SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 16, PART 1

20TH ANNUAL MEETING ST. LOUIS, MISSOURI OCTOBER 28–NOVEMBER 2, 1990

1990 © Society for Neuroscience

Made in the United States of America.
International Standard Book Numbers:
Part 1 ISBN 0-916110-34-6
Part 2 ISBN 0-916110-35-4
Both parts ISSN 0190-5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume: Soc. Neurosci. Abstr., Vol. 16, Part 1, p. xxx, 1990.

Published by: Society for Neuroscience 11 Dupont Circle, N.W. Suite 500 Washington, DC 20036

Abstracts in Session Order*	
Monday, October 29-Wednesday, October 31	1

^{*7,979} volunteer abstracts, 15 symposia abstracts.

1990 Program Committee

Edward G. Jones, M.D., Ph.D., Chairperson University of California College of Medicine

J. Anthony Movshon, Ph.D. Incoming Chairperson
New York University

Richard W. Aldrich, Ph.D. Stanford University Medical School

Theodore W. Berger, Ph.D. University of Pittsburgh

James E. Blankenship, Ph.D. Marine Biomedical Institute

Dennis W. Choi, M.D., Ph.D. Stanford Medical School

Roland Ciaranello, M.D. Stanford University Medical Center

Suzanne H. Corkin, Ph.D. Massachusetts Institute of Technology

Antonio R. Damasio, M.D., Ph.D. University of Iowa College of Medicine

Robert P. Elde, Ph.D. University of Minnesota

Eberhard E. Fetz, Ph.D. University of Washington School of Medicine

Howard L. Fields, M.D., Ph.D. University of California Medical School

Eric Frank, Ph.D. University of Pittsburgh Medical School Karl Herrup, Ph.D. Eunice Kennedy Shriver Center

Stephen M. Highstein, M.D., Ph.D. Washington University School of Medicine

John P. Horn, Ph.D. University of Pittsburgh Medical School

Robert L. Macdonald, M.D., Ph.D. University of Michigan

Urs S. Rutishauser, Ph.D. Case Western Reserve University

Elaine Sanders-Bush, Ph.D. Vanderbilt University School of Medicine

Gerard P. Smith, M.D. Cornell Medical Center

C. Dominique Toran-Allerand, M.D. Columbia University College of Physicians and Surgeons

Wylie W. Vale, Ph.D. The Salk Institute

Robert D. Wurster, Ph.D. Loyola University of Chicago

Patricia Goldman-Rakic, Ph.D., ex officio Yale University School of Medicine

Robert H. Wurtz, Ph.D., ex officio National Institutes of Health

Larry R. Squire, Ph.D., ex officio University of California, San Diego Medical School

CHRONOLOGICAL LIST OF SESSIONS

(See page xii for Thematic List of Sessions.)

Session Number and Title	Page	Sessio Numb	n er and Title	Page
SUNDAY		33. C	Other biogenic amines and purines	65
		34. (Catecholamines I	68
			Serotonin I	
Animal Care Tutorial—5:30 p.m.			GABA _A receptors I	
1. Psychological Well-Being of Laboratory Pri			Oopamine physiology I	
Regulations and Reality	No abstract		Peptides—receptors: CCK, somatostatin	
Dublic Leature 8:00 mm			Excitatory amino acids: receptors I	
Public Lecture—8:00 p.m.	hambusialasu		Excitatory amino acids: receptors II	
2. Limbic-Cortical Neural Circuits and the Patl	nophysiology		Typothalamic-pituitary-adrenal regulation: CRF.	
of Schizophrenia D.R. Weinberger	No obstract		Neuroendocrine regulation: other I	
D.R. Welliberger	140 austract		Pain modulation: anatomy and physiology I	
			Pain modulation: anatomy and physiology II	
			Chemical senses: central pathways I	101
MONDAY	-		Sensory systems—visual psychophysics	104
MONDAI			nd behavior I	104
			Sensory systems—subcortical visual pathways:	100
Symposia—8:30 a.m.			uperior colliculus and related	
3. Molecular Mechanisms of Neuronal Guidan			Spinal cord and brainstem	
Chaired by: M.E. Hatten	1		Spinal cord and brainstem: motoneurons	
4. Regulation of Pattern Generating Networks			Control of posture and movement I	
Chaired by: K.G. Pearson	1		Auscle: molecular studies	
GW 1 G 1 G 20			Muscle: general	
Slide Sessions—8:30 a.m.			Hippocampus and amygdala: neuroanatomy Limbic system I	
5. Cellular and molecular biology of catechola			Comparative neuroanatomy: fish and amphibia	
receptors			Monoamines and behavior I	
6. Potassium channels I			Orugs of abuse: alcohol I	
7. Sensory systems—visual cortex: motion pat			Learning and memory—pharmacology:	133
8. Peptides—receptors			cetylcholine I	126
9. Acetylcholine—receptors			Mental illness: depression, suicide, other	
10. Cardiovascular regulation I			Neuromuscular diseases	
11. Drugs of abuse: cocaine		00. 1	veuromuseurar diseases	171
12. Alzheimer's disease: amyloid I		J	Presidential Special Lecture—11:45 a.m.	
			Exciting Currents at Hippocampal Synapses: EPS	SPs.
14. Invertebrate learning and behavior I			EPSCs and LTPs	,
15. Epilepsy: basic mechanisms I16. Brain metabolism and blood flow: methods			R.A. Nicoll	o abstract
17. Chemical senses: peripheral mechanisms I				
18. Human behavioral neurobiology		9	Symposium—1:00 p.m.	
16. Human behavioral neurobiology	20	62. I	Hair Cells of the Inner Ear: Structure, Transduction	on, and
Poster Sessions—8:30 a.m.		1	Active Motion	
19. The aging process: neurotransmitters and en	docrine	(Chaired by: D.P. Corey	143
regulation		,		
20. Substances of abuse			Special Lecture—1:00 p.m.	
21. Nutritional and prenatal factors			Excitement, Fos, and Fits: The Role of NMDA R	eceptors
22. Transplantation: general I			and Early Genes in Kindling	•
23. Transplantation: new techniques and cell lin		J	O. McNamaraN	o abstract
24. Synaptogenesis in the CNS I	41	(Special Lecture—2:30 p.m.	
25. Neural plasticity in adult animals I			Strategies for Understanding Gene Defects in Ne	urologic
26. Blood-brain barrier	45		Diseases	arologic
27. Cytoskeleton, transport and membrane targe			S. Davis	o abetract
28. Staining, tracing and imaging techniques I			C. Duvio	o abstract
29. Staining, tracing and imaging techniques II.		9	Slide Sessions—1:00 p.m.	
30. Postsynaptic mechanisms I		65. I	Long-term potentiation I	144
31. Synaptic transmission	59		Stress, hormones and the autonomic nervous	
32. Neurochemistry of transmitter systems	62		system I	146

Sess Nun	ion aber and Title	Page	Session Number	on ber and Title Page
67.	Alzheimer's disease: cognitive and clinical studies	148	116.	Stress, hormones and the autonomic nervous
	Process outgrowth, growth cones and guidance			system II
	mechanisms I	150		Ischemia II
69.	Control of posture and movement II		118.	Ischemia III
70.	Nerve growth factors I	154	119.	Epilepsy: status epilepticus280
	Gene structure and function I		120.	Alzheimer's disease: biochemistry and clinical
	Sensory systems—subcortical visual pathways: LGN			studies
	Pain modulation: anatomy and physiology III	160		0 11 1 1 1 1
74.	Regeneration: general studies and molecular			Special Lecture—4:15 p.m.
	correlates			The Neural Organization of Binocular Vision
	Monoamines and behavior II			R.D. Freeman
76.	Presynaptic mechanisms I	166		Animals in Dasaarch Panal6:30 n m
	D. 4 C 1.00			Animals in Research Panel—6:30 p.m. Animal Activism 102—Fighting Back in the Public
77	Poster Sessions—1:00 p.m.			Schools
//.	Regeneration: genes, inhibitory factors and axonal	160		Schools
70	transport			Presidential Symposium—8:00 p.m.
	Neuronal death: mechanisms			Neurobiology of Drug Action and Drug Abuse: Issues for
	Cell lineage I	1/3		Science and Society
80.	Differentiation, morphogenesis and development:			Cocaine Receptors and Drug Dependence
0.1	glia	1/5		M.J. Kuhar
81.	Differentiation, morphogenesis and development:	177		The Neurobiology of Drug Reinforcement
92	currents, channels, muscle development	1 / /		R.A. Wise
82.	Differentiation, morphogenesis and development:	170		Addicting Drugs: Neurobiology, Pharmacology, and
0.2	cell surface and matrix components	1/8		Policy
83.	Differentiation, morphogenesis and development:	170		A. Goldstein
0.4	cytoskeleton			
	Sodium channels I			
	Sodium channels II			
	Ion channels: modulation and regulation I			TUESDAY
	Peptides: physiological effects I			
	Excitotoxicity I			
89.	Excitotoxicity II			
				Symposia—8:30 a.m.
90.	Excitotoxicity III	197	124.	The Olivocerebellar System: Its Possible Role in Learning
90. 91.	Excitotoxicity III	197 199	124.	The Olivocerebellar System: Its Possible Role in Learning Chaired by: J.A. Harvey283
90. 91. 92.	Excitotoxicity III	197 199 201	124. 125.	The Olivocerebellar System: Its Possible Role in Learning Chaired by: J.A. Harvey283 Direct Ion Channel Gating by Intracellular Ions and

SYMPOSIUM: MOLECULAR MECHANISMS OF NEURONAL GUIDANCE M.E. Hatten. Columbia Univ. Col. Phys. & Surg. (chairperson); L.F. Reichardt, U.C.S.F.; B. Ranscht, La Jolla Cancer Res. Fndn.; T.M. Jessell, Columbia Univ. Col. Phys. Surg.; and C.S. Goodman,

In celebration of the 100th anniversary of Cajal's naming of the "growth cone", this symposium will focus on the molecular mechanisms of neuronal migration and growth cone navigation. Molecular cloning of cell adhesion receptor systems will be used to examine the relationships between cell adhesion molecules, cadherins and integrins, and both in vivo and in vitro approaches will be used to analyze the function and expression of these ligands. Receptor systems that guide neuronal migration will be analyzed with an *in vitro* model system for cerebellar granule neurons, focusing on the neuron-glia ligand astrotactin and its role in orchestrating the movement of the leading process, a growth cone like structure, along the glial fiber. The role of neuronal receptors that regulate axonal growth and growth cone motility will be discussed, focussing on *in vitro*, functional studies with integrins, cadherins and cell adhesion molecules of the immunoglobulin superfamily Cell adhesion molecules in nerve guidance will be examined by analyzing the molecular interactions of growing axons with cell adhesion ligands marked by specific intermediate targets during nerve growth. Cell surface and diffusible molecules that guide developing axons will be examined by analysis of the spatial and temporal regulation of neural members of the immunoglobulin superfamily, and the role of chemotrophic molecules in axon quidance in the developing spinal cord will be discussed. Finally, the molecular genetics of cell adhesion and cell recognition in Drosophila will be examined by a genetic and molecular netic analysis of the structure and function of neural cell adhesion molecules expressed by growth cones in Drosophila

SYMPOSIUM. REGULATION OF PATTERN GENERATING NETWORKS. K.G. Pearson, Univ. of Alberta (Chairperson); E.E. Marder, Bradeis Univ.; P. Wallen, Karolinska Institute; A. Roberts, Bristol Univ.; J.L. Feldman, U.C.L.A.
Many rhythmic pattern generating networks have been shown to be

modified strongly by neuromodulators and by central and peripheral neural signals. This symposium will review recent progress in neural signals. This symposium will review recent progress in establishing the cellular and synaptic events associated with these regulatory processes. E.E.Marder will describe how modifications of synaptic efficacy and intrinsic membrane properties can reconfigure pattern generating networks in lobsters and crabs. This can result in the same neural elements participating in several different neural networks. The modulatory control of the network for locomotion in the lamprey by serotonergic fibres and by sensory feedback from intraspinal stretch receptors will be reviewed by P.Wallen. The use of computer simulations in the analysis of this system will be discussed. Likewise, A.Roberts will present data from modelling studies on the network for swimming in the from the progression of poscillation in this frog tadpole aimed at explaining how the frequency of oscillation in this network is regulated by central neural signals. K.G.Pearson will review data from the locomotor systems of mammals, birds and insects demonstrating that phasic proprioceptive feedback is responsible for establishing the timing of some features of the normal motor pattern. Finally, J.L.Feldman will describe how the neural control mechanisms for respiration in neonatal and adult mammals can be changed either by modulation of the pattern generating network or by transformations of the properties of elements in this network.

CELLULAR AND MOLECULAR BIOLOGY OF CATECHOLAMINE RECEPTORS

DI RECEPTOR ACTIVATION INDUCES C-FOS EXPRESSION IN STRIATO-NIGRAL NEURONS FOLLOWING DENERVATION. G.S. Robertson, S.R. Vincent and H.C. Fibiger. Div. Neurol. Sci., Dept. of Psychiatry, Univ. of British Columbia, Vancouver, B.C., Canada. V6T 2W5

DI, but not D2, receptor agonists activate the proto-oncogene, c-fos, in the striatum (ST) ipsilateral to a 6-hydroxydopamine (6-OHDA) lesion of the nigrostriatal pathway. The ST sends major outputs to the globus pallidus (GP) and the substantia nigra pars reticulata (SNR). The present study examined the nature of striatal neurons containing DI receptor induced c-fos expression using the fluorescent retrograde tracer Fluoro-Gold (FG). FG was injected into the SNR (0.1-0.5µl) or GP (iontophoretic) ipsilateral to a 6-OHDA-lesion of the medial forebrain bundle. Five days later, c-fos expression was induced by injection of the selective DI receptor agonist SKF 38393 (4 mg/kg) which produced circling (12-14 turns/min) that was directed away from the lesioned side. Two hr following SKF 38393 injection, rats were anesthetized and perfused with 4% PFA. Sections 20µM thick were incubated with sheep antic-fos antibody for 48 hr. After incubation for 1 hr with Texas Redlabelled rabbit anti-sheep antibody sections were were observed using a Leitz fluorescence microscope either under ultraviolet light to examine FG, or green light to look at Texas Red fluorescence. C-fos-positive nuclei were frequently located in striatal cell bodies retrogradely labelled from the GP. These results are in agreement with autoradiographic receptor binding studies which suggest that DI receptors are located predominantly on striato-nigral rather than on striato-pallidal neurons.

CHARACTERIZATION AND REGULATION OF DA₁ DOPAMINE RECEPTORS IN OPOSSUM KIDNEY (OK) CELLS. M. D. Bates*, M. G. Caron, and J. R. Raymond*. Depts. of Cell Biology and Medicine, Duke University Medical Center, Durham, NC 27710.

and Medicine, Duke University Medical Center, Durham, NC 27/10.

Peripheral dopamine receptors have been classified on the basis of synaptic location and pharmacology into two categories, DA₁ and DA₂, which are similar to but distinct from central D₁ and D₂ dopamine receptors. Here we report the presence of DA₁ dopamine receptors in opossum kidney (OK) cells, a cell line having characteristics of renal proximal tubules. The specific activity of receptors in OK cell membranes, as defined by [125]ISCH 23982 receptors in OK cell membranes, as defined by [12-1]SCH 23982 binding, is ~100 fmol/mg. Competition with various agonists and antagonists gives a pharmacological profile appropriate for a DA₁ receptor. The receptor is functionally coupled to the stimulation of adenylyl cyclase. Dopamine stimulates OK cell membrane adenylyl cyclase activity ~4-fold, with an EC₅₀ of ~3 µM; this stimulation is blocked specifically by SCH 23390. Treatment of OK cells with dopamine results in desensitization of dopaminergic adenylyl cyclase stimulation in a time- and dose-dependent manner. With greates desensitization, adenylyl cyclase stimulation is decreased to ~20% of control. Treatment of cells with the membrane permeable cAMP analog 8-bromo-cAMP also diminishes adenylyl cyclase stimulation by dopamine, suggesting that heterologous regulation of DA_1 receptors may occur. Thus, OK cells provide a model system for the study of the peripheral actions of dopamine at DA_1 receptors and the regulation of these receptors.

DIFFERENTIAL LOCALIZATION OF EXPRESSION OF THE GENES ENCODING THE D₁ AND D₂ DOPAMINE RECEPTORS IN THE RAT BRAIN. R. T. Fremeau Jr., G. Duncan, G. Breese, J. A. Gingrich*, P. Falardeau, M. G. Caron, & A. Dearry. Depts. of Neurobiol. & Cell Biol., Duke Univ. Med. Ctr., Durham, NC 27710 and BSRC, University of North Carolina, Chapel Hill, NC 27599

D₁ and D₂ dopamine receptors functionally interact to control behavior in both synergistic and opposing manners in different brain regions. To provide a framework for studying the molecular basis of D₁/D₂ receptor interactions, we examined the expression of the genes D₁/D₂ receptor interactions, we examined the expression of the gene encoding the D₁ and D₂ receptors in the rat brain by *in situ* hybridization using ³⁵S-riboprobes. The 0.45kb EcoR1/Cla1 fragment of the rat D₁ cDNA (Dearry et. al., this meeting) and the 1.5kb Sac1/BamH1 fragment of the rat D₂ receptor cDNA (Bunzow et. al., Nature 336: 783, 1988) were subcloned into pBluescript®. High levels of D₁ mRNA were detected in striatum, nucleus accumbens, and olfactory tubercle. No D₁ mRNA was detected in substantia nigra or amygdala. These results confirm that substantia nigra D₁ receptors are on the terminals of the striatonigral pathway neurons. In contrast, hybridization of serial sections with a D2specific probe revealed the expected high level of D2 mRNA in substantia nigra zona compacta, striatum, nucleus accumbens, and olfactory tubercle. Emulsion autoradiograms indicate that D_1 and D_2 receptors are expressed by distinct populations of neurons in the olfactory tubercle. Thus, D_1/D_2 interactions are more complicated than can be accounted for by co-expression of both receptors in the

FUNCTIONAL ACTIVITY AND mRNA LOCALIZATION OF A CLONED D1 DOPAMINE RECEPTOR. EVIDENCE FOR MULTIPLE SUBTYPES. P. Falardeau. M. D. Bates*, J. A. Gingrich*, A. Dearry, R.T.Fremeau Jr., and M.G. Caron, Dept of Cell Biology. Duke Univ. Med. Ctr., Durham, N.C.

We have recently isolated a genomic clone for a human D1 dopamine receptor. In mouse L(tk-) cells stably transfected with the D1 receptor, a 5-fold stimulation of adenylyl cyclase (AC) was elicited by dopamine. The selective D1 agonist SKF38393 also stimulated the enzyme activity, whereas the selective D2 agonist quinpirole was ineffective. The stimulation by dopamine was blocked by the D1 antagonist SCH23390 but not by the D2 antagonist raclopride. Interestingly, dopamine failed to stimulate phosphatidylinositol (PI) metabolism in COS-7 cells transiently transfected with the D1 dopamine receptor. The specificity of coupling of this D1 receptor to AC but not to PI metabolism is in contrast to the recent reports documenting the presence of a D1 dopamine receptor coupled to PI metabolism in striatum and kidney. By northern blot and PCR analysis of mRNA, this receptor appears to be expressed in high abundance in caudate and at lower levels in frontal cortex and hippocampus. Much lower levels in cerebellum and ventral tegmental area were found. No message was detected in kidney, heart and liver. These results agree with the expected distribution for D1 receptor message in the CNS, but suggest that the D1 dopaminergic stimulation of AC and PI metabolism in kidney must be mediated by one or more distinct D1 receptor subtypes

These results coupled with the presence of multiple hybridizing bands on genomic Southern blot analysis at low stringency indicate the possible existence of additional D1 dopamine receptor subtypes

MOLECULAR CLONING AND EXPRESSION OF THE GENE FOR A HUMAN DI DOPAMINE RECEPTOR. A. Dearry, J. Gingrich, P. Falardeau, R. Fremeau, M. Bates, W. Leung, T. Yang-Feng, and M. Caron. Duke Univ. Medical Center, Durham, N.C., & Yale Univ. School of Medicine, New Haven, Ct.

The diverse physiological actions of dopamine are mediated by its interaction with two basic types of G protein-coupled receptor: D1 and D2, which respectively stimulate and inhibit the enzyme adenylyl cyclase. We have isolated and characterized the gene encoding a human D1 dopamine receptor (D1 R). This gene is intronless within its coding region in contrast to that encoding the D2 dopamine receptor (D2 R). The D1 R gene encodes a protein of 446 amino acids having a predicted molecular weight of 49,300 daltons and a transmembrane topology similar to that of other G protein-coupled receptors. Within the putative transmembrane domains, the human D1 R has a sequence identity of approximately 40% with the D2 R, α 2-, β 1-, and β 2-adrenergic receptors, and 5HT1A receptor. The most homologous regions shared by the D1 R and D2 R are found in transmembranes II and III. The D1 R possesses two sites for N-linked glycosylation and several potential sites for regulatory phosphorylation. Expression of the cloned gene into host cells established specific ligand binding characteristic of a D1 R. PCR analysis of tissue RNA revealed that D1 R message is most abundant in caudate. The gene for the D1 R localizes to the long arm of human chromosome 5. Cloning of the gene for a D1 R will facilitate investigation of the molecular processes involved in activation and regulation of this receptor.

5.7

A LARGE RECEPTOR RESERVE (RR) EXISTS FOR DOPAMINERGIC REGULATION OF PROLACTIN (PRL) SECRETION IN VIVO AND IN AN-TERIOR PITUITARY (AP) CELLS IN PRIMARY CULTURE. E. Meller, T. Puza*, J.C. Miller, A.J. Friedhoff and J.S. Schweitzer*.

Dept. of Psychiatry, NYU Medical Center, New York, NY 10016

Dopamine (DA) D2 receptors on lactotrophs of the AP mediate inhibition of PRL secretion. These receptors are func-

tionally similar to D2 autoreceptors since serum PRL levels are reduced by autoreceptor-selective agonists such as 3-PPP. We previously showed that autoreceptor-selectivity can be explained by the presence of a large RR at D2 auto- but not postsynaptic receptors. We therefore determined if AP D2 receptors also have a large RR for agonists.

Male rats were pretreated with vehicle or N-ethoxycarbo-

nyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) and dose-response (DR) curves for N-propylnorapomorphine (NPA)-induced reduction of serum PRL levels in GBL-treated animals were obtion of serum PRL levels in GBL-treated animals were obtained. In control rats the ED50 for NPA was 0.12 ug/kg. The DR curve for NPA was shifted more than 5-fold to the right after EEDQ (lx6 mg/kg) (ED50=0.64 ug/kg), but the maximal response was not reduced. EEDQ (2x6 mg/kg) further shifted the DR curve to the right (ED50=1.04 ug/kg) but the maximal response was still not reduced, indicating the presence of a large RR. A large RR for NPA was also demonstrated. strated in AP cells in primary culture. Interestingly, however, there was no RR for NPA inhibition of forskolin-stimulated extracellular cAMP accumulation, suggesting that D2 receptor coupling to other transduction pathways (e.g. ion channels) may be more related to the observed RR.

5.9

LOCALIZATION OF α_2 ADRENERGIC RECEPTOR SUBTYPES IN BRAIN. 1D.B. Bylund, M.E. Alburges, M. Hunt, L.L. Longlet and J.K. Wamsley. Neuropsychiatric Res. Institute, 120 Eighth Street South, Fargo, ND 58103; 1Department of Pharmacology, Univ. of Nebraska Medical Center, 42nd and Dewey Avenue, Omaha, NE 68198.

Molecular biological studies have confirmed the existence of multiple α_2 adrenergic receptor subtypes originally identified on the basis of their pharmacology. Tritiated rauwolscine ([3H]RAU) has been shown to have a similar affinity for α_{2A} and α_{2B} subtypes whereas, oxymetazoline (OXY) preferentially binds to the α_{2A} subtype, and ARC-239 (ARC) preferentially labels α_{2B} . By inhibiting [3H]RAU binding to rat brain, the IC₅₀ value concentrations of these agents were determined and used to inhibit [3H]RAU binding from slices in autoradiographic to inhibit [3H]RAU binding from slices in autoradiographic experiments. Many brain areas indicated a similar reduction in $[^3H]RAU$ binding with each of the two agents, however, there were a few regions which showed a predominance of one site over the other. Lamina IV of the cerebral cortex was inhibited with OXY but not ARC. These receptors are therefore $\alpha_{\rm 2A}$. The substantia nigra pars reticulata, on the other hand, was inhibited by ARC but not OXY, and consequently does not show the presence of α_{2A} receptors. These studies indicate the existence of α_{2A} receptor subtypes in individual regions of the brain and pinpoint areas for future research. (This research was supported by grant GM 40784.)

Comparison of Expression and Genomic Organization of the D2 Receptor Locus in Inbred and Outbred Strains of Rats R.R. Luedtke, R.P. Artymyshyn*, B.R. Monks* and P. B. Molinoff. Department of Pharmacology, University. of Pennsylvania, Philadelphia, PA 19104

Radioligand binding and Southern blot hybridization techniques were used to look for phenotypic and genotypic differences at the rat D2 receptor locus. Three outbred strains (Sprague Dawley, Wistar and Long Evans) and five inbred strains (Brown Norway, Buffalo, DA, Fisher and Lewis) were used. Radioligand binding studies were performed using $^{125}\text{I-IBZM}$, a D2-selective antagonist. Comparison of the affinities ($K_d = 0.3 \text{ nM}$) and densities (450-580 fmol/mg protein) of binding sites for $^{125}\text{I-IBZM}$ in the striatum of each rat strain did not reveal statistically significant differences. A comparison was made of Southern hybridization blots using genomic DNA from each strain. Blots were hybridized with a DNA probe that codes for the $\mathrm{D2}_L$ receptor isoform. Restriction fragment lengths were conserved between strains for DNA digested with Bam HI, Eco RI, Hind III, Pst I and Taq I. A restriction fragment length polymorphism (RFLP) was identified when DNA was digested with Xba I. The genetic polymorphism was mapped to within 2 kb of the exon coding for the third intracellular loop of the D2 receptor. This RFLP differentiated Sprague Dawley and Brown Norway rats from Wistar, Long Evans, Buffalo, DA, Lewis and Fisher rats. The RFLP for the rat D2 receptor locus provides a genetic marker that can be used to test whether strain differences in behavior and/or in the response to pharmacologic intervention are determined by genetic elements linked to the D2 receptor locus. (U.S.P.H.S grant NS18591)

5.8

BETA ADRENOCEPTOR-INDUCED EXPRESSION OF EARLY RESPONSE GENES IN THE RAT CEREBRAL CORTEX. G. Bing, E.A. Stone, J.C. Miller, A.J. Friedhoff, D. Filer*. Millhauser Laboratories, Dept. Psychiatry, New York Univ. Sch. Med., New York, NY 10016.

Previous studies have shown that activation of beta adrenoceptors in brain cells both in vitro and in vivo produces expression of various early response genes. In the present study we have replicated this finding for the c-fos gene in vivo and have shown that it also occurs in vivo for the TIS-1 gene. Rats were subjected either to stress (handling plus i.p. saline injection or brief restraint) or to yohimbine injection (5 mg/kg) to increase brain norepinephrine release and were killed lTreatments were given with or without prior i.p. administration of propranolol (10 mg/kg). c-Fos mRNA in the cerebral cortex was assayed by Northern blot. The results indicated that both stress and yohimbine administration were effective in eliciting increased cfos mRNA. Yohimbine was also found to increase TIS-1 mRNA. All responses were attenuated by propranolol. results indicate therefore that pharmacological and physiological activation of beta adrenergic receptors in the brain in vivo causes expression of various early response genes. Studies on the involvement of beta receptor subtypes in these responses and their cellular localization are currently in progress. Supported in part by grants AFOSR 89-0208, MH45265 and MH08618.

5.10

A NEW ALPHA-1 ADRENERGIC RECEPTOR: CLONING AND CHARACTERI-ZATION. J.W. Lomasney*, D. Schwinn*, S. Cotecchia*, M. Brownstein*, D. Anthony, M.G. Caron and R.J. Lefkowitz*. HHMI, Duke Univ. Med. Ctr., Durham NC 27710 and *NIMH Bethesda, MD 20892.

The adrenergic receptors are members of the G-protein coupled receptor superfamily, and as such have a putative topology which includes 7 highly conserved stretches of 20-25 hydrophobic aa each thought to span the membrane. Recent pharmacological and functional studies have suggested heterogeneity of alar. Using a fragment of the hamster alb cDNA as a probe, we have isolated two different clones from a rat cerebral cortex cDNA and a rat genomic library. The first clone is the rat homologue of the hamster $\alpha_{\mbox{\footnotesize 1B}}$ receptor. The deduced as sequence of the second clone $\alpha_{\mbox{\footnotesize 1L}}$ while demonstrating features characteristic of G-protein coupled receptors, is most similar to the α_1AR , having 88% amino acid identity in the seven putative transmembrane domains. COS-7 cells transfected with $\alpha_{\rm IL}$ DNA bound the selective $\alpha_{\rm I}$ AR antagonist 125 I-HEAT specifically. In addition, norepinephrine was able to stimulate incorporation of $^{32}\mathrm{P}$ into phosphatidylinositol in these cells. Northern blot analysis of rat tissues shows the α_{1B} mRNA distribution to be liver>heart>cerebral cortex>kidney>hippocampus while that of the α_{1L} as vas deferens>hippocampus>cerebral cortex>heart>kidney. The tissue localization of the α_{1L} mRNA suggests that this receptor may be equivalent to the pharmacologically defined α_{1A} subtype.

E 11

COUPLING OF ALPHA, ADRENERGIC RECEPTOR $(\alpha, -AR)$ SUBTYPES TO DIFFERENT G-PROTEINS. E Duzic*, S Downing*, I Coupry* and SM Lanier*. (Spon. K. Sweadner) Card Unit, Hass Gen Hosp, Harvard Med School, Boston, MA 02114.

α,-AR subtypes are expressed in a tissue specific manner and differ in their ligand recognition properties and perhaps their mechanism of signal transduction. The transduction pathway utilized by the receptor subtypes likely depends on the particular G-protein or effector molecule in any given cell. To address this issue we have stably transfected NIH373 cells with genes encoding α,-AR subtypes(RG10, RG20) and determined 1) the ability of the receptor to exist in a high agonist affinity state and 2) receptor coupling to adenylyl cyclase. RG10 and RG20 differ by 20 fold in their affinity for the α,-AR antagonist H-rauvolscine(RG10 K,=0.6nM) and also in the potency order of competing ligands (RG10 rau) phent> pra> oxy; RG20 phent > rau> oxy> pra>. In cells expressing RG20 (200-3000 fmol/mg) but not in cells expressing RG10 (80-1000 fmol/mg) receptor activation inhibited basal and forskolin-stimulated adenylyl cyclase activity by 40%. For RG10, agonist competition curves were monophasic, of low affinity(K_i=1.2 uM) and Gpp(NH)p insensitive. In contrast, agonist competition curves with RG20 were biphasic, could be resolved into high (K_i=10 nM) and low (K_i=1uM) agonist affinity states and vere Gpp(NH)p sensitive. These data suggest that NIH373 cells express G-proteins capable of interacting with RG20 but not RG10. The major PT sensitive G-protein in NIH-373 cells is apparently G_{i α} suggesting that RG20 but not RG10 can "recognize" this G_i soform.

POTASSIUM CHANNELS I

6.1

CHARACTERIZATION OF TWO VOLTAGE-SENSITIVE POTASSIUM CHANNEL SUBTYPES IN MAMMALIAN SKELETAL MUSCLE. J.S. Trimmer. L. K. Kaczmarek, and W. S. Agnew. Depts. of Cellular and Molecular Physiology and Pharmacology, Yale School of Medicine, New Haven, CT 06510

We have undertaken molecular cloning studies that have established the existence of multiple potassium channel transcripts in rat skeletal muscle library corresponding to the rat brain DRK1 (Frech et al, Nature 340:642) and Kv1 (Swanson et al, Neuron, in press) potassium channels. We have used these cDNAs to study the regulation of expression of the corresponding transcripts in skeletal muscle, and to produce fusion proteins for the production of subtype-specific antisera. We find that the expression of DRK1 in skeletal muscle is constitutive throughout postnatal development, yet increases dramatically upon denervation of adult muscle. In contrast, Kv1 transcripts change both during development and after denervation. Antibodies raised to fusion proteins containing DRK1 and Kv1 fragments react with both brain and skeletal muscle membrane preparations. The DRK1 antibodies react with a Mr=130 kD band on Western blots of brain and muscle membranes, indicating that the 99 kD core peptide predicted from the deduced amino acid sequence has been modified post-translationally. The Kv1 antibodies react with a band of Mr= 84 kD (compare to 66 kDpredicted core peptide). These results indicate that the differential regulation of these two potassium channels in skeletal muscle may underlie the changes in excitability in this tissue during development and after denervation.

MOLECULAR ANALYSIS OF POTASSIUM CHANNELS IN IDENTIFIED CELLS OF API.VSIA. Paul Pfaffinger*, Y. Furukawa*, T. Kubo*, B. Zhao*, & E.R. Kandel, Ctr. Neurobiol. & Behav, Columbia Univ., & HMI, NY, NY 10032.

The molecular diversity of K' channels is important for aspects of

. The molecular diversity of K' channels is important for aspects of neuronal modulation and learning-related plasticity. We are attempting to determine how specific cloned K' channels contribute to the functioning and modulation of identified neurons in Aplysia. As a first step we have cloned the Aplysia homologues of 3 Drosophila K' channels · Shaker · Shaker and have identified other clones that may encode new K' channels. We next compared the A type K' currents in identified Aplysia neurons to the Aplysia Shaker currents expressed in Xenopus occytes. In Aplysia two different 4AP-sensitive A currents are expressed respectively in LUQ cells (L2 to L6) and in RUQ cells (R3 to R8). The LUQ cell A current (I_{Augo}). Also, the inactivation rate of I_{Augo} is voltage-dependent whereas that of I_{Augo} is not. Finally, forskolin depresses I_{Augo} with no change in kinetics, but it both depresses I_{Augo} and changes inactivation to a double exponential. In Xenopus oocytes the Aplysia Shaker clone AK01a directs the synthesis of a AAP-sensitive A type K' channel similar to I_{Augo} . It has a voltage-independent rate of inactivation. In response to forskolin the peak current decreases and inactivation becomes double exponential. However, some properties of AK01a in Xenopus oocytes differ: gating is shifted to more positive voltages and the inactivation rate is faster. To determine whether these differences reflect the properties of expression in oocytes, or are functionally important in nerve cells, we are now trying to express AK01a in Aplysia neurons by RNA microinjection. Combined with parallel studies on other K' channel clones, these experiments should provide insight into the roles various cloned K' channels normally play in the nervous system.

6.2

DESCRIPTION OF A NEW CLASS OF POTASSIUM CHANNEL GENES. Vega-Saenz de Miera, E., Sen, K., Serodio, P., McCormack, T. and Rudy, B. Depts. of Physiology & Biophysics. and Biochemistry. NYU Med. Ctr. NY, NY 10016.

Several K+ channel genes cloned from mammals show large homology to the Shaker gene in *Drosophila*. These genes form three groups based on sequence homology and thus evolutionary relatedness. The members of the first group (Class I genes) are more closely related to the Drosophila Shaker gene, Class II to the Drosophila Shab gene and Class III to Shaw. Several members of Class I genes have been cloned in Aplysia, mouse, rat and human. We now report that Class III genes are also a large gene family. One member (RKShIIIA) was cloned from a rat brain library by this laboratory (PNAS, in press), and another from NG108 cells (NGk2) by Yokoyama et al. (FEBS. Lett 1989). Southern analysis of rat genomic DNA using probes derived from RKShIIIA indicates the presence of multiple genes of this class. Based on the sequence of RKShIIIA, primers were synthesized for polymerase chain reaction (PCR) to obtain partial sequences of other members of this class. Three genes different from RKShIIIA and NGK2 were found. The PCR fragments as well as sequences from the RKShIIIA gene were used as probes to obtain further sequences of Class III genes from rat and human. (Supported by NHI grant GM26976 to B. Rudy).

HYBRID K⁺ CHANNELS ARE NOT FORMED BETWEEN FOUR SUBFAMILIES OF K⁺ CHANNEL GENES. Manuel Covarrubias*, Aguan Wei, David McKinnon and Lawrence Salkoff. Dept. of Anatomy and Neurobiol., Washington Univ. Sch. of Med., St. Louis, MO 63110. K⁺ channel diversity results from a highly conserved extended gene family. In *Drosophila* four separate genes (Shaker, Shal, Shab and Shaw), code for homologous proteins which form distinct K⁺ channels when

K⁺ channel diversity results from a highly conserved extended gene family. In *Drosophila* four separate genes (*Shaker, Shal, Shaha* and *Shaw*, code for homologous proteins which form distinct K⁺ channels when expressed in *Xenopus* oocytes. Each of the four *Drosophila* genes is representative of a separate gene subfamily which is conserved in mammals (Wei, et al., *Science*, in press). Hybrid assembly of different gene products is a possible mechanism for generating K⁺ channel functional diversity. This has been demonstrated for genes within the *Shaker* subfamily (Christie, *et al., Neuron, 4:405, 1990*). We investigated whether hybrids were formed between the products of different subfamilies. cRNAs from *Shaker, Shal, Shab* and *Shaw* were coinjected in pairwise combinations in *Xenopus* oocytes, then assayed by two-electrode voltage-clamp. Currents from coinjected oocytes were analyzed for novel properties. The expressed currents could be separated by kinetics of inactivation, steady-state inactivation and pharmacology into components that closely resemble the properties of currents expressed by singly injected oocytes. In all cases, no novel properties were observed and currents could be modeled as a linear sum of currents from singly injected oocytes. This was in contrast to a novel component of inactivation observed by coexpression of two members of the *Shaker* subfamily, *ShakerH37* and BK2 (a rat homolog). Thus, hybrid assembly between gene products of K⁺ channel subfamilies appears not to be a mechanism of diversity. Supported by NIH 1 RO1 NS24785-01, and research grants from the MDA and Monsanto-Searle.

DECREASED CONDUCTANCE OF THE A CHANNEL BY MUTATION OF A CONSERVED CORE REGION IN SHAKER. Andrea J. Yool and Thomas L. Schwarz. Department of Molecular Cellular Physiology, Stanford Univ. Med. Center, Stanford CA 94305-5426.

The high homology of a sequence designated H5 (amino acids 428 to 455 in ShakerB)* in all reported sequences of K channels, but not Ca or Na channels, suggests an important role in K channel-specific function. The H5 region is of intermediate hydrophobicity, with many thr, ser and gly residues. Homomeric channels with single amino acid substitutions in H5 were expressed in Xenopus occytes and screened for function by 2-electrode voltage clamp. More than 50% of the mutants gave no detectable currents. Mutations that generated A currents were primarily conservative, including asp to glu, phe to tyr, thr to ser, and gly to conservative, including asp to glu, pile to tyr, thr to ser, and gly to ala. Three of these mutants when analyzed by patch clamp showed 20-50% decreases in single channel amplitude and slope conductance. No shifts in reversal potential or voltage-dependent activation have been detected as yet. Channel kinetics were affected in one case, with an increase in mean open time and slowed inactivation. The low conductance mutations may reflect alteration of the pore structure, or stabilization of a subconductance state. Ongoing studies will test our hypothesis that the H5 region of Shaker is involved in K+ ion permeation. (Supported by NIH R01 GM42376 to TLS, and NIH R01-15963 to L. Jan.)

FAST AND SLOW INACTIVATION OF SHAKER POTASSIUM CHANNELS V. N. Zagotta*.T. Hoshi and R. W. Aldrich, Dept. of Molecular and Cellular

Physiology, Stanford University, Stanford, CA 94305.

Deletions or point mutations near the amino terminal drastically slow inactivation of *ShB* potassium channels expressed in *Xenopus* occytes. All of these mutant channels, including large deletion mutations, exhibit a slow inactivation of *ShB* potassium channels expressed in *Xenopus* cocytes. All of these mutant channels, including large deletion mutations, exhibit a slow rate of inactivation, with macroscopic time constants on the order of one to two seconds. This residual slow inactivation occurs at a characteristic rate in the amino terminal mutations and in wild type channels treated with internal trypsin. The similarity of inactivation rates among amino-terminal deletion mutations suggests a slow inactivation process separate from the fast inactivation occurring when the amino terminal is intact. Both macroscopic and single-channel experiments suggest that wild-type *ShB* channels exhibit both fast and slow inactivation processes. We have found that the rate of the slow inactivation is independent of voltage and coupled to activation, similar to fast inactivation. The slow inactivation process can be influenced by altering the carboxyl terminus. Alternative splicing of the *Shaker* gene provides one source for variation. The *ShA* variant is identical to *ShB* except in the carboxyl terminal region where the sequences diverge near the last proposed transmembrane segment. *ShA* channels with mutations in their amino terminus that disrupt fast inactivation exhibit a significantly faster slow inactivation process than *ShB* channels with the same mutations. Large deletion mutations in the putative intracellular carboxyl terminus of *ShB* produced little or no alteration in the rate of slow inactivation. These results suggest two different inactivation processes; one controlled by the amino terminal cytoplasmic domain and one controlled by the carboxyl terminal domain. According to this scheme, wild type *ShB* channels inactivate primarily by means of the amino terminal domain whereas wild type *ShA* channels inactivate by means of the amino terminal domain whereas wild type *ShB* channels inactivate by means of the amino terminal domain whereas wild type *ShB* channels inactivate

6.9

STRUCTURE-FUNCTION ANALYSIS OF DRK1: DELETIONS AT N- AND C-TERMINI AND POINT MUTATIONS IN TRANSMEMBRANE SEGMENTS. A.M.J. VanDongen, G.C. Frech', J.A. Drewe, R.H. Joho and A.M. Brown. Department of Molecular Physiology and Biophysics, Baylor College of Medicine, One Baylor Plaza, Houston, Texas 77030.

Voltage-dependent ion channels are thought to consist of a repeated structural motif of six transmembrane segments (S1-S6), flanked by cytoplasmic domains. S4 appears to form the voltage sensor, while the functions of the other transmembrane segments or the cytoplasmic domains are not known. We have investigated the functional importance of the N- and C-terminus, for a delayed rectifier K' channel from rat brain, drk1 (Frech et al., Nature 340:642). Deletions in these cytoplasmic domains altered activation, deactivation and inactivation. Deletion mutants ΔNI6 (missing 16 amino acids from the N-terminus) and ΔC318 (missing 318 aa's from the C-terminus) had only minor effects on kinetics: activation kinetics and steady state activation curves were shifted 5 mV in the hyperpolarizing direction. For two N-terminal deletion mutants (ΔNI01 and ΔNI39) activation threshold was shifted 30 mV in depolarizing direction, kinetics were slowed dramatically and inactivation was removed. A double mutant (ΔNI01 and ΔNI39) activation threshold was shifted 30 mV in depolarizing direction, kinetics were slowed dramatically and inactivation was removed. A found the minum tander than the six transmembrane segments, is sufficient for the formation of channels with the kinetics of a delayed rectifier. One of the functional roles of the N- and C-terminus could be to modulate activation and inactivation.

Point mutations were made in transmembrane segments S4 and S5. The S4 segment of drk1 contains a threonine at position 311. Shaker and rck channels have a lysine at the corresponding position. A T311K mutation shifted the steady state activation curve 25 mV in the hyperpolarizing direction without changing the slope or kinetics. The S5 s

A SYNTHETIC PEPTIDE WITH SHAKER B SEQUENCE RESTORES INACTIVATION IN MUTANT CHANNELS THAT DO NOT INACTIVATE I.

A SYNTHETIC PEPTIDE WITH SHAKER B SEQUENCE RESTORES INACTIVATION IN MUTANT CHANNELS THAT DO NOT INACTIVATE I. Hoshi. W. N. Zagotta' and R. W. Aldrich. Dept. of Molecular and Cellular Physiology, Stanford University, Stanford, CA 94305.

We have found that deletions or point mutations near the amino terminal drastically slow inactivation of ShB potassium channels expressed in Xenopus oocytes. The lack of voltage dependence of inactivation rates, the ability of internal proteolytic agents to modify inactivation, and the effects of mutations in cytoplasmic domains that after inactivation suggest a mechanism of inactivation similar to the ball and chain model originally proposed by Armstrong and Bezanilla for voltage-gated Na channels. To test this model further, we have examined the ability of the putative "ball" region to cause inactivation when it is not covalently attached to the rest of the channel protein. We applied a synthetic peptide with the amino acid sequence of the first 20 amino acids of ShB to the cytoplasmic surface of noninactivating mutant channels in inside-out patches. The peptide restored inactivation in a concentration-dependent manner with concentrations of 50 to 100 μM mimicking wild type inactivation at macroscopic and single-channel levels. Like wild type inactivation, peptide-induced inactivation has very little if any voltage dependence. Recovery from peptide-induced inactivation is slower than wild type inactivation and requires more negative voltages. Trypsintreated peptide was ineffective as was externally applied peptide. Arginine or lysine (50 μM) did not block the channels. Additional peptides with sequences derived from the first twenty amino acids of noninactivating mutants, including one with only a single amino acid change, did not restore inactivation at comparable concentrations. These results further support the idea that inactivation occurs by a cytoplasmic domain of the protein occluding the pore. They suggest that the structural features of the amino terminal region impo linked to the rest of the channel protein. Supported by NS 23294 and the American Heart Association.

Mutations in the Leucine-Heptad Repeat of Shaker Potassium Channels Alter Voltage-Dependent Gating. K. McCormack*1, J.W. Lin², T. McCormack*1, M.K. Mathew*1, M.Tanouye¹ & B.Rudy². ¹Division of Biology, CalTech, Pasadena, CA 91125?, ²Department of Physiology, New York University, New York, NY 10014 NY 10016.

91125?, ²Department of Physiology, New York University, New York, NY 10016.

The Shaker (Sh) gene encodes several protein products which form voltage-dependent. K+ channels through multimeric association. In order to investigate the mechanism(s) of gating in Sh, we substituted amino acid residues within the leucine-heptad repeat region (which is adjacent to the S4 domain). We expressed these constructs in Xenopus oocytes from which we recorded with two electrode voltage clamp. Substitution of valines for the first two leucines in the heptad (V1 and V2) shifts the voltage-dependence up to 100 mV in the depolarizing direction while substitution of a nearby hydrophobic residue in S4 has essentially no effect. The V1 and V2 mutations also change the slopes of the conductance-voltage and steady-state inactivation curves. Similar substitution for the other three leucines (V3, V4 and V5) shifts the voltage-dependence in the opposite direction by as much as 25 mV with little or no change in slope. Our data is consistent with the ideas that the heptad-repeat region is important in determining the position of the "voltage-sensing" charges or that it transduces the conformational changes produced by charge movement into opening and closing of the pore, or both. Because all of the leucines do not appear to play equivalent roles as might be expected for a leucine zipper, or a "bent-zipper" where the leucines interact through intra-subunit contacts, it is difficult to understand this region in terms of structural models. We are further investigating the extent and properties of this region through random mutagenesis and single channel analysis.

REGULATED GENE EXPRESSION OF A DELAYED RECTIFIER K⁺
CHANNEL IN RAT ASTROCYTOMA C6 CELLS. S-Y Wang, Y. Liu.* N. Castle* and G.K. Wang. Dept. of Biology, SUNY at Albany, Albany, NY 12203 and Dept. of Anesthesia, Harvard Med. Sch., Boston, MA 02115

Med. Sch., Boston, MA 02115

Freshly dissociated astrocytes are known to express both voltage-dependent Na⁺ and delayed rectifier K⁺ channels. To check whether rat astocytoma C6 cells also contain similar type of channels we measured the ionic currents in these cells under patch clamp conditions. Only the delayed rectifier K⁺ current could be readily detected in most of cells whereas the Na⁺ current was absent. The K⁺ current was blocked by TEA with IC50 = 0.5 mM and was abolished by 100 nM Toxin I dendrotoxin. 70.5 mM and was abolished by 100 nM Toxin I dendrotoxin. Through cDNA cloning and sequencing we found that a delayed rectifier \mathbf{K}^{T} channel gene with the coding sequence identical to that of RCK1 gene was expressed. The level of K^+ channel gene transcript in C6 cells is comparable to that in rat brain. Addition of 0.5 mM dibutyryl camp and 0.5 mm theophylline reduced the level of gene transcript by more than 70% within 24 hrs, which then remained constant up to 4 days. This result demonstrates that CAMP can down regulate the expression of RCK1 gene in vitro. Whether or not a similar phenomenon occurs in vivo remains to be seen.

MORPHOLOGICAL DIFFERENTIATION AND K CHANNEL EXPRESSION IN A NEUROBLASTOMA CELL LINE. <u>T. Begenisich and M. Weisenhaus*</u>. Dept. of Physiology, Univ. of Rochester Sch. of Med. and Dent., Rochester, NY 14642.

Untreated cells from the neuroblastoma line, N2AB-1, are relatively homogeneous in their morphology: about 90% of the cells are round; the rest express neurites longer than the cell diameter. After exposure to retinoic acid, about 75% of the cells express extensive neurites and the rest remain round. In a previous study we showed that the round, untreated cells did not express a delayed rectifier K channel but did after morphological differentiation with DMSO/low serum. Our new study was designed to determine if K channel expression was obligatorily linked to morphological differentiation. We used standard, whole cell patch clamp techniques. We found that untreated N_2AB-1 cells, even those with extensive neurites did not express K channels. Cells treated with retinoic acid always expressed K channels including those with a round morphology. These results show that, in this cell line, expression of the delayed rectifier K channel is not obligatorily linked to morphological differentiation.

M-LIKE POTASSIUM CHANNELS IN PATCHES FROM CULTURED RAT SYMPATHETIC NEURONS <u>C.E.Stansfeld</u>, <u>S.J.Marsh</u>* & <u>D.A. Brown</u>, Dept. Pharmacology, University College, London, WC1E 6BT, U.K.

Cultured rat superior cervical sympathetic neurons Cultured rat superior cervical sympathetic neurons possess a prominent time- and voltage-dependent K current, the M-current (Marrion, N.V., Smart, T.G., & Brown D.A.: Neurosci. Lett., 77, 55). Using isolated outside-out membrane patches we have identified single channels which might be responsible for the M-current in these cells. We used asymmetric K (2.5/150 mM) with 0.5 Ca / 5 Mg in the external solution and 1 mM EGTA internally. Sustained activity of single channels with maximum conductance around 9 pS but multiple substates (predominantly 3 - 7pS) were recorded following small depolarizations from 50 mM around 9 ps but multiple substates (predominantly 3 - /ps) were recorded following small depolarizations from -50 mV. maximum Popen was about 0.7 near 0 mV. Channels were insensitive to 1 - 5 mM TEA and 100 uM dTC (which blocks Ca-activated K currents) but were blocked by 1 mM Ba (which blocks M-current but not delayed rectifier or A current). Averaged currents from >80 depolarizing steps yielded slow activation/deactivation relaxations, fitted by single exponentials with mean tau_{on} 147 msec (n=7) between -30 and -10 mV. These kinetics match those of macroscopic M-currents in these cells.

SENSORY SYSTEMS-VISUAL CORTEX: MOTION PATHWAYS

PROJECTION PATTERNS OF MEYNERT CELLS IN PRIMATE VISUAL CORTEX IDENTIFIED BY IMMUNOREACTIVITY FOR NEURO-FILAMENTS. B.A. McGuire & R.M. Siegel, The Rockefeller University, New York, NY 10021 & IBM Research Center, Yorktown Heights, NY 10598.

Meynert cells are the largest pyramidal cells in primary visual cortex of primates. They are sparsely arranged in a thin region of upper layer 6. We have previously shown that Meynert cells in Macaca mulatta are stained with an antibody specific to seurofilaments (McGuire & Naegele, '88). The present study was undertaken to examine the projection patterns of the Meynert cells. In Macaca fascicularis several small injections of retrograde label (red beads or true blue) were made in area 18 sear the V1/V2 border. Patches of retrogradely-labeled cells were found in area 17 in both the superficial layers and layer 48, confirming earlier reports (e.g. Livingstone & Hubel, '87), but no labeled layer 6 cells were found. Thus we found no evidence for a Meynert cell projection to V1.

Area MT is known to receive a prominent input from layers 4B and 6 of striate cortex, and many of the layer 6 cells are thought to be Meynert cells (Tigges et al., '81). Therefore we retrogradely labeled area 17 in squirrel monkeys by making several small injections of red beads in area MT. In two hemispheres, there was strong retrograde labeling in area 17 that consisted of densely packed layer 4B cells in register with a sparser group of layer 6 cells, confirming Tigges et al., '81. Using the seurofilament antibody SMI-32, it was seen that almost all (96%) of the MT-projecting cells in layer 6 were double-labeled with immunofluorescence. These touble-labeled cells were large (26 µm avg. diam. ± 4.6 µm). Scattered throughout the 3.5 x 1.5 mm region of labeled Meynert cells were to large neurons (24 µm avg. diam. ± 4.6 µm) that were neurofilament-positive but not retrogradely labeled. About hirty percent of the double-labeled cells were solely neurofilament labeled. The lack of retrograde label in these

IMPAIRED SPEED DISCRIMINATION RESTRICTED TO THE HEMIFIELD CONTRALATERAL TO AN OCCIPITO-PARIETAL SURGICAL RESECTION. G.T.Plant*, K.D.Laxer*, N.M.Barbaro, K. Nakayama, Smith-Kettlewell Eye Research Institute, 2232 Webster, SF, CA 94115 and Northern California Comprehensive Epilepsy Center, U.C.S.F., CA 94143-0138.

We have studied a patient with partial epilepsy due to a left occipito-parietal cortical developmental anomaly. A Variety of types of visual aura were experienced including a sensation of motion in the right (contralateral) visual a sensation of motion in the right (contralateral) visual field. Drifting sine-wave gratings (spatial frequency 0.5 c/deg) were used to measure visual function before and after resection of occipito-parietal cortex as treatment for intractable epilepsy. The stimuli were located at an eccentricity of 10° and performance compared in the left and right upper quadrants of the visual field. A 2AFC paradigm was employed to measure contrast thresholds for three tasks: grating detection; discrimination of direction of drift; and discrimination between two gratings drifting at 8Hz and at 10Hz respectively (speed discrimination). Pre-operatively there was no difference in performance at these tasks between the two hemifields. Post-operatively there was a ten-fold rise in contrast threshold for speed there was a ten-fold rise in contrast threshold for speed discrimination in the right hemifield only, the remaining parameters were unaffected by the lesion. (G.T.P. is a Travelling Fellow of the Medical Research Council of the United Kingdom).

FUNCTIONAL DEVELOPMENT OF THE CORTICAL VISUAL PATHWAY FOR MOTION ANALYSIS IN RHESUS MONKEYS. C. Distler, L.G. Ungerleider, J. Bachevalier and M. Mishkin. Lab. of

Ungerleider, J. Bachevaller and M. Mishkin. Lab. or Neuropsychology, NIMH, Bethesda, MD 20892.

In primates, the cortical system for motion analysis consists of visual inputs from areas V1, V2, and V3 to MT, outputs of MT to VIP, MST, and FST, and subsequent outputs of MST and FST to the anterior superior temporal sulcus (ASTS). Functional development of this system was studied by means of the 2-deoxyglucose method in 1 adult and 8 infant monkeys (age range 2 days - 6 months) that had received transection of the corpus callosum, anterior commissure, and one optic tract. Local cerebral glucose utilization (LCGU) was measured in visually stimulated awake animals. In animals of all ages, comparison between the intact and visually deafferented hemispheres revealed a progressive decline in hemispheric differences in LCGU along the motion analysis pathway, from a high in V1 to a low in ASTS. Hemispheric differences, however, varied with age. Thus, for each cortical area, the relative difference between the intact and deafferented hemispheres was smallest in the younger animals and reached the was smallest in the younger animals and reached the differences seen in the adult only at 3 months of age. These data suggest that the motion analysis system is not fully developed at birth, but may mature slightly earlier than the occipitotemporal system for object recognition, which reaches adultlike levels at 4 months of age (Macko et al., Soc. Neurosci. Abstr., 9:375, 1983).

7.4

PERCEPTUAL EFFECTS OF CORTICAL MICROSTIMULATION ARE SPATIALLY AND TEMPORALLY RESTRICTED. C. Daniel Salzman*. Chieko M. Murasugi* and William T. Newsome. Dept. of Neurobiology, Stanford University School of Medicine.

We have recently shown that microstimulation of a cluster of MT neurons

with similar preferred directions can influence a monkey's perceptual judgements of motion direction (ARVO Abst., 1990). In those experiments, rhesus monkeys discriminated the direction of motion in a dynamic random dot display placed directly over the receptive field of the stimulated neurons. Microstimulation (10 µA, 200 hz,

over the receptive field of the stimulated neurons. Microstimulation (10 μA, 200 hz, biphasic) occurred on half of the trials, coinciding in time with the onset and offset of the visual motion display. In 29 of 62 experiments, microstimulation significantly biased the monkeys' perceptual decisions toward the preferred direction of the stimulated neurons. We now report the effects of microstimulation when it is dissociated from the visual display in space or in time.

Temporal offset experiments were identical to the previous experiments in all ways except that microstimulation occurred during the intertrial interval rather than during the visual display interval. In all 20 of these experiments, microstimulation had little or no effect on the monkey's psychophysical performance. In the spatial offset experiments, we applied microstimulation during the visual display interval, but at a site in MT remote from the topographic location of the display aperture. We also included control trials in which the visual stimulus overlanped the receptive field of the stimulated neurons. In 15 experiments. overlapped the receptive field of the stimulated neurons. In 15 experiments, microstimulation significantly biased the monkey's choices in the overlapped condition but had little or no effect in the dissociated condition. These results indicate that the effect of microstimulation on perceptual judgements of motion direction is localized spatially within MT and temporally in relation to the occurence

of the visual display.

THE INTEGRATION OF DIRECTION INFORMATION IN AREA MT OF MACAQUE. Robert J. Snowden. Stefan Treue. Richard A. Andersen. Department of Brain and Cognitive Sciences, MIT, Cambridge, MA, 02139. We have shown the response of MT neurons in awake behaving monkeys to a random dot pattern moving in its preferred direction is reduced by the addition of dots moving in the opposite (antipreferred) direction (Snowden et al. 1989). We have extended this study to examine the suppressive effect for a range of directions and for motion discontinuities.

The direction tuning of individual MT cells was assessed by drifting dot patterns in 8 directions. This was repeated save that a constant number of dots were always superimposed drifting in the preferred direction. It was found that directions other than the antipreferred also reduced the response of the cell below that to the preferred alone. The size of this suppressive effect increased with angular difference in directions up to around 90 deg. Directions between 90 - 180 deg generally give similar suppressive effects. When compared to the direction tuning alone it is apparent that a stimulus which by itself causes strong excitation, can cause a suppression of the response to the preferred stimulus. Thus a given stimulus can increase or decrease a cell's firing rate depending upon the context in which it is presented.

We also repeated the direction tuning in the presence of dots moving in the antipreferred direction. Under these conditions we found that the effect of the antipreferred dots was to reduce the response by a constant factor, rather than a constant number of spikes. The suppressive effect can therefore be thought of as divisive rather than subtractive inhibition.

A final set of experiments examined whether the suppressive effect was exclusive to A final set of experiments examined whether the suppressive effect was exclusive to 'transparent' stimuli. The dots were divided into stripes moving in opposite directions. It was found that the suppressive effects remain (though slightly reduced) even if the stimulus was composed of only two sections. Thus the effects described are not exclusive to transparent motions but occur for two spatially segregated motions occur within the cell's receptive field. These results therefore have important implications for processing edges formed by motion discontinuities. Supported by NIH grant EYO7492

A MEAN FIELD MODEL OF OPTIC FLOW ESTIMATION BY MT NEURONS

Allan Dobbinst Steven W. Zucker† Max S. Cynader§ †McGill University, Montreal §University of British Columbia, Vancouver

We consider the problem of obtaining reliable estimates of the optic flow field and its spatial and temporal variation, and develop a dynamical model of neural ele-ments and circuits in the primate motion pathway. Neurons in the middle temporal visual area (MT) are direction and speed selective and many also have direction and speed-dependent antagonism between the RF center and surround. Consequently, such neurons should respond well to spatially restricted translation or to appropriately curving, accelerating, or discontinuous flows. In our model the circuitry in MT is arranged to provide mean field approximations of the optical flow field — maximal neighbourhoods over which the local field is well-approximated as uniform, parallel translation. The basic intuition behind the scheme is this: for a neuron in which the RF center and surround share speed and direction tuning, successful suppression of the center by the surround means that the flow field can be approximated as uniform over a larger area than the RF center of the neuron in question. On the other hand if the neuron is firing strongly, the flow field is approximately constant in the center and either spatially limited or with large spatial variation (rapidly changing speed or direction) in the surround. Therefore the heart of the model is an ensemble of RFs of different size with inhibitory connections running from large to small RF cells. This is repeated at each position and for each of a set of direction and speed classes. Actively estimating the flow field variation with area around each point determines the permissible area for interpolation. The principal neural interactions in the network occur locally within each direction and speed class. One consequence is that unlike most computational schemes proposed to date multi-valued flow fields are not excluded, hence permitting representation of multiple, transparent surfaces. Simulations of the model's behaviour with steady and time-varying optic flow fields will be presented.

ORGANIZATION OF OPTIC FLOW SENSITIVE RECEPTIVE FIELDS IN CORTICAL AREA MST. C. J. Duffy and R. H. Wurtz. Lab. of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

We have classified MSTd neurons as: single component, responding to planar, circular or radial stimuli; double component, responding to planar & circular or planar & radial stimuli; triple component, responding to planar, circular & radial stimuli. We determined whether the circular and radial responses could be understood from the planar responses of sub-fields within the receptive field. In 50 neurons we presented segment stimuli (33° X 33°) consisting of one-ninth of a large-field (100° X 100°) stimulus. Segment studies showed that circular and radial responses could be the product of partial activation of planar directional sub-fields. These findings were consistent with the hypothesis that the convergence of planar direction selective inputs creates circular and radial selectivity

In 160 neurons we presented smaller versions of the full pattern of large-field stimuli. Reducing the size of such patterns and changing the position of these small-field stimuli did not eliminate circular or radial direction selectivity. In addition, small-field stimuli at different positions in the receptive field did not reveal areas of differing planar directionality. These findings suggest that the convergence of planar direction selective inputs does not fully account for circular

Triple component neurons yielded responses which were most cons the view that circular and radial selectivity are derived from the convergence of planar direction selectivities. Single component neurons yielded responses which were more consistent with the view that circular and radial selectivity represent neuronal extraction of a fundamental geometric feature of optic flow fields. These differences suggest that there might be a hierarchy of planar resolvability extending from triple component to single component neurons.

SURROUND PROPERTIES OF MT NEURONS SHOW LAMINAR ORGANIZATION. L. Lagae*, S. Raiguel, D-K. Xiao* and G.A. Orban. Laboratorium voor Neuro- en Psychofysiologie, K.U.Leuven, B-3000 Leuven, Belgium,

We examined the spatial extent and organization of the classical receptive field and its surround in area MT of macaque monkeys. To obtain an area-response curve, we used a series of moving textured patterns of increasing radii centered upon the receptive field. Stimuli were computer-generated white dots on a black background presented at a refresh rate of 100 Hz. For most cells, the response increased linearly for increasing stimulus area up to the border of the receptive field. In 40% of the cells, located predominantly in layer 4, no surround could be detected. In the remaining 60% of the cells, the response gradually decreased to about 35% of maximum as the stimuli exceeded the receptive field, indicating an inhibitory surround. The maximum extent of this surround was taken as the point at which this decrease began to level off. For cells in layer 4, the average area of the surround was only half that of cells in other

Our study shows that the excitatory receptive field of an MT cell and its surround are spatially separated. The laminar differences of surround properties support a hierarchical scheme of receptive field organization in MT. Moreover, these differences may be related to our previous finding that only surrounds of cells outside layer 4 modulate direction selectivity of a moving bar (Lagae et al., <u>Brain</u> Res., 496:361-367, 1989).

A COARSE-TO-FINE MULTIRESOLUTION NETWORK MODEL OF MOTION COMPUTATION IN PRIMATE AREA MT. H. T. Wang*, B. P. Mathur* and C. Koch. Rockwell International Science Center, Thousand Oaks. 91360 and CNS Program, 216-76 Caltech, Pasadena, CA 91125.

All current models of motion processing in the mammalian visual system operate at a single spatial scale. However, receptive field size of direction selective cells in V1 and MT at a constant eccentricity vary by at least one order of magnitude. We developed an adaptive coarseto-fine motion algorithm in the context of computer vision (Battiti, Koch & Amaldi, 1990), which derives a significantly better estimate of the optical flow fields than single scale algorithms. We here adapt this multiscale strategy to our previous model of the primate's motion system (Wang, Mathur & Koch, 1989).

Our model consists of two stages: 1) the local velocity estimates (component selectivity) are computed at multiple spatial scales in the input layers of V1; 2) these estimates of local motion are then combined, using smoothness, to yield the 2-D motion fields (pattern selectivity). We compute the local error, arising primarily due to spatial and temporal aliasing, associated with the motion field at different spatial scales. If this error is below a certain threshold at any spatial scale, the algorithm has converged to the correct solution. Our model neurons show behavior reminiscent of the non-classical type I surround cells in MT (Allman, Miezin & McGuinness, 1985) and provides a novel explanation for the spatial frequency effect in motion capture (Ramachandran & Anstis, 1985). Our multiscale algorithm converges significantly faster than our previous single scale model.

7.10

STIMULUS SELECTIVITY OF NEURONS IN MACAQUE MST. M. Graziano. R. Andersen. and R. Snowden. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA, 02139.

We recorded from single neurons in the medial superior temporal visual area (MST) of the macaque, where previous investigators reported cells selective for stimuli such as a rotating field of dots, or an "expansion" made when a dot field is magnified. We used a novel stimulus which avoided artifacts, such as increase in dot size, decrease in dot density, and decrease in luminance, which appear in expansion, or local shape cues which appear in both expansion and rotation. In our stimuli each dot moved with a constant velocity for 200ms, before being relocated and given a new velocity appropriate to its new location. The effect is an overall motion, such as rotation, or expansion, or contraction, but without confounding artifacts.

We confirmed that MST cells are often selective for expansion or contraction, clockwise or counter-clockwise rotation, or pure translational motion; and that some cells respond to more than one class of motion. Some cells which were selective only for rotation responded regardless of the direction of rotation.

To test if expansion/contraction and rotation selectivities are special, or are just a few of many motion pattern selectivities in MST, we devised a method of comparing expansion, contraction, rotations, and spiraling stimuli, on one scale. Each stimulus can be represented as a velocity vector in a coordinate frame with radial speed on one axis and angular speed on the other. We plotted directional tuning curves in this coordinate system. In preliminary tests, most cells preferred expansion, contraction, or rotation, over any of the spiraling stimuli.

TRANSLATIONAL INVARIANCE AND ATTENTIONAL MODULATION OF

MST CELLS. R. Andersen, M. Graziano, and R. Snowden, Dept. of Brain and Cognitive Sciences, MIT., Cambridge, MA, 02139. Area MST neurons are often selective for expansion, contraction, or for clockwise or counter-clockwise rotation. We tested if these selectivities persist regardless of the location of the stimulus in the receptive field. MST receptive fields are usually at least 40 degrees in diameter. We tested with 10-degree diameter stimuli at five overlapping locations in the receptive field, arranged in a cloverleaf pattern. In every case cells retained the same stimulus selectivity at all five retinal locations, even though, in the area of overlap, the local direction of motion was reversed depending on stimulus location. Thus MST responses to these motion patterns are translation invariant. The cells also showed a degree of size invariance, responding well to 10 and 20 degree diameter stimuli, although they tended to respond better to the larger stimulus.

Attentional modulation was examined using a reaction time task, in which the animal was required to release a lever in response either to a change in the motion of the stimulus, or to a slight dimming of to a change in the motion of the stimulus, or to a slight dimming of the fixation point. The two types of trials were randomly interleaved and the color of the fixation point indicated which detection was required. Many MST cells altered their response when the animal attended to the motion stimulus, showing a facilitated response to the preferred direction of motion, and often a reduction to the non-preferred direction. This result suggests that in some cases the tuning of area MST neurons is sharpened by attention.

Vestibular input to visual-tracking neurons in area FST of awake rhesus monkeys. P. Thier* and R.G. Erickson, Dept. Neurology, Univ. of Tübingen, 74 Tübingen, W. Germ. (Spon: European Neuroscience Association.)

Tübingen, 74 Tübingen, W. Germ. (Spon: European Neuroscience Association.) During visual tracking with the head stationary, the activity of visual tracking (VT) cells within areas MST and FST of the superior temporal sulcus (STS) reflects integration of directionally selective visual responses and directionally selective non-visual responses. While it has been proposed that the non-visual signal may represent an eye movement efference copy, we have found that the pursuit-related discharge of such neurons is the same during "head-tracking" (with the eye stationary in the orbit) and "eye-tracking" (with the head stationary). This observation indicates that non-visual input to VT cells includes both eye- and head-movement components and may be equated to a gaze signal or to motion of the target in extrapersonal space rather than to eye movement alone. A preliminary sample of 20 VT neurons observed during alternating sets of both "eye." and "head-tracking" have been analysed. The majority had the same preferred directions for visual tracking and visual pattern movement and all were recorded from a small region (referred to as FST or MSTI by different labs) on the lower anterior bank of the STS in 2 adult rhesus monkeys. Eyetracking was studied using step-ramp and circular motion of a target rearlabs) on the lower anterior bank of the STS in 2 adult rhesus monkeys. Eyetracking was studied using step-ramp and circular motion of a target rearprojected onto a tangent screen. Head-tracking involved suppression of the horizontal or vertical vestibulo-ocular reflex (VOR) by fixation of an LED rotated in synchrony with the animal in an otherwise dark room. The most striking result was that the activity of all 20 neurons was driven to a similar extent by both head- and eye-tracking, and that the same preferred direction of gaze movement was preserved in each case. The dual nature of the non-visual tracking response was verified by the lack of visual responsiveness to brief periods of target blinks or retinal stabilization during "eye-tracking", and by the consistent observation of vestibular modulation during rotation in complete darkness (VOR alone). The residual modulation by vestibular input amounted, on average, to 50% of the response observed during head-tracking. In summary, our results show that a representation of gaze or target motion in space is available in a small, well-defined visual area within the STS. Support: DFG SFB 307.

PEPTIDES-RECEPTORS

MOLECULAR CLONING AND FUNCTIONAL CHARACTERIZATION OF A cDNA ENCODING THE SWISS 3T3 BOMBESIN/GRP RECEPTOR. E. Giladi, T. Segerson*, P. Brehm, R.H. Goodman and E.R. Spindel. Division of Neuroscience, Oregon Regional Primate Res. Center, Beaverton, OR 97006 and Vollum Institute for Advanced Biomedical Research, Portland, OR 97201

Bombesin and its mammalian homolog, gastrin-releasing peptide (GRP) function as growth factors, neurotransmitters and paracrine regulators of gastrointestinal function. To better characterize the physiologic roles of bombesin-like peptides, our laboratories have cloned the receptor for bombesin that is expressed in murine Swiss 3T3 fibroblasts. A cDNA library was prepared from Swiss 3T3 RNA in the vector \(\lambda \) Zapll. RNA transcribed from pools of 50,000 cDNA clones was expressed in Xenopus oocytes and monitored by twoelectrode voltage clamp and by monitoring changes in intracellular calcium with aequorin. By this process, an initial positive pool of 50,000 clones was narrowed to a single clone by successive rounds of sib selection. Oocytes injected with RNA transcribed from this clone showed a log-linear response to bombesin from 10 $^{10}\,$ to 10 $^6\,$ M bombesin. The ED50 was 3 X 10 $^9\,$ M and the response to 3 X 10^9 M bombesin could be completely blocked by 3 x 10^8 M of the specific bombesin antagonist [D-Phe⁶]bombesin(6-13)propylamide (Biochem. 29:616-622, 1990). DNA sequence analysis revealed a 1.8 kb cDNA encoding a 384 amino acid protein. The protein contained 7 hydrophobic domains and 5 N-linked glycosylation sites. Data base analysis showed highest homology to the tachykinin receptors with next highest homology to the \$2adrenergic receptor. RNA blot analysis showed a major hybridizing band 9.5 kb in size. Consistent with the known distribution of the bombesin receptor, this band was present in RNA from Swiss 3T3 cells but absent from NIH 3T3 cells.

FUNCTIONAL EXPRESSION OF NATIVE AND MUTATED MURINE BOMBESIN/GASTRIN-RELEASING PEPTIDE RECEPTOR cDNA IN MAMMALIAN AND AMPHIBIAN CELLS. TE Segerson*, S. Montgomety*. PJS Stork*, K. Walton, E. Giladi, R. Goddman*, E.R. Spindel. Vollum Institute for Advanced Biomedical Research, Portland OR 97201 & Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Bombesin and its mammalian homologue gastrin-releasing peptide (GRP) are mitogenic in fibroblast and some neuroendocrine cell lines. Our laboratories have mitogenic in librobiast and some neuroendocrine cell lines. Our laboratories nave cloned a cDNA for the bombesin/GRP receptor (B/GRP-R) by expression of a Swiss 3T3 cell library in *Xenopus* oocytes. To study the growth effects of bombesin peptides, we have introduced the B/GRP-R into heterologous mammalian cells. B/GRP-R cDNA cloned into the expression vector pCDM8 was transfected into COS 7 cells by calcium phosphate precipitation. Transfected cells were incubated with 0.4 µCi ¹²⁵I-bombesin (90 pM) for 2h and were washed and were incubated with 0.4 µC. =1-chomoses (90 pM) for *In* and were washed and fixed with 14% glutaraldehyde. Four day exposure not radiographs of dried cell monolayers showed increasing numbers of strongly labeled cells with increasing amounts of B/GRP-R plasmid transfected, blocked by 5 nM cold bombesin. An eight amino acid epitope for a monoclonal antibody (FLAGT^M, Immunex) was introduced into the N-terminal portion of the B/GRP-R in pCDM8. Transcripts of this mutant receptor injected into *Xenopus* oocytes produced bombesin-dependent inward currents of $1-2 \mu A$ ($V_{\text{hold}}=-60 \text{ mV}$). Introduction of the mutated B/GRP-R into COS 7 cells resulted in ¹²⁵I-bombesin labeling equivalent to the native murine receptor. Antibody to this epitope precipitated a protein of appropriate size from *in vitro* translated mutant receptor transcript. In conclusion, we have 1) expressed a cloned B/GRP-R in heterologous cells and demonstrated binding of labeled bombes in to these cells; and 2) introduced an epitope into this receptor without loss of activity in oocytes or binding in mammalian cells. We are isolating stably-transfected fibroblast cell lines with the native and mutated receptor central transfected fibroblast processing the protein interactions in bombesis. to study the role of receptor structure and receptor-protein interactions in hombesin-

XENOPUS OCCYTES. H. Meiri, G. Omri, R.D. Blitzer, E.M. Landau, C. Cyr, E. Scheindling, J. Schlessinger, and R.M. Kris. Dept. Psych., Mt. Sinai Med. Ctr. and Bronx VA Med. Ctr., Bronx NY 10468, Technion Faculty of Medicine, Haifa, Israel, and Dept. Pharmacol., NYU Med Sch., New York, NY 10016.

receptors Peptide that couple phosphoinositide pathway in oocytes stimulate a Ca^{2*} dependent Cl current. We have used this pnosphoinositide pathway in occytes stimulate a Ca^{2*} dependent Cl current. We have used this current to clone a number of peptide receptors. A cDNA library was constructed from rat whole brain RNA in lambdaZAP. Occytes injected with RNA transcribed from this library displayed Cl currents in the presence of NE, 5HT, CCK, neurotensin, substance K, bombesin and bradyknin Fractionation of this library by sib currents in the fractional form of this library by sib selection produced small DNA pools which contained the clones for the receptors for

Isolation and sequencing of the receptor clones for bombesin, bradykinin, and other neuropeptide receptors should be possible using this approach. Supported by the Irma T. Herschl Found. and the VA Merit Program.

CLONING. EXPRESSION AND BIOCHEMICAL ANALYSIS OF HUMAN SUBSTANCE - K RECEPTOR IN NIH 3T3 CELLS. R.M. Kris and C. Cyr. Department of Pharmacology, 550 First Avenue, N.Y.U. Medical Center, New York, NY 10016.

The human substance-K receptor was cloned from a human small intestine cDNA library. The receptor consists of 398 amino acids, including seven putative transmembrane regions. The human substance-K receptor was expressed in mouse 3T3 fibroblasts and Scatchard analysis indicates 97,000 receptors per cell with a single affinity of 12 nM Kd. Cross-linking experiments utilizing ¹²⁵I-substance-K demonstrate an apparent molecular weight of 45 kilodaltons, consistent with little or no N-linked-glycosylation. Early signal transduction events were measured following the binding of substance-K to its receptor. There is a rapid increase in the production of total inositol phosphates and the release of Ca⁺⁺ from internal stores. Growth of the cells transfected with the human substance-K receptor is stimulated by the addition of substance-K to the medium. Therefore, the human substance-K receptor can function as a growth factor receptor when expressed in mouse 3T3 fibroblasts. Stimulation of alternative pathways stimulated by substance-K will also be discussed.

SOLUBILIZATION OF RAT BRAIN BOMBESIN/GRP RECEPTORS IN A HIGH AFFINITY LIGAND BINDING CONFORMATION. T.W., Moody, J. Staley.* L. Naldini.* D. Cirillo.* P. Comoglio.* and R.M. Kris.* Deur Biochem. & Mol. Biol., George Washington Univ. Med. Sch. Washington, D.C. 20037, and Dept. Biomed. Sciences and Oncology, Univ. Torino Med. Sch., Torino, Italy, and Dept. Pharm. NYU Sch. Med., New York, N.Y. 10016. Bombesin/gastrin releasing peptide (BN/GRP) may function as a modulatory agent in the CNS. BN/GRP-like peptides and receptors are localized to certain regions of the rat brain such as the paraventricular nucleus of the hypothalamus where BN is a potent satiety and grooming agent (Chronwall et al., Brain Res. 338:97 (1985)) and Zarbin et al., J. Neurosci. 5:429 (1985)). While the gene for GRP has been cloned, little is known about the molecular properties of the BN/GRP receptor. Here the BN/GRP was solubilized from rat brain membranes using CHAPS/cholesterol hemisuccinate (CHS) and its binding properties determined. The soluble receptor bound (181-Tyr*)BN with high affinity (Kd = 2 nM) to a single class of sites using a filtration assay. GRP and C-terminal fragments such as GRP¹⁴⁻⁷ and GRP¹⁸⁻⁷ inhibited specific (181-Tyr*)BN binding activity with IC₂₀ values of 5, 1 and 2 nM whereas N-terminal fragments such as GRP¹⁴⁻⁷ were inactive. Also, BN/GRP receptor antagonists such as (D-Phe⁶)BN⁵⁻¹³ propylamide and (Psi¹³⁴, Leu¹³)BN had IC₂₀ values of 5 and 50 nM. Using gel filtration techniques the main peak of ¹²¹-(Tyr*)BN binding activity had a Mr of 200 Kdaltons using Sephacryl S-300. The purification of the solubilized receptor using affinity chromatography techniques will be discussed. Because the membrane bound and extracted receptor have almost identicle binding properties, the BN/GRP receptor may be solubilized in its native conformation. Supported by NSF grant BNS 88-15133.

RECEPTOR MEDIATED INTRACELLULAR MOBILIZATION IN TRANSFECTED MURINE FIBROBLASTS A.K. Henderson, T.L. Smith, J. Lai, H.I. Yamamura, and W.R. Roeske. Department of Pharmacology, The University of Arizona Health Sciences Center, Tucson, AZ 85724

Tucson, AZ 85724
We previously demonstrated in vitro expression of a bovine stomach cDNA encoding for an NK₂ receptor into the murine B82 fibroblast cell line. The transfected cells exhibited specific [1237]NKA binding. Agonist induced phosphatidylinositol hydrolysis displayed a rank order of potency of NKA>SP>>senktide. NKA also mediated an increase in intracellular Ca¹² concentration ([Ca²],) in a dose dependent manner. An EC, value of 40.50 M was in intracellular Ca⁻² concentration ([Ca⁻³]₁) in a dose dependent manner. An EC₅₀ value of 40 nM was fluorometerically measured with fluo-3. Basal [Ca⁺²₂]₁ was 57 \pm 18 nM and maximal accumulation of [Ca⁻²₁] at 1 μ M NKA was 45 \pm 18 nM over basal levels. In vitro expression of NK₂ receptors provides a correlation of the structurally defined receptor with its ligand binding defined receptor with its ligand binding properties and its pharmacological and functional mechanisms.

ENDOTHELIN RECEPTORS IN RAT BRAIN TISSUE. H.F. Cheng, S.M. Lee*, J.Y. Wang* and K.J. Chang. Institute of Biomedical Sciences, Academia Sinica and Department of Physiology and Biophysics, National Defence Medical Center, Taipei, Taiwan, R.O.C.

Endothelins (ETs), potent vasoconstrictors originally discovered from cultured porcine aortic endothelial cells, are neuropeptides in the brain. This study was to identify and characterize the receptors for ETs in rat brain by using radioligand binding technique. The iodinated ET bound specifically to receptors in rat brain membrane in a protein-, time- and dose-dependent manner. Scatchard analysis indicated a single class of high affinity binding sites on rat brain membrane. The dissociation rate of iodinated ET from ligandreceptor complex was very slow. Mg⁺² increased iodinated ET binding at the optimal concentration of 5mM. On the other hand, GTPrS inhibited the specific binding of iodinated ET at mM range, suggesting endothelin receptors in rat brain might be coupled to a G-protein. The order of potency for ETs and sarafotoxin S6B to displace the specific binding of iodinated ET from brain membrane is ET-3 > ET-1 ≥ sarafotoxin S6B > ET-2. All these result suggest the presence of endothelin receptors on rat brain membrane which have the highest affinity for ET-3.

THE RAT SUBSTANCE P RECEPTOR: MOLECULAR CHARACTERIZATION OF ITS GENE AND EXPRESSION OF ITS mRNA. A.D. Hershey, L. Polenzani*, R. Miledi and J.E. Krause, Washington University School of Medicine,

St. Louis, MO 63110 and University of California, Irvine, CA 92717.

We have recently reported the cloning and expression of a cDNA encoding a rat Substance P receptor (SPR) and a preliminary analysis of mRNA distribution (Science 247, 958-962, 1990). Ligand binding analysis of this expressed SPR in (Science 241, 336-362, 1390). Ligand onland analysis of this expressed SFR in COS-7 cells with a variety of tachykinins demonstrates that SP is the preferred natural agonist for this receptor. In this study, we have examined functional SP-mediated responses, examined patterns of mRNA expression and determined the structural organization of the SPR gene. When mRNA from this cloned SPR is expressed in Xenopus oocytes, SP application to the oocyte activates an oscillatory inward chloride current which rapidly desensitizes. Examination of mRNA levels encoding the SPR using sensitive nuclease protection assay procedures has revealed that SPR is expressed throughout the CNS and in many peripheral tissues, representing 0.0001 to 0.0016% of total RNA. Using coding region probes, the highest abundance detected is in the urinary bladder, striatum, spinal cord, highest abundance detected is in the urinary bladder, striatum, spinal cord, submandibular gland and sublingual gland, with the majority of the signal represented by a single protected species. These localization results agree with in vitro autoradiographic studies for the distribution of SP binding sites. These results suggest that this cloned SPR mediates the primary actions of SP on its target neurons and tissues throughout the rat. The SPR gene was isolated and extensively characterized, and the transcriptional start site has been defined by nuclease protections assays. The gene consists of five exons containing 958, 195, 151, 197, and 2068 bp and extends over 45 kb. The locations of the exon splice sites are adjacent to the membrane spanning domains of the SPR. Overall, these studies define the molecular nature of a rat SPR and its gene. This work provides a basis for the further exploration of the structure and function of the SPR, and of the mechanism and regulation of SPR gene expression.

HETEROLOGOUS EXPRESSION OF NEUROPEPTIDE Y (NPY) Y1-RECEPTORS IN XENOPUS OOCYTES. C. Wahlestedt. S. Nakanishi* and D.J. Reis. Div. of Neurobiol., Cornell Univ. Med. Coll., New York, NY 10021, USA, and Inst. for Immunol., Kyoto Univ.,

Coll., New York, NY 10021, USA, and Inst. for Immunol., Kyoto Univ., Kyoto, JAPAN

The Y1-receptor is the major vascular NPY receptor and mediates many central NPY actions. Human neuroblastoma cells of the SK-N-MC line preferentially express the Y1-receptors (Springston, et al., Soc. Neurosci. Abstr., 1990). We sought to determine whether this receptor can be expressed in Xenopus oocytes and to identify coupled signal transduction mechanisms. mRNA was prepared from SK-N-MC cells and microinjected into oocytes which were subsequently exposed to NPY. First, in voltage-clamped oocytes, NPY alone elicited negligible changes in chloride currents. However, oocytes in which SK-N-MC mRNA and in vitro transcribed mRNA for the cloned (phosphatidyl inositide (PI)-coupled) substance K (SK) receptor were coinjected, NPY potentiated threshold SK-evoked currents; native Y1-receptors also have the capacity to potentiate PI-coupled responses (Wahlestedt et al., Am. J. Physiol. 258:R736, 1990). Second, NPY elevated intracellular Ca⁺ concentrations in fluo-3 (a Ca⁺-sensitive dye) injected cells. Third, NPY, applied to oocytes in which SK-N-MC mRNA and in vitro transcribed β₂-adrenoceptor mRNA were coinjected, attenuated by ≤60% the isoproterenol-elicited elevations in cAMP concentrations. We conclude: (a) NPY Y1-receptor mRNA from SK-N-MC cells can be expressed in Xenopus oocytes; (b) the expressed receptors initiate increased intracellular Ca⁺ concentration of PI-associated chloride conductances. Such coupling may therefore represent signal transduction mechanisms characteristic of both the native and the heterologously expressed Y1-receptor and may make its expression cloning possible.

ENDOTHELIN RECEPTORS ON FETAL RAT DIENCEPHALIC ASTROGLIA. E.R.Levin, H.J.L.Frank*, A.Pedram*. Dept. of Med., Univ. of Calif., Irvine and Long Beach VAMC, Irvine, CA 92717. Binding activity for endothelin has been found in the brain. To determine the cell type expressing receptors, binding characteristics and potential functions of these peptides in neural cells, we bound ${\tt I}^{125}{\tt -Endothelin-3}$ (ET-3) tures (85% NSE positive) from fetal rat diencephalon. Affinity crosslinking of ¹²⁵I-ET-3 and in-situ autoradiography identified dense binding on astroglia with scattered rim binding on a small subpopulation of neurons. In binding studies, both type 1 and type 2 astroglia specifically bound 8-13% of ET-3 added, while neuron-predominant cultures showed 2-3% binding. Scatchard analysis of saturation binding in glia identified a single class of receptors with a Kd of 0.4±0.05nM (SEM) and a receptor density of 45 fmol/mg protein (54,000 receptors/cell). Affinity crosslinking of labeled ET-3 and SDS-PAGE identified a single predominant band of approximate Mr 52,000. ET-3 at 10⁻⁸M significantly reduced 10^{-8}M atrial natriuretic peptide generation of cGMP, while having no effect on isoproterenol-induced cAMP or basal cAMP or cGMP production. ET-3 caused a significant, dose-related increase in H³-thymidine incorporation in the presence of 1% serum. These studies establish that high affinity, low mol. wt. endothelin receptors exist mainly on astroglia in rat diencephalon and that this peptide might act as a proliferative factor for these cells.

LOCALIZATION OF ³²P-LABELED RELAXIN BINDING SITES IN RAT BRAIN. P.L. Osheroff* and H.S. Phillips#. Dept. of Protein Chemistry* and Developmental Biology#, Genentech, Inc., South San Francisco, CA. 94080.

Relaxin belongs to the insulin family of polypeptide hormones and is best known for its biological activities in the mammalian reproductive system, notably inhibition of uterine contraction and softening of the cervical canal. The biological actions of relaxin are thought to be mediated through specific receptors located in the target tissues. Using a biologically active ³²P-labeled human relaxin we have previously localized by *in vitro* autoradiography specific relaxin binding sites in rat uterine and cervical tissue sections. Using the same approach we describe here the localization of relaxin binding sites in the rat brain. Displaceable relaxin binding sites are found to be distributed in discrete anatomical pattern including the neocortex, the hippocampus, the hypothalamus, the thalamus, the amygdala, and the olfactory bulb. Of special interest is the specific binding of relaxin to two of the circumventricular organs (the subfornical organ and the organum vasculosum of the lamina terminalis) and the neurosceretory magnocellular hypothalamic nuclei (the paraventricular nuclei and the supraoptic nuclei). In view of recent physiological studies showing the effects of centrally administered relaxin in the inhibition of reflex milk ejection and haemotensive response, and that the subfornical organ might mediate the relaxin-induced actions, the present study provides biochemical evidence for the possible site(s) of action of relaxin in the

SPECIFIC BINDING SITES FOR PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE (PACAP) IN RAT ASTROCYTES: INTERACTION WITH VASOACTVE INTESTINAL PEPTIDE (VIP). I.Tatsuno*, P.E. Gottschall*, and A. Arimura U.S.-Japan Biomed. Res. Labs., Tulane Univ. Hebert Ctr., Belle Chasse, LA 70037; Depts. of Medicine, Anatomy & Physiology, Tulane Univ. Sch. of Med., New Orleans, LA 70112.

PACAP stimulates adenylate cyclase activity not only in rat pituitary cell cultures but also in neuron and astrocyte cultures. In

PACAP stimulates adenylate cyclase activity not only in rat pituitary cell cultures but also in neuron and astrocyte cultures. In particular, the considerable stimulation in astrocytes suggested that these cells might be one of the major target cells for PACAP. The existence of specific high (Kd=10-9 M) and low (Kd=10-6 M) affinity binding sites for PACAP was demonstrated in rat astrocyte membrane preparations using radioreceptor assay (RRA) with [1251]PACAP27. PACAP shows a large degree of homology with VIP, but it was approximately 1000 times more potent than VIP in stimulating adenylate cyclase and displacing [1251]PACAP27 binding. At the same concentrations of radiolabeled peptides, the specific binding of [1251]PACAP27 was approximately 50 times greater than that of [1251]VIP. In RRA using [1251]PACAP27, 10-6 M VIP reduced the binding maximal capacity (Bmax) of high affinity binding site for PACAP27 by 50%. However, the Bmax of low affinity binding site and the dissociation constant (Kd) for both high and low affinity binding sites were not altered. This indicates that only high concentration of VIP (10-7 M or larger) shares the high affinity binding site for PACAP which may be linked with adenylate cyclase. These data suggest that PACAP might have an important regulatory role in astrocytes and probably in CNS.

ACETYLCHOLINE—RECEPTORS

Identification of Critical Amino Acids Specifying G Protein Recognition using Muscarinic Acetylcholine Receptor Chimeras. James Lechleiter, David Ennulat **, Kevin Duerson *, Ned David **, David Clapham * and Ernest Peralta **. Dept. Pharmacol., Mayo Clinic, Rochester, MN 55905, **Dept. Biochem. and Mol. Biol., Harvard Univ., Cambridge MA 02138.

Muscarinic acetylcholine receptors (mAChRs) are a family of at least five distinct subtypes, designated m1 - m5, which fall into two functional classes: m1, m3, and

m5 receptors strongly stimulate phosphoinositide (PI) hydrolysis through G proteins, while m2 and m4 receptor subtypes only weakly stimulate PI turnover and preferentially inhibit adenylyl cyclase activity through G proteins. We constructed a series of reciprocal hybrid receptors composed of domains derived from the m2 and m3 subtypes, representing the two functional classes of mAChRs, to identify specific amino acid sequences important for G protein recognition. SP6 receptor transcripts were injected into individual Xenopus oocytes (100 ng/egg) and ACh-induced Ca2+ activated chloride current (I-Cl) responses were measured two days later using two electrode voltage clamp measurements. Hybrid receptors were evaluated by their ability to stimulate I-Cl in comparison to m3 receptors, which produced large rapid inward currents, and to m2 receptors, which produced distinctly slower and reduced I-Cl responses. Based on seven-transmembrane topology, we found that the identity of the third cytoplasmic loop largely determined the type of observed response. A single contiguous domain of 9 amino acids from the third loop was sufficient to transfer this m3-like coupling of PI hydrolysis and intracellular calcium mobilization to the m2 receptor subtype. Site-directed mutagenesis of this region of the m3 receptor also revealed the importance of these sequences in G protein recognition. These results imply that an analogous domain may be responsible for specifying the G protein coupling properties of related neurotransmitter and hormone receptors, however, the location of this domain may vary between different classes of G protein-linked receptors. PRODUCTION OF MUSCARINIC RECEPTOR ANTIBODIES AND REACTIVITY WITH m1-m5 SUBTYPE PROTEINS FROM BRAIN. A. I. Levey, T. M. Stormann, and M. R. Brann. Dept. Neurology, Johns Hopkins, Baltimore, MD. and Lab of Molecular Biology, NINDS, Bethesda, MD. Molecular cloning studies have identified five distinct muscarinic

Molecular cloning studies have identified five distinct muscarinic receptor genes (m1-m5) and each mRNA has a unique localization in brain. However, it has not been possible to determine whether all five receptor mRNAs are translated since there are no ligands specific for the encoded receptor proteins. For this reason we prepared subtype-specific antibodies using recombinant DNA methods. The gene segments corresponding to the i3 loops of human m1-m5 (~150-200 amino acids unique to each subtype) were subcloned into the bacterial expression vectors pET and pGEX2T. High yields of fusion proteins were obtained (~30-50% of total culture protein) and two rabbits were immunized with each SDS-PAGE purified protein. Antibody specificity was verified with two assays. First, all antisera reacted specificially with the respective receptor fusion proteins on immunoblots. Second, cloned receptor subtypes independently expressed in CHO-K cells were labeled with 3[H]-QNB and 3[H]-PBCM, solubilized, and tested for antibody immunoprecipitation. Each antisera bound to the appropriate receptor subtype without significant cross-reactivity to the other subtypes. The antibodies were also able to precipitate labeled receptor subtypes from rat brain in varying proportions depending on brain region. In conclusion, antisera specific for the five muscarinic receptor subtypes have been produced against fusion proteins and have been used to provide the first direct evidence for the proteins in brain.

EFFECTS OF THYMOPOIETIN (TPO) ON NICOTINIC ACETYLCHOLINE RECEPTOR (nACHR) AND NEURONAL NICOTINIC ALPHA-BUNGAROTOXIN BINDING SITE (nBgts) EXPRESSION AND FUNCTION. R.J. Lukas, T. Audhya, G. Goldstein* and L. Lucero*. Div. of Neurobiol. Barrow Neurol. Inst., Phoenix, AZ 85013 (RJL, LL) and Immunobiol. Research Inst., Annandale, NJ 08801.

TPO is a pleiotropic thymic hormone that influences T-cell maturation and immune system balance. It was initially isolated as a thymic factor that could interact with muscle cell nAChR and might play a role in myasthenia gravis. TPO blocks functional responses (IC50 - 30nM) and high affinity radiolabeled alpha-bungarotoxin (Bgt) or acetylcholine (ACh) binding (IC50 - 10nM) of muscle-type nAChR expressed by cells of the TE671 human clone or the BC3H-1 mouse muscle clone. Ganglia-type nAChR expressed by cells of the SH-SY5Y or IMR-32 human neuroblastoma clones are refractory to functional blockade by TPO at concentrations up to luM, but it blocks (IC50 - 80nM) high affinity binding of Bgt to nBgtS, which do not appear to function as ligand-gated ion channels, expressed by those cells. Chronic exposure to luM TPO induces a loss of muscle-type nAChR functional responses on TE671 or BC3H-1 cells. Chronic TPO treatment has no effect on expression of functional ganglia-type nAChR on SH-SYSY cells. The data suggest that TPO or a related substance may be biologically active in both the immune and nervous systems. Some of TPO's functions may be attributable to its interaction with nBgtS or muscle-type nAChR.

9.4

THYMOPOIETIN, A THYMIC POLYPEPTIDE, INHIBITS FUNCTION AND NICOTINIC RECEPTOR BINDING AT THE NEUROMUSCULAR JUNCTION. M. Quik, B. Collier T. Audhya * and G. Goldstein. Dept. Pharmacol., McGill Univ., Montreal, Canada and Immunobiol. Res. Inst., Annandale, NJ, USA.

Thymopoietin (TPO) is a 49 amino acid polypeptide from thymus, linked to immune function and implicated in myasthenia gravis. The present results show that TPO completely blocked transmission at the rat phrenic nerve diaphragm at concentrations as low as $10^{-8}\,$ M. The TPO induced inhibition was dose and time dependent, with the polypeptide being only somewhat less potent than α -bungarotoxin (α -BGT). TPO did not inhibit muscle tension by an action on the muscle contractile mechanism per se. As well, TPO did not alter release of acetylcholine, suggesting it did not interact at a presynaptic level. On the other hand, TPO inhibited the binding of $[^{125}\,\mathrm{I}]\alpha$ -BGT to diaphragm. In intact muscle tissue, the IC50 for inhibition of $[^{125}\,\mathrm{I}]\alpha$ -BGT binding by TPO was 2.1 x $10^{-9}\,\mathrm{M}$, a value similar to the concentration of polypeptide required to inhibit phrenic nerve induced muscle contraction. In muscle membranes, the potency of the TPO in the $[^{125}\,\mathrm{I}]\alpha$ -BGT binding assay was greatly increased (IC50 = 0.35 nM). The results suggest that TPO, a polypeptide linked to immune function, inhibits neuromuscular activity through an interaction at the nicotinic receptor.

STEROID MODULATION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS. D. Bertrand, S. Bertrand, D. Rungger, S. Valera and M. Ballivet. Dpt of Physiology, CMU, 1 Rue Michel Servet, 1211 Geneva 4, Switzerland.

Nicotinic acetylcholine receptors (nAChRs) can be modulated by extracellular or intracellular substances. Application of substance P significantly increases the desensitization rate of neuronal nAChRs in rat sympathetic ganglion (Role, L.W., Proc. Nat. Acad. Sci., 81:2924, 1984) and chromaffin cells (Clapham, D.E. and Neher, E., I. Physiol., 347:255, 1984). More recently it was reported that ACh desensitization in chromaffin cell is also modulated by dexamethasone, a synthetic glucocorticoid. We examine here the action of dexamethasone and other steroids on reconstituted $\alpha 4/n\alpha 1$ neuronal nAChR expressed in Xenopus oocytes following nuclear injection of subunit cDNAs (Ballivet, M. et al., Neuron, 1:847, 1988). The effects of dexamethasone on the $\alpha 4/n\alpha 1$ channel were found to depend upon the batch of oocytes. In some batches 1 μ M dexamethasone had no action while in other an immediate and significant increase of the ACh-induced current was observed in response to 1 μ M agonist. In contrast, application of 10 μ M progesterone always reduces immediately the amplitude of the ACh-induced current. Moreover, ACh-induced currents are abolished within four hours following a progesterone application sufficient to trigger oocyte maturation, whereas cytoplasmic injections of maturation promoting factor does not affect the response to ACh.

9.7

and adult (AChRs) embryonic Properties ο£ acetylcholine receptors (AChRs) transien expressed in COS cells.J.R. Forsayeth*, Y. Gu*, transiently Franco, Jr.*, P. Gardner, J.B. Lansman and Z.W. Hall We have used transient transfection in COS cells to compare the properties of mouse muscle nicotinic AChRs containing α, β, δ and either γ or ϵ subunits. Following transfection with cDNAs of either the $\gamma-$ or $\epsilon-AChR$, toxinbinding activity corresponding to fully assembled receptor was expressed on the surface of COS cells at a level comparable to that seen in cultured muscle cells. Toxinbinding to $\gamma\text{--},$ but not $\epsilon\text{--},$ AChR was partially blocked by a myasthenic serum reported to be specific for the embryonic form of muscle AChR. The E-AChR was also degraded more slowly in the membrane than the γ -AChR (t_{1/2} ϵ : 19 h;t_{1/2} γ : 11 h). Patch-clamp recordings showed that the Y-AChR had the characteristics of embryonic AChR $(\gamma_{\text{C}};41\text{pS};\tau;11\text{ ms})$ and the $\epsilon\textsc{-AChR}$ had those of the adult AChR $(\gamma_{\textsc{C}}\!:\!61\text{pS}\!:\!\tau\!:\!1.0\text{ ms})$. These results demonstrated that some but not all of the differences between AChRs at the adult endplates and those in the extrasynaptic membrane can be explained by the difference in subunit composition of $\gamma-$ and $\epsilon-$ AChRs. Finally, transient expression of AChRs in COS cells is convenient, reproducible, yields high levels of surface AChR, and should be generally applicable to the study of other multi-subunit proteins. Supported by NIH grants (NS28062 and NS13521) to JRF and ZWH.

CLONING OF β 5, A NICOTINIC RECEPTOR SUBUNIT. <u>K. E. Isenberg</u>. Department of Psychiatry, Washington Univ. Sch. of Med., St. Louis, MO 63110.

The neuronal nicotinic acetylcholine receptor is a multisubunit peripheral and central nervous system receptor. Several distinctive acetylcholine binding and nonacetylcholine binding or β subunits have been described in rat. I have cloned a new putative nonacetylcholine binding neuronal nicotinic acetylcholine receptor subunit. The clone was isolated from a rat superior cervical ganglion cDNA library (library provided by J. P. Merlie). The deduced amino acid sequence of the clone, designated $\beta 5$, shows significant similarity with previously described neuronal receptor subunits and lesser but significant similarity with other ligand gated ion channel subunits. Analysis of the amino acid sequence suggests the presence of four putative transmembrane domains. The third and fourth transmembrane domains are separated by a large nonconserved cytoplasmic region. $\beta 5$ lacks the side by side cysteine residues thought to be characteristic of acetylcholine binding subunits. These observations demonstrate the increasing complexity of the neuronal nicotinic acetylcholine receptor gene family.

ACETYLCHOLINE RECEPTOR EXPRESSION IN DEVELOPING CHICK CILIARY GANGLION NEURONS. M.H.Jacob. Word Fnd. for Exp. Biol., Shrewsbury, MA 01545.

Innervation has been proposed to play a role

Innervation has been proposed to play a role in the induction of acetylcholine receptor (AChR) expression in neurons. I have used an anti-AChR mAb and immunolabeling at the ultrastructural level to compare the levels of AChRs in chick ciliary ganglion neurons before and after the establishment of innervation. Using immunolabeling with an anti-synaptic vesicle protein mAb, embryonic day 4.5 (St.24) was established as the earliest time at which synapses could be detected in the ganglion. In older neurons that are innervated, AChRs are present in both surface and internal pools. In embryonic day 4.5 neurons, AChRs are present in the rough endoplasmic reticulum, in the nuclear envelope, in the postsynaptic membrane and occasionally in small patches of extrasynaptic membrane. Before innervation, in embryonic day 4 (St 23) neurons, no AChRs can be detected on the surface and little to no AChRs appear to be present intracellularly. Preliminary results suggest that AChR levels are dramatically reduced in neurons developing in the absence of innervation. The results suggest that regulatory signals from presynaptic inputs cause a large increase in AChR expression in neurons.

9.

EVIDENCE THAT FUNCTIONAL NEURONAL NICOTINIC ACHRS HAVE PENTAMERIC STRUCTURES. E. Cooper. Dept. of Physiol. McGill Un. Montreal, Que. H3G 1Y6

Several lines of evidence suggest that nAChRs on neurons can be made up of only two separate subunits: an a (ligand-binding) subunit and a non-a (B) subunit. However, their stoichiometric arrangement is not known. There are data suggesting that there are 2 a subunits in the functional receptor. Our experiments assess the number of non-a subunits. Experiments were done on outside-out patches from cocyte membranes 2-5 days after co-injecting cDNAs for chick a4 and non-a1 into the oocytes' nuclei. To determine the number of non-a subunits, we first mutated non-a1 at residue 260: the wild type lysine was changed to glutamic acid (referred to as na1E260). This single residue change increased the conductance from 21pS for the wild type a4/na1 receptor to 37.5pS for the mutant a4/na1E260 receptor. Co-injection of na1 and na1E260 together with a4 resulted in patches containing 4 classes of receptors based on conductance: wild type(a4/na1)-21pS; mutant type(a4/na1-E260)-37.5pS; and 2 intermediate conductance receptors, one 26pS and the other 31pS. Our interpretation is that the 26pS channel is made up of 2 wild type na1 subunits and 1 na1E260, and the 31pS channnel is made up of 1 na1 and 2 na1E260 subunits. Therefore, we conclude that functional a4/na1 receptors are pentameric structures containing 2 a subunits and 3 non-a subunits. (I am sincerely gratefully to Dr. M. Ballivet for providing the cDNAs.)

MOLECULAR CLONING AND EXPRESSION OF HUMAN NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNITS. Norman Nash, David Gdula, David Weiner, Mark Brann, and Tom Stormann. LMB/NINDS, Bldg., 36, Rm 3D-02, Bethesda, MD 20892 and Receptor Genetics, Inc..

Bethesda, MD 20892 and Receptor Genetics, Inc...

Molecular cloning efforts have identifed seven rat cDNAs encoding subunits of neuronal nicotinic acetylcholine receptors (nAChRs). Coexpression of the α2, α3, οτ α4 subunits with the β2 οτ β4 subunits in frog oocytes gives rise to six functional nAChRs (Duvoisin et al, Neuron 1989). We have cloned the corresponding human cDNAs as a first step in developing model systems for screening drugs acting on human neuronal nAChR subtypes. Human retinal, cerebral cortical and hippocampal cDNA libraries were screened with oligonucleotide probes derived from the rat cDNA sequences. We have isolated cDNAs encoding the human α2, α3, α4, β2, and β4 subunits. Sequence analysis of these clones has demonstrated that the extracellular and transmembrane domains of the subunits are well conserved between rat and human, while the cytoplasmic domains exhibit much less conservation. The pharmacological profiles of the cloned receptor subtypes have been evaluated in transformed cells. We have found that κ-bungarotoxin binds to cells cotransfected with α3β2 but not to cells transfected with either of the single subunits. Subtype selective probes are being used to localize mRNA in human brain, via in situ hybridization.

EFFECT OF FORSKOLIN ON THE DEGRADATION RATE OF NICOTINIC ACETYLCHOLINE RECEPTORS. S.-L. Shyng and M.M. Salpeter. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

The degradation rate of nicotinic acetylcholine receptors (AChR) in the neuromuscular junction (nmj) of mammalian skeletal muscles depends on the state of innervation. Two populations of junctional AChRs have been described; junctional AChRs synthesized and inserted in innervated muscles (original AChR), whose degradation rate accelerates and decelerates in response to denervation and reinnervation, and junctional AChRs inserted after denervation (new AChR), whose degradation rate does not respond to reinnervation. The present study deals with the regulation of the original AChRs and aims at understanding how the degradation rate of these AChRs can be modulated after they are in the plasma membrane. We used mouse diaphragm muscle in which the degradation half-life $(t_{1/2})$ is 9 days when innervated and accelerates to 2.5 days within a few days after denervation. We found that when these muscles are placed in organ culture the accelerated degradation rate can be decelerated by the addition of forskolin, a compound known to activate adenylate cyclase. By 4 days in 20 μM forskolin the degradation rate decelerated from a t_{1/2} of 2.3 days to one of 5.5 days. In 40 μM forskolin the switch occurred by 3 days and went to a $t_{1/2}$ of 8.5 days. The modulation effect of forskolin on the degradation of original AChRs is reversible. The decelerated degradation rate of original AChRs can be accelerated again by removing forskolin from the culture medium. Forskolin-1,9-dideoxy, a forskolin analog which does not increase the cAMP level, had no effect on the degradation of original AChRs. While the mechanism of post-insertion modification in AChR degradation rate by innervation is not yet understood, the present study suggests that this process might involve protein phosphorylation. Because of the delay in the action of forskolin, the effect of phosphorylation is probably indirect.

CARDIOVASCULAR REGULATION I

10.1

SITE AND MECHANISM OF THE SYMPATHOLYTIC ACTION OF 8-OH DPAT. R.B. McCall and M.E. Clement*. The Upjohn Co., Kalamazoo, MI 49001.

Previous studies indicate that the 5-HT1A agonist 8-OH DPAT acts centrally to inhibit sympathetic activity and lower arterial blood pressure. This study was designed to investigate the site and mechanism of the central sympatholytic action of 8-OH DPAT. The sympatholytic effect of 8-OH DPAT was not altered by mid-collicular transection or midline lesions of the pons and medulla. 8-OH DPAT inhibited the firing of medullospinal 5-HT neurons. However, the inhibition of 5-HT neuronal firing was not correlated with the inhibition of whole sympathetic nerve activity. Iontophoretic 8-OH DPAT failed to affect the firing of preganglionic neurons but blocked the excitatory effects of iontophoretic 5-HT. Intravenous 8-OH DPAT inhibited the firing of sympathoexcitatory (SE) neurons in the rostral ventrolateral medulla (RVLM). The inhibition of unit firing produced by 8-OH DPAT was exactly paralleled by the shutoff of inferior cardiac nerve activity. Iontophoretic 8-OH DPAT and 5-HT onto SE neurons in the RVLM failed to affect the firing rate of these neurons. These data suggest that 8-OH DPAT inhibits sympathetic activity in the lower brain stem by acting on central sympathetic neurons which lie antecedent to the RVLM SE neurons. Alternatively, 8-OH DPAT may act on distal dendrites of the RVLM SE neurons.

10.3

THE BED NUCLEUS OF THE TRANSTEGMENTAL TRACT: A MAJOR AUTONOMIC INTEGRATION CENTER OF THE MEDULLA OBLONGATA. D.J. Reis and D.A. Ruggiero Div. of Neurobiol., Comell Univ. Med. Coll., NY, NY 10021.

A field of the lateral medullary reticular formation, bridging the nucleus tractus solitarii (NTS) and premotor autonomic regions of ventral lateral medulla (VLM) is important in autonomic regulation. We sought to establish the relationship between this field and the projection between NTS and VLM, the transtegmental tract (TT). The TT can be visualized throughout the medulla following: (a) injection of WGA-HRP into NTS or VLM; (b) immunostaining for PNMT, choline acetyltransferase, or enkephalin; (c) labeling, with specific radioligands for cholinergic, angiotensin II, or NPY receptors. Embedded in TT are clusters of neurons forming a bed nucleus of the transtegmental tract (BNTT). Transport studies demonstrate that BNTT neurons: (a) interconnect dorsoventrally, rostrocaudally and, contralaterally; (b) are innervated by and project to autonomic nuclei of brain e.g. parabrachial, lateral hypothalamic, and visceral cortex; (c) contribute to the cervical vagus. The BNTT has distinctive functional domains: e.g. the vasodepressor area of caudal VLM (CVL) which innervates sympathoexcitatory neurons of rostral VLM (RVVL). The BNTT is a heretofore unrecognized nucleus of the medulla oblongata. It may serve as the principal intermeuronal network integrating cardiovascular, respiratory and endecrine responses to stimulation of visceral afference. as the principal interneuronal network integrating cardiovascular, respiratory and endocrine responses to stimulation of visceral afferents and centrally generated behaviors.

POSTNATAL MATURATION OF THE BAROREFLEX IN NEONATAL SWINE H.L. Cohen, P.M. Gootman, B.W. Hundley, G. Condemi* and L.P. Eberle*, Depts. Psychiatry and Physiology, SUNY, Health

Science Center Brooklyn, Brooklyn, New York 11203.

The baroreflex was examined in 13 piglets from <1 to 33 days age, lightly anesthestized with Saffan, paralyzed and artificially ventilated (100% 02). Simultaneous recordings of cervical sympathetic (GS) activity, aortic pressure (AoP) and EKG were made under control conditions and in response to bolus injections of Na nitroprusside (NP, 30 response to bolus injections of Na nitroprusside (NP, 30 ug/kg, iv) and phenylephrine (PE, 20 ug/kg, iv). Data analyses included correlation, repeated measures t tests and power spectral techniques. Resting AoP increased significantly with postnatal age but a decreasing trend in resting heart rate (HR) was not significant. CS periodicities ranged from 1-50 Hz. The baroreflex was present at birth. NP reduced AoP 34.2% and significantly increased (28.6%) the magnitude of the CS power spectrum. The correlation between postnatal age and the NP-induced increase in HR just missed attaining statistical significance at P<.059. PE increased AoP 28.0% and significantly reduced the magnitude (-24.8%) of the CS power spectrum. The correlation between postnatal age and the PE-induced decrease in HR was signficant at P < .05. The results demonstrate that the baroreflex can be elicited in neonatal piglets at birth, but its varied components differ in their rate of postnatal maturation. (Supported by NIH Grant #HL - 20864 to PMG).

10.4

THE DISTRIBUTION OF GLUTAMATERGIC NEURONS IN CENTRAL AUTONOMIC PATHWAYS. D.A. Ruggiero, M. Anwar, M.P. Meeley, T. Kaneko & D.J. Reis, Div. Neurobiol., Comell Univ. Med. Coll., NY, NY 10021.

L-glutamate (L-GLU) has been proposed as an excitatory neurotransmitter in a number of central autonomic pathways; however, the anatomical substrates for such glutamatergic neurotransmission have not been established. We, therefore, examined in adult Sprague-Dawley the anatomical substrates for such glutamatergic neurotransmission have not been established. We, therefore, examined in adult Sprague-Dawley rats the immunocytochemical distribution within central autonomic networks of a polyclonal antibody to L-GLU (courtesy of Drs. P. Petrusz and A. Rustioni) and a monoclonal antibody against the GLU-biosynthetic enzyme phosphate-activated glutaminase (PAG). GLU-like immunoreactivity (GLU-LI) was detected in four principal areas relating to autonomic sensory-motor integration: (1) Sites in nucleus tractus solitarii (NTS) receiving primary visceral afferents of IXth and Xth cranial nerves (e.g. dorsal strip, subpostremal-medial parvocellular n.) contained cells and fibers exhibiting GLU-LI. In NTS PAG-labeled processes were abundant but neurons sparse. (2) Second order projection fields of NTS, the lateral parabrachial n. and locus ceruleus contained cells and processes with GLU-LI and PAG. (3) Brainstem nuclei projecting to spinal preganglionic (rostral ventrolateral, rostral ventromedial, raphe and A5 cell groups) or respiratory motor nuclei (retroambigual n. of n. CVL) contained neurons expressing GLU-LI and/or PAG. (4) Forebrain areas projecting to sensory and visceromotor nuclei of medulla and spinal cord. GLU-LI and PAG were concentrated in perikarya and processes in paraventricular, supraoptic, arcuate and paraventricular hypothalamic n., amygdala and visceral (insular-medial-prefrontal) cortex. These findings add support to pharmacological and physiological evidence that L-GLU may act as a neurotransmitter at multiple sites within autonomic centers of brain and spinal cord.

NEUROANATOMICAL SUBSTRATES FOR FUNCTIONAL DIFFERENTIATION OF THE ROSTRAL VENTRAL MEDULLA. S. Aicher. M. Anwar. E.P. Mrui. D.J. Reis & D.A. Ruggiero. Div. of Neurobiol., Comell Univ. Med. Coll., NY, NY 10021.

The rostral ventral medulla contains two areas of importance in autonomic control: rostral ventrolateral reticular nucleus (RVL) and a poorly defined medial zone, the rostral ventral medial medulla (RVM). We sought to determine if these regions could be distinguished on the basis of their efferent projection fields. In anesthetized Sprague-Dawley rats (chloral hydrate, .5 g/kg i.p.), the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L) was iontophoresed (6 µA, 15 min, 7 s on/off) into RVL or RVM. After 14 days, rats were reanesthetized, perfused and tissue was processed immunocytochemically for PHA-L. Although there was overlap of some projection fields, topographically distinct patterns of projections characterized efferents of RVL and RVM at all levels of the neuraxis. RVL and RVM project by lateral and medial transtegmental tracts, respectively. RVL targets include: dorsal and ventral nucleus tractus solitarius (NTS), n. retroambiguus, locus coeruleus, external medial and lateral parabrachial n., midline thalamic n. (paraventricular), midline hypothalamic n. (paraventricular, arcuate). coeruleus, external medial and lateral parabrachial n., midline thalamic n. (paraventricular), midline hypothalamic n. (paraventricular, arcuate), medial preoptic n. and amygdala. RVM targets include: medial NTS, n. subcoeruleus, laterodorsal tegmental n., central gray, intralaminar thalamic n. (paracentral), dorsal hypothalamic n. and lateral preoptic n. In contrast to RVL, RVM deposits were distinguished by heavy transport to all spinal levels, including lumbosacral. Both sites project to the intermediolateral cell column of the cord. These distinct patterns of efferent projection fields may provide an anatomical basis for functional differentiation between lateral and medial sites in the rostral ventral medulla. ventral medulla.

PROJECTIONS THROUGH THE FASTIGIAL NUCLEUS (FN) AND THE FASTIGIAL PRESSOR RESPONSE (FPR). W.T.

Talman and S.C. Robertson*, Lab. of Neurobiology, VAMC & Univ. of Iowa, Iowa City, IA 52242

The FPR elicited by electrical stimulation of the FN likely results from stimulation of fibers of passage. We have sought to determine the poof passage. We have sought to determine the potential origin of those fibers. In 7 rats the retrograde tracer fast blue, which is transported by fibers of passage, was injected unilaterally into the FN at sites where stimulation elicited the FPR. Dense fluorescent labeling was found bilaterally in the external cuneate, lateral reticular, medial vestibular (MVN), and caudal prepositus hypoglossi nuclei (NPH), and contralaterally in the inferior olivary nucleus. Lesser cellular labelling was present elsewhere. As the NPH had not previously been shown to modulate arterial pressure (AP), we sought to det-As the NPH had not previously been shown to modulate arterial pressure (AP), we sought to determine if electrical or chemical stimulation of the NPH or the adjacent MVN alterred AP or heart rate in 6 anesthetized rats. Both types of stimuli to the caudal, but not the rostral, pole of the NPH or to the MVN produced an increase of AP; bradycardia accompanied the former and tachycardia the latter. Both the NPH and MVN may participate in the FPR and in regulation of AP.

10.9

CONTRASTING CARDIOVASCULAR EFFECTS OF MICROINJECTION OF ENDOTHELIN-1 AND -3 IN THE BRAINSTEM OF NORMOTENSIVE RATS. R. Mosqueda-Garcia, C. Beck, R.M. Robertson*, M. Appalsamy* and D. Robertson. Department Pharmacology and Medicine, Vanderbilt University, Nashville, TN 37232.

At least three isoforms of the 21 amino acid peptide, endothelin, have been described. Endothelin-3 (ET-3) differs from endothelin-1 (ET-1) by six amino acids, exerts more profound initial depressor responses and exhibits less potent constrictor activity both in vivo and in vitro. It has been suggested that ET-3 may be a neural form of endothelin. The purpose of this study was to investigate whether ET-3 and ET-1 differ in their cardiovascular effects after

investigate whether ET-3 and ET-1 differ in their cardiovascular effects after microinjection in specific brainstem nuclei.

Male Sprague-Dawley rats were anesthetized with urethane, and blood pressure (BP) was monitored intraarterially. Intramedullary microinjection (60 nl) of ET-1 or ET-3 (0.5, 1, 2, 4, and 6 pmol) was made into the nucleus of the solitary tract (NTS), or into the area postrema (AP). Site confirmation was done by histological procedures.

Lower doses of ET-3 into the NTS increased BP and HR, an effect which

peaked at 2 pmol (17 ± 3 mmHg, 14 ± 6 bpm, n=7). Maximal changes occurred peaked at 2 pmol (17 ± 3 mmHg, 14 ± 6 bpm, n=7). Maximal changes occurred within 45 seconds and recovered by 15 minutes. Higher doses of ET-3 modestly decreased BP and HR. In contrast, all the doses of ET-1 in the NTS evoked a hypotensive and bradycardic effect (0.5 pmol: -12 ± 4 mmHg, -48 ± 12 bpm, n=5). These effects were maximal between 5-8 minutes and recovered after 25 minutes. In the AP, ET-3 produced no change at the lowest dose but at higher doses, BP and HR fell in a dose-dependent manner. On the contrary, the lower doses of ET-1 in the AP decreased BP and HR, whereas higher doses produced no changes

These studies indicate that ET isoforms exert distinct cardiovascular effects in the brainstem of anesthetized rats and suggest the presence in these meduliary nuclei of more than one subtype of endothelin receptor.

AUTONOMIC REFLEX ARCS FROM THE NUCLEUS TRACTUS SOLITARII TO THE SPINAL CORD. E.P. Mtui, D.A. Ruggiero, M. Anwar*, S. Aicher, R. Gomez* and D.J. Reis. Div. of Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021.

Pathways subserving cardiopulmonary reflexes are believed to be indirect, involving projections from nucleus tractus solitarii (NTS) to reticulospinal neurons in ventrolateral medulla (VLM) that in turn innervate spinal respiratory and preganglionic motor nuclei. We sought to determine whether neurons of the NTS may directly innervate spinal autonomic neurons. Rats were anesthetized with chloral hydrate (0.5g/kg). Retrograde transport: WGA-HRP (2%) or rhodamine microbeads (50%) were microinjected into midcervical or upper thoracic cord. The ventral subnucleus of NTS (NTSv) from obex to spinomedullary junction contained: (a) a dense cluster of small horizontally-oriented neurons; (b) an array of larger diagonally-oriented neurons extending into adjacent n. reticularis dorsalis--a region within the bed nucleus of the transtegmental tract (BNTT) (Reis and Ruggiero, Neurosci. Abstr., 1990); Anterograde transport: Phaseolus lectin (PHA-L) was iontophoresed into loci of NTS containing retrogradely labeled neurons. PHA-L was transported to a diagonal sheet of axons and punctate varicosities radiating through the BNTT and VLM, descending through the lateral funiculus, terminating in laminae VII and X of the cervico-thoracic cord and innervating phrenic and intercostal motor nuclei and intermediolateral cell column. Neurons of NTS The second of th

ROSTRAL VENTROLATERAL MEDULLA (RVLM) AND SYMPATHORESPIRATORY INTEGRATION IN RATS. P.G.Guyenet, R.L.

Depts. of Pharmacology and Pediatrics, Univ. Virginia Sch. of Med., Charlottesville, VA 22908.

Phrenic nerve discharge- (PND-) triggered averages of the

lumbar sympathetic nerve discharge (LSND) were examined in vagotomized, paralyzed, ventilated, halothan-anesthetized rats. The respiratory modulation of LSND (LSNDrm) was on rats. The respiratory modulation of LSND (LSNDrm) was on average i) proportionnal to PND amplitude during CO2 inhalation and ii) attenuated by baroreceptor activation. Bilateral microinjections of kynurenate (2.25 nmoles/ side) into selected sites in the RVLM (N=8) produced central tachypnea, slight reductions in PND amplitude (33%), hypotension (15mmHg) and large reductions in LSNDrm (66%). Injections of bicuculline in the same area (0.22 hypotension (15mmHg) and large reductions in LSNDrm (66%). Injections of bicuculline in the same area (0.22 nmoles/side, N=5) produced bradypnea, hypertension (27mmHg), reductions in PND amplitude (33%), loss of baroreflex and increases in LSNDrm (40%). Strychnine injections into RVLM (0.225 nmoles/side, N=5) were ineffective as were kynurenate

or bicuculline injections into medullary raphe.

In conclusion, blockade of excitatory aminoacid or GABAa receptors in RVLM greatly modifies the coupling between central respiratory generator and sympathetic outflow. The results also indicate that baroreceptor- and CRG- related inputs to RVLM sympathetic premotoneurons are conveyed via largely independant routes. (Supported by NHLBI 28785 and 39841 to PGG).

AORTIC DEPRESSOR NERVE STIMULATION INFLUENCES AREA POSTREMA NEURONS IN THE RAT. S. Papas and A.V. Ferguson. Queen's

University, Kingston, Ontario, Canada, K7L 3N6.
The area postrema (AP) is the most caudal of the circumventricular organs, and as such is highly vascularized and lacks a normal blood brain barrier. In the rat, the AP is a midline structure overlying the nucleus tractus solitarius, at the level of the obex of the fourth ventricle. Although classically thought of as the chemoreceptor in the emetic reflex, the AP has also been attributed with various non-emetic roles, particularly in cardiovascular regulation. Previous studies have demonstrated the existance of neurons in the rat AP which are influenced by increases in blood pressure induced by systemic adrenergic agonists (Papas et al., 1990). The effects of these agonists on neuronal activity may be mediated by adrenergic receptors or, via the baroreceptors.

Electrophysiological experiments have now been done to determine if AP neurons receive input from the baroreceptors. In the rat, the aortic depressor nerve (ADN) carries mainly afferent barorecptor information. Thus, bipolar stimulating electrodes were positioned on either the left or right ADN of anaesthetized Sprague Dawley rats and single unit activity was recorded in the AP. Peristimulus histograms were used to examine the initial effects of ADN stimulation on 17 AP neurons. Thirteen (76%) of the AP cells were excited (Latency 28 ± 0.5 msec, Duration 12 ± 0.4 msec) by stimulation of an ADN. The remaining 24% of neurons were not influenced. These findings suggest that rat AP neurons receive afferent information from the baroreceptors and further support the view that the AP may act as a central

regulator of the cardiovascular system.

ADRENO SYMPATHETICALLY - MEDIATED HEMODYNAMIC EFFECTS OF AREA POSTREMA STIMULATION. D.K. Hartle and A.S. Soliman. Dept. of Pharm. and Toxicology, Univ. of GA, Athens, GA 30602.

Blood pressure, heart rate, and regional blood flow in renal, superior mesenteric and hindlimb vascular beds was monitored while graduating electrical frequency during area postrema (AP) stimulation (0-60Hz, 40µA). Blood flows were monitored by Doppler flowmetric techniques. Two groups of Blood flows were monitored by Doppler flowmetric techniques. Two groups of pentobarbital-anesthetized Sprague-Dawley male rats were tested 1) adrenals intact:CON, 2) acutely adrenalectomized:ADX. AP stimulation increased mean arterial pressure in a frequency-dependent manner in CON, but caused decreases in MAP in ADX. Renal and mesenteric beds actively constricted in CON, but remained passive in ADX. Renal and mesenteric blood flow decreased significantly in both groups. Hindlimb flow increased markedly in CON, but remained unchanged in ADX. Hindlimb resistance decreased displications with the beth CON and ADX. Hindlimb resistance decreased significantly in both CON and ADX. Heart rate was not affected by AP stimulation in either group. We conclude that AP stimulation in CON powerfully augments sympathetic outflow to adrenals causing catecholamine release that produces hindlimb vasodilation and constriction of renal and mesenteric beds. In ADX the overriding effect of massive adrenal catecholamine secretion is eliminated and depression of sympathetic vasomotor efferent activity is unmasked. Renal and mesenteric circulations are rendered passive to blood pressure changes, while hindquarter resistance decreases due to relief of sympathetic tone, which is high in the pentobarbital anesthetized animal. We propose that AP stimulation simultaneously activates both a powerful adrenosympathetic efferent system and a sympathetic vasomotor withdrawal system. A ADX unmasks the sympathetic depressor component.

CARDIOVASCULAR EFFECTS OF MICROINJECTION OF ANGIOTENSIN III IN RAT BRAINSTEM NUCLEI. C.J. Tseng, L.L. Chou* and C.S. Tung*. Department of Pharmacology, National Defense Medical Center, Taipel, Taiwan, Republic of China.

Angiotensin III (AIII) had been reported to be

an equipotent vasoconstrictor as compared to AII. In this study, we investigated the cardiovascular effects of microinjection of AIII into the cerebral ventricle (i.c.v.), the area postrema (AP), and nucleus tractus solitarii (NTS). Male Sprague Dawley rats were anesthetized with urethane and placed in a stereotaxic frame. The animals were prepared for i.c.v. infusion or exposure of the dorsal medulla for intra-AP and NTS administration of AIII. A dose-dependent pressor and brady-cardic effect of AIII was observed in the i.c.v. injection as previously reported. However, a dose dependent depressor and bradycardic effects were noticed when low doses of AIII were microinjected noticed when low doses of AIII were microinjected into both AP and NTS, and the maximal effect was found in 10 ng. As the doses increased to 100 and 500 ng, a pressor and bradycardic effect was found. These depressor and pressor effects of AIII can be blocked by the selective AIII antagonist, Ile⁷-AIII. These results suggest that the cardiovascular role of AIII in the brainstem nuclei need further characterization.

DRUGS OF ABUSE: COCAINE

11.1

DAILY COCAINE TREATMENT REDUCES [3H]DOPAMINE UPTAKE IN VITRO IN RAT NUCLEUS ACCUMBENS BUT NOT IN STRIATUM. S. Izenwasser and B.M. Cox. Department of Pharmacology, Uniformed Services University, 4301 Jones Bridge Road, Bethesda, MD 20814-4799.

Male rats were treated daily with cocaine hydrochloride (15 mg/kg ip x 3 days), a regimen which leads to sensitization to the locomotor stimulating effects of cocaine. There was a decrease in [3H]dopamine (15 nM) uptake in chopped rat nucleus accumbens tissue with no change in the striatum when uptake was measured 24 hours after the last injection. The Km for dopamine uptake was increased in the nucleus accumbens of cocaine-treated rats while the V_{max} was unchanged. Furthermore, cocaine more potently inhibited the in vitro uptake of [3H]dopamine in the nucleus accumbens of rats treated with cocaine than in those which had received saline. The IC50s for cocaine in the nucleus accumbens of animals treated with either cocaine or saline were 20 nM and 400 nM, respectively, and in the striatum 400 nM for both treatment groups. There were not, however, any differences in the KD or Bmax for binding of [3H]GBR 12935 to the uptake site in either the nucleus accumbens or striatum. In contrast to the effects seen after three injections, twenty-four hours after a single injection of 15 mg/kg cocaine there was no change in either the amount of [3H]dopamine uptake or in the potency of cocaine for inhibiting uptake in either brain region. (Supported by a grant from NIDA).

EFFECTS OF COCAINE ON SOMATODENDRITIC DOPAMINE AND SEROTONIN RELEASE IN VENTRAL TEGMENTUM:IN VIVO VOLT AMMETRIC STUDIES. Patricia A. Broderick and Frank T. Phelan* Dept. Pharmacol., CUNY Med. Sch., Depts. Biol. & Psychol., CUNY Grad. Sch., Convent Ave. & W. 138th St., Rm. J910, NY, NY, 10031.

Evidence has accumulated on cocaine mechanisms in neuronal circuitry, which points to the presynapse (Goeders, N.E. and Smith, J.E., Pharmacol. Biochem. Behav., 25:191, 1986) and the mesolimbic area (Roberts, D.C.S. and Koob, G.F., Pharmacol. Biochem. Behav., 17:901, 1982) as a fundamental target. In vivo electrochemical (ELC) studies were done with stearate electrodes. Fabrication and conditioning are described in detail in Broderick, P.A., Brain Res., 495(1):115, 1989. Indicator electrodes were stereotaxically implanted in ventral tegmentum of chloral hydrate anesthetized rats. Ag/AgCl reference electrodes and stainless steel auxiliary electrodes were placed in contact with the cortex. The results showed that cocaine (20 mg/kg sc) decreased ventral tegmental dopamine release in the first hour after drug administration. The signal returned to basal values during the second and third hour. Serotonin release, on the other hand, progressively decreased, an effect consistent with enhanced brain reward. Taken together with freely moving animal data, which showed increased dopamine release in brain reward substrates (Phelan, F.T. and Broderick, P.A., Soc. Neurosci, Abstr., 15:1234, 1989), cocaine may have direct as well as indirect acting dopaminergic agonist properties in brain reward neuronal circuitry. Supp: DHHS, NIDA R01 DA04755-01 A2 and PSC/CUNY Res. Award 669201 to P.A. Broderick.

PHOTOAFFINITY LABELING OF THE DOPAMINE REUPTAKE CARRIER PROTEIN USING A NOVEL HIGH AFFINITY AZIDO DERIVATIVE OF GBR-12935. P.Berger¹.R.Martenson¹*.P.Laing¹*.A.Thurcauf²*.B.DeCosta²*.K.C.Rice²*.S.M.Paul¹. ¹Sect. of Mol. Pharm.. NSB. NIMH; ²Lab. of Chem., NIADDK, NIMH, Beth., MD. 20892. In order to develop a photoaffinity probe for the dopamine reuptake carrier protein, a tritiated (Sp. Act 41.8 Ci/mmol) azido derivative of the dopamine reuptake inhibitor, GBR-12935 has been synthesized. Like [3H] GBR-12935 binding, reversible [3H] azido GBR-12935 binding displays complete sodium dependance, and there is a good correlation between the ability of a series of drugs in inhibiting the specific binding of both azido GBR-12935 and [H] GBR-12935 and reuptake of dopamine into synaptosomes. Incubation of striatal (but not cerebellar) membranes with [3H] azido GBR-12935 followed by UV irradiation leads to its covalent incorporation UV into a protein of Mr = 80,000 as assessed by autoradiography following SDS-PAGE. Photo labeling of this Mr = 80,000 polypeptide is sodium dependent, and blocked rollowing SDS-PAGE. Proto labeling of this Mr = 80,000 polypeptide is sodium dependent, and blocked stereospecifically by (-) but not (+) cocaine. Dopamine (but not serotonin or norepinephrine) reuptake inhibitors also blocked photolabeling. Following WGA lectin chromatography the Mr = 80,000 peptide was detected exclusively in the NAG eluent, indicating that it is highly glycosylated. Purification of the photolabeled dopamine reuptake carries protein using gel, lectin ad HPLC is in progress.

EFFECTS OF REPEATED COCAINE INJECTIONS ON D1 AND D2 BINDING SITES AND DOPAMINE REUPTAKE SITES IN RHESUS MONKEY CAUDATE. G.M. Farfel, M.S. Kleven, B.D. Perry, W.L. Woolverton and L.S.

SITES AND DOPAMINE REUPTAKE SITES IN RHESUS MONKEY CAUDATE. G.M. Farfel, M.S. Kleven, B.D. Perry, W.L. Woolverton and L.S. Seiden. Departments of Psychiatry and Pharmacological & Physiological Sciences, The University of Chicago, Chicago, IL. 60637.

In previous studies we have shown that repeated administration of coaine to rats causes long-lasting decreases in D1 binding sites and transient decreases in D2 binding sites in striatum (Kleven, et al., Brain Res., in press). Evidence of cocaine-induced changes in DA reuptake sites is equivocal. To assess the species generality of these findings, rhesus monkeys were administered either saline (n=4) or cocaine HCl (n=5; 3-4 mg/kg) i.m., q.i.d. for 14 days. One animal did not survive the drug regimen, and the remaining animals were sacrificed 2 wks after the last injection. [125 i] SCH 23982, [3H] spiperone and [3H] GBR 12935 saturation studies were used to label D1, D2 and dopamine (DA) reuptake sites, respectively, in caudate nucleus. The densities of the D1 and DA reuptake binding sites in cocaine-treated animals were significantly decreased (52 ± 13% and 17 ± 19% of control, respectively). There was a small decrease in D2 receptor binding in treated animals (B_{max} = 76% of control, .10-p > .05). Repeated cocaine did not after the affinity (K_d) of any of the ligands for the binding sites. Analysis of neurotransmitter levels using HPLC-EC showed no significant differences between groups in levels of DA, 5-HT and 5-HIAA. Levels of DOPAC and HVA tended to increase, but the effects were not statistically significant. These results indicate that repeated administration of high doses of cocaine has long-lasting effects on both pre- and post-synaptic elements of the caudate dopamineroic synapse (Signorded by high doses of cocaine has long-lasting effects on both pre- and post-synaptic elements of the caudate dopaminergic synapse. (Supported by DA-00085 and The Brain Research Foundation of the University of Chicago.)

[*H]CFT AND [*H]LU 19-005: MARKERS FOR COCAINE RECEPTORS/ DOPAMINE NERVE TERMINALS IN PARKINSON'S DISEASE.

B.K. Madras, M.A. Fahey*, M.J. Kaufman. Harvard Medical
School, New England Regional Primate Research Center,

Southborough, MA 01772.
[3H]CFT (WIN 35,428) and [3H]Lu 19-005 [(±)-(trans)-3-(3',4'-dichlorophenyl)-N-methyl-1-indanamine] bind to cocaine sites associated with the dopamine uptake system in caudate-putamen of monkey brain. The utility of [3H]CFT and [3H]Lu 19-005 as markers for dopamine nerve terminals was evaluated in membranes prepared from human putamen of control and Parkinsonian brains. Tissue homogenates were incubated with [3H]CFT (0.5 nM) alone or with either mazindol (3 µM) or (-)-cocaine (30 µM) to measure non-specific binding. Levels of bound [3H]CFT and [3H]Lu 19-005 were comparable to those in monkey caudateputamen. In putamen of Parkinsonian brains, binding of both radioligands was markedly reduced. Autoradiographic studies in striatal sections of control and Parkinsonian brains confirmed the depletion of [3H]CFT (5 nM) binding sites in the putamen of Parkinsonian brains. Low levels of binding were retained in the caudate nucleus, paralleling the progression of dopamine depletion in Parkinson's disease. The results suggest that markers for cocaine receptors/dopamine nerve terminals in the striatum and may have diagnostic utility. (Supported by USPHS Grants DA06303, DA00499, and RR00168)

COCAETHYLENE BINDING TO NEUROTRANSMITTER RECEPTORS COCAETHYLENE BINDING TO NEUROTRANSMITTER RECEPTORS
AND UPTAKE SITES IN THE HUMAN BRAIN. D. C. Mash, D. D. Flynn,
C.V. Wetli*, and W. Lee Hearn, Departments of Neurology,
Pharmacology and Pathology and the Comprehensive Drug Research
Center, University of Miami School of Medicine and the Metropolitan Dade County Medical Examiner Department, Miami, FL. 33136

Recreational use of cocaine and alcohol is a common practice, with users reporting an enhanced euphoria. Concurrent cocaine and alcoholic beverage use results in the formation of cocaethylene, the ethyl homologue of cocaine (Rafla, F.K. and Epstein, R.L., J. Anal. Toxicol. 3:59-63, 1979). Cocaethylene has been measured in significant amounts in blood and urine. We have demonstrated the presence of cocaethylene in the human brain post mortem from cocaine-related sudden death cases. The reinforcing property of cocaine is attributed to its ability to block the reuptake of dopamine. We report here that cocaethylene is equipotent to cocaine in inhibiting [³H]-mazindol binding to dopamine transporters. Cocaethylene inhibited [3H]-mazindol binding in human striatal membranes with a Ki of 0.64 µM. Cocaethylene was ineffective in displacing [3H]-raclopride and [³H]-SCH23390 binding to dopaminergic receptor subtypes. Competition studies further demonstrate that unlike benzoylecgonine, cocaethylene has a relatively high affinity for muscarinic and putative sigma receptors. Brain concentrations of cocaethylene are in the same range as cocaine levels seen in cases of preterminal excited delerium and sudden death. Taken together, these results suggest that cocaethylene is a neuroactive metabolite of cocaine. The accumulation of cocaethylene in the central nervous system may contribute to the spectrum and incidence of neurologic and psychiatric complications associated with combined cocaine and alcohol abuse. Supported by a grant from NIDA (DA 06227).

Cocaine Abuse in Schizophrenia: Effects on Symptoms and Hospital

John Seibyl MD, Sally Satel MD, Dominic Anthony MSW, Steven Southwick MD, Rajani Nadkami MD, John Krystal MD, Malcom Bowers MD*, and Demnis Charney MD Yale University School of Medicine and Psychiatry Service, West Haven Department of Veterans Affairs Medical Center, West Haven, CT 06516

Cocaine produces profound effects on brain monoamine systems which may be clinically important in schizophrenia including the expression of positive symptoms, negative symptoms, and acute and chronic extrapyramidal side effects. While prevalence of ocaine abuse in schizophrenics is reported to be high, the impact of cocaine abuse in schizophrenia is poorly understood. Methods: Inpatient charts were obtained for every fourth patient from the roster of schizophrenia treated in the Schizophrenia Clinic of the West Haven VA Medical Center. Individual hospitalizations were analyzed for substances used and psychosocial functioning prior to hospitalization, presenting symptoms on admission, inpatient clinical management, course of pharmacotherapy, and duration of hospitalization. Results: Overall prevalence of history of occaine use was 21%, other substance abuse 35% no history of substance abuse 34%, and10% undetermined. Cocaine-abusing schizophrenics (N=16) had greater frequency of hospitalizations compared with non-occaine using substance abusing (N=22) and non-substance abusing patients (N=20). Within the cocaine group there was increased suicidality and depressive symptoms after cocaine use. Symptoms of paranoia and psychomotor agitation were not different in patients presenting after cocaine use compared to their non-occaine admissions. Cocaine hospitalizations required markedly higher antipsychotic doses. Overall, the cocaine cohort exhibited higher rates of unemployment and legal problems than non-substance using patients. Comment: Cocaine use has significant effects on the course of hospitalization in schizophrenics, including neuroleptic dose. Cocaine produces profound effects on brain monoamine systems which

COCAINE AND COCAETHYLENE CONCENTRATIONS IN HUMAN POST MORTEM CEREBRAL CORTEX. S. Rose*, W. Lee Hearn, G. W. Hime*, C.V. Wetli* A. J. Ruttenber* and D. C. Mash. Comprehensive Drug Research Center and Depts. of Neurology and Pathology, University of Miami School of Medicine and the Metropolitan Dade County Medical Examiner Dept., Miami, FL. 33101 and the Center for Environmental Health, CDC, Atlanta, GA. 30333

Recreational cocaine use is frequently accompanied by the consumption of alcoholic beverages. When ethyl alcohol is present, cocaethylene is detected in the urine as a cocaine metabolite. We report here that significant concentrations of cocaethylene are detected in neurological specimens from cocaine-related sudden death cases. Cocaine and cocaethylene were isolated from the cerebral cortex using a liquid-liquid extraction technique with propylbenzoylecgonine as an internal standard. Quantitative analysis of cocaine and its homologue, cocaethylene, was performed using capillary column gas chromatography with nitrogen specific detection. In the cocaine-related sudden death cases, cocaine concentrations ranged in the cerebral cortex from 0.2 to 20 mg/kg. Cocaethylene was detected in significant concentrations in the cerebral cortex in five out of seven cases which had detectable levels of blood cortex in five out of seven cases which had detectable levels of blood alcohol at the time of autopsy. The blood alcohol levels for these cases ranged from 0.01 to 0.3 %. The average cocaethylene concentration measured in brain was 0.3 mg/kg. Studies are currently underway to characterize the pharmacological profile of cocaethylene at neurotransmitter receptors and uptake sites in the human brain. Epidemiological studies of cocaine-related fatalities in Dade County indicate that the combined use of cocaine and ethanol confers an eighteenfold greater risk of sudden death. NIDA grant (DA 06227).

BRAIN GLUCOSE METABOLISM IN COCAINE DEPENDENCE AND

WITHDRAWAL N.D. Volkow, J. S. Fowler, A. P. Wolf, R. Hitzemann, J. Logan, D. Schlyer, S. Dewey, B. Bendriem, Brookhaven National Laboratory, Upton NY 11973.

To investigate changes in brain function associated with cocaine dependence we measured brain glucose metabolism with 2-deoxy-2-[18] fluoro-D-glucose and metabolism with 2-deoxy-2-[NF]fluoro-D-glucose and positron emission tomography in 15 cocaine abusers and 17 normal controls. Patients studied during early withdrawal (< 1 week off cocaine) had significantly higher metabolic rates (ANOVA p \leq .05) in the basal ganglia (BG) (8.1 \pm 0.4 mg/1000/min) and in the orbital frontal cortex (OFC) (7.5 \pm .05) than normals (BG = .7.3 \pm 0.9 OFC = 6.3 \pm .03) or patients studied during late withdrawal (2-4 weeks off cocaine) (BG 7.4 \pm .05 OFC = 6.1 \pm 0.5). The increased metabolic activity in OFC and BG was temporary and was not significantly different BG was temporary and was not significantly different from that seen in normals 2 weeks after cocaine withdrawal. The dependence of these metabolic changes to the time of cocaine withdrawal was tested with regression analyses which revealed a significant relationship between time "off" cocaine and regional brain metabolism in OFC ($r^2 = .517 p \le .003$) and BG ($r^2 = .389 p \le .02$). The OFC and the BG are part of a brain circuit that regulates initiation and termination of behavior. Its temporary dysfunction in the cocaine abuser could explain the compulsive and episodic pattern of cocaine abuse.

WHOLE BODY BINDING AND DISTRIBUTION OF COCAINE

WHOLE BODY BINDING AND DISTRIBUTION OF COCAINE.

P. Som*, Z.H. Oster*, N.D. Volkow, D.F. Sacker*, K.

Maldonado* and D.A. Weber*. Medical Department,

Brookhaven National Laboratory, Upton, NY, 11973.

Whole body distribution of cocaine in the Fischer rat

was investigated using carboxy ¹⁴C benzoyl cocaine (*C) in

conjunction with whole body autoradiography at different

times after *C injection (2,4,6,10,15,30 minutes).

Three stages of *C distribution were observed: 1) very Three stages of *C distribution were observed: 1) very fast initial localization in the brain, spinal cord, heart and adrenals (2-5 min), 2) gradual accumulation in the kidneys and liver (5-10 min), 3) excretion into the urine and bowel (15-20 min).

Characterization of cocaine binding was investigated using specific blocking agents; GBR to block the dopamine (DA) transporter and designamine (DESP) to block the norepinephrine/serotonin (NE/SE) transporter.

In the brain binding of *C was not affected by DESP,

and was decreased by GBR pretreatment suggesting that cocaine binds (in the basal ganglia and cortex) to a site associated with the DA transporter. Binding of cocaine in the heart and kidney was decreased by DESP pretrement. Binding of *C to brain, heart, liver and kidneys could account for some of the toxic effects of cocaine on these organs.

CARDIOVASCULAR (CV) EFFECTS OF NONCONTINGENT COCAINE (C) ADMINISTRATION. TL Smith*, MF Callahan, DC Williams*, SI Dworkin. Dept. Physiol./Pharmacol., Bowman Gray Sch. Med., Winston-Salem, NC 27103.

The CV responses to intravenous C (0.33 mg) in conscious, F344, male rats (291 +/- 20 g, n=6) were evaluated. Rats were instrumented with arterial and venous catheters and EKG electrodes 1-4 weeks prior to study. Three infusions of C were given at either 5 min. or 2hrs. interinfusion intervals (II). Baseline mean arterial pressure (MAP) was 99.3 +/- 2.1 mmHg and heart rate (HR) was 365 +/- 14.1 beats/ min.. C elicited a 52.3 +/- 3.4 mmHg MAP increase and a 15 +/-11.5 beat/min bradycardia. The third dose of C, 10 min later, increased MAP only 7.8 mmHg and decreased HR 43 +/- 8 beats/ min... Greater than 50% of the animals exhibited arrhythmias following C, and a majority demonstrated a prolongation of the QRS complex. At 2 hr. II, MAP & HR changes elicited by the first C dose were a 60.3 +/- 5.7 mmHg increase and a 38 +/-8 beat/ min. decrease. Changes elicited by the second C dose were not different from the first. The final C dose produced a significantly lower MAP elevation from the first (48.3 +/- 10.8 mmHg) although the HR change was not different. Significant tachyphylaxis, at least in MAP responses, occurs with 5 min. II, and, to a lesser degree with 2 hr. II. Interinfusion interval is therefore very important when evaluating the CV effects of intravenous C. DA03628

ALZHEIMER'S DISEASE: AMYLOID I

12.1

AMYLOID NEUROTOXICITY I: MOLECULAR DETERMINANTS. B. A. Yankner and M. Chen. Dept. of Neurology, Harvard Medical School and The Children's Hospital, Boston, MA 02115.

We have shown that a fragment of the amyloid precursor protein (APP), containing the carboxyterminal 106 amino acids, is neurotoxic (Yankner et al., 1989, Science 245:417). The APP sequences necessary for the neurotoxic effect have been examined using purified amyloid-containing proteins with different carboxyterminal extents of APP. The critical carboxyterminal APP sequence has been determined. Aminoterminal regions were inactive. The secreted form of APP was also purified from the conditioned medium of PC12 cells by heparin-sepharose and DEAE chromatography and immunoprecipitation. Purified secreted APP was identified as a 120-125K band on siver-stained SDS gels which could be immunoprecipitated by antibodies against the amino-terminus or Kunitz protease inhibitor domains of APP but not by an antibody against the carboxyterminus. Secreted APP showed a neurotrophic effect on hippocampal neurons but did not show the neurotoxic effect observed with carboxyterminal APP proteins. Our results suggest the possibility that altered patterns of APP processing in Alzheimer's disease can generate neurotoxic amyloid proteins.

12.3

IMMUNOHISTOCHEMICAL LOCALIZATION OF THE ALZHEIMER AMYLOID PRECURSOR PROTEINS CONTAINING THE KUNITZ-PROTEASE INHIBITOR DOMAIN IN ALZHEIMER'S DISEASE.

B.T. Hyman. R. Tanzi. K. Marzloff and D. Schenk, Dept. of Neurology & Neuroscience, Massachusetts General Hosp, Harvard Medical School, Boston, MA 02114 & Athena Neurosciences, So. San Francisco, CA 94080 Senile plaques (SP) of Alzheimer's disease (AD) contain a core of an

Senile plaques (SP) of Alzheimer's disease (AD) contain a core of an amyloid peptide (A4), surrounded by dystrophic neurities. 3 major forms of the A4 precursor protein (APP) are transmembrane proteins of 695, 751, and 770 amino acids. The longer two contain an insert that shares substantial homology with the Kunitz-type serine protease inhibitors (KPI). The KPI forms of APP are relatively preserved in AD brain by Northern analysis, but whether they contribute to SP or tangles (NFT)is unknown. We examined the hippocampal formation in 4 AD and 4 normal control cases using thioflavin S, anti-A4, and anti-KPI domain immunocytochemistry. Tissue was fixed in PLP for 24 hrs, cryoprotected and cut in 50 µ sections. In AD, thioflavin S and anti-A4 showed SP consistently in the molecular layer of the dentate gyrus, in stratum radiatum of CA1, and in the pyramidal and molecular layers of the subiculum. Occasional "tombstone" NFT were also evident. Anti-KPI staining was sensitive to fixation conditions, and diminished with stronger or prolonged exposure to formaldehyde. SP's contain definite anti-KPI staining in the neurites and, to a lesser extent, in the core. As compared to thioS or anti-A4, these SP are a minority of total plaques. Many neurons stained strongly with anti-KPI in both AD and controls. Both neurons that develop NFT (CA1) and those that are less likely to (dentate gyrus granule cells) are strongly stained. These results suggest that the KPI forms of APP are found in neurons and are incorportated into SP. We thank Dr. C. Masters, Melbourne, Australia, for the gift of anti-A4 antisera, the Mass. ADRC tissue bank (Drs. E.T. Hedley-Whyte, N. Kowall and A. McKee) and NIH grant AG08487.

12.2

AMYLOID NEUROTOXICITY II: NEURONAL SPECIFICTY AND PATHOLOGICAL CHANGES. M. Chen and B. A. Yankner. Dept. of Neurology, Harvard Medical School and The Children's Hospital, Boston, MA 02115.

The specificity of amyloid toxicity has been examined on primary cultures from different regions of the central and peripheral nervous system. In primary cultures derived from rat E18 hippocampus or forebrain, neurons were selectively killed but glial cells were resistant. Amyloid neurotoxicity was also observed, but to a lesser extent, in cultures from the region of the medial basal forebrain and septum. Highly enriched cultures of cerebellar granule cells and dorsal root ganglion neurons, two neuronal populations which are unaffected in Alzheimer's disease, were resistant to the toxic effects of amyloid proteins. Addition of purified amyloid proteins to susceptible hippocampal pyramidal neurons resulted in a defined sequence of neurodegenerative changes over 48 hours. The earliest changes were observed in the neurites and were characterized by dendritic retraction and loss of axonal integrity followed by later degenerative changes in the cell body. Thus, amyloid neurotoxicity in culture recapitulates some aspects of the neuronal specificity and pathology observed in Alzheimer's

12.4

IMMINOLOCALIZATION OF AMYLOID P COMPONENT IN THE NEUROFIERILLARY PATHOLOGY OF ALZHEIMER AND OTHER NEURODEGENERATIVE DISEASES.

Pamela G. Galloway, George Perry and Rajesh N. Kalaria. Dept. of Pathology, Children's Hospital Medical Center, Akron, OH 44308, and Depts. of Neurology and Pathology, Case Western Reserve University, Cleveland, OH 44106.

Case Western Reserve University, Cleveland, OH 44106. Amyloid P component, (AP) is an α_1 -glycoprotein shown to be consistently present in all types of amyloid deposits. We investigated the extent of AP reactivity in the neurofibrillary pathology of Alzheimer (AD) and related neurodegenerative disorders. The PAP and immunogold cytochemical methods were used to reveal AP reactivity at the light and electron microscope levels. By light microscopy, heavy deposition of immunoperoxidase reaction product was seen in classical amyloidotic lesions of all cortical areas of AD cases examined. The distribution and intensity of staining in neurofibrillary tangles were similar to that of thioflavin S staining in serial sections. Plaques of revertzfeldt-Jakob disease and Down's syndrome, Pick bodies of a Pick's case and tangles in progressive supranuclear palsy were also stained. At the ultrastructural level, electron dense product was evident in extracellular amyloid fibrils, neuronal filaments and the vascular wall. These results provide evidence for localization of AP in intraneuronal abnormal filaments in addition to extracellular amyloidotic lesions. AP may be important to pathogenesis of neurofibrillary tangles and cerebral amyloidosis.

AMYLOID PRECURSOR PROTEIN IN DYSTROPHIC AXONS. B. Bacci*, E. Cochran*, B. Schaetzle*, S. Hite*, L. Sayre*, B.D. Greenberg, D.E. Lowery*, L. Autilio-Gambetti and P. Gambetti. Division of Neuropathology, Case Western Reserve University, Cleveland OH 44106 and The Upjohn Company, Kalamazoo, MI 49001.

Neuritic plaques of Alzheimer disease (AD) are characterized by ex-

tracellular amyloid deposits and dystrophic neurites which react with antibodies to ubiquitin (Ub) and amyloid precursor protein (APP). Administration of p-bromophenylacetylurea (BPAU) to rats induces the formation of dystrophic axons with accumulation of tubulovesicular structures which are labeled by antisera to Ub. We now report that these dystrophic axons immunostain with antisera to APP both at the light and electron microscopic level. Both APP and Ub epitopes are located in the membranes which fill the BPAU dystrophic axons. We also detected the presence of the inducible form of heat shock protein 70 and of PGP 9.5, a neuron-specific Ub carboxyl-terminal hydrolase that may be responsible for processing Ub conjugates. The present findings indicate that the dystrophic axons induced by BPAU share antigenic characteristics with dystrophic neurites of AD plaques and are a promising model to study the role of dystrophic axons in amyloid deposition. The presence of Ub and heat shock protein 70 along with APP in BPAU-induced dystrophic axons raises the question of whether the heat shock system is implicated in amyloid deposition. Similar findings have been obtained in axons from a case of human infantile neuroaxonal dystrophy, suggesting that APP may play a role in this familial human disease. Should this be the case, infantile neuroaxonal dystrophy would be the first non-amyloid human disease in which APP is involved. Supported by NIH grants AG 00795 and NS 14509.

12.7

INCREASED SYNTHESIS OF ALZHEIMER AMYLOID PRECURSOR PROTEIN IN THE CEREBRAL CORTICES OF RATS WITH LESIONED NUCLEUS BASALIS OF MEYNERT. W. Wallace, V.Bragin, N.K. Robakis, K.Sambamurti, K.L.Davis, and V. Haroutunian. Dept. Psychiatry and Center for Neurobiology, Mt. Sinai School of Medicine, New York, NY 10029

The nucleus basalis of Meynert was lesioned by administration of NMDA unilaterally in adult rat brain. Seven days postlesion we have observed that polysomes isolated from the cerebral cortex ipsilateral to the lesion synthesized 2.6-fold greater amounts of Alzheimer amyloid precursor protein (AAPP) compared to the nonlesioned side of the same brain. This increase exhibited specificity to AAPP in that overall protein synthesis, as either total 35S-polypeptides or translation products on two dimension gels, was not altered by the lesion. In addition, levels of newly synthesized glial fibrillary acidic protein were not different in the lesion samples. The increase of AAPP did not alter the predominance of the AAPP (695) isotype (which lacks the protease inhibitor insert) in the cortex. These observations indicate that compromise of the nucleus basalis results in the specific synthesis of cerebral cortical AAPP.

12.9

THE PROMOTER ACTIVITY OF THE GENE ENCODING ALZHEIMER'S B-AMYLOID PRECURSOR PROTEIN (APP) IS REGULATED BY TWO BLOCKS OF UPSTREAM SEQUENCES. D. K. Lahiri and N. Robakis. Mount Sinai Medical Center, One Gustave Levy Place, New York 10029 Sequence analysis of the B-amyloid promoter revealed sevral regulatory elements including five copies of the GGGGGC sequence, consensus sequences for the transcription factors Spl and AP-l, a heat shock element and a GC rich region characteristic of housekeeping genes. To determine the promoter sequence requirements for the expression of the APP gene, we constructed chimeric genes containing different parts of the APP gene promoter linked to the bacterial chloramphenicol acetyl transferase (CAT) gene. Sequences derived from the 5'-flanking region were then tested for their effects on B-amyloid promoter activity by transient CAT expression in PC12 and Hela cells. Two blocks of regulatory sequences were identified in the 5'-flanking region of the gene. One block extending from -447 bp to -597 bp acts as a positive regulator because its deletion results in a dramatic decrease in promoter activity. A second block of sequences extending from -197 bp to -397 bp acts like a negative regulator as their removal results in increase in promoter activity. A plasmid pAmylE was constructed by inserting 39 bps nucleotide sequence (from -450 to -489) in front of TK promoter of pBLCAT2 plasmid. When PC12 cells were transfected with pAmylE, the CAT activity was found to be five times more as compared to cell transfected with pBLCAT2. Thus the promoter sequence from -450 to -489 may act as a putative enhancer element. These results suggest that by imposing conformational constraints, these regulatory sequences might control the binding of trans-acting factor(s) on the APP gene promoter and thus modulate its expression. The identifica-

ANALYSIS OF NON-NEURAL DEPOSITION OF AMYLOID & PROTEIN IN ALZHEIMER'S DISEASE (AD) AND AGING. D. Selkoe, C. Lemere'H. Mori* and C. Joachim. Harvard Medical School, Brigham and Women's Hospital, Boston, MA 02115.

Growing evidence supports the hypothesis that deposition of the amyloid β protein (A β P) in amorphous, non-fibrillar forms is an early event in AD pathogenesis that may precede cellular pathology. Our recent finding of ASP-immun reactive deposits in certain non-neural tissues of AD and some aged subjects is consistent with this hypothesis. W have now extended this study to >60 human subjects and found that virtually all AD patients examined by skin biopsy showed vascular, perivascular and/or amorphous dermal deposits. About one-quarter of aged non-AD subjects examined to date also showed some amorphous dermal deposits, whereas virtually all non-aged (<63 yr) subjects showed no specific reactivity. Several patients with Down's syndrome and a member of an FAD pedigree linked to chromosome 2lq also showed non-neural ABP deposits. Antisera to native ABP detected the non-neural deposits more sensitively than synthetic $A\beta P$ antisera. Detailed analysis of the distribution of AD dermal staining reveals subepidermal, perivascular and periglandular deposits resembling the sites of cystatin C deposition in patients with Icelandic hereditary cerebrovascular amyloidosis. The discovery of microvessel-associated AβP reactivity in widespread non-neural tissues extends the parallels between AD and certain systemic amyloidoses known to be of circulating origin.

ALZHEIMER-TYPE AMYLOIDOGENESIS. A
TRANSGENIC MOUSE MODEL? B.D. Greenberg. S.M.
Ali* R.A. Altman* D.E. Lowery, P.K. Andrus* and H.G.
Polites* Molecular Biology Research, The Upjohn Company,
Kalamazoo, MI 49001.

The lack of an appropriate animal model is an ongoing
impediment to the development of treatments for Alzheimer's
Disease (AD). While the etiological role for amyloidogenesis in
AD remains unknown, transgenic mice expressing the
Alzheimer Amyloid Precursor (AAP) in appropriate brain
regions would provide a useful system for investigating the role
of AAP expression in Alzheimer-type amyloidogenesis, and the
role of amyloid formation in AD. To address these issues, we
are generating mouse lines transgenic for full length and
truncated variants of the AAP cDNA. These cDNAs have been
placed under the control of several promoter systems designed
to express AAP within neurons in brain regions corresponding
to those which are vulnerable in AD. 83 founder mice have
been born in our facility. We are analyzing their offspring by
in situ hybridization and standard histochemical staining,
During the course of our AAP expression work, we also
developed several highly specific antisera to recombinant AAP
which stain Congophilic and diffuse amyloid, as well as
apparent precursor within normal and degenerating neurites
and perikarya (Arai et al. (1990) PNAS 87: 2249; Cras et al.
(1990) Am. J. Pathol., submitted). We are applying these
antisera to brain sections from these mice to investigate
whether potentially incipient amyloidotic structures can be
visualized. We will report on these studies, and the nature of
the transgenic promoter systems employed.

12.10

EXPRESSION, PURIFICATION, AND CHARACTERIZATION OF THE ALZHEIMER'S AMYLOID PRECURSOR PRODUCED BY BACULOVIRUS. 'D.E. Lowery, 'P.A. Gonzalez-DeWhitt*, 'R.A. Altman*, 'P. Cras*, 'G. Perry and 'B.D. Greenberg. 'Molecular Biology Research, The Upjohn Company, Kalamazoo, MI 49001, and 'Dept. Pathology, Case Western Reserve Univ. Sch. of Med., Cleveland, OH 44106.

To facilitate studies on the role of the Alzheimer's Amyloid Precursor (AAP) in Alzheimer's Disease we have developed the baculovirus expression system (Luckow and Summers (1988) Biotechnology 6: 47) as a means of producing milligram quantities of AAP. Baculovirus expression vectors designed to produce secreted 695, 751 and 770 amino acid AAP forms were constructed and used to infect Sf9 cells. Purification of the resulting AAP from the conditioned media results in a >95% pure preparation of AAP. The recombinant AAP has been used to raise highly specific antisera (Cras et al. (1990) Am. J. Pathol., submitted) which stain Congophilic and diffuse amyloid, as well as apparent precursor within normal and degenerating neurites and perikarya. The 751 and 770 amino acid AAP forms are functional protease inhibitors and have been used to screen a variety of proteases. The final preparations of recombinant protein are also devoid of any detectable protease activity, making them ideal for studies on the proteolytic processing of AAP.

PLATELETS SECRETE AMYLOID β-PROTEIN PRECURSOR (APP). G.M. Cole. D. Galasko, I. P. Shapiro. and T. Saitoh, Dept. of Neurosciences, M-024, UCSD, School of Medicine, La Jolla, California, 92093

The extracellular B-protein deposited in Alzheimer's disease derives from a segment overlapping the membrane-spanning domain of a larger precursor integral membrane protein (APP). Mechanisms for the externalization of this $\beta\text{-protein}$ domain from cells remain hypothetical. Here, we show that human platelets stimulated with thrombin or ionomycin release membranous microparticles which contain ~110kD APP which is both N-terminal and C-terminal anti-APP immunoreactive implying that it contains the entire β-protein sequence. Platelet-derived microparticles are also found in human serum and plasma. This suggests a possible circulating source for β -protein in serum and plasma and a blebbing mechanism for externalization which could also occur in neurons. Stimulated platelets also release soluble, C-terminal truncated APP containing the Kunitz-type serine protease inhibitor domain (nexin II) which has been shown to inhibit part of the prothrombinase complex, Factor Xa. Thus, nexin II derived from platelets and other sources may play a role in regulating the coagulation cascade. This observation provides a potential biochemical connection between Alzheimer's and coronary vascular disease which have been epidemiologically linked.

DESIGN OF DIAGNOSTIC PROBES FOR ALZHEIMER'S BETA/A4 PEPTIDE. WE Klunk, RJ McClure, K Panchalingam and JW Pettegrew Laboratory of Neurophysics, Dept. of Psychiatry, Western Psych. Inst & Clinic, Univ. of Pittsburgh, Pittsburgh, PA 15261

Neuropathologically, two of the most characteristic features of Alzheimer's disease (AD) are senile plaques and neurofibrillary tangles. The protein core of the senile plaque is composed of a peptide termed the beta/A4 peptide. The neuropathologic quantification of plaques and tangles, usually done post-mortem. Here, work to design and synthesize probes to quantify the beta/A4 peptide before death is described. Congo red is a histologic dye which stains plaques and tangles. We have quantified the interaction of this dye, and similar compounds, with synthetic beta/A4. From this, computer models of the dye-peptide interaction have been developed. The peptide portion of this model is being further refined by two-dimensional NMR studies of the synthetic peptide. Using this data, compounds are being developed to cross the blood-brain barrier and bind specifically to the beta/A4 peptide. Quantification of fluorine labelled probes by in vivo NMR spectroscopy or positron emitting probes by PET could then form the basis of an antemortem diagnostic test for AD.

ISCHEMIA I

13.1

SUBCELLULAR MECHANISMS OF ISCHEMIC BRAIN DAMAGE DURING CARDIAC ARREST AND RESUSCITATION. G. Fiskum*, R. F. Chanderbhan*, L. L. Werling and R.E. Rosenthal*. Departments of Biochemistry and Molecular Biology, Emergency Medicine, and Pharmacology, George Washington University School of Medicine, Washington, D.C. 20037.

Membrane lipid degradation and peroxidation and mitochondrial respiratory damage are implicated in the irreversible cell injury that can occur during cerebral ischemia and reperfusion. In this study, mitochondria isolated from the parietal cortex of chloralose-anesthetized female beagles following 10 min of cardiac arrest and 2 and 24 hours of spontaneous circulation exhibited respiratory control ratios that were 50%, 100%, and 75% respectively of those obtained from control animals. Extraction and analysis of lipids from the cerebral cortex indicated the release of free fatty acids following 10 min of ischemia and the generation of lipid peroxides after 2 and 24 hours of reperfusion. These results indicate that delayed post-ischemic mitochondrial damage and lipid peroxidation occur in the cerebral cortex in a clinically realistic model of cerebral ischemia and resuscitation (Supported by a grant from Sigma Tau S.p.A.).

13.2

THE 21-AMINOSTEROID ANTIOXIDANT TIRILAZAD MESYLATE (U-74006F) BLOCKS CORTICAL HYPOPERFUSION FOLLOWING SPREADING DEPRESSION. E. D. Hall and S. L. Smith*. CNS Dis. Res., The Upjohn Co., Kalamazoo, MI 49001.

Cortical spreading depression (SD) has been implicated in the pathophysiology of classical migraine headache and cerebral ischemia. A reduction in cerebral blood flow (CBF), mimicking that seen during the aura and headache phase of migraine, is typically observed following SD in the rat. In the present study, brief cortical exposure to 1M KCl produced a marked suppression of EEG amplitude which persisted 20 min in the rat. Upon normalization of the EEG, cortical blood flow declined 20-30% and remained low for at least 2 hrs, while mean arterial pressure was unaffected. Over the 2 hr. post-KCI time course, arterial pO2 rose significantly while pCO2 and pH were unchanged. The increase in pO2 may indicate a decrease in cerebral oxygen utilization. Treatment with a 1 mg/kg iv dose of the 21-aminosteroid antioxidant tirilazad mesylate (U-74006F), 2 min following KCI application, completely blocked the hypoperfusion while leaving total EEG amplitude and MAP unchanged. The SD-induced rise in arterial pO2 was also prevented. Tirilazad mesylate is a potent inhibitor of oxygen radicalmediated lipid peroxidation both in vitro and in vivo. Based on this fact and present results, oxygen radicals may play a role in the SD-induced cerebral hypoperfusion.

13.3

AMPA RECEPTORS MEDIATE ISCHAEMIC NEURONAL CELL DEATH. M.J. Sheardown, A.J. Hansen, P. Suzdak, K. Eskesen*, P. Jacobsen* and T. Honoré*. Novo Nordisk CNS Division, Sydmarken 5, DK-2860 Soeborg, Denmark.

NBQX is a selective antagonist at the AMPA subtype of excitatory amino acid receptor that protects against neuronal death evoked by global ischaemia.

Here we administered NBQX (30 mg/kg, i.p.) to Mongolian gerbils 4 and 6 h after 5 min of global ischaemia and found a significant protective effect against hippocampal CA1 cell loss evaluated 4 days later. In comparison, MK-801 had only a marginal effect when given (3 mg/kg i.p.) 0.5 h after the ischaemic challenge and no effect when administered after 2 h. The decrease of 3H-AMPA binding in the CA1 hippocampus produced by ischaemia was also prevented by NBQX. When applied in vitro to hippocampus slices NBQX inhibited Schaffer-Collateral evoked synaptic responses in the CA1 region, whereas MK-801 was without any effect. NBQX had no effect on neuronal phospholipid hydrolysis evoked by excitatory amino acids. The data suggest that stimulation of AMPA receptors by post-ischaemic glutamate release is a key mechanism for ischaemic cell death.

13.4

ELEVATED CYTOSOLIC CALCIUM FOLLOWING OXYGEN-GLUCOSE DEPRIVATION IN CULTURED CORTICAL NEURONS. M.P. Goldberg and D.W. Choi. Dept. of Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

We examined hypoxia-induced changes of cytosolic Ca²⁺ in vitro using fura-2 fluorescence videomicroscopy. Astrocyte-poor cortical neuronal cultures were loaded with 5 μ M fura-2/AM, and then transferred to a defined medium lacking both oxygen and glucose. After 20-50 min at 37°C, cultures were returned to oxygen- and glucose-containing medium, and cytosolic Ca²⁺ was determined by 340/380 nm fluorescence excitation ratio measurement.

Immediately following 45-50 min of oxygen-glucose deprivation, cytosolic Ca^{2+} was markedly elevated (500-2000 nM) in greater than 90% of neurons. These extreme elevations in neuronal Ca^{2+} were sustained for at least 1 hr after exposure, and were associated with morphological evidence of injury, including cellular swelling, rapid leakage of intracellular fura-2, and subsequent neuronal degeneration. Exposure durations of 30-40 min increased Ca^{2+} in a smaller proportion of neurons, whereas 20 min exposure did not raise Ca^{2+} above resting levels (50-100 nM), and produced little subsequent neuronal loss. Increased Ca^{2+} and neuronal death could be blocked by NMDA antagonists 10 μ M MK-801 or 100 μ M dextrorphan. Ca^{2+} elevation could also be blocked by removing extracellular Ca^{2+} from the exposure medium (with 50 μ M EGTA); however, cytosolic Ca^{2+} rose when cultures were subsequently returned to normal Ca^{2+} -containing solutions. These observations indicate that hypoxic neuronal injury is associated with sustained failure of Ca^{2+} homeostasis, and suggest that Ca^{2+} influx via NMDA channels is required for intracellular free Ca^{2+}

HIGH CONCENTRATIONS OF DIHYDROPYRIDINES REDUCE NEURONAL INJURY INDUCED BY PROLONGED GLUCOSE DEPRIVATION IN CORTICAL CULTURES. V.M.G. Bruno, K. Rose, S.A. Colamarino*, and D.W. Choi. Dept. of Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

We investigated the protective action of

We investigated the protective action of dihydropyridines against the neuronal injury induced by glucose deprivation in murine cortical cell cultures containing both neurons and glia. Cultures exposed to defined solutions lacking glucose for 6 - 8 hr developed widespread neuronal injury without glial injury when examined 24 hr after insult initiation. As previously reported, both morphological and chemical (lactate dehydrogenase efflux) signs of neuronal injury could be almost fully blocked by the NMDA antagonist MK-801; however, if glucose deprivation was extended to the full 24 hr, this protective effect was overcome. In contrast, 3 - 100 µM concentrations of nifedipine produced concentration-dependent (EC₅₀ about 10 µM) injury reduction even with a prolonged 24 - 36 hr insult. Similar although less consistent prolonged neuronal protection was found with 10 - 30 µM nimodipine. Interestingly, the morphinan dextrorphan was intermediate between MK-801 and dihydropyridines in reducing neuronal injury with prolonged glucose deprivation, perhaps reflecting some ability of dextrorphan to block Ca²⁺ influx through voltage-gated channels (Jaffe et al., Neurosci. Lett. 105: 227, 1989).

13.7

EXTRACELLULAR ACIDOSIS WORSENS INJURY OF CULTURED CORTICAL GLIA BY COMBINED OXYGEN-GLUCOSE DEPRIVATION. R.G. Giffard, H. Monyer and D.W. Choi. Depts. of Anesthesia and Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

The extracellular acidosis associated with brain ischemia has been hypothesized to contribute to the resultant injury. We studied extracellular acid-induced injury in mouse cortical cell cultures. In mixed neuronal and glial cultures, exposure to a defined PIPES-buffered solution at pH 6.4 - 6.5 for 24 hr produced selective glia injury as demonstrated by trypan blue staining; quantitative experiments with pure glial cultures showed that release of lactate dehydrogenase (LDH) into the medium was already detectable after 6 hr. Controls exposed to the same solution at pH 7.4 were not injured. At pH 7.4, glial cultures tolerated combined oxygen and glucose deprivation for up to 9 - 12 hr before cell death occurred; however at pH 6.4, LDH release was already detectable by 3 - 6 hr. Similar results were obtained in other experiments in which the buffer included 25 mM L-lactate.

We previously showed that extracellular acidity at pH 6.4 can attenuate cortical neuronal injury due to combined oxygen-glucose deprivation (Brain Res. 506:339, 1990). Present results support the suggestion that extracellular acidity may also have a deleterious effect in the same setting, potentiating glial injury.

13.9

KETAMINE BLOCKS EARLY CHANGES IN CELL CALCIUM IN CA1 NEUROPII. DURING "ISCHEMIA". <u>D. Lobner and P. Lipton</u>. Dept. of Physiol., Univ. of Wisconsin, Madison, Wi 53706.

Long-term transmission failure between the Schaffer collaterals and CA1 pyramidal cells is induced by 5' exposure to buffer equilibrated with 95%N2-5%CO2 and devoid of glucose (in vitro ischemia). 1mM ketamine prevents this damage (recovery=100±8%).

Measurements of cell calcium were made using 45Ca. Slices were equilibrated with 45Ca for 45' and then exposed to ischemia for various durations. The table shows CA1 neuropil calcium in the presence and absence of ketamine, presented as % of neuropil calcium just prior to ischemia with no drug added. At 1' ischemia there is a net loss of CA1 neuropil calcium, suggesting a release of calcium from intracellular stores. By 2' ischemia there is an increase in neuropil calcium. 1mM ketamine decreases basal calcium levels, blocks the decrease in calcium at 1' ischemia, and inhibits the increase in calcium at 2 & 3' ischemia. These results suggest that ketamine blocks a release of intracellular calcium early during ischemia and also delays the later increase in total neuropil calcium during ischemia. Either, or both, of these actions may account for the protective actions of ketamine.

Period of ischemia	No drug	1mM ketamine
0'	100±2 (72)	78 <u>±</u> 2 (66)
1'	87±2 (27)	80±5 (23)
2'	118±4 (20)	70±3 (29)
3'	131±8 (15)	74 <u>±</u> 4 (15)
5'	137±6 (35)	121±5 (31)

12 6

THE VULNERABILITY OF CULTURED CORTICAL NEURONS TO GLUCOSE DEPRIVATION-INDUCED INJURY IS INFLUENCED BY CLIAL GLYCOGEN STORES. R.A. Swanson 1 and D.W. Choi 2. 1 Dept. of Neurology, VAMC and UCSF, San Francisco, CA; and Dept. of Neurology, Stanford Univ. Med. Sch., Stanford, CA 94305.

CNS glycogen stores are thought to be almost exclusively in glia. Using murine cortical cell cultures, we tested the effect of altering glial glycogen stores on neuronal vulnerability to glucose deprivation-induced injury.

Cultures were prepared with increased glycogen content by 36 hr pretreatment with either 20 mM glucose, or 1 mM methionine sulfoximine (MSO), a compound which reduces glia glucose utilization and inhibits glial glutamine synthetase. Glycogen depletion was accomplished with 30 min exposure to 0.1 mM dibutyryl cAMP (dBcAMP). One day after exposure to several hours of glucose deprivation, cultures pretreated with either high glucose or MSO exhibited less than 50% of the neuronal death seen in control cultures. The effect of MSO was probably not due to reduced glutamine availability since the bathing medium contained 0.5 mM glutamine. Conversely, glycogen depletion with dBcAMP significantly increased neuronal injury. Glial glycogen stores may importantly influence neuronal vulnerability to glucose deprivation, perhaps by maintaining glutamate uptake and reducing excitotoxic injury.

19 Q

CHANGES IN INOSITOL PHOSPHATES DURING 'IN VITRO ISCHEMIA' IN CA1 OF RAT HIPPOCAMPAL SLICES. P. Lipton, J. Suter* and D. Lobner. Department of Physiology, University of Wisconsin, Madison, Wisconsin 53706.

Hippocampal slices were incubated with 3-H myo-inositol for 4 hours, washed for 30 minutes and then exposed to in vitro ischemia (I) for varying lengths of time ranging from 15 seconds to 5 minutes. [In (I), glucose is absent from the buffer and the buffer is equilibrated with $95\%N_2/5\%C0_2$.] In many cases, drugs were included in the buffers; in these cases buffer compositions were changed 10 minutes prior to I. Effects of drugs on control conditions were always measured.

There is a small (to 180%) transient increase in IP $_3$ between 30 and 60" of ischemia. There is a far larger increase in IP $_2$ which rises between 1 and 5 minutes of ischemia to about 500% of control levels. IP rises less, with a similar time course. The changes in IP and IP $_2$ after 5' are unaffected by prolonged incubation in $_2$ 0-Ca $_2$ + and/or low Na $_1$. They are also unaffected by lmM ketamine, lmM atropine, 50 $_2$ M prazosin, or lmM AP3.

The mechanism of the increase is thus not known at present. This, and the relationship of the early increases in IP_3 to ischemic damage are currently being investigated.

13.10

FAILURE OF KETAMINE TO REDUCE INFARCT VOLUME RESULTING FROM TEMPORARY FOCAL ISCHEMIA IN THE RAT. T.R. Ridenour*. D.S. Warner, M.M. Todd*. Neuroanesthesia Lab, Univ. of Iowa Hospitals and Clinics, Iowa City, IA 52242

To determine if a neuroprotective effect could be observed by using the glutamate antagonist ketamine in a model of focal reversible cerebral ischemia, cerebral infarct volumes were evaluated in male SHR rats weighing between 250-350 gms after middle cerebral artery (MCA) occlusion of 2 hrs duration and a subsequent 4d postoperative survival. Three groups were investigated. 10 rats underwent ligation of the right MCA under ketamine anesthesia (2.5 mg/kg/min with a 50 mg/kg loading dose). 8 rats had the same procedure performed with halothane (0.5-1.0%) used as the anesthetic. A sham group (n=5) was treated as were the animals in the ketamine MCA group, but without ischemia. PaO2, PaCO2, cranial temp., and mean arterial BP were controlled throughout and plasma glucose levels were assessed as was EEG. 2 animals in the ketamine MCA group and 1 animal in the halothane MCA group died within the first 24 hrs postoperatively. Neurological examinations were performed prepostoperatively. Neurological examinations were performed pre-operatively and 4 d postoperatively before the animals were killed. The rat brains were harvested, sectioned, and stained with triphenyl tetrazolium chloride. Infarct volume was quantified using computerized planimetric analysis. There was no reduction in infarct volume in rats treated with ketamine compared with those treated with halothane during ischemia (134±51 vs 131±64 mm³). At 4d postoperatively, there was no statistical difference in neurological examination data between the two MCA groups. Performing near baseline, the sham group was superior. The data is not consistent with the belief that ketamine offers an advantage over halothane as a neuroprotective agent during focal temporary ischemia.

KETAMINE INHIBITS LIPID PEROXIDATION IN ISCHEMIC BOVINE RETINA. M.Zhou', T.G.Ma', Z.He', B.M.Rigor and M.T.Tseng. Departments of Anatomical Sciences and Neurobiology, of Anesthesiology, and of Ophthalmology and Visual Sciences, University of Louisville, Louisville, KY 40292

Lipid peroxidation disrupts membrane integrity and causes structural and functional alterations in ischemic tissues. Ketamine is a known ischemic protectant and it prevents Ca*+ influx by antagonistic actions on NMDA receptors. However, its effect on lipid peroxidation is unknown. Here we report the influence of ketamine on lipid peroxidation in retinal preparations. First, P2 membrane fractions from eyes removed minutes after exsanguination were exposed to lipid peroxidation inducer cadmium chloride (200 μ M) or L-ascorbic acid (1 mM) with 0-10 mM ketamine. Second, P₂ membranes were prepared from retinas sustained 60 min of ischemia and were then perfused for an additional 60 min with solutions containing 0 or 1 mM ketamine. Lipid peroxidation were determined by thiobarbituric acid assay. In the first group, ketamine inhibited induction of lipid peroxidation by L-ascorbic acid or cadmium chloride. Similarly, 1 mM ketamine reduced ischemia induced lipid peroxidation in the second group. The data demonstrate that ketamine inhibits ischemia induced lipid peroxidation, and suggests an additional mechanism for ketamine's anti-ischemic actions. (supported in part by a grant from Mobil Oil Corp.)

INVERTEBRATE LEARNING AND BEHAVIOR I

14.1

PARALLEL DISHABITUATION AND SENSITIZATION WITH NO INHIBITION OF GILL-WITHDRAWAL REFLEX IN APLYSIA. R.D. Hawkins, T.E. Cohen*, V.A. Henzi, & E.R. Kandel Ctr. Neurobiol. & Behav., Columbia Univ., NYSPI, & UNIV. NYSPI,

Dishabituation and sensitization in Aplysia can be dissociated, suggesting that they may reflect different processes (Marcus et al., 1988, Mackey et al., 1988). Alternatively, some of the differences may be due to ceiling effects which limit enhancement of nonhabituated responses. To test this possibility, we investigated the effect of preshock response amplitude on sensitization of gill-withdrawal in a dissected mantle organ preparation. We found that when the preshock response is large, sensitization is modest both 2.5 and 12.5 min after shock (med. increase = 26% and 15%, p < .01). However, when the preshock response is small, as it is following habituation, sensitization is robust both 2.5 and 12.5 min after shock (med. = 521% and 554%, p < .001). These results indicate that dishabituation and sensitization of the gill component of the reflex are not dissociated when preshock response strength is equated.

These data also do not show any evidence of inhibition, in contrast to previous reports of transient inhibition preceding sensitization of the siphon component of the reflex in intact animals (Mackey et al., 1987; Marcus et al., 1988). To determine whether these differences are due to different preparations or different responses, we measured both gill and siphon withdrawal in unrestrained animals with their parapodia and purple glands removed. Again, we found that whereas siphon withdrawal is inhibited 2.5 min after shock (p < .01), gill withdrawal is sensitized (p < .01). These experiments demonstrate selective inhibition of the siphon component of the reflex and suggest that, in addition to possible ceiling effects, some of the differences between dishabituation and sensitization of siphon withdrawal may be due to the inhibition.

COMPARISON OF ACTIVITY IN THE APLYSIA ABDOMINAL GANGLION DURING SPONTANEOUS AND TOUCH ELICITED GILL WITHDRAWALS. Jian-young Wu, Vadim Roshin*, Larry Cohen, C.X. Falk* and Avrum Cohen*. Dept. of Cellular and Molecular Physiology, Yale U. Sch. of Med., New Haven, CT 06510.

Gill withdrawals in Aplysia can either occur spontaneously or can be elicited by an external stimulus.

Gill withdrawals in Aplysia can either occur spontaneously or can be elicited by an external stimulus. The withdrawal elicited by a light mechanical touch lasting 0.6 seconds usually begins during the stimulus and reaches a peak shortly thereafter (fast response). In one unusual isolated-siphon preparation we recorded one spontaneous withdrawal and two instances where a light touch to the siphon skin resulted in a withdrawal that reached a peak in about three seconds and that appeared to be similar to the spontaneous withdrawal. We used optical recordings to compare the neuronal substrate of the fast response and the spontaneous withdrawal. In this preparation, the neuronal activity giving rise to the spontaneous contractions was longer lasting (about 3 seconds) compared to the activity giving rise to the rapid response (about 1 second). The number of neurons and the number of spikes per neuron in the two types of withdrawal were similar. There was overlap in the neurons participating in the two types of withdrawals, about 50% of the neurons were identical in the two kinds of withdrawals; about 50% of the neurons participating in the spontaneous withdrawals had not been active during a preceding rapid response.

14.2

THE EFFECT OF INCREASED DIVALENT ION CONCENTRATION ON THE GILL WITHDRAWAL AND THE NEURONAL ACTIVITY IN THE ABDOMINAL ACHIVITY IN THE ABDOMINAL GANGLION OF APLYSIA: AN ATTEMPT TO RESTRICT THE NEURONAL SUBSTRATE OF THE BEHAVIOR. <u>Vadim Roshin*</u>, <u>Jian-young Wu, Larry Cohen</u>, <u>G.X. Falk*</u> and <u>Avrum Cohen*</u>. Dept. of Cellular and Molecular Physiology, Yale U. Sch. of Med., New Haven, CT 06510.

Previous experiments have indicated that approximately 300-400 neurons in the Aplysia abdominal ganglion are activated by a light touch to the stphon skin that elicits the gill-withdrawal reflex. We have investigated the possibility that increasing the divalent ion concentration in the sea water bathing the ganglion would reduce interneuronal activity more rapidly than it reduces the gill-withdrawal and thus lead to a preparation that generates the gill-withdrawal reflex with fewer concomitantly active neurons. In three preparations, a mixture of 80% sea water and 20% high-divalent artificial sea water reduced the gill contraction by 50% but only reduced the number of neurons activated by the touch by 10%. In two preparations, a 50% mixture of sea water and high-divalent ASW completely blocked the gill-withdrawal but reduced the number of neurons activated by the touch by only 40%. The gill withdrawal appears to be more sensitive to the divalent ion concentration than is the number of neurons responding to the touch. Thus, our second attempt to develop a preparation which generates a gill withdrawal with substantially fewer neurons was also unsuccessful.

IDENTIFIED CENTRAL MOTOR NEURONS ARE NECESSARY FOR DIRECTIONAL SIPHON RESPONSES IN <u>APLYSIA</u>. <u>C.Hickie and E.T. Walters</u>. Department of Physiology & <u>Cell Biology</u>, Univ. of Texas Medical School, Houston, TX 77225.

Previous studies revealed 3 responses of the siphon to stimulation of different regions of the body: flaring to

Previous studies revealed 3 responses of the siphon to stimulation of different regions of the body: flaring to tail stimulation (I type response), constriction to head stimulation (H type), and longitudinal contraction to midbody stimulation (M type). M responses can be transformed to H or I type by associative and nonassociative training. We now report that a few previously identified central motor neurons account for H and I responses. The H response is largely mediated by a single motor neuron, RDS, hyperpolarization of which eliminates more than 90% of the H response (recorded by a photocell) to stimulation of head nerves (C2). Redriving RDS with a record of its C2-evoked activity causes a nearly identical H response. LDS cells make minor contributions to the H response. Although 3 LFSA cells also constrict the siphon, they are inhibited by C2 stimulation. The I response is largely mediated by 4-5 LFSB motor neurons, which are weakly electrically coupled. Hyperpolarization of 4 LFSB cells eliminates over 90% of the I response to stimulation of tail nerves (P9). Therefore, if peripheral motor neurons contribute to H and I responses, they must be in series with this small number of central motor neurons. These findings will simplify cellular analyses of the selection and plasticity of siphon responses.

MODULATION OF THE EXCITABILITY OF PERIPHERAL RECEPTIVE FIELDS AND AXONS IN SENSORY NEURONS OF APLYSIA. A.L. Clatworthy and E.T. Walters. Dept. of Physiology & Cell Biology, Univ. Texas Medical School, Houston, TX 77225. We reported last year that tail pinch reduces the

number of sensory neuron action potentials elicited by test shocks to the nerve containing the sensory neuron's axon. We have since found that tail pinch reduces the axon. We have since found that tail pinch reduces the number of spikes elicited by nerve shocks near spike threshold, but has no significant effect on spikes elicited by nerve shocks 2-3 times spike threshold (n=12 cells). Therefore, tail pinch can reduce the excitability of the sensory axon, but the safety factor for central conduction of sensory spikes is usually (although not always) adequate to prevent conduction block. This also suggests that short-term alterations of axonal excitability might occur within the sensory neuron receptive field (RF). Complex short-term modulation of RF excitability was found using cutaneous test stimuli (0.5 sec taps, 0.5 sec dc shocks, and 20 Hz trains of 5 msec shocks). Most stimuli showed "windup", a decrease in spike latency and increase in spike number when the test stimulus was repeated at 5 sec intervals (n=36). Windup was greater with more intense stimuli. Prolonged testing sometimes caused depression of excitability after windup. Depression of RF excitability (for 2-8 min) was also produced by strong shock inside the RF (n=10), as well as by high frequency activation of the soma (n=5).

14.7

CONTRIBUTION OF INTERNEURONS TO TAIL-SHOCK INDUCED

CONTRIBUTION OF INTERNEURONS TO TAIL-SHOCK INDUCED INHIBITION OF THE SIPHON WITHDRAWAL REFLEX IN APLYSIA, W. G. Wright and T. J. Carew. Department of Psychology, Yale University, New Haven, CT 06520.

Strong tail shock (TS) produces transient inhibition of the water-jet elicited siphon withdrawal reflex (SWR) in Aplysia. Our previous experiments suggested that some of this inhibition may be mediated by interneuronal processes (Wright et al. 1988, 1989). The present study explored this suggestion by examining inhibitory interneurons (cells producing IPSPs onto excitatory interneurons or siphon motor neurons (MNs)) which are activated by water jet stimuli to the siphon. Using a semi-intact preparation that shows TS-induced inhibition of both the SWR and the water-jet elicited complex EPSP in siphon MNs, we found the following: 1)Intracellular activation of the inhibitory interneuron L16 (Hawkins et al., 1982; Frost, 1990) inhibits water-jet elicited complex EPSPs in MNs; 2)L16 is activated by TS; 3)The inhibitory connection between L16 and the excitatory interneuron L29 is facilitated by intracellular activation of L16 as well as by TS; 4)L16 may play a causal role in TS-induced inhibition, since hyperpolarizing L16 during TS can diminish inhibition of the complex EPSP (2 of 3 preparations); 5)Similar to L16, intracellular activation of another inhibitory interneuron facilitates its own inhibitory connection to L29, and inhibits the complex EPSP. However, this cell does not appear to be activated by TS (we are currently further characterizing this cell).

In summary, we have identified several interneuronal sites in the SWR that may contribute to TS-induced inhibition. Our goal is to quantitatively determine the decree to which these and other sites can

SWR that may contribute to TS-induced inhibition. Our goal is to quantitatively determine the degree to which these and other sites can account for the magnitude and time course of the behavioral inhibition.

SENSITIZATION AND DISHABITUATION IN TRITONIA: EXCITATORY EFFECTS OF CHEMICAL STIMULI. G. BROWN AND A.O.D. WILLOWS. Friday Harbor Laboratories, Friday Harbor, WA 98250

We are studying the iong-lasting effects of various types and combinations of stimuli on the behavior and neural circuitry of the sea slug Tritonia. Previous studies indicated that a chemical stimulus which triggers escape swimming in Tritonia will sensitize the animal's response to subsequent presentations of noxious stimuli. We now report that a chemical stimulus which does not elicit the swim response can also produce sensitization. An experimental group of animals received five presentations of a ratfish liver extract at five minute intervals followed in ten minutes by .15 mls of 4M NaCl on the tail. Controls were given only this tailsalt stimulus (that typically triggers the escape swim response). Animals that received sensitization training had increased locomotory behavior and a much longer swim episode (avg. 9.7 cycles vs. 5.6 for controls: N=10. p<.05).

A different kind of excitatory effect observed was the restoration of a habituated response by a concentrated salt stimulus to the head. The tailsalt stimulus was given repeatedly at ten minute intervals until the escape swim response was not elicited on five consecutive trials. Experimental animals were then given 1 ml of 4M NaCl to the head to elicit swimming. Control animals were not given this dishabituating stimulus. Experimental animals showed a significantly higher probability of swimming to the next tail-salt stimulus (8/10 vs 1/10 for controls, p< .02).

DIFFERENTIAL MODULATION OF EXCITABILITY AND SPIKE DURATION IN THE TAIL SENSORY NEURONS OF DEVELOPING APLYSIA. E. A. Marcus and T.J. Carew. Departments of Biology and Psychology, Yale University, New Haven, CT 06520.

Recent evidence from a variety of systems has demonstrated that a single modulatory neurotransmitter can have multiple effects on the

Baxter and Byrne (1990), serotonin (5HT) modulates potassium conductances in the tail sensory neurons of adult *Aplysia* to produce an increase in both excitability (principally through modulation of I_{KS}), and spike duration (principally through the modulation of I_{KV}). To understand how such complex biophysical effects of modulatory

neurotransmitters emerge during development, we have characterized the effects of 5HT on excitability and spike duration in tail sensory neurons of Late Stage 12 juvenile *Aplysia*. We found that 5HT (50 µM) neurons of Late Stage 12 juvenile *Aplysia*. We found that 5HT (50 μ M) produces a significant increase in excitability ($\overline{x} = 332\%$, p<0.0025), which is comparable to that reported for adult animals (Baxter and Byrne, 1990). Thus the ability of 5HT to modulate $|_{KS}$ appears to be fully mature by Late Stage 12. In contrast, 5HT produces only a modest increase in spike duration ($\overline{x} = 12.81\%$, p<0.026). This increase is significantly smaller (p<0.001) than that observed in adults ($\overline{x} = 44.8\%$, p<0.0001). These results suggest that the ability of 5HT to modulate $|_{KV}$ is not fully mature by Late Stage 12. Since the effects of 5HT on $|_{KV}$ and $|_{KS}$ are known to be mediated by different second messenger systems in adult Aplysia (Baxter and Byrne, 1990), it should now be possible to use the tail sensory

Byrne, 1990), it should now be possible to use the tail sensory neurons to examine how complex neuromodulatory effects and second messenger interactions are assembled during development.

CHEMICAL CUES MEDIATE INTER-ANIMAL INHIBITION OF SIPHON WITHDRAWAL IN APLYSIA. M. Stopfer, X. Chen*, and T.J. Carew. Department of Psychology, Yale University, New Haven, CT.

It has recently become apparent that noxious stimuli such as strong shock can produce significant inhibition of the siphon withdrawal reflex (SWR) of Aplysia. We here describe that chemical cues released from animals receiving strong shock produce reflex inhibition in neighboring unshocked animals

Aplysia were randomly designated Experimental (EXP) or Control (CON). Each animal was then placed into an individual tank. A second (donor) animal was added to each tank, separated from the EXP or CON animal by a perforated partition. After 15 min, the SWR was elicited in EXPs and CONs by mild tail shock in three pre-tests (10 min ITI). Next, in the training phase, a second experimenter delivered strong head shocks to the donor in the EXP tank. Head-shocked donors invariably inked. Neither animal in the CON tank received head shock; rather, to preserve blind procedures, a dye that was indistinguishable from *Aplysia* ink was added to the CON tank water. The first experimenter then conducted blind tests (identical to pre-tests) 4, 10, 20, and 30 min after training. CONs (n=26) showed no significant change from baseline in any test. In contrast, EXPs (n=24) were significantly inhibited relative to their own pre-scores at all times tested (at least p<0.01). Moreover, they were significantly inhibited relative to CON animals in the 4 and 10 min tests (p<0.001 in each). After the 10 min test, EXP scores trended toward baseline

despite the continued presence of chemical factors in the water.

Preliminary evidence from blind experiments using ink obtained from the ink glands of naive, anesthetized animals suggests that at least one inhibitory cue is the ink itself. Since the neural circuits mediating inking and the SWR in Aplysia are both relatively well understood, our results raise the possibility of examining inter-animal communication in Aplysia at a cellular level.

5-HT MODULATES TWO DISTINCT K+ CURRENTS IN HERMISSENDA TYPE B PHOTORECEPTORS. J. Acosta-Urquidi and T. Crow. Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77030.

Serotonin (5-HT) has been proposed to play a role in conditioning of Hermissenda. Previous research has shown that 5-HT enhances the peak and

plateau phases of the generator potential of identified type B photoreceptors (Crow and Bridge, 1985; Farley and Auerbach, 1986). Two electrode voltage-clamp techniques were employed to investigate the effects of 5-HT on membrane conductances in medial and lateral type B photoreceptors. Here we report two voltage-gated K+ currents not previously described in medial and

lateral type B photoreceptors and their modulation by 5-HT. With I_A and $I_{K(Ca)}$ removed, the dominant outward K^+ current is $I_{K(V)}$, the delayed rectifier. An inward rectifier, termed I_{IR} , evoked by hyperpolarizing detayed rectiner. An inward rectiner, termed $I_{[R]}$, evoked by hyperpolarizing steps is also present in most cells (85% of cells examined under voltage-clamp, n=40). $I_{K/N}$ activates at around -15mV, and has a τ_{off} between 250 and 350 ms. $I_{K/N}$ is blocked by TEA and partially blocked by 4-AP (5mM), and exhibits marked twin-pulse inactivation which is quickly removed by conditioning hyperpolarization. The rate of decay of I_{K(1)} was slowed by 5-HT, and twin pulse inactivation was reduced. After the application of 5-HT the average %

pulse inactivation was reduced. After the application of 5-HT the average % increase in $\tau_{\rm off}$ $I_{\rm K(N)}$ compared to control values was 24 ± 4 (n=5). $I_{\rm IR}$ activates at potentials around -60 mV and is markedly voltage-dependent. $I_{\rm IR}$ is blocked by 4-AP (5mM) and TEA but not by ${\rm Ba}^{2+}$ or ${\rm Cd}^{2+}$. 5-HT (10 4 M) produced a strong enhancement of $I_{\rm IR}$. Following the application of 5-HT, the average % change in $I_{\rm IR}$ relative to baseline values was 127.3 \pm 34 (n=10). The contribution of $I_{\rm K(N)}$ and $I_{\rm IR}$ to the generator potential of type B photoreceptors is under investigation.

NEURAL CORRELATES OF CONDITIONING IN IDENTIFIED PEDAL NEURONS IN HERMISSENDA. T.M. Hodgson and T. Crow. Dept. of Neurobiology and Anatomy, Univ. of Texas Med. Sch., Houston, TX, 77225.

In the course of the investigation of the neural circuitry underlying the expression of behavioral changes associated with conditioning in *Hermissenda*, four light-responsive cell types were identified from intracellular recordings of putative motor neurons in the pedal ganglia. Subsequent experiments showed that the identified pedal cells' light responses were due to input from the photoreceptors (Hodgson and Crow, 1987, 1989). To determine if the light responses of the identified pedal neurons could be modified by conditioning, Hermissenda were subjected to one of two procedures: Paired presentations of light and rotation, or random presentations of the two stimuli. The light responses of the identified pedal neurons recorded from animals which received paired stimuli were reduced, as compared with the light responses recorded from random or normal controls. Pedal cell P7, which shows a hyperpolarizing light response, showed a weaker response to 5 min light steps in animals which received paired stimuli (21.8±11.6% decrease in impulse activity compared with baseline activity in the dark; n=4, mean ± SEM), as compared to random controls (66.0 ± 8.1% decrease in activity vs. baseline activity in the dark;n=2) and a weaker response to 10 sec light steps in paired animals (37.8 \pm 6.11% decrease in activity vs. baseline activity in the dark;n=9) vs. normal controls (48.8 \pm 6.4% decrease in activity vs. baseline activity in the dark;n=29). Pedal cell P8, which has a depolarizing light response, showed weaker responses to 10 sec light steps in paired animals (13.8±4.8% increase in activity vs. baseline activity in the dark;n=5) vs. random controls (33.7±8.3% increase in activity vs. baseline activity in the dark;n=3). Cell P9, which also has an excitatory response to light, showed weaker responses to 10 sec light steps in paired animals (14.5±6.6% increase vs. baseline activity in the dark;n=7) vs. normal controls (24.7±3.5% increase compared to baseline activity in the dark;n=29).

14.12

HERMISSENDA PHOTORECEPTORS EXHIBIT SYNAPTIC FACILITATION AS

HERMISSENDA PHOTORECEPTORS EXHIBIT SYNAPTIC FACILITATION AS WELL AS ENHANCED EXCITABILITY. E.M. Schuman and G.A. Clark. Program in Neuroscience, Princeton University, Princeton, NJ 08544.

Two forms of neuronal plasticity frequently proposed to underlie learning are changes in synaptic strength and changes in neuronal excitability. The relationship between these two changes remains unclear, in part because they have often been analyzed in different systems (e.g., Aplysia and Hermissenda respectively). To help clarify these issues, we investigated whether application of serotonin (5-HT) or activation of protein kinase C (PKC), procedures which mimic the effects of conditioned suppression of phototaxis and enhance cellular excitability in Hermissenda Type B photoreceptors, also modulate synaptic transmission in these same cells. Acute application of 5-HT dramatically enhanced the size of the monosynaptic inhibitory postsynaptic potential (IPSP) elicited by Type B cell stimulation in Type A photoreceptors (mean ± s.e.m.: pre: .31 ± .09 mV; post: .74 ± .18 mV; (9) = 3.81, p < .005). In addition, acute application of phorbol 12-myristate 13-acetate (PMA), a phorbol ester that activates PKC, also produced a marked facilitation of the IPSP produced by B cell stimulation (pre: .37 ± .13 mV; post: 1.31 ± .40 mV; t(7) = 2.85, p < .05). Control preparation exposed to an inactive phorbol ester or sea water showed no significant changes. Consistent with previous findings, 5-HT and PMA application also exposed to an inactive phorbol ester or sea water showed no significant changes. Consistent with previous findings, 5-HT and PMA application also produced an increase in the Type B cell input resistance (5-HT; pre: 38.3 \pm 4.1 Mohm; post: 46.9 \pm 3.6 Mohm; t(9) = 2.41, p < .05; PMA: pre: 38.5 \pm 2.7 Mohm; post: 57.3 \pm 4.8 Mohm; t(7) = 2.96, p < .02), but had no significant effect on Type A cell input resistance, suggesting changes were presynaptic. These results indicate that the same neurotransmitter (5-HT) and intracellular second messenger (PKC) that produce excitability changes in Type B cells also facilitate synaptic transmission. We now plan to investigate whether associative training paradiams also produce synaptic situations. whether associative training paradigms also produce synaptic facilitation in addition to enhanced neuronal excitability, and to explore further the functional and mechanistic relationship between these two forms of plasticity.

EPILEPSY: BASIC MECHANISMS I

GIANT IPSP'S ELICITED BY THE GABAERGIC INHIBITORY CIRCUIT IN THE HIPPOCAMPUS H.B. Michelson & R.K.S. Wong. College of Physicians & Surgeons, Columbia University, 630 W 168th St. N.Y., N.Y. 10032. Feedforward and feedback pathways excite GABAergic interneurons through activation of glutamatergic synapses. We report here a novel mechanism by which GABAergic neurons synchronize in the absence of excitatory amino acid (EAA) neurotransmission.

report here a novel mechanism by which GABAergic neurons synchronize in the absence of excitatory amino acid (EAA) neurotransmission.

Transverse slices of guinea pig hippocampus were used. EAA synaptic transmission was blocked with perfusion of CPP (10 uM) and CNQX (10 uM). Under these conditions, 4-aminopyridine (75 uM) elicits giant IPSP's (6-15 mV; 1-4 sec duration, at a resting potentials of -60 mV) in principal cells throughout the hippocampus. Field responses always accompanied giant IPSP's. These hyperpolarizations were significantly larger than baseline unitary inhibitory events (1-3 mV).

Intracellular recordings of dentate hilar neurons revealed a subpopulation of interneurons which exhibited a burst of action potentials riding on a depolarizing wave during the synchronized event. The amplitude of the underlying wave decreased with membrane depolarization, but could not be reversed because it rectified. Unitary ipsp's reversed at -70 mV. Depolarizing bursts in these neurons were still observed when unitary IPSP's were hyperpolarizing. Paired recordings indicated that the giant IPSP in principal cells occurred simultaneously with the bursting response of this subpopulation of hilar neurons. Both the unitary and synchronized IPSP's in all cells were blocked by picrotoxin (25 uM). Picrotoxin also abolished the depolarizing burst responses. Cells that produced burst responses are probably GABAergic interneurons become synchronized of these neurons produced giant IPSP's in projected neurons. We propose that GABAergic interneurons become synchronized of these neurons produced giant IPSP's in projected neurons. We propose that GABAergic interneurons become synchronized of these neurons

EPILEPTIFORM ACTIVITY IN MICROCULTURES CONTAINING SMALL NUMBERS OF HIPPOCAMPAL NEURONS, Michael M. Segal and Edwin J. Furshpan. Department of Neurobiology, Harvard Medical School, Boston,

MA 02115
Microcultures containing small numbers of hippocampal Microcultures containing small numbers of hippocampal neurons were grown for periods of 3 to 7 weeks. The microcultures were made by spraying drops of collagen onto a layer of agarose. Plating of cells onto such dishes resulted in growth of neurons on glial cells attached to the collagen patches. Connections between nearby microcultures were prevented by the properties of the agarose surface. Within each microculture, neurons formed strong chemical synaptic connections, with monosynaptic fast-excitatory, fast-inhibitory and slow-inhibitory synaptic actions, sensitive to blockers of glutamate and GABA transmission (NMDA, non-NMDA, GABAA and GABAB) blockers). Small networks with as few as one or two neurons cenerated epileptiform activity that closely resembled the generated epileptiform activity that closely resembled the generated epileptiform activity that closely resembled the epileptiform activity seen in mass cultures containing thousands of neurons (Furshpan & Potter, 1989). The epileptiform activity was observed when microcultures that were grown for weeks in blockers of synaptic activity (kynurenate and elevated Mg²⁺) were washed free of these blockers. Such a microculture technique allows study of epileptiform activity in a simplified system and facilitates analysis of the synaptic actions underlying the epileptiform activity.

LAYER 5 IS THE PREFERRED PATHWAY FOR HORIZONTAL PROPAGATION OF EPILEPTIFORM DISCHARGES IN NEOCORTEX. A.E. Telfeian, M.S. Wehr and B.W. Connors, Sect. of Neurobiology, Div. of Biology & Medicine, Brown Univ., Providence, RI 02912.

of Biology & Medicine, Brown Univ., Providence, RI 02912. Epileptiform discharges propagate across neocortex when GABA_A-mediated inhibition is reduced. We examined the preferred routes of propagation in slices of rat SI *in vitro*. Vertical cuts created bridges comprising single layers, which connected areas of intact cortex. Alternatively, horizontal cuts isolated strips with only a subset of the layers. When bathed with high doses of picrotoxin (35 µM) any small bridge (~350 µm wide) or strip (~500 µm wide) sustained propagation, regardless of laminar positions. (35 μ M) any small bridge (~350 μ m wide) or strip (~500 μ m wide) sustained propagation, regardless of laminar position; no particular pathway was necessary. However when picrotoxin was lowered to 2.5 μ M, only bridges and strips containing a patent layer 5 supported propagation. After cutting slices along the layers 4/5 border, we recorded and stained layer 5b pyramidal neurons with most of their apical dendrites removed. The proportions of intrinsic burst-firing (33%) and oscillatory (50%) neurons in intact and cut slices were indistinguishable. Apparently intrinsic bursting and oscillations are not dependent upon the apical dendritic tree. Focal ejections of GABA in layer Vb greatly slowed or arrested propagating discharges. Other greatly slowed or arrested propagating discharges. Other layers were much less sensitive to GABA. We conclude that the neurons and axonal connections of layer 5 are critical for the horizontal propagation of epileptiform discharges. Supported by NIH grants NS01271 and NS25983.

MAPPING THE PATHWAY OF DIFFERENT SEIZURE MODELS BY USING EARLY INDUCIBLE GENE EXPRESSION. P. Lanaud §, R. Maggio †, K. Gale †, and D. Grayson §, §FGIN and †Department of Pharmacology, Georgetown University Medical Center, Washington, D.C. 20007.

Using in situ hybridization histochemistry for the detection of several early inducible genes (EIG) we examined pathways activated by seizures evoked by a focal application of bicuculline in the limbic system or the inferior colliculus. In situ hybridization was performed on 10 µM coronal sections using cDNA probes encoding c-fos, cjun, jun-B, and zif/268. 30 min after the initiation of limbic motor seizures from a highly discrete epileptogenic site in the deep prepiriform cortex, each mRNA was markedly increased in the hippocampal formation, amygdala and entorhinal cortex.

Seizures evoked from inferior colliculus were distinct from the limbic seizures both in terms of behavioral activity and anatomic pattern of EIG expression. Within several hours following the seizures, the expression of EIG mRNA returned to baseline but could be re-induced 24 hours later by a second seizure. It appears that expression of EIG can be used to functionally map pathways involved in seizure propagation and that the anatomic pattern of activation is selectively related to the type of seizure evoked.

ANATOMICAL CHARACTERIZATION OF THE FUNCTIONAL INTERRELATION BETWEEN AREA TEMPESTAS AND SUBSTANTIA NIGRA IN SEIZURE PROPAGATION.
R. Maggio*, A.J. Pazos*, R.F. Ackermann¹ and K. Gale. Dept. of Pharm., Georgetown Univ. Med. Center, Wash., D.C. & ¹UCLA Sch. of Med., Los Angeles, CA.

We performed autoradiographic analyses of brain sections from rats receiving ¹⁴C-2-deoxyglucose (2DG), during bilateral motor seizures evoked from unilateral application of bicuculline methiodide (118 pmol) into an epileptogenic site in the deep prepiriform cortex, "area tempestas" (AT). 2DG accumulation occurred selectively in limbic structures ipsilateral to the stimulated AT: entorhinal cortex, ventral hippocampus, amygdala, n. accumbens and basal forebrain, perirhinal cortex, ventromedial caudate, septum and olfactory bulb. Pronounced bilateral activation occurred in mediodorsal and ventrolateral thalamus and substantia nigra; increases were also seen bilaterally in dorsal hippocampus. Bilateral application of the GABA, agonist muscimol into SN completely suppressed seizures evoked from AT. In these animals, all seizure-associated increases in 2DG accumulation were prevented. Unilateral application of muscimol in SN ipsilateral to the injected AT did not alter seizure activity but eliminated thalamic increases in 2DG, and partially reduced increases in 2DG in other structures. Our results suggest that the anatomic pattern of increase in 2DG accumulation is dependent upon seizure activity and is subject to nigral regulation. perirhinal cortex, ventromedial caudate, septum and activity and is subject to nigral regulation.

LITHIUM MODIFIES CONVULSIONS AND BRAIN PHOSPHO-INOSITIDE TURNOVER INDUCED BY ORGANOPHOSPHATES. K.M. Savolainen^{1,*}, O. Muona^{2,*}, S.R. Nelson¹, F.E. Samson¹ and T.L. Pazdernik^{1,*}, ¹Ralph L. Smith Res. Ctr., Univ. Kan. Med. Ctr., Kansas City, KS 66103, USA, ²Dept. Genetics, Univ. Oulu, SF-90220, Oulu,

Inositol-1-phosphate (Ins1P), an index of phosphoinositide (PI) turnover was measured in frontal and piriform cortices, caudate, thalamus, hippocampus and cerebellum from saline or LiCl (5mEq/kg; sc) pretreated rats 60 minutes after exposure to graded doses of paraoxon or soman. Both organophosphates (OP) produced convulsions at lower doses in LiCl than saline pretreated rats. Both soman and paraoxon when given in a convulsive dose range produced changes in regional Ins1P levels that correlated better with the presence or absence regional Ins1P levels that correlated better with the presence or absence of convulsions than the dose or the OP used. This was true both in saline and LiCl pretreated rats. In saline pretreated nonconvulsing rats, there was a "cholinergic" increase (1.5 - 2 X) in Ins1P in all regions except cerebellum after OP injection. In saline pretreated convulsing rats, there was a marked "seizurogenic" further increase in Ins1P; highest in caudate and cortex. In LiCl pretreated nonconvulsing rats, a "cholinergic" increase in Ins1P was significant only in caudate, thalamus and hippocampus. In LiCl pretreated convulsing rats, the further "seizurogenic" increase in Ins1P was less than in the saline group except in thalamus and hippocampus. Thus, OP produce both a except in thalamus and hippocampus. Thus, OP produce both a "cholinergic" and a "seizurogenic" increase in PI turnover. These data suggest that increased PI turnover in the hippocampus may be involved in the lowering of the seizure threshold for OP in the LiCl pretreated rats. Support: DAMD17-83-C-3242.

THE TEMPORAL PROFILE OF BRAIN DAMAGE FROM PILOCARPINE-INDUCED SEIZURES. <u>D.G. Fujikawa</u>. VA Med. Ctr., Sepulveda, CA 91343 and Dept. of Neurology and Brain Res. Inst., UCLA Sch. of Med., Los Angeles, CA 90024.

Although extensive neuronal damage is known to occur after several hr of pilocarpine (PC)-induced seizures, the time course of appearance of this damage in different brain regions has not been studied. Seizures were induced in male Wistar rats with 400-500 mg/kg PC i.p. Rats underwent brain perfusion-fixation after seizures of 10-20 min, 40 min, 1 hr and 3 hr or were given anticonvulsants after 3-hr seizures and recovered for 24 or 72 hr prior to perfusion. Neuronal necrosis was graded on a 0-3 scale.

Necrotic neurons first appeared in the dentate gyrus (DG) and cerebral cortex 40 min after seizure onset. Mild-to-moderate neuronal damage (grades [gr] 0.5-2) was seen in hippocampal CA1-4 regions, DG, amygdala (A), piriform (PCx), entorhinal and cerebral cortices, and septal nuclei after 1-hr and 3-hr seizures. After 3-hr seizures, thalamus (T), substantia nigra and caudateputamen (CP) also showed mild damage (gr 0.5-1). Neuronal injury worsened in ventral CA1, A and PCx (gr 3), T (gr 1-2) and CP (gr 1) 24 hr after 3-hr seizures but did not progress at 72 hr. Neuronal necrosis first appears 40 min after seizure onset and is maximal 24 hr after 3-hr seizures. Delayed neuronal death does not occur 24-72 hr after seizures. DG, CA2 and CP neurons, believed to be resistant, are vulnerable to seizure-induced damage.

SYNERGISTIC EFFECTS OF CO-INJECTION OF MU AND GLUTAMATE RECEPTOR AGONISTS INTO THE VENTRAL HIPPOCAMPUS IN PRODUCING SEIZURE ACTIVITY. L. Thai, X. P. He, W. Q. Zhang and J. S. Hong. LMIN, NIEHS/NIH, Research Triangle Park, NC 27709.

Previous studies from our laboratory showed that injections of mu opioid receptor agonists into the

injections of mu opioid receptor agonists into the ventral hippocampus produced behavioral convulsions in rats. The purpose of this study was to examine the interactions between opioid and glutamate receptor agonists in the regulation of hippocampal excitability. Coinjection of low doses of kainic acid (3.1 ng) or NMDA (2.5 µg) with a Mu receptor agonist (PLO17, 5 µg) into the ventral hippocampus produced severe, continuous behavioral convulsions within 1 to 2 hours after injections. Injection of either compound alone into the same or other areas of the limbic system such as the dorsal hippocampus, substantia nigra, amygdala, entorhinal cortex. or subiculum would not indure status epilenticustex, or subiculum would not induce status epilepticus. This study provides evidence indicating a positive interaction between Mu and glutamate receptor agonists in the ventral hippocampus in inducing epileptic activity which is consistent with the hypothesis that enkephalin and glutamate might act synergistically in the perforant path terminals to control the excitability of the hippocampus.

DOPAMINE REGULATION OF SEIZURES INDUCED BY LITHIUM+PILOCARPINE. P.Barone, A. de Bartolomeis*, V. Palma*, G. Muscettola* and G. Campanella*. 2nd Sch. of Med, Univ. of Napoli and Inst. Res. Sanatrix, Venafro, Italy.

Experimental evidence links central dopaminergic mechanisms to the control of seizures. For example, D-1 receptor stimulation reduces, while D-1 receptor blockade elevates the threshold for pilocarpine-induced seizures (Barone et al., <u>Neurosci.</u>, 34:209, 1990). The present study evaluates whether dopamine system manipulation may also affect the seizures induced by the combined administration of lithium plus pilocarpine: it is, in fact, well known that lithium chloride (LiCl) may potentiate

pilocarpine: it is, in fact, well known that hithium chloride (LiCl) may potentiate pilocarpine-induced seizures.

Male Sprague Dawley rats were treated with LiCl (4 mEq/kg; i.p.) 24 hr prior to the intraperitoneal injection of either saline or the D-1 antagonist SCH 23390 (0.01-0.1 mg/kg) or the D-2 antagonist haloperidol (0.5-2 mg/kg). After 5 min all rats were given 15 mg/kg of pilocarpine (i.p.), a dose which induces convulsions in 50% of LiCl-pretreated animals.

At all doses tested, the D-1 antagonist prevented, while the D-2 antagonist potentiated, the convulsive activity as revealed by behavioral, electroencephalographic alterations and widespread brain damage.

This study indicates that the two dopamine receptor subtypes, D-1 and D-2, exert opposing roles in the control of epilepsy propagation. Moreover, these results suggest that the toxic effect of lithium on brain excitability may be mediated by the dopamine system.

EFFECTS OF APPLIED ELECTRIC FIELDS ON EPILEPTIFORM NEURONAL ACTIVITY. <u>D. Durand, H. Kayyali</u>; Applied Neural Control Laboratory, Departments of Biomedical Engineering and Neuroscience, Case Western Reserve University, Cleveland, OH., 44106.

Constant electrical fields have been shown to be capable of modulating normal neuronal electrical activity with amplitude around 10mV-20mV/mm. These experiments suggested that it should also be possible to modulate epileptiform activity. We analyzed the effect of applied electric fields using monopolar electrodes on penicillin-induced epileptiform activity in hippocampal CAI neurons in-vitro.

Penicillin (3000 units/ml) was added to the artificial CSF and orthodromic

stimulation was applied in order to generate the epileptiform activity. A 50µm diameter electrode was located above the somatic layer and quasi-static (50ms, 0-50µA) current pulses were applied in order to generate electric fields. The results show that the amplitude of the population spikes was largely decreased as the amplitude of an anodic applied current was increased. This effect was observed in all 52 slices tested and complete abolition of the population spikes was observed at a mean current amplitude of 40uA. The mechanism of this large reduction was attributed to a polarization effect of the current producing hyperpolarization at the soma and depolarization at the dendrites. This mechanism was verified with intracellular recordings in 8 cells. The number of action potentials decreased with the application of the current until all action potentials were blocked. The difference between the intracellular and the extracellular voltage showed a net hyperpolarization at the soma correlated with the amplitude of the applied current.

Further increase of the amplitude of the current produced excitation as

expected but at current levels averaging 80 uA (N=4). Therefore, these results revealed the existence of a stimulation window in which epileptiform activity can be successfully blocked without simultaneous excitation. Supported by NSF Grant #: BNS 8809504

SEQUENTIAL AUTORADIOGRAPHIC ASSESSMENT OF TWO FUNCTIONAL/BEHAVIORAL STATES IN THE SAME ANIMAL J.Y. Chang, M.D. Ginsberg, O.F. Alonso, Y. Loor Cerebral Vascular Disease Research Center, University of Miami, Miami, FL 33136

We have incorporated the FDG/PET sequential-study methodology

Chang et al., J Nucl Med 28:652-860, 1987) and the refined DG model (Chang et al., <u>J Nucl Med</u> 28:652-860, 1987) and the refined DG model (Schmidt et al., <u>J Cereb Blood Flow Metab.</u> 9:290-303,1989) into a sequential-study method with autoradiography. Similar to the described PET method, the proposed tissue autoradiographic method for measuring two sets of lCMRglu values involves two intravenous injections of radiolabeled deoxyglucose, ³H-2DG coupled with ¹⁴C-2DG, 40-45 min apart. At 80-85 minutes(T2) after the first injection, the animal is sacrificed and the brain frozen and sectioned. The tracer concentrations of ³H(C7(T2)) and ¹⁴C(C2(T2)) are separated and measured at the end of the study using photographic methods. The lCMRglu values of the second experimental state (lCMRglu-2) are obtained directly using the measured tracer concentration from the second injection (C7(T2)) and measured tracer concentration from the second injection (C₂(T2)) and the operational equation of the 2DG method. The fact that the concentration of the first tracer measured in the brain at the end of the study $(C_1^*(T2))$ consist of 1) the tracer that has been taken up during the first experimental state but is still present at time T2 (R*(T2:T1)); and 2) the experimental state but is still present at time 12 (k₁(12:11)); and 2) the tracer taken up during the second experimental state (C₁(T2:T1)) from the first injected tracer that is still present in plasma. If the chemical forms of both injected 2DG are identical, C₂(T2:T1) can be approximated by the amount of cerebral uptake from the second 2DG injection (C₂(T2)). Subsequently, C₁(T1) can be estimated from its remnant(R₁(T2:T1)) through their relationship described by the kinetic model, and then ICMRglu-1 can be determined. This method should allow us to elucidate the relationship between behavior and regional cerebral metabolism cerebral metabolism.

A METHOD FOR BAPID REPEAT MEASUREMENTS OF REGIONAL CEREBRAL BLOOD FLOW (rCBF) WITH POSITRON EMISSION TOMOGRAPHY (PET) AND O-15 WATER. P. Herscovitch, R.E. Carson*, B. Zunkeler*, G. Jacobs* and P. Plasciak*, NIH, Bethesda, MD 20892.

O-15 labelled water is widely used to measure rCBF with PET. Although the half-life of O-15 is short, (123 sec), typically one waits about 12 min for the radioactive background to decay before a repeat rCBF study. We have developed an approach to perform sequential rCBF measurements more rapidly by accounting for residual background radioactivity. Immediately after the initial PET study, a new physiologic state, beginning at time T, can be established. A short scan is obtained to record the brain radioactivity remaining from the previous O-15 injection. Then, after a second O-15 injection, further scan data are collected. Brain radioactivity after time T is described by an equation based on the one-compartment Kety model:

Clot(t) = C(T) exp[-f(t-T)/ λ] + f Cart(t)* exp[-ft/ λ], where C(T) is the residual brain radioactivity at T, f the flow, Cart(t) where O(1) in the lost of the arterial time-activity curve, λ the partition coefficient of water, and * the operation of convolution. A rapid least squares method was used to fit values for f, C(T), and λ to the measured scan and blood data after time T. The method was implemented on a Scanditronix PC2048-15B scanner, with automated continuous blood sampling. Its feasibility was demonstrated by repeat rCBF studies obtained within 6-7 min in 2 anesthetized baboons. The correction for residual background ranged from 4-14%, and was greater in lower flow regions. By increasing the frequency at which rCBF measurements with bolus O-15 water can be repeated, our approach provides greater flexibility for brain mapping and other PET studies.

ASSESSMENT OF XE-127 AS A DYNAMIC SPECT rCBF TRACER IN NORMAL SUBJECTS AT REST R. Coppola, S. Marenco*, D. W. Jones* , D. R. Weinberger, Clinical Brain Disorders Branch, NIMH Neuroscience Center, Washington, D.C. 20032

Xe-133 has been the standard for the measurement of rCBF by dynamic SPECT. The need for more usable counts at a lowered patient dose makes the Xe-127 potentially a better isotope. In order to compare actual flow images and quantification we studied eight subjects at rest using both Xe-133 and Xe-127 with a Tomomatic 564 scanner. On each test day the subject had two studies; the first was a sham and the second was the actual study with either Xe-133 or 127. The Xe-133 studies were performed with a high sensitivity five slice collimator (MHS-5) with nominal resolution of 16 mm FWHM. The Xe-127 studies were done with a high resolution (9 mm FWHM) three slice collimator (HR-3), or a medium sensitivity and resolution (12 mm) five slice collimator (MHR-5). The studies were performed one week apart counter balanced for each Xe. Flow was calculated by both the early picture and the sequence of pictures method. Using the SP method gave much more comparable results between the two isotopes. The flow values for Xe-127, though highly correlated with the Xe-133 values, were higher (20%) at the better resolution. Xe-127 with the high resolution collimator clearly produced a more anatomically detailed image with less underestimation due to partial volume in lowered resolution scans. The use of Xe-127 allows higher resolution and thus better quantification.

PHYSIOLOGICAL MAGNETIC RESONANCE IMAGING OF BRAIN: BLOOD FLOW AND BLOOD OXYGENATION LEVEL DEPENDENT CONTRAST. S. Ogawa and T.M. Lee*. APET Bell Labs., Murray Hill, NJ 07974
Blood Oxygenation Level Dependent (BOLD) contrast of brain MRI at high magnetic fields is sensitive to variations of the physiological state of brain. BOLD contrast, caused by paramagnetic deoxyhemoglobin in the venous blood, depicts the brain vasculature by numerous dark lines in the image, although capillaries are too small to be resolved. Since the venous blood oxygenation level is determined by the supply and demand of oxygen at blood capillaries, we examined the correlation between BOLD contrast and the blood flow velocity measured by MRI at the sagittal sinus when the systemic CO2 level and the oxygen content in the ventilating gas were varied (Fig.1). In addition to BOLD contrast, the image signal intensity of tissue water was dependent to some extent on the venous blood oxygenation level, presumably because the water T2 was influenced by the microcirculation of tissue water around capillaries with deoxyhemoglobin. A simple observation was made on an acute effect of ethanol infusion to an anesthetized rat where induced changes in the brain image differed among various regions of the brain image in the brain image differed so for Sdrugon of the brain image differed so for Sdrugon of the brain image of the brain images with these MRI characteristics can be used to study non invasively effects of CNS drugon to the brain image of the brain images with these MRI characteristics can be used to study non invasively effects of CNS drugon to the brain image with the supplementation of the brain image with these MRI characteristics can be used to study non invasively effects of CNS drugon to the brain image with the supplementation to the brain image with the supplementation to the brain image with these MRI characteristics can be used to study non invasively effects of CNS drugon the brain image with the supplementation to the brain the presen on brain physiology.

CEREBRAL BLOOD FLOW (CBF) HETEROGENEITY: COMPARISON OF TWO TRACERS. S.C. Jones, R.M. Bryan, Jr., A.D. Perez-Trepichio and M. Shea*. Div. of Neurosurgery, Hershey Medical Center of Pennsylvania State Univ., Hershey, PA 17033 and Cerebrovascular Research Lab., Cleveland Clinic Foundation, Cleveland, OH 44195.

Foundation, Cleveland, OH 44195. CBF heterogeneity in terms of $\sim\!400~\mu m$ columns has been observed under the conditions of quick brain freezing and with less than 15 sec study times using $^{14}\text{C-iodoantipyrine}$ ($^{14}\text{C-IAP}$) or CBF agents that are highly diffusible and chemically trapped such as Ceretec (Amersham, $^{99}\text{mTc-HMPAO}$) or Spectamine (Mediphysics, $^{123}\text{-IMP}$). This spatial heterogeneity could be due to the temporal ($^{-6}\text{/min}$) heterogeneity of CBF or the vascular architecture of penetrating arteries.

In 8 pentobarbital anesthetized, freely breathing, Sprague-Dawley rats with (mean \pm SEM), MABP 129 \pm 6; PaCO₂ 49 \pm 3; PaO₂ 86 \pm 8; and pH 7.36 \pm 0.01, double tracer autoradiography with the indicator fractionation autoradiographic technique using either $^{99}\text{mTc-HMPAO}$ or $^{123}\text{-IMP}$ and $^{14}\text{C-IAP}$ was performed. Two time dependent protocols were used: one (n = 5) involved

diographic technique using either and in-HMPAO or fiel-IMP and in-C-IAP was performed. Two time dependent protocols were used: one (n = 5) involved the simultaneous administration of ¹⁴C-IAP and ⁹⁹mTc-HMPAO 10 sec before decapitation; in the other (n = 3), ⁹⁹mTc-HMPAO or ¹²³I-IMP was administered either 15 or 25 sec before, and the ¹⁴C-IAP 10 sec before, decapitation. The positions of the columns were compared.

positions of the columns were compared.
In both sequential and the simultaneous protocols, the distribution of the tracers was similar. In all cases the \$^{99m}Tc-HMPAO and \$^{123}I-IMP\$ showed higher contrast and sharper edges, whereas the \$^{4}C-IAP\$ showed the same pattern, but more diffusely. This distribution is most likely due to transport and retention of \$^{99m}Tc-HMPAO or \$^{123}I-IMP\$ in the larger arterioles, as opposed to the capillary distribution of \$^{14}C-IAP\$. Dut could also be due to the post-decapitation diffusion of \$^{14}C-IAP\$. These observations confirm the hypothesis that the columnar distribution of cortical CBF is related to the vascular architecture of the penetrating arterioles.

AN INEXPENSIVE WORKSTATION FOR THREE-DIMENSIONAL, VOLUMETRIC BRAIN RECONSTRUCTION, DISPLAY AND ANALYSIS. S.B. Berger, R.D. Leggiero*, G.F. March*, J.J. Orefice* and D.J. Reis, Div. Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021.

March*, J.J. Orefice* and D.J. Reis. Div. Neurobiology, Cornell Univ. Med. Coll., NY, NY 10021.

We sought to develop an inexpensive, computer-based, three-dimensional (3D) volumetric imaging system suitable for quantitative regional densitometric analysis of brain, and compatible with such imaging modalities as immunocytochemistry and autoradiography. This system permits geometric manipulation and display of reconstructed brain models and comparison of regional changes without reference to traditional, cytoarchitectural boundaries. We have designed and implemented data structures and algorithms for fast, efficient 3D reconstruction, display and analysis using (a) octree data compression; and (b) pipeline architecture imaging hardware, to overcome the computational limitation imposed by interpolative operations (e.g. oblique rotations, arbitrary cross sections - "electronic microtomy").

The system, CAVIS (Computer Assisted Volume Imaging Station), which is implemented on an inexpensive hardware platform, performs shading to reveal 3D shape, electronic microtomy, geometric transformations, and animation sequences. Oblique rotations are performed in approximately 187 s, electronic microtomy in less than 1 s and high-quality surface rendering in approximately 3 s (elapsed, not CPU times). This method (a) does not impose a priori topographical maps; (b) is unbiased with respect to investigator; (c) is less laborious; and (d) permits the use of alternate statistical methods. As a special application, we have modified and implemented these algorithms on two supercomputers for very high resolution imaging. This system may be useful as an inexpensive laboratory imaging workstation for neuroscience applications. neuroscience applications.

THREE DIMENSIONAL SURFACE RECONSTRUCTION OF REGISTERED PET-MRI IMAGES ENHANCES ANATOMICAL LOCALIZATION OF CORTICAL FUNCTION. H.H. Holcomb, H.L. Loats, S.E. Loats C.A. Tamminga, N. Cascella*, P. Loats*, H. Ravert*, R. Dannals,* H. Wagner *. U. Md. Psych. Res. Ctr., Johns Hopkins Medical Institutes, Loats Assoc., Baltimore, and Westminster Md. 21205.

Magnetic resonance images (MRI) provide high resolution of soft tissue boundaries. In contrast, positron emission tomography (PET) reveals local physiological activity. Acquired tomographically, two dimensional images from these diverse methods do not permit easy, accurate identification of cortical surface landmarks. Specific gyri and sulci have been implicated in numerous behavioral repertoires. Subjects performing auditory tone discrimination accurately are likely to exhibit different gyral activity patterns from those detecting differences inaccurately. Accurate gyral localization requires superimposed, registered PET-MRI surfaces.

localization requires superimposed, registered PET-MRI surfaces.

This pilot study of five normal subjects demonstrates the application of image subtraction using two sets of registered PET-FDG and one set of high resolution, 3 mm, MRI 3-dimensional data sets. These PET studies were acquired in subjects performing either low error (95% correct) or high error (70% correct) auditory discrimination tasks (750 Hz versus 1500 Hz) presented in conjunction with a variable background of white noise. A prospective MRI-PET registration method was used with retrospective fine adjustments (boundary matching optimization). Orothogonal data sets were generated and reconstructed to create serial sets of surfaces. These MRI-PET surfaces were then used to superimpose thresholded PET subtraction images onto their corresponding MR surface. Initial analyses indicate that the right superior temporal gyrus and right middle frontal gyrus exhibit significantly higher metabolic activity in subjects discriminating auditory tones accurately 90% of their trials.

VISUALIZATION OF ERYTHROCYTES, LEUKOCYTES, AND BLOOD PLASMA IN THE RAT BRAIN MICROCIRCULATION IN VIVO USING CONFOCAL LASER SCANNING MICROSCOPY (CLSM). <u>A.Villringer*</u>, <u>U.Dirnagl, R.Haber*</u>, <u>L.Schürer*</u>, <u>U.Büttner</u>, <u>K.Einhäupl*</u>. Dept. of Neurology and Dept. of Neurosurgical Research, University of Munich, 8000 Munich 70, FRG.

To investigate the role of different blood components in the physiology and pathophysiology of the cerebral microcirculation, we established a technique to visualize erythrocytes, leukocytes, and blood plasma within the microcirculation of the outer layers of the rat brain cortex. After implantation of a closed cranial window (dura removed) in anesthetized and ventilated rats the brain microcirculation was observed with a Biorad MRC 500 CLSM system (excitation wavelength 488/514 nm, equipped with appropriate filter blocks) attached to a Nikon Optiphot microscope with a x40 objective (NA=0.75, working distance 1.6 mm). Leukocytes were labelled by injection of Rhodamine G (0.1 ml of a 0.1% solution i.v.), blood plasma was labelled with fluorescein (0.3 ml of a 2% solution, erythrocytes were visualized as sparing of fluorescence. Leukocytes could be observed flowing with the blood stream, as stickers, and as rollers (i.e. adhering to or slowly moving along the vessel walls). Based on the fluorescein-labelled plasma filling of the microvessels 3 dimensional reconstructions of the micro-angioarchitecture of the pia and outer 200 µm of the cortex (including capillaries) were

A MULTIDETECTOR POSITRON EMISSION PROBE FOR STUDIES OF HUMAN BRAIN CHEMISTRY IN VIVO. K.I. leffries, H.L. Loats, D.G. Lloyd*, C.A. Tamminga, and H.H. Holcomb. Loats Associates Inc, P.O. Box 528, Westminster, MD 21157; and Maryland Psychiatric Research Center, P.O. Box 21247, Baltimore MD 21228.

The multidetector positron emission probe consists of four pairs of coincidence detectors which can be directed at any selected region-of-interest (ROI) in the brain. Detector positioning is registered to a set of MRI images for the subject. A user friendly computer interface allows the user to select the desired ROI by moving a cursor to the position on the subject's MRI image. A novel gantry design provides for computer controlled automated positioning of the detectors. The focusing of all detector pairs on the ROI in combination with a form of time-of-flight determination allows for quantification of radioactivity within target volumes on the order of 8 cm³.

Time-of-flight measurements with a FWHM of 3 cm have been obtained with an optimized detector design incorporating BaF2 scintillation crystals. Novel high speed coincidence detection circuitry has been developed to improve these measurements. A computer model has been developed to simulate the response of the device for various types of studies.

The device provides many ROI measurements comparable to those obtained with positron emission tomography at much reduced cost and radiation dose. Computer simulations and measurements made with the prototype system will be detailed to demonstrate the capabilities of the multidetector probe.

VIDEOMICROSCOPY OF FLOW IN SINGLE BLOOD VESSELS IN MOUSE BARREL CORTEX *IN VIVO*. <u>T.A.Woolsey</u>, <u>C.M.Rovainen</u>, <u>and O.Robinson*</u> Depts. Neurosurgery and Cell Biology, Washington Univ. Sch. Med., St. Louis, MO 63110

We have implemented optical methods for measuring diameters and velocities in single cerebral microvessels to observe local changes in circulation during neural stimulation. Fluorescent dextrans and 1-2 μm latex beads were injected i.v. and were monitored in pial vessels through a cranial window with a microscope and a SIT camera. Transit times were estimated from the differences in time courses of fluorescence between branches of the middle cerebral artery and veins draining the barrel cortex and were similar for the two plasma markers. Measured inner diameters of arteries and veins were 7-8μm larger with fluorescent markers than with absorption of green light by hemoglobin. Root mean velocities of fluorescent beads in venules were calculated from positions of individual beads in sequential video frames recorded at 30 Hz. Cranial chamber fluids at low pH or with adenosine dilated arteries and reduced AV transit times. Vessels were perfused with photographic emulsion, layer IV barrels were stained for cytochrome oxidase in postmortem histology, and the detailed patterns of arteries, arterioles, and veins were related to whisker barrels. With this approach we are mapping the changes in pial vessels suppling capillary plexuses in single barrels with whisker stimulation.

DETERMINATION OF ERYTHROCYTE FLOW VELOCITY IN SINGLE CORTICAL CAPILLARIES OF THE RAT BRAIN USING CONFOCAL LASER SCANNING MICROSCOPY (CLSM). <u>U.Dirnaql, A.Villringer*, R. Gebhardt* R. Habert*, K. Einhäupt*</u>. Dept. of Neurology, University of Munich, 8000 Munich 70, FRG.

In order to study dynamic phenomena of the brain microcirculation in vivo, we developed a method to determine erythrocyte velocity within single capillaries of the rat brain cortex. A closed cranial window (dura removed, distance brain surface-outer surface of the window < 1 mm) was implanted in anesthetized and ventilated rats. After injection of fluorescein (0.3 ml of a 2% solution i.v.) flowing erythrocytes in cortical capillaries down to 200 µm below the brain surface could be visualized as sparing of fluorescence using a Biorad MRC 500 CLSM system attached to a Nikon Optiphot microscope equipped with a x40 water immersion objective (NA=0.75, working distance 1.6 mm). Full frame images were collected at maximum rates of 16/s , and the scan line was placed parallel or perpendicular to a brain capillary for one dimensional single line determinations of erythrocyte flow velocity at a temporal resolution of 500 Hz. We conclude that CLSM can be used to study dynamic phenomena in the brain microcirculation in vivo.

16.12

QUANTIFICATION OF RELATIVE HALOPERIDOL OCCUPANCY IN VIVO WITH A SIMPLE DUAL DETECTOR PROBE. <u>C.A.</u> Tamminga. K. J. Jeffries. H.L. Loats. D.F. Wong*, A.T. Summerfelt*, L.T. Young*, R.F. Dannals*, and H.N. Wagner*. Maryland Psychiatric Research Center, P.O. Box 21247, Baltimore, MD 21228; Loats Associates Inc.; and Johns Hopkins Med. Inst.

A dual detector probe (Bice, A.N., <u>J Nucl Med</u> 27:184-191, 1986) makes possible positron emission studies of CNS at much reduced radiation dose and cost in comparison to PET. Coincidence counts obtained from the device can be used either directly or in an MRI-registered computer model to obtain potentially useful clinical information. Studies of the correlation between probe measurements and PET ROI data in humans have been carried out. In these studies, subjects were scanned with the probe immediately following a PET scan. Multiple studies were performed on each subject with varied doses of haloperidol. Blockade of ¹¹C-N-methylspiperone binding was used as a measure of occupancy of D-2 receptors in the striatum by these drugs. Coincidence counts were obtained from various positions through the subjects' brains. Ratios of counts from the position intersecting the striatum with other positions were compared with PET ratios from corresponding anatomical regions. Comparison of probe position ratios with PET ROI ratios in 3 subjects demonstrated a linear dependence: striatum/parietal-frontal (r=.82, p=.045) and striatum/cerebellum (r=.72, p=.107). These preliminary data suggest that the probe may provide some information comparable to that obtained with PET. Information which is more anatomically specific obtained with the computer model will be compared with these simple ratios.

CILIA ARE THE SITE OF OLFACTORY TRANSDUCTION, G. Lowe* and G. H. Gold. Monell Chem. Senses Ctr., Philadelphia, PA 19104.

We investigated the spatial distribution of odor sensitivity in tiger salamander olfactory receptor cells by measuring odor-induced currents across the cell body membrane with a suction electrode. Odor stimulation depolarizes the cell, causing an outward current across the somatic K' conductance. The cells were stimulated locally with a puffer pipette, while continuous flow of Ringer's solution, from the cell body toward the cilia, was used to orient the dendrite and cilia along a single axis, and to limit the region of the cell exposed to the stimulus.

Odor sensitivity is restricted to the ciliary region. Starting at the tips of the cilia, response amplitude increased approximately linearly with the length of cilia exposed to the odor stimulus, reaching a maximum at the bases of the cilia. Thus, all portions of the cilia contribute equally to the somatic currents, indicating that the contribute equally to the somatic currents, indicating that the electrotonic length of the cilia is at least several times longer than their physical length. The latency and timecourse of the odor response was independent of the position of the stimulus along the cilia. Thus, transduction is a local process, and does not require the diffusion of odorants or intracellular messengers from the cilia to the dendrite. The distribution of the resting K* conductance was measured by local stimulation with a high K* solution. K* conductance was present in the dendrite and cell body, but absent in the cilia. Exclusion of K⁺ conductance from the cilia may serve to maximize the passive spread of ciliary currents to the cell body.

DELAYED DEPOLARIZING RESPONSES OF NECTURUS TASTE CELLS TO CHEMICAL AND ELECTRICAL STIMULI AT THE APICAL PORE OF TASTE BUDS. <u>Douglas A. Ewald & Stephen D. Roper</u> Dept. of Anatomy & Neurobiology, Colorado State U., Ft. Collins CO 80523 and the Rocky Mountain Taste and Smell Center, Denver CO 80262

& Neurobiology, Colorado State U., Pt. Collins CO 80523 and the Rocky Mountain Taste and Smell Center, Denver CO 80262

Taste buds in Necturus contain two basic cell types: receptor cells with apical ends extending to the surface of the taste bud and basal cells in the basal region. Chemical synapses have been identified ultrastructurally in the basal region of the taste bud from both types to the afferent nerve and also between the two types (Delay & Roper, J. Comp. Neurol. 277 268, 1988). We have used intracellular recording from the basal region of taste buds in transverse slices of lingual epithelium (250 µm thick) to test for synaptic interactions. For chemosensory stimulation, the apical extremittes of receptor cells in each taste bud were transiently depolarized by focal application of 140 mM K+ solution. All cells gave depolarizing responses but in about half the cases the latency of the responses was significantly longer when compared to the receptor potentials recorded at the apical pore. Receptor cells (identified by Lucifer Yellow injection) had responses with latencies <75 msec. For electrical stimulation, the receptor cells were depolarized with a glass stimulating electrode (30 µm tip) applied to the pore with gentle suction. One component of the responses was depolarizations that had a time course of secs, had a delay of ≥75 msec, were fatigued with repetitive stimulation, recovered with a time course of minutes, and were blocked by the Ca++ antagonist Cd++. These slow depolarization of individual taste cells. The properties of the slow depolarization of individual taste cells. The properties of the slow depolarization of individual taste cells. The properties of the slow depolarization suggest that it is due to synaptic interactions in the taste bud. Supported by AGO6557, DCO0374 & PONS20486.

CHORDA TYMPANI SECTION DECREASES ION SPECIFICITY OF SODIUM APPETITE IN RATS. P.A. Breslin*, A.C. Spector, D.I. Luzzi*, and H.I. Grill. Psych. Dept., Univ. of Penn, Phila, PA 19104 The chorda tympani nerve (CT) in the rat is known to innervate highly selective Na* and Li* taste receptors on the anterior tongue. In the following experiment, sodium depleted rats were tested for their ability to respond selectively to a NaCl solution after these receptors had been denervated by bilateral CT section (CTX). A computer controlled quistometer randomly delivered six solutions. receptors had been denervated by bilateral CT section (CTX). A computer controlled gustometer randomly delivered six solutions sequentially via a single drinking spout water, 0.1M sucrose, 0.05 & 0.5M NaCl, and 0.05 & 0.5M NH₂Cl. Rats were provided with multiple, five second access periods to each of the solutions, presented one at a time. The computer recorded each lick and reinforced it with 5 ul of solution. The rats received a different solution approximately every 10 sec. Given this design, the preference for any stimulus [sits / (stimulus licks + water licks)] was most likely guided by afferent signals from the mouth. Intact rats treated with a natriuretic (furosemide) and given Na deficient food selectively increased their preference for NaCl, relative to untreated rats. However, sodium depleted CTX rats increased their preference for both NaCl and NH₂Cl and were thus less selective. The CTX sodium depleted rats expressed different preferences for NaCl and NH₂Cl, demonstrating that they can still discriminate the two salts. Despite their ability to discriminate these salts, the CTX rats failed to increase their sodium preference selectively. These findings suggest that afferent signals in the CT significantly contribute to sodium identification in the rat.

PRIMARY STRUCTURE AND FUNCTIONAL EXPRESSION OF A CYCLIC NUCLEOTIDE-ACTIVATED CHANNEL FROM OLFACTORY NEURONS. R.S. <u>Dhallan*1, K.-W. Yau^{2,4}, K.A. Schrader*3,4</u> and <u>R.R. Reed*2,3,4</u>. Depts. of Biomed. Eng. 1, Neurosci. 2, Mol. Biol. and Gen. 3, and Howard Hughes Med. Inst. 4, Johns Hopkins Sch. of Med., Baltimore, MD 21205.

A cyclic nucleotide-activated cation channel is now thought to mediate odorant signal transduction in olfactory cilia. We report here the molecular cloning and functional cilia. We report here the molecular cloning and functional expression of such a channel from olfactory neurons based on structural homology with the cGMP-gated channel in bovine rods (Kaupp et al., Nature 342, 762, 1989). The coding region of the rod channel was used to screen a rat olfactory cDNA library, and a single class of cDNA clones was identified. The longest of these revealed an open reading frame of 664 amino acids that shares extensive homology with trame of 664 amino acids that shares extensive homology with the rod channel, including the region implicated as the cyclic nucleotide binding site. Northern blot analysis indicated that the message encoding this putative channel protein is present only in olfactory epithelium, and is reduced upon elimination of the sensory neurons induced by olfactory bulbectomy. Inside-out patches of plasma membrane from human 293 cells transfected with the above cDNA showed the expression of a cation channel that is activated by cyclic nucleotides and has properties broadly similar to those of the native channel in olfactory cilia, including the affinities for cyclic nucleotides and the currentvoltage characteristics.

SUCROSE STIMULATION OF RAT TASTE CELLS CAN IN-CREASE MEMBRANE POTASSIUM CONDUCTANCE. M.S. Herness. Lab. of Neurobiology & Behavior, Rockefeller University, New York, NY 10021.

Evidence is presented using whole-cell patch clamp recordings that sucrose application to the bath can reversibly increase outward currents in dissociated rat taste cells. These currents appear to be mediated by potassium channels since they are blockable by either TEA or 4-AP. The sucrose-induced increase in outward currents (approx. 1.5X increase) appears to affect both delayed rectifier type and A-type potassium currents as measured in different cells. NaSaccharin, another sweet stimulus, was observed to increase outward currents in some but not all cells. Since a cyclic nucleotide system has been proposed as a sweet taste transduction mechanism, sucrose plus IBMX, which reversibly inhibits cAMP breakdown, was also tested. This application increased outward currents by 5X and was reversible when the sucrose/IBMX mixture was rinsed out of the bath. Collectively these data suggest that sucrose may open potassium channels and that a cAMP dependent mechanism may be These data could account for previously reported hyperpolarizing receptor potentials with increased input resistance or the repolarization phase of a depolarizing receptor potential to sucrose stimulation.

RABBIT GUSTATORY EPITHELIUM EXPRESSES KERATIN 6-LIKE IMMUNOREACTIVITY. B. Oakley, A. Lawton*, and L. Wong*. Dept. of Biology, Univ. of Michigan, Ann Arbor, MI 48109. Keratins are the dominant class of intermediate filaments of the cell cytoskeleton. Nineteen soft keratins are present in various combinations in human epithelial tissues. This allows one to identify specific types of epithelial cells by their keratin profile. A monoclonal antibody specific for keratin 6 (MAb KL-1) reacted exclusively with basal cells throughout the non-gustatory lingual epithelium of the rabbit tongue, as indicated by heavy staining with either streptavidin Texas Red or reaction products of the avidin peroxidase complex bound to a biotinylated secondary antibody. One group of basal cells in the lingual epidermis did not show keratin 6-like immunoreactivity...the basal cells directly beneath taste buds Inke immunoreactivity—the basal cells directly beneath taste buds (foliate). Moreover, only in the gustatory epidermis did suprabasal cells or flattened squamous cells display keratin 6-like IR. Hence, keratin expression readily distinguishes the gustatory epidermis from ordinary lingual epidermis. The use of other MAbs indicated that fusiform cells of taste buds abundantly expressed keratin 19-like IR that was undetected elsewhere in rabbit tongue epidermis. Keratin 6- and 19-like reactivity was not unique to gustatory tissue as cells comprising the ducts of salivary glands were reactive. We conclude that the gustatory epidermis is highly specialized, since keratin 19-like IR was detected only in taste receptor cells while keratin 6-like IR was observed only in those suprabasal cells adjacent to taste buds. Keratin expression may be a useful way to mark gustatory tissue and assess its state of differentiation. Supported in part by NIH Grant NS-07072

GLYCOCONJUGATE DIFFERENCES IN SECRETORY CELLS OF MAMMALIAN OLFACTORY MUCQSAE. J.D. Foster', M.L. Getchell', and T.V. Getchell', 1, Dept. Physiol./Biophys., & 2, Div. Otolaryngol., Dept. Surg., 3, Assoc., Sanders-Brown Center on Aging, Univ. Kentucky Coll. Med., Lexington, KY 40536.

Distribution of sialic acid (SA), galactose (Gal) and

Distribution of sialic acid (SA), galactose (Gal) and N-acetylgalactosamine (GalNAc) residues in sustentacular cells (SC) and acinar cells of Bowman's glands (BG) of hamster and mouse olfactory mucosae was investigated using fluorescently-labeled lectins. SA binding lectins from Limulus polyphemus (LPA) and Limax flavus (LFA) stained BG only. SA removal by neuraminidase (Nase) resulted in loss of staining. The Gal/GalNAc binding lectins from Peanut (PNA), Soybean (SBA), Bauhinia purpurea (BPA), Dolichos biflorus (DBA), Griffonia simplicifolia I (GSI) & Maclura pomifera (MPA) stained BG differentially. MPA in hamster and BPA in mouse stained most BG. All other lectins except GSI stained a minority of BG, suggesting the presence of a sub-population of BG with glycoconjugates containing terminal Gal and/or GalNAc residues. Pollowing Nase, all the Gal/GalNAc binding lectins in hamster and PNA, BPA and MPA in mouse stained most BG, indicating that SA capped Galgi, 3CalNAC residues are also capped by SA. None of the lectins stained SC. The different secretions of the two populations of BG may reflect specific functional roles in perireceptor events in olfactory transduction. Supported by NSF BNS-88-21074 (MLG) and NIH NS-16340 (TVG).

THE EFFECT OF ODORANTS ON ADENYLATE CYCLASE IN PRIMARY CULTURES OF RAT OLFACTORY NEURONS. G.V. Ronnett, L.D. Hester and S.H. Snyder. Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

A method for primary culture of neonatal rat olfactory neurons has been developed in order to study the mechanisms of olfactory signal transduction. This method yields a homogeneous population of olfactory neurons which stain for vimentin, neuron-specific enolase and olfactory marker protein. Exposure of cell monolayers to odorants such as isobutylmethylxanthine, isovaleric acid, citralva resulted in rapid transient rises in intracellular cAMP levels as demonstrated by RIA. To ascertain whether this was due to activation of adenylate cyclase (AC), cell monolayers were permeabilized and AC was assayed in situ. Odorants which caused elevation of cAMP activated AC over the appropriate time. This method was also used to study desensitization and sensitization.

DIENCEPHALIC AMNESIA AND SELECTIVE VISUAL AGNOSIA IN CHILDHOOD. F. Vargha-Khadem* and E. Isaacs*, (SPON: European Brain and Behaviour Society), Department of Neurology and Developmental Paediatrics and Hospital for Sick Children, Great Ormond Street, London, WCl, England.

Chronic anterograde amnesia resulting from diencephalic damage in childhood is a rare occurence. We had the opportunity to investigate such a patient with normal development until the age of 13 when a metastasised pineal gland tumour was diagnosed. Tested at age 15, he had bilateral optic atrophy, reduced acuity and tunnel vision. Neuropsychological assessment revealed normal verbal IQ, language, planning, fluency, and visuo-spatial abilities, but severely restricted immediate recall and no delayed recall. Autobiographical memory showed 100% recall of retrograde events but little or none anterograde. The latter, however, could be cued through writing. Due to long term consequences of irradiation, the patient developed selective visual agnosia and pure alexia without dysgraphia. As in the case of the amnesia, visual and word recognition could be cued through the kinesthetic feedback provided by drawing and letter-by-letter writing. Devoid of the kinesthetic cues of drawing and writing, the patient could neither read his writing nor recognise his intricate drawings. Despite the selective visual agnosia, the patient demonstrated normal performance on tests of visual matching, orientation of lines and judgement of rotated abstract objects.

NONWORD PRIMING MAY BE ROBUST DESPITE GLOBAL AMNESIA. I.D.E. Gabrieli, M.M. Keane, and S. Corkin. Dept. of Brain & Cognitive Sciences and Clinical Research Center, MIT, Cambridge, MA 02139.

Despite impaired recall or recognition of words, patients with global amnesia show normal magnitudes of repetition priming on word identification and word completion tasks. Two studies (Cermak et al., 1985; Diamond & Rozin, 1984) reported that amnesic patients show little or no repetition priming of nonwords on identification and completion tasks. The absence of nonword priming indicated that amnesic patients may exhibit repetition priming only for premorbidly known words. We report now that H.M., whose amnesia followed bilateral medial temporal-lobe resection, shows robust nonword repetition priming in studies of nonword identification (presented briefly or emerging from a cover of visual noise) and of nonword reading latency. Nonword priming on the visual-noise task was evident after a 24-hour delay. In all experiments, H.M. had impaired recall and recognition of nonwords. Another study with normal subjects revealed that they do not show nonword completion priming unless they are told that the completion is an explicit test of memory (cued recall). Thus, nonword completion priming depends upon recall and recognition mechanisms in normal memory. These results suggest that, under some circumstances, perceptual and productive components of nonword processing may support nonword priming despite severe damage to the limbic structures that mediate recall and recognition of nonwords. MEMORY FOR DIFFERENT ASPECTS OF COMPLEX VISUAL SCENES AFTER RIGHT ANTERIOR TEMPORAL LOBECTOMY. S. Pigott and B. Milner. Montreal Neurological Institute, McGill University, Montreal, Canada, H3A 2B4

To examine the nature of the visual memory impairment observed following right anterior temporal lobectomy, delayed recognition memory for different aspects of complex visual scenes was examined in 65 patients with unilateral temporal—or frontal-lobe excisions and 15 normal control subjects. Right anterior temporal lobectomy, irrespective of the extent of hippocampal removal, resulted in an impairment in memory for figurative detail (the visual characteristics of the objects in a scene) and spatial composition (the arrangement of the filled and empty space in a scene). In contrast, only patients with right temporal lobe lesions that included extensive hippocampal removal were impaired at detecting changes in the spatial location of specific objects. A subsequent study provided no evidence that right temporal lobectomy impairs the immediate recognition of these types of visual information, suggesting that the impairments observed represent a failure of retention or retrieval rather than of encoding.

DEFECTIVE SOMATIC STATE ACTIVATION FOLLOWING VENTROMEDIAL

Percentle Solvante State Activation rollowing verification.

Pept. of Neurol., Univ. of Iowa Col. of Med., Iowa City.

Patients with bilateral ventromedial frontal lobe damage develop severe defects in social conduct. We have damage develop severe defects in social conduct. We have hypothesized that this is due to defective activation of somatic states associated with reward and punishment, which deprives the patients of critical markers for behavioral guidance. Preliminary investigation of this theory confirmed that such patients had defective skin conductance responses (SCRs) to visual stimuli charged with social significance, but generated normal SCRs to with social significance, but generated normal SCRs to simple "orienting" stimuli (e.g., startle). Here we test the theory further in the prototypical patient EVR. Target (high social significance) and nontarget (low social significance) stimuli were presented to EVR in different modalities (visual auditory) forms (verbal nonverbal) modalities (visual, auditory), forms (verbal, nonverbal), and response conditions (PASSIVE-no response, ACTIVE-verbal description). In PASSIVE conditions, EVR showed a verbal description). In PASSIVE conditions, EVR showed a marked failure to generate SCRs to target stimuli, but in ACTIVE conditions, his SCRs were normal. This effect was highly reliable, and it obtained for both verbal and nonverbal stimuli, in both visual and auditory modalities. The findings suggest that EVR does not activate somatic states in response to stimuli whose implications would normally include punishment or reward, and whose experience might trigger states of pain or pleasure.

18.7

SENSORY DETECTION WITH AND WITHOUT AWARENESS, WITH THALAMIC STIMULATION IN MAN B. Libet, D.K. Pearl*, D. Morledge*, C. Gleason*, Y. Hosobuchi* & N. Barbaro, Depts. Physiology & Neurosurgery, Univ. of Calif., San Francisco, CA 94143-0444.

We had demonstrated that stimuli in S-I cortex or n.VPLthalamus at liminal intensity required minimum train durations (TD) of up to 0.5 sec, to elicit a conscious sensory experience. A "time-on" theory was proposed: Durations of appropriate neural activity less than those required to elicit awareness could subserve mental functions that proceed without awareness; transition from the latter to awareness of the event occurs when durations are sufficiently long. The present study provided a

direct test of this proposal.

Patients with electrodes therapeutically implanted in ventro-basal thalamus were given near liminal stimuli (72/sec) with TDs between 0 and 750 msec; TDs were randomly varied among trials. Subjects made a forced choice between which of 2 intervals contained the stimulus even if they were not aware 2 intervals contained the stimulus even it they were not aware of any sensation. Subjects also indicated their level of awareness after each trial. Detection (correct > 50%) occurred even with brief TDs(< 10 pulses) and subjects feeling nothing. Any even uncertain awareness required a statistically very significant and substantial increase in TD. Thus, simply increasing the duration of the same repetitive inputs to cerebral cortex can convert an unconscious cognitive mental function to a conscious one. (Supported by U.S.P.H.S. grant NS-24298).

MODULARITY IN THE VERBAL-VISUAL REPRESENTATION OF SIZE

SHOWN BY CORTICAL ELECTRICAL INTERFERENCE. J. Hart. R.P. Lesser, B. Gordon. Depts. of Neurology, Neurosurgery, and Psychology, The Johns Hopkins University, Baltimore, MD 21205

Modularity has been proposed as a basic organizing principle of cognitive neuroscience. However, while there is abundant evidence of modularity at the single neuron level from animal studies, and for largecognitive fletioscience. Towever, while there is abundant evidence or modularity at the single neuron level from animal studies, and for large-scale modularity of human cognitive functions (e.g., major subcomponents of language) from pathologic conditions such as aphasia, firm evidence as to the existence and the nature of intermediate aspects of modularity of human cognitive functions has been relatively sparse. In a patient undergoing direct cortical electrical interference mapping of language functions as part of a clinical evaluation for epilepsy (Lesser et al., 1987), stimulation of adjacent electrodes over the left (dominant) posterior middle temporal gyrus caused a selective, reversible, abolition of her ability to make verbal judgments of comparative size for objects and animals (e.g., is a lemon larger than an apple?), without affecting verbal judgments of other visual properties, such as orientation and movement. Visual size comparisons by direct access or by imagery were not affected. These and other data (Moyer, 1973) have three implications: 1) analogue size information is kept apart from language in the visual system, 2) access to this size information, or the information itself, is modularized by this quality, rather than by the particular object with which it is associated, which therefore 3) allows verbal access to size information to be selectively rather than by the particular object with which it is associated, which therefore 3) allows verbal access to size information to be selectively affected by the appropriate interference. The anatomic location of the temporary, 'functional lesion' responsible for this disconnection, at the posterior middle temporal gyrus, is consistent with a block between language functions mediated by the superior temporal gyrus and visual recognition systems mediated by inferior temporal and occipital regions and by other systems.

A BRAIN-COMPUTER INTERFACE FOR CURSOR CONTROL. D.J. McFarland, G.W. Neat*, C.A. Forneris* and J.R. Wolpaw. Wadsworth Laboratories, NY State Dept. Health and SUNY, Albany,

NY 12201.

Previous studies showed that individuals can learn to modulate the 9-12 Hz sensorimotor rhythm (SMR) of the EEG quickly and accurately to move a cursor to a target located at the top or bottom of a video screen (Wolpaw et al 1986 and submitted). This study trained subjects to move a cursor up or down in a graded fashion to a given location.

EEG was recorded from the scalp over the central sulcus of the

EEG was recorded from the scalp over the central sulcus of the left hemisphere. SMR amplitude was assessed 3 times/sec by a fast Fourier transform. A cursor began at the midpoint of the right screen edge and moved up or down depending on SMR amplitude. A target began at a random height on the left edge and marched across the screen at that height in 8 sec. The subject's task was to move the cursor so that it intercepted the target.

Performance was evaluated by comparing the vertical distance between the cursor and target at the beginning of the trial to that at the end of the trial. Since the cursor's starting point was, on average, closest to all possible target heights, random performance would have increased this distance. After several weeks of training, three of four subjects reduced this distance to an average of 52% of its initial value (pc.0001 for each of the three subjects).

subjects reduced this distance to an average of 52% of its initial value (p<.0001 for each of the three subjects).

These results show that the SMR can be used to control graded cursor movement. Current efforts are evaluating the possibility of training subjects to control independently SMR from both hemispheres simultaneously. This work may provide a significant new communication and control channel for disabled individuals. (Supported in part by IBM Corporation.)

NEUROMAGNETIC PREMOTOR READINESS FIELDS AND RHYTHMIC ACTIVITY ALTERATIONS PRECEDING SPEECH. $\underline{\mathsf{T.\,T.\,Yang}^*}$. C.C. Gallen. S. Hampson*. F. Bloom. Dept. of Neuropharmacology, Research Institute of Scripps Clinic, La Jolla, CA 92037

This study measured magnetoencephalographic (MEG) slow surface waves and changes in cortical rhythmical activity preceding speech for detection of language output related cortical function. Topographical activity was bilaterally recorded via serial placements of a 14-channel Neuromagnetometer while subjects said "put" at four to seven second intervals. Simultaneous sound output and lip EMG recording with automatic determination of speech initiation allowed isolation of the two second periods preceding and following the speech trigger for further processing. Epochs were (1) averaged to compute slow waves, (2) filtered for specified frequency bands and studied using a moving window method to assess rates and direction of change over time and (3) spectrally characterized by comparison of the power spectrum in different time periods before and after speech onset. Large amplitude shifts in some subjects began in the time period immediately preceding speech, continued during the time of speech output and in some cases were consistent with a generator source which could be modelled by an equivalent current dipole. Subject responses varied in amplitude and complexity. Alterations in rhythmic activity over time were characterized. Recordings of magnetic premotor waves and reactivity have potential utility for detection of speech related cortical function.

Functional Neuroanatomy of Visual Single Word Processing Studied with PET/MRI Sean Marrett, Daniel Bub*, Howard Chertkow,

Ernst Meyer*, Teren Gum*, Alan Evans*. Positron Imaging Laboratories and
Department of Neuroliguistics, Montreal Neurological Institute, Montreal, Que-

The neuroanatomical correlates of visual word and picture processing were investigated with combined PET measurements of tegional cerebral blood flow (rCBF) and magnetic resonance imaging studies in six normal right-handed male subjects. PET studies were performed using intravenously administered H₂-¹⁵O followed by a 60 second scan using a Scanditronix PC-2048-15B PET camera. Following the work of Petersen and co-workers, multiple tasks were used to allow for the planned subtraction of activation states associated with the different conditions. High resolution MRI imaging studies were obtained on all subjects, and were subsequently registered in 3-D with PET data from the same individual. The registered MRI volumes were used to derive a set of anatomical parameters from which the PET images were transformed into a stereotaxic coordinate system. This allowed averaging of data from different subjects in the same activation state (Fox et al, 1988). In the first task, subjects were asked to stare at a video monitor while single words were presented under computer control. When a fixation condition was subtracted from this state, the most robust response was a bilateral activation of striate and extrastriate cortex. There was also clear unilateral activation of occipito-temporal cortex in the dominant hemisphere, along with a unilateral activation of the anterior temporal lobe. These results are consistent with a specific dominant hemisphere (occipito-temporal) locus activating the orthographic description of words, followed by a second component, more anteriorly located, implicated in the derivation of meaning.

INTERREGIONAL CORRELATIONS OF REGIONAL CEREBRAL BLOOD FLOW (rCBF) AMONG POSTERIOR CORTICAL BRAIN REGIONS DURING OBJECT AND SPATIAL VISUAL PROCESSING. B. Horwitz.

J. Haxby*, C. Grady, M. Schapiro*, R. Carson*, P. Herscovitch, L. Ungerleider, M. Mishkin and S. I. Rapoport, Lab. Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892.

Correlation coefficients between pairs of normalized rCBF values, obtained by positron emission tomography with [15-O]-labeled water, were used to examine functional interactions among brain regions in posterior neocortex in 17 young men during two 2-choice, match-to-sample visual tasks: face discrimination (FD), and dot localization with rotation (DL). Compared with a visuomotor control task, both FD and DL activated lateral occipital and occipitotemporal cortex bilaterally, although the activation during FD was significantly greater than during DL. Bilateral activation of superior parietal cortex occurred during DL, but not FD. Correlational analysis revealed that during FD, occipital and occipitotemporal activations correlated significantly, but only in the right hemisphere. During DL, occipital and superior parietal activations correlated significantly, but again only in the right hemisphere. In the left hemisphere, large significant correlations among many posterior brain regions were found during DL, but not FD. In both tasks, large interhemispheric correlations between normalized rCBF occurred. These results support the view that FD and DL processing are carried out to a greater degree by the right posterior hemisphere than the left, but that the DL task may involve, in addition, left intrahemispheric interactions among posterior regions.

THE AGING PROCESS: NEUROTRANSMITTERS AND ENDOCRINE REGULATION

19.1

MUSCARINIC ANTAGONISTS ON ACETYLCHOLINE RELEASE FROM THE HIPPOCAMPUS OF AWAKE RATS: A PROBE OF ACED BRAIN CHOLINERGIC FUNCTION AND OF ITS AMELIORATION BY ACETYL-L-CARNITINE. L. Angelucci, M.T. Ramacci*\$, L. Alivernini*, M.G. Scrocco*, S. Bacchi* and A. Imperato. Farmacologia Medica 2a, Università "La Sapienza", Roma, and \$ Istituto per la Ricerca sulla Senescenza, Sigma Tau, Pomezia, Italia.

The regulation of acetylcholine (ACh) release by different subtypes of muscarinic receptors in young (3 months) and old (24 months) Fischer and Sprague-Dawley rats was investigated by means of brain microdialysis. Atropine induced a remarkable increase of ACh release in the hippocampus of young rats while the effect was drastically reduced in the old ones. The selective MI antagonist pirenzepine also stimulated ACh release in young rats although was ten times less potent than atropine. Differently from atropine, the effect of pirenzepine was not reduced but significantly increased in 24 month old rats, in agreement with recent autoradiographic studies showing an age-dependent increase in the hippocampal MI receptors with parallel reduction in M2 receptors. Six month pretreatment with acetyl-l-carnitine (ALCAR) reduced the significant differences between young and old rats in the receptor-mediated functional release response, suggesting that ALCAR could be utilized to ameliorate cholinergic function in the aged brain.

19.3

REDUCTION IN IMMUNOREACTIVE CATECHOLAMINERGIC NEURONS IN SELECTIVE BRAIN REGIONS OF OLD FEMALE RATS. L. Givon and A. A. Gerall. Dept. of Psychology, Tulane Univ., New Orleans, LA 70118.

This research identifies catecholaminergic neuronal systems which could participate in age-related prolactin hypersecretion and loss of spontaneous ovulation in rats. Examined in young and old animals were noradrenergic (NA) neurons located in brain stem A1 and A2 groups and dopaminergic (DA) neurons in the rostral ventral periventricular area (AVPV), in the arcuate nucleus A12, and the preoptic area A15 clusters.

Young (5-7 mos) cycling and old (30-32 mos) anovulatory Sprague-Dawley rats were ovariectomized 5-7 weeks before being perfused intra-aortically with paraformaldehyde. Brains were sectioned coronally at 50 μ and immunocytochemically processed using a modified Sternberger PAP methodology. Forebrain sections were treated with tyrosine hydroxylase antiserum (1:1000; Eugene Tech, NJ) and hindbrain sections with dopamine-beta-hydroxylase (DBH) antiserum (1:5000; I. Li Chen, Tulane Univ.). Tissues from paired young and old animals were processed simultaneously.

Old animals consistently had fewer DA neurons in the caudal arcuate nucleus (A12), in the AVPv and in the ventral segment of A15. The number of visualizable DBH-immunoreactive neurons in A1, A2 and TH-immunoreactive neurons in the dorsal A15 was not related to age.

19.2

HARMACOLOGICAL CHARACTERIZATION OF THE GABA_A/BENZODIAZEPINE RECEPTOR COMPLEX IN RAT HIPPOCAMPUS DURING AGING. D. Ruano*, J. Cano*, A. Machado*, J. Jiménez-Castellanos¹ and J. Vitórica*. Dept. Bioquíndica, Bromatol. y Toxicol. Fac. Farmacia. ¹Dept. Ciencias Morfológicas. Fac. Medicina. 41012 Sevilla. Spain.

It has been postulated that the benzodiazepine sensitivity may be increased during the human aging. This increased sensitivity could be extlained by age-related changes in either pharmacokinetic and/or pharmacological characteristics of benzodiazepines (Greenblatt et al, J. Clin., Pharmacol., 29:866, 1989). It has also been reported an age-related change in the molecular organization of the GABA/Benzodiazepine receptor complex in the present communication we have evaluated the pharmacological properties of the GABA/Benzodiazepine receptor complex in hippocampal membranes from 3 month and 24 month-old rats.

The results indicated the absence of major changes in ³H FNZ or ³H Macimol binding parameters. Neither the K_ds nor the Bmax for ³H FNZ or ³H Muscimol, determined by Scatchard, were altered during aging in hippocampus. However, in 24 month-old rats the GABA enhancement of 1nM ³H FNZ binding showed a significant increase over 3 month-old rats.

Two Berzodiazepine receptor subtypes can be distinguished by their affinities for the triazologyridazine Cl218-872. In 3 moth-old hippocampus the Berzodiazepine receptor belongs to type II, showing a single low affinity of 2.0560.550M (5 of 5 experiments). However, in 3 of 5 hippocampus from 24 month-old rats, two different affinities for Cl 218-872 can be discriminate: high affinity, 305±202mM and low affinity, 2.02±0.730M. In conclusion, the Ω AFAN/BZD reoptor binding parameters remains unlitered with aging in rat hippocampus. The increase in the GABA enhancement of Ω 4FNZ binding could be due to the increase in the heterogeneity of the Benzodiazepine receptor.

19.4

NOREPINEPHRINE CONTENT AND RELEASE IN CARDIOVASCULAR TISSUES FROM ADULT AND AGED FISCHER 344 RATS. <u>B. Dawson, Jr. and M.J. Meldrum</u>. Dept. of Pharmacodynamics, Univ. Florida, Gainesville, FL 32610

The aim of the present study was to examine cardiovascular tissues and determine if norepinephrine (NE) stores , NE release from sympathetic nerves and α2-adrenergic binding sites declined as a function of age. NE content was determined in adult (8 month) and aged (28 month) male Fischer 344 rats by HPLC with electrochemical detection. [3H]NE release was measured in the caudal artery. [3H]Rauwolscine binding was determined in crude homogenates of whole kidney. Total NE content per organ was not altered in aged rats except for a significant (p< 0.02) decline in ventricular content. NE content in äged rats expressed as ng/g wet weight was significantly (p< 0.02) reduced relative to adults in whole heart, atria, ventricles, kidney and caudal artery, but was not altered in the renal artery or portal vein. [3H]Rauwolscine binding in the kidney was decreased 22% in aged rats when compared to the adults. Neither basal nor KCI stimulated [3H]NE release was altered in aged rats. Yohimbine augmentation of KCI stimulated NE release was of a similar magnitude in both adult and aged rats. In summary, ventricular NE content and renal α2-adrenergic receptors decrease with aging. Normalization of NE stores by tissue weight in aged rats results in the appearance of a significant decline in NE, however, this is due to an increase in tissue weight and not a decline in NE content. NE release is also also unchanged in the caudal artery which suggests that noradrenergic neuroeffector function is relatively intact in the aged rat.

INCREASES IN MONOAMINE SYNTHESIS ARE PROPORTIONAL TO THE RATE OF AGE-RELATED NEURONAL LOSS FOR DIFFERENT MONOAMINERGIC POPULATIONS. C.E. Greenwood, W.G. Tatton and D.

MONOAMINERGIC POPULATIONS. C.E. Greenwood. W.G. Tatton and D. Holland*. Depts. Nutr. Sci. and Phys., Univ. Toronto, Tor., Ont., MSS 1A8. Evaluation of age-related changes in neurotransmitter levels in terminal beds must consider the age-related loss of neurons supplying the transmitter. For example in C57BI mice, striatal levels of dopamine (DA) and its metabolite, DOPAC, show little or no change despite a marked loss of TH+ substantia nigra compacta (SNc) neurons across the lifespan so that striatal DA and DOPAC levels per average remaining TH+ SNc neuron increase progressively (Greenwood et al, Soc. Neurosci. 15:437,1989). To confirm the increased DA synthesis per TH+SNc neuron with aging and to extend the finding to other monoaminergic populations, monoamine synthesis and turnover rates were determined in C57BI mice following NSD-1015 or pargyline administration and were expressed relative to the numbers of remaining TH+ or 5HT+ neurons (Tatton et al, Soc. Neurosci. 15:160,1989). Striatal DA or DOPAC, cortical NE and spinal cord 5HT or 5HIAA levels were similar at 8, 52 and 104 wks of age. Accumulation of DOPA or 5-OH-TRP following NSD or DA, NE and 5HT following pargyline in these same terminal areas was similar in 8 and 104 wk old mice (expressed relative to the remaining proportion of TH+ or 5HT+ somata in each pressed relative to the remaining proportion of TH+ or 5HT+ somata in each nuclei at 104 wks (mean ±SD of 26±1% for locus coeruleus (LC), 30±1% for SNc and 92±3% for medullary raphe neurons), they revealed an approximately SNC and 92±3% for meduliary raphe neurons), they revealed an approximately 3 fold increase in DA and NE synthesis in remaining SNc and LC neurons at 104 wks in comparison to that at 8 wks of age. In contrast, synthesis of 5HT per neuron was unchanged from 8 to 104 wks of age in raphe neurons. Retinal DA and DOPAC levels showed little or no change, expressed per g protein; however, DA, but not DOPAC, levels per TH+ retinal amacrine increased 1.5 fold from 8 to 104 wks. We hypothesize that monoamine synthesis increases in surviving aging neurons proportionally to the extent of the loss of other neurons in the same population in an attempt to compensate. CHANGES IN STRIATAL D, RECEPTOR mRNA IN AGED RATS E.R. Mesco, M.J. Blake, J.A. Joseph, G.S. Roth*. Gerontology Research Center/NIA, Baltimore, MD 21224.

The striatal dopamine D₂ receptor displays decreased total binding (B_{max}) of [³H]-spiperone in the aged rodent as well as several other species, including humans. This reduction can be explained by two mechanisms: neuronal loss and decreased net receptor protein synthesis. In order to determine whether the decreased protein synthesis was due to a change in mRNA, the levels of D₂ mRNA were determined in young (6 mo.) and old (24 mo.) male Wistar

A cDNA probe, complementary to bases 4-51 of the mRNA (5'-GTT CTG CCT CTC CAG ATC GTC ATC GTA CCA GGA CAG GTT CAG TGG ATC -3') which encodes the N-terminal of the protein, was used in dot blot and in situ analysis of striatal RNA extracts and brain slices, respectively. This probe identifies both subtypes of the D₂ receptor molecule. Total mRNA was ascertained by the use of radiolabeled poly-T probes on duplicate dot blots. No significant age changes in total mRNA were detected. Decreases in D2 mRNA, averaging 50%, were seen in old striata when compared to the young on dot blot analysis. The decreases in D_2 mRNA observed in the aged animals suggest that transcriptional changes may contribute to the lower levels of the receptor seen during aging.

NMDA MEDIATED RESPONSES DECREASE WITH AGE IN FISCHER 344 RAT BRAIN. R. A. Gonzales, L. M. Brown, and S. W. Leslie. Inst. for Neuroscience, Univ. of Texas, Austin, TX 78712. N-methyl-D-aspartate (NMDA) receptor-mediated responses were studied

in hippocampus, cortex, and striatum of Fischer 344 rats of various ages (3, 12, and 24 months old) to determine whether aging alters the function of NMDA receptors. The inhibition of muscarinic-stimulated phosphoinositide (PI) hydrolysis by NMDA and the stimulation of release of [³H]norepinephrine (NE) or [³H]dopamine (DA) were used as indices of NMDA receptor function. Carbachol (1 mM)-stimulated PI hydrolysis in hippocampal slices was similar in all age groups. NMDA inhibited the carbachol-evoked PI response in a concentration-dependent manner (10-100 µM), although the NMDA-induced (100 µM) inhibition of the carbachol-stimulated response was markedly reduced in an age-dependent manner with losses of 25% and 53% in middle-aged and senescent rats, respectively, compared to young. The maximal response for NMDA-stimulated [³H]NE release in hippocampal slices was significantly decreased from 6.55 fractional [³H]NE release in young to 4.51 and 4.18 in middle-aged and old rats, respectively, with no age-related changes in the potency of NMDA or slope of the curves. In cortical slices, the maximal response was significantly reduced in an age-dependent manner by 23% in the senescent rats compared to the young rats. NMDA-stimulated [³H]DA release from striatal slices was significantly lower in the senescent rats at concentrations of NMDA from $500\text{-}2000~\mu\text{M}$. These age-dependent decrements in the function of NMDA receptors may underlie, at least in part, some of the cognitive or motor-behavioral impairments seen with advanced age. IN VIVO ELECTROCHEMICAL STUDIES OF AGE-RELATED CHANGES IN DOPAMINE NERVE TERMINAL FUNCTION: A9 VS. A10. M.N. Friedemann and G.A. Gerhardt Departments of Pharmacology and Psychiatry, University of Colorado Health Science Center, Denver, CO

The consequences of aging on dopamine (DA) presynaptic elements and their function remains unclear. In order to investigate the effects of aging on their function remains unclear. In order to investigate the effects of aging on DA nerve terminals we studied DA release and reuptake in the striatum of urethane anesthetized Fischer 344 rats. High-speed (5 Hz) in vivo electrochemical measurements of potassium evoked DA overflow were recorded in dorsal and ventral striatum of 6 and 24 month old rats using reason-coated multiple carbon fiber electrodes. Average response amplitudes were significantly decreased in the 24 vs. 6 month old animals. The decrease in amplitude were response as the decrease in amplitude were response. Nafion-coated multiple carbon fiber electrodes. The decrease in amplitude was more pronounced in ventral vs. dorsal striatum in the 24 month old rats. While the amplitudes were decreased in aged rats, the average time courses of the responses were not different between the two age groups, suggesting an alteration in the reuptake of DA in the aged animals. The results indicate that there are age-dependent changes in the dynamics of DA release and reuptake and that these changes may be more pronounced in the A10 versus A9 DA system. THE EFFECT OF AGE ON HALOPERIDOL—INDUCED BEHAVIORAL HYPERSENSITIVITY.

C.M. Buhrfiend, L.C. Kao, L.R. Ptak*, H.L.
Klawans*, and P.M. Carvey.

Rush Medical College, Chicago, I. 60612
Chronic treatment of rats with haloperidol
(HAL) leads to an enhanced response to subsequent challenge with dopamine (DA) agonists referred to as behavioral hypersensitivity (BH).
Since the incidence of tardive dyskinesia (TD), also a neuroleptic-induced DA BH, is higher in elderly patients, we examined the effect of chronic HAL treatment in young (3 months) and old (20 months) animals to determine if BH was also higher in aged rats, Rats received 24 consecutive daily treatments of haloperidol (HAL).
1.25 mg/kg) or saline (SAL) followed by a 96 hour drug free interval. HAL enhanced apomorphine (0.6 mg/kg) induced stereotypic behavior relative to SAL treatment. The effect of HAL in old animals was also statistically elevated relative to HAL-young. HAL treatment reduced DA and DOPAC content regardless of age. However, these effects were most pronounced and statistically significant in the old animals. Finally, extracts from these animals were evaluated for the presence of a striatal-derived neurotrophic factor (NTF; see Carvey this meeting) in rat E13 mesencephalic cultures. Old animals had less NTF than young animals. HAL treatment enhanced DA neuron growth indices regardless of age, although the effect in old animals was not as pronounced. Taken together, these data suggest that BH is more pronounced in an older animal perhaps as a result of reduced compensatory mechanisms which include alterations in a striatal-derived NTF.

19.10

AUTORADIOGRAPHIC LOCALIZATION OF DECREASES IN NMDA BINDING SITES OCCURRING WITH AGE IN TWO DIFFERENT MOUSE STRAINS. K.R. Magnusson and C.W. Cotman: Dept. of Anatomy & Neurobiology, Colorado State University, Fort Collins, CO 50623; iDept. of Psychobiology, University of California, Irvine, CA 92717.

Previous work in this laboratory (UCI) suggests that BALB/c mice exhibit a 55% decrease in N-methyl-D-aspartate (NMDA) binding with age compared with a 17% decrease measured in C57Bl mice (Neurosci. Lett. 104 (1989) 309-313). In these two genetically-different mouse strains it is important to determine whether age-related changes in NMDA binding sites were homogeneous throughout the brain or were restricted to specific sites were nomogeneous throughout the brain of were restricted to specific brain regions. Quantitative autoradiography was performed on horizontal sections which were incubated with 100nM 3H-L-glutamate and 100µM each of kainate, AMPA and SITS. Significant differences between age groups (3,10,and 30 months) within each strain (BALB/c or C57Bl) for each brain region analyzed were determined by ANOVA of fmol/mg protein values. Old (30 month) BALB/c mice exhibited reductions in binding to NMDA sites, as compared with 3 month old BALB/c mice, in many brain regions (e.g., CA1 stratum lacunosum, caudate nucleus, and frontal, parietal regions (e.g., CA1 stratum lacunosum, caudate nucleus, and frontal, parietal and entorhinal cortex). The percent reduction in binding was heterogeneous between brain regions. Significant reductions in 30 month old C57Bl mice compared to 3 month old C57Bl mice occurred in fewer regions (e.g., entorhinal and frontal cortex, and caudate nucleus). It appears that the strain differences in age-related loss of NMDA binding can be accounted for by the involvement of more brain regions in the BALB/c strain of mice as compared to the C57Bl strain. Furthermore, brain regions, with respect to NMDA binding, do not appear to be uniformly affected by aging-associated changes. Supported by NIA/NIH Physician Scientist Award AC0329. changes. TEMPORAL CHANGES IN THE EXPRESSION OF THE GLUTAMATE TRANSPORTER FROM RAT CORTICAL POLY (A)+ RNA IN XENOPUS OOCYTES

K.P. Gudehithlu, A.M. Duchemin, D.A. Dalia*, N.H. Neff and M. Hadjiconstantinou, Depts. Pharmacology and Psychiatry, The Ohio State University College of Medicine, Columbus, OH 43210.

The excitatory amino acid glutamate (GLU) has been implicated in various neurodegenerative processes. The integrity of the GLU transporter is necessary for the proper catabolism and disposal of GLU released by nerve terminals. To permit a molecular characterization of age dependent changes in the GLU uptake system, we studied the expression of the GLU transporter in Xenopus laevis oocytes after injection of poly (A) + RNA. Poly (A)+ RNA from the cortex of 1, 15, 30 day as well as 3, 6, and 21 month old rats was extracted and injected into oocytes. GLU uptake activity was estimated with [3H]-GLU. GLU uptake was sodium and temperature dependent, similar to that found in neurons. The GLU transporter expression increased with time after birth, and reached adult values by 30 day post-birth. A decline of expressed activity was observed by the 12 month. Similar changes were found when GLU uptake was measured in synaptosomes prepared from cortices of animals of the same ages. This study suggests, that the low GLU uptake found in the brain of aged animals is probably due to a decreased expression of its message.

[35S]TBPS BINDING TO THE GABA IONOPHORE WITH AGE IN RAT BRAIN. P.E. Schauwecker, A.B. Kelly and D.G. Morgan. School of Gerontology and Dept of Biological Sciences, University of Southern California, Los Angeles CA 90089-0191.

The GABAergic system has been examined infrequently in studies of brain aging, in spite of the fact that it is one of the two major transmitter systems in brain. Our initial approach to elucidating age-related changes in this system has been to measure the binding of t-[35S]butylbicyclophosphorothionate (TBPS) to the chloride channel linked to the GABA-A receptor. Membranes from cerebral cortex of Fischer 344 rats aged 6, 15 and 24 months were incubated for 2 hours with 500 mM NaCl and increasing concentrations of TBPS at room temperature (buffered to pH 7.4), and bound and free ligand separated by filtration. The average Kd was 150 nM, and no differences were observed between the age groups. The Bmax values were 4.6, 3.3, and 4.3 pmol/mg protein for the 6, 15, and 24 month groups respectively. ANOVA revealed no significant differences in Bmax as a function of age (n=6 per group). Additional studies are in progress to evaluate effects of aging on [36]Cl uptake into synaptoneurosomes stimulated by brief exposure to GABA. Supported by the Anna Greenwall Award from the American Federation for Aging Research and NIA grant AG07892 to DGM. DGM is an Established Investigator of the American Heart Association.

EFFECT OF AGE ON RESPONSES TO NERVE STIMULATION IN THE RAT TAIL ARTERY: INFLUENCE OF ALTERED TRAIN LENGTH AND CALCIUM J. Buchholz and S.P. Duckles. Dept. of Pharmacology, Coll. of Medicine, Univ. of California, Irvine CA,

Pharmacology, Coll. of Medicine, Univ. of California, Irvine CA, 92717.

Previously we have shown that prejunctional control of norepinephrine (NE) release from the rat tall artery declines with age. This results in significantly greater NE release in the presence of deoxycorticosterone and cocaine from nerves in tall arteries of 20 and 27 month old F-344 rats as compared to 6 and 12 month old animals. Furthermore, there is an age related decline in the effectiveness of prejunctional ag-adrenoceptors. To test the possibility that control of calcium movement across the nerve cell membrane is altered with age, effects of extracellular calcium were investigated with varied stimulation intensity in tall artery segments from 6 and 20 month old F-344 rats. Isometric contractile responses were monitored from arterial segments stimulated transmurally (3 Hz at 3, 9, 15, 30 and 90 sec) in the presence of 1, 1.6 or 5 mM calcium. The effects of altered extracellular calcium were much greater at short train lengths. Furthermore calcium changes had little effect on responses to exogenous NE. The greater sensitivity of contractile responses to TNS to extracellular calcium at low stimulus intensity (short train length) reflects the period of facilitation of transmitter release before peak intracellular calcium levels are achieved. When the effect of age was examined, there were no differences in contractile responses to TNS or NE, regardless of train length or the level of extracellular calcium. These data suggest that the age related increase in NE release may be compensated for at the post junctional site, thus producing no net age related change in contractile response.

SEROTONIN 5-HT_{1A} RECEPTOR DECLINE WITH AGE IN THE FEMALE FISCHER 344 RAT. J. M. Lakoski, E. W. Black and C. Gregg. Department of Pharmacology & Toxicology, Univ. Texas Medical Branch, Galveston, TX 77550.

We have begun to address the role of specific serotonin (5-HT) receptor subtypes in mediating age-related changes in CNS function, including processes altered with the onset of reproductive senescence. We have previously identified age-dependent changes in the cellular physiology of the 5-HT_{1A} autoreceptor in the dorsal raphe nucleus of young and middle-aged vs reproductively old acyclic female rats. These present investigations assessed the age-related changes in binding site characteristics in the hippocampus, a region enriched with 5-HT_{1A}

Female Fischer 344 rats (NIA colony), ages 2, 6, 12, 20, and 28 mo, were either ovariectomized under ether or left intact for several weeks prior to decapitation; brain regions were rapidly dissected and frozen at -80°C until assay. Changes in hippocampal 5-HT_{1A} binding sites were assessed by scatchard analysis using the agonist [³H]8-OH-DPAT (8-hydroxy-2-(di-n-propylamino)tetralin; 0.21-6.7nM) with P2 membranes incubated 15 min at 37°, harvested by vacuum filtration, and data analyzed by LIGAND; non-specific binding was defined by 100_Lm 8-OH-DPAT. Displacement assays with 5-HT (10⁴-10⁻¹²M) were 100/m 8-OH-DPAT. Displacement assays with 5-HT (10⁻⁴-10⁻¹²M) were conducted with 2nM [³H]8-OH-DPAT. Significant age-related decline in receptor numbers (B_{max}) from 2 and 6 mo $(1501\pm222, 1612\pm167 \text{ pmoles/mg protein})$ vs 12, 20 or 28 mo $(1135\pm260, 927\pm180, 917\pm219)$ was observed. With respect to 11, 20 or 28 mo (1135 \pm 200, 92/ \pm 180, 91/ \pm 121) was observed. With respect to affinity characteristics, no consistent alteration of K_d values was observed between ages 2 and 20 mo (7.6, 7.8 nM) or $1C_{50}$ values for 5-HT. Thus, these studies have identified specific age-related changes in the numbers of the 5-HT $_{LA}$ receptor subtype which may, in part, mediate the transition to acyclicity observed in the middle-aged female rat.

ALTERATIONS OF RAT PITUITARY GROWTH HORMONE-RELEASING FACTOR (GRF) BINDING SITES IN AGING: A TIME-COURSE STUDY. T.Abribat, N.Deslauriers*, P.Brazeau* and P. Gaudreau. Neuroendocrinology Lab., Notre-Dame Hospital Research Center, Montreal, Canada H2L 4K8. We have previously documented a decreased GRF-induced GH

secretion in aging rats beginning at 12 mo of age (Deslauriers et al, Int. Symp. on Somatostatin, Montreal, 1989 abst. 51). Therefore we Int. Symp. on Sofialostain, Mortival, 1989 asst. 31). Therefore we have investigated whether this phenomenon is related to an alteration of pituitary GRF binding sites. Cold saturation studies were performed with [125]-Tyr 10 hGRF(1-44)NH₂ (35-50 pM) as radioligand in pituitary homogenates of 2, 8, 14 and 18-mo old male Sprague-Dawley rats. [127]-Tyr 10 hGRF(1-44)NH₂ (0-100nM) was used as competitor and rGRF(1-29)NH₂ (2.4 μM) for non-specific binding evaluation. In young calculation. animals (2 mo), analysis by the Ligand program statistically (P < 0.02) animals (2 mo), analysis by the Ligand program statistically (P<0.02) revealed the presence of two distinct classes of binding sites ($(K_{\rm ps}=0.86\pm0.15~{\rm and}~400\pm210~{\rm nM}~{\rm and}~B_{\rm MAS}=202\pm35~{\rm fmol}~{\rm and}~31\pm14~{\rm pmol}~{\rm per}$ pituitary, respectively). In 8- and 14-mo old rats, there was a concomitant increase of affinity (8 mo, P<0.10; 14 mo, P<0.01) and decrease of capacity (8 mo, P<0.20; 14 mo, P<0.05) of the high affinity site, and an increase of capacity (8 mo, P<0.05; 14 mo, P<0.01) of the low affinity site. In old animals (18 mo), the Ligand program no longer statistically analyzed the data with a two-sites model, indicating a severe blunt of the high affinity site. In conclusion, our results show that in aging, alterations of pituitary GRF binding sites occur in parallel to the impairment of GRF-stimulated GH secretion. Supported by MRCC grants.

RELEASE OF ENDOGENOUS ACETYLCHOLINE AND PHOSPHATIDYLINOSITOL TURNOVER IN BRAINS OF YOUNG AND AGED RATS. T. C. Holmes, R. L. Buyukusal*, and R. J. Wurtman, Department of Brain and Cognitive Sciences, MIT, Cambridge, MA, 02139
Release of endogenous acetylcholine (ACh) from superfused striatal slices and the production of inositol phosphates (IP1 and IP2) in cerebral

superfused striatal slices and the production of inositol phosphates (IP1 and IP2) in cerebral cortical slices were examined in tissues from young (3 month) and aged (24 month) rats. Basal ACh release did not differ between young and aged rats, and the potassium channel blocker 3,4-diaminopyridine (3,4-DAP) increased ACh release in both groups. Electrically evoked ACh release in both groups. Electrically evoked ACh release In both groups. Electrically evoked ACh release was greater in young rats than in aged rats with or without the addition of 3,4-DAP to the medium. Phosphatidylinositol turnover, measured at 30 sec, 1, 2, 5, and 10 minutes following treatment with carbachol (100 uM) did not differ between young and aged groups. These data indicate that the hypothesized age-related defect in central the hypothesized age-related defect in central and observed transmission derives. cholinergic transmission derives from an impairment in evoked ACh release. Supported by

Comparison of Basal Forebrain Cholinergic Neuron Counts in 57 day and 380 day old New Zealand Black (NZB) Mice. S.H. Feldman. Div. of Comparative Medicine, U.T. Southwestern Medical Center, Dallas, Texas, 75235.

NZB/BINJ mice been proposed as a model of senile dementia of the Alzheimer's type because of an early age-related onset of memory impairment, and age-associated behavioral responses to pharmacologic agents (see Retz et al., 1988; Drug Dev Res, 15:275-295). Because NZB mice are not currently available from Jackson labs (Bar Harbor, ME) this author compared the numbers of basal forebrain cholinergic neurons in 57 day (n=2) and 380 day (n=2) female NZB/NCI mice. Immunohistochemical staining with monospecific polyclonal serum against choline acetyltransferase (donated by L.B. Hersh; see Tago et al., 1987; Brain Res, 415:49-62) was utilized to visualize cholinergic neurons All cholinergic neurons in alternate horizontal sections were counted. No significant differences in cholinergic neuron counts were detected in the preoptic magnocellular region, nucleus accumbens, horizontal and vertical arms of the diagonal band of Broca, medial septal nucleus, substantia innominata plus nucleus basalis, oculomotor nucleus and trochlear nucleus between the two age groups. A significant difference (p<0.01) was detected for striatal interneurons. Also, in horizontal section the preoptic magnocellular neurons were organized into "barrel-like" cytoarchitecture where closely associated with olfactory tubercle and pyriform cortex.

ESTRADIOL-INDUCED REPRODUCTIVE ACYCLICITY: EFFECTS ON LHRH AND TUBEROINFUNDIBULAR DOPAMINERGIC NEURON NUMBER AND MEDIAN EMINENCE MONOAMINE LEVELS. S.G. Kohama, S.A. Brown*, H.H. Osterburg*, C.E. Finch, and T.H. McNeill. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089. Orally administered estradiol (E2) induces a premature loss of estrous

Orally administered estration (E2) induces a premature loss of estrous cycles in rodents by putatively "damaging" neuroendocrine loci. To define possible neural mechanisms sensitive to E2, the number of LHRH and tuberoinfundibular dopaminergic (TIDA, arcuate) neurons was evaluated by immunocytochemistry on free-floating sections. Compared to age-matched intact or ovariectomized (ovx) controls, there was no change in the number of LHRH or TIDA neurons in either young (8 mo) or middle-aged (13 mo) intact virgin C57BL/6J mice, made acyclic by 12 weeks of E2 treatment.

In a second study, the same experimental paradigm was employed, but was conducted on a single age group of mice (7 mo). Subgroups of mice from the ovx and intact+E2 groups were also injected with vehicle or NSD-1015 to test for differences in DA turnover. As an additional control, young (2 mo) ovx mice were treated with vehicle or E2 for shorter periods of 3, 7, or 21 days. Following treatment, median eminences were collected for analysis by HPLC with electrochemical detection. In the chronic study, steady state levels of 5-HT, NE, DA and metabolites did not vary by treatment. However, DA turnover as measured by L-DOPA accumulation, was increased by E2 treatment. Acute treatment with E2 caused a reduction in DOPAC which recovered by day 21. In general, 5-HT and NE levels were greater in the younger animals from the acute study.

19.21

EFFECTS OF d-FENFLURAMINE (dF) ON AGE ASSOCIATED CHANGES IN ACTH, CORTICOSTERONE (CORT), AND PROLACTIN (PRL).

R.J. Handa, M.K. Cross*, L.H. Burgess, T.M. Cabrera, J.

Clancy Jr*, S.A. Lorens. Departments of Cell Biology, Neurobiology, Anatomy and Pharmacology, Loyola University

Chicago, Stritch School of Medicine, Maywood, IL 60153 Neuroendocrine changes are associated with the aging process in rats. To examine some mechanisms underlying these changes we administered the serotonin releaser and reuptake inhibitor, dF (0.6 mg/kg/day in the drinking water), to young (5 mo) and old (21 mo) male and female Fischer 344 rats for 30-38 days. Animals were sacrificed upon removal from their home cage (HC) or 20 min. after introduction into a novel environment (open field, OF). Significant increases in ACTH and CORT were found in young and old OF animals (p<0.01 vs HC groups). In old males, HC ACTH, OF ACTH and OF CORT levels were greater than in young males (p<0.05) dF reduced (p<0.02) ACTH and CORT in old OF males to levels similar to young OF males. There was no effect of dF in young males. In old OF females, CORT but not ACTH levels were lower (p<0.05) than in young OF females, and there was no effect of dF. PRL was elevated in old vs young HC females (p<0.01) and was further increased in response to OF. dF treatment reduced (p<0.05) the PRL response to 0F in old females but not young females. These data support a role for serotonin in some age related neuroendocrine changes and suggest that low doses of dF can ameliorate some of these alterations.

THREE DIMENSIONAL RECONSTRUCTION OF THE CHOLINERGIC BASAL FOREBRAIN SYSTEM IN YOUNG AND AGED RATS. M.L. Smith and R.M. Booze. Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27103. Cholinergic neuron dysfunction and/or cell loss has been implicated as one

important event associated with age-related cognitive changes. However, the issue of selective vs. diffuse age-related cholinergic cell loss within the basal forebrain remains unresolved. We have produced three dimensional reconstructions of the rat basal forebrain in order to study the selectivity of cholinergic cell loss

Pairs of young (4-5 month) and aged (24-25 month) Fischer-344 male rats were perfused with an aldehyde solution, and the brains sectioned on a Vibratome (40 um). Serial sections from each pair of young and aged rats were processed simultaneously for ChAT (1:500; Chemicon) using standard ABC immunocytochemical techniques. Cell location and z-value information were used to construct three dimensional maps using a computer-based imaging system (Biographics, Inc).

onal reconstructions spanning the entire cholinergic basal forebrain system from medial septum through nucleus basalis were generated for each animal. The sensitivity of the reconstruction procedure to detect specific cell loss was examined by mapping the distribution of cholinergic cells in animals with a fimbria/fornix lesion. The fimbria/fornix lesioned animals showed a selective decrease in the number of cholinergic cell bodies located in the medial septal area and showed a correspondingly altered cell distribution. In normal aged rats, the number of cholinergic neurons in the medial septum decreased, suggesting selective age-related cholinergic cell loss. Thus, three dimensional reconstructions provide a sensitive means for studying the selective effects of aging in the cholinergic basal

(Supported by the American Federation for Aging Research and NIH RR-05404)

AGE-ASSOCIATED REDUCTION IN PLASMA AND PINEAL MELATONIN LEVELS IN THE RAT IS PREVENTED BY ACETYL-L-CARNITINE. S. Scaccianoce*, G. Cigliana*, G.S. Alemà*, M.T. Ramacci*, J.R. Perez-Polo and L. Angelucci. Farmacologia 2a, Univ. "La Sapienza", 00185 Rome, Italy.

Farmacologia 2a, Univ. "La Sapienza", 00185 Rome, Italy.

In the rat, as well as in humans, a reduction in plasma and pineal levels of melatonin is associated with the aging process. Experimental evidences show that chronic acetyl-1-carnitine (ALCAR) treatment prevents or extenuatessome age-dependent biological modifications especially of neuroendocrine and hormonal type. On these bases, we investigated the effect produced by an 8-month ALCAR treatment (100 mg/kg/day in drinking water) on plasma and pineal immunoreactive melatonin levels at day (1000h) and nightime (0100h), in the old (24 months) male Fischer 344 rat. No differences were found in plasma melatonin levels during the light period between young (3 months) and old rats, while at night a reduction (p< 0.05) was found in the old group; ALCAR treatment completely prevented this reduction. Pineal melatonin content during the light period was unaffected by aging. On the contrary, at night it was reduced in the old rats (p<0.05). This reduction was not present in the old rats treated with ALCAR. The mechanism by which ALCAR produces this effect remains to be studied; we propose, however, that this effect might be involved in the ability of ALCAR to retard age-dependent changes in the CNS and behavioral impairments.

19.22

GLUCOCORTICOID RECEPTOR IMMUNOSTAINING IS INCREASED IN

GLUCOCORTICOID RECEPTOR IMMUNOSTAINING IS INCREASED IN AGED HIPPOCAMPUS. P.W. Landfield, R.M. Booze, S. Vinsant*, L.B. Cadwallader* and J.C. Eldridge, Dept. of Physiol. & Pharmacol., Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27103.
Glucocorticoids appear to contribute to age-related deterioration of the hippocampus (cf. Landfield et al., Science, 1981; Sapolsky et al., J. Neurosci., 1985). In addition, studies using adrenalectomized rats indicate that hippocampal glucocorticoid receptors (GCR) are decreased with aging.

Neurosci., 1983). In addition, studies using adrenalectomized rats indicate that hippocampal glucocorticoid receptors (GCR) are decreased with aging. Nevertheless, the brain appears to deteriorate more rapidly with advancing age. This seemingly is a paradox since, if GCR are decreased with aging, brain cells should be protected from further age-related changes. However, recent studies in intact rats indicate that type II GCR may instead be increased with aging (Eldridge et al., J. Neurosci., 1989).

To attempt to resolve this question we utilized immunostaining against type II GCR in intact animals. Pairs of young (4-5 mo-old) and aged (25-26 mo-old) Fischer-344 male rats were perfused with an aldehyde solution, and the brains were sectioned with a cryostat. Alternate sections were stained for Nissl and AChE. Sections for each young and aged rat were processed simultaneously for immunocytochemistry of GCR using standard ABC procedures. Immunostaining for GCR was consistently more intense in aged animals, notably in hippocampal areas CA1 and CA2, and dentate granule cells, and in the neocortex. CA3 and CA4 stain very little for type II GCR. Qualitatively, these effects were readily apparent, but quantitative analyses are also underway. Thus, in conjunction with previous ligand binding results, the present data indicate that, with aging, there is greater rather than less activation of brain glucocorticoid receptors in intact animals. This observation could have significant implications for mechanisms of accelerating brain cell loss during aging. (Supported by AG04342 and DA03637)

GENE EXPRESSION DURING RAT BRAIN DEVELOPMENT: GENE EXPRESSION DURING HAT BRAIN DEVELOPMENT:
EFFECT OF PRENATAL EXPOSURE TO ETHANOL

D. Maciejewski-Lenoir* and R. J. Milner.
Research Institute of Scripps Clinic, La Jolla, CA 92037.

We have previously shown that exposure of rats to ethanol in

utero affects the postnatal expression of particular brain genes. In those experiments, however, administration of ethanol to young primiparous dams by inhalation resulted in significant young primiparous dams by inhalation resulted in significant differences between treated and untreated dams in weight gain during pregnancy. In contrast, full grown, multiparous dams achieved a much better weight gain in both treated and control animals. As in previous studies, pregnant rats were exposed to ethanol vapor between gestational days 8–21, resulting in BALs of approx. 150 mg/%. At birth, litters from treated and control dams were culled and fostered to normal mothers and RNA was extracted from disconted brain regions at different postnated. extracted from dissected brain regions at different postnatal ages. There were no differences in the weights of control and ages. There were no differences in the weights of control and ethanol treated pups at birth or during postnatal development, although the cortices of the treated pups were consistently lower in weight. In contrast to previous results, there was little difference in the expression of $T\alpha 1$ -tubulin and proteolipid protein (PLP) mRNAs between ethanol-treated and control pups, suggesting that the delay in normal expression of these genes seen previously in ethanol-treated pups was probably due to nutritional factors. There were differences, however, in the number of cells expressing PLP mRNA, detected by in situ hybridization, during the early postnatal period. The expression of other neural cell-specific mRNAs is under investigation.

EFFECTS OF DEVELOPMENTAL ALCOHOL EXPOSURES ON MYELIN IN THE DORSAL COLUMN OF THE ADULT RAT SPINAL CORD. D.E. Phillips, J.E. Rydquist*, H. Brunelle*, Biology Dept., WAMI Medical Education Program, Montana State Univ., Bozeman, MT 59717.

Our previous studies have shown that alcohol exposures for all of gestation plus 10 postnatal days (equivalent to all of gestation in humans) causes a reduction in myelin thickness in adult rat optic nerve. This study was designed to determine if a similar reduction in myelin thickness occurs in other CNS fiber populations from the same animals. Unborn rats were exposed to alcohol via maternal liquid diet, then the artificially reared pups further exposed by diet fed through a gastrostomy tube for 10 days. Control animals were pair fed isocaloric diets. Anesthetized animals were perfused at 90 days with fixative and spinal cord tissues prepared for electron microscopic study. The gross area of the dorsal column in the adult animals was unaffected by the developmental ethanol exposure. The myelin thickness, as a function of axon diameter, was not affected by alcohol, either in the more dorsal, sensory part of the dorsal column, nor in the ventral, corticospinal part of the dorsal column. These results indicate that myelin maturation, like neuronal maturation, can be differentially affected in different regions of the CNS by the same developmental alcohol exposures. Supported by NIAAA AA7042 and NIH MBRS SO6 08218.

EFFECT OF ALCOHOL EXPOSURE DURING THE BRAIN GROWTH SPURT ON COMPOSITION OF FOUR LIMBIC AREAS IN 40 TO 45 DAY OLD RATS. S. J. Kelly and R. R. Dillingham*. Department of Psychology, University of South Carolina, Columbia, SC 29208.

In an attempt to determine the neural bases of changes in behavioral reactivity induced by perinatal alcohol exposure, the chemical composition of the amygdala, the hypothalamus, the septal region and the hippocampus proper was examined. Alcohol exposure occurred between postnatal day (PD) 4 and 10 and was accomplished via an artificial rearing procedure. One group was given 5 g/kg/day alcohol exposure and a second group was given 3 g/kg/day alcohol exposure. A third group was artificially reared but not exposed to alcohol. A final group was reared normally with dams. All artificially reared groups were given milk formula alone from PD 10 to 12 and then fostered back to dams on PD 12. Between PD 40 and 45, the rats were deeply anesthetized and killed. The four limbic regions were quickly dissected free, sonicated in cold 6% trichloroacetic acid, and frozen until the time of assay. Chemical composition was examined using colormetric assays for DNA, cholesterol and protein content (Grant and Samson, Behav. Toxicol. Teratol. 4: 315, 1982; Zamenhof et al. J. Neurochem. 19: 61, 1972). DNA and cholesterol concentration can be taken as approximate measures of cell number and myelination, respectively. Protein content per DNA can be an indicator of cell size

Alcohol exposure during the brain growth spurt did not change DNA oncentration in any of the neural regions in the female rats but did decrease DNA concentration in the amygdala of male rats. In contrast, cholesterol concentration appeared to be increased in all examined neural regions of female rats exposed to alcohol but no changes in cholesterol concentration were detected in male rats. Protein content per DNA in the hypothalamus was decreased by alcohol exposure in both sexes. (Supported by NIAAA Grant AA08080 to S.J.K.)

EFFECTS OF PRE- AND POSTNATAL ETHANOL EXPOSURE ON THE L2 DORSAL ROOT OF THE NEONATAL RAT. <u>E.L. Fagan, R.L. Shew, L.P. Gonzalez and D.L. McNeill.</u> Dept. of Anat. Sci., Univ. of Oklahoma, Oklahoma City, OK 73190

We recently demonstrated that maternal ethanol (ETOH) consumption resulted in a significant reduction in the number of myelinated fibers in the ventral funiculus (VF) of the neonatal spinal cord. Since the VF contains motor and sensory fibers, the present study was designed to focus the effects of ETOH on a pure sensory population of fibers.

Dams were fed either a control or an ETOH-containing liquid diet for 2 weeks, then mated. The diets were continued throughout gestation. 2 weeks, then mated. The diets were continued inroughout gestation.
On postnatal day (PD) 4, the pups were implanted with a gastrostomy tube and artificially reared. Pups from control dams were given an ETOH-free formula while pups from dams on the ETOH diet were given a formula containing ETOH. On PD 10, control and ETOH exposed pups were perfused and their L2 dorsal roots processed for electron microscopy. Quantitative analysis revealed no significant differences between the two groups in dorsal root area, unmyelinated Quantitative analysis revealed no significant axon number, myelinated axon diameter or myelin thickness. However, in the ETOH exposed pups, there was a significant decrease (p < 0.01) in the number of myelinated axons and a significant increase (p < 0.02) in the number of axons with a single wrap of myelin. No significant difference in axonal number was observed when myelinated axons and axons with one myclin wrap were summed. These data suggest that ETOH exposure does not affect total axonal numbers. However, as in the CNS, it appears that ETOH delays the acquisition of myelin in this peripheral sensory system. (Supported by the Presby. Hlth. Found., the OU Alumni Res. Assoc. and OCAST.)

LHRH NEURON MIGRATION IN FETAL MICE EXPOSED TO ETHANOL IN UTERO. H.C. Scott*, E. Westling*, W.K. Paull* and P.K. Rudeen. Department of Anatomy & Neurobiology, University of Missouri School of Medicine, Columbia, MO 65212.

The migration of luteinizing hormone-releasing hormone (LHRH) neurons from the medial nasal placode into the forebrain was analyzed in fetal C57BL/6J mice exposed to forebrain was analyzed in fetal C57BL/6J mice exposed to ethanol (etoh) in utero. Pregnant dams were intubated with 25% etoh solution (0.015ml/kg body weight) or with vehicle at 10 a.m. and 2 p.m. on Day 7 of pregnancy. Animals were sacrificed on Day 18 of pregnancy and the pups were removed and fixed in Bouins. Blood alcohol levels were measured in a seperate group of mice follow-ing a single intubation of ethanol or vehicle. Peak BAC levels were 56mg% within 40 min following ethanol administration. Tissue was processed and serial parasagittal sections were Tissue was processed and serial parasagittal sections were cut at 8um. Immunocytochemical procedures were used to identify LHRH neurons. The brain and nose regions were divided into six neuroanatomical regions: placode, nasal septum, traverse, arch, preoptic area, and caudal preoptic area. The number of LHRH immunoreactive neurons in each area in fetal etoh-exposed and control pups were compared. The data suggest that fetal etoh exposure results in a decrease in the number of LHRH immunoreactive neurons in each neuroanatomical area as compared to vehicle-treated animals. (Supported by NIAAA grants AA07458, AA05893 & AA001071

PURKINIE CELL SURVIVAL FOLLOWING ETHANOL EXPOSURE DURING THE BRAIN GROWTH SPURT DEPENDS ON THE TIMING OF EXPOSURE AND LOCATION IN THE CEREBELLAR VERMIS. K.M. Hamre and J.R. West.

Dept. of Anatomy, College of Medicine, University of Iowa, Iowa City, 1A 52242.

Purkinje cell loss after ethanol exposure during the brain growth spurt does not occur uniformly in different cerebellar lobules. While the factors contributing to this differential cell loss are unknown, one proposed variable is the degree of Purkinje cell maturity at the time of the ethanol exposure. Previous studies from our laboratory have shown that Purkinje cell dendritic maturity during the early postnatal period can maturity at the time of the ethanol exposure. Previous studies from our laboratory have shown that Purkinje cell dendritic maturity during the early postnatal period can be determined using immunocytochemistry with an antibody against microtubule-associated protein 2, and the cells classified as part of early or late maturing regions. In the earliest maturing regions, lobules IX and X, dendritic outgrowth was initiated on postnatal days (P) 4-5 while in the latest maturing regions, the distal part of lobules VI and lobule VII, dendritic outgrowth was initiated on P9-10. The purpose of this study was to test the hypothesis that varying the ethanol exposure to correspond to these developmental stages would affect the amount or location of Purkinje cell loss. Male rat pups were exposed to 6.6 g/kg/day of ethanol, using an artificial-rearing procedure, for one of the following two-day periods: P4-5, P6-7, P9-10 or P12-13. Purkinje cells were counted in lobules VI, VII, IX and X of the cerebellar vermis on P21. Significant Purkinje cell loss occurred across the four lobules in the animals exposed to ethanol on P4-5 or on P6-7, but not in animals exposed on either P9-10 or P12-13. Slight changes in the timing of exposure e.g., P4-5 versus P6-7, led to changes in the amounts of cell loss, but only in lobules VII and XI. In lobule VII, only the group exposed on P6-7 demonstrated a significant cell loss compared to controls. In lobule IX, pups exposed on P4-5 had significant cell loss compared to controls. In lobule IX, pups exposed on P4-5 had significantly greater cell loss than those exposed on P6-7. Within lobules, the loss of Purkinje cells was not uniform across all portions of the lobules. For instance, in lobule IX more gaps in the Purkinje cell layer were seen on the dorsal versus the ventral portion of the lobule. The stage of dendritic maturity is not an accurate predictor of Purkinje cell death, but there do appear to be "windows of vulnerability" which affect the amount of Purkinje cell loss in each region.

DOSE-DEPENDENT DEFICITS IN CEREBELLAR GROWTH INDUCED BY EARLY POSTNATAL ALCOHOL EXPOSURE: DIFFERENCES AMONG INBRED STRAINS OF RATS. C.R. Goodlett, J.M. Nichols* and J.R. West. Department of Anatomy. University of Iowa. Iowa City. IA 52242.

Anatomy, University of Iowa, Iowa City, IA 52242.

Studies in Sprague-Dawley rats have demonstrated that neonatal alcohol exposure permanently restricts growth of the cerebellum and depletes its neuronal populations when blood alcohol concentrations (BACs) reach 150-190 mg/dl. In an effort to identify genetic influences on the severity of cerebellar growth restriction induced by early postnatal alcohol exposure, six inbred strains were evaluated using three doses of alcohol. The strains [ACI, F344, MR, M520, WN and WKY] were derived from breeders originally established from breeding pairs obtained from NIH. Pups from timed pregnancies of each strain were implanted with a gastrostomy tube on gestational day 27 (usually) postnatal day 5), and reared artificially (milk formula feedings every two hours). Treatment groups included 4, 4, 5.5 and 6.6 g/kg/day of alcohol, with the alcohol administered in four consecutive feedings each day as a 5.0%, 6.25% or 7.5% (v/v) solution, respectively. Controls included artificially reared controls and suckle controls. On gestational day 32, the pups were perfused intracardially, the brains were carefully extracted and dissected into forebrain, brain stem and cerebellum, and weights were obtained. Alcohol exposure restricted cerebellar growth in a dose-dependent fashion in all strains, but differences among strains in susceptibility were present and depended in part on the dose used. Susceptibility to cerebellar growth restriction based on the 4.4 g/kg dose, which produced mean BACs between 191-243 mg/dl, indicated that two strains were relatively resistant [WN and M520], two strains were relatively vulnerable [MR and F344] and two were intermediate [ACI and WKY]. These strain differences were not dependent on differences in BAC. Across all doses, the MR strain was consistently severely affected, and the M520 strain was relatively less affected. At the higher doses, exceptions to the susceptibility rankings of the other strains were noted, including a disproportionate cerebellar

20.9

While prenatal exposure to cocaine alone can adversely effect the unborn child, pregnant cocaine abusers typically use other harmful drugs as well (e.g., alcohol, marijuana, nicotine, opiates). Consequently, there is a need to investigate the effects of prenatal exposure to various drug combinations involving cocaine. To investigate the combined effects of cocaine and alcohol, pregnant Long-Evans rats were given either cocaine (30 mg/kg, b.i.d., s.c.), alcohol (2 g/kg, b.i.d., p.o.), or both drugs from gestation days 7 to 20. Ad lib and pair-fed control groups and surrogate fostering were also used (N=8 to 14 litters/group). Compared to the other groups, the cocaine-plus-alcohol offspring showed (a) reduced birth weight and postnatal weight gain and (b) delayed maturation regarding pinna detachment, fur growth, ear opening and vaginal opening (P<0.05), but no delay in eye opening. These results suggest that the cocaine-plus-alcohol combination has a more deleterious effect than either drug alone. (Supported by DA05536)

20.11

IN UTERO EXPOSURE TO METHAMPHETAMINE (METH): EFFECTS ON NEURAL, ENDOCRINE, AND IMMUNE FUNCTIONS IN MALE RATS. T.M. Cabrera, M.K. Cross*, M. George*, L. Petrovic*, J. Clancy Jr.*, R.J. Banda and S.A. Lotens. Depts. of Pharmacology and Anatomy, Loyola Univ. Chicago Medical Ctr., 2160 S. First Ave., Maywood, IL 60153.

Gravid Sprague-Dawley rats received (f)METH (5 mg/kg, sc, bid) or saline (SAL) during gestational days 12-20. One SAL subgroup (WC) had ad lib access to the liquid diet. The pair-fed SAL subgroup (PP) received 25-30% less of the quet than the WC group in order to simulate the reduced food intake of the NETH treated dams. All offspring were cross fostered to lactating normal females. The METH treated dams. All offspring were cross fostered to lactating normal females. The METH treated dams. All offspring were cross fostered to lactating normal females. The METH treated dams. All offspring were cross fostered to lactating normal females. The METH treated dams and lower (24%) body weights than the VC and PF pups, which weighted less (16%; p<0.01) than the VC group. The METH offspring [47-53 days of age (doa)] showed deficits in the acquisition of a food foraging task as evidenced by longer (100%; p<0.01) latencies to locate the reinforcer. METH and PF offspring (59-62 doa) showed a decrease (35%; p<0.05) in the number of nose pokes emitted during a 9 min open field (OF) test. All groups showed comparable increases in OF activity in response to METH (0.5 mg/kg, sc). Interleukin-2 (Tl-2) stimulated natural killer (MK) cytotoxicity was increased (33%; p<0.05) in the METH rats (94-103 doa), but no group differences were found in T- or B-cell mitogenesis. Compared to home cage controls, stressed (2 shocks, 10 sec each, given at 1 and 10 min into a 20 min session) PF rats showed higher (34%; p<0.05) corticosterone (ORT) levels than the other stress induced increase (49%) in MEC 5-HIAA levels than the VC rats. Prenatal METH exposure impairs spatial learning, decreases exploration of a novel environment, increases II-2 stimulated MK activity, and enhances stress induced MFC serotonin turnover. Prenatal malnutrition (PF rats) increases the CORT and inhibits the MFC 5-HIAA hereshors than the VC rats.

20 6

EFFECTS OF PRENATAL COCAINE EXPOSURE ON ISOLATION-INDUCED BEHAVIORS AND DOPAMINE IN NEONATAL RATS C.B. Boylan* and P. Kehoe, Department of Psychology, Trinity College, Hartford, CT 06106

C.B. Boylan* and P. Kehoe. Department of Psychology, Trinity College, Hartford, CT 06106

In the neonatal rat, subcutaneous administration of cocaine during gestation causes alterations in dopamine activity as evidenced by behavioral and neurochemical deficits. To determine the effects of continuous occaine exposure on isolation-induced behaviors and neonatal brain dopamine levels, studies are underway in which cocaine 5, 10, 20 mg/kg/day or vehicle (0.9% sterile saline) is delivered to pregnant albino rats on gestation day 4 through parturition via surgically implanted osmotic mini-pumps (Alzet). Within 24 hours of birth, pups are cross-fostered to untreated lactating females and on postnatal day 10, tested with pharmacological probes for any deviations in isolation-induced ultrasonic vocalizations (UVs), activity levels and analgesia. Since both the dopamine and endogenous opioid systems are known to mediate these behaviors, pharmacological agonists which act on each system (Cocaine 5 mg/kg on the dopamine system & Naltrexone 0.5 mg/kg on the opioid system) were chosen as appropriate probes. In addition, HPLC with Electrochemical Detection was utilized to determine day 10 striatal dopamine concentrations. In general, pups from cocaine treated DAMs have decreased isolation-induced UVs; don't exhibit either normal cocaine suppression or naltrexone elevation of UVs; have decreased activity levels during isolation and have decreased baseline and isolation-induced pain responsivities. In addition, prenatally exposed cocaine pups demonstrate a trend for decreased striatal dopamine concentrations as compared to controls. These results imply that prenatal cocaine exposure produces an attenuation in dopamine activity which may also correspond to a change in the endogenous opioid system, causing neonatal behavioral alterations.

20.10

DEVELOPMENT OF BRAIN BETA RECEPTORS CHANGED BY PRENATAL PROPRANOLOL. <u>Xiao-Ke Gao*, J.C. Miller, K.A. Bonnet and A.J. Friedhoff</u>. Millhauser Labs of the Dept. of Psychiatry, N.Y. Univ. Med. Ctr., NY, NY, 10016.

Rat cortical beta receptors were determined

Rat cortical beta receptors were determined by ³H-DHA receptor binding assay in rats treated prenatally with propranolol (PRO). PRO was administered either i.p. or orally to pregnant rats on gestational days (GD's) 8-11, a period before the kinetic properties of beta receptors mature. A saline (SAL) injection was used as a control on GD's 8-11 as for PRO. SAL injection caused significant stress to the pregnant rats, and induced a significant decrease in the number of ³H-DHA binding sites in the offspring at 7 days of postnatal age compared to offspring of untreated pregnant dams. PRO injection on GD's 8-11 completely prevented the decrease in ³H-DHA binding sites induced by the stress of injection. Exposure to PRO, given orally to avoid stress, produced a significant decrease in brain ³H-DHA binding sites at postnatal age 7 days. From these observations we conclude that prior to phenotypic differentiation developing beta receptors are vulnerable to perturbation by stress or drugs.

20.12

THE EFFECTS OF CHRONIC AMPHETAMINE ON GROWTH AND BEHAVIOR IN MALE AND FEMALE RATS EXPOSED TO ALCOHOL IN LITERO. J.H.Hamnigan and M.L. Pilati, Center for Behavioral Teratology, SUNY-Albany, Albany, NY, USA, 12222.

Fetal Alcohol Syndrome often includes attention deficits treated with CNS stimulants, which can retard

Fetal Alcohol Syndrome often includes attention deficits treated with CNS stimulants, which can retard growth. Since rats exposed to prenatal ethanol (EtOH) are growth retarded and over-sensitive to acute amphetamine, we tested the biobehavioral impact of daily amphetamine. Subjects were male and female pups of dams fed either EtOH or control diets on gestation days 6-20. Rats received amphetamine (0, 2 or 10mg/kg/day) from postnatal days 22 (PN22) to PN43 and were weighed every other day until PN61. On PN22, PN36 and PN42, preand post-amphetamine behavior was measured.

Prenatal EtOH reduced brain and body weight and increased growth rats. However, EtOH rats never "caucht-

increased growth rate. However, EtOH rats never "caughtup" to controls, either during or after amphetamine,
which reduced growth rate equivalently for all groups.
There were no interactions between prenatal treatment,
sex, or amphetamine dose on any growth measure. Behavioral
tests will extend findings of EtOH-induced oversensitivity, plus reduced tolerance to chronic
amphetamine. Results suggest that fetal alcohol induced a
developmental delay in growth rate but did not change the
growth retarding effects of amphetamine.

Supported by RSDA #00111 from NIAAA to JHH.

PRENATAL METHADONE (M) EXPOSURE AFFECTS ANALGESIA AND NEUROTRANSMITTER CONTENT IN NEONATAL RATS. S.E. Robinson, H.-Z. Guo*, E.K. Enters, U. Pandey*, and K.P. McDowell*. Dept. of Pharmacology & Toxicology, Medical College of Virginia, VA 23298-0613.

On day 8 of pregnancy, female Sprague-Dawley rats were implanted under methoxyflurane anesthesia with 14-day Alzet osmotic minipumps filled with water (W) or M (9 mg/kg/day). There was no difference in food or water consumption or weight gain among unhandled control (C) dams or those treated with W or M. Within 24 h of delivery, pups were weighed, sexed, litter size reduced to 10, and fostered to untreated dams. There was no difference in litter size or number of implantation sites among the 3 groups. M-exposed male pups exhibited an enhanced analgesic response to morphine (0.4 mg/kg, s.c.) as measured by tail-flick on postnatal day 4, but no difference in their analgesic response to saline or naloxone (1 mg/kg, s.c.) On day 4, striatal ACh content, as measured by gas chromatography/mass fragmentography in pups euthanized by focussed microwave radiation, was significantly reduced in male M-exposed pups (p<0.05). There were no statistically significant changes in cortical or hippocampal ACh in the M-exposed male pups and nor in the 3 brain areas of M-exposed female pups. Catecholamines and indoleamines were also measured in these areas by reversed-phase HPLC with electrochemical detection. There were no significant changes in dopamine, norepinephrine, or serotonin content in any of these 3 areas. These studies indicate that this method of prenatal exposure to M can produce changes in brain regional ACh and analgesic responses to morphine without substantial maternal or fetal morbidity and mortality. (Supported by NIDA grant DA-05274).

DEGENERATION OF RAT LOCUS COERULEUS (LC) NEURONS IS NOT PARALLELED BY AN IRREVERSIBLE LOSS OF ASCENDING LC PROJECTIONS: EVIDENCE FOR REESTABLISHMENT OF FOREBRAIN INNERVATION BY SURVIVING NEURONS. R. Grzanna and J.-M. Fritschy, Johns Hopkins Univ. Sch. of Med., Dept. Neurosci., Baltimore, aMD 21205.

Johns Hopkins Univ. Sch. of Med., Dept. Neurosci., Baltimore, MD 21205.

Systemic administration of the noradrenergic (NE) neurotoxin DSP-4 induces degeneration of LC axons in rats. This degenerative process is followed by profound loss of LC cell bodies. The present study was conducted to determine whether LC neurons surviving DSP-4 treatment are capable of regeneration. The extent of LC neuron loss was compared to the pattern of NE axon staining between 2 weeks and 1 year after DSP-4 treatment (50 mg/kg, i.p.). LC neurons were counted in 30 m Nissl-stained sections. The distribution of NE axons in the brain was visualized by dopamine-B-hydroxylase immunohistochemistry. After DSP-4 treatment, the number of LC neurons decreased gradually to reach on average 60% of control at 6 months. In some rats up to 75% of LC neurons were lost. Despite the cell loss, extensive regeneration of LC axons occurred in the forebrain, but not in the brainstem and cerebellum. One year after drug treatment, the LC innervation of the forebrain was largely restored, with some regions exhibiting pronounced hyperinnervation. No reinnervation was observed in the brainstem and cerebellum, even in cases with only moderate LC neuron loss. While the regeneration process was slower in animals with severe LC neuron loss, the pattern of reinnervation was strikingly similar in all cases. The results demonstrate that regeneration of LC axons after DSP-4 treatment is region-specific and occurs in the presence of extensive of LC neuron loss. While the surviving LC neurons exhibit an extraordinary capacity to compensate for cell loss, the pattern of reinnervation appears to be controlled by target regions. DSP-4 represents a promising experimental tool to study cell death and regeneration in the CNS. Support MH41977.

21.3

EFFECTS OF PROMETHAZINE HC1 ADMINISTRATION TO GRAVID RATS ON THE BEHAVIOR OF OFFSPRING.

J.H. Patton and M.S. Stanford. Dept. of Psychology, Baylor University, Waco, TX 76798 and Dept. of Psychiatry and Behavioral Science of Psychiatry and Behavioral Color of P

Sciences, University of Texas Medical Branch, Galveston, TX 77550. Promethazine HCL (Phenergan[®], Wyeth) is a phenothiazine used for its anti-emetic and sedative potential during human pregnancy. Research has indicated that rats exposed to promethazine perinatally have lower steady-state levels of brain serotonin than controls (Stanford & Patton, Soc. Neurosci. Abstr., 15(2), p. 1018, 1989). In the present study seventy-nine rats exposed perinatally (during both gestation and lactation) to promethazine or saline vehicle were evaluated developmentally and behaviorally. The drug was injected into dams subcutaneously at a dose of 3.0 mg/kg per day. Pups were evaluated using a standard developmental protocol including somatic measures and reflexive evaluation. Additionally, animals were evaluated in an open-field and with a conditioned avoidance task of pain sensitivity.

There were no differences in gestation time or litter size, dam or pup weight, nor in pup length. There were no differences in surface righting or avoidance conditioning. There were differences in time to eye opening and incisor protrusion, although these were just short of statistical reliability. There were statistically reliable differences in days to ear extension, cliff avoidance behavior, negative geotaxis, and open-field activity attributable to promethazine treatment.

open-field activity attributable to promethazine treatment.

The results of this study suggest that exposure to promethazine HCl transplacentally and through milk has behavioral consequences in addition to the neurotransmitter effects reported earlier.

21.2

NORADRENERGIC (NE) AXON DEGENERATION IS ACCOMPANIED BY TRANSIENT AND GENERALIZED INCREASE IN GFAP IMMUNO-REACTIVITY IN THE RAT BRAIN. <u>J.-M. Fritschy, C.G. Frondoza, C. Cardona and R. Grzanna</u>, Johns Hopkins Univ., Depts. Neurosci. and Immunology & Infectious diseases, Baltimore, MD 21205.

Glial fibrillary acidic protein (GFAP) is a specific marker of astrocytes in the CNS. Increases in GFAP levels in brain have been reported in response to neuronal injuries. We have previously demonstrated that systemic administration of the NE neurotoxin DSP-4 induces extensive degeneration of locus coeruleus (LC) axons within 4-7 days. The present study was conducted to determine whether degeneration of LC axon terminals increases GFAP levels in the brain and whether such increases are restricted to regions containing degenerating NE fibres. Rats were perfused 1, 4, 5, 7, 10, 14 and 28 days after a single systemic injection of DSP-4 (50 mg/kg). Brain sections were processed for GFAP immunohistochemistry using the avidin-biodin peroxidase method. DSP-4 treatment triggered a dramatic and generalized increase in GFAP immunoreativity throughout the brain, including regions not innervated by LC axons. The response of astrocytes was first detectable 4 days after drug treatment, was maximal after 7 days, and declined progressively thereafter. DMI pretreatment (20 mg/kg) prevented the DSP-4-induced LC axon degeneration and the increase in GFAP staining. The induction of GFAP by DSP-4 is unrelated to transmitter depletion from NE axons, since reserpine treatment did not increase GFAP immunoreactivity. The present results demonstrate that drug-induced degeneration of NE axons is paralleled by a pronounced increase in GFAP levels in brain. Unlike after focal lesions, the increase in GFAP levels is transient and occurs throughout the brain. We propose that GFAP may serve as a useful marker to screen for drug-induced neuron degeneration in the CNS. Support MH41977 and CA 45640.

21.4

Dietary Copper Deficiency Modified Resident-Intruder Behavior in Mice. <u>E.S. Halas and L.M. Klevay*</u>. Department of Psychology, University of North Dakota and USDA, ARS, Human Nutrition Research Center, Grand Forks, ND 58202. Thirty-six Swiss-Webster male mice were individually housed with 36 ovariectomized Swiss-Webster females. Each

Thirty-six Swiss-Webster male mice were individually housed with 36 ovariectomized Swiss-Webster females. Each pair was fed an experimental diet deficient in copper. Eighteen pairs were given a drinking solution supplemented with copper (CuS) while the remaining 18 pairs were not so supplemented (CuD). This regimen was maintained for 9 weeks. Once a week for 8 weeks, the female was removed from each cage and was replaced by an intruder male. The two males remained together in the cage for 5 min after the first attack. The interactions between the two males were videotaped. Then the intruder male was returned to its cage. Behavior was scored later by two, independent observers. These procedures were repeated in a second experiment except the drinking water for the deficient group contained 0.5 ppm Cu. In the first experiment, the CuD mice attacked more than the CuS mice during the first week but then attacked less from week 3 through 8. In the second experiment, the CuD mice attacked less from the first week onward. Hematocrits measured in the third week of the second experiment were (mean ± S.D.) 50.3 ± 2.0 and 48.5 ± 3.0 respectively for CuS and CuD mice. A central rather than a peripheral causality is more likely for the passivity of deficient mice as anemia was absent.

21 5

TIMM'S STAINING OF RAT ENTORHINAL CORTEX DECREASED BY SUBCLINICAL DIETARY MICRONUTRIENT DEFICIENCIES. E.J. Root, D.H. Montgomery*, and J. B. Longenecker*. Graduate Nutrition, The University of Texas at Austin, Austin, TX 78712.

Prior studies showed that vitamin and mineral deficiencies too mild to significantly alter weight gain or outward appearance of rats can nevertheless alter brain cell structure & behavior (Nutr. Rep Int. 37:959, 1988; Fed Proc 46:903, 1987). Male weanling rats were fed 6 diets with various combinations of subclinical deficiencies (1/4 the requirement) for 6 months. One rat each from the control group, group 5 (deficient in Mg, Cu, vitamin B6, folacin, & choline), and group 6 (deficient in Mg, Zn, Ca, vitamin B6 & choline) was chosen for Timm's staining by the method of Danscher (Histochem. 71:1, 1981) rather than for conventional electron microscopy.

Group 6 showed a marked decrease of staining in L IV to VI of the entorhinal cortex and also decreased staining of the ventral half of the rhinal sulcus. Group 5 differed little from controls in sulfide-silver staining. Size of neurons and total area of entorhinal cortex were decreased in both groups 5 & 6. Decreased sulfide-silver staining implies decreased numbers of zinc-containing synaptic terminals.

PRENATAL MALNUTRITION AND POSTNATAL NUTRITIONAL REHABILITATION ON THE DENTATE GYRUS IN RATS OF FOUR AGE GROUPS. S. Díaz-Cintra, L. Cintra, A. Galván*, A. Aguilar*, T. Kemper* and P. J. Morgane. Inst. Inves. Biomédicas, UNAM, México, D.F. 04510, Neurol. Unit. Boston City Hosp. Boston MA, 02118 & Worcester Found. for Expt. Biol. Shrewsbury MA, 01545.

Unit. Boston City Hosp. Boston MA, 02118 & Worcester Found. for Expt. Biol. Shrewsbury MA, 01545.

In a previous study on the hippocampal formation we analyzed morphometrically the effects of protein malnutrition (8% casein diet), instituted before mating and continued during gestation and into postnatal life on the granule cells of the dentate gyrus. The objetive of the present study was to use nutritionally rehabilitated animals that were born from a mother fed with 6% casein diet before mating and during gestation. At born they were cross fostered to a normal mother that was fed in a similar conditions, with a 25% casein diet. Using the rapid Golgi method we studied the dentate gyrus in rehabilitated rats at 15, 30, 90 and 220 days of age. We found significant reductions in the major and minor axes due to diet effect. The number of dendritic spines measured in proximal, medial and terminal segments were significantly reduced by the diet and dendritic density measured by the number of intersections 38 microns apart in 9 concentric rings, showed significant reductions on the last five rings. This findings point to a long term effect of prenatal protein malnutrition on the molecular layer of the dentate gyrus in rehabilitated animals. (Supported by CONACyT Fellowships 20518, 27234, México, D.F. and NIH Grants HD-23338 and HD-22539).

PRENATAL PROTEIN MALNUTRITION ALTERS RAPID KINDLING IN THE DENTATE GYRUS. R.J. Austin-LaFrance, J.D. Bronzino and P.J. Morgane. Dept. of Engineering and Comp. Sci., Trinity College, Hartford, CT 06106 and The Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

A rapid kindling paradigm was used to investigate the effects of prenatal protein malnutrition on the development of kindling in adult rats. Dietary groups consisted of pups born to dams fed either a low (6%) or control (25%) casein diet. All pups were fostered at birth to lactating dams fed the 25% casein diet and were designated 6%/25% or 25%/25% based on the pre-/postnatal diet. As adults, animals were implanted with a stimulating electrode in the perforant path and a recording electrode in the dentate gyrus. Kindling consisted of 10 sec. trains of biphasic square-waves applied to the perforant path every 5 min. for 1 hour on 5 consecutive days. Results indicate that control animals exhibit more than twice as many stage 5 seizures during the test period as do 6%/25% animals. Additionally, 2 of 6 malnourished animals failed to achieve a single stage 5 seizure. The results parallel our previous findings with a classical kindling paradigm and indicate that rapidly kindled seizures can be effectively used to study the impact of prenatal insults, such as malnutrition, on the development of kindling and the resultant kindled state. (Supported by NIH Grant # HD-22539)

COMPARISON OF THE BRAINSTEM AUDITORY EVOKED RESPONSE (BAER) DEVELOPMENT IN TAURINE SUPPLEMENTED AND TAURINE-DEFICIENT KITTENS.

M-H. Vallecalle, G. Heaney*, E. Sersen*, J. A. Sturman. Inst. for Basic Res. in Dev. Disabil., 1050 Forest Hill Rd., S.I., NY 10314.

It has been demonstrated that the presence of normal taurine (Tau) concentrations in the cat are essential for the normal development of the retina and visual cortex, at least. Very little information is available on its function within the auditory system despite the report of high level of free Tau in the organ of hearing. Brainstem Auditory Evoked Response (BAER) is widely used for the assessment of hearing function, and undergoes characteristic changes during brain maturation. The aim of this study was to assess the development of hearing function in kittens subjected to variable conditions of Tau nutrition (.02%, .05%, 1%) from their period of conception until 12 weeks of age.

The BAERs were elicited by rarefactions clicks at intensities ranging from 30 - 80 dB (p.e. SPL). For each kitten, thresholds and latencies of successive positive and negative peaks were determined at 4 and 8 weeks of age. Our preliminary results are as follows: Most animals younger than 7 postnatal days are

The BAÉRs were elicited by rarefactions clicks at intensities ranging from 30 - 80 dB (p.e. SPL). For each kitten, thresholds and latencies of successive positive and negative peaks were determined at 4 and 8 weeks of age. Our preliminary results are as follows: Most animals younger than 7 postnatal days are unresponsive, and reliable responses are not observed in all animals until early in the second postnatal week. At this age, waves I and IV are identifiable for intensities ≥ 50 dB (p.e. SPL). Threshold, determined by the lowest intensity at which PIV is present, does not differ significantly between groups at either age. Analysis of latencies suggests longer brainstem transmission time in the .02% Tau group than in the other two groups.

SLEEP DEPRIVATION IN NORMAL AND MALNOURISHED RATS OF 30 DAYS OF AGE. L. Cintra, A. Galván*and S. <u>Díaz-Cintra</u>, Dept. de Fisiología Instituto de Investigaciones Biomédicas. UNAM, México, D.F. 04510.

Sleep deprivation has been employed as an important strategy to unravel sleep functions and recently the homeostatic aspect of sleep regulation was proposed from sleep deprivation experiments, where sleep lost induces a compensatory increase of sleep. However, this strategy as not been used in malnourished animals. The objetive of the present study was to evaluate the effect of protein malnutrition (6% casein diet), instituted before mating and continued during gestation and into postnatal life on the sleep-wake cycle before and after sleep deprivation. A base line-day was followed by one day of sleep deprivation in a continuously rotating cilinder (diam. 32 cm; rotation rate: 1 turn/2.40 min) and three recovery days in normal (25% casein diet) and malnourished rats at 30 days of age. We found a significant increase of slow wave sleep, specially during the activity phase in the second recuperation day. However REM sleep was significantly decreased mainly during the rest phase on the first and third recuperation days. These data reveals that the compensatory increase of REM sleep was more affected by malnutrition in comparison to slow wave sleep. (Supported by CONACyT Grant P219CCOA880341).

PRENATAL PROTEIN MALNUTRITION RESULTS IN THE LOSS OF BEHAVIOR-MEDIATED THETA FREQUENCY SHIFTING. P.J. Morgane, K.B. Austin, S.J. Palmer*, R.J. Austin-LaFrance and J.D. Bronzino. Worcester Found. for Exp. Biol. Shrewsbury, MA 05145, Dept. of Engineering and Computer Sci., Trinity College, Hartford, CT 06106

We investigated the relationship between hippocampal theta frequency and theta behaviors in prenatally protein malnourished adult rats. Diet groups consisted of pups born to dams fed a low (6%) or control (25%) casein diet. All pups were fostered at birth to lactating dams fed the control diet and were designated 6%/25% or 25%/25% based on the pre-/postnatal diet. Theta frequency measures were calculated from EEG activity recorded in the hippocampus during periods of REM sleep and active waking (AW). AW was defined as periods of exploratory locomotion. 25%/25% animals exhibit a significant shift in theta frequency between these two behavioral states, with the slower frequency seen in AW. 6%/25% animals exhibit no change in theta frequency between these states. No between-group difference was found in theta frequency obtained during REM, suggesting that septohippocampal cholinergic systems pacing REM theta remain intact, while non-cholinergic theta systems associated with voluntary movement appear unable to regulate theta frequency shifting to match behavior. (Supported by NIH Grant # HD-22539)

ENVIRONMENTAL ENRICHMENT DURING NUTRITIONAL REHABILITATION

ENVIRONMENTAL ENRICHMENT DURING NUTRITIONAL REHABILITATION INCREASES DENDRITIC SPINE NUMBER. A. Carughi,* L.L. Ring,* K.J. Carpenter* and M.C. Diamond. Dept. of Nutritional Sciences and Dept. of Anatomy/Physiology. University of California, Berkeley, CA 94720.

Environmental enrichment has been reported to aid recovery from behavioral deficits associated with mainutrition in infants and young rats. Our study investigates whether corresponding neuroanatomical changes can be detected. Rats were suckled either by well-fed dams (17% protein) or dams mainourished (8% protein) from the 17th gestational day throughout lactation. At weaning, well-fed male pups were either housed in pairs (standard condition, SC) or 12 per large cage with "toys" (enriched condition, EC) and fed a 17% protein diet (rehabilitation, "rehab") and housed in SC or EC environments. This treatment lasted for 30 days. Spines with a head and a stalk ("Iollipop") and those with equal sized head and base ("nubbin") were counted from segments of oblique and basal dendrites from occipital cortical pyramidal cells. SC-rehab rats had 15% and 16% less "Iollipop" spines on oblique and basal dendrites respectively than SC-control ones. However, ECpyramidal cais. SC-ferial rats flat 15% and 15% are less longop spiries on oblique and basal dendrites respectively than SC-control ones. However, EC-rehab rats had 30% and 34% more "lollipop" spires than SC-rehab rats on these locations. The interaction diet x environment was significant. Thus, environmental enrichment during nutritional rehabilitation increases "lollipop" spine number. These results support those previously reported by our laboratory (Carughi, A.; Carpenter, K.J.; Diamond, M.C. J. Nutr. 119:2005-2016, 1989) on cortical thickness and dendritic branching.

DEPLETION OF "OUTSTANDINGLY HIGH" CEREBRAL DEVELOPMENT IN RAT SUBJECTED TO PRENATAL UNDERNUTRITION OR PRENATAL IONIZING RADIATION. <u>S. Zamenhof.</u> Dept. of Microbiology and Immunology, and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024

In previous reports (Life Sci., 18:1391, 1976) we have identified individual rats whose neonatal cerebral parameters (weight, DNA, protein) were "outstandingly high" (OH) (defined throughout as being more than 1 standard deviation (OH₁), or 2 standard deviations (OH₂) above the mean of <u>normal</u> population, i.e., tail end of normal distribution curve). In neonatal human infants we identified individuals with OH₂ head circumferences (correlated with cerebral weights and DNA) (Fed. Proc., 1990, in press). In the present work we have established that pregnant rats subjected to chronic undernutrition $(^2/3)$ of

neieu.		Cerebiai Weight	DIAM	TIOLOITI
OH₁	Control	7%	16%	8%
	Undernutr.	1%	2.1%	0.5%
OH,	Control	0.8%	0.7%	1.2%
2	Undernutr	0.0%	0.0%	0.0%

The differences between controls (total n=1597) and undernourished (414) are statistically highly significant. Similar results were obtained for chronic ionizing radiation (tritiated drinking water, 3μ Ci/ml). Possible causes are neuronal death, or deficient mitotic phase. Thus, the harmful effects of these treatments are twofold: 1) Significant reduction of mean values of cerebral parameters in the population as a whole, and 2) depletion of cerebral OH individuals. If these parameters are correlated with behavioral performance, the depletion of individuals with outstandingly high cerebral parameters may be even more harmful than the well know reduction of mean values of these parameters in the population as a whole.

TRANSPLANTATION: GENERAL I

22.1

TRANSPLANTATION OF PREMYELINATING CULTURED OLIGODENDROCYTES INTO RAT BRAIN. M.D.A. Espinosa de los Monteros, M. Aymie , M.N. Gordon, M.-S. Zhang , R.A. Korsak , J. Edmond and J. de Vellis. UCLA School of Medicine, Mental Retardation Research Center, Los Angeles, CA 90024-1759.

To study myelination by transplanted, premyelinating oligodendrocytes (ol), we used wild-type and myelin deficient (md) rats. The md rat is characterized by inhibition of ol maturation and almost total lack of CNS myelin. Ol were separated from 12 d glial primary cultures derived of UNS myelin. Of were separated from 12 d gnal primary cultures derived from wild-type neonatal rat brains. Such cultures contain >95% of by ICC for ol specific marker proteins. Premyelinating of in culture were labeled with fast blue prior to grafting. Ols were suspended in a minimal volume of Hank's medium and 2.5 x 10⁵ were stereotaxically injected into the corpus striatum. Grafted ol were identified in brain sections by the presence of the fast blue label and ICC for ol specific proteins at various times after grafting. Implanted of were able to survive, migrate and express of markers. In wild-type rats, fast blue⁺, grafted of were detectable for at least 3 months after grafting. Grafted, fast blue⁺ of were observed primarily ipsilateral to the graft site in the corpus striatum, corpus callosum and cortex. Of also migrated thru-out the rostro-caudal extent of the corpus striatum and corpus callosum, and into the contralateral corpus callosum. Grafted wild type of in *md* rats (grafted at P17) also survived, migrated and expressed the specific markers, but were insufficient to ameliorate motor symptoms tremors and seizures). Future studies will examine grafting into younger md rats, and EM analysis of myelin produced by grafted ol. Supported by USPHS grant HD-06576.

22.2

THE ROLE OF MICROGLIA IN TRANSPLANTED RETINAE

R.Sharma and R.D.Lund. Dept of Neurobiology, Anatomy and Cell Science, Sch. of Med., Univ of Pittsburgh, Pittsburgh, PA 15261 We have shown that embryonic retinae transplanted to the brains of

newborn rats can mediate pupillary responses in the host. During the transplantation procedure the retinal pigment epithelium (RPE) is typically removed. Since RPE is considered to be an essential component of the visual response, why does the transplant continue to function in its

A previous light microscopic study (Perry and Lund, Neurosci. 31:453, 1989) showed that microglia surround the outer border of the transplanted retinae. Here we have examined the transplant/host transplanted retinae. Here we have examined the transplant/host interface at the ultrastructural level using pigmented donor retinae (to allow identification of RPE, if present) and a monoclonal antibody (OX-42) to identify microglia. No pigmented epithelial cells were seen associated with the retinal transplants. However, OX-42 positive cells (having the structural characteristics of microglia) were found surrounding the graft with processes interspersed among photoreceptor outer segments. These OX-42 positive cells were often seen phagocytosing outer segments. These OA-42 positive cells were often seen phagocytosing outer segment membrane. Occasional astrocytes were seen among these cells. In retinal transplants devoid of RPE, the intimate relationship between OX-42 positive cells and outer segments suggests that microglial cells may assume the functions characteristic of retinal pigment epithelium. (Supported by NIH Grant EY 05283).

AND DIVISION OF ASTROCYTES FROM MIGRATION

MIGRATION AND DIVISION OF ASTROCYTES FROM XENOGRAFTS IN HOST RAT MIDBRAIN. H.E.Zhou and R.D.Lund. Dept. Neurobiol., Anat. and Cell Sci., Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15261 Our previous work has demonstrated that the patterns of astrocyte migration from xenografts are primarily influenced by the local structures of host brain when placed in the cortex, subcortical white matter or hippocampus. In the present study, the patterns of glial migration in the midbrain were investigated by transplantation of CD-1 mouse cerebral cortex (E14) or corpus callosum (P3) to the tegmental region of Sprague-Dawley rats (P1). Host brains were fixed with zinc-aldehyde fixative 3 to 5 weeks post-transplantation (PT). A monoclonal antibody to a mouse astrocyte surface antigen (M2) was used to identify the location of the grafts and the astrocytes migrating from the graft. The majority of astrocytes from both cortical and callosal grafts migrated entrally and terminated in the substantia nigra (SN). A small number of cells migrated into the medial geniculate nucleus and central grey region.

In order to determine whether the high density of donor astrocytes in the SN was due solely to cell migration from the transplants, or to active division of some cells which had migrated to that region, a single injection of ³H-thymidine (10 uCi) fram body weight) was administered at either 6, 12 or 18 days PT. All rats were fixed 25 days after transplantation. Sections stained with anti-M2 antibody were processed for autoraciography permitting visualization of double labeled cells. In animals that received an injection of ³H-thymidine (6 days PT, a similar number of dividing cells was found in the SN both insilateral and contralateral to the transplant. Within the SN ipsilateral to the transplant, a high density of donor astrocytes was seen. Among them, 6.4% (29/452) of the donor cells were labeled by thymidine. This decreased to 3.1% (10/325) in the animals injected at 18 days PT. Dividing donor astrocytes were rarely se

FIBROBLAST TRANSPLANTS INTO THE HIPPOCAMPUS. B. P. Vietje, J. Wells and C. J. Cornbrooks.

Anatomy and Neurobiology, University of Burlington, VT 05405.

In order to determine if connective tissue components disrupt CNS sprouting, fibroblasts from embryonic PNS cultures were transplanted into the dentate gyrus. Cultured fibroblasts were suspended in Hanks Balanced Salt Solution (HPSS) and placed in the information allowed places. (HBSS) and placed in the infragranular cleavage plane. Injections of HBSS alone (no cells) killed the granule cells, caused an astrocytic activation, and initiated a sprouting of AChE fibers into the molecular layer. The sprouting was not enough to rescue the molecular layer which continued to atrophy. The transplants were identified and localized to the infragranular layer by the staining of the collagenous fibers. The fibroblast transplants failed to inhibit the sprouting of the AChE fibers. Moreover, the molecular layer over the highest concentrations of collagenous fibers maintained its thickness. Also in those areas, there was a clear increase in the presence of blood vessels, and astrocytic activation was prominent. At lesion sites away from the transplanted prominent. At lesson sites away from the transplanted collagenous fibers the molecular layer continued to atrophy. These data suggest that, rather than disrupt CNS sprouting, fibroblast transplants may support axonal growth.

TRANSPLANTED SCHWANN CELL (SC) CULTURES SUPPORT REGENERATION IN SEVERED NERVES. J.K. Daniloff, D.Kim*1, A.Smith*, S.Connolly*1, and D.G.Kline1. Dept. of Vet.Anatomy,Louisiana State Univ.Sch. of Vet.Med.,Baton Rouge, LA 70803 and Dept. of Neurosurgery, LSU Sch.of Med.,New Orleans,LA 70112

Return of function in transected nerves sustaining gaps is poor. Entubulization produces limited recovery. Although significant functional recovery occurs with autografts of sensory nerves, sensory loss results. The purpose of this investigation was to test the effectiveness of autografts and SC implants to restore gastrocnemius muscle function. Three surgical procedures were used to repair 1 cm gaps in 48 severed sciatic (ischiatic) nerves of young adult rats: collagen tubes containing confluent embryonic SC cultures (n=24) or collagen gel (n=12) and sural nerve autografts (n=12). Nerve conduction velocity was assessed prior to surgery and function was assessed 60 and 120 days post-surgery. At both survival times, conduction velocities with collagen tubes and autografts were not significantly different. The SC group was more rapid at both times. Enhanced recovery was sustained for 120 days indicating that the improvement in regeneration may be permanent.

ALTERATION OF MOTONEURON PROPERTIES FOLLOWING TRANSPLANTATION OF THORACIC NEURAL TUBE TO THE LUMBAR REGION. Y. Qin-Wei and R. W. Oppenheim. Dept. of Neurobiology and Anatomy, Bowman Gray Sch. of Med., Wake Forest Univ, Winston-Salem, N. C. 27103

Previous studies have shown that transplantation of thoracic spinal cord to the lumbar region at the time of neural tube closure in the chick embryo (E2) results in the initial innervation of the hindlimbs and the survival and maintenance of the ectopic thoracic motoneurons. At later stages of embryonic development (E12-E18), regressive changes occur in the neuromuscular system. However, some thoracic motoneurons continue to survive and maintain contact with limb muscles. The surviving, ectopic thoracic neural tube and motoneurons exhibit a number of changes in morphological properties such that they come to resemble the normal in situ lumbar spinal cord and lumbar motoneurons. These include: (1) changes in the proportion of spinal cord area occupied by white and grey matter; (2) increases in motoneuron size; (3) changes in dendritic arborization and distribution; and (4) the establishment of peripheral intramuscular branching patterns similar to those exhibited by lumbar motoneurons. Because these same changes are also observed in thoracic transplants lacking neuroanatomical continuity with the host spinal cord and brain, we assume that they are not induced by afferent input, but rather that they reflect a response to a target-derived retrograde signal which acts to regulate motoneuron differentiation.

22.9

TRANSPLANTATION OF EMBRYONIC CAT SPINAL CORD TISSUE INTO THE ADULT RAT SPINAL CORD. P. J. Reier* and W. J. Streit* Depts. Neurological Surg. and Neuroscience, Univ. Florida Coll. Med., Gainesville, FL 32610.

In previous studies of fetal rat spinal cord transplants into the injured adult rat spinal cord (FSC₂) we found such grafts to be capable of suppressing gliosis and of fostering some ingrowth of host fibers. This ability, however, was of limited duration and may have reflected the relatively rapid maturation of these transplants. We tested this possibility in a series of experiments (Group A) in which grafts of more slowly maturing fetal cat spinal cord tissue (E24-28) were made into the spinal cords of adult rats (FSC_{cx}) immunosuppressed with Cyclosporine A (CsA). We also took advantage of these xenogenic transplants to examine microgilal distributions during rejection induced by withdrawal of CsA (Group B). Group A: At 6 wks. post-transplantation (p-1), conventional light microscopy and anti-GFAP staining of vibratome sections revealed a more extensive fusion of donor and host tissue than seen previously with rat homotypic allografts. Although containing matured neurons, these grafts were still relatively immature as reflected by the paucity of myelinated axons. Immunocytochemistry showed, however, that the ingrowth of host serotoninergic fibers was limited. In contrast, CGRP-immunoreactive axons from the host showed a more robust elongation into these grafts. Similar results were obtained at later p-t intervals (up to 10 wks). The ingrowth of these two axonal populations was thus comparable to that seen with FSC_r transplants. Group B: A battery of staining methods were used to demonstrate microgila in immunosuppressed recipients (CsA⁺) and in hosts 1 wk. after withdrawal of CsA (CsA⁻). No microgila were seen in xenogenic grafts in CsA⁺ rats, whereas some were present in the host. Transplants in the CsA⁻ animals showed extensive lymphocytic invasion; however, no microgila could be demonstrated. In contrast, large and numerous microgila were still seen in the host expecially at the graft Interface. (Supported by NIH 1PO1-NS 27511).

EFFECTS OF CULTURED ADRENAL CHROMAFFIN AND SCHWANN CELL IMPLANTS ON HINDLIMB REFLEXES OF THE 6-OHDA LESIONED SPINAL RAT. B.E.Pulford, A.R.Mihajlov, L.R.Whalen, H.O.Nornes,

Dept. Anatomy & Neurobiology, Colorado State University, Ft. Collins, Co. 80523. The effects of implantation of cultured neuronal and non-neuronal cells on the recovery of neurotransmitter specific reflex activity were studied in the rat spinal cord using an electrophysiological model. Cell suspensions of neonatal adrenal medullary chromaffin (AM) cells, which produce catecholamines, Schwann (Sc) cells, or a mixture of the 2 cell types were implanted into the lumbar region of the rat spinal cord 2 wks after catecholamine (CA) denervation by intracisternal injection of 6-hydroxydopamine (6-OHDA). Cells were taken from 7d neonates and cultured for 10 days in the presence of NGF. Three months after implantation, the extent of implant-associated recovery of reflex activity was determined by electrophysiological measurements of the EMG activity and force of the long latency component of the hindlimb withdrawal reflex, which is CA modulated. After the electrophysiological testing, rats were deeply anesthetized, and the spinal cord was removed and rapidly frozen. Spinal cords were sectioned longitudinally and were stained using immunohistochemical (anti-TH and anti-217c antibodies) or glyoxylic acid techniques. Stained sections were examined to determine the number of implanted cells which survived, and the extent of outgrowth originating from these cells. Results indicated that 1) significant numbers of chromaffin and Schwann cells were able to grow in the segments of the cord into which they had been injected and 2) rats which received AM cells or a mixture of AM + Sc cells had significantly more forceful withdrawal reflexes than those that received Sc cells only or received no implant after lesioning. The level of force was significantly below the level obtained from unlesioned rats. Supported by NIH grant #NS 21309-04 and APA grant #NA3-8801-2

22.8

THE EFFECT OF TRANSPLANTS ON MOTOR BEHAVIOR IN SPINAL KITTENS. D.R. Howland, B.S. Bregman, A. Tessler, and M.E. Goldberger. Department of Anatomy, The Medical College of Pennsylvania, Philadelphia, PA 19129.

The effect of homotypic embryonic transplants on locomotor development was studied. Transplants were placed in the transected spinal cord lesion cavities of one day old kittens. E26 spinal cord survives in the host lesion cavity for as long as eight months. Calcitonin gene related peptide is present in the transplant. The labelled fibers, however, appear abnormal in their pattern and distribution. Serotoninergic fibers are found to descend to the rostral interface. Animals with transplants develop independent quadrupedal treadmill locomotion and conditioned independent overground locomotion. These have traditionally been held to require interspinal and supraspinal communication respectively. Their locomotion has many abnormal characteristics including: a hindlimb stepcycle of increased duration, a broadened base of support, hypermetric hindlimb flexion, postural instability and lack of consistent 1:1 pairing between hind and forelimb stepcycles. The number of falls exhibited during overground locomotion decreases with age by as much as 92.6% from 6 weeks - 8 months The number of full weight supporting hindlimb stepcycles increases with age by as much as 265% from 6 weeks - 8 months. A stepcycle swing analysis suggests that coordination between hind and forelimb stepcycles is present during quadrupedal and overground locomotion. Taken together, these results suggest that embryonic spinal cord transplants are capable of affecting locomotor behavior in the spinal neonatal kitten. (Supported by Grant NS24707 and the Daniel Heumann Fund).

22.10

FETAL GRAFTS ALTER CHRONIC BEHAVIORAL OUTCOME AFTER CONTUSION DAMAGE TO THE ADULT RAT SPINAL CORD. B.T. Stokes, Dept. Physiology, The Ohio State Univ. and P.J. Reier, Dept. Neurosci., Univ. Florida.

Stokes, Dept. Physiology, The Ohio State Univ. and P.J. Reier, Dept. Neurosci., Univ. Florida.

Fetal transplants have been reported to enhance motor recovery in rats when injured and receiving grafts as neonates (Kunkel-Bagden, 1990). Evidence for graft-mediated partial return of certain motor (Buchanan and Nornes, 1986) or sexual reflexes (Privat, 1988) has also been observed in adult rats following transection or neurotoxin-induced lesions. In the present experiments, we have investigated whether fetal neural tissue transplants placed into the contused spinal cord (10 days post-injury) can alter behavioral outcome in a different injury setting. We have used a variety of standard behavioral scoring paradigms (generalized motor activity: open field, inclined plane, and gridwalking) and a modified, sensitive test of motivated behavior (foot-print analysis; Kunkel-Bagden and Bregman, 1990) to examine the results. Rats were extensively pretested in the various trials, anesthetized and injured with an electro-mechanical impactor device. Ten days later they were reanesthetized, transplanted with a suspension of dissociated E. spinal cord cells and then allowed to survive over the next 3 months. In the generalized trials of motor activity, injured controls and transplanted animals showed the same recovery profiles. Footprint analysis, however, revealed statistically significant (pr.006; mutivariate ANOVA) improvements in the base of support and right or left stride lengths. This was seen by 7 days post-transplantation and persisted throughout the post-graft survival period. These results suggest that embryonic spinal cord cells may be able to promote long-term sparing of certain functions in a clinically relevant model of spinal cord injury. Supported by NS-10165 and NO1-NS-7-2300.

EXCITABILITY STUDIES IN THE RODENT SPINAL CORD FOLLOWING CONTUSION INJURY AND NEURAL TISSUE TRANSPLANTATION. Floyd J. Thompson¹. Paul J. Reier¹** Gregory W. Schrimsher¹. Christopher C. Lucas¹. Linda R. Ray¹. Depts: Neurosci¹ & Neurosurg², Univ of Fla, Gainesville. In the present study, hindlimb reflex excitability was studied following midthoracic spinal contusion injury in the adult rat. The injuries were produced by impact of a 10 gm weight dropped from a 2.5 cm height onto the exposed thoracic (Ta) spinal cord, (contusion protocol adapted from Wrathall et al (Exp Neurol., 88:108-122, 1985)). Hindlimb (lumbar) reflex excitability was evaluated at 1 and 2 months following injury.

Contusion injury produced physiological changes characterized by a significant loss of reflex inhibition associated with reflex repetition at low frequency. For example, in normal animals, in response to the frequency test.

requency. For example, in normal animals, in response to the frequency test, reflexes were inhibited 54% of the control. Whereas, 28 days following contusion injury, the same test revealed only a 9.2% inhibition of the test reflexes. The mechanism responsible for low frequency depression reflex

reflexes. The mechanism responsible for low frequency depression reflex amplitude is currently accepted to be presynaptic inhibition. The studies on the contused animals form a baseline for evaluation of neural tissue transplantation to address specific physiological deficits.

Observations have been made on animals which received implants of E-14 fetal spinal cord tissue one week following injury. Tested at 1 and 2 month intervals following the initial contusion injury, the loss of presynaptic inhibition flumbar test reflexes was considerably less in these animals compared to untreated animals. For example, tested at 2 months following the injury, in the animals which had received transplants, the reflexes were inhibited 38 % of control compared to 5 % in the untreated animals. Although preliminary, these observations suggest a sparing function for the treatment of contusion spinal cord injury using transplants of fetal spinal cord tissue. (Supported by NO1-NS-7-2300, NINDS).

SURAL NERVE GRAFTS IN FORNIX TRANSECTED MONKEYS. J.H. Kordowerl, D.M. Gash2, and M.S. Fiandaca3. 1Dept. of Anatomy and Cell Biology, Univ. Illinois Sch. Med., Chicago III. 60612, 2Dept. of Neurobiology and Anatomy, Unix. Rochester Sch. Med. Rochester N.Y. 14642, 3Division of Neurosurgery, Univ. Massachusetts Med. Ctr. Worcester MA 01605. Following peripheral nerve transection, Schwann cells begin a de novo synthesis of trophic factors including nerve growth factor [NGF]. Cholineric basal forebrain neurons are sensitive to trophic factors such

Cholinergic basal forebrain neurons are sensitive to trophic factors such as NGF and consistently degenerate in Alzheimer's disease. Thus peripheral nerve grafts were assessed for their ability to provide trophic

influences upon axotomized primate cholinergic medial septal neurons.

Ten Cebus monkeys received a unilateral transection of the fornix. At the time of the lesion, monkeys received either no graft [n=1], a control tissue graft [n=2], or an intraventricular implant of autologous sural nerve [n=3]. Other monkeys received sural nerve grafts 1-3 weeks prior to the fornix transection [n=4]. Comprehensive decreases of acetylcholinesterase [AChE]-containing fibers within the CA3 and acetylcholinesterase [AChE]-containing fibers within the CA3 and dentate gyrus regions of the hippocampus were observed in all animals 30 days post-lesion. Monkeys receiving no graft, control grafts, or sural nerve grafts at the time of the lesion displayed similar reductions in cholinergic medial septal neurons ipsilateral to the lesion. In contrast, monkeys receiving implants prior to the onset of degeneration displayed a reduced cell loss. Furthermore, sural nerve grafted monkeys displayed an AChE-positive sprouting response in the region of the graft. These data suggest that peripheral nerve can provide trophic and neurite promoting effects upon primate cholinergic basal forebrain neurons. [Supported by AHAF and NS 25655].

BEHAVIORAL IMPROVEMENT AND TRANSPLANT SURVIVAL AFTER FETAL CELL IMPLANTS IN MPTP LESIONED BONNET MONKEYS. C.J. Hutt*, E.H. Kriek, M.L. Reite*, and C.R. Freed, Depts. of Med., Pharm., and Psych., University of Colorado Sch. of Med., Denver, CO 80262.

To test the value of fetal dopamine cell grafts in the

reatment of Parkinson's disease, Bonnet monkeys were made Parkinsonian with systemic or unilateral injections of the neurotoxin MPTP. For systemic lesions, MPTP.HCl 0.5 mg/kg i.m. was given for 5 days (n=8). Unilateral lesions were created with a single carotid infusion of 0.8 mg/kg (n=8). Monkeys were trained to reach for food reward in computer-timed tests and were tested for circling with amphetamine 0.5 mg/kg or apomorphine 0.15 mg/kg. Lesioning reduced the ability to reach for a food reward. Unilaterally lesioned animals showed spontaneous circling ipsilateral to the side of the lesion and apomorphine led to contralateral circling. Mesencephalic dopamine cells from 18-150 mm crown rump length fetus were transplanted in caudate and putamen on one side of brain via 5 needle passes. By 3 weeks after implant, systemically lesioned monkeys showed improved ability to reach. In unilaterally lesioned animals, spontaneous circling contralateral to the side of the lesion was observed and apomorphine circling slowed. At autopsy, tyrosine hydroxylase positive cells were seen along needle tracks of animals transplanted with fetal dopamine cells but not in animals receiving spinal cord implants.

CLINICAL FOLLOW UP OF IMPLANTS OF VENTRAL MESENCEPHALON INTO THE CAUDATE NUCLEUS OF SEVERELY AFFECTED PARKINSON'S PATIENTS.

J.J. Lopez-Lozano, G. Bravo*, J. Uria*, J. Dargallo*1, J. Salmean*1, J. Cerrolaza*2 and CPH. Neural Transplantation Group Lab. Neurobiology.Dept. Neurology and Dept. Neurosurgery Clin. Puerta de Hierro, University Autonoma; Dept. Gynecology-Obstectrics. Hosp. Severo Ochoa¹, Leganes; and Hosp. Mostoles ²: 28035-Madrid. Spain.

Ochoa¹, Leganes; and Hosp. Mostoles ²: 28035-Madrid. Spain.

Based on our previous experience with autotransplants of adrenal medulla (AM) in Parkinson's patients (PP), from Oct. 88 to the present, our group has performed 10 implants of human fetal ventral mesencephalon (VM) into caudate nucleus of grade IV-V PP. The fetal tissue (17w and 8-10w old tissue) was obtained from legal abortions and consent for its use and the research procedure follow the corresponding Spanish laws (BOE 42/88, 30/79). The same protocol was used in fetal VM alloimplants as in AM autotransplants (IJLL'90). Patients were maintained with the optimal dose of autotransplants (JILL'90). Patients were maintained with the optimal dose of L-dopa and all dopaminergic agonists were discontinued. The results obtained seem to indicate the existence of a very moderate (but statistically significant) improvement in the overall Parkinson's disease scale (UPDS) and int the overall assessment of Parkinson's symptoms (MYS). The improvement does not follow the course of the AM implants, occurs later (x=7 mo) and the recovery is lesser. The decrease in the amount of L-dopa required begins in month 2, and is less marked than in AM implants. With respect to dykinesia, there is a decrease in the intensity and duration, but not in the frequency or type. This report will discuss the clinical course of the operated patients and the variations observed in the individual Parkinson's symptoms. (Supported by FIS 90/197, 89/115, CACYT PA86/046). TRANSPLANTATION: NEW TECHNIQUES AND CELL LINES

23.1

A NOVEL STEREOTACTIC SURGICAL PROCEDURE FOR TUMOR IMPLAN-TATION IN RAT BRAIN. V.M. Morreale*, B.H. Herman, V. Der-Minassian*, W. Goldberg, J. Bernstein, M. Palkovits, P. Klubes*, D. Perry & A. Csiffary*. Brain Res Cen, Children's Natl Med Cen, Wash, DC 20010; Dept Psychiat, Ped & Pharm, George Wash Univ Sch Med, Wash, DC; CNS Regen Res Lab, VA Hosp, DC; Lab Cell Biol, NIMH, MD.

A model for implantation of cultured tumor cells into rat brain is presented. Stereotactic implantation reduces tumor variation.

Exp 1: 8 male Wistar rats (225g) were implanted with a permanent caudate cannula using a stereotaxic apparatus. Immediately after cannula implantation, rats were injected(10 ul) as follows:4 with 10⁶ cultured glioma cells, 2 with Walker (WL) 256 cells and 2 with culture medium. Two weeks following implantation, brains were cut, and stained with cresyl violet(CV) or for glial fibrillary acidic protein In all 4 C6 rats, there was no tumor at AP(+5.7) or AP (-2.3), M±SEM tumor area(Loats,mm²): AP(4.7)0.5±0.3, AP(3.7) 4.3±0.8, AP(2.7)7.1±1.2,AP (1.7) 11.4 ±1.6, AP (0.7) 9.2±3.4, AP(-0.3) 4.6±3.6, AP(-1.3)0.4±0.4). WL256 rats showed a much reduced AP tumor extension. Similar tumor areas were indicated in GFA compared with CV. Tumor was found in caudate(6/6), but not in n. accumbens, fornix or hippocampus. Exp 2: 5 rats were implanted with C6 glioma cells using 10⁵ cells and a reduced volume of 1ul to produce a more defined tumor. Thus, reproducible and circumscribed caudate tumors were produced using this procedure. Funded by Cancer Aid Group, Wash, DC and Discovery Funds of CNMC (BHH).

A NEW PROCEDURE ALLOWING MULTI-SITE INTRARETINAL GRAFTING

Eliot Lazar and Manuel del Cerro. Department of Neurobiology and Anatomy,
University of Rochester, Medical School, Rochester, N.Y.

Since our original presentation on intraocular retinal transplantation (del Cerro et al., ARVO 1984), procedures for retinal grafting have been under constant evolution. All of the techniques described to date require surgically opening of the eye through either a trans-scleral or trans-comeal route. This requirement carries with it all the inherent surgical risks as well as the related complications. As a result, these approaches necessarily limit attempts at multiple implantation into a single eye. We describe here a procedure which avoids these restrictions. A 27 gauge needle, sheathed in plastic, with 1.2 - 1.4 mm of the needle tip left exposed is used for the transplantation. The bevelled tip cleanly enters the tissues while the sheath limits the depth of penetration. Under direct visualization a micro syringeis used to inject dissociated donor retinal cells into numerous sites of the adult rat retina. This procedure which is virtually free of complications, avoids the need for surgically entering the eye and therefore makes it possible to perform multiple simultaneous grafts into the intact globe. Results, using ophthalmoscopy as well as light and electron microscopy, have comfirmed the atraumatic nature of this technique. Histologically, the growth and differentiation of the grafts are comparable with those seen in transplants using a surgical approach (del Cerro et al., 1990). Intraretinal injection of colloidal carbon into control animals using the same technique, dramatically illustrates that a large proportion of the host retina is bathed in material when employing this method. The technique initially devised for rodent eyes, is presently being used for grafting of cells

Supported by NEI grant #05262 and the Rochester Eye Bank.

HIPPOCAMPAL CELL-LINE TRANSPLANTATION: IMPROVED LEARNING IN RATS WITH HIPPOCAMPUS LESIONS.

LEARNING IN RATS WITH HIPPOCAMPUS LESIONS.

V.W. Henderson, C.M. Petrucco. Department of Neurology (Division of Cognitive Neuroscience & Aging), University of Southern California, Los Angeles, California 90033

HT4 is neural-precursor cell line derived from embryonic rat hippocampus with a temperature-sensitive conditional oncogene. To evaluate behavioral effects of HT4 transplantation, 13 adult Sprague-Dawley rats were randomized to receive (1) bilateral stereotactic, electrolytic lesions of the dorsal hippocampus followed 2 weeks later by HT4 implantation into the lesion cavity, (2) hippocampal lesions without transplantation, or (3) sham lesions only. Two months later, animals were tested for spatial learning on the Morris water maze (4 trials/d X 15 d). Learning performance of HT4-implanted 15 d). Learning performance of HT4-implanted rats was significantly better than that of lesioned controls (p < 0.05) but worse than that of sham-lesioned animals. These preliminary results in a small number of animals suggest that cell-line implants may be functionally beneficial and support the more general strategy of cell-line transplantation for the treatment of human neurodegenerative disorders.

EXPRESSION OF GLUTAMIC ACID DECARBOXYLASE GENE IN THE FIBROBLASTS-POTENTIAL USE FOR INTRACEREBRAL GRAFTING. L.S.Chen. J.K. Yee. T.Friedmann and F.H.Gage. Dept. of Neuroscience and Pediatrics, Univ. of California, San Diego; La Jolla,

The object of the present study is to develop a potential therapeutic The object of the present study is to develop a potential therapeutic approach to focal seizure disorder using a strategy of gene therapy, namely implanting genetically modified cells into the brain. Local application of GABA receptor agonist or GABA transaminase inhibitor into discrete brain areas suppresses seizure in various animal model of epilepsy. Suppressing seizure by permanent increase of GABA concentration locally in the brain regions where seizure generates or propagates might be achieved by grafting the genetically modified, GABA-producing fibroblasts into the brain. To investigate this possibility, glutamic acid decarboxylase(GAD) gene was transferred into fibroblasts.

A retroviral vector containing the full-length feline GAD cDNA (LGADRNL) was derived from the Moloney murine leukemia virus. This vector expresses GAD from the 5' long terminal repeat and the selectable bacterial neomycin-resistance gene from an internal Rous sarcoma virus bacterial neomycin-resistance gene from an internal Rous sarcoma virus promoter. Immortalized rat fibroblasts of the Ratl cell line and primary fibroblasts obtained from Fisher rats were infected with LGADRNL. Neomycin-resistant colonies were e stablished and soluble extract from cell homogenate was screened for GAD activity using ¹⁴CO₂ trapping assay . The GAD activity (nmol CO₂/mg protein/hr incubation) of infected fibroblasts vs non-infected control was 401 vs 3.3 for Ratl cells and 432 vs 8.7 for primary fibroblasts. Biochemical studies indicated that 35% of GAD expressed in the Ratl fibroblasts was bounded with endogenous cofactor, pyridoxal-5'-phosphate. In addition, the GAD-producing fibroblasts was immunohistochemically labelled.

EFFECT OF LONG-TERM POLYMER ENCAPSULATION OF PC12 CELLS IN VITRO. P.A. Tresco¹, S.R. Winn¹, B. Zielinski*¹, C.B. Jaeger², L.A. Greene³, P. Aebischer¹. ¹Artificial Organ Lab., Brown Univ., Providence, RI; ² Dept. of Anat., SVM Purdue Univ; ³Dept. of Pathol., Columbia Univ., New York, NY.

The effect of long-term encapsulation of an immortal DA-secreting cell line was studied in order to assess the feasibility of using this approach as DA

was studied in order to assess the feasibility of using this approach as a DA-delivery system. PC12 cell suspensions were encapsulated with an acrylic copolymer and maintained in vitro for up to 3 months. DA release from cellloaded, permselective, cylindrical capsules (8mm long x 0.85mm I.D.) was evaluated after a 15 min. static incubation with Hank's basic salt solution. evaluated after a 15 min. static incubation with Hank's basic salt solution. Twenty-four hours after the static incubation, the following parameters were evaluated for each capsule: total cell number; percent viability; and total capsule DA content. Unstimulated DA release increased with time after encapsulation reaching a maximum of 7.86 ng +/- 0.39 (n=6) after 3 months. Total cell number and DA content also increased with time and reached a maximum after 3 months. The rate of increase in cell number and DA content was comparable to the rate of increase in DA released from the polymer capsules suggesting that the increase in DA efflux over time was related to increased cell proliferation. The percentage of viable cells as determined by trypan blue exclusion declined from 91 to 43 percent over the same time period, however, the total cell number increased with time. Light microscopy period, however, the total cell number increased with time. Light microscopy revealed the presence of mitotic figures at all time points. A potential problem with encapsulating an immortal cell line is the accumulation of acellular debris within capsules resulting from cellular necrosis over time. Over the 3 month study period, this condition did not appear to compromise DA output from cell-loaded capsules. Whether this observation is true over longer time periods will have to be addressed by subsequent studies. Supported by grant No. NS27694 from the NINDS-NIH.

PRIMARY FIBROBLASTS THAT PRODUCE L-DOPA: LONG TERM SURVIVAL AND BEHAVIORAL EFFECTS WHEN IMPLANTED IN RATS WITH 6-OHDA LESIONS. L.J. Fisher, H.A Jinnah, P.J. Langlais, G.A. Higgins¹, T. Friedmann* and F.H. Gage. Depts. Neurosci & Pediatrics, UCSD, La Jolla, CA 92093; ¹Dept. Neurobiol & Anat, Univ Rochester Med Ctr, Rochester, NY 14642.

Several investigators have shown that genetically modified cells can Several investigators have shown that genetically modified cells can survive when implanted within the brain (Gage et al., 1987; Shimohama et al., 1989; Uchida et al., 1989), and exert a functional influence over surrounding tissues (Rosenberg et al., 1988; Wolff et al., 1989; Horellou et al, 1990). The majority of studies to date have described results from the use of established cell lines; cells which have the potential capacity for continued, undesired proliferation in the last the present study princes (fixed property against all and as a vivo. In the present study, primary fibroblasts were examined as a possible alternative donor cell type for use in grafting in an animal model of neurological disease. Primary fibroblasts were obtained from inbred Fischer 344 rats and infected with a retroviral vector containing a full length cDNA for rat tyrosine hydroxylase (TH). A clone which expressed TH activity and TH immunoreactivity in vitro was selected for grafting. Grafts were placed within the 6-hydroxy-dopamine denervated striatum of adult Fischer rats. Control lesioned rats were either untreated or received grafts of primary fibroblasts infected with a retroviral vector containing beta-galactosidase. Rats were tested with apomorphine every 2 weeks for 8 weeks after were tested with apomorphine every 2 weeks for 8 weeks after grafting. A pronounced, prolonged decrease in rotational behavior was seen only in those rats with TH-fibroblast grafts. Preliminary anatomical results indicate that all grafted rats contained surviving grafs. Further histological analyses of these grafts is underway.

ULTRASTRUCTURE OF POLYMER ENCAPSULATED PC12 CELLS USED AS BRAIN IMPLANTS AND MAINTAINED IN VITRO. C.B.Jaeger¹, L.A. Greene², S.R. Winn², P. Tresco⁴, and P. Aebischer². ¹Dept. of Anat./CPR, Purdue Univ.SVM, W. Lafayette, IN 47907; ²Dept. of Pathol. Columbia Univ., New York, NY; and ³Artificial Organ Lab., Brown Univ., Providence, RI. The fine structure of PC12 cells growing within polymer capsules was studied because encapsulated cell lines may provide a useful alternative to embryonic neuron grafts for transmitter replacement in the brain. Capsules were prepared from polyvinyl-acrylic copolymer tubing, 800 um in diameter, with a molecular cut-off of 50KDa. Suspended PC12 cells were loaded by ultrafiltration into 3 to 5 mm tube segments, and the ends were closed with liquid polymer. Cell-filled capsules were kept either *in vitro* or implanted in the brains of rats or guinea pigs. Capsules were fixed at 1/2, 1, 3, and 6 months and the ultrastructure of enclosed cells was examined. Structural changes were related to size and distribution of storage granules and were most evident in comparisons of longtion of storage granules and were most evident in comparisons of longterm versus short-term encapsulated cell populations. In short-term culture, PC12 cells typically contained abundant quantities of variable sized electron-dense storage granules that were randomly distributed within the cytoplasm and resembled those in PC12 cells grown in monolayer culcytoplasm and resembled those in PC12 cells grown in monolayer cultures. At periods of ten weeks or more following enclosure, the electron-dense storage granules had a more patchy distribution and were often seen in small cell processes. Increased frequency of 'empty' membrane containers suggested enhanced vesicular release. These morphological changes could reflect alterations of cell/cell contacts due to continued mitosis and crowding of PC12 cells in capsules. The data are relevant for evaluating the usefulness of PC12 cell-filled capsules. Supported by USPHS grant No. NS27694 from NINDS.

23.8

BEHAVIORAL RECOVERY FOLLOWING INTRASTRIATAL IMPLANTATION OF MICROENCAPSULATED PC12 CELLS S.R.Winn¹, B.Zielinski*¹, P.A.Tresco¹, A.P.Signore*¹, C.B.Jaeger², L.A.Greene³, P.Aebischer¹. ¹Artificial Organ Lab., Brown Univer., Providence, RI. ²Dept. of Anat., SVM Purdue Univ., ³Dept of Pathol., Columbia Univ., NY, NY. The motor deficits associated with Parkinson's disease may be controlled with intrastriatal placement of dopamine-secreting cells in a polymer capsule. Water soluble polyelectrolytes were utilized for membrane encapsulation of dopamine-secreting PC12 cells. Microcapsules, 600 μm in diameter, were formed by syringe pump extrusion of a sodium alginate/PC12 cell solution into a multivalent cationic bath. A semipermeable membrane was formed by interfacial adsorption of poly-L-lysine over the gelled microspheres. Membrane permeability studies revealed exclusion of radiolabeled 69 KDa albumin, whereas 30 KDa carbonic anhydrase was able to cross the membrane. In vitro, microencapsulated PC12 cells (MEC/PC12) were assessed by quantifying dopamine release and cell viability over time. One month post-encapsulation, dopamine release and viable cell populations reached levels that were maintained for at least 12 weeks. The behavioral effect of intrastriatal dopamine release from MEC/PC12 cells was evaluated in the 6-OHDA unilaterally lesioned rat model. From two to four weeks post-implantation, MEC/PC12 recipients (n=4) revealed a 60% reduction in rotation behavior under apomorphine challenge as compared to animals which received empty microcapsules (n=4) Intact microcapsules containing tyrosine hydravalase (n=4) revealed a 60% reduction in rotation behavior under apomorphine challenge as compared to animals which received empty microcapsules (n=4). Intact microcapsules containing tyrosine hydroxylase immunopositive PC12 cells were observed after 4 weeks of implantation in animals exhibiting a reduction in turning behavior. Implantation of polymer encapsulated cells may provide a means for long-term delivery of neurotransmitters and growth factors to the nervous system.

Supported by grant No. NS27694 from the NINDS-NIH.

TRANSPLANTATION OF IMMORTALIZED NEURAL CELLS CULTURED ON DEXTRAN BASED MICROCARRIER BEADS PROVIDE A NOVEL ENVIRONMENT FOR AXONAL INGROWTH INTO THE ADULT MAMMALIAN SPINAL CORD. P. Brittis, M. Zeller*, M. N. Goodman*, J. W. Jacobberger*, J. Ruddge*, J. Silver, J. Yoshino* and W. E. Edmonston. Dept. of Neuroscience, Colgate University, Hamilton, NY 13346 and Depts. of Genetics and Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

We have been investigating the use of dextran based microcarrier beads for neural cell transplantation into the mammalian spinal cord. In vivo application of microcarrier beads allows for: accurate placement of cells in the spinal cord, a three-dimensional substrate, contact inhibition of immortalized cells, limited cell migration, and a large transplantable surface area.

Immature (P1) type 1 forebrain astrocytes, neonatal Schwann cells (Tennekoon et al., J. Cell. Bio. 105:2315-2325, 1987), and adult olfactory bulb glial cells (Goodman et al., Soc. Neurosci. Abst., 1989) were immortalized with SV-40 large T antigen via plasmid or retroviral gene transfer. These immortalized cells have been successfully cultured on microcarrier beads and placed in a dorsal root entry zone. We were able to locate the cells up to four weeks after transplantation by allowing them to phagocytize fluorescent microspheres or by labeling the cells with phaseolus vulgaris leucoagglutinin prior to their attachment to microcarrier beads.

beads.

Both the internal and punctate forms of laminin as well as the NGF like receptor [Mab 217c] (Kumar et al., Soc. Neuro-chem. Abst., 1990) have been found to comprise part of the known Schwann and olfactory glial cell authorizing while the astrocytes were GFAP positive and like the interfile, while the astrocytes were GFAP positive and like the interfile at lized Schwann cells, sustained neurite sufforch in vitro By placing immortalized cells attached to microcarrier beads into the dorsal root entry zone, we have created a potentially conducive pathway for the possible ingrowth of dorsal root fibers into the adult rat spinal cord.

NGF PRODUCING FIBROBLAST GRAFTS AND THEIR INTERACTION WITH EXCITOTOXIC STRIATAL LESIONS. J.M. Schumacher, M.P. Short, B.T. Hyman, M.V. Sofroniew, X.O. Breakefield and O. Isacson, Dept. Neurology and Neurosurgery, Harvard Med. Sch., McLean Hospital, Belmont MA 02178 and Massachusetts General Hospital, and Dept. of Anatomy, University of Cambridge, U.K.

Previous studies using pharmacological NGF infusions in parallel with excitotoxic lesions of rat striatum have indicated NGF protective effects (ALoe, 1987). In order to further test this hypothesis we have used a biological delivery system of NGF (Rosenberg et al. 1988), by implanting fibroblasts genetically engineered to produce high levels of NGF into the rat brain, prior to infusing an excitotoxin into the striatum.

A rat derived immortalized fibroblast cell line (208F) was infected by a NGF retroviral vector (N.8) and selected for neomycin resistance. The chosen fibroblasts clones (NGF+) were further selected for highest NGF production by a 2-site enzyme immunoassay (50 ng NGF/mg cell protein). The expanded NGF+ cell-line and and a non-NGF variant (NGF-) of the 208F fibroblast cell line was injected (8 million cells/rat) into the lateral ventricle and mid-line structures. After eight days, quinolinic acid (60 nM in 1µl) was infused into the insilateral striatum. Apomorphine induced behavioral rotation (11 days post-lesion) indicated no difference between NGF+ and NGF- grafted groups. Histological evaluation (25 days post-grafting) showed large surviving Nissl stained grafts in the NGF- group, while NGF+ grafts were much smaller. The NGF+ group had slightly smaller lesions than the NGF-group in Nissl and GFAP stained sections. These studies indicate different growth patterns of intracerebrally grafted NGF vector infected (NGF+) as compared to non-infected rat fibroblast cell-lines (NGF-), and suggest that excitotoxic lesion effects in the striatum may be affected by the presence of NGF.

TWITCH AND MAXIMAL VOLUNTARY CONTRACTION TENSIONS OF NORMAL HUMAN EXTENSOR DIGITORUM BREVIS MUSCLES. J.A. Florendo, D.S. Kirby*, B.C. Schafer*, T.G. Goodwin* and P.K. Law. Depts. of Neurol. and Physiol/Biophys., Univ. of Tennessee, Memphis, TN 38163.

An apparatus was designed and a procedure developed whereby twitch and maximal voluntary contraction tensions of human extensor digitorum brevis (EDB) muscles could be measured. A study of eleven normal adult volunteers was conducted to demonstrate the reproducibility of this technique. Maximal voluntary contraction amplitude, as well as twitch amplitude, maximum rate of rise, and half relaxation time following supramaximal, indirect, electrical stimulation, were determined. A minimum of six measurements of each parameter were obtained from each EDB. All parameters demonstrate relatively low coefficients of variation between individual muscle measurements, but differences exist between right and left feet of some individuals and between different individuals. Therefore, this apparatus and procedure can provide an accurate measurement of muscle function for experimental evaluation.

This apparatus and procedure were used to evaluate muscle function of individual EDBs of eleven boys with Duchenne muscular dystrophy before and after myoblast transfer therapy. Amplitudes of twitch and maximal voluntary contraction tensions were obtained from myoblast- and sham-injected EDBs, to demonstrate functional improvement and efficacy of myoblast transfer therapy. INTRAOCULAR TRANSPLANTATION AND CULTURE OF SECOND-TRIMESTER HUMAN EMBRYONIC RETINAL CELLS.
M. del Cerro, E. Lazar, D. A. Grover*, M. Gallagher*, C. D. Sladek, J. Chu, and C.
del Cerro. Dept. of Neurobiology and Anatomy, University of Rochester Medical School, Rochester, N.Y.

This study tested the viability of second-trimester human embryonic retinal cells for transplantation into the eyes of adult hosts. Tissue procurement followed strict ethical guidelines Retinas obtained from electively aborted embryos aged 13 to 17 weeks were dissected and mechanically dissociated into small cell clusters prior to transplantation. Adult albino rats and Cercopithecus aethiops sabaeus monkeys immunosuppressed with Cyclosporine A served as hosts. Anterior chamber and multisite intraretinal grafts were performed, the later by using our newly developed injection procedure (Lazar and del Cerro, 90). Light (LM) and electron microscopio studies (EM) indicated that the donor fetal retinas had relatively mature neurons and fibers within their inner layers, but they retained an outer neuroblastic layer populated by mitotically active cells. When dissociated donor retinas were cultured in vitro they produced cells endowed with positive immunoreactivity towards the neuronal markers NSE and PGP 9.5, growing over a carpet of flat non-reactive cells. Biomicroscopy allowed us to follow the survival, grow, and vascularization of the grafts. LM and EM showed that many differentiated donor neurons degenerate, while the neuroblastic cells continue their growth and form the mass of the graft. This study indicates that second trimester human fetal retinas are a rich source of viable cells, and retain their capacity to grow and to differentiate morphological and biochemical neuronal characteristics, both in vivo and in vitro. Intraocular grafts of these cells into adult hosts shows vigorous growth and integration with the host. Thus, it appears that the fetal human retina is endowed with a uniquely wide "time window" for successful transplantation, a crucially important feature behind attempts to use these cells to repopulate damaged adult retinas

CHARACTERIZATION OF NEURON-LIKE CELL LINE IMMORTALIZED FROM PRIMARY RAT MESENCEPHALON CULTURES. M. M. Durand.* D. C. Chugani, M. Mahmoudi, *M. E. Phelps. UCLA School of Medicine, Los Angeles, CA 90024

The transplantation of fetal mesencephalic tissue in striatum shows promise as an effective treatment for Parkinson's disease. The limited availability of human retail tissue as well as complex ethical issues regarding the use of the tissue will prevent widespread implementation of this procedure. Reversibly immortalized mesencephalic dopaminergic cell lines may be the answer to this problem. We have produced reversibly immortalized cells from embryonic day 14 rat mesencephalon using a retroviral vector containing the genes for temperature sensitive large T antigen of SV40 and neomycin resistance (G418). This retrovirus was stably produced by a psi 2 cell line obtained from R. McKay, MIT. Primary cultures were enriched for dopaminergic cells by panning in tissue culture plates that had been coated with the monoclonal antibody, neuron specific protein 4 (Rougon et al., (1983) Neurosci. 10: 511). Following panning, cells were grown with supernatant from psi 2 cell line containing the retrovirus (dilution 1:3). After 48 hr the cells were incubated with G418 to select for cells which had incorporated the virus. Surviving cells, selected by dilution, proliferated at 33°C and displayed flat morphology. At 39°C the cells stopped dividing and some cells changed from flat cells with broad processes to neuron-like morphology. One cell line CSM 14.1, expressed tyrosine hydroxylase and neuron specific enolase immunoreactivity when raised to 39°C for one week. These cells were grown in the presence of when raised to 39°C for one week. These cen's were grown in the presence various growth factors in attempt to increase neuronal characteristics. The addition of basic fibroblast growth factor produced greater than 90% neuron morphology after one week in culture at 39°C. These cells in addition expressed neurofilament 68 and OL28 (a putative neuronal marker) immunoreactivity. These data suggest that it may to possible to reversibly immortalize mesencephalic dopaminergic cells for transplantation. (Supported by NS 15654 and DOE DE-FC03-87ER60615)

GRAFTING GENETICALLY ALTERED P19 EMBRYONAL CARCINOMA-DERIVED NEURONS INTO RAT STRIATUM D.I. Morassutti, W. Staines, M. McBurney* and Z. Merali
Depts. of Medicine and Anatomy, School of Psychology and
Pharmacology, University of Ottawa, Ottawa, CANADA, K1H 8M5

Treating murine embryonal carcinoma (EC) cells with retinoic acid (RA) causes them to terminally differentiate into neurons, glia, and smooth-muscle cells. The population of neurons formed displays a smooth-muscle cells. The population of neurons formed displays a heterogenous neurotransmitter phenotype reminiscent of rodent forebrain (Staines et al., SFNS abstr.108.6, 1989) and we are now studying the response of these cell to intracerebral tranplantation. To specifically recognize graft tissue after transplantation, undifferentiated EC-cells were transfected with a bacterial gene for beta-galactosidase (B-GAL) detectable by histochemical, immunocytochemical and EM methods.

B-GAL expressing EC-cells were treated with RA for 3 days and method in the present of the property of th

B-GAL expressing EC-cells were treated with RA for 3 days and grafted into rat striata previously lesioned by ibotenic acid, or deafferented by a 6-OHDA lesion of the MFB. B-GAL expressing cells were demonstrated in vivo for at least 2 wks. post grafting. Through double-labelling using anti-B-GAL in combination with the neuron-specific monoclonal antibody A60 (Mullen et al., SFNS abstr.204.9,1989) we could specifically identify EC-derived neurons within the grafts. Additional double-labelling revealed continued neuropeptide-Y and somatostatin expression by these EC-derived neurons.

A second EC cell line transfected with the rat tyrosine hydroxylase cDNA shows high levels of dopamine production following RA-induced differentiation and results of tranplantation will be reported. (This work was supported by the MRC of Canada).

CONTACT-DEPENDENT REGULATION OF PRESYNAPTIC CALCIUM CURRENT DENSITY DURING SYNAPTOGENESIS. L. R. Funte. E. M. Sievers, and P. G. Haydon, Department of Zoology, Iowa

State University, Ames, Iowa 50011.
It is well established that contact between neuronal growth cones and muscle has widespread effects on postsynaptic properties. The reciprocal actions of target cells on presynaptic development are ill defined. We have investigated the effects of postsynaptic target contact on presynaptic development during synaptogenesis between pairs of identified neurons of

Helisoma trivolvis in cell culture.
To gain direct access to the presynaptic secretory membrane, synapse formation between pairs of neuronal somata was studied. Sustained periods of synaptic contact enhanced both the release of neurotransmitter and the macroscopic calcium current density of presynaptic neuron B5. Thus, in addition to regulating postsynaptic properties, synaptic contact augments the presynaptic calcium current which is responsible for evoking calciumdependent transmitter release.

To extend these studies, we are currently investigating the effects of target contact on the spatial distribution of sites of calcium influx in neurites and growth cones using the calcium-sensitive dye Fura-2. Supported by NIH grants NS24233 and NS26650.

RETINA CELLS IN CULTURE SEQUESTER MUSCARINIC ACH RECEPTORS TO THEIR DENDRITES A.F.Skorupa, W.L. Klein Northwestern Univ. Inst. for Neurosci. Evanston, IL 60208

Retina cells in situ are known to sequester ACh receptors to their dendrites by the time synapses are first detected (J. Neurosci.8:4225). However, younger retina cells in culture show no distinction in receptor distribution between soma and neurite (J. Biol. Chem. distribution between soma and neurite (J. Biol. Chem. 260:8873). The possibility exists that culture conditions might preclude interactions leading to receptor restriction; alternatively, it may be that previous in vitro studies examined only an initial phase of receptor differentiation. The current data favor the latter2 hypothesis. E9 chick retinas were dissociated and cells were grown in high density (1.35 X 10⁵ cells/cm²) for 2 and 6 days. Cells were also grown at 10-fold lower density, but fed media conditioned by high density cultures. Culture conditions favored normal development of receptor subtypes previously seen in vivo (PNAS of receptor subtypes previously seen in vivo (PMAS 82:8785). Cells were labeled with [³H]PrBCM and mAChRs were localized by autoradiography. In both types of cultures, cells were observed expressing mAChRs on cell bodies as well as to dendrites. However, with increasing age, there were numerous cells that segregated mAChR to dendrites. This culture system, in which retina neurons can mimic their in vivo restriction of receptors, should be useful in studying the protein trafficking essential to form synaptic signal transducing membranes in the CNS.

REGENERATING RETINAL GANGLION CELL AXONS CAN FORM SYNAPSES WITH NEURONS IN FOUR DIFFERENT NON-RETINAL TARGETS IN THE ADULT HAMSTER. T.J. ZWIMPFER*, H. INOUE*, A.J. ACUAYO and G.M. BRAY. Montreal General Hospital and McGill University, Montréal, Québec, Canada, H3G 1A4. We have previously demonstrated in adult hamsters

that regenerating RGC axons can form persistent synapses within the cerebellum (Cb) (Zwimpfer et al., 1989 Soc. Neurosci. Abstr. 15: 458). Regenerative synaptogenesis of RGC axons was investigated in 3 additional targets that do not normally receive direct retinal input. In adult hamsters, regrowing RGC axons were guided by a bridging peripheral nerve graft into either the inferior colliculus, visual cortex, or somatosensory cortex.

RGC axons grew into each of these targets and formed terminals with ultrastructural features (clear vesicles, pale mitochondria and predominantly asymmetric axodendritic synapses) that are similar to those of both regenerated RGC terminals within the Cb and RGC terminals within a normal retinal target, the superior colliculus. Further studies on retinal innervation of the Cb revealed that RGC axons exhibited a marked preference for growth and synapse formation in one region of the Cb, the granule cell layer.

These results suggest either that axons regenerating in the adult mammalian CNS synapse indiscriminantly or that molecular determinants of synaptogenesis are shared by certain neurons in diverse regions of the CNS.

REACTIVE SYNAPTOGENESIS AT PHOTORECEPTOR FEEDBACK SYNAPSES IN THE FLY'S LAMINA. J.H. Brandstätter, S.R. Shaw and I.A. Meinertzhagen. Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia. CANADA B3H 4J1 Monopolar cell L2 is one of several unique interneurons found in each module or carridge of the first optic neuropile, the lamina, beneath the fly's compound eye. Its synapses feed back upon the same receptor (R) terminals which provide L2's input at afferent photoreceptor synapses. The number of sites of both photoreceptor afferent and feedback synapses, decreases during normal adult development, after peaking in early adulthood (Meinertzhagen, I.A., *J. Neurobiol.*, 20: 276, 1989). The feedback synapse is usually a dyad L2->R, T1; in which T1 is a higher-order interneuron. In a study of synaptic plasticity we examined by electron microscopy the structure and frequencies of these plasticity we examined by electron microscopy the structure and frequencies of these feedback synapses upon receptor terminals that were degenerating after a 12-min period of illumination following retinal injections of sulforhodamine 101 in *Musca domestica* (Picaud, S. et al., Neurosci. Lett., 95:24, 1988). Although all the receptor terminals in a photoablated cartridge degenerated, depriving L2 of its chief afferent inputs, degeneration did not progress trans-synaptically within the time period examined (14d), nor was T1 affected by photoablation. Presynaptic degeneration was however accompanied by the generation in L2 of dissociated ribbons of the feedback synapse, which had become separated by a process of invagination from their presynaptic membrane sites, to form free-floating organelles. Although floating synapses seem to be degradation products formed following the degeneration of their postsynaptic (R) targets, the frequency of intact synaptic profiles in the L2 axons of photoablated cartridges in fact increased twofold over 8d, indicating that new synapses had formed during this period of reactive synaptogenesis. The elevated frequency of synaptic sites correlates with and presumably arises from a group of smaller synapses (ribbons < 0.14µm wide), that lies outside the size distribution of synaptic contacts seen in control cartridges. Since the mean size of synaptic contacts increases with age for the population, we infer that these smaller synapses were young ones added early on during the period of reactive synaptogenesis. Supported by NCE (Ottawa), NIH (EY-03592) to I.A.M.; NSERC (A 9593) to S.R.S.

ADHESION COMPLEXES OF SYNAPTOGENIC FILOPODIA <u>H-C.T.Tsui.</u>
C.S.Kim*, C.P.Young*, B.Lom*, W.B.Pope* and W.L.Klein.
Inst.for Neurosci., Northwestern University, Evanston, 11.
CNS filopodial junctions differentiate into structurally identifiable synapses (PNAS 82:8256). Nascent junctions are held together by "transjunctional adhesion complexes (TACs), multimeric extracellular filaments that contain components of adheron (Dev.Brain Res. 51:205). We now have begun to characterize the individual components of adherons using monoclonal antibodies. Two mabs generated against adherons recognized antigens with marked developmental regulation.

Labeling with Mab AD2 showed non-selective distribution in chick retina from E7 to E13, but became segregated to the inner plexiform, ganglion cell and optic fiber layers by P40. The antigen was present in two Mr forms (66 kD and 70 kD) in membrane fractions of E13 retina. However, both forms disappeared in membrane fraction of P28 retinas. In contrast, a 70 kD form was present in the soluble fraction throughout development. Another mab, AD1, labeled distinct bands of the inner plexiform layer transiently during the time of neuritogenesis and synaptogenesis. These antigens were only present on a subpopulation of neurons and were absent in non-neural tissue. When examined with the EM immunogold method, these antigens were found to be present on filamentous materials on the cell surfaces and at some of the filopodia junctions. These result suggest that some of the TACs comprise cell- and stage-specific molecules.

In vitro maintenance of a neonatal rat spinal cord/nerve/muscle preparation
G.S. Bewick^{1,2}, W.J. Betz¹ & R.M.A.P. Ridge², Depts.
of Physiology, ¹Univ. Colorado Med. School, Denver, CO
80262 and ²Univ. of Bristol Med. School, Bristol BS8

1TD, U.K.
We have explored methods for maintaining neonatal rat spinal cord/nerve/muscle (4th deep lumbrical) pre-parations in culture. Viability was assessed by measur-ing muscle twitch and tetanic tension in response to peripheral nerve and dorsal root stimulation. A two-chamberred organ bath allowed the the spinal cord and the muscle to be exposed to different culture media. Several different media were assessed, including normal physiological saline, DME and an Earle's BSS/BME mixture, with various supplements (e.g., chick embryo extract, neonatal or fetal calf serum, H₂O₂ and insulin) were asses-

Tension declined first in response to dorsal root stimulation, indicating transmission failure at spinal synapses. This usually began after about 20 hours in culture. Tension evoked in response to peripheral nerve stimulation often lasted 36 hours, and under ideal conditions, for periods as long as 80 hours, with the indirectly elicited muscle tetanus being within 10% of the initial value for the first 45 hours of the experiment.

GLYCINE RECEPTORS ON RAT MOTONEURONS DEVELOPING IN

CLYCINE RECEPTORS ON RAT MOTONEURONS DEVELOPING IN CULTURE. P.A. St. John & S.L. Stephens*. Dept. of Anatomy and Program in Neuroscience, Univ. of Arizona, Tucson, AZ 85724.

We have used embryonic rat motoneurons developing in culture to study what controls the type, number, and subcellular distribution of neurotransmitter receptors expressed by CNS neurons. Last year, we presented studies of substance P (SP) receptors on developing motoneurons. The results suggested that the initial expression of SP receptors by motoneurons is autonomous, apparently not requiring induction by other neurons and able to precede synapse formation. This year's experiments motioneurous is autonomous, apparently not requiring induction by other neurons and able to precede synapse formation. This year's experiments examined a fundamentally different class of receptors, those for glycine. The time-course for development of glycine receptors, assayed by the binding of radioactive strychnine, differed significantly from that for SP binding of radioactive strychnine, differed significantly from that for SP receptors. Neurons in mixed-population cultures had very few, if any, glycine receptors for the first several days in culture. Beginning around day 4, however, the number of receptors increased dramatically to reach a plateau level within 2-3 days. Because the initial expression of glycine receptors coincided with that of SV48, a common synaptic vesicle antigen, it appeared that glycine receptor expression might be induced by other neurons, perhaps through synaptic contact. This question is being addressed using motoneurons purified by cell sorting and cultured in the virtual absence of other neurons. In separate experiments, we used a fluorescent derivative of strychnine to examine the distribution of glycine receptors. In mixed-population cultures of spinal cord neurons, most neurons were labeled on the cell surface. Label was found on both cell bodies and neurites. Much of the labeling was patchy, indicating that many or most glycine receptors were collected in aggregates. Whether these aggregates were sites of synaptic contacts from other neurons is currently being determined. Supported by NSF (BNS-8808506) and the ADCRC (82-9311).

EXPRESSION OF PRESYNAPTIC AND CYTOSKELETAL PROTEINS

FOLLOWING EARLY TARGET REMOVAL IN THE CHICK EMBRYO.

O. Braissant*, M.C. Wilson#, W. Wahli* and S. Catsicas. Institut de
Biologie animale, University of Lausanne, Switzerland and
#Research Institute of Scripps Clinic , La Jolla (CA) USA.

Our aim is to determine whether during neuronal development the expression of specific presynaptic proteins follows an endogenous program of differentiation or is the result of cell-cell interactions. here we have used antibodies directed against the presynaptic proteins synaptosomal associated protein-25 (SNAP-25), synaptophysin and synapsin I to define the onset and patterns of expression of these proteins in the developing neural tube and retina. We have then determined the effect of early target removal on presynaptic proteins expression by spinal motor and sensory ganglia neurons. As a control, we have used a monoclonal antibody against

neurofilament proteins (NF).

SNAP-25 was found to be expressed relatively late during development, at the time of synaptogenesis, whereas synaptophysin and synapsin I seemed already present during initial axonal elongation, well before contact with the target cells occurred. Moreover, preliminary evidence indicate that early limb bud removal does not affect the normal patterns of expression of these proteins, until the target deprived neurons start to degenerate. These results suggest that the expression of presynaptic proteins is independent of neuron/target interactions.

NF proteins were found in subsets of stem cells and most growing axons, but seemed not to be affected by the removal of the target region.

NEURAL PLASTICITY IN ADULT ANIMALS I

25.1

HOUSING ADULT RATS IN ENRICHED CONDITIONS DOES NOT ALTER NEUROGENESIS IN THE OLFACTORY BULB. A.D. York, S.M. Breedlove, M.C. Diamond, and E.R. Greer*. University of California, Berkeley, CA 94720.

Housing adult male rats in enriched conditions increases the

Housing adult male rats in enriched conditions increases the normally low rate of neurogenesis in the hippocampal dentate gyrus (York et al, SN Abstr 15: 962). Neurogenesis also continues in adult rats in the main and accessory olfactory bulbs; the effects of enriched housing on the olfactory bulbs have not been previously investigated. The present study looked for changes in adult neurogenesis in the olfactory bulb due to different housing conditions. Nine 60-day-old male Long-Evans rats were housed 30 days in enriched conditions (common large cage with novel objects, changed daily). Eight controls were housed in standard conditions (3 rats per small cage with no objects). All rats were given 'H-thymidine in 5 semi-weekly i.p. injections starting day 1 of differential housing. After autoradiography, all six layers of the main olfactory bulb and the granule cell layer of the accessory bulb were examined for labeled cells. Labeled neurons were seen in the internal granular and glomerular layers of the main bulb and the granule cell layer of the accessory bulb. No differences were seen between the experimental groups on any measure. When compared to the increased neurogenesis found in the dentate gyrus, this finding suggests that enriched condition housing affects the this finding suggests that enriched condition housing affects the structure of specific cell populations.

WEANLING AGE AND ADULT RATS EXPOSED TO COMPLEX. SOCIAL AND INDIVIDUAL ENVIRONMENTS SHOW SIMILAR NEURONAL DENSITY AND SIZE PLASTICITY. U.S. Hess, A. M. Sirevaag, C. S. Wallace and W. T. Greenough. Dept. Psychobiol., Univ. Calif. Irvine, Irvine, CA 92717. Depts., Psych. & Cell & Struct. Biol., & Neuroscience Prog., Univ. IL, Champaign, IL 61820.

Young rats exposed to complex environments (EC) for 30 days have been reported to have 30% larger neuronal nuclei and an 18% lower neuronal density (Nv) than rats reared in individual cages (IC) (Turner & Greenough, Brain Research, 329, 195-203, 1985). We now report that adult EC rats (60 days old) exposed to their environment for 30 days exhibit similar neuronal plasticity. Adults exposed to their environments for 10 days did not exhibit nuclear size or density differences. Stereological estimates of neuronal size nuclear size or density differences. Stereological estimates of neuronal size and density were made using the nucleator (Gundersen, H.J.G. J. Microscopy, 150, 1988). EC rats had 20% larger neuronal nuclei and a 20% lower Nv than IC rats. This contrasts with an earlier report based on preliminary data (Hwang and Greenough, Soc. Neurosci. Abstr. 12, 1284, 1986). Supported by MH 35321 and HD 07333.

30 Day Exposure Adult Rats

	Nv Neurons	Vv Nuclei	Mean Vol. Nucl

EFFECTS OF FRONTAL LESIONS AND ENVIRONMENTAL ENRICHMENT ON BEHAVIOR AND CORTICAL DENDRITIC ARBOR. B. Kolb and R.

Gibb*. Dept. of Psychology, Univ. of Lethbridge,
Lethbridge, AB, Canada, TIK 3M4.

Adult male rats were given lesions of the frontal cortex, and, along with normal control animals, were housed for 60 days in either enriched environments or standard for 60 days in either enriched environments or standard cages. The rats were then studied on a battery of behavioral tests before Golgi-Cox staining. The lesions impaired performance on tests of spatial navigation, food hoarding, forepaw use, and tongue extension as well as reducing chronic body weight. Enrichment (ENR) produced only a small reduction of the behavioral deficits although it increased brain weight in both control and lesion groups. Layer II/III pyramidal cells were analyzed in Par 1 (about 1 mm from the lesion site) and in Ocl. These groups. Layer II/III pyramidal cells were analyzed in Par 1 (about 1 mm from the lesion site) and in Ocl. These data showed that: (1) frontal lesions increased dendritic arbor relative to controls in Par 1 but not in Ocl; (2) ENR increased arbor in Oc1 but not in Par 1 of frontal rats and in both regions of control animals. These data suggest that the cortex may only show plasticity once (either after the lesion or ENR), which may be significant for understanding the effect of therapy in recovery from brain injury.

25.4

OPTICAL IMAGING OF FUNCTIONAL CHANGES IN THE VISUAL SYSTEM OF ANESTHETIZED ADULT MACAQUES AFTER BRIEF MONOCULAR OCCLUSION. R.D. Frostig. Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

The present study was designed to investigated whether functional changes can be detected in the visual system of adult anesthetized and paralyzed monkeys after short term monocular occlusion. Using optical recording of intrinsic signals with a high resolution CCD camera, images of the ocular dominance columns were first obtained from the visual cortex (area 17) under normal conditions. Next, one eye was occluded for a brief period (10-17 h) with non-transparent material. After the occlusion was removed, images of ocular dominance columns were taken and compared to images taken before the occlusion. In 2 of 3 monkeys the difference amplitude of the ocular dominance stripes were greater after the removal of the occlusion, compared to the pre-occlusion amplitude. In 1 monkey the amplitude did not change. This change in amplitude was due to weakening of the deprived eye and possibly in addition strengthening of the non-occluded eye.

In one monkey imaging of the ocular dominance columns continued for 8 h after the occlusion removal. The difference amplitude between columns gradually returned to the pre-occluded magnitude within 5-6 h, suggesting that such changes are reversible.

These preliminary results indicate that although no major changes were observed in the ocular dominance columns' width, differential activation of one set of inputs seems capable of eliciting short term functional changes in the system's response to a given stimulus.

PLASTICITY IN BINAURAL TUNING OF TECTAL NEURONS IN

THE ADULT BARN OWL. J. F. Olsen and E. I. Knudsen. Dept. Neurobiol., Stanford Univ., Stanford, CA 94305.

The tuning of units in the optic tectum to interaural differences in time (ITD) and intensity (IID) changes adaptively when barn owls are raised with altered external ears (Olsen and Knudsen, Abstr. Soc. Neurosci. 15: 200, 1989). Here we report that a circulture are alteration in a fully ground. 290, 1989). Here we report that a similar ear alteration in a fully grown owl led to similar changes ITD tuning, but did not affect IID tuning. The In ruff-cut owls, ITD varies linearly with the azimuth of a sound source (as in normal owls), but at a rate slightly faster than normal, whereas the pattern of IIDs is radically altered such that IIDs vary with source azimuth rather than with source elevation. The tuning of tectal units for ITD and IID was measured dichotically one month before and three months after ear alteration. To compare tuning before and after ruff-cutting, units were selected from matched tectal sites, based on the locations of visual receptive fields. Before ruff-cutting, the patterns of best ITD and best IID representation were normal (Olsen et al., <u>J. Neurosci.</u> 9:2591 1989). After ruff-cutting, the rate at which best ITD varied with best visual azimuth had increased from 2.4 μ (sec/deg (r = .99; p < .001), the normal rate, to 3.2 μ (sec/deg (r = .96; p < .001), a rate outside the normal range and similar to that seen in owls raised from birth without a facial ruff. The pattern of best IIDs was essentially normal and unchanged. The lack of effect of ruff-cutting on IID tuning in the adult contrasts with the large change in IID tuning seen in baby owls subjected to the same manipulation. The results suggest that, although large adaptive changes in binaural tuning require experience early in life, an appreciable degree of plasticity persists into adulthood. Supported by NIH grant RO1 DC00155-11.

SOMATOSENSORY CORTICAL MAP PLASTICITY: A MODEL AND SIMULATIONS. <u>E. Sklar and M. F. Bear</u>. Program in Cognitive Science and Center for Neural Science, Brown University, Providence, RI 02912.

Plasticity of the cortical somatotopic map in the adult monkey has been described by Merzenich et al. (Neurosci., 8:33, 1983) and others. A number of effects have been noted, including map reorganization following the amputation of digits, map regeneration in re-versible deafferention, artificial syndactyly effects, and use-dependent map reorganization.

We present a model based on the theory of Bienestock et al. (J. Neurosci., 2:32, 1982) which addresses plasticity in the visual cortex of kittens. The model incorporates a Hebb-type process which compares weighted input activity to a 'sliding modification threshold' reflecting time-averaged output activity. Synaptic weights increase or decrease as a product of input activity and output activity relative to this critical value.

Simulation results suggest that the model successfully captures the features of somatosensory cortical map plasticity, e.g. the simulated amputation of a digit produces first an unresponsive map region, followed by the expansion of regions representing adjacent digits. The results also predict several experimental outcomes, e.g. that the results for surgical versus temporal fusion of digits should converge.

In addition, the current model is compatible with proposed

mechanisms of synaptic modification involving the activity of the NMDA receptor complex (Bear et al., Science, 237:42, 1987). This suggests a link between the two types of cortical plasticity at the level of synaptic mechanisms.

ACETYLCHOLINE RELEASE IN THE HINDLIMB SOMATOSENSORY CORTEX OF RATS FOLLOWING SCIATIC NERVE TRANSECTION. N. Kabani', R.W. Dykes', K.M. Brown*2. Dept. Surgery, McGill Univ.; Dept. Physiol., Univ. Montreal, Montreal, PQ, H3C 3J7.

somatosensory cortex contains an organized somatotopic map which may reorganize following deafferentation. Acetylcholine and norepinephrine have been hypothesized to play a role in cortical reorganization. If this is so, the release levels of acetylcholine may be predicted to change during reorganization.

In our study, release levels of acetylcholine were measured following sciatic nerve transection in adult rats using intracerebral microdialysis in combination with high performance liquid chromatography. Preliminary studies show that the acetylcholine release is significantly high (p<0.01), 24 hrs after nerve transection (9.56nM/20min) as compared to the sham operated group (5.48nM/20min). Whereas at day 7, the release rate in transected group (3.78nM/20min) return to levels similar (p<0.05) to those measured in control animals (4.95nM/20min).

We suggest that cortical reorganization begins shortly after injury and is probably, partially complete within 7 days and that acetylcholine plays an important role in this phenomenon. (Supported by the Medical Research Council of Canada).

ADULT RAT NEOCORTEX CONTAINS A LAMINAR-SPECIFIC DISTRIBUTION OF BOTH CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II (CKII) AND GAP-43 mRNA. K.M. Jacobs. R.L. Neve and J.P. Donoghue Center for Neural Science, Brown University, Providence, RI 02912

CKII and GAP-43 have been implicated in mechanisms underlying synaptic plasticity in the adult nervous system. As part of ongoing studies on experience-dependent reorganization in motor cortex, we examined the distribution of the mRNA for CKII and GAP-43 in normal adult rat cerebral cortex using in situ hybridization for CKII and GAP-43 in normal adult rat cerebral cortex using *in situ* hybridization techniques. CKII may play a role in controlling synaptic structure and generating LTP through action on substrates such as synapsin I, tubulin and MAP2. We identified CKII mRNA using a cDNA clone for the alpha subunit of rat CKII. Labeling was heaviest in the hippocampus and neocortex, especially cingulate and prelimbic cortex, and lowest in the brainstem. Throughout neocortex, neurons in the superficial layers expressed the highest levels of mRNA, while neurons in deeper layers expressed only moderate levels of mRNA. There was also substantial neuropil labeling in the

moderate levels of mRNA. There was also substantial neuropil labeling in the superficial layers, suggesting that neuronal processes from deep or superficial layers may produce CKII independently of the soma.

GAP-43 has been shown to be a marker for neurite extension and axonal growth during development and in response to injury. We examined the distribution of GAP-43 mRNA within sections adjacent to those used for CKII hybridization, using a cDNA clone for human GAP-43 which also hybridizes to rat GAP-43. Levels of GAP-43 mRNA were low throughout the brain of normal animals. The most heavily labeled neurons were found in the stratum pyramidale of the hippocampus and in olfactory cortex. Some large cells within the striatum and many cells within thalamus were also labeled. Within the neocortex, the strongest and most consistent labeling was within large pyramidal cells in layer V. Small cells in the deepest part of layer VI were well labeled, while superficial layers contained only a few labeled cells which had moderate levels of GAP-43 mRNA. These results suggest that layer V neurons may retain a potential for axonal growth, while neurons in superficial layers may contain mechanisms necessary for more rapid adjustments of synaptic strength. Supported by mechanisms necessary for more rapid adjustments of synaptic strength. Supported by NIII NS 22517 and March of Dimes 1-1169.

EFFECIS OF AMPHETAMINE ON BIOGENIC AMINE LEVEIS FOLLOWING RIGHT SENSORIMOTOR CORTEX ABLATION IN RAT. K.A. Krobert and D.M. Feeney. Depts. of Psych. and Physiol., Univ. of New Mexico. Albud. NM 8713.

A transient bilateral reduction of norepinephrine (NE) and dopamine (DA) levels has been reported following ablation of the right sensoriancor cortex (RSMCX) in rat (Brain Res. 215:233, 1981). Amphetamine (AMPH) administered 24 hours post-injury produces an enduring facilitation of locomotor recovery assessed on a beam-walk task, considered a result of AMPH increasing NE transmission (CRC Critical Reviews in Neurobiol. 3(2):135, 1987). Using HPLC, this study compared the effect of AMPH or saline upon levels of NE, DA, their major metabolites (3-methoxy-4-hydroxy phenylglycol (MHPG), 3,4-dihydroxyphenylacetic acid (DPAC)) and the serotonin metabolite 5-hydroxyindole acetic acid (5-HIAA) 2 days after RSMCX aspiration. Compared to sham operates, RSMCX lesion resulted in bilateral depression of NE levels in the frontal pole and posterior SMCX, and DA and DOPAC in the caudate/putamen. Interestingly, a marked increase in 5-HIAA was measured in the frontal pole, posterior SMCX, and caudate/putamen ipsilateral but not contralateral to the injury. Administration of AMPH (2 mg/kg i.p.) 24 hrs after injury reversed the depression of DA, NE, and DOPAC levels, whereas 5-HIAA levels remained unchanged. The NE MHPG ratio was significantly decreased in the lett but not the right carbon to the payonate of reduced catecholamine levels in injured rat brain and suggest that AMPH relevance of these consequences of brain injury. Further study of monoamine metabolism in specific brain loci and recovery of locomotion are in progress. Supported by DHHS Grant ROINS20220-03, and funds from the Univ. of New Mexico.

THE BEHAVIOURL SIGNIFICANCE OF A RAT VIBRISSA IN EXPLORATORY BEHAVIOR. J.G.Johannsen*, K.G.Gallo, R.L. Craik, W.J. Carr* & P.J. Hand. Beaver Coll. Glenside, PA 19038 & U. of Penn, Phila, PA 19104. Previous research indicates that rats with sub total vibrissae deafferentation sparing one vibrissa (#3 Row C, $\underline{SC3}$) have a preferred travel direction in a walled, elevated cylindrical maze. The present study examined whether SC3 or control $C3(\underline{CC3})$ was used in exploration. Prior to post natal day 2(PND2), 10 rats underwent unilateral follicle removal sparing SC3 vibrissa. On PND 60, contralateral vibrissae except CC3 were clipped. Animals underwent 4 min trials for 5 days in an elevated circular maze without walls. 8 of 10 experimental animals traveled with SC3 over either inner or outer edges rather than in the center. Animals with R SC3 traveled clockwise(CW) along the inner edge or CCW along the outer edge. The converse occurred for L SC3. No preference was converse occurred for L SC3. No preference was demonstrated by 10 controls with bilateral clipping sparing CC3. 2DG metabolic analysis of SI reveals a 2.2 fold increase (P <.05) in SC3. An enlarged SC3 barrel accounts for 30% of the 2DG activity. CNS reorganization which accompunies subtotal deafferentation appears to result in a preferred vibrissa for exploratory behavior.

UNILATERAL LESIONS TO THE SENSORIMOTOR CORTEX: BEHAVIORALLY-LINKED DENDRITIC CHANGES IN THE CONTRALATERAL CORTEX. T.A. Jones and T. Schallert. Neurosci. Inst. and Psychology Dept, Univ. Texas, Austin, TX 78712. In recent research, we have reported time dependent anatomical changes in the forelimb representation area (FL) of the sensorimotor corte feel leaving unificial visions in the foreign of the contraction of the proposition of the contraction.

cortex following unilateral lesions to the contralateral homotopic area in adult rats (Jones & Schallert, 1989). These changes include an increase in the thickness of the contralateral cortex, an elaboration of astrocytic processes in the vicinity of layer V pyramidal neurons, as well as a behavioral and anatomical vulnerability to damage in this area. These changes were transient, were maximum at 7 days after the lesion, and were specific to the FL area of the cortex. In the present experiment, we examined the possibility that these anatomical events precede changes in neuronal morphology within the FL contralateral to the lesion. At various times following unilateral FL lesions, dendritic arbors of pyramidal neurons were measured in the contralateral cortex. A dramatic increase in the dendritic arborization of layer V pyramidal neurons was found within the FL at 2 to 3 weeks after the lesion, in comparison to sham-operated controls. Between 2 to 4 months, there was a partial reduction in the number of dendritic branches without a complete return to control levels. Furthermore, these anatomical events corresponded to time dependent behavioral asymmetries in the use of the forelimbs for postural support and motor coordination. These findings may be indicative of the initiation and stabilization of a post-injury sequence of behaviorally relevant structural changes evident within the contralateral homotopic cortex of adult rats Supported by grants MH 18837 and NS 23964.

MK-801 REINSTATES FORELIMB PLACING DEFICITS WHEN ADMINISTERED AFTER RECOVERY FROM UNILATERAL CORTICAL LESIONS IN THE RAT T. M. Barth. Lab. Neurophysiol., NIMH, Poolesville, MD 20837.

There is evidence to suggest that drugs acting as noncompetitive antagonists at the N-methyl-D-aspartate (NMDA) receptor might have both beneficial and detrimental effects on recovery of function following brain damage. beneficial and definitional effects on recovery of function following train damages. For example, MK-801 and PCP are neuroprotective when administered shortly before or after ischemia in rodents. In contrast, these agents induce acute histopathological changes in cortical neurons in intact rats, disrupt developmental plasticity and impair learning in adult animals. A previous experiment has shown that when MK-801 was administered 12-16 hrs after unitateral tesions in the somatic that when MK-801 was administered 12-16 hrs after unitateral lesions in the somatic sensorimotor cortex (SMC), there was a slight facilitatory effect on recovery from somatosensory asymmetry (as measured by bilateral-tactile stimulation tests), but there was no effect on the recovery of forelimb placing. The present experiment was designed to investigate the effects of MK-801 administered 14 - 60 days after the lesion when behavioral recovery appears to be complete.

Rats received unitateral lesions of the SMC, were allowed to recover from

somatosensory asymmetry and forelimb placing deficits, and then treated with either a single injection of MK-801 (1 mg/kg) or saline. Forty-eight hours after the MK-801 injection, the rats showed a reinstatement of the contralateral forelimb placing deficit. The impairment endured for at least 6 days following the injection, which is deficit. The impairment endured for at least o taxys following the Injection, which is similar to the duration of the effects following the lesion. Moreover, there was no impairment in placing the forelimb ipsilateral to the damage, nor did MK-801 affect placing reactions in sham operated control rats. Finally, MK-801 did not reinstate the somatosensory asymmetry as measured by bilateral tactile-stimulation tests. These data support the idea that MK-801 may have detrimental effects when administered after recovery and suggest that different mechanisms may be mediating the recovery from somatosensory asymmetry and forelimb placing deficits.

NEW SOMATOSENSORY EPSPS IN REORGANIZED RACCOON CORTEX WITHOUT CHANGE IN THE INCIDENCE OF CORTICOCORTICAL EPSPS. S. Witter E. Smits*, P. Zarzecki and D.D. Rasmusson, Dept of Physiol., Queen's Univ., Kingston, Ontario and Dept. of Physiol. & Biophys., Dalhousie Univ., Halifax, Nova Scotia,

Stimulation of previously ineffective digits evokes epsps when the representation of the paw in somatosensory cortex is reorganized by altering its sensory inputs. Could newly formed corticocortical connections transfer these new inputs? Intracellular recordings were made in the cortical representation of digit four (D4 cortex). Sensory input to the cortex was altered by amputation of D4 or by joining D3 and D4 to form a syndactyly.

In D4 cortex of normal raccoons, stimulation of D3 or D5 evoked epsps in only 25% of neurons, even though about half of the neurons had monosynaptic corticocortical inputs from the "heterogeneous zone", where multidigit inputs are common. Six to ten months after surgical alterations of the paws, most neurons (70% & 76% in the two groups) had epsps evoked by electrical stimulation of D3, D5 or both. In spite of the dramatic increase in inputs from multiple digits, monosynaptic corticocortical epsps were still found in about half of the neurons in each group. Thus, cortical reorganizations induced by altered sensory inputs do not seem to require the formation of new corticocortical connections, but could instead result from an increased effectiveness of existing pathways. SHORT-TERM VIBRISSECTOMY (VBX) AND NOREPINE-PHRINE (NE) DEPLETION EFFECTS ON BARREL CORTEX METABOLISM IN ADULT RAT. A. <u>Dunn-Meynell and</u>
B.E. <u>Levin</u>. Neurology Svc., VA Med. Ctr., E.
Orange, NJ 07019, Dept. Neurosciences, NJ Med.
Sch., Newark, NJ 07103.

Sch., Newark, NJ 07103.

Vibrissal stimulation increases local cerebral glucose utilization (LCGU) in the corresponding "barrel" of the contralateral SmI cortex. The metabolic size of a stimulated C3 barrel increases by 30-40% at 2mo after complete VBX with sparing of C3 (VBX/SC3; Levin et al., 1988). To see if this enlargement was due to a delayed sprouting effect versus an immediate removal of inhibitory inputs, LCGU was measured in the stimulated C3 barrels of adult SD rats 24h after unilateral VBX/SC3 using [14C] 2-deoxyglucose (Sokoloff et al., 1977). Neither absolute LCGU nor areal size of SC3 barrels differed from intact C3 barrels at 24h post-VBX suggesting that enlargement seen at 2mo post-VBX arrered from intact C3 barrels at 24h post-VBX suggesting that enlargement seen at 2mo post-VBX was due to delayed sprouting. When bilateral, 24h VBX/SC3 was preceded by a unilateral locus coeruleus lesion, the SC3 barrel was 28% smaller on the NE depleted side (P<0.01). Thus, removal of NE's inhibitory input to the "inhibitory surround" of the C3 barrel may reduce the spread of neuronal activity in a VBX/SC3 barrel.

EFFECTS OF A GINKGO BILOBA EXTRACT ON FUNCTIONAL RECOVERY AFTER CORTICAL HEMIPLEGIA IN THE RAT. S. Brailowsky,
T. Montiel*, E. Hernández*, J. Flores-Hernández*, S. Alvarez* and R.H. Pineda*. Instituto de Fisiología Celular,
U.N.A.M., México 04510 D.F., MEXICO.
Interested in the pharmacological treatment of subjects

with brain lesions, we studied the effects of chronic trea tments with a Ginkgo biloba extract (EGb761-IPSEN) in two animal models of cortical hemiplegia: one induced by motor cortex aspiration and another using a reversible inactivation of the motor cortex through chronic, localized infusion of GABA, via osmotic minipumps.

The elevated beam test was used in water-deprived rats trained to drink saccharin-sweetened solutions (with or without EGb761) and to perform to criteria before the surgical procedures. From the day after the surgery, the rats were daily administered 100 mg/Kg of EGb761 or its vehicle for 7 or 30 days.

In all groups in which EGb761 was administered, a faster and more complete recovery from the motor deficits was observed, which was significantly different from that of rats in which only saccharin was given.

These results suggest a potential use of EGb761 in patients with brain lesions as this product shows little toxicity in man after chronic administration. The active principle(s) and the mechanism(s) for this beneficial effect remain to be elucidated.

SYNAPTOLOGY OF MONKEY VPL AFTER LESIONS OF THE DORSAL COLUMN NUCLEI. J. Wells, D. D. Ralston and H. J. Ralston, III. Dept. of Anatomy and Neurobiology, University of Vermont and Dept. of Anatomy, U. C. San Francisco.

The synaptology of VPLc was analyzed using EM in 4 control monkeys and 6 lesioned monkeys. Two groups of postlesion survival times were used: 2 - 5 days (n=5) and 5 months (n=1). In the controls, the population density of all synapse types was 14.5 synapses/ $100 um^2$ - half the value found in the VPL of rats. Both the lemniscal terminals (LR) and the terminals of the interneuronal dendrites (P) were significantly decreased after the lesion. The terminals from the thalamic reticular axons (F), the cortical axons (SR) and the total number of terminals/100 um² remained relatively unchanged 2-5 days after the Five months after the lesion the LR and P terminals showed few signs of recovery. The values for the LR and P terminals were within the range of the 2 -5 day group and well below the control group. It appears that there was no reactive synaptogenesis of the principal afferent terminals in the VPL of these monkeys. One suprising finding was that there was little, if any, gliosis at any survival time after the DCN lesion. Supported by NS23347.

25.19

LONG-TERM LOSS OF GABAergic INHIBITION LEADS TO PLASTICITY IN THE RAT THALAMIC VPM NUCLEUS. S.M. Lee. M.H. Friedberg and F.F. Ebner. Center for Neural Science, Brown University, Providence, RI In rats, the major source of GABAergic inhibition in the thalamic ventro-posteromedial (VPM) nucleus arises almost exclusively from the thalamic reticular nucleus (TRN). The role of this inhibition in shaping the responses of VPM neurons was assessed by mapping the receptive field (RF) following acute iontophoretic application of bicuculline, a GABAergic antagonist, or after chronic excitotoxic lesion of the TRN. Standard recording and iontophoretic methods were used while the animals were maintained under urethane anesthesia. The lesion of the TRN was made with 0.1 μl injections of KA (0.3 μg/μl) at 3 different sites (D 5.5 mm, ML 4.1 mm and AP -2.1, -2.7, -3.5) and confirmed histologically. In 4 animals, 14 VPM units were "held" for sufficient length of time to compare the RF and response properties to transient deflections of the mystacial vibrissa before and after iontophoretic application of bicuculline-induced dishribition in VPM was to alter phasically responding units to ones that responded tonically (28.6% of normal VPM neurons responded tonically vs. 75% in the presence of bicuculline). For all units tested, no statistically significant differences in the size of the RF were seen following the application of bicuculline (2.33 ± 0.31 vs. 2.75 ± 0.53).

To assess the long-term effect of disinhibition, 31 VPM neurons (n = 6) were evaluated 5 days following lesion of the TRN. 76% of the neurons tested had an enlarged RF which ranged from 2 to 17 vibrissa (mean 6.08 ± 0.76), and 72% responded tonically for the duration of the stimulus. We conclude from these results that inhibition from the TRN serves a major role in determining the temporal response characteristics of VPM neurons. In addition, the long-term effects of disinhibition suggest that the TRN has the capacity to modulate the size of the peripheral RF unde

LESION OF THE SUPRAGRANULAR LAYERS OF BARREL FIELD CORTEX IMPAIRS THE ACQUISITION BUT NOT THE PERFORMANCE OF A CORTICALLY DEPENDENT BEHAVIORAL TASK. M.H. Friedberg, S.M. Lee, L.R. Hochberg*, and F.F. Ebner.
Center for Neural Science, Brown University, Providence, R.I. 02912.
We investigated the function of the supragranular (SG) layers of barrel

We investigated the function of the supragranular (SG) layers of barrel field cortex (BF) in adult rats by determining their ability to perform the "gap-cross task" of Hutson and Masterton before and/or after cortical lesions. The high density of NMDA receptors in the SG layers enabled us to destroy consistently the SG layers of BF cortex with a 15 minute epidural application of 150 mM NMDA in dH2O. Nissl and cytochrome oxidase staining indicated that the neurons in layers II, III and the superficial part of IV were destroyed. Multiunit recordings of neuronal responses and spontaneous activity demonstrated that evoked and spontaneous activity were present only in layers IV-VI. The gap-cross task, shown to be dependent upon an intact vibrissae-to-BF pathway, was used to compare vibrissae-dependent performance of animals trained before and after the SG lesion.

The performance of the task was unaffected by SG lesions made after training. In contrast, animals were unable to use their vibrissae to perform the task during the first 30 days of training if the lesions were made prior to training (vs. 3 days for controls). These animals, when retested 60 days later, immediately were able to use their vibrissae to perform the

task, indicating that the functional impairment was not pernoament.

These results suggest that the SG layers of BF cortex are not required for the performance of a pre-learned task, but are important in the performance of a novel cortically-dependent behavior. We are investigating the mechanisms responsible for the recovery of vibrissae-dependent function seen at 90 days. (Grants NS13031 and the Whitehall Foundation)

CHLORIDE EFFLUX FROM THE CHOROID PLEXUS OF INFANT AND ADULT RATS. J. E. Preston* C. E. Johanson and J. T. Parmelee. Program in Neurosurgery, Dept. Clinical Neurosciences, Brown University/Rhode Island Hospital, Providence, RI 02903

The rate of cerebrospinal fluid (CSF) secretion in immature mammals is less than adults on the basis of choroid plexus (CP) weight. Chloride (CI) and sodium transport across the choroid plexus is a major part of CSF secretion. To study this process, the CP from various ages of rats was isolated in artificial CSF and the efflux of 36Cl from the epithelial cells measured. In young animals, 1-2 weeks of age, the half time $(t_{1/2})$ for 36 Cl efflux was 22.9±0.3s (n=15) and was not affected by the transport inhibitors bumetanide, acetazolamide or disulfonic stilbenes (10 $^{-4}$ M; all values \pm bumetanide, SE). Choroidal tissues from young adult 6-8 week rats, showed a significantly faster efflux, with $t_{1/2}=15.9\pm1.2$ (n=12; p<0.01) which could be inhibited by the above drugs 30 to 40%. In contrast the CI channel blocker diphenyl carboxylate (DPC) had a significant effect on 36Cl efflux at all ages, with $t_{1/2} = 30.3\pm5.1s$ (n = 4) at 1 week, and $t_{1/2} = 27.9\pm4s$ (n = 4) at 6-8 weeks. These pharmacological results indicate that the transporters responsible for CI efflux in adult rats are not active prior to 2 weeks of age, the major route for CI movement being via channels. This may explain in part the lower rate of CSF secretion in young rats. (supported by NIH grant NS 27601)

26.2

EFFECTS OF VASOPRESSIN AND ATRIOPEPTIN ON CHLORIDE TRANSPORT IN CHOROID PLEXUS. C. E. Johanson, J. R. B. Nashold. J. E. Preston. M. Dyas. N. Knuckey. Program in Neurosurgery, Dept. of Clinical Neurosciences, Brown University/Rhode Island Hospital, Providence, RI 02903
The rate of cerebrospinal fluid (CSF) secretion by adult rat choroid plexus (CP) is affected by neuropeptides such as arginine vasopressin (AVP) and atriopeptin III (AP III). These pentides may alter secretion by modulating choroidal blood

peptides may alter secretion by modulating choroidal flow and/or by changing the transport of chloride and sodium across the CP epithelium. In this study, the CP of adult rats was isolated in artificial CSF and the ³⁶Cl efflux measured. In adult rats, 6-8 weeks of age, the ³⁶Cl efflux rate constant (ERC) significantly decreased by 32% after one hour incubation with AVP, from 0.039±0.006s⁻¹ to 0.026±0.002s⁻¹ (n = 4; values ±SE). AVP in the presence of a V1 receptor antagonist, however, did not change the ERC. AP III (10⁻⁹M) did not alter the ERC, however, 10⁻⁷ M AP III increased ERC by 13% (pc0.05; n = 5). These results indicate that CI efflux systems are inhibited by AVP and that this inhibition is blocked by the addition of a V1 receptor antagonist. In contrast, AP III may stimulate CI efflux. Our electron micrographs of CPs incubated in AVP show increased basal spaces and epithelial fluid retention. This reinforces the concept that AVP has an inhibitory effect on ion transport and CSF formation. (Supported by NIH grant NS 27601)

CONTROL OF INTRACELLULAR pH (pH₁) IN RABBIT CHOROID PLEXUS EPITHELIUM. <u>S.E. Mayer</u> and <u>E. Sanders-Bush</u>. Dept Pharmacology, Vanderbilt Univ., Nashville, TN 37232.

The amiloride-sensitive and HCO3 -dependent mechanisms that control pHi were studied in primary cultures of choroid plexus epithelium (CPE) prepared from rabbit brain. pH, was estimated from the uptake of ¹⁴C-benzoic acid. Control pH, (7.38 ± 0.03) fell to 6.4 with 20 mM NH₄Cl. Recovery was complete within 15 min after re-exposure to either Hepes (KRH) or HCO₃ -buffered (KRB) Krebs-Ringer solution. Recovery was dependent on [Na⁺]_o. In KRH, EC₅₀ for [Na⁺]=3 mM. Hexamethyleneamiloride (HxMA) maximally inhibited recovery in 5 mM [Na⁺] by 85% (IC₅₀ = 180 nM); in 135 mM [Na⁺], maximal inhibition was 20-30%. In contrast, in rat CPE HxMA completely inhibited recovery in 135 mM [Na $^+$] with an IC $_{50}$ of 30 nM. In KRB buffer, the EC₅₀ for [Na⁺] in rabbit CPE was 18 mM; HxMA maximally inhibited 50% with no inhibition at 135 mM [Na⁺]. DIDS (diisothiocyanatostilbene disulfonic acid), 10 to 100 µM, caused a small reduction in pH, from 7.4 to 7.2 regardless of whether or not the cells had previously been acidified. These results indicate the importance of high affinity [Na+]-dependent, but DIDS-insensitive mechanisms for recovery from acidification by rabbit CPE. In Hepes buffer the main component is a Na⁺/H¹ antiport, but in HCO3 buffer additional mechanisms must come into play, since recovery is incompletely blocked by HxMA. (Supported by USPHS grant MH 34007).

CHARACTERIZATION OF PROTEIN KINASE C IN ENDOTHERIAL CELLS OF BRAIN AND PERIPHERAL VESSELS. H.Kobayashi*, T.Mizuki*, Y.Koda*, M.Okazaki*, N.Yanagihara, A.Wada and F.Izumi. Department of Pharmacology, University of Occupational and Environmental Health, School of Medicine. Kitakuushu 807. Japan.

Department of Pharmacology, University of Occupational and Environmental Health, School of Medicine, Kitakyushu 807, Japan,
Protein kinase C is a Ca²+/phospholipid-dependent enzyme which is composed of several isoenzymes. The fact that the expression of protein kinase C subtypes varies from tissue to tissue suggests that each subtype has its own distinct functional role. To study characteristics of protein kinase C of the endothelial cells of the brain and peripheral tissues, subtypes of the enzyme were analyzed. By hydroxyapatite column chromatography, protein kinase C in the rat cerebral microvessels was resolved into two major peaks corresponding to type II and III enzymes with population of 57% and 38 %, respectively. In the endothelial cells of the bovine aorta and adrenal cortex, the protein kinase C was only type III. Thus, the high proportion of type II enzyme in the cerebral microvessels suggests that this type may be involved in specific functions of the cerebral microvessels.

PURIFICATION AND CLONING OF A NOVEL IMMUNOGLOBULIN-LIKE BLOOD-BRAIN BARRIER-SPECIFIC MEMBRANE GLYCOPROTEIN. H. Seulberger*, F. Lottspeich*, U. Albrecht*, R. Jahn, H. Schwarz* and W. Risau*. Max-Planck-Institut für Psychiatrie und Genzentrum, 8033 Martinsried, FRG:

und Genzentrum, 8033 Martinsried, FRG;

The unique properties of endothelial cells forming the blood-brain barrier (BBB) are reflected by the expression of specific cell surface molecules. We have characterized the monoclonal antibody HT7 raised against an antigen of chick BBB endothelium. The HT7 antigen is first expressed on the surface of endothelial cells at arround the same time as the BBB forms in the chick embryo (day 11). The antigen is absent in blood vessels of the circumventricular organs which do not possess a BBB. This indicates that it is a specific molecule of the BBB. Furthermore it is found on epithelial cells of the choroid plexus where the blood-cerebrospinal fluid barrier is localized. We have purified this antigen from the plasma membranes of brains using an immunoaffinity column and reversed phase HPLC. The purified antigen is a highly glycosylated integral membrane protein with a molecular weight of about 45-52 kDa. By using degenerated oligonucleotides and the polymerase chain reaction we have cloned the cDNA encoding the protein. The sequence revealed that it is a new member of the immunoglobulin superfamily. Based on the expression of the HT7 protein on the luminal surface of BBB endothelium, together with the fact that many cell adhesion proteins and receptors belong to this protein superfamily, we suppose that it might be involved in transport or cell surface recognition at the BBB.

26 4

CALCIUM TRANSPORT INTO CSF WITH ACUTE PLASMA [Ca] CHANGES. Vincent Murphy, Quentin Smith, and Stanley Rapoport. Lab. of Neurosciences, NIA, NIH, Bethesda, MD 20892.

This study was undertaken to determine if CSF Ca transport is saturable with acute plasma [Ca] changes, as was found with chronic changes, and to better analyze kinetic parameters of the transport system, as plasma [Ca] can be varied over a wider range acutely. Unanesthetized adult Fischer-344 rats were infused with solutions of Na citrate to reduce and Ca chloride to elevate plasma [Ca] for 10 min. The infusion schedule was programed to yield constant plasma ionized [Ca]. Ca-45 and Na-22 were injected as an i.v. bolus 3 min before termination. Transfer coefficients for Ca-45 (KCa) and Na-22 (KNa) uptake into CSF were cpm/g CSF divided by the integral of ionized tracer in plasma. Plasma ionized [Ca]s of 0.2, 0.4, 0.7, 1.1, 1.4, 1.9, 2.5, 3.5, and 6.4 mmol/l were obtained. In rats with plasma [Ca] of 6.4 had a KCa of 105 while controls, plasma [Ca] of 1.4, had a KCa of 260. The KCa data was corrected for nonspecific changes in CSF flow and permeability using KNa then fit to Michaelis-Menton kinetics which yielded a Km of 0.02 mmol/l, Vmax of 315 pmol/g per s, and a nonsaturable component of 58 nl/g per s. These results demonstrate that saturable influx of Ca occurs during acute alterations in plasma [Ca] and provide an improved estimate of the kinetic parameters of CSF Ca transport.

26.0

STIMULATION BY IL-1 AND TUMOR NECROSIS FACTOR (TNF-0) OF VON-WILLEBRAND FACTOR (VWF) SECRETION BY RAT BRAIN MICROVASCULAR ENDOTHELIAL CELLS (RBMEC) PLATED ON MATRIGEL®, A SUBSTRATE WHICH PERMITS SUSTAINED EXPRESSION OF VWF. D.A. Doron. E. Heldman. D.M. Jacobowitz. G. Feuerstein. H.B. Pollard and J.M. Hallenbeck*. Dept. of Neurology, U.S.U.H.S., Bethesda, MD 20814 and Lab. Cell Biol. and Genetics, NIDDK, and Lab. of Clin. Science, NIMH, NIH, Bethesda, MD 20892.

VWF synthesis and secretion is characteristic of endothelial cells (EC), but maintenance of expression of this molecule in a long term culture of RBMEC's has proved difficult. These difficulties are in marked contrast with results for EC cultures from large vessels, where physiologic properties have been more easily studied. Recently we found that RBMEC when cultured on Matrigel®, develop characteristic morphology of EC's and express VWF. We have quantitated the levels of VWF in the culture media using a sensitive ELISA method. We found that when RBMEC plated on Matrigel® are compared to cells plated on uncoated dishes, only the cells plated on Matrigel® released detectable amounts of VWF into the culture media. Secreted VWF was detectable amounts of VWF into the culture media. Secreted VWF was detectable as soon as 5 min after introducing a fresh medium, reaching a maximum concentration after 6 hr. Stimulation of RBMEC with a mixture of IL-1 and TNF-α resulted in a significant increase in secreted VWF. By contrast stimulation of RBMEC with lipopolysaccharide (100 μg/ml) did not increase VWF levels in the culture media above the control. These data indicate that growth of RBMEC's on Matrigel® in vitro permits expression and secretion of VWF in a manner similar to the behavior of these cells in situ.

26.8

LECTIN BINDING PROPERTIES IN MICROVESSELS IN THE RAT SPINAL CORD. L.J. Noble and J.J. Hall*. Department of Neurosurgery, San Francisco General Hospital and the University of California, San Francisco, CA 94110.

In the central nervous system the role of the endothelial glycocalyx as a barrier to plasma proteins is not clearly understood. As a prelude to a study of structural/functional correlates of permeability to proteins, we have begun to characterize the composition of the endothelial glycocalyx of spinal cord blood vessels. Using lectins that have a high affinity for certain sugar residues, the distribution of manosyl/glucosyl, galactosyl, fucosyl, n-acteyl-galactosaminyl and n-acetyl-glucosaminyl/sialic acid residues was evaluated at both the light and ultrastructural levels.

In general, a homogeneous pattern of lectin staining was apparent in the dorsal horn as compared to the ventral horn and within different regions of white matter. In contrast, lectin staining was more intense in grey matter as compared to white matter. At the light microscopic level all lectins labelled blood vessels. This pattern of lectin binding throughout the microvasculature was confirmed at the ultrastructural level. Staining appeared closely adherent to the luminal aspect of the endothelial cell, following the contours of the plasma membrane including invaginations and endothelial flaps.

In summary, lectin staining was more pronounced in grey as compared to white matter. Both light and ultrastructural findings demonstrate that the endothelial glycocalyx of intrinsic spinal cord vessels is composed of multiple oligosaccharide residues. This composition is similar in arterioles, venules and capillaries. (Supported by NINCDS R01NS23324 to LJN).

EXTRACELLULAR MIGRATION OF BLOOD-BORNE PROTEIN FROM THE PIAL SURFACE AND FOLLOWING TRANSCYTOSIS THROUGH THE BLOOD-BRAIN DARRIER (BBB). J. Villegas*, R. Broadwell, and M. Salcman. Univ. MD, Balto., MD 21201.

Although evidence from this laboratory suggests bloodborne protein has extracellular entry to the mammalian subarachnoid space and that adsorptive transcytosis of protein occurs thru the BBB from blood to brain (ACTA NEUROPATH.79:117, 1989), spread of these proteins beyond the basal lamina into the neuropil has not been reported. Data are now available from rats and mice injected intravenously with native HRP and lectin conjugated HRP to suggest that movement of blood-borne protein into the neuropil from the pial surface and thru the BBB does occur. HRP fails to cross the BBB but gains access to the pial surface. Through 1hr, HRP is conspicuous initially in the Virchow-Robbins space, suggesting large vessels in this space may be leaky. HRP enters the subpial neuropil through the glial limitans above and from the Virchow-Robbins space laterally. Lectin-HRP undergoes transcytosis thru the BBB globally and at 3hrs is evident beyond the basal lamina both extra- and intracellularly within the neuropil. Extracellular lectin-HRP is particularly conspicuous within the hypothalamic paraventricular nucleus at 12hrs in salt-stressed animals and is most likely attributed to transcytosis thru the BBB and neurosecretory cells within this nuclear group. The data suggest that blood-borne molecules enter the CNS parenchyma thru extra- and intracellular routes to a far greater degree than heretofore appreciated.

DEXTRAN-PERCOLL STEP GRADIENT ISOLATION OF CNS ENDOTHELIAL CELLS [ECs] AND ASTROCYTES [As] FROM PRIMATE CORTEX [Ctx], CEREBELLUM [Cbl] AND WHITE MATTER (WM) R. Madden', S. Bjornsted and B.R. Brooks. Neurology Svc., Wm. S. Middleton VA Hosp. and Depts. of Neurology and Medical Microbiology, Univ. Wisconsin Sch. of Med., Madison, WI 53792
ECs and As in situ display different cellular binding and pathological characteristics depending

on their location in Ctx, Cbl or WM. Purified cell preparations were made from dissected Ctx, Cbl and WM regions in 1-5 yr old male Rhesus and female Cynomologus monkeys as previously described [SNS Abst 15: 1026, 1989; abst 409.7]. Cells were isolated on Matrigel, fibronectin or polylys-ine in Hams F-10 or DMEM supplemented with ECGS, ITS, Lac/Pyr, Glutamine and Nuserum. Hams F-10 favored initial isolation of ECs which subsequently grew better in DMEM. Cell isolation was independent of SIV/STLV seropositivity. Cells independent of SIV/STLV seropositivity. Cells were characterized by FACS with acetylated LDL, enzyme polymorphisms, immunostaining and immunoblotting with specific antibodies and growth in vitro. Terminal cell density [TCD] was similar for Rhesus [1.2 ± 1.0 (SD)] and Cynomologus [1.3 ± 0.7] ECs. However, TCD was decreased in Rhesus [0.5 ± 0.1] compared with Cynomologus [4.0 ± 2.1] As. [Supported by VA Merit Review]

EFFECTS OF ACUTE HYPERTENSION ON THE PHOSPHATASE ACTIVITY FEFECTS OF ACUTE HYPERTENSION ON THE PHOSPHATASE ACTIVITY OF CEREBROMICROVASCULAR (Na*+k*)-ATPase. M.L. Caspers, M. Bussone, M.J. Dow, L.J. Ulanski II and P. Grammas. Dept. of Chem., Univ. of Detroit, Detroit, MI 48221 and Dept. of Pathol. Wayne State Univ. Detroit, MI 48201.

Acute hypertension, induced in rats by I.V. injection of angiotensin II, provokes functional alterations of the cerebral endothelium. The phosphatase activity of the cerebromicrovascular (Na $^+$ +K $^+$)-ATPase (CMV-ATPase) from microvessels obtained from hypertensive (HT) and control when compared to controls, a 68% decrease (P<0.02) in the maximum rate (V_{max}) of the enzyme from HT rats was evident with no change in the Michaelis constant. In contrast, \u03c4-glutamyltranspeptidase was not significantly affected. Sodium arachidonate has been shown to stimulate $[^3H]$ ouabain binding to the high affinity isoform of the CMV-ATPase (J. Neurochem.(1988) 50, 1215). However, the presence of sodium arachidonate, linoleate, oleate or palmitate (100 µM each) produced a 79.7, 88.7, 61.0 or 38.7% inhibition of the phosphatase activity of the CMV-ATPase from NT and HT rats. Thus, these data suggest that the CMV-ATPase ([3H]ouabain binding vs. phosphatase activity) is regulated differently by fatty acids and the enzyme is selectively altered during acute hypertension. EVIDENCE FOR A RADIALLY ORIENTED PARAVASCULAR/EXTRACELLULAR FLUID CIRCULATION THROUGH THE MAMMALIAN FOREBRAIN. M.L. Rennels. Depts. of Anatomy and Neurology, Univ. Maryland

Sch. Med., Baltimore, Md. 21201

The mammalian CNS is permeated by 'paravascular' fluid pathways which include the perivascular spaces (PVS) around penetrating arterioles and veins and the basal laminae (BL) of capillaries (Brain Res., 326:47). Routes of paravascular tracer influx, spread and efflux from the forebrain were investigated by introduction of horseradish peroxidase (HRP) into the subarachnoid space (SAS). An $18\,$ gauge needle was inserted into the cisternae magna of volume of 4.0% HRP (Sigma Type II) in Hanks solution. After 4, 5, 10, 15 or 20 minutes, brains were fixed by intravascular aldehyde perfusion and HRP was localized in serial frozen sections using tetramethylbenzidine or 3'-5'-diaminobenzidine. Tracer influx into the forebrain occurs aminoenzidine. Tracer influx into the forebrain occurs mainly through PVS around penetrating arterioles from the circle of Willis. From these ventral pathways HRP enters the linear extracellular spaces (ECS) of the internal capsule and, within 5 minutes, the tracer is distributed throughout the hemispheres. At numerous sites HRP extends along paravascular pathways from the subcortical white matter through the cerebral cortex to the pial surface, possibly reflecting fluid efflux into the SAS. This rapid and consistent pattern of tracer migration may reveal an on-going circulation of CSF/ECF through the forebrain.

NITROGEN MUSTARD AMINO ACID WITH HIGH AFFINITY FOR THE LARGE NEUTRAL AMINO ACID CARRIER OF THE BLOOD-BRAIN BAR-RIER. Y. Takada, N. Greig*, S.I. Rapoport, D. Vi and Q.R. Smith. Lab. of Neurosciences, NIA, NIH, Bethesda, MD 20892.

One reason often cited for the failure of brain tumor chemotherapy is inadequate brain delivery of anticancer drugs. Many chemotherapeutic agents are hydrophilic and show only limited transport across the blood-brain barrier. In an attempt to improve brain delivery, an anticancer agent was sought that showed high affinity transport into brain via the large neutral amino acid carrier of the blood-brain barrier. This carrier is located at the brain capillaries and accepts a wide variety of ligands with the alpha-amino acid functional group. Relative affinity of candidate drugs was evaluated from their capacity to inhibit the blood-brain barrier transport of L-[14C]leucine in rats. Affinity for most agents that were examined, including melphalan, activicin, azaserine, diazo-oxo-norleucine, baclofen and buthionine sulfoxime, was low with transport inhibition constants (Ki; concentration giving 50% inhibition) of 100-4000 uM. In contrast, for a nitrogen mustard derivative of aminotetrahydronaphthoic acid (ATNM), Ki values were only 0.4-0.6 uM and were 10-50 times lower than that for any previously reported compound. The results suggest that ATNM may show improved brain delivery and thus prove of value in the clinical treatment of brain tumors.

THE BLOOD-BRAIN BARRIER IN ALZHEIMER DISEASE: AN ULTRASTRUCTURAL MORPHOMETRIC STUDY. P.A. Stewart, K. Hayakawat, M.-A. Akerst and H.V. Vinterst. 1. Department of Anatomy, University of Toronto, Toronto, Canada, and 2. Department of Pathology (Neuropathology), UCLA Medical Center, Los Angeles, California. It has been hypothesized that abnormalities of the blood-brain barrier (BBB) contribute to or reflect pathologic change in the brains of patients with Alzheimer disease, or senile dementia of Alzheimer type. To test this hypothesis, we measured ultrastructural characteristics thought to be related to microvessel permeability in brain biopsy specimens from patients with this disorder and age-matched control normal tissue. AD tissue was obtained in the course of intraventricular catheter placement for experimental pharmacologic therapy, while control material was obtained from structurally normal areas of corticectomy tissue derived from patients in the course neurosurgical procedures to treat brain tumors. The following parameters showed no difference between the two endothelial populations: vesicular density, vessel wall thickness, pericyte profile area, and total junction length. In contrast, interendothelial junctional clefts (unfused areas of the junctional complex) were significantly longer in AD brains than in controls. In addition, the number of pericytes was greater in AD capillaries than in controls, although the individual pericytes were of comparable size. These findings suggest BBB leakage in AD patients. Interestingly, the mitochondrial density (percentage of endothelial cytoplasmic volume constituted by mitochondria was 20% lower in the AD capillaries than in controls. The numbers of mitochondria in AD capillaries were significantly smaller. This is consistent with work by others showing alterations in capillary function in AD brains. The role that these structural changes play in AD is unclear; they may contribute to, or result from parenchymal abnormalities commonly observed in this neurodegenera

LONG TERM EFFECTS OF INTERLEUKIN-1 BETA IN THE RABBIT RETINA. J.A. Martiney*, C.S. Raine and C.F. Brosnan* Albert Einstein College of Medicine, Bronx, NY 10461.

We have shown previously that intracular injection of human recombinant interleukin-1 beta (hrIL-1b) in the New Zealand White strain of rabbits results in a reproducible set of vascular and inflammatory changes in the blood-retinal barrier. In these experiments, the effect of a single injection of hrIL-1b was followed through 48 hours post-injection (PI). We have now studied the effects of a single injection of hrIL-1b up to 5 weeks PI. Histopathological analysis showed that residual hemorrhage, which is first evident at 24 hours PI, is detected up to 3 weeks PI. Inflammation, which peaked at 24 hours PI, is decreased but still significant at 1 week PI. By 2 weeks PI inflammatory cells are barely detectable but plasma cells appear for the first time, persisting until 3 weeks PI. There is apparent gliosis at 2 weeks PI, with an increase in the thickness of the internal limiting membrane and the presence of pronounced astrocyte bridges associated with epiretinal capillaries. These changes persist until 5 weeks PI. Evidence of increased capillary density of the epiretinal vessels is also present. Quantitation of the extent of the reactive gliosis and of the neovascularization are currently under investigation. These observations show that the effects of intracoular injection of hrIL-1b are long lasting and affect the architecture of the retina. Thus altered local IL-1 production may lead to long term dysfunctions associated with currently under investigation. These observations show that the effects of intracoular injection of hrIL-1b are long lasting and affect the architecture of the retina. Thus altered local IL-1 production may lead to long term dysfunctions associated with acute inflammation of the optic nerve head. Supported by USPHS grant # NS11920.

CHRONIC BLOOD-BRAIN BARRIER IMPAIRMENT IN CENTRAL DEMYELINATING LESIONS REPAIRED BY SCHWANNIAN REMYELINATION. P.A.Felts.K.J.Smith.E.Tilt*. Dept. of Anat.& Neurobiol., East. VA. Med. Sch., Norfolk, VA, 23501

The blood-brain barrier (BBB) arises primarily from

tight junctions between endothelial cells, which may be induced by the intimate presence of astrocytes. We examined BBB integrity in central demyelinating lesions which remain chronically free of astrocytes, but which which remain chronically free of astrocytes, but which become spontaneously remyelinated by Schwann cells (SC). Nine adult male SD rats received injections of ethidium bromide (lul, 0.5mg/ml) into the dorsal column, either alone (n-5), or in conjunction with 40Gy of local beta irradiation. Segmental demyelination was initiated by 7-14 days, and SC remyelination was extensive by 16 weeks. New blood vessels were formed at the lesion. At intervals from 11 to 54 weeks the integrity of the BBB was assessed by the intravenous administration of horseradish peroxidase (HRP, 150-50mg/Kg after 5mg/Kg of Benadryl), and the rats were administration of information peroxidase (nkr, 150-250mg/Kg after 5mg/Kg of Benadryl), and the rats were perfused with aldehydes 15 mins later. Adjacent vibratome sections through the lesion were processed for the presence of extravasated HRP, the distribution of astrocytes (by GFAP immunohistochemistry), and light and EM. Eight of the 9 animals showed evidence of significant HRP leakage in the region of SC repair: these regions were negative for GFAP immunoreactivity. Thus BBB integrity is chronically impaired in central demyelinated lesions repaired by Schwann cells.

Bacterial cerebritis: mediators of acute inflammation & blood-brain barrier (BBB) changes W. Lo, J.D. Mahan, * D. McNeely, * & C. McAllister*

We previously observed in a bacterial cerebritis that the BBB to albumin becomes permeable three days after $\,$ leukocytes have migrated into the inoculated brain of mediators of inflammation act in this model. We stained frozen sections of brain with FITC tagged rabbit anti-rat antibody to complement component C3, IgG, and albumin at 0.5 h, 6 hrs, and 4 days after inoculation with Staphylococcus aureus. C3 and IgG were detectable at 0.5 and 6 hours after inoculation; by 4 days C3 was not detected and IgG was only weakly present. albumin did not appear until 4 days. Our findings indicate that C3 and IgG are deposited soon after inoculation although BBB permeability to albumin does not appear until days later. The sequence of C3 & IgG deposition, and albumin leakage is similar to acute inflammatory changes occurring in non-CNS tissues. Our findings suggest that acute inflammation mediated by C3 and IgG develops in the brain as it does in other tissues, and that in this model the brain is not immunologically privileged.

INTRACAROTID INFUSION OF LEUKOTRIEN C₄ INCREASES BLOOD-BRAIN BARRIER PERMEABILITY IN ISCHEMIC BRAIN OF RATS. Neurosurgery, U.C.L.A., Los Angeles, CA 90024.

To examine the effects of leukotrien C₄ (LTC₄) on brain

ischemia, blood- brain barrier (BBB) permeability in the middle cerebral artery (MCA)-occluded rats was determined by quantitative autoradiography using ¹⁴ C-aminoisobutyric acid. Seventy-two hr after MCA occlusion, LTC₄ (4 µg total dose) infused into the carotid artery ipsilateral to the ischemia selectively increased the unidirectional transfer constant for permeability, Ki, approximately three-fold within core ischemic tissue and tissue adjacent to the ischemic core. No effect on permeability was seen within non-ischemic brain tissue. This finding suggests that normal brain capillaries resist the vasogenic effects of LTC₄ while LTC₄ increases permeability in capillaries of ischemic tissue. Gamma glutamyl transpeptidase (γ-GTP) activity was decreased in capillaries in the ischemic tissue 72 hours after infarction, compared to high γ -GTP in normal brain capillaries and moderate γ -GTP in capillaries in the ischemic tissue 24 hours after infarction. We speculate that γ -GTP may act as an enzymatic barrier and inactivates leukotrienes in normal brain capillaries.

The Temporal Relationship Between the Onset of Clinical Signs, Histological Changes, and Increased Permeability of the Blood-Brain Barrier in Experimental Allergic Encephalomyelytis. K.E. Schlageter and D.R. Groothuis* Evanston Hospital, Evanston, IL 60201.

The temporal relationship between the onset of clinical signs, the appearance of histological changes, and increases in permeability of the blood-brain barrier (BBB) was studied in Lewis Diood-brain barrier (BBB) was studied in Lewis rats with experimental allergic encephalomyelytis (EAE). Permeability of the BBB was assessed with quantitative autoradiography using ¹⁴C labeled ~-aminoisobutyric acid as a marker. Increases in BBB permeability in the dorsal gray matter of the lumbar spinal cord were found to precede both clinical and histological changes by 2 days. At the time when clinical and histological changes by 2 days. the time when clinical and histological signs the time when clinical and histological signs were most severe, focal areas corresponding to dense cellular infiltration were found to have increases in permeability of up to 10 times those of normal animals. Histological changes and increased permeability were still apparent 30 days after induction of EAE. A model was used to calculate the total "pore" area of the capillary surface that could account for the increased permeability and this value was related to permeability and this value was related to attempts to define the morphological substrate responsible for increased permeability in EAE.

REGIONAL CHANGES IN CNS WATER CONTENT IN LEWIS RATS WITH RECURRENT EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS. Edward L. Orr and Nancy C. Stanley*. Dept. Anat. & Cell Biol., Texas College of Osteopathic Medicine, Fort Worth, TX 76107

To assess the roll of edema formation and resolution in recurrent experi-

mental autoimmune encephalomyelitis (rEAE), we have determined the re gional pattern of the water content in the CNS of Lewis rats during key periods of rEAE. rEAE was induced by inoculation of female Lewis rats with guinea pig spinal cord homogenate (gpsch) in *M. tuberculosis*-enriched complete Freund's adjuvant; control rats received an identical inoculum lacking gpsch Beginning on day 7 postinoculation (pi), rats were monitored daily for clinical signs of EAE. Groups of control and EAE rats were killed prior to the appearance of clinical signs (day 7 pi), at the peak occurrences of clinical disease (approx. day 12.5 for Peak 1 and day 24 pi for Peak 2), and during remissions (day 17 and 31pi for Remissions 1 and 2, respectively). Wet and dry weights of the whole spinal cord, brainstem, cerebellum, thalamus, hypothalamus, and forebrain were determined, and percent water content calculated.

Significant changes in percent water were observed in the whole spinal cord, brainstem, and cerebellum during rEAE. The percent water in the spinal cords and brainstems of rats with rEAE increased and decreased in concert with clinical severity, while the cerebellum exhibited an increase and decrease in percent water at Peak 1 and Remission 1, respectively, followed by a gradual increase thereafter. These results are consistent with the possibility that edematous changes in the spinal cords and brainstems of rats with rEAE may contribute to the transient clinical symptoms of rEAE, and that elucidation of the mechanisms involved in edema formation and resolution in rEAE may reveal novel methods for modulating the course or severity of rEAE. THE DIFFERENCE IN VASCULAR VOLUME BETWEEN CEREBRUM AND CEREBELLUM IS IN THE PIA MATTER. J.A. Holash, K.S. Sugamori*, P.A. Stewart. Dept. of Anatomy, Univ. of Toronto M6E 3C4.

Delivery of nutrients and drugs to specific brain regions depends on several factors including the local density of blood vessels. One measure of vessel density, vascular volume (VV), is defined as the volume of the vasculature as a percentage of the total tissue volume. Previous studies using intravascular tracers have shown that the apparent vascular volume in the cerebellum is as much as 50% higher than that in the cerebrum. We questioned whether this additional vascular volume in the cerebellum could be accounted for by the vasculature of the pia mater that covers its highly infolded surface. To test this we used a morphometric technique to make two estimates of Vv in cerebrum and cerebellum; one in which only parenchymal vessels were counted. We found no differences in intraparenchymal Vv between cerebrum and cerebellum. When pial vessels were included, however, the cerebral Vv increased only slightly, whereas the cerebellar vascular volume increased by more than 30%. We suggest that the higher cerebellar Vv measured by others using intravascular tracers is due to inclusion of the pial vasculature. Since pial vessels do not express blood-brain barrier characteristics as prominently as intraparenchymal vessels, we further suggest that estimates of blood-brain barrier permeability in the cerebellum should not be made using simple models developed for cerebrum. CYTOSKELETON, TRANSPORT AND MEMBRANE TARGETING

27.1

SYNTHESIS, AXONAL TRANSPORT AND POST-TRANSLATIONAL MODIFICATION OF SYNAPSIN I IN MOUSE RETINAL GANGLION CELLS. P. Paggi, P.Macioce®*, M. Cippitelli* and T. Petrucci®* - Dipartimento di Biologia Cellulare e dello Sviluppo, Università "La Sapienza" and "Laboratorio di Biologia Cellulare, Istituto Superiore di Sanità, Roma, Italy.

Synapsin I, a neuronal phosphoprotein associated with small synaptic vesicles and cytoskeletal elements at the presynaptic terminals, is thought to be involved in modulating neurotransmitter release. The state of phosphorylation of synapsin I in vitro, regulates its interaction with both synaptic vesicles and cytoskeletal components, including microtrubules and microfilaments. To investigate in vivo, how the phosphorylation state of synapsin I regulates its association with cytoskeletal elements along the axon and at the nerve endings, we have studied the axonal transport of synapsin I in mouse optic system. 355-methionine or 32P-ortophosphate were injected into the eye vitreous body of anesthetized adult mice. Animals were anesthetized and killed at different times after the labeling injection. Segments from the optic nerve, the optic tract, and the superior colliculus were removed. Labeled proteins were analyzed by 2-dimensional non equilibrium pH gel electrophoresis followed by SDS-PACE; radiolabeled synapsin I bands were quantified. We observed that the majority of synapsin I is transported down the axon together with the cytomatrix proteins at a rate characteristic of the slow component b of the axonal transport, and it is phosphorylated. These results are consistent with the hypothesis that in vivo, along the axon the phosphorylation of synapsin I i prevents the formation of a dense network, which could impair the axonal transport. On the other hand, at the nerve endings the dephosphorylation of synapsin I allows the linkage of small synaptic visicles to cytoskeletal components.

EVIDENCE FOR THE RECYCLING OF AXONALLY TRANSPORTED ORGANELLES. R.E. Snyder and R.S. Smith. Depts. of Applied Sciences in Medicine, and Anatomy and Cell Biology, University of Alberta, Edmonton,

Membrane-bounded organelles are presumed to transport molecules synthesized in the cell body of the neuron into its processes. organelles, or derivatives of them, are known to be returned to the cell body following reversal of transport direction in the axon terminal and at axonal lesions. We ask the question here whether, following their return to the cell body, the organelles can serve to carry newly synthesized molecules into the axon. All studies were performed using sciatic nerve of Xenopus laevis. Organelle traffic in isolated myelinated axons was studied using computer enhanced, differential interference-contrast, video microscopy. Transport of molecules labeled with ³H-leucine, ³²PO₄ (>30% phospholipid) or ³⁵S-methionine was studied with either a position-sensitive detector or by liquid scintillation analysis.

Cycloheximide (125 μ g/ml), applied to the cell bodies, was found to reduce export of ${}^3{\rm H}$ and ${}^{32}{\rm P}$ labeled molecules to <1% of their control values during a 20-h period, but organelle traffic, both anterograde and retrograde, and in the same proportion, to only 20-25%. In another experiment, >56% of anterogradely moving organelles reversed direction of transport at a distal lesion compared to <25% of ³⁵S labeled and <10% of ³²P labeled molecules. It is concluded that organelles may be exported from the cell body without the need of recently synthesized molecules and do not depend upon recently synthesized phospholipids for their return, consistent with the hypothesis that retrogradely transported organelles may be recycled to anterograde transport within the cell body. (This work was supported by the Medical Research Council of Canada and the AHFMR.)

PROTEIN DEPOSITION FROM RAPID ANTEROGRADE AXONAL TRANSPORT OCCURS WITHOUT DIMINUTION OF VESICLE TRAFFIC. R. S. Smith, X. Chen' and R. E. Snyder. Depts. of Anatomy and Cell Biology, nd Applied Sciences in Medicine, University of Alberta, Edmonton, Canada

Deposition of protein from the moving phase of rapid anterograde Deposition of protein from the moving phase of rapid anterograde axonal transport to a relatively stationary phase is a well-described but poorly understood phenomenon. We have tested the hypotheses that the deposition may be caused by: 1) loss of protein from transport vesicles, or 2) loss of vesicles from the transport system, possibly by lusion with axonal membrane systems. We used isolated sciatic nerves from the amphibian Xenopus laevis; where appropriate, the 8th and 9th dorsal root ganglia were retained with the preparation. Fast transported proteins were labeled with 35S-methionine and the transport dynamics of a pulse of labeled protein were studied in living preparations with a position sensitive detector of ionizing radiation. Organelle traffic in isolated myelinated axons was studied using computer enhanced, differential interference-contrast, video microscopy.

Protein transport studies showed that 1.2-1.6% of the protein in a labeled pulse was deposited to a stationary phase in each millimeter of nerve (distance required for half amplitude loss = 40-60 mm). Anterograde organelle traffic was estimated, at locations 60 mm apart, as the number of organelles traffic was estimated, at locations of min apart, as the number or organelles that crossed, in a unit time, a unit diameter of axon in the focal plane of the objective. There was no statistical evidence of any difference in organelle traffic at the two locations (proximal mean \pm SEM, 8.07 \pm 0.46 organelles/min/µm, n axons = 46; distal, 8.81 \pm 0.51, n = 52) We conclude that protein deposition is likely to represent protein loss from moving

THE SPATIAL TEMPORAL PATTERN OF DELAYED AXONAL DEGENERATION IN THE C57BL/6 MOUSE SCIATIC NERVE. J.D. Glass*, D. Archer*, and J.W. Griffin The C57BL/6/Ola mouse has previously been shown to the company of the company

exhibit prolonged survival of axons distal to an axotomy. This phenotype appears to be related to a deficient macrophage response. This prolonged axonal survival contrasts with the usual explosive axonal breakdown seen in mammalian peripheral nerves. In standard C57BL/6 mice, axoplasm is reduced to granular and amorphous debris throughout the distal stump within 48 hours of nerve transection. The C57BL/6/Ola model thus offers a unique system to examine the fate of axons disconnected from their cell bodies. We examined the axons of the distal stump at intervals after axotomy. Most axons survived more than 14 days, and many for more than 21. They underwent some redistribution of axoplasm along individual internodes, forming paragraphy are dominantly intervals. forming narrowed segments containing predominantly microtubules, and varicosities containing densely packed neurofilaments. These changes appeared to reflect a local redistribution of cyto-skeletal constituents. We did not find a proximal-to-distal sequence of axonal breakdown, as would be predicted if much of the axoplasm is undergoing continued slow anterograde transport in the distal stump. These data favor models of axonal organiza-tion in which much of the axonal cytoskeleton is relatively stationary, rather than undergoing somatofugal transport.

Mechanisms of Degeneration in Anucleate M-axons of Goldfish.

J. Moehlenbruck, M. Wakefield*, M.E. Smeyers*, G.D. Bittner
Dept. of Zoology, Univ. of Texas, Austin, Tx. 78712

The severed distal (anucleate) segments of giant Mauthner axons (M-axons) of goldfish remain morphologically and physiologically intact for months at 10-30°C, but ultimately degenerate after 30 days at 30°C, 60 days at 20°C, and 160 to 250 days at 10°C. Light microscopic studies suggest that 250 days at 10°C. Light microscopic studies suggest that anucleate M-axons degenerate in a proximal to distal (P-D) direction (Blundon et al., 1990 J. Comp. Neurol., in press). We are investigating whether this P-D degeneration results from slow transport of cytoskeletal elements within anucleate M-axons. In particular, the density and integrity of microtubules and neurofilaments have been examined in electron micrographs from intact M-axons, from anucleate M-axon segments immediately distal to the severance site and from anucleate M-axon segments distal to the severance site, and from anucleate M-axon segments more distal to the severance site. Electron micrographs show a greater depletion of microtubules and neurofilaments in areas near (within 10-20 mm) the severance site, compared to more distal (30-40 mm) segments or to intact M-axons. We are now studying the slow transport of radiolabelled proteins in intact and severed M-axons in order to compare slow transport rates with P-D rates of degeneration. Supported by TAT grant #194 to G.D. Bittner.

DIFFERENTIAL SUBCELLULAR LOCALIZATION OF mRNA'S FOR NEURONAL PROTEINS IN HIPPOCAMPAL NEURONS IN CULTURE R. Neiman, G. A. Banker and D. Steward. Department of Neuroscience, and the Neuroscience program, Univ. of VA, Charlotesville, VA 22908.

Recent studies of in situ hybridization patterns in tissue sections

suggest that neurons are able to sort mRNA molecules into different subcellular compartments. Some mRNA's are found only in the cell body while others are found in neuropil regions containing axons and dendrites (Garner et al., 1988, Nature, 336;674-677). However, in tissue sections it is very difficult to determine the actual subcellular distribution of mRNA's that may be present in neuronal processes. In the present study, we used in situ hybridization to evaluate the subcellular distribution of mRNA's in hippocampal neurons grown in low density cultures, where it is possible to visualize the entire extent of axonal and dendritic arborizations of single neurons. ³⁵S labeled riboprobes complementary to the mRNA's for GAP-43 (F1, B-50), neurofilament-68, MAP2 and beta tubulin were prepared. Autoradiographic analysis revealed that the mRNA for neurofilament-68, beta tubulin and GAP-43 were localized primarily within neuronal cell bodies. For neurofilament and tubulin, the localization was cell body specific. However, hybridization with the GAP-43 riboprobe led to labeling that extended a short distance into the proximal portions of larger dendrites. In contrast to the other probes, the mRNA for MAP2 was localized both in cell bodies and throughout the dendrites. These results demonstrate that there is a differential distribution of mRNA within neurons, suggesting a elective transport of some mRNA's into dendrites. Supported by NIH NS23094 to GB and OS. RK was the recipient of a predoctoral fellowship from NIH HD07323.

ANTI THY-I IgG UNDERGOES TRANSCYTOSIS FOLLOWING RETROGRADE AXONAL TRANSPORT. R.H.Fabian, H.C.Rea. Dept. Neurology and Marine Biomed. Inst., U.T.M.B., Galveston, TX 77550-2778.

There has been increasing interest in the possible involvement of antineuronal IgG in the pathogenesis of motor neuron disease. Since other exogenous proteins have been noted to undergo transcytosis following retrograde axonal transport to neurons, we investigated an anti-Thy-1.2 monoclonal IgG (30-H12, American Type Culture Collection) for this phenomenon at the ultrastructural

Purified 30-H12 IgG was biotinylated using sulfosuccinimidyl 6-(biotinamido) hexanoate and injected into the mystatial vibrissae of anesthetized mice (N = 12). Following survival intervals of 12, 24, and 48 hours, the mice were deeply anesthetized with Halothane inhalation and perfused with 3% glutaraldehyde in cacodylate buffer. Vibratome sections of the medullae were stained for the presence of biotin using streptavidin-peroxidase and then prepared for ultramicrotomy. Observations at the ultrastructural and light level revealed that biotinylated IgG moved quickly though neurons following retrograde axonal transport to become localized diffusely in the neuropil.

These results support the hypothesis that antineuronal IgG is capable of neuronal transcytosis. This pathway may bring antineuronal IgG into contact with motor neurons despite the presence of the blood brain barrier.

Supported by NIH 11255.

FUSION OF THE AMINOTERMINAL 10 AMINO ACIDS OF GAP-43 TO

FUSION OF THE AMINOTERMINAL 10 AMINO ACIDS OF GAP-43 TO BETA-GALACTOSIDASE TARGETS THE CHIMERIC PROTEIN TO NEURONAL PROCESSES. R.L. Neve, L.R. Dawes, A.I. Geller. Dept. of Psychobiology, Univ. of California, Irvine, CA 92717 and Dana Farber Cancer Inst., Boston, MA 02115.

The neuronal protein GAP-43 is thought to be attached to the growth cone membrane via fatty acylation of the protein's only two cysteine residues (J Cell Biol 108: 613, 1989). These cysteine residues are found within a 10-amino acid domain at the amino terminus of the molecule. To determine whether this domain alone is capable of transporting a protein to the neuronal process membrane, and to develop a method for targeting molecules to the neuronal growth cone, we constructed a chimeric clone in which the first 10 amino acids of human GAP-43 were fused to betagalactosidase (GAPlac) in a defective Herpes Simplex Virus (HSV-1) vector. PC12 cells were infected with GAPlac virus and pHSVlac virus, which expresses the unmodified betagalactosidase. Beta-galactosidase activity was detected predominantly in the cell body of PC12 cells infected with galactosidase. Beta-galactosidase activity was detected predominantly in the cell body of PC12 cells infected with PHSVlac virus, whereas it was detected prominantly in the cell processes as well as the soma of cells infected with GAPlac virus. These results suggest that the first 10 amino acids of GAP-43 are sufficient to direct the protein to the cell membrane, and provide a means of targeting recombinant molecules to the neuronal growth cone. Further experiments involve infection of primary hippocampal neurons with the recombinants to determine whether the chimeric protein is directed specifically to the axon.

27.8

A COMPARISON OF LOW MOLECULAR WEIGHT GTP-BINDING PROTEINS IN AXONS AND SYNAPTIC TERMINALS OF SQUID NEURONS. G. J. Chin. Lab. of Developmental Neurobiology, NIH, Bethesda, MD 20892

Recent work in mammalian cells and in yeast suggests that low molecular weight GTP-binding proteins may be involved in the traffic of vesicles among cellular compartments, such as occurs in the constitutive exocytosis of proteins and in the transport of ligands taken up by receptor-mediated endocytosis. As a first step in studying whether this family of proteins might also function in regulated exocytosis in neurons, GTP overlays were used to identify and characterize these proteins in two spatially segregated regions, the axon and the synaptic terminal. Squid giant axon contained five GTPbinding proteins with molecular weights of 19-28 kDa; all were localized mainly to soluble and particulate fractions of extruded axoplasm. Squid optic lobes contained a similar set of GTPbinding proteins; some of these were enriched in a partially purified synaptic vesicle fraction, as assayed by synaptobrevin immunoreactivity. Like axons, optic lobe synaptosomes contained both soluble and particulate GTP-binding proteins.

27.10

A SYNTHETIC LEADER PEPTIDE FOR RAT PRE-ORNITHINE TRANSCARBAMYLASE (pOTC) INHIBITS THE MITOCHONDRIAL TARGETING OF HUMAN MONOAMINE OXIDASE (MAO). C. Titlow, J. Hendrick*, W. Weyler*, and X.O. Breakefield. Prog. in Neuroscience, Harvard Med. Sch., Boston, MA 02115 and Mol. Neurogenetics Unit, Mass. General Hosp., Charlestown, MA 02129. MAO is the primary enzyme involved in degradation of neuro-transmitters, such as denganine, prorepinephrine, and serotonin

MAO is the primary enzyme involved in degradation of neurotransmitters such as dopamine, norepinephrine, and serotonin. MAO exists as A and B forms which can be distinguished by genetic, biochemical, and immunological criteria. Both forms are located in the mitochondrial outer membrane. We have placed a 2 kb cDNA clone containing full-length coding sequences for human MAO-A into a Bluescript vector to allow transcription of sense message under control of a T7 promoter. This RNA generates a full size MAO-A protein when translated in vitro in a rabbit reticulocyte lysate system using ³⁵S-methionine to label the polypeptide. We have examined the binding of ³⁵S-MAO-A to freshly isolated rat liver mitochondria. Binding of ³⁵S-MAO-A is blocked by a synthetic peptide corresponding to the N-terminal, targeting signal of the precursor protein, pOTC, for the mitochondrial matrix protein, OTC. Thus MAO-A appears to share the same recognition site on mitochondria as other proteins targeted to this organelle.

organelle.

EXPRESSION OF THE NEURONAL INTERMEDIATE FILAMENT PROTEIN (IFP) PERIPHERIN IN THE RAT CNS AND OLFACTORY NEURONS. J.D.Gorham, H.Baker', and E.B.Ziff Howard Hughes Med. Inst. and Dept. of Biochem., New York Univ. Med. Ctr., NY, NY 10016 and +Lab. of Mol. Neurobiol., The Burke Rehabilitation Ctr., Cornell Univ. Med. Coll., White Plains, NY 10605.

Peripherin is a type III IFP expressed by all PNS neurons, and by somatic and visceral motoneurons. Using peroxidase immunohistochemistry, peripherin expression was demonstrated in a subset of rat CNS neurons, including the cranial nerves, as well as isolated cortical neurons. The cortex also showed rather extensive networks of small-diameter peripherin-containing fibers, running both parallel and perpendicular to the pial surface. The olfactory bulb (OB) showed a similar network of peripherin-containing fibers. Interspersed among these OB fiber tracts were occasional peripherin-containing cell bodies, which morphologically resembled neurons, not glia. These results indicate that peripherin expression in the brain is considerably more widespread than previously appreciated.

The IFP expression pattern of olfactory receptor neurons (ORNs) was examined. ORNs did not stain for neurofilament light chain, but did react with antisera to vimentin or peripherin. Vimentin immunoreactivity was seen in cell bodies, axons, and some, but not all, termini within OB glomeruli. In contrast, peripherin expression was seen only in axons and not in cell bodies or termini. Thus, ORNs coexpress two type III IFPs, but distribute them within the neuron in an overlapping but non-identical pattern. This differential distribution implies that peripherin and vimentin perform different functions in ORNs. The unusual IFP isotype combination expressed by ORNs may have implications for their regenerative potential.

NEUROFILAMENTS AT THE NODE OF RANVIER ARE DIFFERENT FROM INTERNODAL NEUROFILAMENTS. M.Mata, N.Kupina* and D.J. Fink. VAMC and U.Michigan, Ann Arbor, MI 48104.

In order to study the organization of the cytoskeleton along the length of the peripheral nerve fiber, we performed post-embedding electron microscopic immunocytochemistry with colloidal gold using antibodies specific for different neurofilament (NF) epitopes and for microtubules (MT).

Monoclonal antibodies specific for the 160 kD and 200 Monoclonal antibodies specific for the 160 kD and 200 kD NF subunits (Boehringer-Mannheim) and for phosphorylated epitopes on the 160 and 200 kD NF subunits (SMI-31, Sternberger-Meyer) showed a reduction in the density of immunostaining at the node of Ranvier. An affinity purified polyclonal antibody to microtubules (BTI) showed essentially constant density of gold particles along the axon, with a slight increase in the region of axoplasm underlying the node of Ranvier, as did an antibody specific for the 68kD NF subunit (Boehringer-Mannheim) Mannheim).

Because previous data has shown that the density of NF along myelinated axons is constant, these results suggest that the organized NF cytoskeleton at the node of Ranvier is different from the internodal cytoskeleton. It is possible that post-translational modification of NF epitopes may occur at the node of Ranvier.

ORIGINS OF ACTIN AND TUBULIN IN ANUCLEATE CRAYFISH MEDIAL GIANT AXONS. R.A. Sheller, M.E. Smyers* and G.D. Bittner. Dept. of Zoology, University of Texas, Austin, TX 78712.

In the crayfish, Procambarus clarkii, the distal stumps of severed medial giant axons (anucleate MGAs) exhibit long term survival (LTS) for 50-200 days post severence (G.D. Bittner, Amer. Zool. 28:1165, 1989). LTS of MGAs, previously characterized morphologically and electrophysiologically, was analyzed biochemically in this study. Axoplasmic proteins were collected by perfusing MGAs with an internal saline, electrophoresed on SDS-PAGE gels, and silver stained. The resulting silver stained proteins and the immunological detection of actin and tubulin on Western transfers were the same for anucleate MGAs severed for minutes or months.

If such axoplasmic proteins in anucleate MGAs originated in the soma and were transported to the axon prior to severence, these proteins were not degraded for at least 6 months in the anucleate axon. Alternatively, these axoplasmic proteins could have been synthesized in adaxonal glia and subsequently transferred to anucleate MGAs. Data supporting the latter hypothesis were obtained when 35S-methionine was placed in the bath surrounding an anucleate MGA and radiolabelled proteins were detected in perfused axoplasm. Radiolabelled proteins in the perfused axoplasm (analyzed by SDS-PAGE and fluorography) were very similar to radiolabelled proteins in the glial sheath.

Newly synthesized proteins in MGA axoplasm might replenish some, but not all, existing axoplasmic proteins. Our data suggest that the actin of anucleate MGAs may be synthesized by glia and then transferred to the axons, whereas tubulin apparently originates from some source other than protein synthesis in glia. Microtubule Polymerization Equilibria and Membrane

Microtubule Polymerization Equilibria and Membrane
Depolarization in Rat Sympathetic Neurons. C. H. Keith,
Department of Zoology, University of Georgia.

We have developed methods that allow us to measure
the polymer/total tubulin ratio locally in the neurites of
cells in culture. We inject cells with a fluorescent
analog of tubulin and allow it to equilibrate into
microtubules throughout the neuron. We then digitize the
fluorescence of this cell on a 512 X 512 raster, and store
the digitized image. We then extract the cell in a Triton
Y100-containing microtubuleschalizing buffer, and rethe digitized image. We then extract the cell in a lift of X100-containing microtubule-stabilizing buffer, and rerecord the fluorescence. By aligning the two images and integrating blockwise out the neurite, we can define a ratio of intensities out the neurite in the extracted image (microtubules) to intensities in the unextracted

image (microtubules) to intensities in the unextracted image (total tubulin)

We have been applying this methodology to measure microtubule/tubulin ratios in rat sympathetic neurons that have been exposed to a medium containing 50 mM K*-HEPES. We find that in control, undepolarized cells, measured microtubule/tubulin ratios are of the order of .8-1 throughout the neurite. However, after exposure to K*-HEPES for one hour, microtubule/tubulin ratios drop to 0.50 or less, with a tendency for the growth cone ratio to be lower than than near the cell body. This drop in microtubule / tubulin ratio is probably due to a rise in Ca*i, caused by the opening of plasma membrane voltage-dependent calcium channels on chronic depolarization.

EFFECT OF PHOSPHORYLATION AND DEPHOSPHORYLATION ON GFAP FILAMENT ASSEMBLY. Y.Nakamura, Y.Nakamura, M. Takeda, K.J. Angelides, T. Tanaka, K. Tada, E. Senba, S. Hariguchi, T. Nishimura.

Neuropsychiatry Osaka Univ. Med. Sch., Osaka, 553.

The dynamic nature of GFAP as well as neuro-

filament core protein can be studied by measuring fluorescence energy transfer. Fluorescence-labeled GFAP was shown to be assembled into 10 nm filaments. The fluorometric assay was designed to measure the degree of assay was designed to measure the degree of assembly of fluorescence-labeled GFAP. Among factors modulating GFAP filament assembly, phosphorylation seems to be important. Phosphorylation of soluble GFAP by cAMP dependent protein kinase inhibited filament assembly in proportion to the phosphorylation level, and the assembled GFAP filament was disagraphed by phosphorylation. level, and the assembled GFAP filament was disassembled by phosphorylation. Dephosphorylation of GFAP by unweaned calf intestinal ALP increased the critical concentration of assembly, and vanished its Mg²⁺ sensitivity. Dephosphorylated GFAP formed thicker filaments (Ø:15-20 nm). The possible sites, which were phosphorylated or dephosphorylated, were likely to locate in the HEAD region. HEAD region of GFAP is essential for the modulation of filament assembly.

PSEUDORABIES VIRUS: A HIGHLY SPECIFIC TRANSNEURONAL CELL BODY MARKER IN THE THE SYMPATHETIC NERVOUS SYSTEM. A.M. Strack and A.D. Loewy. Dept. of Anatomy and Neurobiology, Washington University, St. Louis, MO 63110

The present report presents a series of experiments in rats using Bartha's K strain of pseudorabies virus (PRV) that demonstrate specificity of retrograde transneuronal viral transport in the sympathetic nervous system. Three experiments were performed. First, an injection of PRV was made in the anterior chamber of the eye, followed by a second injection of wheat germ agglutinin-horseradish peroxidase (WGA-HRP). PRV infected neurons in the superior cervical ganglion (SCG) always contained WGA-HRP. This dual labeling of SCG neurons suggests that the PRV cell body labeling in the SCG remains specific. Second, after PRV injections into the pinna or eye, a specific segmental distribution of the transneuronal cell body labeling occurred in the intermediolateral cell column (IML) and related spinal areas. After eye in jections, the majority of transneuronally labeled neurons were in the T1-T3 segments. After pinna injections, the majority of labeled cells were in the T2-T5 segments. Since the SCG cells innervating these two end-organs lie in close proximity to each other within the ganglion, these results suggest segments. Since the SCG cells innervating these two end-organs lie in close proximity to each other within the ganglion, these results suggest that a specific transfer of the virus occurred, possibly via a trans-synaptic mechanism. Third, virally infected glial cells were rarely found in the SCG and spinal cord using a dual immunohistochemical staining procedure with antibodies against glial fibrillary acidic protein or galactocerebroside and PRV was used. In summary, Bartha's K strain of PRV can be used as a specific transneuronal retrograde marker in the sympathetic nervous system.

INVESTIGATION OF DISYNAPTIC PATHWAYS IN A DOUBLE-LABELING PARADIGM. K. Bruce and I. Grofova. Dept. of Anatomy, Michigan State University, E. Lansing, MI 48824.

Major problem in the investigation of the synaptic arrangement of

nerve terminals derived from a specific source with neurons projecting to anatomically defined targets has been the lack of tracers that can be used for both, light and electron microscopic studies, and are compatible as to the rate of transport as well as fixation procedures. In efforts to determine the termination of efferent fibers from the pars reticulata of the substantia nigra (SNR) in the rat on neurons projecting to the pontomedullary reticular formation and/or the cervical cord, we have developed a double-labeling technique that combines retrograde transport of cholera toxin B (CTB) with anterograde transport of cholera toxin B (CTB) with anterograde transport of Phaseolus vulgaris-leucoagglutinin (PHA-L). Both anterogradely PHA-L labeled fibers and terminals, and retrogradely CTB labeled somata and primary/secondary dendrites can be visualized in the same section using a sequential immunostaining protocol yielding different colored reaction product. Although the color difference is lost following postfixation in osmium, the two tracers can be readily recognized in ultrathin sections. The CTB reaction product is generally more discrete, and it is associated In eCIB reaction product is generally more discrete, and it is associated mostly with the Golgi apparatus in the cell somata, and with the microtubuli in dendrites. On the other hand, the PHA-L yields a very dense reaction product that fills the matrix of nerve terminals and appears only slightly lighter in unmyelinated and myelinated fibers. Due to its reliability, relative technical simplicity and a high degree of selectivity, this approach is considered an appropriate tool to analyze disynaptic pathways. (Supported by N.I.H. grant NS25744).

EXTRACELLULAR LABELING OF UNMYELINATED PRIMARY AFFERENTS AFTER INJECTIONS OF WGA-HRP IN DORSAL ROOT GANGLIA AND

AFTER INJECTIONS OF WGA-HRP IN DORSAL ROOT GANGLIA AND PERIPHERAL NERVES. <u>D.J. Tracey, R.J. Weinberg and A. Rustioni</u>. Dept. of Cell Biology and Anatomy, University of North Carolina, Chapel Hill, NC 27599.

In anesthetized rats, 0.25 to 0.5 μ l of 2% WGA-HRP were injected into L5 ganglia. Spinal cord sections and dorsal roots were reacted for HRP, using TMB with tungstate stabilization. Label in the spinal cord after 8 h was concentrated in the substantia gelatinosa, where unmyelinated primary afferents terminate. EM observations of substantia gelatinosa revealed labeled dendrites and glia as well as axons and terminal boutons. Label was most prominent, however, in the extracellular space surrounding presumed terminals of unmyelinated fibers. Tracer was also concentrated in superficial laminae after injections in peripheral nerves, although the extracellular labeling was not as prominent. EM observations on dorsal roots after ganglion injections revealed that the tracer is inside unmyelinated and myelinated fibers and in Schwann cells. The evidence suggests that WGA-HRP reaches the spinal cord by fast axoplasmic transport and is then rapidly released at terminals and possibly along unmyelinated fibers WGA-HRP might also be transported along a chain of Schwann cells, and then extruded into the extracellular space. Binding of released WGA-HRP to axolemmal sialoglycoproteins of unmyelinated fibers may contribute to apparent greater affinity of the tracer for these fibers.

SYNAPTIC UPTAKE AND TRANSPORT OF RECOMBINANT TETANUS TOXIN FRAGMENT C (rTTC) IN THE RAT VISUAL SYSTEM T.J.Cavanagh, D.S.Grega, G.Bowker* and F.Dwulet*. Indiana University School of Medicine, Program in Medical Neurobiology and Boehringer Mannheim Biochemicals R&D, Indianapolis, IN 46250

Tetanus toxin is rapidly taken up and transported trans-synaptically within the nervous system, making it an ideal marker for tracing neuronal circuits. The health hazard assumed by working with this molecule has been somewhat ameliorated by the use of an enzymatically derived atoxic fragment (fragment C) of the native tetanus toxin (TTC). However, enzymatically digested native toxin may present two problems: 1) It may not be a homogenous preparation, and 2) A percentage of the impurities may comprise intact (undigested) toxin. Neither of these problems is encountered with recombinant tetanus toxin C fragment. The rTTC was 93% pure as assessed by gel filtration on a TSK G3000SW column. Elution time was consistent with a MW of approximately 50,000. We present evidence that CNS uptake and transportation of rTTC appears identical to that seen with enzymatically-derived TTC. As described for TTC, intraocularly-injected rTTC is taken up and transported anterogradely by retinal ganglion cells to retinorecipient areas, then taken up and retrogradely transported to neurons which innervate retinorecipient areas.

FLUOROGOLD TRACING AFTER CHEMITRODE INJECTIONS OF DORSAL RAPHE: AFFERENTS SUPPORTING BRAIN STIMULATION REWARD. M. P. Vachon, W. Staines and E.Millaressis. Lab. of Neurophysiology and Department of Anatomy, University of Ottawa, Ottawa, Canada K1N 6N5. The dorsal raphe (DR) supports a robust level of brain stimulation reward (BSR). We have oberved that some afferents to the dorsal

reward (BSR). We have oberved that some afterents to the dorsal raphe either support BSR themselves or modulate the efficacy of dorsal raphe BSR. As a prelude to a more detailed study of the effects of DR afferents on BSR elicited from this nucleus we have studied the distribution of neurons labelled by retrograde transport of Fluorogold injected into the DR using a novel, behaviorally-controlled technique. injected into the DR using a novel, behaviorally-controlled technique. Injections of .02 to 0.1 µL of Fluorogold (4% solution) were made via a chemitrode implanted in DR areas highly supportive of BSR. Despite the small target size, behavioral evaluation allowed for very accurate injection placements. Brains were processed after 2 to 3 days survival time and fluorescence microscopy revealed densely retrogradely labeled neurons in various diencephalic, mesencephalic and myelencephalic areas of the brain. Specific nuclei containing labelled neurons included the diagonal band of Broca, septum, interroducular nucleus, lateral proportic area, lateral habenula ventral interpeduncular nucleus, lateral preoptic area, lateral habenula, ventral tegmental area, other raphe nuclei, parabrachial nucleus and the prepositus hypoglossal nucleus. These results are in accordance with already known DR afferents and highlight structures that could influence the DR BSR system.

COMBINED TRACING OF KITTEN RETINOGENICULATE AXONS IN VITRO AND LABELLING OF LATERAL GENICULATE NEURONS IN FIXED SLICES. L-A. Coleman and M.J. Friedlander. Neurobiology Research

SLICES. L-A. Coleman and M.J. Friedlander. Neurobiology Hesearch Center, University of Alabama at Birmingham, Birmingham, Al 35294. As part of our ongoing studies of retinogeniculate development in the cat, we have developed a technique for combining anterograde tracing of retinogeniculate axons and intracellular labelling of geniculate neurons in the target area. In deeply anesthetized, postnatal kittens between one and six weeks of age, the region of the brain containing the LGNd was removed, immersed in ACSF and maintained in a tissue chamber for up to 6hrs to allow for anterograde transport of HRP-Texas Red (Mol. Probes) placed in allow for anterograde transport of HRP-Texas Red (Mol. Probes) placed in the optic tract. Following immersion fixation with 4% paraformaldehyde and 0.1% glutaraldehyde the LGNd was sectioned at 400pm on a Vibratome. Selected cells were injected intracellularly under visual control with a glass micropipette containing 1% Lucifer Yellow (Mol. Probes) and 5% Biocytin in Tris/HCl buffer (pH 7.6). Injection of Biocytin enables cells to be permanently labelled by reacting sections with the ABC complex (Vector), followed by heavy metal intensified diaminobenzidine processing. Axons containing HRP were simultaneously revealed by this processing. GNd Jure Colling and their LGNd Jure Colling and the Colling and their LGNd Jure Colling and the containing HRP were simultaneously revealed by this processing. Our preliminary results show that retinogeniculate axons and their LGNd target cells can be successfully labelled using this technique. We are currently investigating whether apparent contacts at the light level can be confirmed as sites of synaptic contact at the ultrastructural level. To date, the axonal arborizations of 5 retinogeniculate axons and dendritic morphology of 10 LGNd neurons have been studied. Similar experiments are currently being performed using adult cats. This technique offers the potential to evaluate synaptic convergence in young animals where the use of the anesthetized in vivo preparation is problematic.

TRANSNEURONAL DIFFUSION OF DII IN THE VISUAL SYSTEM OF THE HORSESHOE CRAB, LIMULUS. ¹I. Kelly Johnson, ²Robert N. Jinks*, and ^{1,2}Steven C. Chamberlain. ¹Institute for Sensory Research and ²Department

of Bioengineering, Syracuse University, Syracuse, NY 13244.
Crystals of Dil (1,1'-dioctadecyl-3,3,3',3'-tetramethylindocarbocyanine perchlorate, Molecular Probes) were applied to the cut ends of the lateral optic nerve of dissected brains fixed and stored in 4% paraformaldehyde in 0.1 M phosphate buffer (pH 7.2). Tissue was maintained in fixative in darkness at room temperature or at 37°C for 1-4 months. Serial 100-µm sections were cut

with a vibratome, collected on subbed slides, and coverslipped with Gelmount.

Dense fluorescence was noted in the trunk of the lateral optic nerve, the laminar and medullar neuropils, the optic tract and adjacent central body neuropil, and the ocellar ganglion. These are all sites of optic nerve fiber terminations previously demonstrated with cobalt chloride and Lucifer

yellow and were labelled by direct dye diffusion.

Additional structures were clearly transneuronally labelled. Many or all laminar somata were stained. Somata in the medullar group and dorsal medial group were stained. However, some of these somata must belong to circadian retinal efferents (Invest. Ophthalmol. Vis. Sci., 1990, 31(4):286). A few fibers in the median and ventral optic nerves were lightly stained near their central terminations. Two tracts of fibers from medullar neurons, one crossing the midline in the central body neuropil and one running from the

posterior medullar neuropil toward the circumesophageal, were stained.

The mechanism underlying this transneuronal staining is unclear. Although these various structures could be interconnected via gap junctions, it seems equally possible that direct diffusion might occur across small distances including synaptic clefts. In conclusion, transneuronal diffusion occurs in, and is apparently restricted to, the visual system in the brain of *Limulus*. Supported by NIH grants EY06064 and EY03446.

28.9

SELECTIVE "ARGENTAFFIN" STAINING OF NERVE FIBERS AFTER MER CURIC ACETATE POSTFIXATION A Pellegrino de Iraldi and C.J.

Tandler. Instituto de Biología Celular, Facultad de Medici
na, Paraguay 2155, 1121 Buenos Aires, República Argentina.

A novel type of argentaffin histochemical technique (Hg-Ag) (Tandler, Com.Biol.,7,1-8) based on the reduction of diammine silver nitrate by mercuric acetate postfixed tissues has been shown to stain selectively proteins localized within the lateral elements of triads/diads in striated muscle cells (Tandler and Pellegrino de Iraldi, Histochemistry,92,15-22). In this work the Hg-Ag technique was applied to glutaraldehyde-fixed gray and white matter of the brain, cerebellum and spinal cord, retina, sciatic nerve and sympathetic fibers of the rat. Strongly reactive sites appeared related to nerve fibers. Silver grains were localized and unevenly distributed inside the axons. The amount of reactive material was found to be variable within the same or the different tissues studied. In longitudinal sections linear tracks of silver grains were evidenced, strongly suggesting the staining of cytoskeleton structures such as neurofilaments and/or neurotubules and/or their associated proteins. This con-clusion is strenghthened by the finding that pretreatment (15 min) of fresh tissues with 1% Triton X-100 did not extract the silver reducing axonal components. Work supported by grants from CONICET and UBA,R.Argentina.

28.8

STAINING COMPLETE AXON ARBORS IN PRE-FIXED MAMMALIAN NERVOUS TISSUE: OPTIC FIBERS IN RATS AND MARSUPIAL EASTERN QUOLLS (DASYURUS YIVERRINUS). M. Scheel* and W. L. Weller, Univ. of Tasmania, Hobart, Tasmania 7001, Australia.

To be able to study retinogeniculate endings in quolls, we have adapted, for use with mammals, Kageyama and Meyer's method (J. Histochem Cytochem 35:1127) of filling pre-fixed neurons and their processes with horseradish peroxidase (HRP) through a severed optic nerve.
Following standard EM fixation by vascular perfusion of mixed aldehydes (1% paraformaldehyde and 2.5% glutaraldehyde) in 0.1M phosphate buffer (PB), pH 7.4, at 4°C, brains are removed and the lateral geniculate bodies (LGBs) are dissected, with optic nerves and tracts attached. Tissues are immersed in a 30% sucrose-PB solution at 4°C until they sink, then washed in PB. A 7mm length of plastic tubing is fitted over an optic nerve's stump and filled with 152L of 30% HRP in water. Through this solution the nerve's cut end is punctured once with a fine pin. The blocks of tissue, with tubes attached, are stored at 4°C for 11 days. Light microscopy of HRP demonstrated in Vibratome sections with the metal-intensified DAB protocol revealed apparently complete, dense filling of optic fibers in both rats and quolls. The pattern we saw in the dorsal LGB of rats conformed to the pattern seen after in vivo HRP injections into the optic tract (Brauer et al., Exp Brain Res 69:481). Using 2% dimethylsulfoxide as the solvent, instead of water alone, produced weaker staining of acons and staining of LGB glia and neurons. Ultrastructurally we found electron-dense HRP reaction product in the LGB in association with myelin sheaths (around and within the myelin) and, in axons, along outer mitochondrial membranes and neurofilaments, and at retinogeniculate synapses.

Our results indicate that uptake, movement and deposition of HRP in prefixed tissues reveal the same structural relationships and level of detail as they do in living tissues. Therefore

28.10

Activity-dependent fluorescent staini of living rat motor nerve terminals with RH dyes W.J. Betz & G.S. Bewick, Dept. of Physiology, Univer-

sity of Colorado Medical School, Denver, CO 80262.
Exposure of rat 4th deep lumbrical (4DL) muscle for 60 min to the fluorophores RH414 or RH795 (170 uM; Molecular Probes, Inc.) stained motor nerve terminals weakly. However, terminals stained strongly after 15 min exposure to 44 uM RH dye if the muscle nerve was electrically stimulated, or after only 5 min exposure to 60 mM [K] in the presence of dye. The dyes were imaged best with the Leitz H3 cube (excite 420-490 nm; emit >510 nm).

The 4DL muscle receives innervation from two nerves. Electrical stimulation of only the smaller (sural) nerve caused only a few end plates to be stained. Subsequent electrical stimulation of the other nerve (or exposure of the muscle to high [K]) caused many more end plates to become visible. Replacing Ca with Mg and adding 4 mM EGTA during dye exposure did not block staining. Denervation of the muscle produced a loss of end plate staining with high [K] loading within 1-2 days. These data were obtained with adult rats; neonatal preparations gave similar results.

Some structures were stained in an activity-independent fashion. These included myelinated axons and sensory nerve endings (especially IA endings in muscle spindles, but also free sensory endings in tendons).

STAINING, TRACING AND IMAGING TECHNIQUES II

AUTOMATED DELINEATION OF NEUROANATOMICAL STRUCTURES. J. Nissanov, A. Waks*, McEachron, C.R. Gallistel, O.J. Tretiak*. Processing Center, Drexel University, Philadelphia, PA 19104 & Dept. of Psychology, University of California, Los Angeles, CA 90024

A major source of inaccuracy in the analysis of autoradiograms is trial-to-trial and inter-

variability in demarcation anatomical boundaries from the corresponding histology. To reduce this error, we have designed an algorithm which reproducibly locates boundary of neuroanatomical structures on itized images of histological sections. This digitized images of histological sections. This rule-based expert system selects the optimal border for the structure of interest from the set of all smooth boundaries in the vicinity of the expected border location. The boundary selected is that which overall traverses across the steepest grey-scale gradient. The expected boundary location in the vicinity of which the search area is confined is derived from a manually delineated computerized atlas or from the boundary located in one section and projected to subsequent sections in a series of consecutive sections (Supported by NIH Grant # 2 P41 RR01638)

CAJAL MEETS FRACTALS: FRACTAL ANALYSIS OF CAJAL'S NEURONAL IMAGES J. Clay Goodman. Department of Pathology (Neuropathology), Baylor College of Medicine, Houston, Tx 77030 Fractal geometry is the study of objects possessing non-integer

dimensionality. Such entities are known as fractals and they occur frequently in nature including such things as trees, clouds, snowflakes, and neurons. They are characterized by visual complexity and self-similarity. A fractal of dimensionality 1.0-2.0 has geometry lying in between that of a Euclidean line and plane whereas a fractal of dimension 2.0-3.0 lies between a plane and a solid. Fr dimensionality then is a measure of a fractal's ability to fill space.

The fractal dimensions of Cajal's neuronal images were measured using Kaye's structured walk technique to construct Richardson plots. Images were photocopied onto paper bearing grids of varying sizes, and the number of grids through which the perimeter of the neuronal image passed counted. The log of the perimeter was plotted against the log of the grid size. The slope of the line formed by connecting the log perimeter points corresponds to the fractal dimension of the image. The fractal dimensions of Cajal's images correspond to the visual complexity of the neurons. For example, Cajal's studies of pyramidal neurons in various vertebrates revealed increasing complexity with phylogeny. The fractal dimensions of these neurons climb steadily with

phylogeny and complexity.

Fractal analysis can be performed manually or can be computer assisted, and can be applied to previously acquired images. Fractal analysis provides a numerical method of expressing image complexity permitting comparision between objects. The technique has limitations in that it does not express asymmetry or scale so that fractals of different sizes and shapes may have the same fractal dimension.

AUTOMATED SYSTEMATIC-RANDOM THREE-DIMENSIONAL SAMPLING IN STEREOLOGICAL STUDIES OF GEOMETRICALLY COMPLEX COMPARTMENTS L.M.Bookman*, L.T.Malmgren,Dept. of Otolaryngology and Communication Sciences, Head and Neck Morphology Lab., SUNY Health Science Center, Syracuse, N.Y.13210

Stereological techniques rely on geometrical probability to provide statistically unbiased, precise and highly efficient estimates of 3-dimensional morphological parameters (eg. volume, surface, number, length, curvature). The use of "optical sections" (Acta Path Mic Immun Scand 96:857) and systematic random sampling greatly increases the efficiency and versatility of these techniques. However, the "optical section" technique generally requires the use of high power, high numerical aperture, oil immersion objectives to achieve a narrow depth of field (eg. 0.15 microns for Nikon 100X Plan Apo). It can be difficult to accurately confine sampling within the limits of the compartment of interest due to the loss of overall perspective at high magnification. In addition, the efficiency of systematic random sampling relies on the use of a randomly distributed, but regularly spaced lattice of sampling fields along the X,Y and Z axes, which is not practical to do manually. In order to further improve the efficiency and versatility of stereological techniques based on the use of "optical sections", a system has been developed which uses robotic control of X,Y,Z movements of the microscope stage to achieve a systematic random sampling field distribution within compartment borders of any shape traced by the user at low magnification via an optically-linked illuminated cursor. This system also greatly facilitates stratified, systematic random stereological sampling since sample fields can be robotically positioned within geometrical constructs with respect to reference structures (eg. a specified depth from a traced surface of any shape with sampling intervals at regular, but randomly positioned intervals along the reference surface). This equipment and software provides a powerful and general purpose tool for efficient, quantitative morphological analysis in a wide variety of applications.

METHODOLOGY FOR PLASTIC EMBEDDING OF WHOLE BRAIN

METHODOLOGY FOR PLASTIC EMBEDDING OF WHOLE BRAIN SPECIMENS AND EVALUATION OF ADJACENT SECTIONS BY ROUTINE HISTOLOGIC STAINS AND BY ELECTRON MICROSCOPY. D.L. Feeback,* R.A. Brumback, R.W. Leech, J.L. Ketring* Departments of Anatomical Sciences and Pathology, University of Oklahoma College of Medicine and Veterans Affairs Medical Center, Oklahoma City, OK 73104. We have previously reported a technique for embedding whole brain specimens using methyl methacrylate, a low viscosity xylene-soluble ester that readily infiltrates large tissue blocks (Brumback, et al., Ann. Neurol., 26:301, 1989). After polymerization, the block can be cut using a tungsten carbide knife on a sledge microtome. Sections picked up onto slides and dried can be stained (after xylene immersion to remove the plastic) with modifications of most routine paraffin staining techniques. We have now found that for detailed analysis, particular areas of the block can be cut out using a fine-toothed saw and sectioned using a glass for detailed analysis, particular areas of the block can be cut out using a fine-toothed saw and sectioned using a glass knife on a rotary microtome. Semithin sections can be stained with toluidine blue. Thin sections of the same area prepared on an ultramicrotome, picked up onto Formvar or carboncoated grids, and stained with uranyl acetate and lead citrate can be viewed with an electron microscope. Thus, this technique permits whole brain embedding, serial sectioning and staining of the whole block to identify specific areas of interest, and subsequent detailed evaluation of those areas in adjacent sections utilizing routine stains at the light microscopic level as well as with electron microscopy.

OBSERVATIONS OF NODE OF RANVIER STRUCTURE DURING SUSTAINED IMPULSE ACTIVITY IN SINGLE FROG AXONS. Stephen A. Raymond, Scott C. Steffensen, Mark H. Ellisman.

SUSTAINED IMPULSE ACTIVITY IN SINGLE FROG AXONS. Stephen A. Raymond. Scott C. Steffensen. Mark H. Ellisman. Department of Neurosciences, Laboratory for Neurocytology, University of California San Diego, School of Medicine, La Jolla, California 92093. Repetitive action potential propagation has been associated with ultrastructural alterations in peripheral nodes of Ranvier (Wurtz & Ellisman, J. Neurosci. 6:3133-3143, 1986). In these earlier experiments it was not possible to observe the structural changes directly and concurrently with the physiological events produced in the fiber during repetitive activation. Here we introduce a recording system and preparation that allows the observation of changes in structure in the nodal complex during electrophysiological monitoring of activity dependent changes in conduction properties of individual axons. The system resolves latencies to 1µs and digitizes and plots action potential waveforms (12 bit samples) (St samples/S) while recording video enhanced light microscopic images of nodal regions of the fibers being recorded electrically. The optical recording system employs video enhanced Nomarski DIC with image digitizing to 8 bits @ 512x512 pixels for obtaining and reviewing time lapse sequences.

Although diffuse structural changes occur in the nodal complex of frog sciatic nerve fibers that are independent of stimulation, we observe specific sub micron structural changes at densities corresponding to the paranodal loops even with mild levels of simulation (e.g., @ 1H2). More remarkable changes are observed when the fiber is subjected to stimulation paradigms that elicit more substantial activity dependent slowing of impulse propagation (20-30%). As depression of excitability (Raymond, J. Physiol. 2902/73-303, 1979) and impulse slowing develop, the density that emerges in the region of the paranodal loops during tonic stimulation marches toward the node. We are currently engaged in characterizing activity dependent structural dynamics of nodes.

COMPUTED IMAGE ALIGNMENT FOR OBJECTIVE 3D RECONSTRUCTIONS FROM ELECTRON MICROSCOPY. L.S. Hibbard, B.J. Dovey-Washington University School of Hartman*, and R.B. Page. Washington University School of Medicine, St. Louis, MO; UMDNJ/The Robert Wood Johnson Medical School, Piscataway, NJ; and The Pennsylvania State University College of Medicine, Hershey, PA.

Successful reconstruction requires accurate alignment Successful reconstruction requires accurate alignment of serial section images. In principle, alignments can be obtained from cross-correlation (CC) of image features (Frank, et al., Meth. Enzymol., 164:1, 1988) but in practice, correlation may be confounded by abrupt changes in the sizes and shapes of features, and by noise and sectioning artifacts. We have devised empirical solutions involving correlation of thresholded edges of variable weights obtained over variable-sized supports. For a more robust colution, and we are examining the effects of robust solution, and we are examining the effects of various image filters on the structure of the CC function peak density, since it is from that peak's location that the rotation and translation values are derived. Fourier the rotation and translation values are derived. Fourier measures of image similarity suggest (Van Heel, Ultramicroscopy, 21:95, 1987), for example, that for disparate features, alignment may be achieved by iterating over lowpass filtered images with increasing cutoff radii to obtain a least squares best fit.

These methods are applied in 3D reconstructions of the median eminence (ME) of the hypothalamus in support of

studies of neurohypophyseal blood flow. (Support: NIH NS15926)

REAL TIME MULTI-WAVELENGTH FLUORESCENCE IMAGING OF LIVING CELLS. Stephen J. Morris, Division of Molecular Biology and Biochemistry, School of Basic Life Sciences, University of Missouri-Kansas City, Kansas City MO, 64110-2499.

A new fluorescence video microscope design for simultaneous, real-time capture of intensified images of cells containing dual wavelength "ratio" dyes or multiple dyes at video frame rates (30 frames/sec or faster) has been described (BioTechniques 8:296-308 (1990)). Each emission wavelength is imaged by one of two cameras, then digitized, background corrected and combined on a single frame to be stored at high resolution on video tape or digital disk for further off-line analysis. Image intensifiers and CCD cameras produce stable, high contrast images at ultra-low light levels. The design has no moving parts, which overcomes a number of technical difficulties in designs using rotating filter wheels for multiple imaging. Coupled to compatible image processing software, the new design can be built for a significantly lower cost than presently available commercial systems. For ratio imaging, the software can calculate the ratio of the fluorescence intensities pixel by pixel at 30 ratios/sec, and generate false-color maps of ion concentrations as well as other calculations.

Examples are presented for the kinetics of rapidly changing

intracellular calcium detected by the calcium indicator probe indo-1 and emission from multiple vital dyes placed in cells undergoing cell fusion.

THRESHOLD FOR BEADING OF MYELINATED NERVE FIBERS PREPARED WITH COLD-FIXATION. S. Ochs, R. Pourmand and R. A. Jersild Jr. Depts.
Physiology/Biophysics, Neurology, and Anatomy, Indiana
Univ. Sch. of Med. Indianapolis, IN 46202.
Nerves subjected to a mild stretch and freeze-substituted

are beaded, this seen as a series of constrictions and swellings along the fibers. In the constrictions the cytoskeleton is compacted (Ochs and Jersild, Neurosci. 22: 1041, 1987) and this was used to show that slow transport carries cytoskeletal proteins down as soluble subunits (Ochs and Jersild, Neurosci. 33: 421, 1989). We recently found that fibers fixed with glutaraldehyde and paraformaldehyde at 0-5°C also retain beading (Ochs and Jersild, in prep). This was used to determine the tension needed to bead the fibers. Pieces of rat sciatic nerve were mounted so that the bands of Fontana, the wavy disposition of the fibers at rest, were seen. The bands disappeared when the nerves were lengthened 14-15% beyond their resting length at which point a tension of 0.6 gm caused a small degree of beading as seen in cold-fixed nerves. Tensions of 3-5 gm gave optimal beading with no further lengthening or beading seen with tensions up to 40 gm or more. Exposure to collagenase allowed a further small elongation with lower tensions of 0.3 gm giving rise to an exaggerated beading, a "hyperbeading" with longer constrictions and rounder swellings than usual. Fibers may show beading under physiological tensions, the collagen fibrils acting to prevent excessive beading.

INTENSIFIED VIDEO IMAGING OF NEURONAL POPULATION ACTIVITY. J. S. George and J. C. Fowler.

Los Alamos National Lab. MS-M882. Los Alamos, NM 87545. Neuronal membranes contain Ca²⁺ channels gated by ligand binding or

membrane voltage which can serve as useful correlates of cellular excitation. We have employed the Ca²⁺ indicator Fura-2 together with intensified video techniques to visualize spatial and temporal patterns of neuronal population activation in the rat hippocampal slice. Slices were preincubated at 30° C in Ringer's containing Fura-2 AM. Optical measurements used a photomultiplier or a Philips intensifier coupled to a CCD video camera via a pair of photographic lenses or a tapered fiber optic image guide. Bipolar electrical stimulation was delivered by twisted wire electrodes and field potentials were measured with a glass micropipette mounted on the motorized stage of an inverted microscope. Electrical stimuli were delivered every 4-6 sec, timelocked to the vertical sync of the video signal. Up to 256 8-bit images were summed, a baseline image was subtracted from each frame in the sequence, and 340/380 nm sequences were ratioed. The fluorescence transient had a peak latency of 20-40 msec with a 100-300 msec return to baseline and was typically 1% of total fluorescence. Images demonstrated focal activation of CA1 and dentate gyrus. Mn2+ quenched 30-40% of total fluorescence; difference imaging at higher magnification disclosed periodic intensity variations consistent with expected cellular structure. Responses were obtained with antidromic as well as orthodromic stimulation and were not eliminated by APV suggesting that the Ca2+ transient was associated with voltage-gated Ca2+ channels.

EXTRACELLULAR DYE INDUCES PHOTO-DEGENERATION AND PHOTO-PERMEABILIZATION OF VERTEBRATE INVERTEBRATE NEURONS

S. Picaud*1,2, H. Wunderer*1, L. Peichl 2 and N. Franceschini*1; (1) Lab. Neurobiology, CNRS, 13009 Marseille, FRANCE; (2) Dept. Neuroanatomy, MPI für Hirnforschung, 6000 Frankfurt, FRG.

Local irradiation of neural tissue in the presence of an extracellularly applied dye was found to trigger neuronal degeneration and permeabilization with interesting interesting degeneration and permeabilization with interesting applications in neuronal tracing and neuronal ablation. This phenomenon, first reported in fly photoreceptors (Picaud et al., Neurosci. Lett. 95: 24, 1988), has now been extended to (non photoreceptive) rat retinal neurons. A dye was applied to the extracellular space of the retina. A selected patch of neurons was irradiated in vivo for 30 minutes within the absorption band of the dye with the light of a conventional epithuorescence microscope. Immediately after the irradiation fluorescence microscope. Immediately after the irradiation, neurons and fibers displayed degenerative features and became permeable to Lucifer Yellow. After several days survival, degenerating neurons were phagocyted whereas en became permeable to Luciter Yellow. After several days survival, degenerating neurons were phagocyted whereas en passant fibers showed retrograde degeneration or neuronal regeneration. Control experiments demonstrated the involvement of dye-induced photosensitization in this photolesion technique which holds great potential as anatomical and physiological tool for investigating various nervous systems.

29.13

NONINVASIVE MEASUREMENT OF INTRACELLULAR/EXTRACELLULAR WATER RATIOS IN SPATIALLY DEFINED NEURONAL MICROVOLUMES USING MAGNETIC RESONANCE IMAGING. M.A. Martin, W.G. Tatton, C. Lemaire*, R.L. Armstrong*. Departments of Physiology and Physics

University of Toronto, Toronto, Ontario, Canada. M5S 1A8.

To non-invasively study the time course of fluid shifts between extracellular and intracellular (E/I) water compartments in the intact, living brain, we produced a method based on magnetic resonance (MR) imaging. T1 relaxation times from localized tissue subvolumes as small as 2.5 µL were measured using an extracellular relaxation-modifying probe (0.5 mM gadolinium-DTPA) assuming a fast exchange model (Martin et al., J. Mag. Res. 15;1, 1990) to provide tissue water ratios. This approach was tested in the central neuropil and the region of the fast flexor motoneuron (FFMN) giant somata within living, excised abdominal ganglia from crayfish (P. balangii). E/I water shifts were induced by changing extracellular osmolarity via sodium ion levels in a graded series between 270-5546 mOsm (norm.=400 mOsm). The shifts were completed in 20 minutes and were measured from the differences in the steady state levels for one hour before and one hour after the change. T1 recovery curves were found to be monoexponential in concert with the compartmental model we applied. The T1-derived measures were compared with: 1) the average cross-sectional area through the central ganglionic neuropil obtained from either MR images or computer measurement plastic sections immunoreacted either MR images or computer measurement plastic sections immunoreacted for neuron specific enolase as a marker of neuronal cytoplasm. 2) E/I ratios obtained in the FFMN region reconstructed from serial sections. The MR cross-sectional area measures slightly underestimated the histological volumes but linear correlation coefficients between the direct and the T1 relaxation measures ranged from 0.96 to 0.98. The T1 relaxation technique should be readily applicable to the intact rodent brain where nuclear or laminar dimensions are similar to the crayfish ganglia. It should allow measurements of the time course of water shifts that accompany the actions of excitotoxins in the intact, functioning brain. (Supported by MRC grant MT5218)

29.10

PKC LOCALIZATION IN <u>HERMISSENDA</u> CNS. <u>J.Farley</u>, Prog. in Neural Science, Indiana Univ., Bloomington, IN 47405. Previous research has implicated PKC activation as playing a critical role in the induction and maintenance of learning-produced changes in neuronal excitability in <u>H.c.</u> Confocal scanning microscopy, image analysis, and fluorescent derivatives of phorbol esters were used to monitor PKC in living whole mounted <u>H.c.</u> nervous systems. When incubated with 10⁻⁶M NDB-TPA-1 at 19-20°C, virtually all neurons within the pedal and cerebropleural ganglia rapidly accumulated the dye, reaching maximum fluorescence within ~ 20 min. In central neurons, NDB-TPA-1 fluorescence was primarily localized within somatic plasmalemma membranes and as yet unidentified subcellular organelles. Considerably less staining in nerves and axonal fiber tracts was observed. Fluorescence was also observed within somatic membranes of ocular photoreceptors and statocyst hair cells, with little staining observed in photoreceptor rhabdomeres. Pre-incubation with unlabeled TPA decreased the fluorescence of NDB-TPA-1 stained neurons in a dose-dependent manner. Incubation of nervous systems with lower concentrations of NDB-TPA-1 (100-500 nM) resulted in a pattern of staining which was both less intense and less localized to the membrane. Under these conditions, treatment of nervous systems with the calcium ionophore A23187 resulted in fluorescent staining of membranes, reflecting an apparent translocation of the PKC-bound fluorophore.

29.12

DOUBLE-LABELLING FLUORESCENCE FOR SIMULTANEOUS IMAGE ANALYSIS OF BBB-INTEGRITY AND MICROVASCULAR PERFUSION IN FOR SIMULTANEOUS IMAGE FOCAL BRAIN INJURY, Lindsberg P J. Sirén A-L. Hallenbeck J M*. Dept. of Neurology, USUHS, Bethesda, MD 20814

Since brain injury and ischemia involve localized areas of neuronal vulnerability and microvascular failure, methodology with high spatial resolution is mandatory to monitor the hemodynamic microenvironment of maintactry to monitor the newtoynamic microenvironment of discrete neuron populations. Two fluorescent dyes (Evans-Blue albumin (EBA), FITC-dextran) were infused to map simultaneously microvascular perfusion deficits and BBB-leakage in progressive focal Nd-YAG laser-induced (1.0s, 20W) secondary brain damage in rats. EBA was allowed to circulate for 30 min and mark BBB-damage and FITC-dextran was infused 20 s before decapitation. Fresh-frozen sections were laser-excited at 488 mm, emissions were optically split, individually detected, quantitated and recombined with computerized image-analysis. In an article processing legislation and acutely progressive lesion, the ongoing BBB-damage and capillary perfusion deficit coexisted in the penumbral zone surrounding neuronal necrosis in this model. Acute regional perfusion impairment without BBB-opening was observed (0.5-2 hrs after injury) in the CA1 hippocampal region, an area of delayed neuronal death at 24 hrs. This technique permits high-resolution temporal and spatial correlation of focal microvascular derangements to neighboring neuronal damage.

COMPOUND 48/80 INCREASES NEURONAL EXCITABILITY WITHOUT MAST CELL ACTIVATION. T.J. Heppner and

VI. F. Fiekers. Dept. Anat. and Neurobiol., Univ. of Vt. Coll. Med., Burlington, VT 05405.

The action of compound 48/80 was examined in sympathetic ganglion cells located in the 9th and

rine action of compound 48/80 was examined in sympathetic ganglion cells located in the 9th and 10th ganglion of Rana catesbeiana. When treated with compound 48/80, intracellular recordings obtained from B-type ganglion cells showed a reversible reduction in: 1) the duration of the AHP from (mean+S.E.) 282+28.0 ms to 129+17.1 ms (n=7), 2) the current underlying the AHP from 0.89+0.144 nA to 0.29+0.075 nA (n=8) and, 3) the amplitude of the EPSP following an evoked spike.

The action of compound 48/80 was primarily postsnayptic, because puffer applications of ACh showed a concentration-dependent (0.25-25 ug/ml) decrease in the amplitude of the ACh potential. Compound 48/80 increased the number of spikes evoked during depolarizing pulses both in intact and dissociated ganglion neurons. These findings suggest that compound 48/80 has actions on ganglion neurons, which include a direct action to increase neuronal excitability. Supported by NIH grant #NS27319 to JFF.

CHARACTERIZATION OF VESICULAR CARRIERS AT NERVE MUSCLE CONTACTS. S. Bursztain. Y.J. Jong. and S.A. Berman. Baylor College of Medicine and M.D. Anderson Mospital, Houston, Texas 77030

Our previous studies have shown that both acetylcholine receptors (AChRs) and acetylcholinesterase (AChE) are transported via coated vesicles some of which accumulate beneath the neuromuscular synapse where AChRs cluster. To investigate the mechanisms by which these proteins are transported and the remodeling which the postsynaptic membrane undergoes, we have purified coated vesicles and have raised monoclonal antibodies to the epitopes of the vesicular membranes. We isolated vesicles and purified them on Sephacry S-1000 columns. We checked fractions for purity by assaying for 1) AChE (coated vesicle enriched) 2) hexosamindase (lysosomal contaminants) and 3) NADH cytochrome C reductase (mitochondrial). We obtained 95% pure coated vesicles, as judged by electron microscopy using negative staining with 2% uranyl acetate, and used them (after removing their coats) as immunogens to prepare monocolonal antibodies: G-33, Cl71 and F-22. Immunoblots of purified vesicles revealed that mab C-33 stained a 180K band and almounofluorescence revealed punctate staining. C-171 stained a 100K band and also gave punctate immunofluorescence revealed punctate staining. Stained a 180K band and c-171 stained a 100K band. The distribution of punctate fluorescence appears to depend upon the stage of myotube development. Myotubes stained with C-33 or Cl71 3-4 days after plating show punctate fluorescence throughout the myotube, whereas those stained 8 days after plating show a punctate perinuclear distribution. Myotubes inmervated by cfliary neurons show punctate fluorescence throughout the myotube, whereas those stained most concentrated around nuclei which are located beneath the neurons. We suggest these vesicles may be involved in membrane insertion and removal at the neuronuscular synapse.

M-CURRENT SUPPRESSION AFTER MANIPULATION OF MEMBRANE PHOSPHORYLATION. J.A. Zidichouski, H. Chen* and P.A. Smith. Dept. of Pharmacology, Univ. Alberta, Edmonton, Canada, T6G 2H7.

There is considerable interest in the possible role of cytosolic second messengers in agonist-induced M-current (I_M) suppression. This

induced M-current ($I_{\rm M}$) suppression. This mechanism would involve phosphorylation (or mechanism would involve phosphorylation (or perhaps dephosphorylation) of the channel protein. We tested this possibility using the whole-cell patch-clamp technique to study $I_{\rm M}$ suppression by 2 μ M muscarine in Rana pipiens sympathetic neurones. Inclusion of 1 or 2 μ M ATP-gamma-S in the pipette, which either reduces steady-state membrane phosphorylation (by antagonising ATP) or promotes irreversible 'thiophosphorylation', decreased steady-state $I_{\rm M}$ to 56.1 \pm 11.5 \pm 8 (n=8) of control after 10 μ m in Despite this, muscarine always produced the same Despite this, muscarine always produced the same percentage depression of the remaining $I_{\rm M}$. Also, inclusion of the phosphatase inhibitor, diphosphoglyceric acid (lnM) failed to alter the amplitude or duration of muscarine-induced responses. These results are inconsistant with the involvement of phosphorylation and/or dephosphorylation mechanisms and cytosolic second messengers. Receptors may instead be 'directly coupled' to M-channels via a G-protein.

EFFECT OF CCK ON GUINEA PIG CELIAC GANGLIA NEURONS, IN PRIMARY CULTURE. S.R. Knoper, T.L. Anthony, D.L. Kreulen. University of Arizona, Department of Internal Medicine and Pharmacology, Tucson, AZ 85724.

Pressure ejection of cholecystokinin (CCK)

depolarizes guinea pig sympathetic neurons in intact ganglia. Our goal was to analyze CCK's cultured sympathetic effects in primary cultured sympathetic neurons. Dissociated neurons from adult guinea pig celiac ganglia were maintained in primary culture for 1 to 4 days prior to whole cell recording. Cell attached patch recording (n=4) revealed spontaneous channel activity control periods. Pressure ejection of CCK (100 ms, 10⁻⁶ M) elicited an increase in open time. In whole cell recording mode CCK produced an in whole cell recording mode ctx produced an inward current at a holding potential of -100 mV which reversed at -30 to -50 mV (n=2). Peak amplitude ranged from -400 pA at -100 mV to 500 pA at +20 mV. Two cells showed only outward currents at potentials from -100 to +100 mV. These results suggest that there exists a non-specific cation channel mediating the CCK induced slow depolarization in prevertebral sympathetic neurons. Supported by DK36289, HT-27781.

EFFECTS OF AMMONIA ON PRESYNAPTIC AND POST-

SYNAPTIC GLUTAMATERGIC FUNCTION

J. Lavoie¹, O. Le*¹, P. Fan*², J.C. Szerb² and R.F. Butterworth¹,

Lab. of neurochemistry, CRC A-V, Hôpital St-Luc, Montreal, Que.

H2X 3J4 and ²Dept. of Physiol. and Biophysics, Dalhousie

University, Halifax, N.S., Canada

In order to elucidate the mechanisms involved in the inhibition of synaptic transmission by ammonium ions, the effects of pathophysiologic levels of NH₄Cl on glutamate release and on synaptic transmission from Shaffer collaterals to CA1 pyramidal cells was measured in hippocampal slices from control and portacaval shunted (PCS) rats. Synaptic transmission in control slices was reversibly depressed by NH₄Cl levels in excess of 1 mM. Firing of CA1 pyramidal cells evoked by electrophoretically applied glutamate was inhibited by 2 mM NH₄Cl. 5mM NH₄Cl had no effect on Ca²⁺-dependent release of glutamate evoked by electrical stimulation of slices. PCS rat hippocampal slices superfused with NH₄Cl showed significantly increased glutamate release. This latter finding probably results from decreased glutamate uptake into damaged perineuronal astrocytes following portacaval shunting. Taken together, these observations suggest direct toxic effects of ammonia on glutamate release as well as on postsynaptic glutamatergic transmission in the central nervous system. Such effects could be involved in the neuronal dysfunction associated with acute or chronic hyperammonemic states

EFFECTS OF CHANGES IN EXTRACELLULAR pH (pH_o) ON MEMBRANE PROPERTIES OF RAT CA1 HIPPOCAMPAL PYRAMIDAL NEURONS IN VITRO. J. Church. Dept. of Physiology, Univ. of British Columbia, Vancouver, B.C., Canada V6T 1W5.

The effects of changes in pH_o, elicited by changing [HCO₃]_o at a constant P_{CO2}, on membrane properties of CA1 pyramidal neurons in hippocampal slices prepared from adult rats.

hippocampal slices prepared from adult rats were examined using intracellular recording techniques. Reducing pH₀ to 6.9 attenuated high-threshold Ca²⁺ spikes, the slow after-hyperpolarization following a current-evoked train of action potentials, spike frequency adaptation depolarizing after-notations. adaptation, depolarizing after-potentials, and the rebound depolarization following a current-evoked hyperpolarization to >-80 mV. Raising .9 produced qualitatively opposite
The results suggest that changes in to ¹7.9 pH_O within the pathophysiological range might be an important mechanism whereby transmembrane Ca²⁺ flux and/or cytosolic free [Ca²⁺] is modulated and indicate at least one mechanism whereby carbonic anhydrase inhibitors such as acetazolamide might exert anticonvulsant activity and how mild acidosis might exert a neuroprotective effect. Supported by the Medical Research Council of Canada.

GABAERGIC SYNAPTIC CURRENTS IN SLICES OF NEOCORTEX ANALYZED WITH WHOLE-CELL AND CELL-DETACHED PATCH-CLAMP TECHNIQUES. A.R. Kriegstein and J.J. LoTurco. Dept. of Neurology and Neurological Sciences, Stanford Univ. Sch. of Med., Stanford, CA 94305 In order to study fundamental properties of GABAergic inhibition in the neocortex we have made both whole-cell and outside-out patch-clamp recordings from pyramidal neurons in slices of rat neocortex.
Whole cell recordings were obtained as described by Blanton et. al. (1989). Spontaneous synaptic currents (mean conductance = 457 pS) were shown to be mediated by GABAa receptors by their sensitivity to bicuculline methiodide and picrotoxin (PTX). As little as 0.5 uM bicuculline was effective at blocking these spontaneous currents, indicating that an effective GABA concentration of below 5 uM is reached at the synaptic cleft. The decay of spontaneous GABAergic synaptic currents increased with depolarization from a time constant of 34 msec at -70 mV to 150 msec at 40 mV. After recording synaptic currents in the whole-cell configuration, electrodes were slowly removed from the slices to form outside-out patches. The patches were then moved rapidly between different concentrations of GABA. The resulting macroscopic currents had an EC50 of 1 uM and exhibited desensitization that became faster with increasing GABA concentration (tau = 3 sec in 1 uM GABA and 830 msec in 1 mM GABA). Following the removal of GABA, macroscopic currents decayed exponentially. This decay largely reflects the off rate of GABA from receptors, and similar to the decay of synaptic currents, increased with depolarization from 65 msec at -70 mV to 10 units of GABA in the constraint of the decay of synaptic currents with a major unitary conductance of 23 pS and rarely occurring minor conductances of 7 more reports, and similar to the decay of synaptic currents with a page of the synaptic currents are largely determined by activation and deactivation and not by desensitization.

INTRADENDRITIC RECORDINGS FROM IDENTIFIED SITES IN CA3 HIPPOCAMPAL PYRAMIDAL CELLS. <u>K.L. Smith,* J.N. Turner, D.H. Szarowski</u>* and <u>J.W. Swann</u>. Wadsworth Center for Labs and Research, NY State Dept. of Health, Albany, NY

Recent reports suggest that ion channels are not uniformly distributed in the membranes of dendrites of CNS neurons. Previous indradendritic recordings in hippocampal slices have been assumed when impalements were made some distance from the cell body layer. However, precisely where in the dendritic tree an impalement was made was unknown. In experiments reported here recordings were made from stratum radiatum of the CA3 subfield with microelectrodes filled with either lucifer yellow or carboxyfluorescein. After electrophysiological characterization of the impaled element the cell and electrode were imaged by video microscopy. This was achieved by using a SIT camera mounted on a stereomicroscope, equipped with an epifluorescence illuminator. Framed averaged images were stored on VCR tape. Afterwards slices were fixed and the cell was again imaged. This time by confocal laser scanned microscopy. A graphics workstation was employed for three dimensional reconstruction. By direct comparison of images from video and confocal microscopy, the precise location in dendrites where recordings wer obtained could be identified in 3 dimensional space. Such methods should allow a detailed examination of the differential distribution of voltage gated conductances in dendrites. Support NS18309, RR02984, RR01219.

LACK OF OUTWARD CI TRANSPORT AND LATE DEVELOPMENT OF HYPERPOLARIZING IPSPs IN HIPPOCAMPAL CAI NEURONS OF THE L. Zhang & P.L. Carlen, Playfair Neurosci. Unit, Toronto Western Hosp., Dept. of Physiology, University of Toronto

We studied the mechanisms underlying the late development of GABA_A-mediated IPSPs in postnatal 2-5 (P2-5) and 7-14 (P7-14) day old rats, using whole cell patch recordings in hippocampal slices. Slices were perfused with standard ACSF ([CI]=130 mM). Patch pipettes were filled with KGluconate, and the pipette [CI] was adjusted as required. Postsynaptic potentials were evoked orthodromically from stratum radiatum. GABA was applied onto the soma by pressure injection in the presence of TTX. The table summarizes the resting potentials and reversal potentials for IPSP (E_{IPSP}) and GABA currents (E_{GABA}) in the two groups of neurons. The E_{IPSP} and E_{GABA} were 6 to 14 mV positive in P2-5 neurons compared to those of P7-14 neurons at each different internal [CI]. When pipette solutions contained [CI] of 15-30 mM and the extracellular [K] was increased from 2 to 15 mM, there was no 13-30 mM and the extracellular [K] was increased from 2 to 15 mM, there was no change in E_{0,BAB} in P2-5 neurons (n=10), whereas a depolarizing shift of 11.8 ± 6.1 mV (n=13, mean \pm S.D.) was found in P7-14 neurons. We conclude that a lack of outward Cl transport may account for the absence of the hyperpolarizing IPSP in P2-5 neurons. Supported by the MRC of Canada.

ANTIFACILITATION AT A RECTIFYING ELECTRICAL

SYNAPSE. D.H. Edwards, W.J. Heitler & E.M. Leise, Department of Biology, Georgia State University, Atlanta, GA 30303.

Mechanosensory interneurons (MSIs) in the crayfish abdominal nerve cord make electrical connections with the Lateral Giant (LG) interneuron, which is the command neuron for tailflip. Single impulses in one MSI, interneuron A (Int A) evoke 1 mV EPSPs in the proximal segment of LG. Stimulation at 300 Hz produces summating PSPs that rapidly decrease in amplitude as a 2 mV plateau depolarization is achieved. The first PSP in the train is of normal size, but the fifth and all subsequent PSPs are reduced by 90%, to 0.1 mV.

Because PSPs from ohmic electrical synapses will sum linearly in passive dendrites, we considered the possibility that synapses between MSIs and LG were rectifying rather than ohmic electrical connections. We found that hyperpolarizing, but not depolarizing current will spread from LG to Int A, whereas depolarizing, but not hyperpolarizing current will spread from Int A to LG. Orthodromic PSPs increase in amplitude when LG is hyperpolarized and decrease when LG is depolarized; antidromic PSPs in Int A from LG impulses increase when Int A is depolarized and decrease when it is hyperpolarized.

We conclude that the antifacilitation results from the postsynaptic depolarization created by the summed PSPs. The depolarization will reverse-bias the rectifying electrical synapse and thereby limit further entry of synaptic current. It may also activate any existing dendritic membrane conductances that would shunt the postsynaptic current. We are investigating the relative importance of these two mechanisms. Supported by NIH Research Grant NS26457.

ADENOSINE DECREASES CALCIUM ENTRY IN RAT LOCUS COERULEUS NEURONS. W.J. Pan, S.S. Osmanovic, and S.A. Shefner. Dept. of Physiology and Biophysics, University of Illinois College of Medicine, Chicago, IL 60612.

We have previously shown that adenosine may activate a K⁺ conductance that leads to hyperpolarization in locus coeruleus (LC) neurons. In the present study, the effect of adenosine on the shape of the action potential was examined. Intracellular recordings from LC neurons were obtained in a submerged rat brain slice preparation. All drugs were administered by bath application. LC neurons fired spontaneously at rates of 0.1 to 3.5 Hz. Adenosine (100 μ M) reduced the peak afterhyperpolarization (AHP) following spontaneous spikes in 57% of cells (n=7). The reduction of the peak AHP was 1.5±0.2 mV (mean±S.E.M.). In 86% of these cells, the late phase of the AHP was increased, which was associated with a decrease in firing rate. 2-chloroadenosine (2CA) (1-2 μ M) reduced the peak AHP in all cells tested (1.4±0.2 mV, n=5). Ba²+ (1 mM) was added to the superfusate to enhance the calcium component of the spike. Adenosine (100 μ M) reduced the duration of the Ba²⁺ spike measured at 33% of the peak amplitude (12.7±6.8%, n=3). 2CA (1 μ M) also reduced the duration of the Ba²⁺ spike (10.6±1.2%, n=7). The effect of 2CA on the duration of the spike was concentration-dependent. Adenosine (100 μ M) reduced the amplitude of TTX-resistant "Ca2+ action potentials" by 5.2 ± 1.3 mV and also reduced the peak AHP by 1.8 ± 0.3 mV (n=4). The adenosine-induced reduction of the amplitude of TTX-resistant "Ca²⁺ spikes" and the duration of Ba²⁺ spikes suggests that adenosine decreases Ca2+ entry in LC neurons.

MODELLING CHANGES IN [Ca²⁺]; IN HIPPOCAMPAL CA3 NEURON BY VOLTAGE-GATED Ca²⁺ CHANNELS. D.B. Jaffe and D. Johnston, Div. of Neurosci., Baylor College of Medicine., Houston, TX 77030.

Recent work in our laboratory indicates that the induction of mossy fiber LTP in area CA3 of the hippocampus is dependent upon postsynaptic depolarization and an increase in $[{\rm Ca^{2+}}]_i$, but independent of NMDA receptor activation. Our working hypothesis is that voltage-gated ${\rm Ca^{2+}}$ channels proactivation. Our working hypothesis is that voltage-gated Ca^{2+} channels provide a source for raising $[Ca^{2+}]_i$. A multi-compartmental model of a CA3 pyramidal cell was created using CABLE (Hines, J. Biomed. Comput. 24:55, 1989) to examine changes in $[Ca^{2+}]_i$ produced by postsynaptic depolarization. Low- and high-threshold, inactivating Ca^{2+} conductances and a high-threshold, non-inactivating Ca^{2+} conductance were added to CABLE. Ca^{2+} conductances were located on spines as well as on dendrites and somata. $[Ca^{2+}]_i$ was regulated by the three Ca^{2+} currents, Ca^{2+} buffering, a Ca^{2+} extrusion pump, and by best partial and largetization diffusion. Descharing was achieved at and by both radial and longitudinal diffusion. Depolarization was achieved either through a change in synaptic conductance with appropriate kinetics at the spine head or by a comparable somatic depolarizing current injection. There spine head or by a comparable somatic depolarizing current injection. There was no difference between peak $[\mathrm{Ca^{2+}}]_i$ achieved by synaptic current versus somatic current injection. Peak $[\mathrm{Ca^{2+}}]_i$ was higher at the spine head than in dendrites due to larger surface to volume ratios. However, $[\mathrm{Ca^{2+}}]_i$ decayed faster in spines than in dendrites due to longitudinal diffusion. In addition, we examined the effect of two $\mathrm{Ca^{2+}}$ chelators, EGTA and BAPTA, on $[\mathrm{Ca^{2+}}]_i$ transients. Both EGTA and BAPTA at low concentrations $(10\text{-}20~\mu\mathrm{M})$ were effective at buffering $\mathrm{Ca^{2+}}$ following depolarization. During depolarization, however, a concentration of EGTA 100 times that of BAPTA was required to comparably buffer $[\mathrm{Ca^{2+}}]_i$. Changes in $[\mathrm{Ca^{2+}}]_i$ within small, distal distal dendritic spines and larger, proximal thorny excrescences was also compared. (Grants NS11535, MH44754, and AFOSR 88-0142)

ELECTROPHYSIOLOGY OF NICOTINIC ACTION IN RAT MEDIAL PONTINE RETICULAR FORMATION IN VITRO.

U. Gerber, D.R. Stevens, R.W. McCarley, and R.W. Greene.

Harvard Medical School/VAMC, Brockton, MA 02401

The medial pontine reticular formation (mPRF) receives cholinergic afferents from pontine cholinergic nuclei. Previous studies have characterized muscarinic cholinergic effects in the mPRF which have been implicated in the generation of REM sleep. The nicotinic agonist, diphenylpiperazinium (DMPP), was bath applied (5-40 µM) for 1 minute to neurons of the mPRF during intracellular recording using an in vitro brainstem slice preparation. In 8 of 13 neurons, DMPP caused an increase in membrane conductance associated with an inward current (0.1-0.5 nA). The reversal potential for this response was extrapolated to be close to 0 mV. This would be consistent with a nonspecific cation channel. In 3 of 13 cells, DMPP caused an increase in conductance associated with an outward current. The reversal potential for this response was examined in two of these three cells and was found to be -85mV in [K], of 5mM. The conductance, which was blocked by 10mM TEA, showed marked inward rectification at membrane potential positive to -70 mV. Nicotine (400 µM) evoked the same response as DMPP. With both types of response to DMPP, exposure to tetrodotoxin had no effect consistent with a postsynaptic site of action. DMPP had no effect on two cells which did respond to muscarinic agonists. Three cells in the median raphe nucleus in the same slice from which mPRF neurons were recorded also did not respond to DMPP.

BURSTING AND NONBURSTING NEURONS IN THE RAT DORSOLATERAL SEPTAL NUCLEUS. M. J. Twery, K. D. Phelan, and J. P. Gallagher. Department of Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX 77550

Electrical activation of neurons in the dorsolateral septal nucleus (DLSN) entrains the activity of medial septal neurons and facilitates expression of hippocampal rhythmical slow wave (theta) activity in a frequency dependent manner. In order to characterize the firing properties of spontaneously active DLSN neurons, we have examined membrane potential (V_m)-dependent

DLSN neurons, we have examined membrane potential (V_m)-dependent changes in repetitive firing using intracellular recording techniques and a submerged slice preparation of septum in vitro.

DLSN neurons were spontaneously active at rest (V_m=-67mV) and exhibited a rhythmic pattern of either single spike (n=9) or burst (n=25) firing. In the majority of nonbursting neurons, single spikes were followed by a prominent afterhyperpolarization. In bursting DLSN neurons, an initial fast spike was followed either by a prominent shoulder giving rise to 1-2 high threshold spikes or by a train of spikes arising at increasingly depolarized threshold levels. When hyperpolarized (5-10mV) by current injection, neurons which fired in bursts at the resting V_{ex} exhibited single spike activity (50%). On which fired in bursts at the resting V_m exhibited single spike activity (50%). On the other hand, hyperpolarization of nonbursting neurons from the resting V_m produced burst firing (60%). Both of these effects were reversed when V_m was restored to resting levels.

The present study demonstrates DLSN neurons have burst and nonburst modes of spontaneous activity and suggests the existence of neuronal subtypes with distinct intrinsic membrane properties. Similar burst discharges from DLSN neurons in vivo may underlie facilitatory effects of DLSN stimulation on hippocampal theta rhythm.

A TRANSIENT ELEVATION OF INTERNAL CALCIUM IS ASSOCIATED WITH THE ONSET OF A LONG-LASTING CHANGE IN EXCITABILITY OF BAG CELL NEURONS T.E.Fisher, S.Levy and L.K.Kaczmarek. Dept. of Pharmacology, Yale Univ. Sch. Med., New Haven, CT 06510 and Dept. of Physiology, Boston Univ., Boston, MA 02118

Following a train of action potentials stimulated via an afferent nerve, the bag cell neurons of *Aplysia* depolarize by 20-30mV and begin to generate action potentials repetitively. This afterdischarge continues for about 25 minutes while the membrane potential gradually repolarizes. We have measured internal calcium (Ca.) in bag cell neurons during the afterdischarge using calcium selective (double-barrelled) electrodes. There is a large but transient (30 to 120 sec.) increase in Ca, during the onset of the afterdischarge. This is followed by a smaller, gradual build-up of Ca, over the remainder of the afterdischarge. When calcium in the external medium is replaced with barium an early increase in Ca, still occurs, indicating that this elevation involves release of Ca from intracellular stores. In external media lacking both calcium and barium, stimulation results in neither the increase in Ca, nor the depolarization that underlies the afterdischarge. This depolarization is not prevented by removal of sodium from the external medium. Our results suggest that release of calcium from intracellular stores accompanies the afterdischarge and that an increase in Ca, is necessary for the initiation of the afterdischarge.

30.16

EFFECTS OF APAMIN ON CHOLINERGIC AND NON-CHOLINERGIC MEDIAL SEPTAL/DIAGONAL BAND (MS/DB) NEURONS OF THE GUINEA PIG IN VITRO. R.T. Matthews and W.L. Lee, Department of Anatomy, Texas A&M University, College Station, TX 77843.

The MS/DB region contains a variety of electrophysiologically distinct types of

neurons. One cell type recorded in vitro is slow firing with a broad action potential and a slow (200-800 msec) after hyperpolarization (S-AHP) seen after single action potentials. These neurons stain positively for acetylcholinesterase and are presumed to be cholinergic (Neurosci. Lett., T1:169-174, 1986). The present experiments were done in an in vitro brain slice preparation of the MS/DB region. We tested the hypothesis that S-AHPs regulate the firing rate of cholinergic MS/DB neurons. The bee venom toxin, apamin, was used to selectively block the Ca2+-dependent K+ conductance responsible for the S-AHP.

In extracellular unit recording experiments where firing was maintained by microiontophoresed glutamate, apamin at 3-30 nM increased firing of cholinergic neurons in a dose-related fashion (250 \pm 55% increase at 30 nM, n=5), but had much less effect on fast firing non-cholinergic neurons (35 \pm 7% increase, n=9). In intracellular current clamp experiments, apamin (30 nM) blocked the S-AHP but not other AHPs in cholinergic neurons (n=6) and increased firing induced by current injection from a constant holding potential (>100% increase, n=4). Some, current injection from a constant holding potential (>100% increase, n=4). Some, but not all, non-cholinergic MS/DB neurons had a 20-150 msec AHP which was blocked by apamin (30 nM, n=5). Firing rate after current injection was unchanged or moderately increased (<100%) by apamin in these cells. In all cell types, the percent increase in firing rate caused by apamin was dependent upon the size of the depolarizing current pulse.

Our results suggest that the S-AHP found in cholinergic MS/DB neurons is important for their characteristic slow firing rate.

30.18

OSCILLATORY ACTIVITIES OF THALAMOCORTICAL OSCILLATORY ACTIVITIES OF ITALIAMOCONTICAL CELLS: PHYSIOLOGY, PHARMACOLOGY AND LOW-DIMENSIONAL DYNAMICS. V. Crunelli, N. Leresche, D. Jassik-Gerschenfeld, A. Aszodi and I. Soltesz. Dept. Visual Science, Inst. Ophthalm., London; MRC Unit, Dept. Pharm., Oxford and Inst. Neurosci, Univ. P. & M. Curie, Paris.

Thalamocortical cells in vitro (0.5-0.8mM Mg²⁺ and 2.2-3.0mM

Thalamocortical cells in vitro (0.5-0.8mM Mg²* and 2.2-3.0mM Ca²*) are capable of generating four types of membrane potential oscillations that are unaffected by TTX, GABA_R, GABA_B and non-NMDA excitatory amino acid antagonists: i) the "pacemaker" oscillations (0.5-2.5Hz, present between -60 and -70mV) that consist of rhythmic, low threshold Ca²* potentials; ii) the "NMDA" oscillations (2-4Hz, present only in 0mM Mg²*) which lack rhythmic, pacemaker properties and show additional depolarizations on the falling phase of the low threshold Ca²* potentials; iii) the "spindle-like" oscillations, which are similar to the "pacemaker" type but occur in discrete periods every 5-20sec; iv) an oscillation, consisting of a slow (3mV/sec) hyperpolarization followed by a slow and a faster depolarization that bring the membrane potential back to its original level (full cycle: 35-90sec). original level (full cycle: 35-90sec).

The dynamics of the "pacemaker" and the "NMDA" oscillations is

low-dimensional and has properties indicative of chaos. Selective blockade of NMDA receptors, which transform the latter into the former type of oscillation, result in reproducible changes of the calculated dimensions.

ANTIDEPRESSANTS ACTION SITES IS ON THE or SUBUNIT OF G PROTEIN. H.Yamamoto*;U.Tomita*;M.Mikuni¹,A.Kagaya*;I.Kobayashi*;T.Katada*²& K.Takahashi*¹(SPON:M.Mikuni). Div. Mental Disorder Res., Natl.

Institute of Neurosci., NCNP, Tokyo 187, Dept. Life Sci., Tokyo Institute of Technol., Yokohama 227
Our previous study showed that antidepressant (AD) affects the in vitro [3H]GTP binding in the rat crude cortex membrane, in a pertussis toxin (PTX) sensitive manner, suggesting an important role of Gi/Go. To investigate the direct action of AD on the function of G protein, we examined the effect of various ADs on the GTPase activity using purified Go. A dose-dependent activation of the GTPase activity was observed in the presence of typical or atypical AD except MAO-I.Lineweaver Burk analysis of the GTPase activity with AD revealed a decreased affinity and an increased catalytic rate for GTP. These results suggest that one of the action sites of AD is on the Go, and that AD causes dissociation of α o subunit from $\beta\gamma$. The enhancement of GTPase activity by AD was moderately prevented by PTX-induced ADP-ribo-sylation. In addition, AD antagonized the effect of receptor-resemble activator. Taken together, these results lead to provide a hypothesis that AD may decrease the efficiency in transmembrane signalling to shorten $\alpha o\text{-GTP}$ complex state.

EARLY AND LATE ALTERATIONS OF TRANSDUCTIONAL GTP-BINDING PROTEINS IN THE CENTRAL NERVOUS SYSTEM OF DIABETIC ANIMALS. M.P. Abbracchio, F. Cattabeni, A.M. Paoletti *A.M. Di Giulio*, M.L. Malosio*, B. Tenconi** and A. Gorio, Inst. Pharmacol. Sciences., School of Pharmacy, Dept. Med. Pharmacol., School of Medicine, Univ. of Milano, 20133 Milano, Italy

Alterations of cell-to-cell communication seem to develop in the CNS of alloxan treated diabetic rats as a consequence of the pathology. We have shown that Gs- and Gi-mediated transductional processes are altered in late shown that Gs- and Gi-mediated transductional processes are altered in late diabetes, i.e. 14 weeks after alloxan-injection (Abbracchio et al., J. Neurosci. Res. 24:517-523, 1989). In this study, we have monitored the onset of such transductional alterations in various CNS tissues at early and late stages of the pathology (5 and 14 weeks after diabetes induction, respectively) by measuring Gs and Gi modulation of adenylate cyclase activity and by direct 32-P-ADPribose radiolabelling of G protein subtypes with pertussis (PTX) and cholera (CTX) toxins. Results show that the retina is precociously compromized in diabetic animals. In 5 week diabetes, when no consistent alterations were detected in the other examined CNS regions, an early reduction of retinal PTX-sensitive G-proteins was observed, which was causally related to the pathology being reversed by treatment of diabetic reduction of refunal PTA-sensitive G-proteins was observed, which was causally related to the pathology, being reversed by treatment of diabetic animals with insulin. At later stages of diabetes, also Gs proteins were markedly affected, as shown by both adenylate cyclase studies and CTX-radiolabelling. These data therefore suggest that an early defect of Gi/Go proteins might be responsible for the detected transductional changes, which is later followed by involvement of also Gs proteins.

SYNAPTIC TRANSMISSION

TPA, FORSKOLIN AND BACLOFEN CHANGE THE SUBCELLULAR DISTRIBUTION OF SMALL CTP-BINDING PROTEINS IN PRIMARY CULTURES OF RAT CEREBELLAR NEURONS. R.E. Paulsen. E. Costa and D.R. Grayson FIDIA-Georgetown Inst. for Neurosciences, Georgetown University, Washington, DC 20007

Two classes of GTP-binding proteins have been identified in mammalian tissue, based on differences in molecular weight. G proteins are heterotrimers transducing receptor-mediated signals across plasma membranes to specific effector systems. The functions of the "low molecular weight GTP-binding proteins" (20-30 kDa) or ras-related proteins, are still unknown. The subcellular distribution of small (low molecular weight) GTP-binding proteins was examined using a [8-32P]CTP blot binding assay on protein fractions prepared from primary cultures of rat cerebellar granule cells. At least 4 different sizes of GTP binding proteins (25 to 29 kDa) were detected, differing in subcellular distribution. Small GTP-binding proteins with similar molecular weights were detected in the membrane fraction and in the high speed (100 000 g) supernatant from adult rat cerebellum. The forskolin elicited increase in cAMP or the TPA induced increase in protein kinase C activity lead to an increased GTP binding activity of certain bands in the 25-29 kDa region in the membrane fraction prepared from rat cerebellar granule cells. Treatment of these cells with baclofen, which has been reported to inhibit adenylate cyclase, resulted in a decrease in GTP-binding to the membrane fraction, preferentially to the P1 fraction (800 g pellet containing nuclei and sheets of plasma membrane). These results suggest that protein kinases A and C may be involved in the regulation of the subcellular distribution of certain members of the 25-29 kDa GTP binding proteins.

NORADRENERGIC MODULATION OF SYNAPTIC RESPONSES IN RAT PREFRONTAL CORTEX NEURONS IN VITRO. J.C. Hirsch & F. Crépel*. CNRS URA 1121, Bat. 440, Université Paris- Sud 91405 Orsay, France.

Considerable evidences suggest that norepinephrine (NE) may increase the signal/noise ratio in the cerebral cortex. This modulatory influence could be of significance in controlling the use-dependent changes in synaptic efficacy we observed in prefrontal cortex neurons maintained in vitro (Hirsch & Crépel, J. Physiol., 1990, in press). In the present investigation we examined the effect of NE on the postsynaptic potentials (PSP) evoked in layer V pyramidal cells following electrical stimulation of layer II. Seventeen neurons were recorded with Kacetate QX314-filled micropipettes (12 in the presence of bicuculline (0.5-1 uM) and 5 without). The input resistance was 65 + 20 M (mean + SD) at a resting potential of 61 + 5mV. Suprathreshold stimulation activated polysynaptic responses peaking around 100ms after the early EPSP- IPSP sequence. Superfusion with NE (10 uM) reduced the amplitudes of all the PSPs. However, the decrease was most prounounced for the polysynaptic responses i.e. 76 + 19% at 100ms (N=10/10); 34 + 15% for the early EPSP (N=14/17) and 42 + 23% for the disynaptic IPSP (N=12/13). A similar reduction of the late components occurred in 4 cells subsequently tested with APV (20µM), an NMDA channel blocker. In these cells, no further

reduction was noted when the 2 drugs were simultaneously applied.

Overall, these data indicate that NE has a general depressant effect on synaptic efficacy, but still selectively favors mono or paucisynaptic inputs over polysynaptic ones. Support: INSERM (896004) and HFSP grants.

PROPOFOL FACILITATES POSTSYNAPTIC RESPONSE TO SUBSTANCE P IN THE GUINEA PIG INFERIOR MESENTERIC GANGLION.

PROPOFOL FACILITATES POSTSYNAPTIC RESPONSE TO SUBSTANCE P IN THE GUINEA PIG INFERIOR MESENTERIC GANGLION.

W.H. Stapelfeldt and J.H. Szurszewski. Departments of Anesthesiology and Physiology & Biophysics, Mayo Medical School and Foundation, Rochester, MN 55905.

Propofol (PF) is a new intravenous anesthetic agent whose mechanism of action is unknown. The present study was designed to determine the effects of PF on nicotinic fast EPSPs and on noncholinergic slow EPSPs in a sympathetic ganglion in vitro. Inferior mesenteric ganglia (IMGs) were dissected from guinea pigs and superfused with Krebs solution at 35-37°C. Intracellular recordings were obtained from IMG neurones. Fast and slow synaptic inputs were evoked by electrical stimulation of lumbar splanchic (LSN) and lumbar colonic (LCN) nerves, respectively. PF (5µg/ml) had no effect on fast EPSPs evoked by LSN stimulation. In contrast, PF increased slow EPSPs evoked by LCN stimulation by 35% (P<0.05). Since slow EPSPs are known to be mediated by substance P (SP) and VIP, effects of PF on exogenous SP and VIP were tested. PF increased the postsynaptic depolarization to exogenous SP by 43% (P<0.05), whereas responses to exogenous VIP remained unchanged. When tested in IMGs obtained from animals depleted of SP by prior capsaicin (100 mg/kg) treatment, the SP dependent slow EPSP was abolished and PF had no effect on the remaining slow EPSP. These data suggest that PF: 1) does not function as a ganglionic blocking agent; 2) specifically facilitates SP-mediated slow EPSPs by a postsynaptic mechanism of action.

AN ANALYSIS OF THE MUSCARINIC DEPRESSION OF SYNAP-TIC TRANSMISSION AT THE CA3 MOSSY FIBER SYNAPSE. S.H. Williams & D. Johnston, Division of Neuroscience, Baylor College of Medicine, Houston, Tx 77030.

Acetylcholine generally acts to excite mammalian CNS neurons, primarily acting through muscarinic receptors. These actions can be attributed to reduction in various postsynaptic potassium conductances. However, in many parts of the CNS muscarinic agonists also depress synaptic transmission. We have studied this latter action at the mossy fiber CA3 synapse of the hippocampus in the in vitro slice preparation. Standard single-electrode voltage clamp techniques were used and picrotoxin (10 µM) was routinely added to the saline to block inhibition.

Both 1 and $10\mu M$ muscarine significantly increased the input resistance of CA3 cells. However, while $1\mu M$ muscarine had little effect on synaptic transmission, $10\mu\mathrm{M}$ caused a significant decrease of the measured EPSP and EPSC. The actions of $10\mu M$ muscarine were compared in two groups of cells, one recorded with KCl electrodes, the other with CsCl. The synaptic depression was very similar in both groups. In the Cs⁺ loaded cells the I-V relation of the synaptic current was measured before and after muscarine application. $10\mu\mathrm{M}$ muscarine depressed the synaptic conductance by $33\pm6\%$ (n=4), but did not significantly alter the reversal potential of the current. There was no significant effect of muscarine on the half decay time of synaptic current.

The muscarinic depression of synaptic transmission cannot be accounted for by changes in postsynaptic membrane resistivity or alteration of synaptic reversal potential. While a postsynaptic locus of action cannot be entirely excluded, it seems likely that muscarine acts presynaptically.

LOW Ca^{2+} - HIGH Mg^{2+} BLOCKS TRANSMITTER RELEASE NOT RECEPTORS IN MOUSE NIGRO-STRIATAL BRAIN SLICE. J.A. Wilson. Creighton Univ. School of Medicine, Omaha, NE 68178

Release of neurotransmitter from brain slices is blocked by decreasing the Ca²⁺ concentration in artificial cerebrospinal fluid (ACSF). In practice, Ca²⁺ concentrations below 0.5 mM can produce a nonreversible inhibition of transmitter release. Increasing the Mg²⁺ concentration in conjunction with decreases in the Ca²⁺ concentration may prevent the non-reversibility. However, high Mg²⁺ concentrations are known to block the responsiveness of NMDA receptors, making it difficult to distinguish whether a decrease in the amplitude of a field potential is due to the action of Ca²⁺ on release or the action of Mg²⁺ on the receptor. This study was carried out to determine whether a low Ca2+ - high Mg2+ ACSF which blocked synaptic transmission was acting pre- or postsynaptically. Cortico-striate transmission is reversibly blocked by lowering Ca²⁺ concentration from 2.4 mM to 0.3 mM and raising Mg²⁺ concentrations from 1.2 to 3.3 mM. The field potential's amplitude and latency did not change when Mg²⁺ was raised from 1.2 mM to 3.3 mM while Ca²⁺ concentration was held constant at 2.4 mM. This indicates that low Ca²⁺ - high Mg²⁺ ACSF blocks release of transmitter without significantly altering the sensitivity of postsynaptic NMDA receptor channel complex.

THE DUAL EFFECTS OF DAGO ON GLUTAMATE MEDIATED SYNAPTIC TRANSMISSION OF TRIGEMINAL NEURONS IN THIN RAT MEDULLARY

TRANSMISSION OF TRIGEMINAL NEURONS IN THIN RAT MEDULLARY SLICES. L. Chen and L.-Y.M.Huang, Marine Biomed. Inst., Univ. TX Med. Br., Galvestop, TX 77550.

The effects of DAGO (D-Ala², N-Me-Phe⁴, Gly⁵-ol-enkephalin) on the evoked synaptic activities and glutamate responses were studied in neurons located in the subnucleus of trigeminal caudalis of thin medullary slices. Under whole cell patch recording conditions, afferent fiber stimulations evoked excitatory postsynaptic current (EPSC) which was blocked by NMDA antagonist, APV, and non-NMDA antagonist, CNQX. We found that 1 µM DAGO reduced or completely abolished the EPSC evoked by afferent fiber stimulations. The EPSC recovered rapidly once DAGO was washed away. The The EPSC recovered rapidly once DAGO was washed away. The inhibitory effect of DAGO was reversed by naloxone. To determine whether the effect of DAGO was presynaptic or postsynaptic, we have examined the action of DAGO on the pressure applied glutamate responses. In Mg-free solution, glutamate induced a large APV-sensitive inward current. Postsynaptically, DAGO potentiated the glutamate responses. This enhancement took a few min to develop and often lasted more than 20-30 min after DAGO was washed away. This enhancing effect of DAGO was also naloxone reversible. Thus DAGO had dual effects on the trigeminal cells. Presynaptically it inhibited the glutamate release and postsynaptically, it enhanced the NMDA response. DIRECT EFFECTS OF 17 β -ESTRADIOL ON THE MEMBRANE EXCITABILITY OF CA1 PYRAMIDAL NEURONS IN THE RAT HIPPOCAMPUS. M. Wong and R.L. Moss. Dept. Physiology, University of Texas Southwestern Medical Center, Dallas, TX 75235.

The gonadal steroid, 17-βestradiol, has been found to exert direct, short-term effects on the electrical activity of neurons in the hypothalamus, amygdala and hippocampus. These rapid actions of estradiol have been attributed to non-genomic mechanisms. In the hippocampus, estradiol causes an increase in amplitude of the extracellular CA1 field potential (Teyler et al., Science 209:1017, 1980). In the present study, we utilized intracellular recording to investigate further the direct effects of estradiol on membrane excitability of CA1 pyramidal neurons in the rat hippocampal slice preparation. Hippocampal slices were prepared from 12 Sprague-Dawley rats (9 female, 3 male, 75-125 g) using a Lancer vibratome and were superfused with artificial cerebrospinal fluid. Intracellular recordings were obtained from 27 CA1 neurons with resting membrane potentials of at least 50 mV, using glass microelectrodes filled with 4 M potassium acetate. The biologically active 17g-estradiol or the inactive control analogue, 17α-estradiol, in concentrations of 10⁻¹⁰ M to 10⁻⁸ M were applied to the tissue by switching a valve in the superfusion system. 17g-estradiol, but not 17α - estradiol, caused a depolarization and increased firing rate in 8 out of 27 (29.6%) CA1 neurons tested. These effects occurred within a minute after application of 17β-estradiol in all 8 cases and were completely reversed within five minutes after washout of the drug in 5 out of the 8 cells. Neurons that were excited by 17β-estradiol were found in both female (6 out of 19 cells, or 31.67%) and male (2 out of 8 cells, or 25 %) rats. Furthermore, estradiol-responsive cells were found in prepubertal females and adult females in various stages of the estrous cycle. 17β-estradiol had no observable effect on accommodation and after-hyperpol

PATCH-CLAMP RECORDING OF SPONTANEOUS SYNAPTIC CURRENTS FROM CA3 PYRAMIDAL NEURONES IN RAT HIPPOCAMPAL SLICES. C. J. McBain and R. Dingledine. Dept. of Pharmacology, University of North Carolina at Chapel Hill NC.

27599. Whole-cell patch recordings were made from CA3b/c pyramidal neurones maintained in the in vitro hippocampal slice (350-450μm). On cell resistances of up to 4GOhm were typically encountered using CsCl filled microelectrodes (electrode resistance of <4Mohm). The input resistance of neurones was 213 ± 15 Mohm; (mean ± s.e.m, n=13) at a resting membrane potential of -54 ± 3.1mV (n=13). High frequency (<11Hz) spontaneous synaptic inward currents 20-150pA, 5-30msecs in duration were observed. The majority of inward currents were blocked on bath application of 5μM bicuculline methobromide, those events remaining were abolished by CNQX (10μM). Tetrodotoxin (1μM) eliminated most synantic currents. In three cells however, bicuculline sensitive abolished by CNQX ($10\mu M$). Tetrodotoxin ($1\mu M$) eliminated most synaptic currents. In three cells however, blucualline sensitive unitary ipses (20-50p4; \leq 5Hz) persisted in the continued presence of TTX. Elevation of [K $^{-}$], to 8.5mM, a manipulation known to induce interictal burst firing in CA3 neurones, resulted in a persistent inward current of 92 \pm 8.6pA (n=5), an event not observed with conventional current clamp recordings (Korn et al J. Neurophysiol. 57; 325-340, 1988). Potassium elevation however did not influence the rate of spontaneous ipses, epses or TTX resistant unitary currents, but did induce spontaneous interictal bursts. Interictal events were abolished by TTX ($1\mu M$) or CNQX ($10\mu M$) with no effect on the persistent inward current.

FREQUENCY-DEPENDENT CHANGES IN EFFICACY OF THE HIPPOCAMPAL RECURRENT INHIBITION. B. Esplin and R. Capek. Dept. of Pharmacology and Therapeutics, McGill University, Montreal, Quebec, H3G 1Y6, Canada.

We have examined the dependence of inhibition on the

frequency of activation of the recurrent inhibitory pathway in rat hippocampal slices using extracellular recordings of field potentials. Population spikes recorded in the CAI pyramidal cell body layer were evoked by orthodromic stimulation of stratum radiatum. They were inhibited by conditioning antidromic stimulation by a single pulse or by a train of 20 pulses to the alveus at different inter-vals before orthodromic stimulation.

Antidromic stimulation by a train of pulses at low frequencies (10 and 20 Hz) produced less inhibition at various time intervals after the last stimulus in the train than a single antidromic stimulus. Antidromic stimulation at high frequencies (100 and 200 Hz) produced more and much longer inhibition than a single pulse of the same intensity. Picrotoxin (3 to $10~\mu\text{M}$) attenuated preferentially tensity. Picrotoxin (3 to 10 µM) attenuated preferentially the inhibition produced by a single pulse, whereas 2-hydroxysaclofen (100 µM) had a greater disinhibitory effect on that produced by high frequency trains. These results suggest a greater involvement of the GABA_B receptor activation in the prolonged inhibition produced by repetitive activation of the inhibitory pathway at high frequencies.

BINDING OF INHALATION ANESTHETICS TO THE NICOTINIC ACETYLCHOLINE RECEPTOR. L. Lin*, D. Koblin* and H. H. Wang. Dept. of Biology, Univ. of California, Santa Cruz, CA 95064, and Dept. of Anesthesia, Univ. of California, San Francisco, CA 94121 (DDK). The most likely targets of general anesthetic action are the synaptic receptors in the brain. The nicotinic acetylcholine receptor from the Torpedo californica was used as a model to test the hypothesis that

<u>Torpedo californica</u> was used as a model to test the hypotnesis that inhalation anesthetics are able to act directly on synaptic receptor proteins at clinical concentrations. If the hypothesis is correct, we expect to observe specific binding of inhalation anesthetics to the acetylcholine receptor. The receptor is a chemically gated, cation channel which is blocked by non-competitive inhibitors such as phencyclidine (PCP). PCP at concentrations below 20 μM has been shown to bind to a single class of sites in the acetylcholine receptor at high affinity ($K_d = 0.4 \mu M$) with a stoichiometry of one per receptor monomer. Nitrous oxide which has a minimum alveolar concentration (MAC) in humans at 105% was used to inhibit the specific binding of ³H-PCP (at 10 nM) to the acetylcholine receptor. The results showed that, in acetylcholine receptors pre-treated with carbamylcholine, equilibration with 100% binding. In the control, 100% ³H-PCP binding was determined from the identical preparation but equilibrated with 100% nitrogen. This finding is comparable to the inhibition of ³H-PCP binding at the minimum alveolar concentration of halothane (MAC = 0.75%). These findings indicate that both halothane and nitrous oxide bind to the non-competitive inhibitor site in the acetylcholine receptor with affinities which correlate with their anesthetic potencies. nitrous oxide led to an approximately 20% decrease in specific ³H-PCP

CATECHOLAMINE-MEDIATED COMPONENT OF THE SLOW-INHIBITORY POSTSYNAPTIC POTENTIAL IN THE SUPERIOR CERVICAL GANGLION OF THE RABBIT. C. G. Acosta, B. J. Kolls and J. H. Ashe, Neuroscience Program, Dept. of Psychology, University of California, Riverside, CA 92521

The mode of generation of the slow-inhibitory postsynaptic potential (s-IPSP) is a matter of controversy. A central issue is whether the s-IPSP is mediated via a disynaptic pathway involving catecholamine-containing interneurons. Data are presented in support of a catecholamine mediated pathway for the generation of the s-IPSP.

Paired superior copyrical ganglia of rabbits were excised and mounted in successe.

presented in support of a catecholamine mediated pathway for the generation of the s-IPSP.

Paired superior cervical ganglia of rabbits were excised and mounted in sucrose gap chambers. Micromole amounts of norepinephrine (NE), dopamine (DA) and the specific D1 agonist, SKF-38939, were applied by injection into the superfusion medium and resulting changes of ganglionic potential were recorded. Synaptic potentials, the s-IPSP, the fast-excitiony postsynaptic potential (FEPSP), and the slow-excitiony postsynaptic potential (st-EPSP), and the slow-excitiony postsynaptic potential (s-EPSP), were elicited by supramaximal stimulation applied to the preganglionic nerve (d-tubocurarine: 3SIM).

SKF-38393, NE and DA all induced a hyperpolarization (HP) of the ganglionic potential; the amplitudes varying with NE-SKF-38393-2DA. Subsequent applications of SKF-38393 either failaid to elicit a HP or elicited a reduced amplitude HP. Following exposure to SKF-38393, the amplitude of the s-IPSP was reduced (by 20-50%) as was the amplitude of the NE-induced HP (by 30-70%). The amplitudes of the DA-induced HP was also reduced, however, the magnitude of the effect was less (10-30%). The amplitudes of the s-IPSP and the f-EPSP were unattered.

The HP typically induced by the initial exposure to SKF-38393 was not observed when the alpha-receptor antagonist, vohimbine, was present at concentrations sufficient to partially reduce the amplitudes of the catecholamine-induced HPs and of the s-IPSP. Yohimbine did not after the amplitudes of the SFPSP and the f-EPSP. Exposure to small amounts of SKF-38393 resulted in the reduction of subsequent SKF-38393-mediated HPs. Following exposure to SKF-38393, the amplitude of the s-IPSP was selectively reduced as were the amplitudes of the s-IPSP and an t-IEPSP is generated via a pathway requiring the effect of catecholamine. These data, of course, do not exclude the possibility of acetylcholine acting directly upon principal cells of the ganglion and thereby contributing in part to the generation

DUAL EFFECTS OF THE PROTEIN KINASE INHIBITOR H-7 ON CA1 RESPONSES IN HIPPOCAMPAL SLICES. J. C. Leahy and M. L. Vallano. Dept. of Pharmacology, SUNY Health Science Center, Syracuse, NY 13210.

An attractive neural model of learning and memory is long-term potentiation (LTP) in the hippocampus. In the pathway from CA3 to CA1, LTP can be observed as an enhancement in CA1 responses following high frequency stimulation of the Schaffer collaterals. Recent studies employing protein kinase inhibitors (300µM H-7) support a role for calcium-dependent kinases in EPSP potentiation (e.g. Malinow et al., 1988). However, both a negligible effect on EPSP potentiation (Muller et al., 1988), and an enhancement in CA1 responsiveness (Corradetti et al., 1989) have been observed with lower concentra-tions (30-100μM) of H-7. The goal of this study was to examine the effects of low (50μM) and high (300μM) concentrations of H-7 on CA1 responses.

Experiments were performed using the in vitro rat hippocampal slice preparation. Two bipolar stimulating electrodes were placed in stratum radiatum, on either side of an extracellular microelectrode positioned in stratum pyramidale for recording the CA1 population spike. LTP was induced in one of the two pathways followed by perfusion with medium containing either 50µM or 300 μM H-7. The CA1 responses in the presence of 50μM H-7 were characterized by the onset of multiple spikes (2-4) and an increase in the population spike by the onset of multiple spikes (2-4) and an increase in the population spike amplitude, particularly in the previously unpotentiated (control) pathway. In the presence of 300µM H-7, the population spike amplitude was inhibited, particularly in the previously potentiated (LTP) pathway. These results, in conjunction with pharmacological studies using GABAergic compounds, suggest that H-7 exerts concentration-dependent effects in different pathways. At low concentrations, H-7 disinhibits CA1 neurons by reducing inhibition from local circuit neurons. At high concentrations, H-7 inhibits CA1 neurons either presynaptically or postsynaptically in the CA3-CA1 pathway

EPSPs in rat ambigual oesophageal motoneurons in vitro. R.S. Neuman, Y.T. Wang and D. Bieger, Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland A1B 3V6

The major if not principal afferent pathway to the oesophagomotor of the ambigual complex originates from the subnucleus centralis of the nucleus tractus solitarii and has been characterized with retro-and anterograde tracing methods. Based on this anatomical information, we have developed a sagittal brainstem slice containing both oesophagomotor neurons and the solitarial efferent pathway. In this investigation we report monosynaptic responses elicited by electrical stimuli applied along the trajectory of the solitario-ambigual fibres. Both simple and complex EPSPs were recorded, the latter having three discernible components based on activation thresholds. With few exceptions, kynurenate blocked both the simple and complex EPSPs, whereas AP-7 suppressed a high-threshold, rapidly-rising component in complex EPSPs, but failed to decrease the simple EPSP.

In conclusion, the use of appropriately cut brainstem slices permits examination of synaptic inputs to ambigual motoneurones which are thought to be involved in swallowing and oesophageal Supported by MRS (Canada) peristalsis.

COMPARISON OF STATIC AND DYNAMIC STIMULATION PARADICMS:

**T-STIMULATED AMINO ACID RELEASE FROM CULTURED CEREBELLAR
NEURONS. K.L. ROGERS', R.A. PHILIBERT', G.R. DUTTON',
Department of Psychiatry and Department of
Pharmacology², University of Iowa, College of Medicine,
Iowa City, IA 52242.

Two stimulation paradigms were employed to investigate the amino acids released from rat neuronal cultures following K^+ exposure at varying concentrations with and without ${\rm Ca}^{2^+}$. An increased sensitivity in stimulated without Ca²⁺. An increased sensitivity in stimulated release of the neurotransmitters aspartate (ASP), glutamate (GLU) and GABA at a given [K⁺] in the static vs. dynamic paradigm was seen. ASP, GLU and GABA were released in a dose- and Ca²⁺- dependent manner, while rates of proline (PRO) efflux were not. Release rates of taurine (TAU) and the nucleoside adenosine (ADN) increased with depolarization, but removal of Ca²⁺ caused a marked increase in basal release such that efflux rates fell during depolarization. Basal alamine (ALA) and serine (SER) release rates were increased in Ca²⁺-free serile (san, but further increases were seen over and above this change with elevated $[K^+]$. Results suggest a number of different classes of efflux: neurotransmitternumber of different classes of efflux; neurotransmitter-type release (ASP, GLU, GABA), depolarization-insensitive release (PRO), an osmoregulatory, possibly neuromodulatory-type, release (TAU), a Ca $^{2+}$ -insensitive neuromodulatory-type release (ADN) and a class partially Ca $^{2+}$ -sensitive (SER, ALA). Supported by NS20632.

SELECTIVE REDUCTION OF INHIBITION AT THE CRAYFISH OPENER NEUROMUSCULAR JUNCTION BY LOW CONCENTRATIONS OF ETHANOL. J.A. Blundon and G.D. Bittner. Department of Zoology and Institute for Neurological Sciences Research, University of Texas, Austin, TX, 78712.

We have examined the effects of ethanol (EtOH) exposure on behavior, central nervous system activity, and synaptic transmission penavior, central nervous system activity, and synaptic transmission in crayfish (*Procambarus clarkii*). We have previously reported that crayfish show behavioral changes we interpret as sedation within 6-24 hours after adding 75-150 mM EtOH to aquarium water (Friedman et al., 1988, IPET 246:125-131). However, within minutes of EtOH exposure at these concentrations, crayfish first show signs of increased excitability. Coincident with this initial behavioral change is an increase in spontaneous activity recorded within the crayfish ventral nerve cord within the crayfish ventral nerve cord.

The opener muscle of the crayfish walking leg receives excitatory input from one axon only (the opener excitor or OE). This muscle also receives direct inhibitory input from the opener inhibitor axon (OI). In addition, the OI makes direct contact with the OE, thereby providing presynaptic inhibition to the opener muscle. We now report that 60 mM EtOH reduces inhibition of the opener muscle but has no effect on excitatory postsynaptic current. Further, 120 mM EtOH reduces inhibition of the opener muscle but also decreases excitatory postsynaptic current and muscle fiber membrane resistance as well. Selective reduction of inhibition by low concentrations of EtOH metures are proposed to the behavioral professional and the second to EtOH may in part be responsible for behavioral excitability in crayfish seen within minutes of exposure. GLUTAMERGIC EXCITATORY SYNAPTIC TRANSMISSION IN THE RAT

SENSORIMOTOR CORTEX. G.G.C.Hwa & M.Avoli. MNI, McGill Univ., Montréal, Qué., Canada.

In the present study, intracellular recording techniques were used to characterize the excitatory postsynaptic potential (EPSP) evoked in cells located in layers II/III of the rat sensorimotor cortex. The EPSPinhibitory postsynaptic potential (IPSP) sequence was evoked by focal stimulation of the white matter or layers IV/V. The voltage behaviour displayed by the EPSP was dependent on the stimulus intensity. At above threshold intensity, the EPSP usually displayed conventional voltage characteristic. At lower intensity, the EPSP sometime increased and decreased in size during membrane depolarization and hyperpolarization respectively. This type of anomalous volatage behaviour 1) was observable following the blockade of GABAergic IPSP 2) was insensitive to NMDA antagonist CPP 3) could be mimicked by a brief pulse of depolarizing current. The non-NMDA antagonist CNQX (0.5-2.5 µM) reduced the EPSP in a concentration-dependent manner. Our results suggest that the EPSP in the rat sensorimotor cortex is primarily mediated by non-NMDA receptors. In addition, the shape of this EPSP is also contributed by intrinsic voltage-dependent currents whose expression is controlled by the GABAergic inhibitory mechanism. This work is supported by the MRC and the Savoy Foundation.

INTERACTIONS OF TETRAHYDROAMINOACRIDINE AND PHENYLMETHYLSULFONYL FLUORIDE ON ACETYLCHOLINESTERASE. K.A. Skau. U. Cincinnati, College of Pharmacy, Cincinnati,

Recent results suggest that phenylmethylsulfonyl fluoride (PMSF) selectively inhibits acetylcholinesterase (AChE) associated with membranes. Thus, brain AChE, which is primarily membrane bound, was inhibited more than the enzyme in tissues with a large proportion of cytosolic AChE. Tetrahydroaminoacridine (THA) has been reported to concentrate in brain and inhibit AChE-an action that may be beneficial in Alzheimer's disease. However, THA inhibition of AChE <u>in vivo</u> is difficult to demonstrate. To show such an action, rats were injected with THA (3.2 mg/kg ip) or vehicle and 15 min later PMSF (85 mg/kg in sesame oil) was administered by gavage. The rats were sacrificed 24 hr later, various tissues were harvested and AChE activity was assayed. PMSF had the greatest effect on brain and bladder; THA protected these tissues to the greatest extent. Salivary gland and muscle (both skeletal and smooth) AChE were also protected by THA. In vitro, THA (10 μ M) appeared to enhance the irreversible inhibition of AChE by PMSF (5mM) but prevented AChE inhibition by echothiophate ($S_{\mu}M$). These results provide evidence that THA does interact with AChE <u>in vivo</u> and can protect the enzyme from irreversible inhibition.

MUSCARINIC RESPONSES OF CELLULAR SUBTYPES IN RAT BASOLATERAL AMYGDALA IN VITRO M.S. Washburn and H.C. Moises

BASULAIEKAL AMYGDALA *IN VITRO* M.S. Washburn and H.C. Moises Neuroscience Program and Dept. of Physiology, Univ. of Mich, Ann Arbor, MI 48109. We recently reported that pyramidal-type neurons in the rat basolateral amygdala (BLA) respond to pressure-application of carbachol or muscarinic agonists with an initial hyperpolarization followed by a prolonged depolarization (Washburn and Moises, Neurosci. Abstr., 1989). The hyperpolarization reversed near E_{Cl}, and was blocked by GABA antagonists, TTX and Cd⁺⁺. These results suggest that the initial inhibitory response was indirect in nature and mediated by short-latency muscarinic excitation of intrinsic GABAergic interneurons.

intrinsic GABAcrgic interneurons.

In this study, we examined muscarinic responses of presumptive intrinsic interneurons in BLA using intracellular recordings from rat brain slices. These cells were distinguished from the predominant pyramidal type by their short duration action potentials (0.6 ± 0.1 ms, mean ± SEM, n=7), short time constants (4.9 ± 0.7 ms) and absence of spike frequency accomodation in response to a depolarizing current pulse. In contract to premide leafly presumpting interesponse to a depolarizing current pulse. In absence of spike frequency accomodation in response to a depolarizing current pulse. In contrast to pyramidal cells, presumed interneurons depolarized immediately to local application of carbachol or muscarine. The depolarization was associated with an increase in R_{input} and was blocked by atropine (0.1-1 μM). An additional class of cells (n=32) was identified by their negative V_m (-80 mV) and distinct synaptic responses. Unlike pyramidal cells and interneurons, these cells did not fire action potentials during the initial phase of the depolarization evoked by a current pulse. This property appeared to be due to a large intrinsic A-current since it was blocked by 4-AP (100 μM) or by holding the membrane potential to a depolarized level. While these cells depolarized immediately to pressure application of carbachol or muscarinic agonists, Lucifer yellow labelling revealed a morphology distinct from that of interneurons. Our ability to demonstrate short-latency muscarinic excitation of presumptive interneurons provides a neuroanatomical substrate for the initial hyperpolarization recorded in pyramidal type cells. Thus, a common mechanism apppears to underlie the inhibitory muscarinic action seen in pyramidal cells in BLA, hippocampus and cortex. (Supported by NIDA grant 03365)

PHARMACOLOGY OF EXCITATORY POSTSYNAPTIC POTENTIALS OF PURKINJE CELLS AND NEURONS OF THE DEEP NUCLEI IN OLIVO-CEREBELLAR CO-CULTURES. E. Audinat, B. Gähwiler and T. Knöpfel. Brain Research Institute, University of Zürich, CH-8029 Zürich.

The olivary climbing fibers which form synapses on both Purkinje cells (PCs) and neurons of the deep cerebellar nuclei (DCN), have been proposed to use an excitatory amino acid as neurotransmitter. We have compared the pharmacology of the excitatory postsynaptic potentials (EPSPs) evoked by the stimulation of the inferior olive (IO) in morphologically identified PCs and in neurons of DCN. Slices of cerebellum and IO were obtained from 1 to 3 old day rats and co-cultured for 2-4 weeks. In PCs, all or none climbing fiber responses evoked by field stimulation of the IO were reversebly abolished by bath application of CNQX (10 uM) but were unaffected by D-APV (20 uM) or by superfusing the slices with magnesium-free solution. In neurons of the DCN, stimulation of the IO induced sequences of neurons of the DCN, stimulation of the 10 induced sequences of excitatory and inhibitory postsynaptic potentials. After blockade of the inhibition with bicuculline (20 uM), CNQX (10 uM) abolished only the fast rising component of the EPSPs. The remaining, slowly rising, CNQX-insensitive part of the EPSPs was blocked by D-APV (10 uM) and also by magnesium in a voltage-dependent manner. We conclude that in PCs climbing fibers responses are mediated by the activation of non-NMDA excitatory amino acid receptors while, in neurons of the DCN, both NMDA and non-NMDA receptor subtypes are involved in the EPSPs evoked by IO stimulation.

MUTUAL ANTAGONISM OF THE ENHANCING EFFECTS OF INDOMETHACIN AND CAPTOPRIL ON VASCULAR NORADRENERGIC NEUROTRANSMISSION. W.H. Cline and L.L. Stephenson. Dept. of Pharmacology, Southern Illinois Univ. Sch. of Med., Springfield, II. 62794-9230. We previously reported that captopril (CAP), enhanced periarterial nerves stimulation (PNS)-induced release of endogenous norepinephrine (NE) when Infused into isolated, perfused mesenteric vascular-intestinal loop preparations from 13 to 16 week old normotensive Wistar Kyoto rats (WKY) and spontaneously hypertensive rats (SHR). We have also reported that indomethacin (IND), enhanced PNS-induced release of endogenous NE from WKY but not SHR preparations. Since it had been reported that 1ND releases mesenteric vascular-intestinal loop preparations of 13 to 16 week old WKY and age-matched SHR. The effect of concurrent infusion of CAP at 5 μM and IND at 3 μM on PNS-induced NE release was determined at PNS of 4 to 14 Hz in WKY and SHR preparations. PNS-induced NE release did not differ from untreated control values during this combined treatment in WKY preparations. PNS-induced NE release from WKY preparations during this combined treatment was significantly less at 4 to 14 Hz than that observed during IND treatment alone. PNS-induced NE release did not differ from untreated control values during this combined treatment in SHR preparations. The significant increases in PNS-induced NE release did not differ from untreated control values during this combined treatment in SHR preparations. The significant increases in PNS-induced NE release did not differ from untreated control values during this combined treatment in SHR preparations. The significant increases in PNS-induced NE release did not differ from untreated control values during this combined treatment in SHR preparations. The significant increases in PNS-induced NE release observed at 4 to 14 Hz during CAP infusion alone were prevented at all PNS frequencies during IND infusion in SHR preparations. These finding suggest t

TAURINE AND THE DEVELOPMENT OF CAT-AND MOUSE-CEREBELLUM IN CULTURES. <u>E. Trenkner</u>, Ph.D. Institute for Basic Research in Developmental Disabilities, 1050 Forest Hill Road, Staten Island, NY

Two lines of evidence suggest the importance of taurine in early postnatal cerebellar development of cat and mouse. Female cats, when raised on a taurinedeficient diet produce offspring with severe brain abnormalities, particularly in the cerebellum, (1). Similar morphological defects were described for the autosomal recessive neurological mutation weaver (wv/wv), (2). The function of the wv/wv gene is unknown but it appears to be inherent to cerebellar granule cells, (3). The v/wv defect might be related to reduced concentrations of taurine at early stages

of postnatal development (4), in this respect resembling taurine-deficient kittens.

Taurine is synthesized in rodents but not in cats and primates, including man, (5). Thus cat cerebellum as well as the wv/wv cerebellum seem to be ideal systems to investigate the function of taurine during early postnatal development. This study compares the effect of taurine on survival and behavior of cerebellar cells in culture of the taurine deficient mutant mouse weaver and in cerebellar cultures of cat under taurine deficient conditions. We found that in the presence of high concentrations of taurine the survival rate of weaver cerebellar cells was up to 80% of that of normal mice. Surprisingly, however, cultured cat cerebellar cells died in the presence of taurine but thrived in the absence of taurine as well as in the presence of taurine-uptake blockers, suggesting a qualitatively different mechanism from that postulated for mouse. Implications and possible mechanisms will be discussed.

EFFECTS OF MEMBRANE $\,\,\omega$ 6 POLYUNSATURATED FATTY ACIDS ON ADENOSINE UPTAKE AND 5'-NUCLEOTIDASE ACTIVITY IN N1E-115 NEUROBLASTOMA CELLS. M.G.
Murphy and Z. Byczko*, Department of Physiology
& Biophysics, Dalhousie University, Halifax,
Nova Scotia B3H 4H7

We have examined the effects of increasing we have examined the effects of increasing the membrane polyunsaturated-fatty-acid (PUFA) content of N1E-115 neuroblastoma cells on processes that could regulate the availability of extracellular adenosine (Ado). Measurement of uptake of [3H]Ado (1.3 - 20 μ M) for 20 sec (+ NaCl) demonstrated that PUFA-enriched N1E-115 NaCl) demonstrated that PUFA-enriched NIE-115 cells have an >2-fold higher capacity (V_{max}) to take up the nucleoside than do control cells (e.g., 0.66 & 0.30 nmol/mg protein, respectively). Values for K_{T} were also higher in the PUFA-rich cells (e.g., 25 vs 9 $_{\mu}$ M). Assays of 5'-nucleotidase activity indicated that conversion of [3H]5'-AMP to [3H]Ado was not affected greatly by increasing the $_{\omega}$ 6 PUFA content of the cells. Apparent values for V_{max} were 6 & 7 nmol/mg protein, and for K_{A} were 15 & 23 $_{\mu}$ M in the control and PUFA-enriched cells, respectively. The results of this study suggest that increases in extracellular Ado in PUFA-enriched cells can not be explained by PUFA-dependent changes in Ado uptake or in 5'-nucleotidase activity. EFFECTS OF BROFAROMINE ON TRACE AMINE LEVELS IN THE

RAT STRIATUM. L. E. Dyck and A. A. Boulton.

Neuropsychiatric Research Unit, Dept. of Psychiatry, Univ. of Saskatchewan, Saskatoon, Canada S7N 0W0

Previous studies have shown that endogenous phenylethylamine (PE) in the rat striatum is a substrate for type B MAO, while tryptamine (TRA), m- and p-tyramine (mTA and pTA) appear to be substrates for both types A and B MAO. In pTA) appear to be substrates for both types A and B MAO. In the following study, brofaromine (BFO), a reversible type A MAOI, and tranylcypromine (TCP), an irreversible A and B MAOI, were injected i.p. into male Wistar rats and the trace amine levels in the striatum quantified. Four h after the injection of 10 mg/kg TCP the levels of PE were increased 25-fold, TRA 69-fold, mTA 3.3-fold and pTA 6.7-fold compared to saline controls. By contrast, 4 h after the injection of 10 mg/kg BFO, the levels of PE and TRA did not change, but mTA increased 1.9-fold and pTA 4.7-fold. 100 mg/kg BFO did not alter PE levels. This lack of effect on striatal PE by the high dose of BFO is further evidence for the specific inhibition of type A MAO by BFO. The magnitude of the increases in the levels of TRA, mTA and pTA permitted the detection of significant increases in these amines at lower doses of BFO than is possible with serotonin and the catecholamines. For than is possible with serotonin and the catecholamines. For those reversible MAOI's which do not bind to MAO, then, measurement of their effects on endogenous TRA and TA levels would be superior to ex vivo assessment of MAO activity. Supported by Saskatchewan Health and Ciba-Geigy Canada Ltd.

SYNTHESIS OF 3,4-DIHYDROXYPHENYLGLYCOLALDEHYDE, THE BIOGENIC ALDEHYDE OF NOREPINEPHRINE. M.A. Javors*, M.S. Sabaratnam*, T.S. King, and C.L. Bowden. Departments of Psychiatry, Pharmacology, and Cellular Structural Biology, University of Texas Health Science Center, San Antonio, Texas 78284-7792.

Although they are implicated in various physiological or pathological processes, the role of biogenic aldehydes in these processes has yet to be studied in depth. Since these aldehydes are not commercially available, the purpose of this study was the synthesis of the biogenic aldehyde of norepinephrine (NE), 3,4-dihydroxyphenylglycolaldehyde (DHPGA). We synthesized DHPGA from NE using partially purified monoamine oxidase-B (MAO-B) from human platelet membranes. DHPGA was extracted from the reaction mixture with alumina due to the catechol structure of DHPGA. The conversion of 1 mM NE to DHPGA was 100% complete within 5-6 h after the start of the reaction. DHPGA was stable in storage at 0-4°C or -80°C with or without 1 mM sodium metabisulfite for at 0-4°C or -80°C with or without 1 mM sodium metabisulitie for up to 14 days. DHPGA was quantitated using reverse phase HPLC (3 micron, C18) with coulometric detection. DHPGA was sensitive coulometrically and the voltage at half-maximal oxidation was approximately 40 millivolts. We have identified this aldehyde in human CSF and urine using an alumina extraction procedure. These results indicate that DHPGA can be synthesized in quantity and stored with stability for use as a standard in studies that require the measurement of DHPGA in biological tissues.

32.7

DEPOLARIZATION INDUCED ATP RELEASE FROM MOUSE BRAIN SYNAPTOSOMES: CALCIUM-DEPENDENT AND INDEPENDENT MECHANISMS. J.L. Fiedler . H.B. Pollard and E.Roias*. Lab. Cell Biology and Genetics. NIDDK. NIH. Bethesda, MD. 20892.

ATP is stored in secretory vesicles of presynaptic nerve endings. A sudden elevation of K+ causes membrane depolarization and secretion of ATP together with specific neurotransmitters. We demonstrated here that ATP is secreted both in the presence of physiological external Ca2+ concentration and in the absence of this divalent cation. The aim of our work has been to characterize the kinetics of both modes of ATP secretion from highly purified preparation of mouse brain synaptosomes. We meaured the time course of ATP release using luciferin-luciferase included in the external solution. The rate constant of the ATP secretion increases with $[{\rm Ca^{2+}}]_{\rm o}$. In the absence of Ca2+, the release process is slow. This calcium independent modality of ATP release could be induced by either KCI or RbCI but not by CsCl. These results are consistent with the idea of different permeabilities for K+, Rb+ and Cs+ across K+-channels known to be present in the membrane of synaptososmes. Moreover, experiments conducted with impermeant anion isethionate keeping the product [K+]ox[CI-]i constant showed that ATP release was as in controls, indicating that ATP release was not due to osmotic lysis. Using potenciometric dye (DISC₃(5)) we obtained an empirical relationship between [K+]o and membrane potential. The extent of ATP release follows a linear relationship with the membrane depolarization.

COMPARATIVE EFFECTS OF MAO-A AND MAO-B INHIBITORS ON STRIATAL DOPAMINE STUDIED BY IN VIVO VOLTAMMETRY. M. Hong, B. Milne* and K. Jhamandas. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Drugs that inhibit the disposition of dopamine (DA)

inhibitors of monoamine oxidase (MAO) or monoamine re-uptake - have the potential to enhance the actions of L-DOPA on striatal DA function. To evaluate their effects on DA function, in vivo voltammetry was employed. Catechol oxidation current (CA-OC), reflecting accumulation of DOPAC and DA, was measured using carbon fibre electrodes implanted in the striatum of halothane anesthetized rats. Administration of clorgyline (1.0 and anestnetized rats. Administration of clorgyline (1.0 and 2.5 mg/kg i.v.), a MAO-A inhibitor, produced a dose-dependent decrease in CA-OC, peak effect occurring 45 min following the drug. Deprenyl (2.5, 5.0 and 10 mg/kg i.v.), a MAO-B inhibitor, and pargyline (5.0 mg/kg i.v.), a mixed MAO inhibitor, also decreased CA-OC, but their effect was weaker than that of clorgyline. Following inhibition of CA OC, L-DOPA (200 mg/kg i.p.) produced a large and sustained increase in CA OC which was blocked by 3-hydroxybenzylhydrazine (25 mg/kg i.v.), a centrally-acting decarboxylase inhibitor. It appears that in the rat MAO-A inhibitors produce a more effective decrease in DA metabolism and may have a greater potential to augment the action of L-DOPA.

ELEVATION OF TAURINE IN HIPPOCAMPAL EXTRACELLULAR FLUID AND CSF IN ACUTELY HYPOSMOTIC RATS: EXTRACEREBRAL ORIGIN? A. Lehmann¹ and C. Carlström*², ¹Inst. of Neurobiol. and ²Dept. of Neurol., Univ. of Göteborg, Göteborg, Sweden.

Previous studies have demonstrated a selective increase in extracellular

taurine in the pyriform cortex of water-intoxicated rats. The present work examined whether this response could be due to influx of the amino acid from blood. Urethane-anesthetized rats were injected (i.p.) with distilled water (150 ml/kg) and plasma osmolality and amino acids were determined. CSF was collected for measurement of amino acids, osmolality and albumin, an indicator of the integrity of the blood-CSF barrier. In separate experiments, water or 0.9% saline (150 ml/kg of each) were administered, and hippocampal amino acids (intracellular amino acids) and specific gravity were determined. Finally, amino acids were measured in hippocampal microdialysates after water administration. CSF osmolality decreased less than plasma osmoafter water administration. Cor osmolality decreased less than plasma osmo-lality which reflects the osmoconserving capacity of the CNS. Taurine, phos-phoethanolamine (PEA) and ethanolamine (EA) increased in micro-dialysates, CSF and plasma during acute hyposmolality. CSF albumin was transiently elevated after water administration. The level of taurine in hippocampal tissue decreased with respect to the volume increase (8%) whilst there was a significant diminution in PEA and an increase in EA. Opening of the blood-CSF barrier in parallel with a 25-fold increase in plasma taurine during water intoxication indicates that the augmented levels of the amino acid in cerebral extracellular fluids may partly be caused by influx from blood. The origin of the increase in plasma taurine is unknown, and dilution of blood with water in vitro showed that only a small fraction derives from lyzed blood cells. The results indirectly suggest that acute hyposmolality alters phosphatidylethanolamine metabolism which may affect membrane composition and, eventually, transmembrane fluxes of ions and water.

32.8

APOMORPHINE-INDUCED ALTERATIONS IN DOPAMINE RELEASE AND METABOLISM IN THE NEOSTRIATUM OF DEVELOPING RATS.

R.A. Gazzara and S.L. Andersen*. Center for Developmental Psychobiology and Dept. of Psychology, SUNY-Binghamton, NY 13901.

Apomorphine (APO) has been shown to inhibit dopamine (DA) release and synthesis in the neostriatum of adult rats, and to inhibit DA synthesis in the neostriatum of rat pups 14 days of age or older. This action of APO has been attributed to its activity as a DA autoreceptor agonist.

The study reported here analyzed the effect of APO on spontaneous and K⁺-evoked DA release in the neostriatum of urethane-anesthetized rat pups aged 10-11 days, 21-22 days, and 35-36 days, using in-vivo microdialysis. Samples were collected every 15 min and extracellular levels of DA, DOPAC, and HVA were measured by HPLC-EC. Rats were injected s.c. with 0.05, 0.1, or 1.0 mg/kg APO or vehicle. APO produced a dose-dependent decrease in spontaneous DA release in all three age groups at all three doses. Similarly, APO produced a dose-dependent decrease in K+-evoked DA release in all three age groups at all three doses. In addition to these APO-produced effects, agerelated trends were found in both pre-drug spontaneous DA release and pre-drug K⁺-evoked DA release. These data suggest that DA autoreceptors in the neostriatum are functional by 10 days of age in the rat, but that DA release mechanisms mature at a later age. Supported by USPHS BRSG SO7RR07149 and SUNY-Binghamton Faculty Grant.

MULTIPLE KINETICALLY DISTINGUISHABLE
COMPONENTS OF ³H-DOPAMINE RELEASE FROM
NERVE TERMINALS. S. Katragadda ^{**}, M. L. Brown ^{**}, T.

3H-dopamine (DA) release from rat brain synaptosomes was characterized at -60 msec time resolution by a rapid superfusion method (c.f. Turner et al. [1989] Anal. Biochem. 178, 8). The level of ³H-DA uptake and subsequent K⁺stimulated release were -6-fold higher in striatal vs. whole brain synaptosomes. A large, decaying Ca-dependent component of DA release was superimposed upon a small, persistent Ca-independent component. The decay of DA release was analyzed by a variety of power and logarithmic transformations as alternative models. A biphasic exponential

decay model best fit the data, with time constants for the 2 components of decay of 0.12 sec and 1.8 sec.

As compared with ³H-GABA release studied by the same method, maximal Ca dependent DA release required a stronger depolarization (60 mM K⁺ vs 30 mM K⁺). The Caindependent component of DA release was much smaller than the corresponding component of CABA release (8% vs 25%) of the component of CABA release (8% vs 25%). independent component of DA release was much smaller than the corresponding component of GABA release (8% vs 25% of maximum rate). DA release can be restimulated following decay by repolarization for at least 0.3 sec; 10 sec of repolarization produced 80% recovery of DA release amplitude. DA release was not blocked by nimodipine.

IN VITRO INHIBITION OF [3H]5-HT, [3H]NOREPINEPHRINE (NE), AND [3H]DOPAMINE (DA) UPTAKE BY AN EXTRACT OF THE GINKGO BILOBA PLANT (EGB761 Ipsen). <u>J. E. Taylor</u>. Neuropharmacology Laboratory, Biomeasure Inc., 9-15 E Ave, Hopkinton, MA 01748. A standardized extract of the leaves of Ginkgo biloba (EGB761) known to

contain flavonglycosides, proanthocyanidins, terpenes, and organic acids has been used clinically to treat peripheral and cerebral vascular insufficiency, and been used clinically to treat perpirieral and defecta vascular insulindency, and behavioral deficits associated with aging. In addition, pre-clinical studies in rodents have also indicated that EGB761 may be effective in the treatment of acute mechanical damage to the frontal cortex (Attella et al., Exp. Neurol. 105:62, 1989). Previous studies in isolated vascular tissues and *in vivo* regarding the biochemical mechanism(s) of EGB761 have suggested that a potentiation of NE activity and down-regulation of β -adrenergic receptors may underlie, in part, some of the pharmacological actions of the extract (Auguste et al., Gen. Pharmacol. 13:225,1982; Gen. Pharmacol. 13:169, 1982; Brunello et al., Pharm. Res. Comm. 17:1063, 1985). To further explore these et al., Fharm. Hes. Comin. 17-1063, 1985). To further explore mese observations using *in vitro* techniques, the actions of EGB761 on [³H]NE, [³H]5-HT, [³H]DA uptake into isolated synaptosomes has been assessed. Initial experiments employing a single concentration (1 mg/ml) showed that EGB761 inhibited NE uptake by 999%. DA uptake was inhibited 95% and 5-HT 60%. Dose - response curves yielded the following Ki values (mg/ml ± SEM):

5-HT = 0.44 + 0.02 $NE = 0.12 \pm 0.01$ $DA = 0.21 \pm 0.01$

These results provide evidence that EGB761 contains constituents which are active in vitro as inhibitors of biogenic uptake, and this information may contribute to an understanding of the in vivo behavorial effects of the extract. Additional studies are required to determine which components of the extract produce this effect

32.13

INTERACTION OF METAPHIT, AN ISOTHIOCYANATE ANALOG OF PHEN-CYCLIDINE, WITH VOLTAGE-DEPENDENT SODIUM CHANNELS. I. Zimanyi A.E. Jacobson K. K.C. Rice and M.E.A. Reith Dept. Vet. Pharm. Tox. UC Davis, Davis, CA 95616; NIDDKD, NIH, Bethesda, MD 2087; Center for Neurochemistry, NKI, Ward's Island, New York, NY 10035.

Our previous work on the effect of metaphit on electri-cally induced release of [3H]dopamine from rat striatal slices suggested an action on the voltage-dependent sodium channels. Indeed, the binding of [H]batrachotoxinin A 20-a-benzoate (BTX-B) to voltage-dependent sodium channels in rat striatal synaptoneurosomes was inhibited by the presence of metaphit ($IC_50^{-7} \mu M$) or phencyclidine (PCP) ($IC_{50}^{-} = 6 \mu M$). This effect was due primarily to an increase in the dissociation rate of [H]BTX-B binding: a 2-fold increase in k I was observed with 10 µM metaphit or 3 µM PCP.

Treatment with metaphit at 36 °C followed by its removal by washing, reduced (H]BTX-B binding (IC₅₀=22 µM),in contrast to the lack of effect of PCP under these conditions. Finally, tetrodotoxin (TTX)—sensitive, veratridine(30 μ M)—induced influx of [C]guanidine ion was inhibited by metaphit (IC_M=11 μ M) and POP (IC_M=26 μ M). At a lower concentration of veratridine (5 μ M) both metaphit and POP became more potent (7 and 18 µM). Unexpectedly, also the TTX curve shifted to the left (from 88 to 11 nM), suggesting a possible interaction between site 1 and 2. The resent results indicate that the voltage-dependent sodium channel should be added to the growing list of sites of action of metaphit. Supported by grant DA 03025 to M.E.A.R..

EFFECTS OF TETRAHYDROBIOPTERIN (BH4) ON DOPAMINE (DA) AND SEROTONIN (5-HT) SYNTHESIS IN RAT BRAIN SLICES.
P.Z. Anastasiadis¹, E. Ziaja², W.A. Wolf², D.M. Kuhn², and R.A. Levine¹. Cellular and Clinical Neurobiology Program, Department of Psychiatry, Wayne State University, and 'Laboratory of Molecular Neurobiology,
²Laboratory of Neurochemistry, Lafayette Clinic, Detroit, MI, 48207, USA. BH₄ has been shown to influence the metabolism of DA and 5-HT,

presumably through regulating the activities of tyrosine and tryptophan hydroxylase (TPH). We previously showed that BH₄ was devoid of effects on 5-HT metabolism in rat brain synaptosomes (Wolf et al., J. Neurochem., 1990). This is in contrast with other reports that showed a BH₄-induced stimulation of tryptophan hydroxylase (TPH) and 5-HT metabolism in vivo and in rat midbrain slices. These data suggest that BH_4 may have a greater effect on 5-HT synthesis in cell body regions, or that stimulation of 5-HT synthesis is not related to its role as hydroxylase cofactor. Indeed, BH_4 has been shown to enhance DA release into dialysis media from rat striatum (Koshimura et al., J. Neurochem., 1990), which could account for some of the effects of BH₄ on striatal DA metabolism. The present studies are examining the anomaly between our synaptosomal data and other in vitro and in vivo data, and the mechanism of BH4 action in influencing 5-HT and DA metabolism. In preliminary experiments, we have been able to show that BH₄ can stimulate 5-HT synthesis in rat midbrain slices (0.5 mm). Control slices produced a total 5-HTP + 5-HT accumulation of 0.58 pmol/min/mg prot. Incubation of slices with 200 uM BH, increased 5-HTP + 5-HT accumulation to 1.33 pmol/min/mg. We are currently examining the effects of BH₄ on 5-HT and DA metabolism in slices enriched with aminergic cell bodies or terminals.

IMPROVED METHODS FOR THE ASSESSMENT OF HUMAN PLATELET FUNCTIONING AND SEROTONIN-RELATED PHYSIOLOGY. $\underline{G.M.}$ Anderson*, W.C. Horne*, D. Chatterjee*, L.M. Hall*, A. Chatterjee*, B.A. Shaywitz, and D.J. Cohen*. Child Study Ctr., Yale Univ. Sch. of Medicine, New Haven, CT 06510. An improved method for the isolation of platelet

dense granules has permitted the first observation of affinities and capacities of granular 5-HT uptake (Kd 1.07 uM, Vmax 1.4 nmol/mg/min) and granular tetrabenazine (TBZ)-displaceable [³H]-ketanserin binding (Kd 9.4 nM, Bmax 5.4 pmol/mg). Observation of reserpine-blockable 5-HT uptake and of [³H]-ketanserin binding in crude membrane/organelle fractions indicated that the crude fraction can be used for determining capacities when blood volumes are limited.

blood volumes are limited.

The responsivity, temporal stability, and intrasubject variability of ADP-induced platelet aggregation were improved by anticoagulating with 60 uM PPACK instead of 11 mM citrate. The extents of aggregation (1-1.5 uM ADP, N=9) at 1.5 and 4.5 hours with PPAK were 37.8 ± 5.8% and 37.2 ± 4.4%, with citrate 19.1 ± 4.3% and 14.5 ± 4.4%, respectively. Stable and highly responsive (ED50 20-50 nM) 5-HT-induced platelet shape change was also observed in PPACK-anticoagulated, syringe-stored, plasma. Release of endogenous platelet 5-HT could be assessed in PRP (25ul) or whole blood (50ul) using glass fiber filtration and HPLC analysis. Dose-response curves for release induced by thrombin and A23187, and very rapid (< 1 sec) stoppage, could easily be obtained.

rapid (< 1 sec) stoppage, could easily be obtained.

WIDESPREAD REDUCTIONS IN KYNURENIC ACID CONCENTRATIONS IN HUNTINGTON'S DISEASE. M.FLINT BEAL, WAYNE R. MATSON*. KENTON J. SWARTZ, PAUL MILBURY*, ELIZABETH A. RYAN*, ELSDON STOREY, TATSUO OGAWA AND EDWARD D. BIRD. Neurochemistry Laboratory, Mass. Gen. Hosp., Boston, MA 02114 and ESA Inc., Bedford,

Huntington's disease (HD) is characterized by gradually evolving selective Huntington's disease (HD) is characterized by gradually evolving selective neuronal death. Several lines of evidence suggest that an "excitotoxin" mechanism may play a role. Tryptophan metabolism leads to both the excitatory amino acid agonist, quinolinic acid and the excitatory amino acid antagonist kynurenic acid. We recently found increased kynurenine/kynurenic acid rations in HD postmortem putamen. In the present study we used HPLC with 16 sensor coulometricelectrochemical detection to measure kynurenic acid and 20 other electrochemically active compounds in 8 cortical regions callates and cerebellum from controls. HI compounds in 8 cortical regions, caudate and cerebellum from controls, HD, Alzheimer's disease (AD) and Parkinson's disease (PD) patients. Kynurenic acid was also measured in CSF with HPLC with fluorometric detection. acid was also measured in CSF with HPLC with fluorometric detection. Significant reductions in kynurenic acid concentrations were found in the following cortical regions: Brodmann areas 4, 6, 9, 17, 20, 21, and 22. Reductions were as large as 75%. Kynurenine was also reduced in a few regions. Tryptophan showed no significant changes. Smaller reductions in caudate, cerebellum and Brodmann area 10 did not reach significance. No significant reductions in kynurenic acid were found in the AD and PD patients. Kynurenic acid was significantly reduced in HD CSF. Significant changes in guanosine concentrations and tyrosine/xanthine ratios were found in several regions amongst the various disorders. These figures. found in several regions amongst the various disorders. These findings show a widespread deficiency of kynurenic acid in HD. Since kynurenic acid is an antagonist of NMDA receptors, a deficiency could contribute to the pathogenesis of neuronal degeneration in HD.

DIFFUSION CHARACTERISTICS OF INTRASTRIATALLY INJECTED β-ENDORPHIN ANALYZED BY IMMUNOCYTO-CHEMISTRY AND CONFOCAL LASER MICROSCOPY WITH 3-DIMENSIONAL RECONSTRUCTION: RELATIONSHIP TO VOLUME TRANSMISSION

Bejelke and K.Fuxe. Dept.of Histology & Neurobiology, Karolinska Institutet, 104 01 Stockholm, Sweden.

In previous work using intrastriatal adenopituitary transplants (Bjelke.B et al. Neurosci. Lett. 93:1988, 107:1989) it was evident that extracellular concentrations of dopamine could inhibit the release of prolactin from the transplant. Prolactin diffused into the striatal neuropil for distances up to 1.5 mm. In the present study immunocytochemistry show that intrastriatally injected (inj) β -enorphin (β -End) (1 μ g/l μ l) not only diffused into the adjacent neuropil but was also taken up into discrete nerve cell populations in neostriatum and far away located nerve cells in the basal layers of the piriform cortex. β -End immunoreactivity (IR) was present within the cytoplasm of these cellbodies and their dendrites. Following inj of β -End into the the cytoplasm of these cellbodies and their dendrites. Following inj of β -End into the external capsule diffusion was observed along the extraneuronal space surrounding the myelinated axons radiating into the cerebral cortex. Some scattered pyramidal cellbodies were surrounded by strong β -End IR immediately adjascent to the nervecell membrane probably located within the extrapericaryal space. Following an intraventricular inj of β -End $(0.1~\mu g)$ only some tanycytes of the median eminence (ME) became strongly IR with visualization of their processes all the way from the ventricular wall into the external layer of the ME. Thus, diffusion of peptides is not only dependent upon tortuosity and diffusion coefficient of the peptide but also on the ability of certain nerve cells to take up and inactivate peptides. The extracellular space surrounding the fiber bundles appear to give rise to anisotropic diffusion patterns. -The tanycytes in the ME may participate in the transport of large peptides from the CSF into the primary capillary plexus of the ME and also into the surrounding medianosomes. -The present results give new aspects on the transport pathways for volume transmission

ANALYSIS OF RATES OF ELECTRON TRANSFER BETWEEN ASCORBIC ACID AND CYTOCHROME b561 IN SECRETORY VESICLES. Patrick M. Kelley. Vishram Jalukar* and David Njus*, Dept. of Biological Sciences, Wayne State Univ., Detroit, MI 48202.

Chromaffin vesicles from the adrenal medulla and secretory vesicles from the neurohypophysis contain monooxygenases involved in the synthesis of catecholamines and/or neuropeptides. These enzymes require reducing equivalents which, in vivo, are provided by ascorbic acid. Internal ascorbate is maintained by transferring reducing equivalents from external ascorbate across the vesicular membrane through a transmembrane protein, cytochrome b₅₆₁. Electron transfer between the cytochrome and ascorbate/semidehydroascorbate seems to occur via bimolecular reactions characterized by first-order rate constants. The rate constant for the reduction of cytochrome b_{561} by external ascorbate measured by stopped-flow is 450 (±190) $M^{-1}sec^{-1}$ at pH7.0 and increases slightly with pH. The rate constant for oxidation by external semidehydroascorbate is 1.2 (±0.5) x $10^6\,M^{-1}\mathrm{sec}^{-1}$ at pH 7.0 and decreases strongly with pH. The strong pH-dependence of the rate constant for oxidation can be explained by a pH-dependent membrane surface charge. The pH dependence of the rate constant for reduction can be rationalized by the greater reducing power of the ascorbate dianion. The rate constants are consistent with the midpoint reduction potential of cytochrome b_{561} and suggest that the cytochrome is maintained in a reduced state poised to reduce internal semidehydroascorbate as it is formed by intravesicular monooxygenases. Supported by NIH grants GM30500 and GM33849.

HEMICHOLINIUM-3 BINDING IN SYNAPTOSOMAL PROTEINS FROM LIMULUS CENTRAL NERVOUS TISSUE C. Torrence-Campbell, G.A. Lartey*, J.G. Townsel, Department of Physiology, School of Medicine, Meharry Medical College, Nashville, TN 37208.

In our effort to isolate and characterize the high affinity choline transporter we report here on hemicholinium-3 (HC-3) binding in protein fractions prepared from a crude synaptosomal preparation from Limulus central nervous tissue. HC-3 is a specific inhibitor of the High Affinity Choline Uptake System (HAChUS). Our laboratory has demonstrated a HAChUS in Limulus that is significantly inhibited by micromolar concentrations of HC-3. This has been demonstrated in both whole tissues and synaptosomes (Sukumar,et al.,Comp.Biochem.Physiol.75:317,1983, Ivy,et al,Comp.Biochem.Physiol.86:103,1987). Since HC-3 specifically binds but is not transported by the HAChUS, the HC-3 binding site is thought to be on or very closely associated with the high affinity choline transport protein. Ammonium sulfate concentrations from 30 to 70 per cent were used to fractionate proteins from crude synaptosomal homogenates prepared from pooled circumesophageal ring glands and abdominal ganglia. The fractions containing bound [3H]HC-3 were seperated by polyacrylamide gel electrophoresis and visualized by fluorography. Labeled bands corresponding to HC-3 binding sites had a molecular mass similar to that of the HC-3 binding proteins described by Knipper et al.,(Neurochem.Int.14:211,1989). We also demonstrate that binding of [3H]HC-3 can be blocked Nethylmaleimide (NEM). This HC-3 binding site will be utilized in protocols aimed at isolating the high affinity choline transport protein for molecular characterization. (Supported by the MBRS Grant RR08037 and the NSF/MRCE Grant 871485).

STIMULATION OF ^{45}Ca INFLUX IN FRTL-5 CELLS BY MONENSIN. M.L. Koenig, I.D. Gist, and R.C. Smallridge

M.L. Koeniq, I.D. Gist, and R.C. Smallridge Divisions of Neuropsychiatry and Clinical Physiology, Walter Reed Army Inst. Research, Washington, DC 20307. It has been reported recently that Na † currents can alter the Ca $^{2+}$ homeostasis of isolated cardiac myocytes by a Na † -Ca $^{2+}$ exchange-mediated increase in Ca $^{2+}$ influx (Science 248, 372-376, 1990). We have found that at least part of the Ca $^{2+}$ uptake into FRTL-5 cells which have been exposed to the Na † ionophore monensin can be attributed to a similar reversal of the Na † -Ca $^{2+}$ exchange process. Under physiological conditions (135 mM NaCl; 1.3 mM CaCl₂), monensin has no measurable effect on 45 Ca influx in suspended FRTL-5 cells. However, if the Na $^{+}$ -Ca $^{2+}$ in suspended FRTL-5 cells. However, if the $\mathrm{Na}^+\mathrm{-ca}^{2+}$ exchange protein is "primed" by reducing the extracellular Na^+ concentration to 67.5 mM (with an equimolar substitution of choline chloride), monensin (500 uM) promotes a 296 \pm 33 percent increase in the uptake of 45 Ca uptake measured after 10 min. When extracellular Na $^+$ is completely removed, monensin (500 extracellular Na is completely removed, monensin (500 uM) is still able to elicit a significant increase in the amount of 45 Ca influx. This suggests that the effect of monensin on Ca $^{2+}$ fluxes in FRTL-5 cells is not solely due to the promotion of Na $^+$ entry. We are investigating the possibility that monensin-induced changes in intracellular pH (BBA $\underline{1051}$, 242-249, 1990) may also play a role in the alteration of Ca $^{2+}$ homeostasis in these

cDNA CLONING AND SEQUENCE DETERMINATION OF OCTOPAMINE LIGAND BINDING PROTEINS. L. Kantham,* E. Hunnicutt, and J.A. Nathanson. Dept. of Neurology, Harvard Medical School and Neuropharmacology Research Lab., Massachusetts

School and Meuropharmacology research tab., Massachusetts General Hospital, Boston, MA 02114.

Octopamine (OA) functions in invertebrates as a neurotransmitter and hormone with actions analogous to those which norepinephrine and epinephrine manifest in We have recently designed a photoaffinity verterrates. We have recently designed a photoarfinity probe for OA receptors which specifically labels three proteins in the firefly light organ, a tissue highly enriched in OA receptors. These are: Al (MW 79 kDa), A2 (MW 75 kDa), and B (MW 75 kDa). A2 has recently been isolated and the first 20 amino acids of its N-terminal determined. Using oligonucleotides synthesized according to this sequence a lambde GIIO cDNA library constructed to this sequence, a lambda GT10 cDNA library constructed from firefly tail mRNA was screened and 8 positive clones were isolated from 80,000 plaques. All of these contained identical inserts of approximately 2200 bp. On Northern blots, the common insert labeled an RNA band of 2300 bp from firefly lanterns but not from firefly abdomen, thorax, head, or from rat liver or brain. The insert was cloned into pCDM8 and sequenced, nucleotides 17-76 corresponding to the original protein sequence of the A2 band. The structure of the A2 clone will be described and its relationship to OA receptors discussed. In addition, the isolation of other putative OA receptor clones will be described.

33.2

AGE AND STRAIN RELATED CHANGES IN THE RAT MELATO-NIN RECEPTORS. J.T. Laitinen, M. Viswanathan and J.M. Saavedra. Section on Pharmacology, Lab. Clin. Sci., NIMH, Bethesda, MD 20892.

Apart from GTP and cation modulation of agonist binding to melatonin (MT) receptors, little is known about factors regulating these receptors. We have therefore assessed MT receptor status in the rat, using several experimental models and quantitative autoradiography in vitro.

Experiments planned to clarify short term homologous regulation (pinealectomy or MT injecin the area postrema (AP) and suprachiasmatic nuclei (SCN). On the contrary, age-related changes in MT receptor expression were evident in the AP, SCN, pituitary/pars tuberalis and in two recently identified (Viswanathan, M. et.al., this issue) MT receptor sites, the caudal artery and the arteries forming the circle of Willis.

A role for water and salt balance in the regulation of MT receptors in the AP is suggested based on selective upregulation of these recepafter manifestation of hypertensive rats only after manifestation of hypertension.

These and additional experimental models are

likely to deepen our understanding on the factors regulating mammalian MT receptors.

PURIFICATION OF HUMAN BRAIN A, ADENOSINE RECEPTOR. H. Nakata, Lab. of Clinical Science, NIMH, Bethesda, MD

A complete purification of A₁ adenosine receptor from rat brain membranes was recently reported using a novel affinity chromatography system (Nakata, H.,J. <u>Biol. Chem. 264: 16545, 1989).</u> In this study, purification of A₁ adenosine receptor from human brain membranes has been performed in order to obtain more knowledge about human adenosine receptors. The A₁ adenosine receptor was solubilized with digitonin from human cerebral cortex membranes and then purified more than 18,000-fold by sequential use of chromatographies on XAC-agarose, hydroxylapatite, re-XAC-agarose and TSK-3000. As assessed with a specific A₁ adenosine receptor antagonist [H]DPCPX (2mM), the membrane preparation, the digitonin-solubilized preparation and the final purified preparation showed the specific binding activity of 0.7, 1.3 and 13,000 pmol/mg of protein, respectively. SDS-PAGE of the final receptor preparation showed one predominant protein band of approximately 35 kDa with silver stain. Antibodies raised against purified rat brain A₁ adenosine receptor were also shown to react with the 35kDa band of the purified human A₁ adenosine receptor were should facilitate the precise screening of various drugs which act on adenosine receptors in human tissues.

CHARACTERIZATION OF ADENOSINE A₁-RECEPTORS IN BOVINE RETINAL MEMBRANES <u>C. Blazynski</u> and <u>C.L. Woods.*</u> Depts. of Biochemistry & Molecular Biophysics, Washington University School of Medicine, St. Louis, MO 63110

Using retinas prepared from freshly dissected bovine eyes, we have characterized the binding of the A_I- selective agonist, ${}^3\mathrm{H}]$ -PIA. Specific binding was linear over a range of membrane proteins from 0.10 to 1.0 mg, and accounted for an average of 90% of the total binding. At room temperature (24° C), binding reached equilibrium at 60 minutes, and was reversible upon addition of an excess of cold ligand. Saturation analysis and Scatchard transformation revealed two apparent populations of receptor binding sites. The higher affinity site exhibited a K_d of 0.134 \pm .007 nM and $B_{\rm max}$ of 26.18 \pm 3.06 fmole/mg protein. The lower affinity site exhibited a K_d of 21.83 \pm 4.39 nM and $B_{\rm max}$ of 53.94 \pm 15.8 fmole/mg protein. Using 0.3 nM [$^3\mathrm{H}]$ -PIA, kinetic analysis of association and dissociation rates yielded a calculated affinity constant of 0.2 nM, in agreement with saturation experiments. Competition studies with a number of purine nucleoside agonists and antagonists were performed, using radioligand concentrations of 1 nM or less to examine binding at the high affinity site, and revealed a rank order of potency consistent with the reported pharmacology of A₁ receptors. We have also assayed for adenylate cyclase activity in this same preparation and determined that PIA inhibited forskolin-activated adenylate cyclase in a dose-dependent manner. Maximum inhibition (40%) was observed with 1 nM PIA, and 10 μ M CPDPX completely antagonized this modulation by PIA. Similar results have been reported previously for homogenates of rabbit retina (J. Neurosci. 7:2522). Supported by EY02294.

NEONATAL CAFFEINE EXPOSURE ALTERS ADENOSINE A1 RECEPTOR KINETICS DURING A CRITICAL DEVELOPMENTAL PERIOD. R. Guillet. Dept. Psychol., Univ. of Rochester, Rochester, NY 14627.

Neonatal caffeine exposure of rats over postnatal d2-6, which mimics therapeutic caffeine exposure in the premature human infant with apnea of prematurity, has been shown in this laboratory to result in lasting effects on adenosine A1 receptor kinetics and on behavioral responses to acute treatment with caffeine, an adenosine antagonist, and with D-phenylisopropyl adenosine (D-PIA), an adenosine agonist. Specifically, control 18d pups responded to acute caffeine injection with an increase in activity, whereas neonatally caffeine-exposed rats did not. Initial kinetic studies done on tissue from 14, 21, 28d (and older) rats suggested no change in binding affinity but an increase in receptor density in cortex (CTX), cerebellum and hippocampus at these ages.

In the present study, cortical tissue from 18d rats that had been unhandled (NH) or exposed to caffeine (C) over postnatal d2-6, at doses yielding serum caffeine levels of 4-15 mg/L over the 24h period, was assayed for specific binding of 3H-cyclohexyl adenosine. While specific binding in 18d NH CTX was not different from 14d or 21d NH CTX, specific binding was significantly lower (p=.006) in CTX from 18d C pups compared with that in CTX from 14 and 21d C pups or that in 18d NH CTX. Furthermore, kinetic analysis demonstrated that this effect was due to a significant decrease (p<.0001) in binding affinity (Kd: NH=.78±.07; C=3.63±.20). It thus appeared that the A1 adenosine receptors in 18d C pups were primarily in a lower affinity state than in 18d NH pups. Analysis of other brain regions is currently underway.

The developmental period between 15 and 18d appears to be a critical period for the appearance of a stimulatory effect of caffeine in control rats and earlier caffeine exposure may interfere with receptor changes that take place over this period. Supported by NIH grant no. HD22782.

A DISCRETE HIGH MOLECULAR WEIGHT COMPLEX CONTAINING THE ADENOSINE A₁ RECEPTOR SOLUBILIZED FROM RAT CEREBRAL CORTEX. M.R. Sherman, F.B. Tuazon* and M.N. Martin*. Dept. of Biological Sciences, Rutgers University, Newark, NJ 07102. There is general consensus regarding the binding specific-

There is general consensus regarding the binding specificity, inhibition of adenylate cyclase and electrophysiological responses mediated by adenosine A_1 receptors. Reported values of the physicochemical parameters, however, differ widely. Values of M_r vary from 34-38 kDa for the purified ligand-binding unit to c. 60 kDa for receptors studied by radiation inactivation in situ. We have characterized the A_1 receptors solubilized from rat cerebral cortex by glycerol gradient centrifugation and Agarose gel filtration in buffers containing 2.5 mM MgCl₂, protease inhibitors and various detergents. Receptors were labeled with 3H -R-phenylisopropyladenosine and stripped of unbound ligand on Sephadex LH-20 columns. Solubilization in 24 mM CHAPS and analysis in 4 or 24 mM CHAPS revealed highly aggregated receptor forms ($s_{20,w}$ = 24-28 S). Combinations of CHAPS and digitonin (Dig.) released mixtures of receptor forms (4-11 S). Solubilization in 1% Dig. and analysis in 0.2% Dig. revealed a single discrete complex ($s_{20,w}$ = 14 S, Stokes radius = 6.1 nm). For a protein of normal density, these parameters correspond to M_r = 360 kDa. Others have shown that Dig.-solubilized receptor forms contain G-protein(s). Our results indicate that the 14 S complex must contain more than one receptor and one G-protein (c. 88 kDa). The discrete form and the stability of this complex suggest that it is not the product of adventitious association following solubilization.

DIFFERENTIAL EFFECTS OF A GUANINE NUCLEOTIDE AND A CATION ON ADENOSINE RECEPTOR AGONIST AND ANTAGONIST BINDING. J.Deckert, P.F. Morgan, J.C.Bisserbe*, K.A.Jacobson*, K.L.Kirk*, J.W.Daly* and P.J.Marangos . NIMH and NIDDK, NIH, Bethesda, Md. 20892.

Guanine nucleotides have been demonstrated to decrease adenosine receptor agonist binding, cations in general increased it in brain membranes. Antagonist binding appeared not affected (Goodman, R.R. et al., Mol.Pharmacol., 21:329, 1982).

With the availability of high affinity antagonist radioligands (Jacobson, K.A. et al., PNAS U.S.A., 83:4089, 1986) we decided to investigate the effects of 100 uM Gpp(NH)p and 2 mM MgCl $_2$ on adenosine receptor antagonist and agonist binding in brain slices using as radioligands (3 H)XAC and (3 H)CHA.

As expected Gpp(NH)p decreased and MgCL2 increased (3H)CHA binding while Gpp(NH)p had no effect on (3H)XAC binding. Surprisingly, however MgCl2 decreased (3H)XAC binding.

TENTATIVE SUBCLASSIFICATION OF THE ADENOSINE A1 (AD A1) RECEPTOR IN MAMMALIAN HIPPOCAMPUS. H.L. Wiener, B. Craddock-Royal* and S. Maayani. Coll. Pharmacy, St. John's Univ., Jamaica, NY 11439 (H.L.W.), and Depts. Anesthesiol. (H.L.W., B.C.-R., and S.M.) and Pharmacol. (S.M.), Mt. Sinai Sch. Med., CUNY, NY, NY 10029.

The reported species-related diversity of the adenosine A1 (AD A1) receptor may be accounted for by the existence of different receptor subtypes across the species. Classification of receptor subtypes by pharmacological methods can be accomplished by determination of affinity constants of antagonists (but not agonists) as they should display the same affinity for the multiple receptor affinity states. Dissociation constants (Kd) of 8-cyclopentyltheophylline (CPT) and 8-cyclopentyl-1,3-dipropylxanthine (CPX) were determined in membrane preparations from bovine, rat, and guinea pig hippocampi. Three populations of the AD A1 receptor affinity states were assayed: 1. the low affinity agonist state (L) by assaying adenylyl cyclase (AC) activity: AD A1 agonists inhibited forskolin-stimulated AC activity and Kd values of antagonists were calculated from the dextral shifts of concentration-response curves. 2. High-affinity, 5'-guanylylimidodiphosphate-insensitive agonist state (H) by [3H]R-PIA binding. Binding curves of antagonists for these sites exhibited simple competitive behavior. 3. L and H affinity states by [3H]CPX. Antagonists competed for these sites in a simple competitive manner while agonists exhibited a shallow curve, best described by two affinity states. In a given species, the Kd values of CPT and CPX were independent of the population of the affinity state. Across species the Kd values varied over a log unit, being the lowest in the bovine. These data suggest that the observed species related diversity of the AD A1 receptor can be explained by subclasses that exist across species. (US PHS GM 34852).

MODULATION OF MOSSY FIBER INPUT TO CA3 HIPPOCAMPAL PYRAMIDAL CELLS BY ADENOSINE AND HIGH FREQUENCY STIMULATION C. Janusz¹, M.F. Jarvis² & R. F. Berman³. Depts. ¹Physiol. & ³Psych., Wayne State Univ., Detroit, MI and ²CIBA-GEIGY Corp., Summit, NJ.

The hippocampal mossy fiber system provides a major excitatory synaptic input to CA3 pyramidal neurons. The aim of the present study was to examine adenosinergic modulation of synaptic input into area CA3 of the hippocampus using the hippocampal slice preparation. Extracellular field potentials were recorded from CA3 pyramidal cells while stimulating the stratum radiatum of CA3 in the region of the hilus. Current-source density analysis showed regional differences in the appearance of the field potentials elicited from each of the subdivisions of CA3. Also, high frequency mossy fiber stimulation elicited at least two forms of LTP; one rapid and one slowly developing. Superfusion with adenosine produced a dose-dependent reduction in the amplitude of the evoked EPSP and of the population spike (PS). Addition of theophylline to the perfusate produced a dose-dependent enhancement of the field EPSP and PS. Application of the A2 specific agonist CGS-21680 using the interface slice preparation also resulted in a dose-dependent reduction of the field EPSP and PS which could be reversed by application of theophylline. These results suggest both Al and A2 inhibitory modulation of hippocampal synaptic activity. (Supported by NIH Grant No. RR-08167).

33.11

CHARACTERIZATION OF EXTRACELLULAR ADENOSINE IN THE RAT STRIATUM WITH IN VIVO MICRODIALYSIS. D.J. Fontana, A. Mele, M. Clark, R.M. Post and A. Pert. Biological Psychiatry Branch/National Institute of Mental Health Bethesda MD 20892

Institute of Mental Health, Bethesda, MD, 20892. Although adenosine (ADO) is an important catabolite of ATP there are also indications that it may serve as a neuromodulator or neurotransmitter. The origin and processes underlying its extracellular levels in brain are not fully understood, however. The purpose of this study was to characterize the extracellular levels of ADO in the the rat striatum utilizing *in vivo* microdialysis. *In vitro* studies indicate that recovery of ADO through a 3mm microdialysis probe (CMA) perfused with artificial CSF at 2 µl/min was approximately 3%. The ADO levels in the dialysate from striatal perfusion were 41.4 nM immediately following probe insertion and decreased gradually over 3 hours. From 3-7 hours ADO levels remained stable at approximately 2.5 nM in the dialysate. These data suggest the basal levels of ADO in the striatal extracellular space are approximately 83 nM. Basal levels of ADO were not altered following pefusion with artificial CSF containing 10 uM TTX or with Ca⁺⁺-free aCSF containing high levels of Mg⁺⁺ or Co⁺⁺. Addition of high concentrations of K⁺ to the perfusion medium enhanced striatal ADO levels by 439%. This K⁺-evoked ADO release was attenuated by both TTX and Co⁺⁺ treatments. These findings suggest that whereas basal levels of striatal ADO are not derived from exocytotic release, the K⁺-evoked release of ADO may be.

33.13

THE CONTRIBUTION OF ADENOSINE TO BRADYKININ-INDUCED PLASMA EXTRAVASATION IN THE RAT KNEE JOINT. Paul G. Green, Allan I. Basbaum and Jon D. Levine* Dept. Medicine, UCSF, Box 0452A, San Francisco, CA 94143.

The potent inflammatory mediator bradykinin (BK) produces plasma extravasation (PE) in the knee joint of the rat that is dependent on intact sympathetic postganglionic neuron (SPGN) terminals (*J. Neurophysiol.* 62:48, 1989). Although BK releases a variety of mediators from SPGN termi-nals, it is not known which of these mediators contributes to PE. We have examined the contribution of adenosine, a cotransmitter stored in and released from SPGNs, to BK evoked PE in the rat knee joint.

Male rats were anesthetized and injected i.v. with Evan's blue dye. The knee was continuously perfused with saline, and baseline PE levels were established. BK alone or with adenosine agonists or antagonists were then added to the perfusion fluid. PE was quantified by measuring Evan's blue concentration in the perfusate (absorbance at 620nm).

The A₂ selective agonist, CGS21680, enhanced BK PE; the A₁ agonist. CPA antagonized BK PE. Inhibition of adoption

The A2 selective agonist, CGS21680, enhanced BK PE; the A1 agonist, CPA, antagonized BK PE. Inhibition of adenosine metabolism (with deoxycofornycin) and uptake (with dipyridamole) also enhanced BK PE. We conclude that SPGN-derived adenosine contributes to neurogenic inflammation.

INHIBITION OF SYNAPTIC POTENTIALS BY ENDOGENOUS ADENOSINE IN HIPPOCAMPAL SLICES FROM YOUNG AND AGED FISCHER-344 RATS. Lisa A. Bauman and Valentin K. Gribkoff. CNS Pharmacology. Dept. 404, Bristol-Myers Squibb Pharmaceutical Research Institute. 5 Research Parkway. Wallingford. CT 06492.

Institute, 5 Research Parkway, Wallingford, CT 06492.
Endogenous adenosine has been suggested to play a potentially important tonic inhibitory role in the rat hippocampus. Little is known, however, about the integrity of this system in the hippocampus of aged rats. In these ex-periments, the degree of endogenous adenosinergic inhibition was assessed in hippocampal slices from young (1-3 mo) and aged (24-27 mo) F-344 rats. In normal medium, CA_1 population responses from slices from young rats were single peaks that increased in amplitude with increased stimulation currents. In slices from aged rats, high current levels produced multiple peaks, suggesting that cell excitability was enhanced. The specific adenosine A_1 receptor antagonist, 8-cyclopentyltheophylline (8-CPT; 250 nM-2 $\mu M)$ produced an increase in the amplitude of synaptic responses in slices from both young and aged rats, but appeared to enhance excitability to a greater extent in slices from aged rats. Multiple peaks were observed at relatively low stimulus levels in slices from aged rats in 8-CPT, but the antagonist did not produce this response profile in slices from young rats even at high stimulus currents. These data suggest that aged rat hippocampal neurons may be more excitable than young counterparts and that the tonic inhibitory role of adenosine may be particularly important in the aged hippocampus.

33.12

ADENOSINE AGONISTS AND DOPAMINE ANTAGONISTS BLOCK THE CONTRAVERSIVE CIRCLING BIAS INDUCED BY UNILATERAL INTRASTRIATAL CAFFEINE. S. A. Josselyn and R. J. Beninger, Dept Psychol, Queen's University, Kingston, K7L 3N6 Canada

Although caffeine is generally classified as a psychomotor stimulant, the neurotransmitter systems mediating its behavioral effects have not yet been established. Evidence suggests possible involvement of adenosinergic and/or dopaminergic (DA) systems. Previous evaluation has shown that unilateral intrastriatal microinjections of caffeine (10.0 ug) produced a contraversive circling bias in otherwise intact rats (Beninger and Josselyn, Soc. Neurosci, Abstr., 1989). To evaluate the neurotransmitter systems involved in this, three experiments examined the effect on circling behavior of 1) 2-chloroadenosine (2-CADO; an adenosine agonist) alone, 2) caffeine and 2-CADO co-injection and 3) caffeine and co-injection of the DA receptor antagonist, cis-flupenthixol. Each experiment consisted of seven test sessions; the first and sevent were preceded by no treatment, the second and sixth by a control microinjection (either saline or cis-flupenthixol) and the third, fourth and fifth by drug microinjections. Results showed that 2.0, 5.0 but not 1.0 ug doses of 2-CADO produced an ipsiversive circling bias, opposite in direction to that produced by caffeine. Rats pre-treated with central 2-CADO or cis-flupenthixol (in doses that did not influence circling bias when administered alone) prior to caffeine (10.0 ug) failed to exhibit a contraversive bias. Results strongly suggest that the effects of intrastriatal caffeine on motor behavior are mediated by antagonism of endogenous adenosine which, in turn, functionally increases DA. Supported by NSERC.

IDENTIFICATION OF MULTIPLE H₃ HISTAMINE RECEPTOR SUBTYPES. R.E West, Jr., A. Zweig*, M.I. Siegel*, R.W. Egan* and M.A. Clark*. Department of Allergy and Immunology, Schering-Plough Research, 60 Orange Street, Bloomfield, NJ 07003.

We have characterized binding to the rat brain H_3 histamine autoreceptor with the agonist $[^3H]N\alpha$ -methylhistamine ($[^3H]NAMHA$). $[^3H]NAMHA$ saturation binding and NAMHA inhibition of $[^3H]NAMHA$ binding were consistent with an apparently single class of receptors ($K_D=0.37$ nM, $B_{max}=73$ fmol/mg protein). Competition assays with other agonists and the antagonists impromidine and dimaprit also disclosed only a single class of sites. In contrast, the specific, high-affinity, H_3 antagonist thioperamide revealed two classes of sites ($K_{iA}=5$ nM, $B_{maxA}=30$ fmol/mg protein; $K_{iB}=68$ nM, $B_{maxB}=48$ fmol/mg protein.) The distinction between H_{3A} and H_{3B} receptor subtypes, the former a high-affinity and the latter a low-affinity thioperamide site, draws support from published in vitro data.

THE EFFECTS OF HISTAMINE ON THE MEMBRANE POTENTIAL OF RAT MAGNOCELLULAR SUPRAOPTIC NEURONS RECORDED INTRACELLULARLY IN VITRO. B.N. Smith and W.E. Armstrong. Dept. of Anat. Neurobiol., Univ. Tenn., Memphis, The Health Science Center, Memphis,

The effects of histamine on magnocellular neurons in the rat supraoptic nucleus were investigated using intracellular recording techniques from the hypothalamoneurohypophysial explant. Exogenous application of histamine depolarized 75% of the neurons and hyperpolarized the remaining 25%, with no predictable effect on input conductance. Interestingly, the neurons which were depolarized had resting potentials more negative than -45 mV (-45 to -80 mV), whereas the hyperpolarized neurons had resting potentials between -40 and -45 mV. Depolarizations exhibited a rapid onset and slow recovery, while hyperpolarizations generally exhibited a slower onset and were occasionally preceded by a small, transient depolarization.

Tetrodotoxin (1 µM) failed to block histamine's effect on membrane potential. Neurons which depolarized in response to histamine exhibited a decrease in the amplitude of the afterhyperpolarizing potential following individual spikes or current-evoked trains of spikes, and an increase in the depolarizing afterpotential following current-evoked trains of spikes, when measured at the pre-histamine membrane potential. Opposite effects on afterhyperpolarizing potentials and depolarizing afterpotentials were exhibited by neurons which were hyperpolarized by

The present findings indicate that histamine directly depolarizes or hyperpolarizes magnocellular supraoptic neurons and affects the afterpotentials which shape the firing patterns of these neurons. Supported by NIH grant #NS23941 and the Neuroscience Center of Excellence

RECOGNITION OF H, AGONISTS AND ANTAGONISTS BY HJHISTAMINE-LABÉLED SITES IN GUINEA-PIG CEREBRAL CORTEX.

William G. Sinkins* and James W. Wells. Faculty of Pharmacy,
University of Toronto, Toronto, Ontario, Canada M5S 2S2.

Tritiated histamine and H₂-specific ligands distinguish between at least two states of putative H₂ receptors in membranes from guinea-pig cerebral cortex. GMP-PNP promotes a conversion of sites from higher to lower affinity for histamine, with no change in the equilibrium dissociation constant for either state (log $\rm K_1=-8.46, \log K_2=-6.54$). The labeled sites thus resemble G-linked receptors. Among 12 agonists tested, apparent binding affinity for the appropriate state correlates with H_a functional potency in guinea-pig right atrium (P = 0.0045); the labeled sites thus reveal a pharmacological specificity characteristic of ${\rm H_2}$ receptors. There is no correlation in a similar comparison with ${\rm H_2}$ antagonists, which nevertheless appear to recognize the labeled sites as Ha receptors: inhibitory behavior at two concentrations of [3H]histamine shows that four antagonists and the weakly efficacious agonist impromidine reveal the reverse preference $(K_2 < K_1)$ to that of histamine and four other agonists $(K_1 < K_2)$ for the labeled sites. Such a reverse preference is typical of those G-linked receptors that reveal a dispersion preference is typical of those d-linked receptors that reveal a dispersion of affinities for antagonists. Among H_2 antagonists, the ratio of affinities for the two states ($K_1/K_2=4-250$) is comparable to that observed for agonists ($K_2/K_1=4-600$); in other systems, the ratio for antagonists typically is much smaller than that for agonists. Liganddependent differences in the inferred affinity of histamine and in the apparent distribution of sites between the two states suggest that inhibition of the radioligand is at least partly noncompetitive.

Voltage-dependent, Ca2+-activated Outward Potassium Currents in Explanted Cells of Neonatal Swine Carotid Arterial Smooth Muscle. Hossein Hashemzadeh-Gargari, Yong I Kim and Christopher M. Rembold From the Division of Cardiology, Departments of Medicine, Biomedical Engineering, and Physiology, University of Virginia Health Sciences Center, Charlottesville, VA 22908, USA

Using the patch-clamp technique, we measured whole-cell K+ currents (lk) in neonatal (1-5 days) swine carotid arterial smooth muscle explanted cells and determined their biophysical and pharmacological characteristics. The identity of the cultured smooth muscle cells was determineed by immunocytochemical staining of the cytoskeleton using rhodamine-phalloidin and antibodies against smooth muscle myosin, desmin and actin. The cell length of explanted smooth muscle in M199 medium ranged 150-200 μm in cell culture and had a resting potential of about -40 mV in different passages. K+ currents from the cells held at -80 mV and depolarized to -30 to +120 mV with a pulse duration of 60 ms exhibited exponential rise with little inactivation. The total outward K+ current was variable, but reached up to 3 nA at 120 mV. These K+ currents appeared to at least partially consist of Ca2+-activated currents since replacement of Ca2+ with consist of Ca2+-activated currents since replacement of Ca2+ with 1 mM Co2+ and 11 mM EGTA resulted in an approximately 40% reduction in lk. The outward K+ current was reduced by external bath application of tetraethylamonium (10 mM) or 4-AP (5 mM). Histamine (100 μM) increased the total amplitude of the K+ currents in neonatal explanted smooth muscle cells. Histamine also transiently increased intracellular [Ca2+] as measured with INDO-1 at 37 0C. These data suggest that a Ca2+-dependent outward K+ current exists in white participations. swine carotid cells and this current is activated by histamine.

BRAIN L - HISTIDINE DECARBOXYLASE (HDC) MEASUREMENT BY CO₂ TRAPPING. H. Kishikawa. S. Willinger, S. Jackowski, and L. B. Hough, Dept. Pharmacol. Toxicol. Albany Medical College, Albany, NY 12208.

A convenient and sensitive method for measuring HDC in crude brain homogenates was developed by modification of existing CO₂ trapping methods. Crude homogenates

of existing CO₂ trapping methods. Crude homogenates prepared from male Sprague-Dawley rat hypothalamus containing 0.1 M sodium phosphate, pH 6.8, 0.2 mM containing 0.1 M sodium phosphate, pH 6.8, 0.2 mM dithiothreitol, 0.1 mM disodium EDTA and 1% polyethylene glycol - 300 were incubated (37°) in the presence of ¹⁴C-L-histidine (0.1 uCi, 2.9 nmol) and pyridoxal phosphate (1 nmol) in a total of 0.1 mL. ¹⁴CO₂ was trapped and counted as described by Beaven et al. (Analyt. Biochem. 84:638, 1978). Hypothalamic homogenates (8 mg, 3.5 hr) typically yielded 630 - 860 cpm, with buffer blanks and boiled homogenates giving 80 - 125 cpm. Enzyme activity was linear with incubation - 125 cpm. Enzyme activity was linear with incubation time (0.5-4~hr) and tissue content (2-10~mg), and the crude enzyme was stable for up to 10~weeks at -80° . A-fluoromethylhistidine and a-hydrazino-histidine (MDC inhibitors, 10⁻⁴ M) inhibited activity by 95%, whereas chelidonic acid, difluoromethylornithine and amethylDOPA (inhibitors of glutamate, ornithine and DOPA DC, respectively) had little or no effect. Results from substrate-velocity and brain regional studies are similar to previous findings with brain HDC measured by other methods (supported by DA-03816).

TYROSINE HYDROXYLASE mRNA IN THE ARCUATE NUCLEUS IS MORE ABUNDANT IN THE FEMALE THAN THE MALE RAT. S.L. Cottingham. K.J. Lookingland. and K.M. Moore. Dept. Pharmacology, Michigan State University, East Lansing, MI 48824.

The activity of tuberoinfundibular dopamine (TIDA) neurons is greater in female than in male rats. This difference may lead to differential expression of the gene for tyrosine hydroxylase (TH), the rate-limiting enzyme in catecholamine synthesis. The following experiment tests the hypothesis that TH mRNA is more abundant in TIDA neurons in female than in male rats. Males (n=4) and diestrous females (n=4) were decapitated and brains frozen on dry ice. Twelve µm frontal sections were taken from the rostral periventricular hypothalamus through the arcuate nucleus. In situ hybridization histochemistry was performed using a ³⁷⁵-labelled oligonucleotide probe against TH (gift from Brian Martin, NIMH). Emulsion autoradiograms were obtained from labelled sections and grains/cell were counted manually, at 400% magnification. For analysis, cell bodies in the arcuate nucleus (A₁₂ cell group) were classified by anatomical location as periventricular or ventrolateral. The amount of TH mRNA in the periventricular arcuate nucleus was significantly higher in female than in male rats (30.9+1.8 v. 20.9+2.0 grains/cell). There were no female-male differences in the ventrolateral arcuate nucleus (22.9+3.8 v. 18.6+2.6 grains/cell) or the rostral periventricular hypothalamus (A₁₄ cell group; 25.0+2.6 v. 23.8+1.8 grains/cell). These data suggest that the gender difference in the rate of activity of TIDA neurons. Ongoing studies will explore the role of prolactin in regulating TH gene expression in TIDA neurons. (Supported by ADAMHA grant MH 42802.)

EFFECT OF AGING ON TYROSINE HYDROXYLASE PROTEIN CONTENT AND THE NUMBER OF DOPAMINE NERVE TERMINALS IN HUMAN CAUDATE. M.E. Wolf. P.A. LeWitt, M.J. Bannon, L.J. Dragovic, and G. Kapatos. Center for Cell Biology, Sinai Hospital, The Cellular and Clinical Neurobiology Program, Wayne State Univ. Sch. of Med. and The Wayne County Medical Examiner's Office, Detroit, MI 48235.

To examine the effect of aging on dopamine (DA) nerve terminals in human caudate nucleus, two measurements were performed on post-mortem tissue obtained from normal subjects (1 mo to 63 yrs). First, a synaptosomal fraction was prepared and dopaminergic synaptosomes were selectively labeled with a monoclonal antibody to tyrosine hydroxylase (TH) and a fluorescent secondary antibody. Fluorescence-activated cell sorting was then used to identify dopaminergic synaptosomes and to quantify the percentage of caudate synaptosomes which were dopaminergic. Second, quantitative immunoblot studies were used to examine the concentration of TH protein in the same synaptosomal preparations. Our findings indicate that the normal aging process does not alter either the relative number of DA nerve terminals or the concentration of TH protein and therefore, by inference, the amount of TH protein per DA nerve terminal. The immunoblot studies identified 3 forms of TH monomer differing in molecular weight (60.6, 61.7 and 65.1 kDa), providing the first evidence that mRNAs coding for high molecular weight forms of TH may be actively translated in human brain. No age-related differences in the relative abundance of these forms were found. Supported in part by the United Parkinson Foundation (GK) and NS 27892 (PAL). To examine the effect of aging on dopamine (DA) nerve terminals in human

DOPAMINE RECEPTOR ANTAGONISTS RAPIDLY INCREASE AROMATIC L-AMINOACID DECARBOXYLASE (AADC) ACTIVITY, IN AROMATIC L-AMINOACID DECARBOXYLASE (AADC) ACTIVITY, IN RAT STRIATUM. M. Y. Zhu, A V. Juorio,J. A. Paterson and A.A. Boulton, Neuropsychiatric Research Unit, M.R. Bldg, University of Saskatchewan, Saskatcon,Saskatchewan, Canada. S7N 0W0

Decarboxylation of phenylalanine by AADC is the rate limiting step in

2-phenylethylamine (PE) synthesis. Since neuroleptics increase striatal PE levels it suggested that this effect may be mediated by a change in AADC activity. It has been reported that D1 receptor antagonists increase AADC activity in the retina and recent investigations suggest that DA receptor blockers increase the rate of accumulation of PE in the striatum. The object of the present study was to investigate the effects of some DA receptor antagonists on AADC activity and to examine the interaction between AADC activity and PE synthesis in the striatum and nucleus accumbens. AADC activity was determined in rat brain homogenates by measuring the amount of DA formed from L-DOPA using HPLC-ED. The drugs SCH 23390 and pimozide were administered intraperitoneally 2 hours before death. SCH 23390, at doses of 0.01-1 mg kg⁻¹ significantly increased AADC activity in the striatum (16-33 %). Pimozide (0.1-3 mg kg⁻¹) increased AADC activity in the striatum (25-41 %) and similar increases were observed in the nucleus accumbens. These findings suggest that AADC activity in the striatum is modulated by D1 and D2 receptors and indicate that the increase in the rate of accumulation of PE after administration of DA receptor blockers, may be related to the activation of AADC and this could have implications with respect to the mechanism of the effect of some neuroleptic drugs. Supported by Saskatchewan Health, Saskatchewan Health Research Board and the M.R.C. of Canada.

INTERACTION OF NUCLEAR PROTEINS WITH THE PROMOTER REGION OF THE TYROSINE HYDROXYLASE GENE. A. W. Tank, L. H. Fossom, J. Best*, E. Lynd and R. Patil*, Department of Pharmacology, University of Rochester, Rochester, NY 14642.

The transcription rate of the tyrosine hydroxylase (TH) gene is influenced by a large number of extracellular stimuli including nicotinic These stimuli are thought to regulate TH gene expression by influencing the DNA binding properties and/or transcriptional regulatory activities of intracellular trans-acting protein factors that interact specifically with sequences within the TH gene. We have investigated the binding of nuclear proteins isolated from rat pheochromocytoma PC18 cells to the promoter region of the TH gene extending 149 bp upstream from the transcriptional initiation site. Using a gel shift assay we have identified PC18 cell nuclear proteins that apparently bind to three segments within this region of the gene; two proteins bind to the sequences between bp -149 to -106 (this region contains a consensus SP1 binding site); two 149 to -106 (this region contains a consensus SP1 binding site); two proteins bind to sequences between bp -108 to -58; and three proteins bind to sequences between bp -60 to -27 (this region contains a consensus cyclic AMP response element). Competition studies suggest that at least 4 of these proteins bind specifically to these regions of the TH gene. Furthermore, treatment of the PC18 cells with cycloheximide for 4 hr prior to isolation of the nuclear proteins results in a decreased amount of binding for a number of these nuclear proteins. Since cycloheximide treatment also decreases basal transcription of the TH gene, these protein factors may be involved in maintaining the basal rate of transcription of the gene

(Supported by AHA grant 89-050G and DA 07232.)

VIP, SECRETIN, AND PHI EFFECTS ON TYROSINE HYDROXYLASE GENE EXPRESSION IN PC12 CELLS. M. Wessels-Reiker, A.C. Howlett, and R. Strong. Departments of Pharmacology and Medicine, St. Louis University School of Medicine, and GRECC, St. Louis VA Medical Center, St. Louis, MO,

As the rate limiting enzyme in catecholamine biosynthesis, tyrosine hydroxylase (TH) is important in determining sympathetic tone. The activity of TH is regulated in the short term by changes in the phosphorylation of the enzyme and in the long term by changes in expression of the tyrosine hydroxylase gene. Vasoactive intestinal peptide (VIP) has recently been established as a neurotransmitter within the splanchnic nerve which innervates the adrenal medulla (Wakade,89) and both VIP and secretin, homologous perticles within the discretions with hydroxyners to select the secretic percentage. peptides within the glucagon family, have recently been demonstrated to elicit short term activation of tyrosine hydroxylase (Zigmond,89). We therefore undertook a series of studies to determine whether VIP, secretin, and peptide histidine isoleucine (PHI), another related peptide, could induce long-term changes in gene expression which parallel their short term effects on TH activity.

Experiments were performed in PC12 cells, a rat chromaffin cell line. Preconfluent cells were incubated 6 hours with various concentrations of hormone. Following total RNA extraction, Northern and slot blots were performed using a full length TH.36 cDNA probe. We found secretin to be more potent at low doses while VIP had a greater maximal effect. Our findings with these neuropeptides parallels what has been reported for their effects on short term activity, suggesting that TH phosphorylation and gene expression may be regulated by the same intracellular signals.

CHARACTERIZATION OF TWO cDNA FORMS OF BOVINE AND RAT DOPAMINE B-HYDROXYLASE, K.T. Kim, T. Wessel, K.S. Kim, C. Carver and T.H. Joh. Lab. Molec. Neurobiol., Cornell Univ. Med. College, The Burke

Rehabilitation Center, White Plains, NY 10605.

Dopamine β-hydroxylase (DBH) is one of the key enzymes in catecholamine biosynthesis, catalyzing the conversion of dopamine to noradrenaline. This enzyme serves as specific marker protein for noradrenergic neurons. We have cloned DBH cDNA from bovine adrenal medullary cells (Soc. Neurosci. Abstr. 15:818, 1989) and rat PC-12 cells (FASEB J. 4:A318 1990). Both the bovine and rat DBH cDNAs have two forms that differ in the 3'-terminal region, as prevoiusly described for the human DBH cDNA (Kobayashi et al., Nucl. Acid. Res. 17:1089,1989). The bovine DBH messages were of 2.8 kb and 4.4 kb size, compared to the rat cDNA forms of 2.5 kb and 2.8 kb, seen on Northern blot compared to the lat CDNA forms of 2.50 and 2.50, seen on Nothern blot analysis. The ratio of small and large message in bovine and rat adrenal gland was approximately 10:1. The two forms of DBH cDNA share the same coding sequences but have different 3'-untranslated regions that possess alternative polyadenylation sites. It is presently unknown whether the different mRNA sizes represent cytosolic and membrane-bound forms of DBH. Twenty-four hours after a single injection of reserpine (10 mg/kg) comparable increases in mRNA for both sizes were observed in the rat adrenal gland. In situ hybridization using a rat cDNA probe for DBH specifically localized to the locus coeruleus in central nervous system as well as the adrenal gland. Supported by MH44043.

NICOTINE INCREASES TYROSINE HYDROXYLASE GENE

NICOTINE INCREASES TYROSINE HYDROXYLASE GENE TRANSCRIPTION IN RAT ADRENAL MEDULLA. L.H. FOSSOM AND A.W. TANK. Department of Pharmacology, University of Rochester, Rochester, NY 14642.

The amount of tyrosine hydroxylase (TH) increases in rat adrenal medulla after prolonged stress or treatment with catecholamine-depleting drugs. Recent studies have shown that TH-mRNA levels increase prior to the increase in TH enzyme levels. This induction of TH is blocked by pretreatment with nicotinic antagonists, suggesting that stimulation of nicotinic receptors on adrenal chromaffin cells may be a necessary step in the trans-synaptic suggesting that stillulation of intential eceptors on adrenation cells may be a necessary step in the trans-synaptic induction of TH. In the present study the effects of acute treatment of rats with nicotine on TH enzyme activity, TH-mRNA levels and TH gene transcription rate have been investigated. The transcription rate of the TH gene (as measured by in vitro nuclear run-on assay) increased 2-3-fold 10 min after injection of 3.3 mg/kg nicotine, remained elevated for at least 1 h and returned to control level by 3 h. There was a dose-related increase in TH gene transcription rate 20 min after administration of 1.0-3.3 mg/kg nicotine. A single dose of nicotine (0.33-3.3 mg/kg sc) failed to alter TH enzyme or TH-mRNA levels, although doses of 1.0-3.3 mg/kg resulted in a dose-related activation of TH. Our results indicate that a single dose of nicotine rapidly stimulates TH gene transcription in rat adrenal medulla, but that the stimulation is transient. Apparently, an increase in gene transcription that persists for longer than 1 h is required to induce THmRNA and enzyme

MULTIPLE NEUROTRANSMITTER SYSTEMS MEDIATE THE REGULATION OF TYROSINE HYDROXYLASE BY SPLANCHNIC NERVE ACTIVITY. J. Haycock. R. Shukla^{2*}, T. Wakade^{2*} & A. Wakade², Dept. Blochem., LSU Med. Ctr., New Orleans, LA and ²Dept. Pharmacol., Wayne State Univ. Sch. Med., Detroit, MI

Splanchnic nerve activation, which releases ACh and VIP, increases the phosphorylation and activity of tyrosine hydroxylase (TH) in rat adrenal medulla. Because TH is phosphorylated in situ at multiple sites (ser8, 19, 31 and 40), the site-specificity of the increases was determined and correlated with alterations in TH activity. Nicotinic, muscarinic and VIP receptor involvement was also studied.

Isolated rat adrenal glands were perfused retrogradely with Krebs solution (± 2 mCi ³²P₁/ml) for 85 min, treated during the last 30-300 s (300 pulses at 1 Hz or mCi ⁻⁻P₋/ml) for 85 min, treated during the last 30-300 s (300 pulses at 1 Hz or 10 Hz; 3 µM nicotine, 100 µM muscarine, or 1 µM VIP for 180 s), and frozen on dry ice immediately thereafter. For ³²P incorporation, TH was immunoprecipitated from solubilized samples and isolated by SDS-PAGE. ³²P-TH was normalized to ³²P-total cellular protein and to TH protein levels. and ³²P-tryptic peptides were analyzed by HPLC. TH activity was measured in desalted extracts and normalized to TH protein levels. At 10 Hz, stimulation increased ³²P incorporation into ser19 and ser40 whereas at 1 Hz, ³²P incorporation into ser19, ser31, and ser40 was increased. VIP selectively increased ser40 phosphorylation. Nicotine increased ser19 and muscarine increased both ser19 and ser31 phosphorylation several fold;

neither cholinergic agent produced comparable effects on ser40 phosphorylation. All treatments increased TH activity (pH 7.2) at either 30 or 300 μ M BH₄. VIP and 1 Hz stimulation produced the largest increases. 10 Hz stimulation produced an intermediate activation whereas nicotine and muscarine produced smaller increases. In pH-activity profiles (pH 6.0-7.1), activation by electrical stimulation and VIP was larger at the more neutral pHs.

Both cholinergic and VIP receptors mediate effects of splanchnic nerve activity on TH phosphorylation, but VIP may be more important in regulating TH activity.

INFLUENCE OF LONG-TERM NICOTINIC CHOLINERGIC STIMULATION OF ISOLATED CHROMAFFIN CELLS ON THE ACETYLCHOLINE-MEDIATED SHORT-TERM REGULATION OF TYROSINE HYDROXYLASE AND DOPAMINE SYNTHESIS. G.L. Craviso, J.B. Redell* and J.C. Waymire. Dept. Neurobiology and Anatomy, Univ. Texas Medical School, Houston,

Dept. Neurobiology and Anatomy, Univ. Texas Medical School, Houston, TX 77225.

We have previously reported that exposing isolated bovine adrenal chromaffin cells in culture to the nicotinic agonist dimethyl-phenylpiperidinium (DMPP; 1 uM) for 3 days leads to a 2-fold induction of tyrosine hydroxylase (TH) immunoreactive protein and enzyme activity, that this induction enhances the dopamine synthesis capacity of the intact cell severalfold and that dopamine synthesis rates are enhanced even further by acute stimulation of these induced cells with acetylcholine (Ach). To explore the basis of the effects of Ach on dopamine production after prolonged DMPP treatment, we examined the phosphorylation and activation of TH in induced cells in response to Ach and compared these results to those obtained in non-induced cells. As in our earlier studies characterizing the short-term cholinergic regulation of TH in these cells, stimulation of non-induced cells with 100 uM Ach for 30 sec led to the rapid activation of TH and increased phosphorylation of the enzyme on 3 RP-HPLC tryptic phosphopeptides (serines 19 and 40). This rapid response was followed by a later phosphorylation of 2 other RP-HPLC phosphopeptides (serines 19 and 40). This rapid response was followed by a later phosphorylation of 2 other RP-HPLC phosphorylation of serines 19 and 40 in response to Ach were apparent. In contrast, the later increased phosphorylation of the TH subunit on serine 31 following Ach stimulation was observed in induced cells. These results suggest the presence of two separate phosphorylative mechanisms which enhance dopamine synthesis in response to Ach and that chronic nicotinic cholinergic stimulation of the chromaffin cells results in only one of these mechanisms being expressed. Supported by USPH NS 11061 and NS 27550.

Amino acid sequence analysis of endogenously phosphorylated tyrosine hydroxylase (TH). J.C. Waymire', L. Denner', G.L. Craviso' and R. Van Horn', 'Dept. Neurobiology and Anatomy, Univ. Texas Medical School, and ²Dept. Cell Biology, Baylor College of Medicine, Houston, TX 77030.

Previous studies have shown that TH in bovine adrenal medullary chromaffin

cells is phosphorylated on 7 tryptic phosphopeptides and that acetylcholine produces a phosphorylation of 5 of these (Waymire et al., JBC 263:12439, 1988). In the present studies amino acid sequence analysis of these tryptic peptides has been used to establish the number and location of phosphorylated serines within the TH subunit. Bovine chromaffin cells in culture were treated with 8-Br-cAMP for 3 days to increase the quantity of TH per cell, followed by a 60 min incubation with 2 uM okadaic acid to maximize the phosphorylation of the enzyme. TH was isolated using a 20-35% ammonium sulfate fraction of the chromaffin cell supernatant, subjected to SDS-PAGE, transferred to nitrocellulose, and digestie with trypsin (3:50 ratio trypsin:TH). Each tryptic phosphopeptide was purified using a combination of RP-HPLC with 0.1% TFA/acetonitrile and 0.1% HCl/acetonitrile. Comparison of the sequence of each phosphopeptide with the published sequence of bovine TH (De Mello et al., J. Neurosci. Res. 19:440, 1988) showed that the peptides eluting in the 3rd and 5th positions are serine 19, the peptide eluting 4th is serine 31, and the peptide eluting in the 6th position is serine 40. Peptides eluting in the 1st, 2nd and 7th positions were of insufficient quantity to be sequenced. These results are of particular interest when taken together with our previous analysis of the influence of cholinergic stimulation of TH showing that acetylcholine stimulates a large increase in the phosphate labelling of peptides 3, 5, 4, and 7 and only a small increase in peptide 6. This implies that serines 19 and 31 are involved in the cholinergic regulation of TH while serine 40 plays only a minor role. The protein kinase responsible for the phosphorylation of serine 19 is Ca₂/CaM kinase II. The protein kinase responsible for phosphoryating serine 31 remains unknown.

34.13

EFFECTS OF γ-AMINOBUTYRIC ACID RELATED DRUGS ON TYROSINE HYDROXYLASE ACTIVITY IN CULTURED BOVINE ADRENAL CHROMAFFIN CELLS. <u>A. NAKANISHI, N. WEINER</u> Dept. Pharmacol. University of Colorado Health Science Center., Denver, Co

We examined the effects of γ-aminobutyric acid (GABA) related drugs on tyrosine hydroxylase (TH) activity in order to elucidate the regulation of catecholamine biosynthesis by GABA receptors in cultured bovine adrenal chromaffin cells. Chromaffin cells were isolated by the method of Waymire et al. (J. Neurosci. Methods, 7:329, 1983) and were cultured for 3-7 days. GABA which has been reported to have a stimulatory action on the secretion of catecholamines from bovine adrenal chromaffin cells (Kataoka et al. J. Neurochem, 50:1765, 1988.) decreased the activity of TH in cultured bovine adrenal chromaffin cells (60% inhibition with 1mM of GABA). 4,5,6,7-tetrahydroisoxazolo [5,4-c] pyridin-3-ol (THIP) which has been reported to increase the release of enkephalin from intact adrenal gland (Fujimoto et al. J. Pharmacol. Exp. Ther. 243:195, 1987) also decreased the activity of TH in these cells (60% inhibition with 1mM of THIP). Moreover, baclofen which is GABA_α agonist also decreased the activity of TH in cultured bovine adrenal chromaffin cells (30% inhibition with 1mM of baclofen). GABA and THIP inhibited the activity of TH in high K'-stimulated chromaffin cells but baclofen does not. We are continuing the investigation of the mechanisms for this inhibitory effect of GABA related drugs on TH activity in cultured bovine adrenal chromaffin cells. (This research is supported by grant from the USPHS NS-09199). We examined the effects of γ -aminobutyric acid (GABA) related drugs USPHS NS-09199).

INFLUENCE OF OKADAIC ACID ON TYROSINE HYDROXYLASE ACTIVITY AND PHOSPHORYLATION IN ADRENAL CHROMAFFIN CELLS: COMPARISON WITH ACETYLCHOLINE (Ach) STIMULATION. R. Van Horn*, G.L. Craviso, and J.C. Waymire. Dept. Neurobiology and Anatomy, Univ. Texas Med. Sch., Houston, TX 77225.

Our recent studies have shown that the enhanced phosphorylation of tyrosine hydroxylase (TH) in bovine adrenal chromaffin cells in response to Ach occurs on serines 19, 31, and 40. The report by Haavik et al. (FEBS Letters 251:36, 1989) that treatment of chromaffin cells with the protein phosphatase 2A and 3A inhibitor, okadaic acid, leads to the increased phosphorylation of TH, prompted us to examine which TH sites are affected by this compound in the intact cell. Using 2 uM okadaic acid, we observed increased phosphorylation of serines 19, 31 and 40, those phosphorylated in response to Ach, as well as an increased phosphorylation of one additional site tentatively identified as serine 8. The phosphorylation of each of these serines occurred in a time-dependent manner, maximally increasing 4-fold over basal levels by 60 minutes. When measured at this time, in situ catecholamine synthesis rates were elevated 5-fold and TH catalytic activity 2-fold. Kinetic analysis showed an increased affinity of TH for the pterin cofactor with no change in the Vmax of the enzyme. This contrasts with the characteristics of the Ach-mediated phosphorylation of TH in which changes in both cofactor affinity and Vmax occur. These studies suggest that phosphatases 2A and 3A may be the major enzymes in the chromaffin cells which are responsible for the dephosphorylation of TH following the phosphorylation of the enzyme in response to Ach. Further, the kinetic properties of the enzyme under conditions in which serines 19, 31 and 40 are maximally phosphorylated, as observed in this study using okadaic acid treatment of the cells, are similar to those observed for the cAMP-mediated phosphorylation of serine 40, alone, rather than for the Ach-mediated phosphorylation of these three serines. That Ach causes a greater increase in the phosphorylation of serines 19 and 31 relative to serine 40 would explain this difference in the kinetic characteristics of the enzyme.

TYROSINE AND PHENYLALANINE AS SUBSTRATES FOR DOPAMINE SYNTHESIS IN PC12 CELLS. R.P.S. Kwok, F. R. DePietro*, J.C. Byrd, and J.D. Fernstrom. Department of Psychiatry, University of Pittsburgh, Pittsburgh PA 15213.

Phenylalanine (PHE) has been reputed to be both a substrate for and an inhibitor of tyrosine (TYR) hydroxylase. Previous work in striatal synaptosomes suggested PHE is an important substrate, with ≈1/3 of all dopamine (DA) deriving from PHE. However, only single TYR and PHE concentrations were studied, well below the enzyme TYR and PHE concentrations were studied, well below the enzyme $K_m s$ and $\underline{\text{in vivo}}$ concentrations. We are therefore examining DA synthesis from 3H -TYR and 3H -PHE over a range of amino acid concentrations. thesis from 3 H-TYR and 3 H-PHE over a range of amino acid concentrations, initially in PC12 cells. The cells are grown under standard conditions, and used at 2×10^5 cells/ml. For an experiment, the growth medium (RPMI 1640, containing 10% horse serum/5% fetal bovine serum) is replaced with Krebs-Ringer bicarbonate buffer, pH 7.4, supplemented with 1-10 μ Ci 3 H-TYR or 3 H-PHE and different concentrations of cold TYR and/or PHE (0.1-100 μ M). The cells are incubated at 37 $^\circ$ C for 0-150 min, and then analyzed for DA by HPLC. Endogenous DA is detected by on-line electrochemical detection; fractions are collected to count 3 H-DA. 3 H-TYR conversion to 3 H-DA was found to be linear for 60-90 min. Using the 45 min timepoint, and varying cold TYR level, 3 H-DA synthesis increased with increasing TYR level up to 100 μ M (the highest concentration thus far tested). 3 H-PHE was also clearly converted to 3 H-DA in the PC-12 cells; preliminary estimates indicate DA synthesis rate from PHE to be 15-20% that from TYR. The results suggest that, at least in this cell line, DA synthesis from PHE is clearly evident, and may in this cell line, DA synthesis from PHE is clearly evident, and may be an important component of overall DA synthesis.

INSULIN HYPOGLYCEMIA RAPIDLY INCREASES PHENYL-ETHANDLAMINE-N-METHYL TRANSFERASE (PNMT) IN THE BRAIN AND SPINAL CORD. <u>T.D. Gbadebo</u>, S.A.Wagers, and <u>J.K. Stewart</u>. Dept. of Biology, Virginia Commonwealth Univ., Richmond, Virginia 23284

Oscillation and immobilization stress, hypertension, and diabetes are associated with increased PNMT activity in the medulla/pons but not in the hypothalamus. In this study, male Sprague Dawley rats were sacrificed 4 hrs after a single injection of saline or insulin (10 U/kg body wt, s.c.). Insulin significantly elevated PNMT activity in the hypothalamus, medulla/pons and spinal cord:

TISSUE	SALINE	INSULIN	p<	
Spinal Cord	0.62±.08(7)	1.11±.16(7)	0.05	
Medulla/Pons	2.35±.28(7)	3.71±.33(6)	0.01	
Hypothalamus	4.3 ±.41(9)	7.9 ±.64(5)	0.001	
Values=mean±S.E.M. (pmol/(60 min x mg protein) The number of animals is in parentheses.				

These findings suggest that insulin hypoglycemia is a potent and rapid stimulator of PNMT activity in the hypothalamus as well as the medulla and spinal cord. Supported by NIH grant NS 26992

ALTERATION OF BRAIN NEUROTRANSMITTERS METABOLISM IN RATS CHRONICALLY EXPOSED TO ALCOHOL. M.C. YU and K.W. CHUNG*, Depts. of Anatomy, New Jersey Med. Sch., Newark, NJ 07103 and College of Med. Univ. of Oklahoma Health Sci. Center, Oklahoma City, OK. 73190.

The purpose of this study was to determine the altera-

tion of several neurotransmitters and their metabolites in several brain regions after chronic ingestion of ethanol. Sixty days old male rats were fed a liquid diet for 3 months containing 36% of total calories as entanol or the isocaloric equivalent of sucrose. For control, another group of rats of similar age was fed a regular rat chow diet. Tissues were dissected out and homogenized in 10 volumes of IN perchloric acid containing 1 ng/#1 DHBA as internal standard, centrifuged and filtered. The supernatant was used for quantitative assay by HPLC while the lower solid phase was used for protein analysis.

The norepinephrine levels in cerebrum, corpus striatum, hypothalamus and hippocampus were significantly higher in alcoholic rats than controls. The dopamine levels in the striatum and hippocampus were higher in alcoholic rats than controls, whereas in the cerebrum it was less than the controls. The 3,4-dihydroxyphenyl-acetic acid levels in the second of the second in the corpus striatum and hypothalamus showed no dif-ference between the control and alcoholic rats, but in the cerebrum it was higher in the controls. The serotonin levels showed no difference between controls and alcoholic animals in the 4 brain regions examined.

EFFECT OF REDUCED NICOTINAMIDE ADENINE DINUCLEOTIDE (NADH) ON MONOAMINE METABOLISM IN RAT BRAIN. A.B. Naini*, B.A. Haslund, L.J. Cote*, V. Jackson-Lewis*, J.L. Cadet*. Department of Neurology, College of P &S, Columbia University, New York, NY 10032 NADH given IV significantly ameliorates the symptoms of Parkinson's disease (Birkmayer et al., J Neural Transm 1: 297, 1989). In the present study

we investigated the effect of NADH injected i.p. on regional monoamine

metabolism.

Sprague-Dawley rats, 5 per group, received NADH (100mg/kg) i.p. and were decapitated at timed intervals after NADH administration. The striatum, nucleus accumbens and hippocampus were quickly dissected out and assayed for monoamines by HPLC-EC.

Effects of NADH on Regional Monoamines in Bat Striatum

	Control	30 min	60 min	120 min
DA	56.2 +2	60.0 +3	45.4 +4*	42.5 +2*
HVA	4.4 ± 0.4	4.4 ±0.3	5.6 ±0.2*	5.6 ±0.3*
NE	24+03	27+02	18+02*	19 -01

^{*} Significantly different from control (p<0.05)

Results (table) show decreases in dopamine (DA) and norepinephrine (NE) with an increase in homovanillic acid (HVA) in the striatum. No changes were seen in the hippocampus or the nucleus accumbens. Serotonin was not seen in the hippocampus or the nucleus accumbens. Serotonin was not affected in the regions studied. The mechanism by which NADH affects

catecholamine metabolism is under investigation.

DETERMINATION OF DOPAMINE AND SEROTONIN IN SINGLE CELL CYTOPLASM BY CAPILLARY ELECTROPHORESIS. A. Ewing,
T. Olefirowicz and P. Curry, Jr. Dept. of Chemistry,
Eberly College of Science, Penn State Univ., Univ. Park, PA 16802.

Dopamine and serotonin concentrations have been measured in the cytoplasm of single invertebrate nerve cells. An injection scheme capable of acquiring picoliter $% \left(1\right) =\left(1\right) +\left(1\right) +\left$ volumes of cell cytoplasm and subsequently injecting these samples into an electrophoresis capillary has been developed. This injector is constructed at the end of a $5-\mu m$ diameter fused silica capillary column. An 8-10 µm tip is formed by removing the polyimide coating and then etching the fused silica in hydrofluoric acid. Electromigration is used to inject analytes into the injector tip and through the separation capillary. Attomole detection limits are obtained in volumes as small as 0.3 picoliters.

ESTRADIOL MODIFIES THE EFFECT OF LITHIUM ON RAT BRAIN DOPAMINE METABOLISM M. Morissette and T. Di Paolo. Dept of Molec. Endocrinology, CHUL Res. Centre, Laval Univ. Medical Centre, Québec, G1V 4G2 and Sch. of Pharmacy, Laval Univ., Québec, G1K 7P4, CANADA.

The effect of 17B-estradiol(E2) on the response of dopamine (DA) to lithium in the brain of ovariectomized (OVX) rats was investigated. An E2 injection (100 ng,sc) left striatal DA levels unchanged while its metabolites levels, DOPAC and HVA, increased 30 min later. Injection of LiCl (10 mEq) decreased striatal DA levels while DOPAC levels as well as DOPAC/DA and Striatal DA levels while DOPAC levels as well as DOPAC/DA and HVA/DA ratios increased at 60 and 90 min and HVA levels slightly decreased at 30 and 120 min. A combined injection of LiCl (10 mEq) with E2 gave a similar effect in the striatum than LiCl alone but the response of LiCl increased at 30 min where the levels of DOPAC, HVA and DOPAC/DA and HVA/DA striats were higher than these observed with LiCl or F2 alone. ratios were higher than those observed with LiCl or E2 alone. In the frontal cortex, an E2 injection left DA and HVA levels unchanged while DOPAC levels, DOPAC/DA and HVA/DA ratios increased 30 min later. An injection of LiCl (10 mEq) increased frontal cortex DA levels at 30 min and HVA levels at 90 and 120 min while DOPAC levels remained unchanged. DOPAC/DA and HVA/DA ratios decreased at 30 min but an increase of HVA/DA occured from 60 to 120 min. Injection of LiCl (10 mEq) with E2 enhanced the effect of LiCl in the frontal cortex on DA, DOPAC and HVA levels 60 min later. Our results indicate that E2 can modify the effect of lithium on brain DA metabolism. Supported by the MRC of Canada.

A TYROSINE HYDROXYLASE ASSAY IN MICROWELLS USING COUPLED NONENZYMATIC DECARBOXYLATION OF DOPA. J.R. Bostwick*, W. Le*, and S.H. Appel. Dept. of Neurology, Baylor College of Medicine. Houston, Texas 77030

A radiometric assay for tyrosine hydroxylase employing a coupled nonenzymatic decarboxylation of 14C-L-dopa formed from 14C-L-tyrosine has been adapted for performance in a 96 microwell culture plate. The method requires the use of an easily manufactured plate holder to compress blotting paper impregnated with methylbenzethonium hydroxide against the top rim of each well. This forms isolated, air-tight compartments in which $^{14}\mathrm{CO}_2$ is evolved and quantitatively absorbed into the blotting paper. The method is sensitive enough to detect less than 0.3 x 10-6 units of enzyme activity. Tyrosine hydroxylase activity in homogenates of adult rat striata was linear with time (up to 25 minutes) and protein. The enzyme exhibited an apparent K_m of 155 µM for Ltyrosine. A major advantage of this system is that cells can be grown in tissue culture and subsequently assayed for tyrosine hydroxylase activity in the same well. A 3.8-fold increase in enzyme activity was measured in cultures of dissociated cells from rat ventral mesencephalon grown in a defined medium for six days. The method is more facile than previously devised procedures, allowing for the simultaneous assay of up to 96 samples totally contained in a single, compact, portable unit. IMRPOVEMENTS IN NEUROBIOLOGICAL ANALYZER (NEUBA®) FOR RAPIDLY DETERMINING MULTIPLE NEUROCHEMICAL SPECIES, D.L. TURK AND C.L. BLANK, Dept of Chemistry and Biochemistry, U. of Oklahoma, Norman, OK 73019.

The determination of a wide variety of catecholamine, indoleamine and

acetylcholine related neurochemicals and metabolites has been demonstrated using a novel Neurobiological Analyzer previously. This multiple column, multiple electrode system provides substantial amounts of quantitative and qualitative information useful in the analysis of a variety of interesting electroactive neurochemicals during a single 22-30 minute analysis.

The device consists of four individual liquid chromatographs connected to one

autoinjector and one multiple potential-controlling, current-monitoring potentiostat. The three primary liquid chromatographs possess multiple amperometric electrochemical detectors to aid in qualitative identification of individual components and overall selectivity of determinations. The fourth primary system is devoted to and overall secretary or destinations. The found primary system is devoted the determination of acetylcholine, choline, and related species. Improvements in the data acquisition, hardware and software associated with this unit have resulted in a linear dynamic range of 6-7 orders of magnitude and detection limits for favorable species in the low femiormole range (at a S/N ratio of 2).

PRENATAL COCAINE PRODUCES LASTING CHANGES SEROTONIN AND CATECHOLAMINE FIBER ORGANIZATION IN RAT BRAIN.

H.M. Akbari and E.C. Azmitia.

Dept. of Biology, N.Y.U., New York, NY 10003.

Cocaine is neurotoxic to cultured fetal rat serotonin (5-HT) neurons (Azmitia et al., 1989). We examined the effects of prenatal exposure to cocaine. Pregnant rats were injected subcutaneously with either cocaine (40 mg/kg/2cc) or vehicle on days 13-16 of gestation. At 4 and 6 weeks postnatal, male pups were perfused and brains were processed for 5-HT and tyrosine hydroxylase (TH) immunocytochemistry. Decreases in 5-HT and TH immunoreactive (IR) fibers were found in the trigeminal motor nucleus and raphe magnus. 5-HT IR fiber density was decreased in the ventral tegmental area, the nucleus accumbens septi, and layer IV of cortex. An increase in TH IR fibers was observed in the cerebellum. Interestingly, increased 5-HT and decreased TH IR fiber densities were seen in the dorsal striatum. In the septohippocampal system, the density of 5-HT IR fibers was increased in the hippocampus, while TH IR fibers were decreased in the septum. No differences in either 5-HT or TH IR cell number were observed. We are in the process of doing biochemical assays to correlate with our anatomical findings. Our results indicate that cocaine is a potent drug for disrupting the normal balances between the serotonergic and catecholaminergic systems within the brain. The implications of these effects to the functional abnormalities seen in "crack babies" remains to be established. Supported by NIDA Contract 271-87-8114.

ACTIONS OF COCAINE AND AMPHETAMINE IN NUCLEUS PREPOSITUS HYPOGLOSSI. D.H. Bobker & J.T. Williams. Vollum Institute,

Oregon Health Sciences University, Portland OR 97201 Intracellular recordings were made from guinea-pig prepositus hypoglossi (PH) neurons in vitro. Neurons within 300 µm of the 4th ventricle are innervated by terminals that upon electrical stimulation release 5-HT to mediate an inhibitory postsynaptic potential (IPSP). Cocaine caused a prolongation of that IPSP. The prolongation was dependent on the concentration of cocaine applied and was 11.5 fold at 10 μ M. The amplitude of the IPSP was increased by concentrations of cocaine <3 μ M and was depressed by higher concentrations. Fluoxetine had similar actions on the IPSP and procatne (10 μ M) was without effect. Cocaine (up to 10 μ M) had no action on the membrane potential or rate of spontaneous firing. The prolongation of the IPSP can be explained by inhibition of Inhibition of the IPSP, an action shared 5-HT reuptake. with other uptake inhibitors but not local anesthetics is most likely due to a presynaptic action, possibly resulting from local accumulation of 5-HT acting on presynaptic 5-HT_{1D} receptors.

Amphetamine, unlike cocaine, evoked the release of 5-HT Amphetamine, unlike cocaine, evoked the release of 5-HI from the nerve terminals causing a spiperone-sensitive hyperpolarization. In addition, amphetamine depressed the amplitude and prolonged the duration of the IPSP.

MANIPULATION OF LIGHT/DARK CYCLE ALTERS THE DEVELOPMENT OF THE SUPRACHIASMATIC SEROTONIN INNERVATION.

N.M. Kheck¹, H.M. Akbari¹, E.C. Azmitia¹, and B.L. Jacobs². ¹Dept. Biology, New York University, NY, NY 10003 and ²Prg. Neurosci., Princeton Univ., Princeton, NJ 08544

The serotonin (5-HT) innervation of the suprachiasmatic nucleus (SCN) is among the densest in the mammalian CNS. 5-HT fibers innervate the SCN on postnatal day 10 following the arrival of optic tract fibers on postnatal day 4. We examined whether altered physiological activity in the SCN mediated by visual inputs could influence the 5-HT innervation of the nucleus. Rat pups were reared from birth in either constant light (L), constant dark (D), or a 12 hour light/dark cycle (L/D). The SCN in male pups was then examined with 5-HT immunocytochemistry at 4 and 8 weeks postnatal. 5-HT fibers in the SCN of the L/D animals emanated from the ventral and medial aspects of the nucleus to cover its full extent. L animals had an abnormal innervation pattern with decreased fiber density along the medial and dorsal aspects, and general flattening and dimunition of the area of innervation. D animals had normal patterns yet significantly sparser 5-HT innervation. The 5-HT innervation of a non-visual hypothalamic region (the pre-optic area) was unchanged by these environmental manipulations. These results indicate that the physiological activity of the target neurons can determine the development of the pattern and density of 5-HT innervation in the SCN.

FUNCTIONAL CONSEQUENCES OF THE INTERACTION OF COCAINE WITH THE SEROTONIN TRANSPORTER. W.A. Wolf* and D.M. Kuhn, Lafayette Clinic and Cellular and Clinical Neurobiology Program, Department of Psychiatry, Wayne State University School of Medicine, Detroit, MI 48207 USA

An important role for the 5-HT transporter in mediating the rewarding aspects of cocaine use is suggested by recent results which indicate that fluoxetine, a 5-HT uptake inhibitor, can reduce self-administration of cocaine in rats. We have investigated the mechanism by which cocaine interacts with the 5-HT transporter and whether cocaine modifies 5-HT release through its actions at the 5-HT uptake site. Cocaine displaces ³H-paroxetine binding to rat brain membranes in a competitive manner with a Ki of 150 nM in rat brain membranes. Solubilisation of the 5-HT transporter (0.9% digitonin) did not alter the kinetics of ³H-paroxetine binding or the Ki of cocaine (155 nM), suggesting that cocaine interacts directly with the macromolecular transporter complex. The effects of cocaine on 5-HT release were examined in superfusion studies using rat hippocampal slices. Cocaine enhanced both basal and KCI-induced 3H-5-HT release from slices which were prelabelled with ³H-5-HT. The effects of cocaine on KCI-induced release were attenuated by the 5-HT uptake inhibitor. fluoxetine, as well as by the 5-HT₁ agonist, 5-methoxytryptamine (5-MeOT), although release of endogenous 5-HT release from superfused slices was not altered by 5-MeOT. The data suggest complex interactions occur between cocaine, the 5-HT transporter and presynaptic autoreceptors to modify 5-HT release from different intraneuronal pools.

CORRELATION BETWEEN [*H]PAROXETINE BINDING AND REGIONAL SEROTONIN CONCENTRATION IN RAT AND RABBIT BRAIN. K.M. Dewar, T.A. Reader, L. Grondin* and L. Descarries. CRSN, Département de physiologie, Université de Montréal, Montréal Québec, Canada H3C 3J7.

Serotonin (5-HT) uptake recognition sites were quantified by measuring

serotonin (3-11) uptake recognition sites were quantified by measuring the high affinity binding of [3H]paroxetine to membranes (Habert et al., Eur. J. Pharmacol. 118:107, 1985) from different regions of adult rat and rabbit brain: cingulate, frontal, parietal, piriform, entorhinal and visual cortex; dorsal and ventral hippocampus; rostral and caudal neostriatum (rat) or caudate nucleus and putamen (rabbit). From the same brain regions, the levels of 5-HT and its metabolite 5-HIAA were determined by HPLC. [³H]Paroxetine binding showed a considerable regional between the highest $B_{\rm max}$ values in the entorhinal and pinform cortex and the neostriatum. The concentrations of 5-HT and 5-HIAA were also the highest in these same brain regions. Regions with low 5-HT and 5-HIAA contents, such as the visual cortex and the dorsal hippocampus, showed lower densities of [³H]paroxetine binding. In contrast, the 5-HIAA/5-HT ratio was constant throughout. Interestingly, [3H]paroxetine binding and 5-HT content were high in the rat and not in the rabbit cingulate cortex. Therefore, in both species, there was a close correlation between the B_{max} of [3H]paroxetine binding and the concentrations of 5-HT and 5-HIAA, confirming that the high affinity binding of this 5-HT uptake blocker is a reliable index of 5-HT innervation density

DOSE-DEPENDENT SEROTONERGIC MODULATION OF CORTICAL EPSPS. H.L. Read and N.J. Dun. Dept. of Pharmacol., Loyola Univ. Med. Center, Maywood,

Induction of synchronous cortical activity appears to be inhibited by brainstem serotonergic input. Accordingly, intracortical EPSPs which are necessary for the entrainment of neighboring pyramidal neurons are inhibited by 5-HT. In contrast, 5-HT can act postsynaptically to increase the NMDA component of cortical EPSPswhich should promote synchronization. Using the in vitro slice preparation, we have investigated the physiologic and pharmacologic differences between these opposing effects. Intracellular recordings were restricted to lamina V of the rat dorsal anterior cingulate and precentral motor cortices. Stimulation of the callosum evokes a shortlatency EPSP which has an early APV-insensitive and a late APV-sensitive component. Superfusion of 5-HT for 3 minutes reversibly inhibited both components of the EPSP causing little or no change in membrane potential or input resistance. The dose-response relationship for the inhibition was steep such that the threshold concentration was 1 μ M and the maximal inhibition was attained with 50 μ M. When stimulus intensities were adjusted to attain a 60-90% maximal amplitude EPSP, the maximal inhibition by 5-HT was 70-90%. At lower doses (1 to 10 μ M) 5-HT reversibly increased the EPSP amplitude (10-20%) and with repeated brief exposures this augmentation persisted for a longer period (minutes to hours). When the NMDA component of the EPSP was blocked by D-APV (10-20 μ M), the doseresponse relationship for 5-HT inhibitory effect was shifted to the left. The inhibitory effect is probably presynaptic since the depolarizing response to glutamate (in the presence of APV) was not reduced by 5-HT. Since the opposing effects of 5-HT occur in tandem, the presynaptic inhibition may mask the postsynaptic excitation. Functionally, activation of serotonergic input could have dual modulatory affects on cortical synchronization: i.e. inhibiting the synchronization and at the same time 'priming' the cortex for future synchronization. (NS18710 & NS24226)

5-HT_{1C/2} MODULATION OF REFLEXES, POTASSIUM RELEASE, AND EXCITATORY AMINO ACID RESPONSES IN THE FROG SPINAL CORD.

EXCITATORY AMINO ACID RESPONSES IN THE FROG SPINAL CORD. LC. Hackman, A.M. Holohean, S.B. Shope and R.A. Davidoff, Dept. Neurology, Univ. Miami Sch. of Med. and Neurophysiology Lab, VAMC, Miami, Fl. 33101. The present studies investigated the effects of activating 5-HT_{2/1C} receptors with high concentrations (> 3 μ M) of serotonin (5-HT) on reflexes, motoneuron depolarizations, and changes in [K⁺]₀ evoked by single and tetanic stimulation of dorsal root (DR) fibers and by application of excitatory amino acid (EAA) agonists. Sucrose gap recordings were made from the ventral root (VR) of the isolated, hemisected frog spinal cord superfused with HCO3-buffered Ringer's solution. K+ levels were measured with ion sensitive microelectrodes positioned in the dorsal horn.

Superfusion with 5-HT (100 \(mu\)M, 20 min) significantly reduced motoneuron depolarizations evoked by supramaximal DR stimulation $(73 \pm 9\%, n = 11)$ and the release of K⁺ caused by tetanic DR stimulation (1.0 msec) pulses, 25 Hz, 10 sec) (71 + 18%, n = 3). Motoneuron depolarizations produced by addition of Lglutamate or L-aspartate (1 mM, 10 sec applications) were also reduced by 5-HT glutamate or L-aspartate (1 mM, 10 sec applications) were also reduced by 5-HT (80 \pm 4%, n = 5; 82 \pm 5%, n = 5 respectively). Similar results were obtained by 5-HT following the addition of N-methyl-D-aspartate (NMDA, 100 μ M, 10 sec, 81 \pm 3%, n = 3), quisqualate (30 μ M, 10 sec, 80 \pm 4%, n = 5) and kainate (10 μ M, 10 sec, 80 \pm 3%, n = 3). Addition of ketanserin (10 μ M) reversed the 5-HT-induced depression of NMDA responses. Changes in [K $^+$]₀ evoked by NMDA was reduced (68 \pm 12%, n = 2), but quisqualate-induced changes were unaffected (111 \pm 6%, n = 2). In sum, concentrations of 5-HT (> 3 μ M) that activate 5-HT_{1C/2} receptors reduce the amplitude of VR reflexes, EAA-evoked depolarizations, and the release of K $^+$. These results differ those produced by low concentrations of 5-HT that activate 5-HT, receptors and facilitate NMDA responses. (Supported by

that activate 5-HT_{1A} receptors and facilitate NMDA responses. (Supported by VA MRIS Funds and USPHS grants NS17577 & NS07044.)

35.9

CHARACTERIZATION OF 5-HT RESPONSES IN RAT MOTONEURONS. $\underline{\mathbf{M}}$. Y. Wang*, S. Y. Wu*, N. J. Dun and A. G. Karczmar. Dept. of Pharmacol., Loyola Univ. Med. Ctr., Maywood, IL 60153

Intracellular recordings were obtained from motoneurons (MNs) in transverse spinal cord slices (500 μm) of neonate (12-22 days) rats. 5-HT (10-50 μM) elicited in 70% of MNs a slow depolarization (inward current) and a slow hyperpolarization (outward current) in 10% of MNs. 5-HT responses persisted in a low Ca/high Mg solution or in TTX (0.3 µM), indicating a direct action on MNs. The inward current was indicating a direct action on the annual associated with decreased membrane conductance and nullified between -80 and -100 mV; the reversal potential was shifted to a positive direction in high K solution. outward current was associated with increased membrane conductance. The depolarization was antagonized by methysergide, spiperone and ketanserin and mimicked by the $5-\mathrm{HT}_2$ agonist DOI. The hyperpolarization was mimicked by 8-OH-DPAT, a S-HT_{1A} agonist. In addition, 5-HT consistently attenuated the EPSPs evoked by dorsal root stimulation. The depression occurred independent of any membrane potential change of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of any reduction of the MNs and in the absence of the MNs and in the absenc agonist. In addition, 5-HT consistently atglutamate-induced depolarizations. The depressant effect was not antagonized by methysergide, ketanserin and MDL 72222. 8-OH-DPAT diminished the EPSPs in a manner similar to 5-HT. It is concluded that 5-HT depolarizes and hyperpolarizes MNs by decreasing and increasing membrane K conductance via 5-HT $_2$ and 5-HT $_1$ A receptors. Additionally, 5-HT acting on presynaptic 5-HT $_1$ A-like receptors reduces the release of transmitter.

SEGMENTAL DISTRIBUTION OF SEROTONINERGIC FIBERS AND CELL BODIES IN CAT SPINAL CORD.

H. Zhuo*, S.J. Fung, V.K. Reddy* and C.D. Barnes. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

The segmental distribution of serotoninergic fibers and cell bodies in the spinal cord of the cat were studied, using the immunofluorescent staining technique. Immunoreactive serotoninergic fibers and terminals were seen in the gray matter of all spinal cord segments, with the highest density in the nucleus intermediolateralis pars principalis (IMLp) and pars funicularis (IMLf), with less density in the nucleus intercalatus (IC), the central autonomic areas (CA), dorsal and ventral horns, and with the lowest density in the nucleus thoracicus (Clarke's column). In the white matter of the spinal cord, these immunoreactive serotoninergic fibers were located immediately subjacent to the pia mater in the dorsolateral and ventrolateral funiculi.

Two types of serotoninergic immunoreactive cell bodies, multipolar and bipolar, were found in the areas dorsal and ventral to the central canal and in the medial half of the lamina VII of the cervical, lumbar, sacral and caudal segments. Some of the serotoninergic immunoreactive neurons were in close proximity to blood vessels. (Supported by NIH grant #NS24388).

CELLULAR MECHANISM UNDERLYING FAST TRANSIENT INCREASE IN HIPPOCAMPAL PYRAMIDAL CELL EXCITABILITY BY 5-HT. Beck. Department of Pharmacology, Loyola University Chicago Stritch School of Medicine, Maywood, IL 60153 In the presence of 10 µM spiperone, 5-hydroxytrypt-

amine (5-HT) elicits a rapid and transient increase in the extracellularly-recorded population spike amplitude evoked by stratum radiatum stimulation (Beck et al., EJP, 116, 1985). This response cannot be attributed to the 5-116, 1985). This response cannot be attributed to the 5-HT-mediated decrease in afterhyperpolarization (AHP) amplitude due to the difference in the time course of the responses. We have been investigating the cellular mechanism(s) underlying the increase in pyramidal cell excitability using intracellular recording techniques in area CA1 of the hippocampal slice preparation. In the presence of 10 µM spiperone, 5-HT (3-15 µM) increased EPSP amplitude in 50% of the cells tested. This response occurred within 1 min of the start of drug perfusion, without affecting EPSP rate of rise, IPSP amplitude, membrane potential, or the amplitude of the AHP. 5-HT increased the rectification in the subthreshold region of the current-voltage plot, requiring less current to elicit an action potential. The selective 5-HTZ/1C agonist DOI (0.1-10 µM) increased EPSP amplitude, subthreshold rectification and the amplitude of the AHP. These data DOI (0.1-10 µM) increased EPSP amplitude, subthreshold rectification and the amplitude of the AHP. These data support the hypothesis that the receptor mediating the fast transient increase in pyramidal cell excitability is different from the 5-HT_A receptor and the 5-HT receptor mediating the decrease in AHP amplitude. Supported by MH41917.

SEROTONIN IN THE CERVICAL SPINAL CORD OF NEONATAL RAT. A.D. Lindsay, N.E. Schwartz* & J.L. Feldman. Systems Neurobiology Laboratory, Dept. of Kinesiology, UCLA, LA, CA, 90024-1568 In the mid-cervical spinal cord of adult rat, axons immunoreactive for serotonin (5-HT) form dense arborizations throughout the gray matter and make numerous presumptive synappic contacts with phrenic motoneurons (PMNs; Zhae et al, Neurosci. 31:105, 89). In addition, 5-HT mediates some of the raphe-spinal excitation of PMNs in the adult cat (Holtman et al, Brain Res. 417:12, '87). We investigated:

et al., Neurosci. 31:105, '89]. In addition, 5-HT mediates some of the raphe-spinal accitation of PMNs in the adult cat (Holtman et al, Brain Res. 417:12, '87). We investigated:

(i) The termination pattern of axons immunoreactive for 5-HT in the midcervical spinal cord of neonatal (0-7 day old) rats. PMNs were retrogradely labeled with horseradish peroxidase (HRP), the tissue frozen, sliced in 10 µm horizontal sections and reacted on slides with diaminobenzidine and 5-HT antisera. 5-HT positive fibers formed a dense network throughout the cervical spinal cord of all ages of neonatal rats studied. Labeled fibers formed bands of varying density spanning the ventral horn and perpendicular to the midline. Many presumptive synaptic contacts were made with PMNs.

(ii) The responses of cervical motoneurons to exogenously applied 5-HT agonists in 0-7 day old rats. C4 ventral root, phrenic nerve and vagus nerve activity were recorded in a neonatal rat brainstem-spinal cord preparation maintained in viro. A Vaseline partition separated the spinal cord compartment from the brainstem compartment. 5-HT (210µM) applied to the spinal cord caused tonic firing of all cervical motoneurons. The tonic activity was more robust in the C4 ventral root than the phrenic nerve. There was no change in respiratory rate after spinal cord application. When 5-HT was applied to the brainstem, no tonic motoneuron firing was produced, but time and concentration-dependant changes in respiratory rate and pattern were seen. Spinal cord application of 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane HCl (DOI-HCl; 210µM), a potent and selective 5-HT2 agonist, mimicked the tonic firing produced by application of 5-HT to the spinal cord, and produced an increase in respiratory rate when applied to the brainstem. High concentrations (1mM) of phenylbiguanide, a 5-HT3 agonist, had no effect when applied to either the brainstem or spinal cord.

ULTRASTRUCTURAL FEATURES OF SEROTONIN (5-HT) AXON TERMINALS IN ADULT RAT HIPPOCAMPUS. S. Oleskevich. K.C. Watkins* L. Descarries and P. Séguéla. Centre de recherche en sciences neurologiques, Université de Montréal, Montréal (Qué.), Canada H3C 317.

PAP-immunocytochemistry with a polyclonal antiserum against 5-HTglutaraldehyde-protein conjugate (kindly donated by Michel Geffard, Bordeaux) was used to characterize the 5-HT innervation of adult rat hippocampus at the electron microscopic level. Initial fixation of the tissue was by perfusion with 3% glutaraldehyde; 100-µm-thick-vibratome sections were processed free-floating without Triton X (1:1000 dilution of the primary antibody), and serial or single ultrathin sections were respectively cut perpendicular or parallel to the surface of vibratome sections. Several hundred immunostained varicosities from the oriens and the radiatum layer of CA3, or the molecular and the polymorph layer of the dentate gyrus (DG) were examined in single sections (n = 338); those examined in serial sections (n = 57) were all from CA3. The average size, vesicular content and relative frequency of synaptic membrane specialization, synaptic targets and juxtaposed elements were similar in each layer of both regions. A junctional complex (most often asymmetrical) was present on 10% of the single-sectioned profiles, indicating a 24% synaptic incidence when stereologically extrapolated to whole varicosities. A comparable value of 18% was directly observed in serial sections. In CA3, only dendritic shafts were synaptically contacted by 5-HT varicosities, whereas in both layers of DG, a few axo-spinous synapses were also seen. The most frequent neuronal elements in the immediate microenvironment of immunostained profiles were other axonal varicosities (30%), neurites (25%) and dendritic shafts (13%). Dendritic spines were relatively infrequent (4%). Thus, the 5-HT innervation of adult rat hippocampus is predominantly nonjunctional (70-80% of its varicosities) and shows similar internal and relational features in the neuropil layers of CA3 and DG. (Supported by the FRSQ and MRC grant MT-3544).

METABOLISM OF ¹⁴C-SEROTONIN BY HUMAN AND RAT PINEAL GLANDS. S. Daya and F. Briceland* Department of Biochemistry, Rhodes University, Grahamstown, South Africa, 6140.

Investigations were carried out to determine whether differences exist in the metabolism of exogenous radiolabelled serotonin by the rat and human pineal gland. Human pineals were obtained 6h after death from medicolegal autopsies. Pieces of pineal tissue were weighed and incubated for 24h in BGJb culture medium with 0.4 μ Ci and incubated for 24h in BGJb culture medium with $0.4~\mu$ Ci carbon 14 labelled serotonin creatinine sulfate. Rat pineals were removed immediately after sacrifice of the animals by neck fracture and cultured individually as above. All culture media were analysed for their content of radiolabelled indoles using two dimensional thin layer chromatography as described elsewhere (Daya, S. and Fata, M. IRCS Med. Sci., 14: 1153, 1986). The results indicate that human and rat pineals produce relatively similar proportions of indoles from exogenous serotonin. The human pineal removed 6h after death appears to be metabolically active and could be used for a variety of scientific manipulations.

used for a variety of scientific manipulations.

5-HT, RECEPTORS REGULATE HIPPOCAMPAL S100_B, A 5-HT AND CORTICAL GROWTH FACTOR

E.C. Azmitia, X.P. Hou, Y. Chen¹, D. Marshak² and P.M. Whitaker-Azmitia³
1. Dept. Biology, N.Y.U, New York, NY 10003:

- 2. Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724: 3. Dept. Psychiatry, State Univ. NY, Stony Brook, NY 11794.

5.7-DHT intracerebral injections into fornix or cingulum bundle produces a delayed increase in hippocampal (HIPP) 5-HT homotypic collateral sprouting and increased soluble trophic-extract. S-100₈ but not NGF, EGF, Insulin and calmodulin, is a serotonergic growth factor in dissociated mesencephalic calmodulin, is a serotonergic growth factor in dissociated mesencephalic cultures (Azmitia et al, <u>Brain Res.</u> 1990). Ipsapirone (IPS), a specific 5-HT, agonist, releases a 5-HT trophic factor from cultured astrocytes which is sensitive to antibodies raised against S-100_B. Desipramine pretreated adult female Sprague-Dawley rats (200 gms) were bilaterally injected with 5,7-DHT (5 ug/0.4ul) into fornix-fimbria/cingulum bundle ug/0.4ul) into fornix-importa/cingulum buriole and after one month intraperitoneally injected with 1 mg/kg ipsapirone at 12:00, 18:00 and 9:00 four hours before decapitation. The S-100_{beta} levels were measured in soluble or detergent-treated homogenates by RIA. Free S-100_{beta} was not increased in control HIPP by IPS injections (0.226 ± .06 vs 0.232 ± .06 ugm/mg protein). One month after HIPP 5-HT deafferentation the S-100_{beta} levels were reduced from control levels (0.201 ± .014) but significantly increased after IPS treatment (0.287 ± .012). Detergent extracted S-100_{beta} levels were not changed after 5,7-DHT or IPS treatment. Our results indicate that 5-HT can regulate its own growth by activation of 5-HT_{1,A} astroglial receptors which increase the availability of 5-100_{bets}. Our results may be applicable to Alzheimer's disease since S-100_{bets} is a cortical trophic factor and this factor and 5-HT_{1,A} receptors are changed in post-mortem Alzheimer's brains. Supported by NSF 88-12892 and NINDS.

CHANGING SEROTONERGIC INNERVATION OF THE CEREBRAL CORTEX IN THE FIRST TWO POSTNATAL MONTHS OF LIFE. D.H. Yu and I. Törk. School of Anatomy, University of New South Wales, Kensington, NSW 2033, Sydney, Australia.

The cerebral cortex is densely innervated by serotonergic (5-HT) axons which arise from the dorsal and median raphe nuclei. The axons appear in the cortex already in fetal life but there is a significant change in their disposition and density during early postnatal life. In postnatal cats aged P1 to P60 we have demonstrated the serotonergic axons with immuno-histochemical methods and, using a semiautomatic computerized technique, determined the changing density and innervation patterns of the two types of serotonergic axons (Mulligan and Törk, J. Comp. Neurol. 270: 86-110, 1988) in the cortex. In the prefrontal, primary auditory and primary visual cortical areas we have found that while at birth the 5-HT fiber distribution is relatively even across the cortical layers, later a reorganization of the innervation pattern occurs in each cortical area. Although there is a steady increase in the density of serotonergic innervation in the supragranular layers, the increase is strongest in layer II of the prefrontal and layer I of the visual and auditory cortex. The increase in fibre density seems particularly significant in the case of the small varicose fibers. The large varicose fibers are hardly demonstrable at birth but their density increases evenly across the cortex with increasing age. At P23 the first pericellular basket-like arrays can be observed and their number increases with age. These observations indicate that the development of the serotonergic innervation pattern in the neocortex may be linked to the maturation of the intrinsic cortical elements. Moreover the results indicate that the two independent serotonergic systems develop according to a differential timescale and that the large varicose (basket) fibers innervate their target areas of the cortex later than the fine varicose systems. Th

STIMULATION OF ATROGLIAL 5-HT $_{\rm 1A}$ RECEPTORS RELEASES THE SEROTONIN GROWTH FACTOR, S-100, AND ALTERS ASTROGLIAL MORPHOLOGY. P.M. Whitaker-Azmitia and E.C. Azmitia Dept. of Psychiatry, SUNY, Stony Brook, New York and Dept. of Biology, NYU, New York, N.Y. We have recently shown that stimulation of a subtype

of serotonin receptor, the 5-HT_{1a} receptor, on astroglial cells, causes the release of a factor or factors into the culture media, which can regulate the development of serotonergic neurons in primary culture (Brain Res. 497:80, 1989). In order to identify this factor, we preincubated the conditioned media (referred to as GCM) with an antibody raised against S-100, an astroglial specific protein which has been shown by others to be releasable by cAMP and to be a neurite extension factor. Specifically, we tested media produced by stimulating astroglial cultures with the 5-HT_{1a} receptor agonist ipsaperone (the media is thus referred to as GCM-IPS). found that the growth-promoting properties of GCM-IFS). we found that the growth-promoting properties of GCM-IFS on serotonin neurons is inhibited by pre-incubation with this antibody. Moreover, the morphology of the IFS treated astroglial cultures is changed to a more mature form.

SEROTONIN RELEASE FROM HYPOTHALAMIC TISSUE IS MODULATED BY TRYPTOPHAN AVAILABILITY.

S.Giraudo, R.Seerley*, W.Chang*, R.Barb*, B. R. Martin. Dept. of Animal Science and Dept. of Foods & Nutrition, University of Georgia, Athens, Georgia and USDA-ARS, Athens, Georgia.

ARS, Athens, Georgia.

Experiments performed in vivo have provided evidence for a physiological coupling between brain tryptophan (trp) levels and serotonin (5HT) release. However, variable results regarding trp effect on 5HT have been reported with in vitro studies. We examined the relationship between trp availability and 5HT release under experimental conditions that resemble those occuring physiologically. An in vitro perifusion system was established to examine the release 5HT from perifused hypothelamit taken from mature prigs. from perifused hypothalami taken from mature pigs under basal conditions and in response to trp and KCl administration. Hypothalami were perifused with Dulbecco's modified eagle's medium continuously at $37^{\circ}C$ for 5 hrs at a flow rate of $100~\mu$ l/min. The basal release level plus 2 flow rate of 100 μ l/min. The basal release level plus 2 standard deviation was used as reference value to determine a significant response. Tryptophan significantly increased 5HT levels (P<0.05). At the end of the experiment, potassium depolarization caused a rapid and significant release of 5HT (P<0.05) indicating viability of the neuronal tissue. We conclude that availability of tryptophan modulates the hypothalamic output of serotonin.

INVESTIGATING RELATIONSHIPS BETWEEN 5-HT SYNTHESIS AND EXTRACELLULAR CONCENTRATIONS BY BRAIN DIALYSIS IN INDIVIDUAL, CONSCIOUS RATS. C.Portas*, G.S.Sarna*, M.T.O'Connell*, P.H. Hutson and G.Curzon*. Dept. of Neurochemistry, Inst. of Neurology., 1, Wakefield St., London WClN 1PJ (U.K.).

We have adapted rat brain dialysis procedures to allow studies of the effects of altered 5-hydroxytryptamine (5-HT) synthesis on extracellular 5-HT concentrations in individual, conscious rats. Concentric dialysis probes (5mm membrane length) were implanted in the frontal cortex of anaesthetised rats. 18-24 hours later, basal and K⁺ stimulated changes (100mM in perfusate, 20 min) of dialysate 5-HT concentration were determined. 5-HT synthesis rates were then investigated in the same animals as indicated by the accumulation of 5-hydroxytryptophan (5-HTP) after tryptophan hydroxylase inhibitor, p-chlorophenylalanine (150 reduced basal and K+ evoked dialysate 5-HT values (approximately 60%) even though the rates of accumulation of dialysate 5HTP and also frontal cortex 5-HT and 5-HIAA values of the subsequently killed rats showed only small changes. The above procedures should be applicable in studies of relationships between the synthesis of 5-HT and its availability to receptors.

Modulation of [3H]-Paroxetine Binding by Ca++ and but not by GTP-gamma-S.

J.C. Poblete1, P.M. Whitaker-Azmitia2, and E.C. Azmitia1

 Dept. of Biology, New York University. NY, NY 10003.
 Dept. of Psychiatry, State Univ. of NY, Stony Brook, NY 11794.
 We have previously seen that 5-HT_{1b} receptor agonists, RU24969 and TFMPP, and the 5-HT₂ receptor agonists, DOI and and NPP, interact with the binding of [3H]-paroxetine to the serotonergic high-affinity uptake site (transporter) in rat brain membrane preparations (1mg/ml). To examine which regulator or effector systems might be involved in these interactions, we tested the effects of GTP-gamma-S on the binding of [3H]-paroxetine. 1 uM GTP-gamma-S, a non-hydrolyzable GTP analogue, did not affect the Kd nor the Bmax suggesting that the interaction does not occur at the level of the receptor/G-protein complex. Application of 2 mM EGTA, a Ca++ chelator, increased the Bmax (Ctl=134 fmol/mg prot;EGTA=184 fmol/mg prot) without changing the Kd (Ctl=0.09nM;EGTA=0.1nM). Different calcium concentrations (5,10,20mM) were tested. The affinity (Kd=0.18,0.35,0.57nM) and the Bmax values decreased as [Ca++] is increased. Mg++ was tested to control for increasing divalent ion concentrations. We found that the affinity (Kd=0.11,0.15,0.27) and the Bmax values decreased but not as potently as seen in the presence of Ca++. This suggests that Ca++, which is a primary regulator of signal transduction, may play a role in the interaction between the 5-HT1b and 5-HT2 receptors and [3H]-paroxetine binding. We are currently probing the effects on [3H]-paroxetine binding with co-administrations of the 5-HT receptor agonists with EGTA or increasing Ca++ concentrations on rat membrane preparation and tissue culture. REGULATION OF TRYPTOPHAN HYDROXYLASE ACTIVITY BY PROTEIN KEOLATION OF TRYPTOPHAN HYDROXYLASE ACTIVITY BY PROTEIN KINASES. P.A. Johansen and D.M. Kuhn, Lafayette Clinic and Cellular and Clinical Neurobiology Program, Department of Psychiatry, Wayne State University School of Medicine, Detroit, MI 48207 USA Tryptophan hydroxylase (TPH) is the initial and rate limiting enzyme in

the biosynthetic pathway of the neurotransmitter serotonin (5-HT). TPH the biosynthetic pathway of the neurotransmitter serotonin (5-H1). IPH activity is increased when the enzyme is exposed to in <u>vitro</u> conditions favoring protein phosphorylation. Previous studies established that the activation of TPH by phosphorylating conditions was mediated by a Ca²⁺-calmodulin-dependent protein kinase. Certain <u>in vitro</u> experiments have suggested that a cAMP-dependent protein kinase can also activate TPH. Our experiments were aimed at determining if TPH, like tyrosine Our experiments were aimed at determining if IPH, like tyrosne hydroxylase, is regulated by different protein kinases. Exposure of TPH from rat brain to conditions favoring protein kinase A (cAMP-dependent) including cAMP (1-100 μ M), the phosphodiesterase inhibitor theophylline, or the catalytic subunit of protein kinase A, did not activate TPH. Furthermore, the stimulation of TPH activity by Ca²⁺-calmodulin dependent protein kinase was not decreased by the protein kinase inhibitors W-7 or the Wolbh inhibitor. TPH was the activated in a calendal in independent protein kinase was not decreased by the protein kinase inhibitors W-7 or the Walsh inhibitor. TPH was also activated in a calmodulin independent manner by Ca^{3+} and phosphatidylserine. The ability of the protein kinase C inhibitor staurosporine to block this effect indicate that protein kinase C can also activate TPH. As previously reported, the largest stimulation of TPH was mediated by calmodulin dependent conditions. The activation of TPH by protein kinases was manifested as a decrease in the K_{m} of TPH for BH_{4} , with no change in the apparent kinetic constants of TPH for the protein structure of the protein structure. tryptophan. Studies are underway to determine which serine residues in TPH are phosphorylated by the different protein kinases in brain.

PKC Stimulation of 5-HT Release is Sensitive to An L-type Ca++ Channel Blocker But Independent of External Ca+ Xi Gu and E.C.Azmitia Dept. of Biology, New York University. Washington Square East, NY, NY.10003

The intracellular mechanisms regulating evoked neurotransmitter release were studied in synaptosome by adding PMA (phorbol 12-Myristate 13-Acetate)-PKC activator. A release assay was used to study the differential effects of Ca++ channel blockers (Nickel, Cobalt and Nimodipine) and TTX (tetrodotoxin) on PMA in different media, (i,e, Ca⁺⁺-free, and Na⁺-free Krebs-Ringer media). Synaptosomes were preload the with ³H-5HT (5x10⁻⁸M) at 37⁰C for 25 min, incubate it with drugs 10 min before adding PMA at 37°C for 5 min. Our results showed that in both Ca⁺⁺-containing and Ca⁺⁺-free medium, PMA stimulated the release of 5-HT at 10⁻⁴M to 5x10⁻⁶M and Ionomycin (10⁻⁵M)-an Ca⁺⁺ ionophore potentiated the effect of PMA. The stimulatory effects of PMA in Ca⁺⁺-free medium was not fluoxetine-sensitive. The effects of PMA in Ca⁺⁺-containing medium was attenuated by Nickel (10⁵M), Cobalt (10⁵M) and Nimodipine (10⁸M). In addition, TTX (10⁸M) blocked PMA effects and there is no stimulatory effects of PMA in Na++-free medium. PKC may regulate release of 5-HT from synaptosomes by a voltage-dependent mechanism sensitive to L-type Ca⁺⁺-channel antagonist but not to external Ca⁺⁺. Supported by NIDA Contract 271-87-8114.

GABAA RECEPTORS I

36.1

ANTAGONISTS OF THE NMDA SENSITIVE GLUTAMATE RECEPTOR DOWN REGULATE mRNAS ENCODING VARIOUS GABA, RECEPTOR SUBUNITS IN CEREBELLAR GRANULE NEURONS. D.R. Grayson, M. Memo, P. Bovolin and E. Costa. FGIN, Georgetown University, Washington, D.C. 20007.

The genes encoding the subunits of the GABA, receptor constitute a complex and probably tightly regulated multigene family. At least 14 different, evolutionarily related cDNAs have been cloned, each of which encodes a receptor subunit located in both neurons and glial cells. Two allosteric modulatory sites of GABA action located in extracellular and channel domains, have different structural requirements. The modulatory properties of the extracellular domain receptors on GABA operated channels are expressed only when the heteroligomeric complex includes α and γ subunits.

Using quantitative PCR, we have analyzed the levels of GABA, receptor subunit mRNAs present in primary rat cerebellar granule cells. Isosteric agonists and antagonists of GABA, receptors fail to change the expression of GABA, receptor subunits indicating that homologous receptor stimulation is not involved in the regulation of the receptor subunit genes. In contrast, specific antagonists of NMDA-sensitive glutamate receptors mediate a pronounced down regulation of the mRNAs encoding the α -1, β -1, β -2 and γ -2 receptor subunits. The results indicate that the regulation of the GABA, receptor subunit genes may involve an interplay between cell specific signals and signals generated through heterologous receptor stimulation.

36.2

DIFFERENTIAL EXPRESSION OF GABA, RECEPTOR SUBUNITS IN PRIMARY NEURONAL AND GLIAL CELL CULTURES. P. Bovolin, M. Memo, E. Costa, and D. R. Grayson. FGIN, Georgetown University, Washington, D.C. 20007.

To determine the pattern of GABA, receptor subunit mRNAs expressed in defined cell types, we have quantitated the mRNA levels corresponding to various receptor subunits present in primary neuronal and glial cell cultures, prepared from neonatal rat brain, using the polymerase chain reaction. Subunit specific oligonucleotides were used to amplify the reversed transcribed mRNA isolated from each culture. Cerebellar granule cells maintained in culture for 7 days contained comparable amounts of the α_1 , β_1 , β_3 and δ subunit mRNAs and smaller amounts of α_4 , β_2 and γ_2 . We found that the mRNA levels encoding the β_2 subunit decreased continuously from day 5 to day 15 in culture, while changes in the α_1 , α_4 and γ_2 subunit mRNAs with time in culture are presently under investigation. In contrast, in primary cortical glial cells, the α_4 , β_1 and β_3 were the most abundant with minor amounts of the α_1 , β_2 and γ_2 mRNAs. A similar analysis of the GABA, receptor subunit mRNAs present in cerebellar glial cells, including data for the γ_i subunit, will be presented. Our results suggest that the GABA, receptor subunit mRNAs are regulated by both an ontogenetic program, which provides environmental cues related to cell type specificity, and heterologous receptor stimulation, which allows for an additional modulation through neuron to neuron and neuron to glial cell signalling.

EXPRESSION OF GABAA RECEPTOR SUBUNIT mRNAs IN CULTURED CEREBELLAR NEURONS: ANALYSIS BY THE POLYMERASE CHAIN REACTION. C.E. Beattle and R.E. Siegel. Dept. of Pharmacology, Case Western Reserve University, Cleveland, OH 44106.

Molecular biological studies have revealed that the GABAA receptor

complex is composed of multiple subunits. For most of these subunits multiple subtypes exist. In earlier studies we have examined the distribution of these subunits in the developing and adult rat brain by in situ hybridization histochemistry. These studies have raised the possibility that cell-cell interactions play a role in subunit gene expression in the rat cerebellum. To begin to address this issue, we have developed a system for detecting subunit mRNA expression in tissue culture. Cerebellar neurons dissociated from embryronic day 19 rats are maintained for several weeks in culture in medium containing 25mM potassium. To analyze mRNA expression, cells are lysed in the culture wells and processed for the reverse transcriptase reaction utilizing random primers. The polymerase chain reaction (PCR) is then performed with primers for neuron specific enolase (NSE) and GABAA subunit specific primers. Our studies indicate that NSE mRNA can be detected from as few as ten neurons in culture. In addition, the $\beta 2$ and $\gamma 2$ subunits, which are relatively abundant in early postnatal development, can readily be detected by PCR in culture wells plated at a density of two thousand cells. This experimental paradigm is being used to examine GABAA receptor subunit mRNAs and factors that modulate their expression.

COMPARATIVE STUDY OF AGONIST AND ANTAGONIST BIND-ING TO GABA RECEPTORS IN RAT BRAIN. Y.Ito, K.lshige*,M.Makimura*,H.Fukuda*and Y.Murakoshi*. Dept. of Pharmacology, Col. of Pharmacy, Nihon Univ. Funabashi-shi, Chiba 274, Japan.

The properties of 3H-SR 95531, a synthetic GABA, antagonist, binding in the frontal cortex (FC), cerebellum(CB) and cultured cerebellar granule cells(CBCUL) were compared with those of 3H-GABA. The treatment of the membranes with Triton X-100 and phospholipase A2 dramatically increased 3H-GABA binding, whereas 3H-SR 95531 binding was significantly decreased in the FC, CB and CBCUL. Scatchard analyses revealed that the and CBCUL. Sc Triton X-100 Scatchard analyses revealed that the and CBCUL. Scatchard analyses revealed that the Triton X-100 treatment caused a significant decrease in the Bmax values of high- and lowaffinity sites for $^3\text{H-SR}$ 95531 in the FC, while it increased those for $^3\text{H-GABA}$. The K_{D} values for both radiolabelled ligands were not affected in this region. On the other hand, in the CB, the treatment increased the Kp values of high- and low-affinity sites for $^3\text{H-SR}$ 95531, whereas it decreased the values for $^3\text{H-GABA}$ with no change in the Bmax values. These results suggest that there are different conformational states of that there are different conformational states of the GABA receptor binding, and that the regulatory mechanism of these states in the FC is different from that in the CB.

SYNTHESIS OF AN AFFINITY AGAROSE SPECIFIC FOR THE PERIPHERAL-TYPE BENZODIAZEPINE RECEPTOR. A.L.

PERIPHERAL-TYPE BENZODIAZEPINE RECEPTOR. A.L. Parola*, N. R. MacKenzie*, and H. E. Laird II, Dept. of Pharmacology and Toxicology and Dept. of Pharmaceutical Sciences, Univ. of Arizona, College of Pharm., Tucson, AZ 85721 PK 14105, a photoaffinity ligand specific for the peripheral-type benzodiazepine receptor (PBR) was photochemically coupled to ω-aminobutyl agarose (ABAg) to yield PK 14105 agarose (PKAg). 19F and 1H nuclear magnetic resonance spectroscopy was consistent with the proposed site of coupling at the 2'-fluorine of PK 14105 by the primary amine moiety of ABAg. Quantitation of the affinity gel using two different colorimetric assays for primary amines suggests approximately 50% of the available primary amine groups of ABAg were bound by PK 14105. The estimated concentration of PK 14105 bound to ABAg was 2.3 µmol/ml of settled gel (2.3 mM immobilized ligand concentration). PKAg specifically binds the bovine PBR solubilized by digitonin. The affinity of PKAg for the soluble PBR was estimated by varying the concentration of PKAg. PBR binding to PKAg was saturable and the apparent affinity of PKAg for the bovine receptor was estimated from the saturation data. A PKAg affinity column bound 85% of the solubilized PBR from cow adrenal or from rat adrenals partially purified by anion exchange chromatography. These results indicate PKAg is a receptor specific affinity media which may be useful in the purification of the native PBR from various species. (Supported by Ariz. Dis. Control Res. Comm. #82-9290 and Coll. of Pharm., BRSG Fund).

DIFFERENTIAL EXPRESSION OF RAT GABAA RECEPTOR SUBUNIT mRNAs DURING DEVELOPMENT. C. Gambarana, C. E. Beattie, and R. E. Siegel. Dept. of Pharmacology, Case Western Reserve University, Cleveland, OH 44106.

Reserve University, Cleveland, OH 44106. The GABA_A receptor complex, site of action of the inhibitory neurotransmitter γ -aminobutyric acid (GABA) and the anxiolytic benzodiazepines, is composed of multiple structurally distinct subunits. For most of the subunits, several isoforms have been identified by molecular cloning, and the mRNAs encoding these subunit subtypes exhibit different regional distributions in the adult brain. In addition, our previous studies indicated that the expression of at least one subunit, α 1, changes during ontogeny. To further examine the developmental expression of GABA_A receptor subunit mRNAs, we have performed quantitative hybridization histochemistry with probes specific for the α 1, β 1, β 2, β 3, and γ 2 subunits. Our studies demonstrate that all subunit mRNA levels increase for 2-3 weeks postnatally, although significant regional differences in the onset of demonstrate that all subunit mRNA levels increase for 2-3 weeks postnatally, although significant regional differences in the onset of expression are apparent. For example, while the $\beta 2$, $\beta 3$, and $\gamma 2$ mRNAs are observed in the cerebellar cortex during the first postnatal week, the $\alpha 1$ mRNA only becomes detectable in the second week. Furthermore, the levels of all subunit mRNAs peak by approximately day 21 and then decline to the adult levels. In the mature brain, the $\alpha 1$, $\beta 2$, and $\gamma 2$ mRNAs are widely distributed and exhibit similar regional patterns of expression. In contrast, the $\beta 3$ subunit is abundant only in the hippocampus and cerebellar granule cell layer. Furthermore, the $\beta 1$ subunit mRNA, whose expression declines to the greatest extent, is present in relatively low levels in the cerebral cortex and hippocampus. These findings underscore the differential regulation of GABAA receptor subunit genes. receptor subunit genes.

THE RELATIVE EFFICACY OF THE BENZODIAZEPINE RECEPTOR ANTAGONIST (Rol5-1788) IN THE $^{36}\mathrm{Cl}^-$ UPTAKE ASSAY DEPENDS ON GABA CONCENTRATION AND THE PRESENCE OF GABA RECEPTOR Giroux*, ANTAGONISTS. E.Malatynska, S.C. Dilsaver, M.L. R.J. Knapp and H.I. Yamamura. Dept. of Pharmacology, The University of Arizona, Tucson, AZ 85724 and Dept. of Psychiatry, The Ohio State Univ., Columbus, OH 43210.

The benzodiazepine antagonist (Rol5-1788) has been shown to have narrial acciet or cartial.

to have partial agonist or partial inverse-agonist activity to have partial agonist or partial inverse-agonist activity in some behavioral and electrophysiological studies. In this study we have shown that in the ³⁶Cl uptake assay, Ro15-1788 may have agonist, antagonist, and inverse-agonist efficacy at the benzodiazepine receptor depending on the GABA concentration. Ro15-1788 did not alter the effect of 30 μ M GABA on ³⁶Cl uptake. However, it did inhibit ³⁶Cl uptake produced by 100 μ M GABA, and enhanced ³⁶Cl uptake mediated by 10 μ M GABA. 1 μ M Ro15-1788 shifted the concentration-response curves of the GABA, recentor 3 Cl uptake mediated by 10 $\mu\rm M$ GABA. 1 $\mu\rm M$ Ro15-1788 shifted the concentration-response curves of the GABA, receptor antagonists (bicuculline, SR 95531, amoxapine and amitriptyline) to the left. The shift in EC-50 value by Ro15-1788 for these drugs was inversely proportional to their affinity for the GABA, receptor. We suggest that the activity of Ro15-1788 depends on changes in the conformational state of the GABA, receptor produced by increasing concentrations of GABA or the GABA receptor antagonists.

EFFECT OF THIOL REAGENTS ON THE GABA/BENZODIAZEPINE CHLORIDE CHANNEL COMPLEX A.M. Allan and G.G. Mayes* Department of Psychiatry, Washington University School of Medicine, St. Louis, MO 63110.

Agents which modify thiol groups have been shown to alter ligand binding at a variety of receptor sites; in addition, alkylation of sulfhydryls have been shown to block ion channel conductance. We studied the effects of thiol reagents on: GABA activated chloride flux (%CI) (JPET 247:1012, 1988),[3H]-muscimol (Life Sci. 39:2005, 1986) and [3H]-diazepam (Brain Res. 452:118, 1988) binding in mouse brain membrane preparation (microsacs). Incubation of microsacs in the presence of: mercuric chloride (HgCl2), p-chloromercuriphenylsulfonic acid (pCMBS) or hydroxymercuribenzoate (HMB) attenuated GABA-stimulated Cl uptake (IC₅₉S 130-150 uM). Iodoacteic acid (IAA) also attenuated Cl uptake, but was not as potent as the mercurial compounds. The thiol reagents reduced both maximal stimulation and the potency of GABA to induce Cl uptake. Supernatant prepared from pCMBS (200 uM) treated microsacs stimulated Cl uptake (3 sec exposure) in the absence of GABA agonist in microsacs unexposed to thiol reagents. The supernatant was still effective after boiling or the addition of 1mM dithiothreitol (DTT). pCMBS treated supernatant lowered specific binding of [3H]-muscimol but stimulated [3H]-diazepam binding. Stimulation of diazepam binding by supernatant was blocked by 50 uM bicuculline. From the present findings it appears that these thiol reagents may act either to release or prevent the reuptake of GABA, although other explanations have not been excluded. Supported by USPHS grants AA08219 and DA06106.

FUNCTION OF GABA BINDING SITES ON GABAA RECEPTORS
R. P. Shank, D. J. Bennett*, and M. O. Ferguson*.
R.W. Johnson Pharmaceutical Research Institute at McNeil
Pharmaceutical, Spring House, PA 19477-0776.

Experiments with never-frozen membranes from rat
cerebral cortex incubated at 37°C for 10 min in the
presence of 100 or 400 mM NaCl and (-)-nipecotate (50 \(\mu^M \))
indicate that CARA binds to these sites on CARA consenters.

Experiments with never-frozen membranes from rat cerebral cortex incubated at 37°C for 10 min in the presence of 100 or 400 mM NaCl and (-)-nipecotate (50 $\mu{\rm M})$ indicate that GABA binds to three sites on GABAA receptors, the $K_{\rm d}$ values of which are ~30 nM, >0.3 but <3 $\mu{\rm M}$, and >3 $\mu{\rm M}$. Under these conditions GABA increases ³H-flunitrazepam binding by 2.5-fold (EC50 ~1 $\mu{\rm M}$), and exerts a biphasic effect on ³5S-TBPS binding; increasing the amount bound at concentrations <1 $\mu{\rm M}$, but decreasing the amount bound at higher concentrations. For 10 min incubation periods the GABA-induced increase in ³5S-TBPS binding was enhanced by increasing NaCl from 100 to 400 mM. Concentration-response curves for the GABA-induced increase in ³5S-TBPS and ³H-flunitrazepam binding were coincident up to 1 $\mu{\rm M}$ GABA, but at higher GABA concentrations the curves diverged due to the GABA-induced inhibition of TBPS binding. The EC50 for the inhibition of TBPS binding was ~10 $\mu{\rm M}$, similar to the EC50 for GABA-induced Cl- fluxes in neurosomes. Our results suggest that only the low-affinity site is associated with receptor activation, whereas the middle-affinity site serves a negative modulatory function, and contributes to the apparent positive cooperativity of receptor activation. The high-affinity site may exist only on immature or desensitized receptors.

36.11

ENHANCEMENT OR INHIBITION OF ³⁵S-TBPS BINDING BY BICUCULLINE IS REGION SPECIFIC IN RAT BRAIN. <u>J. Peris.</u> Dept. of Pharmacodynamics, University of Florida Health Science Center, Gainesville FL, 32610.

Center, Gainesville FL, 32610.

The GABA_A receptor/chloride ionophore complex includes at least three additional binding sites that can allosterically affect GABA receptor binding: the benzodiazepine receptor, the barbiturate receptor and the picrotoxin/convulsant receptor. Occupation of the benzodiazepine and barbiturate sites by agonists increases GABA binding while occupation of the picrotoxin site inhibits GABA receptor binding and vice versa. Recent measurements of the regional expression of a variety of mRNAs for the different subunits of the GABA_A receptor complex using in situ hybridization revealed markedly different profiles of the subtypes for the a, β and γ subunits in different brain regions, particularly substantia nigra (SN), cerebellum (CBL) and inferior colliculus (IC; Richards et al., Soc. Neurosci. Abstr. 15:642, 1989). It is thus possible that allosteric interactions of the binding sites would differ across brain regions. Specific binding of ³⁵S-TBPS to the picrotoxin site was studied in homogenates of cortex (CTX), superior colliculus (SC), CBL, IC and SN and the allosteric regulation of this binding was measured. Bicuculline methiodide, a GABA_A antagonist, enhanced binding by 50% in CTX and SN (EC₅₀ = 300 nM) and enhanced binding in IC by 30% (IC₅₀ = 4 μ M) and did not affect binding in SC. This regional difference was also found using quantitative autoradiographic analysis of binding in thin tissue sections. These findings provide a functional basis in support of the heterogeneity of GABA_A receptor subunit composition in different brain regions. This work was supported by PHS grant AA 08262.

36.13

THE NMDA RECEPTOR ANTAGONIST MK-801 PREVENTS KIN-DLING INDUCED BY PENTYLENETETRAZOL (PTZ) IN RATS. M.G. Corda, O. Giorgi, M. Orlandi*, D. Lecca*, G. Biggio. Dept. of Exp. Biology, Chair of Pharmacology, Univ. of Cagliari, ITALY.

The present study was designed to investigate the role of GABA and excitatory aminoacid (EAA) neurotransmissions in the chemical kindling produced by PTZ, a selective blocker of the Clahannel coupled to the GABA receptor. Chemical kindling was observed in 90% of the rats treated with 30 mg/kg of PTZ daily or every second day for 8 to 10 weeks. This effect was remarkably enduring since rats were still sensitized to PTZ up to one year after drug discontinuation. The administration of the non-competitive NMDA receptor antagonist MK-801, at a dose of 1 mg/kg, i.p., 30 min before each injection of PTZ completely prevented the development of kindling. In fact no convulsions were observed in rats receiving PTZ plus MK-801 during the chronic treatment or following a challenge dose of PTZ administered 5 days after the last injection of PTZ plus MK-801. Biochemical studies revealed a decrease in both 35S-TBPS binding and GABA-stimulated 36Cl uptake in the cerebral cortex of rats chronically treated with PTZ up to 24 days after the completion of the chronic treatment, suggesting an involvement of the GABAergic transmission in PTZ-induced kindling. We are at present investigating whether MK-801 is able to prevent the neurochemical changes in the GABA receptor complex induced by PTZ-kindling.

ALLOSTERIC INTERACTIONS AT THE GABAA RECEPTOR BINDING DOMAINS IN RAT BRAIN SYNAPTONEUROSOMES. T. M. DeLorey, G. B. Brown, and I. Kissin.* Behavioral Neurobiology, Dept. of Psychiatry, and the Dept. of Anesthesiology, Univ. of Alabama at Birmingham, Birmingham, AJ 35294.

of Anesthesiology, Univ. of Alabama at Birmingham, Birmingham, AL 35294. The rat brain cerebrocortical synaptoneurosomal preparation has in the last few years become a useful model for the study of GABA_A receptor pharmacology in the brain. Studies from several laboratories have demonstrated the suitability of this vesicular model for measurement of GABA-mediated ³⁶Cl⁻ flux. Since the ³⁶Cl⁻ flux measurements are performed under more physiological conditions and the data appear to reflect a more physiologically relevant description of the GABA_A receptor complex than the standard binding data, we initiated a series of studies to adapt the synaptoneruosomal model to direct radioligand binding measurements. We have previously reported results with GABA agonists and antagonists in this system. Estimates of kinetic parameters describing the dose-response curves of these ligands in this system revealed significant differences from those determined by the standard radioligand binding measurements using frozen/thawed brain membrane fragments (Soc. Neurosci (abstracts) 14:977, 89). We have extended these studies and report initial results for the binding of benzodiazepines, barbiturates, and their allosteric interactions, at the GABA_A receptor complex in rat brain synaptoneurosomes. ³H-diazepam binding experiments revealed a K_d comparable to that using standard assay techniques. Muscimol potentiates ³H-diazepam binding of pentobarbital could not be directly measured, we did observe a dose-dependent increase in ³H-muscimol produced by this barbiturate (EC₅₀=40 µM with max. enhance.=40%). A similar result has been reported by Willow and Johnston (Neurosci. Lett. 18:323-7, 80) with crude synaptosomal membranes. The standard assay fails to display this pentobarbital-mediated enhancement of muscimol binding. Other allosteric interactions between the GABA, benzodiazepine and barbiturate sites were studied using this new protocol, and were found to be qualitatively different. (Support: NIH grant GM 39344

DIFFERENT TEMPERATURE SENSITIVITY OF TYPE I AND TYPE II BENZODIAZEPINE RECEPTORS. <u>P.A. Maguire</u>, <u>M.F. Davies, H.O. Villar</u>, and <u>G.H. Loew</u>, Molecular Research Institute, Palo Alto, CA 94304.

The temperature dependence of the binding kinetics of

The temperature dependence of the binding kinetics of BDZ receptors was studied in two putative single receptor tissues, rat cerebellum (Type I) and spinal cord (Type II). Displacement of [3H]Ro15-1788 (1nM) by flunitrazepam and zolpidem (agonists), β -CCE (inverse agonist), Ro15-1788 (antagonist) and AHR11797 (selective muscle relaxant agonist) was carried out at 0°C and 3°C. Our results indicate that each tissue contains only one BDZ receptor. Using LIGAND, a one-site model in both cerebellum and spinal cord provided the only reliable set of Kas for each ligand and $B_{\rm max}s$ for each tissue at each temperature. The results at 0°C predict significant Type I selectivity only for zolpidem and β -CCE (47 and 7.5 respectively). Increasing the temperature to 3°C produced a shift in the Ka to a lower affinity in both tissues. This shift was 8-10 fold in the cerebellum for all ligands except AHR11797 (3.5 fold). In the spinal cord, the temperature-induced shift in Ka was ~1/2 that in cerebellum for all ligands except flunitrazepam, which was equally sensitive to temperature dependence of binding at the two receptor subtypes, is the loss of Type I selectivity at elevated temperatures, with only zolpidem retaining significant (19-fold) Type I selectivity, but with modest affinity (136 nM). Thus at 37°C there does not appear to be a high affinity selective ligand for either receptor type.

36.14

FAILURE OF EXCITATORY AMINO ACID TO ALTER THE FUNCTION OF GABA, RECEPTOR COMPLEX

M. Serra*, A. Concas, E. Sanna*, C. Foddi*, G. Santoro* and G. Biggio, Dept. of Experimental Biology, University of Cagliari, Italy Recently, it has been proposed that excitatory amino acids may affect the strength of synaptic inhibition by GABA (Nature 337: 170, 1989). Thus, we sought to determine whether kainic acid was able to modify the function of GABA, receptor. Kainic acid (8 mg/kg, i.p.) markedly potentiated the convulsant activity of isoniazid, an inhibitor of GABAergic transmission; in fact, it shortened the latency of the appearance of convulsion and augmented the expression of each seizures induced by isoniazid. On the other hand, [35]TBPS binding, which is very sensitive to the modulatory action of drugs that affect GABAergic transmission, was not significantly changed after "in vivo" administration of kainic acid. Moreover, kainic acid does not modify the isoniazid-induced increase of [35]TBPS binding. Consistently, [35]TBPS binding in the cerebellum was not modified following either the activation of the climbing fibers by harmaline or the degeneration of this pathway induced by 3-acetylpyridine. The data suggest that the activation of excitatory amino acid system does not alter the function of GA-BA, receptor complex.

IS GABA THE ONLY ENDOGENOUS LIGAND FOR GABA-RECEPTOR? M. Yarom, X. W. Tang*, J. Bao*, Y. H. Lee* & J.-Y. Wu. Department. of Physiology and Cell Biology, University of Kansas, Lawrence, KS 66045.

J.-Y. Wu. Department. of Physiology and Cell Biology, University of Kansas, Lawrence, KS 66045.

y-Aminobutyric acid (GABA) is a major inhibitory neurotransmitter in the mammalian CNS. The complexity and heterogeneity of GABA receptors led us to search for possible endogenous compounds which may interact with GABA receptors and modulate GABA binding sites. Pig brain P2 membranes were used as a source for those modulators. Successive extractions of the membranes were filtered through a PM 10 membrane (exclusion limit: 10,000-dalton) and concentrated by lyophilization. Samples of the concentrated filtrates were tested for their ability to affect [3H] muscimol (GABAA-receptor agonist) binding, using the extensively washed pig brain membranes as the receptor source. The extracts that contained inhibitory activity were purified by a series of column chromatographies; gel filtration, ion exchange, and C1B HPLC columns. Three peaks of inhibition were obtained by Bio-Gel P-2 column. The major peak co-migrated with [3H] GABA and couldn't be distinguished from GABA by further chromatographies. The two minor peaks which were separated from GABA, were not retained on anion exchange column, AG-1-X8, suggesting that they are probably neutral or positively charged compounds. It is most likely that they represent a new group of substances that can modulate GABA receptor activity. These two inhibitors are now subjected to further characterization and purification. (Supported by NIH Grant NS20978 and BNS-8820581 from NSF).

EFFECTS OF GABA, PROPOFOL AND PENTOBARBITONE ON CHLORIDE CONDUCTANCE IN CHICK EMBRYO SENSORY NEURONS.

M. Nobile*, V. Magnelli*, E. Maestrone*+, and C. Usai* (SPON: European Neuroscience Association) Istituto di Cibernetica e Biofisica, Genova, Italy, and tospedale Civile di Sondrio, Sondrio, Italy.

The effects of gamma-aminobutyric acid (GABA) and of general anaesthetics Propofol (PR) and racemic Pentobarbitone (PB) on Chloride channels in neurons of the chick embryo dorsal root ganglion, were investigated using the patchclamp whole-cell recording technique. External and internal solutions blocking Na*, K* and Ca* ionic currents were employed. GABA and PR increased PR and GABA induced Icl, respectively. Similar results were observed using either GABA and PB, or PR and PB. This potentiating effect occurred pretreating the preparation with one of the three drugs. Every drug elicited Icl in cells insensitive to both the other ones, and, in some cases, this activity induced a subsequent response to the or picrotoxin inhibited cell responses to GABA, PR and PB. Further investigations are in progress in order to assess the antagonistic effects of blockers on drugs induced Icl. Our results might display the response of the developing GABA, receptor complex with different binding sites for the three agents described or drugs' different receptors.

BENZODIAZEPINES INHIBIT TRIIODOTHYRONINE TRANSPORT INTO HUMAN LIVER CELL LINE L Kragie & D Dovle * Depts. of Medicine & Biological Sciences, State University of New York at Buffalo, Buffalo, NY 14260

L-triiodothyronine (T3) accumulates stereospecifically, with energy-dependency and pM affinity, into HepG2 cells. The postulated iodothyronine carrier, though not yet isolated, is characterized by analogue competition and enzyme kinetic studies (Movius et al Endocrinology 124: 1988). CNS benzodiazepine (BZ) receptors are modulated by thyroid hormones in vitro (Nagy & Lajtha J Neurochem 40:414) and in vivo (Go et al J Neurochem 51:1497). Peripheral BZ sites are not linked to GABA receptor /Cl channel complexes and bind with micromolar affinity. Specific ligands bind CNS (RO15788) and peripheral (RO54864) sites. We report here, for the first time, that diazepam and its peripheral site analogue inhibit high affinity T3 accumulation into Hep G2 cells.

Confluent HepG2 cells in multiwell plates were incubated prior to assa with serum free media. Wells +/- drug and 60 pM 125I-T3 incubated x 1 hr, then cells were placed on ice, media was aspirated and cells washed. NaOH 0.5 M was added to wells and the hydrolysate was gamma counted. Nonspecific proportion equalled uptake with 1 uM unlabelled T3 or on ice. MEAN % CONTROL (N): 1 uM unlab T3 61 (5) 4 C x 1 hr 34 (4Cx1hr 34(7) 1 uM Diazepam 78 (3) RO54864 68 (2) 97 (2) RO15788 65 (5) No effects of BZ's were seen under low temperature and uM T3 conditions. We conclude that peripheral BZ ligands interfere with high affinity T3 transport into liver cells and may be interacting directly with the iodothyronine carrier. Study supported by NIH grant 1K11DK0145601A2 to Dr. Kragie. Dr. DJ Triggle generously provided H. LaRoche BZ analogues and advice.

THE GENERAL ANAESTHETIC PROPOFOL ENHANCES THE FUNCTION OF THE GABA, IONOPHORE RECEPTOR COMPLEX. A. Concas, G. Santoro, H.P. Mascia, M. Serra, E. Sanna and G. Biggio, Dept. of Experimental Biology, Chair of Pharmacology, University of Cagliari, Italy

The effect of the general anaesthetic propofol (PF) has been evaluated "in vitro" on the function of the GABA, ionophore receptor complex and compared to that of pentobarbital (PB) and alphaxalone (AF) drugs known to enhance the GABAergic transmission. PF, minicking the action of PB and AF, inhibited 35S-TBPS binding to rat cortical membranes in a concentration dependent-manner. However, while the efficacy of these drugs was similar (maximal inhibition 100%), they differed markedly in potency being AF > PF > PB. Consistently with its action on 3SS-TBPS binding, PF, like AF and PB, enhanced muscimolstimulated 36Cl uptake in membrane vesicles from rat cerebral cortex (maximal enhancement +50% at 10 µM) but failed to affect basal 36Cl uptake in the absence of GA-BA agonist. Although the effect of PF was similar to that of steroids and barbiturates, different sites of action were demonstrated by the observation that these drugs, when included together with PF, produced additive effects on 35S-TBPS binding as well as on 36Cl uptake. The effect of PF bon the function of the GABA-coupled chloride channel is dependent on the interaction of GABA with its recognition site. In fact, bicucultine reversed completely the effect of this drug on 35S-TBPS binding and muscimol-stimulated 36Cl uptake. However the effect of these compounds is not due to a competitive interaction with GABA, receptors. In fact PF, like AF and PB enhanced 3H-GABA binding in the rat cerebral cortex. These data suggest that PF exerts its pharmacological effect by enhancing the function of the GABA, ionophore receptor complex.

EFFECT OF CYPROHEPTADINE, BICUCULLINE, PICROTOXIN, AND PCPA ON NEGATIVE CONTRAST. P.S. Grigson and .F. Flaherty. Rutgers University, New Brunswick, NJ

Rats shifted from a 32% to a 4% sucrose solution drink less 4% sucrose than controls having only experienced the 4% sucrose. This contrast effect was eliminated by the non-specific serotonin antagonist cyproheptadine (3 or 6 mg/kg), but was not reduced by the ip administration of PCPA (150 or 300 mg/kg). The effect of cyproheptadine was not altered by PCPA pretreatment. Additional studies with bicuculline, picrotoxin, buspirone, gepirone, ritanserin, ketanserin, and methysergide suggest that the effects of cyproheptadine are not mediated by a serotonergic system, but may partly involve the BDZ/GABA complex. In addition, an independent contrast reducing action of bicuculline (2 mg/kg) and picrotoxin (1 and 2 mg/kg) raises the possibility than an endogenous ligand may be responsible for the initiation of contrast and that this ligand may act via the BDZ/GABA complex.

EFFECTS OF GABA ON EXTRACELLULAR PH IN TURTLE CEREBELLUM, ICT Chen. M Chesler & ME Rice. Dept. Physiology & Biophysics, Dept. Neurosurgery, NYU Med. Ctr., 550 1st. Ave., N.Y., NY 10016.

The GABA-gated anion channel is permeant to HCO3 in CNS neurons (Bormann, J. et al., <u>I. Physiol.</u> 385:243, 1987) and crayfish muscle (Kaila & Voipio, <u>Nature</u> 330:163, 1987). To determine if such channels can therefore modulate brain pH, we studied the effect of GABA on pH₀ in turtle cerebellum *in vitro*. Microelectrodes were used to measure pH₀, [K⁺]₀, and field potentials in the molecular layer in 35mM HCO₃⁻ (5% CO₂) or 35mM HEPES Ringer.

Superfusion of 1mM GABA caused an alkaline shift (AS) of 0.05±0.02 pH units (±SD, n=29 animals, range 0.02-0.09). A similar AS was evoked in the granular layer. The AS was blocked by picrotoxin and was evoked by the GABA-A agonists muscimol and isoguvacine (10⁻⁵-10⁻³M), but not by the GABA-B agonist baclofen inuscritton and isoguracine (10 $^{-1}$ U $^{-1}$ M), but not by the GABA-B agoinst bactoren (10 $^{-3}$ M). Since GABA and isoguracine also caused a 1-3 mM rise in [K $^{+}$]₀, we tested for a synaptic origin of the AS: solutions containing zero Ca²⁺ or 4mM kynurenate did not block the AS. Replacement of HCO₃ with HEPES reversibly abolished the AS, suggesting that the response was caused by the efflux of HCO₃ through GABAgated anion channels. Indeed, formate (which passes through these channels), when

added to HEPES Ringer, restored the GABA-evoked AS.

Since excitatory synaptic activity is known to evoke an extracellular alkalinization (Kraig R.P. et al. J. Neurophysiol. 49:831, 1983) we tested whether GABA plays a role in such responses. In contrast to the GABA-evoked AS, the AS evoked by parallel fiber stimulation (5-10 Hz) was blocked by 1 mM GABA, was insensitive to picrotoxin (10-3M), and was enhanced in HCO₃--free solution. These data indicate that the GABA and parallel-fiber-evoked alkalinizations arise through different mechanisms. Our results suggest that local brain pH may be modulated independently by excitatory and inhibitory synaptic transmission. Supported by NINDS: NS27011 & NS13742.

ELECTROPHYSIOLOGICAL EVIDENCE DEMONSTRATING THAT BOTH D1 AND D2 RECEPTORS MEDIATE THE INHIBITORY EFFECT OF DOPAMINE IN THE MEDIAL ZONA INCERTA. M.J. Eaton and R.L. Moss. Dept. Physiol., Univ. of Texas Southwestern Med. Ctr., Dallas, TX 75235.

In vitro electrophysiological experiments have demonstrated that dopamine (DA), which is contained within many medial zona incerta (ZI) neurons, inhibits the spontaneous activity of one third of these neurons. D1 receptors in the medial 7.1 have been implicated in facilitation of luteinizing hormone secretion, whereas D2 receptors are believed to be the autoreceptor subtype. The purpose of the present study was to determine which DA receptor subtype is mediating the inhibitory response of medial ZI neurons to DA applied via micropressure. This was investigated in two ways: by attempting 1) to mimic DA inhibition with the selective D1 and D2 agonists, SKF82526 and LY163502; 2) to block the inhibition

with the selective D1 and D2 antagonists, SCH23390 and sulpiride.

Out of 33 neurons tested, the inhibition noted during DA application was mimicked in 14 cases by only the D2 agonist. Only the D1 agonist mimicked the DA inhibition in 6 of the cells tested. In 5 cases, both agonists effectively inhibited the neuronal firing of the medial ZI neuron under test. In the antagonist portion of this study, 20 neurons which were inhibited by DA were tested with the selective DA receptor antagonists. In 10 of 19 cases tested with the D2 antagonist, there was at least 30% attenuation of the DA inhibition. In 7 of 11 neurons tested, the D1 antagonist attenuated the DA inhibition. In one instance, both selective antagonists attenuated the inhibition caused by exogenous DA application. The results of this study suggest that both D1 and D2 receptor subtypes may mediate the inhibitory effect of DA on medial ZI neurons. In some cases, only one receptor subtype appeared to be involved in the inhibitory response, whereas in other neurons, activation of either DA receptor subtype caused inhibition of cellular firing in the medial ZI. Supported by NIH grants HD09988 & HD07062.

DIHYDREXIDINE ACCUMULATES RAPIDLY AND SPECIFICALLY IN RAT BRAIN AFTER SYSTEMIC ADMINISTRATION. Q. David Walker, Cindy P. Lawler, Barbara Faggin, Stan Southerland, Julie Bennett, Mark H. Lewis, D.E. Nichols*, and Richard B. Mailman. Curriculum in Toxicology, Brain and Development Research Center, Departments of Psychiatry and Pharmacology, University of North Carolina at Chapel Hill, NC 27599 and School of Pharmacy, Purdue University*, West

Research Center, Departments of Psychiatry and Pharmacology, University of North Carolina at Chapel Hill, NC 27599 and School of Pharmacy, Purdue University*, West Lafayette, IN 47907

Dihydrexidine (trans—10,11—dihydroxy—5,6,6a,7,8,12b—hexahydrobenzo[a]phen—anthridine) is a high potency full efficacy D₁ dopamine receptor agonist which we hypothesize will have specific utility as both a neuropharmacological probe and a potential therapeutic agent for parkinsonism. An HPLC method was developed to permit the quantification of dihydrexidine in discrete brain nuclei following systemic administration. Dihydrexidine was separated from endogenous monoamines, their metabolites and precursors on a reverse phase 10 cm C18 3 µm column. Monoamines were selectively retained by 18—crown—6—ether, enabling a total analysis time of 15 minutes. Dihydrexidine was detected electrochemically (750 mV), with a detection limit of about 10 pg. Striata and cerebelli were dissected on ice, and homogenized in the mobile phase. After centrifugation, an aliquot of the supernatant was alumina—extracted. Recovery of dihydrexidine was ca. 55%.

Adult Sprague—Dawley rats were treated with 3 mg/kg dihydrexidine (s.c.) and sacrificed 0, 10, 20, 40, or 120 minutes after dosing. This dose has been shown to induce selectively and rapidly behaviors commonly thought to be mediated by D₁ dopamine receptors. Peak concentrations of dihydrexidine was almost undetectable at 120 minutes after treatment. Concentrations of dihydrexidine was almost undetectable at 120 minutes after treatment. Concentrations of dihydrexidine in striatum (ca. 18 pg/mg tissue) was about twice as great as that in cerebellum 10 and 20 minutes post dosing. The dihydrexidine concentrations of dihydrexidine would to dopamine receptors, as well as drug non—specifically bound to tissue or blood. The time course of peak brain concentrations of dihydrexidine would to dopamine receptors, as well as drug non—specifically bound to tissue or blood. The time course of peak behavioral effec

Using HS/Ibg mice as the parent strain, we have selected mice over nine generations for response/ non-response to haloperidol-induced catalepsy. The selection has been asymmetric, with a greater selection divergence for the HNR line. The haloperidol ED₅₀, at S₆ for the HR and HNR line were 0.4 ± 0.1 and 4.3 ± 0.4 mg/kg, respectively. Fluphenazine, trifluoperazine, spiroperidol and raclopride showed a 7-fold or greater discrimination between lines. Chlorpromazine, (+) butaclamol, cis-flupenthixol and thiothixene showed a 3-4 fold discrimination. SCH-23390, was a potent cataleptogenic agent (ED₅₀ = 0.1 mg/kg), which did not discriminate between the lines. D₂ receptor density in either the whole caudate or nucleus accumbens was similar in both lines. However, D₂ somatodendritic receptor both lines. However, D_2 somatodendritic receptor density in the substantia nigra, was 80% higher in the HNR line. Evidence that this difference in receptor density may be involved in the differential response to haloperidol will be presented.

EFFECT OF SKF 77434 ON A9 DOPAMINE NEURONS FIRING RATE IN IMMOBILIZED RATS. M. Diana, A. Mura, V. Boi, S. Aramo and G.L.

Dipart. di Neurosci. "B.B. Brodie", Universita' di Cagliari ITALY. Previous studies (Diana et al 1989 Soc Neurosci Abstr. vol 15 mart 2 m

1001, 1989) have shown that the new selective dopaminergic D1 agonist SKF 77434, administered intravenously, dose-dependently decreases the firing rate of nigro-striatal dopaminergic neurons through a mechanism which appears to be located posterior to the globus pallidus since SKF 77434induced inhibition of firing persisted after hemitransection of the brain. These experiments were performed in urethane-anesthetized rats. In order to avoid possible interactions with urethane we repeated the experiments in immobilized, d-tubocurarine paralized and artificially respired rats. Male Sprague-Dawley (200-350 gr) rats were temporarily anesthetized with alothane then incannulated with a tracheal catheter for artificial respiration and in the femoral vein for intravenous administration of drugs. D-tubocurarine (4mg/kg iv) was administered and once muscular paralysis was obtained the rats were placed on a stereotaxic frame (Kopf). SKF 77434 was administered at exponentially increasing doses (12.5-1600 ug/kg). When dopamine neurons were recorded from anterior substantia nigra pars compacta (coordinates from lambda: AP 2.0; L 1.9 nose bar -2.5) SKF 77434 decreased the firing rate of the majority of dopamine neurons (65-70%). However, when dopamine neurons were recorded from a different subregion (coord. AP 1.8; L 1.8) only a small number of neurons (10-15%) were found to be sensitive to SKF 77434. Experiments are under way to characterize the differences between the two populations.

DIHYDREXIDINE, A NOVEL AGONIST TO STUDY THE PHARMACOLOGY AND STRUCTURAL REQUIREMENTS OF D, DOPAMINE RECEPTORS. D.M. Mottola¹, W.K. Brewster², D.E. Nichols² and R.B. Mailman¹. University of North Carolina¹, Chapel Hill, N.C. 27599. Purdue University², West Lafayette, IM. 47907
Dihydrexidine is a member of a new class of D₁ dopamine receptor ligands (trans-hexahydrobenzo[a]phenanthridines). This agent possesses high affinity for the D₁ receptor, is a full efficacy agonist, and is a structurally rigid compound. These features make dihydrexidine an important tool to study the pharmacology and structural requirements of D₁ dopamine receptors. Pharmacological studies have shown that dihydrexidine competes steroselectively for D₁ (i.e. 3H-SCH23390) binding sites in rat striatal membranes with an IC50 of ca. 12 nM and for D₂ sites (i.e. 3H-spiperone) of ca. 120 nM. Adenylate cyclase assays show that dihydrexidine is able to activate the D₁ receptor to the same degree as dopamine Rself. The N-alkyl derivatives of dihydrexidine show higher IC50 values for D₁ sites, but lower IC50's for D₂ sites.

This study also reports preliminary data regarding the functional groups required for activation of the D₁ receptor. The D₁ receptor pharmacophore was assessed by computerized molecular modeling of dihydrexidine, the thienopyridine compound THP (a less potent, full efficacy D₁ agonist), and (R)-SKF38393 (partial agonist). These three agonists were overlaid and minimized by the Maximin program in SYBYL. Comparisons of these ligands allowed various hypotheses to be generated. First, based on the degree of overlap with (R)-SKF38393, it was predicted that 6a(R),12b(S)-dihydrexidine and (R)—THP are the active enantiomers. Secondly, the orientation of the phenyl ring of (R)—SKF38393 was perpendicular to the catechol moiety, while the accessory rings of the two full agonists were essentially planar. Perhaps this ring orientation is responsible for the fact that (R)—SKF38393 is a partial agonist. In addition, all three agonists were abl

THE DENSITY AND TURNOVER OF POST-SYNAPTIC D2 DOPAMINE RECEPTOR ON THE HALOPERIDOL-RESPONSIVE (HR) AND HALOPERIDOL NON-RESPONSIVE (HNR) LINES (HR) AND HALOFERIDOL NON-RESPONSIVE (HRK) LINES OF MICE. Y. Qian, R. Hitzemann and B. Hitzemann*. Dept.'s of Psychiatry, and Neurobiology, SUNY at Stony Brook, NY 11794.

The HR and HNR lines of mice differ >10 fold

in their sensitivity to haloperidol-induced catalepsy. We now report on D_2 density in discrete regions of the caudate-putamen. Significant regions of the caudate-putamen. Significant caudal to rostral differences were found between the HR and HNR lines in D_2 density. The HR line the HR and HNR lines in D₂ density. The HR line showed the typical caudal-to-rostral decrease in D₂ receptor density whereas the HNR line showed the highest density in the medial caudate. In the rostral caudate, the receptor density was significantly higher in the HR line. In the caudal caudate, density was higher in the HNR line. Receptor turnover, assessed by N-ethoxy-carbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ), was significantly faster in both lines in the caudal aspects of the caudate as compared to the more medial and rostral areas. In the rostral caudate, receptor turnover was faster in the HNR line. In contrast, in the caudal part of caudate, line. In contrast, in the caudal part of caudate, it was faster in the HR line. These data illustrate that there are discrete differences in post-synaptic D2 receptor density between lines.

DUAL ACTION OF FCE 23884. A NEW ERGOLINE DERIVATIVE. ON DAGRAIC SYSTEM. M. Carfagna*, C. Caccia*, S. Cavanus*, M.G. Fornaretto*, M. Buonamici* and R.G. Fariello

R&D., Farmitalia Carlo Erba - Erbamont Group, CNS Bept, 20014 Merviano, Italy

FCE 23884 has been shown to possess an unusual pharmacological spectrum. Behaviorally, the compound exhibited dopamine (DA) antagonistic profile in normal animals and a strong DA agonist action in models of denervation, such as 6-OHDA lesioned rats, reserpinized rodents and MPTP-treated monkeys.

We studied the interaction of FCE 23884 with central DAergic system in normal and reservine-treated rats.

In vitro binding assays showed that FCE 23884 bound to D-2, q-2 and 5-HT+A sites in the nM range; the affinity for 0-1 and S-2 receptor was moderate (sub μ M). FCE 23884 potently stimulated the basal activity of adenylate cyclase in vitro (E_{Se} =0.6 μ M). The compound dose dependently accelerated the turnover of DA rat brain as demostrated by the increased levels of HVA, and DOPAC (EDse ≈0.1 mg/Kg s.c.) and by the enhancement of DA synthesis in both striatum and n. accumbens of normal rats. FCE 23884 was also able to reverse apomorphine inhibitory action on y-butyrolactone activity indicating a presynaptic DA antagonistic action. These profiles are consistent with the antidopaminergic effect of FCE 23884 in normal animals. In reserpine pretreated rats (18hr), FCE 23884 (1 mg/kg s.c.) significantly antagonized reservine induced striatal HVA and DOPAC elevation (z40x), an effect notably displayed by DA agonists. Taken as a whole our neurochemical data support the earlier assumption based on behavioral studies that FCE 23884 possesses both DA antagonist and agonist actions depending on the substrate.

As judged from this unique pharmacologic profile FCE 23884 is expected to be of therapeutic value in the neuropsychiatric disorders associated with DA dysfunction.

TWO NEW RADIOIODINATED LIGANDS WITH HIGH AFFINITY AND SELECTIVITY FOR D-1 AND D-2 DOPAMINE RECEPTORS. M.P. Kung. J. Billings. S. Chumpradit. R. Murphy .Y. Yang and H. Kung. Univ. of Pennsylvania, Philadelphia, PA 19104.

Radioodinated ligands with high specific activity and selective affinity are

useful probes for various neurotransmitter systems. Several selective iodinated benzamides for D-2 receptor and benzazepines for D-1 receptor have been developed.

One of the benzamides,5-iodo-7-N-[1-ethyl-2-pyrrolidinyl)methyl] carboxamido-2,3-dihydrobenzofuran(IBF) displays in vitro binding specificity to D-2 dopamine receptors with high affinity and low nonspecific binding (Kd=0.106nM, rat striatum). The competition data with various neurotransmitter ligands indicate that IBF is very selective and the results are consistent with the pharmacological profile of a D-2 receptor antagonist. In vivo biodistribution studies and ex vivo autoradiography results in rats with IBF further confirmed studies and ex vivo autoraciography results in rats with the intriner confirmed the specific localization of this agent in the basal ganglia region where the D-2 receptor is concentrated. 7-chloro-8-hydroxy-1-(3-iodophenyl)-3-methyl-2,3,4,5-tetrahydro-1H-3-benzazepine(TISCH) is the best D-1 ligand for in vitro and in vivo characterization. The binding constant is comparable to that of SCH-23390 (0.2nM vs 0.32nM, rat striatum). The displacement studies with various ligands indicated that TISCH binds specifically to D-1 receptor with high selectivity and the binding is stereoselective with the preference for the nigh selectivity and the binding is stereoselective with the preference for the R(+)isomer. Furthermore, the in vivo organ distribution and the ex vivo autoradiography studies with R(+) TISCH displayed high uptake in striatum and substania nigra, region known to have a high concentration of D-1 receptors, while the S(-) isomer(inactive) displayed no specific uptake.

Radioiodinated IBF and TISCH are valuable pharmacological tools for probing D-1 and D-2 dopamine receptors under in vitro and in vivo conditions.

37.11

QUANTITATIVE AUTORADIOGRAPHY OF DOPAMINE RECEPTORS IN THE SPONTANEOUSLY HYPERTENSIVE RAT. K. Kujirai*, S. Przedborski, V. Kostic*, V. Jackson-Lewis, S. Fahn and J. L. Cadet. Columbia University, New York, New York 10032.

The spontaneously hypertensive rat (SHR) has been used to evaluate the role of catecholaminergic systems in the development of hypertension. Some differences in the dopamine system have been reported between SHR and normotensive rats. The present study assessed possible differences in dopamine (DA) D1 and D2 receptors between SHR and normotensive rats. The status of DA uptake sites was also evaluated. Quantitative receptor autoradiography revealed significantly higher binding of D1 and D2 receptors in the caudate-putamen (CPu), the nucleus accumbens (NAc) and olfactory tubercle (OT) of SHR in comparison to Sprague-Dawley (SD) rats. High-to-low lateromedial gradients were observed in D2 receptors in both strains. There were no differences in DA uptake sites between the two strains. Unilateral injection of 6-hydroxydopamine (6-OHDA) into the rat striatum resulted in greater than 90% depletion of dopamine uptake sites in the striatum of both strains of animals. These changes were associated with significant increases in striatal D2 receptors which were of similar magnitude in both strains of rats. Striatal D1 receptors were not affected by the 6-OHDA-induced lesions. These results demonstrate that, although the SHR have higher concentration of both D1 and D2 receptors in the basal ganglia, these receptors are influenced in a similar fashion by striatal DA depletion.

THE EFFECT OF SCH 23390 AGAINST TOXIC DOSES OF COCAINE. d-AMPHETAMINE AND METHAMPHETAMINE. R.W. Derlet, Albertson and P. Rice*. Dept. Internal Med. & Pharmacology, U.C.D. School of Med., Davis, CA 95616.

The effect of SCH 23390, a dopamine-one (D₁) antagonist, in preventing acute toxicity induced by lethal doses of cocaine, d-amphetamine, and methamphetamine was studied in the rat. Animals were first pretreated with SCH 23390 (0.0, 0.5, 1.0, and 2.5 mg/kg, i.p.) and then were challenged with cocaine (70 mg/kg, i.p., an LD₈₅), d-amphetamine (75 mg/kg, i.p., an LD_{90}), and methamphetamine (100 mg/kg, i.p., an LD_{90}). SCH 23390 did not significantly alter the incidence of seizures compared to the vehicle controls for each of the three stimulants tested. Significant protection against cocaine-induced death was afforded only by the lowest dose of SCH 23390 tested, with death occurring in 50% of the animals ($p \le 0.05$). Significant protection against d-amphetamine-induced death was provided by all doses, with a dose dependent effect noted so that the death incidence decreased from 95% for vehicle to 30% ($p \le 0.01$) with 2.5 mg/kg SCH 23390 pretreatment. No statistically significant reduction in the incidence of methamphetamine-induced death was seen with SCH 23390 pretreatment. The ability of SCH was seen with Sch 23390 pretreatment. The ability of Sch 23390 to protect against d-amphetamine, but not methamphetamine-induced death, suggests differing mechanisms of toxicity may exist between these drugs at high doses. The antagonistic effect of SCH 23390 against cocaine at a low dose is consistent with other reports.

BEHAVIOURAL, BIOCHEMICAL & ELECTROPHYSIOLOGICAL STUDIES ON THE MOTOR DEPRESSANT & STIMULANT EFFECTS OF BROMOCRIPTINE D.M. Jackson + ■ L.P. Martin, L.-G. Larsson *+, R.F. Cox®, B.L. Waszczak® A S.B. Ross** Astra Research Centre, Södertälje, Sweden, Pharmacology Department, Sydney University, NSW, Australia, Pharmacology Section, Pharmacy & Allied Health Professions College, Northeastern University, MA 02115, USA.

Bromocriptine (BRC) produced a biphasic motor effect in mice: early de-pression which lasted for about 1 h & later stimulation which lasted from about 1 to 5 h & which was blocked with SCH23390. Both phases were accompanied by reductions in dihydroxyphenylacetic acid (DOPAC) & ho-movanillic acid (HVA) levels & a reduction in DOPA accumulation (after inhibition of nigro-striatal dopamine (DA) nerve firing & of DOPA decar-boxylase). However, while the autoreceptor (AR) effects were still evi-dent during the stimulant phase, there was a gradual rise in DOPAC & HVA from 1 to 4 h after injection, indicating an increase in DA turnover, due perhaps to acute desensitization of the synthesis regulating DA ARs. Using behavioural & biochemical paradigms, no change in DA AR sensitivity occurred after one dose of BRC & challenge with a second dose. In electrophysiological studies, it was found that prior exposure of rats to 1 dose of BRC rendered them subsensitive to the rate-inhibiting effects of a 2nd dose of BRC, as measured in anaesthetized animals using extracellular recordings of DA neurons in the substantia nigra pars compacta. In conclusion (1) the stimulant phase of BRC in mice occurs despite continued occupation of the DA ARs by BRC because adequate DA is available to provide the required D1 receptor stimulation; (2) the terminal ARs in the striatum may be regulated differently from the somatodendritic ARs.

37.12

COMPARISON OF THE SELECTIVITY AND SPECIFICITY OF ASCORBIC ACID ANTAGONISM OF DOPAMINERGIC AGONIST BINDING. L.C. Tolbert, J.J. Spollen*, P.E. Morris*, Dept. of Psychiatry and Behavioral Neurobiology, University of Alabama at Birmingham, Birmingham, AL 35294.

Ascorbic acid (AA) is a water-soluble vitamin with multiple known functions

Ascorbic acid (AA) is a water-soluble vitamin with multiple known functions in the body. In recent years a number of investigators using both in vivo and in vitro techniques have raised the possibility that AA may function as a neuromodulator in CNS dopaminergic function. For example, it has been reported to modulate dopamine agonist binding and cyclic AMP stimulation as well as antagonize the behavioral and physiological effects of amphetamine and potentiate the effects of haloperidol. The purpose of the present study was to evaluate the selectivity and specificity of the AA effect on dopaminergic function. In vitro binding studies were utilized as a system uncomplicated by questions of transport, etc. [3H]N-0437,, was chosen as the ligand to define D₂ agonist binding for reasons of stability and selectivity. The effect of AA, d-ascorbic acid (iso) and D-glucoascorbic acid (gluco) on the binding of these two ligands to striatal membranes from rats was evaluated. The rationale for the choice of these three compounds was that they have relatively similar redox ligands to stratal membranes from rats was evaluated. The rationale for the choice of these three compounds was that they have relatively similar redox properties but if the AA effect was a specific receptor-mediated phenomena the compounds should have differences in potency. Using 2.5 nM 3 H-N-0437 (\sim K_D) and increasing concentrations of the 3 compounds we confirmed significant differences in their inhibition curves. The IC₅₀ were: AA 93.3, iso 199.5, and gluco 9,549.9 micromolar. Using a similar paradigm for SKF 38393 a similar rank order of potency of the three compounds was obtained but all were significantly less potent at inhibiting the D₁ agonist binding (IC₅₀/s): AA = 100 (100). Receible differences in mechanisms of 1,897 and ISO = 2,828 μ M). Possible differences in mechanisms of antagonism will be discussed.

919), A NEW DOPAMINE D-2 DECREASES THE EXTRACELLULAR PRAMIPEXOLE (SND PRAMIPEXOLE (SND 919), A NEW DOPAMINE D-2 RECEPTOR AGONIST, DECREASES THE EXTRACELLULAR CONCENTRATIONS OF DOPAMINE AND ITS METABOLITES IN THE STRIATUM OF FREELY MOVING RATS. A. J. Carter and R. E. Müller (SPON: R. Anderson), Department of Pharmacology, Boehringer Ingelheim KG, 6507 Ingelheim, West Germany.

Pramipexole is a new D-2 autoreceptor agonist

Pramipevole is a new B-2 autoreceptor agonist which is structurally related to the potential antipsychotic agent, B-HT 920. We have studied the effects of pramipexole on the extracellular concentrations of dopamine (DA), 3,4-dihydrophenylacetic acid (BOPAC) and homovanillic acid (HVA) in the striatum of freely moving rats by means of microdialysis and HPLC with electrochemical detection. Pramipexole (0.1 mg/kg s.c.) chemical detection. Pramipexole (0.1 mg/kg s.c.) caused long-lasting (≥ 2 h) decreases in DA. DOFAC and HVA. Haloperidol (0.3 mg/kg s.c.), a DA antagonist, caused a transient (ca. 20 min) increase in DA and long-lasting (≥ 2 h) increases in DOFAC and HVA. Haloperidol also reversed the effects of pramipexole. These results indicate that the D2 autoreceptor agonist, pramipexole, reduces the extracellular concentrations of DA and its metabolites in vivo concentrations of DA and its metabolites in vivo by a reversible interaction with the DA receptor. Pramipexole could therefore be used as an alternative treatment for schizophrenia.

REGULATION OF BASAL GANGLIA GLUCOSE UTILIZATION BY THE D1 DOPAMINE RECEPTOR. J.M. Trugman, C.L. James and G.F. Wooten. Dept. of Neurology, Univ. of Virginia, Charlottesville, VA 22908.

In rats with unilateral dopamine depletion, D1 agonists increase regional cerebral glucose utilization (RCGU) in the subthalamic nucleus, entopeduncular nucleus, and substantia nigra pars reticulata (SNr) (<u>J. Neurosci</u>. 7:2927, 1987). In contrast, it has been reported that RCGU is not altered by D1 stimulation or antagonism in rats with intact dopamine innervation (Brain Res. 327:390, 1985). To re-examine this question, we studied the effects of a selective D1 question, we studied the effects of a selection of agonist (SCH 38393, 30 mg/kg) and antagonist (SCH 23390, 0.5 mg/kg) on RCGU in naive, male Sprague-Dawley rats using quantitative [14C]-2-deoxyglucose autoradiography. Administration of SKF 38393 increased RCGU in the SNr (+26%), but did not alter RCGU in other basal ganglia regions. Administration of SCH 23390 decreased RCGU in the caudate-putamen (-15%), globus pallidus (-29%), entopeduncular nucleus (-30%), subthalamic nucleus (-26%), and SNr (-28%); RCGU was increased in the lateral habenula (+17%). We conclude that stimulation of the D1 receptor by endogenous dopamine contributes substantially to RCGU in multiple basal ganglia nuclei of naive, awake, behaving rats.

STRIATAL INJECTION OF RECEPTOR INACTIVATOR EEDQ REVEALS NO ROLE FOR STRIATAL DOPAMINE (DA) RECEPTORS IN INHIBITION OF NIGRAL DA CELL FIRING BY I.V. R(-NPA. R.F. COX, L.P. Martin and B.L. Waszczak. Pharmacol. Sect., Northeastern Univ., Boston, MA 02115.

We previously reported that intranigral injection of EEDQ reduced the ability of i.v. R(-NPA. M-rpropylnorapomorphine (NPA) to inhibit substantia nigra (SN) DA cell firing (Soc. Neurosci. Abstr. 15:427,1989). This effect was revealed as a 4-fold increase in the ED50 for NPA and a 20% decline in maximum response. We have now carried out complementary studies to assess the contribution of striatal DA receptors toward the same response. Rats were anesthetized and pretreated with i.p. prazosin (5 mg/kg), idazoxan (1.3 mg/kg), and ketanserin (5 mg/kg) 30 minutes before striatal lnjections. EEDQ (200 nmol, 2 ul total) or hydroxypropyl-B-cyclodextrin vehicle (VEH) were injected stereotaxically at 3 sites in the left striatum. Extracellular single unit recording studies were performed on the next day. Unlike results after intranigral injections of EEDQ, responses of SN DA cells to i.v. NPA were not significantly affected by striatal DA receptor inactivation. The mean ED50 was 0.38 ± 0.20 ug/kg after intrastriatal EEDQ (n=9) versus 0.37 ± 0.12 ug/kg after vEH injections (n=6). In both groups full inhibition of DA cell firing occurred at the same dose of NPA (5 ug/kg). Autoradiographic analysis of the degree of DA receptor loss after similar intrastriatal EEDQ injections showed >90% losses of D-1 (3H-SCH 23390) and D-2 (3H-YM-09151-2) binding sites in the injected striata. These studies confirm previous assertions that nigral DA receptors (most likely somatodendritic autoreceptors) play a predominant role in mediating the inhibition of SN DA cell firing by systemically administered direct-acting agonists like NPA. Conversely, striatal DA receptor appear to be unnecessary for this response. (Supported by NS 23541.)

PHARMACOLOGICAL CHARACTERIZATION OF THE INHIBITORY RESPONSES INDUCED BY VTA STIMULATION IN THE RAT PREFRONTAL CORTEX.
R. Godbout, J. Mantz', S. Pirot', A.M. Thierry', J. Glowinski'
Chaire de Neuropharmacologie, Collège de France, 75231 Paris Cedex 05, France.

The medial prefrontal cortex (PFC) receives converging projections from DA neurons located in the VTA and NA fibers running through the dorsal VTA. Electrical stimulation (1Hz) of the VTA induces an inhibition (Dur.=110ms) of spontaneous firing in 80% of the PFC cells recorded in layers III to VI. To determine the type of receptor mediating this response, we analyzed the effect of microiontophoretic applications of NA and DA receptor antagonists on VTA-induced inhibitions in NA and DA receptor antagonists on VTA-induced inhibitions in ketamine-anesthetized rats. Firing inhibition following VTA stimulation was suppressed by application of the selective D_x/D_a antagonists sulpiride (61% of the 48 cells tested), RIV 2093 (88% of 16 cells), and LUR 2366 (88% of 8 cells). Inhibitions were still present upon the application of the D, antagonist SCH-23390 (n=11) as well as that of the B-(propranolol; n=11), α_r -(prazozin; n=7) and α_z - (yohimbine; n=13) adrenoreceptor antagonists. In conclusion, the receptor mediating the inhibition of PFC spontaneous firing induced by VTA stimulation has the pharmacological profile of a D/D, recognition site. of a D₂/D₄ recognition site.

EFFECTS OF DOPAMINERGIC AGONISTS ON CULTURED SUBSTANTIA NIGRA NEURONS. K-M. Kim*, Y. Nakajima and S. Nakajima. Dept. of Pharmacology and Dept. of Anatomy and Cell Biology, Univ. of Illinois, Chicago, IL 60612.

We have cultured neurons separately from the pars compacta and the pars reticulata of the substantia nigra of newborn rats and investigated dopamine effects with the whole-cell patch clamp When the cell was clamped at -74mV, dopamine technique. $(0.1-30\mu\text{M})$ or (-)-quinpirole (D₂ agonist, $0.1-10\mu\text{M}$) produced a conductance increase concomitant with an outward current, suggesting that the agonists increased K-conductance. These effects were found mainly on neurons from the pars compacta, and were blocked by 1-3 μM of S(-)-sulpiride (D₂ antagonist). Pretreatment of cultures with pertussis toxin (500 ng/ml) overnight abolished the conductance increase induced by the agonists. But in some cells an outward current, not accompanied by conductance increase, remained after the pertussis toxin treatment, suggesting that two different effects are produced by the agonists. Intracellular application of GTP-γS (500 μM) through the patch pipette spontaneously increased conductance concomitant with an outward current in the absence of agonist. In some cells, especially neurons from the pars reticulata cultured for a long time (> 3 weeks), dopamine (10 - 20 μ M) or R(+)-SKF38393 (D₁ agonist, 25 μ M) decreased conductance concomitant with an inward current. Supported by NIH grant, NS24711.

RECEPTOR-MEDIATED PRESYNAPTIC REGULATION OF DOPAMINE SYNTHESIS IN RAT STRIATAL TISSUE. R.G. Booth* and R.J. Baldessarini. Harvard Medical School (Psychiatry & Neuroscience), and Mailman Research Center-McLean Hospital, Belmont, MA 02178

Modulation of striatal dopamine (DA) synthesis by presynaptic receptors in minced rat corpus striatum was probed by measuring the ability of selective agents to inhibit or stimulate tyrosine hydroxylase (TH) activity monitored with [1-14C]-L-tyrosine. S(+)N-propylnorapomorphine (NPA), a relatively potent D2 autoreceptor agonist, inhibited TH (IC₅₀=1.0 μM) as did the D₂ agonists R(-)-NPA (0.3 μM) and quinpirole (5.0 μM); these effects were blocked selectively by D2 antagonists and reversed by c-AMP-increasing agents (eg, forskolin). The D1 agonist CY-208-243, as well as $\alpha_1,\,\alpha_2,\,\beta_1,$ and β_2 adrenergic agonists and 5HT agonist quipazine, had no effect on TH (up to 10 μ M). The adenosine A₁ agonist, N⁶-cyclopentyladenosine, weakly inhibited TH (IC₃₀=100 μM) but the A_1 - A_2 agonist 2-Cl-adenosine stimulated TH activity (EC₅₀=60 μ M); this stimulation was blocked by theophylline (A1-A2 antagonist) but not 8cyclopentyltheophylline (A $_1$ antagonist), suggesting A $_2$ mediation, and was attenuated by D₂ agonists but not additive with excess forskolin, suggesting involvement of c-AMP. (+)N-allylnormetazocine (σ opiate agonist) also potently stimulated TH (EC30=0.1 μ M); this effect was attenuated by S-NPA and not additive with forskolin. The results suggest that D2 autoreceptors negatively modulate striatal DA synthesis while presynaptic A_2 , and perhaps σ receptors, act via opposing positive neuroregulatory mechanisms that may be cAMPmediated. THE D1/D2 AGONIST PERGOLIDE AND THE D2 AGONIST BROMO-CRIPTINE MEDIATE BODY TEMPERATURE DIFFERENTIALLY IN RE-SERPINIZED MICE THROUGH DISTINCT RECEPTOR SUBTYPES. D. R. Helton, D. O. Calligaro, and D. L. Modlin. Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN 46140.

The honselective potent D1/D2 agonist, pergolide, and the selective D2 agonist, bromocriptine, both produce hypothermia in control mice. However, in male CD-1 mice made hypothermic by prior administration of reserpine (2.5 mg/kg IP), these compounds produced differential effects. Administration of pergolide (0.3 to 30 mg/kg, PO) or the selective D1 agonist, SKF 38393 (1 to 10 mg/kg, IP), produced significant dose-dependent increases in body temperature. Bromocriptine (0.3 to 30 mg/kg, PO) and the D1 antagonist SCH 23390 (1 to 10 mg/kg, IP) further decreased body temperature in reserpinized mice. Increasing doses of SKF 38393 in combination with bromocriptine (3 to 10 mg/kg) produced a temperature increase in hypothermic mice equal to those seen with SKF 38393 alone. In addition to the hypothermia, the change in D1/D2 receptor density in reserpinized mice was determined using radiolabeled SCH 23390 and spiroperidol. These results indicate that the hypothermic and hyperthermic effects of dopamine agonists are mediated via distinct receptor subtypes. Activation of the D1 receptor is responsible for the increase in body temperature in reserpinized mice, while activation of the D2 decreases temperature.

D₁ AND D₂ DOPAMINE RECEPTORS IN THE INFANT HUMAN NEOSTRIATUM. C.E. Adams and S.J. Boyson. Department of Neurology, University of Colorado Health Sciences Center, Denver, CO. 20022

 D_{I} and D_{2} receptors were examined in the infant human neostriatum using quantitative autoradiographic techniques. D_{I} receptors were labeled with $^{3}\mathrm{H}\text{-SCH-}2390$ while D_{2} receptors were labeled with $^{3}\mathrm{H}\text{-spiperone.}$ $^{3}\mathrm{H}\text{-diprenorphine}$ binding was used as a marker for the striosomal compartment.

 D_{l} and D_{2} dopamine receptors were heterogeneously distributed within the neostriatum at both ages examined (32 weeks and 4 days postnatal), although this heterogeneity differs from that reported in adults. Islands of intense receptor binding were embedded in a background of moderate intensity. Occasionally, the islands were bordered by narrow regions of little to no binding. The D_{l} and D_{2} islands were only partially coextensive and bore no relation to the striosomes as defined by the $^{3}\mathrm{H}$ -diprenorphine binding.

 D_2 receptor density was greater than D_1 receptor density within each age group, the reverse of adult data. Total D_1 receptor density was greater at 32 weeks than at 4 days, possibly due to a decrease in neostriatal cellular density with increasing age. Subdivisions exhibiting greater D_1 receptor densities at 32 weeks included the ventromedial quadrant of the caudate as well as the dorsomedial, dorsolateral and ventrolateral quadrants of the putamen.

MOLECULAR CLONING OF A CCK/GASTRIN-RESPONSIVE G PROTEIN-COUPLED RECEPTOR. L.D. McVittie, F.J. Monsma, Jr. C.R. Gerfen, R.M. Burch*, D.R. Sibley & L.C. Mahan*. ETB, NINDS & LCB, NIMH, NIH, Bethesda, MD 20892 & Nova Pharmaceutical Corp., Baltimore, MD 21224.
We have used the polymerase chain reaction (PCR) method to selectively

We have used the polymerase chain reaction (PCR) method to selectively amplify G protein-coupled receptor cDNA sequences from rat striatal mRNA. Poly (A)+ RNA was first sized on sucrose gradients followed by reverse transcription of the 2-3 kb mRNA fractions. The resulting cDNAs were amplified using sets of highly degenerate primers derived from the transmembrane sequences of previously cloned G protein-coupled receptors. A novel cDNA fragment was identified which exhibits considerable homology to various members of the G protein-coupled receptor family. This PCR fragment was used isolate a full-length cDNA from a rat striatal library. A 2.2 kb clone was isolated encoding a 326 amino acid protein which contains 7 transmembrane domains as predicted by hydropathy analysis. The extracellular NH2 terminus consists of 10 amino acids and lacks N-linked glycosylation sites while the 3rd cytoplasmic loop is 35 residues long and contains 1 phosphorylation site for cAMP-dependent protein kinase. Northern blot analysis in brain tissues reveals 2 transcripts of 5.6 and 3.1 kb. Both mRNAs are highly abundant in cortex, hippocampus, cerebellum, and striatum with lower levels in the olfactory bulb, mesencephalon, pituitary and retina. In situ hybridization analysis also indicates a high abundance of mRNA in the cortex, hippocampus and thalamus with lesser amounts in the striatum. To establish the identity of this receptor, we have transcribed RNA from the cDNA clone for expression in Xenopus occytes. Out of numerous agonists tested for their ability to induce ⁴⁵Ca²⁺ efflux activity, both CCK and gastrin exhibited the greatest stimulation of efflux (2-4 fold) in RNA- but not H₂O-injected oocytes. Additional pharmacological experiments to confirm the identity of this receptor clone are presently being performed.

NT AND CCK RECEPTOR cDNAs: ENRICHMENT BY OOCYTE EXPRESSION AND cDNA LIBRARY SIB SELECTION. B.F. O'Hara, J.M. DiGiorgianni, * S. Shimada, E.M. Landau, G.R. Uhl and H. Meiri. Lab. of Mol. Neurobiol., NIDA/ARC, and Depts. of Neurol. & Nsci., Johns Hopkins Sch. of Med., Bx 5180, Baltimore, MD 21224. Mt. Sinai Sch. of Med. & Bronx VAMC, Dept. of Psych., Bronx, NY 10468.

Baltimore, MD 21224. Mt. Sinai Sch. of Med. & Bronx VAMC, Dept. of Psych., Bronx, NY 10468.
Receptors for the neuropeptides cholecystokinin (CCK) and neurotensin (NT) participate in many CNS and peripheral functions. Injection of appropriate RNAs into Kenopus occytes can lead to the expression of either receptor. This expression can be monitored by electrophysiological recording following the application of ligand. Occytes injected with RNA from rat cerebral cortex gave positive signals for both receptors. In vitro RNA transcripts from a L-Zap cDNA library constructed from this RNA also produced responses to CCK and NT, in addition to 5-HT, bombesin and bradykinin. Fractionation of this library by sib selection has produced small pools of clones, one of which appears to contain a cDNA for the CCK receptor and another for the NT receptor. Under voltage clamp conditions (-70mV), inward currents have ranged from 20-3000nA upon application of ligand. In general, signal size has increased at each fractionation level consistent with an increased purification of receptor clones. Isolation of individual cDNAs encoding the CCK and NT receptors should be possible using this approach.

38.3

EVIDENCE THAT GASTRIN RECEPTORS ON AR4-2J CELLS ARE DISTINCT FROM CCK-B RECEPTORS, USING NOVEL PYRAZOLIDINONE CCK ANTAGONISTS. J. J. Howbert, K. L. Lobb*, R. F. Brown*, J. K. Reel*, L. G. Mendelsohn, N. R. Mason, D. F. Mahoney*, and R. F. Bruns. Lilly Research Labs., Eli Lilly & Co., Indianapolis, IN 46285.

The CCK/G receptor family is thought to contain three receptor subtypes: CCK-A (pancreas) [A], CCK-B (brain) [B], and gastrin (stomach fundus) [G]. B and G subtypes are difficult to distinguish with existing tools, suggesting they are very similar or identical receptors. Several studies have demonstrated that pancreatic acinar tissues and cell lines contain a B or G-like receptor, as well as an A receptor. This study reports characterization of the former on the rat acinar cell line AR4-2J, using a novel series of non-peptide, pyrazolidinone CCK antagonists.

Four compounds (including LY262684 and LY262691) were evaluated. They inhibited binding of ¹²⁵I-CCK-8S to mouse brain (IC₅₀'s 6-31 nM) and ¹²⁵I-gastrin I to guinea pig stomach (IC₅₀'s 25-490 nM). IC₅₀'s vs. ³H-MK-329 in rat pancreas were ≥ 6 µM, showing their high selectivity for B and G over A receptors. Phosphoinositide turnover elicited in AR4-2J cells by gastrin was clearly mediated by a B or G-type receptor, since the A-selective antagonist MK-329 blocked it only at higher concentrations (Ki > 100 nM). The LY compounds reversed the gastrin response with K's of 16-270 nM, with the same rank order of potency as in B and G binding. Absolute potencies in PI turnover, however, correlated much more closely with G binding than B binding. This provides evidence that the second PI-linked CCK/G receptor on AR4-2J cells is a true gastrin, rather than a CCK-B, receptor. While G to B ratios for the compounds were modest (4-18), use of several with differing potencies greatly strengthened comparisons among assays, and illustrated the utility of this series for studying CCK-dependent systems.

LY262684, A NOVEL PYRAZOLIDINONE CCK ANTAGONIST: STUDIES OF CONTRACTION IN GUINEA PIG ILEUM. V. L. Lucaites*, L. G. Mendelsohn. N. R. Mason. M. L. Cohen*, K. L. Lobb*, B. F. Brown*, J. K. Reel*, and J. J. Howberl. Lilly Research Labs., Eli Lilly & Co., Indianapolis, IN 46285.

Studies of contraction induced by CCK peptides in longitudinal muscle of guinea pig ileum suggest mediation by at least two CCK receptors, corresponding to CCK-A (pancreatic) and CCK-B (brain) receptors. This tissue has now been further studied with LY262684, a new CCK antagonist with a novel non-pertide pyrazolidipone structure.

novel, non-peptide, pyrazolidinone structure. LY262684 displaced 125 -CCK-8S from mouse brain with an IC $_{50}$ of 6 nM, and 3 H-MK-329 from rat pancreas with an IC $_{50}$ of 7900 nM, documenting its otent and highly selective interaction with CCK-B receptors. This was very similar to the binding profile of L-365,260, a known CCK-B-selective antagonist (IC $_{50}$ of 8 nM in brain and > 1000 nM in pancreas). In ileum, L-365,260 showed greater potency as an antagonist of contractions to CCK-4 (pK $_{b}$ = 9.24) than contractions to CCK-8S (pK $_{b}$ < 7), consistent with the selectivity of CCK-4 as an agonist for CCK-B receptors. LY262684, however, while showing B receptor affinity similar to L-365,260 in brain binding, was less potent in blocking CCK-4 contractions (pK $_{b}$ = 8.45), and more potent against CCK-8S contractions (pK $_{b}$ = 7.64) than L-365,260, thus showing less selectivity for the putative CCK-B receptor in the ileum. Similar results were found for several analogs of LY262684. The differential effects of LY262684 and L-365,260 underscore the heterogeneity of CCK-induced contractions in the ileum, and raise the possibility that they are mediated, in part, by a novel non-A, non-B-type CCK receptor for which these antagonists have differential affinity. This finding helps establish LY262684 as an important new tool for probing CCK-dependent mechanisms in smooth muscle and other systems.

VISUALIZATION AND CHARACTERIZATION OF CHOLECYSTOKININ BINDING SITES IN THE PITUITARY INTERMEDIATE LOBE.

P. Gaudreau, M. Migneault* and G.L. Lavigne. Notre-Dame Hosp. Res. Center and Faculty of Dental Medicine, Univ. of Montreal, Montreal, CANADA. H2L 4K8.

Peripheral administration of cholecystokinin octapeptide (CCK-26-33) elevates plasma immunoreactive concentrations of B-endorphin in rats and the effect can be antagonized by L-364,718. However, the locus of this action has not yet been established. We therefore searched, by in <u>vitro</u> autoradiography, for CCK binding sites in rat and guinea pig pituitary. Twenty um-thick slide-mounted sections of pituitaries were pre-incubated at 23°C for 35 min in 50 mM Tris.HCl buffer containing 0.2% BSA, pH 7.4. They were incubated at 23°C for 120 min in the preincubation buffer containing 5 mM MgCl₂, 0.35 mM bacitracin and 35 pM N [¹²⁵ I-desaminotyrosyl] CCK-26-33, pH 7.4 in the absence or presence of CCK-A and CCK-B receptor agonists and antagonists and submitted to two 14-min washes in 4°C pre-incubation buffer. Slidemounted sections of rat brain were used as control. These sections were dried and apposed to tritrium-sensitive film for 30 days. The autoradiograms revealed a high level of CCK specific binding confined to the intermediate lobe of guinea pig pituitary. This binding was totally inhibited by 1 nM of CCK-26-33, CCK-28-33, L-364,718 and L-365,260. A low and homogeneous level of binding was observed in the rat gland. Altogether, these results suggest that only in guinea pig, the CCK-induced B-endorphin secretion could be mediated by pituitary CCK binding sites. Supported by MRCC.

38.7

BINDING OF [125]-D-TYR⁰(NLE^{28,31})-CCK 26-33 TO CCK RECEPTORS IN CORTICAL MEMBRANES AND BRAIN SECTIONS. M. Carlberg B. Jarrott B.G. Livett and P.M. Beart. University of Melbourne, Clinical Pharmacology and Therapeutics Unit and Department of Biochemistry, Parkville 3052, Australia.

High affinity binding to cholecystokinin (CCK) receptors is dependent on the tetra C-terminal sequence of CCK-8S. We have characterized the binding of a new commercially available, non-oxidizable, peptidase resistant and iodinable CCK analogue, D-Tyr 0 (Nle²⁸, 31)-CCK 26-33 in cortical membranes and sections of rat brain. The peptide was reacted with Na¹²⁵1 in the presence of Chloramine-T and purified by reverse phase liquid chromatography. Binding to cortical membranes was of high affinity (K_d ± s.e. m 0.14 ± 0.03 nM, n=3), saturable (B_{mas} 60 ± 31 fmol/mg protein, n=3), reversible (t_{1/2} association 20 min, k₊₁ 8.9·10⁻³ min⁻¹pM⁻¹, t_{1/2} dissociation 27 min, k₊₁ 0.025 min⁻¹) and to a single population of sites. Specific binding represented 50-70% of the total binding, Binding was dependent on divalent cations and inhibited by the non-hydrolyzable guanine nucleotide Gpp(NH)p, indicating binding to a receptor coupled to a G protein. Binding could be completely displaced by CCK analogues and inhibitors with the following K₁ values (n=3): CCK-88 3.3 ± 2.3 mM, unsulfated CCK-8 23 ± 9 nM, CCK-4 27 ± 18 nM, L-365,260 6 ± 3 nM, L-364,718 130 ± 28 nM. These competition data indicate receptors of the CCK_B type. Binding to 10 µm slide-mounted sections showed 80-90% specificity and the same pharmacological characteristics as those found in cortical membranes. Several parts of the brain were discretely labeled, including anterior nucleus accumbens, anterior cingulate, frontoparietal and primary olfactory cortex. The high specific activity of the iodinated peptide, its stability and low non-specific binding make it an excellent ligand for the autoradiographic localization of CCK receptors. Supported by NH&MRC (Australia) and the Swedish Natural Science Research Council.

CHOLECYSTOKININ ANTAGONISTS: NOVEL COMPOUNDS WITH A DEFINED PHARMACOPHORE LINKING A NUMBER OF TYPE A CCK ANTAGONIST SERIES. James F. Kerwin, Jr., Frank Wagenaar*, Hana Kopecka*, Chun Wel Lin*, Thomas Miller', David Witte', Alex M. Nadzan, Neuroscience Research Division, Pharmaceutical Discovery D-47H, Abbott Laboratories, Abbott Park, Illinois 60064.

We have reported on the structural similarities of glutamic acid based CCK antagonists (A-64718, A-65186) and the benzodiazepine CCK antagonist L-364,718 and also recently presented a new series of antagonists that attempts to relate benzotript with proglumide and with the benzodiazepine class of CCK antagonists. Here we report an array of new classes of CCK antagonists that still maintain potency and selectivity for the CCK type A receptor. Capitalizing on our previous design concepts, a minimium pharmacophore for all these classes was found along with a corresponding variable region of the CCK antagonist construct. This variable position was extensively examined by structural substitution for changes in potency and selectivity and was found to permit great latitude in substitution as evidenced by the number and types of charged groups as well as hydrophobic residues that were accommodated. With a larger variety of functional groups at this site sub-differentiation of the CCK type A receptor may be more feasible. We will report on the discovery of these compounds and provide preliminary in vitro chacterization of the binding and functional activity (amylase release) for these derivatives. Examples of these classes (IC50° s < 100 nM) are depicted in the contraction of the transport of the contraction of the transport of these classes (IC50° s < 100 nM) are depicted in the contraction of the transport of the tra

LESION OF THE PARABRANCHIAL NUCLEI INCREASES CCK-RECEPTOR BINDING IN THE VENTROMEDIAL NUCLEUS OF THE HYPOTHALAMUS.

M. Schumacher, H. Coirini, L. Zaborszky and B.S. McEwen.
The Rockefeller University and University of Virginia.
The ventromedial nuclei (VMN) of the hypothalamus

The ventromedial nuclei (VMN) of the hypothalamus contain high levels of CCK receptors (Neuroendocrinology, 45: 257) and are innervated by CCK-immunoreactive fibers which originate from the nuclei parabrachialis (PDB) (Brain Ress., 303: 225; J.Neurosci.,4: 1289). Within the VMN, estrogen decrease the binding of sulfated [1251]CCK (Neuroendocrinology, 45: 257) but do not affect the binding of sulfated [3H]CCK . Ovariectomized females were injected with vehicle (controls) or with estradiol benzoate (EB; 50 ug/100 g body weight) and brain were sampled 48 hrs later for the quantitative autoradiography of [3H]CCK receptor binding. The estrogen treatment did not affect the binding of [3H]CCK within the VMN. In a second experiment, either the right or the left PDB of ovariectomized females was lesioned. Two week later, females were injected with vehicle or with EB like in the previous experiment. Unilateral lesion of the PDB increased [3H]CCK receptor binding by about 30% within the ipsilateral VMN, but not in the area surrounding the VMN or in other brain nuclei. There was no effect of the EB-treatment on [3H]CCK binding in the VMN ipsilateral or contralateral to the lesion site.

We conclude that CCK fibers originating from the PDB selectively innervate the ipsilateral VMN where CCK interacts with postsynaptic receptors.

38.8

CHARACTERIZATION AND AUTORADIOGRAPHIC LOCALIZATION OF CHOLECYSTOKININ (CCK) RECEPTORS IN THE BOVINE BRAIN. M.A. Morency, L.K. Srivastava and R.K. Mishra. Neuropharmacology Laboratory, Departments of Psychiatry and Biomedical Sciences, Health Sciences Centre 4N52, McMaster University, Hamilton, Ontario, Canada I 8N 375.

Cholecystokinin (CCK) binding sites have been characterized in the rodent, primate and human brain. In the present communication, we report the characterization and autoradiographic localization of CCK receptors in the bovine brain.

Bovine cortical membrane homogenates were incubated with $[^3\text{H}]\text{pCCK}_8$ for 120 min at 25°C. Nonspecific binding was determined in the presence of 1 $_{\rm H}$ M unlabelled CCK $_8$. Scatchard analysis revealed saturable binding to a single class of high affinity sites; K $_{\rm d}$ = 0.922 \pm 0.047 and B $_{\rm max}$ = 51.87 \pm 8.22. Hill coefficients did not differ significantly from unity; n $_{\rm H}$ = 1.02 \pm 0.05. Quantitative autoradiography revealed that [125 I]BH-CCK $_8$ and [3H]pCCK8 binding sites were heterogeneously distributed in bovine

Quantitative autoradiography revealed that [125|]BH-CCK₈ and [3H]pCCK8 binding sites were heterogeneously distributed in bovine brain. Moderate to high densities were present in the cortex, olfactory bulb, nucleus accumbens, caudate, claustrum, amygdala, hippocampus, superior colliculus, and substantia gelatinosa of the cervical spinal cord. Very, low to low binding densities were observed in the globus pallidus, internal capsule, cerebellum, and most thalamic and hypothalamic nuclei. Thus, the autoradiographic distribution of CCK binding sites in bovine brain is fairly similar to those reported in rodent, primate, and human brain. Supported by the Natural Sciences and Engineering Research Council of Canada.

PHYSICAL PROPERTIES OF THE SOLUBILIZED RAT BRAIN SOMATOSTATIN RECEPTOR. S. Rens-Domiano and T. Reisine. Dept. of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104

Somatostatin (SRIF) is a neurotransmitter in the brain, whose physiological actions are mediated by cell-surface receptors. Previous studies have suggested that these receptors are glycoproteins, but little is known about the composition of the oligosaccharide component(s), or its functional role. We have begun to address these issues using lectin affinity chromatography and exoglycosidases. High affinity SRIF receptors were solubilized from rat brain using the detergent CHAPS, and detected using the SRIF analogue, [125I] MK-678. Lectin affinity chromatography revealed that the solubilized receptor bound specifically to WGA (NAcGic, Sialic acid), *Ricinus Communis* I (β-Gal) and II (β-Gal/NAcGal) and Sambucus nigra L. (Neur5Acc(2,6)Gal/NAcGal), but not to Con A (Mannose), succinylated WGA (NAcGlc), DBA (NAcGalo(1,3)), *Ulex Europaeus* (L-Fucose) nor Jacalin (O-linked). These results suggest that the carbohydrate moities are either an N-linked complex or hybrid structure that contains terminal sialic acid groups. In order to assess the functional significance of the oligosaccharide component of the SRIF receptor, solubilized membranes were treated with neuraminidase from *Vibrio Cholerae*, which cleaves all terminal sialic acid residues. After a 24 hr incubation, no detectable agonist binding was present. In contrast, treating the solubilized membranes with Newcastle Disease Virus, which removes only α(2,3)-linked sialic acids, did not result in any loss in agonist binding. This would suggest that sialic acid, in an α(2,6)-linkage plays a functional role in agonist binding to the solubilized SRIF receptor. Supported by NIMH 45533, MH 14654 and the Juvenile Diabetes Foundation.

IDENTIFICATION OF G PROTEINS COUPLED TO SOMATOSTATIN RECEPTORS S.F. Law, S. Rens-Domiano, D. Manning*, and T. Reisine Dept. of Pharmacology, Univ. of Pennsylvania, School of Medicine, Philadelphia, PA 19104. Somatostatin (SRIF) is a neurotransmitter in brain that modulates various cellular effector systems by interacting with membrane bound receptors. Many receptors are coupled to second messengers via a family of G proteins. The ability of neurotransmitter receptors to modulate effector systems may be influenced by the specificity of receptor/G protein/second messenger interactions. In order to study these interactions, SRIF receptors from the cell line AtT-20 (which expresses a high density of SRIF receptors were solubilized and their coupling to G proteins studied using peptide directed antisera against different alpha subunits of the G proteins. The AtT-20 cell SRIF receptor couples to its cellular effector systems via pertussis toxin sensitive G proteins (either Gi and/or Go). Immunoprecipitation studies using antisera 8730, directed against Gia, removes 60% of SRIF receptor binding from the supernatant, as measured using the high affinity SRIF agonist [1251] MK 678, This effect is specific since it is blocked by the peptide to which the antisera was generated. Furthermore an antisera directed against the beta36 subunit of G proteins did not precipitate the SRIF receptor. Western blotting on solubilized AtT-20 cell membranes revealed that all the subtypes of Gi and Go are expressed in these cells. Further studies are in progress to characterize which Gia subunits are coupled to the SRIF receptor. Supported by NIMH grant 45533 and the NIH Cardiovascular Training Grant 5T32HL07502.

DIFFERENTIAL REGULATION OF SOMATOSTATIN RECEPTOR SUBTYPES IN ADULT RAT BRAIN. Melanie Tallent, Karen Raynor, and Terry Reisine. Depts. of Pharmacol. and Inst. of Neurol. Sci., Univ. of PA, Philadelphia, PA 19104.

Pharmacologically and functionally distinct subtypes of somatostatin (SRIF) receptors are expressed in the rat brain. These SRIF receptor subtypes are distinguished by the SRIF analogues MK 678 and CGP 23996 and are found to be differentially localized by autoradiographic analysis. We now show that these receptor subtypes can be differentially regulated in the rat striatum. Rats were treated with 0.9% NaCl or cysteamine (300 mg/kg, s.c.), a compound previously shown to deplete SRIF-like immunoreactivity in the rat brain. The specific binding of [1251] CGP 23996 in the striatum was found to be increased by 13% at 30 min and by 58% at 4 hrs after cysteamine treatment relative to saline-injected animals. Neither the cortex nor the hippocampus demonstrated corresponding increases in specific [1251] CGP 23996 binding. Likewise a 33% increase was found in the specific binding of [1251] MK 678 binding at 4 hrs with no change in the other regions of the brain. Whether these increases reflect changes in affinity or binding capacity will be discussed. We have shown that the striatum expresses a high density of MK-sensitive SRIF receptors, but that this subpopulation of receptors does not appear to be efficiently coupled to the inhibition of forskolin-stimulated adenylyl cyclase in the striatum. However, MK 678 can inhibit forskolin-stimulated adenylyl cyclase activity in both the hippocampus and the cortex to the same extent as SRIF. The differential effects of SRIF depletion on receptor subpopulations in the striatum vs. other brain regions further substantiates heterogeneity of MK-sensitive SRIF receptor subpopulations in the brain. Supported by NIMH Grants 45533 and MH17168.

DIFFERENTIAL DISTRIBUTION OF SOMATOSTATIN RECEPTOR SUBTYPES IN RAT BRAIN REVEALED BY NEWLY DEVELOPED SOMATOSTATIN ANALOGS. J-L. Martin*, M-F. Chesselet* and T. Reisine*. Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Somatostatin (SRIF) receptor subtypes were labeled with the SRIF analogs [1251] CGP 23996 and [1251] MK 678 and the distribution of these receptors in rat brain was investigated using quantitative autoradiography. [1251] CGP 23996 and [1251] MK 678 specifically label different populations of SRIF receptors in rat brain. In a number of brain regions striking differences in the distribution of the SRIF receptor subtypes labeled by each peptide were observed. High levels of binding sites for both [1251] CGP 23996 and [1251] MK 678 were present in the cerebral cortex, CA1 region and subiculum of the hippocampus. In contrast, high levels of [1251] MK 678 binding were found in the dentate gyrus of the hippocampus while few [1251] CGP 23996 binding sites were observed in this brain region. [1251] CGP 23996 binding was detected in the central region of the interpeduncular nucleus whereas the dorsal and lateral subnuclei of this brain area expressed mainly SRIF receptors with high affinity for MK 678. The locus coeruleus as well as regions of the superior colliculus and hypothalamus selectively express [1251] MK 678 sensitive SRIF receptors. Furthermore, limbic structures such as the lateral septum, the nucleus accumbens and ventromedial striatum had much higher levels of [1251] MK 678 binding sites than [1251] CGP 23996 binding sites. Differences in the expression of the SRIF receptor subtypes were also detected in the substantia nigra. [1251] CGP 23996 binding was present in the pars reticulata but not the pars compacta whereas the reverse distribution of [1251] MK 678 binding sites was observed. The differential distribution of [1251] CGP 23996 and [1251] MK 678 binding sites in rat brain supports the hypothesis that these peptides selectively label different SRIF receptor subtypes in the central nervous system.

SUBTYPES OF SOMATOSTATIN RECEPTORS CAN BE DIFFERENTIALLY REGULATED AND CAN COUPLE TO DISTINCT CELLULAR EFFECTOR SYSTEMS. Terry Reisine, Karen Raynor, Hung-Li Wang, and Marc Dichter Depts. of Pharmacol. and Neurol., Univ. of Pennsylvania and Graduate Hospital, Philadelphia, PA 19104.

Subtypes of somatostatin (SRIF) receptors can be distinguished by the peptides MK 678 and CGP 23996. Each peptide binds to pharmacologically distinct SRIF receptors in brain as well as other tissues. Two model cell systems, GH3 cells and rat neocortical neurons in culture, were used to further explore the properties of the SRIF receptor subtypes. GH3 cells express SRIF receptor subtypes with similiar characteristics as those in rat brain. The SRIF receptor subtypes with similiar characteristics as those in rat brain. The SRIF receptor subtypes with similiar GH2 cell membranes but did not significantly affect [1251] MK 678 binding to GH3 cell membranes but did not significantly affect [1251] CGP 23996 binding sites further indicates that these peptides bind to distinct receptors. To further examine the cellular effector systems coupled to each SRIF receptor subtype, the actions of MK 678 and CGP 23996 on K+ currents in rat neocortical neurons in culture were measured using whole cell patch clamp techniques. We previously showed that somatostatin-14 stimulated a delayed rectifier K+ current in these cells. MK 678 also stimulated this current (26 ± 2% increase in 8 of 14 neurons tested) but 1 uM CGP 23996 did not. These studies indicate that CGP 23996 and MK 678 sensitive SRIF receptors can couple to different cellular effector systems, possibly to mediate distinct biological actions of SRIF. Supported by NIMH grant 45533, the Office of Naval Research and the Juvenile Diabetes Foundation.

THE SOMATOSTATIN ANALOGUE MK 678 PRODUCES INCREASES IN LOCOMOTOR ACTIVITY WHEN INJECTED INTO THE NUCLEUS ACCUMBENS OF THE RAT. Karen Raynor, Irwin Lucki, and Terry Reisine. Depts. of Pharmacology and Psychiatry, Univ. of PA, Philadelphia, PA 19104.

The tetradecapeptide somatostatin (SRIF) is found in higher concentration in the nucleus accumbens than in any other region of the striatum. However, the function of SRIF in the nucleus accumbens has not been elucidated. Subtypes of SRIF receptors are distinguished in the rat brain by the stable SRIF analogues, MK 678 and CGP 23996. Autoradiographic analysis reveals a moderate density of MK-sensitive sites (94 fmol/tissue slice) in the nucleus accumbens with fewer corresponding CGP 23996 sites (15 fmol/tissue slice). SRIF administered icv has been shown to increase locomotor activity in rats. Here we report that MK 678, a stable and specific analogue of SRIF, produces increases in locomotor activity similar to that seen with amphetamine when microinjected directly into the anterior nucleus accumbens of the rat.

Rats were surgically implanted with indwelling cannulae aimed at the anterior nucleus accumbens. After recovery, animals received bilateral injections of amphetamine, MK 678, or saline and locomotor activity was measured in automated activity cages. Amphetamine (10 ug/ul/side) produced a 4-fold increase in activity. The metabolically stable SRIF analogue MK 678 (3-100 ng/ul/side) produced an effect similar in magnitude to amphetamine. The effects of CGP 23996 on locomotor activity and the possible mediation of the effects of SRIF analogues by dopaminergic systems will be discussed. Supported by NIMH Grants MH455 3 and MH17168.

LACK OF CROSS-DESENSITIZATION OF SOMATOSTATIN-14 AND SOMATOSTATIN-28 RECEPTORS COUPLED TO POTASSIUM CHANNELS IN RAT NEOCORTICAL NEURONS. <u>Hung-Li Wang , Marc Dichter and Terry Reisine ,</u> Departments of Pharmacology and Neurology, University of Pennsylvania School of Medicine and Graduate Hospital, Philadelphia PA 19104.

The effects of somatostatin-14 (SOM-14) and somatostatin-28 (SOM-28) on the delayed rectifier K+ current (IK) in rat neocortical neurons in culture were measured using whole cell patch clamp techniques. SOM-14 stimulated IK in a reversible manner. Continuous application of SOM-14 to the neocortical neurons led to a gradual desensitization of the SOM-14 response. Many cells completely desensitized to SOM-14. SOM-28 also modulated IK in neocortical cells. However, SOM-28 reduced IK. This response was also reversible. Continuous application of SOM-28 to neocortical neurons led to a desensitization of the SOM-28 inhibition of IK. Many of the neurons that responded to SOM-28 became completely refractory to the peptide following prolonged SOM-28 pretreatment. While most neocortical neurons responded either to SOM-14 or SOM-28, a population of neurons responded to both peptides. Chronic application of SOM-14 to these neurons completely desensitized the SOM-14 stimulation of IK, but did not affect SOM-28 inhibition of this potassium current. Similarly, complete desensitization of SOM-14 stimulation of IK, The lack of cross-desensitization between SOM-14 and SOM-28 induced responses suggests that these peptides act through different receptors to regulate IK. This work was supported by NIMH grant 45533, the Office of Naval Research and Juvenile Diabetes Foundation (TR) and NIH grant NS24927 (MD).

MECHANISM OF ACTION OF A LONG-ACTING ANALOG OF SOMATOSTATIN G. Hermann. M.S. O'Dorisio*, T.M. O'Dorisio*, and W.B. Malarkey*, Depts Physiology, Pediatrics and Medicine, OSU, Columbus, OH These experiments were designed to compare the mechanism of action of somatostatin (SOM) and octrectide acetate, a long-acting analog of somatostatin being used to treat several neuroendocrine diseases. The GH3 rat pituitary tumor cell line, an in vitro model of prolactin secretion, was utilized for these studies. Prolactin secretion can be stimulated by VIP while SOM inhibits VIP-stimulated release. These studies examined the mechanism of SOM inhibition of VIP-mediated prolactin secretion and tested whether the synthetic analog of SOM, octrectide, acts by a similar mechanism. Octrectide competitively inhibited binding of 1251-(tyr") SOM to GH, cells; the apparent affinity of octrectide was 100-fold less than SOM. Similar to SOM, octrectide was an effective antagonist of VIP-mediated stimulation of adenylate cyclase but did not inhibit forskolin-mediated stimulation of adenylate cyclase. Octrectide treatment did not affect either the number or affinity of VIP receptors expressed on GH, cells. Taken together, these results suggest that SOM and octrectide block VIP-mediated prolactin secretion by interfering with VIP-receptor G-protein coupling to the adenylate cyclase complex. The ability of octrectide to mimic native somatostatin actions and its resistance to degradation make it a valuable research tool for further delineation of the multiple physiological functions of SOM as well as being useful in the clinical treatment of selected neuroendocrine disorders.

EXCITATORY AMINO ACIDS: RECEPTORS I

RESPONSES MEDIATED BY N-METHYL-D-ASPARTATE RECEPTORS IN CULTURED HIPPOCAMPAL NEURONS FROM MOUSE TRISOMY 16, A MODEL OF DOWN SYNDROME. E.J.Coan, B.Ault & S.I. Rapoport. LNS, NIA, NIH, Bethesda, MD 20892.

The trisomy 16 (Ts16) mouse is considered to be a model of human trisomy 21 (Down syndrome) because of genetic homology between human chromosome 21 and mouse chromosome 16. This laboratory previously has reported that cultured dorsal root ganglion neurons from the Ts16 embryo have several voltage dependent electrical properties that differ from those of neurons from littermate controls. Down syndrome subjects show developmental retardation and, after the third decade of life, develop Alzheimer-like dementia and neuropathology. As the N-methyl-D-aspartate (NMDA) receptor may play a significant role in development and may also be involved in Alzheimer's disease experiments were performed to investigate responses to NMDA in cultured hippocampal neurons from Ts16 mice. Whole cell patch clamp recordings were made from 2-4 week old primary cultures of hippocampal neurons prepared from Ts16 embryos and littermate controls at gestation day 14-16 using standard techniques. Tetrodotoxin (0.2 uM) picrotoxin (50 uM) and glycine (1 uM) were added to a standard extracellular medium. Intracellular medium included KMeSO4 + TEA or CsCl, and ATP. NMDA was applied either via a puffer pipette (200 uM) or via a fast perfusion system (20 uM) while the cell was voltage clamped at membrane potentials between -80 mV and +20 mV. I-V plots were then constructed. In 7/7 cells from Ts16 mice, NMDA produced an inward current which was voltage-dependent, and had a reversal potential of approximately 0 mV. The differences between NMDA responses produced in cultured hippocampal neurons from Ts16 mice and controls are being investigated.

EQUILIBRIUM AND KINETIC MEASUREMENTS SUGGEST NMDA RECEPTOR ACTIVATION REQUIRES BINDING OF TWO MOLECULES EACH OF NMDA AND GLYCINE. M.L. Mayer. M. Benveniste and D.K. Patneau. Unit of Neurophysiology and Biophysics, NICHD, Bethesda, MD 20892.

The activation of ligand gated ion channels usually requires binding of more than

one molecule of agonist (e.g., nicotinic ACh: 2; GABAa: 2; neuronal ATP: 3). The NMDA receptor is unusual in that both glutamate and glycine must bind to activate the receptor channel complex. We have used whole cell recording to study the stoichiometry of activation of NMDA receptors by measuring the concentrationdependence and kinetics of activation of NMDA receptors evoked by rapid application

of glutamate- and glycine-site agonists and antagonists.

With 3 µM glycine present, a log-log plot of the NMDA dose-response curve had a limiting slope of 2 at low concentrations of agonist, suggesting two binding sites for NMDA. Consistent with this, at low concentrations of NMDA, activation kinetics were non-exponential, but could be well fit by a model which assumed two equivalent excitatory amino acid binding sites (for NMDA we obtained $k_{on} = 2.08 \mu M^{-1} \text{ sec}^{-1}$ $k_{Off} = 22.87 \text{ sec}^{-1}$). The microscopic dissociation constant calculated from these values is 11 μ M, close to that obtained when a 2 equivalent binding site model was used to fit the NMDA equilibrium dose response curve (16 µM).

Interpretation of the limiting slope of the glycine dose-response curve, recorded with 100 µM NMDA, is complex due to contamination by an unknown concentration of endogenous glycine. However, the activation kinetics for both glycine and for the lower affinity analogue L-alanine were also sigmoidal, and could be fit by a model which assumed two equivalent binding sites for glycine-like amino acids. Experiments with 7Cl-Kynurenic acid, a competitive antagonist for the glycine site, confirmed that a single binding site model would not fit the onset of and recovery from antagonism in the presence of 100 µM NMDA and 100 µM L-alanine, but a model assuming two equivalent sites for L-alanine gave good fits (7CI-Kynurenic acid k_{on} = 40.77 μ M⁻¹ sec⁻¹, k_{off} = 10.68 sec⁻¹; K_i = 262 nM).

39.2

MULTIPLE EFFECTS OF TETRAETHYLAMMONIUM (TEA) ON N-METHYL-D-ASPARTATE RECEPTOR-CHANNELS IN CULTURED MAMMALIAN NEURONS. Jerry M. Wright and Linda M. Nowak, Dep't of Pharmacology, NYSCVM Cornell University, Ithaca, NY 14853

The effects of TEA on NMDA receptor-channels were studied in outside-out patches. The extracellular solution contained 300 nM TTX and (in mM): 150 NaCl, 2.8 KCl, 1.0 CaCl₂, 10 HEPES-Na. The patch pipette solution was (in mM): 140 CsCl, 10 EGTA-K/1.0 CaCl₂, and 10 HEPES-K. Different effects were seen depending upon which membrane surface was exposed to TEA. Extracellular TEA produced two inhibitory effects: 1) channel conductance (γ) decreased, and 2) the frequency of channel events decreased. The γ decrease was voltage-dependent and the data were fit by the Woodhull model with the block site sensing 60% ($\delta=0.6$) of the transmembrane potential. The apparent dissociation constant (Kd) of channel block was 11 mM at -60 mV and 45 mM at 0 mV. There was no change in mean open time and no new fast closed time was observed. The greater inhibitory effect was the reduction in frequency of opening with an IC50 of 5 mM TEA; this effect was apparently voltage independent. The reduction in frequency of apparently voltage independent. The reduction in frequency of opening was not due to competitive inhibition at either the NMDA or glycine sites. Partial (70 mM) or total substitution of TEA for Cs in patch pipetts revealed that NMDA channels are TEA permeable with PTEA/PCs = 0.45. Supported by NS24467

INDEPENDENT STRUCTURAL FEATURES INFLUENCE BINDING AND DISSOCIATION KINETICS FOR NMDA COMPETITIVE ANTAGONISTS M. Benveniste and M. L. Mayer, Unit of Neurophysiology and Biophysics, LDN, NICHD, NIH, Bethesda, MD 20892.

Antagonism of NMDA activated currents was studied using whole cell voltage clamp of mouse dissociated hippocampal neurons cultured for 10 to 15 days. The kinetics of NMDA receptor antagonism were measured by applying drugs with a multibarrel flow pipe, allowing rapid solution changes around the cell in less than 10 msec. Mathematical solutions for both one and two equivalent site models for antagonism were determined according to the differential equations outlined by D. Colquhoun and A. G. Hawkes (Proc. R. Soc. Lond. B. 199:231, 1977). Conquioun and A. G. Hawkes (FIG. N. Soc. Land. B. 199:251, 1977). The kinetics for the onset of (k_{OR}) and recovery from (k_{Off}) antagonism gave better fits for the two-equivalent site model, and also yielded k_{Off} / k_{OR} values which well approximated equilibrium K_i 's. Six competitive antagonists were compared to determine how changes in structure influence ligand binding and dissociation. The results indicate that single chain non-constrained compounds associate faster than cyclic constrained antagonists; and that compounds in which the α-carbon and phosphorous are 5 atoms apart associate faster than their 7-atom analogs. However, the number of atoms separating the α -carbon and phosphorous atoms does not influence $k_{\rm Off}$. Our results suggest that sterically restricted antagonists are more tightly bound when compared to non-constrained antagonists.

EFFECTS OF SIGMA LIGANDS ON NMDA-INDUCED SINGLE CHANNEL CURRENTS. E. Siqueira—Rocha, E.X. Albuquerque, and A.S. Ramoa. Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, RJ, 21944, Brazil and Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201.

The antipsychotic agent haloperidol, a high affinity ligand for sigma (o) receptors, modulates the NMDA response of hippocampal neurons (Rocha et al., Soc. Neurosci. Abst., 1989). Here, we have examined whether σ -haloperidol receptors mediate this effect. Using outsideout patches from rat hippocampal neurons in culture, we compared the effects of haloperidol and high affinity σ ligands 1,3-di(2tolyl)guanidine (DTG) and 3-(3-hydroxyphenyl)-N-(propyl)piperidine (3-PPP) on single channel ion currents induced by application of NMDA (0.5-20 μ M). Each patch was studied at several concentrations of each σ At relatively low concentrations (0.1-1 \(\mu M \), haloperidol potentiated the NMDA response in 20 out of 30 patches by increasing the frequency of NMDA-induced openings. In contrast, potentiation was not observed after application of DTG (1-50 nM) or 3-PPP $(0.1-1 \mu M)$ at concentrations that, according to previous binding studies, assured a high level of specificity for σ receptors. At higher concentrations, DTG (0.1–100 μ M) and 3–PPP (1–100 μ M) shared with haloperidol (1–30 μ M) the ability to reduce the NMDA response by markedly decreasing frequency of openings and channel lifetime. These blocking effects may result from low affinity binding at a site within the NMDA receptor ion channel. Although mechanisms under lying the potentiating effects of haloperidol remain unknown, the results observed with DTG and 3-PPP suggest that σ receptors are not directly involved with modulation of NMDA receptor function. Support: CNPq, FINEP Brazil, FINEP Maryland, and NIH #P50-MH44211.

COMPUTER SIMULATIONS OF QUANTAL EVENTS MEDIATED BY NMDA RECEPTORS. 1.C. Wathey. Computational Neurobiology Laboratory, Salk Institute, POB 85800 San Diego, CA 92138.

Postsynaptic currents mediated by N-methyl-D-aspartate (NMDA) receptors typically decay to baseline with a time constant on the order of 100 ms. Singlechannel recordings indicate, however, that the mean open time of these channels (~10 ms) is too short to account for this slow decay. One possible explanation is that the diffusion of neurotransmitter molecules from the synaptic cleft is retarded by repeated binding to receptors, thus limiting the decay phase of the postsynaptic current. To test the plausiblity of this hypothesis, quantal events mediated by NMDA receptors were simulated using a computer program originally developed for modeling the quantal event at nicotinic synapses (Wathey et al. 1979, Biophys J 27:145-164). The program simulates the diffusion of transmitter within the cleft and the reaction of transmitter with receptor molecules and with an uptake system. The NMDA receptor was modeled using a 3-state reaction scheme, in which two independent binding sites bind transmitter, and the doubly-bound receptor opens via a rate-limiting conformational change. The closing rate was set to 100/s, the reciprocal of the mean open time. The other rate constants were chosen so as to be consistent with the doseresponse data of Patneau & Mayer (I Neurosci, in press). With 70 receptor molecules covering a postsynaptic area of 0.07 µm², in a synaptic cleft 0.6 µm² in area, a quantum of 1000 glutamate molecules opened 11 NMDA receptor channels, a value similar to experimentally observed peak amplitudes (Bekkars & Stevens 1989 Nature 341:230-233). The decay phase was exponential with a time constant of 13 ms. Diffusion of transmitter became the rate-limiting process in the decay only with unrealistically small diffusion constants or unrealistically large values of receptor density or cleft size. These manipulations produced peak amplitudes much larger prolonged decay may instead result from intrinsic properties of the receptors, such as their tendency to open in bursts or clusters of bursts.

39.9

CONCENTRATION-DEPENDENT SINGLE CHANNEL KINETIC PROPERTIES OF NMDA RECEPTORS OF MOUSE SPINAL CORD NEURONS IN CULTURE. D.M. Rock@, T. Ryan-Jastrow+, R.E. Twyman+ and R.L. Macdonald+#. Neuroscience Program@ and Depts. of Neurology+ and Physiology#, Univ. of Michigan, and Parke-Davis Pharm. Res.@, Ann Arbor, MI 48104.

To investigate the gating kinetic properties of the NMDA receptor, single channel currents evoked by NMDA (1-50 μM) and glycine (2 μM) were studied using the outside-out patch clamp technique. Patches were obtained from cultured mouse spinal cord neurons at room temperature in a 1 mM Ca⁺⁺ and nominal Mg⁺² recording solution.

Currents with multiple amplitudes were evoked by NMDA. However, openings of channels with 52 and 37 pS conductances were predominant. Kinetics of these conductance states were analyzed. Percent open and opening frequency of both conductance states increased with NMDA concentration. Mean open duration increased at low concentrations but remained relatively constant at high concentrations. Analysis of open duration frequency histograms for both conductance states revealed the presence of multiple open states that had concentration-dependent properties. Closed and burst duration frequency histograms analyzed in a similar fashion also revealed the presence of multiple closed and burst states. Microscopic kinetic gating schemes for the two dominant conductance states are presented. Low µM concentrations of CPP, a

competitive NMDA antagonist, reduced opening frequency.

The results suggest that the gating properties of the NMDA receptor were similar to those described for the nicotinic acetylcholine, glycine and GABAA receptors.

PYRAZOLE ACTIVATES N-METHYL-d-ASPARTATE (NMDA)-LIKE CURRENTS. E.F.R. Pereira, Y. Aracava and E.X. Albuquerque. Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, RJ, 21944, Brazil and Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD, 21201.

Pyrazole prevents alcohol toxicosis and some experimental data show that this compound potentiates other general depressants (J. Pharm. Pharmacol., 39:658, 1987). In this work we have examined the effects of pyrazole on hippocampal pyramidal cells in culture using the outside—out patch clamp technique. We used a nominally ${\rm Mg}^{2+}$ -free external solution for our records. Pyrazole (0.5–10 $\mu{\rm M}$) did not block significantly the NMDA-activated currents. Surprisingly, however, pyrazole alone activated currents that appeared as bursts similar to those evoked by NMDA itself. They had a conductance of about 54 pS at 28°C. The frequency and characteristics of channel bursts were both concentration- and voltage-dependent. The closures within the burst could be fit to a double exponential function whereas the openings disclosed a single exponential distribution. In addition, hyperpolarization decreased the open time, increased the number of intraburst events and prolonged the burst duration. Potentials more negative than -100 mV decreased the channel open probability such that long bursts were followed by silent periods that lasted several seconds. Furthermore, APV ($50~\mu\text{M}$), a competitive antagonist of the NMDA receptor, blocked the pyrazole—activated currents. Though some subtle differences were noticed, these data altogether suggest that pyrazole may activate NMDA receptors. Support: CNPq/ FINEP/ UFRJ-UMAB Training Program.

39.8

EVIDENCE THAT ZINC INHIBITS NMDA RECEPTOR-GATED ION CHANNEL ACTIVATION BY NON-COMPETITIVE ANTAGONISM OF GLYCINE BINDING. G.C. Yeh, D.W. Bonhaus, J.O. McNamara. Duke & V.A. Medical Center. Durham, N.C. 27705

Zinc noncompetitively inhibits NMDA receptor-mediated responses. To investigate the mechanism of this inhibition, we measured the effects of zinc on ligand binding to three distinct sites (phencyclidine, glycine and NMDA binding sites) on the receptor-channel complex. Zinc dose-dependently decreased the association and dissociation of [3H]TCP but had no effect on steady-state levels of binding. suggests that zinc inhibits the receptor-gated access of $[^3H]TCP$ to (and from) its binding site. Zinc inhibition of $[^3H]TCP$ binding was not mediated by an action on NMDA recognition sites since zinc had no effect on NMDA-sensitive [³H]glutamate binding. However, zinc dosedependently inhibited [³H]glycine binding by a non-competitive mechanism. Stoichiometric analysis of equilibrium binding data disclosed the presence of two [³H]glycine binding sites per [³H]TCP binding site. Comparison of the potencies of zinc in inhibiting glycinedependent [³H]TCP association and [³H]glycine binding suggests that blockade of only one of the two glycine sites is sufficient to prevent [3H]TCP association. We hypothesize that synaptically released zinc inhibits NMDA receptor mediated responses by binding to a distinct site on the receptor-channel complex, reducing glycine binding, and thereby decreasing what would otherwise be a tonically present action of endogenous extracellular glycine.

39.10

CHANNEL BLOCK BY Mg²⁺ OF THE NMDA RECEPTOR LARGE CONDUCTANCE STATES OF MOUSE NEURONS IN CULTURE. R.L. Macdonald+#, N.M. Porter+, R.M. Green+, and R.E. Twyman+. Depts. of Neurology+ and Physiology#, Univ. of Michigan, Ann Arbor, MI 48104.

The actions of magnesium (Mg2+) on NMDA receptor currents were characterized by studying the kinetic properties of the large conductance states (50 and 38 pS) of the NMDA receptor. Outside-out patches from cultured mouse spinal, cortical, and striatal neurons were obtained in 1 mM Ca+2 and nominal Mg2+ solutions. Single channel data were digitized at 20 kHz with a 2 kHz Bessel filter interposed. Currents evoked by NMDA (50 μ M) and glycine (2 μ M) were reduced by Mg²⁺ and were voltage-dependent. At -75 mV, Mg²⁺ (1 to 200 μ M) produced a concentration-dependent decrease in mean channel open time and opening frequency. Frequency distributions of channel open, closed and burst durations of the conductance states were analyzed by curve fitting to sums of exponential functions.

Open duration time constants decreased and closed time constants were altered with increasing Mg²⁺ concentration. Mean burst durations increased slightly and then decreased as Mg²⁺ concentration was

These results suggest that Mg²⁺ reduced NMDA-activated current by a mechanism that cannot be explained purely by simple open channel blockade. Channel block appeared to occur by a complex open channel block mechanism and/or by allosteric regulation of channel gating. A microscopic reaction scheme consistent with the results is presented.

NOREPINEPHRINE MODULATION OF THE NMDA RESPONSE IS AFFECTED BY GLYCINE. M.S. Rocha and A.S. Ramoa. Lab. Mol. Pharmacol. II. UFRJ, RJ 21944, Brazil and Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201.

Norepinephrine (NE) has been suggested to modulate the NMDA receptor function in hippocampal neurons (Stanton et al., Exp. Brain Res., 77:517, 1989). Here, we have examined whether NE directly interacts with the NMDA receptor macromolecular complex. Single channel ion currents were recorded from cultured rat hippocampal neurons using the outside-out patch-clamp configuration. Application of NE (0.1-100 μ M) frequently led, within a few seconds, to an increased frequency of NMDA induced channel openings and longer burst durations (40% of 41 patches). These effects are similar to those previously reported for glycine, suggesting a common mechanism of action. Consistent with this possibility, kynurenic acid (10 μ M), an antagonist of glycine at its strychnine-insensitive site, blocked the NE potentiation. In addition, the NMDA response was not potentiated or even depressed by NE, when glycine was previously added at a high concentration (10 μ M). Thus, effects of NE are dependent on extracellular glycine concentration. These findings indicate that complex interactions are involved in the regulation of NMDA response by NE. Direct interaction with the NMDA receptor could contribute to the role of NE in modulation of synaptic transmission and plasticity. Support: CNPq, FINEP (Brazil & US).

SPONTANEOUS AND EVOKED OSCILLATIONS OF INTRACELLULAR CALCIUM IN CULTURED RAT CEREBELLAR GRANULE CELLS. $\underline{L},\underline{D}$ Artman* and E.F. Nemeth. Natural Product Sciences Inc., Salt Lake City, UT 84108.

The concentration of intracellular free calcium ([Ca]_i) was measured in cultured rat cerebellar granule cells using fura-2. In 6-8 day old cultures incubated in nominally magnesium-free buffer supplemented with 1 µM glycine, we occasionally observed rapid and transient increases (oscillations) in [Ca]₁ that peaked within 30 sec and then plummeted to baseline levels. Oscillations could be elicited almost at will simply by adding 1 mM dithiothreitol. The magnitude of the oscillations varied from 200-2000 nM calcium (basal = 80-150 nM). Oscillations occurred with a frequency of 1-3/min and were dependent on the presence of extracellular calcium. Stepwise increases in the concentration of N-methyl-d-aspartate (NMDA) produced increases in [Ca]_i and progressively damped oscillations of cytosolic Ca²⁺. Competitive (CPP) and noncompetitive (MK-801) inhibitors of the NMDA-receptor/channel complex were found to totally block the oscillations. Tetrodotoxin (TTX) at 1 µM inhibited oscillatory activity. Low concentrations (10 nM) of ω-conotoxin GVIA decreased the frequency of oscillations without changing the amplitude, whereas concentrations above 1 μM were capable of reducing both amplitude and frequency. GABA (1 mM) and the GABA-B agonist baclofen (100 μ M) blocked the oscillations. Picrotoxin (100 μ M) increased the frequency of the oscillations without changing the magnitude. The competitive antagonist of glycine, 7-chlorokynurenic acid, blocked the glycine-induced oscillations. The subsequent addition of glycine (100 μ M) reversed the inhibitory effects of 7-chlorokynurenic acid. Nifedipine (5 μ M) reduced the amplitude and frequency of oscillations but did not produce a complete inhibition. The effects of ωconotoxin, together with those of the NMDA antagonists, suggests that excitatory amino acid synaptic transmission contributes significantly to these oscillatory changes in [Ca];.

REDUCTION OF NMDA-INDUCED RISES IN [Ca++], BY PHORBOL ESTERS IN CULTURED RAT HIPPOCAMPAL NEURONS. K.G. Baimbridge and G.A. Joy*

Physiology, University of British Columbia, Vancouver, B.C., Canada, V6T 1T7

The potential intracellular regulation of NMDA receptors by protein kinase C (PKC) was studied by determining the effect of the phorbol ester, PMA, on the [Ca++]i response to transient applications of NMDA to cultured rat hippocampal pyramidal neurons.

to transient applications of NMDA to cultured rat hippocampal pyramidal neurons. The cultures were loaded with Fura-2-AM and [Ca++], was monitored from single neurons perifused with a salt solution containing no added Mg++, lµM glycine and 0.5 µM TTX.

PMA perifused at 500 nM for 10 min caused a partial blockade of NMDA responses in 9 of 14 cells tested. The effect was highly dependent upon the age of the cultures in that three week old cultures more consistently responded to PMA whereas no effect was seen after one week in culture. These results are consistent with the reported development of PKC in vivo, and may also reflect a differential response of the pyramidal cell types present in the cultures. (Supported by the MRC of Canada)

EXCITATORY AMINO ACID-EVOKED INTRACELLULAR CALCIUM TRANSIENTS IN SPINAL CORD NEURONS MEASURED WITH INDO-1. D.B. Reichling and A.B. MacDermott. Dept. Physiology and Cellular Biophysics, and Center for Neurobiology and Behavior, Columbia Univ., New York, NY 10032.

Columbia Univ., New York, NY 10032.

The calcium indicator dye, indo-1, was used to measure changes in intracellular free calcium ion concentration ([Ca²⁺]_i) evoked in spinal cord dorsal horn neurons by excitatory amino acid agonists. Cultured neurons from the embryonic rat dorsal horn were loaded with indo-1-AM. The flowing bath contained 5x10⁻⁷ M TTX and 5 μM glycine. Drugs were applied rapidly via a large Y-tube to the entire neuron. Fluorescence was monitored in single cell bodies using dual photometers. Concentrations of NMDA from 5 to 50 μ M stimulated photometers. Concentrations of NMDA from 5 to 50 μ M stimulated peak [Ca²⁺]; increases of 50 nM to >1 μ M. [Ca²⁺]; transients evoked by a non-saturating dose of NMDA (20 μ M) were maximally antagonized by 1 mM magnesium (Mg²⁺); while at a saturating dose of NMDA (100 μ M), 10 mM Mg²⁺ was required to completely block the [Ca²⁺]; transients. Thus, physiological [Mg²⁺] can modulate excitatory amino acid-evoked [Ca²⁺]; transients. The dose-response relationship for kainate-evoked [Ca²⁺]; transients between 10 and 50 μM kainate was steeper than that for NMDA. 100 μM lanthanum (La³⁺), which blocks voltage-gated calcium channels as well as NMDA-gated channels, almost completely inhibited [Ca²⁺], transients evoked by saturating doses of NMDA. This [La3+] enhances kainategated currents by about 50%, yet it blocks nearly all of the $[Ca^{2+}]_i$ increase evoked by kainate, implying that under these conditions $[Ca^{2+}]_i$ elevation results mainly from entry of extracellular Ca^{2+} .

REDOX STATE ALTERS NMDA RECEPTOR-MEDIATED RISE IN [Ca²⁺]; IN RETINAL GANGLION CELLS (RGCs). Linda A. Wong. Nikolaus J. Sucher & Stuart A. Lipton. Dept. of Neurol, Children's Hospital & Harvard Med Sch, Boston, MA.

In patch-clamp recordings, the reducing agent dithiothreitol (DTT) selectively increases NMDA responses in RGCs and other central

(DTT) selectively increases NMDA responses in RGCs and other central neurons; the oxidizing agent DTNB reverses this effect (Aizenman, Lipton & Loring, Neuron 1989;2:1257). Glutamate or NMDA kills RGCs in a Ca²⁺-dependent manner (Hahn, Aizenman & Lipton, PNAS 1988;85:6556). Furthermore, we have shown that NMDA receptor-mediated neurotoxicity in RGCs is increased with DTT treatment and that this effect is blocked by DTNB (Levy, Sucher & Lipton, Neurosci. Lett. 1990;110:291). These previous findings suggest that the redox state of the NMDA receptor is crucial for the survival of neurons facing slutamate-related injury and predicts that excessive calcium entry may be glutamate-related injury and predicts that excessive calcium entry may be associated with cell death. Therefore, the present study was undertaken to investigate the effect of NMDA receptor activation on [Ca²⁺]; and its modulation by DTT. Cultured RGCs from postnatal rat (P2-11) were exposed to the fluorescent dye fura-2/AM (20 µM, 1 h). Fluorescence (excitation: 350 and 380 nm, emission: 495 nm) was recorded with a SIT (excitation: 350 and 380 nm, emission: 495 nm) was recorded with a S11 camera and fed to a Quantex image-processing system. $[Ca^{2+}]_i$ was calculated from intensity ratios (350/380 nm). Baseline $[Ca^{2+}]_i$ was 56 ± 7 nM (n = 14). In low $[Mg^{2+}]_0$, 200 μ M NMDA reversibly increased $[Ca^{2+}]_i$ to 421 ± 70 nM in ~80% of the cells tested (n = 11). This effect was completely blocked by 200 μ M APV or 1 mM $[Mg^{2+}]_0$, but only slightly (<20%) by 10 μ M CNQX. Exposure to 2 mM DTT had no effect on resting levels of $[Ca^{2+}]_i$. The NMDA-induced rise in $[Ca^{2+}]_i$, however, was increased up to two fold after DTT treatment.

NMDA STIMULATED CALCIUM UPTAKE INTO PRISMS FROM CHICKEN FOREBRAIN: CHANGES DURING MATURATION J.A.P. Rostas, J.M.Kavanagh* and D.A.Powis* The Neuroscience Group,
Faculty of Medicine, University of Newcastle, NSW Australia In chicken forebrain the maturation phase of synapse

development, which has been proposed as a model for plasticity in the adult, is protracted and occurs well after synapse formation. We have investigated whether, during maturation, there is a change in functional response (Ca^{2+}) uptake) to stimulation of the NMDA receptor since this receptor is known to be associated with postsynaptic densities (PSDs) which themselves change markedly during maturation. At 10-12 weeks (mature brain) and 8-14 days (when most synapses are immature but synapse formation is virtually complete) ⁴⁵Ca²⁺ uptake was measured into 250um prisms at 30°C under conditions which were linear for both time and protein. NMDA (1mM) stimulated 45Ca2+ uptake was maximal by 4 min (37%, p<0.05) in mature brain and was maintained for at least 10 min. In immature brain NMDA stimulated 45 Ca²⁺ uptake was much slower and did not reach statistical significance until 10 min (29.5% 9<0.05). The stimulation was totally inhibited by 1mM CPP. At both ages glutamate (2.5mM) stimulated $^{45}Ca^{2+}$ uptake was more rapid, reaching similar maximal levels at 2.5 min (31% and 38%, respectively) and was only partially blocked by CPP. This change in the NMDA receptor response appears to occur slowly over the same period as the changes in PSD suggesting that PSDs may modulate receptor-mediated events.

GLUTAMATE AND QUISQUALATE EVOKE AN OUTWARDLY-RECTIFYING CURRENT IN APLYSIA NEURONS. P.S. Katz and I.B. Levitan. Graduate Department of Biochemistry, Brandeis University, Waltham, MA 02254.

Neurons of the sea hare, Aplysia californica, have been previously shown by other researchers to have a variety of different responses to glutamate and glutamatergic agonists. We are currently performing voltage clamp recordings in neurons isolated in primary cell culture and have found a previously undescribed voltage-sensitive response to pressure-applied glutamate. This response is a sustained outward current due to a conductance increase. The current is outwardly rectifying; it goes to zero at holding potentials more negative than -75mV. Occasionally, this current was observed to reverse to a small inward current at this potential, which is the equilibrium potential for potassium in Aplysia neurons. Quisqualate also evokes this outwardly rectifying current. Furthermore, saturating concentrations of quisqualate prevent glutamate from activating this current, but do not antagonize another transiently activated, nonrectifying response to glutamate. Thus, it is likely that quisqualate is a specific agonist for the glutamate-evoked outwardly-rectifying current. This response to glutamate is not present in all Aplysia neurons, but has been seen repeatedly in the large identified buccal neurons, B1 and B2.

EXCITATORY AMINO ACIDS: RECEPTORS II

40.1

B₆B₂, A MONOCLONAL ANTIBODY THAT BINDS TO NMDA RECEPTORS, MODULATES NOREPINEPHRINE RELEASE FROM HIPPOCAMPAL SLICES IN A GLYCINE-LIKE MANNER. <u>P.E. Polter</u>¹, <u>J.R. Moskal</u>². Departments of Anesthesiology ¹, Neurosurgery² and Neuroscience ², Albert Einstein College of Medicine, Montefore Medical Center, Bronx, N. Y. 10467.

We have previously shown that a monoclonal antibody, B_6B_2 , binds to the N-methyl-D-aspartate receptor-ionophore complex (NMDAR) in a glycine-like fashion. To further characterize the interaction of B_6B_2 with NMDAR, we have examined NMDAR-mediated release of 3 H-norepinephrine (NE) from hippocampal slices.

Hippocampal slices were labelled with ${}^3H\text{-NE}$ in normal Krebs for 30 min, then perfused at 0.4 ml/min with Mg 2* -free Krebs. NE release was induced by perfusion with 60 μ M NMDA for 5 min. Two stimulation periods were used. Drugs to be tested were added between the first (S₁) and second (S₂) stimulation periods. Results are expressed as the ratio between the amount of NE release in the two periods (S₂/S₁). A decrease in this ratio indicates inhibition of release.

Kynurenic acid (100 μ M) decreased the S₂/S₁ ratio by almost 50% from a control value of 0.80 \pm 0.11 to 0.44 \pm 0.09. Addition of 100 μ M glycine reversed this effect and brought the S₂/S₁ ratio back up to 0.99 \pm 0.22. The antibody B₆B₂, like glycine, also increased the S₂/S₁ ratio in the presence of kynurenic acid to 0.81 \pm 0.12. These results further support the hypothesis that B₆B₂ binds to the glycine site of the NMDAR, and that glycine-like modulation of NMDAR regulates release of NE in vivo.

40.3

INHIBITION OF NMDA-EVOKED DOPAMINE RELEASE FROM MESENCEPHALIC CELL CULTURES BY NEUROPEPTIDE Y (NPY) AND PEPTIDE YY (PYY). H. Mount, I. Chaudieu, Y. Dumont, P. Boksa, & R. Quirion, Douglas Hospital Research Ctr., Depts. Pharmacol. & Therap. and Psychiat., McGill University, Verdun, PQ, Canada.

NPY and PYY have recently been reported to possess high affinity for the PCP receptor (within the NMDA receptor channel)(Roman et al., <u>Eur. J. Pharmacol.</u> 174:301-302, 1990). To test for a functional interaction with the PCP receptor, we examined effects of NPY-related peptides on NMDA-stimulated [3H]dopamine ([3H]DA) release from fetal rat dissociated mesencephalic cell cultures. We have previously shown NMDA-evoked [3H]DA release to be potently and selectively inhibited by PCP (Boksa et al., <u>Soc. Neurosci.</u> 15:946, 1989).

NMDA-stimulated [³H]DA release was significantly blocked by high concentrations (10 uM) of PYY or NPY. Spontaneous and kaimate-evoked [³H]DA release were only marginally affected by either peptide. NPY[13-36] (≤ 10 uM), an NPY fragment that selectively activates Y₂ NPY receptors, had no effect on NMDA-evoked [³H]DA release. Calcitonin gene-related peptide (hCGRP), another neuropeptide for which binding sites are localized in dopaminergic regions of the brain (T₂ Dennis et al., this meeting) failed to affect spontaneous or NMDA-stimulated [³H]DA release. Thus, NPY and PYY may affect the NMDA receptor complex. However, the physiological relevance of this action remains to be established, since relatively high concentrations of the peptides were required to produce the effect. Supported by the FRSQ.

40.2

A MONOCLONAL ANTIBODY WHICH MIMICKS GLYCINE ACTIONS ON N-METHYL-D-ASPARTATE RECEPTORS HAS COMPLEX EFFECTS ON CHANNEL ACTIVATION AND NEURONAL SENSITIVITY TO HYPOXIA.

We have previously demonstrated that monoclonal antibody B_6B_2 binds to the N-Methyl-D-Aspartate (NMDA) receptor and acts like glycine in its ability to stimulate [3H]TCP binding to extensively washed hippocampal membrane preparations. In electrophysiological recordings from hippocampal slices, B_6B_2 application prior to a hypoxic insult led to long-term potentiation of synaptic transmission, but did not exacerbate the loss of synaptic function. In order to explain this apparent paradox, we have measured the actions of B_6B_2 and glycine on 3H IMK-801 binding to rat cortical and hippocampal slices.

 B_6B_{21} at 1, 5, and 10 μg/ 100 μl in 5 mM Tris-acetate buffer (pH 7.4) increased βH]MK-801 binding by 120%, 140% and 210%, respectively. In contrast, 50 μg/ 100 μl B_6B_{21} reduced binding to 87% of control. Glycine also showed a biphasic effect on [³H]MK-801 binding. At 0.1 μM, glycine stimulated binding to 130% of control, but was not significantly increased when the glycine concentration was increased to 1 or 10 μM. Glycine at 0.1 μM also potentiated glutamate-stimulated [³H]MK-801 binding (130% of control) but at 1 μM or 10 μM, glycine reduced this binding to 110% and 105% of control, respectively. With 1, 5 and 10 μg/ 100 μl B_6B_{21} in the presence of glutamate, binding was 160, 130 and 105% of control. Thus, modulation of the glycine site of the NMDA receptor appears to be biphasic, with potentially important implications in regulation of the neurotoxic effects of ischemia

40.4

HIGH AFFINITY [³H]-DEXTRORPHAN RECOGNITION SITES IN RAT BRAIN ARE ASSOCIATED WITH THE NMDA-OPERATED CATION CHANNEL. P.H. Franklin and T.F. Murray

Change of Pharmacy, Oregon State University, Corvallis, OR 97331.

Although essentially devoid of µ opioid receptor activity, electrophysiological, behavioral and ligand binding data indicate that dextrophan(DX), the dextrorotatory analog of morphine in the morphinan series, is a non-competitive antagonist of NMDA receptor activation(Church, et al. Eur. J. Pharmacol., 111:185, 1985; Murray and Leid, Life Sci., 34:1899, 1984) Based on electrophysiological data DX and other PCP-like drugs have been proposed to act as open-channel blockers of NMDA gated conductances. We report evidence of a high affinity DX recognition site at or near the NMDA-operated cation channel. Employing assay conditions which promote the binding of non-competitive NMDA antagonists(NCNA), equilibrium saturation analysis of [³H]DX binding indicates that DX labels a site in rat forebrain with an apparent K_D of 60.2 ± 3.5 nM and B_{max} of 2.62 ± 0.06 pmol/mg protein. Regional analysis of [³H]DX binding demonstrates a differential distribution in rat brain: hippocampus ≥ cortex > striatum ≥ thatamus > cerebellum > hypothalamus. As with other NCNA, specific [³H]DX binding is increased by glycine and glutamate in a concentration-dependent manner, and is completely blocked by the specific NMDA antagonist AP-5. [³H]DX binding is stimulated by the polyamines spermidine and spermine but not by putrescine. Competition analysis reveals the following rank order of potency against [³H]DX: MK-801 > phencyclidine ≥ DX > dextromethorphan > (+)-3. (+)-4.

CPP MORE POTENTLY ANTAGONIZES HIGH AFFINITY BINDING SITE FOR ${\rm Mg}^{2+}$ THAN L-GLUTAMATE RECOGNITION SITE. FOR Mg²⁺ THAN L-GLUTAMATE RECOGNITION SITE.

K.Hatta*, T.Yamamoto, T.Hori*, K.Yoshikawa and T.Moroji*.

Dept. of Psychopharmacology, Psychiat. Res. Inst. of Tokyo, Tokyo 156, JAPAN.

10xyo 150, JAFAN.

3-(2-Carboxypiperazine-4-yl)propyl-1-phosphonate (CPP) has been demonstrated to be highly selective and competitive NMDA antagonist. Recently, we have shown that low concentrations of Mg²⁺ markedly stimulate [³H]TCP binding to rat cortical membranes, indicating the presence of a novel Mg²⁺ recognition site with high affinity on the NMDA/PCP receptor ion channel complex. In this study, we report PCP receptor ion channel complex. In this study, we re the effects of CPP on [3H]TCP binding in rat cerebral

CPP markedly inhibited [3H]TCP binding stimulated by 300 uM Mg²⁺ in a concentration-dependent manner with an IC₅₀ of uM Mg²⁺ in a concentration-dependent manner with an 1050 o: 0.427±0.043 uM compared to those stimulated by 1 uM L-glutamate (IC50=36.0±3.8 uM). CPP did not affect the basal level of [3H]TCP binding. The IC50 value of CPP for Mg²⁺-stimulated [3H]TCP binding was one eighty-fourth of that for L-glutamate-stimulated [3H]TCP binding. The present results show that CPP more potently antagonized [3H]TCP binding stimulated by Mg²⁺ than L-glutamate.

INHIBITION OF $[^3h]$ CPP BINDING TO BRAIN SYNAPTIC MEMBRANES BY ORGANOPHOSPHORUS AGENTS. P.S. Johnson and E.K. Michaelis Dept. of Pharmacology and Toxicology,

University of Kansas, Lawrence, KS 66045
Several competitive antagonists of the N-methyl-D-aspartate
(NMDA) subtype of excitatory amino acid receptors are phosphonate analogs of L-glutamic acid. The position of the phosphonate has been shown to be important in the structure-activity relationships of these analogs. To investigate whether other phosphorous-containing compounds had activity at the NMDA receptor, several neurotoxic compounds had activity at the NMDA receptor, several neurotoxic organophosphorous compounds were tested for the ability to inhibit the specific binding of 3-((±)-2-carboxypiperazin-4-yl)-(1,2³Hlpropyl-1-phosphonic acid ([³H]CPP), a selective antagonist of NMDA receptors, to brain synaptic membranes. Diisopropylfluorophosphate (DFP) was found to be the most potent of the organophosphates tested (K_1 = 6 uM) and this inhibition was irreversible. Also, preincubation with excess NMDA receptor agonists and antagonists prior to exposure to DFP prevented inhibition by DFP of [3 H]CPP binding. These observations are suggestive of an interaction between organophosphates and the NMDA receptors. Current studies are focusing on determining which binding site the organophosphates may be interacting with. (Supported by grants AA04732 and DAAL 03-88-K0017).

EX VIVO [3H]MK-801 BINDING TO MOUSE CEREBRAL MEMBRANES: EFFECT OF COMPETITIVE AND NON-COMPETITIVE NMDA RECEPTOR ANTAGONISTS. C.E. Stidsen, Novo Nordisk A/S, Dept. of Biochemical Pharmacology, CNS Division, DK-2880 Bagsvaerd,

Pharmacousty.

Denmark.

[H]MK-801 binds specifically and with high affinity to freshly dissected and homogenized mouse forebrain.

Non-competitive NMDA receptor administered administered forebrain. Non-competitive NMDA receptor antagonists (MK-801, PCP, Ketamine) administered i.p. to NMRi mice 15-30 mins before decapitation displaced [3 H]MK-801 in a dose-dependent manner. The ED₅₀ values obtained for the individual compounds correlated well with IC₅₀ values found by in vitro binding to the same homogenate and was comparable to ED₅₀ values reported from inhibition of pentylenetetrazole induced seizures in mice On the other hand competitive NMDA recentor the other hand competitive NMDA receptor antagonists (CPP, CGP 37849, CGP 39551) as well as glycine antagonists (HA-966 and 7-chlorokynurenic

glycine antagonists (HA-966 and 7-chlorokynurenic acid) up to 100 mg/kg had no effect on ex vivo [⁵H]MK-801 binding.

These results suggest that this method could be predictable for behavioral effects of noncompetitive NMDA antagonists. On the other hand high levels of endogenous glutamate and glycine might abolish the antagonistic effects of competitive NMDA antagonists or glycine antagonists.

ETHYLENEDIAMINETETRAACETIC ACID (EDTA) POTENTIATES A ETHYLENEDIAMINETETRAACETIC ACID (EDTA) POTENTIATES A GLYCINE-STIMULATED [3H]TCP BINDING IN RAT CORTICAL MEMBRANES. T.Yamamoto, T.Hori*, K.Hatta* and T.Moroji*. Dept. of Psychopharmacology, Psychiatric Research Institute of Tokyo, Tokyo 156, JAPAN.

The binding of [3H]TCP to the well washed rat cortical membranes was stimulated by glutamate and glycine. The prior reports indicate that glycine requires for the

stimulation of [3H]TCP binding by glutamate, and vice

However, it remains unclear whether or not these two amino acids stimulate [3H]TCP binding in an additive manner. The present study was conducted to examine the effects of glutamate and glycine on binding properties of [3H]TCP in the presence of EDTA.

EDTA markedly potentiated [3H]TCP binding stimulated by glycine. The basal and glutamate-stimulated binding were only slightly stimulated in a concentration dependent manner (max. at 1 mM EDTA). In the absence of EDTA, glycine had an additive effect on glutamate-stimulated [2H]TCP binding. In the presence of 1 mM EDTA, however, no additive effect was observed. Similar results were obtained with EGTA. These results suggest that EDTA modulates an inter-relationship between glutamate- and glycine-sites on the NMDA/PCP receptor ion channel complex via unknown membrane factors.

40.8

TCP BINDING TO CEREBRAL CORTEX MEMBRANES FROM DEVELOPING AND ACEING MICE. P. Saransaari and S.S. Oja. Tampere Brain Research Center, Department of Biomedical Sciences, University of Tampere, Box 607, SF-33101 Tampere, Finland. TCP (N-[1-(2-thienyl)cyclohexyl]piperidine) is an analogue of phencyclidine which is bound to sites associated with the NMDA subclass of excitatory amino acid recentors.

with the NMDA subclass of excitatory amino acid receptors in the brain. We characterized the binding of tritiated TCP to cerebral cortex membranes isolated from developing and ageing mice. TCP binding was saturable in the studied concentration range of 2 to 200 nM, exhibiting one binding component in the cortex of 7-day-old mice as well as during the whole lifespan up to 24 months of age. The maximal binding capacity calculated per protein content decreased during restricted development with 13 methods of age. decreased during postnatal development until 3 months of age, remaining thereafter constant in ageing mice. The binding constant did not change during development and adulthood but increased during the second year of life. Glycine potentiated the binding concentration-dependently Glycine potentiated the binding concentration-dependently in the adult cerebral cortex, whereas only a small stimulation was discernible in 7-day-old mice. L- and D-glutamate also enhanced TCP binding; the effects being again somewhat smaller in the developing brain. The differences in the properties of cortical PCP binding sites in the developing and ageing brain are likely to be of great importance in the function of NMDA receptors. Supported by the Emil Aaltonen Foundation, Finland.

OF THE INTERACTIONS OF N-ACETYL-ASPARTYLGLUTAMATE (NAAG) WITH NMDA, QUISQUALATE AND KAINATE BINDING SITES IN COMPETITIVE EQUILIBRIUM BINDING ASSAYS. H. M. Valivullah, J. Lancaster*, P. Sweetnam and J.H. Neale, Dept. Biology, Georgetown University, Wash, D.C.

20057 and NOVA Pharmaceutical Corp., Balt, MD 21224.

The structure of the neuropeptide, NAAG, suggests that it may act through acidic amino acid receptors. However, attempts to test this concept with physiological and ligand binding assays often have provided equivocal results. One reason for this is the presence in neuronal membranes of peptidase activity which hydrolyzes NAAG to glutamate and N-acetylaspartate. In this study, we have obtained equilibrium binding conditions which study, we have obtained equilibrium binding conditions which substantially reduce or abolish the peptidase activity while permitting assay of 3H-GGS 19755 (NMDA-receptor antagonist), 3H-AMPA (quisqualate agonist), and 3H-Kainic acid (kainic acid agonist) binding. At the NMDA receptor, N-acetylaspartate (NAA) showed no inhibition, but NAAG had an IC₅₀ of >3 µM. Under ³H-CGS 19755 binding conditions, peptidase activity was not totally inhibited. Therefore, this very modest apparent competition for the NMDA site may have been due to glutamate (IC50=350 nM) released from NAAG in the course of the assay.

N-METHYL-D-ASPARTATE RECEPTORS IN BATS AND SHREWS. D. S. Higgins, R.L. Albin, J.B. Penney, A.B. Young. Department of Neurology, University of Michigan, Ann Arbor, MI, 48104-1687.

Arbor, MI, 48104-1687.

Using an autoradiographic assay we describe the regional distribution of N-methyl-D-aspartate (NMDA) receptors in the brain of megachiroptera and microchiroptera, insectivora and rodentia. Twenty three regions in the forebrain, brainstem and cerebellum were examined. NMDA receptor binding was greatest in forebrain structures, the highest levels being found in the hippocampal formation and outer cortical laminae. Within the hippocampus, the stratum radiatum of the CA-1 subfield uniformly evidenced the highest number of NMDA receptors. Certain thalamic nuclei and the caudate-putamen contained 30% of the binding seen in the stratum radiatum of the hippocampus. The external plexiform layer of the olfactory bulb contained at least 50% greater binding than other olfactory laminae. Binding minimally above background was found in most brainstem structures, the reticular nucleus of thalamus and the granular layer of the cerebellum. NMDA receptor distribution was similar amongst these eutherian mammals though there was some inter-species variation in the rank order of receptor density found in the medial geniculate nucleus and the superficial layers of the superior colliculus. Supported by USPHS Grants NS 01300, NS 19613, and NS 07222.

[³H]MK-801 BINDING IN PIGEON FOREBRAIN. S.Y. Sakurai, R.L. Albin, A. Reiner, and A.B. Young. Dept. of Neurology and Neuroscience Program, University of Michigan, Ann Arbor, MI, 48109; Dept. of Anatomy, University of Tenn. Health Science Center, Memphis, TN 38163.

Pigeons have been used extensively in excitatory amino acid (EAA) behavioral pharmacology. We have examined the distribution and pharmacology of NMDA receptors in White Carneaux pigeon brains using [³H]MK-801 and NMDA-sensitive [³H]glutamate quantitative autoradiography.

Specific [³H]MK-801 binding was present in pigeon forebrain regions homologous to mammalian cortex and striatum. In the pigeon neostriatum, TCP (100 μM) and ketamine (100 μM) displaced [³H]MK-801 binding by 94% and 98%, respectively. The competitive NMDA antagonist, CPP (100 μM), inhibited specific [³H]MK-801 binding by 93%. Zinc ions (100 μM) inhibited specific binding by 81%. In addition, the quinoxalinedione compound, CNQX (100 μM), reduced [³H]MK-801 binding by 40%. The distribution of NMDA-sensitive-[³H]glutamate binding sites in pigeon forebrain was similar to the distribution of [³H]MK-801 binding sites. NMDA-sensitive [³H]glutamate binding was inhibited by CPP but not by CNQX. These data suggest that the pharmacology of the NMDA receptor in pigeon brain is similiar to the mammalian brain. Supported by USPHS Grant NS 19613.

THE DISTRIBUTION OF N-METHYL-D-ASPARTIC ACID RECEPTOR BINDING IN NEONATAL AND ADULT MOUSE LUMBAR SPINAL CORD D.L. Gonzalez, J.L. Fuchs, M.H. Droge. Dept. of Biol., Texas Woman's Univ., Denton, TX. 76204; (ILF) Dept. of Biol. Sci., Univ. of North Texas, Denton, TX. 76203.

The objective of this study was to characterize the distribution of N-Methyl-D-Aspartic Acid (NMDA) receptors in the lumbar spinal tissue of young (aged birth to 10 days) and adult Balb/C mice. Transverse, 20 µm frozen sections were mounted and dried. Sections were incubated in 200 nM [3H]-glutamate in the presence of 1 uM quisqualic acid to inhibit non-NMDA glutamate binding. To determine nonspecific binding, adjacent sections were treated as above but with excess NMDA present. Sections were apposed to tritium sensitive Hyperfilm for 3 weeks. Densitometric analyses were carried out using a videobased image analysis system. In neonates, binding was slightly higher in the ventral horn than dorsal horn. This order was reveresed in adults. While the neonatal gray matter was fairly uniformly labeled, the adult showed the highest levels in the substantia gelatinosa, along the medial border of the dorsal horn, and in lamina X. Supported by NIH-MBRS Grant 41424

[³H]MK-801 AND NMDA-SENSITIVE [³H]GLUTAMATE BINDING IN TURTLE BRAIN. <u>A.B. Young, S.Y. Sakurai, and R.L. Albin</u>. Dept. of Neurology and Neuroscience Program, University of Michigan, Ann Arbor, MI, 48109.

Turtle neurons are resistant to glutamate neurotoxicity (Wilson and Kriegstein, <u>Soc. Neurosci.</u>, p. 763, 1989). Since NMDA receptors have been implicated in the pathogenesis of glutamate neurotoxicity, we examined NMDA-sensitive [³H]glutamate binding and [³H1MK-801 binding in the red-eared turtle (P. Scripta).

[³H]MK-801 binding in the red-eared turtle (P. Scripta).

NMDA-sensitive [³H]glutamate binding was present in turtle forebrain. The competitive antagonists, CPP (100 μM) and AP7 (100 μM) completely inhibited NMDA-sensitive [³H]glutamate binding. Specific [³H]MK-801 binding was also present in the turtle forebrain. The non-competitive NMDA antagonists, PCP, TCP and ketamine (each 100 μM) displaced total binding by 80%. CPP (1mM) inhibited only 20% of specific [³H]MK-801 binding. CNQX (100 μM) did not inhibit binding while 7-chlorokynurenic acid (100 μM) inhibited specific binding by 40%. Glutamate (1mM) enhanced binding by 200% whereas glycine (1mM) had no effect. These data suggest that the pharmacology of the NMDA-receptor complex in turtle may differ from mammalian brain. Supported by USPHS Grant NS 19613 and NS 01300.

AGE-RELATED CHANGES OF THE NMDA RECEPTOR COMPLEX IN THE RAT BRAIN STUDIED BY IN VITRO AUTORADIOGRAPHY. R. Miyoshi, S. Kito and T. Nomoto*. Dept. of Pharmacology, Tokyo Women's Medical College, Tokyo 162 and Division of Health Sci., Univ. of the Air, Chiba 260, Japan.

Receptors for excitatory amino acid, L-glutamate have

Receptors for excitatory amino acid, L-glutamate have been divided into three subtypes referred to N-methyl-D-aspartate (NMDA), quisqualate and kainate receptors. Among them, the NMDA subtype has been supposed to play an important role in long term potentiation and neuronal cell death due to brain ischemia and Alzheimer's disease. This type consists of the receptor complex containing an agonist recognition site, a cation channel and a strychnine-insensitive glycine modulatory site. For observing age-related changes of these binding sites, quantitative in vitro autoradiography with H-CPP, H-MK 801 and H-glycine was done with use of the rat brain. H-glycine binding sites were severely decreased in telencephalic regions including the hippocampus and cerebral cortex of aged animals. H-CPP binding sites were well preserved in the aged brain. H-MK 801 binding itself was at very low levels throughout the brain and qid not significantly changed in aged animals. However, H-MK 801 binding in the presence of both L-glutamate and glycine was potentiated and this potentiation was reduced in telencephalic regions of aged rats. These results indicate that glycine binding sites are primarily affected in the normal aging process.

AGE-RELATED DECREASES IN CORTICOTROPIN-RELEASING FACTOR RECEPTORS IN THE BRAIN AND ANTERIOR PITUITARY GLAND OF THE RAT. J.A. Heroux, D.E. Grigoriadis, and E.B. De Souza. Neurobiology Laboratory, Addiction Research Center, National Institute on Drug Abuse, Baltimore, MD 21224
Age-related changes in basal and stress-induced hypothalamic-pituitary-adrenocortical (HPA) hormone secretion have been previously exercised. In the present study, corticotropin releasing factor (CRE)

Age-related changes in basal and stress-induced hypothalamic-pituitary-adrenocortical (HPA) hormone secretion have been previously reported. In the present study, corticotropin-releasing factor (CRF) receptors were measured in homogenates of discrete areas of brain and in anterior pituitary of 4, 12, 18, and 24 month old male Fisher rats using \$^{125}I-Tyr^0-ovine CRF\$ (\$^{125}I-CRF\$)\$. At a single saturating concentration of CRF (InM), significant decreases were observed in the anterior pituitary (60% decrease) such hypothalamus with respect to increasing age. Maximal reductions in CRF binding were observed in the anterior pituitary (60% decrease) and hypothalamus (27% decrease) of 24 month old rats when compared to binding in 4 month old rats. No significant age-related changes in CRF binding were observed in midbrain, cerebellum, olfactory bulb, pons medulla, hippocampus, striatum, frontal cortex, parietal cortex, or spinal cord. Saturation experiments of \$^{125}I-CRF\$ binding in the anterior pituitary of 4 and 24 month old rats revealed about a 60% reduction in the density of CRF receptors (B_max) in 24 versus 4 month old rats with no age-related differences in the affinity (K_D) of CRF for it's receptor. The mechanisms involved in the age-related decreases in CRF receptors in the anterior pituitary and hypothalamus are currently being investigated. The age-related decline of CRF receptors in the hypothalamus and anterior pituitary may play an important role in the changes in basal and stress-induced HPA hormone secretion seen in aged rats.

IN VITRO REGULATION OF PITUITARY ACTH SECRETION IN INFLAMMATORY DISEASE SUSCEPTIBLE LEWIS (LEW/N) AND INFLAMMATORY DISEASE RESISTANT FISCHER (F344/N) RATS. P. Zelazowski*. M.A. Smith. P.W. Gold*. G.P. Chrousos. R.L.Wilder* and E.M. Sternberg NIMH, NIAMS, NICHD, NIH, Bethesda, MD 20892 We have previously shown that susceptibility to inflammatory disease in LEW/N rats is related to deficient glucocorticoid counter-regulation of the immune response resulting from deficient hypothalamic corticotropin releasing hormone (CRH) responsiveness to inflammatory and other stress mediators. LEW/N rats also show deficient in vivo ACTH responses to CRH stimulation. In order to determine whether this blunted ACTH response is related to secondary changes in the functional responsiveness of the pituitary or to enhanced sensitivity to glucocorticoid negative feedback, we studied basal and CRH stimulated ACTH secretion and content in primary pituitary cells and pituitary organ explants, and POMC mRNA expression by in situ hybridization in LEW/N and histocompatible F344N pituitaries. LEW/N rats contain 50% fewer POMC expressing pituitary cells and 50% less ACTH compared to F344N rats. Basal ACTH secretion and the peak ACTH response to CRH is also 50% less in LEW/N compared to F344N rats. The percent secretion of ACTH stimulated by all doses of CRH, when corrected for the lower baseline, is the same in LEW/N and 1544N rats. At low doses of CRH stimulation, LEW/N pituitary cells show a dose-dependent greater sensitivity of both basal and CRH-stimulated ACTH secretion to dexamethasone suppression compared to F344N cells, suggesting enhanced sensitivity of LEW/N pituitary cells to glucocorticoid negative feedback. We speculate that the lower LEW/N ACTH responses and lower percent of POMC-expressing cells reflect the long-standing CRH hyporesponsiveness and/or the sustained effects of enhanced glucocorticoid negative feedback on the pituitary. This could reflect either a global defect in glucocorticoid receptor function that restrains P

CHARACTERIZATION OF THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS IN THE ZUCKER OBESE RAT. <u>P.M. Plotsky, S. Otto*, C. Rivier and S.W. Sutton*</u>. The Clayton Foundation Labs for Peptide Biol, The Salk Institute, La Jolla, CA 92037.

Genetically obese rats of the Zucker strain have numerous endocrine, metabolic and behavioral abnormalities. Compared to non-obese littermates (Fa/-), Zucker obese (fa/fa) rats have larger adrenals (45 ± 2 vs 37 ± 1 mg; p<0.01), elevated morning corticosterone (24±4 vs 49±10 ng/ml; p<0.01), and lack a robust pituitary-adrenocortical circadian rhythm. Although both ACTH and corticosterone responses to exogenous rCRF-41 challenge (1 μg , iv) in the morning were equivalent, the duration of the corticosterone response was prolonged in the fa/fa rats. Possibly underlying these changes, initial secretion of hypothalamic corticotropin releasing factor (CRF) was significantly lower in fa/fa vs Fa/- rats (65±8 vs 237±34 pg/ml; p<0.001) and no increased secretion in response to hypotensive challenge was evident. Despite these differences in CRF secretion into the hypophysial-portal circulation, neither hypothalamic CRF content (762±45 vs 836±49 pg/median eminence; p>0.5) nor mRNA levels were significantly different in fa/fa and Fa/-These characteristics are similar to those of the chronically stressed rat model.

41 9

EFFECT OF SHORT AND LONG DURATION HYPOTHYROIDISM AND HYPERTHYROIDISM ON HYPOTHALAMIC CORTICOTROPIN-RELEASING HORMONE MRNA RESPONSES TO STRESS. T.C Kamilaris, J. Redwine, M. Smith. E.O. Johnson. P.W. Gold. and G.P. Chrousos. CNB/NIMH & DEB/NICHD, Bethesda, MD, 20892.

We used in situ hybridization histochemistry on rat hypothalamus to examine the effect of the duration of hypo- and hyperthyroidism on the levels of mRNA encoding corticotropin-releasing hormone (CRH mRNA). We studied parvocellular neurons of the rat paraventricular nucleus under basal and prolonged stress conditions in male SD rats with short-(7 days) or long-standing (60 days) hypothyroidism (thyroidectomy + placebo), euthyroidism (sham thyroidectomy + placebo), or hyperthyroidism (thyroidectomy + thyroxine 50 ug/day). Prolonged stress was induced by daily ip injections of 1.5 M hypertonic saline at 09:00 for 5 consecutive days (Lightman & Young, PNAS 86:43-6, 1989). Control animals received an equivalent volume (1.8 ml/Kg BW) of 0.15 M saline or no saline. Hypo- and hyperthyroidism of short duration had no significant effect on basal or stress-stimulated CRH mRNA levels. In contrast, long-lasting hypothyroidism was associated with reduced stress-stimulated CRH mRNA levels (p<0.001). No changes in basal or stress-stimulated CRH mRNA levels were found in long-standing hyperthyroid animals. These findings suggest that stressstimulated synthesis of hypothalamic CRH mRNA is significantly affected in severe, long-standing hypothyroidism which may compromise their responsiveness to and coping with stress. The data also suggest a central effect of thyroid hormone on CRH system independently from the known effect on corticosteroid secretion and metabolism.

INCREASE IN CORTICOTROPIN RELEASING HORMONE (CRH) CELL SIZE IN MALE AND FEMALE FISCHER 344 RATS IN RESPONSE TO CHRONIC BEHAVIORAL STRESS. D.D. Kelly and A.J. Silverman. NYS Psychiatric Inst. & Dept. Anat. & Cell Biol., Columbia Univ., NY, NY, 10032

The neurohormone CRH is synthesized in the hypothalamic paraventricular nucleus (PVN). In previous studies, we observed a significant increase in detectability, staining intensity and size of PVN CRH cells in male Wistar rats exposed for 10d to a chronic behavioral stress paradigm. We since serendipitously observed that in Fischer 344 rats, both staining intensity and CRH cell number were high in non-stressed individuals. We have now examined whether males (n=8) and females (n=8) of this strain respond similarly to stress with an increase in CRH cell size. Experimental animals were placed in a sound proof chamber, food and water ad lib. and exposed to alternating 30-min sessions of white noise (90db) and conditioned emotional response training for 10 d. Controls remained in their home cage. Animals were perfused and tissue prepared for CRH immunocytochemistry. Cell size measurements were made without knowledge of the animal's condition. CRH cells of non-stressed females were larger than those in age matched males (117. 8 ± 40.3 vs 99.8 ± 54.0 µm², respectively). In both sexes, there was a robust response to stress with mean cell size increasing to 142. 6 ± 49.3 and 151.2 ± 64.1 µm2. These results suggest that alterations in CRH cell size are not attributable to the amount of reaction product per cell, but to a real increase in plasma membrane and intracellular organelles. These data also indicate that the PVN of both sexes responds to chronic stress in a similar, morphologically plastic manner, but not to the same degreee. NS 23858

41.6

MODULATION OF HYPOTHALAMIC CRF-41 BY ACTIVIN-A. <u>S.W. Sutton*</u>, <u>A. Kjaer*</u>, <u>W. Vale and P.M. Plotsky</u>. The Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

A diverse array of inputs modulates corticotropin releasing factor (CRF-41) secretion and gene expression in the hypothalamic parvicellular paraventricular nucleus (PVN). Among these inputs is an inhibin βA subunit immunopositive pathway arising from the caudal nucleus of the solitary Central (icv) administration of recombinant activin-A, an inhibin $\beta A/\beta A$ homodimer with growth factor activity, is associated with stimulation of adenohypophysial ACTH At concentrations of 0.6-3.0 nmole, activin-A facilitates hypothalamic secretion of CRF-41 (maximal 4.1fold elevation from mean initial levels of 228+48 pg/ml), but is without effect on vasopressin secretion. This response is attenuated by bilateral PVN infusion of inhibin \$A-antiserum into the PVN prior to challenge. In vitro, activin-A (24 h, 10 ng/ml) enhances basal and norepinephrine-stimulated CRF-41 release from primary cultures of neonatal rat hypothalamic cells in an additive fashion, but is without effect on acetylcholine-stimulated CRF-41 secretion. Interactions between activin-A and other putative transmitters on CRF-41 secretion and gene expression are being characterized.

NEONATAL ISOLATION INCREASES HYPOTHALAMIC CORTICOTROPIN RELEASING FACTOR mRNA. B.L. Firestein and P.M. Plotsky. The Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

Neonatal stress can lead to long-term changes in hypothalamicpituitary-adrenal (HPA) axis function, including hyper- or hyporesponsiveness of the axis to stressors and glucocorticoid feedback. We have examined the effects of neonatal handling or isolation on hypothalamic CRF mRNA levels in adult rats. Litters of 8 pups each (n=3/treatment) were subjected to one of 3 treatments: UNDISTURBED (no human contact until weaning), HANDLED (5 min handling every morning), and ISOLATED (6 hr separation from dam removed every morning to incubator) during the second neonatal week. Total hypothalamic RNA was prepared when rats were 40 days old for sequential Northern blot analysis of rCRF mRNA (riboprobe a32P-UTP labeled; 1x106 cpm/ml) and human β-actin mRNA (40-mer oligoprobe 5'-end labeled with $\gamma^{32}P$ -ATP; 1x106cpm/ml). RNA was loaded onto a formaldehyde gel (20 µg/lane). After transfer of the blots to HyBond membrane, hybridization was performed (65 C) and films exposed for 3 days. Films were semiquantified by scanning densitometry. Rat hypothalamic CRF mRNA (1.3 kb band) from the ISOLATED group was significantly elevated (p<0.05) in comparison to the UNDISTURBED or HANDLED groups. No differences were apparent between these latter two groups, nor was a sex difference observed for any treatment. These studies provide a central molecular basis for long-term changes in HPA axis function following neonatal stress.

ALTERATIONS IN C-FOS EXPRESSION IN THE RAT SUPRAOPTIC AND PARAVENTRICULAR NUCLEI AFTER ADRENALECTOMY, DEXAMETHASONE,

AND CLONIDINE. M. Jarnot and L. Jennes, Dept. of Anatomy, Wright State Univ. Sch. of Med., Dayton, 0H 45435.

The presence of the protooncogene c-fos was used to examine the effects of adrenalectomy, dexamethasone treatment, and the noradrenergic agonist clonidine or cells of the supraoptic (SON) and paraventricular (PVN) nuclei of the rat. In untreated control as well as in adrenalectomized animals, c-fos immunoreactivity was absent in cell nuclei of the SON. I hr after dexamethasone (100 ug/kg BW, iv) and I hr after clonidine (100 ug/kg BW, iv), certain vasopressin (VP), but not oxytocin containing neurons showed c-fos in their nuclei. In the control PVN, c-fos was concistantly resent in many payrocallule. c-fos was consistently present in many parvocellular neurons, but absent from the magnocellular compartment. After adrenal ectomy, the number of c-fos containing neurons in the parvocellular PVN was slightly reduced. However, iv injections of clonidine as well as dexamethasone caused a strong transient increase in the number of c-fos immunoreactive neurons in both the parvo- and magnocellular PVN. This increase in c-fos immunoreactivity was restricted to VP and corticotropin releasing factor (CRF) containing neurons. The results suggest that both clonidine and dexamethasone affect selectively the VP-CRF neuronal system through different mechanisms which result in an increased expression of c-fos. Supported by NIH HD-24697.

41.11

CORTICOTROPIN-RELEASING HORMONE STIMULATION TEST IN PATIENTS WITH DEPRESSION SECONDARY TO OTHER PSYCHIATRIC ILLNESSES, PRIMARY DEPRESSION, SCHIZOPHRENIA AND NORMAL CONTROLS. SD Samuelson. RG Kathol, TL Gehris*, BT Carroll, AF Pitts, WH Meller*, and J Carter*. The University of Iowa College of Medicine, Iowa City, IA 52242.

Disturbances in the hypothalamic-pituitary-adrenal (HPA) axis have been well documented in depressed patients. In this study, we investigated HPA axis functioning in patients with other psychiatric illness

The ovine corticotropin-releasing hormone (oCRH) stimulation test (0.1 μ g/kg) was performed at 1600 hours on twenty-five patients with primary major depressive disorder (MDD), twelve patients with major depressive episodes secondary to concurrent or previous diagnoses of other psychiatric lilinesses (SDD), eight patients with schizophrenia, and twenty-seven healthy controls. No statistically significant group differences in cortisol or ACTH response to oCRH could be demonstrated between MDD, schizophrenic, or control subjects. However, SDD patients had significantly (p < 0.05) higher baseline and peak stimulated cortisol levels, and greater mean area under the curve for the cortisol response compared with the controls. Our SDD group, however, was atypical in that most of these patients had depressi secondary to psychotic illnesses, or to drug or alcohol abuse. Although no differences in ACTH or cortisol secretion could be attributed to the presence of psychosis, there was a significant association between previous alcohol or drug history and a blunted ACTH response (t=2.8; p=0.01) as well as increased cortisol secretion (t=3.4; p=0.005) following oCRH administration when compared to the SDD without a history of alcohol or drug abuse.

TIME-COURSE OF NEUROPEPTIDE AND PROTO-ONCOGENE UP-REGULATION IN NEURONS OF THE PARVOCELLULAR PARAVENTRICULAR NUCLEUS. <u>S. S. Kollack, I. P. Herman, and S. I.</u> <u>Watson</u>. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48198-0720.

Arbor, MI 48198-0720.

We have looked at the inductive effects of immobilization stress on parvocellular neurons of the rat paraventricular nucleus (PVN). Male rats were sacrificed at various time points following the onset of immobilization stress, including: 15 min., 30 min., 45 min., 1 hr., 1.5 hr., 2 hr., 4 hr., 6 hr., and 1 day. Animals that received no stress served as controls. cRNA probes complementary to corticotropin releasing hormone (CRH) mRNA and c-fos mRNA were used to assay levels of message via in situ hybridization histochemistry. Results demonstrated a different time-course of induction of these two messages. Expression of c-fos mRNA was undectectable in the PVN of unstressed rats. In response to stress, c-fos mRNA was induced in PVN neurons, achieving peak levels 30 minutes after onset of stress and neturning to undetectable levels by 90 minutes. In contrast, induction of CRH mRNA peaked 90 minutes after onset of stress and declined more slowly. These data demonstrate that increases in cytoplasmic proto-oncogene and CRH mRNAs occur in different time domains, perhaps commensurate with different post-stress functions.

These observations indicate that immobilization stress activates the hypothalamo-pituitary-adrenocortical axis and results in transient increases in levels of message for both CRF and c-fos in parvocellular neurons of PVN. We are currently assessing the relationship between stress-induced changes in CRH and c-fos mRNA with that of other ACTH secretagogues (e.g., vasopressin) and proto-oncogenes (e.g., c-jun) in the parvocellular PVN.

MODULATION OF CORTICOTROPIN-RELEASING FACTOR (CRF) OR GLUCOCORTICOID RECEPTOR (GR) GENE EXPRESSION IN TRANSGENIC MICE: MODELS FOR NEUROENDOCRINE CHANGES SEEN IN DEPRESSION Nicholas Barden, Francine Morin*, François Pothier*, James Lee† and Marie-Claude Pepin, Molecular Psychogenetics, Laval Univ. Hospital Research Ctr, Ste Foy, Québec, Canada, G1V 4G2. † Psychiatry Dept., Duke University Medical Ctr, Durham, N.C. Pegin. Molecular Psychogenetics, Laval Univ. Hospital Research Ctr, Ste Foy, Québec, Canada, G1V 4G2. † Psychiatry Dept., Duke University Medical Ctr, Durham, N.C. Increased activity of the HPA axis, as indicated by hypersecretion of CRF and cortisol, and premature escape from the cortisol suppressant action of dexamethasone is often associated with mood disorders. The resistance of cortisol secretion to suppression by dexamethasone is suggestive of GR malfunction at the limbic-hypothalamic system level and this hypothesis is supported by our finding of tricyclic antidepressant drug modulation of GR mRNA concentrations in hypothalamic neurons. We have attempted to reproduce in an animal model, by manipulation of genes involved in the control of the HPA axis, two of the changes which can accompany depression, namely, increased CRF secretion and a reduced neuronal sensitivity to glucocorticoids. In order to produce animals hypersecreting CRF, the cloned human CRF gene was introduced into the mouse genome by micronijection of vector-free DNA into a pronucleus of a fertilized mouse egg. When this gene was under control of its homologous promoter, insertion into mouse DNA was generally lethal. However, construction of a chimeric gene consisting of the metallothionein promoter/human CRF gene coding region permitted the establishment of a stable line of transgenic animals with characteristic phenotype. To reduce neuronal GR levels in transgenic mice, cellular GR production was modified by introduction of a complementary GR anti-sense RNA strand. To produce anti-sense RNA, an 1800 bp GR cDNA fragment was inverted downstream from a human neurofilament gene promoter This construction lead to transcription of the anti-sense strand of the GR cDNA fragment instead of the sense strand and, when transfected in cell cultures, caused a functional reduction in GR activity. When incorporated into the mouse genome, a line of animals which pass the transgene from generation to generation and show modified HPA axis parameters was es

TIME-COURSE OF ACTION OF THE TRIAZOLOBENZODIAZEPINE, ALPRAZOLAM, ON HPA AXIS FUNCTION IN RATS. M.A. Vargas*.
M.J. Owens, J.C. Ritchie and C.B. Nemeroff. Depts.
Psychiatry & Pharmacology, Duke Univ., Durham, NC 27710.
Corticotropin-releasing factor (CRF) functions to

integrate not only the endocrine, but autonomic and behavioral responses to stress. We have previously shown that 60 minutes following a single injection of alprazolam or adinazolam, biochemical indices of HPA axis function are altered in a pattern opposite to that observed after exposure to stress. To further scrutinize the effects of triazolobenzodiazepines on HPA axis function, rats received a single sc injection of alprazolam (1 mg/kg) and were killed at various times (15-240 min) post injection. In contrast to our previous data in which alprazolam $\mbox{\tt decreased}$ plasma ACTH and corticosterone concentrations in non habituated rats, alprazolam did not alter the already low basal concentrations of the pituitary adrenal hormones at any time point studied. Similarly, median eminence CRF content was unchanged. However, in agreement with our previous work, CRF concentrations in the locus coeruleus were decreased between 30-180 minutes post-injection. These results further suggest that the anxiolytic and/or purported antidepressant properties of alprazolam may be related to their direct or indirect actions on CRF neurons innervating the locus coeruleus. These results will be discussed in relation to the pharmacokinetics of alprazolam in plasma and brain. Supported by NIMH MH-42088.

EFFECT OF RESERPINE AND COLCHICINE ON NEUROPEPTIDES mrna levels in the rat hypothalamic paraventricular NUCLEUS. S. Ceccatelli, R. Cortés and T. Hökfelt. Dept. of Histology and Neurobiology, Karolinska Institutet, P.O. Box 60400, S-104 01 Stockholm,

In the present study we have analysed peptides in the hypothalamic paraventricular nucleus (PVN), using in situ hybridization and paraventricular nucleus (PVN), using <u>in situ</u> hybridization and immunohistochemistry. We have studied possible changes in mRNA and peptides levels in the PVN 24 hr after a single large dose of reserpine (10 mg/kg) and 24 hr after colchicine (120 µg/20 µl NaCl) intraventricularly (i. c. v.) injected. Sections of the PVN were hybridized using synthetic oligonucleotide probes complementary to CRH, NT, ENK, VIP and TRH mRNAs. For immunohistochemistry rabbit antiscra to CRH, NT, ENK, VIP and TRH were used. In situ hybridization showed a clear increase in CRF mRNA as compared to control rats after both treatments. Also NT and VIP mRNA could be seen in parvocellular neurons in reserpine and in colchicine treated rats, whereas we so far have not been able to demonstrated these mRNAs in untreated rats. No changes in TRH mRNA could be detected after reserpine. With immunohistochemistry, after reserpine, many CRH-, but not NT- or VIP- positive neurons could be observed in the parvocellular part of the PVN. This immunoreactivity could only be seen in a few cells in normal rats with the present sensitivity of our immunohistochemical technique and increase dramatically after i. c. v. colchicine.

The present results demonstrate that treatment with two drugs, the monoamine depleting drug reserpine and the mitosis inhibitor colchicine, causes increased levels of mRNA for several peptides in neurons of the PVN, located almost exclusively in its parvocellar part and confined to the hypothalamo-pituitary adrenal axis.

41.14

EFFECTS OF INTRAHIPPOCAMPAL COLCHICINE ON HYPOTHALAMIC CORTICOTROPIN-RELEASING HORMONE mRNA LEVELS IN RATS. L. S. Brady, A. B. Lynn, H. J. Whitfield and M. Herkenham. Section on Functional Neuroanatomy, Clinical Neuroendocrinology Branch, NIMH, Bethesda, MD 20892.

Evidence suggests that the hippocampus exerts an inhibitory influence on corticotropin-releasing hormone (CRH) gene expression in the paraventricular nucleus (PVN) of the hypothalamus. We examined mRNA expression of CRH in rats after selectively lesioning the dentate gyrus of the hippocampus with colchicine. Rats were sacrificed at varying time intervals after bilateral infusion of colchicine (15 µg/rat) into the hilus of the dentate gyrus. Cryostat-cut sections through the PVN were hybridized with an ³⁵S-labeled probe for CRH and exposed to film for quantitative autoradiography. CRH mRNA was reduced in a time-dependent manner:

CRH mRNA (% of unoperated control)

Time (days)_	1	2	3	7	14
Lesion	71±7 [†]	64±3*	39±12*	45±12*	59±22*
Sham	85±15	84±7	132±17 [†]	142±12†	95±12
	† p < 0.003; * p < 0.0001 relative to control				

Our findings show that selective lesion of the dentate gyrus decreases CRH mRNA in the PVN in contrast to hippocampectomy which increases CRH mRNA levels (J. Neurosci. 9: 3072, 1989). These data suggest that discrete subfields of the hippocampus differentially modulate CRH gene expression in the hypothalamus.

NEUROENDOCRINE REGULATION: OTHER I

6-HYDROXYDOPAMINE (6-OHDA) EFFECTS ON PITUITARY INNERVATION: DEGENERATIVE AND REGENERATIVE CHANGES. L.C. Saland, J.A. Carr, A. Samora*, S. Benavidez* and T. Romero*. Dept. of Anatomy, Univ. of New Mexico Sch. Med., Albuquerque, NM 87131.

The catecholamine neurotoxin, 6-OHDA, has been shown to induce degeneration, and to alter serotonin (5-HT) immunostaining in pituitary neurointermediate lobe (NIL) nerve fibers. Here, pituitaries from 6-OHDA treated rats were studied for possible regenerative changes after initial degeneration of terminals. Adult male Sprague-Dawley rats received two 6-OHDA injections by tail vein (150 mg/kg in 1mg/ml ascorbic acid in saline) on days 1 and 3, then were ether anesthetized and perfused with buffered aldehydes for light or electron microscopy (EM) at 1, 2, 3 or 4 weeks after day 1 of injection. Initial fiber degeneration in the NIL was confirmed by EM after 1 week, with gradual reappearance of normal appearing terminals over the remaining time. Tyrosine hydroxylase (TH) immunostaining was intensified, as compared to vehicle-treated controls, with "swollen" terminals seen at 1 week. Fiber controls, with swollen terminals seen at 1 week. Floer staining gradually returned to more normal patterns over 2-4 weeks. TH-containing cell bodies in the hypothalamus appeared normal at 1 and 2 weeks. Chemical denervation of the NIL, followed by apparent regeneration, can be used to examine plasticity of neural regulation of the endocrine cells of the intermediate lobe. Supported by NIH NS 21256, GM 08139, BRSG 400257 (LCS); F32 NS 08447 (JAC).

IN-VIVO EFFECTS OF SEROTONERGIC AGENTS ON PEPTIDE RELEASE FROM RAT INTERMEDIATE PITUITARY. J.A. Carr.

L.C. Saland, A. Samora*, S. Benavidez*, T. Romero*, Dept. of Anatomy, Univ. of New Mexico Med. Sch., Albuquerque, NM 87131. We used an <u>in-vivo</u> pharmacological approach to investigate the potential influence of serotonin (5-HT) on pro-opiomelanocortinderived peptide release from the intermediate lobe (IL) of the pituitary in adult male Sprague-Dawley rats. After drug treatment, rats were rapidly decapitated and plasma collected for RIA of α -melanocyte-stimulating hormone (α -MSH) and β -endorphin. Pituitaries were collected for the ultrastructural analysis of IL cells. Administration of 5-hydroxy-L-tryptophan (30 mg/kg ip), the synthetic precursor to 5-HT, or the 5-HT reuptake blocker fluoxetine (10 mg/kg ip) elevated plasma levels of β -endorphin but not α -MSH. The non-selective agonist MK-212 produced an elevation in plasma β -endorphin at both doses tested (2.5, 5.0 mg/kg ip) while only the larger dose elevated plasma α-MSH. Rats treated with three successive daily ip injections of the 5-HT synthesis inhibitor parachlorophenylalanine (300,100,100 mg/kg) and then sacrificed one week after the first injection showed an elevation in plasma β -endorphin but no change in plasma α -MSH. Qualitative ultrastructural analysis of IL cells revealed changes consistent with drug effects on plasma α-MSH. Drugs which influence 5-HT synthesis/reuptake alter release of Brugs which influence $5\pi 11$ syndresis/feuptake after release of θ -endorphin but not α -MSH, suggesting an action on anterior lobe (AL) but not IL POMC cells. MK-212 appears to stimulate POMC peptide release from both the AL and the IL. Supported by F32 NS08447 (JAC); NIH NS21256, GM 08139, BRSG 400257(LCS).

TEMPORAL CHARACTERISTICS OF DOPAMINERGIC REGULATION OF THE RAT INTERMEDIATE PITUITARY: SECRETION, POMC AND D2 RECEPTOR GENE EXPRESSIONS AND CELL PROLIFERATION. <u>Bible M. Chronwall</u>*, John M. Farah^a, Stephen J. Morris^a, David R. Sibley^a and William R. Millington^a, a. UMKC School of Basic Life Sciences, Kansas City Mo, b. G.D. Searle & Co, St. Louis, MO, c. NIH, Bethesda, MD.

This study demonstrates the time sequence of changes in proopiomelanocortin (POMC) mRNA, rough endoplasmic reticulum, mitochondria, secretion, D2 dopamine receptor mRNA and proliferation induced in melanotropes after treatment with the D2 dopamine receptor antagonist haloperidol. A detailed time course study (10 min, 30 min, 1 h, 2h, 4h, 6 h, 12 h and 24 h) after a single injection of haloperidol (5mg/kg) showed that peptide secretion increased rapidly, peaking at 30 min and depleting the secretory vesicles. Within 2 h of treatment POMC mRNA levels were significantly elevated; POMC mRNA was maximally elevated at 6 h and remained at these levels throughout the 24 h period. An increase in the number of biosynthetically active organelles was first observed at 24 h and after two days there was an increase in melanotrope proliferation. Subchronic treatment (2.5 d) with haloperidol (2 mg/kg), stimulated peptide secretion from the IL and elevated POMC mRNA levels to 180% of control values. Chronic treatment (12 d), increased the amount of biosynthetically active organelles in melanotropes and further increased POMC mRNA to 300% and cell proliferation to 200%. D2 receptor mRNA increased to 150% of control values. These studies show that the dopaminergic regulation of the IL is multifaceted, incorporating a triad of temporally related events and that the IL functions as an integrated multicellular unit that uses both intra- and intercellular mechanisms to coordinate its total production of peptide hormones

42.4

POMC GENE EXPRESSION IN RAT PITUITARY INTERMEDIATE LOBE: A COMPARISON OF RADIOACTIVE AND NON-RADIOACTIVE IN SITU HYBRIDIZATION HISTOCHEMISTRY. B. Pratt, S.J. Morris and B.M. Chronwall, School of Basic Life Sciences, University of Missouri-Kansas City, Kansas City,

School of Basic Life Sciences, University of Missouri-Kansas City, Kansas City, MO 64108.

Individual melanotropes of the intermediate lobe (IL) differ in their content of biosynthetically active organelies as well as pro-opiomelanocortin (POMC) mRNA. POMC gene expression is mainly regulated by dopaminergic agents; haloperidol increases and bromocriptine decreases POMC mRNA. The focus of this study is to use quantitative in situ hybridization histochemistry to further demonstrate melanotrope biosynthetic heterogeneity and to quantitate relative changes in gene expression in the IL after drug treatment. A comparison of radioactive and non-radioactive detection of the hybrids was made to develop a method that detects cellular biosynthetic heterogeneity in a histologically homogenous tissue. The results are as follows. Radioactive detection of hybrids: Highly sensitive, can be used on 15µm frozen and 3µm paraffin sections as well as on floating lobules fixed in 4% paraformaldehyde and 0.1% glutaraidehyde and postfixed in OSO,, which are then embedded in plastic and semithin sectioned. The tissue preservation in paraffin sections allows assignment of grains to individual cells. In the plastic sections silver grains can be quantitated over cells with retained cytology. Relative quantitation over whole sections after drug treatments is easy to perform using automated counting of silver grains. It is possible but time consuming to count grains over individual cells in paraffin and plastic sections. Refocusing is sometimes necessary to see cell borders. The long exposure time (2 weeks using 35%) is a draw back. Non-radioactive detection of hybrids: Less sensitive, does not readily detect hybrids to mRNA in paraffin mebedded tissue. Better cellular resolution than radioactive labeling on 15µm frozen sections. Possible but not easy to quantitate by densitometry; less accurate than grain counting. Results can be obtained in 2.3 days. In summary, radioactive detection of these and on the paraffin sections and sections. easy to quantitate by densitometry; less accurate than grain counting. Results can be obtained in 2-3 days. In summary, radioactive detection gives a more exact quantitation at a higher level of resolution.

42 5

CHARACTERIZATION OF PROLACTIN RECEPTORS IN DOVE BRAIN BY AUTORADIOGRAPHY AND EFFECTS OF PROLACTIN INJECTIONS ON

AUTORADIOGRAPHY AND EFFECTS OF PROLACTIN INJECTIONS ON BINDING ACTIVITY. J.D. Buntin and E. Ruzycki*, Dept. of Biol. Sciences, Univ. of Wisconsin, Milwaukee, WI 53201.

Prolactin (PRL) receptors have been detected and characterized in ring dove brain membranes (Gen. Comp. Endocr. 65:243,1987). In addition, in vitro autoradiographic data indicates that 1251-ovine PRL (oPRL) binds specifically to several dove forebrain and midbrain areas, with highest levels in the preoptic region and medial-basal hypothalamus (Br. Res. 487:245,1989). In this study, we examined the affinity, specificity, and in vivo saturability of ¹²⁵I-oPRL binding in several of these regions ability of **1-OPRL binding in several of these regions using film autoradiography and densitometry on slidemounted sections (20µm). In specificity tests, 44, 440, or 4400 pM unlabelled oPRL significantly reduced the in vitro specific binding of *125I-OPRL (30pM) in preoptic area (POA) and three hypothalamic regions. In contrast, turkey GH, ovine GH, and ovine LH were ineffective competitors at these concentrations. Binding affinity was similar across the brain regions examined (average $K_d=.17 \text{nM}$). Unlabelled oPRL (37nmoles) reduced the uptake of $^{125}\text{I-oPRL}$ (37 pmoles) in POA and tuberal hypothalamus by 30-45% at 2 hours after intravenous injection. Moreover, chronic oPRL treatment (590nmoles/day x 7 days, s.c.) reduced the specific binding of ¹²⁵I-oPRL to these areas in vitro by over 65%. These results suggest the existence of specific, high affinity PRL receptors in dove brain that are accessible to blood-borne PRL. Supported by MH 41447.

ASSESSMENT OF HYPOTHALAMIC DOPAMINERGIC AND SEROTONERGIC ACTIVITY DURING PREGNANCY-INDUCED PROLACTIN SURGES USING PUSH-PULL PERFUSION. A. M. MISTRY* AND J. L. VOOGT Dept of

PUSH-PULL PERFUSION A. M. MISTRY* AND J. L. VOOGT Dept of Physiology, Univ Kansas Med Ctr, Kansas City, KS 66103

Mating results in two daily surges of prolactin (PRL) in the rat. A nocturnal (N) surge occurs between 0200h and 0600h. This study evaluated dopaminergic and serotonergic activity in the hypothalamus during the entire time period of the N surge on day 8 of pregnancy and on day 16, at which time the surge is no longer present. Female Sprague-Dawley rats were implanted with push-pull cannulae so that the cannula tip was in the arcuate-median eminence region. On day 8 or 16 artificial cerebrospinal fluid was perfused from midnight to 0600h using two identically precalibrated pumps. Perfusates were collected over ice every 15 min and injected immediately onto a HPLC column. Blood samples were withdrawn hourly from precaiorated pumps. Pertusates were collected over ice every 15 min and injected immediately onto a HPLC column. Blood samples were withdrawn hourly from previously implanted carotid catheters and plasma PRL assayed by RIA. Histological sections determined correct placement of the cannula. Dopamine (DA) and serotonin (5-HT) were detected in a limited number of samples. However, dihydroxyphenylaceticacid (DOPAC) which reflects neuronal dopaminergic activity, and 5-hydroxyindoleaceticacid (5-HIAA) the metabolite of 5-HT were consistently detected. Approximately half the rats failed to show a N PRL surge on day 8. These rats had significantly (p≤.001) lower 5-HIAA levels compared to rats which displayed a surge of PRL. There was no difference in DOPAC levels between these two groups. On day 16 when PRL surges were absent, 5-HIAA levels were significantly (p≤.01) lower than in rats that surged on day 8. Release of DOPAC was also significantly (p≤.01) lower compared to day 8 rats, suggesting that low PRL at this time is not dependent on increased dopamine secretion. In conclusion a greater overall release of 5-HIAA is seen *in vivo* during early pregnancy in freely moving conscious rats which display a surge of PRL. During the second half of pregnancy, when PRL release was low there was a remarkable reduction in 5-HIAA suggesting that a positive serotonergic input is important for generating the PRL surge. This is supported by studies showing that 5-HT antagonists blocked the PRL surge. (Supported by grant HD 24190)

DIFFERENTIAL PROLACTIN RESPONSE TO DOMPERIDONE DURING THE NOCTURNAL PROLACTIN SURGE IN PREGNANT RATS. J. R.

THE NOCTURNAL PROLACTIN SURGE IN PREGNANT RATS. J. B. Mathiasen and J. L. Voogt. Department of Physiology, University of Kansas Medical Center, Kansas City, KS 66103.

Pregnant rats exhibit 2 daily surges of prolactin (PRL) during the first half of pregnancy. The nocturnal surge peaks at 0400h and the diumal at 1800h. PRL is under the inhibitory influence of dopamine (DA). Domperidone (DOM), a DA D2 antagonist causes release of PRL by inhibiting the action of DA at the pituliary. DOM was used to measure the degree of endogenous DA inhibition of nitritary PRI at various times prior to and during the DA at the pituitary. DOM was used to measure the degree of endogenous DA inhibition of pituitary PRL at various times prior to and during the nocturnal PRL surge on Day 8 of pregnancy. A large PRL response to DOM suggests substantial DA interaction at the lactotroph, whereas a smaller PRL response to DOM indicates less DA acting at the lactotroph. Carotid cannulas were placed in pregnant rats on Day 6 and blood samples were taken hourly from 2400h through 0500h on Day 7. On Day 8, DOM (100 ug/kg i.v.) was given at either 2400h, 0200h, 0400h or 1200h, and blood samples taken 0, 5, 15, 30 and 60' after DOM. Whole blood was assayed for PRL by double antibody RIA. PRL levels in response to DOM averaged 630 ng/ml above preinjection levels of 15 ng/ml at 2400h and 1200h, two times when a PRL surge is not normally present. PRL response to DOM given at 0400h was moderate, increasing 442 ng/ml above the preinjection surge level of 146 ng/ml. PRL response to DOM at 0200h, however, was significantly lower, increasing 330 ng/ml above a preinjection level if 5 ng/ml, suggesting that at the beginning of the nocturnal PRL surge there was a transient fall in DA interaction at the pituitary lactotroph. This transient fall in DA could serve to initiate the PRL surge, while PRL-releasing factors may maintain the surge. Supported by NIH grant HD 24190.

CO-CULTURE OF ANTERIOR AND POSTERIOR PITUITARY CELLS INCREASES PROLACTIN CELL CONTENT AND RESPONSIVENESS TO TRH. J. Dymshitz* and N. Ben-Jonathan. Dep. Physiology, Indiana Univ. Med. Sch., Indianapolis, IN 46202.

The synthesis and release of PRL are regulated by multiple hypothalamic and posterior pituitary (PP) factors. We have shown that cells of the intermediate lobe produce PRL-releasing factor. The objective of this study was to determine whether co-culturing of anterior pituitary (AP) and PP cells influences the production and release of PRL. Pituitaries from adult male rats were separated into anterior and posterior (intermediate+neural) lobes and the cells were cultured in serum-free medium; AP cells were plated either alone (control) or with PP cells (AP+PP). PRL and GH in cells and media were measured by R1A. After 4 days, the PRL cell content (ng/10,000 cells) in AP+PP was 157±5 vs 80±3 in controls; GH cell on PRL cell content was observed after 8 days. Moreover, the PRL levels in medium from AP+PP were 40% higher than those in for 20 min) increased PRL release from controls and AP+PP by 350% and 700%, respectively. In contrast, dopamine (50 nM) caused a 50-60% inhibition of PRL secretion in either group.

Conclusions: 1) PP cells selectively stimulate the accumulation of PRL by lactotrophs, 2) the rise in intracellular PRL levels reflects, at least in part, an increase in the releasable pool of this hormone. Supported by NIH grants DK 39551 and NS 13234.

SPONTANEOUS ELECTRICAL AND SECRETORY ACTIVITY OF RAT LACTO-TROPES ARE INDEPENDENT OF SODIUM CURRENTS, K.A. Greger

Depts. Pediatrics & Physiology, Univ. MD, Baltimore, MD 21201. Sodium currents (I_{Na}) play a critical role in the function of nerve and muscle cells, but their importance in secretory mechanisms of endocrine cells has not been determined. We have investigated the contribution of I_{Na} to electrical properties and secretory function of ret to electrical properties and secretory function of rat lactotropes. Cells were derived from female rats and identified for patch clamp studies using the hemolytic plaque assay. Whole-cell voltage clamp recordings demonstrated no inward current that was sensitive to either TTX (4uM) block or substitution of external Na⁺. These prolactin (PRL)-secreting cells can exhibit spontaneous depolarizing action current which may correlate with their secretory activity. Again, TTX had no effect on this spontaneous spiking activity as monitored during whole-cell current clamp. Moreover, PRL release from acutely dissociated or primary cultures of lactotropes was unchanged by TTX as primary cultures of lactotropes was unchanged by 11A as determined by both quantitative plaque assay of individual cells and static release studies of pituitary cell populations. GH₃ cells, clonal cells derived from a rat pituitary tumor which secreted both PRL and growth hormone, did exhibit a large, rapidly-inactivating INa which could be blocked by TTX. However, TTX did not alter PRL release from these cells either. A TTX-sensitive $I_{\rm Na}$ does not appear to be important for spontaneous PRL release. Further studies are required to determine if INa plays a role in regulated PRL secretion. Supported by NIH grant DK-40336.

CENTRAL CATECHOLAMINES AND THE PROLACTIN RESPONSE TO NICOTINE. <u>SG Matta and BM Sharp*</u>, Minneapolis Medical Research Fndn. and Depts. of Med., Hennepin County Medical Center and Univ. Minn., Minneapolis, MN, 55404.

Medical Center and Univ. Minn., Minneapolis, MN, 55404. The mechanism(s) whereby i.v. nicotine stimulates prolactin (PRL) release has not yet been described. The current studies showed that a fourth ventricular (IV) injection of nicotine (N; 0.125 - 2.5 ug) produced a dose-dependent PRL response [Buffer < N 0.125 = N 0.25 (p<.05) < N 0.5 = N 2.5 (p<.01)]. Injection of mecamylamine [nicotinic (NAch) antagonist] into IV (20 or 40 ug) or i.v.(0.5 mg/kg b.wt.) prior to nicotine given by the alternate route showed nicotine's effect was due to NAch receptors accessible from the IV and that sites adjacent to IV mediate the PRL response to i.v. nicotine. Since brainstem catecholaminergic neurons project to hypothalamic structures modulating PRL release, the role of these neurons in nicotine-stimulated PRL release was studied. 6-Hydroxydopamine i.c.v. abolished the PRL response to nicotine injected into the IV (1 or 2.5 ug) or i.v.(0.03 or 0.05 mg/kg b.wt.). To determine the role of pinephrine,SKF 64139 or DCMB (synthesis inhibitors) were given prior to nicotine (0.05 mg/kg b.wt.); both reduced the PRL response epinephrine, SkF 64139 or DCMB (synthesis inhibitors) were given prior to nicotine (0.05 mg/kg b.wt); both reduced the PRL response (p<.01). These compounds may also act at alpha2 adrenoreceptors; yohimbine (1 ug), injected into the third ventricle prior to nicotine (1 ug) into IV blocked the peak PRL response (p<0.05). Further evaluation showed that both alpha1 or \(\beta \) antagonists were effective (p<.05). Thus, i.v. nicotine acts centrally via catecholaminergic neurons to stimulate the release of PRL. (Supported by DA03977).

CHRONIC, BUT NOT ACUTE, EXPOSURE TO PHENCYCLIDINE FACILITATES THE 5-HYDROXYTRYPTOPHAN (5HTP)-INDUCED RELEASE OF PROLACTIN James F. Hyde, Dept. of Anatomy and Neurobiology, Univ. Kentucky, Coll. of Med., Lexington, KY 40536.

Phencyclidine (PCP) is known to interact with dopaminergic and serotonergic neurons which inhibit and stimulate prolactin secretion, respectively. Acute exposure to PCP inhibits prolactin release, presumably by increasing hypothalamic dopamine release. The affects of PCP on hypothalamic serotonin neurons are not clear. To determine if PCP alters the serotonergic control of prolactin release, female Sprague-Dawley rats (n=5-7/group) were injected with PCP (10 mg/kg, ip) or vehicle (saline) for 14 days. Jugular cannulae were implanted one day prior to experiments. Serial blood samples were collected before and 10, 20, 30, 60 and 90 min after 5HTP (20 mg/kg, iv) injection. In control rats, plasma prolactin levels peaked (199.5 ± 29.2 ng/ml) 20 min after 5HTP injection and returned to basal levels (12.9 ± 3.4 ng/ml) by 90 min. Chronic PCP treatment did not alter (12.9 \pm 3.4 ng/ml) 69 90 min. Chronic PCP treatment did not after basal prolactin levels (13.9 \pm 3.3 ng/ml), however, 5HTP increased prolactin levels to (682.3 \pm 170.9 ng/ml) at 20 min (p<0.05). Prolactin levels remained elevated at 90 min (44.0 \pm 19.2 ng/ml). A single injection of PCP, 90 min prior to 5HTP administration, did not after the profile of prolactin release. Although basal prolactin levels (5.9 + 1.6 ng/ml) were lowered by acute exposure to PCP, peak prolactin values (224.0 ± 23.7 ng/ml) were similar to vehicle controls. These data indicate that chronic, but not acute, exposure to PCP alters the function of the hypothalamic serotonergic system involved in the regulation of prolactin secretion. REGULATION OF PROLACTIN SECRETION IN THE DIABETIC MALE RAT. S.G. Kienast, R.N. Hails and R.W. Steger, Dept of Physiology, Southern Illinois University School of Medicine, Carbondale, IL 62901.

S.G. Kienast. R.N. Hails and R.W. Steger. Dept of Physiology, Southern Illinois University School of Medicine, Carbondale, IL 62901.

We have previously demonstrated that diabetes in the male rat is associated with abnormalities in gonadotropin secretion secondary to changes in hypothalamic neurotransmitter metabolism (Endocrinology 124:1737, 1989). In the present study we looked at the effect of streptozotocin-induced (STZ) diabetes on prolactin (Prl) secretion. Adult male rats made diabetic with STZ(50mg/kg) showed markedly reduced plasma levels of Prl within 1 wk of treatment and levels remained low for at least 2 months. Insulin replacement restored normal Prl levels in diabetic rats. Pituitary Prl content, in vitro Prl secretion and the in vitro response to the Prl inhibitory effects of 10-8 M DA did not differ between diabetic and control animals. The diabetes-related reduction of in vivo Prl secretion did not appear to be due to changes in tuberoinfundibular dopaminergic activity since DA turnover (as estimated by measuring the rate of DA depletion after tyrosine hydroxylase inhibition) in the median eminence did not differ between control and STZ-treated rats. The ability of exogenous Prl (1 ug ovinePrl/day for two days)to increase DA synthesis (as estimated by measuring DOPA accumulation after decarboxylase inhibition) in the median eminence was similar in control and STZ-treated rats. However, STZ-treatment was shown to reverse hyperprolactinemia resulting from the grafting of donor pituitaries under the kidney of male rats while insulin replacement restored the ability of ectopic pituitary grafts to secrete Prl. In conclusion, diabetes related changes in Prl secretion are not due to changes in DA metabolism or pituitary DA response but may be due to the direct effects of hypoinsulinemia on pituitary Prl secretion. (Supported by a graft from the grafting Days the Diabetes Februatch of Supported by a graft from the luvacilia Diabetes Februatched. but may be due to the direct effects of hypoinsulinemia on pituitary Pri secretion. ANALYSIS OF PULSATILE TSH SECRETION IN THE RAT. ANALYSIS OF PULSATILE TSH SECRETION IN THE RAT.

T.O. Bruhn, M.B. McFarlane* and I.M.D. Jackson.
Division of Endocrinology, Rhode Island Hospital, Brown University, Providence, RI 02903.

To determine the pattern of TSH secretion, adult male rats were fitted with indwelling ve-

nous and arterial catheters exteriorized through a spring tether and connected to a swivel.

Blood was constantly withdrawn under low stress conditions with a roller pump which also served to reinfuse blood for maintainance of volume and hematocrit. Blood samples were fractionated at 2.5 min intervals. TSH data was subjected to 2.5 min intervals.
"Pulsar" analysis.

TSH secretion was pulsatile in both eu- and hypothyroid rats. Mean TSH plasma concentrations and peak amplitude were 18.2 and 25.8 fold elevated in hypothyroid rats in comparison to euthyroid controls. Pulse frequency and peak lengths were similar in both groups (1-1.5 pulses/h and 10-12 min). Passive immunization pulses/h and 10-12 min). Passive immunization with TRH antiserum caused a significant 55% decrease of TSH levels and the disapperance of TSH pulses in hypothyroid rats. We conclude that 1. TSH secretion is pulsatile in the rat, 2. TRH appears to control both basal TSH secretion and TSH pulsatility and 3. hypothyroidism upregulates both basal and peak TSH levels without influencing the pattern of TSH secretion.

MECHANISM FOR DECREASED RESPONSIVENESS TO β-ENDORPHIN DURING THE NOCTURNAL PROLACTIN SURGE IN PREGNANT RATS.

C.A. Sagrillo and I.L. Yoogt. Dept. of Physiology, University of Kansas Medical
Center, Kansas City, KS 66103.

Center, Kansas City, KS 66103.

Exogenous opioids stimulate prolactin (PRL) release in the pregnant rat. We reported (Endocrine Society Meeting, 1990) that Day 8 pregnant rats showed dramatic PRL responses to Beta-endorphin (B-end) when given at midnight (presurge) or 1200h (intersurge), but greatly attenuated responses at 0200h (early surge) and 0400h (peak surge), animals treated at 0600h (postsurge) showed recovered responsiveness to B-end. The following experiments were designed to determine what accounts for these significantly lower PRL increases to B-end during the surge. To determine what dose to use, Day 8 pregnant rats received 2.5, 10, 25 or 100 ng/µl/min B-end at 1200h, a nonsurge time, for 15 minutes via a right lateral ventricular brain cannula. The dose used in subsequent experiments was chosen to ensure maximal onioid receiptor stimulation. Day 8 pregnant rats received. chosen to ensure maximal opioid receptor stimulation. Day 8 pregnant rats received ventricular infusions of 100ng/μl/min β-end at 1000h and then again at 1200h. All animals showed PRL increases greater than 1100ng/ml at 1000h, and those that responded again at 1200h (4 of 7) had 50% lower PRL levels. The other 3 rats were unresponsive. In another experiment, β-end was infused at midnight and the animals unresponsive. In another experiment, β -end was infused at midnight and the animals were monitored for a subsequent endogenous nocturnal PRL surge. All animals showed a rapid increase in PRL after β -end, followed by a decrease to near pretreatment levels. Subsequently, 5 of 8 rats did not have a nocturnal PRL surge. This suggests that the initial β -end may down regulate its receptor or deplete significant amounts of pituitary PRL. To determine whether pituitary PRL reserves may be a factor for the low response to β -end during the surge, hemipituitary content was measured and found to be significantly lower (ρ <0.01) at 0200h compared to 1200h, whereas serum PRL was 456ng/ml (0200h) and 26ng/ml (1200h). Based on these results, lower pituitary PRL response to β -end. Continuous PRL secretion throughout surge periods may lower releasable PRL which is then restored during postsurge periods for subsequent surges. Supported by HD24190.

ANGIOTENSIN II (AII) AND PROLACTIN (PRL) SECRETION IN THE MALE RAT. M.K.Steele and L.S.Myers. Dept. of Physiology, University of California, San Francisco, CA 94143 and Dept. of Psychology, CSU, Stanislaus, Turlock, CA 95380

We have previously shown that intracerebroventricular (ICV)

We have previously shown that intracerebroventricular (ICV) injections of AII lower plasma PRL levels in female rats; however endogenous brain AII actively inhibits PRL only in the presence of ovarian steroids (Myers and Steele, J. Neuroendo, 1:299, 1989). The present studies investigated the role of the brain renin-angiotensin system in the regulation of PRL secretion in the intact male rat. Third ventricle cannulae were implanted at least one week prior to and jugular cannulae were inserted 48 hours before use in experiments. Blood samples were taken from conscious rats prior to and following administration of test substances. In the first series of experiments, we determined the sensitivity of the PRL response to ICV-AII. In the second series, we investigated the role of endogenous AII by ICV infusion of saralasin, an AII receptor blocker, (15 ug/25 ul/hr) or ICV injection of enalaprilat, a converting enzyme inhibitor, (100 ug/2 ul). PRL levels were significantly suppressed, in a dose-related manner, by AII (500 to 10 ng). A dose of l ng did not affect PRL, compared to values from vehicle-injected animals. Neither saralasin nor enalaprilat values from venicle-injected animals. Neitner saralasin nor enalaprilat administration resulted in any significant changes in PRL levels. These results suggest that, while exogenous AII can suppress basal PRL levels and this response is quite sensitive, endogenous AII in the brain does not play a role in the tonic regulation of basal PRL levels in the intact male rat. THYROIDECTOMY INDUCES FOS-LIKE IMMUNOREACTIVITY IN THE PARVOCELLULAR PARAVENTRICULAR HYPOTHALAMIC NUCLEUS OF THE RAT. N. Koibuchil', R.B. Gibbs', M. Suzukil', and D.W. Pfaff'. 'Lab. of Neurobiology and Behavior, Rockefeller University, N.Y., N.Y. 10021, 'Dept. of Physiology, Inst. of Endocrinology, Gunma University, Maebashi

371, Japan.

The expression of fos-like immunoreactivity (IR) was examined in the adult rat brain as a function of thyroidectomy (TX). Thirty-two male, Sprague Dawley rats (250-300g) were used. All animals were handled for at least 1 week prior to surgery. Of the 32 animals, 20 had their thyroid gland surgically removed while remaining animals received sham surgery. One (n=10), 3 (n=10), and 6 (n=12) days after surgery, rats were sacrificed by transcardiac perfusion with 4% paraformaldehyde in 50 mM PBS. Blood was collected and plasma levels of T₄, T₅, and TSH were measured by radioimmunoassay. Brains were removed and 30 µm frozen sections were cut and processed for immunocytochemistry using a rat monoclonal antibody (IgG) which binds to immunoprecipitated fos protein (Microbiological Associates, Inc., Bethesda, Md.). Numbers of fos-like It cells in the magnocellular and parvocellular regions of the paraventicular nucleus of the hypothalamus (mPVN & pPVN), the anterior hypothalamus, and the pyriform cortex were subsequently counted and compared.

the lateral hypothalamus, and the pyriform cortex were subsequently counted and compared.

Within 6 days after TX, a specific increase (212%) in the number of foslike IR cells in the pPVN was observed. In contrast, no specific change in the number of fos-like IR cells was observed, independent of environmental variables, within any of the other brain areas examined 1-6 days after TX. The time course for the effect of TX in the pPVN correlated with changes in plasma levels of TSH (r=0.748, p=0.001). Since levels of TSH are, in part, a reflection of TRH release, we are currently examining whether TX induces fos-like IR specifically within TRH-containing neurons located in the pPVN.

This study was designed to establish whether fluidity and

This study was designed to establish whether fluidity and lipid composition of brain membranes were affected by hypothyroidism, in the hope of clarifying the mechanisms through which hypothyroidism might influence nerve cell functions. Rats were made hypothyroid by injections of PTU (dissolved in 0.005 M NaOH, 50 mg/kg, ip, daily for 28 days). Membrane fluidity, chol and PL content, and PL and their fatty acid composition were measured in plasma, erythrocyte plasma membranes, liver microsomes and brain subcellular fractions. P2 pellets from brains of hypothyroid rats were less fluid than those of euthyroid ones; subcellular fractionation showed that mitochondrial membranes were responsible for the rigidity observed. Similar changes were found in erythrocyte "ghosts". The reduced fluidity seemed to be related more to alterations in the ratios between PC, Sph and PE, than to those of chol/PL, protein/PL or FA unsaturation index. The well known alteration in hypothyroidism-induced desaturase activity, which in peripheral tissue leads to a reduction of 20:4n-6 and to an increase in its precursors (18:2n-6 and 20:3n-6) barely detectable in brain membranes. Only in PC of synaptosomes and myelin did slight changes in percentages of the n-6 family fatty acids result in a significant alteration of 20:4n-6/20:3n-6 ratios.

PAIN MODULATION: ANATOMY AND PHYSIOLOGY I

RAPHE-SPINAL AND SUBCOERULEO-SPINAL MODULATION OF TEMPERATURE SIGNAL TRANSMISSION IN RATS.
H. Sato* and H. Nishino. Dept. of Physiology, School of Medicine, Nagoya City University, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan.
To verify the possibility that the nucleus

To verify the possibility that the nucleus raphe magnus (NRM) and subcoeruleus (SC) modulate the spinal transmission of temperature signals from the periphery, extracellular recordings of dorsal horn neuron activity responsive to unnoxious thermal stimulation (10-40°C) of the scrotal skin were made in urethane-anesthetized Wistar rats, and effect of electrical stimulation in the NRM and SC on these activities was investigated. NRM stimulation suppressed excitatory responses of the neurons induced by skin warming (92%) whereas facilitated those of the neurons induced by skin cooling (57%). SC stimulation suppressed excitatory responses of both types of neuron (62%, 80%). Data suggest that the spinal transmission of temperature signals contributing to thermoregulation is descendingly controlled by both the raphe-spinal and subcoeruleo-spinal pathways in such the manner that warm signals are inhibited by both pathways whereas cold signals are facilitated by the former and inhibited by the latter.

43.3

DIFFERENCES IN COERULEOSPINAL PROJECTIONS IN RAT SUBSTRAINS. H.K. Proudfit, D.C. Yeomans and F.M. Clark, University of Illinois at Chicago, Chicago, IL 60680.

Noradrenergic neurons in the locus coeruleus (LC) are known to have prominent projections to the spinal cord. However, reports that describe the location of terminal fields arising from these neurons in the rat are conflicting. For example, some studies indicate that coeruleospinal neurons project primarily to the dorsal horn while others have demonstrated major projections to the ventral horn. Since some of these conflicting results were obtained using nearly identical anatomical methods, it is difficult to reconcile these divergent results on the basis of methodological differences. However, these conflicting results may be due to genetic differences in rats obtained from different vendors. To test this hypothesis unilateral injections of the retrograde tracer Fluoro-Gold (FG) were made into the ventral horn of rats obtained from Harlan or Sasco. Many retrogradely-labeled neurons were seen in the ipsilateral LC in Sasco rats, but very few LC neurons were labeled in Harlan animals. These results are consistent with previous observations using anterograde tracers which indicate that LC neurons in Sasco rats project primarily to the ventral horn. These results are also consistent with similar experiments done using Harlan rats which demonstrated that LC neurons have sparse projections to the ventral horn. These observations indicate that different substrains of rats exhibit fundamental differences in the projections of coeruleospinal neurons. (This work was supported by USPHS Grant DA C3980.)

PROJECTIONS FROM THE VENTROMEDIAL MEDULLA TO PONTINE CATECHOLAMINE NUCLEI. F.M.Clark and H.K. Proudfit. Dept of Pharmacol., Univ. of II at Chicago, Chicago II. 60680.

Stimulation of neurons in the ventromedial medulla (VMM) produces antinociception which is partially mediated by bulbospinal noradrenergic (NE) neurons. Since no NE neurons are located in the VMM, it is likely that neurons located in the VMM have axonal connections with the spinally-projecting NE neurons located in the A5, A6 (locus coeruleus), or A7 NE nuclei. To provide evidence for such connections, the anterograde tracer, phaseolus vulgaris-leucoagglutinin (PHA-L), was injected into the VMM and labeled axons were identified near NE neurons labeled with dopamine-8-hydroxylase-immunoreactivity (D8H-ir). A dense field of PHA-L-positive terminals was seen within the A7 nucleus. Many PHA-L-positive terminals were closely apposed to DßH-ir A7 perikarya or proximal dendrites. A modest number of terminals was seen within the A5 and LC nuclei. In the second experiment, a unilateral injection of the retrograde tracer, Fluoro-Gold (FG), was made into the A7 nucleus and brainstem sections were processed for serotonin (5HT) immunocytochemistry. Many neurons retrogradely labeled with FG were seen in the VMM but less than 5% of these FG-labeled cells contained 5HT-immunoreactivity. The results of these experiments indicate that the VMM has a substantial population of non-5HT neurons which project to the A7 NE nucleus. (This was supported by USPHS Grant DA 03980.)

43.4

DESCENDING FACILITATION AND INHIBITION OF SPINAL NOCICEP-TIVE TRANSMISSION FROM THE NUCLEI RETICULARIS GIGANTOCEL-LULARIS (NGC) AND GIGANTOCELLULARIS PARS ALPHA (NGCo) IN THE RAT. M.Zhuo and G.F.Gebhart. Dept. Pharmacology, Univ. of Iowa, Iowa City, Iowa 52242.

The effect of activation of the NGC/NGC on responses of spinal dorsal horn neurons to noxious heating of the skin was studied. At 30 of 51 sites in the NGC/NGC o, electrical stimulation facilitated responses of dorsal horn neurons to noxious heating at low intensities (12.7 \pm 1.3 $\mu\text{A})$ and inhibited the responses of the same neurons at greater intensities (46.2 \pm 3.0 $\mu\text{A})$ of stimulation. Stimulation produced only inhibition at the other 21 sites of stimulation in the NGC/NGC of Stimulation in the NGC/NGC decreased the slope of the stimulus response function (SRF) at intensities inhibiting unit responses to noxious heating; stimulation at facilitation-producing intensities produced a leftward parallel shift of the SRF. Glutamate microinjection into the NGC/NGC also facilitated responses of dorsal horn neurons to noxious heating at a low concentration (1.7 nM) and inhibited responses at a greater concentration (50 nM). Inhibition produced by electrical stimulation was attenuated by transection of the dorsolateral funiculi (DLF), but facilitation was unaffected or enhanced. The results suggest that (1) activation of the NGC/NGC can facilitate and inhibit spinal noclceptive transmission and (2) different descending pathways are involved in mediating descending facilitation and inhibition.

RVM STIMULATION REDUCES NOXIOUS STIMULUS-EVOKED FOS EXPRESSION AND IS ANTAGONIZED BY THE ALPHA1 ANTAGONIST PRAZOSIN. A.Z. Murphy, F.P. Zemlan, R.M. Murphy and M.M. Behbehani. Depts. of Psychiatry and Physiology, Univ. of Cincinnati College of Medicine, Cinti., OH 45267-0559

Microinjection of glutamate into the rostral ventral medulla (RVM) inhibits nociceptive dorsal horn neurons. The present study determined whether the selective alpha; antagonist prazosin could attenuate the antinociceptive actions produced by microinjection of glutamate into the RVM using immunocytochemistry to examine the pattern of noxious-stimulus evoked expression of the protooncogene c-fos in the spinal cord of the rat. Prior to microinjection of glutamate into the RVM, animals received bilateral injection of 4% formalin into the hind paws; animals were then post-treated i.p. with either prazosin (5 mg/kg) or its vehicle. Two and one half hours after formalin injection, animals were perfused intracardially with 4% paraformaldehyde and 60 micron sections of the lumbar spinal cord were immunostained for Fos protein. Quantitative analysis revealed that formalin injection alone produced intense bilateral Fos-like immunoreactivity (FLI) in produced intense bilateral Fos-like immunoreactivity (FLI) in laminae I, II, V and VI. Less intense labelling was noted in lamina VII, VIII, and X. RVM stimulation produced a unilateral suppression of FLI in all laminae, most notably in the deeper laminae, V, VII, VIII, and X, and a substantial reduction in FLI occurred in lamina I and II. This inhibition of FLI was partially reversed by administration of prazosin. It is concluded that RVM induced analgesia involves activation of alpha1 adrenergic receptors.

AUTORADIOGRAPHIC MAPPING OF SEROTONINI RECEPTORS IN HUMAN SPINAL CORD. R.M. Murphy and F.P. Zemlan. Dept. of Psychiatry, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267-0559.

In vitro autoradiography was used to study the distribution and types of serotonin₁ (5-HT₁) receptors in human spinal cord. Tissue sections (10 uM) from cervical and lumbar spinal cord were cut at -15°C with a cryostat and thaw-mounted onto gelatin-coated slides. Following preincubation, sections were incubated for one hour with 2 nM ³H-5-HT or ³H-8-OH-DPAT, and for 2 hours with 5 nM ³H-mesulergine in a 0.17M Tris-HCl buffer (pH 7.6), in the presence and absence of 10 uM cold 5-HT, washed twice with ice-cold (4°C) buffer, and dried with cool air. Slides were opposed against 3H-Ultrofilm, exposed for 1-2 months, and analyzed by micro-densitometry

Across both spinal cord levels, the total number of $5-HT_1$ receptors was 2-3 times higher in the dorsal horn than in the ventral horn, with the highest densities in the substantia gelatinosa and dorsal funicular gray. The highest densities of 5-HT1 receptors and dorsal function gray. The inguist defisites of 3-111 receptors in the ventral horn were found within the motor nuclei. Approximately 30-40% of the 5-HT₁ receptors in human spinal cord were labelled by ³H-8-OH-DPAT (5-HT_{1A} subtype) and 4-15% were labelled by ³H-mesulergine (5-HT_{1C} subtype). Presently, experiments are being conducted to determine if the 35-65% 5-HT₁ receptors remaining in the cord are similar to the 5-HT_{1S} receptor subtype recently identified in rat spinal cord.

43.9

NUCLEUS RAPHE MAGNUS (NRM) STIMULATION INHIBITS NOCICEPTIVE DORSAL HORN CELL ACTIVITY AND INCREASES DORSAL HORN AMINO ACIDS LEVELS WITHOUT DETECTABLE CHANGES IN SEROTONIN (5HT) LEVELS. L.S. Sorkin, D.J. McAdoo and W.D. Willis. Univ. of TX Medical Branch, MBI, Galveston, Texas 77550.

We collected excitatory (EAA) and inhibitory amino acids and 5HT from the dorsal horn during NRM stimulation, while recording from nearby cells. The NRM was stimulated at several intensities to determine the relationship between NRM-induced inhibition and neurotransmitter release. Dialysis tubes were positioned in the dorsal horn of anesthetized (a-chloralose) adult cats and perfused (5µl/min) with artificial CSF; continuous samples were collected in 15 min aliquots. Microelectrodes placed rostral to the tube recorded activity from cells with nociceptive input. Stimulating electrodes were placed in the NRM. Chemical analysis was done with HPLC; amino acids with fluorescence detection, 5HT with electrochemical detection. Detection limits were approximately 104 M for 5HT and 107 M for the amino acids. NRM stimulation at 1-4 times the intensity necessary to inhibit 50% of peripherally evoked activity increased levels of aspartate, glutamate, glycine, serine and/or GABA. 5HT increases were observed only with higher stimulus intensities. These results suggest that there is an EAA mediated raphe-spinal pathway that inhibits nociceptive activity via an inhibitory interneuron. THE ONTOGENY OF ANALGESIA INDUCED BY INTRASPINAL INJECTION OF SEROTONERGIC DRUGS. M. N. Schwarz and G.A. Barr. Biopsychology Doctoral Program, Dept. of Psychology, Hunter College, CUNY, New York, N.Y. 10021

Recent evidence has shown that descending bulbospinal monoamine pathways are involved in pain modulation. Intrathecal application of noradrenergic compounds in infant rats attenuates the withdrawal response to a painful mechanical stimulus to a greater extent than to a noxious thermal stimulus. Therefore, norepinephrine receptors in the spinal cord are functional in the modulation of specific types of pain in neonatal rat pups. The present study examines the ability of serotonergic drugs to produce analgesia in young infant rat pups, with attention paid to stimulus modality and to somatotopic localization of the analgesia. Intraspinal injection of serotonin in 4 and 10 day old rat pups was tested using a thermal or a mechanical stimulus applied to the forepaws, hindpaws or tail. Serotonin produced analgesia at both ages that was more pronounced in the hindpaws and tail than the forepaws and against the thermal stimulus more than the mechanical stimulus. These results demonstrate the presence of functional spinal cord 5-HT receptors in infant rats and provide evidence for the differential modulation of thermal and mechanical pain in the developing animal.

43.8

SELECTIVE 5HT₃ AGONIST INHIBITS EXCITATORY AMINO ACID (EAA)-EVOKED EXCITATION IN RAT SPINAL PROJECTION NEURONS. Sizheng Lei and George Wilcox. Department of Pharmacology, University of Minnesota, Minneapolis, MN 55455, U.S.A.

The function of serotonin in mammalian spinal cord has been controversial. At least part of the effect mediated by spinal 5HT receptors is believed to be involved in spinal antinociception, possibly through only certain subtypes of 5-HT receptors including the recently identified 5-HT₃ receptor. The action of the selective 5TH₃ agonist, 2-methyl serotonin (2-me-5-HT), on EAA-induced excitation of lumbar dorsal horn projection neurons in adult rats was examined.

Extracellular recordings were conducted in situ in the lumbar spinal cord of urethane-anesthetized male rats. Tungsten microelectrodes $(1M\Omega)$ glued to seven barreled borosilicate micropipettes were used to record from single spinal neurons and to apply various drugs iontophoretically. All neurons tested were dorsal horn projection neurons and the cutaneous receptive field for each neuron was characterized by mechanical stimuli. NMDA was used as a selective NMDA receptor agonist and α-amino-3-hydroxy-5-methyl-4-methyl-4-isoxasole-proprionic acid HBr (AMPA) was used as an AMPA receptor agonist. One or both of these selective excitatory amino acid agonists excited the cells studied here when applied iontophoretically.

Iontophoretic application of the 5-HT3 agonist produced profound current-related inhibition of the neuronal excitation produced by NMDA in all twenty spinal projection neurons tested. In addition, NMDA-induced excitation was also blocked by projection neurons tested. In addition, NMDA-induced excitation was also blocked by the selective GABA, receptor agonist, musicmol. Both the 5-HT'3 antagonist, zacopride, and the GABA, antagonist, bicuculline, reversed the inhibition of 2-me-5-HT in a dose-dependent manner. A similar but less consistent inhibitory effect was seen when AMPA was used as the excitant. In conclusion, this study has demonstrated that spinal 5-HT3 receptors produce inhibition of nociceptive neurotransmission in spinal cord dorsal horn, perhaps by causing release of the inhibitory neurotransmitter, GABA. (Supported by USPHS grants DA-01933 and DA-04274).

43.10

"5HT-ONLY" CELLS DO NOT CONSTITUTE A SPECIFICALLY ANTINOCICEPTIVE CATEGORY OF SEROTONERGIC NEURON.

W. Wu and M. Wessendorf. Dept. Cell Biology and Neuroanatomy,
Univ. Minnesota, Minneapolis, MN 55455

Univ. Minnesota, Minneapolis, MN 55455

Although fibers containing serotonin (5HT) are common in the superficial dorsal horn, few of these also stain for substance P (SP) or thyrotropin-releasing hormone (TRH). This suggests that 5HT cells containing neither SP nor TRH ("5HT-only cells") might constitute a specifically antinociceptive subpopulation of 5HT cells. The present study examined whether coexistence of SP or TRH was less common among the 5HT fibers apposing a projective group of cells (spito-

specifically antinociceptive subpopulation of 5HT ceils. The present study examined whether coexistence of SP or TRH was less common among the 5HT fibers apposing a nociceptive group of cells (psinothalamic tract neurons: STT cells) than among a non-nociceptive group of cells (post-synaptic dorsal column cells: PSDC cells).

Injections of Fluoro-Gold were made into either the thalamus or the dorsal column nuclei of rats. After perfusion, tissue was immunofluorescently stained either for 5HT and SP, or for 5HT and pre-pro-TRH 160-169 (ppT: a marker peptide for TRH). Sections were examined for immunoreactive fibers apposing retrogradely labeled cell profiles. A minimum of 50 cell profiles were examined in each case.

Among 5HT-stained fibers apposing PSDC cell profiles, only about 19% were also stained for SP and none was stained for ppT. Among 5HT-stained fibers apposing STT cell profiles, only 1% were also stained for SP but 15% were stained for ppT. This difference was statistically significant (pc.005; chi-square test).

The apposition of numerous "5HT-only" fibers to PSDC neurons suggests that "5HT-only" neurons are not specifically antinociceptive. In addition, the apposition of "5HT-ppT" fibers to STT neurons suggests some "5HT+ppT" cells might have antinociceptive actions.

Oklahoma, Oklahoma City, OK 73190 and Dept. of Physiology,
Univ. of North Carolina, Chapel Hill, NC 27599.
Until recently, the NRM has been considered to be
composed primarily of serotonin-containing neurons.
However, it is now recognized that the NRM is a
heterogeneous population of cells. The objective of this
study was to re-examine the serotonergic raphespinal
projection to the lumbar spinal cord. The retrograde
tracer apo-horseradish peroxidase-wheatgerm agglutinin
conjugated to colloidal gold (apo-HRP-WGA*gold) was used
in combination with serotonin immunohistochemistry. in combination with serotonin immunohistochemistry.
Visualization of the apo-HRP-WGA*gold and serotonin
immunoreactivity was achieved using silver precipitation immunoreactivity was achieved using silver precipitation and avidin biotin techniques, respectively. Following microinjections (8-10µ1) of apo-HRP-WGA*gold into the lumbar spinal cord of adult, male Sprague Dawley rats, large numbers of retrogradely labeled neurons were identified in the pons and medulla. To date (n=4), regional distributions of retrogradely labeled neurons also demonstrating serotonin-like immunoreactivity have been noted throughout the rostral-caudal and medial-lateral extent of the NRM. Few serotonergic raphespinal neurons have been identified in the rostral NRM; in the caudal NRM, double-labeled neurons extend into the lateral aspects of the NRM. Supported by DA05341 and NS16433.

AN ANALYSIS OF A REAL ANTINOCICEPTIVE NEURONAL SYSTEM IN THE ROSTRAL VENTROMEDIAL MEDULLA OF ANAESTETIZED RATS. S. McGaraughty* and S. Reinis, Department of Psychology, University of Waterloo, Waterloo, ON., Canada.

The functional interactions of cells in the rostral ventromedial medulla (RVM) were investigated using a computer-assisted method developed in our laboratory. This technique allows the simultaneous recording of activity of small groups of neurons with the calculation of their interactions. The effects of noxious heat applied to the end of a rat's tail on the activity of individual neurons and groups of neurons were analyzed with rats under Ketamine-Rompun anesthesia. Auto-, mass- and cross-correlograms were calculated, and showed existence of three types of systems which were active both in control and stimulated condition. All systems initially responded to a common input. Then, in some cellular systems, there was an abundance of short interspike intervals, less than 10 ms long. The second type of systems inhibited themselves, after the initial input, for about 30 - 40 ms, and then resumed firing, while yet others showed neither an inhibition nor preference for any duration of interspike intervals. We assume that of the three classes of RVM cells, it is the inhibited type that is involved in the control of analgesia; the higher is the number of inhibited cell systems in response to pain the more analgesia is produced.

43.15

LACK OF INHIBITION OF A NOCICEPTIVE REFLEX BY HETERO-SEGMENTAL NOXIOUS INPUT: BEHAVIOR CORRELATES WITH ACTIVITY IN RVM NEURONS. M.M. Morgan, M.M. Heinricher and H.L. Fields. Depts. of Neurology and Physiology, Univ. of California, San Francisco, CA 94143.

Two neuron populations in the rostral ventromedial medulla (RVM) show abrupt changes in activity immediately preceding nocifensive reflexes. These changes consist of a burst (on-cell) or a pause (off-cell), and appear to play an important role in modulation of nociception. Since sustained noxious tail heat has been shown to inhibit nociception, the effect of such a stimulus on RVM neurons was assessed in lightly-anesthetized rats.

Male Sprague-Dawley rats were anesthetized with pentobarbital for surgical preparation and then maintained on a continuous infusion of methonexital for extracellular unit recording in RVM. The latency to elicit a paw-withdrawal reflex to noxious heat was determined before, during, and after submersion of the distal half of the tail in 40 or 50 °C water for 5 min. Such stimulation produced a prolonged on-cell burst and off-cell pause. The occasional change in cell activity during stimulation appeared to constitute part of the cycling typical of these neurons (such changes were more common with 40 °C water). At no time was the paw-withdrawal reflex inhibited by tail heating.

These findings demonstrate that RVM neurons respond in a consistent manner to **sustained** as well as brief noxious stimuli. In addition, the pattern of cell activity is consistent with the observed preservation of the paw-

withdrawal in the presence of a continuing heterosegmental noxious stimulus. Supported by PHS grants DA01949, NS07265, and a Pain Research Grant from the Bristol-Myers Squibb Company.

INCREASED RESPONSIVENESS OF DORSAL HORN NEURONS DURING LIDOCAINE BLOCKADE OF THE DORSOLATERAL FUNICULUS. N.A. Bernau, D.A. Simone, J.A. Atkinson*, and L.M. Pubols. R.S. Dow Neurological Sciences Institute, Good Samaritan Hospital & Medical Center, Portland, OR 97209.

The responses of cat lumbar dorsal horn neurons to mechanical stimulation of skin and electrical stimulation of the tibial nerve were examined before and after lidocaine injection into the ipsilateral T dorsolateral funiculus (DLF). Cells that responded maximally to innocuous mechanical stimuli (LT) were unaffected by lidocaine blockade. However, cells that were activated by noxious, but not by innocuous, mechanical stimuli (HT), and those that responded in a graded fashion to both types of stimuli (MR) showed enhancement of responding to stimulation of tibial nerve A-delta and C fibers during lidocaine blockade of the DLF. A majority of these cells also showed increased sensitivity to natural stimuli during blockade, and 2 of 4 HT studied acquired responsiveness to innocuous stimuli. The white matter region common to all lidocaine injections causing a C-fiber response greater than twice the pre-injection level was located ventromedially in the DLF, adjacent to the grey matter. A lesion of this region also caused a large increase in C-fiber responding.

These experiments have confirmed the existence of a powerful, tonic, descending inhibitory projection in the ipsilateral DLF, which acts selectively on cells with nociceptive inputs. (Support: NIH NS19523)

MORPHINE APPLIED IONTOPHORETICALLY DEPRESSES ACTIVITY OF CELLS IN ROSTRAL VENTROMEDIAL MEDULLA OF LIGHTLY-ANESTHETIZED RATS. M.M. Heinricher, M.M. Morgan and H.L. Fields

Depts. of Neurology and Physiology, Univ. Calif., San Francisco, CA 94143 The rostral ventromedial medulla (RVM) is involved in opioid-sensitive mechanisms that modulate nociceptive transmission. Two classes of putative nociceptive modulatory neurons have been identified in the RVM, and morphine, when given in doses sufficient to block the tail-flick response (TF), invariably has the same effect on all neurons of a given class: off-cells (which are likely to exert a net suppressive effect on nociceptive transmission) show an increase in spontaneous activity and an elimination of the TF-related pause, whereas the activity of on-cells (which appear to have a facilitating effect on nociception) is suppressed. These effects are seen whether morphine is given systemically or by microinjection into the periaqueductal gray. The present experiments use single unit recording and iontophoretic techniques to determine the direct effects of opiates on activity of on- and

Rats are maintained in a lightly-anesthetized state by a continuous infusion of methohexital. On-cell firing can be depressed by iontophoretic application of morphine: spontaneous, TF-related, and glutamate-evoked activity are substantially reduced. These effects can be reversed by naloxone (given systemically or by iontophoresis). In contrast, we have not to date observed an effect of iontophoretically-applied morphine on the firing of off-cells.

These findings indicate that morphine can have a direct action upon the activity of on-cells, and underscore the importance of the on-cell as a site of access for opiate action in the RVM.

DISTRIBUTION OF GABA-IMMUNOREACTIVE SYNAPSES ONTO NOCICEPTION-MODULATING NEURONS IN THE ROSTRAL VENTROMEDIAL MEDULLA. K. Skinner, P. Mason, A.I. Basbaum and H.L Fields. Depts. of Neurology, Anatomy and Physiology, UCSF (94143) and the

Institute on Aging, Mount Zion Hospital, San Francisco, CA. (94115).

The rostral ventromedial medulla (RVM) makes an important contribution to opioid antinociception. One class of RVM cells, the off-cells, is inhibited by noxious stimulation and excited by opiate administration. Off-cells are hypothesized to inhibit nociceptive transmission in the dorsal horn. To examine the anatomical basis for the hypothesis that opioid excitation of off-cells results from removal of a GABA-mediated inhibition, off-cells in the nucleus raphe magnus were intracellularly characterized and filled with horseradish peroxidase in the lightly anesthetized cat. The labeled cells were reconstructed from vibratome sections and prepared for electron microscopy. The soma and fourteen regions of the dendritic arbor, at defined distances from the soma center, were then immunolabeled for GABA using a postembedding immunogold method. Although off-cell some and proximal dendrites receive an extensive synaptic input, few GABA-labeled boutons are found within 50um of the soma. A GABAergic synaptic input onto distal dendrites is, however, more common. Both the number of boutons and the percentage of synaptic membrane contacted by the labeled boutons increase distally. The GABA synapses onto labeled off-cells are all symmetrical and contain predominantly round vesicles and often dense core vesicles. These results demonstrate an anatomical substrate for the GABAergic control of offcells, consistent with the hypothesis that the opioid excitation of off-cells is mediated by an opioid inhibition of this GABAergic inhibitory regulation.

TAIL-FLICK PARAMETERS CAN DETERMINE WHETHER NALTREXONE DECREASES OR INCREASES FLICK LATENCIES FOLLOWING FOOTSHOCK STRESS. J.T. Cannon, E.W. Walsh*, R.F. Henry* and E.A. Bolan*. Depts. of Psychology and Chemistry, University of Scranton, Scranton, PA 18510-2192.

D'Amour & Smith's (1941) seminal work on the tail-flick response to heating involved average baseline latencies in the 4.5-5.0 sec range. A survey of recent investigations found that test stimuli differed sufficiently across laboratories to produce average baseline latencies ranging from approximately 1.5 to 10.0 sec. Such variations in test parameters may alter the tail-flick, potentially changing its neural substrates and/or its sensitivity to antinociceptive mechanisms (e.g., Jensen & Yaksh, 1986; Ness & Gebhart, 1986). We examined whether tail-flick test parameters could alter the effects of naltrexone on elevations in latencies produced by footshock stress. Forty-eight male albino rats (Holtzman) were individually housed with food and water freely available on a 12/12 hour light/dark cycle. Testing occurred during the dark phase of this cycle. Animals (8/group) were assigned to either footshock stress or no stress conditions that were paired with one of 3 sets of tail-flick test parameters: 1) 3.5 sec baseline, 7.0 sec cutoff; 2) 4.5 sec baseline, 7.0 sec cutoff; or 3) 4.5 sec baseline, 7.0 sec cutoff; 6 or 3 min. Tail-flick latencies were measured at 1 min intervals: 5 pre- and 12 post-footshock. Ten min prior to pre-shock testing the animals were injected with either naltrexone (5 mg/kg/ml) or an equal volume of saline. Naltrexone significantly reduced post-shock tail-flick latencies in the 3.5 sec baseline condition; no significant Trial x Drug interaction.

These data demonstrate that tail-flick test parameters can modify the direction and time-course of naltrexone's effect on post-shock tail-flick latencies. Such dynamics may be a source of some conflicting observations across laboratories. These and other findings (see above) also suggest tha

DEVELOPMENT AND REVERSAL OF HYPOALGESIC RESPONSES IN RHESUS MONKEYS. A. L. Beggs. Department of Psychology, University of Southwestern LA, Lafayette, LA 70504.

Two experiments were conducted to examine the effects of inescapable shock on foot withdrawal responses to radiant heat. In the first experiment, latency measures of left foot withdrawal to radiant heat indicated that inescapable shock to the right leg increased reaction Hescapanise shock to the High leg increased search time compared to no-shock control subjects ($\mathbf{p} < .05$). Additionally, reaction times for all subjects decreased over stimulus presentations ($\mathbf{p} < .01$). Assuming that the group differences observed in the first experiment were mediated by endogenous opiates, a second experiment was conducted to compare foot withdrawal responses of naloxone treated subjects to saline controls which had also received right leg shocks. Analysis of the latency data revealed group differences with the naloxone treated subjects demonstrating faster reaction times treated subjects demonstrating faster reaction times (p < .01). Again, reaction times decreased over trials for both groups (p < .01). The results of this study indicate that shock activated an opioid system sensitive to naloxone antagonism and suggest neural mediation of reaction to radiant heat over trials.

LATENT INHIBITION AND OVERSHADOWING OF A CONDITIONED ANTINOCICEPTIVE RESPONSE IN THE SPINALIZED RAT. J.A ANTINOCICEPTIVE RESPONSE IN THE SPINALIZED RAT. J.A. Salinas* P.A. Illich and J.W. Grau. Dept. of Psychology, Texas A&M University, College Station, TX 77843.

We have previously shown that a conditioned antinociception can be established and extinguished in the

ception can be established and extinguished in the spinalized rat (Grau et al., <u>Beh. Neurosci.</u>, <u>104</u>, 489, 1990). The present study explored whether this condictioned response would exhibit latent inhibition and overshadowing. In both experiments testing was conducted 24 hr after subjects received a spinal transection at T2. Mild shock to the left or right paw served as the conditioned stimulus (CS). The unconditioned stimulus (US) was an intense tail-shock. Antinociception during the CS was assessed with the tail-flick test 1 hr after training. To show latent inhibition subjects were preexposed to either the CS+, CS- or nothing (n=10). All of the subjects then received differential conditioning in which one CS (the CS+) was paired with the US while the other was presented alone (the CS-). We found that preexposure to either the CS+ or CS- attenuated classical conditioning. To test for overshadowing subjects received either: 1) a mild CS paired with the US; 2) the mild CS plus a strong CS paired with the US; or 3) the mild CS and US unpaired. Only subjects in the first training condition exhibited conditioned antinociception. Supported by BNS 881981 to J.W.G.

EFFECT OF IT NALTREXONE ON INESCAPABLE TAIL SHOCK ANALGESIA. J. Grisel, L. Watkins, L. Yuva, S. Ryan, & S. Maier. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

Some forms of stress induced analgesia are mediated by endogenous opiates. Increasing numbers of inescapable tail shocks produce 3 successive analgesic peaks as measured by the tailflick test. IP naltrexone (7mg/kg) blocks the first & third analgesias, induced by 1-5 & 40-80 1.6 mA shocks respectively. Also, rats given 100 inescapable tail shocks demonstrate naltrexone-blockable (7mg/kg) analgesia when later exposed to 5 mild grid shocks (8 m A).

Experiment I tested intrathecal (IT) naltrexone on analgesia induced by inescapable tail shock. Male Holtzman rats (400-500 g), implanted with lumbar IT catheters, were randomly divided into 2 groups receiving either naltrexone (2.0 μg in 0.5 μl; n=7) or 0.5 ml saline (n=8). All rats received 80 0.5 sec 1.6 m A tail shocks; tail flick latencies were recorded prior to (baseline), & after 1, 5, 10, 20, 40, 60, & 80 shocks. IT naltrexone or vehicle was delivered before shock, & after 10 & 40 shocks, implicating spinal opiate mediation.

Experiment II used parallel methods to investigate IT naltrexone on reinstatement analgesia. Rats, implanted with lumbar IT catheters, received restraint (n=8) or 80 5 sec 1.0 m A tail shocks (n=24). Twenty-four hr later, previously shocked rats were given either no injection, IT saline (0.5 μl) or IT naltrexone (2.0 μg in 0.5 μl; n=8 in all groups), & all rats were exposed to 5 0.8 m A grid shocks, in a plexiglass chamber. Naltrexone significantly blocked analgesia compared to saline-injected & non-injected shock groups, and produced latencies equal to the previously non-shocked group. These data indicate a spinal opiates clearly play a part in the analgesias induced by inescapable tail shock, continuing studies attempt to test the effect of κ, δ & μ specific opiate antagonists on the 3 peaks of analgesia produced during acute tail

inescapable tail shock, continuing studies attempt to test the effect of κ , δ & μ specific opiate antagonists on the 3 peaks of analgesia produced during acute tail shock, as well as the analgesia observed during reinstatement. BNS-8808840.

ADRENALECTOMY AND DEXAMETHASONE ATTENUATE MILD SHOCK-INDUCED ANALCESIA. M.K. Biles, J.M. Barter* and J.W. Crau. Department of Psychology, Texas A&M University, College Station, TX 77843.

Prior work suggests that the opioid analgesia Prior work suggests that the opioid analgesia observed in rats after an extended exposure (e.g. 20 min or more) to intermittent shock is "hormonal" in nature because it is blocked by adrenalectomy and dexamethasone. The opioid analgesia observed after less severe shock schedules is thought to be "neural" in nature since it is not affected by manipulations that disrupt the pituitary-adrenal axis (Terman, G.W. et al., Science, 226, 1270, 1984). We have previously shown that exposure to very mild shock (3, 0.75-s, 1.0 mA tail-shocks) can elicit both a transient poponoid and long-lasting opioid analgesia on the 1.0 mA taii-shocks) can elicit both a transient nonopioid and long-lasting opioid analgesia on the taii-flick test (Grau, J.W., <u>Beh. Neurosci., 101, 272, 1987)</u>. It is currently unclear whether the pituitary-adrenal axis plays a role in this analgesia. We addressed this issue by testing the impact of adrenalectomy and dexamethasone (1 mg/kg administered 2 hrs before testing) on mild shock-induced analgesia. We found that both manipulations attenuated, but did not eliminate, the analgesia. The results suggest that the pituitary-adrenal axis also plays a role in the production of mild shock-induced analgesia. Supported by DA-05846-01 to J.W.G.

THE IMPACT OF SCOPOLAMINE ON CONDITIONED AND SHOCK-INDUCED ANALGESIA. P.S. Chen*, P.A. Illich, M.W. Meagher and J.W. Grau. Department of Psychology, Texas A&M University, College Station, TX 77843.

Rats exposed to long shocks exhibit a nonopioid analgesia on the tail-flick test which is eliminated by spinal transection but not decerebration. It is cur rently unclear whether cholinergic sytems play a role in this analgesia. We addressed this issue by testing the impact of the cholinergic antagonist scopolamine (1 mg/kg) on the analgesia observed after three 25 s, 1.0 mA, tail-shocks. Prior to shock, scopolamine treated subjects exhibited a significant hyperalgesia. The drug did not attenuate the analgesia observed after shock. In fact, when we controlled for the impact of scopolamine on baseline levels of pain reactivity, it actually potentiated shock-induced analgesia. Methylscopolamine, which does not cross the blood-brain barrier, had no effect. We also tested whether cholinergic systems play a role in conditioned analgesia. One stimulus (the CS+) was paired with shock while the other was presented alone (CS-). Each subject received 6 presentations of each stimulus spaced over 2 hr. Testing was conducted 24 hr later. We found that saline treated subjects were analgesic during the CS+ relative to the CS-. This conditioned analgesia was blocked by scopolamine but not methylscopolamine. Supported by BNS 881981 to J.W.C.

VAGAL STIMULATION ALTERS THE ACTIVITY OF NEURONS IN THE ROSTROVENTRAL MEDULLA (RVM) WHICH RESPOND TO NOXIOUS STIMULI. C. L. Thurston and A. Randich, Department of Psychology, The University of Iowa, Iowa City, IA 52242. Electrical stimulation of the vagus produces antinociception which is dependent on the RVM. The

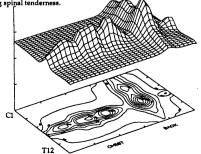

present studies examined the effects of vagal stimulation on RVM neurons which respond to noxious stimuli. Rats were anesthetized with pentobarbital sodium and prepared for electrophysiological recordings of RVM neurons and for electrical stimulation of the left cervical vagus. Rats were maintained in a light plane of anesthesia with methohexital to enable classification of neurons as ON, OFF, or NEUTRAL cells based on their response to tailflick trials. Vagal stimulation appears to have no effect on NEUTRAL cells. However, vagal stimulation excited 14/19 ON cells, inhibited 1, had variable effects on 1, and had no effect on 3. In contrast, vagal stimulation inhibited 4/7 OFF cells, excited 1, and had no effect on 2. These data are contradictory to present knowledge of vagal stimulation produced antinociception and the proposed role of ON and OFF cells in antinociception derived from the NRM, since excitation of OFF cells and inhibition of ON cells would be predicted to support antinociception. Supported by NIH grants NS24958 and HI.07121.

CHARACTERIZATION OF THE VISCEROMOTOR RESPONSE TO COLORECTAL DISTENSION IN THE HALOTHANE LIGHTLY-ANESTHETIZED RAT. T.J. Ness and G.F. Gebhart. Departments Pharmacology and Anesthesia, University of Iowa, Iowa City, Iowa, 52242.

Responses to colorectal distension have been demonstrated to be useful in studying visceral pain when performed in awake, unrestrained rats. The present study was undertaken to validate the use of this model in the halothane lightly-anesthetized rat the use of this model in the halothane lightly-anesthetized rat to facilitate parametric evaluations of visceral and cutaneous pain. Male Sprague Dawley rats were initially deeply anesthetized with 5% halothane and 95% 0_2 ; a tracheotomy was performed and animals were maintained in the lightly-anesthetized state with constant inhalation of 0.5-1.5% halothane and 0_2 . Vigorous flexion reflexes were present in this state. A reliable visceromotor response was obtained with research colorrectly distraction (80 mm/s; 10e) at 2 min intervals. repeated colorectal distension (80 mmHg; 10s) at 2 min intervals Abdominal constriction was assessed using EMG Graded EMG responses to graded intensities of for 2 hrs. recordings. distension were also demonstrated. There was an obvious threshold for the response using a phasic stimulus. Electrical stimulation in the midbrain produced a reliable and reproducible inhibition of the response at intensities as low as 40 µA. The use of this model in the lightly-anesthetized animal will allow comparative studies of descending modulation of visceral and cutaneous pain.

THE HYPERALGESIA OF MYOCARDIAL INFARCTION: A PROSPECTIVE STUDY. G. A. C. Jones' and R. J. Milne. Dept. of Physiol., Univ. of Aucklard, New Zealand. Hyperalgesia (musculoskeletal tenderness) of cardiac origin, potentially dangerously misleading in the evaluation of chest pain, is known to occur but has not been systematically documented. As well as an important clinical question viscerosomatic hyperalgesia paralleling somatosomatic hyperalgesia is an important neurophysiological question. Hence this study. All cases admitted to the 5 bed coronary care unit of a general hospital over a 12 week period with 20 minutes or more of cardiac-like chest-pain were reviewed on the morning following admission. A single examiner blind to the diagnosis graded tenderness to palpation over 151 points of the cervical spine and thorax. Of the 56 cases subsequently confirmed to have infarction 52% showed hyperalgesia. The graph below shows probability of hyperalgesia on the z axis, Cl-712 levels along the y axis and location around the chest wall on the x axis. Hyperalgesia was commonest over the thoracic spine at segments 13, T4 and T5 and to a lesser extent over the corresponding costosternal joints and anterolateral chest-wall maximal on the left. 40% of infarcts were associated with sex-salled "costochondritis", 95% of these also having spinal tenderness.

SPINAL NEUROTRANSMITTERS INVOLVED IN FACILITATION OF THE NOCICEPTIVE TAIL FLICK REFLEX BY VAGAL AFFERENT STIMULATION. K. Ren, A. Randich and G.F. Gebhart.

Departments of Pharmacology and Psychology, The University of Iowa, Iowa City, IA 52242.

We have previously demonstrated that the nociceptive

tail flick (TF) reflex in the rat is facilitated at low and inhibited at high intensities of vagal afferent stimulation (VAS) (Brain Res. 446:285,1988). This experiment was conducted to characterize the spinal neurotransmitter(s) involved in the facilitation of the TF reflex produced by VAS. Rats were liganesthetized with pentobarbital (5-10 mg/kg/hr iv). lightly central end of the cut vagus nerve was electrically stimulated (2.0 ms, 20 Hz and 2-15 μ A). VAS at a mean intensity of 7 \pm 1 μ A (n=39) facilitated the TF reflex independent of the baseline TF latency. Intrathecal administration of pharmacologic receptor antagonists into the subarachnoid space of the lumbar enlargement indicated that the facilitation of the TF reflex by VAS was antagonized by methysergide, naloxone or nor-BNI, but not by the 5-HT₂ and 5-HT₃ receptor antagonists LY53857 and ICS 205-930, the delta opioid receptor antagonist naltrindole, or the adrenoceptor antagonists yohimbine or prazosin. These results suggest that subtypes of spinal 5-HT and opioid, but not noradrenergic receptors are activated by a group of low threshold cervical vagal afferents to facilitate spinal nociceptive processing.

44.10

EFFECT OF LASER ACUPUNCTURE ON ANIMAL PAIN THRESHOLD AND STUDY OF ITS MECHANISMS. C. Yu, K. Zhang*, G. Lu* and O. Wang*, College of Veterinary Medicine, Beijing Agricultural University, Beijing, P. R. China.

In order to investigated the changes of the animal pain threshold and the

action of endorphin, serotonin etc., in the process of irradiating the acupoints of animals with laser, from 1977-1985, the animals of different kinds-50 rats, 51 dogs, 463 rabbits, 15 pigs, 68 goats and 73 sheep-were divided into experimental groups and control groups. Experimental groups were irradiated and then injected the drugs D-phenylalanine, D-leucine etc. or irradiated and at the same time injected the drugs L-tryptophan, insulin, acetylcholine etc. The control groups were only irradiated or only injected the drugs aforementioned or normal saline. The changes of animal pain threshold were observed by using WQ-9D SURVEYING INSTRUMENT OF PAIN THRESHOLD with the penetration of potassium ion (K+) to be measured. The result in the present study was the average of three measured values of the pain threshold. The summary of the results are as follows:
(1). The pain threshold in rabbits, dogs, pigs, sheep and goats significantly increased (p<0.01) before and after irradiation of laser. The pain threshold significantly increased (p<0.05) in irradiation group of laser than in traditional acupuncture group in rabbits, and in irradiation group, the effect of CO₂ laser stronger than that of He-Ne laser in dogs. (2). The increase of pain threshold were related to endorphin, serotonin and neurotransmitter releasing from cholinergic neurons, which potentiated each other in analgesic process. (3). The increase of pain threshold were enhanced by Ltryptophan, D-phenylalanine, D-leucine, acetylcholine and insulin.

RESPONSES TO TOOTHPULP STIMULATION IN CONSCIOUS CATS: DIGASTRIC REFLEX AND PROPERTIES OF NEURONES IN THE TRIGEMINAL BRAINSTEM. D.Banks* and B.Matthews. (SPON: Brain Research Association). Dept. of Physiology, University of Bristol, England BS8 1TD.

We have investigated the digastric response to toothpulp stimulation and recorded from trigeminal brainstem neurones in lightly anaesthetised and awake, unrestrained animals. The animals were prepared under general anaesthesia (alphaxalone/ alphadolone, 18mg/kg I.M. and 5-8mg/kg/h I.V.). A connector block with a miniature socket and venous injection port was fixed to the skull over the frontal sinus. Stainless-steel wires were passed subcutaneously from the block to Ag/AgCl fillings in the right canine teeth for electrical stimulation and to the right digastric and masseter muscles for recording EMGs. A cannula from the injection port was inserted into the anterior facial vein. A small plastic block was positioned stereotaxically over a craniotomy which was sealed with silicone elastomer. The block held a miniature micromanipulator which remained in place between recording sessions. Recordings were made with Teflon-coated platinum/ iridium

As shown previously, the conscious animals showed no aversive behaviour to toothpulp stimulation over the range tested (up to 1mA, 0.1ms and 0.1Hz). The digastric reflex stimulus/ response curve in the awake and lightly anaesthetised (alphaxalone/ alphadolone, 4mg/kg, I.V.) animal had one and sometimes two notches in the range 25-100µA. Under similar conditions the responses to toothpulp stimuli recorded from neurones in the trigeminal brainstem nuclei (spinal, pars oralis) also showed a decrease in excitability corresponding to the notches in the digastric stimulus/ response curve. The inhibition of neuronal activity applied equally to the short (-3ms) and long (-25ms) latency discharges. The results indicate that toothpulp afferents produce inhibitory as well as excitatory effects on neurones in the trigeminal brainstem and on digastric motoneurones.

TAIL FLICK LATENCY IN LACTATING RATS. P. Pacheco, R. Chirino*, M.Martinez-Gómez and F.Mena*.Instituto Investigaciones biomédicas-UNAM, México 04510, DF.; CIRA-UAT-CINVESTAV, Panotla, Tlax. México; CIB-U. Veracruzana, Xalapa, Ver. México.

During suckling the lactating mother rat exhibits immobility and relaxated behavior, synchronous EEG, increased autonomic activity, and changes in peripheral cathecolamines levels. This suggests that sensitivity to nociceptive stimuli may be altered during lactation. We analyzed the tail flick latency (TFL) evoked by noxious heating of the tail before, during and after suckling of lactating rats. Before each test the pups were separated from the mother 6 or 12 h. RESULTS: a) During lactation TFLs progressively decreased as compared to those measured in the same rats before pregnancy. At weaning the TFLs values were increased. b) Mothers separated 12 h from their pups, showed higher TFLs than mothers separated 6 h. c) TFLs were significantly decreased during a 15-30 min suckling period. Following suckling TFLs gradually returned to previous values. d) The reduction in TFLs during suckling was significantly higher at mid lactation. We conclude that, lactating rats as compared to virgin rats show hyperalgesia, which may be due to suckling by the pups. Such effect of suckling may blocks central inhibitory influences on nociceptive input. Supported by: SEP C89-01-0136 and SEP C90 (P.P.);

AGING-RELATED DECREMENTS IN THE ANALGESIC EFFECT OF VAGINO-CERVICAL STIMULATION (VS) IN RATS. J.L. Steinman, S. Chinapen*, K. Repola* and B.R. Komisaruk. Institute of Animal Behavior, Rutgers-The State University, Newark, NJ 07102.

CONACYT 90 (M.M-G.).

The present study compared the magnitude of VS-produced analgesia in sexually mature rats (age 8-9 mos.) with that in substantially older rats (age >16 mos).

>16 mos).

After determination of pre-VS measurements of tail flick latency (TFL) to radiant heat and vocalization threshold (VOCT) to electrical shock of the tail, VS was applied as a continuous force against the cervix with a calibrated syringe assembly (5-mm probe); pain thresholds were then determined during VS. All rats were ovariectomized at least one week prior to testing.

TFL and VOCT were significantly elevated during VS (100g) in the 8-9 mo. group but not in the >16 mo. group. At 300g VS, TFL was significantly elevated during VS in both age groups, but VOCT was significantly elevated only in the younger group. These findings indicate that while VS is capable of producing analgesia in both age groups, the magnitude of the analgesia declines significantly with age. A more marked age-related decrement was found on the VOCT than the TFL test. (Support: NIH grants NS 22948, RR 08223 and the Charles and Johanna Busch Foundation [BRK])

CAROTID SINUS NERVE STIMULATION INHIBITS SPINOTHALAMIC AND SPINORTICULAR TRACT MEURONS. W. S. Ammons. Dept. of Physiology, Thomas Jefferson Univ. Philadelphia, PA 19107.

This study was designed to test the hypothesis that stimulation of the carotid sinus nerve inhibits activity of ascending pain pathways. Extracellular recordings were obtained from lumbosacral spinothalamic tract (STT) neurons in 5 monkeys and spinoreticular tract (SRT) neurons in 10 cats under chloralose anesthesia. A bipolar electrode was placed on the left carotid sinus nerve. Stimulation of the carotid sinus nerve (20 Hz, 0.1 ms, 7-12 V) inhibited spontaneous activity of 9/16 STT and 12/20 SRT cells. Two response patterns were observed: rapid (< 1 s) inhibition that was maintained during the 10 s stimulus period; rapid inhibition that decreased (escaped) during the stimulus period. Vagotomy attenuated or abolished inhibitory escape. Mean activity of STT neurons decreased from 14 ± 3 to a minimum level of 2+1 spikes/s 3 s into the stimulus period. Activity of SRT cells was reduced from 6 ± 2 to 2 ± 1 spikes/s. Responses to stimulation of A delta and C-fibers in the left sural nerve were inhibited by conditioning the carotid sinus nerve (50 - 200 ms trains). On a percentage basis carotid sinus nerve stimulation reduced responses to C-fiber input significantly more than responses to A delta input. Responses to pinch of skin or skin and muscle of the hindlimb were inhibited by an average of 89%. The results indicate that afferents in the carotid sinus nerve, perhaps baroreceptors, exert antinociceptive effects at the spinal level.

CHEMICAL SENSES: CENTRAL PATHWAYS I

LOCALIZATION OF DOPAMINE RECEPTOR SUBTYPES IN THE OLFACTORY BULB: [³H]SPIPERONE (D2) BINDING IN THE GLOMERULAR AND NERVE LAYERS. W.T. Nickell. A.B. Norman. L.M. Wyatt. and M.T. Shipley. University of Cincinnati College of Medicine, Cincinnati, Ohio 45267.

There is a substantial population of dopaminergic neurons located in the glomerular layer of the olfactory bulb. Although the structure and development of these neurons has been extensively studied, their cellular targets and physiological function have not been determined. The localization of DA receptor subtypes might provide clues to the function of the dopaminergic neurons; hence, we determined the quantity and localization of D1 and D2 dopamine receptor subtypes using [3H]SCH23390 and [3H]spiperone, respectively.

Saturation studies in homogenates of olfactory bulb demonstrated barely detectable levels of D1 binding and a relatively high level of [3H]spiperone binding (B_{max} = 5.9±0.6 pmol/g tissue). All assays included ketanserin (40 nM) to preclude binding to 5-HT2 receptors. The location of [3H]spiperone binding in the bulb was determined by autoradiography. As expected there was significant [3H]spiperone binding in the glomerular layer. Unexpectedly, however, there was also a high level of specific binding of [3H]spiperone in the olfactory nerve layer.

Spiperone binding in the nerve layer suggests that olfactory nerve terminals in the glomeruli may be postsynaptic to DA neurons. This hypothesis would provide an explanation for the loss of DA from the glomerular layer following lesion of the olfactory nerve. Lesion of the nerve would then result in loss of the synaptic targets of the DA neurons, thus explaining the loss of DA from the glomerular layer following lesion of the olfactory nerve. Experiments to test this hypothesis are in progress

Supported by NIDCD DC00347 and DAMD17-86-C-6005.

EXPRESSION OF CALCIUM BINDING PROTEINS IN THE MAIN OLFACTORY BULB DIFFERS AMONG SPECIES. M.R. Diño*, and E. Mugnaini. Lab. of Neuromorphology, Univ. of Connecticut, Storrs, CT, 06269-4154.

Calcium binding proteins have been used as cell population markers in numerous studies of the CNS. In this investigation we have compared neuron immunostaining with antisera to CaBP 28K and PEP-19 in the main olfactory bulb of rat, guinea pig and cat. Antisera (gift of S. Christakos and J.I. Morgan) were characterized previously. The CaBP 28k antiserum did not cross-react with mammalian CaBP 29k in Western blots. In rat and cat, PEP-19 immunostaining was similar and very dense. It revealed periglomerular cells, granule cells, and superficial and deep short axon cells. In guinea pig, the same types of cells were immunopositive, but only granule cells in the superficial half of the internal granular layer and deep short axon cells were densely stained; the overall staining was moderate. In rat and guinea pig, CaBP immunostaining was similarlt revealed perigiomerular cells and a few deep short axon cells. In cat, all types of neurons except the mitral and tufted cells were stained, but the most densely immunoreactive cells were superficial and deep short axon cells, and, particularly, numerous short axon cells in EPL. Thus, the distribution of both calcium binding proteins vary in these species, with CaBP being more variable than PEP-19. This indicates that neurospecific gene expression is not regulated in a conserved manner . These differences reflect species variations in intracellular signal transduction pathways that may ultimately shed light on the biochemical functions of these proteins. (Supported by PHS Grant NS 09904).

CONVERGENCE OF PRIMARY OLFACTORY AXONS IN RAINBOW TROUT. D.R. Riddle and B. Oakley. Dept. Biology, Univ. of Michigan, Ann Arbor, MI 48104.

To evaluate convergence in the primary olfactory projection of rainbow trout, we labeled the olfactory receptor neurons terminating in small regions of the olfactory bulb by injecting fluorescently tagged latex beads into the glomerular layer of each bulb in 9 trout. In 7 of the fish each bulb was injected at one site with rhodamine beads and at another site with FITC beads. The smallest injections labeled fewer than 100 receptor cells and the largest more than 20,000. Shifting the injection site in the bulb failed to systematically alter which of 12-16 lamellae of the olfactory rosette were best labeled. On each lamella, retrogradely labeled receptor neurons were present and widely distributed, regardless of the size or site of the bulbar injection. Labeled axons were also widely dispersed in the olfactory nerve. Even with maximal separation, double injections in the bulb produced extensively overlapping distributions of labeled receptor neurons in the mucosa. These results provide direct evidence that the olfactory axons that terminate at a given site in the bulb arise from widely dispersed olfactory receptor neurons. This evidence for a convergent projection agrees with our observation that the lectin pokeweed agglutinin (PWA) labels a defined subpopulation of olfactory receptor neurons that is widely distributed in the olfactory mucosa but makes convergent projections to restricted and predictable regions of the glomerular layer. The distribution of labeled axons in the olfactory nerve after discrete injections of fluorescent tracers in the olfactory bulb is consistent with the dispersion of PWA positive axons in the olfactory nerve. Both experiments indicate that there is significant resorting of axons at the interface between the olfactory nerve and bulb, where axons that terminate together first appear to aggregate.

DEVELOPMENTAL CHANGES IN THE OLFACTORY BULBS OF RAT PUPS FOLLOWING EARLY OLFACTORY LEARNING. C.C. Woo and M. Leon. Department of Psychobiology, University of California, Irvine, CA 92717.

Rat pups will learn to approach an artificial odor following exposure to the odor with concurrent tactile stimulation. Accompanying this

behavioral preference is an increase in ¹⁴C 2-deoxyglucose (2DG) uptake within the glomerular layer of the olfactory bulb in response to the trained odor on postnatal day (PND) 19. There also is a sensitive period during the first postnatal week for acquisition of this neurobehavioral response (Woo, C.C. and Leon, M., <u>Dev. Br. Res.</u>, 36:309, 1987).

In this study we determined the point in development when the behavioral and neural changes emerge. Pups were exposed to peppermint odor and given reinforcing tactile stimulation from PND 1 to PND 8, 11, or 14, and then tested on the following day, rather than on PND 8, 11, or 14, and then tested on the following day, rather than on PND 19, to assess their 2DG uptake and behavioral preference for that odor. Both an increase in 2DG uptake and a behavioral preference were observed beginning on PND 9. The increased 2DG uptake persists despite a subsequent increase in 2DG uptake on PND 12 followed by a continuing decrease through PND 19 by both groups.

IMMUNOHISTOCHEMICAL ORGANIZATION OF THE HUMAN OLFACTORY BULB. Robin L. Smith*¹, Harriet Baker², Kaare Kolstad*¹, Dennis D. Spencer¹ and Charles A. Greer¹. Sec. Neurosurgery and Neuroanatomy¹, Yale Univ. Sch. Med., New Haven, CT and Laboratory of Molecular Neurobiology², Cornell Univ. Med. Coll., White Plains, NY

Comparatively little is known of the cytochemical organization of the human olfactory system, despite a growing awareness of its potential involvement in disease states such as Alzheimer's. Consequently, we initiated a series of studies to characterize the organization of the human olfactory bulb (OB) using immunohistochemical probes as phenotypic markers. Thus far we have examined immunoreactivity using antibodies to olfactory marker protein (OMP), tyrosine hydroxylase (TH), 5HT, CCK, GABA, substance P, somatostatin (SST) and synaptophysin (SYP). OMP localized to the olfactory nerve and glomerular layers (GL). TH staining was predominant in the somata and processes of juxtaglomerular neurons. 5HT positive processes were evident as varicose axons in the subependymal core of the OB and in the interglomerular neuropil. CCK axons were evident in the granule cell layer (GCL) and in the interglomerular neuropil. GABA positive neurons occurred in both the GCL and GL layers. Substance P immunoreactive axons localized to the external plexiform layer (EPL) while labeled somata were present in the deep GCL. SST positive somata were seen in the anterior olfactory nucleus, deep to the GCL. Occasional SST positive axons were also found in the EPL. immunoreactivity was strongest in the intraglomerular neuropil and the EPL, consistent with the notion that synaptic density is highest in these areas. Thus far, the results are concordant with prior reports delineating the localization of these antibodies in other mammals.

45.4

LACK OF EFFECT OF VALPROIC ACID ON FOOD FINDING IN THE

MOUSE <u>T.J.</u> Hoeppner and <u>T.</u> Krug*. Dept. Neurol. Sci., Rush Medical College, Chicago, IL 60612.

We have previously shown that systemically administered valproic acid (VPA) concentrates selectively in the olfactory bulb (OB). Since the primary function of the OB is olfaction we hypothesized that systemically administered VPA would alter olfactory function. Olfactory function was assessed by measuring the time to find a food pellet buried under wood shavings.

Twenty mice (Swiss derived, male, 8-10 weeks of age, approximately 30 g body weight) were deprived of food overnight for eleven nights. On the morning after the first overnight fast each mouse received an i.p. injection of 0.3 ml of saline (.09%) and then 30 min later the time required to find a buried food pellet was determined. On the next 10 mornings 10 animals received an anticonvulsant dose of VPA (300 mg/kg, i.p., as the sodium salt, in 0.3 ml of .09% saline) 30 minutes prior to behavioral testing. Ten control animals received saline injections without VPA prior to behavioral testing. All animals in both groups found the buried pellet each day within 5 minutes. The time required to find the food pellet did not differ significantly for the

These findings indicate that an anticonvulsant dose of VPA does not disturb the ability to find buried food under the conditions of this experiment.

ODOR AND TACTILE STIMULATION EACH INCREASE
OLFACTORY BULB CATECHOLAMINE RELEASE IN RAT PUPS.
R. Coopersmith. F.B. Weihmuller. J.F. Marshall and M. Leon, Dept.
of Psychobiology, Univ. of California, Irvine, CA 92717.
Pairing an odor with tactile stimulation induces an odor preference in

rat pups which is associated with an increase in the number of olfactory bulb juxtaglomerular neurons in focal glomerular regions. Drug studies raised the possibility that the reinforcing properties of the tactile stimula-tion are mediated by noradrenergic pathways. We therefore used *in vivo* microdialysis in awake 3-day-old rat pups, to determine whether extracellular olfactory bulb noradrenaline (NA) increases in response to tactile or odor stimulation. Stroking rapidly increased bulb NA levels, followed by a fall to baseline 20 min later. Odor exposure increased NA, but only after a delay of 30 min; this peak was followed by a rapid fall to baseline levels. Dopamine (DA) is present in some juxtaglomerular neurons and we found that DA gradually increased during stroking, with a peak response (> 2-fold) 1 hr post-stimulation. DA also increased slightly (10%) during odor exposure and continued to rise to 200% of baseline 1 hr later. This dual activation of bulb juxtaglomerular neurons by both primary sensory and centrifugal stimulation may play a role in mediating learning-associated changes in these neurons.

SOMATOSTATIN-28-LIKE IMMUNOREACTIVITY IN THE RAT ACCESSORY OLFACTORY BULB. S. Takami*, G.D. Fernandez*, M.H. EL-Hawary and P.P.C. Graziadei. Dept. Biol. Sci. Florida State Univ., Tallahassee, FL 32306-3050. Dept. Zool., Fac. Sci., Assiut Univ., Egypt (M.H.E.-H.). To characterize the vomeronasal (VN) system morphologically and

neurochemically, we have recently investigated its primary CNS center, the accessory olfactory bulb (AOB). We report here that somatostatin (SS)-28-like immunoreactive (LIR) neurons are present in the AOB, and describe their location and morphology.

Brain sections from adult Sprague-Dawley rats were processed following the conventional avidin-biotin-peroxidase complex method. Two kinds of commercially available antibodies (*Incstar*) were used at the dilution of 1,000 to 10,000 times.

In the glomerular layer (GL), a small population of neurons with small somata is SS-28-LIR. The antibodies stain some profusely branched dendrites, but in some cases, they stain only stem dendrites and very few dendritic branchings. In the external plexiform layer (EPL), a subpopulation of the mitral/tufted cells (Takami & Graziadei, Soc. Neurosci. Abstr., 15: 928 '89) is IR. IR dendrites directing to the GL can be sometimes traced into the inside of the glomeruli. A very few interneurons located in the EPL are also SS-28-LIR. In the granule cell layer (GRL), the antibodies stain a scattered population of multipolar neurons whose somata are larger than those of the granule cells. The IR dendrites spread in the GRL, but they cannot be tranced into the EPL. The GRL also contains abundant IR fibers some of which are originating from the somata located in the region below the GRL. The above reactivity was completely inhibited when SS-28 was added into the diluted antibody solution, but not weakened when SS-14 was added.

Since the mitral and tufted cells of the MOB are negative to SS-28 antibodies, it can be concluded that the presence of the SS-28-LIR output neurons in the AOB is one of the chemical characteristics of the VN system. Supported by a grant from the NIH (NS 20699) to P.P.C.G.

LECTINS LABEL SUBPOPULATIONS OF OLFACTORY RECEPTOR CELLS W.B. Stewart and C.E. Touloukian*. Sect. of Gross
Anatomy, Dept. of Surgery, Yale Univ. Sch. Med., New
Haven, CT. 06510
Several lines of evidence suggest there are subclasses

of olfactory receptor cells. Our experiments tested the hypothesis that subpopulations of receptor cells could be of offactory receptor cells. Our experiments tested the hypothesis that subpopulations of receptor cells could be distinguished based on lectin binding. A number of lectins were screened on sections of decalcified rat skull that included the olfactory epithelium (OE) and olfactory bulb (OB). Bandeiraea simplifolicia and Vicia villosa stained the vomeronasal organ, nerve and the glomerular layer of the accessory OB. Tetragonolobus pupureas (Lotus) and Glycine max, on the other hand, were of considerable interest because they stained a subgroup of receptor cell bodies, dendrites and axons in the OE as well as a subgroup of OB glomeruli. A detailed map was constructed of the distribution of Lotus staining in the OE and OB. The results were consistent with previous studies on the topography of olfactory nerve projection. There was also close correspondence to maps made by Schwob and Gottlieb (J. Neurosci 6:3393-3404, 1986) for the staining by a monoclonal antibody that recognized a glycoprotein. In conclusion, these studies suggest that there are distinct groups of olfactory receptor cells that differ in membrane glycoprotein specificity and that project to specific regions in the OB. THE EFFERENT PROJECTIONS OF THE BED NUCLEUS OF THE STRIA TERMINALIS IN THE SYRIAN HAMSTER. M. Damlama and J. M. Swann, Institute of Animal Behavior, Department of Biological Sciences, Rutgers University, Newark, NJ. 07102.

The Bed Nucleus of the Stria Terminalis (BNST) is an important center in the neural

regulation of reproductive behavior in rodents. In the male Syrian hamster, which relies heavily on chemosensory input for the initiation of mating behavior, lesions of this nucleus disrupt sexual behavior. While the inputs to this nucleus have been identified, the efferents remain to be characterized in this species. This study identifies the efferent projections of

the BNST to further elucidate the central pathways controlling mating behavior.

Adult male Syrian hamsters were anesthetized with pentobarbital and iontophoretically

Adult mate Synta trainsters were arestretized with perindarbital and ionitophoretecany injected with PHA-L. Following a one week survival period, animals were perfused with 4% paraformaldehyde, brains removed and sectioned at 40 µm. Free floating sections were immunolabelied using biotinylated antisera to PHA-L and the Vectastain ABC kit. Injections of PHA-L confined to the preoptic portion of the BNST resulted in intense terminal labeling in the septohypothalamic nucleus, the anteroventral and medial preoptic nuclei, the rostral extent of the paraventricular hypothalamic nucleus, the retrochiasmatic area, the tuberal area surrounding the ventromedial nucleus of the hypothalamus, the dorsal and ventral mammillary nuclei, and the medial nucleus of the amygdala. Moderate varicose fiber labelling was also seen in the nucleus accumbens, the nucleus of the horizontal limb of the diagonal band, the anterior and lateral hypothalamic areas, the arcuate nucleus, and the dorsal hypothalamic area. Finally, scattered fibers were observed throughout the septum, the ventromedial nucleus of the hypothalamus, the supramammillary nuclei, the zona incerta, the basal and central amygdaloid nuclei, the substantia nigra, and the ventral tegmental area.

substantial migra, and the ventral tegmental area. The preliminary results indicate extensive BNST connections with limbic areas strongly implicated in the control of sexual behavior and endocrine reproductive functions. In addition, projections to the nucleus accumbens and the substantia nigra suggests that BNST may relay motivational information to areas involved in the execution of motor behavior.

PROJECTIONS TO OROMOTOR NUCLEI USING TRANS-NEURONAL TRANSFER OF HERPES SIMPLEX VIRUS. J.B. Travers, L.M. Jackson*, T. Copelin*, I. Plaza* and J. Sheridan. Oral Biology, Ohio State Univ. Coll. Dent., Columbus, OH 43210 Decerebration experiments suggest that both gustatory and intraoral tactile stimuli influence ingestive responses through local brainstem substrates but the exact anatomical pathways are still unknown. In the present experiments, pre-motor neurons to still unknown. In the present experiments, pre-motor neurons to the lingual and masticatory muscles were mapped using the retrograde transneuronal transfer of Herpes simplex virus. Either the tongue or anterior digastric muscle (AD) of the hamster was injected with 50 ul of HSV-1 McIntyre (4 x 10⁹ pfu/ml) followed by a variable survival time. The distribution of the virus was detected using avidin - biotin immunohistochemistry with a primary anti-HSV glycoprotein antibody. As previously reported (Ugolini et al, 1987), immunoreactivity was detected in motoneurons within 48 hours and Golgi-like labelling was observed in neuron outside the motor nuclei within 72 hours motoneurons within 48 hours and Golgi-like labelling was observed in neurons outside the motor nuclei within 72 hours. The first cells to be labelled outside the hypoglossal nucleus following lingual injections included cells in caudal subdivisions of the solitary nucleus (NST) at the IXth nerve level, and the subjacent reticular formation (RF). Following HSV injection into the AD, neurons were also labeled in the caudal NST and the subjacent RF. Only at longer survival times following either muscle injection were cells in the anterior NST labelled. This suggests that the VIIth nerve gustatory zone of the NST may influence lingual and masticatory muscles indirectly via interneurons in the caudal NST and subjacent RF but that IXth nerve influences on oral motorneurons are more direct. INTRAMEDULLARY CONNECTIONS OF THE ROSTRAL NUCLEUS OF THE SOLITARY TRACT IN HAMSTER. M. Beckman* and M. Whitehead. Ohio State Univ. College of Dentistry, Columbus, OH 43210.

The rostral nucleus of the solitary tract (NST) is the major

medullary center that receives input from all of the gustatory cranial nerves. Pathways ascending from the rostral NST to the forebrain are better documented than are pathways through the forebrain are better documented than are pathways through the caudal brain stem. To study the latter connections HRP was injected into the rostral NST or into the subjacent reticular formation (RF). NST injection labelled axons extending ventrally into the reticular formation and the facial motor nucleus. Labelled axons also projected caudally within the NST. Cells in the RF below the injected NST were labelled by retrograde transport. Injection of this RF region labelled axons in the NST and dense collections of axons that terminated in the facial, hypoglossal (XII nuc.) and trigeminal motor nuclei and the supratrigeminal nucleus. Injecting the RF ventral to the caudal NST labelled a XII nuc.projection but projections to the other motor nuclei were sparse. Injections of each RF site labelled cells in the rostral NST; injection of the XII nuc. labelled cells in both RF sites. These results indicate that in hamster the rostral NST in the rostral NS1; injection of the XII nuc. labelled cells in both RF sites. These results indicate that in hamster the rostral NST projects only lightly to one oromotor nucleus but the NST projects more heavily to premotor sites below the NST. These RF sites connect reciprocally with the NST and, as in rat (Tavers and Norgren, '83), project heavily and differentially to oromotor nuclei. The brain stem pathways defined in the present study provide a substrate for gustatory-motor interactions. Support: NIH grant DC00452 and OSU College of Dentistry.

DESCENDING PROJECTION FROM THE INSULAR CORTEX TO THE GUSTATORY NTS IN THE HAMSTER. J.A. London, M.A. Barry, and T.S. Donta*. (Dept. BioStructure and Function, Center for Neurological Sciences, UConn Health Center, Farmington, CT 06032)

The descending projection from the insular cortex to the rostral pole of the nucleus tractus solitarius (NTS) was examined in detail in the golden syrian hamster, Mesocricetus auratus. Multiunit activity was recorded in the rostral NTS during the application of taste stimuli to the anterior tongue in order to delimit the boundaries of a taste responsive region. Wheat germ agglutinin horseradish peroxidase was then iontophoretically injected into the center of the taste responsive region. Retrograde label was found bilaterally in the dysgranular and dorsal part of the agranular insular cortex, with the heaviest label being contralateral to the injection site. Neurons were found deeper in Layer 5 ipsilaterally than contralaterally. Neurons that project to non-gustatory NTS were found deep in Layer 5 within middle to ventral parts of the agranular insular cortex. This study has shown the of the agranular insular cortex. This study has shown the specific location of forebrain neurons which directly project to a gustatory region in the NTS. Further studies on these projections will include double-labelling experiments

ANATOMICAL EVIDENCE FOR DIFFERENTIAL OLFACTORY PROCESSING IN THE PRIMATE PREFRONTAL CORTEX, S. T. Carmichael, J. L. C. Clugnet. Dept. Anatomy & Neurobiology, Washington Univ. Sch. Med., St. Louis. MO 63110

Past investigations have revealed several areas of primate orbital cortex responsive to offactory stimulation. Using electrophysiological recording and retrograde and anterograde tracers we have investigated the olfactory inputs to the monkey (Macaca fascicularis) prefrontal cortex (PFC). Electrical stimulation of the olfactory bulb in halothane-anesthetized monkeys evoked short latency responses in primary olfactory cortex (PC-piriform cortex and AON--anterior olfactory nucleus) as well as posterior and ventral agranular insula (lap and lav) and the posteromedial part of area 13 (13a--located just rostral to AON). Electrode penetrations rostral and lateral to these areas did not reveal any responses. Axonal tracer experiments largely confirmed these results. ³H-Leu injections into the PC produced anterograde label in lap, lav and 13a. Retrograde tracer injections into lav and 13a labelled many cells in the PC

Retrograde tracer injections into other parts of orbital PFC indicate that the projections of these three olfactory-recipient areas may form the basis for two distinct projection patterns. lap and lav project to lateral 13. Lateral 13 also receives a projection from the primary gustatory area. Lateral 13 in turn projects rostrally to part of area 11. 13a, on the other hand, projects directly to part of area 11. Thus, orbital PFC contains two different olfactory streams beginning in primary offactory cortex and proceeding to rostral orbital areas: one directly through a secondary offactory area, 13a, and a second, more indirect, projection through an area which also receives gustatory input, lateral 13. SENSORY SYSTEMS-VISUAL PSYCHOPHYSICS AND BEHAVIOR I

46.1

TONIC SUPPRESSIVE INFLUENCE FROM THE DARK ADAPTED EYE. Thor Eysteinsson*, N. Denny*, and T. E. Frumkes, Dept. Physiol., Univ. Iceland Reykjavik; Dept. Psychol., Queens Col., Flushing, NY 11367 Monocular spatial sensitivity to foveally centered stimuli was examined in humans as a func-

tion of the adapted state of the contralateral eye. tion of the adapted state of the contralateral eye. Visual Occipital Potentials (VOPs) evoked by alternating checkerboards with a Fourier fundamental of 12 cycles per degree (cpd) approximately double in amplitude if the contralateral eye is light adapted and decrease again if the rods in the "adapting eye" are dark adapted. Similarly, psychophysical (PD) medulation sensitivity to sinusoidal oratinos (PP) modulation sensitivity to sinusoidal gratings with spatial frequencies of 2-20 cpd increases if the contralateral eye is light adapted, and gradually decreases as rods in the "adapting eye" gradually decleases as associated and adapt. For psychophysical observers, the effect of interocular light adaptation can be duplicated by pressure blinding the "adapting eye." Both our PP and VOP data show that sensitivity with binocular viewing is very similar to that obtained with interocular light adaptation and monocular viewing. Collectively, our results For psychophysical observers, the monocular viewing. Collectively, our results suggest that the increase in visual sensitivity resulting from binocular viewing should be attributed to removal of interocular suppression, and not to binocular convergent summation.

PERCEIVED SPEED VARIES INVERSELY WITH LENGTH OF THE MOTION PATH: A MULTI-SENSORY ILLUSION. E. Katz, M.S. Gizzi, E. P. Gardner, B. Malach. Dept. of Neurol, Mt. Sinai Sch. of Med., New York, 10029. Dept. of Physiol. and Biophys., NYU Sch. of Med., New York, 10016. Dept. of Neurobiol., Weizmann Inst. of Sci. Rehovot, Israel. The dependence of motion perception on spatial frame of reference in the

visual and tactile sensory systems of humans was studied using a two-alternative forced-choice paradigm.

Visual targets (0.4x2.0 deg) moving linearly at constant velocities ranging from 11-20 deg/s over distances ranging from 5-25 deg were viewed on a CRT screen placed at a distance of 114 cm. Targets moving at identical velocities but over a shorter distance were provised as moving faster (p. 0.1) for both screen placed at a distance of 114 cm. I argets moving at identical velocities but over a shorter distance were perceived as moving faster (p<.01) for both periodic motion and for single sweeps across the motion path. The visual illusion of increased speed at shorter path lengths was equally powerful when subjects were free to track the target or fixated a point at the center of the motion path. Decreasing the visible portion of the target path by masking also increased the perceived speed. Matching acceleration profiles at the limits of periodic excursions diminished, but did not eliminate the illusion suggesting that excelerations at the reversal points are important in udiging object expends. that accelerations at the reversal points are important in judging object speed.

Tactile studies were done on the index finger using an OPTACON stimulator

containing a 6x24 matrix of probes spaced 1.2 mm apart. Sequential pulses applied to adjacent rows at 17-100 Hz produced sensations of a bar moving applied to adjacent rows at 17-100 -12 produces sensations of a bar moving along the finger over distances of 9.6-24 mm. Subjects judged stimuli displaced periodically over a shorter distance as moving faster when rows were pulsed at 100 and 50 Hz (pc.05). These rapidly applied stimuli were perceived as smooth motion along the finger. However, performance was random at lower frequencies where individual pulses were perceived as discrete events. Thus, in both sensory systems, path length affects speed perception in

similar ways, suggesting that motion perception in both modalities is context

HUMAN SPEED PERCEPTION IS CONTRAST DEPENDENT. L. S. Stone, P. Thompson, and A. B. Watson. Vision Group, NASA Ames Research Center, Moffett Field, CA 94035-1000.

A moving grating is judged slower than an otherwise identical grating of higher contrast moving at the same speed. However, the uncertainty in this type of speed judgment is largely independent of the contrast ratio. We quantified this phenomenon using a 2AFC staircase paradigm in which both a reference and a test grating patch were presented simultaneously for 500ms above and below a fixation point. Subjects were asked which patch moved faster. For a 1.5 c/d reference grating moving at 2°/s, the percent bias in perceived speed is a linear function of log contrast ratio (mean slope: 1.6 % bias/dB; N = 2). Furthermore, this effect appears robust to changes in spatial frequency, temporal frequency, and even absolute contrast. This latter result suggests that the contrast effect does not saturate, e.g. a 30% contrast grating appeared, on average, 10% slower than one of 70% contrast. Our results shed light on visual motion processing within human cortex.

46.4

PATTERN MOTION PROCESSING IN BINOCULAR FUSION OF TWO 2-D PLAIDS. W.A.Ho* and M.A.Berkley. Dept. of Psychology, Florida State Univ., Tallahassee, Fl. 32306.

When two low contrast and low spatial frequency orthogonal drifting square-wave gratings are presented dichoptically to human observers, a fused, coherent drifting 2-D plaid is perceived without the subjects experiencing binocular rivalry (Ho & Berkley, 1989). Our ability to see a single coherent moving pattern in such a display suggests that the underlying motion mechanism is able to generate a unique pattern of image motion by combining separate motion components. However, the combination scheme of Adelson and Movshon (1982) does not predict how the pattern motion mechanism would respond to complex scenes that contain multiple motion components. To study how various motion components are combined in the visual system, we presented two drifting monocular square-wave plaids (of changeable physical parameters) dichoptically to human subjects (so that they could be recombine in six different ways) and timed various perceptual phases during 60 secs long test trials. Our observations indicated that the pattern motion mechanism actively reorganized the 1-D grating components to generate new 2-D drifting plaids when binocular fusion occurred. For example, when a subject was shown two 135 deg monocular plaids (each made up of two 1-D components of .2 c/deg and 10% contrast) that were drifting at right angles to each other, the subject saw mostly (over 50 secs) two transparent 90 deg plaids sliding at an angle of 135 deg to each other. Yet, another possible pair of oppositely drifting 2-D plaids which had different speeds were not seen. Further experiments showed that the pattern motion mechanism preferred to generate pairs of coherent 2-D plaids that belong to one family (i.e. those containing same angle and speed) and avoided yielding pairs that were too different. It is suggested that the pattern motion mechanism functions to minimize the difference in velocity between the two plaids. (Supported by NEI 00953)

SEGREGATION OF HEXAGONAL MESH TEXTURES FOURIER ANALYSIS. P.E. Hallett* and M.I. Hofmannt. *Department of Physiology, Institute of Biomedical Engineering and †Department of Toology, University of Toronto, Toronto, Ontario,

Beginning with a hexagonal mesh, a family of equiluminuous geometric textures can be formed by rotating each line segment by a fixed amount. Such textures vary both in line orientation and in the sizes of the intervening spaces. In the Fourier domain the textures have the same discrete components but the amplitudes vary. The segregation of texture pairs as figures in grounds has been assessed for free viewing from the ratings of ten subjects. Line segment orientation information alone cannot explain the results. Linear regression techniques show a significant correlation between the subjects' ratings and the amplitudes of the low-frequency Fourier harmonics of the textures. Patterns composed of mirror-image pairs are very poorly discriminated.

46.7

IS SPATIAL INFORMATION FOR THE RED-GREEN INPHASE AND ANTIPHASE STIMULI PROCESSED BY THE SAME SPATIAL FREQUENCY-TUNED MECHANISMS?

ANTIPHASE STIMULI PROCESSED BY THE SAME SPATIAL FREQUENCY-TUNED MECHANISMS?

Ram L.P. Vimal and Rita Pandey, Eye Research Institute, 20 Staniford St., Boston, MA 02114.

The bandwidth and peak spatial frequency (SF) of most striate neurons were reported to be the same for both luminance (red-green inphase) and color-varying (antiphase) gratings. However, for antiphase gratings, some cells had lower peak SF and broader bandwidth, and others were spatial low-pass (Thorell et al Vis Res 24:751, 1984). Some of the cells responded more to chromatic or achromatic grating depending on spatiotemporal characteristics of the stimuli (Lennie et al J Neurosci 10:649, 1990). For achromatic patterns, a minimum of 6 SF-tuned mechanisms were necessary to obtain the best fit for the photopic masking data (Wilson et al Vis Res 23:873, 1983). We investigated whether spatial information for red-green inphase and antiphase stimuli was processed by the same SF-tuned mechanisms, and whether they shifted to a lower SF range for the latter. The contrast sensitivity functions (CSF) for the inphase and antiphase, spatially localized stimuli (sixth derivative of spatial Gaussian: 40 or 80 on dark surround) were measured at about 29 cd/m² by the method of constant stimuli. The minimum flicker isoluminant criterion was used to determine the relative intensities of red vs. green stimuli as a function of SF. The SF range was 0.25-11 repd in 0.5-octave steps. The pattern was presented for 500 msec on a color raster display system (Adage 3006). Powell's achromatizing lens was used to minimize the chromatic aberration. Two observers with normal color vision initiated a trial and reported whether the pattern was seen or not. We found that the CSF for the antiphase stimuli was spatial low-pass (if a sufficient number of cycles were included) and that for the inphase stimuli was band-pass. The six SF-tuned mechanisms were sufficient to predict the inphase CSF but were unable to explain the low-pass antiphase CSF. At least one low-pass mechanism is

46.9

PERCEIVED BRIGHTNESS IS DEPENDENT UPON PERCEPTUAL TRANSPARENCY AND STEREO DISPARITY. G.R. Stoner, K.R. Dobkins and T.D. Albright. Vision Center Lab., The Salk Institute, San Diego, CA 92138.

The factors known to effect changes in perceived brightness constrain the types of mechanisms which might underlie brightness perception. For example, if adjacency in the retinal image were the only determinant and depth relationships between objects were irrelevant, then simple lateral inhibitory mechanisms might suffice as an explanation of brightness constancy. However, factors such as perceived depth plane (Gilchrist, <u>Science</u>, 195:185, 1977) have been shown to play a part in apparent brightness. Such findings demonstrate the need for more sophisticated models. We've investigated the conjoint effects of perceptual stransparency and stereo disparity on perceived brightness. It was found that perceived brightness depended upon transparency relationships implied by stereo disparity. Human subjects adjusted the brightness of a test disc having a dark "surround" so that it matched the brightness of a reference disc having a bright "surround". This was done under three different stereo disparity conditions: 1) discs in same stereo plane as surrounds 2) discs behind surrounds 3) discs in front of surrounds. As expected from simultaneous contrast induction, subjects consistently adjusted the brightness of the test disc to a much lower luminance than the reference disc in all three conditions. The adjusted luminance values were smallest, however, when the discs were placed behind the surrounds. This attenuation of the matched luminance value is consistent with viewing an object placed behind a dark transparent surface. These findings suggest that knowledge about the depth ordering of surfaces and transparency contribute to perceptual brightness. They provide further demonstration of the insufficiency of lateral inhibitory mechanisms as a full explanation of brightness constancy.

46.6

DISCRIMINATION OF PHASE DIFFERENCES IN PATTERNS COMPOSED OF ROTATED SINE-WAVE GRATINGS.
Hofmann* and P.F. Hallettt. *Departme GRATINGS. M.I. *Department of or Toronto, Toronto, Ontario, Canada.

We have performed experiments in order to examine the visual processing of phase relations

we have performed experiments in order to examine the visual processing of phase relations between different orientation components of a stimulus. Each pattern is composed of a superposition of three sine-wave gratings rotated 60° relative to one another. The patterns varied in global orientation and relative phase. Subjects were asked to rate the difference between pairs of patterns presented in a figure/ground configuration at 10° retinal eccentricity. The results indicate that subjects used both orientation and phase differences in making their ratings. However it was found that it was not simply the difference in relative phase but rather the difference in the absolute values of the relative phase that was the major phase related cue. This means that mirror image patterns (which may have a large phase difference) were generally poorly discriminated. These results suggest that the visual system does not simply perform local Fourier analysis, but must use some kind of feature detection. must use some kind of feature detection.

A NEW TECHNIQUE FOR DETERMINING EQUILUMINANCE. A. Chaudhuri. The Salk Institute, La Jolla, CA 92037.

It is generally believed that motion processing in the human visual system is greatly attenuated if the foreground and background components of the stimulus are made to be equiluminant. This has served as psychophysical evidence for the proposed separate neural processing of color and motion. We have now developed a display that produces a vivid and coherent motion percept only at isoluminance. The stimulus is a random-dot pattern composed of red and green elements within which some luminance noise has been added in the form of randomly placed black pixels. If this pattern is displaced in one direction and accompanied by a contrast-reversal of the colored elements, motion of the black pixels is seen only when the red component luminance matches that of the green. This is a very robust effect since it can be observed over a large range of displacements (2.6 - 26.0 min arc), duration of stimulus between displacements (50 - 400 ms), and viewing time (200 - 1000 ms). When the colored components are non-isoluminant, the movement of the black elements is masked by an overriding flicker that is caused by the contrast reversals. The red and green component intensities at which motion is perceived is taken to be equiluminant because the same intensities produce minimum flicker with a 2 deg arc field in a heterochromatic flicker photometry test. We have also found that the moving pattern is capable of generating optokinetic nystagmus (OKN) in both humans and monkeys (Macaca mulatta), as determined by magnetic search coil oculography. If used in this manner, the technique provides an independent assessment of isoluminance in chromatic patterns that can be used in addition to

46.10

VISUAL SEARCH IN THE PRESENCE OF CONFLICTING DEPTH CUES. Y.S. Ramachandran, D.J. Plummer, and H. Pashler, Psychology Department, UCSD, La Jolla, CA 92093.

How are different "depth cues" such as perspective, stereopsis, shading, and

an observer's perceptual judgement. (Supported by NIH EY07605).

occlusion combined in the brain?

We constructed a stereogram composed of 8 pairs of squares. One member of

each pair partially occluded the other. All the squares were at zero disparity except for one member of a pair that was stereoscopically nearer than the others. This square was easier to detect when the two cues (occlusion and disparity) were consistent with each other than when the two cues were in conflict. When the cues were in conflict, the occlusion vetoes the stereopsis and makes the target difficult to locate.

Next, we had an identical stereogram which had eight square-pairs but no occlusion cues. In this situation the stereoscopically nearer target square was occursion cutes. In this statumout the stereospheaty incare target square was even easier to detect than when both stereo and occlusion were present (and consistent). To explain these findings we postulate that different depth cues converge on to a common "depth-cue" invariant feature map in which cells respond to relative depth but are indifferent to the actual cue that is used. Such a map would report that each member of a square-pair is in front as a result of occlusion. If the stereo-cue is "redundant" (i.e. consistent) the target does not

occurson. It also state-to-us is returnable (i.e. consistent) the target uses not pop out as easily as when the stereo cue alone is present.

Lastly, we created a stereogram composed of 8 squares. The target square was either smaller or larger than the distractors and was also either stereoscopically nearer or further. It was easier to detect when smaller and nearer (or larger and further). We conclude that "pop-out" occurs after size-constancy correction; it is not based on retinal size alone.

We conclude that visual search and "pop-out" occur in a common "depth-cue invariant" feature map and not at an earlier stage where different cues are represented separately. We thank AFOSR for support.

AUDITORY-VISUAL INTERSENSORY TEMPORAL RESOLUTION IN HUMAN SUBJECTS. L. J. Achor. Dept. of Psychology, Baylor Univ., Waco, TX 76798.

Auditory-visual intersensory temporal resolution (i.e., the ability to discriminate whether a mixed pair of auditory and visual stimuli is simultaneous as opposed to successive) was investigated in human subjects by determining the intersensory fusion threshold (i.e., the point at which subjects judge successively presented stimuli to be simultaneous 50% of the time).

A double staircase variation of the method of limits was used to determine the intersensory fusion threshold, with 20 stimulus pairs presented from each of the two staircases. 120 young adults were presented stimuli in two conditions: (1) flash followed by a tone and (2) tone followed by a flash. Half of the subjects received the tone-delayed condition first and half received the flash-delayed condition first. Thresholds were obtained for stimulus trials 21-30 (Block 3) and 31-40 (Block 4). Blocks in which a subject made a judgment error on catch trials of 0 or 500 msec temporal separation were excluded from the data

analysis.

There was no significant difference in the intersensory fusion thresholds between Blocks 3 and 4 for either the tone-delayed or flash-delayed condition. There was a significant order effect for tone-delayed vs flash-delayed and a significant difference between tone-delayed and flash-delayed conditions.

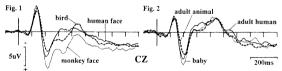

The intersensory fusion thresholds determined in this study provide an indication of intersensory processing ability. The thresholds will provide normative data for assessing developmental changes and they may also be useful in the evaluation of individuals with perceptual disorders.

CATEGORY-SPECIFIC EVOKED POTENTIALS RELATED TO PICTURES OF FACES OF MAN AND ANIMALS. O.-J. Grüsser. L. Fuhry*, M. Seeck*, W. Seidler*. Dept. Physiol. Freie Univ. Berlin (FRG)

In primate studies particular components in epidural monkey-EEGs (EPs) related to pictures of monkey and human faces were found. With the present studies the reverse test was performed: b/wphotographs of monkey, other animal faces and human faces to humans. Differences in the EPs could also be found when pictures of adult humans, babies, adult animals and "baby-animals" of various species were shown (electrodes F3, F4, T5, T6, Cz, Oz, intern. 10/20-recording system, linked mastoids, 16 subjects).

Category-specific differences were most pronounced in the frontal electrodes and Cz. Faces of animals and human babies led to a prominent negative peak at 400-450 ms. The decreasing similarity between the animal and human species was reflected in the averaged EP between 200 and 400 ms. Comparing adult/baby faces, only differences between human adult and baby faces could be found (larger positive peak at 200 ms in the category "human baby"). (DFG Gr 161, \$520)

OPTOKINETIC NYSTAGMUS (OKN), ACCOMMODATION, AND BINOCULAR ALIGNMENT IN NATURALLY STRABISMIC MONKEYS. M. W. Quick*, J. Newbern*, L. Place* and R. G. Boothe. Dept. of Psychology, Ophthalmology, and Yerkes Regional Primate Research Center, Emory University, Atlanta GA 30322.

A photographic corneal light reflex method was used to assess eye alignment in 10 monkeys with naturally occurring strabismus. Assessments were made at 35 target locations throughout the monkey's visual field. Two major findings were: (1) Most monkeys showed nasally directed alignment errors (esotropia); (2) 1/2 of the monkeys showed deficits associated with an accommodative component.

To further examine (1), contrast thresholds for eliciting

associated with an accommodative component.

To further examine (1), contrast thresholds for eliciting OKN were measured for nasally and temporally directed drifting stripes. Asymmetric OKN was present in all the strabismic monkeys. This asymmetry was due to abnormally high thresholds for temporal motion. The nasal OKN preference correlates with the nasal alignment deficits and supports the theory that motion asymmetry may play a role in esotropia (Tychsen & Lisberger, J. Neurosci., 1986).

To further examine (2), infrared photorefraction was used to assess accommodative errors at four viewing distances. Two major types of errors relating to the eye alignment deficits were noted during binocular viewing. First, several monkeys exhibited direct accommodative errors in one eye for some fixation targets. Second, some eye alignment errors were consistent with abnormally high AC/A ratios. FACES, HANDS AND OTHER BODY PARTS EVOKE DIFFERENT CATEGORY-RELATED VISUAL RESPONSES IN THE ELECTRO-ENCEPHALOGRAM, Margitta Seeck*, O.-J. Grüsser, Elke Heusser* W. Seidler*. Dept. Physiol. Freie Univ. 1 Berlin 33, Germany (SPON: European Brain and Behaviour Society)

In the present study we investigated how evoked potential (EP) components related to hands and faces as described in earlier reports change when photographs of parts of hands or faces are used as stimuli. In the first paradigm, slides of black and white photographs of the whole hand, its radial or ulnar half, as well as single fingers were used as stimuli (EEG recordings from T3, T4, T5, T6, C2, C2, reference linked mastoids, 8 female, 8 male subjects). In the second paradigm EPs to b/w photographs of the whole face, the face without eyes and both eyes only, positioned horizontally or vertically, were studied (EEG recordings from F3, F4, T5, T6, Cz, Oz, same reference, 9 female, 7 male subjects).

A hand-responsive component was confirmed, consisting of two positive peaks at about 200 and 370 ms (Fig.1). Also the face-responsive component (distinct positivity at 200 ms and rapid consecutive negativity) was found. All EPs have a pronounced positive peak at about 200 ms when different body parts

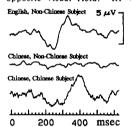

are used as stimuli. The more the hand or face was "mutilated", the less pronounced was the hand- or face-responsive component beyond 200 ms. (DFG Gr 161, S520).

THE RECOGNITION POTENTIAL: A VISUAL RESPONSE EVOKED BY RECOGNIZABLE IMAGES. A. P. Rudell. Dept. of Physiology, SUNY, Health Science Center at Brooklyn, Brooklyn, NY 11203.

The recognition potential (RP) occurs when a subject views a recognizable image. Words, cartoon faces, simple pictures, and geometric patterns evoked RP. Controls (mozaics of small pieces of recognizable images) or words in languages unfamiliar to a subject (Arabic or Chinese) did not. Chinese ideographs did evoke RP for subjects whose native language was Chinese. Fig. 1 shows responses to English or Chinese minus responses to control shows responses to English or Chinese minus responses to control stimuli. RP had shorter latency than P300 and was less sensitive than P300 to novelty. P300, but not RP, could be recorded from a lead on the vertex, referenced to the forehead. RP was largest RP was largest for occipital leads when the images were displayed in the opposite visual field. RP for steadily presented recognizable English Non-Chinese Subject ** LVV images was equivalent to RP when

they were intermixed with controls. Reaction time (RT) and RP latency increased in equal amounts with increasing degradation of the images. RP latency was about 150 msec less than RT. The results imply that RP is not caused by differences in the physical attributes of the stimuli or an emotional, P300-like response. depend on a subject's perception and learning experience.

LONG TERM MD CAT'S DEPRIVED EYE SHOWS A RAPID VISUAL SENSITIVITY INCREASE AFTER EYE LID OPENING. Z. He* and M. S. Loop Physiological Optics, Sch. of Optometry, Univ. Alabama at B'ham., Birmingham, AL 35294

It is well known that, within classic critical period, visual experience plays a very important role for the development of mammalian visual system. Here, we ask if there is any effect of visual stimulation on the long term (beyond critical period) monocularly deprived (MD) eye. To answer this question, we measured, for three MD cats', increment thresholds (16° yellow test light on 30 cd/m² white background) after opening the eye lid which had been closed for more than 12 months since birth.

had been closed for more than 12 months since birth.

Before deprived eye opening, cat Hwa had already learned the two choice task, cats Li and Shou the reaction time task. After Hwa's deprived eye saw normal light for 6 days, sensitivity increased rapidly till day 16 (about 2 log units) followed by a small amount of increase later on. The sensitivities of cats Li and Shou could be obtained after days 9 and 11 of deprived eye open, respectively, and showed a similar sensitivity improvement. However, the reaction time showed a similar sensitivity improvement. However, the reaction time vs subjective intensity (threshold defined) curves of deprived eye showed little change. Compared to the fellow normal eye, the reaction time in deprived eye is not faster at same subjective intensity, which indicates that the abnormally rapid signal transmission by MD LGN Y-cells (Sestokas & Lehmkuhle, 1986) does not translate simply into faster perceptual latencies. This visual sensitivity improvement in long term deprived eye immediately after the eye ido opening may suggest an uncovered neural synaptic mechanism for neurobiologists to explore. BLINDSIGHT: SPATIAL SUMMATION IN VISUAL FIELD DEFECTS. Petra Stoerig, (SPON: European Neuroscience Association)
Institute of Medical Psychology, Ludwig-MaximiliansUniversity, Goethestr.32, 8000 Munich 2, FRGermany

The residual visual functions that may be observed in visual field defects caused by striate cortical damage (Blindsight) can be used to study the functional properties of the remaining visual pathways. As pathways can be classified by their spatial summation for wavelength and intensity information, increment thresholds were measured as a function of stimulus size in the circumscribed visual field defects of five stimuli, from 7-116' in diameter, were presented on a white photopic background. At a Tübinger perimeter, the patients fixated a central spot and guessed whether or not a target (200ms) that appeared in random alternation with blank trials had been presented. Target luminance was increased in steps of 0.1 log units until the detection became statistically significant. Spatial summation curves measured with the white targets show a marked dip whose position depends on white targets show a marked dip whose position depends on neetinal eccentricity, and indicates a change in summation mode. In contrast, curves for the red targets show a smooth increase in sensitivity with stimulus size. Colour-opponent Type I ganglion and LGN cells show a combination of antagonistic summation for intensity and synergistic summation for wavelength information that could explain this result. VISUAL PERSISTENCE IS IMPAIRED IN PATIENTS WITH COMPRESSION OF THE OPTIC CHIASMA C.A. Marzi 1, M.Girelli 1, G.Tassinari 1, L. Cristofori 2, A. Talacchi 2, G. Marchini 3, M. Gentilin 3 (Spon.: European Neuroscience Association). Inst. of Physiol. 2 Dept. of Neurosurg. 3 Inst. of Ophthalmol., Univ. of Verona, Italy. Optic fibers originating from retinal ganglion cells of different classes may be selectively affected as a result of compression and stretching due to tumors of the chiasmatic region. To verify this possibility we have studied 8 patients suffering from pituitary adenomas as assessed by NMR. We tested both speed and accuracy in naming digits monocularly presented at 5° of eccentricity assessed by NMR. We tested both speed and accuracy in naming digits monocularly presented at 5° of eccentricity in either hemifield. Each of the four digits (2,5,6,9) was randomly split in two portions and each half was flashed for 4 msec, with an interstimulus interval (ISI) of 15,30,45 or 60 msec. Recognition depended on the visual persistence of the first portion and its integration with the second portion. 12 naive subjects of similar age as the patients served as controls. The vocal reaction time of patients was significantly slowed at the longest ISI in the nasal field of both eyes. This result suggests an impairment of beta cell axons, whose sustained pattern of response should allow temporal integration at long ISIs. Recent anatomical data on a monkey with a similar tumoral compression are in agreement with this interpretation (Reese and Cowey, Clinical Vision Science, 4: 341-356, 1989).

ATTENTION: ACETYLCHOLINE, NOREPINEPHRINE AND THE FRONTAL CORTEX. K. Pang, D.S. Olton and H. Egeth. Dept. of Psychology, Johns Hopkins Univ., Baltimore, MD 21218.

Attention is the mechanism that allows expected stimuli to be processed more effectively than unexpected stimuli. A two-choice reaction time task was used to assess attention in rats. Attention was manipulated by varying the relative probability of two stimuli, light and tone; each stimulus required a different response. On each trial, a single stimulus was presented. The rat responded by releasing the appropriate lever. As the percentage of visual stimuli increased, the reaction time to the light decreased and the bias to respond to the lever indicating light increased. As the percentage of auditory stimuli increased, the reaction time to the tone remained constant and the bias to respond to the lever indicating tone increased. Stimulus detectability (d') remained constant for all stimulus ratios. Thus, attention was shifted to the more probable stimulus and away from the less probable stimulus, which produced a shift in response bias without a change in stimulus detectability. When light was the expected stimulus, the reaction time to the visual stimulus was decreased. The ability to allocate attention between two stimuli is currently being examined following administration of selective cholinergic and noradrenergic drugs and also following frontal cortical lesions. (Supported by AFOSR-89-0481 and PHS NS08358).

VISUO MOTOR DISTURBANCES IN DYSLEXIC PATIENTS. RE HABILITATION BY ANIMATED COMPUTER PROGRAMS. I.Zar co de Coronado, A. Gutiérrez López*. Departamento de Fisiología, Facultad de Medicina. AP. P. 70250 U.N.A.M. and Insto. Nal. de la Comunicación Humana. C.P. 01480 México.

Altered visuo motor coordination in dyslexic patients make them disable readers. In order to correct learning problems their training programs rust help the patients to mecanizate the procedures involved in the focusing of visual attention and spatial control. The velocity and diversity of stimuli generated by the computer make it a useful instrument for this kind of programs.

It was developed a animated computer program which is going to be used with mexican dyslexic Comunication. This program is fully automated and it is based on standard rehabilitation methods and also evaluate and store the results of each session. The difficulty of the next exer-cise depends of the every day qualification.

DETECTION AND RECOGNITION THRESHOLDS FOR SPATIALLY DEGRADED IMAGES BASED ON LASER RETINAL INJURY. Zwick, H.*, Robbins, D.O., Mastrianni, G.*, and Monroe, D.* Division of Ocular Hazards, Letterman Army Institute of Research, Presidio of San Francisco, CA. 94129

In previous work, we showed that the rhesus contrast sensitivity function following acute small spot laser exposure was suppressed over a broad range of spatial frequencies. We observed such effects over a wide range of exposure intensities ranging from levels that produced only transient effects to levels that also produced permanent morphological changes in the retina. Long levels that produced only transient effects to levels that also produced permanent morphological changes in the retina. Long term changes in contrast sensitivity following punctate foveal damage revealed a steepening of the slope of these contrast sensitivity functions suggesting parafoveal compensation for foveal damage. Changes in contrast sensitivity have often been suggested to reflect changes in suprathreshold spatial vision. To evaluate this notion, we have measured human stationary and temporally this notion, we have measured human stationary and temporally modulated detection and recognition thresholds for suprathreshold images that have been spatially filtered to reflect the type of contrast sensitivity deficits measured in our exposed animals. A microcomputer system from Delta Technologies was used to fourier filter computerized images and to visually display such images under increasing contrast conditions. Image detection and recognition thresholds for these filtered images were consistent with changes in contrast sensitivity measured in our animal experiments. Differences between image conditions reflect suppressive as well as enhancement effects of exposure, suggesting that spatial contrast threshold mechanisms are relevant to suprathreshold detection and recognition mechanisms. suprathreshold detection and recognition mechanisms.

VISUAL ACUITY FOLLOWING CHIASMATECTOMY IN UNILATERAL ESOTROPIC CATS. P. Bouchard M. Pitto. F. Lepore. S. Ouessy and J.P. Guillemot, Dép. de psychologie, Université de Montréal et Dép. de kinanthropologie, UQAM.

kinanthropologie, UQAM.
Unilaterial esotropia surgically induced early after birth leads to amblyopia of the deviated eye (DE). This effect is usually explained in terms of binocular competition and suppression at the cortical level. In order to attenuate this competition and hence decrease the influence of the normal eye (NE) over DE, we sectioned the optic chiasma (OC) in kittens rendered strabismic soon after birth. For purposes of comparison, we also used normal cats and kittens with either unilateral esotropia or comparison, we also used normal cats and kittens with either unilateral esotropia or chiasmatectomy. Visual acuity (VA) was measured behaviorally using a two-choice discrimination procedure on a jumping stand. Stimuli were square-wave gratings of various spatial frequencies and thresholds were derived using two-methods: constant stimuli and staircase procedure. In normal cats, the average threshold value for monocular viewing was identical for each eye (5 cyc/deg.). In OC cats, VA was found to be lower than that of the normal cats by about a factor of 2 (2.5 cyc/deg.) In strabismic cats, VA values obtained for DE were quite low (mean=9 cyc/deg.) whereas for NE they reached an average 3.6 cyc/deg. In strabismic cats with an OC section, VA values for DE were about .32 cyc/deg. and for NE about 2.0 cyc/deg. The results suggest that chiasmatectomy performed on otherwise normal kittens results in a lower visual acuity for each eye as previously reported by Timney and results in a lower visual acuity for each eye as previously reported by Timney and Landsdown, 1987. Hewever, it dramatically reduces VA of both DE (which is actually almost blind) and NE (which is about two times worse than NE of ESO cats and three times worse than normal cats), the section of the optic chiasma does not seem to suppress binocular competition and has on the contrary a detrimental effect on both NE and DE.

BILATERAL ABLATION OF THE FOREBRAIN ENHANCES OPTOMOTOR RESPONSES IN GOLDFISH. M.G. Yoon. Dept. of Psychology Dalhousie University, Halifax, N. S. Canada B3H 4J1

The topographic pattern of visual projection from the eye to the brain in the goldfish can be experimentally induced to undergo two types of neural reorganizations: 1)Field Compression following a partial excision of the optic tectal lobe, and 2) Retention of the Original Topographic Polarity by tectal tissue following reimplantation after 180° rotation. We study the pattern of changes in the visuo-motor behaviors of the goldfish following the two types of microsurgical manipulations of the visual system (which result in the neural reorganizations of the afferent retinotectal pathways) by various behavioral tests. One of the innate visual behaviours we use for the tests is the optomotor response. In normal goldfish, we could hardly elicit a reliable optomotor response in tracking a single rotating bar. Two weeks after bilateral ablation of the forebrain in the goldfish, however, we find that the operated fish tend to follow the single rotating visual target with remarkably enhanced consistency. Thus, the forebrain seems to exert a distracting influence on the optomotor response generating mechanism in the normal goldfish.

SENSORY SYSTEMS-SUBCORTICAL VISUAL PATHWAYS: SUPERIOR COLLICULUS AND RELATED

COLLICULAR MAGNIFICATION IS NOT SCALED TO THE INTRARETINAL DENSITY OF AFFERENT GANGLION CELLS. <u>D.M. Berson and J.J. Stein</u>*. Div. Biology & Medicine, Brown Univ., Providence, RI, 02912

Magnification in central visual maps is usually thought to be proportional to the intraretinal density of afferent ganglion cells. To learn if this is true for the cat's retinocollicular projection, we made local comparisons between the densities of tectally projecting ganglion cells and areal magnification in the superior colliculus (SC) at matching retinotopic locations. Collicular magnification factors were estimated from McIlwain's map of the SC (Vision Res. 23:507, '83). Densities of afferent ganglion cells were determined from retrograde labeling patterns after deposits of fluorescent microspheres confined to the contralateral SC (n=4). For selected retinotopic sectors, we calculated the ratio of collicular areal magnification to the intraretinal density of tectopetal ganglion cells. If SC magnification were scaled to ganglion cell density, these ratios should have remained constant over the map. Instead they varied markedly, being three to five fold higher for the area centralis than for the periphery. (Incorporating the relatively small numbers of ipsilaterally projecting retinotectal ganglion cells into our analysis would not have substantially affected this conclusion). The observed topographic variations imply that incoming retinal axons are more widely spaced in the area-centralis representation than elsewhere in the SC. This may account for anatomical and physiological evidence for topographic variations in the density of retinotectal input (see Berson et al., Exp. Brain Res. 79:459, '90). Our findings suggest that collicular magnification is specified by some mechanism other that simply related to the density of retinal ganglion cells. The expansion of the area-centralis representation beyond what would result from peripheral scaling alone could enhance stimulus detection or localization near the center of gaze. Supported by EY06108 and a Sloan Foundation Fellowship to DMB.

ANTI-CALBINDIN LABELING IN THE LATERAL GENICULATE NUCLEUS OF THE RHESUS MONKEY AND ITS REDUCTION BY ENUCLEATION. Q. Luo¹, B.R. Mize¹, and M. Tigges², 1Dept. Anatomy and Neurobiology Univ. of Tennessee Health Sci. Ctr., Memphis, TN, 38163 and ²Yerkes Regional Primate Research Center, Emory University, Atlanta, GA 30322.

Primate Research Center, Emory University, Atlanta, GA 30322. Calbindin 28Kd, a calcium binding protein, is found in selected neurons in the CNS where it is thought to regulate intracellular calcium. We have studied the distribution, density, and morphology of cells labeled by antibodies to calbindin in the lateral geniculate nucleus (LGN) of the Rhesus monkey. The effects of monocular deprivation on antibody labeling were also studied. One eye was enucleated 2 weeks prior to sacrifice in 6 monkeys, 3 of which were also monocularly occluded from birth. Another 3 animals were occluded without enucleation. In some cases, the lens of the opposite eye was removed and the aphakia corrected with a contact lens.

Anti-calbindin positive neurons were found throughout the LGN. They were densely distributed within the intralaminar zones (ILZ) and layer S and more sparsely distributed within all 6 main laminae, a pattern complementary to that of GABA-labeled neurons. Calbindin neurons had small somas and elaborate dendritic trees. Dendrites of cells in the main laminae never crossed laminar borders while those in ILZ did cross those borders.

Monocular enucleation with or without occlusion produced a significant reduction in antibody labeling in the deafferented laminae. Field measures of optical density made with an image analyzer revealed an average 12.6% reduction in optical density in each deafferented lamina compared to its adjacent layer. Calbindin neurons were still present but their labeling was sometimes reduced. Occlusion without enucleation had no effect. Thus, deafferentation but not light deprivation reduces concentrations of calbindin. Supported by NEI EY-02973, EY-05975 and EY-RR00165.

47.2

ANTIBODIES TO CALBINDIN LABEL DISCRETE SUBPOPULATIONS OF INTERNEURONS IN THE CAT SUPERIOR COLLICULUS. R.R. Mize¹, C.J. Jeon¹, G.D. Butler¹, and P.C. Emson², ¹Dept. of Anatomy and Neurobiology, Univ. of Tennessee Health Science Center, Memphis, TN, 38163 and ²AFRC Inst. of Animal Physiol. Cambridge, UK.

Calbindin is a calcium binding protein thought to play a role in regulating intracellular calcium. We have localized calbindin (CaBP) in the cat superior colliculus (SC) using antibody immunocytochemistry. Anti-CaBP labeled neurons were found in three distinct bands, one within the upper one-half of the superficial gray layer (SGL) , another bridging the deep optic (OL) and intermediate gray layers (IGL) and a third in the deep gray layer (PGL) where the cells sometimes formed vertically oriented patches. 48.5% of the anti-CaBP labeled cells were found in the SGL, 43.7% in OL and IGL, and 7.8% in the deepest layers of SC. Most anti-CaBP positive neurons were small (mean average diameter = 12.0 µm), but varied in morphology. Labeled neurons within the SGL had horizontal, pyriform, or stellate morphologies. Many of the labeled neurons in the OL-IGL band were stellate-like with highly varicose dendrites and broad dendritic trees. A few very large neurons within the DGL were lightly labeled. Smaller labeled neurons were also found throughout the deep layers.

Retrograde transport studies demonstrated that all but a small fraction of anti-CaBP labeled neurons were interneurons. No anti-CaBP positive neurons were retrogradely labeled after HRP injections into the predorsal bundle, dorsolateral midbrain, or lateral posterior nucleus. Only 2.4% of anti-CaBP neurons were labeled after HRP injections into the dorsal and ventral lateral geniculate nuclei. Double-labeling with calbindin and GABA antibodies showed that some but not all calbindin neurons also contained GABA. Supported by NEI Grant EY07973

EFFERENT CELL CLUSTERS WITHIN THE CHOLINERGIC PATCHES IN THE INTERMEDIATE GRAY LAYER OF THE CAT SUPERIOR COLLICULUS. C. J. JEON and B.R. Mize, Dept. of Anatomy and Neurobiology, Coll. of Med., Univ. of Tennessee, Memphis, The Health Sci. Ctr., Memphis, TN, 38163.

Several cortical and subcortical afferent projections to the superior colliculus (SC) have patch-like terminations in specific laminae. One of these is a cholinergic input which forms distinct patches in the dorsal intermediate gray layer (IGL) and is thought to arise from the pedunculopontine tegmental nucleus (PPTN). In this study, we have examined the relationship of these cholinergic patches to specfic efferent cell groups in the cat SC using combined retrograde transport of horseradish peroxidase (HRP) and choline acetyltransferase (ChAT) immunocytochemistry. HRP injections were made into the medial predorsal bundle (PB), the lateral tecto-pontine-bulbar pathway (TPB), and/or the PPTN in 7 adult cats. The labeled cell distributions were mapped using a computer-based microscope plotter. Distinct clusters of labeled cells were seen after two small injections which involved both the PB and TPB. Four to seven clusters were found in each section through the caudal one-half of SC. No clusters were found in more rostral sections. The cell clusters were more frequent in the medial than in the lateral portion of IGL. Most clusters consisted of 7-15 cells, all of which were small to medium size (12.2-27.1 μm in average diameter). No very large predorsal bundle cells were ever labeled within the clusters. In sections combining HRP and anti-ChAT labeling, the cell clusters were found to precisely overlap the cholinergic patches in the IGL. These cell clusters were not found after injections confined to PPTN and TPB where HRP backfilled cells were for the most part located outside of the ChAT patches. These results suggest that specific cell groups, distinguished by size and projection site, form modules that match the patch-like innervation of cholinergic afferents to SC. Supported by EY-02973.

ANTIBODIES TO CALBINDIN DELINEATE RETINAL PROJECTION ZONES WITHIN THE PRETECTUM. L. Burt Nabors and R. Ranney Mize. Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, TN 38163

The pretectum is an important visual reflex center. However, the location, boundaries, and connections of individual nuclei of the pretectum are poorly understood. Traditionally the pretectum has been divided into 5-7 component nuclei based on cell size and shape, three of which receive retinal input. This retinal input has recently been described as forming 4 projection zones running through the rostro-caudal extent of the region from medial to lateral. The relation of these zones to individual pretectal nuclei remains unclear.

We have used an antibody against the calcium binding protein, calbindin 28kd, to study the relationship between pretectal cells and the retinal projection zones in cat. Four cell clusters were labeled by calbindin within the pretectum. Reconstruction of these cell clusters also revealed zones which run the rostro-caudal length of the pretectum from medial to lateral. By combining anterograde HRP labeling of retinal terminals with calbindin immunocytochemistry, these calbindin positive cell clusters were found to overlap precisely the retinal projection zones. A percentage of these calbindin neurons were projection neurons back-filled by HRP injections into the lateral geniculate nucleus. They varied in morphology, but most were medium to large neurons. Small GABA immunoreactive cells were also found within these zones but no GABAergic cells were retrogradely labeled following LGN injections and very few colocalized calbindin.

In summary, calbindin is a precise marker of cell clusters in the pretectum which overlap the retinal projection zones. Many of these cells are large, non-GABAergic projection neurons whose target is the LGN. Whether all of the calbindin positive cells receive direct retinal input remains to be determined. Supported by NEI grant EY-02973 and an HHMI MSRF.

HABITUATION FUNCTIONS OF MULTISENSORY NEURONS IN THE AMPHIBIAN TECTUM. M.M. Nikoletseas.

Department of Anatomy, School of Medicine, University of Puerto Rico, San Juan, PR 00936 Multisensory tectal neurons integrate informa-

Multisensory tectal neurons integrate information from diverse sensory modalities by such processes as excitation, inhibition and habituation. In the present study quantitative analysis of the habituation of these cells was undertaken. Animals were anesthetized and paralyzed. Multimodal cells were identified and subsequently a single or a multimodal stimulus was presented repeatedly. Extracellular signals were amplified, and analyzed on-line. Spurious signals were excluded by a window discriminator and waveshape recognition filters, and histograms were constructed for immediate visualization of the habituation functions. Multisensory cells showed steeper functions when unimodal stimuli were presented. In addition a variety of firing as well as habituation functions were obtained, not allowing for easy categorization of cells. These data suggest that the known intrinsic plasticity of tectal cells is modulated not only by the various parameters of afferent stimuli but also by the presence or absence of one component of the afferent multimodal stimulus.

NEURONS PROJECTING FROM THE SUPERIOR COLLICULUS TO THE PRINCIPAL TECTORECIPIENT ZONE OF THE LATERAL POSTERIOR-PULVINAR COMPLEX ARE IMMUNOREACTIVE FOR SUBSTANCE P. Leffrey I. Hutsler and Leo M. Chalupa. Dept. of Psychology, Neurobiology and Physiology Graduate Groups, University of California, Davis, CA 95616.

Neurons within the superficial layers of the cat's superior colliculus (SC) have been shown to project to multiple visual areas of the extrageniculate thalamus (Abramson and Chalupa, 1988). We have sought to identify subpopulations of these projection neurons based upon their peptide content as demonstrated by immunocytochemical techniques. Substance P or tachykinin-related immunoreactivity has been identified in a morphologically diverse group of cells within the superficial layers, including triangular, bipolar, granular, and some pyramidal neurons. Substantial proportions of these immunoreactive cells were demonstrated to be projection neurons based upon their labeling with rhodamine latex beads following injections of this tracer into the lateral posterior-pulvinar (LP-Pul) complex. A terminal zone of substance P immunoreactivity was also observed in a discrete region in the medial portion of the LP-Pul. When adjacent thalamic sections processed for acetylthiocholinesterase staining were examined, substance P label was found to be localized within the heavily stained cholinesterase region, which has been shown to be the principal tectorecipient area of the LP-Pul complex (Graybiel and Berson, 1980). The thalamic labeling decreased markedly in animals that sustained unilateral lesions of the SC, demonstrating the collicular origin of the substance P immunoreactivity. These results suggest that substance P is involved in conveying visual information from the superficial layers of the SC to the principal tectorecipient zone of the cat's LP-Pul complex.

SENSORY-TRIGGERED OSCILLATORY ACTIVITY IN THE AVIAN TECTUM. S.Neuenschwander* and F.J.Varela Institut des Neurosciences, CNRS - U. Paris VI, 9, Quai St.Bernard; 75005 - Paris.

We have recorded from tectal neurons in the optic tectum of awake pigeons whose receptive field was stimulated by a moving bar in sequences of 10 identical trials of 0.5-1.0 sec. These responses were processed to match the treatment reported for oscillatory activity in the cat's visual cortex¹.². Local field potential (LFP), obtained by digitally filtering the responses between 1-100 Hz, displayed oscillatory activity shortly after the stimulation began (50-100 msec). The peak frequency varied from trial to trial between 25-45 Hz (average of 30), and it was also visible in the power spectra obtained by the FFT of the LFP, as well as from their respective autocorrelograms. The average LFP preceding and following 50 msec every spike in a trial showed that spikes covary with the negative going phase of the oscillation. These oscillations were seen in both single and multiple activity and at various tectal depth. We conclude that in all these respects the tectal oscillatory activity matches remarkably well that of visual neocortex. This strengths the universality of oscillatory activity as possibly functional mechanism in the formation of neuronal assemblies, and shows that a model for it cannot rely on neocortical features such as columnarity.

ALTERATION OF SENSORY RESPONSIVITY IN RAT SUPERIOR
COLLICULAR NEURONS DURING STIMULATION OF THE STRIATUM OR
SEPTAL NUCLEUS. J. L. Petrie* and D. A. Weldon. Dept. of
Psychology, Hamilton College, Clinton, NY 13323.
Excitation of neurons in the caudate-putamen causes
tectospinal/tecto-diencephalic cells to discharge vigorous-

Excitation of neurons in the caudate-putamen causes tectospinal/tecto-diencephalic cells to discharge vigorously. This effect has been attributed to inhibition of the GABA-ergic nigrotectal system by striato-nigral cells and suggests a possible mechanism by which orientation movements are elicited from the striatum (Chevalier et al., Brain Res. 334:215, 1985). To determine whether sensory functions of the superior colliculus (SC) are modulated by activity in the striatum, we investigated responsivity in SC neurons in urethane-anesthetized Long-Evans rats to a 300 msec flash of light or burst of white noise during electrical stimulation of the ipsilateral caudate-putamen (0.1 msec duration square wave pulses of 100µA for 100 msec at 100 Hz). We also studied the effects of stimulation of the septal nucleus on SC sensory responses. Responsivity, as measured by the number of action potentials elicited by the effective sensory stimulus, was modified in 26% of the cells by striatal stimulation and in 11% of the cells by septal stimulation. Responsivity increased in 71% and 83% of the neurons modified by striatal and septal stimulation, respectively. The results suggest a significant influence of the striatum on sensory processing in the SC.

EFFECTS OF INACTIVATION OF THE SUPERFICIAL LAMINAE UPON THE VISUAL RESPONSIVITY OF DEEP LAYER NEURONS IN THE HAMSTER'S SUPERIOR COLLICULUS. R.D. Mooney, X. Huang, and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo OH 43699.

Visual cells in the superficial superior collicular (SC) layers innervate the deep laminae. As yet, however, nothing is known about functions of this projection. We used micropressure ejection of CoCl₂ to reversibly block synaptic activity in portions of the superficial laminae and assessed the effects of this blockade upon the responses of deep layer cells to visual and optic chiasm (OX) stimulation. All deep layer neurons tested had receptive fields in topographic register with the part of the superficial laminae silenced by CoCl₂ injection. Of 28 deep layer cells tested, 21 had their visual and/or OX responses reduced by at least 50% during inactivation of the superficial laminae; the remaining 7 cells were not affected. Five cells with responses that were suppressed by CoCl₂ injections were filled with HRP. All had cell bodies in the stratum griseum intermediale (SGI), 3 had dendrites that ascended into the stratum griseum superficiale, one had dendrites extending into the stratum opticum (SO), and the third had dendrites that reached the SGI-SO We recovered one cell that was not affected by CoCl2 ejection. It was a widefield vertical cell whose soma was located at the SO-SGI border. Input from the superficial laminae is thus important for the visual responsivity of many deep layer neurons in the hamster's SC. Supported by EY 08015 and EY 04170.

EFFECTS OF CORTICAL AND NIGRAL DEACTIVATION ON VISUAL NEURONS IN CAT SUPERIOR COLLICULUS. D.D. Dunning, B.E. Stein and J.G.

SUPERIOR COLLICULUS. D.D. Dunning, B.E. Stein and J.G. McHaffie. Department of Physiology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA, 23298.

Deactivation (cooling) of posterior aspects of lateral suprasylvian cortex (PMLS, PLLS, DLS & VLS) decreased the visually-evoked responses of deep laminae superior colliculus neurons as previously reported (Ogasawara et al., J. Neurophysiol., 52:1226, 1984). The present experiments also demonstrated that some of the neurons affected by suprasylvian cortex also send descending axons into the brainstem, thereby providing the first direct evidence that cortex controls the activity of output neurons and, by inference, visual orientation behaviors mediated by superior colliculus. This is consistent with previous experiments in behaving animals (Hardy and Stein, J. Comp. Neurol., 273:527, 1988).

Deactivation (microinjected GABA) of substantia nigra pars reticulata and pars lateralis dramatically enhanced the visually-evoked activity of superior colliculus neurons but had little affect on their spontaneous activity (reflecting an unexpectedly phasic nature of nigrocollicular influence). Furthermore, despite anatomical studies indicating that the nigrocollicular projection is overwhelmingly ipsilateral, substantia nigra deactivation proved to have bilateral physiological effects. In addition, and perhaps most surprising, superficial as well as deep laminae superior colliculus neurons were modulated by the basal ganglia. Generally, the effects of deactivating cortex and substantia nigra offset one another and indicated that the balance of these inputs is critical for normal deep laminae visual activity.

DISTRIBUTION OF CORTICOTECTAL CELLS IN THE SUPERIOR TEMPORAL SULCUS OF THE MACAQUE. T.M. Lock, J.S. Baizer and D.B. Bender*, Depts. of Physiology and Pediatrics, University at Buffalo, Buffalo, N.Y., 14226.

The superior temporal sulcus (STS) contains a number of visual areas, including V4t, MT, MST, and STP; areas V4, TEO, and TE also extend into STS. The superior colliculus (SC) receives widespread extend into STS. The superior colliculus (SC) receives widespread inputs from visual cortex. However, the distribution of corticotectal cells in the different functional zones of STS is not known. We plotted the location of labeled cells in STS following injections of retrograde fluorescent tracers into SC. There were clear differences in the distribution of corticotectal cells within STS. When the injection included superficial and deep layers of SC, much of the STS contained labeled cells. Labeled cells were densely distributed through the posteric half of the laware host of the subset. contained labeled cells. Labeled cells were densely distributed through the posterior half of the lower bank of the sulcus, (areas V4, V4t, MT and MST). In the anterior half of the lower bank, the density of labeled cells decreased, so that the most anterior portions (area TE) were free of labeled cells. In the posterior half of the upper bank of STS, another area free of labeled cells extended into the densely myelinated part of MST, overlapping the region where pursuit cells have been found (Komatsu and Wurtz, 1988). Anteriorly, in area STP, labeled cells were present to the tip of STS. With an injection restricted to superficial layers, label in STS was much sparser, and confined to the lower bank. These results suggest that visual areas of the STS differ in their contributions to the corticotectal system. (Supported by EY02254, MH4213 and The Whitehall Foundation.)

SUBCORTICAL CONNECTIONS OF INFERIOR TEMPORAL CORTEX IN SQUIRREL MONKEYS. G. E. Steele, D. M. Kopp and R. E. Weller. Dept. of Psychology, University of Alabama at Birmingham, Birmingham, AL 35294.

Patterns of cortical connections have suggested that IT cortex (area TE) of squirrel monkeys (Saimiri sciureus) contains caudal (IT_C) and rostral (IT_R) subdivisions (Weller et al., <u>Soc. Neurosci.</u>
<u>Abst.</u>, 15: 1108, 1989). Injections of the neuroanatomical tracers wheat germ agglutinin conjugated to horseradish peroxidase, proline and leucine, Fast Blue, Fluoro-Gold, and Diamidino Yellow were made under sterile conditions in IT_C and IT_R . Both IT_C and ITp injections labeled similar structures, including the locus coeruleus, dorsal raphe, caudate, putamen, claustrum, basal nucleus of Meynert, and lateral hypothalamus. Differences were found, however, between IT_C and IT_R in connections with the superior pulvinar and the amygdala. IT_C injections labeled the central and lateral subdivisions of the superior pulvinar, whereas $IT_{\mathbf{p}}$ injections labeled primarily the medial subdivision of the superior pulvinar. In the amygdala, ${\rm IT_C}$ injections revealed connections with the basal lateral nucleus, whereas ${\rm IT_R}$ injections labeled the lateral, basal lateral, and medial basal nuclei. These results support the hypothesis that ${\rm IT}_C$ and ${\rm IT}_R$ are separate subdivisions of cortex. Supported by EY07147 to REW.

BIMODAL VISUAL-TACTILE RESPONSES IN THE MACAQUE PUTAMEN. Gross and M.S.A. Graziano*. Psychology Department,

Princeton University, Princeton, N.J. 08544
We recorded from the putamen of immobilized macaques anesthetized with N. 2.0. Somatotopic organization and receptive fields were essentially as described by Crutcher and DeLong for unanesthetized macaques (Exp.Brain Res., 53:233-243,1984). Cells in the face and arm area often responded to visual as well as tactile stimuli, or only to visual stimuli. The bimodal cells tended to have large, bilateral visual receptive fields, with a smaller region of best response which matched the location of the tactile receptive field. The optimal visual stimulus was usually one moving toward the monkey within 20 cm of the tactile receptive Five cells with tactile receptive fields on the arm only responded to visual stimuli when the arm was placed within the monkey's field of view. Cells that were exclusively visual tended to have a uniform response strength throughout their large, bilateral receptive fields.

SPINAL CORD AND BRAINSTEM

REFLEX ASYMMETRY RESULTING FROM LESIONS OF THE SPINAL CORD, AND EFFECTS THEREON OF ANESTHESIA. J.S. Taylor, R.M. Friedman, J.X. Bao, D.P. Theele*, C.J. Vierck, and J.B. Munson, Dept. of Neuroscience, Univ. of Florida, Coll. of Med., Gainesville, FL 32610.

We are studying cellular mechanisms responsible for augmented reflexes following spinal lesions (spasticity). As a model, we are using cats with unilateral damage to the spinal cord. Reflexes are measured by recording EMG activity from both triceps surae of trained unanesthetized cats while both hind feet are flexed or extended simultaneously. Lesions of a low-thoracic dorsal quadrant (confirmed only by MRI to date) result in augmented stretch reflexes ipsilateral to the lesion. Since terminal cellular experiments will require an anesthetic procedure consistent with expression of these altered reflexes, we test these same animals similarly for the presence both of stretch reflexes and of reflex asymmetry with surgical doses of anesthetics. Brisk stretch reflexes and reflex asymmetries persist with ketamine anesthesia (30mg/kg). Supported by NS27511, NS15913, NS17474, MH15737.

QUANTITATIVE BEHAVIORAL MEASURES OF CAT TAIL REFLEXES: A MINIMALLY DISRUPTIVE MODEL TO STUDY THE CONSEQUENCES OF SPINAL CORD INJURY.

R. M. Friedman, C. J. Vierck, Jr., and L. A. Ritz.

Departments of Neuroscience and Neurosurgery,
Univ. of Florida, Gainesville, FL 32610.

Rhoton et al., (1988) observed qualitatively that hemisection or transection at Cal of the cat sacrocaudal spinal cord can produce a long-lasting hypertonia, cutaneous hyperreflexia and clonus of the tail. We are now developing quantitative measures of tail behaviors. As a measure of cutaneous hyperreflexia and clonus, we are characterizing the thresholds and magnitudes of responses by tethering the tip of the tail to a force trans-ducer. For muscle tone, we determine resistance of the tail to displacement in the horizontal or vertical axis. Preliminary results indicate that spinal cord transection (n=3) or left hemisection (n=3) increase the amplitude of the cutaneous flexion reflex. In cats with transections, clonus flexion reflex. In cats with transections, clonus is initiated by cutaneous stimulation. In cats with a tail that tonically deviates (n=2), there is greater resistance to movements away from the preferred position. With these sensitive assays, we hope to evaluate the behavioral consequences of spinal cord injury and repair.

Supported by NS27511 and NS07261.

SUPRASPINAL AND CERVICAL PROJECTIONS TO THE RAT SACROCAUDAL SPINAL CORD. R.L. Masson Jr., C.R. Murray* and L.A. Ritz. Depts. of Neurosurgery and Neuroscience, University of Florida, Gainesville, Fl., 32610.

The sacrocaudal spinal cord, which innervates the tail, is the subject of anatomical, physiological and behavioral investigations within our laboratory. Supraspinal and cervical neurons of the rat, projecting to the sacrocaudal spinal cord, were labeled following injection of Fluoro-Gold into the S₃-Ca₁ segments bilaterally. Supraspinal neurons were observed in the medullary and pontine raphe nuclei, the reticular nuclei, the dorsal column nuclei, the vestibular complex, noradrenergic groups, the red nuclei, periaqueductal gray, posterior hypothalamus and motor cortex. Within the cervical spinal cord, neurons were localized to laminae III-VIII and X, with the majority in the intermediate gray. Significant descending projections to the sacrocaudal spinal cord exist, with similar Significant descending distributions as compared to other spinal cord levels. Functionally, important interactions involving the extremities, pelvic viscera and tail may be mediated by these connections.

DORSAL ROOT POTENTIALS AND PRESYNAPTIC INHIBI-DURSAL ROOT POTENTIALS AND PRESYNAPTIC INHIBI-TION DURING DEVELOPMENT IN KITTENS. P. Bawa. School of Kinesiology, Simon Fraser University, Burnaby, B.C. Canada, V5A 1S6. Experiments were carried out on kittens

anaesthetised with Nembutal. Dorsal root potentials (DRPs), resulting from the stimulation of various peripheral nerves, were recorded from 1/3 distally cut L6DR. Amplitude of the DRPs was small in the first 2 weeks of age (mean approx. 50 uV) and then increased to adult values (400-500 uV) in the first 3 months of age. Duration of DRPs was longer during the first 20 days (100-400 msec) declining by 30 days of age to a range of 100-250 msec, increasing again after 3 months of age.

To examine the dependence of presynaptic inhibition on the magnitude and duration of DRPs, effect of conditioning on monosynaptic reflex (from gastroc-soleus nerve) recorded from L7VR, (trom gastroc-soleus nerve) recorded from L7VR, was evaluated. At any age, presynaptic inhibition produced by superficial peroneal nerve (a cutaneous nerve) was of much shorter duration than produced by the deep peroneal nerve (a muscle nerve) even though there was no difference in the duration of DRPs. Duration of presynaptic inhibition also depended on the receiving afferents. Supported by NSERC.

ACTION OF (-)-BACLOFEN ON SEGMENTAL PATHWAYS PRODUCING PAD. J. Quevedo*, J.R. Eguiber*, I. Jiménez and P. Rudomín. Dept. Physiol. Biophys and Neurosc. CINVESTAV, México, D.F. 07000 and Dept. Physiol Sci ICUAP, México.

We have shown previously (Neurosci. Abst. 15: 365, 15), that monosynaptic EPSPs produced in spinal motoneurons by activation of group Ia fibers are significantly more depressed after i.v. injection of 1-2 mg/kg (-)-baclofen than monosynaptic EPSPs produced by stimulation of the bulbar reticular formation (RF). This lead to the proposal that descending fibers also have GABAb receptors, but in lower density than Ia fibers. We have now studied in the anesthetized cat the effects of this GABAb agonist on the PAD elicited in single Ib gastrocnemius fibers. PAD was estimated by measuring the intraspinal threshold changes of the fiber. Ten minutes after 1-2 mg/kg (-)baclofen, the PAD evoked by PBSt stimulation (3 shocks, 300 Hz, 2xT, 25 ms before the test pulse) was depressed to about 50% of control values and was completely abolished after 30-40 minutes. However, the Values and was completely arothshed after 30-40 minutes. However, the PAD produced by RF stimulation (10 pulses, 400 Hz, 80 μA, 75 ms before the test pulse) was depressed only to about 50%. Intraspinal microstimulation may produce monosynaptic PAD by direct activation of last order interneurons synapsing onto the Ib fibers. This PAD was also depressed by (-)-baclofen but only to about 50%. Our data suggest that in addition to the effects that baclofen may have on afferent and descending fibers, the last order PAD mediating interneurons also have CABAb receptors. Those receptors located on the axon terminals of the interneurons would function as autoreceptors regulating the release of GABA. Partially supported by grants NIH 09196, CONACyT 41739 and 891571. Baclofen was a gift from Ciba-Geigy.

DIFFERENTIAL EFFECTS OF TRAUMA ON SENSORY AND MOTOR SPINAL CORD TRACTS IN ANESTHETIZED CATS. M. Javachandra* and V.E. Amassian, Dept. of Physiology, State University of New York, Health Science Center, Brooklyn, N.Y. 11203.

The series included 14 cats, which were anesthetized throughout with Na pentobarbital (initially 40 mg/kg I.P), supplemented by I.V. doses). Population direct (D) responses were usually recorded from the lateral corticospinal tract (CT) to contralateral motor cortical stimulation and from the posterior tibial nerve to antidromic dorsal column (DC) stimulation at C1. A modified Allen weight drop produced the spinal cord trauma, usually between T2-T2. During stimulation and the weight drop, gallamine triethiodide was used as a muscle relaxant, supplemented by artificial ventilation. Responses were reduced within a second of impact; therefore, neither edema nor vascular changes accounted for the initial deficit. The deficit in the directly conducted CT usually exceeded that in the DC, although the weight fell more over the DC which also showed greater histological changes. With a submaximal drop, partial recovery could occur over a time course of, e.g., 30 min. Subsequently, a secondary depression could occur over a period of hours, suggesting more than one cause of the deficit. A DC volley transmitting through a partial block facilitated the response to local stimulation. Summarizing, a suitable electrophysiological test system is proposed for analyzing differential functional effects of spinal trauma.

RETICULO-SPINAL INHIBITION OF RECURRENT DORSAL ROOT POTENITALS IN THE ISOLATED NEIROAKIS OF THE FROS. H. González*, I. Jinénez and P. Rudoufin.
Dept. Physiol. Biophys. and Neurosci. CINVESTAV, México 07000 DF.

Most of the work concerning descending influences on segmental spinal mechanisms in the frog has been made by stimulating spinal funiculi. We now use the isolated neuroaxis to investigate the action of reticulo-spinal inputs on transmission along the recurrent pathway from motoneurons to afferent fibers (RM-AF). The reticular formation in the brain stem (RF) was stimulated with fine bipolar tungsten electrodes. Suction electrodes were employed to record DRPs and to stimulate the motor nerves from hindlimb extensors. Stimulation of the RF (3-5 pulses at 60-100 Hz) with intensities below those necessary to produce DRPs (60-200 µA), inhibited the DRPs produced by stimulation of motor nerves (VR-DRPs), to a mean value of 82 ± 6% of their control amplitude (n=5). The depression had an onset between 15-30 ms, became maximal at 40-70 ms and lasted more than 100 ms. Stronger stimulation of the RF (200-300 μ A) produced DRPs lasting up to 120 ms and also depressed the VR-DRPs, but had no effect on the amplitude of the field potentials recorded in the motor pool following antidromic stimulation of motor nerves (n=8). This suggests that the reduction of the VR-DRP's produced by RF stimulation is not due to conduction block in axon collaterals of motoneurons, but rather to inhibition of impulse transmission exerted on interneurons interposed in the RM-AF. The reduction of recurrent inhibition by reticulo-spinal inputs would allow sensory input to act on motoneurons and interneurons during the execution of movements. Partly supported by grants NIH 09196, CONACYT 41739 & 891571, & UNAM fellowship (H.G.).

48.8

THE IDENTIFICATION AND CENTRAL DISTRIBUTION OF JAW-MUSCLE SPINDLE AFFERENTS IN THE RAT Dean Dessem, Division of Anatomy, Washington University Dental School, St. Louis, MO 63110 Single units were recorded from the mesencephalic trigeminal nucleus of rats deeply anesthetized with alpha-chloralose and pentohaphital Spindle afferent types were

pentobarbital. Spindle afferent types were identified by their response during ramp muscle stretches prior to and during the infusion of the depolarizing drug suxamethonium (100-200 ug/kg/min). Extracellular spike triggered averaging from clear primary and secondary afferents revealed short-latency, repeatable field potentials (3-18 uV) dorsal to and within the Nissl-stained confines of the trigeminal motor nucleus (MotV) Control average first motor nucleus (MotV). Control averages from non-spindle cells showed no evidence of fields. Afferents which showed a small increase in dynamic index during depolarization presumably represent secondary afferents with terminations onto bag fibers. Extracellular field potentials generated by these afferents were also found dorsal to and within MotV. These results indicate that a wide diversity of jaw-muscle spindle afferent types project to MotV and to interneurons and/or distal dendrites of trigeminal motorneurons dorsal to MotV.

RESPONSE PATTERNS AND POST-SPIKE EFFECTS OF DORSAL ROOT GANGLION UNITS RECORDED DURING WRIST TORQUE TRACKING IN MONKEYS. D. Flament, P.A. Fortier & E.E. Fetz. Dept. of Physiology & Biophysics and Regnl. Primate Res. Ctr., Univ. of Washington, Seattle, WA 98195.

We documented the task-related activities and post-spike effects of peripheral afferents in dorsal root ganglia (DRG) under behavioral conditions similar to those used to study corticomotoneuronal (CM) [Fetz et al., Prog Brain Res 80:437, 1989] and rubromotoneuronal (RM) cells [Mewes & Cheney, Neurosci Abst 12:1303, 1986]. In 2 monkeys generating isometric ramp-and-hold wrist torques, we isolated 59 units in C8 and T1 DRG long enough to generate spike-triggered averages (STAs) of forearm muscle activity; 29 afferents produced post-spike facilitation (PSF) of 1 or more of the 12 EMGs. The PSFs often appeared on top of "synchrony facilitation", which began earlier than the shortest latency of electrically evoked muscle responses (3.0 ms); the PSF parameters were measured after subtracting these synchrony effects. The PSF onset latencies of DRG units averaged 4.9 ms ± 0.2 ms (S.E.) [c.f. 6.3 ms for CM cells and 5.6 ms for RM cells]. The magnitude of the PSFs, calculated as the mean percent increase of the PSF above the pre-spike baseline, was 4.6% ± 0.3 for DRG afferents [c.f. 7.0% for CM cells and 5.1% for RM cells]. DRG units facilitated 49% of the coactivated muscles [c.f. 40% for CM and 50% for RM cells]. DRG units producing PSF discharged during wrist flexion (10) or extension (13) torques or both (6). Most DRG units (52%) exhibited a tonic discharge pattern; 21% were phasic-tonic and 27% were phasic. On average, DRG unit discharge began 52 ms ± 13 prior to activation of their target muscle [c.f. -40 ms for CM and -89 ms for RM cells]. Phasic cells tended to begin earlier (-150 ms ± 59) than phasic-tonic (-72 ms ± 14) and tonic (-24 ms ± 17) cells. 7 tested DRG units responded with bursts to torque pulses which stretched their target muscles. Thus, peripheral afferents can significantly facilitate muscle activity and may be activated prior to their target muscles. (Support: NIH grants NS12542 and RR00166 and the MRC of Canada.)

48.11

PERIPHERAL ACTIVATION OF THE PATTERN GENERATOR FOR HIND-LIMB STEPPING IN CORDOTOMIZED, NEONATAL RATS. J.W. Commissiong. NIH, 10/5N214, Bethesda, MD 20892. Previous results have shown that spontaneous recovery of hindlimb coordination occurs in adult rats that were cordotomized before postnatal day 14 (PN14) (Exp. Brain Res. 78: 597-603, 1989). When adult rats previously cordotomized at PN7 are placed on an inclined surface of mental bars spaced at 10 mm, the hindlimbs appear paralyzed, and dangle between the bars. Therefore, to be functional, the hindlimbs must be in contact with a surface. The present experiments were done in the decerebrate, non-anesthetized preparation to determine the role of peripheral afferents in activating the hindlimb pattern generator. The spontaneous discharge of alphamotoneurons innervating the gastrocnemius and soleus muscles is higher in the PN7 group versus the PN14 group. The motor output, measured as an integrated electromyogram, in response to controlled stretches of varying rates and amplitudes, is greater in the PN7 versus the PN14 rats. These differences may result from augmented peripheral input (eg. Increased Gp.Ia activity) or from a greater central amplification of a normal peripheral input in the PN7 group. Future experiments will determine the contribution of these mechanisms to the recovery.

PATHWAYS CONDUCTING MOTOR EVOKED POTENTIALS IN THE SPINAL CORD OF RAT. Y.-G. PARK, J.-S. CHEON, W. H. LEE, and J. H. KIM, The Miami Project to Cure Paralysis, University of Miami School of Medicine 1600 NW 10 Ave. R48, Miami FI 33136.

of Medicine, 1600 NW 10 Ave., R48, Miami, FL 33136.

Recently, several laboratories have used the MEP as an electrophysiological monitioring tool for predicting the degree of spinal injuries in the rat. However, the origins and the conduction pathways of these MEPs remain controversial. The goal of this study was to investigate the origins and intraspinal pathways of MEPs. Female rats (200-250 gr) were used in this study. To define the pathways conducting MEPs in the spinal cord, the following methods were utilized: (1) field mapping technique, and (2) controlled serial spinal cord lesions. The motor cortex was directly stimulated using silver ball electrodes or screws placed on the cranium. Two pairs of teflon-coated wire electrodes with an 1 mm exposed tip were implanted at T2/3 and L2/3 levels and used for recording MEPs. To construct field maps of MEPs, intracord recordings were made using glass electrodes filled with 2 M NaCl (1.5 M Ohm). Serial spinal cord lesions were made using a #11 surgical blade at T8 level. Suprathreshold stimulation produced one to four consecutive positive-negative waves which were monitored in thoracic and lumbar cord. The amplitudes and latencies of MEP components were affected very little by dorsal cord lesions including dorsal corticospinal tract and rubrospinal tract. However, lesions encompassing ventral and ventrolateral funiculi dramatically altered the amplitudes and latencies of MEP components monitored below the lesion. The results of MEP field mapping suggested that the MEPs in the rat spinal cord conducted bilaterally in the reticulospinal tracts. This study was supported by The Miami Project Research Fund.

SYNAPTIC INPUTS ONTO PUDENDAL MOTONEURONS FROM SACRAL SEGMENTAL AND BRAINSTEM PATHWAYS IN THE CAT. B. Fedirchuk, S. Hochman and S.J. Shefchyk. Depts. Med. and Physiol., Univ. of Manitoba, Winnipeg, Canada R3E 0W3.

This study examined polysynaptic input onto identified pudendal motoneurons (MNs) produced by electrical stimulation of lumbosacral segmental afferents and the pontine micturition centre (PMC). Intracellular recordings from sacral MNs antidromically activated from the external urethral sphincter (EUS) or external anal sphincter (EAS) branch of the pudendal nerve were made in chloralose anaesthetized or decerebrate male cats. Electrical stimulation at strengths 2 & 5 x threshold (T = minimum strength for activation of afferent fibres) of peripheral nerves innervating cutaneous, muscle and pelvic visceral targets was used to identify synaptic inputs to pudendal MNs. Excitatory postsynaptic potentials (EPSPs) were produced in both EUS and EAS MNs by stimulation of the ipsi- and contralateral pudendal mixed sensory nerves with no apparent difference in latency between the two sides. The latencies of EPSPs in EUS MNs (mean 3.5 ms) tended to be slightly longer than those seen in EAS MNs. Stimulation of the ipsilateral pelvic nerve (branch to the bladder) produced later excitation while stimulation of the ipsilateral superior perineal cutaneous nerve produced EPSPs at a mean latency of 2.6 ms. Mixed EPSP/IPSP were sometimes revealed using step current depolarization of the MN membrane potential. IPSPs produced by trains of stimuli to the PMC were observed in several EUS MNs but not in EAS MNs. Hyperpolarization of EUS MNs (n = 2) was observed during PMC-evoked voiding while membrane depolarization or no change was observed in EAS MNs (n = 2).

BEHAVIORAL CORRELATES OF CERVICAL SPINAL CORD CONTUSION INJURY IN THE RAT. <u>G.W. Schrimsher, F.J. Thompson, and P.J. Reier.</u> Dept. of Neuroscience, U. of Florida, Col. of Med., Gainesville, FL 32610.

Dept. of Neuroscience, U. of Florida, Col. of Med., Gainesville, F. 1. 32610. The focus of this study is to establish a cervical spinal cord contusion injury model in the rat in conjunction with a battery of quantitative behavioral tests that are predictive of the extent and severity of the injury. A model of this nature will provide significant advantages as compared to midthoracic contusion models. The proximity of axonal damage relative to the cell bodies of origin of descending supraspinal systems may enhance regeneration potential. Cervical lesions will allow assessment and quantification of forelimb behavioral deficits and recovery following injury, and thus provide a new arsenal of behavioral tests that can be used to evaluate spinal cord damage. The contusion injury methodology used is an adaptation of that used by Wrathall et al. (Exp. Neuro., 88:108-122, 1985). A weight-drop contusion injury is produced by dropping a 10 gm weight from a height of 2.5 cm onto a 2.5 mm tip diameter impounder resting on the exposed dura of the C4 spinal segment. All rats that received this injury (n=10) survived and became self-sufficient within seven days of the injury. The acute (i.e. first 72 hours) recovery period is characterized by total forelimb impairment and lack of body weight support. Body weight support and locomotion usually returned within seven days (n=9). At one month, the lesion sites are characterized by a large cystic cavity involving the majority of the grey matter at C4. The cavities taper off in the dorsal columns within 3 mm of the lesion epicenter both rostrally and caudally. Rats are being examined on the following behavioral tasks: limb placement, sunflower seed shelling, horizontal reaching, force regulation, inclined plane, grid walking, and beam walking. Preliminary results (n=3) indicate at four weeks post-injury the mean crossing time increases 430% on the beam walking task and 400% on the grid walking task. Seed shelling ability was lost in 2 of 5 rats following the injury. Testing on the

SUPPRESSION OF SOMATOSENSORY INPUT TO THE RED NUCLEUS DURING MOVEMENT IN THE ANESTHETIZED TURTLE. R. Sarrafizadeh. J. Keifer, and J.C. Houk. Department of Physiology, Northwestern University Medical Center, Chicago, IL 60611-3008.

Bursts of red nucleus discharge are associated with discrete limb movements in the behaving monkey and are not modified when the movement is perturbed, suggesting that central motor programs rather than feedback from the periphery may be responsible for these signals (A.R. Gibson et al., J. Physiol. 358: 551, 1985). A recent theory of motor control suggests that sensory input may trigger the execution of preprogrammed motor commands by activating recurrent excitatory feedback in the cerebellorubral circuit (J.C. Houk In: Models of Brain Function, p. 309, 1989). To study sensorimotor integration in the red nucleus, we recorded extracellularly from single rubral cells in turtles (Chrysemys picta) anesthetized with sodium pentobarbitol (10 mg/kg).

pentobarbitol (10 mg/kg).

Bursts of action potentials were obtained from the red nucleus during the execution of a scratch reflex of the contralateral hindlimb. Units increased their rate of discharge when scratching commenced, and the rate of activity returned to the spontaneous level seconds after the movement had ended. During the scratching episode, unit activity was phasically modulated with the ongoing movement as evidenced by electromyographic signals obtained from the contralateral hindlimb. These rubral units also responded to somatosensory input with excitation or inhibition which was evoked by light touch to the shell and body surface. Responses to somatosensory input typically lasted the duration of stimulation. Sensory responses, however, could not be elicited from units in the red nucleus during scratching. Rubral burst frequency and duration were indistinguishable during scratching with or without sensory perturbation. Red nucleus sensitivity to sensory input returned after the movement had ended.

This suppression of somatosensory information in the red nucleus during movement suggests that motor programs may not be instantaneously modified during the course of their execution. Sensory information may be used, however, to select appropriate motor functions prior to movement and to trigger their release.

POST-STIMULATORY INHIBITION: AN ADDITIONAL MEDULLARY INHIBITORY MECHANISM. E. Schenkel, Y.Y. Lai and J.M. Siegel. Sepulveda VAMC, UCLA Sch. Med., Sepulveda CA 91343.

Recent studies of our group have shown that medullary stimulation produces nonreciprocal inhibition of muscle tone

in both the decerebrated and intact cat (Sleep Res, 18: 347, 1990). We now show that the medulla is also capable of causing inhibition by means of a poststimulatory mechanism.

Concentric bipolar electrodes were inserted in four cats, (Neurosci. Lett. 98:159-165, 1989) to targets at P 8-17, H 5-10 and L 0-2. Electrical stimulation at 26/60 stimulated sites was followed by a long latency, long lasting inhibition. For example, with stimulation in ventrocaudal medulla (200 msec trains at 200 Hz and 20 μ A, n=8), the maximal inhibitory effect was observed 1-4 sec after the termination of the stimulus, with return of baseline tone 9-16 sec later. The post-stimulatory inhibition was observed at sites at which excitation appeared during the stimulus trains, as well as at sites at which inhibition appeared during trains. When the stimulation was performed in alert waking, the behavioral response consisted of a sudden turn ipsilateral to the stimulation, followed by a slow dropping of the head. Our studies suggest the existence of a long lasting in-hibitory mechanism by which medullary activation may produce muscle tone suppression. (Supported by the VA and PHS grants MH43811 and HL41370.)

SYMMETRIC AND ASYMMETRIC COLLISION EFFECTS SUGGEST THAT MONOSYNAPTIC CONNECTIONS IN CAUDAL PONTINE RETICULAR FORMATION MEDIATE STARTLE-LIKE RESPONSES. J. S. Yeomans, C. M. E. Hempel and C. A. Chapman*, Dept. of Psychology, Univ. of Toronto, Toronto, Canada M5S 1A1.

Stimulating electrodes were placed bilaterally in the caudal pontine reticular formation (RPC) and the medulla. A conditioning (C) pulse was delivered via one electrode and a test (T) pulse was delivered via a second electrode at C-T intervals from -50 to +50 ms. A sharp decrease in the current required to evoke a startle response often occurred as C-T intervals increased from +0.4 to +1.0 ms or decreased from -0.4 to -1.0 ms (Hempel & Yeomans, 1989). This symmetric collision suggests that the startle response is mediated by axon bundles connecting those two sites.

Between other electrode pairs, a sharp decline in required current was observed as C-T intervals rose from +0.4 to +1.0 ms, or fell from +0.2 to -0.2 ms. This asymmetric collision suggests that the axons mediating startle in these sites were interrupted by single synapses in the caudal RPC transmitting from rostral to caudal. The transmission times were estimated to be 0.3 ms, and the conduction times between RPC and medial medulla 2-3 mm caudal were near 0.1 ms. Single action potentials must be evoked with high probability across these RPC synapses.
Collision effects were greater between RPC and ipsilateral, rather than contralateral, medulla. These collision tests,

STARTLE RESPONSES EVOKED FROM RETICULAR FORMATION IN RATS: DI-I AND COLLISION TESTS SHOW BILATERAL CONNECTIONS. E. Hempel, Zhou Si-shun*, J. S. Yeomans. Dept. of Psychology, Univ. of Toronto, Toronto, Canada M5S 1A1

Electrical stimulation of the nucleus reticularis pontis caudalis (RPC) with one pulse evokes startle-like responses with short latency (Davis, 1984). If a conditioning (C) pulse is delivered to one RPC site and a test (T) pulse is delivered to the contralateral RPC, collision-like effects occur at C-T intervals from 0.4 to 1.0 ms (Hempel & Yeomans, 1989). These results suggest that the neurons mediating startle have bilateral axonal connections between the two RPCs. The conduction velocities are estimated to be 7 to 40 m/s, by dividing the interelectrode distances by the difference between the refractory periods and the collision intervals. Collisions ranged from 19 to 50%.

The fluorescent tracer DiI was injected into the RPC post mortem and observed a few weeks later. DiI was taken up by myelinated fibers and transported over 10 mm into the ipsilateral longitudinal tracts of the reticular formation, the contralateral pyramidal tract and the contralateral RPC, although several weaker-labelled projections were observed. The projections to the contralateral RPC included many coarse fibers (1 to 5 um). These diameters are consistent with the behaviorally estimated conduction velocities using Hursch's (1939) ratio of 6. Therefore, post mortem DiI labels myelinated axons which may be responsible for the symmetric collision effects.

VERTICAL AND HORIZONTAL SACCADIC HEAD MOVEMENTS ARE ELICITED BY ELECTRICAL STIMULATION OF THE BRAINSTEM TEGMENTUM IN BARN OWLS. T. Masino and E.I. Knudsen, Dept. Neurobiology, Stanford University, Stanford, CA 94305.

Neural control of saccadic head movement in the barn owl appears to involve a

transformation from a retinocentric code (retinal and tectal levels) to a Cartesian-like code in which four functionally distinct generators control orthogonal directions of saccadic movement (up, down, left, and right). As part of an effort to locate these saccade generators, we focally stimulated brainstem sites including those regions where tectal efferent fibers overlap with spinal cord afferent cell bodies. Movements were recorded using a search coil attached to the freely moving head while body movements were restricted. At each location from which movements were elicited, nitial head position was varied and the dependence of movement direction on stimulus parameters (train-length, pulse-width, frequency, intensity) was determined. Different types of head movements were evoked from different brainstem sites.

However, saccadic head movements have been elicited from only two sites. From one medial region at the mesencephalic-rhombencephalic border, movements were directed vertically downward, the direction being independent of initial head position or of variations in stimulus parameters. Current thresholds were as low as 40 µA cathodal, and latencies as short as 16 msecs from stimulus onset. In contrast, stimulation and latencies as short as 16 msecs from summus onest. In contrast, summand applied to the other saccade generating site, in the rostral medial mesencephalon, produced horizontal movements that were directed ipsilaterally. Unlike the vertical downward movements, these horizontal movements depended on the head being initially positioned in the contralateral hemifield (relative to the body); however, large variations in starting position within that hemifield had little effect on movement direction. Current thresholds were as low as 75 µA cathodal, and latencies as short as 19 msecs from stimulus onset.

These results are consistent with the hypothesis that saccadic head movements are controlled by circuitry, residing in the brainstem tegmentum, that encodes independently horizontal and vertical components of movement. (NIH:RO1:NS27687-01)

SPINAL CORD AND BRAINSTEM: MOTONEURONS

LATENCIES OF CUTANEOUS EVOKED IPSPs AND EPSPs IN EDL MOTONEURONS OF CAT SUGGEST DISYNAPTIC CIRCUITRIES. R.G. Durkovic and J.C. Leahy. Dept. Physiology, SUNY Health Science Center at Syracuse, Syracuse, NY 13210. Intracellular recordings were obtained from extensor

digitorum longus motoneurons during electrical stimulation of cutaneous saphenous or superficial peroneal nerves in the unanesthetized, decerebrate, T-Only motoneurons spinal cat. with membrane potentials >55 mV and action potentials >60 mV were analyzed.

Postsynaptic potentials were complex, either initial hyperpolarization or depolarization. Saphenous nerve stimulation most often evoked initial EPSPs. These had relatively long latencies between the cord dorsum "S" wave and EPSP onset that averaged about 4 ms. However, initial IPSPs with latencies near 1.8 ms were occasionally observed. Stimulation of cutaneous superficial peroneal nerve most often evoked cutaneous superficial peroneal nerve most often evoked IPSPs, some with latencies below 1.8 ms. Furthermore, occasional initial EPSPs of short latency (<1.8 ms) were also observed. The results suggest that the minimal circuitries for cutaneous excitatory and inhibitory inputs to certain motoneurons of the cat hindlimb involve single interneurons interposed between cutaneous afferents and these motoneurons. MODULATION OF AFTERHYPERPOLARIZATION AMPLITUDE IN LUMBAR MOTONEURONS DURING FICTIVE LOCOMOTION IN THE RAT SPINAL CORD IN VITRO. B.J. Schmidt Dept of Medicine, Faculty of Medicine, University of Manitoba, Winnipeg Canada R3E 0W3.

Previous in vivo studies suggest that modulation of afterhyperpolarization (AHP) may regulate motoneuron firing during locomotion (Jordan and Shefchyk Soc Neurosci Abstr 10:1847, 1984; Brownstone et al ibid 12:241.2 1986; ibid 13:244.15 1987). In an effort to further understand the mechanisms by which cell firing is controlled during locomotion the present series employs an in vitro model of mammalian locomotion (Smith et al FASEB 2:2283 1988). Bilaterally intact spinal cords were transected at the C1 level and rhythmic alternating ventral root activity was induced by the application of NMDA or acetylcholine to the bath. The intracellular records of some motoneurons demonstrated spontaneous firing, predominately during the active phase of the step cycle as judged by the occurrence of the depolarizing phase of rhythmic membrane potential oscillations and ventral root discharge from the corresponding lumbar segment. Occasionally action potentials also fired during the otherwise inactive phase of the locomotor cycle. The amplitude of AHFs occurring during the peak active phase were reduced by up to 75% compared with AHFs occurring at other times in the step cycle. In other motoneurons, demonstrating rhythmic membrane potential depolarizations without spontaneous firing, action potentials were evoked by brief (< 1ms) depolarizing current pulse injections delivered throughout the step cycle, followed by hyperpolarizing pulses (5ms) to test for the presence of rhythmic changes in somatic conductance. Averaged responses showed that AHPs following the evoked spikes were also reduced during the active phase of the step cycle is mediated by the spinal cord locomotor circuitry and does not depend on supraspinal neuromodulatory inputs. The data also suggest that the reduction in AHP amplitude duri

PGO CLUSTERS AND MOTONEURON MEMBRANE POTENTIAL DURING ACTIVE SLEEP, <u>F Lopez-Rodriguez*</u>, <u>I. Stafford-Segen</u>, <u>F.R. Morales and M.H. Chase</u>. Dept of Physiology, Dept. of Anatomy and Cell Biology and the Brain Research Institute, UCLA School of Medicine, Los

Angeles, CA 90024.
Pontogeniculooccipital (PGO) waves that occur during active sleep have Pontogeniculooccipital (PGO) waves that occur during active sleep have been associated with the inhibition of somatic motoneurons (Morales et al., Sleep Res., 18:20, 1989). This association was determined during the non-REM periods of active sleep when the predominant synaptic input to motoneurons is inhibitory rather than excitatory. However, during clusters of REMs and PGO waves, a complex pattern of motoneuron excitatory and inhibitory synaptic activity takes place (Chase and Morales, Science, 221:1195-1198, 1983). Consequently, the question was raised whether, within these clusters, excitatory synaptic activity is also temporally related to PGO waves. Experiments were performed in chronic cats that were prepared for intracellular recording from lumbar motoneurons during sleep and PGO waves. Experiments were performed in chronic cats that were prepared for intracellular recording from lumbar motoneurons during sleep and wakefulness (Morales et al., *Physiol. Behavior.*, 27: 355-362, 1981). The following relationships between PGO waves and motoneuron membrane potential were observed. (1) Clusters of PGO waves were correlated with sequences of IPSPs. (2) Excitatory potentials did not have a clear temporal relationship with the PGO clusters; they appeared even when the PGO waves were not present. These observations lead us to conclude that an active sleep-specific inhibitory system is phasically activated during clusters of PGO waves as it is during isolated PGO waves, suggesting that a single identical system is involved in motoneuron inhibition during both REM and non-REM periods. In addition, we conclude that the neuronal systems responsible for periods. In addition, we conclude that the neuronal systems responsible for the depolarizing shifts in motoneuron membrane potential that take place during REM periods are not directly linked to those that generate PGO waves. ALTERATIONS IN MOTONEURON MEMBRANE CURRENTS ARE CORRELATED WITH DEVELOPMENTAL CHANGES IN THE PATTERN OF MOTOR ACTIVITY IN THE ISOLATED SPINAL CORD OF THE CHICK EMBRYO. <u>Evelyne Sernagor and Michael O'Donovan</u>. Laboratory of Neural Control, NINDS, NIH, Bethesda MD 20892.

Previous studies have revealed an increase in the intensity and duration of motoneuron discharge during each cycle of motor activity generated by the chick embryo spinal cord. Early in development (E7-E9) flexor motoneurons fire predominantly at the beginning of each cycle whereas at later stages (E12-E13) they fire a second burst out of phase with extensor activity. We have used the whole cell patch clamp technique to investigate developmental changes in motoneuron membrane currents which may be responsible for these changes in activity. Whole cell patch clamp recordings were obtained from antidromically identified motoneurons in the isolated spinal cord of E9 to E13 embryos.

From E9 to E13 motoneurons are depolarized throughout the cycle even when firing is inhibited. At E9 voltage clamp recordings reveal that the predominant current is a transient inward current that peaks during the flexor inhibition and reverses at -56.9±11.2 mV, leaving a small sustained inward current (mean = -2.8 pA) that is relatively insensitive to membrane potential and that we have been unable to reverse. Later in development the transient current reverses at -34.5 ± 10.3 mV leaving a substantially larger sustained inward current (mean = -25.7 pA).

These findings suggest that the transient current is mediated by an

inhibitory synaptic potential and that the sustained current is excitatory. It is not clear at present if the excitatory current is synaptic. The increase in the magnitude of the excitatory current may account for developmental changes in the firing pattern of motoneurons.

TIME COURSE OF MOTONEURONAL ADAPTATION IN RESPONSE TO EXTRACELLULAR ACTIVATION. J.M. Spielmann, Y. Laouris*, M.A. Nordstrom, B.M. Reinking* and D.G. Stuart. Dept. of Physiology, Univ. of

Nordstrom, R.M. Reinking* and D.G. Stuart. Dept. of Physiology, Univ. of Arizona, Tucson, AZ 85724.

We have previously reported the feasibility of studying motoneuron adaptation using sustained and repetitive extracellular activation (Spielmann et al., Soc. Neurosci. Abstr., 15:920, 1989). In the present study, we quantified several features of motoneuronal adaptation for 13 individual medial gastrocnemius motoneurons (6 FF, 1 FR, and 6 S) in response to sustained anodal extracellular stimulation (for up to 4 min). The discharge rate of the motoneurons was monitored via their EMG patterns. Motoneuronal responses usually showed an initial rapid increase in firing rate followed by a more slowly-developing adaptation. The time course of firing rate (Y) was fitted with a double exponential equation [Y = K1*exp(-t/t₁) + K2*exp(-t/t₂)]: the first time constant for the initial increase was relatively short (mean ± SD; 4.1 ± 4.3 s) and may be attributable to mechanisms associated with extracellular stimulation. This initial increase is in sharp contrast to the early, rapid decrease in rate reported by Kernell and Monster (Exp Brain Res. extracellular stimulation. This initial increase is in sharp contrast to the early, rapid decrease in rate reported by Kernell and Monster (Exp Brain Res., 43:197, 1982) using intracellular current injection. The second time constant in the present work (194.1 ± 177.3 s) was comparable to the "late adaptation" described by Kernell and Monster (1982) and was correlated with the duration of discharge (p<0.001). Discharge duration averaged 149.5 ± 94.8 s (cf. Kernell, vide supra; 110 ± 83), with a mean total spike number of 2434 ± 1685. This study has demonstrated that sustained extracellular stimulation is a viable method for studying repetitive firing in motoneurons and may provide information that is a necessary compliment to that obtained by use of intracellular stimulation. FREQUENCY POTENTIATION IN AN INHIBITORY PATHWAY TO DIGASTRIC AND MASSETER MOTONEURONS. F.R. Morales, C. Pedroarena*, P. Castillo* and M.H. Chase. Depto. de Fisiologia, Fclid. de Med., Univ. de la Republica, Montevideo (Uruguay), Brain Res. Instit, Dept. of Physiology and Dept. of Anatomy and Cell Biology, UCLA Sch. of Med., Los Angeles, CA 90024 (USA).

A wealth of information now exists on plastic synaptic phenomena such as frequency potentiation and postetanic potentiation. Most of these studies have examined excitatory synapses. The data which are obtained are commonly extrapolated to all synapses, including inhibitory synapses, in spite of the fact that there are only a very few examples of these phenomena in inhibitory synapses, and none in vertebrates. In the present work, we examined a monosynaptic pathway from the parvocellularis reticular formation to trigeminal motoneurons to determine whether it exhibited frequency potentiation and postetanic potentiation. Experiments were performed on anesthetized cats. Intracellular recordings were obtained from antidromically identified masseter and digastric motoneurons. A region in the caudal medulla, adjacent to the hypoglossal nucleus and contralateral to the recording site, was stimulated with supramaximal current pulses (.2 ms duration, 80-120 μA). Short latency IPSPs were induced in masseter motoneurons (mean 1.08, range 0.9 to 1.2 ms). These IPSPs followed frequencies between 1 to 150 cps without decrement in their amplitude. At frequencies higher than 50 cps an increase in the size of IPSPs during the application of a standardized stimulation train of 100 cps; the increase in amplitude ranged from 94 to 170%. Following the train, the IPSPs' amplitude remained augmented. In conclusion, a pathway in the brainstem was found whose inhibitory postsynapsia actions included frequency potentiation and postetanic potentiation. This research was supported by NS 09999.

THE EFFECTS OF SELECTIVE ABLATIONS ON THE RHYTHMIC MOTOR OUTPUT OF THE ISOLATED CHICK SPINAL CORD. S.M. Ho & M.J O'Donovan. Laboratory of Neural Control, NINDS, NIH, Bethesda, MD 20892

The isolated spinal cord of the chick embryo is capable of generating spontaneous episodes of alternating motor activity in flexor (SART) and extensor (FEM) motoneurons. Previous experiments have indicated that both classes receive a common excitatory drive and that SART motoneurons are inhibited during each cycle coincident with extensor activity. The present experiments were designed to localize the relevant interneurons by determining the effects of various ablations on the motor output of the cord. Lesions were made with sharpened tungsten needles while recording from the SART and FEM muscle nerves, or from ventral roots.

The experiments revealed a difference in the capacity of isolated rostral (T7-LS3) and caudal (LS4-LS8) portions of the cord to sustain rhythmic activity. The rostral portion generates 3-4 cycles spontaneously and up to 10 cycles in the presence of NMDA (10-25₄ M) whereas the caudal cord produces only 1 or 2 cycles even after NMDA application. In addition, a single segment of the rostral cord (LS1) is capable of several cycles of activity.

In the hemicord, several ablations can modify or abolish the inhibitory component of SART discharge without affecting cyclic activity. These include: isolation of LS1 and LS2 from caudal and rostral inputs, and deletion of the dorsal and medial input to T7 - LS3. However, normal alternation of flexors and extensors could be observed in some cords that had the dorsal and medial portions removed over the T7-LS3 segments *providing* that the rostral and caudal segments were left intact.

These findings suggest that the excitatory inputs to motoneurons and some of the SART inhibitory input is localized in the ventro-lateral portion of the spinal cord.

RECURRENT INHIBITION OF MOTONEURONS IN THE RAT SPINAL CORD IN VITRO. R.E.W. Fyffe, S.P. Schneider, B.D. Gynther*, E.G. Casale. Department of Physiology, Univ. of North Carolina, Chapel Hill N.C. 27599-7545.

During studies of the mechanisms of recurrent inhibition of might be a superior of the property of the propert

spinal motoneurons, we investigated morphological and functional substrates of the recurrent pathway in isolated preparations of spinal cords from rats 5 to 12 days old.

Motoneurons were identified by antidromic activation

following stimulation of ventral roots. In many cells, subthreshold stimulation evoked an antidromic depolarising potential (electrotonic coupling) in addition to recurrent ipsps. The polarity of ipsps reversed near the resting membrane potential, and after intracellular injection of chloride ions. The largest ipsps were evoked by stimulating motor axons in a The largest ipsps were evoked by stimulating motor axons in a single ventral root; stimulation of adjacent roots produced much smaller potentials. Ipsp latency (at 27°C) was consistent with a disynaptic pathway. Ipsps were decreased by bath application of strychnine and, surprisingly, bicuculline. Motor axons had well developed recurrent collateral branches as revealed by intracellular HRP staining. Neurons located near motoneuron pools were synaptically excited by antidromic stimuli and usually responded with more than one action potential.

We conclude that the neural circuitry mediating recurrent

We conclude that the neural circuitry mediating recurrent inhibition of motoneurons is present and functional in neonatal rats and resembles that in adults of other species.

FORCE MODULATION DUE TO FIRING RATE VARIATION IN SINGLE MOTOR UNITS DURING CENTRALLY EVOKED MUSCLE CONTRACTIONS. K.E. Tansey, A.K. Yee, and B.R. Botterman. Departments of Cell Biology & Neuroscience and Physiology, UT Southwestern Medical Center, Dallas, TX 75235.

The CNS can control muscle force by changing the number of recruited motor units and/or by altering their firing rates. Of these two mechanisms, less is known about motoneuron firing rate variation and the muscle-unit force modulation it produces. To further investigate this issue, pairs of motor axons were isolated in the cat medial gastrocnemius (MG) nerve by intracellular techniques and, following characterization of their associated muscle units' mechanical properties, their activation patterns were recorded during graded isometric contractions evoked in MG by brainstem stimulation. Subsequently, each axon was stimulated separately with its previously recorded activation pattern to approximate the unit's force output in the preceding contraction.

Once recruited, most motor units showed a steady increase in firing rate over

a narrow range of increasing whole muscle force and then stabilized at a relatively high firing rate. At this point, muscle-unit force was close to maximum and was relatively insensitive to any additional fluctuations in motoneuron firing rate. Other motor units were recruited during rather steep increases in whole nuscle force and fired with multiple short inter-pulse intervals before settling into a fairly constant discharge rate. This activation pattern generated a muscle-unit force profile with a fast onset that reached the unit's maximum output and then declined. Almost all of the motor units studied showed a brief decrease in firing rate and force output just before they were de-recruited. These results suggest that the firing rate modulation of a motor unit's force output contributes to changes in whole muscle force only at output levels just above that unit's recruitment threshold. Supported by NIH grant NS17863.

TRICEPS SURAE MOTONEURONS AND IA AFFERENT CONNECTIONS: FURTHER ANATOMICAL STUDIES.

CONNECTIONS: FURTHER ANATOMICAL STUDIES. C.L. Lee, J.S. Carp, and J.R. Wolpaw. Wadsworth Labs, NY St Dept Health & SUNY, Albany, NY 12201.

In order to define the spinal cord alterations produced by operant conditioning of the primate (Macaca nemestrina) triceps surae (TS) H-reflex, the electrical analog of the monosynaptic stretch reflex (Wolpaw & Carp, TINS 13:137-142, 1990), we are studying TS motoneurons (MNs) and primary afferents in naive animals and in animals in which one leg's TS H-reflex has been increased or decreased.

one leg's TS H-reflex has been increased or decreased.

Animals are deeply anesthetized, HRP is injected into TS MNs after assessment of their physiological properties, HRP crystals are crushed onto dorsal rootlets, and after an appropriate interval the anesthetized animals are sacrificed by overdose and perfused. Sections are processed by the conventional nickel-DAB method. MNs are reconstructed by

conventional nickel-DAB method. MNs are reconstructed by camera lucida and afferent connections are evaluated. In 11 TS MNs reconstructed to date from naive animals, soma diameters averaged 48 um (range 32-73) and appeared to correlate with conduction velocities. Dendritic trees had 7-13 primary dendrites and were flattened ellipsoids with longest axis usually rostral-caudal (mean 2.2 mm, range 1.7-2.5). Putative Ia connections were distributed throughout the dendritic tree and ranged from 1.0-4.9 um in diameter. Their size did not correlate with distance from the soma distance from the soma

MOTONEURON PHYSIOLOGY AFTER H-REFLEX OPERANT CONDITIONING: INITIAL STUDIES. J.S. Carp and J.R. Wolpaw. Wadsworth Labs, NY St Dpt Health & SUNY, Albany, NY 12201.

Earlier studies showed that monkeys (Macaca nemestrina) can gradually increase or decrease the size of the triceps surae (TS) H-reflex (HR), the electrical analog of the monosynaptic spinal stretch reflex, and that such conditioning changes the spinal cord (Wolpaw & Carp, <u>TINS</u> 13:137-142, 1990).

In order to define these spinal cord alterations, we are recording intracellularly from motoneurons (MNs) in naive animals and in animals in which one leg's TS HR has been increased (HRup) or decreased (HRdown). Animals are deeply anesthetized during recording and sacrificed by overdose

To date we have studied 179 MNs (130 TS MNs) in 10 naive and 5 HRup animals. TS MNs from HRup animals appear to show changes in rheobase and membrane potential that are consistent with our previous TS nerve volley studies in conditioned and naive animals (J Neurophysiol 61:563-572, 1989). Additional data are needed to confirm these preliminary findings and to assess the effects of HR conditioning on MN responses to afferent

A COMPUTER SIMULATION APPROACH TO QUANTITATE DENDRITIC MORPHOLOGY W. B. Marks and R. E. Burke. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892

At this meeting in 1989, we described the use of quantitative data from At this meeting in 1989, we described the use of quantitative data from cat α -motoneuron dendrites to derive probabilities of branching and terminating per unit of branch length as exponential functions of local dendrite diameter, \mathbf{d} , (Pbr(\mathbf{d}) and Ptrm(\mathbf{d}), respectively). Experimentally observed distributions of individual branch lengths for any given initial diameter, \mathbf{d}_0 , were reasonably well fit by a simulation using these empirical probabilities, plus an exponential equation relating dendritic taper to \mathbf{d} . We have extended this model to build complete dendritic trees by introducing a rule to specify the diameters of daughter branches at branching points. The branch point rule takes account of the relation between parent and daughter branch diameters in proposuron branches at branching points. The branch point rule takes account of the relation between parent and daughter branch diameters in motoneuron dendrites (approximating the "3/2 power rule"), as well as an observed negative dependence between daughter branch diameters. Complete trees simulated using **Pbr(d)** and **Ptrm(d)** exhibited many of the features found in real motoneuron dendrites (Cullheim et al., *J. Comp. Neurol*. 255:68, 1987) but had, on average, 3-5 fewer branch points than expected for any given <u>stem</u> diameter. Re-examination of the original data showed some dependance of **Pbr** and **Ptrm** on the distance, **L**, of the growth point from the branch origin. The use of probabilities, **Pbr(d,L)** and **Ptrm(d,L)**, that are strongly dependent on **d** and weakly dependent on **L**, produced better fits to the experimental data for complete motoneuron dendrites. This simulation approach is very sensitive to subtle features of dendrites. This simulation approach is very sensitive to subtle features of dendritic architecture and may be useful for making quantitative comparisons between dendrites from different groups of neurons.

CONTROL OF POSTURE AND MOVEMENT I

50.1

SPONTANEOUS NEURONAL ACTIVITY IN THE BASAL GANGLIA-MOTOR CORTICAL LOOP IN NONHUMAN PRIMATES BEFORE AND AFTER METHYLPHENYLTETRAHYDROPYRIDINE (MPTP) A.S. Mandir, E.B. Montgomery, Jr., S.R. Buchholz, A. DeLitto, R.L. Watts, Depts. of Physiology and Neurology, Emory Univ. Sch. Med., Atlanta, GA 30322, and Depts. Neurology and Psychology, Washington Univ. Sch. Med., St. Louis, MO 63110.

The neurotoxin MPTP selectively destroys the nigrostriatal dopaminergic pathway in primates and reproduces the characteristic motor deficits of Parkinson disease. This lesion disrupts information processing in the basal ganglia-motor cortical pathway. To explore how this affects basal neuronal discharge patterns in macaques, we recorded spontaneous single cell activity in the primary motor cortex (MC;n=4 animals), supplementary motor area (SMA;n=2), putamen (PT;n=6), globus pallidus external segment (GPe;n=6) and ventrolateral thalamus pars oralis (VLo;n=2) in the normal state and weeks to months following induction of MPTP parkinsonism. No significant differences were observed in median discharge frequencies or median interspike intervals following MPTP in MC (# neurons pre-/post-MPTP, 262/228), SMA (92/21), PT (176/75), GPe (83/51), or VLo (38/16), as determined by Mann-Whitney and Kolmogorov-Smirnov statistical tests. While spontaneous single neuronal activity in the chronic MPTP parkinsonian state does not differ significantly from normal, previous work has shown that dynamic modulation of neuronal activity is disrupted.

50.2

NEURONAL, KINEMATIC AND ELECTROMYOGRAPHIC (EMG) CHARACTERIZATION OF SELF- AND STIMULUS-INITIATED MOTOR TASKS IN NORMAL AND MPTP PARKINSONIAN NON-HUMAN PRIMATES. <u>R.L.Watts</u>, <u>A.S.Mandir</u>, Depts. of Neurology and Physiology, Emory University Sch. Med., Atlanta, GA 30322 and <u>E.B.</u> Montgomery, Jr., Washington Univ. Sch. Med., St. Louis, MO 63110.

Two macaques were trained to perform self- and stimulus-initiated rapid wrist movements in response to visual instruction signals. Each motor task consisted of a preparation phase and an execution phase. In the <u>stimulus-initiated task</u> an external "GO" signal (illumination of final target light) was employed following a specific "prepare to move signal; in the <u>self-initiated task</u> the animal had to generate the movement without external prompting after waiting at least 2 seconds following a different "prepare to move" visual cue. We recorded reaction time (RT), movement time (MT), maximum movement velocity (V_{max}) , agonist EMG activity, and primary motor cortex (MC) movement-related neuronal activity, in the normal state and following induction of MPTP parkinsonism. In the normal state self-initiated tasks differed from stimulus-initiated tasks by exhibiting reduced maximum velocities and first agonist EMG bursts; MC activity showed a reduced rate of change and peak discharge frequency. Following MPTP, MT was prolonged, V_{max} was reduced, and EMG and MC movement-related activity were disorganized for both tasks, but to a greater extent for the self-initiated task

RECOVERY OF LOCOMOTOR MOVEMENTS IN SPINALLY LESIONED MONKEYS. J.A. Vilensky, E. Eidelberg, A. Moore* and J.G. Walden*. Dept. of Anatomy, Ind. Univ. Sch. of Medicine and Division of Neurosurgery, Univ. of Texas Health Science Center, San Antonio, TX 78284

In a 1981 study (Brain 104:647-663) Eidelberg et al. briefly described the effects of various spinal lesions at Texas the locameter behavior of 10 members. They care less than the complete the

T8 on the locomotor behavior of 10 monkeys. They concluded that sparing of pathways in the ventrolateral sector is most important for the recovery of stepping. In this report we present a detailed kinematic analysis of the recovery of 4 of these monkeys and a qualitative description of the recovery (or lack of it) for the remaining 6, as well as a reanalysis of the lesion sites. Six of the animals initially showed purely unilateral hind limb movements. Hind limb cycle durations were commonly increased during recovery whereas forelimb cycle durations were commonly reduced. Ipsilateral interlimb phase values were initially inconsistent, and even when stable values were reached they were different from preoperative values. That is, the animals adopted more of a pacing type gait. Our analysis of the lesion sites and the behavioral recovery supports the previous finding that pathways in the ventrolateral quadrant (i.e., reticulospinal and vestibulospinal) are important for locomotor recovery However, it is noteworthy that there are cases reported in the literature of monkeys with bilateral lesions in these pathways that apparently recovered some locomotor function.

INTERACTIONS BETWEEN CENTRALLY PATTERNED BEHAVIORS: INTERACTIONS BETWEEN CENTRALLY PATTERNED BEHAVIORS:
RESPIRATION, MASTICATION, AND DEGLUTTION. D. McFarland, D.
Veilleux, C. Valiquette, and J.P. Lund. Centre de Recherche en Sciences
Neurologiques, Université de Montréal, Montréal, Canada, H3C 3J7.
Although many rhythmical movements occur simultaneously, little is
known about the mechanisms coordinating interactions between them. We
have begun to look at the interrelationship between three such behaviors:

known about the mechanisms coordinating interactions between them. When we begun to look at the interrelationship between three such behaviors: breathing, chewing, and swallowing. Experiments were performed on awake rabbits prepared for chronic recording of the EMG activity of throat and lower jaw muscles. These signals were recorded together with movements of the rib cage and lower jaw during spontaneous breathing and the mastication of rabbit chow. Our preliminary results can be summarized as follows. The respiratory rate increased or decreased at the start of mastication so that the masticatory and respiratory rhythms were approximately equal in frequency. However, no coupling occurred, since the phase relationship between the two rhythms was variable. Two characteristic types of swallowing patterns were observed, coincident (C) and terminal (T). C swallows occurred without a pause in the masticatory rhythm, while T swallows came at the end of a masticatory sequence. Most C swallows took place during jaw closure (97% closure, 82% opening); these proportions were significantly different (X²=50.48, p<0001). However, there were no significant differences in the proportion of C and T swallows coinciding with the two major phases of respiration (X²=.1058, p=.7449), both occurred preferentially during inspiration (C: 87%, T: 85%).

NUCLEUS AMBIGUUS NEURONAL ACTIVITY DURING VOCALIZATION IN THE AWAKE MONKEY. C.R. Larson and Y. Yajima*. Comm. Sci. & Dis. and Neurobiol. & Physiol.

Yajima** Comm. Sci. & Dis. and Neurobiol. & Physiol.

Northwestern University, Evanston, IL 60208.

The nucleus ambiguus (NA) region contains interneurons related to vocalization, respiration and swallowing and motoneurons controlling laryngeal and pharyngeal muscles. The midbrain periaqueductal grey (PAG) also contains neurons related to vocalization, and it projects to the NA region. The present study was designed to define the unit discharge patterns of the NA as they relate to the above behaviors and to compare discharge properties of vocalization-related PAG and compare discharge properties of vocalization-related PAG and NA cells. Macaca nemestrina monkeys were trained to vocalize for a fruit-juice reward. EMG electrodes were surgically implanted into laryngeal muscles and a single unit recording chamber was affixed to the skull with screws and dental cement. A cuff electrode on the recurrent laryngeal nerve allowed antidromic identification of motoneurons. Some NA neurons were active only during vocalization, while others were also related to respiration or swallowing. Ensemble averages of unit activity were similar for NA and PAG neurons, but the unit activity were similar for NA and PAG neurons, but the mean firing rate was higher in the NA. Pre-vocal activity times were much shorter in NA cells than in PAG cells. Spike-triggered-averaging EMGs from NA neuron spikes revealed specific effects on laryngeal muscles with 4-5 ms latencies.

QUANTITATIVE ANALYSIS OF NECK MUSCLE ACTIVATION PATTERNS DURING CONTROLLED HEAD BEHAVIORS IN CATS. E.A. Keshner, J.F. Baker, J. Banovetz*, and B.W. Peterson. Department of Physiology, Northwestern University Medical School, Chicago, IL 60611.

When the head rotates, vestibulocollic reflexes (VCR) counteract the rotation by

causing contraction of the neck muscles that pull against the imposed motion. With voluntary head rotations, these same muscles contract to assist the movement of the head. Does the CNS select a consistent and unique muscle pattern for the same head movement whether performed in a voluntary or reflex mode, or do voluntary head movements involve an infinite variety of motor patterns as is theoretically possible (Peterson et al., Amer Zoologist, 1989)? EMG activity of six neck muscles was (Peterson et al., Amer Zoologist, 1989)? EMG activity of six neck muscles was recorded in three alert cats during sinusoidal head rotations about 23 different axes. Cats were trained to voluntarily follow a water spout with their heads. VCR responses were recorded in the same cats during rotations in an equivalent set of planes. Gain and phase of the EMG response was calculated, and analyzed to determine a vector representing the direction of rotation for which a muscle produced its greatest EMG output. The azimuth and elevation angles of these vectors were quantified and compared to see if VCR and voluntary movements involved directionally opposite (180°) maximal activation directions (MADs). MADs differed directionally of 200 from this broatbasis to 200 to 50° sees where of MADs. significantly (p < 0.03) from this hypothesis by 20° to 50°. Analysis of MAD variability within and between cats revealed small variances in the reflex task, implying that a single optimality criterion can account for VCR activation patterns. A significant feature to emerge from the tracking task was large variations in the A significant feature to emerge from the tracking task was large variations in the MADs between cats, yet very small day to day variability within each cat. Consistent patterns of voluntary activation within an animal suggest that each CNS may select its own criteria to produce its unique pattern of activity. Simultaneous flouroscopic and electromyographic analyses of these movement behaviors is currently underway to determine intra-individual relations between head movements, intervertebral arrangements, and muscle activation patterns.

AN ELECTROMYOGRAPHIC (EMG) ANALYSIS OF OROFACIAL MOTOR ACTIVITIES DURING TRAINED TONGUE-PROTRUSION AND BITING TASKS IN MONKEYS. E.M. Moustafa, L.-D. Lin, G.M. Murray and B.J. Sessle. Fac. Dentistry, Univ. of Toronto, Toronto, Ont., M5G 1G6.

The aim of this study was to characterize orofacial EMG activity patterns in two monkeys (M. fascicularis) trained to perform tongue-protrusion and biting tasks; EMG activities were recorded from digastric, genioglossus, masseter, platysma, zygomaticus major and orbicularis oris inferior and superior muscles. For each muscle, we assessed the mean EMG amplitude (MA) and mean area (MSA) under the integrated EMG signal during the task period (TP) and the pre-trial period (PTP), as well as the mean EMG amplitude ratio (MAR) i.e. (MA during TP)/(MA during PTP). For tongue task trials, the MA and MSA values during TP were significantly (P<0.0001) increased above PTP values for each of the genioglossus, orbicularis oris inferior and superior and digastric, respectively; the highest MAR occurred in the former two muscles (P<0.0001). For biting task trials, however, a corresponding analysis showed significant increases (P<0.0001) for MA and MSA values during TP in the masseter, platysma, and zygomaticus; MAR was highest in the masseter (P<0.001). While tongue protrusion at different forces was associated with no significant change in MAR for each muscle, a significant (P<0.0001) change in MAR of the masseter and digastric during TP was noted at different bite forces. These EMG patterns were noted in both animals and were consistent between different recording sessions in the same animal. These data clarify orofacial muscle activity patterns during trained tongue protrusion and biting in the monkey. Supported by Canadian MRC.

CUTANEOUS DESENSITIZATION OF THE ABDOMEN AND INNER THIGHS DISRUPTS COPULATION IN MALE RATS. <u>C.-A. Maillard & D. A. Edwards</u>. Dept. of Psychology, Emory University, Atlanta, GA 30322.

For a male rat, copulation involves mounting coupled with vigorous pelvic thrusting and forelimb palpation of the female's flanks. Penile insertion is almost invariably associated with a rapid, spring-like, dismount that provides an index of literal intromission, and ejaculation is easily recognized by a deep final thrust and prolonged clasp of the male to the female. Appropriately oriented mounts and pelvic thrusting provide sensory feedback undoubtedly essential for intromission and ejaculation -- the penis appears to play an important role here inasmuch as penile desensitization, produced by the topical application of a local anesthetic or transection of the sensory nerves of the penis, decreases the display of intromission and ejaculation (e.g., Adler & Bermant, J. Comp. Physiol. Psychol., 1966; Sachs et al, Neurosci. Abstracts, 1989).
We used subcutaneous injections of the local anesthetic procaine (a 2%

solution in physiological saline) to study the role of non-penile somatosensory feedback in the regulation of male sexual behavior in rats. Cutaneous desensitization (produced by injections of 0.1 ml of procaine underneath the skin) of the chest or back had no effect on copulation. Desensitization of the lower abdomen and inner thighs decreased the display of intromissions and ejaculations, and dramatically increased the number of incomplete mounts i.e., appropriately oriented mounts without pelvic thrusting or flank palpation These results suggests that the tactile stimulation of the abdomen and thighs associated with mounting plays an important role in the elicitation of forelimb palpation and the elicitation of the pelvic thrusting necessary for intromission and ejaculation. Supported by NSF Grant BNS-8718797.

3-D KINEMATIC ANALYSIS OF HINDLIMB WIPING MOVEMENTS IN SPINAL FROGS. L.E. Sergio, J.R. Flanagan, A.G. Feldman and D.J. Ostry. McGill University, Montreal, Canada and Institute for Information Transmission Problems, Moscow, USSR.

The 3-D kinematics of wiping movements to the back were examined in spinal frogs. The aim was to identify the elements of the frog's back wipe and their functional role. Wiping movements were elicited in spinalized adult Rana Catesbeiana by placing small pieces of blotting paper soaked in $5\%\ H_2SO_4$ in ten different positions covering the full area of the back. The data show that there are three essential components, or phases, of the wiping movement: a placing phase, a quick flexion of the hip and knee (absent in 20% of the wipes), and a whisk/extension phase. The first, or placing phase, appears to be the only phase dependent upon stimulus location. Furthermore, the spinal frog only takes account of stimulus location in the rostro-caudal direction (consistent with Giszter et.al., J. Neurophys., 62:750, There is no hindlimb adjustment for stimulus position in the medial-lateral direction in this phase. In the second phase, previously described as the 'aiming' phase, the final endpoint position shows no dependence on stimulus location, contrary to previous findings for Rana Temporaria (Berkinblit et.al., Behav. Brain Sci., 9:585, 1986). It is proposed that the second phase serves as a preparatory movement for the extension portion of the wipe. When the wipe is partitioned into the elements described, the motion was found to be planar for the first and third phases. During the second phase there was a transition from one plane to another.

DIRECTED MOVEMENT IN THE FROG: ELECTROPHYSIOLOGICAL

DIRECTED MOVEMENT IN THE FROG: ELECTROPHYSIOLOGICAL FINDINGS IN THE VENTRAL MIDBRAIN. C. Smeraski and P. Grobstein. Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

Previous anatomical and lesion studies suggest that a neuronal column in the ventromedial midbrain of the frog may be an important relay for a subset of the descending tectofugal signals underlying prey orienting movements in the frog, and the origin of a signal representing stimulus location in a generalized coordinate frame. We were interested in determining whether this anatomically defined region is also physiologically identifiable and distinctive.

is also physiologically recitatizate and distribute.

Vertical penetrations using tungsten microelectrodes were made through the midbrain in Rana pipiens anesthetized with MS-222. On many penetrations, there midbrain in Rana pipiens anesthetized with MS-222. On many penetrations, there was a dorso-ventrally delimited region distinctive in having high levels of spontaneous multiunit and single unit activity. The activity could often be driven by visual and/or tactile stimuli, and occasionally by auditory stimuli. Responses, while clearly present, were labile. The dorso-ventral location of the areas of spontaneous activity was defined using electrolytic lesions visible in histological sections, and corresponded well with the previously defined ventromedial column. Medially located penetrations, which did not pass through the column, did not exhibit dorsoventrally delimited regions of spontaneous activity. The same was true of penetrations which missed the column laterally. Whether the area of spontaneous activity has sharp borders rostrally and caudally is still under investigation.

Our findings suggest that there is indeed a physiologically distinctive area which Our findings suggest that there is indeed a physiologically distinctive area which corresponds to the anatomical area previously implicated as a relay for descending tectofugal signals involved in orienting. The high levels of spontaneous activity is this area may be significant for understanding the transformation from a retinal signal to one in a generalized coordinate frame. The finding of both visual and tactile excitability in this area is consistent with prior studies indicating that visual and tactile signals converge at the level of the generalized coordinate frame circuitry. NEURAL CONTROL OF A MUSCULAR HYDROSTAT: SIMULATION OF THE BIOMECHANICS OF A REPTILIAN TONGUE. P.E. Crago. H.J. Chiel and J.M. Mansour*, Depts. of Biomedical Engineering, Biology, and Mechanical and Aerospace Engineering, Case Western Reserve University, Cleveland, OH 44106.

We are investigating the control of a muscular hydrostat: the tongue of the lizard Tupinambis nigropunctatus. A functional movement, lapping, as the circulated by controlling two intrinsic manages. A learning of the lizard Tupinambis nigropunctatus.

can be simulated by controlling two intrinsic muscles. A longitudinal muscle contracts to produce shortening. This muscle is wrapped by a circumferential muscle that produces lengthening by decreasing the diameter of the longitudinal muscle. The tongue is modeled as a circular cylinder of constant volume: decreasing the diameter causes an increase in length. The mathematical model is based on the mechanics of a pressure vessel. The longitudinal muscle exerts pressure on the ends of the cylinder, and this pressure is balanced by the pressure developed by the tangential forces in the cylinder walls by the circumferential muscle.

The models of the individual muscles are based on studies in cats, with parameters adjusted for the dimensions of the lizard tongue muscles. The model includes activation dynamics, the dependence of force on muscle length and stimulus period, force velocity properties, and passive stiffness. The model tongue displays kinematics similar to published recordings of

the lizard tongue, when driven by neural inputs similar to EMGs recorded in intact lizards. We are investigating the sensitivity of the motor output to the model structure and parameter values, and are focusing in particular on the role of the biomechanical nonlinearities.

THE ORGANIZATION OF LIMB MOTOR SPACE IN THE SPINAL CORD. Giszter, F.A. Mussa-Ivaldi*, and E.Bizzi. Dept. Brain and Cognitive ces, M. I. T., Cambridge MA 02139.

We have examined the role of the premotoneuronal spinal areas in organizing posture and movement in spinalized frogs. We recorded the forces produced in the leg by stimulation of various spinal cord loci using a six axis force transducer attached to a spinal frog's ankle. The frog's ankle was positioned in a number of workspace locations. At each such workspace location we measured the force elicited by stimulating the same single site within the spinal cord. In this way we estimated the spatial distribution of forces and EMG activation generated by stimulation of a single spinal cord

We discovered that microstimulation of the upper and middle layers of the frog spinal cord grey matter, in conjunction with positioning of the leg in different workspace locations, generated a force field with a single equilibrium point. The equilibrium point is that spatial location at which the leg would be at steady state were it free to move. In contrast, when the stimulating electrode was placed in the ventral roots or among the motoneurons, the force field found was characterized by parallel or divergent force vectors with no detectable equilibrium point. During the stimulation of the middle layers of interneurons the activation of some muscles was modulated as a function of leg location in the workspace while others were activated uniformly and were independent of the limb's location. Taken together these results indicate that activation of the spinal cord's premotoneuronal networks acts to impose a

structure upon the forces generated by the limb muscles.

These results provide a neurophysiological underpinning for the equilibrium point hypothesis and its role in the control of posture and movement in the spinal cord.

DIRECTED MOVEMENT IN THE FROG: MOTOR EQUIVALENCE, MULTI-DIMENSIONALITY, INTERNAL FEEDBACK? P. Grobstein. J. Meyer*. and R. Egnor*. Dept. of Biology, Bryn Mawr College., Bryn Mawr, PA 19010.

Videotape study of the directed movements made by frogs in response to live mealworms has revealed two novel and significant aspects of this behavior.

The initial ballistic movement made by a given frog to a stimulus at a given 3-D location is similar on successive trials in that it aligns the longitudinal body axis with the stimulus. There are however detectable differences from trial to trial in how with the stimulus. There are however detectable differences from trial to trial in how this similar end result is achieved. Individual movements result in both a rotation of the body axis and a 2-D body translation. Each of these components varies substantially from trial to trial; we have been as yet unable to relate the variations to any other variable, such as initial body posture. The similar end result reflects a systematic covariation of the movement components. We conclude that frogs have and use a variety of different motor patterns to orient toward a given 3-D location, and that one dimension in a Euclidean description of stimulus location corresponds to at least three dimensions in the motor output pattern. Like earlier findings, the present ones suggest that there exists in the frog nervous system a signal specifying movement objective without specific reference to motor pattern. The present findings

raise new questions about how a signal related to objective is translated into a specific motor pattern, and suggest that a probabilistic element may be involved. Following certain unilateral lesions, the initial movement of a frog in response to a lateral stimulus is forwardly rather than laterally directed, apparently because some a lateral stimulus is forwardly rather than laterally directed, apparently because some of the information specifying objective fails to reach the stage of translation into a motor pattern. We now report that some such frogs may, by a series of movements, achieve a successful turn toward the stimulus location, even when the stimulus has been removed. The findings suggest the hypothesis that the objective signal remains present until a comparison with reafferent and/or corollary discharge signals indicates that the objective has been achieved. Such an internal feedback loop, coupled with a probabilistic element in motor pattern determination, would provide a basis for creating nowleaves to achieve a particular chiestive. creating novel ways to achieve a particular objective.

RANCE FRACTIONATION IN RESPONSES OF SPIKING INTERNEURONS THAT DETECT JOINT MOVEMENT IN LOCUSTS. S. N. Zill and S. F. Frazier. Dept. Anat., Marshall Univ. Sch. Med. Huntington, WV 25755

Two different types of reflex effects have been shown to occur when the metathoracic femoral chordotonal organ (FCO), a joint angle receptor of the locust hindleg, is mechanically stimulated. In the flexion mode, afferent firing indicating changes in joint angle in any direction excites tibial flexor motoneurons. We now show that this reflex is elicited when the FCO is stimulated in freely standing locusts and that it preferentially occurs when the leg is in positions of low mechanical advantage of tibial muscles. We postulate that this reflex serves to move the leg to a position of high stability when postural perturbations occur and have examined responses of local circuit spiking interneurons to mechanical stimulation of the FOO. These studies show that: some interneurons respond to displacements signalling changes in joint angle in any direction; these interneurons show only phasic excitatory or inhibitory responses and exhibit little hysteresis; interneurons show range fractionation and respond only in some but not all ranges of joint angle. We conclude that these interneurons preserve information provided by the FCO that could form a basis for this adaptive postural reflex. Supported by NIH NINDS grant NS22682 and the Whitehall Foundation.

HINDLIMB MOTOR ACTIVITY ELICITED BY BRAINSTEM STIMULATION IN AN ISOLATED BRAINSTEM, SPINAL CORD PREPARATION OF THE CHICK EMBRYO. G.N. Sholomenko and M.J. O'Donovan. Lab of Neural Control, NINDS, NIH, Bethesda, MD 20892.

We have developed an isolated brainstem/spinal cord (B/SC) preparation to study the development of descending pathways involved in the regulation of embryonic motor activity in the chick embryo. The cooled embryo (E12-E15) is decerebrated to the midbrain level and continuously superfused with Tyrodes solution. The ventral surface of the entire brainstem and spinal cord is exposed by laminectomy and various hindlimb muscle nerves are exposed for recording. The B/SC is then placed in a double partition bath which isolates the brainstem, cervical and lumbosacral cord into independently perfused chambers. Our results demonstrate that: 1) the isolated B/SC (E12) produces spontaneous bouts of alternating activity in the isolated spinal cord preparation 2) low threshold stimulation (0.1-1 ms biphasic/25-50µA) of the brainstem consistently evoked short bouts of rhythmic neural activity closely resembling spontaneous activity. The stimulation-evoked activity could be elicited for at least 24hrs, indicating the prolonged viability of the brainstem 3) the addition of a low Ca⁺⁺ high Mg⁺⁺ to the middle bath (cervical cord) did not abolish brainstem-evoked rhythmic activity recorded from hindlimb muscle nerves. 4) NMDA (5-50µM) placed in the brainstem bath facilitated both spontaneous and brainstem-evoked lumbosacral activity.

These results suggest that descending pathways capable of initiating lumbosacral motor activity are present by stage 37 in the chick embryo.

PROPRIOCEPTIVE MODULATION OF HEAD SCRATCHING IN CHICKS.

M.B. Smith and A. Bekoff. EPO Biology Dept., University of Colorado,
Boulder, CO 80309-0334.

Head scratching is one of many behaviors that are believed to be controlled by a central pattern generating circuit. This study was undertaken to determine how the influence of joint proprioceptive information modulates the motor pattern.

Six muscles of the right leg were surgically implanted with bipolar EMG electrodes in domestic chicks between the ages of 3 and 6 days. Muscles studied included the gastrocnemius lateralis (GL), tibialis anterior (TA), sartorius (SA), femorotibialis (FT), caudilioflexorius (CF), and iliofibularis (IF). EMG recordings were made 24 hours following implantation. To remove joint proprioceptive information, lidocaine hydrocholoride (2%) was injected into the right ankle joint of experimental chicks. This resulted in loss of sensation within minutes. In both normal (n=5) and experimental chicks (n=5), head scratching was elicited by placing a small piece of tape over the external ear. For each chick EMG recordings were obtained from at

least three bouts of scratching.

There are no significant differences among the first four sequential cycles within a bout of scratching in either the normal or experimental condition. Although the scratch in the experimental condition appears qualitatively normal some EMG characteristics have been altered. For example, a two-way ANOVA reveals that injection of lidocaine significantly alters the duration of the cycle period (p=0.033) of each scratch. Loss of joint proprioception also significantly diminishes the number of scratches that occur within a bout of scratching.

Supported by NIH grant NS 20310.

AN EMG STUDY COMPARING FOOT SHAKING AND WALKING IN CHICKS. S. M. Woolley*. N. S. Bradley. and A. Bekoff. EPO Biology Dept., University of Colorado, Boulder, CO 80309-0334. In chicks, foot shaking is an episodic unilateral behavior performed

In chicks, foot shaking is an episodic unilateral behavior performed to remove an irritant from the foot or tarsus and is similar to the paw shake response seen in cats (Smith J. L., et al., *J. Neurophysiol.* 54:1271, 1985). In this study, we first characterized the foot shaking behavior and its underlying motor output pattern. We then compared these results to those obtained for walking.

Fine wire hook electrodes were implanted in 6 muscles of the right leg in 1- to 6-day old chicks. Foot shaking was elicited by placing a small piece of tape on the foot. Walking was elicited by enticing the chick to walk down a stationary runway. Parameters used to quantify the EMG data were: cycle period, burst durations, phase relationships and interburst intervals.

The two behaviors differ in that foot shaking involves very rapid unilateral leg movements, while walking involves alternating motions of the two legs over a wide range of cycle periods. Nevertheless, results show that foot shaking shares some common features with walking. For example, both are characterized by similar muscle synergies. Unlike walking, foot shaking exhibits similar burst durations of extensors and flexors within a cycle as well as considerable overlap of extensor and flexor activity at the onset of the flexor phase but not at the onset of the extensor phase. We suggest that the overlap of activity at the onset of the flexor phase functions to brake the rapid extensor movements of foot shaking. Supported by NIH grant NS 20310.

MUSCLE: MOLECULAR STUDIES

51.1

Identification and Localization of a 94 kDa Glycoprotein to the Triad Junction C.M. Knudson, K.K. Stang and K.P. Campbell. Howard Hughes Medical Institute and Dept. of Physiology and Biophysics, University of Iowa College of Medicine, Iowa City, IA 52242.

Monoclonal antibodies have been produced against an array of rabbit skeletal muscle membrane proteins. Using subcellular fractionation of skeletal muscle membranes and immunoblot staining, two antibodies have been shown to recognize proteins (apparent MW of 90 and 94 kDa) which are greatly enriched in triads and junctional face membranes, but not detectable in T-system or surface membranes. Immunocytochemical localization of these proteins, using immunofluorescent microscopy, indicates a junctional distribution. Based upon scans of Coomasie blue stained SDS gels, the 94 kDa protein was found to be a major component (5-10%) of junctional face membrane. The 94 kDa band was identified as a glycoprotein based on Con A Peroxidase staining and treatment with Endo H. The 94 kDa band was labeled by the hydrophobic probe 3-(Trifluoromethyl)-3-(m[125]jiodophenyl)diazirine (TID), suggesting the 94 kDa protein may contain membrane spanning domaln(s). An interesting but unique property of the 94 kDa complex was found when junctional face membrane was run on polyacrylamide gels under non-reducing or partially reducing conditions. Under reducing conditions with 2-mercaptoethanol, immunoblot staining with 94 kDa protein monoclonal antibodies revealed a single intense band, however, under non-reducing conditions with N-ethlymaleimide, immunoblot staining identified only multiple high molecular weight bands. No 94 kDa band was detected by the antibody or present on gels under non-reducing conditions. The localization of these proteins to the triad junction suggest that they may play a role in the egulation or modulation of sarcoplasmic reticulum Ca²⁺ release. K.P. Campbell is an Investigator of the Howard Hughes Medical Institute.

PG-1000, A LARGE CHONDROITIN SULFATE PROTEOGLYCAN IS FOUND IN THE TRANSVERSE TUBULE SYSTEM OF FISH, FROG, CHICK AND RAT SKELETAL MUSCLE. A. K. Davis* and S. S. Carlson. Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195.

We have purified, biochemically characterized, and raised antibodies against a large (106 daltons) CS proteoglycan (PG-1000) from the extracellular matrix of the electric organ of the marine elasmobranch, Torpedo californica (Carlson, S. and Wight, T., 1987; Iwata, M., Davis, A. and Carlson, S., 1989). Using a monoclonal antibody that specifically recognizes PG-1000, we have detected PG-1000 immunoreactivity in skeletal muscle of a variety of organisms: electric fish, frog, chick and rat. In all four species, we observe a regular banding pattern of immunoreactivity that resembles the distribution of the transverse tubule system, the network of tubules that penetrates the muscle cell and has a lumen that is continuous with the extracellular space. PG-1000 antigenicity co-localizes with a known transverse tubule marker, the dihydropyridine receptor, confirming our hypothesis. In fish and chick, we also detect PG-1000 antigenicity in the basal lamina that surrounds muscle cells. Biochemically, the skeletal muscle antigen resembles PG-1000 isolated from electric organ. Both of the proteoglycans recognized by our antibody are similar in size to the well characterized proteoglycans isolated from cartilage. Cartilage proteoglycans occupy large hydrodynamic volumes and therefore act as aqueous space fillers. We hypothesize that PG-1000 in the lumen of the transverse tubules has an analogous structural function; we propose that it helps maintain the integrity of transverse tubules by holding them open, preventing their collapse and also providing aqueous space for diffusion.

SYSTEMATIC EXPRESSION OF ALPHA-CARDIAC MYOSIN IN MULTIPLY-INNERVATED FIBERS OF EXTRAOCULAR MUSCLE. J. Jacoby, K. Kôţ J. Davidowitz*, C. Weiss*+ and J.I. Rushbrook*+. Dept Ophthalmol, NYU Med Ctr, NY,NY 10016 †Dept Biochem, SUNY Downstate Med Ctr, Bklyn, NY 11203. 10016 & Unlike mammalian skeletal muscle, extraocular muscles (EOMs) contain, in addition to singly-innervated fibers (SIFs), multiply-innervated fibers (MIFs) which exhibit tonic contractile properties. MIF and SIF populations, which are distributed within orbital and global layers, collectively express at least 6 different isoforms of which are distributed within Orbital and global layers, collectively express at least 6 different isoforms of myosin heavy chain including neonatal and EOM-specific forms. Using a type-specific McAB (RCM37) from R. Zak, we find that alpha-cardiac heavy chain, previously believed to be expressed only in heart and some muscle spindles, is present also in rabbit EOM. In EOM, RCM37 labels populations of MIFs which exhibit both acid- and alkali-stable ATPase activity, and do not co-label with a fast-specific antibody. RCM37 labels 2 populations of fibers in the global layer; one, confined to the deep global layer also co-labels with an antibody for type I slow myosin (S58), and the second, distributed in the intermediateglobal layer labels with RCM37 alone. In the orbital layer, RCM37 labels one population, which in the EPB labels with RCM37 exclusively, but distally co-labels with ALD180, a McAB that labels embryonic/neonatal myosin and labels the entire orbital layer. Support: NY Heart, EY 06232 and Research to Prevent Blindness.

COORDINATION OF SUCCINATE DEHYDROGENASE ACTIVITY BETWEEN MOTONEURONS AND MUSCLE FIBERS IN THE NORMAL AND FUNCTIONALLY OVERLOADED CAT PLANTARIS G. R. Chalmers. R. R. Roy, and Y. R. Edgerton. Dept. of Kinesiology and Brain Research Institute. UCLA, Los Angeles, CA 90024.
Given the interdependence of motoneurons (MNs) and muscle fibers, the oxidative capacity of these two cell types might be coordinated within a neuromuscular unit. capacity of these two cell types might be coordinated within a neuromuscular unit. To test this hypothesis the soleus and gastrocnemius muscles in five adult cats were excised bilaterally, functionally overloading (FO) the plantaris. For 4-12 wks post-surgery the cats were exercised for 15-25 min/day. Four nonoperated cats served as controls. After treatment all cats had the right plantaris muscle injected with HRP and 96 hr later the S1-L5 spinal cord segments and left plantaris muscle were removed and frozen. Size and SDH activity of light and dark myosin ATPase (alkaline pH) muscle fibers and HRP positive MNs were measured (Chalmers and Edgerton J. Histochem. Cytochem, 37:1107, 1989).

There were no significant differences in MN SDH activity and soma size (mean HSD) between the control (11.440, 210-30) (min. 361/341154).m. 23 on HSD)

 \pm SD) between the control (11.4 \pm 0.3 x10⁻³OD/min, 3613 \pm 1154 μ m²) and FO (10.5±1.1 x10-3OD/min, 3910±1127μm²) groups. Mean muscle fiber SDH activity was lower and the size larger in FO plantaris compared to control (FO:light ATPase, $6.7\pm2.3 \times 10^{-3}$ OD/min, $4266\pm1533\mu m^2$ and dark ATPase, 4.6 ± 1.4 x10⁻³OD/min, 7493±3144μm², control:light ATPase, 14.0±1.9 x10⁻³OD/min, 2285±421µm² and dark ATPase, 10,7±2.8 x10°30/min, 41±494µm²). Before and after FO total SDH activity was similar in MNs (control: 39.62±9.94, FO:

and after PO total 3DP activity was similar in MNs (control: 39,02±3,94; PO: 38,04±9.55 OD x μ m²/min) and muscle fibers (for light and dark ATPase combined, control:32.08±1.91, FO:33.94±22.14 OD x μ m²/min). These data indicate that although the oxidative potential is similar in MNs of a motor pool and in the muscle fibers innervated by that pool, the size and mean SDH activity of the MNs and muscle fibers can change independently. Supported in part by NIH Grant NS16333.

THREE DIMENSIONAL ANALYSES AND IMAGING OF ALL FIBERS BELONGING TO A MOTOR UNIT. E.S. HSu*, A. Garfinkel, E.

FIBERS BELONGING TO A MOTOR UNIT. E.S. Hsu*. A. Garfinkel, E. Eldred. R.R. Roy, and V.R. Edgerton. Department of Kinesiology and Brain Research Institute, UCLA, Los Angeles, CA 90024-1568.

Cross-sectional area (CSA), selected enzyme activities, lengths, shapes and spatial distribution were characterized in 98 fibers belonging to a motor unit (MU) of an adult cat tibialis anterior muscle. The MU was functionally isolated, physiologically characterized and glycogen depleted as described by Bodine et al. (J Neurophysiol 57: 1730, 1987). The MU had a contraction time of 56 ms and a maximum tetanic tension of 3.0 g. The muscle-tendon unit was frozen en bloc at Lo, then cut into 1 cm blocks. The intact muscle length after freezing was 9.0 cm. Serial cross-sections were stained for glycogen by the periodic acid Schiff (PAS) method and for myosin ATPase pre-incubated under acidic and alkaline conditions. Fibers belonging to the motor unit were identified by their low level of glycogen and light myosin ATPase staining. Enzyme activity and substrate reaction products were quantified as optical motor unit were identified by their low level of glycogen and light myosin ATPase staining. Enzyme activity and substrate reaction products were quantified as optical density (DD) units using digital image processing (J Histochem Cytochem 33:1053, 1985). Fiber CSA and centroidal coordinates were obtained simultaneously at 14 different levels along the length of each fiber. In addition, serial microscope slides in 20 um increments were carefully visualized to determine lengths and shapes at the ends of individual fibers. Motor unit fibers had consistently lower ODs in PAS staining along their lengths relative to non-MU fibers. Mean fiber length was 4.52 ± 0.4 cm. The mean of all CSA measurements of all fibers was 2308 ± 509 um². The MU specific tension was 1.3 kg/cm². Most fibers began and ended at musculotendinous junctions with modest changes in CSA along their length. Nine fibers were significantly shorter and ended mid-fascicularly, some tapering to a miniscule CSA. Spatial distribution analyses at 14 levels along the length of the fibers showed no evidence for MU fibers to cluster or be dispersed non-randomly within the unit territory. These data demonstrate the complex 3-D architecture of a MU with significant variation in total CSA along the length of the MU territory. It seems that these anatomical features could contribute significantly to the MU's mechanical output potential. Supported by NIH Grant NS16333.

IDENTIFICATION OF OPTIMAL INTERPULSE INTERVALS (IPIs) FOR PRODUCTION OF OPIMAL INTERPULSE INTERVALS (IPIS) FOR PRODUCTION OF A RAPID RATE OF RISE OF FORCE IN RAT SOLEUS MUSCLE. S.A. Binder-Macleod. School of Life and Health Sciences, Univ. of Delaware, Newark, DE 19716.

As technology continues to improve, the increased use of electrical stimulation of skeletal muscle to aid function (FES) appears inevitable. Most functional activities (see well-re) resulting the second being the

stimulation of skeletal muscle to aid function (FES) appears inevitable. Most functional activities (eg, walking) require muscle to generate bries submaximal levels of force with a rapid rate of rise. The combination of a rapid rate of rise and submaximal force necessitates the use of a stimulation pattern with IPIs of varying duration. This study attempts to identify the duration and number of IPIs needed at the onset of a contraction to produce a rapid rate of rise of force. Rat soleus muscle was used to define trains of pulses which most rapidly approached, but did not exceed, targeted levels of force (50-75% of maximum tetanic force). The optimal initial IPI (IPI*1) was defined as the IPI of a two pulse train which produced the greatest force and reached this peak within the shortest time. After IPI*1 was identified, it was used as the first IPI of a three pulse train while the third IPI was varied. This basic procedure was repeated until a train was developed which reached the targeted level of force. Results to date suggest that to produce targeted levels of force between 50-75% of maximum, a relatively simple pattern of stimulation between 50-75% of maximum, a relatively simple pattern of stimulation is required with either 1 or 2 short IPIs (10-15 ms) needed at the onset of stimulation. The addition of one or two pulses at these short IPIs at the onset of stimulation takes advantage of the catchlike property of skeletal ousci of simulation takes advantage of the catchilke property of skeletal muscle to markedly increase the total force output of the muscle over constant frequency trains needed to produce comparable submaximum forces. Preliminary analysis has shown that the duration of these initial short IPIs must be slightly greater than the time to maximum of the first derivative of the twitch force produced by a single pulse. This work has been funded by a grant from the Foundation for Physical Therapy.

RELATION BETWEEN FIBER DIAMETER AND FIBER TYPE COMPOSITION IN THE RECTUS FEMORIS MUSCLE OF CATS. L.L. Glenn and P.J. Rebeta Department of Physiology, Ohio College of Podiatric Medicine, Cleveland, OH 44106.

The present study was conducted to determine if the difference in diameter between muscle fibers of different fiber types were related to local fiber type composition. The neuromuscular compartments of rectus femoris (RF) were identified by glycogen-depletion using PAS Frozen sections (20 µm thick) of RF were stained for alkaline ATPase, acid ATPase, and NADH; fiber types were determined (SO, FOG, FG) and minor diameters measured. Fibers with homogeneous diameters had higher proportions of type SO.

		RFpm	RFpl	RFdm	Rfdl
SO Diameter	(mm)	30.5	33.8	36.3	34.6
FG Diameter			48.5	44.2	41.4
Type SO	(%)	9.4	10.6	29.4	28.3

NEURAL INACTIVATION WITH TETRODOTOXIN PREVENTS RAT PLANTARIS ADAPTATIONS TO TENOTOMY OF ITS SYNERGISTS. R. N. Michel. School of Human Movement, Laurentian University, Sudbury, Ontario,

Canada, P3E 2C6.

This study was constructed to examine the extent to which the morphological and functional changes that occur in the rat plantaris (PL) muscle in response to synergist tenotomy are dependent on neural activation. This was acheived by superimposing synergist tenotomy and neural inactivation. One group of Sprague-Dawley rats had the sciatic nerve of one hindlimb superfused with the sodium channel blocker tetrodotoxin (TTX) for 2 wks, and the soleus and gastroenemius muscle tendons of both hindlimbs cut. A second group of animals that had undergone these same procedures, had the ankle of their silenced limb fixed in flexion placing the PL under passive stretch. A third group of animals served as sham-operated control. Two weeks of synergist tenotomy caused PL muscles to have greater absolute (g. 41%) and relative (mg/g body wt.; 53%) mass, and whole (18%) and individual slow-twitch (18%) muscle cross-sectional areas, compared to sham-operated controls. In these muscles, isometric contractile characteristics measured in situ in response to sciatic muscles, isometric contractile characteristics measured in sign in response to sciatic nerve stimulation were not improved over control. Consequently, specific twitch and tetanic tensions were 20% smaller in these muscles. Superimposition of TTX superfusion and synergist tenotomy prevented any of the morphological improvements associated with synergist tenotomy from occurring. PL in this group had reduced absolute and relative mass (58%), and whole (51%) and individual slowhad reduced absolute and relative mass (S8%), and whole (51%) and individual slow-twitch (60%) muscle cross-sectional areas, compared to their contralateral overloaded counterparts. Functionally, these muscles had a prolonged twitch, a decreased rate of tension development, and a reduced capacity to generate maximum forces at high, but not low, stimulation frequencies. Interestingly, fixation of the ankle had no effect on any of these parameters, and did not alter muscle rest length. The results suggest that neural activity is necessary to induce changes in the PL that are characteristic of the compensatory overload model. Clearly the mechanism of stretch-induced hypertrophy must be revisited.

NERVE-INDUCED EFFECTS ON MUSCLE PHENOTYPE IN FETAL SHEEP.

NERVE-INDUCED EFFECTS ON MUSCLE PHENOTYPE IN FETAL SHEEP. J.W. Hermanson. M.J. Daood*. W.A. LaFramboise and P.W.N Nathanielsz*. Coll. of Vet. Med., Cornell Univ., Ithaca, NY 14853, Magee Womans Hospital, Pittsburgh PA. 15213 and University of Pittsburgh, Pittsburgh, PA 15217. To study neurogenic effects on developing fetal muscle, transection of the common peroneal nerve was undertaken in early gestation age (dGA 71, N=4) and late gestational age (dGA 110:N=1; and dGA 121:N=1) fetal sheep. Animals were allowed to survive until dGA 91 and 131, respectively. Denervated and contralateral sham-operated control peroneus longus (PL) muscles were evaluated grossly, histologically, histochemically and electrophoretically. Control PL muscle samples from adults and from fetal sheep at dGA 71, 110, and 141 were similarly studied. Early-gestation age denervated muscles exhibited growth and hyperplasia relative to control dGA71 PL, but were reduced in size relative to contralateral dGA91 controls and failed to show fiber type differentiation whereas control muscle expressed type I and II fiber myosin ATPase. Denervated PL exhibited many fibers with central nuclei (approximately 15%) while contralateral control muscles contained few fibers with central nuclei (less than 4%). In two of the animals central nuclei (approximately 15%) while contralateral control muscles contained few fibers with central nuclei (less than 4%). In two of the animals studied, denervated PL muscles contained 39,036 and 38,931 fibers, while estimated fiber numbers in contralateral control PL muscles were 45,000 and 51,340, respectively. Electrophoretic analysis of native myosin isoforms in 4% pyrophosphate gels showed a slow myosin band in late-gestation age (greater than dGA 110) muscle. Two or three fast native myosin isoforms were present in all PL muscles. Denervated extensor digitorum longus muscle (EDL) at dGA 131 were also reduced in size relative to contralateral controls and lacked the fiber type differentiation present in control EDL. Peripheral nuclear migration occurred in late-gestational age denervated as well as control EDL. These data indicate that fetal denervation reduces growth but also inhibits muscle differentiation as indicated by a failure for nuclei to migrate peripherally, and by failure to exhibit histochemical fiber type differentiation. Supported in part by NIH 21350. NIH 21350.

PATTERNS OF MOTONEURONE SPROUTING IN THE CAT TRICEPS SURAE MUSCLES. <u>V.F. Rafuse*, T. Gordon, R. Orozco* and M.J. Gillespie.</u> Div. of Neuroscience, Univ. of Alberta, Edmonton, Canada T6G 2S2.

Although it is well recognized that intact motoneurones will sprout to

innervate denervated fibers after partial denervation (PD), the extent and limits of sprouting of the unit population are not well understood. To determine 1) whether motoneurones increase their innervation ratio (IR) in proportion to their size as predicted by the size principle and 2) the limits to which motor unit types can sprout, we examined muscles which contain 5, 25, and 100% slow motor units, MG, LG and soleus muscles, respectively. If each motoneurone sprouts in proportion to its size, IR should increase by a constant factor y which will equal 1/N where N is the proportion (or %) of remaining units. 10-90% of the innervation was removed by unilateral section and ligation of the L7 or S1 root and the number, force, fatigability and conduction velocity of remaining motor units was determined 4- 18 months later. An average of 25% of the unit population was sampled prior to removal of the nerves and muscles for histological examination. The distribution of unit force was found to shift to progressively higher values in proportion to N for values of N>20%, if redistribution of muscle fiber size was taken into account. Since axon size did not change, the size relationship between force and axon potential amplitude was shifted by the same factor along the force axis. Thus, the data indicates that the IR of all motoneurones increases by a constant factor y, without affecting axon size. However, for N=5-20%, the smaller slower units did not increase beyond 4-5 times and the IR of remaining motor unit population showed a disproportionate increase which led to full muscle recovery in the LG and MG but not in the soleus. Thus there is a size-dependent sprouting which is more limited in the smaller than the larger motor units. (Supported by MRC and MDAC).

METABOLIC RESPONSE OF ADULT AND NEONATAL RAT MUSCLE TO A HIGH-FAT DIET. B.W.C. Rosser, R.M. Choksi*, B.J. Norris*, K.M. Baker* and P.M. Nemeth. Depts. of Neurology, and of Anatomy and Neurobiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

Adult and neonatal rats were exposed to a high-fat low-carbohydrate diet to

determine the effect of substrate availability on the metabolic phenotype of muscle. Neonatal laboratory rats normally switch from high-fat mother's milk to a high-carbohydrate lab chow diet at about 2 weeks of life and exhibit a gradual decline in lipid metabolism (Nemeth et al., J. Neurosci. 1989). By a gradual decline in lipid metabolism (Nemeth et al., J. Neurosci. 1989). By extending the exposure to high-fat, we found that β-hydroxyacyl CoA dehydrogenase (βOAC), carnitine acetyltransferase (KCAT) and thiolase activities were increased by over 50% at 1 week after weaning in soleus, EDL and diaphragm muscles. The activities continued to increase during the subsequent 5 weeks of the high-fat diet to attain levels 100% higher than controls. Kreb's cycle oxidative enzymes (MDH, SDH), glycolytic enzymes (LDH, PFK) and enzymes of high energy phosphate metabolism (AK, CK) were essentially equivalent to controls in homogenate assays.

Adult rats had a similar response with βOAC. KCAT and thiolase activities 25-100% higher than normal by 1 week after the onset of the high-fat diet. Examination of individual muscle fibers in the adult experiments revealed the increased lipid metabolism occurred in fibers of all types, with the IIb fibers

Examination of individual muscle floets in the adult experiments revealed increased lipid metabolism occurred in fibers of all types, with the IIb fibers having the largest increase. At 4 weeks βOAC was 45% higher than control in type I fibers, 33% higher in IIa fibers and 310% higher in IIb fibers. The IIb fibers also exhibited a 125% increase in Kreb's cycle enzymes, while

these did not increase significantly in type I and IIa fibers.

The data indicate that both adult and neonatal muscles are capable adjusting their energy metabolism in response to dietary factors, and would support a dietary strategy to increase oxidative capacity. Supported by NIH grant DK38375.

Patterns of motoneurone sprouting in the rat Tibialis Anterior - T.Gordon, N.Tyreman, S.Erdebil & S.Devasahayam, Univ.of Alberta, Edmonton, T6G 2S2

The factors that promote or limit sprouting of motoneurones following nerve injury are not completely understood. Since it is impossible to accurately measure the extent of sprouting of individual motor units -i.e., the size before and after sprouting - it has been difficult to answer these questions reliably. Using the motor unit force as a measure of the unit size, the distribution of units from partially denervated muscles can be compared with units from normal control muscles to estimate the extent of sprouting. Since, comparison of distributions is greatly improved by the number of units sampled from each muscle, we obtained a large sample of units (20-30% of the muscle) in the rat tibialis anterior by recording incremental twitch forces from bundles of axons in the spinal roots. We have determined that using the contralateral side as a control, the extent of partial denervation in experimentally denervated muscles can be reliably measured. Finally, to address the fact that motor unit force is an indirect measure of the unit size that assumes that variations in fibre size do not confound the data, we counted the number of fibres in individual units that were identified by depleting the glycogen in one unit in each muscle.

The data shows that the unit sizes change uniformly proportional to the denervation in the whole muscle therefore maintaining the size relationship after sprouting as before. The maximum sprouting capacity of the units in the rat TA seems to be a fourfold increase (75% denervation) from normal, beyond which incomplete recovery of muscle force is seen, as has also been reported for the rat soleus. The spatial distribution of the unit fibres identified by glycogen depletion shows closer clustering of sprouted unit fibres than normal, which suggests that unit territory can limit sprouting of individual units.(supported by the Rick Hansen Legacy Fund, and MRC).

CYTOARCHITECTURE OF THE SOLEUS MUSCLE IN THE C57BI/KsJ-dbm DIABETIC MOUSE David Porta and Kathleen M. Klueber, Department of Anatomical Sciences and Neurobiology, University of Louisville, School of Medicine, Louisville, KY 40292

Diabetes adversely affects both muscle and nerve. Ultrastructural evidence reveals degeneration of both the axon and myofiber thus causing denervation of type 2 myofibers (Feczko and Klueber, Am.J.Anat 182:224-240,1988). However, type 1 myofibers are thought to be more resistant to disease states. The objective of this study was to determine if type 1 myofibers of diabetic muscle exhibit similar cytoarchitectural changes observed in a type 2 muscle. Soleus muscles from 126 day old diabetic (db/db) and control (db/+) mice (n=5/group) were fixed in situ, processed using standard electron microscopic procedures and analyzed under the electron microscope. In the db/db soleus muscles, there was an increase in the lipid stores and an increase in the number of cells with displaced mitochondria. When compared to the type 2 muscle, fewer cells exhibited signs of degeneration and disruption of the mitochondria. In addition, fewer myofibers exhibited signs of denervation and reinnervation and most neuromuscular junctions appeared normal. Therefore, it appears that the soleus muscle has some ability to resist the disease state. Funded by: USHS 1R29DK41553-01

VITAL MARKER FOR MUSCLE NUCLEI IN MYOBLAST TRANSFER: O. Fang*, M. Chen*, H.J. Li*, T.G. Goodwin*, and P.K. Law. Depts. of Neurol.

and Physiol./Biophys., Univ. of Tennessee, Memphis, TN 38163.

A new method is developed using Fluoro-Gold (FG) as a vital stain to label the nuclei of donor myoblasts in Myoblast Transfer studies. In culturo incubation with 0.01% FG for 16 hours resulted in 100% nuclei labelling. Intensive fluorescence persisted following nine days of subculture, when the human myoblasts were injected into the quadiriceps of C57BL/6 mouse recipients immunosuppressed with cylcosporine. Injected muscles showed mosaicism of host and donor nuclei 25 days after injection, indicating (1) survival and fusion among donor myoblasts, and (2) fusion between howt and donor cells. (Supported by USPHS NS 26185, MDA, Sandoz and Walgreens).

ULTRASTRUCTURAL ANALYSIS OF CHRONICALLY ELECTRI-CALLY STIMULATED NERVE. B. Marts, K. Klueber, J. Brown*, and J. Hoffpauir*, Dept. Anat. Sci. & Neurobiol., Univ. of Louisville, School of Medi-cine, Louisville, KY 40292 and Dept. of Surgery, Indiana U. Medical School, Indianapolis, IN 46202

Are there structural changes in the nerve following chronic electrical stimulation? The objective of this study was to examine the cytoarchitive of this study was to examine the cytoarchi-tecture of canine peripheral nerve after constant stimulation for 60, 150 and 365 days. The nerve to the rectus abdominis muscles of 3 female dogs per time point were stimulated electrically (2 her time point were stimulated electrically (2 Hz, 5.9V, 2 msec pulse duration) in order to convert Type 2 to Type 1 myofibers for use in a cardiac assist device. The implanted pacemaker did not interfere with the animals' activities. Following stimulation some myofibers exhibited signs of denervation characterized by: 1) disorganization of sarcomeres, 2) target and ring fibers, and 3) reinnervation. The stimulated nerves exhibited a decrease in the number of axons with a concomitant increase their diameter. In addition, some axons displayed signs of demyelination. A few myelin tubes appeared to contain more than 1 axon. Therefore, electrical stimulation of peripheral nerve causes axonal changes. Funded by: Surgery Dept, Indiana U. Sch. of Med. and 1R29DK41553-02.

HIPPOCAMPUS AND AMYGDALA: NEUROANATOMY

53.1

DIFFERENTIAL PROJECTIONS OF THE ANTERIOR POSTERIOR REGIONS OF THE MEDIAL AMYGDALOID NUCLEUS IN THE SYRIAN HAMSTER. D.M. Gomez and S.W. Newman, Department of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109.

The medial amygdaloid nucleus (Me) is important for controlling mating

behavior in the adult male Syrian hamster (Mesocricetus auratus). Chemosensory inputs from the olfactory bulbs project primarily to the anterior region of Me (MeA) whereas gonadal steroids are actively accumulated by neurons in posterior Me (MeP) and both of these signals are essential for this behavior. Not only are the sites of actions for these signals separated, but lesion studies have demonstrated functional differences between MeA and MeP. The efferent projections of MeA and MeP were investigated using an anterograde neuronal tracer, Phaseolus vulgaris leucoagglutinin (PHAL). Adult hamsters were iontophoretically injected with PHAL into either MeA (n=5) or MeP (n=7). After 10 days, animals were perfused with 4% paraformaldehyde. Coronal brain sections (40 um) were processed immunocytochemically for PHAL and adjacent sections were stained with cresyl-violet. Injection sites in MeP were confined; those aimed at MeA included more rostral areas but did not involve MeP. Both of these areas projected to the bed nucleus of the stria terminalis and the medial preoptic area with selective projections of MeA to the lateral, and MeP to the medial parts of these nuclei. Both areas also project to the ventromedial nucleus of the hypothalamus with MeA terminating in the core and MeP to the shell. In addition, reciprocal connections were observed between MeA and MeP. These findings suggest that both MeA and MeP have connections into distinct parts of reproductive control areas which may be important for the functional differences observed between these two regions. (Supported by NIH, NS #20629 to SWN).

NEUROANATOMICAL MODEL OF INTRINSIC HIPPOCAMPAL

CIRCUITRY IN THE RAT. A. Roskies, B. Armstrong, D.G. Amaral, and T.J. Seinowski. Salk Institute, La Jolla, CA 92037.

Qualitative studies have revealed orderly gradients in connectivity density within and between various subfields of the rat hippocampus along the septotemporal, transverse, and radial axes (Amaral and Witter, Neuroscience 3, 1989). We have developed a method for quantifying these projections and car using these date to develop a prophybilistic 3-10. these projections and are using these data to develop a probabilistic 3-D model of Shaffer collateral projections between CA3 and CA1. Such a

model will be useful for large-scale simulations and analysis of *in vivo* and *in vitro* electrophysiological results.

We first performed densitometric analysis of projections arising from small injections in CA3 of the anterograde tracer phaseolus vulgaris leucoagglutinin (PHA-L). Optical density was sampled in volumes of 50µm x 50µm x 30µm. Natural coordinates of sampled areas were transformed into a coordinate system corresponding to a planer. south x south x south. Natural coordinates or sampled areas were transformed into a coordinate system corresponding to a planar representation of an unfolded hippocampus. The modified coordinate system has major axes originating in the cell fields, corresponding to the CA2/CA1 border longitudinally, the transverse axis, and stratum oriens and stratum radiatum radially. This transformation allows mathematical analysis of connectivity in a rectangular coordinate system. A computational model based upon data from several injection sites is sufficient to predict projection probabilities from novel sites in CA3. Modeling of the connectivity density between areas CA3 and CA1 will provide the basis for predicting complex interactions between populations of cells in various portions of CA3 and their effects on cells in CA1.

CENTRAL NUCLEUS OF AMYGDALA AND BED NUCLEUS OF STRIA TERMINALIS PROJECTIONS TO SEROTONIN OR TYROSINE HYDROXYLASE IMMUNOREACTIVE CELLS IN THE DORSAL AND MEDIAN RAPHE NUCLEI IN THE RAT. <u>D. 1. Magnuson</u> and <u>T. S. Gray</u>, Dept. of Cell Biology, Neurobiology and Anatomy, Loyola University Stritch Sch. of Med, Maywood, Il. 60153

The present study was designed to examine the projections of the bed nucleus of stria terminalis (BST) and the central nucleus of the amygdala to the dorsal raphe, median raphe and adjacent central gray. Injections of <u>Phaseolus vulgaris</u> leucoagglutinin lectin (PHA-L) were made into either the central nucleus of the amygdala or BST in anesthetized 250-350g male Long-Evans rats. Post-injection survival periods ranged from 12 to 16 d. PHA-L-immunoreactive fibers and terminals were visualized with horseradish peroxidase-brown diaminobenzidine reaction product. The tissue was then processed using standard immunocytochemistry for serotonin or tyrosine hydroxylase with a glucose oxidase-nitro-blue tetrazolium reaction product. The densest projections to the dorsal raphe and adjacent central gray were from the ventral lateral bed nucleus. A less dense projection to these regions was seen from the medial central nucleus. The median raphe nucleus was heavily innervated by the ventral lateral bed nucleus but only lightly by the medial central nucleus. Other subdivisions of the central amygdala and BST had limited or no projections to the raphe nuclei. Results demonstrate a topographically organized projection from the amygdala and bed nucleus of stria terminalis to the dorsal and median raphe nuclei. The data also indicate a quantitatively larger projection from the BST as compared to the amygdala. Supported by NS20041.

ORGANIZATION OF CA1 PROJECTIONS TO THE RAT SUBICULUM: A PHA-L ANALYSIS. D. G. Amaral, P. Alvarez-Royo, C. L. Dolorfo and J. Weber. The Salk Institute and Group in Neurosciences, UCSD, La Jolla, CA 92037

We are conducting a comprehensive reinvestigation of the organization of intrinsic circuitry of the rat hippocampal formation using the anterograde tracer, intrinsic arcuitry of the rat hippocampal formation using the anterograde tracer,

Phaseolus vulgaris leucoagglutinin (PHA-L). In this study, iontophoretic injections
have been placed at various transverse and septotemporal positions of the CA1
field and, after a survival period of 7-10 days, the brains were
immunohistochemically prepared for the visualization of the lectin. The
hippocampi were dissected from the brain and extended in the septotemporal axis to facilitate analysis of the longitudinal distribution of CA1 projections. Thirty-two successful experiments are currently available for analysis. CA1 projections to the subiculum terminate in the polymorphic, pyramidal and deep portion of the molecular layers. The outer portion of the molecular layer, in which the perforant path terminates, is free of CA1 input. As suggested by Tamamaki, based on his intracellular labeling studies, the CA1 projection to the subiculum terminates in a strikingly columnar fashion. CA1 cells located close to CA2 terminate in a column located distally in the subiculum, i.e. near the presubiculum. CA1 cells located close to the subiculum, in contrast, terminate in a column just across the CA1/subiculum border. CA1 cells in the mid transverse portion of the field, terminate in an intermediate position in the subiculum. While it is difficult to precisely determine the minimum transverse extent of a labeled column, in our cases it was generally about one-third of the extent of the field. The CA1 projections also appear to be fairly extensive in the septotemporal axis. In most cases, the projection extends for approximately one-third to one-half of the full septotemporal distance of the subiculum.

53 5

THE ORGANIZATION OF CORTICAL INPUTS TO THE PERIRHINAL (AREAS 35 AND 36) AND PARAHIPPOCAMPAL (AREAS TF AND TH) CORTICES IN THE MONKEY. W. A. Suzuki and D. G. Amaral. The Salk Institute and Group in Neurosciences, UCSD, La Jolla, CA 92037.

The perirhinal and parahippocampal cortices provide the major cortical projections to the entorhinal cortex of the monkey hippocampal formation. Although the perirhinal and parahippocampal cortices are reputed to be regions of polysensory convergence, a thorough examination of the cortical inputs to these regions has not yet been conducted. We have begun a series of studies regions has not yet been conducted. We have origin a series of student investigating these inputs by placing injections of the retrograde tracers Fast Blue, Diamidino Yellow, and WGA-HRP into different levels of the perirhinal and parahippocampal cortices in the Macaca fascicularis monkey. Injections have thus far involved area 35, the temporal polar portion of area 36, and area TF. In all cases, retrogradely labeled cells were observed in both unimodal and polymodal association areas of the frontal, cingulate, temporal, insular, and parietal cortices. In our sample of injections, the visual association area TE projected more heavily to area 35 than to area TF. Conversely, the dorsolateral portion of the superior temporal gyrus (presumed auditory association cortex) and the dysgranular and granular portions of the insula (presumed somatosensory association cortices) projected more heavily to area TF. The polysensory areas labeled after injections of areas 35 or TF included the dorsal bank of the superior temporal sulcus, the cingulate cortex, the posterior parietal cortex and areas 46 and 13 of the frontal cortex. Although area 35 did not appear to receive substantial inputs from the parahippocampal cortex, there were some labeled cells in areas 35 and 36 after TF injections. In all cases, there were numerous labeled cells located in layer V of the entorhinal cortex. An understanding of the cortical inputs to the perirhinal and parahippocampal cortices is relevant to recent studies showing that these areas play a prominent role in memory function.

CONNECTIVITY OF THE DORSAL AND VENTRAL PRESUBICULUM OF THE RAT. I.S. Taube¹, F. Scalia², and D.G.Amaral³. ¹Department of Psychobiology, University of California, Irvine, CA 92717, ²Department of Anatomy, SUNY Health Science Center, Brooklyn, NY 11203, and ³The Salk Institute, La Jolla, CA 92037.

The connectivity of the dorsal and ventral portions of the presubiculum were investigated using anterograde (PHA-L) and retrograde (WGA-HRP) tracing techniques. These studies were conducted, in part, to determine whether the connectivity of the dorsal presubiculum was substantially different from that of the ventral presubiculum which would justify the use of the term "postsubiculum" for the dorsal region. Injections of PHA-L were successfully iontophoresed into various regions of the presubiculum in 25 animals and WGA-HRP was iontophoresed in an additional 20 animals.

Examination of Nissl and AChE preparations showed no clear-cut boundary between the dorsal and ventral presubiculum. PHA-L injections into all areas of presubicular cortex resulted in prominent labeling bilaterally in layer III entorhinal cortex; additional labeling was also observed in layers I and II. All injections also led to projections to the anterior dorsal (AD), anterior ventral (AV), and lateral dorsal (LDDM) thalamic nuclei. Lighter labeling was observed in the lateral mammillary nucleus, retrosplenial and cingulate cortices, and contralateral areas of presubiculum. HRP injections into all areas of the presubiculum resulted in the labeling of cells in subicu-lum, AD, AV, and LDDM thalamic nuclei, and contralateral presubiculum. While there were minor variations in the patterns of anterograde and retrograde labeling in the various experimental cases, the connectivity of the dorsal presubiculum appeared to be very similar to that of the ventral presubiculum. These results suggest, therefore, that the dorsal presubiculum should not be considered a separate division of the subicular complex.

53.9

EFFECT OF IBOTENIC ACID LESION OF THE DORSAL HIPPOCAMPUS ON CEREBRAL DOPAMINERGIC SYSTEMS IN THE RAT. B. K. Lioska. G. E. Jaskiw, K. Farouk, J. E. Kleinman, D.R. Weinberger, CBDB NIMH Neuroscience Center at St. Elizabeths Hospital, Washington, D.C. 20032.

We have shown that medial prefrontal cortical lesions alter basal presynaptic DA metabolite indices in anteromedial caudate14 days postoperatively and permanently disrupt normal behavioral responses to mild stress. To examine whether similar behavioral responses to mild stress. To examine whether similar effects result from dorsal hippocampal lesion, rats were lesioned bilaterally (coordinates from bregma AP -3.0 mm, ML +2.2 mm, VD -3.9 mm) with ibotenic acid (5 μ g in 0.5 μ l) or vehicle (buffered saline). Locomotion was assessed on the 14th and 28th days postoperatively. In ibotenic acid-lesioned rats spontaneous but not d-amphetamine-induced (1.5mg/kg) locomotion was increased on the 14th but not 28th day after lesion. The levels of DA, DOPAC, HVA assayed by GC/MS in anteromedial caudate and nucleus accumbens were not afected in lesioned in comparison to sham-operated rats. However, in rats with ibotenic acid lesions, the anxogenic B-carboline FG 7142 and 48hr food deprivationmild stressors - failed to attenuate locomotor exploration in comparison to sham lesioned rats. These results indicate that, unlike medial prefrontal cortical lesions, the lesions of the dorsal hippocampus do not alter basal levels of DA and metabolites, but they disturb the behavioral responses to stress in the unique way.

INTRINSIC CONNECTIONS OF THE MONKEY AMYGDALA: A PHA-L ANALYSIS OF PROJECTIONS ORIGINATING IN THE LATERAL NUCLEUS. A. Pitkänen and D.G. Amaral The Salk Institute, La Jolla, CA. 92037

We have begun a program of studies examining the intrinsic circuitry of the we have begin a program of studies examining the intrinsic circuity of the monkey amygdaloid complex using the lectin anterograde tracer, Phaseolus wulgaris leucoagglutinin (PHA-L). As a first step, PHA-L was focally iontophoresed into different portions of the lateral nucleus in different experimental animals. After a two week survival period, the brains were immunohistochemically processed to visualize the distribution of transported label. To optimize the staining in the monkey brain, several modifications were made to the procedure of Gerfen and Sawchenko. The results of our studies have confirmed many of the projections demonstrated earlier with the autoradiographic method. Projections from the lateral nucleus were observed, for example, to the accessory basal nucleus, the periamygdaloid cortex and the medial nucleus. The major new finding is that the lateral nucleus gives rise to a heavy projection to the basal nucleus of the amygdala. Fiber and terminal labeling was heaviest in the lateral part of the basal nucleus and rostral to the level of the injection site but was distributed to much of the rostrocaudal extent of the nucleus. This projection was not described in previous autoradiographic studies perhaps due to the difficulty in discriminating diffusion of isotope from labeled local projections. Ongoing studies are directed at determining the distribution and topography of intrinsic amygdaloid projections arising from different portions of the lateral nucleus. In particular, we are attempting to determine whether the two major subdivisions of the lateral nucleus (the dorsomedial and ventrolateral regions) are interconnected by intrinsic projections and whether these regions of the lateral nucleus have different projections to the other nuclei of the amygdaloid complex.

HETEROGENEITY OF LAYER II NEURONS IN HUMAN ENTORHINAL CORTEX. M.J. Beall, M. Akil, and D.A.Lewis. Depts. of Behav. Neurosci. and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Layer II neurons of entorhinal cortex (ERC), which cluster and form

islands throughout most of this region, play an important role in relaying cortical information to the hippocampus. Abnormalities in relaying cortical information to the hippocampus. Abnormalities in these neurons have been implicated in neuropsychiatric disorders such as Alzheimer's disease and schizophrenia. However, relatively little is known about the chemical identity of the layer II neurons in normal human ERC. Left ERC was obtained at autopsy (postmortem interval 4.5-8 hrs.) from 3 individuals (ages 32-63) with no known neuropsychiatric disorders. In immunohistochemical studies, antibodies against neurofilament proteins (NF) and 2 calcium binding proteins, candidate in the proteins (NF) and describing (CR) labeled district subropulations. parvalbumin (PV) and calbindin (CB), labeled distinct subpopulations of neurons in layer II and deeper layers. In the layer II islands, a subpopulation of modified pyramidal neurons was intensely immunoreactive (IR) for NF. The number of NF-IR neurons in layer II increased in a medial to lateral gradient along the rostro-caudal axis of the ERC such that at rostral levels of ERC, NF-IR neurons were present only medially and at more caudal levels they extended farther laterally. A similar gradient was observed with smaller PV-IR neurons located in A similar gradient was observed with smaller PV-IR neurons located in the deep half of layer II islands. A different pattern of labeling was observed with CB; layer II islands in rostral ERC contained CB-IR punctate whereas in caudal portions of ERC small CB-positive neurons were grouped between the islands. These data reveal the heterogeneity of layer II neurons in normal human ERC and may provide insight into the differential roles of these neurons in ERC function.

DISTINCT NEUROCHEMICAL FEATURES OF BRAIN

DISTINCT NEUROCHEMICAL FEATURES OF BRAIN METALLOTHIONEINS. M. Ebadi, and A. Earle. Depts. of Pharmacol., Neurol., and Anat., Univ. Nebr. Coll. Med., 600 S. 42nd St, Omaha, NE 68198. Metallothioneins (MT), are low molecular weight metal binding proteins that consist of a single polypeptide chain of 61 amino acids, 25-30% of whose residues are cysteine, and that are devoid of any disulfide bonds or aromatic amino acids. We report that the brain MT possesses unique features which distinguish them from those found in the peripheral tissues. Unlike in the liver, the level of brain MT increases postnatally, and its synthesis is not induced following administration of cadmium, ethyl alcohol, or dexamethasone. On the other hand, the zinc-induced MT synthesis in the brain is associated with an accumulation of mRNA which is analogous to the zinc-induced synthesis of hepatic MT mRNA. In addition, antibodies formed against both the sheep- and rat-hepatic metallothioneins cross react completely with the hippocampal metallothioneins, suggesting that the immunologically dominant regions of the NH₂-terminal domain (residues 1-29) of neuronal metallothioneins are conserved. The regions of brains such as pineal gland, retina, and hippocampus which have high concentrations of zinc, not only synthesize MT on a continuous basis, but also have other low molecular weight zinc binding proteins of unknown nature. Since, the synthesis of brain MT is increased following icv administration of zinc and is decreased in zinc deficiency state, we postulate administration of zinc and is decreased in zinc deficiency state, we postulate that zinc may regulate the synthesis of brain MT. In view of the fact that neither essential elements such as zinc and copper nor non essential elements such as cadmium and barium traverse the brain readily, it is very doubtful that sucut as caumium and oarium traverse the brain readily, it is very doubtful that the brain MTs play major roles in acute metal detoxification. On the other hand, the brain may have developed unique processes for transporting, compartmenting, releasing, and utilizing zinc, copper, calcium and other essential elements, commensurate with the diversified and vital functions endowed and invested in its various regions. (supported in part by a grant from USPHS ES-03949).

AMYGDALOID PROJECTIONS TO HIPPOCAMPAL-RECIPIENT AND -NON-RECIPIENT REGIONS OF THE ORBITOFRONTAL CORTEX IN THE MACAQUE MONKEY. C. Cavada and F. Reinoso-Suárez. Departamento de Morfología, Facultad de Medicina, Universidad Autónoma de Madrid, Spain.

Morfología, Facultad de Medicina, Universidad Autónoma de Madrid, Spain. In previous studies we have shown that the medial sector of the orbitofrontal cortex of macaques, including Walker's areas 14, 10, and the border region between 10 and 11, is the target of direct projections from hippocampal field CA1. This anatomical linkage suggests that the medial orbitofrontal cortex may be involved in memory function. Considering the debate about the participation of the amygdaloid complex in mnemonic processes, we have analyzed the neuronal labeling present in the amygdala in the same brains used in the hippocampal study. Multiple labeling experiments were made in both hemispheres of adult macaque monkeys by injecting retrograde tracers (HRP-WGA, FB and DV) in the various areas of the orbitofrontal cortex. Interestingly, the injections that produced the heaviest. orbitofrontal cortex. Interestingly, the injections that produced the heaviest hippocampal labeling gave the weakest amygdaloid labeling, and viceversa. Moreover, we uncovered a notable topographical organization of the amygdalo-orbitofrontal projections. The hippocampal-recipient medial areas 14 and 10-11 receive sparse amygdaloid projections, that arise in the basal and accessory basal nuclei, principally in their posterior half. Area 14 is also the target of a weak projection from the posterodorsal part of the lateral nucleus. By contrast, the adjacent hippocampal-non-recipient area 13 receives an abundant projection from the lateral and accessory basal nuclei, and a less abundant one from the basal nucleus. Areas 12 and 11, that are also devoid of hippocampal input, are the targets of a heavy amygdaloid projection arising in the basal nucleus, principally in its intermediate subdivision. These findings show that the territories accessed by hippocampal and amygdaloid projections in the orbitofrontal cortex are mutually exclusive rather than convergent, arguing in favor of a functional diversity between medial and lateral orbitofrontal sectors.

RECURRENT SYNAPTIC CIRCUITRY IN THE CA3 REGION OF HIPPOCAMPAL SLICES FOLLOWING FORNIX LESIONS. P.A. Rutecki. Section of Neurophysiology, Dept. of Neurology, Baylor College of Medicine, Houston, TX 77030.

The recurrent excitatory synaptic connections in the CA3 region of the hippocampus appear to be the substrate for the synaptic synchronization that results in epileptiform activity. To investigate these synaptic connections, Sprague Dawely rats were anesthetized and electrolytic lesions were made to deafferent Dawely rats were anesthetized and electrolytic lesions were made to deafferent the fornix of septal and commissural inputs. Animals were allowed to survive 1-10 weeks and then sacrificed for slice preparation. The lesion was demonstrated using cresyl violet staining. On average, there was a $\approx 70\%$ decrease in hippocampal acetylcholinesterase activity on the side of the lesion. Following such lesions, slices from 5 of 26 animals displayed spontaneously occurring or evoked epileptiform activity in 5 mM [K⁺]_e saline. Using single-electrode voltage-clamp techniques in slices without epileptiform activity, stimulation of the fornix produced a robust IPSP that was primarily composed of a chloride conductance. In the presence of 10-50 μ M picrotoxin, a short latency excitatory conductance. In the presence of 10-50 μ M picrotoxin, a short latency excitatory synaptic current was observed; however, in 5 of 8 neurons, the excitatory current could not be studied in isolation because of contamination by an overlapping, residual inhibitory current. In the other 3 neurons the excitatory synaptic current reversal potential was between -7 and -3 mV and was associated with a conductance of 10-20 nS

Hippocampal slices from rats with chronic fornix deafferentation appear to be a useful preparation for studying local recurrent synaptic circuitry. Fornix stimulation evokes overlapping excitatory and inhibitory synaptic currents in CA3 pyramidal neurons. The occurrence of epileptiform discharges suggests that in some cases deafferentation results in new excitatory local circuitry. (Supported by NIH grant NS-11535 and the Klingenstein Fund.)

DYNAMIC CHANGES IN 'EFFECTIVE CONNECTIVITY' BETWEEN SIMULATED HIPPOCAMPAL NEURONS Gy. Gaal 1,2 , Z. Pan $^{1}*$, P.H. Bedenbaugh

LATED HIPPOCAMPAL NEURONS Gy. Gaal. 2, Z. Pan. 2, P.H. Bedenbaugh. G.L. Gerstein. 1 Departments of Physiology and Bioengineering, University of Pennsylvania, Philadelphia, 2 Institute of Experimental Medicine, Eungarian Academy of Sciences, Budapest, Hungary
Dynamic changes in the 'effective connectivity' between simultaneously observed neurons have been found by several laboratories. These can be revealed by Gerstein's gravitational clustering algorithm (Gerstein et. al., J. Neurosci. 5, 1985) and by normalization of the classical joint peristimulus time histogram (Aertsen et. al., J. Neurophys. 61, 1989). Changes of correlation have been observed in the hippocampus with a shift from the presence to the absence of theta rythm (Kuperstein et. al., Exp. Brain Res. 61, 1986), and with a shift from sleep to wakefulness (Noda et. al., Exp. Neurol., 24, 1969). However, these measurements were not corrected for rate changes.

We have constructed a model of the hippocampus using a variation of MacGregor's LRSYS32 program (Neural and Brain Modeling, Academic Press, 1987). This program simulates neurons as four state variable nonlinear systems. Hebbian changes in synaptic strength occur when pre- and postsynaptic cells are

bian changes in synaptic strength occur when pre- and postsynaptic cells are simultaneously activated. The model included a unidirectional trisynaptic excisimultaneously activated. The model included a unidirectional trisynaptic excitatory pathway and feedback and feedforward inhibition within the hippocampus, reciprocal projections with the entorhinal cortex and contralateral hippocampus and a unidirectional input from the septum. The cells in CA3 were of the bursting type. The EEG was adequately simulated by defining it as the total number of neurons active at each time step. The theta rythm was simulated by periodic modulation of the septal input projection.

Changes in correlation similar to those observed experimentally have been observed in our model even when the synaptic strengths are held constant. We are investigating corrections for nonstationarity induced by the theta stimulation, and are comparing changes in effective connectivity induced by synaptic plasticity to those induced by differential activation of neural assemblies. Supported by NIH/Fogarty 1 FOS TW04265-01 BI-5.

INTRAGRANULAR MOSSY FIBERS IN RATS FORM SYNAPSES WITH THE SOMATA AND PROXIMAL DENDRITES OF BASKET CELLS. C. E. Ribak and G. M. Peterson. Dept. of Anatomy and Neurobiol., Univ. of Calif., Irvine, CA 92717 and Dept. of Anatomy and Cell Biol., East Carolina Univ. Sch. of Med., Greenville, NC

Intragranular and supragranular mossy fibers arise from granule cells and occur in the dentate gyrus of hippocampi from normal and epileptic animals. Often, the intragranular fibers appear at periodic intervals perpendicular to the long axis of the granule cell layer. Rats were analyzed to determine whether such mossy fibers are associated with another cell type in the granule cell layer, the basket cell, which sends apical dendrites through this layer at periodic intervals. The brains of normal rats were prepared using the Timm's sulfide silver histochemical method that is specific for axon terminals with high levels of heavy metals and labels the mossy fibers in the dentate gyrus. The light microscopic results show that most intragranular mossy fibers are apposed to the surfaces of the somata and apical dendrites of four types of basket cell. These basket cells have different orientations of their somata and proximal dendrites but all have cell bodies in the granule cell layer. Electron microscopic results show that the labeled mossy fibers form asymmetric synapses with the somata and apical dendrites of basket cells. Previous data indicated that mossy fibers formed synapses in the hilus with only the basal dendrites of basket cells. These new data show that intragranular mossy fibers also form synapses with basket cells, a major GABAergic inhibitory cell type in the dentate gyrus. These data suggest that intragranular mossy fibers provide additional feedback inhibition of granule cells.

PROJECTIONS FROM CA, AND SUBICULUM TO ANTERIOR OLFACTORY NUCLEUS AND OLFACTORY BULB. Th. van Groen, C. Rodenburg', and J.M. Wyss. Dept of Cell Biology and Anatomy, University of Alabama, Birmingham, AL 35294

Most research into the extrinsic projections of the hippocampal formation in the rat has focused on the contribution of subicular neurons and relatively little attention has been given to the contribution of CA neurons. In recent studies we noted a previously undescribed projection arising from area CA₁ and subiculum to the olfactory bulb and the anterior olfactory nucleus. To further investigate this projection of the hippocampal formation, anterograde and retrograde tracing studies were conducted. For anterograde tracing experiments, small injections of PHA-L were made into area CA1 and subiculum. Injections in the temporal third of area CA, labeled a dense axon and terminal plexus in the internal plexiform layer of the olfactory bulb and a less dense terminal plexus in the anterior olfactory nucleus. Following injections in the subiculum a dense plexus of axons and terminals was labeled in the anterior olfactory nucleus and a less dense terminal plexus was labeled in the olfactory bulb. Injections of the fluorescent, retrograde tracer fluorogold into the olfactory bulb labeled neurons in area CA1 and a smaller number of neurons in the subiculum. Injections in the anterior olfactory nucleus labeled many neurons in the subiculum and only a few neurons in area Table and the substantial and superficial to the pyramidal cell layer were labeled by these injections, but all labeled neurons were confined to the temporal one-third of the hippocampal formation. demonstrate that the anterior olfactory nucleus and the olfactory bulb receive a projection from the temporal one-third of CA1 and subiculum.

IN VITRO VISUALIZATION OF THE HIPPOCAMPAL MOSSY FIBER PATHWAY WITH EXTRACELLULAR BIOCYTIN. M.M. Okazaki and J. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr Durham, NC 27710.

Durham, NC 27710.

We have developed a method for visualizing dentate granule cells and their mossy fibers in the rat hippocampal slice after extracellular ionophoresis of biocytin. Horizontal 400-um thick hippocampal slices were prepared from adult male rats with a vibratome. Glass micropipettes with tip diameters of 5 um were filled with buffered 4-6% (w/v) biocytin. Biocytin was ejected into the granule cell body layer by passing positive current through the micropipette (300-600 nA for 5 min, 10 sec on/10 sec off). Uptake and transport were allowed to proceed for 3 hr, after which the slices were fixed in buffered 2% paraformaldehyde/19 glutaraldehyde at 4 °C. Slices were then cut into 50 um-thick sections with a vibratome and the biocytin was visualized with streptavidin-alkaline phosphatase (SAP) followed by the NBT/BCIP chromogen reaction (modified from King et al., 1983). Endogenous alkaline phosphatase activity was suppressed by preincubating the sections for 1 hr in buffered 0.5 mM EDTA. To inhibit the non-specific binding of SAP, the sections were incubated with 3% (w/v) non-specific binding of SAP, the sections were incubated with 3% (w/v) bovine serum albumin and all glassware that contacted the SAP reagent was prefinsed in the albumin solution. This method discretely labeled a small number of dentate granule cells and all their processes with minimal background and blood vessel staining. The full extent of the mossy fiber projection, including the giant boutons, was clearly visualized. (Supported by NIH grant NS 17771.)

ORGANIZATION OF THE ENTORHINAL PROJECTIONS TO THE HIPPOCAMPAL FORMATION OF THE RAT. M.P. Witter*. Dept. of Dept. Anatomy, Vrije Universiteit, Amsterdam, The Netherlands

Anatomy, Vrije Universiteit, Amsterdam, The Netherlands (SPON: European Neuroscience Association).

The organization of the "perforant path" (pp) was analyzed using anterograde tracing with Phaseolus vulgaris-leucoagglutinin. Emphasis was on i) the terminal distribution in each of the subfields of the hippocampal formation (HF), i.e. dentate gyrus (DG), fields CA3, CA2, and CA1, and subiculum (S); ii) the putative dissociation

in lateral, medial, and intermediate components of pp.
All subfields of HF are reached by fibers from the entorhinal cortex (EC). In DG and CA3/CA2, entorhinal fibers terminate along the entire transverse axis of the molecular layer, but show clearly restricted radial distributions. By contrast, in CA1 and S, fibers terminate in restricted portions along the transverse axis but fully cover of the radial width of the molecular layer. A semiquantitative analysis of the terminal patterns in the various subdivisions of HF supports the differentiation between lateral and medial pp and further indicates that artifactual labeling of an intermediate pp results from injections that involve parts of both the medial and lateral EC. The difference between DG and CA3/CA2 on the one hand and CA1 and S on the other with respect to the terminal organizations of the lateral and medial components of pp suggests a functionally different interaction between EC and the two hippocampal entities.

RAT BASAL NUCLEI PROJECT TO THE RETROSPLENIAL CORTEX VIA THE FORNIX. S.L.Gage.S.R.Keim, and W.C.Low, Prog. in Med. Neurobiol. and Dept. of Physiol. and Biophys., Indiana Univ. Sch. of Med., Indpls., IN 48202.

The cholinergic input to the retrosplenial cortex (RSC) has been defined by previous investigators as a single pathway extending primarily from the medial septial nucleus (MSN) and the diagonal band of Broca (DBB). This pathway has been shown to extend from these nuclei anteriorly and superiorly around the genu of the corpus callosum, and then posteriorly towards the RSC in a bundle positioned dorsal and medial to the cinqulum. Our preliminary studies to confirm the nature of the cholinergic input to the RSC support the presence of this pathway, but also suggest the existance of an additional cholinergic projection. The retrograde tracer, Fluoro-Gold was injected into the right RSC of 12 male rats (-5.8 mm AP; 0.7 mm ML; -2.2 to -1.0 mm DV). Prior to injection, 4 rats received bilateral aspiration lesions of the cortex and corpus callosum immediately posterior to Bregma, including all medial grey and white matter laterally through the cingulum. Four additional rats received lesions of the cortex and corpus callosum immediately posterior to Bregma, including all medial grey and white matter laterally through the cingulum. Four additional rats received lesions of the cortex as described, as well as lesions of the underlying fornix. Survival time was two weeks. Following fixation, sections were vibratomed at 50 um. Sections were either mounted on sildes and dried for fluorescopic (UV) inspection, or incubated with acetylthiocholine for 18 hr, reacted with sodium sulfide, mounted on sildes and covered slipped for inspection of acetylcholinesterase (ACHE) staining pattern by light microscopy. Non-lesioned animals displayed the typical laminar pattern by light microscopy. Non-lesioned animals displayed the typical laminar pattern by light microscopy. Non-lesioned animals displayed the injection site. Animals wi

ANTERIOR CINGULATE CORTEX PROJECTIONS TO RETROSPLENIAL AND POSTSUBICULAR CORTICES. Th. van Groen and J.M. Wyss. Dept. of Cell Biology and Anatomy, University of Alabama at Birmingham, Birmingham, AL 35294

Small iontophoretic injections of the anterograde tracer PHA-L were made into the anterior cingulate cortex (infraradiata cortex; IRα, anterior; $IR\beta$, posterior) to characterize the efferent projections of these areas. $IR\beta$ injections labeled dense terminal plexes in the retrosplenial and postsubicular cortices. Following dorsal IR β (IR β c) injections the densest labeling was consistently in the postsubicular and retrosplenial agranular (Rag) cortices, with much less dense labeling in rostral retrosplenial granular a cortex (Rga) and in the ventral half of the retrosplenial granular b cortex (Rgb). The projection to Rag terminated in the dorsolateral one-third of this cortex and extended into the adjacent part of area 18. The results suggest that the anterior to posterior position of IR &c neurons correlates with the anterior to posterior position of the terminal plexes in the postsubiculum. Following ventral IRB (IRBa and IR\$\beta\$b) injections, the densest labeling was consistently in Rgb and Rga cortices, with less dense labeling in Rag and postsubicular cortices. Compared to $IR\beta$ injections, injections into $IR\alpha$ cortex labeled fewer axons and terminals in retrosplenial and postsubicular cortices. These projections primarily originated in the caudal part of IRac and terminated in the rostralmost postsubiculum. Injections made into rostral IRac labeled dense terminal plexes in the contralateral, homotopic cortex, but did not label terminals in postsubicular or retrosplenial cortices.

DIFFERENCES IN CONNECTIVITY WITHIN THE CINGULATE

DIFFERENCES IN CONNECTIVITY WITHIN THE CINGULATE CORTEX IN RAT. D. Zeng and S.L. Stuesse, Dept. of Neurobiology, N.E. Ohio Univ. College of Medicine, Rootstown, OH 44272.

Rat cingulate cortex occupies a large portion of anterior-medial cortex and has been subdivided into three areas based on cytoarchitectonics (Zilles, 1985). We compared afferent and efferent connections of two of these areas, Cg1/Cg2 versus Cg3, by iontophoresing small quantities of wheat germ agglutinated horseradish peroxidase into either of these two divisions and identifying efferent connections and the cell groups which projected to these areas. 50 µm serial sections were processed using Mesulam's tetramethylbenzidene method. Within the thalamus, areas with Cg3 connections tended to be medial to those of Cg1/Cg2. Cg3 received projections from the mediodorsal, ventral reuniens, paraventricular, and paratenial, portions of the ventrobasilar complex, and many of the posterior and pretectal nuclei. Cortical projections were more widespread to Cg3 than to Cg1/Cg2 and included the infralimbic, perirhinal, agranular insular, dorsoendopiriform, and other parts of "limbic" cortex. Cg1/Cg2 was connected with the claustrum while Cg3 was not. Cg3 received input from the CA1 layer of the hippocampus, the lateral hypothalamus, amygdala, globus pallidus, and portions of the ventral striatum. In the brainstem, both received input from Barrington's nucleus, dorsal tegmental nuclei, and raphe dorsalis. Cg3 received input from raphe linearis while Cg1/Cg2 received if the mostal nucleus of the medial longitudinal fasciculus. Projections to the brainstem from Cg1/Cg2 targeted deep layers of the superior colliculus, reticularis gigantocellularis, nucleus cuneiformis, the paramedian pontine reticular formation, and the A5 region. Thus Cg3 should be considered a "limbic" area while Cg1/Cg2 has more "motor" connections and may contain a portion of the frontal eye fields. Supported by NIH MH43363. nections and may contain a portion of the frontal eye fields. Supported connections and ma by NIH MH43363.

ANALYSIS OF PIRIFORM CORTEX NEURONS IN THE GUINEA PIG MITH INTRACELLULAR STAINING TECHNIQUE. <u>K. Kishi, and K. Murakami</u>*. Dept.Anat. Toho Univ. Schl. of Med.

Tokyo. Japan.

This study is aimed at quantatative analysis on the morphology of piriform cortex neurons in the adult guinea pig anesthetized with pentobarbital. Biocytin (Sigma. 4-6% solution) was intracellularly injected into piriform cortex neurons at the level of anterior commissure. Survival time ranged from 4-24 hr. Eighty micron thick frozen sections were stained with ABC reagent. Three cell types were morphologically identified: pyramidal neuron in layer II. pyramidal neuron in layer III. and multipolar neuron in layer III and endopiriform nucleus. Pyramidal neurons in layer III exhibited a single apical dendrite and one to three basal dendrites. Apical dendrites in the layer II. and the terminal branches reached to the layer II. and the terminal branches reached to the layer II. The axon arose from the deep side of the cell body The basal dendrites distributed in layers III and II. The axon arose from the deep side of the cell body or from the stem dendrite, and run caudally in the depth of layer III or to the endopiriform nucleus. Axon collaterals were emitted at first in the layer III of the vicinity of cell body, and then at relatively regular intervals (around 500 μm intervals) through the course of main axon. These preliminary results suggest that majority of pyramidal neurons of layer II at the level of anterior commissure project their axons to the caudal layer III.

90° PHASE LAG IN OUTPUTS OF EXCITATORY AND INHIBITORY NEURONS CHARACTERIZES CORTICAL NEGATIVE FEEDBACK LOOPS

NEURONS CHARACTERIZES CORTICAL NEGATIVE FEEDBACK LOOPS
W. J. Freeman and F. H. Eeckman, Department of Molecular and Cell Biology, University of California at Berkeley CA 94720
Oscillations about "40 Hz" (the gamma range of 20 to 90 Hz) in "spontaneous" and evoked activities of single neurons in the visual, auditory, somesthetic and olfactory cortices raise the question: Are they the property of individual neurons that become entrained, or the property of populations of excitatory and inhibitory neurons, that are coupled by synapses?

Analysis of pulse trains of cortical neurons yields

Analysis of pulse trains of cortical neurons yields unequivocal answers. On the one hand, the mean firing rates of most cortical neurons are far less than the gamma range, and the pulse intervals are not periodic. Hence they are not individual oscillators and cannot entrain each other. On the other hand, interneuronal feedback loops require that two classes of neurons exist in each area of cortex, that show oscillation at the same frequency, but with a quarter cycle of phase lag by the activity of the inhibitory neurons behind the excitatory neurons. These two classes have been seen in every excitatory neurons. These two classes have been seen in every area of cortex where they have been sought, including the "spontaneous" EEG and averaged evoked activity of the olfactory bulb and the pyriform cortex (Freeman,1975), the anterior nucleus and entorhinal area (Eeckman & Freeman,1990), the hippocampus (Horowitz, et al.,1968), and the visual cortex (Gray, 1989). Where ever the inhibitory neurons are identified, their output lags. These findings are necessary and sufficient experimental proof of interneuronal negative feedback and indicate that it is widespread in the cerebral cortex. NIMH06688. indicate that it is widespread in the cerebral cortex. NIMH06686.

MAPPING SEPTAL (S) EFFECTS ON HIPPOCAMPAL (H) POPULATION SPIKES IN CAl OF RAT. P.G. Newlon, and S.K. Gudeman*, Dept. of Neurosurgery, Eastern Virginia Med. Sch., Norfolk, Va. 23507-1912.

Septal facilitation of intrinsic hippocampal population responses has been reported both in the presence and absence of S-induced field potentials in the hippocampus. We examined S-H interactions when S stimulation was aimed at 2 interactions when S stimulation was aimed at 2 sites within the S in each of 20 rats: One in which S stimulation produced a field potential in CA1, and a deeper site in which no field was evoked in CA1. Paired S and H (CA3) pulses were presented over interstimulus intervals (ISI) from 0-1.5 sec, and changes in the CA1 population spike amplitude were examined. When a population response was present in CA1 with S stimulation, facilitation was obtained at ISI's /= 100 msec, and depression at shorter ISI's. However, at Sites that produced no CA1 field potential. desites that produced no CA1 field potential, depression was common. It seems probable that sep-tohippocampal facilitation in the presence of a field response may represent activation of CA1 pression was common. via S-H input to CA3 rather than by monosynaptic S-H input to CA1. The source of the depressant effect is unknown, and deserves exploration. This work was funded in part by an R. Clifton Brooks, Jr., Fellowship and the Jeffress Trust.

RE-EVALUATION OF NEURONAL CONFIGURATIONS IN THE RAT BED

A RE-EVALUATION OF NEURONAL CONFIGURATIONS IN THE RAT BED NUCLEUS OF THE STRIA TERMINALIS (BNST). C-J. Shi, L. Roberts and M.D. Cassell. Dept. Anat., Univ. of Iowa, Iowa City, IA 52242.

Recent studies (Ju and Swanson, 1988) indicate that the rat BNST consists of at least 20 cyto-architectonically distinct subdivisions. In view of the limited amount of information available on neuron morphology in this area, we have evaluated this proposed cytoarchitectonicals. amount of information available on neuron morphology in this area, we have evaluated this proposed cytoarchitectonic division of the BNST using the section-Golgi method. The anterodorsal BNST contains mainly small, round moderately spiny neurons with those in its central core resembling the larger, multipolar type characteristic of the medial central amygdaloid nucleus. The rostral part of the anterolateral BNST (oval nucleus) contains medium-sized spiny neurons resembling those of the caudate-putamen. The caudal part of this subdivision contains larger, but more moderately spiny cells. The anteroventral BNST contains mostly medium-sized, fusiform cells, with larger, sparsely spinous cells resembling preoptic neurons, in the magnocellular division. In the principle nucleus, small neurons with densely spinous secondary dendrites predominate. The interfascicular and transverse nuclei contain medium to large-sized cells with moderately spiny dendrites. Overall, the data indicate that each subdivision of the BNST contains a characteristic, if heterogeneous, population of neurons. The teristic, if heterogeneous, population of neurons. The presence of different types of cells within specific regions of cytoarchitectonic divisions suggests that further fractionation of the BNST may be warranted. Supported by NIH Grant NS25139.

KINETICS OF RO 5-4864-INDUCED CHANGES IN LIMBIC KINETICS OF RO 5-4864-INDUCED CHANGES IN LIMBIC EVOKED POTENTIALS IN THE FREELY BEHAVING RAT. D. E. Woolley, K.-S. DAI* and H.L. Drummer. Dept. of Animal Physiol., Univ. of Calif., Davis, CA 95616.

To learn more about the mechanisms underlying

the convulsive effects of the atypical benzodiazepine Ro 5-4864, a dose (15 mg/kg i.p. in DMSO) which produced only minimal seizure activity, e.g., myoclonus, 7-30 min after administration was studied in 17 rats. Amplitude of the population studied in 17 rats. Amplitude of the population slow wave (SW) evoked in the dentate gyrus (DG) by stimulation of the prepyriform cortex (PPC) was already increased at 20 min (the first recording), with a maximum increase (80%) at the lowest intensity 2 hr after administration. With increasing stimulus intensity the percent increase was not as great (50-70%), but the increase lasted was not as great (50-708), but the increase lasted longer, e.g., through 24 hr instead of 6 hr. Thus, the maximal increase in amplitude of the PPC-evoked DG response occurred one or more hr after seizure activity. Amplitude of the population spike produced in the DG by stimulation of the dorsal perforant path was increased several-fold by 20 min or even earlier, but was back to control levels by 6 hr, and so more closely paralleled seizure activity. Because the SW did not change, Ro 5-4864 appears to have enhanced synaptic efficacy.

PHARMACOLOGICAL MECHANISMS UNDERLYING HIPPOCAMPAL RSA. D.K. Bilkey and A.J. Heynen. Dept. of Psychology, University of Otago, Dunedin, New Zealand.

Using the in vitro model of hippocampal rhythmical slow activity (RSA) developed by Bland and coworkers (1986), we have confirmed the report of McVicar and Tse (1989) that carbachol-induced RSA is rarely observed in slices from adult rats. When the GABA antagonist picrotoxin (PTX) is introduced into the bathing medium, however, carbachol (CARB) reliably produces RSA in adult slices. Furthermore, RSA could also be induced by coinfusion of glutamate (GLU) and PTX, while neither of these substances alone produced rhythmicity. In vitro RSA, therefore, requires both the excitation produced by CARB or GLU, and coincident disinhibition produced by PTX. Similar mechanisms may operate in vivo. In a test of this hypothesis we found that microinfusion of CARB into the rat dentate gyrus produces RSA. This can be blocked by inactivating the medial septum with a procaine microinfusion. The subsequent cannulation of PTX into the dentate produces a recovery of rhythmicity. Similarly, RSA can also be induced in vivo by concurrent microinfusion of GLU and PTX into a rat with a procained septum. The disinhibitory effects produced by PTX may be provided in situ by the septo-hippocampal circuit described by Bilkey and Goddard (1985). The excitation produced by GLU and CARB may model pharmacological events occurring during type 1 and type 2 RSA, respectively.

DISTRIBUTION PATTERNS OF RAT CENTRAL AMYGDALOID (Ce) EFFERENT NEURONS. M.D. Cassell, N. Sun and L. Roberts*. Dept. Anat. Univ. of Iowa, Iowa City, IA 52242.

Previous studies (Veening et al., 1984; Cassell et al., 1986) have reported that Ce neurons projecting to the dorsal vagal complex (DVC), parabrachial complex (PB) and bed nucleus of the stria terminalis (BNST) distribute in overlapping medial/lateral trends that do not correspond to the major cytoarchitectonic divisions of the Ce. In contrast, many Ce afferents (e.g., from the insular cortex), neuropeptides and histochemical markers (e.g. Timm stain) show close correspondence with these divisions. We have therefore re-evaluated the distribution of Ce efferent neurons using double injections of bisbenzimide, Fast Blue and Fluorogold into various combinations of sites in the BNST, PB and DVC. Overall the data indicate that rather than following general medial/lateral trends, the distribution patterns of Ce efferent neurons show a strong correlation with the underlying cytoarchitecture. Ce neurons projecting to BNST distribute over the lateral, lateral capsular, ventral and intermediate subdivisions with numbers of cells located in a distinct caudal part of the medial subdivision. However, cells in individual Ce subdivisions project to distinct regions of the BNST. Ce neurons projecting to the DVC present an almost exact complementary distribution in the rostral and middle parts of the medial subdivision. Ce neurons projecting to the PB are almost exclusively confined to the lateral subdivision where they are intermingled with cells projecting to the BNST. The complementary patterns of BNST and DVC neurons correspond precisely with the differential distribution patterns of insular cortical afferents, dark/light Timm's staining and enkephalin/pro-opiomelanocortin immunostaining. Supported by NIH Grant NS25139.

Input-Output Connectivity of the Sublenticular Continuum of the Basal Forebrain: Introducing the Localization of Fluorescent Axonal Tracers at both the Light and Electron Microscopic Level. L. Schmued and L. Heimer, Ctolaryngology Dept., University of Virginia Health Science Center, Charlottesville, VA 22908.

Extending horizontally beneath the lentiform nucleus lies a continuum which shares many common features including extensive internuclear connections, extensive reciprocal connections with brainstem autonomic nuclei, major inputs from ventral temporal cortical areas, and immunoreactivity to angiotensin II. This sublenticular continuum (SLC) includes the amygdala central nucleus, sublenticular substantia innominata, and lateral bed nucleus of the stria terminalis. The purpose of this study is to examine potential monosynaptic connections of the SLC. To do this, the recently introduced anterograde fluorescent tracer, Fluoro-Ruby, was injected into either allocortical sites, lateral amygdala nuclei, or the parabrachial nuclei. The retrogradely transported fluorescent tracer, Fluoro-Gold, was injected into either the nucleus of the solitary tract or parabrachial nuclei. Examination of the SLC with the fluorescent microscope reveals retrogradely labeled cells following Fluoro-Gold injection into the nucleus of the solitary tract which overlap labeled terminals resulting from Fluoro-Ruby injection into either the parabrachial nucleus or the basolateral amygdala. Only a few fibers could be found in the SLC following Fluoro-Ruby injection into fibers could be found in the SLC following Fluoro-Ruby injection into allocortical regions, in contrast to the basolateral amygdala which contained dense terminal plexi. We are presently examining the first two cases at the electron microscopic level to look for monosynaptic connections. We have been able to visualize the fluorescent axonal tracers electron microscopically by combining an antibody to Fluoro-Gold (H. Chang) with a photo conversion procedure we have recently developed for detection of Fluoro-Ruby. (Supported in part by NIH grants NS-17743 and HD07323.)

The Oncogene c-fos As An Index Of Mesostriatal And Mesocortical Dopamine System Activity R.P. Dilts, T.E. Helton and J.F. McGinty Dept. of Anatomy, ECU School of Medicine, Greenville, NC 27858

The detection of the oncogene c-fos or its protein product, Fos, has been proposed as an index of metabolic changes produced by cellular activity. Unlike previous techniques, the detection of Fos, or Fos related antigens (FRAS), occurs within the nucleus, allowing for the histochemical characterization of the identified neuron. The distribution of FRAS within the rat has been determined by immunocytochemical techniques two hours after the subcutaneous administration of apomorphine (5 mg/kg) or haloperidol (2 mg/kg). When compared to vehicle treated or niave animals apomorphine produces a patch distribution of Fras immunoreactivity (IR) within the striatum. Haloperidol treated animals display a more uniform distribution of FRAS-IR within the striatum which is accompanied by increases in FRAS-IR within the nucleus accumbens, olfactory tubercle and frontal cortex. Additionally, unilateral lesions of the A10-A8 dopamine neurons were performed using 6-hydroxydopamine (6 ug/1.5 ul) administered in the rostral A10 region. Apomorphine (5 m s.c.) produces a patch distribution on the contralateral side to the lesion and a robust increase in FRAS-IR on the ipsilateral side. Attempts are currently being made to semiquantitate these results and to histochemically identify the neurons expressing FRAS-IR within the striatum and other terminal regions of the mesolimbic dopamine system following pharmacological manipulation. Supported by DA03982.

GABA TERMINALS FORM SYMMETRIC SYNAPSES PRIMARILY WITH DOPAMINERGIC NEURONS IN THE RAT VENTRAL TEGMENTAL AREA: GABA-INPUT INVERSELY PROPORTIONAL TO THE LEVEL OF TYROSINE HYDROXYLASE IMMUNOREACTIVITY. V. E. Bayer and V. M. Pickel. Div. of Neurobiology, Dept. of Neurology & Neurosciences, Cornell Univ. Med. College, NY, NY 10021.

We examined the ultrastructural basis for GABAergic modulation of dopaminergic (DA) neurons in the rat ventral tegmental area (VTA). Single sections were labeled with rat GABA-antiserum and a rabbit antiserum against the catecholamine-synthesizing enzyme tyrosine hydroxylase (TH) using peroxidase-antiperoxidase and immunoautoradiographic markers. Of 96 GABA terminals, 66% were in contact with TH-containing cell bodies or dendrites. All junctions with recognized membrane specializations were of the symmetric type, indicative of inhibition. Some GABA-terminals provided dual inputs onto two unlabeled, two TH-labeled, or labeled and unlabeled soma and/or dendrites. Analysis of TH-labeled soma and dendrites confirmed our recent observation (Bayer and Pickel, J. Neurosci., in press) that neurons exhibit differences in levels of detectable TH immunoreactivity and that the more intensely labeled neurons receive more numerous contacts from unlabeled terminals. However, the number of contacts by GABA-labeled terminals was proportionally greater on the dendrites that contained lower levles of TH-immunoreactivity. These results suggest that in the rat VTA, synaptic input from GABAergic terminals may not only inhibit DA neurons, but may influence the level of TH needed for dopamine synthesis. (Supported by grants NIMH MH00078 and MH40342 and NIDA DA04600 to V. M. P.)

AN ULTRASTRUCTURAL STUDY OF MET-ENKEPHALIN AND BETA-ENDORPHIN IN THE RAT PARAVENTRICULAR THALAMIC NUCLEUS.

L.J. Freedman and M.D. Cassell . Neuroscience Program and Department of Anatomy, University of Iowa, Iowa City,

Immunocytochemical studies reveal that the paraventricular thalamic nucleus (PVT) contains a wide variety of peptidergic fibers. However, it is not clear whether these fibers synapse in the PVT or if they pass through, merely connecting other areas rich in peptides. To address this question, we conducted an immunocytochemical study of the rat paraventricular thalamic nucleus at the electron microscope level using antibodies to metenkephalin and beta-endorphin.

Both peptides were located primarily in the lateral part of the nucleus and were found in unmyelinated axons and terminals making synaptic contacts. Enkephalin synapses were usually symmetric, with electron dense regions on both the pre- and post-synaptic membranes, and tended to be on dendritic spines. Endorphin terminals also made symmetric contacts, but these usually did not have synaptic densities on either side, and were more frequently on dendritic shafts. The largest endorphin terminals were about twice the size of the largest enkephalin nals were about twice the size of the largest enkephalin terminals.

These results indicate that beta-endorphin and met-enkephalin are likely to play a role in the function of the PVT. For example, they may be involved in the stimulation-produced analgesia some investigators have described there (Kupers et al., 1988).

COMPARATIVE NEUROANATOMY: FISH AND AMPHIBIA

THE PRESUMPTIVE NUCLEUS PEDUNCULOPONTINUS OF THE ATLANTIC STINGRAY IS NOT PART OF THE MESENCEPHALIC LOCOMOTOR REGION. R.L. Puzdrowski and R.B. Leonard, Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77550.

The functionally defined midbrain locomotor region (MLR) in the Atlantic stingray, Dasyatis

<u>sabina</u>, shares many topological characteristics with the functionally defined MLR in mammals. Nuclei in the region of the mammalian MLR include cuneiformis and pedunculopontinus (PPN). There is debate as to which of these cell groups constitute the anatomical substrate for the functionally defined MLR. We have identified a nucleus in the rostral rhombencephalon, in close association with the cerebellar peduncle, that shares histochemical markers with the mammalian PPN. This nucleus is positive for acetylcholine esterase and more importantly NADPH-diaphorase activity (a characteristic unique to the PPN in this region of characteristic unique to the PPN in this region of the mammalian brain). The presumptive PPN in stingrays lies outside the region identified as the MLR. If additional experiments support the identification of this nucleus as the homolog of the mammalian PPN, they will also support the assertion that the PPN is not a part of the vertebrate MLR. Supported by NSO7185 and NS11255.

GNRH IMMUNOREACTIVITY IN THE BRAIN OF THE ROUND STINGRAY, UROLOPHUS HALLERI. $\underline{L.S.}$ Demski and $\underline{D.E.}$ Wright, UKY, 40506 University of Kentucky, Lexington,

KY, 40506
GnRH-immunoreactivity (ir) was studied using antisera to salmon GnRH. Beaded GnRH-ir fibers were located in the terminal nerve (TN), dorsal and midventral portions of the telencephalic hemispheres, and the septopreoptic area; more diffuse fibers were found in the optic tectum, tegmentum, and spinal cord. Many ir-cells were located in the TN ganglia. In some cases, dense-cored vesicles in the cells and their processes were labeled using EM-immunogold processes were labeled using EM-Immunogold techniques. Few perikarya were seen in the septopreoptic area, although scattered GnRH-ir fibers were present in the median eminence and hypothalamus. Over 800 GnRH-ir cells (10-20µM) were found in the midbrain extending rostrocaudally (1.5mm) along the midline near the oculomotor nerve; the nucleus diverges ventrolaterally at its most rostral level. The presence of well-developed midbrain and TN GnRH systems coupled with a seeming reduction of septopreoptic GnRH cells may be a unique feature of elasmobranchs related to the physical separation of the hypothalamus and the gonadotropin-rich ventral lobe of the pituitary.

SEROTONERGIC, ENKEPHALINERGIC, AND CATECHOL-AMINERGIC CELLS IN THE BRAIN OF A SHARK, <u>HETERODONTUS FRANCISCI</u>. S.L. Stuesse, and W.L.R. Cruce. Dept. of Neurobiology, N.E. Ohio Univ. College of Medicine, Rootstown, OH 44272.

The location of immunopositive cells within the brainstem of elasmobranchs may give us clues to phylogeny. For example, nucleus raphe describe (BED), the legest perspectage of legenty in mampage is not

elasmobranchs may give us clues to phylogeny. For example, nucleus raphe dorsalis (RaD), the largest serotonergic cell group in mammals, is not present in rays, skates, or guitarfish. We chose heterodontid sharks, a sister group to these batoids, for an out-group comparison of this and other characters. We identified cells in the brainstem of Heterodontus francisci which were immunopositive for tyrosine hydroxylase, serotonin, or leu-enkephalin and compared the distribution of these antibodies to descriptions in mammals and other elasmobranchs. The majority of descriptions in maintains and other leastmooranchs. The majority of tyrosine hydroxylase-positive cells were found in the middrain tegmentum (A9, A10) and the hypothalamus, and putative A1, A2, A5, A7 cell groups were found in the metencephalon and myelencephalon. Serotonin-positive cells were found both in midline raphe nuclei and scattered lateral to these orns were round both in minine rapin nuclei and scattered rate at to these nuclei. We identified probable homologs to raphe pallidus, obscurius, magnus, and centralis superior (B8). A small cluster of cells dorsomedial to the medial longitudinal fasciculus was a probable homolog of rat RaD. Brainstem nuclei which were positive for leu-enkephalin usually contained Brainstem nuclei which were positive for leu-enkephalin usually contained serotonin-like immunoreactivity, and the distribution for these two substances was similar. Besides the raphe nuclei, reticular groups which contained both 5-HT+ and LENK+ cells included reticularis (r.) ventralis, r. magnocellularis, r. paragigantocellularis lateralis, r. pontis caudalis, and r. pontis oralis medialis and lateralis. Thus, this shark contains many of the major brain stem raphe and catecholaminergic cell groups described for rats, but the relative distribution of the immunopositive cell groups is different. Supported by NS25895 and OBOR Research Challenge Funds.

ORGANIZATION OF THE FOREBRAIN IN EPTATRETUS STOUTI (MYXINOIDEA). H. Wicht and R.G. Northeutt, Neurobiology Unit, SIO & Dept. Neurosciences, A-001, UCSD, La Jolla, CA 92093

ept. Neurosciences, A-001, OCSD, La Jona, CA 92093 Cytoarchitectonic analysis of the forebrain of the Pacific hagfish revealed ght major regions: olfactory bulb, pallium, preoptic area, central eight major regions: prosencephalic nucleus, epithalamus, dorsal thalamus, ventral thalamus, and hypothalamus, with approximately 40 divisions and subdivisions. The pallium has a division comprising five laminae, further subdivided into seven areas, and a nonlaminated division subdivided into three areas. Histochemical analysis (AchE, 5HT, SP, Met-ENK, Leu-ENK, \propto -MSH, FMRF, and LHRH) confirmed the major regions as well as many of their divisions and subdivisions. Topography and secondary olfactory input indicate that the bulk of the laminated pallium is the homologue of the lateral pallium of other craniates. The nonlaminated pallium may be the homologue of the dorsal and/or medial pallium. The central prosencephalic nucleus is the most enigmatic cell group in the myxinoid brain. This conspicuous cytoarchitectonic formation has previously been regarded as the homologue of the medial pallium or the eminentia thalami, but its histochemical composition (high content of AchE, Leu-ENK, Met-ENK, and SP) and topography (continuity with the ventral thalamus) make this unlikely. The present data suggest that it may be homologous to the striatum or to a rostral diencephalic cell group of other craniates. Alternatively, it may be an autapomorphy of hagfishes. Supported by the DFG (Wi909/1-2) and the NIH (NS24869).

TOPOGRAPHIC ANALYSIS OF SUBPOPULATIONS OF RETINAL GANGLION CELLS IN THE FLORIDA GARFISH, LEPISOSTEUS PLATYRHINCUS. S. P. Collin and R. G. Northcutt. Dept. of Neurosciences A-001 University of California San Diego, La Jolla CA 92093 USA

The topography of the retinal ganglion cell layer of the florida garfish, Lepisosteus platyrhincus was investigated using retrograde labelling with horseradish peroxidase (HRP) and cobaltous-lysine from the optic nerve. After precipitation and intensification, three subpopulations of ganglion cells were characterised on the criteria of soma size and position, dendritic stratification and primary branching pattern. The majority of ganglion cells (95%) lie in a single sublamina and range in size between 5 and 14 µm (soma diameter). At least three further subclasses of cells could be differentiated within this group least three further subclasses of cells could be differentiated within this group but, counted collectively in wholemount, their density changes substantially throughout the retina. This was reflected by a ventral horizontal streak (9400 cells per sq mm) and a temporal area centralis (5900 cells per sq mm) with density gradients of 6:1 and 4:1, respectively. In contrast, a population of giant ganglion cells (with a soma diameter of 18-20 µm and a dendritic field diameter of up to 800µm) that lies within a closely apposed sublamina, is relatively evenly distributed (32 cells per sq mm). The garfish also possesses a distinct population of displaced ganglion cells lying at the border of the inner population of inner nuclear layers ranging in soma diameter from 5 to 9 µm. The topography of these displaced cells (3.75% of the total population) reflects that of the major population although cell densities in both the ventral horizontal streak and the temporal area centralis peak at 625 cells per sq mm

and possess a centro-peripheral gradient of 25:1.

This data provides the basis for continuing studies on the central projections of subpopulations of ganglion cells with special emphasis on ipsilateral input to the optic tectum.

Supported by the AAEF and NH&MRC (SPC) and NIH (NS24869).

GONADOTROPIN HORMONE-RELEASING HORMONE (GnRH)-IMMUNOREACTIVITY IN THE BRAINS OF PRIMITIVE BONY FISHES. D.E. Wright and L.S. Demski. School of Biological Sciences, University of Kentucky, Lexington, KY 40506.

GnRH immunoreactivity (ir) was determined in the brains of two species of brachiopterygian fishes (Polypterus sp. and Calamoichthys calabricus) using antisera to salmon and mammalian GnRH. Small ir-perikarya (<10µm) with mammalian GnRH. Small ir-perikarya (<10µm processes extending rostrocaudally were dispersed along the ventral surface of the caudal offactory bulb and rostral telencephalon. Larger, unipolar ir-cells (15-20µm) were located in the rostral midbrain immediately ventral to the ventricle in the region of the posterior tubercle. Beaded ir-fibers were most abundant in the olfactory bulbs, several areas of the the oritation being several treas of the ventral telencephalon, dorsolateral surface of the pallium, diencephalon, habenula, optic tectum, and tegmentum. Fewer ir-fibers were present in the medulla and spinal cord. Ir-fibers could be followed along the ventral surface of the telencephalon and hypothalamus into the pituitary. The largest fascicles of ir-fibers were present in the rostral telencephalon. They probably correspond to projections of the terminal nerve.

RETINOPETAL AND RETINOFUGAL PROJECTIONS IN LARVAL AND ADULT LAMPREYS: AN IN VITRO STUDY WITH HRP AND FLUORESCENT DEXTRAN-AMINES. B. Fritzsch and R. G. Northcutt. Neurobiol. Unit, SIO, and Dept. of Neurosciences, A-001, UCSD, La Jolla, CA 92093.

The retina of adult lampreys projects bilaterally to the tectum and receives a bilateral retinopetal input from cells of the tegmental midbrain. In birds, which have a comparably large efferent contingent (chickens, 0.5%; lampreys, 2%), the size of the the ipsilateral efferent projection reportedly depends on the size of the ipsilateral retinofugal projection (D. D. M. O'Leary and W. M. Cowan, <u>Dev. Brain Res.</u>, 12: 293, 1984). We studied the afferent and efferent projections of the retina in larval and postmetamorphic lampreys to obtain insights into developmental patterns leading to the adult organization. HRP or fluorescent dextranamines were applied to the cut optic nerve or needle injected in the midbrain. In vitro brains and eyes were kept up to three days in a fish filled with cold Ringer's solution before they were fixed and processed. Application of tracers to the optic nerve in larvae revealed bilateral efferents in the midbrain but a completely crossed retinofugal projection. After metamorphosis, injections into the midbrain revealed ipsilateral ganglion cells concentrated at the nasal and temporal retinal margin; this suggests that they were formed late in development. In contrast to birds, lampreys develop a bilateral retinopetal projection before a bi-lateral retinofugal projection. Moreover, retinopetal and retinofugal fibers do not interact in the chiasm. Supported by the DFG (Fr572) and the NIH (NS24869).

55.8

AN IMMUNOCYTOCHEMICAL COMPARISON OF PURKINJE CELLS AND ACOUSTICOLATERAL PYRAMIDAL (CREST) CELLS IN WEAKLY ELECTRIC GYMNOTIFORM TELEOSTS. M. J. Lannoo, L. Maler, and R. Hawkes. Prog. Neurosci., Ohio Univ. Athens, OH 45701; Dept. Anatomy, Ottawa Univ., Ottawa, Ont. K1H 8M5; Dept. Anatomy and Neuroscience Research Group., Univ. Calgary, Calgary, Alberta

Morphological and functional similarities have suggested a relationship between cerebellar Purkinje cells and acousticolateral pyramidal (crest) cells. We extend this comparison by using two monoclonal antibodies generated against the hindbrain of the weakly electric gymnotiform fish Apteronotus leptorhynchus.: i) anti-zebrin II recognizes a 36 kD protein present in Purkinje cell subsets over a range of species including birds and mammals (Brochu et al. '90 <u>JCN</u> 291: 538-552). We now report that zebrin II in gymnotiforms is also expressed transiently during development by ampullary organ-receptive, but not tuberous organ-receptive pyramidal cells. Thus, anti-zebrin II can be used to distinguish etween two types of electroreceptor inputs at the molecular level. This is the first time zebrin II has been seen in a non-Purkinje cell. ii) in contrast, anti-type I recognizes a 47 kD protein present in the adult in all Purkinje cells and all pyramidal cells (as well as in Mauthner and electric organ pacemaker neurons). This is true only in the genus Apteronotus, surprisingly Eigenmannia spp. and Sternopygus spp. are unreactive. That anti-zebrin II and anti-type I label both Purkinje and pyramidal cells supports the idea that these cells are related either through homology or common function.

NEWBORN CELLS IN THE BRAIN OF ADULT WEAKLY ELECTRIC KNIFE-FISH. <u>G.K.H. Zupanc</u>. Department of Neurosciences, University of California at San Diego, La Jolla, CA 92093.

of California at San Diego, La Jolla, CA 92093. In the central nervous system of warm-blooded vertebrates, neurogenesis is thought to take place predominantly in prenatal or early postnatal development. In the brain of weakly electric knifefish (Eigenmannia sp.), however, new cells continue to be generated extensively also during adulthood. Fish were injected with 5-bromo-2'-deoxyuridine (BrdU) which is incorporated into replicating DNA. After a survival time of 12 hrs, mitotic S-phase cells were localized by a specific monoclonal anti-BrdU antibody (Amersham).

BrdU-labelled cells were found in the periventricular zones of the following brain regions (for nomenclature, see Maler et al., <u>J. Chem. Neuroanat.</u>, in press): Subdivision 1 and 2 of the dorsomedial part of the telencephalon; ventral and dorsal subdivisions of the ventral area of the telencephalon; anterior subdivision of the nucleus preopticus periventricularis; eminentia thalami; medial subdivision of caudal dorsal posterior area of the telencephalon; central-posterior nucleus; hypothalamus ventralis; medial subdivision of the nucleus recessus lateralis; hypothalamus dorsalis; nucleus posterioris periventricularis; periventricular nucleus of posterior tuberculum; nucleus tuberis lateralis pars anterior; nucleus tuberis lateralis; nucleus of the posterior recess. Labelling with ³H-thymidine and survival periods of 2 weeks indicate that part of these newborn cells migrate away from their sites of origin to other areas in the brain.

FREEZE-FRACTURE STUDY OF THE TELEOST MENUNCES. H.J. Caruncho & R. Anadón. (SPON: European Neuroscience Association). Dept. Fundamental Biology; 15706—Santiago de Compostela (Spain).

15706-Santiago de Compostela (Spain).

The structure of the meninges of lower vertebrates differs considerably from that of mammals. Because there are only a few works about the fish meninges, we have studied the ultrastructure of the meninges of the rainbow trout hypothalamus using the freeze-fracture technique.

Four layers can be differentiated in the meninges at this level. Blood vessels are found only in the outermost and the innermost layers. Vessels are non-fenestrated and characteristically have abundant caveolae (20-40 nm in size) in the endothelial cell surface.

ze) in the endothelial cell surface.

The meningeal cells of the outermost layer (layer 1) do not present intercellular junctions between their processes. In layer 2, the outermost cells are flattened and have intermediate to strong tight junctions (according to the classification of Claude, P. and Goodenough, D.A., J. Cell Biol., 58:390, 1973) between their lateral processes. The inner cells of this layer and the cells of the layer 4 have weakly tight junctions (1-3 opened particle strands) that are generally associated with small gap junctions. The layer 3 has five type of cells, none of which have intercellular junctions.

In conclusion, the teleost meninges are well developed and differentiated into four layers; one of them (layer 2) resembles the barrier layer of mammals, although in fish the subarachnoid space is absent.

DISTRIBUTION OF TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN THE SALAMANDER OLFACTORY BULB. <u>K.A.</u>
<u>Hamilton</u>. Cellular Biology and Anatomy, LSU
Medical Center, Shreveport, LA 71130.

In the salamander olfactory bulb, cells in
several synaptic laminae appear to contain GABA

In the salamander olfactory bulb, cells in several synaptic laminae appear to contain GABA and/or dopamine and may inhibit mitral/tufted output cells in response to odor stimulation (see K.A. Hamilton and J.S. Kauer, J. Neurophysiol., 62: 609, 1989). In the present study, the distribution of catecholaminergic cells was further investigated using immunocytochemical methods.

Tyrosine hydroxylase immunoreactivity was

Tyrosine hydroxylase immunoreactivity was observed in a population of granule-layer cells. Smooth dendrites extended from the cell bodies and gave rise to numerous spiny branches in the external plexiform layer and periglomerular region. As in fish, but not mammals, periglomerular cell bodies were unstained (see J.R. Alonso et al., Brain Behav. Evol., 34: 318, 1989). Additional antisera are presently being used to determine which TH-immunoreactive cells in the salamander bulb might contain dopamine.

Supported by NIH Grants DC00300 (K.A.H.) and NS20003 (J.S. Kauer, Tufts-NEMC, Boston, MA).

ONTOGENY OF SEXUAL POLYMORPHISMS IN MONOAMINERGIC INPUTS TO THE SOUND-GENERATING MOTOR SYSTEM OF A VOCALIZING FISH. M. Marchaterre, H. Baker, and A. Bass. Section of Neurobiol. & Behavior, Cornell Univ., Ithaca, N.Y. 14853, Lab. Molecular Neurobiology, Cornell Univ. Medical College, White Plains, N.Y. 10605:

In the plainfin midshipman (Porichthys notatus), large, nest-guarding males ("Type I") generate long duration (up to 1 hr) acoustic communication signals called "hums" during the breeding season. Sonic activity has <u>not</u> been observed in females or a second group of smaller reproductively active males ("Type II"). The sound's fundamental frequency is determined by the synchronous firing of sonic motoneurons whose rhythmic, oscillatory-like discharge is established by nearby pacemaker neurons. Electron microscopic studies indicated the presence of dense core vesicles in synaptic terminals within the sonic motor nucleus (SMN) and thus suggested the presence of monoaminergic inputs. Neurochemical studies were thus initiated to evaluate the ontogeny of possible sexual dimorphisms in the position and extent of serotonin (5HT)- and tyrosine hydroxylase (TH; indicative of catecholamines)-like immunoreactivity (IR) in and around the SMN. Only the adult, vocalizing Type I males were consistent in having a high density of 5HTand TH-IR fibers within the SMN. The onset of high levels of 5HT- and TH-IR was correlated with gonadal hypertrophy in males as revealed in studies of nonreproductive juveniles. 5HT-and TH- IR cells were outside the SMN and did not correspond to pacemaker neuron position. Thus, it is unlikely that monoamines are excitatory transmitters of the pacemaker system. However, given the documented effects of monoamines on other motor systems, including their oscillatory properties, we propose that monoaminergic inputs modulate and/or sustain levels of sonic motoneuron activity in vocalizing Type I males and thus contribute to their ability to generate hums. Supported by NSF and NIH,

WHY ARE NEUROFILAMENTS PRESENT IN FROG OLFACTORY AXONS BUT NOT IN THOSE OF THE TIGER SALAMANDER? M.A. Wentz* and P.R Burton. Dept. of Physiology and Cell Biology, University of Kansas, Lawrence, KS 66045.

EM studies show that olfactory axons of the tiger salamander, Ambystoma tigrinum, rarely contain neurofilaments (NFs), whereas those of the bullfrog, Rana catesbeiana, contain many NFs. Other axons of the salamander nervous system show typical NFs. Using monoclonal antibodies, comparative immunoblot studies of NF proteins were carried out in SDS/PAGE preparations of olfactory nerve and spinal cord extracts of the two species. The studies indicate that the nominal Mr of the presumed high (H), medium (M), and low (L) NF proteins from Ambystoma spinal cord are 230, 160, and 77 kD, respectively, and the equivalent proteins from Rana are 207, 160, and 110 kD. Salamander olfactory axons, which lack NFs, primarily contain the M subunit protein with only trace amounts of the H and L subunits. However, olfactory axons of the frog contain all three subunit proteins. Diameter measurements of salamander and frog olfactory axons show that the former are, on average, larger than those of the frog by about 30%. These studies indicate: 1) epitopic heterogeneity among NF proteins in the amphibian nervous system, 2) that the absence of NFs in Ambystoma olfactory axons may be due to the relative lack of two of the NF subunit proteins, and 3) that the structural and dimensional integrity of these axons are not dependent on assembled NFs. Supported by NIH grant NS25518 and a grant from the K.U. General Research Fund.

VOMERONASAL SYSTEMS DURING AQUATIC PHASES IN SALAMANDERS WITH DIFFERING LIFE-HISTORIES. <u>H.L. Eisthen, D.R. Sengelaub, and J.R. Alberts*.</u>
Program in Neural Science, Indiana University, Bloomington, IN 47405.

The axoloti (Ambystoma mexicanum) is a neotenic salamander that remains aquatic throughout its life. The axoloti's nasal cavity contains separate populations of sensory receptors along the medial wall and in a lateral diverticulum, corresponding to the loci of the olfactory and vomeronasal receptors in terrestrial salamanders. The medially-located receptors project to the main olfactory bulb, and the those in the lateral diverticulum project to an accessory olfactory bulb (AOB), indicating that axolotis possess both an olfactory and a vomeronasal system (VNS). These data contradict Bertmar's (1981) hypothesis that the VNS evolved as an adaptation to terrestrial life.

(1981) hypothesis that the VNS evolved as an adaptation to terrestrial life. We have examined the nasal cavities of both adult and larval tiger salamanders (A, tigrinum), a transforming species from which axolotis are thought to have evolved. The nasal cavities of both larvae and adults possess a lateral diverticulum containing sensory receptors, and the forebrains appear to contain AOBs. Similarly, we have found a receptor-lined lateral diverticulum and AOB in the larva of another ambystomid, the Jefferson's salamander (A, leftersonianum). These findings suggest that the VNS of the adult axoloti is a characteristic of larval ambystomids. We have also examined adults of a secondarily-aquatic species, the Eastern red-spotted newt (Notophthalmus viridescens), and have found similar evidence of a VNS. Our work in progress with the neotenic, aquatic mudpuppy (Necturus maculosis) indicates that this species possesses a lateral diverticulum but not an identifiable AOB.

Because the VNS is present during the aquatic phases of the life cycle in salamanders with diverse life histories, our data suggest that the VNS did not evolve as a terrestrial adaptation.

THE OLFACTORETINALIS SYSTEM DOES NOT CORRESPOND TO THE "TERMINAL NERVE" AS ASCRIBED TO F.FINKUS.T.Szabo,J.-P.
Denizot*,S.Blähser*,M.Véron-Ravaille*,D.Rouilly*,Dept.Neurophysiol.Sens.,Lab.Physiol.Nerveuse C.N.R.S.,F-Gif/Yvette Cedex.-Anatomie und Zytobiologie d.Universität,6300 Giessen GFR.

The olfactoretinalis system (ORS) is widely considered to be the terminal nerve. However, the characteristics of the "terminal nerve" as described by F. Pinkus (1894), are quite different from those of the ORS. "Rising as a fine unmyelinated nerve from the diencephalic brain level, the terminal nerve from the diencephalic brain level, the diencephalic b minal nerve courses cranialwards on the ventral brain surface with the olfactory nerve. Beyond the olfactory epithelium, it disappears in a cell group on the dorsal wall of the anterior nares".

We could demonstrate immunohistochemically a similar structure in several species of gymnotiform fish (Szabo et al.,1989). In Eigenmannia a substance P containing fiber bundle accompanies the olfactory nerve. It originates in a group of ganglion cells located between the olfactory epi-thelium and the nares. Centrally it penetrates into the ol-factory bulb (OB) and forms a glomerular terminal area at the mediocaudal pole of the OB.Peripheral, the ganglion cells seem to project to a particular structure in the epithelial wall of the nares.

Since in the same fish a distinct ORS could be demonstrated at the OB border with anti FMRF-amide antiserum, the described structure should be considered as the terminal nerve.

CONNECTIONS BETWEEN LIMBIC AND NEUROENDOCRINE NUCLEI IN Texas, Austin, TX, 78712.

The preoptic area and ventral hypothalamus act as a bi-

partite control system for pituitary and gonadal hormone secretion. In addition, these areas are important in the control of reproductive behavior. We previously examined auditory inputs to each of these areas (Allison and Wilczynski, Soc. Neurosci. Abst. <u>13</u>:869, 1987; <u>15</u>:374, 1989) In this study we examined connections between telencephalic limbic areas and these neuroendocrine control centers. HRP was iontophoretically injected into either the medial pallium (MP), medial and lateral septal nuclei (MS, LS), preoptic area (POA), or ventral hypothalamus (VH) of adult green treefrogs. After a 7-day survival time, the animals were sacrificed under anesthesia and the brains extracted, fixed, cut at 40u, mounted, and reacted with standard techniques using TMB as the chromagen. The heaviest con-nection noted was a bilateral, reciprocal connection between the POA and the MS and LS. The POA is also recipro-cally connected to the MP and VH. In contrast, the VH re-ceives a light projection from the dorsal MP and the ventral portion of the LS. Each of the projections to the VH were minor in comparison to the projections to the POA. Finally, a projection from the ventromedial portion of the MP to the MS was noted. (Supported by NIMH grant RO1 MH45350)

ORGANIZATION OF BRAIN STEM RETICULAR NUCLEI IN AN AMPHIBIAN, THE NORTHERN LEOPARD FROG, RANA PIPIENS. W.L.R. Cruce and D.S.H. Adli. Neurobiology Department, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272 and Zoology Department, University of Malaya, 59100 Kuala Lumpur, MALAYSIA.

Based on classical neuroanatomical methods only a small number

Based on classical neuroanatomical methods only a small number of distinct subdivisions have been recognized in the reticular formation of frogs. Some of these subdivisions (Potter, J.Neurophys., 1965) have been useful for neurophysiological studies yet the subdivisions have no obvious homologies in other vertebrate brains. We used immunohistochemistry and tract-tracing techniques in combination with cyto- and dendro- architectonics to study reticular nuclei in Rana pipiens. We subdivided the reticular formation based on descriptions of mammalian reticular nuclei (Newman's nomenclature for rat, J.Hirnforschung, 1985). The features used for characterization were neurochemical localization (enkephalin, substance P, somatostatin and serotonin), cell morphology (dendritic arborization, soma shape, soma size, and soma orientation), and descending connections to the spinal cord. In the rhombencephalon we found reticular is (r.) dorsalis, r. vervocellularis, r. paryocellularis, r. paryocellularis, r. paryocellularis, r. paryocellularis, r. ventralis pars alpha and pars beta, r. magnocellularis, r. parvocellularis, r. gigantocellularis, r. paragigantocellularis lateralis, r. paragigantocellularis gigantocellularis, r. paragigantocellularis lateralis, r. paragigantocellularis dorsalis, r. pontis caudalis pars alpha and pars beta, nucleus visceralis secundarius/Kolliker-Fuse complex, raphe obscurus, raphe pallidus, raphe magnus and raphe pontis. In the mesencephalon we found locus coeruleus-subcoeruleus complex, r. pontis oralis pars medialis and pars lateralis, r. pedunculopontinus, r. cuneiformis, r. subcuneiformis, raphe dorsalis-raphe centralis superior, and raphe linearis. This study supports the hypothesis that the reticular formation is a phylogenetically old and conservative part of the brain. Supported in part by N.I.H. grant NS25895 and Ohio Board of Regents Research Challenge funds.

SEPTAL AREA CONNECTIONS IN RANID FROGS. T.J. Neary and R.G. Northcutt. Anatomy Division, Creighton Univ., Omaha, NE 68178 and SIO Neurobiology Unit/UCSD Department of Neurosciences, La Jolla, CA 92093.

The connections of the septal area were studied in bullfrogs, R. catesbeiana, following applications of either HRP or WGA-HRP. Most structures connecting with the septal area were labelled bilaterally, but a few, indiseptal area were labelled bliaterally, but a rew, indi-cated (I), were consistently labelled only ipsilaterally. Labelled cells were found in the main olfactory bulb (MOB)(I), the lateral (I), dorsal (I), and medial pallial fields, the olfactory tubercle/diagonal band nucleus, and the medial and lateral amygdalar nuclei; anterior (ATh) and central (CTh)(I) thalamic nuclei, ventromedial and central (CIn)(1) thatamic nuclei, ventromedial thatamic nucleus (YM), anterior preoptic area (POa), magnocellular preoptic nucleus (Mg), suprachiasmatic nucleus (SCh), ventral hypothalamic nucleus (YH), and posterior tuberculum (TP); nucleus of the MLF (NMLF), and principal toral nucleus (I); isthmal raphe, lateral isthmal reticular formation, and secondary isthmal nucleus Labelled fibers/terminals were found in the MOB and accessory olfactory bulb (I), the medial, dorsal and lateral pallia (all I), and contralateral septal area; ventral habenula (I), ATh, CTh, VM, POa, Mg, SCh, VH, TP, and NMLF; the pretectal and pretoral grey, deep tectal layers, toral laminar nucleus, and periventricular tegmentum.

EXPERIMENTAL EVIDENCE THAT AMPULLARY ORGANS OF SALAMANDERS DERIVE FROM PLACODAL MATERIAL. R.G.Northcutt, B.Fritzsch, and K.Brändle. Neurobiol. Unit, SIO, and Dept. of Neurosciences, A-001, UCSD, La Jolla, CA 92093 and J.W.Goethe-Univ., Frankfurt, FRG.

To test the hypothesis that neuromasts and ampullary organs

develop from the same placode (Northcutt, Soc.Neurosci.Abstr., 12:103,'86), we extirpated or transplanted supraorbital placodes in wild or albino axolotl embryos between stages 26 and 35. Orthotopic or ectopic (i.e. belly) transplants from wild (pigmented) embryos onto albino embryos allowed us to follow development by using a natural marker. After appropriate survival times, the animals were fixed, and the skin was removed, flat mounted on slides and counterstained. Extirpation of the supraorbital placode resulted in marked reduction or loss of both ampullary and code resulted in marked reduction or loss of both ampullary and neuromast organs. Both ectopic and orthotopic transplanted pigmented placodes differentiate into ampullary and neuromast organs in the unpigmented albino hosts. Our data suggest early commitment (at least 10 stages before ampullary organs can be recognized morphologically) and autonomous differentiation of ampullary progenitors. They also suggest that the progenitors of ampullary and neuromasts organs are interspersed within a placed. It applies there in a product the control of the progenitors of the control of the contr code. In axolotis there is no evidence that ampullary organs arise from embryonic sources other than dorsolateral placodes. (Supported by grants from the NIH and DFG.)

REPEATED INTRACEREBRAL MICRODIALYSIS FOR THE MEASUREMENT OF STIMULATED DOPAMINE RELEASE. Dianne M. Camp and Terry E. Robinson. Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48109

We previously reported that with repeated intracerebral microdialysis the <u>basal</u> extracellular (EC) concentration of dopamine (DA) remains stable over two probe insertions separated by two weeks (Camp et al. Soc. Neurosci. Abst. 15, 1989, 559). This suggests that the basal EC concentration of DA is not sensitive to the tissue damage produced by multiple probe insertions. Whether or not the increase in EC DA produced by d-amphetamine (AMPH) is the increase in EC DA produced by d-amphetamine (AMPH) is similarly unaffected by tissue damage produced by repeated probe insertions was addressed in this experiment.

Microdialysis in freely moving male rats was performed twice on the same animals, separated by one week. The effect of AMPH (2.0 mg/kg) on EC DA was greatly attenuated following the second probe insertion, regardless of whether animals received AMPH or saline during the first probe insertion. As reported previously, the basal EC concentration of DA did not differ between the two insertions.

It is suggested that it may not be feasible to use a within-subjects

design using multiple probe insertions to characterize the dopaminergic response to repeated AMPH treatment. However, repeated microdialysis has been used to study the effects of repeated cocaine administration on EC DA, and therefore, this may not be the case for other drugs. Experiments are currently in progress to address whether the effects observed are unique to AMPH.

56.3

PERSISTENT EFFECTS OF NEUROTOXIC DOSES OF METHAMPHETAMINE ON THE EXTRACELLULAR CONCENTRATION OF DOPAMINE IN THE NUCLEUS ACCUMBENS AND NEOSTRIATUM. S.T. Ferrell, D.M. Camp. and T.E. Robinson. Dept. of Psychology and Neuroscience Program, University of Michigan, Ann Arbor, MI 48109. Repeated exposure to high doses of methamphetamine (MA) is toxic

to dopamine (DA) neurons, producing a large, long-lasting depletion of striatal DA in postmortem tissue due to the degeneration of DA terminals. In contrast, MA does not significantly reduce the resting extracellular concentration of DA in the striatum, and MA-pretreated rats are able to greatly increase the extracellular concentration of DA in response to a d-amphetamine (AMPH) challenge [Robinson et al. Neurosci. Lett., 1990: 110, 193]. This normalization of extracellular DA may be responsible for the absence of pronounced behavioral deficits in animals depleted of DA by MA. However, behavioral abnormalities were observed in MA treated animals in response to an AMPH observed. AMPH challenge. Relative to controls, MA treated rats were hypersensitive to the locomotor-activating effects of an amphetamine challenge. We hypothesized that this accentuated behavioral response challenge. We hypothesized that this accentuated behavioral response may be due to sensitized DA release in the nucleus accumbens, which is less depleted of DA by neurotoxic doses of MA. To test this hypothesis, in vivo microdialysis will be used to measure the extracellular concentration of DA simultaneously in the nucleus accumbens and the neostriatum of freely moving rats pretreated with either saline or neurotoxic doses of MA, before and after an amphetamine challenge. The experiment is in progress and the results will be presented at the meeting.

56.5

THE STIMULUS PROPERTIES OF AMPHETAMINE GENERALIZE TO INJECTIONS OF MORPHINE INTO THE VENTRAL ITSEMENTAL AREA BUT NOT THE NUCLEUS ACCUMBENS J.P. Druhan and J. Stewart. Center for Studies in Behavioral Neurobiology. Concordia University, Montreal, Quebec, Canada, H3G 1M8.

The present study investigated whether injections of morphine into either the ventral tegmental area (VTA) or the nucleus accumbens (NAS) could produce discriminative stimuli similar to those of the psychomotor stimulant, amphetamine (AMPH). Rats were trained to discriminate 1.0 mg/kg AMPH from saline using a two-lever successive discrimination procedure with food pellets available on a VI-30 sec schedule. Generalization tests then were conducted during 5 min extinction sessions. When tested with a range of AMPH dose (saline, 0.25, 0.5 and 1.0 mg/kg, jp) the rats showed graded increases in drug-lever responding (20 to 80%) with increases in the AMPH dose. Increases in AMPH-lever responding also were observed following subcutaneous injections of the dopamine receptor agonist apomorphine (0.10, 0.15, 0.20, 0.25 mg/kg), although the response levels reached a maximum of only 57% responses on the AMPH-lever. Bilateral injections of morphine sulphate into the VTA (2.5, 5.0 and 10.0 ug/0.5 ul/side) produced increases in AMPH-lever responding to the same extent as apomorphine (39 - 54%). In contrast, these doses of morphine had no effects on AMPH-lever responding when they were injected into the NAS, although bilateral injections of amphetamine sulphate into the NAS (2.5, 5.0 and 10.0 ug/0.5 ul/side) did increase responding on the AMPH-lever (42 - 56%). These results suggest that activation of opiate receptors within the VTA can produce subjective effects similar to those produced by systemic injections of AMPH. Given the apparent role of meso-accumbens dopamine neurons in mediating the stimulus properties of AMPH-like stimuli produced by intra-VTA morphine.

CIRCADIAN CHANGES IN BEHAVIOR AND EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS DURING AMPHETAMINE WITHDRAWAL. Pamela E. Paulson and Terry E. Robinson. Department of Psychology and Neuroscience Program, The University of Michigan, 1103 East. Huron Street, Ann Arbor, MI 48109.

Rats show a significant decrease in nocturnal locomotor activity during withdrawal from amphetamine (AMPH). This nocturnal hypoactivity (behavioral depression) persists for 1-2 weeks following the discontinuation of pretreatment with escalating, but non-neurotoxic, the discontinuation of pretreatment with escalating, but non-neurotoxic, doses of AMPH, and is accompanied by changes in the postmortem tissue concentrations of dopamine (DA) and norepinephrine. It has been suggested that post-AMPH withdrawal behavioral depression may be related to the "distress syndrome" seen in humans during AMPH withdrawal, which is associated with symptoms of depression, dysphoria and changes in catecholamine function. The present experiment was designed to further characterize the behavioral and neurochemical consequences of AMPH withdrawal in rats. To do this, the extracellular concentrations of DA and its metabolises in the nucleus the extracellular concentrations of DA and its metabolites in the nucleus accumbens will be continuously monitored over 20 minute intervals across the day-night cycle in AMPH-pretreated and control rats at different points in time following the discontinuation of AMPH pretreatment, using a fully automated microdialysis system. At the same time, locomotor activity, feeding patterns and body temperature rhythms will be quantified. This experiment is in progress and the results will be presented at the meeting.

56.4

TROGEN AND STRIATAL DOPAMINE MICRODIALYSIS STUDY. <u>S. A. Castner and</u> RELEASE: **ESTROGEN**

A MICRODIALYSIS STUDY. S. A. Castner and J. B. Becker. Department of Psychology, Neuroscience Laboratory Building, The University of Michigan, Ann Arbor, Michigan 48104-1687.

There are sex-related and estrous cycle-dependent differences in amphetamine (AMPH)-stimulated behaviors and striatal dopamine (DA) release. Intact female rats exhibit a greater behavioral response to AMPH than do males. In addition, following ovariectomy (OVX) AMPH-induced behavior is attenuated, as is the striatal DA response to AMPH in vitro. Estrogen treatment reinstates both responses to that of intact females when given to OVX female rats (Behav. Brain Res. 19:27, 1986). The present study was designed to determine if there are sex differences in the effect of estrogen on the striatal DA response to AMPH in adult rats as assessed using microdialysis in freely moving rats.

Male and female rats were castrated (CAST) or OVX for at least 1 month

microdialysis in freely moving rats.

Male and female rats were castrated (CAST) or OVX for at least 1 month prior to the experiment. Dialysis probes were inserted through chronic guide cannulae aimed at the striatum. On the day of dialysis, 12 to 18 hours after dialysis probe insertion, striatal dialysate samples were collected at 15 min. intervals. After baseline DA release was determined, animals received either estradiol benzoate (5 µg) or oil; 30 min later they received AMPH. DA concentrations were assayed by high performance liquid chromatography with electrochemical detection. Following AMPH administration, behavior was videotaped, and stereotypy ratings were scored from the tapes (stereotyped head/forelimb and sniffing were each rated from 0-4 at 5 min intervals). Preliminary results suggest that estrogen treatment potentiates striatal DA release. Additional results will be presented at the meeting.

DYSKINETIC EFFECTS OF HALOPERIDOL ON AGED AND 6-HDA LESIONED RATS. S.K. Johnson, J.Lee*, H. Fisher* and G.C. Wagner. Depts. of Psychology Nutritional Sciences, Rutgers University, New Brunswick, N.J. 08903

Neurochemical and behavioral effects following a high dose (25 mg/kg) haloperidol treatment were compared in young and aged male rats as well as in rats previously treated with a 6-HDA lesion of the striatum. Rats were administered 2 injections of haloperidol 3 weeks apart and observed for 14 weeks. Aged rats as well as the 6-HDAtreated rats exhibited 10-40% depletions of striatal dopamine relative to controls. In addition, both aged and 6-HDA lesioned rats showed increases in chewing behavior as early as 3 days after the first injection. Drug challenge revealed that aged and 6-HDA lesioned rats showed an increased sensitivity to apomorphine-induced chewing. Finally, both aged and 6-HDA lesioned rats showed a long-lasting haloperidol-induced increase in dopamine. Increasing age is the most powerful predictor of tardive dyskinesia. The present studies suggest that both a dopamine receptor proliferation and a haloperidol-induced elevation in central dopamine may be acting to increase dyskinetic behaviors.

EFFECTS OF METHAMPHETAMINE-INDUCED DOPAMINE LESIONS ON RAT FORCE LEVER PERFORMANCE. G.C. Wagner, G. Woertwein*, and M. Forman*. Psychology Dept. Rutgers Univ. New Brunswick, NJ

Two groups of water deprived, adult, male Long-Evans rats were trained to press a recessed lever with between 10 and 15 g of force for a duration of 1.0 sec in order to procure a water reinforcer. Responses of less than 10 or greater than 15 g of force reset the duration timer. One group of rats (n = 6) had previously been treated with 12.5 mg/kg of methamphetamine administered SC once every 2 h for four injections while the second group (n = 5) received comparable injections of saline.

It was observed that the methamphetamine caused a 34% depletion of striatal dopamine lasting one year. In addition, both groups acquired the force lever response at approximately the same rate. Under baseline conditions, an average of 10.6 or 4.0 force band entrances per reinforcer were made by lesioned or control rats, respectively. Furthermore, lesioned rats were significantly more sensitive to challenge with IP oxotremorine (0.1, 0.2, 0.4 mg/kg, 20 min presession) than controls. These observations are discussed in reference to parkinsonian tremor.

56.9

A68930 AND L-DOPA RAPIDLY DIMINISH THE ROTATION RESPONSE TO D1 AGONISTS IN 6-OHDA LESIONED RATS. P. Curzon, J.W. Kebabian and D.R. Britton. Neuroscience Res., 47U, Pharmaceutical Discovery, Abbott Laboratories, Abbott Park, IL 60064.

Degeneration of dopamine neurons results in the development of supersensitivity of dopamine receptors in both Parkinson's disease and in the animal model using unilateral 6-OHDA lesions of the inigro-striatal pathway (Ungerstedt, 1971). We have investigated the effects of sub-chronic treatment of unilaterally lesioned rats with either 1-dopa (+ carbidopa) or with the selective D1 antagonist, A68930. L-dopa (509 umol/Kg, po) produced continued rotation over 4 consecutive days of treatment. Rats treated with 1-dopa for 3 days followed by either SKF-38393 or A68930 on day 4 showed a decrease in responsiveness to the D1 agonist. When animals were treated with A68930 (1.0 umol/Kg, sc) on day 1 there treated with A68930 (1.0 umol/Kg, sc) on day 1 there was a robust rotation response which was virtually eliminated on the 3rd day of such treatment. Dose response challenges on day 4 following 3 days of treatment with 1.0 umol/Kg substantiated the conclusion of a rightward shift in responsiveness to D1 agonists. Locomotor responsiveness of intact animals to similar doses of A68930 showed no change over 5 days of treatment. These data suggest that both 1-dopa and A68930 reduce the supersensitivity of the denervated D1 receptor mediating rotation.

56.11

IN VIVO VOLTAMMETRY IN FREELY MOVING RATS: EFFECTS OF DOPAMINE AGONISTS AND NEUROLEPTICS ON NEOSTRIATAL ASCORBATE AND BEHAVIOR. R.C. Pierce, S. E. Yount, D.B. Reising*, D.W. Miller*, S.L. Hammes*, S. Davis*, and G.V. Rebec. Prog. Neural Sci., Dept. Psychol., Indiana Univ., Bloomington, IN 47405. Electrochemically modified carbon-fiber electrodes were used to assess the role of dopamine (DA) agonists on ascorbate (AA) release in the neostriatum of awake, behaving rats. Relative to controls, indirect aconists (2,5 mg/kg. damphetamine or 20,0 mg/kg. GBR.

indirect agonists (2.5 mg/kg d-amphetamine or 20.0 mg/kg GBR-12909) produced marked behavioral activation concomitant with a significant increase in AA. Comparable effects were observed significant increase in AA. Comparable effects were observed following the combined administration of selective D1 (10.0 mg/kg SKF-38393) and D2 (2.0 mg/kg quinpirole) agonists, but not after either of these drugs alone. Thus, behavioral activation and AA release were closely related to stimulation of both D1 and D2 DA release were closely related to stimulation of both D1 and D2 DA receptors. The amphetamine-induced rise in AA was studied further in separate animals treated with various known or putative neuroleptics, including 1.0 mg/kg haloperidol (D2>D1 antagonist and sigma antagonist), 2.0 mg/kg SCH-23390 (D1 antagonist), 30.0 mg/kg (±)sulpiride (D2 antagonist), 20.0 mg/kg clozapine (atypical neuroleptic), 10.0 mg/kg BMY-14802 (sigma antagonist), and 4.0 mg/kg MK-801 (NMDA antagonist). All antagonist treatments attenuated various components of the amphetamine behavioral response and rapidly lowered neostriatal AA amphetamine behavioral response and rapidly lowered neostriatal AA to baseline levels, suggesting that neostriatal AA release is linked to behavioral activation.

THE EFFECTS OF METHAMPHETAMINE-INDUCED NEUROTOXICITY ON MOTOR PERFORMANCE IN THE RAT. Walsh S.L. and Wagner G.C. Psychology Dept., Rutgers University, New Brunswick, NJ 08903.

Methamphetamine (MA) is a potent neurotoxin which produces degeneration of both dopaminergic and serotonergic fibers in non-human primates and rodents. The following studies were designed to evaluate the effect of high dose administration of MA on motor performance in the rat.

primates and rodents. The following studies were designed to evaluate the effect of high dose administration of MA on motor performance in the rat.

Long-Evans male rats were trained on either a one-way active avoidance task, the rotorod task or to traverse the balance beam. When the subjects had reached a criterion, they were treated subcutaneously with either saline or MA at 12.5 mg/kg (4 injections with 2 hours between each). Following one week of recovery, the subjects were returned to the task. In the active avoidance task, the MA-treated subjects took significantly longer to respond to the conditioned stimulus in comparison to the controls. This deficit was observed for up to 8 weeks following recovery. No impairments were observed on the rotorod task. However, the MA-treated subjects were significantly impaired on the balance beam for up to 5 weeks post-recovery. The MA-treated subjects made over twice as many footslips on the beam as their control counterparts and this effect was reversible through the administration of I-dopa (100 mg/kg) 30 minutes prior to the test session. Additionally, the MA-treated subjects were significantly less sensitive to the effects of fenfluramine on active avoidance performance and rotorod performance than the controls. The MA treatment produced a significant decrease in the striatal content of both dopamine (47%) and serotonin (39%) in comparison to control subjects.

These results indicate that methamphetamine administration in high doses produces long-lasting impairments in motor performance in the rat including impairments in response time and balance. These deficits may be, in part, attributable to the reduction of dopamine levels resulting from this treatment.

D1 RECEPTORS IN THE MPOA FACILITATE COPULATION AND EX COPULA ERECTIONS. E. M. Hull, R. C. Eaton, V. P. Markowski, L. A. Lumley, J. T. Thompson, and J. Moses. Department of Psychology, SUNY at Buffalo, Amherst, NY 14260.

We have reported that stimulation of D1 and D2 receptors with apomorphine in the medial preoptic area (MPOA) of male rats enhanced copulation and genital reflexes. Blocking D1 and D2 receptors with cis-flupenthixol impaired copulation and reflexes. Recently we reported that the D2 agonist quinelorane (LY-163502) in the MPOA delayed the onset of copulation, but then facilitated ejaculation. Furthermore, D2 stimulation decreased ex copula erections and increased seminal emissions. We suggested that D2 receptors in the MPOA shift the balance of autonomic influence to favor sympathetically mediated seminal emission at the expense of parasympathetically (and somatically) mediated erection.

We now report that the thienopyridine D1 agonist 4-(3',4'-dihydroxyphenyl)-1,2,3,4-tetrahydrothieno[2,3-c]-pyridine (THP), in the MPOA, increased ejaculations in copula and increased erections in restrained supine male rats. Finally, the D1 antagonist SCH-23390 decreased erections ex copula and increased seminal emissions.

These data are consistent with our hypothesis (Hull et al., JPET, 1989) that the ratio of D1 to D2 stimulation in the MPOA regulates the balance of autonomic influence on genital reflexes. Specifically, D1 receptors appear to enhance erectile mechanisms and inhibit seminal emission, whereas D2 receptors enhance seminal emission and inhibit erection.

Supported by NIMH grant MH-40826 to EMH. The D1 agonist was kindly donated by Dr. David E. Nichols, Purdue Univ.

ACUTE AND LONG-TERM AMPHETAMINE TREATMENTS ALTER EXTRACELLULAR ASCORBATE IN NEOSTRIATUM BUT NOT NUCLEUS ACCUMBENS OF FREELY MOVING RATS. G.V. Rebec. S.E. Yount. and P.E. Langley. Prog. Neural Science, Dept. Psychol., Indiana Univ., Bloomington, IN 47405.

Amphetamine elicits a characteristic series of behaviors,

including locomotion and, with increasing dose, a period of focused stereotypy. Although dopaminergic input to both neostriatum and nucleus accumbens has been implicated in these behavioral changes, ample evidence suggests that ascorbate (AA), which is found in high concentrations in both regions, may play a modulatory role (White et al., Psychopharmacology, 1988, 94:284). Preliminary data from the neostriatum of freely moving rats indicate that amphetamine produces a dose-dependent elevation in AA that increases in animals produces a cose-dependent elevation in AA thicreases in animals treated for seven consecutive days, paralleling a progressive augmentation of behavior (Rebec et al., Soc. Neurosci. Abstr., 1989, 15:558). The present study extended this research to the nucleus accumbens. Electrochemically modified carbon-fiber electrodes were positioned in this site, and the voltammetric wave for AA was monitored following acute or long-term amphetamine treatment. Neither 1.0 nor 5.0 mg/kg d-amphetamine altered AA release in nucleus accumbens even when the treatment was continued for up to two weeks. These results suggest that amphetamine-induced AA release may be site-specific and that extracellular AA in neostriatum and nucleus accumbens is regulated by different mechanisms.

Supported by NSF BNS 87-11240.

DOPAMINE- AND SIGMA-RECEPTOR ANTAGONISTS IMPAIR REACTION-TIME CONDITIONED AVOIDANCE RESPONDING IN RATS.

Rebec. Prog. Neural Science, Dept. Psychol., Indiana Univ.,

Bloomington, IN 47405.

Haloperidol and other neuroleptics impair performance on conditioned-avoidance-response (CAR) tasks in rats at doses that parallel their clinical potency. In the present study, we used a version of this task--the rapid, conditioned-forepaw-withdrawal response--to compare haloperidol, a D2-D1 dopamine antagonist and clima entraparity with pleasance on extension and extension and with pleasance on extension and extension sigma antagonist, with clozapine, an atypical neuroleptic, and with BMY-14802, a selective sigma antagonist. Some animals also were prepared for recording single-unit activity during the CAR task. Haloperidol (0.01-0.25 mg/kg), clozapine (0.5-5.0 mg/kg), and BMY-14802 (1.0-10.0 mg/kg) produced comparable decreases in the number of successful avoidances and also increased response latency in a dose-dependent manner. These results suggest that sigma-receptor blockade mimics the effects of some currently used neuroleptics on CAR performance, lending support to the notion that BMY-14802 may exert antipsychotic effects in humans (Taylor et al., In: Schizophrenia, Tamminga and Schulz, eds, 1990). Preliminary single-unit data from the neostriatum, which contains a high density of both dopamine and sigma receptors, indicates the presence of neurons that change activity in response to various components of the CAR task. Further analysis of these cells in response to dopamine- or sigma-receptor antagonists promises to shed light on the neuronal mechanisms of action of these drugs.

INDIVIDUAL VARIABILITY IN EXPLORATORY BEHAVIOR CORRELATES WITH DOPAMINE RELEASE BY AMPHETAMINE IN NUCLEUS ACCUMBENS. C.W. Bradberry, R. Gruen, and R.H. Roth. Dept. of Psychiatry, Yale Univ.Sch. Med., New Haven, CT 06510.

Supported by NIDA (DA02451) and Scottish Rite Foundation.

Dopamine (DA) function in the nucleus accumbens has been linked to exploratory behavior (EB). We wished to determine whether individual variation in nucleus accumbens DA function correlates with individual variations in EB. Rats were placed in a novel environment and EB was rated over a 10 min session. Within one week, animals were anesthetized and implanted with microdialysis probes into the nucleus accumbens. Following attainment of stable basal DA levels, animals were administered 3 mg/kg d-amphetamine sulfate i.p. The increase in DA caused by the amphetamine was compared with the previous behavioral scores for the same animal. A significant correlation was found to exist (R=0.43; P < 0.05) between the maximal increase in DA caused by amphetamine and the duration of EB seen earlier. Basal DA levels did not significantly correlate with EB. These results suggest that presynaptic variability in the nucleus accumbens DA innervation may underlie variations in EB. Possible DA neuronal characteristics responsible include altered distribution of DA between intraneuronal pools, altered regulation of release and/or synthesis, or differences in density of DA innervation. Supported by MH-14092 and DA-05119.

THE BEHAVIORAL EFFECTS OF DIHYDREXIDINE, A HIGH POTENCY, FULL EFFICACY D, DOPAMINE RECEPTOR AGONIST. K.J. Darney, Jr.¹, M.H. Lewis¹, 2, W.K. Brewster⁴, D.E. Nichołs⁴, and R.B. Mailman¹, 2, 3. Brain and Dev. Res. Ctr.¹, Debs. of Psychiat.2 and Pharmacot.3, Univ. of North Carolina, Chapel Hill, NC, 27599 and School of Pharmacy⁴, Purdue Univ., West Lafayette, IN, 47907.

An understanding of the role of D₁ dopamine receptors and D₁/D₂ recaptor interactions in mediating behavior has been hampered by the lack of a potent, full efficacy D₁ dopamine agonist. We assessed the behavioral effects of dihydrexidine, a novel D₁ receptor agonist (trans—10,11—dihydroxy—5,6,6a,7,6,12b—hexahydrobenzo—[a]phenanthridine) which has a ten—fold higher affinity for the D₁ vs. D₂ receptor, and which has a sefficacious as dopamine at stimulating D₁ mediated cAMP synthesis in striatal membranes. In the first study, the dose—response relationship of dihydrexidine was examined using male Sprague—Dawley rats (n=48), each administered a subcutaneous injection of 0.0, 0.3, 1, 3, 10 or 30 mg/tg. The behavioral effects of dihydrexidine were assessed using an observational method that quantified the modified frequency of multiple behavioral topographies. The firequency of three behaviors (groomling, sniffing, and locomotion) was alkered significantly by dihydrexidine. Grooming was increased at 1.0 and 3.0 mg/kg, but returned to control levels at higher doses. The failure of thinydrexidine to stimulate grooming at the two higher doses may well be due to activation of D₂ dopamine receptors. Dihydrexidine increased locomotion and sniffing in a dose dependent fashion over the whole dose range tested. Other behavioral topographies such as licking, gnawing and rearing were not systematically affected by drug administration. In a second study, rats (n=80) were pretrated with either a selective D₂ natagonist (0.1 mg/kg CRT23990), a selective D₂ antagonist (1.0 mg/kg CRT23990), a selective D₂ antagonist (1.0 mg/kg CRT23990), is comotion, and sniffing. Con

TREMULOUS CHEWING MOVEMENTS IN RATS INDUCED BY HALOPERIDOL. PILOCARPINE AND STRIATAL DOPAMINE DEPLETION. R.E. Steinpreis, M.E. Taylor and G. Jicha. Department of Psychology, University of Connecticut, Storrs, CT, 06269-1020.

Tremulous chewing movements in rats have been reported to occur in various drug treatments, but it is not clear how these movements are related to human motor syndromes. Acute administration of 0.4 or 0.8 mg/kg haloperidol (HP) produced only slight, nonsignificant increases in chewing. However, repeated injection of 0.4 mg/kg HP over 10 days significantly increased chewing responses. Acute administration of pilocarpine increased chewing, and combination of 0.4 mg/kg HP with 0.5 mg/kg pilocarpine produced significantly more chewing than either drug alone. Depletion of striatal dopamine with bilateral injection of 6-hydroxydopamine into the ventrolateral striatum also increased chewing resonses. These data indicate that tremulous chewing movements in rats share some characteristics with human Parkinsonian symptoms.

LOCOMOTOR EFFECTS OF CHRONICALLY CO-ADMINISTERED HALOPERIDOL AND NICOTINE IN RATS. L.L. Wing, R. Li*, R.J. Wyatt and D.G. Kirch. Neuropsychiatry Branch, NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

In a previous study, we found that in the rat striatum and hippocampus chronic co-administration of nicotine and haloperidol significantly decreased DA and 5-HT turnover compared to saline-treated animals. In the present study, behavioral associations of these biochemical effects were observed during 6 wks of treatment. Fifty-two male Sprague-Dawley rats (375g +15g) were implanted with Alzet 2ML4 osmotic pumps. Half the animals received pumps filled with isotonic saline, and half with pumps containing nicotine (free-base, 12 mg/kg). Thirteen of the saline controls and thirteen of the nicotine treated animals were given 21 mg/kg, IM haloperidol decanoate at 2 wk intervals, and the rest saline. Animals were tested for 1 hr in Omnitech activity monitors at 1, 3 and 6 for 1 hr in Omnitech activity monitors at 1, 3 and 6

weeks after implantation.

Haloperidol decreased locomotor activity, an effect which was potentiated by nicotine during the first 30 min of the first week. This potentiation had disappeared by week 6. These data have clinical implications given the widespread concurrent use of these drugs by schizophrenic patients, especially those having dyskinesias.

EFFECT OF COCAINE AND STRESS CROSS-SENSITIZATION ON EXTRACELLULAR DOPAMINE RELEASE IN RAT NUCLEUS ACCUMBENS. B.A. Sorg and P.W. Kalivast, Department of Psychology and Department of VCAPPt, Washington State University, Pullman, WA 99164-4820

The in-vivo dialysis technique was used to evaluate the effects of daily cocaine treatment (15 mg/kg) on the ability of acute footshock (0.45 mA/200m sec/sec for 20 min) to alter extracellular levels of dopamine and its metabolites, DOPAC, and HVA. The reciprocal experiment, in which the ability of daily shock to alter dopamine release upon acute cocaine treatment, was also performed. The levels of dopamine, DOPAC and HVA in the rostral nucleus accumbens were measured by HPLC-EC. Dopamine and DOPAC levels were only slightly increased in cocaine- vs. saline-pretreated animals upon acute footshock. In contrast, in the reciprocal experiment, dopamine release by cocaine was increased in shock vs. sham-shock pretreated rats (maximum levels were 125% and 69% above baseline levels, respectively). In addition, the maximum level of dopamine release occurred earlier in shock-sensitized animals. Concurrent measures of locomotor activity showed a similar increase in motor behavior in shock vs. sham shock animals. Both shock and sham shock groups showed a slight decrease in DOPAC and HVA levels upon acute cocaine injection.

MICRODIALYSIS AND TISSUE LEVELS OF BASAL DOPAMINE ARE UNCHANGED AFTER CORTICAL LESIONS, BUT ACUTE AMPHETAMINE-EYOKED EFFLUX IS ELEVATED AND DISSOCIATED FROM ROTATIONAL BEHAVIOR. E. Castañeda, I. Q. Whishaw, and S. D. Oddie. Department of Psychology, University of Lethbridge, Lethbridge, Alberta T1K 3M4.

It has been proposed that neocortical damage leads to It has been proposed that neocortical damage leads to acute and chronic changes in rotational behavior and subcortical dopamine (DA) activity. We gave rats hemidecortications and evaluated: (1) rotational behavior, (2) extracellular dopamine levels (using dialysis) during spontaneous and amphetamine-induced activity, and (3) postmortem tissue DA concentrations. Extracellular and tissue DA levels were unchanged acutely and chronically. After amphetamine administration (1.5 mg/kg, s.c.) acute hemidecortication produced ipsiversive circling and extracellular DA was elevated bilaterally. Chronically, hemidecorticate rats were not different from control rats. The results suggest that: (1) cortical damage does not produce asymmetrical changes in DA activity and (2) injury-induced rotation is unrelated to DA activity. The unexpected finding of acutely elevated amphetaminestimulated release suggests that cortical injury produces a nonspecific acute suppression of DA turnover.

INTRACRANIAL SELF-STIMULATION ON FR15 ENHANCES THE BEHAVIORAL RESPONSE TO LOW DOSES OF AMPHETAMINE SULFATE IN THE RAT. P. R. Hartley and D. B. Neill. Dept. of Psychology, Emory University, Atlanta, GA 30322.

Systemic administration of amphetamine is well known to induce increased responding for intracranial self-stimulation (ICSS). We observed that rats performing lever-press ICSS at lateral hypothalamic electrodes on a fixed ratio 15 (FR15) schedule of reinforcement completely ceased bar-pressing at 2 mg/kg d-amphetamine sulfate (AMPH). Dose-response analysis revealed a shift left for FR15 rats compared to FR1 rats. Rats on the FR1 schedule showed either an increase or decrease in responding at 2 mg/kg, dependent on nondrug response rate; however, unlike the FR15 rats, all continued lever-

Observation of the FR15 rats at 2 mg/kg showed them to be in a form of stereotypy that consisted of sniffing, rearing, and head-bobbing. Preliminary investigation of ambulatory behavior obtained immediately following the ICSS session revealed that the FR15 rats showed less of a following the ICSS session revealed that the FR15 rats showed less of a response than the FR1 rats; this is consistent with the enhanced stereotypy in the FR15 rats. In addition, post-session baseline ambulatory activity was higher in the FR15 rats. We propose that the FR15 schedule induced an elevated dopamine release; the addition of AMPH to this elevated baseline resulted in stereotypy and cessation of

DRUGS OF ABUSE: ALCOHOL I

EFFECTS OF CHRONIC ETHANOL ADMINISTRATION AND WITHDRAWAL ON NUMBERS OF VASOPRESSIN-CONTAINING NEURONS. GP Kozlowski and JH deSchweinitz* Dept. of Physiology, University of Texas Southwestern Medical Center, Dallas TX, 75235-9040.
Vasopressin (VP) enhances learning and memory which are

reduced in alcoholics. Previous studies using the PAP technique (Neurosci Abstr 15,416) showed that ETOH given 30 days, reduced the numbers of VP neurons by 62% in comparison days, reduced the numbers of VP neurons by 62% in comparison to control (CTRL) rats. Here, we compare numbers of VP-containing neurons in rats on either CTRL (n=5) or ETOH (n=5) liquid diets using a simultaneous pair-feeding method for 30 days followed by 10 days Lab Chow and water ad lib. The more sensitive ABC Elite kit (Vector Labs) was used for immunocytochemistry of serial-sectioned rat brains. Means of cell numbers of CTRL vs. ETOH were: ant hypothal area-767±74 vs. 750±83; ant commissural nuc- 52±21 vs. 63±27; supraoptic nuc- 2064±192 vs. 1835±185; suprachiasmatic nuc-1169±189 vs. 811±140; paraventricular nuc- 1046±70 vs. 1060±105; and retrochiasmatic supraoptic nuc-385±90 vs. 345 ± 111 . Means of total numbers of neurons/brain were 5482 ± 458 CTRL vs. 4865 ± 425 ETOH. There was no statistical difference between the two treatment groups indicating that VP synthesis resumes within 10 days after ETOH treatment. Supported by NIAAA AA-06014

EFFECT OF ETHANOL ON NEURONS IN FRONTAL AND PREFRONTAL

EFFECT OF ETHANOL ON NEURONS IN FRONTAL AND PREFRONTAL CORTEX AND MEDIAL DORSAL (MD) THALAMUS IN AWAKE, BEHAVING RATS. Kosobud, A.E., and Chapin, J.K. Department of Physiology and Biophysics, Hahnemann University, Philadelphia, PA 19102.

Although ethanol (EiOH) has profound depressant actions, it has been shown to be a stimulant at low doses, and in initial stages of intoxication. It has been proposed that multisynaptic processess are particularly vulnerable to EiOH, and that the loss of descending inhibition from higher order cortical association areas may be responsible mutusynaptic processess are particularly vulnerable to EtOH, and that the loss of descending inhibition from higher order cortical association areas may be responsible for some EtOH-induced stimulation. Prefrontal and frontal cortex play a role in sensorimotor integration, in planning and selection of appropriate behavior, and in short-term task-related memory. In the present experiments, we examined the effects of ethanol on single unit activity in MD thalamus and various sites in medial frontal and prefrontal cortex. Multiple bundles containing 4-6 microwire electrodes were chronically implanted in female rats, 250-300 g. In general, all implants were in one hemisphere, but in some cases, symmetrical bilateral implants were made. Continuous recordings were obtained from cells in rats locomoting on a timed treadmill before and after EtOH administration (1 g/kg i.p.). A videocamera was used to record behavior throughout the experimental session. In general, cells in the frontal and prefrontal cortex showed higher rates of firing either during locomotion (treadmill on) or rest (treadmill off), but in addition, displayed some more specific responses. For instance, one cell showed increased activity when the animal was at rest, but right hindlimb movement-related firing during locomotion. Most thalamic cells showed higher activity rates during movement. EtOH tended to inhibit the firing rate of cells in both cortex and thalamus. Furthermore, the difference in firing rate between locomotion and rest was reduced or eliminated, especially in the first 10 minutes of intoxication. Thus, it is possible that the disruption in higher cortical function induced by low doses of EtOH reflects a loss of selective activity, rather than a pure inhibition. Supported by grants NS26722, AA06965, K02-AA00089 and AFOSR 90-0266

57.3

EFFECTS OF ACUTE ETHANOL TREATMENT ON THE FIRING THRESHOLD OF HIPPOCAMPAL GRANULE NEURONS. G.L.F.Yuen. M.Patil and D.Durand. Applied Neural Control Lab., Dept. of Biomedical Engineering, Case Western Reserve University, Cleveland, Oh 44106.

Although low dose, acute exposure of ethanol has been reported to

affect the unit activities and field potentials of hippocampal neurons (Folger and Klemm 1978; Wiesner, Henriksen and Bloom 1987), the cellular basis for these changes are unclear. As a step towards clarifying the underlying mechanism(s), detailed intracellular recordings were performed in hippocampal granule neurons with control and ethanol (50mM) media using the *in vitro* slice preparation. Recordings obtained from 12 cells showed that the *in vitro* sice preparation. Recordings obtained from 12 cells showed that 91% of the cells displayed specific changes in the firing properties of the soma and/or dendrites after an exposure time of 15 minutes or more. 4 out of 6 neurons (67%) showed an *increase in the orthodromic firing threshold* measured at various pulse-widths of excitation. This effect was reversible in 2 out of 3 cells (67%). Such an increase in the dendritic firing threshold was observed simultaneously (3 out of 4 cells) with a decrease in the amplitude of the EPSPs (53-71%) evoked by identical stimuli after ethanol treatment. 7 out of 9 cells (77%) showed increased sometic excitability as measured by the treatment. (77%) showed increased somatic excitability as measured by the strength-duration relationship and repetitive firing responses. These effects were reversible in 2 out of 3 cells. Although more recovery data are needed, these somewhat opposite effects of ethanol on the soma and dendrites of these neurons may help to account for some of the inconsistent results from previous single cell studies. An increase in the dendritic firing threshold is also consistent with recent voltage-clamp studies showing a reversible depression of the NMDA-induced current by ethanol in dissociated hippocampal neurons (Lovinger, White and Weight 1989) and the demonstration of a role of the NMDA receptor in the EFSPs of normal hippocampal granule neurons (Lambert & Jones 1989). DISSIMILAR EFFECTS OF ETHANOL AND CHLORDIAZEPOXIDE ON INHIBITION IN THE FASCIA DENTATA AND HIPPOCAMPUS REGIO SUPERIOR SLEffensen. S.C. and Henriksen. S.J., Research Institute of Scripps Clinic, La Jolla, CA 92037.

Scripps Clinic, La Jolla, CA 92037.

Acute intoxicating levels of ethanol increase paired-pulse (PP) inhibition in the dentate while having no effect on population spike (PS) amplitudes evoked by perforant path stimulation suggesting that ethanol specifically targets recurrent mechanisms in the dentate (Wiesner and Henriksen, Neurosci, Letts. 79:169, 1987). In the present study, we describe and compare the effects of ethanol and the benzodiazepine, chlordiazepoxide, on evoked PSs, PP responses, spontaneous activity and interneuronal single-unit excitability in the dentate gyrus and CA1. In the dentate, chlordiazepoxide had no effect on PS amplitudes decreased dentate granule cell (DFC) expragators fright single-unit excitability in the dentate gyrns and CA1. In the dentate, chlordiazepoxide had no effect on PS amplitudes, decreased dentate granule cell (DGC) spontaneous firing rate (65%) and increased PP inhibition, effects similar to those of ethanol in the previous study. In CA1, ethanol decreased PS amplitudes (31%) evoked by Schaffer collateral stimulation, decreased pyramidal cell (PC) spontaneous firing rate (42%) and had no effect on PP responses. Chlordiazepoxide produced similar effects on these measures. Since GABA interneurons are believed to be activated by recurrent collaterals from DGCs and PCs, these results suggest that ethanol, like the benzodiazepines, potentiates GABA-mediated inhibition in the dentate and CA1. However, ethanol and chlordiazepoxide appear to have dissimilar effects on the excitability of putative interneurons recorded in these regions. Interneurons were categorized by conventional interneurons recorded in these regions. Interneurons were categorized by conventional criteria; however, the most stringent criterion was that these cells showed nondecremental impulse discharges following stimulation of their respective afferents. Impulse discharges were evident in CA1 after single shocks whereas, in the dentate, impulse discharges were evident only after paired-shocks. In all cells studied, ethanol markedly increased (200-800%) and chlordiazepoxide abolished the number of interneuronal discharges in both the dentate (N=18) and CA1 (N=4). These results suggest that the inhibitory effects of ethanol are produced by increases in interneuronal discharge and that benzodiazepines inhibit by a facilitatory action at the GABA receptor/chloride ionophore complex.

ETHANOL AND MK-801 DIFFER ON BEHAVIORAL AND ELECTROPHYSIOLOGICAL MEASURES. P.E. Simson, K.B. Johnson, H.E. Criswell, and G.R. Breese. Brain and Development Research Cntr., Univ. of North Carolina, Chapel Hill, NC, 27599.

A number of studies have suggested that ethanol (ETOH) blocks N-methyl-D-aspartate (NMDA) receptors. In this study, we compared the effects of ETOH and the NMDA antagonist MK-801 on behavioral and electrophysiological measures. In a behavioral test measuring spontaneous activity, ETOH, in doses up to 1.5 g/kg, i.p, decreased spontaneous activity while MK-801, in doses up to 0.3 mg/kg, i.p., increased spontaneous activity. In an electrophysiological test, single unit recordings of medial septal neurons were obtained from urethane-anesthetized rats, and the effects of ETOH and MK-801 on the excitation of these neurons by iontophoretically-applied NMDA were observed. At the highest dose tested, ETOH (2.5 g/kg, i.p.) blocked NMDA-evoked activity in only 56% of neurons tested; lower doses of ETOH blocked correspondingly smaller proportions of neurons. In contrast, MK-801 (0.6 mg/kg, i.p.) blocked NMDA-evoked activity in 100% of neurons tested. While these data indicate that some of the effects of ETOH may occur through blockade of NMDA receptors, this action may not explain all of the effects of ETOH. Supported by AA-08024, MH-33127, NS-26595 and HD-03110.

INTERACTION OF ETHANOL AND L-GLUTAMATE IN THE GUINEA PIG ILEUM G.D. Frye Medical Pharmacology, Texas A&M Col. of Med., College Station, TX 77843 CNS depressant actions of ethanol (ET) appear to involve inhibition of excitatory amino acid receptors as shown by blockade of N-methyl-D-aspartate (NMDA) activated currents in hippocampal neurons by ET (Lovinger et al., Science 243: 1721-1724, 1989). Whether this interaction occurs in the peripheral nervous system was tested in the longitudinal muscle-myenteric plexus preparation (LMMP). Both ET (Frye et al., J. Pharmacol. Exp. Ther. 252:474-481, 1990) and L-glutamate (GLU; Moroni et al. Neurosci. Lett. 68:57-62, 1986) induce brief atropine-labile contractions in LMMP. Confirming previous reports, GLU responses were found to be 2-amino-5-phosphonovalerate (APV; 100uM) and Mg²⁺ sensitive. Preincubation with ET (30-100mM) for 2 min inhibited contractions to GLU (60uM) and caused additive inhibition with 100uM Mg²⁺. ET (65mM) did not inhibit contractions to acetylcholine (0.1uM), serotonin (0.1uM) or histamine (0.3uM). On the other hand ET contractions were not blocked by either APV or Mg²⁺. These results suggest that ET may selectively inhibit peripheral NMDA receptors as well as those in the CNS. Supported by PHS grants AA00101, AA06322.

INFLUENCE OF CHRONIC ETHANOL TREATMENT ON SLEEP TIME AND HIPPOCAMPAL CALCIUM CURRENTS OF LONG- AND SHORT-SLEEP MICE. S.P. Aiken, G.-J. Huang, and J.J. McArdle New Jersey Medical School (UMDNJ), Newark, NJ 07103.

Since tolerance to ethanol is associated with an increase in the number of dihydropyridine binding sites in rat cortex (Ann. N.Y. Acad.Sci. 560:465), we measured hippocampal Ca^{2+} currents (I_{Ca}) in Short(SS)- and Long-sleep (LS) mice which differ in their sensitivity to ethanol. Specifically, SS mice lost their righting reflex for 78 min after an i.p. injection of 5g/kg of ethanol. Sleep time for LS mice was 131 min in response to only 4 g/kg. Whole cell recording of I_{Ca} from hippocampal cells, enzymatically isolated from normal adult SS and LS mice, revealed equivalent (p>0.01) maximal values of 463 and 527 pAmps, respectively. In order to evaluate the effect of chronic ethanol treatment on I_{Ca}, we placed SS and LS mice on a calorically controlled liquid diet containing 3.8% ethanol. Subsequent measurement of sleep time or I_{Ca} was made 24 hrs after temporarily placing the mouse on a normal liquid diet. Within 7 days of beginning this treatment, sleep time had declined to a plateau of 52% and 50% of control for LS and SS mice, respectively. Since Ica of the tolerant LS mouse (600 pAmp) was significantly (p<0.01) greater than Ica of the SS mouse (400 pAmp), we suggest that exposure to chronic ethanol is associated with an increase in the number of calcium channels in LS but not SS mice. (supported by grant R01 AA08025-01 from the NIAAA).

ETHANOLAMINE CONTROL OF LIPID PEROXIDATION CAUSED BY ETHANOL. F. Poldrugo, A. Fiore*, G.Z. Abakumov*, I.L. Bykov*, Yu.A. Tarasov*. Alcohol Research Group, Univ. of Trieste, 34100 Italy; Inst. of Biochemistry, BSSR Acad. Sci., Grodno 230009 USSR

The activation of lipid peroxidation (LPO) during ethanol (ETOH) intoxication is well documented. In this research the effect of a natural bioantioxidant: ethanolamine (EA) on the acute and withdrawal effect of ETOH has been investigated.

In the acute studies, male albino rats were injected i.g. with a 25% ETOH solution at doses of 1g/kg b.w. The alcohol withdrawal syndrome (AWS) was obtained after discontinuation of exposure to ETOH vapors (30mg/1) for a 14 day period. EA (100 mg/kg b.w.) was injected i.p. one hour before ETOH injection and before withdrawal evaluation (10 hours after ETOH withdrawal).

Hydroxyperoxide concentrations and the antioxidative activity (AOA) of EA (measured through chemiluminescence parameters) were detected in plasma. Plasma hydroxyperoxide concentrations were increased by 207% vs control rats after acute ETOH injection. EA administration counterbalanced this effect. LPO was not increased during AWS. However, plasma AOA was decreased both during acute ETOH intoxication and AWS. EA increased AOA in both conditions.

Thus, the antioxidative property of EA has been proven to counteract ETOH oxidative effects.

CHRONIC ETHANOL TREATMENT AND HIPPOCAMPAL CELL RESPONSES TO CARBACHOL. L. Taylor, G.D. Frye, W.H. Griffith. Dept. of Med. Pharmacol., Texas A&M Col. of Medicine, College Station, TX 77843 Chronic ethanol (ET) irreversibly damages fore-

Chronic ethanol (ET) irreversibly damages fore-brain cholinergic neurons (Arendt et al., Neurosci. 33:435-462, 1989) and may lead to persistent increases in muscarinic receptors in the hippocampus (HIP). To test this, rats were fed a nutritionally complete ET liquid diet for 3 months, were withdrawn from ET for 4 months and then preand postsynaptic sensitivity of CA1 pyramidal cells to carbachol (CCh) was examined. In both ET treated or control HIP slices, bath applied CCh (1-10uM) similarly reduced dendritic field EPSPs following stimulation of the Schaffer colateral. CCh (0.02-2 uM) also inhibited slow afterhyperpolarizations (AHPs) in CA1 cells following a train of action potentials. Based on the number of cells where AHPs were inhibited by 0.02-0.2uM CCh, ET treatment appeared to increase sensitivity to CCh compared to pairfed controls or young (2 mo old) diet naive animals. Although preliminary, these results suggest that longterm ET treatment may cause persistent increases in postsynaptic sensitivity to muscarinic agonists in CA1 neurons. EFFECTS OF ETHANOL ON THE HINDBRAIN OF DEVELOPING AXOLOTLS. M. W. Egař. V. J. McAdoš. and D. M. Schroeder. Anatomy Dept., Indiana University School of Medicine, Indiana University, School of Medicine, Bloomington, IN 47405

Behavioral effects of the recessive lethal gene (matilda) indicated possible cerebellar or hindbrain dysfunction. These behavorial effects are only expressed after the larvae have reached approximately 12 weeks of age. This coincides with the maturation of the hindbrain and cryptic metamorphosis. In an attempt to produce phenocopies, larval axolotls (Ambystoma mexicanum) 4-10 weeks after spawning, were grown for 4 weeks in 1% ethanol. Control and experimental groups of 20 animals each were selected from non-matilda spawnings. All animals were fed brine shrimp following the daily change of their solution. For the experimental groups the alcohol was added to the 1:4 concentration of Holtfreter's solution. Observations throughout the experimental period indicated an abnormal gill posture similar to that seen in homozygous matilda larvae. The ethanol treated larvae also showed an erratic swimming pattern. These animals were smaller than the controls at the end of the 4 weeks when all animals were sacrificed. The hindbrains were fixed and processed for light and electron microscopy. An apparent increase in the amount of lipids in the ependymal layer of the treated hindbrains may be due to the delayed development caused by the ethanol. The matilda hindbrains showed an even more pronounced accumulation of lipids.

THE EFFECT OF TREATMENT PARADIGM ON THE CONTRIBUTION OF LEARNING TO ETHANOL TOLERANCE. J.L. Weiner* and J.M. Khanna. Dept. of Pharmacology, Univ. of Toronto, & Addiction Research Foundation, Ontario, Canada.

We demonstrated previously that cycloheximide, an amnestic drug, could block the development of chronic tolerance to ethanol when measured on the

block the development of chronic tolerance to ethanol when measured on the moving belt test but had no effect on tolerance assessed by the tilt-plane and hypothermia tests using a gavage treatment paradigm.

A second study was done to characterize the effect of treatment paradigm on the contribution of learning to the development of ethanol tolerance using the hypothermia test. For this purpose, a conditioning treatment protocol was used. Four groups of male, Sprague-Dawley rats were treated daily with saline or ethanol (2.0 g/kg) preceeded by saline or cycloheximide (0.3 mg/kg) in an environment made distinct from the colony room by the addition of white noise and dim lighting. The group receiving saline/ethanol displayed significant tolerance when tested in the distinct environment, a conditioned hyporthermic response when given a placebo injection in that conditioned hyperthermic response when given a placebo injection in that same room but no tolerance when tested in the colony room. In contrast, the cycloheximide/ethanol group showed no tolerance in either test room and failed to exhibit the conditioned compensatory response.

These studies demonstrate that the treatment paradigm used in the induction of tolerance can significantly affect the contribution of learning to

tolerance development.

GABA MEDIATION OF ETHANOL'S ANTI-CONFLICT EFFECT Rassnick and G.F. Koob. Department of Neuropharmacology, Research

Institute of Scripps Clinic, La Jolla, CA 92037.

Previous results have shown that the anti-conflict effect of ethanol (EtOH) was antagonized by isopropylbicyclophosphate, a ligand that binds at or near the chloride ionophore at the picrotoxinin site of the GABA/benzodiazepine ionophore complex (*Alcohol* 5 p 437 1989). The GABA/Denzodiazepine ionophore complex (Alcohor 5 p 43/ 1999). The purpose of this study was to further evaluate the reactivity of this receptor complex to GABA-selective neuropharmacolgical agents during acute EtOH treatment in male Wistar rats. A modified Geller-Seifter conflict test measured food reinforcement paired with incremental shock and unpunished responding (random interval-30 sec schedule). In separate experiments we tested: (1) the non-competitive GABA antagonist picrotoxin (0, 0.25, 0.50, 1.0 mg/kg ip 20 min pretreatment; (2) the quarternary competitive antagonist bicuculline methiodide (0, 50, 100, 200 ng icv 20 min pretreatment); and (3) the GABA transaminase inhibitor amino-oxyacetic acid (AOAA 0, 7.5, 15, 30 mg/kg ip 90 min pretreatment) for their ability to mediate the anti-conflict effect of EtOH (0.75 g/kg 15 min pretreatment ip). As shown previously, EtOH increased punished responding, and here this effect was antagonized by picrotoxin (1.0 mg/kg) and bicuculline methiodide (200 ng). In contrast, the depression of unpunished responding produced by EtOH was not reversed by either treatement. AOAA (30 mg/kg) enhanced EtOH's effects on conflict responding. When subjects were tested without EtOH treatment, neither GABA antagonist affected responding, and AOAA (30mg/kg) attenuated unpunished responding. These results sugest that GABA may interact with the "anxiolytic" effects of EtOH, but at the doses tested, antagonism of GABA receptor activity did not antagonize EtOH's sedative properties (Supported in part by NIAAA 05297 and NIAAA 06420).

ETHANOL LEVELS IN PREGNANT MICE AND FETUSES. L.D. Middaugh and W.O. Boggan. Dept. Psychiatry, Med. Univ. S.C., Charleston, SC 29425

Offspring of pregnant C57BL/6 mice fed liquid diets containing 25% ethanol (E) derived calories have increased neonatal mortality, growth deficits extending into adulthood, and behavioral deficiencies as adults. Control procedures established that the observed effects are not due to nutritional deficiency; however, ethanol concentrations attained in the dam ingesting the diet and in her fetuses are not published. The present study characterized the drinking pattern and ethanol exposure in pregnant mice and fetuses maintained on the E-diet. In Experi-ment 1, pregnant mice increased diet ingestion across pregnancy to maintain a rather constant dosage (23.6 to 22.1 g/Kg/Day on Gestation 5-7 vs 15-17). Ethanol and pair-fed sucrose controls ingested equivalent volumes of diet over a 24-hr period; however, controls consumed 90% of their diet within 14 hr of the diet change at 0800 hr compared to 50% for mice fed the E-diet. In Experiment 2, ethanol concentrations in samples taken at intervals after the diet was changed indicated no detectable ethanol during the day time (0800, 1200, 1600 hr). At night (2000, 2200, 2400, & 0200 hr), maximum ethanol levels were 130 mg% for maternal plasma, 1243 ug/g for maternal brain, and 1121 ug/g for fetal brain. The highest individual sample values were at the 2200 hr sampling; however, the ethanol levels were least variable and the group average was highest at 2000 hr (1 hr after lights out). Maternal plasma values correlated well with maternal and fetal brain values (r2=0.99). (Grant #AA06611).

TIME COURSE AND PATTERN OF ASTROCYTE HYPERTROPHY THIAMINE DEPLETED RATS. P. Nellis*, M. Khurgel, THIAMINE DEPLETED RATS. P. Nellis*, M. Khurgel, N.W. Milgram and G.O. Ivy. Div. Life Sci., Univ. of Toronto at Scarborough, Ont. MIC 144 Canada

We have previously shown that chronic thiamine depletion leads to abnormal neuronal responsiveness within 5 days and to motor seizures by 12 days. We have also shown that heightened neuronal activity causes astrocyte hypertrophy (AH). We thus decided to examine AH and other anatomical changes in thiamine depleted rats. Rats were maintained on a thiamine depleted diet supplemented with pyrithiamine for 5, 8 or 12 days, followed by normal diet for 1d, 1 wk or 1 mo prior to sacrifice. Astrocyte hypertrophy (AH) was visualized using immunoreactivity for anti-glial fibrillary acidic protein; nissl stains were also used. AH was present in hippocampus, pyriform cortex and amygdaloid nuclei (with the exception of the posterior basolateral nucleus) in all rats with ld recovery from thiamine depletion. AH appeared rats with ld recovery from thiamine depletion. AH appeared to be increased in these areas in all rats with lwk survival times and persisted for at least one month. In addition, all 12d treated rats which underwent motor seizures incurred extensive neuronal death in thalamus. It remains to be determined if AH precedes the thalamic necrosis and why the first brain regions to undergo AH are not the regions which experience neuronal death. Similar morphological changes may occur in humans with severe malnutrition or following alcohol withdrawal seizures.

57.14

ALCOHOL AFFECTS FEEDFORWARD BUT NOT FEEDBACK INHIBITION OF HIPPOCAMPAL CA1 NEURONS IN VIVO. J.R. Criado and R. Thies. Depts. of Psych. and Behav. Sci. and of Physiol. and Biophysics, Univ. of Okla. Health Sci. Ctr., Oklahoma

We studied the effects of acute alcohol (1.5 g/kg, i.p.) on field potentials evoked by orthodromic and antidromic stimulation of CA1 neurons. Metal electrodes recorded from the hippocampal CA1 field in male rats anesthetized with 1.0% halothane anesthesia. Bipolar concentric stimulating electrodes produced synaptic excitation and feedforward inhibition from the Schaffer collaterals. Electrodes in the alvear region produced antidromic excitation and feedback inhibition. Alcohol increased the amplitude of field potentials elicited by synaptic excitation, but this was not sensitive to dose. The response to a second stimulus given 40 msec after the first is decreased. This was further decreased in the presence of alcohol, suggesting enhanced inhibition. Alcohol did not affect the amplitude of antidromic field potentials, or of responses to second stimuli given antidromically. These findings suggest that inhibitory interneurons in the Schaffer collateral pathway are more sensitive to the effects of alcohol than interneurons located in the recurrent pathway.

57.16

BEHAVIORALLY-RELEVANT DOSE OF ETHANOL STIMULATES VASOPRESSIN RELEASE FROM MOUSE NEUROINTERMEDIATE LOBE, IN VITRO. T. van Teunenbroek* and D. L. Colbern. Department of Physiology and Biophysics, University of Illinois at Chicago, IL 60680. We have reported that post-training administration of moderately high

doses of ethanol (2-3 g/kg) improves passive avoidance conditioning in mice (Colbern, et al., 1980, 1986). Retrograde facilitation of memory by ethanol has also been observed in humans for both visual (Parker, et al., 1980, 1981) and verbal information (Mueller, et al., 1983). Ethanol affects many neurotransmitter and endocrine systems implicated in memory processes. We are investigating whether the release of vasopressin (VP) is involved in the facilitation of memory by ethanol.

In the present study, the neurointermediate lobe of the pituitary (NIL) was rapidly dissected from 16 male Swiss-Webster mice killed by decapitation. The NILs from two mice were placed in each superfusion chamber (200 µl) and perifused (200 µl/min) for two hours with oxygenated Krebs Ringer Bicarbonate Buffer (KRB, 37°C) to achieve a stable baseline of VP release. For the next 24 min, the NILs were perifused with either 50 mM ethanol in KRB or KRB alone. Superfusate was collected every 6 min and VP was measured by radioimmunoassay. Superfusion with ethanol resulted in a dramatic increase in VP release (mean \pm SD, 11.83 \pm 1.01 pg/50µl) compared to basal release (1.35 \pm .48 pg/50µl). These data are consistent with our earlier studies in which ethanol

produced marked VP release from rat neurointermediate lobe. Further in vitro and in vivo investigation will focus on factors mediating VP release by ethanol and the possible role of this neuropeptide in the effects of ethanol on memory. Supported by PHS Grant AA06747 to DLC.

ETHANOL INHIBITS CALMODULIN-DEPENDENT ACTIVATION OF DIHYDROPYRIDINE-SENSITIVE CALCIUM CHANNEL IN NEURONAL MEMBRANE. Paul Y.Sze, Alex Canda* and Byung H. *. Dept. of Pharm. & Mol. Biol., The Chicago Medical School, North Chicago, IL 60064.

Specific binding of [3H] PN-200-110 to particulate preparations from rat brain was increased by 3-fold after incubation of the membrane with 50 uM ATP, 5 mM Mg, 1 mM Ca and 1 uM calmodulin. The presence of all four components was necessary for the activation; addition of 1 mM EGTA or 0.2 mM trifluoperazine prevented the activation. The radioligand binding was also increased by incubation of the membrane with MgATP binding was also increased by incubation of the memorane with MgATP and the catalytic subunit of bovine heart cAMP-stimulated protein kinase (50 units/ml). MgATP together with 1 mM cAMP was ineffective, indicating that addition of an exogenous cAMP-stimulated protein kinase was required in the activation. These results are consistent with the interpretation that the L-subtype calcium channel in brain could be activated by both a calmodulin-dependent and a cAMP-dependent mechanism.

Ethanol at 25-200 mM had no effect on the basal level of [3H] PN-200-110 binding to the membrane (i.e., without the activating system). However, the presence of ethanol markedly inhibited the calmodulindependent activation of the radioligand binding, whereas the cAMP-dependent activation was not affected. At 150 mM, ethanol inhibited more than 50% of the activation. Thus, from the in vitro characterization, it appears that ethanol does not act directly on the calcium channel; instead, its action is on calmodulin-dependent mechanisms regulating the channel activity. These data are in support of our hypothesis that calmodulin plays a pivotal role in mediating ethanol actions on membrane function in brain. (Supported by AA07230)

LEARNING AND MEMORY-PHARMACOLOGY: ACETYLCHOLINE I

58.1

INTRASEPTAL INFUSION OF THE GABA-A AGONIST MUSCIMOL IMPAIRS THE ACQUISITION AND RETRIEVAL OF MEMORY. $\underline{A.H.}$ Nagahara and J.L. McGaugh. Department of Psychobiology & Center for the Neurobiology of Learning and Memory, Univ. of California, Irvine, CA 92715.

We previously reported that intraseptal infusion of muscimol (1, 5 nMol) decreases high-affinity choline uptake in the hippocampus and impairs acquisition in a water-maze place learning task (PLT). The present experiments investigated the effects of intraseptal injections of muscimol on the learning and retention of an

inhibitory avoidance task (IAT) and a PLT.

Sprague-Dawley rats with implanted intraseptal cannula received buffer or muscimol (1 or 5 nMol) either 5 min prior or immediately after training. The first set of experiment examined the effects of pretraining and posttraining injection of muscimol on the IAT and PLT. In both tasks, pretraining, but not posttraining,

muscimol on the IAT and PLT. In both tasks, pretraining, but not posttraining, injections of muscimol impaired memory retention.

The second set of experiments examined the effects of pretraining intraseptal muscimol on memory over various retention delays on the IAT (15 s, 15 min, 48 hr-retest) and on a single-trial PLT (15 s, 5 min). On the IAT, the 5 mMo muscimol group showed normal retention at 15 s, but was impaired on the 15-min test and 48-hr retest. On the single-trial PLT, the 1 nMol muscimol group showed normal memory on the 15-s retention test, but was impaired on the 5-min retention test. These findings indicate that intraseptal muscimol impairs long-term memory, but not short-term memory performance.

The third set of experiments examined the effects of pretest (5 min prior) intraserval muscimol or retention retermance on an IA task and on a free swim

The third set of experiments examined the effects of pretest (5 min prior) intraseptal muscimol on retention performance on an IA task and on a free swim probe after acquisition of a PLT. Intraseptal muscimol impaired retention performance in the IA task (5 nMol) and on the PLT (1, 5 nMol). These sets of experiments suggest that the GABAergic system in the MSA and its regulation of the septohippocampal cholinergic system play a role in the acquisition and retrieval of logic ferm percent.

CHLORDIAZEPOXIDE-INDUCED WORKING MEMORY IMPAIRMENT: SITE SPECIFICITY AND ANTAGONISM WITH RO15,1788. R.W. Stackma and T.J. Walsh. Rutgers University, Deptartment of Psychology, New Brunswick, NI 08903

The following experiments examined (1) the site-specificity of CDP induced memory impairments and (2) whether the BDZ antagonist RO15,1788 would attenuate these impairments.

Adult Sprague-Dawley rats were trained to perform a working memory version of the eight arm radial maze (RAM) task, in which a one hr delay was imposed between the fourth and fifth arm choices. Following acquisition of this task, nimals were implanted with either a single guide cannulae in the medial septum (MS) or bilateral cannulae in the amygdala. Following surgery, rats were retrained on the task and injected immediately following the pre-delay session with CDP or vehicle. Intraseptal injection of 30, but not 15, nmoles of CDP impaired working memory performance. No memory impairments were observed when CDP was injected into the MS 15 mins following the pre-delay session or when CDP (10, 20, 30 nmoles) was bilaterally injected into the amygdala

In the final experiment, rats were injected intraperitoneally with either an amnestic dose of CDP (5 mg/kg) or saline immediately following the pre-delay session. They were then infused, into the MS, with either 10 nmoles of RO15,1788 or the 5% polyethylene glycol vehicle. Systemic injection of CDP produced a working memory impairment that was blocked by administration of the BDZ antagonist into the MS. These data suggest that CDP-induced amnesia is mediated by BDZ receptors in the MS. Supported by BRSG grant 07058 to TJW.

INTRASEPTAL ADMINISTRATION OF BICUCULLINE PRODUCES

INTRASEPTAL ADMINISTRATION OF BICUCULLINE PRODUCES MEMORY DEFICITS IN THE RAT. J.J.Chrobak & T.C.Napier, Dept. of Pharmacology, Loyola Univ. Chicago Sch. Med., Maywood, IL 60153. Septohippocampal neurons are critical to neurophysiological processes within the hippocampus and thus support the cognitive processes subserved by activity within that structure. Acute pharmacological manipulations within the septum can alter performance in working memory tasks. Infusion of the GABAergic agonist muscimol produces deficits in the performance of a delayed-non-match-to-sample (DNMTS) radial arm maze (RAM) task. The present report indicates that acute septal infusion of the GABAergic antagonists bicuculine (BIC) can also produce a deficit in the GABAergic antagonist bicuculine (BIC) can also produce a deficit in the performance of this task.

GABAergic antagonist discussion (bit) can also produce a delical manager performance of this task.

Male Sprague-Dawley rats, trained to perform a DNMTS-RAM, were implanted with a single cannula aimed at the medial septal nucleus. A within-subjects design was utilized to examine the effects of BIC (0.5ug) on performance of this task with one and four hir retention intervals. Administration of BIC immediately following the first four choices produced an impairment in maze performance at both retention interval. This treatment also produced an increase in latency per choice. BIC-induced impairments were not observed when administered two hours following the nradelay session. These data support previous observations that predelay session. These data support previous observations that pharmacological manipulation of GABAergic activity within the septum modifies working memory processes. (This work was supported by a Illinois Department of Public Health grant to JJC, and a BRSG grant to TCN).

58.4

GABAergic CONTROL OF BASAL FOREBRAIN CHOLINERGIC NEURONS AND MEMORY. M. Sarter and P. Dudchenko*. Dept. of Psychology, The Ohio State University, Columbus, OH 43210.

The involvement of the GABAergic innervation of basal forebrain cholinergic neurons in the rats conditional visual discrimination performance was examined. Performance in such a task is based on the subject's ability to retrieve information about response rules. Following the acquisition of the task, guide cannula were implanted bilaterally into the substantia innominata (SI) of both hemispheres. Administration of the GABA agonist muscimol into the SI (0, 25, 50 ng/0.5 µl/ hemisphere) dosedependently decreased the number of correct responses, increased the number of errors of responses, increased the number of errors of omission, and increased response latency. Systemic co-administration of the cholinesterase inhibitor physostigmine (0, 0.1, 0.2 mg/kg; i.p.) exclusively interacted with the effects of muscimol on correct responding, producing both increasing and attenuating effects on the impairment induced by muscimol. These results support the hypotheses that the activity of basal forebrain cholinergic neurons is under inhibitory control by a GABAergic input, and that this neuronal link is involved in mnemonic processing.

EFFECTS OF DM-9384, A NEW COGNITION-ENHANCING AGENT, ON CHOLINERGIC SYSTEM IN RAT CORTEX. S. Watabe, H. Yamaguchi* and S. Ashida*. Research Institute, Dailchi Pharmaceutical Co. Ltd., Tokyo 134, Japan.

We have reported that DM-9384(N-(2,6-dimethyl-phenyl)-2-(2-oxo-1-pyrrolidinyl) acetamide) accelerates both the metabolic turnover of GABA and ACh uptake in rat cortex(Soc. Neurosci. abstr.,1989). DM-9384 also activated choline acetyltransferase(ChAT) activity in rat cortex. These results indicate the possibility that DM-9384 acts on GABAergic and cholinergic systems. In the present study, we have examined the effects of DM-9384 and its congeners (aniracetam and oxiracetam) on both ['H]-ACh release(in virto and ex vivo) and GABA-induced ['H]-ACh release from rat cortical slices. The amount of released ['H]-ACh from slices was significantly increased (65%) by oral adminstration of DM-9384 (3mg/kg), although DM-9384(10-"M) had a little effect in vitro. GABA showed a dose-dependent increase in ACh release. The GABA-induced ACh release was enhanced by DM-9384 (10-"M). Aniracetam and oxiracetam had a similar but slight effect on the ACh release. These results suggest that DM-9384 stimulates ACh release through acting on GABAergic system in rat cortex.

EARLY ONSET OF IMPAIRED LEARNING AND MEMORY IN SENESCENCE ACCELERATED MICE (SAM). J.F. Flood and John E. Morley. Geriatric Research, Educational and Clinical Center VA Medical Center, and Division of Geriatric Medicine, St. Louis University, St. Louis MO 63104

The SAM P/8JF mouse strain has a 40% shorter life span than other mice such as the C57BL/6J strain. When SAM mice were trained on left-right Tmaze footshock avoidance task, they showed an age-dependent decrement of learning and memory. Whereas C57BL mice have been reported to show impaired learning and memory starting at 24 months of age, the SAM mice showed such decrements beginning at 10 months of age for learning and at 8 months of age for retention. Normal retention for simple passive avoidance conditioning and an analysis of footshock escape latencies suggests that agerelated difference in footshock sensitivity did not account for impaired retention in T-maze conditioning. Similar age-related impairments were found in learning to avoid shock in a shuttlebox and in learning to press a lever for milk reinforcement. A battery of drugs was tested to determine if abnormal functioning of any specific neurotransmitter system might account for the impaired learning and memory. SAM mice showed improved retention for drugs effecting dopamine, norepinephrine, GABA and opioids but compounds that effected serotonin or acetylcholine failed to improve retention. Present data indicates that higher doses of arecoline, an ACh agonist, were needed to improved retention in SAM mice. The memory impairment maybe related to alterations in the cholinergic and serotonergic systems. SAM P/8JF mice show an early onset of impaired learning and memory in spite of good general health.

58.9

INTENSITY-DEPENDENT EFFECTS OF SCOPOLAMINE IN PASSIVE AVOIDANCE. S. E. Cruz-Morales, M. Durán-Arévalo and R. A. Prado-Alcalá. Behav. Pharmacol. Prog., ENEP-Iztacala, Anahuac Univ., and Physiol. Dept., Med. Sch., National Univ. of México.

Anticholinergic-induced amnesia prevented by increasing the magnitude of the reinforcers during learning. It is not known wheter this is a gradual or an "all-or-none" effect. To test these possibilities, rats were trained in a one-trial passive avoidance task; retention was tested 24 hr later. During training different footshock intensities were During used: 2.5, 2.6, 2.7, 2.8, 2.9, and 3.0 mA; half the groups were injected with 8 mg/kg of scopolamine (SCOP) and the other half was not Streated. Isotonic saline or methylscopolamine (8 mg/kg) were injected to two additional groups, trained with 2.5 mA. Injections were given 5 min posttraining (i.p.). SCOP produced amnesia in the 2.5, 2.6 and 2.7 mA groups; all other groups showed near-perfect performance. These results suggest that once a certain level of training-related stimulation is reached, the cholinergic system is switched-off, and other neurochemical systems mediate the consolidation process. NIMODIPINE ENHANCES LEARNING OF THE 8-ARM RADIAL MAZE

NIMODIPINE ENHANCES LEARNING OF THE 8-ARM RADIAL MAZE IN YOUNG RATS. A. Levy, R. M. Konq*, H. R. Lieberman and T. M. Rauch*. U. S. Army Research Institute of Environmental Medicine, Natick, MA 01760.

Several investigators have reported that the calcium channel blocker nimodipine improves cognitive performance in aged and brain-damaged animals. In the present study, 20 mg sustained-release (3 weeks) nimodipine pellets were implanted subcutaneously into young Fischer-344 rats (5 month old; 290 g). Training in the 8-arm radial maze began two days later. In the 6-arm radial maze began two days later. Nimodipine significantly improved learning of the maze as compared to placebo (n=12; P<.001 for main drug effect on correct choices out of the first 8). Nimodipine treated rats also made twice as many Nimodipine treated rats also made twice as many choices per unit time during the first week of training (P=.005). Their average serum nimodipine concentration on day 17 was 7 ng/ml. Hippocampal microdialysis, using a 3 mm probe placed at the CA1 and DG regions (AP=-3.8; L=1.6; V=1.5-4.5 with respect to Bregma), was performed on days 18-20 of the treatment. Thirty ul dialysate samples were collected at 2 ul/min and analyzed for acetylcholine and choline content on an HPLC-EC, using the BAS assay kit. Significantly higher extracellular ACh levels were found in nimodipine treated rats $(71.4\pm3.6 \text{ nM}; \text{ n=4})$ as compared to controls $(52.5\pm2.5 \text{ nM}; \text{ n=5})$ (P=.003).

CHOLINERGIC MODULATION OF MEMORY AND PERFORMANCE OF LONG-EVANS RATS IN THE T-MAZE. J.M. Ordy, T.M. Wengenack, G.J. Thomas, A.S. Howell*, and W.P. Dunlap*. Fisons Pharmaceuticals, Univ. of Rochester, Rochester, NY 14623, and Tulane Univ., New Orleans, LA 70118.

Studies with Alzheimer's (AD) patients, normal humans, and animal models have shown enhancement of memory by physostigmine (PH) and arecoline (AR), and memory impairment by scopolamine (SC). Reversal of SC memory impairment by indirect or direct agonists has been used in animal models of drug development for memory impairment in AD. Conflicting findings exist concerning: 1) disso-ciation of drug effects on memory from effects on performance, and 2) efficacy and selectivity of cholinergic agonists used for reversal of SC memory impairment. In dose-response and time-course studies, the aims were to compare the effects of SC, methyl scopolamine (MESC), PH, and AR on spatial-working memory and on performance of adult Long-Evans rats in the T-maze. In "double-dissociation" comparisons, SC impaired memory independent of effects on performance, MESC impaired performance independent of effects on memory. Both PH and AR reversed SC memory impairment independent of effects on performance. The cholinergic dose-response and time-course findings indicated a potential utility for the use of animal models for studying drug modification of memory impairment in AD.

NEW METHODS TO DETERMINE IN VIVO ACTION OF REVERSIBLE ACETYLCHOLINESTERASE INHIBITORS: TACRINE AND E2020.

K. A. Sherman, Dept. Pharmacol., So.IL. Univ. Sch. Med., Springfield, II.

The reported efficacy of tetrahydroaminoacridinc (THA) in ameliorating Alzheimer dementia focussed attention on a distinct class of acetylcholinesterase (AChE) inhibitors-centrally active drugs which inhibit the enzyme allosterically by reversible binding. Inhibition of AChE by these drugs is more potent at lower ACh concentrations; therefore, they may be better able to selectively reverse age- and Alzheimer-related hypofunction without producing cholinergic hyperactivity in unaffected brain areas. However, reversible inhibitors such as THA (in contrast to carbamates or organophosphates) readily dissociate from AChE upon dilution for brain homogenization and assay, making it difficult to quantify their action in vivo. Using minimal tissue dilution, we compared the inhibition of AChE measured radioenzymatically in discrete rat brain regions and blood after systemic THA. These results and direct fluorometric HPLC assay of THA indicate that this drug selectively accumulates in certain brain regions, and reaches concentrations (6.5 μM peak) which inhibit AChE over 90% in rat cortex after 5 mg/kg s.c., a dose without marked locomotor inhibitory action. AChE inhibition in cortical homogenates diluted 8-fold at assay is only 50-60%, but declines more slowly than THA level. A novel, reversible and specific AChE inhibition feed in hibition in cortical homogenates diluted 8-fold at assay is only 50-60%, but declines more slowly than THA level. A novel, reversible and specific AChE inhibition. E2020 (Yamanishi et al. Soc.Neurosci.Abst. 14-59, 1988), is also characterized; and a new approach is presented for quantifying the in vivo effect of reversible AChE inhibition of AChE measured ex vivo in 5-fold diluted cortex is 70% and AChE inhibition of ache measured by the folding the in vivo interaction of E0220 with AChE inhibition by DIFf for up

STAUROSPORINE FACILITATES RECOVERY FROM THE BASAL FOREBRAIN-LESION-INDUCED AMNESIA AND DEFICIT OF CHOLINERGIC NEURON IN RATS. Alzheimer's disease is characterized by the loss of cholinergic neurons in the nucleus basalis of Meynert and by a primary loss of memory function. Since staurosporine has been reported to induce differentiation in the human neuroblastoma cell in vitro, we have investigated whether an administration of staurosporine in vivo attenuates the amnesia induced by basal forebrain-lesion in rats. The multiple dosage of staurosporine at the doses of 0.05 and 0.1 mg/kg (i.p.) attenuated the impaired performance of water mg/kg (1.p.) attenuated the impaired performance of water maze and passive avoidance tasks, although the drug-administration was started 2 weeks after basal forebrain-lesion. Moreover, staurosporine (0.1 mg/kg) partially reversed the decrease of choline acetyltransferase activity in the cortex induced by basal forebrain-lesion. These results suggest that the administration of staurosporine attenuates amnesia through reversal of deficits in cholinergic neurons induced by basal forebrain-lesion. This evidence indicated that neurotrophic factor-like substances may open the way for novel therapeutic approaches to Alzheimer's disease.

CHOLINERGIC MODULATION OF INTRINSIC FIBER SYNAPSES MAY INCREASE AUTO-ASSOCIATION MEMORY CAPACITY OF RAT PIRIFORM (OLFACTORY) CORTEX.

M.E. Hasselmo and J.M. Bower, Div. Biology 216-76, Caltech, Pasadena, CA, 91125. Computational modeling in our laboratory suggests that piriform cortex may function as an auto-association memory (Wilson and Bower, 1988, Neural Information Processing Systems. D. Anderson ed. AIP Press, N.Y., pp. 114-126). In simulations, the efficiency of such a memory is enhanced when there are differences in the physiology and neurochemical modulation of afferent and intrinsic fiber synapses. Using in vitro slice preparations, we have found physiological differences between these two populations of synapses (Hasselmo and Bower, J. Neurophysiology, in press). To study possible differences in their neurochemical modulation, we tested the effect of

the acetylcholine analog carbachol on afferent and intrinsic fiber synaptic potentials. Carbachol selectively suppressed synaptic potentials elicited by stimulation of intrinsic fibers in layer 1b (average 82.8% suppression at 100µM, I.C. 50 near 5µM) while having little effect on potentials evoked by stimulation of afferent fibers in layer la (average 10.5% suppression at 100µM). Carbachol did not change the time course of intracellularly recorded potentials, but increased intrinsic fiber paired-pulse facilitation measured extracellularly (average 44.4% increase at 100µM), suggesting a presynaptic mechanism of suppression. Cells also showed an increase in excitability,

which may compensate for reduced synaptic input.

Recent modeling shows that selective cholinergic modulation of intrinsic connections may increase the sparseness of pyramidal cell activity by reducing the spread of excitation, thus allowing a stronger effect of lateral inhibition. This greater sparseness of activity would increase the capacity and efficiency of auto-association storage. This model might provide a theoretical framework for the memory deficits associated with the loss of cortical cholinergic innervation in Alzheimer's disease.

RADIO-FREQUENCY LESIONS OF THE NUCLEUS BASALIS MAGNO-CELLULARIS AND CHOLINERGIC DRUGS IMPAIR DIFFERENTIAL CONDITIONING IN RATS. J. E. Dencoff, A. E. Butt, B. G. Cooper*, K. Nopp-<u>Dvorak*, G. K. Hodge.</u> Department of Psychology, University of New Mexico,
 Albuquerque, NM 87131.
 Deficits in differential conditioning performance resulted from bilateral

radio-frequency lesions of the nucleus basalis magnocellularis that were exacerbated by scopolamine but were not attenuated by physostigmine. Twenty-nine male white rats were trained on a differential conditioning bar-press task and tested for performance following injections of the cholinergic drugs scopolarnine (0.125 mg/kg) and physostigmine (0.03 mg/kg), alone or in combination. Rats were then given bilateral lesions of the nucleus basalis, allowed a short period of recovery, and again tested for performance under scopolamine or physostigmine. Lesions of the nucleus basalis resulted in significant task impairments, including reduced success rates and prolonged task completion times. Performance deficits were exaggerated by administration of scopolamine, but were not alleviated by physostigmine. These results may be explained by factors such as lesion specificity, drug dosage, task complexity, drug supersensitivity, and animal age. suggest that although lesions of the nucleus basalis interfere with cholinergic systems, which may be involved in the processes of learning and memory, cholinergic replacement treatment alone may be insufficient to remedy neuronal loss in the nucleus basalis.

QUISQUALIC ACID LESIONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS (NBM) DIFFERENTIALLY AFFECT WORKING AND REFERENCE MEMORY IN RATS. S.L. Biggan*, R.J. Beninger, J. Cockhill, K. Jhamandas & R.J. Boegman, Dept. of Psychol. and Dept. of Pharmacol. & Toxicol., Queen's University, Kingston, K7L 3N6, Canada.

Excitotoxic lesions of cholinergic cell bodies of the nbm have been shown to produce memory loss like that seen in both normal and shown to produce memory loss like that seen in both normal and pathological aging. The purpose of the present study was to investigate the effects of quisqualic acid lesions of the nbm on working and reference memory in a double-Y maze. Rats were trained to an 88% correct criterion, and were then given either bilateral quisqualic acid lesions (60 nM, 0.5 ul) or sham lesions (0.9% saline, 0.5 ul) of the nbm. One week post-surgery, rats were tested on the double-Y maze task with delays of 0, 5, or 30 seconds being introduced prior to both the working and reference memory choice. Nbm lesions produced a 63.2 ± 6.2% decrease of cortical choline acetyltransferase. (ChAT) $63.2\pm6.2\%$ decrease of cortical choline acetyltransferase (ChAT) compared to shams. Delays affected only the working memory of the sham group. Rats with lesions showed a significant impairment of working memory at all delays, but no change in reference memory. Results indicate that quisqualic acid lesions of the nbm that produce significant reductions in cortical ChAT selectively impair working memory. (funded by NSERC)

INVOLVEMENT OF NICOTINIC CHOLINERGIC SYSTEMS IN SHUTTLE-ESCAPE DEFICITS PRODUCED BY INESCAPABLE SHOCK IN RATS. S.R. McGurk, T.R. Minor, and L.L. Butcher. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563. Exposure to inescapable tail-shock produces subsequent deficits in shuttle-escape responding in rats. Other investigatiors have shown that central muscarinic chalinerais sustant and involved in this

that central muscarinic cholinergic systems are involved in this response. We now report that nicotinic cholinergic systems are involved as well.

Male rats were exposed to inescapable tail-shock and on the next Male rats were exposed to inescapable tail-shock and on the next day tested for shuttle-escape performance. Before escape testing, rats were given either scopolamine (0.1. or 1.0 mg/kg); mecamylamine (5, 10, 20 mg/kg); hexamethonium (10 mg/kg); or saline. Shock-induced deficits in escape performance were significantly attenuated by scopolamine (1.0 mg/kg) and mecamylamine (10 and 20 mg/kg). Hexamethonium was ineffective, indicating the importance of central nicotinic systems in this escape.

Finally, a group was given a combination of subthreshold doses of scopolamine + mecamylamine (0.1 and 5 mg/kg, respectively). The combination treatment attenuated shuttle escape deficits. That subthreshold doses of nicotinic and muscarinic antagonists summate suggests both are acting on the same or interconnected neural circuits underlying escape responding. LEARNING DEFICITS IN RATS (NBM LESION) ARE ATTENUATED BY A NOVEL ACETYLCHOLINESTERASE INHIBITOR 3-PYRIDINOL DIMETHYLCARBAMATE. M.E.Bach*, M.Sano L.J.Cote S.Ginsburg and R.Mayeux. Dept. of Neurology, College of P&S, Columbia University, New York, NY 10032.

Lesions of the nucleus basalis magnocellularis (nbm) result in

decreased cholinergic activity, and learning and memory deficits in humans and animals. The performance of lesioned rats on a new learning task, the repeated acquisition paradigm (Peele & Baron, JEAB, 49:275-290, 1988) employing an 8 arm rotary maze, was compared to sham and control groups. Quinolinic acid (120 nmol in 1ul) or saline (1ul) was delivered unilaterally at the following coordinates (Paxinos and Watson): AP 7.5mm, LAT+/-2.4mm and DV 2.9mm to lesioned and sham groups respectively. The nbm lesions were confirmed via acetylcholinesterase staining. Each session of the repeated acquisition task, a new set of 4 arms were baited with food reinforcements and the rats were required to learn, across 10 trials, which arms were baited. The lesioned rats required significantly more sessions to acquire the task when compared to sham and control rats. Physostigmine (.09 and .12mg/kg) and 3-pyridinol dimethylcarbamate, "Norpyridostigmine" (10mg/kg) both diminished the acquisition deficit in the lesioned rats when administered ip 15 min prior to testing. Norpyridostigmine was as effective as physostigmine in attenuating the learning deficit associated with nbm lesions. The repeated acquisition task is sensitive to cholinergic manipulations and therefore a useful model for evaluating potential treatments for memory deficits of dementia. Supported by the Charles S.Robertson Foundation, the Parkinson Disease Foundation and NIH grant AG08702-01

NUMBER OF REM PERIODS AND WEIGHT CHANGE IN MAJOR DEPRESSION. T. Hsu, M.D.*, J. E. Shipley, M.A. M.D., Al, S. Eiser, Ph.D., R. F. Haskett, M.D., L. J. Grunhaus, M.D., A. C. Pande, M.D. Department of Psychiatry, Univ. of Michigan Sch. of Med., Ann Arbor, MI 481100

In a previous study, we reported that depressed patients with comparable depressive seventy differed with respect to a number of measures of EEG sleep, depending on whether they reported loss or gain of weight during their depressive episode. Because of recent reports linking REM sleep with metabolic function, we examined the association between self-reported weight change and the number of REM periods per night in a sample of patients with MDD.

patients with MDD.

All 107 patients in the study had MDD by RDC. Subjects were divided into three groups according to 1) whether they had 1-2, 3-4, or 5-6 mean REM periods per night, and 2) whether they reported a loss or gain of weight during their current depressive episode. These groupings were similar with respect to age, sex, in-vs. out-patient status, HDRS, and MDD subtype. All recordings of EEG sleep were made after two weeks drug-free, and the data from two consecutive inoits were averaged.

from two consecutive nights were averaged.

The three REM-period groups differed significantly with respect to their distribution within the three weight-change groups (pc.002 by Chi-square); weight-losers exhibited significant variation while weight-maintainers and weight-gainers had very little variation. Comparison of the REM-period groups with respect to REM latency and other selected measures of EEG sleep by multiple ANOVAs did not reveal any significant differences. These results suggest that further metabolic characterization of depressive patients may be of value in defining depressive subtypes.

59.3

NEUROPHYSIN RESPONSE TO ELECTROCONVULSIVE THERAPY IN DEPRESSED PATIENTS.
A.I.F. Scott*, J.J.Legros*, and L.J. Whalley.

A.I.F. Scott*, J.J.Legros*, and L.J. Whalley. Department of Psychiatry, Edinburgh Univ., Edinburgh, EH10 5HF, U.K.

Our previous studies have shown a strong association between the neurophysin response to ECT and outcome in depression. Serum neurophysins were measured at the first and last treatments in a course of ECT monitored by EEG given to 17 depressed patients. The findings confirm that the release of oxytocin-associated neurophysin (NNPII) after the first ECT correlated with the extent of eventual improvement but this was not a useful predictor of recovery. hNpII release did not change between first and last treatments and hNpII release was not related to EEG measures of seizure activity or improvement in depression. The hypothesis is advanced that hNpII release is a measure of electrical stimulation of mid brain. (Scott et al, Lancet 1986 i 1411: Whalley et al, Psychol.Med. 17: 312, 1987).

CEREBRAL GLUCOSE UTILIZATION IN HUNTINGTON'S DISEASE: INFERIOR FRONTAL HYPOMETABOLISM IDENTIFIES PATIENTS WITH MAJOR DEPRESSION. HS Mayberg. SE Starkstein, CE Peyser*, SE Folstein*, RF Dannals*, MF Folstein*, HN Wagner, Jr.* Johns Hopkins Medical Institutions, Baltimore, MD 21205.

Positron Emission Tomography (PET) studies in patients with Huntington's Disease (HD) have identified decreases in glucose patabolism (CMPGIN) in the stream simplete and frontal exists.

Positron Emission Tomography (PET) studies in patients with Huntington's Disease (HD) have identified decreases in glucose metabolism (CMRGIc) in the striatum, cingulate and frontal cortices. While depression is present in more than 40% of HD patients, the relationship between the mood disorder and regional CMRGIc abnormalities have not been directly assessed. CMRGIc was measured using ¹⁸FDG and PET in 10 HD patients (4 depressed, 6 non-depressed) and 7 controls. All patients (mean age 41±13 years) had < 7 years duration of chorea and comparable scores on measures of apathy, irritability, cognitive function, neurological impairment, overall disability, and cortical and subcortical atrophy. Significant decreases in striatal and cingulate CMRGIc were seen in both HD groups compared to the normal subjects. Normalized CMRGIc (region/whole brain) was reduced in orbital and inferior prefrontal cortex (Fr) in the depressed patients (1.06±.13) and the controls (1.09±.05) (group x region F(2,9)=7.63, p=.0001). After adjustment for age, there was a significant correlation between depression severity (PSE score) and Fr CMRGIc (r²=0.72, p<.02). These selective metabolic changes suggest that dysfunction of specific cortico-striatal pathways may undertie the affective disorder common in HD.

DOSAGE FOR THE SALIVARY DST IN DEPRESSED PREPUBERTAL CHILDREN. I.L. Extein and D.R. Porter*. Fair Oaks Hospital, Delray Beach, FL. 33484

The recognition of major depression in children and the utility of antidepressant medications underline the impor-

The recognition of major depression in children and the utility of antidepressant medications underline the importance of accurate diagnosis. Nonsuppression of serum cortisol on the dexamethasone suppression test (DST) has been suggested as a marker for major depression in children as in adults, but the multiple blood samples required has limited the application of the DST in children. Since serum and salivary cortisol levels are highly correlated in depressed adults and children, a salivary DST has been developed. We studied two dosages of dexamethasone to determine optimal parameters for the salivary DST in children - the 1.0 mg standard for adults, and a reduced 0.5 mg dosage. Dexamethasone was administered at 11 PM to hospitalized children. Saliva was obtained the next day at 8 AM, 12 N, 4 PM, and 11 PM for assay of cortisol by radioimmunoassay (RIA). A cortisol >90 ng/dl at any time point defined non-suppression. The first 13 patients (10 major and 3 bipolar depression by DSM III-R; ages 8-13, mean age 10) received 1.0 mg. One was a nonsuppressor. The next 14 patients (12 major and 3 bipolar depression; ages 6-13, mean age 10) received 0.5 mg. Six were nonsuppressors. The sensitivity of the 0.5 mg salivary DST for depressive disorders of 43% was significantly higher than that of 8% for the 1.0 mg test by Chi-Square, and similar to the reported sensitivity of the DST in adults. Specificity needs to be studied.

59.4

PITUITARY AND ADRENAL ALTERATIONS IN MAJOR DEPRESSION: MRI AND CT STUDIES. C.B. Nemeroff, N.R. Dunnick*, O. Boyko*, G. Figiel*, D. Reed, P.M. Doraiswamy and K.R.R. Krishnan. Depts. of Psychiatry and Radiology, Duke Univ. Med. Ctr., Durham, NC 27710.

It is now well established that a large percentage of patients that fulfill criteria for major depression exhibit hyperactivity of the hypothalamic-pituitary-adrenal (HPA) axis. We present here the results of two studies: (1) evaluation of the size of the adrenal gland in 37 depressed patients and 12 normal controls by computed tomography (CT). We hypothesized that depressed patients would exhibit adrenal enlargement secondary to hypersecretion of ACTH, and perhaps other POMC products, (2) evaluation of the size of the pituitary gland by magnetic resonance imaging (MRI) in 19 depressed patients and 19 normal controls. There is considerable evidence from preclinical studies that hypothalamic hypophysiotropic hormones such as CRF are trophic to anterior pituitary cells. We hypothesized that if CRF and TRH are hypersecreted in major depression, depressed patients would exhibit pituitary enlargement. The results obtained supported both hypotheses: depressed patients exhibited adrenal enlargement (35% of depressed patients exhibited adrenal hypertrophy) and pituitary enlargement. Studies in progress will determine whether these changes are reversible, or related to clinical or neuroendocrine features of depression. (Supported by NIMH MH-42088, MH-40189 and MH-44716).

59.6

CEREBRAL HEMISPHERE ASYMMETRIES IN DEPRESSION AFTER STROKE R.G.Robinson, S.E.Starkstein, J.B.Bryer*, M.L.Berthier*, B.Cohen*, T.R.Price. Dept. Psychiatry, Johns Hopkins Univ. Sch. Med., Balto., MD 21205

We examined the association between post-stroke depression and the pattern of brain asymmetries visualized on computerized tomography (CT) scan, in patients with a single acute cerebrovascular lesion. Based on CT scan measurements, patients were divided into those with typical (N= 39) or reversed (N=17) frontal and/or occipital asymmetries. Among patients with a typical occipital asymmetry, those with left frontal or left basal ganglia lesions showed a significantly higher frequency of major depression (i.e., 7 of 8, 88%) and significantly higher depression scores than patients with similar lesion location but reversed occipital asymmetry (i.e., 0 of 9) or those with a typical asymmetry and lesions in other (left or right) brain areas (i.e., 5 of 31, 16%) (Fisher Test p < 005). Among patients with a reversed occipital asymmetry, 3 of 8 (38%) with right hemisphere lesions but 0 of 9 with left hemisphere lesions had major depression ($p \le 1$). Similar findings were observed when patients were divided into those with typical or reversed frontal plus occipital asymmetries. This study demonstrates that the previously reported significant association between post-stroke ma jor depression and lesion location is restricted to patients with a typical occipital asymmetry, and is not present in patients with a reversed occipital asymmetry.

NEUROPEPTIDE Y CONCENTRATIONS IN POST-MORTEM BRAIN FROM NEUROPEPTIDE Y CONCENTRATIONS IN POST-MORTEM BRAIN FROM VICTIMS OF SUICIDE AND CONTROLS P.S. Widdowson*, G.A. Ordway and A.E. Halaris. Depts. Psychiatry, Neuroscience, Pharmacology, Case Western Reserve Univ. and MetroHealth M.C., Cleveland, OH 44109. Neuropeptide Y (NPY) is found in large concentrations in human brain. The presence of specific binding sites for NPY in human brain suggests that NPY may play an inportant role in powerters religion.

important role in neurotransmission. In brain, NPY coexists with norepinephrine, serotonin and GABA, transmitters which have been implicated in suicide. We measured NPY in four regions of brains from victims of measured NPY in four regions of brains from Victims of suicide (s) (mean age 46.3 ± 3.5 ; n= 14) and sudden death controls (C) (mean age 40.6 ± 4.3 ; n= 19). NPY was extracted from tissue by boiling in acetic acid, sonication and centrifugation. Lyophilized supernatants were stored at -80 C and NPY measured by RIA and expressed as pmol/g tissue. Means and S.E.M. were calculated and data analyzed by two-tailed Student's t-test. NPY was data analyzed by two-tailed Student's t-test. NPY was reduced significantly in frontal cortex by 23% (C, 86±4; S, 66±3; p<0.005), in temporal cortex by 25% (C, 76±4; S, 57±1; p<0.05), in caudate by 47% (C, 168±16; S, 98±19; p<0.05), but not in cerebellum (C, 2.6±0.6; S, 31±0.7). NPY concentrations did not correlate with either subject age or post-mortem interval suggesting that these factors did not contribute to the NPY reduction. This data provides guidence for a role of NPY. reduction. This data provides evidence for a role of NPY in suicide.

59.9

ALPHA2-ADRENERGIC BINDING IS NOT ALTERED IN SUICIDE.

V. Arango, P. Ernsberger, M.D. Underwood and J.J. Mann.

Labs. of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

We have previously shown that there is an increase in 5-HT₂ receptor binding in the prefrontal (PFC), but not in the temporal cortex of suicide victims compared to controls (Arch Gen Psychiatry, 43:954-9, 1986; Arch Gen Psychiatry, in press). In addition to the well-documented changes in a variety Psychiatry, in press). In addition to the well-documented changes in a variety of indices of the serotonergic system, other neurotransmitter systems seem to be involved in suicidal behavior. In the noradrenergic system we found that β-adrenergic receptor binding is increased in PFC of suicide victims compared to controls, and that α₁-adrenergic binding is increased in layers IV-V of PFC in the suicide group. Using quantitative autoradiography we now sought to study α₂-adrenergic binding in PFC of controls dying acutely from causes other than suicide and compare it to suicide victims. Both groups were paired for assay by matching for postmortem delay, age and gender (N=12 pairs). Toxicology was negative for centrally active drugs. Sections (15 μm) were pre-incubated, pre-washed and incubated in 4nM ³H-p-amino clonidine (²H-PAC) to label α₂-receptors. Non-specific binding was defined by parallel incubation with 100 μM epinephrine. Tissue sections and ³H-standards were exposed to Hyperfilm for 16-18 weeks, developed in GBX and quantified using a PC-based image analysis system (Imaging Inc.). The distribution of α₂-adrenergic receptors was the same in both groups and formed 5 isodensity bands corresponding to layer I, layer II, upper III, layers III-IV and α_2 -adrenergic receptors was the same in both groups and formed 5 isodensity bands corresponding to layer I, layer II, upper layer III, layers III-IV and layers V-VI. Binding was densest in layer I and upper layer III and lowest in layers V-VI. The suicide group did not differ from the control group in the level of α_2 -adrenergic binding in any of the cortical layers. The binding did not correlate with age (39 \pm 6 y) or postmortem delay (15 \pm 2 h). We conclude that, despite binding alterations in other adrenergic receptor subtypes, α_2 -adrenergic binding is not altered in PFC of suicide victims. This work was supported in part by PHS grant MH40210.

SPONTANEOUS ALTERNATION: AN ANIMAL MODEL FOR OBSESSIVE-COMPULSIVE DISORDER? E. Yadin, D. Pilchak, E. Friedman and W.H. Bridger. Dept. of Psychiatry, The Medical Colle of Pennsylvania, Philadelphia, PA 19129.

This study entailed the adoption of a well-known beha-The Medical College

vioral paradigm, spontaneous alternation, as a possible animal model for some of the symptoms observed in obsessive-compulsive disorder (OCD) in humans. Food- $\,$ deprived rats were run in a T-maze in which both a black and a white goal box were equally baited with a small chocolate chip. Each rat was given 7 trials every other day during which it was placed in the start box and allowed to make a choice. The mean number of choices till an alternation occurred was recorded. After a stable base-

of spontaneous alternation was achieved the effects of manipulating the serotonergic system were tested. Both the nonselective 5-HT agonist 5-MeODMT (1 mg/kg) and the more selective 5-HT_A agonist 8-OH-DPAT (3 mg/kg) disrupted spontaneous alternation, a change that was reversed by the nonselective 5-HT antagonist methiotherical control of the service of the servi (1 mg/kg). A course of chronic treatment (2x5 mg/kg for 21 days) with the selective 5-HT reuptake blocking agent fluoxetine had a protective effect on the 5-MeODMT-induced disruption of spontaneous alternation behavior.

Serotonergic manipulations of spontaneous alternation may be a simple animal model for the perseverative symptoms (or indecisiveness) seen in people diagnosed with OCD.

NEUROCHEMISTRY OF THE HUMAN LOCUS COERULEUS IN SUICIDE AND DEPRESSION, G.A. Ordway, P.S. Widdowson*, K. Streator-Smith and A.E. Halaris. Depts. Psychiatry, Pharmacology and Neuroscience, Case Western Reserve Univ. and MetroHealth Medical Center, Cleveland, OH 44109.

A role of norepinephrine (NE) in depression has been debated for many years. The principal source of NE in brain is the locus coeruleus (LC), which projects to many brain regions including the limbic system. Activation of alpha-2 adrenceptors (AARs) located in the LC modulates release of NE and activity of LC cells. We obtained post-mortem brain tissue from victims of suicide (n=13) and age-matched sudden death controls (n=13) to study AARs and NE in the LC. AARs were quantitated by autoradiography of binding of [125I]iodoclonidine (ICLO) to sections through the rostral LC. NE was measured by HPLC-EC in adjacent sections. No significant differences in ICLO binding (mean±S.E.M.) between control (29±4 fmol/mg protein) and suicide tissue (29±2 fmol/mg protein), or in NE concentration in LC between control (6.1±0.8 ng/mg protein) and suicide tissue (5.0±0.4 ng/mg protein) were observed. Comparisons of ICLO binding and NE in LC from those suicides with a history of depression (n=7) or violent suicides (n=7) to their respective age-matched controls revealed no differences. These data suggest that if the central NE system is perturbed in depression or suicide, then alterations in AARs or NE may be detected in terminal fields, but not in the LC.

BETA-ADRENERGIC BINDING IN SUICIDE VICTIMS. K.Y. Little, G.E. Duncan and G.R. Breese. University of North Carolina, Chapel Hill,

The catecholamine theory of Schildkraut and Prange postulates that changes in noradrenergic functioning lead to mood disorders. Although only 50% of suicide victims suffer mood disorders, studies of beta-adrenergic receptors in the brains of uncategorized suicides have provided mixed evidence generally suggesting increased numbers. In this study, we explored beta receptor binding in Broadmann's area 10 of 15 suicides versus matched controls, using homogenated membranes and I¹²⁵ pindolol, a specific beta receptor ligand.

homogenated membranes and 1225 pindolol, a specific beta receptor ligand. Autoradiography of hypothalamic beta binding was also done in 5 pairs.

Brain tissue was obtained at autopsy as authorized by the Chief Medical Examiner and quick frozen with dry ice. Control subjects were chosen to match suicides by age, sex, race, post mortem interval, and suddenness of death. About 20mg of tissue from the middle frontal gyrus at the medial header of the constraint comments were received in each subject. The accounts were received in each subject. border of the cerebral convexity was examined in each subject. The assay conditions were: tissue concentration 5mg/ml, total tube volume .2ml, 24°C for 30 minutes, dilution with cold buffer and rapid filtration. 150 pM of I 125 pindolol and 100 mM of isoproterenol were used. Specific binding averaged 70%. Autoradiography of hypothalamic sections was done with the same ligand and competition concentrations, and quantified using optical densitometry

Our results in suicides demonstrate a significant decrease in cortical betareceptors compared to controls (p = .01), an increase in hypothalamic beta receptors, and an inverse correlation between this binding within individuals. There appeared to be racial differences in the regulation of beta receptors.

59.12

ORBITAL GYRUS METABOLISM CORRELATES WITH EXPRESSED DISTRESS/ANXIETY AND TREATMENT RESPONSE IN OCD PATIENTS. JM Schwartz, LR Baxter*, ME Phelps, BH Guze*, JC Mazziotta, MP Szuba*, J Barrio*. UCLA School of Medicine, Los Angeles, CA 90024

Work by several groups using PET demonstrates increased metabolic rates (MR) in the orbital gyrus (OG) of patients with obsessive-compulsive disorder (OCD). We are studying a series of patients with OCD, attempting to demonstrate changes in regional MR prior and subsequent to treatment with either pharmacologic or cognitive biobehavioral therapy. Commensurate clinical responses were seen for both of these

Preliminary data analysis (N = 14) shows significant correlations (p≤.02) between right (rt) OG MR with respect to ipsilateral hemisphere MR (Hem) (OG/Hem) and Profile of Mood States (POMS) Anger/Hostility, Tension/Anxiety, and Depression/Dejection scales. Further, 10 subjects studied prior and subsequent to treatment (5 medication, 5 behavioral) showed a significant correlation between % change on Yale-Brown Obsessive Compulsive Scale scores and change in rt OG/Hem ratio $(r_s = .57, p = .045; tau = .41, p = .05).$

These data indicate that orbital gyrus may be involved in the mediation of sensations relevant to symptom expression in OCD.

ELEVATION IN PAIN THRESHOLDS IN BULIMIA NERVOSA P. L. Faris, N. C. Raymond*, L. A. Howard*, R. McCollister*, J. E. Mitchell* and E. D. Eckert*. Department of Psychiatry, University of Minnesota, Minneapolis MN 55455.

Converging lines of evidence suggest that some components of nociception and food intake may be subserved by common neurochemical mechanisms. In particular, short-term satiety is known to involve peripheral responses to the ingestion of a meal which are mediated in part by afferent vagal fibers. The vagus nerve has also been implicated in opioids. Other neurotransmitters, e.g. CCK, are thought to function in

opioids. Other neurotransmitters, e.g. CCK, are thought to function in both short-term satiety and in nociception. Thus, we hypothesize that eating disorders involving disruption of short-term satiety mechanisms may also be accompanied by alterations in nociceptive processing.

Bulimia nervosa is characterized by prolonged feeding bouts, without a feeling of satiety; in other words, an abnormality in short-term satiety mechanisms. We have investigated nociceptive and tactile responsivity in 28 subjects fulfilling DSM-IIIR criteria for bulimia nervosa and 31 normal volunteer. Tactile thresholds were determined with Voo Eraw fibers wind volunteer. Tactile thresholds were determined with Von Frey fibers using an ascending/descending method of limits. Tactile thresholds were not found to differ between the two groups (t=.237). Nociceptive thresholds were determined using a Ugo Basile analgesia meter, which steadily increases the force placed on the dorsal surface of a finger. Both pain detection (DT) and pain tolerance (TT) thresholds were determined for each finger. Bulimic subjects were found to have a consistent elevation in both DT and TT compared to normal controls (p <. 004, DT; p<.006, TT).[Supported by MH 43077, MH43296 (JEM), & RSDA MH00595(PLF)]

PHENYTOIN IMPROVES BRAIN FUNCTIONS AMONG IMPULSIVE AGGRESSIVE PRISONERS. E. Barratt, T. Kent*, S. Bryant, A. Felthous, M. Stanford. Dept. of Psychiatry and Behavioral Sciences, Univ. of Texas Medical Branch,

Galveston, TX 77550.

Phenytoin has been shown to reduce impulsive aggressive behaviors (Barratt, et al., J. Clin. Pharm., 29:851, 1989). In the current extension of this research, phenytoin significantly changed cortical event related potential topomaps (ERPT) toward a more normal profile.

Prisoners (N=20) with a history of aggressive behaviors were administered phenytoin (300mg/day) or a placebo (6 weeks each) in a double-blind cross over study. ERP's were recorded during several tasks including an "off-target" task designed to study impulsiveness. Data were target" task designed to study impulsiveness. Data were analyzed using topographical and related statistical analyses. In contrast to medical students (N=20) and adult controls (N=20), the prisoners had well defined frontal lobe and diffuse right hemisphere positivity during the window for the late positive component (LPC)(250-600ms) in their baseline recordings. Phenytoin significantly reduced the frontal lobe activity and diffuse right hemisphere activity with a better focused posterior LPC. The placebo did not. These data are consistent with the hypothesis that impulsiveness is a frontal lobe function and suggests, further, a right hemisphere involvement.

NEUROMUSCULAR DISEASES

SKELETAL MUSCLE ULTRASTRUCTURAL PATHOLOGY IN ACUTE POLY-RADICULONEUROPATHY. A. Márquez*, H.J. Finol, B. Muller* and I. Montes de Oca*. Medicine, Sciences and Dentistry Faculties. Universidad Central de Venezuela. Apartado 50587. Caracas 1050. VENEZUELA. Although motor disturbances are the main features in acute polyradiculoneuropathy (Guillain-Barré syndrome)and muscular atrophy and pain can be present in it, the skeletal muscle pathology of this syndrome has been poorly studied. In this work we report the ultrastructural alterations observed in a muscle biopsy made for diagnostic pur ations observed in a muscle biopsy made for diagnostic pur poses in a patient with an acute polyradiculoneuropathy, a 15 years old girl who developed an ascending, bilateral muscle weakness which produced a nearly complete flaccid paralysis from the neck down. The patient needed respir-atory assistance. Lumbar puncture showed an increase in protein content and no pleocytosis. The study exhibited the typical abnormalities of neurogenic atrophy (loss of myofibrils, alterations of sarcotubular system and folding of muscle basement membrane) and several findings not usually observed in denervated muscle as fiber necrosis, sually observed in denervated muscle as fiber necrosis, capillary alterations and mononuclear cell infiltration. The histopathological picture we observed is similar to that in the muscle compromise of autoimmune diseases. This.work suggests the possibility for a common autoimmune mechanism in the muscular and nervous lesion in this disease. Supported by grants from the CDCH of UCV, the British Council Venezuela and Fundación Polar.

MUSCLE PROTEIN SYNTHESIS IN CHRONIC ETHANOL-FED ADULT RATS. I. Held, H. Yeoh* and K. Price*. Neuroscience esearch, VA Hospital, Hines, IL 60141 and Dept.

Biochem. Loyola Univ. Med Sch., Maywood, IL 60135.
Alcoholic myopathy frequently occurs during chronic alcoholism, but the biochemical alterations that lead to the loss of muscle proteins are not clear. The objective of this preliminary study was to determine the effect of long-term ethanol ingestion on protein synthesis in different types of skeletal muscle of adult rats. The ribosomal activity and protein content were determined in the soleus and extensor digitorum longus (EDL) from 16-month-old Fisher 344 rats fed a nutritionally complete liquid diet containing 6.7% ethanol for 2, 4 and 6 months, and from weight-matched control rats pair-fed an isocaloric liquid diet. Evaluation of muscle ribosomal activity was based on the in vivo incorporation of 3H-puromycin during elongation of peptide chains on the ribosome. The level of 3H-label (DPM) incorporated into trichloroacetic acid-precipitable material extracted from the whole muscle was measured at 30 min after tail-vein injections of 3Hpuromycin (2.5 μ Ci/ μ mole; 3 μ moles/100 gm rat), and the specific radioactivity was expressed as dpm/mg muscle protein. Altogether, the results suggest that the ethanol-induced loss of muscle protein observed at 6 months may be due to earlier alterations in protein synthesis at the ribosomal level.

EXPERIMENTAL DIABETIC NEUROPATHY: EARLY FEATURES AND EFFECTS OF MICROVESSEL MANIPULATION

D.W. Zochodne, L.T.Ho*. Department of Medicine, Queen's University, Kingston, Ontario K7L 3N6. Studies of streptozotocin-induced diabetic neuropathy (ESDN) at 4 months have identified endoneurial oligemia and hypoxia - features which might respond to microvessel manipulation. In normal nerve, guanethidine adrenergic sympathectomy enhances perfusion. We studied 6 week ESDN in Sprague-Dawley rats: controls, diabetics and diabetics with concurrent guanethidine sympathectomy. In diabetic animals there was slowed mixed caudal conduction and resistance to ischemic conduction failure (RICF). Oligemia was not present, but oxygen tensions were shifted in the hypoxic direction. In the sympathectomized animals, microvascular resistance was not lowered, but there was less shift of the oxygen tension histogram. Mixed caudal conduction velocity and RICF values were similar to non-sympathectomized diabetics, but motor amplitudes recruited from caudal fibers motor amplitudes recruited from caudal libers were higher. In summary, our studies suggest that hypoxia may be more prominent than oligemia in early ESDN and sympathectomy may improve the oxygen profile. (Supported by CDA, MDA and MRC).

NEUROFILAMENT PHOSPHORYLATION AND UBIQUITINATION IN FROG MOTONEURONS AFTER VENTRAL ROOT AXOTOMY <u>S. Murayama, D. L. McIlwain & K. Suzuki</u>, Depts of Pathology and Physiology, Univ. Of North Carolina, Chapel Hill, NC, 27599-7525

Phosphorylation of neurofilament and ubiquitination were studied immunocytochemically in frog motoneurons after axotomy. The ninth and tenth ventral roots of grass frogs (Rana pipiens) were transected unilaterally on the left side and sacrificed at 10, 20 or 40 days after operation. The corresponding segments of the spinal cord were fixed in 4% paraformaldehyde for two hours and frozen sections were immunostained with avidin biotin complex method by monocloncal anti-neurofilament (SMI31 and 06-17, Sternberger) or anti-ubiquitin antibody (DF2, Mori et al 1987). Both SMI31 and 06-17 recognize phosphorylated epitopes of the middle molecular weight staining of motoneurons with SMI31 or 06-17 was observed on the operated, but not the control side, and reached a peak by 20 days post-axotomy. Perikaryal staining of injured motoneurons with DF2 also reached a peak by 20 days, while it remained weak on the control side. Our study demonstrates axotomy-induced phosphorylation of neurofilament and ubiquitination in perikaryal cytoplasm of motoneurons. This system may be a good model for the study of human motor neuron disease, where lower motoneurons contain epitopes for phosphorylated neurofilament and ubiquitin.

REGULATION OF EXCESSIVE INTRACELLULAR CALCIUM ACCUMULATION (EICA) AND MUSCLE DECENERATION BY DILTIAZEM (DTZM) IN DYSTROPHIC HAMSTERS (DH). S.K. Bhattacharya, P.L. Johnson, T.A. Adamec*, and D.R. Shanklin*. Departments of Surgery, Neurobiology & Pathology, U. of Tenn., Memphis, TN 38163. Membrane-mediated EICA plays a fundamental pathogenetic role in muscular dystrophy. Oral DTZM (25 mg/kg BW/day) reduced EICA, plasma CK, and histopathology in heart (HT) and rectus femoris (RF) of DH (Muscle & Nerve, 5:73, 1982). DTZM was reported safer and more effective than and rectus femoris (RF) of DH (<u>Muscle & Nerve</u>, 5:73, 1982). DTZM was reported safer and more effective than Nifedipine or Verapamil. Since t_{1/2} of DTZM in circulation is short, we studied i.p. DTZM (80 mg/kg BW/day) in CHF-146 strain DH and CHF-148 normal hamsters (NH), for 7 months starting at age 37 days; untreated hamsters served as controls. HT and RF were biopsied for Ca and Mg quantitation, histology and EM. Relative cardiac enlargement (RCE) was measured in mg HT/100 gm BW. EICA in HT and RF, plasma CK, RCE, and mortality of DTZM treated DH were reduced (p<0.001). Muscle degeneration, fatty infiltration and fibrosis were also Ca deposition, fatty infiltration, and fibrosis were also reduced. EM of dystrophic myocardium revealed calcified mitochondria and destruction of normal striations, whereas treated HT had no calcification. The larger dose of i.p. DTZM, compared to oral, produced much superior and lasting effects in DH. Higher dose and improved delivery may enhance therapeutic prognosis in DMD boys treated with 8 mg of DTZM/kg BW/day (Neurology, 38:609, 1988). These data reconfirm that DTZM has profound cardioprotective and overall salutary effects in DMD. NIH Grant #AR-38540.

A NOVEL MECHANOTRANSDUCING CHANNEL IN SKELETAL MUSCLE FROM THE *mdx* MOUSE. A. Franco¹ and J.B. Lansman².

Graduate Program in the Neurosciences and ² Department of Pharmacology, UCSF, San Francisco, CA. 94143.

An alteration of myoplasmic calcium homeostasis involving elevated

intracellular Ca is characteristic of Duchenne's muscular dystrophy. The mechanism by which calcium accumulates is not known. We recently described the presence of a novel mechanotransducing channel in myotubes from the mdx mouse, an animal model for human Duchenne's muscular dystrophy (Nature 344: 670-673, 1990). Unlike previously described mechanotransducing channels in normal muscle which open in response to stretching the membrane, a subset of channels in *mdx* myotubes are open continuously at rest and become silent when the membrane is stretched. Both the stretch-activated and stretch-inactivated channels observed in mdx myotubes have identical single-channel conductances and selectivities for divalent and monovalent cations, but are ~5 times more permeable to Ca²⁺ than to monovalent cations. Furthermore, both channel types are equally sensitive to stretch regardless of whether it opens or closes the channel and both types of channel open in response to membrane depolarization. In some instances, conversion of stretch-activated to stretch-inactivated gating can be observed while recording from a single patch. We propose that stretch-inactivated channels appear in max myotubes through the modification of existing stretch-activated channels and that these channels may provide a pathway for calcium leakage into dystrophic muscle.

Characterization of the Dystrophin Glycoprotein Complex in Isolated Skeletal Muscle Sarcolemma. K. Ohlendieck, J. M. Ervasti and K. P. Campbell, Howard Hughes Med. Inst., Dept. of Physiology & Biophysics, Univ. of Iowa Col. of Med., Iowa City, IA 52242.

A library of monoclonal antibodies that are specific for the sarcolemma, the sarcolemma and transverse tubular system, or the transverse tubular system of rabbit skeletal muscle have been prepared and used in the development of a isolation procedure for skeletal muscle sarcolemma. Briefly, light muscle membranes were treated with 0.6M KCl and a crude surface preparation was isolated by sucrose density gradient centrifugation. A highly purified preparation of sarcolemma was isolated from the crude preparation by wheat The purified sarcolemma was enriched in the germ agglutination. sarcolemma marker proteins and including the components of the dystrophin glycoprotein complex. The dihydropyridine receptor, a t-tubule marker, and the Ca2+-ATPase of sarcoplasmic reticulum were greatly diminished in the sarcolemma preparation. SDS-PAGE and densitometric scanning indicated that dystrophin comprised one percent of the total protein in the sarcolemma Furthermore, immunofluorescence labeling localized components of the dystrophin glycoprotein complex to the cell periphery of skeletal muscle cells. Fast and slow muscle fibres exhibited the same intensity of immunofluorescence staining in the sarcolemma. Our results demonstrate that the dystrophin glycoprotein complex is exclusively localized in the sarcolemma and that dystrophin is the major component of the cytoskeletal network underlying the sarcolemma of the skeletal muscle cell. KPC is an Investigator of the Howard Hughes Medical Institute. JME is an NINDS postdoctoral fellow.

IMMORTALIZATION AND DIFFERENTIATION OF MDX MOUSE

DE Bredesen, MD Seelig*, J Yang*, and N Kedersha*. UCLA Neuropsychiatric Institute, Los Angeles, CA 90024-1769.

Therapy for Duchenne's muscular dystrophy (DMD) may now be feasible because of (1) identification of the dystrophin gene (Koenig et al., Cell 1987;50:509) and (2) conversion of muscle fibers of mdx mice from dystrophin-negative to dystrophin-positive by injection and fusion of normal myoblasts (Partridge et al., Nature 1989;337:176). One of the remaining problems is the production of large numbers $(>10^8)$ of autologous dystrophin-positive myoblasts, since Duchenne's myoblasts obtained at biopsy have a reduced mitotic capacity (Blau et al., PNAS 1983:80:4856).

We and others have recently found that temperature-sensitive (ts) immortalized neural cells may be utilized to produce genetically engineered neural transplants (Whittemore et al., Neurosci Abs 1988:233.1; Bredesen et al., Neurol 1989;39:124; Bredesen et al., Ann Neurol 1990;27:205). We have used a similar approach with mdx myoblasts. Control C57Bl/6 and mdx myoblasts were cultured at postnatal day 1, and infected with a recombinant retrovirus constructed by Frederiksen et al. (Neuron 1988;1:439) that effects expression of a ts large T antigen of SV40 (IsAS8). Cells from both C57BI/6 and mdx selected in G418 proliferated at 34°; at 38°, the cells fused to form myotubes, then exhibited frequent contractions. After 7 days at 38°, striations began to appear. Immunocytochemical staining for spectrin, for a cytoskeletal marker, and for vaults (a ribonucleoprotein structure) was for a cytosketetal marker, and for valuts (a monucleoprotein structure) was indistinguishable from control primary cultures. PCR of total RNA was performed using primers flanking the mdx point mutation. Dystrophin sequences were detected in both groups at 34°, increasing in both cases with fusion at 38°. We hope that a similar approach may be useful for the expansion, modification, and reimplantation of autologous cells from patients with degenerative disorders

such as DMD.

A Sarcolemmal Glycoprotein Linked to Dystrophin is Deficient in Dystrophic Muscle. J.M. Ervasti, K. Ohlendieck, S.D. Kahl and K.P. Campbell. Howard Hughes Medical Institute and Dept. of Physiology and Biophysics, University of Iowa College of Medicine, Iowa City, IA 52242.

We have previously shown that dystrophin can be purified from detergent solubilized rabbit skeletal muscle membranes using WGA Sepharose because of its tight association with a sarcolemmal glycoprotein (Campbell, K.P. and Kahl, S.D. <u>Nature</u>, 338:259-262, 1989). Here, we report that dystrophin from rabbit skeletal muscle is part of a large (-18S) oligomeric complex as determined by sucrose gradient centrifugation. In addition to dystrophin, the complex contains a 59 kDa protein triplet and four glycoproteins of 156 kDa, 50 kDa, 43 kDa and 35 kDa, all in stoichiometric concentrations relative to dystrophin. Monoclonal antibodies specific for the 156 kDa or the 50 kDa glycoprotein showed immunofluorescence staining only on the cell periphery of cryostat sections which indicates a restricted localization of the complex to the sarcolemma of skeletal muscle. Immunoaffinity beads specific for dystrophin or the 50 kDa glycoprotein selectively adsorb the dystrophin-glycoprotein complex indicating that the complex is tightly associated. Of particular interest was the marked reduction of the 156 kDa glycoprotein in muscle from mdx mice and patients afflicted with Duchenne muscular dystrophy. In dystrophic muscle, thus, the absence of dystrophin may lead to the loss of a dystrophinassociated glycoprotein(s) which may be the first step involved in the molecular pathogenesis of muscular dystrophy. The elucidation of the function of these proteins should help to define the function of dystrophin and explain how its absence results in Duchenne muscular dystrophy. K.P. Campbell is an Investigator of the Howard Hughes Medical Institute. J.M. Ervasti is an NINDS post-doctoral fellow (NS07247-04). This work was also supported by MDA.

DOES DYSTROPHIN ACCUMULATES PRE OR POSTSYNAPTICALLY AT THE NEUROMUSCULAR JUNCTION? Lab. of Neurobiology, Hôp. Enfant-Jésus and Laval Univ., Québec, P.Q., Canada, G1J 1Z4.

Muscle cross sections of female mouse heterozygote for the mdx (dystrophic) gene were examined for the colocalization of dystrophin an acetylcholine receptors. The site of neuromuscular junctions (NMJs) were localized by revealing the acetylcholine receptors with α-bungarotoxin coupled to cascade blue. The presence of dystrophin on the same cross sections was revealed by an immunoperoxidase method. Four different observations were made in these heterozygote animals for the coexistence of AChR and dystrophin. First, α -bungarotoxin sites (i.e. NMJs) were observed on dystrophin positive muscle fiber cross sections with an accumulation of dystrophin at these sites. Secondly, α-bungarotoxin sites were observed on dystrophin positive fibers without a dystrophin accumulation at NMJs. In a third type of observations, there was a coexistence of α -bungarotoxin and dystrophin labelling at NMJs on muscle fibers which remaining perimeter was negative for dystrophin. The fourth observation was the presence of NMJs, identified by α -bungarotoxin, on muscle fibers completely negative for dystrophin even at the NMJ. These observations suggest that either dystrophin is initially expressed by the muscle fiber near the NMJ possibly due to a trophic effect of the nerve terminal or that dystrophin is present not only in the muscle membrane but also in the presynaptic nerve terminals.

EFFECTS OF BETA-ADRENERGIC AGONISTS IN MUSCULAR DYSTROPHY OF THE CHICKEN. R.K. Entrikin, R.T. Abresch* and D.B. Larson*. Univ. of California, Davis, CA 95616.

Of over 1,000 compounds evaluated previously for beneficial effects on hereditary avian muscular dystrophy, glucocorticoids were the most effective. Unfortunately, they improved muscle function only at doses that reduced growth rate. Isoproterenol, however, increased muscle function at doses that had little effect on growth rate. In the present study two specific beta-2 agonists, on growth rate. In the present study two specific beta-2 agoinsts, salbutamol and metaproterenol (Sigma, St. Louis), were administered i.p., once-daily to dystrophic Line 413 chicks, beginning on day two ex ovo, according to an approved animal use protocol. Effects were assessed by exhaustion scores (ES, the consecutive number of times a chick could rise from the supine in immediatesuccession during a single trial) and plasma creatine kinase (CK) activity. In brief, beta-2 agonists were equally effective to isoproterenol. ESs of dystrophic birds were increased 15-fold (to 75% of normal Line 412 control levels), and plasma CK activity was reduced by up to 90%. Compounds with beta-1 effects have not been evaluated in human Duchenne muscular dystrophy (DMD), mainly due to concerns over the known cardiac abnormalities in DMD patients. Since beta-2 agonists have fewer adverse cardiac effects, they seem more promising as candidates for human trials. (Supported by NIDRR Grant #H133B80016 and the Muscular Dystrophy Association.)

MONOCLONAL ANTI-TITIN IGG AUTOANTIBODIES
PRODUCED BY MYASTHENIC THYMIC B CELLS. C. L.
Williams, J. E. Hay*, T. W. Huiatt*, V. A.
Lennon. Mayo Clinic, Rochester, MN 55905 and
Iowa State University, Ames IA 50011.
Striational autoantibodies (StrAb) binding

to contractile elements of muscle occur in to contractile elements of muscle occur in patients with myasthenia gravis (MG) or thymoma. We reported previously that monoclonal IgM StrAb from MG patients bound to actin, α -actinin and myosin (J Exp Med 164: 1043, 1986). We now have isolated myasthenic thymic B cell clones secreting IgG StrAb that bind to titin, a major myofibrillar protein unique to striated muscle. Titin specificity was established by 1) immunoblot reactivity was established by 1) immunoblot reactivity with bovine skeletal muscle titin and immunofluorescent staining of myofibrils 2) immunofluorescent staining of myofibrils and cultured muscle cells in a pattern identical to that produced by polyclonal rabbit anti-titin IgG. IgG anti-titin anti-bodies were similarly identified in serum from four patients with MG and thymoma (including the donor of the B cell clones), but not in serum from four patients without thymoma. Our data implicate titin as a major specificity of StrAb associated with thymoma. Supported by NIH grant NS 23537 (VAL) and an MDA grant (TWH). (TWH)

SYMPOSIUM. HAIR CELLS OF THE INNER EAR: STRUCTURE, TRANSDUCTION, AND ACTIVE MOTION. D.P. Corey, Mass. Gen. Hosp.

SYMPOSIUM. HAIR CELLS OF THE INNER EAR: STRUCTURE, TRANSDUCTION, AND ACTIVE MOTION. D.P. Corey, Mass. Gen. Hosp. (Chairman); L. Tilney*, Univ. Penn.; A.J. Hudspeth, Southwestern Med. Ctr.; J.F. Ashmore, Univ. Bristol.

Two recent advances in sensory neuroscience have been a greater understanding of the active biomechanics of the auditory system, and a growing appreciation of mechanically activated ion channels as a third class of channel, distinct from voltage- and ligand-gated channels. This symposium will pull together these areas by discussing sensory transduction and force generation by hair cells, the receptor cells of the auditory and vestibular systems.

Recent work has given us a good model for transduction by hair cells: The mechanically sensitive organelles of the cell are the stereocilia, each one a membrane-bounded, ordered array of actin filaments cross-linked by fimbrin. A remarkable developmental sequence produces the variable lengths and arrangement of stereocilia within the bundle. A fine filament extends from the tip of each stereociliam to the side of the tallest adjacent stereocilium; these 'tip links' are thought to be directly attached to ion channels near the tips of the stereocilia. The geometry of the bundle is such that displacement of the bundle in the excitatory direction stretches each tip link, increasing tension on the channels and thereby increasing their probability of opening. The movement associated with the conformational change of opening has been measured as about 4 nanometers. The increased tension initiates an adaptation process that restores the channel's open probability to its resting level; this seems to involve a movement of each tip-link attachment point along the side of each stereocilium by an active cytoplasmic motor, which has some similarities to myosin. Two observed mechanical correlates of the adjustment are a change in bundle stiffness with the same timecourse as adaptation and an active movement of an unrestrained bundle with correlates of the adjustment are a change in bundle stiffness with the same timecourse as adaptation and an active movement of an unrestrained bundle with manipulations that affect the adaptation process. Outer hair cells of mammalian cochlea have an additional active movement that is a rapid, longitudinal contraction with depolarization; this may mediate mechanical amplification of vibration by the basilar membrane.

DYSTROPHIN EXPRESSION IN THE BRAIN. F.M. Boyce¹. M.P. Rosenberg², A.H. Beggs¹ and L.M. Kunkel¹. ¹Children's Hospital and Howard Hughes Medical Institute, Harvard University, Boston, MA 02115, and ²Dept. of Molecular Biology, Squibb Institute for Medical Research, Princepts 11, 108642. Princeton, NJ 08543.

Princeton, NJ 08543.

Dystrophin is a large (427 kD) protein with homology to the spectrin/actinin family of cytoskeletal elements. Dystrophin is expressed in all types of muscle tissue, and absence of dystrophin in muscle results in Duchenne muscular dystrophy, a relatively common and lethal inherited disease of young males. The only other tissue that contains significant levels of dystrophin is the brain. The function of dystrophin in the brain has not been established, but about 30% of Duchenne patients exhibit some degree of mental retardation. This raises the possibility that dystrophin may play a role in brain independent of its function in muscle.

We have isolated the genomic region which encodes an alternative

in brain independent of its function in muscle.

We have isolated the genomic region which encodes an alternative promoter for dystrophin in the brain. This region is located over 90 kb 5' to the promoter used in muscle. Cellular transfection experiments using established cell lines have suggested that the brain promoter is much weaker than the muscle promoter in each cell line tested. To more accurately assess the transcriptional activity of each promoter, we have constructed several lines of transgenic mice containing either the brain or muscle promoter linked to a bufferse reporter erec. The existence of a separate linked to a luciferase reporter gene. The existence of a separate transcriptional apparatus for dystrophin in the brain is further evidence of a functional role of dystrophin in the brain.

60.14

INHIBITION OF NEUROMUSCULAR TRANSMISSION IN THE LIZARD BY SERUM FROM PATIENTS WITH LAMBERT-EATON MYASTHENIC SYNDROME (LEMS).

C.A. Lindgren and D.R. Mellon. Dept. of
Biology, Allegheny College, Meadville, PA

Lambert-Eaton Myasthenic syndrome (LEMS) Lambert-Eaton Myasthenic syndrome (LEMS), a human autoimmune disorder characterized by a decrease in acetylcholine release at the neuromuscular junction, is thought to be caused by the production of antibodies which react with calcium channels in the motor nerve terminals. Previous studies have demonstrated that blood serum from affected humans can passively transfer the symptoms of LEMS to mouse and rat. The present study shows that LEMS effects can be induced at the neuromuscular junction of the lizard (Anolis neuromuscular junction of the lizard (Anoli neuromuscular junction of the lizard (Anolis carolinensis) by applying serum from patients with LEMS in vitro. Although sera from humans without demonstrated LEMS symptoms had no effect, sera from certain patients diagnosed with LEMS significantly impaired neuromuscular transmission. The exact time course of the effect was variable; however, impaired transmission typically appeared within 4-6 hours of the application of serum.

SYMPOSIUM

TETANIC STIMULATION CAUSES AN APV-SENSITIVE INCREASE IN CAMP LEVELS IN RAT HIPPOCAMPAL CA1 REGION. D.M. Chetkovich and J.D. Sweatt. Div. of Neuroscience, Baylor College of Medicine, Houston, Texas, 77030.

Cyclic AMP has been implicated as being important in learning and memory in Drosophila and Aplysia, as well as in playing a role in the induction of long-term potentiation (LTP) in the dentate gyns and CA3 region of the hippocampus. The aim of the present study was to identify changes in cAMP in rat hippocampal CA1 region after tetanic stimulation and to investigate possible mechanisms for these changes. High frequency stimulation (100 Hz for 1 sec, 5x at 2. Hz, sufficient to induce LTP in >95% of slices) of the Schaeffer collaterals caused a 46±9% (n=16) increase in cAMP levels in the CA1 region. This increase was blocked by bath application of 50 μM D.L-2-amino-5-phosphonovaleric acid (APV) (6±8% increase in cAMP, n=5), suggesting that the NMDA subtype of excitatory amino acid (EAA) receptor mediates the cAMP increase. Furthermore, a 10 minute bath application of 5 mM glutamate caused a 121±9% increase in cAMP (n=3), and this response was attenuated (10±5% increase above control, n=4) by bath application of 50 μM APV. This finding further substantiates a role for NMDA receptors in controlling cAMP levels. To determine the mechanism by which EAA receptors might elicit an increase in cAMP levels, adenylyl cyclase (AC) activity was assayed in membranes prepared from rat CA1 region. 10 μM GTP and 10 μM forskolin were found to elevate AC activity 45±5% and 1300±320% (n=4), respectively, while 5 mM glutamate did not affect AC activity when applied alone or with 10 μM GTP. However, in the presence of 400 nM calmodulin, Ca++ affected AC activity in a biphasic manner. AC was inhibited when free Ca++ was above 100 μM but stimulated to 600% above control when free Ca++ was in the low micromolar range. These data suggest that NMDA receptor activation causes an increase in cAMP secondary to increases in intracellular Ca++. Thus, tetanic stimulation and the resultant NMDA receptor activation may cause an elevation in cAMP levels in hippocampal CA1 region via this mechanism. Overall, these data suggest the possibility that

65.3

THE ROLE OF THE CALPAINS IN LONG-TERM POTENTIATION. J.B. Denny*, J. Polan-Curtain*, A. Ghuman*, M.J. Wayner and D.L. Armstrong. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78285

While the calpains have been proposed to play a role in memory, their action in the development of long-term potentiation (LTP) has heretofore not been defined. We show that LTP is blocked by the extracellular application of two newly-developed, highly potent calpain inhibitors. Incubation of hippocampal slices with 6 micromolar N-acetyl-leu-leu-norleucinal or N-acetyl-leu-leu-methioninal for 1 hr blocked the induction of LTP in the Schaffer collateral-CAl synaptic zone but had no effect if applied 1 hr after tetanization. Injection of the above peptides or leupeptin into the intact rat brain blocked the induction of LTP in the perforant path-granule cell synaptic zone. Baseline synaptic transmission in all cases was unaffected by the presence of the inhibitors. Although the calpains have been shown to convert purified protein kinase C to protein kinase M, we find that this conversion is not required for LTP maintenance since application of the membrane-permeable PKM inhibitor staurosporine has no effect on established LTP. The action of the calpains on other substrates is required, however, and these substrates may be cytoskeltal proteins and possibly other kinases. Supported by NIH grants CMO7717-10 and RR08194.

KINETICS OF PKC ACTIVATION CONSTRAIN THE TEMPORAL SPECIFICITY OF PKC-BASED NEURONAL PLASTICITY: A QUANTITATIVE MODEL. <u>C. Chen.</u> Computation & Neural Systems Program, 216-76 Caltech, CA 91125.

Protein kinease C (PKC), activated by phospholipid, calcium and diacylglycerol (DG), underlies various neuronal plasticity mechanisms. However, the kinetic interaction among these activators remains unclear. Based on various experimental data, a quantitative two-step model is proposed for PKC activation kinetics. PKC activation consists of: (1) a calcium- and phospholipid-dependent translocation from the cytosol to the membrane, and (2) a DG-dependent activation within the membrane. Phospholipid is rich near the membrane, and therefore is not a limiting factor. Three calcium kinetics (slow, intermediate and fast), representing a wide range of calcium dynamics in living cells, are used to test the model along with the DG kinetics empirically derived from experiments in human platelets (Takai, Y. et al., Adv. in Cyclic Nucleotide Res., 14:310, 1981). The model predicts that the degree of PKC activation depends on the timing between DG and calcium. Maximal PKC activation occurs when the peak of calcium lags DG for 5-10 sec. Consequently, the model indicates that the cooperative nature of PKC activation constrains the temporal window in which two intracellular messengers can induce PKC-based neuronal plasticity, such as associative LTP in hippocampal neurons.

PERSISTENT ALTERATION OF PROTEIN KINASE ACTIVITY DURING THE MAINTENANCE PHASE OF LONG-TERM POTENTIATION. E. Klann and J.D. Substit. Phys. of Neurosians Physics Claigns of Medicine Neurosian Physics (1984) 2014.

Sweatt. Div. of Neuroscience, Baylor College of Medicine, Houston, Texas, 77030. Various reports have suggested a role for persistent kinase activation as a mechanism for the maintenance of long-term potentiation (LTP) in the hippocampus. To test this hypothesis, we measured protein kinase activity in homogenates of the CA1 region of rat hippocampusl slices 45-60 minutes after the induction of LTP. LTP was induced by tetanic stimulation of the Schaffer collateral pathway (100 Hz for 1 sec., 3 trains delivered 5 min. apart, 181±15% of control EFSP slope, n=16). Slices were frozen, dissected, and homogenized in buffer containing 50 mM HEPES, pH 7.4, 10 mM MgCl₂, 1 mM EGTA and 1 mM EDTA. Homogenate was added to reaction mixtures containing 100 μM ³²P-ATP and 2 μg of the exogenous kinase substrate myosin light chain (MLC). After SDS-PAGE, incorporation of ³²P into MLC was quantitated using autoradiography and densitometric scanning. We have detected an LTP-induced increase in phosphorylation of both MLC (215±29% of control, n=9) and endogenous substrates using this assay. As the assay mixture contained EGTA, the elevated phosphorylation is independent of Ca²⁺. The increase in Ca²⁺-independent substrate phosphorylation is due to increased kinase activity rather than decreased phosphatase activity as sodium pyrophosphate (1-2 mM) did not alter this increase (326±64% of control MLC phosphorylation, n=7). Treatment of the slices with 50 μM D,L 2 amino 5-phosphonovaleric acid (APV) blocked both the induction of LTP (111±6% of control EPSP slope, n=3) and the induction of the alteration in protein kinase activity (90±24% of control MLC phosphorylation, n=3), indicating NMDA receptor activation is necessary for the establishment of the long-term change in protein kinase activity. We also have found that the increased kinase activity in homogenates is blocked by the addition of PKC (19-36), a selective peptide inhibitor of protein kinase activity in homogenates is blocked by the addition of PKC (19-36), a select

MODULATION OF AMPA/QUISQUALATE (A/Q) RECEPTORS BY PHOSPHOLIPASE A₂ (PLA₂): A NECESSARY STEP IN LTP? <u>G. Massicotte_P. Vanderklish*. G. Lynch and M. Baudry.</u> NIBS Program, University of Southern California, Los Angeles, CA 90089-2520.

The expression of LTP in area CA1 of hippocampus has been proposed

The expression of LTP in area CA1 of hippocampus has been proposed to result from an increased responsiveness of the AMPA/quisqualate receptors, while the induction of LTP is triggered by the activation of Cadependent processes including possibly calpain and PLA2. Systemic administration of kalnic acid (KA) produces a rapid activation of calpain in the hippocampus and we used this procedure to explore the relationships between calpain, PLA2 and LTP. We determined both the degree of LTP in hippocampal silces and the effect of PLA2 on the binding properties of the A/Q receptors in brain membranes from control and KA-injected rats. In both hippocampal and cerebellar membranes from control rats PLA2 treatment produced a significant increase (40%) in the binding of ³H-AMPA to the quisqualate receptors. The effect of PLA2 on ³H-AMPA binding to hippocampal membranes was markedly reduced in KA-treated rats, while the effect was not significantly modified in the cerebellum. A large reduction in the magnitude of LTP induced by a theta burst stimulation paradigm was observed in area CA1 of hippocampal slices prepared from KA-treated rats. Injection of KA was accompanied by an important breakdown of spectrin, a substrate for calpain, in the hippocampus but not in the cerebellum. Treatment of telencephalic membranes with calpain also blocked the PLA2 effect on the ³H-AMPA binding. These findings suggest that the PLA2-induced modification of A/Q receptors is a necessary step in the development of LTP.

EVIDENCE FOR A PRESYNAPTIC ROLE OF PROTEIN KINASE C IN HIPPOCAMPAL MOSSY FIBER SYNAPTIC TRANSMISSION. <u>D.M. Terrian</u>, <u>D.K. Ways* and R.L. Gannon</u>. Depts. of Anatomy and Medicine, East Carolina University School of Medicine, Greenville, NC 27858.

it has been suggested that long-term potentiation in the hippocampal mossy fiber (MF) synapse involves fundamentally different presynaptic mechanisms from those employed by other hippocampal synapses, since both protein kinase C (PKC) and phosphoprotein F1 appear to be absent in MF terminals. In the present study we evaluated this proposal by directly comparing the metabolic properties of hippocampal MF synaptosomes and a conventional P2 synaptosomal fraction prepared from the same hippocampal tissue. PKC-dependent histone phosphotransferase activity was found to be comparable in MF and P2 synaptosomes. Western blot analyses were performed to confirm this unexpected finding and the results demonstrate that the alpha, beta and gamma subspecies of PKC are all present in relatively equivalent amounts in these two different subcellular fractions. However, an SDS-PAGE analysis of the endogenous substrates phosphorylated by PKC indicated that protein F1 is not present in MF synaptosomes. A functional role for PKC in the hippocampal MF nerve endings seems to be indicated by the finding that phorbol-12,13-dibutyrate (PDB) and phorbol-12,13-diacetate produce a dose-dependent potentiation of the K*-evoked increase in the availability of cytosolic free calcium and the concomitant release of endogenous glutamate and dynorphin B. The biologically inactive 4-e-phorbol was without affect on any of these parameters and the PDB enhancement of Ca²*-dependent release was blocked by the PKC antagonist staurosporine. It is concluded that hippocampal MF nerve endings possess a variety of PKC isoforms and that their activation is sufficient to have an important influence on MF synaptic transmission and plasticity. Supported by AFOSR 89-0531.

TWO FORMS OF LTP IN HIPPOCAMPAL CA3 PYRAMIDAL CELLS R.A.Zalutsky and R.A. Nicoll, Dept. of Pharmacology, U. of California, San

We have investigated the mechanisms of LTP at the associationalcommissural (a/e) and the mossy fiber (mf) synapses onto the same CA3 pyramidal cells using intracellular, whole cell, and field potential recordings in

guinea pig hippocampal slices.
Intracellular recordings confirmed the observation on extracellular fields
(Harris & Coman, Neurosci. Letts. 70:132-137,1986) that a/c but not mf LTP is
blocked by the NMDA antagonist APV. Further intracellular experiments injecting current or calcium chelators into cells demonstrated that the induction injecting current or calcium chelators into cells demonstrated that the induction of a/c LTP depends on post-synaptic calcium concentration and membrane potential, as does NMDA dependent LTP in CA1 pyramidal cells. However, inf LTP in the same cells was not affected by these manipulations nor by more drastic alterations of the cells interior using whole cell recording and voltage clamp with high concentrations of BAPTA and fluoride in the recording

As has been previously shown for NMDA dependent LTP (McNaughton, J.Physiol. 324:249-262,1982) paired pulse facilitation (PPF), a presynaptic phenomenon, is not altered during a/c LTP. On the other hand PPF is clearly

pnenomenon, is not attered outing a/c LTP. On the other hand PPF is clearly reduced in mf LTP (measured under voltage clamp with whole cell recording). Our results indicate that CA3 pyramidal cells express two fundamentally different forms of LTP. The results suggest that in a/c LTP induction is postsynaptic and the consequent increase in synaptic strength is postsynaptic (or perhaps presynaptic but independent of PPF), and in mf LTP both induction and the increased synaptic strenth are presynaptic.

ARACHIDONIC ACID-INDUCED, ACTIVITY-DEPENDENT POTENTIATION OF SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS. T.V.P. Bliss and J.H. Williams (SPON: ENA). National Institute for Medical Research, Mill Hill, London NW7 1AA, U.K. Arachidonic acid (AA) when transiently perfused into the dentate gyrus in vivo or in vitro produces a persistent potentiation of the population EPSP if the frequency of synaptic activation is increased during the period of exposure to exogenous AA (Williams et al., Nature, 341, 739, 1989). A similar effect is seen in area CA1 in vitro. Population EPSPs were simultaneously recorded from str. radiatum in CA1 and from the molecular layer of the dentate gyrus. Perfusion for 30 min with medium containing AA (50µM), together with an increase in the rate of stimulation from 1/30 Hz to 1/4 Hz was followed by a slow potentiation of the EPSP in both pathways, which reached a plateau in 30-90 min and which showed no decline in the next 1-3 h. In neither area was induction of the effect and which showed no decline in the next 1-3 h. In neither area was induction of the effect blocked by D(-)APV (50µM) or NDGA (100µM). Occlusion experiments suggest a shared mechanism for the expression of AA-induced plasticity and LTP. Similar activity-dependent potentiation was not produced by perfusion with other fatty acids (linolenic, linoleic, oleic, palmitic or docosahexaenoic acids; 50µM in each case).

PRESYNAPTIC ENHANCEMENT DURING LONG-TERM POTENTIATION (LTP) REVEALED BY WHOLE-CELL RECORDINGS. R.W. Tsien & R. Malinow. Depts. of Molecular & Cellular Physiology, Stanford University and Physiology & Biophysics, University of lowa.

LTP is triggered postsynaptically in the CA1 region of the hippocampus, but the locus of persistent modification of synaptic transmission remains controversial. To test for possible changes in presynaptic function, we have analyzed the variability in synaptic currents elicited by minimal stimulation (0.25 Hz) before and during LTP. Whole cell recordings were obtained from CA1 neurons 2-3 cell diameters below the surface in rat hippocampal slices, cut 400-500 µm thick. This method allows recordings from cells with largely intact dendritic structures, while also providing much better signal resolution and biochemical access than conventional microelectrode recordings. We found that robust LTP could be evoked by pairing a steady postsynaptic depolarization to -0 mV with continued minimal activation of the test pathway (40 stimuli at 2 Hz). Typically, mean synaptic current (M) was increased 3-fold after pairing. Prolonged dialysis of the postsynaptic cell blocked the triggering of LTP, with no effect on expression of LTP. Synaptic currents displayed a large trial-to-trial variability, reflecting the probabilistic nature of transmitter release. Block of postsynaptic receptors with CNQX attenuated the responses but left their relative variability unchanged. In contrast, maneuvers that alter presynaptic release (elevated [Ca³], lowered [Mg²³], CNQX attenuated the responses but left their relative variability unchanged. In contrast, maneuvers that alter presynaptic release (elevated [Ca²¹]_s, lowered [Mg²¹]_s, added 4-AP or increased stimulus strength to recruit more fibers) produced expected alterations in synaptic variability: M²¹/variance increased, and the histogram of synaptic current amplitudes shifted from a distribution skewed to small currents, toward a symmetrical bell-shape. We found consistent and qualitatively similar changes during LTP (14 experiments). In addition, the proportion of synaptic failures sharply decreased with LTP when failures could be clearly resolved (5/5 recordings) While not excluding the possibility of some change in postsynaptic responsivity, increases in M²/variance and decreases in failures both support an enhanced likelihood of transmitter release during LTP.

AN APV INSENSITIVE COMPONENT OF LTP IN AREA CA1 OF RAT HIPPOCAMPUS. L.M. Grover & T.J. Teyler. Neurobiology Department, N.E. Ohio Univ. College of Medicine, Rootstown, OH 44272.

Department, N.E. Ohio Univ. College of Medicine, Rootstown, OH 44272.

Long-term potentiation (LTP) of Schaffer collateral/commissural synapses in area CA1 of hippocampus is sensitive to NMDA receptor antagonists. We have observed a component of LTP at these synapses that is selectively induced by high frequency (200Hz) tetanic stimulation, and that is not prevented by the competitive NMDA receptor antagonist APV (50-200µM). We studied this APV insensitive component of LTP using intra- and extracellular recordings. This component of LTP is induced under conditions where NMDA receptor mediated synaptic responses are demonstrably blocked, has a delayed onset beginning 2-5 min post-tetanus, and develops gradually over 15-20 min. Intracellular injection of the calcium chelator BAPTA prevents both the APV sensitive and insensitive components of LTP, suggesting that an increase in [Ca²⁺], is essential for induction of the APV insensitive component. Bath application of the dihydropyridine Ca²⁺ channel antagonist nifedipine (10µM) reduces the APV insensitive component of LTP, suggesting that cartain patterns of tetanic stimulation may be capable of promoting sufficient Ca²⁺ influx through voltage dependent Ca²⁺ channels to induce LTP. Supported by the ONR.

Intracellular recordings from pyramidal cell pairs in cultured rat hippocampal slices J.A. Kauer and R.W. Tsien, Dept. of Molecular and Cellular Physiology, Stanford University Medical Center, Stanford, CA 94305.

Hippocampal slices were cultured for 1.4 weeks (B.H. Gahwiler, J. Neurosci. Meth. 4: 329-342, 1981). PSP responses from neurons were recorded in response to stratum radiatum (s.r.) stimulation. Many similarities to acutely prepared slices were observed: 1) HRP staining showed normal cell morphology; 2) 10 µM CNQX abolished EPSPs; 3) EPSP duration increased with depolarization and reversed near 0 mV; 4) epileptiform burst firing was sometimes observed; 5) pairing depolarization to 0 mV with stimuli to s.r. (which triggers LTP in acute slices) produced EPSP potentiation lasting over 35 minutes in about 40% of neurons. Finding this potentiation suggests that all factors and transmitters required for LTP in acute slices are intrinsic to the hippocampus. Some differences from acute slices were also noted. Spontaneous PSPs were prominent and paired pulse facilitation was often not observed. Tetanic stimulation did not cause potentiation. Constant stimulation to s.r. elicited a wide range of EPSP sizes, from failures to PSPs of 10 mV or more. The EPSPs recorded simultaneously from two unconnected CA1 or CA3 cells in response to s.r. stimulation often covaried throughout an experiment.

Pairs of CA1 or CA3 neurons were examined for synaptic interactions. There was no electrotonic coupling between pairs, and the EPSPs reversed near 0 mV. Whereas in acute slices, the chance of synaptic connectivity within CA1 or CA3 is less than one in 100, it was roughly one in four in our cultured slices. The EPSP size averaged over 10 mV, ten times that reported in acute slices. The relatively frequent and strong synaptic connectivity in this system may be favorable for explorations of presynaptic mechanisms of synaptic plasticity and neuronal function.

LONG-TERM POTENTIATION OF SYNAPTIC TRANSMISSION BETWEEN INDIVIDUAL CA3 AND CA1 NEURONS IN RAT HIPPOCAMPAL SLICES. R. Malinow & R.W. Tsien, Depts. of Physiology & Biophysics, University of Iowa and Molecular & Cellular Physiology, Stanford University.

LTP has been studied extensively between populations of neurons. A general

but unproven assumption has been that enhanced transmission is a property expressed by single synapses, rather than an emergent property of many synapses. However, this assumption has been questioned by the most complete study to date (Friedlander et al., J. Neurosci., 1990). Apart from its significance

study to date (Friedlander et al., J. Neurosci., 1990). Apart from its significance to theories of learning, finding LTP at one-to-one connections between presynaptic and postsynaptic neurons would facilitate analysis of statistical properties of transmission and the cellular mechanisms that underly LTP. We have found robust LTP of transmission between pairs of individual CA3 and CA1 neurons. The CA3 neuron was impaled with an intracellular electrode, and the postsynaptic CA1 neuron was accessed with a whole-cell pipette. Potentiation was induced by pairing postsynaptic depolarization with presynaptic activity. Enhancement was observed in 3/4 pairs with detectable synaptic connections, and in 1 of 5 pairs with no apparent connection prior to pairing. The increase in mean synaptic current was as large as 10-fold and lasted for the connections, and in 1 of 5 pairs with no apparent connection prior to pairing. The increase in mean synaptic current was as large as 10-fold and lasted for the duration of the recording (up to 1.5 hr). Transmission in a control (non-paired) pathway did not change, suggesting that the enhancement was synapse-specific. After pairing, we noted a marked decrease in the proportion of synaptic failures, and the amplitude distribution, which was initially skewed toward small currents, changed toward a more symmetrical shape with LTP. Thus, we conclude that (1) LTP can be expressed at connections between individual neurons (although without anatomical analysis we cannot say whether the connection occurs at a single synapse), and (2) expression of LTP in one-to-one connections, as with minimal stimulation, involves a presynaptic modification that increases the likelihood of transmitter release.

HOMO- AND HETERO-SYNAPTIC LONG-TERM POTENTIATION IN THE OLFACTORY-HIPPOCAMPAL CIRCUIT IN THE ADULT GUINEA PIG ISO-LATED BRAIN MAINTAINED IN VITRO. M. de Curtis, A. Alonsoll, and R. Llinás. Dept. of Physiolgoy & Biophysics, N.Y.U. Medical Center, 550 First Ave, N.Y., N.Y., 10016 and Dept. of Neurology & Neurosurgery, Montreal Neurological Inst., McGill Univer., Montreal, Quebec, Canada, H3A 2B4(1)

Long-term potentiation (LTP) was investigated along the olfactory system from the lateral olfactory tract (LOT) to the piriform cortex, entorhinal cortex. and hippocampus. Experiments were performed in the arterially perfused adult guinea pig isolated brain maintained in vitro (Llinás, et al., J. Physiol. 414:16P, 1989; de Curtis and Llinas Soc. Neurosci. Abstr. 15, 660, 1989). Trains of electrical stimuli (4 msec, 100 Hz bursts) were delived to the LOT at 5-8 Hz for 1-3 seconds. stimuli (4 msec, 100 Hz bursts) were delived to the LOT at 58 Hz for 1-3 seconds. These produced a clear potentiation of the monosynaptic and associative evoked potentials in the piriform and anteromedial entorhinal cortices. As opposed to most research on LTP, this potentiation did not required the use of picrotoxin for its generation. Direct stimulation of the periamygdaloid cortex (PAC) induced potentiation of the mono- and disynaptic EPSPs elicited in the entorhinal cortex, while basolateral amygdala (BLA) stimulation induced LTP mainly in the lateral entorhinal cortex. Following addition of 2-APV (100 µm) to the perfusate, long-lasting potentiation of the mono- and disynaptic associative EPSPs could not be evoked. 2-APV also blocked the LTP induced in the entorhinal cortex by PAC stimulation, indicating that NMDA-mediæd mechanisms are responsible for both the induction and the expression of LTP in the entorhinal cortex (Llinas and Alonso, Soc Neurosci. Abstr.16, 1990). Prolonged potentiation of evoked potentials in both the entorhinal cortex and dentate gyrus were obtained after application of a tetanizing train to the PAC. Once potentiated, the amplitude of the entorhinal cortex and dentate gyrus responses evoked by BLA stimulation were also increased, indicating that hetero-synaptic long-term potentiation is present in the entorhinal cortex-dentate gyrus circuit in the in vitro isolated brain preparation. Supported by grant 13742 from NINDS and by Italian CNR grant 2042856.

IN VITRO HEBBIAN AND NON-HEBBIAN LTP IN ENTORHINAL CORTEX LAYER II STELLATE CELLS. R. Llinás and A. Alonso¹, Dept. of Physiology & Biophysics, N.Y.U. Med. Ctr, 550 First Ave., N.Y., N.Y. 10016 and Dept. of Neurology & Neurosurgery, McGill University, Montreal, Canada, H3A 2B41

Long term potentiation (LTP) of synaptic transmission following single stimulation of the white matter (WM) and following direct, rhythmic subthreshold membrane potential change was studied intracellularly in the entorhinal cortex (EC) in rat brain slices in the presence of picrotoxin (50-100µM). EPSPs evoked by WM stimulation comprised an early and late component. APV (50 µM) reduced the amplitude of the early component and abolished the late component (which also demonstrated "anomalous" voltage-dependent properties). These results indicate that part of the fast component and all of the slow component of the EPSP are mediated through activation of MNDA receptors. Tetanic or rhythmic single-shock WM stimulation (5-10 Hz for 10-20 sec) induced LTP in 19 of 27 cells tested. Similar results were found in field potential and intracellular recordings in the isolated brain preparation where LTP may be evoked in the EC in the absence of picrotoxin (deCurtis et al., Soc., Neurosci. Abst., 16, 1990). Also, in 15 of 23 cells tested in slices the EPSP was enhanced for as long as 3 hrs by intracellular stimulation for 20 sec with a train of subthreshold, 10-12 mV, 100 ms current pulses delivered at 5 Hz (without pairing with white matter stimulation). While present in the early component, the enhancement was most prominent in the late component. LTP was prevented by APV superfusion. More significantly, LTP, induced by white matter or single cell direct stimulation, was blocked by APV. However, the block of acquired LTP was reversed by washing indicating that this drug did not interfere with the maintenance of LTP, but only with its expression. These results indicate the presence of Hebbian and non-Hebbian NMDA-induced and expressed LTP in the entorhinal cortex. Supported 13742 from NINDS and Fogarty Foundation.

STRESS, HORMONES AND THE AUTONOMIC NERVOUS SYSTEM I

66.1

EFFECTS OF STRESSORS ON CARDIOVASCULAR SYSTEM, PLASMA AND TISSUE CATECHOLAMINE LEVELS IN RATS. H. M. Rhee. Dept. of

ORU Med. Sch., Tulsa, OK 74137.

Various types of stress cause an increase in systemic blood pressure, which eventually produce cardiac, renal, and other end organ damage. The elevation in blood presand other end organ damage. The elevation in blood pres-sure is usually caused by release of adrenocorticotropin from the anterior pituitary gland, of norepinephrine from sympathetic nerve terminals and of epinephrine from the adrenal medulla. Studies show that stress alters adrenal catecholamine synthesis which is controlled by primarily neuronal and humoral factors. Adrenal catecholamines are co-released stoichiometrically with enkephalins upon stress, which suggests an involvement of opioid receptors in stress physiology. Young male Sprague-Dawley rats were anethetiz-ed for a chronic cannulation of the carotid artery and jugular vein. After 3 days recovery from the surgery the rats were subjected to either immobilization, heat stress or treadmill exercise for various durations. Heat stress under a red light for 5 min, three times with 5 min interval, increased blood pressure and heart rate. Immobilization and forced running also increased the parameters and plasma catecholamines. Although a pretreatment of the animals with naloxone or beta-funaltrexamine did not produce always uniformed effects against the stressors, the data suggest that opioid receptors in the central as well as in the periphery modulate adrenergic and cardiovascular activities under stressful conditions.

PLASMA DOPA AND TISSUE TYROSINE HYDROXYLASE DURING ACUTE AND REPEATED IMMOBILIZATION STRESS R. Kvetnansky, D.S. Goldstein*, V.K. Weise*, G. Bagdy*, K. Szemeredi*, C. Holmes* and I.J. Kopin, Clinical Neuroscience Branch, NINDS and Hypertension-Endocrine Branch, NHLBI, NIH, Bethesda, MD 20892.

Recent studies suggest that plasma dopa levels reflect in vivo catecholamine synthesis, but the relationship between tyrosine hydroxylase (TH) and dopa levels has not been assessed directly. In this study, plasma concentrations of catechols were measured by a liquid chromatographic-electrochemical technique and adrenal and splenic TH by a CO2-trapping technique in conscious intact or adrenaldemedullated (DEMED) rats during acute and after repeated 2 hr intervals of immobilization stress (IMO). Dopa levels increased beginning within 1' of IMO and plateaued after 5', but adrenal and splenic TH was unchanged. Even 1' of gentle handling increased plasma dopa. After IMO or handling, dopa levels decreased to baseline within 20'. Increases in dopa were similar in intact and DEMED rats. Catecholamine levels increased more rapidily than dopa levels. After 7 daily 2 hr intervals of IMO, dopa levels were the same as before the first interval of IMO, whereas TH was increased significantly. The results indicate that plasma dopa levels increase rapidly during IMO. The increases are independent of adrenomedullary activation and are not simultaneous with increases in catecholamine levels. Since dopa levels were increased when TH was not, and since TH was increased when dopa levels were not, increases in plasma dopa levels during IMO stress in rats do not directly reflect alterations in tissue levels of tyrosine hydroxylase.

66.3

EFFECTS OF BENZODIAZEPINES ON METABOLIC STRESS IN HUMANS. A. Breier, O. Davis*, R. Jones*, B. Kirkpatrick, R. Buchanar*. Outpatient Program, Maryland Psychiatric Research Center, Baltimore, MD 21228
Several preclinical studies have demonstrated that

benzodiazepines affect a number of systems involved in the stress response such as HPA axis activation and increases in catecholamine turnover. There exists comparatively little information about the effects of benzodiazepines on the stress response in humans. In the present study, we examine the effects of the benzodiazepine, alprazolam (1.5mg), on the neuroendocrine, neurochemical and physiologic effects of metabolic stress in healthy volunteers (N-11). Metabolic stress was induced by double-blind, placebo controlled IV stress was induced by double-blind, placebo controlled IV administration of 2-deoxyglucose (2DG) (50mg/kg) which competitively inhibits glucose metabolism resulting in intracellular glucoprivation. 2DG alone produced significant increases (mean†sem; pre-to 2hr post-2DG infusion) in plasma cortisol (13.5±2 to 26.6±2 mg/dl) and glucose (65±3 to 137±13 mg/dl). Alprazolam pretreatment attenuated 2DG-related increases in plasma cortisol and allucose by 25% and 20% represtively. These data suggests glucose by 25% and 20%, respectively. These data suggest that the GABA/BZ receptor may play a role in modulating glucoprivic stress in humans. The effects of alprazolam on 2DG-induced changes in plasma catecholamines, physiologic function (HR, BP, temperature) and behavioral responses will be presented.

66.4

TOLERANCE TO NICOTINE MAY BE MODULATED BY CORTICOSTERONE. A. C. Collins, E. U. Grun and J. R. Pauly. Institute for Behavioral Genetics, Univ. of Colorado, Boulder, CO

Behavioral Genetics, Univ. of Colorado, Boulder, CO 80309.

Chronic treatment with nicotine often results in tolerance to the behavioral and physiological effects elicited by this drug. Several studies have demonstrated that chronic nicotine treatment also results in increases in the number of brain receptors that bind nicotine but other studies have failed to detect alterations in receptor numbers in animals that showed tolerance. This finding suggests that factors other than changes in receptor numbers may regulate tolerance. In the present study, the effects of chronic saline or nicotine injection (three times daily for 12 days, 2 mg/kg) on nicotine sensitivity were determined in DBA/2 and C5/BL/6 mice. Chronic nicotine injected mice showed reduced sensitivity to nicotine but brain nicotinic receptors were not changed. This tolerance persisted at least 4 weeks after the last chronic nicotine injection. Plasma corticosterone (CCS) levels were also measured. Chronic nicotine treatment resulted in tolerance to nicotine-induced CCS release, but pre-injection levels of CCS rose as injection continued. Because previous studies from our laboratory have demonstrated that elevated CCS levels results in reduced sensitivity to nicotine, we suggest that the tolerance to nicotine that occurs following chronic injections is due, in large part, to the chronically elevated CCS levels.

ADRENAL MEDULLECTOMY EFFECTS ON CHRONIC RENAL HYPERTENSION. T.C. Herzig and J.R. Haywood. Department of Pharmacology, University of Texas Health Science Center at San Antonio, San Antonio, Texas 78284-7764.

Antonio, San Antonio, Texas 78284-7764.

The goal of this study was to determine the effects of adrenal medullectomy on chronic renal hypertension. Rats were made hypertensive with a one-kidney, figure-8 renal wrap; sham operation consisted of unilateral nephrectomy. Four weeks later, catheters were inserted into the femoral artery and vein for blood pressure (BP) and heart rate (HR) measurements, and administration of drugs. After 24 hours, BP and HR were recorded for a control period; then, rats underwent adrenal medullectomy (MX) or sham operation (MS), producing four groups: wrap-MX, sham-MX, wrap-MS, sham-MS. BP and HR were recorded daily for 7 days. The contribution of the sympathetic nervous system to the maintenance of BP was assessed on the seventh day pharmacologically. Demedullation produced a transient fall in BP to normotensive levels in the wrapped animals (155±7 mmHg to 127±6 mmHg); by day 3, BP rose to hypertensive levels. BP in the sham-MX group was unaffected by this manipulation. MS had no affect on BP in either the wrap-MS or sham-MS groups. MX decreased plasma epinephrine while plasma norepinephrine tended to rise on day 2 post-MX in wrap and sham animals. Ganglionic blockade was greater in the wrap and sham animals. Ganglionic blockade was greater in the wrap and sham animals. The sham animals in both the MX (-46±3 mmHg) groups. These observations indicate that the adrenal medulla contributes significantly to the maintenance of renal wrap hypertension. (Supported by HL36080.)

OVARIAN STEROID MODULATION OF CRH STIMULATION OF CORTISOL IN RHESUS MONKEYS. L. E. Heisler, R. L. Reid and D. A. Van Vugt. Departments of Physiology and Obstetrics and Gynecology, Queen's University, Kingston, Ontario, Canada KT. 3N6

Ovarian steroids appear to modulate cortisol secretion in a positive manner in rhesus monkeys since reduced cortisol concentrations in ovariectomized monkeys can be reversed with ovarian steroid replacement. To examine the site of action of ovarian steroids in this regard we compared the cortisol response to administration of 100 ug CRF in ovariectomized and intact female rhesus monkeys. In addition, we determined cortisol concentrations in both groups while restrained in primate chairs. Cortisol is elevated during this condition presumably due to increased CRH secretion. CRH administration caused an elevation of cortisol in intact monkeys from 14.7 ± 1.46 ug/dl to 33.2 ± 3.292 ug/dl 75 minutes post-injection. In ovariectomized monkeys cortisol rose from 11.9 ± 1.18 ug/dl to 32.5 ± 2.77 dl. The increase in cortisol concentration was not significantly different between intact and ovariectomized monkeys. Similarily, the rise in cortisol levels in response to chair restraint was not significantly different between these two groups. Cortisol levels rose to 33.5 ± 3.78 ug/dl from the normal midday level of 18.2 ± 2.51 ug/dl in intact monkeys while in ovariectomized monkeys the rise was from 12.6 ± 0.56 ug/dl to 33.6 ± 3.781 ug/dl. These data indicate that ovarian steroids on thifluence pituitary-adrenal responsiveness to CRH and suggest that during basal states, ovarian steroids modulate circulating cortisol levels by an action on hypothalamic CRH neurons. Since chair restraint stress caused similar cortisol elevations in intact and ovariectomized animals, we conclude that this effect of ovarian steroids on CRH release can be negated by this form of acute stress.

66.9

NERVE GROWTH FACTOR DOWN-REGULATES ANGIOTENSIN II RECEPTORS IN PC12 CELLS. R.C. Speth and K.H. Kim, Dept. of VCAPP and Program in Biochem. Biophys. Genetics and Cell Biol., Washington State Univ., Pullman, WA 99164-6520.

Adrenal chromaffin cells, which are derived from the neuroectoderm, do not display a neuronal phenotype. They contain angiotensin II (AII) receptors that mediate catecholamine release. The PC12 cell line derived from a rat pheochromocytoma offers a tool to study the adrenal chromaffin cell under varying influences. PC12 cells (gift of Dr. Robert Perlman) contain ¹²3I-sarcosine¹, isoleucine⁸ AII (¹²³I-SI AII) binding sites in a high concentration 804 ± 127 fm/mg protein. In the presence of mercaptoethanol, binding affinity for ¹²³I-SI AII is enhanced, 152 ± 25 pM, vs. 402 ± 96 pM in the absence of this sulfhydryl reducing agent. Competition assays indicate the following order of potency for ¹²³I-SI AII binding: AIII > SI AII > AII > p-aminophenylalanine⁹ AII = AI > 3-8 hexapeptide AII. This suggests that PC12 cells contain the AII₂ receptor subtype (see Grove et al., this volume). When the cells are grown in the presence of retinoic acid (RA, 10⁻⁹ M) they retain an endocrine cell phenotype, while addition of nerve growth factor (NGF, 5 ng/ml) causes them to develop a neuronal phenotype. RA did not significantly alter the density or affinity of ¹²³I-SI AII binding in the PC12 cells, but NGF decreased the density of ¹²³I-SI AII binding sites by 70% without significantly altering the binding affinity. Thus, development of a neuronal phenotype is associated with a reduction in AII receptor density. Supported by grants from NIH (NS 21305) and American Cancer Society (IN-119K).

BIOCHEMICAL ISOLATION, CHARACTERIZATION AND PARTIAL PURIFICATION OF CORTICOTROPIN-RELEASING FACTOR (CRF) RECEPTORS FROM RAT BRAIN. D.E. Grigoriadis, J.A. Heroux, D.M. Pearsall', and E.B. De Souza, NIDA / ARC, Baltimore, MD 21224

The primary role of CRF in regulating pituitary-adrenocortical secretion is well established. Recent studies in the laboratory have focused on elucidating the biochemical characteristics of CRF receptors in brain, endocrine and immune tissues and on purification of CRF receptors in brain. Central and peripheral CRF receptors differ in their molecular size (58,000 Da and 75,000 Da, respectively) as determined by SDS-PAGE. These differences in molecular size do not appear to be due to structural differences in the proteins themselves but rather due to alterations in the post-translational modification of the glycosylation profiles. In order to purify CRF receptors we used ¹²⁵1-oCRF affinity cross-linked rat brain membranes, solubilized in 1% digitonin. Cross-linked solubilized CRF receptors (2 g protein) were applied to 40 ml wheat-germ agglutinin, washed and eluted with 250 mM β-N-acetylglucosamine. Eluted receptors (40 ml) were concentrated to 10 ml and applied to a DEAE ion-exchange column. The matrix was washed and eluted with a gradient of 0 - 500 mM NaCl. Samples of the eluates of both columns were electrophoresed on SDS-PAGE confirming that both the WGA-purified and DEAE-purified receptor had a molecular weight of 58,000 Da. In parallel, eluted samples were processed for 2-dimensional electrophoreses. Radiolabeled proteins were processed for 2-dimensional electrophoresed in the second dimension, dried and exposed to X-ray film for autoradiography. The use of the affinity cross-linked CRF receptors as a tracer will be a valuable tool in the purification and identification of the native receptor protein.

ACUTE HYPOGLYCEMIC STRESS INFLUENCES THE ACTIVITY OF NEUROPEPTIDE Y AND GALANIN NEURONS IN THE RAT HYPOTHALAMUS. J.I. Koenig, R.M. Strauss* and L.M. Kaplan, Physiology Dept., Georgetown Univ. Sch. of Med., Washington, DC and Gastrointestinal Unit, Massachusetts General Hosp., Boston, MA.

The induction of hypothalamic-pituitary-adrenal axis activity by hypoglycemic stress is well-characterized. We have recently observed that galanin (Gal) inhibits, and NPY stimulates, pituitary ACTH secretion. Because these effects appear to be mediated by peptide actions within the hypothalamus (HT), we sought to determine the response of HT Gal and NPY neurons to hypoglycemic stress. Fasted, male Sprague-Dawley rats were sacrificed at various times after the injection of insulin (5 IU/kg, ip). Plasma ACTH levels increased 15-fold within 30 min after insulin injection. Gal and NPY concentrations in HT fragments were determined by RIA and mRNA levels by blot hybridization analysis. HT Gal concentrations were unchanged at 30 min. However, 90 min after insulin treatment, the concentration of Gal in the median eminence (ME) increased 55%. Concurrently, Gal concentrations decreased 33% in the HT fragment (POA) containing the paraventricular (PVN) and supraoptic nuclei, and Gal mRNA increased 2-fold exclusively in the basal HT fragment (MBH). Insulin treatment increased ME NPY concentrations 2-fold over 90 min, but consistently reduced POA NPY levels by 55-60%. In contrast, MBH NPY levels were reduced 45% at 30 min but tripled to 145% of control by 90 min. These observations suggest NPY and Gal neurons are differentially affected by hypoglycemic stress. NPY projections from the MBH to the PVN and ME appear to be activated early and may be involved in stimulating ACTH secretion, whereas Gal neurons in the MBH are activated later and likely attenuate the early increase in ACTH secretion.

A ω-CONOTOXIN-SENSITIVE Ca²⁺ INFLUX PATHWAY IS
SELECTIVELY ACTIVATED BY ANGIOTENSIN II (AII) IN BOVINE
ADRENAL MEDULLARY (BAM) CELLS. M. K. McMillian, R. K.
Tuominen, P. M. Hudson, H. H. Suh and J. S. Hong. LMIN,
NIEHS/NIH, Research Triangle Park, NC 27709.
ω-Conotoxin blocks Ca²⁺ influx and neurotransmitter
release in response to depolarization in sympathetic
neurons, but has little effect on Ca²⁺ and exocytotic
responses to KCl or piccipie in cultured RAM cells. AII

—Conotoxin blocks Ca²+ influx and neurotransmitter release in response to depolarization in sympathetic neurons, but has little effect on Ca²+ and exocytotic responses to KCl or nicotine in cultured BAM cells. AII stimulates catecholamine secretion from both sympathetic nerve endings and BAM cells. We find that conotoxin blocks AII-stimulated, but not nicotine- nor bradykininstimulated [³H]NE and [²²P]ATP release from cultured BAM cells. AII-stimulated *⁵Ca²+ uptake is also inhibited, but Ca₁ responses (Fura 2) to AII are not blocked, unless intracellular Ca²+ pools are depleted with ionomycin or cells are pretreated with phorbol myristate acetate. [³H]Inositol phosphate accumulation in response to AII is unaffected by conotoxin. Since bradykinin stimulates [³H]inositol phosphate accumulation more effectively than AII, yet none of the bradykinin responses are blocked by conotoxin, it seems likely that the conotoxin-sensitive Ca²+ influx in response to AII is independent of phospholipase C activation.

C-FOS IMMUNOREACTIVITY IN HYPOTHALAMIC NUCLEI AFTER DEHYDRATION STRESS. J. M. Ding. P. J. DeCoursey*, and J. Buggy. Depts. of Physiology and Biology, Univ. of South Carolina, Columbia, SC 29208

The proto-oncogene c-fos codes for a nuclear

The proto-oncogene c-fos codes for a nuclear phosphoprotein (Fos) that binds to DNA and appears to act as a transcription regulator coupling physiologically relevant stimuli to long-term responses by altering gene expression. Since water deprivation has been reported to increase Fos immunoreactivity (Fos-IR) in nuclei of neurons of the paraventricular (PVN) and supraoptic (SON) nuclei, this study in rats examined other dehydration stimuli. In both Sprague-Dawley and Brattleboro rats, acute intracellular dehydration (hypertonic NaCl, sc) induced Fos-IR in several hypothalamic nuclei associated with body fluid regulation including the OVLT and median preoptic nucleus, subfornical organ, and nucleus circularis as well as SON and PVN. Intracerebroventricular injection (ICVT) of carbachol (which produces responses similar to intracellular dehydration) also induced Fos-IR in SON and PVN. In contrast, hypovolemia or ICVT angiotensin did not potently induce Fos-IR in the above brain areas. These results suggest that osmotic but not volemic hydrational stimuli activate Fos in several hypothalamic nuclei associated with regulation of body fluids.

ALZHEIMER'S DISEASE: COGNITIVE AND CLINICAL STUDIES

67.1

NEUROPSYCHOLOGICAL TEST PERFORMANCE OF ALZHEIMER'S DISEASE PATIENTS WITH AND WITHOUT EXTRAPYRAMIDAL SIGNS.
K. Edwards*, D. Salmon, D. Galasko, N. Butters and L. Thal. UCSD School of Med., San Diego, CA 92093.
A variant of Alzheimer's disease (AD) has been

A variant of Alzheimer's disease (AD) has been described in which the neuropathological changes typical of AD occurred concomitantly with diffusely distributed neocortical and brain stem Lewy bodies. Patients with the Lewy body variant (LBV) evidenced mild extrapyramidal signs (EPS) on neurologic examination and were more impaired than patients with "pure" AD on neuropsychological measures. This study suggested that clinically identified AD patients with EPS differ neuropsychologically from AD patients without such signs. To address this issue, the neuropsychological test performance of 10 clinically diagnosed AD patients with EPS (AD-EPS) (i.e., rigidity, bradykinesia, and masked facies) was compared to that of 10 clinically diagnosed AD patients without EPS. Although the two patient groups were matched for age, education and overall level of dementia, the AD-EPS patients were significantly more impaired than the AD group on a test of verbal fluency and a visuospatial/constructional task but performed similarly on tests of language. The results suggest that AD patients with EPS have a pattern of neuropsychological deficits distinguishable from typical AD patients, and that the deficit profile is similar to that reported for patients with neuropathologically verified LBV.

67.3

JUDGEMENT OF RECENCY IN ALZHEIMER'S DISEASE.

D.S. Knopman and Bret Haake*. Dept. of Neurology
University of Minnesota Hospital, Minneapolis,
MN 55455

University of Minnesota Mospital, Minneapolis, MN 55455.

To quantitate working memory processes in Alzheimer's disease (AD), a judgement of recency test (JOR) was given to 17 AD patients (pts) and 21 normal elderly (NE) subjects. In the JOR test, drawings of common objects were repeated after 0-9 intervening items. Subjects estimated the lag (number of intervening items plus current one) each time a drawing was reshown. Both groups overestimated true lag for items of < lag 4 for AD pts and < lag 6 for NE. Above CL, both groups underestimated true lag, with estimated lags all of approximately (CL + 1). Thus, AD pts judged recency qualitatively similar to NE, but the CL below which the AD pts differentiated one lag from others was much lower than for the NE. Beyond CL. AD pts did not perform randomly: their responses suggested that they based their estimates on weak but still extant memory traces, the weakness of which they interpreted as being approximately one item beyond CL. Alternatively, the defect in AD could represent a contraction of working memory space for intervening items.

67.2

NEUROPSYCHOLOGICAL-NEUROPATHOLOGICAL CORRELATES IN ALZHEIMER'S DISEASE, D. Salmon, E. Masliah, R. DeTeresa, L. Hansen, N. Butters, R. Katzman and R. Terry. UCSD Sch. of Medicine, San Diego, CA 92103.

Quantification of synapses by microdensitometry of tissue sections reacted with anti-synaptophysin was performed on the midfrontal (MF), inferior parietal (IP) and superior temporal (ST) brain regions of 13 patients with Alzheimer's disease (AD). Plaques, neurofibrillary tangles (NFT), large neurons and ChAT levels were also quantified. Prior to death these patients had been assessed neuropsychologically with Blessed's Information-Memory-Concentration (IMC) test, the Mini-Mental State (MMS) exam, and the Dementia Rating Scale (DRS). Significant correlations were obtained between density of MF synapses and IMC (r=.67), MMS (r=.67) and DRS (r=.58) scores. MF tangles (r=.65) and large neurons (r=-.58) correlated significantly with only IMC scores. In the IP region, synapse density correlated significantly only with the MMS (r=.60). However, IP NFT correlated significantly with the IMC (r=.79), MMS (r=-.66) and DRS (r=-.63), and IP large neurons with the IMC (r=-.57) and DRS (r=-.64). MF and IP ChAT levels correlated significantly with all three neuropsychological tests. These results suggest that the loss of neurons, synapses and acetylcholine play as important a role as plaques and NFT in the development of the dementia associated with AD, and may be the primary determinant of cognitive loss.

67.4

IMPLICIT AND EXPLICIT MEMORY FUNCTIONS IN ALZHEIMER'S DISEASE AND HUNTINGTON'S DISEASE.

C. Randolph* and C. Hagger. Clinical Brain Disorders Branch, NIMH Neuroscience Center, Wash. DC 20032

Implicit and explicit memory functions were studied in normal controls, patients with Alzheimer's (AD) and Huntington's disease (HD) using a priming paradigm involving a word-stem completion task. This paradigm has been previously used to demonstrate "preserved" implicit memory function in amnestics. It has also been reported that AD patients do not exhibit this preserved susceptibility to priming. A measure of explicit memory was obtained in the present study, under the same conditions that the implicit measure was made. Explicit and implicit recall were positively correlated in all groups. After controlling for explicit recall ability through ANCOVA, AD patients were found to be normally susceptible to the effects of priming on implicit recall. HD patients, however, demonstrated increased susceptibility to priming. The results suggest that implicit memory performance is dependent in part on explicit memory ability, and that cognitively impaired patients may adopt response strategies on indirect measures of memory that differ from those of normal controls.

INITIAL SYMPTOMS AND LATER NEUROPSYCHOLOGICAL PERFORMANCE IN ALZHEIMER'S DISEASE. D. Freed, C. Hoss*, A. Piccinin* and V. Henderson. Department of Psychology and Alzheimer's Disease Research Center, University of Southern California, Los Angeles, CA 90089.

This study examined the possible relationship between initial symptoms and later neuropsychological performance in a group (N=23) of patients with probable Alzheimer's disease (AD). Two independent raters classified (when unambiquous) caregiver-reported initial symptoms as primarily involving either language or visuospatial function. Inter-rater reliability approached r=.80. For the 13 patients classified with early language (n=4) or visuospatial (n=9) initial symptoms predicted impairment, performance on two analogous neuropsychological tests (WMS-R subtests Digit Span and Visual Memory Span) administered an average of 4.8 years after caregiverreported onset of symptoms. A chi-square analysis indicated a significant association (p < .05) between initial symptoms and later neuropsychological performance. These results suggest that initial symptoms may predict cognitive impairment observed years later in AD patients.

VISUAL EVOKED POTENTIAL COMPONENTS IN DEMENTIA: SELECTIVE DELAY OF FLASH P2 IN PROBABLE ALZHEIMER'S DISEASE.

Coburn and J.W. Ashford. Brain Mapping Lab, Southern
Illinois Univ. Medical School, Springfield, IL 62702.
Earlier studies have shown that the P2 component of the flash visual evoked potential (VEP) is delayed, while earlier flash and pattern reversal VEP components are not, in etiologically mixed groups of demented patients compared to nondemented patients or normal controls. This compared to nondemented patients or normal controls. This study tested the hypothesis that the flash P2 delay is characteristic of Alzheimer's disease (AD) rather than a general feature of dementia by comparing probable AD (n=23) and unlikely AD (n=8) demented patients to elderly normal controls (n=12). The flash P2 was found to be the only delayed VEP component and the delay was found only in the probable AD group. These results imply that earlier findings were due to inclusion of AD patients in the etiologically mixed demented patient groups, and that VEP testing may be of value in the differential diagnosis of AD within demented populations.

LINKAGE OF LATE-ONSET FAMILIAL ALZHEIMER'S DISEASE ON CHROMOSOME 19. A.D. Roses, J. Bebout*, L. Yamaoka*, P.C. Gaskell*, W-Y. Hung*, A.P. Walker*, M.J. Alberts*, C. Clark*, K. Welch*, N. Earl*, A. Heyman* and M.A. Pericak-Vance*. Dept. of Medicine and Dept. of Neurobiology, Div. of Neurology, Duke Univ. Med. Ctr., Box 2900 Durham, NC 27710.

We have studied 28 families with late-onset Alzheimer's Disease (LOAD;

mean=69.8 yrs). The linkage analysis included 258 family members (129 affected). Twenty-five fammilies had 3 or more affecteds and 15 were autopsy confirmed. Due to the late-onset, the mode of inheritance (i.e., recessive vs. dominant AD) could not be clearly determined so the data were initially examined with the Affected Pedigree Member Method of Weeks and Lange (Am. J. of Hum. Genet., 42:315-326, 1988) which detects linkage and/or association but does not depend on the mode of inheritance and uses data on affecteds only. This analysis produced significant test results for two markers on chromosome 19: BCL3 and D19S13. These markers were then tested using standard likelihood methods assuming autosomal dominant inheritance. When the analysis was limited to the affecteds only, making no assumptions concerning the disease status of other family members: BCL3, z=2.5 at θ =0.00; for D19S13, z=1.84 at θ =0.05. Another polymorphic probe, ATPIA3 was then selected for testing because of its location between the other two probes on chromosome 19. ATP1A3 analysis gave z=1.73 at $\hat{\theta}$ =0.05. Multipoint analysis (MA) which combines data from several loci (BCL3-ATP1A3-D19S13): gave z=4.6 for affecteds only analysis, inclusion of at-risk individuals in the analysis after the adjustment for age of onset gave z=2.48 Six additional probes from the proximal long arm of chromosome 19 are under investigation. D19S19, D19S29, Cyp2a/2b, D9S9, ApoC2, CKMM. To date (4/90) each probe has demonstrated positive lod scores. Updated lod scores including MA analysis will be presented.

67 G

ACTIVATION OF REGIONAL CEREBRAL BLOOD FLOW (rCBF) IN EXTRA-STRIATE CORTEX DURING A FACE MATCHING TASK IN PATIENTS WITH DEMENTIA OF THE ALZHEIMER TYPE (DAT). C. Grady, J. Haxby*, B. Horwitz, M. Schapiro*, R. Carson*, P. Herscovitch, S. Rapoport, Lab.

of Neurosciences, Nat. Inst. on Aging, Bethesda, MD 20892.
We showed in young and old healthy subjects that rCBF, as measured by [150]-water and positron emission tomography, is activated bilaterally in occipitotemporal extrastriate cortex during a vated bilaterally in occipitotemporal extrastriate cortex during a visual face matching task (Grady et al., J Cereb Blood Flow Metab, 1989, 9:5574). In this study we measured rCBF in 4 patients with mild-moderate DAT (mean age 65±5 yrs) and in 10 healthy older controls (66±5 yrs) during face matching and a sensorimotor control task. All patients performed well above chance on the tasks. The DAT patients did not have significantly lower whole brain CBF in the control task (32.9±3.4 ml/100g/min) compared to controls (36.7±4.5), but did show regions of low flow in temporal cortex. Pixel-by-pixel difference images were computed by normalizing flow values to whole brain CBF and subtracting the control task images from the face matching images. The areas of activation in the difference images from all subjects were then mapped to a standard brain. Patients and controls showed activated rCBF in the same regions of occipitotemporal extrastriate cortex during face matching. In addition, the mean activation in the patients was not significantly different from controls (22±10% vs. 13±7% in controls). These results show that the appropriate areas of extrastriate cortex are activated during object vision in DAT patients even though these regions have low flow, suggesting that the mechanism recruiting these regions for cognitive processing is functionally intact.

DISCORDANCE AND CONCORDANCE OF ALZHEIMER'S DISEASE (AD) IN MONOZYGOTIC TWINS INDICATE TWO MODES OF TRANSMISSION. S.I. Rapoport and M.B. Schapiro. Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892 Studies indicate that genetics play an important role

in the etiology of AD, but the extent of this role is controversial. Two forms of AD have been suggested, a familial hereditary form (with estimated frequencies of 50 to 80% or more); and a sporadic nonheritable form. To test the hypothesis that both forms exist, we determined the incidence of affected first degree determined the incloence of affected first degree relatives of pairs of monozygotic twins concordant or discordant for AD. A total of 29 pairs of twins (4 from our laboratory, 25 from the literature) were evaluated, where disease, monozygosity and family history were documented. Of 14 concordant twin pairs, 11 had affected first degree relatives, whereas 3 did not. Of 15 discordant pairs, 3 had affected first degree relatives, whereas 12 did not. Fisher's exact test indicated that the concordant twins had a significantly more frequent family history of AD than did the discordant twins, (p < 0.003). The results suggest that concordant but not discordant twins are more likely to have a heritable form of AD. AD in discordant twins me result from environmental influences or a post-zygotic somatic chromosomal change.

67.10

NICOTINE AND HUMAN COGNITION B.J. Sahakian, G. Jones*, R. Levy*, J. Gray*, D. Warburton* Institute of Psychiatry, London, SE5 8AF, U.K. The reduction in nicotine receptors in the neocortex and hippocampus of patients dying with dementia of the Alzheimer type (DAT) suggests that stimulating the remaining receptors with nicotine might enable an alternative approach to cholinergic treatment of patients with mild/moderate DAT. A preliminary study of with maid/moderate DAT. A preliminary study of subcutaneous nicotine in groups of young normals and patients with DAT (all n=7) is described. Tests of rapid visual information processing (RIP)(non-spatial working memory), short term spatial working memory and cortical arousal (critical flicker fusion test (CFF)) were modified to allow the baseline performance of the DAT patients to approximate that of normal subjects. Nicotine (0.4, 0.6, 0.8 mg s.c.) produced dose-dependent improvements in the DAT patients in the accuracy and speed of responding in the RIP task, reduced the threshold for CFF, but had no beneficial effect on the test of spatial short term memory. These preliminary observations are extended in two ways: by studying the effects of acute nicotine on larger populations of subjects, including equivalent numbers of smokers and non-smokers; and by investigating the effects of chronic nicotine, administered in the form of chewing gum, on similar measures, but also including an evaluation of effects on indices of everyday living.

DRINKING HABITS OF EARLY AND LATE ONSET ALZHEIMER'S PATIENTS. M.Bidaut-Russell and G.T.Grossberg. Dept. of Psychiatry and Human Behavior, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Alcohol as a causative or contributing risk factor for Alzheimer's disease (AD) has been previously evaluated (Amaducci, L.A. et al., Neurology, 36:922-931, 1986; Heyman, A. et al., Ann Neurol., 15:335-341, 1984). We reviewed 52 deceased patients (35 women and 17 men) with an autopsy-confirmed clinical diagnosis of AD to see whether certain drinking patterns could affect the time of onset of AD in male and female patients. Information about drinking habits was obtained through a questionnaire answered by a patient's next of kin. Ten patients (4 men and 6 women) had early onset AD (EOAD) (first symptoms appearing before age 65). Forty two patients (13 men and 29 women) had late set AD (LOAD)(first symptoms after age 65). Patients were divided into non drinking, occasional, light, moderate and heavy drinking categories. Four men (23%) and 11 women (31%) did not drink. Forty six percent of women were considered occasional drinkers, 20% light drinkers and 3% moderate drinkers. Twelve percent of men were described as light drinkers, 47% as moderate drinkers and 18% as heavy drinkers. LOAD/EOAD ratio were calculated for male non drinkers (3) and drinkers (3.33) and for female non drinkers (4.5) and drinkers (5). In the female group, occasional drinkers with LOAD outnumbered those with EOAD by a 15 to 1 ratio while light drinkers with LOAD outnumbered those with EOAD by a 2.5 to 1 ratio. Only 1 woman belonged to the moderate drinker category and she had EOAD. All male light drinkers were LOAD patients. Male moderate and heavy drinkers with LOAD outnumbered those with EOAD by a 3 to 1 and 2 to 1 ratio respectively.

These results suggest that, although male patients were more likely to develop

early onset AD than female patients, different drinking patterns had little influence on the time of onset of AD within the male and female patients groups.

67.12

ANXISTY AND LOCUS CERULEUS CELL COUNT IN ALZHEIMER DISEASE P.D.Fleming, J. Shaw*, K. Burbank*, P. Engel*, R. Carraway* U. Mass Med.Sch., Worc., MA. Ol655, U. Conn., N. Britain Gen. Hosp. N. Brit.CT., Harvard Med. Sch., McLean Hosp., Belmont MA. 021/8 The noradrenergic system may mediate anxiety in part but the nature and extent of this mediation remains unknown. Alzheimer disease (AD) creates a partial lesion of locus ceruleus (LC) in many cases and provides an opportunity to investigate the consequence of noradrenergic cell loss. We studied the LC in 25 AD and 5 control cases. After formalin fixation, the pons was sectioned at ~2 mm intervals, and 3 serial sections were macroscopically selected at sites of greatest LC density, embedded in paraffin, cut at 8 µ sections, stained with hematoxylin and eosin. In each of the 3 sections all LC cells and all pigmented cells were counted bilaterally by two investigators. Hospital records of each case were reviewed and rated for presence of anxiety and agitation each on a 0-5 scale for 3 time periods: before onset of dementia, early in dementia, and middle to late in the dementia. Ratings were also performed on three subtests of Hamilton Depression Scale for agitation, psychic anxiety and 10% agitation before the onset of dementia, and 50% anxiety and 25% AD cases showed evidence of anxiety and 10% agitation before the onset of dementia, and since for an increase of 35% for anxiety and 65% for agitation. LC cell counts ange from 11.109/unilateral nucleus/section for AD group, (mean = 58.3+25.7 SD), and 73-112 (88.4+13.7) for the control group. Thiflal statistical analysis by correlation suggests the following possible trends: a possible positive correlation between LC cell count and agitation before onset and early in the course of the illness.

PROCESS OUTGROWTH, GROWTH CONES AND GUIDANCE MECHANISMS I

THE ROLE OF THE BASAL LAMINA MATRIX ON AXONAL GROWTH AND GUIDANCE IN THE RETINA. W. Halfter. Dept. of Neurobiology, Anatomy, and Cell Science, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

During early development of the retina optic axons navigate with high precision toward the optic disc. The localization of the neurites close to the vitreal

surface suggests that axonal guiding molecules are found at this site. To approach this question, the vitreal surface of the retina (inner basal lamina, covered by a monolayer of ventricular endfeet) was isolated. basal laminae were obtained from the pigment epithelium and skin. The vetricular endfeet and all basal laminae proved to be excellent substrata for neurite outgrowth, however, guidance cues were not found in all of these preparations. Antisera raised against the various basal laminae inhibited neurite extension not only on the basal laminae but also on the ventricular endfeet. Moreover, the antisera disturbed the morphology and the fasciculation of the neurites. The results show that 1. and axonal navigation extension regulated, 2. basal laminae independently ventricular endfeet contain similar or even identical neurite promoting molecules, and 3. matrix components also have a function on the morphology and fasciculation of the neurites.

68.3

ANTI-ASTROTACTIN BLOCKS NEURONAL MIGRATION IN VITRO. G.

ANTI-ASTROTACTIN BLOCKS NEURONAL MIGRATION IN VITRO. 6. Fishell and M.E. Hatten. Dept. of Pathology, College of Physicians and Surgeons of Columbia University, NY, N.Y. 10032

The interplay of neurons with glia is critical in the morphogenic placement of neurons during development. Previous work suggests that astrotactin plays a central role in mediating developmental neuron/glia interactions. astrotactin expression is developmentally regulated on in vitro migrating neurons. Furthermore, a series of in vitro assays has demonstrated that antisera against astrotactin can prevent the formation of neuron/glia contacts (Edmondson et al. J. Cell Biol. 106:505, 1988), and significantly reduce neuron/glia adhesiveness (Stitt and Hatten. Soc. and significantly reduce neuron/glia adhesiveness (Stitt and Hatten, Soc. Neurosci Abtr. 15;568 1989). To study neuronal migration in vitro, we Neurosci Abtr. 15:568 1989). To study neuronal migration *in vitro*, we have developed an assay which allows us to simultaneously track hundreds of migrating neurons in the presence or absence of a variety of immune activities. Culture conditions optimized for neuronal migration were generated by taking granule cell enriched cerebellar preparations and plating them at low density on matrigel. Using this assay we have demonstrated that anti-astrotactin is able to reduce neuronal migration to less than 10% control levels. In contrast, Fab fragments against L1, NCAM and TAG, antisera against the β1 integrin chain or combinations of these Fabs and artifora have no effect on the set of neuronal migration. antisera have no effect on the rate of neuronal migration. To investigate the mechanism by which anti-astrolactin blocks neuronal migration, we have recorded actively migrating neurons at high power using DIC optics in a Berg chamber and subsequently micro-perfused anti-astrolactin into the chamber. Within 1hr of the addition of antibodies migration was completely arrested and the cytological features of a migrating neuron (ie the presence of a leading process, a caudally positioned nucleus and cytoplasmic streaming into the leading process) disappeared. This suggests that astrotactin may not only help mediate neuron/glial adhesion but may also orchestrate the events involved in neuronal migration.

NEURITE-INHIBITING PROTEOGLYCANS MAY HELP DETERMINE UNIDIRECTIONALITY OF NEURITE GROWTH IN THE DEVELOPING OR REGENERATING CNS. Diane M. Snow and Jerry Silver, Department of Neurosciences, CWRU, Cleveland, Ohio 44106.
In many regions of the nervous system, axons elongate unidirectionally. However, the

mechanisms that control this stereotyped axon guidance are unknown. In the developing eye, the retinal ganglion cells (RGC), positioned at the center of the retina, generate an axon preferentially toward the optic fissure. Similarly, in the dorsal root entry zone (DREZ) of the spinal cord during regeneration of transected/reimplanted roots, axons can exit the CNS into the root, but cannot travel from the PNS into the CNS along the same pathway. What is the

reason for these unidirectional growth patterns?

Previous work in our laboratory has shown that a chondroitin-sulfate-containing proteoglycan (KS/CS-PG) is present in functional barriers *in vivo* (e.g. the roof plate) and is inhibitory to DRG neurite outgrowth in a concentration-dependent manner *in vitro*. In the present study, we examined whether this molecule may be involved in the patterning of unidirectional outgrowth in

Using immunocytochemical techniques, we found that C-6-S is expressed in the central retina of E13 rats and gradually moves peripheral to the optic fissure as the ganglion cells differentiate. By E17, the level of C-6-S is significantly reduced. At the DREZ, C-6-S is

contentinate. By EIT, the level of Co-SI s significantly reduced. At the Orlea, Co-SI s expressed on astrocytes in amounts far exceeding controls following root injury. In both examples, axons grow away from or avoid regions which express this molecule.

To test the effect of a CS-PG on directional behavior of neurites in culture, we grew E9 chick dorsal root ganglia on dishes coated with various concentrations of KS/CS-PG mixed with dorsal root ganglia on dishes coated with various concentrations of KS/CS-PG mixed with taminin (LN) on one half and only LN on the other half, since LN is expressed both in retina and in the DREZ. The growth pattern in both paradigms was analyzed. DRG neurites which begin on LN stop abruptly at the border of LN and PG/LN. However, the subpopulation of DRG neurites which initiate on the mixture of PG/LN grow undirectionally toward the LN side of the dish. This same paradigm is currently being used to test direction of growth of RGC neurites. These in vitro and in vivo data suggest that C-SS may play a role in the choice of direction of neuronal elongation. These data also provide evidence that the response of a neurite to CS or other such molecules may depend upon whether the neurite was initiated on the

PG or approached the PG after first elongating on a growth-promoting substrate.

ENTACTIN IS EXPRESSED IN THE EARLY EMBRYONIC AVIAN BRAIN, V. I. Miller and S. A. Moody. Department of Neuroscience, University of Virginia,

Entactin is an RGD bearing, sulfated glycoprotein that forms stable, non-covalent complexes with laminin in basement membranes. Laminin also occurs along forming axon tracts and may play a role in axon guidance. Therefore, we examined the developmental course of the expression of entactin in order to determine whether it might play a similar role. Tissue sections were labeled with polyclonal antibodies made against recombinant entactin (gift of Albert Chung, Univ. Pittsburg). The entire st 12-13 brain was immunopositive, with outlines of virtually all of the neuroepithelial cells visible in a radial array. The st 15-16 brain continued to be brightly labeled, however staining was most intense in the ventricular layer where cells were still proliferating. Staining was reduced in the intermediate and marginal zones of the hindbrain, which correspond to areas of cell migration and axon tract formation, respectively. By st 17 there was a rostral to caudal gradient in entactin expression; labeling in rostral regions was similar to earlier stages while that in the hindbrain was markedly reduced. By st 18/19 cellular elements in the brain were less discernable and the entactin immunofluorescence was homogenous in appearance. At st 20 the brain was stained less intensely than the surrounding mesenchyme. At st 24 staining in the brain was not above control levels. We have demonstrated that entactin is expressed early in the developing avian brain. However, its expression is not coordinated with that of laminin: entactin expression is ubiquitous and is not restricted to forming axon tracts, regions of cell migration or the basement membrane. Highest levels of entactin expression are associated with those time periods and locations in which the neuroepithelium is a cohesive germinal zone. Therefore, entactin may play a role in cell-cell attachment. Supported by NINDS NS23158

BIOCHEMICAL CHARACTERIZATION OF THE ROCA1 ANTIGEN: A MOLECULE EXPRESSED IN ROSTRO-CAUDAL GRADIENTS IN THE MAMMALIAN NERVOUS SYSTEM. Z. Kaprielian, T. Suzue**, C.S. Yee*, and P.H. Patterson. Div. Biol., 216-76, California Institute of Technology, Pasadena, CA 91125 and *Dept. of Physiology, Tokyo Medical and Dental Univ., 5-45, Yoshima, 1-Chome, Bunkyo-Ku, Tokyo, Japan

Spinal cord axons display a rostrocaudal, positional bias in their innervation of sympathetic ganglia and intercostal muscles (Wigston, D.J. and Sanes, J.R., J. Neurosci., 5:1208-1221, 1985). To examine the molecular basis of this positional specificity, mAbs were produced using the immunosuppression technique which bind preferentially to rostral sympathetic ganglia. We previously reported that the staining of one of these mAbs, ROCA1 (ROstroCAudal), is highest in rostral sympathetic ganglia and intercostal nerves and declines in a graded manner in the caudal segments. ROCA1 stains satellite cells in the ganglia and Schwann cell sheaths in the nerves, suggesting that molecular rostrocaudal differences exist on glial surfaces. We have used an immunoblot analysis to identify the ROCA1 antigen as a 60 kD protein present in membrane fractions of newborn and adult rat sympathetic ganglia and intercostal nerves. Quantification of the rostrocaudal distribution of the antigen in intercostal nerves demonstrates a gradient like that seen with the immunohistochemistry, with about four-fold more protein present in rostral than in caudal nerves. Deglycosylating membrane preparations with ENDO-H or ENDO-F does not eliminate the binding of ROCA1 to the 60 kD protein, and fails to alter the mobility of the 60 kD protein on SDS-PAGE.

DEFASCICULATION OF NEURITES INVOLVES THE MANNOSE-CONTAINING EPITOPE OF THEIR SPECIFIC 130 KD SURFACE GLYCOPROTEIN. B. Zipser and R. N. Cole. Department of Physiology, Michigan State University, E. Lansing, MI 48824 In leech neuronal development, bundles of sensory

afferents enter the CNS and defasciculate, dispersing to their connections. This defasciculation is inhibited by three independent perturbation experiments that target the interaction between the sensory afferents' unique 130 kD interaction between the sensory afferents' unique 130 kD glycoprotein and a carbohydrate-binding protein within the neurites' environment. The experiments are performed in the germinal plate of 10-11 day embryos. The macromolecular permeability of the germinal plate allows us to experimentally manipulate neuronal growth in a virtually intact nervous system. This is important since cell-type specific surface glycoproteins can be differently regulated in vivo and in vitro (Barakat et al. Biology of the Cell, 66, 1989). The binding Lan3-2 Fab fragments (6-12 nM) to the mannose-containing epitopes of the 130 kD glycoprotein forces the neurites to remain associated in a tightly fasciculated axon tract. A similar result is obtained by deglycosylating the 130 kD glycoprotein with N-Glycanase (4 units/300 ul). Addition of mannosylated BSA (1 uM), which competes for the mannose-binding protein, also inhibits the defasciculation of sensory afferents. These results suggest that carbohydrate recognition, which is well documented outside the nervous system, plays a major role in regulating neuronal architecture in the CNS.

ANTIBODIES TO 9-O-ACETYLATED GANGLIOSIDES CAUSE RETRACTION OF NEUROBLASTOMA AND DRG GLIAL PROCESSES. J.E. Friedman, S.M.

Fortune* and M. Constantine-Paton. Dept. of Biology, Yale Univ., New Haven, CT The JONES monoclonal antibody (MAb) recognizes a family of gangliosides identified as 9-O-Acetylated-GD3 and -GQ1c (Lipids 24:680,1989). These antigens are expressed along both spatial and temporal gradients in the developing rat embryo nervous system (Nature 324:459,1986), suggesting a role in neuronal guidance. We have asked whether the application of JONES interferes with process extension. B65 neuroblastoma cells which express both A2B5 and JONES antigens were selected by neuroblastoma cells which express both A2B5 and JONES antigens were selected by "panning". Cells were plated at a very low density (1-10,000 cells/ml) on collagen or poly-L-lysine (PLL) coated coversips. After several hours, when cells had sprouted processes, we recorded using video-enhanced microscopy. Approximately 50% of the cells are quiescent, 35% are extending processes and 15% are oscillating colls grow for 15-20 minutes and then retract at about the same rate. Continuously growing cells do so for >3 hrs. We taped single cells for 20-30 minutes to determine if they were growing, non-oscillating cells. The medium was replaced with one containing JONES (0.5 mg/ml). Within 5-10 minutes a rapid retraction of growing processes could be observed. Usually within 40 min, the cells rounded up but continued to extend and retract filopodia. This rapid retraction was not observed on PLL coated coverslips or with similar concentrations of MAb A2B5, which recognizes several gangliosides including GD3 and GQ1c. In primary DRG explants grown on fibronectin, addition of the JONES MAb caused elongated GPA positive cells to several gangliosides including GD3 and GG1c. In primary DRG explants grown on fibronectin, addition of the JONES MAb caused elongated GFAP positive cells to round up. Neurites were not affected directly by JONES. However, glial rounding was associated with collapse of the neurite web. Addition of the anti-integrin B1-subunit antibody induced retraction of neurites only and A2B5 had no effect. We are continuing our investigations with both the neuroblastoma and DRG explants using different substrates. We propose that the gangliosides 9-O-acetylated-GD3 and -GQ1c can modulate adhesion and thus, by virue of their topological and temporal distribution, influence the circuitry of the developing nervous system.

CLONING OF THE NEURON-GLIA LIGAND ASTROTACTIN USING cDNA LIBRARIES FROM EARLY POSTNATAL GRANULE NEURONS ME Ross^{2,3} S Vidan¹, N Heintz², and MB Hatten 1 Columbia Univ, NY, NY 100321, Rockefeller Univ, NY, NY, 100212, and Mass Gen Hosp, Boston MA, 021143

NY. 100214, and Mass Gen Hosp, Boston MA, 021143

In the developing cerebellum, we have identified astrotactin and shown that it is the major ligand forming contacts between young granule neurons and radial processes of Bergmann glia, implementing glial guided migration into the internal granule layer (Edmondson et al., J. Cell Bio 106.505, '88. Stitt et al., submitted). It is first expressed in mouse just before birth, is active during the first postnatal week and is absent in the adult. We sought to clone astrotactin for structural and functional analyses by first producing mouse cDNA libraries, directionally cloned into a modified Agt11 vector, starting from from 2x108 granule cells taken at postnatal day 3-5 and purified on Percoll granule cells taken at postnatal day 3-5 and purified on Percoll gradients. In the primary library, approximately 10⁷ recombinants, of average size 2 kb and with defined orientation, were obtained. After amplification, 10⁶ recombinant phage were screened with astrotactin antibody which, for the tertiary screen, had been purified by absorption with PC12 cells and adult cerebella. Of 3 clones selected, AN 1 contains a 500 bp insert which has a DNA sequence not found in our searches of GenBank. Moreover, antibody eluted from plaque lifts of this phage produces a 100 kD band on Western blots, corresponding to the molecular, weight of authorities astrotactin. We conclude to the molecular weight of authentic astrotactin. We conclude that AN 1 is a likely candidate cDNA coding for astrotactin and are now generating the full length species.

CHEMOTROPIC INDUCTION OF AXON COLLATERAL BRANCH FORMATION BY TARGET TISSUE IN VITRO C.D. Heffner and D.D.M. O'Leary Neurosurg and Anat & Neurobiology, Washington U Sch Med, St Louis, MO 63110

The corticopontine projection, which arises from layer 5 of neocortex, develops by delayed interstitial budding of collaterals from corticospinal axons, rather than by a direct ingrowth of primary axons or by a bifurcation of the growth cone; branches form in the axon tract overlying the basilar pons (O'Leary & Terashima 1988 Neuron 1:901). When co-cultured with explants of cortex in 3-dimensional collagen gel matrices, basilar pons elicits the directional growth of cortical axons and collaterals (Heffner, Lumsden & O'Leary 1990 Science 247:217). Here we present quantitative evidence that basilar pons induces interstitial branching of layer 5 cortical axons in the cortical explant and in the collagen gel. Full thickness pieces of PO-P1 rat motor cortex were explanted into collagen gels. 24 hrs later, PO "target" explants of basilar pons or a control tissue (olfactory bulb) were placed in the gel lateral to axons already extending from the ventricular surface of the cortical explant. After 48 total hrs, the cultures were aldehyde fixed and Dil was injected into the "target" explant, or directly into the collagen in the path of the outgrowing axons in cases in which no "target" explant was added, to retrogradely fill cortical axons, branches and their cells of origin. In cultures of cortex alone or with control tissue later added, branches are not seen in the collagen gel but occasional branches form randomly to right or left in the cortical explant; labeled cell bodies are distributed through all cortical layers with 29% in layer 5. In cultures with basilar pons added, cortical axons branch in the collagen gel with all branches directed toward the pons, and many branches are seen in the cortical explants with 93% directed toward the pons; 86% of labeled cortical neurons are in layer 5. We conclude that basilar pons release

OLIGODENDROCYTES CULTURED FROM ADULT RAT ARE PERMISSIVE FOR RETINAL NEURITE OUTGROWTH. M. D. Ard. Dept. of Anatomy, Univ. Mississippi Med. Ctr., Jackson, MS 39216.

To test the hypothesis that oligodendrocytes inhibit neurite outgrowth (and therefore axonal regeneration in CNS), explants of embryonic day 15 rat retina have been co-cultured with oligodendrocytes from adult rat spinal Dissociated spinal cord cultures were treated with fluorodeoxyuridine for 2 wks then replated onto polylysine-coated coverslips. Cells were labeled with antibodies to galactocerebroside (>90 % of cells positive) and glial fibrillary acidic protein (<5 % positive), showing the cultures to be mostly oligodendrocytes with few astrocytes present. explants placed on these cell layers all extended neurites within 5 days (n=44). Explants placed directly on polylysine did not extend neurites (n=23). Neurites, identified by antibodies to neurofilaments or by phase contrast, grew both on the comparatively rare astrocyte surfaces and on the galactocerebroside-positive processes of oligodendrocytes, which spread to cover $% \left\{ 1\right\} =\left\{ 1\right$ most of the area of the cultures. Neurites neither followed oligodendrocyte processes as if guided by them nor avoided them. It is concluded that oligodendrocytes in some circumstances can provide a permissive substratum for neurite outgrowth. Supported by NIH BRSG 2 SO7 RRO5386.

IN VITRO INTERACTIONS BETWEEN MERKEL CELLS AND APPROPRIATE (SENSORY) AND INAPPROPRIATE (SYMPATHETIC) NEURONS. Randall N. Pittman, Weslia Patterson*, Steve Pakola*, and Peter Vos. Dept. of Pharmacology, Univ. of PA School of Medicine, Philadelphia, PA 19104.

Cultured Merkel cells contain NGF and provide trophic support for NGF-dependent sympathetic and sensory neurons. Sensory neurons extend neurites onto Merkel cells in vitro and branch extensively following contact. Neurites of sympathetic neurons routinely do not grow onto Merkel cells, and growth cones often collapse and retract following contact with Merkel cells. Fixation of Merkel cells with paraformaldehyde does not alter the number of contacting sensory or sympathetic neurons; however, the extensive branching of sensory neurons is decreased to control levels. Studies branching of sensory neurons is decreased to control levels. Studies are underway to investigate the effects of altering levels of NGF produced by Merkel cells on the extent of neurite arborization on Merkel cells, and to determine the molecular mechanisms responsible for the selective contact of Merkel cells by sensory neurons and the avoidance of Merkel cells by sympathetic neurons. TEMPORAL AND SPATIAL REGULATION OF SIALATED GANGLIO-SIDE (GQ)-LIKE IMMUNOREACTIVITY ON A STEREOTYPED GROWTH CONE ARRAY J. Jellies. Neurobiology Research Center & Dept. of Physiology & Biophysics, Univ of Alabama, Birmingham, AL, 35294. Each oblique muscle organizing cell (Comb- or C-cells) in the embryonic medicinal leech (Hindo medicinalis) projects a parallel array of about 70 growth cones that navigate through the germinal plate in a stereotyped fashion. These growth cones exhibit two distinct phases of motility; an early, slowly advancing phase as they align parallel and second, a rapidly advancing phase where all growth cones extend toward the edges of the germinal plate. One might predict that molecules favoring the different motility phases would be differentially expressed. The IgM mAb A2B5 recognizes a sialated ganglioside -GQ- (Eisenbarth, et al., PNAS, 76:4913, 1979), has been used extensively as a cell-specific marker of vertebrate neurons and type 2 astrocytes (Raff, Science, 243:1450, 1989) and recognizes most, if not all embryonic leech axons as well as the C-cells in acid/alcohol-fixed whole-mounts. Embryos from each of three groups of siblings were dissected and fixed at 24 hour intervals from embryonic day 9 to 14 then at 48 hour intervals to day 18. The GQ-Like Immunoreactivity (GQLI) is temporally regulated - C-cells exhibit no GQLI during the slowly advancing phase but do label intensely just after the onset of, and during the rapidly advancing phase. Furthermore, GQLI on C-cells is largely restricted to the growth cones, with little staining of processes or somata. In negative controls, sibling embryos processed without primary mAb, or with a different IgM show no specific staining. Although the function of GQ is not understood, and the antigen recognized by mAb A2B5 in leech has not yet been identified, carbohydrate moieties have been implicated in neuronal pathfinding and recognition. The spatial and temporal distribution of GQLI on C-cell growth cones to advance through an otherwise hig

PROMOTION OF PROCESS OUTGROWTH FROM ADULT FROG MOTONEURONS IN CULTURE BY A MUSCLE ECM EXTRACT Damien P. Kuffler and Theres Luethi*. Institute of Neurobiology, Univ. of Puerto Rico, Old San Juan, Puerto Rico 00901; *Dept. of Pharmacology, Biocenter, Basel, Switzerland.

Motoneurons isolated from adult frogs, Rana pipiens, survive and

sprout for four weeks in culture in a defined medium (Erulkar et al., '90, J. Physiol., in press). Macrophages cultured along with the motoneurons interact with the motoneuron processes to bring about their elongation. Contact by a migrating macrophage with the tip of a motoneuron process, but not along its length, causes the process to elongate in association with the continued migration of the macrophage

In a further series of experiments the influence of various substrates on process outgrowth from adult motoneurons have been tested. Substrates tested include polylysine, Con A, mouse EHS laminin and a 10 mM EDTA extract of innervated skeletal muscle extracellular matrix (ECM). Of these, muscle ECM promotes the best process outgrowth. Motoneurons attach to this substrate and extend processes after 1.5 days and the processes reach an average length of 150 μ m by 14 days. We have now partially purified an ECM fraction that is far more effective in promoting attachment of motoneurons and process outgrowth. On this extract process outgrowth starts within 12 hours and the processes achieve a ten fold greater length, 1.5 mm by 14 days. When run on a SDS gel bands are seen to co-migrate with mouse EHS laminin under reduced and non-reduced conditions. These results suggest that the ECM fraction might contain a laminin-like molecule. We are presently attempting to characterize this ECM factor.

REGIONAL CEREBRAL BLOOD FLOW CHANGES IN IPSILATERAL AND CONTRALATERAL MOTOR AREAS DURING UNILATERAL MOVEMENTS.

T. Zeffiro and M. Hallett. Human Motor Control Section, NINDS, National institutes of Health, Bethesda, MD 20892.

In order to determine the relative involvement of cortical and subcortical motor areas ipsilateral and contralateral to limb movement, we have examined the changes in regional cerebral blood flow (rCBF) in subjects performing unilateral flexion and extension movements of the wrist. We studied 12 subjects with positron emission tomography utilizing 30 mCi injections of Ha⁰¹⁵. Emission scanning continued for 1 minute following injection of the tracer. Each subject underwent 6 scans: 2 at rest, 2 during alternating wrist movements and 2 during passive vibration of the palm. All movements were self-paced, with an average rate of 1 cycle per second. For analysis, each scan was scaled to a mean of 100 and then active and rest scans were subtracted to obtain a difference image representing the net change in rCBF. Circular regions of interest (8mm diameter) were examined in both subcortical and cortical motor areas.

regions of interest (8mm diameter) were examined in both subcortical and cortical motor areas.

The largest increases were observed in cortical areas, including: the ipsilateral and contralateral sensorimotor cortex, premotor cortex, posterior parietal cortex and the supplementary motor area. There was a strong relationship between the contralateral and ipsilateral increase in sensorimotor cortex in each subject, such that the ipsilateral increase was 30% to 40% of the corresponding contralateral change. Increases in premotor and supplementary motor areas were less lateralized.

These results demonstrate a previously unreported activation of pisilateral motor cortex during the performance of a relatively simple, unilateral motor task. The involvement of ipsilateral cortical motor areas in the planning or execution of simple, alternating limb movements may be more extensive than previously thought.

69.2

"VIRTUAL TRAJECTORIES" OF SINGLE-JOINT MOVEMENTS SHOW TWO BASIC STRATEGIES. M.L.Latash and G.L.Gottlieb. Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612

Medical Center, Chicago, IL 60612

We have recently described a method for reconstructing shifting joint compliant characteristics (JCCs) during slow movements. Further processing of the data leads to reconstructing "virtual trajectories" (VTs) of the movements. Calculating total torque as a sum of inertial and external components allowed applying this method to movements of higher speeds. In our experiments, the subjects learned a simple elbow flexion movement against a torque bias and were asked to reproduce the learned command irrespective of possible external torque changes. In different series, the amplitudes were about 18°, 36°, and 54°, and movement times were about 250 ms, 500 ms, and 800 ms. Slow torque changes (loadings or unloadings over 300, 500, or 800 ms) took place in half of the trials starting 100 ms after the tone signal to initiate the movement. The individual trials were later aligned according to the beginning moment of visible deflection of the acceleration trace corresponding to the beginning of the voluntary movement (t_0) . Acceleration, angle and torque values were measured at different times t_i after t_0 . Angle and total torque for each t_i were plotted in the at different times t_i after t₀. Angle and total torque for each t_i were plotted in the torque-angle plane and linear regression equations were computed (coefficients of linear correlation over 0.8 for more than 50% of the sets). The regression equations let one assess changes in the JCC threshold and slope during a movement and calculate a VT. For slow movements, the VT was monotonic and ahead of the averaged "actual trajectory". VTs of fast movements were N-shaped irrespective of movement amplitude. There was a considerable increase in the JCC stiffness in the middle of the fast movements. Fast movements over different amplitudes (Speed-Insensitive Strategy) had coinciding VTs during the initial phase. Both ascending arms of the N-shape were directly scaled with the amplitude. VTs for movements with different speeds (Speed-Sensitive Strategy) diverged at the very beginning. The method allows reconstruction of VTs in a wide range of movement speeds.

The study was supported by NIH grants AR 33189 and NS 15630 and American Paralysis Association grant LA1-8901-1.

GUIDANCE OF VOLUNTARY MOVEMENT. P.R. Burgess and T.A. Cooper*. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108.

Two strategies might be used to move an object from one ace to another. <u>Model A</u>: The voluntary motor system place to another. uses preselected torque-angle relationships to guide a load to a particular final position. Any unanticipated difference in the size of the load will produce a position error whose magnitude is determined by the steepness of the torque-angle profiles and the size of the difference, the torque-angle profiles and the size of the difference, assuming that sensory feedback is not used to make a voluntary shift to a more appropriate torque-angle relationship. Thus, the greatest accuracy is achieved with the steepest profiles (the stiffest joint). Model B: If involuntary torque-angle relationships are not steep but relatively flat, even a small unanticipated difference in lifted weight, if uncorrected by an appropriate change in effort, would result either in little or no movement or an overshoot error that could easily be many degrees in amplitude. As a result, Model B is highly dependent on feedback to regulate voluntary commands. When subjects are asked not to intervene voluntarily during an abrupt change in load, Model A is supported. When they are asked to make the same effort in isometric tests at different joint angles, Model B is supported. What are the implications of these observations for the role of high level sensory feedback in the guidance of voluntary

PREMOVEMENT MODULATION OF THE SOLEUS H REFLEX IS NOT ALTERED BETWEEN MON-TRACKING, TRACKING, AND PERTURBED TRACKING TASKS. D.P.Collins.
J.D.Brooke, W.E.McIlroy. Neurophysiology Lab., School of Human Biology, University of Guelph, Guelph, Ontario, Canada, NIG 2VI.

Plasticity of gating of the homonymous Ia afferent pathway to Soleus (Sol) motoneurons just prior to bilateral ankle movement was studied in six subjects. The research investigated if the characteristic agonist and antagonist premovement modulation could be altered when the "need" for that afferent input was changed. Montracking, tracking, and perturbed tracking tasks were used as low, medium and high "need" situations respectively. Each subject took part in two sessions; in one, the movement was plantarflexion (Sol agonist), and the other, dorsiflexion (Sol antagonist). The perturbations rotated the ankle in the direction of movement, requiring correction by the antagonist, and were delivered after the response signal and before movement onset. They were introduced before approximately 20% of the trials within a block, in a random order. Sol H reflexes were evoked between the response signal and movement onset in all trials. Only H reflexes from the non-perturbed trials were collected for analysis. They were separated into 20 ms bins, relative to contralateral EMG onset, and averaged (95% CI=;15%). Control reflexes were collected during each experimental session, prior to the delivery of the warning signal. Stimulation intensity was maintained at the lowest level at which the H reflex could be evoked concommitantly with a small but stable H wave. Results indicate that this task "need" does not alter the pre-movement modulation. Also, comparison of the control reflexes indicates no change in the ongoing tonic control exerted on this pathway between these tasks. The lack of plasticity in the afferent gating shows that adaptations for such task changes are achieved through other inputs to the motoneurons.

FUNCTIONAL CHARACTERISTICS OF REFLEX COACTIVATION IN MAN. F. Lacquaniti, N.A. Borghese* and M. Carrozzo*. I.F.C.N., C.N.R.,

20131 Milano, Italy.
The behavior of stretch reflexes in man has most often been investigated during tasks involving position control. Only recently has it begun to investigate reflex behavior during mechanical interaction of the limb with an object. Thus, it was found that the desired the desired that the stretch of th an object. Thus, it was found that during a catching task the reflex responses evoked by ball impact on the hand the reflex responses evoked by ball impact on the hand violate the law of reciprocal innervation, since antagonist muscles are coactivated. To discriminate between central preset and peripheral effects (e.g. skin stimuli) on the reflex, we studied here the behavior of stretch reflex responses evoked by torque motor perturbations applied before and during catching. Under basal conditions, such responses do conform to the law of reciprocal innervation. Thus, we considered that if reflex coctivation was contigent on the peripheral stimulus of ball impact, no changes in the stretch reflex evoked by torque pulses would occur prior to impact, while if reflex coactivation can be centrally preset, a reversal of the stretch reflex would occur prior to impact. The latter case was experimentally found. By computing the temporal changes of the mechanical impedance of the hand during catching, we found that this parameter is effectively maximized around impact time.

KINESTHETIC TRIGGERING MECHANISMS IN MOVEMENT SEQUENCES. P. J. Cordo, R. S. Dow Neurological Sciences Institute, Portland, OR 97209 This experiment examined how the nervous

This experiment examined how the nervous system processes kinesthetic input from 1 joint to trigger movement at another joint in movement sequences. Human subjects opened the right hand without visual feedback as the right elbow was passively extended through a target angle 25 deg from the starting angle. Seven constant velocities (18-85 deg/s) were presented in random order. Two variations of this experiment included rotations which either stopped or changed velocity before reaching the target. The results indicate that:

1] Subjects can use kinesthetic input from the

1] Subjects can use kinesthetic input from the passively rotating elbow to open the hand with passively rotating elbow to open the hand with great accuracy. Depending on the velocity, the average error ranged from 0.5-3 deg.

2) The latest time at which kinesthetic input can influence the timing of the hand movement is 100 ms before the hand begins to open.

3) During the elbow rotation, the nervous system continuously calculates the angle in front of the target at which the motor command must be triggered so the hand opens at the target angle.

4) The calculation of this "triggering angle" is based on kinesthetic input related to the elbow velocity. Presumably, this triggering angle is compared to elbow angle during the rotation.

REFLEX REVERSAL DURING HUMAN RUNNING: DIFFERENTIAL CONTROL OF BICEPS FEMORIS AND TIBIALIS ANTERIOR. J.Duysens, A.A.M.Tax*, M.Trippel* and V.Dietz* Dept. of Med. Physics & Biophysics, K.U.Nijmegen, 6500 HB Nijmegen, The Netherlands and Dept. of Clin. Neurology & Neurophysiology, Univ. of Freiburg, D-7800 Freiburg i. Br., F.R.G.

By electrically stimulating the sural nerve at the ankle one obtains ipsilateral reflex responses with a latency between 57 to 85 ms in biceps femoris and tibialis anterior in humans at rest. This coactivation suggests that both muscles participate in a common flexor reflex. During running the two muscles differ in their spontaneous activity pattern and the question arises whether reflex coactivation would persist under these conditions. Therefore the modulation of these reflex responses to sural nerve stimulation during the step cycle was studied in human volunteers running on a treadmill.

responses to sural nerve stimulation during the step cycle was studied in human volunteers running on a treadmill.

Biceps femoris showed a small amount of spontaneous activity during early and middle stance, while a large burst occurred in the second half of the swing phase. In contrast, the reflex responses in this muscle reached quite a large amplitude at the beginning and near the middle of the stance phase while being small during swing. Tibialis anterior was active at the start and the end of the swing phase and this roughly corresponded to the period of maximum reflex activations. Hence the ipsilateral biceps femoris had responses which were out of phase both with its spontaneous activation during running and with the responses in the tibialis anterior. This reversal indicates that reflex pathways to these two muscles are controlled indepently during running. Equivalent results were obtained in the leg contralateral to the Equivalent results were obtained in the leg contralateral to the stimulation: crossed biceps femoris responses with a latency of about 80 ms occurred predominantly during the contralateral stance phase

69.8

KINEMATIC AND KINETIC CHANGES DURING THE LEARNING OF A MULTI-ARTICULAR KICKING MOVEMENT. R.P. Young and R. Marteniuk. Dept. of Kinesiology, University of Waterloo, Waterloo, Ont., Canada, N2L 3G1.

The present study examined the changes in kinematics and kinetics that accompany the learning of a kicking task. Subjects performed 15 blocks of 16 right-legged kicking movements with a 1.67 kg weight attached to the sole of their foot. Subjects attempted to perform all movements as close as possible to a goal MT of 400 ms. Changes in temporal accuracy indicated that subjects learned the movement. Movement kinematics, as measured by end-effector path and hip-, knee-, and ankle-angle trajectories, changed minimally as the movement was acquired. In contrast, net muscle moments, as calculated using inverse dynamics, became stereotypic as the movement was learned, even after temporal accuracy had stabilized. Also, net-musclemoment trajectories for adjacent joints became more coordinated as the movement was learned. Therefore, subjects learned to perform the movement by producing a preferred set of motor commands, in the form of coordinated net-musclemoment trajectories.

BIOMECHANICS OF HUMAN HEAD MOVEMENT CONTROL IN THE SAGITTAL PLANE. W. Graf, D.H. Wang, C. de Waele*, P.P. Vidal and B. Jaenisch*. The Rockefeller University, New York, NY 10021; Lab. Physiologie Neurosensorielle, CNRS, 75270 Paris, France; Schildautal-Klinik, 3370 Seesen/Harz, FRG.

The range of motion of the head-neck joints was measured form X-ray photographs taken at rest, in extreme flexion and extension. Movement strategies of flexion/extension movements were obtained via fluoroscopy imaging. Most of the data could be retrieved from the published literature.

he data could be retrieved from the published literature. As in other vertebrates, including monkeys, there is only a limited range of motion between most cervical vertebrae with the largest excursions possible in the atlanto-occipital articulation and at the cervico-thoracic junction. As in monkeys, the range of motion of the atlanto-occipital articulation is very limited (8-13 deg). However, unlike in other vertebrates, all cervical vertebrae in human are much more brought into play during the observed flexion/extension movements. In particular, significant translational excursions are obvious. Nevertheless, flexion/extension movements are largely constrained to occur at the atlanto-occipital articulation and at the cervico-thoracic junction. In particular, the latter is used for most flexion/extension movements. Similar to the monkey, this may be a consequence of the limited range of motion of the atlanto-occipital articulation. Thus, large flexion/extension movements of the head-neck ensemble are only possible by moving the entire cervical column in the sagittal plane. - Supported by USPHS grant EY-04613.

RED NUCLEUS DISCHARGE DURING REACHING IN CATS. K.M. Horn, P.L.E. van Kan and A.R. Gibson. Barrow Neurological Institute, Phoenix, AZ, 85013.

Magnocellular red nucleus (RNm) contains discrete populations of neurons that discharge during movements of the forelimb or hindlimb. This study was undertaken to determine if a coordinated whole limb movement recruits activity in a high proportion of RNm neurons. To date, we have recorded from 17 forelimb RNm neurons in a cat trained to reach out and retrieve a lever. The lever was mounted on a

torque motor so that loads and perturbations could be introduced during movement.

All units have shown large modulations in discharge during the task. Mean firing rate increased from 25 ± 18 imp/sec at rest to 161 ± 88 imp/sec during movement. While the responses of RNm neurons were consistent across repeated reaches, individual neurons preferentially responded to different aspects of the task. Surprisingly, no unit has shown a response to perturbations introduced during movement, and only one unit has shown a load-related response (a firing decrease with increased load). The reaching paradigm promises to be a valuable motor task for analyzing the contribution RNm makes in the control of forelimb

QUANTIFICATION OF ELECTROMYOGRAPHIC ACTIVITIES USING CIRCULAR STATISTICS. D. Bourbonnais, M. Goyette*, J. Filiatrault*, J. Gauthier*, A.B. Arsenault, and D. Gravel*, Montreal Rehabilitation Institute and School of rehabilitation, University of Montreal, Montreal, Quebec, Canada, H3C 3J7.

Circular statistics were used to characterize electromyographic activity (EMG) recorded in the lower limb of normal subjects. Subjects (n=12) were required to maintain a static torque (approximately 30% Max) at the hip in abduction(0°), adduction(180°), flexion(90°), extension(270°) and in intermediate directions (45°, 135°, 225°, 315°). EMG activity of each muscle was represented by a vector. The vector's magnitude was determined by the average value of the rectified EMG and its angle was determined by the direction of the torque. The EMG vectors, in all of the eight directions, were summed for each subject. The resultant vector represented the mean angle and mean EMG magnitude. Among subjects, the mean EMG activity of the gluteus medius, rectus femoris, gracilis, biceps femoris and gluteus maximus was observed at 28°, 70°, 150°, 274° and 325° respectively. The Hotelling two-sample test revealed that activity of these muscles was significantly different amongst themselves (p<.05). These results indicate that circular statistics are a potential tool to characterize direction and magnitude of muscle activities

NOCICEPTIVE INFLUENCES UPON RUBROSPINAL CELLS IN THE CAT.

H. Steffens* and Y. Padel. Lab. Neurosciences
Fonctionnelles, Equipe "Mécanismes Sensori-Moteurs", CNRS, 13009 Marseille, France.

The red nucleus (RN) in the cat receives somaesthetic The red nucleus (RN) in the cat receives somaesthetic messages through a medial subdivision of the spinothalamic system which gives off collateral fibers to the RN (Padel, Y. et al., Behav. Brain Res., 28:139-151, 1988). It is a common knowledge that nociceptive messages are conveyed to the upper nervous system through the spinothalamic system. The aim of the present experimental series was to check whether nociceptive information is able to modify the rubral activity when the RN is isolated from cerebellar and cortical influences.

Acute experiments were carried out on cats decerebrated at the level of the caudal thalamus and in which the brachium conjunctivum was sectioned stereotaxically. The RN cell activity was recorded while noxious radiant heat was locally applied to the skin.

In this cat preparation it was confirmed that the tonic activities of the red nucleus cells are modulated when the cutaneous temperature reaches the nociceptive threshold. When the stimulation is applied inside the somaesthetic peripheral field of the cell under study, it induces progressive acceleration or deceleration of spike

progress_ frequency.
This result demonstrates that the information participates in the sensori-motor regulation through the spino-rubro-spinal loop.

NERVE GROWTH FACTORS I

70.1

NERVE GROWTH FACTOR RECEPTOR IMMUNOREACTIVITY IN HYPOTHALAMO-PITUITARY AXIS, PINEAL GLAND AND CEREBELUM IN HUMANS AND MONKEYS, E.J. Mufson, S.D. Styren, Inst. for Biogerontology Research., Sun City, AZ 85351, G.A. Higgins, NIA, Bethesda, MD and J. H. Kordower, Univ. Illinois Med. Sch., Chicago, IL.

The degree to which nerve growth factor (NGF) may be involved with non-cholinergic systems remains unclear. Using a monoclonal antibody (NGFRS), nerve growth factor receptor (NGFR) immunoreactive (IR) profiles were observed in the hypothalamo-pituitary axis, pineal gland and cerebellum in postmortem paraformaldehyde fixed tissue from aged normal humans and adult New World monkeys (Cebus apella).

The human hypothalamic tuberoinfundibular region contained NGFR-IR small bipolar type cells and fibers of varying thickness as seen with light and electronmicroscopy (EM). Thin IR fibers appeared beaded with swellings indicative of Herring bodies. The infundibulum (median eminence) exhibited a dense matrix of NGFR immunoreactivity including vascular, recellular and fiber staining in both species. Human pituitary reacted for NGFR and viewed with light and EM revealed IR fibers, cells as well as vascular staining within the pars distalis and pars nervosa.

Fineal gland processed for NGFR-IR and analyzed at the light and EM levels revealed IR cells in the human.

Cerebellum reacted for NGFR-IR revealed periodic columns of immunoreactivity extending from the Purkinje cell layer throughout the molecular layer within the lateral cerebellar (neocerebellum) and floccular nodular (archicerebellum) lobes, Receptor immunoreactivity was present in a large percentage of Purkinje cells and dendrites. Regional differences in columnar and Purkinje cells staining occurred with the most intense NGFR immunoreactivity in the floccular nodular lobe. mRNA NGFR in situ hybridization also revealed positive Purkinje cells.

These findings suggest NGF may play a key role in primate neuroendocrine and motor function. Support AHAF, NS 26146 NS 25655 a

TEMPORAL EXPRESSION, IN VIVO, OF LOW AND HIGH AFFINITY NERVE GROWTH FACTOR RECEPTORS IN QUAIL EMBRYOS J. Speight and P. Bernd. Dept. of Anatomy and Cell Biology, SUNY Health Science Center, Brooklyn, NY 11203.

Since nerve growth factor (NGF) receptors, as detected by ¹²⁵I-NGF binding, are not demonstrable in neural crest (NC) cultures until 3 days past explantation (comparable to E5 in vivo), premigratory and early migratory NC cells probably do not require NGF for initial differentiation and migration. We examined quail embryos *in vivo* at stages 19 to 24 (E3 to E4) for both low and high affinity NGF receptors. Serial cryostat sections (10µm) were exposed to either high (20ng/ml; 800pM) or low (2ng/ml; 80pM) concentrations of ¹²⁵I-NGF (90 min, 37°C); nonspecific binding was estimated with an excess of nonradioactive NGF (1µg/ml). Dorsal root ganglia (DRG) in stage 35 (E8) embryos were used as positive controls. NGF receptors were localized with radioautography, while migrating NC cells were identified in adjacent sections with the monoclonal antibody, HNK-1. At the higher concentration, specific ¹²⁵I-NGF binding was first seen at stage 21 (E3.5) to the lateral motor columns (LMC) and to HNK-1 positive cells beneath the ectoderm. The NGF receptors on the LMC and NC cells appear to be only of the low affinity subtype, because of the absence of ¹²⁵I-NGF binding at the low concentration. At the lower concentration, specific ¹²⁵I-NGF binding, characteristic of the high affinity receptor subtype, was first seen at stage 23 (E3.5 to 4) to DRG. These studies have shown the exact stage at which NGF receptors appear, and for the first time, differentiated between the appearance of the low and high affinity receptor subtypes. Supported by grants from the March of Dimes (#1-1090) and NSF (BNS-8896101).

INTRACEREBROVENTRICULAR (ICV) ADMINISTRATION OF MGF TO NEWBORN RATS ULTIMATELY INDUCES A PERMANENT DEFICIT OF CHOLINERGIC MARKERS IN THE HIPPOCAMPUS (THE NGF PARADOX). G. Vantini, M.A. Tria*, N. Schiavo*, M. Fusco, A. Zanotti* and A. Leon. Fidia Research Laboratories, 35031 Abano Terme, Italy

Septohippocampal cholinergic neurons respond in vivo to i.c.v. administration of NGF with a prominent increase of choline acetyltransferase (ChAT) activity. In both developing and adult animals the increase of ChAT activity returns to control levels upon discontinuation of NGF treatment. In this study we have further analyzed the time-course of the response of ChAT activity to a number of NGF treatment schedules (all injections were performed in the first postnatal week) in the hippocampus of newborn animals. Results indicate that i) all NGF treatments ultimately cause a decrease of ChAT activity in the hippocampus; ii) such a decrease is paralleled by a concomitant reduction of acetylcholinesterase and iii) these cholinergic alterations are still present at postnatal days 28 and 120. All together these data suggest that administration of NGF to newborn rats can paradoxically produce a selective cholinergic denervation in the hippoproduce a selective challergic denervation in the hippo-campus. Since similar alterations have not been detected in rats treated with NGF in adulthood, we suggest that developing septal cholinergic neurons might undergo to a "tropic" influence by exogenous NGF, thus disturbing proper hippocampal innervation.

IN RATS THE RESERPINE INDUCED INCREASE OF BRAIN NGF BIOSYNTHESIS IS MEDIATED BY CORTICOSTEROIDS.

M.Fabrazzo*. E.Costa and I.Mocchettis. FGIN and \$Department of Anatomy and Cell Biology, Georgetown Univ., Washington, DC 20007.

Nerve Growth Factor (NGF) has been suggested to play an important role as a modulatory molecule on neuro-endocrine-immune functions (Montalcini et al., 1990). This consideration has prompted us to investigate the possible mechanism(s) regulating NGF biosynthesis during stress. We used reserpine, a drug known to activate the pituitary-adrenocortical system, thereby producing a persistent hypersecretion of ACTH and a consequent increase in blood

hypersecretion of ACTH and a consequent increase in blood corticosterone levels.

In 21 day old rats, a single injection of reserpine (0.125-2 mg/kg, s.c.) induced a time and dose dependent increase in plasma corticosterone which is followed by an increase in NGF-mRNA (3-4 fold) and NGF-protein (50%). The increase in NGF biosynthesis is specifically localized in the cerebral cortex; in fact the content of NGF failed to change in other brain structures. In 3 month old rats the response to change in other brain structures. In 3 month old rats the response to change in other oran structures. In 3 month old rats the response to reserpine is still present but the doses of the drug required are greater than in 21 day old rats. To further characterize the role of glucocorticoids in mediating the reserpine induced increase in NGF expression, we performed studies in adrenalectomized (ADX) animals. When an effective dose of reserpine was given to ADX rats, the alkaloid failed to increase NGF biosynthesis in cerebral cortex.

These results confirm that adrenal hormones play a crucial role in the regulation of NGF during stress and support the current hypothesis that the increase in NGF biosynthesis may establish a link between endocrine and central neuronal function and might be operative in modulating individual immunoreactivity.

70.7

INVOLVEMENT OF SECOND MESSENGER SYSTEMS IN THE INTERLEUKIN-1 STIMULATION OF NGF SECRETION FROM CORTICAL ASTROCYTES. M. Carman-Krzan and B.C. Wise. FGIN, Georgetown University, Washington, D.C. 20007.

Our previous studies demonstrated that interleukin-1 (IL-1) stimulates NGF secretion from rat neonatal cortical astrocytes in primary culture by a mechanism independent of cell growth. In the present study, we investigated the possible intracellular second messenger mechanisms involved in the IL-1 induced NGF secretion. The IL-1 stimulation of NGF secretion was Ca2+ dependent since IL-1 (10 U/ml) did not increase NGF secretion from astrocytes maintained in Ca2+-free media for 24 hours. Treatment of cells with the phospholipase A2 inhibitor mepacrine (1-30 µM) inhibited the IL-1 induced NGF secretion at the highest dose used (30 μ M). Indomethacin (10 μ M), a cyclo-oxygenase inhibitor, produced a slight increase in basal NGF secretion, but failed to inhibit NGF secretion stimulated by IL-1. In contrast, treatment of cells with nordihydroguaiaretic acid (10 μ M), a lipoxygenase inhibitor, inhibited NGF secretion by IL-1. We also tested whether the second messenger cAMP would affect NGF secretion from astrocytes. Treatment of cells with the membrane-permeable cAMP analog 8-(4-chlorphenylthio) adenosine-3':5'-monophosphate (100 μ M) had no significant effect on NGF secretion during a 24 hr period. The results suggest that one of the mechanisms of the IL-1 stimulated NGF secretion from astrocytes is activation of the phospholipase A2-lipoxygenase pathway.

THE PRESENCE OF NGF OR ITS MEMORY ARE NECESSARY FOR THE INDUCTION OF C-FOS PROTEIN BY SERUM, DEPOLARIZATION. CYCLIC AMP OR TRAUMA IN CULTURED RAT SYMPATHETIC NEURONS. A.M. Tolkovsky' and A. E. Buckmaster' (SPON: Brain Res. Assoc.) Dept. Human Anatomy, Oxford University, UK We have defined the conditions that are required to obtain c-FOS

(protein) expression in cultured rat sympathetic neurons as part of a program aimed at defining the cellular mechanisms that mediate the actions of NGF

Using an antibody raised against the N-terminal portion of c-FOS by Gerard Evan (ICRF, St. Barts), we show that NGF induces c-FOS independently of any other stimulus both in established cultures when NGF is added after its deprivation and in newly isolated neurons. In contrast, induction of c-FOS by brief depolarization, by cutting neurites or spiking cell bodies with a needle, by cyclic AMP or by serum requires the presence of NGF or its memory. In established cultures, NGF must not have been withdrawn for more than 8-12 hr to enable induction of c-FOS. while in newly excised neurons the trauma of preparation, depolarization or serum are not able to induce c-FOS at all. Cyclic AMP can still induce c-FOS within 3-4 hr of neruonal isolation but not later. At the point when no c-FOS is induced by these stimuli, the rates of protein and RNA synthesis are still ~80% of the rates obtained in the presence of NGF.

These results show that NGF is unique among several stimuli in its ability to induce c-FOS in these neurons. Furthermore, the results suggest that c-FOS may be a useful indicator for the memory of the presence of NGF, a memory which clearly exists for a very limited period after removal of neurons from the animal.

Secretion of Nerve Growth Factor (NGF) by glial cells in vitro. I. Neveu, R. Houlgatte, D. Wion and P. Brachet. INSERM U298, CHRU, F-49033 Angers, France.

The ability of glial cells to secrete NGF in their culture medium was investigated during the first week following their transfer in vitro. Use of a double-site ELISA assay indicated that the production of NGF remained undetectable during at production of NGF remained undetectable during at least one week, when cells were cultured in a serum-free medium. In low serum (0.05%) containing medium, induction of cell division by growth factors such as EGF or FGF had no effect on NGF production. In contrast, a release of NGF was observed in high serum (5%) containing medium, and was more elevated in exponentially growing cultures that in confluent cultures. This effect was depressed in the presence of effect was depressed in the presence of dexamethasone. Promotion of NGF production by serum appears more important when cells have been cultured for several days in a serum-free medium. This suggests that NGF synthesis in response to serum depends on some permissive event which is triggered in vitro. Phorbol esters, unlike cyclic nucleotide analogs, mimick the effect of serum. Therefore, a protein kinase C appears involved in the up regulation of NGF synthesis.

NGF regulates the differentiation of neuronal precursor cells. Elena Cattaneo and Ron McKay, E25-435, MIT, Cambridge, MA 02139

Recent studies have shown that NGF and its receptor are distributed in many regions of the developing brain. However until now the only population of CNS cells demonstrated to be NGF responsive are the cholinergic neurons of the basal forebrain and striatum. In the present study we suggest that, during development, NGF may have an earlier and district function consistent with the wide distribution of its mRNA and receptor. In E13.5-14.5 rat striatal primary culture we show that NGF (150ng/ml) after 2 days of bFGF priming (5ng/ml), increases the number of nestin-precursor cells 17.7 times compared to the control in 9 days treatment. At this time, following NGF withdrawal, these proliferating precursor cells are capable of differentiating morphologically and immunohistochemically into neurons. The specificity of the NGF effect has been confirmed incubating the culture with other combination of growth factors and with an antibody against NGF. Therefore during factors and with an antibody against NGF. Therefore during development NGF, in combination with other growth factors may have a role in the control of neuronal cell number. Critical fate choices are made at the transition from precursor to post-mitotic neuron, the serum free in vitro system of dissociated precursor cells defined in this study, can be used to determine the signalling mechanisms regulating neuronal number and type in the CNS.

SYSTEMIC NERVE GROWTH FACTOR REGULATES THE PHENOTYPE OF DEVELOPING SYMPATHETIC AND SENSORY NEURONS AT THE GENETIC LEVEL. F.D. Miller, T.C. Mathew* and J. Toma. Dept. of Anatomy and Cell Biology, Univ. of Alberta, Edmonton, Alberta.

We have examined, using Northern blot and in situ hybridization We have examined, using Northern blot and in situ hybridization analyses, changes in gene expression in neonatal rat superior cervical and dorsal root ganglia following systemic treatment with nerve growth factor (NGF). Daily administration of 5 mg/kg 2.55 NGF from postnatal days 2 to 11 induced increases in mRNAs encoding NGF receptor and Tal e-tubulin, the major growth-associated e-tubulin, in both sympathetic and sensory neurons. In addition, systemic NGF differentially regulated genes associated with the systemic NGF differentially regulated genes associated with the transmitter phenotype of sympathetic neurons: tyrosine hydroxylase mRNA increased, while neuropeptide Y mRNA was not affected. Interestingly, the NGF-mediated increase in NGF receptor mRNA was specific to developing neurons, and was not observed in nonneuronal cells of the sciatic nerve, which also express NGF receptor mRNA. A similar NGF-mediated up-regulation of NGF receptor and Tal mRNAs occurred in NGF-treated PC12 cells and was mediated at the transcriptional level. Together, these data demonstrate that systemic NGF induces tyrosine hydroxylase, Tal a-tubulin, and NGF receptor gene expression in developing peripheral neurons. Thus, endogenous, target-derived NGF may not only promote neuronal survival, but may also provide essential protein for terminal arborization, and may play a role in maturation of neuronal phenotype. Increases in NGF receptor levels could also provide a cellular mechanism for potentiating the effects of NGF on NGF-responsive neurons during the period of neuronal competition and cell death. and cell death.

MOLECULAR CLONING, EXPRESSION AND BIOLOGICAL ACTIVITIES OF A NOVEL NEUROTROPHIC FACTOR WITH STRUCTURAL SIMILARITIES TO

NOVEL NEUROTROPHIC FACTOR WITH STRUCTURAL SIMILARITIES TO NOF H. PERSSON, PERNORS, CF. IBÁSEZ* TEBENDAL Department of Medical Chemistry, Laboratory of Molecular Neurobiology, Karolinska Institute, Box 60400, S-10401 Stockholm, Sweden; and *Department of Developmental Biology, Biomedical-Center, Uppsala University, S-75123 Uppsala, Sweden.

Recently, a genomic clone for brain derived neurotrophic factor (BDNF) was isolated and nucleotide sequence analysis of this clone showed that BDNF is structurally similar to NGF. We have used a pool of degenerate oligonucleotides representing all possible codons in regions of homology between BDNF and NGF to prime rat hippocampal cDNAs in the polymerase chaine reaction. The amplified DNA included a product with significant similarity to NGF and BDNF which was used to isolate a 1020-nucleotidelong cDNA from a rat hippocampal library. From the nucleotide sequence, a 282-amino-acid-long protein with approximately 45% amino acid similarity to both pig BDNF and rat NGF was deduced. In the adult brain the mRNA for this protein was predominantly expressed in the hippocampus. The developmental expression of the novel factor in brain showed a clear peak of mRNA shortly after birth, one and two weeks earlier than maximal expression of BDNF and NGF, respectively. It was also expressed in several peripheral tissues with the highest level in kidney. The protein, weeks earlier than maximal expression of BDNF and NGF, respectively. It was also expressed in several peripheral tissues with the highest level in kidney. The protein, transiently expressed in COS-cells, was tested on chicken embryonic neurons and readily stimulated fiber outgrowth from explanted Remak's ganglion and to a lower extent the nodose ganglion. A weak, but consistent fiber outgrowth response was also seen in the ciliary ganglion and in paravertebral sympathetic ganglia. Moreover, the protein displaced binding of NGF to its receptor, suggesting that it can interact with the NGF-receptor. Thus, although structurally and functionally related to NGF and BDNF, this novel factor is expressed in a temporal and spatial arrangement different from both NGF and BDNF, and has unique biological activities, suggesting that this protein is a member of a family of neurotrophic factors that may cooperate to support the development and maintenance of the vertebrate nervous system. Due to its restricted the development and maintenance of the vertebrate nervous system. Due to its restricted expression in the brain, being mostly confined to the hippocampus, we have named this protein hippocampus-derived neurotrophic factor.

DEPOLARIZING INFLUENCES REGULATE NERVE GROWTH DEPOLARIZING INFLUENCES REGULATE NERVE GROWTH
FACTOR (NGF) mRNA EXPRESSION IN CULTURED
HIPPOCAMPAL NEURONS. <u>B. Lu. M. Yokoyama. C. F.</u>
Dreyfus. and I. <u>B. Black.</u> Div. Devel. Neurol., Cornell Univ.
Med. Coll., New York, NY, 10021, and Dept. Neurosci. & Cell
Biol, UMDNJ/Robert Wood Johnson Med. School., Piscataway, N.I. 08854

Both trophic influences and impulse activity have been invoked in environmental regulation of neuronal plasticity. However, the relationship between neuronal activity and the trophic effects in neural development remains unclear. Using cultured hippocampus as a model system, we studied the effect of neuronal depolarization on NGF mRNA expression. Depolarizing stimuli, such as 35 mM K+ or the Na+ channel agonist, veratridine, elicited a 4-fold increase in NGF mRNA in cultured hippocampal neurons. Interestingly, the levels of NGF message increased with time in vivo and in vitro, paralleling the well known profile for synaptogenesis in the hippocampus. Tetrodotoxin, which synaptogenesis in the hippocampus. Tetrodotoxin, which antagonizes depolarization by blocking voltage-dependent Natchannels, prevented the developmental rise of NGF mRNA. In contrast, disruption of endogeneous inhibitory GABA activity in culture with the antagonist, picrotoxin, increased NGF gene expression two-fold. These results suggest that NGF gene expression is enhanced by depolarizing influences, and raised possibility that impulse activity and trophic gene expression may be causally linked. (Supported by NIH grants HD23315, NS10259) NS10259)

A DEVELOPMENTAL CHANGE IN CHOLINE ACETYLTRANS-FERASE GENE TRANSCRIPTION: A POTENTIAL ROLE FOR NERVE GROWTH FACTOR? M.V. Lorenzi, F. Hefti, B.Knusel and W.L. Strauss. Dept. of Pharmacology, Univ. of Miami, Miami, FL 33101 and Andrus Gerontology Center, USC, Los Angeles, CA 90089. Choline acetyltransferase (ChAT) enzyme activity in the mammalian CNS increases both diving development and in the presence of translation. increases both during development and in the presence of trophic substances such as nerve growth factor (NGF). An 800 bp restriction fragment of the human ChAT gene (pCHAT1.2) detects 2 species of That in the following the control of of this transcript parallels that of cholinergic neurons in different regions of the rat brain (septum>basal forebrain>striatum>cortex). In contrast, pChAT1.2 detects 2 species of mRNA in samples isolated from embryonic rat brain. Both the 3700 and 2300 nt transcripts detected by pChAT1.2 in embryonic brain also were observed in mRNA isolated from cultures embryonic brain also were observed in mRNA isolated from cultures prepared from E17 rat medial septum. Scanning densitometry revealed that these mRNAs were approximately equally abundant in 10 day old cultures (ratio 3700 nt:2300 nt = 1.4:1). Septal neurons grown in the presence of NGF (100 ng/ml) for an equal period showed an increase in the abundance of the 3700 nt species and a reduction in the 2300 nt species (ratio 3700 nt: 2300 nt = 7.3:1). These data suggest a developmenting of the standard of the tally regulated switch in ChAT gene transcription which may be, in part, due to the effects of nerve growth factor.

GENE STRUCTURE AND FUNCTION I

71.1

CHARACTERIZATION AND DEVELOPMENTAL ACTIVITY OF A RETINAL PROTEIN THAT BINDS TO A REGION OF THE RAT OPSIN PROMOTER M.A. Morabito and C.J. Barnstable. Yale Univ. Sch.

of Medicine, Dept. of Ophth. & Visual Science, New Haven CT 06510. The developmental expression of the rat rod opsin gene is under transcriptional regulation. Transcripts can first be detected by nuclear run-off assays at PN1 and there is a 30 fold increase in the rate of transcription to reach the adult level. We have previously shown by a combination of DNase I protection and gel retardation assays that the region 5' to the opsin gene contains a number of sites that interact with nuclear proteins from adult retina but not from other tissues. One of these sites (region B) includes a CTAAT motif and is recognized specifically by retinal proteins from both rat and bovine tissues. Quantitative inhibition studies have shown that the proteins recognizing region B are different from those binding to other retina-specific sites. The importance of this region in the developmental regulation of the opsin gene is suggested by the increase in binding activity found in nuclear extracts from retinas of different ages. Between PN1 and adult

there was over 70 fold increase in the binding activity as normalized to the ubiquitous binding to an OCT 1 consensus sequence.

A bovine retinal extract was fractionated by PAGE, proteins were eluted from gel slices and tested in a gel retardation assay for binding to an from get slices and tested in a get retardation assay for binding to an oligonucleotide derived from region B. Activity corresponding to the retina-specific complex was detected in a protein fraction of approximate molecular weight 24 kD. These results indicate that the retina-specific factor binding to region B is a single protein, or oligomer of similar sized proteins. Supported by NIH grants NS20483, EY05206, EY00785 and by Research to Prevent Blindness, Inc.

THE HUMAN CHOLINE ACETYLTRANSFERASE GENE CONTAINS A NERVE GROWTH FACTOR RESPONSIVE ELEMENT. Gabriele Mues*, E. Edward Baetge, Craig M. Sampson, Chuang Fong Kong, and Louis B. Hersh. Depart. of Biochem., Univ. of Texas Southwestern Medical Center, Dallas, TX 75235 and Molecular Neurobiology, Bristol-

Myers-Squibb, Wallingford, CT. 06492 An approximately 10 Kb genomic clone containing the 5' flanking region of the human choline acetyltransferase (ChAT) gene has been isolated. Identification of the 5' flanking region of this gene was made, in part, on the basis of sequence homology with the porcine ChAT gene. An expression vector was constructed which included 3 Kb of expression vector was constructed which included 3 Kb of the 5' flanking region of the human ChAT gene behind a promotorless vector containing the luciferase gene. This vector was transfected into PC12 cells and its promoter activity assessed by measuring luciferase activity. The human ChAT gene sequences were found to promote basal expression of the luciferase gene. The addition of NGF or FGF to the cells increased expression of the luciferase reporter gene some 3 to 6 fold. These studies demonstrate the presence of a nerve growth factor responsive element in the human gene. Studies are currently in progress to define this element. this element.

IDENTIFICATION OF REGULATORY ELEMENTS IN THE RAT DOPAMINE BETA-HYDROXYASE GENE. <u>E.J. Lewis and J. Shaskus*</u>, Dept. Biochemistry and Molecular Biology, Oregon Health Sciences University, Portland, OR 97201

Dopamine beta-hydroxylase (DBH) catalyzes the conversion of dopamine to norepinephrine in the catecholamine biosynthetic pathway, and is synthesized primarily in noradrenergic and adrenergic tissue. We wish to gain understanding into the mechanisms which govern the expression of the DBH gene, and have isolated a DNA clone for DBH from a rat genomic library. The genomic clone contains the start site of transcription of the DBH gene, as determined by RNAse protection assay and comparison of the DNA sequence of the genomic clone with the sequence of the rat cDNA (McMahon et al., J. Neurosci Res 25:395,1990). The results of the RNAse protection assay indicate that the 5'-terminal 200 bases of the DBH RNA transcript is the same in rat adrenal, superior cervical ganglia and locus ceruleus. Comparison of bovine, human and rat cDNA and genomic clone sequences predicts that the signal sequences for the proteins will differ in length by up to17 amino acids between species.

The 5'-flanking sequence of the DBH gene contains putative genetic regulatory elements for response to cyclic AMP and phorbol ester. We have fused the DBH genomic sequences from -406 to +13 to the bacterial chloramphenicol acetyltransferase gene. The recombinant 5'DBH-CAT' construct has been transfected into tissue culture cells and is expressed in both rat pheochromocytoma PC12 and human neuroblastoma SHSY5Y cells. In PC12 cells, CAT activity is induced approximately 4-fold with forskolin or 8-(p-chlorophenylthio)-cyclic AMP, indicating the presence of a functional cyclic AMP response element. CAT activity is induced approximately 2 fold by either phorbol ester or forskolin in SHSY5Y cultures. We conclude that the genetic information for both basal and regulated expression of the DBH gene are present in these 400 bases of the 5'-flanking DNA.

71.5

TISSUE- AND STIMULUS-SPECIFIC EXPRESSION OF THE RAT OXYTOCIN GENE IN TRANSGENIC MICE. W. Scott Young, K. Reynolds* and E. A. Shepard* Laboratory of Cell Biology, N.I.M.H., Bethesda, MD 20892

The oxylocin (OT) gene codes for a nonapeptide that participates in the regulation of parturition and lactation. Transcripts encoding the OT preprohormone are made in magnocellular neurons of the supraoptic (SON) and paraventricular (PVN) nuclei of the hypothalamus. The preprohormone is processed into OT and an associated neurophysin during axonal transport to the posterior pituitary where the products are secreted into the circulation. OT mRNA and serum peptide levels increase with parturition, lactation, and hyperosmolality.

Little is known about factors that trans-activate the OT gene or cis-acting sequences that allow control of expression. An estrogen responsive element has been described in the OT 5'-flanking region by Richard and Zingg and by Burbach et al.

Interactions between trans-acting factors and response elements found in vitro need to be validated in vivo. In order to study the elements of the OT gene that are responsible for its tissue specific expression and regulation we inserted a 5.8kbp rat DNA fragment containing 1.7kbp of OT gene sequence with 0.36kbp of 5'-flanking sequence and 3.8kbp of vasopressin (VP) gene sequence with 1.4kbp of 5'-flanking sequence into CD1 mice. Three of four lines of transgenic mice expressed rat OT mRNA in the PVN and SON. One line that exhibited no ectopic expression was examined for its response to dehydration. Levels of rat OT mRNA were increased, as were levels of mouse OT mRNA in control mice. Our results provide a starting point for studies of OT gene regulation and put an upper limit on the size of the DNA sequence to be studied. We are currently examining the role of orientation of the rat OT and VP genes with respect to each other as well as the expression of each gene alone.

MULTIPLE SIGNALING PATHWAYS INTERACT TO REGULATE NGF GENE TRANSCRIPTION <u>G. Heinrich and Santosh R. D'Mello.</u> Department of Medicine, University Hospital and Department of Biochemistry, BUSM, Boston, MA 02118.

The combined effects of agents that individually regulate NGF mRNA levels were studied in L929 fibroblasts. The phorbol ester TPA raises, corticosterone (C) rapidly lowers, and forskolin (F) has no effect on NGF mRNA levels. F inhibited the TPA-induced stimulation of NGF mRNA without effect on basal levels. C rapidly reduced NGF mRNA levels despite the presence of TPA. We recently showed that the effects of TPA are mediated transcriptionally via AP-1 complexes that bind to an AP-1 element of the NGF gene, and that the AP-1 complexes contain fos and jun antigens. We therefore measured the effects of F and C on the TPA-induced levels of these mRNAs. C failed to affect the translent induction of c-fos and jun B mRNAs by TPA whereas F had synergistic effects. Jun C mRNA was not detectable before or after treatments. Gel-shift analyses using an AP-1 oligonucleotide revealed a minute change in the migration of the largest one of three DNA/protein complexes in TPA/F treated but not in TPA/C treated L929 cells compared with TPA treatment alone. These results suggest that multiple signaling pathways affect AP-1-mediated transcription by distinct mechanisms, and that the AP-1 site serves to integrate their effects.

MAPPING OF TRANSCRIPTIONAL CONTROL ELEMBNTS MEDIATING CELL-SPECIFIC AND ESTROGEN-INDUCED EXPRESSION OF THE HUMAN OXYTOCIN GENE. S.Richard#A. S.J.G.Richard#and H.H.Zinqq. Laboratory of Molecular Endocrinology, Royal Victoria Hospital, Montreal, P.Q., Canada. H3A 1A1.

To investigate basal and hormone-induced expression of

To investigate basal and hormone-induced expression of the human oxytocin (OT) gene, parts of the 5'flanking region were linked to the CAT gene and transfected into neural and non-neural cell lines. Using Neuro2a cells cotransfected with an estrogen-receptor expression plasmid, we identified an estrogen response element (ERE) at -164, that mediates a 12-fold transcriptional activation in response to estradiol (E₂) (JBC 265:6098, 1990). We have now identified a region R49 (-49 to +36) that mediates cell-specific expression: R49 is transcriptionally active in Neuro2a cells but virtually silent in C6 glioma or placental JEG-3 cells. Deletions within R49 which left the TATA box intact (-49-30; -11+-6; +8++36) reduced its activity to levels observed in C6 and JEG-3 cells.

To investigate to what extent the function of the ERE

To investigate to what extent the function of the ERE depends on a synergistic interaction with the R49 region, the BRE was inserted at its original position upstream of an intact or mutated R49 region. Independent of the basal expression levels, the relative responses to $\rm E_2$ remained unaltered in all constructs. We conclude that transcriptional activation by the ERE and by the R49 region represent two separate mechanisms that operate independently of each other.

71.6

MOLECULAR ANALYSIS OF NGF GENE STIMULATION BY PHORBOL ESTER. <u>S.R. D'Mello and G. Heinrich</u>. Dept of Med, University Hospital and BUSM, Boston, MA 02118.

The phorbol ester TPA stimulates NGF mRNA 10-15 fold in L929 and kidney fibroblasts but not in dispersed salivary cells. Induction is delayed for 2 hours, maximal at 4 hours, and followed by increased NGF secretion. Present evidence suggests that the induction is transcriptionally mediated via an AP-1 element at the exon 1/intron 1 junction. The induction is abolished by cycloheximide suggesting a role for immediate early gene products. Since the AP-1 element binds fos, jun, and related proteins we measured levels of the corresponding mRNAs. C-fos and jun B mRNA inductions precede NGF mRNA stimulation by TPA. C-jun mRNA is undetectable before and after TPA treatment. Gel retardation assays using L929 cell nuclear extracts and an AP-1 oligonucleotide revealed 3 protein/DNA complexes. The largest complex increased 3-5 fold upon TPA treatment. Preincubation of nuclear extracts with fos and jun antisera abolished DNA-binding confirming the presence of fos and jun-related proteins in the AP-1 complex. Serum and forskolin robustly increased c-fos and jun B but not NGF mRNA. Thus, the TPA response may be mediated by modified forms of c-fos, jun B, or both. Other proteins related or unrelated to fos and jun may also be involved.

71.8

REGULATION OF C-FOS-RELATED PROTEINS IN ADRENAL MEDULLA (AM). A.Goc, E.K. Stachowiak, J.S. Hong, M.K. Stachowiak, Div. Of Neurobiol. Barrow Neurol. Inst., Phoenix, AZ 85013, *NIEHS/NIH, Research Triangle Park, NC 27709

Stress increases expression of c-fos gene in AM cells. This report characterizes c-Fos-related proteins expressed in cultured bovine AM cells and describes their regulation by nicotine (Nic) and angiotensin (Ang). Western analyses of total cell proteins with c-Fos antibody and god-conjugated IgG revealed presence 54 Kd c-Fos protein and at least 19 additional Fos-related-antigens (FRAs; 24-68 Kd). Nic and Ang produced approximately 2 fold increases in p54 c-Fos and 10-20 fold increases in c-fos mRNA, suggesting that induced c-fos mRNA was only partially translated. While c-fos mRNA levels returned to control after 3 hours, p54 remained elevated during entire 20 hours of stimulation. The abundance of 15 and 9 FRAs was changed by Nic and Ang respectively. Nic-affected FRAs exhibited the following patterns of changes: (1) stable increases which occurred at different rate and remained elevated for at least 20 hours; (II) transient increases; and (III) decreases. Similar patterns were produced by Ang although different FRAs appeared to participate. In Ang-treated cells a group of FRA exhibited increases or decreases with a delayed onset (approx. 3 hours), whereas effects of Nic were always detected within 45 min. Most of FRA were present in nuclear fraction. p68 which may represent phosphorylated product(s) of the c-Fos was predominantly detected in cytoplasm. Expression of multiple differentially regulated FRAs in AM cells suggests that they may mediate diverse effects of hormonal and transynaptic stimulation of AM cells.

REGULATION OF C-JUN-RELATED PROTEINS IN ADRENAL MEDULLA. M.K. Stachowiak, E.K. Stachowiak*, J.S. Hong[†], A. Goc, Div. of Neurobiol. Barrow Neurol. Inst., Phoenix, AZ 85013, [†] NIEHS/NIH, Research Triangle Park, NC.

Nicotine (Nic) or angiotensin (Ang) receptors increase activities of several neurotransmitter genes in cultured bovine adrenal medullary (BAM) cells. The effects of Ang and Nic are produced through partially independent pathways. and could be mediated through induction/activation of AP-1-related transcriptional factors. Western analyses of BAM cell proteins with c-Jun/AP1 antibody and gold-conjugated IgG revealed the presence of 5 distinct c-Junrelated antigens (31,34,36,38 and 71 Kd) which were detected in nuclei but not in the cytosol. The most prominent were p36 and p38 which may represent postranslational forms of c-Jun. Incubation of BAM cells with Ang resulted in a 3-6 fold increases in the p38 and p36 levels within 45 min-20 hour period. Small and delayed increases in the p36 and p38 were observed in Nic-treated cells. Northern analysis of c-jun MRNA indicated that the changes in the steady-state levels of p36-38 reflect their enhanced synthesis. The largest p71 antigen is likely to be a product of a novel c-jun-related gene. Both Ang and Nic increased its levels, however changes produced by Ang developed more rapidly. p31 and p34 antigens were not affected by Ang but appeared to be slightly increased by Nic. These results suggest that different Jun-related proteins participate in trans-synaptic and in hormonal regulation of adrenal medullary cells.

OLFACTORY MARKER PROTEIN GENE FLANKING SEQUENCES INVOLVED IN DNA-PROTEIN INTERACTIONS. C. Stein-Izsak, M. Grillo* and F.L. Margolis. Dept. of Neurosci., Roche Inst. of Molec. Biol., Nutley, NJ 07110.

The olfactory marker protein (OMP) gene is a neuronal gene expressed in a tissue specific and developmentally-regulated manner. In a previous study with a chimeric construct using presumed upstream promoter elements of the rat OMP gene to drive the Thy 1.1 coding region, we showed that expression of this reporter gene is confined to olfactory receptor neurons in the CNS of transgenic mice (PNAS, 86:8565-8569, 1989). Peripherally, expression of the transgene is seen only in thymus due to the presence of Thy 1.1 intron 3 in the construct. Although sequence intronless, TATA-less gene.

REGULATION OF PREPROENKEPHALIN DNA BINDING PROTEINS IN THE STRIATUM. E.F. La Gamma, G. Weisinger, and J.D. istofaro, Pediatrics & Neurobiology, SUNY at Stony DeCristofaro, Pediatr Brook, NY 11794-8111.

Nuclear proteins interacting with cis-acting DNA elements form the final step in the biochemical cascade cis-acting DNA linking cellular signal-transduction pathways linking cellular signal-transduction pathways to gene regulation. Our previous gel retention studies identified SP1-, cfos-, and cjun- like binding activity on a 166 bp fragment of the 5' region of the rat gene (-249 to -83) using oligo or antibody competitors. We now observe differences in banding between basal and cholingergic induced states which are revealed by competition studies. Methylation protection footprinting confirmed these observations showing fewer SP1 protected sites, and weaker footprints over the cAMP/phorbol responsive element of Comb et al (Nature 323, 353-356, 1986) when compared to the induced state. Other intensification features were also unique to each state. Moreover, although shifted also unique to each state. Moreover, although shifted bands migrated to the same position, footprint analysis revealed a complex pattern for each gel shifted band, characteristic of each state. These data suggest that the transcription complex in basal and induced states causes a characteristic combination of protein binding at protected regions of the rat promoter in native cells. Deletion/transfection functional assays are being performed to further evaluate this speculation using cell lines and in vitro transcription assays. Supported by the National Science Foundation Grant #BN8719872.

TRANSCRIPTIONAL PAUSING AND THE RAT PREPROENKEPHALIN GENE.

TRANSCRIPTIONAL PAUSING AND THE RAI TREPROGRAFHALIN GENE.

G. Weisinger, J.D. DeCristofaro and E.F. La Gamma, Peds & Neurobio, SUNY at Stony Brook, NY 11794-8111.

The level of cholinergic induction of striatal preproenkephalin (ppENK) RNA is 10-15 fold greater when measured at the level of RNA initiation (S1 or primer extension assays) compared with steady state mRNA levels.

This research of the same assays compared with steady state mRNA levels. extension assays) compared with steady state mRNA levels. This was supported by experiments probing the same northern blots with different oligomeric DNA fragments that hybridize to ppENK exons 1 and 3. These data suggest a down regulating transcriptional or post-transcriptional event between the end of exon 1 (<17 bp) and the beginning of exon 3. One possible mechanism that could result in these observations is transcriptional pausing or attenuation. To address this possibility, S1 assays were performed using uniformly labeled single stranded S1 probes that overlap the whole of ppENK exon 1 as well as a portion of intron A (229 bp). Probes were hybridized to rat striatal total RNA from basal and induced animals. A 10 fold reduction of the appropriately spliced exon 1 band 10 fold reduction of the appropriately spliced exon 1 band 10 fold reduction of the appropriately spliced exon 1 band (152 bp) was observed in the induced compared to the basal state. There was no co-ordinate increase in unspliced exon 1 (ie. 229 bp), but the appearance of at least 2 smaller molecular weight species was noted. These data are consistent with a blockage of transcriptional elongation occurring towards the end of the first untranslated exon of the rat ppENK gene. Additional experiments including transcriptional run-on and other S1 studies are in progress. Supported by NSF #BNS8719872. studies are in progress. Supported by NSF #BNS8719872.

SENSORY SYSTEMS-SUBCORTICAL VISUAL PATHWAYS: LGN

72.1

DIRECTION SENSITIVE RELAY CELLS IN THE LGNd OF CATS AND

DIRECTION SENSITIVE RELAY CELLS IN THE LGNd OF CATS AND MONKEYS. Kirk G. Thompson, Yifeng Zhou, Steven J. Ault, and Audie G. Leventhal, Anat. Dept., Univ. of Utah, Sch. of Med., Salt Lake City, UT 84132

Direction sensitivity is a well known receptive field property of neurons in mammalian visual cortex. This property is generally assumed to be generated intracortically. We now report that about 30% of X and Y type relay cells in the A laminae of the LGNd of normal cats as well as of cats in which visual cortex has been inactivated exhibit some degree of direction sensitivity. Direction sensitive cells were also found has been inactivated exhibit some degree of direction sensitivity. Direction sensitive cells were also found in the magnocellular and parvocellular layers of the monkey's LGNd. While all LGNd cells studied responded to all directions of stimulus motion, some cells responded up to four times more strongly to stimuli moving in the preferred than non-preferred direction. In general, direction sensitivity was most pronounced when relay cells were tested with low spatial frequency sinusoidal gratings. However, some cells were direction sensitive over a wide range of spatial frequencies. Many of the direction sensitive relay cells studied were also sensitive to the direction of moving spots and bars. Some cells were orientation sensitive as well as direction sensitive. Finally, direction sensitive cells Dars. Some cells were orientation sensitive as well as direction sensitive. Finally, direction sensitive cells were distributed nonrandomly and were encountered in clusters. The presence of relay cells with direction sensitive responses similar to those of cortical cells in normal cats, decorticate cats, and monkeys indicates that direction sensitivity may originate in subcortical visual pathways. Supported by EY04951.

72.2

ORIENTATION AND DIRECTION SENSITIVITY OF LGND AND AREA The CELLS IN DARK REARED CATS. Audie G. Leventhal, Yifeng Zhou, Kirk G. Thompson, and Steven J. Ault, Anat. Dept., Univ. of Utah Sch. of Med., Salt Lake City, UT 84132

We have studied over 500 LGNd and visual cortical

We have studied over 500 LGNd and visual cortical cells in six month old cats reared in total darkness from birth. Relay cells in dark reared cats responded well to visual stimulation and their orientation sensitivity (85% of cells) and direction sensitivity (30% of cells) did not differ from normal. As in normal cats, there were relative overrepresentations of cells preferring stimuli oriented radially and tangentially. Direction selective cells as well as cells preferring similar orientations were clustered normally.

As reported previously, most striate cortical cells

As reported previously, most striate cortical cells in dark reared animals were only weakly orientation biased and relatively few were direction biased. The magnitude of the orientation biases of cortical cells in dark reared cats did not differ from those of LGNd relay cells. In fact, the most strongly selective cortical cells. In fact, the most strongly selective cortical cells exhibited the same degree of bias as did the most strongly selective LGNd cells. Moreover, the orientation biases of area 17 cells tended to be clearest when the stimuli employed were drifting sinusoidal gratings not drifting bars. Our results indicate that ontogenetic mechanisms mediate the development of the orientation and direction sensitivity of LGNd relay cells. We suggest that the intrinsic orientation and direction sensitivity of total contributes to the development of these properties in visual cortex. Supported by EY04951.

LOW THRESHOLD CALCIUM SPIKES IN LGN CELLS DURING RESPONSES TO VISUAL STIMULI. S.-M. Lu, W. Guido, and S.M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

Thalamic cells display a low threshold (LT) spike, which is a large depolarization due to an increased Ca²⁺ conductance, and typically riding its crest is a burst of 2-7 action potentials. The LT spike is voltage dependent: if the cell's membrane voltage is more depolarized than roughly -65mV, the spike is inactivated, if more hyperpolarized, the spike is de-inactivated and can be activated by a small depolarization, such as a retinal EPSP. Prior studies suggest that, once initiated, LT spiking continues spontaneously at roughly 10Hz, and while in this burst mode, the cell's activity relayed to cortex does not reflect retinal input. This suggests a dramatic interruption of retinogeniculate transmission compared to that seen while the cell responds in the relay mode, during which LT spiking is inactivated and more tonic firing occurs. To test this hypothesis, we recorded intra- and extracellular responses to drifting sinusoidal gratings from LGN cells in cats. Our results indicate that bursts of action potentials occur only during LT spiking, so we could recognize these events extracellularly. X and Y cells displayed similar LT spiking. LT spikes were activated reliably via visual stimulation and seemed identical to those activated by direct current injection or optic chiasm shock; likewise, activation of inputs from the parabrachial region of the midbrain blocked LT spiking activated from either visual or chiasm stimulation. When the cell's membrane was relatively depolarized, it responded tonically to drifting gratings. With further hyperpolarization, tonic discharges decreased and LT spiking began; however, the LT spike occurred at the beginning of the response cycle and was often followed by more tonic firing. We observed similar duality in extracellular recording: an initial burst followed by ionic firing, or simply tonic firing. The

CORTICOGENICULATE FEEDBACK GATES RETINOGENICULATE

TRANSMISSION BY ACTIVATING NMDA RECEPTORS. M. Esquerra and M. Sur. Department of Brain and Cognitive Sciences, MIT, Cambridge, MA 02142. Physiological and pharmacological evidence indicates that the NMDA subtype of glutamate receptor is present in the mammalian retinogeniculate projection (Sillito et al., J. Neurophys. 63: 347, 1990; Esquerra et al., Neurosci. Abstr. 15: 175, 1989). We wished to determine whether cortical projections to LGN cells elicit sufficient depolarization to activate NMDA receptor-mediated components of the retinogeniculate e.p.s.p.

retinogeniculate e.p.s.p.
Intracellular recordings were made in the A-laminae of LGN slices prepared from 10 ferrets 8 to 12 weeks of age. Stimulation electrodes placed on the optic tract (OT) and the optic radiations (OR) elicited postsynaptic responses from retinal and corticofugal afferents respectively. In particular, at membrane potentials between -55 and -35 mV, the OT-evoked e.p.s.p. included both early and late components that were reduced by the NMDA receptor antagonist d-APV (20 µM; n=9).

Paired stimulation of the OR and OT also activated the NMDA-receptor mediated component of the OT e.p.s.p. (n=6). The effect was manifested as a nonlinear increase in response amplitude, i.e. an OT e.p.s.p. that was larger than the algebraic sum of the single OR and OT e.p.s.p.'s, as well as a lengthening of e.p.s.p. duration. This response showed the same voltage-sensitivity and d-APV sensitivity as the NMDA-receptor mediated component of the OT e.p.s.p. in the absence of OR stimuli. The response enhancement was most pronounced when OR stimulation preceded OT stimulation by 1 - 6 ms.

These results indicate that activity in the corticofugal feedback projection to the

These results indicate that activity in the corticofugal feedback projection to the LGN can lead to a depolarization sufficient to activate NMDA receptors at the retinogeniculate synapse. We propose that a possible role of corticogeniculate feedback is to modulate the gain of retinogeniculate transmission by increasing e.p.s.p. amplitude and duration at membrane potentials at or near the action potential threshold.

BRAINSTEM MODULATION OF LAGGED AND NONLAGGED CELLS IN THE CAT LATERAL GENICULATE NUCLEUS. E.Hartveit* and P.Heggelund. Institute of Neurophysiology, University of Oslo,

A major distinguishing characteristic of lagged and nonlagged cells is their markedly different temporal re sponse properties (Mastronarde, J.Neurophysiol., 57:357, 1987). However, the visual response of LGN cells is strongly influenced by input from the midbrain peribrachial region (PBR). This raises the problem whether the distinction between lagged and nonlagged cells is maintained during PBR activation. We have therefore compared the ef-fects of electrical stimulation of the PBR on the visual response properties of lagged and nonlagged cells. The response of single cells to a stationary light spot was recorded before, during and after PBR stimulation.

The visual response of both lagged and nonlagged cells was enhanced by PBR stimulation. The mean response of nonlagged cells increased more than that of lagged cells. The latency to onset of the visual response did not change significantly for the nonlagged cells. Lagged cells with long latencies in the control recordings had reduced latencies during PBR stimulation, but no lagged cells had their latency reduced to values for nonlagged cells. We conclude that the visual response of both lagged and nonlagged cells can be enhanced by PBR stimulation, but that the division of geniculate cells into lagged and nonlagged cells is maintained during PBR stimulation.

72.4

N-METHYL-D-ASPARTATE (NMDA) AND NON-NMDA RECEPTORS PARTIC-IPATE IN EPSPS OF CAT LATERAL GENICULATE NEURONS RECORDED IN THALAMIC SLICES. S.M. Sherman, H.E. Scharfman, S.M. Lu, Guido, and P.R. Adams. Dept. of Neurobiology and the Howard Hughes Medical Institute, SUNY at Stony Brook, Stony Brook, N.Y. 11794-5230.

Intracellular recordings from coronal slices (400 um thick) of thalamus were used to examine the possible NMDA and non-NMDA receptor mediated components of EPSPs evoked by stimulating optic tract and optic radiations. Stimulation of either input evoked EPSPs with two components; one peaked less than 10 ms after stimulation ("early") and one peaked more than 10 ms after stimulation ("late"). The late component was reversibly blocked by the NMDA receptor antagonist APV (drop or bath application, 25-50 uM), whereas agonist hiv (dipp of bath application), wheteas the early component was unaffected. The APV-sensitive component was decreased in amplitude and duration by hyperpolarization, while the early component increased with hyperpolarization. At hyperpolarized membrane potentials syn-aptic stimulation of either input often evoked a low threshold spike (LTS) that was blocked by APV; there was no effect on the LTS elicited by intracellular current injection. Morphological identification by intracellular dye injection (Lucifer yellow or Neurobiotin) revealed that the recorded neurons had diverse morphology. The presence of functional NMDA receptors in the retinogeniculate and corticogeniculate pathways may allow for geniculate neurons to act as more than simple relays of visual information.

POSSIBLE IONIC BASIS FOR LAGGED VISUAL RESPONSES IN CAT LGNd

RELAY NEURONS <u>David A. McCormick</u>, Neuroanatomy, Yale School of Medicine X-cells in cat LGNd can exhibit *in vivo* two types of visual response: lagged and X-cells in cat LGNd can exhibit *in vivo* two types of visual response: lagged and non-lagged. Lagged X-cells are characterized by a delay and slow rise (10's of mesc) in response to the presentation of a visual stimulus (Mastronarde, J. Neurophys. 57: 357; Humphrey & Weller, JCN 68: 429). Although lagged and non-lagged responses have been proposed to define different cell groups, recent results suggest that they are actually different functional states of the same class of neuron (Uhlrich et al., PNAS 87: 2560). Here we investigate the possible ionic basis of lagged responses using intracellular recording techniques in cat and guinea pig LGNd relay neurons *in vitro*. Intracellular injection of a depolarizing current pulse into all cat (n=12) and guinea pig (n=22) LGNd relay neurons resulted in a train of action potentials after a variable delay. The duration of the delay was determined largely by two factors: the value of the current pulse. Injection of a strong depolarizing current pulse, and the amplitude of the current pulse. Injection of a form genolarizing current pulse (>1 nA) at resting membrane potential (e.g. -65 mV) resulted in a train of action potentials after a delay of approximately 50-150 msec, while injection of the same, or even a much smaller (e.g. 0.1 nA), current pulse when the membrane potential was depolarized with d.c. to

(e.g. 0.1 nA), current pulse when the membrane potential was depolarized with d.c. to near firing threshold (-55 mV) resulted in a delay of < 5 msec. In contrast, injection of smaller current pulses (< 1 nA) at resting membrane potential could lead to delays of up to 5-10 sec. Voltage clamp and pharmacological analysis reveal that this delay to firing is mediated by two transient potassium currents which inactivate with different time constants, $I_{Af} (\approx 100 \text{ msec})$ and $I_{AS} (\approx 1 \text{ sec})$. Sudden depolarization of relay neurons from resting membrane potential results in the activation of I_{Af} and IAs, which subsequently delay the onset of firing. In contrast, tonic depolarization of the neuron to near firing threshold inactivates these currents, and therefore abolishes the neuron to near turing threshold inactivates these currents, and interiore abousnes this initial delay. We suggest that LGNd relay neurons in the cat are capable of both "lagged" and "non-lagged" responses depending in large part upon the state of the membrane potential of the neuron, which itself depends upon the status of ascending neuromodulatory transmitters from the brainstem (McCormick, TINS 12: 215). Supported by NINCDS and the Klingenstein Fund.

A PROJECTION FROM THE THALAMIC RETICULAR NUCLEUS TO THE DORSAL LATERAL GENICULATE NUCLEUS IN THE CAT: A COMPARISON WITH THE PERIGENICULATE PROJECTION. J.B.

DORSAL LATERAL GENICULATE NUCLEUS IN THE CAT: A COMPARISON WITH THE PERIGENICULATE PROJECTION. J.B. Cucchiaro, D.J. Uhlrich, and S.M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

In mammals, the visual portion of the thalamic reticular nucleus (TRN) is the major extrinsic source of inhibitory, GABAergic innervation to the lateral geniculate nucleus (LGN). In cats, the most widely recognized source of extrageniculate, GABAergic innervation is the perigeniculate nucleus (PGN), which may be part of the TRN. However, the PGN innervation is virtually confined to the LGN A-laminae. The cat's TRN may be the source of innervation to regions of the LGN not innervated by the PGN. We tested this with pathway tracing methods. First, we identified the part of the TRN that projects to the LGN by retrograde transport of WGA-HRP injected into the LGN A- and C-laminae (3 cats). We combined this with anti-GABA staining (1 of the 3). We found many retrogradely labeled TRN cells and, of these, 75% were double labeled for GABA. Second, we made small iontophoretic injections of an anterograde tracer, PHA-L, into the TRN (3 experiments). We found labeled axons in all LGN laminae. The NRT axons labeled with PHA-L were beaded and formed a dense column that extended along projection lines through all the A- and C-laminae. Beaded axons were also labeled in the medial interlaminar nucleus (MIN), the geniculate wing (GW), and the lateral division through all the A- and C-laminae. Beaded axons were also labeled in the medial interlaminar nucleus (MIN), the geniculate wing (GW), and the lateral division of the lateral posterior complex (LP). Because we cannot exclude the possibility that we labeled some PGN cells in our injections to the TRN, we cannot address the question of whether the NRT provides an innervation to the A laminae separate from that provided by the PGN. However, after our injections into the TRN, we found a projection that is much more extensive than that seen with injections limited to the PGN. Therefore, we conclude that the TRN, rather than the PGN, is the major extrinsic source of GABAergic innervation to the C-laminae, MIN, GW, as well as to visual thalamic regions not in receipt of direct retinal input, such as lamina C3 and LP.

A GABAERGIC PRETECTAL PROJECTION TO THE LATERAL GENICULATE NUCLEUS IN THE CAT. M.E. Bickford, J.B. Cucchiaro, and S.M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

The pretectum contains a high proportion of cells that use the neurotransmitter, y-aminobutyric acid (GABA). The observation that many large GABAetgic cells reside in the pretectum, particularly in the nucleus of the optic tract (NOT), plus our previous observation that pretectal terminals in the lateral geniculate nucleus (LGN) have morphology similar to that defined for GABAergic terminals (Cucchiaro et al., Soc. Neurosci. Abstr. 15:1392, 1989), suggested the possibility that some of the pretectal cells projecting to the LGN are GABAergic. To test this possibility, we identified the projection cells by a retrogradely transported label and then determined which of these also stained positively for GABA. We used as our retrograde label wheat germ agglutinin conjugated to horseradish peroxidase (WGA-HRP), which was unilaterally injected into an LGN in each of 6 cats, and revealed the transported WGA-HRP in pretectal cells by stabilized tetramethyl benzidine histochemistry. With larger pressure injections (3 cats), WGA-HRP extended into tissue surrounding the LGN, and these led to retrograde labeling in the NOT, the posterior pretectal nucleus, and the pretectal olivary nucleus; with smaller iontophoretic injections (3 cats), WGA-HRP was confined to the A- and C-laminae of the LGN, and these led to retrogradely labeled pretectal cells were also stained with an antibody directed against GABA. Among the retrogradely labeled cells, the GABA-positive and GABA-negative populations were similar in soma size (mean: \$26 \text{Lm}) the control of the trogradely labeled retrogradely labeled cells projecting to the LGN differ from those not projecting (i.e., putative interneurons) on the basis of soma size. We also conclude that a substantial fraction of the pretectal cells projecting to the LGN, particularly those from the NOT, are GABAergi

72.11

BINOCULAR INTERACTIONS IN THE CAT'S DORSAL LATERAL GENICULATE NUCLEUS. III. ORIENTATION AND DIRECTION SENSITIVITY OF NONDOMINANT-EYE INFLUENCES. R.J. Moore, P.D. Spear, J.-T. Xue*, and C.B.Y. Kim*. Dept. of Psychology and Center for Neuroscience, Univ. of Wisconsin, Madison, WI 53706.

Although LGN neurons give brisk excitatory responses to only one eye (the dominant eye), most also are influenced by stimulation of the other (nondominant) eye. A possible source of the nondominant-eye influence is the cortico-geniculate pathway, which arises from orientation- and directionselective neurons. To assess the role of this pathway, we examined whether the nondominant-eye influence on LGN cells is orientation or direction selective. In experiment I, 1-sec duration 3-Hz sine-wave gratings were presented at 4-7 spatial frequencies drifting in 8 directions at 4 orientations. All stimuli were interleaved, and responses were measured against activity during interleaved "blank" trials with no grating. In experiment II, we used binocular stimulation to examine the orientation and direction selectivity of one of the dominant-eye influences on the responses of LGN cells to stimulation of the dominant eye at its optimal spatial frequency. In addition, 3-sec trials were used to allow for the possibility that orientation-selective nondominant-eye influences take up to 1 sec to appear (Varela & Singer, 1987). In both experiments, about 50% of the 72 cells tested were significantly influenced by nondominant-eye stimulation. Only about 10% of the responsive cells showed any evidence of orientation or direction sensitivity, and no cells showed clear selectivity. These results suggest either that cortico-geniculate pathways play little role in nondominant-eye influences on LGN cells or that LGN cells receive converging inputs from cortical cells with different preferred orientations and directions of movement.

GABAERGIC MODULATION OF THE TRANSFER RATIO IN CAT LATERAL GENICULATE NUCLEUS (LGN). <u>Dwayne W. Godwin and Thomas T. Norton.</u> Dept. of Psychology and Dept. of Physiological Optics, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Previous studies (Holdefer et al. & Norton et al., <u>Brain Res.</u> 488, 341-352, 1989) have found that GABAergic inhibition affects visual signal detectability and receptive-field sensitivity in LGN cells. To determine the mechanisms underlying these effects, we examined the transfer ratio (TR) from retinal input to LGN output by recording S-potential/LGN action potential pairs. Changes in the TR appear to produce the normal response variability of the LGN cells. In addition, when the TR was compared during maintained and In addition, when the TR was compared during maintained and during visually-driven activity, it was found that cells with a high TR during the maintained discharge tended to have a reduced TR during the maintained discharge tended to have a reduced TR during visual driving (r = -.59, p < .05). This reduction may be due to activity-dependent inhibition. Local microiontophoretic application of GABA decreased the TR in 6 of 7 cells including both X and Y and On and Off types. Application of the GABAa receptor antagonist bicuculline reversed the effect of GABA on the TR and increased visual signal detectability (2 of 2 cells). We conclude that GABAergic inhibition in the LGN reduces the TR, particularly during visual details. during visual driving, thereby reducing both the visual signal detectability and receptive-field sensitivity. Brainstem control of this inhibition may account for changes in information flow in the LGN MH-09693, RO1 EY02909, EY-03039 (CORE), BRSG grant RR-05807, T32 EY-07033.

PAIN MODULATION: ANATOMY AND PHYSIOLOGY III

73.1

EFFECTS OF NEONATAL CAPSAICIN ON INFLAMMATION-INDUCED HYPERALGESIA AND SPINAL FOS ACTIVATION. J.L.K. Hylden, B. Allen*, E. Humphrey*, K. Noguchi, A. Steinberg* and M.A. Ruda, Neurobiology & Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892. Neonatal capsaicin (Cap) treatment destroys a subpopulation of peptidecontaining small diameter primary afferents and decreases sensitivity to noxious thermal stimuli. This study examined the effect of neonatal Cap on the production of inflammation-induced hyperalgesia and on nociceptive activation of spinal Fos protein. Rats were treated with Cap (50 mg/kg) or vehicle (Veh) on day 2 of life. Paw withdrawal latency (PWL) was measured at 5.6,7 and 8

on day 2 of life. Paw withdrawal latency (PWL) was measured at 5.6.7 and 8 wk of age. Inflammation was induced by s.c. administration of Complete Freund's Adjuvant (CFA) into the left hindpaw at 8 wk of age. PWL was again measured at 6, 24 & 72 h after CFA. Fos protein was localized to lumbar spinal cord using standard PAP methodology.

At 5-8 wk of age, Cap-treated rats had longer PWLs as compared to Vehtreated littermates (\$\frac{x}{2} = 12.0 vs. 9.6 s. p. 6.0.5, n = 32). At 6, 24 & 72 h after CFA, inflamed paws in Cap-treated rats had longer PWLs than inflamed paws in Veh-treated rats (\$\frac{x}{2} = 5.4 vs. 3.5 s. p. 6.0.01). However, the magnitude of inflammation-induced hyperalgesia (net change from pre-inflammation baseline) was similar in the 2 groups of rats. At 48 h an increase in the number of Foslabeled cells was observed primarily in medial laminae I-II of L5 in Vehretated rats (mean left-right difference = 21.0 cells/30 um section, p. 6.0.01). labeled cells was observed primarily in medial laminae 1-II of L5 in Vehtreated rats (mean left-right difference = 21.0 cells/30 μ m section, $p\!<\!0.01$). Cap-treated animals also exhibited an increase in the number of Fos-labeled cells (6.3 cells/section, $p\!<\!0.01$). Fos activation in Cap-treated rats was significantly less than in control rats $(p\!<\!0.01)$. These data show that Cap-treated rats demonstrated inflammation-induced hyperalgesia and Fos activation; however, Fos activity was significantly attenuated. Thus, inflammation-induced hyperalgesia is minimally affected by Cap treatment and likely involves activity in primary afferent fibers that are not Cap sensitive. In contrast, activation of Fos in the CFA model of inflammation appears to depend to a large extent on input from a population of Cap sensitive small diameter primary afferents.

MORPHOLOGICAL EFFECTS OF ELECTRICAL TRIGEMINAL GANGLION STIMULATION (ETG) ON INTRA- AND EXTRACRANIAL VESSELS. M.G. Buzzi,**, V. Dimitriadou*, T.C. Theoharides*, and M.A. Moskowitz. Depts. of Neurosurgery and Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA 02114 and *Department of Pharmacology, Tufts University School of Medicine, Boston, MA 02111.

Electrical trigeminal ganglion stimulation (1 mA, 5 msec, 5 Hz, for 5 min) provokes vasodilation and plasma extravasation, both in innervated intracranial and extracranial blood vessels. Here, we report the ultrastructural effects of unilateral ETG (n=14). Unilateral ETG was followed by intracardiac perfusion of 2.5% glutaraldehyde and preparation for electron microscopy. Ultrastructural examination revealed the following within postcapillary venules exclusively on the stimulated side: erythrocyte diapedesis, occasional endothelial damage, platelet adhesion and degranulation. Ganglion-stimulated adult rats treated as neonates with capsaicin (n=6) did not show these changes. Pretreatment with the antimigraine drug dihydroergotamine (50 µg/kg. I.V.) (n=6) significantly reduced plasma extravasation and vascular changes within the dura mater, but not within the tongue.

These preliminary findings suggest a novel mechanism for the action of antimigraine drugs and explain, in part, the platelet and serotonin involvement in vascular headaches.

IN VIVO AND IN VITRO ULTRASTRUCTURAL EVIDENCE FOR STIMULATION OF DURA MAST CELLS BY NEUROPEPTIDES. V. Dimitriadou, M.G. Buzzi,* M. Lambracht-Hall,* M.A. Moskowitz* and T.C. Theoharides. Dept. of Pharmacology, Tufts Univ. and 'Dept. of Neurosurg, & Neurology, MGH, Boston, MA. Mast cells are known to participate in allergic and inflammatory conditions. Here we investigated the effects of neuropeptides on dura mast cell secretion in vivo and in vitro. One trigeminal ganglion was stimulated electrically (0.1 or 1 mA, 5 msec, 5HZ, for 5 min), which provokes vasodilation and plasma extravasation, in male adult rats (n=14), which were then fixed intracardially with 2.5% glutaraldehyde. Ultrastructural examination of the dura mater showed that whereas mast cell granules in the contralateral side were intact, with homogenous and electron dense core, those in the ipsilateral (stimulated) side showed distinct changes ranging from slight alterations of the granular core to its complete intracellular dissolution. As previously reported, extrusion of metachromatic granules was not found.¹ There was also platelet aggregation and degranulation, as well as erythrocyte diapidesis within postcapillary venules. Similar changes were not observed in adult rats treated as neonates with capsaicin to destroy perivascular sensory fibers (n=6). In vitro, 30 min incubation of the dura with SP and CGRP (10⁸ M) led to similar morphological changes of dura mater mast cells, and also to significant histamine release (n=4). In conclusion, sensory nerve terminals could trigger mast cell secretion without obvious degranulation, very likely in response to SP and/or to CGRP, leading to neurogenic inflammation.

73.5

LONG-LASTING ENHANCEMENT OF RESPONSES OF SPINOTHALAMIC TRACT (STT) NEURONS TO EXCITATORY AMINO ACID (EAA'S) BY COMBINED IONTOPHORETIC APPLICATION WITH SUBSTANCE P (SP). P.M.Dougherty and W.D.Willis. Mar. Biomed. Inst. & Dept. of Anat. & Neurosci., UTMB, Galveston, TX 77550.

EAA's and SP are co-localized in afferent fibers and when released may activate and sensitize nociceptive neurons, leading to secondary hyperalgesia. To test this, we studied the effects of iontophoretically released EAA's and SP, alone or in combination, on the responses of 42 STT cells in 25 anesthetized monkeys ($\underline{\text{M. fascicularis}}$). Repeated applications of the same EAA produced either a similar or a decreased excitatory action. SP at the dosage used (15 to 50nA) produced no consistent change in background discharge. However, the co-application of an EAA and SP generally resulted in a potentiation of the excitation produced by EAA's. In about 1/3 of the cells tested, the potentiation of the NMDA responses outlasted the SP application by 15 min to as long as 4 h. The responses to ASP were enhanced in parallel to those of NMDA. In 4 cases, the QUIS response was potentiated for 25 min to 3-1/2 h. The response to GLUT paralleled that of QUIS. We have not found any cases of potentiation of the AMPA response by SP to date. We conclude that potentiation of STT cell responses to NMDA and non-NMDA may contribute to the central sensitization underlying secondary hyperalgesia. (Supported by NIH grants NSO8860 (P.D.), NSO9743 and NS11255.)

VAGAL AFFERENT STIMULATION (VAS) MODULATES TRIGEMINAL NEURONAL RESPONSES TO NOXIOUS STIMULI. <u>D.B. Bossut and W. Maixner</u>, Dental Research Ctr., University of North Carolina at Chapel Hill.

Previous experiments in cats have established that electrical stimulation of cardiopulmonary vagal afferents inhibits the digastric reflex elicited by tooth pulp stimulation. This study assessed VAS effects on the responses of trigeminal sensory neurons to noxious heat and electrical pulses (EP).

Continuous VAS (5 Hz, 1 mA) inhibited the Continuous VAS (5 Hz, 1 mA) inhibited the responses of 23/32 wide dynamic range neurons in n. caudalis to a 5 sec 50°C contact heat pulse; 8/14 of these cells projected to the thalamus VPM area. VAS facilitated the heat evoked response of 5/32 and had no effect on 4/32 neurons. All cells received A-6 input and 13 received additional C-fiber input. VAS (7 pulses, 333 Hz, 5 mA) delivered 200 msec prior to EP diminished A-6 and C-fibers input. VAS also decreased the tooth pulp-evoked input. VAS also decreased the tooth pulp-evoked responses of 6 trigeminothalamic neurons in n.

These results suggest cardiopulmonary VAS impairs nociceptive reflexes by modulating sensory transmission and VAS may play a role in modulating

73.4

RELEASE OF SUBSTANCE P IN THE DORSAL LUMBAR SPINAL CORD RELEASE OF SUBSTANCE P IN THE DORSAL LUMBAR SPINAL CORD OF THE CONSCIOUS, FREELY MOVING RAT: EFFECTS OF KAINIC ACID, CAPSAICIN AND SUBSTANCE P(1-7). C.W. Murray, S.R. Skilling*, D.H. Smullin and A.A. Larson. Dept. of Veterinary Biology, University of Minnesota, St. Paul, MN 55108. We have previously reported that NMDA and substance P (SP) antagonists are analgesic, that excitatory amino acids (EAAs) are released in the dorsal horn in response to SP C-terminal fragments and formalin, and

in the dorsal horn in response to SP C-terminal fragments and formalin, and that $\underline{SP(1-7)}$, an endogenously-generated metabolic fragment, inhibits spontaneous EAA release. In the present study we examined the interactions between EAAs and SP to test the hypotheses that EAAs can alter SP release and that SP(1-7) also decreases the release of SP from primary afferents. Rats were anesthetized with pentobarbital and implanted with transverse dorsal 50 kd MW cutoff microdialysis fibers at ca. L4-5 and chronic intrathecal (i.t.) catheters injecting rostrally at L4-5. After overnight recovery, Ringer's with 0.2% BSA and 1.2 mM Ca⁺⁺ was infused at 6 μ L/min and fractions were collected at 20 min intervals. Animals were collection of hasal fractions. SPinfused at 6 μ L/min and fractions were collected at 20 min intervals. Animals were equilibrated for 4 hr before collection of basal fractions. SP-like immunoreactivity (SPLI) was measured by commercial RIA. Data are expressed as mean % change from each subject's basal [SPLI]. Intradialysate infusions of 10 mM of the EAA agonist, kainic acid, for 5 or 10 min caused respective increases in SP release of 98 ±41 % (p<0.05) or 624 ±142 % (p<0.001). A 10 min infusion caused no neuronal damage. Intradialysate infusion with 200 μ M capsaicin for 20 min, to cause selective depolarization of primary afferents, induced a 160% (p<0.05) increase in SP release. The capsaicin effect was inhibited (p<0.05) by i.t. pretreatment with 1 nmole of SP(1-7). These data suggest that reciprocal interactions between neurokinin and EAA systems are important in pain transmission and further support our hypothesis that SP(1-7) acts as an endogenous regulator of nociceptive transmitter release. [USPHS Grants DA04090, DA04190, DA00124, DA07234 and CA01342.]

LONG-LASTING ENHANCEMENT OF RESPONSES OF SPINOTHALAMIC TRACT (STT) CELLS TO MECHANICAL STIMULATION OF SKIN DURING POTENTIATION OF AMINO ACID (EAA'S) RESPONSES BY SUBSTANCE P (SP). W.D.Willis and P.M.Dougherty. Mar. Biomed. Inst. & Dept. of Anat. & Neurosci., UTMB, Galveston, TX 77550.

& μept. or Anat. & Neurosci., UTMB, Galveston, TX 77550.

Secondary hyperalgesia may result from sensitization of central nociceptive neurons. Since iontophoretic application of EAA's and SP sensitize STT cells, we tested for changes in responses to mechanical stimuli during this process. The activity of STT cells from 25 monkeys (M. fascicularis) were recorded in response to the following mechanical stimuli; brushing the chiral stimuli. ing mechanical stimuli: brushing the skin with a soft-bristled brush (BRUSH); pressure (PRESS) on the skin applied with an arterial clip (near pain threshold in humans); pinching the skin (PINCH) with a different arterial clip with a firmer grip (well above pain threshold). The responses of STT cells were usually increased during application of EAA's and decreased by AP7. SP alone had little or no effect on background activity or responses little or no effect on background activity or responses to mechanical stimuli. However, in cells that showed enhancement of responses to EAA's after co-application of SP, the responses to mechanical stimulation showed a parallel increase. We conclude that the enhanced responses of STT cells caused by combined application of EAA's and SP may contribute to hyperalgesia. (Supported by NIH grants NSO8860 (P.D.), NSO9743 & NS11255.)

EFFECTS OF CAGE BEDDING CHANGE AND TAIL TEMPERATURE MEA-SUREMENTS ON NOCICEPTION IN RATS. J Hulse Neufeld*, Brenda Hall* and Matthew B. Weinger. Department of Anesthesiology, VA Medical Center, San Diego, CA 92161.

As a prelude to measuring the behavior of chronically

stressed rats with a tail dip assay, methods were devel oped to differentiate groups of male Wistar control rats from rats subjected to the stress of changing the cage bedding and to the stress of measuring the tail temperabedding and to the stress of measuring the tail temperature. Three sequential tail dips at 10-min intervals into 52.5°C water were used with the rats only briefly (less than 15 sec) restrained at the base of the tail. The data from individual rats were subjected to linear regression analysis and a mean slope (SLP) and y-intercept (INT) were calculated. The mean SLP and INT values of treatment groups were compared for significance of difference using ANOVA. Changing the cage bedding 6 hr before latency determinations increased SLP. Measuring the tail temperature 6 hr before latency determination increased INT and lowered SLP. The changes in the parameters SLP and INT were not related to changes in tail temperature when the tail temperature was measured after tail dips. Tail temperature could be shown to correlate only in control groups and only with SLP and INT. SLP and INT are useful parameters with which to differentiate rats stressed by experimental manipulations.

METABOLIC ALTERATIONS ASSOCIATED WITH ISCHEMIA ACTIVATE A0 AND C FIBER NOCICEPTORS. D.L. Tanelian and M.B. MacIver. Dept. of Anesthesia, Stanford Univ. Sch. of Med., CA 94305.

Mechanisms of pain following ischemia remain unknown, but are thought to involve hypoxia, glucose depletion and/or an increase in lactic acid, resulting in excitation of nociceptor nerve endings. This study investigated the effects of hypoxia, hypoglycemia and lactic acid on the discharge activity of A∂ and C fiber nociceptors using an *in vitro* preparation of rabbit cornea. Corneas were maintained at 35 °C and perfused from behind with artificial aqueous humor solution (AQH) to maintain a normal 'intraocular' pressure of 18 mmHg. Glass suction electrodes were used to record single and multi-unit action potential discharge from corneal nerve bundles. Substituting N₂/CO₂ for O₂/CO₂ increased discharge frequencies to 213 +/- 3.4 % of control (+/- SD; p < 0.001 ANOVA, n=12). Substitution of L-glucose for D-glucose produced a significantly greater increase in discharge frequency (653+/- 28%; n=8, p<0.001 compared to N_2 data). Increased discharge occurred 20 to 30 min after substitution of N2 or L-glucose and was followed by depression. A brief period of increased discharge was observed during recovery. Lactic acid at concentrations up to 500 μg/ml did not alter discharge activity. Combining N2 and L-glucose substitution did not produce a significant increase in discharge, compared with L-glucose alone (671+/-14%, p > 0.05, n=6). conclusion, depletion of glucose appears to be the major factor which contributes to nociceptor activation following ischemia.

73.11

INHIBITION OF RUBRAL NEURONS BY NOXIOUS AND NON-NOXIOUS PRESSURE. R.R. Matsumoto and J.M. Walker. Department of Psychology, Brown University, Providence, RI 02912.

Single unit, extracellular recordings were conducted in halothane-anesthetized rats. The responses of 170 neurons in and around the red nucleus (RN) to a 2.8 kg/cm² (1s) pinch to the hindpaws and tail were assessed. Cells in both the magnocellular (RNm) and parvocellular (RNp) divisions of the RN were most sensitive to pinch to the contralateral hindpaw. Furthermore, cells in the RNm were more likely to respond to pinch than cells in the RNm. The percentage of cells that responded to pinch in each of the divisions of the RN is summarized as follows: RNm-contralateral hindpaw (73%), ipsilateral hindpaw (34%), tail (37%); RNp-contralateral hindpaw (37%), ipsilateral hindpaw (15%), tail (23%). Cells in the surrounding reticular formation did not show a lateralized response: contralateral hindpaw (39%), ipsilateral hindpaw (25%), tail (36%). Some cells in the RN were also tested for their responses to a graded pressure stimulus to the contralateral hindpaw (0-2.8 kg/cm² in 4s): 26% exhibited no response, 32% responded only during the non-noxious part of the stimulus, 21% responded to the noxious part, and another 21% showed two separate responses, one during the non-noxious part of the stimulus and one during the noxious part. These data suggest that the RN may be involved in the processing of noxious as well as non-noxious tactile stimuli.

73.10

CHARACTERISTICS OF PAIN PROCESSING IN THE FLUOROCARBON
PERFUSED RAT. C.L. Cleland and G.F. Gebhart. Department of
Pharmacology, University of Iowa, Iowa City, IA 52242

The processing of pain by the central nervous system depends on network, synaptic and cellular properties. Although network and synaptic properties have been extensively investigated, research into the role of cellular properties has been limited by the difficulties of obtaining stable intracellular recordings using in vivo, whole animal preparations, and the problems of identification and functional interpretation using in vitro slice and culture preparations. In order to surmount these difficulties, we have developed a whole animal, perfused preparation which should permit stable intracellular recording and control over the composition of the perfusate while retaining the connectivity and behavior of the intact animal.

Adult rats were perfused through the ascending aorta using non-pulsatile flow of a fluorocarbon-based artificial blood containing pentobarbital and maintained at 37° C. The somatic pain system was assessed using mechanical and thermal noxious stimuli. Visceral pain processing was tested using colorectal distension.

We found that appropriate withdrawal and pressor responses to noxious somatic and visceral stimuli were maintained for up to 6 hours. Respiration, EEG and arterial pressure remained stable and responsive to changes in O₂ concentration, afferent input and pharmacological manipulation for 6-8 hours. Thus, the perfused preparation provides the opportunity to investigate pain processing using intracellular recording, manipulation of the neuronal environment, assessment of the contributions of circulating factors to pain transmission, and independent perfusion of different systems, paradigms difficult to pursue in alternative *in vivo* preparations.

REGENERATION: GENERAL STUDIES AND MOLECULAR CORRELATES

74.1

THE ULTRASTRUCTURE AND CURRENT DENSITY OF GROWTH CONES IN REGENERATING NERVE. J.M. Kerns and J.A. Freeman. Dept. of Anatomy, Rush Medical College, Chicago, IL 60612 and Dept. of Cell Biology, Vanderbilt University, Nashville, TN 37232.

Previous studies have suggested that peaks of

Previous studies have suggested that peaks of current density (J) in the regenerating nerve detected with the vibrating probe are associated with underlying growth cones. The present study is a morphometric analysis of this correlation. Four sciatic nerves from adult rats were lesioned under nembutal anesthesia. After 7 days the J was measured along the distal segment with a circularly vibrating probe followed by perfusion fixation. Profile counts were made on electron micrographs (n=10) at 3500x from selected regions. The mean density of growth cones profiles per .01mm² was higher (p<.001) at the peak (28.1 +/-1.4) than before (16.3 +/-1.1) or after (11.2 +/-0.8). Unmyelinated axons were reduced after the peak (p<.001), while Schwann cell nuclei were uniform. The haline J (μ A/cm²) before (0.7 +/-0.2) and after (0.6 + 0.2) was higher at the peak (2.7 +/-0.8) and correlated (r = 0.72, p<.01) with the growth cone density. In conclusion, the vibrating probe is a sensitive in vivo detector of growth cones in a regenerating nerve. Supported by the Enelow Foundation and NIH grants NS-19769, NEI-EY01117 and NSI8103.

74.2

OLIGODENDROCYTE RESPONSE TO AXONAL INJURY: IMPLICATIONS TO REGENERATION. <u>T.Sivron*,A.Cohen* and M.Schwartz</u>. Dept. of Neurobiology, The Weizmann Inst. of Science, Rehovot, Israel.

Crushed axons of fish optic nerves readily regenerate, while similarly injured axons of rat optic nerves do not. The reasons for the difference in the regenerative ability of these axons may lie in differences in the number of surrounding oligodendrocytes, known to be inhibitory to axonal growth. We have cultured nonneuronal cells from previously crushed optic nerves of fish and rat, and examined them using indirect immunofluorescence. In the rat cultures, mature, GalC-positive oligodendrocytes were abundant, while in the fish cultures oligodendrocytes, marked by the 6D2 antibody, were rare. In order to check whether the control of the oligodendrocyte response to injury is intrinsic to the optic nerve we have isolated the optic nerve immediately after the injury and kept it in organ culture, after which it was dissociated. In the rat organ cultures the number of oligodendrocytes was similar to that of optic nerves crushed in vivo. In the fish organ cultures, however, about 15 times more oligodendrocytes developed than in in vivo crushed optic nerves. In addition, macrophage-like cells which were abundant in the cultures of in vivo crushed fish nerves, were absent from the fish organ cultures. This suggests that the factor/s which regulates the oligodendrocyte response originates from blood-borne cells. Finally, medium conditioned by regenerating fish optic nerves (CM), which was shown to have a cytotoxic effect on rat oligodendrocytes, was found in this work to reduce the number of oligodendrocytes in organ cultures of both rat and fish (by factors of 6 and 2.5, respectively). The demonstrated difference in the response of oligodendrocytes to optic nerve injury may be responsible, in part, for the different regenerative ability of fish and rat optic nerves.

AXOTOMY-INDUCED REMODELLING IN THE DENDRITES OF ADULT RAT GANGLION CELLS. <u>Solon Thanos and Jens Vanselow*</u>, Dep. of Ophthalmology, Univ. Tübingen and Max-Planck-Inst. for Dev. Biology, Tübingen, FRG.

We investigated the response of ganglion cells and their dendrites to optic nerve injury. The ganglion cells were labeled post-mortem with DiI and examined after optic nerve crush in situ (group A), after axotomy and reconnection of the retina via transplanted peripheral nerve (PN) pieces with fetal targets (group B) and after axomoty and subsequent explantation of the retina in vitro (group C). In group A animals, in which cut axons can not regrow, many ganglion cells which survived the axotomy responded with dendritic growth. In group B animals, axons grew through the PN grafts andreached co-grafted fetal targes where they formed axonal terminals. The dendrites of these retinal cells were not enlarged compared to the normal ganglion cells in the retina. Explantation of the axotomized retina (group C) was accompanied with both dentritic and axonal growth. The results suggest that in the adult ganglion cell, transection of the axon can result in dendritic growth when regrowth of the cut axon is not permitted because of the inhibiting optic nerve environment.

THE DEVELOPMENT OF RUBROSPINAL LATERALITY IN THE NORTH THE DEVELOPMENT OF RUBROSPINAL LATERALITY IN THE NORTH
AMERICAN OPOSSUM. X.M. Xu and G.F. Martin, Department of Anatomy
and Neuroscience Program, The Ohio State University, Columbus, OH 43210.
Rubral axons can grow around a lesion of their spinal pathway during
specific stages of development in the opossum (Martin and Xu, Dev. Brain Res.

39:303-308) and such plasticity results primarily from the growth of new axons. There is evidence, however, that true regeneration of cut axons may also occur (Xu et al., Soc. Neurosci. Abstr. 15:870). In order to interpret the results of experiments designed to determine if true regeneration contributes to rubrospinal plasticity, it became necessary to determine the degree to which the red nucleus projects ipsilaterally to the spinal cord during the critical period for that plasticity. Although rubrospinal axons are primarily crossed in adult opossums, an ipsilateral projection exists and it is possible that it is particularly robust during development. Pouch-young opossums of the appropriate ages were anesthetized so that the rubrospinal tract could be cut at the T8-T9 level on the right side of the spinal cord. Immediately after the lesion was made, Fast Blue was injected into the lumbar enlargement on the opposite side Seven days later, the animals were sacrificed and the tissues prepared for fluorescence microscopy. Although labeled neurons were numerous in the red nucleus contralateral to the injection, they were sparse on the ipsilateral side. Counts of labeled neurons on the two sides suggested that only 1% of the rubrospinal neurons projecting to the lumbar cord did so ipsilaterally. In a set of similar experiments on older pouch-young and adult opossums, the results were comparable. At all ages, the distribution of the ipsilaterally projecting neurons varied from case to case. Our results suggest that during the critical period for rubrospinal plasticity, as well as during later stages of development, the rubrospinal tract is almost entirely crossed. (Supported by NS-25095).

74.7

REAPPEARANCE OF II/TENASCIN AND THE 473 PROTEOGLYCAN

REAPPEARANCE OF JI/TENASCIN AND THE 473 PROTEOGLYCAN FOLLOWING DISCRETE LESIONS IN THE ADULT MOUSE CEREBRAL AND CEREBELLAR CORTICES. E. Laywell*A. Faissner. M. Schachner, and D.A. Steindler, Dept. of Anatomy & Neurobiol., Univ. of Tenn., Memphis; Dept. of Neurobiol., University of Heidelberg; Swiss Federal Inst. of Tech., Zurich. Our previous studies (Laywell & Steindler, Neurosci, Abs., 15:590, 1989) have shown that lesions of the somatosensory cortex produce characteristic cellular and molecular changes around the wound. J1/tenascin and a chondroitin sulfate containing proteoglycan termed the 473 antigen, two constituents of the extracellular matrix, are prevalent in boundaries around developing brain structures such as cortical whisker barrels, the neostriatal mosaic, and nuclei throughout the neuraxis. After the whisker barrels, the neostriatal mosaic, and nuclei throughout the neuraxis. After the second postnatal week, these boundaries are no longer apparent. Because of their location and transient expression during plastic developmental events, J1/tenascin and the 473 proteoglycan likely have a role in segregating developing neural elements. Furthermore the scarcity of these molecules in the mature brain may reflect a suppression of inhibitory factors when pattern formation is completed and the brain is anatomically stabilized. Do lesions in the adult brain provoke a "re-expression" of such developmentally regulated molecules?

Stab lesions were made in the cerebral or cerebellar cortex of adult B6C3H mice.

Stab lesions were made in the cerebral or cerebellar cortex of adult B6C3H mice. Following various survival times of up to 21 days, the brains were processed for immunocytochemistry of J1/tenacin, 473 proteoglycan, N-CAM, GFAP, vimentin, AMOG, and a variety of other neural antigens. Many of these antigens are visible only in the vicinity of the wound, perhaps in a time-dependent gradient fashion, and are associated with reactive glia. For example, discrete clusters of vimentin-positive Bergmann glia also exhibit increased immunostaining for J1/tenascin, the 473 proteoglycan, and N-CAM 4-6 days after small cerebellar lesions. In situ hybridization experiments, using e.g. cDNA probes to J1/tenascin, will determine the cellular sources of these novel molecular expressions. J1/tenascin and the 473 proteoglycan are but two constituents common to both developmental boundaries and glial scars. The re-expression of such molecules in brain wounds may present an glial scars. The re-expression of such molecules in brain wounds may present are inhibitory substrate to regenerating neurites. Supported by the NIH, NSF, & DFG.

Abortive Regeneration of Cortical Projection Axons. P.S. Fishman and D.A. Farrand*. V.A. Res. Labs., Dept. of Neurology, Univ. of Md. Sch. of Med. Baltimore, Md. 21201.

Corticospinal axons cut in the spinal cord or medullary pyramid show a primarily degenerative response in adult mammals. It has been proposed that this lack of an initial regenerative response may relate to the remaining axon collaterals and their synaptic contacts. We wished to determine the response of cortical projection axons to lesions in the subcortical white matter close to their cell bodies of origin. Using anterograde labeling with cholera B chain conjugated to horseradish peroxidase, axons projecting from motor cortex were traced into the area of injury during a three week period after a stab wound through the neighboring cortex and subcortical white matter in adult mice. During that period the majority of labeled axons project directly into the area of injury, with a variety of axon morphologies including terminal bulbs. Ultrastructural examination of the region of axonal termination was also performed. During the first 10-14 days after injury the site contains not only degenerating axon terminals, but a large number of small processes of neuronal, glial and macrophage origin. But by three weeks after injury the area of injury contains predominantly astrocytic processes. projection neurons can maintain a viable axon after close axotomy, and may show a more pronounced initial regenerative attempt than to more distant lesions in the medulla or spinal cord. TRANSFERRIN RECEPTOR EXPRESSION IN THE INJURED AND REGENERATING RAT SCIATIC NERVE. G.Raivich, M.B.Graeber*, J.Gehrmann* and G.W.Kreutzberg. Department of Neuromorphology, Max-Planck Institute for Psychiatry, D-8033 Martinsried, F.R.Germany

Iron-saturated transferrin is an ubiquitous growth factor which plays a critical role in the cellular iron uptake¹. Here we have studied the expression and the distribution of the cellular receptors to this protein following peripheral nerve

injury and during regeneration.

Axotomy led to a massive but transient increase (days 1-9, maximum day 4) in specific [125]I-transferrin binding at the site of the injury and in the distal, denervated part of the crushed or resected sciatic nerve, coinciding with the pattern of cellular proliferation. Immunocytochemistry using Ox-26 monoclonal antibody revealed strong and synchronous expression of the transferrin receptor antioody revealed strong and synchronous expression of the transferrin receptor protein on two different cell types: a subpopulation of blood-borne macrophages invading the injured peripheral nerve as well as on the denervated Schwann cells. Finally, studies using intravenously injected ⁵⁵Fe³⁺ (0.2 mCi) showed an aproximately 20-fold increase in the endoneural iron uptake confined to the directly injured and the distal part of the axotomised sciatic nerve with the same timecourse as observed for the transferrin receptor expression.

In summary, there is a dramatic increase in transferrin receptor

immunoreactivity, specific transferrin binding and iron uptake in the injured and regenerating endoneurium of the sciatic nerve. Since iron is an essential cofactor of several enzymes needed for energy metabolism and DNA synthesis, these data suggest that the induction of transferrin receptor expression plays an important role in the regulation of cellular growth and proliferation during nerve egeneration.

EXPRESSION OF INHIBITORY PROTEOGLYCANS IN A MODEL OF ASTROGLIAL SCARRING FOLLOWING LESIONS IN THE CNS

OF ASTROGLIAL SCARRING FOLLOWING LESIONS IN THE CN R. J. McKeon, R. C. Schreiber*, J. S. Rudge and J. Silver. Dept. of Neuroscience, Case Western Reserve University, Cleveland, OH 44106

The failure of neurons to regenerate following CNS injury has been attributed to the formation of an astroglial scar which may create a mechanical barrier for axons, thereby limiting the amount of regeneration. Alternatively, cells which make up the astroglial scar may be a poor substrate for growing axons or produce inhibitory molecules which prevent regeneration. In order to examine whether, following lesions, inhibitory molecules exist in CNS regions that lack oligodendrocytes, Millipore filters were implanted in the gray matter of the cortex of either newborn or adult Sprague-Dawley rats. Newborn animals were sacrificed at 6 days or 30 days while adult animals were sacrificed 10 days or 30 days following implantation. Sections through the filter were stained with antibodies to either GFAP, NCAM, laminin, fibronectin, collagen type IV, to the putative inhibitory molecule chondrotin-6-sulfate (CS) or its ECM ligand, cytotactin (CT). GFAP staining was increased in a large area surrounding the implant but was most intense within and immediately adjacent to the implant in both neonatal and adult animals. Laminin, fibronectin, and collagen exhibited a more diffuse staining pattern in and around the implant. In contrast, CS and CT staining only occurred within and around the implants of adult animals and in the 30 day post- implanted neonates. The expression of CS and CT was coincident with the distribution of GFAP-positive cells close to the implant, suggesting that, in addition to growth promoting molecules, reactive astrocytes in the immediate vicinity of a gray matter lesion produce inhibitory molecules following injury. The production of these inhibitory molecules following cortical lesions may act to limit regeneration in the CNS. Supported by NS 25713 and the Daniel Heumann Fund for Spinal Cord Research.

THE MOLECULAR ENVIRONMENT OF THE DORSAL ROOT ENTRY ZONE DURING DEVELOPMENT AND AFTER ROOT CRUSHES. R.R. Pindzola and J.Silver. Department of Neuroscience, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

The glial environment of the spinal cord dorsal root entry zone (DREZ) was analyzed to determine if purported axon inhibitory molecules increase on the CNS side after the critical period (PD2-3, the age when afferents no longer regenerate into the cord). We studied normal rats from E14 to PD37 and rats that sustained crush injuries to dorsal roots on PD1-2 and PD23 (2 wk. survival). We used immunohistochemistry on sections through the DREZ to visualize the presence of the potentially inhibitory molecules chondroitin-6 sulfate proteoglycan (CS-PG) and its extracellular ligand, cytotactin (CT). The growth promoting molecules, NCAM and laminin, were also studied. GFAP antibodies were used to visualize astroglia.

CS-PG first appears in the dorsal columns of normal PD1 animals in two narrow bands on either side of the roof plate. Staining for CS-PG spreads laterally to the DREZ and ventrally to the region above the corticospinal tract during the next few days. The spatio-temporal pattern of staining for CT mimics that of CS-PG. In animals with root crushes at PD23 there is an increase in the staining intensity only on the lesion side of both CT and CS-PG that mimics the pattern of reactive GFAP-positive astrocytes in the DREZ and the dorsal columns. In neonates with root crushes the pattern and intensity of CT, CS-PG and GFAP staining is comparable on the two sides of the cord. CT and CS-PG are not found on Schwann cells but CS-PG is found in the endoneurium in normal and crush lesioned animals. Our results suggest that the concentration of putative neurite inhibitory molecules on reactive astrocytes, after the critical period, may help cause regenerative failure of sensory afferents into the spinal cord.

ACCUMULATION OF APOLIPOPROTEIN A-I AND E

ACCUMULATION OF APOLIPOPROTEIN A-I AND E IN THE RABBIT FACIAL NERVE FOLLOWING TRANSECTION AND NERVE REPAIR. L.T. Wang-Bennett, D.P. Slaughter*, D.J. Liebl* and S. Moore*. Dept. of Otorhinolaryngology and Communicative Sci., Baylor College of Med., Houston, TX 77030. Studies have shown increased synthesis of apolipoprotein (Apo) E and A-I in degenerating distal stumps of peripheral nerve and discussed their role in a local lipid transfer system needed for regeneration. We describe the identification and relative quantification of Apo E and A-I in the case of transection without repair and for two surgical repair models of rabbit facial nerve. Nerve extract proteins were separated by SDS-PAGE and transferred onto Immobilon membrane. Apo's were detected by specific primary antibodies which were recognized by alkaline phosphatase-conjugated second antibodies. Quantitative data was derived from densitometric measurement of the blots.

A similar time course for Apo E and Apo A-I was found for stumps that underwent simple transection. The time course showed two peaks; one during the first wk and a second during wk showed two peaks; one during the first wk and a second during wk 2 to 4. There were higher amounts of Apo E than Apo A-I in the chamber- and cable-repaired nerve, and Apo E was elevated at wk 7 while the Apo A-I declined to normal. A greater accumulation of both Apo's occurred in the chamber model versus the cable model. The results demonstrate the presence of Apo E and Apo A-I in regenerating rabbit facial nerve and support their cooperative role in nerve regeneration. A different pattern of accumulation was observed than has been reported for crushed rat sciatic nerve. (Supported by the Texas Advanced Technology Program and by Coker Memorial Research Foundation.)

THE EFFECTS OF PHYSIOLOGICAL STOP PATHWAY ACTIVATION AT THE DORSAL ROOT TRANSITIONAL ZONE ON NF GENE EXPRESSION IN DRG NEURONS. F.J. Liuzzi and B.Tedeschi*. Dept. of Anatomy and Neurobiology, Eastern Virginia Medical School, Norfolk, VA 23501.

After dorsal root crush in adult mammals, many regenerating axons stop among dorsal root transitional zone (DRTZ) astrocytes. NFs are absent in DRTZ axoglial endings, but accumulate and swell physically blocked axon endings within ligation neuromas. Based on these observations, Liuzzi and Lasek (Science, 237:642, 1987) proposed that astrocytes in the DRTZ stop axonal growth by activating the physiological stop pathway, part of which is the protease-dependent breakdown of NFs.

This study uses 2-D gel electrophoresis to examine NF synthesis in DRG neurons after root crush and $% \left(1\right) =\left\{ 1\right\} regeneration into the DRTZ or into a physical barrier regeneration into the DRTZ or into a physical barrier formed by tightly ligating the root. By 3 days post-crush, 68KDa NF protein synthesis is decreased compared to normal control levels. Yet by 10 days post-crush, the time that the axons reach the DRTZ, 68KDa NF protein synthesis returns to control values. By contrast, at 10 days post-crush, 68KDa NF protein synthesis in DRGs with physically blocked axons remains depressed.

TRIGEMINAL NEURONS RESPOND TO INJURY OF THEIR SENSORY TERMINALS IN CORNEA BY INCREASING LEVELS OF GAP-43 (GROWTH ASSOCIATED PROTEIN-43) PROTEIN AND mRNA. H.E.P. Bazan, R.E. Martin,* Y. Tao,* and N.G. Bazan, LSU Eye Center and Neuroscience Center, New Orleans, LA 70112.

The role of GAP-43 in neuronal signal transduction is an area of intense investigation. This phosphoprotein was previously implicated in the resurgence of neurons after ischemic insult, but the role of GAP-43 in neuronal wound healing is only beginning to be elucidated. We have colocalized GAP-43 and neuronal cell adhesion molecule (N-CAM) in the sensory nerve fibers of adult rabbit cornea. Immunocytochemical data indicate that these antigens are present in deep stromal fiber bundles and fibers of the subepithelial plexus. An immunoassay using mouse anti-GAP-43 and [125]]-protein A quantitated relative abundance of GAP-43 in various tissues and subcellular fractions and Northern blot analysis was used to probe for GAP-43 mRNA production in the trigeminal ganglia. We have demonstrated that 48 h after mild alkali injury GAP-43 levels increased in the cornea and 72 h after injury, GAP-43 mRNA increased in the ganglia. These temporal differences suggest the initial transport of endogenous GAP-43 to the cornea and subsequent synthesis of GAP-43 mRNA in the ganglia. The epithelial and stromal tissue layers were assayed for relative abundance of membrane-associated and cytosolic GAP-43. More GAP-43 was membrane-associated than soluble, and some GAP-43 was retained by the membrane fraction after detergent solubilization. Collectively these data indicate that GAP-43 may play a role in corneal wound healing and that corneal trigeminal sensory neurons provide a good model for study of GAP-43 in vivo. GAP-43 may also be a useful marker of nerve repair during wound healing. Supported by NIH grant EY06635.

STRESS IMPAIRS PREFRONTAL CORTEX COGNITIVE FUNCTION IN MONKEYS: ROLE OF DOPAMINE. A.F.T. Arnsten and P.S. Goldman-Rakic. Sect. of Neuroanatomy, Yale Medical School, New Haven, CT 06510.

Humans exposed to mild stress (white noise ≥ 95dB) show cognitive deficits

Humans exposed to mild stress (white noise ≥ 95dB) show cognitive deficits similar to those produced by lesions to the prefrontal cortex (PFC). These deficits may arise from excessive dopamine (DA) activity in the PFC, as mild stress selectively activates the meso-prefrontal cortical DA system in rats. The present study explored this hypothesis in monkeys by determining 1) whether exposure to mild stress would induce a pattern of cognitive deficits consistent with PFC dysfunction, and 2) if stress-induced deficits could be blocked by treatments which decrease DA stimulation in the PFC. Monkeys were tested on either the delayed response task, a spatial working memory test dependent on the PFC, or a visual pattern discrimination task which does not rely on the PFC. Exposure to 100 dB white noise for 30 min prior to testing significantly impaired delayed response performance but had little effect on visual discrimination performance, consistent with PFC dysfunction. Pretreatment with haloperidol (0.005 mg/kg, I.M. 60 min before testing) impaired delayed response performance under control conditions, but improved performance with natopeaton (0.000 liggles, 1.20. to final nectice teaming) impaired delayed response performance under control conditions, but improved performance when given prior to stress. Higher haloperidol doses which caused motor impairment were ineffective. The alpha-2 adrenergic agonist clonidine, which decreases stress-induced DA turnover in the PFC of rats, also ameliorated the cognitive deficits produced by stress. These results suggest that there is an optimal range of DA stimulation in the PFC and that either too little (haloperidol alone) or too much (stress) results in diminished PFC function. Supported by PHS grant #MH44866.

PHYSIOLOGICAL CORRELATES OF ADAPTIVE BEHAVIOR IN A VISUAL DISCRIMINATION TASK IN MONKEYS. <u>T. Alexinsky</u>¹, <u>G. Aston-Jones, J. Rajkowski</u> and <u>R.S. Revay</u>, Div. Behav. Neurobiol., Dept. Mental Health Sci.,

Rajkowski and R.S. Revay. Div. Behav. Neurobiol., Dept. Mental Health Sci., Hahnemann Univ., Philadelphia, PA, USA, and ¹U. René Descartes and LPN2 CNRS, 91198, Gif-sur-Yvette, France.
Previous studies have implicated the rostral pontine nucleus locus coeruleus (LC) in vigilance and adaptive sensory-behavioral responding. Here we have examined this framework by recording neurons in the LC area of cynomolgus monkeys performing an "oddball" visual discrimination-vigilance task. Monkeys were trained with colored lights serving as S+ or S-. Four bundles of 6 micro-wires (25-µm) were implanted bilaterally in the LC area for recording neuronal impulse activity. Event-related potentials (ERPs) were recorded from skull screws. Stimulus duration, time to respond, interstimulus interval, S+/S- ratio, and session duration were systematically varied to alter task difficulty and attentiveness. Monkeys were also subjected to reversal training. Histologic reconstruction of all recording sites is not completed, but certain classes of neuronal responses in the rostral pons are apparent. Apart from cells that could not be driven by any aspect of the task (25%), many neurons were classified as sensory (23%), motor (14%) or reward cells (296). However, a large population of cells in the LC area (36%) exhibited activity that was specifically related to meaningful stimuli (i.e., driven by S+ but not S-). These cells altered their responsiveness to be activated by the new S+ during reversal training in close correlation with behavioral performance. ERPs were also specifically

their responsiveness to be activated by the new S+ during reversal training in close correlation with behavioral performance. ERPs were also specifically evoked by the S+, whether overlearned or during stimulus reversal (correlation between ERP amplitudes and behavioral performance during reversal = 0.89). Thus, strong relationships exist among activity of certain cells in the LC area, cortical ERPs and adaptive behavior in a task requiring sustained attention. These relationships are being examined in more detail by monitoring attention via eye position and autonomic activity via pupillary diameter in a more sophisticated discrimination task. Supported by AFOSR grant 90-0147, and ONR contract N00014-86-K-0493.

NORADRENERGIC INNERVATION OF THE THALAMIC NUCLEUS VENTRALIS POSTEROLATERALIS: A MORPHOLOGICAL BASIS TO ACCOUNT FOR THE CONTROL OF CAT ATTENTIVE BEHAVIOR. P. Delagrang.* J.J. Bouyer, M. Contath. C. Durand. M. Geffard. and A. Rougeul. Institut des Neurosciences, Département de Neurophysiologie comparée, CNRS-Université P. & M. Curie, 9 quai St Bernard, F-55005 Paris. We could previously show that acting upon the central noradrenergic system (pharmacologically or through lesioning locus coeruleus) markedly priviledged a particular pattern of attentive behavior in cat, that of expecting a non-visible target (while it impaired the animal's focused attention on a visible one). Expectancy was always accompanied by the development of 14 Hz ("mu") "rhythms localized on the somatosensory SI cortex, these rhythms being commanded by a small portion of the thalamic nucleus ventralis posterior (VP) (anterior part of its posterior third). Moreover a retrograde HRP study has shown that this thalamic area receives affectents from the locus coeruleus. These various data prompted a more thorough investigation of the noradrenergic innervation of VP. This has now been carried on using an anti-conjugated NA antibody. This antibody being employed for the first time in the cat, several controls were performed, such as preincubation of the antibodies with NA, Dopamine or GABA before slices incubation and control labelings of nuclei and fibers known to contain NA.

Moown to contain NA.

We could then notice, in the VP zone that we knew to be the control site for mu rhythms, numerous NAergic axonal endings, mostly located around non-labeled cell bodies and proximal dendrites, and only a few labeled cell bodies. On EM pictures, the NAergic endings appeared as either axo-somatic or axo-dendritic without visible synaptic differentiation and the labeled pericarya did not show characteristics of

intracellular NA synthesis.

The lack of synaptic differentiation could indicate that NA release is non-synaptic. with receptors being remote from the endings as was previously shown in other structures (Descarries et al 1977). After its release in the intercellular space, NA could increase the signal/noise ratio in the thalamic transfer of sensory messages to the cortex. A thalamic modulation of the afferent information may thus be one of the mechanisms involved in the regulation of the various types of attentive behaviors. Supported by DRET (Nr 86-101) and Fondation pour la Recherche Médicale.

ELEVATED DORSAL NORADRENERGIC BUNDLE TURNOVER AND PLASMA CORTICOSTERONE RESPONSES TO STRESS IN RATS SELECTIVELY BRED FOR HIGH SWIM TEST ACTIVITY. M.A. Cierpial. A.C. Grobin*, E.F. Hargrove*, K.P. McLean*, J.C. Ritchie, C.D. Kilts & J.M. Weiss. Department of Psychiatry, Duke University Medical Center, Durham, NC 27710.

We previously reported on the development and behavioral characterization

We previously reported on the development and behavioral characterization of rats selectively bred for high or low motor activity in a swim test (Cierpial et al., Neurosci Abst, 1989). In the present studies, we have examined regional brain norepinephrine (NE) turnover and plasma corticosterone (CORT) responses to stress in 6th generation male High and Low rats.

High and Low rats were exposed to one of three stressors: a 15 minute swim test (swim stress), 5 mild electric tail shocks delivered over a 30 minute period (mild shock stress), or 90 minutes of intermittent tail shock. Animals were sacrificed immediately following the stress procedure. Trunk blood was collected for assay of CORT and brains were dissected for assay of NE and its two major metabolites, MHPG and DHPG in various regions. Nonstressed, home-cage animals served as controls.

High rats responded to swim stress and mild shock stress with greater increases in plasma CORT than did Lows. Following 90-min intermittent shock stress, plasma CORT levels were highly elevated and did not differ between Hlghs and Lows.

Highs and Lows

NE, MHPG and DHPG levels were similar in home-cage Highs and Lows; however, High animals responded to each stressor with greater increases in NE turnover, primarily in dorsal bundle projection regions. For example, following mild shock stress High rats displayed greater increases in MHPG in the hypothalamus (HY), frontal cortex (FC), and dorsal hippocampus (DH) with the largest differences observed in the FC and DH (dorsal bundle projection areas). These data indicate that rats bred for high activity in the swim test display an

exaggerated adrenocortical response to mild stressors and heightened dorsal bundle activity to stress compared with animals bred for low activity.

75.7

WITHDRAWN

THE BINDING OF 125 I-IODOPINDOLOL (125 I-IPIN) TO SUBTYPES OF & ADRENOCEPTORS (BARs) IN THE BRAINS OF H & L RATS. P. Areso¹ M.A. Cierpial², J.M. Weiss ², K. Williams¹, A. Frazer¹, ¹Univ. of Pa & Dept. Vet. Affairs Med. Ctr., Phila., PA 19104; ²Duke Univ. Med. Ctr., Durham,

Weiss and his colleagues have successfully bred rats which display either high (H rats) or low (L rats) motor activity in a 15 min swim test. They have found that H rats exhibit higher dorsal bundle activity than L rats (see abstract by Cierpial et al.). As central BARs are regulated by their rats (see abstract by Clerpial et al.). As central bars are regulated by their exposure to norepinephrine (NE) released from noradrenergic neurons, we measured BARs in the brains of H and L rats. Subtypes of BARs were measured by quantitative autoradiography using ¹²⁵I-IPIN as the radioligand (*Proc. Natl. Acad. Sci.*, 81:1585, 1984). Also, these rats were given a 15 min swim test to determine if this mild stress altered their BARs. In several regions of brain, the H rats had higher binding of 125 I-IPIN to both β_1 and β_2 adrenoceptors than that found in the brains of L rats. This was particu-larly evident in the dentate gyrus (granular layer) of the hippocampus and caudate-putamen. Such an effect was not found in amygdaloid or hypothalamic nuclei. Most striking were relatively large (about 40%) swim stressinduced increases in 125 I-IPIN binding to g_2 but not g_1 adrenoceptors in the H rats. This effect occurred in hippocampal, cortical, and hypothalamic areas. By contrast, swim stress did not change 125 I-IPIN binding to 82 adre-noceptors in the L rats. Although these changes in BARs may reflect differences in activity of noradrenergic neurons in the H and L rats, it is equally plausible that other, perhaps hormonal, factors are responsible for the differences observed. (Supported by Research Funds from the Dept. of Vet. Affairs & USPHS grant MH 42637).

THE SAME MANIPULATION OF LOCUS COERULEUS (LC) ACTIVITY PRODUCES DIFFERENT BEHAVIORAL AND NEUROENDOCRINE RESPONSES IN RATS SELECTIVELY BRED FOR HIGH AND LOW SWIM TEST ACTIVITY. J.C. Stout, M.A. Cierpial, A.C. Grobin, K.P. McLean, P.A. Scott, J.C. Ritchie, C.D. Kilts, & J.M. Weiss. Depts. of Psychology and Psychiatry, Duke University, Durham, NC 27706.

Studies of a model of behavioral depression in rats have shown that

Studies of a model of behavioral depression in rats have shown that behavioral inactivity in the swim test is associated with depletion of norepinephrine (NE) in the LC (Weiss et al.,[1981] B.F.Res.Rev.3, 167). Animals selectively bred for behavioral differences in the swim test also show marked differences in NE-LC function (Clerpial et al., see adjacent abstract). To study the role of the LC in behavioral activity, microquantities of drugs that affect LC firing were infused into the LC. Manipulation of LC activity (by infusion of the «-2 antagonist idazoxan to stimulate LC activity, or desiprimine to decrease LC activity) over 30 minutes before and during the swim test had no significant effects in normal (i.e. non-selectively bred) animals or in animals bred to show low activity in the swim test. However, in animals bred for high activity. Neurochemical measurement of NE and its major metabolites (DHPG and MHPG) in LC tissue collected immediately following the swim test confirmed that the drugs infused had the intended effects of increasing or confirmed that the drugs infused had the intended effects of increasing or decreasing LC activity.

Measurements of plasma corticosterone (CORT) also indicated that idazoxan produced divergent effects on the selectively-bred animals. Idazoxan-induced stimulation of LC firing elevated CORT in low-active animals but reduced CORT in high-active animals.

The results of these studies demonstrate that direct pharmacological manipulation of LC firing produces different behavioral and neuroendocrine responses in animals that possess particular behavioral and genetic

EFFECTS OF PUNISHMENT ON NEUROTRANSMITTER TURNOVER. S.I. Dworkin, S. Izenwasser, C. Co*, R. Kaltenback* and D. Yoshishige*. Dept. of Physiol/Pharmacal, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27104

This study was a replication and extension of our previous work on the neurochemical effects of punishment. Ten littermate triads, of adult male F-344 rats, were studied using a procedure which allows for the determination of the specific neurochemical effects of punishment. Similar rates of punished and nonpunished responding, maintained with equated rates of reinforcement, were established in two rats of each triad. The third rat of each triad was exposed to noncontingent food and shock presentation yoked to the littermate on the punishment procedure. Thus, the specific effects of punishment could be determined from comparisons of the three conditions. When responding was stable all rats were implanted with jugular catheters for pulse labelling of neurotransmitters. The rats were pulsed labelled with [3H]-tryptophan and [14C]-glucose and sacrificed after either 60 or 90 minutes exposure to the schedule contingencies. The turnover rates of dopamine, norepinephrine, serotonin, aspartate, glutamate, glutamine and GABA were determined in several brain regions. Punishment specific changes in turnover of the biogenic amines included NE in the frontal cortex and caudate putamen, dopamine in the caudate putamen and pyriform cortex and 5HT in the pyriform cortex and nucleus accumbens. Punishment specific changes in GABA turnover were observed in the frontal cortex, pyriform cortex and nucleus accumbens. The turnover of aspartate, glutamate and glutamine was increased in several regions in the two groups exposed to electric shock. (Supported in part by USPHS DA-01999)

CEREBRAL DOPA DECARBOXYLASE ACTIVITY IN SCHIZOPHRENIA MEASURED BY POSITRON EMISSION TOMOGRAPHY: J. Reith, C. Benkelfat, H. Kuwabara, G. Chouinard, P. Etienne, S. Bachneff and A. Gjedde (Positron Imaging Laboratories, McConnell Brain Imaging Center, Montreal Neurological Inst. and Dept. of Psychiatry, McGill Univ., Canada).

To test the hypothesis that positive symptoms in schizophrenia are associated with increased dopaminergic neurotransmission in brain, regional cerebral DOPA decarboxylase activity was determined in male schizophrenic patients and healthy volunteers by [¹⁸F]fluoro-L-DOPA and positron emission tomography. Evaluation of patients was made independently by two psychiatrists using the semi-structured clinical interview (SCID). Patients met the DSM-IIIR criteria for schizophrenia, with a mean age of 37 y and mean duration of illness of 15 y. All were drug-free for more than 1 year. The enzyme activity was calculated on the basis of a kinetic model, that enabled the estimation of the rate constant (k_3) for the conversion of [18F]fluoro-L-DOPA to [18F]fluoro-L-dopamine. Patients were scanned by a Scanditronix PC2048 15 plane PET scanner for 90 min, after i.v. injection of 2.5-5 mCi [18F]fluoro-L-DOPA. Serial arterial blood samples were obtained and counted, and plasma samples were assayed immediately by HPLC. PET images were correlated by MRI. The regional values of caudate DOPA decarboxylase activity (k_3) in units of min⁻¹ in schizophrenic (n=3) and control (n=5) groups respectively were: 0.088 ± 0.011 and $0.068 \pm 0.011.$ This increase was not significant.

CSF 5-HIAA AND HVA CORRELATE WITH THE MMPI PSYCHOPATHIC DEVIATE SCALE IN DEPRESSION BUT NOT SCHIZOPHRENIA W.O. Faustman, R.J. King*, K.F. Faull, J.A. Moses, Jr.*, K.L. Benson*, V.P. Zarcone*, and J.G. Csernansky. Stanford/VA Mental Health Clinical Research Center, 4C2, VA Med Center, Palo Alto, CA, 94304.

Med Center, Palo Alto, CA, 94304. Brown et al. (Am J Psychiatry, 139:741-746,1982) found a correlation between the Minnesota Multiphasic Personality Inventory psychopathic deviate scale (Pd, Scale 4) and CSF 5-hydoxyindoleacetic acid (5-HIAA) in personality disordered men. The Pd scale is widely thought to reflect impulsivity and risk taking. We found that the CSF 5-HIAA/Pd relationship extends ($r_g = -38$, P < .05) to a sample of 21 unmedicated males extends $(r_s = .38, F < .05)$ to a sample of 21 dimensional mates meeting RDC criteria for depression. A trend (P < .1) was found between HVA and Pd in depression. There was also a significant correlation between the MMPI Depression Scale (D, scale 2) and HVA $(r_s = .46)$, but the D scale was not correlated with 5-HIAA. The Pd and D scales were not correlated with 5-HIAA. (D, scale 2) and HVA (r_S = -.46), but the D scale was not correlated with 5-HIAA. The Pd and D scales were not intercorrelated in this sample. No relationship was noted between CSF metabolites and the MMPI scales in 24 RDC-diagnosed schizophrenics. Though our diagnostic methods could not fully assess for the presence of concurrent personality disorders defined by more recently developed diagnostic systems, our results suggest the Pd/5-HIAA relationship extends to patients with a primary diagnosis of a mood disorder. In addition, self-report measures of overall depression appear to relate to CSF monoamine metabolites. Supported by MH 30854 from the NIMH.

PRESYNAPTIC MECHANISMS I

SELECTIVE INHIBITION OF EXCITATORY SYNAPTIC CURRENT BY ADENOSINE. K.-W. Yoon and S.M. Rothman
Departments of Pediatrics and Anatomy and Neurobiology Washington University School of Medicine, St. Louis, MO

We examined the effects of adenosine and baclofen on inhibitory (IPSC) and excitatory (EPSC) synaptic currents in dissociated rat hippocampal neurons with the tight seal whole cell voltage clamp method. Adenosine (100 μM) reduced monosynapatic evoked EPSC's to 21.9 \pm 4.2% (n=7) of control but had no significant effect on the evoked control but had no significant effect on the evoked IPSC's (n=9). In separate experiments adenosine (50 μ M) diminished the peak EPSC to 19.6±4.0% of control (n=3) and this effect was attenuated by coapplication of theophylline (0.5 mM) to 38.1±4.3% of control (p<.01). Baclofen (100 μM) reduced EPSC's to 21.9±2.4% of control (n-6) and IPSC's to 29.1±5.3% of control (n-5). We were unable to elicit any significant changes in resting membrane potential or membrane conductance by bath application of either adenosine or baclofen. findings indicate that adenosine and baclofen have different presynaptic effects and that excitatory and inhibitory neurons have different presynaptic pharmacology. By its selective action on excitatory transmission, adenosine may be an attractive agent for controlling abnormal neuronal excitation in epilepsy Supported by NIH NS14834 and NS19988 and the McDonnell Center for Cellular and Molecular Neurobiology.

ARACHIDONIC ACID-INDUCED CALCIUM MOBILIZATION HIPPOCAMPAL MOSSY FIBER SYNAPTOSOMES. D.S. Demo D.S. v. Dept.

Biological Sciences, Kent State Univ., Kent, OH 44242
Exogenous arachidonic acid, melittin and KCl stimulate
dose-dependent increases in intraterminal free Ca²+
([Ca²+]i). However, it is unclear to what degree these
increases can be attributed to the influx of external Ca²+ or its mobilization from intraterminal stores. Therefore, we incubated Fura-2/AM loaded hippocampal mossy fiber synaptosomes with and without external Ca2+ and a mixture of voltage-sensitive calcium channel blockers (VSCCB). The increase of [Ca²⁺]; induced by 45 mM KCl was reduced by 65% when Ca²⁺ was omitted, while the addition of the VSCCB to the Ca2+-free incubations caused a further reduction to 93% of the stimulated control. The increase in [Ca2+]i induced by 35 uM arachidonate was reduced 53% in the absence of external Ca^{2+} , while the addition of the VSCCB caused a 63% reduction. The increased $[Ca^{2+}]_i$ stimulated by the phospholipase A2 activator melittin (0.88 uM) was by the phospholipase A2 activator melittin (0.88 uM) was reduced 45% in the absence of Ca²⁺, while the VSCCB caused a further reduction to 69% of the stimulated control. It appears, therefore, that the increased [Ca²⁺]; induced by membrane depolarization with K⁺ is due primarily to Ca²⁺ influx. In contrast, approximately 30% of the increases in [Ca²⁺]; observed in the presence of arachidonate or melittin are due to Ca²⁺ mobilization from intraterminal stores. Supported by AFOSR 89-2045.

EXOCYTOSIS OF LARGE DENSE-CORE VESICLES FROM CULTURED HIPPOCAMPAL PYRAMIDAL CELLS MONITORED BY REVERSE HEMOLYTIC PLAQUE ASSAY. A. Malgaroli & R.W. Tsien, Dept. Molecular and Cell. Physiology, School of medicine, Stanford University, Stanford CA

and Cell. Physiology, School of menticine, Stanford University, Stanford CA 24305.

Like many other neurons, hippocampal pyramidal cells express large dense core vesicles (LDCV) containing peptides (e.g. substance P, NPY) as well as small synaptic vesicles (SSV). Little is known about the role of these peptides or the factors governing their release during normal or enhanced synaptic transmission. Differential control of the exocytosis of these vesicle types has been found in organ systems but not in individual central neurons. We have been studying the release of LDCV from single rat hippocampal pyramidal neurons in cell culture (6-15 days). As a general marker of LDCV, we used chromogranin A (ChrA), a secretory protein found in LDCV but not in SSV. A reverse hemolytic plaque assay (RHPA) was carried out using a polyclonal antibody against ChrA, which detected a clear immunoreactivity in our cultured neurons. Action potentials were blocked by 1 µM TTX. ChrA release was detected by complement-induced lysis of sheep red blood cells coated with protein A to bind the antibody. Exocytosis was evoked by 2-4 hours incubation with various stimulating agents (e.g. 20-30 mM KCl, 50-100 µM glutamate): about 40-50% of the neurons were associated with clear evidence of haemolysis (10 experiments). In parallel controls, plaques were not seen if either the stimulant or complement was omitted or if preimmune serum replaced the ChrA antiserum. The spatial pattern of hemolysis suggests that LDCV are released from the larger dendritic-like ramifications, and in some cases, the cell body as well. Thus, RHPA can be applied to measure peptide release from single CNS well. Thus, RHPA can be applied to measure peptide release from single CNS

As a preliminary step toward comparing release of LDCV and SSV, we have monitored glutamate release by recording miniature EPSCs in postsynaptic neurons under whole cell voltage clamp (also with TTX present). The frequency of minis was greatly increased by α -latrotoxin.

CHARACTERISTICS OF ACTION POTENTIAL INDEPENDENT SPONTANEOUS INHIBITORY CURRENTS. T.S. Otis, K. J. Staley and I. Mody, Dept. of Neurology & Neurol. Sci., Stanford Univ. Sch. of Med., INDEPENDENT

Spontaneous inhibitory postsynaptic currents (sIPSCs) were recorded in granule cells using the whole-cell slice patch technique, in 400 μm rat hippocampal slices maintained at 34±1° C. These GABA_A receptor mediated currents persist in 1 μ M TTX, suggesting that they are independent of action potential generation in the GABAergic interneurons. This is an ideal preparation for studying both presynaptic and postsynaptic functioning of the interneurongranule cell synapse. With this in mind, all of the described experiments were carried out in 1-1.5 µM TTX, in symmetrical Cr concentrations.

At -70mV, an ensemble average of hundreds of sIPSCs shows a

monoexponential decay with a time constant (TDECAY) of 5 to 6 ms. Amplitude histograms of events sampled over two minutes were best fitted by Gaussian distributions, with mean values of 35 pA. Inter-event intervals recorded during the same time periods were plotted as exponential probability density functions, with time constants (T_{FREQ}) corresponding to mean inter-event intervals, ranging from 50 to 450 ms. While these values show wide cell to cell variation, they are extremely stable in individual cells. Increasing [K], from 2.5 to 18mM reversibly decreased $T_{\rm FREO}$ by 55%. Conversely, 50 $\mu{\rm M}$ baclofen reversibly doubled $T_{\rm FREO}$. The GABA uptake inhibitor nipecotic acid (500-1000 μM) also increased T_{FREQ} in a concentration dependent manner. These results present a method for quantiflying the amount of presynaptic inhibition at GABAergic terminals, as well as the transmitter pool available for release.

ACTION POTENTIAL INSENSITIVE SPONTANEOUS EXCITATORY POSTSYNAPTIC CURRENTS IN DENTATE GYRUS GRANULE CELLS. K.J. Staley, T.S. Otis and I. Mody, Dept. of Neurology & Neurol. Sci., Stanford Univ. Sch. of Med., Stanford, CA.

TTX-resistant spontaneous postsynaptic currents (PSCs) were recorded in dentate gyrus (DG) granule cells using the whole-cell patch technique in 400 μm thick half-brain slices maintained at 34±1°C. Slices were cut either in the coronal plane, with disruption of perforant path (PP) fibres from the entorhinal cortex (EC), or in the horizontal plane, with preserved connections between the EC and DG (demonstrated by EC antidromic responses evoked by 100 Hz DG stimulation). Both bicuculline(BMI)-sensitive IPSCs and BMI-insensitive EPSCs could be recorded in the DG. IPSCs reversed near -55 mV (intracellular solution: Cs-gluconate, 135 mM; MgCl₂, 2 mM; HEPES 10 mM; pH 7.2). The average IPSC frequency measured at +10 mV was 112 events/minute in the coronal slices and 104 events/minute in the horizontal slices. spontaneous EPSCs reversed near 0 mV and were blocked by the excitatory amino acid antagonists kynurenic acid or CNQX/APV. The average EPSC frequency measured at -75 mV in BMI was 61 events/minute in horizontal slices (EC afferents intact) and 26 events/minute in dorsal coronal slices.

Cutting slices in the coronal plane disrupted the PP and reduced EPSC, but not IPSC frequency. Since IPSC's are generated by local interneurons which synapse on or near the granule cell soma, our results suggest either that cutting in the plane of the PP preserves more excitatory PP synapses on the distal granule cell dentritic tree, or that that presynaptic neuronal integrity influences spontaneous action potential-independant synaptic transmission. Experiments addressing these possibilities will also be reported

FMRFAMIDE MODULATION OF ACTION POTENTIAL EVOKED SYNAPTIC TRANSMISSION IS MEDIATED BY A PERTUSSIS TOXIN-SENSITIVE G PROTEIN. H. J. Man-Son-Hing and P. G. Haydon. Department of Zoology, lowa State University, Ames, IA, 50011. Under specific culture conditions, a chemical synapse will form between cell bodies of Helisoma neurons. These large spherical somata provide a model

for studies of synaptic modulation.

FMRFamide, a neuropeptide endogenous to <u>Helisoma</u>, reduces synaptic transmission at this giant synapse (Man-Son-Hing et al., <u>Nature</u> 341:237, transmission at this giant synapse (Man-Son-Hing et al., Nature 341:237, 1989). Presynaptic action potentials evoke postsynaptic currents which are decreased in amplitude by FMRFamide. This modulation is due to 1) a reduction in the magnitude of the presynaptic calcium current and 2) a coordinate reduction in the sensitivity of the secretory machinery to internal calcium. A PTX-sensitive G protein(s) is involved in mediating the actions of FMRFamide on both ion channels and secretory machinery (Man-Son-Hing et al., Soc. Neurosci. Abst., 15:1148, 1989; Haydon et al., Soc. Neurosci. Abst., 1900). In this etudy, we have descripted whether a PTX-censitive Caretain. 1990). In this study, we have determined whether a PTX-sensitive G protein mediates FMRFamide's action on spike evoked transmitter release.

mediates FMRFamide's action on spike evoked transmitter release. PTX or heat-inactivated toxin was pressure injected into the presynaptic cell 4 hours before assessing synaptic connectivity. FMRFamide (1µM) reduced the amplitude of spike-evoked postsynaptic currents in cells injected with inactivated toxin. In contrast, in synapses pretreated with active PTX, the extent of FMRFamide's modulatory effect was significantly decreased. Thus, PTX-sensitive G protein(s) pathways mediate FMRFamide's modulatory effect on action potential evoked synaptic transmission. This work was supported by NIH grant NS26650.

ACETYLCHOLINE RELEASE BY ISOLATED NERVE TERMINALS (SYNAPTOSOMES) IS QUANTAL. R. Girod M.-M. Poot, L. Eder Colli, J. Medilanski, S. Ofori and Y. Dunant. Department of Pharmacology, Centre Médical Universitaire, 1211 Geneva 4, Switzerland. Department of Biological Sciences, Columbia University, New York NY 10027, USA.

Cholinergic synaptosomes isolated from the electric organ of Torpedo were laid down on a culture of Xenopus embryonic muscle cells. Whole cell recording in one of the myocytes revealed spontaneous synaptic currents (SSCs) that were generated soon after synaptosomes application. These SSCs very much resembled those occuring normally in Xenopus during synaptogenesis at early times after nerve-muscle contact. The SSCs produced by the Torpedo synaptosomes were blocked by tubocurarine, indicating that they were due to pulsatile release of acetylcholine (ACh). Thus, isolated nerve terminals retain in vitro their capacity to release ACh in a discontinuous, quantal manner.

PROTEIN KINASE C ACTIVATORS SELECTIVELY ENHANCE SYNAPTIC TRANSMISSION IN THE CEREBRAL GANGLION OF *APLYSIA*. <u>S.M. Fredman</u> Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

The synaptic connections between the A and B cluster neurons in the cerebral ganglion of Aplysia exhibit a novel form of enhanced synaptic transmission, slow developing potentiation (SDP, Fredman, 1988; Neurosci. Hallsingsion, sow developing potentiation (3DF, Fredman, 1998, Neulosci. Abst. 14: 1207). A single 2 sec, 20 Hz train in an A neuron causes a long-lasting, synapse specific increase in the amplitude of subsequent EPSPs in B neurons tested at 3 min intervals. The slow rise (5 min to peak) and decay $(\tau$ = 25 min) of SDP suggests that it may be in part mediated by a second messenger. Evidence now indicates that the diacylglycerol (DAG)/protein kinase C (PKC) second messenger system may be involved. Phorbol esters are potent activators of PKC. Bath application of 2 µM phorbol 12,13 diacetate (PDA) selectively increased SDP mean EPSP amplitude 49% from 7.5±1.4 to 11.2±2.0 mV. There were no short-term changes in test EPSPs prior to the tetanizing train [4.2 ±0.6 v 4.0 ±0.1 mV with PDA]. Adding 30 µM OAG (oleoylacetylglycerol, a DAG analog), caused a significant increase in potentiated EPSPs [from 143% to 214% of initial EPSP amplitude], but had no effect in the absence of a tetanizing train. Injecting PDA directly into presynaptic A neurons also caused a selective increase in EPSP amplitudes of comparable magnitude (14.6 \pm 2.8 mV) following the tetanizing train. A neurons injected with 4- α -phorbol did not exhibit increased SDP. The actions of the PKC inhibitor H7 were also selective. Bath application of 40 µM H7 had or the PNC inhibitor h7 were also selective. Buth application of 40 µm H7 had no effect on synaptic transmission and did not reduce test EPSPs, but completely blocked SDP. These findings suggest that activation of PKC may play a key role in modulating synaptic transmission at the A-B neuron synapse and mediating SDP. This work was supported by NIH grant NS20846, RCMI grant RR03032 and NSF MRCE grant RII8714805.

FMRF AMIDE MODULATION OF SECRETORY MACHINERY IS MEDIATED BY A PERTUSSIS TOXIN SENSITIVE G PROTEIN. P. G. Haydon. R. T. Doyle and H. J. Man-Son-Hing. Department of Zoology, lowa State University, Arnes IA 50011.

The neuropeptide Phe-Met-Arg-Phe NH₂ (FMRFamide) causes a

presynaptic inhibition of neurotransmitter release from identified neuron B5 of Helisoma trivolvis. Previous studies (Man-Son-Hing et al., Nature 341:237, Helisoma trivorius. Previous studies (Man-Son-Hing et al., <u>Nature</u> 341:237, 1989) have demonstrated that FMR-amide coordinately reduces the magnitude of the voltage-sensitive-calcium current and reduces the secretory response to internal calcium. The action of FMRFamide on the calcium current is mediated through a PTX-sensitive G protein pathway (Man-Son-Hing et al., <u>Soc Neurosci. Abst.</u> 15: 1148,1989). In this study we determined whether a similar G protein mediates FMRFamide's actions on secretory machinery. Pairs of neuronal somata were cultured for three days in conditions which prevent neurite extension and allow the formation of a unidirectional chemical

synapse between somata of presynaptic neuron B5 and cholinoceptive neuron B19. To monitor actions on secretory machinery, the frequency of spontaneous miniature inhibitory postsynaptic currents (MIPSCs) was recorded under conditions of basal free calcium levels in the presynaptic cell. Application of FMRFamide (≥1nM) reliably reduced MIPSC frequency without Application of FMH-famile (\$\text{InM}\) reliably reduced MIPSC frequency without changing the resting calcium level. To test for G protein involvement in mediating this inhibitory action, the non-hydrolysable analog of GTP, GTPyS, was injected presynaptically in the absence of FMHFamide. GTPyS injection reliably reduced MIPSC frequency, while GTP injection had no significant affect. Injection of the A protomer of pertussis toxin (PTX) 20 minutes prior to FMRFamide application (1µM) prevented FMHFamide from reducing MIPSC frequency. Taken together these data demonstrate that the modulation of the sensitivity of secretory machinery to internal calcium can be mediated by a PTX reporting of Sensitin pathways. sensitive G protein pathway. EXTRACELLULAR CALCIUM MARKEDLY AFFECTS INTRA-CELLULAR CALCIUM DIRECTLY MEASURED IN MOUSE MOTOR NERVE TERMINALS. Z.-P. Fang and N. Robbins. Dept. of Neuroscience, Case Western Reserve Univ., Sch. of Med., Cleveland, OH 44106

Intracellular [Ca2+] of motor nerve terminals critically affects transmitter release and many other cell functions, but resting values in vertebrates and effects of varying extracellular [Ca²⁺]_o have not been determined. In order to address this issue directly, a new technique was used to inject fura-2 into preterminal axons in mouse soleus muscle maintained at room temperature (Fang & Robbins, Neurosci. Abstr. 15: 484, 1989), and to determine putative [Ca²⁺ by ratio imaging, averaging values in three different areas of each nerve terminal. In normal Krebs solution with $2.5 \text{mM} \left[\text{Ca}^{2+} \right]_{\text{o}}$ computed $\left[\text{Ca}^{2+} \right]_{\text{i}}$ was 170 \pm 50 nM, remarkably similar to values computed [Ca²⁺]_i was $1/0 \pm 90$ into, iterinatably similar to values reported in crayfish nerve terminals (Delaney et al., I. Neurosci. 9: 3558, 1989). In 0.05 mM [Ca²⁺]_o, [Ca²⁺]_i was 45 ± 20 nM, i.e. there was a 4-fold change in [Ca²⁺]_i in response to a 50-fold extracellular change. In going from low to high [Ca²⁺]_o, a steady state [Ca²⁺]_i was attained in less than 10 min, in agreement with previous $\frac{1}{2}$ was $\frac{1}{2}$ with $\frac{1}{2}$ min, in agreement with previous $\frac{1}{2}$ was $\frac{1}{2}$ with $\frac{1}{2}$ with $\frac{1}{2}$ was $\frac{1}{2}$ with $\frac{1}{2}$ with $\frac{1}{2}$ with $\frac{1}{2}$ was $\frac{1}{2}$ with $\frac{1}{2}$ was $\frac{1}{2}$ with $\frac{1}{2}$ with $\frac{1}{2}$ was $\frac{1}{2}$ with \frac physiological studies of MEPP frequency. The regulation of [Ca²⁺]_i at physiological temperatures, the relation of [Ca²⁺], to transmitter release, and effects of aging can now be investigated directly.

EFFECTS OF CURARE ALONE OR COMBINED WITH THIOPENTAL OR HALOTHANE ON THE END-PLATE CURRENT AT THE FROG NEUROMUSCULAR JUNCTION. B. Bhattacharyya* and M. Sokoll. Department of Anesthesiology, University of Jowa College of Medicine, Iowa City, IA 52242.

The ability of potent inhalation (but not barbiturate)

anesthetics to potentiate curare-like muscle relaxants is long recognized. The underlying mechanisms are not clear. Both recognized. The underlying mechanisms are not clear. Both types of anesthetic agents produce ion channel blockade. We studied the effects of curare alone and combined with either halothane or thiopental on the end-plate current (EPC) of the R. pipiens sciatic nerve-sartorius muscle preparation. End-plate currents were recorded using the two micro-electrode voltage clamp technique at stimulation rates of 0.4 and 40 Hz. After control recordings, curare was applied for 20 min and a further group of EPC's recorded. The perfusate was then changed to include either thiopental or halothane in addition to curare. A range of concentrations of all drugs were studied. to curare. A range of concentrations of all drugs were studied.

RESULTS: Curare alone caused a significant decrease in EPC amplitude and a slight decrease in time constant of decay (tau) at 0.4 and 40 Hz. Addition of thiopental caused no significant decrease of EPC amplitude and a small decrease in tau. With halothane the EPC amplitude showed a further significant decrease. Tau was decreased to a similar extent with both halothane and thiopental.

CONCLUSIONS: Halothane potentiates curare induced neuromuscular block by decreasing the release of

release of neuromuscular block by decreasing the acetylcholine from the motor nerve terminal.

ALTERED EXPRESSION OF NEURONAL CYTOSKELETAL GENES AFTER CORTICOSPINAL AXOTOMY IN THE ADULT HAMSTER. S.A. Kost-Mikucki and M.M.Oblinger, Dept of Cell Biology and Anatomy,

Chicago Medical School, North Chicago, IL 60064.
Injury to the nervous system provokes a number of molecular responses.
In peripheral neurons which have the ability to successfully regenerate, axotomy alters the expression of genes encoding the major cytoskeletal proteins. Tubulin and actin mRNA levels increase while neurofilament (NF) axotomy alters the expression of genes encoding the major cytoskeletal proteins. Tubulin and actin mRNA levels increase while neurofilament (NF) mRNA expression is downregulated after axotomy of peripheral neurons. Because neurons of the CNS generally do not successfully regenerate after injury, it was postulated that the pattern of changes in cytoskeletal gene expression after axotomy might differ from that in peripheral neurons. To examine this issue, in situ hybridization and immunoblotting were used to characterize changes in NF-L and tubulin mRNA and tubulin levels in axotomized corticospinal neurons in the adult male Golden hamster. The corticospinal tract was unliaterally transected in the medulla and animals were sacrificed at 2, 7 and 14 d after axotomy. Corticospinal neurons were retrogradely labeled with the dye Fast Blue at the time of axotomy. This allowed their subsequent identification and confirmed survival. Histological sections of motor cortex (where the cell bodies for corticospinal neurons are located) were hybridized with 35 S-labeled α -tubulin and NF-L cDNA probes and prepared for autoradiography. The results of *in situ* hybridization experiments revealed that both tubulin and NF-L mRNA levels were decreased after axotomy and remained decreased for at least 14 d. Immunoblotting experiments indicated that changes in cell body gene expression were reflected as changes in the composition of the corticospinal axons at later post-axotomy times. These results clearly show that a major aspect of the CNS neuronal response to axotomy, the tubulin gene response, differs from that in PNS neurons. This may be one of the factors contributing to regenerative failure of adult CNS neurons factors contributing to regenerative failure of adult CNS neurons.

A cDNA FOR A NOVEL TYPE III INTERMEDIATE FILAMENT PROTEIN FROM GOLDFISH RETINA DURING REGENERATION. E. Glasgow*, P. Tesser*, and N. Schechter. Departments of Biochemistry and Psychiatry, SUNY at Stony Brook, NY 11794.

The goldfish visual pathway displays a remarkable capacity for development and plasticity throughout life. Furthermore, functional regeneration occurs after optic nerve injury. The intermediate filament (IF) protein composition of this pathway differs from that of higher vertebrates. Certain of these IF proteins may have structural attributes which support the growth characteristics associated with the goldfish visual pathway. A PCR technique, using synthetic oligomers to conserved IF core domains, and a 15 day post crush retinal lambda gt11 library was used to generate several cDNA clones. Sequence data from a portion of the coil 2 domain from two of these clones predicts a novel type III IF having highest homology with vimentin and a low homology with the neurorfilament-L protein. (EY 05212 to N.S.)

RAPID CHANGES IN NONNEURONAL CELL GENE EXPRESSION FOLLOWING SCIATIC NERVE TRANSECTION.

J.G. Toma, P.A. Barker, S. Pareek*, A. Acheson, and F.D. Miller. Dept. of Anat. and Cell Biol., Univ. of Alberta, Edmonton, ALBERTA.

We have examined changes in nonneuronal cell gene expression at early timepoints following transection of the rat sciatic nerve. In situ hybridization analysis demonstrated changes in expression of several different mRNAs in both Schwann cells and epineurial fibroblasts as early as 3 hr postaxotomy. Histone H3.3 mRNA was dramatically increased at 3 hr in cells of the epineurium, while PomRNA, a major myelin transcript, was decreased in Schwann cells of both the proximal and distal stumps. The changes in histone H3.3 and P_0 mRNAs were even more dramatic at 36 hr, while remaining localized to the same cell types. By 72 hr postaxotomy, P₀ mRNA was decreased in all of the Schwann cells of the distal segment. In contrast, epidermal growth factor receptor (EGFR) and nerve growth factor receptor (NGFR) increased in both Schwann cells and epineurial fibroblasts, as detected by in situ hybridization and immunocytochemistry. Three hr postaxotomy, the increase in EGFR and NGFR was limited to the epineurium, while at 36 and 72 hr, elevated levels were detectable throughout the epineurium and the body of the nerve. Interestingly, by 72 hr, receptor levels were increased in a proximal-distal gradient in the proximal segment, but uniformly throughout the distal segment. These data demonstrate that there are rapid and dramatic changes in Schwann cells and epineurial fibroblasts as early as 3 hours posttransection, and that these changes occur in spatial and temporal gradients during the first 3 days following axonal injury.

77.4

REGROWTH OF DORSAL ROOT AXONS INTO THE SPINAL CORD FOLLOWING IRRADIATION. <u>I.J. Sims and S.A. Gilmore</u>. Dept. of Anatomy, Univ. of Arkansas for Medical Sciences, Little Rock, AR 72205-7199.

This study examined the ability of injured dorsal root ganglion (DRG) axons to regrow into the irradiated spinal cord of the rat. Exposure of the lumbar spinal cord in early postnatal rats to X-rays induces a marked reduction in the population of both astrocytes and oligodendrocytes. This reduction in CNS glia is present throughout maturation of the spinal cord and continues into early adulthood. Upon this background maturation of the spinal cord and continues into early adulthood. Upon this background of an altered glial environment the right L3 and L4 dorsal roots were crushed and then frozen. Dorsal root lesions were performed on three groups consisting of 13, 23 and 43 day old irradiated rats and age matched non-irradiated controls. Between 30 and 80 days following dorsal root lesion rats from each group were subjected to one of three different labeling procedures: anterograde labeling by cutting the root distal to the injury site and applying WGA-HRP to the cut end for transport into the spinal cord or retrograde labeling of nerve cell bodies in the L3 and L4 DRG's by injections of True Blue or Fluoro-Gold into the spinal cord. The number of retrogradely labeled, fluorescent neurons was counted in the DRG's on both injured and contralateral, non-injured sides. Anterograde labeling with WGA-HRP revealed a robust regrowth of DRG axons in the irradiated but not in the non-irradiated control cords. These observations were strengthened by the finding of True Blue or Fluoro-Gold labeled neurons in the DRG on the injured side, in non-injured side, in neurons in the DRG on the injured side, as well as the contralateral, non-injured side, in irradiated rats. Non-irradiated rats lacked labeled DRG neurons on the injured side, whereas the contralateral, non-injured side appeared to have a full complement of labeled DRG neurons. Ultrastructural observations from the 23-day-old injury group revealed that the irradiated cords did not develop a thick astrocytic scar at the dorsal root entry zone as did the non-irradiated controls. Thus, it appears that reduction of the normal complement of glia creates a permissive environment for regrowth of DRG axons into the spinal cord. Supported by Grants SCRF 745 from the PVA and NIH

ANTIBODIES AGAINST MYELIN-ASSOCIATED NEURITE GROWTH INHIBITORS COMBINED WITH TROPHIC FACTORS AND BRIDGES IMPROVE REGENERATION OF LESIONED NERVE FIBERS IN SPINAL CORD AND OPTIC NERVE. M.E. Schwab, L. Schnell and D. Cadelli. Brain Research Institute, University of Zurich, August-Forel-Str. 1, CH-8029 Zurich/

Neurite growth inhibitors (NI-35, NI-250) are constituents of rat CNS myelin and inhibit neurite growth in a variety of in vitro systems. In vivo application of a neutralizing antibody (IN-1, Caroni and Schwab, 1988) leads to long-distance regeneration of lesioned cortico-spinal tract (CST) axons (Schnell and Schwab, 1990) in the spinal cord. Cyst and scar formation remains, however, a major mechanical obstacle for the sprouting CST. We now combine release of IN-1 from incapsulated hybridomas with peripheral nerve-, extracellular matrix-, or astrocyte-bridges, and trophic factor sources. E14 spinal cord tissue is a good source of neurorector sources. E14 spinal cord tissue is a good source of neurotrophic activity provoking increased sprouting of the lesioned CST, but does not serve as a bridge since only few CST axons grow into the transplants, and end within the implant. - Intracranially lesioned optic nerve fibers of young adult rats survive and sprout under the influence of bFGF, and, in presence of antibody IN-1, reelongate into and through the optic nerve chiasm. Interaction of regenerated axons with their target regions is under investigation.

77.7

STIMULATION OF MAMMALIAN NEURITE OUTGROWTH BY TELEOST PNS. M.J.Anderson, T.D.Hassinger and L.R.Whalen. Dept. Anatomy & Neurobiol., Colorado State Univ., Ft.Collins, CO 80523.

Several lines of evidence indicate that white matter in mammalian CNS possesses inhibitory properties that prevent the regrowth of axons in that environment. In order to test the limits of "white matter inhibition," we have plated postnatal rat dorsal root ganglion (DRG) neurons on sections of CNS and PNS tissue from the teleost Apteronotus albifrons. Previous results have shown that postnatal DRG neurons do not show significant growth on mammalian CNS white matter or nondegenerated mammalian PNS. In Apteronotus, regeneration of spinal cord and peripheral nerves normally does occur after injury, and it was expected that mammalian neurons would grow on these substrata. DRGs from 1-day postnatal rats were dissociated in collagenase/trypsin, and enriched for neurons by preplating. Teleost spinal cord and/or electric organ (comprised of PNS axons) were quick-frozen, and 10 um sections were thaw-mounted on glass-bottomed dishes. DRG neurons plated on sections of Apteronotus electric organ (DMEM 10 um sections were thaw-mounted on glass-bottomed dishes. DRG neurons plated on sections of Apteronotus electric organ (DMEM medium, 10% CFCSS, 37°C) showed exceptional neurite outgrowth. The number of cells with neurites and neurite lengths far surpassed that on other tissue substrates. In contrast, DRG neurons did not grow on sections of normal Apteronotus spinal cord. We conclude that Apteronotus electric organ lacks the inhibitory properties of mammalian white matter, and may contain neuron stimulating factor(s). Apteronotus spinal cord, although it can regenerate in response to injury, is not normally growing, and may have growth-inhibiting properties similar to those of mammalian spinal cord (but reversible in nature). ASTROCYTES MAINTAINED IN THE PRESENCE OF SOLUBLE ASTROCYTES MAINTAINED IN THE PRESENCE OF SOLUBLE MEDIATORS OF INFLAMMATION RELEASE INHIBITORS OF NEURONAL GROWTH FACTORS BOUND TO A LAMININ SUBSTRATUM. R.J. Riopelle, P.C. Johnson-Green*, M. Guo*, K.E. Dow. Apps Medical Research Centre, Kingston General Hospital, Queen's Univ., Kingston, Canada K7L 3N6.

Astrocyte enriched cultures release molecular species that copurify with heparan sulphate (HS) proteoglycans (PGs) and promote neurite growth following pretreatment of a laminin substrate in the absence, but not in the tollowing pretreatment of a laminin substrate in the absence, but not in the presence, of HS glycosaminoglycans (GAGs). Biosynthetic studies reveal that astrocytes release at least two families of HSPG, one of which may form a heparan sulphate-chondroitin sulphate hybrid proteoglycan. The titer of neurite promoting activity bound to the laminin substrate in conditioned medium (CM) of astrocyte monolayers treated with interleukin-1 (IL-1-CM) was 50% of of astrocyte monolayers treated with interleukin-1 (IL-1-CM) was 50% of untreated control (ACM). In the presence of lipopolysaccharide endotoxin the titer of neurite promoting activity of the conditioned medium (LPS-CM) was 1% of control. A 50-50 mix of ACM and LPS-CM had a titer of neurite promoting activity identical to that of LPS-CM suggesting the presence of inhibitors of neurite growth in LPS-CM. Excessive concentrations of free GAGs did not account for the inhibitory effects of LPS-CM.

The present studies suggest that soluble mediators of inflammation influence the functional phenotype of astrocytes directly or via astrocyte-microglia interactions and may begin to address a molecular basis for failure of the astrocyte milieu to support regenerative neurite elongation following injury to the

A GLYCOPROTEIN FRACTION FROM ADULT CHICKEN GREY MATTER CAUSES COLLAPSE OF CNS AND PNS GROWTH CONES IN VITRO. Roger J. Keynes, Alan R. Johnson*, Caroline J. Picart*, Olenka M. Dunin-Borkowski & Geoffrey M.W. Cook*. Department of Anatomy, University of Cambridge, Cambridge

A glycoprotein fraction which causes collapse of dorsal root ganglion growth cones <u>in vitro</u> has been isolated recently from chick somites by affinity isolated recently from chick somites by affinity chromatography with peanut agglutinin (PNA) (Davies et al., Neuron 4, 11-20, 1990). Immobilised polyclonal antibodies directed against the 48K and 55K components of this fraction can be used to eliminate the collapse activity. We now find that these antibodies also cross-react with a component of $M_{\rm T}$ 48K in the adult chicken brain, and that detergent (2% CHAPS in PBS) extracts of grey matter contain potent collapsing activity for both CNS (retina) and PNS (PRS) growth cones in culture. The CNS (retina) and PNS (DRG) growth cones in culture. The activity can be removed from the extracts by treatment with PNA-agarose, and can be recovered by elution of the immobilised lectin with 0.4M lactose. SDS-PAGE of the lactose eluate demonstrates that material of $\rm M_{r}$ 48K is recovered as the major component. To date, we have been unable to detect collapse activity in chicken white matter using these assay procedures. The presence of the 48K component in grey matter raises the possibility that this material could contribute to the failure of effective regeneration following injury to the adult CNS.

EFFECT OF ASTROCYTIC AGE AND CONFLUENCE ON THE GROWTH OF PC12 NEURITES. D.M. Baorto and M.L. Shelanski. Dept. of Pathology, Columbia University, New York, NY 10032.

At the site of injury in the CNS, an astrocytic scar forms which is thought to impede the regrowth of nerve fibers through the area. However, tissue culture studies have shown that plating neurons onto confluent monolayers of astrocytes results in neurite outgrowth over the cells. In this study we tested neuronal decision-making between two substrates (collagen and astrocytes in low density culture), where extending neurites would reach a border between collagen and the astrocytic surface. Astrocytes that had been cultured from neonatal cortex either for 2 days or for 4-6 weeks in confluent culture were harvested and replated at low density on collagen-coated dishes. NGF-treated PC12 cells were added after attachment of the astrocytes. In cocultures with 2 day old astrocytes, we found that neurites extending along the collagen substrate grew freely over the astrocytes they encountered. contrast, the growth of neurites from the collagen substrate onto the in vitro aged astrocytes was strongly inhibited. There was a marked preference for the collagen substrate, with neurite-bare areas often observed around the astrocytes. These findings suggest that astrocytes aged in confluent cultures undergo a change which results astrocytes aged in common testines underly a change which results either in their becoming less suitable substrates for neurite growth or in their actively inhibiting this growth. This change is preserved after replating at low density. This may model the situation *in vivo*, and suggests that mature astrocytes may serve to impede nerve regeneration through mature CNS tissue.

AXOTOMY ACCELERATES SLOW COMPONENT b OF AXONAL

AXOTOMY ACCELERATES SLOW COMPONENT b OF AXONAL TRANSPORT. JM JACOB and IG McQUARRIE. DEPT. NEUROSCI., CASE WEST. RES. U., CLEVE., OH 44106. Because the integrity of the axon depends on the supply of structural proteins that are synthesized in the nerve cell body, we examined the effect of axotomy on the delivery of these via slow axonal transport. We labeled newly synthesized proteins in rat motor neurons with 35S-methionine 7 d after crushing the distal sciatic nerve. The sciatic nerve system was harvested 7-21 d later for SDS-PAGE; tubulin, actin, calmodulin, and the 68 kD neurofilament protein (NF-L) were identified from fluorograms and removed for liquid scintillation counting. The peaks of labeling for SCb, the faster subcomponent of slow transport that represents subcomponent of slow transport that represents the moving cytomatrix, advanced at 4.2 ± 0.2 mm/d in proximal axons, vs. 3.5 ± 0.2 mm/d after sham axotomy (p < 0.01). There was no change in the rate of transport for NF-L labeling that marks SCa—the moving microtubules and neurofilaments. Our findings suggest that the motors driving SCa and SCb differ, and that the SCb motor can adapt to the changing needs of the axon tip.

ENHANCED TUBULIN DELIVERY CORRELATED WITH ALTERED MAP PHOSPHORYLATION DURING REGENERATION. Denis Larrivee, Dept. Physiology, Cornell Univ. Med. Coll., NY, NY 10021.

While investigating the role of protein phosphorylation in regenerating goldfish optic nerves, we identified a microtubule associated phosphoprotein (MAP), designated p9, that underwent a prominent pI shift during synaptogenesis. The shift in pI paralleled a redistribution of p9 from the assembled to unassembled tubulin compartment, suggesting that p9 phosphorylation regulated tubulin exchange between both compartments. To test this hypothesis tubulin labelling was monitored along the length of the axons following intraocular pulse labelling with H-proline. At 16 and 25 hours post injection, tubulin labelling was greatly increased, but evenly distributed, suggesting that a fast transported tubulin fraction was incorporated into a more slowly moving tubulin pool. By contrast, GAP and synapsin showed well defined labelling peaks. When tubulin labelling was monitored in synaptosomal preparations during synaptogenesis, it remained elevated for many weeks. Labelling of the 2 synaptic proteins, however, was increased only transiently at the onset of synaptogenesis. TTX-induced impulse blockade from 21 to 35 days further increased tubulin labelling by 2 fold but had little effect on the synaptic proteins. These results suggest that an increase in tubulin exchange, mediated by p9 phosphorylation, may facilitate activity dependent, optic fiber reorganization during synaptogenesis.

PROTEOGLYCAN TRANSPORT IN REGENERATING GOLDFISH RETINOTECTAL PROJECTION. K.E. Dow, R. Levine*, M. Solc*, P. Merchant*, R.J. Riopelle. Queen's Univ., Depts. of Pediatrics & Medicine, Kingston, Canada K7L 3N6 & MeGill Univ., Dept. of Biology, Montreal, Canada. Retinal biosynthesis and fast axonal transport of glycoproteins and proteoglycans were examined in the regenerating retinotectal projection of the

proteoglycans were examined in the regenerating retinotectal projection of the goldfish (Carassius auratus). At various times following optic nerve crush animals received intraocular injections of ³H-glucosamine (³H-Glc, 100 µCi) and were allowed to survive for 24 hours. Labelled glycopeptides (GP), heparan sulphate GAGs (HS) and chondroitin sulphate GAGs (CS) were separated and quantified in retina (R), optic nerve (N) and optic tectum (T) by HPLC.

³H-glucosamine incorporation into GP, HS and CS in R increased dramatically between days 10/21 and day 35. The amount of ³H-HS and ³H-CS in N decreased from days 10/21 to day 35 while ³H-GP decreased from day 10. Finally, in T, ³H-GP and ³H-CS followed the same general pattern seen in R while ³H-HS decreased between days 10/21 and then increased to day 35. The

ratio of HS/CS was approximately 1.5 at all times except at day 35 in R and T where it was increased

These patterns of incorporation of ³H-Glc into glycopeptides and GAGs do not correspond to previously reported patterns of precursor incorporation into new axon segment total protein. Furthermore, there was a differential increase in the HS/CS ratio in R and T as compared to N at day 35.

These observations suggest that the stages of regeneration in the goldfish retinotectal projection may correlate more closely with posttranslational processing of glycoprotein and proteoglycans than with gene expression of core proteins. Furthermore, in R and T, the markedly increased incorporation of ³H-Glc into glycoconjugates at day 35 and the increased ratio of HS/CS at that time suggest that separate regulatory events may control posttranslational modifications during regeneration (days 10 and 21) and synaptogenesis (day 35).

ANTEROGRADE AXONAL TRANSPORT AND RELEASE OF THE PERMISSIVE TROPHIC FACTOR TRANSFERRIN IN REGENERATING PERIPHERAL NERVES. W. R. Kiffmever and A. L. Mescher, Medical Sciences Program, Indiana Univ. Sch. of Med., Bloomington, IN 47405.

L. Mescher. Medical Sciences Program, Indiana Univ. Sch. of Med., Bloomington, IN 47405.

Transferrin supplies iron to cells for use as a cofactor in several enzymes, including the rate limiting enzyme in DNA synthesis and those involved in respiration. Developing neurons contain relatively large amounts of this iron transport factor. We are testing the hypothesis that neural transferrin is involved in the growth-promoting effects of peripheral nerves in processes such as amphibian limb regeneration. Using a sensitive ELISA procedure for transferrin from the salamander Ambystoma mexicanum, we have examined axonal transport and release of this factor in intact and regenerating adult sciatic nerves. Bilateral effects were seen following unilateral amputation, but regenerating nerves showed higher concentrations of transferrin than controls. In the double ligature technique for determining direction and rate of transport, transferrin accumulated proximal to the first ligature at a concentration 2.5 times higher than the average value between the ligatures. The rate of transferrin transport in the fast anterograde component was approximately 3 mm per hour. There was no evidence for retrograde transport of this factor. Colchicine implanted around the lumbar plexus in a matrix of slow release polymer abolished the accumulation, indicating the increase was due to axonal transport rather than to edema or vascular blockage. In vitro studies with a 2-chambered system demonstrated release of transferrin from regenerating nerves four weeks after crush injury and this release was also blocked by colchicine. These studies suggest that the permissive trophic effect of nerves in avascular tissues may be due to axonal release of transferrin. (Supported by the US Army Med. Res. Contract DAMD17-87-C-7098). NEURONAL DEATH: MECHANISMS

78.1

POLYAMINES INCREASE NERVE CELL SURVIVAL. G.M. Gilad and V.H. Gilad. Neuropsychiatry Branch, NIMH Neuroscience Center at St Elizabeths Hospital, Washington, DC, 20032.

The biochemical mechanisms that underlie the

capability of neurons to survive after trauma capability of neurons to survive after trauma are still unknown. Recently, an immediate early and transient elevation in polyamine biosynthesis (termed "the polyamine response") was found to be a general characteristic of peripheral and probably of CNS neurons after trauma. This finding led us: 1) to postulate that the polyamine response is an essential part of a protective molecular program mounted by neurons responding to trauma, and 2) to the rationale for the use of exogenous polyamines (PA) to enhance neuron survival after trauma. We have demonstrated that treatment with PA for a limited time interval (days) can prevent nerve cell loss during the period of programmed cell death and after axonal, neurotoxic, or ischemic injuries. Studies on the possible site(s) of polyamine action indicate that the injured neurons themselves can transport and use exogenous PA and that PA may act indirectly by increasing neurotrophic factor production.

78.2

EFFECTS OF MUSCLE INACTIVITY AND DENERVATION ON THE REGULATION OF A PUTATIVE MUSCLE-DERIVED NEUROTROPHIC AGENT: IN VIVO AND IN VITRO STUDIES. L.J. Houenou, L. Haverkamp*, R. Kunzi & R.W. Oppenheim. Dept. of Neurobiology and Anatomy, Bowman Gray Sch. of Med., Winston-Salem, N.C. 27103 and *Dept. of Neurology, Baylor College of Med., Houston, TX 7020

Motoneuron (MN) survival <u>in vivo</u> can be enhanced by treatment with muscle extracts. Muscle activity and innervation have both been suggested to down regulate the availability of a putative muscle-derived neurotrophic agent. To test this notion we have examined MN survival in vivo and choline acetyltransferase (ChAT) activity in spinal cord neurons in vitro following treatment with partially purified extracts from inactive, denervated, aneural, and slow tonic and fast twitch muscles from embryonic and postnatal animals. MN survival in chick embryos treated in vivo with extracts from active and chronically inactive embryonic muscles did not differ. Extracts from fast twitch and slow tonic postnatal avian muscles are equally effective in promoting both MN survival in vivo and ChAT activity in vitro. Preliminary results indicate that denervated postnatal avian muscle affective than inproved muscle extract is more effective than inproved muscle. muscle extract is more effective than innervated muscle extract in promoting both MN survival in vivo and ChAT activity in vitro. Assessment of trophic agent levels in aneural avian embryonic muscle is in progress. At present, our results suggest that the availability of putative neurotrophic agent(s) may be regulated by innervation but not muscle activity.

IDENTIFICATION OF DEATH-ASSOCIATED PROTEINS SYNTHESIZED BY NGF-DEPRIVED NEURONS. D.P. Martin, R.M. Leimgruber,* and E.M. Johnson, Jr. Dept. of Pharmacology, Washington Univ. School of Medicine, Monsanto Co., St. Louis, MO 63110.

We have previously demonstrated that the death of NGF-

We have previously demonstrated that the death of NGF-deprived neurons requires the synthesis of RNA and protein. We hypothesize that neurons synthesize new proteins that actively mediate cell death after trophic factor deprivation. To test this hypothesis, we have asked whether new proteins are significantly induced in rat sympathetic neurons in vitro after NGF deprivation.

Neuronal cultures from E21 rat superior cervical ganglia

Neuronal cultures from E21 rat superior cervical ganglia were grown for one week in the presence of NGF. Triplicate cultures were acutely deprived of NGF, and at various times thereafter pulsed with $[^{38}{\rm S}]$ methionine/cysteine. Proteins were extracted and separated by 2D gel electrophoresis. Autoradiograms reproducibly resolved about 1300 spots. Different exposures from each gel were digitized and merged into a composite database, which permitted quantification of differential protein synthesis.

Several proteins were induced greater than ten-fold by NGF deprivation. The timecourse of their appearance was compared to the timecourse of commitment, the duration of NGF deprivation after which inhibitors of RNA and protein synthesis no longer prevent neuronal death. Samples were also prepared from living NGF-deprived neurons maintained in the presence of a cAMP analogue, interferon $\gamma,$ or a depolarizing concentration of potassium. Some proteins were significantly decreased after NGF deprivation.

78.5

FLUNARIZINE PROTECTS SENSORY NEURONS FROM DEATH IN VIVO AND IN VITRO. K.M. Rich, J.P. Hollowell. Depts. of Neurosurgery and Neurobiology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Flunarizine, a diphenylpiperazine calcium channel blocking agent protects neurons from death both in vitro and in vivo. Rat E-15 DRG neurons cultured in the presence of NGF for 10 days consistently died 48 to 72 hours after NGF deprivation. Flunarizine (30-40 µM) added to the culture media at the time of NGF deprivation protected the neurons from death both morphologically and biochemically as revealed by phase contrast microscopy, scanning electron microscopy, and [355] methionine protein incorporation assay. In vivo experiments demonstrated the protective effects of flunarizine on DRG neurons in neonatal rats after sciatic axotomy. Newborn rats (PND-1) were injected subcutaneously with flunarizine (25 mg/kg) every 12 hours. Unilateral sciatic nerve axotomy was performed under hypothermic anesthesia on PND-2, with continuation of flunarizine injections. On PND-3, 24 hours after nerve injury, the L4 and L5 DRG were removed bilaterally. Untreated rats experienced a 32% neuronal loss compared to only 14% neuronal loss in the flunarizine-treated group. Another group of rats was treated similarly, but with the twice daily dose of flunarizine increased to 50 mg/kg on PND-3 and continued until DRG removal on PND-8. These rats experienced a 35% loss in the untreated control group, compared to only a 10% loss in the flunarizine-protected group. The mechanism of this protection is not known. In cell culture, lidoflazine, another type IV calcium channel blocker appears similarly protective, while nimodipine, a dihydropyridine, did not demonstrate these protective effects. The effective dose range of flunarizine (30-40 µM) greatly exceeds that which is required for blockade of calcium channels (3-10 µM) and is the range at which flunarizine is known to inhibit calmodulin. However, calmidazolium, a potent calmodulin inhibitor dose not provide the protective effects of flunarizine in tissue culture. Other intracellular mechanisms, in addition to calcium channel blockade, may explain its neuronal protective effects.

78.7

INCOMING IMPULSE ACTIVITY DETERMINES NEURONAL DEATH IN THE DEVELOPING RAT SUPERIOR COLLICULUS. E. Fusco*, A. Gravina*, B. Margheritti* and L. Galli-Resta. Istituto di Neurofisiologia CNR, 56127 Pisa Italy.

In the developing rat visual system extensive cell death is observed in the retina and in the superior colliculus during the first postnatal days. It has been suggested that elimination of topographically incorrect projections and numerical matching of connecting structures result from cell death. Little is known of the mechanisms triggering this phenomenon. We have reasoned that electrical activity of incoming afferents could determine cell death in a developing brain structure. To test this hypothesis we have either blocked retinal ganglion cell impulse activity with intraocular injection of tetrodotoxin or temporarely increased the frequency of ganglion cell firing by threshold electrical stimulation in neonatal rats. Blocking retinal impulse activity caused a consistent decrease of cell death in the superior colliculus while increasing the firing frequency of incoming retinal fibers caused a significant increase of cell death. We conclude that incoming electrical activity can trigger the phenomenon of neuronal death during development.

78 4

Ciliary Neurotrophic Factor (CNTF) prevents the degeneration of motoneurons after axotomy in new-born rats.

Sendtner M., G. W. Kreutzberg and H. Thoenen, Max-Planck-Institute for Psychiatry, D-8033 Martinsried. FRG.

The developmental period of naturally occuring motoneuronal cell death in rats is followed postnatally by a period of high sensitivity to axonal injury. After transection (on postnatal day 1) of the facial nerve, which was chosen as an experimental system, 81% of the corresponding motoneurons degenerated within 1 week. Application of \$\mathcal{5}\mu g \text{up} purified CNTF in gelfoam to the lesion site rescued 76% of the corresponding motoneurons. Morphological changes, such as chromatolysis and eccentric location of the nuclei occuring in the facial motoneurons after lesion, were markedly reduced by CNTF. However, a significant increase in GFAP-immuno-reactivity detectable in astrocytes surrounding the lesioned facial motoneurons was not eliminated by CNTF administration. CNTF, which is immunohistochemically detectable in the cytoplasm of Schwann cells in peripheral nerves, is only expressed at low levels in the first postnatal week, but then CNTF mRNA and protein increase more than 30 fold to the high adult levels, as determined by Northern blot and ELISA. As soon as these high levels of CNTF are reached, axonal lesion no longer results in neuronal degeneration. Thus, in adult rats endogenous CNTF is released by nerve lesion from Schwann cells and protects motoneurons from degeneration, whereas in new-born rats the endogenous levels of CNTF are too low to protect the axotomized neurons.

78.6

ALTERED CYTOSOLIC FREE CALCIUM, ATP AND CELL VIABILITY WITH REDUCED OXYGEN AND GLUCOSE AVAILABILITY IN PCI2 CELLS. Gary Gibson and Lourdes Toral-Barza. Cornell University Medical College at Burke Rehabilitation Center. White Plains, NY 10605

College at Burke Rehabilitation Center. White Plains, NY 10605 Previous studies in synaptosomes demonstrate that either hypoxia or hypoglycemia will elevate cytosolic free calcium $([Ca^{2+}]_i)$ and diminish ATP. To examine these interactions in a cellular system, the availabilty of oxygen and/or glucose to PC12 cells was manipulated under basal conditions and after stimulation with K^+ . With potassium depolarization, basal $[Ca^{2+}]_i$ (92 \pm 3 nM) rapidly peaked (587 \pm 38 nM) and then declined to a new plateau (262 \pm 4 nM). Decreasing oxygen availability with KCN or removing glucose from the media did not significantly alter $[Ca^{2+}]_i$. However, reducing the availability of both glucose and oxygen elevated $[Ca^{2+}]_i$ basal values (310 \pm 6 nM), the peak after K^+ (848 \pm 55 nM) and the plateau level after K^+ (724 \pm 4 1 nM). Although reduced oxygen availability diminished ATP by only 14% and a lack of glucose was without effect on ATP, the combined treatment with or without K^+ reduced ATP by 94% within 5 minutes. Decreased oxygen availability diminished viability only 3% and lack of glucose was without effect, whereas reduced availability of glucose and oxygen diminished viability 10% within the 5 minutes treatment period. These studies demonstrate that $[Ca^{2+}]_i$ in these cultured cells is less sensitive to hypoxia and hypoglycemia than in isolated nerve endings. However, even within short time intervals a lack of glucose and oxygen can alter cell viability, perhaps through altered $[Ca^{2+}]_i$ and ATP.

78.8

CORTICOSTERONE ENHANCES KAINIC ACID-INDUCED CALCIUM MOBILIZATION IN CULTURED HIPPOCAMPAL NEURONS. E.M. Elliott, I.J. Chang * R.M. Sapolsky. Dept. Biol. Sci., Stanford Univ., Stanford, CA 94305

Corticosterone (CORT), the rat adrenal steroid secreted during stress, increases hippocampal vulnerability to excitotoxins, metabolic poisons, and hypoxia-ischemia. Energy supplementation and NMTDA receptor blockers prevent this CORT effect. As calcium (Ca) regulation is energy dependent and a large Ca influx accompanies NMDA receptor activation, we investigated whether CORT exacerbates the mobilization of Ca induced by the excitotoxin Kainic Acid (KA). Primary cultures of fetal rat hippocampal neurons and glia were treated with 1 uM CORT for 24 hours. Following incubation in 6 uM fluo-3 AM (fluorescent Ca indicator), each neuron was exposed to 100 uM KA for 300 seconds.

CORT caused a 7-fold increase in the magnitude of the Ca response to KA and a 2-fold increase in recovery time. Raising the glucose concentration from 5 to 30 mM decreased the magnitude of the CORT effect by 70%. CORT decreases hippocampal neuronal glucose transport by 30%; decreasing glucose concentration 30% in control neurons (from 5.5 to 3.9 mM) mimicked the CORT effect on [Ca]. Thus, CORT increases the cytosolic free [Ca] following KA exposure in hippocampal neurons. This may be due to CORT's effects on neuronal neuronal vulnerability and toxicity evident following CORT exposure.

THE PROTEIN SYNTHESIS INHIBITOR, ANISOMYCIN, REDUCES NEURONAL DEATH IN YOUNG ADULT RATS. L. López-Mascaraque and J.L.Price. Dept. Anat. & Neurobiol., Washington Univ., St. Louis, MO 63110.

Previous studies have shown that inhibition of protein synthesis can delay or prevent NGF-dependent neuronal death (Martin et al., <u>I.Cell Biol.</u>, 106.829, 1988). In this study, we tested whether a similar phenomenon occurs in non-NGF-dependent system, using layer lla of the rat piriform cortex as a model. After the removal of olfactory bulb in the rat this layer undergoes consistent and very rapid transneuronal cell death (Heimer & Kalil, <u>I.Comp.Neurol.</u>, 178:559, 1978).

Sprague-Dawley rats (50-100 g) were anesthetized with halothane and the olfactory bulb was removed. Three to six subcutaneous injections of anisomycin (100 mg/k) were given every two hours, beginning 15 to 30 minutes prior to the surgery. During a 24 h postoperative survival period, the body temperature was maintained at 35.5°-37.5°C. Brain tissue was stained with thionin and the De Olmos cupric-silver method for degenerating neurons. A control group did not receive anisomycin.

In the control group, many degenerating picnotic and/or argyrophilic cells were found in layer lla of the piriform cortex. The group of rats with 6 anisomycin injections showed almost no neuronal death, but the mortality of the animals was very high. Most rats with lower numbers of anisomycin injections survived. In these rats, the number of degenerating cells in layer lla of the piriform cortex, was significantly lower than in the control animals.

These results implicate protein synthesis in mechanisms of neuronal death in adult rats.

78.11

CHARACTERIZATION OF A PROTEIN THAT APPEARS IN THE NERVOUS SYSTEM OF THE MOTH MANDUCA SEXTA COINCIDENT WITH NEURONAL DEATH. S.E.Fahrbach, M.E.Montemayor, C.S.Giometti*, and E. J. Roy. Neurosci. Program, Univ. Illinois, Champaign, IL 61820; Bio. & Med. Res. Div., Argonne National Laboratory. The 3 unfused abdominal ganglia of the moth Manduca

The 3 unfused abdominal ganglia of the moth Manduca sexta provide an enriched preparation for the study of neuronal death, as half of their nerve cells die shortly after adult ecdysis. Continued synthesis of RNA and protein is needed to mediate this postmetamorphic cell death, as treatment with cycloheximide and actinomycin D promotes neuronal survival (Fahrbach & Truman, 1988).

Two-dimensional gel electrophoresis followed by silver staining was used to discover potential neuronal death-related proteins in the moth. When protein patterns of ganglia taken prior to adult ecdysis (at a time when no neuronal death is occurring) were compared with protein patterns of 1-day old adults, an acidic protein of approximately 40,000 M.W. was detected in all samples from moths undergoing neuronal death. Identification of this protein and studies of its cellular distribution should yield insight into whether its expression is related to the functioning of neurons fated to die or to the continued existence of the survivors.

78.13

TESTOSTERONE FAILS TO REDUCE AXOTOMY-INDUCED NEURONAL CELL LOSS IN PREWEANING RATS. W.H.A. Yu and C.G. Cao*. Dept. of Cell Biol. & Anat.Sci., CUNY Med. Sch., New York, NY 10031. Motoneuron loss from axotomy in adult rats has been shown to correlate inversely with the level of testosterone (T) in circulation (Yu, W.H.A., Exp. Neurol. 102:230, 1988; J. Neurosci. 9:3908, 1989). The primary site of T action for enhancing neuronal survival appears to reside at the muscles. To further explore this view, axotomy was done in rats 10 days of age when androgen receptors were already present in muscles (Tremblay et al., Steroids, 29:185, 1977) but presumably not yet developed in motoneurons. Following unilateral transection of the facial nerve, two 5 mm-long Silastic capsules filled with T or saline were implanted subcutaneously. Neuronal cell number in the facial motor nucleus was counted in serial Paraplast-embedded sections stained with cresyl violet. Results indicate that cell loss was rapid and severe without gender difference or attenuation by T. Two weeks after axotomy, the cell number in the axotomized nucleus was reduced nearly in half. By 4 and 9 weeks after axotomy, less than 50% neuronal cell population remained. Failure of T to reduce cell loss could be due to the absence of androgen receptors in the facial motoneurons and their target muscles at young age. Alternatively, motoneurons of immature rats may be vulnerable to target deprivation, whereby muscle-derived trophic substances stimulated by T could not be brought to bear on motoneurons in a timely manner to prevent cell death.

A PUTATIVE CELL DEATH MRNA IN THE RAT CENTRAL NERVOUS SYSTEM: CONSTITUTIVE AND DEVELOPMENTAL EXPRESSION.

G.A. Garden. M. Bothwell and E. W Rubel Depts. of Physiology & Biophysics and Otolaryngology, Univ. of Washington, Seattle, WA 98195
Testosterone repressed prostate message - 2 (TRPM-2) encodes clusterin, a secretory glycoprotein. Expression of this message is induced in systems

Testosterone repressed prostate message - 2 (TRPM-2) encodes clusterin a secretory glycoprotein. Expression of this message is induced in systems of tissue regression and programmed cell death. In order to begin exploring the relationship of TRPM-2 regulation to programmed cell death in the nervous system, we examined the expression of TRPM-2 using in situl hybridization in E15, P8 and adult rat central nervous system.

TRPM-2 is expressed widely throughout the rat CNS. At all three ages, the highest level of expression was found in the choroid plexus and ependyma. In developing neural tissue, expression correlated with the gradient of differentiation; TRPM-2 is not detectable in the proliferative zone of the E15 animals, but levels of expression increase as cells migrate from the ventricular zone. In the adult, TRPM-2 is expressed throughout the CNS and certain distinct neuronal populations show enhanced expression. Neuronal populations known to be undergoing peak levels of

Neuronal populations known to be undergoing peak levels of developmental neuronal death, motor neurons in the ventral horn of the spinal cord at E15 and cortical subplate neurons of P8 animals, were examined. Moderate to high levels of TRPM-2 expression are found in these two neuronal populations. Since these are also the most differentiated neurons in their respective regions, we cannot yet distinguish whether TRPM-2 expression is related to neuronal death or advanced differentiation.

IHPM-2 expression is related to neuronal death or advanced differentiation. We conclude that TRPM-2 is constitutively expressed in CNS tissue at these three stages. This mRNA is localized to stable adult neuronal populations as well as neuronal populations undergoing developmental cell death. It is therefore unlikely that induction of TRPM-2 in rat CNS is exclusively related to neuronal cell death. (Support: Hartford Foundation Fellowship and N.I.H. grants DC00395 and NS43323)

IDENTIFICATION OF DYING NEURONS WITH ALZ-50: EFFECTS OF INFRAORBITAL TRANSECTION ON THE TRIGEMINAL PRINCIPAL SENSORY NUCLEUS (PSN). M.W. Miller and W.M. Al-Ghoul. Dept. Anatomy, Univ. Med. Dent. N.J.- Sch. Osteopathic Med. and R.W. Johnson Med. Sch., Piscataway, NJ 08854.

During normal development, many neurons in the rat PSN

During normal development, many neurons in the rat PSN die in the period from 2 days before to 5 days after birth. We examined the expression of Alz-50 in the developing and mature PSN using two sets of subjects: (1) normal neonates and 30-day-old rats and (2) rats in which the right infraorbital nerves were transected on the day of birth or on postnatal day 30. Few immunoreactive neurons were present in the PSN of neonatal rats, but none were evident in 30-day-old rats. Three days after a neonatal lesion, a few immunoreactive neurons were scattered in sections of the left (unaffected) PSN and 5-10-fold more labeled cells were detected in the ventral portion of the right PSN (a termination site of the infraorbital nerve). Ten days after birth, no Alz-50-positive neurons were evident in the right or left PSN, but the number of Niss1-stained neurons in the right PSN was lower. Three and 10 days after transection of the right infraorbital nerves of 30-day-old pups, there were no Alz-50-immunoreactive neurons, nor was there a change in the number of neurons in the PSN. Thus, Alz-50 appears to label dying neurons when the degeneration occurs during the period of naturally occurring neuronal death. Funded by DE 07734 and AA 06916.

CLONAL AND POLYCLONAL ARCHITECTURE OF THE CHIMERIC MOUSE RETINA. <u>Dan Goldowitz</u> and <u>Robert W. Williams</u>. University of Tennessee, School of Medicine, Memphis, TN 38163

University of Tennessee, School of Medicine, Memphis, TN 38163
Chimeric mice were made by combining Mus musculus and Muscaroli embryos. At maturity, retinas were processed to identify retinal cell genotypes using species-specific DNA probes (Rossant et al. '83). Using these in situ probes we find that all retinal cell types are labeled in a perfectly complementary pattern in alternate 4-5 µm sections. The chimeric retina is composed of large and small blocks of cells called cohorts. Borders between cohorts are remarkably sharp. There are usually 10 to 50 cohorts in a cross section. Some are clones but many appear to be collections of clones (polyclones). The chimerism ratio in retinas of the five cases is close to that in ventral diencephalon (Goldowitz '89), suggesting that these structures arise from a common progenitor population. Differences in the size and position of cohorts in different parts of the retina do not appear to be systematic; this variation may reflect early mixing of the two sets of stem cells.

The majority of cohorts span all three layers in well-defined ontogenetic units. This pattern is consistent with the idea that many stem cells are pluripotent. However, the particular cellular

ontogenetic units. This pattern is consistent with the idea that many stem cells are pluripotent. However, the particular cellular composition of cohorts can differ markedly and a few cohorts are confined to a single layer. This raises the possibility that there are a variety of stem cell types in embryonic retina. An analysis of serial sections demonstrates that cohorts can be skewed across the layers of the retina at surprising angles. As a result, functional units in the mouse retina, which are oriented straight across the layers, often combine cells from both species.

6-HYDROXYDOPAMINE AND PROLIFERATION IN GOLDFISH RETINA. J.E. Braisted & P.A. Raymond. Dept. Anat. & Cell Biol., Univ. Mich., Ann Arbor, MI

Negishi, et.al [Neurosci.Res.Suppl.,1988, 8:S43] reported that dopaminergic interplexiform cells (DAergic reported that dopaminergic interplexiform cells (DAergic IPCs) in goldfish retina can be permanently destroyed by intraocular injection of 6-hydroxydopamine (6OHDA), estimated intraocular concentration .023µg/µl. However, after a higher dose of 6OHDA (.23µg/µl), DAergic IPCs are regenerated after 2 mons. One hypothesis to explain this result is that non-specific damage to the retina at high dosages triggers proliferation of rod precursors, high dosages triggers printeration of rod precursors, which we have previously shown to be the source of regenerated neurons in ouabain-treated retinas. To test this hypothesis, we injected 60HDA intraocularly (.14-.29 μ g/ μ I) and assessed loss of cells other than DAergic IPCs using various antibodies. Results thus far have not demonstrated reappearance of DAergic IPCs, and there was no evidence that other neurons were lost. To determine whether proliferation was stimulated, we injected bromodeoxyuridine (BrdU) at 6-23d after 60HDA, and we found no increase in BrdU-labeled cells. In further experiments we will increase the dose of 60HDA and inject BrdU to look for double-labeled, regenerated DAergic IPCs.

CLONAL CELLS FROM EMBRYONIC RETINAL CELL LINES EXPRESS QUALITATIVE ELECTROPHYSIOLOGICAL DIFFERENCES. D. Lenzi, K. Radke (1) and M. Wilson. Depts. of Zoology and Avian Sciences (1), University of California, Davis CA 95616.

We have established immortal cell lines from the embryonic retina of the quail

by infecting cells with the avian retrovirus MH2 PA200 (RAV-1 pseudotype), which carries the mil oncogene. We have shown previously (Lenzi et al, 1988 Soc. Neurosci. Abstr. 14:147.13) that putative clones derived by limiting dilution are heterogeneous in their electrophysiological phenotype. We now show that at least two of these populations are true clones, and we have identified some of their membrane currents.

Viral integration site was used to assess clonality of cell populations. Genomic DNA was digested with Hind III and Southern blots were probed with a v-mil fragment expected to hybridize with one band per viral integration site. Each of eight populations tested revealed three to seven v-mil-specific bands. We therefore repeated Southern blot analysis on three subclones of each of two parent populations. For each subclone and its parent line we found the same pattern of probe hybridization with restriction fragments. We conclude that both parent lines are truly clonal, and each cell within a line contains several integrated proviruses.

We have used whole-cell patch-clamp to examine in detail the phenotype of 85 cells within one subclone. Inward rectifier potassium current was found in 97% of cells. This current was blocked by 5mM external cesium, was abolished in the absence of external potassium and was fully activated in less than 10msec. A noninactivating delayed-rectifier-like current, blocked by 25mM external TEA, was expressed in 41% of the cells. Sodium current, blocked by 300nM TTX, was seen in 18% of the cells. Four percent of cells showed non-inactivating inward currents that were blocked by 3mM cobalt, and were probably carried by calcium ions.

These data show that clonal cells can express distinct sets of channel proteins.

REGULATION OF CELL NUMBER IN THE FROG RETINA. I. ABLATION STUDIES. Richard Wetts, Robert F. Quon, and Scott E. Fraser. Dept of Physiology & Biophysics and the Developmental Biology Center, Univ Calif, Irvine, 92717.

To fully understand the mechanisms that underlie the formation of the diverse cell types in the CNS, it is necessary to also understand the regulation of their numbers. Four possible mechanisms are: 1) extrinsic factors (ie growth factors), 2) intrinsic factors (ie counting divisions), 3) positional information, and 4) total population size. The latter two appear able to regulate some non-neuronal populations after experimentally removing a portion of the tissue. To determine whether experimentally removing a portion of the tissue. To determine whether either of these two factors are involved in regulating cell numbers in the *Xenopus* retina, we examined total size or clonal numbers following

removal of more than half of the retina at St 30-32.

Individual optic cup cells were labeled with a lineage tracer (rhodamine dextran) at the time of the ablation. After 2 days (St 43), each precursor had formed a clone of labeled descendants in the experimental (tissue removed) and the operated-control (no tissue removed) retinas

(tissue removed) and the operated-control (no issue removed) retinas. These clones showed no significant difference in size (12.1 cells ± 2.4 vs 10.8 ± 1.8, respectively), suggesting that no regulation had occurred. Does the ablation affect the ciliary margin cells (which proliferate at the front of the eye throughout life)? As the animals grew (2-48 d after the ablation), the size difference between the experimental and the contralateral (un-operated control) eyes increased, suggesting that the experimental eye did not compensate for the ablated cells but instead grew 10% slower than the control eye. Thus, the ciliary margin, like the optic cup, does not use size or position to regulate cell numbers, implying that they use either extrinsic or intrinsic information.

ROD PRECURSORS DO NOT EXPRESS OPSIN. Jennifer K. Knight and Pamela A. Raymond Neuroscience Program and Department of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109.

Rod photoreceptors are generated continuously by dividing rod recursor cells located in the outer nuclear layer of the mature retina. In this study we asked when young rods commit to the rod pathway of differentiation. The possibilities are: rod precursors could be committed to the rod fate while still in mitosis, at terminal mitosis but before differentiation, or the young rods could commit during differentiation.

Goldfish were injected intraocularly with the thymidine analogue bromodeoxyuridine (BrdU) and sacrificed from 4 hours up to 1 month after injection. Cells were visualized with immunofluorescent microscopy using two antibodies, one against opsin (rho 4D2) and the other against BrdU. Our assay was to look for cells double labelled

If mitotic rod precursor cells are committed, we would expect to find double-labelled cells within a few hours after BrdU injection. We found that between 4 hours and 3 days, rho 4D2 cells are not double found that between 4 hours and 3 days, tho 4D2 cells are not double labelled; the first double labelled cells appear at 4 days after BrdU injection. The number of double labelled cells peaks at 10 days, and then falls off, disappearing completely at 1 month. These results support previous work in our laboratory and also work by Watanabe and Raff (Neuron 4: 461, 1990). We suggest that rod precursor cells are multipotent stem cells not committed to the rod cell fate. This work supported by NIH grants T32EY07022 and RO1EY04318.

CELL LINEAGE IN THE CEREBRAL CORTEX STUDIED WITH RETROVIRAL VECTORS. E.A. Grove, J. Read* and J. Price, Lab. of Embryogenesis, N.I.M.R., London NW7 1AA, U.K.

Lineage relationships in the cerebral cortex have been studied using retroviral vectors, such as BAG, to mark embryonic progenitor cells. BAG inserts the E.coli β galactosidase (lac-Z) gene into the genome of infected cells whose progeny can then be identified histochemically. types of progenitor cells are revealed by the composition of clones in postnatal animals. One generates only astrocytes; the second both neurons and glia (Price & Thurlow, Dev. 104:473, 1988). Current studies address two issues: (1) Labelled cells have been classified only by light microscopy. EM and cell type-specific markers can determine the variety of neuronal subtypes present in single clones, and characterize the glial cells that appear in mixed clones.

(2) Features of the BAG vector could lead to an underestimate of clonal variety. Because the endogenous retroviral promoter in BAG controls expression, a sub-population of infected cells may not express the gene, as is the case in embryonic stem cells. In another vector, PIRV (Beddington $\underline{et\ al.}$, Dev. 106:37, 1989), lac-Z expression is driven by the rat β promoter. Preliminary studies indicate that labelling of clones in cortices infected with high titers of PIRV is quantitatively and qualitatively similar to that seen in BAGinfected brains. It thus appears unlikely that previous analysis of cortical cell lineage was compromised by a selective failure of some cells to express the marker enzyme.

GRANULE CELL NEUROGENESIS IN VITRO W.-Q. Gao and M.E. Hatten. Dept. of Pathology, Center for Neurobiology and Behavior, Columbia Univ, College of Physicians and Surgeons, New York, NY 10032

Previous studies on neurogenesis in developing brain have assumed that neuronal proliferation is controlled by a chronological sequence of cell divisions, sometimes termed a "clock". The cerebellar granule cell presents an ideal system to examine neurogenesis, because the precursor neurons can be purified in large numbers at early postnatal periods, and cultured in vitro. When cultured in uncoated plates at high density in serum-supplemented medium, conditions where the cells reaggregate, granule cell DNA synthesis, measured by ³H-thymidine and BrdU incorporation, continues for at least 10 By BrdU immunocytochemistry, the labeling index was 30-50% in medium supplemented with serum. In contrast, when neurons were prevented from interacting homotypically, by dispersing them on a polylysine substrate, they ceased DNA synthesis within 24-72h. Similar results were seen with granule cells harvested from the mutant mouse weaver, an animal that suffers a failure of glial-guided migration. DNA synthesis was also stimulated by bFGF, EGF, and IGF-1 (5-20ng/ml), but not by NGF, PDGF and insulin (5-100ng/ml). To test whether the neuronal proliferation induced by homotypic neuron-neuron interactions can be overrided by heterotypic interaction with astroglia, we added purified astroglial cells to dividing granule cell precursors. In co-culture with glia, neuronal ³H-thymidine incorporation dropped rapidly and neuronal cell division was arrested dramatically, as measured by BrdU labeling.

These results suggest that cell-cell interactions play a regulatory role in neuronal proliferation and that the weaver gene does not perturb granule cell neurogenesis. Supported by the Pew Memorial Trust (MEH) and NS 15429 (MEH).

PURKINJE CELL LINEAGE MAP IS CONGRUENT TO THE ANTIGENIC MAP OF ZEBRIN II IN THE MOUSE CEREBELLUM. K. Herrup, N. Leclerc, D. Drinkwater and R.B. Hawkes. Devel. Neurobiol., E.K. Shriver Ctr, Waltham, MA & U. Calgary, Alberta, Canada.

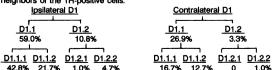

A monoclonal antibody against Zebrin II (ZII) defines a series of parasagittal compartments in cerebellar cortex. ZII is expressed by a subset of Purkinje cells distributed in 7 parasagittal bands in each hemicerebellum. This pattern is particularly evident in the vermis, and the phenotype of positive and negative Purkinje cell has proven to be resistant to a variety of experimental manipulations. This suggests a cell autonomous nature to the staining pattern and led us to ask whether the Zebrin phenotype had a relationship to the lineages of the constituent Purkinje cells. Aggregation chimeras were made between two embryos that differed in activity levels of the enzyme B-glucuronidase. The cerebellar cortices of these animals were stained for both Zebrin II and B-glucuronidase. 3-D reconstruction of the Purkinje cells in lobule III reveals a high level of correlation between the lineage map and the ZII antigenic zonation pattern. These results are consistent with an early, lineage based establishment of the Zebrin staining phenotype.

QUANTITATIVE CLONAL ANALYSIS OF TYROSINE HYDROXYLASE IM-MUNOREACTIVE CELLS IN THE HYPOTHALAMUS-INFUNDIBULAR AREA OF XENOPUS TADPOLES. S. Huang and S.A. Moody. Department of Anatomy and Cell Biology, University of Virginia, Charlottesville, VA 22908
At stages 41-44 tyrosine hydroxylase immunoreactive cells form a discrete

At stages 41-44 (your learning land) in the Xenous hypothalamus-infundibular area. This small number of cells allows a quantitative clonal analysis of a neurotransmitter-related phenotype. A lineage dye was injected at the 16- or 32-cell stage into certain blastomeres that are known to give rise to cells in ventral forebrain. $14\mu m$ frozen sections were immunoreacted with an antibody to tyrosine hydroxylase (TH). TH-positive cells were visualized by FITC- or AMCAconjugated secondary antibody. TH cells descend exclusively from bilateral D1.1 and D1.2 at the 16-cell stage and their daughters (see Diagram). Other blastomeres do not produce TH cells, although some of them give rise to neighbors of the TH-positive cells.

42.8% 21.7% 1.0% 4.7% 16.7% 12.7% 0 1.0%

The number of TH cells produced by a given blastomere varies greatly between embryos, e.g., ipsilateral D1.1 may contribute between 10-90% of the TH cell population. Futhermore, the clones from a particular blastomere in different embryos occupied different positions within the TH cell clusters. These results indicate that neurochemically specified phenotype is not associated with one progenitor. Supported by NINDS NS23158.

CORRELATION BETWEEN MAPS OF SOMATOSENSORY RECEPTIVE FIELD AND PURKINJE CELL LINEAGE IN THE CEREBELLUM OF MOUSE CHIMERAS. H. Shojaeian Zanjani, J. Bower and K. Herrup. Devel. Neurobiology, E.K. Shriver Center, Waltham, MA and Div. Biology, Caltech, Pasadena, CA Studies of cerebellar cortex reveal a consistent pattern that resembles a fractured mosaic. The pattern is repeated in many modalities as shown by a variety of anatomical, physiological and biochemical studies. The overlap of these systems led us to ask whether this seemingly fundamental pattern was also revealed in the spatial organization of the constituent Purkinje cell lineages.

pattern was also revealed in the spatial organization of the constituent Purkinje cell lineages.

Somatosensory projections to cerebellar cortex were used as a model system. Aggregation chimeras were made between two inbred mouse strains that differed in activity levels for the enzyme ß-glucuronidase. Multiple unit activity was recorded in the granule cell layer of Crus II (CII) of the chimera using light touch stimulation of the body surface. In this measure a recognitive field man of CII was of the chimera using light touch stimulation of the body surface. In this manner a receptive field map of CII was made. Subsequent B-glucuronidase histochemistry on a set of serial 10µm sections through this region was then used to reveal the Purkinje cell lineage map. The distribution of the Purkinje cells lineages across the crown of CII was reconstructed. The results from 3 chimeras demonstrate that, in Crus II, there is a near perfect correspondence between transitions in the Purkinje cell lineage map and in the physiologically defined receptive field map.

Supported by NIH (NS18381) and the March of Dimes (#1-1175).

DEVELOPMENT OF PRIMARY AND SECONDARY TYROSINE HYDROXYLASE POSITIVE CELLS IN XENOPUS. S.A. Moody and S. Huang. Department Anatomy & Cell Biology, University of Virginia, Charlottesville, VA 22908.

Using an antibody to tyrosine hydroxylase (TH), a rate-limiting enzyme for catecholamine synthesis, we investigated the development of TH-positive cells in Xenopus embryos. Two categories of cells, primary and secondary, were identified in earlier and later embryos, respectively. At stage 10 primary TH-positive cells were found in epidermis. By stage 20 they were detected in somitic muscle, the gut wall, notochord and neural crest. The staining was located in both the nucleus and cytoplasm of these cells. The distribution of primary TH-positive cells in the CNS was widespread. TH-positive cells were present in the neural plate as early as stage 17. At stage 20 most of the THositive cells were confined to the dorsal part of the spinal cord, including Rohon-Beard and commissural neurons, and the ventro-lateral part of the hindbrain, most of which were commissural neurons. TH-positive cells were first detected in the forebrain at stage 25. Through the tailbud stages more and more CNS neurons became TH-positive. These included most of the sensory neurons, motoneurons and interneurons that comprise the primary nervous system. Non-neural TH-staining began to decrease by stage 34, and primary TH-staining in the CNS began to decrease after stage 37; most primary cells were TH-negative by stage 48. The function of this transient TH-

activity in the primary cells is unknown.

At stage 40 secondary TH-positive neurons, which were generally more darkly stained than the primary ones, began to appear. The secondary neurons were found only in the hypothalamus, retina, and KA neurons of the spinal cord, and are believed to be the dopaminergic neurons identified in the adult. As in the adult, TH-staining in these cells was exclusively cytoplasmic. Supported by NINDS NS23158

GRANULE NEURONS REGULATE ASTROGLIAL DIFFERENTIATION VIA TGFB1. S.

Vidan, D. Cooper, R. Silverman, P. Scala and M.E. Hatten.
Dept. Pathology and Ctr. for Neurobiology and Behavior,
Surgeons of Collumbia University, New York, NY 10032
Previous studies have shown that neurons regulate the differentiation of

Previous studies have shown that neurons regulate the differentiation of astroglial cells by a membrane-mediated mechanism (Hatten, <u>J. Cell. Biol</u> 104:1353, 1987), and that neuron-glia contacts alter the dose reponse of glial cells to bFGF (Hatten et al <u>Devl. Biol</u>,125:280,1988). To test the role of growth factors in glial proliferation and differentiation, we purified astroglial from early postnatal mouse cerebellum and cultured them in the presence of EGF, PDGF, bFGF, insulin, IGF-1 and TGFB1 (1-200g/ml). Among these, EGF, PDGF and bFGF were glial mitogens (1-20ng/ml); none of these factors induced astroglial process extension. In the presence of a combination of TGFB1 and either EGF, PDGF or bFGF (10ng/ml), however, glial DNA synthesis arrested and the glial extended long processes, generating glial forms which resembled forms seen in co-culture with neurons and *in vivo*. By Northern blot analysis, differentiated glial cells expressed higher levels of the glial filament protein. To determine whether the cells express TGFB1, we carried out Western and Northern blot analysis. These experiments indicate that TGFB1 RNA and protein are expressed in co-cultures of neurons and indicate that TGF β_1 RNA and protein are expressed in co-cultures of neurons and astroglia. We are presently using *in situ* hybridization to determine which cell, the neuron or the glial cell, provides TGF β_1 . To test the function of TGF β_1 in co-cultures of neurons and glia, conditions where extensive glial differentiation is usually seen, we added antibodies to TGFB1 and visualized glial form with immunocytochemical localization of antibodies against the glial filament protein. TGFB1 antibodies blocked glial process

extension in a cose-dependent manner.

These studies suggest that neuronal regulation of glial differentiation involves alterations in the levels of TGFB₁, a step which decreases the responsiveness of glial cells to mitogens and directs the glial cell toward a differentiation pathway. Supported by NIH grant 21907 (MEH).

OLIGODENDROCYTE MIGRATION IN VITRO IS DEPENDENT UPON TARGET-STIMULATED DIFFERENTIATION OF SPINAL CORD NEURONS. W.L. Muhlach and H.B. Lim*. Dept. of Zoology, Southern Illinois University, Carbondale, IL 62901 Previous culture work has demonstrated that amphibian

hindlimb mesenchyme stimulates, among other things, neurite outgrowth and cholinergic maturation of spinal cord motoneurons in a stage-specific fashion (Int. J. Dev. Neurosci. 7:383, 1989). Non-neuronal cells are often found associated with the nerve fibers in these cord cultures. Immunohistochemical preparations of spinal cord cultures (R. catesbeiana tadpole) demonstrated that cord cultures (<u>R. catesbelana</u> tadpole) demonstrated that these cells were oligodendrocytes (galactocerebroside positive). The association of the oligodendroglia with nerve fibers was dependent upon the developmental state of the spinal cord tissue. It is important to note that target tissue effects on the development of spinal cord neurons in culture were required before the neuroglia would associate with them. The neuroglia were seldom would associate with them. The neurogia were seldom observed with spinal cord explants from young animals, but were often observed associated with explants from older tadpoles. However, co-culture of young spinal cord with target tissue resulted in oligodendrocyte migration along nerve fibers. In addition to effects upon neurite outgrowth, neurite fasciculation, and cholinergic maturation, the target tissue also triggers a change in the interaction between oligodendrocytes and neurons which may be required before myelination proceeds.

A MONOCLONAL ANTIBODY THAT LABELS DEVELOPING SCHWANN CELLS AND A SUBSET OF MIGRATING NEURAL CREST CELLS Anita Bhattacharvya, Eric Frank¹, Robert Brackenbury*, and Nancy Ratner. Dept of Anat & Cell Biol, Univ of Cinti Col Med, Cincinnati, OH 45267, and ¹Dept of Neurobiol, Anat & Cell Sci, Univ of Pitt Sch of Med, Pittsburgh, PA 15261. Specific immunocytochemical markers are needed to study the

migration and differentiation of Schwann cell precursors and their magnitude and differentiation of Schwann cell pictures in the early interactions with extending axons. We have generated a monoclonal antibody, termed 1E8, that stains Schwann cells in mature chicken peripheral nerve. 1E8 reacts in Western blots with a series of proteins migrating at 23-30kD. When serial cryostat sections of chicken embryos are stained with 1E8, immunoreactivity is first detected at stage 19 in isolated cells located between the neural tube and somites. Double labelling with HNK-1 establishes that the 1E8 positive cells represent a small subset of migrating neural crest cells. At stage 21, a small population of cells in the ventral root expresses the antigen. Similarly, a population of cells in the dorsal root is stained at stage 23. 1E8 antigen continues to be expressed on the surface of cells associated with axons as they extend into the hindlimb. 1E8 immunoreactivity is also detected on a subset of HNK-1+ cells near the dorsal aortic arteries, presumed precursors of enteric glial cells, but mature enteric glia are not stained. 1E8 does not stain neurons in the CNS or PNS, muscle, or satellite cells.

Expression of the 1E8 antigen on a subset of migrating crest cells and on cells associated with extending axons suggests that the 1E8 antigen is a specific marker for early Schwann cell precursors. Supported by NIH grants NS27227 and NS24373.

GLIAL-NEURONAL INTERACTIONS IN RAT OLFACTORY BULB GLOMERULUS DEVELOPMENT. Mary S. Bailey, Michael T. GLOMERULUS DEVELOPMENT. Mary S. Bailey, Michael T. Shipley, Dept. of Anatomy and Cell Biology, Univ. of Cincinnati, Cincinnati, OH 45267

Recent studies suggest that astrocytes provide a morphological and/or molecular substrate for growth and target recognition by developing axons, and for the formation of multineuronal assemblies such as the barrel fields. We previously reported that olfactory bulb (OB) radial glia exhibit a unique branching pattern just deep to the nerve layer in early embryonic development (E16-18). At this stage primary olfactory neuron (PON) axons surround the OB with many fibers penetrating to deeper layers. The organization of terminal PON axons into glomerular-like condensations correlates with increasing axons into glomerular-like condensations correlates with increasing complexity of the radial glial plexus in the presumptive glomerular layer. We now report a transition from radial glia to astrocytes in the late embryonic and early postnatal rat OB which correlates with further maturation of glomeruli: GFAP-positive astrocytes increase with a concommittant decrease of vimentin-positive radial glia just below the nerve layer. We are directly testing whether radial glia transform into astrocytes in this layer. The appearence of atrocytes transform into astroyces in this tayer. The appearation of OMP (olfactory marker protein) stained olfactory axons marking further maturation of glomeruli. Preliminary double label experiments show a close association of new astrocytes with the presumptive glomeruli. These results support the idea that dynamic glial-neuronal interactions are results support the local that dynamic gilat-neuronal interactions are critical to the development of the OB glomerulus, and suggest that olfactory axons trigger the transformation of radial glia into astroyctes. Supported by NIDCD-DC00347.

BRAIN MACROGLIA EXHIBIT REGION-SPECIFIC REGULATION OF NEURONAL MORPHOGENESIS IN VITRO. J.Qian, M.Bull, I. Fischer* P.Levitt. Dept. of Anatomy, Med.Coll.of Penn., Phila., PA 19129 and Dept. Biochemistry, E.K. Shriver Ctr., Waltham, Ma. 02254

Neuronal morphogenesis during development appears to be influenced by both intrinsic and extrinsic factors. A neuron-glia co-culture system was used in which neurons from fetal rat spinal cord and hippocampus were grown (without direct contact) with macroglia derived from different CNS regions of perinatal rats to investigate the role that CNS glia may play in regulation of neuronal shape and neurite outgrowth. Examination of the expression of microtubule-associated protein 2 (MAP2), a dendritic marker, and the phosphorylated form of high molecular weight neurofilament protein (NF-H), an axonal marker, revealed that: 1) spinal neurons survived equally well under all co-culture conditions and, when grown with glia from spinal cord, hippocampus, cerebellum and cerebral cortex, they expressed similar patterns of MAP2 expression. NF-H-stained neurites were more extensive in spinal neuron-cerebellar glia co-cultures than other combinations; 2) hippocampal neurons survived equally well when combined with glia from hippocampus or from cerebral cortex, but did not in an environment of spinal cord or cerebellar glia. While MAP-2 expression was similar in a conditioning environment provided by hippocampal or cerebral cortex glia, NF-H neurites were more extensive with cerebral glia. These results suggest that regional specificity of neuron-glia interactions are involved in regulating both survival and neuronal morphogenesis, with axons exhibiting a greater sensitivity to the glial environment than dendrites. Supported by NIMH grant MH45507.

DIFFERENTIAL EXPRESSION OF GLIAL MARKERS IN RADIAL GLIA DURING NEUROGENESIS IN THE RAT AND OPOSSUM BRAIN. J. Pecci Savedra, A. Brusco, L.A. Gómez, I. Benítez and J. Affani. Instituto de Biología Celular and Biology Dept. Univ. of Bs

As., ARGENTINA
We have studied the expression of the glial acidic protein (GFAP) and the S-100 protein in the developing brain of in (GFAP) and the S-100 protein in the developing brain or rat and sauth american opossum (Didelphis albiventris). This study was performed in 16 and 18 days rat embryos, and in 5, 14, and 23 day old opossum pseudoembryos. The animals were perfused intracardially with 4% paraformaldehyde + 0.5% glutaraldehyde, the brains were then immersed in the same fixative solution for an additional 6 hours. Vibratome sections were processed according to the immunocytochemical PAP technique.

The ventral portion of opossum and rat developing brain-The ventral portion of opossum and rat developing brainstem and spinal cord showed a similar pattern of glial organization: radial glia is arranged in parallel cephalocaudal plates, and immature astrocytes appeared in the ventral zone following a ventro-dorsal gradient of maturation. The glial pattern described could only be revealed by the aid of anti-GFAP antibodies in the opossum, and with anti-S-100 serum in the rat embryo.

These differential expression of glial markers suggests that radial glia and immature astrocytes may have acquired new roles during evolution to adapt to the particular development of brain in each species. (work performed with grants from the CONICET, Argentina)

MOLECULAR TYPES RECOGNIZED BY MONOCLONAL
ANTIBODY AB-2, WHICH REVEALS RADIAL GLIA DURING
DEVELOPMENT. S.A. Tobet, R.C. Whorf., G.A. Schwarting & T.O.
Fox. Depts. of Biochemistry & Developmental Neurobiology, EK
Shriver Center, Waltham, MA 02254 & Program in Neuroscience,
Harvard Medical School, Boston, MA 02115.

The expression of monoclonal antibody AB-2 immunoreactivity in
radial glia of developing rat hypothalamus is age and sex-dependent
and regulated by prenatal exposure to gonadal steroids (Tobet & Fox,
PNAS 86:382, 1989). High molecular weight proteins were recognized
by AB-2 and were distributed selectively in subcellular fractions from
neonatal hypothalamus (HYP), remaining forebrain (ROB), and
brainstem regions. Immunoblots revealed 6 major protein bands: a
195kD protein in the cytosolic compartment; a 250kD doublet in
microsomal and crude mitochondrial membrane fractions; and a
220kD doublet in Triton-insoluble and membrane fractions, auggesting a cytoskeletal association. Finally, a 20kD protein was
enriched selectively in brainstem microsomal fractions. AB-2 also
recognized specific glycolipids on immunoblots following high
performance thin layer chromatography. Glycolipid blots of several
brain regions at different postnatal ages indicated sulfatide was the
major glycolipid recognized. AB-2 immunoreactivity in hypothalamic
glycolipids (sulfatide) did not correlate with the timing of AB-2
immunoreactivity in radial glia. Other lower migrating lipids were
noted only in postnatal day 2 cerebellum.

The presence of AB-2 reactive protein and lipid antigens suggests
that the epitope is a carbohydrate present on both types of antigens
in multiple cellular compartments. There were no qualitative sex
differences in the binding of AB-2 to the molecules recognized.
Hormone influences might affect individual AB-2 antigens in
particular cellular elements (i.e., radial glia) or might modify the
glycosylation of multiple AB-2 antigens in selected cell types.

80.9

IDENTIFICATION OF GLIAL AND NEURONAL CELL MARKERS IN TISSUE CULTURE. <u>D.S. Grega+</u>, <u>E. Pertile* and N. Nousek-Goebl*</u>, R&D Division, Boehringer Mannheim Corp.,and *Indiana Univ. School of Medicine, Program in Medical Neurobiology Indianapolis, IN 46250.

Cell identification is critical to the study of cell type development in the nervous system. The presence of epitopes as cells mature can be tracked using specific antibodies and immunohistochemical (IHC) localization.

We are presenting IHC data from two culture systems: we are presenting inc data from two curture systems:

1) oligodendrocyte (oligo) and 2) NGF-treated, mixed
spinal cord/dorsal root ganglia (SC/DRG) neurons, from
neonatal and fetal rat respectively. We compare anti-GalC
(galactocerebroside an accepted marker for oligodendrocytes and Schwann cells) and anti-CNPase (2',3'-cyclic nucleotide 3' phosphodiesterase associated almost exclusively with myelin-producing cells), for oligos over the first 21 days in culture. Little CNPase IHC characterication has been done. The two antibodies stain the same cell type, but differ in the extent of staining of fine processes. The binding of tetanus toxin or its C fragment (TTC) has been used as a neuronal marker. Neurons in the SC/DRG cultures were identified comparing several anti-bodies, anti-A2B5, anti-neuron specific enclase, anti-MAP2 (microtubule associated protein-2 located in the somatodendritic compartment), and the localization of recombinant TTC (rTTC) with anti-TTC. The advantages of these different purposal markers were determined these different neuronal markers were determined.

CULTURING THE GLIAL PROGENITOR CELLS OF THE NERVE FIBER LAYER OF THE OLFACTORY BULB. R. Doucette. Dept. Anat., Univ. Sask., S'toon, Sask., Canada.

Some of the glial progenitor cells (GPC) of the olfactory bulb differentiate <u>in vitro</u> into bipolar cells that contain not only GFAP, but also the 217c and RAN-1 antigenic epitopes; the latter two antigens are normally expressed only by Schwann cells. GPCs of the olfactory nerve fiber layer (NFL) also differentiate into cells expressing phenotypic features of both astrocytes and Schwann cells. The purpose of the present study was to determine whether bipolar cells were still present when the only GPCs that were cultured were those of the NFL, obtained by peeling the NFLs off the olfactory bulbs of E14-16 mouse (Swiss) embryos. Bipolar cells, some of which contained GFAP, were always present in these cultures; these same cells never expressed neurofilament proteins

making it unlikely that they were neurons. Obtaining a purified population of the GPCs of the NFL should make a significant contribution towards identifying some of the factors that control the growth of olfactory axons. (Supported by a grant from the MRC).

EVIDENCE FOR THE PRESENCE OF TWO MEMBERS OF THE THYMOSIN PEPTIDE FAMILY IN DEVELOPING RAT CEREBELLUM. <u>B. Border, S-C. Lin*</u>, <u>W.S.T. Griffin, and M. Morrison-Bogorad</u>, Depts. of Neurology and Biochemistry, University of Texas Southwestern Medical Center, Dallas, and Dept. of Pediatrics, University of Arkansas Medical School, Little Rock.

Polyclonal antisera raised in rabbits against thymosin \$\beta\$ (V416) and

thymosin \$10 (V411) carboxy-terminal synthetic peptides were utilized to demonstrate their presence in rat cerebellum. Immunoperoxidase techniques were applied to Bouin's-fixed, paraffin-embedded rat brain ranging in age from one day (P0) to 30 days (P30) postnatal. At P0, intense V416-immunoreactivity was present within radial fibers of the molecular layer as well as a plexus of fibers and cell somata in the internal granular layer, while antiserum V411 labeled only thick fibers in the molecular layer. At P6, an increased number of V416-immunolabeled cell bodies and processes were present in the white matter and the internal granular layer, in addition to labeled radial fibers; however, little V411 immunolabeling could be discerned. Immunostaining was completely abolished by P14 in V411-treated tissue. Finally, in the adult rat, a population of cell bodies and processes located in the deep white matter near the cerebellar nuclei as well as radial glial fibers in the molecular layer were immunolabeled by V416. Therefore, it appears that antisera against thymosin \$4 immunolabels a subpopulation of astrocytes or oligodendrocytes in newborn and adult cerebellum, while anti-thymosin #10 immunoreactivity becomes undetectable by P14. These findings correlate with quantification of relative levels of thymosin \$4 and \$10 mRNAs in the developing rat cerebellum as revealed by Northern blot analysis (Lin and Morrison-Bogorad, J. Mol. Neurosci., in press). Supported by NIH HD14886 (MM-B).

GLIAL CELL DIFFERENTIATION IN THE DEVELOPING RAT CEREBELLUM. J.M.Levine, F.Stincone* and Y.S.Lee, Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY, 11794

The development of glial cells in the late embryonic and early post-natal cerebellum (CBL) was studied immunohistochemically using antibodies that identify glial

These bipolar cells were distinct from the vimentin+ radial fibers present at this These bipolar cells were distinct from the vimentin+ radial fibers present at this early stage. By ED21, the numbers of the NG2+ cells had increased and they were distributed throughout the CBL. These cells, which had a multi-polar morphology, were only weakly labeled with monoclonal antibodies against GD3 ganglioside (LB1) that have been used to identify oligodendrocyte precursors. Between post-natal day(PND)1-3, a population of intensely LB1+ cells appeared in developing white matter and, over the next 2-3 days, GaIC+ oligodendrocytes developed in the white matter, although a small number of the NG2+ cells co-expressed GaIC and an oligodendrocyte-specific antigen recognized by monoclonal antibody RIP, most of the NG2+ cells within the developing CBL failed to develop into oligodendrocytes. GFAP+ astrocytes were first observed at about PND 5 within the white matter and the distal regions of each folium. As was the case with oligodendrocytes, few of the NG2+ cells expressed GFAP antigens. Rather a population of NG2+, GFAP-, GaIC-cells persisted into the adult.

NG2+ cells expressed GFAP antigens. Rather a population of NG2+, GFAP-, GalC-cells persisted into the adult.

These observations suggest that there may be 3 separate populations of glial precursor cells within the CBL; a vimentin + cell which develops into an astrocyte (Bovalenta, et al., DevBiol:102, 248, 1984), a LB1+ cell which develops into an oligodendrocyte (Reynolds and Wilkin, Development:102, 409, 1988) and the NG2+ progenitor cells which fail to develop either GFAP or GalC immunoreactivity. Although the NG2+ cells display bipotentiality in vitro, most of these cells fail to do so in vivo. These persistent NG2+ cells may represent either a third type of glial cell or an adult form of a bipotential glial progenitor cell.

MICROGLIA IN THE DEVELOPING OPOSSUM SUPERIOR COLLICULUS. L.A. Cavalcante and A.Santos-Silva*, Instituto de Biofisica C. Chagas Filho, Rio de Janeiro, RJ 21944, Brazil.

The differentiation of astrocytes in the opossum superior colliculus (SC) follows both outside-in and medio-lateral gradients (Barradas PC et al., Glia 2: 103, 1989). In order to test whether that reflects non-neural cell influence, we have mapped macrophages and microglia in the maturing SC . Lectin binding shows macrophages only in leptomeninges, SC midline and adjoining, at first, the subventricular zone and later the ependyma. The SC upper layers acquire microglia later (by 24-31 days) than deep and intermediate layers (by 17 days) and still retain a large proportion of ameboid cells as GFAP astrocytes appear (40 days). However, upper layer astroglia still retain augmented GFAP immunoreactivity as microglia change from ameboid to ramified shape. Our results show that sequences of acquisition of microglia neither predict or correlate with the differentiation of astrocytes in the SC. (Support: FAPERJ, CNPq, FINEP, CEPG/UFRJ)

Expression of a Tetrodotoxin-resistant Voltage-dependent Sodium Current in an Immortalized Hypothalamic Cell Line. <u>K.D. Phelan, V. Quinones-Jenab and H.M. Geller.</u> Dept. of Pharmacology, UMDNJ-R.W. Johnson Medical School The Graduate School, Rutgers University, Piscataway, NJ 08854.

The immortalized mouse hypothalamic cell line, V1, is a multipotential precursor cell line that gives rise to glial-like (flat, GFAP*) as well as neuronallike (round, neurofilament⁺) cells (see Quinones-Jenab et al.). The present study utilized whole-cell patch clamp recording techniques to characterize and compare the expression of voltage-gated currents in the "neuronal-like" V1 cells grown at the permissive (33°C) and non-permissive (39°C) temperatures of the immortalizing oncogene.

Sustained (non-inactivating) outward potassium currents were present in all cells cultured at either temperature. However, no inactivating outward potassium currents were observed in either condition. In addition, 45% (9/20) of the cells grown at 33°C exhibited a fast inward current with a peak amplitude that varied between 80 and 1900 pA (median = 240 pA). The proportion of cells expressing this inward current increased to 94% (30/32) after 9-16 days in culture at 39°C (50-2270 pA peak; median = 387 pA). This inward current displayed voltagedependency with an activation threshold near -60 mV and a peak current activation around -20 mV. The current was reversibly reduced by ionic substitution of extracellular sodium, but was completely resistant to bath application of tetrodotoxin (1-20 µM; n=10). This inward current has been stably

expressed by this cell line for one year in continuous culture.

This study demonstrates that the "neuronal-like" cells of the immortalized V1 hypothalamic cell line express a tetrodotoxin-resistant voltage-dependent inward sodium current. This cell line may be a useful model for characterizing the developmental expression of sodium currents during cellular differentiation in the mammalian CNS

CALCIUM CHANNELS IN INSECT MOTONEURONS DURING METAMORPHOSIS. R.B.Levine and J.H.Hayashi. Division of Neurobiology,

Univ. of Arizona, Tucson, AZ 85721.

During the metamorphosis of Manduca sexta identified thoracic leg motoneurons (MNs) persist to innervate the new adult legs. To test for possible developmental alterations in their biophysical properties, we generated primary cultures (technique adapted from Hayashi & Hildebrand, J.Neurosci., '90) and examined leg MNs that had been retrograde labelled with di-I prior to metamorphosis (Griffin & Levine,

S.N.Abs. '89). MNs also constituted a distinctive size class in the cultures.

In most experiments the cells were examined 15-24 hours after dissociation, and In most experiments the cells were examined 15-24 hours after dissociation, and so lacked extensive processes. Immediately after achieving whole-cell patch clamp configuration, depolarization of the MNs in normal saline activated large inward and outward currents. Although we have evidence for K* and Na* channels, the present analysis concentrates on putative Ca** channels. With CsCl (150mM) inside the patch pipette, and external solution containing TTX (10*M), TEA (30mM), and with Ca** replaced with Ba** (6mM), a slowly inactivating inward current was activated by depolarizing commands from -70mV in all MNs examined. This current could be blocked irreversibly with Cd*, and reversibly by Mg**, Ni** and Co⁺⁺. We conclude that the somata of the dissociated MNs contain a voltage-sensitive Ca⁺⁺ channel. From a holding potential of -20mV, a persistent minor current remained. Its activation point was more depolarized than that of the major current which, from a holding potential of -70mV, dominated the records. Thus, there may be two types of Ca^{**} channels in these neurons.

For MNs examined the day after dissociation, the level of Ca^{**} current in MNs

from pharate adults was greater than in MNs from new pupae (P0). A similar increase was noted by comparing cells dissociated from P0 animals, and tested after different numbers of days in culture. Furthermore, the current density was greater for cells grown in the presence of physiological levels of 20-hydroxyecdysone than for cells maintained in the absence of the steroid. (NS28495 & BNS 89-11174).

81.5

DISTRIBUTION OF MUSCLE PRECURSORS IN IMAGINAL DISCS OF WILD TYPE AND MUTANT DROSOPHILA. P.K. Rivlin, A. M. Schneiderman & V. Yu*. Section of Neurobiology & Behavior, Cornell University, Ithaca, NY 14853.

Our focus is on genes that control development of the thoracic motorneurons and muscles necessary for adult flight initiation in

Drosophila. One of our goals is to characterize the postembryonic development of muscles in the jump and flight motor systems. Adepithelial cells of imaginal discs are presumed to be the precursors for at least some adult muscles (Poodry & H. Schneiderman, Roux's for at least some adult muscles (Poodry & H. Schneiderman, Roux's Archiv., 166:1, 1970). We used peanut agglutinin (PNA) as a marker (Brower et al., J. Embryol. Exp. Morph., 67:137, 1982) to follow the distribution and differentiation of adepithelial cells during larval and metamorphic development. In previous screens of imaginal discs PNA has been observed to bind preferentially to the precursors of photoreceptor cells in eye discs (Fristrom & Fristrom, Dev. Biol., 92:418, 1982) and to cells presumed to be adepithelial in wing discs (Provers et al., 1982). Wa sealwast the highing returns of prevides 92:418, 1982) and to cells presumed to be adepithelial in wing discs (Brower et al., 1982). We analyzed the binding patterns of peroxidase-and fluorescein-conjugated PNA in thoracic discs from wild type and mutant flies at various developmental stages. We have confirmed that PNA binding in the wing disc is restricted to cells previously described as adepithelial (Madhavan & H. Schneiderman, Roux's Archiv., 183:269, 1977; Brower et al., 1982) and have found that PNA staining is substantially less in a homologous region of the haltere disc. The distribution of adepithelial cells in abx bx3 pbx / Df(3R)P2 haltere discs resembles that of wild type wing discs. We are extending our analysis to the electron microscopic level to resolve the subcellular location of PNA binding sites. PNA binding sites

CALCIUM CHANNELS IN INSECT CENTRAL OLFACTORY NEURONS DEVELOPING IN VITRO. J.H. Hayashi and J.G. Hildebrand. ARL Division of Neurobiology, University of Arizona, Tucson, AZ 85721.

Neurons derived from the antennal lobe (AL, the primary olfactory center in

the brain) of the moth Manduca sexta thrive in our long-term culture system as solitary cells [J. Neurosci. 10:848 (1990)]. Inward currents are evident in cells only after they have been in culture for about a week [Soc. Neurosci. Abstr. 15:1145 (1989)]. We used the patch-clamp technique and specific blockers to isolate and examine voltage-gated currents that arise in these cultured neurons

isolate and examine voltage-gated currents that arise in these cultured neurons concomitantly with their morphological development. Neurons were dissociated from ALs at stage 6 of the 18 stages of metamorphic adult development and examined after they had been allowed to develop *in vitro* for 1-3 weeks. The voltage-sensitive outward current comprised 3 separable components one that could be blocked by external TEA superfusion, a TEA-insensitive outward current blocked when the patch pipette was loaded with internal Cs⁺ ions in place of K⁺ ions, and a TEA- and Cs⁺ insensitive current that activated at place of K^+ ions, and a TEA- and Cs^+ -insensitive current that activated at about +40 mV. A fast, rapidly inactivating inward current was blocked by TTX (10⁸ M) and presumed to be the channel that underlies the action potential observed in these cells. With these Na^+ and K^+ currents blocked, we were able to observe the slowly activating inward currents in several cell types. Ba^{++} could substitute as the permeant ion, and this current was blocked irreversibly by Cd^{++} (100 μ m) and reversibly by Mg^{++} . We measured an activation potential of about -30 mV from a holding potential of -70 mV. This current inactivated with a time constant of hundreds of msec. When the holding potential was shifted to -40 mV, most of the inward current was abolished, but a residual current with an activation point of roughly -10 mV persisted. We conclude that dissociated central olfactory neurons develop Na^+ and K^+ channels and possibly two types of Ca^{++} channels in the absence of direct contact with other cells. [Supported by NS28495 & Al-23253.] contact with other cells. [Supported by NS28495 & AI-23253.]

DIFFERENTIATION OF THE CALCIUM SEQUESTRATION APPARATUS IN THE SARCOPLASMIC RETICULUM OF FROG MUSCLE

B.E. Flucher*, M. Terasaki*, J. Drazba, S.B. Andrews* and T.S. Reese. Lab.
of Neurobiology, NINDS, National Institutes of Health, Bethesda, MD 20892.

In a variety of cell types, including nerve and muscle, Ca uptake, storage and release are properties of the endoplasmic reticulum (ER). In muscle, these aspects of Ca regulation are located in specialized regions of the sarcoplasmic reticulum (SR); such regions are arranged in an orderly fashion within the sarcomere. Immunolabeling of mature frog muscle with antibodies against BIP (an ER marker protein) and against the fast Ca-ATPase resulted in similar labeling patterns, suggesting that BIP is expressed in the SR. In cultured frog myocytes that have just developed a cross-striated organization of contractile elements, anti-BIP, as well as an antibody against T-tubules (aTT), labeled in cross-striated patterns, indicating that SR and T-tubules had already become arranged in specific domains of the sarcomere. The Ca-ATPase, however, did not codistribute with the SR and T-tubules at this stage, but was restricted to a network of tubular membranes undermeath the sarcolemma. The distribution of Ca-ATPase later became cross-striated, progressing from the periphery toward Ca-ATPase later became cross-striated, progressing from the periphery toward the center of the myocyte. In mature muscle fibers where the Ca-ATPase and the center of the myocyte. In mature muscle fibers where the Ca-ATPase and BIP were co-localized in the sarcomeres, the peripheral network of Ca-ATPase-positive membranes had disappeared. These results suggest that in developing frog muscle Ca regulation resides first in a sub-sarcolemmal membrane system that possibly forms peripheral junctions with the sarcolemma, while the SR proper is still undifferentiated. The differentiation of the Ca sequestration apparatus in the sarcomeres seems to occur after the structural organization of SR is completed and ultimately supplants the peripheral Ca regulation system. The presence of BIP in undifferentiated as well as functionally differentiated SR supports the hypothesis that the SR is a derivative of the endoplasmic reticulum.

81.6

MUSCLE PHENOTYPE IS INDEPENDENT OF MOTONEURON GENOTYPE IN

Markers and the acute <u>shi</u> phenotype (paralysis at 30C) indicated <u>shi</u> ventral ganglion tissue. Serial sectioning (37 flies) permitted a census of DLM and DVM fibers, classified as wild type (±) or <u>shi</u> phenotype. Both muscle phenotypes occurred in 25 mosaics; in two of these, DLM/DVM on each side was all ± or all <u>shi</u>, and thus did not reflect the genetype of the controllers and MM MV. DLM,JUMM on each side was all \pm or all $\pm hi$, and thus did not reflect the genotype of the contralateral DLM MN. Both \pm and $\pm hi$ phenotypes occurred on a single side in 23 mosaics (28 sides), as well as within the 6 DLM fibers of 21 sides. Again, there was no correlation between DLM fiber phenotype and the imputed genotype of its MN. Thus the HP induced $\pm hi$ muscle phenotype is independent of MN genotype, and the MN neuroma is a secondary response. NIH-NRSA (MRH).

ADAPTATIONS OF RAT DIAPHRAGM TO PRENATAL UNDERNOURISHMENT. Y.S. Prakash, M. Fournier and G.C. Sieck. Dept. of Biomed. Eng., Univ. Southern California., Los Angeles, CA 90089.

Pregnant rats were undernourished (UN) from

regnant rats were undernourished (UN) from day 2 of pregnancy, and restored to normal diets after parturition. Body weights of UN pups were lower than controls (CTL) until 2 weeks of age. Formation of secondary myotubes was inhibited or Formation of secondary myotubes was inhibited or delayed in the UN embryonic diaphragm (DIA). Postnatally, the proportion of type I fibers was 75% higher in the UN DIA compared to CTL at birth, and 36% higher at 3 weeks. Cross-sectional areas of both type I and II fibers were greater in the UN DIA compared to CTL throughout the first 3 weeks. Twitch half-relaxation times were longer in the UN DIA, while contraction times were similar. The while contraction times were similar. The postnatal increase in specific tension (force/muscle area) in the UN DIA lagged behind that in CTL until 3 weeks, as did the decrement in UN DIA fatigue resistance. We conclude that prenatal undernourishment decreases the total number of DIA fibers, and, to compensate, fiber size increases. The inhibition of secondary myotube formation also affects the subsequent differentiation of fiber types and postnatal changes in DIA contractile properties.

DIFFERENTIATION, MORPHOGENESIS AND DEVELOPMENT: CELL SURFACE AND MATRIX COMPONENTS

82.1

PATTERNS OF HNK-1 AND NCAM DISTRIBUTION IN THE EARLY <u>XENOPUS</u> SPINAL CORD. R.H.Nordlander and S-X. Liu*. Depts. Oral Biol., Anat., Ohio State Univ., Columbus,OH

The carbohydrate epitope recognized by the antibody HNK-1 is also expressed on several cell surface glycoproteins associated with cell adhesion, including the neural cell adhesion molecule (NCAM). We have compared immunoreactivity (IR) patterns of HNK-1 and anti-NCAM in wholemounts and transverse sections of the developing spinal cord at stages when a range of differentiation states can be followed along the rostrocaudal

differentiation states can be followed along the rostrocaudal developmental gradient.

NCAM-IR appears on the surfaces of neural tube cells outlining borders of adjacent neuroepithelial cells and providing a view of changing cell configuration. This is particularly striking in wholemounts where floor plate cells, for example, are seen to elongate horizontally at the time that commissural axons first cross the cord. Anti-NCAM also outlines the surfaces of differentiating neurons and glia, but, because it stains so many elements, NCAM provides a less clear picture in wholemounts once substantial axonal outgrowth is underway. HNK-1, on the other hand, provides crisp and distinct surface marking of neurons from the beginning of their differentiation. Neither neuroepithelial cells nor developing glial cells show HNK1-IR above control levels. The comparative biochemistry of these patterns is under study Supported by NS 18773.

82.3

TOR 23 IS A PROMINENT BRAINSTEM AND SPINAL CORD MARKER IN THE DEVELOPING RAT CNS. P.D. Kushner, A.O. Esty*, D.A. Garrett*, S. Wright*, and D.T. Stephenson, ALS Research Center, Pacific Presbyt, Med. Ctr, San Francisco, CA 94115. The evaluation of surface markers of subsets of neurons promises to add significantly to our understanding of neuronal relationships in the developing CNS. This study has examined the distribution the monoclonal antibody (MAb) Tor 23 in the rat embryo. Heads from embryonic stage 15 were serially cryosectioned (8 um thick) and stained with Tor 23 and for cytoarchitecture stained for Nissl substance and with MAbs to neurofilament proteins (68 and 180 kDa) and vimentin. We have determined that Tor 23 is an exclusive CNS marker and does not bind any peripheral structures; within the CNS Tor 23 stains neuronal surfaces broadly in the spinal cord and brainstem, marking the myriads of fiber tracts that are present in these regions at this stage; in contrast, forebrain surface staining exists in precisely circumscribed somatic regions, the septum and the presumptive region of the nuclei of the diagonal band and in the rostral portion of the cortex, where significant staining is associated with the top and bottom regions of the cortical plate. These data are generally consistent with the distribution in the adult rat brain (J. Neurosci 8 3035) and support the conclusion of that earlier study that Tor 23 is a motor system marker. The data constitute further evidence for a unique relatedness between the motor neurons and the basal forebrain cholinergic neurons Supported by ADRDA and the ALS Research Center.

DISTRIBUTION OF ADHESION AND CELL SURFACE MOLECULES IN DEVELOPING MOUSE NEOCORTEX. W.-W. Chung, C. Lagenaur, and J.S. Lund. Dept. of Neurobiology, Anatomy and Cell Science, University of Pittsburgh, PA 15261

The differential distribution of a number of cell

adhesion molecules as well as other cell surface molecules during pre- and postnatal cortical development in the mouse emphasizes a complex partitioning of these molecules in the neuropil. For instance, at El6, polyclonal L1 antibody emphasizes fiber staining in the subplate and intermediate zone; polyclonal NCAM antibody shows fiber staining in the same region but includes cell surface markers in the cortical plate, intermediate and germinal layers; 12F8, antibody to the embryonic form of NCAM, emphasizes staining of the subplate region; M6, antibody to another cell surface protein, shows staining in the subplate and intermediate zone (which is not fiberrelated) with extension through the cortical plate. addition, all these antibodies at El6 stain the marginal zone heavily. By postnatal day 0, the two NCAM antibodies stain throughout all layers, except for the germinal zone, with intense staining in the marginal zone; M6 emphasizes staining of white matter and marginal zone; L1 emphasizes staining of white matter, subplate, lower cortical plate and marginal zone. These changing patterns indicate a considerable complexity to the internal milieu of the developing cortex. (Supported by NS25543 and

EXPRESSION OF SC1, A PUTATIVE EXTRACELLULAR MATRIX GLYCOPROTEIN, IN ADULT AND DEVELOPING RAT BRAIN. S. Shahin*, I. Johnston*, I.R. Brown and J.W. Gurd, Scarborough Campus, University of Toronto, Ontario, MIC 1A4.

Polyclonal antisera raised against synaptic junction glycoproteins were used to screen a brain lambda gt11 expression library and isolate a cDNA clone termed SC1 (Johnston et al., Neuron, 2:165, 1990). DNA sequencing suggested that the SC1 protein is a secreted, calciumbinding glycoprotein, regions of which exhibit a striking sequence similarity to the extracellular matrix glycoprotein osteonectin/BM40/SPARC. In cerebellum in situ hybridization showed that the SC1 message was predominately expressed in the Purkinje cell layer and continued out into the molecular layer. Polyclonal antibodies were raised against the fusion protein encoded by SC1 cDNA. The antiserum designated E/P11 recognized a glycoprotein doublet of apparent molecular weight 116kd/120 kd. In cerebellum homogenates the SC1 doublet was present at birth and increased during the first 20 postnatal days. The immunohistochemical localization of the E/P11 epitope in rat cerebellum was determined using 16µm frozen sagittal sections and visualized with FITC-conjugated secondary antibody. In the adult strong immunofluorescence was associated with the Bergmann glia perikarya and their ascending processes. The immunoreactivity was blocked by preincubating the E/P11 serum with a bacterial lysate containing a fully overlapping fragment of the SC1 protein but was not affected following preincubation with a similar lysate lacking the SC1 fragment. The granule cell layer, deep white matter, Purkinje cell bodies and dendrites did not stain. The strong reactivity of the Bergmann glia was observed at postnatal day 10 whereas the glial processes did not stain until day 16. Supported by MRC (JWG) and NSERC (IRB).

PRESENCE OF AN INTRAVENTRICULAR MATRIX IN THE DEVELOPING RAT BRAIN. A. Nadeau, S. Woerly and R. Marchand. Lab. de Neurobiologie, Univ. Laval and Hôp. Enfant-Jésus, 1401, 18e Rue, Québec (QC) Canada, G1J 1Z4.

The present study reports the presence of a floccular matrix within the ventricular system of the developing rat brain. For the

The present study reports the presence of a floccular matrix within the ventricular system of the developing rat brain. For the visualization of this matrix and the determination of its molecular composition, rat embryos aged from E13 to E16 were perfused (neutral buffer formol 10%), dehydrated, embedded in glycol methacrylate and stained following different histochemical methods. The ventricles were also studied with the scanning electron microscope. The results show that this matrix extends from the ependymal lining and completely fills the ventricular lumen of E15 embryos. It is composed of glycoconjugates, glycosaminoglycans and collagen. Necrotic cells and macrophages (microglia) were often trapped within the matrix.

macrophages (microglia) were often trapped within the matrix.

According to its molecular composition and by analogy to the function of similar matrices in other vesicular structures, three different functions can be hypothesized about the physiological significance of this ventricular matrix: it can, 1) act as a filtration system that could entrap cells debris, 2) provide an architectural scaffold for the developing ventricle, 3) be involved in ionic exchanges and hydrodynamic function related to the cerebrospinal fluid. Other preliminary results obtained from chick embryos reveal that a similar matrix is also present in the developing ventricular system of this species. We suggest that the intraventricular matrix is present in the developing ventricules of many species and that it constitutes a key element in the normal morphogenesis of the brain. (Suported by MRC, FCAR and FRSQ).

DEVELOPMENTAL REGULATION OF TENASCIN IN THE CHICK EMBRYO SPINAL CORD. S. E. McKay, R. P. Tucker & R. W. Oppenheim. Department of Neurobiology and Anatomy, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27103

Previous studies have shown that the expression of the

Previous studies have shown that the expression of the extracellular matrix protein tenascin is developmentally regulated in avian neural tissue. Here we describe tenascin expression in the developing spinal cord. Spinal cords from chick embryonic day (E) 5, 7, 10, 14 and 18 were homogenized and studied by western and slot blotting using a tenascin polyclonal antiserum. All three tenascin splice variants (Tn190, Tn200 and Tn230) are expressed at E5, but by E10 a high-molecular weight splice variant (Tn230) is predominant. Tenascin expression at E5 is low, but the relative amount of tenascin in the homogenates increases through E14. Immunohistochemistry reveals tenascin in ventral white matter at E5 and E10, and by E14 there is also anti-tenascin studies reveal tenascin is being expressed by oligodendroglia. Our results show that the expression of tenascin in the spinal cord is primarily associated with neuronal-glial interactions, and not with active neurite outgrowth.

The Role Of The Extracellular Matrix In Photoreceptor Differentiation.

D.D.Hunter 1, M.D.Murphy 2* and W.J.Brunken 2; Dept. of Biology, Boston College 2 and Division of Neurosci., Tufts University 1, Boston, Massachusetts.

The extracellular matrix (ECM) is important for several aspects of neural development in the PNS. However, the role of the ECM in the development of the CNS is only now being elucidated. The vertebrate retina as an ideal model system for studying the role of the ECM in neural migration and differentiation. We have studied the expression of an ECM protein s-laminin, a laminin homologue that is highly concentrated at the neuromuscular junction, in the skate retina by using immunological probes.

The antiserum GP1 recognizes epitopes in the C-terminal 20 kDa of s-laminin. In the adult skate, intense GP1 immunoreactivity is seen in the interphotoreceptor matrix and at the bases of photoreceptors. During development, s-laminin-like proteins first appear after presumptive photoreceptors have migrated to their final position in the outer retina. Subsequent to this expression, synaptic development proceeds, followed by expression of rhodopsin. Thus, s-laminin-like proteins may be important differentiation signals for photoreceptors.

Protein immunobioting demonstrates two GP1-immunoreactive proteins in the skate retina: one 190 kDa protein, and another 350 - 400 kDa protein that may be a dimer of the lower M₁ species. These data are consistent with the original description of s-laminin. We are currently studying the role of s-laminin(s) in a tissue culture system of the developing skate retina in order to elucidate the functional role of this extracellular protein in photoreceptor differentiation.

DISTRIBUTION OF CYTOTACTIN mRNAS IN THE NERVOUS SYSTEM OF CHICKEN EMBRYOS. A.L.Prieto*.F.Jones*.K.L.Crossin*.B.A.Cunningham*.G.M.Edelman. Lab. of Developmental and Molecular Biology, The Rockefeller University, New York, NY 10021.

The localization of alternatively spliced forms of

The localization of alternatively spliced forms of cytotactin mRNA was analyzed by in situ hybridization and compared to the polypeptide distribution throughout chicken embryonic development. Two probes were used, one probe (CT) corresponding to a region that is contained in all forms of cytotactin, and another (VbVc) included portions of two alternatively spliced type III repeats. In telencephalon, optic tectum, cerebellum, spinal cord and peripheral nervous system, the mRNAs were more transiently expressed and more localized than the polypeptides which were diffusely distributed within the extracellular matrix. Levels of mRNA and protein increased from E8 to E15, then gradually decreased to barely detectable levels by P3, except in the cerebellum, where the levels remained comparatively high. Cytotactin mRNA was observed in radial glial somata of the optic tectum and cerebellum, while the polypetide was found distributed along the processes. The hybridization patterns of the CT and VbVc probes overlapped in the spinal cord and cerebellum, but differed in the outermost tectal layers. In the peripheral nervous system, cytotactin mRNA was detected in large ganglia and in the plexi of Meissner and Auerbach. These results emphasize the importance of the study of factors regulating the developmental expression and function of this molecule.

DIFFERENTIATION, MORPHOGENESIS AND DEVELOPMENT: CYTOSKELETON

83.1

MATURATION OF CYTOSKELETAL PROTEINS OF CALLOSAL AXONS. <u>B.Riederer</u>¹, <u>G.M.Innocenti</u>¹ <u>and A.Guadano-Ferraz</u>*². ¹Inst. of Anatomy Univ. of Lausanne, CH 1005 and ²Dpt. of Morphology Univ. of Alicante, 03080, Spain.

Only a fraction of the juvenile callosal axons are maintained in development (Berbel, P. and Innocenti, G.M., <u>J. Comp. Neurol.</u>, 276:132, 1988). In order to characterize molecular features specific to these axons, neurofilament subunit NFH and microtubule associated proteins Tau were studied with electrophoresis, Western blots and immunocytochemistry in the corpus callosum of cats sacrificed on postnatal days (P) 3, 11,19,28,39,adult. Unlike subunits NFL and NFM, which were already present at P2-3 (Figlewicz, D. et al., <u>Dev. Brain Res.</u>, 42:181, 1988), NFH could be demonstrated only from P11-19 onwards with monoclonal antibody NE14 and from P29 onwards with monoclonal antibody SMI-32. Pretreatment of tissue with alkaline phosphatase (50 U/ml of Tris-HCl buffer, pH 8.2, with 135mM NaCl, 1mM EDTA, 1mM PMSF, 10 μg/ml Leupeptin, Antipain and Pepstatin A, and 5 μg/ml E64; at 37°C for 2 or 24 h) eliminated positivity to NE14 in blots and sections indicating that this antibody recognized a phosphorylated form of NFH. The same pretreatment revealed positivity to SMI-32 at P11-19 (but not at P3), suggesting that the recognition is conditional to loss of phosphate. Therefore a partially dephosphorylated NFH may appear late in callosal axons. Tau proteins with adult molecular weights appear at P28. These changes occur at the end of the period of fast elimination of callosal axons and therefore probably only in axons which are maintalmed. They are synchronous with changes in distance between Fs (for NFH) and Ts (for Tau) (Innocenti, G.M. et al., <u>Neurosci. Abs.</u>, 1990).

83.2

MATURATION OF CYTOSKELETAL ULTRASTRUCTURE OF CALLOSAL AXONS. <u>G.M.Innocenti</u> 1 , <u>P.Berbel</u> *2 <u>and R.Kraftsik</u> *1 . ¹Inst. of Anatomy, Univ. of Lausanne, CH 1005 and 2 Dpt. of Morphology Univ. of Alicante, 03080, Spain.

In order to characterize structural changes related to the stabilization of juvenile axons, the distance between neurofilaments (Fs) or microtubules (fs) was studied as function of age, axon area and Fs, Ts or Fs+Ts density. Electron microscopic photographs of corpus callosum from kittens sacrificed on embryonic (E) or postnatal (P) days E53,58, P4,9,18,26,39,57,92,107,150, or a previous study (Berbel, P. and Innocenti, G.M., J. Comp. Neurol., 276:132, 1988) were employed. Three computerized measurements were performed in over 5000 axons. Two of them (D1 and D2) estimated average—the third (Dmin) absolute minimal distances. With age, D1 and D2, between Ts decreased slightly, and increased slightly between Fs. Dmin between Ts showed a progressive and statistically significant decrease from (median values) 57nm at E53 to 38nm at P39 and remained stable thereafter. Dmin between Fs increased slightly between E53 (43nm) and P18 (64nm). Then it decreased to 38mn at P39 and remained unchanged thereafter. When the adult values of Dmin were reached, they became also uncorrelated with, and therefore independent of, the density of Ts, Fs or Ts+Fs. Interestingly, this was simultaneous to the appearance of adult Tau (for Ts) and NFH (for Fs) proteins (Innocenti, G.M. et al., Neurosci Abs., 1990). NFH and Tau cross connect Fs and Ts, respectively; their maturation may influence the spacing of these elements and reflect or cause the stabilization of the juvenile axons.

INTERACTION OF MAP2 WITH THE NEURONAL CYTOSKELETON. B. Brugg and A. Matus. Friedrich Miescher-Institut, P.O. Box 2543, CH-4002 Basel, Switzerland.

Microtubule-associated protein 2 (MAP2) is a 200 kDa neuronal rotein that can bind to and cross-link microtubules in living cells. Little is known about how these inter actions are regulated, but phosphorylation may be involved since it is known to influence the phosphorylation may be involved since it is known to influence the binding of MAP2 to tubu lin polymers in vitro. We have studied this possibility by preparing purified MAP2 in different states of phosphorylation, injecting it into RAT-1 fibroblastic cells, where MAP2 is normally absent, and then following its distribution by immunofluoresecence staining. The results show that MAP2 prepared as close to its native phosphorylation state as possible (10 mole Pi/mole) bound to cellular microtubules immediately after microinjection. Enzymically dephoshorylated MAP2 (2 mole/mole) did not initially bind to cellular microtubules but its distribution slowly changed so that 15 min after injection it was bound to microtubules However, in cells grown in serum-free medium this redistribution did not occur, and MAP2 remained spread throughout the cytoplasm. Since protein kinase activity is high in cells grown in serum and low in those grown in serum-free medium, these results are consistent with the idea that phosphorylation of MAP2 is required for its binding to microtubules. However, further in vitro phosphorylation of MAP2 to 20 mole/mole via kinase activity that co-purifies with microtubules resulted in its not binding to cellular microtubules. We conclude that MAP2 contains various phosphorylation sites that differently influence its binding to microtubules in living cells.

83.5

LOCALIZATION OF PHOSPHATE DEPENDENT (RMO2.4) INDEPENDENT (RMDO9.5) EPITOPES OF THE HEAVY NEUROFILAMENT SUBUNIT IN THE HIPPOCAMPUS AND DENTATE GYRUS OF NORMAL AND MUTANT MICE. P.R. Patrylo and R.S. Nowakowski. Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School

Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School and Physiology/Neurobiology Program, Rutgers University, Piscataway, NJ 08854. The immunohistological localization of phosphate dependent (RMDO.4) and independent (RMDO.9.5) epitopes of the heavy (200kDa) neurofilament subunit was examined in C57BL/6J, NZB/BlNJ, Hdd/Hdl (on a BALB/cB/J) background), n^{Off}/n^{Off} (on a non-inbred background), and dr^{SSL-J}/dr^{SSL-J} (on a B6C3Fe background) mice. In all mice examined the mossy fibers in the hippocampus were RMO2.4 immunopositive, but in NZB/BlNJ and Hdd/Hdl only a few fibers in the infrapyramidal limb were immunoreactive. RMDO9.5 was localized in the soma and dendrites of almost all of the neurons in the noramidal cell laver of CA2 in the infrapyramidal limb were immunoreactive. RMDO9.5 was localized in the soma and dendrites of almost all of the neurons in the pyramidal cell layer of CA2 and CA3 and in the hilus of the dentate gyrus. However, RMDO9.5 immunoreactivity was observed in only a few neurons in CA1 and in the granule cell layer of the dentate gyrus. In addition, ectopic pyramidal cells in CA3 of Hld/Hld, rfof/rfof, drsst-Jqdrsst-Jand NZB/BINJ were RMDO9.5 immunoreactive, while ectopic pyramidal cells in CA1 of rfof/rfof and ectopic granule cells in the dentate gyrus of drsst-Jqdrsst-Jand NZB/BINJ were not. Our data indicates that hose back dependent and phosphate independent heavy neurofilement subuprit dentate gyrus of an and Nazh/Bin were not. Our data indicates that phosphate dependent and phosphate independent heavy neurofilament subunit epitopes are differentially distributed in the mouse hippocampus. Furthermore, we suggest that the expression of RMDO9.5 is a property of cell-class (e.g., CA3 pyramidal cell vs CA1 pyramidal cell) and not laminar position (e.g., stratum pyramidal vs stratum radiatum).

VIMENTIN AND GFAP IN THE IMMATURE RAT SPINAL CORD. M. A. Pippenger*. S. A. Gilmore, and T. J. Sims. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205-7199.
Studies by others have shown that vimentin is the major intermediate filament (IF)

protein in astrocytes early in development, whereas GFAP is the major astrocyte IF protein in adults. Aspects of this vimentin-GFAP transition were examined in the

white matter of the normal immature rat spinal cord using immunohistochemistry.

Rat pups were deeply anesthetized and perfused with fixative on postnatal days
3, 6, 12, and 21. Paraffin sections from the cervical, thoracic, and lumbosard regions of the spinal cords were stained for vimentin or GFAP using the PAP technique. Selected sections were double-labeled for both IF proteins using the 1-naphthol basic dye technique (Mauro et al., Histochem., 86:123, 1986).

naphhol basic dye technique (Mauro et al., Histochem, 86:123, 1986).

The major observations made in this study were: that vimentin was the predominant IF at all cord levels at 3 days of age, that vimentin-positive cell bodies and processes in the white matter decreased rapidly in numbers so that after 9 days of age, only an occasional vimentin-positive process was noted; that GFAP-positive cell bodies and processes increased with age, outrumbering those positive for vimentin by 6 days of age, particularly in the more rostral segments; that a rostrocaudal gradient in development of GFAP positivity occurred; that the adult pattern of GFAP immunoreactivity was reached by day 21; that during this transition only a few double-labeled cell bodies and processes were noted; and that these few double-labeled cells occurred only in younger animals.

This study demonstrates that GFAP is the predominant intermediate filament protein in astrocytes in the white matter of rat spinal cord by 6 days of age. The results suggest that, atthrough a few astrocytes express both vimentin and GFAP simultaneously, most appear to produce GFAP without first producing vimentin. 83.4

MECHANISM OF INSULIN AND INSULIN-LIKE FACTOR DIRECTED NEURITE FORMATION: ROLE OF CYCLIC AMP IN NEUROFILAMENT AND TUBULIN GENE EXPRESSION.

AMP IN NEUROFILAMENT AND TUBULIN GENE EXPRESSION. C. Wang*, Y. Li*, B. Wible*, K. Angelides*, and D.N. Ishii Physiolology Dept., Colorado State Univ., Ft. Collins, CO 80523; Physiology and Molecular Biophysics Dept., Baylor College of Medicine, Houston, TX 77030.

There is a close correlation between insulin-like growth factor (IGF) gene expression and synaptogenesis, and IGFs can enhance neurite growth in vivo and in vitro. We tested the hypothesis that cAMP is a second messenger mediating neurite outgrowth directed by insulin and IGFs in human neuroblastoma SH-SY5Y cells. Neurofilament (NF) 68 kd, NF 170 kd, α-tubulin, and β-tubulin mRNAs were selectively increased in response to insulin, IGF-I, IGF-II, dibutyryl and β -tubulin mRNAs were selectively increased in response to insulin, IGF-I, IGF-II, dibutyryl cAMP, forskolin, or cholera toxin. Theophylline increased the response to insulin, IGF-I, or IGF-II. Like IGFs, dibutyryl cAMP or forskolin enhanced neurite outgrowth. Both 8-bromo cAMP and NGF selectively increased tubulin and NF mRNAs in PC12 cells as well. Therefore cAMP may mediate the insulin-, IGF-, and NGF-dependent increases in selective mRNAs, which encode proteins of the axonal cytoskeleton and support neurite outgrowth. (NIH grant RO1 NS24327)

83.6

VIMENTIN AND GFAP IN THE IRRADIATED RAT SPINAL CORD. S. A. Gilmore, M. A. Pippenger*, and T. J. Sims. Department of Anatomy, University Medical Sciences, Little Rock, AR 72205-7199.

Many previous studies by Gilmore and colleagues have demonstrated that exposure of the lumbosacral spinal cord of the immature rat to x-radiation results in a marked decrease in the glial population. The present study was undertaken to determine the pattern of intermediate filament immunoreactivity in the glial cells that do persist

pattern of intermediate filament immunoreactivity in the glial cells that do persist during the first two weeks post-irradiation (P). Rat pups were irradiated with a single 4000 R dose of 'soft' X-rays to a 5mm length of LS spinal cord. The animals and their non-irradiated litter-mates were deeply anesthetized and sacrificed on postnatal days 6, 9, 12, and 15. Paraffin sections of the spinal cords were stained for vimentin and/or GFAP using the PAP technique. At the earliest age examined (3 days P-I), few GFAP-positive cell bodies and processes were noted in the lateral and ventral white matter. By 9 days of age (6 days P-I) an occasional astrocyte in these areas appeared to have become reactive, i.e. was intensely positive for GFAP, and these reactive white matter astrocytes increased in numbers in the 12- and 15-day-old animals. The gray matter, although initially GFAP negative, underwent an abrupt increase in GFAP-positive astrocytes between 9 and 12 days of age (6 and 9 days PI). Vimentin immunoreactivity was limited to only a few cells and processes and never approached the level of GFAP reactivity.

These results suggest that surviving astrocytes in the irradiated spinal cord include

These results suggest that surviving astrocytes in the irradiated spinal cord include GFAP-positive astrocytes in the white matter, as well as a group of non-immunoreactive gray matter astrocytes which respond to radiation by becoming GFAP-positive without first passing through a wimentin-positive stage.

REMOVAL OF NA INACTIVATION ELIMINATES NA CURRENT ACTIVATION DELAYS. R. Hahin. Dept. of Biological Sciences, Northern Illinois University, DeKalb, IL 60115

Na current activation delays were obtained from voltage-clamped frog skeletal muscle

Na current activation delays were obtained from voltage-clamped frog skeletal muscle fibers. Na currents elicited by depolarizing steps from hyperpolarizing holding potentials are delayed in their activation. In untreated fibers, the magnitude of the delay was maximized by using the most negative holding potentials (-150 mV), and the smallest depolarizing test pulse potentials. Delays, observed following partial inactivation removal using chloramine-T treatment, did not differ from delays observed prior to treatment. Complete removal of inactivation eliminated hyperpolarization-induced delays in activation. Steady-state slow inactivation was virtually unaffected by chloramine-T treatment that removed inactivation. The results suggest that chloramine-T oxidizes methionine residues that play key roles in determining initial channel opening latencies and life-times.

Interleukin-2 (IL-2) plays a pivotal role as

Interleukin-2 (IL-2) plays a pivotal role as a polypeptide mediator of cellular immune response and is a member of the class of molecules termed cytokines that mainly regulate growth and differentiation of cells involved in immunity. In the present work, voltage-activated whole-cell currents and GABA-activated currents have been recorded in hippocampal embryonic nerve cells which, in the rat, exhibit specific IL-2 binding sites. We show here that human recombinant IL-2 (rIL-2), while does not affect neither K+, nor Ca2+currents, nor GABA-activated currents, significantly reduces the amplitude of Na+currents. This may explain, at least in part, the rIL-2-induced modification in the electrical activity of central nerve cells, described elsewhere.

THE PHOTOACTIVE PROBE BATRACHOTOXININ-A ORTHO AZIDOBENZOATE COVALENTLY LABELS LIPID COMPONENTS OF THE BATRACHOTOXIN BINDING SITE OF VOLTAGE-SENSITIVE SODIUM CHANNELS. T.L. Casebolt and G.B. Brown, Dept. of Psychiatry and Behavioral Neurobiology, University of Alabama at Birmingham, Birmingham, AL. 35294.

The voltage-sensitive sodium channel has been extensively studied using at least five classes of specifically-acting neurotoxins, each of which binds to a different site on the sodium channel. Batrachotoxin (BTX), the most potent of the "lipid soluble" class of toxins binds the sodium channel, resulting in profound changes of channel function and electrophysiology. While much has been learned about the interaction of the BTX binding site with other sodium channel neurotoxin binding sites, specific information about the structural components of the BTX binding site is of interest to determine the component or components contributing to altered sodium channel function at the molecular level. To accomplish this goal, a photoreactive [3H]BTX derivative, [3H]BBtarachotoxinin-A ortho azidobenzoate ([3H]BTX-OAB), was prepared by partial synthesis. The probe binds covalently to the BTX sodium channel site, allowing detailed examination of the elements within the site. After photolabeling of rat cerebral cortical synaptoneurosomes with [3H] BTX-OAB, approximately 90% of the specifically labeled material was recovered in lipid extracts. Two specifically labeled products were identified by thin layer chromatography suggested that [3H]BTX-OAB covalently labels a small mw compound, possibly phospholipid, with an estimated mw of 600-800. To test this hypothesis, experiments are in progress to analyze the labeled lipid-like material by chemical cleavage and specific enzymatic hydrolysis using purified phospholipases. Presuming the lipid-like material is phospholipid, this approach is expected to provide information about the point of linkage of [3H]BTX-OAB to the head group or fatty acyl chains.

84.2

NEGATIVE MODULATION OF TETRODOTOXIN-SENSITIVE, CONOTOXIN GIII A-LESS SENSITIVE SODIUM CHANNELS IN CULTURED BOVINE ADRENAL MEDULLARY CELLS. A. Wada, Y Uezono*, M. Arita*, H. Kobayashi* and F. Izumi. Dept. of Pharmac., Univ. of Occupational and Environmental Health, Sch. of Med., Kitakyushu 807, Japan.

181

Med., Kitakyushu 807, Japan.

Existence of multiple subtypes of Na channels has been noted. We previously reported that in adrenal medulla, conotoxin GIII A which blocks Na channels in skeletal muscle and adrenergic neuron but has no effect in brain, inhibits veratridine-induced 22 Na influx (IC $_{50}$ 6 μ M) without affecting 3 H-saxitoxin binding (Jap. J. Pharmac., 49:185p, 1989). In the present study, to examine the regulation of Na channels, cells were pretreated with veratridine, and the number and properties of Na channels were determined. In cells preexposed to 100 μ M veratridine, veratridine-induced influx of 22 Na was decreased by 82% with a half-time of 2-3h. This decrease was reversible and prevented by tetrodotoxin. Potentiation of veratridine-induced 22 Na influx by a α -scorpion venom was 3-4 fold lower in veratridine-pretreated cells. Scatchard plot of 3 H-saxitoxin binding showed that 1h pretreatment with 100 μ M veratridine produced 32% reduction in Bmax, but has no effect on Kd. The number of functional Na channels seems to be reduced by the increased activity of Na channels.

84.4

DIFFERENTIAL PROPERTIES OF TETRODOTOXIN-SENSITIVE AND TETRODOTOXIN-RESISTANT SODIUM CHANNELS IN RAT DORSAL ROOT GANGLION NEURONS. M.-L. Roy and T. Narahashi, Dept. of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611.

Tetrodotoxin (TTX)-sensitive (TTX-S, K_d-1 nM) and TTX-resistant (TTX-R, $K_d-100~\mu\text{M})$ sodium channel currents were analyzed in acutely dissociated dorsal root ganglion neurons isolated from 3-10 day old rats. Currents were recorded using the whole-cell patch clamp technique. These two types of current were found in varying proportions dependent upon the rat age. Cells from younger rats (3-7 days) expressed largely TTX-R current, whereas cells from older rats (7-10 days) expressed either a combination of TTX-S and TTX-R currents or TTX-S current only. TTX-R current showed a distinctively slow time course compared with the much faster time course of TTX-S current. These current types also differed in their steady-state inactivation, with TTX-R $V_{1/2}$ being -40 $V_{1/2}$ and TTX-S current by approximately 60%, and virtually abolished TTX-S current. The biophysical and pharmacological properties of these two types of sodium channels are of particular importance in the development of CNS and in the mechanism of action of drugs on the CNS neurons. Supported by NIH grants ROI NS14443 and F31 MH09839.

SOURCE CONTROL OF STREET BATRACHOTOXIN-MODIFIED SODIUM CHANNELS FROM EEL ELECTROPLAX. D.E. Flash S.R. Levinson, E. Recio-Pinto. Depts. Anesthesiology and Physiology. Cornell Univ. Med. Coll. NY, NY 10021. Dept. Physiology, Univ. of Colorado Med. Sch., Denver, CO 80262. Supported in part by the Lois & Rose Klosk Award.

Sodium channels are an important site of local anes-

Sodium channels are an important site of local anesthetic action. The effects of Lidocaine (LI) in the single sodium channel current and steady-state activation characteristics were studied on purified eel electroplax sodium channels. Sodium channels were incorporated into planar lipid bilayers in the presence of batrachotoxin (BTX), 0.5M NaCl. Under control conditions the channels I-V relationships were linear and symmetrical with a mean slope conductance of 24 pS. LI increased the rate of channel disappearance from the bilayers, suggesting that the LI increases the rate of BTX dissociation. LI reduced the single sodium channel conductance in a dose- and voltage-dependent manner. The block with LI increased with membrane depolarization. The noise level of the open channel increased as the voltage became more positive, as if the kinetics of LI block became slower with depolarization. The maximum curtent at steady-state decreased due to a decrease in the number of BTX-modified channels and a decrease in the single channel current of BTX-modified channels. The steady-state activation characteristics of BTX-modified channels (midpoint potential and apparent gating charge) were not affected by LI.

EFFECTS OF BREVETOXIN ON GUINEA PIG HIPPOCAMPAL NEURONS. J.P. Apland, M. Adler, and R.E. Sheridan. Neurotoxicology Branch, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD 21010.

Brevetoxin (PbTx-3) depolarizes nerve and muscle membranes by shifting the activation potential of voltage-dependent Na channels to more negative values. Since PbTx-3 is lipid soluble and exhibits behavioral effects believed to be of central origin it was of interest to examine its actions on CNS function.

Extracellular recordings were obtained from area CA1 of guinea pig hippocampal slices. PbTx-3 was applied by bath perfusion in a submersion chamber at 32°C. PbTx-3 produced a concentrationdependent depression of the evoked population spike with an EC50 of 82 ng/ml. Concentrations below 30 ng/ml were without effect and concentrations of 300 ng/ml or greater led to total inhibition PbTx-3 did not produce spontaneous of evoked responses. synchronous discharges but did increase single unit activity at concentrations of 100 ng/ml or higher. The toxin appeared to be equally effective in inhibiting orthodromic and antidromic responses, suggesting an action on excitation rather than on synaptic transmission. Recovery from PbTx-3 was slow, requiring up to 3 hr of wash for complete restoration of function. The toxin-induced suppression of spike generation in hippocampal slices resembles its action on skeletal muscle and is consistent with membrane depolarization.

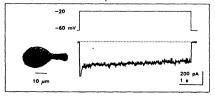

INTERACTIONS BETWEEN THE PUMILIOTOXIN B (PTX-B) SITE AND OTHER SITES ON THE VOLTAGE-DEPENDENT SODIUM CHANNEL. Fabian Gusovsky, William Padgett* and John W. Daly LBC, NIDDK, NIH, Bethesda, MD 20892.

The alkaloid PTX-B "activates" voltage-dependent sodium channels in synaptoneurosomes and neuroblastoma cells (Gusovsky et al., 1989). It appears that PTX-B activates sodium channels by interacting with a site that is allosterically that PTX-B activates sodium channels by interacting with a site that is allosterically regulated by other sites (alkaloid site 2, scorpion toxin sites 3 and 4) on the sodium channel. In guinea pig cortical synaptoneurosomes, α -scorpion toxin and the marine toxin brevetoxin induce a dose-dependent potentiation of PTX-B-induced "Na" influx (EC₅₈: 3 nM and 70 nM respectively). In addition, β -scorpion toxin induces a dose-dependent potentiation of PTX-B-induced "Na" influx (EC₅₈: > 10 nM). The synergism with β -scorpion toxin differentiates PTX-B from the alkaloids batrachotoxin and veratridinc, which induce an activation of sodium channels that is not affected by β -scorpion toxin. Furthermore, PTX-B did not inhibit ['H]BATX-B) binding to sodium channels. On the other hand, aconitine, which activates sodium channels and inhibits ['H]BTX-B binding. induces sodium influx that can be potentiated by α -scorpion toxin. binding, induces sodium influx that can be potentiated by \(\alpha\)-scorpion toxin, brevetoxin and \(\beta\)-scorpion toxin. The type I pyrethroid allethrin, but not the type II pyrethroid deltamethrin, inhibits \(\mathbf{PTX}\)-B-and \(\mathbf{PTX}\)-B/\(\alpha\)-scorpion toxin-mediated sodium influx. Inhibition also is observed with aconitine-mediated sodium flux, but sodium influx, Inhibition also is observed with aconitine-mediated sodium flux, but does not occur with BTX- and veratridine-mediated sodium influx. It is proposed that on the sodium channel there is an "alkaloid binding domain" at which alkaloids exert stimulatory actions. However, depending on the region on the domain on which the binding occurs, different allosteric actions with other sites can be observed. PTX-B is proposed to interact with a part of the "alkaloid binding domain" that is shared by aconitine, but not by batrachotoxin or veratridine, while aconitine interacts with a part of the domain shared by PTX-B and by batrachotoxin/veratridine. Such a model may be useful in defining sodium channel topography. topography.

84.11

VOLTAGE CLAMP ANALYSIS OF A PERSISTENT TTX-SENSITIVE Na CURRENT IN CEREBELLAR PURKINJE CELLS-¹A.R.Kay. ²M. Sugimori and ²R.R. Llinas. ⁻¹AT&T Bell Labs, Biophys. Dept., NJ. 07974 and ²Dept. Physiol. & Biophys., NYU Med. Ctr., New York, NY 10016.

A persistent Na current (I_{Na}^{p}) has been shown to exist in cerebellar Purkinje cells (Llinas & Sugimori, J. Physiol. 1980). Here we have subjected this current to a detailed voltage clamp analysis, in whole-cell recordings from Purkinje cells acutely dissociated (Kay & Wong J. Neurosci. Methods. 1986) from guinea pig cerebellum. I_{Na}^{p} activated rapidly (< lms), deactivated rapidly (< 0.2 ms) and exhibited very little inactivation during voltage clamp pulses as long as 10s (see Fig.). We suggest that I_{Na}^{p} represents a separate current from the conventional Na current on the following grounds: (a) I_{Na}^{p} does not arise solely from the overlap of the steady state activates at a lower threshold than the inactivating current (i.e. it is not a window current). is not a window current).

DIFFERENTIAL ACTIONS OF BREVETOXIN ON PHRENIC NERVE AND DIAPHRAGM MUSCLE IN THE RAT. S. S. Deshpande, R. E. Sheridan and M. Adler. Neurotoxicology Branch, U.S. Army Medical Research Institute of Chemical Defense, APG, MD 21010.

The lethal actions of the dinoflagellate poison brevetoxin (PbTX-3) are thought to be mediated by depression of respiration. We have examined the mechanism of PbTX-3 inhibition of phrenic nerve-diaphragm responses in vitro and found that low-dose effects are mediated largely by inhibition of impulse transmission in the phrenic nerve, while depression of the muscle itself occurs at higher doses. In isolated hemidiaphragms from the rat, nerveelicited twitches were blocked by 50 to 100 nM PbTX-3. Higher toxin concentrations, between 100 and 500 nM, were needed to block directly elicited twitches in the muscle. Intracellular recordings indicated that failure in the evoked endplate potential (EPP) occurred in an all-or-none fashion in PbTX-3, without a graded reduction in the quantal content. Higher spontaneous miniature endplate potential (MEPP) frequencies were observed, but only after EPP failure (20 min. or more) or at the higher concentrations of PbTX-3. At toxin concentrations below 100 nM, direct stimulation of single muscle fibers still elicited action potentials, however, 0.4 to 1 μ M PbTX-3 blocked direct action potentials and depolarized muscle fibers (from a mean of -73 mV to a maximum level of -46 mV with an EC50 of $1.3 \mu M$). Measurements of the compound action potential in the phrenic nerve showed reductions of 30% or more at 50 nM PbTX-3 and complete block at 100 nM, paralleling the loss of nerve-evoked twitch and loss of the EPP. Thus, we conclude that diaphragmatic failure in PbTX-3 is caused by a loss of conduction in the phrenic nerve due to a higher sensitivity of the nerve to the toxin.

84.10

DIVALENT ION SENSITIVE SODIUM CHANNELS IN AtT20/D16-16 CELLS.

Research Institute of Chemical Defense, APG, MD 21010.

The pituitary cell line AtT20/D16-16 produces spontaneous spike activity involving both Na* and Ca** channels. These spikes can be completely abolished by application of 1 to 10 mM CoCl₂ or other traditional divalent cation blockers of calcium channels, leading to suggestions that only calcium was involved in carrying the inward current. However, we have determined that the spikes are also sensitive to tetrodotoxin and involve a sodium channel current that is unusually sensitive to divalent cations

In whole cell patch clamp experiments, application of 1 mM Co** reduced the peak sodium conductance by approximately 50% and shifted the midpoint of activation for both sodium and potassium currents by +10 mV. in 10 mM Co⁻⁻, the sodium current was almost totally suppressed and the activation voltage for Na⁻ conductance was shifted by +30 mV. In single channel experiments, 1 mM Co⁻⁻ reduced the conductance of single Na⁻ channels in a voltage-dependent manner, with approximately 50% block at -60 mV and only modest reductions in current at -20 mV. These data suggest that in the AtT20/D16-16 cell line, the sodium channel has a high affinity for cobalt at a voltage dependent binding site, presumably within the ion channel. The shifts in whole-cell sodium activation voltage seen in cobalt are likely due to a combination of the voltage dependent suppression of sodium conductance at negative potentials and a shift in the surface potential of the cells due to screening effects on fixed negative charge sites in the plasma membrane.

84.12

BLOCKADE OF OUTWARD CURRENT UNCOVERS A PERSISTENT INWARD CURRENT IN HEART INTERNEURONS OF THE LEECH HIRUDO MEDICINALIS. C.A. Opdyke and R.L. Calabrese. Dept. of Biology, Emory University, Atlanta, GA 30322.

In the medicinal leech, a neural oscillator composed of rhythmically active HN interneurons paces heartbeat. HN cell activity is characterized by bursts of spikes that are periodically interrupted by barrages of IPSP's originating from other HN cells (Thompson and Stent, 1976a and Calabrese, 1977). Blockade of competing currents has revealed a sodium dependent persistent inward current, I_p, in these cells that has been studied using the single electrode voltage

Outward current comprising a transient current similar to A-current (Conner and Stevens, 1971 a,b,c) and a delayed rectifier was blocked using a combination of 1.5M TEA-Acetate and 1.5M Cs-Acetate in the recording microelectrodes and 1mM methohexital, a short acting barbiturate, in the saline. Synaptic transmission and Ca⁺⁺ currents were blocked by removing Ca⁺⁺ from the saline and substituting 10mM Co⁺⁺, and the hyperpolarization activated inward current, I_h (Angstadt and Calabrese, 1989), was blocked by adding 4 mM Cs⁺ to the saline. Under these conditions, HN neurons produce periodic plateaus that are accompanied by a conductance increase. These plateaus are associated with a non-inactivating sodium dependent inward current, I_p , that exhibits a maximal activation at -20mV, when stepped from a holding potential of -60mV.

ACTION POTENTIAL LENGTHENING INDUCED BY MEROCYANINE 450 IN SNAKE MUSCLE. <u>S.T. Reikes</u> and <u>R.S. Wilkinson</u>, Dept. of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO 63110.

Merocyanine 450 (MC450) is a voltage-sensitive fluorescent dye which binds to living membranes. We noticed an unusual effect of MC450 on myofibers of the garter snake transversus abdominis muscle while exploring its use as a nerve terminal stain. Action potential (AP) duration increased significantly, from the normal 2-3 ms to 5-250 ms, when MC450 (30-75 μ M) was applied to the bath. The MC450 AP resembled a cardiac muscle AP, with an initial peak followed by a long plateau. Occasionally, the plateau was interrupted by repeated (~15 ms) burst-like oscillations. AP lengthening persisted in a bath containing zero added Ca++ (1 mM EGTA) or in the presence of the calcium channel blocker CdCl, (2 mM). Similarly, the K+ channel blocking agents 3,4-diaminopyridine (1.5 mM) and tetraethylammonium (TEA, 50 mM) had no effect, although TEA slowed the falling phase of control APs. In contrast, venom of the scorpion Leiurus quinquestriatus (0.5 μM) lengthened APs in a manner strikingly similar to MC450; this venom is known to slow Na+ channel inactivation in other preparations. Subthreshold conductance changes in the presence of MC450 were consistent with prolonged Na* channel opening. We conclude that MC450 specifically affects Na* channel kinetics in this snake muscle. Supported by NIH grant NS24752 and the MDA.

ROOM TEMPERATURE CULTURE EXTENDS THE USEFUL LIFE OF ADULT NEURONS FOR VOLTAGE-CLAMP EXPERIMENTS. J.C. Magee and G.G. Schofield. Dept. of Physiology, Tulane Univ. Sch. Med., New Orleans, LA 70112.

The detailed investigation of membrane currents has been greatly advanced in recent years through the use of the patch-clamp technique. The utility of acutely isolated adult mammalian neuronal populations in such investigations has been established. In an effort to increase the utility of these preparations, adult SCG neurons were maintained for four days in a room temperature (22° C) culture (22° C neurons). Under these conditions the neurons retained the advantages of the acutely isolated cells, including the lack of processes. Properties of the voltage-dependent sodium current (I_{Na}) in these neurons were compared with those of neurons of the same cell type maintained in a 37° C culture for the same period of time (37° C neurons) and with neurons used on the day of isolation (acute neurons). The 37° C neurons displayed a hyperpolarized half activation voltage and a smaller inactivation slope factor (K) than the acute neurons. No differences were found between 22° C neurons and acute neurons for these parameters. However, maximal conductance was found to be significantly higher in the 22° C neurons than the other two groups. The observed alterations in the I_{Na} kinetics of the 37° C neurons are most likely indicative of poor spatial voltage control. The 22° C neurons did not show any alterations in I_{Na} kinetics following culture. Thus, short term room temperature culture extended the useful life of the acutely isolated neurons for most voltage-clamp experiments. Supported by the American Heart Assoc.,

A UNIQUE IN VIVO MODEL FOR EVALUATING LOCAL ANESTHETIC AGENTS. V.E. Paris*, N.A. Pahno*, D.D. Rigamonti, V.L. Jimmerson and G.F. Seng*. Dept. Chemistry, Walter Reed Army Medical Center, Washington, DC 20307-5100.

Studies of local anesthetics performed on rat sciatic nerve in vitro, using a standard nerve recording chamber, initially yielded inconsistent results (e.g. lack of long term nerve viability). The present study used an in vivo model to characterize local anesthetics in the PNS. The sciatic nerve of anesthetized rats was stimulated with a pair of electrodes attached proximally at the greater sciatic notch and recorded with a distal pair of electrodes in the tibial division near the ankle. Both pairs were embedded in wax to isolate them from surrounding tissue to avoid signal interference and ensure that the electrical signal traversed only the nerve. The elicited compound action potential was amplified, visualized and averaged (MI^2) . Local anesthetics and saline (\leq 30 μ 1) were injected directly into the nerve distal to the stimulating electrodes via a glass micropipette. Results from the *in vivo* model were consistent with previous reports using the *in vitro* chamber. Unmyelinated C fibers were blocked first, followed by $A-\delta$ fibers, and finally the $A-\alpha$ fractions. EMG response and the conduction in the fiber fractions typically returned in reverse order. These results demonstrate the utility of the model for evaluating local anesthetics.

FUNCTIONAL ANALYSIS OF SODIUM CHANNEL PHOSPHORYLATION. R.D. Smith and A.L. Goldin. Dept of Microbiology & Molecular Genetics, U. California, Irvine, CA 92717.

The effects of phosphorylation on rat brain Na⁺ channel function have been investigated using *Xenopus* oocytes as an expression system. Phosphorylation at protein kinase C (PKC) sites of the Na⁺ channel appears to decrease the amplitude of whole-cell Na⁺ currents, as determined by voltage-clamping. This is suggested by a significant decrease in measured Na⁺ currents when oocytes injected with Na⁺ channel a subunit mRNA are perfused with the phorbol ester PMA. In contrast, channel phosphorylation at protein kinase A (PKA) sites appears to increase the Na⁺ current amplitude, as evidenced by the fact that co-injection of an inhibitor of protein kinase A results in decreased current amplitudes. Co-injection of phosphatase leads to a significant decrease in Na⁺ currents, suggesting that phosphorylation. In addition to effects on current amplitude, phosphorylation at PKA sites is functionally more prominent than PKC phosphorylation. In addition to effects on current amplitude, phosphorylation appears to affect the voltage-dependent properties of the channel. PKC phosphorylation shifts only inactivation shifts only inactivation in the same direction and has no effect on the voltage-dependence of activation. The effects we are seeing may be due to phosphorylation of either the Na⁺ channel a subunit or accessory proteins of the channel. To determine which is the case, we have mutated five consensus PKA sites in the cytoplasmic linker between domains I and II and one consensus PKC site in the same linker region. The effects of these mutations on Na⁺ channel function will be presented.

IDENTIFICATION OF AMINO- AND CARBOXYL- TERMINAL SERINE RESIDUES ON THE VOLTAGE-SENSITIVE SODIUM CHANNEL FROM E. electricus PHOSPHORYLATED BY ENDOGENOUS KINASE. Mark C. Emerick* and William S. Agnew. Dept. of Cellular and Molecular Physiology, Yale University School of Medicine, New Haven, CT 06510.

In a previous study we have identified four amino- and carboxyl-terminal sites on the electroplax sodium channel high-molecular weight glycopeptide that serve as highly active substrates for cyclic-AMP-dependent protien kinase (PKA). The present study reveals two additional sites on the molecule that are susceptible to phosphorylation by PKA, and further demonstrates, by means of back-phosphorylation of purified sodium channels following phosphatase treatment, that four of the identified PKA phosphorylation sites are phosphorylated in vivo by cellular kinases. These sites of endogenous phosphorylation are all on serine residues: 6 or 7, 440, 1680, and 1776. All are on amino- and carboxyl-terminal domains. Threonine-17, while highly susceptible to phosphorylation by PKA in vitro, was not shown by this method to be phosphorylated in vivo. The location of phosphorylated residues on the terminal domains parallels the distribution of PKA consensus sequences in the primary structure of this channel, in contrast to the in situ phosphorylation of mammalian neuronal sodium channel alphasubunits on non-terminal domains, and is consistent with the possibility that these different sodium channel types are regulated in different ways (c.f. Emerick and Agnew Biochemistry, 1989, 28, 8367).

SEQUENCE-SPECIFIC ANTI-PEPTIDE AND ANTI-FUSION PROTEIN ANTIBODIES FOR CHARACTERIZATION OF MUSCLE SODIUM CHANNEL ISOFORMS IN NATIVE AND TRANSFECTED CELL LINES. C.Ukomadu. J.S.Trimmer and W.S.Agnew. Department of Cellular and Molecular Physiology, Yale University, New Haven, CT 06510.

We have previously cloned cDNAs encoding a TTX-sensitive voltage-sensitive sodium channel expressed in adult rat skeletal muscle, designated $\mu 1$. We have generated a panel of antibodies against the $\mu 1$ protein. Antibodies were raised against (1) synthetic peptides constructed from the $\mu 1$ amino acid sequence, and (2) fusion proteins derived by subcloning $\mu 1$ cDNA sequences downstream of the tryptophan E gene of E. coli. These antibodies recognize antigenic sites in rat skeletal muscle membranes (demonstrated by ELISA) and specifically label a glycopeptide of 240,000-260,000 Da on Western blots of the same membranes. Immunocytochemical experiments have revealed one antibody that binds to an extracellular site of the protein. Immunoprecipitation and immunocytochemical experiments indicate that this antibody cross-reacts with a second sodium channel isoform present in L6 cells. This cell line does not express μ1 mRNA or TTX-sensitive sodium currents, but does express a different transcript (μ2, or SkmII; Kallen et al: Neuron, 4:233,1990. Trimmer et al., Dev.Bio., submitted), and TTX-resistant sodium currents. These antibodies have been used to investigate redistribution of sodium channels accompanying formation of L6 myotubes, and in preliminary characterization of sodium channels in rat fibroblasts stably transformed with µ1 cDNA.

MOLECULAR CLONING AND CHROMOSOMAL LOCATION OF TWO HUMAN MUSCLE VOLTAGE-GATED SODIUM CHANNELS

TWO HUMAN MUSCLE VOLTAGE-GATED SODIUM CHANNELS A.L. George, M.E. Gellens, R.G. Kallen, and R.L. Barchi, Mahoney Institute of Neurological Sciences, University of Pennsylvania School of Medicine, Philadelphia PA 19104.

Multiple isoforms of voltage-gated sodium channels have been identified in skeletal muscle, brain, and heart. In rat skeletal muscle, two isoforms (SkM1, SkM2) have been cloned; SkM1 is the predominant tetrodotoxin (TTX)-sensitive sodium channel present in adult muscle, whereas SkM2 is expressed only during early development and following surgical denervation. SkM2 also appears to be identical to the predominant rat cardiac sodium channel, RH1, a putative TTX-resistant isoform. Using cDNA probes derived from rat SkM1 and SkM2, we have now cloned cDNAs representing homologous human muscle sodium channels by screening human skeletal muscle and cardiac cDNA libraries. From the skeletal muscle library we have isolated and sequenced a 3.6 kb cDNA clone which includes a region highly homologous with domain IV and Cmuscle library we have isolated and sequenced a 3.6 kb cDNA clone which includes a region highly homologous with domain IV and Cterminus of rat SkM1. From the human cardiac library, we have isolated and partially sequenced three overlapping cDNA clones (3.6, 4.3, 4.5 kb) which have ~ 85% nucleotide sequence identity with rat RH1 and SkM2, and encompass the entire coding sequence. Both human SkM1 (HSkM1) and human RH1 (HH1) homologs have extensive 3' noncoding regions (> 2 kb) which have distinct subtype specific nucleotide sequences. Using subtype specific probes and Southern blots prepared from BamHI-digested DNA from a panel of hamster/human somatic cell hybrids (BIOS, Corp.) we have assigned the HSkM1 gene to chromosome 17 and the HH1 gene to chromosome 3. In situ chromosome hybridization experiments are underway to confirm and refine these findings. underway to confirm and refine these findings

EFFECTS OF THE SEA AMEMONE TOXIN, ATX II, ON RAT BRAIN NA CURRENTS EXPRESSED IN XENOPUS OCCTIES., D.S. Krafte, K. Dillon, W.A. Volberg, and A.M. Ezzin. Dept. of Cardiovascular Pharmacology, Sterling Research Group, Rensselaer, NY 12144.

We have utilized the Xenopus occyte expression system to study the interaction of Anemonia sulcata toxin II (ATX II) with neuronal Na channels expressed from poly(A+) RNA as well as in vitro transcripts of a plasmid (pM860) encoding a Na channel alpha subunit. Poly(A+) RNA was extracted from the whole brains of two week old rats using a LiC1/Urea procedure while M860 RNA was in vitro transcribed using T7 polymerase. We injected 50-70 ng of poly(A+) or 5-7 ng of M860 RNA and voltage-clamp recording was done 2-5 days later. ATX II (50 nM) decreased rates of inactivation and increased peak current amplitude for channels expressed from poly(A+) RNA. Time constants at -10 mV increased by 19.3% and peak currents increased by 91%. In contrast, ATX II (50 nM) had less of an effect upon Na channels expressed from M860 RNA. The mean time constant increase data suggest that ATX II has a reduced effect upon the Na channel alpha subunit alone compared to its effects on channels expressed from poly(A+) RNA.

EXPRESSION OF SODIUM CHANNEL mRNA IN THE ADULT RAT SKELETAL MUSCLE FOLLOWING SURGICAL AND CHEMICAL DENERVATION. J. Yang. J.T. Sladky, and R.L. Barchi. Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104.

We have recently cloned a second sodium channel characteristic of denervated skeletal muscle (SkM-II). The tissue and developmental expression of SkM-II mRNA correspond to that of a TTX-resistant muscle sodium channel (Neuron 4, 233-42, '90). We are now examining factors controlling expression of this message and of SkM-I mRNA. Rat sciatic nerve was cut in the mid-thigh region and lower leg muscle was sampled at 6hr intervals between 24 and 48 hrs and at longer intervals until 17 days post-section. SkM-II mRNA was first detectable at 30 hr, reached a maximal level by 48 hr, and declined slowly to 50% of maximum by 17 days. Over the same period, SkM-I mRNA exhibited a small but variable increase over control values. The ratio of SkM-II: SkM-II mRNA was 2:1 and the absolute level of SkM-II mRNA ranged between 5 and 10 fmol/mg total RNA. Axotomy close to the innervated muscle resulted in 2 hr left shift in the early increase of SkM-II mRNA compared to section near the hip. 48 hr following intramuscular injection of botulinum toxin, a selective inhibitor of impulse-induced quantal acetylcholine release, a very low but detectable level of SkM-II mRNA was seen. By 5 days post-injection, however, the SkM-II message level was 4 times greater than that seen 5 days after axotomy. The left-shift in the time course of SkM-II expression early in botulinum-treated muscle, suggest that both non-quantal factors and impulse-induced cholinergic vesicle release may be involved in the suppression of SkM-II mRNA. Supported in part by NIH NS-08075 and by the MDA.

Cloning and production of site specific fusion proteins to human skeletal muscle sodium channel

<u>Tejvir S. Khurana and Eric P. Hoffman*</u> - Program in Neuroscience & *Dept. of Pediatrics, Harvard Medical School and The Children's Hospital, Boston, MA 02115.

We have used Trans-species Polymerase chain reaction mediated cloning to isolate cDNA's from the human homologue of the recently described vertebrate skeletal muscle sodium channels. Using this technique we targeted two predicted cytoplasmic domains of the channel for analysis. The Na 2 and Na 3 cDNA's that we have cloned are representative of regions similar to rat sequences that span the predicted cytoplasmic interdomain II-III and carboxyl tail domains, respectively. Na 2 and Na 3 clones were sequenced and the human sequence found to be extremely homologous to the rat sequence. These clones were spliced into pATH protein expression vectors, and 25 mg of homogeneous pure trpE fusion proteins expressed/ 100mL of bacterial culture. Antisera have been raised to these fusion proteins and seem to be quite sensitive, detecting as little as 10 ng of fusion proteins on western blots. The antisera also detect a large, ~250 kDa protein reactive from humas nursely approximation proteins. species from human muscle upon immunobloting.

POINT MUTATIONS IN A CYTOPLASMIC REGION WHICH MODIFY ACTIVATION AND INACTIVATION GATING OF SODIUM CHANNELS. R.H. Joho, J.R. Moorman. G.E. Kirsch, A.M. Brown. Dept. of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX; Dept. of Medicine, University of Texas Medical Branch, Galveston, TX.

We studied single channel gating kinetics of Xenopus oocyteexpressed type III Na* channels with mutations of the putative cytoplasmic segment linking domains III and IV. In cell-attached patches at test potential 0 mV, type III channels had fast activation (mean first latency 1.5 msec), slow inactivation (mean burst duration 11.4 msec), and quickly peaking, slowly decaying average single channel currents. Mutation KKK1453/4/7NNN (net charge change Δ -3) resulted in channels with short first latency (1.5 msec), short bursts (3.2 msec), and quickly peaking, quickly decaying average currents. Mutation R1461E (Δ -2) resulted in channels with long first latency (10.1 msec) and short bursts (2.3 macc). The gating changes were offsetting for this mutation, and average currents were not different from control. Mutation S1452A (Δ0) channels had long first latency (8.2 msec), short burst duration (4.8 msec), and slowly peaking, slowly decaying average currents. We conclude that the segment linking domains III and IV of voltage-dependent sodium channels modulates both activation and inactivation gating. Supported by NIH, Advanced Technology Program of the State of Texas, Kempner and Sealy Foundations, and AHA (Texas Affiliate).

ANALYSIS OF SODIUM CHANNEL INACTIVATION AS EXPRESSED IN XENOPUS OOCYTES FROM A SINGLE MRNA. V. V. Patel, S. R. Levinson and A. R. Martin. Dept. of Physiology. Univ. of Colo. Sch. of Med., Denver, CO

80262.

Sodium channels expressed in the Xenopus oocyte from a cRNA encoding just the α subunit often display slow inactivation kinetics (Auld et al., Neuron, 1:449, 1988). In order to determine the biophysical characteristics of this slow inactivation, we injected Xenopus oocytes with RNA transcribed in vitro from the cDNA of the μ1 sodium channel. Oocytes were assayed 3-5 days later, by the two-electrode voltage clamp technique, and 1-3μA sodium currents were typically recorded. These currents showed two phases in their inactivation, a "fast" component and a "slow" component, as expected. The fast component could be selectively eliminated by lowering the holding potential to -120mV, while the slow component could be eliminated by raising the holding potential to -60mV. The time constant of the slow inactivation depended on the amplitude of the depolarization step. The time constant decreased with depolarization up to about depolarization step. The time constant decreased with depolarization up to about -30mV, and then unexpectedly increased. Both components were equally sensitive to block by TTX with a K_d of about 6nM. Oocytes injected with poly(A)* RNA from rat brain showed only fast inactivating currents, as found in normal neuronal tissue. It does not appear that the fast and slow inactivating components were due to two separate populations of channels, as the peak conductances were not reduced when, for example, the fast component was eliminated. This work was supported by NIH grants NS09660 and NS15879.

ENHANCEMENT OF SODIUM CURRENTS IN THE XENOPUS OOCYTE EXPRESSION SYSTEM BY A COMPONENT OF FUNNEL-WEB SPIDER J.C. Dreixler and J.P. Leonard. Dept. of Biol.

Sciences, U. of Illinois at Chicago, Chicago, Il 60680.
We used <u>Xenopus</u> oocytes to express rat brain total RNA
in order to study the effects of a pure synthetic analog of funnel-web spider toxin (synthetic FTX) on voltage-dependent sodium currents. Using a two electrode voltage clamp technique, currents obtained with 100 nM tetrodotoxin (TTX) application were subtracted from control currents in order to specifically measure TTX-sensitive sodium currents. A second family of currents was obtained, using the same paradigm, with or without application of synthetic FTX (100 nM). The peak inward TTX-sensitive sodium currents increased to 128 \pm 9% (s.e.m.) of control with 100 hM of synthetic FTX versus 96 \pm 10% of control without (P < 0.05; n= 6 oocytes). The enhancement develops over a 2-3 min period after synthetic enhancement develops over a 2-3 min period after synthetic FTX application and seems to be irreversible. This pure component had no obvious effects on calcium-activated chloride tails in the oocytes. Thus the synthetic FTX may mediate the excitatory effects seen by previous investigators using funnel-web spider venom while the calcium channel blocking action may be mediated by a separate component of the venom. We thank Pfizer Central Research and Natural Products Sciences Inc. for the synthetic analog of FTX. (Supported by NIH NS26432)

MOLECULAR CLONING OF A HUMAN BRAIN SODIUM CHANNEL GENE. C.M. Lu, T.A. Rado*1, R.E. Powers* & G.B. Brown, Dept. of Psychiatry and Behavioral Neurobiology and ¹Division of Hematology/Oncology, University of Alabama at Birmingham, Birmingham,

185

AL 35294.

A DNA fragment from a human brain sodium channel gene has been cloned by polymerase chain reaction (PCR). The primers for PCR were designed based on published rat and eel sodium channel amino acid and cDNA sequences. Analysis of these sequences has revealed extensive interspecies homology and sequence conservation. The assumption, therefore, is that amino acid sequences which are most highly conserved in other species would also be conserved in the human gene. Using the BIGPROBE computer program, which takes into account species preferences in codon usage, a pair of primers, 20 nucleotides each, has been designed based on sequences flanking those conserved regions in rat and eel. Å 212bp PCR product was obtained when human genomic DNA was used as templates. This DNA fragment was cloned into M13 and subsequently sequenced, revealing 87% and 91% homology with rat brain sodium channel gene subtype I and II respectively and containing no intron. The presence of RNA transcripts of this gene in human brain tissue was demonstrated by the use of PCR on first strand cDNA (RT-PCR) synthesized from various sources. The RNA transcripts of this gene were found present in human brain tissue but not in T84 cells, a this gene were found present in human brain tissue but not in T84 cells, a human colonic carcinoma line with well defined ion currents in which no numan colonic carcinoma line with well defined ion currents in which no voltage gated sodium mediated excitability has been observed. Two approaches including screening of human brain cDNA libraries and RACE (Rapid Amplification Of cDNA End) technique have been used to extend this clone. This partially cloned gene is the first information concerning the molecular structure of human sodium channels and will serve as a starting point for future studies on the molecular biology of human sodium channel.

IDENTIFICATION AND IN SITU LOCALIZATION OF α SUBUNIT OF VOLTAGE-SENSITIVE SODIUM CHANNELS FROM DROSOPHILA USING POLYCLONAL ANTIBODIES. D. PAURON, M. AMICHOT* and J.B. BERGE*. I.N.R.A., Station de Recherches de Nématologie et de Génétique moléculaire des invertébrés, 123, bd Francis Meilland, B.P. 2078, 06606 Antibes Cedex, France,

Two genes homologous to vertebrate sodium channels have been cloned in Drosophila melanogaster. We have subcloned two cDNA fragn corresponding to the 3' end of one of these genes (the DSC1 one) in the expression vector pEX. The first fragment is 270 base pairs (bp) long and contain the sequence corresponding to a part of the region S2 and regions S3 and S4 of domain d. The other one comprises the S5 and S6 regions of domain d and is 680 bp long. Rabbits were immunized with the fusion products of these constructions. The polyclonal antibodies obtained were tested on purified membranes prepared from *Drosophila* heads in immunoblotting experiments. Both of them specifically recognize a protein with an apparent Mr of 250,000-260,000. This result is in good agreement with the reported size of the α subunit of Na channels present in nervous tissue as well as in other tissues in vertebrates and in invertebrates

We have also used these antibodies as markers of Na channels in frozen sections of adult *Drosophila*. The antibodies clearly stain structures in the central nervous system but no specific labelling can be detected in the rest of the body. These data strongly suggest that DSC1 is a structural gene coding for a functional Na channel. It is expressed at least at the adult stage where it seems to be restricted to the nervous system.

ION CHANNELS: MODULATION AND REGULATION I

86.1

GAP JUNCTION ANTIBODY ATTENUATES ELECTRICAL COUPLING BETWEEN THE GOLDFISH MAUTHNER (M-) CELL AND ITS 8TH NERVE AFFERENTS. <u>Daniel P.Yox</u>, <u>Donald S. Faber and Bruce J. Nicholson*</u>. Depts. of Physiology and Biological Sciences, University at Buffalo, Buffalo, NY 14214.

A highly specific antibody to the 43kD gap junction protein (Cx43) of rat detects this protein in myocytes, glia and CNS neurons, and has been shown to block intercellular coupling in the former. Because the M-cell receives mixed electrotonic and chemical input because the M-cell receives mixed electrotonic and chemical input from the saccular fibers of the 8th nerve, this presented an opportunity to analyze the modulatory role of the electrical component of this input. In five experiments, intracellular injections of affinity purified anti-Cx43 reduced the coupling potential produced by 8th nerve stimulation by 14-88%. This effect lasted the duration of the experiment (20min-2hr). Also, anti-Cx43 injections produced either no change or an increase (up to 97%) in injections produced either no change or an increase (up to 97%) in the chemically mediated EPSP. Resting potential was unchanged, and antidromic spike height, a measure of M-cell input resistance, was either unchanged or reduced. Injections of pre-immune IgG at similar concentrations had no effect on resting potential and antidromic spike height (N=3), while electrotonic coupling was either unchanged or increased slightly.

This suggests that anti-Cx43 recognizes an epitope in M-cell gap

junctions and that the resultant uncoupling enhances chemical transmission at these terminals. One explanation for the latter effect is that uncoupling increases evoked transmitter release by increasing presynaptic spike duration or amplitude. (Supported by DHHS: NS08819, NS15335, NS37109.)

86.2

VOLTAGE DEPENDENCE AND RECTIFICATION AT RAT CONNEXIN 26 AND 32 JUNCTIONS EXPRESSED IN XENOPUS OOCYTES. L.C. Barrio. T. Suchyna*. T. Bargiello. R. Roginski. R.S. Zukin. B. Nicholson and M.V.L. Bennett. Albert Einstein College of Medicine, Bronx, NY 10461 and SUNY Buffalo, Buffalo, NY 14260.

cRNAs encoding rat Cx26 or 32 were injected into defolliculated Xenopus oocytes. Antisense cDNA oligonucleotides to Xenopus Cx38 were coinjected to block endogenous coupling selectively. 24 hours later, vitelline membranes were removed and oocytes were paired. After 24-48 hours dual voltage clamp was used to measure junctional conductance (g.). In Cx26 pairs "instantaneous" g, (time resolution seloms) increased by about 1.3/V for depolarization of either cell, and decreased similarly for hyperpolarization of either cell (range ±100mV). This result indicates dependence on inside-outside voltage (V₁₀). For these pairs slow (r.) si decreases in g, up to 80% were caused by polarization of either cell. Decreases were nearly equal for equal de- and hyperpolarization of either cell indicating dependence on transjunctional voltage (V₁) and not on V₁₀. Y, at which the change was half maximal (V₂) was c. ±85mV. The g/V₁ relation was well fit by a Boltzmann relation, with sensitivity parameter A of 0.17, indicating an equivalent movement of c. 4 electron charges through the applied field. Cx32 pairs formed junctions with no V₁₀ dependence but with V₁ dependence similar to that of Cx26; Boltzmann parameters were V₁₀s.55mV and Aso(0.09mV. Oocytes expressing Cx36 formed rectifying junctions with oocytes expressing Cx32. Instantaneous g, depended linearly on V₁ with a slope of ≈3.3/V over a range of ±100mV with positive V₁ defined as positive on the Cx26 side. Large positive V₁ caused large (>90%) slow decreases in g₁ with V₂ and A more characteristic of Cx26 than of 32. In summary, 1) both Cx26 and 32 encode gap junctions that are voltage dependent, and 2) hemichannel properties are changed in the heterotypic 26/ that may be similar to those of rectifying electrical synapses.

HETEROGENEITY BETWEEN BRAIN AND HEART CONNEXIN43 R.Kadle and B.J.Nicholson*. Dept of Bi Sciences, SUNY at Buffalo, Buffalo, NY 14260.

Sciences, SUNY at Buffalo, Buffalo, NY 14260.
Western blots of rat heart ventricle and brain homogenates reveal different electrophoretic mobilities of Connexin43 (Cx43). While heart ventricle contains a major 43 kD band and a minor 39-40 kD doublet, the brain has only the lower doublet, with the 39 kD band being the more prominent of the two. The 39-40 kD doublet is not a proteolytic product of the 43kD band since both are recognized by N- as well C-terminal antibodies. Alkaline phosphatase treatment of immunoprecipitated material from heart ventricle reduces the 43 kd band to 39 kD. heart ventricle reduces the 43 kd band to 39 kD, but has no effect on the brain pattern. Thus the 39 kD band appears to be a the 39 kD band appears to be a non-phosphorylated form of Cx43. This is further supported by the observation that the in vitro translated Cx43 also migrates at 39kD and that translated Cx43 also migrates at 39kD and that phosphate incorporates only into the 43kD band in myocyte cultures. These observations suggest that different tissues maintain different overall levels of Cx43 gap junctional phosphorylation, with brain gap junctions being largely dephosphorylated. Supported by AHA largely dephosphorylated. Supporte 88-115F (RK) and NIH HL37109-05 (BJN).

86.5

HUMAN CONNEXIN43 CHANNELS UNITARY CONDUCTANCE IS ALTERED BY TREATMENTS THAT ACTIVATE PROTEIN KINASES AND IN MUTANTS LACKING PHOSPHORYLATION SITES. A.P. Moreno, G. Fishman* L. Leinwand*, and D.C. Spray. Depts. Neuroscience and Microbiology & Immunology, A. Einstein Coll. Medicine, Bronx, N.Y.

Gap junctions formed between SK Hepl cells after stable transfection with human connexin43 (Cx43) cDNA exhibit three channel sizes: 30 pS, due to low level expression of an endogenous channel, and 60 and 90 pS corresponding to Cx43 (see Fishman et al. abstract). This raises the question of why there are multiple channel sizes associated with expression of a single connexin. The amino acid sequence of human Cx43 predicts numerous phosphorylation sites on its carboxyl terminus. To determine whether modification of these sites might influence unitary conductance, we compared event histograms from cell pairs before and after exposure to 8Br-cAMP (1 mM) and phorbol ester (TPA, 100 nM). Within minutes of treatment, the relative frequency of the largest channels decreased and that of the 60 pS events increased. Thus, treatments that activate kinases A and C may change unitary conductance of the gap junction channel. The potential phosphorylation sites in the human Cx43 sequence might also be necessary for posttranslational processing and entry into the surface membrane. To test this hypothesis, cells were stably transfected with vectors containing mutagenized human Cx43, in which a stop codon was inserted in the 3' portion so as to encode proteins of about 32 and 26 kDa. Transfectants expressing these mutations were coupled; thus phosphorylation of Cx43 is not required for insertion or assembly of functional channels. Single channel conductances were about 168 and 48 pS for the longer and shorter constructs. Together, these findings indicate that the carboxyl terminal region of Cx43 is a domain influencing the unitary conductance of the Cx43 channel.

ADEMOSINE RECEPTORS MODULATE THE NAM-CAME EXCHANGER IN CEREBBAL MERVE ENDINGS.

It is now well accepted that Adenosine (A), by a presynaptic mechanism, prevents depolarization-induced release of various neurotransmitters in several brain regions. Although it has been proposed that A may prevent Cambridge and the several brain regions. dependent neurotransmitter release by blocking Ca entry through Voltage -operated Channels, the results are conflicting.

-operated Channels, the results are convicting.

The ais of the present study was to investigate the role played by A on the activity of the Na-Ca exchanger when this antiporter operates as a Ca influx pathway in Percoll-purified rat brain synaptosomes.

The methylxantine A receptor antagonist, theophylline(0.3-10 mH), dose dependently reinforced Na dependent Ca uptake elicited by extracellular Na removal (145 mH choline). This effect could not be ascribed to the inhibition of phosphodiesterase since either 8 Br-cAMP or forskolin failed to enhance Scarring influx due to the activation of the Na -ca exchanger.

30 ain. exposure of synaptosomes to 2.5 and 10 U/al of the enzyme adenosine

degainsse (ADA), which catabolizes A to inosine, caused an enhancement of the Na dependent 45Ca uptake. The selective agonist of A1 receptor, L-PIA (100 uH), which is not metabolized by ADA, completely counteracted the ADA-induced reinforcement of Na⁻-dependent ⁵Ca⁺ uptake, whereas the rather selective A receptor agonist, NECA (100 uH) was uneffective.

Collectively, these results are compatible with the hypothesis that A endogenously released from brain synaptosomes inhibits the activity of the Na -Ca antiporter when this exchanger works as a Ca influx pathway. (Supported by C.N.R. and M.P.I.60%-40% Grants to L.A., G.D.R.)

HUMAN CONNEXIN 43: FUNCTIONAL PROPERTIES DETERMINED IN STABLY TRANSFECTED HEPATOMA CELLS. G. Fishman*, A.P. Moreno, L. Leinwand*, and D.C. Spray. Depts. Microbiology & Immunology and Neuroscience, A. Einstein College of Medicine, Bronx, N.Y. 10461

Connexin 43 (Cx43) is the major gap junction protein in the cardiovascular system and is also expressed elsewhere, including between astrocytes and between leptomeningeal cells in brain. To compare the properties of the human Cx43 channel to those of other between astrocytes and between leptomeningeal cells in brain. To compare the properties of the human Cx43 channel to those of other gap junctions, a communication-deficient human hepatoma cell line (SKHep1) was transfected with a vector containing the full length coding sequence of human Cx43 (Fishman et al., (1990) J. Cell Biol., in press). After 3-4 weeks of selection, individual cells were injected with Lucifer Yellow and clones showing strong dye transfer were picked and subcultured. Pairs of these cells were voltage clamped using the dual whole cell method. Junctional conductance (g_j) in pairs of the transfected cells averaged >10 nS, compared to a very low level of coupling in the parental cell line. Voltage dependence of g_j was evaluated with transjunctional voltage (V_j) steps of \pm 70 mV. For V_j < 50 mV, g_j was constant (to within 10%); at higher voltages, g_j declined, reaching minimal values (still >50%) at the highest potentials. Unitary conductances of the human Cx43 channels were measured after g_j was reversibly reduced by exposure to halothane (2 mM). Three channel sizes were recorded. The smallest, about 30 pS, were the size of the channels occasionally recorded in the parental cell line. The others, 60 and 90 pS, were similar to sizes recorded from gap junction channels in other tissues expressing Cx43. All channels were distinct from 120-150 pS channels expressed in SKHep1 cells transfected with Cx32 cDNA (Eghbali et al., (1990) PNAS 87:1238). Connexin type thus appears to be a primary determinant of physiological properties of gap junction channels.

LONG-TERM STIMULATION OF Na*/Ca2+ EXCHANGE BY Mg.ATP IN GIANT EXCISED MEMBRANE PATCHES: PRIMARY PROTEIN IN GIANT EXCISED MEMBRANE PATCHES: PRIMARY PROTEIN OR LIPID EFFECT?. D.W. Hilgemann & A.Collins / UTSW / Dept. of Physiology / Dallas, Tx., 75235.

Outward Na*/Ca** exchange current in giant excised cardiac sarcolemmal patches is strongly stimulated by 'cytoplasmic' Ca** and Mg·ATP (Hilgemann, NATURE 334: 242, 1990). [Ca**]; is effective in the absence of ATP, and Mg·ATP (0.5 to 8 mM) is effective in the absence of [Ca**]; (10 mM EGTA). For the following reasons, involvement of a (serine) protein kinase in the ATP action appears unlikely:

1) H7 and peptide kinase inhibitors do not block, 2) ATP-gamma-S is ineffective. and 3) exceptous 1) H7 and peptide kinase inhibitors do not block, 2) ATP-gamma-S is ineffective, and 3) exogenous phosphatases do not accelerate decay of the ATP effect (t_{1/2}>15 min). The following findings support further testing of a possibility that the ATP action could involve establishment of lipid asymmetry by a phospholipid 'flipase': 1) Oxidizing agents, known to inhibit flipase activity, are highly effective blockers of [Mg·ATP], action from the external (pipette) side without inhibiting exchange (or sodium pump) current. 2) Reveral of ATP action is greatly accelerated by cytoplasmic diamide (1mM), which induces aminophospholipid flip. 3) Negatively charged detergents (<10, μM) imitate ATP action while positively charged detergents (<1 μM) imitate reversal of ATP action.

AN INHIBITOR OF ARACHIDONIC ACID METABOLISM INCREASES THE AMPLITUDE OF SPONTANEOUS VOLTAGE FLUCTUATIONS IN NEURONS K.S. Madden, G.D. Lange, A. Prasad, and J.L. Barker Laboratory of Neurophysiology and Instrumentation and Computer Section, NINDS, NIH Bethesda, MD 20892

We are using the acetylenic analogue of arachidonic acid, ETYA (5,8,11,14eicosatetraynoic acid), to probe the function of essential fatty acid (EFA) metabolism in spinal cord cells from the embryonic (E7.5-9) chick. In these studies, the drug's effects were assessed using conventional whole cell patch methods for recording intracellular voltages. Under control conditions, the membrane potential spontaneously fluctuated regardless of whether acutely dissociated or cultured cells were used. Superfusion with ETYA (0.01-1 mM) increased the magnitude of the fluctuations. Less often, it also hyperpolarized cells (range: 3-10 mV). Power spectra of the voltage noise showed a ten-fold increase in the signal amplitude with no change in the shape of the power density function. The corner frequency closely approximated the measured membrane time constant. The data were then analyzed using an algorithm developed to identify chaotic behavior [Albano et al, Phys. Rev. A 38(6): 3017 (1988)]. The voltage time series consistently generated the diagnostic of a deterministic system, a geometric display describing a chaotic attractor as shown in the stereogram below. The knotted configuration of this display can differ between cells, but it appears to be a generally stable characteristic of individual

cells. ETYA seems to "relax" the knots within the display. The relationship between this specific observation and the ability of ETYA to block EFA metabolism is not yet clear.

DIFFUSION AND DURATION OF PHYSIOLOGICAL INACTIVATION PRODUCED BY MICROINFUSIONS OF LIDOCAINE. D.C. Smith, R.L. Berry, M.L. Maring, M.A. Statnick*, C.L. Faingold and R.A. Browning, Dept. of Psychology and School of Medicine, Southern Illinois University-Carbondale, IL 62901.

Lidocaine hydrochloride is a local anesthetic which reversibly blocks sodium

Lidocaine hydrochloride is a local anesthetic which reversibly blocks sodium channels. As such, when microinfused into discrete brain loci, it reversibly blocks action potential generation. While we have demonstrated the effectiveness of such microinfusions in vivo (see Smith et al., Neurosci. Abst. 1983,84,85,87,88) in reversibly altering behavior, the diffusion characteristics and duration of inactivation following lidocaine microinfusion into the brain remained to be cuspified.
