. EY-05516.

A CHROMATIC HORIZONTAL CELL IN THE XENOPUS RETINA: MORPHOLOGY AND SYNAPTIC PHARMACOLOGY. S.L. Stone. P. Witkovsky and M. Schütte*. Dept. of Ophthalmol., NYU Medical Center, New York, NY 10016.

We identified a chromatic type horizontal cell (C-cell) in Xenopus retina by intracellular dye injection with Lucifer Yellow or HRP. Under photopic or mesopic conditions, moderate intensity blue and cell light flower sucked servorse which were invested with capacity.

We identified a chromatic type horizontal cell (C-cell) in <u>Xenopus</u> retina by intracellular dye injection with Lucifer Yellow or HRP. Under photopic or mesopic conditions, moderate intensity blue and red light flashes evoked responses which were inverted with respect to each other but of similar kinetics, waveform and latency. Both hyperpolarizing and depolarizing response components showed similar large receptive fields with no center-surround antagonism. The perikaryon, located in the distal INL, emitted 4-7 long tapering processes that ran horizontally for 90-100 \(mu\)m. Two kinds of terminal dendrites, short and long, extended from the tapering processes towards the photoreceptor terminals.

terminal dendrites, short and long, extended from the tapering processes towards the photoreceptor terminals.

Superfusing the retina with glycine eliminated the depolarizing light response; the hyperpolarizing waveform evoked by blue light was unaffected. In contrast, GABA had no obvious effect on either component. cis-PDA modified the C-cell light response in two stages; first the depolarizing response disappeared, then the membrane potential hyperpolarized concomitant with a large reduction or elimination of the hyperpolarizing response. In contrast, APB had no obvious effect on either response component, or on the dark membrane potential.

The pharmacological results support the view that the hyperpolarizing C-cell response is mediated by direct synaptic input from a blue-sensitive photoreceptor. The depolarizing response could be mediated by direct input from a red-sensitive cone or via an indirect pathway involving L-type horizontal cells. Supported by EY0 6960 to S.L.S. and EY0 3570 to P.W.

201.2

SIGN INVERSION OF SIGNAL TRANSFER FROM SALAMANDER RODS TO HORIZONTAL CELLS AT LOW EXTERNAL CALCIUM CONCENTRATION.
J. Kleinschmidt, Dept. of Ophthalmology, NYU Med. Ctr., New York, NY 10016.

Normal synaptic transmission from rods and cones to horizontal cells (HC's) in the superfused salamander retina persists when the medium is "Ca-free" (no Ca salts added) or when external Ca (Ca) is buffered to a level as low as 30 μ M but fails rapidly and completely when Ca is buffered to $5\,\mu$ M or less. In the intervening range of buffered free Ca $_{o}$ (10-25 μ M), light-evoked responses of HC's which are normally purely hyperpolarizing become depolarizing. These depolarizing light responses are spectrally univariant and derive exclusively from rods; rods, however, still produce purely hyperpolarizing light responses. Thus in this range of Ca $_{o}$, cone input to horizontal cells is abolished whereas rod input persists but inverts its sign. Hyperpolarizing light responses of HC's at normal Ca $_{o}$ (1 mM) and depolarizing light responses at low Ca $_{o}$ are fully blocked by 1 mM kynurenate or 50 μ M DNQX indicating that both types of response are mediated by activation of glutamate receptors on HC's.

Since at these low levels of Ca_o, Ca_o-dependent tonic vesicular transmitter release in the dark has probably ceased, horizontal cell light responses under these conditions appear to reflect a mode of sign-inverting, rod-exclusive signal transfer with a mechanism different from that of vesicular transmitter release. Reverse mode operation of a plasma membrane glutamate uptake carrier can be ruled out as the mechanism underlying this signal transfer. A remaining possibility is glutamate secretion through a voltage-dependent glutamate transporter present in glutamatergic synaptic vesicles and incorporated continuously into the rod plasma membrane during tonic vesicular transmitter release.

INHIBITION BY GABA OF DEPOLARIZATION-INDUCED CALCIUM INFLUX IN GOLDFISH RETINAL BIPOLAR NEURONS. Ruth Heidelberger and Gary Matthews, Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

Fura-2 measurements from retinal bipolar cells have shown that depolarization elicits Ca-influx via voltage-activated Ca-channels (Heidelberger & Matthews, 1990, Invest. Ophth. Vis. Sci., 31, 389). Because bipolar cells receive GABAergic feedback synapses from amacrine cells, we examined whether GABA might affect such depolarization-induced Ca-influx. Goldfish bipolar cells were isolated after papain treatment and were incubated with fura-2AM for monitoring [Ca]. Increases in [Ca] produced by 62.6 mM [K], with & without 50 μM GABA were compared. With GABA, the peak increase in [Ca], averaged 35 ± 10% of the control response (mean ± s.e.m., n=16). In 50% of the cells, GABA completely abolished the K-induced increase in [Ca]. Baclofen (50 μM) had no significant effect on Ca-influx (92 ± 2% of control; n=8). In whole-cell current-clamp recordings, 62.6 mM K₀ depolarized bipolar cells to −17.5 ± 3.3 mV (mean ± s.e.m.; n=4), which is sufficient to activate Ca-currents (Matthews & Heidelberger, this meeting). When combined with 50 μM GABA, however, 62.6 mM K₀ produced only a small depolarization to −43.5 ± 1.8 mV, which is insufficient to activate Ca-current. This is due to a large GABA-activated chloride conductance that is the dominant conductance in the cell (average 3.9-fold increase in Gia produced by GABA). A simple interpretation is that GABA affects Ca-influx in Goldfish bipolar cells by activating chloride conductance and clamping membrane potential near the resting level, even in the face of high K₀. This suggests that the GABAergic feedback synapses in the intact retina might have a similar inhibitory action on Ca-influx into bipolar terminals and thus on presynaptic transmitter release.

201.6

HORIZONTAL CELLS CONTAIN TWO TYPES OF INHIBITORY AMINO ACID RECEPTORS. T. A. Gilbertson*, S. Borges and M. Wilson.

Department of Zoology, University of California, Davis CA 95616

The amphibian retina is thought to contain both glycinergic and GABAergic interplexiform cells (IPCs). To find out if these IPCs modulate the performance of the outer retina, as is the case for the dopaminergic IPCs of teleosts, we have examined the effects of glycine and GABA on isolated horizontal cells (HCs) of the salamander.

Morphologically identified HCs were studied under whole-cell patch clamp conditions. These cells showed large TEA-sensitive outward currents which were activated positive to -30 mV. A minority of the cells (<20%) also displayed an inward current that was TTX-sensitive. Both glycine and GABA activated conductances that had a Nernstian dependence on Cl concentration. GABA and glycine responses desensitized at concentrations above 10 μM. The timecourse of desensitization in each case was approximated by a single exponential with a time constant of about 2-2.5 seconds. The glycine response was completely blocked by the competitive antagonist strychnine (2 μM). The GABA-induced current appeared to be mediated entirely by GABA_Λ receptors as the response was abolished by 10 μM bicuculline methlodide. The response of HCs to bath-applied glycine had an EC₅₀ of 28.7 μM and a Hill coefficient of 1.0, while for GABA these values were 42.5 μM and 1.04 respectively. Rapid application of GABA produced a Hill coefficient of 2.1, indicating the presence of faster desensitizing states.

LOCALIZATION OF IP₃ RECEPTOR IN THE VERTEBRATE RETINA. Y.-W. Peng*1,², A. H. Sharp², S.H. Snyder² and K.-W. Yau¹,². Howard Hughes Medical Institute¹ and Dept. Neuroscience², Johns Hopkins School of Medicine, Baltimore, MD 21205.

We have carried out immunocytochemical localization of the IP₃ receptor in the retina using a rabbit polyclonal antibody (Sharp & Snyder, in preparation) against the IP₃ receptor protein purified from rat cerebellum. Positive staining was observed in rat retinal sections at the outer and the inner plexiform layers. In addition, the outer and the inner limiting membranes (composed of Muller cell processes) were also stained. Western blotting of retinal proteins from rat showed a band that corresponds in molecular weight to the purified IP3 receptor from rat cerebellum. Very similar patterns of staining were observed in retinae of primate, salamander, and other species (except for some variability in staining of the outer and inner limiting membranes). Study of dissociated retinal neurons from salamander indicated that the staining at the outer plexiform layer came predominantly from the synaptic terminals of photoreceptors, while that of the inner plexiform layer came from amacrine cell processes and the synaptic terminals of bipolar cells. Horizontal and ganglion cells did not show staining. The specific localization of the ${\rm IP_3}$ receptor to synaptic terminals suggests a role of ${\rm IP_3}$ in synaptic modulation (e.g., gain control) in the retina. The absence of staining in the photoreceptor outer segment also argues against a role for ${\rm IP}_3$ in phototransduction.

DISTINCT CELL TYPES IN LIVING MACAQUE RETINA DISPLAY AN UNEXPECTED GRANULAR FLUORESCENCE. <u>D.M. Dacey.</u> Dept. of Biological Structure, The Univ. of Washington, Seattle, WA 98195. When the isolated, superfused retina of the macaque monkey is observed under blue episcopic illumination an unexpected fluorescence is present in distinct subpopulations of inner retinal neurons. This fluorescence appears as a profusion of intense yellow 'granules' in the cytoplasm of the soma and in some cases the proximal dendrites of cells in the ganglion and amacrine cell layers. The size and shape of the granules suggests that the fluorescence may be restricted to lysosomes.

Intracellular injections of horseradish peroxidase made into the fluorescing cells reveals a distinct ganglion cell type and two amacrine cell types. The ganglion cells have large somata (~20 µm diameter) and extremely large, sparsely branched dendritic trees. One amacrine cell type shows spiny, sparsely branched dendritic trees. One amacrine cell type shows spiny, sparsely branched dendritic tree. The other amacrine cell type shows a densely branched tree composed of extremely thin, smooth processes that are studded with distinct varicosities.

The event and the intensity of the grapular, fluorescence varies from distinct varicosities.

distinct varicosities.

The extent and the intensity of the granular fluorescence varies from retina to retina. This variability, and its yellow color suggests the possibility that the fluorescent granules somehow result from uptake of serotonin (5-HT) released by small and variable amounts of blood present during the dissection of the retina from the eye. It has recently been shown that intense 5-HT immunoreactivity can be demonstrated in the rabbit by 5-HT-accumulating amacrine cell types after exposure of the retina to blood (Sandell, J.H. and Masland, R.H. Histochem., 92:57,1989). If the yellow fluorescence does result from exposure to blood then it might be possible to enhance and control the effect by incubating the retina in known concentrations of 5-HT.

DISPLACED GANGLION CELLS OF RABBIT RETINA.

E. V. Famiglietti and J. E. G. Downing. Dept. of Anat. and Lions' Sight Ctr., Univ. of Calgary, Calgary, AB, Can. T2N 4N1.

Displaced ganglion cells (GCs) with cell bodies in the amacrine cell sublayer of the inner nuclear layer (INL) were first identified by Dogiel (1891), and were subsequently characterized in greater detail by Cajal (1893), who identified them in amphibians, reptiles and birds but not in mammals. Common characteristics of these cells are dendritic branching in stratum 1 (or 1-2) of the inner plexiform layer (IPL), cell bodies of relatively large size, and in birds at least (Karten et al., 77) axonal projections to the accessory optic system (AOS). Subsequently, displaced GC bodies have been demonstrated in the INL of most mammalian retinas by retrograde transport of markers. In rabbit, displaced cell bodies of all sizes have been labelled by retrograde transport from injections in superior colliculus (SC), giving rise to the suggestion that GC displacement is accidental, and not typical of any GC type (Vaney et al., 81). We have identified a unique type of displaced GC in Golgi preparations of rabbit retina with a small soma in the INL and typically three years long (60, 700 mm). displaced GC in Golgi preparations of rabbit retina with a small soma in the INL and typically three very long (600-700 µm) unbranched dendrites lying in stratum 1. We have confirmed by retrograde transport of HRP from SC that the predominant displaced GC is in the smallest soma-size group. These cells evidently bear no relationship to the previously characterized directionally selective and AOS-projecting GCs of rabbit retina. (Supported in part by the AHFMR and MRC of Canada).

"DAPI-3" CELLS IN RABBIT RETINA: GLYCINE-ACCUMULATING AMACRINE CELLS THAT CO-STRATIFY WITH CHOLINERGIC AMACRINE CELLS. H.M. Young*, G. Elston*, J.F. Dann and D.I. Vaney*. Vision, Touch and Hearing Research Centre, University of Queensland, Queensland 4072, Australia. In rabbit retina, the fluorescent nuclear dye, 4.6-diamidino-2-phenylindole (DAPI), selectively labels the type b cholinergic (Cb) amacrines in the ganglion

(DAPI), selectively labels the type b cholinergic (Cb) amacrines in the ganglion cell layer (GCL) and three types of amacrines in the inner nuclear layer (INL), including the matching population of type a cholinergic (Ca) amacrines (Tauchi, M. & Mastand, R.H. *Proc. R. Soc. Lond.*, B223:101, 1984; Vaney, D.I. *ibid.*, B220:501, 1984). Most of the remaining DAPI-labelled cells in the INL comprise a distinct type of small-field amacrine with fine convoluted dendrites, termed the "DAPI-3" amacrine cell (Vaney, D.I. *Prog. Retinal Res.*, 9:49, 1990). The dendritic morphology of the DAPI-3 cells was revealed by Lucifer Yellow injection under microscopic control. The dendritic-field diameter of the DAPI-3 amacrines ranges from 100 µm on the peak visual streak to 330 µm in far-superior retina, with an estimated two- to three-fold dendritic-field overlap. Although the DAPI-3 cells have previously been characterized as "diffuse" amacrines, examination of photoconverted neurons indicates that the DAPI-3 dendrites are essentially bistratified. Lucifer injection of three overlapping neurons comprising DAPI-3, Ca and Cb amacrines showed that the DAPI-3 dendrites costratify with the cholinergic dendrites in strata 2 and 4 of the IPL. In neurons comprising DAPI-3, Ca and Cb amacrines showed that the DAPI-3 dendrites costratify with the cholinergic dendrites in strata 2 and 4 of the IPL. In order to determine the transmitter content of the DAPI-3 amacrines, DAPI-labelling was combined with GABA immunohistochemistry and [³H]glycine-uptake autoradiography. Glycine was accumulated *in vitro* by about 30% of the DAPI-labelled cells in the INL, but by none of the DAPI-labelled Cb amacrines in the GCL. We have previously reported that all of the Cb amacrines and about 70% of the DAPI-labelled INL cells (presumably the Ca amacrines) show GABA-like immunoreactivity (Vaney, D.I. & Young, H.M. Brain Res., 438:369, 1988). None of the DAPI-labeled cells showed both [³H]glycine-uptake and GABA-like immunoreactivity. We conclude that the DAPI-3 amacrines correspond to the glycine-accumulating population of DAPI-labelled cells.

201.10

A SUBGROUP OF ALPHA GANGLION CELLS IN THE ADULT CAT RETINA EXPRESSES SOMATOSTATIN-LIKE IMMUNOREACTIVITY (SRIF-IR) C.A. White and L.M. Chalupa. Department of Psychology and the Neurobiology and Physiology Graduate Groups, University of California, Davis, CA 95616.

Two types of cells in the ganglion cell layer of the adult cat retina are immunoreactive for somatostatin or a somatostatin-like substance

(White et al., JCN, 293:134,1990). One of these types is a large cell that resembles the alpha ganglion cell in soma size and shape. The other is a small-to-medium size cell that we have identified on the basis of morphological criteria as a wide-field amacrine cell. Both types are distributed preferentially in the inferior retina. We now provide unequivocal evidence that the large cells are alpha cells. Retinal ganglion cells were labeled by injections of rhodamine-filled microspheres or Fluoro-gold into the superior colliculus and the dorsal lateral geniculate nucleus. The retinas were processed for immunocytochemistry with a mouse monoclonal antibody to somatostatin 14 (Buchan et al., *Histochem.*, 83:175,1985). SRIF-IR large cells were labeled with either retrograde tracer, but the SRIF-IR wide-field amacrine cells were not. The diameter of SRIF-IR large cells ranged from 33-47 µm, comparable to alpha ganglion cells (Boycott and Wässle, *J. Physiol.*, 240:397,1974). Within a local patch of inferior retina, the mosaic of SRIF-IR large cells differed significantly from random and was more regular than that of the overall alpha cell population. Thus, use of a somatostatin antibody has revealed a cytochemically distinct subgroup of alpha cells that are arrayed regularly and preferentially within the inferior hemiretina. (Supported by NINCDS T32 NS07300 and EY03991)

GANGLION CELL SURROUND INHIBITION IS DIVISIVE, NOT LINEAR, IN RABBIT RETINA DK Merwine & FR Amthor Optometry, ²Psychology/NRC, U. Alabama Birmingham 35294

We have shown that the linear difference-of-gaussians model frequently used to describe the center-surround receptive field structure of retinal ganglion cells does not hold in rabbit retina, because the effect of surround stimulation on the center response is divisive, not subtractive, causing a decline in the slope, rather than a parallel shift downward, of the center's response versus contrast We now report that this result holds not only for directionally selective ganglion cells, but also for most concentric ganglion cells, including brisk-transient, brisk-sustained and sluggish cells. The time course of the surround inhibition appears to be longer for concentric than directionally selective ganglion cells, but still decays markedly by 500 ms. We have also determined that both stimulus onset and offset in the surround inhibit the center response of both ON-center and OFF-center ganglion cells, but mixed sign interactions differ somewhat in dynamics. stimulation protocol has also revealed that some previously thought "silent" inhibitory surrounds are actually excitatory, but suppressed by the center mechanism. The overall effect of this surround inhibition is to linearize the center response as a function of contrast and therefore increase the contrast dynamic range. Supported by EY05070, EY07033(T32) and the Sloan Foundation.

GENESIS OF INHIBITORY POSTSYNAPTIC POTENTIALS (IPSPs) BY INTERNEURONS IN THE FELINE ANTERIOR THALAMIC (AT) NUCLEI. D. R. Curro Dossi and M. Steriade. Lab. Neurophysiol., Sch. Med., Univ. Laval, Québec, Canada,

Interneurons can influence relay cells through their presynaptic dendrites (PSDs) and their axon. Prethalamic fibers arising in the mammillary body (MB) (PSDS) and their axon. Pretinating more anising in the maintiniary coop (MD) and mostly on PSDs while cortical (Cx) terminals usually synapse on parent dendrites. We now provide evidence that this synaptic arrangement has an electrophysiological counterpart in the IPSPs evoked by MB and Cx stimulation (St) in AT cells, known to be devoid of input from the reticular thalamic nucleus.

(St) in AT cells, known to be devoid of input from the reticular thalamic nucleus. Three types of MB-evoked IPSPs were distinguished: 1- a "miniature IPSP" (ER: -75 mV; latency; 6 ms); 2- an early IPSP (ER: -75 mV; latency: 13 ms); and 3- a late IPSP (ER: from -86 to -100 mV; latency: 55 ms). The first one was evoked selectively by MB St and the other two by MB and Cx St. In decorticated cats, weak MB St elicited only miniature IPSPs. At low rates (≤ 0.5 Hz), MB and Cx St evoked biphasic IPSPs composed of an early and a late phase. While Cx-evoked IPSPs were abolished at high rates (≤ 3 Hz), MB-evoked IPSPs were replaced by a miniature IPSP. At intermediate rates (1-2 Hz), the amplitude of MB- and Cx-evoked IPSPs varied in a stepwise manner. Yet the amplitude of the early and late part of the IPSPs remained highly correlated. These findings suggest that the miniature IPSPs reflect the action of PSDs while the biphasic IPSPs are caused by the firing of a small group of interneurons. The ER of these IPSPs indicate that the miniature and the early IPSPs are mediated by GABAA receptors while the late IPSP is mediated by GABAB receptors. Since weak MB shocks evoked only miniature IPSPs in decorticated cats it is likely that conticothalamic axons provide an excitatory input which allows otherwise subthreshold EPSPs mediated by prethalamic axons to bring the soma of interneurons to the firing threshold. Supported by MRC grant MT-3689.

SLOW EPSPS ARE MEDIATED BY ACETYLCHOLINE AND NOREPINEPHRINE IN RAT NEOCORTEX. L.S. Benardo. Dept. of Neurology, College of Physicians and Surgeons, Columbia University, New York, N.Y. 10032.

Intracellular recordings were obtained from 90 cells recorded in layers IV-V of rat somatosensory cortex (Sml) slices maintained in vitro. In approximately 90% of cells repetitive stimulation at high stimulus intensity gave rise to a slow excitatory postsynaptic potential (EPSP), often preceded by a slow inhibitory postsynaptic potential (EPSP). The optimal stimulus paradigm was 20 Hz for 100-400 msec (1-8 stimuli). Slow hyperpolarization began with the first stimulus of the train and lasted seconds, followed by slow depolarization, lasting tens of seconds. Slow EPSPs were voltage-dependent, such that depolarization with DC current resulted in larger slow EPSPs. Thus, while slow EPSPs elicited at rest potential (about -70 mV) were often low amplitude and subthreshold for spike generation, those triggered when cells were gradually depolarized from rest were larger, and usually generated bursts or trains of action potentials. The slow IPSP was associated with increased conductance while the slow EPSP was associated with decreased conductance. Slow events resisted blockade of excitatory amino acid and GABAA receptors. Muscarinic or beta-adrenergic antagonists alone reduced slow EPSPs, but when added in concert reversibly blocked them. Catecholamine reuptake blockers or an acetylcholinesterase inhibitor resulted in more prolonged slow EPSPs. When bath potassium concentration was increased from 3 to 10 mM, both the slow IPSP and EPSP were diminished, implying both processes result from interactions with potassium channels. These experiments suggest that synaptic release of acetylcholine and norepinephrine can be effected in neocortical slices, and provide the first demonstration of slow synaptic events resulting from such transmitter release in the neocortex in vitro. (Supported by CIDA NS01386-01)

OPTICAL IMAGING OF BACLOFEN-INDUCED CALCIUM ACCUMULATION IN CA3 PYRAMIDAL CELL DENDRITES IN THE HIPPOCAMPAL SLICE. W.Müller, A.Preuss and J.A.Connor Dept. of Neurosciences, Roche Institute of Molecular Biology, Nutley, NJ 07110

The GABA-derivative baclofen is well known to inhibit hippocampal pyramidal neurons via activation of dendritic, G-protein-linked receptors. It inhibits calcium-currents and activates a potassium current. In the present study we used high activates a potassium current. In the present study we used high resolution microfluorometric imaging of CA3 pyramidal neurons in the guinea pig hippocampal slice to study directly the effects of baclofen on somatic and dendritic calcium levels. CA3 pyramidal neurons were filled with the potassium salt of fura-2 by iontophoretic microinjection. Bath applied baclofen induced a fast rise of dendritic calcium levels, up to 400% of resting levels, followed several 10's of seconds later by a relatively smaller rise in the soma. Dendritic as well as somatic calcium levels recovered to resting levels with washout of baclofen. Our levels recovered to resting levels with washout of baclofen. Our study suggests a messenger role for intracellular calcium increases in a receptor-mediated postsynaptic inhibition.

Supported by the DFG (W.M., Mu 809/2-1).

CORTICALLY- AND SUBCORTICALLY-EVOKED IPSPS IN ANTERIOR THALAMIC (AT) CELLS ARE AFFECTED DIFFERENTIALLY BY STIMULATION OF A BRAINSTEM CHOLINERGIC NUCLEUS. M. Steriade, R. Curro Dossi and D. Paré. Lab. Neurophysiol., Sch. Med., Univ. Laval, Québec,

The influence of ACh and brainstem stimulation on thalamic inhibitory processes is a controversial topic. McCormick and Pape (1988) reported that ACh applied in vitro hyperpolarizes morphologically-identified interneurons (Is) of the lateral geniculate nucleus. In view of data demonstrating an ACh-induced enhancement of short-range inhibitory processes, we have suggested that the cholinergic inhibition may affect the soma of Is without depressing the

cholinergic inhibition may affect the soma of Is without depressing the intraglomerular inhibition mediated by presynaptic dendrites (PSDs). The present study was performed to test the hypothesis that brainstem cholinergic afferents affect differentially the inhibitory processes mediated by the axons and PSDs of Is. We have studied how stimulation of the cholinergic laterodorsal tegmental (LDT) nucleus affects the IPSPs evoked by subcortical (mammillary body, MB) and cortical (Cx) stimulation in 26 intracellularly recorded AT relay cells, devoid of inputs from reticular thalamic nucleus. MB and Cx stimulation evoked a biphasic inputs from reticular thalamic nucleus. MB and Cx stimulation evoked a biphasic IPSP in respectively 66% and 100% of the cells. In all cases, Cx-evoked IPSP were abolished by LDT stimulation. The MB- evoked early IPSP was reduced or abolished by LDT stimulation in 50% of cells, whereas the late IPSP disappeared or underwent great reduction in 100% of cells. In the cells where MB stimulation evoked only miniature IPSPs (37%) LDT stimulation had no effect or increased the size of the IPSPs. Since miniature and biphasic IPSPs are respectively mediated by the PSDs and axons of Is (see Paré et al., this meeting), our findings suggest that brainstem cholinergic stimulation inhibits Is somatically while preserving the inhibitory processes mediated by PSDs. ELEVATION OF INTRACELLULAR Ca INHIBITS GABAERGIC IPSPs IN HIPPOCAMPAL NEURONS. <u>T.A. Pitler & B.E. Alger</u>, Dept. of Physiol., Univ. of MD Sch. Med., Baltimore, MD 21201

GABAergic synapses provide a powerful inhibitory influence on neurons in the CNS, and their depression may be an important disinhibitory mechanism that facilitates epileptic burst potentials and the development of LTP. GABA receptor function can be suppressed by intracellular calcium (Cai), but it is not known if IPSPs can be suppressed by Ca, under physiological conditions. We provide evidence using intracellular recording techniques in the hippocampal slice preparation that GABA IPSPs are potently inhibited by increases in Ca_i. KCl electrodes were used to cause spontaneous IPSPs to be depolarizing and easily observed. These spontaneous depolarizations were blocked by picrotoxin. The IPSP frequency was increased dramatically by carbachol, which provided a sufficient background of activity so that their regulation could be studied.

Following short trains of action potentials induced by intracellular current injection (5-100 at 20 Hz), the number of spontaneous IPSPs decreased. The magnitude and duration of the effect was proportional to the degree of stimulation. Including EGTA or BAPTA in the recording electrode prevented inhibition of spontaneous IPSPs, while bath application of BAY K 8644, which increases Ca influx, enhanced the effect. The duration of the IPSP block was transient, but was not related to the activation of Cadependent K conductance since this was blocked by carbachol.

The time course of the NMDA and non-NMDA synaptic currents in hippocampal neurons. Shaul

synaptic currents in hippocampal neurons. Shaul Hestrin, Pankaj Sah* and Roger A. Nicoll. Depts. of Physiology and Pharmacology. U.C.S.F., S.F. CA 94143
We studied the mechanisms that generate the dual-component EPSC recorded from pyramidal neurons using patch-clamp techniques. The NMDA mediated EPSC is much slower than the EPSC mediated by non-NMDA receptors. The slow time course of the NMDA component is surprising given that both receptor types respond to transmitter released from the same nerve terminal. We considered two models to explain the time course of the NMDA considered two models to explain the time course of the NMDA component: 1) Effective transmitter concentration rise and fall is slow. 2) Transmitter concentration increase is brief but NMDA channel activation-deactivation is slow.

To test model 1 we considered diffusion and glutamate uptake as

mechanisms controling the concentration of transmitter. We found that the time course is highly temperature sensitive ruling out diffusion. The uptake blocker: dihydrokainic acid while greatly effecting the response to exogenous glutamate did not effect the NMDA component time course. This data suggests that diffusion or uptake do not determine the time course of the NMDA component. On the other hand the NMDA channel blockers: MK-801 and ketamine greatly reduced the decay time constant of the NMDA component. Since drugs which reduce channel life time decrease the EPSC time course we suggest that the NMDA mediated EPSC reflects slow channel kinetics rather than slow transmitter clearance.

WHOLE-CELL RECORDINGS OF PARALLEL-FIBER AND CLIMBING-FIBER EPSCs FROM PURKINJE CELLS IN RAT CEREBELLAR SLICES D. J. Perkel, S. Hestrin, P. Sah* & R. A. Nicoll Depts. Physiol. and Pharmacol. UCSF, San Francisco, CA 94143-0444.

To investigate the conductances underlying the two different types of excitatory input to Purkinje cells we used whole-cell recording in thin (100-250 excitatory input to Purkinje cells we used whole-cell recording in thin (100-250 µm thick) sagittal slices of adult rat cerebellum. Cells were visualized directly using Nomarski optics, and debris overlying the soma was removed with a large "cleaning" pipette (Edwards et al., 1989, Pflugers Arch, 414:600). Recording pipettes contained (mM): 140 CSF, 10 NaC1, 10 HEPES, 10 EGTA. Electrical stimulation of the white matter caused an all-or-none excitatory post-synaptic current (EPSC) that displayed paired-pulse depression. Stimulation of the molecular layer, on the other hand, resulted in a graded EPSC that exhibited paired-pulse facilitation. Both EPSCs showed reversal potentials

that exhibited paired-pulse facilitation. Both EPSCs showed reversal potentials around 0 mV, and were entirely blocked by application of the non-NMDA receptor antagonist CNQX (10 μ M). When the cell was voltage clamped at -40 mV and/or bathed in Ringer containing no added Mg²⁺, neither type of EPSC was affected by the NMDA-receptor antagonist DL-APV (50 μ M). We conclude that both types of EPSC are mediated entirely by non-NMDA receptors.

Bath application of NMDA (100 µM) did not evoke an inward current, even

Bain application of NMDA (100 μ M) and not evoke an inward current, even in Mg²⁺-free Ringer or at a holding potential of -40 mV. Superfusion of aspartate (0.1 - 1 mM) caused an inward current, but this was blocked by 10 μ M CNQX. Non-NMDA receptors thus appear to mediate all the electrophysiological effects of excitatory amino-acids on Purkinje cells.

ARE SPINES AND DENDRITES DYNAMICALLY DISTINCT CALCIUM COMPARTMENTS? Menahem Segal, Peter Guthrie, and Stanley B. Kater. The Program in Neuronal Growth and Development and the Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

Dendritic spines are likely to be a primary site for neural plasticity.

Intracellular calcium is thought to be the prime tool for regulating neural plasticity. Despite extensive interest, little is known about calcium's resting levels and dynamic changes in spines. One major unresolved question is whether spines constitute a functional unit separable from adjacent dendritic shaft. That is, is calcium in the spine ([Ca]s) regulated differently than intradendritic calcium ([Ca]d)?

We have injected CA1 pyramidal neurons in hippocampal slices from adult rats with fura-2 and monitored [Ca]d and [Ca]s with high power adult rats with tura-2 and monitored [Ca]d and [Ca]s with high power objectives in a dual wavelength Ca imaging system. Resting calcium levels in spines and dendrites were not notably different. Calcium was elevated in individual dendrites by irradiating a distant site with a brief pulse of light. Resting [Ca]d (approx. 175 nM) rose to 600 - 2500 nM after irradiation. This increase traveled as a wave from the site of irradiation to the distant site where spine measurements were made. In most (n=20) spines on the irradiated dendrite, there was a parallel rise in

Notably, in 11 cases, the [Ca]s was lower; as low as 20% of the level in the parent dendrite. In three other cases, [Ca]s actually exceeded [Ca]d by as much as 200%. Clearly, these data are obtained near the limits of current resolving power. Nonetheless, these data strongly suggest that [Ca]i is heterogeneously regulated in spines and parent dendrites of the same neuron. (supported by Alzheimer's Association)

CAN SOMATIC SHUNT CONDUCTANCE BE MEASURED BY PEELING EXPONENTIALS? C.J. Wilson, Dept. of Anat. and Neurobiol., U.T. Memphis, Memphis, TN, 38163, USA.

The uniform membrane neuron model originally proposed for the motoneuron by Rall, and by Jack and Redman can be thought of as a mapping function that allows extraction of the physiologically meaningful values, dendritic length and dendritic dominance, from the less meaningful measured values, the equalizing time constants and their coefficients. As such, it is very well-behaved, that is, errors of measurement of the time constants and coefficients make roughly commensurate errors in the estimates of dendritic length and dendritic dominance. Viewing the somatic shunt model as a mapping function yielded a very different result. The surface generated by the function in the space defined by the first two equalizing time constants and their coefficients was very complicated. Although is was not multivalued, it folded back and approached itself in several places. It was most complex when the dendritic length was less than one length constant. Adding the third time constant and its coefficient helped only a little.

As a result, small errors in measurement of time constants and coefficients can produce large and unexpected errors in the estimate of dendritic length and dendritic dominance when using the somatic shunt model to extract these parameters. With some values of time constants and coefficients, the uniform and somatic shunt models both fit the data reasonably well, but with very different values for dendritic length and dendritic dominance. These results suggest that measurement of somatic shunt conductance, and even the determination of which model best fits neurophysiological data, should be approached with caution.

EXCITATORY AMINO ACID RECEPTORS UNDERLYING THE

EXCITATORY AMINO ACID RECEPTORS UNDERLYING THE ASSOCIATIONAL/COMMISSURAL AND MOSSY FIBER SYNAPTIC CURRENTS OF CA3 PYRAMIDAL NEURONS. J. S. Issaeson and R. A. Nicoll. Depts. of Physiology and Pharmacology, Univ. of Cal., San Francisco, CA 94143. CA3 pyramidal neurons receive two anatomically distinct types of synaptic input that exhibit different forms of long term potentiation (LTP): an associational/commissural (a/c) input that requires NMDA receptor activation for the induction of LTP and mossy fiber (mf) input which does not. NMDA receptor binding is low at the forwards region commend to the aforements region because thirthe serves in the serves in the serves are served to the serves the mf synaptic region compared to the a/c synaptic region, however, little more is known concerning the contributions of non-NMDA and NMDA receptors at these

To address this question, synaptic currents in CA3 pyramidal neurons were studied using the method of "blind" whole-cell recording (Blanton, M. et al., J. Neurosci. Meth., 30: 203, 1989) in thick (500 μm) hippocampal slices from adult guinea pigs. A/c excitatory post synaptic currents (EPSCs) were elicited by a conventional bipol stimulating electrode placed in stratum radiatum. To eliminate the contribution of

stimulating electrode placed in stratum radiatum. To eliminate the contribution of contaminating non-mf inputs which can be activated by conventional stimulating electrodes, "pure" mf EPSCs were evoked by the direct stimulation of granule cells with a glutamate-filled iontophoretic electrode positioned in the dentate gyrus. EPSCs evoked from stimulation of a/c fibers displayed a slow component at depolarizing holding potentials (> -40 mV). The slow component to the EPSC was blocked by the addition of APV to the perfusing medium.

Glutamate-evoked mf responses, presumably reflecting the activation of single fibers, often yielded EPSCs ranging in amplitude from 200 to 1000 pA at a holding potential of -80 mV. These EPSCs also contained a small, slow component at more depolarized membrane potentials which was blocked by APV. A larger APV-sensitive component to mf EPSCs was observed in slices perfused with Mg++-free Ringer.

These results provide evidence that both the a/c and mf inputs to CA3 prograndal

These results provide evidence that both the a/c and mf inputs to CA3 pyramida neurons activate NMDA and non-NMDA receptors. The functional role of NMDA receptors at the mf-CA3 synapse remains to be elucidated.

INTRACELLULAR ATP AND PHOSPHOCREATINE IN CORTEX AFTER NMDA, QUISQUALATE AND KAINIC ACID : NMR SPECTROSCOPY ON NEONATAL RAT BRAIN SLICES. J. Champagnat*, G. Fortin*, T. Jacquin*, B. Gillet*, J.C. Beloeil* and M. Denavit-Saubié Laboratoire de Physiologie Nerveuse & Institut de Chimie des Substances Naturelles, CNRS, 91198 Gif-sur-Yvette,

France.

31P- and 1H- nuclear magnetic resonance spectroscopy
of 3-10 day-old rat cortical slices were used to monitor or 3-10 day-old rat corrical sites were used to monitor evolution of intracellular ATP, phosphocreatine (Pcr), lactate and pH following 0.5-1 min application of excitatory amino acids agonists. Pcr was dephosphorylated during agonist-induced neuronal excitation and afterward fully rephosphorylated within 15-100 min, a duration related to the amount of agonist applied (threshold agonist concentration: 1μM). Reversion was abolished by mitochondrial impairement (atractyloside 50 μM, 5 min) or suppression of glucose supply. In the presence of glucose (10 mM), agonists raised lactate level and decreased pH reversibly. Effects were reproducible and sensitive to selective pharmacological blockers of neuronal membrane receptors. <u>Dose/response analysis</u> revealed situations in which [ATP]i was reversibly decreased and provided evidence for two different desensitizing mechanisms: one preventing change of [ATP]i following quisqualate, another one reducing NMDA effect on Pcr after decrease of [ATP]i. Neither mechanism was found after kainate.

INHIBITORY INTERNEURONS MAY HELP SYNCHRONIZE FIRING OF POSTSYNAPTIC CELLS. W.W. Lytton and T.J. Seinowski. Salk

Institute, La Jolla, Ca 92037.

Phase locking within groups of neurons is a ubiquitous phenomenon in the central nervous system. This synchronization may reflect the operation of a central oscillator that owes its periodicity to the intrinsic properties of individual cells or it may be a resonance property of small neuronal networks. We studied a resonance property of small neuronal networks. We studied a model of a cortical pyramidal cell that had Hodgkin-Huxley type sodium and potassium channels. Frequency entrainment was seen to a rapid train of brief, strong (20-100 nS) compound inhibitory postsynaptic potentials (IPSP) onto proximal apical dendritic shaft, soma or axon initial segment. The IPSP in this case modulated postsynaptic cell behaviour by either increasing or decreasing the rate of firing. Facilitation by the IPSP was caused by activation of sodium channels and turning off potassium channels, both reducing the threshold to firing. Using an intermediate sized IPSP (60 nS), entrainment to a 40 Hz input frequency occured when the initial rate of firing of the postsynaptic cell was between 32 and 47 Hz. The phase relation between the inhibitory cell and the postsynaptic cell phase relation between the inhibitory cell and the postsynaptic cell generally varied from $\pi/2$ to π depending on the initial rate of firing of the postsynaptic cell. Phase locking could also be demonstrated in cells which initially showed irregular firing due to uncorrelated synaptic input. The phase locking of cell firing observed in visual cortex in response to a visual stimulus may involve these facilitatory IPSP effects in combination with direct excitatory connections. Thalamic rhythms such as spindling involve inhibitory projections from the reticular nucleus that may utilize similar mechanisms.

CHROMAFFIN CELL GRAFTS TO RAT CEREBRAL CORTEX REVERSE LESION-INDUCED MEMORY DEFICITS: CHOLINERGIC DRUG CHALLENGE. S.A. Welner, Z.C. Koty* and P. Boksa. Douglas Hosp. Res. Ctr., Dept. Psychiatry, McGill Univ., Montreal, Quebec, Canada, H4H 1R3.

Lesions of the nucleus basalis magnocellularis (NBM) in the rat produce

deficits in spatial memory, usually suggested to be due to a loss of cholinergic input to the cerebral cortex. In the present experiments, adrenal chromaffin cells, which are normally catecholaminergic but can express a cholinergic phenotype under certain conditions, were isolated from donor adult rats and transplanted to the cerebral cortex of bilaterally NBM-lesioned rats. After three months, the effects of grafts on memory impairments were tested in a T-maze alternation task; our pre-vious finding that chromaffin cell grafts to lesioned animals completely reversed the spatial memory deficit seen in lesioned alone animals were confirmed (Brain Research, in press). In order to test whether maze performance in these rats could be modulated by cholinergic drugs, animals were challenged with the antagonist scopolamine (1.0 mg/kg), the acetylcholinesterase inhibitor physostigmine (0.05 mg/kg) and vehicle, injected i.p. to each rat 20 minutes prior to the test ses alternating days. Results showed that scopolamine worsened performance in all three groups, but this difference was significant only for the control group $(p \le 0.02)$. Physostigmine significantly bettered performance on the memory task or the control group when compared to that under vehicle conditions ($p \le 0.03$). For the lesioned alone and lesioned plus graft groups, a similar effect was suggested, but not significant. However, when compared to that under scopolamine, maze performance under physostigmine was significantly increased for control, lesioned and lesioned plus graft groups ($p \le 0.001$, $p \le 0.02$, $p \le 0.008$, respectively). These results suggest that cholinergic modulation of spatial memory is present in lesioned alone and lesioned plus chromaffin cell grafted animals but to a lesser degree than in unlesioned-ungrafted controls.

STRIATAL IMPLANTS PROVIDE LONG TERM PROTECTION AGAINST BEHAVIORAL, REGULATORY, AND MORPHOLOGICAL CHANGES INDUCED BY QUINOLINIC ACID. S.H. Pearlman 1, M. Levivier 2, and D.M. Gash 1. Dept. of Neurobiology and Anatomy, University of Rochester, Rochester, NY 14642¹; Dept. Neurosurgery, Erasme Hospital, Universite Libre de Bruxelles, Brussels,

Our laboratory has previously demonstrated that transplants are able to protect

Our laboratory has previously demonstrated that transplants are able to protect the host from subsequent neurotoxic insult. We report here our continued studies to elucidate the mechanisms underlying this protective effect. Adult female Long Evans rats (n=54) were divided into four groups: fetal striatum, gelfoam (control), gelfoam/aFGF, and non-grafted (control). Rats received two 2µl striatal implants followed 8-9 days later by a 240 nmol quinolinic acid challenge. Animals were tested for rotational asymmetries before grafting, 1 week post-implant, 14 days and 28 days post-lesion. Animals grafted with fetal striatum or gelfoam did not show changes in rotation after quinolinic acid lesions. The gelfoam/aFGF treated group did exhibit a small increase in turning behavior. Animals receiving fetal striatal grafts also demonstrated consistent protection in ambulatory, vertical and stereotypic small increase in turning behavior. Animals receiving fetal striatal grafts also demonstrated consistent protection in ambulatory, vertical and stereotypic locomotor activities. The adipsia and aphagia often associated with striatal lesions were also ameliorated. Morphometric analysis demonstrated that afferent, intrinsic and efferent systems are all better preserved in the grafted animals as compared to the non-grafted group. For example, both the endogenous cholinergic and enkephalinergic systems were better preserved in all three transplanted groups as compared to the non-grafted animals. These results support the hypothesis that there is a host generated response which is activated by the tissue implantation procedure alone (gelfoam group), but the most consistent and reproducible protection is found in those animals which received fetal striatal implants. Supported by NIH NS15109.

SUBSTANCE-P-LIKE IMMUNOREACTIVE ELEMENTS IN FETAL STRIATAL GRAFTS IN THE RAT: A LIGHT AND ELECTRON MICROSCOPIC STUDY. G.A. Helm,* J.P.Bennett,* and J.A. Jane. Dept. of Neurological Surgery, University of Virginia, Charlottesville, VA 22908.

Fetal striatal neurons were transplanted into the ibotenic acid lesioned rat striatum. Three months after transplantation, the grafted tissue was processed for substance P-like immunoreactivity, and the tissue was examined at the light and electron microscopic levels. The study demonstrated that substance P-like immunoreactive (SP-LI) neurons measuring 10 to 25 microns were homogeneously present in the fetal striatal grafts. These immunoreactive neurons could be classified into two types based on their ultrastructural characteristics. Type I neurons contained an unindented nucleus which was surrounded by a moderate amount of cytoplasm, whereas Type II immunoreactive neurons contained an indented nucleus which was surrounded by copious cytoplasm. The dendrites of these neurons were contacted by multiple axon terminals which made both symmetric and asymmetric contacts. In addition, numerous SP-LI axon terminals forming symmetric junctions were present within the graft. Fifty-four percent of these SP-LI axon terminals made axodendritic contacts, 19% made axospinous contacts, and 27% made axosomatic contacts. The SP-LI axon terminals made axosomatic contacts with cells displaying both indented and unindented nuclei, demonstrating that both spiny and aspiny cells within the graft received substance P input. This study demonstrated that many of the neuroanatomical features of substance P immunoreactive elements in the normal rat striatum are repeated in mature fetal striatal grafts.

TRANSPLANTS OF EMBRYONIC VENTRAL FOREBRAIN INTO CHOLINERGICALLY DEPLETED RATS RESTORE DIMINISHED METABOLIC UPTAKE IN BARREL CORTEX. S.E. Jacobs 1. A. Fine 2. D. Eslin 1. and S.L. Juliano 1. 1 Anatomy, USUHS, Bethesda, MD; 2 Physiol. and Biophys., Dalhousie U Halifax N.S.

Transplantation of acetylcholine (ACh)-rich fetal tissue into adult hosts can alter the behavior of cholinergically depleted or aged rats. The impact of such transplants on sensory systems, however, has not yet been identified. To address this issue, we studied the effects of embryonic ACh-rich or neocortical grafts on evoked metabolic activity in the barrel cortex of adult rats, which previously received basal forebrain lesions that depleted the cortex of ACh. Findings from earlier 2-deoxyglucose (2DG) studies indicate that cholinergic depletion leads to a decrease in barrel configuration. In the present studies, the animals received unilateral ibotenic acid lesions of the basal forebrain that depleted the cerebral cortex of ACh. One week later the lesions were followed by injecting cell suspension grafts of either embryonic ventral forebrain from 16 day old fetuses or neocortical tissue from young (13-14 day old) or older (19-20 day old) fetuses into the cholinergically depleted hemisphere. In rats that received basal forebrain grafts, the transplants innervated the previously ACh-depleted cortex with acetylcholinesterase-rich fibers, as demonstrated histochemically. 2DG studies in the same animals revealed that stimulation of multiple vibrissae led to metabolic uptake enhanced in dimension and intensity in barrels adjacent to ventral forebrain grafts compared with activated barrels in the same animals farther from the transplant. Surprisingly, in animals that received young cortical transplants, the evoked metabolic activity in the barrel field adjacent to the graft was enhanced compared to evoked activity in the normal hemisphere. Grafts of older neocortex did not appear to enhance evoked metabolic activity.

c-fos INDUCTION IN INTRASTRIATAL GRAFTS OF FETAL NIGRAL AND STRIATAL TISSUE: FUNCTIONAL ROLE OF D1 DOPAMINE RECEPTORS IN GRAFT-HOST INTERACTIONS, M.A. CENCI* R.J. MANDEL, P. KALÉN*, K. WICTORIN*, and A. BJORKLUND. University of Lund, Department of Medical Cell Research, Biskopsgatan 5, S-223 62 Lund, Sweden.

The proto-oncogene protein product, c-fos, has been reported to be induced by stimulation of striatal D1 receptors and c-fos induction in striatum is increased on the side mediating dopamine (DA) agonist-induced rotational behavior after DA denervation (Robertson et al., *Brain Res.* 503:346-349, 1989). In the present study, denervation (Robertson et al., Brain Res. 503:346-349, 1989). In the present study, we examined c-fos induction in two different grafting models, heterotopic grafting of DA-rich fetal ventral mesencephalon (VM) into the DA denervated striatum and homotopic grafting of fetal striatum into the excitotoxically lesioned striatum. The induction of c-fos was studied immunohistochemically using a commercially available polyclonal antibody. Rats with unilateral 6-hydroxydopamine lesions treated with apomorphine (APO) displayed high levels of c-fos induction in the lesioned striatum while similarly lesioned rats treated with amphetamine (AMPH) displayed c-fos induction predominantly in the intact striatum. Behaviorally compensated unilateral DA depleted rats bearing VM grafts displayed a reinnervation dependent pattern of striatal c-fos induction that was normalized, i.e., high AMPH-induced c-fos in the grafted striatum. Rats that were behaviorally overcompensated in response to AMPH (rotated contralateral to the graft) displayed higher striatal c-fos induction near the VM graft compared to their intact striatum. Rats with fetal striatal grafts placed in the ibotenic-acid lesioned striatum displayed AMPH-induced c-fos induction both in the intact striatum and within the grafts. Unlike the intact striatum, the c-fos positive nuclei within the striatal grafts tended to lie in clusters that coincided with patches of high AChE staining in adjacent sections. Thus, fetal DA-rich grafts may exert their functional staining in adjacent sections. Thus, fetal DA-rich grafts may exert their functional effects at least partially through normalization of D1 receptor function. The data from the homotopic striatal grafts indicate that the D1 receptors are present in the grafts and can be affected by the host's DA projection.

203.6

INCREASED TYROSINE HYDROXYLASE IMMUNOREACTIVITY

INCREASED TYROSINE HYDROXYLASE IMMUNOREACTIVITY (TH-IR) IN THE 6-OHDA LESIONED STRIATUM OF RATS IMPIANTED WITH AMNION CELIS. M.A.Palmatier. J.G.Sheng*, R.J.Plunkett* and I.J.Kopin. Clin. Neurosci., NINDS, NIH, Bethesda, MD. 20892. Amnion cells (AmCs) produce an activity which, in vitro, increases process outgrowth in rat sympathetic neurons and appears to have similar effects in rat ventral mesencephalon. To determine if AmCs could induce sprouting of DAergic nerve fibers in vivo, the substantia nigra of rats were lesioned unilaterally with 6-OHDA. Live or killed AmCs were implanted into or rats were lesioned unilaterally with 6-OHDA. Live or killed AmCs were implanted into the denervated striata. Rats were assessed weekly for 1 month before and 4 months after implant for a turning response to amphetamine. The brains were processed for TH-IR.

Rats implanted with live AmCs (n=13) showed a significant decrease in the turning response to

amphetamine post-implant and showed increased TH-IR in the lesioned striatum, particularly around the implants. These changes were not seen in rats implanted with killed AmCs (n=4).

These results suggest that implantation of AmCs in a parkinsonian animal model can lead to behavioral recovery and DAergic fiber growth in the denervated striatum. The NIH Guide for the Care and Use of Laboratory Animals was followed.

EFFERENTS FROM MOUSE FETAL STRIATAL GRAFTS RAPIDLY INNERVATE THE ADULT LESIONED RAT BRAIN, EVIDENCED BY A MOUSE-NEURON SPECIFIC MARKER. Wictorin*, C.F. Lagenaur#, R.D. Lund# and A. Björklund (SPON: European Neuroscience Association). Dept. Med. Cell Res., Univ. Lund, Lund, Sweden, and Dept. Neurobiol., Anat., Cell Sci., Univ. Pittsburgh Sch. Med., Pittsburgh, PA, U.S.A.#

The developmental time-course and pattern of efferent fiber growth from cross-species cell suspension grafts of mouse fetal striatum (E13) implanted into adult ibotenic acid lesioned rat striatum were investigated using a cell surface monoclonal anti-body (M6) specific for mouse CNS neurons (Lund et al, 1985).

As soon as 3-5 days after implantation, fascicles of graft-derived fibers began to extend out of the implants, into the adjacent bundles of the host internal capsule. The graft-derived fibers notably extended along and inside the white matter fiber tracts on their way through the host brain, and by 8 days post-grafting, efferent fibers reached the rostral globus pallidus, where small terminal-like networks began to form. The terminal-like areas were more dense at 2 weeks, and present at all longer survival times (up to 15 weeks after implantation), whereas the stainability of the efferent fibre fascicles was reduced over time, which, consistent with previous studies using this marker on retinal implants (Lund et al, 1985), could indicate a gradual myelination. Fetal neocortical control implants showed a greater growth capacity, whereas fetal cerebellar grafts did not extend efferents into the host brain.

CO-TRANSPLANTATION OF EMBRYONIC NERVOUS TISSUE AND PERI-PHERAL NERVE AUTOGRAFTS TO THE CERVICAL SPINAL CORD OF THE ADULT RAT. J.C.Horvat, C.Baillet-Derbin*, J.H.Ye*, F.Rhrich* and F.Affane*. Neurobiology Lab., Univ. Paris V,

75270 Paris Cedex 06, France.
In order to study the possibilities of a reconstruction of the spinal cord and of its peripheral connections folof the spinal cord and of its peripheral connections fol-lowing severe injury, a cavity, made in the cervical en-largement, was filled with either solid heterotypic (cortex (CT), E14-E18) or homotypic (spinal cord (SC), E14) embryonic CNS tissue; or, alternatively, with peri-pheral embryonic tissue (dorsal root ganglia (DRG), E14). In addition, one end of an autologous peripheral nerve graft (PNG) was inserted in the center of the transplant, its other end being driven extraspinally and made blind. From one to six months later, the animals were proces-sed for GFAP and Weelin Rasic Protein immunocytochemistry.

sed for GFAP and Myelin Basic Protein immunocytochemistry, HRP histochemistry following retrograde axonal transport from the PNG, and silver staining.

Integration of the three types of transplants with the host spinal cord was the rule. Surviving transplanted neurons differentiated processes, some of them becoming myelinated. Yet, growth of some of these processes into the PNG was extensive from DRG, moderate from SC and nonexistent from CT transplants, recalling the axonal re-growth of the corresponding fully differentiated neuronal populations of the adult animal, under similar conditions. (Supported by IRME/AFM 89, INSERM 886 007 and DRET 88-212)

DONOR VESSELS IDENTIFIED USING MONOCLONAL ANTIBODIES IN CEREBROVENTRICULAR ALLOGRAFTS. B.J. Baker*, M. Puklavec*, H.M. Charlton* and R.D. Broadwell. Dept. of Human Anatomy, Univ. of Oxford, U.K. and Univ. of MD, Balto., 21201

Donor vessels in xenogeneic grafts to the CNS constitute only a proportion of graft vasculature; however, the fate of donor vessels in allogeneic grafts remains to be elucid-To achieve this goal, MRC OX-27, a monoclonal antibody (Mab) specific for the MHC Class I of the PVG-RT^Crat strain, appeared an ideal candidate. Another Mab, MRC OX-26 which recognizes the rat transferrin receptor and appears to be only present on CNS blood-brain vessels, was utilized to determine the overall vasculature of the grafts. One day neonatal PVG-RTI cortex was transplanted to the third ventricle of PVG-RTI hosts (differing only at their MHC) and vice-versa. Six months later the animals were sacrificed and their brains processed for immunohistochemistry. Host vessels always vascularized the grafts. Donor vessels were identified in 50% of the grafts, and a rich network of donor vessels was observed at the level of the median eminence (m.e.). A few OX-27 positive (donor) vessels were observed in the host m.e. These vessels were large and OX-26 negative, suggesting that the vessels lost their OX-26 phenotype and possibly became fenestrated. Apart from the m.e. region, no OX-27 positive (donor) vessels have been identified in the host brain. Supported by the I.S.R.T.

EMBRYONIC MOTONEURONS GRAFTED INTO THE ADULT

CNS CAN SURVIVE, DIFFERENTIATE AND MIGRATE

A.C. Kato, P. Ruiz-Flandes* & B. Demierre* Division of Clinical

Neurophysiology and Dept. Pharmacology, C.M.U., and Dept.

Neurosurgery, Univ. Hospital of Geneva, Geneva, Switzerland

Most experimental studies on grafting of neural tissue have involved the transplantation of a heterogeneous population of cells due to the difficulty of dissecting out a particular class of central neurons. Here we describe experiments in which an identified neuronal cell population has been grafted into the adult CNS. Embryonic mouse motoneurons were labelled by retrograde transport using a fluorescent tracer, dil and then partially purified on a Nycodenz density gradient or completely purified on a fluorescence activated cell sorter. Motoneurons were grafted into either the cervical, anterior horn region of the spinal cord or into the striatal region of the adult mouse brain. After 4 to 10 weeks of grafting, the tissues were analyzed for the presence of the fluorescent motoneurons. Neurons were found to survive, differentiate (i.e. ability to grow neurites) and migrate at least 2 mm in the spinal cord and 4 mm in the brain; they were also found in contralateral sites. These studies could be important for determining whether the grafted neurons are being guided by a neurotropic agent and whether this capacity to migrate could be exploited for developing more beneficial grafting procedures.

ORGANOTYPIC NEURAL GRAFTS ARE BEST ACHIEVED IN NONHUMAN PRIMATES FROM EARLY GESTATION DONORS. J.R. Sladek, Jr., T.J. Collier, R.H. Roth+, J.R. Taylor+, J.D. Elsworth+, and D.E. Redmond, Jr+. Dept. Neurobiology and Anatomy, Univ. of Rochester School of Medicine, Rochester, NY 14642 and [†]Depts. Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06510.

Based on rodent experiments, it was assumed that the survival window for embryonic tissue was narrow, however our initial examination in nonhuman embryonic tissue was narrow, however our initial examination in nonhuman primates showed a much wider fetal window. The degree to which optimal survival is achieved, however, with different aged donors, and the extent to which grafts display morphological organotypy is not well understood. We examined a wide range of gestational ages, including 11 different crown rump lengths (CRL) from 1.3-21.0 cm in African Green monkeys. Grafts at 10-30 weeks of ventral mesencephalon, including the substantia nigra, the locus coeruleus and adjacent subcoeruleal region, ventral hypothalamus, including A-12 dopamine neurons and the careful substantial ventral hypothalamus, including A-12 dopamine neurons and the cerebellar cortex were examined using tyrosine hydroxylase and routine stains.

Optimal survival was seen from 1.3-11 cm CRL donors. Within this range, it Optimal survival was seen from 1.3-11 cm CRL donors. Within this range, it was common to observe clusters of neurons arranged in patterns resembling their adult counterparts, e.g. grafts of mesencephalon contained clusters comparable to the zona compacta with dendrites similar to those that radiate into the zona reticulata. Similarly, pontine grafts contained juxtaposed clusters of densely packed, rounded neurons with few processes (resembling the locus coeruleus) and a more dispersed group of larger neurons with multipolar branching reminiscent of the subcoeruleus. Hypothalamic grafts contained small bipolar neurons similar to tuberoinfundibular dopamine neurons. Cerebellar grafts showed Purkinje neurons between molecular and granular cell layering. Such organotypy was not observed in late gestational grafts, although cell survival was seen; the numbers were greatly reduced in comparison to the best survival in younger donors. These data suggest that early gestational tissue from nonhuman primates produce the best survival and chances for functional interactions following transplantation. Supported by NS24032.

MORPHOLOGY OF BLOOD VESSELS SUPPLYING GRAFTED TISSUES/CELLS IS GRAFT DETERMINED. R. Broadwell, B. Baker*, P. Ebert*, J. Villegas*, and A. Wolf, Univ. MD, Balto., MD 21201.

Data were presented previously suggesting that intracere bral CNS allografts possess blood-brain barrier (BBB) vessels contributed by donor and host; conversely, peripheral tissue grafts exhibit non-BBB vessels of only donor organ. We now focus on endothelia free, intracerebral cell suspensions and syngeneic, fetal CNS grafts placed under the kidney capsule of adult rats. Individual populations of purified neonatal astrocytes, fibroblasts, PC12, glioma, medulloblastoma, and neuroblastoma cell lines (2.5 x 10⁵) cells) were delivered to the striatum of adult, homozygous athymic mice. Cell suspension grafts were vascularized by 3 days. With the exception of astrocytes, cell grafts contained vessels leaky to blood-borne HRP and exhibited open intercellular junctions; vessels supplying PC12 and neuroblastoma cell lines also were fenestrated. Host rejection of cell grafts was not evident. Vessels supplying CNS grafts to the kidney were leaky to HRP, but their endothelia were of the BBB type; the grafts were inhabited by host immune system cells identified immunohistochemically and by EM. Graft rejection most likely rendered graft vessels permeable to HRP. Intracerebral cell grafts in nonhomozygous nude rats also were rejected. The data confirm that the morphology of blood vessels supplying grafted tissue/cells is dictated by the graft and that the host immune response is a factor for acceptance of cell suspension grafts. EFFECTS OF OVARIAN HORMONES ON ELECTROPHYSIOLOGICAL ACTIONS OF OXYTOCIN ON HYPOTHALAMIC NEURONS IN VITRO. L.-M. Kow, A.E. Johnson', S. Ogawa, D.W. Pfaff The Rockefeller University, New York, NY 10021 and 'SCSBB/LCS, NIMH, MD 20837 Since both estrogen (E) and, subsequently, progesterone (P) affect oxytocin (OT) receptors in the hypothalamus, and since infusion of OT into the hypothalamus facilitates lordosis, these ovarian hormones might later CT exting a hypothalamus facilitates. oxytocin (OT) receptors in the hypothalamus, and since infusion of OT into the hypothalamus facilitates lordosis, these ovarian hormones might alter OT action on hypothalamic neurons in a behaviorally-relevant way. This was investigated by recording single-unit activity of neurons in the ventrolateral portion of the ventromedial nucleus in hypothalamic slices, and subjecting these neurons to bath application of OT and related agents. Slices prepared from ovariectomized rats either treated with E (OVX+E) or not (OVX) were used to examine E effect. To help assess relevance to lordosis, the response of a neuron to OT was compared to its responses to two lordosis-relevant neurotransmitters, norepinephrine (NE) and acetylcholine (ACh). Perifused with OT at near-threshold concentration, 2X10¹⁹M, only neurons from OVX+E preparations responded (11/50 units), whereas none of the 54 OVX units did (p-0.001). At 10⁴M, OT affected neurons from both groups, but the responsiveness was still higher (p<0.05) in OVX+E (24/44 units responded) than in OVX (14/48 units). Most (>80%) of the responses to OT were excitatory, and all the OT-responsive units tested also responded in the same way to a highly selective agonist, [Thr', Gly']-OT. Some weak modulation of responses to NE and ACh by OT has been observed, but was not affected by E. Neither affected was neuronal responsiveness to vasopressin, a peptide closely related chemically to OT. In OVX+E, but not OVX preparations, neurons responsive to OT were also more likely to respond to NE or ACh (both p's<0.05). Thus, estrogen not only enhanced neuronal responsiveness to lordosis-relevant transmitters NE and ACh. The effect of P is currently under study.

EXPRESSION IN BRAIN AND OTHER TISSUES OF mRNA FOR AN ESTROGEN-INDUCED PROTEIN (HIP-70), AN ISOFORM OF PHOSPHOLIPASE C-ALPHA M.G.Kapitt, S.P.Kleopoulos, D.W.Ptaff and C.V.Mobbs, Rockefeller University, New York,N.Y. 10021

We have recently described a protein induced by estrogen in ventromedial hypothalamus (VMH) and by LHRH in pituitary (Science 247:1477,1990). We have subsequently shown through sequence analysis and immunoreactivity studies that this protein, HIP-70, is an isoform of the phosphoinositide-specific phospholipase C-alpha (PLC-q) isopenzyme family (Mobbs, et al. this volume). This study was isoform of the phosphoinositide-specific phospholipase C-alpha (PLC-a) isoenzyme family (Mobbs, et.al., this volume). This study was undertaken in order to analyze brain and tissue distributions of mRNA for PLC-a/and another isozyme, PLC-B/, as well as to determine whether PLC-a/induction by estrogen is controlled primarily at the mRNA level. Northern and slot blot analyses using probes from C-F.Bennett and C.A.Ross revealed that PLC-a/mRNA levels were greatest in pituitary and uterus, high in VMH and preoptic area (POA), moderate in cerebral cortex and hippocampus, low in caudate and negligible in skeletal muscle. By contrast, PLC-B/mRNA was highest in caudate, slightly lower in hippocampus and cortex, moderate in cerebellum, VMH and POA and barely detectable in other tissues such as pituitary, uterus, and muscle. Finally, although PLC-a/mRNA levels were greatest in estrogen responsive tissues and brain regions, it does not appear likely that estrogen induction of PLC-a/mRNA by itself can account for the observed induction of the HIP-70 protein isoform. Therefore, the observed induction of the HIP-70 protein isoform. Therefore, the induction Implications of more acidic PLC-a/isoforms, as previously proposed (Science, 1990).

204.2

A POTENT OXYTOCIN ANTAGONIST REVERSES GONADAL STEROID FACILITATION OF SEXUAL BEHAVIOR. D.M. Wit. C.R. Harbaugh* and T.R. Insel. Section on Comparative Studies of Brain and Behavior, Laboratory of Clinical Science, NIMH, Poolesville, MD 20837.

Several studies suggest that the neuropeptide oxytocin (OT) is involved in the ovarian steroid regulation of sexual behavior in female rats. Recent results have shown that icv injections of OT facilitated sexual receptivity, as measured by lordosis quotient, in female rats that were maximally primed with ovarian steroids. However, it is not yet clear if OT has a physiological role in regulating sexual behavior. To determine if blocking endogenous oxytocin alters sexual behavior, we administered (icv) a potent oxytocin receptor antagonist, [d (CH₂)5, Tyr (Me)², Thr⁴, Tyr-NH₂⁹]- OVT (herein called OTA), to female rats receiving differential gonadal steroid priming. Ovariectomized females were primed for two days with either 10 µg or 1 µg estradiol benzoate (EB) followed on the third day by progesterone stimulation (250 µg, P4). In initial experiments with OTA (1 µg) administered 4 hours post P4, just prior to behavioral testing, no significant effects were noted. Subsequently, OTA (1 µg) or artificial CSF was delivered by icv injection immediately prior to progesterone administration, 4 hours prior to behavioral testing. OTA reduced lordosis quotients by 40% in the $10~\mu g~EB+P4$ and 63% in the 1 µg EB+P4 groups. Significant reductions were also observed in proceptive behaviors following OTA administration in both high and low EB groups receiving P4. In a subsequent experiment, lordosis quotients from ovariectomized females receiving EB (10 µg) without P4 (or OTA) were nearly identical to the low EB+P4 OTA-treated females. It appears that antagonism of endogenous OT reduced the effects of P4 on reproductive behavior. This interaction may be complex however, as high doses of OTA given to EB-treated females without P4 may significantly facilitate sexual receptivity.

AN ESTROGEN-INDUCED HYPOTHALAMIC PROTEIN, HIP-70, IS AN ISOFORM OF THE PHOSPHOINOSITOL-SPECIFIC PHOSPHOLIPASE C-ALPHA ISOENZYME. C.V. Mobbs, U.E. Olazabal, and D.W. Pfaff. Rockefeller Univ., New York, NY 10021.

We recently described a protein, HIP-70, which is induced by estrogen in the ventromedial hypothalamus and by luteinizing hormone-releasing hormone (LHRH) in the pituitary (Science 247:1477). Recent computer searches have revealed that the N-terminal sequence of HIP-70 (DVLELTDENFESRVSDT) matches the N-terminal sequence of a phosphoinositol-specific phospholipase C isoenzyme, PLC-alpha. PLC generates the endogenous activator of protein kinase C (PKC), and we have shown that pharmacological activation of PKC facilitates the estrogen-dependent behavior, lordosis (Pharm. Biochem. Behav. 34:865). Furthermore, effects of LHRH and substance P, both of which facilitate tordosis, are mediated in part through the phosphoinositol pathway: PLC, like LHRH, can stimulate LH release. To corroborate the identity of HIP-70, we examined the relationship between HIP-70 and immunoreactive PLC-alpha isoforms with 2-D gel immunoblots. Proteins from the ventromedial hypothalamus of estrogen-treated rats were separated on 2-D gels and transferred onto polyvinyuniuniuoride. Filters were incubated with an antibody against PLC-alpha (gift of C.F. Bennett) diluted 1:1000 in 2% serum/Tween blocking buffer, then visualized by an anti-rabbit antibody conjugated with alkaline phosphatase. After development with NBT/BCIP, blots were stained with 0.1% India ink. Based on the protein pattern context provided by the ink stain, HIP-70 precisely co-migrated with the most basic of 4 major PLC-alpha immunoreactive isoforms detected by this procedure. We therefore propose that HIP-70 is an isoform of the PLC-alpha isoenzyme family, an that activation of this isoform by estrogen, LHRH, and substance P m:y mediate some effects of these substances on neuronal function and behavior.

PROGESTERONE-FACILITATED LORDOSIS BEHAVIOR DOES NOT APPEAR TO BE CORRELATED WITH MODIFICATION OF PROTEIN PATTERNS IN VENTROMEDIAL HYPOTHALAMUS OF THE FEMALE RAT. M.E. Montemayor, C.S. Giometti', J. Taylor', and E.J. Roy. Neurosci. Program, Univ. Illinois, Champaign, IL 61820 and Biol. & Med. Div., Argonne National Lab., Argonne, IL 60439.

Does progesterone modify protein patterns in the ventromedial hypothalamus (VMH)? OVX rats (N=14) were divided into two groups: estradiol only (4 ug/kg at 0 and 18 hrs) and an estradiol plus progesterone (2 mg/kg at 37 hrs). [35S]-cysteine & methionine (0.2 mCi/animal) were infused in the VMH of freely moving animals from 37 to 41 hrs. Following infusions, animals were tested for sexual behavior and sacrificed. The VMH was assayed for changes in the patterns of newly synthesized proteins using two-dimensional gel electrophoresis followed by fluorography. Pattern analysis was done using the Tycho II software system (Clin.Chem. 27(1981)1807).

No proteins were induced or lost as a result of being treated with progesterone following estradiol. Although several proteins exhibited changes that were statistically significant (P<0.05), an independent replication (N=12) of the experiment using 0.8 mCi of labeled amino acids/animal indicated that none of these changes was reproducible. Therefore, we concluded that progesterone does not cause detectable alterations in VMH protein expression among proteins in the range of 10-100 kDa and the apparent 4.8-6.7 pI range. ESTROGEN AND PROGESTERONE RECEPTOR IMMUNOREACTIVITY (ER-IR & PR-IR) IN THE BRAIN OF PRAIRIE VOLES EXPOSED TO DIFFERENT SOCIAL CONDITIONS. Q.C. Hnatczuk, C.A. Lisciotto. L.L.DonCarlos, C.S. Carter, and J.I. Morrell, Inst. Animal Behavior, Rutgers Univ, Newark, NJ 07102; Dept. Zoology, Univ. of Maryland, College Park, MD 20742.

The prairie vole's (Microtus ochrogaster) reproductive strategy is different from most mammals. It is reproductively quiescent until it contacts an unfamiliar vole of the opposite sex. The monogamous bonded pair undergoes a charge in behavior and physiology including

The prairie vole's (Microtus ochrogaster) reproductive strategy is different from most mammals. It is reproductively quiescent until it contacts an unfamiliar vole of the opposite sex. The monogamous bonded pair undergoes a change in behavior and physiology, including mating and ovulation. To examine the effect of social stimuli on the brain, we used immunocytochemistry to visualize the ER-IR & PR-IR cells of paired (sexually receptive) and unpaired (naive) male and female voles. The largest number and most intensely labeled ER-IR cells were observed in the medial preoptic area (MPOA), bed nucleus of the stria terminalis (BNST), ventromedial nucleus (VMN) of the hypothalamus, the arcuate, and the medial amygdala. ER-IR cells were also seen in the central grey, lateral hypothalamus, lateral septum, the diagonal bands, the dorsomedial hypothalamus, zona incerta, superior colliculus, and the dorsal spinal cord. PR-IR was observed in the MPOA, BNST, the anterior, paraventricular and VMN of the hypothalamus and the medial amygdala. Social stimulation resulted in dramatic changes in the number of ER-IR neurons and in the intensity of ER labeling. Supported by Sigma Xi (OCH).

DEVELOPMENT OF SEXUALLY DIMORPHIC SPATIAL ABILITY: NEURAL SITES OF ESTRADIOL ACTION. Christina L. Williams. Rebecca A. Cohen, and Warren H. Meck. Departments of Psychology, Barnard College and Columbia University, New York, NY 10027.

Previous research has demonstrated that perinatal exposure to estradiol improves choice accuracy during acquisition of a 12-arm radial maze task in Sprague-Dawley rats (Williams et al., Behav, Neurosci., 1990). The current study was designed to examine the possible neural sites at which estradiol might act to cause organizational changes in visuospatial memory. Five groups of male Sprague-Dawley rats were treated as follows within 6 hrs of birth: HP-neonatally castrated and given bilateral implants of estradiol (E) aimed at the medial hippocampus; FC-neonatally castrated and given bilateral implants of E aimed at the frontal cortex; HY-neonatally castrated and given bilateral implants of E aimed at the ventromedial hypothalamus; CS-neonatally castrated; CN-castrated at puberty. At 60 days of age, subjects were trained on a 12-arm radial maze with 8-baited and 4-unbaited arms. After rats' choice performance reached steady-state reacquisition of the task was conducted in a novel training environment. Results revealed that CN, HP, and FC groups were significantly more accurate in choice performance than CS and HY groups during the initial acquisition phase; these differences disappeared at steady-state and re-emerged during the reacquisition phase. These data provide preliminary evidence to suggest that the hippocampus and frontal cortex are sites of estradiol action for the organization of sexually dimorphic visuospatial ability.

INTRAUTERINE POSITION PHENOMENON AND PRECOPULATORY BEHAVIOR OF HOUSE MICE. B. M. Jubilan and J. G. Nyby. Dept. of Psychology, Lehigh University, Bethlehem, PA 18015.

Fetuses are exposed to different testosterone titers prenatally depending on intrauterine position. In general, fetuses located between two males (2Ms) are masculinized relative to those located between two females (0Ms). Fetuses next to single male (1Ms) are intermediate. Most studies examining the behavioral significance of intrauterine position have focused on copulatory behavior.

studies examining the behavioral significance of intrauterine position have focused on copulatory behavior. In the present study the effects of intrauterine position upon two precopulatory behaviors, sexual preference and ultrasonic courtship vocalizations were investigated. Three strains of mice were used. The anogenital distances were as predicted (2M>OM) but not statistically significant. Although the effects on sexual preferences were not profound, some subtle effects seemed evident: the OM males among the males and the 2M females among the females appeared more discriminating in their preferences for male and female odors. The frequency of ultrasonic vocalizations was not significantly different for the different intrauterine categories of males. Genotype did not significantly contribute to the variability in either behavior.

In conclusion, with the genotype and sample sizes used intrauterine position did not appear to strongly affect the adult precopulatory behaviors or morphology assayed.

SEX DIFFERENCES IN THE NUMBER, DISTRIBUTION, AND PROJECTIONS OF TESTOSTERONE TARGET NEURONS IN THE MEDIAL PREOPTIC AREA AND BED NUCLEUS OF THE STRIA TERMINALIS OF RATS. C.A. Lisciotto and J.I. Morrell. Inst. Animal Behavior, Rutgers University, Newark, NJ 07102.

Retrograde tracing was combined with steroid autoradiography to investigate the projections of testosterone target neurons in preoptic, limbic and hypothalamic regions to the midbrain in male and female rats. Autoradiograms were prepared from the brains of GDX/ADX male and female rats that had received an injection of a fluorescent retrograde tracer into the midbrain, and an iv injection of [3H]-testosterone. Neurons that concentrate testosterone and project to the midbrain were observed in the bed nucleus of the stria terminalis (BST), the medial preoptic nucleus (MPN) and the ventro-medial nucleus of the hypothalamus. Male rats had more testosterone-concentrating neurons in the MPN and the BST than female rats. Moreover, the subset of testosterone-concentrating neurons in the MPN and BST that project to the midbrain was greater in male than female rats. Sex differences in the neuronal connectivity of androgen target neurons may underlie sex specific behavioral responsiveness to androgens. Supported by HD07243 to C.A.L. and HD22983 to J.I.M.

LESION OF THE HABENULAR COMPLEX DISRUPTS THE HORMONAL ONSET OF MATERNAL BEHAVIOR IN THE RAT. K.P.Corodimas, J.S. Rosenblatt,* A.D. Mayer* and J.I. Morrell. Inst. of Anim. Behav., Rutgers Univ., Newark, NJ 07102.

The habenular complex (Hbc) is reciprocally

The habenular complex (Hbc) is reciprocally connected with the preoptic area, substantia nigra, and ventral tegmental area; regions key to the control of maternal behavior in the rat. This study explored whether the Hbc is part of a neural circuit necessary for the initiation of maternal behavior. On day 12 of pregnancy bilateral radiofrequency lesions were made in the Hbc, or as a control, just dorsal in the medial hippocampus. A third group served as unoperated controls. All animals were hysterectomized, ovariectomized, and given 20µg/kg estradiol benzoate on day 16 of pregnancy, then tested 48h later with pups for maternal behavior. Retrieval, nursing, and nest building were severely disrupted following Hbc lesions, whereas control groups displayed shortlatency maternal behavior. Activity levels and body weight changes were similar across groups. These results suggest that the Hbc or axons traversing it are important for the onset of maternal behavior. Supported by Sigma Xi, Grants-in-Aid of Research (KPC).

RETENTION-SPECIFIC DECREASES IN CA1 PKC FROM RABBITS 3 HOURS AFTER CLASSICAL CONDITIONING. J.L. Olds, B.G. Schreurs, M. Stultz* and D.L.

Alkon.LMCN,NINDS,NIH.Bethesda MD. 20892.

It has been demonstrated that membraneassociated PKC (mPKC) undergoes massive changes associated PKC (mPKC) undergoes massive changes in its distribution at 24 h and 72 h after 3 d of rabbit NM conditioning (Olds et al. Science 1989). The present study was designed to investigate shorter term changes in mPKC after NM conditioning. Rabbits received 3 d of training (P), or 3 d of unpaired trials (UP) or were left in their home cages (N). Three h after the last trial, animals from the P and UP groups were sacrificed and mPKC was quantified in all subjects using the [3H]-PDBU technique. Preliminary data shows that conditioned animals Preliminary data shows that conditioned animals had significantly lower mPKC in CA1 compared to control rabbits (P 20.71±.885, UP 24.0±1.1, N 24.1±1.6; p<0.05). We interpret these results to further confirm the involvement of PKC in memory storage processes (Alkon et al,

205.3

A SIMPLE PDP MODEL SIMULATES SPATIAL CORRELATES OF HIPPOCAMPAL NEURONAL ACTIVITY. M.L. Shapiro, P.A. Hetherington*, H.B. Eichenbaum, and W.J. Fortin*, Department of

Psychology, McGill University, Montreal, Quebec H3A 1B1.
Hippocampal place cells fire when behaving rats occupy selective regions of spatial environments, and seem to encode relationships among spatial stimuli. Here, a simple neural network model that computes locations from configurations of distal cues simulates many aspects of place fields and predicts quantitative relationships between place field and environmental

A 3 layer neural network was trained to compute local representations of locations from visual angles of simulated cues using back propagation. Each input unit encoded the visual angle of one cue, and was connected to every association unit; each association unit was connected to every output unit. After training, the network accurately encoded locations, and the activation of units in the association layer resembled place field activity in the hippocampus. Like actual place cells, simulated units: (1) were active in selective locations; (2) were less accurate spatially than the network as a whole, thereby demonstrating coarse coding; (3) had directional, multiple subfields; and (4) persisted after single cue removal, showing graceful degradation. Also, like local groups of place cells, groups of simulated units had fields that covered most of the environment in an overlapped manner. Quantitative variants of the model predict that single place cells will have more subfields as the spatial complexity of an environment increases. Thus, a simple neural network model with 2 striking features of the hippocampal system, distributed connections and synaptic plasticity, can encode spatial locations using a representational scheme similar to that found in the hippocampus, and may predict and explain new properties of place fields.

205.5

EMERGENCE OF BASIC-LEVEL RECOGNITION PHENOMENA FROM SIMULATION OF PRIMARY SENSORY CORTEX.

R.Granger, J. Ambros-Ingerson', G.Lynch. Center for the Neurobiology of Learning and Memory, Univ. of Calif., Irvine, CA. 92717.

A simulation of the physiological activity of the two superficial layers of olfactory paleocortex (prinform cortex) has shown that the network yields coherent activity that can be interpreted as the storage, organization and retrieval of olfactory memories. Moreover, the repetitive sampling operation of the paleocortical network causes it to generate multiple responses to a single input. With learning via synaptic long-term potentiation (LTP), these responses become hierarchically ordered, such that the first-cycle responses are increasingly finer-grained (Ambros-Ingerson, Granger and Lynch, Science, 247:1344-48, 1990). These findings suggest that sensory cues might be "iteratively recognized" at a sequence of successively lower levels, with the first level recognized being a natural "entry level" for perceptual processing. Cognitive studies of visual and conceptual recognition in hierarchically organized domains suggest that such preferred levels do exist and exert a strong influence over early processing: people robustly prefer a "basic level" description (e.g., "bird" in the hierarchy "animal", "bird", "sparrow"), recognizing cues faster at this level and more frequently than either superordinate or subordinate names (Mervis and Rosch, Ann.Rev.Psych., 32:89–115, 1981). We tested the idea that the perceptual processing performed by primary sensory brain structures might visel analogs of basic level "destription feet through the processing and processing performed by primary sensory brain structures might visel analogs of basic level "destription feet through the processing performed by primary sensory brain structures might visel analogs of basic level "destription feet through the processing performed by primary sensory brain structures might visel analogs of basic level "destription feet th superordinate or subordinate names (Mervis and Rosch, Ann.Rev.Psych., 32:89–115, 1981). We tested the idea that the perceptual processing performed by primary sensory brain structures might yield analogs of basic level effects through simulations of piriform cortex using a stimulus structure from a study of basic level effects in human clasification (Corter, Gluck and Bower, Proc.Cog.Sci.Soc., 1988). We find that the first cycle piriform responses of the simulation do prefer the basic level, whereas subsequent responses prefer subordinate levels. This suggests that the unsupervised preprocessing performed by the pirform cortex is directly analogous to aspects of the cognitive phenomena of basic level superiority in early perceptual and conceptual processing. ACQUISITION-SPECIFIC CHANGES IN CA3 PKC FROM RABBITS UNDERGOING CLASSICAL CONDITIONING. $\underline{A.M.}$ Scharenberg, J.L. Olds, B.G. Schreurs, A.M. Craig and D.L. Alkon, LMCN, NINDS, NIH. Bethesda MD. 20892.

It has been demonstrated that membrane-associated PKC (mPKC) undergoes an increase during retention after rabbit NM conditioning (Olds et al. Science 1989). The present study was designed to investigate PKC distributional changes during aquisition. Initially, a time changes during aquisition. Initially, a time point was selected for assessing PKC distributional changes. Rabbits received either 1 d or 2 d of NM training. These animals showed an increase in % CRs on day 1 of conditioning relative to the unpaired (UP) control group (p<0.001). Additionally, for the paired group, the % CRs on day 2 was increased relative to day 1 (p<0.001). A second experiment quantified mPKC in the brains of rabbits sacrificed immediately after receiving either 1 d of paired stimuli after receiving either 1 d of paired stimuli (n=10), 1 day of unpaired stimuli (n=6), or no behavioral manipulation (n=6). [3H]-PDBU binding was increased in the stratum oriens of CA3 for paired animals relative to either of the control groups (Paired 32.4±1.2, UP 27.2±1.4, Naive 27.6±0.9; p=0.009). We interpret this finding to further confirm the importance of PKC in associative learning.

205.4

THE SIGMA-PI MODEL NEURON: ROLES OF THE DENDRITIC TREE IN ASSOCIATIVE LEARNING. B. W. Mel. Computation and Neural Systems Program, Caltech, 216-76, Pasadena, CA, 91125.

A model for associative learning in cerebral neocortex has been previously

proposed (Soc. Neurosci. Abst., 208.5, 1989). In this model, the extrinsicallyprojecting pyramidal cells of layers 2, 3, and 5 of association cortex are modeled as sigma-pi units, where a sigma-pi unit computes its activation level as a sum of contributions from a set of multiplicative (or locally-thresholded) clusters of synapses distributed throughout its dendritic tree. The model demonstrates how a broad class of biologically-relevant nonlinear associative learning prob-lems can be solved in this system by modifying only a single layer of excitatory synapses under the control of a simple Hebb-type learning rule. The model also accounts for a variety of features of cortical anatomy, physiology, and bio-physics whose relations to learning have remained poorly understood. These include, (1) three learning-related roles for the NMDA channel, one of them new, (2) the gross asymmetry in number and patterns of termination of excitatory vs. inhibitory synapses onto cortical pyramidal cells, as well as the apparent lack of plasticity at inhibitory synapses, (3) the replication of like-activated neurons beneath a single point in cerebral cortex, and in particular the clumping of apical dendrites of pyramidal cells on their rise to the cortical surface, (4) the complex 3-dimensional arborizations of axons and dendrites in layer 1, which give rise to a rich "combinatorial" association interface crucial to the current model, and (5) putative rules for activity-dependent axon growth and synaptogenesis during associative learning. Compartmental modeling studies are currently underway to test the crucial assumption of the sigma-pi learning scheme, namely the degree to which a complex dendritic tree can support a large number of independent AND-like operations among local clusters of

205.6

VISUAL RESPONSE PROPERTY CHANGES OF THE MONKEY PREFRONTAL NEURONS DURING THE LEARNING OF A VISUAL GO/NO-GO TASK WITH EYE FIXATION. K. Kubota and A. Mikami. Dept. of Neurophysiol., Primate Res. Inst., Kyoto Univ., Inuyama, Aichi, 484, JAPAN.

During the learning of a visual discrimination task with CO/NO COnformance.

with GO/NO-GO performances, the number of task-related neurons increases progressively with increase of performance level (Neurosci. Res., 3:106, '85). To know how visual responsiveness develops during the learning, 3 Rhesus monkeys were trained to perform a visual GO/NO-GO task with eye fixation and neurons responding to visual cues were recorded from areas 46 and 8. While to visual cues were recorded from areas 46 and 8. While the monkey was fixating his eyes to a pair of slits with lever press, red or green cues (2.4 deg circle, 15 deg left to slits) was presented. On changing slit orientation, the monkey released his hand to red (GO trials), or withheld his hand to green (NO-GO trials). In undertrained stage 14 neurons obtained during 400 penetrations responded to either cue. And in welltrained stage 50 neurons obtained during 84 penetraions responded to either cue (N=38) or both cues (N=12). And about 2/3 of neurons had clear receptive field ipsi- and/or contralaterally. Thus, during the learning are emerging visual neurons, which receive learning are emerging visual neurons, which receive facilitatory influences of wide receptive field and color-cue specific activations.

LEARNING-SPECIFIC DIFFERENCES IN PURKINJE CELLS OF LOBULE HVI: INTRACELLULAR RECORDING IN A RABBIT CEREBELLAR SLICE. B. G. Schreurs, J. V. Sanchez-Andres, and D. L. Alkon. Lab. of Molecular & Cellular Neurobiology, NIH, Bethesda, MD 20892.

We report the development of a rabbit cerebellar slice of lobule HVI and describe classical conditioning-specific differences in the threshold for dendritic spikes within Purkinje cells of ipsilateral lobule HVI.

Intracellular recordings made in rabbit Purkinje cell dendrites of lobule

Intracellular recordings made in rabbit rurkinje cell denorites of footile HVI revealed membrane potential, action potential, and input resistance values that were similar to values described for vermal Purkinje cells in guinea pig and rat. Activation of parallel fibers and climbing fibers produced synaptic potentials also similar to those previously described in other species: however, patterns of autorhythmicity were more marked than previously reported. Indeed, many of our recordings exhibited clear sequences of somatic, dendritic, and hyperpolarized

phases for as long as the cell was held.

A comparison of Purkinje-cell dendritic activity in lobule HVI for animals subjected to classical conditioning, explicitly unpaired, or no treatment procedures revealed a significant (p < .01) decrease in the threshold for dendritic spikes in cells from conditioned animals (1.2 ± 0.18 nA; n = 9 cells) versus cells from unpaired $(1.8 \pm 0.22 \text{ nA}; \text{n} = 9)$ and untreated animals $(2.2 \pm 0.25 \text{ nA}, \text{n} = 7)$. There were no and untreated animals $(2.2 \pm 0.25 \text{ nA}, n = 7)$. There were no significant differences in membrane potential or input resistance among the treatment groups (p's > 10). The present results suggest a conditioning-specific increase in Purkinje-cell dendrite excitability in lobule HVI which may have consequences for classical conditioning of the rabbit nictitating membrane response.

RESPONSES OF PRIMATE NUCLEUS BASALIS NEURONS RELATED TO PPETITIVENESS, AVERSIVENESS, AND AROUSAL. R.T. Richardson and

M.R. DeLong. Dept. Neurology, Johns Hopkins U., Baltimore, MD 21205 In monkeys performing various behavioral tasks, changes in the discharge rates of nucleus basalis neurons are primarily associated with stimuli related to a water reward. To determine whether these responses are related to the appetitive or arousing quality of the reward-related events, we studied the responses of basalis neurons to appetitive stimuli (water rewards), aversive stimuli (air puffs to the snout), and neutral somatosensory (passive displacements of the forearm) and auditory (pure tones) stimuli in two naive rhesus monkeys. With the neutral stimuli, 21% of 141 basalis neurons had significant changes in discharge rate following forearm displacement, and 3% of 74 neurons responded to tones. In contrast, 57% of 249 basalis neurons responded to water delivery, and 59% of 113 neurons responded to air puff. Of 85 neurons responding to either air puff or water, 61% had qualitatively similar responses to both stimuli (i.e. both increases or both decreases), 5% had opposite responses, 21% responded only to water, and 13% responded only to air puff. Moreover, 97 neurons were recorded during delivery of increasing volumes of water (0.1, 0.2, and 0.4 ml). Forty nine neurons were sensitive to the size of the water delivery in that they had progressively larger responses to the larger volumes. Of these neurons, 80% had qualitatively similar responses to the aversive air puff, thus suggesting that they were sensitive to the arousal component of the stimuli. In conclusion, a sub-population of basalis neurons appears to be differentially responsive to appetitive or aversive stimuli, but a larger sub-population appears to be responsive to both appetitive and aversive stimuli. The responses of neurons in the latter group appear to reflect the arousing properties of sensory stimuli.

LEARNING-ASSOCIATED G-PROTEIN, CP20, INHIBITS

LEARNING-ASSOCIATED G-PROTEIN, CP20, INHIBITS ORGANELLE MOVEMENT WITHIN AXONS S. Moshiach. T. Nelson, J.V. Sanchez-Andres, & D.L. Alkon Lab. of Molecular & Cellular Neurobiology, NIH, Bethesda, MD 20892

The concentration of a 20,000 M.W. G-protein, cp20, was increased 24 hrs after classical conditioning of the mollusc Hermissenda but not after control paradigms (Nelson et al, Science, 1990). cp20 potently reduces the same two K+ currents (in the type B cell) reduced by election to artificing the condition of t classical conditionings.

Here we asked whether cp20 might also regulate axonal transport and thereby perhaps initiate persistent structural changes measured on days after the conditioning. The movements of organelles (2-20µm) in length were visualized within sections of Carcinus axons which had been dissected free and exposed to Protease (2mg/ml, 5mins). Images were acquired with video-enhanced DIC, processed with an Image-1/AT analysis system (Universal Imaging), displayed on a SONY PVM-122 monitor and recorded at 30 frames/s. Organelle movements within a 4 min interval were quantified and counted using subtraction with shear as a filter to include cells unsticate which could be unequired. a filter to include only particles which could be unequivocally identified. cp20 (10µM) application was followed within 15 min by highly significant reduction (p<.001) of particles moving across a 10µm length of the axon, from 23.57 ±1.34 to 12.58±1.47 (N=7). Boiled cp20 application under identical conditions did not alter particle movement (20.5±5.8 before vs. 19.25±6.94 during application, N=4, N.S.). This cp20-induced regulation of organelle movement could, therefore, profoundly alter transport to cellular sites which undergo changes of excitability and structure during storage of associative memory.

ROLE OF CEREBELLUM IN CLASSICAL CONDITIONING J.C. Houk. Department of Physiology, Northwestern University Medical Center, Chicago, IL 60611.

The cerebellum is thought to be important in classical conditioning (cf. C. Yeo in Cerebellum and Neuronal Plasticity, Plenum Press, 1987; M.A. Gluck & R.F. Thompson in Neuroscience and Connectionist Theory, Lawrence Erlbaum Assoc., 1990). Several models assume that the US is transmitted to the cerebellum by climbing fibers and that both the CS-US association and the motor command that controls the CR are established within the cerebellum.

command that controls the CR are established within the cerebellum. The adjustable pattern generator (APG) model of the cerebellum suggests a different role for the cerebellum in conditioning (J.C. Houk in Models of Brain Function, Cambridge Univ. Press, 1989; J.C. Houk, S.P. Singh, C. Fisher & A.G. Barto, in Neural Networks for Control, MIT Press, 1990). CSs and USs function as trigger signals that act on motor cortex, red nucleus and brainstem neurons. These inputs initiate activity in recurrent loops through the deep cerebellar nuclei; positive feedback in these loops is postulated to be the driving force for commanding movement (the CR). Climbing fibers train Purkinje cells to control this positive feedback

and shape it into motor programs that control accurate movements.

Thus, the APG model proposes learning at two separate sites.

CS-US associations are learned outside of the cerebellum by cs-us associations are learned outside of the cerebellum by synaptic modification of sensory inputs to motor cortex, red nucleus and brainstem neurons, independent of climbing fiber activity.

Learning accurate motor programs for CRs occurs in cerebellar parallel fiber synapses guided by climbing fiber activity.

SELECTIVE EFFECTS OF LIDOCAINE MICROINJECTIONS IN THE REGION OF THE SPINAL TRIGEMINAL NUCLEUS ON THE CONDITIONED AND UNCONDITIONED RESPONSES OF THE RABBIT NICTITATING MEMBRANE REFLEX. V. Bracha*, J.-Z. Wu*, M. Cartwright* and J. R. Bloedel. Div. of Neurobiology, Barrow Neurological Institute, Phoenix, AZ. 85013

Experiments were performed with intact rabbits to test the hypothesis that regions of the trigeminal nuclear complex are selectively involved in mediating conditioned responses (CR) following the classical conditioning of the nictitating membrane reflex (NMR). The NMR was conditioned in white adult New Zealand albino rabbits using a traditional delay paradigm over a seven day period. The conditioned stimulus, a 1 kHz, 85 db tone superimposed on 70 db white noise, was applied 350 msec prior to an unconditioned stimulus (UCS), a 100 ms duration airpuff. After each animal reached a criterion of 95% CS responding, a baseline series of three-trial sequences was performed. These sequences consisted of one paired CS-UCS trial, one airpuff UCS trial and one light UCS trial. The latter was used as a control to indicate whether changes in response amplitudes could be attributed to spread of lidocaine to output projections of the motor nuclei. The effects of microinjecting 0.3 to 1.0 ul of 4% buffered lidocaine were determined at sites located approximately 3 mm caudal to the facial nucleus. Injections at the lateral aspect of the spinal trigeminal nucleus reduced the amplitude and incidence of the CR and the amplitude of the UCR. In contrast, injections at the junction of the medial spinal trigeminal nucleus and the reticular formation resulted in a reduction in the incidence as well as the amplitude of the CR without a parallel effect on the UCR. The data suggest that the changes in neuronal interactions required for the execution of the conditioned NMR may occur at the initial stages of this reflex pathway. Supported by NIH Grant NS21958.

SPINAL CORD REGENERATION IN AVULSION INJURIES OF THE BRACHIAL PLEXUS Dr. J. Terzis & Dr. H. Kai* EVMS, MRC, Norfolk, VA 23507

The functional deficit following avulsion injuries to the brachial plexus is devastating. To date, it has been impossible to use the axons of the avulsed motor neurons in reconstructive efforts.

We have established an avulsion model in the rat. The normal anatomy of the cervical cord will serve as the control group (A). Total avulsion of C5 to T1 will be carried out in group B, while transection of C5 to T1 will be carried out in group B, while transection of C5 to T1 will be carried out in group C and the involved spinal cord will be studied morphologically for the extent of injury in the ventral horn. In groups D and E, total avulsion and/or transection of the brachial plexus roots will be followed by implantation of C6 spinal nerve into the lateral column of the spinal cord at C7 level. HRP studies of the musculcoutaneous nerve (MC) will lead to identification of the neuronal ventral horn pool in the normal and injured cervical spinal cord. Exact quantitation of the number of these neurons will be correlated with quantitative axonal morphometry of the MC nerve. This data will be correlated with muscle typing and quantitation of end plates in the biceps muscle. EMG and muscle function tests of the normal and reinnervated biceps will be done in all groups.

DORSAL SPINAL VENOUS OCCLUSION MODEL IN THE RAT: PRELIMINARY OBSERVATIONS. <u>A. Martinez-Arizala</u>, J. Mora*, B. Green*, and N. Hayashi*. The Miami Project, University of Miami School of Med., Miami, Fl 33136.

Although vascular disruption occurs with traumatic spinal injury, the effects and involvement of the spinal venous system are undefined. Improper venous drainage can certainly contribute to the development of tissue edema and can impair its resolution. In order to better understand spinal venous dysfunction, we developed a model of spinal venous occlusion in the rat. A T-7 to T-9 laminectomy was performed in anesthetized S-D rats and the dorsal spinal vein was focally coagulated at the caudal and distal ends of the laminectomy. Occasionally, the dorsal vein became visibly engorged and small hemorrhages were seen one to two hours after occlusion. During the first days following occlusion, all animals had hindlimb paralysis from which they slowly recovered. In addition, some animals also developed neurogenic bladders. Pathological examination of the tissues at 1 and 3 days post occlusion revealed marked hemorrhagic infarction and edema affecting primarily the dorsal columns and the dorsal gray matter. At one week these regions were necrotic and extensively infiltrated by macrophages. By one month pronounced tissue loss and some cystic cavitation was present in the lesioned areas. These results demonstrate that extensive behavioral and pathological changes can be associated with dorsal spinal cord venous dysfunction. Nonetheless, its precise in role in spinal injury still remains to be fully elucidated.

TIME - DEPENDENT LAMINECTOMY EFFECTS UPON ENERGY METABOLISM IN THE RAT SPINAL CORD. A.Mautes* and A.C. Nacimiento. Neurosurgical Research Laboratory, Saarland University Medical School, 6650 Homburg/Saar,FRG.

In a study of changes in energy metabolism in the spinal cord following compression trauma, a pretraumatic metabolic base line has to be defined, particularly to take into account the possible effects of laminectomy per se. Using a computer assisted bioluminescence image analysis technique (cf.Nacimiento et al.,Soc.f.Neurosci.Abstr. 1988,14,460.16) we measured simultaneously the regional content of ATP,glucose and lactate in tissue sections of the exposed lumbar, and of the unexposed thoracic cord as internal control. Immediate and delayed (3h) laminectomy effects were compared. Results: a) ATP content did not change significantly;b) glucose content increased after 3h exposure in both lumbar and thoracic sections to levels just short of significance. c) lactate increased significantly after 3h (i)in lumbar sections with and without exposure, and (ii) in thoracic sections after lumbar exposure. Thus the spinal cord energy state cannot be considered as normal under conditions usually prevailing in experimental spinal cord trauma investigations. Supported by DFG-Grant Na 115/5-1.

VENTRAL SPINAL CORD ISCHEMIA MODEL PRODUCED BY PHOTOCHEMICAL LASER OCCLUSION OF THE ANTERIOR SPINAL ARTERY. P.W. Madsen, R. Prado* B. Watson and A. Martinez. The Miami Project, Univ. of Miami Sch. of Medicine, Miami, FL 33136

Although spinal cord ischemia is a significant component of spinal injury, its precise role is poorly understood. Previous attempts to produce spinal ischemia by occlusion of the aorta in the rat produced inconsistent results. We report an effective model of rat spinal cord ischemia produced by occlusion of the cervical anterior spinal artery (ASA). Subtotal corpectomy of C5 or 6 was performed on anesthetized SD rats to expose the ASA which was occluded via the photochemical laser (Watson et al. Brain Res.). Following recovery, rats were subjected to sequential evaluation of motor (modified Tarlov scale, inclined plane and forepaw strength), and sensory function for one month post procedure. Maximal deficit was present within 72 hours post occlusion and the forelimbs were more severely affected than the hindlimbs. The motor deficits then improved until a plateau was reached at the second However, forelimb sensory function deteriorated after an early period of recovery during the first five days. This successful development of a rodent model of spinal cord ischemia will allow further characterization of the contribution of ischemia in spinal cord injury.

206.4

DISTRIBUTION AND CONCENTRATION OF ELEMENTS IN RAT SPINAL CORD AXONS AND GLIA. R.M. LoPachin, R.S. Lagasse, C.M. Castiglia* M. Foster and A.J. Saubermann. Dept. Anesthesiology, SUNY, Stony Brook, NY11794.

Little information is available concerning the elemental composition of spinal cord axons. Acquiring such knowledge is important because elements participate in almost every aspect of axonal function, and because axonal degeneration is presumably mediated by disruption of subaxolemmal Ca, Na and K. To determine water content, and the concentrations (mmol/kg dry or wet weight) and distributions of elements in spinal cord axons, we used electron probe X-ray microanalysis (EPMA). Rat cervical spinal cords were rapidly excised, frozen and then cryosectioned (500 nm). Results show that the most prominent element in myelinated axons was K. Axoplasm of large and medium fibers contained similar concentrations of this element (e.g., 1947±61 dry wt, 175±6 wet wt), whereas small axons exhibited a lower K content (1391±100 dry wt, 149±11 wet wt). Regardless of axon size, low axoplasmic concentrations of Na, S. Ca and Mg were detected. Water content for all axons was approximately 90±1%. Dry wt elemental composition of mitochondria was similar to that of larger axons. However, with a water content of 69±3%, wet wt elemental concentrations were different from axons (e.g.,Kmito=523±35 wt wt). As expected myelin displayed high wet and dry wt concentrations of P with 33±3% water. Glial cell cytoplasm contained relatively high concentrations of both P and K with a water content of 68±4%. These results in spinal cord are remarkably similar to EPMA measurements of axons and glial cells in rat sciatic nerve (J. Neurochem. 51: 764-775, 1988), and form the basis for studies of trauma- and chemical-induced injury in rat spinal cord. (supported by ES03830 and NS21455)

KETAMINE PREVENTS NEURONAL INJURY AND DEATH DURING MULTIPLE IMPACT RAPID ACCELERATION INJURY (RAI)

J. H. Lucas and A. Wolf. Dept. of Biological Sciences and Center for Network Neuroscience, Univ. of North Texas, Denton, TX 76203.

We have developed an in vitro model of RAI in which a ballistic pendulum is used to impact monolayer cultures of mammalian CNS cells. Impacts are delivered normal

to impact monolayer cultures of mammalian CNS cells. Impacts are delivered normal or tangential to the plane of growth at 3-5 sec intervals. Culture medium is removed during RAI (60 sec deprivation). Death of spinal cord (SC) neurons during tangential RAI occurred when the cumulative acceleration exceeded 350 g, and reached a maximum of 50% at 850-1700 g (5-10 impacts). Death was only 10% after multiple normal impacts or medium deprivation. Neuronal death occurred within 15 min with little additional loss at 24 h or 48 h. Common morphological changes observed in 393 selected neurons (11 cultures) after multiple tangential impacts were somal

little additional loss at 24 h or 48 h. Common morphological changes observed in 393 selected neurons (11 cultures) after multiple tangential impacts were somal swelling, nuclear/nucleolar shifting, increased nuclear prominence, and enucleation. Measurements of somal dimensions of 162 neurons (4 cultures) subjected to 10 tangential impacts indicate that smaller neurons may be more sensitive to RAI. For neurons with avg. somal radii of 6-10 µm, 11-15 µm, 16-20 µm and 20-25 µm death was 53%, 45%, 39% and 17% respectively. However, because SC cultures contain a mixed neuronal population, it is possible that these data indicate a sensitivity of neuronal type rather than of size.

When the maximum nontoxic concentration of ketamine (100 µM) was added to 3

When the maximum nontoxic concentration of ketamine (100 µM) was added to 3 SC cultures, neuronal death after tangential RAI (10 impacts, 1700 g) was 15% compared to 44% death in the 3 impacted control (no ketamine) group. Death in 6 nonimpacted cultures (medium deprivation only) in the presence and absence of ketamine was 6% and 12% respectively. Ketamine also prevented morphological changes during RAI. These data suggest: 1) a particular neuronal type(s) may be more sensitive to multiple impact RAI, and 2) neuronal sensitivity to multiple impact RAI may depend on the density of the NMDA receptor/ion channel complexes in the dendrosomatic membranes. Supported by grants to G. Gross from NIH (PHS 23686) and the Hillcrest Foundation of Dallas, TX founded by Mrs. W. W. Caruth, Sr.

ANTIBODIES TO THE 68kD NEUROFILAMENT SUBUNIT READILY IDENTIFY TRAUMATICALLY INDUCED AXONAL SWELLINGS, A Yaghmai* and J.T. Povlishock. Dept. of Anatomy, Medical College of Va., Virginia Commonwealth University, Richmond, VA 23298.

Reactive axonal change has long been recognized as a feature of traumatic brain injury and is a major determinate of morbidity. To follow the genesis of the reactive axonal change, various ultrastructural studies have relied on invasive techniques using anterograde axonal transport which, as such, exert some focal damage on the previously injured brain. To obviate this problem, we have utilized the neurofilamentous change associated with reactive axonal damage to provide a non-invasive way to follow the progression of axonal abnormality. To this end, anesthetized rats and cats were subjected to moderate fluid-percussion brain injury and allowed to survive for periods aunormany. To this end, a meshieruzer lats and cats were surjected to moderate fluid-percussion brain injury and allowed to survive for periods ranging from hours to days. At that time, the animals were reanesthetized, perfused with aldehydes and their brains processed for the immunocytochemical visualization of the neurofilament 68kD subunit as well immunocytochemical visualization of the neurofilament 68kD subunit as well as its phosphorylated and non-phosphorylated epitopes. Through this approach, all reactive axons revealed some immunoreactivity to all employed antibodies; however, the antibody to the 68kD subunit proved most sensitive. Not only did it allow for the consistent recognition of the reactive axons, but also, its use was not complicated by any background staining which was a significant problem in the case of the phosphorylated epitope. The results of this investigation suggest that antibodies to the 68kD subunit constitute excellent markers for the detection of reactive axonal change. Interestingly, the conspicuous presence of this subunit with traumatic brain injury may provide insight into the pathogenesis of the reactive axonal change. Specifically, it is posited that the striking immunoreactivity is associated with the unmasking of the 68kD subunit, perhaps, due to structural failure. Supported by NS-20193

A CONTROLLED CORTICAL CONTUSION MODEL OF TRAUMATIC BRAIN INJURY IN THE RAT: BIOMECHANICAL AND BRAIN INJURY IN THE RAT: BIOMECHANICAL AND NEUROLOGICAL OBSERVATIONS. C.E. Dixon, G.B. Moore, G.L. Clifton, D.C. Viano, J.W. Lighthall, S.A. Ridella, Worrel, P.J., and Hayes, R.L. Depts, Rehabilitation Medicine and Neurosurgery Medical College of Va., Virginia Commonwealth University, Richmond, VA 23298, and Biomedical Science Dept. General Motors Research Laboratories, Warren, MI 48090.

Although rat models have been useful in studying moderate traumatic brain injury, there is currently no model of severe head injury in the rat. The controlled cortical contusion model uses a constrained stroke pneumatic impactor to allow independent control of the contact velocity and compression

The first objective was to determine the relative contributions of contact velocity (V) and compression (C) to acute neurological deficits in response to controlled cortical impact. Sixty-two animals were injured at 1 of 18 different combinations of impact V and C parameters. Results showed that acute neurologic responses correlated better with velocity-compression product (VC) than with either V or C alone. At low contact V, functional impairment is best predicted by maximal C. However, as V increases, injury severity becomes a function of (VC), demonstrating the rate sensitivity of brain tissue

The second objective was to characterize the chronic vestibulo-motor responses to 3 injury levels. Twenty-one rats were injured with a contact V of 6 meter/sec at one of three depths of C: 1, 2, or 3 mm. Performance on beam balance and walking tasks were measured daily for 5 days post-injury. Results show greater deficits with increasing depths of deformation.

The rat cortical contusion model produces a graded injury response that may more closely approximate severe human head injury than other rat brain injury models. Supported by CDC R49/CCR303547 and NIH 12587 and 21458.

SELECTIVE NEURONAL LOSS IN THE THALAMIC
RETICULAR NUCLEUS FOLLOWING INERTIAL CLOSED
HEAD INJURY IN PRIMATES. D. T. Ross, T. A. Gennarelli*,
D.I. Graham*, and J.H. Adams* Head Injury Center, Division of
Neurosurgery, University of Pennsylvania, Philadelphia, PA 19104, and
Dept. of Pathology, Southern General Hospital, Glascow, Scotland.
The thalamic reticular nucleus (RT) is a pure population of GABAergic
neurons which provide inhibitory control for thalamic relay nuclei. Due to
its location, connections, and intrinsic properties the RT has been

its location, connections, and intrinsic properties, the RT has been its location, connections, and intrinsic properties, the K1 has been implicated as playing an important role in attentional processes. The loss of RT neurons has been postulated as an organic basis for some types of post traumatic and post ischemic attentional deficits (Ross and Duhaime, Brain Research. 501:129-143, 1989). Attentional deficits are one of the most frequent persisting sequelae of even minor head injury but the biological basis of these deficits is poorly understood. Since primate insertial dead head injury during the process of the second positions of the secon inertial closed head injury duplicates the neuropathological and neurological aspects of human closed head injury, including post traumatic attentional deficits, we examined head injured primate brains for evidence of RT neuronal loss. In 9 of 10 cases examined selective degeneration of RT neurons was evident throughout the rostral region of the nucleus, the region associated with frontal and prefrontal cortices and related thalamic relay nuclei. The loss of these inhibitory thalamic reticular neurons and resultant thalamic and neocortical neuronal dysfunctions may underlie some forms of attentional deficits which persist following head injury. The selective vulnerability of RT neurons following head injury may, like RT loss due to ischemia and kainic acid toxicity, reflect their sensitivity to excitotoxic degeneration. (Supported by NIH Center Grant NS-08803-20)

RESTUUAL ATTENITIONAL IMPAIRMENTS AFTER PROLONGED COMA RESTURAL ATTENTIONAL IMPAIRMENTS AFTER PROLONGED COMA DUE TO TRAUMATIC BRAIN INJURY. R.F. Zec, J. Miller*, D. Zellers*, J. Belman*, J. Matthews*, D. Belman*, M. Payne*, S. Vicari*, R. Robb*, and S. Verhulst*. SIU Sch. of Med. Springfield, IL 62794. The long-term consequences of severe closed head injury on attentional factors (encode, focus/execute, shift, sustain) was studied using tests specified in a recently proposed model of attention (Mirsky, 1989). The subjects were 32 patients with severe traumatic brain injury (impatients + outpatients) and 42 control subjects. Age and education (t-tests), and gender ratio (Chi square) were not statistically different for the (chi square) were not statistically different for the TBI and control groups. The mean length of coma for the TBI group was 65.4 (SD=70.0) days and time since injury was M=10.1 years; SD=6.5, range 3 to 28 years). Focusing/executing was severely impaired in the TBI Focusing/executing was severely impaired in the TBI group while encoding was only mildly impaired. Shifting and sustaining were intermediate and were moderately to severely impaired. Although the impatient and outpatient TBI group did not differ significantly on a battery of memory test measures, the impatients with TBI scored significantly poorer than the TBI outpatient group on the majority of the attentional test measures. The less severe attentional impairment in the TBI outpatient group is associated with their better outpatient group is associated with their better outcome and may have prognostic value.

NERVE GROWTH FACTORS III

NGF RECEPTOR EXPRESSION IN BASAL FOREBRAIN AND PURKINJE CELLS AFTER PERINATAL HYPO- OR HYPERTHYROIDISM. B.C. Figueiredo, L. Garofalo, E.P. Pioro, P. Piccardo, A.C. Cuello. Dept. of Pharm. & Therap., McGill University, Montreal, P.Q., H3G 1Y6, Canada.

Early hypothyroidism produces deficits in protein synthesis in the developing brain. We compared NGF receptor (NGFr) expression in brains of such animals with that of control and those of thyroxine-treated. rats. Neonatal male rats were rendered hypothyroid (HO) by feeding the dams with a 0.4% propylthiouracilenriched diet from embryonic day 19 until postnatal day (PD) 15 or PD 30. Other newborn rats were made hyper-(PD) 15 or PD 30. Other newborn rats were made hyperthyroid (HR) by injecting them daily (s.c.) with 0.3 or 1.0 µg/gm b.wt. of thyroxine from PDO to PD15 or PD30. Use of a mAb (192-IgO) recognizing rat NoFr (Chandler et al., J.Biol.Chem. 1984), revealed high levels of receptor immunoreactivity (IR) in Purkinje cells of HO rats on PD15 compared to control and HR animals. HO rats also demonstrated a sparse pattern of NGFr staining in the molecular layer. Further experiments will determine whether the increased NGFr-IR in the HO animals is a function of delayed development or is due to an absolute increase in NGFr levels. NGFr-containing basal forebrain neurons and their cortically-projecting fibers displayed relatively greater IR in HR animals when examined on PD15. Supported by MRC Can. & Centre of Excellence for Neural Repair and Functional Recovery

GLIAL CELLS INCREASE THE PRODUCTION OF NERVE GROWTH FACTOR (NGF) FOLLOWING DESTRUCTION OF HIPPOCAMPAL NEURONS. C. Bakhit, M. Armanini, G.L. Bennett*, W-L.T. Wong*, S.E. Hansen*, and R. Taylor*. Genentech, Inc., South San Francisco, CA 94080

The concept that septo-hippocampal cholinergic neurons depend on trophic support for their maintenance and survival was challenged by the recent finding that destruction of the target neurons did not result in the degeneration of the septal cholinergic neurons (Sofroniew et al., Science 247,338, 1990). This discrepancy could be resolved, however, if nonneuronal elements in the target field assume the role of providing trophic support following loss of neurons. To test this hypothesis, we used quinolinic acid to destroy hippocampal neurons. Stereotaxic injection of quinolinic acid in the dorsal hippocampus resulted in a significant increase in NGF-like immunoreactivity (LI) which peaked at 1 week but was still significantly elevated 3 months later. Simultaneous determination of choline acetyltransferase (ChAT) activity showed no significant changes from control. Immunocytochemical localization of NGF-LI showed staining of pyramidal and granule cell neurons in normal rats and loss of the neuronal staining after the lesion. However, intensely labeled astrocyte-like cells stained in the lesion area. Double labeling for NGF and the glial marker GFAP confirmed the glial source of NGF. Thus it appears that glial cells assume the role of providing trophic support following loss of target neurons.

NGF RELEASED FROM A POLYMER MATRIX PREVENTS LOSS OF CHAT EXPRESSION IN BASAL FOREBRAIN NEURONS FOLLOWING A FIMBRIA-FORNIX LESION. D. Hoffman, L. Wahlberg, and P. Aebischer. Section of Artificial Organs, Biomaterials

and Cellular Technology, Brown University, Providence, RI 02912.

Following a unilateral fimbria-fornix lesion, the delivery of nerve growth factor (NGF) to the ipsilateral lateral ventricle of the rat can provent the lesion-induced loss of choline acetyltransferase (ChAT) expression in the ipsilateral medial septum and vertical diagonal band region. In the present study, the ability of polymer rods to deliver NGF, and to prevent a decrease in basal forebrain ChAT expression following fimbria-fornix lesions was assessed. NGF was loaded into an ethylene vinyl acetate copolymer (EVAc) rod, fabricated by a melt-extrusion process. NGF release was established by the ability of the rods to induce neurite extension from PC12 cells and chick E12 dorsal root ganglia. Unilateral aspirative lesions of the fimbria-fornix were performed in adult rats, followed by implantation of a polymer rod into the ipsilateral lateral ventricle. Five animals received EVAc rods containing only the carrier molecule bovine serum albumin (BSA), and six received EVAc rods containing both BSA and NGF. After two weeks, ChAT-positive cells were counted in the medial septum and vertical diagonal band regions. Rats with NGF-releasing rods displayed ChAT(+) cell counts ipsilateral to the lesion equal to 88% of those on the contralateral side. In contrast, ChAT(+) cell numbers were 42% in animals with rods releasing BSA only (p < 0.001). No undue reaction to implanted rods was noted. Following a fimbria-fornix lesion, NGF seleased from polymer metrics of forcing the results of the selection in the selection is the selection of the select released from polymer matrices effectively prevents a lesion-induced reduction in ChAT expression in basal forebrain neurons.

SUPPRESSION OF PC12 TUMORIGENESIS IN RAT BRAIN BY ADULT BRAIN EXTRACT: THE ROLE OF NGF. I.P. Finkelstein, H.S. U* and J.D.

Hatton. Div. of Neurosurgery, UC San Diego, La Jolla, CA 92093.

Previous research has shown that co-injection of PC12 cells with an extract of adult rat brain into neonatal rat brains suppresses PC12 tumorigenicity in a dose-dependent manner. We examined the role of nerve growth factor (NGF), known to differentiate PC12 cells into a neuronal phenotype in vitro, as a tumor-suppressive agent in adult brain extract

ABE was produced by homogenizing whole rat brains in PBS, then collecting and sterile filtering the supernatant after centrifugation. ABE was depleted of NGF by passage over a column of mouse anti-NGF antibodies coupled to CNBr-activated Sepharose 4B. Complete NGF depletion was verified by Western blot. Suspensions containing 104-105 PC12 cells in 4 ul DME medium supplemented with NGF-depleted ABE at 0%, 1%, 10%, 50% were injected with a hand-held Hamilton syringe into the right forebrains of 1-4 day old Sprague-Dawley rats. Animals were sacrificed 2, 4, and 6 days post-injection. Brains were fixed in 10% formalin, paraffin embedded, thin sectioned and examined after hematoxylin and

eosin staining.

In this study (N= 42), more than 90% of the control animals receiving no ABE formed PC12 tumors, while 50 to 75% of experimental animals formed PC12 tumors. Unlike animals treated with unfractionated ABE, those co-injected with NGF-depleted ABE showed increased likelihood of tumor formation. The frequency of tumors in experimental animals suggests NGF plays a major role in the suppression of PC12 tumors. Since some tumor suppression was noted in the experimental groups, the involvement of factors other than NGF is indicated.

LONG TERM EFFECTS OF NERVE GROWTH FACTOR (NGF) AND ITS ANTISERUM ON SYMPATHETIC GANGLION CELL SURVIVAL AND MORPHOLOGY. K. G. Ruit and W.D. Snider, Department of Neurology, Washington Univ. Sch. Med., St. Louis, Mo. 63110

We have administered NGF and anti-NGF to neonatal mice to determine whether treatment during a critical period of development leads to permanent changes in sympathetic ganglion cell morphology and survival. Mice were treated daily with NGF or twice weekly with specific anti-serum for two to three weeks. Cell counts in NGF-treated animals showed markedly increased survival acutely. Superior cervical ganglia (SCG's) had a mean of 29,357 neurons, three times that of controls. In confirmation of our previous study, we also found major effects on dendritic morphology. SCG cells in treated animals had 49% more primary dendrites and 82% more dendritic branch points than controls. Administration of anti-NGF produced converse changes in morphology of surviving neurons. Two points not previously appreciated are that effects of NGF are more pronounced on dendritic branching than on dendritic length and that mouse SCG cells abovate fewer primary dendrites than rat SCG cells even when exposed to similar concentrations of NGF.

tendritic length and that induces SCG ceris elaborate lewer primary dendrities than rat SCG cells even when exposed to similar concentrations of NGF.

Animals treated with NGF or anti-NGF were maintained for six months after treatment was terminated. At the end of six months, the mean number of neurons was 10,283, not significantly different from controls. Apparently all of the neurons which were saved by treatment with NGF during the first three postnatal weeks subsequently died when it was withdrawn. Cross sectional

postnatal weeks subsequently died when it was withdrawn. Cross sectional area of ganglion cell somata in NGF-treated animals was also not different from controls. Dendritic morphology in NGF and anti-NGF treated animals maintained for six months is presently under investigation.

We conclude that NGF exerts a physiologically relevant influence on ganglion cell dendritic growth. Interestingly, there appear to be intrinsic differences among species in the capacity of the cells to respond to NGF. NGF-induced changes regress almost completely over long time periods.

RESCUE OF TOXIC NEUROPATHY BY NERVE GROWTH FACTOR ADMINISTRATION. S. C. Apfel*, R. B. Lipton, J. C. Arezzo, J. A. Kessler. Depts, of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Peripheral neuropathy is a dose limiting toxicity for a number of important therapeutic agents. For example, the new antitumor drug, taxol, causes a painful sensory neuropathy at therapeutic doses. In this study we have established a mouse model of taxol-induced neuropathy and have examined the effects of coadministration of nerve growth factor (NGF). Adult male mice were injected with taxol, taxol plus NGF, or vehicle, and were examined for behavioral, biochemical, and electrophysiologic manifestations of neuropathy. Taxol administration significantly (p < 0.001) elevated the mean tailflick threshold, a behavioral measure of nociception. Coadministration of NGF with taxol completely prevented any change in the tail-flick threshold. Taxol administration also reduced levels of the peptide neurotransmitter, substance P (SP) in the C6 dorsal root ganglion to 12% of control (p < 0.001). Coadministration of NGF completely prevented this decrease. Finally, electrical stimulation of the caudal nerve was measured in the tail. Treatment with taxol reduced the compound nerve amplitudes by 25% (p < 0.05), and coadministration of

NGF completely prevented this decrease.

These results indicate that NGF is capable of preventing taxol neuropathy in mice. We are currently investigating other neurotoxins and neuronotrophic factors using these measures. The striking protective effect of NGF in preventing taxol neuropathy in mice dictates a trial in patients receiving taxol as a chemotherapeutic agent, and suggests that neuronotrophic factors may be useful for preventing the neurotoxicity of important therapeutic agents.

EFFECTS OF NERVE GROWTH FACTOR ON NEURONS FROM MEDIAL BASAL FOREBRAIN GROWN AS SOLITARY CELLS IN THREE-DIMENSIONAL CULTURE. P.W. Coates, E. Dunn' and M.S. Walker', Dept. of Cell Biology & Anatomy, Texas Tech Univ. HSC, Lubbock, TX 79430.

Degeneration of neurons from medial basal forebrain (MBF) has been

Degeneration of neurons from medial basal forebrain (MBF) has been implicated in Alzheimer's disease. Contact with other cells - neurons and/or glia that provide nerve growth factor (NGF) - may ameliorate this loss. To determine whether the neurons can respond appropriately to NGF in the absence of cell contacts and which neuronal structure(s) may be affected at a cellular level, we cultured MBF neurons from late gestation rats in a model three-dimensional system for 72 hr without or with NGF (10 -100 ng/ml). In this system, neurons rapidly express characteristic features as unconnected solitary cells, including two distinct types of processes, an axon and dendrites. Indices of growth and differentiation of NGF-treated or untreated solitary neurons were quantitated using image analysis. Data were analyzed with non-parametric analysis of variance. There was a significant (p<0.05) increase in mean axon and total length of all processes, but not dendritic length with 100 ng NGF compared to control. The average number of primary processes did not change with any length of all processes, but not dendritic length with 100 ng NGF compared to control. The average number of primary processes did not change with any dose of NGF, but there was a significant increase in other indices of differentiation distal to primary processes (mean number of branch points, segments and terminals) with 10 and 100 ng. Differences were present only after 24 hr, indicating time is required for effects to be expressed at the cellular level. Results suggest that at least some neurons in this heterogeneous population from MBF are inherently NGF-sensitive and do not require synaptic or other cell contact-mediated mechanisms to respond. In this model it appears that NGF modifies specific neuronal structures and temporal patterns of development, i.e., axons and complexity of receptive fields. Since evidence suggests NGF acts on cholinergic neurons, work is in progress to determine whether solitary MBF neurons express cholinergic properties independent of cell contacts, and whether such neurons are associated with observed changes. (Support from AA/ITPA, NS20802 and HD22806.)

ANTI-NGF SHORTENS AP DURATION OF A SUBSET OF DORSAL ROOT GANGLION (DRG) CELLS MATURING IN VIVO. A. M. Ritter and L. M. Mendell, Dept. Neurobiol. and Behav., SUNY Stony Brook, NY 11790

Somal spike shape in DRG cells is heterogeneous, and related to peripheral receptor type: cells innervating high threshold mechanoreceptors (HTMRs) have broad, large amplitude spikes with long afterhyperpolarizations (AHPs) and an inflection on the falling phase, while those innervating low threshold mechanoreceptors (LTMRs) are smaller, narrower, and lack the inflection (Ritter and Mendell (1988), Soc. Neurosci. Abst. 14:695). As NGF has been shown to regulate electrical properties of DRG cells in vitro (Chalazonitis et al., (1987) PNAS 84:289), rats were treated starting at birth with anti-serum against mouse 2.58 NGF (5 µl/g every day for the first 7 days, then every other until the day of recording) to see if the different types of spike shape are regulated by NGF. Intracellular recordings were made from α -chloralose anaesthetized animals at 4-6 weeks of age and cells were identified as to peripheral receptor type. Compared to untreated controls or animals treated with pre-immune serum, it was found that the fall time of the spikes of $A\beta$ and $A\delta$ HTMRs decreased, without any accompanying changes in resting potential, input resistance, spike amplitude or AHP duration. $A\beta$ LTMRs were unaffected by the treatment. It can be concluded that NGF may regulate electrical properties of some sensory neurons, and that its actions are not the same as on cells maintained in witto whose spikes are broadened by anti-NGF treatment. Supported by MH 18018 and NS PO1 14899.

GRAFTED SEPTAL NEURONS ARE EXCITED BY NERVE GROWTH FACTOR M. Eriksdotter-Nilsson I. M. R. Palmer 2. A. Henschen 1 T. Ebendal 3 and L. Olson 1. IDept. of Histology and Neurobiology, Karolinska Institute, Stockholm, Sweden, 2Dept. of Pharmacology, Univ. Colorado Medical Center, Denver, CO, 3Dept. of Dev. Neurobiology, Uppsala Univ. Biomedical Ctr, Uppsala, Sweden

Nerve growth factor (NGF) is produced in hippocampus and cortex and is retrogradely transported to the cholinergic neurons in the basal forebrain. We have previously shown that during development septal grafts grow larger in the presence of NGF, partially due to an increase in the number of cholinergic neurons. NGF receptors are present on the membrane of cholinergic neurons in the medial septal nucleus and it is thought that the first step in NGF actions is to bind to these receptors. We have therefore studied the electrophysiological effects of NGF on rat septal and hippocampal neurons, which were grafted to the anterior chamber of the eye of adult Sprague-Dawley rats to permit superfusion of drugs. The hippocampal and septal grafts survived and grew well in oculo. They were studied after 2 months in the eye. The grafts were superfused with NGF (0.02-100 ug/ml) and neurons were recorded extracellularly. Doses ranging between 0.2-100 ug/ml of NGF caused excitations of neurons in septal grafts, whereas 0.02 ug/ml of NGF was without effect. A second application of NGF caused septal neurons to respond with a significantly larger excitation than was observed after the initial exposure. Superfusion of similar doses of NGF on hippocampal grafts did not elicit excitatory responses. Controls consisted of perfusion of cytochrome c and preabsorption of the NGF solution with antibody to the NGF receptor or antibody to NGF. These control perfusions did not cause excitations in the septal grafts. The grafted septal tissue contained clusters of acetylcholine (AChE)-positive neurons and a fiber network as seen using an antibody to AChE. A few AChE-positive cells were also seen in the hippocampal grafts, but the fiber network was not very prominent there. Biochemical measurements of AChE levels showed that septal grafts contained AChE in amounts comparable to those measured in situ. In conclusion, we have shown that NGF has the ability to excite septal neurons, which may be important for the understanding of the interactions

NGF FACILITATES THE REGENERATION OF RAT SCIATIC NERVE ACROSS LONG NERVE GAPS. A. Derby**, G.E. Frierdich, G. Neises*, A. Benz* and D.G. Roufa. CNS Diseases Research, Searle R&D, St. Louis, MO 63191.

Peripheral nerves possess limited intrinsic capability to regenerate. Rat sciatic nerve can regrow across 8mm nerve gap when the cut ends of the nerve are placed in silastic tube and fail to do so when the gap is increased to 13mm. We report here that the addition of NGF to the tube facilitated the regrowth of sciatic nerve across 13mm nerve gap.

A rat sciatic nerve was transected in the mid-thigh region, a 4-5mm section was removed and 15mm section of silastic tubing was implanted. The tube was prefilled with either 100ug NGF or Cyto C. The implants were removed 5 weeks later and the extent of neuronal regeneration within the tube was determined histologically. Only 1/15 implants treated with Cyto. C had a regenerate, and no myelinated fibers were present at the mid-point. In NGF treated implants 7/15 had regenerates, 5 regenerates had myelinated fibers. The mean number of myelinated fibers at the tube's mid-point was 4,266. These results provide strong support for the role of NGF in promoting regeneration of these neurons.

AXOTOMY OR TREATMENT WITH NERVE GROWTH FACTOR (NGF)
INDUCES THE EXPRESSION OF NGF RECEPTOR IN ADULT SPINAL
MOTOR NEURONS: IMPLICATIONS FOR THE PURSUIT OF A MOTOR NEURON TROPHIC FACTOR. D.L. Price, V.E. Koliatsos, T.O. Crawford, W.C. Mobley and W.L. Price*.

Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

This investigation was designed to examine the potential influences of trophic factors on motor neurons in three experimental settings. First, adult rats were treated intraventricularly with NGF; lumbar motor neurons showed increased levels of NGF receptor immunoreactivity (NGF-IR). Second, sciatic nerves of rats were crushed and labeled with Fluoro-Gold (FG), and animals survived for 12 hours or for 1, 2, 7, 14, 21, 28, or 45 days; in FG-labeled motor neurons, NGF-IR appeared at day 2 postaxotomy, peaked between days 7 and 21, and persisted until day 45. Finally, to test the efficacy of trophic factors on motor neurons, we developed in adult rats an experimental model, i.e., proximal ventral rhizotomy, characterized by degeneration of motor neurons. Three weeks following this type of lesion, ca. 70-80% of motor neurons die, and remaining motor neurons show reduced basophilia and alterations in size and shape. This model can be used to assess the effects of NGF and other trophic factors on the survival of spinal motor neurons.

STRESS-INDUCED CHANGES IN RAT BRAIN NERVE GROWTH FACTOR RECEPTOR P.J. Foreman, G. Taglialatela, D. MCNeill, L. Angelucci, M.T. Ramacci & J.R. Perez-Polo. Univ. of TX Medical Branch, Galveston, Tx, 77550. In rodent brain the majority of nerve growth factor receptor (NGFR) synthesis is within cholinergic cells of the synthesis is within challergic cells of the basal forebrain area (BFA). NGFR protein is highest in BFA, hippocampus (H) and cortex (Cx,) all related to limbic functions that regulate all related to limbic functions that regulate the response to stress. Previously, we found that after exposure to 1 hour of cold stress on 5 consecutive days, there was a 50% reduction in NGF binding to BFA and H but not Cx or cerebellum (Cb). Northern analysis revealed that after cold stress steady state levels of NGFR mRNA increase 2-fold in BFA. Using Mab 192, a monoclonal antibody to rat NGFR, we immunohistochemically labeled NGFR in BF and H. Image analysis showed a trend towards decreased NGFR antigen in BFA of stressed rats. We are attempting to confirm this by immunoprecipitation of labelled NGFR. We propose that after stress there is increased turnover of NGFR in BF stress there is increased turnover of NGFR in BF and H and increased NGFR mRNA synthesis to replace reduced levels of NGFR activity. Supported by NINDS and the Sigma Tau Co.

DIFFUSE ALTERATIONS IN NGF RECEPTORS ON SPINAL MOTONEURONS AFTER NERVE CRUSH INJURY. C.M. Bowe and N.H. Evans*, Section of Neurobiology and Department of Neurology, Brown University, Providence, R I 02912

Nerve growth factor (NGF), a neurotrophic protein with multiple

Nerve growth factor (NGF), a neurotrophic protein with multiple effects on sensory, autonomic and cholinergic neurons, may also mediate motoneuron (MN) function. NGF receptor (NGF-r) mRNA is present in spinal MNs during early development and is increased in MNs with regenerating axons following nerve crush. In the present study, we examined the distribution of changes in MN NGF-r in the lumbar spinal cord after sciatic nerve injury.

Unilateral sciatic nerve crushes were performed on adult rats.

Unilateral sciatic nerve crushes were performed on adult rats. Two weeks after nerve crush, lumbar 2-6 spinal cord segments were removed from experimental and control (unlesioned) rats. Cord sections were examined for the presence and distribution of NGF-r in the lateral and anterior horns. NGF-r were identified by a modification of methods described by Yan and Johnson (<u>J. Neurosci.</u>,8: 3461, 1988) employing a selective monoclonal antibody to NGF-r (MAB-192). Prominent labelling for NGF-r antibody was observed on MNs ipsilateral and contralateral to the crush injury throughout the lumbar spinal cord. Comparable labelling was not throughout the lumbar spinal cord. Comparable labelling was not seen in sections from the control rat or in control sections not exposed to MAB-192. These observations indicate that alterations in MN NGF-r seen after axonal injury are not limited to neurons with regenerating axons but, rather, may represent a more diffuse response to axonal injury.

NERVE GROWTH FACTOR (NGF) PROMOTES THE RECOVERY OF NEOSTRIATAL CHOLINE ACE-TYLTRANSFERASE (ChAT) FOLLOWING A MECHANICAL LESION. M. Armanini, S. Feinglass*, C. A. Altar, C. Bakhit. Genentech Inc., South San Francisco, CA 94080.

Recent evidence has implicated NGF as a potential neurotrophic factor for cholinergic interneurons of the rat neostriatum (Mobley et al. 1989; Hagg et al. 1989; Williams et al. 1989). We investigated the effects of a mechanical lesion of the adult rat neostriatum on endogenous NGF levels, high affinity choline uptake (HACU), and ChAT activity and the effects of exogenous recombinant human (th) NGF infusions in promoting the neurochemical recovery of cholinergic activity. A mechanical lesion of the Fisher 344 rat neostriatum was produced by moving a 25 gauge syringe tip 2 mm in the rostral-caudal and medial-lateral directions. NGF-like immunoreactivity (LI), measured by a specific two-site ELISA was increased as soon as 3 days following the lesion. ChAT activity was decreased at 3 days and returned to control values at 2 weeks. Continuous infusion into the lesion site of rhNGF (2.5 ug/rat/week) or a control protein (cytochrome c 2.5 ug/rat/week) resulted in a 25-30 % increase in ChAT activity by rhNGF at 2 and 4 weeks. In contrast HACU, which reflects cholinergic terminal density, was reduced by 28 % after the lesion, but did not recover as a result of the rhNGF infusion. These results demonstrate that rhNGF administration for 4 weeks is capable of inducing processes following a mechanical lesion.

CHRONIC INTRAVENTRICULAR INFUSIONS OF RECOMBINANT HUMAN β -NGF INTO THE AGED RAT: A BEHAVIORAL AND MORPHOLOGICAL STUDY. K.S. Chen ¹, J. Barneut*², H. Chan*², and F.H. Gage ¹. Dept. of Neurosciences (M-024), UCSD, La Jolla, CA¹ and Syntex Research, Palo Alto, CA².

Previous experiments have demonstrated that continuous intracerebral

infusions of the 2.5S form of mouse B-NGF can partially reverse impairments on a spatial memory task and the atrophy of cholinergic neurons in the basal for a spatial intentity task and the distiply of cholinegic neurons in the basis forebrain region of aged rats. In this study recombinant human B-NGF was chronically infused into the lateral ventricles of aged (24 month old) Sprague-Dawley rats. The NGF was administered for 28 days (0.71 µg/day) via a cannula connected to an osmotic minipump [Alzet]. These aged rats had been

cannula connected to an osmotic minipump [Alzet]. These aged rats had been behaviorally characterized on the Morris water maze and had exhibited an impairment on the place navigation task compared to both young rats and a subgroup of aged unimpaired rats. Upon retesting on this task after implantation of the minipumps the NGF-treated aged rats showed improved retention of the platform location compared to the vehicle-treated aged rats. An atrophy of cholinergic cells has also been demonstrated in aged behaviorally impaired rats. In this study cholinergic neurons were immunohistochemically stained with an anitbody to NGF-receptor (NGF-R). The mean size and number of labelled cells in the medial septal, diagonal band, and nucleus basalis regions were obtained for each animal using an image analysis system [Olympus]. There is a significant shrinkage in the size of the NGF-R-positive neurons in the aged impaired animals. Chronic infusions of NGF partially reversed the shrinkage of NGF-R-positive cells. The trophic effect was most evident on the side of the NGF infusion. These findings show that human recombinant B-NGF, similiar to mouse B-NGF, has a trophic effect upon atrophicd neurons in the aged basal forebrain, and an ameliorative effect upon the retention deficit exhibited by these aged animals.

207.17

CHRONIC TREATMENT WITH NGF IMPROVES SPATIAL LEARNING AFTER NBM LESIONS. Ad J. A. M. Dekker.

Donald J. Connor. Fred H. Gage, Leon J. Thal. Dept. of
Neurology, VAMC, San Diego and Dept. of Neuroscience, UC San Diego.

Rats received bilateral lesions of the nucleus basalis magnocellularis by infusion of ibotenic acid (28 nmoles in two injections per side). Fourteen days later, osmotic minipumps, releasing NGF (0.3 ug/day) were implanted subcutaneously. Pumps were replaced every fourteen days. Acquisition of the Morris water maze task was started 1 month after the lesion, using 10 acquisition sessions, with two trials each, over two weeks. NBM-lesioned animals were significantly impaired in the acquisition of the task. Treatment with NGF reduced the average latency to find the platform by approximately 9 sec per trial. In a trial in which the platform was not present, lesioned rats swam closely to the edge (outer annulus), whereas rats treated with NGF swam significantly less in the outer annulus. The mechanism through which NGF infusion improves performance following ibotenic acid lesions is not known, since NGF did not increase ChAT activity in the cortex or the hippocampus. NGF may either affect ACh release, or ChAT levels outside the target areas. Alternatively, NGF might affect non-cholinergic neurons which are damaged by ibotenic acid.

207.19

EFFECTS OF NGF AND FETAL CELL TRANSPLANTS ON SPATIAL LEARNING AFTER HIPPOCAMPAL DAMAGE IN RATS. P. Tandon, S. Barone Jr., and H.A. Tilson. LMIN, NIEHS/NIH, Res. Tri. Pk, NC 27709.

Tri. Pk, NC 27709.

NGF has been implicated in the growth and development of neurons. This study was performed to observe the effects of NGF and hippocampal transplants on functional deficits produced by hippocampal damage. Two groups of male Fischer-344 rats received bilateral injections of colchicine (COL, 2.5 ug/site) or artificial cerebrospinal fluid into the dentate gyrus. Two weeks post-lesion the animals received a suspension of fetal hippocampal cells (1 µ1) or Earle's basic salt solution. Modified mini-osmotic pumps (0.25 µ1) containing NGF (10 ng/µ1) or cytochrome C (20 ng/µ1, as control) were implanted at the same time. The animals were tested in the Morris water maze 6 or 12 weeks post-lesion. COL-lesioned rats were found to be impaired in the behavioral task. NGF treatment ameliorated this functional deficit. The presence of explants did not have any beneficial effect in sence of explants did not have any beneficial effect in the acquisition of this task. However, the group receiving NGF/explants performed better than the lesioned animals alone. Morphological examination done at the end of the study confirmed the presence of viable explants and COL-induced cell loss.

NGF PREVENTS THE RETROGRADE CELL LOSS OF RED NUCLEUS NEURONS AFTER SPINAL CORD INJURY AT BIRTH.

NGF PREVENTS THE RETROGRADE CELL LOSS OF RED NUCLEUS NEURONS AFTER SPINAL CORD INJURY AT BIRTH. Ellen Kunkel-Bagden and Barbara S. Bregman, Dept. of Anatomy and Cell Biology, Georgetown Univ., Washington, DC 22066.

Transplants of fetal spinal cord (target) tissue placed into the site of a spinal cord lesion in newborn animals prevent the retrograde cell death of the axotomized neurons and support the growth of axons across the site of injury. Non-target transplants are only able to support the temporary survival (7 days post-operative) of immature axotomized red nucleus (RN) neurons. Both target and non-target transplants potentially provide trophic support for the axotomized neurons and a favorable terrain for the damaged axons to traverse. In the present study we wished to determine if a trophic substance per se could prevent or delay the retrograde cell loss after neonatal spinal cord injury. A spinal cord "over-hemisection" was made at T6 in 20 rat pups at 2 days postnatal (HX) and matrigel was placed into the lesion site. Twenty normal pups served as controls (CON). NGF (1ug/2ul) or saline (SAL) was injected intraventricularly daily for five days. At 7 days, 30 days, and 12 weeks postnatal the survival of the neurons in the RN was assessed. After axotomy at birth, retrograde cell loss in the RN is apparent within 48 hrs after injury and is complete by 5 days post-operative. Saline treated animals (HX+SAL) show a 50% cell loss after injury, similar to lesion-only animals. At 7 days the number of neurons in the RN of the HX+NGF animals was similar to that in unlesioned control animals. Preliminary results indicate that this rescue of neurons in the RN by NGF is still evident at 30 days. Thus, NGF treatment rescues immature axotomized neurons from retrograde cell death. These results suggest that providing trophic support is sufficient to promote the survival of immature axotomized neurons. Supported by: NIH NS19259, NS01356, NS27054, and APA BA3-8802-1.

EFFECTS OF LONG TERM LOSS OF HIPPOCAMPAL TARGET NEURONS ON SURVIVAL OF AFFERENT BASAL FOREBRAIN CHOLINERGIC NEURONS IN YOUNG ADULT AND AGED RATS. M.V. Sofroniew, J.D. Cooper*, C.N. Svendsen*, S. J. Stevens* and K.J. Baker*, Department of Anatomy, University of Cambridge, England.

M.V. Soffoniew J.D. Cooper. C.N. Svendsen. S. J. Slevens and R.J. Baker*. Department of Anatomy, University of Cambridge, England.

Basal forebrain cholinergic neurons of the medial septum die following proximal axotomy of their projection to the hippocampus (Hp) in adult rats. This retrograde death can be prevented by intraventricular administration of exogenous NGF, suggesting that these neurons, which bear NGF receptors and transport labelled NGF, might normally be dependent for survival upon limiting amounts of NGF produced by target neurons in the Hp. We have found that unilateral excitotoxic ablation of nearly all Hp neurons does not affect the survival of septal cholinergic neurons for up to 120 days in young adult rats (Science 247:338, 1990). To investigate this further, NMDA was injected unilaterally into the Hp in 9 sites, in young adult rats, 3-6 months (n=40), or aged rats, 24-27 months (n=12), of age. After survival times of up to 400 days for young rats, and up to 75 days for aged rats, Hp were stained for AChE, Nissl and GFAP, and the septal region for ChAT and NGF receptor. The amount of Hp tissue remaining, and the number, size and staining intensity of septal cholinergic neurons were quantitatively assessed by computerized image analysis. Some rats received Hp injections of the tracer, True blue, 7 days prior to NMDA, in order to compare any loss of ChAT-staining with loss of TB-labelled neurons. Due to the long survival times, complete sets of data are not yet available. Preliminary findings in 9 rats show a small loss (<20%) of ChAT-stained neurons in the septum of some, but not all, apple and the properties of the septum of some, but not all, and gard rats with complete Hp lesions. These declines in ChAT-stained neurons an, young adult als 200-300 days after Complete in plesions, and a fluorate loss (<40%) of ChAT-stained neurons in the septum of some, but not all, aged rats with complete Hp lesions. These declines in ChAT-stained neurons are considerably less than that seen after axotomy (>75%). Comparison of loss of ChAT staining with loss of TB-lablled neurons, as a marker of cell death, is in progress.

NERVE GROWTH FACTOR ACTION ON PC12 CELLS IS POTENTIATED BY ACETYL-L-CARNITINE TREATMENT.

G.Taglialatela*, L.Angelucci*, M.T.Ramacci*,
L.W.Thorpe, K.Werrbach-Perez* & J.R.Perez-Polo.

Dept. of HBC&G, UTMB Galveston, Texas.

Some morphofunctional impairments of the central nervous system (CNS) during senescence may

be due to reduced action of neuronotrophic agents, such as the nerve growth factor protein (NGF). We have previously shown that treatment with acetylhave previously shown that treatment with acetyl-l-carnitine (ALCAR) prevents various deficits of the CNS of aged rats. Here we have investigated if there is any direct effect of ALCAR on NGF and its receptor (NGFR). We used an <u>in vitro</u> model for cholinergic neurons - the rat pheochromocytoma (PC12) cell line. Treatment of PC12 cells with ALCAR for 6 days increased NGF binding in a dose-dependent fashion. NGF-induced neurite extension was increased by pretreatment with ALCAR at NGF was increased by pretreatment with ALCAR at NGF concentrations that are normally not effective. Also, the ability of NGF to rescue serum-deprived PC12 was augmented 100 fold by ALCAR. Lastly, PC12 was augmented 100 101d by ALCAR. Lastly, ALCAR enhanced choline acetyltranferase (ChAT) activity and protein synthesis in PC12 cells. These result suggest that one possible mechanism by which ALCAR prevents degenerative processes in the CNS during senescence may be the enhancement of neuronal responses to trophic agents. Supported by NIH and the Sigma Tau Co., Italy.

CHARACTERIZATION OF THE HIGH AFFINITY NERVE GROWTH

S.O. Meakin* and E. M. Shooter. Department of Neurobiology, Stanford

University School of Medicine, Stanford, CA, 94305
The NGF receptor subtypes on rat PC12 cells have been investigated The NGF receptor subtypes on rat PC12 cells have been investigated by means of affinity labelling with ¹²⁵I-NGF and then subsequently analysed <u>in vitro</u>. Chemical crosslinking reveals that two distinct NGF-receptor complexes can be detected with apparent molecular weights of 100,000 and 158,000 for the low (LNGFR) and the high (HNGFR) affinity receptors respectively. Although partial proteolysis of each complex generates similar NGF-receptor peptides, suggesting a model in which the HNGFR represents a complex between the LNGFR and a second membrane associated molecule, two distinct antibodies against the LNGFR are found to immunoprecipitate the low affinity but not the high affinity receptor subtype. While the identity of the putative effector molecules(s) is as yet unknown, antibodies to src, ras, yes and raf-1 fail to immunoprecipitate the HNGFR complex suggesting that these protooncogene products are not the associated suggesting that these protocologies products are not the associated molecule. Interestingly, phosphotyrosine residues are found specifically on the HNGFR, but not the LNGFR, indicating that at least one protein in this complex contains p-Tyr residues and implicating tyrosine phosphorylation directly in the NGF induced signal transduction cascade.

208.3

ISOLATION AND SEQUENCING OF A PUTATIVE PROMOTER REGION OF THE HUMAN NERVE GROWTH FACTOR GENE. M. Fahnestock and D. Chen*. Molecular Biology Dept., SRI International, Menlo Park, CA 94025.

The gene coding for nerve growth factor (NGF), including its upstream promoter sequences, has previously been its upstream promoter sequences, has previously been isolated from mouse and rat. The mouse NGF gene contains several small 5' exons more than 32 kb upstream of the coding region (Selby et al., Mol. Cell. Biol. 7:3057, 1987; Zheng & Heinrich, Mol. Brain Res. 3:133, 1988). However, the 5' exons and promoter of the human NGF gene, which also lie far upstream of the NGF coding region, have never been isolated. These sequences presumably carry circacting. isolated. These sequences presumably carry cis-acting elements controlling NGF gene expression.

We have used PCR to amplify a putative NGF promoter region fragment from human genomic DNA. Our primers are based on mouse and rat NGF exon 1A and 1B sequences. We have amplified a 1.3 kb piece of DNA and have cloned and sequenced it. The DNA contains sequences typical of promoter regions such as TATA and CAAT boxes, but does not show a high degree of sequence homology to the mouse and rat NGF promoter regions. We discuss experiments designed to verify that the DNA fragment obtained by PCR is, indeed, part of the human NGF gene promoter.

LOCALIZATION OF NERVE GROWTH FACTOR AND CHOLINERGIC m2 MUSCARINIC RECEPTOR mRNA IN ADULT RAT BASAL FOREBRAIN. B.J. Gwag. G.L. Luthin, R.P. Artymyshyn*, and J.E. Springer. Depts. of Neurology, and Physiology and Biophysics, Hahnemann University, Philadelphia, PA 19102, and Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104

Nerve growth factor (NGF) may play an important role in the development, function, and curvival of cheliparcia neurone located in the bosel forebring.

function, and survival of cholinergic neurons located in the basal forebrain. These cholinergic neurons contain NGF receptors (NGFR) which bind, internalize, and transport retrogradely NGF from target tissue (i.e., hippocampus and cortex) to cell bodies in the basal forebrain. It has been reported that m2 muscarinic receptors (m2R) may be presynaptic autoreceptors located on cholinergic neurons. We used in situ hybridization histochemistry located on cholinergic neurons. We used in situ hybridization histochemistry to identify cells in the adult rat basal forebrain that express m2R and NGFR mRNA. Probes complimentary to NGFR and m2R mRNA were transcribed using radiolabeled (35S) - and digoxigenin-UTP and hybridized to brain sections (16um thickness) for 3-4 hours. We found a similar distribution of NGFR and m2R mRNA in medial septum, vertical and horizontal limb of diagonal band, and nucleus basalis. In addition we identified cells in neostriatum which express m2R but not NGFR mRNA. Because of the similar distribution of m2R and NGFR mRNA, our results indicate the possible colocalization of these two receptors within individual cells in the basal forebrain. This connection between NGF and the muscarinic (i.e., m2) receptor system may further our understanding of the trophic mechanism(s) of NGF on these cholinergic neurons. Supported by NIH grant AG-08969. cholinergic neurons. Supported by NIH grant AG-08969.

POTENTIAL. ENDOCYTOTIC-DEPENDENT MECHANISM GENERATION OF TRUNCATED NERVE GROWTH FACTOR RECEPTORS. A.A. Zupan and E.M. Johnson, Jr. Dept. of Pharmacology,

Washington Univ. Sch. of Med., St. Louis, MO 63110.

Our laboratory has described the existence of truncated forms of the human nerve growth factor receptor (hNGFR_t) in urine and amniotic fluid, as well as in media conditioned by human receptor-positive cell lines. The in vivo forms (45, 40, and 35 kDa) share in common their N-terminal amino acid sequences and do not appear to differ from each other significantly in glycosylation. We propose that these forms are portions of the receptor's extracellular domain generated by of the receptor's extracertural domain generated by differential proteolytic cleavage proximal to the membrane spanning sequence. The elaboration of NGFR_t in cell culture serves as a model system for studying generative mechanisms. A variety of protease inhibitors generative mechanisms. A variety of processe inhibitors representing compounds from all inhibitor subclasses have been tested for their ability to prevent hNGFR elaboration by A875 melanoma cells. While no specific inhibitor has been identified, lysosomal stabilizers $\frac{1}{2}$ (NH₄Cl, methylamine, chloroquine, etc.) reduce the amount of NGFR_t detected by affinity-labeled crosslink immunoprecipitation of conditioned medium. This suggests the possible involvement of an endocytotic, membrane recycling event. Experiments to determine the C-terminal sequence of the in vivo forms are in progress. Supported by a grant from the Monsanto Corporation.

NERVE GROWTH FACTOR (NGF) AND NGF RECEPTOR IMMUNOREACTIVITY IN THE ADULT RAT CNS. J.M. Conner, T. Hagg, M. Manthorpe and S. Varon, Dept. Biol., M-001, UCSD, La Jolla, CA 92093 NGF, a neuronotrophic factor for the NGF receptor (NGFR)-bearing cholinergic neurons of the adult basal forebrain (BF), is presumably derived from their innervation territories - the hippocampal formation (HF), cerebral cortex and olfactory bulb. These CNS regions have high levels of extractable NGF and its mRNA. Using affinity purified antibodies against 8-NGF and a sensitive immunohistochemical ABC-peroxidase method we localized NGF in the adult female Sprague-Dawley rat CNS. Contrary to previous reports we find NGF immunoreactivity restricted to a limited number of brain regions. 1. In the medial septum, diagonal band of Broca and nucleus basalis of Meynert NGF-reactivity was exclusively found within neuronal cell bodies and in one In the medial septum, diagonal band of Broca and nucleus basalis of Meynert NGF-reactivity was exclusively found within neuronal cell bodies and in one or more of their processes. These neurons had a morphology and distribution similar to that of the cholinergic ones found in adjacent sections stained with the 192-IgG monoclonal antibody against NGFR. 2. In the HF diffuse NGF-reactivity was primarily localized in the hylus of the dentate gyrus and extended within stratum radiatum of CA3 and CA2 where it was more intense. HF regions most densely innervated by NGFR-positive axons (i.e. the molecular layer of the dentate gyrus) were devoid of NGF staining. No NGF staining but many NGFR-positive fibers were found in the cerebral cortex. 3. In the olfactory bulb, NGF-positive profiles were detected in the granula and pleyidorn layers and surrounding the glomeruli. In contrast granule and plexiform layers and surrounding the glomeruli. In contrast, intense NGFR-staining was only detected within the glomeruli. Thus, there appears to be an inverse relationship between the presence of detectable NGF and NGFR in the innervation territories of the cholinergic BF neurons. This suggests that brain regions more densely innervated by NGFR-positive cholinergic BF neurons may be subject to a higher rate of NGF removal by which these neurons take up NGF and transport it toward their cell bodies. NGF AND NICOTINIC ACHR EXPRESSION ON RAT NODOSE NEURONS IN CULTURE. A. Mandelzys and E. Cooper. Dept. of Physiol., McGill Univ., Montreal, Que. H3G 1Y6 We have previously shown that NGF increases the propor-

tion of neonatal rat nodose neurons expressing functional nicotinic receptors (nAChRs) when grown alone in culture without affecting neuronal survival. We have now quantified this receptor expression with whole-cell patch clamp techniques. Our experiments indicate that over 2 weeks in culture there is both an increase in the proportion of neurons expressing receptors (28% at day 4 to 64% on day 14), as well as a 5 fold increase in receptor density (3.7pA/pF to 20.7pA/pF) for sensitive neurons over the same time period. By comparison, neonatal rat sympathetic neurons which express nAChRs similar to those on nodose neurons have an initial nAChR density 11 fold greater than that for nodose and maintained this density for at least 2 weeks in culture. We have also addressed whether NGF needs to be continually present in the culture for this receptor expression. In some cultures NGF was withdrawn between day 8 and 14 after most neurons had expressed nAChRs: this resulted in a decrease in the proportion of neurons expressing nAChRs within 2 days. In other cultures, neurons were grown initially without NGF which prevented receptor expression, but began expressing nAChRs within days after addition of NGF. We conclude that NGF induces nAChR expression on nodose neurons and that NGF must be continually present to maintain this receptor expression. (Funded by FCAR, FRSQ and MRC)

PROTEIN KINASE C INVOLVEMENT IN THE NGF-INDUCTION OF THE METALLOPROTEINASE TRANSIN IN PC12 CELLS. G. CIMENT and C.M. MACHIDA*, Department of Cell Biology and Anatomy, Oregon Health Sciences University, Portland, OR 97201

In previous work, we found that nerve growth factor (NGF) induced the mRNA transcript encoding the metalloproteinase transin in PC12 cells. We report here that staurosporine -- a potent inhibitor of protein kinase C (PKC) -- blocks this NGF-induction of transin expression. In contrast, various PKC activators augmented the NGF-induction of transin expression, but did not cause induction in the absence of NGF. These effects of PKC inhibitors and activators on the NGF-induction of transin were also seen in transient transfection assays with a plasmid containing a 750 base pair region of the 5' flanking region of the transin gene fused to a reporter gene, indicating that this region of the transin promoter contains DNA sequences responsible for these effects of NGF and PKC.

These data indicate, therefore, that activation of PKC is necessary, but not sufficient, for the NGF induction of transin. These data suggest, moreover, that coactivation of multiple second messenger pathways, possibly involving various other types of protein kinases, is likely to be involved in the signalling pathway by which NGF induces transin mRNA expression in PC12 cells.

208.9

PRODUCTION AND CHARACTERIZATION OF HUMAN RECOMBINANT NGF. S.L. Meyer, H. Sekhon*, R. Mudd*, R. Siman, C.A.H. Friedman*, K.V. Callison, A. Kish*, P. Vissavajjhala², A.H. Ross², and M.E. Lewis. Cephalon, Inc., West Chester, PA 19380 and ²Worcester Foundation, Worcester, MA 01545.

Production of human recombinant NGF (hrNGF) has been previously hampered by the inability of prokaryotic and lower report here that expression of the portion of the human NGF gene encoding preproNGF using the polyhedrin promoter of baculovirus results in the production of a hrNGF protein that is correctly processed and fully biologically active. The protein can be purified from serum-free media following virus infection and was found to be correctly processed, having the same N-terminal sequence as predicted for mature hNGF. The biological activity of purified hrNGF was compared in a number of systems with that of purified mouse NGF and was consistently found to behave in a similar fashion. For example, hrNGF consistently found to behave in a similar fashion. For example, hrNGF was shown to extend neurites on rat PC12 cells with a similar dose-response curve as mouse NGF and the neurite extension of both mouse and human NGF was blocked by a monoclonal anti-mouse NGF from Boehringer-Mannheim that partially cross-reacts with human NGF. The hrNGF also displaced radioactive mouse NGF from rat PC12 NGF receptors in a manner similar to mouse NGF. Availability of large quantities of consistently biologically-active hrNGF will greatly facilitate testing of NGF as a therapeutic in human neurodegenerative disorders, as well as allow detailed structure-function studies of this protein.

ACETYLCHOLINE RELEASE FOLLOWING CONTINUOUS INTRACEREBRAL ADMINISTRATION OF NERVE GROWTH FACTOR IN ADULT AND AGED FISHER 344 RATS. R.J.Rylett and L.R.Williams. Dept. of Physiology, Univ. Western Ontario, London, Canada, and CNS Diseases Research Unit, The Upjohn Co., Kalamazoo, MI. Intraventricular infusion of NGF increases cholinergic neuronal markers ChAT and high-affinity choline uptake in

frontal cortex, hippocampus and striatum of adult and aged Fisher 344 rats. We have now determined that this apparent enhancement of cholinergic phenotype results in increased ACh release. Potassium-evoked endogenous ACh release from Ach release. Potassium-evoked endogenous Ach release from slices of frontal cortex, hippocampus and striatum was quantitated by the chemiluminescent method of Israel and Lesbats (1982), and newly-synthesized ³H-ACh release was measured from synaptosomes loaded with ³H-choline. NGF was administered by Alzet minipump unilaterally into right lateral ventricle of 4 and 24 month Fisher 344 male rats for 2 weeks. Potassium-evoked endogenous ACh release from slices was increased 62 and 27% relative to controls in striatum of 4 and 24 month rats, respectively, following NGF treatment. Release of endogenous ACh from frontal cortex and hippocampus was not significantly different from controls. Qualitatively different results were obtained when release of newly-synthesized ³H-ACh was measured from synaptosomes; ³H-ACh release evoked by 35 mM K+ was increased in all three brain regions in both age groups of NGF-treated rats, with the rank order of increase being hippocampus > frontal cortex > striatum.

ANALYSIS OF THE INOSITOL PHOSPHATES PRODUCED BY TREATMENT OF PC12 CELLS WITH NERVE GROWTH FACTOR. M. L. Contreras. Dept. of Pharmacology and Toxicology, Michigan State University, East Lansing, MI 49924. In PC12 cells, nerve growth factor (NGF) can

stimulate the hydrolysis of the polyphosphoinositides (J. Neurochem. 48:1466, 1987). The NGF-induced hydrolysis of these lipids was further characterized to determine lipids was further characterized to determine if NGF stimulates an increase in the levels of inositol 1,3,4,5-tetrakisphosphate (Ins(1,3,4,5)P₄), and in the levels of both of the isomers of inositol trisphosphate (Ins(1,4,5)P₃ and Ins(1,3,4)P₃). PCl2 cells were incubated with ³H-inositol for 2 days. Subsequently, the cells were treated with or without NGF for various periods of time, and the without NGF for various periods of time, and the inositol phosphates were then separated by HPLC. NGF did stimulate an increase in the cellular levels of both isomers of ³H-IP₃ and in the level of ³H-Ins(1,3,4,5)P₄. The increase in the level of ³H-Ins(1,4,5)P₃ was apparent as early as 5 sec after the addition of NGF. The appearance of a NGF-induced increase in the levels of ³H-Ins(1,3,4,5)P₄ and ³H-Ins(1,3,4)P₃ was slower and was sustained for several properties supported by NGF grant BNS8000030 minutes. Supported by NSF grant BNS8909030.

RAPID PURIFICATION OF MALE MOUSE SUBMAXILLARY GLAND NGF. N.A. Horn*, B. Matthews*, W. Engleman*, S. Rapp*, J.F. Zobel, N.M. Kimack and D.G. Roufa. Bioprocess Technology and Biological Sciences Monsanto Co. and CNS Diseases Research, Searle R&D, St. Louis, MO 63108

Diseases Research, Searle R&D, St. Louis, MO 63198.

Male mouse submaxillary glands are the richest known source of NGF. Commonly used protocols for the purification of 2.5s NGF employ gel filtration followed by ion-exchange chromatography. We report here a single, scalable ion-exchange method for the rapid isolation of active 2.5s murine NGF.

Submaxillary glands (200gm, wet weight) were homogenized, clarified and the nucleic acids precipitated. Following a second precipitation of impurities at pH 5.0, the extract was chromatographed on Pharmacia CM-Sepharose Fast Flow. The extract was loaded on a 7cm X 17cm column (500ml) equilibrated with 0.2M Acetic Acid pH 5.0 with NaOH. The column was washed with two salt steps and the NGF eluted with a salt gradient. At this scale the procedure yields 60-140mg of biologically active, greater than 85% pure 2.5s NGF as determined by SDS-PAGE, amino acid composition and N-terminal sequence analysis.

The procedure described represents an improvement over previously published protocols. A single, scalable column step with 1.5 days run time results in high yield of biologically active pure 2.5s NGF.

DEVELOPMENT OF POLYCLONAL ANIIBODIES AND PROPERTY OF POLYCLONAL ANIIBODIES AND PROPERTY OF PROPERTY OF POLYCLONAL ANIIBODIES AND PROPERTY OF POLYCLONAL ANIIBODIES ANIIBOD DEVELOPMENT OF POLYCLONAL ANTIBODIES AGAINST THE HUMAN P. Distefano, M. Blake and J.F. McKelvy. Department of Biochemistry, The Chinese University of Hong Kong, Shatin, Hong Kong and Neuroscience Research Division, Abbott Laboratories, Abbott Park, Illinois 60064.

The currently available monoclonal antibodies for the human and rat NGFR are species specific and display little human and rat NGFR are species specific and display little or no cross-reactivity with the NGFR from other species. The present study was undertaken to develop ployclonal antibodies towards different domains of the human NGFR which may be useful in the immunocytochemical studies of NGFR in different species. Appropriate restriction fragments of the human NGFR cDNA (contained in a Bluescript plasmid kindly provided by Dr. Moses V. Chao, Cornell University Medical College) were inserted into the PATH1 TRP E "20" plasmid to produce 3 different constructs coding for TRPE-NGFR fusion proteins containing the cytoplasmic, full-length and extracellular domain of respectively. These engineered plasmids were used to transform E. Coli RRI and CAG456 and transformants carrying the appropriate constructs were cloned. The transformants carrying the construct for the cytoplasmic or the extracellular domain of NGFR produced large quantities of the respective TRPE-NGFR fusion proteins upon induction. These fusion proteins were used to immunize rabbits and antibodies to the human NGFR can be detected in the serum of these animals.

DIFFERENTIAL EXPRESSION OF NERVE GROWTH FACTOR RECEPTOR IN DIFFERENT SUBCLASSES OF BASAL FOREBRAIN MAGNOCELLULAR NEURONS. G.K. Gouras, V.E. Koliatsos and D.L. Price.
Neuropathology Laboratory, The Johns Hopkins University
School of Medicine, Baltimore, MD 21205.
Cholinergic neurons of the basal forebrain

magnocellular complex (BFMC), affected in Alzheimer's magnoceriular complex (BFML), attected in Alzheimer's disease, respond to nerve growth factor (NGF). Much less is known about basal forebrain y-aminobutyric acid (GABA)ergic neurons regarding involvement in disease or responsiveness to trophic factors. To examine the potential responses of these neurons to NGF, adjacent 6-um sections of rat brain were labeled by 6-µm sections of rat brain were labeled by immunocytochemistry and in situ hybridization for glutamic acid decarboxylase (GAD), NGF receptor (NGF-R), and choline acetyltransferase (ChAT); results indicated a nearly 100% colocalization of NGF-R with ChAT but not with GAD. NGF treatment of control animals did not appear to induce expression of NGF-R in noncholinergic neurons. Rats with fimbria-fornix lesions showed a 30-50% decrease in GAD-immunoreactive cells ipsilateral to the lesion; following fimbria-fornix lesions, NGF treatment did not rescue GABAergic neurons. Thus, GABAergic neurons of the BFMC do not appear to respond to NGF as do adjacent cholinergic neurons. We plan to evaluate the possible effects of other trophic factors on GABAergic neurons of the basal forebrain.

208.15

SN-1,2-DIACYLGLYCEROL (DAG) IN SYNCHRONIZED C12 CELLS DURING PROLIFERATION AND DIFF ERENTIATION P. G. Holbrook and J. W. Daly Bldg 8A, Room 1A-15, NIH, Bethesda, MD 20892 DAG was measured in PC12 cells by a radioenzymatic assay [Preiss et al. (1986); JBC 261, 8597]. Levels in exponentially-growing cells maintained in serum-containing media were 1.3 \pm 0.29 nmol DAG/100 nmol lipid phosphorous and decreased to 0.71 \pm 0.14 nmol phosphorous and decreased to 0.71 ± 0.14 hmol DAG/100 nmol lipid phosphorous when serum was removed. Exponentially-growing cells are in various stages of the cell-cycle. The effects of nerve growth factor (NGF) on different-iation may be cell-cycle specific [Rudkin et al. (1989); EMBO Journal 8, 3319]. PC12 cells were serum starved for 3 days prior to treatment with either serum-containing media, to elicit proliferation, or serum free media with NGF (50 ng/ml), to elicit differentiation. Cells appeared to be synchronized in the G₁ phase of the cell cycle; phospholipid content doubled 40 to 50 hours after readdition of serum, a time when mitosis is known to occur. DAG remained at basal levels up to 74 hours after the addition of serum but was elevated 5 to 6 fold 48 hours after NGF.

208.17

NGF AUGMENTS THE CALCIUM BINDING PROTEIN, CALBINDIN-28K, IN RAT OLFACTORY BULB *in vivo*. <u>A.M.</u> Iacopino, S. Christakos, and C.A. Altar¹ Biochemistry Mol. Biololgy, UMDNJ, Newark, NJ and ¹Developmental Biology, Genentech, Inc., South San Francisco, CA 94080.

Calbindin-28K (CaBP) is a 28,000 MW calcium binding protein

that protects against excitatory amino acid (EAA) induced neurodegeneration (K.G. Baimbridge and J. Kao, Soc. Neurosci. 14:1264). CaBP is widely distributed in brain and is found in areas that contain NGF and NGF receptor.

areas that contain NGF and NGF receptor.

Via Alzet 2002 pumps, male rats received for 10 or 14 days a lateral ventricle infusion (n = 7/group) of 12 ul PBS/day containing either 1.0 or 1.5 ug cytochrome C (control) or an equal amount of recombinant human NGF (rhNGF). Six other animals received the rhNGF infusion into the left central neostriatum. CaBP was elevated by 70% and 86% (p < 0.01) in the olfactory bulb following rhNGF in each of two experiments and was not elevated in the temporal cortex bimpostances. was not altered in the temporal cortex, hippocampus, olfactory tubercle or cerebellum and was not altered in the neostriatum following direct or icv injections.

These findings demonstrate that NGF can augment the content of CaBP in olfactory bulb neurons. In addition to its classic neurotrophic role, we propose that NGF, and possibly other neurotrophic factors such as FGF (M.P. Mattson et al, Soc. Neurosci. 15:1260) function as neuroprotective factors by augmenting the ability of CaBP-positive neurons to sequester cytoplasmic calcium and retard calcium-mediated neurodegeneration.

NERVE GROWTH FACTOR RECEPTOR IMMUNOREACTIVITY IN THE VISUAL CORTEX OF EMBRYONIC RHESUS MONKEYS, D.L. Meinecke and P. Rakic, Section of Neuroanatomy, Yale Sch. of Med., New Haven, CT 06510.

It is now known that CNS neurons contain nerve growth factor (NGF), but the functional implications are unclear. Some evidence suggests that NGF derived from sources such as the basal forebrain may play a role in fetal cortical development. For example, neurons of the basal forebrain are among the earliest generated cells of the telencephalon giving rise to some of the first projections to the developing cortex, and several studies with monoclonal antibodies show that while receptors for NGF are expressed through adulthood in basal forebrain, they are only transiently expressed in fetal telencephalon. Here we report the results of studies at the cellular and subcellular level using a monoclonal antibody to NGF receptor (ME20.4, Ross et al., PNAS #81, 1984) examining NGF receptor localization in fetal monkey visual cortex at stages of active cortical neurogenesis and migration. Light and electron microscopic observations show that many of the neurons located in the marginal and transient subplate zones are labeled. In addition, labeling occurs on many small processes in the intermediate zone which resemble growing axons. Immunolabeling does not appear to be correlated with synaptic sites, but is broadly localized on the plasma membranes of labeled neurons and processes. Migrating neurons and neurons located in the cortical plate are seldom labeled, but distal segments of radial glial processes in the cortical plate are positively labeled. The segments of radial glial processes in the cortical plate are positively labeled. The most intense labeling in the cortex is on the extracellular surfaces of endothelial cell membranes lining capillaries throughout the telencephalic wall. These findings support the possibility of multiple roles for NGF in cortical development considering the diverse sites of cortical NGF receptor localization. Furthermore, these results support the possibility of receptor mediated trophic interactions in the transient subplate zone with early NGF-containing projections from sources such as basal forebrain. Supported by grants form US Public Health Service.

THE EFFECT OF THE ENDOGENOUS GANGLIOSIDE GM1 ON SENSITIVITY OF DORSAL ROOT GANGLIA NEURONS TO NERVE GROWTH FACTOR. D.F. Chen and F.J. Roisen. Department of Anatomical Sciences and Neuroblology, Univ. of Louisville, School of Medicine, Louisville, KY 40292. Exogenous gangliosides potentiate the action of several neurotrophic factors including Nerve Growth Factor (NGF). Previously, we have shown that the ganglioside GM1 potentiated NGF-mediated neuritogenesis of chick embryonic sensory ganglia (DRG) during the periods when neuritogenesis was submaximal, embryonic day (ED) 7 & 11-13. During the peak of NGF-mediated development (ED 8-10), GM1 had no effect on neuritogenesis. The mechanism by which GM1 potentiates NGF-mediated development remains unclear. To determine whether the differences in the capacity of GM1 to enhance NGF-mediated development were related to endogenous levels of GM1 in the axoderma, a direct method of fluorescence using the cholera toxin B subunit labeled with FITC was employed, since the cholera toxin has been shown to have a high specificity for GM1. Trypsin dissociated DRG (ED 7-13) were cultured in medium containing NGF for up to 3 days. Specific fluorescence was detected on the perikaryal and neuritic surfaces. Nonneuronal cells remained unlabeled. Two different populations of neurons Specific fluorescence was detected on the perikaryal and neuritic surfaces. Nonneuronal cells remained unlabeled. Two different populations of neurons could be identified in the DRG based on the intensity of fluorescent labeling. These different neuronal types could not be distinguished by respective size. Overall, the fluorescence increased from ED 7-13. Our previous quantitative analysis with HPTLC binding with B-cholera toxin-horseradish peroxidase demonstrated that the concentration of endogenous GM1 in the mixed neuronal and nonneuronal population was specifically high at ED 7 and dramatically decreased to its lowest level on ED 8. Later on, the GM1 level increased markedly from ED 8-13. These results suggest that the mechanism by which GM1 potentiates neurotrophic factors is mediated through the neuronal membrane and that the concentration of endogenous GM1 regulates neuronal sensitivity to NGF. NGF AND FGF-LIKE ACTIVITY IN CSF OF HUMAN HEAD TRAUMA PATIENTS. S.L. Patterson! M.S. Grady? A.G. Balllet! and M. Bothwell. Dept. Physiology & Biophysics! and Dept. Neurosurgery? University of Washington, Seattle, WA 98195.

One of the factors determining the degree to which elements of central nervous system (CNS) can recover from injury may be the availability of neurotrophic substances. Neurotrophic activity has been reported in the fluid secreted into wounds in developing and adult rat brains (Nieto-Sampedro, M., et al., Science, 217:860-861, 1982), and in the CSF of human head trauma patients (Longo, F.M., et al., Exp. Neurology, 84:207-218, 1984). Since low levels of NGF are detectable in the CSF of young rats, we set out to determine if the neurotrophic activity associated with CSF following trauma might be attributable to the presence of NGF. We report here the presence of low levels of NGF in CSF samples collected from human head trauma patients soon after injury. The NGF was quantitated against a recombinant human NGF (Genentech) standard in an ELISA using antibodies against murine B NGF. When the CSF was assayed for the ability to promote neurite outgrowth from PC12 cells, neurite outgrowth was reduced, but not completely blocked, by antibodies to NGF, suggesting the possibility that there were other biologically active factors present. FGF is also reported to promote neurite outgrowth in PC12 cells. In an initial screening for the presence of FGF, we employed PC12 cells and NR119 cells, PC12 variants in which NGF, but not FGF, promotes neurite outgrowth. CSF from head trauma patients promoted greater neuritic growth from PC12 cells than from NR119 cells, suggesting that some of the biological activity associated with the trauma CSF may be due to basic FGF. Interestingly, there was no detectable NGF or FGF-like biological activity remaining in CSF collected from the same patients 2-3 days after the first sampling.

SELECTIVE INHIBITION OF NGF-MEDIATED MAP2 KINASE ACTIVATION BY K252a, K252b, AND STAUROSPORIN. <u>L.K. TAYLOR AND G.E. LANDRETH</u>. Alzheimer Research Laboratory. Departments of Neurology and Neurosciences, Case Western Reserve University, Cleveland, OH 41106

The activation of MAP2 kinase is an early response following the treatment of PC12 cells with NGF. MAP2 kinase is activated through its phosphorylation by an as yet unidentified protein kinase. MAP2 kinase is also activated by EGF and bFGF treatment of PC12 cells. The means by which NGF activates MAP2 kinase is mechanistically distinct from those of EGF and bFGF. The antimicrobial alkaloid K252a, as previously reported, blocks the ability of NGF to activate MAP2 kinase as well as all other affects of NGF on these cells. Two structurally related alkaloids, K252 and staurosporin, are equally selective in their capacity to inhibit the NGF-mediated activation of MAP2 kinase.

K252b is not as potent of an inhibitor of MAP2 kinase activation as K252a. In vivo, K252b inhibits MAP2 kinase activation with an IC50 of 160 nM while in vitro inhibition of the kinase occurs at an IC50 of 360 nM. Staurosporin inhibits NGF-induced activation of MAP2 kinase in vivo with an IC50 of 10 nM, while producing little inhibition of the kinase in vivo at concentrations up to 400 nM. These data strongly suggest that NGF activation of MAP2 kinase is mediated through a protein kinase which is uniquely stimulated by NGF and not other growth factors. This alkaloid-sensitive kinase must be positioned at a very early point in the cascade of events following NGF receptor occupancy and may be the seminal event of NGF-action.

TROPHIC MATERIAL WHICH ARE CAPABLE OF PROMOTING THE NEURITE OUTGROWTH OF RAT ADRENAL CHROMAFFIN CELLS. K. Shimoda and H.-Y.T. Yang, NIMH, Lab. of Biochem. Genetics, Neuroscience Center at St. Elizabeths, Washington, DC 20032

Adrenal chromaffin cells, which are derived from neural crest, can differentiate into sympathtic neuron like cells in responding to neuro-trophic factors. Previously, we have observed that 2 month old cultured chromaffin cells prepared from adult rats can extend neurites spontaneously if culture media are not changed for a week. Subsequent studies have suggested that trophic material, which is distinct from NGF but protein in nature, is produced or released and accumulated in the culture medium. In this study, this trophic material was further characterized and found to differ from bFGF, aFGF, EGF and insulin like growth factor because all these factors were inactive in inducing the neurites outgrowth from the primary culture of chromaffin cells prepared from adult rats. While the exact nature of this trophic material awaits further characterization, this neurite outgrowth promoting activity may be an interesting factor to be considered in adrenal gland transplantations in experimental Parkinsonian models.

CYTOKINE REGULATION OF NEUROPEPTIDE EXPRESSION IN CULTURED SYMPATHETIC NEURONS. M. Freidin* and J.A. Kessler. Depts. of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

We have been studying the effects of cytokines on neurotransmitter

We have been studying the effects of cytokines on neurotransmitter phenotypic expression cultures of the neonatal rat sympathetic superior cervical ganglion (SCG). In explants of the SCG, treatment with interleukin 1β (IL1- β) significantly increased levels of substance P (SP). Similarly, treatment of dissociated sympathetic neurons cultured in the presence of ganglion nonneuronal elevated levels of the peptide 2 - 10-fold. However, treatment of pure neuronal cultures with IL1- β failed to elevate levels of SP. Several other cytokines failed to influence sympathetic neuropeptide expression. However treatment with leukemia inhibitory factor (LIF) also elevated levels of SP in cultured neurops.

To examine the specificity of the effects of IL1- β , levels of neuropeptide Y (NPY) were also measured in these cultures. NPY is abundant in pure neuronal cultures and coculture with nonneuronal cells decreases levels by half. Treatment with IL1- β only slightly increased levels of NPY in contrast to the large increase to SP.

These observations suggest either that the effects of IL1- β reflect an indirect effect on nonneuronal cells or that an additional nonneuronal

These observations suggest either that the effects of $IL1-\beta$ reflect an indirect effect on nonneuronal cells or that an additional nonneuronal cell factor is necessary for the $IL1-\beta$ effect on neurons. In conclusion, our observations suggest that $IL1-\beta$ and LIF each influences neuropeptide expression by cultured sympathetic neurons. This supports the hypothesis that neuronal transmitter expression and function are regulated, in part, by interactions with specific immunoregulators.

CILIARY NEUROTROPHIC FACTOR (CNTF) mRNA IS LOCALIZED TO NEURONS IN RAT HIPPOCAMPUS. <u>G.M. Dobrea*, B.J. Wilcox and J.R. Unnerstall.</u> Dept. of Neurology and The Alzheimer Center, Case Western Reserve University School of Medicine, Cleveland, OH 44106

CNTF is a 24 kd protein with trophic and differentiation effects on sympathetic and parasympathetic ganglia and astrocyte progenitor cells *in vitro*. The primary structure of CNTF has been confirmed using the DNA sequence obtained from mRNA extracted from rat sciatic nerve. We have utilized a 45mer oligonucleotide probe based on this DNA sequence to study the expression and cellular localization of CNTF mRNA in the adult rat CNS by *in situ* hybridization histochemistry. Following hybridization with [³⁶S]ATP labeled probe and washing under stringent conditions, sections through the rostral-caudal extent of the rat forebrain were dipped in molten emulsion. The autoradiograms were developed after 6-8 weeks. Specific clusters of grains were uniquely localized to neurons of the hippocampal formation. Occasional granule cells of the dentate gyrus and pyramidal cells of the hippocampus proper were labeled. Neurons of the CA2 transition zone and CA1 subfields were most noticeably labeled. This limited distribution was confirmed by Northern analysis. These data demonstrate that CNTF is expressed in specific neurons of the CNS. The limited distribution of CNTF mRNA in the adult hippocampus indicates that this neurotrophic factor has a selective role in maintaining neuronal viability and plasticity in this dynamic brain region.

IDENTIFICATION OF NEURONAL TARGETS FOR CNTF USING "EPITOPE TAGGING" TECHNOLOGY.

S.P. Squinto, T.A. Aldrich*, R.M. Lindsay, D.M. Morrissey, N. Panayotatos, S.M. Bianco*, M.E. Furth, and G.D.Yancopoulos. Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Road, Tarrytown, NY 10591.

Ciliary neurotrophic factor (CNTF) promotes the survival of a variety of neuronal cell types and affects the differentiation of both embryonic sympathetic neurons and type-2 astrocytes. In the absence of antibodies to either CNTF or its receptor, the aim of these studies was to develop methods for the identification of other neuronal target cells with functional CNTF binding sites. We have engineered and expressed in E. Coli a "tagged" recombinant chimeric rat CNTF (rCNTF) which carries at its C-terminal a 10 amino acid epitope of the human c-myc gene. Purified rCNTF and rCNTF/myc were equally bioactive when assayed against E8 chick ciliary ganglia neurons. Using a rosetting assay we identified several human neuronal tumor cell lines as well as primary neurons derived from embryonic chick dorsal root ganglia that were positive targets for CNTF/myc binding. Functional binding of rCNTF/myc to these target neuronal cells was indicated by demonstrating a perfect correlation between rosette-positive cells and the rapid induction of either c-fos and or c-jun mRNA by CNTF in these target cells. This new methodology should prove useful in mapping the in vivo targets for CNTF.

209.7

CHARACTERIZATION OF CILIARY NEURONOTROPHIC FACTOR IN RAT ASTROCYTES. <u>I.S. Rudge, R.F. Alderson, N.Ip and R.M. Lindsay</u>. Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Road, Tarrytown, NY 10591.

Ciliary Neuronotrophic Factor (CNTF) has been shown to have neuronal survival properties for a wide range of peripheral neurons and more recently central neurons (van de Stadt et al, 1990 Soc. Neurosci. Abs.) as well as a putative effect on type II astrocyte differentiation (Hughes et al, 1988 Nature, 335:70). The source of CNTF in the CNS is unknown but a potential candidate is the neonatal type I rat cortical astrocyte which has been shown in vitro to express biologically active CNTF (Rudge et al, 1983 Dev. Brain Res, 19:161). We have further characterized this astrocytic form of CNTF in rat hippocampal astrocyte cultures and find it to be present on the surface of type I astrocytes using specific antisera and immunocytochemistry. It was found to be identical to the 22.5kd form of rat CNTF purified from E. coli lysates on Western blots. Messenger RNA (1.2kb) for CNTF was also detected at high levels in these astrocytes. Further characterization of the regulation and expression of this molecule in astrocytes in vitro is underway.

209.9

RAT HIPPOCAMPAL NEURONS IN CULTURE: EFFECTS OF CILIARY NEUROTROPHIC FACTOR (CNTF). I. van de Stadt. Y. Li*, R. M. Lindsay, R. F. Alderson, and N. Y. Ip. Regeneron Pharmaceuticals Inc., 777 Old Saw Mill River Rd., Tarrytown, NY 10591.

CNTF has been shown to act as a neurotrophic factor towards parasympathetic and sympathetic neurons in culture. The possibility that CNTF may have similar actions in the CNS has been examined. Hippocampal neurons derived from E18 rat embryos, when treated with CNTF for 8 days in vitro, showed enhanced neurite outgrowth. Utilizing an Elisa assay, we have demonstrated that CNTF treatment increased the levels of neurofilament protein (200kd) by 4-fold. In addition, the uptake of GABA via a neuron-specific high-affinity process, and GAD enzyme activity were increased in a dose-dependent fashion by CNTF. GABA uptake was maximally increased, 3-fold over non-treated controls, with 1ng/ml of CNTF. The ability of CNTF to induce GABA uptake is cell density dependent, with high plating densities being inhibitory. In addition, the response of GABAergic neurons to CNTF is not diminished in neuron-enriched cultures, suggesting that CNTF is not acting via glial cells.

200 6

EFFECTS OF CILIARY NEUROTROPHIC FACTOR (CNTF) ON VENTRAL SPINAL CORD NEURONS IN CULTURE. Y. Wong, R. Arriaga*, and R.M. Lindsay. Regeneron, Tarrytown, NY 10591.

CNTF was originally characterized as a target-derived neurotrophic factor supporting the survival of chick ciliary ganglion neurons in vitro. However, it showed a broad spectrum of additional activities including the survival of chick sensory and sympathetic neurons, the shifting of rat optic nerve O-2A progenitor cells towards type 2 astrocytes, and inducing cholinergic properties in sympathetic neurons. In this study, we examined the effects of CNTF on ventral spinal cord cultures which were enriched with somatic motorneurons. Treatment of CNTF on the day of plating resulted in a 5-fold increase in choline acetyltransferase (CAT) activity. The increase diminished, though significant, when treatment was postponed to day 1 or 2 after plating, but CAT activity remained at control levels when treatment was postponed to day 6. These observations suggest that CNTF enhances the survival of ventral cholinergic spinal cord neurons in culture. This increase in CAT activity was dose dependent and saturating effect of CNTF was reached at approximately 1ng/ml. Both neurofilament and protein levels were elevated in CNTF-treated cultures. NGF and bFGF had no effect on CAT activity, suggesting the specificity of CNTF on ventral cholinergic spinal cord neurons.

209.8

CILIARY NEURONOTROPHIC FACTOR (CNTF) IMMUNOREACTIVITY IN THE RAT SCIATIC NERVE M. Rende*, T. Hagg, E. Magal, S. Varon and M. Manthoroe Deot. Biol., M-001, Univ. Calif. San Diego, La Jolla, CA. 92093

Manthorpe Dept. Biol., M-001, Univ. Calif. San Diego, La Jolla, CA 92093 In vitro, CNTF has potent neuronotrophic activity for the cholinergic motor neurons of ciliary ganglion and also for sympathetic and dorsal root sensory ganglionic neurons. CNTF is very abundant in extracts of adult rat sciatic nerve and is produced by purified Schwann cell cultures. Two peptides were synthesized corresponding to internal residue Nos. 45-59 and carboxy terminal sedue Nos. 181-200 of rat nerve CNTF (Stöckli et al, Nature 342: 920, 1989). These internal and carboxy-terminal sequences possess at least 80% and 50% sequence homology, respectively, among the cloned rat, rabbit and human CNTFs. Polyclonal rabbit anti-peptide antibodies were generated and affinity-purified with immobilized peptide. The antibodies reacted with rat sciatic nerve CNTF protein by ELISA and by immunosequestration of CNTF neurotrophic activity. Immunostaining was carried out on 5-20 µm paraformaldehyde-fixed cryostat sections using a sensitive ABC-peroxidase method. In normal adult rat sciatic nerve, CNTF immunoreactivity was restricted to nearly all Schwann cell bodies where it appeared to be particulate, intracellular and perinuclear. Staining was also observed in the Schwann cell cytoplasm surrounding the myelin sheaths. Electron microscopy is being undertaken to determine the intracellular location of Schwann cell CNTF. No staining was observed in axons, endothelial, epineural, perineurial or endoneurial cells nor in skeletal muscle innervated by sciatic nerve. This Schwann cell localization is in contrast to presence of CNTF staining of most CNS cells (Varon et al., Soc. Neurosci. Abstr., 16, 1990). The exclusive and preponderant immunolocalization of CNTF to Schwann cells suggests that these cells produce CNTF in vivo where they may provide it to sensory, sympathetic and motor nerve axons. REGULATION OF THE EXPRESSION OF SURFACE ADHESION MOLECULES ON CULTURED ASTROCYTES. S. Choi-Kwon, R.E., Petroski, J.P., Grierson and H.M. Geller. Department of Pharmacology, UMDNJ-Robert Wood Johnson Medical School and The Graduate School, Rutgers University, 675 Hoes Lane, Piscataway, NJ 08854.

Basic Fibroblast Growth Factor (bFGF) has trophic actions on neurons and astrocytes. However, our data indicate that actions of bFGF on hypothalamic neurons might be mediated indirectly through its effects on astrocytes (see Petroski et al.). The present study focuses on the effects of bFGF and culture conditions on the expression of surface adhesion molecules by rat cerebral cortical astrocytes in culture. Confluent monolayers of astrocytes were grown for 7 days in FCScontaining medium (CM), chemically defined serum free medium (N2), or CM containing 5 ng/ml bFGF. The cells were stained in suspension with polyclonal antibodies directed against surface antigens (tenascin/cytotactin or NCAM) followed by a fluorescein conjugated secondary antibody. FACS analysis revealed that bFGF treatment significantly enhances the expression of tenascin/cytotactin and NCAM whereas N2 medium significantly decreased the expression of these adhesion molecules compared to those levels expressed in CM alone. The present data suggest that the trophic effects of serum-free medium or bFGF on neurons might be mediated by regulating the expression of adhesion molecules, thereby providing an altered substrate for neural attachment and neurite outgrowth. Supported by Grant # NS 25168 to HMG.

Biphasic Actions of Basic Fibroblast Growth Factor (bFGF) on the Development of Astrocytes R.E. Petroski, S. Choi-Kwon, J.P. Grierson and H.M. Geller. Dept. of Pharmacology, UMDNJ-Robert Wood Johnson Medical

School and The Graduate School, Rutgers University, Piscataway, NJ 08854 bFGF is an angiogenic factor and has also been found to be neurotrophic in several brain regions. The specificity of its action has been questioned as it is found ubiquitously in the brain. We have examined the putative trophic effects of bFGF on developing neurons in vitro using a dissociated cell culture system derived from embryonic rat hypothalamus.

Treatment of these cultures with bFGF had no effect on neuronal survival in FCS or N2 media. However, a profound mitogenic effect on hypothalamic astrocytes in FCS was observed. Astrocyte proliferation was quantitated by loading fixed cells with propidium iodide and counting the nuclei. The optimum dose of bFGF (0.5 ng/ml) yielded an average count of greater than 10 times control. The dose-response was biphasic in that 5 ng/ml produced fewer counts. The mitogenic effect of bFGF was dependent on the presence of FCS and was completely abolished by treating the cultures with 1 µM Ara-C. We also tested the ability of bFGF to promote neuronal survival when the dissociate of embryonic hypothalamus was plated on a substrate of confluent cortical astrocytes, bFGF had no effect on neuronal survival and the highest dose (5 ng/ml) reduced neuronal counts. At this dose, bFGF induced morphological

changes in that the flat astrocytes became "grainy" and more fibrillar.

We conclude that bFGF mediates a complex series of events in neural development. While bFGF acts as a potent mitogen for astrocytes, higher doses stimulate differentiation of the immature glial phenotype to one which is a poorer substrate for neuronal adhesion and survival. This may involve the altered expression of surface molecules (see Choi-Kwon et. al. this meeting). We have not been able to detect any direct trophic effect on hypothalamic neurons

INSULIN-LIKE GROWTH FACTOR II (IGF II) IN RAT BRAIN AFTER CEREBRAL ISCHEMIA. W.L.Russell, L.A.Phebus, K Rash*, P.B. Summerlin*, A.P.Evan*, J.A.Clemens, D.P.Henry.

Lilly Lab. for Clin. Res. Eli Lilly & Co., and Dept. of Anatomy, Indiana Univ. Sch. of Medicine, Indianapolis, IN 46202

IGF II is hypothesized to be a fetal growth factor. In adult rat brain, IGF II mRNA levels remain high after birth as the levels of both IGF II and IGF II mRNA decrease in other tissues. The function of IGF II in brain is unknown. Cortical ischemia method or by middle cerebral artery occlusion. Rats were sacrificed at 0, 3, 6, or 9 days after ischemia. IGF II was extracted from cortex with a formic acid/acctone method as described previously (Abstr. Soc. Neurosci. 15(1), 231), and quantified by RIA. Three days after stroke, IGF II levels in the infarcted cortex (32.2 ± 3.7 ng/g tissue; mean±SEM; n=6) were higher than that in contralateral cortex (18.5 ± 3.2; p<0.05) and returned to normal by day 9. The distribution of IGF II was examined immunocytochemically using a monoclonal Ab to IGF II. One day after artery occlusion, enhanced immunoreactive staining was observed only in the infarcted hemisphere especially in the glia of the corpus callosum and anterior commissure. By the third day, pronounced IGF II immunoreactivity was observed in the infarcted cortex and probably resulted from IGF II produced in glial cells. Therefore, the production of IGF II is increased in response to cerebral ischemia, suggesting that IGF II may be involved in the tissue repair process after stroke. was induced in 3 mo. old male rats by either a photochemical

BASIC FIBROBLAST GROWTH FACTOR MODULATES ADHESIVE PROPERTIES OF CHICK NEURAL TUBE CELLS IN CULTURE. Y. Kinoshita. C. Kinoshita. J. G. Heuer and M. Bothwell.

Dept. of Physiology & Biophysics, Univ. of Washington, Seattle, WA 98195.

Fibroblast growth factors (FGFs) have been shown to serve as mitogenic and trophic factors for neuronal as well as glial components of the CNS. Little is known, however, of their functional roles in early embryonic CNS development. Our in situ hybridization studies have revealed abundant FGF receptor mRNA expressed in the neural tube (NT), prompting us to examine the effect of basic FGF (bFGF) on NT cells' behavior in culture. Cells obtained from a thoracic region of E2.5 (26-30 somites) chick embryo NT were cultured on collagen substrate in F12 + 10% FBS and bFGF, when present, at 5 or 10 ng/mL. Addition of bFGF markedly improved cell spreading with half-maximal and maximal effects being attained at ~0.4 and 2 ng/mL; this effect was discernible 6-8 hrs after cell plating, abolished by cychioheximide treatment, and seen on collagen, laminin, or more poorly on fibronectin substrate but not on others tested (vitronectin, RGD-peptide, poly-lysine, etc), suggesting an involvement of a specific type(s) of the integrin family induced upon bFGF treatment. bFGF-treated cells showed enhanced cell attachment and spreading but similar cell aggregation ability as compared with control cells. NT (spinal cord) cells from older embryos (E3.5, E5, E8) were found to become less dependent on bFGF for spreading with age. In contrast, NT cells from younger embryos (6.10, 16-19 somites) required bFGF not only for cell appreading but also cell survival. Thus, the cell spreading ability of NT cells and its dependence on bFGF appeared to be highly developmentally regulated and the cell spreading response to bFGF is probably inherent to neuroepithelial cells. bFGF also promoted cell proliferation. These results suggest that, in an early stage of the NT development, bFGF is critically involved in the regulat

ONTOGENIC PROFILES OF RAT BRAIN INSULIN AND INSULIN-LIKE GROWTH FACTOR-I BINDING SITES. J.-G. Chabot, J. Tsang* and R. Ouirion. Douglas Hospital Research Centre, Department of Psychiatry, McGill University, Montreal, Quebec, Canada.

In recent years, insulin and insulin-like growth factor-I (IGF-I) gene,

protein expression and specific binding sites has been demonstrated in the mammalian central nervous system (CNS). Additionally, some results have suggested that insulin and IGF-I may act as neurotrophic and/or neuromodulatory substances in the brain. The autoradiographic distribution of both insulin and IGF-I binding sites was examined in the rat CNS during postnatal development and maturation. Under our incubation conditions, we observed a widespread and differential distribution of brain insulin and IGF-I binding sites during postnatal ontogeny. Both classes of sites appeared early postnatally and reached maximal adulthood levels over the third to fourth weeks. However, the respective ontogenic profiles of these sites differed between regions. For example, insulin binding appeared as early as days 1 to 4 in the cortex and olfactory bulb while it was absent up to day 7 in the thalamus. Moreover, the respective ontogenic appearance of insulin and IGF-I receptor sites was unique. For example, while IGF-I sites in the thalamus appeared on sites was unique. For example, while ICF-I sites in the thalamus appeared on day 1, insulin binding sites were present in this area only at the end of the first week. This reveals that insulin and IGF-I binding sites represent two distinct populations of receptor sites. The presence of these binding sites in the adult CNS may also indicate possible neuromodulatory roles of insulin and IGF-I, in addition to their better known trophic actions in developing tissues.

209.14

EFFECT OF INSULIN ON MORPHOLOGICAL PHYSIOLOGICAL DIFFERENTIATION OF EMBRYONIC DROSOPHILA NEURONS. D. K. O'Dowd Department of Anatomy and Neurobiology, California College of Medicine, Irvine, CA 92717

Tryine, CA 92117

Drosophila embryos can be dissociated and cultured in vitro. In the presence of 10-20% serum supplements morphologically undifferentiated gastrula cells give rise to both myotubes and neurons that express a variety of functional ion channels. In order to identify environmental factors that might be involved in the differentiation of these Drosophila cells I have examined cultures grown in a serum-free defined medium. Cells with neuronal morphology that express voltage-gated sodium channels are clearly differentiated 1-2 days after plating and can be maintained in culture for at least two weeks. However, there are few cells resembling myocytes weeks. However, there are few cells resembling myocytes or myotubes. Previous studies have shown that addition of exogenous insulin to serum-based media is important in the development of cultured myotubes but does not affect the development of cultured myotubes but does not affect neuronal differentiation. Therefore, the effects of different concentrations of insulin on the differentiation of cells grown in defined media were examined. In contrast to earlier studies, the addition of insulin up to 10 uM failed to support morphological differentiation of myotubes and it did result in an increase in both the size of neuronal somata and processes. Supported by NS27501 and National Multiple Science (Science MG 2160.4.1) National Multiple Sclerosis Society RG 2160-A-1.

ACIDIC AND BASIC FGF EXERT TROPHIC EFFECTS ON INTRAOCULAR FETAL BRAIN TISSUE GRAFTS MB Giacobini*1, B Hoffer2, L Olson1, 1Dept. of Histology & Neurobiology, Karolinska Institutet, Stockholm Sweden, and ²Dept. of Pharmacology, Univ. of Colorado, Denver, CO, USA

Basic fibroblast growth factor (bFGF) mRNA is present in considerable amounts in many areas of the central nervous system including cerebral cortex and bFGF has been suggested as a trophic factor for both developing and lesioned neurons. By using the in vivo model of intraocular transplantation with repeated injections of growth factors into the eye chamber, we have followed the survival and growth of small defined areas of the central nervous system under the influence of acidic FGF (aFGF) and bFGF. Acidic FGF significantly enhanced growth of transplanted parietal cortex (E19-20) and hippocampus (E19-21), but not spinal cord (E14). Acidic FGF brought about a volume increase of approx 100% of both parietal cortex and hippo-campus grafts. The trophic effects of bFGF stimulation were even more remarkable. Basic FGF enhanced growth of intraocularly transplanted cortex (E19) by up to 400% when compared to the vehicle alone, and bFGF was therefore clearly more potent than aFGF. Other CNS areas are now under investigation with bFGF stimulation. Effects on all areas tested so far were seen using 5-µl injections into the eye chamber of concentrations of both aFGF and bFGF down to at least 25 $\mu g/ml$. Histological and histochemical observations of the growth factor-stimulated grafts will also be presented. We conclude that both aPGF and bPGF are potent stimulators of volume growth of several but not all grafted fetal brain areas during development. These studies suggest that exogenous fibroblast growth factors might enhance survival and/or stimulate proliferation of cells in fetal brain tissue grafts.

Membrane-Associated Factor Inhibits Neuroblast Mitosis and Fosters Neuronal Differentiation. J-M. Lee, I.B. Black, E. DiCicco-Bloom and J.E. Adler Div. Dev. Neurology, Cornell Univ. Med. Coll., New York, NY 10021, Dept. Neurosci. and Cell Biol. UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ, and Dept. Neurology, Wayne State Univ. Sch. of Med., Detroit, MI.

Numerous studies have suggested that differentiation proceeds only after mitosis ceases in developing neurons. However, the mechanisms underlying these apparently obligatory sequential events are largely unexplored. We now present evidence that a single factor regulates both neuronal proliferation and neurotransmitter differentiation at distinct ontogenetic stages.

We have previously found that a membrane-associated protein factor induces the de novo appearance of choline acetyltransferase (CAT) activity in cultures of neonatal sympathetic neurons (Lee et al., Exp. Neurol. in press). To investigate the role of this factor al., Exp. Neurol. in press). To investigate the role of this factor during development, we defined a critical period during which the factor induced CAT activity. The factor elicited significant CAT induction in cultured neurons from embryonic day 20 (E20) to postnatal day (P7), in the absence of effects on neuronal survival. CAT activity was not altered at earlier or later stages. However, while E15.5 neurons failed to exhibit CAT induction by the factor, DNA synthesis was markedly reduced in this mitotically active population. Cell survival and morphology were unchanged. Thus, the factor appears to inhibit neuroblast mitosis at this embryonic age. These observations suggest that a single molecule may influence the cessation of neuroblast mitosis while reciprocally fostering neuronal differentiation. (Support: NIH grants NS10259 and HD23315)

CHARACTERIZATION OF A SOMATOSTATIN STIMULATING ACTIVITY FOR CULTURED CILIARY GANGLION NEURONS. J.N.Coulombe, F.P.Eckenstein, and R.Nishi Dept. of Cell Biology and Anatomy, Oregon Health Sciences University, Portland, Oregon. 97201

We previously found that induction and maintenance of somatostatin in cultured ciliary ganglion neurons (CGNs) depends upon the presence of soluble macromolecules released by cells of choroid layer. Here we present further characterization of this somatostatin stimulating activity (SSA). <u>In vivo</u>, only half of the CGNs innervate the choroid layer and express somatostatin, however, SSA can induce somatostatin expression in more than 90% of cultured CGNs. When ciliary neurons were labelled by retrograde transport after transection of the choroid nerves and cultured in the presence of SSA, many of the labeled ciliary neurons were found to contain somatostatin. Thus, SSA can induce neuropeptide expression in ciliary neurons which would not normally have expressed somatostatin. SSA can be obtained from choroid cells cultured in low serum (0.1% v/v) or serum-free medium and is ammonium sulfate precipitable. SSA is unusually heat stable and withstands 10' of exposure to 100°C but loses activity after 30' at 100°C. Using FPLC gel filtration chromatography we found that SSA has an apparent size of 30-40kD. These observations suggest that SSA is a protein serving an instructive role regulating neuropeptide expression in the avian ciliary ganglion.

LAMININ-LIKE NEURONAL IMMUNOREACTIVITY IN THE ADULT AND AGED RAT BRAIN USING ANTIBODIES AGAINST CHAIN-SPECIFIC SEQUENCES. M. Jucker, C.F. Hohmann, H.K. Kleinman, and D.K. Ingram. Gerontol. Res. Ctr., NIA, NIH, Baltimore, MD 21224; Dept. Psychiat., Johns Hopkins Med. Sch., Baltimore, MD 21205; Lab. Dev. Biol. Anom., NIDR, NIH, Bethesda, MD 20892

Intraneuronal laminin-like immunoreactivity was examined by avidin-biotin peroxidase technique using polyclonal antibodies against EHS tumor-derived laminin (AB_{lam}) and against laminin-derived synthetic peptides (A-chain, AB_a) and fusion proteins (B1- and B2-chain; AB_{B1} and AB_{B2}). AB_A was raised against peptide PA22-2 which promotes neurite outgrowth in fetal septal cell cultures (Jucker et al., Soc. Neurosci. Abstr. 15:575, 1989). Immunostaining with AB_{lam} revealed specific but widespread reactivity in most parts of the adult and aged rat brain confirming reports by others (Yamamoto et al., J. Neurol. Sci. 84:1, 1988; Hagg et al., Neuron 3:721, 1989). A similar immunoreactivity distribution was elicited by applying the peptide-specific AB. This immunoreactivity appeared even stronger, and light microscopy revealed distinctly labeled neuronal processes in several regions, including processes in the vertical diagonal band, and apical dendrites of cortical and hippocampal pyramidal cells. When AB_{lam} was preincubated with purified laminin, intraneuronal immunostaining was greatly diminished. Depending on fixation technique of the tissue, only intraneuronal or both intraneuronal and basement membrane laminin of vascular structures could be visualized. Results suggest that neuronal laminin-like molecules are similar to basement membrane laminin and share epitopes with all three laminin chains. Future studies will address further analysis of laminin-like neuronal immunoreactivity with aging and immunohistochemical mapping of injury-induced laminin-like molecules

ROLE OF MESENCEPHALIC GLIA IN THE NEURONOTROPHIC RESPONSE OF DOPAMINERGIC NEURONS TO GROWTH FACTORS. J. Engele and M.C. Bohn., Dept. of Neurobiology and Anatomy, University of Rochester, Med. Ctr., Rochester, N.Y. 14642,

Our previous studies demonstrated that the purified growth factors acidic FGF (aFGF), basic FGF (bFGF), and NGF, and conditioned media (CM) from the macroglia cell line B49, the microglia-like cell line R33, and the Schwannoma cell line JSC11 support the survival of dopaminergic neurons in serum-free low density cultures of the dissociated E14.5 rat mesencephalon. In the present study, we investigated whether these neuronotrophic effects are mediated via glial cells. The number of cells expressing the astroglial marker glial fibrillary acid protein (GFAP) increased 10-15-fold in mesencephalic cultures maintained for 8 days in the presence of all three CM and 4-5-fold after treatment with aFGF, bFGF, or NGF. The proliferative effect of aFGF, but not of bFGF, on glia was enhanced 100-fold by heparin. Moreover, medium conditioned by mesencephalic glia grown in aFGF and heparin stimulated the survival of dopaminergic neurons 2-3 fold without affecting glial number. In contrast, other growth factors, e.g. PDGF and Interleukin I, which had no survival-promoting effect on dopaminergic neurons, also did not enhance the number promoting effect on dopaminergic neurons, also did not enhance the number of GFAP-immunoreactive cells.

These results suggest that an array of factors which have neuronotrophic effects on dopamine neurons act indirectly by stimulating proliferation of glia and that mesencephalic glia may actually be a source of a dopaminergic trophic factor. Supported by NIH: NS25778, Amer. Parkinson's Disease Assoc., and DFG (En 187/1-1).

THE EFFECTS OF PRENATAL EXPOSURE TO DEXAMETHASONE (DEX), HALOPERIDOL (HAL) OR UNDERNUTRITION ON BRAIN GROWTH. M. Scalzo, S.F. Ali, R. Williams* and D.K.
Division of Reproductive and Developmental Hansen*. Toxicology, National Center for Toxicological Research, Jefferson, AR 72079.

Exposure to many chemical substances during pregnancy acutely depresses maternal food intake and permanently ${\bf r}$ stunts brain size in offspring. To better understand stunts brain size in offspring. To better understand drug-induced brain growth impairment, it is necessary to examine the confounding effect of drug-induced maternal anorexia on pre- and post-natal brain growth. Reported here are the results of exposure to DEX (0.4 mg/kg over gestational days (GD) 9-14), HAL (5 mg/kg over GD 6-20), or pair-feeding (PF). DEX reduced GD 20 body weight (by 25%) while causing a 10% reduction in brain weight. PF controls showed a near-identical GD 20 decrease in brain weight. HAL reduced body weight at birth by 15% of control, and also caused a 10% reduction in brain weight. PF controls for HAL had a 5% reduction in brain weight at pain weight PF controls for HAL had a 5% reduction in brain weight at birth. Thereafter, brains of PF controls showed catch-up growth, attaining control levels by 4 weeks after birth. DEX and HAL offspring showed no such recovery. Prenatal DEX and HAL thus have a long-term depressive effect on brain weight that is not due to drug-induced maternal undernutrition.

PARAMETERS AFFECTING MOTONEURON SURVIVAL IN VITRO. B.H.J. Juurlink, L.-C. Ang* and D.G. Munoz, Depts. of Anatomy and Pathology, University of Saskatchewan, Saskatoon, Canada

Although motoneurons can be isolated and grown in vitro, only a relatively small number survive for more than a few days. This poor survival may be related to problems in coping with the extensive damage the neurons have undergone during the isolation procedures. The objectives of this study were to examine the effects of gangliosides, of this study were to examine the effects of gangliosides, pyruvate, c-ketoglutarate as well as alterations in the medium potassium levels on the survival of chick motoneurons in vitro. Motoneurons were isolated from F6 chick embryonic spinal cords and planted at low densicy [=60 cells/mm] on polyornithine coated glass coverslips [Juurlink et al. 1990, J. Neurosci. Res., 26 (in press)]. The standard growth medium consisted of DMEM/F12 containing horse serum and muscle extract. Our observations demonstrated that the addition of GMI ganglioside [10,µM], pyruvate, c-ketoglutarate [2mM] or additional potassium [10-20mM] to the medium resulted in increased survival of motoneurons. The most crucial time for these additions appears to be the first 24 hours suggesting that they act in part to support repair of the damaged motoneurons. At 6 DIV motoneuron survival could be increased from the 20% under standard conditions to 40% when potassium was elevated and an additional energy source was present. Such cultures have been maintained for as long as 4 weeks. (Supported by the ALS Society of Canada).

EXPRESSION OF PROTEASE NEXIN-II IN THE NEURONS OF DORSAL ROOT GANGLIA IN MAN: A CORRELATIVE IMMUNOCYTOCHEMICAL AND IN-SITU HYBRIDIZATION STUDY. T.S. Kim*, B.H. Choi, W. Choe*, R.C. Kim. W. Van Nostrand*, S. Wagner* and D. Cunningham*. University of California, Irvine, CA 92717.

Protease nexin-II (PN-II) is a protease inhibitor that forms SDSresistant inhibitory complexes with the epidermal growth factor-binding protein, the $\gamma\textsubunit}$ of nerve growth factor and trypsin. The deduced amino acid sequence of PN-II is identical to that of amyloid precursor protein (APP), and neuritic plaques of Alzheimer's disease is shown to be immunoreactive for PN-II. The presence of APP mRNA in the CNS has also been demonstrated. In order to examine expression of PN-II in the peripheral nervous system, freshly obtained human dorsal root ganglia were processed for light and EM immunocytochemical procedures using highly characterized monoclonal antiserum for PN-II, and in-situ hybridization using 35S-RNA PN-II probes. Strong and highly specific immunoperoxidase and immunogold reactions for PN-II were demonstrated within the cytoplasm of neurons of dorsal root ganglia in cryostat sections, and vibratome sections fixed in 2% paraformaldehyde. In-situ hybridization demonstrated the presence of intense labeling of an antisense 35S-RNA PN-II probe in the neurons. Labeling was not observed when the corresponding sense ³⁵S-RNA PN-II probe was used. These results indicate the presence of PN-II in the peripheral neurons of man, and provide a valuable information for elucidation of potential roles of PN-II in normal and abnormal functioning of the central and peripheral nervous system. (Supported by NIEHS grant ES 02928)

IMMUNOCYTOCHEMICAL (ICC) LOCALIZATION OF INSULIN IN RABBIT SPINAL CORD NEURONS. <u>C.K. Haun, G. Goubran*, W.K. Engel, V. Askanas and I.Tan</u>*. Depts. of Anatomy & Cell Biology and of Neurology, USC School of Medicine, Los Angeles, CA 90033. To trace the distribution of insulin administered

intra- thecally (IT) in adult (2.5-4 kg) NZ white rabbits, ICC staining techniques were applied to lightly formalin-fixed cryostat sections of lumbosacral cord. ALZA 2ML2 pumps were filled with different doses of human insulin, recombinant, (Humulin BR, Lilly) to deliver 0.5-5.0 U/kg/d, IT, for 2 wks. (see Haun et al, Soc. Neurosci. Abstr. 15, 278, 1989). Alternatively, 25 or 50 U of insulin was given as a 0.25 or 0.5 ml bolus, and the animals were sacrificed after 3 or 1 h, respectively. Controls were cord specimens from untreated rabbits and from rabbits infused with artificial CSF;

processed with the same techniques.

Mouse monoclonal anti-human-insulin-antibodies, detected by FITC and PAP methods, were present in large, detected by FITC and PAP methods, were present in large, medium and small neurons of ventral, intermediate and dorsal horns, and were strongly localized in the cytoplasm. Minor staining of glial elements in both gray and white matter was also seen. Rabbits given bolus IT insulin had 3X to 4X greater staining than controls. In rabbits infused chronically for 2 weeks or longer, staining varied from .75X to 2X that of controls.

COMPLEX INTERACTIONS BETWEEN POLYAMINES AND CA-DEPENDENT PROTEOLYSIS. I. Naim. P. Vanderklish*. A. Etebari*. G. Lynch and M. Baudry. NIBS Program, University of Southern California, Los Angeles, CA 90089-2520 and Bonney Center, UC Irvine CA 92717.

Polyamines have been implicated in mechanisms of cell growth and differentiation but their mechanisms of action remain to be defined. Because they often mimic the effect of other cations and in particular calcium, we were interested in determining their actions on calcium-dependent proteolytic mechanisms.

Putrescine and spermidine did not modify the activity of purified calpain I, while spermine produced an inhibition at millimolar concentrations. None of the polyamines interfered with purified calpain II. On the other hand, spermine potentiated calpain activity from rat brain soluble fractions when using ¹⁴C-casein as a substrate. Moreover, each of the three polyamines potentiated Cadependent proteolytic activity of rat brain soluble fractions as determined by the degradation of endogenous protein substrates, such as high-molecular weight microtubule-associated proteins and such as high-molecular weight microtubule-associated profeins and spectrin. The potentiating effect of polyamines was observed at physiological concentrations (100 µM). Preliminary experiments suggest that the complex effect of polyamines on cacium-dependent proteolysis might reflect their interaction with calpastatin, the endogenous calpain inhibitor. In any event, these results provide a potentially important new mode of action for polyamines in the regulation of protein degradation as well as protein synthesis. Supported by grant NS 18427 to M.B.

TRANSPLANTATION: ANATOMICAL PROJECTIONS

210.1

FETAL RAT OLFACTORY BULB TRANSPLANTS SEND

FETAL RAT OLFACTORY BULB TRANSPLANTS SEND PROJECTIONS TO HOST OLFACTORY CORTEX. L. E. Westrum¹. J. N. Kott¹. H. Vickland¹. M. H. Hankin². and R. D. Lund²: ¹University of Washington, Seattle, WA 98195; ²University of Pittsburgh, Pittsburgh, Pa 15261.

We are using the rat olfactory system as a model to study developmental details of neurotransplantation. Time-mated dams received subcutaneous pulses of tritiated (3H) thymidine at embryonic (E) days 12-14. Olfactory bulbs (OB) from fetal rat donors of E14-15 were immediately grafted into neonatal rats in the site from which the host OB had been removed. Following survival times of 2-4 months, a small congulation lesion was the site from which the host OB had been removed. Following survival times of 2-4 months, a small coagulation lesion was placed in the region of the transplanted OB and the subjects perfused after 2-3 days. The majority of the subjects showed variable sized "new" OBs. Alternate frozen saggital sections of egg yolk-embedded brains were processed for autoradiography (and Nissl stained) or silver stained for degeneration. Only OBs with extensive 3H label and precise lesions confined to the labeled areas were used. Degeneration could be traced from the lesion through the olfactory peduncle and into the superficial layers of the ipsilateral olfactory cortex. The results demonstrate "viable" donor OBs successfully grafted into hosts that send their axons to appropriate target areas of the host brain. (Sponsored by NIH Crants NS 09678 and NS 07144. LEW is a research affiliate of the CDMRC at the UW). CDMRC at the UW).

210.2

TRANSPLANT-DERIVED SYNAPSES IN THE SUPERIOR COLLICULUS OF ANOPHTHALMIC MUTANT (OR)
MICE. G.M. Horsburgh, M.H. Hankin and R.D. Lund. Department of
Neurobiolgy, Anatomy & Cell Science, School of Medicine, Univ. of
Pittsburgh, Pittsburgh, PA 15261.

The ocular retardation mutant mouse (or 1) undergoes early eye degeneration and, as a result, the retinal target nuclei are never innervated by optic axons. We have shown previously (Hankin and Lund, <u>Dev. Biol.</u> 138:136, 1990) that

We have shown previously (Hankin and Lund, Dev. Biol. 138:136, 1990) that embyonic retinae from normal mice transplanted to the midbrain of newborn or mice are capable of developing robust projections to the superior colliculus (SC). In the present study, we have examined the ultrastructure of transplant-derived terminals using fiber tracing and conventional techniques. Terminals of transplant origin are restriced to the superficial SC and display many characteristics of normal retinal terminals. They are typically larger than non-retinal terminals, contain large pale mitochondria and many synaptic vesicles, and make asymmetric synapses. Comparison of the proportions of asymmetric and symmetric synapses in the SC of normal (C57BL/6I) adult mice, of adult or mice in the absence of retinal transplants, and of adult or mice which received retinal transplants at birth has provided an indication of the degree of innervation by transplant projections. The superficial layers of the SC of or mice which did not receive transplants contained few asymmetric synapses (10-15% of synapses sampled), while in or mice with transplants the synapses (10-15% of synapses sampled), while in or mice with transplants the proportion of asymmetric synapses was up to four times higher, levels approaching those seen in normal mice.

approximing mose seen in normal mice.

These results show that retinae transplanted to genetically 'blind' animals not only project to appropriate target nuclei, but are also are capable of establishing synaptic connections in a manner which closely resembles the pattern seen in normal animals. Supported by NIH grants NS26777 (MHH) and EY05308 (RDL).

CHOLINERGIC FIBER GROWTH INTO FASCIA DENTATA TRANSPLANTS DIFFER BETWEEN NEWBORN AND ADULT RECIPIENT RATS. M. Schulz, Sørensen, N. Tønder* and J. Zimmer. PharmaBiotec, Inst.

of Neurobiology, Univ. of Aarhus, Denmark.
Blocks of fascia dentata from newborn rats were grafted into the hippocampal area of newborn or adult rats, left to survive for 1-6 weeks before staining for AChE. In newborn survive for 1-6 weeks before staining for ACRE. In newborn recipients few or no ACRE+ fibers were detected in the grafts (and the host fascia dentata) after 1 week. After 2 weeks AChE+ fibers were present throughout the grafts (with the highest density near the host-graft interface). A lami-nar distribution of the AChE+ fibers became visible in the host dentate molecular layer at this time. This was not yet seen in the similar aged transplants. After 3 weeks the AChE staining in the grafts had increased, and in grafts positioned to receive host perforant path fibers the AChE+ fibers displayed a laminar distribution as in the host fas-cia dentata. In adult recipients single AChE+ fibers were present in the grafts after 1 week. After 4-5 weeks the graft AChE staining was still patchy in some areas and not as dense as normal. Fimbria-close parts of the grafts were usually more heavily innervated than more distant parts. After 6 weeks the graft AChE staining was almost as dense as normal, but a laminar distribution was not achieved.

We conclude, that the growth of AChE+, host septohippo-

campal fibers into homotopic grafts of neonatal hippocampal tissue depends on the recipient age, which affects both the rate of ingrowth and the distribution of the ingrowing

210.5

FETAL VENTRAL MESENCEPHALIC GRAFTS CONTAIN NON-DOPAMINERGIC NEURONS WHICH PROJECT TO THE HOST STRIATUM: COMBINED IMMUNOCYTOCHEMISTRY AND RETROGRADE TRACING WITH FLUOROGOLD. T.J. Mahalik, G. H. Clayton and T.E. Finger, Dept. of Cellular and Structural Biology, U. of Colorado Medical School. Denver, CO. 80262.

Grafts of fetal ventral mesencephalon have been used to correct the motor

Grafts of fetal ventral mesencephalon have been used to correct the motor deficits in a rat model of Parkinson's disease. These grafts contain dopaminergic neurons which project to the host brain; however, it is clear that VM grafts are heterogeneous with respect to their neurotransmitter content. In this study we combined immunocytochemistry with retrograde tracing with fluorogold to chemically identify neurons in VM grafts that projected to the striatum of adult hosts.

Ventral mesencephalon from E14 fetuses was grafted to 6-hydroxydopamine-lesioned striatum of adult hosts; hosts were allowed to survive from 6 weeks to 1 year. Fluorogold was then injected into the striatum adjacent to VM grafts. After 4 days, rats were perfused and the brain was prepared for immunocytochemistry.

Immunocytochemistry showed that VM grafts contained cell bodies which were positive for either GAD, substance P, serotonin, enkephalin, or tyrosine hydroxylase. Double labeling with fluorogold revealed that, except for enkephalinergic cells, a subset of neurons of each type projected to the host

enkephalinergic cells, a subset of neurons of each type projected to the host

We have demonstrated that VM grafts contain a heterogeneous population of neurons. The major finding of our study is that a substantial number of non-dopaminergic neurons project to the host striatum. These results indicate that there is no 'tight' control on the specificity of graft to host

INTRACEREBRAL TRANSPLANTS OF THE RAT FASCIA DENTATA - EFFECTS ON THE SYNAPTIC ORGANIZATION BY HOMO- AND HETERO-TYPICAL AFFERENT CONNECTIONS. T. Sørensen and J. Zimmer. PharmaBiotec, Inst. of Neurobiology, Univ. of Aarhus, DK-8000 Aarhus C, Denmark.

We examined the synaptic morphology of fascia dentata

transplants, which after grafting to newborn rats received major connections from the host brain. The transplants were placed either in host hippocampus, where they received homotypic entorhinal perforant path or commissural projecnomotypic entorninal periorant path of commissural projec-tions, or in the neocortex, where they received heterotypi-cal callosal afferents in the outer parts of the dentate molecular layer. At an age of 3 months the ingrowth was shown in half of the recipient rats by anterograde, electron dense axonal degeneration, 3 days after transection of the host perforant path, hippocampal commissure or corpus callosum, respectively. For the other half of the recipient rats the ingrowth of host corresponding afferents was judged from the placement of the grafts and previous results. The ultrastructural results show that dentate transplants will accept both homotypic and heterotypic afferents. The synaptic contacts were of the morphological types seen in the normal fascia dentata. Preliminary quantypes seen in the indicate that both homotypic and heterotypic afferents compensate for the reduction of synaptic density seen in isolated grafts.

REGENERATION: SPECIFICITY AND FUNCTIONAL RECOVERY

211.1

NEURAL REGENERATION LEADS TO DYSFUNCTION IN LAMPREY SPINAL CORD. A.H.Cohen, M.T.Baker, L.Guan, T.Kiemer, Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

Because substantial regeneration of CNS neurons and their processes is so rare, it is seldom possible to ask if regeneration of central neurons leads to functional recovery. This lab and others have shown that after spinal transection, adult lampreys can regenerate CNS neuronal processes and these processes can contribute to the function of a behaviorally relevant central pattern generator. However, we here show that the regenerated

neuronal processes also lead to Aysfunction of that same circuit.

Isolated spinal cord-notochord preparations were made from adult lampreys which had had partial or complete spinal transections with 5, 8, or 10 months to recover. The quality of the preparations' most stable fictive swimning was assessed and compared to fully intact controls and controls with acute lesions comparable to the transections. At their best, the bursting of all groups of cords with regenerated fibers was significantly less stable than any group of control cords. The extent and location of the transection could worsen this effect, but no transected group was as stable as any control group. The phase delays across the transection site were also significantly more variable in the regenerated animals even in the presence of the intact fibers, i.e., prior to acutely cutting the formerly spared fibers. Again, this was true regardless of the control animals to which they were compared, including the animals with acute lesions comparable to the transections. Thus, the capacity of the intact fibers was functionally reduced by the neuronal regeneration which resulted from spinal transection. A mathematical model illustrates possible problems stemming from the regeneration of long fibers to explain the disturbance. Support: NIH no. NS16803 and AFOSR contract F49620-88-C-0013 to AHC

ANALYSIS OF THE FUNCTIONAL ACTIVITY OF REGENERATING GIANT RETICULOSPINAL NEURONS DURING UNDULATORY BEHAVIOR IN LAMPREY. Joseph Ayers, Department of Biology and Marine Science Center, Northeastern University, East Point, Nahant, MA 01908.

Sea lamprey, Petromyzon marinus, can recover undulatory behavior following complete spinal cord transection. We have been developing procedures for the analysis of functional activity of regenerating giant reticulospinal neurons (RNs) to determine the relationships between functional recovery of neuron activity and overall behavioral recovery in ammocoete larvae. Specimens are prepared for recording from RN axons by implanting fine wire electrodes in the extradural space of the spinal cord. Correlated electrophysiological and kinematic recordings are obtained by recording the signals from the two electrodes on the audio tracks of a stereo video recorder while recording the undulatory movements on the video signal. We have adapted the program NIH Image to perform stop-frame analysis of undulatory movement. Correlated digital signal processing of the stereo electrophysiological signals allows us to extract the activity patterns of individual RNs and directly relate them to features of the ongoing undulations. In acute preparations where recordings are made anterior (25% of body length) to a caudal transection (75% of length), action potentials (APs) in RN's disappear over a time course of several hours and in 24 hours are no longer observed during swimming. Propagating APs in RNs are observed during swimming in intermediate stages of recovery although distal APs are considerably reduced in amplitude. In long term (>1 yr.) regenerated specimens a small proportion of reticulospinal axons exhibit large amplitude APs both proximal and distal to the lesion and occasional anterior propigating APs are observed. We conclude that it is feasable to study the functional activity of regenerating RNs and to relate these events to behavioral recovery. Supported by NSF Grant DIR-8917532.

REGENERATION OF NEUROMUSCULAR CONNECTIONS AFTER GANGLIA ALLOTRANSPLANTS IN THE CRAYFISH. K. Krause, D. Sheldon*, R. Kang*and S. J. Velez. Dept. of Biological Sciences, Dartmouth College, Hanover, N. H. 03755.

Anny and S. J. Velez. Dept. of Biological Sciences, Dartmouth College, Hanover, N. H. 03755.

The superficial flexor nerve of the crayfish Procambarus clarkii is capable of regenerating a specific pattern of connections with its muscle target within 10 weeks after axotomy. We have postulated that the position-dependent pattern of connectivity in this system could be the result of a gradient over the muscle surface that provides positional cues to the growing axons. In the present work we use allotransplants to test this idea, forcing the nerve to grow into the muscle field in a direction that is opposite from normal. The third abdominal ganglia with the nerve attached to it was removed from one crayfish and transplanted to the lateral edge of a denervated muscle field of another crayfish. The host animal did not reject the transplant. At different intervals after the surgery, the muscles were exposed and the muscle fibers were impaled with microelectrodes to look for junction potentials (jp's) generated by the spontaneous activity of the transplanted neurons. At 4 weeks we detect small, long jp's (<0.5 mV, >25 msec) near the insertion point of the nerve. By 6 weeks jp's are detected over many lateral fibers, some still small and long, others with normal characteristics (>1 mV, <20 msec). Thus, these neurons can survive, grow and form new synaptic contacts when transplanted from one animal to another. We are now studying the connectivity patterns of these cells in order to test the gradient hypothesis.

211.5

FIN ORIENTATION AND REGENERATION OF ELECTRORECEPTORS IN GLASS CATFISH. M.M. Bever* and R.B. Borgens. Center for Paralysis Research, Purdue Univ., W. Lafayette, IN 47907. Regeneration of electroreceptors (ERs) of adult glass

Regeneration of electroreceptors (ERs) of adult glass catfish (Kryptopterus) was studied to understand the relative roles of epidermis and axons. In the anal fin, these receptors, innervated by 1 axon each, are found along the dorsal 1/3 of the caudal face of each fin ray.

We removed pieces (approx. 2 mm X 1 mm) of anal fin

We removed pieces (approx. 2 mm X 1 mm) of anal fin (thereby severing ER innervation) and replaced them with one of the following types of fin autografts: (A) normal orientation, with ERs, (B) reversed rostrocaudally (ERs along rostral fin ray face), (C) reversed dorsoventrally (ERs at distal end of transplant), (D) normal orientation, ERs absent.

ERs present at surgery disappeared by 1 week owing to nerve interruption. By 2-3 weeks, new receptors appeared in all graft types. In A grafts, most new ERs formed along caudal faces of fin rays. In B grafts, ERs formed along rostral faces. In C grafts, some ERs formed at the distal end of the graft. In D grafts, ERs formed mainly in the proximal portion of the graft. In all grafts, some ERs were also found in ectopic positions.

These results indicate that any epidermis (whether

These results indicate that any epidermis (whether containing ERs or not) can form new ERs after induction by regenerating ER axons. Patterns of ER formation in type A, and B grafts are probably due to regenerating axons following old axon pathways. In addition, degenerated ERs may serve as targets for regenerating axons.

211.7

SPONTANEOUS AND ABERRANT REGENERATION OF OPTIC AXONS RESTORES VISUAL RESPONSE TO ADULT RAT SUPERIOR COLLICULUS. A.P.Foerster. Dept. of Biomed. Sci., McMaster University, Hamilton, Ontario L8N 325

McMaster University, Hamilton, Ontario LBN 375

An implanted cutting device, that permanently identified the lesion site (APF, J. Comp. Neurol. 210: 335, 1982), completely severed the brachium of the right superior colliculus (SC). HRP, traced from the left eye 9 months later, revealed that a newly routed pathway had developed from the severed tract. Beginning from a ventral location, it ascended to the laterodorsal thalamus and stria medullaris, then passed caudally around a huge lesion-related cavity to innervate the medial SC. Microelectrode mapping revealed a partial recovery of visual responses in this previously silenced SC. This remarkable example of delayed functional recovery (cf. APF, Exp. Brain Res. 79:564, 1990; Can. J. Physiol. Pharmacol. abstract in press) now appears to provide proof of spontaneous regeneration of severed axons in adult mammalian CNS. Moreover, they grew to their appropriate target. (MRC Canada)

211.4

SPECIFIC REGENERATION OF CUTANEOUS AFFERENTS IN THE FROG'S SPINAL CORD. <u>S.C. Mears and E. Frank</u>. Dept. of Neurobiology, Anatomy, and Cell Science, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261

Regeneration of nerve axons is not a common occurrence in the central nervous system of vertebrates. However, sensory axons, transected in the dorsal root, re-establish connections in the spinal cord of postmetamorphic bullfrogs. Although muscle sensory fibers are known to regenerate specifically, the specificity of regenerating cutaneous afferents has not been examined directly. We have used anatomical tracing techniques to determine where these afferents form their terminal arborizations.

The brachial dorsal root was repeatedly frozen with forceps cooled in liquid nitrogen and left to regenerate for several months. A cuff containing horseradish peroxidase and lysolecithin was then applied to the superior cutaneous branch of the radial nerve. Two weeks later the perfused spinal cord was serially sectioned in the transverse plane and reacted with tetramethy-benzidine. Regenerated cutaneous afferents arborized specifically within the dorsal neuropil of the dorsal horn as in normal frogs. They did not pentrate more deeply into the spinal gray matter where muscle afferents terminate.

An interesting highlight involves the course taken by the regenerating fibers to reach the neuropil. In a previous study of regenerating muscle sensory fibers, the axons grew around the circumference of the spinal cord just under the pia and entered the spinal gray more ventrally to arborize in the ventral neuropil. Regenerating cutaneous afterents, however, took a normal course through the dorsal columns to the dorsal neuropil. These observations show that cutaneous afferent axons can regenerate and seek out their original target areas in the spinal cord. Supported by NS24373 to E.F.

211.6

LOCAL REGENERATION IN THE RETINA OF THE GOLDFISH. <u>P.F.</u>
<u>Hitchcock</u>, University of Michigan, Depts. of Ophthalmology and Anatomy and Cell Biology, Ann Arbor, MI.

To begin elucidating the mechanisms that control retinal regeneration in goldfish, small patches of retina were excised, and dopaminergic interplexiform cells were anatomically assayed in the regenerated patches.

Two groups were prepared. Group 1: A patch of retina was removed transclerally, and four months later the retinas were isolated, fixed, and processed as wholemounts for anti-tyrosine hydroxylase (anti-TH) immuno-histochemistry. Group 2: Patches of retina were excised three weeks after the eyes were injected with 15ug of 6-OHDA, to destroy the dopaminergic cells, and two months later these retinas were processed for anti-TH.

In group 1 (n=8), the regenerated patches contained qualitatively normal planimetric densities of TH-positive cells, although they were not as regularly arrayed as those outside the patch. In group 2 (n=3), the retinas were completely free of TH-positive cells, except at the proliferative margin and within the regenerated patches.

These results suggest that the same mechanisms that control de novo retinal growth at the margin also control retinal regeneration.

Supported by NIH grants EY07060 and EY07003 (CORE).

211.8

SPONTANEOUS AXONAL REGENERATION IN THE CORPUS CALLOSUM (CC) OF THE ADULT RAT. L.G. Clements and A.P. Foerster. Dept. of Biomedical Sciences, McMaster University, Hamilton, Ontario CANADA L&N 375

A double labeling approach was used, with one label taken up immediately by the cut axons, and the other at a later time by their distant terminals. Fluoro-Gold (FG) was applied via a razor-ended blade which cut the middle part of the CC. A series of 80 µm coronal sections revealed masses of labeled neurons in the contralateral cortex in register with the cut, and extending to <1 mm on either side of it. Rhodamine latex microspheres (RLM), injected into the ipsilateral cortex by half mm spaced injections, labeled 80-150 neurons/section in the contralateral cortex. When these injections were made 4 days after a blade cut, the count reduced to zero in a zone in approximate register with the central part of the lesion. This zero "window" was 270-750 µm after a 2 mm cut and about 1500 mm with a 3 mm cut. Some double labeling was seen in regions in register with the ends of the lesion, indicating FG uptake by intact axons. When the RLM were injected 4 weeks postlesion, the zero "window" was replaced by up to 100 or more RLM-containing neurons per section; up to 90% of these were double labeled. We suggest that a spontaneous and massive regeneration of severed CC axons had occurred. [Work supported by MRC Canada. LC is a MS Society (Canada) Student].

SEROTONIN-IMMUNOREACTIVE (5HT-IR) AXONS FORM SYNAPSES BEFORE WITHDRAWING FROM HIPPOCAMPUS AND CORTEX TRANSPLANTS IN SPINAL CORD OF YOUNG RATS. H. Bernstein-Goral, M.M. McAtee*. B.S. Bregman. Dept. Anatomy and Cell Biology, Georgetown University School of Medicine, Washington, D.C. 20007.

Bulbospinal 5HT-IR axons initially grow into both appropriate (spinal cord, SC) and inappropriate, (hippocampus, HC and cortex, CX) CNS transplants placed into the site of neonatal spinal cord lesions. 5HT-IR axons are withdrawn from inappropriate transplants between 21-26 days following transplantation. Only appropriate transplants (SC) can maintain 5HT ingrowth permanently. The present study has examined whether 5HT-IR fibers which transiently grow into hippocampus and cortex transplants form synaptic contacts prior to withdrawal. Fetal rat SC (E14), HC or CX (E18) was transplanted into mid-thoracic spinal cord "over-hemisections" in neonatal rat pups. Animals survived for 14 days post-operative (dpo, short term) or 8 weeks (long term). Transplants were stained for 5HT-IR fibers form synaptic contacts with dendrites and somata within the neuropil of both hippocampus and cortex transplants. At long survival times, 5HT-IR fibers are present only within spinal cord transplants, where they form axo-dendritic and axo-somatic synaptic contacts. These results demonstrate that although bulbospinal 5HT-IR fibers are not maintained in HC or CX, they initially innervate these inappropriate targets and form classical synaptic contacts prior to withdrawal. Supported by NIH NS 19259 and NS 01356.

SIMPLE METHOD OF ASSESSING MOTOR AND SENSORY INNERVATION AFTER NERVE DAMAGE IN RAT SCIATIC NERVE MODEL. Y. Torigoe, C.Z. Hong, M. Gharibian R. Farboudmanesch, J. Yu. Anat. & Neurobiol. and Dept. Phys. Med. & Rehab., Univ. Calif. Irvine, CA 92717

MODEL. Y. Torigoe, C-Z. Hong, M. Gharibian . R. Farboudmanesch , J. Yu. Anat. & Neurobiol. and Dept. Phys. Med. & Rehab., Univ. Calif. Irvine, CA 92717

A cross extensor reflex (CER) method of evaluating functional recovery after nerve crush is compared with sciatic functional index (SFI) and traditional nerve conduction velocity (CV) method. In unanesthetized, gently restrained rats, one paw was electrically stimulated to elicit a CER in the contralateral leg. The evoked compound muscle action potentials (CMAP) were recorded from the contralateral leg muscles using surface recording electrodes that is unobtrusive to normal movements. After nerve crush, stimulation of the uninjured and recording from the innipured side tests for motor recovery; and stimulation of the injured and recording from the uninjured side tests for the sensory recovery. For each measurement, the average of 8 latencies of the first wave of CMAP was obtained for analysis. Eighteen days after nerve crush, SFI showed some functional return and in 25 days the SFI returned to nearly normal levels. The first measurable CMAP appeared approximately 30 days after nerve crush with the stimulation of the uninjured side (notor test) followed shortly, 33 days, by the stimulation of the uninjured side (sensory test). The amplitude of the CMAP increased and the latency shortened before finally returning nearly to its original values by 3 months. The major difference in the rate of recovery as seen by SFI and CER methods may be explained by longer length of time required for nerve regeneration to the most distal portions of the leg innervated by the sciatic nerve. Another difference may be attributable to SFI requiring only partial innervation for the walking behavior to appear normal, but for the normal reflex, the axons innervating the distal musculature and sensory innervation of the palmar surfaces must be fully regenerated to produce short latency muscle contractions. However, other tests including CV and CER methods, require full neural and muscula

THE NIGROSTRIATAL SYSTEM IN ORGANOTYPIC SLICE CULTURES: A TH-IMMUNOCYTOCHEMICAL STUDY. J. Zimmer, K. Østergaard and J.P. Schou*. PharmaBiotec, Inst. of Neurobiology, Univ. of Aarhus, DK-8000 Aarhus C, Denmark.

Organotypic slice cultures of rat ventral mesencephalon were used to study the development of dopaminergic (DA) neurons and fibers in the absence of their normal striatal target tissue and in co-cultures with striatal tissue. For exposure to minor or non-target areas co-cultures with hippocampus and cerebellum were used. Slices of rat VM, striatum, hippocampus and cerebellum were prepared from E21 to P7 rats and cultured by the roller tube technique for 3 to 60 days before immunocytochemical staining for tyrosine hydroxylase (TH), a marker of catecholaminergic neurons. The TH immunoreactive (TH-i), DA neurons of the substantia nigra (SN) retained their morphological in vivo characteristics in single slice cultures. The basic morphology of the neurons did not change when co-cultured with striatal slices, even in cases with extensive TH-i innervation of striatum. In co-cultures with hippocampus, a minor target for DA fibers, TH-i nerve fibers mainly grew into the opposing peripheral parts of the hippocampal slices. In co-cultures of VM and cerebellum (not a DA fiber target) only occasional ingrowth of single TH-i nerve fibers was ob-served. The observations, which suggest a target orientated growth of TH-i DA fibers, in some cases even with patch formation in the striatum, have clear implications for the use of VM slice cultures in studies of the plastic and regenerative properties of DA neurons.

LONG-TERM POTENTIATION II

212.1

OPTICAL SYSTEM FOR REAL-TIME IMAGING OF ELECTRICAL ACTIVITY WITH A 128 x 128 PHOTOPIXEL ARRAY. G. Matsumoto and M. Ichikawa*. Electrotechnical Laboratory, Tsukuba, Ibaraki 305, JAPAN.

We have developed a compact optical recording system for real-time imaging of electrical activity with a 128 x 128 photopixel array. Each pixel has a light-to-electricity conversion surface with $70 \times 70 \,\mu\text{m}$ in size and a FET on the surface. The signals that the array receives simultaneously at the 128 x 128 pixels can be converted into electric ones and transfered to a computer system at the frame rate of 0.5 msec. The fered to a computer system at the frame rate of 0.5 msec. The data are integrated during the period of time until they are transfered so that the signal-to-noise ratio becomes greatly improved. When the system was applied to guinea pig hippocampal slice preparation stained with RH-155, the optical change of 3×10^{-4} was detected without averaging. We found that the system was greatly useful to analyze functional connections of neuronal circuits of the hippocampal slice; that is, the spatio-tempral patterns of the activities thus obtained gave us a deep insight about (1) the main pathways of the informa-

as a deep insight about (1) in main painways of the information that it is not feed-forward and feed-back inhibitory connections.

We acknowledge to Dr. Iijima for physiological experiments and Mr. Murayama (Fuji Photo Film Co.) for fabrication of the array.

MEASUREMENT OF CALCIUM TRANSIENTS IN PYRAMIDAL NEURONS OF HIPPOCAMPAL SLICES VISUALIZED BY CONFOCAL MICROSCOPY. R.J.Adams and T.J.Sejnowski, Computational Neurobiology Laboratory, The Salk Institute, La Jolla, Ca 92037

Combrational Neurobiology Laboratory, The Salk Institute, La Joha, ca 92037.

Central to models of long-term potentiation is the role of postsynaptic elevations in calcium ion concentration in mediating synaptic modifications. The major path for this influx is thought to be through the NMDA receptor. Calcium influx through voltage-dependent calcium channels may also significantly contribute to the total cytoplasmic elevation. Initiation of various calcium-activated processes are then thought to give rise to an increase in synaptic efficacy.

We are investigating changes in intracellular calcium concentration in pyramidal neurons of hippocampal slices in vitro. Individual neurons are impaled using a glass microelectrode filled with the fluorescent calcium indicator fluo-3. A cell may then be filled with the dye by iontophoresis and followed physiologically during the course of the experiment. Fluorescent signals are monitored using a Bio-Rad MRC-600 laser scanning confocal microscope. Fluorescent measurements are made at high spatial resolution, with < 1 um depth of field. Individual scan lines may be taken at 2msec intervals to provide a fine dynamic record of the calcium changes within the intervals to provide a fine dynamic record of the calcium changes within the cell. Electrical and calcium signals are recorded from cells activated either synaptically by axons stimulated with bipolar electrodes in the stratum radiatum or by depolarization by direct current injection through the intracellular electrode. Sustained elevations in calcium are seen in the basal and apical dendrites and the soma following high frequency stimulation under conditions that induce LTP.

CHARACTERIZATION OF CALCIUM ACCUMULATIONS IN HIPPOCAMPAL PYRAMIDAL CELLS W.G. Regehr & D.W. Tank AT&T Bell Labs, Murray Hill NJ 07974.

Individual pyramidal cells in guinea-pig hippocampal slices were filled with fura-2 and calcium accumulations were slices were filled with fura-2 and calcium accumulations were measured in response to antidromic and synaptic stimulation using a cooled CCD and a photodiode array. The NMDA-receptor-antagonist AP5 blocked a component of accumulation localized to regions receiving synaptic input. This component was larger for higher stimulus frequencies. In the presence of AP5 similar distributions were observed for antidromic and orthodromic stimulation independent of the region receiving synaptic input. These accumulations peaked in proxyimal-noiral and basal input. These accumulations peaked in proximal-apical and basal dendrites and were much smaller in the soma and distal dendrites. Antidromic stimulation produced calcium increases that were largely blocked by 500 μM Cd⁺⁺, partially blocked by either 2 μM nifedipine or 5 μM ω-conotoxin, and enhanced by 5 μM Bay-K 8644. These findings indicate that it is primarily influx through voltage-dependent calcium channels that produces AP5-insensitive accumulations. Intracellular injection of the sodium channel blocker QX-314 decreased AP5insensitive accumulations without significantly altering the spatial distributions. The lack of appreciable calcium accumulations in the presence of AP5 in distal apical dendrites likely represents a much lower density of voltage-dependent calcium channels in this region. Experiments with FURAPTRA (K_d=50μM for Ca⁺⁺) confirm the basic findings obtained with fura-2 (K_d =200nM). We are currently characterizing calcium accumulations observed during associative LTP induction.

EXCITATORY SYNAPSES BETWEEN CA1 PYRAMIDAL NEURONES ARE MEDIATED BY BOTH NMDA AND NON-NMDA RECEPTORS. A.M. Thomson and S. Radpour Physiology, Physiology, Royal Free Hospital Medicine, London NW3 2PF UK. School

Double recordings from pyramidal neurones in the CA1 region of hippocampal slices, with spike triggered averaging revealed single axon epsps that displayed voltage relations and sensitivity to antagonists typical of responses mediated in part by NMDA receptors. Co-activation of an epsp displaying these properties, at 1-2Hz, with a displaying these properties, at 1-2Hz, with a minimal Schaffer collateral epsp, led to lasting enhancement of the Schaffer epsp, but not of the local epsp. These results suggest that lasting enhancement of unitary Schaffer epsps can be achieved in the absence of generalized postsynaptic depolarization and without addition of GABA antagonists, provided an NMDA receptor mediated epsp is co-activated. Pairing of Schaffer epsps with local insps led to depression Schaffer epsps with local ipsps led to depression of Schaffer epsps. Preliminary experiments indicate that traditional protocols used for the induction of LTP in CA1 may be unsuccessful if local excitatory circuits are interrupted.

212.7

CHARACTERIZATION OF AN LTP-LIKE PHENOMENON INDUCED BY A TRANSIENT INCREASE IN EXTRACELLULAR POTASSIUM CONCENTRATION. M. W. Fleck. A. M. Palmer. & G. Barrionuevo. Depts. of Behavioral Neuroscience & Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Long-term potentiation (LTP) is a long-lasting, use-dependent increase in synaptic efficacy that is well characterized in the rat hippocampus and is typically induced by tetanic stimulation. LTP induction requires the concomitant depolarization of pre- and post-synaptic elements, and so should be inducible via potassium depolarization. Using the in vitro hippocampal slice preparation, we have induced an LTP-like phenomenon in the Schaffer collateral-CA1 synapses by translently increasing potassium concentration (50 mM for 20 seconds) in the perfusion medium. Potassium-induced LTP, as monitored in stratum radiatum of the CA1 subregion, resembled that induced by tetanic stimulation in several ways: 1) the amplitude of the population EPSP increased by at least 20% (n=9), 2) this increase in population EPSP amplitude lasted for at least 20 minutes, 3) potassium-induced LTP prevented the subsequent induction of LTP by tetanic stimulation (n=2), and 4) induction was blocked by bath application of 20 µM D-APV (n=6). Thus, potassium-induced LTP and LTP induced by tetanic stimulation probably share a common induction mechanism. Preliminary results indicate that potassium-induced LTP provides a useful model for the in vitro analysis of transmitter release during LTP. Supported by grants NSO1196 and NS24288.

NMDA-Dependent LTP of Monosynaptic Entorhinal Input To CA3 and the Dentate Gyrus Alters Propagation of Activity Through the Trisynaptic Pathway. M.F. Yeckel and T.W. Berger, Depts. of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA, 15260. We have demonstrated recently that stimulation of entorhinal perforant path axons leads to monosynaptic single unit and population discharge in the three major subfields of the hippocampus (dentate, CA3 and CA1; Yeckel and Berger, Proc. Natl. Acad. Sci., in press). Propagation of perforant path input through the trisynaptic pathway to CA3 and CA1 reachs suprathreshold levels only in response to frequencies of 10-20 Hz. Therefore, the modulatory influence of dentate granule cells and CA3 pyramiadl cells on entorhinal input to CA1 cells is conditional on the pattern of input from entorhinal neurons. We examined the consequences of long-term potentiation (LTP) of monosynaptic entorhinal input on the propagation of activity through the trisynaptic monosynaptic entorhinal input on the propagation of activity through the trisynaptic

pathway.

Trains of stimulation (10 Hz; 20-30 impulses) with intensities that evoked a 50% maximal response, were delivered to perforant path fibers of halothane anesthetized rabbits. The number of impulses necessary to evoke suprathreshold di- and trisynaptic responses, and the maximal amplitude of polysynaptic responses, were determined Monosynaptic LTP was then induced with 400 Hz stimulation trains delivered to Monosynaptic LTP was then induced with 400 Hz stimulation trains delivered to perforant path fibers. LTP could be blocked reversibly in the dentate gyrus and/or CA3 subfields with the NMDA-antagonist, d-APV (50-100 μM; n=8). Following LTP induction, 10 Hz stimulation trains were again delivered to perforant path fibers but with lower intensities so as to evoke the pre-LTP amplitude dentate population spike. Results showed that increasing the synaptic strength for monosynaptic input significantly decreased the number of impulses necessary to evoke suprathreshold significantly decreased the number of impulses necessary to evoke suprathreshold activation of di- and trisynaptic responses in the pyramidal cells. Additionally, the amplitude of the maximal polysynaptic response was increased (CA3: n=5; CA1: n=5). These data provide evidence that NMDA-mediated changes in synaptic efficacy alter frequency dependent propagation of activity through the trisynaptic pathway. Supported by NIMH (MH00343) and NSF (BNS 8945137).

212.6

BLOCKADE OF FIMBRIAL RESPONSES DURING MOSSY FIBER TETANIZATION DOES NOT PREVENT HETEROSYNAPTIC FIMBRIAL LTP INDUCTION IN CA3 NEURONS. G. Barrionuevo, X. Xie and J. E. Bradler. Depts. of Behavioral Neuroscience & Psychiatry, University of Pittsburgh, Pgh,

We have previously shown that in the CA3 subfield, mossy fiber tetani induce heterosynaptic LTP in nontetanized fimbrial afferents¹. Induction of heterosynaptic fimbrial LTP does not require NMDA receptor mediated transmission²; in contrast, homosynaptic fimbrial LTP evoked by tetanization of fimbrial afferents is blocked by APV2. This dissociation between homoand heterosynaptic LTP induction argues against the involvement of CA3 collateral LTP in the heterosynaptic enhancement. However, mossy fiberconactan LTP in the neterosynaptic enhancement. Flowever, mossy noer-elicited quisqualate activities at the fimbrial input may be necessary for heterosynaptic LTP induction. In the present study, EPSPs from hippocampal CA3 neurons maintained in an *in vitro* slice preparation were evoked from two stimulation sites: i) the s. granulosum of the dentate gyrus, to activate mossy fibers; and ii) the ventral fimbria. Slices were superfused with medium containing D-APV (50 μ M), and picrotoxin (10 μ M). Prior to mossy fiber tetani, fimbrial responses were selectively blocked by focal applications of tetani, fimbrial responses were selectively blocked by focal applications of CNQX (40 μ M) onto the s. oriens. Following washout of CNQX, fimbrial EPSPs expressed LTP (mean 38% of control, n=3). Focal application of CNQX alone did not have any long lasting effect on fimbrial synaptic efficacy (n=6). These results indicate that heterosynaptic fimbrial LTP proceeds in the absence of either NMDA or quisqualate receptor mediated activation. Supported by grants RCDA NS01196, NS24288 and AFOSR.

ARACHIDONIC AC!D HIPPOCAMPAL

ARACHIDONIC ACID IN HIPPOCAMPAL SLICES: ELECTROPHYSIOLOGICAL AND BIOCHEMICAL FINDINGS. L. Pellerin, M. Avoli and L.S. Wolfe. Neurobiology Unit, Montreal Neurological Institute, McGill Univ., Montreal, Canada H3A 2B4 Arachidonic acid (AA) metabolites have been proposed recently to be retrograde messenger in long term potentiation (LTP), a model of synaptic plasticity. Following NMDA receptor activation and AA release, AA or its metabolites act postsynaptically and/or diffuse and act on presynaptic terminals to increase transmitter release. We studied arachidonic acid metabolism in rat cerebral cortex and found glutamate and NMDA. but not kainate stimulated 12-(S)-HETF formation, one of NMDA, but not kainate stimulated 12-(S)-HETE formation, one of the 12-lipoxygenase metabolites of AA. Using a different approach, we have examined the hippocampal slice, a well-characterized preparation for the study of LTP. AA (50 μ M) was perfused on hippocampal slices maintained in vitro and extracellular responses of the CA1 region monitored. In 12 out of 18 experiments, a long-lasting potentiation of the stratum radiatum-induced response was observed. In five out of 18 experiments, arachidonic acid evoked a depression of the same response. When melittin, a bee venom peptide known to induce release of AA in immune cells, was applied to hippocampal slices a long-lasting potentiation was observed. Melittin induced AA release in hippocampal slices and the effect was dose-dependent. Glutamate and NMDA also released AA. Thus glutamate mobilizes AA from phospholipids which is then available for metabolism by lipoxygenases to products involved in neuromodulation at these synapses.

PHORBOL ESTERS ENHANCE SYNAPTIC TRANSMISSION IN WHOLE-

PHORBOL ESTERS ENHANCE SYNAPTIC TRANSMISSION IN WHOLE-CELL VOLTAGE CLAMP RECORDINGS: EVIDENCE FOR A PRE-SYNAPTIC ACTION. K.D. Parfitt and D.V. Madison, Dept. of Molecular and Cellular Physiology, Stanford Univ. Sch. of Med., Stanford, CA 94305-5426.

Bath application or presynaptic application of phorbol esters, activators of protein kinase C, potentiate synaptic transmission in hippocampal slices, mimicking tetanus-induced long term potentiation (LTP). We have used the whole-cell voltage clamp technique to study synaptic transmission in area CA1 of standard 400-500 un-thick hippocampal slices. LTP can only be induced in these recordings during approximately the first 30 min. after breaking into a cell, but can be maintained for hours once induced (Malinow and Tsien, in press). The loss of the ability to induce LTP after 30 min. of recording presumably results from the dialysis of postsynaptic intracellular contents with the contents of the pipette. In neurons dialyzed for >30 min., in which post-tetanic potentiation (PTP) but not LTP could be induced, bath application of phorbol diacetate (PDAc) was still capable of enhancing synaptic transmission. As has been observed with extracellular recording, this enhancement decays within 90 min. of PDAc washout. Previous studies suggest that a presynaptic protein kinase is involved in the induction of LTP, Whereas postsynaptic stinases are involved in the induction of LTP (Malinow et al., 1989). Phorbol esters have many presynaptic actions, including the enhancement of the kinases are involved in the induction of LTP (Malinow et al, 1989). Phorbol esters have many presynaptic actions, including the enhancement of the phosphorylation of synapsin, a mechanism that is thought to result in enhanced transmitter release. In addition, phorbol esters enhance depolarization-induced opening of N- and L-type calcium channels, which might also lead to enhanced transmitter release from presynaptic terminals. Since phorbol esters were capable of potentiating synaptic transmission even when the induction of LTP was blocked by postsynaptic dialysis, our data are consistent with the hypothesis that phorbol esters enhance synaptic transmission via a presynaptic mechanism. QUANTAL MODEL OF SYNAPTIC CURRENT FLUCTUATIONS IN HIPPOCAMPAL NEURONS. Z. Xiang*, E.W. Kairiss, C.L. Keenan, E.M. Landaw* and T.H. Brown. Dept. of Psychology, Yale Univ., New Haven, CT 06520 and Dept. of Biomathematics, Univ. of Calif., Los Angeles, CA 90024.

There has been considerable interest in the quantal mechanism responsible for certain forms of synaptic plasticity in the hippocampus--particularly long-term

certain torns or synaptic plasticity in the injpocanipus-particularly long-term potentiation (LTP). Here we describe a general approach for fitting a quantal model of synaptic transmission to postsynaptic current fluctuations.

The full model incorporates (i) either a one-parameter Poisson or two-parameter binomial probability function to describe the number of quantal releases; (ii) a twobinomial probability function to describe the number of quantal releases; (ii) a two-parameter Gaussian or a three-parameter gamma density function to describe the distribution of single-quantal amplitudes; and (iii) a two-parameter Gaussian density function to describe the noise. A maximum likelihood estimation procedure has been developed to fit jointly all model parameters to observed data. Individual parameters can be fixed to measured or hypothesized values. Likelihood ratio tests are used to test hypotheses about parameter subsets or to test changes in specific parameters in comparing two data sets. This methodology also provides standard errors and confidence intervals of estimated parameters. A modified Kolmogoroverrors and confidence intervals of estimated parameters. A mounted nonnegator-Smirnov goodness-of-fit test is used to compare the empirical and theoretical cumulative probability distributions. In applying the model, we selected the mossy-fiber input to pyramidal neurons of the CA3 region because these synapses are electrotonically near the somatic recording site and because single quantal currents

can be resolved in these cells.

Thus far, the model has been successful in providing adequate fits to all of the observed frequency distributions of currents. We are now comparing changes in estimated parameter values with changes expected to occur as a function of various experimental manipulations. This approach may be useful for evaluating the mechanism underlying the expression of LTP. (Supported by the AFOSR)

212.13

BIOPHYSICAL MODEL OF A HEBBIAN SYNAPSE. A.M. Zador. C.K. Koch and T.H. Brown. Dept. of Psychology, Yale Univ., New Haven, CT 06520 and Computation and Neural Systems Program, Calif. Inst. Tech., Pasadena, CA 91125.

The induction of long-term potentiation (LTP) in certain hippocampal synapses depends on activation of NMDA receptors and can be described as a "Hebbian" modification (reviewed in Brown et al., Ann. Rev. of Neurosci., 13:475, 1990).

We have constructed a biophysical model for the induction of this type of

hippocampal LTP. The model is similar to that of Gamble and Koch (Science, 236:1311, 1987) in that it includes electrical and Ca²⁺ dynamics in the dendritic spine. The present model differs in that (Ca²⁺ influx into the spine head is through NMDA receptor-gated channels rather than through voltage-dependent Ca channels. The parameters for the NMDA receptor-mediated conductance were within the range measured in hippocampal slices (see Nobre et al., Soc. Neurosci. Abstr., 1990).

measured in hippocampal slices (see Nobre et al., Soc. Neurosci. Abstr., 1990).

Our model accounted for much of the phenomenology of LTP induction in pyramidal neurons of hippocampal region CA1 and granule cells of the dentate gyrus. The simulations suggested that spines may perform four important functions in this Ca²⁺-dependent synaptic modification: compartmentalizing transient changes in [Ca²⁺], restricting the changes to spines associated with active synapses; amplifying the [Ca²⁺] changes relative to the case of a synapse on the dendritic shaft; isolating the spine head from changes in [Ca²⁺] at the dendritic shaft; and steepening the voltage dependence of the processes underlying LTP induction. The latter effect was important because the current-voltage relationship for the NMDA receptor-mediated conductance is not very steep (see Nobre et al., Soc. Neurosci. Abstr., 1990).

This proposed role of spines in the regulation of Ca²⁺ dynamics contrasts with

This proposed role of spines in the regulation of Ca²⁺ dynamics contrasts with traditional approaches to spine function that have stressed electrotonic properties. We have begun to use this model to explore the self-organizing properties of Hebbian synapses in realistic representations of hippocampal neurons (see Mainen et al., <u>Soc. Neurosci. Abstr.</u>, 1990). (Supported by DARPA and ONR)

212.10

MECHANISM OF POST-TETANIC POTENTIATION OF QUANTAL SYNAPTIC TRANSMISSION IN THE DENTATE GYRUS OF THE RAT. A. Baskys, P. L. Carlen and I. M. Wojtowicz. Playfair Neuroscience Unit and Dept. of Physiology, Univ. Toronto, Toronto, Ontario M5T 2S8, Canada. Synapses in the hippocampus exhibit a variety of plastic phenomena. In this study the rat hippocampal slice preparation in conjunction with quantal analysis was used to examine the mechanism of post-tetanic potentiation in granule neurons of the dentate. With the use of intracellular recordings we identified a population of spontaneous depolarizing potentials which were dentate. With the use of intracellular recordings we identified a population of spontaneous depolarizing potentials which were resistant to $10 \mu M$ bicuculline and therefore presumably originated from excitatory synapses. The potentials were true quantal events since they persisted in the presence of TTX and Mn^{2+} which blocked Na^{2+} and Ca^{2+} dependent action potentials. The mean amplitude of these miniature EPSPs varied between $400-600 \mu V$ in 11 neurons studied thus far. Occasionally, $V_{cont} = V_{cont} = V_{con$ rgiant* quanta reaching up to 8 mV were observed. Tetanic stimulation at 400 Hz (8 trains lasting 20 ms each) of afferent axons contacting the granule neurons produced an increase in quantal content of evoked minimal EPSPs and the frequency of quantal content of evoked minimal EPSFs and the frequency of spontaneous quantal events. The mean amplitude of quanta remained unchanged. These results point to a presynaptic locus of the post-tetanic potentiation lasting for at least 15 min.

Research Council of Canada and The Whitehall Foundation.

VOLTAGE-DEPENDENCE OF THE NMDA RECEPTOR-MEDIATED SYNAPTIC CONDUCTANCE IN HIPPOCAMPUS A.C. Nobre, Z. Xiang*, A.M. Zador and T.H. Brown. Dept. of Psychology, Yale Univ., New Haven, CT 06520.

The voltage-dependence of the N-methyl-D-aspartate (NMDA) receptor-mediated

rie voitage-dependence or the N-menty-D-asparate (NMDA) receptor-incutate synaptic conductance is critical for explaining the induction of long-term potentiation (LTP) at certain Hebbian synapses of the hippocampus (reviewed in Brown et al., Ann. Rev. of Neurosci., 13:475, 1990). Here we characterize the voltage-dependence of this conductance in hippocampal pyramidal neurons of region CA1.

Synaptic currents evoked by stimulation of Schaeffer collateral/commissural synaptic currents evoked by stimulation of Schaeffer collateral/commissural synaptic currents.

inputs were recorded from rat hippocampal slices. CNQX (10 - 12.5 µM) and picrotoxin (10 µM) were added to the bath and the extracellular Mg²⁺ concentration ([Mg²⁺]) was varied from 1 to 3 mM. The synaptic current was measured at holding potentials ranging from -110 mV to +25 mV.

The three free parameters in the following equation were fit to the observed

current-voltage relation:

$$I_{syn}\left(V_{m}\right) = \frac{E_{syn} \cdot V_{syn}^{\bullet}}{1 + \eta \left[Mg^{2+}\right] \exp\left(\cdot \gamma V_{syn}^{\bullet}\right)} \; ,$$
 where I_{syn} is the recorded peak synaptic current, V_{m} is the holding potential, E_{syn} is

the reversal potential, $V_{syn}^{\bullet} = E_{rest} - \delta \cdot (E_{rest} - V_m)$ is the estimated voltage at the subsynaptic membrane, E_{rest} is the resting potential, and η , γ and δ are free parameters. The first two parameters arise from a model of channel function in which the rate constant for Mg²⁺ binding to the NMDA receptor-associated channel varies as a function of voltage. The third parameter compensates for the imperfect space clamp resulting from the electrotonic distance from the soma to the synapses.

This equation provided an adequate fit to the data and the resulting parameter estimates were used to help construct a computational model (see Zador et al., Soc. Neurosci, Abstr., 1990) of LTP induction. (Supported by AFOSR)

212.14

HEBBIAN SYNAPSES INDUCE FEATURE MOSAICS IN HIPPOCAMPAL DENDRITES. Z. F. Mainen*, A.M. Zador, B. J. Claiborne and T.H. Brown. Dept. of Psychology, Yale University, New Haven, CT 06520 and Div. of Life Sciences, University of Texas, San Antonio, TX 78285.

Networks of simple processing elements (PEs) can exhibit interesting self-organizing properties when the strengths of the interconnections are governed by a Hebbian modification algorithm (reviewed in Brown et al., <u>Ann. Rev. of Neurosci.</u> 13:475, 1990). In studies of "neural networks", the PEs and their interconnections are sometimes likened to abstract representations of neurons and their synapses,

respectively. We have been exploring the computational consequences of more realistic representations of neurons containing Hebbian synapses.

Here we evaluated the proposal (Brown et al., In: Landfield & Deadweyler (Eds.)

Long-Term Potentiation: from Biophysics to Behavior, 201, 1988) that Hebbian synapses can "... cause the formation of spatial domains (mosaics) of enhancement among electrotonically proximal and functionally related synapses." The effects of three kinds of parameters were explored: the structure and physiology of the neuron; the details of the rules for synaptic modification; and the types of spatiotemporal patterns of synaptic input to the neuron. Hippocampal granule cells were simulated using compartmental models that captured much of the known morphology and using compartmental models that captured much of the known morphology and physiology. Synaptic enhancement was based on a biophysical model of LTP induction (see Zador et al., Soc. Neurosci. Abstr., 1990) plus various models of synaptic depression. The simulated "environment" consisted of numerous spatiotemporal patterns of synaptic input activity, denoting "features".

Over a wide range of conditions, patterned inputs did indeed induce mosaics of feature-specific clusters of strengthened synapses across the dendritic tree. The nature of the mosaic pattern was dependent on all three of the above categories of parameters. This form of self-organization may have interesting computational implications for hippocampál neurons. (Supported by ONR and DARPA)

INSIGHTS INTO LTP FROM COMPUTATIONAL MODELS. SYNAPTIC INPUT DISTRIBUTIONS AND SPINE HEAD [CA2+]. W.R. Holmes and INPUT DISTRIBUTIONS AND SPINE HEAD [CA²⁺]. <u>W.R. Holmes and W.B Levy.</u> Math. Research Branch, NIDDK, NIH, Bethesda, MD 20892, and Dept. of Neurosurgery, U. Virginia Med. School, Charlottesville, VA 22908.

Computational models of single dentate granule cells are helping us to understand the role of Ca^{2+} and NMDA receptors in the induction of long-term potentiation (J. Neurophysiol. 63(5)). In this published model all synaptic activation occurred on the same dendritic branch. We now generalize the model by activating inputs distributed throughout the cell.

When activated inputs were distributed evenly throughout the cell, the depolarization in the cell was close to uniform. Although the soma was more depolarized when inputs were evenly distributed rather than concentrated on number of active afferents, spine head [Ca²⁺] changes were smaller than when synaptic inputs were localized to one dendrite. Yet, there was still a steep nonlinearity in spine head [Ca²⁺] as a function of frequency and the number of co-activated afferents

White et al. (PNAS 85:2368-2372) describe a requirement for spatial convergence of weak and strong inputs to produce associative potentiation of a weak input to the dentate gyrus. Our published model fails to reproduce this experimental result: the model predicts a cooperative interaction between strong and weak inputs that are spatially separated on the outer and middle thirds of the dendritic tree. We modified the model to include inhibition. Although this new model did not completely resolve the discrepancy, the results suggest that certain spatial patterns of dendritic inhibition might be part of the answer. (Supported in part by NS15488 and NIMH RSDA K02-MH00622 to WBL.)

DEVELOPMENT AND PLASTICITY-VISUAL SYSTEM: CORTICAL ANATOMY

213.1

NUMBERS OF BLOBS IN THE PRIMARY VISUAL CORTEX OF INFANT AND ADULT MONKEYS. A.-S. LaMantia and D. Purves, Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, Missouri 63110. Purves.

Several regions of the primate cerebral cortex are characterized by iterated circuits or modules. It is not known whether the entire complement of such circuits is present at birth, or, alternatively, whether modules are added gradually during postnatal development. Accordingly, we have examined a particularly accessible type of module in the monkey cortex, the cytochrome oxidase positive blobs of Area 17. Three monatal and 3 adult rhesus monkeys were anesthetized and perfused with fixative. In the left hemisphere of each animal, the primary visual cortex was dissected, flattened, sectioned tangentially, and reacted for cytochrome oxidase to reveal the areal density of blobs. In the right hemisphere, serial coronal sections were cut through the occipito-parietal region to measure the extent of Area 17. Blob density did not differ significantly between infant and adult animals. In significantly between inrant and adult animals. In contrast, the area occupied by the primary visual cortex was found to increase by about 50% during postnatal maturation. Multiplying the blob density in the left hemisphere by the area of the primary visual cortex determined in the right shows that the total number of blobs in the rhesus monkey brain is about 8,400 at birth and 12,000 at maturity. Evidently, these complex iterated circuits are added postnatally.

CORRELATION OF GENICULOCORTICAL GROWTH INTO THE CORTICAL PLATE WITH THE MIGRATION OF THEIR LAYER 4 AND 6 TARGET CELLS. B.S. REINOSO and D.D.M. O'LEARY, Depts of Neurosurgery and of Anatomy & Neurobiology, Washington Univ Sch Med, St. Louis, MO 63110. We have studied the timing of ingrowth of geniculocortical axons into the developing cortical plate in relation to the migration of their layer 4 and 6 target cells. Time-pregnant dams were injected intraperitoneally with the thymidine analogues tritiated thymidine ([3H]TdR) at E14 and 5-bromodeoxyuridine (BrdU) at E16 to label layer 6 and layer 4 neurons, respectively. Some embryos were removed by C-sections at ares 18-21; the the thymidine analogues tritiated thymidine (3H]TdR) at E14 and 5-bromodeoxyuridine (BrdU) at E16 to label layer 6 and layer 4 neurons, respectively. Some embryos were removed by C-sections at ages 18-21; the remaining pups were delivered normally and analyzed on P30 to confirm the population of cortical neurons labeled by the thymidine analogues. The embryos and newborn pups (PO-P2) were perfused with 4% paraformaldehyde, their brains removed, transected rostral to the colliculi and Dil crystals placed in the region of the dorsal lateral geniculate nucleus (dLGN). The brains were stored in a 28-300 oven and vibratome-sectioned (100um thick) 1-2 months later. By E18, when geniculcoortical (GC) projections are first seen in the occipital pole (Reinoso and O'Leary, Soc Neurosci. Abst., 1988), most layer 4 cells are still migratory although some have already reached superficial regions of the cortical plate (CP). By this time, layer 6 cells have already reached the deep cortical plate. At E19, GC axons are within the subplate area whereas many presumptive layer 4 cells have reached the cortical plate (some are still migrating). At these developmental stages, many GC axonal collaterals were noted within layer 6. Furthermore, some bipolar and subplate-like cells were labeled. GC axons invade layer 6 by E20 and start extending into layer 4 by birth (PO). By P2, GC projection to layer 4 is quite robust. Thus, GC axons do not "follow" layer 6 and 4 cells as they migrate through the intermediate zone and into the cortical plate. Rather, the nascent layers 6 and 4 are invaded by GC axons about 3 days after each of these neuronal populations reach their positions in the cortical plate.

AN IMMUNOHISTOCHEMICAL STUDY OF DEVELOPING HUMAN VISUAL CORTEX. L.S. Honig*, K. Herrmann and C.J. Shatz. Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

The developing neocortex contains not only the immature neurons that will comprise the adult cortical layers, but also a transient zone, the subplate, destined to become the sub-cortical white matter. Studies in higher mammals have shown that the subplate contains, in addition to radial glia, migrating neurons and growing axons, a transient population of neurons that receive synapses. This special zone is also prominent in humans. To identify cellular elements and interactions in human cortical development, we examined visual cortex at conceptional ages 24 to 38 weeks (W), using neuron-specific (GAP-43 [D. Schreyer]; MAP-2 [R. Vallee]) and glial-directed (GFAP [L. Eng]; vimentin) monoclonal antibodies. At 24-38W, antivimentin densely immunostained radial glial cells in the ventricular and subventricular zones; subplate staining increased from 24W to 38W. Anti-GFAP stained astrocyte somata and processes strongly throughout cortex and subplate, intensifying from 24W to 38W. Immunoreactivity for GAP-43, an axonally transported growth associated protein, was most strongly present in a bilaminar pattern of fibers running parallel and just above the ventricular surface at 24W. The location of these fibers corresponds to the optic radiations and other long axonal projections. Subsequently, GAP-43 immunoreactivity increased in cortex and bplate, and by 38W became particularly intense in layers I (marginal zone) and IV. In contrast, reactivity to MAP-2 was strongest in the somata and processes of subplate neurons at 24W, and in neuronal cell bodies of the forming cortical plate, particularly the pyramidal cells of layer V. Staining of processes also was noted in the subventricular zone. Thus, the developmental pattern of immunostaining in humans for these antigens resembles that of other mammals, suggesting common cellular mechanisms in neocortical development. DENDRITIC DEVELOPMENT OF LAYER III PYRAMIDAL CELLS IN KITTEN VISUAL CORTEX. N. Zec and S.B. Tieman. Dept of Pathology, Hershey Medical Ctr, Hershey PA 17033 and Neurobiology Research Ctr, SUNY, Albany NY 12222.

The cat's visual cortex is immature at birth and undergoes extensive postnatal development. For example, cells of layers II and III do not complete migration until about 3 wks postnatal (Shatz and Luskin, J. Neurosci. 1986, 6:3655). Despite the importance of dendritic growth for synaptic and functional development and the many studies on visual cortical development in the cat, there are few studies of dendritic development this system. Accordingly, we have used the Golgi method to study the development of the dendrites of layer III pyramidal cells in the kitten's visual cortex. A series of kittens were deeply anesthetized and perfused with 10% formalin. Blocks of visual cortex were impregnated by the Golgi-Kopsch method and sectioned in the tangential plane. Layer III pyramidal cells were drawn with a camera lucida and analyzed by Sholl diagrams. In kittens less than 2 wks old, these cells are very immature, with only an apical dendrite and few or no basal dendrites. By 2 wks, all of the basa dendrites have appeared, but they have few branches and are tipped with growth cones. By 4 wks, they have finished branching, but continue to grow in length until, by 5-6 wks, they have reached their adult size. Thus, dendritic development occurs very rapidly over a time period that precedes and overlaps with the peak periods of synaptogenesis and of sensitivity to the effects of early visual experience. (Supported by NSF grants BNS 8217479 and 8811039 to SBT.)

MORPHOLOGY OF KITTEN VISUAL CORTICAL NEURONS DURING THE CRITICAL PERIOD, LABELLED BY INTRACELLULAR BIOCYTIN INJECTIONS. K. Grant, Y. Frégnac, F. Hester*, M. J. Friedlander, D. Smith*, and D. Debanne* Neurobiology R.Center, Univ. of Alabama at Birmingham, AL 35 294.

The activity of neurons of the primary visual cortex was recorded intracellularly in "in vitro" preparations taken from kittens at the peak of the critical period (5 weeks of

age). Most cells, recorded in 450 µm kittens at the peak of the critical period (5 weeks of age). Most cells, recorded in 450 µm hick slices, in standard bicuculline free ACSF, exhibited a "regular" pattern of excitability, as classically reported in adult neurons.

21 neurons were labelled by intracellular iontophoresis of biocytin (concentration 5%, dissolved in 0.05M TRIS buffer (pH= 7.4) containing 0.5M KCl; electrode resistance 60-120 MΩ, current pulses: -0.5/-1.0 nA, 200/300 ms duration, added on a constant -0.5 to -1.0 nA current). The tissue was fixed by immersion overnight in 4% paraformaldehyde and 0.1% glutaraldehyde in phosphate buffer, and resectioned at 80 µm after albument/gelatin embedding. Slices were pretreated in alcohol to extinguish endogenous peroxidase activity. Labelling was revealed by incubation (40 mins on ice) in ABC complex (Vectastain) followed by reaction with DAB.

Biocytin labelling showed that neurons of many different morphological types had been recorded - spiny pyramidal cells, smooth cells, layer IV spiny stellate cells although these showed rather uniform electrophysiological properties. Dendritic arborisations were comparable in their complexity to those found in the adult, Axonal arborisations were comparable in their complexity to those found in the adult. Axonal arbors were labelled over several millimeters in these slices, revealing the presence of long horizontal connections (in both supra- and infragranular layers), as well as descending projections towards the optic radiations. In some cases horizontal axons showed a periodic branching pattern, with a spatial period similar to that of the intracortical orientation network. In supragranular spiny pyramidal cells, recurrent axonal collaterals projected back through the dendritic territory of the parent cell.

From these neurons identified at the peak the critical period for visual development, it is concluded that 1) their morphology and their axonal projections were essentially adult-like, and 2) most of them showed "regular" firing. It is therefore unlikely that neuronal susceptibility to activity-dependent changes during the critical period results from spontaneous bursting behavior or from an immature morphology.

period results from spontaneous bursting behavior, or from an immature morphology.

213.7

DEVELOPMENT OF SYNAPSES IN MACAQUE MONKEY STRIATE CORTEX SHOWS AN "INSIDE-OUT" PATTERN DEVELOPMENT OF SYNAPSES IN MACAQUE MONKEY STRIATE CORTEX SHOWS AN "INSIDE-OUT" PATTERN. B. Zielinski# and A.E. Hendrickson§, Dept. Biological Sciences #, Univ. Windsor, Windsor, Ontario N9B3P4 Canada and Dept. Biological Structure & Ophthalmology §, Univ. Washington, Seattle, WA 98195. A quantitative study of synaptic density (contacts/100µm2) during development of primary visual cortex has found at gestational day (E) 75 that immature contacts occurred mainly in the marginal zone (adult layer 1) or in the subplate (adult white matter). Those few contacts in the cortical plate were confined to layer 6. A comparison of synaptic density.

and morphology in layer 2 vs layer 6 was done from El13 - adulthood. Before birth synapses in layer 2 contained fewer vesicles and had minimal synaptic densities, while those in layer 6 were much more minimal synaptic densities, while those in layer 6 were much more mature. Synaptic density in upper layers is relatively low at E113 (2 vs. 8), and still lags slightly behind lower layers at E152 (25 vs. 28) and postnatal (P) 2d (32 vs. 37). By P 12 wks synaptic density is 30% higher in layer 2 (69 vs. 49). By P 2 yr synaptic distribution has declined to the approximate level at birth (44 vs. 33), is relatively even throughout all layers and is similar to adult density (37 vs. 39). Between P 12 wk and P 6 yr asymmetric contacts in all layers acquire more pre- and postsynaptic membrane density that clearly differentiates between

asymmetric and symmetric types.

These results confirm other work showing a transient overproduction of synapses in early postnatal monkey cortex. Our laminar analysis shows that visual cortex has a generalized "inside-out" prenatal synaptogenesis pattern which is more correlated with neuron age than input. After birth upper layers have the highest synaptic density, and may take slightly longer to reach final adult levels. (EY01208 and EY04536)

MORPHOLOGY OF CORTICOGENICULATE AXONS IN ADULT FERRETS (Mustela Putoris). G.J. Condo.' A. Claps*,' and V.A. Casagrande1,2. Dept. of Cell Biology1 and Psychology2, Vanderbilt Univ. Nashville, TN 37232

The lateral geniculate nucleus (LGN) receives a major input from visual cortex. While the function of this input is not fully understood, one approach to understanding the organization of this pathway is to determine the anatomical details of corticofugal axons. In this study we examined the structure of individual axons labelled in the LGN and adjacent nuclei following injections of Biocytin in area 17 of adult ferrets. The majority of corticogeniculate axons resemble the Type I axons described in the cat (Guillery, J. Comp. Neurol., 128: 21-50, 1966; Robson, J. Comp. Neurol., 216: 89-103, 1983). These axons are of fine caliber and typically course perpendicular to the LGN laminae with terminals en passant and at the end of short collateral stocks in both the A- and C-laminae. Similar to the pattern seen following ³H proline injections in developing ferrets (Claps and Casagrande, this meeting), a subset of axons have more extensive terminals in interlaminar and interleaflet zones and/or long lateral branches and terminals in the C-laminae. Single axons are often seen terminating in both the perigeniculate nucleus (PGN) and A-laminae of the LGN. In contrast, fine axons terminating in the medial interlaminar nucleus (MIN) appear to be a separate population, having more complex terminals which end in clusters of boutons aligned along a projection column. Large caliber axons terminating in the lateral posterior nucleus (LP) have larger boutons and more elaborate terminal fields than axons found in the LGN, PGN, or MIN. These results suggest that in the ferret the feedback pathway to the thalamus is complex and composed of several classes of axons with different terminal patterns. DEVELOPMENT OF SOMATIC INHIBITORY SYNAPSE COVERAGE ON THALAMIC RECIPIENT NEURONS OF MACAQUE MONKEY PRIMARY VISUAL CORTEX. J.S. Lund and T.R. Harper. Department of Psychiatry and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261 Two channels of visual input, differing in physio-

logical properties, terminate on spiny stellate neurons in separate divisions (alpha and beta) of layer 4C in cortical area V1. We have examined the postnatal development of type II (inhibitory) synapses on the cell bodies of these neurons. A clear temporal and numerical correlation was found between the alpha and beta neurons in terms of the percent of their cell body surface area occupied by synapse apposition sites. This coverage rises swiftly after birth to a peak on both groups around 12 weeks postnatal, falling by 24 weeks to a level close to that found in the adult. This common developmental pattern of inhibitory coverage contrasts with the development of excitatory synapses and dendritic arbors which show quite different patterns of development between birth and thirty weeks of age on the alpha and beta neurons. This suggests that development of inhibitory coverage is coordinated between the two layers and does not directly relate to the ongoing differential development of excitatory contacts and dendritic arbors on the two cell groups. Supported by EY05282.

THE DEVELOPMENT OF CORTICOGENICULATE CONNECTIONS IN THE FERRET A. Claps' and V.A. Casagrande. Dept. of Cell Biology and Psychology V. Vanderbilt Univ., Nashville, TN 37232.

In ferrets lateral geniculate nucleus (LGN) layers form between posnatal day 7 (P7) and P14 and do not form without retinal input (Guillery, J. Neurosci. 5:1370). However, the LGN also receives input from the visual cortex and it is unclear what role extraretinal input plays in LGN maturation. To address this issue, we studied the development of corticogeniculate axons in ferrets, by injecting WGA-HRP and ³H proline into area 17, at weekly intervals from P0 to P28. In addition, we examined axonal morphology in adults following Biocytin injections and in vitro at P0 following Dil injections. In the adult, injections of WGA-HRP, produce columns of anterograde and retrograde label, that extend across all cell layers and interlaminar zones (ILZs). Injections of ³H proline produce anterograde label only, that is densest within the ILZs. Corticogeniculate Biocytin labeled axons are structurally simple with en passant boutons and short collateral side branches (see also Condo et al. this meeting). At P1, the same tracers produce light diffuse label in the LGN. Dil at the same age labels many axons and cells; the axons that appear to be of cortical origin are fine and beaded. At P7, the corticogeniculate projections are e dense and organized into discrete but still uniform columns. Even at P14 when ILZs are evident corticogeniculate axons are still not concentrated in these zones. The corticogeniculate projection appears adult-like by P28. Thus, the temporal sequence of maturation of corticogeniculate axons does not seem to be correlated with ILZ formation. However, the results show that cortical axons are already in the LGN, at a time when they could influence the process of retinal afferent segregation. Supported by EY05038 and BNS 8708429.

POSTNATAL DEVELOPMENT OF VISUAL CALLOSAL PROJECTIONS IN THE STRIATE CORTEX OF THE RABBIT. A.M. Grigonis¹, Y. Wang*² and E.H. Murphy². Departments of Anatomy, ¹Hahnemann University, Philadelphia, PA 19102-1192, and ²Medical College of Pennsylvania, Philadelphia, PA 19129.

The cell distribution of the corpus callosum (CC) projection in the visual cortex of the adult rabbit is restricted to the 17/18 border. Previous studies have reported exuberant visual callosal projections, extending throughout area 17, on day 7, and mature, restricted callosal projections on day 15 (Chow, et al., Exp. Brain Res., 42:126, 1981). We determined the postnatal development of callosal projections in normal Dutch-Belted rabbits at intermediate ages between 1 and 15 days. Multiple injections of HRP (Boehringer, 20% in H₂O) were made throughout one entire visual cortex (9 µ.l). Animals were perfused 24 hours later and the brains were cut and reacted with TMB. In three animals. following fixation, Dil was injected into one visual cortex, the brains were stored for six weeks, cut and observed under florescence microscopy. On the day of birth the tangential extent of the CC cell distribution was exuberant, 47% more than the adult tangential extent. At the time of eye opening, which occurs between days 10 and 11, the CC cell projection was also exuberant, 38% more than the tangential extent of the adult. Since we have previously demonstrated a maintenance of callosal exuberance in rabbit visual cortex following deprivation of visual experience, the present data support the hypothesis that the potential for visual experience to modify callosal development depends on the degree of callosal maturity at the time of eye opening. Supported by grant NS26989.

TRANSCALLOSALLY EVOKED RESPONSES IN THE VISUAL CORTEX OF NORMAL AND MONOCULARLY ENUCLEATED RABBITS. R.J. Clarke, B. Datskovsky*, A.M. Grigonis¹, and E.H. Murphy. Depts. of Anatomy, Medical College of Pennsylvania, Phila. PA, and ¹Hahnemann University, Phila., PA.

In the visual cortex of normal adult rabbits, callosal fibers originate and terminate in a narrow zone at the 17/18 border. In adult rabbits which are monocularly enucleated (ME) on the day of birth, the callosal zone maintains an immature pattern, extending into the medial regions of area 17 in the cortex contralateral to the enucleated eye. In order to determine the functional topographic organization of this expanded callosal zone, we investigated the region over which stimulation could evoke a transcallosal response. Visual field mapping was used to identify the 17/18 border electrophysiologically in the cortex of normal animals and in the cortex contralateral to the intact eye in ME rabbits. The electrode was maintained in this position to record responses to stimulation of the opposite cortex with bipolar electrodes placed in a homotopic location. The stimulating electrodes were then moved medially in 1mm steps, and the responses evoked at each location averaged. In the normal rabbit, stimulation at a position homolateral to the recording electrode evoked a consistent response with a positive deflection at a latency of 16-18ms. At a distance of 1mm or more from this optimal position, this short latency response was either absent or dramatically decreased in amplitude, reflecting the precise topographic projection pattern of the normal callosal projection. In ME rabbits, stimulation at a position homolateral to the recording electrode also evoked a consistent positive deflection response with a latency of 17-20ms, but responses of similar or only slightly decreased amplitude could be evoked when the stimulating electrodes were moved 2 or 3mm medial to this optimal position. Thus, the expanded callosal projection can be demonstrated electrophysiologically, suggesting that abnormal callosal projections in ME rabbits can mediate functional interactions between topographically disparate areas of the primary visual cortices. Supported by grant NS26989.

NEONATAL HYPOXIA-ISCHEMIA INCREASES THE NUMBER OF VISUAL CALLOSAL PROJECTIONS IN THE CAT. B.L. Finlay, B. Miller. S. Nioka.* D. Nagy*, A. Zaman*, and B. Chance, Department of Psychology, Comell University, Ithaca, NY, 14853, and Department of Biochemistry and Biophysics, University of Pennsylvania, Philadelphia, PA, 19104.

Perinatal hypoxic-ischemic insult has been shown to produce neuroanatomica and behavioral pathology. One of the main features of perinatal cortical development is the exuberance and retraction of transient callosal projections. We examined the effect of hypoxia-ischemia on developmental axon retraction.

Cats were subjected to hypoxia-ischemia by bilateral carotid artery ligation at 7 days of age. The cats were given neurological examinations, every week for 2 months and then bi-weekly up to 3 months of age, consisting of locomotor, superficial and deep reflex and sensory nerve function, including visual cliff and visual placing tasks. At 3 months of age, multiple HRP injections were made into the visual cortex of one hemisphere during aseptic surgery. The tangential extent of retrogradely labeled callosal cells was measured from the border between primary and secondary visual cortex, and the number of cells was counted in 200µm increments. A comparison of the distribution of callosally projecting cells was made between 4 hypoxic-ischemic animals and 3 controls.

Two hypoxic-ischemic animals failed the visual cliff task. These animals were also grossly hydrocephalic. Performance on other visual and behavioral tasks were normal. The hypoxic-ischemic animals had twice the number of callosally projecting cells. The overall tangential extent of callosal cells was not different than normals.

Postnatal development of the connections of the feline cortical region extends along the anterior ectosylvian sulcus (AEs): WGA-HRP study. Masao Norita, and Hideaki Shimizu*. Dept., Anat., & Embryol., Tokyo Metropolitan institute for Neurosciences, Fuchu, Tokyo 183, Japan.

Cortical and subcortical projections to and from the AEs in neonatal cats were studied with anterograde and retrograde WGA-HRP methods. The projections of AEs with cortical and subcortical structures are already present at birth, and the origins and terminations of the most of these projections are arranged topologically. Following deposit of the tracer in AEs, cortical label was found mainly in the presylvian sulcus, the cingulate gyrus, the cruciate sulcus, the medial prefrontal area, the splenial sulcus, the lateral suprasylvian sulcus, the posterior suprasylvian gyrus, the posterior rhinal sulcus; subcortically, thalamic label could be detected in the VM, LPm and LM-Sg, and axonal label was seen in the superior colliculus and the pontine nuclei. However, the cortical laminar distribution of the afferents arising from AEs changes with aging: in neonates, relatively dense label was found in layer I, the infragranular layers and white matter, while in adults labeling was seen mainly in the supragranular layers.

These data indicate that the major neuronal connection of AEs seems to be a prenatal event, while its corticocortical projection is still developing postnatally.

213.12

DEVELOPMENT OF OCCIPITAL CALLOSAL AXONS IN HAMSTER: ANTEROGRADE TRACING WITH DI-I. S.E. Fish, R.D. Mooney, and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699 and Dept. of Anatomy, Marshall University School of Medicine, Huntington, WV 25704.

Anterograde diffusion of Di-I was used to label callosal axons in hamsters from birth (P-0) through P-12. On P-0 and P-1, labelled fibers were visible crossing the midline in both the corpus callosum and anterior commissure, but only a very small number were seen in the cortex contralateral to the tracer deposits. As these ages, many fibers ended in elaborate growth cones. By P-2, many axons were visible in the white matter beneath presumptive area 17. These fibers gave off many branches extending short distances into the subplate. A smaller number of adult-like fibers with short side branches reached all the way to the pial surface. On P-2, long fibers with many side branches were also visible in the marginal layer paralleling the pial surface. By P-3, many more fibers extended from the white matter to the pia and they were similar to callosal fibers in adult hamsters. By P-4, numerous mature callosal axons could be seen and they appeared to be concentrated in the region of the presumptive area 17-18a border. At this age, axons in the white matter still gave off many short collaterals and a few fibers had long horizontal trajectories in layers V and VI. By P-6, most of the short branches of callosal axons had disappeared and the vast majority of labelled fibers were similar to those that have been observed in normal adult hamsters. Supported by EY 04170 and EY 08015.

DII LABELED INTERHEMISPHERIC FIBERS DURING CAT POSTNATAL DEVELOPMENT SHOW TRANSITORY CORPUS CALLOSUM AXON TERMINAL DISTRIBUTIONS THROUGHOUT STRIATE CORTEX WITHIN SUPRA AND INFRAGRANULAR LAMINAE. A.J. Elberger. Dept. of Anatomy and Neurobiology, Univ. Tennessee, Memphis Memphis, TN 38163.

Previously it was shown that an intact corpus callosum (CC) during postnatal month 1 in cat is critical to normal visual functional development; this was hypothesized to be due to extensive, abundant CC/visual cortex interactions in early postnatal development (Elberger 1984; Elberger & Smith 1985). To examine this hypothesis CC axons/terminals were labeled by placing crystals of the lipophilic dye, DiI, in vitro in the mid-sagittal CC of normal cats 1-13 weeks old. The number and location of CC axons in striate cortex were compared at different developmental stages.

The results show that in the youngest cats, CC axons penetrate supra- and infragranular layers throughout the visual field representation; terminals are in layers 1-6. At increasing ages axons are reduced first in intermediate and then peripheral/central regions of the visual field representation. In older animals CC axons are located in striate cortex predominantly, but not exclusively, within the central visual field representation. This indicates that many transitory CC axons have the opportunity to interact with developing cortical cells representing all of the visual field. The abnormal visual development that follows neonatal CC section may be due to lack of CC and cortical interaction. Support by EY08466, (BRSG) RRO5423.

SEX DIFFERENCES IN CORTICAL DEVELOPMENT WITH VISUAL DEPRIVATION. D.E. Fleming, R.B. Burr* and R.W. Rhees Departments of Psychology and Zoology, Brigham Young University, Provo UT 84602

Control and visually deprived albino rats of both sexes were compared with respect to size (area) and thickness of Brodmann's areas 17, 18 and 18a of the cerebral cortex. Both groups were reared under conditions of a 12/12 light/dark schedule for 90 days, then were sacrificed. The light phase for the visually deprived group was dim red light. The cortical size and thickness measurements of the control males were greater than those of the control females. With visually deprived animals, both males and females had smaller cortical values than did the control animals. However, males and females of the deprivation group did not differ from each other in their cortical measurements. The control males had a modest R > L cortical asymmetry that was not present in female rats of either treatment group or in visually deprived males. These data suggest that varied levels of visual experience are important not only for maintaining brain size but also sex differences. (Funding provided by the College of Family, Home and Social (Funding Sciences, Brigham Young University.)

VISUAL CORTEX METABOLIC ACTIVITY INCREASES IN RESPONSE TO FLASHING DIFFUSE LIGHT IN NEONATAL RATS. A. C. Gafka and R. M. Cooper. Behavioral Neuroscience Research Group, Psychology Dept., University of Calgary, Calgary,

Alberta, Canada, T2N 1N4.
Past 2-deoxyglucose (2-DG) work has shown that normal lab-reared adult rats monocularly exposed to flashing diffuse light (one eye covered with translucent mask) show increased metabolic activity in contralateral subcortical visual structures, with visual cortex remaining virtually unresponsive relative to the unstimulated hemisphere. In the present study, neonatal rats at the time of eye opening (14 d), to 3 weeks of age (28 d) were injected with 2-DG and monocularly exposed to 4 Hz flashing diffuse light (one eye covered by a translucent mask, the other by an opaque occluder). In all neonatal groups, flashing diffuse light significantly increased cortical metabolic activity in monocular area 17 and in area 18a of the hemisphere contralateral to the diffusely masked eye. These findings suggest that at the time of eye opening and shortly after, visual cortex neurons in the rat lack adult-like receptive field specificity; the development of response selectivity may be the result of experience, maturation, or both.

A HIGH MOLECULAR WEIGHT CHONDROITIN SULFATE PROTEOGLYCAN FROM BRAIN IS RELATED TO THE LARGE AGGEGATING CARTILAGE PROTEOGLYCAN. H.J.L. Fryer, L. Molinaro*, and S. Hockfield, Sect. of Neuroanat., Yale Univ. Sch. of Med., New Haven,

Cat-301 is a monoclonal antibody which stains the surfaces of subsets of neurons in the CNS. The expression of the Cat-301 antigen coincides of neurons in the CNS. The expression of the Cat-301 artigen coincides with the end of periods of synaptic plasticity during postnatal development and is dependant upon normal patterns of neuronal activity. We have recently shown (Neuron 2:1207) that the Cat-301 antigen is a high molecular weight chondroitin sulfate proteoglycan (CSPG). Using Western blot analysis of tissue extracts from cat we have determined that a Cat-301 antigen, similar in molecular weight to the brain CSPG, is found in non-neural tissues including articular cartilage (AC). The

CSPG, is found in non-neural tissues including articular cartilage (AC). The AC artigen is similar to the brain CSPG in many respects. Both react with a second monoclonal antibody, Cat-304. Both are CSPGs, shown by a shift in apparent molecular weight of the antigen following digestion with chondroltinase ABC and by identification with antibodies to the stubs of chondroltin sulfate chains following chondroltinase digestion. The two CSPGs are distinct in that AC CSPG has a much higher buoyant density. Keratan sulfate substitution on the AC CSPG, which is not found on the brain CSPG, may account, in part, for this difference.

Cartilage contains high molecular weight CSPGs which bind to hyaluronic acid and form large aggregates. The AC CSPG which stains with Cat-301 belongs to this family of aggregating proteoglycans. In the presence of added hyaluronic acid the brain Cat-301 CSPG is found in higher density fractions of CSCI gradients, indicating that it to may be an

higher density fractions of CsCl gradients, indicating that it too may be an aggregating proteoglycan. Our data suggest that the high molecular weight brain Cat-301 CSPG may belong to the family of large aggregating proteoglycans identified in other tissues. [Supported by EY05511]

KERATAN SULFATE PROTEOGLYCANS ASSOCIATED WITH NEURONAL SURFACES IN CNS. Sam Zaremba, Gail Kelly*, Robert Kalb and Susan Hockfield, Sect. of Neuroanatomy, Yale Univ. School o

Medicine, New Haven, CT 08510.

In order to further our understanding of the molecular structure of the mature mammalian CNS we have been interested in the identification and characterization of CNS proteoglycans. Here we demonstrate that antibodies to keratan sulfate (KS) identify antigens on the surfaces of neuronal subpopulations in adult CNS of several mammalian species. KS immunoreactivity is discontinuous along the surface of neuronal cell bodies and extends a considerable distance along neuronal processes. We have shown that some of the KS reactive cells in hamster spinal cord are motorneurons by retrograde labeling with Fast Blue from the sciatic nerve. Staining is abolished by preadsorbtion of anti-KS antibodies with KS, demonstrating that the surface antigen is a KS-containing moiety.

Previous biochemical analyses demonstrated the presence of KS immunoreactivity in CNS but had not identified the macromolecules responsible for such reactivity. We have identified major anti-KS reactive molecules as 600-700 kd species on Western blots of unfractionated CNS homogenates. In addition, we have reported that one KS-positive molecule is part of the high molecular weight glycoconjugate immunoprecipitated by mAb VC1.1 (Zaremba et al, J. Neurosci, in press). Consistent with this identification, we also demonstrate that individual neurons in cat CNS can be double labeled with VC1.1 and anti-KS antibodies. The diversity of surface-localized proteoglycans (KS and other types) may be a means for generating specificity in recognition events in the developing CNS and stabilizing those connections in the adult CNS. [Supported by EY06511]

DISTINCT NEURONAL SUBSETS EXPRESS ANTIGENICALLY DISTINCT SURFACE PROTEOGLYCANS IN MAMMALIAN CNS. Susan

Univ. School of Medicine, New Haven, CT, 06510.

Monoclonal antibody Cat-301 recognizes a suface-associated chondroitin sulfate proteoglycan. The Cat-301 proteoglycan is expressed on subsets of neurons in several areas of the mammalian expressed on subsets of neutrons in several areas on the mammalian CNS. We have demonstrated that the expression of the Cat-301 proteoglycan develops postnatally and is regulated by neuronal activity during a circumscribed period in development. We now report that Cat-301 is one member of a family of chemically related, neuronal cell surface-associated antigens. Antibodies to chondroitin sulfate moieties reveal associated alligers. Antiocures to chandroll status in the related, but distinct, staining patterns to that observed with Cat-301.

Three different antibodies all show the same surface-associated ocalization previously observed with Cat-301. This surface-associated staining develops postnatally, but with a time course different from that of Cat-301. Each antibody recognizes a subset of neurons distinct from the other and from that recognized by Cat-301. Consistent with this finding, we have identified several high molecular weight antigens on Western blots that react with antibodies to chondroitin sulfate but not with Cat-

These results are consistent with the possibility that distinct proteoglycans are present at the surfaces of functionally distinct neuronal subpopulations. Their spatial and temporal appearance suggests that they might play a role in specific recognition events during the acquisition of mature CNS structure. [Supported by EY06511]

PG-1000: A GENERAL PROTEOGLYCAN COMPONENT OF BRAIN EXTRACELLULAR MATRIX ? M. Iwata, and S.S. Carlson. Dept. of Physiology and Biophysics, University of Washington, Seattle, WA.

PG-1000 (formerly TAP-1) is a large (10⁶ daltons) chondroitin sulfate proteoglycan identified, purified, and characterized from electric organ. When the purified molecule is visualized in the electron microscope it has the "bottlebrush" structure of a large space-filling proteoglycan with a total length of about 350nm and about 20 side chains of 110 nm (Carlson and Wight, J Cell Biol. 105: 3075, and about 20 size chains of 10 lini (carison and wight, <u>Cell Biol</u>, 103: 3071). 1987). Originally, it was proposed that this molecule might act as a nerve terminal anchorage protein, because of its apparent exclusive nerve terminal localization. However, using a new monoclonal antibody which identifies a protease sensitive epitope (T1) on PG-1000, we find that this proteoglycan is has a much wider cellular distribution. By immunocytochemistry it is present on both the synaptic and non-synaptic face of the electrocyte and the Schwann cell basement membrane in electric cells.

in electric organ.

PG-1000 is present throughout the fish and mammalian brain. Immunocytochemical localization of the T1 antigenicity shows it to be present in both the gray and the white matter. Strong staining of T1 antigenicity is seen surrounding the large electromotor nucleus cells in the fish. In fish and mammalian brain extracts the T1 antigenicity behaves like a proteoglycan, eluting from DEAE Sephacel at about 0.7M NaCl with the pH 4.9. In addition, the fish brain antigen shows a shift in molecular weight upon digestion by chondroitin ABC lyase. Finally, PG-1000 can only be extracted from brain tissue under denaturing conditions. This is quite unlike most proteoglycans which have been studied in the brain; these are solubilized by salt extraction or non-denaturing detergents. In the brain, PG-1000 behaves like it does in peripheral nervous tissue, as a component of a detergent insoluble matrix. of a detergent insoluble matrix.

Because PG-1000 appears to be present throughout the brain and acts like part of an insoluble matrix, we hypothesize that it is a general extracellular matrix component of the adult brain. Only a few general components of such a matrix are

PROTEOGLYCAN-LIKE ANTIGEN MOLECULES IDENTIFIED BY MONOCLONAL ANTIBODIES GIVING PERINEURONAL STAINING IN THE RAT BRAIN. S.C.Fujita, J.Kudo, and S.Sano. Laboratory of Neurochemistry, Mitsubishi Kasei Institute of Life Sciences, 11 Minamiooya, Machida 194, Japan

Monoclonal antibodies(MAbs) 473 and 376 stain perimeters of limited numbers of central neurons that form partially overlapping subsets, and these immunoreactivities are obliterated by pretreatment of the sections with chondroitinase ABC. MAb 1B5 with established specificity to an epitope uncovered by chondroitinase ABC also stains a subset of central neurons in their perimeter. (Fujita et al., Neurosci. Res., 7, 117, (1989)) The antigens for these MAbs were sought by immunoblotting in the rat brain homogenate. Using acrylamide/agarose gels, diffuse bands of low mobility were found. The bands for MAbs 473 and 376 were not detected after, and that for MAb 1B5 was detected only after, treatment of the blots with chondroitinase ABC. The 473 and 376 bands were not found in tissue homogenates of canus were not round in tissue homogenates of rat liver, skeletal muscle, or kidney. Molecular weight of the antigens was estimated to be around 700kD, a size similar to that of Cat-301 antigen proteoglycan. (Zaremba et al., Neuron, $\underline{2}$, 1207 (1989))

Ganglioside binding activities solubilized from rat brain membranes. P.J. Schwartz, I. Krop*, J.A. Mahoney*, P. Swank-Hill*, and R.L. Schnaar. Depts. of Pharmacol., Neurosci., and Toxicol., The Johns Hopkins Medical Institutions, Baltimore MD 21205

Gangliosides and complementary ganglioside binding proteins may be involved in neural membrane interactions. We synthesized and used conjugates of ganglioside G_{T1b} bound to radioiodinated bovine serum albumin to identify a high-affinity, ganglioside-specific binding protein on isolated rat brain membranes (Tiemeyer, M., et al. (1989) J. Biol. Chem. 264, 1671).

Using differential detergent extraction, we defined two pools of ganglioside binding activity in crude rat brain P2 membranes. A "detergent sensitive" pool was extracted with 0.1% Triton X-100 in low ionic strength buffer. A "detergent resistant" pool required 0.5% Triton X-100 and 400 mM KCl for solubilization. Binding activities were assayed using a polyethylene glycol precipitation assay. The detergent resistant ganglioside binding activity was found predominantly on myelin membranes (Tiemeyer, M., et al. (1990) J. Biol. Chem. 265, in press), while the detergent sensitive activity was enriched in synaptosomes. Both activities were inhibited by similar gangliosides and selected phospholipids. The two ganglioside binding pools may reflect different molecular receptors, or similar receptors associated with brain membranes in different ways. Supported by PHS Grants HD14010, GM07626 and ES07141.

EXPRESSION OF CARBOHYDRATE ANTIGENS IN RAT OLFACTORY CELL CULTURES. G.A. Schwarting, M. Yamamoto, D. Gattey* and J.E. Crandall, E.K. Shriver Center, Waltham, MA 02254; and Program in Neuroscience, Harvard Medical Sch., Boston, MA. We have previously described the expression of three unique carbohydrate antigens (CCl, CC2, and 1B2) in the rat olfactory system. CCl antibody reacts with an N-acetylgalactosamine containing glycolipid which is expressed in the vomeronasal organ (VNO), vomeronasal nerve (VNN) and the accessory olfactory bulb (AOB). CC2 antibody, which reacts with α -galactose and α -fucose-containing glycoconjugates and 1B2 antibody, which react with a β -galactose terminal glycolipid, stain the VNO, VNN and AOB and also are on subsets of the main olfactory epithelium, olfactory nerve and olfactory bulb. Cells taken from embryonic day 15 rat olfactory epithelium are grown in serum free medium on a laminin substratum. Within a day of plating, the laminin surface is coated with a layer of non-neuronal cells. Olfactory epithelial cells grow on the surface of a non-neuronal monolayer either in large aggregates or as individual cells. Double label immunofluorescence studies have demonstrated that CC1 is co-expressed with NCAM cell nave demonstrated that CCI is co-expressed with NCAM ce bodies at the periphery of kerating aggregates. However, only the proximal portion of NCAM processes are CCI CC cells are NCAM and keratin. At day 5 in culture they appear as columns of cells migrating away from the epithelial aggregates. 1B2 cells are keratin and NCAM. These data suggest that 1B2 may be a marker for immature olfactory neurons.

DIRECT EVIDENCE FOR INVOLVEMENT OF MEMBRANE GLYCOSPHINGO-LIPIDS IN SKELETAL MUSCLE DIFFERENTIATION.

and K.C. Leskawa. Dept. Anatom. Sci. & Neurobiology, University of Louisville, Louisville, KY 40292

We have reported that differentiation of skeletal muscle cells in vitro was characterized by transient muscle cells in vitto was characterized by transient increases in glycosphingolipid synthesis at the time of contact and membrane fusion. This response was abberant in dystrophic avian myoblasts and absent in fusion defective varients. Also, normal myoblast contact was accompanied by a dramatic rise in lactosyltransferase activity (GalT-2), which was missing in fusion-defective cells (Leskawa et al., Soc. Neurosci., 1985, 1986, 1987, 1989).

To further explore roles of membrane GSLs in myoblast fusion, we examined the effect of an inhibitor of gluco-sylceramide synthase (Glc-T), D-threo-PFMP, on clonal (E63) myoblast fusion. Exposure of normal E63 rat myo-blasts to PFMP resulted in an inhibition of fusion (20% of control). This inhibition was partially overcome by concurrent incubation of cells with PDMP and excepences Laccer or ganglioside GM3 (60 to 70% of control). PDMP did not affect the synthesis of protein, DNA or phospholipids. Incorporation of serine into phospholipids. Incorposphingolipids was unaffected.

These studies directly demonstrate a role for membrane glycosphingolipids in formation of multinucleated myotubes by skeletal myoblasts in vitro.

CHARACTERIZATION OF PHOSPHOLIPIDS AND OTHER MEMBRANE COMPONENTS OF THE JELLYFISH CYANEA CAPILLATA. John A. Schetz and Peter A. V. Anderson. Department of Neuroscience, Univ. of Florida, Gainesville, FL 32610.

As a prerequisite for preparing artificial membranes for the study of a novel voltage-dependent Na channel of the Scyphozoan iellyfish Cyanea capillata (P.A.V. Anderson

jellyfish <u>Cyanea capillata</u> (P.A.V. Anderson (1987), <u>J. exp. Biol.</u> 133, 231-248), the composition of the neural membrane must be determined. Phospholipid, sterol and ganglioside contents of the membranes of nerve rich tissue were assessed. Membrane components were purified by a series of chemical extractions, separated by thin layer extractions, separated by thin layer chromatography, and identified and quantified using various chemical tests. Preliminary data shows that whole jellyfish membranes contain at least phosphotidylcholines, phosphotidylserine, phosphotidylethanolamine, cholesterol, and various other sterols, but apparently no gangliosides. We conclude that these jellyfish either have unique or very low levels of gangliosides. Supported by NSF Grant BNS-

Electrical stimulation of rat striatal slices increases the level of lysophosphatidylcholine and decreases that of phosphocholine. S. A. Father', R. L. Buyukuysal', B. E. Slack and R. J. Wurtman Department of Brain and Cognitive Sciences, MIT. Cambridge, MA

Department of State 202139, USA
We previously showed that electrically-stimulated rat brain
State 2 and release large amounts of

We previously showed that electrically-stimulated rat brain slices continue to synthesize and release large amounts of acetylcholine (ACh) even when superfused without exogenous choline (Ch) (Ulus et al. <u>Brain Research</u>, 484:217-227). Under these conditions membrane phospholipid levels decreased by 15%, but adding free Ch to the medium completely protected against this decrease. The present ctudy examined the effects of electrical stimulation on levels of various choline-containing intermediates in phosphatidylcholine (PtdCh) synthesis and catabolism

Slices were superfused with Krebs-Ringer buffer containing 20 will esserine, and electrically stimulated for 1 hour (1 Hz. 100 mAmp and 1 msec duration); perfusates were collected for later analysis of ACh and Ch levels. The slices were then incubated for 30 or 60 minutes with 20 uGi of [^1C]Ch (45 uM), and after labeling were washed, homogenized in methanol and water, and extracted with chloroform. The water soluble fraction was assayed for labeled and unlabeled phosphocholine (PCh), ACh and Ch; the organic phase was assayed for labeled and unlabeled PtdCh and other phospholipids.

We confirmed that electrical stimulation had no effect on cissue Ch levels but depleted membrane phospholipids by 16 - 37%. This treatment also increased the total lysoPtdCh levels from .062 ± .004 to .13 ± .02 mmols/ug DNA (33%; P<.05). The accumulation of [^1C]PtdCh and [^1C]Pth were reduced by 40 and 32% respectively. Stimulation had no effect on the specific activity of [^1C]Ch in either the tissue or the incubation medium.

These findings suggest that both decreased PtdCh synthesis and increased degradation can mediate the depletion in this membrane phospholipid that occurs when the tissue is stimulated for prolonged periods in the absence of Ch.

ANALYSIS OF MEMBRANE PHOSPHOLIPIDS IN ALZHEIMER'S DISEASE BRAIN BY ³¹P NMR. Pettegrew JW. Panchalingam K. Strvchor S and Branthoover G. Laboratory of Neurophysics, Dept of Psychiatry, U. of Pittsburgh, Pittsburgh, Pa.

Neurophysics, Dept of Psychiatry, U. of Pittsburgh, Pittsburgh, Pa. 15261

Recent in vivo and in vitro nuclear magnetic resonance (NMR) studies demonstrate elevation of phosphomonoesters and phosphodiesters in Alzheimer's disease (AD) brain. This would indicate an abnormality in brain phospholipid synthesis. In this study, membrane phospholipids of Alzheimer's Disease autopsy brain tissues were analyzed by ³¹P NMR technique. Quantitative assessment of phosphatidylcholine (PtdC), phosphatidylethanolamine (PtdE), phosphatidylserine (PtdS), phosphatidylinositol (PtdI), phosphatidic acid (PtdA), cardiolipin, sphingomyelin, and some of their lyso- and plasmalogen derivatives were made. The results demonstrate a reduction in PtdC, PtdE (p=0.02) and PtdA in AD brain (21 samples, 10 brains) compared to non-AD diseased controls (16 samples, 8 brains) of the same age group. The phospholipid PtdI is not altered. PtdS, sphingomyelin (p=0.03), PtdE plasmalogen and cardiolipin are elevated. Correlation studies indicate PtdC is negatively correlated (p=0.002, r=0.8) with the number of senile plaques (SP) per x 200 magnification between cortical layers II and IV in the same brain region. This would indicate a reduced synthesis of this phospholipid as the disease progresses. Cardiolipin which is present only in the inner mitochondrial membrane is positively correlated with the number of SP (p=0.01, r=0.8) indicating that this lipid synthesis is elevated with the progression of the disease. The possible implications of these findings will be discussed.

A OUABAIN-SENSITIVE NA, K-ATPASE IN TENTACLES OF THE SEA ANAMONE STOICHACTIS HELIANTHUS. Susan C. Specht, Roberto López Rosado, Rosa Figueroa Nieves and Sonia Soto. Department of Pharmacology and Institute of Neurobiology, University of Puerto Rico, Medical Sciences Campus, San Juan, Puerto Rico 00936

Innervated portions of one species of jellyfish (Cyanea capillata) and two sea anemones (Aiptasia tagetes and Stoichactis helianthus) were examined for evidence of a ouabain-inhibited, Na,K-stimulated ATPase. Robust activity was found only in the innervated tentacles of Stoichactis helianthus, a large sea anemone whose sting produces a powerful and persistent burning sensation. Na,K-ATPase activity was completely inhibited by ouabain or strophanthidin at $10^3\ \mathrm{M}.$ The K for strophanthidin (prepared in dimethylformamide) was approximately 10⁴ M, assayed for K-stimulated p-nitrophenyl phosphatase activity; in rat, the K determined by this assay is about one order of magnitude higher than if assayed for Na,K-ATPase activity. SDS-PAGE of the crude preparation revealed a protein band in the region of 90 kD. (Supported by NIH grants NS-07464 to R. Orkand and SO6 RR 08224 to E. Santiago Delpin).

DIFFERENT RESPONSE OF BRAIN AND HEART MITOCHONDRIAL CARDIOLIPIN FATTY ACID PROFILES TO ALTERATIONS IN DIETARY POLYUNSATURATED FATTY ACIDS. P.B. Lieberman, C.E. Greenwood and G.H. Anderson. Dept. Nutr. Sci., Fac. Med., Univ. of Toronto, Toronto, ONT

We previously reported that alterations in the amount of dietary linoleic acid We previously reported that alterations in the amount of dietary linoleic acid (18:2n-6) induced large and rapid changes in brain mitochondrial (MI) cardiolipin (CL) 18:2n-6 content in rapidly growing rats (Dyer and Greenwood, 1989). MI membrane characteristics vary tremendously amongst different tissues. For example, brain MI have relatively less cristae and hence less inner MI membrane where CL is localized, less CL, and less CL 18:2n-6 compared to heart. Hence, MI membrane response to the same dietary challenge may vary amongst tissues. To compare the relative effect of dietary polyunsaturated fatty acids (PUFA) on MI with differing membrane characteristics, the fatty acid profile of (PUFA) on MI with differing membrane characteristics, the fatty acid profile of MI CL from rat heart and brain were measured 4 weeks after feeding 20% (w/w) fat diets with 3-13% PUFA. Heart had significantly higher amounts of MI CL 18:2n-6 (45% vs. 10%, heart and brain MI, respectively) and PUFA (55% vs. 55%) and lower levels of saturated (20% vs. 24%) and monounsaturated fatty acids (18% vs. 38%) and 20:4n-6 (4% vs. 16%) than brain. Absolute changes in MI 18:2n-6 levels associated with dietary PUFA were higher in heart than brain (increased from 35% to 55% and 8% to 16%, respectively), while the relative changes were similar. While both dietary 18:2n-6 and 18:3n-3 were positively correlated (p < 0.0001) with MI membrane 18:2n-6, dietary 18:2n-6 was a slightly better predictor of MI 18:2n-6 than was dietary 18:3n-3. Dietary 18:2 n-6 and 18:3n-3 accounted for 81% and 74% of the variance in brain MI 18:2n-6 and 18:3n-6 is sensitive to dietary fat manipulation but, heart MI 18:2n-6 might be exquisitely sensitive expressed as larger absolute changes in membrane 18:2n-6. The effects of dietary fat manipulations on CL fatty acid profiles are of specific interest as they may after the function of CL-dependent enzymes and impact on MI respiratory efficiency. (ILSI-NF and NSERC funded)

CALSEQUESTRIN AND CEREBELLAR CA2+ STORES.

CALSEQUESTRIN AND CEREBELLAR CA²⁺ STORES. P. Volpe, E. Damiani* and A. Margreth*. UTMB, Galveston, TX, and CNR Unit for Muscle Biology and Physiopathology, Università di Padova, Italy.

Calsequestrin (CS) is the Ca²⁺-binding protein (CBP) of sarcoplasmic reticulum of striated muscle. The existence in non-muscle cells of a protein, sharing with CS structural and functional properties, is still debated. We have re-investigated this problem, in chicken cerebellum microsomes. By identified a 51 kDa CBP which shared with thicken muscle CS Stains All-staining properties. chicken muscle CS Stains All-staining properties and pH-dependent electrophoretic behavior. By Western blot, this protein was found to be immunologically related to chicken muscle CS. The 51 kDa CBP exhibited Ca²⁺-dependent hydrophobic changes, as demonstrated by Ca²⁺-dependent elution from phenyl-Sepharose column. Finally, the amino terminal sequences and Finally, the amino terminal sequences and Cleveland's peptide maps of chicken muscle CS and of the cerebellum 51kDa CBP were found to be identical. Thus, chicken cerebellum contains a protein truly belonging to the CS class. A cerebellum microsomal fraction obtained by differential centrifugation, was enriched in CS, Ca²⁺-pump and inositol 1,4,5-trisphosphate receptor. (NIH GM40068-02).

PERIPHERAL BENZODIAZEPINE RECEPTOR LIGANDS INDUCE MORPHOLOGICAL CHANGES IN MITOCHONDRIA OF CULTURED GLIOMA CELLS. T. Shiraishi, K.L. Black and K. Ikezaki. Div.of Neurosurgery, Univ. of Calif., Los Angeles, Sch.of Med., Los Angeles, CA 90024

To further elucidate the cellular biological function of the peripheral benzodiazepine receptor which localize to the peripheral benzodiazepine receptor which localize to the mitochondrial outer membrane, morphological changes of mitochondria after treatment with peripheral benzodiazepine ligands were examined. C6 and T98G glioma cell lines were incubated with the medium containing low (10nM) or high (10µM) concentration of PK11195(PK), Ro5-4864(Ro) (peripheral type ligand) and clonazepam(CL) (central type ligand) for 24 or 48 h. After exposure to R123(10µg/ml) for 30 min at 37°C, cells were examined by fluorescent microscopy. Prior to treatment, mitochondria were diffuse throughout the cell in filamentous pattern. After 24 h of exposure to low concentration of PK and Ro, the mitochondria became more compact in the perinuclear region. After 48 h exposure, compact in the perinuclear region. After 48 h exposure, mitochondria recovered to their filamentous diffuse pattern. CL treatment had no influence on morphology. Electron micrographs showed that the cells after low PK treatment for 24 h had increased numbers of swollen mitochondria. These morphological changes might relate mitochondrial activity.

DIFFERENTIAL DISTRIBUTION OF (Na,K)-ATPase α ISOFORMS IN THE CENTRAL NERVOUS SYSTEM G. Siegel, V. Hieber, D.J. Fink, and M. Mata. VAMC and U. Michigan, Ann Arbor, MI 48104 THE CENTRAL NERVOUS SYSTEM

In order to study the expression of the different α in order to study the expression of the different α isoforms of (Na,K)-ATPase in the central nervous system of the rat, we used riboprobes prepared from the unique 3' untranslated region of α 1 cDNA, and the translated region of α 3 cDNA in in situ and dot blot hybridization assays of the brain.

al was found predominantly in the cerebral cortex where it labeled pyramidal neurons in the superficial layers. al was also found in neurons of the dentate gyrus of hippocampus, and in the locus ceruleus and inferior olives of the brain stem. In contrast, α3 was found in pyramidal neurons in the deep layers of cerebral cortex, pyramidal and dentate gyrus neurons of the hippocampus, and in neurons of most subcortical structures of the thalamus, basal ganglia and brainstem nuclei. There was thalamus, basal gangila and brainstem nuclei. There was no substantial labeling of glial cells, nor of vascular endothelial cells with either probe, but the ependyma of choroid plexus contained only αl.

In the cerebellum, Purkinje cells showed predominantly α3, as did stellate and basket cells. The granule cells

contained both $\alpha 1$ and $\alpha 3$.

These experiments show that both $\alpha 1$ and $\alpha 3$ isoforms of (Na,K)-ATPase are found in neurons of the CNS, though the distribution of the two isoforms differs.

214.19

BIOCHEMICAL STUDIES ON RAT BRAIN TRANSGLUTAMINASE. Y. Takeuchi, P.J. Birckbichler and M.K. Patterson, Jr. Biomedical Division, The Samuel Roberts Noble Foundation, Inc., Box 2180, Ardmore, OK 73402

Transglutaminases (TGase) are a class of calcium-dependent enzymes that catalyze an acyl transfer reaction between peptide-bound glutaminyl moieties and primary amines including the ε-amino group of peptide-bound lysine. Since little is known about the involvement of TGase in CNS function, we initiated studies on rat brain TGase. The tissue was homogenized and TGase activity was found in both soluble and particulate fractions fol-lowing ultracentrifugation. Two immunoreactive protein bands (79 kDa and 75 kDa) were detected in both fracbands (79 kba and 75 kba) were detected in both fractions following SDS-PAGE and Western blotting using an antibody specific for "tissue" TGase. While the catalytic activity was approximately equally distributed between the two fractions, considerably higher amounts of immunoreactive material were found in the soluble fraction. The soluble form of the enzyme was inhibited by GTP and attempts at purification were made using a GTP-agarose column. Solubilization of the particulate form was accomplished with detergents with an apparent increase in activity suggesting masking of catalytic sites in particulate structures. Studies utilizing purified rat brain TGase should be useful in investigating the possible interaction between the enzyme and neurotransmitter(s) or neuropeptide(s).

214.18

DIFFERENTIAL DISTRIBUTION OF (Na,K)-ATPase α ISOFORMS IN THE PERIPHERAL NERVOUS SYSTEM. V. Hieber, G. Siegel, D.J.

THE PERIPHERAL NERVOUS SYSTEM. V.Hieber, G. Siegel, D.J. Fink and M.Mata. VAMC and U.Michigan., Ann Arbor, MI 48104 mRNA transcripts for 3 isoforms of the α subunit of (Na, K)-ATPase have been identified in the nervous system (designated αl, α2, and α3). The αl isoform in rodent is more resistant to ouabain inhibition and binding than are

In order to study the localization and expression of the different α isoforms, we prepared probes from the unique 3' untranslated region of α l cDNA, and from the translated region of $\alpha 3$ cDNA. These probes were used in dot blot and in situ hybridization assays of rat spinal cord, dorsal root ganglia (DRG), and peripheral nerve.

Within the ventral horn of spinal cord, a discrete

subset of laterally placed motor neurons contained αl , while $\alpha 3$ was found in all motor neurons including those containing $\alpha 1$. In the DRG, most neurons, but no satellite cells, contained both $\alpha 1$ and $\alpha 3$. However, some DRG cells had $\alpha 3$ but not $\alpha 1$. Schwann cells were labeled with $\alpha 1$ probe in a perinuclear distribution, but contained no detectable $\alpha 3$. Data from dot blot analysis agreed with the in situ hybridization pattern.

These experiments imply that: (1) The riboprobes are able to distinguish αl from $\alpha 3$ isoform mRNAs, (2) Both αl and α3 isoforms of (Na,K)-ATPase are found in neurons, and (3) Schwann cells contain the α 1 isoform.

LOCALIZATION AND STRUCTURE OF RUBROPHILIN. B.W. Moore, H.A. Rosenthal and K.E. Isenberg. Dept. Psychiatry, University Sch. of Med., St. Louis, MO 63110.

Rubrophilin is a 53Kd membrane-associated nervoussystem-specific protein. Immunohistochemistry using polyclonal antisera with fetal rat brain cultures demonstrated exclusive staining of neurons. On polyacrylamide SDS gels rubrophilin stains red by an identified component of Coomassie Brilliant Blue R-250 and it has a distinctive amino acid composition. Rubrophilin was purified to homogeneity and shown to have a blocked N-terminus. The purified protein was digested to completion with the protease AspN (Boehringer-Mannheim) and peptides purified for sequencing by reversed phase high pressure liquid chromatography. Sequences of six peptides confirm the properties, its specificity to neuronal membranes, and its presence in several vertebrates suggests an important function for rubrophilin in the nervous system.

SYNAPTIC STRUCTURE AND FUNCTION I

215.1

FREQUENCY DEPENDENT LOSS OF SYNAPTIC VESICLE

SUBCLASSES. G.Q.Fox. AbG. 161, Max-Planck-Inst. für biophysikalische Chemie, 3400 Göttingen, FRG. The presynaptic terminals of Torpedo electric organ have a synaptic vesicle population composed of different size classes. The 68 and 90 nm subclasses are known or suspected of containing ACh and their numbers are influenced by electrical and chemical stimulation. Electrical stimulation at 10, 1 and 0.1 Hz to less than 20% of the evoked response of the organ(fatigue) has been found to produce specific declines in vesicle numbers of these 2 subclasses with 10 Hz effecting the 68 nm vesicles, 0.1 Hz the 90 nm vesicles and 1 Hz producing an intermediate condition. No change was found in the amount of terminal membrane nor could it be demonstrated

terminal membrane nor could it be demonstrated that vesicles were able to incorporate a dextran marker during 10 and 1 Hz stimulation.

Overshoots of control numbers of 68 nm vesicles were obtained after 3.5 h of recovery, confirming previous observations of the presence of a 68 nm endocytotic mechansim. This mechanism is not to be confused with recycling processes postulated to be operative during stimulation.

215.2

HIGH LEVELS OF SYNAPSIN II IN OLFACTORY NERVE TERMINALS IN THE OLFACTORY BULB. T.E. Finger and M.D. Browning, Dept. Cellular & Structural Biology and Dept. Pharmacology, Univ. Colorado Hith. Sci. Ctr., Denver CO 80262

Denver CO 80262

Synapsin I and synapsin II are synaptic vesicle-associated phosphoproteins that are thought to play a role in regulating some aspects of synaptic transmission. The ratio of synapsin I to synapsin II is a constant 2:1 in virtually all areas of the brain. One salient exception to this rule is the olfactory bulb where levels of synapsin II match or exceed those of synapsin II. We have recently examined the olfactory bulb with antibodies specific for synapsin I and for synapsin II, and the results of these studies may provide an explanation for the unusually high levels of synapsin II in the olfactory bulb. Immunocytochemistry of the olfactory bulb reveals that the glomeruli have higher levels of synapsin II-like immunoreactivity than do the outer plexiform layer or other layers of the bulb. Conversely synapsin I-immunoreactivity is lower in the glomeruli than in the outer plexiform layer and deeper layers of the bulb react like other areas of the CNS such as cerebral cortex, the glomeruli are unusual in reacting more heavily for synapsin II than synapsin I. Microdissection studies corroborate the immunocytochemical data. Western blots of tissue dissected from the central two-thirds of the bulb (including the granule cells, mitral cells and inner half of the outer plexiform layer) show the usual 2:1 ratio of synapsin I. inner half of the outer plexiform layer) show the usual 2:1 ratio of synapsin I: synapsin II. In contrast, blots of tissue taken from the outer third of the bulb (glomeruli and outer half of the outer plexiform layer) exhibit a 1.3:I ratio. These results suggest that olfactory receptor nerve terminals within the glomeruli contain high levels of synapsin I in comparison to synapsin I. This unusual ratio is more similar to the ratio of synapsins in ganglia and effector organs than the ratio in

MICROSCOPIC STUDIES OF LOW pH COMPARTMENTS IN NEURONS AND E.Augenbraun* and E.Holtzman. Biol. Sci., Columbia Univ. NY 10027.

Previously Sulzer and Holtzman identified low pH

compartments in the presynaptic terminals of frog retinal photoreceptors by staining with weak base vital dyes and by vacuologenic effects of ammonia. The present work extends these findings: 1) We find that chloroquine has vacuologenic effects on presumptive acidified compartments in photoreceptors; these effects are evident at much lower concentrations than are needed with ammonia so chloroquine concentrations than are needed with ammonia so chloroquine should prove more widely useful than ammonia. 2) We demonstrate accumulation of the weak base DAMP in photoreceptors and in cultured hippocampal neurons. DAMP is aldehyde fixable and immunocytochemically demonstrable, and is potentially usable for electron microscopy (cf Anderson). Our best results are obtained when HRP is included in the medium used to administer DAMP; evidently HRP provides sites to which DAMP can be fixed within acidified endocytic structures. DAMP staining is seen in structures within cell bodies, in photoreceptor terminals, and in "varicosities" along hippocampal processes that appear to include regions rich in synaptic vesicles.

CYTOPLASMIC ORGANIZATION IN THE DENDRITIC SPINES OF RAT HIPPOCAMPAL CORTEX IN ORGANOTYPIC CULTURE. Dennis M. D. Landis, Lucas D. Pozzo Miller* and L.A. Weinstein*, Depts. Neurology and Neurosciences, School of Medicine, Case Western Reserve University, Cleveland, OH 44106

We have previously used rapid freezing, freeze fracture and shallow etching to show that the cytoplasm of Purkinje cell dendritic spines in mouse cerebellar cortex contains a core of actin-like microfilaments, and more peripherally distributed filamentous proteins of unknown nature (J. Cell Biol. 97: 1169, 1983). The structure of the postsynaptic density has at least two components, and the relative amounts of the two components vary as different spines are compared (Synapse 1: 552, 1987).

The dendritic spines of CA1 hippocampal cells are located too far from the brain's surface to be accessible with our usual freezing methods. We therefore prepared organotypic cultures of hippocampal slices obtained from 6-7 day old rats and maintained for 14-21 days in vitro. These cultures were rapidly frozen, and prepared by freeze fracture or freeze substitution techniques.

The cytoplasm of hippocampal dendritic spines in these cultures also contains a core of actin-like filaments, and filamentous proteins just below the membrane of the spine. The postsynaptic density appears to have a lattice-like substructure with adherent globular proteins, and the relative amounts of these structures vary spine to spine. These features of cytoplasmic organization thus appear to be characteristic of dendritic spines in the central nervous system.

THE 17K Mr PROTEIN, A MAJOR SPECIFIC SUBSTRATE FOR PROTEIN KINASE C FOUND IN RAT POSTSYNAPTIC DENSITY FRACTION. T. Suzuki'*, S. Dohmae'*, P. Siekevitz, and R. Tanaka'*. 'Dept. of Biochem. Nagoya City Univ. Med. Sch., Nagoya 467, Japan.

Postsynaptic density (PSD) fraction isolated from rat cerebral cortex contained the activity of kinase C, which phosphorylated 17K Mr protein endogenous to the fraction. The electro-phoretic mobility of the protein was slightly smaller than that of myelin basic protein and the protein was not contained in the purified rat myelin. The isoelectric point of the 17K Mr protein was in neutral range, while that of myelin basic protein was calculated to be The 17K Mr protein did not cross-react with anti-myelin basic protein antibody. Thus, the 17K Mr protein was clearly distinct from myelin basic protein. Phosphorylation of the protein by the endogenous kinase C was greater in the PSD isolated from hippocampus and from cerebellum than in the fraction from cerebral cortex.

IMMUNOEXTRACTION OF BRAIN NA/CA EXCHANGER WITH IMMUNOEXTRACTION OF BRAIN NA/CA EXCHANGER WITH
ANTIBODIES TO A 36-KDA PROTEIN. M.L. Michaelis, C.K.
Jayawickreme*, S. Schueler*, M.S. Hurlbert*, and C.
Guilly*. Dept. Pharmacology and Ctr. Biomed. Res.,
Univ. of Kansas, Lawrence, KS 66047.
The Na/Ca antiporter is a plasma membrane system
which plays a role in both Ca²⁺ influx and efflux.

Attempts to isolate the antiporter protein have been limited due to the lack of selective high affinity ligands. Through the use of several chromatographic ligands. Through the use of several chromatographic techniques with solubilized bovine synaptic plasma membranes, we have consistently found an enrichment in 2 protein bands (36 and 50 KDa) when the antiporter activity was enriched (J. Cell Biol. 1989, 107, 127a). We have now electroeluted those bands from SDS-PAGE gels and immunized rabbits. The IgG's produced against each of the proteins exhibited strong immunoreactivity in both ELISA assays and Western blots with solubilized membranes. And, more importantly, the anti-36K antibodies immunoextracted greater than 95% of solubilized membrane antiporter activity while the preimmune IgG's extracted none. Since the protein is not inactivated by low pH, we recovered almost all of the immunoextracted activity with a sodium acetate, pH 3.5 wash of the column. Our observations strongly suggest that these 2 proteins are involved in antiporter activity in brain plasma membranes. (NIAAA grant #AA04732 and ARO grant #DAAL03-88-K-0017).

IMMUNOHISTOCHEMICAL IDENTIFICATION OF A IMMUNOHISTOCHEMICAL IDENTIFICATION OF A
POSTSYNAPTIC COMPONENT OF THE NEUROMUSCULAR
JUNCTION. S. H. Astrow and W. J. Thompson. Dept. of Zoology,
Univ. of Texas, Austin, TX 78712.
We prepared monoclonal antibodies against a membrane-enriched

preparation derived from neonatal rat muscles and obtained one (3G2) which recognizes a molecule at the neuromuscular junction in adult animals. The epitope appears to be intracellular, since staining of intact muscles with 3G2 is only obtained after permeabilization. The antigen may be unique to neuromuscular synapses as staining is not detectable in sections of other tissues including smooth muscle, spinal cord and autonomic ganglia. To determine when the antigen appears in developing muscles we double-labeled hindlimb sections with antibody 3G2 and rhodamine-conjugated α -bungarotoxin (R-BTX; an acetylcholine receptor ligand). At embryonic day 17 (E17), R-BTX diffusely labels the surface of many fibers, but there is no corresponding 3G2 staining. Rather, the antibody stains the cytoplasm of each fiber, near myotendonous junctions. Although acetylcholine receptor clusters are prominent at E20, 3G2 staining is not apparent at these sites until about postnatal day 4 (P4). At earlier times, 3G2 antigen is also present extrajunctionally in (P4). At earlier times, 3G2 antigen is also present extrajunctionally in some small (presumably secondary) muscle fibers scattered throughout the muscle. By P7, staining of extrajunctional regions is not above background and 3G2 staining closely follows the distribution of R-BTX. In contrast with many other postsynaptic molecules localized to the neuromuscular junction, 3G2 antigen rapidly disappears upon denervation. Thus, this molecule appears to be a novel junctional component that may play a role in the stabilization of neuromuscular synapses.

EVIDENCE THAT THE MAJOR POSTSYNAPTIC DENSITY PROTEIN (mPSDp) MAY BE DISTINCT FROM THE ALPHA SUBUNIT OF CALMODULIN KINASE II (a.CK II). K. Wu, Y. Huang* J. E. Adler and I. B. Black Div. Dev. Neurology, Cornell Univ. Med. Coll., New York, N.Y., Dept. Neurosci. and Cell Biol., UMDNJ/ Robert Wood Johnson Med. Sch., Piscataway, N.J., Div. Neurosci., New York State Psych. Inst., New York, N.Y. and Dept. Neurology, Wayne State University School of Medicine, Detroit, MI.

Increasing evidence suggests that the mPSDp plays a critical role in synaptic communication and plasticity. The mPSDp and $\alpha\text{-CK}\ II$ have long been considered to be identical. However, the two proteins do differ in solubility and antigenicity, raising the possibility of nonidentity. To further define the relationship between the two proteins, we purified the mPSDp to homogeneity from adult rat cerebral cortex, and compared the proteins (α -CK II and its polyclonal antiserum were kindly supplied by Drs. Cernik and Greengard, Rockefeller Univ.). The PI of the mPSDp was 6.2, whereas that of $\alpha\text{-CK}$ II was 7.2, suggesting physicochemical differences. Purified mPSDp bound calmodulin (CaM) in the presence of Ca²⁺, and autophosphorylated in a Ca²⁺/CaM-dependent manner. These activities were inhibited by a polyclonal antiserum against the mPSDp (Ab-mPSDp). Ab-mPSDp recognized the mPSDp in the purified state or in total synaptic membrane. However, Ab-mPSDp did not react with α-CK II, and $Ab\text{-}\alpha\text{-}CK$ II reacted only weakly with mPSDp, suggesting similarity but not identity of the proteins. Finally, V-8 digestion of mPSDp revealed at least an 8-amino acid sequence not present in $\alpha\text{-CK II}$. These results suggest that mPSDp and $\alpha\text{-}CK$ II may be similar, but not identical.

NEUROCHEMICAL AND MORPHOLOGICAL COMPARISONS OF POSTSYNAPTIC DENSITIES (PSDs) ISOLATED FROM RAT AND HUMAN BRAIN. Y. Huang*. M. Stanley and K. Wu Div. Neurosci., N.Y.S. Psych. Inst., Dept. Psych. & Pharmacol., Columbia Univ., New York, N.Y. and Div. Dev. Neurology, Cornell Univ. Med. College, New York, N.Y.

Growing evidence suggests that the PSD, a subcellular organelle attached to postsynaptic membrane at a chemical synapse, plays a critical role in synaptic communication and plasticity. During our characterization of PSDs from human and rat brains, we found, among others, interesting differences in electron microscopic morphology of the two entities. PSDs were isolated from cerebral cortex of frozen brain according to the procedures of Carlin et al. (J. Cell Biol. 86:831-843, 1980). The SDS-gel profiles of human and rat PSDs revealed similar proteins but with different quantities. Electron microscopic examination indicated that most rat PSDs appeared as concave-shaped, single stranded bars while human PSDs showed mixture of straight, single stranded as well as double stranded bars. The double stranded bars seen in human PSDs probably resulted from association of two PSDs from different synapses. Alternatively, they may be the presynaptic dense projection and postsynaptic density present in the same synapses. Overall, the double stranded bars could be derived from the symmetric synapses while the single stranded bars were from the asymmetric synapses. The underlying cause of the relative abundance of double stranded bars in human preparation remains to be determined. Cyclic AMP- and Ca²⁺/calmodulin (CaM)-dependent protein kinase activities, as well as CaM-binding proteins, in the PSD preparations from the two species were also determined and compared.

PRESYNAPTIC MECHANISMS II

HISTAMINE H₃ RECEPTORS IN THE CNS: RECEPTOR BINDING, BIOCHEMICAL RESPONSE AND MOLECULAR MODELING. S. Ghodsi-Hoysepian, D. Ngur*, P. Weiland** J. Woodruft**, G.J. Durant** and W. Hoss. Center for Drug Design and Development and Department of Medicinal and Biological Chemistry, The University of Toledo, Toledo, OH 43606.
Histamine H₃ receptors inhibit the release of histamine presynaptically. Unlike other histamine receptors (H₁ and H₂), H₃ receptors have not been well characterized. Previously we have shown that H₃ agonists stimulate low-K_m GTPase activity in the brain (S. Ghodsi-Hovsepian et al., Soc. Neurosci. Abstr., 1989), indicating that H₃ receptors are coupled to their effectors through GTP-binding proteins. A binding assay for histamine H₃ receptors utilizing [3H]-N^α-methylhistamine as the radioligand and unlabeled α-methylhistamine to account for nonspecific binding was established. Specific binding to rat cortical membrane receptors was of high affinity (overall K_d = 0.5 nN) and saturable. Nonspecific binding was 20-30% of the total binding at the K_d value. A Scatchard plot of the specific binding was curved, suggesting the presence of more than one affinity state for the receptor, more than one receptor or negative cooperativity. The specific binding of [3H]-N^α-methylhistamine to rat cortical membranes was completely inhibited by burimamide, which is an antagonist at H₃ receptors (as well as H₂ receptors), in the concentration-dependent manner. To determine if H₃ receptors were linked to phosphoinositide (Pl) turnover in the brain, the effects of histamine and α-methylhistamine were determined in rat cortical slices. Although histamine produced a concentration-dependent increase in this preparation, α-methylhistamine was inactive over the concentration range of 10 - 500 μM, suggesting that H₃ receptors do not attenuate histamine release in the brain by a mechanism involving the stimulation of Pl turnover. Low-energy conformations of histamine, C. Stills program Macro

FURTHER CHARACTERIZATION OF DEPHOSPHORYLATION OF B-50 IN SYNAPTIC PLASMA MEMBRANES FROM RAT BRAIN. Y. F. Han and L. A. Dokas*. Departments of Biochemistry and Neurology*, Medical College of Ohio, Toledo, OH 43699.

B-50 is a neuronal-specific, presynaptic membrane-associated protein. Although protein kinase C-mediated B-50 phosphorylation has been well characterized, the dephosphorylation of B-50 has not been as extensively studied. Previous work from this laboratory has suggested in synaptic plasma membranes (SPM) the existence of membrane-bound phospha-tase(s) that dephosphorylate B-50. The present study further characterizes B-50 phosphatase activity in SPM by using okadaic acid (OA), a new specific inhibitor of type 1 and type 2A protein phosphatases. At low concentrations of $[\gamma^{32}P]$ ATP, phosphorylation of B-50 reaches a maximal value at 30 seconds, followed by dephosphorylation. OA, added 30 sec after the initiation of phosphorylation, partially prevented the dephosphorylation of B-50 at 2 nM, a dose which inhibits type 2A phosphatase. At the higher concentrations of 1 μ M, a dose of OA which inhibits type I phosphatase, a more pronounced effect on B-50 dephosphorylation is seen. Spermine at 2 mM could antagonize the inhibitory effects induced by 2 nM OA. Heat-stable protein phosphatase inhibitor 2 (I-2) also inhibited dephosphorylation of B-50. The effects of OA and I-2 on B-50 phosphatase activity were additive. The B-50 phosphatase activity that remained in the presence of OA and I-2 was found to be sensitive to chelation of divalent cations. These results indicate that type 1 phosphatase is the major B-50 phosphatase in SPM and that type 2A and a cationnsitive form might account for the remainder. (Supported by grants from NIH (NS23598) and the Ohio Department of Aging.)

THE ROLE AND POTENTIAL INTERACTION OF ADENYLATE CYCLASE, PROTEIN KINASE C, AND CALMODULIN ON ANGIOTENSIN RELEASE

PROTEIN KINASE C, AND CALMOUDLIN ON ANGIDIENSIN RELEASE FROM DISSOCIATED BRAIN CELL CULTURES. A.P. Gadbut, S.M. Cash*, T.R. Radice*, J.A. Noble* and J.A. Weyhenmeyer. Neuroscience Program, Univ. of Illinois, Urbana, IL 61801. Several studies have suggested that angiotensin (ANG) can be released from CNS tissue in a neurotransmitter-like fashion. We have shown previously that ANG release is dependent upon the influx of Ca²⁺ through primarily N-type voltage gated calcium channels and the subsequent activation of calmodulin (Gadbut et al., FASEB J., 4:Al199, 1990). In this study, we examined the effects of forskolin and the phorbol estern, TPA, on AMG release from dissociated cell cultures of fetal rat hypothalamus/braindissociated cell cultures of fetal rat hypothalamus/prasemen. Increasing concentrations of forskolin (2 µM-200 µM) stimulated ANG release in a dose dependent manner. The addition of cholera toxin also resulted in ANG release, providing further evidence for an adenylate cyclase/G, coupled mechanism. In contrast, ANG release was not effected following the addition of TPA under either ionically neutral or stimulating conditions. Finally ANG release was attenuated in the presence of 20 μ M forskolin/25 μ M W-7 as compared to 20 μ M forskolin alone. These results suggest that both the adenylate cyclase and intracellular Ca²⁺ (calmodulin) are important in the regulation of ANG release from dissociated cultures fetal rat brain cells.

NEURONAL EXPRESSION OF PARVALBUMIN AND CALCIUM/CALMODULIN DEPENDENT PROTEIN KINASE II FROM HSV-I VECTORS. M.J. During, A.I. Geller, A. Freese, and R. Neve. Dept. Neurosurg., Yale Sch. Med., New Haven CT 06510; Dana Farber Can. Inst., Boston MA 02115; HST, MIT, Cambridge MA 02139; and Dept. Psychobiol., U CA, Irvine CA 92717.

and Dept. Psychobiol., U CA, Irvine CA 92717.
We are using defective Herpes Simplex Virus (HSV-1) vectors to study neuronal physiology by altering signal transduction pathways including calcium calmodulin dependent protein kinase II, parvalbumin, and protein kinase C. The calcium/calmodulin binding domain and the catalytic domain of calcium/calmodulin dependent protein kinase II are on separate regions of the protein; following limited proteolysis the catalytic domain of calcium calmodulin protein kinase II is active in the absence of calcium. We have expressed the catalytic domain of calcium/calmodulin dependent protein kinase II from a HSV-1 vector (pHSVCaCK) in PCI 2 cells as demonstrated by in situ hybridization. pHSVCaCK increases protein phosphorylation and neurotransmitter release from PC 12 cells and from sympathetic neurons.

Parvalbumin, a calcium binding protein, is found in most rapid Parvalbumin, a calcium binding protein, is found in most rapid firing GABAergic neurons; expression of parvalbumin in neurons which do not normally contain this protein may alter the physiological properties of those neurons. Expression of Parvalbumin from a HSV-1 vector (pHSVparv) has been demonstrated by immunofluorescence in PC12 cells; its effects on PC 12 cells and rat sympathetic neurons are now under study. Additional HSV-1 vectors containing the catalytic domain of protein kinase C have been constructed and are now being studied. We conclude that HSV-1 vectors expressing proteins involved in signal transduction can modify neuronal physiological and may record in signal transduction can modify neuronal physiology and may reveal the roles of various second messenger pathways in producing stable, long term modification of neuronal function.

STABLE MODIFICATION OF RAT SYMPATHETIC NEURON PHYSIOLOGY AND NEUROTRANSMITTER RELEASE BY EXPRESSION OF ADENYLATE CYCLASE FROM A HSV-1 VECTOR. A.I. Geller, A. Freese, K. Neve, M.J. During, and R. Neve. Dana Farber Can. Inst., Boston MA 02115; HST, MIT, Cambridge MA 02139; VA Med. Cntr., Portland OR; Dept. Neurosurg., Yale Sch. Med., New Haven CT 06510; and Dept. Psychobiol., U CA, irvine CA 92217.

To study neuronal signal transduction mechanisms and synaptic plasticity, we are using defective Herpes Simplex Virus (HSV-1) vectors to express in neurons the catalytic domains of second messenger enzymes such as adenylate cyclase. These catalytic domains are no longer regulated but are continuously active. The resulting increase in activity of a second messenger enzyme allows us to study its role in such processes as neurotransmitter release. We have established that HSV-1 vectors can stably express <u>E. coli</u> B-galactosidase in cultured PNS and CNS neurons (Science 241, 1667, 1988; Proc. Natl. Acad. Sci. 87, 1149, 1990); and following stereotactic injection into the adult rat brain, in neurons around and projecting to the injection site. Using a HSV-1 vector, we now express the catalytic domain of yeast adenylate cyclase in PC 12 cells and rat sympathetic neurons. Expression of the catalytic domain of adenylate cyclase in PC 12 cells resulted in a 20 fold increase in cAMP concentration, an increase in protein phosphorylation similar to that obtained using dibutyryl cAMP, and a 2 fold increase in monoamine neurotransmitter release. Adenylate cyclase was also expressed in sympathetic neurons; the yeast adenylate cyclase protein and the resulting increase in cAMP concentration were localized to the cell body as determined by immunofluorescence and an increase in protein phosphorylation was also observed. Of interest, a 3 fold increase in monoamine neurotransmitter release was obtained: the increase in neurotransmitter release was calcium dependent, was inhibited by tetrodotoxin, and was stable for at least one week. In conclusion, elevation of cAMP concentration is a possible mechanism to achieve stable, long term modification of neuronal function. Furthermore, HSV-1 vectors expressing catalytic fragments of other second messenger enzymes can be used to further study neuronal physiology.

MODULATION OF ELECTRICALLY STIMULATED ³H-DA RELEASE FROM RAT STRIATAL SLICES BY DOPAMINERGIC (DA) AGENTS. LJ Wichlinski, RH Song^{*}, JH Gordon & JZ Fields. Res Svce 151, VA Hosp, Hines, IL 60141 and Dept of Pharmacology, Loyola Univ Med Sch, Maywood, IL 60153.

Pre-synaptic DA autoreceptors (auto-r) on nigrostriatal terminals mediate inhibition of DA release. Using inhibition by apomorphine (APO), of electrically evoked ³H-DA release, these auto-r have been studied using superfused striatal slices from rabbit and rat with controversial results in rat. We incubated rat slices in ³H-DA and superfused with Krebs buffer. Slices were stimulated (unipolar pulses, 10 Hz, 23 mA, 12-16 V, 4 ms for 5 min) 90 min later (\$1) & again at 150 min (\$2). APO was added to the superfusate 20 min before \$2. The dependent measure was the ratio \$2/\$\$, of the values for % of total tissue [³H] released. APO (10⁻⁷ and 10⁻⁶ M) reduced the \$2/\$1 ratio relative to controls (p < .05), while the change at 10⁻⁵ M APO was also lower but not significant. The median \$2/\$1 ratio was 0.65 for vehicle slices (n=22), 0.35 for 10⁻⁷ M APO (n=7), 0.30 for 10⁻⁶ M APO (n=11), and 0.43 for 10⁻⁵ M (n=8). Our results confirm DA auto-R inhibition of electrically evoked ³H-DA release by APO in rat striatum.

Further studies are currently in progress to investigate the effects on DA auto-receptors of the peptide cyclo(leu-gly), a neuromodulator which we showed down-regulates DA receptors. (Supported by grants from the VA, Scottish Rite Schizophrenia Res Pgm-NMJ, & NS26449).

216.9

DIFFERENTIAL IONIC REGULATION OF THE DOPAMINE TRANSPORTER BINDING IN THE RAT AND HUMAN FRONTAL CORTEX. A. Hitri, D. Venable* and R.J. Wyatt. Neuropsychiatry Branch, NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

In the striatum, GBR 12935 dopamine transporter binding is sodium-facilitated, while in the frontal cortex (FC) it is sodium-inhibited. We have studied 3H-GBR 12935 binding in the rat and human FC as a function of sodium concentration with and without potassium. For rat and human, in the absence of potassium increasing sodium concentrations decreased the Bmax, without changing the Kd. In the human FC, inclusion of 5 mM KCl reversed the sodium-induced inhibition. In the absence of Kd, using 30 mM NaCl the Bmax was 203, while with KCl it was 92 fmoles/mg. Using 120 mM NaCl the Bmax was 112 without, and 261 fmoles/mg with KCl. In the rat FC the sodium inhibition was not affected by potassium ions. Benztropine was more potent with 30 than with 120 mM NaCl, in the absence of KCl in human FC. The addition of 5 mM KCl reversed the sodium effect; 30 mM NaCl shifted the curve to the right compared with 120 mM NaCl. In the rat, benztropine inhibition was more potent in 30 than in 120 mM NaCl, and was not reversed with potassium ions. The data indicate a differential regulatory effect of sodium and potassium ions on the dopamine transport or in rat and human FC.

ASSOCIATION OF RAB3 WITH THE SYNAPTIC VESICLE MEMBRANE. P.A. Johnston, G.A. Mignery, R. Jahn, K. Robinson and T. G. Südhof. Howard Hughes Medical Institute, and Department of Molecular Genetics, UT Southwestern Medical Center, Dallas, TX, 75235, MPI für Psychiatrie, Planegg-Martinsried, 8033, FRG.

The mechanism of membrane attachment of rab3, a synaptic vesicle-specific GTP-binding protein, was investigated. Rab3 is covalently modified by a posttranslational process causing it to behave like an integral membrane protein in the synaptic vesicle membrane (Fischer v. Mollard et al., Proc. Natl. Acad. Sci 87:1988, 1990). Antibodies were generated against amino- and carboxy-terminal peptides of rab3 and used to test the association of rab3 fragments with the membrane after partial proteolysis. A mutant form of rab3 that lacks the carboxy-terminal cysteine residues was transfected into cells to test the role of those cysteine residues in membrane attachment. And finally, the release of rab3 from synaptic vesicles after different chemical treatments was studied. Results from these experiments together indicate that rab3 is attached to the synaptic vesicle membrane via its carboxy-terminal cysteines by an unknown covalent hydrophobic modification that differs from farnesylation and palmitoylation.

216.8

DIFFERENTIAL REGULATION OF MAZINDOL (MAZ) AND AMPHETAMINE (AMPH) BINDING SITES ON DOPAMINE (DA)-TRANSPORTER COMPLEX (DTC) IN RAT STRIATUM. I. Shimizu and C. Prasad. Dept. Medicine, LSUMC, New Orleans, LA 70112.

DTC modulates inactivation and recycling of DA

DTC modulates inactivation and recycling of DA released into synaptic area. Available data suggest association between DA-reuptake and entities such as NaT/KT ATPase and binding sites for DA uptake inhibitors (e.g. cocaine, MAZ, AMPH). Studies into pharmacologic potencies of phenylethylamine derivatives and their ability to inhibit H-AMPH or H-MAZ binding suggest that both of these ligands label the same site. To further examine relationship between these two binding sites on DTC, following experiments were conducted. Rats were treated intraperitoneally with vehicle, cyclo(His-Pro)(CHP)(2mg/Kg/day X 7 days), MAZ (0.5 mg/Kg/day X 7 days), or AMPH (12, 24 and 30mg/Kg/day for 3, 3 and 4 days respectively), and killed 1-2 days after last treatment. Striata were dissected and Bmax of H-MAZ- and H- AMPH- binding sites determined. Both CHP and MAZ elevated MAZ- and decreased AMPH- binding sites, whereas AMPH decreased both binding sites. The results of these studies suggest that in striatum H-MAZ and H-AMPH may not label same population of sites.

Ca-DEPENDENT POTASSIUM CURRENT IN PRESYNAPTIC MOTOR TERMINALS IN *Drosophila* LARVAE. <u>M. Gho* and B. Ganetzky.</u> Lab. of Genetics. University of Madison-Wisconsin, Madison WI 53706.

Transmitter release at the presynaptic terminal is triggered by the entry of Ca^{2+} in response to depolarization. Repolarization of the terminal regulates transmitter release. At the *Drosophila* neuromuscular junction, several different potassium currents have been proposed to play a role in repolarization. Mutations that eliminate specific ionic currents can be used to dissect the functional roles of these different currents. For exemple, the mutation slowpoke (slo) has been shown to eliminate a fast Ca^{2+} -dependent potassium current (ICF) from larval and adult muscles. Here we investigate the effect of this mutant on repolarization of the nerve terminal.

Synaptic currents evoked by nerve stimulation were measured in voltage-clamped body wall muscles of mutant and normal larvae. In $5.4\,$ mM [Ca²⁺] Ringer's, elimination of either I_A alone or I_{CF} alone had no marked effect on synaptic transmission. However, simultaneous elimination of both currents resulted in greatly prolonged synaptic current. slo exerted its effects directly on the terminal reather than by broadening axonal action potentials because the same results were observed when the slo terminals were depolarized electrotonically. Furthermore, under these conditions, better voltage control of the presynaptic terminal could be obtained in the Sh slo double mutant than in Sh mutant or normal larvae, suggesting the absence of an additional repolarizing mechanisms in slo. These results indicate that slo mutants affect I_{CF} in presynaptic terminals as well as in muscles and that I_{CF} along with I_A, plays an important role in repolarization of the presynaptic terminal.

ANALYSIS OF MINIATURE END-PLATE CURRENT (MEPC) DECAY KINETICS REVEALS TWO POPULATIONS OF QUANTA RELEASED FOLLOWING ACUTE AND CHRONIC EXPOSURE TO THE PARALYTIC AGENT 2,4-DITHIOBIURET (DTB). J.M. Spitsbergen and W.D. Atchison, Dept. Pharmacol./Toxicol., Neurosci. Program, Mich. State Univ., E. Lansing, MI 48824.

Rats treated with small daily doses of DTB develop neuromuscular weakness

Rats treated with small daily doses of DTB develop neuromuscular weakness following 4 to 6 days of treatment. Previous intracellular recording studies demonstrated an increase in the frequency of abnormally large slow miniature end-plate potentials (MEPPs) in muscles from rats exhibiting muscle weakness following chronic treatment with DTB and in muscles from rats exhibiting no weakness following a single dose of DTB. In addition, a generalized slowing of the rise and decay times for all MEPPs was observed. Since prolongation of rise and decay times for synaptic potentials are some of the earliest alterations observed following DTB exposure and may represent subtle effects on transmission which could lead to the deficits observed in chronically-treated rats, we wished to study these changes in more detail. MEPCs were recorded, using two microelectrode voltage clamp, from hemidiaphragms of rats following acute and chronic exposure to DTB. One hr following exposure to DTB the frequency of MEPCs with amplitudes more than 2 times the mode was increased from 5.1% of all MEPCs in controls to 28.4%. By 24 hr after treatment abnormal MEPCs comprised 32.4% of all MEPCs, while in muscles from chronically-treated rats, however, if the abnormal MEPCs are not included in the calculation of r then \(\tau_{MEPC} \) is decreased in muscles from chronically-treated rats, however, if the abnormal MEPCs are not included in the calculation of r then \(\tau_{MEPC} \) is decreased in muscles from chronically-treated rats, however, if the abnormal MEPCs are not included in the calculation of r then \(\tau_{MEPC} \) is decreased in muscles from chronically-treated rats, however, if the abnormal MEPCs are not included rats. \(\tau_{MEPC} \) is also decreased in muscles from chronically-treated rats. \(\tau_{MEPC} \) is decreased in muscles from chronically-treated rats. \(\tau_{MEPC} \) is decreased in muscles from chronically-treated rats. \(\tau_{MEPC} \) is decreased in muscles from chronically-treated rats. \(\tau_{MEPC} \)

A KNOWN CHAOTIC SYSTEM MIMICS THE GENERATION OF MEPPS AND SUB-MEPPS. J.Vautrin. J.Holsapple and M.E. Kriebel. Dept. of Physiology. SUNY Health Science Center at Syracuse, Syracuse, NY 13210.

Unitary end plate potentials and spontaneous end plate potentials (MEPPs) recorded at the neuromuscular

Unitary end plate potentials and spontaneous end plate potentials (MEPPs) recorded at the neuromuscular junction were attributed to the secretion of preformed quantal packets of ACh (Fatt & Katz, J.Fhysiol., 117: 109, 1952). However, studies at higher resolving power reveal ACh subpackets (ACh-SPs) that generate 3.2 nano-siemens postsynaptic conductances (Erxleben & Kriebel, J. Physiol., 400: 645, 1988) which are not explained by the quantal hypothesis. All MEPPs (bell-, sub-, skew-, slow, giant) can be described by combinations of ACh-SPs in different numbers and intervals. Previously we have shown that most treatments increasing ACh release rapidly change ACh-SP composition of MEPPs. Our goal is to identify the process that generates and combines ACh-SPs. Droplet formation (see "The Dripping Faucet as a Model Chaotic System" R. Shaw, Aerial Press, 1984) mimics the changes in the ACh-SP composition of MEPPs. A stream of water produces quantal and subquantal drops which "combine" in a manner similar to that seen for MEPPs. MEPP and drop amplitude and interval dependencies suggests that both are generated dynamically by a flow. A.F.M. and NIH NS25683.

COMPARATIVE EFFECT OF VESAMICOL AND TROXYPYRROLIUM ON MINIATURE END-PLATE CURRENTS IN THE RAT. I.G. Marshall*, T. Seart*, C. Prior* and K. Pemberton* (SPON: Brain Research Association). Dept. of Physiology and Pharmacology, University of Strathclyde, Glasgow, U.K.

(-)-Vesamicol (VES) selectively inhibits the transport of acetylcholine (ACh) into rapidly recycling synaptic vesicles (Marshall, I.G., et al., <u>J. Physiol.</u>, in press, 1990), as evidenced by the production of two populations of miniature end-plate currents (MEPCs). However, it is not clear whether preformed ACh stores are affected by VES. In an attempt to determine this we compared the effects of VES on transmitter release to those of troxpypyrrolium (TXP) an inhibitor of the nerve terminal high affinity choline uptake system. MEPCs were recorded for a 4 minute period following drug application from cut rat hemidiaphragm muscle fibers voltage-clamped at -55 mV. The motor nerve was then stimulated at 10 Hz for 5 minutes, and MEPCs were recorded again for a further 4 min period directly on cessation of stimulation. Stimulation in controls had no effect on the mean MEPC amplitude (pre-stim., 2·34 ± 0·17 nA; post-stim., 2·08 ± 0·15 nA, n=7). As reported previously, stimulation in VES (50 nM) produced a decrease in mean MEPC amplitude with a bimodal amplitude distribution. Stimulation in TXP (40 μM) caused reductions in MEPC amplitude from 2·63 ± 0·23 nA to 1·82 ± 0·14 nA (n=4), but had no effect on the distribution of amplitudes (CV, pre-stim., 0·24 ± 0·02; post-stim. 0·27 ± 0·05, n=4). Since, in the presence of VES preformed quantal size is unaffected, ACh exchange between the cytoplasm and preformed vesicles must be inhibited by VES, if at all, in both directions equally. However, the uniform reduction in MEPC amplitudes following stimulation in the presence of TXP suggests that both preformed and recycling vesicles continually exchange ACh with the cytoplasmic pool.

ABNORMAL MINIATURE POTENTIALS OCCUR PRIOR TO NEUROMUSCULAR WEAKNESS INDUCED IN RATS BY DITHIOBIURET. W.D. Atchison, Dept. Pharm., Tox., & Neurosci. Prgm. Mich. State Univ. E. Lansing, MI. 48824. The purpose of the present study was to investigate whether the large amplitude, slow rise and decay miniature end-plate potentials (MEPPs) that

The purpose of the present study was to investigate whether the large amplitude, slow rise and decay miniature end-plate potentials (MEPPs) that accompany neuromuscular depression caused by dithiobiuret (DTB) occur prior to block of neuromuscular transmission. Experiments were conducted using transected hemidiaphragm muscles of rats treated for 7-8 days with 1 mg/kg/day, ip of DTB or with 0.9% NaCl (1 ml/kg/day) as control and conventional intracellular recording techniques. At the time of observable hindlimb muscle weakness in DTB-treated rats, quantal content of EPPs from diaphragm end-plates was not different from control. In DTB-treated hemidiaphragms exposed to solutions containing elevated Mg² (6 mM) and lowered Ca² concentrations (1 mM), stimulation of the motor nerve from DTB-poisoned rats was associated with decreased quantal content compared to similarly-treated control preparations. Prolongation of rise and decay times of MEPPs occurred from end-plates of DTB-treated rats irrespective of whether or not low Ca² (high Mg² solutions were used. However, these effects were more pronounced when low Ca² (high Mg² solutions were used. Diaphragm-derived end-plates of the DTB-treated group were also characterized frequently by the presence of very large amplitude MEPPs with prolonged decay times. The overall percentage of the total population of MEPPs which these abnormal MEPPs made up in the DTB-treated rats was increased dramatically by exposure to low [Ca² 1)/high [Mg² 1) solutions. In DTB-treated preparations treated with normal Ca/Mg solutions, these MEPPs of amplitude > 1 mV made up 19% of all MEPPs, compared to <1% in controls. Conversely, in DTB preparations treated with low Ca/high Mg solutions, 44% of all MEPPs had amplitudes > 1 mV while only 4% of control MEPPS had similar amplitudes. Thus, aberrant MEPPs occur at motor terminals treated with DTB prior to failure of evoked release, and may represent an early subtle effect of DTB on the release process. Supported by NIH grant NS20683 and a grant fro

FREQUENCY FACILITATION IS NOT CAUSED BY RESIDUAL IONIZED CALCIUM AT THE FROG NEUROMUSCULAR JUNCTION. R. Robitaille and M.P. Charlton. Dept. of Physiology, Univ. of Toronto, Toronto, Canada, M5S 1A8.

Frequency facilitation of transmitter release may be caused by the summation of Ca ions entering the synapse with the residual free Ca ions left from prior activity.

Frequency facilitation of transmitter release may be caused by the summation of Ca ions entering the synapse with the residual free Ca ions left from prior activity. This hypothesis was tested in conditions of increased intracellular Ca buffering capacity by loading the frog NMJs with the Ca chelator dimethyl-BAPTA (DMRAPTA). Mathematical models predict that mobile buffers should alter the distribution of free Ca and increase its rate of decay from the release sites (Duffy et al. Soc. Neurosc. Abst. p475, 1989). Therefore, the amount of facilitation should be reduced and its rate of decay increased in the presence of the Ca chelator. Experiments were performed in low Ca-High Mg Ringer and transmitter release was monitored using conventional recording techniques. Loading the NMJ with the Ca chelator reduced the size of the EPPs by 50%. These effects are presynaptic in origin since MEPP amplitude was not affected by the buffer. The amount of facilitation as well as the rate of decay were greatly reduced in presence of the Ca chelator. The reduction in the decay rate of facilitation does not agree with the predictions from the residual free Ca hypothesis and, therefore, other mechanisms must be considered. Supported by the Medical Research Council of Canada.

CALCIUM CURRENTS IN CULTURED EMBRYONIC MOTOR NERVE TERMINALS. S.C. Hulsizer, S.D. Meriney and A.D. Grinnell. Jerry Lewis Neuromuscular Res. Ctr., UCLA School of Medicine, Los Angeles, CA 90024.

We have chosen to study the calcium currents in presynaptic structures of embryonic Xenopus laevis nerve-muscle cultures, since the mature motor nerve terminal is not amenable to patch clamp techniques. After plating, spinal cord neurons send out neurites which grow to nearby muscle cells and make functional synapses within minutes after contact (Kidokoro and Yeh, 1982). One to two days later, electron microscopic observations reveal presynaptic specializations, reminiscent of those seen at mature synapses (Weldon and Cohen, 1979). We have made "whole-cell" patch clamp recordings from varicose enlargements (5-7 µm in diameter) of neurites which are found either isolated, or on muscle cells. Using barium as the permeate ion, and 140 ms depolarizing pulses from a holding potential of -60 mV, we have seen both inactivating and non-inactivating current types. We will present comparisons of the biophysical and pharmacological properties of the different calcium currents recorded from isolated varicosities and those associated with muscle cells. Supported by grants from the MDA, NIH and NSF.

MECHANISM OF REPETITIVE NERVE FIRING INDUCED BY ANTICHOLINESTERASE AND POTASSIUM CHANNEL BLOCKERS AT THE FROG NERVE TERMINALS. R.A. Maselli and B.J. Distad. Dept. of

Neurology, University of Chicago, Chicago, IL 60637.

The mechanism underlying the repetitive nerve firing induced by anticholinesterases is not well understood. It has been speculated that repetitive anticonnesterases is not well understood. It has been speculated that repetitive nerve action potentials may result from an impaired process of nerve terminal repolarization secondary to K⁺ channel blockage. In order to test this hypothesis we performed focal recordings of presynaptic currents in the cutaneous pectoris muscle of the frog in the presence of 10 uM d-tubocurarine. Under these conditions 4-aminopyridine and guanidine produced repetitive nerve firing and effectively blocked fast K⁺ currents in the nerve terminals. On the other hand, neither the irreversible cholinesterase inhibitor diisopropylfluorophosphate nor neostigmine induced repetitive nerve firing or resulted in significant K⁺ current blockage. These results highlight the difference between the mechanisms of repetitive nerve firing induced by anticholinesterases and K⁺ channel blockers and suggest that endplate potentials of prolonged duration in unblocked preparations are required for the generation of anticholinesterase induced repetitive nerve

A SLOW COMPONENT OF FACILITATION IS LINEARLY RELATED TO PRESYNAPTIC CALCIUM AT CRAYFISH NEUROMUSCULAR

TO PRESYNAPTIC CALCIUM AT CRAYFISH NEUROMUSCULAR JUNCTION. 1.2K.R. Delaney, 2R.Llinas and 1D.W. Tank 1AT&T Bell Labs Murray Hill NJ, 07974 and 2New York Univ. NY, 10016

Simultaneous fura-2 measurements of presynaptic intracellular calcium concentrations ([Ca²+]_i) and postsynaptic excitatory junction potentials (ejps) were made at neuromuscular synapses of crayfish walking leg. We have quantitatively related residual [Ca²+]_i to facilitation of evoked transmitter release under normal and altered calcium loading and handling conditions. release under normal and altered calcium loading and handling conditions. We observe that a component of facilitation, (r = 1-5 seconds), which develops during, and decays after, 1Hz to 16 Hz trains of action potentials, is <u>linearly</u> related to residual [Ca²⁺]; measured in presynaptic terminals. The linear relationship persists and is more accurately measured when the time constants of development and decay of facilitation are increased 5-8 fold by increasing intraterminal calcium buffering capacity with injection of EDTA or EGTA. Consistent with this relationship between [Ca²⁺]; and facilitation, broadening the action potential with TEA increases both the accumulation of calcium and the amount of steady-state facilitation seen during tetanic stimulation by the same factor. A linear relationship between facilitation calcium and the amount of steady-state facilitation seen during tetanic stimulation by the same factor. A linear relationship between facilitation and $[Ca^2+]_i$ is also seen if residual $[Ca^2+]_i$ is increased through inhibition of Na^+/Ca^{2+} exchange by ouabain-mediated Na^+ accumulation. Our data indicate that models relating $[Ca^2+]_i$ to transmitter release should treat this slow component of facilitation as an independent multiplicative factor linearly related to residual $[Ca^2+]_i$ over the range examined (150 to 800 nM). The data suggest that a binding site or enzyme with a relatively high affinity for calcium is responsible for one component of facilitation while calcium binding to a low affinity site(s) is required for release. A MATHEMATICAL PROCEDURE FOR CONSTRUC-TION OF DELAY HISTOGRAMS OF NEUROTRANS-MITTER RELEASE. Y.Aumann* and H.Parnas. Department of Neurobiology, The Hebrew University of Jerusalem, Jerusalem 91904, ISRAEL.

A procedure for construction of delay histograms of neurotransmitter release, from the epc and mepc has been developed. The relationship of the delay histogram to the epo and the mepc is described in a set of linear equations. With the epc and the mepc obtained experimentally (or otherwise), solution of these equations offers a simple, quick and highly automated procedure for determining the delay histogram. No approximation of the mepc shape is required.

Previously, direct experimental techniques have been described for the histogram construction. Aside from being highly tedious and time consuming, these techniques are limited to very low quantal contents. The proposed procedure does not share this restriction.

Methods to overcome noise effects were developed and tested.

The results obtained by the suggested procedure were compared to those obtained experimentally. Reasonable agreement was achieved.

DIVALENT IONS USED AS CA CHANNEL BLOCKERS ALLOW CA²⁺ INFLUX IN PRESYNAPTIC BOUTONS OF CRAYFISH AS MEASURED WITH FURA-2. R.M. Mulkey and R.S. Zucker. Dept. of Mol. & Cell Biology, Univ. of Calif., Berkeley, CA 94720.

Mn²⁺ and Mg²⁺ have been used at the crayfish neuromuscular junction as Ca channel blockers to study 1) the Ca dependence of long term facilitation (Wojtowicz and Atwood, J. Neurosci., 8(12):4667,1988) and 2) the voltage dependence of transmitter release (Hochner et al., Nature, 342:433,1989). Fura-2 was used to measure the internal Ca²⁺ concentration at crayfish presynaptic and Atwood, J. Neurosci., 8(12):4667,1988) and 2) the voltage dependence of transmitter release (Hocher et al., Nature, 342:433,1989). Fura-2 was used to measure the internal Ca²+ concentration at crayfish presynaptic terminals during high frequency stimulation (100 Hz) in the presence of Mn²+ or Mg²+ and transmitter release was measured postsynaptically. High frequency stimulation in 6 mM Mn²+, with no added Ca²+, or 2mM Mn²+, with .2mM external Ca²+, produced a 250 nM to 1.2 μ M increase in intracellular Ca²+ respectively, accompanied by evoked release. Likewise, high frequency stimulation in 12.5 mM Mg²+ with no added Ca²+ gave a 400 - 800 nM rise in internal Ca²+ and produced evoked release. When high frequency stimulation was given in zero Ca²+, plus either 2mM EGTA or 13.5 mM Co²+, a 30 - 70 nM rise in intracellular Ca²+ was seen with no evidence of evoked release. These results indicate that Mn²+ and Mg²+ do not block Ca²+ influx and evoked release at high frequency stimulation, whereas zero Ca²+ with EGTA or Co²+ keep Ca²+ influx to a minimum with no evoked release.

PHOSPHATASE INHIBITOR OKADAIC ACID (OA) IN-CREASES SYNAPTIC TRANSMISSION AT THE CRAYFISH NEUROMUSCULAR JUNCTION (NMJ). J.E. Swain and M.P. Charlton. Department of Physiology, Univer-sity of Toronto, Toronto, Ontario, M5S-1A8. Protein phosphorylation is controlled by kinases and phosphatases. We assayed the role of

phosphatases in synaptic transmission at the crayfish NMJ using the permeable phosphatase inhibitor OA. Excitatory postsynaptic potentials (EPSP) evoked by electrical nerve stimulation were recorded as a measure of neurotransmitter release. OA caused a dose-dependent, reversible increase in EPSP amplitude (174% @ 1uM, 401% @ 10uM). At low concentrations, there was an increase in spontaneous neurotransmitter release (>100%), and no change in muscle input resistance. However, at higher concentrations, the muscle input resistance also increased (26% @ muscle input resistance also increased (26% @ 10uM). Thus, at lower concentrations, OA has presynaptic effects, but at higher concentrations, there are both pre- and postsynaptic effects. OA also caused a decrease in facilitation (3 pulses @ 100Hz; 33% @ 1uM, 34% @ 10uM). Studies of the presynaptic action potential and calcium levels in the presence of OA are in progress. Supported by the MRC of Canada, and the Savy Foundation-Foilepsy. the Savoy Foundation-Epilepsy.

BLOCK OF PRESYNAPTIC Ca++ CURRENTS BY HYPERTONICITY D.C. Brosius, J.T. Hackett and J.B. Tuttle. Depts of Physiol. and Neurosci., Univ. of Virginia, Health Science Center, Charlottesville, Va 22908

Hypertonic (HOSM) solutions block neuromuscular transmission presynaptically but enhance spontaneous quantal release. The nerve terminal Ca++-channel is a likely site for this presynaptic modulation of release. Synaptic Ca++-currents were recorded from dissociated chick ciliary ganglion neurons. Synaptic transmission was measured as postsynaptic currents using whole cell patch recording from chick pectoral myotubes co-cultured with the neurons.

Ca⁺⁺ currents were characterized by their I-V relationships and kinetics of activation $(\tau=1.91\pm0.03 \text{ msec}, n=9)$, inactivation $(\tau=57.2\pm3.2 \text{ msec}, n=8)$ and deactivation $(\tau=0.63\pm0.08 \text{ msec}, n=6)$. Only a single type of Ca⁺⁺ current was observed. Extracellular Cd⁺⁺ blocked depolarization evoked Ca⁺⁺ currents (IC₅₀ = 6 uM), but did not block repolarization evoked tail currents. Evoked transmission was blocked by 20 uM Cd⁺⁺ but spontaneous release was not affected. HOSM bathing uM Cd++ but spontaneous release was not affected. HOSM bathing solution (tonicity adjusted to 660 mOsm with sucrose) blocked depolarization-evoked release while consistently enhancing spontaneous release. HOSM solutions reduced depolarization-evoked Ca⁺⁺ currents by release. HOSM solutions reduced depolarization-evoked Ca ** currents by 27% but did not affect tail current amplitude. Neither Cd** nor hypertonicty affected Ca** current kinetics. Measurements of free intracellular Ca** using indo-1 showed that HOSM solutions increase [Ca***], even in the absence of extracellular Ca**.

[Ca⁺⁺], even in the absence of extracellular Ca⁺⁺.

In conclusion: HOSM solutions may inhibit evoked release by blocking the Ca⁺⁺ channels coupled to the release machinery, and may enhance spontaneous release by increasing the resting free [Ca⁺⁺]_i. Supported by NSF BNS 87-08162 and NIH NS25669.

DEPOLARIZATION IN POTASSIUM PROPIONATE WITH ELEVATED CALCIUM DEPLETES MOTOR NERVE TERMINALS AT TWITCH ENDPLATES BUT NOT AT TONIC ENDPLATES. L.M. Coniglio and R.L. Parsons, University of Vermont College of Medicine, Burlington, VT 05452

We showed previously that in isotonic potassium propionate (KP) with normal concentrations of Ca2+ and Mg2+, the rate of quantal release (estimated from MEPC frequency) increased at snake twitch and tonic muscle fiber endplates. Ultrastructurally, terminals did not deplete, consistent with a sustained elevation of MEPC frequency over several hours (Coniglio et al. Neuroscience Absracts 15:257, 1989). In the several hours (Coniglio et.al. Neuroscience Absracts 15:257, 1989). In the present study, snake nerve-muscle preparations were maintained in KP with elevated Ca2+ (3.6mM) and no Mg2+. Under these conditions, MEPC frequency at twitch endplates increased greatly, then declined, so that at most endplates, no MEPCs were recorded after 2 hours. The mean MEPC amplitude also declined over time in this solution. Ultrastructurally, terminals showed depletion of synaptic vesicles after 6 hours. MEPC frequency at tonic endplates also increased under these conditions, but remained elevated for at least 18 hours. No change in mean MEPC amplitude was observed. Ultrastructurally, nerve terminals at tonic endplates contained numerous vesicles after 6 hours. We conclude that depolarization of nerve terminals in KP containing 3.6mM Ca2+ and no Mg2+ depletes terminals at twitch endplates but not those at tonic endplates.

PRESYNAPTIC REGULATION OF NEUROMUSCULAR TRANSMISSION BY NICOTINIC AND MUSCARINIC RECEPTORS. D.F. Wilson and R.H. Thomsen* Dept. of Zoology, Miami Univ., Oxford, OH 45056

The presynaptic effects of the muscarinic antagonist, atropine and the nicotinic antagonists, hexamethonium and tubocurarine were tested on evoked transmitter release at the neuromuscular junction using intracellular recording techniques to identify the role of presynaptic receptors in regulating evoked transmitter release. Endplate potentials (EPPs) and miniature end-plate potentials (MEPPs) were recorded from isolated cut-muscle rat diaphragm-phrenic nerve preparations to measure quantal release. In the presence of 400 uM hexamethonium a significant increase in quantum content (42%) was observed with a single stimulus relative to control but not during repetitive stimulation (50 Hz) and enhanced the magnitude of tetanic fade from 0.61 to 0.42. This concentration significantly depressed the amplitude of the MEPPs but not the first EPP. In the presence of 75 nM tubocurarine, the quantum content of the first EPP was significantly increased by 36% and the plateau EPPs by 18%. Tetanic fade was significantly enhanced from 0.61 to 0.53. This concentration of tubocurarine significantly depressed the amplitude of the MEPPs but not the first EPP. Atropine (2.5 uM and 7.5 uM) was also tested on the neuromuscular junction but failed to significantly alter any of these parameters. The failure of atropine to alter transmitter release suggests that the nerve terminal lacks muscarinic receptors. These results support the hypothesis that acetylcholine released from the nerve terminal normally has a negative feedback effect by depressing transmitter release via nicotinic receptors. (Supported by NIH Grant NS-27260)

CYCLIC AMP AND THE MOBILIZATION OF TRANSMITTER STORES. W.F. <u>Dryden.</u> Dept. Pharmacology, University of Alberta, Edmonton, Alberta, Canada T6G 2H7.

Quantal release of transmitter at the neuromuscular synapse is increased by measures that raise the level of cytosolic cyclic AMP (cAMP) (Dryden, W.F. et al. <u>Can. J. Physiol. Pharmacol.</u>, 66:207, 1987) and mobilization of the secondary transmitter store is apparently dependent on cAMP dependent protein kinase (Dryden, W.F. & Marshall, I.G. Soc. Neurosci. Abst., 15: 190.7, 1989) The present experiments were conducted to examine depletion of the immediately available store of neurotransmitter, and mobilization of the immediately available store of neurotransmitter, and mobilization of the secondary store under conditions of raised cytosolic cAMP. End plate potentials (EPP's) were recorded from cut murine hemidiaphragms superfused with Bretag's SIF solution containing 2.4 mM Ca⁺⁺, 0.3 μ M alcuronium and 200 μ M troxypyrrolium. The quantal content of EPP's during 1 s trains of stimuli at various frequencies and in paired pulses of varying interpulse intervals were evaluated before and following treatment with either stimulants of cAMP production (forskolin, fluoroaluminate) or phosphodiesterase inhibitors (IBMX, SQ20,009). As expected, the quantal content of the first EPP of a train was increased, but the loss of quantal content in subsequent EPP's in trains and paired pulses (rundown) was much greater that control. Transmission was, however, maintained at a depressed level. These results suggest that cAMP facilitates transfer of quanta into the immediately available store from the secondary store which becomes relatively depleted. Mobilization from the secondary store may still occur to maintain transmission, but to a reduced extent.

217.16

TETRAHYDROAMINOACRIDINE (THA) INCREASES NEUROSECRETION AT A CHOLINERGIC SYNAPSE BY INCREASING PROBABILITY OF TRANS-MITTER RELEASE. S.D. Provan* and M.D. Miyamoto. Dept. of

Pharmacol., E. Tenn. State Univ., Johnson City, TN 37614.

THA is a long-acting, membrane permeable anticholinesterase which has been tried with varying success to offset the cholinergic deficit in Alzheimer's Disease. We have examined the effects of THA at the motor nerve ending to elucidate the mechanism of its reported clinical action. Miniature endplate potentials (mepps) were recorded from isolated frog cutaneous pectoris, and unbiased estimates of \underline{m} (no. of quanta released), \underline{p} (probability of release), and \underline{n} (no. of activated release sites) made using a new method (Physiologist 31: A84, 1988). [K+] was raised to 10 mM to increase mepp frequency and ensure usable (binomial) results. Data were recorded at 5 min intervals, after 10 min equilibration. THA (3 $\mu M)$ caused a monotonic after 10 min equilibration. THA (3 μ M) caused a monotonic increase in m (25% after 20 min), which was due to an increase in p, as n was unaffected. By contrast, physostigmine (3 μ M) produced a 20% decrease in m, which was due primarily to a decrease in p. Neostigmine, which does not enter the nerve ending, had no effect on p. Spatial variance in p was unchanged in all experiments. Although THA and physostigmine are both membrane permeating anti-Tha and physostigmine are both memorane permeating anti-cholinesterases, their opposing effects on p suggest fundamental differences in their presynaptic actions. This may involve influx of Ca²⁺, and/or release of Ca²⁺ from intracellular stores (Supported by NIH NS22457).

MUSCARINIC AUTORECEPTORS ARE PRESENT ON CENTRAL AND

MUSCARINIC AUTORECEPTORS ARE PRESENT ON CENTRAL AND PERIPHERAL CHOLINERGIC NERVES INNERVATING THE GUINEA PIG INFERIOR MESENTERIC GANGLION (IMG). H. P. Parkman and J. H. Szurszewski. Department of Physiology and Biophysics, Mayo Medical School, Rochester, MN 55905. The aim of this study was to determine if cholinergic nerves innervating the IMG contain presynaptic autoreceptors which regulate release of acetylcholine (ACh). Isolated ganglia with attached lumbar colonic nerves (ING) and splanching nerves (SNR) were loaded with (LCNs) and splanchnic nerves (SpNs) were loaded with H-choline (750 nM, 80 Ci/mmole) followed by washing with 50 μ M eserine and 10 μ M hemicholinium-3. The amount of H-ACh and H-choline released during 5 minute periods was $^3\text{H-ACh}$ and $^3\text{H-choline}$ released during 5 minute periods was determined by radio-thin layer chromatography. Addition of atropine (1 $\mu\text{M})$ augmented the release of $^3\text{H-ACh}$ during SpN stimulation by 55% (p<0.01) and during LCN stimulation by 78% (p<0.01). When eseripe was not present in the superfusate, the release of $^3\text{H-choline}$ plus $^3\text{H-ACh}$ was still augmented by the presence of atropine (1 $\mu\text{M})$ during stimulation of the central SpNs (35%, p<0.01) and during stimulation of the peripheral LCNs (24%, .05<p<.10). These results suggest that both the peripheral LCNs and central SpNs contain presynaptic muscarinic receptors which inhibit release of acetylcholine from cholinergic nerves. Furthermore, the results suggest that these autonerves. Furthermore, the results suggest that these auto-receptors may function in vivo when acetylcholinesterases are present to metabolize the released acetylcholine. (Supported by NIH DK 17632 and DK 07198.)

INHIBITION OF TACHYKININ RELEASE FROM ENTERIC NERVE ENDINGS BY ADENOSINE A¹ AND A₂ RECEPTOR AGONISTS. R.M. Broad, T.J. McDonald* and M.A. Cook. Depts. of Medicine and Pharmacology, U. of Western Ont, London, Canada, N6A 5C1.

McDonald and M.A. Cook. Depts. of Medicine and Pharmacology, U. of Western Ont, London, Canada, N6A 5Cl.
Previous work has shown Ca²⁺-sensitive evoked release of the tachykinins (TK) Substance P (SP) and Neurokinin-A (NKA) from perifused guinea pig (g.p.) enteric nerve varicosities (enteric synaptosomes). Recent experiments using the A₂-selective agonist [2-p-carboxyethyl]-phenylamino-5'-N-carboxamidoadenosine (CGS 21680, 10µM) demonstrated inhibition of release of both SP (86.3 ± 13.7%) and NKA (84.1 ± 15.9%) from synaptosomes as well as inhibition of field stimulated contractions of the intact g.p. ileum (EC₅₀=9.6x10⁻⁶M). In synaptosomes, determinations in the presence of incrementing concentrations of the adenosine analogs CPA and NECA revealed the graded nature of the responses with EC₅₀'s for inhibition of SP release of 3.44x10⁻⁶M and 7.6x10⁻⁶M respectively. Pre-incubation with pertussis toxin (500 ng/ml) had no effect on the ability of CPA (50 nM) to inhibit the evoked release of these TK's. Pre-treatment of the synaptosomes with dibutyryl-cAMP (1 nM) similarly had no effect on the ability of CPA to inhibit evoked TK release. These data suggest the presence of both subtypes of adenosine receptors functionally linked to the release of TK's from enteric nerves. These data do not support a role for intracellular cAMP in mediating the responses and do not support involvement of a susceptible G-protein. Supported by MRC, Canada.

VOLTAGE-CLAMP ANALYSIS OF POTASSIUM CURRENTS IN BASOLAT-ERAL AMYGDALA NEURONS, H.C. Moises and M.D. Womble Dept. Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

of Physiology, Univ. of Michigan, Ann Arbor, MI 48109. Neurons of the basolateral amygdala (BLA) receive an extensive cholinergic input from the basal forebrain. We previously reported (Washburn & Moises, Neurosci. Abstr. 15:193, 1989) that application of the cholinomimetic carbachol produces a slow depolarization and reduces both accommodation and the slow afterhyperpolarization (AHP) in these cells. In this study, the single electrode voltage-clamp technique was used to survey membrane currents in BLA neurons in rat brain slices as a prelude to identifing targets of cholinergic action. M-current (Im) was seen as a voltage-sensitive inward current relaxation during hyperpolarizing steps from a holding potential (Vh) of -40 mV. Im was not affected by extracellular Cs (2 mM) or TEA (5 mM). Two Ca-activated K currents were identified underlying the AHP: the rapidly decaying Ic and the slowly decaying Tahp. Both were blocked by Cd (100 uM) but only Ic was blocked by TEA. Neither were affected by extracellular Cs. Negative steps from a Vh of -80 mV produced a slowly activating inward current, Iq, which was blocked by 2 mM extracellular Cs, while large depolar-izations from this Vh induced Ia, a rapidly decaying outward current. Iq and Ia were insensitive to Cd and TEA. Thus, BLA neurons have many of the same K currents seen in other cortical neurons, several of which have been identified as targets of cholinergic modulation (ie., Iahp and Im). (Supported by NIDA grant #03365.)

A VOLTAGE- AND TIME-DEPENDENT RECTIFICATION IN RAT DORSAL ROOTS. B.D. Birch, J.D. Kocsis, F. DiGregorio*, R.B. Bhisitkul and S.G. Waxman, Dept. of Neurology, Yale Med. Sch. and VA Med. Ctr., West Haven, CT. 06516.

An increase in membrane conductance in response to hyperpolarization, which has been referred to as inward (anomalous) rectification, is observed in many types of biological membranes. In this study we investigated the ionic, pharmacological, and kinetic properties of inward rectification in rat dorsal root axons using the sucrose gap technique.

Spinal roots were excised from rats and placed in a sucrose gap chamber.

Spinal roots were excised from rats and placed in a sucrose gap chamber. Constant hyperpolarizating current pulses elicited a time-dependent hyperpolarization characterized by a relaxation of membrane voltage toward resting potential followed by a slower decay away from resting potential during the current pulse. The relaxation in the hyperpolarization was reduced, but not eliminated, by the removal of either potassium or sodium from the perfusate. Removal of both potassium and sodium virtually abolished the relaxation and decay, indicating that the conductance is dependent on sodium and potassium. Pharmacologic blockade of voltage-dependent sodium channels with tetrodotoxin and potassium channels with tetraethylammonium or 4-aminopyridine did not reduce the relaxation or decay, suggesting that inward rectification is not mediated by these channels. Inward recfification was partially blocked by barium and completely abolished by cesium as seen in rat optic nerve (Eng et al. J. Physiol. 421:185-202, 1990). Simultaneous pulse experiments reveal that inward rectification becomes progressively refractory to activation during the decay phase; current pulses given later during the decay do not. This phenomenon suggests that the voltage decay during the current pulse represents inactivation of a conductance which mediates inward rectification.

218.2

SPIKE FREQUENCY ADAPTATION OF RAT DORSAL ROOT AXONS FOLLOWING NEUROMA FORMATION IN SCIATIC NERVE <u>D.A.</u> <u>Utzschneider</u>, R.B. <u>Bhisitkul</u>, J.D. Kocsis, Dept. of Neurology, Yale Med. Sch. and VA Med. Ctr., West Haven, CT. 06516.

Peripheral axons display a number of hyperexcitability phenomena following nerve ligation and neuroma formation. Much of this activity is attributed to altered electrophysiological properties of the axon region near the site of the transection. To study proximal sensory axon regions following nerve injury, dorsal roots of adult rats were studied in vitro in a sucrose gap chamber twenty days after sciatic nerve ligation. Current clamp of normal dorsal roots reveals a prominent inward rectification upon hyperpolarizing constant current passage. In general, the axons give rise to a single action potential during passage of modest levels of depolarization, but repetitive action potential discharge does occur during passage of large currents. The burst is marked by high frequency discharge which accomodates after 5-10 spikes. This is in contrast to dorsal roots obtained from rats where neuroma was present. Although inward rectification was still present in these roots, even large depolarizing current steps could not elicit repetitive firing. Dorsal roots obtained from rats whose sciatic nerves were crushed and allowed to regenerate showed reduced burst activity to depolarization as compared to control animals, but exhibited greater burst activity than the neuroma group. The increased spike frequency adaptation of sensory axons proximal to the site of neuroma indicates that the axonal hyperexcitability associated with neuroma formation is not generated over this region of the injured axon. Brismar et al. (BRAIN RES 378:347-356, 1986) have demonstrated an increase in axonal K and leak conductance proximal to the site of neuroma, possibly by loosening of paranodal myelin. An increased K and leak conductance could account for the reduction in the ability of these axons to generate bursts of action potentials.

218.4

WHY IS THE INPUT CONDUCTANCE OF HIPPOCAMPAL NEURONES IMPALED WITH MICROELECTRODES SO MUCH HIGHER THAN WHEN GIGA-SEAL PATCH PIPETTES ARE USED?

ILF. Storm., Institute of Neurophysiology, Karl Joh. gt. 47, 0162 Oslo, Norway.

In preparations where both microelectrode (µ-el.) and whole-cell patch (gigaseal) recordings have been done, the latter technique usually yields about tenfold higher input resistance (Rinp) than the former (e.g. in hippocampal neurons; Edwards et al., Pfluegers Arch 414:500). If the giga-seal value is representative, it has many implications for our understanding of the functions of the cells, and several ideas based on µ-electrode data may have to be revised, e.g. regarding the resting potential (RMP) mechanism, electrotonic structure, and the impact of synanses, ion channels and pumps.

implications for our inderstanding of the functions of the cetts, and several neess essect on p-electrode data may have to be revised, e.g. regarding the resting potential (RMP) mechanism, electrotonic structure, and the impact of synapses, ion channels and pumps. Until the reason for the Rinp difference is understood, however, one cannot be sure which technique is most reliable. The difference is often attributed to a leak through the hole made by the p-electrode. However, such a hole (probably nonselective and accounting for ~90% of the input conductance) should cause a severe depolarization (e.g. from about -70 to -5 mV, if Rinp drops from about 500 to 50 MQ, as seems to occur in hippocampal neurons), but this is not observed. Possible explanations for this discrepancy include: the impalement could activate either (1) a K conductance (e.g. by depolarization, or influx of Ca or Na ions), or (2) a conductance for a passively distributed ion (e.g. Cl.), or (3) a pump which maintains the RMP in spite of a non selective leak. However, none of these ideas seem to be supported by the available data, at least for hippocampal neurons: (1) the resting K conductance shows little or no voltage-dependence, and the low Rinp and RMP with p-els seems to persist in Ca-free medium and after injection of Ca-buffers, which abolish the Ca-activated K currents IC and IAHP; (2) injection of Cl ions have little or no effect; (3) inhibiting the Na/K pump with cooling or drugs does not immediately depolarize the cell.

Thus, the discrepancy between p-el. and giga-seal does not seem to be satisfactori-

Thus, the discrepancy beteween µ-el. and giga-seal does not seem to be satisfactor ly explained. We have therefore started to re-examine this problem.

A TRANSIENT VOLTAGE-DEPENDENT OUTWARD CURRENT RECORDED FROM PAT CEREBELLAR PURKINJE CELLS (PCs) UNDER VOLTAGE CLAMP. S.-J. Li*, Y. Wang*, H.K. Strahlendorf and J.C. Strahlendorf, Depts. of Physiol. and Neurol., Texas Tech Univ. Plth. Sci. Ctr., Lubbock, TX 79430.

Current-clamp recordings of turtle PCs demonstrate a

transient hyperpolarization (TH) that outlasts electrotonic response of the membrane to hyperpolarizing current injection (Hounsgaard, 1988). This TH displays voltage, time and ionic dependencies suggestive of the transfent outward K current $(\mathbf{I}_{\mathbf{A}})$ recorded in many neurons. Recordings of rat PCs in our laboratory also revealed this TH and it is augmented by serotonin. PCs were voltage-clamped with a single electrode system and superfused with modified Kreb's solution containing 2.5 mM Ni $^{2+}$, 10 mM TEA, 0 Ca $^{2+}$ and 3 μ M TTX. From a holding potential (HP) of -70 mV, 10 mV depolarizing steps elicited a transfent outward current (TOC) at steps more positive to -50~mV that declined to a steady state over a period of about 200 msec. At holding potentials near substantially was -40 mV TOC was substantially inactivated. Hyperpolarizing commands to near -100 mV from a HP of -50 mV also revealed the TOC upon return to the HP for steps more negative than -60 mV. Bath application of 500 μM 4-AP markedly reduced the TOC. Our results suggest the TH seen in PCs may be mediated by this TOC which is similar to I_{A} seen in other cells. Supported by NS 19296 and the Tx. Adv. Res. Prog., Grant 010674-020.

WHOLE-CELL CLAMP OF RAT THALAMIC NEURONS REVEALS TWO DIS-

WHOLE-CELL CLAMP OF RAT THALAMIC NEURONS REVEALS TWO DISTINCT TRANSIENT K CURRENTS J.R., Huguenard, D.A. Coulter and D.A. Prince. Dept. Neurology, Stanford Univ. Medical Center, Stanford, CA 94305.

We have recently described a prominent transient Ca current (I-r) in relay neurons (RNs) that is both necessary and sufficient for the generation of Cadependent, low-threshold spikes (LTS; Coulter, et al., J. Physiol. 414:587,1989). However, these cells are also characterized by K conductances that are activated concurrently with I-r, and thus tend to slow or retard the development of Ca-dependent spikes. In order to further understand the regulation of LTS burst firing in RNs, we examined the various K currents activated in the voltage range near threshold for LTS activation.

RNs were obtained from rat VR complex by acute isolation, and current

range near threshold for LTS activation. RNs were obtained from rat VB complex by acute isolation, and current recordings were made via whole-cell clamp. The pipette solution consisted of KCI, EGTA-Ca, MgCl₂ and HEPES, Na currents were blocked with TTX, and Ca currents were minimized by using low (0.5 - 1 mM) extracellular Ca. Most experiments were performed 22-24°C. Depolarizations to between -50 and 0 mV from a holding potential of -90 mV produced an outward current that was largely inactivating during a 300 ms depolarization. A rapidly activating (peak < 4ms) current, I_A, was activated at a threshold near -60 mV, and inactivated with a time constant (r) of 20-30ms. I_A was half-inactivated at a holding potential of -83 mV, was blocked by 4AP (5mM), but not by TEA. In addition to I_A, a second, smaller inactivating current ($\frac{1}{A-2}$) was also present. In comparison to I_A, I_A2 was steady-state inactivating, ($\frac{1}{A-2}$) was also present. In comparison to I_A, I_A2 was steady-state inactivating ($\frac{1}{A-2}$) was also present. In comparison to I_A, I_A2 was steady-state inactivating ($\frac{1}{A-2}$) was also present. In comparison to I_A, I_A2 was steady-state inactivating ($\frac{1}{A-2}$) was also present. In comparison to I_A, I_A2 was steady-state inactivating ($\frac{1}{A-2}$) was also present. In comparison to I_A, I_A2 was steady-state inactivating ($\frac{1}{A-2}$) was remarked with a slightly higher threshold (-40 mV) and was blocked by TEA but not by 4AP. Both currents were K dependent, with reversal potentials governed by the Nemst relationship.

Since I_T, I_A and I_{A-2} are partially inactivated at rest (= -70 mV), hyperpolarizing influences will promote subsequent activation of all three currents. Implications of the interactions of these conductances for LTS generation will be discussed. Supported by NIH grants NS06477 and NS12151.

UNITARY 'A' CURRENT CHANNELS IN CENTRAL NEURONS. I.D. Forsythe, P. Linsdell & P.R. Stanfield. Dept. of Physiology, University of Leicester, P.O. Box 138, Leicester LE1 9HN, UK.

Ion channels underlying the transient outward potassium current (Connor & Stevens, <u>J. Physiol</u>. 213: 21, '71) were studied in locus coeruleus and hippocampal neurons grown in dissociated cell culture, using the patch-clamp technique in the 'oncell' and 'inside-out' configuration. Patch electrodes contained 140 or 3 mM KCl. 'Inside-out' patches were perfused with 140 mM KCl using three flow pipes, through which different media were perfused at a constant temperature of 20 ± 0.1 °C. The current-voltage relation of the channels were studied in response to both step and ramp voltage protocols.

Peak open probabilities were in the range of 0.6-0.9, while activation and inactivation of unitary channels were similar to whole cell 'A' currents. In the 'on cell' configuration single channels had peak conductances of 41.3 ± 1.1 pS (n=4, \pm SEM) and 15 \pm 0.6 pS (n=7), [K+]₀ was 140 and 3 mM, respectively. The unitary conductance rectified in a voltage dependent manner at positive potentials. With 'inside-out' patches, channels had a linear I/V and conductance of 17.8 ± 1.9 pS when perfused on the inside with medium containing 140 mM K+ and no added Mg2+, Ca^{2+} or Na^{+} ([K+]₀ = 3 mM). Addition of 2 mM Mg²⁺ or 10 mM Na⁺ to the internal perfusate reduced the unitary amplitude and increased open state noise in a voltage dependent manner, with Kds at 0 mV, of 15.5 and 76 mM, respectively. This rectification was similar to that observed in 'on-cell' patches. This phenomenon could serve to limit the contribution of the 'A' current to repolarization during the overshoot of an action potential. Kinetic analysis shows a single open state and at least three closed states, plus an inactivated state. A subconductance state with approximately 60% of the fully open conductance is also observed.

AMINOPYRIDINE BLOCK OF K CHANNELS IN NEUROBLASTOMA

CELLS. J. K. Hirsh * and F. N. Quandt Multiple Sclerosis Center and Dept. of Physiology, Rush University, Chicago, Il. 60612
The action of 4-aminopyridine (4-AP) and derivatives on voltage-dependent K channels was examined using whole cell and excised membrane patch clamp techniques applied to N1E-115 neuroblastoma cells grown in tissue culture. Half maximal block of the steady state current measured with whole cell voltage clamp was obtained at a concentration of 0.35 mM when 4-AP was added to the external solution. Approximately 10 percent of the current was resistant to 4-AP. The time course of K current in the presence of submaximal doses of 4-AP was altered. First, a slow phase of outward K current developed in response to a step depolarization after exposure to 4-AP. Second, the decay of current during a maintained depolarization was eliminated. Block by 4-AP did not decrease when depolarizations were applied repetitively at intervals between 1000 to 60 mS. The alterations in whole cell current are consistent with the presence of a channel type with slow activation and inactivation kinetics, which is resistant to 4-AP. However, single channel analysis indicated that block by 4-AP is modulated under certain conditions. 4-AP effects on single delayed rectifier channels were studied using inside-out membrane patches, since K channel current was more sensitive to application of 4-AP to the inside surface of the membrane. With current through the K channel carried by Rb, the latency of opening of K channels in inside-out excised membranes increased in the presence of 4-AP. 4-AP produced a component in the closed time histogram with a duration of 200 mSec, presumably representing the blocked state. 4-AP had little effect on the open time or amplitude of single channel current. Supported by the National Multiple Sclerosis Society.

EXPRESSION OF POTASSIUM A CURRENT CHANNELS IN XENOPUS MYOCYTES DURING DIFFERENTIATION IN CULTURE.

U. Ernsberger & N.C. Spitzer. Department of Biology and Center for Molecular Genetics, UCSD, La Jolla CA 92093.

The developmental regulation of potassium currents plays a major role in the differentiation of electrical activity in excitable cells. Outward currents carried by potassium can significantly influence the extent of calcium influx through voltage dependent channels, and thus may affect a variety of processes regulated by calcium. To understand the maturation of potassium currents, we have analyzed single potassium channels in inside-out patches from Xenopus myocytes differentiating in vitro.

Under conditions that suppress the activity of calcium and calcium-dependent channels, ~90% of the channels from 1 day old myocytes are selective to potassium ions and are referred to as potassium channels. Although ~70% of the patches from one day old myocytes showed no ion channel activity between -80 and +40mV, ~80% of the patches with activity showed superimposed channel openings. The pattern of activity in patches with channel openings to only a single current level suggest that the superimposed openings do not reflect substates of a single active channel but clustering of independent channels.

The abundance of channels with properties characteristic of potassium A current increases by roughly one order of magnitude between 9 and 30 hrs in culture. The A creases by roughly one order of magnitude between 9 and 30 hrs in culture. The A current channels, with conductances of ~20pS, are inactivated at depolarized potentials. When depolarized from holding potentials of -80 or -120mV, they activate within milliseconds, at activation rates that are voltage dependent. Several other channel classes were distinguished on the basis of conductance, dwell time distributions and in-activation behavior. Ensemble average currents indicate that these channels do not contribute to the voltage-dependent A and delayed rectifier currents. There is little or no increase in their density during the period in which the A current density increases. Thus the A current channels are likely to play an increasing functional role during this development period. developmental period.

DEVELOPMENTAL EXPRESSION OF A SLOWLY-INACTIVATING, VOLTAGE-DEPENDENT K CURRENT IN ACUTELY-DISSOCIATED NEOSTRIATAL NEURONS. D. I. Surmeier, R. C. Foehring, A. Stefani, S. T. Kitai, Department of Anatomy and Neurobiology, College of Medicine, The University of Tennessee, Memphis, Memphis, TN 38163

Cultured embryonic rat neostriatal neurons have two voltage-department K currents. A current (AA) and delayed registion (Surmeion).

dependent K currents: A current (IA) and delayed rectifier (Surmeier et al. Neurosci. Lett. 103: 331, 1989). We have found evidence for a third current in neurons dissociated from postnatal rats older than 2-3 weeks. This current is similar to the D current described in CA1 neurons by Storm (Nature 336: 379, 1988) but in neostriatal neurons this current is more TEA-sensitive and recovers more rapidly from inactivation.

Conventional whole cell recording techniques were used on acutely dissociated rat striatal neurons at room temperature. Neurons were dissociated from rats between P1 and P120 with a protocol modified from Mody et al. (Neurosci. Lett. 96: 70, 1989). Extracellular solutions were designed to minimize the contribution of Cl and Ca currents. Whole-cell recordings of neurons from rats older than P14 revealed two K currents which inactivated at potentials positive to -40mV. Half-

inactivation voltages of the two currents were around -50 and -90 mV. These currents differed in inactivation recovery kinetics (at -100 mV, time constants were 20-50 ms and 80-1500 ms), deactivation kinetics and sensitivity to 4AP and TEA. (Supported by NINDS grant NS 26473 and NS 20702).

HYPERPOLARISATION ACTIVATED INWARD CURRENT IN HISTAMINE NEURONS OF RAT HYPOTHALAMUS. <u>Anita Kamondi and Peter B. Reiner</u>, Kinsmen Laboratory of Neurological Research, Dept. of Psychiatry, Univ. of British Columbia, Vancouver, B.C. VGT 1W5

The hyperpolarisation activated inward current $(I_{\rm h})$ was studied in histaminergic tuberomammillary (TM) neurons using single electrode voltage clamp technique in an in vitro slice preparation of the rat hypothalamus. Hyperpolarizing voltage steps from a holding potential of -60 mV evoked an inward current in a time and voltage dependent manner, causing inward rectification of the steady state current-voltage relationship measured between -60 and -130 mV. The time constant of the fully activated current was -300 ms and the current did not inactivate. The activation curve for $I_{\rm h}$ fitted to the Boltzman equation showed a V $_{1/2}$ =-100 mV, and k=1.12. The reversal potential of $I_{\rm h}$ was close to -35 mV measured in control extracellular solution containing 2.5 mM K $^+$ and 156.2 mM Na $^+$. When the external potassium concentration was raised to 10 mM, $I_{\rm h}$ increased and the reversal potential shifted in a depolarized direction. Partial replacement of the external sodium by choline decreased both the instantaneous and steady state current and displaced the reversal potential in a hyperpolarized direction. Removal of extracellular Ca $^+$ and Cl did not affect $I_{\rm h}$. Changes in the external ionic concentration did not affect the voltage dependence of $I_{\rm h}$. Extracellularly applied Cs $^+$ (1 mM) reversibly inhibited the current. External Ba $^+$ (2 mM) caused an outward current at holding potential -60 mV, decreased the instantaneous conductance, but did not block $I_{\rm h}$.

NONSTATIONARY FLUCTUATION ANALYSIS OF M-CURRENTS IN BULLFROG SYMPATHETIC AND RAT PC-12 CELLS. N.V. Martion*. A. Villarroel*. W. Gruner* and P.R. Adams. Howard Hughes Medical Institute, SUNY at Stony Brook, NY 11794.

at Stony Brook, NY 11794.

We have used nonstationary, ensemble variance measurements (Sigworth, J.Physiol., 307:97, 1980) to estimate single channel conductance for the M-channel in both bullfrog sympathetic neurons and rat PC-12 cells, M-current (I_M) was activated by whole-cell voltage-clamping both cell types at positive holding potentials (between 40 and -30 mV) and deactivated by 20 mV hyperpolarizing voltage steps.

A J

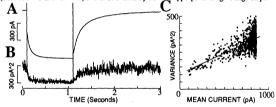

Figure A shows the average membrane current trace of 84 records obtained by stepping the voltage of a bullfrog sympathetic neuron from -35 mV to -55 mV for 1 second. The variance, computed from 21 groups of four records, fell in a time-dependent manner as M-channels closed during the voltage step and increased as M-channels reopened at the cessation of the pulse (figure B). Linear regression of variance versus mean current during the first 400 ms of repolarization (figure C) gave a single channel conductance estimate of approximately 5 pS (reversal potential -98 mV). Similar results were obtained from PC-12 cells. These results accord with single channel recordings from bullfrog sympathetic neurons (Gruner et al, Soc. Neurosci. Abstr., 15:990, 1989) and suggest that the M-channel in PC-12 cells may also have similar properties.

218.15

TWO CALCIUM-ACTIVATED POTASSIUM CONDUCTANCES GENERATE THE POST-STIMULUS HYPERPOLARIZATION IN RAT LOCUS COERULEUS NEURONS. <u>S.S. Osmanovic and S.A. Shefner</u>. Dept. Patho-Physiology, Medical Faculty Belgrade, Yugoslavia and Dept. Physiology and Biophysics, University of Illinois College of Medicine, Chicago, IL 60612.

The properties and ionic mechanisms underlying the post-stimulus hyperpolarization (PSH) which follows trains of action potentials in rat locus coeruleus (LC) neurons were investigated. Intracellular recordings were made from LC neurons in a totally submerged brain slice preparation. The PSH following trains of action potentials evoked by small depolarizing currents was monophasic. When larger depolarizing stimuli were used, an additional, earlier, phase of PSH occurred immediately following the train. Thus, PSH elicited with stronger stimuli consisted of two distinct components: a faster, early (PSH₂) and a slower, late one (PSH₃). The time course of PSH decay could be fit by a biexponential function. Artificial CSF containing low Ca²⁺ (0.25 mM) and high Mg²⁺ (20 mM), or Ca²⁺ (0.5-1 mM) blocked both components (n=5). Apamin (2-500 μ M) selectively blocked PSH₈ (n=22). TEA (2-6 mM) decreased the amplitude of PSH₄, but not PSH₈ and prolonged both components. Addition of apamin after TEA caused complete block of PSH and the appearance of a large, long-lasting depolarization (PSD). This depolarization was associated with firing and decreased input resistance. External Ba²⁺ (1-2 mM) depressed both PSH₈ and PSH₄, (n=5), but for short trains the reduction was greater for PSH₈. With longer trains in Ba²⁺, both phases of PSH were abolished, being replaced by PSD. These data suggest that PSH in LC neurons is mediated by two different Ca²⁺-activated K conductances. PSH₈ is mediated by an apamin-insensitive conductance which is blocked by Ba²⁺ and reduced by TEA. Grant support: US PHS AA 5846.

PATCH CLAMP STUDIES ON CULTURED SMOOTH MUSCLE CELLS FROM RAT CEREBRAL ARTERIES. Y. Wang and D.A. Mathers, Physiology Department, University of British Columbia, Vancouver, B.C. V6T 1W5 Canada

Electrical properties of smooth muscle cells (SMCs) cultured from conducting vessels of the rat cerebral circulation were studied using standard patch clamp methods. Cells were dispersed to small clumps by treatment of basilar, middle and posterior cerebral arteries with 0.3% collagenase at 37°C. Whole-cell current clamp recording showed that the average resting potential (RMP) of the cells declined slowly with passage of time in vitro. After 3-4 days in culture, the mean RMP was -44 ± 3.2 mV (mean ± S.E.M.) with mean input resistance 2.85 ± 0.675 GΩ. Cell-attached patch recording showed biphasic currents indicative of spontaneous action potential generation in only a few percent of cells tested. Application of 10 μM serotonin induced this type of activity in 5/10 cells tested. Serotonin also activated a high conductance membrane channel with kinetic and conductance properties resembling the calcium dependent potassium channel of rat myotubes and aorta SMCs.

POTASSIUM CURRENTS AND SENSORY CODING IN THE TOADFISH SACCULAR HAIR CELLS. A. Steinacker and A. Romero*, Dept. Otolaryngology, Washington University School of Medicine, St. Louis, MO 63110.

Sensory coding of characteristic frequency (CF) in auditory hair cells has been modelled around the interaction of an outward calcium activated potassium current (IKCa) and an inward calcium current to produce resonance at the CF. Using whole cell patch clamp analysis of hair cells of the putative auditory end-organ, the saccule, of the toadfish (Opsanus tau), we have found two distinct classes of hair cells, on the basis of their outward currents. There are only two major outward currents of the hair cell of the saccule of the toadfish IKCa and a voltage gated potassium current (IK). The temporal and voltage sensitivity of kinetics of activation and deactivation of these two currents are markedly different. One class of saccular cells contains only IKCa and no IK. The second class contains IK in addition to IKCa. (They may both additionally contain a small A current). These two classes of cells must code auditory stimuli in different ways. We have measured the kinetics of activation and deactivation of these two currents as they appear in individual cells to ascertain whether their rates are linked in individual cells and find that they are. This suggests that the two currents are functionally linked in sensory processing. The role of IKCa alone and these two currents in tandem in resonance phenomena was also investigated since the current model for resonance is based on the kinetics of only IKCa. We conclude that at least two forms of sensory processing are taking place in the hair cell. Supported by DRF.

LARGE CONDUCTANCE POTASSIUM CHANNELS IN DISSOCIATED RAT SUBSTANTIA NIGRA NEURONS. X. Gu, K. Breedlove*, S.G. Speciale, A.L. Blatz and D.C. German. Depts. of Psychiatry and Physiology, UT Southwestern Medical Center, Dallas, TX 75235.

Cell-attached patch-clamp recordings of dissociated rat substantia nigra neurons revealed the presence of large-conductance K channels. Single neurons from the zona compacta were isolated using either a trypsin or protease dissociation method. At least one-half of the neurons exhibited large inward currents which were active as soon as seals were formed. These channels were active at the normal resting membrane potential, and exhibited single channel currents of 5-6 pA under the following conditions: bath solution (mM) - 150 NaCl, 4 KCl, 2 CaCl₂, 5 TES, pH 7.0; pipette solution - 140 KCl, 1 EGTA, 5 TES, pH 7.0. Assuming a resting membrane potential of -60 mV, the single channel slope conductance was 100-150 pG. These channels were observed whether or not the D2 dopamine agonist quinpirole (1-10 uM) was present in the pipette solution. Recordings from excised, inside-out patches demonstrated that these channels were sensitive to uM concentrations of intracellular Ca, and were voltage dependent. The observation that these channels are active at normal resting membrane potentials suggests that they are either more sensitive to intracellular Ca than BK channels in tissue-cultured skeletal muscle, or that under typical dissociation conditions the neurons become loaded with Ca. Research supported by MH-30546, DA-05314 and GM-39731.

CA²⁺-ACTIVATED K⁺ CURRENTS IN ACUTELY ISOLATED EMBRYONIC CHICK CILIARY GANGLION NEURONS. S. E. Dryer, M. E. Wisgirda* and M. Dourado*. Department of Biological Science, Florida State University, Tallahassee, FL 32306.

Department or Biological Science, Florida State University, Tallahassee, FL 32306.

Patch clamp recordings were made from neurons obtained from E11-E14 embryos. Depolarizing voltage steps from holding potentials of <-50 mV evoked K $^+$ currents that were abolished by perfusion with Ca $^{2+}$ -free salines ($I_{K(Ca)}$). Application of 10 MM TEA completely blocked $I_{K(Ca)}$. The MTEA caused 60 - 90% block of $I_{K(Ca)}$. The effects of TEA were completely reversible. Saturating concentrations of apamin (200 nM) blocked 40-70% of the TEA-sensitive $I_{K(Ca)}$. Apamin effects were not reversible in 20 minutes. At least three different $I_{K(Ca)}$ conductance states were detected in inside-out patches. These had conductances of 190 pS, 110 pS, and 45 pS with [K]_0 = 150 MM and [K]_1 = 75 MM. The 45 pS state showed the greatest sensitivity to Ca $^{2+}$. Three different $I_{K(Ca)}$ conductance states were observed in cell-attached and outside-out patches. $I_{K(Ca)}$ channels in outside-out patches were completely blocked by 10 MM TEA, and partially blocked by 1 MM TEA. Current-clamp recordings showed that both $I_{K(V)}$ and $I_{K(Ca)}$ contribute to spike repolarization and the a.h.p. Surprisingly, 200 nM apamin produced only a small and inconsistent reduction in the a.h.p. Supported by NS-27013.

VOLTAGE-GATED IONIC CURRENTS IN EPITHELIAL SENSORY CELLS FROM SEA ANEMONE TENTACLES. D. A. Hessinger * and P. Brehm. Dept. of Physiology, Loma Linda University School of Medicine, Loma Linda, CA 92350 and Dept. of Neurobiology and Behavior, SUNY Stony Brook, Stony Brook, NY 11794.

Nematocysts, the eversible prey-capturing organelles of cnidocytes, are triggered to discharge by calcium-dependent exocytosis following mechanical and chemical stimulation. The sensory receptors for these stimuli reside on adjacent supporting cells (SCs) in sea anemone fishing tentacles. Using whole cell, voltage-clamp techniques on SCs isolated from excised anemone (Haliplanella luciae) tentacles we have identified and partially characterized three voltage-dependent currents: (i) transient outward potassium; (ii) late outward, carried in part by potassium; and (iii) inward calcium. Both transient and late outward currents are eliminated by substituting either CsCl2 or N-methylglucamine (NMG)eliminated by substituting either CsCl2 or N-methylglucamine (NMG)-Cl for internal KCl. The transient outward current is blocked by external 4 mM 4-aminopyridine (4-AP) while causing an unexpected reciprocal increase in the late outward current. The late outward current is dependent on divalent cations; substitution of barium by calcium results in a 2 to 3 fold increase in late outward current with no corresponding change in transient current. The voltage dependent inward current is carried by calcium or barium and is blocked by external 2 mM CdCl₂. Given the central role of calcium to nematocyst discharge and the role of SC sensory receptors in controlling discharge, it is likely that modulation of calcium action potentials in these cells via sensory stimulation may regulate exocytosis in adjacent cnidocytes. [Supported by NSF grants 8609859 (DAH) & 8503159 (PB)].

COMPARISON OF VOLTAGE-DEPENDENT POTASSIUM CURRENTS IN RAT LACTOTROPHS AND CLONAL PITUITARY CELLS (GH3). S.M. Simasko. Dept. of Physiology, School of Medicine, S.U.N.Y. at Buffalo, Buffalo, NY 14214. The activity of voltage-dependent potassium channels are an important element in the control of membrane potential and hence Ca²⁺ influx through voltage-dependent calcium channels. In this study whole-cell patch shape technique ware used to tridly whole activities and the control of t

patch-clamp techniques were used to study voltage-dependent potassium patch-clamp techniques were used to study voltage-dependent potassium currents in rat lactotrophs identified by reverse-hemolytic plaque assay and in the rat pituitary cell line GH3. Ca^{2+} currents and Ca^{2+} activated K^+ currents were eliminated by recording in Ca^{2+} -free bath buffer (replaced with Mg^{2+}). In both cell types, when the cells were held at -76 mV and then pulsed to positive potentials, an outward current activated that then relaxed to a sustained level. The inactivating portions activated that then relaxed to a sustained level. The inactivating portions of the current traces could be fit to a double exponential (time constants of ~75 msec and ~4 sec in both cell types). The relative proportion of fast inactivating current (I_{Kf}) and slow inactivating current (I_{Kf}) varied from cell to cell, suggesting that these currents are due to different channels. In both cell types I_{Kf} was completely inactivated when the holding potential was reduced to -40 mV. Half-maximal conductance of I_{Kf} in both cell types occurred at ~0 mV. However, whereas recovery from inactivation of I_{Kf} in GH3 cells was slow and best fit by two exponentials (time constants of 350 msec and 7 sec), the recovery from inactivation in lactotrophs was rapid and best fit by a single exponential inactivation in lactorrophs was rapid and best fit by a single exponential (time constant of 90 msec). The more rapid recovery from inactivation of Ikf in lactotrophs would suggest that this current is much more influential in the control of membrane potential in these cells. The basis for the differences in recovery rate is at present unknown.

VOLTAGE-ACTIVATED IONIC CURRENTS FROM MYOEPITHELIAL CELLS ISOLATED FROM THE SEA ANEMONE CALLIACTIS TRICOLOR. M.A. Holman and Peter A.V. Anderson. Whitney Laboratory and Depts. of Physiology and Neuroscience, Univ. of Florida, St. Augustine, FL 32086.

The Cnidaria are the most primitive phylum to possess a recognizable nervous system and are thus useful models for studying the evolution of the nervous system and electrical excitability. Little is known about the Anthozoa, the most primitive of the cnidarians. We have examined the electrical properties of myoepithelial cells from the sea anemone *Calliactis* tricolor. These cells have resting potentials in the range of -60 to -90 mV and produce fast action potentials when depolarized. The ionic currents underlying this excitability were examined using the whole-cell patch clamp configuration.

These cells possess two inward currents, both carried by Ca++. These were distinguishable by their tail currents, and had the unusual ionic permeability sequence Ca⁺⁺>Ba⁺⁺>Sr⁺⁺. We identified five outward K⁺ currents: 1) a fast, transient 4-AP sensitive current, 2) a Ca⁺⁺-dependent K⁺ current, 3) a fast transient K⁺ with slow inactivation, 4) a steady-state K⁺ component, and 5) a small, very fast transient outward current that was insensitive to internal Cs/TEA, but was shown not to be Cl dependent. With a few exceptions, these currents are similar to those seen in other organisms

CALCIUM CHANNELS: PHARMACOLOGY

NEOMYCIN INHIBITS VOLTAGE-SENSITIVE CALCIUM CHANNELS (VSCC) WHICH ARE INSENSITIVE TO ω-CONOTOXIN GVIA (ω-CT) AND DIHYDROPYRIDINES (DHP). R.A. Keith, T.J. Mangano, W.C. Moore, C. Thompson, J. Patel and A.I. Salama. Department of Pharmacology, ICI Americas Inc., Wilmington, DE 19897. The effects of neomycin, ω-CT and DHP on VSCC-dependent neuronal responses were compared. ω-CT and DHP partially inhibited the K[†]-evoked (K[†]-E) release of ³H-norepinewhich are insensitive to ω -conotoxin gvia (ω -ct) and

phrine (NE) from rat cortical slices and the K+-E increase in intracellular calcium ([Ca++]i) in neocortical neurons in intracellular calcium (La''ll) in neocortical neurons in primary culture, but had no effect on the K+E release of ³H-D-aspartate (asp) from hippocampal slices. This suggests that K'-E release of ³H-NE and the K+E increase in [Ca'+] i are only partially dependent on L- and N-type VSCC, whereas the K+E release of ³H-D-asp has no dependence on N- or L-type VSCC. In contrast, neomycin caused denice on N=07 N=type vsct. In contrast, neomycin caused a concentration-dependent and virtually complete inhibition of K+= 2 H=NE and 3 H=asp release and K+= 2 increase in [Ca++] I (IC₅₀ values 100-300 μ M). At 1 μ M neomycin there was only a slight inhibition (8%) of carbachol-induced phosphoinositide turnover, suggesting direct inhibition of phospholipase C is not the mechanism underlying the inhibition of K^+ -E responses. Thus neomycin inhibited depolarization-induced neurotransmitter release and calcium influx that was not inhibited by $\omega\text{-CT}$ and DHP. This suggests that neomycin inhibits a neuronal voltage sensitive calcium influx pathway that is critical for neurotransmitter release yet distinct from N-or L-type VSCC.

OF NIMODIPINE-SENSITIVE ACTIVATION OF NIMODIPINE-SENSITIVE L-TYPE CALCIUM CHANNELS ON BRAIN DOPAMINERGIC TERMINALS BY POTASSIUM PLUS PICOMOLE OF MPP.

C. C. Chiueh and S.-J. Huang*, Lab. of Cerebral Metabqlism, NIMH, Bethesda, Maryland 20892.

MPP (1-methyl-4-phenylpyridinium ion) is the major cerebral metabolite of MPTP and is retained in monkey dopaminergic nerve terminals.

Millimolar MPP increases Ca²⁺ influx and dopamine (DA) overflow in the lateral striatum which might lead

Millimolar MPP increases Ca²⁺ influx and dopamine (DA) overflow in the lateral striatum which might lead to a selective lesioning of nigrostriatal neurons (Miyake et al., 1990). In this study, MPP (5 to 500 pmol) caused only a monophasic DA efflux from striatum of anesthetized rats into a microdialysis probe. K depolarization of nerve terminals (15 to 90 mM for 5 min) enhanced DA response to MPP. Therefore, similar to BAY K 8644, picomoles of MPP can activate nimodipine-sensitive L-type calcium channels only when membrane potential is being depolarized by K. This K-induced potentiation of MPP evoked DA release depended on extracellular Ca and was reduced one half by nimodipine (10 μM). This enhanced DA efflux was augmented further by 4-aminopyridine (1 mM), a K channel blocker. These results indicate that MPP could alter the gating mode of voltage-regulated L-type calcium channels on brain dopaminergic terminals. Furthermore, MPP might also function like an organic cation and interact with K channel.

HIGH THRESHOLD CALCIUM CURRENTS IN RABBIT SENSORY NEURONS: DIFFERENCES IN SENSITIVITY TO ω-CONOTOXIN (w-CTX) AND NIMODIFINE (NIM). P.E. TanPiengco* and R.T. McCarthy. Inst. for Preclinical Pharmacol., Miles Inc., West Haven, CT. 06516 The patch voltage clamp in the whole cell and cell attached modes has been used to measure Ca++ channel currents (I_{Ba}) in freshly dispersed dorsal root ganglia (DRG) cells. A variable amount of high threshold peak inward current was amount of high threshold peak inward current was inhibited by ω -CTX (5μ m;n=10). In some cells this inhibition was complete even for current elicited from depolarized potentials (VH=-30 mV). In such cells, BAY K 8644 (BK;100 nM) had no effect. When half-maximal I_{Ba} inactivation was very positive (V1/2 = -30mV), ω -CTX block was minimal. This (VI/2 = -30mV), ω -CTX block was minimal. This ω -CTX resistant current (I_B) remained unaffected by higher concentrations of ω -CTX (10-20 μ M). I_R contained dihydropyridine (DHP) sensitive I_B inhibited by NIM and enhanced by BK. Single channels (VH=-50mV; 28pS; 110 Ba), enhanced by pretreatment with BK, could be potently inhibited by NIM. However, in both whole cell and cell atby NTM. However, in Both whole cell and cell attached records a small component of I_n was also resistant to NIM(200nM; \cong 70% block). These results suggest that pretreatment with ω -CTX can be used to more easily study DHP sensitive currents and demonstrate high affinity of NIM for L-type Ca⁺⁺ channels.

EFFECTS OF NIMODIPINE ON RABBIT CA1 HIPPOCAMPAL NEURONS. J.R. Moyer, Jr., J. Black' & J.F. Disterhoft. Depts. of Cell, Molecular & Structural

J.R. Moyer, Jr., J. Black' & J.F. Disterhoff, Depts. of Cell, Molecular & Structural Biology and of 'Pharmacology, Northwestern Univ. Med. Sch., Chicago, IL 60611. Nimodipine, a dihydropyridine calcium channel antagonist, facilitates acquisition of trace eye-blink conditioning in aging rabbits (Deyo et al., 1989). This task depends upon an intact hippocampus for acquisition (Moyer et al., 1990), and results in learning-specific reductions of the afterhyperpolarization (AHP) following a burst of 4 action potentials in CA1 (deJonge et al., 1990). Intravenous administration of nimodipine alters spontaneous activity of hippocampal neurons in an aging- and dose-dependant fashion in vivo (Thompson et al., 1989). Since nimodipine also has vasodilatory effects, the present experiments investigate whether nimodipine may alter cellular activity by acting directly on hippocampal neurons in vitro.

	ELECTROPHYSIOLOGICAL CHARACTERISTICS						
	Max AHP size @ RMP	Area of AHP (800 ms)		Max AHP size (depolarized)			
Mean Change after 10µM Nimodipine		-47.3 ± 13%	+76.4 ± 1.3%	-26 ± 2.8%	-33.2 ± 4%		

Current clamp recordings were taken from 25 CA1 neurons in submerged 400 µm Current clamp recordings were taken from 25 CA1 neurons in submerged 400 μ m slices from young adult rabbits at 31°C. Only cells with an input resistance of greater than 30 M Ω , a resting potential of at least -55 mV, and an action potential amplitude greater than 70 mV were studied. Nimodipine: 1) decreased the peak voltage of the afterhyperpolarization following a train of 4 action potentials (both at rest and depolarized 10 mV from rest); 2) decreased the overall integrated area of the AHP and 3) decreased spike-accommodation to an 800ms depolarizing pulse. Additional studies will be conducted on CA1 neurons from aging rabbits. These

data are consistent with the hypothesis that nimodipine exerts its behavioral effects via a direct action on calcium-mediated events in hippocampal neurons. Supported by 1 RO1 AG08796 and The Miles Institute.

PHENCYCLIDINE BLOCK OF CALCIUM CURRENT IN ACUTELY DISSOCIATED HIPPOCAMPAL CA1 NEURONS: SPECIFIC EFFECTS ON CHANNEL GATING. J.M.H. ffrench-Mullen and M.A. Rogawski². ¹Laboratory of Neurophysiology and 'Neuronal Excitability Section, Medical Neurology Branch, NUMBER MILL Bethard MD. 60206. NINDS, NIH, Bethesda, MD 20892.

CA1 neurons were enzymatically dissociated from the hippocampi of adult CA1 neurons were enzymatically dissociated from the hippocampi of adult guinea-pigs and whole-cell patch-clamped in solutions containing 3 mM external Ba²⁺ and internal Cs²⁺, BAPTA and Mg²⁺. ATP. 1_{ga} was examined with 5 ms to 1 s depolarizing command steps from a holding potential of -80 mV. The dissociative anesthetic phenocyclidine (PCP) reversibly depressed 1_{ga} with an IC₅₀ of 7 μM. The inhibition of 1_{ga} was voltage-dependent so that the fractional block decreased at positive potentials. Analysis according to the method of Woodhull indicated that the PCP blocking site senses 56% of the transmembrane electrostatic field. Time-dependent activation, inactivation and deactivation of I_{8,8} were unaffected by PCP. Steady-state inactivation of the current showed an inverted U-shaped voltage dependence, similar to that observed in sympathetic neurons by Jones and Marks (J. Gen. Physiol. 94: 169-182, 1989), which is compatible with a 3-state cyclic model of channel gating (with rate constants depending only upon voltage). Kinetic modeling suggested that PCP acts specifically to slow the transition of the channel from the inactivated to the open state. Our data indicate that PCP produces a potent and specific block of voltage-dependent Ca²⁺ channels in mammalian CNS neurons, possibly by affecting a single step in the gating process.

[3H]-NIMODIPINE IDENTIFIES A LOW AFFINITY DIHYDROPYRIDINE BINDING SITE IN DEVELOPING CORTICAL ASTROCYTES. M.C. Howell 1, M.J. Litzinger² and H.S. White 1. 1Dept. of Pharmacol. & Toxicol. and ²Depts. of Biol., Physiol.and Pediatrics & Neurology, Univ. of Utah, S. L. C., UT 84108 Nimodipine has been shown previously to block K*-stimulated ⁴⁵Ca²⁺ influx in mouse cortical astrocytes in nanomolar concentrations thereby suggesting that astrocytes express a high affinity dihydropyridine receptor (Hertz et al., J. Neurosci. Res. 22(2):209,1989). Previous binding studies with [3H]nimodipine in mouse spinal cord astrocytes have only identified a low affinity binding site. The present study examined the developmental profile of [3H]nimodipine binding in cultured mouse cortical astrocytes. Results obtained from displacement studies identified the presence of a low affinity binding site (micromolar) throughout development (2 to 9 weeks in culture). Binding was maximal between 3 and 4 weeks in culture. This low affinity binding was also confirmed in 3 to 4 week old cultures using the dihydropyridine ligand [3H]-PN-200. These results are consistent with those of Bender and Hertz (Eur. J. P'Col. 110:287,1985).

Younger cultures displayed a greater sensitivity to displacement by unlabeled nimodipine than did older cultures. This observation would suggest that astrocytes are better able to regulate extracellular calcium concentrations during certain periods of development. Whether or not astrocytic regulation of extracellular calcium plays an important role in neurodevelopmental processes such as neurite extension which are dependent in part on extracellular calcium has yet to be elucidated but is worthy of further investigation. (Supported by NIH grant 2-RO1-NS-22200).

DIHYDROPYRIDINE EFFECTS ON NON-INACTIVATING CALCIUM CHANNELS IN CA1 NEURONS J. Black¹, J.F. Disterhoft², & J.Z. Yeh¹, Departments of ¹Pharmacology and ²Cell, Molecular, and Structural Biology, Northwestern University Medical School, Chicago, IL 60611, U.S.A. The dihydropyridine calcium channel antagonist nimodipine has been shown to enhance learning in aging rabbits tested in a hippocampally-dependent conditioning task (Deyo et al., 1989). Further, i.v. nimodipine administration to enhance learning in aging rabbits tested in a inprocampany-dependent conditioning task (Deyo et al., 1989). Further, i.v. nimodipine administration alters spontaneous firing of CA1 neurons recorded *in vivo* (Thompson et al., 1989). We have used whole-cell voltage-clamp techniques to test for a direct effect on Ca²⁺ channels of CA1 neurons. Acutely dissociated CA1 hippocampal neurons from young guinea pigs were prepared per Kay and Wong (1986). Extracellular recording solution contained (in mM): TAC-CI, 140; BaCIg., 3; MgCIg., 1; HEPES, 10, glucose, 6. Pipette solution contained (in mM): N-methyl-glucamine-CI, 110; EGTA, 5; MgATP, 5; HEPES, 10; phosphocreatine 10. Under these conditions CA1 cells exhibited a non-inactivating ('L-type') calcium channel current, which was activated at potentials more positive than -50mV, reaching peak at -20mV. This current was reversibly blocked to 80% of control by 10µM nimodipine (control vs drug paired t =-2.679, DF-6, p<-0.05). Nimodipine did not alter the apparent voltage-dependence of activation or inactivation of the Ba²⁺ current, but did reduce calculated peak Ba²⁺ permeability. In contrast, 10µM Bay K 8644 reversibly shifted the voltage-dependence of activation approximately 8mV in the hyperpolarizing direction (paired t =6.165, DF=5, p<0.01) and markedly prolonged the tail current. As a result of this shift, current during a pulse to -20mV was increased to 175% of control (paired t =6.562, DF=5, p<0.01). These results suggest that the dihydropyridines have direct effects upon These results suggest that the dihydropyridines have direct effects upon calcium channels in CA1 hippocampal neurons.

FUNNEL-WEB TOXIN BUT NOT ω -CONOTOXIN BLOCKS HIGH THRESHOLD Ca** CURRENTS IN INTERMEDIATE PITUITARY (IP). P.J. Williams, Q.J.Pittman, B.A MacVicar and *R.R. Llinas. Neuroscience Research Group, Univ Calgary, Calgary Canada, & *New York Univ Med Centre, New York, U.S.A.

We have previously identified three Ca** conductances in

cells of the IP based on their different activation and inactivation thresholds. We used single electrode voltage clamp and bath application of pharmacological agents to further characterize these currents in cells of the isolated intact intermediate pituitary. BAY K8644 $(1\mu M)$, a dihydropyridine agonist which increases current through L channels, produced an increase in the high threshold noninactivating current of 46 ±25% (mean ± S.D,n=4). Funnel-web spider toxin (FTX, 1:1000 dilution, Llinas et al, Ann N.Y. Acad Sci (1989) 560, 103) decreased the peak high threshold current by 49 ±26% (mean ±S.D,n=5). Effects were seen within 1 min after application of the toxin and were maximal after 6 min. Currents remaining after FTX were predominantly non-inactivating, indicating that FTX inhibited the high threshold inactivating current. In contrast to FTX, ω-conotoxin (5μM) had no effect on any of the currents, even after 20 minutes exposure. This suggests that the high threshold inactivating current may not be identical to the N channel described in SCG neurons but may be more similar to the P channel found in cerebellar Purkinje cells. Our results suggest the presence of three separate Ca** currents in IP cells having characteristics in common with T, L, and P channels.

HYDROXYPEREZONE ACTION ON GUINEA PIG PAPILLARY MUSCLE. X. García, E. Gijón and Alcántara*. Dept. Of Physiol. and Dept. of Pharmacol. Sch. of Med. Universidad Nacional Autónoma de México, Ap. P. 70-250, México, D.F. 04510. MEXICO. Perezone causes positive inotropic effect

on rat auricular muscle and increases its conon rat auricular muscle and increases its contraction duration. It increases auricular action potential duration and amplitude (Gijón, E., García, X. and Alcántara, G. Res. C. Nacl. Farmacol. 13:8, 1989). The purpose of this study was to know if the perezone isomer, hydroxyperezone shares some of the perezone properties, on 300 g Hartley male guinea pig papilary. muscles prepared for isometric and cellular recordings, they were electrically driven. Hydroxyperezone like perezone produces a positive inotropic effect and increases papila positive inotropic effect and increases papillary action potential duration, it may be observed an increase in threshold for electrical stimulation, with partial blockade 1:2. Action potential duration recovers and reduces up to 34% of control values, which hardly doubles with adrenaline. These results show that hydroxyperezone behave like perezone, it probably affect the papillary muscle by interfering with the calcium movement from the internal deposits and on the muscle membrane.

Voltage-dependence of μ -opioid inhibition of calcium channel current in SH-SY5Y cells. C. Hammond* G. Henderson* E.P. Seward.* and C. Kennedy.* Department of Pharmacology, University of Cambridge, Cambridge CB2 1QJ, U.K.

In the human neuroblastoma cell line SH-SY5Y μ-opioid receptor activation results in a G protein-mediated inhibition of the whole cell, peak inward N calcium channel current (Henderson and Seward, J_Physiol. 422: 19P,1990). The present experiments were designed to examine the voltagedependence of the opioid inhibition of the calcium channel

Inward calcium channel currents (carried by barium) or outward calcium channel currents (carried by caesium) were evoked by depolarising voltage steps from -90 to +10 or +100mV respectively. Both the inward and outward currents were markedly reduced by ω Conus toxin (1 μ M) and abolished by lanthanum (100μM). The μ-opioid agonist [D-Ala2, N-MePhe 4 ,glyol]enkephalin (DAMGO, 200nM) produced a marked inhibition (48 \pm 7%, mean \pm standard error, n=7) of the inward current but was ineffective in inhibiting the outward current. In addition to reducing the amplitude of the peak inward current, DAMGO also markedly reduced its rate of rise. There was no discernable effect of DAMGO on the rate of rise of the outward current. Taken together these results indicate that the opioid inhibition of the calcium channel current in SH-SY5Y cells is reversed by membrane depolarisation. (Supported by grants from the MRC)

PHARMACOLOGICAL EVIDENCE FOR A THIRD COMPONENT OF CALCIUM CURRENT IN RAT RETINAL GANGLION CELLS. H-S. Vincent Chen and Stuart A. Lipton. Dept. of Biol. Chemistry and Molec. Pharmacology, Harvard Medical School & Dept. of Neurology, Children's Hospital, Boston, MA 02115.

School & Dept. of Neurology, Children's Hospital, Boston, MA 02115. At least two types of unitary calcium channels have been identified in postnatal rat retinal ganglion cells (RGCs) (Karschin & Lipton, J. Physiol. 1989;418:379): a T-type and an L-type [dihydropyridine (DHP)-sensitive]. However, the existence of an N-type channel, a major component of calcium current in other neurons, is still unclear. In isolated rat RGCs, we used the whole cell patch-clamp method with the DHP agonist (+)-(S)-202-791 (1 μM) and synthetic ω-conotoxin (ω-CgTx; 10 μM, Peninsula) to separate the various components of calcium current (Plummer et al., Neuron 1989;2:1453). In 16 of 22 RGCs (73%), ω-CgTx irreversibly blocked the peak Ba²⁺ current (I_{Ba}) by 10-30% but did not affect tail currents prolonged by the DHP agonist. The 30% but did not affect tail currents prolonged by the DHP agonist. The irreversible block of a component of I_{Ba} suggests the existence of an N-type component. Approximately 20% (3/16) of the ω -CgTx-sensitive cells had an additional I_{Ba} component that was blocked reversibly; in 27% (6/22) of the RGCs, ω -CgTx had no effect. In some cells, the DHP agonist dramatically prolonged the tail current but only modestly increased the peak current even after ω -CgTx block. Furthermore, in these same cells the current remaining after block by ω -CgTx was mostly inactivated at a holding potential of -40 mV. Since N-type current is largely inactivated by this voltage protocol, the current remaining after ω -CgTx block in these cells was probably mostly N-type. We conclude that at least some rat RGCs have a third component (probably N-type) of Ca current a portion of which is insensitive to ω -CgTx Ca current, a portion of which is insensitive to ω-CgTx.

DIFLUNISAL ACTION ON PAPILLARY MUSCLE FROM THE GUINEA PIG. E. Gijón, E. Castillejos* and García, X. Dept. of Physiol. Sch. of Med. Universidad Nacional Autónoma de México, Ap. P. 70-250, México, D.F. 04510. MEXICO.

Diflunisal causes a contraction followed by a relaxation in intestinal muscle (Gijón, E., Castillejos, E. and García, X. Abs. Soc. Neurosc. 14(2):1072(432.13), 1988). Diflunisal decreases the transport rate and calcium accumulation by the sarcoplasmic reticulum (Holouín. decreases the transport rate and calcium accumulation by the sarcoplasmic reticulum (Holguín, J.A. <u>Biochem. Pharmac.</u> 37(21):4035-4040, 1988). Diflunisal acting as a calcium ionophore would induce positive inotropic effects in cardiac muscle. Papillary muscles from 350 g Hartley male guinea pig were prepared for isometric and intracellular recordings, they were electrically driven. It is shown that diflunisal 0.39 mM, from Merck Sharp and Dohme de México, causes a positive inotropic effect. a decrease in a positive inotropic effect, a decrease in basal muscle tension and an increase in action potential duration, followed by a negative inotropic effect, an increase in basal muscle tension and a decrease in action potential duration and amplitude. These results suggest a calcium ionophore action of diflunisal at the cardiac muscle membranes.

PHARMACOLOGICAL ANALYSIS OF CALCIUM CURRENTS IN IDENTIFIED EMBRYONIC MOUSE MOTONEURONS. M. Mynlieff and K.G. Beam. Dept. of Physiology, Colorado State Univ., Fort Collins, CO 80523.

The application of calcium channel antagonists at the neuromuscular junction has been used by other investigators to attempt to identify specific calcium channels involved in neurotransmitter release.

junction has been used by other investigators to attempt to identify specific calcium channels involved in neurotransmitter release. There is relatively little known, however, about the specificity of these calcium channel antagonists in motoneurons. The purpose of this study was to determine the specificity of various calcium channel antagonists and agonists on E14 mouse motoneuron calcium currents. Motoneurons were identified by retrograde labelling with the carbocyanine dye dil prior to dissociation. Voltage clamp "whole-cell" patch recording was used to measure calcium currents 24 hours after dissociation. Previous work in our laboratory has shown that the motoneurons possess 3 different calcium currents which can be distinguished on the basis of kinetics and voltage dependence. There was a low-voltage-activated transient current, with characteristics similar to the T current described in sensory neurons, as well as a high-voltage-activated (HVA) transient current and an HVA current which was sustained for at least 200 ms. Amiloride (1-2 mM) caused a ~50 % block of the T current without affecting the HVA currents. Sandoz +202-791 (100 nM - 2 uM), a dihydropyridine agonist, specifically increased the sustained component of the HVA current and shifted its activation to more negative potentials (10 mM barium as charge carrier). Thus, L-type channels contribute to the sustained current. Omega-conotoxin GVIA (10 uM) blocked the T current 90.1 ± 4.9% (n=7), the HVA transient current 75.8 ± 3.7% (n=8), and the HVA sustained current 68.4 ± 5.0% (n=8). Supported by NIH grant NS-26416 to KGB and NIH fellowship NS-08769 to MM.

HALOTHANE BLOCKS LOW-VOLTAGE-ACTIVATED CALCIUM CURRENTS IN RAT SENSORY NEURONS. M. Takenoshita*

Washington U. Sch. Med., St. Louis, MO 63110.

Volatile anesthetics may act by blocking at least some neuronal voltage gated calcium currents (I-Ca; Krnjevic and Puil, Can J Phys Pharm, 66, 1570). We studied I-Ca in dissociated neonatal rat doreal root grapiling colls (Schrooder et al.) 1570). We studied I-Ca in dissociated neonatal rat dorsal root ganglion cells (Schroeder et al, J Neurosci, 10, 947). Cells were whole-cell voltage clamped 12-24 hours after dissociation. Halothane (HAL) was applied from a closed perfusion system; bath concentrations were assayed by gas chromatography. Low-voltage-activated I-Ca (LVA I-Ca; I-Ca elicited at -30mV from a potential of -80mV) was reversibly blocked by low concentations of HAL (EC50 of 50-100 \(mu\)M). The block developed within 10 sec of application of HAL but often within 10 sec of application of HAL, but often required several minutes for reversal. The block by HAL apparently did not result from a shift in the voltage dependence of inactivation nor of activation for LVA I-Ca. Isoflurane was slightly activation for LVA 1-Ca. ISOTIUTAINE WAS SITURILY less effective on a molar basis than HAL, but produced qualitatively identical effects. High-voltage-activated I-Ca (I-Ca at +20mV from -80mV) was less strongly blocked by HAL or isoflurane in these experiments. Estimated clinically effective concentrations of HAL are 200-800 µM.

DORS ${
m H_2O_2}$ DECREASE I_{Ca} BY REGULATING [Ca]_i IN LOBSTER NEURONS? R.S. Hernandez, R.J. Lowy, D.A. Miller, D.R. Livengood. Physiol. Dept., AFRRI, Bethesda, MD 20814.

Free radical damage is implicated in such pathological ree ractical damage is implicated in such pathological insults as toxins, reperfusion injury, and radiation exposure. H₂O₂ is an active oxygen compound that can generate free radicals. We previously reported that H₂O₂ blocks I_{Ca} by 50-100% in the lobster cardiac ganglion. We proposed that an increase in [Ca]₁ was responsible (Biop. J. 53: 555a, 1988). Neurons #1 and #2 of the ganglion were ligated and bathed in lobster seline with TEA, 4-AP, and TTX at $18^{\circ}C$ for 30 min., followed by superfusion with 3.5 mM $\rm H_2O_2$ added to the m.in., followed by supertusion with 3.5 mm $n_2 v_2$ added to the saline for 30 min., and then washed with control saline. Using a 2-electrode voltage clamp to measure I_{Ca} , we observed that the block developed within 10-15 min. and progressed with time. In parallel experiments [Ca]₁ levels were progressed with time. In parallel experiments [ta]; levels were determined by pressure injecting cells with the Ca sensitive dye Fura-2 (free acid pentapotassium salt). Fluorescence changes were quantified using a low-light-level video microscope and image processing system. Perfusion with H₂O₂ saline for 30 min. failed to alter [Ca]; from control values. Cells and dye responded to 100 mM KCl saline exposure, resulting in the expected large reversible increase in [Ca]₁. In vitro exposure of Fura-2 acid to hydroxyl free radical generating conditions failed to alter the amount or Kd of the dye. These results provide evidence that $[{\tt Ca}]_i$ does not increase during the same free radical treatment conditions that result in ICa block.

219.17

GADOLINIUM NON-SELECTIVELY BLOCKS BOTH N-TYPE AND L-TYPE CALCIUM CHANNELS. T.A. Brown, L.M. Boland, and R. Dingledine. Dept. Pharmacology, Univ. North Carolina-Chapel Hill and Dept. Neurobiology, Harvard Medical School, Boston, MA, 02115.

The effect of gadolinium (Gd) and other lanthanides on voltage-activated barium (Ba) currents in a rat dorsal root ganglion (DRG) cell line (F11-B9), rat and frog DRG neurons, and rat atrial and ventricular myocytes was studied using the whole-cell patch clamp technique. In contrast to the Gdresistant current reported for NG108-15 cells (Docherty, J. Physiol., 398: 33-47, 1988), all current components in these cells could be completely inhibited in a dose-dependent manner by Gd. F11-B9 cells express two current components (sustained and transient) which are both blocked by Gd. The dihydropyridine-sensitive sustained current component (30 mM Ba) was maximally blocked by 30 μ M Gd with an IC50 of 0.36 μ M, and the dihydropyridine-insensitive transient component was maximally blocked by 30 μ M Gd with an IC50 of 0.95 μ M. Complete block of rat and frog DRG currents (5 mM Ba), which consist of both Ω -conotoxin- and dihydropyridine-sensitive components, was achieved with 1 µM Gd. L-type current from atrial and ventricular myocytes (5-10 mM Ba) could also be abolished with 1 µM Gd. Other lanthanide cations also blocked all Ba currents in F11-B9 cells. Lutetium blocked all of the sustained and transient current at 100 μ M with IC50s of 0.31 μ M and 1.26 μ M, respectively. Lanthanum provided complete block of the sustained current at 10 μ M with an IC50 of 0.14 μ M and of the transient current at 100 μ M with an IC50 of 1.73 μ M. These findings suggest that Gd blocks both N-type and L-type currents. (Supported by NS23804)

METHYLMERCURY BLOCKS CURRENTS MEDIATED BY VOLTAGE-DEPENDENT Ca CHANNELS IN NERVE GROWTH FACTOR-DIFFERENTIATED PHEOCHROMOCYTOMA CELLS. <u>T.J. Shafer and W.D. Atchison</u> Dept. of Pharm./Tox. and Ctr. for Environ. Tox., Michigan State Univ., E. Lansing, MI

The effect of the neurotoxic organic heavy metal methylmercury (MeHg) on Ca channels was examined by measuring effects of MeHg on currents carried by 20 mM Ba in pheochromocytoma (PC12) cells using whole cell patch voltage-clamp. Cells cultured in the presence of nerve growth factor for 3-5 days exhibited voltage-dependent currents containing inactivating and non-inactivating exhibited voltage-dependent currents containing inactivating and non-inactivating components in response to depolarizing voltage steps from a membrane holding potential of -70 mV; the non-inactivating component was not observed during depolarizing steps from a holding potential of -40 mV. The non-inactivating component of current accounted for approximately 10% of the total current observed. Peak current amplitudes were observed following voltage steps to +10 mV from a holding potential of -70mV. Addition of 40-100 µM MeHg to the recording medium resulted in a rapid block of inactivating and non-inactivating Ba currents which was apparent after 10-15 sec and complete within 1 min. Within this concentration range and duration of exposure, MeHg did not cause alterations in the membrane capacitance nor alter nonspecific leak currents in FC12 cells. These results indicate that PC12 cells cultured in nerve crowth factor. PC12 cells. These results indicate that PC12 cells cultured in nerve growth factor for 3-5 days may contain two types of Ca channels, and that MeHg reduces inactivating and non-inactivating Ba currents by interacting with voltage-dependent Ca channels in PC12 cells, not by disruption of membrane electrical properties. (Supported by NIH grant ES03299; TJS is the recipient of a Student Fellowship sponsored by Hoffman-LaRoche, Inc.)

H2O2 BLOCKS ICA IN LIGATED LOBSTER NEURONS AT SITES REMOTE FROM THE SOMA. D.A. Miller, R.J. Lowy, R.S. Hernandez, and D.R. Livengood. Physiol Dept., AFRRI,

We have previously reported that H2O2, a model for free radical damage, produces a time and concentration dependent block of the early inward calcium current (I_{Ca}) in ligated neurons of the lobster cardiac ganglion (Biophys. J. 53: 555a, 1988). In the present study, the anterior two giant neurons were ligated approximately 0.3 mm from the soma. TTX,TEA were ligated approximately 0.3 mm from the soma. TTA, FEA and 4-AP were used to block Na and K currents. $I_{\rm Ca}$ evoked in response to voltage steps to -20 mV or greater from a holding potential of -50 mV was without initial delay. However, with voltage steps to -45 or -40 mV from holding potentials of both -50 and -80 mV, $I_{\rm Ca}$ had a delayed time of onset and frequently had two or more components, suggestive of one or more remote, non-space clamped loci of origin of I_{Ca} . 3.5 mM H_2O_2 produced a progressive time dependent block of I_{Ca} without appreciable alteration of the shape or time of onset. Subsequent to electrical measurements, so me neurons were pressure injected with Lucifer Yellow (1% in 200 m M KCl) and examined using a low-light-level video microscope and image processing system. Simultaneous viewing of bright field and fluorescent images showed that dye was untraceable past the axon ligature but was present in a number of fine "dendritic" processes. The dendrites are suggested as a possible remote, non-spaced clamped locus for the H₂O₂ sensitive I_{Ca}.

CALCIUM CHANNEL BLOCKING ACTIONS OF CHARGED AND UNCHARGED

CALCIUM CHANNEL BLOCKING ACTIONS OF CHARGED AND UNCHARGED MERCURIALS IN RAT FOREBRAIN SYNAPTOSOMES. S.J. Hewett, M.E. Welke and W.D. Atchison. Dept. Pharm./Tox., Mich. State Univ., E. Lansing, MI 48824. The relative blocking efficacy of methylmercury (MeHg), ethylmercury (EtHg), divalent mercury (Hg^{2*}), dimethylmercury (2MeHg), p-chloromercuribenzoate (PCMB) and p-chloromercuriphenylsulfonate (PCMB) on Cg^{2*} in fliux into rat forebrain synaptosomes was assessed to provide information as to the mechanism(s) by which mercurials interact with membrane Ca channels. Sc^{2*} uptake into synaptosomes was measured after 1. ("East inactivation phase") and 10. forebrain synaptosomes was assessed to provide information as to the mechanismis(s) by which mercurials interact with membrane Ca channels. 45 Ca 24 uptake into synaptosomes was measured after 1 ("fast, inactivating phase") and 10 ("total") sec of depolarization by 77.5 mM KCl and during 10 sec of depolarization into synaptosomes that were previously depolarized for 10 sec in the presence of 77.5 mM K' but no external Ca ("slow, noninactivating phase"). In the range tested (10-500 μ M), total uptake, as well as the "fast" and "slow" components of "Ca" influx into synaptosomes, were blocked in a concentration-dependent manner by MeHg, EtHg and Hg $^{\prime\prime}$ (> 10 μ M). In contrast, 2MeHg, PCMB, and PCMBS (10-500 μ M) caused no appreciable reduction in any phase of uptake. To characterize the interaction of charged mercurials with nerve terminal Ca $^{\prime\prime}$ channels, experiments were designed to determine whether charged mercurials blocked Ca $^{\prime\prime}$ channels in a voltage-dependent manner. The magnitude of depolarization caused by each K' concentration and thus the voltage-dependence of influx was estimated by incubating synaptosomes for 2 sec in Na-free K' solutions (5mM-60mM) containing 1 μ Ci $^{\prime\prime}$ E- inecurials (100 μ M). Of the three mercurials tested (MeHg, EtHg, Hg $^{\prime\prime}$), only MeHg blocked uptake of 50 Ca $^{\prime\prime}$ in a voltage-dependent manner. Uptake in synaptosomes exposed to 100 μ m MeHg was reduced significantly from controls at all K' concentrations tested with a clear voltage-dependence of block being exhibited between 5 and 50mM KCl. In addition, uptake in 37.5 and 50 mM K' was significantly reduced from uptake in 5 mM K'. Thus mercurials of dissimilar charge and lipophilicity, differentially affect 45 Ca $^{\prime\prime}$ influx into the synaptosome and likely have different mechanisms of action at synaptosomal membranes. (Supported by NIEHS grant ES03299.)

LEAD BLOCKS VOLTAGE GATED CALCIUM CHANNELS OF CULTURED DORSAL ROOT GANGLION NEURONS. M. L. Evans. D. Büsselberg.
C. Trautman and D. O. Carpenter. Wadsworth Labs and
School of Public Health, Albany, NY 12201 and Johannes
Gutenberg University Mainz, D-6500 Mainz, FRG.
We have previously demonstrated Pb²⁺ to be a potent and
reversible blocker of voltage dependent calcium currents

in Aplysia neurons, and now report similar effects in mammalian neurons. Dorsal root ganglion cells were cultured from neonatal rats and used for whole cell patch clamp recordings after 1 to 10 days in culture. Calcium clamp recordings after 1 to 10 days in culture. Calcium channel currents were recorded in the following external solution (mM): TEA Cl 130, HEPES 10, glucose 10, BaCl₂ 10, MgCl₂ 1, TTX 0.02. A cesium based internal solution containing 2 mM ATP was used. Depolarizing steps of 80 mV applied for 100 ms from a holding potential of -80 mV activated a calcium channel current with both activating and non-inactivating components. Pb^{2*} produced a dosedependent reduction of the current amplitude with threshold less than 0.2 μM and greater than 95% reduction at 20 μM . The IC $_{50}$ was 0.64 μM . The block reached a steady state within 2 min and was partly reversible after Steady state within 2 min and was partly reversible after 5 min wash. Over the 100 ms duration of the current the degree of time dependent inactivation was greater in Pb²⁺. The current voltage relationship for the peak current was not altered by Pb²⁺ at 0.5 μ M. Voltage dependent sodium but not potassium currents were reduced by about 5% at 2 $\mu M \ Pb^{2+}.$

A VOLTAGE-INDEPENDENT, DIVALENT-SELECTIVE ION CHANNEL IS BLOCKED BY INTRACELLULAR MAGNESIUM. J. A. Strong, Dept. of Biol. Sci., Purdue Univ., W. Lafayette IN 47907.

Previous reports 1-2 have described a voltage-indepen-

Previous reports 1-2 have described a voltage-independent, 24 pS divalent-selective ion channel in neurons of the mollusc Lymnaea. Though present in high density the channel rarely opens during cell-attached recording (using 45 mM Ba as the charge carrier) but is unmasked by formation of a cell-free patch. I now report that application of 1 mM Mg to the cytoplasmic face of cell-free patches causes a complete, rapid, reversible block of this channel. A partial block is seen in 0.1 mM Mg, which enhances long channel closings without affecting the size or duration of openings. Hence, Mg may be the physiological substance which normally inhibits the channel (based on values of intracellular Mg measured in other cells). Selectivity experiments show that the size of the single channel current saturates at relatively low concentrations of extracellular Ba. In the range of 5-15 mM Ba, the size of the single channel current increases with increasing Ba, and is independent of the monovalent cation present (Na or TRIS). In some experiments a second, smaller Mg-sensitive channel is also seen, which may be analogous to a Mg-sensitive, non-specific cation channel recently described in lobster neurons 3. TRIVALENT LANTHANIDES BLOCK MULTIPLE CALCIUM CHANNELS IN SECRETORY CELLS. B.A. Biagi, and J.J. Enyeart. Departments of Physiology and Pharmacology, The Ohio State University, Columbus, OH 43210.

Several types of voltage gated calcium channels have been identified in endocrine and neuroendocrine secretory cells. These channels differ in their sensitivity to inorganic Ca²⁺ antagonists. We have studied the effects of the trivalent lanthanides, gadolinium (Gd³⁺) and lanthanum (La³⁺), on whole cell calcium currents in rat pituitary GH₄C₁ and rMTC6-23(clone 6) thyroid C-cell lines. In both cell types, 5 μ M Gd³⁺ completely blocked T-type Ca²⁺ currents in a reversible manner. In comparison, 5 μ M Ni²⁺ inhibited T-type current by 12% while 50 μ M produced a 60% block. Block of L-type Ca²⁺ current was promoted by channel activation. With long depolarizing test pulses, 200 nM Gd³⁺ inhibited L current completely. Other trivalent cations, including lanthanum and yttrium, blocked both currents with similar characteristics and potency. In C cells, a third current component with characteristics of N-type Ca²⁺ channels was also blocked by the trivalents. These results indicate that Gd³⁺ and other related trivalent cations are nonselective inhibitors of low and high threshold Ca²⁺ channels in endocrine and neuroendocrine cells. In this respect, they are among the most potent inorganic Ca²⁺ antagonists yet discovered.

SEX DIFFERENCES IN THE REGULATION OF OXYTOCIN RECEPTOR BINDING BY OVARIAN STEROIDS IN THE VENTROMEDIAL HYPOTHALAMIC NUCLEUS OF THE RAT. H. Coirini. A.E. Johnson. M. Schumacher and B.S. McEwen. Lab of Neuroendocrinology, The Rockefeller University, New York, NY 10021 and SCSBB/LCS, NIMH, Poolesville, MD 20837.

The facilitation of sexual receptivity by oxytocin is related to the regulation of oxytocin receptors (OTR) in the ventromedial nucleus (VMN) by ovarian steroids. In female rats, estradiol benzoate (EB dramatically increases OTR binding in this brain region while progesterone (P) not only modulates binding by also increases the area occupied by OTR. In a previous study, we showed that while males are relatively insensitive to the facilitative effects of EB and P on sexual receptivity, they are equally sensitive to EB with respect to the induction of [²H]-Oxytocin binding in the VMN (Neuroendocrinology 50:193, 1989) In the present study, we compared the effects of P on OTR binding in male and female rats primed with EB to determine if sex differences in the regulation of OTR by P are related to these behavioral differences.

Adult male and female rats were gonadectomized and adrenalectomized and were treated one week later for two successive days with either 10 µg EB or oil. Forty four hours later, half of the EB treated animals were injected with P (0.5 mg) and the others with vehicle. All the animals were killed 4 hrs later and brain prepared for labelling with 1251-OVTA (a ligand of high affinity and selectivity for OTR) using autoradiographic methods. In agreement with a previous study, P increased the region of OTR binding in and around the VMN in EB primed females (Proc Natl Acad Sci, 86.6798, 1989). However, P did not alter the distribution of OTR in males. These results suggest that the relative insensitivity of males to ovarian hormones with respect to the induction of sexual receptivity may be related to sex differences in the modulatory effects of P on OTR binding.

MEAL-DEPENDENT CHANGES IN CENTRAL BOMBESIN RECEPTORS C. Kateb¹, Z. Merali^{1,2}, G. Fouriezos.¹. ¹School of Psychology and ²Department Pharmacology, University of Ottawa, Ottawa, Ontario, K1N 6N5.

The objective of this experiment was to explore the possibility that changes in bombesin (BN)-receptor binding may be an important variable in the satiety response. Male Sprague-Dawley rats (300-350 g) were used for this experiment. Pairs of animals were food deprived for 12 hr and only one from the pair allowed to eat ad libitum for a period of 35 min. One pair was processed per day until n = 8 in both the pre- and post-prandial groups. Animals were sacrificed, brains rapidly removed and frozen. Fresh-frozen brains were sliced from interaural 14.2 mm to 2.96 mm, (16 um thickness) and processed for <u>in vitro</u> autoradiography, using a buffer containing ¹²⁵I-Tyr⁴-BN (9000 cpm/50 ul buffer). Brain slices were applied, in pre- and post-prandial subject pairs to Amersham (RPN.10; Arlington, Illinois) Hyperfilm-pmax film. Quantitative analysis of the autoradiography films was performed using ¹²⁵I standards cross-calibrated with ¹⁴C standards (Baskin et al, 1989), and an image analysis system (MCID; Imaging Research Inc., St. Catherines, Ontario, Canada). T-Test for correlated samples was used to analyze this data. Our results indicate a generalized increase in receptor density postprandially, although statistically significant (p < .05) increases were discovered in hypothalamic nuclei (medial preoptic area; periventricular nuclei), cingulate and rhinal cortical areas, fundus striatum, central amygdaloid nucleus, vertical limb of the diagonal band, septal hippocampal nuclei and, most notably, within the hippocampus and nucleus accumbens (p<.005). Thus, BN receptor binding characteristics can change rather rapidly in relation to the feeding state. If increased binding does reflect increased sensitivity then these data indicate that rats become more sensitive to the peptide effects post-prandially; a suggestion which would support BN's suggested role as a satiety peptide. (This research was supported by grants from NSERC and MRC)

220.2

ESTROGEN INCREASES OXYTOCIN RECEPTOR AFFINITY IN THE MEDIAL PREOPTIC AREA. <u>Pedersen.</u> C. A., Walker, C. H., Mason. G. A. and Caldwell, J. D.; Dept. of Psychiatry and BDRC, School of Medicine, Univ. of North Carolina, Chapel Hill, NC. 27599-7250

In this study we used a radiolabelled OXT analogue (OTA), ornithine-vasotocin, to study OXT receptor dynamics in the medial preoptic area-anterior hypothalamus (MPOA-AH), medial basal hypothalamus (MBH) and hippocampus of ovariectomized rats injected im once daily for three days with an oil vehicle or with 0.5 ug or 5 ug estradiol benzoate (EB). We found that, at a concentration of 0.1 nM $^{125}\text{I-OTA}$, membranes from animals treated with 5 ug EB showed significantly more binding than did membranes from oil treated controls. Scatchard analyses showed that the 5 ug EB dose signi-ficantly increased OXT receptor affinity over oil vehicle controls in membrane fractions taken from the MPOA-AH (Kp = 0.21 $^{\pm}$.01 nM for controls versus Kp = 0.12 $^{\pm}$.01 for 5 ug EB); similar changes in binding affinity in the MBH were not significant. There were no changes in binding affinity in hippocampal tissue across estrogen treatments. There was a significant reduction in receptor densities in the MPOA-AH (Bmax's were 17.1 fmol/mg protein $^{\pm}$ 1.6, 12.5 $^{\pm}$.9 and 11.9 $^{\pm}$ 1.0 for oil, 0.5 ug and 5 ug EB, respectively); with a similar but non-significant decrease in the MBH. OXT and a utgentonic antagonist analogue PM-OXT both competed with $^{125}\text{I-OTA}$; however, the OXT metabolite OXT4.9 had no effect. MPOA-AH OXT receptors may mediate the receptivity facilitating effects of central OXT.

220.4

DISTINCT DISTRIBUTION OF BOMBESIN AND NEUROMEDIN B BINDING SITES IN THE RAT BRAIN. E.E. Ladenheim. R.T. Jensen*, S.A. Mantey*, P.R. McHugh and T.H. Moran. Dept. Psychiatry, Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205 & NIDDKD, NIH, Bethesda, MD 20892.

Bombesin/gastrin releasing peptide (BBS/GRP) and neuromedin B (NMB) are structurally related compounds which are biologically active in the rat central nervous system. Despite their similarity, differences in their regional distribution and bioactivity suggest that they may possess separate receptor populations. In order to investigate this possibility, we examined the regional distribution of binding sites for 125i-[Tyr4]BBS and 125i N-D-Tyr-NMB in the rat brain using receptor autoradiography. Our results indicate that the distribution of BBS binding sites is distinct from that of NMB. In the forebrain, NMB binding sites were observed in the olfactory bulbs, dentate gyrus, pyriform cortex, septum and thalamic nucleus accumbens, hippocampus, median preoptic nucleus, arcuate nucleus, median emminence and paraventricular nucleus. Binding differences were also observed in brainstem structures. NMB binding sites were located in the interpeduncular nucleus, dorsal raphe nucleus and the nucleus of the solitary tract. BBS binding sites were seen in the central gray and the caudal aspect of the spinal trigeminal nucleus. The differences in the distribution of binding sites for BBS and NMB suggest that they may function as distinct neuropeptides in the rat central nervous system.

REFECTS OF ALKYLATING AND REDUCING AGENTS ON NEUROTENSIN BINDING TO PORCINE BRAIN MEMBRANE RECEPTORS. S.P. Mitra, R.B. Carraway and C.F. Ferris. Dept. of Physiology, Univ. of Massachusetts Med. Ctr., Worcester, MA. 01655.
The importance of sulfhydryl (-SH) & disulfide (S-S) groups in the binding of ¹²⁵I-labeled neurotensin (NT) The importance or surface of 125 Labeled neurotensin (NL) to porcine brain membranes was investigated at 4 C. Pretreatments (1 hr, 4 C) with reducing agents e.g., dithiothreitol (DTT), enhanced binding by ~2-fold (ED₅₀, 10 µM), whereas alkylating agents e.g., 10μ M), reduced binding (ED₅₀, 10μ M) (EU₅₀, 10µM), whereas alkylating agents e.g., N-ethyl-maleimide (NEM), reduced binding (ED₅₀, ~100µM), even when washed away. This appeared to result from alterred receptor function since the stability of 1251-labeled NT was not changed. Scatchard analysis indicated that 1 mM DTT increased by ~60% and 2 mM NEM decreased by ~40% the number of high affinity (Kd,~0.4 nM) and low affinity (Kd,~10 nM) high states with the labels of the control of the co nm) binding sites with little effect on the Kd's. The additional receptors gained by exposure to DTT were not sensitive to NEM unless pretreated with DTT, suggesting that reduction of S-S in latent receptors gave active receptors with -SH. Preincubation of receptors with 10 nM NT prior to treatment with NEM blocked the inhibitory effect on NEM on binding, suggesting that the critical -SH group(s) were located at the NT-binding site. These findings are consistent with the idea that -SH group(s) within the binding pocket of the NT-receptor have critical role(s) in the binding reaction. NIH DK28565.

CGRP BINDING SITES IN THE NUCLEUS ACCUMBENS: ONTOGENIC APPEARANCE, PHARMACOLOGICAL PROFILE AND PHYLOGENIC DIFFERENCES. T.Dennis', A.Fournier', S.Guard', S.St Pierre', R.Quirion'. 'Douglas Hospital Res. Ctr. & Dept. of Psychiatry, McGill University, Mortreal, Canada, H3A 141. 'INRS-Santé, Pointe Claire, P.Q., Canada.

Autoradiographic studies have previously demonstrated high densities of [128][GGRP binding sites in rat nucleus accumbens (Sexton et al., Neurochem [121.142323, 1999)]. While the psychological effects of this provided are

Ind., 12:323, 1988) while the neurobehavioral effects of this peptide are suggestive of a possible modulatory role on dopaminergic neurons (Jolicoeur et al., Reg. Peptides, submitted, 1990).

We now report that the use of quantitative autoradiography showed that

et al., <u>New Pepinoes</u>, submitted, 1990).
We now report that the use of quantitative autoradiography showed that [128][hCGRPα binding sites in rat n. accumbens rapidly increased in density between postnatal days 4 and 14. Furthermore, regional competition studies in adult rat brain showed that salmon calcitonin was almost as effective as hCGRPα in competing for [128][hCGRPα binding sites in n. accumbens but was without affinity in other regions such as the mesolimbic cortex confirming the existence of atypical CGRP sites in the n. accumbens. Marked species differences in [128]hCGRPα binding were observed in n. accumbens. In the rat, a high density of labelling was seen in the medial posterior region of n. accumbens, while low levels were found in striatum and fronto-parietal cortex. Similar distributions, of varying densities, were observed in mice and guinea pig. Very high densities of CGRP sites were observed in rabbit n. accumbens, caudate nucleus and putamen, while low levels were present in cortex. Very high densities of [128][hCGRPα binding sites were localized throughout the basal ganglia and cortical ribbon of pig brain. In both monkey and human brain, only very low densities of specific binding sites were seen in n. accumbens and surrounding structures. Thus, marked species differences are apparent. This may have physiological and behavioral implications.

behavioral implications.

HIGHLY POTENT GROWTH HORMONE-RELEASING FACTOR

HIGHLY POTENT GROWTH HORMONE-RELEASING FACTOR (GRF) ANALOGS AND ENZYMATICALLY CLEAVED FRAGMENTS: CORRELATION BETWEEN RECEPTOR BINDING AND ACTIVITY. T.F. Mowles*, Y. Lee*, J. Rivier*, A.B. Davidson and R.M. Campbell*. Dept. of Animal Science Research, Hoffmann-La Roche Inc, Nutley, NJ 07110.

Scatchard analysis of [His¹, ¹25¹-Tyr¹0, Nle²7]-hGRF(1-32)-NH₂ binding to rat anterior pituitary homogenates indicates a single high affinity class of receptors (54.40 ± 12.68 fmol/pituitary; Kq = 202 ± 27 pM). Binding of [His¹, ¹25¹-Tyr¹0, Nle²7]-hGRF(1-32)-NH₂ was highly specific, as homologous (secretin, glucagon, VIP and PHI [1-27]) and non-homologous (SRIF[1-14], TRH, bGH) peptides (≤ 1 μM) did not displace the bound radioligand. With all hGRF analogs examined, *in vitro* GH-releasing activity was directly correlated with GRF receptor binding affinity. Deamination of Tyr¹ did not examined, in vitro off-recessing activity was unexty contented when GRF receptor binding affinity. Deamination of Tyr¹ did not significantly affect hGRF(1-29)-NH₂ binding, while D-Ala² (replacement of L-Ala²) increased affinity ≈2-fold. hGRF(1-29)-NH₂ analogs with Ala¹5-substitution (for Gly¹5) displayed 4-5 times higher analogs with Alar-substitution (for Giy¹⁻³) displayed 4-5 times higher affinity for the GRF receptor relative to hGRF(1-44)-NH₂. Replacement of Gly¹⁻⁵ with Sar¹⁻⁵, known to disrupt helix formation, resulted in a dramatic loss of GH-releasing activity and receptor binding. The present data supports the proposal that Ala¹⁻⁵-substitution increases receptor affinity, and hence potency, due to increased amphiphilic a-helical interactions. Furthermore, hGRF(1-44)-NH₂ and hGRF(1-20) NH₄ fragments representative of placema DRP IV and hGRF(1-29)-NH₂ fragments, representative of plasma DPP IV and trypsin-like cleavage products, are virtually inactive *in vitro* as a consequence of greatly diminished binding to the GRF receptor.

FURTHER CHARACTERIZATION OF NEUROTENSIN RECEPTORS IN MICE BRED FOR DIFFERENCES IN SENSITIVITY TO ETHANOL. A.D. Campbell, B.C. Jones, and V.G. Erwin. Alcohol Research Center, School of Pharmacy, University of Colorado, Boulder, CO 80309.

The tridecapeptide neurotensin (NT) is widely distributed in brain and may serve as a neurotransmitter or neuromodulator in systems affected by ethanol. Studies in this laboratory have shown that NT produces a dosedependent increase in ethanol sensitivity in SS but not LS mice, which were selectively bred for their differences in sensitivity to ethanol. Our studies have shown B_{max} values for ³H-NT binding to be greater in SS mice in every brain region assayed. Scatchard analysis revealed two distinct binding sites for NT (K_D 's 0.3 and 5 nM), and the histamine (H_1) antagonist levocabastine appeared to inhibit NT binding to the low affinity (NTL) form of the receptor. Scatchard analysis in the presence of 50 μ M levocabastine revealed one site , with K $_{\rm D}$ and B $_{\rm max}$ values similar to the high affinity form (NT $_{\rm H}$) of the receptor. Using levocabastine, we characterized $^3{\rm H-NT}$ receptor binding in nine brain regions. Significant regional differences in both NTH and NTI receptors were found between LS and SS mice. Furthermore, we observed line differences in the ratio of NTH and NTI receptors in several brain regions, including entorhinal cortex and caudate putamen. The differences in the NT receptors between brains of LS and SS mice further support the role of NT in ethanol actions. (Supported by NIAAA Grants Number 003527, 00079 and 07330).

BRADYKININ RECEPTORS EXPRESSED IN XENOPUS OOCYTES. A.E. McEachern, E. Shelton*, K. Jamagin* and R.W. Aldrich, Dept. of Molecular and Cellular Physiology, Stanford University, Stanford, CA 94305 and Syntex Research, Palo Alto, CA 94304.

Stanford, CA 94305 and Syntex Research, Palo Alto, CA 94304.

Activation of bradykinin receptors (BKR) elicits phosphoinositide turnover and increases in intracellular Ca⁺⁺. We have expressed BKRs by injecting poly A⁺ mRNA derived from a number of tissue sources into Xenopus oocytes. BK-induced inward Ca⁺⁺-activated Cl⁻currents were measured by two electrode voltage clamp. Only rat uterus mRNA produced large, consistent responses 2-4 days after injection. Responses had lag times after BK application on the order of seconds and generally included a fast, transient component followed by a generally included a fast, transient component followed by a slower current upon which fast oscillations were often slower current upon which fast oscillations were often superimposed. Guinea pig ileum mRNA produced a smaller response. mRNA from many tissues and cell lines gave very small and inconsistent responses (<10 nA): rat neural tissue (olfactory bulb, midbrain, cerebellum, first cervical dorsal root ganglion), guinea pig brain, and HSD-1, PC12-BK, NG108, and MDCK cell lines. mRNA from rat thalamus and cortex produced no detectable response. produced no detectable response.

Pharmacological studies indicate that BK interacts with a B2type receptor and not with Angiotensin Converting Enzyme.

The EC₅₀ for BK is about 100 nM. These BKRs may be translated from exogenous mRNA, however, the possibility exists that injected mRNA activates transcription from an endogenous Xenopus BKR gene or translation, processing or expression of endogenous BKRs. Supported by the American Cancer Society.

INTRACELULAR EVENTS INDUCED BY AN ANTIOPIATE PEPTIDE (Tyr-MIF-1) IN A HUMAN NEUROBLASTOMA SH-SY5Y CELL LINE ^{1,3}S.L. Chang, ^{2,3},⁴J.E. Zadina, and ⁴J. Doucet^e, ¹Depts. of Anatomy, ²Medicine and ³Neuroscience Training Program, Tulane Univ. Sch. of Med., New Orleans, LA 70112; ⁴VA Med. Ctr., New Orleans, LA 70146; ⁵Dept. Biochem. Molec. Biol., Louisiana State Univ. Med. Ctr., New Orleans, LA 70119.

Tyr-MIF-1 (Tyr-Pro-Leu-Gly-NH2) is a naturally- occuring antiopiate peptide and has been suggested to play a biological role in opiate addiction. Zadina et al. (Excerpta Medica, 1990, in press) have recently shown Tyr-MIF-1 binding sites on SH-SY5Y cells, a neuroblastoma cell line which has predominently mu-type opiate receptors. In this study, we explored intracellular events induced by Tyr-MIF-1 in SH-SY5Y cells, presumably through activation of Tyr-MIF-1 binding sites. The SH-SY5Y cells were grown or tyr-Mir-1 binding sites. The Sh-Start cells were grown at 37°C in EMEM:F12 (1:1) medium supplemented with 10% FCS in a CO₂ incubator until 80% confluency. The cells were incubated with Tyr-MIF-1 in concentrations of 10⁻⁵, 10⁻⁷ and incubated with Tyr-MIF-1 in concentrations of 10°, 10° and 10°10M for 1 hour before harvest. Hybridization of the total cellular RNA prepared from cells with a [32P]-labeled c-fos cRNA probe (SP65asfos) revealed 25%, 60% and 43% increases after treatment with 10°5M, 10°7M, and 10°10M Tyr-MIF-1. Tyr-MIF-1 at 10°4M also elevated the cytosolic calcium concentrations, as measured with an indo-1/AM calcium probe, in undifferentiated SHSY-5Y cells. In cells differentiated with retinoic acid, Tyr-MIF-1 decreased intracellular ${\sf Ca}^{+2}$ concentrations.

MONOCLONAL ANTI-IDIOTYPIC ANTIBODIES AGAINST DES-ENKEPHALIN-γ-ENDORPHIN (DEγE) INTERACT WITH THE PUTATIVE RECEPTOR FOR γ-TYPE ENDORPHINS E. Ronken¹, J.W. Bruning²¹, J.A.D.M. Tonnaer³, V.M. Wiegant¹. 1) Rudolf Magnus Institute Dept.of Pharmacology, University of Utrecht; 2) Dept. Immunohematology, University of Leiden; 3) Dept.

CNS Pharmacology, Organon International B.V., Oss, The Netherlands

Des-enkephalin-γ-endorphin (DEγE) is an opioid-inactive fragment of β-endorphin, which elicits certain behavioral effects upon central or peripheral administration in rats. These effects are independent of opioid nechanisms, and are shared with other non-opioid γ-type endorphins. High affinity binding sites for γ -type endorphins are present in rat forebrain regions in extremely low concentrations. For further study of these sites monoclonal anti-idiotypic antibodies were raised against a monoclonal anti-DEYE antibody specifically recognizing the C-terminal part of DEYE. The anti-ID MoAb CR14.1 was selected, characterized by RIA- and ELISA-techniques, and found to act as a functional antagonist for DEγE in vivo in rats. CR14.1 itself has no affinity for γ-type endorphins. Binding sites for intrinsically labeled [35S]CR14.1 in rat endorphins. Binding sites for intrinsically labeled [38]CR14.1 in rat brain cryosections had an anatomical distribution similar to those for [38]Met-DEyE. Furthermore, CR14.1 completely inhibited the binding of [38]Met-DEyE to rat brain binding sites, whereas a control serum did not. CR14.1 specifically recognized two protein bands on western blots from rat brain membranes, with apparent molecular weights of 59 kD and 83 kD. Finally, CR14.1 interfered with affinity labeling of [38]Met-DEyE to a 60 kD protein band. These results suggest that CR14.1 recognizes the putative receptor for non-opioid γ-type endorphins.

220.13

EFFECTS OF CATIONS AND NUCLEOTIDES ON BINDING OF AN AMINOTERMINAL FRAGMENT OF SUBSTANCE P IN MOUSE BRAIN MEMBRANES. O.J. Igwe. D.C. Kim*, *V.S. Seybold and A.A. Larson. Univ of Minn., Dept. of Vet. Biology, 1988 Fitch Ave., St. Paul, MN

55108 and *Dept. of Cell Biology & Neuroanatomy. Mpls., MN 55455. We have recently shown that the SP aminoterminal heptapeptide, [3H]-SP1-7, labeled a homogeneous population of binding sites (B_{max} [³H]-SP1-7. labeled a homogeneous population of binding sites (B_{max} = 29.2 fmol/mg protein) with high affinity ($\rm K_d$ = 2.5 nM) in the mouse brain membranes. To determine whether SP1-7 binding reflects an interaction with G protein-linked receptors, we studied the effects of cations and nucleotides on [³H]SP1-7 binding. Using EDTA-washed membranes that are nominally free of divalent cations, [Ca²+] over a range of 1 to 100 μM increased specific [³H]SP1-7 binding, while 0.5 to 10 mM Ca²+ was inhibitory. Mg²+ (1μM - 100mM) and K+ (1μM - 10mM) decreased specific binding in a concentration-dependent manner. Na+ had no effect on [³H]SP1-7 specific binding by 33% compared to controls incubated under conditions of no additional cations. Addition of GTP or ATP in the incubation medium decreased both $\rm K_d$ and B_{max} of the ligand, implicating modulatory roles for both nucleotides in specific binding of [³H]SP1-7. Maximally effective concentrations of either Ca²+ or Mg²+ alone (0.1 μM) had no effect on [³H]SP1-7 binding parameters, but Na+ alone μM) had no effect on [3H]SP1-7 binding parameters, but Na+ alone decreased the B_{max} . In the presence of 250 mM Na⁺ or 100 μ M Mg²⁺, the inhibitory effects of GTP were abolished. There appears to be a negative cooperativity in guanine nucleotide and cations modulation of SP aminoterminal specific binding to the SP N-terminal receptor complex. NIDAO4090, DAO4190 and DAO0124.

NEUROKININ (NK) MODULATION OF Na, Cl, and HCO3 TRANSPORT IN PROXIMAL JEJUNUM MUCOSA (PJM) OF PIGS. A.M. Parsons*, R. Chandan and D.R. Brown. Dept. of

Veterinary Biology, Univ. of Minnesota, St. Paul, MN 55108. Substance P (SP) and related NKs exist in neurons terminating in jejunal mucosa. We characterized NK effects on ion transport across pig PJM, a tissue whose function is similar to humans. Muscle-free PJM was mounted in Ussing chambers. NKs increased short-circuit current ($I_{\rm sc}$), a measure of active ion transport, maximally by $\simeq 60$ - $70~\mu A/cm^2$ with an order of potency: SP > NKA > NKB and respective ED₅₀s of 13, 73 and 1281 nM. SP activity was reduced by 30% after atropine-induced blockade of muscarinic cholinoceptors, but remained unaltered by H_1 -histamine antagonists. Tetrodotoxin (TTX; $0.1~\mu M$) respectively reduced NKA and SP efficacy by 50 and 75% and nearly abolished NKB activity. Rank NK potency in the presence of TTX was NKA \geq SP >> NKB. The NaCl influx blocker burnetanide (10 μ M) or external CI removal decreased SP action on L. Radiotracer flux and pH-stat titration analyses revealed that SP increases net Na and HCO₃ secretion, effects inhibited by TTX or by 10 μ M acetazolamide in HCO₃-free media. Thus, NKs in pig PJM produce Cl secretion through interactions with a non-neuronal NK-1 receptor. In contrast, NKs act through a different receptor type situated on enteric neurons to stimulate Na-HCO3 secretion and regulate luminal pH in small bowel.

SUBSTANCE P RECEPTOR DESENSITIZATION: INVOLVEMENT OF A GTP BINDING PROTEIN. L.N. Holland, B.D. Goldstein and R.S. Aronstam, Department of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912-2300.

The repeated administration of intrathecal substance P (SP) has been shown to produce behavioral "desensitization" characterized by an increase in the tail flick latency and attenuated SP-induced biting and scratching. It has been suggested that the mechanism of "desensitization" invol activation of an endogenous opioid system. We examined the effects of repeated intrathecal SP administration on SP receptor binding in the rat

Preliminary studies of SP receptor binding using ³H-SP as a probe indicated two populations of binding sites (nonlinear regression analysis). We focused on the high affinity site by using 126 LSP. Repeated intrathecal injection of SP (0.7 μ M) reduced the number of high affinity 126 LSP binding sites as compared to controls (intrathecal saline). Intrathecal SP also increased the K₀ for this high affinity binding component. The addition of 5'guanylylimidodiphosphate (10⁻⁴ M), a nonhydrolyzable GTP analog, produced a similar decrease in 1251-SP binding affinity.

These data indicate that repeated intrathecal administration of SP alters SP receptor activity. These changes may reflect the development of a desensitized state. The altered agonist affinity seen under desensitizing conditions raises the intriguing possibility that desensitization in this system involves an alteration in receptor-G protein coupling.

220.14

CROSSLINKING OF THE SUBSTANCE P RECEPTOR TO A POLYPEPTIDE: A POTENTIAL G PROTEIN ALPHA SUBURIT. S.G.

Macdonald*, J. Luber-Narod and N.D. Boyd.* Dept. of
Physiology, U. Mass. Med. Sch., Worcester, MA 01655.

We have previously shown, through a reconstitution
assay, that association of the substance P (SP) receptor

We have previously shown, through a reconstitution assay, that association of the substance P (SP) receptor with a G protein is required for high affinity binding of SP to its receptor. In the present study, we have utilized chemical crosslinking strategies to characterize the G protein that couples to the SP receptor. [1251]-p-benzoyl-phe⁸-SP, a photoreactive derivative of SP, is covalently incorporated into the SP receptor. The photolabelling is GTP-sensitive, indicating that the G protein is associated with the receptor under the conditions employed in photolabelling. Subsequent incubation of the photolabelled receptor with a homobifunctional crosslinking reagent, followed by SDS/PAGE analysis, results in the appearance of a band on autoradiograms which has an Mr that is approximately 43 kDa greater than that of the receptor. This molecular weight is typical of G protein alpha subunits. Chemical crosslinking of the photolabelled receptor is blocked by the incubation of the photolabelled receptor with a nonhydrolyzable analog of GTP prior to the addition of the chemical crosslinker, whereas incubation of the photolabelled receptor with a nonhydrolyzable analog of ATP has no effect. These data suggest that the photolabelled, crosslinked receptor represents a ternary complex of SP, the SP receptor and the alpha subunit of a G protein.

RECEPTOR-SELECTIVE ANALOGS DEMONSTRATE NPY/PYY RECEPTOR HETEROGENEITY IN HUMAN NEUROBLASTOMA CELL LINES AND RAT BRAIN.

M. Springston, S. Aicher, D.J. Reis, T.W. Schwartz* and C. Wahlestedt, Div. of Neurobiol., Cornell Univ. Med. Coll., NY, NY

M. Springston, S. Aicher, D.J. Reis, T.W. Schwartz* and C. Wahlestedt, Div. of Neurobiol., Cornell Univ. Med. Coll., NY, NY 10021, USA and Lab. Mol. Endocrin., Univ. Copenhagen, DENMARK. Neuropeptide Y (NPY) receptors are heterogeneous consisting of two subclasses, Y1 and Y2 (Wahlestedt, et al., Reg. Pept. 13:317, 1986). We sought evidence for differential expression of NPY receptor subtypes in human neuroblastoma (NB) cell lines and rat brain. Cells from SK-N-MC or SK-N-BE(2) NB lines were incubated with ¹³¹-peptide YY (PYY) which labels NPY and PYY binding sites (Lynch, et al., J. Neurosci. 9:2607, 1989). pNPY, pPYY, the Y1-selective agonist p[Ile³1,Pro³4]NPY, and the Y2-selective agonist pNPY was 2.1±0.18 nM, for pPYY 0.86±0.12 nM. p[Ile³1,Pro³4]NPY was approximately equipotent (1.7±0.21 nM) while pNPY 13-36, was much less potent (880±260 nM) suggesting preferential expression of the Y1-receptor. In contrast, SK-N-BE(2) cells displayed binding characteristics indicating preferential expression of Y2-receptors (K, values for pNPY, pPYY, pI[Ile³1,Pro³4]NPY and pNPY 13-36 were 0.87±0.15, 0.49±0.11, 430±170 and 5.4±0.4, respectively). Similar results were obtained using ¹³⁵1-NPY. Comparable competitive binding studies in membranes or sections of rat brain revealed selective expression of Y2-receptors in hippocampus. The autoradiography analysis also indicated further regional receptor heterogeneity. We conclude that Y1- and Y2-receptors may be independently expressed in NB lines and brain.

CHARACTERIZATION OF TWO NEUROPEPTIDE Y BINDING PROTEINS IN BOVINE TISSUES BY AFFINITY-LABELING. W. Li. MacDonald and T.D. Hexum. Depts. of Pharmacol. Biochem.', Univ. Neb. Med. Ctr., Omaha, NE 68198-6260.

Neuropeptide Y (NPY) is a 36 amino acid messenger that has a variety of effects including stimulation of feeding behavior and inhibition of norepinephrine release; its binding sites have been identified in several tissues. To elucidate NPY receptor structure, we affinity crosslinked 125 I-NPY to receptors present in hippocampal or adrenal medulla membranes using disuccinimidyl suberate (DSS, 1 mM). SDS-polyacrylamide gel electrophoresis followed by autoradiography revealed the presence different NPY binding protein in each tissue. A 50 kD 125I-NPY-labeled species was present in bovine hippocampal membranes. Competitive inhibition by unlabeled NPY resulted in an IC₅₀ of 8.0 x 10^{-10} M. 125 I-peptide YY (PYY) also bound and could be cross-linked to this receptor. Either unlabeled NPY or PYY could displace the binding of both ¹²⁵I-NPY and ¹²⁵I-PYY and NPY > NPY¹³⁻³⁶ > NPY¹⁴⁻³⁶ ≥ NPY²⁰⁻³⁶ ≥ NPY²⁸⁻³⁶in displacing ¹²⁵I-NPY. Cross-linking of ¹²⁵I-"* \geq NPY"*-36 in displacing '121-NPY. Cross-linking of '121-NPY to bovine adrenal medulla membranes identified a 90 kD species which had an IC_{30} of 1.1×10^{-7} M for unlabeled NPY. '121-PYY was not cross-linked to this protein. NPY \geq NPY'13-26 > NPY'13-26 > NPY'13-26 > NPY'13-26 > Pancreatic polypeptide (bovine, human or avian) did not displace the binding of '121-NPY on either of these receptors. PEPTIDES: PHYSIOLOGICAL EFFECTS II

221.1

PLASMA VASOPRESSIN INCREASES AFTER INTRAVENTRICULAR DES-LEU-ANGIOTENSIN I. D.G. Changaris, J.R. Claybaugh*#, and R.S. Levy. Depts. Neurology & Biochemistry & Lab. Biol. Psychiatry, University of Louisville School of Medicine, Louisville, KY 40292; #Dept. Clinical Investigation, Tripler Army Medical Center, Honolulu, Hawaii 96859.

Intracerebroventricular (ICV) injection of angiotensin II (AII) induces vasopressin secretion. An alternate pathway in the brain for the synthesis of AII requires the intermediate nonapeptide, des-leu angiotensin I (des-leu AI). To confirm that a second carboxyl cleavage causes vasopressin secretion, we compared the plasma vasopressin levels after ICV injection of des-leu AI and the D-

substituted analog, des-leu D-His AI.
Twenty-four male Sprague Dawley rats with
ventriculostomies received random ICV injections of either 3.3 nmole des-leu AI or des-leu D-His AI. sacrificed at 2, 6, and 12 min. by decapitation. blood was collected and, after centrifugation, the plasma was frozen for subsequent radioimmunoassay. Those rats receiving the L analog nonapeptide had significantly higher plasma vasopressin levels at 6 & 12 min (p<0.05) than those plasma vasopressin levels at 6 & 12 min (p<0.05) than those receiving the D analog. Since the octapeptide AII causes vasopressin secretion, these data suggest that the nonapeptide requires a single carboxyl hydrolysis to generate AII and the D for L substitution blocks this hydrolysis. (Supported by NIH-GIDA 531621; VA-DOD 002; and the Glenmore Foundation.)

BOMBESIN ACTIVATES TUBEROINFUNDIBULAR (TI) AND TUBEROHYPO-PHYSIAL (TH) DOPAMINE (DA) NEURONS AND DECREASES BASAL AND STRESS-INDUCED SECRETION OF PROLACTIN AND α-MELANOCYTE STIMULATING HORMONE (αMSH) IN THE MALE RAT. I.W. Toney. J.M. Manzanares, K.J. Lookingland and K.E. Moore, Dept. of Pharmacology, Mich. State Univ., East Lansing, MI 4824

The purpose of the present study was to examine the effects of bombesin on the activity of TIDA and THDA neurons, and the secretion of prolactin and αMSH in non-stressed and stressed (30 min supine restraint) male rats. For comparison, the effects of bombesin on mesotelencephalic DA neurons were also examined. The activity of DA neurons was estimated by measuring the concentrations of 3,4-dihydroxyphenylacetic acid and the accumulation of 3,4-dihydroxyphenylalanine following administration of a decarboxylase inhibitor in brain regions containing terminals of these neurons. In non-stressed rats bombesin (0.3and increased the activity of TIDA neurons terminating in the median eminence and THDA neurons in the intermediate lobe (IL), but had no effect on mesotelencephalic DA neurons or THDA neurons projecting to the neural lobe. In stressed animals bombesin (2.5 µg; icv) increased the activity of TIDA and IL THDA neurons, and reduced plasma levels of prolactin and aMSH. These results suggest that bombesin-induced suppression of basal and stress-induced prolactin and αMSH secretion is due, in part, to activation of TIDA and IL THDA neurons. (Supported by ADAMHA Grant MH 42802.)

PHYSIOLOGICAL ACTIONS OF FIBROBLAST GROWTH FACTOR (FGF) IN CENTRAL NERVOUS SYSTEM, Y. Oomura, K. Sasaki, T. Muto, K. Suzuki, K. Hanai, I. Tooyama, H. Kimura, and N. Yanaihara, Toyama Med. & Pharmaceu. Univ., Toyama 930-01, Fac. Sci., Kyushu Univ., Fukuoka 812, Shiga Univ. Med. Sci., Shiga 520-01, Univ. Shizuoka Sch. Pharmaceu. Sci., Shizuoka 422, Japan.

Sch. Pharmaceu. Sci., Shizuoka 422, Japan.
Glucose effects on the release of acidic FGF (aFGF)
into cerebrospinal fluid (CSF) from the ependimal cells
which produce aFGF, and the effects of aFGF, basic FGF which produce artr, and the elects of artr, dasic for (bFGF) and related peptides on food intake and neuronal damage by ischemia were examined. The aFGF in CSF of rats was increased 1000 times in a 2 hour period after glucose infusions into the 3rd ventricle (3V). Food intake was intusions into the 3rd ventricle (3V). rood intake was dose-dependently decreased by infusions of aFGF or bFGF into the 3V of rats, and increased by bilateral infusions of their antibody into the lateral hypothalamus. The potency of aFGF on food intake inhibition was twice as compared with that of bFGF. When peptides, which consist of 1 to 15 (N-aFGF) or 114 to 140 (C-aFGF) amino acids of aFGF, were infused into the 3V to investigate the active rotion of aFGF. investigate the active portion of aFGF, N-aFGF decreased food intake dose-dependently, but C-aFGF did not. Continuous infusions of aFGF into the lateral ventricle of the gerbil prevented the delayed neuronal death of hippocampal CAI pyramidal cells induced by 5 min ischemia. The results suggest that FGF has various physiological actions in the central nervous system.

221.4

CATECHOLAMINERGIC AND ENKEPHALINERGIC MEDIATION OF THE HYPOTHALAMIC ACTIONS OF ATRIAL NATRIURETIC PEPTIDE. F_1 -L.S. Huang* and W.K. Samson, Anatomy and Neurobiology, Univ. of

MO, School of Medicine, Columbia, MO 65212.

Atrial natriuretic peptide (ANP) acts within the hypothalamus to inhibit luteinizing hormone (LH) and prolactin (PRL) secretion (Endo. 122:1573; Neuroendo. 47:268). Both dopaminergic and opioidergic mechanisms have 47:268). Both dopaminergic and opioidergic mechanisms have been suggested. Third cerebroventricular (3V) injection of 2nmole ANP reduced LH (p<0.0001) and PRL (p<0.05) levels in conscious, ovariectomized female rats. Dopamine turnover was stimulated significantly in the arcuate (ARC) and paraventricular (PVN) nuclei. Bilateral injection of 0.1nmole ANP into either the PVN or ARC significantly reduced plasma LH levels, indicating potential sites of action since preparity measures indicating potential sites of action since preoptic nucleus infusions were ineffective. The LH inhibitory effect of ANP was mimicked by 3V injection of 1nmole the enkephalin analog, DP2DP5ENK. The effects on LH secretion of both ANP and DP²DP⁵ENK were blocked by pretreatment with 50 ng naltrindole, a specific delta opioid antagonist. The PRL lowering effect of ANP was not altered by naltrindole pretreatment; however, the PRL stimulatory effect of enkephalin was blocked. These studies support our hypothesis that the effect of ANP on PRL is mediated via increased DA turnover and establishes an enkephalinergic mechanism for the inhibitory hypothalamic effect of the peptide on LH secretion. Supported by NIH Grant HD25373.

THE DEPRESSOR ACTION OF INTRATHECAL NEUROPEPTIDE Y (NPY) IS MEDIATED BY SPINAL Y, RECEPTORS. X. Chen, M.M. Knuepfer and T.C. Westfall Dept. Pharmacol. St. Louis Univ. Sch. Med. St. Louis, MO

Previously we have shown that the intrathecal (int) injection of NPY produces a decrease in AP. In the present study we examined the nature of the receptor subtype mediating the depressor effect of int NPY as well as the effect of the peptide on the spinal micro-vasculature. For int injections, one PE 10 catheter was inserted down the spinal subarachnoid space (about T10). Drugs were dissolved in saline and slowly injected at a volume of 10-15 µl. A laminectomy was performed to expose the dorsal surface of the spinal cord between T₁₁ and L₁. Spinal vascular blood flow was measured by a laser Doppler flowmeter. The left carotid artery was cannulated for AP measurement. Int NPY C-terminal fragments (NPY¹¹⁻³⁶, NPY¹¹⁻³⁶) produced concentration dependent depressor effects suggesting that the depressor effect of int NPY may be mediated by a Y₂ receptor. Co-administration of the same amount (0.1 nmol) of NPY and NPY¹⁴⁻³⁶ or NPY¹⁸⁻³⁶ did not affect the depressor effect of NPY. The int injection of NPY (0.1 mmol) significantly decreased AP and concomitantly, gradually decreased spinal vascular resistance suggesting that the depressor effect of int NPY was not due to local ischemia or neuronal damage by this vasoconstrictor (Supported by HL 26319 and HL 35202).

MICROINFUSIONS OF AII AND AIII INTO THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS (PVN) INDUCE DIPSOGENIC AND PRESSOR RESPONSES IN ALERT RATS. Laurie L. Jensen, Joseph W. Harding, and John W. Wright. Washington State University, Pullman, WA., 99163. Microiontophoretic applications of angiotensin II (AII) and angiotensin III (AIII) have been shown to excite cells in the PVN (Harding & Felix, 1987). Brosnihan et al. (1987) reported increases in blood pressure following PVN microinjections of AII(800 fmoles). Further, our laboratory has observed dose-dependent increases to microinfusions of All and AllI into the PVN of anesthetized rats (Jensen, et al., 1989). In the present investigation, alert normotensive rats received PVN microinfusions of AII and AIII at doses of 0, 10, 50, 100, and 250 pmoles in a total volume of 50 nl aCSF. Preliminary data indicate that PVN microinfusions of All and AllI increase blood pressure and induce dipsogenic responses in a dose-response fashion. These results indicate an important role for the PVN in central angiotensin control of blood pressure and body water balance.

221.9

PROTEIN SYNTHESIS INHIBITION ALTERS THE CHARACTERISTICS OF FEVER INDUCED BY INTRACEREBROVENTRICULAR INTERLEUKIN-W. M. Zawada, J. Clarke and W. D. Ruwe,

13. W. M. Zawada, J. Clarke and W. D. Ruwe. Department of Physiology & Biophysics, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

Pretreatment with a protein synthesis inhibitor, anisomycin (ANI), suppresses fevers normally evoked by endotoxin or crude endogenous pyrogen, EP [Ruwe, W. D. and Myers, R. D. Brain Res. Bull. 4:741-745, 1979]. The effect of ANI on hyperthermias evoked by prostaglanding of the particular (PCP) is less clear. Moreover recent of the E series (PGE) is less clear. Moreover, recent reports suggest that ANI may significantly prolong fevers induced by EP or PGE₂ [Morimoto, A. et al., Pflügers Arch. 408:414-416, 1987]. A series of experiments was Arch. 408:414-416, 1967]. A series of experiments was conducted to further evaluate the importance of protein synthesis in the generation of fever. Stainless steel guide tubes were implanted above the lateral cerebral ventricle (LCV) of male Long Evans (280-325 gm). Injections of either human recombinant IL-16, 5 ng/20µ1, Injections of either human recombinant IL-1 β , 5 ng/20 μ l, or PGE₂, 250 ng/10 μ l, were made 30 min after an LCV infusion of artificial cerebrospinal fluid (aCSF), 10 μ l, or ANI, 80 μ g/10 μ l. ANI significantly altered the febrile response to IL-1 β , within 45-90 min after injection of the peptide. The response to PGE₂ was unaffected by the inhibitor. These results are consistent with a role for an unknown peptide/protein mediator in the neurochemical pathway to fever. [Supported by a grant (#NS26045) from NINDS to WDR.]

221.6

FACILITATION OF BARORECEPTOR REFLEX RESPONSE BY ENDOGENOUS SOMATOSTATIN IN THE RAT. Julie Y.H. Chan, S.S.Lin* and Samuel H.H. Chan. Taipei Veterans General Hospital and National Yang-Ming Medical College, Taipei, Taiwan, R.O.C.

We evaluated the participation of endogenous brain somatostatin (SOM) in the modulation of baroreceptor reflex (BRR) response, using Sprague-Dawley rats anesthetized with pentobarbital sodium. Intracerebroventricular (i.c.v.) pentobarbital sodium. Intracerebroventricular (1.c.v.) application of SOM (2 or 4 nmol) promoted a significant elevation in BRR response. Blocking the endogenous SOM activity with its specific antagonist, cyclo-(7-aminoheptanoyl-phenylalanyl-D-tryptophyl-lysyl-threonyl [benzyl]) (2 nmol, i.c.v.), or antibody against SOM (1:20, i.c.v.), on the other hand, appreciably attenuated the same response. These modulatory effects on the BRR were essentially duplicated upon bilateral microinjections of SOM (320 pmol), SOM antagonist (320 pmol) or anti-SOM (1:20) into the caudal portion of the nucleus tractus solitarius (NTS), the caudal portion of the nucleus tractus solitarius (NIS), the terminal site for baroreceptor afferents. Furthermore, microinjection of pertussis toxin (25 ng) or n-ethylmalei-mide (2 nmol) into the bilateral NTS also reversed the facilitatory action of SOM on the BRR response. These results suggest that neurons in the central nervous system that contain SOM may participate in cardiovascular control by tonically facilitating the BRR, possibly by exerting an influence on the NTS, in a signal transduction process that may involve a pertussis toxin sensitive GTP-binding regulatory protein(s), possibly Gi.

RELATIONSHIP BETWEEN THE CENTRAL KININ SYSTEM

RELATIONSHIP BETWEEN THE CENTRAL KININ SYSTEM AND BLOOD PRESSURE IN SPONTANEOUSLY HYPERTENSIVE RAT. K.Kariya, M.Sasaki*, A.Yamauchi* and N.Gemba* Dept. of Pharmacology, Fac. of Pharm. Sci., Kobe-Gakuin Univ., Kobe 673 JAPAN

We have reported that bradykinin(BK, Neuro-pharmacol., 20, 1221, 1981) and kininogenase(KL, Japan.J.Pharmacol., 43, 129, 1987) injected intraventricularlly produced a dual pressor response in Sprague-Dawley rat. In this study, we observed about the sensitivity on blood pressure related to the central kinin system using spontaneously hypertensive rat(SHR) and WKY as the control. control.

Intraventricular injection of BK(1-5 nmole) caused a pressor response with dose dependent manner in WKY, but such increase was depressed in SHR. However, KL(2-16 KU) prodused a marked increase of the blood pressure in SHR comparing with WKY. Further, the response in male WKY was more sensitive for BK than in the female. But that for KL was vice versa. On the otherhand, KL produced more enhancement of the pressor response in male SHR than in the female. But, the response by BK in female SHR was higher than in the male rat.

Above results suggest that the central kinin may participate in regulation of blood pressure.

221.10

CENTRALLY ADMINISTERED NEUROPEPTIDE Y ENHANCES THE HYPOTHERMIA INDUCED BY PERIPHERAL ADMINISTRATION OF ADRENOCEPTOR ANTAGONISTS. M.C. Ruiz de Elvira* and C.W. Coen (Spon: Brain Research Association, UK). Division of Biomedical Sciences, King's College, London W2R 2LS, UK.

The distribution of neuropeptide Y in the brain includes extensive coexistence within adrenaline- and noradrenaline-containing neurons and many of its actions are often associated with adrenergic systems. Since neuropeptide Y immunoreactivity

with adrenergic systems. Since neuropeptide Y immunoreactivity is particularly intense in the preoptic area, one of the principal sites for thermoregulation, we have tested the effects of neuropeptide Y on core temperature in normothermic rats, and neuropeptide Y on core temperature in normothermic rats, and rats rendered hypothermic by systemic treatment with adrenergic antagonists. In the normothermic rat, intracerebroventricular administration of 1 μ g of neuropeptide Y did not have a significant effect on core temperature. Intraperitoneal treatment with the α_1 -adrenoceptor antagonist, prazosin, or the β -adrenoceptor antagonist, propranolol, caused an immediate and significant hypothermia; the intracerebroventricular administration of 1 μ g of neuropeptide Y, 10 minutes after these drugs, strongly potentiated their hypothermic effect. Although drugs, strongly potentiated their hypothermic effect. Although intraperitoneal treatment with the α_2 -adrenoceptor antagonist, idazoxan, had no hypothermic effect per se, the intracerebroventricular administration of NPY 10 minutes after this antagonist led to a significant decrease in core temperature. The site at which these interactions take place, and their nature, remain to be established.

BOMBESIN INFUSION INTO THE PREOPTIC AREA ALTERS PLASMA METABOLIC FUELS AND PRODUCES HYPOTHERMIA IN FOOD-DEPRIVED AND INSULIN-PRETREATED RATS. A.M. Babcock^{1*}, M.W. Cunion², M.J. Rosenthal^{2*}, P. Lomax³ and C. Barton^{1*}.

Toept. of Psych., Univ. of S. Äl, Mobile, AL 36688;

2GRECC, Sepulveda VAMC, Sepulveda, CA 91343;
3Dept. of Pharm., UCLA School of Medicine, Los Angeles, CA 90024.

Bombesin (BN; 0, 50 ng/.25 µl) was infused into the preoptic area (POA) through previously implanted unilateral guide cannulae. Rats (n=8) were tested under conditions of food satiation, food deprivation (18hrs), and insulin pretreatment (Regular Iletin I; 10U/kg im). Blood samples (120µl) were collected from the tail tip at 0, 60, and 120 min postinfusion. Changes in rectal temperature and food intake were also measured. BN increased plasma glucose in food-deprived rats and attenuated insulin-induced hypoglycemia. BN elevated free fatty acids in food-sated rats and prevented a reduction in food-deprived rats. Corticosterone was increased following BN under all conditions. As previously reported, BN produced hypothermia and hypophagia in food-deprived and insulin-treated rats. These results suggest that the POA is an important site for BN action on thermoregulation and metabolic fuel regulation. In addition, this action appears dependent on the metabolic state of the test animal. (Supported by USARC funds [AB], NS20660 [MC], ACO4793 [MR], and Vet. Adm. research funds [MG, MR].)

The effect of delta sleep-inducing peptide (DSIP) on the body temperature changed by dopamine (DA) and 5-hydroxytryptamine in rat.

K.Tsunashima*, A.Masui*\$, N.Kato \$ and K.Takahashi*Division of Mental Disorders Research, N.C.N.P.,
Kodaira 187, and \$Dept.Psychiat., Shiga Univ.

Med.Sci., Ostu 520-21, Japan
DSIP, a putative endogenious sleep-promoting substance, had an enhancing effect of hypothermia induced by i.p. injection of apomorphine at an ambient temperature (241°C). A minimal effective dose of this peptide was 10ng and the dose response relationship exhibited an inverted bell-shape with maximal effective dose of lmcg. The action of this peptide was antagonized by haloperidol. By the pretreatment of anti-DSIP, this enhancing effect was totally abolished. As it is well-known that both DA and 5-HT are involved in the thermoregulation, the relationship between DSIP and 5-HT was further examined. Rats were injected i.p. with 5-MeODMT and 8-OH-DPAT, serotonergic agonists, and then DSIP(lmcg) was injected icv. DSIP had an enhancing effect on hypothermia induced by these substances at an ambient temperature. It is suggested that DSIP may have a physiological role in the thermoregulatory mechanismsby enhancing the action of DA and 5-HTla receptors.

INTRACISTERNAL INJECTION OF THE ENDOPEPTIDASE INHIBITOR PHOSPHORAMIDON INHIBITS GASTRIC ACID SECRETION IN PYLORUS-LIGATED RATS. R.L.Stephens, Jr. and P. E. Ward, Department of Physiology, The Ohio State Univ., Columbus, Ohio 43210.

Endopeptidase 3.4.24.11 (Endo 24.11) is thought to

Endopeptidase 3.4.24.11 (Endo 24.11) is thought to contribute to the metabolism of endogenous CRS peptides such as choids, substance P and bombesin. Phosphoramindon (P) is a specific inhibitor of Endo 24.11. In 2 hour pylorus-ligated rats, intracisternal (ic) injection of phosphoramidon (1-100mmol) produced a marked dose-dependent inhibition in gastric acid output and concentration. In contrast to the effect of ic phosphoramidon, ic injection of the aminopeptidase inhibitor amastatin (A) (100nmol), was ineffective in altering gastric acid output.

Treatment	N	volume	acid output	acid conc
(nmol)		(ml/2 hr)	(µBq/2 hr)	(µEq/ml)
vehicle	10	3.6 ± 0.6	343 + 81	89 ± 6
P(100)	6	2.1 ± 0.2*	61 + 14*	33 ± 10 **
P(10)	6	2.1 ± 0.3*	88 ± 25*	39 ± 8 **
P(1)	4	3.1 + 0.9	213 + 84	65 + 7 *
A(100)	4	2.9 + 0.7	260 + 82	84 + 7

(**: p< 0.01; *: p<0.05; significantly different from vehicle treated rats). The data suggest that an endogenous Endo 24.11-sensitive peptide in the brain may act as an inhibitor of gastric acid secretion and concentration. The specific brain site of action of this effect remains to be elucidated. Supported by OSU Seed Grant 221192 and NIH-DK 28184.

VASOPRESSIN RELEASE WITHIN THE RAT BRAIN DURING DRUG-INDUCED ANTIPYRESIS. M.F. Wilkinson* and N.W. Kasting. Dept. of Physiology, Univ. of British Columbia, Vancouver, B.C., Canada. Arginine vasopressin (AVP) is an endogenous antipyretic within the ventral septal area (VSA) of the rat brain. Experiments were conducted in conscious superestrained rate to

Arginine vasopressin (AVP) is an endogenous antipyretic within the ventral septal area (VSA) of the rat brain. Experiments were conducted in conscious, unrestrained rats to measure VSA AVP release, using push-pull perfusion (ppp), before and after antipyretic treatment with indomethacin (Indo) or acetaminophen (Aceta). Surgical preparation consisted of cannulas directed toward a lateral cerebral ventricle (LCV) and the VSA and an ip transmitter for monitoring of body temperature. Fever was induced by E.coli endotoxin injected into a LCV. Ppp was initiated 120min postendotoxin. Following the first ppp period (30min) Indo or Aceta was injected ip. In the first ppp period following Indo, but not Aceta, AVP in VSA perfusates increased 188% (0.85±0.11 to 1.6±0.22 pg/sample, pc0.05). This corresponded to the greatest decrease in body temperature. Neither ip Tris buffer (febrile rats) nor Indo (non-febrile rats) evoked significant changes in VSA AVP release. These data support a role for VSA AVP release.

221.14

VASOPRESSIN IS INVOLVED IN CENTRAL AMYGDALOID REGULATION OF STRESS-RELATED CHANGES. B.Roozendaal*, G.H.M.Schoorlemmer*, J.M.Koolhaas* and B.Bohus*. (SPON: European Brain and Behaviour Society) University of Groningen, Dept. of Animal Physiology, P.O. Box 14, 9750 AA Haren, The Netherlands.

The central nucleus of the amygdala (CEA) has been implicated in the control of autonomic and behavioural correlates of conditioned stress. Central arginine-8-vasopressin (AVP) elicits cardiovascular, neuroendocrine and behavioural changes. The CEA contains high densities of vasopressin V1 and oxytocin receptors through which AVP may be effective. A nine-minute infusion of 200pg AVP (dissolved in 1 µl artificial CSF) into the CEA of conscious male Wistar rats under resting conditions, led to an increase in heart rate during the infusion period, but neither noradrenaline (NA), nor adrenaline (A) were elevated. This suggests that the tachycardia is due to a reduced parasympathetic control rather than a stimulation of the sympathetic outflow. Furthermore, AVP infusion into the CEA resulted in a behavioural activation and a slight increase in plasma corticosterone.

The present studies suggest that regulation of stressrelated autonomic and behavioural changes in the CEA involves vasopressinergic mechanisms through parasympathetic and/or adrenal cortical output.

221.16

NEUROIDXIC EFFECTS OF THYROTROPIN RELEASING HORNONE (TRH) ON FETAL RAT HIPFOCMPAL CULTURES. J. Phillips, A. Winokur, and J.R. Buchhalter. Depts. of Psychiatry, Pharmacology, and Neurology, U. of PA School of Medicine, Philadelphia, PA 19104

TRH is widely distributed in the ONS and has been implicated as a facilitatory neuromodulator and a trophic factor. TRH enhanced both the number and size of cell processes in cultured ventral horn neurons derived from rat embryo. Additionally, there have been several reports of clinical benefit to amyotrophic lateral sclerosis patients treated with TRH. In light of these findings, we examined the effect of TRH on the development and survival of cultured hippocampal neurons.

Dissociated hippocampal neurons from fetal day 18-19 rats were plated at a density of 100,000 viable cells in Petri dishes containing poly-lysine coated glass coverslips. Cells were incubated in serum supplemented Dulbecco's modified Eagle's medium for 24 bours, and then transferred to 24 well plates containing media with 10 to 10 1 M TMH. Cells were incubated for 1 week, fixed, and neurons counted. A concentration dependent TMH toxicity was noted. By 24 hours all neurons were dead with a dose of 10 1 M TMH. At 1 week, 10 1 M TMH, the lowest concentration tested, reduced the survival of neurons by 51% as compared to controls. TMH-CH, a TMH metabolite, was 50% less toxic than TMH at conversible concentrations. The clustemeta presentor

A concentration dependent INH toxicity was noted. By 24 hours all neurons were dead with a dose of 10^{-2} M TRH. At 1 week, 10^{-1} M TRH, the lowest concentration tested, reduced the survival of neurons by 51% as compared to controls. TRH-CH, a TRH metabolite, was 50% less toxic than TRH at comparable concentrations. The glutamate receptor antagonist 2-emino-phosphonovalerate did not inhibit the effects of TRH on neuronal death. These results indicate that TRH produces profound neurotoxic effects on fetal rat hippocampal cultures, but that these effects are not being exerted through glutaminergic mechanisms (via a glutamate metabolite of TRH). Further studies are required to elucidate the mechanism of action of TRH on hippocampal neurons.

CORTICOTROPIN-RELEASING FACTOR-IMMUNOREACTIVE (CRF-IR) NEURONS ARE LOCALIZED IN NUCLEI WHICH PROJECT TO THE LOCUS COERULEUS (LC). R.J. Valentino. E. J. Van Bockstaele. and G. Aston-Jones. Department of Mental Health Sciences, Division of Behavioral Neurobiology, Hahnemann University, Philadelphia, PA 19102.

Jones, Department of Mental Health Sciences, Division of Behavioral Neurobiology, Hahnemann University, Philadelphia, PA 19102. CRF-IR fibers have been visualized in the noradrenergic nucleus, LC (Swanson et al., 1983; Sakanaka et al., 1987), and physiologic studies suggest that CRF may serve as a neurotransmitter in the LC during stress (Valentino, 1989). To further test the hypothesis that CRF acts as a neurotransmitter in the LC, the origin of CRF-IR fibers in LC was investigated using combined immunohistochemical and retrograde tracing techniques. CRF-IR cells were found in two medullary nuclei which are the primary sources of LC afferents, the nucleus paragigantocellularis (PGi) and the nucleus prepositus hypoglossi (PrH), in colchicine-treated rats. Additionally, CRF-IR cells were found in the pericoerulear region, particularly along the lateral border of the LC and in Barrington's nucleus. Preliminary double labeling studies suggest that the pericoerulear CRF-IR cells are not noradrenergic neurons. Microinjection of the retrograde tracer, cholera toxin B subunit coupled to 7 nm colloidal gold particles (CT-Gold), into the LC resulted in labelling that was similar to that produced by iontophoretic injection of the retrograde tracer, Fluoro-Gold, into LC. Cells in PGi, PrH, and the dorsal cap of the paraventricular nuc. of the hypothalamus ever labelled with the retrograde tracer. A few cells in PGi and the hypothalamus exhibited double-labelling for CRF-IR and CT-Gold. In the PrH most CRF-IR cells were lateral to cells containing the retrograde label. These results suggest that a small population of CRF cells in PGi and the hypothalamus project to the LC and that CRF-IR fibers in the LC may also be derived from local pericoerulear circuits. This work was supported by PHS Grants MH 40008, MH 42796, NS 24698 and DA 06214.

222.3

CYTOCHEMICAL LOCALIZATION OF INSULIN-LIKE IMMUNOREACTIVITY IN THE RAT SPINAL CORD. S.S.W. Tay and W.C. Wong, Department of Anatomy, National University of Singapore, Kent Ridge, Singapore 0511.

Insulin-like immunoreactivity has been localized in the cervical, thoracic, lumbar and sacral segments of the spinal cord. Neurons in both the dorsal and ventral horns showed positive staining. Under the light microscope, staining appeared to be localized mainly in the cell nucleus but not its nucleolus. Normal serum and preabsorbed controls showed an absence of staining. With the electron microscope, fine grains of the reaction product were distributed within the nucleoplasm as well as on the chromatin materials and nuclear membranes. Only small traces of the reaction product were found in the cytoplasm of the neuronal cell bodies. Dendrites were labelled and the reaction product was localized mainly alongside the parallel arrays of neurotubules. Labelled dendrites were mostly distal dendrites, being postsynaptic to non-immunoreactive axon terminals. A few labelled dendrodendritic contacts were present. Axons and axon terminals appeared to be non-immunoreactive. The present results suggest that insulin-like substance(s) in the spinal cord may be modulating neuronal activity in the cell nucleus as well as at the synapse.

222.5

ACUTE C-FIBER STIMULATION CAUSES A DECREASE IN SUBSTANCE P-, GALANIN- AND DYNORPHIN- IMMUNO-REACTIVITY IN THE RAT DORSAL HORN. C.M. Klein, L.J. Sorkin, S.M. Carlton, K.N. Westlund and R.E. Coggeshall. Dept. of Anat., MBI, Univ. of Texas Med. Br., Galveston, TX 77550.

In this study, we measured changes in immunoreactive staining in the LA-L5 dorsal horn following acute stimulation of C-fiber afferents in the sciatic nerve. Specifically, we were interested in changes in 3 peptides, all of which have been found in primary afferent fibers and/or intrinsic systems--substance P (SP), galanin (GAL) and dynorphin (DYN)--and have been shown to increase in the dorsal horn following various peripheral manipulations. The sciatic nerve of adult Sprague-Dawley rats was electrically stimulated (1 Hz, 0.2ms) for 20 mins.; the compound action potential (including both A and C fiber volleys) was monitored and did not diminish during the entire stimulation period. Control animals received A fiber stimulation only for the same length of time. Immediately after stimulation, the rats were perfused with 3% paraformaldehyde, 3% glutaraldehyde, 0.1% picric acid in cacodylate buffer. The L4-L5 spinal cord segments were removed and processed for immunocytochemistry by the PAP method. Immunoreactive staining was decreased (SP-53%, GAL-58%, DYN-41%) in the medial part of the superficial dorsal horn as compared to the unoperated side. These findings are interesting in that electrical stimulation of A and C fibers (but not A fibers alone) causes a decrease in staining for these 3 peptides. Supported by grants: NS10161, NS11255 and NS07185.

DISTRIBUTION OF NEUROPEPTIDE Y-LIKE IMMUNOREACTIVITY (NPY) IN THE FELINE PONS AND MIDBRAIN. P.J. Gatti, Y. Tizabi, and V.J. Massari. Dept. Pharmacol., Howard Univ. Coll. of Med., Washington, D.C. 20059.

We have examined the distribution of NPY perikarya and terminals in the pons and midbrain of colchicinized cats. Frozen sections were processed for immunohisto-

We have examined the distribution of NPY perikarya and terminals in the pons and midbrain of colchicinized cats. Frozen sections were processed for immunohistochemistry using an avidin-biotin based method, and a rabbit anti-NPY antibody diluted 1:1000 (Peninsula). In the pons, hundreds of NPY perikarya were noted scattered throughout the inferior colliculus. A large group of densely packed NPY cells was found in the dorsal third of the N. cuneiformis. Substantially fewer labeled cells were seen in the dorsal tegmental nucleus, locus coeruleus, the medial and lateral tegmental field, and the periaqueductal gray. Fewer NPY perikarya were found in the midbrain than in the pons. They were observed in the central tegmental field, the posterior pretectal nucleus, the ventral periaqueductal gray, substantia nigra, and the ventral tegmental area. Very few NPY cells were seen in the superior colliculus. Tyrosine hydroxylase immunoreactive cells in the locus coeruleus, substantia nigra, and ventral tegmental area were vastly more numerous than NPY cells in these nuclei. Therefore, although co-localization of NPY and catecholamines may occur, the vast majority of NPY cells in the pons and midbrain do not contain catecholamines. Supported by A.H.A./N.C.A.

222.4

SOME SPINOTHALAMIC NEURONS ARE IMMUNOREACTIVE FOR SUBSTANCE P.

G. Battaglia, #A. Rustioni, R. Spreafico. Neurological Institute "C.Besta", 20133 Milan, Italy. #Dept. of Anatomy and Cell Biology, University of North Carolina, Chapel Hill, NC 27514

The undecapeptide Substance P(SP) has been shown to act as a neuromediator in the transmission of sensory stimuli, possibly of noxions origin, from small primary sensory neurons to the superficial laminae of the spinal cord. The presence of SP in neurons relaying sensory imputs from the spinal cord to the thalamus has been investigated in the present study, by means of immunocytochemistry and tracing experiments in the rat and the cat. The present experiments reveal the existence of SP-positive neurons in cervical spinal laminae known to contain spinothalamic neurons, and the presence of SP-positive fibers and nerve terminals in thalamic nuclei known to receive spinothalamic afferents. Lesion experiments reveal an evident depletion of SP fibers in some thalamic nuclei after spinal hemisection at high cervical levels. Tracing experiments demonstrate the presence in the spinal cord of SP-immumoreactive neurons retrogradely labeled after injection of the tracer in the thalamus. These data, taken together, indicate that a fraction of spinothalamic neurons do contain high levels of SP. SP may thus act as a synaptic mediator also in second order sensory neurons, possibly involved in nociception.

222.6

RELATIONSHIP OF IMMUNOREACTIVE (IR) NEUROKININ A (NKA) AND SUBSTANCE P (SP) IN VENTRAL MEDULLARY (VM) NEURONS THAT PROJECT TO THE INTERMEDIOLATERAL CELL COLUMN (IML) AND IN IML FIBERS. C. Sasek, M. Haxhiu & C. Helke, Dept. of Pharmacol. Uniformed Services Univ., Bethesda MD 20814.

Multiple mammalian tachykinins have been identified. It has previously been impossible to immunohistochemically distinguish and compare the distributions of these peptides due to the unavailability of specific antisera. The present study uses extensively characterized, specific antisera to compare the distributions of SP and NKA in VM IML-projecting neurons and in their termination site, the IML.

Rats received 40nl injections of rhodamine beads into the T3 IML (Sasek, 1989). Tissue was sectioned and processed for immunofluorescence. Anti-NKA (S. Leeman) and SP (Incstar) were characterized using absorption controls and immunoblotting. To verify that neither antiserum was cross-reacting with neurokinin B (NKB), sections were stained with a specific antiserum to NKB (J. Krause) and the distribution of NKB compared to that of NKA and SP.

NKA and SP were similarly distributed in VM IML-projecting neurons and in fibers in the IML. No NKB IR was identified in the IML, suggesting that the SP and NKA IR in VM IML-projecting neurons was not due to cross reactivity with NKB. The results of these studies demonstrate: 1) the presence of NKA in VM IML-projecting neurons, & 2) the presence of several distinguishable tachykinin systems in the CNS. (NS 24876)

SUBSTANCE P- AND CALCITONIN GENE-RELATED PEPTIDE-IMMUNOREACTIVITY IN NGRVES OF THE RAT UTERUS: LOCALIZATION, COLOCALIZATION AND EFFECTS ON UTERINE CONTRACTILITY. R.L. Shew and R. E. Papka. Dept. Anatomical Sciences, Univ. Oklahoma, Hlth. Sci. Ctr., Oklahoma City, OK 73190.

Immunoreactivity to the neuropeptides substance P (SP)

Immunoreactivity to the neuropeptides substance P (SP) and calcitonin gene-related peptide (CGRP) were examined in nerves in the rat uterus as a prelude to studying their effects on uterine contractility. SP-immunoreactivity (SP-I) and CGRP-I were localized in myometrial nerves throughout the uterine horns. Double labeling revealed SP-and CGRP-I coexist in a subpopulation of uterine nerve fibers, e.g., SP-I was not present in all CGRP-I nerves. Effects of these neuropeptides on uterine contractility was evanined in with one uterine horns. From was examined <u>in vitro</u> on uterine horns from diethylstilbestrol-treated rats (50ug/rat, i.p., 14-16 hrs prior to study). SP (10^{-6} to $10^{-7}M$) stimulated uterine contraction in a dose-related manner. While CGRP has no effect on baseline uterine tension, it (10-M) reduced 10-M SP-stimulated uterine contraction by 56%. These results demonstrate that SP- and CGRP-I are present in, results demonstrate that SP- and CGRP-I are present in, and coexist in some, uterine nerves, presumably afferent nerves. Coexisting SP and CGRP could be co-released from the afferent fibers in an "efferent fashion" and affect uterine contractility; SP having a contractile effect and CGRP having a relaxing effect. (Supported by NIH grant NS 22526, Alumni Grant from OUHSC and Presbyt.Health Fdn.)

222.9

PEPTIDERGIC NEURONS OF POSTNATAL RAT SPINAL CORD AND DORSAL ROOT GANGLION ARE MAINTAINED IN ORGANOTYPIC CULTURES Z. Korade, K. Jeftinija*and S. Jeftinija.

Dept. Veterinary Anatomy, Iowa State University, Ames, Iowa 50011

The aim of the present study was to determine weather culturing of the neurons or injury due to tissue extirpation may evoke a out of place synthe of the peptides in cultured neurons. The neuronal distribution of calcitonin gene-related peptide (CGRP), galanin, Met-enkephalin (Met-enk), and substance P (SP) in cultures obtained from postnatal (P) rats of different age (P1 to P18) and cultured for different periods of time were studied. Explants of spinal cord (SC) and dorsal root ganglion (DRO) were dissected and cultured on chicken plasma-coated slides in Petri dishes or in rotating test tubes. By using immunocytochemistry we were able to identify peptidergic neurons and observe their distribution and relationship with the total population of cellular ments. CGRP-immunoreactivity (IR) was observed in DRG, dorsal horn (DH) neurons and in motoneurons of the spinal cord. The mean diameter of DH CGRP-IR neurons varied from 9.4 to 12.15µm white ventral horn neurons v from 18.96 to 25.91 µm. The number of CGRP-IR neurons per explant was r in dorsal than in ventral horn. Size of DH neurons IR to galanin, Met-enk, and SP were similar to CGRP-IR neurons (10.76 to 11.34µm). The distribution and SP were similar to CGHP-IR neurons (10.76 to 11.34µm). The distribution of Met-enk-IR neurons of Dr resembled very much the distribution of enkephalinergic neurons in freshly sectioned spinal cord. The number of CGRP, SP and galanin-IR cell bodies in DRG explants varied from preparation to preparation. These result demonstrate that number of peptidergic neurons from DRG and spinal cord survive in organotypic culture in arrangements similar to that in vivo. Only the CGRP-IR neurons distribution was found different from that found in freshly sectioned SC. Work was supported by NIH grant NS27751 and USDA grant PL95-113...

222.11

CHARACTERIZATION OF TARGET SPECIFIC NEURONS IN THE RAT SUPERIOR CERVICAL GANGLION. J. I. Luebke and L.L. Wright. Dept. Anatomy, Boston Univ. Sch. Med., Boston, MA 02118

The present studies investigated several aspects of the organization and development of target specific neurons in the rat sympathetic superior cervical ganglion (SCG). A series of retrograde tracer, immunocytochemical, and double-labeling studies revealed significant differences in the size, number, localization and neuropeptide content of SCG neurons that project to the submandibular glands (SMGs), the eyes or the pineal gland. The mean areas of the cell bodies of SMG, eye and pineal projecting neurons are 928, 434, and 794 um², respectively. More neurons are found to project to the SMG than to the eye or the pineal gland (a total of 1704, 90, 116 respectively). A greater percentage of SMG than of pineal projecting neurons display vasoactive intestinal peptide- like immunoreactivity (VIP-LI), but there are no differences in the percentage of neurons displaying neuropeptide Y (NPY)-LI or somatostatin (SS)-LI between the target specific groups. In the entire SCG, more neurons displaying NPY-LI are found than VIP-LI, while differences between the numbers of neurons displaying NPY-and SS-, and SS- and VIP-LI are not significant. No topographic localization of immunoreactive neurons is observed in the SCG. Neonatal deafferentation does not result in changes in the size of neurons, number of neurons, or number of immunoreactive neurons in these target specific populations, or in the total number of immunoreactive neurons in the SCG. In conclusion, these studies describe differences and similarities among target specific populations of SCG neurons, and provide further evidence for the heterogeneous nature of SCG neurons.

Supported in part by NIH grant #3925-5 and GSGC #0147-9

DORSAL ROOT GANGLIA ORIGIN OF A SUBPOPULATION OF SYNAPTIC TERMINALS IN THE FEMALE RAT PELVIC PARACERVICAL AUTONOMIC GANGLIA AND VARICOSITIES IN THE UTERUS CONTAINING CGRP. R.

GANGLIA AND VARICOSITIES IN THE UTERUS CONTAINING CGRP. R. E. Papka. Dept. Anatomical Sciences, Univ. Oklahoma, Hlth. Sci. Ctr., Oklahoma City, OK 73190.

Immunohistochemistry and retrograde axonal tracing with fluorogold was used to examine the origin of a subpopulation of synaptic terminals, containing calcitonin gene-related peptide (CGRP), in the pelvic paracervical ganglia (PG) and varicosities in the uterine cervix. Antiserum against synapsin I (SYN) revealed synaptic endings, while antiserum against CGRP revealed a subpopulation of nerves and terminals. Double labeling revealed the existence of CGRP-immunoreactivity (CGRP-ir) in SYN-ir terminals. SYN-ir was present in punctate granules abutting PG neuron somata and in varicose nerve fibers of cervical myometrium, vasculature and epithelium. CGRP-ir existed in subpopulation of SYN-ir terminals in PG CGRP-ir existed in subpopulation of SYN-ir terminals in PG and nerves in the cervix. Fluorogold injection of PG labeled neurons in dorsal root ganglia (DRG) and spinal cord; however, fluorogold-labeled neurons containing CGRP-ir were visualized only in DRG. Fluorogold injection of uterine cervix labeled neurons in FG and DRG; but, only those in DRG contained CGRP-ir. Co-containment of CGRP and SYN in a subpopulation of terminals in the PG suggests and SYN in a subpopulation of terminals in the PG suggests that CGRP is present in synaptic terminals and not merely in fibers of passage. Also, CGRP-ir terminals in the PG and uterine fibers originate from DRG. (Supported by NIH Grant NS 22526, OU Alumni Grant and Presbyt. Hlth. Fdn.)

222.10

ORIGIN OF BRAIN NATRIURETIC PEPTIDE - LIKE IMMUNOREACTIVE INNERVATION OF THE CEREBRAL ARTERIES. S.E. Spencer, M. Kibbe, K.M. Hurley and C.B. Saper, Department of Neurology, Washington Univ., St. Louis, MO 63110 and Depts. of Pharm. & Physiol. Sci. and Neurology, Univ. of Chicago, Chicago, IL 60637

We recently reported that the cerebrovascular tree in the rat is richly innervated by porcine brain nartiuretic peptide-like immunoreactive (pBNPir) axons. To determine the origin of these fibers, we examined the trigeminal (TRG), pterygopalatine (PTG), superior cervical (SCG), otic and geniculate ganglia for neurons retrogradely labeled with Fast Blue dye transported from the surgically exposed middle cerebral artery, and for cells stained with antiserum against pBNP. On the ipsilateral side, 54% of retrogradely labeled cells were found in the SCG, 28% in the TRG and 19% in the PTG. Of these, 31% in the SCG, 74% in the TRG and 24% in the PTG were pBNPir. Similar staining patterns were seen on the contralateral side, where 14% of retrogradely labeled neurons were found. Unilateral extirpation of the SCG and the contents of the ethmoidal foramen (including the nasociliary nerve) reduced the circumferential Difficult of the Confidence of

222.12

SUBSTANCE P AND CALCITONIN-GENE-RELATED PEPTIDES IN THE SYNOVIAL MEMBRANE AND JOINT FLUID IN NORMAL AND PATHOLOGI-CAL CONDITIONS. R. M. Bowker, Dept. Anat., J. P. Caron*
Dept. LCS, Michigan State Univ., East Lansing, MI 48824 and <u>R. H. Abhold</u>, Dept. Biol., California State Univ. at Fresno, Fresno, CA 93740.

Recent evidence has suggested that neural factors may be

involved in the mediation of arthritic disease. Experimentally, the peptide substance P (SP) is released from nerve terminals in joints (Yaksh, 1988) and may contribute to the severity and symmetry of arthritis (Levine et al., 1985). In spontaneous arthritis in man SP content of synovial fluid from the stifle joint appears to vary. In the present study we sought to investigate these peptides in different joints under both normal and pathological con-Samples of the equine synovial membrane and fluid were obtained and prepared for routine immunocytochemistry (ICC) and radioimmunoassay (RIA). The synovia and fluid samples obtained from the radiocarpal, intercarpal, tibiotarsal and phalangeal joints. The sectioned synovia were incubated in antisera raised to SP and CGRP while the fluid samples were processed for RIA. The ICC demonstrated that SP and CGRP were present in the synovium in association with the vasculature and the intimal layer. samples revealed the presence of these peptides normally, but differences between joints as to their peptidergic content were observed. These differences in peptides may be related to the clinical incidence of arthritic disease in theh different joints.

ORGANIZATION OF PEPTIDE-CONTAINING NERVES OF THE PANCREAS. C. Sternini, R. De Giorgio, K. Anderson, V. L. W. Go, and N. Brecha. Departments of Medicine and Anatomy & Cell Biology and CURE, UCLA School of Medicine, Los Angeles, CA 90024.

The pattern and origin of peptide-containing nerves of the adult rat pancreas were analyzed by immunohistochemistry to gain further insights into the functional organization of peptides that affect pancreatic secretions. In the islets, varicose and thin processes immunoreactive (IR) for bombesin or gastrin releasing processes immunoreactive (IR) for bombesin or gastrin releasing peptide (BBS/GRP) and vasoactive intestinal peptide (VIP) are abundant, those IR for calcitonin gene-related peptide (CGRP) and neuropeptide Y (NPY) are moderate, and those IR for substance P or related tachykinins (SP/TK) are sparse. The density of peptidergic nerves in the stroma and acini is: CGRP, NPY and VIP > BBS/GRP > SP/TK. The vasculature receives prominent NPY, CGRP, and SP/TK innervations. Within the intrapancreatic ganglia, IR fibers are: BBS/GRP and CGRP > NPY and VIP > SP/TK. BBS/GRP-, VIP- and NPY-IR also label cell bodies. Superior abdominal ganglionectomy, but not vagotomy, results in a loss of CGRP- and SP/TK-IR nerves and a reduction of NPY- (with loss of the perivascular NPY) and vagotomy, results in a loss of CURF- and SF/IK-IR nerves and a reduction of NPY- (with loss of the perivascular NPY) and BBS/GRP-IR nerves. The VIP innervation is not affected. CGRP- and SP/TK-IR colocalize extensively. A few CGRP fibers appear to contain BBS/GRP- or VIP-IR. These findings are consistent with a neural input from intrinsic and extrinsic peptidergic neurons in the control of the endocrine and exocrine pancreas.

IMMUNOCYTOCHEMICAL LOCALIZATION OF VASOPRESSIN AND VASOPRESSIN-ASSOCIATED NEUROPHYSIN IN HUMAN JEJUNUM. A.S. FRIEDMANN, V.A. MEMOLI*, S.W.T. CHENG*, AND W.G. NORTH. Departments of Physiology and

Pathology, Dartmouth Medical School, Hanover, NH 03756.

While the neuropeptide vasopressin (VP) is classically recognized to be a product of hypothalamic neurons, it is now known to be produced by cells of the adrenal medulla and ovaries. Recent studies have reported the localization of this peptide in neuronal fibers of the myenteric plexus and muscularis externa of rat duodenum and throughout the small and large intestine of the cat. In the present study we carried out immunocytochemical examination of human jejunum for the presence of VP and vasopressin-associated human neurophysin (VP-HNP) using a mouse monoclonal antibody to VP and a rabbit polyclonal antibody to VP-HNP. Both of these antibodies were produced in these laboratories and shown to exhibit a high degree of antigen specificity. Acetone-fixed human intestine was embedded in paraffin. Sections of Acetone-fixed human intestine was embedded in paraffin. Sections of 0.4 microns were incubated overnight with primary antibody and stained using the avidin-Biotin complex technique. Visualization was achieved by the conversion of 3,3' diaminobenzidine to an insoluble, brown precipitate by peroxidase, following which the slides were counterstained with hematoxylin, dehydrated and coverslipped. VP and VP-HNP immunoreactivity was found to be colocalized in neuroendocrine cells at the base of jejunal crypts. This colocalization suggests that VP production by these cells is similar to that occurring in neurons and that VP may perform an endocrine function in the human gastrointestinal tract. gastrointestinal tract.

INTERACTIONS BETWEEN NEUROTRANSMITTERS II

PROGESTERONE PROMOTES GLUTAMATE-INDUCED RELEASE OF GABA FROM PREOPTIC AREA SYNAPTOSOMES. A. Fleischmann, A.M. Etgen and M.H. Makman. Depts. Psychiat., Biochem., Mol. Pharmacol. & Neurosci., Albert Einstein College of Medicine, Bronx, NY 10461.

Glutamate-induced release of newly-synthesized GABA was measured in preoptic area (POA) synaptoneurosomes from

heasterd in proprie area (1973) synaptone to solutions from ovariect omized rats injected with estrogen alone (2 μ g of estradiol benzoate, EB, 24 and 48 hr before sacrifice) or with EB plus progesterone (P, 500 μ g, 3-4 hr before sacrifice). Glutamate had little effect on GABA release in synaptosomes from EB-treated animals. However, glutamate induced a robust, concentration-dependent release of GABA when POA synaptosomes were prepared from animals injected with both EB plus P. P affected neither the rate of conversion of ³H-glutamic acid to GABA nor glutamate-induced glutamate release. Aspartate and several excitatory amino acid analogs also released GABA from POA synaptosomes from EB+P-treated rats. Glutamate did not influence synaptosomal GABA uptake, nor did a glutamate uptake inhibitor prevent glutamate-stimulated GABA release. Glutamate-dependent GABA release was calciumrelease. Glutamate-dependent GABA release was calcum-independent and was not blocked by excitatory amino acid receptor antagonists. Thus P may promote a novel, calcium-independent release of GABA by excitatory amino acids in a brain region of importance for the regulation of female reproductive physiology and behavior. Supported by MH41414 and by a fellowship from the Camp David Institute (A.F.).

CRF AND ALPHA-ADRENERGIC AGONISTS MODULATE EXCITATORY AMINO ACID RESPONSES IN CULTURED CEREBELLAR PURKINJE NEURONS. Edward A. Fox, Nadine M. Di Julio*, and Donna L. Gruol. Res. Inst. of the Scripps Clinic, La Jolla, CA, 92037.
Inputs to cerebellar Purkinje neurons (PNs) include adrenergic

fibers arising from the locus coeruleus and climbing fibers originating from the inferior olive. Corticotropin-releasing factor (CRF) and glutamate are colocalized in the latter. Potential interactions between CRF or monoamines and glutamate at these synapses were investigated using extracellular recordings of cultured cerebellar PNs.

Quisqualic acid (Quis), a glutamate receptor agonist, evoked a complex response in PNs which typically consisted of an initial abrupt increase in firing rate, followed by a smaller maintained increase, then a decrease of firing below baseline rate and finally a gradual recovery to baseline.

CRF had either no effect on PN spontaneous activity or decreased it. However, when CRF was applied 3-5sec prior to Quis, components of the PN response to Quis were often altered in a dose-dependent manner. Additionally, such CRF exposures prevented trains of doublet or triplet bursts of action potentials which characterized the Quis response of some PNs. The respective a1- and a2-adrenergic agonists phenylepherine and clonidine similarly altered components of the PN response to Quis including the bursting. the bursting.

The mechanisms of these modulatory actions are being investigated with intracellular recordings and calcium imaging. Supported by NS21777 and AA07456.

EFFECTS OF ADRENAL STEROIDS ON MONOAMINE-INDUCED CELLULAR RESPONSES IN RAT HIPPOCAMPUS. M. Joëls* and E.R. de Kloet. Rudolf Magnus Institute, Utrecht, The Netherlands.

Kloet. Rudolf Magnus Institute, Utrecht, The Netherlands.

Adrenal steroid hormones can enter the brain and bind to two types of intracellular receptors: The mineralocorticoid receptor (MR) and the glucocorticoid receptor (GR). Pyramidal cells in the rat CA1 hippocampal area contain both MR and GR. In previous electrophysiological studies we have shown that the steroids (perfused for 20 min.) do not change passive membrane properties of CA1 pyramidal cells, but do affect the accommodation and slow afterhyperpolarization (acc/AHP) associated with a short depolarizing pulse. Thus, activation of the MR decreases the acc/AHP with a delay of at least 15 min. In contrast, occupation of the GR increases the acc/AHP. While the GR-effect is slower in onset, it gradually overrides the acc/AHP. While the GR-effect is slower in onset, it gradually overrides the MR-effect. The acc/AHP is under control of many transmitters in the hippocampus; e.g. norepinephrine (NE) decreases the acc/AHP, probably through the cAMP-linked B-receptor, while serotonin (5HT) decreases the AHP through a pharmacologically undefined receptor not linked to cAMP. In the present study we observed that the NE-evoked decrease in acc/AHP is (in comparison to slices from ADX rats) diminished both in slices from is (in comparison to sinces from ADX rats) diminished both in sinces from sham-operated rats and in slices treated with corticosterone (1 µM) or the glucocorticoid RU 28362. In contrast, 5HT-induced reductions of the acc/AHP observed in slices from ADX rats were not changed in sham-controls or in slices treated with GR-agonists, indicating that the interaction between NE and the steroids is not at the level of the small Ca-dependent K-channels. 5HT-induced hyperpolarizations which are presumably mediated by the 5HTIa-receptor, were markedly reduced by MR-agonists. The results suggest that MR- and GR-activation in hippocampal cells affects both intrinsic properties and cellular responses to transmitters, such that MR-agonists increase and glucocorticoids decrease cellular excitability.

223.4

EXCITATORY AMINO ACID ANTAGONISTS BLOCK AMPHETAMINE—INDUCED ORAL STEREOTYPIES FOLLOWING MICROINJECTION INTO THE VENTROLATERAL STRIATUM. J.M. Delfs and A.E. Kelley. Dept. of Psychology, Harvard University, Cambridge, MA 02138.

Microinjection of amphetamine (AMPH) into the ventroateral striatum (VLS) elicits intense oral stereotypy (licking, biting, self-gnawing) in rats. The striatum receives glutamatergic projections from cortical regions which may interact with dopaminergic nerve terminals. The present experiments examined the role of excitatory amino acid (EAA) receptors in AMPH-induced oral stereotypies. acta (EAA) receptors in ANTH-Induced oral stereotypies, EAA receptors are classified as NMDA, kainate or quisqualate (QUIS) subtypes. All EAA antagonists were administered as intra-VLS pretreatments immediately prior to AMPH microinjection (20 ug) into the VLS. Kynurenic acid (0, 0.05, 0.5, 5.0 ug), an NMDA antagonist, markedly reduced oral stereotypy induced by amphetamine. In contrast, VNN failed to block pourh presents induced by high states of the contrast. KYN failed to block mouth movements induced by cholinergic stimulation of this region. The NMDA antagonist, AP-5 (0, 0.3, 1.0, 3.0 ug) completely blocked stereotypy at all doses. DNQX (0, 0.05, 0.25, 0.5 ug), a QUIS antagonist, significantly reduced stereotypy while GDEE (0, 10, 20, 30 ug), a short-acting QUIS antagonist, failed to block stereotypy at any dose. The time course of GDEE may account for its ineffectiveness in blocking stereotypy. These results suggest that glutamatergic inputs may modulate the expression of amphetamine-induced oral stereotypies.

CCK_B RECEPTOR ACTIVATION CAUSES INCREASED STRIATAL ASPARTATE RELEASE IN VIVO. <u>S Barnes*, F Marshall*, J C Hunter, G N Woodruff and</u> J Hughes Parke-Davis Research Unit, Cambridge,

In vitro studies have demonstrated that CCK_B receptor stimulation causes an increase in aspartate, glycine and GABA release. In receptor stimulation causes an increase this study, the technique of in vivo microdialysis was used to determine whether this action of CCK also occurred in the whole animal. Male Wistar rats of 200-280g were maintained under chloral hydrate anaesthesia and microdialysis probes were stereotaxically implanted into the striatum. Basal amino acid release was stimulated by high potassium aCSF and reduced by TTX and ω -conotoxin.

10 M CCK-8S, when administered down the

10 M CCK-8S, when administered down the microdialysis probe, caused a significant increase in aspartate release (3338 ± 23) and this could be blocked by prior i.p. injection of the CCK selective antagonist L-365,260 (lmg/kg). BL-364,718, at doses selective for the CCK receptor, had no effect on CCK-8S evoked aspartate release.

These data suggest that CCK receptor activation in the striatum of the rat results in increased aspartate release.

N-METHYL-D-ASPARTATE EVOKES DOPAMINE RELEASE FROM RAT STRIATUM VIA DOPAMINE UPTAKE SYSTEM. G. Lonart and M.I. Zigmond. Department of Behavioral Neuroscience and Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260 Glutamate releases dopamine (DA) from striatal slices via an NMDA receptor. Since NMDA receptors are inhibited by Mg²*, they usually are examined in the absence of this ion. Mg²* can affect DA release at multiple sites. Thus, to investigate this phenomenon we have employed a physiological concentration of Mg²* (1.20 mM), adding excess K* (10 mM) to reduce the presence of Mg²* in the NMDA-modulated channel.

	DA overflow (% basal control)			
	300 uM NMDA	10 mM K*	10 mM K ⁺ +300 uM NMDA	
Control Nomifensine	2 <u>+</u> 1%	66 ± 6% 59 + 8%	293 <u>+</u> 23% 68 + 8%	

Whereas NMDA increased DA efflux only at very high concentrations (3-10 mM) under standard conditions, excess K' reduced to 300 uM or less the dose of NMDA needed to elicite this response. Nomifensine (10 uM), an inhibitor of high affinity DA uptake, had no effect on the response to K' alone but reduced the response to K' plus NMDA by 77%. These data suggest that glutamate may initiate the release of DA in striatum via an NMDA-mediated reversal of the high affinity DA transporter. (Supported in part by USPHS grants NS19608, MH43947, and MH00058.)

GLYCINE STIMULATES GABA EFFLUX FROM RAT STRIATAL SLICES <u>S. Bernath, E.S. Vizi and M.J. Zigmond,</u> Dept. of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260; Institute of Experimental Medicine 1083 Budapest, Hungary

We have investigated the effects of glutamatergic and glycinergic drugs on spontaneous and electrically evoked release of GABA from striatum. Tissue slices (350 um) prepared from adult rat striatum were incubated in the presence of [PH]GABA, then superfused (250 ul/min) with Krebs bicarbonate buffer and stimulated twice by electrical field depolarization (20 mA, 10 Hz, 9 sec). Drugs were destricted 20 min before the second citizal triangle and test writing electrical field depolarization (20 mA, 10 Hz, 9 sec). Drugs were administered 20 min before the second stimulation and total tritium efflux was used as a measure of GABA release. Resting GABA efflux was elevated by kainic acid (100 uM, +38%); quisqualic acid (10 uM) also increased GABA efflux but this effect rapidly decayed; NMDA (100 uM) had no impact. None of these drugs had any significant impact on electrically evoked GABA overflow. The effect of kainate and quisqualate on resting GABA efflux was not antagonized by CNQX (10 mM). Under our standard conditions glycine (1 mM) had a variable impact on GABA efflux; however, at a higher perfusion rate (1 ml/min) glycine elevated both spontaneous (+35%) and electrically evoked (+138%) GABA efflux. Although neither 7-chlorokynurenic acid (10 uM) nor MK-801 (1 uM) modified the impact of glycine on resting GABA efflux, both Authough neither 7-chlorokynurenic acid (10 uM) nor MK-801 (1 uM) modified the impact of glycine on resting GABA efflux, both of these drugs antagonized the effect of glycine on evoked GABA overflow. These results are consistent with the hypothesis that depolarization-evoked GABA release is modulated by glycine through a mechanism that may involve the NMDA receptor complex. (Supported in part by USPHS grants NS19608, MH43946, and MH45146.)

DOPAMINERGIC (D2) MODULATION OF STRIATAI GLUTAMATE RELEASE: PHARMACOLOGICAL EVALUATION IN-VIVO. S.J. DAVY and B.K. YAMAMOTO. DEPT. OF PHARMACOLOGY, N.E. OH. Univ. Col. of Med., Rootstown, OH, 44272 and Dept. of Psychiatry, Case Western Reserve Univ., Cleveland, OH., 44106.

Corticostriatal glutamate release appears be under presynaptic control via D2-type dopamine receptors. interaction was dopamine receptors. The mechanism of this interaction was studied using <u>in-vivo</u> microdialysis to measure potassium-induced glutamate release in awake, behaving rats. rats (350-450 g) were chronically implanted with guide cannulae. Forty-eight hours later a dialysis probe was lowered into the caudate. Dialysates were collected every 20 min. and analyzed for glutamate and other amino acids by the cleatrochemical detection. HPLC with electrochemical detection. Local perfusions of high (80 mM) potassium buffer containing the D2 agonist LY171555 were found to containing the D2 agonist LY171555 were found to block potassium-induced glutamate release in a dose-dependent manner. Perfusions with high potassium plus the D2 antagonist (-)sulpuride significantly (p<.05) increased the potassium-induced release of glutamate. These studies support the theory that striatal glutamate release is modulated by the D2 receptor.

IN VIVO EVIDENCE THAT BASAL DOPAMINE EFFLUX IN STRIATUM IS NOT REGULATED BY ENDOGENOUS EXCITATORY AMINO ACIDS. K.A. Keele, M.J. Zigmond, 8.E.D. Abercombie, Depts. of Behavioral Neuroscience and Psychiatry and the Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

A number of in vitro and in vivo studies have shown that exogenous excitatory amino

A number of *in vitro* and *in vivo* studies have shown that exogenous excitatory amino acids (EAAs) or their agonists can increase dopamine (DA) release in striatum. Using *in* vivo microdialysis, we examined the extent to which endogenous EAAs are able to regulate the resting level of DA in extracellular fluid (ECF) in striatum of unanesthetized rats. The EAA antagonists kynurenate (KYN), 6-cyanor-7-ritroquinoxaline-2,3-dione (CNQX), and DL-2-amino-5-phosphonovalerate (APV) were administered into striatum directly via the dialysis probe. Depending on the concentration applied, these compounds produced either no change or an increase in the DA level in ECF.

Antagonist (mM)

Basal DA (pg/20ul)

Drug DA (pg/20ul)

CNQX (0.1; n=3)	12.4 ± 1.8	13.3 + 1.7
(1; n=3)	38.5 + 9.9	87.4 + 28.1
APV (0.1; n=3)	24.7 - 5.4	27.8 + 6.1
(0.75; n=3)	32.4 + 0.8	46.9 + 8.8
KYN (1; n=6)	17.3 ± 3.4	20.7 + 4.3
(10: n=4)	23.7 + 2.3	50.8 + 12.9

To determine whether these antagonists completely and specifically blocked EAA receptors, the EAA agonists kainate (KA; 0.1 mM) and N-methyl-D-aspartate (NMDA; 1 mM) were administered into striatum with or without co-infusion of the antagonists. KA and NMDA elevated DA in dialysate by 424±78% (n=4) and 249±122% (n=3), respectively. The kainate-induced increase was blocked by co-infusion of CNOX (0.1 & 1 mM; n=384) and the NMDA-induced increase was blocked by co-infusion of APV (0.75 mM; n=3) but not CNOX (1 mM; n=2). Thus, although the application of exogenous EAAs or their agonists can increase DA release, the present findings using EAA antagonists suggest that endogenous EAAs do not exert a tonic excitatory effect on basal DA release in striatum (Supported by grants NS 19608 and MH 18273).

223.10

NOREPINEPHRINE POTENTIATES GABA-INDUCED CURRENTS IN CEREBELLAR PURKINJE CELLS. <u>I.E. Cheun and H.H. Yeh</u> Dept. Neurobiology and Anatomy, Univ. Rochester Med. Ctr., Rochester, NY 14642. Extracellular single unit recording studies in the rat cerebellum have shown that norepinephrine (NE) facilitates GABA-induced suppression of Purkinje cell spike activity. Although various lines of indirect evidence suggest that NE may

spike activity. Authoright various lines of indirect evidence suggest that NE may exert its effects by directly influencing Purkinje cell responsiveness to GABA, unequivocal demonstration of such a postsynaptic site of NE action in a preparation which is amenable to further studies of the underlying membrane and intracellular mechanisms has been lacking. Here, using whole-cell patch-clamp recording procedures, we examined under voltage-clamp the effect of NE on GABA-activated currents (IGABA) in Purkinje cells acutely dissociated from the postpatal rate cereballum. postnatal rat cerebellum.

postnatal rat cerebellum.

Immunoreactivity to a Purkinje cell marker, the PEP-19 monoclonal antibody, aided morphological identification following acute dissociation. IGABA was found to be mediated exclusively by the GABAA receptor, being associated with an increase in chloride conductance, mimicked by muscimol and potentiated by diazepam. Baclofen (100 uM) produced no conductance change. In 26 Purkinje cells, the amplitude of IGABA elicited in response to brief (150-250 ms) pressure pulses of GABA (10-20 uM) was compared before, during and after a period of continuous NE (\leq 500 uM) application. In all but two cases (24 of 26), exposure to NE resulted in a reversible, fractional increase in IGABA. Importantly, at the concentrations tested, NE by itself had no detectable effects on membrane conductance. Norepinephrine potentiated IGABA at all holding notentials tested but did not alter GABA reversal potential. Consistent holding potentials tested but did not alter GABA reversal potential. Consistent with an interaction with GABA_A receptor-mediated activity, both muscimol-induced and GABA-activated chloride currents were potentiated by NE. Thus, our results establish definitively the presence of a postsynaptic mechanism by which NE may modulate GABA_A receptor function in cerebellar Purkinje cells.

CYCLIC AMP AS AN INTRACELLULAR MODULATOR OF GABAA

CYCLIC AMP AS AN INTRACELLULAR MODULATOR OF GABAA RECEPTOR FUNCTION IN CEREBELLAR PURKINJE CELLS. H.H. Yeh and J.E. Cheun, Dept. Neurobiology & Anatomy, Univ. Rochester Med. Ctr., 601 Elmwood Ave., Rochester, NY 14642.

Based on results of the preceding study that GABA-induced currents are potentiated by norepinephrine (NE) and on reports that ligand-gated ion channels can be modified by cyclic nucleotides, we are testing the hypothesis that NE alters GABAA receptor function in cerebellar Purkinje cells via the beta-receptor/cyclic AMP-dependent protein kinase pathway. Purkinje cells were identified morphologically following acute papain dissociation from the postnatal rat cerebellum. Conventional whole-cell patch-clamp techniques were used to record under voltage-clamp there.

patch-clamp techniques were used to record under voltage-clamp their current responses to brief (50 - 200 ms) pressure pulses of GABA (5 - 20 uM). In separate series of experiments, isoproterenol (500 uM) or forskolin (200 uM) was used to stimulate directly the beta-receptor or adenylate cyclase, respectively. In all cells tested, continuous application of either agents between GABA test pulses resulted in a fractional increase in GABA-induced current similar to that observed with NE. In addition, exposure of Purkinje cells to the membrane permeable analog, 8-bromocyclic AMP (\leq 500 uM), increased the amplitude of the GABA-induced current. This effect was reversible and was observed in 6 of 7 cases. Ongoing experiments are focusing on examining other steps along the beta-receptor/cyclic AMP-dependent protein kinase cascade to provide further insight into determining whether a phosphorylation of the GABA_A receptor by the cyclic AMP-dependent kinase may be involved. Thus far, our results clearly indicate that an elevated intracellular level of cyclic AMP can lead to a modification of GABA_A receptor function.

POTENTIATION OF THE BEHAVIORAL EFFECTS OF BUSPIRONE BY THE and ADRENERGIC ANTAGONIST PRAZOSIN. <u>S. Gleeson and J.E. Barrett</u>, Dept. of Psychiatry, Uniformed Services University of the Health Sciences, 4301 Jones Bridge Rd., Bethesda, MD 20814-4799.

The novel anxiolytic buspirone generally is thought to exert its therapeutic effects by decreasing serotonin neurotransmission. However, buspirone has substantial effects on noradrenergic neurotransmission that probably involve

a-adrenoceptors.

α-adrenoceptors.
Pigeons were trained to keypeck under a multiple schedule of reinforcement in which responding during one component also was suppressed by punishment. Unpunished responding was not significantly affected by buspirone except at higher doses which decreased responding. Low rates of responding suppressed by punishment were increased substantially by doses of 0.1 to 5.6 mg/kg buspirone. Prazosin (1 mg/kg) had no effect on unpunished responding, and only slightly increased punished responding. However, a combination of prazosin (0.1 to 3 mg/kg) and buspirone (0.1 to 5.6 mg/kg) produced increases in punished responding that were greater than the increases produced by buspirone alone.

were greater than the increases produced by buspirone atone. In a second experiment, pigeons were trained to discriminate 1 mg/kg buspirone from saline using standard drug discrimination procedures. Generalization gradients obtained for buspirone showed little or no drug-key responding when low doses of buspirone were administered, although higher doses produced full generalization. Prazosin (1 to 10 mg/kg) produced predominantly saline-key responding in most birds, but these doses in combination with 0.1 or 0.3 mg/kg buspirone resulted in a dose-dependent increase in the proportion of drug-key responses, and in some cases

increase in the proportion or drug-key responses, and in some cases produced complete generalization.

Although the mechanism by which buspirone's effects are potentiated by prazosin remains obscure, the present results suggest that at least some of the effects of buspirone may involve the noradrenergic as well as the serotonergic neurotransmitter system.

STIMULATION OF DORSAL RAPHE NUCLEUS NEURONS ENHANCES DOPAMINE AND SERVICIONIN RELEASE IN THE NUCLEUS ACCUMENS.
K. Yoshimoto, W.J. McBride, L. Lumeng*, and T.-K. Li*.
Psychiatric Res. & Regenstrief Insts., Indiana Univ.
Sch. Med. & VAMC, Indianapolis, IN 46202.
The effects of microinfusion of glutamate (GIU),
muscimol (MIS) and serviconin agonists into the dorsal

muscimol (MUS) and serotonin agonists into the dorsal raphe nucleus (DRN) on dopamine (DA) and serotonin (5-HT) release in the ipsilateral nucleus accumbens (ACC) were studied in freely moving adult, male Wistar rats using brain microdialysis. In all experiments, a 0.5 ul volume was injected over a 5-min period. Within 15 to 60 min after the microinfusion of 0.75 ug GIU, the amounts of DA and 5-HT in the ACC dialysates increased over the baseline values 150 to 200% (N=3, P<0.05). Microinfusion of 0.5 ug MUS did not alter the amounts of either DA or 5-HT in the dialysates although there was a tendency for a reduction of 5-HT levels 45-60 min after infusion. Microinfusion of 2.0 ug 5-HT or 1.0 ug 8-OH infusion. Microinfusion of 2.0 ug 5-HT or 1.0 ug 8-OH DPAT (5-HT_{1A} agonist) into the DRN decreased the levels of 5-HT 20-50% in the dialysates. There was also a tendency for lower levels of DA in the dialysates following administration of 8-OH DPAT into the DRN. receptors can stimulate DRN 5-HT neurons; (b) activation of GIU receptors can stimulate DRN 5-HT neurons; (b) activation of DRN 5-HT_{1A} cell body autoreceptors decreases terminal 5-HT release; and (c) DRN 5-HT projections stimulate VTA DA neurons. (AA 03243, AA 07611)

223.12

GABAERGIC INNERVATION IN CEREBRAL ARTERIES: A MORPHOLOGICAL AND PHARMACOLOGICAL STUDY. T. OKUNO, T. J-F. LEE, H. IMAL, T. ITAKURA, M. UENO, Y. NAKA, K. NAKAL, S. HAYASHI, 2 and N. KOMAI, Department of Pharmacology, Southern Illinois University School of Medicine, Springfield, IL 62794, USA., Department of Neurological Surgery, Wakayama Medical College, Wakayama (40, JAPAN).

Our recent studies have demonstrated that cerebral blood wessels receive dense GABAergic innervation (Imai et al., 1990). It has been suggested that neuronal GABA may act as a modulator altering the release of transmitters from the neighboring nerve terminals. The morphological relationship between GABAergic and other autonomic innervations and the effect of GABA on transmural nerve stimulation (TNS)- and drug-induced vasoreactions were examined in cerebral artery. GAD-immunoreactive (I) nerve fibers were found to overlap with most choline acetyltransferase (ChAT)-I, 62% of calcitonin generelated peptide (CGRP)-I and 42% of vasoactive intestinal polypeptide (VIP)-I fibers in the cat cerebral artery. Exogenously applied GABA (10⁻³-10⁻³M) inhibited TNS-induced contraction of rabbit basilar and ear arteries, and TNS-induced relaxation of pig basilar artery. GABA also inhibited NE- and 5HT-induced contractions, and isoproterenol-induced relaxation. These results indicate that in cerebral arteries GABAergic innervation has close morphological relationship with other autonomic innervations, and further suggest that the neuronally released GABA may act postsynaptically to modulate vasomotor response induced by other transmitters. (Supported by NIH HL27763, AHA/IHA and Southern Illinois University School of Medicine)

223.14

THE EFFECTS OF 5HT RECEPTOR ANTAGONISM ON DOPAMINE AND 5HT LEVELS IN RAT BRAIN TISSUE AND DIALYSATE. L. L. DEVAUD and E. B. HOLLINGSWORTH, Division of Pharmacology

Ritanserin, a specific serotonin₂ (5HT₂) receptor antagonist, was employed to investigate interactions between dopamine (DA) and 5HT neurotransmission in brain areas relevant to psychosis. After a single dose of 0.63 mg/kg ritanserin, ip, rats were sacrificed at either 2 hours (acute) or 4 days. Acute ritanserin elicited a 13.6 ± 6.5% increase in DA levels and a 7.1 ± 3.0% increase in 5HT levels in the caudate. An increase of Increase in 5H levels in the caudate. An increase of the second in the cortex. In the nucleus accumbens (n.a.), both DA and 5HT levels were decreased by 14.6 ± 6.5 and 11.5 ± 5.3 %, respectively, with increased turnover. Microdialysis studies of the n.a. showed increases in both DA and 5HT levels by two hours after ritanserin treatment, with no changes in metabolite levels. At four days after the single dose of ritanserin, DA levels were now decreased 10.4 ± 2.4% and 5HT levels decreased 22.0 \pm 4.7% in the caudate. A 12.9 \pm 2.1% decrease in 5HT levels was seen in the cortex. The acute decreases in both DA and 5HT levels noted in the n.a. persisted (14.2 + 4.0 and 23.9 \pm 8.2%, respectively) to the four day time point. These results suggest that 5HT₂ receptor antagonism modulates both DA and 5HT transmission in a complex, site-selective fashion which varies over time.

223.16

PRESYNAPTIC MODULATION OF DOPAMINE EFFLUX BY 5-HT₃ RECEPTOR-MEDIATED MECHANISMS IN RAT NUCLEUS ACCUMBENS: IN VIVO BRAIN MICRODIALYSIS STUDIES. J. Chen, H.M. van Praag*, and E.L. Gardner. Departments of Neuroscience and Psychiatry, Albert Einstein College of Medicine, New York, NY 10461.

CNS serotonergic (5HT) mechanisms are known to innervate and modulate the mesolimbic dopamine (DA) system (de Belleroche & Bradford, <u>J. Neurochem.</u> 35:1227, 1980), suggesting novel pharmacological approaches for psychosis and drug addiction (Tricklebank, <u>Trends</u> Pharmacol.Sci. 10:127, 1989). To further study these 5HT-DA interactions, we examined DA efflux in the rat nucleus accumbens by in vivo microdialysis and the effect on such efflux of the selective 5HT₃ agonist 1-phenylbiguanide. At concentrations of 0.01-1.0 mM in the perfusate, 1phenylbiguanide caused a robust dose-dependent enhancement of presynaptic DA efflux in nucleus accumbens of awake, freely moving rats. This agonist effect by 1-phenylbiguanide was antagonized by co-perfusion of the selective 5HT₃ antagonists GR38032F or zacopride at concentrations of 1 mM in the perfusate. Similar effects were observed in 5HT-denervated rats. These findings suggest 1) that there is a potent modulation of presynaptic DA efflux in the mesolimbic DA system mediated via 5HT₃ receptors; and 2) the modulating 5HT₃ receptors appear not to be located on 5HT afferents to the accumbens but may be located presynaptically on DA terminals of the mesolimbic DA pathway.

SUBREGIONAL EFFECTS OF COCAINE IN THE NUCLEUS ACCUMBENS. Y.L Hurd, H.C. Fibiger and C. Gerfen, Clinical Neuroscience Branch and Lab. of Cell Biology, NIMH, Bethesda, MD 20892 and Psychiatry Dept., Univ. British

Columbia, Vancouver, Canada¹.

The mesolimbic dopamine (DA) system is considered the site of action for the reinforcing properties of drugs of abuse. the present study subregional alteration of DA transmission within the nucleus accumbens (NAS) was assessed following ucleus accumbens (NAS) was assessed following cocaine. Cocaine, a potent DA uptake inhibitor, potentiated DA overflow to a greater extent in rostral areas of the NAS, as measured by in vivo microdialysis. This subregional effect of cocaine might be linked to the fact that the density of DA transport sites (labelled by mazindol ligandbinding autoradiography) was higher in rostral NAS.

Furthermore, DA transport sites were virtually absent from the most dorsomedial area of the caudal "shell" region of the NAS.

Other transmitter systems under the regulation of DA were also monitored by in situ hybridization histochemistry. The mRNA expression for e.g., dynorphin, enkephalin and substance P presented a heterogeneous distribution within the NAS and was affected by exposure to cocaine.

INTERACTION OF AZIDO-A⁸-THC WITH THE CANNABINOID RECEPTOR IN BRAIN. A.C. Howlett, D.M. Evans, D. Houston, G. H. Wilken*, A. Charalambous* and A. Makriyannis*. Dept. of Pharmacology, St. Louis University, St. Louis MO 63104 and School of Pharmacy and Institute of Materials Science, University of Connecticut, Storrs, CT 06268

The cannabinoid receptor in rat brain has been described using the agonist ligand [³H]CP-55940 and has been characterized for its ability to inhibit cyclic AMP accumulation through a Gi mechanism (Bidaut-Russell et al, J. Neurochem. '90). Ligands for several classes of neuroreceptors fail to displace binding of [³H]CP-55940, including opioid, sigma, benzodiazepine, GABA, serotoninergic, nicotinic, muscarinic, catecholaminergic and certain peptide ligands.

Further characterization of the cannabinoid receptor has used azido derivatives. Azido-A⁸-THC and iodo-azido-A⁸-THC displace [³H]CP-55940 binding with IC₅₀ values of 10 and 100 nM, respectively. Following equilibration and irradiation, azido-A⁸-THC prevents [³H]CP-55940 binding to the cannabinoid receptor. Thus, these compounds can be used as covalent modifiers of the cannabinoid receptor.

receptor.

BINDING OF [3H]-NISOXETINE TO RAT BRAIN: A NEW RADIOLI-GAND FOR NOREPINEPHRINE UPTAKE SITES. S.M. Tejani-Butt, M. Bauer*, D.J. Brunswick and A. Frazer. Dept. Psychiatry, Univ. of Pa Sch. of

Med. & Dept. Vet. Affairs Med. Ctr., Phila., PA 19104.

The uptake site for norepinephrine (NE) in brain has been studied much less than the uptake site for 5-HT, probably due to the absence of an adequate radioligand for this site. This report describes the binding properties of [3H]-nisoxetine, a selective inhibitor of the uptake of NE. In rat cerebral cortical homogenates, the binding of [3 H]-nisoxetine is saturable and a single class of binding sites (K_d =1nM) was obtained even at radioligand concentrations up to 20 times the Kd value. At the K_d concentration, about 70% of total $[^3H[$ -nisoxetine binding is specific (as defined by $1\mu M$ mazindol). The specific binding of [³H[-nisoxetine was sodium dependent. The potencies of drugs to inhibit the uptake of NE correlate highly with their potencies to inhibit [3H]-nisoxetine binding. High concentrations of [3H[-nisoxetine binding sites were measured in the hypothalamus and cerebral cortex with lower concentrations in the corpus striatum. Studies using [3H]-nisoxetine for mapping of sites associated with NE uptake by quantitative autoradiography indicate that the pattern of binding of [³H]-nisoxetine is consistent with the pattern of noradrenergic innervation. Destruction of central NE neurons by i.p. administration of DSP4 resulted in large decreases in the binding of [3H]-nisoxetine in areas of brain receiving innervation from the locus coeruleus (LC), with little change in binding in the LC itself. [3H]nisoxetine should be a useful tool to study noradrenergic innervation in discrete anatomical regions in post-mortem samples of brain from patients with neuropsychiatric disorders. (Supported by research funds from the Department of Veterans Affairs and USPHS grant DA 05137).

224.3

LIGHT AND ELECTRON MICROSCOPIC CHARACTERIZATION OF DOPAMINERGIC PROCESSES IN HUMAN NEOCORTEX. <u>LF, Smiley, K.</u> Szigeti, S.M. Williams, and P.S. Goldman-Rakic. Sec. of Neuroanatomy, Yale

Univ. Sch. of Med., New Haven, CT 06510.

While dopaminergic axons have been demonstrated in the neocortex of non-human primates, they have not been directly visualized in the human cortex. In the present study, human neocortex was removed during tumor excision, or during neurosurgical treatment of intractable epilepsy. Tissue used was resected in order to access the pathological locus, and did not appear grossly abnormal. In 5 cases, cortex was from the amerior temporal lobe, and in 1 case from the frontal pole. Tissue was immediately fixed, and later processed for immunocytochemistry with a monoclonal antibody directed against dopamine, or with a polyclonal antibody against tyrosine

Light microscopic analysis revealed that in all areas examined, dopamine-like immunoreactive (DA) fibers were more abundant in the superficial layers (lower I,II) and in the infragranular layers (V, VI), and less dense in the intermediate cortical layers (III, IV). In all layers, fibers were seen to form numerous varicosities, and to layers (III, IV). In all layers, libers were seen to form numerous varincostites, and overy in size from thick fibers with long trajectories, to very fine fibers usually having shorter trajectories. Fibers usually were relatively straight, sparsely branched, and were oriented in various planes within the cortex. However, in layer I there were abundant fibers running parallel to the pial surface. TH showed a similar distribution and morphology of fibers, except it also labeled a population of cells in layers V and VI, which were not seen with DA.

VI, which were not seen with DA.

This distribution and morphology of DA fibers is similar to that previously described in the monkey neocortex. Electron microscopic analysis also showed similarities to monkey. In human, DA varicosities were vesicle filled, and formed symmetrical synapses. Spines, dendrites, and axons were seen to receive synaptic input from DA processes. Similar spines and dendrites receiving DA input were demonstrated to belong to pyramidal cells in monkey (Goldman-Rakic et al., PNAS, 86:9105, 1989). Supported by MH44866.

ANATOMICAL DISTRIBUTION AND PHARMACOLOGY OF THE DOPAMINE UPTAKE COMPLEX IN RODENT AND HUMAN BRAIN. E.K. Richfield and K. Farrell. Neurology Dept, University of Rochester, Rochester, NY 14620

Rochester, NY 14620

The dopamine uptake complex (DAUC) is responsible for the reuptake of dopamine (DA) after release by neurons. The DAUC is implicated in neurolologic and psychiatric disorders. A quantitative autoradiographic assay using [3H]-GBR 12935 was developed to study the pharmacology and anatomy of the DAUC in rat and human brain.

The pharmacology of the DAUC is similar in rat and human brain. Binding to this site is saturable and reversible. All competitors tested at this complex displace DAUC specific binding with a single affinity except for cocaine and the cocaine congener WIN 35,428 in both rodent and human brain. These two compounds display biphasic displacements and are best modeled as two sites. The rank order of all competitors is in agreement with drugs active at this complex.

The density of the DAUC in rodent brain is very high in the dorsal and ventral striatum, olfactory tubercle, substantia nigra and ventral tegmental area. Areas with moderate density include the basolateral n. of the amygdala, subthalamic nucleus, and hippocampus. Low, but specific binding is also seen in a wide variety of regions including the cerebral cortex, thalamus, brainstem, and spinal cord.

The regional density in man is less than in rat. The density of the

cortex, thalamus, brainstem, and spinal cord.

The regional density in man is less than in rat. The density of the DAUC is heterogeneous in caudate n. similar to that of acetylcholinesterase staining. Other regions are less heterogeneous.

These findings support the existence of two sites for cocaine on the DAUC in rat and man. These findings support the widespread distribution of the DA neuron system in rodent brain. Human basal ganglia displays a heterogeneous pattern of the DAUC which may have clinical implications in several disease states including Parkinson's disease and schizophrenia.

224.4

PATTERN AND EXTENT OF DOPAMINE CELL DEATH IN RATS FOLLOWING INTRAVENTRICULAR 6-HYDROXYDOPAMINE, J.R. Hollerman & A.A. Grace, Depts of Behavioral Neuroscience & Psychiatry, Univ of Pittsburgh, Pittsburgh, PA, 15260.

Specific destruction of forebrain dopamine (DA) terminals in rats using intracerebroventricular (ICV) administration of 6-hydroxydopamine (6-OHDA) also causes retrograde degeneration of DA cell bodies in the midbrain. Lesions produced in this manner have been used as an animal model of Parkinson's disease. We investigated the relationship between striatal DA depletion (indicative of DA terminal destruction) and DA cell death in the midbrain in rats treated with 75, 100 or 200µg of 6-OHDA ICV, using HPLC to measure striatal DA and SPG-induced histofluorescence to count DA cell bodies. With the two lower doses, we found a sparing of DA cell bodies in the midbrain relative to striatal DA depletion, especially in anterior regions of the midbrain. With the 200µg dose, cell death was equivalent to striatal DA depletions in central and posterior regions, while anterior regions again were spared. We also attempted to determine the influence of DA cell firing rate on susceptibility to 6-OHDA toxicity. Because ICV 6-OHDA exerts its toxic effect upon entering DA terminals via high affinity uptake, changes in 6-OHDA toxicity with alterations in firing rate should reflect any relationship between cell activity and this uptake process. Neither pretreatment with GBL nor with HAL (to decrease or increase DA cell activity, respectively) prior to administration of 150µg 6-OHDA ICV produced appreciable effects on either the extent of striatal DA depletion or DA cell death produced by this dose of 6-OHDA. Overall, the pattern and extent of cell death are consistent with ICV 6-OHDA having a preferential effect on nigrostriatal DA neurons, although increasing doses have greater effects on other DA projections. Our results with GBL and HAL do not support the idea that high affinity uptake and cell activity are interrelate

A COMPARATIVE ANALYSIS OF THE DOPAMINERGIC SYSTEM IN THE BRAIN OF AMPHIBIANS. A.Gonzalez*, W.J.A.J.Smeets¹ and G.E.Meredith¹. Dept.Cell.Biol., Univ.Complutense, Madrid, Spain and ¹Dept.Anat., Vrije Univ. Amsterdam.

The dopaminergic system of an anuran, Rana ridibunda, and an urodele, Pleurodeles waltlii was investigated

immunohistochemically with antibodies against dopamine (DA) and tyrosine hydroxylase (TH). In both species, DA-immunoreactive (DAi) cell bodies are located in the olfactory bulb, the preoptic area, several hypothalamic nuclei, including the nucleus of the periventricular organ (NPv), the pretectal area, the midbrain tegmentum, and around the solitary tract. CSF-contacting cells are present in the caudal rhombencephalon and spinal cord. The TH antiserum revealed additional cells in the olfactory bulb and the isthmal region, but failed to stain the CSF-contacting cells in NPv.

DAi fibers are widespread throughout the brain in both species. Major differences were noted in the forebrain. In R. ridibunda, the densest DA innervation occurs in the nucleus accumbens, in contrast to P. occurs in the nucleus accumbens, in contrast to r. walthii where most fibers are found in the striatum. Furthermore, DAi fibers were observed in the pallial areas of the urodele, but not in the corresponding regions of the frog brain. When compared with other vertebrates, it appears that the dopaminergic system of amphibians shares many features not only with other anamniotes, but also with amniotes.

224.7

CONTINUOUS CEREBRAL MICROINJECTION TECHNIQUE AS A SUBSTITUTION OF NEURAL TRANSPLANT FOR NEUROSECRE

SUBSTITUTION OF NEURAL TRANSPLANT FOR NEUROSECRETORY MODULATION. K.Nishino and M.Kowada*, Dept. of Neurosurg., Akita Univ.Sch.of Med., Akita OlO, Japan. We studied whether certain molecules diffuse in the brain. Mini-osmotic pumps (model 2001, Alza, USA) were implanted in the intraperitoneal cavities of mongolian gerbils (BW 50-75gm,male). Then PE 60-tubes connected to the pump were sterectactically placed in the brain. First, each of the six animals were injected 50 l of 1% methylene six animals were injected 50 l of 1% methylene blue(MB) into the ventricles(gr 1) or 1% MB continuously in the brain (gr 2) to determine to what degree the dye diffuses. Second, seven animals were continuously injected 40 l norepinephrine(NE)(gr 3). Two weeks later the four animals in gr 3 were decapitated, and the brains were divided into 2.5 mm thick hemicoronal slices. NE assay was done with HPLC and ED. 11 animals of the grs 2 and 3 were neurologically free except in two cases with the infection. MB diffuses more in gr 2 than in gr 1. The NE level was 5-30 times and twice higher on the injected and non-injected sides than the brain damage was not associated with the injection even at the ultrastructural level. The data show that a implanted DDS would be one of rational sub-stitutions of neuronal transplant for neurosecretory modulation.

224.9

PHARMACOLOGICAL CHARACTERIZATION OF NORADRENERGIC RESPONSES IN RELAY NEURONS FROM RAT LATERAL GENICULATE NUCLEUS. $D_{\rm A}$. Coulter, I.R. Huguenard and D.A. Prince, Dept. Neurology, Stanford University Medical Center, Stanford, CA 94305. The thalamus receives an adrenergic projection from locus coeruleus, and autoradiographic studies have demonstrated α_1 , α_2 , and β -adrenergic binding sites in thalamus. Using whole-cell voltage-clamp recording in 400 μ m thalamic slices, we have characterized the response of relay neurons in rat dorsal lateral geniculate nucleus (dLGN) to norepinephrine (NE) and α -adrenergic agonists. Drop application of NE (500-2000 μ M) to the surface of the dLGN elicited an inward current and conductance decrease in all neurons. In addition, in 33% of these cells, an outward current with a conductance increase preceded the inward current could be blocked by the α_1 antagonist pracoins (1 μ M bath applied, or 100 μ M drop application to the prechamber), but not by the α_2 antagonist yohimbine (1 μ M bath, or 100 μ M drop) or the β antagonist propranolol (1 μ M bath). A similar inward current accompanied by a conductance decrease could be elicited by the α_1 agonist 6-fluoronorepinephrine (1 mM drop), but not by the α_2 agonist condindine (CL, 200 μ M drop), which elicited an outward current accompanied by a conductance increase. In higher concentrations (500-1000 μ M drop), CL evoked an outward current elicited by NE and/or CL varied in a Nernstian manner with the external [K⁺]₀. In addition, both the outward and inward currents elicited by CL or NE showed inward rectification at potentials more negative than 80 mV, and outward rectification more positive than -60 mV.

These data suggest that the response to NE in adult rat dLGN cells results from activation of at least two receptors. A portion of the response appears to be elicited by activation of α_2 receptors, turning on an inwardly rectifying potassium current with similar rectification. This study dem

PURTHER OBSERVATIONS ON THE DOPAMINERGIC CELLS IN THE HYPOTHALAMIC PERIVENTRICULAR ORGAN OF NONMAMMALIAN VERTEBRATES. W.J.A.J.Smeets and A.Gonzalez. Dept.Anat., Vrije Univ.Amsterdam, The Netherlands.

Recently, it was shown that the hypothalamic periventricular organ (OPH) of reptiles contains liquor (CSF) contacting cells that are immunoreactive to dopamine (DA) antibodies, but do not stain with tyrosine hydoxylase (TH) antisera (Smeets, W.J.A.J. and H.W.M.Steinbusch, J.Chem.Neuroanat. 3:25, 1990).

In the present study, DA- and TH- immunohisto-chemistry was applied to the brains of two amphibians, the anuran Rana ridibunda and the urodele Pleurodeles waltlii, and the chicken, Gallus domesticus. As in reptiles, DA-immunopositive/TH-immunonegative CSF-contacting cells were observed in OPH suggesting that this is a primitive brain character of nonmammalian vertebrates.

Furthermore, 8 lizards (Gekko gecko) received intra-

Furthermore, 8 lizards (Gekko gecko) received intraperitoneal or intraventricular injections of a-methylpara-tyrosine, a DA synthesis inhibitor. Survival times ranged from 1.5-5 hours. Subsequent staining with DA antiserum revealed an almost unaffected staining in OPH, but a dramatic decrease in the other DA cell groups supporting the notion that the cells in OPH may accumulate DA. It is suggested that the CSF plays an important role in dopamine neurotransmission in nonmammalian vertebrates.

ALPHA,-ADRENOCEPTOR AUGMENTATION OF THE AFTER-HYPERPOLARIZATION OF FROG VENTRAL ROOT POTENTIALS INVOLVES A OUABAIN-SENSITIVE PUMP. S.B. Shope, A.M. Levinson*, A.M. Holohean, J.C. Hackman, and R.A. Davidoff, Neurophysiology Lab., VAMC and Dept. of Neurology, Univ. of Miami School of Medicine, Miami, FL 33101.

School of Medicine., Miami, FL 33101.

Spinal cords were dissected from adult *Rana pipiens*, hemisected, and placed in a sucrose gap recording chamber. The 10th dorsal root was tetanically stimulated (supramaximal 1.0 msec pulses, 25 Hz, 10 sec) and the reflex responses were recorded from the 9th ventral root. The and the reflex responses were recorded from the 5th ventral root. The ventral root response consisted of a sustained motoneuron depolarization followed by a long-duration (50 sec), large (4.4 mV) after-hyperpolarization (AHP). Norepinephrine (10 μ M) caused an augmentation of both the amplitude (188%) and duration (50%) of the AHP. This effect was mimicked by the α_2 agonist, clonidine (100 μ M). Both the norepinephrine and clonidine induced AHP increases were blocked by the selective α_2 antagonist, yohimbine (10 μ M), but not by the β antagonist, propranolol (100 μ M). Addition of ouabain or dihydro-ouabain in a concentration (10 μ M) sufficient to block sodium pumping in frog neurons, eliminated the motoneuron AHPs both in normal Ringer's solution or during the application of 10 µM clonidine

Thus, the AHP produced in spinal motoneurons by tetanization of afferent fibers and its augmentation by activation of α_2 adrenoceptors are ouabain-sensitive. The data suggest an involvement of the Na⁺/K⁺ pump in the potential. (Supported by VAMC Funds and USPHS grants NS17577 & NS 07044).

NORADRENERGIC ENHANCEMENT OF GABA-INDUCED MEMBRANE CONDUCTANCE INCREASES IN PYRAMIDAL NEURONS OF RAT SOMATOSENSORY CORTEX. F.M. Sessler. M.L. Kirifides. W. Liu. C.S. Lin and B.D. Waterhouse. Dept. Physiol and Biophys. Hahnemann Univ.,

CS. Lin and B.D. Waterhouse. Dept. Physiol and Biophys. Hahnemann Univ., Phila., PA 19102

Previous in vivo studies have shown that microiontophoretic application of norepinephrine (NE) and isoproterenol (ISO) can enhance GABA-induced depressant responses of rat somatosensory cortical neurons. In the present investigation we have examined the transmembrane electrophysiological events which are associated with interactions between NE and GABA in layer IV/V pyramidal neurons of rat somatosensory cortex. Intracellular recordings were made from electrophysiologically identified cells in a submerged tissue slice preparation before, during and after bath application of GABA, NE and ISO, alone or in combination. Superfusion of GABA (0.5 - 3mM) produced small decreases in resting membrane potential associated with a reduction (22%) in membrane input resistance. NE and ISO also produced small membrane depolarizations (1-4mV) but no concomitant changes in membrane conductance. Simultaneous application of NE with GABA potentiated amino acid-induced changes in input resistance in 4 cases and antagonized (n = 4) or had no effect (n = 3) on GABA associated membrane events in 7 other cases. However, when the alpha blocker, phentolamine, was added to the medium (10-20 uM), NE-induced enhancement of the GABA response was observed in 5 of 6 cases suggesting alpha receptor masking of this noradrenergic potentiating action. Consistent with this interpretation was the finding that the beta agonist, ISO, produced net increases in GABA-induced conductance changes in the majority (92%) of cases tested (n = 13). The potentiating effect of NE and ISO was mimicked by the adenyl cyclase activator, forskolin (n = 2), and a membrane permeant analog of cyclic AMP, 8-bromo-cyclic AMP (n = 1); and could also be demonstrated when the GABA A agonist muscimol (1-5uM) was substituted for GABA. These findings suggest that previous demonstrations of NE potentiating effects on GABA inhibition are mediated by beta-receptor/cyclic AMP linked actions on

THE EFFECT OF ALPHA-METHYL-PARA-TYROSINE (AMPT), AN INHIBITOR OF TYROSINE HYDROXYLASE, ON SLEEP LATENCIES OF RESTED AND SLEEP DEPRIVED VOLUNTEERS. U. McCann, D. Penetar, D. Thorne, H. Sing, M. Thomas, A. Schelling, J.C. Gillin, and G. Belenky. Dept of Behavioral Biology, Walter Reed Army Institute of Research, Washington, DC 20307-5100

Pharmacological, anatomical, and electrophysiological evidence suggests that CNS catecholamines play an important role in maintaining wakefulness. The effect of catecholamine depletion on physiological sleepiness was tested in 40 healthy male volunteers, by preventing the synthesis of catecholamines with AMPT, an inhibitor of tyrosine hydroxylase. Subjects were randomized to one of four experimental conditions. Twenty subjects were sleep deprived for 36 on our experimental conductions. I went you goes select 1.5 hours nightly for the duration of the study (R). In both the SD and R conditions, half of the subjects received oral AMPT at a dose of 750 mg QID, for a total of 7 doses. Physiological sleepiness was assessed using multiple sleep latency tests (MSLTs) during the two days of drug administration and the day following the last drug dose. AMPT treatment was associated with a marked decrease in SLT times in both SD and R groups. Treatment with AMPT in the R condition produced an MSLT profile similar to treatment with sleep deprivation with and without AMPT. These findings are consistent with the hypothesis that catecholamines are important mediators of behavioral arousal and alertness. Further, they suggest that decreased catecholaminergic activity may be responsible for physiological sleepiness in normal humans.

224.13

A COMPARISON OF BEHAVIORAL SENSITIZATION IN RESPONSE TO D-AMPHETAMINE (AMPH) IN SEVERAL STRAINS OF MICE. B.A. Sieber and R.E. Heikkila. Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

AMPH is a potent releaser of dopamine and a powerful CNS stimulant. The acute injection of AMPH is known to cause a heightened behavioral response in experimental animals previously treated with AMPH compared to that observed in vehicle-pretreated or in naive animals. This phenomenon is known as behavioral sensitization. The purpose of this study was to examine the degree of sensitization occurring in response to daily injections of AMPH in several strains of mice (SJL/J, BALB/CByJ, DBA/Z), C57B1/65 from Jackson; CFW from Charles River). Initially, the capacity of AMPH (at doses from 0.4 to 6.25 mg/kg) to cause increases in locomotor activity was measured. In some strains (e.g. CFW and SJL/Z) there was a large increase in locomotor activity and a steep dose-response curve for AMPH. For example, in CFW mice, increased locomotor activity was first observed at 0.4 mg/kg AMPH and was nearly maximal at 2.5 mg/kg. In other strains (e.g. BALB/CByJ), however, there were minimal to marginal increases in locomotor activity at all doses tested. Based on the results of these experiments, a specific dose was selected with which to pursue sensitization studies in each strain. The animals were injected daily with the chosen dose of AMPH and locomotor activity was monitored on the first day of injection and at various times thereafter (on days 3, 7 and 22-24). An indication of sensitization was seen in each of the strains, and was particularly striking in certain strains (e.g. SJL/J). Experiments done in these strains of mice may well aid in the elucidation of neuronal mechanisms underlying the sensitization phenomenon.

224.15

MONOAMINES OF THE COMMON CAROTID ARTERY WITH CHRONICALLY REDUCED LOCAL BLOOD FLOW IN THE SPONTANEOUS HYPERTENSIVE RATS. K.H.Lee and Y.H.Kim.* Dept. of Neurosurgery and Pharmacology*, Hallym Univ. Sch.of Med., Chuncheon, Korea. It has been known that the arterial size depends on the

role of the endothelium on changing local blood flow and the final morphological accommodation of the artery wall may be in the tunica media innervated by sympathetic fibers containing catecholamine as a neurotransmitter. Using high containing catecholamine as a neurotransmitter. Using high performance liquid chromatography and electrochemical detection system we have measured the monoamines of the common carotid arterial wall with the intact endothelium of the chronically reduced local blood flow by ligation of the ipsilateral external carotid artery and also the monoamines of the chemically denuded common carotid arterial wall with 2% Triton X-100 of the same state and compared them with the monoamines of the each normal opposite common carotid artery in the spontaneous hypertensive rats. Norepinephrine of the common carotid artery in the normal site (n=6) was 2.13 \pm 1.197 ng/mg protein. The levels of norepinephrine of the common carotid artery with the intact endothelium in chronically reduced local blood flow (n-4) were higher than the levels of the normal opposite ateries but the levels of the denuded (n-3) lower. Epinephrine and dopamine were infrequently detected. Norepinephrine may play a role in the morphological accomodation of the artery on changing local blood flow chronically.

COMPARATIVE ANALYSIS OF THE EFFECTS OF IONTOPHORETICALLY APPLIED DOPAMINE IN DIFFERENT REGIONS OF THE RAT BRAIN. M. Beauregard, A. Ferron and L. Descarries. Centre de recherche en sciences neurologiques (Dép. physiologie), Univ. Montréal, Montréal, Canada H3C 37.

The effects of microiontophoretically applied dopamine (DA) were examined in the anterior cingulate (ACg), prefrontal (PF) and parietal (Par) cortex, neostriatum (NS) and nucleus accumbens (Acb) of urethane-anesthetized rats treated or not with the DA uptake blockers GBR 12909 or Bupropion, the DA were testical treated. neostriatum (NS) and nucleus accumbens (Acb) of urethane-anesthetized rats treated or not with the DA uptake blockers GBR 12909 or Bupropion, the DA synthesis inhibitor a-MPT, or 6-OHDA. In every region and condition tested, a majority of spontaneously firing neurons were inhibited by DA. Responsiveness was quantitatively assessed by the IT50 (estimate of the amount of DA required to obtain a 50% reduction of firing rate) and the RT90 method (measure of the time interval between the offset of application and return to 90% of initial firing). The average IT50 was comparable in every region irrespectively of the treatment, indicating that it was independent of the regional density of the DA receptors or that of the DA innervation. Rather, the constancy of this parameter suggested the availability of a critical number of postsynaptic DA receptors on most of the neurons tested, sufficient to induce 50% inhibitions (RT90) was considerably greater in the ACg (575 s) than in the PF, Par, NS and Acb of control rats (50-100 s), regions between which the differences were not significant. Moreover, treatment with both DA uptake blockers prolonged the duration of the DA inhibitions in PF, NS and Acb, but reduced it 4- to 9-fold in ACg while remaining without effect in Par. DA depletion (\alpha-MPT) and 6-OHDA denervation similarely induced a marked reduction (9-fold) of the duration of DA inhibitions in ACg without effect in Par. It thus appeared that, in all regions except ACg, a sufficient number of DA uptake sites were present in the vicinity of responsive neurons to inactivate the ejected amounts of DA. In ACg, the data obtained with Bupropion provided further evidence for the possible existence of a presynaptic positive feedback mechanism triggered by DA and favouring the further release of this transmitter upon its reuptake (Beauregard et al., Experientia, 45:888, 1989).

PREFERENTIAL RELEASE OF DOPAMINE OR NOREPINEPHRINE IN CAT CAROTID BODY EVOKED BY HYPOXIA AND NICOTINE IN VITRO. A. Gomez-Ninot C. Gonzalez, B. Dinger and S. Fidone. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108.

Previous studies in our laboratory with rabbit carotid body demonstrated that

revious studies in our abortatory with rabbit carotin body demonstrated that nicotine primarily evokes the release of norepinephrine (NE) from chemoreceptor type I (glomus) cells, while hypoxic stimulation results in release profiles dominated by dopamine (DA). However, because the ratio of DA to NE (8.2) in the low-O₂ superfusates approximates their ratio in tissue catecholamines (CA) stores, it was not possible from these studies alone to determine if hypoxia preferentially mobilized NE or DA, respectively. The present experiments evaluated DA and NE release evoked from cat carotid

bodies, a species in which these CA are stored at nearly equal concentrations.

3H-CA release (synthesized from ³H-tyrosine) was evaluated <u>in vitro</u> in sequential 10 min control, 5 min stimulus and 10 min post-stimulus collection periods. The tissues were superfused with modified Tyrode's media (37°C) periods. In Casacts were superfused with moduler Yrodes in least $(3/C_2)$ except during stimulation when the superfusion media contained nicotine $(100 \,\mu\text{M})$, or was equilibrated with $10\% \, O_2$. Nicotine evoked the preferential release of $^3\text{H-NE}/^3\text{H-DA} = 1.33$). In contrast, low- O_2 media resulted in a ratio for $^3\text{H-NE}/^3\text{H-DA} = 0.37$. Calculation of the absolute amounts of DA and NE, released based upon measured specific activities of ³H-NE and ³H-DA, showed that exposure to nicotine and hypoxia resulted in NE/DA ratios of 6.20 and 0.36, respectively. The data confirm our earlier findings with the rabbit carotid body in suggesting that NE and DA stores are preferentially mobilized by nicotine and hypoxic stimulation, respectively. Supported by USPHS Grants NS12636 and NS07938.

ATP-EVOKED RELEASE OF CATECHOLAMINES FROM PHEOCHROMOCYTOMA PC12h TREATED WITH NGF. N.Nakanishi, K.Hirayama, K.Aono*
S.Onozawa*, S.Yamada* Dept. of Biochem., Meikai Univ. Sch.
Dent., Sakado, Saitama 350-02, Japan.

We found that ectracellular ATP increases cytosolic Ca2+ of PC12 and PC12h cells, a subclone of PC12. Comparison of the effect of adenine nucleotides on the $[Ca2+]_{\dot{1}}$ suggests that this ATP effect is mediated by P2 type purinergic receptors. In the present study, we examine the effect of ATP on secretion of catecholamines from PC12h cells and compared with that of KCl. PC12h cells cultured in collagen-coated dishes were treated with NGF for 2 days, and then culture medium was replaced with release medium with 1 mM ATP, 50 mM KCl, or vehicle. At 5, 10, and 20 min after stimulation, catecholamines released into the medium were analyzed by HPLC. ATP and KCl evoked epinephrine (EP) release from the cells with the similar manner: EP released into the medium lineraly increased upto 20 min and similar amounts of EP were detected with ATP and KCl. On the contrary, ATP also evoked the dopamine (DA) release, while KCl had little effect. Furthermore, the DA amount released by ATP showed the maximal value at 5 min after stimulation. These results suggest that although both ATP and KCl increase [Ca2+] i of PC12h cells, these agents evoke catecholamines by different mechanisms and that release of EP and DA is controled independently from each other. Supported by Grants from the Ministry of Education

Culture and Science of Japan (Nos. 62570841 and 01571027).

ISOLATED ADRENAL GLAND OF THE RAT CAN BE USED TO STUDY RELEASE OF ACETYLCHOLINE. S.V. Bhave, R. Shukla*, and Arun R. Wakade. Dept. of Pharmacology, Wayne

State Univ., School of Medicine, Detroit, MI-48201.

Perfused rat adrenal gland has been used to study secretion of catecholamines (CA). Major advantage of the preparation is that secretion of CA is evoked by stimulation of splanchnic nerves and exogenous acetylcholine (ACh). Although pharmacological and denervation experiments have established the involvement of ACh, release of ACh after stimulation of splanchnic nerves was not shown. Adrenal glands were perfused with Krebs containing ³H-choline chloride (50 µCi/5ml) for 1 hr, excess label was washed with Krebs containing choline chloride (10 mg/ml) for 30 min and then medium was changed to Krebs containing 10 μ M eserine. Perfusates were processed to separate ³H-ACh from total tritium. Field stimulation significantly enhanced fractional release of ³H-ACh over the background release, and the evoked-release increased with increase in frequency of stimulation (4.5±0.9x10⁻² at 1 Hz for 5 min and 7.4±1.1x10⁻² at 10 Hz for 30 sec). Stimulation -evoked release of ³H-ACh was abolished when calcium was omitted from or cadmium plus nickel were added to the perfusion medium. Evoked release of ³H-ACh was not modified by atropine (0.5 μ M) and muscarine (100 μ M), but greatly potentiated by tetraethylammonium chloride (5 mM). Thus isolated adrenal gland of rat is useful to study secretion of cholinergic, adrenergic and peptidergic substances.

EFFECTS OF LITHIUM ON THE NICOTINE- AND POTASSIUM-INDUCED CATECHOLAMINE SECRETION FROM BOVINE ADRENAL CHROMAFFIN CELLS. S.Boehm* and S.Huck (SPON: European Neuroscience Association). Department of Neuropharmacology, University of Vienna, Währingerstraße 13a, A-1090 Vienna, Austria

 ${
m Li}^+$ has been shown to reduce catecholamine (CA) release from adrenergic nerve endings. This study investigates acute and chronic effects of ${
m Li}^+$ on cultured chromaffin cells, isolated from bovine adrenal glands.

CA release was elicited in a secretion buffer by either 20µM nicotine or by 56mM K⁺, which mediates secretion independently of the nicotinic acetylcholine receptor. Chronic Li⁺ effects were studied in cultures exposed for 4 effects were studied in cultures exposed days prior to the secretion. For acute effects, Li[†] just added to the secretion buffer. Li[†] concentrate concentrations ranged from 0.25 to 8mM. The CA secretion was measured as the [3H]noradrenaline release from cultures that had been

preloaded with [3H]noradrenaline. The K^+ -induced secretion was unaltered by acute Li^+ applications and was even enhanced (by as much as 15%) following chronic treatment of the cultures. The secretion elicited with nicotine, however, decreased in a dose-dependent manner by 13% after acute, and by 20% after chronic Li⁺ administrations. Withdrawal of Li⁺ from chronically-treated cultures 1 day prior to the secretion caused the CA release to return to control levels.

Our results indicate contrasting effects of Li⁺ on basic

secretion mechanisms in bovine chromaffin cells.

POTASSIUM CHANNEL BLOCKERS DISRUPT INHIBITION OF DOPAMINE RELEASE BY D-2 DOPAMINE, BUT NOT A1 ADENO-SINE, RECEPTORS IN RAT STRIATUM. W.A. Cass and N.R. Zahniser. Department of Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80262.

D-2 dopamine (DA) autoreceptors and A1 adenosine heteroreceptors inhibit evoked release of DA from rat striatum. We examined the processible mechanism underlying these precipitations with the processible mechanism underlying these precipitations.

D-2 dopamine (DA) autoreceptors and A1 adenosine heteroreceptors inhibit evoked release of DA from rat striatum. We examined one possible mechanism underlying these presynaptic modulatory actions, activation of a K⁺ conductance. Release of endogenous DA was evoked by electrical stimulation (1 Hz, 1 min) from rat striatal slices superfused with Krebs' buffer containing 10 μM nomifensine. Maximally-effective concentrations of the D-2 DA receptor agonist N-0437 (10 nM) and adenosine (50 μM) both caused a 30% inhibition of DA overflow, and their effects were additive. Next, we investigated the effects of three K⁺ channel blockers - quinine, tetraethylammonium (TEA), and 4-aminopyridine (4-AP). By itself, quinine (100 nM) significantly increased evoked DA overflow by 17%. When co-perfused with N-0437, quinine blocked the inhibition caused by N-0437 in a dose-dependent manner; 100 nM quinine produced a complete blockade. Similar effects were found with low concentrations of TEA (0.3 mM - 1 mM) and 4-AP (3 μM). Binding experiments confirmed that none of these K⁺ channel blockers are direct-acting D-2 DA receptor antagonists. In contrast, the inhibitory modulation produced by adenosine was not affected by quinine (1 μM), TEA (0.3 mM) or 4-AP (3 μM). These results suggest that D-2 DA and A1 adenosine receptors inhibit DA release in the striatum by different mechanisms. D-2 DA autoreceptor action involves a K⁺ channel, whereas A1 adenosine receptor action does not. The present results indicate, for the first time, a mechanism that appears to mediate the actions of release-modulating D-2 DA receptors in the brain. Supported by USPHS NS26851 and AA07464.

EFFECT OF INORGANIC THIOPHOSPHATE ON CHROMAFFIN CELL STRUCTURE AND FUNCTION. J.C. Brooks, M. Brooks* and S.W. Carmichael. Marquette Univ. Sch. of Dent., Milwaukee, WI 53233, Mayo Clinic, Rochester, MN 55905. We have previously suggested that ATPYS irreversibly thiophosphorylates cellular proteins and inhibits chromaffin cell secretion. It might then be expected that incubation of cells with inorganic thiophosphate (TP) would result in its incorporation into cellular ATP pools with a deleterious impact on secretion. Chromaffin pools with a deleterious impact on secretion. Chromaffin cells were cultured with phosphate (P)-free medium or media containing P or TP for periods of 1-3 days. Assay of cellular metabolic activity indicated enhanced activity at day 1 of TP exposure and decreased activity by day 3. There was a profound reduction in total cellular catecholamine content and secretion by day 3 of culture. There was no change in the DNA content of the cultures, showing that the decreased metabolic activity was not due to cell death. Uptake of the dye neutral red was reduced for cells treated with TP, indicating impairment of chromaffin vesicle function. Electron was reduced for cells treated with TP, indicating impairment of chromaffin vesicle function. Electron microscopic evaluation of the TP treated cells revealed depletion of vesicle contents and disruption of mitochondria. Radiolabelled TP was incorporated into a group of high molecular weight proteins, possibly of mitochondrial origin. The data suggest that TP damages the secretory system, perhaps secondarily to disruption of mitochondrial energy production. Supported by NIH Grant R15 NS 23101-01A2.

LYSOPHOSPHATIDYLCHOLINE INHIBITION OF ION CATECHOLAMINE SECRETION IN CHANNELS BOVINE ADRENAL MEDULLA Toyohira*, H. Kobayashi* Izumi, Y. N. Yanagihara. Department of Pharmacology, University Occupational and Environmental Health, School Medicine, Kitakyushu 807, Japan

In cultured bovine adrenal medullary cells, lysophosphatidylcholine (LysoPC) inhibited carbachol-induced influx of sodium/calcium, and the secretion of catecholamines. The inhibitory effect of LysoPC was reversible. LysoPC did not inhibit the influx of calcium and secretion of catecholamines evoked by high potassium depolarization. LysoPC did not inhibit the veratridine-evoked influx of sodium and secretion veratridine-evoked influx of sodium and secretion of catecholamines. These findings show the preferential inhibition of acetylcholine-receptor preservential inhibition of acetylcholine-receptor associated ion channels by LysoPC. LysoPC which arises from membrane phosphatidylcholine by phospholipase A_2 may be involved in the feedback regulation of catecholamine secretion by receptor stimulation.

224.22

COMPARISON OF AXONAL AND SOMATODENDRITIC DOPAMINE RELEASE USING IN VIVO DIALYSIS. P. W. Kalivas, Ph.D. and P. Duffy*. Department of Veterinary Pharmacology, Washington State University, Pullman, WA 99164-6520.

The release of dopamine from the dopamine cell bodies in the A9 and A10 region has been known for over a decade. However, only recently has the release of endogenous dopamine from the A9 and A10 cell groups been measured in vivo. The present studies characterize the release of somatodendritic dopamine from the A10 region and compare this to axonal release using the technique of in vivo dialysis. Dialysis probes were placed into the A10 region or the nucleus accumbens using a removable probe system the night before experimentation. The following movanies 20 min baseline samples were obtained, after which various drugs were administered through the dialysis probe. Removal of calcium and substitution by magnesium markedly decreased the release of dopamine in both the nucleus accumbens and A10 region. When TTX was placed in the buffer, a marked reduction in the nucleus accumbens was produced, and a much smaller reduction was observed in the A10 region. A D2 agonist inhibited equally axonal and somatodendritic dopamine release. Dopamine release was augmented with the addition of potassium chloride, amphetamine, or the reuptake blocker nomifensin to the buffer. The release induced by these agents was significantly greater in the nucleus accumbens than in the A10 region. The following data indicate that like terminal field release of dopamine, somatodendritic dopamine release is calcium dependent and regulated by D2 autoreceptors. However, the somatodendritic release does not appear to be as totally dependent on action potential generation, and agents which release dopamine do not appear to do so as effectively in the A10 region as they do in the nucleus accumbens.

CHARACTERIZATION OF DENDRITIC DOPAMINE RELEASE IN THE SUBSTANTIA NIGRA OF FREELY MOVING RATS BY IN VIVO MICRODIALYSIS. G. Damsma, G.S. Robertson, D. Wenkstern, H.C. Fibiger. Div. of Neurol. Sci., Dept. of Psychiatry, Univ. of British Columbia, Vancouver, BC, V6T 1W5.

Dopamine (DA) is released not only from the terminals of the

nigrostriatal pathway that innervate the striatum (ST) but also from the dendrites of these neurons which arborize in the substantia nigra pars reticulata (SNR). Although ST-DA release has been extensively studied by in vivo microdialysis, dendritic DA release in the SNR has not been characterized by this technique. Extracellular DA was monitored simultaneously in the ipsilateral ST and SNR. The nigral probe was implanted on a 45 degree angle permitting 2mm of SNR to be dialysized. Inclusion of 50mM KCl to the SNR perfusion solution produced a 3 fold increase in DA and a 50% reduction in DOPAC in the SNR; in contrast, DA release was decreased by 20% while DOPAC increased by 50% in the ST. Local administration of nomifensine (10uM) in the SNR produced an 8 fold increase in SNR-DA but had no effect on ST-DA. Amphetamine (2mg/kg, s.c.) elevated DA in the SNR and ST 5-7 fold while DOPAC was decreased in both structures by at least 40%. To determine the effect of tetrodotoxin (TTX) on SNR-DA release, basal SNR-DA (0.7 fmol/min) was first elevated 4 fold by inclusion of nomifensine ($1\mu M$) in the nigral perfusion solution. Under this condition TTX (luM) reduced DA release in both the SNR and ST by 90%. These results demonstrate that ST-DA release can be influenced by manipulations which alter SNR-DA release and that dendritic-DA release in the SNR shares many of the characteristics of ST-DA release.

SIMULTANEOUS MONITORING OF DOPAMINE OVERFLOW AND OXYGEN USE DURING ELECTRICAL STIMULATION IN SLICES OF RAT CAUDATE NUCLEUS USING FAST SCAN CYCLIC VOLTAMMETRY. Kennedy and R. M. Wightman. Dept. of Chemistry, Univ. of N. Carolina, Chapel Hill, NC 27599-3290.

Nafion-coated carbon-fiber microelectrodes were

implanted at a depth of $75\mu m$ into slices of rat caudate nucleus. A twisted pair of bipolar stimulating electrodes (tip spacing of 500 μ m) were placed on the surface of the slice and within 100 μ m of the voltammetric electrode. A potential waveform was applied to the voltammetric electrode which allowed the oxygen and the dopamine concentration to be measured nearly simultaneously (within concentration to be measured nearly simultaneously (with 10 ms of each other) at 100 ms intervals. After short stimulations (2 pulse, 480 μ Amp, biphasic, 2 ms wide and 100 ms apart) the dopamine levels rose to 0.99 \pm 0.07 μ M (n=6) and then returned to basal level within 500 ms. During the same stimulations, oxygen levels decreased by $43 \pm 6.9 \mu M$, reaching a minimum between 5 and 20 s after stimulation and not returning to basal level until after $30\ s$. The response of both of the compounds to the short electrical stimulation was reversibly eliminated after the removal of Ca++ from the medium. These results indicate that it is possible to investi-gate the interaction between neurotransmitter release and oxidative energy metabolism with a time resolution of 100 ms by this method.

224.27

N-2-CHLOROETHYL-N-ETHYL-BROMOBENZYLAMINE HYDROCHLORIDE (DSP4) ENHANCES THE SPONTANEOUS AND THE POTASSIUM EVOKED RELEASE OF 3H-NOREPINEPHRINE FROM RAT CORTICAL SLICES.M.E.Landa*,G.Dziewczapolski*,L.M.Zieher*, M.C.Rubio* and G.Jaim-Etcheverry.Instituto Investigaciones Farmacológicas, Junin 956, Buenos Aires, Argentina.

In the search for clues about the mechanisms involved in

the long-lasting depletion of brain norepinephrine (NE) produced by DSP4 in rodents, we studied in vitro the effects of the compound (10 umol/1) on the release of NE from rat cortical slices preloaded with 3H-NE (0.4 umol/1) Both the spontaneous and the K+-evoked efflux of tritium were markedly enhanced. While coincubation with desipramine (DMI) abolishes the spontaneous release produced by DSP4, it does not modify the enhancement of the K+-evoked release that is reversed by washing. Coincubation of the slices with the opioid receptor antagonist naloxone (0.1 umol/1) does not affect the increase of spontaneous NE outflow caused by DSP4 but increase of spontaneous NE outflow caused by DSP4 but prevents the enhancement of the K+-evoked efflux that it produces. Pretreatment of rats with naloxone (2 mg/kg ip) 10 min before the injection of DSP4 (25 mg/kg ip) does not modify the depletion of NE produced by the compound. Since pretreatment with DMI prevents the depletion of NE caused by DSP4 in vivo, this effect seems to be more directly related to the increase of spontaneous NE release produced by the compound under in vitro conditions than to the potentiation of the K+-evoked tritium outflow.

RELEASE OF DOPAMINE FROM NORADRENERGIC NEURONS

Chasemzadeh, P. Capella, R.N. Adams. Dept. of Chemistry, University of Kansas, Lawrence KS66045

The last step in the synthesis of NE is the conversion of DA to NE by the enzyme DBH. The tissue content of DA and its major metabolite DOPAC in predominantly NE innervated DOPAC in predominantly NE innervated areas and NE cell body region Locus coeruleus is very low compared to NE. The source of DA and DOPAC in these structures has been traced to the Noradrenergic neurons. We have investigated the effect of DBH inhibition on tissue Catecholamine content in specific areas of rat brain. In NE cell body and terminal fields the levels of NE was significantly reduced as expected but DA and DOPAC were elevated. In addition, DA levels in Caudate nucleus was increased significantly.

Using In-Vivo Electrochemistry, the effect of DBH inhibition on stimulated release of NE in Thlamus was investigated. The evoked response was not changed after FLA-63 although chemical analysis shows 50% reduction in NE.The DA and DOPAC content were increased by several fold. Since our method can not distinguish between NE and DA, it may be that upon inhibition of DBH the NE neurons will utilize either the storage pool of NE or DA as their neurotransmitter for release.

224.26

REGULATION OF NORADRENALINE RELEASE IN RAT HIPPOCAMPUS: IN VIVO MICRODIALYSIS. R.B. Holman and D.N. Thomas*. Reckitt & Colman Psychopharm. Unit, The Medical School, Bristol BS8 1TD UK.

Results with the specific alpha₂ antagonist idazoxan (IDX) suggest that presynaptic alpha₂ adrenoreceptors play a major role in regulating release of cortical noradrenaline (NA) (Dennis, T. et al. 1987 JPET. 241:642). We now show that systemic IDX causes a dose dependent increase in the release of NA from the hippocampus of chloral hydrate anaesthetised rats. The reuptake blocker desipramine (DMI 0-20µM) administered via the dialysis probe also increased basal NA release in a dose dependent manner. Further, the effects of IDX at the lower dose now become apparent in the presence of DMI.

Treatment	NA release	Treatment	NA release
	(pg/sample)	(pg/sample)	
control basal	$4.0 \pm 0.5 (n=9)$	DMI 20µM basal	30.6 ± 1.7(n=6)
IDX 1mg/kg	$5.7 \pm 0.8(n=3)$	DMI/IDX 1mg/kg	43.2 ± 5.6(n=5)
IDX 10mg/kg	$9.6 \pm 1.3(n=4)$	DMI/IDX 10mg/kg	$66.8 \pm 8.3(n=6)$

These results suggest that under the above conditions, the extracellular content of NA in the hippocampus may be regulated to a greater extent by reuptake of the transmitter than by its interaction with the presynaptic

RU38486 BLOCKS THE INCREASE IN TRYPTOPHAN HYDROXYLASE (TRPH) ACTIVITY TO ACUTE SOUND STRESS (SS) OR INTRACRANIAL INFUSIONS OF CORTICOTROPIN-RELEASING FACTOR (CRF). M.C. Boadle-Biber, V.B. Singh*, K.C. Corley, and T.H. Phan*.
Physiol. Dept., Va Commonwealth Univ., Richmond, VA 23298.
The activity of TrpH, the rate-limiting enzyme in

serotonin synthesis is enhanced in an alkaline phosphatase reversible manner by an acute SS consisting of a 1-2 h exposure of male rats to randomly presented sound pulses (110 or 120 dB intensity, 100 msec or 2 sec duration, VI 1 min) (Brain Res. (1989) 482 306-316). This increase in enzyme activity requires the presence of glucocorticoid: It is blocked by adrenalectomy 3 days prior to the SS, and is restored by dexamethasone treatment (Brain Res. (1990) 516 66-76). Intracranial infusion of CRF also activates TrpH (Faseb J. (1989) 3 A729; Abstr. Soc. Neurosci. (1989) 15 91.18). Bilateral intraventricular (ICV) infusions of the glucocorticoid antagonist, RU38486 (100) ug in 5 ul vehicle per side over 30 sec) or vehicle alone (95% propylene glycol, 5% ethanol, 0.1 % acetic acid, and 0.01% ascorbic acid, v/v/v/w) were given daily, via chronic indwelling guide cannulae, for 4 days. The increase in TrpH activity in response to acute SS and to ICV CRF (1.5 ug per side; 60 min treatment), were blocked by RU38486, but enzyme activity from sham-stressed and vehicle infused water was unabased. Supported by NEL4000 vehicle-infused rats was unchanged. Supported by NS14090 to MCBB. RU38486 was a gift from Roussel Uclaf.

225.3

EFFECTS OF 5-HYDROXY-L-TRYPTOPHAN ON BRAINSTEM AMINE METABOLITES AND BLOOD PRESSURE IN SPONTANEOUSLY HYPERTENSIVE RATS. D. Ghosh*, B. O. Anyanwu*, and H. R. Leuchtag. Department of Biology, Texas Southern Univ., Houston, Tex. 77004.

The effects of three doses (50 mg/kg, 25 mg/kg, and 12.5 mg/kg, i.p.) of 5-hydroxy-L-tryptophan (5-HTP) were studied in male spontaneously hypertensive rats (SHRs). All three doses reduced blood pressure at 2 hrs. from the base-line values at the 5% or lower level of significance. The metabolites were assayed employing HPLC/electro-chemical detection. The higher the concentrations of 5-hydroxytryptamine (5-HT) and 5-hydroxy indole acetic acid (5-HIAA), the more pronounced were the blood pressure reductions. Concentrations of norepinephrine, dopamine, 3, 4-dihydroxyphenylacetic acid and homovanillic acid were almost identical in these three groups of rats, and as such, these neurochemicals did not exert any effect on blood pressure reduction. Thus, the brainstem conversions, 5-HTP -- 5-HT -- 5-HIAA, appear to play a key role in blood pressure reduction in SHRs. (Supported by NIH grant RR03045).

TRYPTAMINE-4,5-DIONE, A SEROTONIN DERIVATIVE PRODUCED BY HYPOXANTHINE AND XANTHINE OXIDASE.

PRODUCED BY HYPOXANTHINE AND XANTHINE OXIDASE.

J.-C. Chen and L. Volicer. Dept. Pharmacology,
Boston Univ. Sch. Med., Boston, MA 02118 and
ENRM Vet. Hosp., GRECC., Bedford, MA 01730.

Previously, we have reported a novel neurotoxin, tryptamine-4,5-dione (4,5-DKT) which
could be synthesized electrochemically from
acidic serotonin (5-HT) solution (JPET 250:141,
1989; Brain Res. 504:247, 1989). 4,5-DKT can
also be produced dose-dependently from 5-HT
when reacted with hypoxanthine/xanthine also be produced dose-dependently from 5-HT when reacted with hypoxanthine/xanthine oxidase, an oxygen free radical generation system. In the presence of 0.1mM 5-HT, 0.1mM FeSO₄, 0.3mM EDTA, 0.1mM hypoxanthine and 0.1U of xanthine oxidase, the yields of 4,5-DKT varied with pH values with maximal response at pH7.0 (7.2µM). At this pH and reaction condition, the rate of 4,5-DKT production was increased linearly up to 60min and gradually decreased during the next 2h. In addition, the 4,5-DKT has high affinity to glutathione which can be monitored by HPLC with 16-channel coulometric detectors. This study suggests that endogeneous indole neurotoxin could be produced by 5-HT and free radicals under condition such as ischemia-reperfusion. (supported by USPHS AG06419 and VA Administration).

DYNAMIC SUPPRESSION OF REM SLEEP BY THE SEROTONIN AGONIST ELTOPRAZINE. J. Quattrochi, D.Binder*, A. Mamelak*, J. Williams*, C.Rittenhouse* and J.A.Hobson. Laboratory of Neurophysiology, Harvard Medical School, Boston, MA 02115

We report that parenteral administration of eltoprazine leads to REM sleep suppression via serotonergic inhibition of the brainstem REM generator. We recorded continuously for 15 days from 4 cats prepared with EEG, EMG, EOG, and LGB electrodes. During the control period (days 1-5) mean REM% was 13.0. Eltoprazine administration (days following drug withdrawal (days 11-15) REM% rebounded to nearly twice baseline levels in the first two days and was still elevated throughout the recovery period. Total suppression of PGO waves in all behavioral states during eltoprazine administration was followed by an intense potentiation of PGO activity during the recovery period. We interpret these results based upon the assumption that eltoprazine acts at 5-HT $_{
m 1}$ receptors. REM is suppressed via the inhibition of the distributed brainstem generator, while complete suppression of PGO activity may be due to inhibition of the trigger zone in the dorsolateral pons. REM rebound is probably a compound effect of increased excitability of the generator and prolonged suppression of the endogenous 5-HT system. Supported by NIH grant MH13923 and Duphar, B.V.

EARLY INCREASES OF SEROTONIN TURNOVER IN BRAIN FOLLOWING PORTACAVAL ANASTOMOSIS:
RELATION TO ALTERED SLEEP PATTERNS AND
DIURNAL RHYTHMS? M. Bergeron*1, M.S. Swain*1, T.A.
Reader², L. Grondin*2 and R.F. Butterworth¹, ¹Lab. of
Neurochemistry, CRC A-V, Hôpital St-Luc, Montreal H2X 3J4,
2Dept. Physiology, Univ. Montreal, Que., Canada.

Portagoral prestomosic (PCA) in the ret results in increased

Portacaval anastomosis (PCA) in the rat results in increased brain tryptophan and alterations of sleep-waking cycles and diurnal rhythms. Administration of ammonium salts to rats with PCA precipitates severe signs of encephalopathy progressing to coma. In order to assess the relationship between serotonin (5HT) and neurological status in these animals, 5HT and its metabolite 5HIAA were measured in several discrete brain nuclei by HPLC with electrochemical detection at various stages during the development of encephalopathy. Results demonstrate significantly increased 5HIAA/5HT ratios in Raphe Nucleus (127%), Locus Coeruleus (112%) and Caudate/Putamen (70%) respectively following PCA. However, onset of coma was not accompanied by additional changes in 5HIAA/5HT ratios. Increases of 5HIAA/5HT ratios were previously observed in postmortem brain tissue from cirrhotic patients with hepatic encephalopathy (Neurochem. Res. 14 853, 1989). These findings suggest that early signs of encephalopathy, such as altered sleep patterns and diurnal rhythms, following PCA in rats may result from increased 5HT turnover in brain. (Funded by MRC Canada).

8-SUBSTITUTED-2-AMINOTETRALINS: 5-HT1A AGONIST STRUCTURE/ACTIVITY REATIONSHIP J.M. Schaus, R.D. Titus*, D.L.

Huser* C.S. Hoechstetter*, D.T. Wong, R.D. Marsh*, and R.W. Fuller.
Lilly Research Laboratories, Eli Lilly and Co. Indianapolis, IN 46085
8-Hydroxy-2-dipropylaminotetralin (8-OH-DPAT, 1(X=OH, R=Pr)) is recognized as a selective 5-HT_{1a} serotonin agonist. Structure activity studies which have been performed to date have concentrated on studying enantioselectivity, the effects of substituents on the amino group, and the effects of incorporation of a methyl group at positions on the saturated ring. Little work has been reported to date on the effect of varying the substituent at C-8 of the aminotetralin system. We report here the synthesis of a series of twentyfive 8-substituted aminotetralins of the the synthesis of a series of twentyfive 8-substituted aminotetralins of the general structure 1. These compounds were evaluated for affinity at the 5-HT $_{1a}$ receptor by 3 H-8-OH-DPAT binding studies and compounds with significant affinity were tested for their ability to decrease brain 5-HIAA concentrations. The compound with the highest affinity was LY232067 (1, X=SMe, R=Pr) with [C50=1.23 ± 0.32 nM at the 5-HIT $_{1a}$ receptor. This compound had higher affinity than either its 8-OH or 8-OMe analogues (IC50 = 2.73 ± 0.47 and 4.87 ± 0.32 nM, respectively). LY232067 lowered brain 5-HIAA levels indicating that it is a serotonin agonist. The affinity of the 8-halogen substituted aminotetralins decreased in the following order: I > Br = Cl > F.

8-OH-DPAT INCREASES PLASMA GLUCOSE AND INSULIN IN RATS: INVESTIGATION OF THE ROLE OF CNS SEROTONIN IN REGULATING GLUCOSE METABOLISM. A. B. Thiagarajan, K. M. Wozniak, M. J. Durcan, M. Linnoila and R. L. Eskay*. Laboratory of Clinical Studies,

NIAAA, National Institutes of Health, Bethesda, MD 20892.
The intravenous (i.v) administration of 8-Hydroxy-2-(dinpropylamino)tetralin (8-OH-DPAT) has been shown to increase plasma levels of glucose and catecholamines in rats without changing plasma insulin.

Adult, male Sprague-Dawley rats were implanted with lateral ventricle catheters for drug delivery and jugular vein cannulae for blood sampling. Intracerebroventricular (ICV) administration of 0.01 mg/kg of 8-OH-DPAT, a dose which was peripherally inactive, increased plasma insulin levels two fold at fifteen and thirty min post infusion, when compared to saline injected animals. In the same animals plasma glucose increased from 102± 5 mg %(baseline) to 156±10 and 154±8 mg % at 15 and 30 min , respectively. ICV injection of 0.01 mg/kg 8-OH-DPAT in adrenal demedullectomized animals resulted in a three to five fold increase in insulin levels at 5, 15 and 30 minutes without any change in glucose levels. Pretreatment of rats with 5,7 dihydroxytryptamine abolished the increase in plasma insulin and glucose following ICV administration of 0.01 mg/kg

These results suggest that the 8-OH-DPAT-induced release of insulin is mediated via 5-HT1A presynaptic autoreceptors in the

225.9

GEPIRONE BLOCKS THE REVERSIBLE INCREASE IN RAT CORTICAL AND MIDBRAIN TRYPTOPHAN HYDROXYLASE (Trph) ACTIVITY IN RESPONSE TO INTRACEREBRAL CORTICOTROPIN-RELEASING FACTOR (CRF). K.C. Corley, V.B. Singh*, T.H. Phan*, and M.C. Boadle-Biber. Dept Physiol., Va Commonwealth University, Richmond, VA 23298.

CRF, when infused intracerebroventricularly or

bilaterally into the amygdaloid central nucleus (ACE), produces an increase in TrpH activity, in vitro, that can be reversed by alkaline phosphatase (Faseb J. 3: A729, 2977, 1989; Soc. Neurosci. Abstr. 15: 91.18. 1989) A729, 2977, 1989; Soc. Neurosci. Abstr. 15: 91.18. 1989) and resembles the increase in enzyme activity to acute sound stress (Brain Res. 482: 306-316, 1989; 516: 66-76, 1990). Gepirone, i.p. or infused directly into the dorsal raphe nucleus (DRN) via an indwelling cannula dorsal raphe nucleus (DRN) via an indwelling cannula blocks the increase in TrpH activity to sound stress (Faseb J. 4: 3146, 1990). In the present studies, gepirone (or saline vehicle) was given i.p. (10 mg/kg) or by direct infusion into the DRN (14 ug in 2 ul) 15 min before bilateral infusion into ACE of CRF (0.5 ug/2ul per side; in PO, buffered saline, pH 6.8, with 0.1% BSA and 0.01 mM ascorbic acid). Rats were killed 30 min after CRF infusion. Gepirone totally blocked the CRF-induced increase in TrpH activity possibly through an action on 5-HT, receptors in the DRN. SUBCHRONIC BUSPIRONE, MESULERGINE, AND ICS205-930 LACK EFFECTS ON D1 AND D2 BINDING IN THE
RAT STRIATUM DURING CHRONIC HALOPERIDOL
TREATMENT . P.B. Hicks. R.J. Zavodny* and K.A. Young.
Dept. of Psychiatry, Scott and White Hospital/Foundation and Dept. of
Pharmacology, Texas A&M College of Medicine, Temple, Texas, 76508.
It has been reported that buspirone reverses neuroleptic-induced dopamine
D2 receptor up-regulation (McMillan, B.A., J. Neural, Transn. 64: 1-12,
1985). We tested the hypothesis that other serotenergic agents that reverse
catalepsy would also reverse D2 receptor up-regulation. We administered
catalepsy would also reverse D2 receptor up-regulation. We administered
suspirone, mesulergine and ICS-205-930 during the last two weeks of a 4
week chronic haloperidol treatment regimen and determined dopamine receptor
binding after a 5 day drug washout. As expected, D1 receptor binding was
not affected by any treatment. Chronic haloperidol treatment produced a
significant increase in the density of D2 receptors for all groups including the
groups that were administered serotonergic compounds.

D2 DA Binding: (3H-spiroperidol, sulpiride blank)

4 wk	2 wk(mg/kg/d	ay) Kd	± SEM	Bmax (fmol/mg	± SEM
Vehicle	Vehicle	306	16	261	13
HAL	Vehicle	326	12	335*	15
HAL	ICS (2)	338	15	326*	19
HAL	BUS (10)	297	24	338*	14
HAL	MES (0.2)	326	27	326*	16
P<0.05 according to ANOVA with Duncans Multiple Range Test					

Our findings suggest that the ability of these drugs to reverse catalepsy does not predict their ability to reverse D2 receptor up-regulation.

8-OH-DPAT SUPPRESSES MOTION SICKNESS IN CATS WITH NO EFFECT ON HABITUATION: POSTSYNAPTIC SITES. J.B. Lucot.

8-OH-DPAT SUPPRESSES MOTION SICKNESS IN CATS WITH NO EFFECT ON HABITUATION: POSTSYNAPTIC SITES. J.B. Lucot. Dept. Pharmacol., Wright State Univ., Dayton, OH 45435.

These experiments were designed (1) to test for pre-vs postsynaptic sites of action for the antiemetic effects of 8-OH-DPAT (DPAT) and (2) to determine if suppression of motion sickness by DPAT prevents habituation to the motion stimulus. Motion sickness was induced by a device modelled after a Ferris wheel in 29 cats screened for susceptibility to the device. Tests lasted 30 min followed by 1 min observation at rest and were separated by at least 2 wk except in habituation studies. (1) The failure of metergoline (0.1-3 mg/kg) or PCPA (150 mg/kg x 3 D) to suppress motion sickness suggests that postsynaptic sites underlie the antiemetic effects of DPAT. If the relevant sites were presynaptic, then these two treatments also should have suppressed emesis. Further, 3 d of treatment with 0.04 mg/kg DPAT did not these two treatments also should have suppressed emesis. Further, 3 d of treatment with 0.04 mg/kg DPAT did not decrease the antiemetic effect of DPAT, an effect consistant with a postsynaptic site of action. (2) Habituation was induced by 4 consecutive days of motion testing in 2 series, one with daily saline and one with 3 d of DPAT followed by 1 d of saline. The absence of a difference on the 4th d of motion testing between the two series suggests that suppression of motion sickness by DPAT does not prevent habituation to the stimulus. Thus, stimulation of postsynaptic 5-HT $_{1A}$ sites suppresses motion sickness without interfering with habituation to abnormal vestibular input.

CHRONIC INFUSION OF TANDOSPIRONE AND IMIPRAMINE ALTERS 5-HT-MEDIATED BEHAVIORS AND 5-HT RECEPTORS. <u>S. Wieland</u>¹, C. T. <u>Fischette² and I. Lucki</u>¹ Dept. Psychiatry¹, Univ. Pennsylvania, Philadelphia,

Fischette² and I. Lucki¹ Dept. Psychiatry¹, Univ. Pennsylvania, Philadelphia, PA 19104 and Pfizer Inc.², New York, New York 10017

The 5-HT1A agonist buspirone and related congeners such as tandospirone, have been reported to be useful antidepressant drugs. Because of the involvement of 5-HT in depression, we compared the ability of tandospirone with the antidepressant imipramine to alter behavioral and biochemical measures of 5-HT receptor function following their continuous administration. Rats (N=10/group) were implanted subcutaneously with Alzet osmotic minipumps (2ML2) set to release either saline, tandospirone, imipramine or 1-PP, a metabolite of tandospirone, at a dose of 20 mg/kg/day. Tandospirone significantly inhibited development of the 5-HT behavioral syndrome by the 5-HT1A selective agonist 8-OH-DPAT (4.0 mg/kg) when tested 24 hr and 14 days after the start of infusion, and 24 hr following the cessation of drug treatment. Imipramine inhibited the syndrome after 14 days of drug treatment and also 24 hr after a drug washout period, but not acutely. Treatment with 1-PP did not after the 5-HT behavioral syndrome.

The effects of drug treatment were also examined on the head shake response mediated by activation of 5-HT2 receptors with DOB (1 mg/kg). Tandospirone significantly inhibited the head shake response when tested 24 hr and 14 days after pump implantation, and after a 24 hr drug washout period.

Tandospirone significantly inhibited the head shake response when tested 24 hr and 14 days after pump implantation, and after a 24 hr drug washout period. Similarly, imipramine significantly reduced the number of head shakes when tested at all three time points. 1-PP had no effect on the head shake response. Continuous administration of tandospirone, imipramine, and 1-PP did not alter 5-HT1A receptor density in hippocampus. However, tandospirone, imipramine, and 1-PP significantly reduced 5-HT2 receptor density in frontal cortex. Imipramine significantly reduced 6-adrenergic receptor number in remaining cortex, while tandospirone and 1-PP had no effect. These results suggest certain similarities between continuous infusion of tandospirone and imipramine in rats that may contribute to their effects as antidepressant drugs.

A COMPARISON OF SEROTONIN TURNOVER RATES IN DIFFERENT BRAIN AREAS IN THE FAWN-HOODED AND THE WISTAR RAT-STRAINS. T. I. Tolliver, C.S. Aulakh, J.M. Tolliver and D.L. Murphy. Lab. of Clinical Science, NIMH, Bethesda, MD 208

We have recently demonstrated that the Fawn-Hooded (FH) rat strain is functionally subsensitive to m-chlorophenylpiperazine (m-CPP, a 5-HT₁, agonist)-induced decreases in food intake (Wang et al 1988) and locomotor activity (Aulakh et al 1989), and increases in plasma prolactin (Aulakh et al 1988) relative to Wistar and Sprague-Dawley rat strains. Other investigators have also demonstrated altered behavioral responses to serotonin agonists. have also demonstrated altered behavioral responses to serotonin agonists in FH rats relative to Sprague-Dawley rats (Gudelsky et al 1985). In the present study, we compared the effects of various doses of m-CPP on plasma growth hormone levels as well as the effects of various doses of ipsapirone (a 5-HTIa agonist) on rectal temperature in FH and Wistar rat strains in FH and Wistar rats. The turnover rates in different brain areas in FH and Wistar rats. The turnover rates of serotonin were estimated on the basis of the increases in brain 5-HT concentrations as well as the decline of 5-hydroxyindoleacetic acid which followed inhibition of monoamine oxidase after administration of pargyline hydrochloride (75 mg/kg, i.p.). The increases in plasma growth hormone levels following administration of various doses of m-CPP were significantly less in the FH rat strain relative to the Wistar rat strain. Similarly, decreases in rectal temperature following administration of various doses of jpsapirone were also significantly less in the FH rat strain relative to the Wistar rat strain. We will present the data on the 5-HT turnover rates in different brain areas (raphe, hypothalamus, on the 5-HT turnover rates in different brain areas (raphe, hypothalamus, frontal cortex, hippocampus and striatum) in these two rat strains.

XYLAMIDINE, A PERIPHERAL SEROTONIN ANTAGONIST, ATTENUATES THE PRESSOR RESPONSE TO CENTRAL SEROTONIN. P.E. Pergola and R.H. Alper. The University of Kansas Medical Center, Kansas

Recently, we demonstrated that the intracerebroventricular (i.c.v.) injection of serotonin (5-HT) increases mean arterial pressure (MAP) by sympathoexcitation and by stimulating vasopressin release in conscious rats (FASEB J 4:A1064, 1990). In addition the effects of centrally administered 5-HT were abolished by the i.v. injection of the selective 5-HT₂ antagonist LY 53857. The present studies were to determine if the peripheral 5-HT₂ antagonist xylamidine, administered i.v., altered the pressor response to centrally infused 5-HT in conscious, unrestrained male Sprague-Dawley rats. It was found that at both 100 or 300 μ g/kg, i.v., xylamidine significantly attenuated the pressor response to 5-HT (2.5 μ g/5 μ l, i.c.v.) by approximately 27%. In contrast, LY 53857 (100 μg/kg, i.v.), which in vitro is equipotent to xylamidine at blocking 5-HT₂ receptors, abolished the effect of 5-HT on MAP. A combination of xylamidine with the α_1 -antagonist prazosin (100 $\mu g/kg$, i.v.) or with a V1-vasopressin antagonist (10 $\mu g/kg$, i.v.) did not prevent the increase in MAP produced by 5-HT i.c.v.. In all rats the blood-brain-barrier was determined to be intact since i.v. infused Evans Blue was localized to the circumventricular organs; the ability of xylamidine to attenuate the pressor response to 5-HT was not due to disruption of the blood-brain-barrier. Therefore, it can be suggested that i.c.v. injection of 5-HT elicits a pressor response that is mediated in part by circumventricular organs of the brain to which the peripheral 5-HT2 antagonist xylamidine gains access. The residual increase in MAP is assumed to be a central action of 5-HT on vasopressin release and sympathetic nerve activity.

HIPPOCAMPAL SEROTONIN RELEASE IN RATS BRED FOR

HIPPOCAMPAL SEROTONIN RELEASE IN RATS BRED FOR LEARNED HELPLESSNESS BEHAVIOR. E. Edwards.
P.VanHouten, D. Campbell, and F.A. Henn, Dept. Psychiatry, SUNY, Stony Brook, NY 11794.

We have been able to successfully inbreed learned helpless behavior (LH) into rats. We have previously demonstrated that presynaptic serotonin mechanisms modulate learned helpless behavior in Sprague Dawley rats. In the present experiments we have examined the in vitro release of serotonin in hippocampal slices of rats from the 19th generation of inbred LH and non-learned helpless (NLH) strains.

Spontaneous 3H-5HT release was significantly higher in the hippocampus of rats from the LH strain (+ 55%) as compared to naive controls (NC) and NLH strain rats. K* stimulated 3H-5HT release was also significantly increased in the hippocampus of the LH strain rats (% stimulated 3H-5HT release: 7.2 ± 0.87, NC; 6.7 ± 1.0 NLH strain rats; 12.1 ± 0.7 LH strain rats; N=7 separate experiments).

Cumulative dose-response curves to the autoreceptor agonist, 5-HT were constructed (1nM to 1 μ M). 5HT caused a concentration dependent inhibition of the K⁺ stimulated ³H-5HT release in dependent inhibition of the K * stimulated \$^3H-5HT release in hippocampal slices from all three groups NC, NLH and LH. In the LH strain, 5-HT caused a greater inhibition of K * stimulated \$^3H-5HT release (at 100nM 5-HT, % inhibition: 75% LH strain vs 47% NC and NLH strain). 5-HT's effect on K * stimulated \$^3H-5HT release was mimicked by TFMPP and CGS 12066, two purported 5-HT agonists but not by the 5-HT at drugs tested.

These experiments demonstrate differences in the regulation of the 5-HT autoreceptor of the LH strain and suggest that the increased stimulation in 5-HT release may be mediated by the 5-HT to receptor. (Supported by BNS 8614098 to E.E.)

SEROTONERGIC STIMULATION OF OXYTOCIN SECRETION IN CONSCIOUS MALE RATS: A PHARMACOLOGICAL CHARACTERIZATION. J.A. Saydoff, P.A. Rittenhouse, L.D. Van de Kar, and M.S. Brownfield. Neuroscience Training Program, Sch. Vet. Med., Univ. Wisconsin, Madison, WI 53706, Sch. Med.,Loyda Univ., Maywood, IL 60153.

We studied the role of serotonin (5-HT) in oxytocin (OT) secretion in

conscious male rats. Selected 5-HT agonists, antagonists, and releasers were administered to conscious male rats which were later killed by decapitation. Plasma OT concentration was measured by

decaphation: "rashia of concentration was measured by radioimmunoassay.

Both 5-HT releasers, ferifluramine and p-chloroamphetamine, significantly increased plasma OT concentration. D-ferifluramine was more potent than Herifluramine with a minimum effective dose of 5.0 mg/kg i.p. This suggests that endogenous 5-HT can stimulate OT secretion.

that endogenous 5-HT can stimulate OT secretion.

The 5-HT,₄₂ agonist, m-CPP (0.5-20 mg/kg i.p.), dose-dependently stimulated OT secretion. In contrast, the 5-HT,₄₈ agonist, RU24969 (6.0 mg/kg i.p.), did not elevate plasma OT concentration. Another 5-HT,₄₂ agonist, MK212 (10 mg/kg i.p.), increased plasma OT and this effect was attenuated by the 5-HT,_{1c42} antagonist, ritanserin (2.5 mg/kg i.p.). The 5-HT,_{1c42} agonist, DOI, dose-dependently increased OT secretion with a minimum effective dose of 0.5 mg/kg i.p. Pretreatment with spiperone (5-HT₂ antagonist) or ritanserin (both at .01 or .1 mg/kg i.p.) dose-dependently inhibited the increase in plasma OT DOI dose-response. Intracerebroventricular injection of 200 ug/kg DOI to conscious rats also increased plasma OT concentration.

These studies provide evidence that enhanced serotonergic transmiss

increased plasma OT concentration.

These studies provide evidence that enhanced serotonergic transmission stimulates OT secretion. Because spiperone has a higher affinity for 5-HT, than for 5-HT_{1c} receptors, these data also suggest that the stimulation of OT secretion by DOI is mediated by 5-HT₂ receptors. The site where 5-HT acts to stimulate OT secretion remains to be established. Supported by Univ. Wisc. Grad. Sch. and NIDA DA04865.

SPONTANEOUS ORAL DYSKINESIA IN RESERPINIZED RATS.

I. L. Neisewander. I. Lucki. and P. McGonigle. Departments of Pharmacology and Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

We reported previously that reserpinized rats develop spontaneous oral dyskinesia. To characterize the time course of this response, rats were treated with either reserpine (1 mg/kg, SC) or vehicle once daily for 4 days and then every other day for 6 weeks. Oral dyskinesia was measured by recording the incidence of tongue protrusions (TPs) for 30 min. TPs developed rapidly, reaching a maximal level after only 3 days and then remained steady throughout treatment. TPs persisted at a maximal level for up to 20 days post-treatment, and continued to persist in some animals for at least 60 days post-treatment using quantitative autoradiography. D1 receptors were increased in the caudate-putamen (CPu) and nucleus accumbens (NAc) 1 day, but not 20 or 60 days, post-treatment. D2 receptors, however, were increased at all three time points in the CPu, although the magnitude of up-regulation was less at 60 days than at 1 and 20 days. D2 receptors were also increased in the NAc, but only at 1 and 20 days post-treatment. We also examined the effects of dopamine D1 and D2 agonists on reserpine-induced oral dyskinesia. Both SKF-38393 and quinpriote dose-dependently decreased TPs, but only at doses that also produced stereotypy. Therefore, the stereotypy may have masked the TPs. Lastly, we examined whether TPs could be prevented by concurrent administration of SKF-38393. Animals were treated with reserpine plus SKF-38393 exhibited fewer spontaneous TPs, but more TPs following acute injection of SKF-38393 (5 mg/kg, SC), than animals treated with reserpine plus SKF-38393 exhibited fewer spontaneous TPs, but more TPs following acute injection of SKF-38393 (5 mg/kg, SC), than animals treated with reserpine alone. These results may have important implications for understanding and reating tardive dyskinesia. (Supported by

[125I]EPIDEPRIDE BINDING TO DOPAMINE D2 RECEPTORS IN HUMAN BRAIN. J.N. Joyce. A. Janowsk and K.A. Neve. Departmentsof Psychiatry and Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA (JNJ) and Veteran's Administration Center, Portland, OR (AJ,

Philadelphia , PA (JNJ) and Veteran's Administration Center, Portland ,OR (AJ, KAN).

[125]Epidepride is a substituted benzamide with high affinity and selectivity for dopamine (DA) Dz receptors in rat brain (Neve et al, JPET 252:1108-1116.) We examined the distribution and pharmacology of this radioligand in human brain. Scatchard analysis of the binding of this ligand to membranes derived from striatum demonstrated a Kd of 31 pM and a Bmax of 150 fmol/mg P. Binding to frontal and temporal cortex evidenced a significantly higher affinity (18 pM) and lower Bmax (5 and 13 fmol/mg P, respectively). The pharmacological profile of binding in frontal and temporal cortex was similar to striatum (epidepridessingerone-shutaclampol-flupenthibos-loc/azapine). Autoradiography also spiperone-butaclamols-flupenthixols-clozapine). Autoracingraphy also demonstrated the greatestbinding in the striatal complex with D2 receptor density higher by 20-50% in the matrix than striosomal compartments, as demonstrated by comparison to AChE-rich and poor areas in serially adjacent berinstrated by Comparison to Actification and Donards in serially adjacent sections. The density declined somewhat at more caudal levels of the striatum, with striosomal/matrix patterns less discernable. The striatum showed 2-fold higher binding than the globus pallidus external which was 50-70% greater in density than the globus pallidus internal. Binding was also dense in a ventral extension of the putamen. Binding in the substantia nigra was 1/8 of that in the striatum, with the A8 and A10 complex exhibiting very low binding. Binding to striatum, with the AB and A10 complex exhibiting very low binding. Binding to all cortical areas showed a laminar pattern. Binding in the frontal cortex was densest in the internal layers. Temporal cortex showed higher binding with the order being external layer > internal > middlle layers. Within the hippocampal complex binding was low but evident in CA1 and subiculum and almost nonexistent in the presubiclum or other regions of parahippocamapl gyrus. Binding in the occipotemporal gyrus was similar to other regions of temporal cortex. Funded by MH 43852, MH 43880, MH 45372.

[125] Epidepride Autoradiography and In Situ Hybridization of Extrastriatal Dopamine D2 receptors. A. Janowsky, K.A. Neve, J.M. Kinzie*, T. dePaulis*, G. Higgins, and J. Belknap. VAMC, Portland, OR; Vanderbilt Univ., Nashville, TN; NIA/NIH, MD. The rank order of potency for the displacement of sodium-dependent [125] Tepidepride binding by various drugs suggests that the radioligand is binding to D2 receptors in extrastriatal regions that contribute on the contribution of binding sites. Autoradiographic the radioligand is binding to D2 receptors in extrastriatal regions that contain a very low density of binding sites. Autoradiographic analysis of rat brain sections (16um) indicated that 1^{125} lepidepride binding reached equilibrium within 30-45 min in the presence, or within 15 min in the absence of NaCl. K_d values for binding to coronal sections through the caudate or hippocampus were similar to those described for ligand binding to membranes (30-60pM). The B_{max} in sections of caudate nucleus (24 fmol/section) was 15x higher than the hinding site density in hippocampul sections. In higher than the binding site density in hippocampal sections. In addition to very high binding in striatum, accumbens, and olfactory tubercle, binding to D2 receptors was observed in cerebellar lobes 9 and 10, in specific layers of the hippocampus, amygdaloid nuclei, and the entorhinal cortex. In situ hybridization using probes for D2₄₁₅ and D2₄₄₄ indicated that the long form was more abundant in the olfactory tubercle and entorhinal cortex. The two forms were more evenly distributed in neocortex. The effect of chronic administration of a number of psychotropic drugs, including clozapine, haloperidol, and amphetamine, was also examined. Data suggest that [¹²I]epidepride is useful for characterizing changes in D2 receptors in brain regions that contain a small density of D2 receptor sites. Supported by NIMH grant MH42894 (A.J.).

226.5

EFFECTS OF 6-OHDA AND PERTUSSIS TOXIN LESIONS.ON D₁ AND D₂ RECEPTOR ACTIONS IN THE STRIATUM. Ingrid Strömberg and Paula Bickford-Wimer 1 Dept Histology, and Neurobiology, Karolinska Institute, Stockholm, Sweden, and 2 Vet Admin Med Ctr, Denver, CO, USA

The relationship between dopamine D₁ and D₂ receptors was investigated in the rat striatum using a combination of lesioning investigated in the far stratum using a combination of lesioning techniques. Differences in the transduction mechanisms for 1 \& D_2 receptors were exploited to selectively inactive D_2 receptors with pertussis toxin (PT). Rats were injected with 6-OHDA into the medial forebrain bundle and those showing a double peak rotational pattern with apomorphine were selected for further investigations. PT was injected into the DA depleted striata. Two days after the PT lesion extracellular electrophysiological recordings were performed with multibarrel glass micropipettes in urethane anesthetized rats. The D_1 agonist SKF 38393 (1mM) or the D_2 agonist NO437 (1mM) were applied locally by micropressure ejection. There was a significant duction in response to N0437 from striatal cells in rats with 6-OHDA/PT with 80% of cells demonstrating no response, while 90% of cells responded in the contralateral control stiata. The response to SKF 38393 was also altered in these rats with a reduction in SKF 38393 responses on the lesioned side. Striatal cells from rats with only 6-OHDA lesions showed supersensitivity to NO437 on the lesioned side, however, SKF 38393 was equipotent in both striata. In conclusion, these data demonstrate that a combination of 6-OHDA and PT lesions gives rise to a subsensitivity of D_1 receptors in striatal neurons, which might be due to the inactivated D_2 receptor. (VAMRS and NS09199)

MICRODIALYSIS MEASURES OF DOPA ACCUMULATION AFTER GBL ADMINISTRATION: AN IN VIVO MEASURE OF DOPAMINE SYNTHESIS MODULATING AUTORECEPTORS. Lory, C.W. Bradberry and R.H. Roth. Depts. Pharm. & Psych., Yale Univ.Sch. Med., New Haven, CT 06510.
We developed an in vivo model system for determining

the presence of synthesis modulating autoreceptors in distinct dopamine projection areas in rat brain. The L-aromatic amino acid decarboxylase inhibitor, NSD 1015 (10 $^{-5}\mathrm{M})\,,$ was infused through the dialysis probe and L-DOPA accumulation monitored as an index of tyrosine hydroxylation (TH). Inhibition of impulse flow after the administration of γ -butyrolactone (GBL) produced a 2-3 fold increase in the rate of TH in the caudate. This effect was blocked by addition to the perfusion buffer of a micromolar concentration of the autoreceptor agonist EMD-23488. Since EMD 23488 does not exert direct inhibitory effects on TH activity in vitro, the blockage of the GBL induced increase was consistent with an autoreceptor mediated event. In the prefrontal cortex, a brain region believed to lack synthesis modulating autoreceptors, in vivo TH was unaffected by blocking impulse flow with GBL. These observations suggest that extracellular DA does not influence prefrontal DA synthesis and that regionally selective changes in DOPA accumulation following GBL administration may be a useful marker of functional synthesis modulating DA autoreceptors. Supported by MH 14092 and the Amer. Heart Assoc.

226.4

[125]SCH 23982 BINDING TO DOPAMINE D1 RECEPTORS IN HUMAN BRAIN. A. Murray.* A. Ouyang and J.N. Joyce. Departmentsof Psychiatry, Pharmacology and Medicine (GI section), University of Pennsylvania School of Medicine, Philadelphia, PA. [125]SCH 23982 shows high affinity and selectivity for dopamine (DA) D1 receptors in rat brain (Manik et al, 1988; J. Neurochem, 51:391-397) We are examining the distribution and pharmacology of this radioligand in human brain. Autoradiographic analysis also demonstrated the densest binding in the striatal complex with D1 receptor binding 2-fold higher than the globus pallidus external which was 50-70% greater in density than the globus pallidus internal. Binding to all contical areas showed a laminar pattern. Binding in the frontal cortex was densest in the internal layers. Temporal cortex showed a different pattern with the order being middles, internal. Binding in the frontal cortex was densest in the internal layers. Temporal cortex showed a different pattern with the order being middle> internal = external layers. Insular cortex showed higher binding than other cortical regions with two distinct lamina exhibiting higher binding. Binding in the substantia nigra was low... Within the hippocampal complex binding was low but evident. Binding in the occipotemporal gyrus was similar to other regions of temporal cortex. Scatchard analysis of the binding of this ligand to membranes derived from striatum appears similar to that in cortical regions. The pharmacological profile is being currently examined for different regions. Preliminary studies indicate that postmortem tissue derived from cases diagnosed with Parkinson's disease and schizohrenia exhibit reduced density of binding in cortex and limbic regions of striatum. Funded by MH 43852, MH 43880-

226.6

DOPAMINE D2 RECEPTORS IN THE NUCLEUS ACCUMBENS AND STRIATUM OF ALCOHOL-FED RATS. M.J. Druse and S. Pellegrino* Department of Biochemistry, Loyola U. of Chicago, Stritch Sch. of Medicine, Maywood, IL 60153.

The present study examined the effects of chronic alcohol consumption on dopamine D $_2$ receptors in the nucleus accumbens and striatum. Male Fisher 344 rats were pair-fed control or 6.6% (v/v) ethanol-containing liquid diets for 4-5 weeks prior to sacrifice at 3 Inquid diets for 4-5 weeks prior to sacrifice at 3 months of age. Total dopamine D₂ receptors were measured using the antagonist, [3H]-spiperone. The number of high affinity D₂ receptors and their conversion to the low affinity form were determined using [3H]-NPA (propylnor-apomorphine) in the absence and presence of 300 AM GTP.

Following 4-5 weeks of ethanol consumption, rats had blood alcohol levels of "100 mg/dl during the active feeding period. In the nucleus accumbens and striatum no statistical differences were found in either the Bmax or Kd of total D_2 binding sites. In addition, we did not detect any significant differences in the number of high affinity dopamine D_2 binding sites or in their conversion to the low affinity form. A normal D_2 receptor number differs with our observation of significantly decreased dopamine D_1 receptors in the nucleus accumbens and cortex of similarly treated rats.

226.8

SOME TERMINAL RELEASE CHARACTERISTICS OF DOPAMINE NEURONS AFTER CHRONIC HALOPERIDOL TREATMENT. B.S. Bunney and B. Moghaddam, Dept Psychiatry and Pharmacology, Yale Univ. Sch. Med. New Haven, CT 06510.

Functional consequence of chronic treatment with haloperidol (CHAL, 0.5 mg/kg s.c. for 21-23 days) on terminal release of dopamine (DA) in the striatum was examined in the rat using microdialysis techniques. Basal extracellular DA concentrations were not significantly different in vehicle and CHAL treated animals. Local application of 30 mM K⁺ increased release similarly in both sets of animals. A challenge dose of haloperidol two days post treatment increased DA release more in CHAL animals than in controls. Direct application of TTX onto the DA terminals or the medial forebrain bundle completely abolished extracellular DA in both control and CHAL treated animals. These results suggest that DA release after CHAL is impulse-dependent and that depolarization block induced by CHAL does not decrease DA release below basal levels. Furthermore, extracellular DA as measured by microdialysis does not appear to be dependent on afferent striatal inputs (e.g. glutamate) since blockade of axonal impulse flow by TTX completely abolished DA release. Supported in part by MH 28849 and MH 25642.

TURNOVER RATES OF D1 DOPAMINE (DA) RECEPTORS IN THE STRIATUM (ST), N. ACCUMBENS (NA), S. NIGRA (SN), AND RETINA (RET) OF ADULT AND AGED RATS.
O. Giorgi, M.G. Piblri*, R. Dal Toso 1, G. Toffano Tand G. Biggio, Dept. of Exp. Biology, Chair of Farmacology, Univ. of Cagliari, and 1 fIDIA Res.
Labs, Abano Terme, ITALY.
The present study was designed to investigate the steady state levels and the turnover rates (TR) of D1 DA receptors in the ST, SN, NA, and RET of 4 months old and 23 months old Sprague-Dawley rats by monitoring the increase in the density (Bmax) of 3H-SCH 23390 binding after irreversible inactivation of D1 DA receptors by Nethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ, 10 mg/kg, s.c.). Significant differences were detected in the TR of D1 DA receptors in the neural tissues analyzed in adult rats, as reflected by the estimated half-lives (T1/2), 36 h, 75 h, 78 h, and 154 h in the RET, ST, NA, and SN, respectively. These differences may be related to the presynaptic (i.e., SN) versus postsynaptic (i.e., ST and RET) localization of the D1 DA receptors. A decrease in the steady state density of D1 DA receptors was observed in the ST (-25%), in the SN (-23%), and in the NA (-28%) of aged rats as compared with their adult counterparts. In contrast, an age-related increase in the density of D1 DA receptors was detected in the RET (+31%). The receptor turnover studies revealed that both the receptor turnover studies revealed that both the receptor synthesis and degradation rates are reduced in the ST NA, and SN of aged rats. In contrast, the degradation rate of D1 DA receptors decreases in the RET of aged rats, whereas the synthesis rate remains unchanged. The latter results may account for the age related changes in the density of D1 DA receptors of D1 DA rece

DOPAMINE DEPOLARIZES RAT SUPRAOPTIC NEURONES BY AN INTRACELLULAR CALCIUM-DEPENDENT CATIONIC CURRENT: AN IONIC SUBSTITUTION STUDY. C.R. Yang, C.W. Bourque and L.P. Renaud. Centre for Research in Neuroscience, Montreal General Hospital & McGill University, 1650 Cedar Avenue, Montreal, Canada, H3G 1A4.

Magnocellular neurosceretory neurones (MNCs) of rat supraoptic nucleus (SON) receive a prominent dopaminergic innervation. Activation of post-synaptic dopamine(DA) D2 receptors on MNCs depolarizes the cells by an increase in conductance via TTX-insensitive, voltage- and [Ca*1]-o-independent mechanisms (Yang et al., Soc. Neurosci. Abst., 15:425, 1989). We now further characterize the ionic basis of the DA-mediated conductance change and evaluate its [Ca*1]-idependence as a possible link in signal transduction.

Intracellular recordings were obtained from MNCs in superfused rat hypothalamic explants. In 10 MNCs recorded in normal ACSF ([Na*1]o-140mM), DA (20-70µM) induced depolarization with a mean reversal potential (V_a) of -20 ±4mV. Complete substitution of [Na*1]o with equimolar TRIS (TRIZMA, Sigma) resulted in a significant (p<0.001) negative shift of V_a to -70±3.7mV, consistently less negative than the equilibrium potential for K'. Hence, the DA-induced response is largely mediated by Na* influx through cationic channels that are also permeable to TRIS. To determine if this DA-induced depolarization was mediated by [Ca*1]i, recordings were obtained with microelectrodes containing BAPTA (0.2M in 2M KAC+0.4M KCl), a Ca*-chelator, in 6 MNCs. Intracellular injection of BAPTA (90±5mins) blocked the DA-induced depolarization, as well as the Ca*-dependent post-burst after-hyperpolarization (evoked by 1-2s, 0.2 to 0.7nA pulses) while glutamate-induced depolarization remained unchanged. These data suggest that the depolarizing response of MNCs to DA is associated with an increase of non-selective cationic conductance and requires mobilization of [Ca*1]i, (Supported by FCAR, FRSQ & MRC)

NIGRAL INJECTIONS OF EEDO OR PERTUSSIS TOKIN (PT) PREVENT D-2 AGONIST EFFECTS ON SUBSTANTIA NIGRA PARS RETICULATA

NIGRAL INSCRIPTIONS OF ENDO OF PERIOSIST TORIN (PT) PREVENT D-2 ACONIST EFFECTS ON SUBSTANTIA NIGRA PARS RETICULATA (SNpr) NEURONS. L.P. Martin, R.F. Cox, and B.L. Waszczak. Pharmacol. Sect., Northeastern Univ., Boston, MA 02115.

Iontophoresis of dopamine (DA) increases the firing rates of SNpr neurons, and it lessens their inhibition by applied GABA. The excitatory effect, which is mimicked by the D-1 agonist SKF 38393, was previously attributed to activation of D-1 receptors on striatonigral terminals. These studies were undertaken to determine if the GABA-modulatory effect, which is reproduced by the D-2 agonist LY 171555 (LY; 0.05 M), might be mediated by D-2 receptors intrinsic to SNpr neurons. Extracellular single unit recordings were made in anesthetized male rats which received: 1) nigral injections of either the receptor inactivator EEDQ (12.5 ug/0.5 ul in 22.5% Molecusol) or the Gi protein inactivator FT (1 ug/ul) 24 hrs prior to recording, or 2) striatal injections of kainic acid (KA; 1 ug/0.5 ul @ 2 sites) 1-2 wks prior. SN injections of both EEDQ and PT prevented the ability of LY to attenuate responses of SNpr cells to CABA (i.e. GABA potencies were reduced by 61±4% at 10 nA LY in control rats, but only by reduced by 61+4% at 10 nA LY in control rats, but only by reduced by 61448 at 10 MA LY in control rats, but only by 5±10% in EEDQ- and not at all in PT-treated rats; n=7-17). Similar EEDQ treatments reduced SN D-1 and D-2 receptor densities by >90%. In contrast, striatal KA lesions which destroyed striatonigral inputs did not prevent the CABA-modulatory effect of LY. These data suggest that the attenuation of CABA effects by DA and LY is likely mediated by D-2 receptors located on SNpr cells. Support: NS 23541.

CANDIDATE AFFINITY LIGANDS FOR D1 AND D2 DOPAMINE RECEPTORS.

CANDIDATE AFFINITY LIGANDS FOR D₁ AND D₂ DOPAMINE RECEPTORS.

J.L. Neumeyer, R.J. Baldessarini, N.S. Kula*, V. Bakthavachalam*, J. Yuan*,

N. Baindur* and A. Campbell.* Research Biochemicals, Inc., 1 Strathmore Road, Natick, MA 01776; Neuroscience Program, Harvard Medical School, Mailman Research Center-McLean Hospital, Belmont, MA 02178

Novel derivatives of known D₁ or D₂ selective dopamine agonists and antagonists were prepared and tested for affinity in radioreceptor assays, using rat striatal membranes and 3H-SCH-23390 (D₁) or 3H-YM-09151-2 (D₂) as radioligands. Among D₁ agonist derivatives, 6-halogen-7,8-di-OH-benz-azepines (including N-allyl congeners) had high D₁ affinity (IC₅₀=4-10 nM) azepires (including N-airy congeners) had high by allimity (lo56=4-10 ml) and D₁/D₂ selectivity (70-900x) as racemates or as their more potent R[+] isomers. Of several D₁ antagonist 1-(p-aminophenyl)-7-Br-8-OH-benzazepines with alkylating substituents on the phenyl moiety, the p-(β-chloroethylamino) derivative was the most potent (IC₅₀=1 nM) and selective (4500x) for D₁ receptors. Of several D₂ agonist N-propyl-N(p-aminophenylethyl)-5-OH-tetralins (PPHTs), those with isothiocyanate, N-ethylfumaryl, or N-bromoacetyl alkylating p-substituents on the phenylethyl moeity were highly potent (IC_{50} =0.2–0.7 nM) and selective (300–1500x) for D₂ over D₁ receptors. Several D₂ antagonist N-p-aminophenylethylspiroperidols (NAPS derivatives) with the same alkylating moieties on the N-phenyl substituent also were highly potent ($IC_{50}=0.4-1.9$ nM) and $IC_{20}=0.4-1.9$ nM) Biological activity of compounds with and without alkylating moieties was compared by ability to block radioreceptor binding in vitro or ex vivo, or ability to block behavioral actions of apomorphine, over time. The duration of action of NAPS was similar to that of its presumably alkylating isothiocyanate congener (NIPS). Some of these compounds or other analogs containing alkylating moieties may be suitable for development as selective, irreversible affinity labeling agents for D₁ or D₂ receptors. [Supported by grants from the USPHS (MH-34006, MH-45692, and MH-47370) and the Bruce Anderson Foundation.]

CHARACTERIZATION OF A NOVEL ANTAGONIST, [3H]SCH39166, AND AUTORADIOGRAPHIC COMPARISON

ANTAGONIST, [3H]SCH39166, AND AUTORADIOGRAPHIC COMPARISON WITH [3H]SCH23390. M.E. Alburges, M. Hunt. R.D. McQuade¹ and J.K. Wamsley. Neuropsychiatric Res. Inst., Fargo, ND 58103. ¹schering-Plough Res., Bloomfield, NJ 07001. In the search for a more selective D₁-antagonist, Schering-Plough Research synthesized a new benzazepine compound, SCH39166. We have characterized the binding of this D₁-antagonist to the rat brain and compared the distribution of [3H]SCH39166 and [3H]SCH23390 labeled sites. The Kd, determined from dissociation and association rate constants (1.09 nM) was comparable to the K, value obtained from saturation studies (1.74 nM). association rate constants (1.09 hm) was comparable the K₄ value obtained from saturation studies (1.74 nM). [^3H]SCH39166 binds in a saturable manner with high affinity and low nonspecific binding to cortical tissue. Inhibition of the [^3H]SCH39166 binding by a series of dopaminergic and serotonergic antagonists substantiate the D₁ specificity of this compound.

Autoradiographic localization of D₁-receptors, using

[3H]SCH39166, indicates that binding density is high in caudate putamen, nucleus accumbens, olfactory tubercle, substantia nigra, and entopeduncular nucleus. Low binding occurs in lamina IV of cortex and in the choroid plexus (both areas where high receptor binding has been previously reported with [3 H]SCH23390). At low concentrations, [3 H]SCH39166 is a selective D₁ dopamine receptor antagonist with very little interaction with 5HT receptors in the CNS.

BHT 920 SELECTIVELY STIMULATES A SUBTYPE OF DOPAMINE

BHT 920 SELECTIVELY STIMULATES A SUBTYPE OF DOPAMINE D-2 RECEPTOR M.Pizzı*, M.Memo, A.Valerio*, C.Missale,L.Castelletti*,M.O. Carruba*,P.F.Spano.
Inst. of Pharmacology and Exper. Ther., Brescia University, Brescia 25124-Italy
We have recently described the existence of two D-2 receptor subtypes named D-2a and D-2b. In particular, studies on mammotrophs (Castelletti L, et al. J.Physiology 410:251, 1989) have evidentiated that dopamine, through a receptor mediated mechanism. stimulates the opening of two different al. J.Physiology 410:251, 1989) have evidentiated that dopamine, through a receptor mediated mechanism, stimulates the opening of two different K+ channels, a calcium- and a voltage-dependent channel and that the activation of the former only, is related to a reduction of cAMP formation. In the present study we evaluated the ability of different dopaminergic drugs to selectively activate a single receptor-mediated transduction pathway. We found that quinpirole inhibited basal adenylate cyclase activity (IC-50 = 3uM) and activated both voltage-dependent and calcium-dependent (cAMP sensitive) K+ permeability (measured as 86-Rb efflux) in mammotroph cells. On the contrary, BHT 920 did not modify adenylate cyclase attivity up to 1 mm concentration and it did not activate calcium-dependent 86-Rb efflux. BHT 920 induced a stimulation of voltage-dependent component of K+ flux which was selectively blocked by 1-sulpiride (5 uM). The azepine derivative BHT920 rubtype (named D-2b) which is uncoupled to adenylate cyclase and selectively associated to voltage-dependent K+ channels.

SELECTIVE DOPAMINE D1 AND D2 AGONISTS AFFECT DIFFERENT COMPONENTS OF FREE-RUNING CIRCADIAN ACTIVITY IN RATS. N. Yamada* and M.T. Martin-Iverson. Neurochemical Research Unit, Dept. of Psychiatry, Univ. Of Alberta, Canada T6G 287
We investigated the effects of vehicle (V) or selective D1 (SKF 38393, S) and D2 (PHNO, P) agonists, given alone or together, on circadian rhythms of locomotor activity in rats kept singly housed under constant lighting conditions (continuous light or dark). Male Sprague Dawley rats (N=12 per group) were given subcutaneous infusions of V, P (5μg/h) and/or V or S (336μg/h) sustained for 14 days using Alzet osmotic minipumps. There were 4 independent drug-treated groups in each lighting condition, consisting of V+V, V+P, S+V or S+P. Locomotion was continuously determined by counting interruptions of infrared photobeams transecting the home cages, and reported in blocks of 1 h. Actograms were plotted, and the circadian rhythms were determined by the least squares methods. Parameters of the the rhythms were subjected to analysis of variance to determine significant drug effects. Circadian rhythms in locomotion were found to decompose under constant light, relative to the dark condition, with smaller amplitudes, less discrete onsets of activity, and variability in periods. The D2 agonist increased the amplitude (F(1,44)=23.1, P < 0.001) and the mesor (F(1,44)=20.2, P < 0.001) of the activity cycle, but had no effects on the length of the period. On the other hand, the D1 agonist increased the length of the period of the cycle (F(1,44)=9.13, p < 0.005), but had no effects on the amplitude and the mesor. There were no statistically significant interactions between the D1 and D2 agonists no circadian rhythms in locomotion. Acknowledgments: These studies were funded by AHFMR and PMHAC.

METABOLIC CORRELATES OF D1 / D2 DOPAMINE RECEPTOR INTERACTION
A.R. Braun. K. Vladar. R.H. Sexton Ill. T.N. Chase, D.R. Weinberger. ETB, NINDS,
and CBDB, NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032
2-deoxyglucose autoradiography was used to characterize patterns of cerebral
metabolism associated with D1 and D2 receptor stimulation in rats. In addition to
controls treated only with saline, six groups of animals were pretreated with AMPT and
then received s.c. injections of vehicle or of the selective D2 dopamine agonist
LY171555 (LY) or D1 agonist SKF38393 (SKF) administered alone (3 mg/kg and 32
mg/kg respectively) or in combination: three drug combinations were utilized in which a
fixed dose (3mg/kg) of the D2 agonist and escalating doses (2, 8 and 32 mg/kg) of the
D1 agonist have been shown to produce increasing levels of behavioral
disorganization characterized by intense stereotypy and sensory inattention.
Neither catecholamine depletion or the administration of LY or SKF alone to depleted
animals produced significant changes in contical glucose metabolism. The dose of LY
3mg/kg+SKF 2 mg/kg, which elicited organized motor activity and enhanced responsiveness to exteroceptive stimuli, also failed to produce such changes. However, the
dose combinations which resulted in behavioral disorganization were characterized by
significant decreases in metabolic activity in anterior and posterior cingulate and
concomitant increases in lateral frontal and parietal cortices. These doses produced
similar increases in metabolic activity in anterior and posterior cingulate and
concomitant increases in hetaral frontal and parietal cortices. These doses produced
similar increases in metabolic activity in anterior and posterior cingulate and
concomitant increases in hetaral frontal and parietal cortices. These doses produced
similar increases in metabolic activity in anterior and posterior cingulate and
concomitant increases in hetaral frontal and parietal cortices. These doses produced
similar increase

NUCLEUS ACCUMBENS. M.E. Meyer, T. Potter* and C. Van Hartesveldt. Psychology Dept., University of Florida, Gainesville, FL 32611.

Dopamine D1 receptor agonists such as SKF 38393 have not been reported to elicit locomotor activity when given peripherally; only at high doces have smiffing and growing been observed.

doses have sniffing and grooming been observed. Thus the role of the DA D1 agonist in behavior has been questioned. However, it has recently been shown that SKF 38393 injected directly into the nucleus accumbens (Acb) increased gross activity (Dreher and Jackson, 1989).
We have further examined the effects of SKF

system in the rutther examined the effects of Ski system in the Acb measured every 10 min for 2 hr in an activity monitor. Doses of 0.1, 1.0, and 10 ug/side all induced highly significant increases in locomotor activity relative to the vehicle, but the lowest dose induced the highest level of horizontal, vertical, and stereotyped activity. The effect of the lowest dose peaked at about 100 minutes after injection.

Since SKF 38393 injected directly into the Acb elicits dose- and time-dependent increases in locomotor activity, the role of DA D1 receptors in behavior must be reconsidered.

226.16

DELAYED EFFECTS OF D1 DOPAMINE RECEPTOR BLOCKADE IN THE MEDIAL PREFRONTAL CORTEX ON PRE- AND POSTSYNAPTIC DOPAMINE FUNCTION IN THE NUCLEUS ACCUMBENS.

P. Vezina, G. Blanc*, J. Glowinski* and J.-P. Tassin*. Chaire de

Neuropharmacologie, INSERM U. 114, Collège de France, 75231 Paris Cedex 05 France

Acutely, D1 dopamine (DA) receptor blockade in the medial prefrontal cortex (mPFC) has been shown to potentiate the locomotor activating effects of amphetamine in the nucleus accumbens (N.Acc.). We now report that blockade of D1 DA receptors in the mPFC also produces delayed effects on DA function in the N.Acc. Rats received one intra-mPFC injection of saline (Control animals) or the D1 DA receptor antagonist SCH-23390 (0.25 µg/0.5µl/side). When tested two days post-injection, mPFC-SCH pretreated animals showed lower levels of locomotor activity than Control animals in response to intra-N.Acc. injections of amphetamine (1.5 µg/0.5µl/side). However, these animals also showed higher levels of locomotor activity (+98%) when tested with intra-N.Acc. injections of the D1 DA agonist SKF-38393 (1.0 μg/0.5μl/side) and a 30% increase in maximal DA-sensitive adenylate cyclase activity in comparison to Control animals.

These results demonstrate a delayed action resulting from cortical D1 DA receptor blockade and suggest, in a way consistent with previous findings (Hervé et al., <u>J. Neurosci.</u>, 9: 3699, 1989), that mPFC D1 DA receptors are involved in the postsynaptic regulation of D1 DA receptors as well as the presynaptic regulation of DA activity in subcortical DA receptor fields such as the N.Acc.

EFFECTS OF MONOVALENT CATIONS ON DOPAMINE D, RECEPTORS LABELED WITH ['H]RACLOPRIDE. T.A. Reader, S. Boulianne', E. Molina-Holgado' and K.M. Dewar. CRSN, Département de physiologie, Université de Montréal, Montréal Québec, Canada H3C 3J7.

Specific binding of [3H]raclopride ([3H]RAC) to dopamine (DA) D₂ Specific binding of ['H]raclopride (['H]RAC) to dopamine (DA) D₃ receptors in the rabbit neostriatum was investigated in the presence of Na^{*} and Li^{*}. Both cations produced dose-dependent elevations in specific ['H]RAC binding; NaCl increased maximal binding two-fold as compared to LiCl. The inhibition of ['H]RAC binding by the antagonlist (+)butaclamol was unaffected by the addition of either Na^{*} or Li^{*} while the potency of DA to compete with ['H]RAC was reduced. Both Na^{*} and Li^{*} diminished the affinity of DA for the high- and low-affinity states of the D₂ receptor and this effect was more pronounced in the presence of Na*. The guanine nucleotide derivative 5'-guanylylimidodiphosphate or Gpp(NH)p reduced the potency of DA to compete with ['H]RAC both in the presence and absence of cations; however, this effect of Gpp(NH)p was to shift the D₂ receptors from a high to a lower affinity state. Saturation curves revealed that these ions increased the affinity and the maximum density (B_{max}) of [³H]RAC binding; the presence of Na* elicited maximum density (B_{max}) of (FIRAC binding; the presence of Na cincture a significantly greater change in the apparent dissociation constant (K_o) as compared to Li*. In conclusion, our results show that [²H]RAC binding to rabbit striatal membranes is regulated by cations. Moreover, although Li* and Na* influence specific [³H]RAC binding in a similar manner, suggesting a similar site of action, there appear to be quantitative differences between the effects of these two long. [Supported by MRC grant MT-6967 and the FRSQ].

227 1

MUSCARINIC RECEPTOR MODULATION OF $\begin{bmatrix} 3 \\ 1 \end{bmatrix}$ ACETYLCHOLINE RELEASE IN MECHANICALLY-DISSOCIATED ADULT RAT HIPPOCAMPUS E. Cadman* and M. McKinney, Neuroscience Research Division Pharmaceutical Discovery, Dept.47W, Abbott Laboratories,

Abbott Park, IL 60064 We have previously shown that a mechanical sieving method with adult rat brain tissue produces a metabolically active intact cellular preparation with which the study of active intact cellular preparation with which the study of M1 and M2 receptor coupling to phosphoinositide and cyclic AMP second messenger systems is facilitated (Mol. Pharmacol. 35:39). In the present study we evaluated whether autoreceptor modulation of evoked release of [H]acetyl-choline (Ach) could be observed in this preparation. Adult rat hippocampal tissue was prepared as described and intracellular Ach stores were labeled with [H]choline in a Krebs buffer under 0,:00, (95.5). In the presenge of 100 uM physostigmine, 25 mM K+ was used to evoke [H]Ach release, which was purified by extraction and quantitated. 100 uM physostigmine, 25 mM K+ was used to evoke [3 H]Ach release, which was purified by extraction and quantitated. High K+ stimulation for 15 min evoked 6.5 +/- 4.1 fold [3 H]Ach release over basal levels from dissociated hippocampal cells (about 4 mg per vial). Oxotremorine-M (EC,0=260 nM) and oxotremorine (EC,0=2.5 uM) inhibited the evoRed release by 55 +/- 7 8 and 42 4 -/- 8%, respectively. Atropine fully reversed the effects of the agonists. These results indicate that this method of tissue preparation may provide a simple system for the evaluation of muscarinic autoreceptor function in brain.

EVIDENCE FOR PAIRED M2 MUSCARINIC RECEPTORS.

EVIDENCE FOR PAIRED M2 MUSCARINIC RECEPTORS.
L.T. Potter, L.A. Ballesteros*, L.H. Bichajian*, C.A. Ferrendelli*, A.
Fisher, H.E. Hanchett* and R. Zhang. Department of Pharmacology,
University of Miami School of Medicine, Miami, FL 33101.

Mattera et al (JBC 260, 7410) found Hill coefficients of 1.3-1.5 for the
binding of ³H-quinuclidinyl benzilate (QNB) to cardiac M2 receptors
exposed to the guanine nucleotide, GppNHp, suggesting bivalent
receptors coupled with G-protein. Potter et al (Cell. Mol. Neurobiol. 8,
181) found equal numbers of GppNHp-sensitive high affinity sites (H)
and GppNHp-insensitive low affinity sites (L) on hippocampal M1
receptors, suggesting dimeric receptors. Peterson et al (PNAS 81, 4993)
found ~50% H sites on pure M2 receptors in solution. The possibility
of naired receptors was examined further using M2 receptors from the rat found ~50% H sites on pure M2 receptors in solution. The possibility of paired receptors was examined further using M2 receptors from the rat brainstem. Binding assays with ³H-N-methylscopolamine and QNB showed Hill coefficients close to 1.0 in the presence or absence of GppNHp. However competition curves between agonists and ³H-NMS showed equal numbers of GppNHp-sensitive H sites and GppNHp-insensitive L sites for tertiary (e.g. coxotremorine), quaternary (e.g. cisdioxolane) and alkylating agonists (acetylethylcholine mustard). The 50% H phenomenon persisted at different temperatures, after halving the number of receptors (and thus doubling the remaining G protein: receptor ratio), and after membrane solubilization. Selective occupation H sites with agonist mustard, or of L sites with irreversible antagonists of H sites with agonist mustard, or of L sites with irreversible antagonists (in the presence of an agonist on H sites), yielded residual free receptors showing predominant L or H sites, respectively. The results support the concept of paired receptor sites.

227.5

N-ETHYLMALEIMIDE (NEM) AFFECTS [3H]QUINICLINIDIL-BENZILATE ([3H]QNB) BUT NOT [3H]PIRENZEPINE ([3H]PZ) BINDING IN THE PRIMATE CEREBRAL CORTEX. M.G. Vannucchi M.S. Lidow, and P.S. Goldman-Rakic. Section of Neuroanatomy, Yale University, School of Medicine, New Haven, CT 06510

It is well established that the sulfhydryl alkylating agent, NEM, modulates the affinity of muscarinic receptors for agonists by uncoupling them from nucleotide regulatory proteins (uncoupling of R-Gi complex). However, the influence of sulfhydryl alkylation on antagonist binding is still a matter of controversy. We have investigated the effect of NEM on the binding of muscarinic antagonists, $[^3H]QNB$ and $[^3H]PZ$ in the primate cerebral cortex. Temporal cortex of the rhesus monkey (n = 3) was homogenized in 10 mM Na-K-phosphate buffer (pH 7.4) containing 1mM EDTA. Incubation with $[^3H]QNB$ and $[^3H]PZ$ was carried out in the same buffer in the presence or in the absence of NEM and was terminated by rapid filtration. Nonspecific binding was determined in the presence of 1 μ M atropine sulphate. In the absence of NEM, an analysis of the $[^3H]QNB$ saturation curve allowed to discern only a single site with $K_d=9.4\pm1.7$ pM ($B_{max}=56.9\pm8.1$ fmol/mg prot.). In the presence of NEM, however, an additional site with $K_d=297.6\pm96.0$ pM ($B_{max}=188.6\pm36.3$ fmol/mg prot) could be easily detected. The addition to incubation media It is well established that the sulfhydryl alkylating agent, NEM, modulates the 188.6:13.6 fmol/mg prot.) could be easily detected. The addition to incubation media of 2 μ M PZ resulted in the disappearance of the high but not the low affinity sites indicating that the former are likely of M_1 type. The substitution of NEM with 5'guanyl imidodiphosphate (which along with NEM uncouples R-Gi complex) did not unmask the low affinity sites. Thus, the effect of NEM on [3H]QNB is probably not unmask the low arininy sites. Thus, the effect of New on [*H]QNB is probably not connected with uncoupling of R-61 (complex. In contrast, we found no influence of sulfhydryl alkylation on specific binding of [3 H]PZ. In the temporal cortex, this radioligand binds to a single site with K_d = 3 .0±0.4 nM (B_{max} = 6 5.2±3.7 fmol/mg prot.) in the presence and in the absence of NEM. Thus, although it is widely believed that sulfhydryl alkylation does not affect muscarinic antagonist binding in the central nervous system, our data reveal that sulfhydryl alkylation agent, NEM, can influence the binding of some antagonists in the primate cerebral cortex.

227.2

"M-TOXIN", A NOVEL LIGAND FOR M1 MUSCARINIC RECEPTORS. S.I. Max and L.T. Potter. Department of Pharmacology, University of Miami School of Medicine, Miami, FL 33101.

Mamba venoms contain neurotoxins which act in unusual ways at cholinergic synapses. The venom of the green mamba, *Dendroaspis angusticeps*, contains dendrotoxin, which increases the release of acetylcholine by blocking potassium channels, fasciculin, which causes fasciculations by inhibiting acetylcholinesterase, and several toxins which partially block the binding of quinuclidinyl benzilate (QNB) to muscarinic receptors (Adem et al., Biochim. Biophys. Acta <u>968</u>, 340). We purified receptors (Adem et al., Biochim. Biophys. Acta 2006, 340). We purified the major antimuscarinic component of this venom, which we call "m-toxin", to assess whether it might be useful for receptor research. Active fractions were assayed for their ability to block the binding of ³H-QNB or ³H-pirenzepine to receptors in membranes from rat and rabbit brains. M-toxin was readily separated from other toxins by gel filtration, since it behaved like a globular protein of about 4000 D unlike other toxins of 6000-9000 D. Purification was completed by cation exchange 6000-9000 D. Purification was completed by cation exchange chromatography. The N-terminal sequence of m-toxin appears unique. M-toxin was active on receptors from fresh or frozen tissue in the presence of EDTA, N-ethylmaleimide, PMSF or digitonin, but was inactivated by heat or SDS. M-toxin fully blocked the binding of 1 nM ³H-pirenzepine to all parts of the rat brain, and reduced the binding of 1 nM ³H-QNB to all M1 receptors as defined by the high affinity binding of pirenzepine. It was inactive on preparations rich in M2 receptors. Binding was effectively irreversible. Radiolabelling of m-toxin and production of antibodies are in progress. Thus, m-toxin appears very promising for studies of M1 receptors.

227.4

Serotoninergic and Muscarinic Cholinergic Stimulation of Phosphoinositide-specific Phospholipase C in Rat Brain Cortical Membranes. M.A. Wallace and E. Claro*, Dept. of Biochemistry,

University of Tennessee, Memphis, TN 38163.

Exogenously supplied substrates were used to measure guanine nucleotide dependant stimulation of phosphoinositide-specific phospholipase C (PLC) by muscarinic cholinergic and serotoninergic agonists in rat brain cortical membranes. Serotonin (5-HT), 5-methyltryptamine (5-MT), 5-fluorotryptamine and tryptamine respectively. These agonists were all equally efficacious, with maximal PLC stimulation reaching about 30% of that obtained with carbachol. The rank order of potency for the muscarinic agonists was oxotremorine-M > pilocarpine = arecoline > carbachol = bethanecol. Unlike the case when using cortical tissue slices, all these agonists were fully efficacious at stimulators of PLC. Muscarinic agonists significantly lowered the apparent guanine nucleotide requirement for PLC stimulation. Serotoninergic agonists enhanced PLC activity but without any shift in guanine nucleotide requirements. Ketanserin blocked serotoninergic but not cholinergic activation of PLC, while atropine blocked the latter but not the former response. Dopamine inhibited the carbachol response (Wallace, M.A. and Claro, E. Neurosci Letts 110: 155, 1990) but not that due to 5-MT. The results indicate that serotoninergic and muscarinic cholinergic agonists stimulate PLC through distinct mechanisms in brain cortex.

227.6

AN IMMUNOCYTOCHEMICAL AND AUTORADIOGRAPHIC STUDY ON THE CELLULAR LOCALIZATION OF CHOLINERGIC MARKERS IN THE HUMAN CEREBELLUM. M.F. Casanova, * M. Zito, * D.R. Weinberger, J.E. Kleinman. Clinical Brain Disorders Branch, Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

Although the existence of cerebellar muscarinic receptors and afferent cholinergic projections is well known, the cellular localization for the binding of acetylcholine remains controversial. Several studies have suggested the presence of cholinergic markers in different types of cerebellar neurons (Kan et al, <u>Brain Res</u> 193:165-171; Neustadt et al, <u>Brain Res</u> <u>Bull</u> 20:163-172, 1988). The purpose of this study was to elucidate the cellular localization of muscarinic receptors in the humans cerebellum by using [3H]ONB autoradiography (1 nm, 20 mm Tris, pH 7.4) and choline acetyltransferase (ChAT) immunocytochemistry (1:3 dilution, Boehringer Mannheim). Our results indicate that muscarinic receptors in the cerebellar folias are primarily found in the granule cell layer. [3H]QNB binding was completely abolished when using atropine (1 um) as a blocker but not when using pirenzepine (1 um), suggesting the receptors are of the non-M1 type. Immunocytochemistry for ChAT revealed positive staining fibers surrounding granule cells and occasionally in structures resembling glomeruli. Positive staining varicosities aggregated around stellate and basket cells. Both Golgi varicosities aggregated around stellate and basket cells. Both doily and Purkinje cells revealed no signs of ChAT immunoreactivity. In summary, the human cerebellum contains muscarinic (non-M1 type) receptors in the mossy fibers that terminate in the granule cell layer. The prominent ChAT immunoreactivity of terminals in the molecular layer but non surrounding Purkinje cells suggests the presence of cholinergic afferents stemming from a source other than climbing fibers.

COCAINE INTERACTIONS WITH PRIMARY AND SECONDARY RECOGNITION SITES ON MUSCARINIC RECEPTORS. A.A. Vaishnav. D.C. Mash and D.D. Flynn. Depts. of Pharmacology and Neurology. Univ. of Miami School of Medicine, Miami, FL 33101.

Several lines of evidence have suggested that muscarinic receptors may possess more than one ligand binding site. Muscarinic receptors contain several aspartic acid residues, which are conserved in other members of the large family of membrane-spanning, G-protein coupled receptors. These residues appear to be differentially involved in ligand binding (Fraser et al., Mol. Pharmacol. 36: 840, 1989). In addition, a number of quaternary muscarinic antagonists, most notably gallamine, display both competitive as well as allosteric binding properties at the muscarinic receptor. We have characterized the binding of cocaine to muscarinic receptors in membrane homogenates from post-mortem human brainstem. (-)Cocaine inhibits binding of the tritiated muscarinic antagonists, N-methylscopolamine (NMS) and pirenzepine, to an apparent single class of sites with a K, of 200-300 µM. (+)Cocaine is 10-fold more potent in inhibiting binding of these ligands. The binding of cocaine is unaffected by guanine nucleotides and is not apparently selective for either the MI or M2 receptor subtypes. Rosenthal analyses of saturation binding data obtained in the presence of increasing concentrations of cocaine demonstrated that both the K₄ and B_{max} values for ³H-NMS are increased. These data suggest both competitive and non-competitive interactions of cocaine with muscarinic receptors. Kinetic data revealed a slowing of the rate of dissociation of ³H-NMS by cocaine by 20-fold, but not of ³H-QNB, ³H-pirenzepine or ³H-Oxotremorine-M. This finding is consistent with previous reports that binding of ³H-NMS is more susceptible to allosteric modulation than ³H-QNB or ³H-pirenzepine (Lee and El-Fakahany J-Pharmacol-Exp. Ther. 246: 829, 1988). These results suggest that cocaine may recognize two distinct bindi

227.9

COMPARATIVE EXPRESSION OF CHOLINERGIC MARKERS DURING BRAIN DEVELOPMENT. <u>LAubert, D.Cécyre*, D.M.Araujo, S.Gauthier and R.Quirion</u>. Douglas Hospital Research Centre, McGill University, Dept. Neurology & Neurosurgery, and McGill Centre for Studies in Aging, Montreal, Quebec, Canada H4H 1R3.

The comparative ontogenic profiles of various cholinergic markers were studied in the rat brain using an *in vitro* receptor autoradiographic method. Brain sections from animals at embryonic days 18 and 20 (E18 & E20), postnatal days 1 to 35 (P1 to P35) and adult (3 months) were processed with either [³H]QNB (total population of muscarinic sites), [³H]pirenzepine (M1 sites), [³H]acetylcholine, [³H]AF-DX 116 or [³H]AF-DX 384 (putative M2 sites), [³H]/V-methylcarbamylcholine (nicotinic sites) and [³H]hemicholinium-3

(HC3) (high affinity choline reuptake sites).

Our results reveal the early appearance of the M1 receptor sites in most brain regions labelled in adult brain, including the striatum (E18) and the hippocampus (E20). In contrast, M2 binding sites, labelled by various ligands, seemed to have developed more slowly. Significant labelling was observed only during the second and third weeks of development (P14-P21), with few possible exceptions such as the anteroventral nucleus of the thalamus which is labelled at E20.

This may suggest that the appearance of M2 sites is delayed (compared to M1 sites) because of their presynaptic location. Another marker of presynaptic cholinergic terminal (HC3) also possessed a slow maturation.

Finally, nicotinic sites are present as early as E18 and E20 in various brain regions suggesting a postsynaptic localization in addition to a possible presynaptic distribution in certain areas (Araujo et al., *J.Neurochem*, 51:292-299, 1988). (MRC, Canada).

RETENTION OF COUPLING BETWEEN M1 MUSCARINIC RECEPTORS AND G-PROTEIN AFTER CHOLINERGIC DENERVATION, WITH AGING, AND IN ALZHEIMER'S DISEASE (AD). B.D. Pearce and L.T. Potter. Deptartment of Pharmacology, University of Miami School of Medicine, Miami, FL 33101

Numerous studies have shown that cerebral M1 receptors are retained after sholiness in dearwaring and in AD but four this hours addressed

after cholinergic denervation and in AD, but few studies have addressed the functional status of these receptors after long-term denervation. We examined the first step in the M1 transduction mechanism, the interaction examined the first step in the M1 transduction mechanism, the interaction between receptors and G-protein, one year after unilateral denervation of the rat hippocampus, with aging, and in normal and Alzheimer cerebral cortex. Competition experiments were performed between 1 nM ³H-pirenzepine (which selectively labels the m1 subtype of muscarinic receptors) and oxotremorine-M in the absence and presence of the guanine nucleotide, GppNHp (Potter et al, Cell. Mol. Neurobiol. §, 181). Retention of a high percentage of high affinity binding sites (% H) and of a substantial loss of these sites in the presence of GppNHp was taken as evidence of receptor: G protein interactions. Normal and denervated hippocampi showed similar % H values (\$2.3 vs 56.5%) and 3/4^{ths} of these sites converted to low affinity with 0.2 mM GppNHp. The cortices from five human controls and seven AD patients also showed similar. from five human controls and seven AD patients also showed similar % H values $(37.4 \pm 6.4 \text{ vs } 31.7 \pm 4.5\%)$ and $3/4^{\text{ths}}$ of these sites were also respectively. The AD and 3/4" of these sites were also sensitive to GppNHp. The AD tissue had 68% less choline acetyltransferase activity. There was no correlation between % H and age in rats 1.5-29 months old, or in humans aged 10-85 years. The affinities of high and low affinity binding sites were constant. The data indicate that early steps in receptor transduction remain functional despite prolonged receptor inactivity.

DISTRIBUTION OF MUSCARINIC CHOLINERGIC RECEPTORS IN THE DEVELOPING HUMAN BRAINSTEM. H.C. Kinney, V. Greenier*, W.F. White. Children's Hospital, Boston, MA 02115.

Acetylcholine has been implicated in brainstem mechanisms of cardiorespiratory control and arousal. Information about the quantitative distribution of muscarinic receptors in the developing human brainstem is relevant to under standing putative brainstem disorders of cardiorespiration and/or arousal, e.g., apnea of infancy, congenital central hypoventilation syndrome, sudden infant death syndrome. We determined the quantitative distribution of [3H]quinu-clidinyl benzilate (QNB) binding to muscarinic receptors with computer-based, tissue section autoradiography. Frozen, serially-sectioned brainstems (postmortem interval 4-24 hrs) were analyzed from 3 fetuses (19-21 wks), 5 infants (1-9 months), 1 child, and 1 adult without neurologic disease. In infants, nuclei with high binding include: nucleus tractus solitarii (NTS), parabrachial complex, griseum pontis, cranial nerve motor nuclei; intermediate binding: reticular formation; low binding: inferior olive. By mid-gestation the relative distribution of muscarinic receptors is established and is similar to that in the infant. Quantitative changes in [3H]QNB binding occur in individual nuclei across the time period studied. The relative distribution also appears to change in the mesencephalic reticular formation from infancy to adulthood. This study provides baseline information for muscarinic receptor analysis in developmental brainstem disorders.

LONG-TERM CHANGES IN PHOSPHOINOSITIDE HYDROLYSIS

LONG-TERM CHANGES IN PHOSPHOINOSITIDE HYDROLYSIS FOLLOWING COLCHICINE LESIONS OF THE NUCLEUS BASALIS. W. R. Mundy, P. Tandon, S. Barone Jr. and H. A. Tilson. Lab. of Molec. and Integrative Neurosci., NIEHS/NIH, Research Triangle Park, NC 27709.

Long-term changes in the functional integrity of cholinergic muscarinic receptors following lesion-induced cholinergic denervation are not well studied. We examined muscarinic receptor-mediated phosphoinositide (PI) hydrolysis in rat cortical slices up to 14 months after hydrolysis in rat cortical slices up to 14 months after lesions of the nucleus basalis (NB). Rats received bilateral injections of colchicine $(1.5 \ \mu\text{g}/0.5 \ \mu\text{l})$ into the NB and were sacrificed at 1, 3, or 14 months after surgery. Colchicine lesions resulted in a loss of ChAI-immunoreactive cells at 1 month after surgery which was still apparent at 14 months. Choline acewhich was still apparent at 14 months. Choline ace-tyltransferase activity in the cortex was decreased by 43% one month after lesioning, but returned to control levels by 3 months. The muscarinic agonist carbachol produced a concentration-dependent increase in PI hy-drolysis, which was enhanced 3 and 14 months after NB lesions compared to sham-lesioned controls. No change lesions compared to snam-lesioned controls. No change was observed 1 month after lesioning. Norepinephrine and quisqualate-stimulated PI hydrolysis was also enhanced 14 months after NB lesions. These results suggest a slowly developing up-regulation of post-synaptic receptor function following pre-synaptic loss of neurotransmitter.

227.12

NEUROPEPTIDE MODULATION OF CARBACHOL-STIMULATED PHOSPHOINOSITIDE METABOLISM IN FRONTAL CORTEX OF AGED RATS. M. A. Rice* and N. W. Pedigo. Dept. Pharmacology, Univ. Kentucky, Lexington, KY 40536.

Several neuropeptides are thought to play an important role in modulating muscarinic transmission in the CNS. Neurotensin (NT), cholecystokinin (CCK), somatostatin (ST), and vasoactive intestinal polypeptide (VIP) were assayed for their ability to modify carbacholstimulated phosphoinositide (PI) metabolism in cortical slices from young (3 mo) or senescent (27 mo) rats. At least 6 concentrations of carbachol were used in the absence or presence of neuropeptide (1.0 µM final concentration). Results indicated that NT, CCK and VIP were able to potentiate the effects of carbachol in young rats, while somatostatin was without effect. However, only neurotensin significantly enhanced carbachol's effects in senescent animals.

Table 1:	ED50 for Carbachol (µM)		
Drug	<u>3 mos</u>	27 mos	
Control	$168 \pm 15.5 (10)$	146 ± 20.7 (8)	
Neurotensin	$74 \pm 5.8 (6)^*$	$50 \pm 8.6 (7)^*$	
CCK	$82 \pm 16.7 (5)$ *	$87 \pm 15.9 (4)$	
Somatostatin	$193 \pm 30.9 (5)$	$154 \pm 20.2 (3)$	
VIP	$70 \pm 8.9 (5)*$	$78 \pm 17.7 (4)$	
* p<.05 vs age-r	natched control (Dunn	ett's test)	

These results show the ability of certain neuropeptides to facilitate carbachol-stimulated PI metabolism is not completely retained in cortical tissues of senescent rats.(Supported by an ADRDA grant).

CHOLINERGIC RECEPTOR ALTERATIONS IN THE CNS OF POST-MORTEM CHOLINERGIC RECEPTOR ALTERATIONS IN THE CNS OF POST-MORTEM HUMAN ALZHEIMER'S DISEASED TISSUE. X. Ming, L. Tsiokas, Z. Jelisijevic*, S.C. Zhang* and M. Watson. Dept. of Pharmacology, Univ. of Medicine & Dentistry of New Jersey-New Jersey Medical School, Newark, N.J. 07103-2714. Expression cloning and molecular pharmacologic studies

reveal the existence of five muscarinic acetylcholine receptor (mAChR) subtypes. Attention has focused on changes in mAChR subtypes in Alzheimer's Disease (AD). Binding, biochemical and radioautographic studies of human postmortem brain tissue from AD and control (C) patients have been performed. Our data suggest alterations may occur in mAChR subtypes seen on both pre- and postsynaptic neurons. Assays of [3H](-)quinuclidinylbenzilate ([3H](-)QNB), a highly specific but non-subtype selective antagonist, [3H](+)cis-methyldioxolane ([3H](+)CD), which labels a super high affinity mAChR agonist state, [3H]pirenzepine ([3H]PZ), an M1 selective antagonist, [3H]AF-DX 116, a ([3H]PZ), an M1 selective antagonist, [3H]AF-DX 116, a somewhat M2 selective antagonist and [3H]hemicholinium-3 ([3H]HC-3), an inhibitor of sodium-dependent high affinity choline uptake were done as described. No differences in affinity (Kd) values were seen. Among the alterations in receptor density in AD were in the hippocampal formation where [3H]HC-3 was as low as 18% of C and [3H]PZ was 67% of C. Loss of presynaptic input to the hippocampus and an inability to up-regulate mAChR subtypes may reflect a pathological process in AD. Study of mAChR subtypes via in situ hybridization histochemistry offers an additional means by which such data may be further confirmed. MH43024.

MUSCARINIC CHOLINERGIC RECEPTOR AGONISTS INHIBIT THE ACTIVITY OF SEROTONIN N-ACETYLTRANSFERASE IN BOVINE GLAND EXPLANTS IN CULTURE. P. Phansuwan-Pujito, P. Govitrapong, and M. Ebadi. Lab. of Neurobiol., Mahidol Univ., Salaya, Thailand, and Depts. of Pharmacol. and Neurol., Univ. of Nebraska Coll. of Med., Omaha, NE 68198-6260, U.S.A. The mammalian pineal gland by synthesizing melatonin and by functioning as a

biological clock orchestrates the actions of a plethora of receptors and synchronize the functions of numerous neurotransmitters in the CNS. By using tritiated muscarinic cholinergic receptor antagonist, quinuclidinyl benzilate ([3H]QNB) as a ligand, Govirapong, Phansuwan-Pujito, and Ebadi (Comp. Biochem. Physiol., 94:159-164, 1989) have identified muscarinic cholinergic receptors in the bovine pineal gland with K_D value of 0.423 \pm 0.01 nM and B_{max} value of 69.75 \pm 20.91 fmol/mg protein. In addition, a specific choline acetyltransferase has been reported in the bovine pineal gland by Phansuwan-Pujito, Govitrapong, and Ebadi (<u>J. Pineal Res.</u>, 7, 1990, in press). In this communication, we report that cholinergic receptor agonists such as metacholine (10 μ M), carbachol (10 μ M), and oxotremorine (10 μ M) inhibited the activity of serotonin N-acetyltransferase (SNAT) in the bovine pineal explants in culture, from a control value of 5.02 ± 0.45 to 1.25 ± 0.25 , 1.30 \pm 0.15, and 1.22 \pm 0.20 pmol/mg protein/min; and this effects were blocked by atropine (20 µM) or QNB (20 µM). The presence of high affinity muscarinic cholinergic binding sites, of a specific choline acetyltransferase, along with dichotomous interaction of muscarinic receptors agonists antagonists with SNAT, are interpreted to indicate that muscarinic cholinergic fibers modulate the synthesis and actions of pineal melatonin.

227.14

AGING-INDUCED AUTERATIONS IN ONS MUSCARINIC ACETYLCHOLINE RECEPTOR SUBTYPES AND MRNA LEVELS IN A RODENT MODEL. Matson, I. Tsiokas, F. Hameed* and S.C. Zhang*. Dept. of Pharmacology, Univ. of Medicine & Dentistry of New Jersey-N.J. Medical School, Newark, N.J. 07103.

Molecular cloning data show the existence of five mus-

carinic acetylcholine receptor (mAChR) subtypes previously studied only by data from selective antagonists in binding and functional assays. A senescent rat model was used to study age-related changes in CNS mAChR subtypes. Assays of study age-related changes in CNS mAChR subtypes. Assays of [³H](-)quinuclidinylbenzilate, a highly specific nonsubtype selective antagonist, [³H](+)cis-methyldioxolane, which labels the highest affinity agonist state, [³H]pirenzepine, a specific M1 antagonist, [³H]AF-DX 116, a somewhat M2 specific antagonist, and [³H]hemicholinium-3 an inhibitor of sodium-dependent high affinity choline uptake were done as described. Quantitative receptor localization and in situ hybridization histochemistry (ISSH) was done with oligonucleotide probe complementary to 4-48/4-51 base sequence of m1-m5 mAChR mRNA by 3'-end labeling via ³⁵S-dATP (specific activity>2.4×10⁹dpm/ug) by terminal deoxynucleotidyltransferase. Slices were hybridized (25°C; 24h), washed (Tm=55°C;2xSSC), dried, film-apposed (4wk;0-4°C) and quantified. No affinity (Kd) differences were noted. Despite low densities (<80%C) in many areas in 24m vs 3m old rats, many areas had no mRNA changes. Notably, cortex, with a huge loss in mAChRs had higher m3 mRNA levels. One may speculate this implies attempted up-regulation and is linked to lower cognition often seen in aging. MH-43024.

SECOND MESSENGERS II

228.1

MODULATION OF PHOSPHOLIPASE D ACTIVITY BY CLONED MUSCARINIC ACETYLCHOLINE RECEPTOR SUBTYPES.

MODULATION OF PHOSPHOLIPASE D ACTIVITY BY CLONED MUSCARINIC ACETYLCHOLINE RECEPTOR SUBTYPES.

J. Sandmann, B.E. Slack, E.G. Peralta and R.J. Wurtman, Department of Brain & Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139, and Department of Biochemistry and Molecular Biology, Harvard University, Cambridge, MA 02138(E.G.P.).

Human embryonic kidney cells (HEK), stably transfected with expression vectors for either the human muscarinic acetylcholine receptor (mAChR) subtypes Hm2 or Hm3 (Peralta et al., Nature 33: 434-437, 1988), were used to assess changes in the activities of phospholipiase D (PLD) and of phospholipiosis were labeled by incubating transfected HEK-cells for 24 h in the presence of [f] H]inositol and f] H]oleic acid (2.5 uCi and 5 uCi per culture dish, respectively). For assaying PLD we used the transphosphatidylation property of this enzyme which, in the presence of ethanol, results in the production of phosphatidylethanol (PETH; e.g. Kobayashi, Kanfer, J. Neurochem. 48:1597-1603, 1897). When incubated in the presence of lithium chloride (10 mM) and ethanol (400 mM) for 10 min, the muscarnic agonist carbachol (1 mM) elevated [f] H]PETH levels by 14770+2015 cpm/mg protein (mean+SD from one representive experiment) in Hm3-expressing HEK-cells. In the same cells, the accumulation of [f] H]inositol phosphates was increased 9-fold (from 3180+280 to 27460+2440 cpm/mg protein) by carbachol. In Hm2-expressing cells, [f] H]PETH levels were elevated by \$850+1450 cpm/mg protein and [f] H]Ps levels increased 4-fold after a 10 min incubation with carbachol. The results show that the Hm3 mAChR subtype strongly activates PLD and PI-PLC whereas the that the Hm3 mAChR subtype strongly activates PLD and PI-PLC whereas the Hm2 subtype stimulates the activities of either phospholipase much less effectively.

(Supported by NIMH grant MH-28783 and by a postdoctoral fellowship of the Deutsche Forschungsgemeinschaft to J.S.)

PRESENCE OF THE ANF-RECEPTOR COUPLED GUANYLATE CYCLASE IN CNS SYNAPSES. N. G. F. Cooper, A. A. Fedinec, and 1R, K. Sharma. Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, TN 38163 and ¹Dept. of Brain and Vascular Research, Cleveland Clinic Foundation Res. Institute, Cleveland, OH 44195.

The ANF-receptor coupled guanylate cyclase is a particulate guanylate cyclase which contains a receptor for atrial natriuretic factor (ANF). The peptide, ANF, is reportedly present in the synaptic layers of the retina. ANF and the cyclic nucleotide, cGMP, have both been implicated in synaptic transmission in various regions of the been implicated in synaptic transmission in various regions of the nervous system. The objective of the present study was to determine if the antibody to particulate guanylate cyclase binds to synapses. Rats and chicks were overdosed with anesthetic, and perfusion fixed with 0.1% glutaraldehyde and 4% p-formaldehyde in buffered saline. Vibratome sections of retina and cerebellum were incubated with rabbit primary antibodies for 12 hrs, and then incubated in peroxidase conjugated secondary antibodies for 12 hrs. After peroxidase cytochemistry, sections were processed for electron microscopy, and thin sections were examined for presence of reaction product. Electron micrographs demonstrate the presence of the antigen in retinal micrographs demonstrate the presence of the antigen in terminal synaptic terminals, in association with synaptic vesicles and synaptic terminal plasma membranes. In the molecular layer of the cerebellum, the antigen is present in postsynaptic densities and dendrites. The presence of antigen in these two different loci, strongly support a role for particulate guanylate cyclase in events associated with synaptic transmission, but the mechanism of its activation requires further study. Supported by NIH:NEI-EY2708 (N.G.F.C.), NIH:NS-23744, and NSF:DCB-8800953 (R.K.S.).

EFFECTS OF (n-3) FATTY ACID DEFICIENCY ON CALCIUM STIMULATION OF 1,2 DAG AND PA FORMATION IN RAT SYMAPTICOMES.

G. Augert* and K. Ornstein. Nestlé Research Center, Nestec Ltd., Vers-chez-les-Blanc, CH-1000 Lausanne 26, Switzerland.

We have studied the effect of dietary deprivation of (n-3) fatty acids on the generation of 1,2 DAG and PA in response to Cartionophore A23187 in rat cortical synaptosomes. Experiments were conducted in 9-month-old rats raised on semi purified diets containing either safflower oil [(n-3) deficient diet] or soybean oil (control diet). The levels of docosahexaenoic acid [22:6 (n-3)] in synaptosomal phospholipids and PA were significantly decreased in (n-3) deficient rats (25 to 35 % of control levels). This was compensated by a rise in 22:5 (n-6), the total content of polyunsaturated fatty acids remaining approximatively constant. Levels of phospholipids, PA and 1,2 DAG, were not affected by dietary treatment. Addition of the calcium ionophore A23187 (20 µM for 10') caused a two fold increase in the amounts of PA and 1,2 DAG. 1,2 DAG and PA generated in this condition have a different fatty acid compositions, suggesting that increase in the amounts of the cattern of the condition have a different fatty acid compositions, suggesting that increase in different fatty acid compositions, suggesting that increase in intracellular Ca** stimulates both phospholipases C and D pathways. Long term administration of (n-3) fatty acid deficient diet to rats results in a decreased production of 1,2 DMG in response to Ca** ionophore, without modification of PA formation. These results indicate that (n-3) fatty acid deficiency can modulate the activation of phospholipase C pathway in response to Ca⁺⁺ in rat synaptosomes independently of modification of PA formation.

EFFECTS OF 8R AND 8S ISOMERS OF HEPOXILIN A3 (HxA₃) AND A GLUTATHIONE CONJUGATE (HxA₃-C) AT NANOMOLAR CONCENTRATIONS ON MEMBRANE PROPERTIES OF RAT HIPPOCAMPAL CA1 NEURONS.

N. Gurevich¹, P.H. Wu*², C.R. Pace-Asciak*^{2,3}, E.J. Corey*⁴, W-G Su*⁴, P.L. Carlen¹. Playfair Neuroscience Unit, Toronto Western Hospital and Addiction Research Foundation¹; Dept. of Pharmacology, University of Toronto², Research Institute, Hospital for Sick Children³, Canada; and Dept. of Chemistry⁴

Hospital for Sick Children³, Canada; and Dept. of Chemistry⁴ Harvard University, Cambridge, MA, USA.

The hepoxilins (Hx) are hydroxy epoxide derivatives of arachidonic acid formed via the 12-lipoxygenase pathway. HxA₃ is metabolized in vitro by the rat hippocampus into a glutathione conjugate (HxA₃-C). We have previously shown that HxA₃ and HxA₃-C display neuromodulatory effects on rat hippocampal CA1 neurons in vitro. We now report that both isomers (8R and 8S) of HxA₃ and HxA₃-C at less than 30 nM concentrations were able to hyperpolarize the resting membrane potential (RMP), increase the amplitude and duration of the post-spike train afterhyperpolarization (AHP), increase the inhibitory postsynaptic potential (IPSP) and decrease the spike threshold with a threshold concentration of 3 nM. These findings suggest that products in the hepoxilin pathway are biologically active and may represent new lipid modulators of are biologically active and may represent new lipid modulators of neuronal excitability.

NADPH-DIAPHORASE SYNTHESIZES A SECOND MESSENGER; YES OR NO. B.T. Hope, G. Michaels K.M. Knigge S. Sr. Vincent. Kinsmen Lab. of Neurol. Res., Dept. of Psychiat., Univ. of British Columbia, Vancouver, Canada V6T 1W5, & Neuroendocrine Unit,

Univ. of Rochester, Rochester, NY 14642.

The NADPH-diaphorase reaction is used for histochemical studies, however, the function of this enzyme has been completely unknown. The reaction is based on the NADPH-dependent reduction of nitro blue tetrazolium (NBT) to a visible formazan product. have used a similar method to monitor this activity during purification of this enzyme from whole rat brain using ion exchange followed by affinity chromatography with 2',5'-ADP-agarose. A similar procedure has recently been used to purify the NADPH-dependent enzyme, NO synthetase from rat cerebellum (Bredt & Snyder, '90). This enzyme produces nitric oxide (NO) and citrulline from arginine. NO synthetase activity was monitored by measuring the production of [3H]-citrulline from [3H]-arginine, and was found to copurify with NADPH-diaphorase activity. NO synthetase was inhibited by micromolar concentrations of NBT, the electron accepting substrate of the NADPH-diaphorase reaction. The NO synthetase inhibitor NGmonomethylarginine did not inhibit NADPH-diaphorase activity.

Immunochemical studies were performed with an antibody (HAN) which recognizes NADPH-diaphorase (Michaels & Knigge, (HAIN) which recognizes NADPH-diaphorase (Michaels & Knigge, 189). In Western blots of fractions following affinity chromatography, a single 150 kD band was labelled. This is the same size as NO synthetase. Thus NADPH-diaphorase activity is associated with NO synthetase. This histochemical reaction may therefore identify neurons in which the production of NO is associated with the stimulation of soluble guanvivi cyclase.

PURIFICATION AND CHARACTERIZATION OF BOVINE BRAIN CYTOSOL PHOSPHOLIPASE A2 Y. Hirashima*, J. Mills*, A.A. Farooqui* and L.A. Horrocks. The Ohio State University, Department of Physiological Chemistry, Columbus, OH 43210
With the exception of a microsomal enzyme acting on phosphatidylinositol (Gray and Strickland, Lipids 17:91-96, 1982), the purification of phospholipase A2 from the CNS has not been reported yet. We developed a new assay method for plasmalogen-specific phospholipase A2 using pyrene-labeled plasmenylethanolamine as the substrate (BBA, in press). Using this assay method, we purified bovine brain cytosol phospholipase A2. After ammonium sulfate fractionation (40% saturation), gel filtration on AcA54 gave two active peaks. Peak I was eluted in the void volume and Peak II eluted in the position of a 34 kDa protein. Both peaks were purified eluted in the void volume and Peak II eluted in the position of a 34 kDa protein. Both peaks were purified further with affinity chromatography (PlsEtn-Affige 10) and HPLC (MA 7Q). Final purifications for Peaks I and II were 1500 and 1000 fold respectively. With AcA34 gel filtration, Peak I was approximately 110 kDa. Both peaks were nearly pure with SDS-PAGE. The optimal pH for Peaks I and II were 8.0 and 7.4 respectively. Interestingly, both are Ca²⁺ independent. The optimal concentrations of Triton X-100 were 0.05% and 0.1% for Peaks I and II respectively. Peak I is specific to diacylGropEtn(Pyr) and Peak II is active with both diacylGropEtn(Pyr) and Peak II is active with both diacylGropEtn(Pyr) and PlsEtn(Pyr). The Km value of Peak I is 29 µM (diacylGropEtn). The Km values for Peak II are 70 µM (diacylGropEtn) and 40 µM (PlsEtn(Pyr)).

228.6

FATTY ACIDS ENHANCE SYNAPTIC EFFICACY IN GUINEA PIG

HIPPOCAMPAL SLICES. T. C. Pellmar, Physiology Dept., AFRRI, Bethesda, MD 20814.

Release of fatty acids may accompany generation of free radicals in a number of pathological states. The present experiments were initiated to evaluate the role of fatty acids in free radical damage.

Input-output curves were generated by stimulation (0-0.5 mA, 300 µs) of s. radiatum in field CA1. Resultant population spikes (PS) and population synaptic potentials (pPSP) were recorded in s. pyramidale and s. radiatum. Slices were exposed to fatty acids for 30 min and subsequently washed with normal aCSF for at least 30 min.

sequently washed with normal aCSF for at least 30 min.
Capric acid (CA, 250 µM), oleic acid (OA, 100 µM) and
arachidonic acid (AA, 50 µM) all had qualitatively
similar effects. At these doses, the fatty acids had
minimal effects on the pPSP when first applied: The pPSP
was slightly decreased by AA, slightly increased by OA
and unchanged by CA. Upon washout of fatty acids, pPSPs
were consistently potentiated and remained so for the
duration of the experiment (30-60 min). In addition,
large pPSPs were more effective in generating PSs but
small pPSPs were less effective. Higher doses of CA (500
µM) produced a larger inhibition of the pPSP during initial application but subsequent potentiation with washout tial application but subsequent potentiation with washout was not as strong as with the lower dose. These data suggest that fatty acids modulate neuronal excitability through complex mechanisms.

AGE-RELATED DEFICITS IN MUSCARINIC AGONIST RESPONSIVE-NESS MAY OCCUR AT THE LEVEL OF THE RECEPTOR-G-PROTEIN COMPLEX IN SIGNAL TRANSDUCTION. J.A. Joseph, M. Anson, R. Cutler, K. Yamagami, and G.S. Roth. Gerontology Research Center/NIA, Baltimore, MD 21224.

Cholinergic (ACh) agents used to improve memory in the aged show reduced efficacy that may be the result of defects in the signal transduction process (STP). Using muscarinic (m) (e.g., carbachol) enhancement of K*-evoked endogenous dopamine release (K* ERDA) from perifused striatal tissue, we previously observed defects in K*-ERDA in the aged Wistar rat. However, no age-related deficits in K*-ERDA were seen if A23187 or IP, were applied to the tissue, suggesting that the decrements following mAChR stimulation may appear early in STP, (e.g., at the level of mAChR-G-protein interface). To investigate this, NaF (5, 10 mM), which has recently been shown to initiate STP through the G-proteins, was used to enhance K+-ERDA. No age differences were seen (e.g., 5 mM NaF, 6 mo, 146.15+16.66, 24 mo, 166.70+ 13.67 p moles DA/mg protein), indicating that the age-decrements in STP may occur at the level of the mAChR-G-protein interface. A subsequent experiment using carbachol displacement of [*H]-QNB in the presence or absence of 1 mM GppNHp (the hydrolysis-resistant analog of GTP) indicated that GppNHP was effective in uncoupling (conversion of hi to lo affinity) mAChR sites from their respective G-proteins in the striata and hippocampi from 6 mo but not 24 mo animals. Thus, loss of efficacy of m agonists may be the result of deficits in mAChR-Gprotein uncoupling upon agonist stimulation.

THE ROLE OF G PROTEINS IN MEDIATING THE SUPERSENSITIVITY OF BIOGENIC AMINES H.Y. Wang, P. Butkerait and E. Friedman, Dept of Psychiatry and Pharmacology, Med. Coll. of Pennsylvania, Philadelphia, PA, 19129

Denervation supersensitivity of biogenic amine systems has been repeatedly reported, but the mechanisms have not yet been fully explored. Since G proteins serve an important function in signal transduction, alteration in G protein activation following changes in neuronal inputs were examined. Activation of surface receptors by selective agonists or neurotransmitters lead to elevation in the Mg²*-dependent GTP binding to specific G proteins. The specific [85]GTPdependent GTP binding to specific G proteins. The specific [15]GTPS

S-bound G proteins were immunoprecipitated by antisera against specific Go subunits. The results indicate that in cortex (C), (1) 5-HT increases [36S]GTP S binding to G, and G, (2) isoproterenol activates G, exclusively, (3) carbachol elevates [36S]GTP-S labeling of G, and G, and (4) in striatum (S), dopaminergic system was found to be linked to G, and G_I. Following 7-days of repeated reserpine administration, [³⁵S]GTPS binding to G proteins induced by isoproterenol(C), 5-HT (C) and dopamine (S) were markedly increased. No changes in carbachol responses in C and S were observed. Single injection of reserpine induced no changes in agonist-evoked [38S]GTP7S bindings. These results suggest an important role for membrane G proteins in mediating neuronal plasticity.

KINETICS OF G PROTEIN-MEDIATED MODULATION OF M CURRENT. H.S. Lopez, Howard Hughes Medical Institute. Dept. Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794.

Lopez. Howard Hughes Medical Institute. Dept. Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794.

The G-protein mediated modulation of the voltage-dependent potassium M current (I_m) was quantitatively examined in whole-cell voltage-clamped B neurons (40-60 μm) of bullfrog ganglia. I_m were recorded by applying 1 s, 20-30 mV hyperpolarizing pulses from a -30 mV holding potential while the cells were internally perfused by exchanging the content of the pipette tip (0.2-1.5 MΩ), via a fine PE tubing (exchanging [Na], to 100 mM progressed exponentially with τ=13-40 s (n=5), and could be reversed.) Perfusion with control solution alone (in mM); 100 KCl, 4 MgCl₂, 1 K₂EGTA, 5 Na₂ATP, 2.5 (Na)Hepes (pH 7.2), or with added GTP (500 μM) had no effect on I_m or on its inhibition by muscarine, while GTPγS/GTP in the perfusate (ratios [analog];[GTP] 0.5, 1, 2, 5, 10, 20) caused a receptor-independent, usually complete, inhibition of Im, with time courses well fitted by single exponentials, and rates dependent on the ratio GTPγS/GTP (limiting rate = 0.51 min¹ ±0.05 SD, n=5, ratio 20). The Hill equation fitted well the data (Vmax=0.52 min¹, K_{as}=0.75, n=1.02). No recovery of Im occurred over up to 1:40 h following repeated perfusion with control solution or application of muscarine. GppNHp and GppCH₂p inhibited I_m less potently than GTPγS (GTPγS>GppNHp>GppCH₂p) but with a similar limiting rate (about 0.5 min¹, similar to the rate of GDP dissociation from G proteins). No shifts in the I_m I-V curves was seen in the range -100.0 mV. Fast application of muscarine at subeffective concentrations (10-100 nM) accelerated the rates of GTPγS:GTP(=20)-induced Im inhibition, with time courses also well fit by single exponentials, and an hyperbolic dependence on concentration with midpoint 0.43 μM, and plateau at about 20 min¹ (1 μM muscarine). I_m recovered with a rate 3.5-7 min¹ upon fast washout of muscarine (1 μM) with 1-10 μM atropine (normal solution in the pipette). These data suggest that the kine

228.13

COUPLING PATHWAY OF THE CLONED α_1 ADRENERGIC RECEPTOR IN XENOPUS OOCYTES. G.Omri,S.Cotecchia, M.G.Caron,R.J.Lefkowitz, R.Iyengar* and E.M.Landau. Departments of Psychiatry and Pharmacology Mount Sinai School of Medicine and the Bronx VAMC N.Y. and Howard Hughes Institute, Duke Univ.Med.Ctr.,Durham,N.C.

The cloned α_1 adrenergic receptor was expressed in occytes of Xenopus laevis. Superfusion with norepinephrine resulted in a calcium mediated chloride current which was due to phospholipase C activation by the activated receptor. The Kact was 50 nM and the response was completely inhibited by 10.8 M prazosin. The response was insensitive to overnight treatment with pertussis toxin (PTX) the average response after PTX being 91±8% (n=5). This contrasts with the marked sensitivity of the native muscarinic response to

PTX (Moriarty et al., Proc.Nat.Acad. Sci.U.S.A., 85,8865;1988). These results indicate that the occyte contains two different G protein pathways to couple receptors to the phosphoinositide pathway. Supported by a merit VA grant to E.M.L.

A NOVEL Gs IN THE RAT STRIATUM. S.L. Drinnan, B.T.Hope, S.R.Vincent, Kinsmen Lab. of Neurol. Research, Dept. of Psychiatry, Univ. of British Columbia, Vancouver, B.C., Canada, V6T IWS. Activation of the dopamine D1 receptor stimulates adenylyl cyclase presumably by coupling with a heterotrimeric GTP-binding protein, Gs. We have used a synthetic oligonucleotide probe to detect the portion of the Gsα mRNA coding for the cholera toxin ADP-ribosylation site. Northern blot analysis of whole rat brain with this probe identified a single band of about 1900 bases. Compared to other rat brain G-protein mRNAs (ie: Gi-2, Go), Gsα was the most abundant. This probe was also used for in situ hybridization of rat brain sections. Highest levels of Gsα mRNA were observed in the cortex, hippocampus and cerebellum. Of particular interest was the extremely low signal in the striatum and other areas such as nucleus accumbens and olfactory tubercle which receive a heavy dopaminergic innervation from the midbrain.

Although there appears to be very little Gsα mRNA in the striatum, substantial amounts of a Gsα-like protein are present. Cholera toxin activates Gsα by ADP-ribosylation. In the presence of ³²P NAD, cholera toxin ribosylates a major band of 45 and a minor band of 52 kD in striatal membranes. This is opposite to the pattern observed in cortex and cerebellum where the 52 kD band was more strongly labelled. An antibody against the C-terminal decapeptide of Gsα was used for western blotting and immunohistochemistry. Immunoperoxidase staining resulted in heavy labelling in the striatum, nucleus accumbens, olfactory tubercle and substantia nigra pars reticulate. Western blot analysis of striatal homogenates revealed the expected bands of 45 and 52 kD and an additional major band at 46.6 kD. These results indicate that a form of Gsα arising from a distinct mRNA is present in regions receiving heavy dopaminergic input. This novel Gsα may couple the D1 receptor to adenylyl cyclase. cvclase.

DIFFERENTIAL REGULATION OF G-PROTEINS IN THE RAT BRAIN BY CHRONIC ETHANOL ADMINISTRATION: T.Akompong,R.L.Spencer and B.S.McEwen. Lab. of Neuroendocrinology, Rockefeller Univ. New York, New York 10021.

Ethanol is thought to produce most of its toxic effects by directly fluidizing membranes. Some of the physiological effects of chronic alcohol may be produced by modulating specific signal transduction systems, such as the adenylate cyclase system. Whereas chronic ethanol affects the production of cAMP both in vivo and in vitro it is not known which component(s) in the adenylate cyclase cascade is modified. In this study chronic ethanol(2.5g/Kg,BW 15% v/v in 0.9% NaCl) was administered i.p two times a day for 6 days to ovariectomized female rats. The $G_{\rm S}$ and $G_{\rm i}(1\&2)$ content in 5 brain regions were determined by western blot with polyclonal antibodies raised against the carboxyl terminal of $G_{\rm S}$ and $G_{\rm i}(1\&2)$ (donated by Drs A. Spiegel & C. Unson). The amounts of $G_{\rm S}$ and $G_{i}(1\&2)$ in the caudate were significantly reduced in the alcohol treated rats compared to the saline treated controls. The amounts of $G_{\rm S}$ and $G_{\rm I}(1\&2)$ did not change in the cortex, cerebellum, hippocampus and hypothalamus. These results suggest a differential modulation of G_S and G_1 in different regions of the rat brain. In areas like the cortex and the hippocampus where chronic alcohol has been shown to cause changes in cAMP, other components of the adenylate cyclase system, rather than the G-proteins, may be targets for ethanol modifications.

PEPTIDES DERIVED FROM G-PROTEIN SEQUENCES AFFECT

PEPTIDES DERIVED FROM G-PROTEIN SEQUENCES AFFECT TRANSMITTER-GATED CURRENTS IN RAT HIPPOCAMPAL NEURONS AND XENOPUS OOCYTES. O. Gil, G. Omri, R.D. Blitzer, A. Buku*, R. Iyengar*, M.G. Caron, S. Cotecchia*, R.J. Lefkowitz* and E.M. Landau. Psychiatry Svce., Bronx VAMC, Bronx NY 10468

G-proteins mediate numerous transmitter-gated responses in excitable cells. A promising strategy for the study of G-protein coupling is the intracellular application of peptides with sequences specific to various G-proteins, which might mimic, block, or enhance the effect of the transmitter. We have employed this technique in CA1 pyramidal cells (using the 5HT-activated K' current) and Xenopus oocytes (using the expressed a, adrenergic-activated Cl current). Decapeptides were synthesized using the COOH terminus sequence of Go, Gi, Ge, and Ge (referred to as Po, etc.). In both preparations, Po increased the current induced by the transmitter and Pe reduced the current, while Pe and Pe had little effect. In no case did the peptide itself evoke the currents under study. The enhancing effect of Pe may reflect a cooperative interaction of Pe/Go with the receptor, so that Pe, although devoid of intrinsic signalling activity, improves the coupling of Ge with the receptor. Supported by NIA Grant AGO2219 and the VA Merit Program.

A NEUROTOXIC PEPTIDE FROM CONE SNAIL BLOCKS NMDA-INDUCED CURRENTS IN XENOPUS OOCYTES INJECTED WITH mRNA FROM CHICK BRAIN. L.G. Hammerland, B.M. Olivera, and D. Yoshikami, Dept. of Biology, University of Utah, Salt Lake, City UT 84112.

Marine snails of the genus *Conus* have venoms with neurotoxins targeted at a variety of ion channels. Recently a family of conus peptides, called conantokins, has been identified as glutamate antagonists (Haack et al. (1990) J. Biol. Chem. 265, 6025-6029). We report here the effect of these toxins on glutamate receptors expressed in Xenopus oocytes injected with mRNA from chick

Brain.
Glutamate receptor agonists, NMDA, quisqualate, and kainate, were applied separately in boluses to a voltage-clamped oocyte in a antagonist (either AP5 or CNQX) or conantokin-G (a 17 amino acid peptide). The currents induced by NMDA were specifically blocked by 10 μ M AP5, whereas those induced by kainate and quisqualate were specifically blocked by 10 µM CNQX. Conantokin-G, at concentrations near 1 µM, blocked 50% of the NMDA-induced current. In contrast, quisqualate- or kainate-induced currents were unaffected by the toxin, even at concentrations of $10~\mu M$. These results provide a direct demonstration that the toxin is a selective antagonist of the NMDA receptor.

NMDA RECEPTORS AND THE DOPAMINERGIC NEUROTOXIC ACTION OF METHAMPHETAMINE. W. D. Sullivan, A. L. Martello, G. Hatzidimitriou and G. A. Ricaurte. Dept. of Neurology, Johns Hopkins School of Medicine, Baltimore, MD 21224.

N-methyl-D-aspartate (NMDA) receptor antagonists block the dopamine-depleting effects of methamphetamine in the rat striatum (Sonsalla et al., Science 243: 398, 1989). This interesting observation has implicated excitatory amino acids (EAAs) in the dopaminergic neurotoxic action of methamphetamine. The goal of this study was to further evaluate the role of EAAs and NMDA receptor stimulation in the long-term dopamine-depleting effects of methamphetamine. Two experiments were performed. In the first, the influence of cortical ablation on methamphetamine-induced dopamine depletion was investigated, since a major source of EAA input to the striatum comes from the cerebral cortex. In a second experiment, the effect of direct investigated, since a major source of EAA input to the striatum comes from the cerebral cortex. In a second experiment, the effect of direct intrastriatal administration of NMDA on nigrostriatal dopaminergic nerve terminals was evaluated. Both experiments were performed in male albino Sprague-Dawley rats weighing approximately 200 grams at the time of the experiment. Unilateral cortical ablation performed two weeks prior to methamphetamine administration did not alter the dopamine-depleting effects of methamphetamine in the ipsilateral striatum, even though it markedly reduced the in vitro striatal uptake of 3H-glutamate. Direct administration of NMDA (100, 200 or 400 ug in 10 ul vehicle) into the striatum did not cause a lasting depletion of striatal dopamine. By contrast, comparable doses of intraventricular 6-hydroxydopamine (6-OHDA) caused profound reductions of striatal dopamine. These findings suggest that while EAAs and NMDA receptor activation may be involved in the dopaminergic neurotoxic action of methamphetamine, the nature of this involvement is complex and will methamphetamine, the nature of this involvement is complex and will require further elucidation

REGULATION OF TRANSCRIPTION FACTOR PROTEINS BY SYNAPTIC NMDA RECEPTOR ACTIVATION IN CULTURED CORTICAL NEURONS. <u>T.H.</u>
<u>Murphy, Y. Nakabeppu*, P.F. Worley and J.M. Baraban</u>. Depts.
of Neuroscience and Molecular Biology and Genetics, Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

Synaptic activation of transcription factor genes may elicit long-term effects of neuronal stimulation. We have examined the regulation of Jun-B and c-Jun, components of the AP-1 transcription factor complex, in primary cortical cultures immunohistochemically with affinity purified antisera. For the first two weeks in culture (prepared on E17), less than 10% of neurons display immunostaining with these antisera, however, after 3 weeks approximately 30% of neurons are stained by each of these antisera. To determine whether these basal levels are induced by ongoing synaptic stimulation, we examined the effect of tetrodotoxin, and the NMDA receptor antagonists APV or MK-801. After 6 h exposure to these agents, the number of Jun-B immunoreactive neurons fell by over 60%, while c-Jun staining was unaffected. In contrast, cycloheximide reduces both c-Jun and Jun-B immunostaining to a similar extent. Blockade of inhibitory activity with picrotoxin doubles the number of Jun-B positive neurons. This rise is also blocked by tetrodotoxin or MK-801. Whole cell recordings from neurons maintained in vitro for 3 weeks, demonstrate large, 300 pA, spontaneous synaptic currents that are suppressed by APV. Accordingly, these NMDA receptor mediated synaptic currents may induce expression of Jun-B.

CONANTOKINS AND GLUTAMATE RECEPTOR SUBTYPES. J.A. Haack, G.J. Rose, T.N. Parks+, B. Olivera, Dept. of Biology, Univ. of Utah and +Natural

Product Sciences, Salt Lake City, Utah.

The conantokins are peptides from the venoms of fish-hunting Conus snails which The containing are peptides from the venoms of rish-nuturing <u>Contains</u> shalls which elicit age-dependent behaviors upon intracerebral injection into mice (Haack et. al.,1990, JBC. 256:6025-6029, L.Cruz this meeting). Earlier experimental evidence indicated that these peptides were antagonists for a subset of glutamate receptors; with specificity for the NMDA receptor subtype. We have examined the effects of these peptides on glutamate receptor activity using three separate phylogenetic systems-electric fish, xenopus oocytes (L. Hammerland, this meeting), and

systemistic events a list, kenopus occytes (c. naminerand, uns meeting), and mammalian central nervous system neurons.

The specificity of conantokins for particular glutamate receptor subtypes was tested using the weakly electric fish, <u>Eigenmannia</u>. In their social communication, these fish produce gradual or abrupt modulations of the frequency of their electric organ discharges (EODs). These two types of communication signals can be independently elicited by iontophoresis of L-glutamate (1.0 M, 50-100 nA negative current) within

elicited by iontophoresis of L-glutamate (1.0 M, 50-100 nA negative current) within particular subregions of a pretectal region known as the prepacemaker nucleus. Iontophoresis of the conantokins into this region strongly attenuated the glutamate-induced gradual modulations of the EOD frequency, but failed to attenuate the abrupt form of modulations evoked by glutamate. The effects of the conantokins on NMDA receptor-mediated influx of calcium in dissociated rat central nervous system neurons, were monitored by fura-2 fluorescence. The conantokins produce a dose-dependent antagonism of NMDA induced increases in cytosolic free calcium concentration in both cultured cerebellar granule and cortical cells, with half maximal inhibition occurring in the low micromolar range. Thus, experimental evidence from several systems indicate that the conantokins are the first pentides targeted to specific subclasses of glutamate the conantokins are the first peptides targeted to specific subclasses of glutamate

REGULATION OF 3H-NOREPINEPHRINE RELEASE BY N-METHYL-D-AS-PARTATE IN SLICES FROM DENTATE GYRUS AND CA1-CA3 AREA OF THE RAT HIPPOCAMPUS. K. Gysling, M.E. Andrés* and G. Bustos. Lab. of Biochemical Pharmacology, Faculty or Biological Sciences, Catholic University of Chile, Chile.

The hippocampus presents the highest density of N-methyl-D-aspartate (NMDA) type receptors for excitatory ami-

no acids in the CNS. The purpose of this study was to investigate possible functional relations of NMDA-mediated excitatory amino acid neuronal systems and norepinephrine

(NE) nerve terminals in two hippocampal regions: the dentate gyrus (DG) and CAI-CA3 area.

Minislices from DG and CAI-CA3 area were superfused to study the effects of ligands of the NMDA-type receptors upon the release of recently taken up 3H-NE. NMDA (10-50 uM) induced a calcium dependent release of 3H-NE from DG and CA1-CA3 slices in the absence of Mg+2. The effect DG and CA1-CA3 slices in the absence of Mg+2. The effect was significantly higher in the DG than in the CA1-CA3 area and significantly inhibited by the selective NMDA type receptor antagonist, amino-phosphonovaleric acid (APV). In addition, the effect of NMDA was suppressed by 60% in the presence of tetrodotoxin. Finally, NMDA potentiated the release of 3H-NE evoked by 25 mM K+ in the DG but not in the CA1-CA3 area.

The results suggest that the excitatory amino acids differentially regulate NE release from DG and CA1-CA3 area of the hippocampus.

area of the hippocampus. Supported by grants # 820/90 and 744/90 FONDECYT, Chile.

POLYAMINE BINDING SITES ON SYNAPTOSOMAL MEMBRANES C.R. Mantione, S. Demirgören, and E. D. London. Neuropharmacology

C.R. Mantione, S. Demirgören, and E. D. London, Neuropharmacology Laboratory, NIDA Addiction Research Ctr., Baltimore, MD. 21224. The polyamines, putrescine, spermidine, and spermine, are intracellular diamines, triamines, and tetramines, respectfully. Spermine stimulates the binding of [3H]MK-801 to the cationic channel of the N-methyl-D-aspartate (NMDA) receptor in neuronal tissue (Ransom, R.W. and Stec, N.L., J. Neurochem., 51:850, 1988). This finding suggests the presence of polyamine recognition sites in brain membranes. We have described the binding of [3H]spermidine to rat whole brain membranes (Mantione, C.R. et al., Eur., J. Pharmacol., in press, 1990). Binding is maximal at pH 8, is destroyed by freeze/thawing, and occurs at 25°C but not at 8, is destroyed by freeze/thawing, and occurs at 25°C but not at 4°C. It has the following parameters: Kd = 564 \pm 97.7 μ M, Bmax = 63.4 \pm 5.89 nmoles/mg protein (mean \pm S.E.). The rank order of potency for polyamines to inhibit [3H]spermidine binding is as follows: spermine > spermidine > putrescine. The only other compounds with significant activity observed at this site are poly-L-arginine (IC50 = 7.7 μ M) and poly-L-lysine (IC50 = 207 μ M). Basic amino acids are inactive. Cations such as Na+ (100 mM), basic animo actos are inactive. Cations such as Na* (100 Imit), Li+ (50 mM), and Ca++ (2 mM) produce as much as 66-70% inhibition of binding. We now report that synaptosomal preparation of the tissue results in a 200-fold increase in the binding affinity for $[^3H]$ spermidine ($Kd=2.7~\mu\text{M}$) and a 100-fold lower Bmax (593 pmoles/mg protein). The characterization of a synaptosomal membrane binding site for $[^3H]$ spermidine is an important step in elucidating the molecular role of polyamines in the nervous system.

IN VIVO LABBILING OF SIGNA SCHES IN THE MOUSE BRAIN WITH ³H-IFFNFRODIL.

J. Benavides, B. Peny*, H. Schoemaker* and B. Scatton. Synthélabo Recherche (L.E.R.S.), 31, av. Paul Vaillant-Couturier, 92200 Bagneux (France).

The arti-ischaemic drugs ifenprodil and SL 82.0715 interact in vitro with two different binding sites : a polyamine sensitive site associated with the MDA receptor complex (Carter et al, Europ. J. Pharmacol. 164, 611, 1989) and the sigma site (Schoemaker et al, Eritish Pharmacol. J., in press). We here demonstrate that, in vivo, 'H-ifenprodil selegtively labels sigma sites in the mouse brain. I.v. injection of 5 μ Ci 'H-ifenprodil resulted in an accumulation of brain radioactivity which was maximal at 5 min post-injection and decreased in a biphasic fashion, Under standard experimental conditions (radioactivity measured 2 h after 'H-ifenprodil administration) more than 65 % of the incorporated label was displaced by ip administration (30 min before the radiotracer) of SL 82.0715 (10 mg/kg). At this time, most of the radioactivity (80 %) present in the brain corresponded to authentic 'H-ifenprodil. When administered 30 min before the radiotracer, several ligands with affinity for sigma sites inhibited 'H-ifenprodil accumulation (ID_'s mg/kg ip): haloperidol (0.23) > ifenprodil (0.83) > SL 82.0715 (1.37) EMY 14802 (5.5) > DIG (18). (4)-3-PPP, phency-clidine, TCP and MK-801 were inactive at 10 mg/kg ip. The potency of ifenprodil, SL 82.0715 and haloperidol as inhibitors of in vivo 'H-ifenprodil or 'H-(+)-3-PPP binding was similar. The present results demonstrate that 'H-ifenprodil is a suitable ligand for labelling mouse brain sigma sites in vivo.

EFFECTS OF POLYAMINES ON [3H]MK-801 BINDING IN DIFFERENT REGIONS OF THE RAT BRAIN. S. Subramaniam and P. McConigle. Department of Pharmacology, Univ. of Pennsylvania School of Medicine Philadelphia PA 19104

of Medicine, Philadelphia, PA 19104.

Polyamines have been shown to modulate the NMDA receptor channel complex through a distinct receptor site. Assays using brain membranes have suggested the possible existence of more than one polyamine receptor. We have studied the effects of a number of polyamines on [3H]MK-801 binding in anatomically discrete brain regions using quantitative autoradiography. The polyamine agonists spermidine and spermine enhanced [3H]MK-801 binding in all the regions studied. Pre-washing the sections in buffer at room temperature for 1 hr increased the magnitude of this effect. The antagonist diethylenetriamine significantly reduced binding in unwashed sections suggesting the presence of residual endogenous polyamines. This effect was attenuated but not eliminated after washing. The inverse agonist diaminodecane significantly inhibited [3H]MK-801 binding in washed sections. There was considerable regional heterogeneity in the magnitude of the effects of the polyamines. In washed sections of the striatum a maximally effective concentration of spermidine enhanced [3H]MK-801 binding to a greater extent in the medial as compared to the lateral striatum. There was an inverse correlation between the enhancement produced by spermidine and the inhibition produced by diethylenetriamine in all the regions studied suggesting that regional variations in polyamine effects might be due to differences in levels of endogenous polyamines. The effects of polyamines on [3H]MK-801 binding have been further characterized in synaptic plasma membranes made from different brain regions. (Supported by USPHS GM 34781 and the Pew Charitable Trusts)

229.11

MECHANISMS UNDERLYING THE INTERACTION OF POLYAMINES WITH THE NMDA RECEPTOR. I.J. Reynolds. Department of Pharmacology, University of Pittsburgh, Pittsburgh PA 15261.

The polyamines (PA) spermidine and spermine increase [¹H] MK801 binding at physiological concentrations (Ransom & Stec, J.Neurochem. 51:830, 1988) suggesting a possible role as endogenous modulators of the NMDA receptor. I have investigated the mechanisms by which PAs modify the NMDA receptor by monitoring [²H] MK801 binding and NMDA-induced [Ca²¹], changes in cultured forebrain neurons.

Spermidine-induced increases in [³H] MK801 binding were competitively

Spermidine-induced increases in [³H] MK801 binding were competitively reduced by arcaine (IC₂₀.1.5µM). Arcaine also reduced binding in the absence of added PAs which implies that agonist occupation of the PA site is obligatory for [³H] MK801 binding. Arcaine blocked Sr²·-, Ca²·- and Ba²·-induced increases in [³H] MK801 binding, suggesting that these cations act at the PA site. Spermidine increased the affinity of [³H] MK801 at equilibrium (2 4hr + 100µM Glu and 30µM Gly) in an arcaine-reversible fashion. However, PA-induced changes in ligand dissociation were arcaine insensitive. Thus, PAs apparently do not increase activation of the NMDA receptor but instead increase ligand affinity at the phencyclidine binding site. This is distinct from the mechanism of action of NMDA and glycine.

NMDA (30 μ M) and glycine (1 μ M) increase [Ca²¹], in individual forebrain neurons measured using fura-2 microspectrofluorimetry. Spermine and spermidine (0.5-500 μ M) and arcaine (0.3-30 μ M) had no effect on NMDA/Gly-induced [Ca²¹], changes. Arcaine (300 μ M) did not affect kainate or KCl-induced [Ca²¹], increases. Thus, although PAs may profoundly alter the function of the NMDA receptor monitored with [³H] MK801 binding, these drugs may not gain access to their site of action in intact cells.

NMDA-INDUCED CURRENTS IN HIPPOCAMPAL NEURONS CAN BE MODULATED BY THE POLYAMINE SPERMINE. V.L. Dawson', K. Williams', C. Romano', P.B. Molinoff', and M.A. Dichler's Dept. Neurology' and Pharmacology', University of Pennsylvania, Dept. Neurology', Graduate Hospital, Philadelphia, PA.

Philadelphia, PA.

NMDA receptor activity can be regulated by a number of endogenous modulators including Mg²⁺, Zn²⁺, H⁺, and glycine. Recently radioligand binding studies have suggested a role for polyamines as another endogenous modulator of the NMDA receptor. Electrophysiological studies were performed on cultured rat hippocampal neurons using whole cell patch-clamp to examine this possibility. The dose-response curve of the spermine effect on NMDA-induced currents was biphasic. Low concentrations of spermine enhanced NMDA currents with maximal enhancement of 84% occurring at 1 μM spermine. Higher concentrations of spermine inhibited NMDA currents with 70% inhibition observed at 100 μM spermine. Both effects of spermine were blocked by the specific polyamine antagonist, diethylenetriamine (DET). The voltage dependence of the spermine effect at both low and high concentrations was examined and neither the enhancement nor the inhibition of NMDA currents were voltage dependent. Additionally, in the presence of Mg²⁺ in the extracellular bath 1 μM spermine did not shift the voltage dependence, but did elicit enhancement at all membrane potentials that NMDA induced currents. Spermine did not alter currents induced by other amino acid neurotransmitters, quisqualate, kainate or GABA. In addition to exogenously applied NMDA, spermine modulated responses to endogenously released excitatory neurotransmitter in culture. The amplitude of spontaneous postsynaptic currents is increased by 20 μM spermine and decreased by 50 μM DET (DET in the absence of spermine has no effect on NMDA currents), suggesting that there may be an endogenous spermine "tone" in the cultured neurons. These data suggest that spermine may have a physiological role as a modulator of excitatory neurotransmisstion in the mammalian CNS.

WITHDRAWN

PURIFICATION OF CPP BINDING PROTEINS FROM IBOTENATE-TRISACRYL MATRICES AND CHARACTERIZATION OF PROTEIN INTERACTIONS WITH OTHER MATRICES. <u>K.T. Eggeman and</u> <u>E.K. Michaelis</u>, Department of Biochemistry, University of Kansas, Lawrence, Kansas 66045

We have previously isolated a fraction from rat synaptic membranes enriched in 58-60kDa proteins that specifically interact with CPP, a selective antagonist of the NMDA type of excitatory amino acid receptor. These proteins also interact strongly with 2-AP5, 2-AP7 and CNQX, suggesting that they may contain the antagonist binding site [Cunningham & Michaelis, J. Biol. Chem, in press]. The ioslation of these proteins was achieved through affinity chromotography on ibotenate-agarose columns. The agonist-binding proteins were retained on the column by specific and non-specific interactions with the agorose matrix and could be eluted with high salt. Recently we have shown that proteins with similar activities can be enriched by using an ethanolamine -blocked affigel column alone, suggesting that interactions of these proteins with hydroxyl residues of the matrix may play a significant role in these purifications. The same CPP binding proteins can be isolated together with other proteins that may form the NMDA receptor complex through chromotography on ibotenate-trisacryl matrices. This procedure is being pursued to obtain proteins for sequencing and production of polyclonal antibodies.

(Supported by grant AA04732 and DAAL 03-88-K0017).

cDNA CLONING OF A KAINATE BINDING PROTEIN FROM PIGEON CEREBELLUM. H.P. Ottiger. B. Niederöst. and P. Streit Brain Research Institute, University of Zürich, August-Forel-Str. 1, CH-8029 Zürich, Switzerland.

In the vertebrate central nervous system, the excitatory amino acid (EAA) glutamate plays a role as major neurotransmitter via various types of pharmacologically defined receptors and its action is thought to be terminated by neuronal and glial uptake. Litle is known, however, about the molecular characteristics of these receptors, of certain pharmacologically related binding proteins and carrier systems. A characterization at the molecular level, on the other hand, should yield a better understanding of EAA function, not the least by facilitating the development of important tools.

should yield a better understanding of EAA function, not the least by facilitating the development of important tools.

Binding sites pharmacologically related to EAA receptors are highly enriched in the molecular layer of the pigeon cerebellum as shown autoradiographically using tritiated kainate as tracer. A similar labelling pattern is obtained by means of a monoclonal antibody which precipitates a 50 kD kainate binding protein from detergent extracts of pigeon cerebellum. The relationship between this kainate binding protein and functional kainate receptors remains to be defined.

As a step to meet this goal, a further characterization of the protein is being conducted by analysing cDNA clones identified through screening of pigeon brain cDNA libraries. We are currently investigating the extent of cross-species expression, chromosomal origin, and developmental onset of expression. The results on the identification and characterization of these clones will be presented. Supported by Swiss National Foundation grant 3.118.88.

SOLUBILIZED RAT BRAIN AMPA RECEPTOR BINDING TO LECTIN COLUMNS. W. McNeel. J. Mills*, P. Crowley*, and A.B. Young. Neuroscience Program and Dept. of Neurology, University of Michigan, Ann Arbor, MI 48109.

AMPA, (α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid), is

Michigan, Ann Arbor, MI 48109.

AMPA, (a-amino-3-hydroxy-5-methylisoxazole-4-propionic acid), is an agonist at a subtype of excitatory amino acid receptor which is a glycoprotein, and can be solubilized in Triton X-100. Specific [3H]AMPA binding in solubilized tissue was determined by a filter binding assay using 0.3% PEI (polyethylenimine) treated filters and 0.1 mM glutamate as a blank. Sugar residues of this glycoprotein can be determined by binding to lectin columns. The AMPA receptor bound to Con A (Canavalia ensiformis), WGA (Triticum vulgaris), and RCA-1 (Ricinus communis) columns, indicating the presence of mannose and/or glucose, N-acetylglucosamine, and galactose residues, respectively, in its carbohydrate structure. The AMPA receptor did not bind to the PNA lectin, suggesting that it contains a terminal sialic acid. Treatment of the AMPA receptor with sialidase permitted some binding to the PNA column. The SNA lectin has an affinity for B-D-Gal (1-34)-D-Gic, which is increased if there is a terminal sialic acid. Some, but not all of the solubized AMPA receptor bound to the SNA column, suggesting the possibility of multiple AMPA receptor subtypes with the differing carbohydrate structures. Treatment of the AMPA receptor with sialidase prevented all binding to the SNA column. The use of lectin columns may differentiate AMPA receptor subtypes and aid in their purification. Supported by the Markey Foundation.

230.2

IN SITU HYBRIDIZATION OF THE mRNA FOR KAINATE RECEPTORS IN RAT BRAIN USING THREE DISTINCT PROBES. Y. Fujiwara¹, K. Akiyama¹, I. Sora^{*1}, H. Tomita^{*1}, S. Otsuki^{*1}, M. Tyler^{*2} and H.I. Yamamura³ Dept. of Neuropsychiatry, Okayama Univ. Med. Sch. Okayama 700, Japan, Medical Products Dept. E.I. Du Pont De Nemours & Co. Boston, MA 02118, ³Dept. of Pharmacol. Univ. of Arizona, Tucson, AZ 85724

It was reported that the cDNA clone for the kainate receptor was isolated (Hollman, M. et al. Nature 342:643-648, 1989). To investigate the regional distribution of mRNA encoding the kainate receptor, the present study conducted in situ hybridization histochemistry in the rat brain using three distinct probes, each of which consists of separate 45 consecutive sequence (4-48, 262-306, 1951-1995, according to Hollman, M. et al., 1989). Each 45 base probe was 3'-end labeled using terminal deoxy nucleotidyl transferase with [35s]dATP. In situ hybridization was conducted with a probe concentration of 1x106 dpm/100 µl of buffer [1xSSC, 50% formamide, 1x Denhardt's solution, salmon sperm DNA, 100mM DTT, and 10% dextran sulfate] per brain slice at 37°C for 18-20 h in a humid chamber. Slices were washed four times for 15 min at 55°C in 1xSSC and for 60 min at room temperature also in 1xSSC. Slides were dried and exposed to x-ray film for 1 week. The autoradiograph showed that mRNAs were present at high level in the pyramidal cells of the hippocampus. Identical patterns of labeling were obtained using the three distinct probes and a mixture of three probes.

Recently, a cDNA clone (GluR-K1) encoding a member of

Recently, a cDNA clone (GluR-KI) encoding a member of the glutamate receptor family was isolated from a rat brain cDNA library (Hollmann, M. et al., Nature 42: 643, 1989). Injection of GluR-KI transcripts into Xenopus cocytes induces the expression of functional receptor-channel complex activated by kainic acid (KA), domoic acid (DA) and glutamic acid (GA, ibid). The same receptor-channel complex is now shown to respond to both KA and quisqualic acid (QA). The apparent affinity (EC₅₀) of QA (0.1 µM) is higher than that of KA (50 µM). However, the maximal response induced by QA corresponds to only 1/10 of the KA maximal response. QA and GA competitively inhibit KA induced current. The "non-NMDA" receptor antagonist 6,7-dinitroquinoxaline-2,3 dione (DNQX) blocks the effects of both KA and QA. Currents induced by KA, QA and DA in cocytes expressing GluR-KI show the same voltage sensitivity: no outward current and exponential increase upon hyperpolarization. These data provide direct synthesis of ligand gated channels activated by both KA and QA agonists, suggesting that these two agonists act at the same receptor.

Phosphorylation of A Kainic Acid Binding Protein. <u>D.R. Hampson and M.F. Hullebroeck</u>. Faculty of Pharmacy, University of Toronto, Toronto, Ontario Canada M5S 2S2

Kainic acid receptors or binding proteins have been purified and/or cloned from frog, chicken, and rat brain. The proteins from frog and chicken brain are approximately 50,000 daltons while the rat protein is 99,000 daltons. All 3 proteins have a high degree of homology, particularly the frog and chicken protein. In each case there appears to be 4 membrane spanning domains and a large intracellular loop. In each species, this intracellular loop contains a number of consensus sequences for potential protein kinase-mediated phosphorylation. We have examined the cyclic AMP-dependent protein kinase phosphorylation of the proteins from frog and chicken CNS.

Kainic acid binding proteins were solubilized and then purified from frog whole brain and chicken cerebellum using ion exchange chromatography and domoic acid affinity chromatography. Cyclic AMP-dependent protein kinase was from bovine heart. In vitro experiments using purified kainate proteins and purified kinase demonstrated that the protein from chicken CNS was phosphorylated by protein kinase A. The frog protein did not appear to be phosphorylated under the same conditions. The phosphorylation of the chicken receptor was very rapid; detectable P-32 incorporation was observed within the first 1 minute of incubation at 30°C. These results support the findings by others [e.g. see Liman, Knapp, and Dowling; Brain Res. 481:399(1989)] that protein kinase A modulates kainate induced currents and suggest that phosphorylation may be a physiologically important mode of regulation for this class of receptors. Supported by the NSERC and the MRC of Canada.

SOLUBILIZATION AND RECONSTITUTION OF ACTIVE NMDA RECEPTORS FROM RAT BRAIN. D.E. Pellegrini-Giampietro, R. Haring* and R.S. Zukin, Department of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

The NMDA receptor complex, defined by specific binding of [3H]TCP, was solubilized from rat forebrain membranes with the

[3HJTCP, was solubilized from rat forebrain membranes with the zwitterionic detergent CHAPS. A nearly complete (> 80%) restoration of binding activity was achieved upon incorporation of solubilized membrane proteins into lipid vesicles prepared by addition of a total brain lipid extract and 60-fold dilution of CHAPS.

Proteoliposomes displayed saturable [3HJTCP binding. Scatchard analysis showed the recovery of an apparent single high affinity binding site (K_D=20nM; Bmax=5.1 pmol/mg protein). Six-fold purification of binding sites was achieved. The rank order of potency of drugs binding to the PCP site was retained (MK-801 > TCP, dexoxadrol >> levoxadrol, haloperidol). In proteoliposomes prepared from well-washed membranes, glutamate (0.1-100 µM) dosedexoxatoris - levoxatori, naioperiodi). In proteoliposomes prepared from well-washed membranes, glutamate (0.1-100 μ M) dose-dependently increased [3 H]TCP binding; potentiation of binding by glutamate was enhanced in the presence of glycine (1-10 μ M). The competitive NMDA antagonist APV inhibited [3 H]TCP binding (K=100 nM). In photoaffinity labeling experiments, [3 H]azido-PCP labeled two polypeptides, M, 59,000 and 98,000, as was observed for

These results indicate the successful reconstitution into liposomes of TCP binding sites associated with the NMDA receptor/ion channel complex. This preparation may be helpful in the purification of active receptors and in electrophysiological studies on artificial lipid bilayers.

CHARACTERIZATION OF SOLUBILIZED AMPA BINDING SITES WITH POLYCLONAL AND MONOCLONAL ANTIBODIES C. Hunter R.J.Wenthold. Laboratory of Molecular Otology, NIDCD, NIH, Bethesda, MD 20892.

In previous work, we have solubilized and partially purified an AMPA binding protein (ABP) from rat brain (J. Neurochem 54,118 1990) using Triton-X 100. We have now obtained a highly purified preparation of ABP from bovine brain. SDS-PAGE of the purified ABP gives one band which migrates at M_r=114,000. Scatchard analysis of purified ABP in the presence of KSCN resolves the binding into both a high and low affinity component similar to other reports. In competition studies quisqualate and AMPA are the most potent displacers of 911 AMPA binding while kainic acid is 150 fold less effective. To further study the ABP, monclonal and polyclonal antibodies were made to the purified preparation. Polyclonal anti-ABP immunoprecipitated greater than 60% of AMPA binding activity solubilized from frog, chick, rat, guinea pig or bovine brain. Further, antisera tested with solubilized membranes from rat and frog immunoprecipitated high affinity ³H AMPA binding while ³H kainate binding at 5nM was unaffected. These data suggest that the AMPA and kainic acid binding proteins are distinct in the rat and frog brain. Monoclonal antibodies which selectively immunoprecipitate quisqualate and kainic acid receptors will be useful in disinguishing between these two receptor subtypes.

230.11

LOCALIZATION OF mRNA FOR KAINATE RECEPTORS IN THE RAT BRAIN BY IN SITU HYBRIDIZATION HYSTOCHEMISTRY,

LOCALIZATION OF mRNA FOR KAINATE RECEPTORS IN THE RAT BRAIN BY IN SITU HYBRIDIZATION HYSTOCHEMISTRY.

P. McGonigle. S. Subramaniam and D. Brousseau. Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania, 19104.

Three [355]-labelled oligonucleotides derived from unique portions of the coding region of the rat kainate receptor CDNA have been used as probes for the mRNA for this receptor. Cells in the rat brain containing mRNA coding for the kainate receptor were localized using in situ hybridization hystochemistry. A 48 base oligonucleotide of random sequence served as the control. Two of the oligonucleotide of random sequence served as the control. Two of the oligonucleotides produced a heterogeneous and comparable distribution of labelling and combination of these probes improved the signal to noise ratio. The highest level of hybridization was observed in the CA1, CA2 and CA3 fields of the hippocampus as well as the dentate gyrus. High mRNA content was observed in the anterior olfactory nuclei and the pyramidal layer of the olfactory tubercle, and the olfactory nuclei and the pyramidal layer of the olfactory tubercle, and the soft frontal and orbital cortex and the amygdaloid nuclei. In most of these areas, the distribution was similar to the distribution of kainate receptor labelled with [3H]-kainate. However, in the hippocampus, the level of hybridization was comparable in all of the CA fields, whereas [3H]-kainate preferentially labels the CA3 field. In some areas, like the striatum, kainate receptors have been visualized but no significant hybridization signal could be detected. The mRNA coding for these receptors in these areas could be contained in cells outside of the brain area, be different from the one recognized by our probes or be present at levels below the detection limits of our procedure. DEVELOPMENTAL REGULATION OF mRNAs ENCODING RAT BRAIN GLUTAMATE RECEPTORS. G.M. Durand, R. Roginski, M.Y.L. Bennett and R.S. Zukin. Dept. Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

The developmental regulation of kainate receptor gene expression in embryonic and neonatal rat brain has been examined. We used the ploymerase chain reaction to clone a cDNA with a sequence apparently identical to that reported by Hollmann et al. (Nature 342: 643-648, 89). Messenger RNA translated from this cDNA and injected into Xenopus occytes directed the translation of functional kainate channels. Northern blot analysis carried out with a riboprobe made to the full length kainate receptor cDNA under conditions of high stringency revealed the presence of large amounts of a RNA species, 5.2 kb in size, in poly(A)*RNA from adult rat brain. Additionally, a minor band corresponding to RNA 3.8 kb in size was observed. In contrast, mRNA from a 7-day-old rat brain showed the 5.2 kb RNA and two minor bands at about 2.0 and 1.6 kb. These findings indicate developmental regulation of the expression of the smaller mRNA species. When RNA samples from the brain tissue of embryonic E-18, neonatal days 1, 4, 7 and 11, and adult rat brain were analyzed by Northern blot, the density of 18s rRNA, which does not appear to change during development), increased monotonically until neonatal day 11, then decreased by about 16% in adult. These findings indicate changes in both quantity and species of kainate receptor mRNA expressed at different stages of brain development.

230.10

INTERSPECIES DIFFERENCES IN THE POPULATION OF MULTIPLE GLUTAMATE RECEPTORS EXPRESSED IN XENOPUS OOCYTES AFTER INJECTION OF RODENT FOREBRAIN MESSENGER RNAS. S. Kaneko*, M. Sugimura* and M. Satoh. Dept. of Pharmacol., Fac. of Pharm. Sci., Kyoto Univ., Kyoto 606, Japan.

Expression of multiple responses to glutamatergic agonists was compared in Xenopus oocytes several days after injection of poly(A)+RNAs from guinea pig, mouse and rat forebrains. No difference was observed in the pharmacological characteristics of the electrical responses of oocytes to N-methyl-p-aspartate (NMDA), kainate (KA), α-amino-3-hydroxy-5-methyl-4-isoxazole-propionate (AMPA), or quisqualate (QA) among the oocytes injected with mRNA from the different species. However, KA responses produced by guinea pig brain mRNA or mouse brain mRNA was about half the magnitude of that by rat brain mRNA. Moreover, the peak amplitude of oscillatory QA responses by guinea pig mRNA was 1/6 times of that by rat brain mRNA, or 1/4 times of that by mouse mRNA. The amplitude of NMDA responses were equivalent among these mRNA preparations. These results may reflect that the proportion of metabotropic QA receptor subtype in the guinea pig forebrain is much lower than that in the rat or mouse brain, and that the non-NMDA/NMDA ratio of ionotropic receptor density is higher in the rat brain than in the guinea pig or mouse brain.

FUNCTIONAL CHARACTERIZATION OF THREE GLUTAMATE RECEPTOR cDNA CLONES OF THE KAINATE SUBTYPE SUGGESTS A HETERO-OLIGOMERIC STRUCTURE FOR THE NATIVE RECEPTOR. M. Hollmann*, J. Boulter*, M.E. Hartley*, A. O'Shea-Greenfield* and S. Heinemann. Mol. Neurobiol. Lab., Salk Institute, La Jolla, CA 92037.

Using GluR-K1 (K1), a glutamate receptor cDNA clone of the kainate subtype (Hollmann, M. et al, Nature, 243:843, 1989) as a probe in low-stringency hybridization experiments, we have identified two additional clones that show high a mino acid sequence identify (arround 65%) to GluB.

stringency hybridization experiments, we have identified two additional clones that show high amino acid sequence identity (around 65%) to GluR-K1 (K1). Upon injection into *Xenopus* oocytes of RNA synthesized *in vitro* from clones GluR-K2 (K2) and GluR-K3 (K3) we observed functional kainate receptors. This proves that each of the proteins encoded by these cDNAs is sufficient to form functional receptors, probably by forming homoligomers in the oocyte membrane. K3 RNA elicited responses to kainate receptor agonists similar in size to those seen with K1, while K2 gave significantly smaller responses. The pharmacological characteristics of the three receptors, though being very similar in general, differ slightly. Notably, dose-response curves reveal different apparent Kd's for receptor agonists. Pairwise injections of K1, K2 and K3 transcripts into single oocytes led to a ~5-fold increase in responses over the sum of the responses detected with the individual transcripts. Combining all three transcripts in one oocyte yielded no further stimulation of the response. This finding suggests that the interaction of different receptor subunits, probably through formation of hetero-oligomers, is responses elicited by combinations of subunits than to responses seen with individual subunits. This indicates that native receptors most probably are hetero-oligomers

This indicates that native receptors most probably are hetero-oligomers consisting of at least two different subunits. Supported by the Deutsche Forschungsgemeinschaft (M.H.), and NINCDS

MOLECULAR STRUCTURE AND EXPRESSION RAT GLUTAMATE RECEPTORS.

J.Boulter* I.Hermanns-Borgmeyer*, A.O'Shea-Greenfield*, M. Hollmann*, M. Hartley*, C.Moll*, R.Papke and S.Heinemann Molecular Neurobiology Laboratory, The Salk Institute, San Diego, CA 92138.

Recently our laboratory has characterized a cDNA clone encoding a functional glutamate receptor of the kainic acid subtype (GluR-K1; Hollmann et al., Nature, 342:643, 1989). Low stringency screening of cDNA libraries constructed from rat central nervous system RNAs has resulted in the isolation of four additional cDNAs with similarity to GluR-K1. Two of these cDNAs (GluR-K2/GluR-K3) encode kainate-sensitive ion channels (see abstract by Hollmann et al.), the functional properties of the two other isolates are under investigation. We compare the primary structure of all five cDNA clones isolated and present an in situ hybridization analysis in the rat and developing mouse nervous systems. Recently our laboratory has characterized a

developing mouse nervous systems.

EXCITOTOXICITY IN RAT 2 FIBROBLASTS STABLY EXPRESSING A cDNA ENCODING A MEMBER OF THE GLUTAMATE RECEPTOR FAMILY. S.W. Rogers and S. Heinemann. Molecular Neurobiology Lab., The Salk Inst., LaJolla, CA 92037.

This laboratory has used a molecular approach to identify cDNAs which encode members of the glutamate-gated ion channel family. One cDNA encodes for a functional glutamate receptor of the kainic acid subtype and was named GLUR-KI (Hollmann, et al., Nature 342:643, 1989). We have stably transfected cultured Rat 2 fibroblasts with this cDNA to produce cell lines which express functional receptors of the GLUR-KI type. Employing the methods of molecular biology and immunology, we are evaluating in detail the pharmacology and cell physiology of kainic acid induced excitotoxicity. Preliminary analyses of these cell lines indicate that cell survival in glutamate-containing culture medium is enhanced by the presence of kynurenic acid. In addition, GLUR-KI expressing cells die in response to prolonged exposure to kainic acid. This approach offers the advantage of studying the contribution of individual excitatory amino acid ligand-gated channel subtypes to the more general process of excitotoxic cell death. (Supported by NICDS and a NIH post-doctoral fellowship to SWR)

IMMUNOCHEMICAL PURIFICATION AND CHARACTERIZATION OF BRAIN SYNAPTIC MEMBRANE GLUTAMATE-BINDING PROTEINS. K.N.Kumar, M.J. Eaton, K.T. Eggeman and E.K. Michaelis. Depts. of Pharmacology & Toxicology, Biochemistry and Center for Biomedical Research, University of Kansas, Lawrence, Kansas 66045

Two glutamate binding proteins (GBP's) were previously purified from rat brain synaptic membranes. [J. Biol. Chem 263, 417 - 426, 1988]. The ligand binding characteristics of two proteins were suggestive of a role as glutamate receptors in synaptic membranes. Polyclonal antibodies were raised against the denatured 71 and 63 kDa GBP's in rabbit, including sets of antibodies against each of the 71 and 63 kDa proteins. The antibodies recognized the denatured form of the proteins in Western blots and the native state of the proteins in ELISA assays. The two proteins were closely related immunologically but the reactivity on Western blots differed between the two proteins. An immunoaffinity purification procedure was developed to purify the two proteins. This method involved linking of the antibodies to a Trisacryl matrix. The proteins purified by this procedure had molecular sizes of 71 and 63 kDa on SDS-PAGE. The molecular size of native proteins estimated by sucrose density centrifugation was 75 and 135 kDa, i.e., indicative of monomer and dimer formations. Immune extraction of the 71 and 63 kDa proteins from solubilized synaptic membrane proteins led to a 60% decrease in L-[³H] glutamate binding activity suggesting that the 71 and 63 kDa proteins are the major group of glutamate binding entities in synaptic

(Supported by grants AA 04732 and DAAL 03-88-K0017)

THE KAINATE SUBTYPE OF THE GLUTAMATE RECEPTOR FAMILY: BIOCHEMICAL CHARACTERIZATION. G. Gasic, M. Hollmann*, T. Hughes, S.W. Rogers and S. Heinemann. Molecular Neurobiology Lab., The Salk Inst., LaJolla, CA 92037.

This laboratory has used a molecular approach to identify cDNAs which encode members of the glutamate-gated ion channel receptor family. One cDNA encodes for a functional glutamate receptor of the kainic acid subtype and was named GLUR-K1 (Hollmann, et al., Nature 342:643, 1989). We have made rabbit polyclonal antibodies to a portion of the putative extracellular and intracellular domains using the trps bacterial overproduction the putative extracellular and intracellular domains using the trpE bacterial overproduction method to aquire antigen. These antibodies reveal on western analysis a 105 kD glycoprotein which is predominantly found in crude membrane extracts of the rat hippocampus and cerebellum and to a lesser extent in the cortex and midbrain. Antigen is not observed in the brain stem or liver. Further fractionation of these membrane preparations demonstrates that this protein is enriched in demonstrates that this protein is enriched in synaptic plasma membranes and that it co-localizes with post-synaptic densities suggesting that the GLUR-K1 is a post-synaptic ligand-gated ion channel. (Supported by NICDS and HHMI)

230.16

THE KAINATE SUBTYPE OF THE GLUTAMATE RECEPTOR FAMILY: IMMUNOHISTOCHEMICAL LOCALIZATION IN THE RAT BRAIN. T.E. Hughes, S.W. Rogers, G. Gasic, M. Hollmann, S. Heinemann. Dept. of Neurosciences, UCSD & Molecular Neurobiology Lab., The Salk Institute for Biological Studies, La Jolla CA 92037.

The kainate subtype of the glutamate receptors is thought to mediate The kannate subtype of the guitamate receptors is thought to mediate excitatory neurotransmission at many synapses, and has been implicated in excitotoxic cell death, but little is known about the cellular distribution of this receptor. Rabbit antisera against a putative extracellular portion of GluR-K1 (see Gasic et al. abstract) provides an immunohistochemical means to study the receptor's distribution. The antiserum labels many neurons in the forebrain; there is a dense labeling of the cytoplasm within their somata and a fine granular labeling of their dendrites and axons. The majority of the labeled neurons are in the hippocampus, amygdala, lateral septum, and the bed nuclei of the stria terminalis. In the hippocampus, the pyramidal cells throughout Ammon's horn are labeled, as well as somata in the dentate gyrus, taenia tecta and indusium griseum. The lateral septum, which receives a large input from the cells of Ammon's horn, contains many large, labeled multipolar cells. Within the amygdala, there is a dense plexus of labeled processes and medium-sized round somata in the central nucleus. From this nucleus a path of labeled fibers and cells can be followed through the stria terminalis into the oval and juxtacapsular bed nuclei (Ju & Swanson, I.Comp.Neurol., 280:587, 1989) which contain many tightly packed round to oval receptor-positive cells. These findings provide an initial glimpse of the cellular distribution of the receptor. With electron microscopy, it should be possible to further define the distribution of the receptor and it's relationship to the synapse. Supported by the NEI & NINCDS.

IMMUNOLOCALIZATION OF GLUTAMATE-BINDING PROTEINS (GBP's) IN CULTURED PRIMARY BRAIN NEURONS. M.J.Eaton, S.Schuler *, M.L.Michaelis and E.K. Michaelis, Dpt of Biochem & Ctr for BioMed Res, Univ of Kansas, Lawrence, KS 66045.

Polyclonal antiserum against the 63/71 kDa GBP's from rat brain synaptic membranes was used in immunolocalization studies with cultured primary neurons. Neonatal rat brain cortex, cerebellum, and hippocampus were non-enzymatically dissociated and cultures were grown in serum-free supplemented DME/F12 media. Mature neurons had L-(³H)glutamate binding sites with a Kd equal to 0.5uM. L-Glutamate binding to these sites was inhibited by metal ligands and quisqualate, ligands that inhibit binding to purified GBP's. The antibody used is selective for brain synaptic membrane GBP's and inhibits most of the specific L-(3H) glutamate binding to synaptic membranes. GBP-like immune reactivity was localized in mature cultured neurons by means of silver-enhanced immuno-gold reaction. This reactivity was seen on membranes of cell bodies and neuronal processes. Image analysis of immune reaction sites in developing cortical neurons revealed that the highest concentration of label was in immature and the lowest in mature neurons. The distribution of labeling changed from an exclusively somal location in immature cells to one of distal membranes of neuronal processes in mature cells. Much of the latter reactivity was localized to apparent synaptic contracts GBP immune reactivity was also demonstrated by Western blot analysis of proteins from cultured neurons. Based on these observations it is proposed that some of the glutamate-binding sites in cultured neurons are identical to the 63/71 kDa GBP's.

(Supported by grants AA04732 and DAAL 03-88-K0017).

IMMUNOLOCALIZATION OF GLUTAMATE-BINDING PROTEINS (GBP'S) IN GLUTAMATERGIC PATHWAYS IN RAT BRAIN. E.K. Michaelis and M.J. Eaton, Dpt of Biochem, Univ of Kansas, Lawrence, Kansas 66045

A polyclonal antiserum against the 63/71 kDa GBP's from rat brain synaptic membranes was used for immuno-gold localization of the protein in rat brain sections and synaptosomes. Silver-enhanced immuno-gold GBP like immunoreactivity was visualized in sections of cerebral cortex. hippocampus, and cerebellum by light microscopy. Electron microscopy was used to visualize colloidal gold reactivity in whole brain synaptosomes and dendritic areas of the different brain regions. Somal membranes and terminal dendritic fields of the perforant path, mossy fiber and Schaffer collateral paths of the hippocampus were well labeled for GBP-like immunoreactivity at the light microscopic level. Post-synaptic membranes and post-synaptic densities contained the immuno-gold reaction product in these areas at the electron microscopic level. Immunoreactivity was localized also to the granule cell membrane and dendrites and the parallel fiber synapses in the cerebellum and in neuronal membranes and dendrites in the sensory cortex. In synaptosomes from whole brain, reactivity was localized exclusively to post-synaptic membranes and post-synaptic densities. Immune labeling with a polyclonal antibody directed against phosphate activated glutaminase (PAG) localized to the pre-synaptic terminals in many of the GBP-containing synaptosomes. In brain sections, the most intensely double-labeled synapses were the mossy fiber terminals in the hippocampus and the parallel fiber synapses in the cerebellum. Most terminals that contained PAG immunoreactivity also contained GBP immunoreactivity. (Supported by grants AA 04732; DAAL 03-88-K0017).

CHARACTERIZATION OF EXCITATORY AMINO ACID STIMULATED TURNOVER OF PHOSPHOINOSITIDES IN NEONATAL HIPPOCAMPAL TISSUE. S.D. Flagg and M.B. Robinson, Children's Seashore House, Depts. Ped. and Pharm., Univ. of Pennsylvania, Philadelphia, PA 19104.

It has been suggested that there are two pharmacologically distinct excitatory amino acid (EAA) receptors that are coupled to increased turnover of phosphoinositides (pl) (For review see Sladezek at al., 1986), one of which is blocked by phosphonate-containing analogs of glutamate. Using hippocampal tissue prepared from neonatal (5-11 days) rats, the EAA stimulated production of inositol phosphates was characterized. Compounds tested for stimulation were quisqualate characterized. Compounds tested for stimulation were quisqualate (Quis), ibotenate (Ibo), and trans-1-amino-cyclopentane-1,3-dicarboxylic acid (trans-ACDP) with EC50's of 0.56, 45, and 70 μM, respectively. N-Methyl-D-aspartate was inactive. DL-2-amino-3-phosphonopropionate (DL-AP3), an inhibitor of EAA stimulated turnover of pI (Schoepp, J. Neurochem, 53 (1989) 273), blocked all three agonists with similar potency. The IC50's were as follows: Ibo (IC50 = 500 μM), Quis (IC50 = 833 μM) and trans-ACDP (IC50 = 684 μM). µM). All three of these inhibition curves were consistent with a single site. The concentration dependence of the Quis stimulated turnover of pI was determined in the presence of 300 μM and 1000 μM DL-AP3. In preliminary studies, DL-AP3 decreased the maximum response induced by Quis with no effect on the EC50. These studies suggest that DL-AP3 may non-competitively inhibit the EAA receptors that are coupled to increased turnover of phosphoinositides. Further, the present data are consistent with a single EAA receptor coupled to pI hydrolysis in hippocampal tissue prepared from neonates.

EXCITATORY AMINO ACIDS: RECEPTORS V

POLYAMINE SPIDER TOXINS ARE POTENT UN-COMPETITIVE ANTAGONISTS OF NMDA AND KAINATE RECEPTORS. "M.S.Davies", "T.M. Volkova" 'E.V. Grishin' 'T.H. Lanthorn, 'G.B. Watson and 'R.C. Wiegand. 'Monsanto Corporate Research, G.D. Searle Co, 700 Chesterfield Village Parkway, Chesterfield, MO 63198 and "Shemyakin Institute of Bioorganic Chemistry, Academy of Sciences of the USSR, Moscow.

We examined the effect of argiopine and argiopinine 3, low molecular weight polyamine components of the spider Argiope labata venom [1], on rat brain EAA receptors expressed in Xenopus oocytes. Using a single intracellular microelectrode, oocytes injected with rat brain poly A+RNA were voltage clamped at -60mV while drugs were applied to the cell via a flowing stream of Mg" free Barth's medium. Responses to 100µM NMDA with 10µM glycine were potently blocked by both polyamine toxins in a dose dependent manner; argiopine was slightly more potent than argiopinine 3. Both compounds had similar potencies against 100µM KA but were unable to block more than 50% of the response, possibly suggesting the existence of more than one subtype of KA receptor. Another KA antagonist, BOAA, was able to block all of the KA response [2]. Oscillatory response curves for NMDA/glycine and KA both with and without the polyamine toxins demonstrated that the antagonism against these two sites was not competitive; increasing agonist concentrations were unable to overcome the antagonism by either spider toxin. We were able to demonstrate a use-dependent phenomenon similar to that of PCP; neither polyamine toxin affected the NMDA or KA response without the presence of the respective agonist. The work presented here suggests that these compounds may prove useful in distinguishing among the different classes of glutamate receptors, particularly among QA and KA receptors. ARE NMDA RECEPTORS IN THE RETINA EQUIVALENT TO THOSE IN THE BRAIN? H-CPP BINDING STUDIES. A.M. López-Colomé and F. Somohano. Instituto de Fisiología Celular, UNAM. Apdo. Postal 70-600, 04510 México, D.F., México.

CPP (3-(RS)-2 carboxypiperazin-4-yl) propyl-1-phosphonic acid has been known for some years as one of the most selective antagonists at the NMDA receptor in the brain. We selective antagonists at the NMDA receptor in the brain. We have measured $^3\mathrm{H-CPP}$ binding to membranes from chick retina in the presence and absence of Mg * . Saturation curve and Scatchard analysis revealed a single site in the absence of Mg * , with $\mathrm{K_p=400}$ nM and B $_{\mathrm{max}}=9.5$ pmol/mg protein. In the presence of Mg * however, a second, high affinity component of binding was evident, with $\mathrm{K_p=59}$ nM and B $_{\mathrm{max}}=2.2$ pmol/mg protein. Bound CPP was preferentially displaced from the high affinity site by CPP=AMPA=APH but not by L-Asp; at the low affinity site. the most efficient displacers were also low affinity site, the most efficient displacers were also CPP=AMPA=APH, L-Asp being as potent. Reciprocal experiments binding H-AMPA showed that APV and APH were experiments blinding n-AMPA showed that APV and APPA were potent displacers at this site. Our results suggest that either 3H-CPP is not such a specific ligand for the NMDA recognition site, or alternatively AMPA sites are not restricted to QA receptors in the retina.

This work was supported in part by grant P228CCOX891617 from CONACyT.

DEVELOPMENTAL CHARACTERISTICS OF L-ASPARTATE BINDING SITES IN NEURONS AND GLIA FROM THE RETINA. F.Somohano, M.Romo de Vivar* and A.M.López-Colomé. Instituto de Fisiología Vivar* and A.M.López-Colomé. UNAM. Apdo. Postal 70-600, 04510 México, D.F., Celular. México.

studies in the whole chick retina demonstrated that receptors which bind L-Asp and NMDA are present in very low concentrations and rise markedly between days 14 and 18 of embryonic development. Since these receptors could be of neuronal or glial origin, we studied H-L-Asp binding to membranes from neuronal (N) and glial (G) cultures from chick retina at DIV 1,5,8 and 12. H-Asp binding to N and G decreased 50% from day 1 to day 12 IV. Scatchard analysis of saturation curves in N was biphasic at all ages with K_B=35 nM and K_B2=400 nM, B decreasing from 0.4 to 0.2 pmol/mg protein from day 1 to day 8 IV. The most potent displacers of H-L-Asp at 1 DIV were L-Asp=NMDLA= L-Glu>AMPA=APV, whereas at 8 DIV, AMPA no longer displaces L-Asp. This is in agreement with the increase in specificity observed in ED of whole retina. In increase in specificity observed in ED of whole retina. In G, kinetics of L-Asp binding revealed three sites: $K_{\rm B}$ =30 nM, $K_{\rm B}$ =400 nM and $K_{\rm B}$ 3=1.5 μ M; while $K_{\rm B}$ 1 and $K_{\rm B}$ 2 coexist at 1 DIV, $K_{\rm B}$ 2 and $K_{\rm B}$ 3 are present at 12 DIV. In these membranes (G), while inclusion of Na in the medium yielded the pharmacological profile reported for high affinity uptake systems, in the absence of this ion, pharmacology is in line with that described for QA metabotropic receptors in astrocytes. Supported by grant P228CCOX891617 from CONACyT.

DECREASED 3H-AMPA BUT NOT 3H-TCP BINDING IN HIPPOCAMPUS AFTER KAINIC ACID ADMINISTRATION. K.K. Devgan, G. Tocco, S. Hauge*, I. Naim, M. Baudry, & R. F. Thompson, Program in Neuroscience, University of Southern California, Los Angeles, CA 90089-2520.

Systemic or intracerebral administration of kainic acid (KA)

in rats induces limbic seizures and extensive neuronal damage throughout the limbic system. We were interested in evaluating changes in different subtypes of glutamate receptors that might be

involved in determining seizure susceptibility.

Sprague Dawley rats received KA (10 mg/ Kg, i.p.) and were Sprague Dawley rats received KA (10 mg/ Kg, i.p.) and were sacrificed 12-15 hours after drug administration. Quantitative ligand binding autoradiography was performed on brain sections with either 3H-AMPA, a ligand specific for the ionotrophic quisqualate receptor, or 3H-TCP, a ligand which binds inside the NMDA receptor channel. 3H-AMPA binding was significantly reduced in different regions of the brain with the highest reduction in stratum radiatum of hippocampal field CA1. 3H-TCP binding, however, was not decreased in any structure, suggesting that the decreased AMPA binding is not likely to reflect neuronal cell death. These results indicate that AMPA/quisqualate receptors may be down-regulated as a result of intense physiological activity. It is possible that the activity- dependent regulation of the AMPA/quisqualate receptor may participate in long term changes in hippocampal function.

DESENSITIZATION OF THE IONOTROPIC QUISQUALATE RESPONSE IN XENOPUS OCCYTES IS DUE TO AN AUTOINHIBITION. B.Lambolez*, M.Geoffroy*, J.Bossier and B.T.Kado. Centre d'Etudes de Système Nerveux, C.N.R.S. Gif sur Yvette, 91198 FRANCE

The responses of Xenopus oocytes injected with mRNA from rat cerebral cortex to Quisqualate (QA), a-amino-3-hydroxy-5-methyl-isoxazole-4-proprionate (AMPA) and myuroxy-o-methyl-isoxazole-4-proprionate (AMPA) and glutamate (GLU) have been studied using standard two-electrode voltage clamp techniques. QA doses >2x10-6M ([QA]m) applied to mENA injected occytes held at -60mV, produced rapid initial current responses which with hydroxy-5-methyl-isoxazole-4-proprionate ([QA]m) applied to mRNA injected oocytes held at -60mV, produced rapid initial current responses which quickly decreased to a steady level. At wash-out, the current initially increased making a "hump" before returning to the holding level. The wash-out hump was suppressed by returning to [QA] <10-6M or if [DNQX] <1/10 [QA] was applied, both increased the currents but wash-out did not produce a hump. The hump indicated that the steady current was an inhibited state of the response. [QA]m doese applied after starting at doese (10-6M did not doses applied after starting at doses <[0.6] (id not produce the initial peak but did reduce the current. Risetimes for the initial peaks at [QA]s doses were markedly slower than for lower concentrations. These results showed that the QA response was rapidly inhibited by [QA]s doses and passed through a disinhibited state on by [4A]s doses and passed through a disiniplited state on wash-out before complete agonist removal. The effect was more pronounced with QA than with AMPA or GLU. This receptor may therefore have a low affinity inhibitory site which can be occupied by QA at sufficient doses.

QUISQUALATE-EVOKED RELEASE OF VASOPRESSIN FROM ISOLATED SUPRAOPTIC NUCLEI OF THE RAT C.R. Jarvis, B. Hu, and L.P. Renaud. Centre for Research in Neuroscience, Montreal General Hospital & McGill University, Montreal, Canada H3G 1A4; Neuroscience Unit, Ottawa Civic Hospital, Ottawa, Canada K1Y 4E9.

The release of vasopressin (VP) from hypothalamic magnocellular nuclei in vitro has been demonstrated under conditions which increase neuronal activity. Glutamate is known to have potent excitatory actions on magnocellular supraoptic neurosecretory neurons via activation of postsynaptic receptors. The present study examines the ability of the non-NMDA glutamate agonist, quisqualate, to release (VP) from isolated supraoptic nuclei maintained in perifusion chambers supplied with oxygenated (95% O2 5% CO2) artificial cerebrospinal fluid and maintained at 37°C. Perfusate samples were collected over 10 minute intervals and assayed for VP by radioimmunoassay. Following an initial incubation period (45-60 mins.) perifusion with quisqualate (up to 100 uM) induced a dose-dependent increase (up to 10-20 fold) in the basal levels of VP. These results support the proposal that VP can be released locally (e.g. from somas and dendrites) as well as distally (e.g from axon terminals) in response to stimulation by neurotransmitters. Supported by FCAR, FRSQ, and MRC.

FUNCTIONAL CORTICAL KAINATE RECEPTORS IN THE RAT ARE EXPRESSED LATER THAN SODIUM CHANNELS AND GABA RECEPTORS IN EMBRYOGENESIS. N.S. Nadi, V.Smallwood*, S.V. Smith* and J.L. Barker, Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD.

The development of functional glutamate receptors (Glu-R), sodium channels (Na* Ch) and GABA receptors (GABA-R) was investigated in acutely dissociated cortical neurons of the rat from embryonic day (E) 13 to postnatal day (PN) 13 using tetraphenylphosphonium (TPP*) method and fluorescence activated cell sorter (FACS) analysis using cells stained with the voltage sensitive dye, oxonol. The TPP* analysis revealed an average membrane potential (MP) of -30 mV in early embryonic cells (E13-E16). The MP became more hyperpolarized and reached a level -60 mV at PN3. Depolarization (DPL), induced by Glu and kainate appeared at E17. CNQX partially blocked this effect at E19. Glu DPL became more pronounced in the early PN reaching a maximum at PN13. Throughout this period only a partial block with CNQX could be shown. AP-5 had no effect on Glu DPL. The Na+ Ch, as demonstrated by veratridine DPL, developed at E13 and was blocked by tetrodotoxin. GABA and muscimol caused DPL at E15, which was blocked entirely by bicuculline and partially by picrotoxin. The DPL induced by GABA decreased in later embryogenesis. FACS analysis of the cells of the same population was complementary to the TPP+ findings While being more qualitative in nature, FACS allowed visualization of several cell populations (based on size and fluorescence) with different responses to Glu, kainate, veratridine and GABA. The results demonstrate that functional Glu-R develop later than the GABA-R and Na and that the first subtype to emerge is the kainate response.

FUROSEMIDE, A LOOP DIURETIC, DIFFERENTIALLY AFFECTS GLUTAMATE RECEPTORS IN CULTURED SPINAL CORD

NEURONS. J. Lerma and R. Martín del Río⁺, Instituto Cajal, C.S.I.C. and Dept. Investigación, Hospital Ramón y Cajal^{*}. Madrid, Spain.

Glutamate receptors, in particular of the NMDA type, have been implicated in the pathophysiology of epilepsy, stroke and neurodegenerative disorders. With the probable exception of dissociative anesthetics and some σ opioids ligands, clinical useful drugs acting on excitatory amino acid receptors are not currently available. Preliminary experiments in our laboratory have shown that furosemide, a well characterized loop diuretic widely used for edema treatment, blocks the response to locally applied NMDA in the "in vivo" rat hippocampus. To determine the action of furosemide on glutamate receptors, we have used the patch-clamp technique in the whole-cell configuration and a fast perfusion system to apply excitatory amino acids to spinal cord neurons maintained in culture. Furosemide inhibited the NMDA-induced current in a dosc-dependent manner. IC₅₀ value was calculated from dosc-inhibition curves to be 1.2 mM. Hill coefficient was close to unity. Block was non-competitive, since IC₅₀ values obtained with 30 and 300 µM NMDA were similar. Inhibition of NMDA-induced responses by furosemide developed fast and was fully reversible upon antagonist withdrawal and independent of voltage (-80 to +30 mV). In a few cells furosemide (5 mM) induced a slight inhibition (10%) of kainate-evoked current while in others no effect was observed. In contrast peak and steady responses to AMPA (100 μ M) were both slightly potentiated by furosemide. Degree and time course of desensitization remained unaltered. This result provides evidence supporting K and Q receptors as separate structures. We suggest that furosemide may be a good starting structure for designing specific, non-competitive, voltage-independent NMDA antagonists as well as for synthesis of new compounds to pharmacologically separate K and Q

MAGNESIUM DIFFERENTIALLY MODULATES EXCITATORY AMINO ACID EFFECTS ON THE AXOLOTL VESTIBULAR SYSTEM AFFERENTS. M.E. Pèrez*, R. Vega* C. Erostegui* and E. Soto, Univ. Autônoma de Puebla - ICUAP, P.O. Box 406, Puebla, México.

Numerous reports have indicated that divalent cations play a major modulatory role upon the activity of excitatory amino acid (EAA) agonists. The aim of this study was to evaluate the effects of Mg* on the vestibular afferent fibers response to EAA agonists.

Multiunit spike activity of the axolot! (Ambystoma tigrinum) semicircular canal afferents was extracellularly recorded with a suction electrode. Kainate (KA, O.1 to 100 uM), quisqualate (QA, 0.01 to 100 uM) and NMDA (1 uM to 10 mM), were pressure ejected from a pipette in volumes of 20 ul in a 10 ml bath. Preparation was perfused with Mg** free, 1, 3 and 5 mM Mg** Ringer. In Mg** free Ringer, EAA agonists tested induce a dose dependent excitatory effect. Increasing Mg** in the bath solution to 1, 3, and 5 mM, increments the duration and amplitude of the QA action up to 3 times control, diminish the NMDA effect to 0.1 times control, and apparently does not affect KA dose response.

These results indicate that extracellular Mg** concentration changes might be a valuable tool to discern between NMDA, KA and QA receptor evoked responses.

SENSITIVITY OF QUISQUALATE AND KAINATE CHANNELS TO D-2-AMINO-5-PHOSPHONOVALERATE (APV) IN CULTURED RAT CEREBELLAR GRANULE NEURONS.

C.E.Herron* and S.G.Cull-Candy. Dept. Pharmacology, University College London, London WC1E 6BT.

NMDA, kainate and quisqualate activate channels with conductance levels ranging from 6 to 50pS in cultured cerebellar granule neurons. The 50pS channel however is preferentially operated by NMDA. We have therefore examined the effect of the competitive NMDA antagonist APV on channels activated by quisqualate and kainate to determine if large conductance openings correspond to those activated by NMDA. Current amplitude distributions where fitted with 1-4 Gaussian components and only completely resolved channel openings where used (duration> 2.5τ). In all patches quisqualate ($10-30\mu M$) produced large conductance openings ($\sim\!48pS$ comprising 58% of openings n=5) with measurements ranging from 7 to 56pS Kainate (10-30μM) also activated channels of either large or small Kainate (10-30µM) also activated channels of either large or small conductance; in 4 out of 6 patches 90% of openings had an amplitude of 46pS while in two patches 80% of openings where 7pS. APV (20-50µM) reversibly abolished or reduced the frequency of opening of the large (~50pS) channels activated by both agonists and had no apparent effect on the frequency or amplitude of the small (7-20pS) conductance openings. This suggests that the large conductance kainate and quisqualate channels originate from activation of the NMDA type receptor in granule neurons. *Present address: Wyeth Research (UK), Huntercombe Lane South Taplow BERKS SIG OPH South, Taplow, BERKS SL6 OPH.

EFFECT OF WHEAT GERM AGGLUTININ ON QUISQUALATE CHANNELS IN CULTURED POSTNATAL RAT HIPPOCAMPAL NEURONS. L.L. Thio, D.B. Clifford, and C.F. Zorumski. Dept. of Psychiatry, Washington Univ. School of Medicine, St. Louis, MO

The lectin wheat germ agglutinin (WGA) markedly inhibits rapid quisqualate receptor desensitization in cultured postnatal rat hippocampal neurons. We have examined the effect of WGA on quisqualate channels in outside-out patches to determine whether quisqualate desensitization results from a decrease in the number of channels, the channel open probability, or the single channel conductance. Quisqualate (2.5-1000µM) in the presence of 1mM D,L-2-amino-5-phosphonovalerate (APV) evokes bursts of openings having a primary single channel conductance of 8.6pS. The bursts are well-defined as the closed time histogram is described by three exponentials having time constants of <1, 1-5, and 30-500ms. If closures belonging to the two fastest components are defined to be within a burst, the burst length histogram is described by one or two exponentials and gives an arithmetic mean burst length of 8.3 ± 0.6ms (mean ± SEM, n=24) for all concentrations of quisqualate examined. WGA (25µg/ml) does not alter the single channel conductance (8.4pS) and tends to increase the mean burst length $(17 \pm 3.5 \text{ms}, n=15)$. These results suggest that WGA inhibits quisqualate receptor desensitization by increasing the channel open probability.

L-AP4 REDUCES HIGH THRESHOLD CALCIUM CURRENTS IN OLFACTORY BULB NEURONS. P.Trombley †, and G.Westbrook. †Dept. Biology, Univ. Oregon & Vollum Inst., Oregon Hith. Sci. Univ., Portland, OR.

The glutamate analogue L-AP4 acts presynaptically to reduce transmitter release at excitatory nerve terminals in the CNS, although the mechanism is unclear. L-AP4 also reduces EPSPs evoked by stimulation of cultured mitral/tufted cells (Trombley & Westbrook, J. Neurophysiol.,1990). We tested whether L-AP4 inhibits

voltage-gated calcium currents as a possible mechanism of presynaptic inhibition.

Acutely dissociated olfactory bulbs neurons from PN 5-7 rat pups were whole-cell voltage clamped at -60 mV. L-AP4 (3-300 µM) was delivered by a multibarrelled flow pipe in solutions containing (mM): Ba 10, Na 145, K 2.5, Mg 1, glycine 0, Hepes 10, Glucose 10; patch pipettes contained (mM): Cs 140, ATP 5, GTP 0.5, Ca 0.1, EGTA 11, Hence 10. Ca 0.1, EGTA 11, Hepes 10.

High (HT) threshold calcium currents were activated by 50 ms jumps to 0 mV. HT currents were reduced by L-AP4 (30/38 cells) as well as by NE (34/38 cells). Peak current was reduced 25% (range 11-53, n=30) by 30 μM L-AP4 compared to 34% by 30 µM NE. However HT currents in neurons cultured from PN 1 pups were not inhibited by L-AP4 or NE, although evoked EPSPs were reduced by L-AP4. Inhibition by L-AP4 was irreversible after intracellular perfusion with GTP S (100 µM), suggesting coupling of the AP4 receptor via a G protein.

Supported by the McKnight Foundation, PHS grant NS26494 (GW) and a predoctoral NIH traning grant (PT).

231.15

EFFECT OF POSTNATAL D,L-2-AMINO-3-PHOSPHONOPROPIONATE (D,L-AP3) TREATMENT ON PHYSICAL DEVELOPMENT, BEHAVIOR, AND PHOSPHOINOSITIDE (PIn) HYDROLYSIS IN THE RAT. J,P. Tizzano, R,L. Bailey*, J,A. Engelhardi*, and D,D. Schoepp. Lilly Research Laboratories, Eli Lilly and Company, Greenfield, Indiana 46140.

Previous studies have shown that D,L-AP3 is a preferential inhibitor of metabotropic (Pln hydrolysis-coupled) excitatory amino acid (EAA) receptors as opposed to ionotropic EAA (MMDA, AMPA, kainate) receptors. Metabotropic EAA receptor coupling is greatly enhanced during the early period of neonatal development in the rat, suggesting that these receptors play a role in brain development. This study evaluated the postnatal treatment effects of D,L-AP3 on 1) EAA-stimulated Pln hydrolysis in brain slices 2) various behavioral tests including locomotor activity, auditory and tactile startle, and passive avoidance, and 3) gross pathology of the brain and visual system. Fiteen litters of CD rats were dosed i.p. (1 pury/sex/litter) on postnatal days 3-12 with 0, 125, 250, or 500 mg/kg/day D,L-AP3. Hippocampal slices from rats at different ages during and after D,L-AP3 treatment were examined for trans-(±)1-amino-1,3-cyclopentanedicarboxylic acid (ACPD)-stimulated Pln hydrolysis was greatly inhibited. However, in adult rats at all doses ACPD-stimulated Pln hydrolysis was not different from control. Auditory and tactile startle were increased in the 250 and 500 mg/kg D,L-AP3 groups at 19 and 38 days of age. In 21 and 30 day old rats, the 500 mg/kg D,L-AP3 groups at 19 and 38 days of age. In 21 and 30 day old rats, the 500 mg/kg D,L-AP3 groups at 19 and 38 days of age. Auditory and tactile startle were increased in the 250 and 500 mg/kg D,L-AP3 groups at 19 and 38 days of age. In 21 and 30 day old rats, the 500 mg/kg D,L-AP3 treatment impaired passive avoidance learning and increased motor activity, respectively. Retinal and optic nerve dysplasia was found in the 250 and 500 mg/kg D,L-AP3 dose groups, with severe atrophy of the optic nerve and chiasm at the higher dose. These studies show that dosing with D,L-AP3 during postnatal development inhibits the metabotropic EAA receptor in a reversible manner. This is associated with deficits in behavior and profound degeneration of the rat visual system.

THE MODULATION OF KAINATE RECEPTOR CHANNELS BY Ca IONS IN THE MODULATION OF NAMED RECEPTOR CHANNELS BY CA TONS IN ISOLATED TRIGEMENAL NEURONS OF RAT. Y.-P. Gu and L.-Y.M.Huang, Marine Biomed. Inst., Univ. of TX Med. Branch, Galveston, TX 77550.

The effects of divalent cations, especially Ca⁺⁺, on N-methyl-D-aspartate (NMDA) responses have been studied in many preparations. In contrast, the role of Ca⁺⁺ in non-MMDA responses is not well described. We have studied the permeation of Ca⁺⁺ and its blockade of kainate receptor permeation of Ca⁺⁺ and its blockade of kainate receptor channels in isolated trigeminal neurons using the patch clamp method. Under whole cell recording conditions, kainate responses were blocked substantially when 10-50 mM Ca⁺⁺ were included in the external solution. The equilibrium dissociation constant (Kd) for the Ca block of kainate channels was 30 mM. The blocking effect of Ca was slightly voltage dependent. The Kd increased e-fold per 127 mV depolarization. The electrical distance of the binding sites, δ , was 0.1. The affinity of kainate to its receptor, on the other hand, did not change in different Ca medium. With an increase in external Ca concentration, the reversal potential of kainate response shifted in the depolarizing potential of kainate response shifted in the depolarizing direction. The permeability ratio $P_{\rm Ca}/P_{\rm K}$ calculated from the shift was 0.20. These results suggested that kainate receptor channels were moderately permeable to ${\rm Ca}^{++}$, and the binding site for Ca was located near the extracellular surface of the kainate receptor channels. Supported by NS01050, NS23061, John Sealy Mem. Endow. Fund.

EFFECTS OF 2-AMINO-4-PHOSPHONOBUTYRATE (AP4) ON GUINEA PIG HIPPOCAMPAL SLICE PHOSPHOINOSITIDE (PI) TURNOVER.

S.J.Gibbons*1, P.J.Roberts1, A.C.Foster2, 1Dept. Physiology and Pharmacology, University of Southampton, U.K., 2Merck, Sharp and Dohme Neuroscience Research Centre, Harlow, Essex. U.K.

AP4 has both inhibitory and stimulatory effects on inositol monophosphate formation in guinea pig hippocampal slices (Gibbons and Roberts, <u>Br.J. Pharm.</u> in press). Some of its analogues possessed the same mixed effects as L-AP4 e.g. 1mM L-serine-O-phosphate (inhibition v ibotenate (ibo) 37.4% P<0.001 n=4, effect alone 148±7% n=6 P<0.05), other compounds were more potent inhibitors of PI turnover than L-AP4 but had no stimulatory effects (e.g. lmM 2-amino-4-arsenobutyrate: inhibition vs ibo 50% P<0.001 n=4, effect alone 101±3% n=4) whilst the ω -phosphino analogues (Fagg and Lanthorn, Br.J. Pharm. 86:743, 1985) only had stimulatory effects (5mM 134±8% n=4). The replacement of chloride ions by equimolar acetate reduced the stimulation of PI turnover by 1mM ibo (63% p<0.001), quis (68% p<0.001) and 3mM carbachol (56% p<0.001) but not 10mM L-AP4. From these results we conclude that AP4 has a weak non-specific stimulatory effect on guinea pig hippocampal PI turnover which is distinct from its inhibitory effect. Neither of these effects is comparable with the inhibition of synaptic transmission or chloride dependent glutamate binding by AP4 and its analogues. This work was supported by the SERC and MSD. The w-phosphino analogues were a gift of Dr.G.E.Fagg.

BETA-METHYL-AMINO-L-ALANINE (BMAA) ACTIVATES BETA-METHYL-AMINO-L-ALANINE (BMAA) ACTIVATES METABOLOTROPIC GLUTAMATE RECEPTORS IN BRAIN SLICES AND NEURONAL CULTURES. A. Copani*, P.L. Canonico.
M.V. Catania*, V. Bruno. E. Ratti#*. G. Gaviraghi#* and F. Nicoletti*. Institute of Pharmacology, Catania University School of Medicine, Catania, and #GLAXO Research Laboratories, Verona, Italy.

Although the effects of BMAA have been ascriwas much more potent in inhibiting [3H]glutamate binding than the binding of the selective NMDA ligand, [3H]CPP in rat brain membranes. This suggests the existence of a non-NMDA receptor component in the action of BMAA. Accordingly, BMAA potently increased inositol phospholipid (PPI) hydrolysis in both hippocampal slices and cultured cerebellar neurons. BMAA stimulated [3H]inositol-monophosphate formation to a much greater extent opnosphate formation to a much greater extent slices from newborn than from adult animals and its action was antagonized by L-AP4 and its action was antagonized by L-AP4 but not by D-AP5. BMAA was more potent and efficacious than glutamate and nearly as effective as ibote-nate or trans-ACPD. In cultured cerebellar neurons, stimulation of PPI hydrolysis by BMAA was largely insensitive to D-AP5 and was not reduced by Mg2+ ions. We conclude that BMAA acts as a potent agonist of metabolotropic glutamate receptors in the brain.

DESENSITIZATION OF METABOLOTROPIC GLUTAMATE CEPTORS IN NEURONAL CULTURES. M.V. Catania* Aronica*, A. Copani*, F. Nicoletti*, M.A. Sortino and P.L. Canonico. Institute of Pharmacology, University of Catania School of Medicine, Italy.

Pretreatment of cerebellar, cortical or hypothalamic neurons with glutamate reduced the stimutation.

lation of inositol phospholipid hydrolysis induced by subsequent addition of glutamate without affecting the response to carbamylcholine. Desensitization of metabolotropic glutamate receptors developed rapidly and persisted for a long time (24-48 hours) after removal of glutamate from the incubation medium. NMDA and quisqualate did not induce cross-desensitization, supporting the existence of two distinct metabolotropic glutamate receptor subtypes. Desensitization induced by a 30-min (but not 6-hour) preexposure to glutamate was attenuated by putative protein kinase C inhibitors, including the gangliosides GM, and GT, b, sphingosine and polymyxin B, but not by inhibitors of arachidonic acid metabolism, by the calpain inhibitor, leupeptin, or by the lectin, concanavalin A. These results suggest that desenintization of metabolotropic glutamate receptors involves, at least in its rapid component, activation of protein kinase C.

AP3 AND L-BMAA DISPLACE [3H]GLUTAMATE BINDING TO THE METABOTROPIC RECEPTOR. I.J. Cha. R.L. Makowiec, J.B. Penney, and A.B. Young. Neuroscience Program and Department of Neurology, University of Michigan, Ann Arbor, MI 48104-1687.

Michigan, Ann Arbor, MI 48104-1687.

A novel excitatory amino acid (EAA) receptor linked to phosphoinositide (PI) metabolism has been described. This "metabotropic" EAA receptor is activated by quisqualate, ibotenate, glutamate, and trans-1-amino-cyclopentyl-1,3-dicarboxylic acid (trans-ACPD). We have described an autoradiographic binding assay for the metabotropic receptor using [3+Ilplutamate as a ligand (Cha et al., Neurosci, Lett., in press). Binding to this receptor was distinguished by its low affinity for (R.S)-α-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid (AMPA) but high affinity for quisqualate, glutamate, ibotenate, and trans-ACPD. D.L-2-amino-3-phosphonopropionate (AP3) has been reported to be a relatively selective inhibitor of EAA stimulated PI hydrolysis (Schoepp and Johnson, J. Neurochem., 53:273-278, 1989). AP3 inhibited [3+Ilglutamate binding to the metabotropic receptor with an IC₅₀ = 190±30 μM. This IC₅₀ is consistent with reports of AP3 inhibition of EAA stimulated PI hydrolysis and suggests AP3 may be a useful pharmacological tool in studying the metabotropic receptor.

may be a useful pharmacological tool in studying the metabotropic receptor

The plant neurotoxin β-N-methylamino-L-alanine (L-BMAA) has been implicated in the pathogenesis of amyotrophic lateral sclerosis-Parkinsonismdementia of Guam. L-BMAA has recently been found to stimulate PI hydrolysis via the metabotropic receptor (Nicoletti et al., <u>Eur. J. Pharmacol.</u>, in press). L-BMAA inhibited binding to the metabotropic receptor with an $IC_{50} = 2113 \,\mu\text{M}$. These data support the idea that L-BMAA can activate metabotropic receptors and raises the possibility that metabotropic receptors may participate in

neurodegenerative processes.

ENHANCEMENT OF SYNAPTIC RESPONSES IN AREA CA, OF THE HIPPOCAMPUS BY SELECTIVE ACTIVATION OF THE ACPD SUBTYPE OF EXCITATORY AMINO ACID RECEPTOR. M.A. Desai and P.J. Conn. Dept. of Pharmacology and Div. of Neuroscience, Emory Univ. Atlanta, GA 30322.

Evidence suggests that an excitatory amino acid (EAA) receptor subtype exists that employs phosphoinositide hydrolysis for signal transduction. This receptor is clearly distinct from NMDA, kainate, and quisqualate receptors and has been named the ACPD receptor (Monaghan et al. (1989) Ann. Rev. Pharmacol. Toxicol. 29:365). This is based on the finding that the glutamate analogue trans-ACPD (trans-1-amino-1,3-cyclopentanedicarboxylic Neurosci. Lett. 109: 157; Palmer et al. (1990) Eur. J. Pharmacol. 166: 585). To investigate the physiological role of this receptor, we measured the effects of trans-ACPD on extracellular field potentials in area CA1 of rat hippocampal slices. trans-ACPD induced a transient increase in the amplitude of population spikes in area CA₁ in response to stimulation of the Schaffer collateral.

Concentrations of *trans*-ACPD that are effective in stimulating phosphoconcentrations of trans-ACPD that are enective in stimulating phospholosinositide hydrolysis increased population spike amplitude in 21 of 22 slices investigated (mean increase = 74.4 ± 11.9%; range = 14.3% - 172%). In addition, trans-ACPD induced formation of a second population spike in 15 of 22 slices. In 3 of these slices, 3 or more population spikes were observed. These effects occurred in the absence of a change in the initial slope of field EPSPs measured in the stratum radiatum. These data suggest that activation of the ACPD receptor enhances responses at the Schaffer collateral-CA1 synapse. It is likely that this effect is not mediated by an increase in glutamate release but involves changes in pyramidal cell excitability or blockade of recurrent inhibition. Supported by P.M.A. Foundation, Emory Univ. Research Committee, and N.I.H. (NS28405-01 and BRSG S07 RR05364).

TRANSMITTERS IN INVERTEBRATES II

232.1

RELEASE OF A MODULATORY NEUROPEPTIDE FROM CULTURED APLYSIA NEURONS. J.D. Hall and P.E. Lloyd. Dept. Pharm. Physiol. Sci., Univ. of Chicago, Chicago, IL 60637.

Pedal peptide (Pep) is a prevalent neuropeptide in Aplysia. It is found throughout the CNS, but is predominantly localized to a band of more than 60 neurons on the dorsal surface of each pedal ganglion. We have previously shown that Pep has a modulatory effect on foot muscle during Aplysia locomotion. Specifically, it increases the amplitude and relaxation rate of foot muscle contraction.

Examination of Pep release upon stimulation of pedal nerves has proven to be difficult due to the proteolytic activity of the foot tissue and the hemolymph. In an attempt to circumvent these problems we have set up a system for the primary culture of individual Pep-neurons isolated from the pedal ganglia dorsal cluster. This allows an *in vitro* analysis of the release of pedal peptide. After several days in culture these cells regenerated neurites which exhibited extensive branching and contained many large varicosities and growth cones. Both the neurites and the growth cones exhibited Pep-immunoreactive staining. Neurons were labeled for 48 hr in a medium containing ³⁵S-methionine. Liquid scintillation counting of HPLC fractions of these neurons has shown that radiolabeled Pep was synthesized in these cells and was transported into the regenerated neurites. In addition, following intracellular stimulation of cultured Pep-neurons, radiolabeled Pep was detected in the releasate. Thus, we have seen synthesis, transport, and release of pedal peptide by cultured Pepneurons. Supported by NS 23569. 232.2

IDENTIFICATION OF APLYSIA MOTOR NEURONS THAT EXPRESS MODULATORY

PEPTIDES. P. J. Church and P. E. Lloyd. Committee on Neurobiology, The University of Chicago, Chicago, Il 60637.

Neuropeptide synthesis was determined for individual identified ventral cluster neurons in buccal ganglia of Aplysia. These cells were motor neurons (MNs) which innervate buccal muscles that generate biting and swallowing movements during muscles that generate biting and swallowing movements during feeding. Individual neurons were identified by a battery of physiological criteria, stained with intracellular injection of fast green, and the ganglia incubated in ³⁵S-methionine for 24 hr. Peptide synthesis was determined by measuring the appearance of labeled peptides by HPLC of extracts from individual neurons. Five identified peptides were observed to be synthesized by individual neurons including buccalin, FMRFamide, myomodulin, and the 2 small cardioactive peptides (SCPs). Each of these neuropeptides has been shown to (SCPs). Each of these neuropeptides has been shown to modulate responses of the muscles of the buccal mass. Identified neurons consistently synthesized the same peptide(s), however, neurons consistently synthesized the same peptide(s), however, MNs which innervate the same muscle often expressed different peptides. Neurons which synthesized SCPs also contained SCP-like activity as determined by snail heart bioassay. Our results indicate that every MN synthesized a subset of the 5 methionine-containing peptides. In addition, several neurons consistently synthesized multiple peptides likely to be processed from separate precursors. Supported by NS 23569.

THE SEROTONERGIC HEART EXCITER NEURON, RBHE OF APLYSIA CALIFORNICA SYNTHESIZES R15α2 PEPTIDE. M.E. Skelton, K.R. Weiss & J. Koester, Center for Neurobiology and Behavior, Columbia University, 722 W 168 St., New York, N.Y. 10032.

The neuron R15 in the abdominal ganglion of Aplysia expresses an mRNA that is translated into R15α1 neuropeptide. The precursor for this mRNA is spliced differently in other neurons to encode R15α2 peptide (Buck et al., 1987). This study aims to determine the identity and function of neurons that express R15α2 peptides.

Karagogeos et al. (1989) raised 2 antibodies that recognize R15α1 and R15α2 peptides. Antibody 1 binds only to R15α1 peptide; antibody I/II binds to both peptides. Alevizos (1989) found that both antibodies label processes in the heart and both peptides are cardioexcitatory, R15 has been shown to innervate the heart, so some cardiac immunoreactivity is likely to be present in R15's processed due to R15α1 peptide. We attempted to determine whether other neurons also contribute to the immunoreactivity in the heart.

One neuron that bound antibody I/II appeared from its location and size to be RBμΕ, the serotonergic heart exciter. We confirmed this by identifying RBμΕ physiologically and labeling it with lucifer yellow before double-labeling it with antibody I/II. We assumed that the antibody labeled R15α2 peptide in this case, because antibody I does not bind to RBμΕ (Alevizos, 1989). To test this hypothesis, ganglia were incubated in the presence of 35S-methionine, RBμΕs were dissected, pooled and ran on 3 different reverse phase HPLC gradients. In each case a peak of radioactivity coeluted with synthetic R15α2 peptide, confirming that RBμΕ synthesizes R15α2 peptide. Thus, R15 may use 5-HT and R15α2 peptide derived from RBμΕ innervation. The effects of R15α1 and R15α2 peptide derived from RBμΕ innervation. The effects of R15α1 and R15α2 peptide derived from RBμΕ innervation. The effects of R15α1 and R15α2 peptide derived from RBμΕ innervation. The effects of R15α1 and

DISTRIBUTION OF GABA IN THE PLEURAL-PEDAL GANGLIA OF APLYSIA. L.J. Cleary and T. Li*. Dept. of Neurobiology and Anatomy, Univ. Texas Med. School, Houston, TX 77225.

Sensory neurons mediating the tail-siphon withdrawal reflex in Aplysia receive no spontaneous synaptic input. They are hyperpolarized, however, when a stimulus is applied outside their receptive fields. GABA is one transmitter that could elicit is applied outside their receipter fields. OADA is one transmitted that could each this hyperpolarization. As a first step towards investigating a role for GABA-circ neurons in tail-siphon withdrawal, we examined the distribution of GABA-like immunoreactivity in the pleural and pedal ganglia. Adult ganglia were sectioned serially with a cryostat and stained with conventional immunocytochemical techniques. In addition to immunoreactivity in these two ganglia, we found GABAergic processes in the cerebral, buccal and abdominal ganglia.

In the pleural ganglion, there are a small number of immunoreactive neurons scattered irregularly through the medial cluster. In the neuropil, the majority of immunoreactive processes are located at the root of the pleural-abdominal connective. The cell bodies of the tail sensory neurons do not receive axosomatic input from GABA-containing neurons. Thus, the distribution of GABA differs markedly from the modulatory transmitters 5-HT, SCP_B and FMRFamide. In the pedal ganglion, there are several clusters of immunoreactive cell bodies. Although variable, these clusters are generally located on the surface of the neuropil at the base of pedal nerves, the pedal commissure and the cerebral-pedal connective. Immunoreactive processes within the neuropil project toward peripheral nerves, but end in dense arborizations that may extend 200-700 µm into the proximal segment of the nerve. Fibers exit the ganglion primarily through the pedal commissure or the cerebral-pedal connective. These results suggest that GABAergic neurons in the pleural-pedal ganglia are primarily interneurons. While they do not appear to synapse on tail sensory neurons within the pleural ganglion, GABAergic neurons could make synapses as the sensory neurons traverse or exit the pedal ganglion.

THE SEARCH FOR A CLASSICAL TRANSMITTER IN A PEPTIDERGIC INTERNEURON. K. McKenney. N.I. Sved. A.G.M. Bulloch. Department of Medical Physiology, University of Calgary, 3330 Hospital Dr. N.W., Calgary, Alberta, T2N 4N1, Canada.

The goal of this research project is to determine the identity of colocalized transmitters. We have chosen for study an identified interneuron in the snail, Lymnaca stagnalis, that plays a role in coordinating many rhythmic behaviors. VD4 makes predictable excitatory, inhibitory or biphasic synaptic connections with more than 30 identifiable follower neurons. VD4 was previously shown to contain the neuropeptide FMRFamide and related peptides using immunohistochemical and radioimmunoassay techniques. When FMRFamide (10⁻⁶ M) is bath applied over isolated brain preparations in a low Ca⁺⁺ (0.1 mM)/high Mg⁺⁺ or normal saline many of VD4's follower neurons are hyperpolarized. In none of the cells tested, including neurons which are strongly excited by VD4, was FMRFamide excitatory. The above indicates that the excitatory actions of VD4 are brought about by a second transmitter. To test whether the excitatory actions of VD4 are mediated by a classical transmitter, various putative transmitters were bath perfused over isolated brain preparations while recording intracellularly from follower neurons that are excited by VD4. Of the transmitters tested, which include acetylcholine, glutamate and glycine, the amines (octopamine, serotonin and dopamine) were best able to mimic the excitatory actions of VD4.

The results from these initial experiments suggest that VD4 may use more than new classical neurotransmitter.

The results from these initial experiments suggest that VD4 may use more than one classical neurotransmitter, in addition to FMRFamide. Alternatively, VD4 is using an excitatory neuropeptide which has yet to be determined. Either way, VD4 promises to be an excellent neuron for studying cotransmission at a neuro-neuronal

Supported by MRC (Canada), AHFMR and NSERC.

THE DISTRIBUTION OF IMMUNOREACTIVE FMRFAMIDE IN NEURONAL FIBERS, VARICOSITIES, AND SOMATA IN THE HEART OF THE SEA HARE, APLYSIA CALIFORNICA. L. L. Harris* and J. K. Ono. Dept. of Biological Science, California State University, Fullerton, CA 92634.

The tetrapeptide FMRFamide, The tetrapeptide FMRFamide, first isolated using a molluscan heart as a bioassay, has been shown to be present in the CNS of the sea hare, <a href="https://documents.org/length://docu heart is being investigated. Immunohistochemical localization of the peptide indicates that immunoreactive (IR) nerve fibers, varicosities, and neuronal somata occur in the Aplysia heart. and neuronal somata occur in the <u>Aplysia</u> heart. Despite earlier studies indicating that FMRF-amide affects the mechanical activity of the ventricle, the most dense innervation appears to occur in the auricle and especially in the AV and aortic valves. FMRF-amide-IR neuronal somata in the areas near the valves indicate that the heart also contains intrinsic neurons that may play a role in modulating cardiac activity. (Supported by D.A.C. grants to L.L. Harris)

THE DISTRIBUTION OF CARDIOACTIVE TRANSMITTERS IN THE HEART AND NERVOUS SYSTEM OF THE NUDIBRANCH, <u>Archidoris montereyensis</u>.

B.L. Wiens and P.H. Brownell. Oregon State University, Corvallis, OR. 97331. The heart of the nudibranch mollusc Archidoris montereyensis is regulated by at least five excitatory and inhibitory motor neurons located in the right pleural and visceral ganglia. We are currently interested in determining the transmitters that mediate the actions of these neurons on the heart. A number pleural and visceral ganglia. We are currently interested in determining the transmitters that mediate the actions of these neurons on the heart. A number of common molluscan cardioactive transmitters are active when bloassayed on an isolated preparation of the *Archidoris* heart. The aminergic transmitters serotonin and dopamine (thresholds = 10°-10° M), and the peptides SCP₈ (10°-10° M) and FMRF-NH₂ (10°-10° M) excite the heart, while acetylcholine (10°-10° M) inhibits the heart. Using whole-mount immunocytochemical techniques we have mapped the distribution of serotonin, FMRF-NH₂, and SCP₈ in the heart and CNS. The pericardial nerve, which innervates the heart and other visceral organs, contains processes immunoreactive (-ir) for all 3 transmitters. However, only serotonin-ir and FMRF-NH₂-ir processes are present in cardiac tissues. Nerves containing serotonin-ir appear to terminate diffusely throughout the ventricle and attrium with a concentration of terminals on the atrio-ventricular valve. FMRF-NH₂-ir processes densely innervate the anterior aorta, the aortic and atrio-ventricular valves, and the efferent gill vein, but not ventricular or attrial muscle. Preliminary studies in the CNS indicate that the right pleural ganglion contains neurons immunoreactive for all 3 transmitters, but only FMRF-NH₂ antisera appears to label cells in the region of the heart motor neurons. Additionally, each of the antibodies labeled processes, but not neurons, within the visceral ganglia. In summary, the differences in the pattern of serotonin and FMRF-NH₂-ir processes and physiological studies of the respective actions of these transmitters. (NIH fellowship #MH09818-02, Sigma Xi)

NOVEL NEUROPEPTIDES REVEALED BY CDNAS CLONED FROM Helix aspersa NERVOUS SYSTEM.

NOVEL NEUROPEPTIDES REVEALED BY CDNAS CLONED FROM Helix aspersa NERVOUS SYSTEM.

EM. Lutz, W. Lesser, M. Macdonald* and J. Sommerville*. Dept. of Biology, Univ. of St. Andrews, Fife KY16 9TS, Scotland; Whitney Lab, St. Augustine, Fl. 32086-8623.

Two tetrapeptides (FMRFamide and FLRFamide) and five heptapeptides (pQDPFLRFamide, NDPFLRFamide, NDPFLRFamide, SDPFLRFamide, SEPYLRFamide, Properties of the snail Helix aspersa. All seven FMRFamide analogues are cardioactive in Helix, though they have different potencies. These peptides are also active on other Helix muscles and neurones. Evidence from immunohistochemistry, HPLC and RIA suggests that the tetrapeptides and heptapeptides have different distributions within Helix issues.

To determine how these analogues are organized on the precursors, we have isolated and sequenced a series of CDNA clones derived from mRNA of the Helix CNS. Clone HF1 (1.9 kb) encodes 10 copies of FMRFamide and 1 copy of FLRFamide, each flanked by basic amino acids (potential cleavage sites). The peptides are spaced out over a total length of ~150 amino acids by acid-rich regions. Clone HF4 encodes only N-terminally extended forms of FLRFamide. In addition to the heptapeptides previously described, 3 novel neuropeptides are found: pQDPFLRIamide (2 copies) and putative peptides of 9 and 16 residues. The extended forms all follow on immediately from a hydrophobic signal sequence and are tightly organized with no acidic spacers. Hybridization experiments indicate that the two clones are derived from different mRNA molecules and that the mRNAs are transcribed from separate genes.

The 9 and 16 residue peptides are also cardioexcitatory in Helix, with their apparent potencies in line with those of the other peptides; pQDPFLRamide is currently being synthesized.

Funded by SERC grant GR/F 33889 (EML, MM and JS) and NIH grant HL28440 (WL).

EFFECT OF NEUROTRANSMITTERS ON CELL F1 OF THE LAND SNAIL HELIX ASPERSA IN PRIMARY CELL CULTURE. Seema Tiwari* and Michael L.Woodruff. Department of Chemistry and Biochemistry, Southern Illinois University, Carbondale, IL 62901-4409.

The giant F1 cell of *Helix aspersa* circumoesophageal ganglia exhibits endogenous oscillatory activity. Bursts of action potentials oscillate with interburst hyperpolarizations. The frequency and pattern of the bursts can be modulated by different neurotransmitters and analogues of cyclic GMP and cyclic AMP.

Primary cell culture of F1 cells from adult organisms has been difficult. In this study cells were mechanically dissociated from ganglia without the aid of enzyme digestion and plated onto polylysine coated coverslips in "co-culture" with Helix ganglia (1 ganglion/ml of solution) in conditioned Helix media. The F1 grow processes (3 to 5) and have resting potentials between -70 mV and -80 mV. Cells can be recorded from multiple times and used for several days (placed back in culture overnight) before they show deterioration. When the F1 are exposed to 5-HT and forskolin they depolarize to between -40 mV and -50mV and fire action potentials spontaneously (beating). After the addition of both 5-HT and dopamine the F1 show "oscillatory" activity with small bursts of actions potentials (2 or 3) alternating with hyperpolarizations.

THE GENITAL GANGLION OF THE SNAIL MELAMPUS BIDENTATUS CONTAINS NEURONS IMMUNOREACTIVE TO THE PEPTIDES aBCP, SCPB, BUCCALIN, AND CARP. S. B. Moffett. Dept. of Zoology, Washington State Univ., Pullman, WA 99T64-4236.

The family of peptides associated with egg-laying in

The family of peptides associated with egg-laying in Aplysia and Lymnaea has been studied in bag cells/caudodorsal cells in the CNS as well as in nonneural tissue. When an antibody to alpha bag cell peptide (aBCP) was used to map the Melampus CNS and reproductive organs, the genital ganglion was discovered. A pair of large neurons, a bilaterally symmetrical cluster and an unpaired right cluster are in the cerebral ganglia. Neurons probably homologous to bag cells/caudodorsal cells are in pleural and visceral ganglia and along nerves innervating reproductive organs, but many more aBCP immunoreactive neurons are in the genital ganglion. It is strategically located for control of gamete release at the juncture of the genital nerve with the common duct; it fans out in the region of the hermaphroditic duct, mucus gland and albumen gland and innervates spermoviduct, ovotestis, oviduct and vas deferens. The ganglionic nature of the genital ganglion is evidenced by the presence of neurons with other transmitter immunoreactivities, including SCPB, buccalin, catch relaxing peptide (CARP) and by projections into the ganglion of 5-HT and FMRFamide immunoreactive axons. The genital ganglion may be the site of neural coordination of gamete release. (Supported in part by NS27514 to J.E. Blankenship and NS22896 to SBM.)

ISOLATION AND IDENTIFICATION OF SCPs IN BIVALVED MOLLUSCS. A. Candelario*, D.A. Price, K.E. Doble* and M.J. Greenberg.

The Whitney Lab, Univ. of Florida, St. Augustine, FL 32086-8623.

Greenberg. The Whitney Lab, Univ. of Florida, St. Augustine, FL 32086-8623.

Using an RIA with an antiserum raised to SCP_B, a neuropeptide from Aphysia, we have purified related peptides from a clam, Mercenaria mercenaria, and have characterized them by FAB mass spectroscopy and by sequencing. At least two SCP-like peptides occur in the clam: YFAFPROA (927 da) and IAMSFYFPRMa (1277 da); another peptide, AMSFYFPRMa (1148 da), may be a fragment formed during purification. The 1277 da decapeptide has the same C-terminal tetrapeptide amide as that of the gastropod SCPs; but YFAFPROA has a Gin substituted for the terminal Met residue and is quite distinct, notwithstanding its clear homology to SCP_B (MNYLAFPRMamide). The same three peptides have been detected in each of several clam tissues examined separately, so there is no evidence of tissue specific expression or processing. Immunohistochemical staining with a monoclonal antibody raised to SCP_B revealed conspicuous staining in cell bodies and fibers in the visceral ganglion, and less so in the cerebral and pedal. Nerve fibers innervating muscle in the rectum were also stained. Low doses of synthetic clam SCPs relaxed the rectum (threshold, <10⁴ M), but higher concentrations (>10⁴ M) contracted the tissue or produced a biphasic response. These actions, and the immunohistochemical localization, are reminiscent of the putative role of the SCPs as modulators of feeding in gastropods. The clam peptides had virtually no effect, at moderate doses, on cardiac or somatic muscles of Mercenaria. Funded by NIH grant HL28440.

232.10

SEASONAL VARIATIONS OF IR-MET AND IR-LEU ENKEPHALIN CONTENT IN THE PERIO-ESOPHAGEAL GANGLIA OF HELIX ASPERSA. R.Gutiérrez and M.Asai*, Lab. Neuro-physiol. Neurosci. Div. Instituto Mexicano de Psiquiatría, México 14370.

Increasing body of evidence suggests the presence of opioid mechanisms in invertebrates. In molluscs, it has been proven that opioid agonists and antagonists exert a number of behavioral and electrophysiological res ponses, though there are some reports on the lack of effects of opioids at both levels. This lack of effects can be explained if one considers the high dependence of these animals on environmentally precipitated and endogenous rhythmic physiological changes. In order to determine the pres ence of opioid peptides and their possible seasonal variation in the terrestrial snail <u>Helix aspersa</u>, we carried out radioimmunoassays with speci-fic antisera risen for mammalian Met— and Leu-enkephalins. A pool of 20 perioesophageal ganglia were monthly dissected from snails kept in labora tory conditions. They were divided into three regions: ventral, dorsal, and cerebroid ganglia. IR-Met and IR-Leu enkephalin contents were determined for each pool and the results were expressed in IR-pmol/g tissue. Our results show: A) A clear variation in both IR-Met and IR-Leu enkephalin contents, being January, May, and August the months where peak concentrations are reached. March, June and December have the lowest contents, B) A higher content of Leu-Enkephalin than that of Met-enkephalin is evident in all the CNS regions throughout the year. C) Met-enkephalin contents are higher in the ventral ganglia and no clear regional differences were observed in regard to Leu-Enkephalin. These results provide evidence of the presence of Met- and Leu-Enkephalins in the CNS of Helix aspersa. Moreover, these peptides appear to vary throughout the year showing se sonal peaks. It is noteworthy to point out a striking resemblance of this pattern of variation found in opioid binding studies in other mollusc species (Stefano and Leung, CRC Handbook Com. Opioid. Vol I, 1986).

232.12

IDENTIFICATION OF A FMRFAMIDE-LIKE PEPTIDE BINDING PROTEIN IN SQUID NERVOUS TISSUE. K.Payza, D.A.Price#, M.J.Greenberg# and G.J.Chin*. Laboratory of Developmental Neurobiology, NIH, Bethesda, MD 20892 and #C.V.Whitney Laboratory, University of Florida, St. Augustine, FL 32086.

The neuropeptide FMRFamide and FMRFamide-like peptides have been identified in many animals. As a first step towards molecular characterization of the molluscan FMRFamide receptor, we undertook to identify a binding protein in squid (*Loligo pealii*) optic lobes, which have been shown to contain immunoreactive FMRFamide that co-eluted with the authentic peptide on reverse-phase HPLC. A photoreactive analogue of FMRFamide was synthesized, radio-iodinated and purified by HPLC. This ligand was incubated at 4°C with a crude membrane fraction and irradiated to effect covalent attachment. The membranes were washed and analyzed by SDS gel electrophoresis and autoradiography. Incorporation of radioactivity into a 52,400 dalton protein was reduced by incubation in the presence of 100 µM acFnLRFamide.

232.14

OCTOPAMINE-IMMUNOREACTIVE NEURONS IN INVERTEBRATE NERVOUS SYSTEM. T. Karhunen* and P. Panula. Department of Anatomy, University of Helsinki, Siltavuorenpenger 20 A, Helsinki, Finland.

Octopamine acts as a neurotransmitter in invertebrate nervous system, but the anatomy of the octopamine-containing neuron systems is poorly known. Antisera against octopamine conjugated to hemocyanin with carbodlimide were produced in rabbits, and the specificity of the antisera was established with dot-blot tests on nitrocellulose membranes.

For immunocytochemistry, specimens of two molluscan species, Mytilus edulis (Bivalvia) and Macoma balthica (Bivalvia) and common earthworm (Oligochaeta) were fixed by immersion in 4% carbodiimide overnight and washed in buffer overnight. In cryostat sections, octopamine-immunoreactive neurons were found in the ganglia of all species studied. The distribution of octopamine in the pedal ganglion of Macoma differed from that of histamine, GABA and taurine. Adsorption studies indicated that GABA and histamine did not affect the staining, while octopamine completely abolished all immunoreactivity. The results suggest that the method enables detailed studies on the organization of octopamine-containing systems.

EXPRESSION OF OCTOPAMINE RECEPTORS IN DROSOPHILA. L. M. Hall, F. Hannan*, J. Pursey*, and D. Urquhart. Dept of Biochem. Pharmacol., SUNY AT BUFFALO, BUFFALO, NY 14260.

Octopamine is a neurotransmitter, neuromodulator, and neurohormone in invertebrates. Three pharmacologically distinct receptor subtypes (octopamine 1, 2A & 2B) have been defined in locust using adrenergic agonists and antagonists (Evans, P.D., L. Physiol., 318:99, 1981). An octopamine-1 receptor cDNA (OctoR1) has recently been cloned and sequenced from *Drosophila* (Arakawa, S. et al., Neuron, 2:343, 1990). This cDNA hybridizes at high stringency to four distinct poly A+ mRNA species. The expression of two of these (3.7 kb and 4.2 kb) is greatly enriched in heads and is also developmentally regulated. Expression of the 3.7 and 4.2 messages is first detected during nervous system formation in 11 to 22 hour old embryos. Expression is seen throughout the larval stages. It decreases at the time of initial pupae formation but rises after 24 hours and is seen throughout the pupal phase of the life cycle. A 2.7 kb mRNA is enriched in bodies and a 1.4 kb mRNA is present in all tissues. PCR technology has been used to amplify DNA across the intracellular loop between transmembrane segments III and VI using either genomic or cDNA as a template. The expected product from this reaction using OctoR1 as a template is 1 kb. With wildtype genomic DNA as the template, 7 distinct DNA fragments ranging in size from 0.4 kb to 1.7 kb were produced. Only the 1.7 kb fragment hybridized at high stringency to OctoR1, suggesting the OctoR1 gene contains an intron in this region. Some of the other products may correspond to other members of the octopamine receptor family. Wild-type cDNA prepared from head mRNA produced a major fragment of 1 kb corresponding to OctoR1 and a minor product of 0.8 kb. None of the products hybridized to a *Drosophila* muscarinic receptor probe under high stringency conditions. The major products will be analyzed using asymmetric PCR and fluorescence based sequencing and localized to the chromosome using in situ hybridization to determine which are receptor genes and where they map in the genome.

232.17

CHARACTERIZATION OF MUSCARINIC BINDING SITES IN THE COCK-ROACH BRAIN. G.L. Orr, N. Orr and R.M. Hollingworth*. Pest Res. Ctr., M.S.U. (Neurosci. Prog.) E. Lansing, MI, 48824 Muscarinic acetylcholine-receptors in cockroach brain

Muscarinic acetylcholine-receptors in cockroach brain were characterized using the muscarinic antagonist, ³H-quinuclidinyl benzilate (QNB). QNB bound saturably with low levels of non-specific binding (defined with atropine). Scatchard and Hill analysis indicated a single population of non-interacting receptor sites (Kd=0.25 nM, Bmax=604 fmoles/mg, Hill coeff.=0.97). The kd values calculated from kinetic data indicated a high affinity (kd=0.02 nM) and a lower affinity (kd=0.23 nM) population of binding sites. Displacement studies defined the muscarinic nature of the QNB binding site(s) and compounds selective for vertebrate muscarinic receptor subtypes displayed an order of effectiveness similar to vertebrate MI receptors but the absolute affinities of these compounds were at least an order of magnitude lower than expected for MI receptors. Analysis of these displacement curves provided no evidence for multiple binding sites for the selective compounds. Displacement of QNB by carbachol was modulated by Mg²⁺ and GppNHp indicating the presence of a G protein associated with this receptor site. Autoradiographic analysis of brain slices showed QNB-binding sites to be heavily concentrated in the calyces but to be absent from other neuropile areas in the brain. QNB-binding was also visualized in the neuropile of the sixth abdominal ganglion.

232.19

CHARACTERIZATION OF AN INSECT CELL LINE AS A MODEL FOR STUDYING OCTOPAMINE RECEPTORS. N. Orr, G.L. Orr and R.M. Hollingworth*. Neuroscience Prog./Dept. of Zoology and Pesticide Research Center, Michigan State University East Lansing, MI 48824

The Sf9 cell line (American Type Culture Collection, MD) derived from Spodoptera frugiperda ovarian tissue is readily grown in culture. In order to evaluate it as a ready source of octopamine (OA) receptors, its responses to biogenic amines were characterized. A radioimmunoassay was used to measure changes in cyclic AMP (cAMP) levels. In intact cells, 100 uM OA increased cAMP levels 3X over control, whereas dopamine and serotonin were without effect. This OA-mediated production of cAMP was blocked in the presence of 10 uM phentolamine. The diterpene forskolin (10uM), enhanced cAMP production 4.4X over control.

Washed-membrane preparations of Sf9 cells exhibited dose-dependent stimulation of cAMP in the presence of forskolin, sodium fluoride and ${\sf Gpp}({\sf NH})p$. The OA-mediated cAMP production (Ka=0.3 uM) was GTP-dependent and enhanced in the presence of 0.5 uM forskolin. It is apparent from the absence of interfering amine-sensitive adenylate cyclases and the pharmacology of the OA-mediated response, that the Sf9 cell line may be a good candidate for reliably and easily screening the adenylate cyclase coupled OA-receptor and for further studies to characterize the receptor and its signal transducation mechanisms.

RECEPTORS FOR EXCITATORY AMINO ACIDS IN THE INSECT CENTRAL NERVOUS SYSTEM K.A. Wafford, M-I. Sepulveda* & D.B. Sattelle, AFRC Lab. of Molecular Signalling, Dept. of Zoology, Univ. of Cambridge, Cambridge, CB2 3EJ, U.K.

An identified neuronal cell body in the cockroach (Periplaneta americana) has been used to examine the effects of a number of excitatory amino acids. On this cell at resting membrane potential (-60 to -80mV), glutamate elicited a fast hyperpolarization, sometimes followed by a longer, smaller depolarization, which was more apparent at high concentrations (1.0mM). Reversal at the chloride equilibrium potential and dependence on external chloride ions indicated a glutamate-activated chloride channel. Cross-desensitization experiments and antagonist studies showed that glutamate activated a receptor distinct from that operated by GABA. Ibotenate and aspartate mmicked the chloride-mediated response, while quisqualate and kainate application produced small, slow depolarizations. Other agonists such as NMDA and homocysteate, which are active on vertebrate preparations were inactive on this insect neurone. A number of non-NMDA type receptor antagonists were tested and found to be active only at concentrations higher than 100uM. Thus there are at least two distinct glutamate receptor subtypes in the insect central nervous system, that do not readily correlate with those described in vertebrates, and in this case are co-localized on the same cell.

232.18

VENTRAL GIANT INTERNEURON SYNAPSES TO THORACIC INTERNEURONS IN THE COCKROACH ARE CHEMICAL AND CHOLINERGIC.

J.L. Casagrand and R.E. Ritzmann. Dept. of Biology, Case Western Reserve University, Cleveland, OH 44106.

We are interested in how populations of neurons are organized to generate a defined behavior. We have been investigating several thoracic interneurons (TIs) in the cockroach which receive inputs from ventral glant interneurons (vGIs). Type A TIs follow the vGIs with short latency at high frequencies (up to 20 Hz). Previous morphological and developmental studies indicated that this input is direct. These connections are important in the integration of directional wind information involved in determining the escape response. In an attempt to learn more about the integration process, we have begun to investigate the biochemical nature of these connections.

We report here on several experiments that provide evidence that the vGI to TI connections are chemical and that the transmitter involved is acetylcholine (ACh). Injection of hyperpolarizing or depolarizing current into the postsynaptic TIs resulted in an appropriate alteration in PSP amplitude. In addition, bathing cells in zero calcium saline resulted in a gradual decrement of the PSP, and ultimately block of synaptic transmission. The response recovered when calcium was replaced. To identify the actual transmitter used at these synapses, we tested the actions of various cholinergic drugs on vGI input to type A TIs. ACh is a major excitatory neurotransmitter in insects, and is known to be the transmitter at the synapses between sensory neurons and vGIs. We found that cholinergic antagonists reversibly blocked transmission at concentrations similar to those previously reported for nicotinic synapses in insects indicating that the transmitter released by vGIs at these synapses is also ACh.

USE OF FLUORESCENT TRACERS TO IDENTIFY LIVING PREGANGLIONIC CARDIAC MOTORNEURONS IN THE MEDULLA. D. Mendelowitz and D.L. Kunze. Dept. of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX 77030.

Neurophysiological studies of preganglionic cardiac motorneurons (PCMs) have generally relied upon antidromic stimulation techniques to identify these neurons in the medulla. These in vivo preparations have been limited in that only extracellular recordings are typically possible. To characterize the spontaneous and synaptically evoked ionic currents in these neurons, and identify the neurotransmitters that influence PCM activity, either a slice or dissociated preparation is necessary. As a preliminary step to studying dissociated PCMs we have examined various fluorescent dyes to determine which can be taken up by the PCM terminals in the heart, transported to the soma in the medulla and retained in the neuron during slicing and/or dissociation.

terminals in the heart, transported to the soma in the medulla and retained in the neuron during slicing and/or dissociation.

Rats were anesthetized with pentobarbital, respirated and a right thoracotomy was performed to expose the heart. Fluorescent dyes were applied to the epicardial surface of the atrial muscle. After a 3-5 day survival period the animals were sacrificed, perfused with fixative and the medulla was examined for labeled PCMs. Rhodamine (XRITC, Molecular Probes) was very effective, labeling 80-120 PCMs in the nucleus ambiguus and 5-15 PCMs in the vagal nucleus per rat. In contrast, fluorescent dextrans (10,000 and 70,000 mol. wt.) were ineffective. Rhodamine (XRITC) has also been used to identify labeled PCMs in living slices 150 microns thick. These results demonstrate that fluorescent dyes can be used to select identified PCMs for study in either a "thin-slice" or dissociated preparation.

ROSTRAL VENTROLATERAL MEDULLARY (RVL) LESIONS AFFECT PLASMA CATECHOLAMINES IN THE CONSCIOUS DOG K.J. Dormer, R.D. Stith*, R.E. Papka and A.F.Sved. Depts. Physiol. and Anat. Sci., Oklahoma Univ.,Okla. City, OK 73190 and Dept. Behav. Neurosci., Univ. Pittsburgh, Pittsburgh, PA 15260.

To further identify the role of RVL as a vasomotor center in regulation of arterial pressure (AP) 6 chronically instrumented dogs were observed before and after partial excitotoxin (kainic acid, 75-100 nl, 100 mM) lesions were made in RVL. Resting AP and heart rate (HR) were obtained from aortic solid-state pressure transducers while norepinephrine (NE) and epinephrine (E) were determined by radioenzymatic assay of venous plasma amples. Subsequent immunocytochemical staining for phenylethanolamine N-methyl transferase documented the extent of RVL lesions. Mean ± S.E. results include:

	NE (pg/ml)	E (pg/ml)	AP (mmHg)	HR (bpm)
pre	228±102	47±27	100±5	89±8
nost	276+71	33+13	88+4	101+9

Two way analysis of variance with repeated measures indicated the means were probably different (F=2.99), there was a significant difference between the pre- and post lesion states (F=0.017) and there was significant interaction between variables (F=0.10). HR always increased when AP decreased after lesions. Postlesion E was also lower than 15 normal dogs (45±15 pg/ml) tested by the same protocol. Thus, it appears RVL lesions affect adrenal medullary function, contributing to the hypotension in conscious dogs. Supported by NIH grant HL 39105.

233.5

SYNAPTIC CONNECTIONS BETWEEN CARDIOVASCULAR REGIONS OF THE NUCLEUS TRACTUS SOLITARIUS (NTS) AND NEURONES IN THE VENTRO LATERAL MEDULLA OF THE CAT.

J. Deuchars*, K.M. Spyer, and P.N. Izzo*. Department of Physiology, Royal Free Hospital Sch. Med., Rowland Hill Street, London NW3 2PF, U.K. Unilateral ionophoretic injections of the anterograde

tracer biocytin were made into discrete regions of the NTS, in some cats at sites identified by recording evoked potentials to stimulation of the carotid sinus nerve. Sites of injection were characterised by a core of labelled neurons, from which labelled axons coursed bilaterally through the NTS, dorsal vagal motor nuclei (DVM), hypoglossal motor nuclei and reticular formation. Labelled axons in the reticular formation were observed mainly in a band extending from the NTS to the lateral reticular nucleus (LRN). At the light microscopic level these fibres could be distinguished as either myelinated axons coursing in fibre tracts or fine varicose fibres. In some animals anterogradely labelled axons in both the DVM and nucleus ambiguus (NA) were observed in the vicinity of vagal preganglionic neurons identified by the injection of cholera toxin-HRP into either the cervical vagus or the myocardium. Ultrastructural examination of labelled axons in the NA and LRN revealed a number of them to be in synaptic contact with dendritic shafts and occasionally cell bodies. Identification of the postsynaptic neurons awaits further investigation.

233 2

RESPONSES OF VENTROLATERAL MEDULLARY NEURONS WITH CARDIORESPIRATORY RELATED DISCHARGE TO HYPOXIA AND HYPERCAPNIA. P.C. Nolan* and T.G. Waldrop. Dept. Physiology, Univ. of Illinois, Urbana, IL 61801. Dept. of

A previous study from this laboratory demonstrated that microinjection of an excitatory amino acid antagonist into the ventrolateral medulla (VLM) produces a large augmentation of the respiratory response to hypoxia with a smaller effect on the hypercapnic response. The purpose of the present study was to determine if individual neurons in the VLM are affected by both hypoxia and hypercapnia. Single unit responses were recorded during inhalation of hypoxic (10% 0_2) or hypercapnic gas (5% 0_2) in anesthetized, spontaneously breathing rats. Hypoxia produced a stimulation in 70% of the neurons and a depression in 20%of the neurons. Hypercapnia elicited increases in the discharge frequency in 40% of the neurons and depressed the activity in 15% of the neurons. The discharge frequency of fifty percent of the neurons was affected by both hypoxia and hypercapnia. The resting discharge of most neurons studied was related to the cardiac (45%) and/or the respiratory cycle (50%); however, the observed responses to hypoxia and hypercapnia were not caused by baroreceptor input. In conclusion, these results suggest that both hypoxia and hypercapnia can affect the same VLM neurons and that the respiratory responses to these stimuli may be modulated by neurons in this area. (Supported by NIH 38726; American Heart Assoc.)

233.4

SERIAL TRANSECTIONS THROUGH MID-MEDULLA AFFECT SYMPATHETIC NERVE POWER AND COHERENCE BUT NOT RAPID RHYTHM GENERATION. M.J. Kenney, S. Zhong and G.L. Gebber. Dept. of Pharmacol., Michigan State Univ., E. Lansing, MI 48824.

We studied the effects produced by serial brain stem transections on 1) total power in inferior cardiac and renal postganglionic sympathetic nerve discharge (SND), 2) the 2- to 6-Hz rhythms in these nerves and 3) the coherence of inferior cardiac and renal SND in baroreceptor-denervated cats anesthetized with chloralose. Methods used included autospectral and coherence analyses. Before transection, most of the power in SND was between 2 and 6 Hz and the discharges of the inferior cardiac and renal nerves were correlated between 0.2 and 12 Hz (peak coherence value, 0.64±0.16). Midbrain transection at stereotaxic plane A3 reduced total power in SND to 76% of control without affecting the 2- to 6-Hz rhythm (i.e., shape of autospectrum of SND was unchanged) or the strength of coherence of inferior cardiac and renal SND. Serial transections at rostral and mid-medullary levels progressively decreased total power and the coherence of inferior cardiac and renal SND. This occurred without a change in shape of the autospectra of SND. In some experiments, the coherence of inferior cardiac and renal SND between 2 and 6 Hz was eliminated by rostral medullary transection. The power in SND was reduced to ~17% of control after mid-medullary transection. High spinal transection essentially eliminated SND. These results suggest that 1) the 2- to 6-Hz rhythm in SND arises from multiple brain stem sources, 2) these sources form a distributed system since they are normally coupled, and 3) coupling involves rostro-caudal connections. (Supported by NIH grant HL13187.)

CENTRAL PATHWAY INVOLVED IN THE SYMPATHOLYTIC RESPONSE TO STIMULATION OF THE SUPERIOR LARYNGEAL NERVE. D. Huangfu* and P.G. Guyenet. Dept. of Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

The central pathway involved in the hypotensive and sympatholytic response to stimulation of the superior laryngeal nerve (SLN) was studied in halothane-anesthetized and paralyzed rats. Stimulation of SLN evoked a stimulating intensity, frequency and pulse duration-dependent hypotensive response as well as inhibition of lumbar sympathetic nerve discharge (LSND) (onset latency to single pulse stimulation: 120.242.3 ms).

The hypotensive response and LSND inhibition were markedly attenuated by bilateral microinjection of 100 nl of 45 mM kynurenic acid (glutamate receptor-antagonist) into caudal ventrolateral medulla (CVL), or by bilateral administration of 50 nl of 4.5 mM bicuculline methiodide (GABA-receptor antagonist) into rostral ventrolateral medulla (RVL). In most cases the baroreceptor reflex (to aortic constriction)

antagonist) into rostral ventrolateral medulla (RVL). In most cases the baroreceptor reflex (to aortic constriction) was also blocked. Injection of these drugs elsewhere in the medullary reticular formation did not affect the hypotensive response and LSND inhibition to SIN stimulation. Out of 25 RVL reticulospinal barosensitive neurons recorded, the activity of 18 neurons was inhibited by SIN stimulation (onset latency: 45.5±1.4 ms). This inhibition was attenuated by iontophoretic application of bicuculline (n=5). The remaining 7 RVL reticulospinal barosensitive neurons were unaffected by SIN stimulation.

In conclusion, glutamate in CVL and GABA in RVL are probable transmitters involved in the sympathoinhibition produced by stimulation of SIN.

CHANGES IN ARTERIAL BLOOD PRESSURE INDUCED BY LOCAL INJECTION OF ATRIAL NATRIURETIC FACTOR AND ARGININE VASOPRESSIN INTO THE ROSTRAL VENTROLATERAL MEDULLA OF THE VASDRESSIN INTO THE ROSTRAL VENTROLATERAL MEDULLA OF THE RAT. D. BHASKARAN and C.R. FREED. Depts. of Med. and Pharm., Univ. of Colo. Health Sci. Ctr., Denver, CO 80262.

We have reported changes in extracellular fluid neurotransmitter levels that occur after drug-induced alterations in arterial blood pressure (JPET 249: 660-666, 1989). We have now studied the cardiovascular effect of atrial natriuretic factor (ANF) and arginine vasopressin (ANF) locally injected into the recent vactorial state. atrial natriuretic factor (ANF) and arginine vasopressin (AVP) locally injected into the rostral ventrolateral medulla (RVLM). Urethane anesthetized male Sprague-Dawley rats (250-300 g) were artificially ventilated and the femoral artery was catheterized to measure the blood pressure (BP). Doses of ANF of 2 to 40 pmols and AVP 10 to 1000 pmols were injected into the RVLM through a 32 gauge stainless tubing stereotaxically implanted into the Phosphate buffered saline served as a control. Nucleus tractus solitarius and medial ventral medulla were studied as control sites. Local injection of ANF RVLM produced a dose-dependent increase in BP. produced a biphasic effect. Low doses of AVP reduced BP produced a biphasic effect. Low doses of AVP reduced BP whereas the 1000 pmol dose increased BP. ANF injected into other brain regions did not show a hypertensive effect. Since ANF increased BP and low doses of AVP reduced BP when given into the RVLM, these compounds may be activating specific receptors involved in regulating sympathetic tone.

233.9

EFFECT OF CENTRAL ADMINISTRATION OF ANGIOTENSIN II ON THE NEURONAL ACTIVITIES IN ROSTRAL VENTROLATERAL MEDULLA AND BLOOD PRESSURE OF SPONTANEOUSLY HYPERTENSIVE AND NORMOTENSIVE RATS. R.K.W. Chan*, Y.S. Chan and T.M. Wong*. Dept. of Physiology, University of Hong Kong, Sassoon Road, Hong Kong.

To determine whether rostral ventrolateral medulla (RVL) is a site of action of angiotensin II (Ang II), which had been shown to increase arterial blood pressure (BP) and sympathetic nerve activities, the effects of central administration of Ang II on the spontaneous neuronal activities of RVL and BP changes in pentobarbital anesthetized normotensive Wistar Kyoto rats (WKY) and spontaneously hypertensive rats (SHR) were studied. Extracellular activities of RVL neurons were recorded either by a tungsten electrode in experiments involving intracerebroventricular (i.c.v.) administration or by a double barrel glass pipette in experiments involving iontophoretic application to RVL. In WKY and SHR, both i.c.v. and iontophoretic administration of Ang II increased the firing rates of single and double discharge RVL units dosedependently. Following i.c.v. or iontophoretic administration, the increase in firing rates was greater and the duration of the responses was longer in SHR than in WKY. With iontophoretic administration, RVL units also showed lower threshold current and longer duration of response in SHR than in WKY. The BP elevation accompanying the increase in firing rate of RVL neurons following i.c.v. administration of Ang II was significantly greater and lasted longer in SHR than in WKY; BP change following iontophoresis was too small for statistical analysis. The effects of i.c.v. and iontophoretic administration of Ang II on BP and RVL neuronal activities were completely abolished by co-administration of saralasin, an Ang II antagonist. These findings suggest that the enhanced neural and pressor responses to brain Ang II probably act via RVL neurons, leading to the genesis of hypertension. (Supported by grants from Lee Wing Tat Fund, Sun Yat Sen Fund, C.R.C.G. of H.K.U., and Croucher Foundation.)

233.11

EFFECTS OF 5-HT_{1A} AND 5-HT₂ AGONISTS ON AUTONOMIC OUTFLOW IN CATS. S.L. Shepheard* D. Jordan¹ & A.G. Ramage, Dept. Pharmacology and ¹Physiology, Royal Free Hospital School of Medicine, London, U.K.

Administration of the 5-HT_{1A} agonist 8-OH-DPAT i.v. to anaesthetised cats causes sympatho-inhibition, hypotension and increased vagal tone (Ramage & Fozard, Eur. J. Pharmacol., 138: 179, 1987), whilst the 5-HT2 Adamse α τυζαίν, <u>Cur. J. Phalmacol.</u>, 130- 177, 1707), Whilst the 3-min agonist DOI causes a potent sympathoexcitation and hypertension (McCall & Harris, <u>Fur. J. Pharmacol.</u>, 151: 113, 1988). The central site/s at which these agonists produce these effects remain to be determined.

In α-chloralose anaesthetised cats recordings were made of renal,

splanchnic, inferior cardiac and phrenic nerve activity, heart rate, femoral flow, arterial, tracheal and intragastric pressures. Drugs were administered cumulatively into the IVth ventricle and their effects on autonomic outflow compared. Compounds with 5-HT_{1A} agonist properties; 8-OH-DPAT, 5-CT, n-dipropyl-5-CT and sumatriptan produced hypotension, a potent inhibition of renal nerve activity and varying degrees of inhibition in the other sympathetic nerves. Only 8-OH-DPAT caused an increase in cardiac and gastric vagal tone. 5-HT had variable effects but in the presence of the 5-HT $_2$ antagonist cinanserin produced effects similar to the 5-HT $_1$ A agonists but no increase in vagal tone. DOI produced a weak hypertension, only a slight generalised sympathoexcitation but a large decrease in femoral arterial conductance.

These results indicate that renal sympathetic outflow is the most sensitive to the sympatho-inhibitory action of 5-HT_{IA} agonists, and the tryptamine-related 5-HT_{IA} agonists failed to increase vagal drive when given into the IVth ventricle. 5-HT₂ receptor activation at this level of the brain causes only a surprisingly weak sympatho-excitation. This work was supported by the Wellcome trust.

233.8

INTRACISTERNAL INJECTION OF HEMICHOLINIUM-3 DOES NOT LOWER BLOOD PRESSURE IN THE ADULT SPONTANEOUSLY HYPERTENSIVE RAT.

H.M. VARGAS and B. RINGDAHL* Department of Pharmacology,
UCLA-School of Medicine, Los Angeles, CA 90024-1735.

Brain cholinergic mechanisms are known to be linked to the expression of hypertension in the spontaneously hypertensive rat (SHR). Evidence suggests cholinergic processes in the hypothalamus and brainstem may be involved. Our study assessed the role of brainstem cholinergic neurons in the maintenance of hypertension in SHR. Mean arterial in the maintenance of hypertension in SRR. Mean arterial pressure (MAP) was recorded from freely-moving, unanesthetized SHR (18 week; basal MAP: 190 \pm 5 mmHg) which were previously implanted with a chronic indwelling cannula aimed at the cisterna magna (icm) or lateral ventricle (icv). After infusion of saline or Hc-3 (10 μ g/5 μ 1), MAP was followed for 2 hours. Treatment with icv HG-3 produced a maximal fall in blood pressure (-25 mmHg; at 30 min) which recovered to baseline levels by 120 min. In conwhich recovered to baseline levels by 120 mill. In contrast, icm HC-3 or saline did not cause a hypotensive effect in the SHR throughout the treatment period. Two hours after treatment, however, the iv physostigmine pressor response was significantly inhibited (>80%) by both HC-3 treatments when compared to the saline group (Δ MAP: +34 \pm 4 mmHg). These results suggest that brainstem ± 4 mmHg). cholinergic neurons may not be tonically active or only secondarily related to the maintenance of hypertension in adult SHR. (Supported by GM37816 to B.R.)

DIFFERENTIAL LOCALIZATION OF ANGIOTENSIN II (AII) AND MU OPIOID BINDING SITES IN THE AREA POSTREMA (AP) OF SPONTANEOUSLY HYPERTENSIVE RATS (SHR). C.O. Andrews C.F. Phelix, R.L. Tackett; D.K. Hartle. Dept. Pharmacology and Toxicology, College of Pharmacy, UGA, Athens, GA 30602

Previous reports from our laboratory have described anatomical subdivisions of the rat AP based upon immunohistochemical analysis of aminergic and peptidergic neuronal elements, and glutamate-sensitive neurons in SHR and Wistar Kyoto rats. For the present study we used autoradiography to map in sistu peptide binding sites within these AP subdivisions. Fresh frozen coronal sections (30 µm) of the medulla oblongata were incubated with ¹²⁵I-[Sar¹, Ile⁸]-AII or ¹²⁵I-DAGO. Autoradiograms (film and emulsion) were examined or quantitated with a Zeiss IM-3000 Real Time Image Analysis System or by dark field microscopy. Three major subdivisions were established: the rostral level or APr (150 μm), middle level or APm (210 μm), caudal level or APc (150 μm). These AP levels were further subdivided into dorsal and ventral, midline or lateral regions using two parasagittal and one horizontal reference planes. Both AII and DAGO overall binding was greatest in the APm with the APc showing the next highest binding density. In APr binding density decreased significantly more for AII than DAGO. Binding density for DAGO was lowest in midline and highest in dorsolateral AP; lowest in dorsolateral and highest in ventral midline AP for AII. In conclusion, both AII and DAGO binding densities exhibit non-homogeneous distributions in SHR AP. Correlation of peptide binding maps with histochemically-identified neuron and afferent fiber localization may yield useful information about diverse functions of peptides within the AP. HL37705 to DKH.

FURTHER CHARACTERIZATION OF SEROTONERGIC MEDULLARY RAPHE NEURONS. M.E. Clement,* R.B. McCall, and C.J. Hudson, Cardiovascular Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

The midline medulla is believed to play a role in the cardiovascular regulation. We recently showed that this area contains spinally projecting serotonergic neurons with similar electrophysiological and pharmacological properties as 5-HT neurons in the dorsal raphe (DR). We have now investigated further the pharmacologic characteristics of serotonergic neurons in the raphe pallidus and obscurus.

We examined the sensitivity of medullary 5-HT neurons to noradrenergic input using the α_1 antagonist prazosin. I.V. prazosin decreased unit activity with a maximum inhibition of 75%. We also found that iontophoretic norepinephrine had variable effects on firing rates, usually producing excitation at lower ejection currents and inhibition at higher currents. These results reflect similar data obtained in the DR.

The effects of two 5-HT agonists, 5-MeOHDMT and DOI, were examined. Iontophoretic 5-MeOHDMT inhibited unit firing for extended periods of time. In addition, i.v. 5-MeOHDMT exhibited a dose-dependent decrease of unit activity with complete inhibition by 100 µg/kg. Conversely, DOI, a selective 5-HT, agonist, had no effect on medullary 5-HT activity given iontophoretically or in i.v. doses up to 1 mg/kg. These results indicate that medullary 5-HT neurons are similar to but not identical to DR 5-HT neurons.

233,13

CARDIOVASCULAR ACTIONS OF CENTRAL AND PERIPHERAL ADMINISTRATION OF A SEROTONIN 5-HT, RECEPTOR AGONIST. A Dedeoglu* and L.A. Fisher. Department of Pharmacology, College of Medicine, University of Arizona Health Sciences Center, Tucson, AZ 85724. Dedeoglu* and L.A. Fisher. Department of Pharmacology, College of Medicine, University of Arizona Health Sciences Center, Tusson, AZ 85724. Serotonin (5-HT) receptors comprise several distinct subtypes and are distributed nonuniformly throughout the central nervous system (CNS) and periphery. While it is well known that vascular smooth muscle 5-HT, receptors mediate pressor responses, several studies suggest that stimulation of CNS 5-HT, receptors also activates sympathoadrenal outflow and produces pressor responses. The present experiments were performed to compare the effects of intracerebroventricular (Icv) and intravenous (iv) administration of 1-(2,5-dimethoxy-4-lodophenyl)-2-aminopropane (DOI), a 5-HT, receptor subtype-selective agonist that crosses the blood-brain barrier. All studies utilized conscious unrestrained male Sprague-Dawley rats fitted with indwelling icv cannulae and iliac arterial and venous catheters. Iv injections of DOI (10-300 nmol/kg) produced dose-related elevations of diastolic pressure (DP), systolic pressure (SP), mean arterial pressure (MAP), and pulse pressure (PP) whereas no consistent changes in heart rate (HR) occurred. DP, SP, MAP, and PP were increased maximally by 1 min postinjection and returned to control levels by 30 min except after treatment with the highest dose. Icv administration of DOI (3-100 nmol) produced dose-related elevations of DP, SP, MAP and PP and transient increases of HR; moderate reductions of HR followed the transient tachycardia after icv injection of 100 nmol DOI. In general, DOI-Induced elevations of DP, SP, MAP and PP were 20-30% greater after iv administration versus icv administration. Moreover, in contrast to the short latercy between iv injections and maximal responses, cardiovascular changes did not reach peak magnitudes until 10 min after icv injections of DOI. These data suggest peak magnitudes until 10 min after icv injections of DOI. These data suggest that a significant component of the cardiovascular responses to icv injection of DOI may result from leakage of DOI from the CNS to the periphery.

CLONIDINE FAILS TO INHIBIT THE CARDIOVASCULAR DEFENCE REACTION IN AMESTHETIZED RATS. L. L. Watkins and W. Maixner. Dental Research Center and Dept. of Pharmacology, Univ. of North Carolina, Chapel Hill, N.C. 27514.

The cardiovascular defence reaction (CDR) is an adaptive response characterized by an increase in blood pressure, heart rate, respiration, hindlimb blood flow and sympathetic tone. Electrical stimulation of the dorsal periaqueductal grey region (50 uAmp, 100 Hz, 10 sec) produces the CDR in pentobarbital anesthetized rats. Increases in blood pressure (39.5 \pm 5 mmHg), heart rate (32 \pm 6 bpm), and hindlimb blood flow (200%) were observed during electrical stimulation of the periaqueductal grey region. The increase in blood pressure was transient (1 sec) and was followed by a transient drop after stimulation. Clonidine did not alter the peak increase in blood pressure or heart rate but prolonged the duration of the pressor response and eliminated the post-stimulation decrease in blood pressure. Clonidine significantly inhibited the increase in hindlimb blood flow. These results suggest that clonidine does not lower blood pressure by inhibiting the CDR. Supported by DEO8013 and RR05333.

CARDIOVASCULAR AND AMINO ACID LEVEL CHANGES AFTER MICRODIALYSIS OF THE FASTIGIAL NUCLEUS "PRESSOR REGION" WITH KAINIC ACID IN CONSCIOUS RATS. T. J. Parry and J. G. McElligott. Dept.

of Pharmacology, Temple Univ. Sch. of Med., Philadelphia, PA 19140.

Previous work with microinjected kainic acid (KA) in the rostral fastigial nucleus (RFN) of anesthetized rats has indicated neurons intrinsic to the nucleus modulate cardiovascular function. In this study, changes in cardiovascular parameters as well as extracellular amino acid (AA) levels were examined in response to KA microdialysis extracellular amino acid (AA) levels were examined in response to KA microdialysis in the RFN of conscious male rats. A microdialysis probe equipped with an intramembrane stimulating electrode was stereotaxically positioned within the RFN of previously adapted awake head restrained rats. Electrical stimulation (50 µA), used to locate the pressor region, evoked a rise in mean arterial pressure (MAP; 40 mmHg) and heart rate (IRR; 90 bpm). After 30 min, the probe was perfused with an isosmotic buffered solution (1 µl/min) for 90 min followed by 30 min perfusions with 0.5 and 1 mM KA. After KA administration, a control perfusion (60 min) using the isosmotic solution was also performed. Dialysates were collected every 10 min and analyzed for AA levels using HPLC with fluorimetric detection. MAP and HR remained unchanged during the 90 min predrug control period. During KA perfusion, a steady dose dependent increase in MAP and HR was seen (maximum response 25 mmHg and 100 bpm, respectively). In addition, phasic increases in MAP (75 mmHg) and HR (100 bpm) were seen at two minute intervals with the 1 mM dose. mmHg) and IT of the minute intervals with the 1 mM dose. After KA washout, the phasic responses decreased in frequency and magnitude, HR Atter KA washout, the phasic responses decreased in frequency and magnitude, HR decreased to normal predrug values, but MAP remained slightly elevated (12.5 mmHg). KA caused large increases over baseline controls in glutamate (2.3X), taurine (2.7X), and alanine (2.1X) while aspartate, threonine, glycine, and GABA increased slightly (1.3X). The KA induced increase in extracellular glutamate indicates the possible involvement of glutamate in the production cardiovascular changes by the RFN. This glutamate increase supports previous studies which show the need for intact glutaminergic innervation for KA induced excitation. The role of taurine is unknown; however, it is known to be inhibitory and may be released in response to excessive excitation.

KETANSERIN SYMPATHO-INHIBITION MEDIATED BY A CNS α_2- ADRENOCEPTOR MECHANISM. M.C. Koss. Dept. Pharmacology, Univ. Okla. Hlth. Sci. Ctr., Oklahoma City, OK 73190. Experiments were undertaken to determine if sympathoinhibition produced by ketanserin is due to central antagonism of α_1 -adrenoceptors rather than CNS 5-HT $_2$ receptors and if (like prazosin) it produces sympathoinhibition indirectly via a CNS α_2 -adrenoceptor mechanism. Intravenous administration of ketanserin (0.1-3.0 mg/kg) caused a dose-related depression of amplitude of sympathetic-cholinergic electrodermal responses (EDRs) evoked by electrical stimulation of the posterior hypothalamus in pentobarbital anesthetized cats. No effect of ketanserin was observed when EDRs were evoked by preganglionic sympathetic nerve stimulation. Pretreatment with α_2 -adrenoceptor antagonists yohimbine, idazoxan, or rauwolscine significantly blocked ketanserin-induced sympatho-inhibition Depletion of CNS monoamines totally prevented ketanserininduced sympatho-inhibition although clonidine (30 $\mu g/kg$) continued to be effective. These results suggest that ketanserin acts in the CNS to reduce sympathetic reactivity by blocking α_1 -adrenoceptors and not 5-HT, receptors. In this regard, ketanserin appears to act in a manner similar to other α_1 -adrenoceptor antagonists (e.g. prazosin and indoramin) by an apparent "prejunctional" facilitation of α_2 -adrenoceptor mediated tonic inhibition descending from the lower brainstem.

INTEGRATION OF CARDIOVASCULAR AND VESTIBULAR INPUTS OCCURS IN THE CAUDAL MEDULLARY PARAMEDIAN RETICULAR FORMATION OF

IN THE CAUDAL MEDULLARY PARAMEDIAN RETICULAR FORMATION OF THE CAT. B.J. Yates and Y. Yamagata. Lab. Neurophysiol., The Rockefeller University, New York, NY 10021.

There is considerable evidence to suggest that inputs from the vestibular system influence sympathetic outflow and blood pressure. Electric stimulation of the vestibular nerve (VN) elicits reflexes recordable from sympathetic nerves (Uchino et al., Brain Res. 22). In addition, VN transection compromises the ability of a cat to compensate for hypotension produced by 60° tilt (Doba and Reis, Circ. Res. 34). However, little is known about the neural circuitry which underlies vestibulosympathetic reflexes. cuitry which underlies vestibulosympathetic reflexes

In this study we considered whether the paramedian reticular formation (PRF) mediates vestibular inputs to spinal autonomic neurons. We made extracellular recordings from 47 neurons in this region which were driven by electric stimulation of the VN, in chloralose/urethane-anesthetized cats. Il were excited by VN stimulation at latencies LE 2 msec, and thus apparently received disynaptic inputs from the labyrinth. 20/47 of the cells in the PRF which responded to VN stimulation also received convergent car-diovascular inputs elicited by electric stimulation. How-ever, only a small fraction (2/13) was shown to be reticulospinal by antidromic stimulation. The PRF may participate in vestibulosympathetic reflexes indirectly, by relaying inputs from the VN to reticulospinal neurons located elsewhere. Supported by NIH grants NS02619 and DC00693.

CENTRAL SITE OF THE HYPOTENSIVE RESPONSE INTRACEREBROVENTRICULAR ANGIOTENSIN II IN OF TO ANESTHETIZED RAT. D.M. Campos* and F.M.A. Corrêa. Pharmacology, Sch. Med. Rib. Preto-USP, SP, Brazil, 14049.
ICV AII caused biphasic responses in urethane-anesthetized rats, characterized by short lasting pressor followed by long lasting depressor components. To identify CNS regions involved in the hypotensive response, we compared dose-effect curves for AII administered into the lateral and the fourth ventricles and the effect of occlusions of ventricular spaces on the response to AII. Male Wistar rats (240-280g) were used. Cannulas were stereotaxically implanted into the lateral or fourth ventricles for dose-effect experiments. occlusions, cannulas were simultaneously implanted into the lateral ventricle and the aqueduct or the fourth ventricle. ED50 for AII in the fourth ventricle (0.06nmoles) was significantly lower than in lateral ventricle. (0.06nmoles) was significantly lower than in lateral ventricle (0.7nmoles). Ventricle occlusions were performed with Nivea cream. A 50% reduction in the response to AII was observed after the occlusion of the aqueduct (-23 ± 3mmHg to -12 ± 2mmHg, n=9), whereas occlusion of the fourth ventricle did not modify the response (-23 ± 3mmHg to -20±3mmHg, n=12). Our results indicate the involvement of two sites in the response to AII, one anterior to the aqueduct and the other in the fourth ventricle floor. Acknowledgements: I.I.B. Aguiar; Grants: FAPESP, USP-BID.

ONTOGENY AND DISTRIBUTION OF GABA RECEPTORS IN THE RAT BRAINSTEM AND HIGHER BRAIN AREAS. Y. Xia and G.G. Haddad. Dept. of Pediatrics, Section of Respiratory Medicine, Yale Univ. Sch. Med., New Haven, CT 06510.

Considerable evidence suggests that GABA is involved in

Considerable evidence suggests that GABA is involved in regulating cardiorespiratory function under physiologic and pathophysiologic conditions such as 02 deprivation. Recently, we have shown that newborn brainstem neurons respond differently to hypoxia than those in the adult. This age-related difference may be due to differences in neuro-transmitter release or in the activity of GABA receptors in the brain. However, little is known about the development of the GABA receptor system, especially in the brainstem. The purpose of this study is to investigate GABA receptor distribution in the rat brainstem as well as in higher brain areas. We used autoradiographic methods and rats at ages of postnatal 1 (P1), 5 (P5),10 (P10),21 (P21) and 120 (adult) days. Sections (10 um) from various levels of the brain were incubated in Tris-citrate buffer with 50 nM 3H-muscimol. We found that 1) in the adult, 3H-muscimol binding was much less in the brainstem than in higher brain, 2) in most brainstem nuclei, the density of 3H-muscimol sites were much higher in the newborn than in the adult with a maximum at P5 or P10, and 3) in higher brain areas (e.g. cortex), 3H-muscimol binding density increased with age and reached the highest density at P21 or adult. Our results demonstrate that GABA receptors develop earlier in the brainstem than in higher brain areas and may play an important role in brainstem function in early life.

PHYSIOLOGICAL ANATOMY OF THE PARABRACHIAL NUCLEUS IN THE RAT. NJ. Chamberlin and C.B. Saper, Dept. Pharm. & Physiol. Sci., Univ. of Chicago. Chicago II. 60637.

Physiol. Sci., Univ. of Chicago, Chicago IL 60637.

Electrical stimulation of different subregions of the parabrachial nucleus (PB) can produce an increase or decrease in blood pressure and apnea or tachypnea. The goal of this study was to use small injections of glutamate to determine which PB subnuclei and projections mediate each type of response

determine which PB subnuclei and projections mediate each type of response. Glutamate (25 ni; 1-10 mM) was injected from one barrel of a triple-barrel micropipette while changes in blood pressure and heart rate were measured with an arterial catheter connected to a pressure transducer and respiratory rate was determined with a diaphramatic electromyograph. Saline was injected from an adjacent barrel to control for pressure artifacts. Phaseolus vulgaris leukoagglutinin (PHA-L) was iontophoresed from the third barrel of the micropipette to label the injection site as well as its efferent pathways.

Apnea, associated with a small depressor response, or tachypnea, often accompanied by an increase in blood pressure, was produced by injections of glutamate near the ventrolateral tip of the superior cerebellar peduncle. In these cases PHA-L labeled terminal fields were located in the lateral facial nucleus, periambiguous area, the rostral ventrolateral medulla, the nucleus tractus solitarious (NTS), the hypoglossal nucleus, and the phrenic motor column of the spinal cord. Projections from sites where glutamate caused a decrease in blood pressure without a respiratory change terminated mainly in forebrain areas including the hypothalamus, amygdala and basal forebrain. Since the PB is the main target of NTS efferents, dissection of the PB into functional subregions should shed some light on its role in processing visceral sensory information.

233.23

The parabrachial nucleus (PBN) within the dorsolateral pons is a major recipient of autonomic-related inputs from more caudal levels of the neuraxis, and in particular the nucleus of the solitary tract (NTS). Although projections from the NTS to the PBN are well-characterized anatomically, the type of cardiovascular information that is transmitted within such pathways is less clear. The present study examined, in urethaneanesthetized rats, the influence of baroreceptor activation on PBN neurons that responded to electrical stimulation within the NTS. Extracellular recordings revealed 60 PBN neurons that increased their firing frequency in response to NTS stimulation and of these, 6 of 14 cells also increased their firing rate consequent to baroreceptor activation, achieved by brief metaraminol-induced hypertension. Thirty-seven PBN cells decreased their activity following NTS stimulation and 7 of 9 such cells displayed a similar depressant response to baroreceptor activation. These observations reveal a population of neurons within the PBN that display a striking similarity of responses both to the activation of synaptic inputs originating in the NTS as well as peripheral arterial baroreceptors. EFFECTS OF ENDOTHELIN-1 (ET) ON MEDULLARY CARDIOVASCULAR NEURAL SUBSTRATES. M.A. Hashim* and A.S. Tadepalli. Division of Pharmacology, Wellcome Research Labs., Research Triangle Park, NC 27709.

Centrally mediated cardiovascular effects of ET were

Centrally mediated cardiovascular effects of ET were examined in anesthetized, ventilated rats. ET was applied to the exposed 4th cerebral ventricle (4CV) or microinjected into discrete sites within the nucleus of the solitary tract (NTS). ET (1,3,10 pmol) applied to the 4CV elicited, within 0.5 min, dose-dependent decreases in mean arterial pressure (12-77%), heart rate (4-37%) and renal blood flow (RBF; 33-50%) which lasted 30 to 180 min. ET produced similar effects when administered into the 3rd or lateral CV, but the latency was long (2-5 min). Similar responses occurred when ET (1-30 fmol) was microinjected at discrete loci within a 500 µm long dorsal strip and the commissural subnucleus of the NTS. However, at glutamate-responsive deglutitive solitarial sites, ET was ineffective. An ET-antiserum, but not normal serum, applied to 4CV prevented the action of ET. Vehicle microinjections into NTS, or equal doses of ET given i.v. were without effect. These data indicate that ET evokes hypotension, bradycardia and decreases RBF by a specific action on medullary cardiovascular substrates which include the NTS

ASCENDING INPUTS TO THE NUCLEUS OF THE DIAGONAL BAND FROM THE A1 NORADRENERGIC GROUP AND PARABRACHIAL NUCLEUS. W.B. Mathieson, G.J. Pittman and W.L. Veale. Dept. Med. Physiol., U. Calgary, Alberta, Canada.

Neurons in the diagonal band of Broca (DBB) are responsive to increases in arterial blood pressure and regulate the activity of supraoptic neurosecretory neurons (Jhamandas & Renaud, Can. J. Neurol. Sci.14:17, 1987). To investigate ascending pathways that may relay this baroreceptor input, injections of Fluorogold (FG) were made into the DBB and the distribution of retrogradely labeled neurons within brainstem cardiovascular centres was recorded. FG-labeled cells were located in parabrachial nuclei, rostral and caudal ventrolateral medulla and nucleus of solitary tract (NTS). Immunohistochemical staining revealed that 28% of retrogradely labeled neurons in the caudal VLM were tyrosine hydroxylase-immunoreactive whereas FG-labeled parabrachial and solitary tract neurons were non-catecholaminergic. The results suggest that A1 noradrenergic cells, parabrachial neurons and possibly non-catecholaminergic cells in the NTS may relay ascending baroreflex input via the DBB.

CHARACTERIZATION OF A PROJECTION FROM THE PARABRACHIAL NUCLEUS TO THE HYPOTHALAMIC SUPRAOPTIC NUCLEUS IN THE RAT. T.L. Krukoff, K. Harris* and J.H. Jhamandas. Depts. of Anatomy & Cell Biology, and Medicine (Neurology), Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E1.

While the pontine parabrachial nucleus (PBN) has been implicated in central cardiovascular control and neuro-

While the pontine parabrachial nucleus (PBN) has been implicated in central cardiovascular control and neuro-endocrine responses, including the release of vasopressin (VP), the pathways mediating the latter are uncertain. This study, using anatomical and electrophysiological methods, describes a projection from the lateral PBN towards the hypothalamic supraoptic nucleus (SON). Rats received iontophoretic injections of the anterograde tracer, PHA-L, in the PBN region. After 14-18 days, brains of perfused animals were processed for immunofluorescence to visualize projections to the SON region. PHA-L labelled terminals were found primarily in a region dorsal to the SON. Extracellular recordings from 36 antidromically-identified SON neurons revealed a set of complex synaptic responses after electrical stimulation in the PBN. Excitatory (31/36) and inhibitory (5/36) responses were found; a few cells showed excitation with durations of over 100 msec. These results suggest that the PBN projection to the SON is indirect via the adjacent dorsal perinuclear zone. The variety of synaptic influences on SON neurons may help to explain recent conflicting reports about VP release after stimulation in the PBN region. Supported by the MRC of Canada and AHFMR.

NICOTINE ALTERS HYPOTHALAMIC GARAERGIC MECHANISMS IN HYPERTENSIVE RATS. R.W. Stremel, A.E. Jimenez and J.C. Passmore*. Dept. of Physiol. & Biophys., School of Medicine, Univ. of Louisville, Louisville, KY 40292. Chronic nicotine exposure exacerbates the blood pressure increase in salt sensitive hypertension. GABA

Chronic nicotine exposure exacerbates the blood pressure increase in salt sensitive hypertension. GABA related mechanisms within the posterior hypothalamus (PH) are known to be altered in some forms of hypertension and the PH also contains nicotinic receptors. Therefore, we studied the cardiovascular and respiratory responses to PH microinjection of the GABA antagonist, bicuculline methicolide (BMI, 5 ng/nl), in chloralose-urethane anesthetized rats. Deoxycorticosterone acetate - salt (DOCA) hypertensive rats, with chronic nicotine infusion (2.4 mg/kg/day; DOCA-NIC) or vehicle (DOCA-VEH), and normotensive controls were studied. In DOCA-VEH and normotensive controls, BMI increased blood pressure (BP), heart rate (HR) and diaphragmatic activity (DA). These effects were reversed by muscimol. BMI in DOCA-NIC rats elicited a similar BP increase (40-60 mm Hg) but produced a dramatic fall in HR (-100 to -150 b/min); DA in response to BMI was attenuated in the DOCA-NIC group. These data suggest that nicotine alters the posterior hypothalamic GABAergic influence over cardiovascular and respiratory control mechanisms and thus nicotine may act at this site to influence salt sensitive hypertension. AV3V LESION REDUCES THE PRESSOR, DIPSOGENIC, NATRIURETIC AND KALTURETIC RESPONSES INDUCED BY CHOLINERGIC STIMULATION OF THE MEDIAL HYPOTHALAMUS AND SEPTAL AREA IN RATS. J.V. Menani*; A.S. Valladão*; E. Colombari*; W.A. Saad; L.A.A. Camargo*; A. Renzi*; L.A. De Luca Jr.* and W.A. Saad*. Department of Physiology, Dentistry School, UNESP, Araraquara 14800 SP and Department of Surgery, School of Medicine, USP, São Paulo 01000 SP, Brazil.

Injection of the cholinergic agonist carbachol into several areas of the rat forebrain induces pressor, dipsogenic, natriuretic and kaliuretic responses. The anteroventral third ventricle (AV3V) region is important for the cardiovascular and electrolytic balance in rats. In the present study we investigated the effect of AV3V lesion on the pressor, dipsogenic, natriuretic and kaliuretic responses produced by carbachol (2 nmol) injection into the medial septal area (MSA) and into the ventromedial hypothalamic nucleus (VHN) in rats. These responses were almost abolished in the AV3V-lesioned rats. The decrease in all responses was 50 to 95% in AV3V-lesioned rats. These results show that the AV3V region is essential for the pressor, dipsogenic, natriuretic and kaliuretic responses induced by cholinergic stimulation of the MSA and VHN in rats.

DIFFERENTIAL INNERVATION OF FOREBRAIN STRUCTURES BY THE DORSAL AND VENTRAL MEDIAN PREOPTIC NUCLEUS IN THE RAT: A PHA-L STUDY. A.M. Zardetto-Smith, T.G. Beltz* R.J. Johnson, and A.K. Johnson, Depts. of Psychology and Pharmacology and The Cardiovascular Center, Univ. of Iowa, Iowa City, IA 52242.

Cardiovascular Center, Univ. of Iowa, Iowa City, IA 52242.
The periventricular region surrounding the anteroventral third ventricular (AV3V) region has been demonstrated to play a critical role in body fluid homeostasis and cardiovascular regulation. The median preoptic nucleus (MnPO), an important component of this region, is comprised of a dorsal (dMnPO) and ventral (vMnPO) subdivision, which functional data suggest may play varying roles in the drinking response to All. As part of a study comparing the cytoarchitecture and connectivity of dMnPO and vMnPO, the efferent projections of dMnPO and vMnPO within the forebrain were examined using the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L). Small deposits of PHA-L were iontophoretically placed within the dMnPO or vMnPO of male Long-Evans rats. PHA-L fibers and terminals were visualized using the avidin-biotin immuno-peroxidase technique. Injections confined to dMnPO produced dense labeling in the organum vasculosum of the lamina terminalis (OVLT) and subfornical organ. The paraventricular, supraoptic and perifornical/lateral hypothalamic nuclei, and ventral bed nucleus of the stria terminalis received moderate innervation. Sparse label was also noted within the central and basomedial amygdaloid nuclei and septal nuclei. In comparison to dMnPO injections, PHA-L deposits confined to vMnPO produced sparse, fine innervation of the periventricular and paraventricular hypothalamic nuclei, and OVLT. These preliminary results suggest that efferents to the forebrain from MnPO may arise primarily from its dorsal subdivision. (Supported by NHLBI.)

PRESSOR RESPONSES TO COMMON CAROTID OCCLUSION IN CONSCIOUS RATS WITH COMBINED LESIONS OF THE ANTEROVENTRAL THIRD RECION AND THE MEDIAL FOREBRAIN BUNDLE. M.T.B.Bedran de Castro*, J.V.Menani* and J.C.Bedran de Castro. Dept. of Physiology, UNESP, Araçatuba SP 16015 and Dept. of Physiology, UNESP, Araraquara, SP 14800, Brazil.

In conscious rats, the antero ventral third ventricle region (AV3V) lesion depresses both components of the pressor response to common carotid occlusion (cco), especially the initial peak (IP) which is of carotid reflex origin. Furthermore, medial forebrain bundle (MFB) lesion depresses more intensely the maintained response (MR) which is probably of central ischemic origin. In the present study we investigated the effects of combined AV3V and MFB lesions on the pressor responses to cco in conscious rats. Short-term (6h) and long-term (2 and 6 d) lesions greatly depressed the pressor responses to 60 seconds of cco. The IP was reduced by 52% (from 44±2 to 21±3 mm Hg), and the MR was reduced by 54% (from 24±1 to 11±1 mm Hg). Aortic denervation performed eight days before, in lesioned rats, potentiated the pressor responses to cco with no difference between the IP and MR (40±6 and 35±7 mm Hg, respectively). These data indicate that combined lesions of AV3V and MFB produce an overall depression of the development of the pressor response to cco but maintain almost unchanged the inhibitory action of the aortic baroreceptors on the responses.

FUNCTIONAL AND ANATOMICAL ORGANIZATION OF POSTERIOR HYPOTHALAMIC CARDIOVASCULAR PRESSOR AND DEPRESSOR SITES. G.V. Allen and D.F. Cechetto. Robarts Research Inst., Univ. of Western Ontario, Canada.

The present study describes the anatomical organization of projections from functionally defined cell groups of the lateral hypothalamic area (LHA). In anesthetized rats, cardiovascular pressor and depressor sites were identified following microinjection (5-30 nl) of D,L-Homocysteic acid (0.1-1.0M) and the efferent projections of these sites were mapped following injections of phaseolus vulgaris leucoagglutinin or WGA-HRP. Decreases in blood pressure (5-40 mmHg) and heart rate (20-70 beats/sec) were elicited from tuberal and posterior regions of the LHA. Depressor cell groups project to the central gray, pedunculopontine region, parabrachial nucleus, laterodorsal tegmental nucleus, locus coeruleus, nucleus of the solitary tract and rostrocaudal ventral lateral medulla. In contrast, increases in blood pressure (5-15 nl) and heart rate (20-60 beats/sec) were elicited from neurons in the perifornical area. These pressor cells project to the parventricular hypothalamic nucleus and lateral preoptic area as well as to the central gray, laterodorsal tegmental nucleus and locus coeruleus. Both pressor and depressor cells have direct projections to cervical and thoracic levels of the spinal cord. The results demonstrate that functionally distinct cell groups in the posterior hypothalamus have differential pathways to forebrain and brain stem autonomic structures.

IMMUNOCYTOCHEMISTRY (ICC) AND ELECTRICAL STIMULATION (ES) OF BED NUCLEUS OF STRIA TERMINALIS (BST): CONNECTIONS WITH MEDULLARY CARDIOVASCULAR (CV) REGULATORY CENTERS (CRCs) IN SPONTANEOUSLY HYPERTENSIVE (SHR) AND NORMOTENSIVÉ RATS. <u>C.F. Phelix, W.K. Paull: D.K. Hartle.</u> Cardiovascular Res. Laboratories, College of Pharmacy, UGA, Athens, GA 30602.

This study implicate corticotropin releasing factor (CRF) neuromessenger in BST-paraventricular nucleus of hypothalamus (PVH)-CRC circuits involved in stress-related activation of the CV system that is exaggerated in SHRs vs Wistar Kyoto (WKY) and Sprague Dawley (SD) normotensive rats. ICC was used to study CRF neurons or axons in BST, PVH and CRCs (nucleus tractus solitarius, NTS, dorsal motor - vagus, DMNX; rostral ventrolateral medulla, RVLM) in SHR and SDs. CRF axons contacted catecholamine (CA)or acetylcholine-synthesizing neurons in the NTS, RVLM or DMNX. CRF neurons in BST were more numerous in SHR. A tract tracing study using injected lectin or anitbody in BST showed synaptic connections with PVH. BST efferents contacted CRF PVH and CA NTS neurons; both were CRF or CA afferent neurons of BST. In both SHR and WKY, ES of BST produced a decreased heart rate (HR) and decreased blood pressure (BP) with pentobarbital anesthesia, decreased HR and increased BP with urethane anesthesia, and increased HR and BP in conscious SHR. The magnitude of response was greater in SHR (p < .05-.01). Thus the BST is part of a limbichypothalamic-brainstem circuit involved in an augmented CV responsivity in rats with hereditary spontaneous hypertension. Support by Georgia Heart Association to CFP and NIH-NS19266 to WKP.

RESPONSES OF HYPOTHALAMIC CARDIOVASCULAR NEURONS TO HYPERCAPNIA AND HYPOXIA IN BARODENERVATED CATS. Biophysics, University of Illinois, Urbana, IL 61801.

Our laboratory has shown recently that the majority of

hypothalamic neurons stimulated by hypercapnia or hypoxia in baroreceptor intact cats have a discharge related cardiovascular activity (cardiac cycle and/or sympathetic activity). The purpose of this study was to determine if this relationship was dependent upon input from baroreceptors and peripheral chemoreceptors. Experiments were performed on anesthetized, barodenervated, artificially ventilated cats. Single unit recordings from hypothalamic neurons were performed; computer averaging techniques were used to determine if neuronal discharge was related to cardiovascular activity. Neuronal responses to inhalation of a hypercapnic (5% CO₂) and a hypoxic (10% O₂) gas were recorded. Hypercapnia activated 38% of hypothalamic neurons studied in barodenervated cats; 75% of those activated had a discharge related to cardiovascular activity. Forty-six percent of the neurons were stimulated by hypoxia; a cardiovascular-related discharge was observed in 67% of these. The above results are similar to those obtained in cats with intact baroreceptors. Thus, these results indicate that baroreceptor and peripheral chemoreceptor afferents are not required for: 1) stimulation of hypothalamic neurons by hypercapnia or hypoxia or 2) neuronal discharge related to cardiovascular activity.

EXPOSURE OF BORDERLINE HYPERTENSIVE RATS TO A HIGH NaCI

EXPOSURE OF BORDERINE HYPERTENSIVE RATS TO A HIGH NaCI DIET DURING WEANING ALTERS CONTROL OF ADULT BLOOD PRESSURE. R. Hunt and D.C. Tucker. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294
Borderline hypertensive rats (BHR) show an increase in adult BP when exposed via the maternal diet to 3% NaCl from conception to weaning (Domino et al., 1990). We tested the hypotheses that exposure to 8% NaCl during the weaning period (14-28 days of age) would elevate adult BP and alter the BP response of BHR to 8% NaCl in adulthood. All BHR were fed 1% NaCl from 4-8 wks of age. At 8 wks, half of the males from within a litter were placed on 8% NaCl. BP measured by femoral artery cannula at 17 wks did not differ between rats fed 1% and 8% NaCl during weaning. BHR fed 8% NaCl during weaning showed attenuated depressor responses to administration of chlorisondamine (2.5 mg/kg, i.v.), suggesting decreased sympathetic control of adult BP. In ganglion-blocked rats, responses to saralasin (100 angiotensin II to BP is attenuated in BHR fed 8% NaCl in adulthood. Administration of the arginine Administration of the arginine approach. n adulthood. Administration of the arginine vasopressin antagonist Manning compound (100 $\mu g/kg$, i.v.) to BHR pretreated with chlorisondamine and saralasin suggested increased AVP influence on BP in rats fed 8% NaCl during adulthood. The data suggest that while ingestion of 8% NaCl during the weaning period is not sufficient to increase adult BP in BHR, it does affect sympathetic control of BP and may alter other controls of BP as well.

MECHANISMS INVOLVED IN THE PRESSOR RESPONSE TO CARBACHOL (CARB) INJECTED INTO THE POSTERIOR HYPOTHALAMIC NUCLEUS (PHN). J. R. Martin, Dept. of Pharmacology, Kirksville College of Osteopathic Medicine, Kirksville, MO 63501. Microinjection of CARB into the PHN of conscious rats increases arterial pressure (AP) partly due to sympathoexcitation. The present study further evaluated the mechanisms of this CARB-induced pressor effect. Sprague-Devley rats were instrumented for arterial pressure (AP) Dawley rats were instrumented for arterial pressure (AP) measurement, systemic drug administration, and micro-injection of 5.5 nmol of CARB into the left PHN. Pretreatment of rats with prazosin (PRAZ; 1 mg/kg, i.v.), methyl-atropine (ATR; 2 mg/kg, i.v.), or a vasopressin V_1 receptor antagonist (V_1 ANT; 20 μ g/kg, i.v.) attenuated the CARB-induced rise in AP. Coadministration of PRAZ and ATR produced an additive blockade while the combination of PRAZ, ATR, and V_1 ANT reversed the CARB-induced pressor effect to amodest, transient depressor response. Propranolol (PRO; 2 mg/kg, i.v.) pretreatment potentiated the CARB-induced increase in AP. This potentiation was blocked by administration of the V₁ ANT resulting in a change in AP identical to that evoked by CARB alone. Furthermore, the V₁ ANT blocked a CARB-induced suppression of the baroreceptor reflex. These results suggest that the pressor response to PHN injection of CARB is complex and involves, in addition to sympathoexcitation: 1) the sympathoedrenal axis; 2) circulating vasopressin; and 3) a cholinergic pressor mechanism. INTRACEREBROVENTRICULAR CAPTOPRIL LOWERS PRESSURES IN DAHL SALT-SENSITIVE RATS. L. A. Lark and J. A. Weyhenmeyer. Neuroscience Program and College of Medicine, University

Neuroscience Program and College of Medicine, University of Illinois, Urbana, IL 61801.

In the present study we assessed the ability of intracerebroventricular (i.c.v.) injection of the angiotensin converting enzyme (ACE) inhibitor captopril to lower mean arterial pressure (m.a.p.) in conscious, freely moving inbred Dahl salt-sensitive (DS/JR) rats and their normotensive control inbred Dahl salt-resistant (DR/JR) rats. tensive control inbred Dahl salt-resistant (DR/JR) rats. Four week-old rats were placed on a maintenance 8% salt diet. At 7 weeks of age, a cannula was implanted in the lateral ventricle. One week later a catheter was inserted into the femoral artery and exteriorized between the scapulae. Animals were allowed to recover overnight. Captopril (10 µg/4 µl) or vehicle (4 µl) were administered i.c.v. while m.a.p. was constantly monitored. DS/JR rats had significantly elevated m.a.p.'s as compared to DR/JR rats (188 \pm 9 vs. 99 \pm 1 mm Hg, p < .01). A significant depressor response with a maximum of -17.6 \pm 4.1 mm Hg lasting for several hours duration was observed in DS/JR rats after i.c.v. captopril administration. Captopril had rats after i.c.v. captopril administration. Captopril h
no effect upon the m.a.p. of DR/JR rats. Both strains
were unaffected by i.c.v. injection of vehicle. Further
studies will be necessary to elucidate the antihypertensive mechanism of centrally administered captopril in
DS/JR water Captopril had

STIMULATION OF HISTAMINERGIC NEURONS RESULTS IN INCREASED PLASMA NOREPINEPHRINE. V. Akins and S.L. Bealer. Dept. Physiol. and Biophysics. Univ. Tenn., Memphis, TN 38163.

Neurons containing histamine (HA) are found in the tuberomammillary nucleus (TMN) in the posterior hypothalamus of the rat brain and may function in cardiovascular regulation and fluid balance. To test the effects of stimulated HA release on plasma vasopressin (PAVP) and norepinephrine (PNE) levels, male Sprague-Dawley rats were instrumented with a chronic bipolar electrode in the TMN, a microdialysis probe near the supraoptic nucleus (SON) to measure changes in HA release from nerve terminals, and femoral venous and arterial catheters. The SON of conscious rats was dialyzed with saline at 2 μ l/min and 4 30-minute collections of the effusate were made. Three blood samples for measurement of PNE and PAVP were taken. During the third 30minute collection period, the TMN was stimulated with a 1 minute train of 0.5 msec pulses of 1-10V and 100 HZ every 5 minutes. Increases in extracellular HA concentrations near the SON during TMN stimulation (+88%) were correlated with significant increases in PNE (+52%). Both values returned to baseline levels during the recovery period. No changes in PAVP were measured. Increases in PNE were abolished when the H1 antagonist, pyrilamine, was continuously administered iv throughout the protocol. These results support the conclusion that brain HA mediates activation of the peripheral sympathetic nervous system through central H1 (Supported by NIH and AHA.) receptors.

REGIONAL HEMODYNAMIC CHANGES PRODUCED BY ACTIVATION OF THE CORONARY VASOCONSTRICTOR PATHWAY. L.F. Jones, D.D. Gutterman and M.J. Brody. Depts. Pharmacol., Int. Med. & Cardiovasc. Ctr., Univ. of Iowa, Iowa City, IA 52242. Hemodynamic characteristics following electrical activation of the coronary vasoconstrictor pathway in the

Hemodynamic characteristics following electrical activation of the coronary vasoconstrictor pathway in the anterior hypothalamus (AHA) were studied to determine if activation of the pathway produces specific profiles of regional hemodynamic changes. Coronary, femoral, renal and mesenteric blood flow velocities (BFV) were recorded in cats. Following vagotomy and propranolol, electrical stimulation of the AHA produced a decrease in CBFV associated with the defense reaction, an integrated response including a decrease in hindquarter vascular resistance (HqVR) and an increase in renal vascular resistance (RVR) and mesenteric vascular resistance (MVR). In a second area of the AHA, the defense reaction was elicited without a decrease in CBFV, while a third region produced an increase in both HqVR and MVR. The decrease in CBFV and FVR was also produced by electrical stimulation in the parabrachial nucleus, in an area close to the ventral surface of the pons lateral to the pyramidal tract, and in rostral ventrolateral medulla. These results support the existence of different patterns of hemodynamic responses between coronary vasoconstrictor regions and other sites. These data also support the hypothesis that coronary vasoconstriction is a component of the defense reaction.

ENHANCED PRESSOR RESPONSES TO INTRACEREBROVENTRICULAR (ICV) VASOPRESSIN AFTER PRETREATMENT WITH ICV OXYTOCIN.
Y. Takahashi*, A. Komulainen*, P. Poulin, Q.J. Pittman, Neuroscience Research Group, U of Calgary, Calgary, Can.

Arginine vasopressin (AVP) given ICV causes motor disturbances in rats. The severity increases and the threshold dose decreases following prior sensitization with oxytocin (OXY). As ICV AVP also increases heart rate (HR) and blood pressure (BP), we have asked if these cardiovascular responses could also be sensitized. Rats were given ICV saline (5 µl) or were sensitized with 1 pmole OXY (ICV). 24 h later rats anaesthetized with urethane received ICV vehícle which was without effect on BP or HR. AVP (1 pmole) increased BP (4.2 ± 1.8 mm Hg) and HR (19 ± 11 bpm) less in control (n=8) than in sensitized rats (8.4 ± 2.6 mm Hg; 43 ± 8 bpm; n=6); 2 other sensitized rats died after AVP. In sensitized rats, 5 pmole AVP caused 50% mortality; survivors (n=6) displayed increases in BP (19.0 ± 4.5 mm Hg) and HR (81 ± 22 bpm) significantly greater than those of controls (8.1 ± 1.6 mm Hg; 38 ± 7 bpm; n=13). 10 pmole AVP increased BP (10.3 ± 2.2 mm Hg) and HR (39 ± 5 bpm) in controls but sensitized rats all died following wide oscillations in BP and HR. These responses to AVP (and no mortality) were also observed when rats were paralyzed and ventilated. We conclude that prior exposure to OXY can sensitize brain AVP receptors involved in central cardiovascular control.

THE EFFECTS OF VASOPRESSIN ANTAGONIST ON PHYSOSTIGMINE INDUCED PRESSOR RESPONSES IN CONSCIOUS RABBITS. M. Hav. Y. Nishida*and V.S. Bishop. Dept. of Pharmacology, Univ. of Texas Health Science Center, San Antonio, TX 78284.

A number of previous studies have shown that intravenous administration of physostigmine (PHYS) results in an increase in mean arterial pressure (MAP), heart rate (HR) and sympathetic activity. It has been suggested that PHYS may act at central sites to enhance sympathetic outflow and ultimately increase MAP. However, it has also been suggested that the pressor effects of PHYS may be due to a central activation of arginine-vasopressin (AVP) release. The present study was designed to determine the effects of V1 AVP antagonist d(CH2)sTYR(ME)AVP (AVPX) on PHYS induced increases in MAP and HR in conscious rabbits. New Zealand rabbits were chronically instrumented with arterial and venous catheters for the monitoring of MAP and HR, and the administration of drugs. Some animals were also instrumented for the recording of renal sympathetic nerve activity (RSNA). Resting MAP and HR were 79 ± 4 mmHg and 248 ± 26 beats/min., respectively. PHYS (75 µg/kg) was infused intravenously (i.v.) and changes in MAP and HR were recorded. Intravenous PHYS resulted in an averaged 22 ± 3 mmHg increase in MAP and an averaged 15 ± 8 beat/min. increase in HR. In 2 animals instrumented for the recording of RSNA, PHYS was found to induce only minimal changes in RSNA possibly due to buffering capabilities of the intact baroreflex. In all animals tested, administration of ganglionic blocking agent hexamethonium (25 mg/kg) did not alter the pressor effects of i.v. PHYS. Intravenous administration of AVPX (10 µg/kg) had no effect on baseline MAP or HR. However, following AVPX administration, i.v. PHYS increased pressure by only 9 ± 6 mmHg and raised HR 31 ± 11 beats/min. These results suggest that, in the conscious rabbit, the pressor effects of i.v. administered PHYS may be the result of increased levels of circulating AVP. (Supported by HL36880 and HL12415).

RELEASE OF PARAVENTRICULAR NUCLEUS (PVN) NOREPINEPHRINE DURING HYPOTENSION IN DIABETIC RATS. <u>S.L. Bealer</u>, Dept. Physiol., Univ. Tennessee, Memphis, TN 38163.

Reductions in blood pressure increase extracellular norepinephrine concentration in the PVN (PVNne) in normal animals. Furthermore, studies have shown that central noradrenergic systems are altered in diabetes mellitus. The present studies used in vivo microdialysis to evaluate PVNne in control rats (Cont) and animals made diabetic (DM) with streptozotocin during hemorrhage. Two-three wks after treatment animals were prepared with arterial catheters and microdialysis probes adjacent to the PVN. Brain dialysate was collected before, during, and following hemorrhage which lowered blood pressure to 75 mmHg. Blood glucose was elevated in DM (338± 39 mg/dl) compared to Cont animals (106± 7 mg/dl). Prior to hemorrhage, there were no differences in blood pressure or PVNne between Cont (105±5 mmHg; 99±16 pg/ml) and DM rats (110±4 mmHg; 74±10 pg/ml). However, during hemorrhage, PVNne increased significantly more in DM (312 \pm 40%) than in Cont animals (140±15%). These results indicate an enhanced PVN noradrenergic nerve activity in DM animals during hypovolemic hypotension compared to normal animals. (Sponsored by grants from the National Institutes of Health and the American Heart Association).

CENTRAL CARDIOVASCULAR REGULATION OF TACHYKININS: IN-VOLUMENT OF THE SYMPATHETIC NERVOUS SYSTEM AND VASOPRESSIN RELEASE. H.Kamiya*, A.Nagashima*, T. Hagio*, R.Saito* and Y.Takano. Dept. of Pharmacol., Fac. of Pharmaceutical Sci., Fukuoka Univ., Fukuoka 814-01, Japan.

Five mammalian tachykinins have been so far isolated, substance P(SP), neurokinin A (NKA), neurokinin B(NKB), neuropeptide K and neuropeptide $\gamma(NP\gamma)$. Here we report studies on the mechanisms of central cardiovascular regulation of tachykinins. Intracerebroventricular (i.c.v.) injections of tachykinins caused dose-dependent increases in the blood pressure and heart rate. The pressor responses to SP, NKA and NP7 were blocked by sympathetic blocking agents. In contrast, the pressor responses to an NKB analogue senktide (10 μ g, i.c.v.) was not blocked by the ganglionic blocker or adrenalectomy. The senktideinduced pressor response was inhibited by pretreatment with a vasopressin antagonist (10 μ g/kg, i.v.), and senktide caused an increase in plasma vasopressin level. However, the vasopressin antagonist did not influence the $\ensuremath{\mathsf{SP-}}$ and NKA-induced pressor responses. These results suggest that central SP and NKA increase the blood pressure and heart rate via sympathetic nerve activity, whereas central NKB increases the blood pressure via release of vasopressin from the hypothalamus.

VASOPRESSIN (VP) mRNA, BUT NOT OXYTOCIN (OT) mRNA
IN THE PARAVENTRICULAR HYPOTHALAMIC NUCLEUS (PVN)
IS ASSOCIATED WITH SALT-INDUCED HYPERTENSION.
B. H. Hwang and J.-K. Zhang*. Terre Haute Ctr.
for Medical education, Indiana Univ. School of
Medicine, Terre Haute, IN 47809.
The VP and OT are abundant in several brain

The VP and OT are abundant in several brain regions including the PVN and supraoptic nucleus (SON). However, exactly how VP and OT neurons participate in the development of hypertension remains to be studied. In this study, we used 35S-VP and -OT oligonucleotide probes in conjunction with in situ hybridization to study how VP and OT mRNAs in the PVN and SON are related to salt-induced hypertension. Male Dahl salt-resistant (SR) and salt-sensitive (SS) rats were fed with high salt diet containing 8% NaCl for 4 weeks. SS rats developed hypertension (191 mm Hg) with cardiac hypertrophy, whereas SR rats remained normotensive (119 mm Hg). Further, quantitative autoradiography showed that SS rats contained more VP mRNA (310 fmol/mg protein) in the PVN than SR rats (254 fmol/mg protein). OT mRNA in the PVN and SON were not significantly different between SR and SS rats. Results suggest that increased VP gene expression may play a role in pathogenesis of salt-induced hypertension. Supported by NIH grant NS 25087.

OPIOID μ_1 - AND μ_2 -RECEPTOR EFFECTS ON HEART RATE IN THE RAT. P. Paakkari, G. Feuerstein and A.-L. Sirén. Dept of Neurology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814, Dept of Pharmacology, SmithKline & Beecham, King of Prussia, PA 19406.

The possibility that μ -opioid-induced tachycardia and bradycardia could be mediated by different subtypes of the $\mu\text{--receptor}$ was studied in conscious male Sprague-Dawley rats. The selective μ -receptor agonist dermorphin (DM) and its analog

μ-receptor agonist dermorphin (DM) and its analog TAPS (Tyr-D-Arg-Phe-sarcosine), a proposed μ₁-receptor agonist (Paakkari P, et al, <u>Progr Clin Biol Res</u> 328:385, 1989), were given centrally. TAPS 0.3, 3 and 30 pmol increased the heart rate (HR) by 71±22, 49±14 and 30±17 beats/min (bpm), the response being inversely correlated to the dose. DM 1 pmol increased HR by 39±14 bpm while DM 10 pmol had no effect. After treatment with the μ-selective antagonist naloxonazine while DM 10 pmol had no effect. After treatment with the μ_1 -selective antagonist naloxonazine (NX), TAPS 30 pmol and DM 1 pmol decreased HR by -22±10 and -24±7 bpm, respectively. The brady-cardic effect of 10 nmol DM (-25±8 bpm) was potentiated by NX (-97±22 bpm, p<0.01) but abolished by naloxone (non-selective antagonist). These data suggest that the high affinity μ_1 -

opioid receptors mediate tachycardic responses and μ_z -receptors mediate bradycardic responses.

ELECTROPHYSIOLOGICAL EVIDENCE FOR HYPOTHALAMIC DEFENSE AREA INPUT TO CELLS IN THE LATERAL TEGMENTAL FIELD OF THE MEDULLA IN RABBITS. R.W. Winters'. P.M. McCabe, E.J. Green, Y-F. Duan'. Y. Huano'. C.G. Markgraf, and N. Schneiderman. Department of Psychology, University of Miami, Coral Gables, FL. 33124.

There is considerable evidence that neurons in the lateral tegmental field

of the medulla (LTFM) are involved in cardiovascular regulation. Pressor responses are elicited by electrical stimulation of the LTFM, and cells in this region are activated antidromically by stimulation of the rostral ventrolateral medulla, a structure that is essential to the maintenance of vasomotor tone. medulla, a structure that is essential to the maintenance of vasomotor tone. The present study sought to determine if neurons in the posterior hypothalamic defense area (HYP) make functional connections with cells of the LTFM. Albino rabbits were anesthetized with isofluorane and a bipolar electrode was implanted into the HYP. This site was verified by the presence of a large tachycardia/pressor response elicited by electrical stimulation. A recording/stimulating electrode was lowered into the LTFM, primarily in the nucleus reticularis parvocellularis, approximately 2.0 to 3.5 mm rostral to obex. Stimulation of LTFM elicited a tachycardia/pressor response. Responses of single cells in LTFM were then recorded during hypothalamic stimulation. Less than one-half of the cells recorded in LTFM changed their firing rate in response to HYP stimulation. Approximately 50% of the cells influenced by HYP stimulation were excited. In some cases this excitation was secondary to an increase in blood pressure. A substantial number of was secondary to an increase in blood pressure. A substantial number of cells that were affected by HYP stimulation showed a change in discharge cells that were allected by HTP stillinguistics is sowed a charge in discharge rate in response to phenylephrine (1µg/kg, i.v.) and/or showed spontaneous activity that was phasically modulated within the cardiac cycle. These findings provide evidence that LTFM receives input from the posterior hypothalamic defense area, and that this input may be important in the mediation of the cardiovascular components of the defense response in rabbits. (Supported by NIH grants HL36588, HL 07426, NS 24874).

DISCHARGE DEPENDENCIES OF AMYGDALA CENTRAL NUCLEUS NEURONS TO THE CARDIAC AND RESPIRATORY CYCLE FOLLOWING LOCAL COCAINE ADMINISTRATION. J.X. Zhang. H. Ni. and R.M. Harner. Brain Research Institute and Dept. of Anatomy & Cell Biology, UCLA,

Harper. Brain Research Institute and Dept. of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

We examined dependencies of amygdala central nucleus (ACE) neuronal discharge to the cardiac and respiratory cycle in freely moving cats following microinjection of cocaine (100 μg in 0.2 μL) into that structure, a nucleus with heavy projections to cardiorespiratory regions of the parabrachial pons and the nucleus of the solitary tract. Cats were instrumented with EEG, ECG, and diaphragmatic EMG electrodes and indwelling ACE cannulae and microwire bundles. Following surgical recovery, each cat was allowed to sleep undisturbed in a quiet chamber and then administered cocaine through the indwelling cannula. A second sleep-wake recording was taken following occaine microinjection. Cardiac R-R intervals, respiratory breath-to-breath intervals, and interspike ACE neuronal intervals were stored on digital disks, and cross-correlation dependencies were calculated between neuronal discharge and cardiac and respiratory intervals were calculated between neuronal discharge and cardiac and respiratory intervals in baseline and post-cocaine administration periods. Cross-correlation dependencies between neuronal discharge and respiratory and cardiac cycles were found in 3 of 15 cells, respectively, during baseline periods. The dependencies between the cardiac cycle and neuronal discharge vanished or greatly weakened following cocaine administration. One respiratory dependency disappeared while the period of the perio weats-new routowing cocaine administration. One respiratory dependency disappeared while two remained with a phase shift in the respiratory cross-correlation after cocaine administration. We suggest that cocaine alters ACE neuronal phasic discharge with the respiratory and cardiac cycle when administered locally. Supported by R01-DA04913.

EFFECTS OF CENTRAL INJECTIONS OF DILTIAZEM ON BLOOD PRESSURE. R. de Beaurepaire and S.N. Thornton*. Lab. de Psychopharmacologie Experimental, CHU Côte de Nacre, Faculté de Med., Caen 14032 and Lab. de Neurobiologie des Régulations, Collège de

France, 11 Place Marcelin Berthelot, 75231 Paris Cedex 05, France.
The calcium channel inhibitor Diltiazem (DLT) is widely used in the treatment of cardiovascular diseases. It also has been successfully used in the treatment in some psychiatric disorders but this effect is not easy to understand since DLT crosses only poorly the blood brain barrier. Neverthless, the hypothesis of the central action of calcium channel inhibitors has been raised for their psychiatric as well as for their cardiovascular effects.

We tested the effects of DLT on blood pressure (femoral artery catheter)

following peripheral and central administration in urethane anesthetized rats. The effective dose of DLT injected intravenously appears between 1 ug/kg (no effect) and 10 ug/kg (significant decrease in blood pressure). With intracerebroventricular injections (3 ul into the lateral ventricle) no effect on blood pressure was observed with 1 ug/kg but a significant decrease in blood pressure appeared with 10 ug/kg. Similar results were obtained with injection of DLT, in very small volumes of vehicle, into several hypothalamic sites; no effect with 1 ug/kg, decrease in blood pressure with higher doses.

If, as has been proposed, DLT acts through the central nervous system to produce its effects, in this case a decrease in blood pressure, we would have presumed that the central doses should have been smaller than the peripheral ones. As this was not the case, our results do no support the hypothesis that DLT acts through the central nervous system to decrease blood pressure

234.22

BULBAR ORIGIN OF CATECHOLAMINERGIC PROJECTIONS TO THE CENTRAL AMYGDAL-OID NUCLEUS IN THE RAT. B.R. Due & J.S. Schwaber, Neural Computation Group, E.I. duPont Co., Wilmington, DE 19880-0352

The central amygdaloid nucleus (CeA) is known to modify autonomic function through projections to autonomic centers in the medulla and pons. Norepinephrine (NE) and other catecholaminergic (CA) terminals are present in the CeA, and NE injected into the CeA has potent influences on autonomic funcceA, and Ne injected into the CeA has potent interiors of autonomic time-tion, including heart rate, blood pressure and cardiac rhythm (Leonzio et al., Soc. Neuro. Abstr., 80.1, 1987). CeA NE is known to be of bulbar origin. In order to determine the specific cells groups of origin, rhodamine beads or Fluo-rogold was injected into the CeA and brainstem sections processed for tyrosine hydroxylase (TH), or alternate sections for TH, phenylethanolamine-n-methyl-transferase (PNMT) or dopamine-beta-hydroxylase (DBH). In some cases the lateral bed nucleus of the stria terminalis (BNST) was also injected. groups projecting to the CeA and BNST were largely co-extensive but distinct. The great majority of neurons double-labeled for CA enzyme and CeA projections were located in the medulla in the A1 and A2 regions, plus a distribution of neurons extended through the medulla between the two. On average somewhat more double-labeled cells/section were located ventrolaterally at levels caudal to the obex. A significant proportion (approx. 40%) of NTS neurons that project to CeA, both caudal and rostral to the obex, appear to also be CA neurons. On the other hand, ventrolaterally located neurons in the A1 region were about 25% CA, and only a very few C1 area neurons were CA cells. Unexpectedly, only a relatively few A6 (locus coeruleus) and A7 neurons project to the CeA

234.24

INTERVAL PATTERNING FOLLOWING

CARDIAC INTERVAL PATTERNING FOLLOWING COCAINE ADMINISTRATION TO THE CENTRAL NUCLEUS OF THE AMYGDALA. R.M. Harper, R.K. Harper, C.A. Richard, R.R. Terreberry and R.C. Frysinger, Brain Research Institute and Dept. of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

We examined sequencing of cardiac R-R intervals in freely moving cats following administration of 3 dose levels of cocaine (0.625, 1.25, 2.5 mg) into the central nucleus of the amygdala (ACE), a limbic structure with heavy projections to the parabrachial pons and the nucleus of the solitary tract. Cats were instrumented with EEG, ECG, indwelling ACE cannulae, laryngeal dilator muscle, and diaphragnatic EMG electrodes Following recovery, each cat was allowed to sleep undisturbed in a quiet chamber and then administered cocaine through the indwelling cannulae. Cardiac R-R intervals were stored on digital disks. Each cardiac interval was plotted successively prior to and following through the indwelling cannulae. Cardiac R-R intervals were stored on digital disks. Each cardiac interval was plotted successively prior to and following cocaine administration, and the distribution of variation and determination of respiratory and slower sources of variation was assessed from these plots and from measures of interquartile range of intervals. Although ACE cocaine administration elicited a variety of behavioral and respiratory sequelae, the extreme tachycardia with abolition of respiratory and slower variation found following intravenous or intraventricular administration was not a prominent feature. Slow variation from sources yet undetermined was present following ACE administration. We suggest that the extreme tachycardia associated with intraventricular cocaine administration results from other than ACE influences. intraventricular cocaine administration results from other than ACE influences. Supported by R01-DA04913.

ANALYSIS OF OVERNIGHT CARDIAC INTERVAL PATTERNS IN PATIENTS WITH COMPLEX PARTIAL SEIZURES.
R.C. Frysinger, M.F. Levesque*, and R.M. Harper. Dept. of Anatomy and Cell Biology, Division of Neurological Surgery, and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA

We have shown that single cell discharge in temporal structures is modulated by the cardiac cycle and by changes in heart rate, and stimulation and lesion studies in animals suggest that mesial temporal structures play a role in modulation of cardiovascular patterning as well as in the genesis and propagation of seizure activity. Patients with epilepsy may thus show alterations in cardiac rate patterns associated directly or indirectly with changes in mestal temporal structures associated with epileptogenesis. We assessed overnight cardiac interval (RRI) records from 19 patients with intractable epilepsy who were candidates for anterior temporal lobectomy. We examined the amplitude and frequency characteristics of RRI variation, and partitioned presumed sources of the variation on the basis of morphology and frequency characteristics.

Two patients showed a dramatic reduction in RR variability,

probably resulting from peripheral vagal neuropathy. Of the remainder, nine patients showed high-amplitude rhythmic variation at 4-6/min, with a time constant overlapping that ascribed to the baroreflex. The high relative amplitude of this variability may reflect diminished modulation of the baroreflex by mesial temporal structures such as amygdala.

PLASMA AND ORGAN CATECHOLAMINE LEVELS FOLLOWING INSULAR CORTEX STIMULATION. S. Oppenheimer, T. Saleh*, J. Wilson*, D. Cechetto. Robarts Research Institute/Department of Physiology, University of Western Ontario, London, Ontario, Canada. Phasic microstimulation of the rat insular cortex triggered by the ECG R wave produces heart rate changes independent of blood pressure and respiratory effects. Bradycardia, tachycardia and control pressure and respiratory effects. Bradycardia, tachycardia and control responses (no heart rate change) were identified and respectively formed three groups of ketamine anesthetised rats. Blood samples were taken immediately before, and I hour after insular stimulation for catecholamine analysis. Hearts and kidneys were removed after I hour of stimulation, and immediately frozen in liquid nitrogen for subsequent catecholamine analysis. Heart rate changes significantly correlated with changes in plasma norepinephrine (p<0.01). No correlation between intracardiac or intrarenal norepinephrine and heart rate or plasma norepinephrine was seen at bradycardia or control sites; at tachycardia sites, stimulation elevated plasma norepinephrine (ρ <0.05), while intracardiac norepinephrine levels inversely correlated with heart rate change (ρ <0.02). No changes in plasma epinephrine were seen; epinephrine was not detected in organ samples. Stimulation induced tachycardia possibly results from increased cardiac norepinephrine release and is not balanced by increased synthesis. (Supported by the Heart and Stroke Foundation of Ontario).

234.26

ELECTROPHYSIOLOGICAL AND OPTICAL STUDY OF VAGAL Anatomical studies have suggested that the vis-

ceral sence is represented in the insular cortex although very little functional evidence was available. To examine this physiologically, responses to vagal stimulation were recorded. SD rats were anesthetized with sodium amobarbital, ventilated artificially, and mounted on a stereotaxic apparatus. Cervical vagus nerves were stimulated and excited fiber components were monitored at the solitary tract nucleus (NTS). No cortical response was detected under the stimulus intensity of the A-fiber range. A surface-negative field potential (FP) appeared bilaterally with 40-60ms latency when the C-fiber response was obtained at NTS. This FP was recorded mainly around the border between the granular and dysgranular subareas anterior to the middle cerebral artery. Topical application of GABA diminished this FP. These results indicate that vagal C-fiber afferents projsults indicate that Vagal C-fiber afferents project to the superficial layers to produce EPSPs in the rostral insula. Attempts were made to record this response optically with voltage-sensitive dye. Optimal staining condition differed from that of the somatosensory cortex probably because the sites of origin of the main signal differ.

SPINAL CORD: ANATOMY AND PHYSIOLOGY

235.1

PROPOFOL ALTERS DORSAL HORN NEURONAL RESPONSES TO LOW INTENSITY RECEPTIVE FIELD STIMULATION. H. Uchida*, J.G. Collins,

K. Kishikawa, H.Hirata. Dept. Anesth. Yale Sch. Med. New Haven. CT 06510 General anesthetics (GAs) have the potential to influence all areas of the neuraxis but anesthesia is often thought of as a supraspinal event. This is one of a series of studies examining the effects of GAs on spinal sensory processing. Tungsten microelectrodes were used to record extracellularly from single spinal orsal horn neurons in physiologically intact, awake, drug-free cats. Each neuron's low threshold receptive field area and baseline response to brushing and pinching was determined. Propofol (2,6-diisopropylphenol), an I.V. anesthetic agent, was administered (7.5-10.0 mg/kg iv). Drug injection produced a brief period of apnea (15-30 sec.) that was followed by a deep anesthetic state that quickly dissipated with full recovery apparent within 30 to 45 minutes.

Propofol reduced the low threshold receptive field size of 11 of the 18 neurons studied by at least 20%. Five receptive fields were reduced in area by at least 70%. When recovery was studied most receptive fields returned to their baseline size as the animals regained consciousness. Neuronal responses to brush (n=15) and non-noxious pinch (n=15) were also depressed. Brush responses returned to baseline with recovery, pinch was not studied during recovery. General anesthesia has been defined as the loss of all sensation. We have previously reported that pentobarbital also depresses low intensity stimulation but ketamine does not. The ability of some GAs to reduce low threshold sensory input at the level of the spinal dorsal horn as well as their ability to depress responses to noxious stimulation within the spinal cord may contribute to the reduction in sensory input that ultimately results in the state of sensory impairment known as anesthesia. This possible spinal site of action warrants further study as we begin to appreciate the complex nature of sensory modulation within the spinal dorsal horn. Supported by NIH GM 29065

PRECISION OF CAT DORSAL HORN SOMATOTOPIC MAP. P.B. Brown, H.R. Koerber, and G.R. Hobbs. Dept. of Physiol. and Dept. of Stat. and Computer Sci., W. Va. Univ. Health Sciences Ctr., Morgantown, WV 26506; and Dept. of Neurobiol., Anat., and Cell Sci., Univ. Pittsburgh Med. School, Pittsburgh, PA 15261.

Statistical methods were used to estimate pre- and post-fixation, deviations from bilateral symmetry, and precision of the dorsal horn map of the hindlimb skin. Light touch excitatory receptive fields (RFs) of 150 single units were mapped, and recording sites were marked by small electrolytic lesions, in six

napped, and recording sites were marked by smarr electrolytic lesions, in six random-source urethane-anesthetised adult cas.

Sigmoid functions were fitted to plots of RF distance from tips of toes (D) as a function of mediolateral (ML) position in the dorsal horn, combining data across cats, for each segmental level. Data from individual cats were shifted rostral or caudal for best fits with the sigmoids. The average shift magnitude was 0.22 segment, with a range of 0.4 caudal to 0.3 rostral (pre- and post-fixations). The difference between predicted and observed ML for an observed D was assumed to be a combination of interanimal variation, measurement error, modeling error, deviations from bilateral symmetry, and intra-animal variation. Measurement error was estimated as $30 \, \mu m$. Bilateral symmetry and acrossanimal errors were both ca. 60 μ m, or 7.5% of the dorsal horn width, substantially less than the width of a dendritic tree or the terminal distribution of a single primary afferent. Within-dorsal horn error was ca. 5 μ m, 0.6% of the dorsal horn width, less than a soma diameter. Modeling error was $27 \,\mu\text{m}$.

This remarkable precision implies that errors in map organization would contribute an average of only 0,2 mm to errors of stimulus localization along the 30 cm length of the leg. Due to varying map scale, such contributions would be smaller than the average on the toes, and larger on the proximal leg.

DEVELOPMENT OF CUTANEOUS AND PROPRIOCEPTIVE AFFERENT PROJECTIONS AND MOTONEURONAL DENDRITES IN CHICK SPINAL CORD. B. Mendelson, H.R.

DENDRITES IN CHICK SPINAL CORD. B. Mendelson. H.R. Koerber and E. Frank. Dept. of Neurobiology, Anatomy and Cell Science, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Muscle and cutaneous nerves were individually labeled with Dil in developing chick embryos fixed at different stages. After allowing 6-14 d (at 37° C) for diffusion, the detailed anatomy of sensory afferent arbors and motoneuronal dendrites was analyzed. At first, cutaneous and muscle afferents exhibited similar morphologies. Between stages 28-29 (E5.5-6) the first small branches began to penetrate the gray matter. Both cutaneous and muscle afferents had processes in the primordium of the dorsal funiculus (the oval bundle of His) extending for at least 2 segments rostral and caudal to their point of entry. At stage 33 (E7.5) both types exhibited collaterals coursing ventrally through the superficial laminae of the dorsal horn (to lamina V). Target-specific differences in projections were first observed shortly thereafter (St 34, E8) when some muscle afferent projections extended unbranched through the dorsal horn to the level ent projections extended unbranched through the dorsal horn to the level of motoneuronal somata. In contrast, cutaneous afferents branched and remained within the dorsal horn. These results suggest that cutaneous and muscle afferent collaterals enter the dorsal horn simultaneously and

subsequently grow to appropriate destinations.

At the earliest stages examined, the motoneurons studied (sartorius) extended dendrites both dorsally and medially along the gray-white border. By stage 34 (E8) dendrites arborized extensively in the marginal border: by stage 34 (E8) demontes arbonzed extensively in the marginal zone (white matter), but in the gray matter dendrites were restricted to the lateral motor column. Dorso-medially directed dendrites were observed in St 40 (E14) embryos and thus grow into a region already occupied by muscle afferents with which they form synaptic connections.

AFFERENT NEURONES INNERVATING A NOVEL TARGET FORM SOMATOTOPICALLY APPROPRIATE CONNECTIONS IN THE DORSAL HORN. By <u>Gary Lewin and Stephen McMahon</u>, Dept. Physiology U.M.D.S. (St Thomas' campus), London SE1 7EH.

We have previously shown that when muscle afferents innervate skin they become capable of exciting dorsal horn neurones (DHN)(Lewin & McMahon, Soc Neurosci Abs. 15: 13.9, 1989). We have now examined the receptive field (RF) properties of DHN's driven by redirected afferents. In adult rats the nerve to the gastrocnemius muscle (GN) and the cutaneous sural nerve (SN) were self- and cross-anastomosed on left and right, respectively. Ten to 12 weeks later, recordings were made from functionally isolated DHN's driven by electrical stimulation of the GN, in urethane anaesthetised animals. When the GN innervated skin, 24 DHN's were found with brush, pinch or brush and pinch RF's including the skin exclusively innervated by the GN. For 76% of these, the RF extended contiguously into adjacent nerve territories. Moreover, DHN's activated by the GN were restricted to areas of the spinal cord normally receiving SN input: DHN's with medial foot RF's (n=23) lacked inputs from the GN. Finally, electrical stimulation of the GN innervating muscle failed to activate more than the occasional DHN with a RF inside or outside the SN territory.

Thus when the GN innervates a foreign target it contributes to

approximately normal RF's in the dorsal horn, and more remarkably it appears to selectively establish connections with somatotopically appropriate DHN's.

TOPOLOGY OF PRIMARY SOMATOSENSORY CORTICAL (SmI) MODULATION OF CUTANEOUS AFFERENT INPUT TO THE CAT BRACHIAL DORSAL HORN. R. Sonty, Department of Physiology, WV Univ. Med. Ctr., Morgantown, WV 26506.

SmI modulation of cutaneous afferent input to the cat brachial dorsal horn was investigated by observing change in amplitude of the N-1 component of cord dorsum potentials (CDPs) evoked by stimulation of forelimb peripheral cutaneous nerves, before and after application of cortical surface conditioning volleys at a rectangular grid of loci spaced 1mm apart. Topology of cutaneous nerve representation was determined by mapping the somatotopic projection of the nerves to the brachial dorsal horn and SmI using averaged evoked nerves to the brachial dorsal horn and SmI using averaged evoked potential techniques. Topology of descending effects was determined by correlating modulation of CDPs by cortical stimulation on a point on the grid. Results showed that (1) SmI effects on afferent input were predominantly inhibitory (n=204; p<.0001). (2) Maximal inhibition was observed at a 20 ms interval between the cortical conditioning stimulus and the peripheral nerve stimulus (F=18.63;p<.003).(3) The biphasic, initially negative, slow wave recorded of the cord on cortical stimulation attained a maximal negative value at 20 ms (4) Polysynaptic pathways were preferentially inhibited. (n=103; p<.0001) (5) A precise topology of SmI effects were seen, with maximal effects at corresponding locations in the two maps. This topology of effects may play a significant role in mechanisms of selective attention, spatial discrimination, and dorsal horn plasticity.

SPECIFICITY OF REGENERATION AND EFFECTS ON CENTRAL FUNCTION FOLLOWING PERIPHERAL AXOTOMY. H.R. Koerber, A.W. Seymour and L.M. Mendell. Dept. of Neurobiol., Anat. & Cell Sci. Univ. of Pittsburgh, Pittsburgh, PA 15261 and Dept. of Neurobiol. and Behav., SUNY, Stony Brook, NY 11794.

Primary afferents were impaled in the L7 ganglion of 15 ← chloralose anesthetized cats 6-17 months after tibial nerve transection. After characterizing their reinnervated receptor, single fibers were stimulated and the resulting cord dorsum potentials (CDPs) averaged. Previous studies have shown slowly (SA) vs rapidly adapting (RA) receptor-dependent functional specializations of central connections (Koerber & Mendell, J.Neurophysiol.'88) that are maintained after faulty reinnervation (Koerber et al., Neurosci, Lett.'89). These criteria were used to evaluate 427 of 543 tibial afferents (79%) that had successfully reinnervated peripheral targets. Many (46%) of these fibers had reinnervated inappropriate tissue or receptors (i.e. center-periphery mismatches). However, cutaneous afferents reinnervating subcutaneous tissue tended to be SA (3:1), and non-cutaneous fibers reinnervating skin favored SA over RA receptors (4:1). SA cutaneous afferents reinnervating skin preferred SA over RA receptors (4:1), and RA afferents also displayed some preference for RA receptors (2.5:1). The fate of regenerating fibers also affected the amplitude of the monosynaptic CDPs produced by their stimulation. Previously cutaneous fibers reinnervating any structure evoked larger CDPs than those that were unsuccessful (p<.01). Those reinnervating skin produced larger CDPs than those supplying muscle (p<.025). RA afferents reinnervating RA receptors produced larger CDPs than control RA fibers (p<.005), but CDPs produced by SA fibers reinnervating SA receptors were similar to controls. In summary, although center-periphery mismatches occur after tibial nerve regeneration, SA and RA fibers exhibit some selectivity in reinnervation. Furthermore, the appropriateness of the reinnervated target can influence the effectiveness of a fiber's central projections which can differ depending on the afferent's original receptor type. PROPERTIES OF MUSCLE AFFERENTS CROSS-INNERVATING SKIN IN CATS. H. Nishimura*, R.D. Johnson* and J.B. Munson*, *Departments of Neuroscience, College of Medicine and *Physiological Sciences, College of Veterinary Medicine, University of Florida, Gainesville, FL 32610.

We are investigating the ability of muscle and cutaneous afferents to innervate foreign tissue and foreign receptors, and the effects of such innervation on the electrical properties and synaptic efficacy of those afferents. Part or all of the medial gastrocnemius (MG) muscle nerve of cats was cross-connected with the caudal cutaneous sural (CCS) nerve, thus giving muscle afferents the opportunity to innervate skin and skin receptors. Individual MG-->CCS afferents were classified physiologically (up to 3 years later) with regard to receptor innervation, response properties, and conduction velocity. Of 18 analyzed afferents, 2 innervated hair follicle G₂ type receptors, 4 innervated SA I type receptors, and 12 innervated SA II type stretch receptors. Thus, like group I muscle afferents, all had static response properties. Conduction velocities, measured distal of the coaptation, ranged from 7-47 m/s. Stroking of the skin normally innervated by CCS evoked synaptic activity in triceps surae motoneurons similar to that elicited by muscle stretch. Electrical stimulation of the CCS nerve cross-innervated by MG produced EPSPs in triceps surae motoneurons like those produced by normal MG Ia afferents. MG nerve axotomized 1 year produced no such PSPs. Thus MG muscle afferents innervate and are activated by cutaneous receptors; this innervation preserves the synaptic efficacy of Ia afferents to motoneurons, which is seemingly sustained equally by innervation of muscle or skin receptors. Supported by NS15913 and NS27511.

BLADDER DISTENSION MODULATES LUMBOSACRAL DORSAL HORN NEURON RESPONSIVENESS. J.W. Downie and D.X. Zhang*. Dept.Pharmacol, Dalhousie Univ, Halifax, Canada, B3H 4H7

Convergent neural inputs onto sacral spinal neurons may account for aberrant reflexes subsequent to spinal injury. We sought to determine whether subthreshold visceral inputs to dorsal horn neurons could influence responsiveness to tactile stimuli.In chloralose-anesthetized cats extracellular unit recordings were made with carbon-filament electrodes. Receptor fields were mapped and responsiveness was assessed, with the bladder empty and distended, using 4 tactile stimuli ranging from innocuous to intensely noxious. Of 13 neurons studied to date 7 responded (>20% change in activity) to bladder distension. Activity increased in 4 units (42-112%) and decreased in 3 (42-71%). The overall responsiveness to tactile stimulation (basal activity subtracted) was decreased during bladder distension in 7 units (17-81%) and increased in 3 (43-106%). In 3/13 neurons bladder distension changed the modality producing maximum response from noxious to innocuous. In one neuron the reverse change was seen and there was no change in the others. The data indicate that bladder distension can modulate the responsiveness of dorsal horn neurons to tactile stimuli. Whether these effects are mediated by a spinal path of vesical afferents or to a pathway relaying at a supraspinal level has not yet been determined. (Supported by CPA and MRC of Canada)

INHIBITORY ROLE OF MECHANORECEPTIVE AFFERENTS FROM THE DISTAL GLANS PENIS ON SPINAL REFLEXES IN THE RAT. R.D. Johnson. Department of Physiological Sciences, College of Veterinary Medicine, University of Florida, Gainesville, FL 32610.
 Mature male Wistar rats were anesthetized with urethane (i.p. induction

and i.v. maintenance) and cannulated for vital signs monitoring. The spinal cord was acutely transected at T6-7 and the L5-S1 cord exposed for single cell recording. Stimulating electrodes were placed over the ipsilateral and contralateral dorsal nerve of the penis (DNP). The ipsilateral motor branch (MB) of the pudendal nerve was prepared for whole nerve recording. The glans penis and prepuce were mechanically stimulated with hand held

probes or a Chubbuck electromagnetic mechanostimulator.

Reflex discharges in the MB were elicited by electrical stimulation of either the ipsi- or contralateral DNP. These evoked discharges could be completely inhibited by a conditioning stimulus consisting of gentle squeezing or pressure on the inner prepuce, ventral glans raphe or distal glans provided the stimulus was given not more than approximately 50 ms prior to the electrical stimulus. A very small distal glans region (within 2 mm of the tip) was the most effective penile inhibitory site.

Almost all of the Class 2 and 3 spinal interneurons responding to penile

input exhibited an excitatory response to gentle squeeze, pressure, and stretch of the distal glans region. These neurons exhibited a short peripheral latent period and their evoked impulse discharge was temporally related to the short inhibitory period (20-40 ms following interneuron burst) for the reflex discharge in MB. These temporal relationships suggest that the inhibitory period may result from activity in these interneurons and is restricted to activity originating in myelinated penile mechanoreceptors. NOCICEPTIVE AND NON-NOCICEPTIVE DORSAL HORN NEURONES DIFFER IN SUBSTANCE P AND OTHER SYNAPTIC INPUT: A COMBINED ELECTROPHYSIOLOGICAL AND IMMUNOCYTOCHEMICAL STUDY IN THE CAT. A. Ribeiro-da-Silva, Y. De Koninck, A.C. Cuello and J.L. Henry. Depts. Pharmacology & Therapeutics, Physiology and Anaesthesia Research, McGill Univ., Montréal, Qué., H3G 1Y6

This study focuses on functionally classified dorsal horn neurones and examines the morphological and immunocytochemical characteristics of axonal varicosities contacting these neurones. In anaesthetized cats, intracellular recordings were obtained from dorsal horn neurones at the lumbar level using electrodes filled with HRP. Cells were classified on the basis of their responses to natural stimulation of the receptive field. Subsequently, HRP was injected intracellularly and the cats were perfused with an aldehyde mixture. The relevant tissue was processed for demonstration of HRP and Substance P-like immunoreactivity (SP-LI) at the light and electron microscopic levels, by means of a bi-specific anti-SP monoclonal antibody. With neurones which were exquisitely sensitive to noxious stimuli, up to 40% of the synaptic boutons contacting them contained SP-LI. Distal dendrites had a lower proportion of SP-LI positive boutons. These neurones did not appear to be associated with synaptic glomeruli. In contrast were large lamina III neurones, with axons projecting in the dorsal column and in the dorso-lateral funiculus, and neurones of inner lamina II; they were strongly associated with low threshold hair afferent input and with weak nociceptive responses if any. These cells were found to have a very low proportion of synaptic boutons containing SP-LI. These neurones also had a large number of dendritic spines and their dendrites were strongly associated with synaptic glomeruli in laminae II₁-III but very few in laminae I-II₀. Based on their anatomical localization, these glomeruli are likely to be associated with non-nociceptive low threshold mechanical input. These results suggest that nociceptive and non-nociceptive neurones differ in the chemistry and morphology of their synaptic inputs. (Supported by the NIH, YDK is funded by the FRSQ.)

ORGANIZATION OF LOCAL AXONAL CONNECTIONS IN NUCLEUS PROPRIUS OF HAMSTER SPINAL DORSAL HORN IN VITRO. S.P. Schneider. Department of Physiology, Univ. of N. Carolina, Chapel Hill, NC 27599.

As a prelude to study of mechanisms underlying local synaptic transmission in the mammalian dorsal horn, the distribution of axon branches of nucleus proprius (NP) neurons was analyzed in an isolated spinal cord preparation with intact innervation from a patch of hairy skin.

Twenty NP neurons were characterized by their responses to electrical volleys in a cutaneous nerve and to mechanical stimulation of the skin surface and then stained intracellularly with horseradish peroxidase.

with horseradish peroxidase. Axons of NP neurons terminated in two general patterns, each with a substantial local distribution. One group of neurons had axons that formed dense "patches" of terminals, 100-200 μ m in extent, oriented rostrocaudally in laminae II., III and IV of a single spinal segment. Axons of a second group were directed ventrally and bifurcated into long rostrocaudal branches that extended into adjacent segments, giving off periodic terminal arborizations in laminae deep to the parent cell body. Sensory input to both groups of neurons was dominated by innocuous mechanoreceptors with myelinated afferent fibers.

The results suggest that the integrative functions of the NP are subserved by at least two different groups of interneurons with distinctive patterns of local axon terminations.

neurons with distinctive patterns of local axon terminations. Supported by grant NS 25771 from the NINCDS.

TRIGEMINAL AND CERVICAL INPUT ONTO SINGLE NEURONS IN THE C1 SPINAL CORD. E.H. Chudler, C.E. Poletti* and W. Foote*. Lab. of Pain Research, Depts. of Neurosurgery and Psychiatry, MGH and Harvard Med. Sch., Boston, MA

Previous anatomical studies have shown that trigeminal and cervical afferent nerve fibers project to the upper cervical segments of the spinal cord. determine the degree of convergence between these pathways, we studied the response properties of C1 dorsal horn neurons to electrical and mechanical stimulation of the face, head and neck in paralyzed cats anesthetized with sodium pentobarbital. Neurons were classified as low threshold mechanoreceptive Were classified as 10w threshold mechanoreceptive (LTM), wide-dynamic-range (WLR), nociceptive-specific (NS) or unresponsive based on their responsiveness to graded mechanical stimulation. Extracellular single unit recordings were obtained from 71 neurons electrically excited by cervical (21), trigeminal (15) or both cervical and trigeminal (35) stimulation and from 16 neurons unresponsive to peripheral stimulation. WDR and NS neurons exhibited more convergence, had larger receptive fields and longer first spike latencies than LTM neurons. These data suggest that some upper cervical spinal cord neurons receive convergent input from trigeminal and cervical pathways and may be involved in mediating orofacial and cranial pain.

PAIN MODULATION: ANATOMY AND PHYSIOLOGY IV

236.1

RECIPROCAL PROJECTIONS BETWEEN THE MEDIAL PREOPTIC AREA AND MIDBRAIN PERIAQUEDUCTAL GRAY. T. Rizvi, M. Ennis, M. Behbehani and M. Shipley, Depts. Anatomy & Physiology. Univ. Cincinnati. Coll. Med., Cincinnati, OH 45267.

Previous anatomic studies indicate that the medial preoptic area

(MPO) is a source of afferent input to the periaqueductal gray (PAG). Here, we have examined the topography of reciprocal connections between these two structures.

WGA-HRP injections into several rostrocaudal levels of PAG retrogradely labeled large numbers of neurons in MPO which shift mediolateraly along the rostrocaudal axis; rostral MPO contained heavy retrograde labeling restricted to the medial region while in caudal MPO, neurons in the lateral zone are retrogradely labeled. In addition, tracer injections in PAG produced dense anterograde labeling in both medial and lateral MPO.

WGA-HRP injections in MPO resulted in dense anterograde labeling in PAG. In most cases the labeling comprised two discrete longitudinal bands in dorsomedial and lateral PAG. Labeling was heavier in the central than the peripheral part of PAG. In addition, MPO injections produced retrograde labeling of neurons located in dorsomedial and ventral/ventrolateral parts of PAG.

The present findings suggest that connections between PAG and

MPO are heavy, reciprocal and spatially organized. This circuit may play important roles in forebrain-brainstem integration of thermoregulation, analgesia, maternal and reproductive behaviours. (Supported by PHS Grants NS20643, NS24698 and HL08097).

HYBRIDIZATION HISTOCHEMICAL ANALYSIS OF NEUROTENSIN AND EN-KEPH ALIN mRNA IN POLYARTHRITIC RATS. F. G. Williams*. G. D. Kaufman* and A. J. Beitz. Dept. of Vet. Biology, University of Minnesota, St. Paul, MN 55108 Chronic polyarthritis was induced in male Sprague-Dawley rats (275 - 300 grams body weight) by injecting 150 µl Freund's Complete adjuvant in the tail base. Control animals received mineral oil. Several parameters were quantitated to monitor the development and progression of the disease, including tail-flick latency, paw size, and tibio-tarsal joint size. Animals were decapitated 4, 8, and 24 days following injection and their brains were rapidly removed and frozen. Fifteen µm cryosections of the midbrain were prepared for hybridization histochemistry by formalin fixation, alkylation, dehydration and delipidation. Hybridization to biotinylated oligonucleotides complementary to pro-neurotensin/neuromedin N (NT) or pro-enkephalin A (Enk) mRNA was carried out as previously described and detected using fluorescen-avidin. The frequency and distribution of fluorescent neurons containing Enk and NT mRNA were mapped and the relative fluorescence intensity of subsets of hybridization-positive neurons was noted.

The onset of polyarthritic symptoms occurred approx. 7 days following injection. By day 24, average tail-flick latencies had decreased 10% to 4.2 seconds (p=.02), hind paw circumference increased 13.5% to 2.9 cm (p-.01), and tibio-tarsal joint circumference increased 17.1% to 3.1 cm (p=.02). The distribution and frequencies of hybridization-positive neurons were most frequent in the dorsal raphe (DR) and ventral periaqueductal gray (PAG). Polyarthritis increased the frequencies of positive neurons in these regions, but had the greatest effect lateral to these regions, where numbers of hybridization-positive neurons in the tegmental and cuneiform nuclei were significantly increased. Enk mRNA-positive neurons and cureiform nuclei were significantly increased. Enk mRNA-positive neurons and cureiform nucle

MAPPING OF BRAINSTEM CHOLINERGIC PATHWAYS INVOLVED IN THE MODULATION OF NOCICEPTION. L.F. Fitzgerald and H.K. Proudfit. Dept. of Pharmacology, Univ. of Illinois at Chicago. Chicago, IL 60680.

The pedunculopontine tegmentum (PPT) is a cholinergic cell group in the brainstem that modulates nociception. These studies identified interconnections between PPT neurons and those in the nucleus raphe magnus (NRM), gigantocellular reticular nucleus pars alpha (Giα) and the A7 catecholamine cell group.

An anterograde tracer, phaseolus vulgaris leucoagglutinin (PHA-L), was injected into the PPT and axon terminals were labeled in the NRM and Gi α . In a separate experiment, a retrograde tracer (Fluoro-Gold or Fast Blue) was injected into the NRM or Gi α , and choline acetyltransferase-reactive PPT neurons were labeled with tracer. This suggests that PPT neurons project to the NRM and Gi α .

Retrograde tracer was then injected into the A7 while PHA-L was injected into the PPT. Axon terminals of PPT neurons in the NRM and Gi α were adjacent to neurons which project to the A7. This suggests that antinociception produced by stimulation of the PPT may be mediated by neurons in the ventromedial medulla which project to the A7 nucleus.

INTERPEDUNCULAR NEURONS ARE UNRESPONSIVE TO PINCH WHILE VENTRAL TECHENTAL NEURONS CAN BE INHIBITED. J.L. Kim*, L. Gollapudi*, and I.D. Hentall. Univ. of Illinois, College of Medicine, Rockford IL 61107.

The interpeduncular nucleus (IPN) inhibits or excites cells in the nucleus raphe magnus (NRM) which respectively suppress or facilitate nociception. To decide whether this polysynaptic pathway is active during acute pain, we recorded spontaneously active neurons extracellularly in the IPN and adjacent catecholaminergic ventral tegmental area (VTA) and interfascicular nucleus (IF) in rats anesthetized with pentobarbital. Recording micropipettes contained 2M sodium acetate and saturated fast green (which marked recording sites later found histologically). Metal stimulating microelectrodes were placed bilaterally in the medial habenula, and their locations confirmed with electrolytic lesions.

Of cells calculated to be in the IPN, 93% (n=15) did

Of cells calculated to be in the IPN, 93% (n=15) did not respond to noxious squeezing of the skin on the hindlimb (one border cell was excited). Habenula stimulation caused synaptic excitation with a long delay (>10ms) in 86% (n=14) IPN cells. In the VTA and IF (n=28), 36% of cells were markedly inhibited by pinch, 14% weakly excited and 50% unaffected. Inhibition in the VTA had a typical onset of 1-2s and recovery of 1-2 min.

We conclude that the IPN modulates nociception via the NRM without reference to levels of pain input. (Supported by NINDS grant NS26116).

236.7

INTERACTION BETWEEN THE INSULAR CORTEX (IC) AND THE PERIAQUEDUCTAL GRAY (PAG). M. Jiang and M.M. Behbehani. Dept. of Physiology. U. of Cincinnati. Cincinnati OH 2/2/57.051.

The objectives of the current studies were to determine the physiological interaction between PAG and IC and to examine the roles of glutamic acid and enkephalin in the interaction between these sites. Experiments were conducted on chloral hydrate anesthetized 250-300 gram male rats. Of 403 PAG cells that were recorded, 143 neurons responded to electrical stimulation of the IC. The responses to electrical simulation of IC at 1 or 0.5Hz could be classified in two major categories. 1)In 50 cells IC stimulation produced excitation with onset latency that ranged between 11 and 34 msec (mean 27.3 ±2.13 (SEM)), average duration of 38.5±.3.55 (SEM) followed by inhibition with mean duration of 89±4.7 (SEM) msec. 2) In 83 cells IC stimulation produced inhibition with mean onset latency of 26.18±1.68 (SEM) msec and duration of 108.±8.97 msec. The remaining 10 neurons showed more complex triphasic responses. In 13 out of 29 cells that were excited by IC stimulation local application of kynurenic acid (KA) blocked the excitatory response. In these neurons, KA had very little effect on the inhibition that followed the excitatory phase of the response. Local application of naloxone had no effect on the response of PAG cells to IC stimulation (n=30). It is concluded that: 1) Approximately 30% of PAG cells are responsive to IC stimulation. 2) the interaction between the IC and PAG includes a slow conducting monosynaptic and one or more polysynatic pathways. 3) The excitatory response is not mediated by enkephalin. Supported by PHS grant # NS20643.

236.4

PHARMACOLOGIC EVIDENCE FOR A PATHWAY BETWEEN THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS (PPTn) AND THE NUCLEUS RAPHE MAGNUS (NRM) MODULATING NOCICEPTION. <u>E.T. IWAMOTO</u>. Dept. of Pharmacology. Coll of Med. Univ. of Kentucky, Lexington. KY 40536.

of Pharmacology, Coll. of Med., Univ. of Kentucky, Lexington, KY 40536. Antinociception assessed by the hot-plate and tail-flick assays was induced by subcortical microinjection of nicotine in 0.5 µl of phosphate buffer in unanesthetized male Sprague-Dawley rats implanted with subcortical guide cannulas. Out of the 185 brain sites examined, PPTn and NRM were the most sensitive with median effective doses of nicotine ranging between 1.4 and 2.9 mmole. Parenteral naloxone administration had no effect on PPTn nicotine-induced antinociception. Coadministration of mecamylamine or pirenzepine with nicotine in the NRM competitively antagonized nicotine antinociception. Methoctramine alone into the NRM induced strong antinociception which was blocked by 1 hr pretreatment of the NRM with hemicholinium-3 (HC-3; no effect when injected alone). HC-3 pretreatment of either the PPTn or NRM antagonized the antinociceptive effects induced by nicotine at these sites. HC-3 pretreatment of the NRM also antagonized the antinociceptive effects of a subcutaneous injection of 0.5 mg/kg of nicotine. Ibotenic acid lesions of the PPTn or HC-3 pretreatment of the NRM abolished the antinociception induced by nicotine or (+)-cig-dioxolane microinjections into the PPTn. Neither unilateral blotenic acid lesions nor bilateral electrolytic lesions of the PPTn alone altered hot-plate or tail-flick nociceptive responding. Procaineamide microinjection into the NRM abolished the antinociception induced by pilateral nicotine microinjections into the PPTn. Bilateral microinjections of procaineamide into the PPTn did not alter the antinociception induced by nicotine injected into the NRM. A cholinergic pathway which modulates nociception originating in the PPTn and terminating in the NRM is proposed. Activation of the cell bodies in the PPTn results in acetylcholine is regulated by autoinhibitory M₂ receptors. We propose that stimulation of this PPTn-to-NRM pathway activates known descending pain control systems. (Supported by the KTRB).

INHIBITION OF PERIAQUEDUCTAL NEURONS BY SEROTONIN IS MEDIATED THROUGH 5HT_{1A} RECEPTORS. H. Liut S. Chandler, M. Jiang and M.M. Behbehani. U. of Cincinnati, Dept. of Physiology, Cincinnati OH 45261-0576

The midbrain periaqueductal gray contains a high concentration of 5HT immunoreactive terminals and 5HT receptors. The goals of this study were to determine the effect of 5HT on PAG neurons and to characterize the effect of 5HT $_{1A}$ agonist and antagonist on these cells. Rats were used for both in vivo and in vitro experiments. In the in vitro studies, extracellular recordings were made from neurons in 400 μ thick PAG slices. Drugs were applied by pressure from electrodes placed near the recording site. In vivo experiments were conducted on chloral hydrate anesthetized adult male rats and the effects of iontophoretically applied serotonin, 8-OH-DPAT (DPAT), methysergide (MET) and spiperone (SPIP) were recorded.

In the in vitro experiments, responses of 203 neurons to 5HT and DPAT were tested. 5HT and DPAT inhibited 46% and 60% of the cells respectively. In contrast 30% of the cells were excited by 5HT compared to 14% that were excited by DPAT. The inhibitory effect of 5HT and DPAT could be blocked by SPIP but the excitatory effect of 5HT was more effectively blocked by MET.

In the in vivo experiments recordings were made from 130 neurons In 54 cells DPAT altered the baseline firing rate. The majority of these cells were inhibited (44/54) and a small population were excited (10/44) The effect of DPAT could be blocked by spiperone. It is concluded that the major effect of 5HT on PAG neurons is

It is concluded that the major effect of 5HT on PAG neurons is inhibition that is mediated by 5HT_{1A} receptors. Supported by PHS grant #NS20643.

ANALGESIA PRODUCED BY LIDOCAINE INJECTION INTO RAT DENTATE GYRUS. J.E. McKenna and R.Melzack*, Department of Psychology, McGill University, Montreal, Quebec, Canada H3A 1B1.

Previous studies in our laboratory have indicated that injection of a local anesthetic into discrete sites within the rat brain, including the lateral hypothalamus and anterior cingulum bundle, causes a significant long-lasting analgesia during the formalin test.

As a continuation of this work, the present study investigated the analgesic effects of lidocaine injected into regions of the dentate gyrus. Anesthetized Long-Evans rats were stereotaxically implanted with cannulae unilaterally. Eight to ten days after surgery each rat received a 1.0 μl injection of 2% lidocaine or saline. The injection was given either before or after the ipsilateral or contralateral hindpaw received an injection of 50 μl of 2.5% buffered formalin. The strength and time course of analgesia differed according to laterality and time of the microinjection. The implications of these results are discussed. Supported by NSERC grant A7896.

TOWARD OBJECTIVE MEASURES OF POST-SURGICAL PAIN: NALOXONE AND EEG SPECTRAL ANALYSIS IN RATS. Vahn A. Lewis. Dept. Pharmacology, Dental Branch, U. of Texas, Houston, Tx. 77030.

Computerized EEG (electrocorticographic) record-

Computerized EEG (electrocorticographic) recordings have been used measure surgery induced changes in EEG. 11 S-D rats were anesthetized with pentobarbital(PB) and EEG, EMG electrodes and intrajugular catheter implanted. This surgery was the pain stimulus. Recordings of EEG and EMG and body movement were made at 4, 8 and 27 hours post surgery. One week following surgery, animals were again anesthetized with PB and controls recorded at equivalent times to the earlier recordings. Ten minutes prior to all recordings 10 mg/kg naloxone was administered to antagonize endogenous opiate activity. Data were automatically sampled (2 seconds every 30 seconds of run time). The power spectrum (PS) was calculated over 8 samples representing samples 5-9 minutes (E, early samples) and 15-19 minutes (L, late) samples after placing the animals in the recording chamber. At 8 hours following surgery the log of the area under the PS curve was depressed relative to control at E -22%, P=<0.05, and L -46% P=<0.001. At 27 hours the PS was depressed in the L -26% P=<0.05). This research will lead to improved methods for assessing pain after injury in man and animals.

MAMMALIAN NEURONAL BRADYKININ RECEPTORS: DIF-FERENTIAL AFFINITY OF THE ANTAGONIST [D-ARG(0), HYP(3),D-PHE(7)]-BRADYKININ. D.J. Dooley, M. Belledin* and K.I. Bär*. Gödecke Research Institute, D-7800 Freiburg, F.R.G.

Belledin* and K.I. Bär*. Gödecke Research Institute, D-7800 Freiburg, F.R.G.

Pain is one pathophysiologic effect of bradykinin (BK) which reflects activation of BK receptors associated with nociceptors of afferent sensory neurons (Steranka et al., PNAS, 85:3245, 1988). These receptors of four mammalian species (bovine, rat, guinea pig, monkey) were characterized by using spinal cord membranes and selective BK-related drugs in a [H]-BK binding assay. Across the species, the BK receptor agonist [des-Arg(9)]-BK (10 µM) and antagonist [Leu(8), des-Arg(9)]-BK (10 µM) were ineffective to inhibit [H]-BK binding (0.25 nM). The BK receptor agonist [Tyr(Me)(8)]-BK (0.3 nM) inhibited [H]-BK binding by ~50-70%. The BK receptor antagonist [D-Arg(0),Hyp(3), D-Phe(77]-BK (10 nM), in contrast, differentially inhibited [H]-BK binding as evidenced by a range of ~10% (guinea pig) to ~70% (bovine). These results suggest that mammalian neuronal BK receptors are of the BK_-subtype, and that the affinity of a BK_ receptor antagonist for these receptors can vary across different species.

236 10

ROLE OF DESCENDING INHIBITION ON THE RELEASE OF CALCITONIN GENE-RELATED PEPTIDE AND SUBSTANCE P FROM RAT DORSAL LUMBAR SPINAL CORD IN-VITRO. L.D. Aimone and T.L. Yaksh. Dept. of Anesthesiology, UC, San Diego, La Jolla, CA 92093.

The content of norepinephrine (NE, measured by HPLC) in the

The content of norepinephrine (NE, measured by HPLC) in the dorsal lumbar spinal cord was reduced to 35% and 24% of control levels by spinal cord transection (T8, Trans) or the intrathecal administration of 6-OHDA (100 µg) 7 days prior. Calcitonin gene-related peptide (CGRP) and substance P (SP) content (measured by RIA) in the dorsal lumbar spinal cord was only slightly reduced by Trans (11% & 8%.) or 6-OHDA pretreatment (22% & 20%). In-vitro perfusion of dorsal lumbar spinal cord slices revealed that trans or 6-OHDA resulted in a marked increase in the basal release of CGRP and SP. Basal NE release was reduced by 6-OHDA, while Trans actually resulted in a small increase. The K+ (50 mM) evoked release of NE was decreased by either of the pretreatments with only slight changes in the evoked release of either CGRP or SP. (pg/mg)

		CONTROL	TRANS	6-OHDA
NE	basal	5.37±0.54	7.45±1.40	1.43±0.36
	evoked	23.7±2.96	14.4±3.13	5.68±2.14
CGRP	basal	8.08±1.01	15.8±2.55	11.3±0.73
	evoked	50.6±6.38	37.0±4.60	47.8±18.4
SP	basal	0.34±0.04	1.13±0.22	0.90±0.16
	evoked	1 73+0 19	2.43+0.39	1.99±0.42

These observations suggest that basal release is subject to a local control by systems which arise from bulbospinal pathways and 6-OHDA sensitive terminals.

THE FORMALIN TEST IN MICE: INFLUENCE OF THE AMBIENT TEMPERATURE. K.Hole, J.H.Rosland, A.Tjølsen, A.Lund and O.-G.Berge. Dept. of Physiology, Univ. of Bergen, Bergen, N-5009 Norway.

The late phase in the formalin test may be due to inflammation, and it is possible therefore that the response may be influenced by blood flow and tissue temperature. When the test was performed at different ambient temperatures, the licking response in the late phase was weak in a cool environment (20 °C) and increased with increasing ambient temperature up to 28 °C. In the early phase there was no effect of temperature.

Lesioning of descending serotonergic systems with I.th. 5,6-dihydroxytryptamine (5,6-DHT) increased the licking response in the late phase at 20 °C compared to controls, but not at 25 °C. The response in 5,6-DHT treated animals at 20 °C was approximately the same as for animals tested at 25 °C, indicating no effect of ambient temperature in 5,6-DHT lesioned animals. 5,6-DHT lesions caused an increase in paw skin temperature of animals kept at 20 °C, indicating that the increased licking response may be due to a higher blood flow and increased tissue temperature in the paw, facilitating the inflammatory response.

It was concluded that the paw skin temperature may influence the response in the late phase of the formalin test. An apparent hyperalgesia in the late phase after lesions of raphe-spinal 5-HT systems may be due to an increase in blood flow.

PAIN MODULATION: PHARMACOLOGY II

ANTINOCICEPTION PRODUCED BY A HIGH DOSE OF MEDETOMIDINE DUE TO SPINAL ALPHA-2-ADRENERGIC MECHANISMS. A.Pertovaara, T.Kauppila, E.Jyväsjärvi, and E.Kalso, Depts.Physiol. and Anesthes. Univ.Helsinki, Helsinki, Finland.

In the current study we determined the effect of a high, anesthetic dose of medetomidine, an alpha-2-adrenoceptor agonist, on nociceptive reflex and sensory neuronal responses in rats. In intact rats, the latencies to the mechanically- and heat-induced tail reflex responses were prolonged by systemic medetomidine (300 $\mu g/kg$). This antinociceptive effect was reversed by a high systemic dose (1.5 mg/kg) or a small intrathecal dose (25 μg) of atipamezole, an alpha-2-adrenoceptor antagonist. Also in spinal rats, the latencies to the heat-induced tail flick were prolonged by the high dose of systemic medetomidine in an atipamezole-reversible way. In 50 % of the nociceptive spinal dorsal horn projection neurons systemic medetomidine produced an atipamezole-reversible suppression of peripherally-evoked responses. The results suggest that systemic medetomidine at a high, anesthetic dose can produce antinociception due to segmental spinal alpha-2-adrenergic mechanisms.

ANTAGONISM OF NALOXONE-INSENSITIVE STRESS-INDUCED ANALGESIA IN MICE BY SPECIFIC NMDA RECEPTOR ANTAGONIST MK-801. P. Marek, G. Page, S. Ben-Eliyahu and J. C. Liebeskind. Department of Psychology, University of California, Los Angeles, CA 90024. The effect of a specific NMDA receptor antagonist MK-801 on analgesia

The effect of a specific NMDA receptor antagonist MK-801 on analgesia produced by 3 min forced swimming in 20°C water was studied in CXBK and CXBH mice. Analgesia was measured using the hot-plate test (52°C) with hind paw flick as the criterion pain response. In opiate receptor deficient CXBK mice, swim-induced analgesia was completely insensitive to naloxone (10 mg/kg, i.p.), but was abolished by MK-801 (0.075 mg/kg, i.p.). In CXBH mice, rich in brain opiate receptors, analgesia induced by swim was more pronounced and only partially antagonized by naloxone or MK-801 alone. When administered in combination, MK-801 and naloxone at the same doses almost completely blocked swim-induced analgesia. In CXBH mice, using the same doses of naloxone and MK-801, the former completely antagonized and the latter had no effect on the robust morphine analgesia caused by 10 mg/kg. These results indicate that stress may produce parallel activation of naloxone-sensitive and naloxone-insensitive analgesia mechanisms, the latter of which involves NMDA receptors. Supported by Unrestricted Pain Research Grant from the Bristol-Myers Squibb Company and NIH grant NS 07628.

SUBSTANCE P (SP) MICROINJECTIONS INTO THE A7 NUCLEUS PRODUCES ANTINOCICEPTION IN THE RAT D. C. Yeomans and H. K. Proudfit. Dept. of Pharmacology, University of Illinois at Chicago, Chicago, Illinois 60680.

Antinociception evoked by stimulation of the raphe magnus (RMg) may be mediated in part by projections from the SPcontaining cells in the RMg to noradrenergic (NA) neurons in the A7 nucleus. SP released onto the A7 cell bodies may activate spinopedal projections and thereby induce antinociception.

To test this hypothesis, hindlimb nociceptive reflexes were tested bilaterally in 24 lightly anaesthetized rats, prior to, during, and following microinjection of 0.5, 5.0, 50 ng of SP or vehicle into the A7 area. A "bell"-shaped dose-response curve was obtained, with the strongest anti-nociceptive effect observed after injection of 5.0 ng, both in terms of increased response latencies and the duration of the effect. The SP-induced antinociceptive effects were more pronounced when the hindlimb ipsilateral to the microinjections site was tested. This observation is consistent with anatomical findings that NA A7 neurons project ipsilaterally to the spinal cord dorsal horn.

The antinociceptive effect of SP appears to be mediated by activation of spinally-projecting NA neurons in the A7, since intrathecal phentolamine completely blocked the antinociceptive effects of SP. (Supported by USPHS Grant DA03980)

ANALGESIC EFFECT OF SYNTHETIC FRAGMENTS OF VASQACTIVE

ANALGESIC EFFECT OF SYNTHETIC FRACMENTS OF VASOACTIVE INTESTINAL PEPTIDE IN THE RAT. B.R. Komisaruk¹. C. Banas*¹. A. Mehta*². P. Cash*². B. Whipple*² and F. Jordan*². Inst. Animal Behavior¹, Dept. Chemistry², and Coll. Nursing³, Rutgers University, Newark, NJ 07102 Vasoactive Intestinal Peptide (VIP 1-28), produces analgesia when administered intrathecally (1.t.) to the spinal cord (Ann. NYAS: 527:650, '88). Incubation of VIP 1-28 with spinal cord homogenate yielded several fragments, including VIP 1-10 and 11-28 (Ann. NYAS: 527:582' 188). Inc including VIP 1-10 and 11-28 (Ann. NYAS: 527:582, '88). In the present study, these were synthesized, injected i.t., and tested on two measures of pain threshold: vocalization and tested on two measures of pain threshold: vocalization threshold to tail shock (VOCT), and tail flick latency to radiant heat (TFL). Results (all dosages reported are the molar equivalent of 25 ug VIP 1-28; a lower [1/5] dose of each fragment had little or no effect). VOCT: VIP 11-28 significantly elevated VOCT (50-100+%) from 1-60 min postinjection. At 30 min, this effect was significantly ereater than that of 25ug morphine sulfate (i.t.). VIP 1greater than that of 25ug morphine sulfate (1.t.). VIP 1-10 produced a significant but lesser elevation for 5 min. The effect of another fragment, VIP 8-11, did not differ from saline. TFL: VIP 11-28 produced a significant, but shorter-lived elevation (75%, 5 min) than on the VOCT test. VIP 1-10 produced a significant (10-20%) elevation for 20 min, and VIP 8-11 produced a significant elevation (<20%) for 10 min. Thus, native VIP 1-28 can apparently be cleaved by spinal cord enzymes into peptide fragments that are analgesically active. Support: NIH NLS-2 5R01 NS 22948 and GRS 5 S06 RRO8223 (BRK) and Busch Fdtn (FJ, BW, BRK).

ANTINOCICEPTIVE CONCEQUENCES OF B-16 MELANOMA CELL TRANSPLANTS IN MOUSE AND RAT SPINAL CORD.

H. Wu, B. R. Lester*, Z. Sun* and G. L. Wilcox, Department of Pharmacology, University of Minnesota, Minneapolis, MN 55455, U.S.A.

It has been observed that α_2 agonists potentiate the antinociceptive effect of morphine in mouse and rat spinal cord. The aim of the current study was to determine whether catecholamine-containing cells transplanted into mouse and rat spinal cord would potentiate the antinociceptive effect of subthreshold doses of morphine. Two B-16 melanoma clones were chosen. The F10-C23 clone was considered to have low catecholamine content while the F1-C29 clone was considered considered to have low catecholamine content while the F1-C29 clone was considered to have high catecholamine content. Recipients were 20-24 g male ICR mice or 75-100 g male Sprague-Dawley rats. Mice were given 50,000 cells in 5µl PBS and rats were given 50,000 cells in 10 µl PBS by intrathecal (i.t.) injection. The control group received the same amount of PBS solution with no cells i.t. After 2, 4 and 7 days, a subthreshold dose of morphine, 0.1 µg for mice and 0.3 µg for rats, was given i.t. The tail flick and hot plate tests were performed before and after drug injection. Antinociception was quantified as the percentage of maximum possible effect (%MPE) which was determined in the usual way. Two days after cell injection, in both mice and rats, the groups that received F1-C29 (high catecholamine content) cells showed significantly higher antinociception than both the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catecholamine content) cells and the groups that received F1-C23 (low catechola content) cells showed significantly higher antinociception than both the groups that received F1-C23 (low catecholamine content) cells and the groups that received f1-C23 (low catecholamine content) cells and the groups that received no cells. This effect of morphine was blocked by the opioid antagonist naloxone (mice) and by the α2 adrenergic antagonist idazoxan (mice and rats). Therefore, α2 adrenergic receptors seem to be involved in manifestation of this antinociception. This result indicates that B16 melanoma cells transplanted into mouse and rat spinal cord may potentiate the antinociceptive effect of morphine, apparent involving activation of α2 adrenergic receptors. ANTINOCICEPTIVE EFFECT OF INTRATHECAL NEUROPEPTIDE Y ANALOGS ON HOT PLATE AND PAW PRESSURE TESTS.

J.M. Thomas, X.Y. Hua, M. Spicer*, J. Rivier*, T.L. Yaksh, Department of Anesthesiology, University of California, San Diego and *The Salk Institute for Biological Studies, La Jolla, California.

Neuropeptide Y (NPY) is found in bulbospinal pathways. We have previously shown (Hua, et al in preparation) that NPY (1-36) administered intrathecally in rats will elevate the hot plate response latency, but not the paw pressure threshold while NPY (18-36) will elevate both the hot plate response latency and paw pressure for withdrawal. In the present studies, we examined a number of truncated analogs given intrathecally in chronically catheterized rats on the 52.5C hot plate (60 sec cut off) and the paw pressure test (0-400 gm). The intrathecal ED₅₀ of these agents is presented below. For active agents, maximum effects were observed in the absence of any detectable motor impairment. We also synthesized and tested several truncated and cyclic 26- to 28- peptides that conserved both the N- and C- termin of native NPY. These cyclic analogs were found to have activity profiles similar to that of NPY (18-36) but with significantly greater potencies. These results suggest the possible presence of more than one NPY-sensitive receptor type associated with spinal systems which modulate nociceptive processing for thermal and spinal systems which modulate nociceptive processing for thermal and mechanical stimuli.

	Hot Plate	Paw Pressure
INTRATHECAL DRUG	(ED 50) ua	(ED 50) ua
NPY (1-36)	5	>100
NPY (18-36)	32	51
Des - NH ₂ -Ala ¹⁸ - NPY (18-36)	>100	>100
NPY (18-32)	>100	>100

BRADYKININ MODULATION OF A NOCICEPTIVE REFLEX.

BRADYKININ MODULATION OF A NOTICE TIVE KERLEY.

Bauer, S.T. Meller, and G.F. Gebhart. Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242

The objective of the present study was to examine the effect of bradykinin (BK) administered the effect of bradykinin (BK) administered intravenously on the nociceptive tail flick (TF) reflex. BK (12 - 288 µg/kg) produced dose-dependent increases in TF latency and heart rate and a dose-dependent decrease in blood pressure. Maximal TF dependent decrease in blood pressure. Maximal inhibition was observed 10 sec post administration. To determine if tachyphylaxis developed to the effect of BK on the TF reflex, BK was administered at 5, 10, or 40 min intervals. There was no significant difference in BK-induced alterations in TF latency at the three different dosing intervals. At the doses tested, in BK-induced alterations in A.

different dosing intervals. At the doses tested, complete spinal cord transection at a low thoracic level (TlO-12) markedly attenuated BK-induced by the TF reflex. Bilateral vagotomy did level (T10-12) markedly attenuated BK inhibition of the TF reflex. Bilateral vago not alter BK-induced inhibition of the TF whereas bilateral stellate ganglion removal shifted the whereas bilateral stellate ganglion removal shifted the dose response curve to the right. These results suggest that at the doses used, BK does not act directly on the spinal cord to induce a change in the TF latency and is able to modify the TF reflex by engaging descending inhibitory systems at least partially by engaging visceral afferents.

FORMALIN-EVOKED FOS EXPRESSION IN RAT SUPERFICIAL DORSAL HORN: REDUCTION BY AN NMDA ANTAGONIST. L.J. Kehl. A.L. Basbaum K.R. Gogas. C.H. Pollock*. M. Mayes*. G.L. Wilcox. Graduate Program in Neuroscience and Departments of Pharmacology and Psychology, University of Minnesota, Minneapolis, MN 55455, USA and Department of Anatomy, University of California San Francisco, San Francisco, CA 94143, USA.

Various forms of natural stimulation induce the expression of Fos, a nuclear phosphoprotein product of the *c-fos* proto-oncogene. Since endogenous excitatory amino acids (EAA's), which terminate densely in laminae I and II, have been implicated as neurotransmitters of nociresponsive primary afferents, the present experiments were designed to test the involvement of N-methyl-D-asparatae (NMDA) receptors in Fos induction using the non-competitive NMDA antagonist, MK801.

Sprague Dawley rats (100 - 150 gm) from either Bantin & Kingman (CA) or Harlan (IN) were intrathecally pretreated with either vehicle or MK801 (3.0 or 10.0 $\mu g/10$ μl) followed by subcutaneous injection of 2.5% formalin (50 μl) in the hindpaw. Two hours later the rats were perfused intracardially with 4% paratormaldehyde and 50 μm sections of lumbar spinal cord were immunostained for

Bantin & Kingman rats had substantially lower background Fos levels than Harlan rats. In Bantin & Kingman rats, MK801 did not have a pronounced effect on behavior elicited by formalin and did not evoke Fos-like immunoreactivity (FLI) above basal levels. Formalin elicited intense ipsilateral FLI in laminae I and II, in the neck of the dorsal horn (laminae V and VI) and in ventral horn laminae VIII and VIII. Quantitative analysis revealed that MK801 significantly reduced staining 36% in the superficial dorsal horn (p. C.018). superficial dorsal horn (p < 0.05).

These data support the hypothesis that NMDA receptors contribute to the induction of Fos by noxious stimulation, particularly in the superficial dorsal horn. [Supported by NIDR - K15 DE00225 (LJK); NIDA - DA01933, DA04274 (GLW) and NINDS - 14627, NIDR - DE08973 (AIB)].

EFFECTS OF BACLOFEN AND MORPHINE ON THE PERSISTENT EXPRESSION OF C-FOS IN RAT SPINAL CORD FOLLOWING PERIPHERAL NERVE INJURY S.-I. Chi. J.D. Levine* and A.I. Basbaum Depts. of Anatomy, Physiology and Medicine, UCSF, CA 94143.

We previously reported that both baclofen and morphine suppress the short-lived noxious stimulus (formalin)-evoked expression of the Fos product of the c-fos protonoxious stimulus (formalin)-evoked expression of the Fos product of the c-fos protooncogene in the spinal cord dorsal horn of the rat. Since nerve injury evokes a
persistent expression of Fos (Chi et al. 1989), it was of interest to study the effects
of baclofen and morphine in this proposed model of neuropathic pain. To produce a
neuroma, the sciatic nerve was cut and ligated in the thigh. The effects of baclofen
(7.5mg/kg, i,p) or morphine (5mg/kg, s.c) on Fos expression were studied two
weeks later. To maintain drug levels beyond the half life of the Fos-like
immunoreactivity (FLI), the drugs were given twice over a four hour period and then
the rats were perfused with 4% paraformaldehyde. The lumbar spinal cord was
removed and processed for FLI.
Systemic baclofen significantly reduced the number of FI I named in leaving at large and a spinal cord was

removed and processed for FLI.

Systemic baclofen significantly reduced the number of FLI neurons in laminae 1-7, by 50-60% (n=4, p<0.05). The reduction was comparable in all regions of the spinal gray matter. This pattern of inhibition was similar to that produced by the same dose of baclofen on formalin-evoked FLI. In contrast, although morphine produced a profound inhibition of formalin-evoked Fos (comparable to that seen for baclofen), we found no effect of morphine on the expression of fos in the nerve injury model at two weeks after nerve section. weeks after nerve section.

weeks after nerve section.

The effect of baclofen on the persistent Fos expression produced by sciatic nerve section suggests that the GABAergic inhibitory circuitry in the dorsal horn is intact at two weeks after nerve injury. The failure of morphine to reduce nerve injury-evoked FLI, however, suggests that the integrity of the dorsal horn opiate receptor is compromised. Importantly, our results are consistent with the fact that narcotics are often ineffective in the treatment of neuropathic pains in humans. Supported by NS14657 an NS21465. NS14627 an NS21445.

237.11

THE NORADRENERGIC PROJECTION TO THE RAT DORSAL HORN ARISES FROM SEVERAL BRAINSTEM CATECHOLAMINE CELL GROUPS. G.C. Kwiat and A.I. Basbaum. Dept. of Anatomy, UCSF, CA 94143.

The noradrenergic (NA) innervation of the spinal dorsal horn has recently been reported to arise predominantly, if not exclusively, from the locus coeruleus (Lyons, W.E. et al., <u>L. Neurosci.</u>, 9:1481, 1989). Our present study using restricted injections of the retrograde tracer, WGAapoHRP-Au, into the cervical (C5) dorsal horn of rats suggests that the origin of the catecholamine (CA) innervation of the

norm of rats suggests that the origin of the catecholamine (CA) innervation of the dorsal horn is more widespread.

Approximately 0.5 µl of a WGAapoHRP-Au suspension was injected unilaterally into the dorsal horn gray matter using a glass micropipette. Brainstem sections were silver-enhanced to visualize the retrograde tracer and then reacted for either tyrosine hydroxylase (TH)- or serotonin (5-HT)-immunocytochemical staining using the ABC method. We found that the locus coeruleus, subcoeruleus, A5 and A7 CA cell populations all contribute to the CA innervation of the dorsal horn. In two rats, the tracer injection was concentrated in the superficial laminae of the dorsal horn. In these cases the ipsilateral A5 cell population contained the largest number of TH-immunoreactive projection neurons; up to 40% of the TH-immunoreactive cells in the insilateral subcocruleus projected to the cord. Almost no double labeled cells were found in medullary CA cell groups. In contrast to the widespread origin of the TH projection, the 5-HT-immunoreactive neurons which projected to the dorsal horn were located exclusively in the rostral ventromedial medulla at the level of the nucleus raphe magnus (NRM). About 16% of the retrogradely labeled cells in this region were 5-HT-immunoreactive. It is of interest that the majority of the 5-HT projection neurons were located <u>lateral</u> to the NRM in the n. gigantocellularis pars α and n. paragigantocellularis lateralis.

pars of and in paragigantocenturals faterains.

These results suggest that the NA contribution to antinociceptive descending controls results from activation of several brainstem CA cell groups and that the 5-HT contribution may predominantly arise from activation of 5-HT neurons located lateral to the NRM. Supported by NS14627 and 21445.

237.13

SPINAL ANTINOCICEPTION BY ADENOSINE ANALOGS AND MORPHINE FOLLOWING INTRATHECAL (i.t.) PRETREATMENT WITH CAPSAICIN, 6-HYDROXYDOPAMINE (60HDA) AND 5,7-DIHYDROXYTRYPTAMINE (57DHT). J. Sawynok. A. Reid and D. Nance Depts. Pharmacol. and Anatomy, Dalhousie University, Halifax, NS, Canada B3H 4H7

(57DHT). J. Sawynok, A. Reid and D. Nance Depts. Pharmacol. and Anatomy, Dalhousie University, Halifax, NS, Canada B3H 4H7
Spinal antinociception by morphine and Ca²+ appears to be due to release of adenosine from capsaicin-sensitive primary afferent neurons. The action of Ca²+ also is reduced by i.t. pretreatment with 60HDA. In this study, the effects of capsaicin, 60HDA and 57DHT on spinal antinociception by analogs of adenosine (NECA, CHA) and morphine have been examined. All drugs were administered via chronically implanted i.t. cannulas 7-14 days following the toxin or respective vehicle. I.t. pretreatment with capsaicin 50µg (which depletes substance P in the substantia gelatinosa as revealed immunohistochemically) did not alter spinal antinociception by NECA or CHA in the tail flick or hot plate tests, or morphine in the tail flick test, but markedly reduced the action of morphine in the hot plate tests. 60HDA 50µg significantly reduced spinal antinociception by NECA and CHA in both tests, while 57DHT 50µg was without effect. Both 60HDA and 57DHT were without significant effect on morphine. Depletion of amines with these toxins was confirmed by HPLC. These results suggest (a) i.t. capsaicin may be useful for separating out pre- and postsynaptic components of antinociceptive action within the spinal cord, and (b) the spinal antinociceptive action of purines depends on intact noradrenergic but not serotonergic systems. (Supported by MRC Canada)

237.10

MICRODIALYSIS OF SEROTONIN FROM RAT SPINAL CORD: EFFECTS OF OPIOIDS. F. F. Matos, H. Rollema and A. I. Basbaum. Dept. of Anatomy,

MICRODIALYSIS OF SEROTONIN FROM RAT SPINAL CORD: EFFECTS OF OPIOIDS. F. F. Matos. H. Rollema¹ and A. I. Basbaum. Dept. of Anatomy, UCSF and ¹Dept. of Medicinal Chemistry, Univ. of Groningen, The Netherlands. This study tested the hypothesis that the effects of opioids at supraspinal levels results from activation of serotonin (5-HT) containing neurons of the medullary raphe which project to and inhibit dorsal horn neurons. We used microdialysis coupled to HPLC-ECD to monitor 5-HT release from the spinal cord of the awake rat. A dialysis probe was inserted across the L4 spinal cord segment (Skilling et al., 1988); the next day the probe was perfused with Ringer solution (2μl/min) and sequential samples collected. To study the properties of 5-HT in the dialysate, various drugs were infused through the dialysis probe: tetrodotoxin (TTX, 10μM), K* (120mM) or imipramine (1.0mM). Basal levels of 5-HTAA were much higher (400 fold) than 5-HT. Extracellular levels of 5-HT were reduced by TTX (50%) and increased in the presence of K* (seven fold) and imipramine (ten fold). Under each of these conditions 5-HIAA levels are a poor indicator of 5-HT release. Although 5-HT release often increased after opioid administration, the results were highly variable. Thus, systemic injection of morphine (0.5mg/kg, i.p.) increased 5-HT by eight fold, in 50% of the animals. 5-HIAA levels, however, decreased, by about 20%, in all animals. Morphine (10μg, i.c.v.) also increased 5-HT by six fold. The muselective opioid peptide, DAMGO (0.5 μg, i.c.v.) increased 5-HT release by 13 fold. Our results demonstrate that 5-HT release in the spinal cord of awake rats is primarily derived from neuronal activity. Furthermore, the increased release of 5-HT by morphine and DAMGO is consistent with the hypothesis that narcotics activate descending serotonergic controls that operate at the level of the spinal cord. However, since behavioral analgesia was produced in some rats in which an increase in 5-HT was not observed, our results suggest that releas

REGULATION OF NOXIOUS STIMULUS-EVOKED FOS EXPRESSION BY INTRATHECAL MORPHINE G. I. Botchkina*, K.R. Gogas, J.D. Levine* and A.I. Basbaum, All-Union Cardiology Center, Moscow, 121552, USSR and Depts. of Anatomy, Physiology and Medicine, UCSF, CA 94143.

of Anatomy, Physiology and Medicine, UCSF, CA 94143.

Systemic or supraspinal injection of morphine reverses both noxious stimulusevoked pain behaviors and spinal cord fos-like immunoreactivity (FLD). The present
study examines the effects of intrathecal (i.t.) injection of morphine sulfate (MS).

One week after implantation of i.t. catheters, male Sprague-Dawley rats received
injections of either saline, MS (0.1-50µg) or MS (Sµg) plus naloxone (NX; 10µg).
Ten min later, the animals received a formalin injection (100µl, 5%) into the
plantar surface of the hindpaw, and behavioral responses were recorded over a 1 hr
period. The animals were anesthetized and perfused with 4% paraformaldehyde. The
lumbar spinal cord was removed and processed immunocytochemically for fos.
Formalin evoked FLI neurons were most numerous in laminae I, IIo and V of the
L4-5 segments of the cord. MS (i.t.) produced a dose-related, NX-reversible
inhibition of both the pain behaviors and the FLI evoked by formalin. Although
both 5 and 50µg MS produced comparable levels of antinocicention in the formalin

inhibition of both the pain behaviors and the FLI evoked by formalin. Although both 5 and 50µg MS produced comparable levels of antinociception in the formalin test, there was approximately 20% greater inhibition of superficial dorsal horn FLI at the 50µg dose. The density of the residual fos in laminae I,II was comparable to that seen after systemic morphine injection (and less than that seen after icv morphine). These data suggest that analgesia produced by systemic or i.t. morphine involves interactions with a dorsal horn opiate receptor that is neither accessed directly nor synaptically via icv opioids. Our preliminary findings show that the delta antagonist ICII 74864 partially reduced the analgesic effects of i.t. morphine (5 µg). Although ICI did not reverse the fos suppressive effects of i.t. morphine in the superficial dorsal horn, the density of the residual fos appeared to be increased over that of animals receiving morphine only. These findings suggest that a component superioral orising information in the <u>designation</u> of the resonant rost appeared to be <u>infortased</u> over that of animals receiving morphine only. These findings suggest that a component of the morphine-induced fos suppression (particularly in superficial dorsal horn) is mediated via interaction with the delta receptor. MODULATION OF RECEPTIVE FIELDS OF CAT NOCICEPTIVE THALAMIC NEURONS BY CHOLINERGIC MECHANISMS H. Angus-Leppan, B. Olausson*, G.A. Lambert*, Department of Medicine, Univ. of New South Wales,

Receptive field (RF) modulation represents a change in sensory processing of importance in understanding mechanisms of acute pain, and in particular, allodynia and hyperalgesia. It appears that the phenomenon involves both peripheral and central components. The experiments described here focused on the central component of components. The experiments described here focused on the central component of RF responses relevant to trigeminally-mediated nociceptive pathways, especially those that may be involved in headache and toothache. The effect of cholinergic agonists and antagonists on receptive field properties were examined, as acetylcholine (ACh) is a known mediator of certain ascending pathways to thalamic neurons, including a projection from the parabrachial nucleus, and brainstem pathways considered important in attention and arousal. Cutaneous RFs of thalamic ventrobasal cells receiving nociceptive input from superior sagittal sinus (SSS), tooth pulp (TP) or both were studied. Cats were anesthetized with chloralose. Multi-barreled electrodes with a central tungsten core allowed extra-cellular recording and iontophoresis. Units excited by electrical stimulation of SSS (40-120V, 25)us, 0.2 s⁻¹), TP (train of 3 x 600 Hz pulses:500LA, 0.5ms) or both were identified and their recentive fields chartical stimulation of SSS (40-120V, 25) and the recentive fields chartical stimulation of SSS (40-120V, 2014). 600 Hz pulses,500µA, 0.5ms) or both were identified, and their receptive fields characterised. ACh, atropine (Atr), hexamethonium (Hex), homocysteic acid (HCA) and saline were ejected iontophoretically. Twenty-two units in 9 cats were located, with facial (16) or forelimb (6) RFs. RFs were characterised as wide-dynamic range (11), facial (16) or forelimb (6) RFs. RFs were characterised as wide-dynamic range (11), nociceptor-specific (5) or low-threshold mechanoreceptors(6). In 16 out of 22 units tested, RFs increased in area after iontophoretic ACh. Atr decreased the RF area in 15 units, while Hex had no significant effect on RF size. In addition, changes in RF modality occurred following ACh administration, with increased response to non-noxious (brush) stimulation demonstrated in 2 units, and increased response to noxious (pinch or prick) stimulation in 5 units. These results demonstrate central cholinergic modulation of RF characteristics, of relevance to trigeminally-mediated recipients are hybrare. nociceptive pathways.

ATROPINE PREVENTS NOXIOUS STIMULUS-INDUCED PERSISTENT DEPRESSION (PD) OF HIPPOCAMPAL CA1 PYRAMIDAL CELL SYNAPTIC EXCITABILITY. S. Khanna* and I. G. Sinclair. Div. of Pharmacol. & Toxicol., Faculty of Pharmaceutical Sciences, Univ. of British Columbia, Vancouver, B.C., Canada, V6T 1W5.

An intense peripheral noxious heat stimulus induces a PD of the dorsal hippocampal CA1 population spike (PS; Khanna and Sinclair, 1989) and activates septo-hippocampal neurones of the medial septal-vertical limb of the diagonal band of Broca (MS-VLDBB; Dutar et al., 1985). Further, MS-VLDBB tetanic stimulation produces a cholinergic mediated depression of the apical dendritic field excitatory postsynaptic potential (dfEPSP; Rovira et al., 1983). Here we report results consistent with the notion that acetylcholine is released in the apical dendrites results consistent with the notion that acetylcholine is released in the apical dendrites of CA1 pyramidal cells following a noxious stimulus resulting in depressed CA1 synaptic excitability. Experiments were done in rats (250-350 g) lightly anaesthetized with urethane 1.0 g/kg, i.p. Noxious hot water (55°C, 15 sec) applied to the left hind paw produced a PD of the submaximal CA1 PS evoked upon contralateral CA3 stimulation. Following recovery, preadministration of the cholinergic muscarinic antagonist, atropine sulphate (40 mg/kg, i.p.), prevented the normally produced PD of the PS to noxious heating of the tail. This dose of atropine also antagonized the cholinergic mediated MS-VLDBB tetanus-induced, but not the corresponding paired-pulse, facilitation of the threshold CA1 PS. In different corresponding paired-pulse, facilitation of the threshold CA1 PS. experiments, atropine iontophoresed at the cell body recording site did not prevent the PD of the submaximal CA1 PS following noxious heating of the tail although it antagonized PS facilitation by iontophoretic Ach. However, atropine iontophoresed at the apical dendritic recording site prevented the noxious stimulus-induced PD of the dfEPSP. It also antagonized iontophoretic Ach, but not GABA, induced-depression of the dfEPSP. (Supported by the Medical Research Council of Canada and B.C. Health Care Research Foundation).

ANTAGONISM OF BACLOFEN-INDUCED ANTINOCICEPTION BY INTRATHECAL PHACLOFEN OR 2-OH-SACLOFEN, BUT NOT δ-AMINOVALERIC ACID. D.L. Hammond and S. Aran. Dept. of Anesthesia and Critical Care, The University of Chicago, Chicago, IL. 60637.

Phaclofen (PHAC), 2-OH-saclofen (SAC) and δ-aminovaleric acid (DAVA) are purported to be GABA_B receptor antagonists. This study examined their ability to antagonize the antinociception produced by intrathecal (i.t.) administration of baclofen (BAC) in

The dose-response relationships of BAC on the tail flick (TF) and hot plate (HP) tests were first determined in the absence of GABA, antagonists and then redetermined in the presence of fixed doses of PHAC (10-100 μg i.t.), SAC (10-30 μg i.t.) or DAVA (10-100 μg i.t.). Intrathecal injection of PHAC produced rightward parallel shifts in the dose-response relationship of BAC in both the TF and HP tests. Although SAC (10 μ g) produced a parallel shift to the right, no further shifts could be obtained with higher doses of SAC. Although 10-30 μg i.t. DAVA did not antagonize BAC, 100 μg i.t. DAVA augmented the antinociceptive effect of BAC in the TF test.

The results of this study suggest that PHAC is the antagonist of choice to study the role of GABA_B receptors in the spinal cord.

237.19

SUPPRESSION OF MEDIAL THALAMIC RESPONSES TO SPINAL AND NOXIOUS STIMULI BY COCAINE. B.C.Shyu*, J.A.Kiritsy-Roy, T.J.Morrow and K.L.Casey. Depts. of Neurology, Physiology and Inst. of Gerontology, Univ. of Michigan and Neurology Research, V.A. Medical Center, Ann Arbor, MI 48105.

Cocaine is a potent, centrally active non-opioid analgesic in the rat (Brain Res. 479:306-312,1989). We have shown that cocaine inhibits nociceptive responses of units in the medial thalamus and medial reticular formation. The aim of this study was to determine if cocaine suppresses nociceptive responses of thalamic neurons by acting at spinal or supraspinal level

Rats were anesthetized with chloral hydrate, paralyzed and ventilated artificially. Stimulating electrodes were positioned at T8 to T10 of the spinal cord and subcutaneously in the foot pad. The dorsal columns were sectioned about T5 to T6. Recording sites in medial or lateral thalamus were chosen by identification of unit responses evoked by electrical stimulation (0.2 msec duration, $500 \mu A$ intensity at spinal cord; 5 - 10 mA intensity at foot pad) or noxious stimulation (pinching of the foot pad).

Cocaine (1mg/kg iv) produced significantly greater suppression of medial thalamic unit responses to noxious somatic stimulation ($49.4 \pm 8.7\%$ of control) than to spinal cord stimulation ($76.2 \pm 6.6\%$ of control). The effect of cocaine on unit responses to somatic stimulation was dose related in the range of 0.3 to 3.5 mg/kg and attenuated by eticlopride, a D-2 selective dopamine receptor blocker. Cocaine had no effect on lateral thalamic neuronal responses to either somatic or spinal cord stimulation. Morphine (0.09 to 2.9 mg/kg) also inhibited medial thalamic neuronal responses to somatic stimulation. These results suggest that the antinociceptive effect of cocaine is mediated by dopaminergic mechanisms and is exerted at thalamic and spinal levels (Supported by awards from the Swedish Medical Council, Bristol-Myers Squibb and VA Merit Review).

THE ANTINOCICEPTIVE EFFECTS OF INTRATHECAL BACLOFEN IN PATIENTS WITH CHRONIC SPINAL LESIONS. S.C. D'Luzansky, Samaritan Rehabilitation Institute, Phoenix, AZ 85006; Department of Pharmacology, University of Arizona, Tucson, AZ 85724.

Baclofen, the prototypic GABA_B receptor agonist, is often administered to reduce spasticity of spinal origin. When ineffective orally, continuous intrathecal (i.t.) infusion of baclofen by an implanted pump can be clinically beneficial. Prior to implantation of the pump, a double-blind study comprising bolus i.t. injections of baclofen (50 μg) and saline into the L_{1-2} interspace was conducted to adjudge the antispasticity and antinociceptive^{2,3} action of baclofen in patients with complete (n=3) and incomplete (n=3) chronic suprasacral spinal lesions. Motor (flexor reflexes) and sensory (discrimination) responses to noxious (pinch, electrocutaneous) stimulation of the foot, and perception (analog scale) of both spasmrelated and chronic, radiating pain were analyzed. Our results indicated that i.t. baclofen increases the motor and sensory threshold to a noxious stimulus, and decreases the magnitude of spasm-related and chronic pain (n=3). The antinociceptive action is ascribed to the local, spinal action of i.t. baclofen.

ADRENAL MEDIATION OF BUSPIRONE-INDUCED HYPOTHERMIA AND ANTALGIA IN RATS. L. Rogers. D. McBride* and J. Giordano. Drake Univ., Des Moines, IA 50311

The 5-HT₁A agonist buspirone produces analgesia in rats. Buspirone (1-5 mg/kg,ip) induced dose-related decreases rats. Buspirone (1-5 mg/kg,1p) induced dose-rotated line core temperature (.5-1°C) that were co-terminal with analgesia. Both hypothermic and analgesic effects of macfacted by naloxone (1 mg/kg,sc). The analgesia. Both hypothermic and analgesia effects of buspirone were unaffected by haloxone (1 mg/kg,sc). The lack of opioid involvement and documented role of 5-HT-mediated neuroendocrine substrates in thermoregulation and pain modulation prompted study of adrenal function in these buspirone-induced effects. Administration of the PNMT inhibitor dichloromethylbenzylamine (DCMB:25 mg/kg,ip) did not affect buspirone-induced hypothermia, while circulationally radiations. not affect buspirone-induced hypothermia, which significantly reducing analgesia. Pretreatment with cortisol synthesis inhibitor aminoglutethemide (2) mg/kg,ip) did not alter busprirone-elicited hypothermia, but reduced analgesia. This decrease was less than effects produced by DCMB. Sham operated and injected controls did produced by DCMB. Sham operated and injected controls did not show changes in buspirone-induced hypothermia or antalgia. These data suggest that buspirone-induced hypothermia and analgesia may be functionally related. Analgesia appears to be reliant upon sympathoadrenomedullary mechanisms to a greater extent than adrenocortical substrates. It is possible that antalgia due to increased sympathetic-adrenal activity may be a functional response to buspirone-induced hypothermia.

SOME DOPAMINE D₂ RECEPTORS MAY NOT BE COUPLED TO ADENYLATE CYCLASE IN THE RAT RETINA. <u>M. Hadjiconstantinou¹²</u>, <u>X-Z. Qu²and N.H. Neff</u>, Departments of Psychiatry¹ and of Pharmacology², The Ohio State University College of Medicine, Columbus, Ohio 43210

Dopamine (DA) D, and D, receptors are present in rat retina. Based on studies with other tissues, D, receptors are apparently positively coupled to adenylate cyclase, while some D₂ receptors are negatively coupled and some are not coupled. We have studied DA receptor subtypes in the rat retina following the intraocular injection of 6-hydroxydopamine (6-HODA). Male Sprague-Dawley rats 150 to 200 g were anesthetized and injected intravitreously with 6-HODA or saline. 6-HODA, 30 μ g/4 μ l, was injected into the right eye, 2 injections 24 hr apart, and an equal volume of sterile saline injected into the left eye. Rats were decapitated 7 days later. After injection of 6-HODA there was depletion of retinal DA by about 90 percent, as well as about a 40 percent decrease of the number of D, and D₂ receptor binding sites using [⁹H]SCH 23390 and [⁹H]spiperone for D, and D₂ sites, respectively. Following the 6-HODA lesion, there was an enhancement of the D, receptor-stimulated accumulation of cyclic-AMP, suggesting receptor supersensitivity. Furthermore, there was a loss of responsiveness of D, receptors that are negatively coupled to adenylate cyclase. Our results suggest that some retinal D_2 receptors are coupled to adenylate cyclase and some are not. The adenylate cyclase coupled D_2 receptors appear to be associated with 6-HODA sensitive neurons.

CHRONIC INTRACORTICAL MICROSTIMULATION OF PRIMATE VISUAL CORTEX. I. EVALUATION OF MATERIALS AND METHODS FOR A VISUAL PROSTHESIS.

Bak, F. T. Hambrecht, C. Kufta* and J. S. McIntosh. Lab. of Neural Control, Neural Prosthesis Program (F.T.H.) and Surgical Neurology (C.K.), NINDS, NIH, Bethesda, MD 20892
Intracortical microstimulation of visual cortex in human subjects elicits the sensation of small points of light called phosphenes (Bak et al., Med. Biol. Eng. & Comput. 28, 1990). Implantation of arrays of intracortical electrodes may provide a means of producing a visual prosthesis for a blind individual. In order to evaluate materials and stimulation parameters that could be used in a visual prosthesis for humans, a primate was implanted with 9 pairs of microelectrodes, under sterile operating conditions, and stimulated over a period of 105 days. The electrodes were fabricated from 37.5 μm iridium wire that was electropolished to a tip diameter of 1-2 μm and coated with Parylene C. The tips were exposed with a high voltage arc and activated to form an iridium oxide on the exposed surface. The spacing between tip pairs ranged from 175 μm to 450 μm. Electrode areas ranged in size from 35 to 300 μm². To evaluate stability and tissue reactions, electrodes were stimulated for two hours each day, five days/week, 0.2 ms/phase biphasic pulses at 50Hz, with current densities ranging from zero to 3200 μC/cm² The animal was sacrificed, by intracardiac perfusion with aldehyde fixative, to evaluate the electrodes (this abstract) and tissue reactions (see companion abstract, Azzam, N.A. et al.). Scanning electron micrographs of the electrodes revealed excellent stability of the Parylene C insulation and possible slight erosion of the electrode tips. The insulation was degraded at the tip of one electrode, which was attributed to improper tip exposure. The mechanical and electrical properties of the electrodes look promising for evaluating the feasibility of a visual prosthesis.

238.3

HUE DISCRIMINATION AFTER FOCAL CEREBRAL EXCISION IN HU-

HUE DISCRIMINATION AFTER FOCAL CEREBRAL EXCISION IN HUMANS. A. Ptito, M. Jones-Gotman and J. Crane. Montreal
Neurol. Inst., McGill Univ., Montreal, Canada. H3A 2B4.

The role of inferotemporal cortex (IT) in color discrimination is unclear. In monkeys, IT lesions have
resulted in little or no impairment in some studies
(e.g. Gross et al, 1971, J. Comp. Physiol. Psychol. 76:
1-7), but severe deficits in others (Heywood et al,
1988, Exp. Brain Res. 437-441). Studies in humans also
vielded no definitive results: most reported few cases yielded no definitive results; most reported few cases or ill-defined lesions. In the present study, 61 patients with focal excision from right or left frontal patients with focal excision from right or left frontal or temporal lobe and 22 normal control (NC) subjects were tested on the Farnsworth-Munsell hue discrimination test. All temporal-lobe lesions included partial removal of IT cortex. Results showed no impairment in either temporal lobectomy group, but both frontal-lobe groups were markedly deficient. Thus it seems that the analysis of color information does not lie in anterior temporal neocortex. However, one patient whose temporal-lobe removal extended posteriorly into anterior temporal-lose removal extended posteriorly into anterior cocipital lobe performed poorly, supporting the notion that occipitotemporal areas are important in hue discrimination (Pearlman et al, 1979; Ann. Neurol. 5: 263-261). The significance of the deficit in frontal-lobe groups is not clear. It may not reflect a true hue discrimination deficit, but perhaps a difficulty in ordering crimilia. ing stimuli. This will be explored in a future study.

238.5

ATTENTIONAL CHANGES AS A FUNCTION OF AGING. <u>D.</u>
A. Robin and M. Rizzo. The University of Iowa, Iowa City, IA 52242.
There is relatively little information on

the effects of aging on attention. But changes are important to understanding But such associated cognitive decline because of attention's broad influence on human behavior. We tested 20 elderly and 20 young adults on five attention paradigms which examined their ability to orient in vision and audition and sustain attention across a visual array. Results showed increased reaction times in results showed increased reaction times in elderly subjects on all tasks. They could orient attention similarly to young adults but performed more poorly on the sustaining task. Signal detection analyses showed no age-related Signal detection analyses showed no age-related differences in response bias (beta), although true sensitivity (d') was reduced in the elderly. These data suggest that aging reduces attentional capacity which may impair performance on perceptual tasks. We hypothesize that aging reduces a pool of attention related neurons similar to those identified in the prestriate region of primates.

238.2

CHRONIC INTRACORTICAL MICROSTIMULATION OF PRIMATE VISUAL CORTEX. II. LIGHT AND ELECTRON MICROSCOPIC EVALUATION FOR A VISUAL PROSTHESIS.

A. A. Zalewski, E. M. Schmidt and R. N. Azzam*. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892

We examined the anatomical response of the visual cortex in a monkey (Macaca mulatta) to chronic implantation and stimulation of nine pairs of microelectrodes. These electrodes were made of indium and insulated with Parylene C (see companion abstract, Schmidt, E.M. et al.). The design is intended for ultimate use in a visual prosthesis for blind people. When unstimulated and stimulated electrodes were compared, each was associated with minimal neuronal loss that was limited to a few micrometers around and between the electrode tips. The major difference between electrodes was an infiltration of macrophages around the stimulated electrodes, which increased in intensity with higher current densities. Pia mater and astrocytic foot processes ensheathed the shafts and tips of the unstimulated electrodes. However, multinucleated giant cells, with very dense cytoplasm and rich in endoplasmic reticulum, surrounded the tips of the stimulated electrodes. Pial fibroblasts and collagenous fibers surrounded the giant cells and they in turn were isolated from the neuropil by a very dense concentration of reactive astrocytic foot processes. Together they formed a dense basement membrane similar to the glial limitans which suggested the re-establishment of the blood-brain barrier. The larger blood vessels close to the implantation site were similarly ensheathed. Macrophages entered the neuropil around the lesions and were seen in the perivascular compartments and in the pia-arachnoid, indicating movement of these cells, laden with inclusion bodies, to the cerebrospinal fluid. These macrophages had ingested cellular debris as well as electron dense particulate matter, possibly dissoluted iridium. A few homogeneous electron dense intracellular globules were observed and seemed to be fragments

238.4

SIGNAL DETECTION IN HUMAN BRAIN LESIONS. M. Rizzo, D. Department of Neurology, Univ. of Iowa College

Robin. Department of Neurology, Univ. of Iowa College of Medicine, Iowa City, Iowa 52242. Signal detection (SD) theory characterizes system performance on perceptual tasks. We evaluated how the SD variables, d' (true sensitivity) and β (response bias), depend on cerebral damage. We tested 35 subjects with focal structural brain lesions on an attention task. They reported on sequential perturbations at unpredictable intervals and locations, of any single element in a random dot display (Starry Night paradigm, Neurology 40:447-455. 1990).

element in a random dot display (Starry Night paradigm, Neurology 40:447-455, 1990).

Results showed low d' with occipital and parietal damage mostly from failure to report events in the field opposite the lesions. But low d' could also follow pure frontal lobe lesions in the absence of hemianopia or neglect. β was abnormal in bifrontal cases (m=3) who often reserved to no signal Parkingon(s) (m=7) and other reserved to no signal Parkingon(s) (m=7) and often reacted to no signal. Parkinson's (n=7), and Alzheimer's (n=8) cases showed combined aberration of d' and β despite normal acuity and fields.

The results suggest that d' and β each depend on multiplex interactions which include bottom-up processes toward the receptor interface, and top-down factors related to knowledge and decision making. Damage in visual cortex and adjoining regions mostly reduce signal strength. Lesions in frontal ("amodal") cortex alter performance in complex ways, explained in SD parlance by an increase of internal noise relative to signal.

VISUALLY EVOKED MAGNETIC FIELDS: RETINOTOPY AND CORTICAL MAGNIFICATION FACTOR. R.J. Ilmoniemi and S. Ahlfors*. Low Temperature Laboratory, Helsinki University of Technology, Rakentajanaukio 2, 02150 Espoo, Finland.

We have measured the magnetic field over the occipital part of the human brain in response to small visual stimuli with a 24-channel SQUID magnetometer. The black, white, and striped (diameter < 1 degree) stimuli against a gray background were shown on a computer screen (MacintoshTM) for 250 ms in different locations of the visual field in order to learn how retinotopic order is reflected in the responses

Magnetic field measurements make it possible to determine locations of brain activity with an accuracy of 5-10 mm, although shifts in activation sites of 1-2 mm can be detected. To avoid complications from multiple simultaneously active cortical sites, we presented small stimuli and analyzed only the earliest deflections of the evoked response. Locations of cortical activity were obtained as minimum-norm estimates of the source current or as equivalent dipoles. Retinotopic order was evident in

the dependence of the source estimates on visual-field locations.

We found that small shifts in the visual-field location of the stimulus normally resulted in regular small shifts in the location of the estimated source current. However, for stimulus shifts in some parts of the visual soulte current. However, for stimulus shifts in some parts of the visual field, the magnetic field pattern changed dramatically even for relatively small changes in stimulus location. We suspect that these cases correspond to cortical locations where sulci give rise to sharp turns in the surface of the cortex. From the regular shifts, we could estimate the cortical magnification factor, finding agreement with earlier estimates that have been obtained with less direct methods (J. Rovamo and V. Virsu, Exp. Brain Res. 37:495, 1979).

A MODEL OF SUBLAMINAR AND THALAMOCORTICAL CONTRIBUTIONS TO THE SURFACE VEP: IMPLICATIONS FOR CURRENT SOURCE DENSITY (CSD) ANALYSIS. C.E.Tenke and C.E.Schroeder, Dept. Biopsych./Psychophysiol., NYS. Psych.Inst.,NY and Dept. Neuroscl., A.Einstein Coll.Med,Bronx,N.Y.

One dimensional CSD analysis greatly facilitates exploration of both

regional neural processes and the physiological basis of surface recorded field potentials. Optimal utilization of a CSD requires a sampling and computational resolution adequate to describe current sources and sinks which are reliable, valid and physiologically relevant. Previous simulation studies have shown that large, open field generators may be reasonably studied using high resolution CSD methods. However, the adequacy of these methods for the study of sharply localized and closed field generators has not been established. High resolution analysis of the CSD profile in macaque striate cortex underlying the surface N40 of the flash visual evoked potential (VEP) reveal one or more prominent current sinks in Lamina 4C, with sources distributed below. However, it has been argued that neither Lamina 4 stellate cells nor their thalamic afferents should behave as open field generators. We therefore simulated these contributions using ensembles generators. We intereste similated mease communities using ensembles of dipoles with variable orientations, dipole lengths and locations. Comparisons with physiological data indicate that: 1) A closed field component of stellate lamina activation produces artifactual sources in suprajacent recording sites, identifiable by changing the differentiation grid; 2) small deviations in symmetry of activation produce an open field generator; 3) the widely distributed sources deep to Lamina 4 are incompatible with a Lamina 4 generator alone, but conform to the open field profile required of current return related to terminal depolarization. (Supported by MH36295 and MH06723)

238.9

SPATIOTEMPORAL ANALYSIS OF VISUAL ACTIVITY IN PRIMATES IV: EXTRASTRIATE CONTRIBUTIONS TO THE SURFACE VEP INCLUDING A MANIFESTATION OF DIRECT THALAMOCORTICAL INPUT. \$\frac{5}{2}\text{Givre}\$, \$\frac{6}{2}\text{C.E.Schroeder}\$, & J.C.Arezzo Depts. Neuroscience and Neurology, Albert Einstein Coll. Med. Bronx, NY 10461

The flash-evoked potential (f-VEP) recorded from the occipital surface in the awake macaque includes N40, P55/65, N95 and P120 components. To elucidate their generators, we compared intracortical profiles of f-VEP, current source density (CSD) and multiunit activity (MUA) obtained from Area 17 (V1) with those obtained from extrastriate cortex in the prelunate gyrus of an awake monkey. Profiles were recorded with multicontact electrodes which spanned the cortical laminae. As previously shown, V1 substantially contributes to surface N40 and P55/65 components. In this region, N40 represents thalamocortical afferent activity and the initial postsynaptic activation of Lamina 4C. The associated current sinks have a mean onset of 26.4 msec (±2.9 msec). P55 reflects divirisynaptic activation of the supragranular laminae; the associated current sinks begin at 34.6 msec (±3.5 msec). Intracortical passes in prelunate cortex (N=6) are characterized by consistent inversions of a small N40, and a robust P120. In medial prelunate gyrus, an inversion of the N95 is also observed. Prelunate N40 appears to represent initial activation of this area. The current sink associated with this component has a mean onset of 28.4 msec (±2.9 msec). It is unlikely that this activity represents input from an earlier cortical stage since it precedes the initial activation of supragranular laminae in V1. Thus, these findings support a direct input from thalamus to prelunate visual areas. CSD analysis shows significant current flow coincident with both N95 and P120 in prelunate cortex supporting a significant curribution of this area to the generation of each of these surface potentials. In contrast, V1 appears to contribute little t generation of surface f-VEP components by striate and extrastriate cortex may increase the clinical utility of this measure in assessing the function and integrity of the cortical visual pathways. (Supported by MH06723).

SPATIOTEMPORAL ANALYSIS OF VISUAL ACTIVITY IN PRIMATES II: A METHOD FOR DIRECTLY INTEGRATING HUMAN AND MONKEY DATA. <u>G.V.Simpson, A.Mehtå & C.E.Schroeder</u> Depts. Neurol. & Neurosci., Einstein Coll. Med., Bx, NY 10461.

Einstein Coll. Med., BS, NY 11461.

Brain Electric Source Analysis (BESA) of scalp-recorded VEP yields estimates of the location, orientation and temporal activity pattern of multiple VEP generators (equivalent dipoles). Brain regions represented by BESA equivalent dipoles are approximated by projecting dipole locations onto the subject's MRI. Combined VEP/BESA/MRI describes the spatial and temporal subjects with Combined very Bes Aymix describes the spatial and temporal brain activation pattern during visual processing. We applied this approach to comparison of activity patterns engaged by spatial attention vs. pattern discrimination tasks in humans. The results show sequential and temporally overlapping activation of striate, dorsal extrastriate, dorsal parietal areas in the spatial attention task, versus striate, inferior extrastriate, inferior parietal and inferior temporal areas in the pattern discrimination task. These data are consistent with visual pathway organization as deduced from monkey studies, however, data in monkeys and humans are rarely directly comparable. To integrate the respective strengths of human and monkey research we extended human VEP/BESA/MRI procedures to monkeys. This initial experiment used whole-field flash stimulation, producing sequential temporally overlapping activation of medial and lateral striate and of medial and lateral striate and of medial and temporally overlapping activation of medial and lateral striate and of medial and lateral extrastriate regions in and near the prelunate gyrus. Preliminary indications support an analogous spatiotemporal activation pattern in humans. Our findings demonstrate that VEP/BESA/MRI can provide a view of the temporal and spatial organization of visual processing which directly translates between monkeys and humans. As a consequence, we can improve our understanding of human visual processing by virtue of the anatomic/physiologic specificity achieved in monkeys. An accompanying poster illustrates how VEP/BESA/MRI findings can be validated and extended through intracranial recordings in monkeys. recordings in monkeys.

INTRACORTICAL CONNECTIVITY REVEALED BY EVOKED POTENTIALS IN CAT VISUAL CORTEX. M. Kitano, T. Kasamatsu & A.M. Norcia. Smith-Kettlewell Inst., S.F. 94115

Various functional modules are horizontally connected in visual area V1 and V2. Extensive intracortical and interhemispheric connections are also known anatomically in other visuocortical areas.

We studied the extent of the visual field which gives rise to inputs to a small cortical area by recording visual evoked potentials (VEPs) transcortically between a skull electrode and a cannula/electrode placed near the projection of the area centralis. Stimuli consisted of 5 deg patches of phase-reversing gratings (4 or 10 Hz) which were swept in spatial frequency. Test stimuli were presented sequentially on a grid spanning ±30 deg. Response maps were created before, during and after local inactivation of the cortex with a continuous infusion of 10mM muscimol.

We found that: 1) In control, mapping of the visual field revealed a response field larger than that expected on the basis of cortical retinotopy. 2) Stimulation of the nasal and temporal hemifield evoked VEPs in the contra- and ipsilateral cortex, respectively, beyond the direct retino-geniculo-occipital projection. 3) VEPs diminished gradually after the start of muscimol infusion. 4) By terminating the infusion, VEP responsiveness gradually increased to become larger than control. 5) The muscimol-induced changes were field-specific. They were not confined to visual cortex ipsilateral to the infusion, but were observed concurrently in the contralateral hemisphere as well.

SPATIOTEMPORAL ANALYSIS OF VISUAL ACTIVITY IN PRIMATES I: RETINOTOPIC ACTIVATION OF HUMAN VISUAL CORTEX.

A.D. Mehta*¹, G.V. Simpson*, M. Scherg*, H.G. Vaughan, Jr.^{1,2} & K. Weiss*³, Depts. Neurosci.¹, Neurol.², Radiol.³, Einstein Coll. Med., Bx., N.Y. 10461 & Max Planck Inst. f. Psychiatr.⁴, Munich, FRG.

Application of Brain Electric Source Analysis (BESA) to scalp-recorded VEP yields estimates of the location, orientation and temporal activity paragraphs. VEP

VEP yields estimates of the location, orientation and temporal activity pattern of multiple VEP generators (equivalent dipoles). These equivalent dipoles locations are projected onto the MRI of individual subjects, providing a description of the spatial and temporal brain activation during visual processing. description of the spatial and temporal brain activation during visual processing. We used this approach to examine the pattern of responses in human visual cortex to stimulation at different locations in the visual field. We presented small, white-on-black square stimuli at different locations in the fovea and at varying degrees of eccentricity in the periphery. Stimuli at different eccentricities were adjusted in size (0.5-2.5 degrees), according to estimates of the human cortical magnification factor, to activate comparably small regions of visual cortex. The results reveal a retinotopic pattern of activation of human visual cortex in which foveal stimuli activate regions at or near the occipital pole, and stimuli at increasing eccentricities in the visual field activate increasingly deeper (anterior) regions along the calcarine fissure. Stimulation at points in the superior vs. inferior and left vs. right fovea activate inferior vs. superior and right vs. left regions of the occipital pole, respectively. Variations in VEP across subjects were correlated with variations in each individual's cortical configuration. The findings correspond with known features of the retinotopic organization of visual cortex based upon prior human studies. This further supports the physiological/anatomical validity of the VEP/BESA/MRI approach. The utility of this method as a means of integrating human and monkey research is addressed in the accompanying poster (Simpson et al.)

238.12

SPATIOTEMPORAL ANALYSIS OF VISUAL ACTIVITY IN PRIMATES III: INTEGRATED SURFACE AND INTRACRANIAL INVESTIGATION OF VEP IN AWAKE MONKEYS. C.E.Schroeder, S.J.Givre, G.V.Simpson, N.Nicholson & C.E.Tenke, Depts. Neurosci. & Neurol. Einstein Coll. Med., Bx, NY 10461, Dept. Biopsych. NYS Psych. Inst., NY, NY.

Epidural analysis of flash-VEP in awake macaques outlines a frontolateral N22 component and posterior N40/P55-65 and N95/P120 complexes. Brain Electrical Source Analysis (BESA) of VEP extends the analysis to a hypothetical configuration of intracranial generators, defined by location, orientation and temporal pattern. Mapping the locations defined by BESA to each monkey's MRI supports the origin of: N22 in LGN, N40/P55-65 in striate and (less) in extrastriate cortices and N95/P120 primarily in extrastriate regions in and near the prelunate gyrus (N95 - medial, P125 - medial to lateral). Profiles of concomitant flash-evoked VEP, current source density (CSD), and multiunit activity (MUA) obtained with multicontact electrodes from five awake macaques, evaluated these hypotheses. N22 was traced from its surface maximum to its origin in LGN; it arises primarily from a current sink reflecting depolarization of cells in Lamina 6. As shown previously, a major contribution to N40 arises from current sinks in Lamina 4C of V1, reflecting depolarization of stellate cells and thalamocortical terminals, and P55/65 arises from current sources reflecting depolarization of supragranular pyramidal cells and net hyperpolarization of 4C stellate cells respectively. A similar set of processes, with a slight latency lag (2-5 ms) underlies the smaller contribution of Area V2 to the surface N40/P55-65. The contributions of prelunate extrastriate cortices are detailed in an accompanying poster. Integration of surface and intracranial VEP analyses provides a powerful and unique whole brain view of visual processes, which may directly link human and simian studies. BESA yields detailed hypotheses concerning location and temporal activity p

CONTRAST SENSITIVITY FUNCTIONS (CSF) IN PIGMENTED RATS ESTIMATED FROM VISUAL EVOKED POTENTIALS (VEP) ELICITED WITH COUNTERPHASE OR ON/OFF MODULATED GRATINGS. W.K. Boyes¹, E.A. Manring² and H.K. Hudnell¹. ¹US EPA, RTP, NC 27711 and ²NSI Technology Services. VEPs recorded using suprathreshold stimuli can be used to extrapolate sensory thresholds. Steady-state VEPs elicited with on/off modulation of sinusoidal gratings have power at both the stimulus rate (1F) and at twice the stimulus rate (2F), but when elicited with counterphase modulation have primary response power only at 2F. On/off VEP amplitude at 1F has a bandpass spatial frequency profile, but at 2F a low pass profile. Amplitudecontrast functions of 2F are more steep than those of 1F. These results prompted us to examine if CSFs derived from VEPs would differ if elicited with counterphase or on/off modulation, and if derived from 1F, 2F or 1F+2F amplitude. Nine male Long-Evans rats were tested in two sessions for either counterphase or on/off modulation. During each session 50 averaged VEPs were recorded in random order; 10 spatial frequency by 5 contrast values. CSFs were based on extrapolations of the amplitudecontrast functions to threshold. Some values were dropped due to unreasonable thresholds estimates. Functions based on 2F gave fewer missing values. CSFs were similar whether based on on/off 1F, 2F, 1F+2F or on counterphase 2F. The results suggest that spatial frequency response profiles differ at threshold and at suprathreshold contrast levels.

MODULATION OF VEP N. LATENCIES INDUCED BY PATTERN CONVERGENCE AND ORTHOGONALITY. E.Micheli-Tzanakou. N.Cottaris and R.Iezzi.Dept. of Biomedical Engineering, Rutgers Univ., PO Box 909, Piscataway, NJ 08855-0909

It has recently been shown that the global structure of orthogonally inducing (biasing) patterns appears to be a necessary component in generating certain aftereffects. In this paper patterns that gradually evolved from random to ordered configurations are generated using an optimization technique called ALOPEX. Two types of experiments are then performed using the above sequence of stimuli to record the Visual Evoked Potentials (VEPs) in humans. In the first set of experiments VEPs are recorded using a sequence of fifteen stimuli starting from a random pattern which in time converges to an ordered pattern (a vertical bar). During the OFF period, either a blank pattern or a horizontal bar, which is a biasing pattern orthogonal to the final ON pattern of the series is used. The reverse sequence of ON patterns is also used. In all cases, the N₂ peak of the VEP is examined. Our results show that in the unbiased case, the N₂ peak exhibits a strongly increasing latency, while in the orthogonally biased case there exists a correspondingly strong negative correlation. In the second set of experiments, N₂ latencies demonstrate trends that are exactly opposite to those described earlier.

238.17

RAT VISUAL SYSTEM 2-DEOXYGLUCOSE UPTAKE IN RESPONSE TO FLASHING-DIFFUSE AND FLASHING-PATTERN STIMULATION AS A FUNCTION OF ILLUMINATION LEVEL. R. M. Cooper, G. A. Thurlow and S. Pepperdine.* Behavioral Neuroscience Group, Psychology Dept., U. Calgary, Calgary, AB, T2N 1N4,

In our search for CNS structures which mediate intensity discriminations we examined the effects of 5 hz "flashing-diffuse" (eye covered with white diffusing mask) and 5 hz "flashing-pattern" (eye exposed to square-wave gratings) over a 6 log range of luminance on C-14 2-DG uptake in the alert and freely-moving hooded rat. Only flashing pattern increased 2-DG uptake in area 17, an increase equivalent in degree over the 6 log range. In the dorsal and ventral LGN, LPN, and colliculus, however, the increases produced by flashing-diffuse and flashing-pattern were indistinguishable, and declined monotonically as luminance decreased. These 2-DG results, consistent with a sparing of intensity discrimination capacity after cortical ablation, and unit findings which emphasize the importance of contrast rather than luminance level in cortical activation, suggest that in carrying out its major function of allowing visual object perception, area 17 does not process intensity information. This processing is more likely to occur subcortically.

DIAZEPAM INDUCED EFFECTS ON VISUAL EVOKED POTENTIALS AND VISUAL CONTRAST DETECTION THRESHOLDS IN HUMANS. H. Ken Hudnell , Will K. Boyes and Wayne B. Countys . Neurotoxicology Div., U.S. EPA, RTP, NC 27711; NSI Environmental Services, RTP, NC 27711.

The benzodiazepine, diazepam (Valium), is an indirect agonist of the inhibitory neurotransmitter, GABA. We previously reported that diazepam altered rat and human steady-state visual evoked potentials (VEPs) elicited by on-off modulation of sine-wave gratings (SFN, 52.3, 1989). Amplitude of the spectral 1F component (1 x the modulation frequency) was uneffected by diazepam, but 2F amplitude was reduced in both species.

We currently investigated diazepam induced effects on the vision of thirty human subjects who received either 10 mg of diazepam or a placebo capsule in a double-blind study. Contrast sensitivity functions for 1F and 2F, and contrast thresholds for detecting pattern and for detecting motion

vision of thirty human subjects who received either 10 mg of diazepam or a placebo capsule in a double-blind study. Contrast sensitivity functions for 1F and 2F, and contrast thresholds for detecting pattern and for detecting motion or flicker, were measured before and after treatment. Sine-wave gratings with spatial frequencies of 0.5 and 4.0 cpd, on-off modulated at 5 Hz, were used with both measurement techniques. VEPs were elicited by gratings set to 2,4,8,16 and 32% contrast, whereas, contrast was varied using a modified version of the ascending method of limits to measure detection thresholds. The results indicated that VEP alterations induced by diazepam manifest as alterations in contrast detection thresholds, suggesting that GABA has an important role in processing visual information.

238.16

WITHIN- AND BETWEEN-SESSION CHANGES IN PEAK N₁₆₀ AMPLITUDE OF FLASH EVOKED POTENTIALS (FEPs). D.W. Herr ^{1,2}, V.T. Griffin ³, W.P. Watkinson ⁴, W.K. Boyes ⁴, and R.S. Dyer ¹. ¹US EPA, RTP, NC 27711 and ³NSI Technology Services. Peak N₁₆₀ amplitude of FEPs may reflect a sensitization and/or habituation process (Dyer, R.S., Physiol. & Behav., 45:355-362, 1989). Manipulation of testing parameters may delineate the influence of these constructs in the development of this peak. In these experiments, we examined changes in the amplitude of peak N₁₆₀ over trials (within-session) and over days (between-sessions). Additionally, we monitored heart rate as an index of behavioral "arousal". Long-Evans hooded rats were implanted with epidural electrodes over the visual cortex. Subcutaneous ECG electrodes were placed over the left and right dorsal chest areas. Blocks of 50 trials and test days were within-subject variables. Relative flash intensity (in dB) was a between-subject factor. On each of 13 consecutive test days, 350 flashes/day (0.3 Hz) were presented. Peak N₁₆₀ amplitude increased over days (between-sessions), but decreased over trials (within-session). These results, combined with decreases in heart rate within the test sessions, suggest there may be processes which resemble between-session sensitization and within-session habituation involved in the development of peak N₁₆₀ amplitude. ²DWH was supported by a NRC Research Associateship.

EFFECT OF AMPHETAMINE ON REGIONAL CEREBRAL METABOLIC RATE IN NORMAL SUBJECTS. J. T. Metz. H. de Wit*. N. Wagner*. and M. Cooper*. University of Chicago, Chicago, IL 60637.

As part of our series of studies on the effects of drugs of abuse on regional cerebral metabolism of glucose (rCMglu), we used positron emission tomography to examine the response of normal subjects to oral administration of amphetamine

PET data were collected with a PETT-VI (5 simultaneous slices, intraslice resolution of 8 mm full width, half max). Subjective effects were evaluated with the Profile of Mood States (POMS). Eleven normal males (aged 21 to 35) were studied. Eight subjects were included in Study 1 in which they received placebo, 0.07 and 0.14 mg/kg AMPH. Drugs were administered double blind in counterbalanced order 90 minutes prior to injection of 8-10 mCi 2FDG. In all three sessions, subjects performed a visual monitoring task (VMT) during the period of FDG equilibration. The other 3 subjects were studied in 4 sessions each during which they received placebo or 0.28 mg/kg AMPH while performing the VMT in 2 sessions and the

same doses while resting quietly in the scanner during the other 2 sessions.

Subjects in Study 1 showed a decrease in average rCMglu relative to placebo over the whole brain in response to the higher dose of the drug (means±SD for placebo, 0.07, and 0.14 doses: $8.47\pm1.78,\ 8.59\pm1.62,\ 7.27\pm1.38\ mg/100g/min)$. Individual subjects, however, varied in their response to the drug and the decrease was not statistically significant. In Study 2, subjects tended to show increased rCMglu in the AMPH sessions. Sessions in which the VMT was performed generally had higher rCMglu than those with no task; there was no clear drug by task interaction. In both studies, rCMglu changes after AMPH were not limited to particular brain regions although drug-induced mood changes and VMT performance changes were solved to be solved the scenific AMPH were not limited to particular brain regions although drug-induced mood changes and VMT performance changes were

related to localized changes in rCMglu.

These studies demonstrate that the effects of AMPH on rCMglu are complicated and influenced by dose, task demands, and subjective factors.

RESTING BRAIN GLUCOSE METABOLISM AND EEG FINDINGS IN ALCOHOLIC KORSAKOFFS SYNDROME. E.M. Joyce*, J.W. Rohrbaugh*, D.E. Rio* and M.J. Eckardt. LCS/NIAAA, NIH Building 10, Rm 3C102, Bethesda, MD 20892. Groups of age-matched male normal volunteers (n=10) and abstinent alcoholics with Korsakoff's syndrome (KS, n=11) underwent resting 18FDG PET. EEG recordings were taken at baseline and throughout the FDG uptake period. EEG spectral power analysis showed that alpha was temporarily suppressed immediately after injection in controls but not KS. PET scans were analysed by placing regions of interest over specified brain areas and the rate of glucose metabolism was calculated (rCMRglu). There were no group differences in any absolute rCMRglu comparisons. Subtraction of rCMRglu from the average grey matter CMRglu for each subject revealed , in KS, relative cerebellar hypermetabolism and relative hypometabolism in right sensorimotor cortex, midline parietal cortex and bilateral cingulate cortex. Correlational analysis demonstrated that the groups had the cortex. Correlational analysis demonstrated that the groups had the same number of associations within neuroanatomical areas (frontal, same futinos of associations within futional temporal, subcortical and cerebellar) but that KS had fewer associations between these regions. In addition, thalamic rCMRglu was positively associated with that of all frontal regions in controls but not that of midline frontal cortex (cingulate and superior frontal gyri) in KS. The data suggest that the groups were in different states of arousal during FDG uptake and that the different metabolic profiles may reflect under-activation of the cerebral cortex in KS. There also appeared to be a functional dissociation between thalamic and cingulate rCMRglu in KS which may contribute to the mnemonic deficits of this group.

EXCITATORY AMINO ACID INJECTION <u>K.Nakai,Y.Naka*,K.Kubo*,</u>
<u>M.Nakai,T.Itakura*,S.Hayashi*,N.Komai*,T.Shirokawa.</u> Dept.
Neurol.Surg.,Wakayama Med.College, Wakayama 640 and Dept. Physiol., Akita Univ., School of Medicine, Akita 010, Japan Lines of evidence have suggested a role of excitatory amino acid in the pathogenesis of lesions due to an ischemic insults to the brain. However, it is controversial whether an amino acid itself as still cerebral circulation as a result of a metabolic change the nervous system or through a direct action on the blood vessels. Present study tried to elucidate how excitatory amino acids exert influences on the cerebral blood flow, amino acids exert influences on the cerebral blood flow, using the injection technic combined with laser flow-metry (Nakai et al. 1989). Under urethan anesthesia, 1, u, u, of_2saline containing NMDA or L-glutamate (1x10 of 1x10 of by up to 30% of that before the injection throughout showed a phasic increase in the blood flow for 3-4 minutes by over 100%. Usually two phasic increases were showed a phasic increase in the blood flow for 3-4 minutes by over 100%. Usually two phasic increases were observed during the injection of NMDA, suggesting a different underlying mechanism from that at lower doses. The result together with morphological findings obtained after the injection may imply the existence of both direct and indirect actions of NMDA on cerebral blood vessels.

TONIC AND PHASIC INCREASE IN CEREBRAL BLOOD FLOW CAUSED BY

TEMPORAL LOBE DYSFUNCTION IN PSYCHIATRIC PATIENTS IDENTIFIED BY ADJUNCTIVE ELECTROENCEPHALOGRAPHY AND REGIONAL CEREBRAL PERFUSION STUDIES WITH SINGLE PHOTON EMISSIONCOMPUTEDTOMOGRAPHY.K.J.Shedlack.B.T.Woods*,J.S. Curtis* and T.C.Hill*. Depts. of Psychiatry & Neurology (McLean Hospital) and Radiology (New England Deaconess Hospital), Harvard Medical School, McLean Hospital, 115 Mill Street, Belmont, MA 02178.

Improved neurodiagnostic specificity in psychiatry is desired as clinical data are often insufficient to support accurate psychiatric diagnosis and rational psychopharmacologic therapy. Among psychiatric patients with abnormal electroencephalogram (EEG) referred for single photon emission computed tomography (SPECT), we have identified cases in which focal regional cerebral blood flow abnormalities were coincident which focal regional cerebral blood flow abnormalities were coincident with the electrical abnormality. Psychiatric diagnoses were varied and no case had a history of seizure. EEG, 24-hour EEG, or brain electrical activity mapping (BEAM) revealed focal temporal lobe slowing or sharp activity while 99m Tc-HMPAO (Ceretec) SPECT scan performed on a 12camera, head-dedicated system revealed unilaterally decreased or increased tracer uptake. Focal areas of SPECT abnormality ranged in size from 7-22% of pixels in the ipsilateral temporal lobe and in magnitude from 8-23% of the mean counts/pixel in the contralateral temporal lobe when measured in a single transverse slice. A subset of cases thus identified have shown remarkable improvement in their clinical symptoms when treated with anticonvulsants suggesting that EEG and SPECT can identify a subpopulation of psychiatric patients who may be best diagnosed as having "temporal lobe dysfunction" and best treated with anticonvulsants rather than customary psychotropic medications. (Support: Fund for Research in Head Injury/Harvard Medical School)

EFFECT OF CHEMICAL STIMULATION OF VENTROLATERAL MEDULLARY DEPRESSOR AREA (VLDA) ON CEREBRAL BLOOD FLOW (CBF) IN THE RAT.

MEDULLARY DEPRESSOR AREA (VLDA) ON CEREBRAL BLOOD FLOW (CBF) IN THE RAT.

M. Maeda, A.J. Krieger and H.N. Sapru, Departments of Neurosurgery & Pharmacology, UMDNJ-New Jersey Medical School, Newark, NJ 07103.

In anesthetized (chloralose and urethane), paralyzed and artificially ventilated rats, the VLDA was chemically stimulated by microinjections of Leglutamate and the changes in CBF were determined by using microspheres. Unilateral chemical stimulation of VLDA (n=10) decreased CBF on the ipsilateral side significantly (P<0.05). The decrease in blood pressure (BP) induced by the chemical stimulation of the VLDA was not responsible for the decrease in CBF because similar decrease in BP induced by controlled hemorrhage did not alter CBF significantly (n=10). In another group of rats (n=6), the BP was raised moderately by transfusion of blood so that it did not decrease below normotensive levels during the chemical stimulation of VLDA. In these rats also, VLDA stimulation decreased CBF (P<0.05) and increased cerebrovascular resistance (P<0.05) and increased cerebrovascular resistance (P<0.05) and interests cerebroached in relativity of the cerebral vessels to increase in arterial PCO2 (n=5) was not altered during the stimulation of the VLDA. These results suggest that VLDA neurons may participate in the regulation of cerebral circulation. Support: NIH (HL 24347) and Am. Heart Assoc.(NJ).

PIAL VESSEL REACTIVITY FOLLOWING TOPICAL APPLICATION OF SOMATOSTATIN. D.D. Rigamonti, J.B. Long, A. Martinez-Arizala and C.P. Wingfield. Neuropharmacology Branch, Div. Neuropsychiatry, Walter Reed Army Institute of Research, Washington, DC 20307.

Pial arterioles react to a variety of compounds including adenosine, vasopressin, dynorphin, oxytocin, serotonin, and substance P. The neuropeptide somatostatin (SOM), causes a dose dependent reduction in blood flow following its application to the lumbosacral spinal cord, neuropathological changes and motor deficits including paralysis. To further describe vascular reactions with somatostatin, we examined cortical vessel diameters following its topical application. Adult Sprague-Dawley rats were anesthetized and a craniotomy performed using microsurgical techniques. Animals were divided into three groups: Group I, Saline, Group II, SOM (6.25 nmoles) and Group III, SOM (25 nmoles). Vessel diameters were recorded on film at the beginning of each experiment, following saline exposure and 1, 5, and 10 min after application of SOM. Pial arterioles ranged in size from 0.18 to 1.20 mm and following exposure to saline negligible changes were observed. However, Group II animals showed sustained arteriolar constriction of 47%, 17%, and 31% at 1, 5 and 10 min respectively. Group III animals exhibited changes of 84%, 80% and 83% at the same time intervals. These results suggest that somatostatin causes profound and sustained vasoconstriction of cortical vessels which may be implicated to cause neural injury in the CNS.

CEREBRAL ISCHAEMIA INDUCED BY ENDOTHELIN-1 IN THE RAT. I.M.Macrae, M.J.Robinson, M.A.McAuley, J.L.Reid and J.McCulloch. Department of Medicine, University of Glasgow, Glasgow G12 8QQ, UK.

The existence of endothelin-1 (ET-1) binding sites within the cerebral circulation and a potent vasoconstrictor activity implicate this peptide in the physiology and pathophysiology of cerebrovascular control.

Intracisternal injection of ET-1 (30pmoles) in conscious

rats increased mean arterial pressure by 40+10 mmHg $(\text{pc0.005}, \text{n=5}) \text{ within 2 mins of administration. Simultaneous measurement of cerebral blood flow (CBF; [^{14}\text{c}] - iodoantipyrine autoradiography) revealed profound reductions in flow$ throughout the caudal medulla and cerebellum (>80% reduction, p<0.005) with significant hyperaemia in a number of forebrain structures (eg. 78% increase in sensorimotor cortex, p<0.005).

Local application of ET-1 (lnmole) onto the exposed left middle cerebral artery (MCA) of anaesthetised rats produced significant reductions in CBF at 10 mins in those areas supplied by this vessel (eg. 78% reduction in dorsilateral caudate nucleus and 72% reduction in sensorimotor cortex (p<0.01,n=5). Hydrogen clearance studies of CBF in the caudate nucleus revealed the prolonged duration of ischaemia induced by ET-1 on the MCA. With 2.5pmoles, CBF in the caudate was 33% of control at 10 mins, 50% at 20 mins, 60% at 1 hr and approaching control values at 2 hrs.

These studies demonstrate the endogenous peptide ET-1 to be capable of reducing CBF to pathologically low levels.

HEMIDECORTICATION IN RAT PUPS: EFFECTS ON LOCAL CEREBRAL METABOLIC

RATES FOR GLUCOSE IN ADULTHOOD. <u>J. Kunchandy</u>, H.T. Chuqari, Y. Nassir, UCI.A School of Medicine, Los Angeles, CA 90024. We previously reported (Soc Neurosci Abstr 15:448, 1989).that measurements of local cerebral metabolic rates for glucose (CMRGIc) obtained with position emission tomography cerebral metabolic rates for glucose (ICMRGIc) obtained with positron emission tomography (PET) in children following hemidecortication reveal the recovery of crossed cerebellar hypometabolism (diaschisis) and, in one infant, the reappearance of ICMRGIc in the deafferented caudate after a period during which ICMRGIc in this structure was absent on PET. In order to explore further the local cerebral energy requirements of remaining brain tissue in hemidecorticates, we measured ICMRGIc by 14-16-2-deoxyglucose autoradiography in a rat model of hemidecortication. Six-day-old rat pups (N=7) underwent gentle suction removal of cerebral cortex of one hemisphere following induction of hypothermia. Striatum and thalamus were spared. Following surgery, the rat pups were returned to their mothers. At maturity (6-9 months), ICMRGIc for 28 neuroanatomical structures were measured and compared to those of sham-operated controls (N=8) using Student'es thest. Most later was the state most structures were measured and compared to those of sham-operated controls (N=8) using Student'es thest. maturily (6-9 months), ICMRGIc for 28 neuroanatomical structures were measured and compared to those of sham-operated controls (N=6) using Students's t-test. Most structures <u>contralateral</u> to the side of hemidecortication tended to have <u>lower ICMRGIc than</u> controls. This was highly significant (pc.001) for lateral septum, striatum, lateral geniculate, dentate gyrus and visual cortex. ICMRGIc in the surgically spared but largely deafferented striatum was not significantly different from that in controls, or from striatal ICMRGIc in the intact side. Ipsilateral thalamic ICMRGIc (ventral and lateral nuclei), however, were significantly lower than in controls (pc.001) and compared to the intact side (pc.05). In the cerebellum, there was no ICMRGIc asymmetry in the cortex, white matter or dentate nuclei. Patterns of ICMRGIc for subcortical structures in this model are similar to those obtained with PET scanning in hemidecorticated children and will be further explored in terms of anatomical and biochemical aspects of programization. anatomical and biochemical aspects of reorganization.

-3PPP EFFECTS ON LOCAL CEREBRAL GLUCOSE UTILIZATION IN THE RAT <u>I. Pongstaphone*</u>, <u>L. Goodman*</u>, <u>O. Shirakawa</u>, <u>L. Dixon*</u>, <u>J.R. Walters</u>, <u>C.A. Tamminga</u>, Maryland Psychiatric Research Center, University of Maryland at Baltimore, Baltimore, MD 21228, NINDS, NIH, Bethesda, MD 20892
Partial dopamine (DA) agonists, including the prototypical 3-(3-

hydroxyphenyl)-N-(1-propyl)piperidine (3PPP), are currently of considerable interest in the treatment of schizophrenia. At low doses, -3PPP selectively stimulates the autoreceptor to reduce DA release and neuronal firing. At higher doses, -3PPP blocks apomorphine's postsynaptic actions. Thus, -3PPP may diminish DA-mediated transmission through two distinct actions. The goal of this study is to:

1) assess -3PPP action on local cerebral glucose utilization (LCGU) in rats to demonstrate its functional localization at low and high doses and, 2) to compare its effects with that of a typical neuro-leptic, haloperidol. -3PPP doses were selected from electrophysiologic evidence of DA auto- and postsynaptic-receptor action. Results: Low dose -3PPP produced significantly increased glucose uptake in cortical areas (e.g. medial prefrontal, cingulate, sensorimotor, auditory, p < .05) as well as in limbic regions, including hippocampus, septal nucleus, nucleus accumbens, and medial and basolateral amygdala (p < .05) compared with saline control. The higher dose of -3PPP produced virtually no significant changes in LCGU. The distribution of metabolic changes induced by either the low (autoreceptor) or high (postsynaptic) dose is distinctive for each dose, as predicted from other preclinical findings. Metabolic data following apomorphine with and without high dose -3PPP will be reported.

VASOPRESSIN MODULATES BRAIN BLOOD FLOW AFTER SPREADING CORTICAL DEPRESSION IN AWAKE RATS. R. B. Duckrow Department of Medicine, Division of Neurology, Th Pennsylvania State University, Hershey, PA 17033.

The peptide vasopressin constricts or dilates cerebral arteries in vitro but has little effect on cerebral blood flow when studied in vivo. However, tone-dependent cerebral vascular responses to vasopressin suggest that vasopressin could mediate tone-dependent cerebral blood flow (CBF) responses measured during spreading cortical depression (SD) in awake and anesthetized rats. To test this a bipolar electrode was placed in the left cerebral hemisphere of pentobarbital-anesthetized rats and secured with dental acrylic. Two days later rats were prepared using halothane-nitrous oxide anesthesia, restrained with a plaster hip-cast, and allowed a one hour recovery period. SD was induced with a 3 mA direct current lasting 5 seconds. [14C]iodoantipyrine was used to measure CBF in regions isolated by gross dissection. Pretreatment with the $\rm V_1$ receptor blocker MEAVP, 100 $\mu \rm g/kg$ i.v., prevented hypoperfusion normally measured 2 minutes after the onset of SD in awake rats. MEAVP had no effect on the contralateral hyperperfusion measured in awake rats and had no effect on the pattern of CBF measured during and after SD in rats reanesthetized with pentobarbital. Vasopressin is involved with cerebral vasoconstriction following SD in awake rats but not in anesthetized rats. (Supported by PHS NS24109 and an AHA Established Investigator Award)

SIMULTANEOUS MEASUREMENT OF DOPAMINE AND OXYGEN IN THE RAT CAUDATE NUCLEUS DURING STIMULATED RELEASE OF DOPAMINE. Zimmerman and R. M. Wightman. Dept. of Chemistry, Univ. of N. Carolina, Chapel Hill, NC 27599-3290.

Changes in O₂ concentration in the extracellular fluid

of the caudate nucleus during electrical stimulation of the medial forebrain bundle (MFB) were studied in an effort to understand some of the rapid metabolic changes that occur during neurotransmission in the striatum. Simultaneous measurement of synaptic dopamine (DA) overflow and oxygen was accomplished with a Nafion-coated carbon-fiber disk microelectrode using fast-scan cyclic voltammetry (300 or 400 V/s). The oxidation current for DA was measured at +0.6 V and reduction current for O_2 at -1.2 V (vs. saturated calomel reference electrode). MFB was stimulated with a twisted bipolar electrode at frequencies of 5-60 Hz and duration 2 s. The $\rm O_2$ response showed a marked (40 μ M) increase characterized by 2 maxima: one shortly following stimulus initiation (3.5-5 s) and a broader feature much later (15-20 s). The amplitude of the first is frequency-dependent, while that of the second is not. Theophylline (60 mg/kg i.p.) causes rapid disappearance of the second maximum. The effects of α -methyl-p-tyrosine, yohimbine and atropine were also investigated. The increase in 0_2 concentration during and following stimulation is apparently caused by local dilation of the cerebral microvasculature mediated by changes in the extracellular fluid composition.

Cultured hippocampal neurons regulate pHi via an amiloride-insensitive Na+/H+ exchanger. K.M. Raley-Susman. R.M. Sapolsky and R.R. Kopito*. Dept. Biol. Sci. Stanford Univ. Stanford, CA 94305.

Regulation of intracellular pH (pHi) is critical for neurons. Excessive acidosis contributes to neuronal damage following ischemia, hypoglycemia and seizure activity. We investigated pHi regulatory mechanisms in cultured hippocampal neurons using the fluorescent pHi indicator dye Bis-carboxyethylcarboxyfluorescein. Mixed neuronal/glial cultures were prepared from day 18 fetal rat hippocampi. Fluorescence of dye-loaded single neurons was continuously monitored and pHi was calculated from a standard curve determined by exposing cells to nigericin-high K+ solutions at different pH's.

The maintenance of resting pH_i was dependent on extracellular Na⁺, with or without HCO₃. Resting pH_i maintenance also involved a minor, HCO₃-dependent component, as evidenced by the slightly higher resting pHi in HCO3-containing solutions. Recovery from an acute acid load (pulsing with 20 mM NH4Cl for 1-2 min) was also Na+-dependent, with or without HCO3. The Na+-dependent, HCO3-independent mechanism exhibited many characteristics of the Na+/H+ antiporter described in other cells. The recovery from an acid load in nominally HCO3-free solutions showed a saturable dose-dependence on extracellular Na+; Km=26 mM. The recovery rate increased with decreasing intracellular pH; and lithium substituted for sodium as a substrate for the exchanger. The exchanger was electroneutral, as membrane potential collapse did not affect the recovery from an acid load. However, in contrast to reports in other cells, amiloride and its potent 5-amino-substituted analogues did not inhibit the recovery from an acid load. Thus, intracellular pH is regulated in large part by an amiloride-insensitive Na+/H+ antiporter.

MANIPULATION OF HIPPOCAMPAL SLICE ADENYLATE LEVELS BY ADENOSINE AGONISTS AND ANTAGONISTS. T.S. Whittingham, J.J. Klemens. H. Assaf and W.D. Lust. Div. of Neurosurgery and School of Dentistry, Case Western Reserve University, Cleveland, OH 44106. In a previous study, we found that a three hour exposure of hippocampal slices to 1 mM adenosine resulted in a time-dependent 50% increase in total adenylate levels (ATP+ADP+AMP = AXP), and that most of this increase was maintained in the form of ATP. However, the prolonged exposure to high extracellular levels of adenosine appeared to also produce long-lasting changes in orthodromic evoked resonoses in area also produce long-lasting changes in orthodromic evoked responses in area CA1 after the adenosine was removed.

We have now tested several additional methods of increasing slice AXP content while trying to avoid electrophysiological deficits. Rats were anesthetized, decapitated and 400 μ m transverse hippocampal slices prepared. The slices were allowed to equilibrate in control artificial cerebrospinal fluid (ACSF) for one hour prior to exposure to one of the following ACSF solutions for up to three hours: 1) 1 mM adenosine; 2) 1 mM adenosine + 100 μ M IBMX + 100 μ M theophylline; 3) 1 mM adenosine + 100 μ M dipyridamole; and 4) 1 mM adenine. Appropriate pharmacological control media were tested, and all paradigms also included a one hour washout period.

a one hour washout period.

The results indicate that adenine can also serve as an AXP precursor in brain slices, although it was not as effective as adenosine. The use of adenosine receptor antagonists decreased AXP levels in the absence of exogenous adenosine, and depressed the adenosine-stimulated AXP increase in other slices. Conversely, dipyridamole was used to block adenosine uptake, but was found to increase AXP in both adenosine-treated and untreated slices. These results suggest that brain slice AXP levels could be maximized by preparation in the presence of dipyridamole. A model for the dynamics of brain slice adenylate homeostasis has been constructed, and is currently being tested. constructed, and is currently being tested.

METABOLISM OF HYDROXYEICOSATETRAENOIC ACIDS (HETES) BY MOUSE BRAIN ENDOTHELIUM. M.J. Giordano* and S.A. Moore. Dept. Pathol., Univ. of Iowa, Iowa City, IA 52242.

Various eicosanoids including the HETEs are produced in various types of brain injury. To better understand their effects on brain microvessels, various HETEs and 12(S)-hydroxyeicosapentaenoic acid (12-HEPE) were incubated with cultured mouse cerebromicrovascular endothelium (CME) to ascertain which substances were metabolized by the cells. The eicosanoids listed below were incubated with CME for 1, 2 and 4hr, the media lipids extracted and analyzed by HPLC. As shown below, 5(S)-HETE, 8(RS)-HETE and 9(RS)-HETE are not metabolized by CME. 11(RS)-, 12(R)-, 12(S)-, 15(S)-HETE, and 12(S)-HEPE are metabolized primarily to a single, more polar compound. The data suggests that the enzyme system responsible does not distinguish between enantiomers, however, the enzymatic pathway is sensitive to the position or number of double bonds and is selective based on the position of the hydroxyl group. This selectivity may be one basis for the varied biological effects among the HETEs.

Metabolite (% of total HETE remaining in medium)

A SIMPLE AND SENSITIVE COLOROMETRIC ASSAY CAPABLE OF DETECTING PICOMOLE QUANTITIES OF PYRIDINE DINUCLEOTIDES. C.H. Kang and J.W. Kebabian. Neuroscience Research Division, Abbott Laboratories,

Neuroscience Research Division, Abbott Laboratories, Abbott Park, IL 60064.

We report a modification of a cycling assay (CA) for pyridine dinucleotide that generates a colored reaction product (in a 96 well microtiter plate format). The CA uses an enzymatic redox cycle with alcohol dehydrogenase, ethanol and iodonitrotetrazolium (INT) to detect either DPN or DPNH. The amount of reduced INT formed in the CA assay is quantified with a microtiter plate reader at 492 nm. Using this assay protocol, less than 1 pmole of NAD or NADH can be detected and a linear standard curve generated between detected and a linear standard curve generated between

detected and a linear standard curve generated between 0.5 and 10 pmole. We apply this technique to quantify the amount of 2-deoxyglucose-6-phosphate (2DG6P) in the substantia nigra of the rat brain using alkaline phosphatase to convert 2DG6P to 2DG and bacterial glucose dehydrogenase to quantitatively convert the 2DG and NAD to 2-deoxygluconolactone and NADH. Control animals have low levels of glucose and glucose-6-phosphate (2.2 and 1.7 pmole/µg protein). Rats treated with 2-deoxyglucose (1.4 mmole/kg, i.v.) have 10.7 \pm 1.3 pmole of deoxyglucose and 17.6 \pm 1.26 pmole/µg protein of 2DG6P in the substantia nigra.

LOCALIZED <u>in vivo</u> ³¹P SPECTRA OF THE RAT BRAIN USING SPECTRAL LOCALIZATION BY **IM**AGING (SLIM): A BETTER METHOD FOR STUDIES OF BRAIN DEVELOPMENT. E.S. Fletcher, C.D. Gregory*, H. Lee*, W.T. Greenough, M.J. Dawson*, and P.C. Lauterbur, Biomedical Magnetic Resonance Laboratory, Beckman Institute and Neuroscience Program, Univ. Illinois, Urbana, IL 61801

We are investigating the metabolic correlates of neuronal plasticity. The SLIM method¹² makes possible the non-invasive, selective chemical analysis of an arbitrarily shaped region of the rat head. SLIM is superior in many ways to other NMR methods of spectral localization.

Anesthetized rats were studied using a 4.7 T, 33 cm bore SISCO imaging spectrometer with a ³¹P surface coil (2.7 cm) and a ¹H imaging saddle coil. 3D image and 4D chemical shift imaging (CSI) data were obtained. The image data were used to define two compartments: brain (2.3 cm²) and the rest of the head. The SLIM algorithm was then used to obtain compartmental spectra from the CSI data set, compartment information, and the surface coil position. Muscle spectra show the three ATP peaks and a peak for phosphocreatine (PC). Very little inorganic phosphate (P) is seen. Brain spectra also show ATP, PCr, and a small P, peak, as well as peaks in the phospho-monoester and diester regions.

We are using this new method to study changes in metabolism in the developing brain. Experiments are also underway to assess whether this method detects differences³ among rats raised in environments varying in metriod detects differences affining fats falsed in environments varying incomplexity. SUBREGIONAL TOPOGRAPHY OF CAPILLARIES IN THE MEDIAN EMINENCE AND ARCUATE NUCLEUS OF RATS. S.W. Shaver, J.J. Pang*, K.M. Wall, D.S. Wainman*, and P.M. Gross. Neurosurgical Research Unit, Departments of Surgery & Physiology, Queen's University, Kingston, Canada K7L 3N6
Cytoarchitectural and neurochemical differentiation of distinct median

Physiology, Queen's University, Kingston, Canada K7L 3N6
Cytoarchitectural and neurochemical differentiation of distinct median eminence (ME) zones and adjacent arcuate (ARN) and ventromedial (VMN) nuclei in the hypothalamus prompted our structural and functional studies of their respective capillary networks. From morphometric analysis of 1 μm-thick aldehyde-fixed sections, we determined that capillary densities in the subependymal (SEZ) and internal zones (IZ) of ME were low (range of 147-221 profiles/mm²) in relation to the rich capillarity of the external zone (EZ, 1079/mm²). True (3-7.5 μm lumen diameter) and sinusoidal (>7.5 μm) fenestrated capillaries were found throughout ME by electron microscopy. Pericapillary spaces in SEZ and IZ occupied 1-3% of the tissue area and, in EZ, 14%. ARN and VMN had 171-231 capillaries/mm² with fine structural characteristics of bloodbrain barrier (BBB) endothelium. We noted in ARN a region of transition at the proximal borders with ME where capillary density (323 profiles/mm²) and pericapillary space area (1%) were higher than in distal ARN. Measurements of capillary blood flow and tissue uptake of the tracer amino acid, ["C[α-aminoisobutyric acid, permitted calculation of permeability x surface area products (PS) which indicated uniformly high PS throughout ME (285 μl g²min²), substantial PS in proximal ARN closuring the presence of a BBB. We speculate that confluent pericapillary and interstitial spaces between ME zones and ARN allow rapid dispersion of blood-borne molecules from permeable EZ capillaries into other ME zones and proximal ARN.

HISTAMINERGIC NEURONS IN HUMAN TUBEROMAMMILLARY NUCLEUS:

HISTAMINERGIC NEURONS IN HUMAN TUBEROMAMMILLARY NUCLEUS: NORMAL ANATOMY AND CHANGES IN ALZHEIMER DISEASE. M.S. Airaksinen, A. Paetau*, L. Paljärvi*, K. Reinikainen*, P. Riekkinen and P. Panula. Depts. of Anatomy and Pathology, Univ. Helsinki, and Dept. Neurology, Univ. Kuopio, Finland. We have reported the presence of histamine-immunoreactive (HA-IR) neurons in the posterior hypothalamus and nerve fibers in the cortex of human adults (Panula, Neurosci., 34:129, 1990). In this study, the anatomy of HA-IR cell bodies in normal human brain and in cases of Alzheimer disease (AD) was examined and compared to the distribution of neurofibrillary tangles (NFT) in the same sections.

As in rodents, HA-IR cell bodies in human brain were found only in the hypothalamus, concentrated in the tuberomammillary (TM) nucleus. Its about 50000 cells formed one continuous cell group that embodied a major part of the hypothalamus. Its major ventral part included the classical TM nucleus, the intercalate nucleus and most of the lateral

TM nucleus, the intercalate nucleus and most of the lateral hypothalamic area. The medial part comprised the supramammillary nucleus and part of the posterior hypothalamic

mammillary nucleus and part of the posterior hypothalamic area. Most of the neurons were large and multipolar. Preliminary results indicated a small reduction of the TM neurons in AD. Although located in similar large neuronal profiles and concentrated in the TM area, hypothalamic NFT were seldom found within the HA-IR neurons. As the nucleus of these profiles did not stain with hematoxylin, they may represent those TM neurons that have died and lost their histamine content.

HYPOTHALAMIC REGIONAL DIFFERENCES IN NEURONAL RESPONSES TO TEMPERATURE AND CYCLIC AMP.

J.D. Griffin, M.L. Kaple and J.A. Boulant.

Department of Physiology, College of Medicine,
Ohio State University, Columbus, OH 43210.

Our previous experiments suggest that cyclic

Our previous experiments suggest that cyclic adenosine monophosphate (cyclic AMP) enhances neuronal thermosensitivity, especially in warm sensitive neurons in the preoptic area and anterior hypothalamus (PO/AH). Using horizontal tissue slices from rats, the present study examined the effect of cyclic AMP on neuronal temperature sensitivity throughout the entire diencephalon. Intracellular cyclic AMP was increased by 10 or 100 uM IBMX (3-isobutyl-1-methylxanthine, a phosphodiesterase inhibitor) or by 0.5-5.0 uM forskolin (an activator of adenylate cyclase). Neurons lacking thermosensitivity were not affected by increasing cyclic AMP, while most PO/AH warm sensitive neurons increased their thermosensitivity. In areas that contain inherently cold sensitive neurons (such as, the posterior hypothalamus), increased cyclic AMP often caused prolonged inhibition during tissue warming. This suggests that cyclic AMP may contribute to the thermosensitivity of both warm and cold sensitive neurons. (Supported by NIH grant NS-14644.)

IDENTIFICATION OF HAMSTER PARAVENTRICULAR HYPOTHALAMIC CELLS PROJECTING TO THE SPINAL CORD. J. Blanchard and L.P. Morin. Dept. Psychiatry, HSC, SUNY, Story Brook, NY 11794.

Dept. Psychiatry, HSC, SUNY, Stony Brook, NY $\overline{11794}$. Hamster brains were processed using the ABC method for immunoreactivity to VP or OXY, or animals received 1 μ I 4 % FluoroGold (FG) in saline in T1-T2 of the spinal cord followed 10 days later by 100 μ g colchicine in the lateral ventricle and perfusion 24 hr later. These brains were processed for immunohistofluorescence using Texas Red.

OXY cells are widely distributed throughout the PVN. The densest concentrations are in the lateral half of mid-rostrocaudal extent of the nucleus. In the lateral "wings," cells tend to be greatly elongated in the mediolateral direction. No obvious subdivisions based on cell size or morphology are found. VP cells are located throughout the same general regions as the OXY cells. Again, there are no obvious anatomical subdivisions. However, VP cells consist of 2 intermingled types: large, darkly staining cells (similar to the magnocellular VP cells of the supraoptic nucleus) or smaller, lightly staining cells.

An average 391 FG cells were counted in the PVN. Rostrally, there is extensive overlap of FG labeled cells with OXY and VP cells, but no double labeling. About 9.1% of all FG cells were also immunoreactive for OXY and 6.2% for VP and they are concentrated in a zone of the caudal PVN along the ventrolateral border extending dorsally and laterally 1-1.5 mm into the "wings."

ventrolateral border extending dorsally and laterally 1-1.5 mm into the "wings." The data reveal different cell classes according to immunoreactivity, density of immunoreaction, size, general location and co-localization with label retrogradely transported from the spinal cord. However, distinct PVN subdivisions do not appear as obvious as in the rat. NINDS NS22168

SUPRACHIASMATIC NUCLEUS (SCN) NEURONS RECEIVING RETINAL INPUTS ARE UNDER THE CONTROL OF γ-AMINO-BUTYRIC ACID (GABA). Y.I. Kim and F.E. Dudek. Mental Retardation Res. Ctr., UCLA Sch. of Med., Los Angeles, CA 90024.

The neurotransmitter GABA has been implicated in the light-induced phase shifts of free-running locomotor rhythms of hamsters (Ralph, M.R. and Menaker, M., J. Neurosci., 9:2858, 1989). Light-sensitive neurons in the SCN are considered as a possible site of the GABAergic action.

To provide neurophysiological evidence that the light-sensitive neurons receive GABAergic inputs, intracellular recordings were obtained from SCN neurons in parasagittal brain slices (500-650 μm) of adult male rats (n=11) and guinea pigs (n=5). Twenty-six neurons (16 from rats and 10 from guinea pigs) that responded with excitatory postsynaptic potentials (EPSPs) to optic nerve stimulation were selected for investigation. Since no apparent difference was present between data from the two different species, they were combined. In normal perfusion medium, virtually all neurons studied (15 of 16) showed spontaneous, fast inhibitory postsynaptic potentials (IPSPs). Stimulation of a site dorsocaudal to the SCN usually evoked an IPSP (13 of 16), which was often preceded by a small EPSP. Bicuculline (50 μM), a GABA_A receptor anatgonist, completely blocked both the spontaneous (n=2) and evoked (n=6) IPSPs. The neurons encountered in 50-μM bicuculline (n=10) exhibited neither spontaneous nor evoked IPSPs.

The results indicate that SCN neurons receiving retinal inputs are under GABAergic control and GABA_A receptors mediate the neurotransmission. Supported by U.S. Air Force Grants (87-0361 and 90-0056) to F.E.D.

EFFECTS OF PARAVENTRICULAR STIMULATION ON ULCER FORMATION: ROLE OF GASTRIC CONTRACTILITY AND GASTRIC ACID. A.S. Morrow, C.V. Grijalva and D. Novin. Dept. of Psychology, UCLA, Los Angeles, CA 90024.

Changes in gastric contractility and gastric acid were

Changes in gastric contractility and gastric acid were measured during electrical stimulation of the paraventricular nucleus (PVN) in urethane anesthetized rats. Gastric contractility was monitored continuously by a pressure transducer connected to an open-ended catheter inserted in the rumen; acid secretions were collected through a gastric cannula positioned in the corpus. To localize PVN sites, blood pressure responses to 5 sec of monopolar stimulation (25 µa, 60 Hz, 100 µs, 200 µa, 100 Hz, .5 ms) were recorded through a femoral artery catheter. After 1 h of stimulation, sites were lesioned. Results indicated that stimulation within the PVN and in surrounding hypothalamic sites (most notably the zona incerta) produced damage in the stomach and somewhat less reliably in the duodenum. Changes in gastric contractility and gastric secretions were correlated with erosion scores. In control rats, stimulation anterior to the PVN was not ulcerogenic and no significant changes in contractility or acid secretion were observed. It is suggested that disturbances in motor and secretory functions mediate the gastrointestinal damage produced by PVN stimulation. [Supported by NINH Fellowship Grant T32MH17140 and Univ. Research Grant SF86]

ELECTRICAL AND MORPHOLOGICAL CHARACTERISTICS OF NEURONS IN THE REGION OF THE MALE SEXUALLY DIMORPHIC NUCLEUS (SDN) OF THE RAT MEDIAL PREOPTIC AREA (MPOA). N.W. Hoffman, Y.I. Kim, R.A. Gorski, and F.E. Dudek., Mental Retardation Res. Ctr., UCLA School of Medicine, Los Angeles, CA 90024.

The SDN lies within the MPOA, which has been implicated in several biologically important functions. However, the signalling and morphological properties of SDN and other MPOA neurons have not been well-characterized (though see Curras, M.C., & Boulant, J.A., Soc. Neurosci. Abst., 15: 1090, 1989). We intracellularly recorded (n=19) and labeled these cells with biocytin and determined their positions (n=13) in slices from adult male rats. Neurons displayed a mean resting potential of -61 \pm 2 mV, spike amplitude (from threshold) of 59 \pm 1 mV, spike duration (at half amplitude) of 0.93 \pm 0.1 ms, and post-burst afterhyperpolarizations. In response to positive pulses superimposed on steady hyperpolarizing current, all cells displayed low-threshold potentials that generated Na $^{+}$ spikes. Mean input resistance and membrane time constant was 192 \pm 24 M Ω and 14.9 \pm 1.9 ms, respectively. Current-voltage plots were linear in the hyperpolarizing direction. Dorsal stimulation evoked an EPSP-IPSP complex in 93% of recorded neurons; IPSPs were reversed at -73 \pm 2 mV (n=5) and blocked with bicuculline (n=1). Local axon collaterals may mediate the IPSPs, since labeled collaterals appeared to terminate near the stained cell. Labeled neurons generally had horizontal or vertical orientations, somata diameters (longest axis) of 10-20 μm , and 2-4 sparsely spiny to aspiny primary dendrites. They resided in SDN (n=6) or elsewhere in MPOA (n=7). Preliminary findings suggest similarity between SDN and other MPOA neurons. Future studies will address whether sex steroids, in addition to increasing cell number, developmentally alter electrical and morphological properties of male SDN neurons.

240.8

RESPONSES OF PARAVENTRICULAR NUCLEUS NEURONS TO AN OPIOID PEPTIDE SELECTIVE FOR MU-RECEPTORS IN GUINEA PIG. M. Kasai*, J.P. Wuarin and F.E. Dudek Mental Retardation Res. Ctr., UCLA Sch. of Med. Los Angeles CA 90024

Sch. of Med., Los Angeles, CA 90024.

Recent intracellular studies concerning the effects of a mu-receptor agonist, [D-Ala², NMe-Phe⁴, Gly³-ol] enkephalin (DAGO, 10⁻⁶ M), on neurons in the supraoptic and paraventricular nuclei have suggested a direct action through an increase in potassium conductance in about half of the cells (Wuarin, J.P. and Dudek, F.E. Neuroscience, in press). Experiments combining intracellular recording and staining with neurophysin immunocytochemistry in the paraventricular nucleus have defined three cell types: (1) magnocellular neuroendocrine cells that lack low-threshold calcium spikes (LTS), (2) parvocellular neurons with small LTS responses that do not generate bursts, and (3) neurons near the paraventricular nucleus which have LTS potentials that evoke bursts (Hoffman, N.W., Tasker, J.G. and Dudek, F.E. Soc. Neurosci. Abstr. 14:1178, 1988; jbid, 15:1088, 1989). Bath application of DAGO (10⁻6M) inhibited 40% of the non-LTS cells, 38% of the non-bursting LTS neurons, and 80% of the bursting LTS cells. In preliminary experiments quinine (1 mM), which blocks calcium-activated potassium channels, reduced the inhibitory effect of DAGO (n=3). These results suggest that DAGO inhibits approximately half of the magnocellular and parvocellular neurons in the paraventricular nucleus, and nearly all of the bursting LTS cells in the perinuclear region. These data are consistent with an action of mu-agonists on calcium-activated potassium channels, similar to previous studies in the locus coeruleus (North, R.A. and Williams, J.T. J. Physiol. 364:265, 1985).

CURRENT-CLAMP PROPERTIES OF MAGNOCELLULAR NEUROSECRETORY CELLS (MNCs) ACUTELY DISSOCIATED FROM THE SUPRAOPTIC NUCLEUS OF THE ADULT RAT. Oliet S.H.R.' and Bourque C.W. Centre for Research in Neuroscience. Montreal General Hospital and McGill University, Montreal, Canada. H3G 1A4.

MNCs were acutely dissociated from the supraoptic nuclei of adult rats using the procedure of Kay & Wong (J. Neurosci. Meth. 16, 1986). The cells obtained were plated onto petri dishes and superfused (1-2 ml/min) with artificial CSF. All recordings were obtained from phase bright somata exceeding 17 X 17 µm in size and corresponding to the morphology of neurons immunoreactive for vasopressin and oxytocin. Intracellular impalements lasting up to 34 min were obtained oxytocin. Intracellular impatements lasting up to 34 min were obtained from 22 cells showing a mean resting potential of $\cdot 57.9 \pm 1.4$ mV, input resistance of 290.7 ± 50.8 M Ω and spike amplitude of 74.2 ± 2.2 mV. When evoked at 0.5 Hz, spike duration averaged 2.1 ± 0.5 ms at 29° C, or 3.1 ± 0.4 ms at 23° C. In response to current injection, repetitive firing was associated with progressive spike broadening and was followed by a protracted afterhyperpolarization. When measured from holding potentials (V_{ii}) near rest, voltage-current (V-I) relationships were linear below spike threshold. Each of 18 cells tested from $V_{\rm H}$ <-80 mV displayed a prominent transient outward rectification during depolarizing pulses. The characteristics described above are typical of those of adult rat MNCs recorded in vivo in anesthetized rats, or in vitro in slices or explants of hypothalamus. Dissociated MNCs, therefore, represent a useful preparation for the study of MNCs. Supported by FCAR, FRSQ and MRC.

SERIAL SECTION ANALYSIS OF SYNAPSE FORMATION ASSOCIATED WITH MOTHERHOOD IN THE RAT SUPRAOPTIC NUCLEUS (SON). I. L. Smithson* and G. I. Hatton. Neuroscience & Biological Sciences Programs, Michigan State University, E. Lansing, MI 48824.

The SON dendritic zone has been shown to exhibit an increased occurrence of double synapses (i.e. one axon terminal simultaneously contacting two post-synaptic dendrites, each possessing a post-synaptic density, PSD) in response to stimuli associated with motherhood (Perlmutter, L. S. et al., Neurosci., 13:769, 1984). Recently, it has been shown that axon terminals in the SON somatic region which only appose a cell body will eventually form a conventional synapse possessing a PSD (Modney, B. K. & Hatton, G. I., J. Neuroendo., 1:21, 1989). The present study sought to determine whether a similar situation exists within the SON dendritic zone during conditions associatied with motherhood. Using tissue from a previous study (Taubitz, I. L. et al., Soc. Neurosci. Abst., 13:1594, 1987), a representative animal from each of the following groups was serial sectioned: virgin female, prepartum (day 21 of gestation), 2-24 h postpartum, 14 day lactating and 30 day postweaning rats. In all conditions, 90% of dendrites eventually formed a conventional synapse in serial sections. We estimated PSD length and apposition length between a terminal and a dendrite based on the number of sections which displayed these features. The lengths of the PSD and terminal The SON dendritic zone has been shown to exhibit an increased occurrence of apposition length between a terminal and a definite based on the fumber of sections which displayed these features. The lengths of the PSD and terminal apposition in single synapses were decreased in the prepartum animal, suggesting the occurrence of a synaptic reorganization. In the postpartum animal, the length of terminal apposition in multiple synapses increased compared to the prepartum animal. A given multiple synapse with ≥ 2 PSDs appeared in more sections in postpartum animals compared to other groups. In conclusion, multiple synapses while not uncommon, are uniquely sensitive to the stimulation of parturition. Supported by NS 09140.

INVOLVEMENT OF INWARD SODIUM CURRENTS IN PHASIC FIRING OF RAT HYPOTHALAMIC SUPRAOPTIC (SON) NEURONS. K. INENAGA*, S. YAMAMOTO*, N. AKAMATSU*, H. KANNAN and H. YAMASHITA, Dept. Physiol., Univ. Occupational & Environmental Health, Sch. of Med., Kitakyushu 807, Japan.

A phasic firing pattern consisting of a plateau potential and bursting discharges was observed in the SON of rat hypothalamus. It has been reported that Ca currents and Ca-activated K currents are involved in the generation mechanisms of phasic firing. To investigate whether Na currents are involved in the generation, intracellular recordings were made from phasically firing neurons in the SON of rat slice preparations. Application of low Na solution suppressed phasic firing. In a Ca free medium or a Ca free/EGTA medium containing veratridine, the phasic firing remained and a plateau potential evoked by depolarizing pulses through the recording electrode was also observed. Amplitude and duration of the plateau potential increased with the number of pulses. TTX blocked the veratridine-induced phasic firing and the pulse-evoked the veratridine-induced phasic firing and the pulse-evoked plateau potential in the Ca free medium. Application of extracellular TEA or intracellular Cs ions failed to block the phasic firing but prolonged duration of the plateau potentials. From these results, it is suggested that inward currents by Na ions as well as Ca currents and Ca-activated K currents may play an important role in generation of the phasic firing of rat SON neurosecretory cells. AN IN VITRO NEUROPHYSIOLOGICAL APPROACH TO THE IDENTIFICATION CONNECTIONS AND ELECTROPHYSIOLOGICAL PROPERTIES OF HYPOTHALAMIC ARCUATE NEURONES. S.J.A. MacMillan and C.W.Bourque, Centre for Research in Neuroscience, Montreal General Hospital & McGill University, Montreal, Canada. H3G 1A4

Although the hypothalamic slice has enabled us to classify neurones into sub-populations on the basis of extracellular discharge patterns and permits the combined application of intracellular recording and immunocytochemical identification, input-output relationships are limited by the plane of section. We have therefore evaluated the use of an intact superfused hypothalamic explant preparation, in which extensive pertinent afferent and efferent circuitry is preserved, for physiological studies.

Stable intracellular recordings were obtained from 78 neurones in the ventro-medial aspect of the arcuate nucleus. These cells which were recorded for between 20 mins and 6 hrs exhibited stable membrane potential (Em) of -55 to -73mV, action potential amplitudes of 66 to 95mV and input resistances of 174 to 422MΩ.

action potential amplitudes of 66 to 95mV and input resistances of 174 to 422MΩ. When held at hyperpolarized potentials (beyond -80mV), depolarizing current pulses activated either 'low threshold responses' and bursts of action potentials in 35% of the cells, or transient outward rectification and delayed firing characteristics of 'A'-current activation in another 20% cells. Electrical stimulation of the median eminence served to identify antidromically 14 tuberoinfundibular of the median eminence served to identify antidromically 14 tuberoinfundibular neurones (onset latencies, 3 to 10ms). Stimulation of the NIL evoked antidromic responses from 2 cells, excitatory PSP's from 9 cells, and mixed excitatory and inhibitory PSP's in 2 others. Selective stimulation of the SON activated antidromically 8 putative 8-endorphin neurones (onset latencies, 8 to 16ms). Stimulation of the medial preoptic area evoked mixed compound synaptic responses in 10 arcuate cells tested. This preparation, therefore, is suitable to characterize the physiology and pharmacology of arcuate neurones with identified anatomical connections. (SJAM is a Beit Fellow. MORPHOLOGICAL CHANGES IN THE POSTERIOR PITUITARY IN RESPONSE TO ACUTE DEHYDRATION. G.H. Beagley. B.K. Modney & G.I. Hatton. Psych. Dept. & Neurosci. Program, Michigan State Univ., E. Lansing, MI 48824. In the posterior pituitary, nerve terminals contact the basal lamina (BL) of the neurohypophysial vascular zone where they release the hormones vasopressin and oxytocin. Glial cells (pituicytes) also normones vasopressin and oxytocin. Glial cells (pituicytes) also contact the BL and alter their morphology in response to physiological challenges. Nerve terminal contact with the BL was compared in male rats given intraperitoneal injections of hypertonic (1.5 M) or normal (0.15 M) NaCl solution. Rats were sacrificed five hours after the injections. Morphometric analysis of electron micrographs revealed that the three animals in the 1.5 M NaCl condition showed 66%, 72% and 77% (mean = 73%) nerve terminal contact with the BL. Animals in the program NaCl condition bethe showed 42% nearly contact. These in the normal NaCl condition both showed 42% neural contact. These data suggest that the relationship of pituicytes to the BL can change rapidly in accordance with the hypothesis that pituicyte processes withdraw from the BL to allow increased neural contact to facilitate hormone release under appropriate physiological conditions. CHANGES IN RENAL SYMPATHETIC NERVE ACTIVITY, HEART RATE AND ARTERIAL BLOOD PRESSURE ASSOCIATED WITH DRINKING IN RATS.
H.KANNAN, T.NAKAMURA*, Y.HAYASHIDA* and H.YAMASHITA'.
Dept.Physiol and Dept. Systems Physiol., University of Occupational and Environmental Health, Kitakyushu 807, Japan Renal

sympathetic nerve activity(RSNA), heart rate(HR) and arterial blood pressure(AF) were simultaneously recorded in conscious rats during drinking which was induced or occured spontaneously. In rats not allowed to drink, intraventricularly(ivt) administered angiotensin II(AII)(10ng) elicited an increase in AP and decreases in HR and RSNA. When rats were allowed to drink, an additional increase in AP occured concomitantly with onset of drinking induced by ivt AII, while the decreases in HR and RSNA were significantly attenuated, compared with those in nonsignificantly attenuated, compared with those in non-drinking rats. Similar drinking-dependent responses were observed with drinking induced by ivt carbachol(200ng) and hypertonic sodium solution(5%,2ul). Spontaneous drinking elicited increases in AP, HR and RSMA. Cardiac-related grouped discharges of RSMA, which were observed at rest, increased during drinking. We conclude that RSMA increases in association with drinking behavior and that activation of the sympathetic efferent activity to the kidney is involved in the cardiovascular adjustment associated with drinking behavior. SEX DIFFERENCES IN THE VASOPRESSIN INNERVATION OF THE GERBIL FOREBRAIN UNDER VARIOUS HORMONAL CONDITIONS. B. Crenshaw, G.J. De Vries, and P. Yahr, Dept. Psychology and Prog. of Neurosci. and Behav., Univ. Mass., Amherst, and Dept. Psychobiol. Univ. Cal., Irvine.

The medial preoptic-anterior hypothalamic region of gerbils contains a sexually dimorphic area (SDA) which has a subgroup-the SDA pars compacta (SDApc)that is absent in females. Many vasopressin-immunoreactive (AVP-IR) fibers are present in the medial SDA and SDApc. Previously, we found that the bed nucleus of the stria terminalis (BST) and medial amygdaloid nucleus (MA) project to the SDA. Since the SDA in gerbils and AVP projections of the BST and MA in rats respond to steroids in adulthood, we studied how gonadectomy and testosterone treatment affected AVP-IR fibers in the SDA and lateral septum in both sexes.

In both sexes, AVP-IR fibers were clustered in the region that in males houses

the SDApc. In every treatment group, this cluster was larger in males than in females (ANOVA; P<0.0001). Males had also more AVP-IR fibers in the medial SDA than females (P<0.005). There were no treatment effects for either the SDApc or the medial SDA, but sex and treatment interacted to affect the innervation of the SDApc. Gonadectomy decreased the cluster size in males and increased it in females. Testosterone reversed these effects (P<0.05). This differs from hormonal effects on the AVP innervation of the lateral septum, which comes from the BST. In this area AVP-IR fiber density was much higher in males than in females (P<0.0002), and gonadectomy decreased--and subsequent testosterone

treatment increased-VP fiber staining in both sexes (P<0.0001).

The fact that AVP-IR fibers in the SDA and lateral septum differ, suggests that they come from a different source. The SDA-fibers might come from AVP-IR cells that we have found in this study at the dorsal aspect of the suprachiasmatic nucleus.

ROLE OF THE PARAVENTRICULAR NUCLEUS IN THE PROJECTION FROM NUCLEUS OF THE SOLITARY TRACT TO THE OLFACTORY BULB. R. Guevara-Guzman, D.E. Garcia-Diaz, L.P. Solano-Flores and M.J. Wayner. Depto. de Fisiologia, Fac. de Medicina, U.N.A.M. and Div. of Life Sciences, Univ. of Texas at San Antonio, San Antonio, Texas, USA.

The paraventricular nucleus (PVN) is clearly involved in feeding behavior. Morphological and electrophysiological evidence demonstrate a bidirectional connection between the nucleus of the solitary tract (NTS) and the PVN. In a previous report we established the existence of a functional connection between visceral vagal afferents and cells of the periglomerular layer of the olfactory bulb (OB). The purpose of the present study was to determine the connections between the NTS, PVN, and the The experiments were conducted in anesthetized rats. Evoked potentials were recorded by means of concentric electrodes in the PVN and the OB in response to electrical stimulation of the NTS, before and after electrolytic lesions (2-10 mA DC for 30-60 s) were produced in the PVN. We found that the lesions of the PVN enhance the amplitude of the positive and negative components of the evoked potential in the OB. Activation of the pathway from the PVN to OB apparently exerts a suppressive influence on the effects of the NTS on the OB.

THE EFFERENT CONNECTIONS OF THE VENTRAL PREMAMMILLARY NUCLEUS: A PHASEOLUS VULGARIS LEUCOAGGLUTININ TRACT-TRACING STUDY IN THE RAT. N.S. Canteras* R.B. Simerly and L.W. Swanson, Dept. of Biology, University of Southern California, Los Angeles, CA 90089 & Oregon Regional Primate Research Center, Beaverton, OR 97006.

Regional Primate Research Center, Beaverton, OR 97006.

The ventral premammillary nucleus (PMv) is a compact nucleus in the tuberal region of the hypothalamus immediately caudal to the ventromedial nucleus and has been implicated in the control of gonadotropin secretion. Cells in this nucleus appear to express receptors for sex-steroid hormones and also receive strong inputs from several nuclei in the forebrain linked to the sexual dimorphic circuit, including the amygdalo-hippocampal area, medial nucleus of the amygdala, encapsulated nucleus of the bed nuclei of the stria terminalis, and medial preoptic nucleus. Nevertheless the projections of the PMv remain largely unknown. In order to clarify the organization of the ferror connections of the PMv we applied the Phaseolus vulgaris leucoagglutinin (PHA-L) anterograde tract-tracing method. Iontophoretic injections of PHA-L were made into the region of the PMv in 25 male rats and the brains processed as described elsewhere (Gerfen & Savchenko, '84).

chenko, '84).

From injection sites centered in the PMv labeled fibers ascend through the periventricular zone of the hypothalamus and appear to provide massive inputs to all parts of the periventricular nucleus, the arcuate nucleus, and anteroventral periventricular nucleus of the preoptic region. In addition, a dense plexus of labeled fibers was found in the medial propoitic nucleus, and was largely localized to its medial subdivision. Labeled fibers also pass dorsolaterally from the periventricular zone toward the bed nuclei of the stria terminalis and provide inputs to the encapsulated nucleus, as well as to the ventral part of lateral septal nucleus. Fibers from this pathway continue through the stria terminalisal and end as a dense terminal field in the posterodorsal part of the medial nucleus of the amygdalo-hippocampal area.

These results suggest that the PMv may convey hormone-sensitive information to regions of the forebrain primarily involved in the neuroendocrine regulation of the anterior pituitary.

INVOLVEMENT OF DOPAMINERGIC MECHANISMS IN GASTRIC INVOLVEMENT OF DOPAMINERGIC MECHANISMS IN GASTRIC EROSIONS INDUCED BY LATERAL HYPOTHALAMIC (LH) LESIONS. B. Roland and C.V. Grijalva. Dept. Psychology, UCLA, Los Angeles, CA 90024.

Dopamine (DA) agonists provide protection against gastric erosions induced by cold restraint

against gastric erosions induced by cold restraint or certain types of brain damage, whereas DA antagonists facilitate gastric erosion formation. LH damage alters brain dopamine levels and results in gastric pathology. The present study examined whether DA agonists or antagonists would alter the incidence of LH lesion-induced gastric erosions.

whether Da agonists of antagonists would after the incidence of LH lesions-induced gastric erosions. Six groups of male rats were given bilateral electrolytic LH lesions preceded by a subcutaneous injection of either apomorphine (DA agonist) or domperidone (peripheral DA antagonist) in the following doses: 1, 5, or 10 mg/kg. An additional LH group was injected with an equivolume of vehicle (2 ml/kg). A second injection was given 6-8 hr. postoperatively. Stomachs were analyzed 24 hr. following surgery. Only the highest dose of apomorphine significantly reduced the incidence of gastric erosion (p<.02). No significant facilitation of gastric damage was seen with domperidone. The findings suggest alterations in dopamine levels induced by LH damage may contribute to gastrointestinal pathophysiology. (Supported by UCLA University Research Grant).

ULTRASTRUCTURAL EVIDENCE FOR SYNAPTIC INPUT TO THE RAT SUPRAOPTIC NUCLEUS FROM THE OLFACTORY BULB AND THE SUBFORNICAL ORGAN. M.L. Weiss, A. Tackman', L.E. Koran', F. Marzban' & G.I. Hatton. Neuroscience Prog., Psychology and Anatomy Depts., Michigan State University, E. Lansing, MI 48824-1117.

We have previously described inputs to the supraoptic nucleus from both the main olfactory bulb (MOB; Smithson et al., Neurosci., 31:277, 1989) and the subfornical organ (SFO; Weiss et al., Soc. Neurosci. abstr., 10:609, 1984) using light microscopic techniques. Here the input from SFO or MOB to supraoptic nucleus (SON) was examined ultrastructurally using anterograde transport of either <u>Phaseolus vulgaris</u> leucoagglutinin or a horseradish peroxidase-based tracer. The input from the MOB terminates on small dendrites, most likely from SON neurons. On the other hand, the SFO axons terminate upon dendrites closer to SON somata. Our data corroborate the results of previous tract-tracing and electrophysiological studies and demonstrate monosynaptic inputs to SON from these two telencephalic structures.
