SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 16, PART 2

20TH ANNUAL MEETING
ST. LOUIS, MISSOURI
OCTOBER 28–NOVEMBER 2, 1990

Made in the United States of America.
International Standard Book Numbers:
Part 1 ISBN 0–916110–34–6
Part 2 ISBN 0–916110–35–4
Both parts ISSN 0190–5295
Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:
Soc. Neurosci. Abstr., Vol. 16, Part 2, p. xxx, 1990.

Published by:
Society for Neuroscience
11 Dupont Circle, N.W.
Suite 500
Washington, DC 20036

Contents—Part 2

*7,979 volunteer abstracts, 15 symposia abstracts.

1990 Program Committee

Edward G. Jones, M.D., Ph.D., *Chairperson*
University of California College of Medicine

J. Anthony Movshon, Ph.D.
Incoming Chairperson
New York University

Richard W. Aldrich, Ph.D.
Stanford University Medical School

Theodore W. Berger, Ph.D.
University of Pittsburgh

James E. Blankenship, Ph.D.
Marine Biomedical Institute

Dennis W. Choi, M.D., Ph.D.
Stanford Medical School

Roland Ciaranello, M.D.
Stanford University Medical Center

Suzanne H. Corkin, Ph.D.
Massachusetts Institute of Technology

Antonio R. Damasio, M.D., Ph.D.
University of Iowa College of Medicine

Robert P. Elde, Ph.D.
University of Minnesota

Eberhard E. Fetz, Ph.D.
University of Washington School of Medicine

Howard L. Fields, M.D., Ph.D.
University of California Medical School

Eric Frank, Ph.D.
University of Pittsburgh Medical School

Karl Herrup, Ph.D.
Eunice Kennedy Shriver Center

Stephen M. Highstein, M.D., Ph.D.
Washington University School of Medicine

John P. Horn, Ph.D.
University of Pittsburgh Medical School

Robert L. Macdonald, M.D., Ph.D.
University of Michigan

Urs S. Rutishauser, Ph.D.
Case Western Reserve University

Elaine Sanders-Bush, Ph.D.
Vanderbilt University School of Medicine

Gerard P. Smith, M.D.
Cornell Medical Center

C. Dominique Toran-Allerand, M.D.
Columbia University College of
Physicians and Surgeons

Wylie W. Vale, Ph.D.
The Salk Institute

Robert D. Wurster, Ph.D.
Loyola University of Chicago

Patricia Goldman-Rakic, Ph.D., *ex officio*
Yale University School of Medicine

Robert H. Wurtz, Ph.D., *ex officio*
National Institutes of Health

Larry R. Squire, Ph.D., *ex officio*
University of California, San Diego
Medical School

CHRONOLOGICAL LIST OF SESSIONS

(See page xii for Thematic List of Sessions.)

TUESDAY

WEDNESDAY

THURSDAY

FRIDAY

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions, and symposia only.)

Session Number	Session Title	Type	Day & Time Mon.	Tue.	Wed.	Thu.	Fri.
Theme A: Development and Plasticity							
79.	Cell lineage I	Poster	mPM				
273.	Cell lineage II	Poster			wAM		
524.	Cell lineage III	Slide					fAM
135.	Cellular and molecular studies I	Slide		tuAM			
334.	Cellular and molecular studies II	Slide			wPM		
404.	Cellular and molecular studies III	Slide				thAM	
464.	Development and plasticity—visual system: connections	Slide				thPM	
213.	Development and plasticity—visual system: cortical anatomy	Poster		tuPM			
331.	Development and plasticity—visual system: molecular and cellular mechanisms I	Slide			wPM		
409.	Development and plasticity—visual system: molecular and cellular mechanisms II	Poster				thAM	
147.	Development and plasticity—visual system: retina and optic nerve	Poster		tuAM			
532.	Development and plasticity—visual system: retinotectal connections	Poster					fAM
82.	Differentiation, morphogenesis and development: cell surface and matrix components	Poster	mPM				
81.	Differentiation, morphogenesis and development: currents, channels, muscle development	Poster	mPM				
83.	Differentiation, morphogenesis and development: cytoskeleton	Poster	mPM				
141.	Differentiation, morphogenesis and development: fiber guidance and synaptogenesis	Poster		tuAM			
476.	Differentiation, morphogenesis and development: forebrain	Poster				thPM	
80.	Differentiation, morphogenesis and development: glia	Poster	mPM				
271.	Differentiation, morphogenesis and development: molecular correlates	Poster			wAM		
474.	Differentiation, morphogenesis and development: neurogenesis and survival	Poster				thPM	
272.	Differentiation, morphogenesis and development: neurotransmitters, peptides, hormones	Poster			wAM		
477.	Differentiation, morphogenesis and development: position and form	Poster				thPM	
475.	Differentiation, morphogenesis and development: tissue culture models	Poster				thPM	
143.	Endocrine control and development I	Poster		tuAM			
144.	Endocrine control and development II	Poster		tuAM			
196.	Formation and maturation of synaptic connections	Slide		tuPM			
391.	**Genetically Modified Cells: Development and Applications for the Neurosciences**	**Symp.**				**thAM**	
521.	**Glia: Synthesis of and Responses to Growth Factors and Neuropeptides**	**Symp.**					**fAM**
351.	Limbic system II	Poster			wPM		
65.	Long-term potentiation I	Slide	mPM				
212.	Long-term potentiation II	Poster		tuPM			
274.	Long-term potentiation III	Poster			wAM		
348.	Long-term potentiation IV	Poster			wPM		
407.	Long-term potentiation V	Poster				thAM	
3.	**Molecular Mechanisms of Neuronal Guidance**	**Symp.**	**mAM**				
145.	Motor systems: development and plasticity I	Poster		tuAM			
146.	Motor systems: development and plasticity II	Poster		tuAM			
70.	Nerve growth factors I	Slide	mPM				
132.	Nerve growth factors II	Slide		tuAM			
207.	Nerve growth factors III	Poster		tuPM			
208.	Nerve growth factors IV	Poster		tuPM			
342.	Nerve growth factors V	Poster			wPM		
343.	Nerve growth factors VI	Poster			wPM		
410.	Nerve growth factors VII	Poster				thAM	
411.	Nerve growth factors VIII	Poster				thAM	
467.	Nerve growth factors IX	Slide				thPM	
25.	Neural plasticity in adult animals I	Poster	mAM				
150.	Neural plasticity in adult animals II	Poster		tuAM			

Session Number	Session Title	Type	Day & Time Mon.	Tue.	Wed.	Thu.	Fri.
276.	Neural plasticity in adult animals III	Poster			wAM		
481.	Neural plasticity in adult animals IV	Poster				thPM	
347.	Neuronal death: deafferentation and prenatal studies	Poster			wPM		
408.	Neuronal death: lesion studies	Poster				thAM	
78.	Neuronal death: mechanisms	Poster	mPM				
456.	Neurotoxicity: other II	Poster				thAM	
350.	Neurotransmitter and neuromodulator development	Poster			wPM		
21.	Nutritional and prenatal factors	Poster	mAM				
149.	Ontogeny of dopaminergic systems	Poster		tuAM			
534.	Ontogeny of neuroendocrine systems	Poster					fAM
209.	Other trophic agents I	Poster		tuPM			
413.	Other trophic agents II	Poster				thAM	
68.	Process outgrowth, growth cones and guidance mechanisms I	Slide	mPM				
139.	Process outgrowth, growth cones and guidance mechanisms II	Poster		tuAM			
140.	Process outgrowth, growth cones and guidance mechanisms III	Poster		tuAM			
197.	Process outgrowth, growth cones and guidance mechanisms IV	Slide		tuPM			
262.	Process outgrowth, growth cones and guidance mechanisms V	Slide			wAM		
338.	Process outgrowth, growth cones and guidance mechanisms VI	Poster			wPM		
339.	Process outgrowth, growth cones and guidance mechanisms VII	Poster			wPM		
416.	Process outgrowth, growth cones and guidance mechanisms VIII	Poster				thAM	
417.	Process outgrowth, growth cones and guidance mechanisms IX	Poster				thAM	
463.	Process outgrowth, growth cones and guidance mechanisms X	Slide				thPM	
529.	Regeneration: chambers and grafts	Poster					fAM
479.	Regeneration: enhancement factors	Poster				thPM	
414.	Regeneration: general	Poster				thAM	
74.	Regeneration: general studies and molecular correlates	Slide	mPM				
77.	Regeneration: genes, inhibitory factors and axonal transport	Poster	mPM				
148.	Regeneration: molecular correlates	Poster		tuAM			
211.	Regeneration: specificity and functional recovery	Poster		tuPM			
265.	Sensory systems—development and plasticity I	Slide			wAM		
344.	Sensory systems—development and plasticity II	Poster			wPM		
345.	Sensory systems—development and plasticity III	Poster			wPM		
336.	Specificity and enhancement of regeneration	Slide			wPM		
142.	Specificity of synaptic connections	Poster		tuAM			
340.	Sprouting and sprouting mechanisms	Poster			wPM		
20.	Substances of abuse	Poster	mAM				
24.	Synaptogenesis in the CNS I	Poster	mAM				
533.	Synaptogenesis in the CNS II	Poster					fAM
415.	Synaptogenesis of neuromuscular junctions	Poster				thAM	
480.	The aging process: cell biology, morphometry, other	Poster				thPM	
349.	The aging process: learning and memory, growth factors, physiology	Poster			wPM		
19.	The aging process: neurotransmitters and endocrine regulation	Poster	mAM				
210.	Transplantation: anatomical projections	Poster		tuPM			
275.	Transplantation: behavioral and electrophysiological effects	Poster			wAM		
530.	Transplantation: expression of specific neuronal markers	Poster					fAM
22.	Transplantation: general I	Poster	mAM				
203.	Transplantation: general II	Slide		tuPM			
531.	Transplantation: general III	Poster					fAM
23.	Transplantation: new techniques and cell lines	Poster	mAM				
399.	Transplantation: new techniques, immune rejection and behavior	Slide				thAM	
478.	Transplantation: receptor expression	Poster				thPM	
346.	Transplantation: transmitter expression	Poster			wPM		
341.	Trophic interactions I	Poster			wPM		
412.	Trophic interactions II	Poster				thAM	

Theme B: Cell Biology

26.	Blood-brain barrier	Poster	mAM				
27.	Cytoskeleton, transport and membrane targeting	Poster	mAM				
71.	Gene structure and function I	Slide	mPM				
154.	Gene structure and function II	Poster		tuAM			
278.	Gene structure and function III	Poster			wAM		
483.	Gene structure and function IV	Poster				thPM	
214.	Membrane composition and cell surface macromolecules I	Poster		tuPM			

Session Number	Session Title	Type	Day & Time Mon.	Tue.	Wed.	Thu.	Fri.
418.	Membrane composition and cell surface macromolecules II	Poster				thAM	
277.	mRNA regulation: endocrine connection	Poster			wAM		
151.	mRNA regulation: general	Poster		tuAM			
484.	mRNA regulation: neuropeptides	Poster				thPM	
526.	mRNA regulation: peptides and c-fos	Slide					fAM
352.	mRNA regulation: transcription factors	Poster			wPM		
397.	mRNA regulation: transmitter enzymes and receptors I	Slide				thAM	
535.	mRNA regulation: transmitter enzymes and receptors II	Poster					fAM
153.	Neuroglia and myelin I	Poster		tuAM			
279.	Neuroglia and myelin II	Poster			wAM		
402.	Neuroglia and myelin III	Slide				thAM	
482.	Neuroglia and myelin IV	Poster				thPM	
28.	Staining, tracing and imaging techniques I	Poster	mAM				
29.	Staining, tracing and imaging techniques II	Poster	mAM				
152.	Staining, tracing and imaging techniques III	Poster		tuAM			
	Theme C: Excitable Membranes and Synaptic Transmission						
261.	Calcium channels I	Slide			wAM		
283.	Calcium channels II	Poster			wAM		
395.	Calcium channels III	Slide				thAM	
525.	Calcium channels IV	Slide					fAM
485.	Calcium channels and cellular calcium	Poster				thPM	
486.	Calcium channels: molecular properties	Poster				thPM	
219.	Calcium channels: pharmacology	Poster		tuPM			
125.	**Direct Ion Channel Gating by Intracellular Ions and Molecules**	**Symp.**		**tuAM**			
536.	Ion channels: cell function	Poster					fAM
280.	Ion channels: chloride and other channels	Poster			wAM		
420.	Ion channels: ligand-gated I	Poster				thAM	
421.	Ion channels: ligand-gated II	Poster				thAM	
86.	Ion channels: modulation and regulation I	Poster	mPM				
155.	Ion channels: modulation and regulation II	Poster		tuAM			
329.	Ion channels: modulation and regulation III	Slide			wPM		
522.	**Physiology of Peptidergic Nerve Terminals in the Vertebrate Neurohypophysis**	**Symp.**					**fAM**
30.	Postsynaptic mechanisms I	Poster	mAM				
202.	Postsynaptic mechanisms II	Slide		tuPM			
6.	Potassium channels I	Slide	mAM				
156.	Potassium channels II	Poster		tuAM			
218.	Potassium channels III	Poster		tuPM			
281.	Potassium channels IV	Poster			wAM		
76.	Presynaptic mechanisms I	Slide	mPM				
216.	Presynaptic mechanisms II	Poster		tuPM			
217.	Presynaptic mechanisms III	Poster		tuPM			
419.	Presynaptic mechanisms IV	Poster				thAM	
84.	Sodium channels I	Poster	mPM				
85.	Sodium channels II	Poster	mPM				
215.	Synaptic structure and function I	Poster		tuPM			
282.	Synaptic structure and function II	Poster			wAM		
31.	Synaptic transmission	Poster	mAM				
	Theme D: Neurotransmitters, Modulators, and Receptors						
353.	5HT receptors: behavior and pharmacology	Poster			wPM		
427.	$5HT_{1a}$ and other 5HT receptor subtypes	Poster				thAM	
537.	$5HT_3$ receptors	Poster					fAM
91.	Acetylcholine I	Poster	mPM				
434.	Acetylcholine II	Poster				thAM	
540.	Acetylcholine III	Poster					fAM
9.	Acetylcholine—receptors	Slide	mAM				
92.	Acetylcholine—receptors: muscarinic I	Poster	mPM				
227.	Acetylcholine—receptors: muscarinic II	Poster		tuPM			
435.	Acetylcholine—receptors: muscarinic III	Poster				thAM	
93.	Acetylcholine—receptors: nicotinic I	Poster	mPM				
285.	Acetylcholine—receptors: nicotinic II	Poster			wAM		

Session Number	Session Title	Type	Day & Time Mon.	Tue.	Wed.	Thu.	Fri.
165.	Behavioral pharmacology: acetylcholine, monoamines, and benzodiazepines	Poster		tuAM			
433.	Behavioral pharmacology: dopamine and hormones	Poster				thAM	
492.	Behavioral pharmacology: opiates, NMDA and others	Poster				thPM	
96.	Brain glutamate systems	Poster	mPM				
34.	Catecholamines I	Poster	mAM				
224.	Catecholamines II	Poster		tuPM			
332.	Catecholamines III	Slide			wPM		
431.	Catecholamines IV	Poster				thAM	
432.	Catecholamines V	Poster				thAM	
487.	Catecholamines VI	Poster				thPM	
164.	Cell biology of catecholamine receptors	Poster		tuAM			
5.	Cellular and molecular biology of catecholamine receptors	Slide	mAM				
493.	Cellular biology of 5HT receptors	Poster				thPM	
37.	Dopamine physiology I	Poster	mAM				
226.	Dopamine physiology II	Poster		tuPM			
490.	Excitatory amino acids: anatomy and physiology I	Poster				thPM	
491.	Excitatory amino acids: anatomy and physiology II	Poster				thPM	
356.	Excitatory amino acids: NMDA receptor antagonists	Poster			wPM		
430.	Excitatory amino acids: NMDA receptor glycine and polyamine sites	Poster				thAM	
489.	Excitatory amino acids: non-NMDA receptors	Poster				thPM	
161.	Excitatory amino acids: pharmacology I	Poster		tuAM			
200.	Excitatory amino acids: pharmacology II	Slide		tuPM			
284.	Excitatory amino acids: pharmacology III	Poster			wAM		
39.	Excitatory amino acids: receptors I	Poster	mAM				
40.	Excitatory amino acids: receptors II	Poster	mAM				
229.	Excitatory amino acids: receptors III	Poster		tuPM			
230.	Excitatory amino acids: receptors IV	Poster		tuPM			
231.	Excitatory amino acids: receptors V	Poster		tuPM			
259.	Excitatory amino acids: receptors VI	Slide			wAM		
396.	Excitatory amino acids: receptors VII	Slide				thAM	
88.	Excitotoxicity I	Poster	mPM				
89.	Excitotoxicity II	Poster	mPM				
90.	Excitotoxicity III	Poster	mPM				
128.	Excitotoxicity IV	Slide		tuAM			
461.	Excitotoxicity V	Slide				thPM	
36.	$GABA_A$ receptors I	Poster	mAM				
162.	$GABA_A$ receptors II	Poster		tuAM			
289.	$GABA_A$ receptors III	Poster			wAM		
335.	$GABA_A$ receptors IV	Slide			wPM		
429.	$GABA_B$ receptors	Poster				thAM	
257.	**Galanin: Multidisciplinary Studies**	**Symp.**			**wAM**		
134.	Interactions between neurotransmitters I	Slide		tuAM			
223.	Interactions between neurotransmitters II	Poster		tuPM			
354.	Interactions between neurotransmitters III	Poster			wPM		
290.	Localization of 5HT receptor subtypes	Poster			wAM		
470.	Localization of neurotransmitter receptor subtypes	Slide				thPM	
288.	Localization of neurotransmitter receptors I	Poster			wAM		
291.	Localization of neurotransmitter receptors II	Poster			wAM		
541.	Localization of peptide hormones and monoamines	Poster					fAM
287.	Mechanisms in transporter physiology	Poster			wAM		
94.	Molecular biology of dopamine receptors	Poster	mPM				
462.	Molecular neurobiology of 5HT receptors	Slide				thPM	
32.	Neurochemistry of transmitter systems	Poster	mAM				
423.	Opioids: anatomy and physiology I	Poster				thAM	
424.	Opioids: anatomy and physiology II	Poster				thAM	
95.	Opioids: behavior	Poster	mPM				
158.	Opioids: receptors I	Poster		tuAM			
159.	Opioids: receptors II	Poster		tuAM			
333.	Opioids: receptors III	Slide			wPM		
33.	Other biogenic amines and purines	Poster	mAM				
157.	Peptides: anatomical localization I	Poster		tuAM			
222.	Peptides: anatomical localization II	Poster		tuPM			

Session Number	Session Title	Type	Day & Time Mon.	Tue.	Wed.	Thu.	Fri.
166.	Peptides: biosynthesis and metabolism I	Poster		tuAM			
425.	Peptides: biosynthesis and metabolism II	Poster				thAM	
328.	Peptides: biosynthesis, metabolism and biochemical characterization	Slide			wPM		
87.	Peptides: physiological effects I	Poster	mPM				
221.	Peptides: physiological effects II	Poster		tuPM			
422.	Peptides: physiological effects III	Poster				thAM	
8.	Peptides—receptors	Slide	mAM				
471.	Peptides—receptors, metabolism and actions	Slide				thPM	
286.	Peptides—receptors: angiotensin, endothelin	Poster			wAM		
38.	Peptides—receptors: CCK, somatostatin	Poster	mAM				
220.	Peptides—receptors: other	Poster		tuPM			
428.	Receptor modulation: up and down regulation I	Poster				thAM	
468.	Receptor modulation: up and down regulation II	Slide				thPM	
539.	Receptor modulation: up and down regulation III	Poster					fAM
163.	Regulation of catecholamine receptors	Poster		tuAM			
459.	**Regulation of Nicotinic Acetylcholine Receptor Expression and Function**	**Symp.**				**thPM**	
160.	Second messengers I	Poster		tuAM			
228.	Second messengers II	Poster		tuPM			
264.	Second messengers III	Slide			wAM		
400.	Second messengers IV	Slide				thAM	
488.	Second messengers V	Poster				thPM	
538.	Second messengers VI	Poster					fAM
35.	Serotonin I	Poster	mAM				
225.	Serotonin II	Poster		tuPM			
426.	Serotonin III	Poster				thAM	
473.	Serotonin IV	Slide				thPM	
137.	Transmitters in invertebrates I	Slide		tuAM			
232.	Transmitters in invertebrates II	Poster		tuPM			
266.	Transmitters in invertebrates III	Slide			wAM		
355.	Transmitters in invertebrates IV	Poster			wPM		

Theme E: Endocrine and Autonomic Regulation

10.	Cardiovascular regulation I	Slide	mAM				
133.	Cardiovascular regulation II	Slide		tuAM			
98.	Cardiovascular regulation: brainstem and baroreflexes	Poster	mPM				
233.	Cardiovascular regulation: brainstem mechanisms	Poster		tuPM			
97.	Cardiovascular regulation: bulbospinal mechanisms	Poster	mPM				
234.	Cardiovascular regulation: hypothalamic, limbic, and cortical mechanisms	Poster		tuPM			
195.	Hypothalamic-pituitary-adrenal regulation	Slide		tuPM			
41.	Hypothalamic-pituitary-adrenal regulation: CRF	Poster	mAM				
292.	Hypothalamic-pituitary-adrenal regulation: other	Poster			wAM		
439.	Hypothalamic-pituitary-adrenal regulation: steroids	Poster				thAM	
126.	Hypothalamic-pituitary-gonadal regulation I	Slide		tuAM			
393.	Hypothalamic-pituitary-gonadal regulation II	Slide				thAM	
168.	Hypothalamic-pituitary-gonadal regulation: GnRH	Poster		tuAM			
167.	Hypothalamic-pituitary-gonadal regulation: modulation by peptides	Poster		tuAM			
495.	Hypothalamic-pituitary-gonadal regulation: modulation by steroids and monoamines	Poster				thPM	
403.	Neural-immune interactions I	Slide				thAM	
497.	Neural-immune interactions II	Poster				thPM	
498.	Neural-immune interactions III	Poster				thPM	
499.	Neural-immune interactions: interleukins	Poster				thPM	
494.	Neural-immune interactions: stress and behavior	Poster				thPM	
42.	Neuroendocrine regulation: other I	Poster	mAM				
359.	Neuroendocrine regulation: other II	Poster			wPM		
542.	Neuroendocrine regulation: other III	Poster					fAM
438.	Neuroendocrine regulation: oxytocin, vasopressin	Poster				thAM	
460.	**Neuronal Regulation of Renal Function: A Model System for Nervous System Interactions**	**Symp.**				**thPM**	
269.	Regulation of autonomic and respiratory functions	Slide			wAM		
437.	Regulation of autonomic function: control of lumbosacral autonomic outflow	Poster				thAM	

Session Number	Session Title	Type	Day & Time Mon.	Tue.	Wed.	Thu.	Fri.
358.	Regulation of autonomic function: gastrointestinal control	Poster			wPM		
357.	Regulation of autonomic function: peripheral autonomic organization and functions	Poster			wPM		
496.	Regulation of autonomic function: temperature regulation and neural-immune system interactions	Poster				thPM	
436.	Respiratory control	Poster				thAM	
405.	Steroids: receptors and actions	Slide				thAM	
	Theme F: Sensory Systems						
192.	**Brain Modulation of Sensory Signals**	**Symp.**		**tuPM**			
45.	Chemical senses: central pathways I	Poster	mAM				
170.	Chemical senses: central pathways II	Poster		tuAM			
17.	Chemical senses: peripheral mechanisms I	Slide	mAM				
363.	Chemical senses: peripheral mechanisms II	Poster			wPM		
364.	Chemical senses: peripheral mechanisms III	Poster			wPM		
392.	**Differential Processing of Visceral and Somatic Input in the Central Nervous System**	**Symp.**				**thAM**	
62.	**Hair Cells of the Inner Ear: Structure, Transduction, and Active Motion**	**Symp.**	**mPM**				
169.	Invertebrate sensory systems	Poster		tuAM			
43.	Pain modulation: anatomy and physiology I	Poster	mAM				
44.	Pain modulation: anatomy and physiology II	Poster	mAM				
73.	Pain modulation: anatomy and physiology III	Slide	mPM				
236.	Pain modulation: anatomy and physiology IV	Poster		tuPM			
173.	Pain modulation: pharmacology I	Poster		tuAM			
237.	Pain modulation: pharmacology II	Poster		tuPM			
267.	Pain modulation: pharmacology III	Slide			wAM		
172.	Pain modulation: spinal opioid pharmacology	Poster		tuAM			
294.	Pain: pathways I	Poster			wAM		
472.	Pain: pathways II	Slide				thPM	
440.	Pain—pathways: response to injury	Poster				thAM	
298.	Sensory systems—auditory system: central pathways I	Poster			wAM		
330.	Sensory systems—auditory system: central pathways II	Slide			wPM		
299.	Sensory systems—auditory system: central physiology I	Poster			wAM		
362.	Sensory systems—auditory system: central physiology II	Poster			wPM		
361.	Sensory systems—auditory system: hair cells and cochlea I	Poster			wPM		
442.	Sensory systems—auditory system: hair cells and cochlea II	Poster				thAM	
360.	Sensory systems—auditory system: models	Poster			wPM		
300.	Sensory systems—auditory system structure: function of identified cells	Poster			wAM		
171.	Sensory systems—retina: receptors, outer retina, ERG	Poster		tuAM			
441.	Sensory systems—retina: retinal chemistry and anatomy	Poster				thAM	
201.	Sensory systems—retina: retinal circuits	Slide		tuPM			
501.	Sensory systems—retina: retinal ganglion cells	Poster				thPM	
297.	Sensory systems—retina: retinal signals	Poster			wAM		
72.	Sensory systems—subcortical visual pathways: LGN	Slide	mPM				
543.	Sensory systems—subcortical visual pathways: midbrain, etc.	Poster					fAM
296.	Sensory systems—subcortical visual pathways: retinal projections and thalamus	Poster			wAM		
47.	Sensory systems—subcortical visual pathways: superior colliculus and related	Poster	mAM				
130.	Sensory systems—visual cortex: architecture and function	Slide		tuAM			
295.	Sensory systems—visual cortex: connections	Poster			wAM		
238.	Sensory systems—visual cortex: evoked potentials and stimulation	Poster		tuPM			
260.	Sensory systems—visual cortex: extrastriate cortex	Slide			wAM		
523.	Sensory systems—visual cortex: intracortical interactions	Slide					fAM
7.	Sensory systems—visual cortex: motion pathways	Slide	mAM				
502.	Sensory systems—visual cortex: response properties	Poster				thPM	
102.	Sensory systems—visual cortex: theoretical approaches	Poster	mPM

SCOPOLAMINE DISRUPTS WORKING MEMORY MORE IN THE MORNING THAN IN THE AFTERNOON. S.D. Drastal*, W.N. Tapp, B.H. Natelson, T.A. Pritzel*. VA Medical Center & New Jersey Medical School, East Orange, NJ 07019.

Performance fluctuates across the day in both people and animals. To examine the psychobiological influences on performance rhythms, this study determined the role of working memory in daily performance of rhesus monkeys. We studied the effects of scopolamine on performance at two different times of the day. Scopolamine injections were given at 1 and 5 hrs after lights-on. We used doses reported to affect working memory selectively.

To earn their food, monkeys had to perform a vigilance task followed by a color-position discrimination task. Trials were delivered on the average of every 2.4 min, and response latencies and choices were recorded. We noticed there was a pause in performance after the scopolamine injection. This pause lasted longer after the morning dose than in the afternoon and their performance recovered sooner in the afternoon.

Normally, these monkeys made only 1 to 3 discrimination mistakes per day. We compared performance for the 5 hrs following scopolamine with the comparable time period in baseline nodrug- and saline-injected conditions. The monkeys made 5.15 times more mistakes when given scopolamine ($p < 0.001$) . The monkeys made nearly twice the number of mistakes in the morning (6.78) as they did in the afternoon (3.52) following a scopolamine injection ($p < 0.02$).

The time of day differences in mistakes under the influence of scopolamine suggests that working memory is more susceptible to disruption in the morning. This pattern of susceptibility might be adaptive if we assume that natural disruptions of memory, such as fatigue, are more likely to occur in the afternoon when the animal is resistant to such disruptions. Supported by VA Research.

374.14

CONTINUOUS INTRACEREBROVENTRICULAR (ICV) INFUSION OF SCOPOLAMINE IMPAIRS CONTINUOUS PERFORMANCE IN RHESUS MONKEYS. M.J. Callahan, J. Kinsora, R.E. Davis, R. Harbaugh and T. Reeder. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105 and Dept. of Neurosurgery, Dartmouth Med. Sch., Hanover, NH 03756.

Scopolamine impairs cognitive function in animals and humans when adminstered systemically. Since scopolamine has profound effects on peripheral and central cholinergic function, we developed a convenient refillable system for continuously adminstering compounds to the central nervous system of rhesus monkeys.

Two eight year old male rhesus monkeys were implanted with a subcutaneous infusion pump connected to a cannulae stereotaxically directed toward the right lateral ventricle. Continuous ICV infusion of scopolamine produced a dose-dependent decrease in the number of responses. The magnitude of the response decrement produced by scopolamine was dependent on the stimulus duration with fewer responses occurring at the shorter stimulus durations. This decrease in performance was also time dependent and occurred mainly during the last half of the test session.

These data suggest that scopolamine produces a deficit in sustained attention that is mediated through direct central cholinergic blockade in the rhesus monkey. These procedures were well tolerated and the system has remained functional over an extended time period.

374.15

EFFECTS OF SCOPOLAMINE AND CLONIDINE ON RECOGNITION MEMORY IN RHESUS MONKEYS WITH LESIONS OF THE BASAL FOREBRAIN CHOLINERGIC SYSTEM. C. Chavoix, T. Aigner, H. Ogura* and M. Mishkin. Laboratory of Neuropsychology, NIMH, Bethesda, MD, 20892.

Both acetylcholine (ACh) and norepinephrine (NE) are thought to play critical roles in processes of memory. Recent evidence suggests that NE may influence the activity of ACh neurons in the basal forebrain (BF). In an attempt to investigate the mnemonic contributions of these 2 neurotransmitters, we administered the muscarinic antagonist scopolamine (SCOP) and the α_2 agonist clonidine (CLON) to 4 monkeys with BF lesions (group L) and 3 unoperated control monkeys (group C). Animals were first trained in delayed nonmatching-to-sample with a 10-s delay between sample presentation and choice. Bilateral BF lesions were then made by injecting ibotenic acid into 17 target sites in each hemisphere. Magnetic resonance imaging was used to locate the target sites and to confirm the accuracy of the lesions. Postoperatively, group L was slower than group C to relearn the task, but performed normally at delays up to 120 s. At the most difficult test of remembering a list of 20 items, performance of group C improved by 14% with continued practice, whereas that of group L remained the same. Although SCOP (0.32, 1, 3.2, 5.6, 10 & 17.8 µg/kg, IM) impaired the performance of both groups, the effect was greater in group L. Moreover, CLON (0.032, 0.1, 0.32, 1, 3.2, 10, 32, and 42.3 µg/kg, IM) differentially affected performance in the two groups. These results emphasize the role of ACh and, further, suggest a complementary role of NE in recognition memory in primates.

374.16

SINGLE DOSE PHARMACO-EEG PREDICTS RESPONSE TO TETRAHYDROAMINOACRIDINE TREATMENT IN ALZHEIMER'S DISEASE. H. Soininen*, K. Alhainen*, J. Partanen* and P. Riekkinen. Dept. of Neurology and Clinical Neurophysiology, University of Kuopio, P.O.Box 6, 70211 Kuopio, Finland.

Only 30-50% of Alzheimer (AD) patients benefit from various cholinomimetics such as tetrahydroaminoacridine (THA). Because we recently showed that progressive EEG decline is perhaps related to cell damage of the nucleus basalis of Meynert, it was reasonable to assume that EEG may help to identify responders to THA. We selected 12 AD patients (NINCDS-ADRDA criteria) and 7 controls with AAMI (age associated memory impairment without dementia). AD patients had 7-week THA treatment and seven of them were responders. In both groups a baseline EEG and another EEG at 90 min after a single dose of 50 mg THA were recorded.

In responders alpha-delta ratio increased 57.6% and alpha-theta ratio increased 61.4% compared to baseline. In nonresponders alpha-delta ratio and alpha-theta ratio decreased 33.3% and 10.7%, respectively. The AAMI group showed no change in these parameters. These results suggest that a single dose pharmaco-EEG predicts treatment response to THA.

NEUROPEPTIDES AND BEHAVIOR III

375.1

MU-OPIOID AGONIST AUGMENTS LOCOMOTOR ACTIVITY AFTER BILATERAL 6-HYDROXYDOPAMINE LESIONS IN THE NUCLEUS ACCUMBENS WITHOUT INVOLVING RECEPTOR UPREGULATION. L. Churchill and P.W. Kalivas. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

The mesolimbic dopamine system was lesioned by bilateral injection of 6-hydroxydopamine into the nucleus accumbens of rats. Ten days or more after the lesion, loçomotor activity increased to a significantly greater extent after microinjection of the μ-opioid agonist, Tyr-D-Ala-Gly-mePhe-Gly-OH (DAGO). A much smaller lesion-induced increase was observed after the δ-opioid agonist [D-penicillamine^{2,5}]-enkephalin (DPDPE). Receptor autoradiography with [^{125}I]DAGO or [^{125}I]DPDPE binding to the opioid receptors showed no significant differences between control and lesioned rats at 10 days after the lesion. Forskolin (1 μM) stimulated adenylate cyclase to a greater extent in the lesioned rats than in the sham treated rats (ascorbic acid treatment), but the opioid inhibition of forskolin stimulation did not differ between controls and lesioned rats. DAGO appeared more effective than DPDPE at inhibiting forskolin-stimulated adenylate cyclase. In conclusion, the behavioral analyses argue for a greater upregulation of the μ-opioid induced motor activity than that of the δ-opioid after dopamine depletion. The mechanisms underlying this augmentation do not appear to be caused by an increase in opioid receptor binding or inhibition of adenylate cyclase.

375.2

NEUROENDOCRINE MODULATION OF LOCOMOTOR ACTIVITY IN AN AMPHIBIAN: CORTICOTROPIN-RELEASING FACTOR AND OPIOIDS. C.A. Lowry, P. Deviche and F.L. Moore. Oregon State Univ., Corvallis, OR 97331.

Studies using mammals indicate that corticotropin-releasing factor (CRF) may coordinate physiological, autonomic and behavioral responses to stressful stimuli. We present evidence that CRF is involved in regulating stress-induced behavior in amphibians and further that the behavioral effects of CRF are modulated by the opioid system. Intracerebroventricular (icv) injections of ovine CRF dose-dependently stimulated locomotor activity in male rough-skinned newts (*Taricha granulosa*). This effect of CRF was completely blocked by the CRF receptor antagonist, α-helical CRF$_{9\text{-}41}$ (ahCRF). In other experiments, exposure to stressful environmental stimuli (either warm water or a 30 s period of handling) also stimulated locomotor activity. Injections of ahCRF reduced stress-induced locomotor activity regardless of the nature of the stressful stimulus.

Studies with opioid agonists and antagonists suggest that CRF and opioids interact to control locomotor activity in *T. granulosa*. The opioid μ-receptor agonist, morphine, at a dose that did not affect spontaneous locomotor activity, suppressed CRF-induced locomotor activity in a naloxone-reversible manner. In contrast, the preferential opioid kappa-receptor agonist, bremazocine, which dose-dependently suppressed spontaneous locomotor activity, did not affect CRF-induced locomotor activity. Experiments using the opioid receptor antagonist, naloxone, found that naloxone had no effect on spontaneous locomotor activity but under certain conditions enhanced CRF-induced locomotor activity. Although the effect of naloxone on CRF-induced locomotor activity is opposite to that typically observed in mammals, our other results are consistent with observations in mammals. Thus the neuroendocrine mechanisms controlling stress-induced locomotor activity appear to be evolutionarily conserved among vertebrates.

375.3

PERIPHERALLY ADMINISTERED SUBSTANCE P: EFFECTS ON FUNCTIONAL RECOVERY AFTER NIGROSTRIATAL 6-OHDA LESIONS AND ON STRIATAL DOPAMINE AS MEASURED BY IN-VIVO MICRODIALYSIS.
F.Boix*, R.Mattioli*, F.Adams*, R.K.W.Schwarting and J.P. Huston. Inst. of Physiol. Psychol. I, Univ. of Düsseldorf, Universitätsstr. 1, 4000 Düsseldorf, FRG

A close neural and functional relationship has been shown between nigrostriatal dopamine (DA) and the neuropeptide substance P (SP). Furthermore, SP can improve recovery after lesions of neural tissue. These results indicate that SP might have ameliorating effects after lesions aimed at nigrostriatal DA. To test this hypothesis, rats received daily injections of SP (50ug/kg, ip) after unilateral 6-OHDA lesions of the substantia nigra. 12 hours after each injection, they were tested for behavioral asymmetries. SP affected behavior in animals with moderate DA depletions. These animals showed no asymmetry in turning and an enhanced recovery from the asymmetry in scanning behavior. They also showed an increased striatal DA metabolism (post mortem). In a second study, the effect of SP was analyzed on extracellular DA in intact, freely-moving animals by means of the microdialysis technique. SP increased neostriatal DA, and this effect could be observed for several hours. These results demonstrate behavioral and neurochemical effects of SP related to DAergic mechanisms both in intact and brain-damaged animals. They are discussed with respect to the possible central and peripheral actions by which this neuropeptide may affect central DA and the recovery from DAergic lesions.

375.4

CHOLECYSTOKININ-INDUCED REDUCTION IN BODY TEMPERATURE ABOLISHED BY VENTRAL TRUNK VAGOTOMY.
E.H. South and P.D. Huff*, Dept.of Vet.Sci., Univ.of Idaho,Moscow,ID 83843.

The sensory neurotoxin, capsaicin, abolishes reduction of body temperature as well as the vagally mediated suppression of food intake by cholecystokinin octapeptide (CCK)(South,et al;NS Abst,1989). We now find that rats with a complete transection of the subdiaphragmatic ventral trunk of the vagus (VAGX) do not reduce rectal temperature (RT) in response to 4 µg/kg CCK although their CCK-induced suppression of food intake is equivalent to sham vagotomized controls (SHAM). The RT (^{o}C) of the VAGX and SHAM rats 20 min after ip saline or CCK and the shift in RT from preinjection to the 20 min time point (^{o}C diff) are tabulated below.

	Saline ip		CCK 4 µg ip	
	20 min	^{o}C diff	20 min	^{o}C diff
VAGX	37.7±0.0	0.5±0.1	37.5±0.1	0.4±0.1
SHAM	37.6±0.1	0.5±0.1	37.0±0.1	-0.1±0.1*

[means ± SE; * RT significantly (p<.01) less than 20 min SHAM and CCK saline and VAGX CCK day]

In tests with a preferred food present, there was no difference in percent suppression of food intake in response to 4 µg/kg CCK between VAGX (93±4%) and SHAM (96±1%) groups. Our findings indicate that the reduction of body temperature by CCK is mediated by vagal neurons which appear to be distinct from the vagal neurons mediating suppression of food intake.

375.5

CRF-MICROINFUSION INTO THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS (PVN) HAS DUAL EFFECTS ON BEHAVIORAL PARAMETERS IN RATS.
H. Mönnikes*, I. Heymann-Mönnikes* and Y. Taché.
CURE/VA Wadsworth Medical Center, Dept. of Medicine and Brain Research Institute, UCLA, Los Angeles, CA 90073.

CRF injected ICV has dual dose-related effects on behavior in rats (increased locomotion at low and freezing-behavior at high doses). CRF injected into the PVN increases locomotion and grooming but whether the PVN is involved in mediating these dose-related behavioral responses to central CRF is unknown. Therefore, in this study we assessed if different CRF doses microinfused into the PVN mimick the ICV-effects of the peptide on behavior. 90 SD-rats were implanted with a 22G guide cannula 3 mm above the PVN or the lateral hypothalamus (LH). 7 days later, in fasted freely moving rats, CRF or vehicle was microinjected (100 nl) via a 30G cannula. Behavioral parameters were monitored 15 min later for 45 min in a familiar environment. Results: (mean±SEM; $^{(1)}p<0.01$, $^{(2)}p<0.001$, $^{(3)}p<0.005$; t-test). CRF microinjected into the PVN increased grooming dose-dependently from 12±4 (vehicle) to 60±15$^{(3)}$ (0.06 nmol), 69±11$^{(2)}$ (0.2 nmol) and 114±2$^{(2)}$ (0.6 nmol). Locomotion increased from 19±4 to 40±9$^{(1)}$ (0.06 nmol) whereas at the higher dose (0.6 nmol) it decreased to 3±2$^{(3)}$ and freezing-behavior occured in 30%. CRF (0.2 nmol) microinfused into the LH had no effect on these parameters. These data show that the PVN is a sensitive site for the dose-related and dual alterations of behavior induced by CRF. This results and previous studies (Gastroenterology 98: A512, 1990) suggest, that the PVN is an important site to integrate both behavioral and visceral effects of CRF.

IN VIVO EVIDENCE FOR A NEUROTENSIN/ADENOSINE INTERACTION IN CNS.
F.B. Jolicoeur and D. Ménard. Departments of Psychiatry and Pharmacology, University of Sherbrooke, Faculty of Medicine, Sherbrooke, Québec, Canada, J1H5N4.

Although much emphasis has been placed on the interaction of neurotensin and dopaminergic transmission, it has become increasingly evident that the peptide interacts with a multiplicity of transmitters. To our knowledge the possibility that "purinergic transmission" is involved in neurotensin's central actions has not been examined previously, and is the focus of the present study. This was prompted by the observation that the neurobehavioral effects of adenosine agonists are strikingly similar to those produced by neurotensin.

In preliminary experiments we determined that the IP administration of 10 mg/kg of the adenosine antagonist, theophylline, did not in itself affect either body temperature or motor activity of rats. We then examined the effects of pre-administration of this dose of the drug 30 min prior to the ICV administration of several doses of neurotensin (3.75-30.0 µg) on hypoactivity and hypothermia induced by the peptide.

Results indicate that theophylline completely blocked or significantly attenuated the hypothermia induced by 3.75 and 7.5 µg neurotensin respectively. The decrease in body temperature induced by larger doses of the peptide were not affected by the adenosine antagonist. For motor activity, theophylline systematically abolished the hypoactivity produced by 3.75, 7.5 and 15 µg neurotensin. On the other hand, the reduction in activity induced by 30 µg of the peptide was not significantly affected by theophylline.

Although the exact nature of theophylline's blockade of neurotensin's central actions remains to be determined, these early results point to a neurotensin/adenosine interaction.

NEUROTENSIN IN CHRONIC NEUROLEPTIC EFFECTS.
A. J. Stoessl & E. Szczutkowski*. Dept. of Clinical Neurological Sciences, Univ. of Western Ontario, London, Ontario, Canada.

Chronic neuroleptic administration produces a syndrome of vacuous chewing mouth movements (VCM's) in rodents, which may serve as a model for tardive dyskinesia, and also results in elevations of striatal neurotensin (NT)-like immunoreactivity and nigral NT binding. We examined the effects of NT manipulations on chronic neuroleptic-induced VCM's in the rat. Male Sprague-Dawley rats received fluphenazine (FLU; 12.5 mg/kg) or its vehicle (VEH; sesame oil) IM every 3 weeks for 18 weeks, and beginning 4 weeks after the last injection of FLU or VEH, were then observed continuously for 60 min. following the intracerebroventricular administration of NT (1ug, 2ug), the NT antagonist D-Trp^{11}-NT (1ug, 2ug, 5ug), or their vehicle (0.9% saline). NT significantly increased the duration of VCM's in both FLU and VEH groups ($p<0.001$), but the effect was more pronounced in animals treated with FLU. Although there was a tendency for D-Trp^{11}-NT to suppress VCM's in both groups, this effect did not reach significance. Locomotion was decreased in animals treated with FLU ($p=0.001$ in NT experiment, 0.003 in D-Trp^{11}-NT experiment), but neither NT nor D-Trp^{11}-NT modified this response. These results are compatible with a contribution of NT to the dyskinetic effects of chronic neuroleptics, but further delineation will require the development of better NT antagonists.

ASTROCYTIC BENZODIAZEPINE RECEPTORS AND THEIR ENDOGENOUS LIGANDS IN HEPATIC ENCEPHALOPATHY.
J.F. Giguere[1], J. Lavoie[1], M.C. Tonon*[1], L. Desy*[3], H. Vaudry*[2], G. Pelletier[3] and R.F. Butterworth[1], [1]Lab. of Neurochemistry, CRC A-V. Hôpital St-Luc, Montreal, Que., [2]Lab. Endocrinol., Université Rouen, France, [3]Groupe Endocrinol. CHU, Laval, Que., Canada.

There is evidence to suggest that benzodiazepine receptors or their endogenous ligands may play a role in the pathogenesis of hepatic encephalopathy (HE). Although central GABA-related benzodiazepine receptors are unchanged in HE, previous studies have shown that astrocytic "peripheral-type" benzodiazepine receptors (PTBR's) are significantly increased in density in postmortem brain tissue from cirrhotic patients who died in hepatic coma (Lavoie et al., Hepatology (1990). Following portacaval anastomosis (PCA) in the rat, binding sites for the PTBR ligand ^{3}H-PK 1195 were found to be similarly increased 2 to 3 fold in brain without concomitant changes of binding affinities. Diazepam Binding Inhibitor (DBI) is an endogenous ligand for benzodiazepine receptors, found both in astrocytes and neurons. Tryptic digestion of DBI yields Octadecaneuropeptide (ODN). The localization of ODN in brain was evaluated by immunohistochemical techniques using an ^{125}I-antibody of high specificity. Following PCA, ODN-immunoreactive material was found to be increased 3-fold in astrocytes of several brain regions. These findings suggest a role for astrocytic benzodiazepine receptors in the pathogenesis of experimental and human HE. (Funded by MRC Canada)

VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) IS A SECRETAGOGUE FOR PROTEASE NEXIN I (PNI) RELEASE FROM ASTROCYTES. B. W. *Festoff, J. S. Rao,* and D.E. Brenneman*, Department of Neurology, University of Kansas Medical Center, Kansas City, KS 66103, and Neurobiology (151), DVA Medical Center, Kansas City, MO. 64128. *LDN, NICHD, NIH, Bethesda, MD.

Communication between neurons and glia is a fundamental process underlying nervous system development. Signals arising from either cell type have critical actions on the other. VIP has been shown to increase survival (PNAS 83: 1159-1162, 1986) mediated through glial cells (JCB 104, 1603-1604, 1987). VIP, a known secretagogue, may enhance the release of glial-derived neuron survival factors. We now investigate if VIP may promote secretion of the serpin, GDN/PNI, from astrocyte cultures. Seventy percent confluent new born rat cortical astroglial cultures were incubated for 3 days with ^{35}S-methionine. Following the removal of excess label, VIP, VIP inactive analog, or somatostatin (at 0.1 nM) were incubated for 3 hours. The labeled medium was removed and incubated with non-immune serum or monospecific IgG against 47 kDa PNI. VIP doubled the proteins compared to control or VIP analog cultures, while somatostatin reduced it by fifty percent. Autoradiography showed a specific 3-fold precipitation of PNI by anti-PNI only after VIP treatment. These results indicate that VIP is a potent secretagogue of GDN/PNI which may have a fundamental influence on neuronal development.

THE ISOLATED EYESTALK OF THE CRAYFISH MAINTAINS A CIRCADIAN RHYTHM OF NEUROSECRETION. L. Rodríguez-Sosa*, J. Calderón*, J. Hernández and H. Aréchiga. Depto. de Fisiología, Biofísica y Neurociencias and Depto. de Biología Celular, CINVESTAV-IPN. Apdo. Postal 14-740, 07000 México, D.F.

The crustacean eyestalk is a putative circadian neurosecretory pacemaker. However, its capability to maintain a self-sustained circadian rhythm in vitro has not been demonstrated. In this work we report the persistence of a circadian rhythm in the amount of a neuropeptide in the isolated eyestalk of the crayfish Procambarus clarki.

As a marker of neurosecretion we used the Red Pigment Concentrating Hormone (RPCH) which was quantified. a) by immunoenzymatic assay (ELISA), with an antibody raised in our laboratory. b) by HPLC, and c) by bioassay on isolated crayfish epithelia. Isolated eyestalks were kept in organ culture during the experiment, in 20%Leibovitz medium, with 1% fetal calf serum. While in culture, they were subjected either to continuous darkness (D:D), cycles of 12:12 hrs. of light and darkness (L:D), or continuous light (L:L). In isolation the RPCH amount in the eyestalk varied in a circadian manner within a range of $2x10^{-12}$ gr to $8x10^{-9}$ gr, with maximum during night phase. τ was 25.5 $\pm$ 1.5 L:L; and 25 $\pm$ 1 in D:D.

TEMPERATURE MODULATES THE REGULATORY ACTIONS OF ALPHA BAG CELL PEPTIDE. R. Sanger Redman and R.W. Berry. Dept. Cell, Molecular, and Structural Biology, Northwestern Univ., Chicago, IL 60611.

Egg-laying in Aplysia californica is seasonal, occurring mainly in the summer, and is caused by a peptide egg-laying hormone (ELH) released during a discharge by the bag cells. Alpha bag cell peptide (α-BCP), one of the peptides secreted along with ELH, is suspected to play an autoregulatory role in modulating the characteristics of the discharge. The feedback effects of α-BCP have been reported as autoexcitatory by some and autoinhibitory by others, in experiments performed at 14°C and room temperature respectively. These temperatures approximate winter and summer water temperatures experienced by the animal; thus the effect of α-BCP may be temperature-dependent and may be a factor in determining the seasonality of egg laying. To test this possibility, α-BCP's effect on bag cell membrane potential was determined. At 15°, α-BCP caused a hyperpolarization, whereas at 20°, the peptide caused a small depolarization. Extracellular recordings revealed that at 15° α-BCP shortened the duration of the bag cell discharge and decreased the total number of action potentials generated. At 20°, the peptide lengthened the discharge and increased the number of action potentials. A transient rise in cAMP is associated with the discharge; therefore, we measured α-BCP's effect on bag cell cAMP levels at various temperatures throughout the animal's natural environmental range (12°-22°). The influence of α-BCP is highly temperature-sensitive. The function of the peptide reversed from inhibition (12-15°) to stimulation (17.5-22°) over a 2.5° range. These results imply that α-BCP is temperature-sensitive, functioning in an autoinhibitory manner at 15° and becoming autoexcitatory at 20°. Thus, it may function in coordination with other factors to control egg-laying in response to seasonal temperature variations.

INGESTIVE BEHAVIOR: MONOAMINES

Histidine, Histamine, and Amino Acid Neurotransmitter Dynamics of Hypothalamic Nuclei in Meal fed Rats. Dodds, S.J., L.P. Mercer* and J.D. Dunn. Dept. of Biochem. Oral Roberts Univ. Sch. of Med., Tulsa, OK 74171.

Neurotransmitter patterns are assessed under regimented meal conditions and compared to previous findings of elevated histidine in protein energy malnutrition.

Quantitive experiments were preformed to evaluate histamine (HA), Gly, Tau, GABA, Glu, Asp, levels of hypothalamic nuclei, in relation to meal fed rats.

In meal regimented rats, his dynamics of the lateral hypothalamus (LH) and ventromedial hypothalamus (VMH) are inversely related. Over the course of the meal, high VMH his and low LH his reflect hunger, and low VMH his and high LH his correlate with satiated states. In contrast no significant dynamics are demonstrated with HA, however VMH HA decreases with increasing hunger in the premeal (ac) period. Median Eminence/Arcuate nuclei (ME) reveal increasing HA with increasing satiety. The paraventricular nucleus (PVN) was found to have elevated HA in ac period. Levels fall significantly during the ingestive phase and return to ac levels 1 hour postmeal. Putative amino acid neurotransmitter dynamics were also found to correlate anatomically with food intake changes.

Data is obtained by microdissection of freeze-dried brain sections, obtained at appropriate time interval. Amino acid analysis is done by HPLC methodogy and HA levels are obtained with a radioimmunoassay.

INDEPENDENT INGESTION OF WATER AND MILK BY PRE-WEANLING RAT PUPS FOLLOWING SYSTEMIC HISTAMINE. Steven M. Specht, Robyn M. Cashmore* and Kevin B. Dempsey*. Psychology Department, Lebanon Valley College of Pennsylvania, Annville, PA 17003.

An independent ingestion paradigm, in which pre-weanling rat pups are allowed to consume fluid from the floor of a test chamber, was used to assess intake levels in 13 day-old rat pups. Each pup received a subcutaneous injection of either: 1) 0.15M NaCl; 2) 1.0M NaCl; 3) 40 mg/kg histamine (HA) or 4) 80 mg/kg HA and was placed in a test chamber (35°C) for 30 min with either water or milk spread on the floor. Although pups exhibited increased water intake following hypertonic 1.0M NaCl, there was no apparent increase in water intake following either dose of HA. Pups in all treatment groups exhibited similar milk intake levels during the 30 min test. These results suggest that 1) the independent ingestion procedure may be useful to examine *water* intake following homeostatic challenges in pre-weanling rat pups, and 2) there may be a relative insensitivity to the dipsogenic effects of HA for pups at this age tested with this procedure. These results are consistent with the finding that weanling rats are less sensitive than adults to the dipsogenic effects of HA, requiring higher doses of HA than adults to elicit drinking (20 vs. 5 mg/kg, respectively)(Specht, S.M. and Spear, L.P., Physiol. Behav., 45:63, 1989).

DEVELOPMENTAL PATTERNS OF NUTRIENT INTAKE, SPECIFIC APPETITES AND BODY WEIGHT: RELATION TO HYPOTHALAMIC α_2-NORADRENERGIC RECEPTOR SITES AND CIRCULATING LEVELS OF GLUCOSE AND INSULIN. D.J. Lucas*, M. Jhanwar-Uniyal, K. Leibowitz*, Y.S. Jhanwar* and S.F. Leibowitz. The Rockefeller University, New York, N.Y. 10021

In female (n=23) and male (n=18) rats, raised on pure macronutrient diets from birth, measurements were taken of body weight (BW, days 1-77), post-weaning 24hr nutrient intake (days 21-77), 10-min intake of sucrose (8%) or half & half (10.5%) solution (days 30-50), and blood levels of glucose and insulin or hypothalamic α_2-noradrenergic (3H-p-aminoclonidine) receptor binding sites measured at sacrifice (day 77). The main findings are: (1) BW 3 days after birth, in male and female rats, is positively related to the rats' preference (measured from days 21-77) for carbohydrate (but not protein or fat) and for sucrose. (2) At weaning (day 21), carbohydrate and fat intake (for females) and protein, carbohydrate and fat intake (for males) is positively related to the rats' nutrient intake patterns at maturity (day 77). (3) At puberty (days 40-50), females exhibit a strong preference for carbohydrate and males for protein. In both sexes, 24hr carbohydrate intake is correlated with appetite for sucrose, whereas preference for half & half reflects fat intake. In female rats, a positive relationship exists between BW and appetite for sucrose or half & half at puberty. (4) At maturity, BW is strongly related to appetite for sucrose (days 30-50), fat intake (days 21-77), and blood levels of insulin (day 77). (5) α_2-noradrenergic receptor sites, in the paraventricular nucleus (PVN) of female rats and dorsomedial nucleus (DMN) of male rats, are positively related to measures of protein intake and BW, while these measures are inversely related to α_2 receptors in the ventromedial nucleus (VMN) and perifornical lateral hypothalamus (PLH) of female rats only. Circulating glucose is positively related to α_2 receptors in the PVN, VMN and DMN but inversely related to α_2 receptors in the PLH. These results reveal a close relationship between nutrient intake and appetite, BW, circulating hormones and α_2 receptors in these hypothalamic sites.

α_2-NORADRENERGIC RECEPTOR AGONISTS AND ANTAGONISTS HAVE OPPOSITE EFFECTS ON CARBOHYDRATE AND PROTEIN INGESTION IN THE RAT. W.K. Cheung*, C.B. Dietz*, J.T. Alexander*, J. Ade*, G. Brennan and S.F.Leibowitz. Rockefeller Univ, N.Y., N.Y.10021

α_2-Noradrenergic receptors in the paraventricular nucleus (PVN) of rats are believed to have opposite effects on carbohydrate and protein ingestion at the onset of the active (dark) cycle. To examine the physiological role of α_2 receptors in controlling natural patterns of nutrient intake at this time, experiments with the selective α_2-receptor antagonists, idazoxan (IDA) or rauwolscine (RAU), and the α_2 agonist clonidine (CLON) were conducted in Sprague-Dawley rats.

Tests with i.p. injection of IDA or RAU (0.25-1.0 mg/kg) and 90-min measurements of nutrient intake (protein, carbohydrate and fat) demonstrate that these antagonists produce dose-dependent effects on carbohydrate and protein intake opposite to those observed with CLON or norepinephrine (NE). Whereas carbohydrate ingestion is stimulated, and protein intake inhibited, by PVN NE or CLON injection, carbohydrate intake is either reduced or unaffected by i.p. IDA and RAU, while protein ingestion is potentiated. The rats' relative preferences for these diets (% concentration of total intake) reveal a reliable decrease in appetite for carbohydrate and a small increase in protein appetite. Fat consumption is unaffected by IDA but is increased by RAU, resulting in a significant potentiation of total Kcal intake. However, tests with RAU injection directly into the PVN (10-25 pmols) show a reliable suppression of carbohydrate intake, consistent with this drug's effects after i.p. injection, but fail to reveal the stimulatory effect on fat ingestion, suggesting that it is mediated through a different neural system. Additional tests with i.p. CLON confirm earlier results demonstrating that α_2-noradrenergic stimulation increases the number of carbohydrate-rich meals at dark onset, while protein meals are strongly inhibited. These findings support the proposal that PVN α_2 receptors are physiologically active in balancing patterns of carbohydrate and protein intake at the onset of the active period.

376.5

CLONIDINE DIFFERENTIALLY AFFECTS MACRONUTRIENT INTAKE IN GENETICALLY OBESE AND LEAN MICE: DOSE-EFFECT RELATIONSHIPS. **P.J. Currie and L.M. Wilson. Psychol.Dept., Univ.Manitoba, Winnipeg, Canada, R3T2N2.**

Clonidine [CLON], the α2-noradrenergic agonist, reduces total energy intake primarily through suppression of carbohydrate [CHO] and fat consumption in both genetically obese [*ob*] and lean mice at doses of .1 and .5 mg/Kg (Currie, P.J., Wilson, L.M., *Neurosci. Abstr. 14*:966, 1988). Lower doses, however, selectively potentiate CHO intake, but only in *ob* mutants (Currie, P.J., Wilson, L.M., *Int.J.Obes.* 13:550, 1989). This study extended the dose-effect curve for clonidine [CLON] in *ob* and lean mice: [1] to identify an optimal dose for intake potentiation in *ob*s; [2] to determine whether CLON also exerts a bidirectional dose-dependent effect on CHO intake in lean mice.

After adaptation to a 6-h feeding regimen, *ob* and lean mice [*n*=14/genotype] were injected IP with .15 M NaCl for 2 days 30 min before simultaneous access to CHO, fat, and protein. On the 3rd day, mice were injected with either .025 or .05 mg/Kg CLON or an equivalent volume of .15M NaCl 30 min before meal access. The lower dose augmented *ob*s' total caloric intake and calories obtained from fat [expressed as % of vehicle control intakes] compared to leans', especially within the 1st h of food access [*Genotype X Dose X Time:* $p<.05$,$p<.01$, respectively]. CLON potentiated CHO intake in *ob*s at both doses at 1 h; the effect declined by 6 h. The lower dose did not affect lean mice's CHO intake, but the higher dose suppressed 1-h intakes, as had doses of .1 and .5 mg/Kg in previous research [*Genotype X Dose X Time:* $p<.025$]. With previous results, these comparisons suggest enhanced pharmacological sensitivity of an α-noradrenergic mechanism in genetic obesity. [*Supported by NSERC #7907 to LMW and MHRC Graduate Studentship to PJC]*

MECHANISM OF TYROSINE(TYR) POTENTIATION OF MIXED-ACTING SYMPATHOMIMETIC ANOREXIANTS (MASA). K.M.Hull* and T.J.Maher. Dept. Pharmacol. Mass.Coll. Pharm., Boston,MA 02115.

We previously reported a TYR specific potentiation of the MASA (±)-phenylpropanolamine (PPA), (+)-amphetamine and(-)-ephedrine (EPH). Thus we examined the dependence on functioning TYR hydroxylase (TH), brain TYR and the release of catecholamines (CA) in this potentiation. To determine if the potentiation by TYR required TH-mediated conversion for CA synthesis, we pre-treated with α-methyl-p-tyrosine (αMPT) and then administered EPH (20mg/Kg) with or without TYR (200mg/Kg). αMPT blocked both the anorectic activity of EPH and its potentiation by TYR in hyperphagic rats. To determine the requirement for central TYR we coadministered equimolar valine (VAL), which competes with TYR for uptake into brain, to food-deprived rats, TYR, or VAL+TYR with either saline (SAL) or PPA (20 mg/Kg). Neither VAL, TYR or VAL+TYR altered food intake when administered to SAL pretreated animals. While VAL alone failed to alter PPA-induced anorexia, VAL+TYR attenuated the normally observed pot-entiation by TYR. We also administered two add-itional MASA: (+)-norpseudoephedrine, (+)-pseudoephedrine, and two direct-acting agonists: salbutamol and methoxyphenamine. Only the MASA were potentiated by TYR. These results suggest that TYR's potentiation results from a central action involving increased CA synthesis via TH.

376.7

THE EFFECTS OF 1-(2,5)-DIMETHOXY-4-IODOPHENYL-2-AMINOPROPANE (DOI) ON THE MEAL PATTERNS OF RATS R. Bauman* and R. Pastel. Dept. of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307.

The meal patterns of non-deprived rats were used to evaluate the effects of DOI, a $5HT_2$ agonist, on food intake. A 12 hour light/dark cycle was maintained in each rat's cage and at any time a rat could eat by pressing a lever once for each 45 mg food pellet. A meal was defined as a bout of eating that was not interrupted by a pause longer than 10 mins. Thirty minutes before the onset of darkness, either DOI or saline was delivered IP. A maximum dose of 1 mg/kg was used because in a prior study, it reduced the total intake of deprived rats by 50%.

Meal frequency and total food intake were greater during the dark than during the light. A 1 mg/kg dose but not a 0.3 mg/kg dose of DOI significantly reduced the size of a meal (pellets/meal) and total intake during the dark without affecting meal frequency or rate of eating pellets. Meal size was reduced for the first several meals of the dark period. These data suggest that serotonin is an important determinant of meal patterning and total intake in the rat.

376.8

OPPOSITE EFFECTS ON INGESTIVE BEHAVIOR FOLLOWING CHRONIC MUSCIMOL ADMINISTRATION INTO THE MEDIAN RAPHE OR VENTRAL TEGMENTAL AREA, T.R. Stratford and D. Wirtshafter, Dept. Psychology and Committee on Neuroscience, University of Illinois at Chicago, Chicago, IL., 60680.

Previously, our lab has demonstrated large increases in food and water intake in rats during the 2 hours following acute microinjections of the GABA-A agonist muscimol into the median raphe (MR). Smaller increases were observed following similar injections into the VTA. In order to assess the effects of chronic administration of muscimol into these brain areas, Alzet osmotic minipumps were attached to injector cannulae terminating in either the MR or the VTA and were implanted using ether anesthesia. The muscimol was administered in a dose of 25ng/0.5ul at an infusion rate of 0.5 ul/hour.

Animals receiving the muscimol infusion in the MR exhibited extremely large increases in water intake and, to a lesser extent, food intake, along with a severe disruption of the normal day/night ingestion cycle. The hyperdipsia and hyperphagia appeared within a few hours of the minipump implantation and seemed to continue for the life of the pump (7-9 days). Peak 24 hour water intakes were in the 280-350 ml range with food intakes in excess of 40 g for the same period. In contrast, chronic infusions of muscimol into the VTA lead to a complete aphagia and adipsia which was completely reversed within a few hours of terminating the infusion. (Supp. by NS21350)

376.9

THE EFFECT OF INTRAPERITONEALLY ADMINISTERED ICS 205-930 AND QUATERNIZED ICS 205-930 ON FOOD INTAKE OF RATS FED AN AMINO ACID IMBALANCED DIET.

B.J. Hrupka*, D.W. Gietzen, Q.R. Rogers.
Dept VM:Physiol. Sci. and Food Intake Lab, Univ. Calif., Davis, CA, 95616.

We have previously reported that the anorectic response of rats to an amino acid imbalanced diet (IMB) is blocked by intraperitoneal (ip) injections, but not intracerebroventricular injections of the serotonin$_3$ ($5HT_3$) antagonist ICS 205-930 (ICS). ICS has been shown to cross the blood brain barrier (BBB), while quaternized ICS (Q-ICS) should not. Since evidence indicates that the feeding response to IMB is mediated centrally, we used ip administration of ICS and Q-ICS to determine whether the $5HT_3$ receptors that are involved in the rat's response to IMB are located centrally or peripherally. Male Sprague-Dawley rats (n=7 rats/gp) were prefed a low protein basal diet for 10 days. Rats received ICS, Q-ICS, (7.8 or 28.1 μmoles/kg body weight) or saline within 30 min of onset of the dark cycle, and were then fed IMB. Food intake was recorded after 3, 6, 12, and 24 hr. From 0 to 6 hr, rats that received ICS and Q-ICS injections ate similar amounts of IMB (P>.10). Rats injected with 28.1 μmoles/kg ICS and Q-ICS ate significantly more IMB (P<.01) from 6 to 24 hr than rats injected with 7.8 μmoles/kg of these drugs, demonstrating a dose-dependent response to these $5HT_3$ antagonists. There were no significant differences (P>.10) between ICS and Q-ICS in IMB intake. If Q-ICS does not cross the BBB, these results suggest that a major portion of the effect of ICS in blocking the anorectic response to IMB is mediated peripherally. 376.10

SUPPRESSION OF FOOD INTAKE BY MK212 AND OTHER ARYLPIPERAZINES IN FOOD-DEPRIVED RATS. S. M. Snyder*, L. R. Reid*, J. L. Buelke-Sam, and D. T. Wong.
Toxicology Division and Central Nervous System Research, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

The arylpiperazine class of serotonin (5-hydroxytryptamine, 5HT) agonists is known to suppress food consumption in rats[1]. In the present study, food-deprived male Sprague-Dawley rats were treated with 0.3, 1.0, 3.0, or 10.0 mg/kg i.p. doses of either quipazine, m-chlorophenylpiperazine, or MK212. A dose-related suppression of food intake was observed in all groups at 1 and 3 hours of food access. The anorectic effect of MK212 at 10 mg/kg was reversed by pre-treatment with 0.3-5.0 mg/kg i.p. of metergoline (a non-selective antagonist of 5HT-1 and 5HT-2 receptors), 3-10 mg/kg i.p. of mianserin or 3-10 mg/kg i.p. of LY53857 (antagonists of 5HT-1C and 5HT-2 receptors). The anorectic effect of MK212 was not reversed by pre-treatment with 1-3 mg/kg i.p. of ketanserin (an antagonist of the 5HT-2 receptor). At the highest doses used, the antagonists, except LY53857, alone suppressed food intake. The present findings, however, are consistent with the involvement of the 5HT-1C receptor mediating the anorectic effect of MK212. [1]David T. Wong and Ray W. Fuller, Serotonergic Mechanisms in Feeding, International Journal of Obesity (1987) 11, Suppl. 3, 125-133.

INHIBITORY EFFECTS OF 5-HYDROXYTRYPTOPHAN ON FEEDING IN HUNGRY RATS. C.T. Tsai. Department of Biology, National Changhua University of Education, Changhua, Taiwan, ROC

The effects of the serotonin precursor, 5-hydroxytryptophan (5-HTP) on food intake in free-feeding and food deprived rats were examined. In free-feeding rats, 5-HTP (100 mg/kg, i.p.) reduced food intake by 86.3%. The anoretic effect of 5-HTP was antagonized by cyproheptadine (CYP, 4 mg/kg, i.p.), a serotonin blockade. However, following food deprivation, the food intake was increased 24.3% in control rats, whereas, the food intake was decreased 42.8% in 5-HTP treated rats. That is, the feeding of hungry rats was still inhibited by 5-HTP. Nevertheless, this inhibition of 5-HTP on food intake in hungry rats was almost recovered by CYP. The evidences indicated the anoretic action of 5-HTP in free-feeding and in hungry rats were mediated by serotonergic mechanism. As to analysis of meal patterns, the 5-HTP treated hungry rats ate only 0.16 gms in the initial 2 hr session and took 3.74 gms in the later 6 hr period, while the saline controls ate 10.3 gms in the initial 2 hr session and 2.1 gms in the later 6 hr period. This opposite result apparently showed that the effect of 5-HTP on feeding was inhibition of the initial phase of hungry period. These evidences are in favor of a conclusion that there is an existence of a serotonergic mechanism in brain to be inhibitory for feeding via inhibition of hunger.

376.12

CAN 2,3,7,8-TETRACHLORODIBENZO-P-DIOXIN (TCDD)-INDUCED APPETITE SUPPRESSION BE OVERCOME BY ALTERATIONS OF CENTRAL SEROTONIN LEVELS? B.U. Stahl*, R.H. Alper, E.J. Walaszek and K. Rozman*. Dept. Pharm. Tox. and Therap. Univ. Kansas Med. Center, Kansas City, KS 66103 (USA), and Section of Environ. Tox., Ges. f. Strahlen und Umweltforschung mbH München, D-8042 Neuherberg (FRG).

There is evidence that the appetite suppression which is the apparent cause of TCDD-induced death, may be a result of reduced activity of gluconeogenic enzymes followed by an elevation of serum and hypothalamic tryptophan levels and finally resulting in a serotonin (5-HT) mediated reduction of feed intake. Consequently, depletion of central 5-HT should alter the TCDD-induced starvation syndrome. Central 5-HT depletion was accomplished by using i.c.v. infusions of the neurotoxin 5,7-dihydroxytryptamine (5,7-DHT, 150 μg of free base per 20 μl 0.9%NaCl containing 0.1% ascorbic acid). Rats (n=5) were pretreated with desipramine (25 mg/kg i.p.) 30 min. before i.c.v. infusion. Two weeks after infusion these rats and a group of non-lesioned rats (n=3) were treated with a lethal dose of TCDD (125 μg/kg i.p.). Three naive control rats were injected with vehicle alone (corn oil, 4 ml/kg i.p.). All rats were monitored daily for feed intake and body weight development. On day 13 after treatment all rats were sacrificed and 5-HT and its metabolite 5-hydroxyindoleacetic acid (5-HIAA), dopamine (DA) and its metabolite dihydroxyphenylacetic acid (DOPAC) were quantitated in the hypothalamus using HPLC with electrochemical detection. In 2 out of 5 of the 5,7-DHT lesioned animals hypothalamic 5-HT was depleted more than 90% and 5-HIAA more than 85% compared to control animals. In the remaining 3 animals depletions were between 30% and 61% for 5-HT and 36% and 57% for 5-HIAA. No alterations were found in the hypothalamic levels of DA and DOPAC. No differences were observed regarding body weight development and feed intake in TCDD treated rats with or without central depletion of 5-HT. These results suggest that although TCDD increases central 5-HT levels as a result of increased plasma tryptophan, this may not be the sole cause for reduced feed intake and lethality. In further studies it needs to be determined whether elevations in peripheral tryptophan and/or 5-HT can cause TCDD induced starvation.

THE EFFECT OF A SUBLETHAL DOSE OF TCDD ON THE TURNOVER OF BIOGENIC AMINES IN SUBREGIONS OF RAT BRAIN. M. Unkila[1], L. Tuomisto[2], R. Pohjanvirta[1], E. MacDonald[2] and J. Tuomisto[1], National Public Health Instit., Dept. of Environ. Hyg. & Toxicol., P.O.B. 95, SF-70701 Kuopio, Finland, [2]Dept. of Pharmacol. & Toxicol., Univ. of Kuopio, Kuopio Finland.

Male Han/Wistar rats given a sublethal dose of TCDD (1000 ug/kg ip in corn oil) showed disturbed metabolic control of food intake and lowered body weight for months after TCDD administration (Pohjanvirta et al., in this abstract book). In the present study we examined whether TCDD is interfering with brain aminergic systems, well known to participate in the control for energy homeostasis. 3 1/2 Months after TCDD exposure the rats were given alpha-methyl-p-tyrosine (AMPT; 250 mg/kg ip) and 4 hr after AMPT or vehicle injection their catecholamine (CA) or indoleamine (IND, only AMPT-controls) concentrations were measured by HPLC-EC. TCDD had only minor effects on brain monoamines. The turnover of CA:s was accelerated about 5-10 % in almost all brain areas in the TCDD group. The steady-state concentration of CA:s and IND:s were unaffected as well as of tryptophan which is usually elevated in fasted rats. These results support our previous findings suggesting only a minor or secondary role for the brain monoamines in TCDD toxicity.

376.14

2,3,7,8-TETRACHLORODIBENZO-p-DIOXIN (TCDD) ENHANCES RESPONSIVENESS TO SATIETY SIGNALS AND CAUSES PERSISTENT ALTERATIONS IN RESPONSES TO FEEDING REGULATORY CHALLENGES IN HAN/WISTAR RATS. R. Pohjanvirta* and J. Tuomisto. Natl. Public Health Inst., Dept. of Environ. Hyg. & Toxicol., P.O.B. 95, SF-70701, Kuopio, Finland.

A single sublethal dose of TCDD (1000 or 3000 μg/kg ip) led to persistent hypophagia along with permanent retardation of growth in Han/Wistar rats. In one-bottle tests, these rats showed diminished sucrose drinking accompanied by a progressive tendency toward increased saccharin consumption over control levels. In contrast to control rats, they did not display hyperphagia in response to cellular glucopenia by 2-deoxyglucose and reduced their feed intake after inhibition of fatty acid oxidation by mercaptoacetate. Their feeding behavioral responses to insulin and naloxone were attenuated. Parenterally administered glucose and (even more so) fructose significantly suppressed starvation-induced eating in TCDD-treated rats while being without effect in controls. These findings argue in favor of a central site of action for TCDD. They also suggest enhanced responsiveness to postingestive satiety signals coupled with insensitivity to metabolic cues to be crucial factors underlying the permanently subnormal body weight maintained by TCDD-treated rats.

376.15

INDEPENDENT INGESTION AND INTRAORAL INFUSION OF 10% SUCROSE PRODUCE DIFFERENT PATTERNS OF CENTRAL DOPAMINE METABOLISM IN 14-DAY-OLD RATS. L. Broder*, G.P. Smith, A. Tyrka*, and J. Gibbs. Bourne Lab, NY Hosp.-Cornell Med. Ctr., White Plains, NY 10605

The D-2 antagonist, raclopride, and the D-1 antagonist, SCH 23390, inhibit intake of 10% sucrose in 14-day-old rat pups when a pup ingests 10% sucrose by licking it from the floor of a tissue-lined beaker (Independent Ingestion, II), but not when a pup ingests 10% sucrose infused into its mouth through an anterior, sublingual, oral catheter (OC; Smith et al, 1989; Tyrka et al, this meeting). The differential potency of the antagonists may be due to a differential effect of the ingestion of 10% sucrose on central dopaminergic (DA) activity in the two tests.

Method: To test this hypothesis, DA, DOPAC and HVA were measured by HPLC-EC in 14-day-old, male and female pups at the end of a 20-min II or OC test.

Results: Ingestion of 10% sucrose by II, but not by OC increased DOPAC/DA in hypothalamus and olfactory tubercle ($p<.05$). Both II and OC increased caudate DOPAC/DA ($p<.05$). In contrast, ingestion of 10% sucrose by OC increased HVA/DA in amygdala and hypothalamus ($p<.05$), but II of 10% sucrose had no effect on HVA/DA in any region.

Conclusions: (1) Regional pattern of DA metabolism depends on the mode of ingestion (II or OC) of 10% sucrose; (2) increased DOPAC/DA in hypothalamus and olfactory tubercle by II, but not by OC, correlates with the inhibitory effect of raclopride and SCH 23390 on II, but not OC; (3) the significant increase in hypothalamic DOPAC/DA produced by II of 10% sucrose in 14-day-old pups extends our observation of this in adult rats (Smith et al, 1987) and suggests that this effect is innate rather than acquired.

SCH 23390 INHIBITS INTAKE OF SUCROSE MORE DURING INDEPENDENT INGESTION THAN DURING INTRAORAL INFUSION IN RATS AS EARLY AS POSTNATAL DAY 7. A. Tyrka*, G.P. Smith, and J. Gibbs. Bourne Lab, NY Hospital-Cornell Medical Center, White Plains, NY 10605.

SCH 23390, a D-1 dopaminergic antagonist, decreases the sham feeding of sucrose in adult rats (ID_{50}=60 $\mu g \cdot kg^{-1}$, ip, Schneider et al, 1988). To determine the ontogeny of this effect, intake of 10% sucrose was measured at postnatal days 7, 14, and 21. Pups were removed from the litter for 4h and then placed in a warm, humid chamber for one of two 20-min tests: (1) continuous infusion of 10% sucrose through an anterior, sublingual catheter (Hall, 1979) or (2) independent ingestion of 10% sucrose from the bottom of a test beaker. A dose of SCH 23390 (30-267 $\mu g/kg$) or saline alone was injected ip 15 min prior to an intake test. Each pup was tested only once. SCH 23390 was significantly more potent for decreasing intake in the independent ingestion test than in the intraoral infusion test at each of the three ages (Table).

POTENCY OF SCH 23390 (ID_{50}, $\mu g \cdot kg^{-1}$, ip)

DAY	INTRAORAL CATHETER	INDEPENDENT INGESTION
7	>240	60
14	>229	14
21	>267	67

Although the reason(s) for the differential potency in the 2 tests is not clear, the results suggest that D-1 receptor activity is necessary for the positive reinforcing effects of sucrose on independent eating as early as postnatal day 7. In contrast, D-2 receptor activity is not necessary for independent ingestion until day 14 (Smith et al, 1989).

THE INTERPRETATION OF SHAM FEEDING DATA: CURVE SHIFT STUDIES. H.P. Weingarten, A. Duong*, S. Gowans* & D. Elston*. Department of Psychology, McMaster University, Hamilton, Ontario, Canada, L8S 4K1.

Changes of sham feeding are often assumed to reflect alterations of palatability. However, sham feeding is influenced by many performance variables independent of palatability. We adapted the curve shift paradigm, used in the brain stimulation reward field to distinguish reward from performance effects, to sham feeding to discriminate manipulations which alter palatability from those which influence sham feeding performance independent of any influence on taste.

Adult rats sham fed sucrose solutions ranging from .03M to 1.50M. Concentration-intake functions were generated which plotted sham intake (in mls/30 min) versus log of sucrose concentration. Curve shifts were indexed by calculating the log sucrose concentration which produced 50% of asymptotic sham intake, ie the half-max sucrose. Decreasing sucrose palatability by quinine adulteration reduced asymptotic intake by 27% and shifted the concentration-intake function to the right. Half-max values were .89 for unadulterated, and 1.24 for adulterated, sucrose. Dopamine antagonism (.5 mg/kg pimozide) mimicked effects of degrading palatability: reduced asymptotic sham intake with a rightward shift of the concentration-intake function. Pimozide increased half-max sucrose concentration from .7 to 1.1. In contrast, rats sham feeding after 1, 6, 12, or 18 hrs food deprivation showed a two-fold change in asymptotic sham intake but no shift in the concentration-intake functions; half-max sucrose concentrations were identical at all deprivation levels. These data suggest that: i) the effects of a treatment on sham feeding must be assessed by examining the entire concentration-intake function, and; ii) congenial with the conclusion from analogous studies in the brain stimulation reward literature, although many variables alter sham feeding performance, only those treatments which curve-shift operate by altering the motivating capacity of taste.

376.18

EFFECTS OF PIMOZIDE AND AMPHETAMINE ON THE MICROSTRUCTURAL COMPONENTS OF FEEDING. *A.K. Houlihan*, M.L. Volkov*, and S.M. Feldman.* Department of Psychology and Center for Neural Science, New York University, NY, NY, 10003.

Using a discrete trials paradigm, we investigated the effects of systemic pimozide and amphetamine on the microstructural components of the first meal following 24 hour food deprivation in rats. Deprived subjects were adapted to trial-structured meals of wet mash (Purina rat chow and water, 3:2, w/w) and i.p. injections of physiological saline over 11 days. Each animal served in all conditions. Experimental sessions consisted of a maximum of 30 feeding trials, each of 30 sec. duration, separated by a 90 sec. intertrial interval. Food intake was measured following each trial, and bites and pauses were measured on-line within each trial. Sessions were videotaped for subsequent verification of latency; duration; and bite frequency and distribution.

Consistent with previous work in our laboratory, all groups showed a decline in intake rate over the course of a session that was a function of decreasing bite size; bite frequency remained constant over trials. In addition, pimozide (0.5 and 1 mg/kg i.p.) and amphetamine (0.5 and 1 mg/kg i.p.) each decreased cumulative intake in a dose-dependent manner, by both reducing amount eaten per trial and decreasing duration of eating per *session*, compared to vehicle controls. Pimozide also decreased number of trials on which eating occurred, leaving duration of eating per *trial* unaffected. Therefore, pimozide reduced amount eaten per trial by slowing local rate of intake. By contrast, amphetamine reduced intake per trial by decreasing duration of eating within 30 sec. trials, either by increasing latency or pausing, and not by altering local intake rate. The basis for pimozide's reduction of local intake rate is apparently a decrease in bite size, because there was no alteration of local bite rate.

376.19

THE DOPAMINERGIC REGULATION OF FEEDING BEHAVIORS: AN EXAMINATION OF THE INVOLVEMENT OF DISCRETE STRIATAL SUBREGIONS IN THE RAT BRAIN. A.E. KELLEY and V.P. BAKSHI*, Dept. of Psychology, Harvard Univ., Cambridge, MA 02138.

Dopamine (DA) is thought to be critically involved in motor and motivational aspects of behavior. In particular there is considerable evidence that DA may modulate certain components of feeding behavior. Both neuroleptics and amphetamine disrupt feeding, but little is known about the specific striatal subregions involved in these effects. Food-deprived rats were injected with either haloperidol (0.025, 0.25, 2.5 µg) or amphetamine (1, 10, 20 µg) in one of three striatal sites: nucleus accumbens (N.Acc.), ventrolateral striatum (VLS), and dorsolateral striatum (DLS). It was found that food intake, feeding rate, food spillage and feeding durations were differentially affected following drug administration into N.Acc. and VLS. Injections into DLS produced no significant changes in ingestive behaviors. Results were found to be compatible with previous work that indicates a functional heterogeneity of the striatum. Moreover, it is hypothesized from these results that VLS is specifically involved in the regulation of oral motor mechanisms and that N.Acc. may regulate attentional or switching mechanisms that are required for the maintenance of feeding behavior.

EFFECT OF LITHIUM CHLORIDE AND DESIPRAMINE ON HIV REPLICATION, D.L.Evans, M.S. Smith*, J. Petitto*, R.N. Golden*Depts of Psychiatry & Medicine, and Lineberger Cancer Research Center, Univ of North Carolina, Chapel Hill, N.C.

Lithium and tricyclic antidepressants are used for the treatment of affective disorders in patients with HIV-related illness. Because lithium has immunoactive properties, we studied the effects of lithium chloride (LiCl) and the antidepressant, desipramine (DMI), on HIV replication in order to determine if these agents demonstrate an anti-HIV effect or conversely, an enhancement of HIV replication.

We studied the effect of LiCl and DMI on HIV replication in T-lympochytes in culture, and the effect of LiCl on reverse transcriptase activity in vitro. H9 and C3 cells were infected with the LAV-1 strain of HIV-1 and the production of HIV from drug treated cells was estimated by reverse transcriptase activity.

We found no effect of LiCl (20uM - 20mM) on the activity of HIV to replicate in T cells, as well as no effect of DMI (10 ng per mL - 1 mg per mL) on virus replication. In addition, we found no effect of LiCl (.01 mM-20mM) on the reverse transcriptase enzyme itself.

These preliminary data suggest that neither lithium, nor the antidepressant, DMI, diminish HIV replication. Thus, these findings do not support an anti-HIV role for lithium or DMI. However, and importantly for the clinical management of individuals with HIV infection, these pilot data show no enhancement of HIV replication and therefore do not call into question the use of these agents for the treatment of affective illness in these individuals.

[3H]OPIPRAMOL LABELS A NOVEL BINDING SITE AND THE SIGMA RECEPTOR IN RAT BRAIN MEMBRANES. D.J. Hirsch, C. D. Ferris, B. P. Brooks, A. M. Snowman, and S. H. Snyder, Dept. of Neuroscience, The Johns Hopkins Univ. Sch. of Medicine, Baltimore, MD 21205.

Opipramol is a tricyclic antidepressant that has a structure which is very similar to the major clinically effective antidepressants. Though its structure is similar to other antidepressants, and though opipramol itself has been used extensively as an effective antidepressant medication, it is virtually inactive when assayed for inhibition of catecholamine uptake (a mechanism though which many antidepressants are thought to exert their therapeutic effects). We have used tritium labeled opipramol to study its high affinity binding to brain membranes. [3H]opipramol labels two sites in brain membranes for which it has equal high affinity (Kd=4-6nM, Total Bmax=3 pmol/mg protein). Haloperidol, which has very high affinity for sigma receptors, differentiates these two site clearly. Haloperidol has a Ki of 1nM for the sigma receptor component of [3H]opipramol binding and a Ki of 350nM for the novel opipramol binding site. Therefore, we have blocked the sigma component with 50nM haloperidol to study this novel site in isolation. Pharmacological characterization has confirmed that [3H]opipramol labels the sigma receptor and that the second binding site is not any known neurotransmitter receptor. Also, several drugs which are relatively inactive at inhibiting catecholamine uptake and yet active as antidepressants are potent inhibitors of opipramol binding to this novel site. We suggest that this site may mediate some of the antidepressant effects of these drugs

377.3

EFFECTS OF CHRONIC IMIPRAMINE ON TYROSINE HYDROXYLASE ACTIVITY IN NORADRENERGIC AND DOPAMINERGIC REGIONS OF RAT BRAIN. D.L. Rosin, A.M. Knorr, E.J. Nestler, R.H. Roth, and R.S. Duman. Depts. of Pharm. & Psych., Yale Univ. Sch. Med., New Haven, CT 06510.

We previously reported that chronic antidepressants produce a decrease in tyrosine hydroxylase (TH) mRNA and in TH immunoreactivity in locus coeruleus (LC) but not in substantia nigra (SN) (McMahon et al., Soc. Neurosci. Abst. 15:986, 1989). To further investigate this finding we measured the enzymatic activity of TH (assayed *in vitro*) in several regions of rat brain after chronic imipramine treatment. In the dopamine cell body regions, TH activity was decreased by 20% in SN (A9) and by 45% in the ventral tegmental area (A10). In an analogous fashion, TH activity was decreased by 20-40% in projection regions of dopamine A10 neurons, i.e. nucleus accumbens and medial prefrontal cortex, and by 30-60% in subregions of the striatum, an area which receives projections from both A9 and A10 cell body regions. Despite previously observed decreases in TH immunoreactivity and mRNA in LC, no significant decrease in TH activity was found in LC, the noradrenergic cell body region, or in the hippocampus, which receives projections from the LC. These results demonstrate that TH activity is diminished in dopamine neurons by chronic imipramine and support a growing body of evidence that antidepressants also alter dopaminergic function. It remains to be seen whether the effects on TH in dopamine regions are relatively more selective for dopamine A10 vs. A9 neurons and whether other noradrenergic regions are affected. (Supported by USPHS MH45481 and MH14092).

MIANSERIN ATTENUATES LOCUS COERULEUS (LC) ACTIVATION ELICITED BY PHASIC SENSORY STIMULI, HEMODYNAMIC STRESS, AND I.C.V. CORTICOTROPIN-RELEASING FACTOR (CRF): POSSIBLE MODE OF ANTIDEPRESSANT ACTION. A.L. Curtis and R.J. Valentino, Department of Mental Health Science, Division of Behavioral Neurobiology, Hahnemann University, Philadelphia, PA 19102.

CRF hypersecretion has been postulated to occur in depression. Because CRF alters LC discharge characteristics, we hypothesized that antidepressants interfere with CRF effects on LC discharge. Previous results supporting this showed that chronic administration of desmethylimipramine (DMI) attenuated LC activation elicited by nitroprusside infusion, a hemodynamic stress which is thought to require endogenous CRF release for LC activation. To further test this hypothesis, the acute and chronic effects of the atypical antidepressant, mianserin, on LC discharge characteristics were quantified in the present study. Acute i.v. administration of mianserin (0.0001 - 1.0 mg/kg) to halothane anesthetized rats increased LC spontaneous discharge and decreased LC discharge evoked by repeated sciatic nerve stimulation. Mianserin (0.1 mg/kg, i.v.) completely blocked LC activation elicited by hemodynamic stress produced by i.v. infusion of nitroprusside (10 ug/30 ul/min; 15 min). Mianserin also inhibited LC activation produced by i.c.v. administered CRF (3.0 ug in 3.0 ul). Chronic mianserin administration (10 mg/kg, i.p./day for 21 days) resulted in tolerance to its effects on LC spontaneous discharge, LC sensory evoked discharge, and LC activation by i.c.v. CRF. In contrast, LC activation by hemodynamic stress was still greatly attenuated in chronically treated rats. The results indicate that acute mianserin administration attenuates LC activation by a variety of stimuli and that tolerance occurs to some of these effects with chronic administration. Persistent attenuation of LC activation by hemodynamic stress after chronic mianserin administration suggests that interference with putative CRF neurotransmission in the LC may be an important mode of action of mianserin and other antidepressants. This study was supported by PHS Grants MH 42796 and MH 40008 and a NARSAD award to ALC.

PROPHYLACTIC AND THERAPEUTIC EFFICACY OF ADINAZOLAM IN A RAT MODEL OF DEPRESSION. W. W. Woodmansee, L. H. Silbert*, S. F. Maier and P. H. Desan. Dept. of Psychology, Univ. of Colorado, Boulder, CO, 80309, and Dept. of Neurology, Stanford University, Stanford, CA, 94304.

We have reported that exposure of rats to three sessions of repeated inescapable shock induces a long-lasting period of decreased daily running wheel activity, which is antagonized by chronic administration of desipramine following the stress sessions (Desan, Silbert and Maier, Pharmacol. Physiol. Behav. 30(1988)21-29). In the present study we administered adinazolam 30' prior to each stress session (5 and 10 mg/kg i.p.) or in the days after the stress sessions (5 and 20 mg/100 ml in drinking water). Adinazolam both attenuated the stress-induced activity decrease when given prior to stress, and reversed it when given after stress. As in the case of desipramine, the effect of adinazolam required 7 days for maximum effect, produced activity in excess of normal levels and showed a strongly curvilinear dose response curve. Adinazolam in either pattern of administration had minimal effects on the activity of unstressed animals. In general, anxiolytic agents acutely administered prior to stress reduce the effects of inescapable stress such as learned helplessness, but cannot not reverse them. By contrast, antidepressant agents acutely administered prior to stress fail to prevent such effects, but can reverse them in chronic administration. In the present study adinazolam appeared to have both effects. This result is consistent with clinical reports of both anxiolytic and antidepressant efficacy for this and other triazolobenzodiazepines.

377.6

ACUTE ADMINISTRATION OF THE ANTIDEPRESSANT TRAZODONE INCREASES NORADRENERGIC LOCUS COERULEUS NEURONAL FIRING IN ANESTHETIZED RATS. C. P. VanderMaelen and J. P. Braselton. Bristol-Myers Squibb Co., CNS Biology, Dept. 404, 5 Research Parkway, Wallingford, CT 06492.

Trazodone is an antidepressant drug with moderate 5-HT reuptake blockade properties (IC_{50}=115 nM). It also binds to 5-HT_2 (IC_{50}=11 nM), 5-HT_{1A} (IC_{50}=288 nM), and α_1-adrenergic (IC_{50}=23 nM) receptors (A.S. Eison et al., Psychopharmacol. Bull., submitted). The effects of i.v. administered trazodone were assessed on the spontaneous firing of putative noradrenergic neurons in the locus coeruleus (LC) of male Sprague-Dawley rats anesthetized with chloral hydrate. Standard extracellular single-unit recording techniques using glass microelectrodes were employed. Although considerable variability in responses was observed, overall, trazodone increased the firing rate of noradrenergic LC neurons in a dose-dependent manner when assessed both between cells and within cells. The dose estimated to produce an increase in firing rate of 25% (ED_{25}) was calculated to be 0.128 mg/kg, i.v., and the ED_{50}=0.659 mg/kg, i.v. These results agree generally with Scuvee-Moreau and Dresse (1982, Arch. Int. Pharmacodyn., 260, 299-301), who also observed potent inhibition of serotonergic dorsal raphe neurons with trazodone. The combination of potent inhibition of serotonergic neurons and mild excitation of noradrenergic neurons defines a unique electrophysiological profile for trazodone when compared to other antidepressants.

377.7

RAPID TRYPTOPHAN DEPLETION REVERSES ANTIDEPRESSANT RESPONSE AND ALTERS MOOD IN DEPRESSION P.L. Delgado, D.S. Charney, L.H. Price, G.K. Aghajanian, G.R. Heninger, West Haven VAMC and Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06508

Brain serotonin (5-HT) content is dependent on plasma levels of the essential amino acid, tryptophan (TRP). We have previously reported on the effects of rapid dietary TRP depletion in psychiatric patients. This study extends those reports and further characterizes the effects of rapid TRP depletion on mood in depressed patients. METHOD: 87 depressed (DSM-III-R) patients (47 drug free, symptomatic, and 40 in clinical remission on antidepressant) have received tryptophan depletion testing with two 2-day tests each involving a 24-hr., 160 mg/day, low-TRP diet followed the next morning by a 16-amino acid drink, in a double-blind, placebo-controlled (TRP depletion (TD) and control testing), crossover fashion. On one test the diet and drink were supplemented with L-TRP (control) and on the other test neither the diet nor drink were supplemented (TD). Behavioral ratings (Hamilton Depression Scale (HDRS)) and plasma (for TRP levels) were obtained prior to, during and after testing. RESULTS: Total and free TRP decreased 80 to 90% 5 hrs. after the TRP-free drink (TFD). 35% of 47 symptomatic, drug-free depressed patients were unchanged the day of the TFD, but became clinically less depressed (40% mean decrease in HDRS, ≥9 point decrease in total HDRS score) the day after the TFD. 60% of 40 antidepressant-remitted depressed patients relapsed (300% mean HDRS increase) the day of the TFD, with return to remitted state the day after. While 80% of monoamine oxidase inhibitor- or fluvoxamine-treated patients relapsed, only 20% of desipramine-treated patients relapsed. Implications: Rapid depletion of plasma TRP transiently reverses antidepressant response in most remitted depressed patients suggesting that the antidepressant effects of some of these drugs may be more dependent on 5HT availability than that of others. Clinical characteristics and ultimate treatment response of symptomatic, drug free depressed patients in relation to the behavioral response to TD will be presented.

377.8

CHRONIC DESIPRAMINE TREATMENT ELEVATES EXTRACELLULAR NOREPINEPHRINE IN HIPPOCAMPUS WITHOUT ATTENUATING STRESS-INDUCED NOREPINEPHRINE EFFLUX. Elizabeth D. Abercrombie, *Dept. of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.*

We have observed that the stress-induced efflux of norepinephrine (NE) in hippocampus is significantly augmented in animals previously exposed to chronic stress [Nisenbaum et al., Soc. Neurosci. Abstr., 15 (1989), 413]. This effect may be relevant to the role of the locus coeruleus (LC) NE system in stress-induced behavioral disorders such as depression and antidepressants may thus act in part to dampen the transmission of information in that system. Therefore, the effect of treatment for 14 days with the antidepressant drug desipramine (DES; 10 mg/kg/day x 2, i.p.) was examined with regard to both resting and stress-induced efflux of NE in the hippocampus of rats using in vivo microdialysis. In DES treated animals, the basal level of NE in dialysates was 46 ± 5 pg/20 µl sample (corrected for probe recovery) whereas in control animals this value was 10 ± 1 pg/sample. Despite this difference, the magnitude of the increase in NE efflux in response to tail-shock stress was 59 ± 6% in DES treated animals vs. 61 ± 9% in control animals. The dose-response curve for inhibition of NE release by clonidine was shifted significantly to the right by chronic DES treatment over the range of doses tested (.025 to .25 mg/kg, i.p.). Thus, decreased function of inhibitory presynaptic α_2 adrenoceptors could permit continued responding of LC neurons to stress despite the elevated resting NE level. The above changes, along with associated downregulation of postsynaptic β adrenoceptors, may contribute to the antidepressant effects of chronic DES treatment by normalizing the overall level of NE transmission in a system hyperresponsive to activation by stress.

377.9

MEPACRINE BLOCKS DESIPRAMINE INDUCED BETA ADRENOCEPTOR DOWNREGULATION IN C6 GLIOMA CELLS. H. Manji, G. Chen*, I. Bitran*, F. Gusovsky, and W. Z. Potter*. Sec. Clin. Pharmacol., Clin. Neurosc. Branch, NIMH, and Lab of Bioorganic Chemistry, NIDDK, NIH, Bethesda, MD 20892.

Chronic treatment with a number of antidepressants (ADs) results in a downregulation/desensitization of rat cortical beta adrenoceptors (βARs). Although this effect has generally been attributed to an elevation of synaptic norepinephrine, the recent demonstration of similar βAR alterations in C6 glioma cells and human fibroblasts following in vitro incubation with desipramine (DMI), has also implicated direct postsynaptic mechanism(s). Mepacrine (MEP), a phospholipase A_2 (PLA2) inhibitor, has been shown to attenuate agonist and restraint stress induced βAR downregulation in C6 glioma cells and rat hypothalamus respectively. In order to investigate the possible role of PLA_2 in AD-induced βAR downregulation, C6 cells were incubated with DMI (10µM) alone, or in combination with MEP (10µM) for 5 days. DMI resulted in a 25% decrease in the density of βARs, and a similar reduction in isoproterenol (but not forskolin) stimulated cyclic AMP accumulation in intact C6 cells. MEP alone had no effect on βAR numbers or sensitivity but markedly attenuated both the DMI induced βAR downregulation and desensitization; these results suggest that arachidonic acid and/or its metabolites may be involved in DMI's effects. Preliminary results suggest that protein kinase C (PKC) is not involved in DMI's effects in C6 glioma cells.

CHARACTERIZATION OF THE EFFECT OF ANTIDEPRESSANTS IN THE TAIL SUSPENSION TEST USING CD-1 MICE. M.E. Nevins and P.M. Beardsley*, Dept. of CNS Diseases Research, G.D. Searle & Co., Skokie, IL 60077.

The tail suspension test is a new behavioral test for the identification of potential antidepressant drugs. It has been suggested that mouse strain is an important factor in sensitivity to antidepressants in this test. Therefore, the purpose of the present study was to characterize the response of the CD-1 mouse strain to the effects of various types of antidepressants in the tail suspension test. Groups of 15 mice were administered test drug s.c., and either 30 or 60 min later, were suspended from tape attached to their tails for a 6 min test session. The Itematic TST-1 (I.T.E.M.-Labo) was used to record the total time spent in immobility and the average power of the movements the mice made while suspended. The results demonstrate that using CD-1 mice the typical tricyclic antidepressants (i.e., imiprimine, desiprimine, etc.), the DA re-uptake inhibitor, bupropion, and the 5-HT re-uptake inhibitor, zimelidine, decrease immobility. However, the CD-1 mice appear to be very sensitive to the sedative effects of the antidepressants with high sedative liability, such as amitriptyline, mianserin and trazodone. These drugs tended to produce slight, not statistically significant decreases in immobility at low doses, and to increase immobility at higher doses. In conclusion, the CD-1 mouse appears to be sensitive to the antidepressant effects of several types of antidepressant drugs, and therefore, is useful (with the *caveat* that compounds with high sedative liability may not be detected) for the screening of potential antidepressant drugs in the tail suspension test.

377.11

NEUROENDOCRINE EFFECTS OF TANDOSPIRONE (SM-3997) IN HEALTHY MALE SUBJECTS. C. T. FISCHETTE, P. L. DELGADO, J. SEIBYL, J. H. KRYSTAL, G. R. HENINGER, D. S. CHARNEY. Dept. of Psychiatry, Yale Univ. Sch. of Med., New Haven, CT 06508 & Pfizer Pharmaceuticals, Inc. NY, NY 10017.

Tandospirone, a selective 5-HT_{1A} partial agonist, currently is being studied for its efficacy in depression. This study explores the neuroendocrine profile of tandospirone in fasting healthy subjects. Subjects received single doses of either placebo, 30, 40 or 50mg tandospirone at weekly intervals. At each testing session beginning at approximately 8:00 AM, blood was collected via an indwelling catheter at -20, -5, 30, 60, 90, 120, 150 and 240 minutes after oral drug administration for plasma levels of growth hormone (GH), prolactin and cortisol. In preliminary data (N=7) peak minus baseline GH concentrations were (mean ± S.D.): 0.1 ± 1.2ng/ml after placebo and 7.3 ± 7.1ng/ml ($p<.05$), 9.2 ± 7.6ng/ml ($p<.05$) and 7.7 ± 8.4ng/ml ($p<.09$) after 30, 40 and 50mg tandospirone, respectively. Cortisol levels peaked in a few subjects but no effect on prolactin was evident. Tandospirone exhibited rapid absorption and metabolism to 1-phenyl piperazine (1-PP), a common metabolite of this class of drugs which exhibits $alpha_2$ antagonist activity in animal studies. 1-PP levels were much higher than the parent compound. Increases in GH, but not prolactin, suggest differential regulation of these hormones by serotonergic and/or $alpha_2$ noradrenergic receptor systems.

377.12

COMPARISON OF THE EFFECTS OF MIANSERIN ENANTIOMERS AND METABOLITES ON A BEHAVIORAL SCREEN FOR ANTIDEPRESSANT ACTIVITY. G.J. Marek, T.H. Hand and L.S. Seiden. Dept. Pharm/Physiol.Sci., Univ. of Chicago, Chicago, IL 60637.

The behavioral effects of racemic mianserin, its (+) and (-) enantiomers, and its metabolites desmethylmianserin and 8-hydroxymianserin were evaluated on the differential-reinforcement-of-low-rate 72-sec (DRL 72-s) schedule, an operant behavioral screen known to be sensitive to and specific for the antidepressant properties of drugs. Racemic mianserin produced the antidepressant-like effect (increased reinforcement rate, decreased response rate) at 5 and 10 mg/kg. The mianserin enantiomers showed the antidepressant-like effect beginning at lower doses ((+)-mianserin: 0.6 mg/kg; (-)-mianserin: 2.5 mg/kg). The mianserin metabolites showed no clear dose-related effect at doses up to 10 mg/kg. It is concluded that the antidepressant-like effects of mianserin are due to the activity of the parent compound rather than to its metabolites, and that they may be primarily attributable to the (+) enantiomer. Given the known pharmacological profile of the mianserin enantiomers and metabolites, the present results suggest that the antidepressant-like effects of mianserin on DRL behavior are mediated through antagonist action at the 5-HT_2 receptor. This work supported by PHS MH-11191 and RSA-10562 (L. Seiden).

DOWN-REGULATION OF 5-HT2 RECEPTORS AND BEHAVIORAL RESPONSES FOLLOWING CHRONIC TREATMENT WITH ANTIDEPRESSANT DRUGS.

I. Lucki and S. Wieland. Depts. of Psychiatry and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Chronic administration of different types of antidepressant drugs reduce the number of 5-HT2 receptors and diminish the magnitude of behavioral responses mediated by 5-HT2 receptors. This experiment examined the ability of prior depletion of 5-HT content caused by the neurotoxin 5,7-DHT to prevent the effects of chronic treatment with two different types of antidepressant drugs: the tricyclic desipramine or the monoamine oxidase inhibitor phenelzine.

Rats were pretreated with 5,7-DHT (200 ug i.c.v. with 25 mg/kg desipramine) or vehicle 7 days prior to the initiation of chronic drug treatments. Different groups of rats were then injected for 14 days with either 0.9% NaCl, desipramine (10 mg/kg b.i.d.), or phenelzine (10 mg/kg once daily). On Day 16, 24 hours following the cessation of drug treatment, rats were injected with the 5-HT2 agonist DOB (1.0 mg/kg) and tested for the elicitation of head shaking behavior. In separate groups of drug-treated rats, the density of 5-HT2 receptors in the frontal cortex was measured.

Chronic treatment for 14 days with either desipramine or phenelzine reduced the number of head shakes elicited by the 5-HT2 agonist DOB. 5,7-DHT pretreatment diminished the ability of phenelzine to reduce the 5-HT2-mediated response but had no effect on the reduction of the response caused by desipramine. 5,7-DHT pretreatment attenuated the reduction of 5-HT2 receptors caused by chronic phenelzine treatment but did not alter the reduction of 5-HT2 receptors caused by chronic treatment with desipramine. Different mechanisms probably underlie the reduction of 5-HT2 receptor density and 5-HT2-mediated behavioral responses by these antidepressant drugs.

377.14

CHRONIC ADMINISTRATION OF PHENELZINE AND N^2-ACETYLPHENELZINE CAUSES ELEVATION OF WHOLE BRAIN AMINE NEUROTRANSMITTER LEVELS AND α_2 RECEPTOR DOWN REGULATION.

K.F.McKenna*, G.B.Baker, R.T.Coutts* and A.J.Greenshaw*. Neurochemical Research Unit. Dept. of Psychiatry, University of Alberta, Edmonton, Canada, T6G 2B7.

Phenelzine (PLZ), an irreversible nonselective monoamine oxidase (MAO) inhibitor, is widely used in psychiatry for the treatment of panic disorder (PD) and depression. PLZ has long been thought to be acetylated in humans but this is controversial. It has been shown that 1-acetyl-2-(2-phenylethyl)hydrazine [N^2-acetylphenelzine (N^2AcPLZ)] is a metabolite of PLZ in rat brain and blood. We have investigated the effects of chronic 28 d administration of PLZ (0.05 mmol/kg/d) and N^2AcPLZ (0.10 mmol/kg/d) on α_2 adrenoreceptor function using a behavioural test on days 21 and 22. After administration of physiological saline or the α_2 agonist clonidine (0.05 mg/kg), rats treated with PLZ and N^2AcPLZ displayed a significant attenuation of the suppressant effects of clonidine on spontaneous locomotor activity compared to controls, indicating down regulation of α_2 receptors. This finding is of interest as α_2 receptor supersensitivity is hypothesized in patients with PD and PLZ has antipanic efficacy. By day 28 both PLZ and N^2AcPLZ had produced greater then 90% inhibition of MAO-A and -B in liver and heart. Both drugs induced significant elevation of whole brain noradrenaline, 5-hydroxytryptamine (5-HT), and dopamine levels compared to controls. The acid metabolites of dopamine and 5-HT [homovanillic acid, 3,4-dihydroxyphenylacetic acid and 5-hydroxyindole-3-acetic acid (5-HIAA)] were significantly reduced in drug treated animals. There were no significant differences between the effects of PLZ and N^2AcPLZ in these studies (except in the case of 5-HIAA), suggesting that N^2AcPLZ is a potent nonselective MAO inhibitor which can downregulate α_2 receptors.

G-PROTEINS IN RAT BRAIN: EFFECTS OF LITHIUM.

M.B. Williams, F.H. Wagner*, X. Gu, M.S. Baird* and R.S. Jope. Depts. Pharmacology and Psychiatry, University of Alabama, Birmingham, AL 35294.

Lithium is the primary treatment for bipolar affective disorder, but its mechanism of action is unknown. Recent evidence suggests that a primary site of action of lithium may be the G-proteins associated with second messenger systems in the brain. Therefore, we measured the effects of chronic treatment of rats with lithium on the ADP-ribosylation of G-proteins and on the G-protein mRNA levels.

ADP-Ribosylation of G-proteins was measured in tissue from rat hippocampus and cortex. Three processes were measured, ADP-ribosylation induced by pertussis toxin, cholera toxin, and the endogenous ARF (ADP ribosylation factor). ADP-Ribosylation was measured by incubation of membranes (for pertussis or cholera toxin) or homogenates (for ARF) with ^{32}P-NAD, ATP, thymidine, ATP, triton-X-100, and guanine nucleotides followed by electrophoresis on 10% polyacrylamide gels, autoradiography, and quantitative densitometric scans. With pertussis toxin, APD-ribosylation was maximal with GDP and was reduced by a stable analog of GTP, and was limited to proteins of approximately 40 kD. With cholera toxin and ARF, ADP-ribosylation was maximal with a stable analog of GTP and several proteins were labelled.

Total RNA was isolated from rat hippocampus and cortex by acid guanidinium thiocyanate-phenol-chloroform extraction and mRNA was analyzed by Northern blot hybridizations using G_s, G_o, G_{i1}, G_{i2}, and G_{i3} cDNA clones generously provided by Dr. R. Reed.

Rats were treated with dietary LiCl for 4 weeks using a protocol which causes no weight loss and produces plasma lithium levels of approximately 0.8 mM. For each assay, lithium-treated and control rats were run in parallel and the results quantitatively compared. The results of these studies should indicate whether chronic lithium treatment affects the mRNA levels for G-proteins or the G-proteins available for ADP-ribosylation by any of the three methods studied.

377.16

LITHIUM ATTENUATES ADENYLATE CYCLASE ACTIVITY IN INTACT RAT BRAIN: AN IN VIVO MICRODIALYSIS STUDY.

M. I. Masana, J. A. Bitran*, J. K. Hsiao* and W. Z. Potter*. Sec. Clin. Pharmacol., Clin. Neurosc. Branch, NIMH, Bethesda, MD 20892

The effects of chronic and acute lithium treatment on adenylate cyclase activity in intact rat brain were examined using *in vivo* microdialysis. Basal extracellular cyclic AMP was measurable in dialysate when the phosphodiesterase inhibitor, rolipram, was present (0.52 ± 0.06 fmol/min, n=14) and increased in a dose dependent manner after agonists were added to the perfusate. The increase in cyclic AMP in brain extracellular fluid after stimulation with 100 µM norepinephrine was blocked by addition of 1 µM of the ß-blocker, propranolol ($p<0.025$). Chronic lithium treatment (8 weeks, serum level 0.7 mEq) modestly increased basal brain extracellular fluid cAMP levels, while significantly blunting the cyclic AMP response to stimulation with 100 µM norepinephrine (57.9% increase after lithium versus 170.6% increase in controls, $p<0.005$). Acute infusion of lithium also modestly inhibited the cyclic AMP response to norepinephrine stimulation (99.7% increase). The effects of lithium treatment on different components of the adenylate cyclase transduction system (forskolin and cholera toxin stimulated cyclic AMP increase) were also assessed.

377.17

INOSITOL PHOSPHATES IN RAT BRAIN REGIONS: EFFECTS OF LITHIUM AND SEIZURES.

R.S. Jope, R.E. Smith* and R.A. MacQuarrie. Dept. of Psychiatry, University of Alabama, Birmingham, AL 35294 and University of Missouri, Kansas City, MO 64110.

Anion exchange chromatography coupled with detection by chemical suppression was used to measure inositol phosphates in rat brain regions after sacrifice by microwave irradiation. Coadministration of acute lithium and pilocarpine induced seizures which were accompanied with large increases of $InsP_3$ and $InsP_2$ in the hippocampus and cortex.

Chronic dietary LiCl (4 weeks) produced brain Li levels of 0.60-0.97 mmole/kg and resulted in 74 to 87% depletions of $InsP_3$ and $InsP_2$. Stimulation of seizures with pilocarpine only slightly increased $InsP_3$ but significantly elevated $InsP_2$.

In contrast to inositol phosphates, chronic Li did not alter the concentration of cyclic AMP nor did it reduce the elevation induced by seizures.

These results demonstrate directly that chronic lithium treatment severely reduces phosphoinositide metabolism in rat brain regions, but the system is still capable of responding to a stimulus. Furthermore, the effects of chronic lithium were much more evident on inositol phosphates than on cyclic AMP.

377.18

LITHIUM, CALCIUM, AND LOCOMOTOR ACTIVITY IN SYRIAN HAMSTERS.

K.E. Greene*, H. Klemfuss, and D.F. Kripke*. Depts. of Neurosciences and Psychiatry, University of California, San Diego, and VA Medical Center, San Diego, CA 92093.

Lithium (Li+) is an effective antidepressant and anti-manic agent, but its mechanism of action is not well understood. Lithium's primary action may be to compete with endogenous cations for binding sites. This study tested interactions of dietary calcium (Ca++) and lithium on plasma Ca++ concentration, locomotor activity, and toxicity in 30 male Syrian hamsters.

A diet high in calcium (3% $CaCl_2$) significantly increased total running wheel locomotor activity by 65% compared to a low calcium diet (0.1% $CaCl_2$). Addition of lithium (0.4% Li_2CO_3) to either low or high Ca++ diets, producing plasma Li+ concentrations ranging from 0.6 to 2.0 mM, significantly increased both plasma Ca++ and locomotor activity. Overall activity levels were significantly correlated with plasma Ca++ levels. While there was no difference in toxicity between the low and high Ca++ diets, calcium protected against some of lithium's toxic side effects.

Although central homeostatic mechanisms protect the brain from changes in peripheral calcium, we found that a modest change in plasma calcium concentration can have clear effects on CNS-controlled behavior. The data also support a stimulatory action of lithium on locomotor activity, one that may be mediated through calcium.

ALTERED FENFLURAMINE- STIMULATED PROLACTIN RELEASE DURING TREATMENT OF OBSESSIVE COMPULSIVE PATIENTS. W.A. Hewlett*. Dept. of Psychiatry, Stanford University School of Medicine. Stanford.CA.94305.

OCD is a psychiatric disorder which may involve alterations in serotonin functioning. In order to assess serotonergic functioning in OCD patients fenfluramine-stimulated prolactin release was measured in both a medication free condition and during treatment with either clomipramine, clonazepam, clonidine, or diphenhydramine. Two baseline prolactin samples were drawn 30 minutes apart prior to administration of a 60 mg oral dose of fenfluramine. Fenfluramine-stimulated prolactin samples were then drawn hourly over the next five hours. Treatment with clomipramine significantly elevated baseline prolactin levels as compared to the untreated condition. Female patients showed significantly greater elevations in fenfluramine-stimulated prolactin release in both treated and untreated conditions. Fenfluramine-stimulated prolactin release was significantly greater under conditions of clonazepam and clomipramine treatment than that seen during diphenhydramine treatment. These results are consistent with altered serotonergic functioning during serotonergic treatment of OCD.

377.20

NORADRENERGIC DYSFUNCTION IN PANIC DISORDER. D.S. Charney, S.W. Woods, J.H. Krystal, L.M. Nagy, G.R. Heninger. Psychiatry Service, West Haven VA Medical Center, West Haven, CT. 06516.

Abnormal regulation of brain noradrenergic neurons may be involved in the pathophysiology of anxiety disorders. This investigation evaluated noradrenergic function in panic disorder by evaluating responses to intravenous yohimbine and clonidine in the same panic disorder patients and healthy subjects. **METHODS**: Thirty-eight patients and 15 healthy subjects (HS) participated in the study. Infusions of clonidine (0.2 µg/kg), yohimbine hydrochloride (0.4 mg/kg), or saline, over 10 min. was given during a series of 3 test days. Before drug administration, and at intervals thereafter, behavioral ratings, blood pressure, heart rate, and plasma samples for MHPG and growth hormone were obtained. Each patient was assessed to determine whether a panic attack occurred. **RESULTS**: Yohimbine produced panic attacks in 63% of the patients. Patients who experienced yohimbine induced panic attacks (YPA) had greater increases in plasma MHPG than the patients who did not (NPA) and the HS. The YPA, but not the NPA, patients had a blunted growth hormone rise to clonidine compared to the HS. Clonidine produced significant decreases in plasma MHPG and anxiety symptoms in the YPA patients, but not in the NPA and HS. **CONCLUSIONS:** Abnormal yohimbine induced increases in plasma MHPG, blunted growth hormone responses to clonidine, and significant clonidine induced decreases in plasma MHPG and anxiety symptoms are restricted to YPA patients. These patients may represent a subgroup of panic disorder patients with noradrenergic neuronal dysfunction, specific clinical characteristics and treatment response.

377.21

LITHIUM AUGMENTATION IN FLUVOXAMINE-REFRACTORY OBSESSIVE COMPULSIVE DISORDER. W.K. Goodman, M.D., C.J. McDougle, M.D., L.H. Price, M.D., D.S. Charney, M.D., G.R. Heninger, M.D., Yale Univ. Dept. of Psychiatry, 34 Park St., New Haven, CT 06519.

These double-blind placebo-controlled studies examined the efficacy of adding lithium carbonate, which may augment serotonin (5-HT) function, to an ongoing treatment trial of fluvoxamine (FVX) in 30 patients with primary OCD who had failed to respond to FVX. Methods: Study 1: 20 patients (4 inpatients, 16 outpatients) with OCD (DSM-III-R) were randomized to 2 weeks of treatment with active (N=11) or placebo (N=9) lithium augmentation of ongoing FVX treatment. Study 2: An additional 10 outpatients with OCD were randomized to 4 weeks of treatment with active (N=5) or placebo (N=5) lithium augmentation of ongoing FVX treatment. Outcome was assessed with Y-BOCS scores before and after the addition of lithium to FVX. Results: Study 1: Two of 11 (18%) patients met criteria for a meaningful clinical response (1 marked, 1 partial) to active lithium. No patients responded to placebo. Active lithium augmentation of FVX produced a statistically significant improvement in scores on the Y-BOCS (-4.0±5.2, $p<.03$, paired t-test, two-tailed). There was no significant change in severity of OCD symptoms in the placebo lithium-treated group. There were significant between-group differences as measured by the Y-BOCS ($p<.04$, student's t-test). An analysis of all patients treated subsequently with 3-5 weeks of open active lithium augmentation (N=16) found a statistically significant improvement in Y-BOCS scores (-3.1±2.5, $p<.003$), 5/16 (31%) patients showed a qualitative response (1 marked, 4 partial). Study 2: No patients demonstrated a response during the 4-week controlled trial of lithium augmentation of FVX. In addition, there was no significant change in scores on the Y-BOCS. Combined Analysis: For all patients receiving 4 weeks of open active lithium augmentation of FVX (N=20), no significant change in Y-BOCS scores was found (-1.5±5.2, n.s.). Only 4/20 (20%) of these patients showed a response (1 marked, 3 partial). Conclusion: These double-blind placebo-controlled trials suggest that lithium augmentation is not an effective strategy in most OCD patients. The different rate of response to this treatment strategy between patients with OCD and depression suggests that pathophysiological differences may exist between these two disorders.

ORBICULARIS OCULI AND EXTRAOCULAR MUSCLE ACTIVITY DURING UNCONDITIONED AND CONDITIONED EYEBLINKS IN THE RABBIT. N.E. Berthier, J.W. Moore, Department of Psychology, University of Massachusetts, Amherst, MA 01003.

The activity of the retractor bulbi (RB), superior rectus (SR), and orbicularis oculi (OO) muscles were recorded in awake animals using chronically and acutely implanted teflon coated microwires. Eyelid and nictitating membrane positions were measured with potentiometers. All three muscles showed a two component response to trigeminal nerve stimulation, air puff, and periorbital electrostimulation. With periorbital electrostimulation the latencies of the two responses were about 5 and 10 ms. Crosscorrelegrams of EMG activity taken from conditioning trials showed less than 5 ms shift in the peak correlations. Examination of individual conditioning trials showed that the time course of EMG activity in the RB, SR, and OO muscles was highly correlated. Two differences in EMG activity were seen between muscles: (1) The OO showed tonic activity while the RB and SR did not. (2) The SR showed small EMG responses relative to the RB and OO. Given the high correlation between the activity of extraocular and OO activity we conclude that muscle activity during blinks is the result of a single premotor system. (Supported by AFOSR 89-0391 and BNS 88-10624).

GENOTYPE AND REGION DEPENDENT BRAIN DNA SYNTHESIS DURING HABITUATION TO SPATIAL NOVELTY IN THE ALBINO RAT. A.G. Sadile*, A. Cerbone*, C. Lamberti-D'Mello**, T.Menna, C. Buono, F. Rafti & A. Giuditta**. IIGB, CNR, Naples; *Dipt. Fisiol.Um. & Funz.Biol.Integr. "F.Bottazzi"; and **Fisiol.Gen. & Amb., Univ. Naples Federico II, Naples, I.

To investigate the role of brain DNA synthesis in non associative learning, adult male albino rats of a random-bred Sprague-Dawley stock (NRB), and of the Naples High (NHE) and Low-Excitability (NLE) strains, selectively bred for divergent activity in a novel environment (Sadile et al., Soc.Neurosci. 9:643, 1983) were used. Three groups of rats from each strain were exposed or re-exposed one day later, or unexposed to a L-maze. The frequency of corner crossings and rearings were monitored during a 15min-test. Rats received an intraperitoneal injection of 3H-thymidine 15 min before test trial 1 or 2. Brain DNA synthesis was measured in ex-vivo homogenates of neocortex, hippocampus, neostriata, midbrain, hypothalamus and cerebellum by the incorporation of 3H-thymidine into DNA after a 30min pulse. Both NLE/NHE rats had a higher basal DNA synthesis in the hippocampus and neostriata. Upon test trial 1, but not upon re-test, there was a significant decrease in DNA synthesis in the neocortex and hippocampus of both strains, and in the hypothalamus, midbrain and cerebellum of NLE only. The decrease was lower in NHE than in NLE rats. The results support the proposed involvement of brain DNA in information processing and storage.

378.3

IMMUNITY FROM NICOTINE-INDUCED CONDITIONED FOOD AVERSION IN MICE. N.E. Kinney. Dept. of Psychology, SE Missouri State Univ., Cape Girardeau, MO 63701.

Mice (Mus musculus) demonstrated dose-dependent conditioned food aversion (CFA) when novel food (almond) consumption was paired with a subcutaneous injection of (-) nicotine tartrate (0.2 - 1.6 mg/kg). Controls showed no aversion (but rather a significant increase in consumption) at 0.2 mg/kg, and complete aversion at 1.6 mg/kg. This contrasts with reported aversion to nicotine at 0.1 mg/kg in rats. Immunity to nicotine-induced CFA was demonstrated by bilaterally olfactory nerve-sectioned mice on day 7 post-surgery (while anosmic). This protection was lost by day 15 post-surgery.

The novel food effect shown by controls was not observed in nerve-sectioned mice. These findings are in agreement with earlier work using tilted-rotary motion to produce malaise. The loss of CFA in anosmic animals (and its appearance following olfactory nerve regeneration) for both motion-induced and nicotine-induced malaise strengthens support for a dominant role of olfaction in the formation of conditioned flavor aversions.

378.4

PLASTICITY IN THE REINFORCEMENT SYSTEM OF INFANT RATS. R.M. Sullivan and D.A. Wilson. Developmental Psychobiology Laboratory, Dept. Psychology, University of Oklahoma, Norman, OK

Newborn rat pups learn to approach odors paired with tactile stimulation which mimics stimulation during maternal care. This learned behavioral preference is associated with a modified olfactory bulb neural response to that odor. Odor-stroking pairings in pups after PN8-10, however, do not produce these learned neurobehavioral responses, suggesting a sensitive period in early olfactory learning. The present study examined the nature of this age sensitivity.

Pups were trained on PN5, PN12 or PN20 in an olfactory conditioning paradigm employing either STROKING, intra-oral MILK infusions, LOW intensity foot shock (0.5 mA) or HIGH intensity foot shock (1.5 mA) as the UCS. Training consisted of a 10 min CS/UCS pairing, or randomized UCS - CS presentation. Pups were tested for neurobehavioral responses to the odor CS 24 hr later. The results suggested that while STROKING was only effective at PN5, pups could learn odor preferences at all ages if trained with MILK as a UCS. HIGH shock produced odor aversions at all ages, while LOW shock produced odor preferences at PN6 and aversions at older ages.

These results suggest that sensitive periods in early olfactory learning may reflect ontogenetic changes in reinforcement pathways, rather than in the olfactory system itself.

378.5

CHANGES IN MEMORY FUNCTION ACROSS THE MENSTRUAL CYCLE S.M. Phillips and B.B. Sherwin. Department of Psychology, McGill University, Montreal, P.Q., Canada, H3A 1B1

Thirty healthy cycling women (mean age 23.6 years) underwent cognitive testing during the menstrual (M) and midluteal (ML) phases of the menstrual cycle. Radio-immunoassay was performed on blood samples drawn at both test times in order to measure plasma estradiol (E2) and progesterone (P) levels. Based on hormone levels, menstrual cycle phase was confirmed for 25 subjects.

In this confirmed sample, higher scores on a visual memory (30-minute delayed recall) task occurred in the ML relative to M phase ($p<.01$), coincident with higher levels of plasma E2 ($p<.001$) and P ($p<.001$). No significant differences across the menstrual phases were found on verbal memory (immediate or delayed recall), visual memory (immediate recall), digit span, or paired-associate learning. There was, however, a significant positive correlation within the ML phase between plasma P and verbal memory scores (immediate recall, $p<.04$; delayed recall, $p<.03$); whereas plasma E2 was positively correlated with paired-associate learning scores ($p<.03$).

Results indicate that mild variations in memory function occur in some women across the menstrual cycle in association with changes in plasma E2 and P levels.

378.6

MAPPING OF AUDITORY MEMORY WITH 2-DEOXYGLUCOSE: LATERALIZED CONDITIONING EFFECTS IN SPLIT-BRAIN RATS AND GERBILS. F. Gonzalez-Lima, H. Scheich, and A.R. McIntosh. Dept Med Anat, Texas A&M Univ, College Station, TX 77843; Inst Zool, Tech Univ, Darmstadt, W Germany.

The 2-DG method was used to map memory-related activity in twelve split-brain rats and gerbils. Training started 2 weeks after surgery and consisted of unilateral presentations of sound and foot shock in paired (one side) and unpaired (other side) sessions. The next day, subjects were tested for conditioned suppression of drinking, injected with 2-DG, and stimulated binaurally with sound. Differences in 2-DG uptake between the two sides of the brain were quantified. The conditioned hemisphere (side contralateral to paired stimuli) showed striking enhancements of uptake in forebrain structures, including hippocampus, subiculum, accumbens, entorhinal and perirhinal cortex, amygdala, and fundus striati. The largest increase (70%) was in the CA2 region of the hippocampus. The findings revealed for the first time a direct, within subjects, comparison of the cerebral representation of auditory memory. (Supported by NIMH grant RO1-MH43353).

378.7

NEURAL SUBSTRATES FOR DISCRIMINATIVE OPERANT CONDITIONING VISUALIZED USING 2-DEOXYGLUCOSE AUTORADIOGRAPHY. M. Garrosa, F. Gonzalez-Lima and F.J. Helmstetter. Dept Med Anat, Texas A&M Univ, College Station, TX 77843; Univ Valladolid, Spain.

2-DG techniques applied to rats trained in four groups were used to map the neural respresentation of the behavioral components involved in discriminative operant conditiong. 1) Rats trained to bar press for food during a sound discriminative operant conditioning (sound → operant CR → reward); 2) Rats without bars yoked to those in Group 1 (sound → reward); 3) Rats trained to bar press for food, independently of sound, nondiscriminative operant conditioning (random sound, operant CR → reward); 4) Rats without bars yoked to those in Group 3 (random sound and reward). Group 1 rats (disc.) compared to 3 (nondisc.) showed 2-DG changes in accumbens, ventral cochlear and ventroposteromedial thalamic nuclei. Structures with the same 2-DG uptake in the operant groups (1=3) but different than the nonoperant groups (2,4) included frontal cortex, paratenial and reticular thalamic nuclei, medial geniculate and cerebellar vermis. Common changes in the conditioned groups (1=2=3) but different than the random group (4) included the caudal caudatoputamen, posterior parietal cortex, dorsal cochlear nucleus, and cerebellar flocculus. These changes are the first demonstration of brain metabolic alterations related to a learned discriminative response to sound. (Supported by NIMH grant RO1 MH 43353)

378.8

PHYSIOLOGICAL PROPERTIES OF MEDIAL SEPTAL NEURONS (MSNs) IN UNANESTHETIZED RATS. J.E. Sweeney, M.H. Bassant* and Y. Lamour, INSERM U 161, 75014 Paris France.

Rhythmically bursting neurons (RBNs) of the medial septum may trigger one type of hippocampal theta rhythm that correlates to behavior in the rat. Since the activity of RBNs varies with different anaesthetics, we have chosen to characterize their properties in unanesthetized rats habituated to a painless restraint.

In 355 MSNs (recorded from 12 rats), 59 neurons (17%) exhibited a rhythmic bursting activity. This percentage is clearly different from the 45% of bursting MSNs recorded in urethane-anesthetized rats. The bursting activity was also of a significantly higher frequency than with urethane (5.8 ± 0.1 vs. 3.9 ± 0.1 bursts/sec). The majority of bursting neurons were recorded during EEG arousal (with a theta). Nevertheless, 2 bursting neurons were recorded in "drowsy" states (in the absence of a theta) and 10 during paradoxical sleep (with a frequency of 6.2 ± 0.2 bursts/sec). Tactile or electrical stimulation of the reticular formation induced EEG arousal and rhythmicity in 13 of 58 previously non-bursting neurons that had a high (>15 spikes/sec) spontaneous activity.

Clearly, properties of rhythmically bursting neurons differ between unanesthetized and urethane-treated rats. These results also suggest that there may be discrete pools of MSNs--a small number that maintain rhythmicity regardless of the state of arousal and a reserve population of rapidly firing cells that can be recruited by an arousing stimulus to fire rhythmically.

THE CONTRIBUTION OF THE MEDIAL SEPTAL AREA TO ENTORHINAL CORTICAL AND SUBICULAR SINGLE-UNIT ACTIVITY. S. J. Y. Mizumori and K. E. Ward*, Dept. Psych., Univ. Utah, Salt Lake City, UT 84112

Reversible inactivation of the medial septum temporarily disrupts spatially selective discharge of hippocampal hilar/CA3 (and not CA1) cells, reduces movement-sensitivity of stratum granulosum (SG) units, and produces a spatial working memory impairment in rats (Mizumori et al., *J. Neurosci.*, 1989). Recently, we examined the possibility that septal inactivation produced these effects by functionally isolating hippocampus from its primary input (entorhinal cortex) and/or output (subiculum) structures.

Spontaneous single unit activity was monitored in hippocampus (CA1: n=16; FD: n=16), dorsal subiculum (n=20), and medial entorhinal cortex (n=13) before, during, and after septal inactivation in 10 Nembutal-anesthetized F-344 rats. Baseline activity was recorded for 10 min, lidocaine (0.5 µl; 2% solution) was injected into the medial septal area, then unit activity was monitored for at least an additional 20 min. Similar to previous results, few (6%) CA1 complex-spike cells and 50% of SG and hilar/CA3 cells showed altered discharge patterns following lidocaine treatment. A small percentage of subiculum (10%) and entorhinal (15%) cells responded by either increasing or decreasing firing. Ongoing experiments with freely behaving animals thus far confirm this pattern of responses. These data suggest that septal inactivation-induced alterations in subcortical, rather than entorhinal, afferents underlie the hippocampal unit effects. Furthermore, the behavioral impairment described earlier may have resulted from a disruption of hippocampal, and not subicular, unit activity. [Supported by BRSG Grant S07 RR07092]

MEDIAL SEPTAL AREA CODES MNEMONIC COMPONENTS OF A WORKING MEMORY TASK. B. Givens and D.S. Olton. Dept. Psychology. Johns Hopkins University. Baltimore, MD 21218

The contribution of the medial septal area (MSA) to working memory processes was investigated in rats performing a delayed continuous conditional discrimination (CCD) operant task. Single neurons in the medial septum, lateral septum and CA1 hippocampus were analyzed for changes in activity that correlated with components of the task. In addition, MSA neural output was altered by intraseptal microinfusions, and changes in operant behavior and hippocampal EEG were recorded. Single unit analysis revealed that although some CA1 complex spike cells fired differentially to the task components, most hippocampal neurons showed little event-related firing. Conversely, most septal cells fired differentially to the stimulus/response contingencies. Microinfusion of tetracaine or muscimol into the MSA suppressed hippocampal theta and decreased choice accuracy in the CCD task. These changes returned to baseline more rapidly following tetracaine (25 min) than muscimol (60 min), and at shorter interstimulus delay intervals. The changes in EEG and choice accuracy were correlated most strongly at the longest (20 sec) delay. Taken together, these data support a role for the MSA in the neural coding of non-spatial information important for working memory in rats. Supported by NRSA # NS8616.

CHOLINERGIC ACTIVATION OF MEDIAL SEPTAL AREA CAN RESTORE WORKING MEMORY IN OLD RATS AND IN SCOPOLAMINE-TREATED YOUNG RATS. A. L. Markowska, B. Givens, and D.S. Olton, Dept. of Psychology, The Johns Hopkins University, Baltimore, MD 21218.

Functional deterioration in the cholinergic system with age may be partly responsible for age-related memory deficits. Therefore, activation of cholinergic neurons in the basal forebrain may alleviate these memory impairments. In the present study, naive young (4 mo), scopolamine-treated young (4 mo), or naive old (24 mo) rats were microinfused into the medial septal area (MSA) with cholinergic receptor agonists (carbachol, oxotremorine), a GABA receptor antagonist (bicuculine), or saline. Working memory, as assessed by choice accuracy in a spatial alternation task, was tested before and after infusion, then compared to baseline performance during saline and non-infusion trials. Preliminary data indicate that cholinergic agonists infused directly into MSA can partially reverse scopolamine-induced deficits in young rats and may also improve performance in the aged rats in this task. These data suggest that cholinergic drugs may act directly on basal forebrain cholinergic neurons for their mnemonic effects. Hippocampal EEG recordings before and after microinfusion are currently being analyzed for electrophysiological correlates of the behavioral data. Supported by NRSA # NS8616.

A CORRELATE FOR OLFACTORY LEARNING IN AN IDENTIFIED NEURON IN THE HONEY BEE BRAIN. J. Mauelshagen* and R. Menzel. Institut für Neurobiologie, Freie Universität Berlin, Königin-Luise-Str.28/30, D-1000 Berlin 33, FRG.

A single large neuron extrinsic to the pedunculus of each mushroom body, identified by intracellular marking, responds to a variety of sensory inputs with excitation (olfactory, mechanical, taste, vision). Recording experiments were performed under conditions, which in behavioral experiments lead to sensitization and conditioning of olfactory stimuli (Menzel, R. in Olton and Kesner (eds) Neurobiology of comparative cognition, Erlbaum 1990). Compared to the control group, sensitization results in a significant frequency increase during the first 100 msec interval of the response. In contrast, conditioning results in a significant frequency decrease during the third and fourth interval of the response. This suggests different processes involved in coding the olfactory information depending on the temporal order of the CS and US. Further experiments have to ensure that the observed response modulations are specific effects of non-associative and associative memory processing.

Single Cell Specificity of Molecular Changes During Memory Storage. **D L. McPhie, L.D. Matzel, J.L. Olds, A.M. Kuzirian* and D.L. Alkon, LMCN, NINDS, NIH, Bethesda MD, 20892.**

***Hermissenda crassicornis* exhibits a learning-specific increase in Protein Kinase C that is localized to individual types of nerve cells as assessed by 3H-phorbol 12,13-dibutyrate ([3H]-PDBU) emulsion autoradiography in 4µm epon sections of circumesophageal ganglion. The increase is anatomically localized to neurons previously shown to be critically involved in the storage of a classically conditioned response which has been shown to undergo specific biochemical, electrophysiological and morphological modifications. The present study confirms and extends these previous results while implicating anatomically-localized increases in PKC to learning-specific molecular processes.**

The circumesophageal ganglion of animals in three treatments (Paired, Random and Naive) were incubated with 3H-PDBU and then processed for histology and subsequent computerized image analysis. Paired, but not Random or Naive, animals showed a significant increase in 3H-PDBU binding in the medial and intermediate B photoreceptors and in cells of the optic ganglion(17%, 10%, and 16% respectively. $p<.01$, n=6 per group, planned orthagonal contrast). Such increased binding of [3H]-PDBU in *Hermissenda* represents to our knowledge the first conclusive evidence for neuronal specificity of memory-specific changes in the distribution of this regulatory enzyme (Olds et al Science, 1989).

GABA-INDUCED PROTEIN KINASE ACTIVATION IS ENHANCED WHEN PAIRED WITH POST-SYNAPTIC DEPOLARIZATION.
L.D. Matzel and D.L. Alkon
Laboratory of Molecular and Cellular Neurobiology, NINDS-NIH

The characteristic inhibitory influence of vestibular hair cells on the B photoreceptors of the *Hermissenda*'s eye is mediated by a GABAergic synapse. Hair cell impulses (like that which accompany rotation) as well as exogenous GABA (12.5 μM) application activate a primary Cl^- conductance that is accompanied by a decrease in membrane resistance. Activation of a second, slower K^+ conductance, characterized by an increase in resistance is also observed 60-90 sec after GABA application. If the Cl^- channel blocker NPPB (10 μM) was added to the extracellular bath, this increase in resistance was observed within 10 sec of GABA application, suggesting that the second conductance is normally masked by the faster Cl^- conductance. Moreover, if the B cell was depolarized 20-40 mV by positive current injection (analogous to that which occurs in response to light), the magnitude of the GABA-induced increase in resistance was dramatically enhanced. This latter effect was not observed if Ca^{2+} was removed from the extracellular bath or if the protein kinase inhibitor H7 (100 μM) was added to the bath, suggesting that the activity of a GABA-activated protein kinase was enhanced by depolarization-induced intracellular Ca^{2+} elevation in the post-synaptic neuron. These results suggest a mechanism underlying the temporal dependence of stimulus pairings in classical conditioning, and in particular, the biophysical changes in single neurons which accompany light-rotation pairings in *Hermissenda*.

ACTIVATION OF Ca^{++}-DEPENDENT PROTEIN KINASE ALTERS BIOPHYSICAL RESPONSES OF ISOLATED *HERMISSENDA* PHOTORECEPTORS WHEN PAIRED WITH INTRACELLULAR Ca^{++} ELEVATION

I. Lederhendler, L. Matzel, P. Huddie, and D.L. Alkon. Laboratory of Molecular and Cellular Neurobiology, NIH-NINDS.

Following classical conditioning, *Hermissenda* Type B photoreceptors show increased input resistance and light responses. The protein kinase activator, phorbol ester (PDBU), has been shown to reduce outward K^+ currents that underlie this increased excitability. Ca^{++}-dependent activation of protein kinase C mediates long-term reduction of K^+ currents and also produces dramatic outgrowths from the soma of isolated photoreceptors. We studied the relationship of this morphological change to biophysical properties of Type B cells with current and voltage clamp, using specific conditions which produce outgrowth activity. In these isolated photoreceptors only pairing light with PDBU, but not light alone, nor light paired with an inactive phorbol ester, increased the light response and input resistance (ANOVA, $N=18$, $p<.01$). These changes could not be duplicated when Ca^{++} was absent from the bath. Furthermore, single-electrode voltage clamped photoreceptors showed reduced Ca^{++}-dependent K^+ currents when PDBU was present and Ca^{++} influx was increased by depolarizing voltage steps equivalent in magnitude to light stimulation used in the current clamp experiments. These results suggest that certain key biophysical and morphological changes in the Type B soma may be expressions of the same conditioning experience.

RESPONSE OF TEMPORAL LOBE NEURONS TO SOCIAL STIMULI IN MACACA ARCTOIDES . L.A. Brothers, B.D. Ring* and A.S. Kling . UCLA/Sepulveda VA Medical Center, Sepulveda CA 91343

Accurate evaluation of social signals is essential to group-living primates; however, neural processing of the full range of social stimuli remains little understood.

We used laser disks containing 50,400 frames of moving pictures and vocalizations of macaques recorded in natural settings to deliver 2s clips of a broad array of body parts, movements, expressive behavior, and social interactions. Recordings of single unit activity in the region of the right amygdala and neighboring cortical areas were obtained in an alert stumptail macaque.

Of 275 isolated units, 21 were selectively responsive to a subset of the presented stimuli. Of these, 2 responded to one or a few specific pictures only. The remainder responded to a heterogeneous subset of the stimuli or were selective for a single feature common to a number of stimuli. These results suggest that anterior temporal neurons of the macaque brain participate in ensembles coding features of the social environment.

SPATIAL TUNING IN MUSTACHE BAT AUDITORY NEURONS WITHIN THE CONTEXT OF ECHOLOCATION. Z.M.Fuzessery. Dept. of Psychology and Zoology, Univ. of Wyoming, Laramie, WY 82071.

Echolocating animals have the potential to modify both their acoustic emitters and receivers to optimize signal analysis. This study examines how spatial processing in the mustache bat might be optimized. It combines data on the directionality of the external ears and the radiation pattern of the echolocation pulse (Hartley and Suthers, 1990) to determine the distribution of acoustic energy in the frontal sound field of the mustache bat while it echolocates. One finding is that intensity level is almost constant across the center of the sound field, from 40° to either side of the midsagittal plane. This is not the case when only ear directionality is considered. In addition, energy drops away more rapidly at locations lateral to 40°. This suggests that the echolocation system may stabilize one stimulus parameter, intensity level, at the center of the sound field to allow for a less ambiguous analysis of target location, as well as other features of the scanned object. This, for example, would allow the bat to resolve interaural intensity differences independent of absolute intensity level. Moreover, binaurally facilitated neurons that exhibit a broad spatial tuning when only ear directionality is considered show a sharper selectivity when evaluated within the context of echo-location. In addition to maintaining an almost constant intensity level across the center of the sound field, the mustache bat also "intensity compensates" (Henson et al., 1985) to maintain the echo at an absolute intensity level. These findings suggest that this echolocation system may be optimized to reduce the ubiquitious problem of differentiating stimulus quality and quantity. NS-13276, NS-21286.

REPRESENTATION OF TARGET ELEVATION IN UNIFIED IMAGES PERCEIVED BY FM ECHOLOCATING BATS. J.A. Simmons, J.M. Wotton*, M. Ferragamo*, and C.F. Moss[1]. Dept. of Psychology and Section of Neurobiology, Brown Univ., Providence, RI 02912 & [1]Dept. of Psychology, Harvard Univ., Cambridge, MA 02138

The big brown bat, *Eptesicus fuscus*, perceives images that incorporate both target range and shape onto a common psychological axis of range, defined in terms of echo delay (Simmons, J.A., *Cognition*, 33:155, 1989). Target range is represented by the timing of neural discharges encoding echo delay, while target shape (range separation of reflecting points) initially is represented from frequency-dependent stimulus amplitude (notches and peaks in echo spectra) but is transformed into equivalent time-domain information before being expressed in perceived images. The external ears of humans, cats, and FM bats similarly modify sounds entering the ear canal to encode the vertical position of sound sources by adding reverberation and spectral emphasis. As vertical angle changes, a prominent notch in the ear's spectral response moves to different frequencies (from 40 to 55 kHz in *Eptesicus*) and changes occur in the height of an adjacent spectral peak (around 60-65 kHz in *Eptesicus*). The bat incorporates external-ear effects into the images in perceives by transforming these spectral cues into equivalent time-domain information, just as it transforms spectral shape cues. The bat thus recovers external-ear reverberation-time as an estimate of time, not frequency. The resulting images express range, shape, and vertical position along a single, computed psychological axis of range, still defined in terms of echo delay. The neural representation of vertical position may be difficult to identify without consideration of the encoding of spectral notches and the transformation of spectral into temporal estimates. NEURAL PROCESSING OF PULSE REPETITION RATE AND PULSE DURATION IN THE BAT INFERIOR COLLICULUS. A.D. PINHEIRO, M. WU* AND P.H.-S. JEN Div. Bio. Sci. University of Missouri-Columbia,MO 65211

Encoding of stimulus repetition rate and duration by the inferior collicular neurons(IC) of the big brown bat, *Eptesicus fuscus* was studied by recording responses of each neuron to a wide range of repetition rates and durations at several stimulus intensities under free field stimulus conditions. A total of 277 IC neurons were recorded at depths between 147 and 2370 μm with latencies between 3.4 and 28.4 ms. They were tonotopically organized along the dorsoventral axis of the IC according to their best frequencies(BFs). While individual IC neurons varied their number of impulses but not their discharge pattern when stimulated with different repetition rates and durations, they generally discharged with a maximal number of impulses to a specific repetition rate (the best repetition rate) and duration (the best duration). According to the filtering properties for the stimulus repetition rate or duration, IC neurons can be classified as high-pass, low-pass, band-pass (or semi band-pass) and multipass neurons. A wide range of best repetition rates and best durations were identified for IC neurons but they were not correlated with either the BFs or recording depths. Futhermore, the best repetition rates and durations of tonotopically organized IC neurons isolated within an electrode penetration varied unpredictably. According to the correlation of their responses to stimulus duty cycle, IC neurons can be classified into two groups. Responses of one group correlated with the duty cycle thus enable the bat to avoid pulse-echo overlap during echolocation. Responses of the other group do not correlate with the duty cycle. These neurons likely enable the bat to encode the pulse emission rate and duration effectively during different phases of hunting. The effect of stimulus repetition rate and duration on the intensity rate function of IC neurons was examined. While the stimulus repetition rate might affect the dynamic range and overall profile of the intensity rate function curve, only little effect was observed with different stimulus durations.

SPECTRAL SELECTIVITY OF DELAY-SENSITIVE NEURONS IN THE AUDITORY CORTEX OF AN FM BAT. D. Wong and M. Maekawa, Anatomy Dept., Indiana Univ. School of Medicine, Indianapolis, IN 46202.

Spectro-temporal processing plays prominently in auditory perception. In the echolocating bat, *Myotis lucifugus*, delay-sensitive, cortical neurons process target-distance information in the time domain. The concurrent role of spectral processing in target perception was further examined neurophysiologically. Delay-sensitive neurons were isolated by stimulation with FM-FM sound pairs at frequency excursions mimicking this species' natural echolocation sounds (pulse) and echoes. The pulse and echo FMs were each arbitrarily divided into four spectral quarters and the quarter essential for delay-sensitivity was determined. Neurons typically required a spectral combination consisting of both the IV pulse-quarter and the III or IV echo-quarter. The essential echo component did not change when the rate of pulse-echo stimulation was increased. The preservation of this spectral combination for delay-sensitivity suggests that throughout echolocation FM bats employ specific parts of their pulse-echo spectra for perceiving target structure. EFFECT OF GONADAL STATE ON SEXUALLY DIMORPHIC BRAIN AREAS OF TWO SPECIES OF WHIPTAIL LIZARDS: A QUESTION REVISITED. J. Wade[1] and D. Crews[1,2] Departments of [1] Psychology and [2] Zoology, and the Institute of Reproductive Biology, University of Texas, Austin, TX 78712.

Cnemidophorus inornatus is a sexually reproducing species. The closely related *C. uniparens* is all-female and reproduces by parthenogenesis. However, *C. uniparens* consistently display reproductive behaviors common to both male and female *C. inornatus*. Both the anterior hypothalamus-preoptic area (AH-POA), a critical location of androgen action on mounting, and the ventromedial hypothalamus (VMH), where estrogen implants elicit receptivity, are sexually dimorphic in *C. inornatus*. The AH-POA is larger in males, while the VMH is larger in females. In *C. uniparens*, both brain regions are comparable in size to female *C. inornatus* (Crews et al., *Brain Behav. Evol.* In press). To investigate whether these brain areas change in volume with the reproductive state, the AH-POA and VMH were measured during the breeding season, during a simulation of winter hibernation and in gonadectomized male and female *C. inornatus* and *C. uniparens*. Neither brain area was significantly different in female *C. inornatus* or *C. uniparens* as a function of season or gonadal state. The AH-POA results in female *C. inornatus* were consistent with a previous study (Wade & Crews, *Soc. Neurosci. Abst.* 15: 1089). However, the VMH results did not replicate, perhaps due to procedural differences or different lengths of time the animals were in captivity. The magnitude of change in the female VMH volume was the same in both studies, but when corrected for brain size the second year, the difference was not statistically significant. In contrast, the AH-POA was smaller in hibernating and gonadectomized males than in reproductively active males (ANOVA: $F(2,22)=21.5$, $p<.01$). Conversely, the VMH was larger in hibernating and castrated than reproductively active males (ANOVA: $F(2,22)=7.2$, $p<.01$). In both cases the non-breeding males had brain areas that were not significantly different from those of intact females.

CENTRAL MONOAMINES and BEHAVIOR IN THE LIZARD, *ANOLIS CAROLINENSIS* N. Greenberg[1], Cliff H. Summers[1], and P. H. Desan[2]. University of Tennessee, Knoxville, Graduate Program in Ethology[1]; Stanford University Medical Center[2].

To clarify monoamine function in stereotyped behavior, the selective neurotoxin MPTP was used to deplete dopamine (DA) and norepinephrine (NE) in a model species, the lizard, *Anolis carolinensis*.

Following the intraperitoneal injection of MPTP, animals manifested reduced spontaneous activity but normal or slighly facilitated aggression and reproductive behavior. Body color change, an index of altered autonomic sensitivity, suggested enhanced responsiveness.

Earlier work (Font *et al. 1987*) revealed MPTP-induced central neuropathies. Immunohistochemistry was employed to discriminate specific central catecholaminergic systems thereby affected. DA and NE immunoreactive perikarya were found in several sites in and near the periventricular hypothalamus, ventral tegmentum, substantia nigra, locus ceruleus, nucleus of the solitary tract, and raphe; while immunoreactive 5HT cells were found at one periventricular hypothalamic site and in the raphe nuclei.

Estimates of quantitative change in catecholamine levels obtained with high pressure liquid chromatography revealed that 100 hr after MPTP injection, DA and NE levels were 26% and 7% of control, respectively, while 5-HT was elevated to 200%.

EVENT RELATED POTENTIALS IN TECTUM AND CORTEX OF FREELY MOVING TURTLES TO VISUAL STIMULI. J.C. Prechtl and T.H. Bullock. Department of Neurosciences A-001., School of Medicine & Neurobiology Unit, Scripps Institution of Oceanography., UCSD, La Jolla, CA 92093

Pond turtles *(Chrysemys picta, Pseudemys scripta elegans)* were chronically implanted with 13-20 epipial electrodes on the midbrain and dorsal cortex. After recovery the turtles were placed in plastic chambers with 2 cm of water (20-23°C), and responses were recorded to single flashes and trains of flashes. Tectal visual evoked potentials (VEPs) with long interstimulus intervals (ISI=20 s) consist of a principal positive peak at ca. 95 ms (P95) and smaller waves. A change in the ISI from 20 s to 3 s, delivered for 1 min, attenuates the P95, peak-to-peak by 23±3% (SEM). The largest cortical VEPs were dominated by an N130 that showed a greater response attenuation (40±6%) at the 3 s ISI. Distinct from the tectum, the cortical VEP includes a late, broad (ca. 230-490 ms) negative wave especially sensitive to repetition rate; it declines by 68±6% with the shorter (3 s) ISI. Tectal VEPs to trains of flashes show 1:1 following up to ca. 20 Hz, without averaging. At 35 Hz in averages of 10 sweeps fusion is complete, whereas, from the cortex fusion occurs at less than 25 Hz.

As in the fish tectum (Bullock et al. 1989, *Soc. Neurosci. Abstr.*, 15:1137) event related potentials are evoked in the turtle tectum and cortex by the omission of a flash after a conditioning series. The latency of this omitted stimulus potential (OSP) after the due-time of the first missing flash tends toward a constant, ca. 50 ms, as though the brain had learned an expectation. Jitter in the ISI however, does not reduce the OSP greatly. The form of the OSP is not the same in the tectum and cortex. Its amplitude increases with conditioning flash rate, which must be minimally 3 Hz for tectal OSPs, <2 Hz for cortical OSPs. On some electrodes, after certain conditioning frequencies, the OSP included conspicuous oscillations between 16 and 25 Hz. The findings suggest that the OSP reflects a release from an accumulated inhibition, hence endogenous processes although minimal cognition.

379.9

INVOLVEMENT OF MECHANOSENSORY LATERAL LINE SYSTEM IN FEEDING BEHAVIOR OF THE AXOLOTL. H.-A.Takeuchi[1], H.Namba[1]* and T.Nagai[2]. [1]Dept. Biol., Fac. Sci., Shizuoka Univ., Shizuoka 422, Japan, [2]Dept. Physiol., Teikyo Univ. Sch. Med., Tokyo 173, Japan.

Axolotls (Ambystoma mexicanum) exhibit a series of feeding behavior to the prey objects moving in the water. The feeding behavior is elicited by the artificial moving object. To understand the neural mechanisms of thus elicited feeding behavior, we identified the effective parameters of the vibrational stimuli applied to the water. Feeding behaviors were compared between normal and genetically blind (eyeless) axolotls. Then, we studied the effects of blocking the lateral line system on the feeding behavior. We used two methods to block the lateral line system: 1) the exposure to cobalt solution [Co treatment] and 2) the transection of ramus ophthalmicus superficialis (r.o.s) and ramus buccalis (r.buc.) of anterior lateral line nerve [ALL transection]. We also examined the central projection of r.o.s and r.buc. by using the transganglionic transport of cobaltic lysine.

The feeding behavior was evoked by the water movement produced by the vibrating sphere (frequency: 2-35Hz; amplitude: 1-4mm). The vibrational stimuli were effective in normal as well as blind axolotls, suggesting that sensory system other than vision was involved in the feeding behavior. In the blocking experiment of lateral line system, the feeding responses were significantly reduced in the animals exposed to 0.05-1.0mM Co^{2+} solution. Experiment of ALL transection showed that the transection of r.o.s. and r.buc. significantly suppressed the feeding behavior. The present results suggest that the mechanosensory signals mediated by anterior lateral line nerve (r.buc. and r.o.s.) are involved in the release of feeding behavior in the axolotl.

379.10

ROLE OF PHASIC NEURONS IN THE PROCESSING OF TEMPORAL INFORMATION IN THE FROG AUDITORY SYSTEM. C.J. Condon[1], S.-H. Chang, D.M. Gooler, J.C. Hall, W.Y. Lin*, K.R. White, and A.S. Feng. [1]Neuroscience Program, and Dept. of Physiology and Biophysics, Univ. of Illinois, Urbana, IL 61801.

While phasic neurons are considered to be essential for encoding the time of occurrence of a sensory event, other specific functions these neurons serve in acoustic information processing have not been fully elucidated. Given that various temporal parameters [e.g. rise-fall time, duration, and rate of amplitude modulation (AM)] of frog calls serve as essential cues for call discrimination, one might predict that phasic neurons are likely to be involved in the coding of temporal patterns of complex sounds. With this as a working hypothesis, we have systematically recorded single unit activity at various levels in the auditory system of the leopard frog (*Rana p. pipiens*) in order to characterize the role of phasic neurons (relative to tonic neurons) in the encoding of such behaviorally significant temporal sound parameters.

With respect to the processing of signal rise-fall time and duration, phasic neurons in the auditory brainstem nuclei (dorsal medullary, superior olivary, and torus semicircularis) develop temporal selectivities typically not manifested by tonic neurons. For example, many neurons that were found to be "tuned" to a narrow range of AM rates (i.e. BAND-PASS response functions) were phasic responders in the various auditory stations examined. Thus, in addition to coding for the arrival time of an acoustic stimulus, phasic neurons also act as "temporal filters" with respect to rise-fall time, signal duration, and the rate of AM. This suggests that the temporal selectivity of phasic neurons for various temporal parameters may contribute to the recognition of complex sounds in the acoustic communicative behavior of frogs and perhaps other species. [Research supported by NSF grant BNS 88-09490]

379.11

THE INFLUENCE OF SOUND DIRECTION ON PROCESSING OF COMPLEX SOUNDS BY MIDBRAIN AUDITORY NEURONS. D.M. Gooler, C.J. Condon[1], and A.S. Feng. Dept. of Physiology and Biophysics, and [1]Neuroscience Program, University of Illinois, Urbana, IL 61801.

Head and body orientations are important for acoustic communication in complex environments. Whether animals change orientations to improve sound localization, and/or to aid the detection of complex sound features is not clear. In the complex acoustic environment of a breeding pond, frogs can discriminate between different signals as well as perceive the locations of multiple sources. We are interested in the mechanisms by which the frog's nervous system forms a coherent image of acoustic space. This study focuses on the influence of sound direction on the neural processes underlying sound pattern recognition, especially those of behaviorally meaningful sounds.

We have recorded from single neurons in the auditory midbrain, the torus semicircularis (TS), of leopard frogs to investigate the influence of sound direction on frequency tuning characteristics (FTCs) and responses to amplitude modulated sounds. Free field acoustic stimuli were presented to the frog from equidistant azimuthal locations. The process of encoding sound pattern and direction by neurons in the TS appears to be complex. In many cases a change in sound direction elicited pronounced changes in the FTCs and modulation transfer functions (MTFs) of individual TS neurons. Most notable changes were shifts in the unit's characteristic frequency (CF), threshold at CF, and shape of the FTC and the MTF. The relationship between sound incident angle and specific changes in the features of the FTCs and MTFs varied from cell to cell. In contrast, some neurons showed no change in CF or MTF with a change in sound direction.

379.12

COMPARISON OF TIME-LOCKED RESPONSES OF FROG'S CENTRAL AUDITORY NEURONS TO SINUSOIDAL-AMPLITUDE-MODULATED SIGNALS WITH PHASE-LOCKED RESPONSES TO SINUSOIDAL CARRIERS. W.-Y. Lin*, K.R. White, and A.S. Feng. Department of Physiology and Biophysics, University of Illinois, Urbana, IL 61801.

Single unit recordings were made from the frog's dorsal medullary nucleus (DMN), a homolog of cochlear nucleus, to determine whether or not the phase-locked response capacity of a central auditory neuron to sinusoidal stimuli can be used to predict the time-locked response capacity to sinusoidal-amplitude-modulated (SAM) signals, and vice versa. For each cell, we first determined the best excitatory frequency (BF) and the frequency tuning curve (FTC) of the unit. We then quantitatively analyzed the unit's responses to: (1) tone bursts at a number of frequencies within the unit's FTC at 10 dB above the respective thresholds of excitation, and (2) SAM stimuli at various modulating frequencies (ranging from 5Hz to half of the BF or 1000 Hz, whichever was less) using the unit's BF as the carrier at 10 dB above the excitatory threshold at BF. The synchronization coefficient (SC) was calculated from the period histogram derived from each of these responses using the formula given by Goldberg and Brown (1963). The SCs from time-locked and phase-locked responses at comparable frequencies (modulating vs carrier frequency) were compared.

We found that for mid- to high- frequency neurons (BF>700 Hz), SCs for SAM stimuli were typically lower than SCs derived from phase locked responses to sinusoidal carriers of comparable frequencies. For low-frequency sensitive neurons (BF=100-650 Hz), the SCs derived for the two types of stimuli at comparable frequencies were similar.

WITHIN AND BETWEEN POPULATION VARIATION IN THE ACOUSTIC COMMUNICATION SYSTEM OF CRICKET FROGS. A. C. Keddy-Hector,* W. Wilczynski, and M. J. Ryan.* Depts. of Psychology and Zoology, Univ. of Texas, Austin, TX, 78712.

We compared variation in basilar papilla (BP) tuning and call dominant frequency in populations of Acris crepitans from Wimberley (WB) and Stengel Ranch (SR), Texas. The best excitatory frequencies of BP afferents were obtained in 28 females and 16 males, calls recorded from 107 males, and snout-vent lengths measured in all individuals. In both populations, females were tuned lower than males and lower than the dominant frequency of male calls. An inverse relationship existed between body size and BP tuning in both sexes (WB male r= -0.38, female r= -0.57; SR male r= -0.62, female r= -0.64). However, analysis of covariance showed that body size differences do not account for the sex difference in BP tuning (WB F=9.32, df=1,20; SR F=4.5, df=1,15). The analysis also showed that tuning and calls differ between populations independent of body size. The slopes of female tuning or male calls vs. body size did not differ in the two populations, but the y-intercepts did (F=728, df=1,12; F=4.92, df=1,104). Slopes of male tuning vs. body size differed between populations (F=7.35, df=1,13). These results suggest that in cricket frogs interpopulational differences in vocal and auditory traits result from concomitant shifts in the intrapopulational allometry of these traits with body size. (Supported by NIMH 1T32 MH18837 and NSF BNS 8606289.)

SEXUALLY DIMORPHIC LARYNGEAL MORPHOLOGY IN CRICKET FROGS (ACRIS CREPITANS). B. E. McClelland, W. Wilczynski and M. J. Ryan*. Depts. of Psychology and Zoology, University of Texas, Austin, TX 78712.

In every frog species studied so far, male larynges are significantly larger than females', but differences exist among the species in the relative development of the female larynx. The degree of sexual dimorphism in the laryngeal morphology of a species may be related to the presence or absence of vocalizations in the female's behavioral repertoire. Because female cricket frogs (Acris crepitans) are completely silent, we predict extensive quantitative and/or qualitative laryngeal differences between the sexes.

In this study we used morphometric techniques to explore the differences between the anatomy of male and female larynges. Although the body size [snout-vent length: male (n=13) =2.30 mm, female (n=8) =2.24 mm] and head widths of the males (.79 mm) and females (.78 mm) were not significantly different, the volume of each male (M) laryngeal component was much larger than the corresponding feature of the females' (F) larynx (arytenoid cartilage: M=.68, F=.046; vocal cord: M=.048, F=.004; constrictor muscle: M=.64, F=.064; dilator muscle: M=.182, F=.023; all volumes mm^3). Female vocal cords were rudimentary and did not stretch across the laryngeal lumen which may have rendered them non-functional. Within each sex, the volumes of all the laryngeal features are positively correlated with body size. However, the slopes describing the male relationships are, in all cases, much steeper than the females'. Additionally, within each sex, the size relationships among the laryngeal components appear to be the same. In summary, although male larynges are considerably larger, the anatomical components of male and female larynges maintain the same allometric relationship within the sex. Not only the small size, but also the lack of vocal cord development may prevent females from vocalizing. (Research supported by NSF BNS 8606289.)

ACOUSTICALLY SUBOPTIMAL MALE SPACING IN HYLA CINEREA CHORUSES **J. H. Fox, W. Wilczynski, and W. M. Moss*. Dept. of Psychology, University of Texas, Austin, TX 78712**

Previous computer models of frog chorus acoustics have revealed that males can maximize per-capita mating call active space by utilizing "optimal" neighbor spacing (Fox and Wilczynski, 1986. SN Abst. 12:314). Here, we examine whether local green treefrog (Hyla cinerea) males utilize this strategy. For this species, optimal **interindividual distance** (**IID**) depends on **threshold distance** (**TD** -- the distance at which a female can just detect a male's call), **call duty cycle** (**DC** -- the proportion of time the male produces sound), and **chorus population**. TD was determined by filtering calibrated call FFTs with female audiograms, derived from multiunit auditory midbrain (torus semicircularis) responses to sinusoidal acoustic stimuli. DC was measured by playing tape recordings of long calling bouts into an electronic timing apparatus. We find that TD = 377 ± 181 m, DC= .128 ± .033, and chorus population is typically ca. 10 - 20. Therefore, computer models predict an optimal IID of 310 m. Actual IID, 8.21 ± 7.28 m, is much lower than optimal. Such a large optimal IID must be impractical for H. cinerea, because the resulting chorus would be too large for the breeding area and would be difficult for females to traverse; therefore, "optimal spacing" would have little biological relevance. It now seems likely that active space maximization through use of optimal IID may be feasible only for species with lesser TD values, such as Acris crepitans (Fox, 1988. SN Abst. 14:88). (Supported by NSF BNS 8606289.)

379.16

REPRODUCTION AND FEEDING OF THE FEMALE FROG, RANA PIPIENS AFTER ADMINISTRATION OF YOHIMBINE, CLONIDINE, AND NEUROPEPTIDE Y. C. Diakow, M.C. Lanzillotta* and J.T. Clark, Biol. Dept., Adelphi U., Garden City, NY 11530 and Physiol. Dept. Meharry Med. Col., Nashville, TN 37208.

This study provides evidence that both α_2 receptors and neuropeptide Y(NPY) play roles in enhancing reproductive behavior of the female frog, and that α_2 receptors play a role in reducing the tendency to feed.

When females become receptive to males there is a decline in the tendency to emit a vocalization, the release call, in response to tactile stimulation. In this experiment, the number of release calls in response to manual stimulation declined after administration of 0.08 µg/g yohimbine, or 0.001769 nmoles/g NPY, but not after injection of 0.08 µg/g clonidine. Injections were administered through cannulae surgically implanted in the 3rd ventricle. Control and drug injections were counterbalanced one day apart. Each female received only one drug and there were eleven, 30 sec. release call tests between 5 min. and 3 hr. after injection.

Between tests for the release call, females were placed in a tank with crickets. The number of crickets eaten was not affected by drug treatment, but the latency to eat the first cricket was highest after yohimbine injection.

380.1

TESTOSTERONE IMPLANTS RESTORE STEROID-SENSITIVE VASOPRESSIN INNERVATION IN CASTRATED RATS. G.J. De Vries, and R.M. Buijs*, Prog. in Neurosci. and Behav., Univ. of Mass., Amherst, and Netherlands Inst. for Brain Res., Amsterdam.

Vasopressin-immunoreactive (AVP-IR) projections of the bed nucleus of the stria terminalis (BST) and the medial amygdaloid nucleus (MA) are steroid-sensitive. Gonadectomy wipes out AVP staining while subsequent testosterone treatment restores it. We studied whether unilateral implantation of testosterone in and around the BST and MA could restore this staining in long-term castrated rats.

Implants in the BST of long-term castrated rats restored most of the innervation at the side of the implant, but there were differences depending on where the implants were placed. For example, implants in medial regions of the BST restored most of the original fiber staining in the lateral septum but not the staining in the lateral habenular nucleus. Implants in lateral regions of the BST restored some fiber staining in the lateral habenular nucleus. Most fiber staining in the lateral habenular nucleus was restored, however, by implants in the MA. Since implanting testosterone between the BST and MA did not restore any fiber staining, the steroids acted probably locally in both nuclei. The differences in the effects of the implants might be directly related to differences in projections of subgroups of AVP cells in the BST and MA. Steroid implants may restore AVP fiber staining only in areas that receive direct AVP projections from the site of the implant. Alternatively, steroid implants might have stimulated other steroid-sensitive neuronal systems that, in turn, might have activated steroid-sensitive AVP neurons transsynaptically. This would explain why implants in the MA restored much of the AVP innervation of the lateral septum, even though the MA projections to the lateral septum are much less dense than those of the BST.

380.2

SPECIES AND SEX DIFFERENCES IN VASOPRESSIN PATHWAYS OF VOLES THAT SHOW DIFFERENT PATTERNS OF PARENTAL CARE. M. Bamshad, G.J. De Vries, M.A. Novak*, Prog. of Neurosci. and Behav. and Dept. of Psychol., Univ. of Mass., Amherst, MA 01003.

Prairie voles (*Microtus ochrogaster)* spend longer time in close contact with their young than meadow voles (*Microtus pennsylvanicus*). In addition, meadow vole males do not show any parental care towards their young, whereas prairie vole males do. In rats, body temperature of the mother appears to determine how long she nurses the young during each nesting bout (Leon M, *Phys. Behav.* 1978 21:793). Since vasopressin-immunoreactive (AVP-IR) projections of the bed nucleus of the stria terminalis (BST) and medial amygdaloid nucleus (MA) have been linked to body temperature regulation (Pittman Q, *Brain Res. Bull.* 1988 20:887) we studied whether there were differences in these projections that could be related to the aforementioned sex and species differences.

Brains of sexually inexperienced voles and voles that were six days postpartum were stained immunocytochemically for vasopressin. In both species, AVP-IR projections of the BST and MA were much denser in sexually inexperienced males than in females. This pattern was changed in parental animals. In females of both species, AVP-IR projections of the BST and MA were just as dense as in sexually inexperienced males. In meadow vole males, there were no differences between parental and inexperienced males, whereas in prairie vole males BST and MA projections showed less staining in parental animals. These findings suggest that, in females, BST and MA projections are involved in changes that take place when animals become parental. The sex difference in the direction of changes in parental prairie voles that become parental suggest that vasopressin might serve different functions related to parental behavior in both sexes.

380.3

GABA IN THE MIDBRAIN CENTRAL GRAY FACILITATES LORDOSIS IN THE FEMALE RAT. M.M. McCarthy, D.W. Pfaff and S. Schwartz-Giblin, Rockefeller University, New York, NY 10021

The inhibitory neurotransmitter GABA has been implicated in the control of female reproductive behavior. Microinfusion of the GABA-A agonist, muscimol, into POA inhibits lordosis whereas muscimol into medial hypothalamus facilitates lordosis (McCarthy et al, Brain Res. 507: 1990).

Using a 2-chamber apparatus in which a sexually active male is restricted to one chamber, several parameters of female sexual behavior were measured during 10 min tests. After pre-testing, steroid-primed females were infused with GABAergic drugs via bilateral cannulae (0.25µl/side) in the midbrain central gray (MCG). In estrogen (E) + progesterone (P)-primed females with high lordosis quotients during pre-tests, the GABA-A antagonist, bicuculline, significantly reduced lordosis and proceptive behaviors by 5 min at a dose of 30ng but not 10ng ($p<.05$; Wilcoxon Test). By one hour post-infusion, lordosis quotients were equal to pre-test levels. Infusion of muscimol (50ng) did not affect behavior in E + P-primed females. Conversely, with low lordosis quotients and high avoidance index (# rejections / # mounts) in E-primed females, muscimol (50ng) significantly increased lordosis quotient while decreasing avoidance index as compared to saline-infused controls at 5 and 60 min post-infusion ($p<.05$; Mann-Whitney U). Locomotion and time spent in the male's chamber did not change after treatment with either drug.

Infusion of the retrograde tracer Fluorogold (0.25µl) through each cannula after behavioral testing showed strong descending projections to MCG from the anterior hypothalamus, zona incerta, ventromedial nucleus of the hypothalamus and amygdala (central and medial nuclei). Ascending projections from lumbar cord included cells in laminae I, V, X and lateral spinal nucleus. Therefore, in addition to being facilitatory in the medial hypothalamus, GABA also facilitates lordosis at MCG sites which receive behaviorally relevant afferent inputs from forebrain as well as spinal cord.

380.4

GABAERGIC CONTROL OF SEXUAL RECEPTIVITY IN THE FEMALE RAT. D.B. Masters, J.M. Fiber and M.M. McCarthy, Institute of Animal Behavior, Rutgers University, Newark, N.J. 07102 U.S.A.

Recently, we reported that GABA agonist infusion into medial hypothalamus (mHYP) and preoptic area (POA) has facilitory and inhibitory actions on lordosis behavior, respectively (McCarthy et al, Brain Res. 507, 1990). These data suggest that GABA differentially mediates receptive behavior. Therefore, in this study we hypothesized that endogenous GABA levels will be greater in mHYP than in POA in receptive (Rec) and opposite in non-receptive (NRec) females along with concomitant changes in GABA receptor binding.

Intact and ovariectomized (OVX) rats were tested for receptivity 24 and 1 hr before their mHYP, POA & cortex (CTX) were dissected & frozen (liq N_2). Sections were homogenized in 1 ml 4% perchlorate & 50 µM norvaline (int std.), centrifuged, and the supernatant was measured for GABA (blinded procedure) by high pressure liquid chromatography (HPLC).

The results (fig. 1), normalized by [CTX-GABA], show a significant* difference between mHYP and POA [GABA]/mg tissue in Rec & NRec females. The [CTX-GABA] was unchanged ($p > 0.83$). The mHYP/POA GABA ratio was significantly* greater in Rec vs NRec & OVX rats, 1.34 ± 0.07, 0.90 ± 0.08, & 0.88 ± 0.09, respectively (avg ± sem). In a parallel experiment ^{3}H-muscimol binding (Bmax) to the high affinity receptor site was significantly* lower in POA of Rec vs NRec & OVX rats. Receptor affinity in mHYP of Rec rats was significantly* less (3 fold greater K_D) than NRec & OVX groups.

In conclusion, the data support our hypothesis that GABA plays a dual role in control of female mating behavior. Increased GABAergic activity in mHYP with a concurrent reduction in POA activity promotes receptivity, whereas the reverse inhibits this behavior. It is possible that tonic GABA levels and receptor dynamics in mHYP and POA are modulated by systemic steroids associated with the estrus cycle, regulating the natural onset and termination of receptive behavior in female rats. *ANOVA ($p < 0.05$) was used.

STEROID MODULATION OF CHOLINE ACETYLTRANSFERASE ACTIVITY IN THE ZEBRA FINCH BRAIN. A. Gardner* and C.F. Harding, Biopsychology Program, Hunter College, CUNY, New York, NY 10021.

Acetylcholine appears to be present throughout the songbird's vocal control system. Vocal control nuclei (VCN) concentrate steroids, altering neural functioning and activating behavior. Cholinergic neurons have been implicated in the control of steroid-mediated behaviors in other species, and cholinergic enzyme activity in the finch syrinx is hormone dependent. This study examined the effects of androstenedione (AE), the steroid hormone we find best restores hormone-dependent behavior in castrated finches, on cholinergic enzyme activity in the finch brain.

Castrated males received silastic implants of cholesterol or AE and were then paired with females in individual cages for one week prior to sacrifice. Choline acetyltransferase (CAT) activity was measured in 10 steroid-sensitive nuclei (VCN: RA, HVc, DM, NIf, MAN, Area X; auditory area: Field L; hypothalamic nuclei: POA, PVM, IN). CAT activity was measured by radioenzymatic assay and expressed in terms of specific activity, nM substrate/mg protein/hour.

As expected, steroid treatment affected CAT activity in several of the VCN studied. Interestingly, unlike the effects of steroid hormones on catecholamines, which increased neurotransmitter levels and turnover in some areas but decreased them in others, AE always increased CAT activity in those brain areas in which it exerted an effect.

ESTROGEN-DEPENDENT CHOLINERGIC REGULATION OF LORDOSIS IN INTACT CYCLING FEMALE RATS. C.S. Menard and C.P. Dohanich. Dept. of Psychology, Tulane Univ., New Orleans, LA 70118.

Intracerebral administration of the acetylcholinesterase inhibitor, physostigmine, activates lordosis in intact, cycling female rats during proestrus, but not diestrus when estrogen levels are lowest (Neurosci. Abst., 435.9, 1989). Therefore, cholinergic activation of sexual receptivity in intact female rats may be possible only when sufficient estrogen priming exists. In this study, cycling female rats received pulse injections (24 and 36 hrs before behavior testing) of 0.2, 0.1, or 0.05 ug free estradiol or ethanol vehicle at either Diestrus I or Mid-diestrus. On the following day, females that were not sexually receptive (LQ < 50%) received intraventricular infusions of either saline or physostigmine (10 ug bilaterally) and then were tested for lordosis. Lordosis was increased 15 min ($p < .0001$) and 1 hr ($p < .0063$) after physostigmine infusion on both days. The level of facilitation at 15 min ($p < .0001$) and 1 hr ($p < .0212$) increased with the levels of estradiol priming. No facilitation was evident with ethanol priming on either day. These results indicate that in intact female rats, cholinergic systems that regulate sexual behavior are dependent upon sufficient estrogen priming. Furthermore, estrogen levels above normal diestrus levels appear to be necessary for cholinergic regulation to occur.

380.7

SEXUAL DIFFERENTIATION AND MONOAMINERGIC SYSTEMS: STEROID INDUCED BEHAVIORAL AND NEUROCHEMICAL CHANGES. M.A. Abdelnabi*, A. Powell+, C. Rexroad+ and M.A. Ottinger*. * Dept of Poultry Science, Univ. of Maryland, College Park, MD 20742 and +Reproduction Lab, USDA-ARS, Beltsville, MD 20705

Monoaminergic systems and sexual differentiation in Japanese quail were studied by 1) assay of hypothalamic monoamine content and turnover during development and 2) study of long term effects of exogenous steroids on neurochemistry and behavior. In Study 1, female embryonic and perinatal quail had higher levels of norepinephrine (NE) (382.8 ng/g) than males (160.8 ng/g) at day 10 prehatch, while males had higher levels of DA (16.1 and 40.9 ng/g) than female at Days 12 and 16 respectively. 5-HT was higher (25.6 ng/g) in females at Day 14 prehatch, while males showed high levels (1107 and 1416 ng/g) at Day 5 and 7, posthatch. Turnover rates were significantly higher for both NE and DA (51.1 and 54 ng/g/hr) at Day 7 posthatch, respectively and differed with sex. In Study 2, avian embryos, treated on one of 9 ages with estradiol, testosterone or oil showed long term effects on male behavior. Preoptic area monoamine content showed that females had higher levels of NE and 5HT than males. These results demonstrate permanent alteration of the monoamine system with early exposure to steroid hormones. These data indicate that steroid induced behavioral responses in the adult may rely on steroid induced alterations in neurotransmitter systems during sexual differentiation.

380.8

NORADRENERGIC REGULATION OF SONG AND COURTSHIP IN MALE ZEBRA FINCHES. S. R. Barclay, S. A. Waterman and C. F. Harding. Biopsychology Program, Hunter College, CUNY, New York, N.Y. 10021.

Previous studies have suggested that catecholamines (CA) may be involved in controlling courtship behaviors in male zebra finches. Hormone treatments which increased courtship behaviors in castrated males significantly altered CA levels and turnover in both hypothalamic and vocal control nuclei. Similar changes in CA function were seen during the initial phases of the reproductive cycle. While hormone treatment affected both norepinephrine (NE) and dopamine (DA) function, the changes in NE were much more striking. We therefore decided to manipulate NE levels and examine the effects on courtship behavior.

Intact male finches were pretreated with zimelidine and then injected with N-(2-chloroethyl)-N-ethyl-2-bromo-benzylamine (DSP-4, 50μg/g) or saline ip. Birds were observed for 15 minutes in pre- and post-drug pair tests. Vocal control and hypothalamic nuclei were assayed for NE, DA and serotonin (5-HT) using HPLC-EC. DSP-4 birds showed significant post-drug decrements in total courtship behavior. This treatment increased the latency to sing and decreased the total number of song bouts, while the motor patterning of songs appeared unaffected. As expected, DSP-4 significantly depleted telencephalic (i.e., vocal control nuclei) NE while hypothalamic NE was not affected. Zimelidine pretreatment prevented significant changes in DA and 5-HT levels. These results suggest that the noradrenergic system is important in modulating courtship vocalizations in the zebra finch.

EFFERENT PROJECTIONS FROM THE VENTROLATERAL HYPOTHALAMUS IN FEMALE GUINEA PIGS. K.H. Nielsen and J.D. Blaustein, Neuroscience and Behavior Program and Psychology Department, University of Massachusetts, Amherst, MA 01003.

Implants of estradiol in the ventrolateral hypothalamus (VLH) are sufficient to prime ovariectomized guinea pigs to show progesterone-facilitated lordosis. To determine the efferent projections from this area, *Phaseolus vulgaris* Leucoagglutinin (Pha-L) was applied iontophoretically into the rostral VLH of ovariectomized guinea pigs. After a survival period of two weeks, the Pha-L was visualized immunocytochemically. The majority of Pha-L labelling was observed ipsilateral to the injection site, but occasional axons were labelled in the same contralateral structures. The following areas received the heaviest projections: bed nucleus of the stria terminalis, medial preoptic area, anterior hypothalamus, tuber cinereum, ventromedial nucleus, dorsomedial and dorsolateral hypothalamus, posterior hypothalamus, dorsal longitudinal fasciculus, midbrain central gray, and the recess inferior colliculus. The latter three areas also received the heaviest contralateral projections. Areas with fewer labelled terminals and fibers included the diagonal band of Broca, lateral septum, medial and cortical amygdala, lateral preoptic area, paraventricular nucleus, arcuate nucleus, premammillary nucleus, dorsal tegmental area, and pontine central gray. Fibers with few or no terminals were observed in the median forebrain bundle, stria terminalis, and medial lemniscus. Many of these projections are similar to the efferents from the ventrolateral-ventromedial nucleus in rats, the area apparently analogous to the VLH in guinea pigs.

380.10

VENTROLATERAL HYPOTHALAMUS PROJECTIONS TO ESTROGEN RECEPTOR-IMMUNOREACTIVE SITES IN THE FEMALE GUINEA PIG BRAIN. J.C. Turcotte, K.H. Nielsen and J.D. Blaustein, Neuroscience and Behavior Program and Psychology Dept., University of Massachusetts, Amherst, MA 01003

The ventrolateral hypothalamus (VLH), an area in which implantation of estradiol is sufficient to prime guinea pigs to display progesterone-facilitated sexual behavior, contains a large number of estrogen receptor-immunoreactive (ER-IR) cells. In rats, projections from the analogous ventrolateral-ventromedial nucleus, have been traced to a variety of brain sites which contain estradiol-concentrating cells. These projections may be part of a neural network which may be involved in the regulation of sexual behavior. In order to determine if efferents from the VLH project to ER-IR neurons, we iontophoretically applied the anterograde tracer, *Phaseolus vulgaris* Leucoagglutinin (Pha-L) and visualized projections from this area with a double label immunocytochemical procedure. Pha-L injection sites were small and localized in sites containing a high concentration of ER-IR cells. VLH efferents were observed in many sites throughout the brain (Nielsen and Blaustein, 1990 Neurosci. abst.), some of which also contain ER-IR neurons. The ER-IR containing areas which receive VLH projections include the medial preoptic area, the periventricular area and the midbrain central gray. Within these areas, some projections were found closely associated with ER-IR neurons suggestive of synaptic contacts. This finding supports the concept of a neural network of estradiol-sensitive neurons.

380.11

EFFECTS OF PVN LESIONS ON THE RESPONSIVENESS OF OVARIECTOMIZED RATS TO ESTRADIOL P.C. Butera, D.M. Willard* & S.A. Raymond*. Dept. of Psychology Niagara University, NY 14109

This experiment tested the effects of estradiol on ingestive behaviors and body weight in female rats with bilateral lesions of the hypothalamic paraventricular nucleus (PVN). Thirty-two adult females received either bilateral or sham PVN lesions. All subjects were ovariectomized two weeks after the lesion. Two weeks following ovariectomy, half the animals were injected with 2 ug of estradiol benzoate (EB) for 3 days and half were injected with the oil vehicle. After 10 days of recovery the hormone treatments were reversed. Histological analysis indicated that 9 females had bilateral PVN lesions and 4 had bilateral lesions of the dorsomedial hypothalamus (DMH). Eleven animals received sham lesions. There were no significant effects of oil injections on food intake, water intake, or body weight. EB significantly lowered water intake and body weight in all groups, however, food intake was suppressed in the DMH and Sham but not PVN-lesioned females. These findings indicate that the effects of estradiol on feeding behavior are attenuated by PVN lesions. In addition, the results support the hypothesis that the effects of estradiol on food intake are mediated by its actions in the PVN.

HYPOTHALAMIC LESIONS FACILITATE THE DISPLAY OF SEXUAL BEHAVIOR IN THE FEMALE GOLDEN HAMSTER INDEPENDENTLY OF PHOTOPERIOD. A.S. Elliott* and A.A. Nunez, Dept. of Psych., Neuroscience Program, Michigan State University, East Lansing, MI 48824.

In order to further elucidate the role of the suprachiasmatic nucleus (SCN) in photoperiodic control of socio-sexual behaviors, electrolytic lesions aimed at the SCN were made in female golden hamsters (Mesocricetus auratus) and the animals were then placed in either a long or short photoperiod. After ovariectomy, the estrogen-primed animals with lesions showed lordosis more frequently than those without lesions, regardless of photoperiod. No differences were detected when the estrogen treatment was supplemented with progesterone. Animals with lesions also attacked less frequently than controls, again regardless of photoperiod. Histology revealed that the actual placement of the lesions ranged from the preoptic area through the caudal aspects of the SCN. Of the lesion group, those with damage in the anterior hypothalamus (AH), including the SCN, showed lordosis more frequently than those with damage solely in the preoptic area (POA). Conversely, those with AH lesions showed less aggression than those with POA lesions. These data support the findings that the POA, AH and SCN may play a role in mediating the inhibitory action of the septal-POA on lordosis in female hamsters (*Brain Res.* 1980, **181**:267; *Physiol. Behav.* 1982, **29**:1131).

PREOPTIC AREA (POA) KNIFE CUTS AND KNIFE CUTS POSTERIOR TO THE VENTRAL TEGMENTAL AREA (VTA) DISRUPT MATERNAL BEHAVIOR IN RATS. M. Numan, M.J. Numan* and C.E. Lupini*. Dept. of Psychology, Boston College, Chestnut Hill, MA 02167.

The present series of experiments explored the possibility that POA projections through the VTA to lower brainstem regions are critical for maternal behavior in postpartum lactating rats. The first experiment found that bilateral coronal knife cuts posterior to the VTA depressed all aspects of maternal behavior: Retrieving, nest building and nursing behavior. In a second experiment, it was found that a parasagittal unilateral knife cut lateral to the medial POA paired with a contralateral coronal knife cut posterior to the VTA also disrupted maternal behavior, suggesting that POA projections through the VTA to lower regions may be important. In a final anatomical study, animals received knife cuts posterior to the VTA or served as controls. Horseradish peroxidase (HRP) was immediately injected into the knife cut region. Animals with the cuts had more HRP labeled cells in the POA than animals without such cuts, suggesting that the cuts did indeed sever descending POA efferents. However, in the animals with cuts many other brain regions were also labeled with HRP. One functionally relevant area was the sensory trigeminal nucleus. This system may be particularly important for retrieving behavior which is influenced by orosensory input.

TECTORETICULAR NEURONAL ACTIVITY ASSOCIATED WITH BEHAVIOR AND PROGESTERONE ACTION DURING THE INDUCTION OF LORDOSIS RESPONDING IN HAMSTERS. J. D. Rose. Depts. of Psychology and Zoology-Physiology, Univ. Wyoming, Laramie, WY 82071.

Superior colliculus neurons with antidromically-identified projections to the medial medulla were recorded in estrogen-primed golden hamsters during the induction of lordosis by systemic progesterone (P) injection. A crystalline progesterone-horseradish peroxidase conjugate (P-HRP) was applied to the superior colliculus with a removable cannula, near the location of the recording electrode array. P-HRP was used to distinguish non-genomic from genomically-mediated P effects on tectoreticular neurons. Rapid effects of P-HRP and more slowly-developing effects of systemic P were seen, including changes in firing levels, antidromic excitability and antidromic spike configuration. Tectoreticular neurons that fired actively during head movements ceased firing and displayed antidromic spike blockade during lordosis. Other tectoreticular neurons showed changes in antidromic spike configuation during movements, that differed from configuations present during episodes of lordosis. These results identify specific patterns of tectoreticular neuronal activity in relation lordosis and active movements. The activity and excitability of tectoreticular neurons during induction of lordosis appears to be regulated by a combination of membrane and genomic P effects. Supported by NIH Grant NS13748.

GUINEA PIG PERINEAL MOTONEURONS ARE SEXUALLY DIMORPHIC IN SIZE BUT NOT NUMBER. Louise M. Freeman & S. Marc Breedlove, Psychology Dept., U.C. Berkeley, Berkeley CA 94720.

Motoneurons (MNs) innervating the bulbocavernosus (BC), levator ani (LA) and ischiocavernosus (IC) muscles of male guinea pigs are located in the ventral horn of the S1-L6 spinal cord. Caudally these neurons form a single cluster, but more rostrally they separate into two distinct motoneuronal columns, with BC and LA MNs in the medial cluster and IC MNs in the lateral group. Female guinea pigs have a muscle that appears homologous to but smaller than the LA of males; MNs of this muscle, like those of the male LA, are seen predominantly in the medial column. There is no obvious IC in adult female guinea pigs.

To determine whether these MNs were sexually dimorphic in number or size, we examined ten spinal cords from intact adults of each sex. Cords were frozen sectioned at 50 µm and alternate sections mounted and stained with thionin. The caudalmost section in which the medial and lateral motoneuronal columns were distinguishable was chosen as anchor point; MNs of the medial and lateral clusters were counted for 20 sections rostrally. Counts were also made of the "presplit" cluster for 10 sections caudal to the anchor point. Raw counts were corrected for split nuclei by the method of Konigsmark. Nuclear and soma areas were measured from camera lucida drawings of 12 cells/cluster/animal. There was a sex difference in soma area and raw MN count. However, the latter difference appears to be an artifact of the difference in cell size since the correction procedure eliminated the difference in MN number.

	MEAN SOMA AREA±SEM (µ²)			CORRECTED # MNs±SEM		
Cluster:	Presplit	Medial	Lateral	Presplit	Medial	Lateral
Males	942±44	981±47	969±44	179±14	476±12	407±14
Females	786±44	799±24	813±35	156±8	475±16	402±24

2-way ANOVA shows a sex difference in MN size ($p<.001$) but not # ($p=.81$).

ANDROGEN DOES NOT INCREASE MOTONEURONAL UPTAKE OF CT-HRP. Marianne Leslie and S.Marc Breedlove, Psychology Department, U.C. Berkeley, Berkeley, CA 94720.

It has been suggested that systemic androgen may augment cholera toxin-conjugated horseradish peroxidase (CT-HRP) uptake in hormone-sensitive systems. We tested this possibility by gonadectomizing 38 male rats at 50-56 days of age, and implanting of silastic capsules filled with testosterone (T) or blank (B). 25-44 days later, CT-HRP was injected into 2 muscles: the left side of the hormone-sensitive bulbocavernosus muscle (BC) (2ul), innervated by the spinal nucleus of the BC (SNB) and the right *flexor digitorum brevis* (FDB) (1ul), innervated by the retrodorsolateral nucleus (RDLN). Animals were killed 8-22 hours later, perfused, spinal cords frozen-sectioned at 50u, and motoneurons containing HRP reaction product counted by nucleus and by intensity of labeling (heavy or light).

Mean Total # Cells Labeled (heavy & light, both muscles):

Grp	Hrs: 8	10	13	16	19	22
T	0	12±7	27±8	76±5	80±50	56±32
B	0	26±5	50±13	55±5	99±35	70±5

Two-Way ANOVA: Time $p<.01$, Hormone $p=.4$

2-way ANOVA's of heavily labeled SNB and RDLN motoneurons also reveals a significant effect of time but not hormone.

We found no evidence that systemic androgen could increase the rate of CT-HRP arrival in the spinal cord, discounting one potential source of artifact when using CT-HRP to label dendrites.

PELVIC AND PUDENDAL NERVES INFLUENCE PACED MATING AND POSTURAL ADJUSTMENT IN FEMALE RATS. M.S. Erskine and E. Kornberg, Dept. of Biology, Boston University, Boston, MA 02215.

The present studies examined the relative contributions of the pelvic and pudendal genitosensory nerves to lordosis behavior, to the pacing of mating stimulation, and to the postural adjustments required for receipt of cervical-vaginal stimulation in estrous female rats during mating. Bilateral surgical transection of the pelvic (Pe), pudendal (Pu), pelvic and pudendal (Pe+Pu) nerves, or sham surgery (Sh) was performed on ovariectomized Long-Evans rats. Lordosis, pacing, and postural adjustment were measured after the sequential administration of estradiol benzoate (EB, 8µg/kg, s.c.) and progesterone (P, 2 mg/kg) in Experiment 1 and after 7 daily injections of EB only (8µg/kg) in Experiment 2. In both experiments, high levels of lordosis behavior were seen in all groups. Pacing of mating stimulation was disrupted in Pe and Pe+Pu groups after EB and P; these females failed to show the pattern of withdrawal from males which in Pu and Sh groups reflected a discrimination between mounts (M) and intromissions (I). After EB only, Pu animals as well as Pe and Pe+Pu failed to show discriminatory responses to M and I. Thus, the pelvic nerves are necessary for the display of pacing behaviors, and normally depend upon the presence of P to become sensitive to selective mating stimulation. Stimulation of the pudendal nerves by males is not sufficient to induce pacing behavior. Postural adjustment, indicated by the ratio M:I, was similar in all groups given EB and P in Experiment 1, but after EB only M:I was elevated in the Pe and Pe+Pu groups. Thus, neither the pelvic nor the pudendal n. are required for postural adjustment if P is present; without P, intact pelvic ns. are necessary for the female to make postural adjustments which increase the likelihood of intromission. LOCAL SITE OF ACTION FOR DEXAMETHASONE'S CATABOLIC EFFECT ON RAT BULBOCAVERNOSUS. *Mark N. Rand and S. Marc Breedlove*, Psychology Dept., U.C. Berkeley, Berkeley, CA 94720.

We previously found that local treatment of adult rat bulbocavernosus (BC) with testosterone can maintain muscle weight in orchidectomized animals; i.e. steroid capsules placed directly on the muscle show a local anabolic effect (Rand & Breedlove, *Soc. Neurosci. Abstr.* 1987). Last year we reported that the dendritic arbors of motoneurons innervating such T-treated muscles are 37% longer than those of motoneurons innervating the contralateral BC ($p < 0.04$, one-tailed). We now report that local treatment of BC muscle with the synthetic glucocorticoid Dexamethasone (Dex) results in a local *catabolic* effect on the muscle; our analysis of motoneuronal dendritic arbor length is pending.

Gonadally-intact adult male rats 90-180 days of age were implanted with two capsules, one containing Dexamethasone (Sigma), and the other blank. The capsules were sutured on the surface of the muscle, one on one side of the BC, the other on the contralateral side. After 30 days the animals were sacrificed and the BC, spinal cord, and seminal vesicles were dissected out. The left and right BCs were separated and weighed without knowledge of their steroid treatment. Muscle half weights were compared using a repeated measures t-test.

Muscle halves receiving local Dex were 10% lighter than those given blank capsules ($p < 0.003$), indicating that Dex acts at or near the muscle for its catabolic effect.

The effect of this non-androgenic muscle-size manipulation on the length of SNB dendrites should be interesting. If dendrites of motoneurons innervating the Dex-treated muscle half are shorter, they would be shown to vary independently of normal androgen levels. If there is no difference in dendritic length with Dex treatment, then muscle size *per se* would be shown to vary independently of dendritic arbor. We are currently measuring SNB dendrites to test these two possible outcomes.

COMMISSURE FORMATION IN SIX MOUSE STRAINS WITH ABSENT CORPUS CALLOSUM. D. Wahlsten and B. Bulman-Fleming[1], Dept. of Psychology, Univ. of Alberta, Edmonton, AB, T6G 2E9 and[1] Depts. of Psychology and Health Studies, Univ. of Waterloo, Waterloo, ON, N2L 3G1 (Canada).

The study sought evidence of single gene effects on forebrain commissure growth. Brains were studied morphometrically in fetuses of 13 inbred and one hybrid mouse strains ranging from 0.2 g to 1.0 g body size. Among six strains known to suffer absence of the corpus callosum (CC) in the adult, there was an association between a) percentage of adults with total CC absence and b) degree of retarded formation of the hippocampal commissure. The rank order of strains on both measures was I/LnJ (worst), 129/J, BALB/cWah1 and a tie of BALB/cWah2, BALB/cByJ and CXBG/By. This association occurs because in these strains the pioneering CC axons usually traverse the midplane via the HC. The cross-sectional area of the medial septal region at the telencephalic midplane was greatly reduced in certain strains (e.g., I/LnJ and BALB/cWah1) but close to normal in others (129/J and BALB/cWah2). These results support previous findings that there are two genetically and developmentally distinct processes which contribute to absent CC (Wahlsten and Smith, J. Hered., 80:11-16, 1989). The causes of CC absence reside not in the CC axons themselves but in either the generation or migration of cells that form the substrate for axon guidance.

A NEW MOUSE MODEL OF PARTIAL AND COMPLETE AGENESIS OF THE CORPUS CALLOSUM. H.-P. Lipp, R. Waanders* and D.P. Wolfer*. Institute of Anatomy, University of Zürich, CH-8057 Zürich, Switzerland.

Available animal models of callosal agenesis (the mouse strains BALB/c, 129/J and ddN) have the disadvantage of demonstrating a low frequency of this trait. The recently discovered mouse strain I/Ln shows complete penetrance of agenesis of the corpus callosum (personal communication, R.E. Wimer), but has low viability and is only available in small numbers. In order to obtain a complementary mouse model with high callosal variability and high frequency of complete agenesis, we studied the changes in size of the corpus callosum after crossing male I-mice with C57BL/6 females and backcrossing the female offspring.

Changes in midsagittal cross-sectional area of the forebrain commissures were assessed in brains of adult mice (4-8 months of age), 20 per generation. Groups included F1-hybrids (F1), 3 randomly mated generations (F2, F3, F4) and 3 generations from consecutively backcrossing female hybrid mice to the males of the parental strain I/Ln (BX1, BX2, BX3). Area of the corpus callosum changed little in the F2-F4 groups (92-98% as compared to the F1). In the backcross generations, the corpus callosum was increasingly reduced with every generation (BX1: 76%, BX2: 25%, BX3: 5%). This corresponded to the number of mice with apparently complete agenesis of the corpus callosum (BX1: 0 %, BX2: 45% and BX3: 75%). The reduction of the corpus callosum was correlated with a smaller area of the anterior commissure ($r=0.58$, $p < 0.001$) and of the hippocampal commissures ($r=0.86$, $p < 0.0001$), predominantly of their dorsal components.

Thus, variation in size and frequency of agenesis of the corpus callosum can be controlled by means of systematic breeding. Functional and neuroanatomical correlates of callosal variation are studied preferentially in BX2 mice, whereas BX3 mice combine decent viability with a high frequency of complete agenesis of the corpus callosum. COMPLETING THE SPLIT IN THE SPLIT-BRAIN RAT: TRANSECTION OF THE OPTIC CHIASM. M.F. Novotny, D.P. Crowne, and I.S. Russell. Dept. of Psychology, Univ. of Waterloo, Waterloo, Ont. N2L 3G1, CANADA.

To study interocular transfer (IOT), we depend on directing sensory input to a single hemisphere. In studies of cat and monkey, division of the optic chiasm routes all visual inflow in monocularly occluded animals to the ipsilateral hemisphere, enabling tests of IOT by section of forebrain commissures. Hemispheric asymmetries have also been investigated in this preparation. In the rat, section of the optic chiasm is formidable, and the alternative has been to exploit the marked asymmetry of crossed and uncrossed projections. Since the small proportion of uncrossed optic fibres in the rat is functional, the role of forebrain commissures in IOT is not firmly established. We describe a stereotaxic technique using a microknife to transect the optic chiasm in the rat that minimizes superficial damage and mortality, and we present illustrative data on the interocular transfer of visual discrimination in chiasm-sectioned and chiasm-plus-forebrain commissure-sectioned animals. Chiasm-sectioned rats are visually competent and show mean savings (75%) on second-eye transfer. Rats with divided chiasm and corpus callosum show no evidence of transfer on first-eye reversal.

381.4

BEHAVIORAL ASYMMETRY IN MALE, FEMALE AND PERINATALLY GONADECTOMIZED RATS. K. J. Schultz. Psychology Department, Univ. of Winnipeg, Winnipeg, MB, Canada R3M 2E9.

Behavioral asymmetry was examined in 317 Sprague-Dawley rats (105 males, 109 females, 103 perinatally gonadectomized males). Adult animals completed four trials on each of seven side preference tasks. Laterality ratios were derived for each task. A direct discriminant function analysis was performed using these laterality ratios as predictors of condition (male, female, gonadectomized male). The discriminant functions derived significantly separated males from females ($p < .000$) but failed to differentiate the two groups of males ($p = .613$). The loading matrix values suggest that the best behavioral predictors for distinguishing between males and females were two circling tasks, a direction choice task and a water bottle preference task. On each of these tasks females exhibited a greater right preference than did males. None of the behavioral tasks discriminated between males and gonadectomized males. Analyses of hemispheric differences in neocortical volume are in progress and suggest that groups differ significantly on these variables.

SEX DIFFERENCES IN THE ASYMMETRICAL BEHAVIORAL RESPONSE TO BRAIN INJURY IN THE RAT. S.E.Starkstein, J.B.Bryer*, T.H. Moran, R.G.Robinson. Dept. Psychiatry, Johns Hopkins Univ. Sch. Med. Balto., MD 21205.

We have previously reported that right hemisphere or bilateral suction lesions of the dorsal lateral frontal cortex or electrolytic lesions of the nucleus accumbens (NAS) in male rats produce spontaneous running wheel hyperactivity. In the present experiments, we examined these two phenomenon in female rats. Twenty-four adult female Sprague-Dawley rats were given either left, right, bilateral or sham frontal cortical suction lesions and placed in running wheel cages for activity monitoring for 30 days. The results showed no significant between-group differences in locomotor activity, demonstrating, in combination with our earlier findings in male rats, the presence of sexual dimorphism in the lateralized behavioral response to fronto-cortical lesions. In the second series of experiments, 27 adult female Sprague-Dawley rats were given either left, right, bilateral or sham NAS electrolytic lesions and activity was monitored as above. The results showed that rats with either left or right NAS lesions had significantly more locomotor activity than rats receiving either sham treatment or bilateral lesions. These results also contrast with our earlier findings in male rats where right but not left NAS lesions produced significant hyperactivity. Moreover, in adult male rats, bilateral NAS lesions produced more hyperactivity than single right NAS lesions.

ANTERIOR BRAIN ELECTRICAL ASYMMETRIES IN RESPONSE TO REWARD AND PUNISHMENT. S. Sobotka, R.J. Davidson*, & J. Senulis*. Department of Psychology, University of Wisconsin, Madison, WI 53706.

Recent findings on both brain-damaged and normal individuals indicate differential involvement of the anterior regions of the two hemispheres in approach and withdrawal-related emotional processes. In this study, 15 right-handed subjects were tested in a paradigm which manipulated reward and punishment contingencies while brain electrical activity was recorded. Each trial began with the presentation of a fixation point, which was followed by an arrow which was either in the up or down position. Four seconds later, an imperative stimulus was presented. In the arrow up trials, if the subjects responded sufficiently quickly, they received $.25; in the arrow down trials, if the subjects responded too slowly, they lost $.25. RT criteria were adjusted for each trial block based upon the median RT of the previous trial block. After they responded, subjects were given feedback about their performance. Trial type was randomly varied. EEG was recorded from F3,F4,F7,F8,T3,T4,C3,C4,O1,O2,Pz,Cz and sites between T3 & P3 and T4 & P4, referenced to A1-A2. Power in the theta, alpha, and beta bands of the EEG during the 4 s inter-stimulus interval was computed by Fourier Transformation. In addition, the contingent negative variation (CNV) was quantified during this interval. For alpha power, the Condition X Hemisphere interaction was significant for the frontal leads. Punishment trials were associated with less right frontal power (i.e., more activation) compared with reward trials. These effects were present only in the frontal leads and were more robust when the analysis was restricted to trials on which the subjects won or lost money. No significant Condition X Hemisphere interaction was found for the CNV.

INVESTIGATION OF LEFT/RIGHT ASYMMETRIES OF SPATIAL NAVIGATION LEARNING IN RATS WITH UNILATERAL 6-OHDA LESIONS OF THE SUBSTANTIA NIGRA. R. Sullivan* and H. Szechtman Dept. Biomedical Sci., McMaster Univ., Hamilton, Ontario, CANADA L8N 3Z5.

Damage to central dopamine (DA) systems in rats impairs aspects of spatial learning in the Morris water maze task. As the right hemisphere in humans is thought to preferentially mediate spatial processing, we sought to determine if selective damage to the left or right nigrostriatal DA system of rats would differentially impair the profile of spatial learning. Male Sprague-Dawley rats (300-350 g) received unilateral 6-OHDA lesions of the left or right substantia nigra (N=24 per group) or control operations (N=14). Group assignment was based on a pretest for directional bias (undrugged) in a 2-m diameter pool, also used for subsequent watermaze testing. Following a rotometer test on apomorphine (APO) at 2 weeks post-lesion, rats were tested for acquisition of a place task (latency to find a submerged platform) in the water maze, for 4 consecutive days. On day 5 (reversal), the location of the platform was switched to the opposite quadrant. Rats received 4 trials a day (water temp. 25° C). Only in reversal, did group differences emerge. Right-lesioned rats were significantly impaired in escape latencies (P=0.016) while left-lesioned rats did not differ from controls. In controls, a leftward pretest bias was correlated with time spent in the former escape quadrant in reversal (r=.56, P=0.018), suggesting right-sided DA dominance for superior retention, a conclusion supported by significant correlations of APO rotation with the same measure in lesioned groups. [Supported by NSERC. HS is a Research Associate of the OMHF].

SPATIAL DEFICITS AND THEIR LATERALIZATION FOLLOWING UNILATERAL POSTERIOR PARIETAL LESIONS IN THE RAT. S.E. Maier, R.W. Vitols*, M.F. Novotny, & D.P. Crowne, Dept. Psychology, Univ. Waterloo, Waterloo, Ont. N2L 3G1, CANADA.

Both egocentric and allocentric (landmark) cues serve in spatial mapping and navigation. In humans, monkeys, and rats posterior parietal cortex (PPC) is involved in maintaining a reference system to guide spatial movement. Bilateral lesions of PPC yield allocentric deficits. Spatial deficits from unilateral lesions, especially in rats, are less well documented. To show a true homology of PPC function, we tested rats with unilateral lesions on egocentric and allocentric spatial tasks. Rats sustained left or right PPC lesions, lateralized PPC lesions + section of corpus callosum, CC section alone, or sham operations, and were tested on egocentric and allocentric versions of the Morris Water Maze. Both left and right PPC + CC lesions resulted in significant deficits compared to controls on latency and heading error in egocentric place navigation. With reversal of platform location, only controls and animals with left or right PPC lesions were impaired. On the allocentric task, rats with right, but not left, PPC + CC lesions were significantly worse than controls in latency to find the platform. We demonstrate a nonlateralized PPC impairment and a lateralized one in allocentric spatial navigation.

381.9

SOUND LOCALIZATION IN NORMAL AND CALLOSAL AGENESIS HUMAN SUBJECTS. P.Poirier*, S.Miljours*, F.Leporé, L.Richer* and M.Lassonde. Groupe de Rech. en Neuropsy. Exp., Université de Montréal, Mtl, PQ, Canada, H3C 3J7.

In cats, electrophysiological and tracing studies of the primary auditory cortex as well as the corpus callosum suggested the latter's implication in sound localization (Imig et al.,1986; Poirier et al., 1989). The present study examined manual pointing to auditory targets in 4 Ss with callosal agenesis paired to 4 age- and I.Q.-matched controls. Ss were required to locate broadband noise bursts (BBN) at fixed intensity in the horizontal plane in an anechoic chamber. BBNs were delivered randomly through 16 speakers and repeated 5 times. The speakers, which were invisible to the Ss, were mounted at approximately 10° intervals on a perimeter frame having a radius of 50 cm. Ss responses consisted of manual pointing on the frame. Aiming accuracy was assessed by calculating the mean deviation of the pointing responses from the target position. There was no difference between the 2 groups in terms of accuracy. However, acallosal Ss tended to overshoot throughout the field while no such pattern was seen in the control Ss. Furthermore, acallosal and control Ss made significantly more errors when aiming was carried out in the left auditory hemifield. The hemifield differences were not due to sensory deficits in sound localization. This conclusion is supported by visuo-motor pointing task with humans which showed similar differences (Lassonde et al. 1989). (supported by FCAR and CRSNG).

381.10

DEFICITS IN INTERFIELD MEMORY TRANSFER IN CASES OF CALLOSAL AGENESIS. D.J. Ingle, L.S.Jakobson, M.C. Lassonde, & H.C. Sauerwein. Northeastern Univ, Univ.W.Ontario, & Univ. of Montreal.

In man the ease and accuracy with which we remember locations of objects after moving about without vision is taken for granted. When an object is viewed in one hemifield, and the subject rotates so as to "move" the remembered location into the opposite hemifield, does the neural representation of that locus jump from one side of the brain to the other?

We performed a relevant experiment with four subjects with congenital agenesis of the callosum who could point to remembered visual targets (an eye-level cylinder seen for only ½ second) with either hand and in either hemifield. When memory locations remained within the same hemifield all subjects easily discriminated different locations; when the remembered location fell into the opposite hemifield after rotation locations of 30° vs 60° from the midline were very poorly discriminated.

These results support the hypothesis that the underlying memory representations normally do change hemispheres post rotation, since good compensation occurred in controls equated for I.Q.

381.11

EFFECTS OF SEX AND AGE ON REGIONAL MORPHOLOGY OF THE HUMAN CORPUS CALLOSUM. P.E. Cowell, L.S. Allen*, N. Zalatimo*, and V.H. Denenberg. Biobehavioral Sciences Graduate Program, Univ. of Connecticut, Storrs, CT 06269 and Dept. of Anatomy and Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024.

Midsagittal callosal (CC) tracings from MRIs of 73 pairs of age-matched males and females (age 2-79 years) were digitized using computer assisted software. The following parameters were derived: 99 percentile widths along the curved longitudinal axis, length of this axis, area, and perimeter. The width percentiles were grouped into regions based upon prior factor analyses of human callosal material. The regions are widths 3-18 (W3-18), W22-39, W49-62, W65-74, W77-85, W89-94, and W95-99. Trend analyses of these regions with Sex and Age (blocked in 10-year bins) as independent variables, found the following significant effects. The two anterior-most regions (W3-18 and W22-39) had a cubic Sex x Age interaction. In both regions males reached a maximum value at Age 21-30 while females did not peak until Age 41-50. In W3-18 both sexes dropped sharply after peaking. Their callosal widths after age 60 were no greater than seen in childhood. The same phenomenon was seen for females in region W22-39, while male widths remained asymptotic over age. The remaining callosal regions were relatively homogeneous: the CC of both sexes grew with age (quadratic effect) and showed some gradual diminution but no sharp drop off. The genu and anterior body were the CC regions most sensitive to the interactive effects of sex and age.

381.12

CORRESPONDENCE OF AUDITORY AND VISUAL LATERAL ASYMMETRIES FOR LANGUAGE PROCESSING IN DEXTRALS BUT NOT IN NON-DEXTRALS. Z. Caramanos*, R.J. Zatorre and D. Bub*. Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada. H3A 2B4.

Cross-modal correlations of visual and auditory measures of hemispheric language dominance were obtained for 15 dextral and 30 non-dextral human subjects. The auditory measure, ear advantage on the dichotic fused rhymed words test (B. Wexler & T. Halwes, Neuropsychologia, 21:59, 1983) is known to relate to individual hemispheric asymmetry on the intracarotid sodium Amytal test (R. Zatorre, Neuropsychologia, 27:1207, 1989). The visual measure involves the difference between the slopes of mean reaction times to words presented in the left and right visual fields as a function of length, which is taken to reflect hemispheric differences in reading efficiency (D. Bub & J. Lewine, Brain Lang., 33:161, 1988). Both dextrals and non-dextrals showed the expected distributions of asymmetry on the two measures. Dextrals showed a significant correlation (r=.56) between scores on the two tests, suggesting that, to some extent, a common mechanism may underlie the asymmetries observed in the two modalities. Non-dextrals, however, did not demonstrate significant cross-modal correlations (r=.13), which may indicate a partial dissociation between visual and auditory laterality in the non-dextral population.

381.13

HAND AND SEX DIFFERENCES IN SYLVIAN FISSURE MORPHOLOGY S.F. Witelson and D.L. Kigar, Dept. of Psychiatry, McMaster Univ., Hamilton, Ont., Canada, L8N 3Z5

Morphology and asymmetry in the Sylvian fissure (SF) in the human brain was studied by dividing it into 3 segments: anterior (A), horizontal (H), vertical (V). Segment perimeters in each hemisphere were measured in 67 brains (24 men, 43 women) from individuals whose hand preference [consistent-right-handed (CRH) and nonCRH] was tested prior to death. Marked asymmetry was observed: left (L) HSF was greater than right (R); R VSF was greater than L; ASF showed no asymmetry. Sex and Hand were factors in HSF only. (1) Men had greater asymmetry than women. (2) Men had a greater HSF than women but only for L HSF. (3) Only among CRH did men have a greater HSF (over both hemispheres) than women, suggesting that hand has a greater effect in men. In summary, there are two complementary asymmetries in the SF (HSF & VSF). The influence of handedness in men supports the role of SF morphology in functional asymmetry. The sex difference in the association of SF anatomy and handedness is consistent with previous results that area of the isthmus of the corpus callosum varies with hand only in men (Witelson, 1989).

EMERGING SIGHT-WORD READING IN A VISUALLY AGNOSIC AND PROSOPAGNOSIC CHILD. I.S. Brown and F.B. Wood*. Section on Neuropsychology, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC, 27103.

We report a patient who at 16 months of age suffered cardiac arrest and anoxia during bronchoscopy to remove an aspirated bean. Onset of seizures originating in the left hemisphere occurred soon after. Following the anoxic episode visual evoked response showed functioning of the visual pathways. At age 5, magnetic resonance imaging revealed multiple high signal lesions in both parieto-occipital cortices, worse on the right. Now at age 8, seizures are controlled with Tegretol; visual acuity is decreased, but relatively intact with corrective lenses. His verbal IQ is 74 and verbal short-term memory is within normal limits. He does simple computations mentally, spells orally, reads simple sight words in large print, and is able to name many real objects in his environment, apparently employing color and shape cues to do so. However, with few exceptions he cannot identify large pictures of similar objects, or actual faces of familiar people, including his mother. Dissociation of early reading skills and non-verbal skills in this child is striking and informative, not only by reference to a large normal sample of 8 year olds studied through our NICHD Program project on dyslexia, but also (following Caramazza) as a single case existence proof of emerging reading despite visual agnosia.

COORDINATED NONINVASIVE STUDIES (CNS) PROJECT. J.L.Lauter. Speech & Hearing Sciences, Univ. of Arizona, Tucson, AZ 85721

Several noninvasive methods for studying human brain structure and function are combined in a test battery to study aspects of behavior in the same subjects. Each individual is tested with behavioral methods, MRI, EPs, qEEG, PET,and MEG. Current focus is on asymmetries for complex sounds. First each subject is trained on dichotic listening for two sound sets which evoke "opposite" asymmetries. Next brain anatomical asymmetries are measured with MRI, and a repeated measures auditory EP series is done to define brainstem asymmetries. Then each individual subject is run on the two sound sets while being monitored with qEEG, then PET, then MEG. Results to date show: 1) good "internal consistency" comparing behavioral, anatomical, and physiological asymmetries within subjects; 2) individual differences in the specifics of the various asymmetries; and 3) agreement across subjects in the patterns of these asymmetry "profiles." Findings suggest that the approach is not only viable, but that exploiting the complementarity of the noninvasive techniques may reveal unsuspected relations among aspects of human neuroanatomy, neurophysiology, and behavior.

CONDITIONED AND UNCONDITIONED MORPHINE WITHDRAWAL IN THE HAMSTER. P. Schnur. Center for Alcohol and Addiction Studies, Brown University, Providence, RI 02904.

Naloxone-precipitated morphine withdrawal was studied in morphine-pelleted and in subcutaneously injected hamsters. On five days, morphine-pelleted (75 mg) hamsters were injected with naloxone (1 mg/kg) in a distinctive environment. They were observed for signs of withdrawal 10 min before and 30 min after the naloxone injection. Results indicated that a) withdrawal intensity was a direct function of the number of implanted pellets, and b) compared with several control groups, conditioned withdrawal developed among animals withdrawn in the distinctive environment and was evident up to 30 days after pellet removal. To extinguish conditioned withdrawal, some animals were given daily saline injections for 1 wk in the distinctive environment while others remained in the home cage. Conditioned withdrawal was attenuated, but not eliminated by the extinction treatment. A separate experiment indicated that verapamil (10 and 20 mg/kg) did not attenuate naloxone-precipitated withdrawal. In other experiments, withdrawal was precipitated by naloxone (0,0.4, 1 mg/kg) following 4 or 8 sc injections of morphine (15 mg/kg). Withdrawal, measured as above, as well as by the disruption in morphine-elicited running wheel activity, was evident after 4 morphine injections. Again, verapamil failed to attenuate withdrawal. (Supported by NIDA Fellowship and by a Rhode Island Foundation Grant)

MORPHINE AND COCAINE-REGULATED PHOSPHOPROTEINS (MC-RPPs) IN CRITICAL REWARD REGIONS OF RAT BRAIN: IDENTIFICATION OF TYROSINE HYDROXYLASE (TH) AND OTHER DRUG-REGULATED PHOSPHOPROTEINS. D.B. Beitner and E.J. Nestler, Laboratory of Molecular Psychiatry, Depts. of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06508.

The nucleus accumbens (NAc) and ventral tegmental area (VTA) appear to mediate some of the rewarding properties of opiates, cocaine, and other drugs of abuse. In the present study, we have identified a number of phosphoproteins, among which is TH, that are regulated by both chronic morphine and cocaine specifically in these brain nuclei.

Protein phosphorylation was analyzed in brain regions of control rats and rats treated chronically with cocaine or morphine by back phosphorylation with cAMP-dependent protein kinase and 2D-gel electrophoresis. We found that chronic, but not acute, morphine and cocaine treatments regulated a number of the same phosphoproteins in the VTA and NAc. Both treatments increased the total amount of TH in the VTA, but reduced its phosphorylation state (without a change in its total amount) in the NAc. Several other, novel phosphoproteins also showed similar regulation by chronic morphine and cocaine in these brain regions. Drug regulation of most of these various phosphoproteins in the VTA and NAc showed regional specificity in that such regulation was not observed in the substantia nigra and striatum.

We propose that these **M**orphine and **C**ocaine-**R**egulated **P**hospho-**P**roteins (termed "**MC-RPPs**"), together with increased adenylate cyclase and cAMP-dependent protein kinase activities observed in the NAc in response to chronic morphine or cocaine (see Nestler et al., this volume), represent part of the biochemical basis by which these drugs of abuse alter the functional state of brain reward regions.

382.3

A GENERAL ROLE FOR ADAPTATIONS IN G-PROTEINS AND THE CYCLIC AMP SYSTEM IN MEDIATING THE CHRONIC ACTIONS OF MORPHINE AND COCAINE ON BRAIN FUNCTION. E.J. Nestler, D.B. Beitner, M. Hayward,* K.S. Sevarino, and R. Terwilliger. Lab. of Mol. Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Sch of Med, New Haven, CT 06508.

We have shown that chronic morphine increases levels of Giα, Goα, adenylate cyclase (AC), cyclic AMP-dependent protein kinase (cA-K), and certain phosphoproteins (MARPPs) in the locus coeruleus, but not in some other brain regions studied (see *J. Neurosci.* 9:4371, 1989). These changes may occur at least in part at the level of gene expression.

In the present investigation, we surveyed the effects of chronic morphine or chronic cocaine treatments on the G-protein/cyclic AMP system in a large number of brain regions. While most regions showed no regulation in response to morphine, nucleus accumbens (NAc) and amygdala did show increases in AC and cA-K, and thalamus showed an increase in cA-K only. Morphine regulation of G-proteins was variable, with decreased levels of Giα and Goα seen in NAc, increased levels in amygdala, and no change in thalamus. Interestingly, chronic cocaine produced similar changes compared to morphine in G-proteins, AC, and cA-K in NAc, but not in the other brain regions studied.

These results indicate that changes in the G-protein/cyclic AMP system represent mechanisms by which a number of opiate-sensitive neurons adapt to chronic morphine and contribute to varying aspects of opiate tolerance and/or dependence in these cells. The findings that chronic morphine and cocaine produce similar changes in G-proteins, AC, cA-K, and phosphoproteins (see Beitner et al., this volume) in the NAc, a brain region important for the reinforcing actions of abused substances, suggests further that changes in the G-protein/cyclic AMP system may also underlie psychological aspects of drug addiction.

MORPHINE-INDUCED EFFECTS ON EEG AND BEHAVIOR DIFFER IN LEWIS AND FISCHER 344 RAT STRAINS.

L. Mayo-Michelson,* N.C. Paquette, H. Stamidis,* F.R. George* and G.A Young. Dept of Pharmacol., 20 N. Pine St. Sch. of Pharmacy, Univ. of MD., Baltimore, MD 21201.

Previous studies have demonstrated genetic differences in various inbred strains of rats during preference tests and operant self-administration of ethanol, cocaine and various opiate derivatives (George and Goldberg, 1989). Lewis (LEW) rats self-administered and displayed a preference for these drugs, while Fischer 344 rats did not. In the present study, the effects of morphine (10 mg/kg, i.v.) on EEG and behavior were examined and compared in these two strains. Duration of morphine-induced EEG slow-wave bursts and associated behavioral stupor was greater in LEW rats. Latency to onset of slow-wave sleep after morphine injection was also greater in LEW rats. Effects of morphine on EEG spectral parameters are being assessed. These EEG effects may reflect differences in neurosensitivity and/or opioid receptor populations. (Supported by NIDA DA01050 and NIAAA AA07754).

MORPHINE-INDUCED HYPOTHERMIA AND SUPPRESSION OF LUTEINIZING HORMONE (LH) SECRETION: A MECHANISM FOR MORPHINE TOLERANCE. R. Ganesan, T. Romano* & J. Simpkins, Dept. of Pharmacodynamics, Univ. of Florida, Gainesville, Florida 32610.

We investigated the role of opponent processes in morphine tolerance by comparing morphine's effects on body temperature and LH secretion. All experiments used 4-week ovariectomized rats which were administered either a low or a high dose of morphine (5 or 30 mg/kg, s.c.) daily for 6 days. The low dose induced hyperthermia and caused a transient suppression of LH levels (for 0.5 h) following the first exposure. Both responses showed little change with repeated injections. The high dose induced hypothermia and a sustained suppression of LH (up to 6 h) following the first exposure. After the sixth injection of 30 mg/kg morphine, rats showed hyperthermia in contrast to the initial hypothermia. With the LH response, tolerance to the high dose was exhibited by an accelerated rate of recovery to normal LH levels rather than an attenuated suppression of LH. These results are best explained by an opponent-process account of morphine tolerance.

Our previous investigations indicate that luteinizing hormone-releasing hormone (LHRH) attenuates morphine's effects on various response systems by inducing responses which oppose those of morphine. The present results are consistent with the hypothesis that enhanced LHRH release may mediate tolerance to morphine. (Supported in part by AG 02021)

382.6

THE NMDA ANTAGONISTS LY274614 AND MK801 AND MORPHINE WITHDRAWAL: A BEHAVIORAL AND ELECTROPHYSIOLOGICAL STUDY. Kurt Rasmussen, Marsha E. Stockton and Paul Ornstein, Lilly Research Labs, Eli Lilly & Co., Lilly Corporate Center, Indianapolis, IN 46285.

There is a clinical need for improved treatments for opiate dependency, especially since intravenous drug abusers are at increased risk for contracting the AIDS virus. This study was designed to evaluate the effects of compounds that are selective for a subtype of excitatory amino acid receptor (the NMDA receptor) on morphine-withdrawal behavior and withdrawal-induced activation of noradrenergic neurons in the locus coeruleus (LC). Systemic administration of the non-competitive NMDA antagonist MK801 dose dependently blocked the behavioral signs of withdrawal in morphine-dependent rats. However, the same doses of MK801 that blocked morphine withdrawal also simultaneously (and dose dependently) produced PCP-like behavioral effects. The competitive NMDA antagonist LY274614 also dose dependently blocked the behavioral signs of withdrawal in morphine-dependent rats but did not produce any PCP-like behavioral effects. Single unit recordings of LC neurons from morphine-dependent animals showed that neither MK801 nor LY274614 blocked the withdrawal-induced activation of these neurons. These results indicate that non-competitive NMDA antagonists like MK801 may not be useful to alleviate opiate-withdrawal symptoms in man because of their PCP-like side effects. However, competitive NMDA antagonists like LY274614 could be of great benefit for alleviating opiate-withdrawal symptoms in man. In addition, NMDA antagonists (unlike the alpha-2 agonist clonidine, which is currently in clinical use) attenuate the behavioral signs of morphine withdrawal without blocking the withdrawal-induced increase of LC unit activity.

VERAPAMIL REDUCES HYPERCAPNIA AND EUPHORIA PRODUCED BY MORPHINE IN HUMANS. D.B. Vaupel, A. Della-Puppa, W.R. Lange, and E.D. London. NIDA Addiction Research Center, Baltimore, MD 21224.

Verapamil (V), a calcium channel blocker, antagonizes morphine (M)-induced respiratory depression in rats (Szikszay, M. et al., J. Pharmacol. Exp. Ther., 238:192, 1986). As such an antagonism might be useful therapeutically, we extended the earlier work to a study in human volunteers. We tested the ability of V to reduce M-induced respiratory depression and to modulate subjective effects of M in four experienced, male heroin users. Five treatments, each consisting of two, simultaneous 2 min i.v. infusions, included: saline (S) + S; M 10 mg + S; M 10 mg + V 2.5, 5 or 10 mg. Carbon dioxide tension in the blood was measured transcutaneously ($P_{tc}CO_2$), and respiratory rate was determined by impedence pneumography. Questionnaires and visual interval scales were used to evaluate subjective changes. Observations were made from 0.5 hr before to 4 hr after drug administration. M significantly increased $P_{tc}CO_2$ levels above S + S levels ($P < 0.05$), whereas none of the increases in $P_{tc}CO_2$ following M + V combinations differed from S + S condition. No consistent effects on respiratory rates were found. M produced slight to moderate subjective effects, which included self-reports of "good effects", "liking" and of being "high." These marginally significant effects ($P < 0.1$) occurred in 3 of 4 subjects. Additionally, all three doses of V consistently reduced the positive effects of M on mood, as well as the strength of the drug effect. Although further studies are indicated, the present results suggest that co-administration of calcium channel antagonist drugs, such as V, may improve safety and reduce abuse liability of M treatments.

ANALOG OF FMRF-NH_2-LIKE MAMMALIAN PEPTIDE ATTENUATES MORPHINE ABSTINENCE SYNDROME. J.R. Lake, D.H. Malin, M.V. Hammond*, S.L. Brown*, J.L. Sims*, K.R. Arcangeli*, G.M. Moore* and K. Payza. Univ. of Houston-Clear Lake, Houston, TX 77058 and NICHD, Bethesda, MD 20892.

It has been suggested that the peptide FLFQPQRF-NH_2 (F-8-F-NH_2) may play a role in opiate dependence and subsequent abstinence syndrome. This peptide precipitated opiate abstinence syndrome, while IgG from antiserum against this peptide largely prevented subsequent naloxone-precipitated abstinence signs in dependent rats. The peptide desamino-YFLFQPQR-NH_2 (daY-8-R-NH_2) was synthesized as a possible F-8-F-NH_2 antagonist. It appears to be a mixed agonist/antagonist. At doses of 2μg or higher it precipitates abstinence syndrome in dependent rats in a manner similar to F-8-F-NH_2. However, 600ng i.c.v. did not induce withdrawal and attenuated subsequent naloxone-precipitated withdrawal. Fourteen rats were cannulated in the 3rd ventricle and rendered dependent by 7 days continuous s.c. infusion of morphine sulfate (0.3 mg/kg/hr. via Alzet osmotic minipump). Seven rats were injected with daY-8-R-NH_2 i.c.v. while 7 received saline alone. Twenty-eight mins. later, all rats were challenged with 10μg naloxone through the same cannula. During the following 20 mins., each rat was observed under "blind" conditions for standard abstinence signs. The daY-8-R-NH_2-pretreated rats had 80% fewer abstinence signs than saline-pretreated controls, a significant difference, $p<.001$. There were significant differences in writhes/gasps, shakes/tremors, teeth chatter/chewing and ptosis.

BUPRENORPHINE-INDUCED TOLERANCE TO DISCRIMINATIVE STIMULUS EFFECTS OF MORPHINE AND BUPRENORPHINE. G. Kapitsopoulos* and A.M. Young. Department of Psychology, Wayne State University, Detroit, MI 48202

The effects of acute or repeated treatment with buprenorphine (BUP) were examined in Sprague-Dawley rats trained to discriminate saline and 3.2 mg/kg morphine (MS) under a two lever fixed-ratio 15 schedule of food delivery. Cumulative doses of MS (0.1-3.2 mg/kg) or BUP (0.001-0.32 mg/kg) evoked MS-appropriate behavior in a dose-dependent manner, with complete generalization at 1.78 mg/kg MS or 0.032 mg/kg BUP. Acute doses of BUP given 30 min (0.003-0.01 mg/kg) or 24 h (0.1-0.3 mg/kg) before a test decreased the dose of MS or BUP required for stimulus control in an additive manner. In contrast, suspending training and administering repeated doses of BUP (0.32 mg/kg b.i.d.) for 1 to 2 weeks increased the dose of MS or BUP required for stimulus control by at least 3-fold. However, during repeated BUP treatment, MS did not evoke stimulus control in 3 of 8 rats, and BUP did not evoke MS-like stimulus control in 2 of 8 rats. Repeated BUP treatment increased the dose of MS required for rate suppression by >6-fold, and that of BUP by >30-fold. Stimulus control by BUP recovered within 1 week after BUP treatment ended; stimulus control by MS, within 2 weeks. These results suggest that repeated treatment with BUP produces a prolonged tolerance to the MS-like stimulus effects of MS and BUP. (Supported by USPHS grants DA03796 and K02 DA00132.)

HEROIN SELF-ADMINISTRATION ON A PROGRESSIVE RATIO SCHEDULE OF REINFORCEMENT: THE EFFECT OF DOSE MANIPULATION, OPIATE ANTAGONISM AND SALINE REPLACEMENT. S.A.L. Bennett and D.C.S. Roberts Department of Psychology, Carleton University, Ottawa, Ont., K1S-5B6.

Heroin self-administration was examined using a progressive ratio schedule of reinforcement. On the first test day, the response requirements began at 1 and escalated exponentially after each drug infusion. On the second and subsequent test days, the initial response requirements were adjusted according to the previous day's final ratio. An inverted U dose response relationship was established for animals self-administering 12.5, 25, 50, and 100 µg/injection heroin with breaking points peaking at the 50 µg/injection dose. Breaking points were shown to significantly increase following saline substitution for heroin injection and remain elevated for several days before extinction of the self-administration response was observed. Heroin-reinforced breaking points were shown to decrease rapidly following daily IP naltrexone (0.6 mg/kg) pretreatment. These results suggest that progressive ratio schedules of reinforcement are useful in quantifying changes in opiate-motivated behaviour (Supported by the M.R.C).

ULTRASONIC VOCALIZATION AS A MEASURE OF LONG-TERM AND SHORT-TERM TOLERANCE AND WITHDRAWAL IN NEONATAL RATS. C. P. Cramer, R. A. Fite*, and M. S. Fanselow. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Ultrasonic vocalizations are typically reduced by acute adminstration of opiates (eg., Kehoe & Blass, 1986). We compared this behavior to nociceptive responses (pawlift on a hotplate) and used it as an index for studying the development of tolerance to and withdrawal from opiates in neonatal rats.

Morphine sulfate (2, 4, or 10 mg/kg) given once daily for the first 10 postpartum days essentially eliminated vocalizations compared to saline controls on each day. On Day 11, pups from each treatment group were adminstered saline, morphine (1 mg/kg) or naloxone hydrochloride (10 mg/kg). The morphine-exposed groups were as vocally depressed by the test injection of morphine as was the saline control group. Naloxone did not increase vocalization in the drug-exposed groups. Thus, unlike adults, neonatal rats did not develop tolerance and withdrawal using what have been termed "long-term" parameters. An alternative form, "short-term" tolerance, has been proposed for rats given closely-spaced doses of opiate (Baker & Tiffany, 1985). To test this form, pups received morphine (10 mg/kg) or saline at 6-hr intervals for 2 days, beginning on Day 1 or Day 10. They were then given saline, morphine (1 mg/kg) or naloxone (10 mg/kg) 6 or 36 hr after the last exposure and tested using ultrasonic vocalization and pawlift latency. In general, newborn rats appeared to be capable of acquiring tolerance and withdrawal if given massed injections of morphine in high doses. The apparent distinction between infant rats' ability to form long- and short-term tolerance suggests that the mechanisms surbserving each form of tolerance develop at different ages.

382.12

THE OBLIGATORY NATURE OF MORPHINE-INDUCED ORAL STEREOTYPIES. J. Pollock, R. Galli* and C. Kornetsky. Laboratory of Behavioral Pharmacology, Boston Univ. Sch. of Med., Boston, MA 02118.

Three high doses of morphine will produce oral stereotypies in rats that can be re-expressed up to 6 months later. Because amphetamine-induced oral dyskinesias are often dependent on the mode and setting of drug delivery, the present study determined the role of these variables in morphine-induced stereotypy. Male F-344 rats were continuously infused with morphine (53 mg/ml) over 36 hours, or were injected with 3 high doses of morphine (10,20,20 mg/kg, sc) over 24 hours. Throughout the morphine administration, rats were placed in test chambers with steel bar floors. Thirty days later animals received morphine (4.0 mg/kg) and were observed for evidence of oral stereotypy. There was no significant difference in the incidence of stereotypy between the two groups. In a second study rats received 3 high doses of morphine and were placed in either the test chambers with floor bars or in a solid plastic box. Thirty days later, all animals were injected with morphine (4.0 mg/kg) and were placed in the chambers with bar floors. All animals showed oral stereotypy. Unlike amphetamine-induced oral dyskinesias, the stereotypies produced by morphine appear to be obligatory. (Supported by NIDA grant DA02326 and RSA DA00099 to CK).

382.13

THE ROLE OF NIGRAL OPIOID RECEPTORS IN MEDIATING MORPHINE WITHDRAWAL. M. Nagy and A. A. Baumeister. Department of Psychology, Louisiana State University, Baton Rouge, LA 70803.

These studies were conducted to investigate the role of opioid receptor subtypes in the substantia nigra in behavioral symptoms of morphine withdrawal. Male Sprague-Dawley rats were given daily injections of increasing doses of morphine sulfate (20-80mg/kg/5ml, s.c.), dissolved in a sustained release preparation (7.5% mineral oil:42.5% Arlacel A:50% saline). Eighteen hours after the last morphine injection, animals received bilateral intranigral injections of 5nm/0.5µl, naloxone (nonspecific antagonist), beta-FNA (mu specific antagonist), nor-BNI (kappa specific antagonist), or sterile water (0.5µl). Withdrawal behaviors were observed for 20 minutes following intranigral injection. Naloxone produced significant increases in wet dog shakes, ptosis, teeth chatter and squealing (irritability to touch), when compared to the intranigral water control. The only effects produced by beta-FNA and nor-BNI were an increase in teeth chattering and wet dog shakes, respectively. Ptosis and squealing were significantly increased by naloxone compared to beta-FNA and nor-BNI. These data suggest teeth chattering and wet dog shakes in morphine dependent rats are mediated by nigral mu and kappa receptors, respectively, whereas squealing and ptosis are not mediated exclusively by these receptor subtypes.

382.14

Electrophysiological identification of Accumbens (NAS) neurons by evoked responses to multiple afferent stimulation explains variance of NAS opioid drug effects. R. L. Hakan* and S.J. Henriksen, *U. of North Carolina-Wilmington & Research Inst. of the Scripps Clinic, La Jolla, Ca. 92037

The effects of systemic morphine on fimbria-evoked NAS neuronal responses in anesthetized rats have been described as heterogeneous (Hakan & Henriksen, 1987; Neursci. Lett). As part of ongoing studies of the effects of opiate drugs on NAS neuronal activity we currently report that the effects of systemically administered opiates on ventral pallidum (VP)-evoked NAS neuronal activity are also heterogeneous. However, concurrent stimulation of VP and fimbria input to the NAS have shown patterns of convergence and nonconvergence that indicate several different categories of NAS neurons, and has consequently provided a means of functionally identifying distinct NAS neuronal subpopulations (Hakan & Henriksen, 1989). Further analysis of morphine effects in this light has indicated that, in contrast to earlier observations of heterogeneous opiate actions, for some NAS subpopulations morphine effects are largely uniform. For example, those NAS neurons that are monosynaptically driven by both fibria and VP stimulation are consistently inhibited by systemic morphine. Yet the effects of opiates on other NAS subpopulations are still apparently mixed. It is predicted that further functional categorization of these subpopulations by reponses to other afferent inputs will ultimately explain the remaining variance of opiate effects in this region.

382.15

BLOCKADE OF MORPHINE INDUCED STIMULATION OF MESOLIMBIC AND STRIATAL DOPAMINE RELEASE BY IBOGAINE. I.M.Maisonneuve, R.W.Keller, Jr. and S.D.Glick. Dept. Pharmacology & Toxicology, Albany Medical College, Albany, NY 12208.

Ibogaine, an indolalkylamine, has been claimed to abolish the drug craving of a few heroin and cocaine addicts for at least 6 months (patent No. 4,449,096) and, in preliminary studies in this laboratory, one to five doses of ibogaine (40 mg/kg) has decreased I.V. morphine self administration by rats for several days thereafter. Drugs of abuse belonging to different pharmacological classes have been shown to stimulate dopamine (DA) transmission in the mesolimbic system; this is believed to be the basis for the rewarding effects of those drugs. The present study used the microdialysis technique to determine the effects of a single dose of ibogaine on basal extracellular DA levels and also the effects of ibogaine pretreatment on morphine stimulation of brain DA systems. Ibogaine (40 mg/kg, IP) decreased DA extracellular levels in nucleus accumbens and striatum and increased DA levels in the prefrontal cortex. When injected 19 hr prior to a morphine challenge (5 mg/kg, IP), ibogaine (40 mg/kg, IP) prevented the rise in DA levels in the striatum and nucleus accumbens observed after morphine injection alone. These results are consistent with the proposed use of ibogaine in the treatment of opiate addiction. (Supported in part by NDA International, Inc. and NIDA grant DA03817).

382.16

MORPHINE ACTS IN THE PARABRACHIAL NUCLEUS TO PRODUCE DISCRIMINATIVE EFFECTS. T.V. Jaeger* and D. van der Kooy. Dept. of Anatomy, Univ. of Toronto, Toronto, Canada, M5S-1A8.

Previous experiments have shown that the motivational properties of morphine that support conditioned taste aversion and place preference are distinct from those which underlie its discriminative stimulus actions. However, the neural basis for this dissociation is not yet apparent. We attempted to identify the neuroanatomical sites that mediate the discriminative stimulus properties of morphine using a discriminated taste aversion paradigm. Rats were injected i.p. with 5 mg/kg of morphine 15 min prior to the presentation of a 0.1 % saccharin solution. After 20 min of exposure to the flavour, lithium chloride (130 mg/kg i.p.) was injected. On alternate days, an injection of 0.9% saline both preceded and followed the presentation of saccharin. Animals learned to consume significantly less saccharin after morphine than after saline injections. Guide cannulae were then implanted into brain areas containing relatively high densities of opiate binding sites, including the hippocampus, medial prefrontal cortex, ventral tegmental area (VTA), nucleus accumbens, dorsolateral striatum, ventromedial thalamus, parabrachial nucleus and the caudal aspects of the periaqueductal grey. Generalization to central routes of administration was then evaluated following the microinjection of morphine (5, 10 and 20 µg) into these brain areas. Dose-dependent stimulus effects like those of systemic morphine were produced in all rats by the administration of morphine into the parabrachial nucleus. Control data showed that these effects were not due to unconditioned effects of central morphine on fluid consumption. Morphine injected into the VTA, the nucleus accumbens and the ventromedial thalamus produced some morphine-appropriate responses in some of the animals tested. In the remaining brain areas, morphine generalized to the systemic saline condition. The data point to ascending visceral pathways (parabrachial nucleus and ventromedial thalamus) and possibly ascending dopamine projections (VTA and nucleus accumbens) as possible substrates for opiate discriminative effects. These putative discriminative substrates are distinct from the descending medial forebrain bundle pathways mediating the positive reinforcing effects of opiates.

382.17

INCREASED D1 AND D2 RECEPTOR ACTIVITY DURING OPIATE WITHDRAWAL: BEHAVIORAL AND BINDING EVIDENCE. J.W. Tidey and K.A. Miczek. Dept. of Psychology, Tufts University, Medford, MA 02155.

The motor and social-aggressive activity of mice is greatly affected by morphine withdrawal; converging evidence particularly implicates altered dopaminergic activity in these behavioral effects. Previously, we reported that the administration of d-amphetamine to morphine-withdrawn mice results in high levels of aggression which outlast motoric withdrawal signs. We have investigated this effect further by administering the selective D1 and D2 agonists SKF 38393 (1-100 mg/kg) and quinpirole (0.1-1 mg/kg) to mice which had undergone removal of s.c. morphine or placebo pellets at varying time points before evaluation of both motor activity and aggressive behavior toward an intruder. The D1 agonist SKF 38393 decreased aggressive behaviors in both morphine-withdrawn and placebo mice without affecting rearing, walking or grooming. The D2 agonist quinpirole maintained elevated levels of attack, threat, and motor behavior in morphine withdrawn mice while all of these behaviors were suppressed in placebo controls. A similar behavioral profile was seen in mice who were administered 3.0 mg/kg SKF 38393 before quinpirole injection. To determine whether these behavioral changes are due to upregulation of dopamine receptors during withdrawal, D1 and D2 binding of 3H-raclopride and 3H-SCH 23390 was measured *in vivo* in the striatum, olfactory tubercles and cerebellum of mice which had undergone morphine or placebo pellet removal 5, 48, or 96 hours previously. Morphine-withdrawn mice showed high levels of D1 and D2 receptor binding as compared to placebo controls; this increased D1 and D2 receptor occupancy during withdrawal may be relevant to the heightened aggressive behavior.

382.18

SOMATODENDRITIC RELEASE OF DOPAMINE IN THE VENTRAL TEGMENTAL AREA FOLLOWING MORPHINE. M.A. Klitenick and P.W. Kalivas. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

A number of recent studies have suggested a modulatory role for opioids and GABA in the mesolimbic A10 (VTA) dopaminergic system. Opioid injection into the VTA elicits an increase in dopamine (DA) metabolism and locomotor activity, the latter of which can be blocked by DA antagonists. Repeated administration of morphine results in a progressively augmented behavioral response in addition to a decrease in DA utilization within the VTA. GABA has also been shown to regulate DA transmission. Injection of a $GABA_A$ agonist into the VTA activates the mesolimbic DA system, while a $GABA_B$ agonist inhibits DA activity.

In order to further assess the suggested modulatory role of opioids and GABA on the mesolimbic DA system, in-vivo dialysis was used to measure DA and its metabolites in the VTA following administration of morphine (1 and 10 µM) or baclofen (1 and 10 µM) through the dialysis probe. Administration of baclofen through the probe had no effect on DA levels within the VTA; however, morphine was found to elicit a dose-dependent increase in the somatodendritic release of DA, DOPAC and HVA.

382.19

SELF-ADMINISTRATION OF MORPHINE, [D-ALA^2,N-ME-PHE^4-GLY^5-OL]-ENKEPHALIN (DAGO), AND [D-PEN^2,D-PEN^5]-ENKEPHALIN (DPDPE) INTO THE VENTRAL TEGMENTUM OF THE RAT. D. P. Devine and R. A. Wise. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montreal, Canada H3G 1M8.

Intracranial self-administration of opioid agonists which are selective for the µ and ∂ receptor subtypes was demonstrated in independent groups of male Long-Evans rats. Each animal was unilaterally implanted with a chronic guide cannula and was allowed to lever-press for ventral tegmental area (VTA) injections of one of three compounds: morphine (mixed agonist), DAGO (selective µ agonist), or DPDPE (selective ∂ agonist). Each compound was effective in establishing and maintaining a lever-pressing habit in animals with VTA cannulae. Animals with dorsal control cannulae did not learn to lever-press. These results raise the possibility that µ and ∂ receptors in the VTA are involved in the rewarding effects of opiates.

382.20

MORPHINE WITHDRAWAL SYNDROME AFTER LOCAL ADMINISTRATION OF METHYLNALOXONIUM IN SEVERAL BRAIN STRUCTURES. R. Maldonado*, L. Gold, L. Stinus and G.F.Koob. Dept. of Neuropharmacology, Research Institute of Scripps Clinic, La Jolla, CA 92037

Opiate withdrawal is a common occurrence in human opiate addicts that is not life threatening, but is thought to contribute to the maintenance of opiate dependence. Little is known about the neural substrates for the physical signs of opiate withdrawal, although recent work has implicated the region of the nucleus accumbens in the motivational aspects of opiate withdrawal. The purpose of this study was to establish a protocol of morphine withdrawal with minimal between subject variation in order clearly to investigate the neuroanatomical regions implicated in the expression of the physical signs of morphine withdrawal. Morphine withdrawal was precipitated by local administration of methylnaloxonium (MN), a hydrophilic opiate antagonist, into several brain regions in the rat. Cannulae were implanted into the lateral ventricle (ICV), periaqueductal gray (PAG), medial thalamus (MT) and nucleus accumbens (NAC). Following surgery, rats were made physically dependent by sc implantation of two 75 mg morphine pellets. MN (500 ng) was administered to rats with ICV cannulae 60 h after pellet implantation, and was repeated each 12 h until a total of 5 injections was made. MN administered ICV induced a withdrawal syndrome similar to systemic naloxone. Several signs as diarrhea, salivation, lacrimation and rinorrhea did not appear suggesting possible peripheral mediation.The withdrawal syndrome observed after the four last MN injections was similar, showing that it is possible to induce this syndrome several times in the same animals. When MN was injected, 72 h after pellet implantation, into the PAG (250 or 1000 ng) or into NAC (64 or 250 ng) it produced fewer withdrawal signs than when injected ICV (64-4000 ng). Rats injected with MN (64 or 250 ng) into the MT showed almost no signs of withdrawal. These preliminary results suggest that in contrast to the aversive stimulus effects of opiate withdrawal the neuroanatomical substrate for the physical withdrawal signs in the rat seems to depend on multiple brain structures.These results have important implications for our understanding of the basic brain mechanisms involved in opiate dependence, a condition which causes widespread profound human suffering. These studies were performed under protocol ARC 44FEB0 approved by the Institutional Animal Care Committee of the Research Institute of the Scripps Clinic.

383.1

CHF-146 STRAIN DYSTROPHIC HAMSTERS (DH) AS A MODEL FOR MUSCULAR DYSTROPHY WITH CARDIAC HYPERTROPHY. P. L. Johnson, C. I. Tillilie*, T. A. Adamec*, D. R. Shanklin*, and S. K. Bhattacharya. Depts. of Surgery, Anatomy & Neurobiology, and Pathology, University of Tennessee, Memphis, TN 38163.

Membrane-mediated excessive intracellular Ca accumulation (EICA) is a fundamental pathogenetic event in muscular dystrophy (Bhattacharya & Johnson, Neurology India, 37:145, 1989). Concommitant to EICA, elevated plasma CK, histopathology, cardiac dysfunction, and reduced lifespan are common in Duchenne muscular dystrophy (DMD). We have shown striking similarities in pathobiology between DMD and BIO-14.6 strain DH (Muscle & Nerve, 10:168, 1987). Since BIO-14.6 DH are no longer available, we investigated CHF-146 strain male DH from Canadian Hybrid Farms, Nova Scotia, as a model for DMD. CHF-148 strain albino normal hamsters (NH) served as controls. EICA, measured by atomic absorption spectroscopy, was profound in the cardiac and skeletal muscle of DH. Plasma CK and relative cardiac enlargement were also elevated. Among the most noticeable histologic changes in DH were the abundance of atrophic, hypertrophic, and necrotic fibers with fatty infiltration, centronucleation, fascicular disarray, and fibrosis. EM of myocardium revealed mitochondrial Ca deposition and loss of striations. Increased mortality in DH ensues at 90 days of age with average life expectancy of 250 days, compared to 3 years for NH. We conclude that CHF-146 strain DH is an excellent model for therapeutic scanning in DMD. Supported by MDA and NIH Grant AR-38540.

EVOLUTION OF TREMOR IN A NEUROLOGICAL MUTANT OF SPRAGUE-DAWLEY RATS. Doger E., Vega J*, Holmgren B.* and Vega-Saenz de Miera E.* Dept. de Ciencias Fisiológicas ICUAP, Univ. Autónoma de Puebla. P. O. Box 406, Puebla, México.

In the rat colony of our laboratory, a neurological mutation appeared, characterized by tremor, ataxia, tonic immobility episodes and paralysis. The initial neurological sign is a fine tremor in the tail and hindlimbs which is visible at 1 month age. this syndrome is transmitted by autosomal recessive inheritance.

Tremor frequency was recorded in rats from 15 days to 12 months old, using power spectral analysis following a procedure described by Shinozaki (Neurosc. Res. 2:63-76, 1984). One month old rats exhibited tremor at an average frequency of 7 ± 0.3 Hz; at the age of 2 months and until 12 months the main peak frequency is at 5.9 ± 0.4 Hz. Tremor is attenuated by the administration of the dopaminergic agonist apomorphine (APO) (0.01-0.1 mg/Kg), effect which is not observed with higher doses of APO (0.5-1) nor with the dopaminergic antagonist sulpiride (30-100 mg/Kg). The underlying mechanisms of this hereditary neurological syndrome is under current study by our group.

CONTRIBUTIONS OF GENOTYPE TO CEREBELLAR MORPHOLOGY: DIFFERENCES IN PRIMARY FISSURE DISTORTION IN INBRED STRAINS OF RATS . G.R. Ward, C.R. Goodlett, J.M. Nichols,* and J.R. West. Dept. of Anatomy, University of Iowa, Iowa City, IA 52242.

Aberrant development of the primary cerebellar fissure in rats, including fusion in the depths of the fissure and the presence of ectopic neurons, has been reported in a number of studies of outbred rats. Substantial variation in the frequency and extent of such distortion has been found both within and between outbred strains. In this study, we examined the primary fissure of eight inbred rat strains--ACI, Brown Norway [BN], Buffalo [BUFF], Fisher 344 [F344], Maudsley Reactive [MR], Marshall [M520], White Norway [WN] and Wistar-Kyoto [WKY]. All subjects were derived from a breeding colony maintained in our laboratory, originally established using breeding pairs obtained from NIH. Sagittal sections, either 30-µm frozen sections or 2-µm JB-4 sections, were taken through the cerebellum, stained with a Nissl stain, and examined microscopically. Several strains [BN, F344, MR] exhibited severe distortions of the primary fissure within the vermis, with extensive fusion of the fissure and numerous ectopic cell clusters. Others [ACI, M520, BUFF] had mild to moderate distortion, usually limited to partial fusion of the primary fissure, with only occasional ectopias. Little or no distortion of the primary fissure was seen in the remaining two strains [WN, WKY]. Regardless of strain, these perturbations were generally more pronounced in the 10-day-old subjects than in adults. A number of other differences were found in cerebellar structure, ranging from ectopic cells in lobule IX [M520] to dramatically increased gyrification [BN]. Although variation in the extent of distortion was observed within strains, the marked individual differences in severity were predominantly accounted for by differences among strains. These findings demonstrate differences among inbred strains in the morphological development of the cerebellum, and suggest that studies of inbred rats may provide a useful model to evaluate the contribution of genotype to aberrant development of cerebellar fissures and lobules. TESTS OF GENETIC ALLELISM BETWEEN FOUR INBRED MOUSE STRAINS WITH ABSENT CORPUS CALLOSUM. D.J. Livy and D. Wahlsten, Department of Psychology, University of Waterloo, Ontario, N2L 3G1 and Department of Psychology, University of Alberta, Edmonton, Alberta, T6G 2E9 (Canada).

If two inbred strains show absence of the corpus callosum (CC) because they have the same genetic defect, then a hybrid cross between them should also have CC absence. If the hybrid is normal, the parent strains must differ at one or more relevant genetic loci. Over 450 weanling mice were obtained from five inbred strains and 11 hybrid crosses, and their brains were sectioned sagittally and stained for myelin. All crosses with the normal strain C57BL/6J were normal, demonstrating recessive inheritance. When the I/LnJ strain (100% total CC absence) was crossed with less severely affected strains (BALB/cWah1, BALB/cWah2, 129/ReJ), hybrid mice with a BALB/c parent showed numerous CC defects, whereas those with a 129 parent had less severe defects than 129. Crossing either BALB/c strain with 129 yielded offspring with no or very few CC defects. Crossing the two BALB/c strains produced mice resembling BALB/cWah2. It is concluded that the strains BALB/cWah1, BALB/cWah2 and I/LnJ have essentially the same genetic abnormality, differing only in severity of the defective alleles, but that 129/ReJ differs from these three strains, most likely at a single locus.

THE TWITCHER MOUSE: IN VITRO STUDIES OF SCHWANN CELLS (SC) ON ADHESIVENESS AND RATE OF PROLIFERATION. A. Komiyama* and K. Suzuki. Department of Pathology, School of Med. Univ. of North Carolina, Chapel Hill, NC 27514.

A previous study of isolated SC from twitcher revealed apparent differences in the rate of cell growth between suckling and adult mice (Irino and Suzuki, 1990). To elucidate the cause of such differences, we examined adhesiveness and rate of proliferation of SC in vitro. SC were isolated from sciatic nerves and brachial plexus of three genotypes (twi/twi, twi/+, +/+) at P10 (group 1) or P30 (group 2) and were cultured (3×10^4 cells/12mm coverslip). Cell numbers were counted and [^{3}H] thymidine-uptake of the SC were determined at 1, 2, 4, 6, and 8 days in vitro (DIV). SC adhesiveness at 1DIV in group 1 was similar in all genotypes and was significantly higher than that from twi/+ and +/+ in group 2. In contrast, SC adhesiveness in twi/twi in group 2 was higher than any genotype in group 1. Thymidine incorporation was generally higher in group 1 than group 2. However, labelling index in twi/twi was less than twi/+ or +/+ in both groups. In twi/twi in group 2, SC adhesiveness was most pronounced but thymidine incorporation remained low. The results indicate that 1) hypofunction or dysfunction exists in twi/twi SC and is more prominent in the adult; and 2) the apparently accelerated cellular proliferation in adult twi/twi is a result of increased adhesiveness of the SC secondary to demyelination in adult twi/twi nerves.

CHANGES OF NEUROPEPTIDES IN SPINAL CORD AND BRAINSTEM OF WOBBLE MOUSE AT DIFFERENT STAGES OF MOTONEURON DISEASE. K.K.L.Yung*, F.Tang*[1], L.L.Vacca-Galloway. Depts. of Anatomy and Physiology[1], Fac. of Med., Univ.of Hong Hong, Hong Kong.

As a model for study of human motoneuron disease, the autosomal recessive mutant Wobbler mouse (wr) exhibits a progressive loss of motoneurons in spinal cord and brainstem. In early stages of the disease, axons containing substance P (SP) and thyrotropin releasing hormone (TRH) but not leucine enkephalin (LE) appeared increased by immunocytochemistry around cervical motoneurons (Vacca-Galloway, L.L.and Steinberger,C., J. Neurosci. Res., 16:657-670,1986). Recent radioimmunoassay (RIA) studies have shown that TRH, LE and methionine enkephalin (ME) contents increased in the spinal cord at different stages of the wr disease (Tang, F. *et al*, Brain Res., in press, 1990).

In the present study stages of the motoneuron disease were evaluated in NFR/wr mice (NIH, Besthesda, Md.), 3 weeks to 11 months old, identified by behaviorial tests (Lange, D.J. *et al*, J. Neurol. Sci., 61:211-216, 1983). The wr mice (Stages 1 to 4) and their control littermates (Stage 0) were decapitated, the cervical spinal cord, brainstem, also hypothalamus and midbrain were collected, and the TRH, SP, LE and ME contents were compared by RIA.

In experiments wherein all control values were pooled, TRH in wr spinal cord was increased significantly in Stages 1 and 2, SP increased in Stages 1 and 4, and LE increased throughout Stages 1 to 4. When control littermates were statistically pair-matched with wr littermates, SP contents at Stage 1 showed no increase in spinal cord. ME contents increased in Stages 1 and 2 but not 3 and 4 when control values were pooled, but showed opposite results when control and wr values were pair-matched. In wr brainstem TRH increased significantly in Stages 2 and 3, however SP showed no increase. ME and LE became increased in Stages 3 and 4. Trends observed for these peptides in spinal cord and brainstem may relate to disease development.

ABERRANT DEVELOPMENTAL REGULATION OF TYROSINE HYDROXYLASE EXPRESSION IN TOTTERING AND LEANER MOUSE MUTANTS. E.J. Hess and M.C. Wilson, Dept. of Neuropharmacology, Research Institute of Scripps Clinic, La Jolla, CA 92037.

The inherited autosomal recessive mutations, tottering (gene symbol: *tg*) and leaner (gene symbol: tg^{la}) are functional alleles of a single gene locus in mice. The tottering mouse mutant exhibits spontaneous absense seizures, focal motor seizures and mild hindlimb ataxia while the congenic mouse mutant leaner displays severe ataxia and no focal motor seizures. We have previously reported ectopic expression of tyrosine hydroxylase (TH) in the cerebellar Purkinje cells of the adult mouse mutants tottering and leaner (Soc. Neurosci. Abstr. 15:986, 1989). In order to assess the onset of ectopic TH expression, TH mRNA expression was examined by in situ hybridization in postnatal day 1 (P1) through P28 tottering and leaner mouse mutants and age-matched heterozygous littermates. Hybridization of the ^{35}S-cRNA TH probe was detected in the locus coeruleus and substantia nigra in all mice from P1 through adulthood. TH expression in the Purkinje cells of tottering and leaner mice was first observed at P18 and persisted through adulthood. On P18, TH expression was also observed in the Purkinje cells of the heterozygous control mice and in wild type C57Bl/6J mice; the TH expression in Purkinje cells of control mice persisted through P28 and was absent in adult mice. These data indicate that TH is normally transiently expressed in Purkinje cells during postnatal development, similar to transient developmental TH expression observed in other brain regions, such as the inferior colliculus. Moreover, these data suggest that tottering and leaner mouse mutants are deficient in the signal which supresses TH expression in adult Purkinje cells. The identification of such a deficiency may aid in cloning and characterizing the tg gene. Supported by PHS CA33730, NS23038 and an American Epilepsy Society Research Fellowship.

MEANDER TAIL: GENETIC AND HISTOLOGICAL ANALYSIS OF A MOUSE MUTATION WHICH MAY DEFINE A DEVELOPMENTAL COMPARTMENT IN THE MAMMALIAN CEREBELLUM. Colin Fletcher*, Elizabeth Ross, Carol Mason, Mary Beth Hatten, and Nathaniel Heintz. Rockefeller University and Columbia University College of Physicians and Surgeons, NY, NY, 10021.

As part of a comprehensive program to identify the genes responsible for several aberrant neurological phenotypes in the mouse, we have adopted a molecular genetic approach to clone the gene product mutated in the meander tail mouse. Meander tail (*mea*) is a recessive mutation mapping to mouse chromosome 4, whose phenotype is characterized by both neurological and skeletal abnormalities. Thus, the adult *mea/mea* mouse displays normal foliation and cytoarchitecture in the posterior lobes of the cerebellar cortex. However, starting with an abrupt transition, Purkinje cells are completely disorganized in the anterior lobe: their dendrites extend in all directions, including into the white matter. Granule cells are sharply reduced in number at this transition and rapidly become indiscernible. Additionally, glial cell processes extend in all directions.

The *mea* locus has been fine mapped on chromosome 4 by analysis of several hundred progeny of an interspecific backcross to *Mus castaneus*. Closely linked markers are being used to isolate mouse YAC clones for the purpose of walking toward the locus.

The striking transition from normal to grossly disrupted cytoarchitecture involving at least three cell types in the *mea/mea* cerebellum suggests the presence of a discrete developmental compartment in the anterior cerebellum.

RESTING AND EVOKED RELEASE OF ENDOGENOUS DOPAMINE IN STRIATAL SLICES FROM THE WEAVER MUTANT MOUSE. Yu, H., Simon, J.R., Richter, J.A., Vasko, M.R. and Ghetti, B. Indiana Univ. Sch. of Medicine, Indianapolis, IN. 46202

Previous studies revealed that the weaver (wv) mutant mouse has a defect in the nigrostriatal dopaminergic pathway. The objective of this study was to determine if mice homozygous for the wv gene (wv/wv) exhibit an enhanced capacity to release striatal dopamine (DA) in order to compensate for the DA deficiency.

Striatal slices obtained from 3 month old wild type (+/+) and wv/wv mice were superfused and the release of endogenous DA was assayed by HPLC. Resting release of DA (expressed as a fraction of the tissue content) was significantly greater from wv/wv than from +/+ striatum (0.48%/min vs 0.24%/min). Fractional DA release evoked by 1 uM amphetamine was also significantly higher in the wv/wv (0.55%/min vs 0.29%/min), but there were no significant differences between +/+ and wv/wv in the fractional release evoked by either 24 mM or 48 mM potassium. These data suggest that under resting conditions, as well as during amphetamine stimulation, release mechanisms in the wv/wv striatum may adapt in an attempt to compensate functionally for the dopaminergic deficit. (Supported by RO1 NS 14426).

UPTAKE OF DOPAMINE, CHOLINE AND GABA IN THE STRIATUM OF WEAVER MUTANT MICE: TOPOGRAPHICAL DISTRIBUTION. J.R. Simon, A.B. Dunnington*, H. Yu and B. Ghetti. Indiana Univ. Sch. of Medicine, Indianapolis, IN. 46202.

The objective of the present study was to determine the topographical distribution of dopamine (DA), choline and GABA uptake in the striatum of control (+/+) and weaver (wv/wv) mice. Uptake of [3H]-DA, [3H]-choline and [14C]-GABA was determined in sucrose homogenates prepared from the dorsolateral (DL), dorsomedial (DM), ventrolateral (VL) and ventromedial (VM) portions of the striatum from +/+ and wv/wv mice. In 45-60 day old control mice, DA uptake was homogeneously distributed throughout the striatum. This distribution was altered in the wv/wv with the ventral aspects being less severely affected than the dorsal portions, though all areas exhibited significantly reduced uptake rates. In 9 and 12 month old mice choline uptake was higher in lateral than in medial aspects of the striatum of both genotypes with no differences being observed between genotypes. GABA uptake was evenly distributed in both genotypes, and again no differences were observed between +/+ and wv/wv mice. The present observations indicate that the entire weaver striatum is severely deficient in its ability to recapture DA and thus is functionally compromised. The results also indicate that striatal cholinergic and GABAergic interneurons are not directly or indirectly affected by the weaver gene. (Supported by RO1 NS 14426).

GENETIC PERTURBATION OF DENDRITE FORMATION. S. Roffler-Tarlov, A.M. Graybiel and B. Martin . Program in Neurosciences, Tufts Univ. Sch. Med., Boston, Ma 02111 & Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Weaver is an autosomal recessive mutation in mice that results in cell death among the dopamine-containing mesencephalic neurons and in cerebellum early in postnatal development. Previous observations made both of cerebellar granule cells and the dopamine-containing cells suggest that the gene affects neurite development. This hypothesis is supported also by the present comparison of tyrosine hydroxylase (TH)--stained cells in the midbrains of 7-day old mice of three genetic types: homozygous normal, heterozygous weaver and homozygous weaver. The examination was made before the onset of most of the cell death that takes place in the mesencephalon of the homozygous weaver. We saw a dramatic lack of TH-positive dendrites in homozygous weavers in areas of pars reticulata adjacent to densely packed TH-positive cell bodies. The weaver's midbrain contrasted markedly with that of the homozygous normal mice in which TH-positive dendrites formed a curtain of thickly aligned processes in the pars reticulata. In the heterozygous weaver in which dopamine-containing cells do not die, the pars reticulata was nevertheless only sparsely filled with dendrites.

The results show that the gene's effects on dendrites precede the death of vulnerable cells and that a single dose of the gene affects dendrite formation without causing cell death. Supported by NS20181 and MH00655.

TWO GENES FOR TEMPORAL LOBE EPILEPSY MAPPED IN THE MOUSE. M.L. Rise*, W.N. Frankel*, J.M. Coffin*, and T. N. Seyfried. Dept. of Biology, Boston College, Chestnut Hill, MA 02167, and Dept. of Molecular Biology, Tufts Univ. School of Medicine, Boston, MA 02111.

El is a neurological mutant strain of mice which is considered a model for complex partial seizures in humans (Seyfried and Glaser, Epilepsia 26: 143, 1985). Two Fl hybrid populations were generated from the following reciprocal crosses: El x ABP/Le and El x DBA/2J (D2). All of the Fl progeny from both crosses were seizure susceptible, substantiating previous evidence that El is inherited as a dominant trait. Beginning at 30 days of age, the mice were tested by vestibular stimulation twice a week for 10 weeks. The frequency of seizures per 20 tests was used to assess seizure susceptibility. The Fl mice were backcrossed (BC) to their respective non-El parental types. The offspring of both BCs were divided into Fl-like (seizure-susceptible) and D2- or ABP/Le-like (seizure-resistant) groups. Coinheritance of El with 6 conventional genetic markers and 46 endogenous proviruses was studied. El mice are wild-type at the se and d loci and express high ßgl activity, whereas D2 mice are d/d and ABP/Le mice are se/se, with both strains expressing low ßgl activity. A significant association was found between El and the chromosome 9 markers se and d, (which are tightly linked), and ßgl. The apparent recombination frequency between El and the d, se loci was 32%, and that between El and ßgl was 27%. Also, a significant negative association was found between El and two tightly linked chromosome 4 markers: b and an endogenous provirus. These findings indicate that El seizures result in large part from the actions of a major gene on distal chromosome 9, and a minor gene tightly linked to the b locus on chromosome 4. (Supported by NIH grant NS23355).

384.1

THE RELATIONSHIP OF INFARCT SIZE TO BLOOD PRESSURE AND TIME OF OCCLUSION DURING (PHOTOCHEMICALLY INDUCED) THROMBOTIC STROKE-IN-EVOLUTION. BD Watson, H Kanemitsu, R Prado, WD Dietrich, MD Ginsberg, Neurology, University of Miami, Miami, FL USA

The middle cerebral artery of halothane-anesthetized mature male Sprague-Dawley rats was exposed and irradiated with three independently positionable 457.9 nm laser beams. In order to lower the power threshold for thrombus formation and enhance lysis by t-PA, bixin (a singlet oxygen quencher) was injected with flavin mononucleotide (FMN) at 13.4-66 uM and 1.34-2.00 mM respectively. With two beams positioned distal to the rhinal branch and the other just below it, infarct area (A) at epicenter was proportional to the time of occlusion (t) in the blood pressure range of 90-110 mmHg for beams focussed sharply across the arterial diameter ($0<A<6.83$ mmHg^2, 40 min$<t<4$ hr, $n = 7$, $r = 0.96$). Diffuse beam focussing enhanced clot stability ($1.37<A<7.86$ mm^2, 3 hr$<t<4$ hr, $n = 5$, $r = 0.48$). At higher pressures (115 to 130 mmHg and diffuse focussing, A and t were not correlated. These results indicate that infarct susceptibility in thrombotic stroke is fundamentally conditioned by arterial blood pressure and collateralization. The rheological and histopathological characteristics of this minimally invasive and recanalizable (by endogenous or exogenous t-PA) model of arterial thrombotic stroke should provide insights into human clinical stroke.

384.2

ISCHEMIA INDUCES RELEASE OF GLUTAMATE IN REGIONS WHICH ARE SPARED FROM HISTOPATHOLOGICAL DAMAGE. M.Y.-T. Globus, R. Busto, E. Martinez*, I. Valdés*, and W.D. Dietrich. Cerebral Vascular Disease Research Center, University of Miami, School of Medicine, Miami, FL, 33101.

Excessive release of glutamate is thought to play a major role in the susceptibility of neurons to ischemia. In the present study we evaluated whether regional differences in the magnitude of glutamate release could explain selective vulnerability. Ischemia-induced changes in extracellular levels of glutamate in a region selectively vulnerable to 10 min of transient ischemia (CA1 sector of the hippocampus) were compared to the changes occurring in regions which, although rendered ischemic, are usually unaffected by a 10-min insult (thalamus, cortex and striatum). The degree of ischemia and the final histopathological outcome were also evaluated in these regions. Blood flow reduction and energy depletion were severe and uniform in all regions. The histopathological outcome illustrated a severely damaged CA1 sector of the hippocampus while all other brain regions were unaffected. Extracellular glutamate levels, measured by microdialysis, were significantly elevated during ischemia in all four regions. Glutamate levels continued to increase during the early recirculation period and gradually returned to baseline by 30 min of reperfusion, with similar temporal changes in all regions. These results demonstrate that elevated intra-ischemic glutamate levels of themselves are insufficient to engender ischemic damage, and other factors may play a pivotal part in the detrimental role of glutamate during ischemia *in vivo*.

384.3

POSTISCHEMIC (S)-EMOPAMIL THERAPY AMELIORATES FOCAL ISCHEMIC INJURY. E. Morikawa*, M.D. Ginsberg, W.D. Dietrich, and R. Busto. Cerebral Vascular Disease Research Center, Univ. of Miami, FL 33101.

In a previous study, (S)-emopamil (E), a calcium-channel blocker and serotonin S_2 antagonist, reduced cortical infarct volume in rat middle cerebral artery occlusion (MCA-O) (Nakayama et al, Neurology 38:1667, 1988). In this study, we explored the temporal window of therapeutic efficacy. Fifty-four fed male Sprague-Dawley rats underwent permanent proximal right MCA-O plus 30 min halothane-iduced hypotension to 50 mm Hg (Osborne et al, JNNP 50:402, 1987). There were 4 E-treatment groups: Group 1 (n = 9) received E 20-30 min prior to MCA-O; Groups 2 (n = 13), 3 (n = 12), and 4 (n = 8) received E 1, 2 and 3 hours, respectively, following MCA-O. Group 5 (n = 12) consisted of vehicle-injected controls. The initial E dose was 20 mg/kg IP with a 2nd dose 2.5 h later and twice daily x 2 days. Three days after MCA-O, brains were prepared for histologic quantitation of infarct area at 8 standard coronal levels; numeric integration yielded infarct volume. Cortical infarct volume in Groups 1-5, respectively, were (in mm^3, mean $\pm$ S.D.): Group 1, 84.5 $\pm$ 26.4; Group 2, 37.6 $\pm$ 27.6; Group 3, 47.8 $\pm$ 34.1; Group 4, 76.0 $\pm$ 26.9; Group 5, 72.9 $\pm$ 33.3. Striatal infarct volume was not affected. These data confirm a significant reduction of infarct volume with 1-h post-treatment and a trend at 2-h, suggesting a temporal window of efficacy.

384.4

MORPHOLOGICAL AND NEUROCHEMICAL SEQUELAE OF GLOBAL ISCHEMIA: COMPARISON OF SINGLE- AND MULTIPLE-INSULT PARADIGMS. B. Lin*, W.D. Dietrich, M.Y.-T. Globus, R. Busto, E. Martinez, S. Kraydieh and M.D. Ginsberg. Cerebral Vasc. Dis. Research Center, Miami, FL 33101.

To compare the consequences of global ischemia due to multiple vs. single insults, we subjected Wistar rats to either A) a single 15-min high-grade forebrain ischemic insult (n = 7), or B) three 5-min insults separated by one-hour intervals (n = 7). Ischemia was produced by bilateral carotid artery occlusion plus moderate hypotension (50 mm Hg) in rats whose cranial and rectal temperatures were separately thermostated at 36 and 37°C, respectively. Three days later, ischemic cell change (ICC) was quantitated. In hippocampus, caudoputamen, and cerebral neocortex, ICC was equally severe in Groups A and B. The ventrolateral thalamus, in contrast, showed moderate-to-severe ischemic injury in all rats of the multiple-insult group (B) but in only 1 of 7 rats in the single-insult group (A); numbers of ischemic neurons per high-power field were 4.7 $\pm$ 3.2 (mean $\pm$ S.E.) in Group A, and 30.8 $\pm$ 4.0 in Group B ($p < 0.01$). Preliminary intracerebral microdialysis data revealed 1) a delayed massive increase in extracellular striatal glutamate levels associated with 2) diminished extracellular glutamine 5-6 hours following the third multiple insult -- findings not observed in the single-insult group These results indicate cumulative effects of repeated normothermic insults.

Supported by Grants NS22603, NS05820, and NS26784.

384.5

EFFECT OF ISCHEMIA AND REPERFUSION IN VIVO ON ENERGY METABOLISM OF RAT SCIATIC-TIBIAL AND CAUDAL NERVES. P.J. Zollman*, O. Awad*, J.D. Schmelzer*, and P.A. Low. Neurophysiology Lab., Dept. Neurol., Mayo Fdn., Rochester, MN 55905

Our model of severe nerve ischemia consistently results in extinction of the compound nerve and muscle action potential (NAP; CMAP) within 30 minutes. Since impulse transmission may depend on nerve energy metabolism (NEM), we studied the effects of ischemia with reperfusion on NEM in vivo, in vitro and postmortem. Ischemia for 30 minutes postmortem or in deoxygenated Ringer's solution resulted in marked depletion of adenosine triphosphate (ATP), glucose (GLU) and creatine phosphate (CP) and an increase in lactate (LAC) of sciatic-tibial nerve of adult male Sprague-Dawley rats. In vivo ischemia for up to 3 hours in sciatic-tibial nerve was sufficient to extinguish CMAP but did not deplete ATP, CP, or GLU and did not increase LAC. Ischemia sufficient to extinguish NAP (caudal nerve) resulted in reduction of energy substrates to about 50% of resting. Muscle fails to conduct impulses before nerve and in vivo reductions of energy substrates are milder than in vitro changes.

384.6

EFFECT OF ISCHEMIA AND REPERFUSION ON OXYGEN FREE RADICALS IN RAT SCIATIC-TIBIAL NERVES. K.K. Ward*, J.D. Schmelzer*, N. Parinandi*, E. E. Benarroch, and P.A. Low. Neurophysiology Laboratory, Department of Neurology, Mayo Foundation, Rochester, MN 55905

Our model of severe nerve ischemia consistently results in extinction of the nerve impulse, reduced reflow and reperfusion injury to blood-nerve barrier. We therefore examined if oxygen free radicals (OFR) were generated during ischemia and reperfusion. Conjugated dienes (CD), hydroperoxides (OOH) and malondialdehyde (MDA) were measured in rat sciatic nerve. The endoneurial:epineurial ratios for CD, OOH and MDA were 3.46, 0.16 and 0.93 respectively, indicating that CD was mainly in endoneurium, OOH mainly in epineurium and MDA evenly distributed. In vitro deoxygenation resulted in no significant generation in OFR. Reoxygenation resulted in near doubling of MDA without changes in CD or OOH. Ischemia results in a reduction in OOH with a near 3-fold increase above the ischemic value on reperfusion. Smaller changes were seen with CD and MDA. These findings suggest that OFR is generated during reperfusion rather than during ischemia.

384.7

CEREBRAL ISCHEMIA AND REPERFUSION CAUSE BIPHASIC CHANGES IN EXTRACELLULAR DOPAMINE LEVELS IN THE STRIATUM. C.D. BLAHA, E.R. WOOD AND A.G. PHILLIPS. Dept. of Psychology, University of British Columbia, Vancouver, B.C., Canada.

Extracellular striatal dopamine concentrations were measured using 60s repetitive chronoamperometry in urethane anesthetised rats before, during and after transient forebrain ischemia. Stearate-modified carbon paste electrodes were implanted bilaterally into the striatum, and baseline extracellular dopamine was monitored for at least one hour. Ischemia was induced for 20 minutes by bilateral carotid occlusion combined with hemorrhagic hypotension to 30 mmHg. After this period, the carotids were unclamped and the shed blood reinfused over about 10 minutes. Extracellular dopamine levels followed a characteristic biphasic pattern: within three minutes of carotid clamping there was a 15-20 fold rise, followed by a gradual steady increase during the 20 minutes of occlusion. When the arterial clamps were removed there was an immediate decrease in the chronoamperometric signal. This was followed a few minutes later by a second 25-30 fold increase. The second rise in extracellular dopamine lasted for approximately 40 minutes, after which the concentration dropped gradually to a stable, elevated level with respect to the initial preischemic baseline. We suggest that the initial rise in extracellular dopamine is due to ischemic depolarisation of the neuronal membrane, whereas the second, larger increase is a result of reperfusion. Either of these increases in extracellular dopamine may be involved in striatal neuron death following cerebral ischemia.

384.8

EFFECTS OF DICHLORACETATE (DCA) ON LACTATE UPTAKE AND PYRUVATE DEHYDROGENASE ACTIVITY IN CULTURED ASTROCYTES. J.L. Tomsig[1], E. Gruenstein[2] and R.V.W. Dimlich[1,3]. Departments of [1]Emergency Medicine, [2]Molecular Genetics, Biochemistry and Microbiology and [3]Anatomy and Cell Biology. University of Cincinnati, Cincinnati, OH 45267.

Elevated brain lactate is an important contributor to the development of post-ischemic cerebral edema due to astrocytic swelling. DCA has been shown to reduce brain lactate in experimental cerebral ischemia in rats. Therefore we have investigated the effects of DCA on a human astrocytoma cell line, UC-11MG (Lomneth et. al., Brain Res.,486:95, 1989). Two hypotheses were tested: 1) DCA alleviates astrocytic swelling by increasing the rate of lactate metabolism via the stimulation of pyruvate dehydrogenase (PDHC) (E.C. 1.2.4.1) and 2) DCA decreases cell swelling by inhibiting the uptake of lactate into cells. We have found that exposure of cultured cells to 5 mM DCA for 30 min stimulates PDHC activity by 83%. We have also found that DCA acts as a competitive inhibitor of lactate uptake (Ki=1.7 mM at pH 6). Furthermore, cell swelling induced by exposure to 20 mM lactate at pH 6 for 30 min was blocked by 5mM DCA. These results are consistent with DCA acting to reduce ischemic injury by either or both of the proposed mechanisms. Supported in part by grants NIH BRSG SO7 RR 05408-28 and NS 25635 (RVWD), and NS 21663 and NS 27814 (EG).

GENDER-RELATED DIFFERENCES AND GLIAL CHANGES IN A RAT MODEL OF TRANSIENT FOREBRAIN ISCHEMIA. W.R.Woodward, H.Downes*, N.Lessov*, T.Williams* and C.K.Meshul. Depts. of Neurology, Biochemistry and Pharmacology, Oregon Health Sci. Univ. and VA Med. Ctr., Portland, OR 97201.

Transient forebrain ischemia (15 min) was produced in anesthetized ♂ and ♀ rats by bilateral carotid clamping coupled with reduction of blood pressure to 25 torr by rapid removal of blood. During ischemia the EEG became isoelectric, but recovered to normal levels once the carotids were unclamped and the blood reinfused. Animals were sacrificed at 7 d post-ischemia. In the post-ischemic period ♂ rats were slower to recover from the acute procedure than ♀ rats and lost rather than gained weight. In ♂ rats 57±3% of hippocampal circumference from CA1 through CA3 suffered severe neuronal damage (>75% loss) compared to 42±3% for ♀ rats. In both sexes neuron losses in CA1 were severe (≈85%) and less pronounced in CA3 (≈35%). Glia proliferated in CA1 (≈10-fold) and in CA3 (≈3-fold): rod-shaped microglia were prominent in stratum radiatum, and astrocytes and oligodendroglia increased in strata pyramidale and oriens. Gliosis occurred in animals even when there was little or no neuronal loss. We conclude that ♂ rats are more vulnerable to ischemia than ♀ rats and that glial proliferation can occur in areas where only relatively mild neuronal losses are observed. Supported by NIH grant NS17493 and the Veterans Administration.

ARE SODIUM CHANNELS OR SODIUM-CALCIUM EXCHANGE INVOLVED IN MEDIATING ANOXIC INJURY IN MAMMALIAN CENTRAL WHITE MATTER? P.K.Stys, B.R.Ransom, S.G.Waxman. Dept. of Neurology, Yale Univ., New Haven, CT 06510 and Neuroscience Research Center, VA Hospital, West Haven, CT.

White matter (WM) in the mammalian CNS suffers irreversible injury when exposed to extended periods (>30 min) of anoxia. Clinically, strokes involving WM can result in severe neurological disability. In spite of these facts, relatively little is known about the basic pathophysiology of WM anoxia. Using the isolated rat optic nerve (RON) as a model of central WM anoxia, we demonstrated the critical role played by extracellular Ca^{2+} (Stys, P.K. et al., Proc Natl Acad Sci USA, 1990 in press) and suggested that irreversible anoxic injury in WM depends on Ca^{2+} influx into a cytoplasmic compartment. We subsequently investigated how Ca^{2+} might enter cells during anoxia. Adult RONs were exposed to a standard 60 min period of anoxia. Functional recovery was assessed 1hr after re-oxygenation by measuring the area under the compound action potential. Blockade of voltage-dependent Na^+ channels with 1μM TTX significantly improved recovery (81.5±11.1% vs 38.3±10.6%, P<0.00001). This suggested that part of the damaging inward Ca^{2+} flux might occur through these channels. Alternatively, degradation of the transmembrane Na^+ gradient by channel-mediated Na^+ influx might cause reverse operation of the Na^+-Ca^{2+} exchanger, resulting in increased $[Ca^{2+}]_i$. This hypothesis was tested by blocking the exchanger with bepridil (10-100μM), a mechanism-based inhibitor of Na^+-Ca^{2+} exchange; this resulted in significantly enhanced recovery (59.5±13.4 % vs 38.3±10.6%, P<0.005). Inhibition of voltage-gated Ca^{2+} channels by bepridil is unlikely since dihydropyridines did not improve recovery (Stys, P.K. et al., Neurosci Lett, 1990 in press). Combined treatment with bepridil and TTX did not improve recovery (73.6±9.8%) over that seen with TTX alone. These results suggest that transmembrane Ca^{2+} influx during anoxia occurs, at least in part, as a result of reverse operation of the Na^+-Ca^{2+} exchanger. Thus TTX protects WM by slowing the rise in $[Na]_i$, which in turn affects the Na^+-Ca^{2+} exchanger; TTX may also block direct Ca^{2+} influx via Na^+ channels imperfectly selective for this ion.

TEMPORAL CHANGES DURING CEREBRAL EDEMA IN LACTATE AND PH MEASURED IN VIVO BY $^1H/^{31}P$-NMR. **S. Mun-Bryce, G. Rosenberg. Neurology Service, Veterans Medical Center, and the Dept. of Neurology and Physiology, Univ. of N.M., Albuquerque, NM 87131.**

Changes in brain metabolism during the development of brain edema were examined using in vivo ^1H- and ^{31}P-NMR with surface coils and depth pulses. We produced a collagenase-induced intracerebral hemorrhage in adult rats (Rosenberg et al., Stroke, 1990). Collagenase-injected animals had increased water content in the posterior brain region, and a high behavioral injury score. Fifty-five animals had two NMR recordings each prior to injury and at 4, 12, 24, 48, 36, 72 hrs after injury, in a GN300 7T, 89 mm vertical-bore spectrometer. ^1H spectra were graded for peak heights of lactate (1.3 ppm), N-acetyl aspartate (2.0 ppm), and PCr/Cr (3.0 ppm). Differences in chemical shift between Pi and PCr peak determined the pH values from ^{31}P spectra. Lactate was increased over pre-injury values at 4, 12, 24, 36, and 48 hrs ($p<0.05$), but corresponding pH was similar for all time points. These experiments indicate that an increase in brain lactate concentration may occur in the edematous region without a decrease in brain pH.

CI-977, A NOVEL KAPPA OPIOID RECEPTOR AGONIST, REDUCES INFARCT SIZE IN A MODEL OF FOCAL CEREBRAL ISCHEMIA. J.J. Cordon*, P.A. Boxer, M.A. Dominick*, F.W. Marcoux. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105

Both opioid agonists and antagonists have been shown to be beneficial in the treatment of ischemic injury. The current experiments determined the efficacy of CI-977 a novel, potent kappa-selective agonist (affinity=0.11 nM, mu/kappa ratio=905) in reducing damage resulting from focal ischemia. The left common carotid artery of F-344 rats was ligated along with coagulation of the middle cerebral artery at the rhinal fissure. CI-977 or vehicle (saline) was adminstered IV 30 min and 24 hr post occlusion. In one experiment animals were sacrificed 2 days post occlusion and the degree of damage assessed by exclusion of the dye TTC in 2 mm sections. CI-977 (0.05 to 0.5 mg/kg) produced dose-related reductions in infarct volume, which were significant at 0.1 and 0.5 mg/kg. In another experiment the animals were perfusion fixed with 10% buffered formalin at 10 days after occlusion and sections 6 μM thick were taken every 800 μ and stained with iron haematoxylin/cresyl-echt violet. CI-977, at 0.1 mg/kg significantly decreased the volume of ischemic damage by 57% as compared to saline control. At 0.5 mg/kg CI-977 produced a non-significant decrease of 27%. These data suggest that CI-977 may be beneficial in the treatment of abrupt occlusive stroke.

384.13

OPIOID RECEPTOR ANTAGONIST NALMEFENE STEREO-SPECIFICALLY INHIBITS GLUTAMATE RELEASE DURING GLOBAL CEREBRAL ISCHEMIA. S.H. Graham, H. Shimizu*, A. Newman,# P. Weinstein, and A.I. Faden. Dept. of Neurology and Neurosurgery, University of California, San Francisco, CA 94121 and Department of Applied Biochemistry, Walter Reed Army Institute of Research, Washington D.C. 20307#

The opioid antagonist nalmefene, which has increased affinity for κ-opiate receptors, attenuates the reduction in tissue glutamate after global cerebral ischemia/reperfusion (Faden et al, in review). In the present study, the effect of nalmefene upon excitatory amino acid release during global ischemia was studied using the technique of microdialysis. A 4 mm microdialysis probe was stereotactically placed in the dorsal hippocampus and perfused with mock CSF at 2 μL/min in 26 isoflurane anesthetized rats. One hour after insertion of the probe, complete global cerebral ischemia was induced for 30 minutes by the 7 vessel occlusion method. Saline, 0.1 mg/kg of (-) nalmefene or the inactive (+) enantiomer was given 15 minutes prior to ischemia. Samples of dialysate were collected every 10 minutes before, during, and after ischemia and amino acid content determined by HPLC. Peak dialysate glutamate during ischemia was significantly ($P<.05$) less than in (-) nalmefene treated animals (21.3±4.0 μM), while there was no difference between the saline (35.1±4.6 μM) and (+) nalmefene groups (34.9±5.0 μM). These results suggest that κ-opiate receptors may modulate glutamate release during ischemia and that inhibition of excitotoxin release may contribute to the protective actions of opioid antagonists in cerebral ischemia.

THE LACK OF EFFECT OF FLUNARIZINE ON PRESERVING NEUROLOGIC FUNCTION AFTER EXPERIMENTAL STROKE. W. M. Clark*, K. P. Madden, J. A. Zivin. Dept. of Neurosciences, UCSD, La Jolla, CA.

Prior studies using calcium entry blockers in experimental CNS ischemia have produced conflicting results. We studied the efficacy of Flunarizine (Janssen Research) in two models of selective CNS ischemia. A dose of 5mg/kg was given IV to treatment NZW rabbits 5 minutes post ischemia. In the first study, we used a model of spinal cord reperfusion to calculate the average length of ischemia required to produce paraplegia in each of the groups (ET_{50}). The ET_{50} in the Flunarizine group (N=17) was 29.8± 3.6 min., in controls (N=13) 24.1± 2.2 min.; P= .19. In the second study, we used microspheres to produce multiple brain infarcts. The average amount of microspheres required to produce abnormal neurologic function was calculated (ES_{50}). Agents which protect the CNS increase the ES_{50}. For the Flunarizine group (N=9), the ES_{50} was .36± .09 mg; in controls (N=14) .44± .12 mg; P= >.25. Thus, Flunarizine did not improve neurologic function in two sensitive models of CNS ischemia.

FPL 13950, AN ANTICONVULSANT WITH MARKED ANTI-ISCHEMIC PROPERTIES IN ANIMAL MODELS. G.C. Palmer, E.W. Harris, J. C. Strand*, M.L. Stagnitto*, A.R. Borrelli*, E.F. Cregan*, J.C. White*, R.J. Murray* and R.C. Griffith*. Fisons Pharmaceuticals, Div. R&D, Box 1710, Rochester, NY 14603.

FPL 13950 (formerly PR 1013-708 or 2-amino-N-[1,2-diphenylethyl]acetamide) is a moderately potent, safe, orally acting anticonvulsant which protects rodents against maximal electroshock seizures (ED50=20.5 in mice & 15.5 in rats; Garske et al., Soc. Neurosci. 14: 866, 1988). During routine screening with thermoregulated mice, oral FPL 13950 extended the time to death during hypoxia (ED50=19). Analogous tests in rats were confirmatory. In global ischemia models rats were subjected to 30 min. of 4-vessel occlusion, followed by 20 mg/kg FPL 13950 or saline i.p., immediately upon reflow and daily for 1 or 2 weeks. Drug-treated had much less CA1 cell loss and larger CA1 electrophysiological responses (orthodromic & antidromic population spikes recorded in vitro) than saline-treated rats. Dogs were subjected to 8 min global ischemia (clamping the ascending aorta), treating with FPL 13950 i.v. 30 min. post ischemia, then b.i.d. for 3 days and then once daily for 7 days). Histological examination confirmed that FPL 13950 markedly reduced ischemic damage in CA1.

These findings warrant continued development of this or similar compounds for eventual indications in patients suffering from cardiac arrest or coronary by-pass surgery.

REDUCTION IN ISCHEMIC INFARCTIONS PRODUCED BY OCCLUSION OF RAT MIDDLE CEREBRAL ARTERY BY TREATMENT WITH AGENTS ACTING AT IMIDAZOLE RECEPTORS. L. Pek*, K. Maiese, S.B. Berger and D.J. Reis. Div. of Neurobiol., Cornell Univ. Med. Coll., NY, NY 10021.

Treatment with the α_2-adrenergic (α_2) receptor antagonist idazoxan (IDA) reduces the size of the cerebral infarction produced by global cerebral ischemia (Gustafson, I. et al., *J. Cereb. Blood Flow Metab.* 9:171-174, 1989). It is not known whether: (a) IDA can modify a focal ischemic injury; (b) if its effect is entirely attributable to an interaction with α_2-receptors since IDA also binds to imidazole (IM) receptors. Thus, we compared the effects of IDA with the selective non-imidazole α_2-antagonist SKF 86466 (SKF) and the oxazole rilmenidine (RIL), an α_2-agonist which also binds at IM sites, on infarctions produced by occlusion of the middle cerebral artery (MCA) in rat. The MCA was occluded in rats anesthetized with isoflurane in 100% O_2 and drug immediately administered while maintaining arterial pressure and blood gases for 1h. Animals were sacrificed 24 h later, brains stained and lesions measured. IDA (3mg/kg) and RIL (1mg/kg) both significantly ($p<0.05$, n=5 each group) reduced lesion size compared with controls (IDA, 153±4.5 mm^3; RIL, 139±7.8 mm^3; control, 196±6.6 mm^3; n=5). SKF (15 mg/kg) had no effect (186±6.5 mm^3; n=5). We conclude: (a) IDA and RIL can reduce a focal ischemic infarction; (b) the effect of IDA cannot be attributed to antagonism of α_2-receptors. An interaction with IM receptors may underlie the tissue preserving actions of IDA and RIL.

CORTICOSTERONE EXACERBATES ISCHEMIC-LIKE INJURY IN MIXED HIPPOCAMPAL CULTURES. G.C. Tombaugh and R.M. Sapolsky. Dept. of Biol. Sci., Stanford Univ., Stanford, CA 94305

Glucocorticoids can potentiate ischemic neurotoxicity in the rat hippocampus. However, the cellular and biochemical mechanisms underlying this synergy are not known. To begin to characterize this effect we have used primary hippocampal cultures, containing both neurons and astrocytes (~1:1), derived from 18d fetal rats. At 10-12 days of age, cultures were refed with experimental medium containing 5mM glucose with or without 100nM steroid. 24hr later, cultures were refed with steroid-free medium containing varying glucose concentrations, immediately made hypoxic (100% N_2) for 6hr, then refed with fresh medium (5mM glucose). The following day, cell damage was measured by lactate dehydrogenase assay. Pretreatment with corticosterone (CORT) enhanced hypoxic cell damage under low (0.4mM) or no-glucose conditions but had no effect when glucose = 5mM. In normoxic controls, CORT was damaging only in the "no-glucose" group even though glucose-free exposure alone caused no significant damage. Neither progesterone, estrogen, nor testosterone had any measurable effect. Thus, CORT aggravates hypoxic injury in hippocampal cultures only under conditions that are likely to cause energy failure and subsequent cell death. These results are consistent with the idea that glucocorticoids enhance cell vulnerability by weakening cellular energy state. In support of this model, glucocorticoids have been shown to inhibit glucose transport into cultured hippocampal neurons and astrocytes.

HYPERTENSIVE RATS PRODUCE MORE TUMOR NECROSIS FACTOR THAN NORMOTENSIVE RATS IN RESPONSE TO CHALLENGE WITH LIPOPOLYSACCHARIDE. J.M. Hallenbeck*, D.A. Doron, [1]G. Feuerstein, [2]H.B. Pollard and E. Heldman. Dept. of Neurology, U.S.U.H.S., Bethesda, MD 20814 and [1]Dept. of Pharmacology, Smith, Kline and French laboratories, King of Prussia, PA 19406 and [2]Lab. Cell Biol. and Genetics, NIH, Bethesda, MD 20892.

Hypertension is one of the most common risk factors for stroke. Spontaneous hypertensive rats (SHR) have been demonstrated to experience a high incidence of ischemic and hemorrhagic lesions in the brain stem, following a provocative dose of lipopolysaccharide (LPS). LPS stimulates macrophages to secrete the cytokines interleukin-1 (IL-1) and tumor necrosis factor-α (TNF-α), both of which convert the endothelium surface from an anticoagulant to a procoagulant state and thus may cause the production of focal ischemic lesions. In order to determine if increased TNF-α activity were one of the factors which may be responsible for the high incidence of ischemic lesions in LPS-treated rats, we challenged SHR and normotensive rats (WKY) with 1.8 mg/kg LPS and measured TNF-α levels in the blood and cerebral spinal fluid (CSF). We found that LPS induced a marked elevation of TNF-α activity in both SHR and WKY. However, the response of the SHR was significantly higher than that of the WKY controls, resulting in a significantly higher TNF-α level in the blood of SHR 2 h following challenge with LPS. Furthermore, when LPS was delivered intravenously, TNF-α activity was elevated mainly in the blood but not in the CSF. By contrast, when LPS was injected intracerebroventricularly, TNF-α was high in the CSF and low in the blood. These results strongly suggest that TNF-α is produced locally in the brain and thus may cause focal ischemic lesions. The higher incidence of stroke-like events occurring in SHR as compared to WKY may be related to the higher level of TNF-α obtained after challenge with LPS.

ACETAZOLAMIDE-OUABAIN INHIBITS CEREBROSPINAL FLUID PRESSURE RISE BY CEREBROVENTRICULAR INFUSIONS IN RATS.

Morrow, BA*, LC Keil and WB Severs, Hershey Medical Center, Penn. State Univ. School of Medicine, Hershey, PA 17033

Cerebrospinal fluid pressure (CSF-p) rises 2-3 fold about 2 hr after an 8 μl/min x 10 min infusion of artificial cerebrospinal fluid (aCSF) in conscious rats. (*FASEB J.*, 4:A1095, 1990) Elevated resistance to outflow (Ro) accompanied the elevated CSF-p. Acetazolamide (ACTZ), a carbonic anhydrase inhibitor, and ouabain, an inhibitor of Na^+/K^+ ATPase, were both employed to prevent the formation of CSF. Six Male S-D rats (300-400g) were surgically implanted with a sealed 4 mm cerebroventricle cannula (1.5 mm l & 1.0 mm p to bregma) and allowed to heal for 2 days. The evening prior to the experiment, ACTZ, 50 mg/kg, s.c., was given. On the test day, the rats received both ACTZ, 50 mg/kg, i.p., and ouabain, 2.5 μg/5 μl aCSF, ivt, just before connecting to the recording system. Ouabain caused a brief 1-2 min seizure after a 1-3 min delay. Thirty min after dosing, the rats received the infusion, 8 μl aCSF/min x 10 min. Ro and compliance (Comp) were evaluated by boluses of aCSF (10 μl/0.5 sec) at 20 min and 4 hr after the infusion. CSF-p's were not different ($p>0.05$). However, Ro rose (*=$p<0.05$), while Comp fell (*=$p<0.05$). In this study, the increase in CSF-p, but not Ro, was prevented by blocking CSF formation. These data indicate that increased CSF-p is not essential for increased Ro. We propose that elevated Ro causes the increase in CSF-p.

	20 min	4 hr
CSF-p, ($cmH_2O \pm$ SEM)	10 ± 2	13 ± 3
Ro, ($cmH_2O/\mu l/min \pm$ SEM)	1.5 ± 0.6	7.8 ± 2.1 *
Comp, ($\mu l/cmH_2O \pm$ SEM)	2.1 ± 0.6	0.6 ± 0.1 *

CSF-p's of rats receiving the 8 μl/min aCSF infusion with no drug therapy were 9.3 ± 0.9 and 23.6 ± 2.8 ($cmH_2O \pm$ SEM) for 20 min and 4 hr, respectively.

Physiological and Metabolic Changes During Gravity (+Gz) Induced Loss of Consciousness (G-LOC) in Rat Brain. A. R. Shahed, F. G. Aldape*, J. A. Barber* and P. M. Werchan*. USAF School of Aerospace Medicine, Op. Tech. Corp., and Krug Int., Brooks AFB, San Antonio, TX 78235.

High sustained or rapid onset of +Gz is known to cause G-LOC in pilots of high performance aircraft with potentially grave consequences. Relatively little is known about G-LOC and so approaches to its prevention are limited. In the present study a small animal centrifuge (SAC) was used to investigate the neurophysiological mechanism of G-LOC. Rats with surgically implanted electrodes for EEG, ECG and heart rate were loaded on a SAC equipped with a freeze blowing device. Control rats received identical surgical treatment but were not centrifuged. Rats were centrifuged for 30s at 1 to 32.5 Gz to determine G-tolerance and time for G-LOC to occur. Brains were frozen immediately (group 1), or 30-60s (group 2) after G exposures and analyzed for energy metabolites. At 25 + 1 Gz (n=19), G-LOC was observed within 17 + 1s and EEG remained isoelectric for 15-24s. Brain glucose decreased (70%) in group 1 and remained unchanged in group 2 over controls. Brain lactate increased 2- 2.5 fold over control in both groups. ATP and creatine phosphate levels decreased and AMP, ADP and adenosine levels increased significantly in both groups. This is the first report to show metabolic changes during G-LOC. Investigations continue to determine if these and/or other changes contribute to G-LOC.

^{31}P-NMR STUDIES OF ISCHEMIA IN NG108-15 CELLS: EFFECTS OF PHENYTOIN AND MG^{2+} ON RECOVERY OF HIGH ENERGY PHOSPHATES. F.A.X. Schanne*, P.K. Stanton, B.H. Smith and J.R. Moskal. Dept. Neurosurgery, Albert Einstein Col. Med, Bronx, NY 10467.

Intracellular high energy phosphates (HEP) were monitored in differentiated cells by ^{31}P-NMR under conditions of continuous perfusion, no flow and reperfusion to model changes occuring during cerebral ischemia and reperfusion. NG108-15 cells were attached to Cytodex microcarrier beads and differentiated for 5 days in dbcAMP (1 mM). Medium was supplimented with creatine (10 mM) 24 hrs before NMR observation. Cells on beads were transferred to an NMR tube and perfused with artificial cerebrospinal fluid at a flow rate of 1 ml/min. Cells were maintained at 37°C and the perfusion medium was saturated with 95% O_2/5% CO_2 (pH 7.4). Under these perfusion conditions, stable intracellular HEP resonance signals were observed using a Varian VXR 500 spectrometer with a 10 mm probe. Upon stopping the perfusion, there were rapid decreases in pH and in phosphocreatine (PCr), followed by losses in nucleotide phosphates. Upon reperfusion, the pH returned to normal and the HEP recovered towards normal levels, depending upon the duration of no flow. These changes follow a pattern similar to that observed by ^{31}P-NMR of cerebral ischemia *in vivo*. Following 40 min of ischemia and 40 min of reperfusion PCr returned to 52+/-4% of preischemia levels. Treatment with phenytoin at 5ug/ml and 20 ug/ml enhanced recovery to 75+/-6% and 73+/-7%, respectively. 10 mM Mg improved recovery to 80%. These data demonstrate that phenytoin as well as Mg are protective against neuronal damage induced by ischemia. Thus this model system should prove useful in helping to elucidate some of the molecular mechanisms underlying the neurotoxicity induced by ischemia.

FOREBRAIN ISCHEMIA INDUCES SELECTIVE BEHAVIORAL IMPAIRMENTS ASSOCIATED WITH HIPPOCAMPAL CA1 INJURY. J.D. Thomas, T. X. Gionet*, C.R. Goodlett, D. S. Warner, M. M. Todd*, E.A. Wasserman*, and J.R. West. Dept. of Psychology, Anesthesiology, & Anatomy, Univ. of Iowa, Iowa City, IA 52242.

Studies of forebrain ischemia in rats have demonstrated significant loss of hippocampal CA1 neurons and deficits in working memory. The selectivity of the behavioral deficits induced by forebrain ischemia was evaluated using six tasks, tested sequentially: retention of a radial maze discrimination [postoperative days (PO) 5-16], open field activity (PO 18), general motor performance (PO 18), step-through passive avoidance (PO 20-21), the Morris place learning task (PO 26-27), and rotarod performance (PO 28). All rats were trained on a 12-arm radial maze discrimination (6 arms baited and 6 arms unbaited) for 50 days, one trial per day. They were then randomly assigned to either the ischemia condition (n=8) or to the sham condition (n=6). Ten minutes of ischemia with an isoelectric EEG was produced by bilateral carotid artery occlusion and systemic hypotension (mean arterial pressure=50±5 mm Hg). Controls underwent the same surgery except ischemia was not induced. In the postoperative radial maze test, the ischemic group committed significantly ($p<.05$) more working memory errors than controls during the first block of six trials, but recovered to control levels by the second block. The ischemic group also had a nonsignificant trend toward more reference memory errors in the first block. The groups did not differ significantly in open field activity, motor performance, passive avoidance performance, spatial learning in the Morris navigation task, or balance on the rotarod. Neuronal loss in CA1 was rated (scored 0 to 3) from 5-µm coronal sections by an investigator blind to group membership and behavioral performance. The severity of working memory deficits was associated with the extent of CA1 damage. Furthermore, if only the rats with severe, bilateral CA1 loss were considered (n=4), passive avoidance retention deficits were also evident. In summary, none of the tests of motor function distinguished the groups, indicating that generalized motor dysfunction is not a reliable index of the outcome of forebrain ischemia in this rat model. However, ischemia resulted in relatively specific cognitive impairments that were associated with the extent of hippocampal CA1 neuronal loss. (Supported by grants #GM 39771 to DSW and #AA 05523 to JRW)

Immunohistochemical study of "Delayed Neuronal Death" with anti–NF200 antibodies. Y. Kaku, Y. Yonekawa, N. Ogata and T. Tsukahara. Department of Neurosurgery, National Cardiovascular Center, Suita, Osaka 565, Japan.

Selective vulnerability and "delayed neuronal death" of hippocampal CA1 region have been well documented, but its precise mechanism has not been clarified so far. Our previous report demonstrated that the degradation of the neurofilament (NF) triplet proteins occurs in cerebral ischemia and suggested that it may be related to irreversible neuronal cell death (Ogata et al. J. Neurosurg,70:103,1989). In this study, "delayed neuronal death" was induced in a rat by lowering the systemic systolic blood pressure to 50 mmHg in addition to temporal occlusion of the bilateral common carotid arteries, followed by reperfusion. The duration of the ischemia was 2 min, 5 min, and 8 min; and the duration of reperfusion was 1 day and 7 days. The histology was confirmed by hematoxylin–eosin (HE) staining and by immunohistochemical staining with anti–NF200 antibodies (NF staining). In 8 minutes ischmia, HE staning showed the survival of most of the neurons in the CA1 region at 1 day after ischmia and more than 75 % loss of the neurons in the same region at 7 days after ischemia. In contrast, NF staining showed that the reactivity to anti–NF200 in the CA1 region was already decreased at 1 day and remained to be low at 7 days after ischemia. Immunoreactivity in the CA3 region, in which almost all the neurons survived, was unchanged both at 1 day and at 7 days after ischemia. These results suggest that the decrease of the immunoreactivity to anti–NF200 precedes the neuronal cell death.

385.3

RESPONSE OF SOMATOSTATIN NEURONS TO TRANSIENT FOREBRAIN ISCHEMIA IN THE GERBIL: AN IN SITU HYBRIDIZATION STUDY. J. L. Seeburger, J. E. Springer, and C.-S. Lin. Depts of Neurology and Physiology & Biophysics, Hahnemann University , Philadelphia, PA 19102-1192.

The selective vulnerability of specific populations of forebrain neurons to ischemic insult has been well documented. These include neurons in the hippocampal CA1 and dentate hilar areas, layers 2/3 and 6 of the somatosensory neocortex, the dorsolateral striatum, and the lateral septum. Recently, somatostatin positive neurons have been found in these regions. We therefore investigated the response of these somatostatin neurons to ischemic insult. Because different forms of the somatostatin molecule are derived from a single precursor and individual neurons may not express all forms, an in situ hybridization procedure was used to localize neurons containing somatostatin mRNA. Ischemic lesions were produced by 5-min bilateral occlusions of the common carotid arteries in Mongolian gerbils. Fresh sections were collected on a cryostat after 2d, 4d, and 2wk post-occlusion survival periods. Sections were processed with a nonradioactive oligonucleotide probe complementary to somatostatin mRNA. Adjacent sections were stained with Cresyl Violet or silver. A decrease in somatostatin mRNA signal was noted in regions known to be sensitive to ischemic damage as early as 2d post-occlusion. Similar results were obtained with the 4d and and 2wk survival conditions. Furthermore, cell loss and argyrophilia were noted in the same regions stained with Cresyl Violet and silver, respectively. Therefore, the loss of somatostatin mRNA signal was most likely due to cell death. It remains possible, however, that surviving cells ceased to express somatostatin mRNA. Our present results suggest a correspondence between the localization of somatostatin neurons and neurons sensitive to ischemic damage in the gerbil forebrain. Supported by NIH S07RR07241.

EFFECT OF TRANSIENT FOREBRAIN ISCHEMIA ON SOLUBLE PROTEINS FROM CA1 AND CA3 REGIONS OF THE HIPPOCAMPUS. E. A. Heinicke* and A. M. Buchan, Robarts Research Institute, London, Canada.

CA1 pyramidal neurons of the hippocampus die 2 to 3 days after transient forebrain ischemia, whilst neurons of the CA3-dentate gyrus region survive. The distribution of soluble proteins from these regions was examined for changes that might lead to cell death.

Male Wistar rats were subjected to 15 min. transient forebrain ischemia (4-VO model), followed by reperfusion for 1, 3 or 7 days. Normal, untreated rats served as controls. Soluble proteins from CA1 and CA3-dentate regions were separated electrophoretically by SDS-PAGE, stained with Coomassie Blue, and those of less than 87 KD (constituting 83% of the applied sample) were quantitated by densitometer.

The banding patterns from the two regions were identical, with two exceptions; two bands, 58 and 11 KD, occurred in different proportion in CA1 and CA3 in all groups of animals. Only three protein bands - 76, 54 and 26 KD - were affected quantitatively by ischemia. The constancy of the composition of the cytosolic protein compartment of the two regions before and after ischemia suggests that protein breakdown may not be a major factor in ischemic neuronal death.

DISTRIBUTION OF 70 KDa HEAT SHOCK PROTEIN mRNA INDUCTION AFTER TRANSIENT GLOBAL ISCHEMIA IN THE RAT. T. S. Nowak, Jr., G. Nagashima*, K. Kawai* and I. Klatzo. Laboratory of Neuropathology and Neuroanatomical Sciences, NINDS, NIH, Bethesda, MD 20892.

Recent studies have documented the induction of the 70 kDa stress / heat shock protein, hsp70, following transient ischemia in the gerbil, and have suggested its utility as an early marker for neuronal circuitry which may participate in the evolution of subsequent pathology. Since postischemic protein synthesis deficits may variably limit the capacity of cells to express immunoreactive hsp70 protein, localization of hsp70 mRNA by in situ hybridization has proved a more reliable index of the stress response. This method was applied in the present study to evaluate the distribution of hsp70 mRNA in rat brain after 10 min transient global ischemia subsequent to cardiac arrest produced by compression of the major thoracic vessels, followed by resuscitation. Results obtained at 6 h recovery, the time of maximal hsp70 induction in the gerbil ischemia model, demonstrate a generally similar distribution of hybridization in the rat, including all hippocampal pyramidal neurons as well as the dentate granule cell layer, lateral striatum, piriform cortex and neocortex. In contrast to the gerbil, modest hybridization was also apparent in ventral thalamic nuclei, which subsequently show evidence of cellular injury, as well as serum protein and calcium accumulation, in this model. These results provide further support for the use of hsp70 hybridization in the molecular mapping of postischemic neuropathology.

EXPRESSION OF HEAT SHOCK PROTEIN 70 mRNA FOLLOWING REVERSIBLE FOCAL ISCHEMIA IN RAT BRAIN F.A.Welsh and D.J.Moyer. Div. of Neurosurgery, Univ. of Pennsylvania, Philadelphia, PA 19104.

To investigate the relationship between the expression of heat shock proteins and ischemic brain damage, in situ hybridization was performed in postischemic rat brain using an oligonucleotide probe specific for inducible 70-Kd heat shock proteins (HSP-70). Reversible focal ischemia was produced by transient occlusion (1 hr) of both carotid arteries combined with permanent occlusion of the middle cerebral artery. After reperfusion for 2 hr, intense expression of HSP-70 mRNA was evident in the area of ipsilateral neocortex known to undergo infarction. However, HSP-70 mRNA was also expressed in regions not normally injured, including paramedian neocortex, striatum, and hippocampus. After 24 hr reperfusion, expression of HSP-70 mRNA was still evident in neocortex and CA_1 subfield of hippocampus, but not in striatum. These results demonstrate that the postischemic expression of HSP-70 mRNA occurs both in regions undergoing ischemic injury and in regions that recover without histologic evidence of damage.

METABOLIC VIABILITY AND PROTON HOMEOSTASIS IN THE HIPPOCAMPAL SLICE: EFFECT OF ACID LOADING. H.A. Assaf*, T.S. Whittingham, J.C. LaManna, R.A. Ratcheson, and W.D. Lust. Lab. of Experimental Neurological Surgery, Case Western Reserve University, Cleveland, OH 44106.

Intracellular acidification secondary to lactic acid accumulation has been implicated in the evolution of brain damage following an ischemic episode. It has been shown that lactic acid in an acidic medium is more toxic than HCl to cells of neural origin grown in culture (Goldman et al., J. Cereb. Blood Flow Metab., 1989), suggesting that uncharged organic acids may facilitate the flux of protons across membranes. Similar experiments were performed on hippocampal slices to determine the effect of a number of weak acids on pHi during an acid load. The metabolic viability (i.e., ATP levels) and pHi, derived from the creatine kinase equilibrium, were determined in hippocampal slices incubated for up to 30 min in media acidified to pH 4.9 with the following acids: hydrochloric (H), pyruvic (P), D-lactic (DL), L-lactic (LL), formic (F) or acetic (A) acids. While ATP levels in the H and P groups were maintained for up to 30 min (> 80% of cont), those in the remaining groups were depleted (<25% of cont) by 30 min. The loss of ATP in the F and A groups was complete within 5 min of incubation, whereas ATP depletion occurred between 10 and 30 min in the DL and LL groups. The pHi at 10 min of incubation dropped from a control value of 7.62 $\pm$ 0.04 to 7.41 $\pm$ 0.06, 7.20 $\pm$ 0.08, 7.12 $\pm$ 0.20* and 6.61 $\pm$ 0.07* for the H, P, LL and DL groups, respectively (*, $p < 0.05$). In contrast, the pHi decrease in the A and F groups was greater and at 5 min was 6.29 $\pm$ 0.15* and 5.60 $\pm$ 0.21*, respectively. The observed differences in hippocampal slice pHi appear to be determined by both the pK' and lipid solubility of the acids. The ability of weak organic acids to enhance the movement of protons suggests that this process may modulate localized acid-base imbalances following anoxia/ischemia.

DIALYSIS PERFUSION EXACERBATES STRIATAL ISCHEMIC DAMAGE. L.A. Phebus+, R.E. Mincy* and J.A. Clemens. The Lilly Research Laboratories, Eli Lilly and Co. +and The Program in Medical Neurobiology, Indiana Univ., Indpls. In 46285

Ten minutes of four-vessel occlusion (4-VO) in the rat usually produces no striatal ischemic damage. We tested the effect of dialysis probe implantation and perfusion on the striatal cell loss produced by 10 min of 4-VO.

Male Wistar rats were prepared for 4-VO by permanently cauterizing the vertebral arteries and placing an atraumatic snare loosely around the carotids. At the same time, a "loop type" microdialysis probe was stereotaxically inserted in the anterior, lateral striatum. The next day, the rats were placed in a circular chamber and the dialysis probe was perfused at a rate of 1 uL/min with an artificial CSF solution containing 150 mM NaCl, 3 mM KCl, 1.7 mM $CaCl_2$ and 0.9 mM $MgCl_2$ with a pH of 7.4. After about 2 hours of perfusion, 4-VO was produced in the animals by closing the snares around the carotids. Loss of righting reflex was used as an index of adequate ischemia. After 10 min. the snares were opened and reperfusion begun. At least 24 hours later, the rats were sacrificed and striatal damage was assessed histologically. In eleven rats, there was never any ischemic cell loss in the non-perfused striatum. In the perfused striatum, 10 of the 11 rats showed some cell loss and 5 of these showed severe cell loss symmetrically distributed around the dialysis membrane.

REDUCED PARTICULATE PKC ACTIVITY DURING FOCAL CEREBRAL ISCHEMIA. R.C. Crumrine, W.R. Selman*, J.C. LaManna, K.A. Seta*, W.D. Lust. Department of Neurology and Division of Neurosurgery, University Hospitals of Cleveland, Cleveland, Ohio 44106.

Protein kinase C (PKC) is a component of intracellular signaling systems. Activation of PKC has been implicated in the modulation of neuronal excitability, neurotransmitter release and modulation of intracellular pH. Thus, altered PKC activity may have an influence on the ability of cerebral tissue to survive an ischemic insult. Occlusion of the left middle cerebral artery (MCA) in the spontaneously hypertensive rat strain results in a consistent and reproducible area of tissue damage. The MCA was occluded for 6 hours with a snare ligature and then the rats were frozen in situ. The brains were removed and sectioned in a microtome (-20^{0}C) at the level where the right and left aspects of the corpus collosum fused. Representative histological sections confirmed a focal ischemic event and were used for dissecting the appropriate regions. Tissue samples for PKC assay were then obtained from the dorso-lateral cerebral cortex both ipsilateral and contralateral to the occlusion. PKC was assayed by measuring the incorporation of ^{32}P from the gamma position of ATP into exogenous histone (type IIIs).

Total PKC activity (particulate + soluble) in the ipsilateral cerebral cortex was depressed by 56% as compared to the contralateral cerebral cortex (1.24±0.44 vs 2.84±0.14 nmol/min/mg protein; NS, paired t-test). The proportion of particulate PKC activity in the ipsilateral cerebral cortex was 52% of that of the contralateral cerebral cortex (17.6±0.6% vs 33.8±2.0%; p<0.05, paired t-test). Thus, the detectable particulate PKC activity was only 25% of normal in the ipsilateral cerebral cortex after 6 hours of focal ischemia. The marked reduction in activity of this second messenger system may not only influence tissue survival during stroke, but also may retard functional recovery following reperfusion.

385.10

SEGMENTAL BLOOD FLOW IN ISCHEMIC SPINAL CORD OF RABBITS. K.E. Peek, J. Goddard-Finegold, M.J. Joerger*, C.S. Robertson*. Dept. of Neurosurgery, Baylor College of Medicine, Houston, TX 77030.

Blood flow before, during, and/or after spinal cord ischemia may affect neurological recovery. Eight New Zealand albino rabbits, anesthetized with ketamine, were artificially ventilated with supplemental oxygen. A balloon catheter was positioned in the abdominal aorta just distal to the origins of the renal arteries. Somatosensory evoked potentials were recorded at L5-L6 during sciatic nerve stimulation, and functional spinal cord ischemia was determined by the disappearance of postsynaptic potentials following balloon inflation. Segmental spinal cord blood flow (sSCBF) was measured in the 9 caudal segments using 15-micron radiolabeled microspheres at 4 times: before and during ischemia and at 30 and 120 min reperfusion.

Before ischemia, mean±SD sSCBF varied from 12.2±3 mL/100g/min at T12-L1 to 25.7±10 mL/100g/min at L7-S1. During ischemia, sSCBF was reduced between 31.7%±33 (L1-L2) and 91.3%±12 (L7-S1). At 30 min reperfusion, hyperemia was evident at all segments, with the greatest percent change from pre-ischemia values (179%±74) at L7-S1. By 120 min reperfusion, sSCBF values had normalized to control levels at all segments. sSCBF may prove to be an important correlate in acute and chronic measures of functional recovery from spinal cord ischemia.

385.11

TISSUE OXYGENATION AND EVOKED POTENTIAL RECOVERY AFTER GLOBAL CEREBRAL ISCHEMIA. Z.-C. Feng, T.J. Sick and M. Rosenthal. Dept Neurology, Univ Miami Med Sch, Miami, FL 33101
. Recovery following cerebral ischemia may be impaired by effects of reperfusion and 'oxidative stress.' Recordings by optical and electrode techniques in control rats anesthetized with pentobarbital and respired with 30% O_2 showed that reperfusion after ischemia (30 min; 4-vessel occlusion model) is accompanied by: a) recovery of extracellular potassium ion activity (K^+o); b) hyperemia; c) tissue hyperoxygenation; and d) hyperoxidation of cytochrome a,a_3. However, clearance of K^+ after its elevation by direct cortical stimulation remained slowed. Present studies examined effects of increasing or decreasing the fraction of oxygen in the inspired gas mixture (FiO_2) one minute prior to reperfusion. This was done to manipulate amplitudes and durations of post-ischemic mitochondrial hyperoxidation (PIMHo) and tissue hyperoxygenation which were increased by high FiO_2 and decreased or suppressed by low FiO_2. In the former animals, K^+o baseline remained elevated (approx 1 mM) above baseline and there was significantly poorer recovery of somatosensory evoked potentials and EEG activity. In animals respired with 15% O_2 during the first 10 minutes after reperfusion, recovery of evoked potential and EEG activity was enhanced over control animals. Clearance of K^+o following stimulation was not significantly influenced by changes in FiO_2. We suggest that: a) hyperoxygenation and PIMHo residual metabolic dysfunction after ischemia; b) the events may be related to reperfusion or 'oxidative stress' injury; c) events associated with PIMHo and tissue hyperoxygenation may decrease electrophysiological recovery; and d) suppression of PIMHo and tissue hyperoxygenation by respiration of a slightly hypoxic gas mixture in the early post-ischemic period may have beneficial effect.

385.12

SELECTIVE CORTICAL ISCHEMIA AFTER OCCLUSION OF A MIDDLE CEREBRAL ARTERY IN GERBILS. O. Takemoto* and T. Yanagihara. Dept. of Neurology, Mayo Clinic, Rochester, MN 55905

We developed an experimental model of selective cortical ischemia by occlusion of a middle cerebral artery through the suprazygomatic retro-orbital approach in gerbils and followed the evolution of ischemic damage from 30 min to 7 days by using the immunohistochemical reactions for α-tubulin and microtubule associated protein (MAP) 1 and 2. Five gerbils were used for each ischemic period. Ischemic lesions were detected first in the frontoparietal cortex in the layer III/IV at 30 min, in all gerbils after 1 hr with the reaction for MAPs and after 2 hrs with the reaction for α-tubulin. Extensive lesions developed in 12 hrs. Ischemic lesions in the parietal cortex progressed more slowly. Laminar lesions were visible with the reaction for MAPs at 3 hrs, but only a few scattered lesions were recognizable with the reaction for α-tubulin. It took 24 hrs before all gerbils developed extensive lesions in the parietal cortex. This model may be useful for a comparative study of the ischemic focus and the surrounding area with marginal blood flow in the cerebral cortex.

EFFECTS OF BILATERAL CAROTID ARTERY OCCLUSION (BCO) ON $GABA_A$ RECEPTOR FUNCTION IN MONGOLIAN GERBIL BRAIN Beth E. Mileson and Rochelle D. Schwartz, Dept. of Pharmacology, Duke University Medical Center, Durham, NC 27710.

The selective neuronal damage which occurs in the hippocampus (HIP), striatum (STR) and cortex (CTX) following transient forebrain ischemia is thought to be mediated by excessive neuronal stimulation. We examined the possibility that a loss of inhibitory neurotransmission may compound the overstimulation and contribute to cell death. $GABA_A$ receptor function in occluded and sham-operated mongolian gerbils was measured in synaptoneurosomal preparations of HIP, STR and CTX.

Gerbils were allowed to recover from a 5 minute BCO for 1, 4 or 29 days. Since the degree of HIP, STR and CTX damage following 5 minute BCO may vary, all gerbils were screened one day after occlusion for locomotor activity in a novel environment. An increase in this measure is a reliable indicator of HIP damage in the gerbil. A "mini" dose-response curve of muscimol-stimulated ^{36}Cl uptake was produced for each brain region using 2, 5, and 20 μM muscimol. No difference in GABA gated Cl^- uptake was seen in any brain region 1 or 4 days after BCO compared to controls, though a loss of binding to the Cl^- channel of $GABA_A$ receptors has been observed in BCO gerbils on day 4 (see next poster). Twenty-nine days after BCO, no changes in Cl^- uptake were seen in the STR or CTX, but a 30 % decrease was seen in the HIP of BCO gerbils.

These results do not support the hypothesis that a loss of $GABA_A$ receptor function plays a role in overstimulation and neuronal death, but they do not rule it out. GABA neurotransmission may be impared in specific populations of neurons within a brain region, but not detected in synaptoneurosomes from an entire brain structure. 385.14

EFFECTS OF BILATERAL CAROTID ARTERY OCCLUSION (BCO) ON THE $GABA_A$ RECEPTOR/CHLORIDE CHANNEL IN MONGOLIAN GERBIL BRAIN: AUTORADIOGRAPHY USING ^{35}S-TBPS. Martha L. Ehrmann*, Beth E. Mileson, Patricia P. Edgar, and Rochelle D. Schwartz, Dept. of Pharmacology, Duke University Medical Center, Durham, NC 27710.

The role of GABAergic neurotransmission following transient forebrain ischemia was investigated in brain regions selectively vulnerable to neuronal injury. Gerbils were subjected to 5 min of BCO and allowed to recover for 1 or 4 days. Behavioral and histologic analyses were performed to assess the extent of CA1 hippocampal damage. A significant correlation was observed between the extent of CA1 hippocampal degeneration and increased locomotor activity. Gerbils with > 100% increase in locomotor activity were subsequently used for autoradiography. Slices from the cortex, striatum, hippocampus, and cerebellum were incubated with 1 nM ^{35}S-TBPS and exposed to film for autoradiography (Edgar and Schwartz, J. Neurosci. 10:603-612, 1990). Significant decreases in TBPS binding 4 days following BCO were observed in the hippocampus: stratum oriens (CA1, 35%; CA2, 20%), CA1 molecular layer (44%), stratum radiatum (CA1, 14%; CA3, 14%), and in the lateral striatum (55%), n=9. No changes in binding were observed in the cortex or cerebellum. These studies indicate that the binding of a probe to the Cl^- channel of the $GABA_A$ receptor is significantly altered in certain regions of the gerbil hippocampus and striatum that were damaged following transient ischemia. This may represent altered Cl^- ion channel activity associated with loss of specific neurons. Our ongoing studies will indicate whether receptor binding changes occur prior to neuronal degeneration and/or if compensatory changes occur over time following neuronal degeneration.

THROMBOSIS IN PARIETAL CORTEX OF RATS IMPAIRS LEARNING IN A 14-UNIT T-MAZE. D. Ingram, E. Spangler*, B. Jones, P. Garofalo*, M. Jucker, J. Long, M. Pontecorvo. Gerontol. Res. Ctr., NIA, NIH, Baltimore, MD 21224; Nova Pharmaceutical Corp., Baltimore, MD 21224.

Using a photochemical method (Watson B. *et al., Ann Neurol* 17:497, 1985), focal thrombosis was produced in parietal cortex (PCtx) of 3-mo old male F-344 rats. One wk after implantation of jugular catheters, experimental rats (n=7) were anesthetized by halothane; given scalp retraction; injected with rose bengal dye (60mg/kg) via catheter; and then illuminated on cranium (bregma coordinates: A/P=-1.6;M/L=4.3 mm) with a high intensity light source for 40 min bilaterally. Controls (n=7) received identical treatment except for dye injection and skull illumination. After 10 days rats were pretrained in 1-way active avoidance to criterion (8 avoidances/10 trials), and 24 hr later received 15 trials in a 14-unit T-maze with performance sensitive to aging and septo-hippocampal damage (Ingram D., *Neurobiol. Aging*, 9:475, 1988) as well as to aspiration lesions of PCtx during acquisition (Berman R. *et al. Soc. Neurosci. Abst.*, 14:234, 1988) but not retention (Jucker M. *et al. Physiol. Behav.* 47:207, 1990). Rats locomoted to goal through 5 maze segments each within 10 sec to avoid footshock. Compared to controls in the T-maze, PCtx-damaged rats had increased errors, runtimes, shock frequencies and durations. In pretraining, no differences were observed in shock avoidance. Thus, the infarct primarily affected cognitive performance in the maze. Histological assessment showed infarct usually confined to PCtx with no hippocampal encroachment but occasional occipital cortex damage. Additional experiments using occipital cortex infarct will determine the significance of this damage. However, results suggest PCtx involvement in the age-related learning deficit in this task and provide a model of cerebral ischemia with a well-defined functional impairment.

385.16

PHOTOCHEMICALLY-INDUCED ISCHEMIA OF THE FRONTAL CORTEX RESULTS IN A TRANSIENT MEMORY IMPAIRMENT IN RATS. D. B. Clissold, B. E. Jones, R. G. Cutler*, and M. J. Pontecorvo. CNS Pharmacology, NOVA Pharmaceutical Corp., Baltimore, MD 21224.

Exposure of the rat motor cortex to an intense light in the presence of a fluroescin dye initiates a sequence of events, including local thrombosis and subsequent infarct, that mimic the events occurring during a stroke in man. We now report that it is possible to produce a bilateral infarct in the dorsal-medial prefrontal cortex of the rat which results in a reliable impairment of delayed alternation memory performance.

Rats were trained to alternate responses between two levers. Intertrial (retention) intervals of 2.5, 5 and 10 seconds were randomly distributed within each session. Upon reaching criterion rats were assigned to a Lesion or Sham group (n=5). The lesion was produced by administering the fluroescin dye rose bengal, i.v., exposing the skull, and centering a 6 mm diameter beam of high intensity light 2 mm anterior to Bregma for 60 minutes. The lesion produced a significant, retention interval-dependent impairment of alternation accuracy over the first post-operative week . Mean percent correct at the 2.5, 5 and 10 sec intervals was 97, 89, and 78 in the Sham and 96, 87, and 69 in the Lesion group. With continued testing, the magnitude of the deficit diminished. The lesion did not affect one measure of performance (probability of any response) but slightly increased the latency to a response (reaction time).

THE EFFECTS OF TRANSIENT ISCHEMIA ON THE M1 MUSCARINIC RECEPTOR IN GERBIL FOREBRAIN. G.R. Luthin and C.S. Lin. Department of Physiology and Biophysics and Institute for Neuroscience, Hahnemann University, Philadelphia, PA 19102.

Transient ischemia produces selective neuronal death in gerbil forebrain. The goal of this study was to establish the pattern of staining of another marker, the m1 subtype of muscarinic acetylcholine receptor (m1 mAChR), following ischemia. This marker was chosen based on our recent observation that regions known to contain high levels of m1 mAChR are those most affected following ischemia. An anti-peptide antiserum was produced in rabbits, affinity purified and used to localize the m1 mAChR in gerbil brain. Ischemia was produced by bilateral carotid occlusion (5 minutes). 5-7 days following the occlusion, gerbils were sacrificed, perfused with 3% paraformaldehyde, and brains were sectioned with a vibratome. Tissue was blocked with 10% normal donkey serum, incubated with primary and secondary antibodies, and the m1 mAChRs were localized using DAB as substrate for HRP. The brain regions showing a decrease of m1 mAChR staining directly paralleled those evidenced by staining with silver. These include the hippocampus, but not the dentate, and lateral portions of the caudate-putamen. These data indicate that there is a direct correspondence between the neuronal areas containing a high concentration of m1 mAChRs and those most vulnerable to transient ischemia.

SILICONE CYLINDER EMBOLIZATION AS A RAT STROKE MODEL. A.D. Perez-Trepichio and S.C. Jones. Cerebrovascular Res. Lab., Cleveland Clinic Foundation, Cleveland, OH 44195

Reliable stroke models are important for further investigation of the pathophysiology and treatment of stroke. Silicone cylinder embolization, in contrast to the middle cerebral artery (MCA) occlusion, avoids craniotomy, leading to a less traumatic model.

Seven male Sprague-Dawley rats weighing (293 ± 6 g, mean ± SEM) were anesthetized with pentobarbital (50 mg/kg ip). Body temperature was maintained at 37°C during the surgery. Unipolar EEG was recorded over the MCA region. The left common carotid (LCC) was exposed and the pterygopalatine artery electrocoagulated. The LCC was temporarily clamped, for less than 10 min to allow cannulation of the left external carotid. In five animals (embolized) a silicone cylinder (900 μm long, 300 μm diameter) was then infused into the left internal carotid with normal saline. Two sham animals received only normal saline. EEGs were obtained before and after embolization, under anesthesia and 24 hr later in the unanesthetized state and were analyzed using Fourier frequency analysis. Total surgery time was 80 min. After 24 hr the animals were decapitated and 2 mm brain slices were obtained. The slices were incubated with 2,3,5-triphenyltetrazolium chloride in phosphate buffer at 40°C for 30 min and fixed in formalin. The infarct volume was determined using digitized image analysis for at least 8 photographed sections for each animal.

The infarct volume ratio, expressed as percentage of total brain, was 10.68 ± 1.86%, n = 5 in embolized animals (mean ± SEM) and 0.15 ± 0.15%, n = 2 for the sham animals (mean ± range). The EEG analysis showed an immediate decrease in amplitude following embolization in the ipsilateral hemisphere. One hour and 24 hours after embolization, clinical observation showed persistent rotation to the right. This model of focal cerebral ischemia mimics, closely a clinical embolic stroke and could be developed into an awake stroke model.

385.19

DEVELOPMENT OF A NO-REFLOW MODEL OF CEREBRAL ISCHEMIA IN THE RAT USING ANGIOGRAPHY. **R.M. Kline,* T. Panetta,* B.V. Updyke and N.G. Bazan, LSU Eye Center and Neuroscience Center, New Orleans, LA 70112**

The no-reflow phenomenon and its role in the pathophysiology of human stroke are poorly understood. No-reflow is seen in rat models of global cerebral ischemia incorporating cerebrospinal fluid compression or artificially induced hypotension, although neither of these is a feature of human stroke. Because the production of no-reflow is related to the severity of ischemia produced, models that produce no-reflow may be used to help distinguish neurochemical events of pure ischemia from those due to reperfusion. Thus, a more physiologic model of no-reflow would provide unique opportunities to compare ischemic-phase events to reperfusion-phase events.

A novel *in-vivo* angiographic technique using intravascular $BaSO_4$ has been employed to identify collateral sources of blood flow in pure ligation models of cerebral ischemia. Systematic surgical elimination of observed collateral flow was achieved by permanent ligation of the internal thoracic and vertebral arteries at their origins, followed by temporary ligation of the subclavian and common carotid arteries. The hydrogen clearance technique was used to measure average cortical blood flows of 2.7 ± 1.3 cc/100g/min and midbrain flows of 3.3 ± 1.3 cc/100g/min during ischemia. No-reflow was observed in 73% of electrodes upon attempted reperfusion. Use of a standardized neurologic scoring system after 20 min of ischemia and 1 h of reperfusion documented a consistently severe clinical insult. This model provides the unique opportunity to study the effects of severe global ischemia without the additional variables of artificially increased intracranial pressure or artificially induced systemic hypotension.

385.20

DISTRIBUTION OF 14C-PHENYTOIN IN RAT BRAIN FOLLOWING MIDDLE CEREBRAL ARTERY OCCLUSION (MCAO). W.P.McNally, P.DeHart*, J.J.Cordon, D.M.Rock, C.P.Taylor. Parke-Davis Pharm. Res., Ann Arbor, MI 48105

In several rodent models phenytoin (P) has been reported to reduce neuronal cell loss following temporary global ischemia or permanent focal ischemia resulting from MCAO. We examined the distribution of P in brains of MCAO (with ipsilateral carotid artery occlusion) and sham operated rats. Animals were given 30 mg/kg(50 µCi) 14C-phenytoin IV, 30 min. after surgery and sacrificed under halothane anesthesia at 0.25, 1, 2, or 4 hrs after dose for sectioning and quantitative autoradiographic analysis. Radioactivity (R) was evenly distributed in gray matter at 15 min. although slightly lower levels were seen in neocortex on the operated side of MCAO brains. Only a relatively small (2-4mm) area originating in agranular-parietal cortex contained significantly lower R than surrounding tissue, in spite of the fact that in separate studies of matched rats kept two days after MCAO much larger areas were infarcted. From 1 through 4 hours R in this small area (core of infarct) increased and was considerably higher than surrounding cortex or sham operated cortex at 4 hr. Distribution patterns suggest diffusion of R into ischemic regions presumably from residual collateral circulation. Thus, P distributes homogeneously and rapidly to brain tissues despite greatly reduced blood flow in MCAO induced focal ischemia in the rat. Persistence of R in core of infarct may result from lack of circulation in the area.

SEX DIFFERENCE IN VULNERABILITY TO SEVERE FOCAL CEREBRAL ISCHEMIA. K.E. Pazara*, K.L. Linseman*, P.A. Yonkers and E.D. Hall. CNS Dis. Res., The Upjohn Co., Kalamazoo, MI 49001.

Possible gender-related differences in ischemic and post-ischemic pathophysiology and neuronal damage were examined in Mongolian gerbils subjected to a 3 hr. period of unilateral carotid occlusion (UCO). Only gerbils showing neurological signs of UCO-induced cerebral ischemia were studied. In initial experiments, it was observed that females displayed significantly less 24 hr. post-ischemic neuronal necrosis in both the hippocampal CA_1 and lateral cortical regions. Males exhibited 34.8% more necrosis in CA_1 and 38.3% more in the lateral cortex. In a second set of mechanistic experiments, no difference was observed in cortical blood flow between the two sexes before, during or for 2 hr. after the 3 hr. UCO. Moreover, the ischemic decline in cortical extracellular calcium did not differ, but the post-ischemic recovery was significantly greater in the females. Measurement of brain vitamin E levels as an index of lipid peroxidation (LP) showed a 43.5% decline by 2 hrs. after reperfusion in males while in females the decline was only 4.2% ($p<0.05$). Previous studies showing protective effects of antioxidants in this model have suggested an important role of oxygen radical-induced LP. Thus, it is postulated that the lesser ischemic vulnerability and preservation of brain vitamin E in females may be due to an antioxidant effect of endogenous estradiol.

386.2

COUPLING OF METABOLISM AND ELECTRICAL ACTIVITY IN CORTICAL ASTROCYTES IN CULTURE. D.E. Harold and W. Walz. Dept. of Physiology, Univ. of Saskatchewan, Saskatoon, Sask., S7N 0W0, Canada.

The effect of metabolic inhibitors and of ouabain on membrane potential and input resistance of primary cultures of astrocytes from newborn Swiss mice were evaluated. Astrocytes always react to metabolic inhibitors with an immediate depolarization and not with hyper-polarizations as neurons. Antimycin A caused depolarizations of up to 50 mV. These depolarizations are always reversible even after a 60 min exposure time. Thus astrocytes are well capable of surviving a prolonged hypoxic insult. The glycolytic inhibitors Na fluoride and iodoacetic acid caused an initial depolarization rate of 0.6 respective 0.7 mV/min, which is less than the 1.2 mV/min caused by ouabain. Addition of ouabain did not exceed the 1.2 mV/min rate. Thus it seems that inhibition of glycolysis exerts its effects by Na^+, K^+ pump blockade via ATP depletion. Long-term exposure (>20 min) to the reversible glycolytic inhibitor Na fluoride caused irreversible effects depending on the amount of depolarization which were accompanied by a 3-5 times increase in resistance. Astrocytes were usually capable of recovering well from similar depolarizations caused by ouabain. Thus, we conclude that inhibition of glycolysis is causing irreversible damage, which is not directly related to the resulting ion gradient breakdown.

MEASUREMENT OF HYDROXYL RADICALS BY QUANTITATION OF METHANE SULFINIC ACID (MSA). M.A. Elchisak, L. Kendall,* C. Babbs,* and M.C. Scott. Dept Vet Physiol and Pharmacol, Purdue Univ, West Lafayette, IN 47907.

Production of hydroxyl free radicals is difficult to measure due to their short half-lives. We report here a method to measure MSA, the immediate and stable product of a trapping reaction between a hydroxyl radical and DMSO. We used HPLC with dual-coulometric electrode electrochemical detection. The column was silica-based trimethyl (Burdick and Jackson, 5 micron) and the mobile phase (pH 3.4) was sodium acetate (100 mM) and tetrabutylammonium hydroxide (8 mM). Output was monitored from the second working electrode (W2). MSA produces a response approximately 30,000 times greater than DMSO, thus allowing measurement of small amounts of MSA in the presence of large amounts of DMSO, even though the resolution (alpha) between the two compounds is only 1.2. The detector response was linear for MSA between 0.39 and 200 pmol. This method was utilized to quantitate MSA in perfusate from the transendothelially perfused rat lung to study pulmonary generation of hydroxyl radicals during reperfusion injury. No sample preparation was required prior to the HPLC analyses. The within-assay coefficient of variation (CV) for these samples ranged from 0.40 to 1.44 percent (n=3); the between-assay CV was 5.4% (n=2).

BRAIN DAMAGE IN THE NEWBORN PIGLET AFTER HYPOXIA AND SEVERE PNEUMOTHORAX. C.S. Easley*, A.E. Kopelman*, F.S. Wartman*, T. Conner-Kerr*, and T.M. Louis. Depts. of Pediatrics and Anatomy/Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858.

We examined the effect of severe pneumothorax (SP) in combination with hypoxia on brain histopathology in 32 newborn piglets. This model parallels hypoxic ischemia seen in newborn infants with air block syndrome. We randomly assigned the piglets to 4 groups: control, hypoxia only, SP only, or a combination of hypoxia and SP. We produced hypoxia in halothane-anesthetized piglets by having them breathe a 1:1 mixture of air and nitrous oxide for 2 hours. We then induced SP by injecting air into the right pleural cavity until the mean systemic blood pressure fell to 33% of baseline and was maintained for 4-16 minutes. Blood pressure, heart rate, blood gases, and blood chemistries were monitored throughout the surgical procedures. We resolved the SP and re-stabilized and maintained the piglets for 3-7 days. The basal ganglia, neocortex, and hippocampus were examined for pathological changes using a silver impregnation method highly selective for degenerating neurons. The brain regions were scored by an independent observer for the presence or absence of damage and analyzed using a Fisher's exact test. Damage was found only in the animals exposed to a combination of SP and hypoxia. Neurons containing silver precipitate were found in the dorsal lateral basal ganglion and the depths of neocortical sulci. We rarely found degenerating neurons in the hippocampus. (Partially supported by the NC Affiliate of the American Lung Association).

EFFECTS OF HYPOXIC ISCHEMIA ON SOMATOSENSORY EVOKED POTENTIALS IN NEWBORN PIGLETS. T.A. Conner-Kerr*, T.M. Louis, R.H.Ray. Depts. of Anatomy & Cell Biology and Physiology, East Carolina Univ., Greenville, NC 27858

The purpose of this study was to determine the effects of hypoxic ischemia on the somatosensory evoked potential (SEP) of the newborn piglet. Newborn piglets under halothane anesthesia received one of the following treatments: sham (n=3), hypoxia (n=3), ischemia (n=2), hypoxic ischemia (n=4). SEPs were recorded at the following times: baseline, 1 hour, 2 hours, 3 hours, and 7 days after treatment. SEPs were also recorded during the 4 minute ischemia, 8 minutes, 15 minutes, and 30 minutes after ischemia. Stimuli were delivered to the volar pad of the forelimb (20 mv intensity, 0.3 ms duration, 1/s). The active recording electrode was placed intradermally over vertex and the reference electrode was clipped to the ear. A Nicolet 1170 was used to average the SEPs over 128 stimulus trials. SEPs of animals which received hypoxia alone did not become isoelectric at any time. However, SEPs were isoelectric during ischemia in both the ischemia only and hypoxic ischemic animals. Waveshape analysis indicated that the waveshape remained changed after 7 days only in animals which received ischemia and hypoxic ischemia. We conclude that SEPs provide a reliable noninvasive technique for early detection of events leading to hypoxic ischemic encephalopathy in newborns.

PERINATAL HYPOXIC-ISCHEMIC (HI) BRAIN INJURY ALTERS STRIATAL AMINO ACID EFFLUX IN RAT BRAIN: AN IN VIVO MICRODIALYSIS STUDY. K Gordon, J Simpson, D Statman, FS Silverstein. Depts of Pediatrics and Neurology, University of Michigan, Ann Arbor, MI.

We used microdialysis (MD) to determine the influence of an acute HI insult on striatal extracellular fluid (ECF) excitatory amino acid (EAA) efflux in perinatal brain. In 7 d.o. rats, MD probes were inserted into the right striatum. To induce HI injury, the right carotid artery was ligated and animals were exposed to 8 % O2 for 2.5 hr (n=22). Ischemia alone (n=10), hypoxia alone (n=8), and untreated controls (n=17) were also studied. With an HPLC-EC assay, glutamate (GLU), aspartate, asparagine, serine, glutamine, glycine, taurine (TAU), & alanine were consistently detected in dialysates; baseline GLU efflux was 2 pmol/min. In untreated controls, efflux values were stable over 4 hr. During HI, efflux values fluctuated widely and there was marked intra- and inter-animal variability. Significant changes in HI animals included: transient increases in GLU (peaks > mean+2 SD) in 0/17 controls & 8/22 HI, $p<0.03$, 2-tailed, Fisher's exact test; increased taurine efflux in 10/22 HI (vs 1/17 controls), $p = 0.01$, and in 7/8 HI animals with the greatest increases in GLU ($p<.006$). ASP efflux did not change during HI. GLU and TAU efflux did not change in ischemia- or hypoxia- alone controls. In this experimental model of perinatal HI brain injury 1) HI stimulates transient bursts of GLU release, 2) TAU efflux rises co-incident with GLU accumulation, and 3) patterns of striatal EAA efflux differ considerably from findings in stroke models in mature brain.

AGE AND SUBSTRATE DEPENDENCE OF ANOXIC DAMAGE IN RAT HIPPOCAMPAL SLICES. E.L. Roberts, Jr. and T.J. Sick. Department of Neurology, University of Miami School of Medicine, Miami, FL 33136

Metabolic substrate concentrations and type were altered to see if the diminished recovery of ion transport and of synaptic transmission following anoxia in hippocampal slices from aged rats (26-27 mon.) (Roberts, E.L., Jr. *et al.*, *Brain Res.*, in press, 1990) might be due to age-related changes in glycolysis or oxidative phosphorylation. Hippocampal slices from rats of ages 6 (young adult) and 26 (aged) mon. were superfused with an artificial cerebrospinal fluid containing 0-20 mM glucose, and subjected to anoxia (95% N_2, 5% CO_2). Normoxia (95% O_2, 5% CO_2) followed anoxia one minute after complete loss of ion homeostasis (anoxic depolarization) in a slice. In 0 mM glucose, 20-30 mM sodium lactate was added to the superfusate to support oxidative phosphorylation. As glucose concentration increased, the duration of anoxia needed for anoxic depolarization was prolonged in young adult slices. After anoxia, the recovery of ion transport and synaptic transmission, as assessed respectively from reuptake of K^+ and from the orthodromic population spike recorded in hippocampal subfield CA1, improved as glucose concentration increased, but recovery was less in aged slices. Slices exposed to sodium lactate maintained K^+ homeostasis prior to anoxia, but varied greatly in their retention of synaptic excitability. Recovery of synaptic transmission following anoxia in sodium lactate solution was usually not seen. The faster loss of ion homeostasis during anoxia in aged slices may be due to a defect in glycolysis. Also, glycolysis may be necessary for recovery of synaptic transmission following anoxia. (Work supported in part by a research grant from the American Society for Aging Research).

NEUROPROTECTIVE EFFECTS OF ADENOSINE AGONISTS ON CEREBRAL ISCHEMIA IN THE GERBIL. R.L. Dean, D. Lutz, S. Mennerick and R.T. Bartus. CORTEX Pharmaceuticals, Inc., Irvine, CA 92718

Bilateral occlusion of the carotid arteries in the gerbil (a model of cerebral ischemia in humans), followed by reperfusion, results in elevated glutamate levels which lead to hippocampal degeneration. Adenosine A1 receptors exist in areas particularly affected by ischemia (e.g., hippocampus, striatum, cerebral cortex). This distribution is similar to that of the glutamate receptor subtype, NMDA. Since adenosine analogues are potent inhibitors of the presynaptic release of glutamate and down-modulate the postsynaptic effects of NMDA stimulation, adenosine agonists may be useful for the treatment of ischemia and stroke.

This study was designed to determine: 1) the effect of adenosine as a neuroprotectant when compared with NMDA receptor system antagonists, and 2) the neuroprotective role of A1 vs. A2 adenosine receptor-specific compounds. First, we directly compared the effects of pre-occlusion administration (ip) of the adenosine analogue, ADAC, with the selective NMDA antagonist, CPP, and the non-competitive NMDA antagonist, MK-801, for their ability to protect both histologically and behaviorally against Ischemia-induced CA1 neurodegeneration (5 minute occlusion). Next, the effects of a selective A1 agonist (CHA), A2 agonist (DMPA), and the mixed A1/A2 adenosine agonist (NECA) were directly compared to further characterize the neuroprotectant role of adenosine in this model. Because adenosine agonists produce overt side effects (e.g., sedation, hypothermia), the peripherally vs. centrally mediated protective actions were also characterized and will be discussed.

ADENOSINE ANTAGONISTS FAIL TO PREVENT ANOXIC G_K-MEDIATED HYPERPOLARIZATION OF HIPPOCAMPAL NEURONS. K. Krnjević and Y. Xu. Anaesthesia Research Dept., McGill University, Montréal, PQ., Canada H3G 1Y6.

Adenosine (ADN) has a G-protein mediated hyperpolarizing effect on hippocampal neurons (Segal (1982): Eur. J. Pharm. 79, 193). Anoxia causes a liberation of ADN from brain tissue (Berne et al. (1974): Circ. Res. 35, 262). If ADN is responsible for the hyperpolarization seen early during anoxia in pyramidal neurons (Hansen et al. (1982): Acta. Physiol. Scand. 115, 301), its action should be susceptible to block by ADN antagonists. In CA1 pyramidal cells of rat hippocampal slices at 34°, brief anoxia (2-3 min) usually evoked a reversible hyperpolarization, increase in conductance, and loss of action potentials. In 9 slices, superfusion with caffeine (in doses ranging from 0.05 to 1.0 mM) tended to augment synaptic responses and caused some progressive depolarization; but the main anoxic effects (hyperpolarization, conductance increase and inexcitability) were not consistently reduced. Similar negative results were obtained in 7 other slices when applying the even more specific ADN antagonist 8(p-sulfophenyl)theophylline. We conclude that the anoxic hyperpolarization of hippocampal pyramidal cells cannot be principally caused by adenosine release. (Supported by MRC of Canada).

ATP DOES NOT CORRELATE WITH RECOVERY FROM ANOXIA WITH THIOPENTAL IN THE RAT HIPPOCAMPAL SLICE. **I.S. Kass, J.E. Cottrell* and G. Chambers*. Anesthesiology Dept. State University of New York, Health Science Center, Brooklyn, NY 11203**

We used the in vitro hippocampus as a model system to examine whether CA 1 pyramidal cells are protected against anoxic damage by thiopental. The postsynaptic evoked population spike was recorded from the CA 1 pyramidal cells after stimulation of the Schaeffer collaterals. Significance was determined using ANOVA and t-tests ($p < .05$); values are mean ± standard error.

When the CA 1 pyramidal cells are subjected to 3.5 min. of anoxia the postanoxic population spike recovers to only 10±4 % of its preanoxic amplitude. If slices are treated with thiopental (600 uM) 15 min before,during and 10 min after anoxia there is 67±10 % recovery of the response. Thus thiopental significantly improved recovery of the response after anoxia. A lower concentration of thiopental (250 uM) also showed significant protection (24±2 %), however there was a clear dose related effect. The lowest dose of thiopental tested (100 uM) did not show significant protection (17±6 %).

Thiopental (600 uM) significantly decreased the level that ATP fell to in the CA 1 region during 3.5 min of anoxia (2.3±.11 nM/mg dry wt., untreated; vs. 1.6±.07,thiopental). After 5 min of anoxia there was no significant difference between treated and untreated slices. Only after 10 min of anoxia did thiopental show a slight preservation of ATP during anoxia.

Thus neurons in the rat hippocampal slice recover better from short periods of anoxia if they are treated with high concentrations of thiopental but this recovery does not correlate with ATP levels during anoxia.

BEHAVIORAL CHANGES FOLLOWING VARIOUS PERIODS OF TEMPORARY ISCHEMIA IN MONGOLIAN GERBILS. E. Fadda, S. Mazzari, M.M. Zanellato*, R. Zanoni*, A. Zanotti*, G. Toffano and A. Leon. Fidia Research Laboratories, 35031 Abano Terme, Italy

In gerbils, transitory forebrain ischemia can be easily produced by bilateral occlusion of common carotid arteries (CCAo) and there occurs, following reperfusion, delayed neuronal death in the CA_1 hippocampal region. We studied the changes of locomotor activity consequent to different periods of CCAo (1, 2, 3 and 5 min) at 1, 2, 6, 24, 96 hours after reperfusion. CCAo was performed in overnight fasted female gerbils (50-60 gr of body weight) after their exposure under local anesthesia: mortality rate was lower than 5%. Histopathological changes were examined in coronal sections stained with cresyl violet and silver impregnation. Locomotor activity significantly increased only following 3 and 5 min ischemia, reaching in both cases a maximum at 6-24 hrs after reperfusion and then declining. Degeneration of CA_1 pyramidal cells was evident only after 3 min of CCAo and after 5 min of ischemia, neuronal death was observed also in somatosensory cortex. These data indicate that in gerbils 1) the evolvement of hippocampal neuronal death is associated with augmented locomotor activity and 2) the behavioral and histologic changes are dependent on the duration of CCAo.

FOCAL CEREBRAL ISCHEMIA: CHARACTERIZATION OF INFARCT EVOLUTION AND EFFECTS OF GM1 TREATMENT. M.S. Seren, T. Koga*, N. Schiavo*, A. Lazzaro*, G. Vantini, G. Toffano and A. Leon. Fidia Research Laboratories, 35031 Abano Terme, Italy

In the experimental model of rat middle cerebral artery occlusion (MCAo) according to Tamura, both cortex (mainly the parietal portion) and striatum are severely damaged. In these two areas we evaluated the temporal profile of infarct progression by assessment of water accumulation (edema), ionic alterations as well as loss of characteristic neurotransmitter-related parameters. Cerebral edema appeared already at 3 hrs after MCAo reaching its maximum at 24-72 hrs and thereafter declining. Calcium and sodium accumulation showed a similar trend. Furthermore, focal ischemia induced a severe and long-lasting loss of choline acetyl transferase (ChAT) activity as well as of dopamine content. These metabolic alterations were more pronounced in striatum than in cortex and were associated with diffuse morphological damage which began to be histologically evident already after 2 hrs. In addition, the exogenous administration of monosialoganglioside GM1 (30 mg/kg post-operatively) was capable of exerting a significant neuroprotective effect. These latter results strengthen the therapeutic potential of the ganglioside in clinical situations of cerebrovascular insufficiencies.

MEMBRANE FATTY ACID CHANGES IN PRIMARY & PERI-ISCHEMIC CORTICAL TISSUE FOLLOWING ACUTE GM1 GANGLIOSIDE TREATMENT. B. Hungund, V. Gokhale, A. Ortiz, S. E. Karpiak and S. P. Mahadik. Div. Neuroscience, NYSPI & Columbi U. (P&S), N.Y., N.Y.

We have reported that 24hrs after global cerebral ischemia (gerbil) individual membrane fatty acid (FA) losses are reduced with GM1 ganglioside treatment. Here we report this protective effect of GM1 in focal cerebral ischemia [permanent occlusion of the MCAo & ipsilateral common carotid artery (CCAo) & 1hr temporary contralateral CCAo]. Three groups of rats were used - ischemic /GM1 (10mg/kg, i.m.), ischemic/saline & sham/saline. Rats were sacrificed at 3&72hrs, 4&6wks. Ipsi- & contralateral brain areas (primary & peri-ischemic) were dissected out. Total membrane fractions were isolated & treated with ethanolic HCl to produce ethyl esters of individual FAs (palmitic; stearic; oleic; linoleic; arachidonic). FA ethyl esters were analyzed by GC; values were expressed as ugms/mg membrane protein. In the primary infarct, at 72hrs, slightly reduced levels of saturated FAs & significantly reduced levels of unsaturated FAs were found. These losses were slightly reduced in GM1 rats. *In the peri-ischemic area, large (25-35%) losses of unsaturated FAs were observed, but, a (100%) increase in all individual FAs in GM1 treated rats was found.* At 4&6wks, FA levels were similar in the peri-infarct area in all groups. At 3hrs, in all groups there were no changes in FA levels. In contralateral tissue in all groups, FA levels were unchanged. The data indicate that GM1 treatment restores membrane FA acid metabolism in ischemia. Supported in part by NINCDS (NS-2525856) & FIDIA Research Foundation.

386.14

EFFECTS OF GM1 ON SPREADING DEPRESSION. P. Miu, and K. Krnjević. Anaesthesia Research Dept., McGill University, Montreal, Canada. H3G 1Y6.

Spreading depression (SD) is a transient wave of depolarization resulting from disturbances in the composition of the intracellular and extracellular ions and water. Since exogenous monosialoganglioside (GM1) reduces Ca^{2+} current (Agopyan et al., Soc. Neurosci. Abstr., 1990) and enhances Na^+/K^+ pump activity (Vyskocil et al., Pflugers Arch., 403:1, 1985) we examined the possible protective role of GM1 in SD-like depolarization. In the present study, SD-like potential changes were triggered in hippocampal slices (34°-36°) by hypoxia and high $[K^+]_o$. A tungsten bipolar stimulating electrode was placed in the s. radiatum to elicit orthodromic responses in the CA1 region of s. pyramidale.

Extracellular recordings showed that prolonged application of GM1 (1 μM) may reduce the occurrence of SD (SD in 5 out of 10 slices) as compared with controls (SD in 6 out of 9 slices). In GM1 treated slices the latency and duration of SD were increased, and the post-hypoxic positive shift was augmented as compared to the control slices. Intracellular recordings showed that GM1 (1 μM) perfusion consistently induced cell depolarization associated with an increase in R_N. No significant changes were observed in hypoxia-induced hyperpolarization between the control and GM1 perfused slices. However, the ouabain-sensitive post-hypoxic hyperpolarization was greater during GM1 perfusion (-19.4 ± 1.9 mV, n=19) than control (-9.9 ± 1.0 mV, n=14).

The results suggest that exogenous GM1 may have a protective role in ischemia through its ability to reduce Ca^{2+} current and facilitate Na^+/K^+ pump.

Supported by Medical Research Council of Canada.

GM1 GANGLIOSIDE TREATMENT MAINTAINS CAPACITY OF ISCHEMIC TISSUE TO DEFEND AGAINST FREE RADICAL DAMAGE. S. P. Mahadik, J. Murthy*, A. Ortiz & S. E. Karpiak. Div. Neuroscience, NYSPI, and Columbia U., Physicians & Surgeons, New York, NY.

We have shown in rat, that cortical focal ischemia initiates a series of acute biochemical changes: cellular levels of Na+, K+, Ca2+; loss of plasma membrane Na+,K+- & Ca2+-ATPase; and increases in oxy-radicals, which reflect a general failure of plasma membrane function in primary & peri-infarct areas. Plasma membrane failure is thought to result from toxicity due to increased oxy-radical levels. This toxicity can be eliminated by the synergism of superoxide dismutase (SOD), catalase (CAT) & glutathione peroxidase (GSHPOD). We find these enzyme levels very low in normal tissue but increase (SOD=65%; CAT=250%; GSHPOD=120%) in the primary infarct, persisting up to 6 wks. Since irreversible membrane function loss occurs by 72 hrs, enzyme level increases are too slow to fully counteract oxy-radical toxicity. We have reported that acute GM1 ganglioside treatment of ischemia reduces membrane function losses. We have tested whether GM1 increases enzyme levels of oxy-radical metabolism *sooner.* Rats were treated with GM1 immediately after ischemia. Enzymes were assayed at 24,48&72hrs. No differences were found between GM1 treated & saline injected ischemic rats. But, *in GM1 treated rats, no loss of membrane fatty acids or* other membrane function parameters (supra) were seen. These data indicate that GM1 treatment protects membrane function and *preserves* normative physiological responses to defend against oxy-radical toxicity. Supported in part by NIH (NS-2525856) & FIDIA Research Foundation.

GM1 GANGLIOSIDE PREVENTS HYPOXIA-INDUCED NEUROTRANSMITTER CHANGES IN THE BRAIN OF THE DEVELOPING RAT. N.H. Neff, J. Stanisic, D. Krainc, and M. Hadjiconstantinou. Departments of Pharmacology and of Psychiatry, The Ohio State University College of Medicine Columbus, Ohio 43210 USA

Exogenously administered GM1 ganglioside (II^3NeuAc-GgOse$_4$Cer) promotes recovery of biochemistry, morphology and function following selective lesions of the nervous system. We have evaluated the consequence of administering GM1 on hypoxia-induced neurotransmitter changes in neonatal rats. Seven day old rats were exposed to hypoxic conditions (8% O_2, balance N_2) for 2.5 - 3 hr and the concentration of GLU, DA, DOPAC, 5-HT, 5-HIAA and ACh assayed in hippocampus, striatum and frontal cortex 15 min after the insult. Exposure for about 3 hr resulted in significant increases of GLU, DA, 5-HT and their metabolites in all three regions of brain. For ACh there was a decreased content in the three regions of brain. Treating rats daily with GM1, 50 mg/kg i.p., beginning on day 5 and 1 hr before and after exposure to hypoxia corrected these changes including the decrease of ACh. Furthermore, GM1 also decreased the mortality of the hypoxic rats. We conclude that GM1 may be of significant benefit for treating suspected neonatal hypoxia.

AUTORADIOGRAPHIC ANALYSIS OF REDUCED [45]Ca++ LOADING IN CORTICAL ISCHEMIA WITH GM1 GANGLIOSIDE TREATMENT. N. Hernandez, A. Ortiz, M. Durkin*, A.I. Barkai*, S.P. Mahadik & S.E. Karpiak. NY State Psych. Inst., & Columbia U. (Physicians & Surgeons), NY, NY.

GM1 ganglioside treatment reduces injury (edema, Na+, Ca++ increases) & behavioral deficits after CNS ischemia. We report here an autoradiographic study of [45]Ca++ uptake in ischemia, & the effects of GM1 treatment. Ischemia is induced by middle cerebral artery (MCAo) & ipsilat. carotid artery (CCAo) occlusion & 1hr temporary contralat. CCAo. Tissue is restricted to cortex; no tissue pathology occurs in subcortical areas. Our prior studies indicate that maximal Ca++ levels in primary & peri-infarct areas occur 72hrs after ischemia (basal Ca++ levels = 10umoles/gr d.w. tissue; Ca++ in primary infarct = 170umoles/gr d.w. tissue). To visualize the Ca++ increases, at 72hrs after ischemia, rats were injected (i.p.) with 100uCi [45]Ca++. After 5hrs rats were sacrificed & coronal brain slices were prepared for film autoradiography. Data indicate that GM1 reduces both [45]Ca++ loading and infarct size. *We also observed high levels of [45]Ca++ loading in subcortical structures (thalamic nuclei, tracts & the internal capsule).* These regions show no tissue pathology. High levels of Ca++ in tertiary brain areas may reflect injury processes heretofore not included in stroke pathology. These sucortical [45]Ca++ increases were markedly reduced using GM1. The ability of GM1 to reduce Ca++ increases in primary, peri-infarct and *tertiary injury areas* may be the basis for improved recovery seen on a spectrum of complex behavioral paradigms. Supported in part by grants from NINDCS (NS-2525856) and FIDIA Research Foundation.

NERVE GROWTH FACTOR TREATMENT OF CORTICAL FOCAL ISCHEMIA. A. Ortiz, J.S. MacDonall , S.P. Mahadik & S.E. Karpiak. Div. Neuroscience, NYSPI, & Columbia U., Coll. Physicians & Surgeons, N.Y., N.Y.

We are studying the role of NGF in recovery processes following cortical focal ischemia. We report here a study of intraventricularly (icv) injected NGF on neurological, sensory/motor, cognitive functions, and associated biochemical parameters (tissue ion concentrations, and changes in enzymes of oxy-radical metabolism) after cortical focal ischemia in rats. Previous reports indicate that NGF treatment after CNS lesion reduce behavioral dysfunction and protect selective neuronal damage. We have reported that rats with cortical focal ischemia [middle cerebral artery (MCAo) and common carotid artery occlusion (CCAo)], exhibit sensori-motor & cognitive dysfunctions, and, loss of plasma membrane function. Forty rats exposed to cortical focal ischemia and sham controls received 4 icv injections of either mNGF (supplied by Dr. E. Johnson: 2.5S: 10ug dissolved in 5ul saline) or saline, at 0,24,48&72hrs after surgery. After fourteen days, rats are exposed to a series of behavioral tests [days 14-40]. These include the tail-hanging, prehensile-traction, inclined plane and pole balancing tests. Spontaneous activity is also electronically monitored. In addition rats are trained and tested on a cognitive paradigm (spatial reversal learning). After all behavioral testing rats are sacrificed and tissue is analyzed for ion concentrations as well as levels of enzymes involved in oxy-radical toxicity (e.g. catalase). Initial data indicate that NGF treatment can ameliorate behavioral dysfunction associated with the ischemic injury. Supported in part by NINCDS (NS-2525856) & FIDIA Research Foundation.

PATTERN OF BEHAVIORAL DEFICITS FOLLOWING FOCAL CEREBRAL ISCHEMIA IN RATS: SENSORIMOTOR INTEGRATION AND COGNITIVE FUNCTION. C.G. Markgraf, B.E. Hurwitz, E. Morikawa*, W.D. Dietrich, M.D. Ginsberg, E. J. Green, P.M. McCabe and N. Schneiderman. Dep'ts. Psychology and Neurology , Univ. of Miami, Coral Gables, FL 33124.

Assessment of behavioral recovery of animals following focal cerebral ischemia is often difficult due to the subjective nature and limited scope of many behavioral tests. Using a number of behavioral tests, the present study quantified neurologic status in 6 Sprague-Dawley rats with proximal middle cerebral artery occlusion (MCAO) and 6 sham operated rats. MCAO leads to reproducible infarction of the striatum and overlying cortex. Five tests designed to measure forelimb reflexes and sensorimotor integration were given twice weekly for 1 week pre-operatively and 4 weeks post-operatively. ANOVA revealed no differences between the groups pre-operatively. Two days after MCAO, infarcted animals displayed significant neurological deficits compared to controls in abnormal posture when lifted by their tails; in foot faults on an elevated grid; on a bilateral assymmetry test of sensory neglect, and in contralateral limb placing to visual and tactile stimuli. Observed deficits were maximal on days 2-7 post-operatively and gradually recovered to control levels by day 28. Deficits were not seen in ipsilateral limb placing or on a test of strength on an inclined screen. Following the 30 days of neurologic testing, animals were given 10 days of testing in the Morris water maze, a test of spatial mapping ability. While ANOVA revealed that both MCAO and sham groups showed a decrease in latency to locate the hidden platform over days, the MCAO animals were consistently slower (latency=16.8 ± 1.5 sec. vs. 6.3 ± 1.5 sec. on day 10) and significantly less accurate in their initial heading than were controls. This battery of tests reveals a comprehensive picture of the deficits following MCAO and indicates that while sensorimotor integration recovers over 28 days, cognitive mapping deficits persist, paralleling results reported in human patients with striatal infarcts.

ARGININE VASOPRESSIN (AVP) AND EDEMA IN INTRACEREBRAL HEMORRHAGE. G.A. Rosenberg, O. Scremin, E. Estrada*, W.T. Kyner*. Neurology and Research Services, Veterans Medical Center, and Departments of Neurology, Physiology and Mathematics, University of New Mexico School of Medicine, Albuquerque, NM 87131

Vasopressin increases brain water and worsens brain edema. We used a model of edema after an intracerebral hemorrhage to determine the role of the AVP V_1-receptors. Adult rats had hemorrhages induced in the caudate-putamen by the infusion of 0.4 U (n=9) or 0.5 U (n=9) of bacterial collagenase. Two groups had 75 ng of a V_1- receptor antagonist, $d(CH_2)_5$,Tyr(Me),Arg, infused along with either 0.4 (n=9) or 0.5 U (n=9) of collagenase. Twenty-four hours after injection brain water and electrolyte contents were measured in 8 brain regions. Cerebral blood flow (CBF) was measured with the ^{14}C-iodoantipyrine autoradiographic method 24 hours after injection with either 0.5 U of collagenase (n=6) or saline (n=6). The V_1 antagonist significantly ($p<0.05$) reduced edema without altering CBF. AVP V_1-receptors are important in edema after an intracerebral hemorrhage.

ALZHEIMER'S DISEASE: CYTOSKELETON

TAU PHOSPHORYLATION IN HEAT-SHOCKED FEMALE AND MALE RATS AND CEREBRAL EXPLANTS. S. Ch. Papasozomenos and Y. Su . Dept. of Path., Univ. of Texas Med. Sch., Houston, TX. 77225.

We have previously shown that in the somatodendritic compartment of neurons tau becomes phosphorylated at or near the epitope of the antibody Tau-1 preventing its binding. To investigate whether the excessive tau immunoreactivity seen histologically in Alzheimer's disease might be stress-induced, we have studied control and heat-shocked (42°C for 15 min) 2-3-month-old female (5 pairs) and male (8 pairs) Sprague-Dawley rats and control and heat-shocked (42°C for 20 min) fetal rat cerebral explants. Six hr after heat shock, immunoblotts of SDS extracts from rat cerebrum and explants were analyzed by using Tau-1 (provided by Dr. L.I. Binder) and ^{125}I-protein A with and without pretreatment with alkaline phosphatase. In heat-shocked female rats there was: a) excessive phosphorylation of existing tau indicated by an increase in the ratio: phosphorylated + non-phosphorylated = total/non-phosphorylated Tau-1 epitope (4.04 vs 2.02, $p < 0.001$); b) a non-significant change of the total (cpm:5,051 vs 4,525, $p < 0.5$); and c) a marked reduction of non-phosphorylated tau (cpm:1,611 vs 2,627 $p < 0.01$). Similar but less pronounced changes were observed in age-matched male rats with the respective numbers being: a) 2.78 vs 2.42, $p < 0.05$; b) cpm:8,093 vs 10,376, $p < 0.5$; and c) cpm:2,960 vs 3,585, $p < 0.001$. On the contrary, in heat-shocked cerebral explants there was a marked increase in the amount of both total (cpm:8,032 vs 4,453, $p < 0.05$) and (cpm:5,455 vs 1,434, $p < 0.01$) tau and a pronounced decrease in the ratio: total/non-phosphorylated (1.50 vs 3.12, $p < 0.02$) due to excessive amounts of non-phosphorylated tau. This decrease in phosphorylation caused loss of the most slowly moving 60 Kd tau polypeptide. These findings suggest that tau plays a role(s) in the stressful response by altering its state of phosphorylation.

ANTIGENIC HETEROGENEITY OF NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE W.Bondareff, C.M. Wischik,Dept. of Psychiatry, University of So. California, Los Angeles, and M.R.C. Laboratory of Molecular Biology, Cambridge, England.

Antibodies directed against three regions of tau have been used to distinguish two populations of neurofibrillary tangles. Intracellular tangles, immunolabelled by polyclonal antibodies directed against N- and C-termini of tau were shown to be antigenically distinct from extracellular tangles, immunolabelled by monoclonal antibodies against antigens in the triple repeat region of the molecule. Exposure of the latter appeared to be associated with the proteolysis of paired helical filaments occurring in the extracellular compartment. In the CA1 region of hippocampus, a subset of extracellular tangles were immunolabelled also by monoclonal antibodies against B-amyloid in some patients. These patients were characterized by a severe degree of pyramidal cell loss and a high number of extracellular in CA1.

TRANSFECTION OF cDNAs ENCODING DIFFERENT ISOFORMS OF HUMAN TAU. M.M.S. Lo[1], A.W. Fieles*[1], C.B. Caputo[1], L.G. Sygowski[1], C.W. Scott[1], and M. Goedert*[2]. [1]ICI Americas, Wilmington, DE 19897, and [2]MRC Laboratory of Molecular Biology, Cambridge CB2 2HQ, U.K.

Tau proteins are low molecular weight microtubule-associated proteins normally expressed throughout the mammalian nervous system. Tau is also found in the protease-resistant core of the paired helical filament, which forms the bulk of the neurofibillary tangles found in neuropathologic brain samples of Alzheimer's disease. The genes encoding for six different tau isoforms, cloned from human cDNA libraries (Goedert et al., Neuron 3:519, 1989), were subcloned into expression plasmids and transfected into 3T3 fibroblasts and PC12 cells. High levels of transient type I tau (3 repeat) expression were detected by immunofluorescence assays with anti-tau antibodies in 3T3 cells. In most cases tau protein was in either small intense patches within cell bodies or in processes. In one case intense nuclear staining was detected. Stable PC12 transformants, cotransfected with the *neo* gene and selected with G418, showed vey low levels of tau expression In contrast, moderate levels of tau expression was detected in stably transformed 3T3 cells. Tau staining was found in the cytoplasm and in very long, thin, and branched "neurite-like" extensions. The stability of microtubules formed within these cell lines (and others transfected with plasmids encoding for the different human tau isoforms) will be tested by treatment with microtubule-depolymerization drugs such as colchicine and nocodazole.

ALZHEIMER BRAIN FRACTIONS BEARING PHF CONTAIN WHEAT GERM AGGLUTININ BINDING ACTIVITY. L. McLaughlin, F. P. Zemlan, and G. E. Dean. Department of Mol. Genetics, Biochemistry, and Microbiology, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267-0524.

Alzheimer brain neurofibrillary tangles, composed primarily of paired helical filaments (PHF), have been previously reported (Szumanska et al, 1987. Acta Neuropath., Berl. 73:1-11) to bind wheat germ agglutinin (WGA). Fractions of Alzheimer brain extracts highly enriched in PHF have been separated by SDS PAGE, electroblotted, and the blots probed with WGA coupled to horseradish peroxidase (HRP). Alzheimer-specific reactivity was observed at positions corresponding to M_R's of 85, 74, 39, and 37 kD, lacking in similarly obtained fractions from normal brain. When probed with antibodies reactive with purified PHF proteins, immuno-reactivity was observed at M_R positions corresponding to 85 and 37 kD in both Alzheimer and normal samples, suggesting that certain normal proteins are inappropriately glycosylated in Alzheimer brain tissue.

387.5

PHOSPHORYLATED TAU IN ALZHEIMER'S DISEASE PAIRED HELICAL FILAMENTS. L. Baum, E. Masliah, K. Ueda*, D. Iimoto, T. Saitoh, UCSD, School of Medicine, Dept. of Neurosciences, M-024, La Jolla, CA 92093.

Paired helical filaments (PHF) are found in the degenerating neurites surrounding amyloid plaques, and in the neurofibrillary tangles (NFT) of Alzheimer's disease (AD). A major PHF constituent is abnormally phosphorylated tau, a microtubule-associated protein. Phosphorylation of microtubule-associated proteins is known to reduce their ability to promote microtubule polymerization. One could speculate that abnormal phosphorylation of tau may disrupt the neuronal cytoskeleton, contributing to cell injury and death.

Either acid or alkaline phosphatase treatment of AD brain sections enhances NFT staining with anti-tau monoclonal antibody (mAb) Tau-1, suggesting that the Tau-1 epitope is masked by phosphorylation in AD NFT. Phosphatase treatment of immunoblots of AD brain pellet fractions and of purified PHF also enhanced Tau-1 binding to a doublet of ~60 kD mol. wt.

NFT is also stained by Alz-50, a mAb that preferentially stains AD brain and is not sensitive to alkaline phosphatase treatment. However, we found that acid phosphatase reduces Alz-50 staining of NFT. Furthermore, phosphoserine, but not serine or phosphothreonine, diminishes Alz-50 staining of NFT, pointing to phosphorylated serine(s) on tau as the epitope for Alz-50.

The tau sequence contains at least four theoretical serine phosphorylation sites for casein kinase II (CK-II), and tau is phosphorylated by CK-II. We previously found that anti-CK-II immunoreactivity is localized to NFT, and that purified CK-II binds NFT on AD brain sections. We are now investigating the possibility that CK-II may contribute to the phosphorylation of tau at Tau-1 or Alz-50 epitopes.

387.6

A NOVEL NEUROFILAMENT KINASE. H.M.Roder* and V.M.Ingram. Dept. of Biology, Mass. Inst. of Tech, Cambridge, MA 02139

The two heavier subunits of mammalian Neurofilaments (NF) (Mw 68, 160, 200kD) contain repeats of a Lys-Ser-Pro-sequence, which are extensively phosphorylated for as yet unknown reasons. We are purifying and characterizing a corresponding kinase not associated with the cytoskeleton by conventional 32-P-assays and a novel immunoassay. This kinase might act also on an identical site in tau protein, which seems to be phosphorylated and occurs in the carboxy-terminal portion of the molecule incorporated into the hard core of Paired Helical Filaments in Alzheimer's Disease.

A novel immunoassay based on completely dephosphorylated bovine NF-triplet and monoclonal antibodies specific for the phosphorylated Lys-Ser-Pro-sequence paved the way to partially characterize and purify a kinase activity from an ammonium-sulfate fractionated bovine brain supernatant. The activity survives chromatography only on a few media in the presence of Mg ions and ATP. Gel filtration suggests a Mw around 60kD with a probable proteolytic fragment at 40kD. All NF-subunits, native or dephosphorylated, are substrates to a varying extent. Significant levels of PO_4 are incorporated into dephosphorylated NF 160 and 200 with shifts to higher apparent Mw (SDS-PAGE) after 18 hrs of incubation. The properties of the activity, such as lack of association with cytoskeleton proteins, stability, inhibition by ionic strength and kinetic parameters, identify it as a new kinase.

387.7

EXPRESSION OF PAIRED HELICAL FILAMENT ANTIGEN IN ALZHEIMER'S DISEASE AND ISCHEMIA. M.M. Robertson, N.P. Galletly, S. Greenberg, P. Davies and C.B. Saper. Depts. of Pharm. & Physiol. Sci. and Neurology, Univ. of Chicago, Chicago, IL 60637 and Dept. of Pathology, Albert Einstein Medical College, Bronx, NY 10461.

PHF-1 is a monoclonal antibody raised against a denatured preparation of paired helical filaments from brains of patients with Alzheimer's disease (AD) (Greenberg and Schein, Soc. Neurosci. Abstr. 15:1083). We mapped PHF-1 immunoreactivity in the brains of six patients with AD, four controls without neurological disease and one 22 y.o. patient with a transient global ischemic event. In the normal brains, only occasional neurons stained, mainly in a fibrillar pattern. In the AD brains, there was fibrillar staining of cell bodies and associated dendrites, dystrophic axons in fiber pathways and dystrophic neurites in neuritic plaques. The areal and laminar staining pattern was similar to the AD pattern seen with another monoclonal antibody, ALZ-50, as well as the AD neurofibrillary degeneration visualized using thioflavin-S staining, in adjacent sections from the same brains. In the ischemic brain, PHF-1 stained neurons in a granular, cytoplasmic pattern in the medial temporal lobe only. The densest staining was in the CA1 region of the hippocampal formation, and occasional neurons in the entorhinal cortex appeared to contain immunoreactive tangles. Our observations suggest that PHF-1 stains an epitope present on paired helical filaments in AD that is also present on a protein expressed during cellular ischemic stress.

***IN SITU* HYBRIDIZATION OF CALCIUM/CALMODULIN DEPENDENT PROTEIN KINASE II AND TAU mRNAs IN ALZHEIMER'S DISEASE.** V.H. Mah, T.A. Eskin and G.A. Higgins. Univ. Rochester., Rochester NY 14642 and Gerontology Res. Ctr., NIA/NIH, Baltimore, MD 21224.

Abnormal phosphorylation of the microtubule-associated protein tau in Alzheimer's Disease (AD) may be caused by altered expression of calcium/calmodulin dependent protein kinase II (cam kinase II). We performed *in situ* hybridization studies in the human CNS to examine the expression of cam kinase II and tau mRNAs, and correlate their distribution with the presence of neurofibrillary tangles and neuritic plaques in AD. In isocortex, the laminar-specific pattern of neuronal hybridization (layers III, V-VI) was similar for both mRNAs. In some regions of association cortex, cam kinase II mRNA levels were higher than tau in layer II. In allocortex, layer II contained the highest abundance of both mRNAs. The hippocampal formation, amygdala, and nucleus basalis contained high levels of both mRNAs. In AD, areas which appeared to contain viable neurons but had large numbers of plaques and tangles showed similar levels of both tau and cam kinase II mRNAs as in control cases. Future studies will examine the expression of different subtypes of these mRNAs.

A PROGRESSIVE APPEARANCE OF A TAU-RELATED EPITOPE IN NEURITES CHARACTERIZES THE EVOLUTION OF ALZHEIMER'S DISEASE PATHOLOGY. R. Mena*[1], C.M. Wischik*[2], M. Novak*[3], C. Milstein*[4], A.C. Cuello[1]: [1], Department of Pharmacology and Therapeutics, McGill University, Montreal, Quebec, H3G 1Y6, Canada; [2], Department of Psychiatry, Cambridge University, Hills Road, Cambridge, CB2 2QQ, England; [3], Slovak Academy of Sciences, Bratislava, Czechoslovakia; [4], Laboratory of Molecular Biology, Medical Research Council, Cambridge, CB2 2QH, England.

The paired helical filament core (PHFc) present in Alzheimer's disease (AD) brains, contains the microtubule binding domain of tau (Wischik et al., PNAS (USA) 85:4884, 1988). Using the monoclonal antibody 6.423, which specifically recognizes this tau-related epitope of the PHFc, we studied frontal cortex of AD cases with short and long histories of dementia. In all cases, 6.423 mAb recognized both intracellular and extracellular neurofibrillary tangles (NFTs). However, in cases with longstanding dementia, a dense network of immunoreactive (IR) thread-like structures was observed in addition to the NFTs. The appearance of such structures seemed to lag behind that of IR NFTs. The IR thread-like material may represent fragmentation of the tangle and/or aberrant sprouting of affected neurons and, therefore, reflect the progression of AD pathology.

ALZHEIMER NEUROFIBRILLARY TANGLES CONTAIN 2.1±0.2 nm FILAMENTS THAT RESEMBLE ISOLATED BOVINE TAU PROTEIN G.C. Ruben*, °K. Iqbal, °I. Grundke-Iqbal*, °H.M. Wisniewski*, @T.L. Ciardelli* and +J.E. Johnson, Jr. Dept of Biol. Sci., Dartmouth College, Hanover, NH 03755; °Inst. for Basic Res. in Develop. Disabil., Staten Island, NY 10314; Dept of Pharm., Dartmouth Med. Sch., Hanover, NH 03756; Dept of Integ. Biol., UC, Berk., CA and Dept of Neurosci., Stanford Res. Inst., Menlo Park, CA

High resolution transmission electron microscopy (TEM) has shown that neurofibrillary tangles (NFT) contain in addition to paired helical filaments (PHF) numerous 2.1±0.2 nm filaments. These 2.1±0.2 nm filaments are triple-stranded left-handed helical structures composed of three 1.0±0.2 nm strands. These tangle filaments have been compared to purified bovine tau and found to have the same structure as judged by high resolution TEM. The reported amino acid sequence of human and bovine tau have been computer processed to predict secondary structure. Within the constraints imposed by the images, the secondary structure models and other structural information have been used to calculate tau's maximum and minimum length. This work suggests that each ~1.0 nm strand is a tau sequence and that the ~2.1 nm filament is composed of three tau sequences (tau_3). Bovine tau length measurements point out that each tau_3 filament is many times longer than a fully stretched tau monomer. These measurements indicate that tau_3 forms long polymers, $(tau_3)_n$. A inverse temperature transition has been found in the circular dichroism spectrum of tau indicating that its structure is less ordered below 20°C and more ordered at 37°C. This phenomena helps explain how tau can reconstitute microtubules above 30°C and why tau is unable to reconstitute microtubules below 20°C. The inverse temperature transition is also found in the protein elasin which aggregates at body temperature. If tau produced in Alzheimer victims was more hydrophobic than normal tau it could aggregate into tangles similar to the mechanism of elastin aggregation.

387.11

CHARACTERISTICS OF THE TAU THAT IS BOUND TO ALZHEIMER PAIRED HELICAL FILAMENTS. C.B.Caputo, C. Wischik*, W.F. Brunner*, C.W Scott* and A.I. Salama. ICI Pharmaceuticals Group, ICI Americas Inc., Wilmington, DE 19897.

Tau protein is known to be a component of Alzheimer paired helical filaments. The present study investigated the structural characteristics of the tau isolated from pronase treated PHFs (Wischik et al., PNAS,85:4506,1988). Antibodies with tau epitopes N terminal to the tubulin binding region of tau failed to react to pronase treated PHFs. Three of 4 antibodies to pronase treated PHFs reacted only after formic acid or guanidine treatment of PHFs. Two of these antibodies (751 & 795) reacted to tau isolated from normal brain whereas the other 2 (423 & 728) only recognized PHF-derived tau. The phosphate dependent antibody SMI34 also recognized tau from PHFs. The C-terminus of tau was present after pronase treatment based upon reactivity of an antibody raised to a peptide from the C terminus of tau. In conclusion, the C terminus including the whole tubulin binding region appears to be protected from proteolysis by an interaction with other PHF components & may contain phosphorylated sites & other modifications or conformations that are not always present in tau from normal brains.

387.12

MICROTUBULE REASSEMBLY IN ALZHEIMER BRAIN: AN ELECTRON MICROSCOPIC STUDY. E.M. Grollman, D.L. Rapoport* and J.A. Olschowka. Department of Neurobiology & Anatomy and Department of Neurology, University of Rochester Medical Center, Rochester,NY 14642.

Microtubules, vital cytoskeletal structures common to all eucaryotic cells, participate in many important neuronal functions including intracellular compartmentalization, neurite outgrowth and axonal transport. The microtubule-associated protein (MAP), tau, a normally occuring component of axonal microtubules has been shown to have unusual features in Alzheimer's Disease (AD) brain and may be implicated in the pathophysiology of AD. For example, Flament and Delacourte (FEBS. 247: 213, 1989) have reported AD specific isoforms of tau and markedly abnormal patterns of tau immunostaining have been demonstrated in AD brain (Kowall & Kosik, Ann. Neurol. ,22:639, 1987). Of greatest interest is the substantial amount of evidence pointing to tau as a component of the neurofibrillary tangle (NFT) (eg Woods et.al., PNAS. 83:4040,1986; Kosik et.al.,PNAS. 83:4044, 1986; Goedert et.al., PNAS. 85:4051,1988).

Though it has been reported that reassembly of microtubules from AD brain is impaired, possibly because of the presence of a dysfunctional form of tau (Iqbal et.al., Lancet. 2:421, 1986), we were able to reassemble microtubules *in vitro* from homogenates of superior frontal gyrus obtained from AD and control brains (range of postmortem delays: 4 to 14 hours). These preparations were examined electron microscopically after negative staining with 1% uranyl acetate. No intrinsic differences between AD and control were observable by this method. Ongoing research is focused on the antigenic characteristics of the reassembled microtubule in AD.

ACTIONS OF CALCIUM ON THE CYTOSKELETON AND TAU IN CULTURED HUMAN CEREBRAL CORTICAL NEURONS. M. P. Mattson, G. Perry and M. G. Engle*. Center on Aging and Dept. of Anatomy & Neurobiol., Univ. of Kentucky, Lexington, KY 40536; Inst. of Pathology, Case Western Reserve Univ., Cleveland, OH 44106.

Abnormalities in the neuronal cytoskeleton are hallmarks of an array of neurodegenerative disorders (ND). Some of the changes observed in the human brain (e.g., paired helical filaments [PHF] and neuritic plaques) have not been observed in common laboratory species. We have therefore begun to directly examine cell cultured fetal human cerebral cortical neurons (see Rychlik et al., this meeting). Since considerable circumstantial evidence supports the involvement of altered calcium homeostasis in NDs (*Mech. Aging Dev.* 50:103), we studied cytoskeletal changes associated with calcium influx using immunocytochemistry and electron microscopy. Axons in untreated neurons were dominated by parallel arrays of microtubules. Exposure to calcium ionophore A23187 resulted in a dramatic loss of microtubules, accumulations of microfilaments, and the appearance of 12-15 nm straight filaments. PHF-like structures were occassionally observed. Tau immunoreactivity increased in neurons exposed to A23187, but Western blots indicated that tau levels (as well as actin and tubulin) actually decreased as a result of calcium influx. Colchicine (but not cytochalasin D) also increased tau immunoreactivity, by a calcium-independent mechanism, suggesting that depolymerization of microtubules may be the trigger for the altered disposition of tau, and its accumulation in the straight filaments and PHF that characterize neurofibrillary tangles. Immunoelectron microscopy is now being used to more directly determine the fate of tau consequent to calcium influx. (supported by a PSP grant and an ADRDA Faculty Scholar Award to MM).

EPILEPSY: BASIC MECHANISMS II

388.1

FADING OF RECURRENT INHIBITION IN THE RAT DENTATE GYRUS IS MEDIATED BY $GABA_B$ RECEPTORS. David D. Mott and Darrell V. Lewis. Depts. of Pharmacology, Pediatrics (Neurology) and Neurobiology, Duke University Medical Center, Durham, N.C. 27710.

Recent studies have shown that the $GABA_B$ receptor agonist, baclofen, suppresses recurrent inhibition in the dentate gyrus and facilitates the development of long term potentiation. Here, we present evidence showing that released GABA, acting on $GABA_B$ receptors, causes fading of recurrent inhibition.

Fading of inhibition was studied in the dentate gyrus of the rat hippocampal slice. Stimulation was delivered to the mossy fibers (MF) in stratum lucidum of CA3b and to the perforant path (PP) in the white spot on the distal side of the hippocampal fissure. PP stimulation evoked a population spike (PS) superimposed on a population epsp recorded extracellularly in the granule cell layer. MF stimulation inhibited a subsequent PP-evoked PS through $GABA_A$ receptor-mediated recurrent inhibition. A single conditioning MF stimulus depressed subsequent recurrent inhibition. This depression of inhibition was maximal 200 msec after the MF conditioning stimulus and lasted for up to 2 sec. The $GABA_B$ receptor antagonists, phaclofen (1 mM) or 2-OH saclofen (400 uM), reduced this depression of inhibition.

Intracellular recordings from granule cells demonstrated that MF stimulation evoked a biphasic ipsp with an early component sensitive to picrotoxin (50 uM) and a late component sensitive to 2-OH saclofen (400 uM). Paired MF stimulation caused a depression of the ipsp evoked by the second stimulus. This depression was strongest when the interstimulus interval was 200 msec and was antagonized by 2-OH saclofen (400 uM).

We suggest that GABA, released by the conditioning stimulus, acts on $GABA_B$ receptors causing a depression of recurrent inhibition.

Supported by NIH grant NS22170 and CIIT.

388.2

AN AMPA/KAINATE RECEPTOR-MEDIATED COMPONENT TO EPILEPTIFORM ACTIVITY IN THE KAINIC ACID LESIONED HIPPOCAMPUS. L.H.Simpson* and H.V. Wheal, Department of Neurophysiology, University of Southampton, Bassett Crescent East, Southampton, SO9 3TU. UK.
(Sponsored by the Brain Research Association, UK).

In previous electrophysiological studies of synaptic activity in the kainic acid-lesioned rat hippocampus, we have demonstrated graded epileptiform bursting activity that is mediated, at least in part, by NMDA-receptors (Ashwood, T.J. & Wheal, H.V. (1986) Neurosci. Letts. 67, 147-152; Wheal & Turner, (1988) Soc. Neurosci. 14, 709). The purpose of the present study was to pharmacologically determine the contributions of AMPA/kainate-receptors to suprathreshold bursting activity in this model. Both intra- and extracellular studies were performed in the CA1 cells of lesioned hippocampal slices.

The AMPA/kainate-receptor antagonist, CNQX (2uM), completely blocked the evoked action potential in CA1 pyramidal cells in control slices. In contrast, in experiments on lesioned slices, CNQX failed to completely block the evoked burst. The response was reduced to one or two spikes with an increase in first spike latency from 2.8 ms (±0.2, SEM, n=10) to 4.8 ms (±0.9, SEM, n=8). The CNQX insensitive component of the burst was blocked by subsequent perfusion with a selective NMDA-receptor antagonist (D-AP5; 10uM). These data suggest that both NMDA- and AMPA/kainate-receptors contribute to the suprathreshold epileptiform burst in the kainic acid lesioned hippocampus.

Supported by the Wellcome Trust.

388.3

NMDA-RECEPTOR MEDIATED EPILEPTIFORM ACTIVITY IN ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS. T. Sakaguchi, C. Shin, and J. O. McNamara. Duke and VA Med. Ctr., Durham, N.C. 27705.

Organotypic cultures of hippocampus (HPC) provide an excellent longlasting *in vitro* system in which structure and intrinsic connectivity are relatively preserved. Many reports of neuronal activity in these cultures document more epileptiform activity than acute adult HPC slices. To study the excitability of populations of HPC neurons, we used extracellular field recording technique to characterize the organotypic HPC culture electrophysiologically.

Organotypic cultures were prepared from 6-day-old rat HPC according to the methods of Gähwiler. Recordings were made in cultures of 5-35 DIV in a submersion chamber at 36°C with ACSF (95% O_2, 5% CO_2) perfused at 2 ml/min. Extracellular field recordings were made from the pyramidal layer in CA1, with stimulation of Schaffer collaterals in CA3.

Spontaneous interictal activity was uncommonly observed (< 15% of cultures) and spontaneous ictal events were never observed. Evoked CA1 field response showed EPSP with orthodromic population spike (PS) which was often followed by a burst of low amplitude PSs. Bath-applied 50 μM D-APV suppressed the late component of the EPSP and the superimposed bursts. Addition of up to 20 μM CNQX suppressed the remaining field EPSP and PS. Removal of Mg^{++} from the bath induced evoked and/or spontaneous epileptiform activity (interictal and/or ictal) in CA1 which was also suppressed by 50 μM D-APV.

This method of slice culture provides a network virtually devoid of spontaneous epileptiform activity, yet this activity is readily inducible by removal of Mg^{++}. These electrophysiologic features, together with the advantage of long term survival, make the organotypic HPC culture a useful tool for studying the **development** of epileptiform activity in a simplified neural system.

388.4

STIMULUS TRAIN INDUCED SEIZURES IN ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS. C. Shin, T. Sakaguchi, and J. O. McNamara. Epilepsy Research Laboratory, Duke and VA Medical Centers, Durham, NC 27705.

Electrographic seizures (EGS) induced by stimulus trains in slices of adult rat hippocampus (HPC) have provided an **acute** *in vitro* model of epileptogenesis (Stasheff et al., Science, 1989). Development of a **chronic** *in vitro* model would permit study of longterm plasticity in epileptogenesis. Organotypic cultures of HPC, with long survival time, may serve the purpose. We therefore sought to determine whether stimulus train could evoke EGS in this preparation.

Organotypic HPC cultures (12-36 DIV) were studied in a submersion chamber at 36 °C with standard ACSF (95% O_2, 5% CO_2) bath. Extracellular field recordings were made in CA1 pyramidal layer, with stimulation of Schaffer collaterals in CA3. Once orthodromic responses to single shocks were stable, 2 sec trains of 60 Hz rectangular pulses (150-1400 μA) were delivered every 10 min.

Stimulus trains reliably induced EGS with the typical pattern of initial high frequency ("tonic") discharge, followed by slower frequency bursts ("clonic"). Induced EGS were of relatively long duration (5-19 sec), even on the first stimulation. With repeated stimulation, however, the duration of EGS did not reliably increase. Application of the NMDA receptor antagonist, D-APV (50 μM), modified the pattern of the EGS without consistently altering its duration. Even when D-APV was applied prior to the first stimulus, fully developed EGS appeared.

The reliable induction of EGS by stimulus trains offers considerable promise for development of a chronic *in vitro* model of epileptogenesis. The occurrence of a fully developed EGS on the first stimulus and the relative insensitivity to D-APV suggest that this preparation is hyperexcitable prior to stimulation. Study of various factors regulating this hyperexcitability during culturing process may shed light on mechanisms of epileptogenesis and on the ongoing plasticity in culture.

388.5

THE ROLES OF EXCITATORY AMINO ACID RECEPTORS IN EPILEPTIFORM ACTIVITY INDUCED BY 4-AMINOPYRIDINE IN RAT AMYGDALA SLICES. P.W. Gean. Dept. of Pharmacology, College of Med. National Cheng Kung Univ. Tainan City, Taiwan, R.O.C.

The effects of excitatory amino acid receptor antagonists on epileptiform activity induced by 4-aminopyridine (4-AP) were studied in rat amygdala slices using intracellular recording techniques. Five to ten minutes after switching to 4-AP containing solution, spontaneous epileptiform bursts were observed in 35 out of 45 slices studied. Superfusion with kynuretic acid reversibly reduced the duration of the spontaneous bursting discharges in a dose-dependent manner. The IC_{50}, estimated from the graph of the concentration-response relationship, was approximately 130 μM. In addition, CNQX which is a specific non-N-methyl-D-aspartate (NMDA) receptor antagonist blocked the spontaneous and evoked epileptiform bursting. In 11 out of 15 neurons tested, there was a residual depolarizing component remained. This depolarizing component was reversibly blocked by specific NMDA receptor antagonist, DL-2-amino-5-phosphonovaleate (DL-APV). Relative to CNQX-sensitive component, the DL-APV-sensitive component is much smaller in amplitude and shorter in duration indicating that NMDA receptor plays only a minor role in this process. These data suggest that the generation or propagation of spontaneous epileptiform events induced by 4-AP in the neurons of basolateral amygdala is mediated by excitatory amino acids and that activation of non-NMDA receptors is of primary importance.

388.6

DENTATE MOSSY FIBER SPROUTING IN KAINATE-TREATED RATS LEADS TO EPILEPTIFORM ACTIVITY WHEN SYNAPTIC INHIBITION IS DEPRESSED J. Cronin, A. Obenaus, C.R. Houser and F.E. Dudek Mental Retardation Res. Ctr. and Dept. of Anatomy and Cell Biology, UCLA Sch. of Med., Los Angeles, CA 90024.

Sprouting of the mossy fibers (MFs) into the inner molecular layer of the dentate gyrus of kainate-treated rats may cause formation of a recurrent excitatory circuit, which could hypothetically cause epileptogenesis. Extracellular recordings from slices of kainate-treated rats suggested hyperexcitability to hilar stimulation in normal solution (Tauck, D.L. and Nadler, J.V., J. Neurosci. 5:1016, 1985). We have used simultaneous intracellular and extracellular recording in hippocampal slices to examine the electrophysiology of dentate granule cells that have undergone MF sprouting. In normal solution, slices with MF sprouting usually had antidromic and synaptic responses to electrical stimulation of the hilus and perforant path that were similar to those from control animals. However, when inhibition was reduced with the $GABA_A$ receptor antagonist, bicuculline, low-intensity hilar stimulation evoked delayed bursts of action potentials. Spontaneous bursts of population spikes, which were synchronous with intracellular action potentials superimposed on a depolarization, also occurred in bicuculline-treated slices. The delayed bursts to weak hilar stimulation and the spontaneous bursts in bicuculline were not observed in slices from kainate-treated rats without MF sprouting or in control animals. Thus, MF sprouting into the inner molecular layer of dentate granule cells can contribute to epileptiform activity when synaptic inhibition is reduced.

388.7

SYNCHRONOUS ACTIVITY INDUCED BY 4-AMINOPYRIDINE (4AP) IN THE CA3 SUBFIELD OF THE RAT IMMATURE HIPPOCAMPUS. **M. Avoli, V. Tancredi, C. Zona and Y. Fueta*. MNI and McGill Univ, Montreal, QC, Canada.**

Field potential recordings were made in the CA3 area of hippocampal slices obtained from 10 to 30-day-old rats during perfusion with medium containing the convulsant 4AP (50 μM). Three types of spontaneous potentials were observed. The first one was a 0.4-1.1 s long potential (frequency of occurrence: 0.6-1.3 Hz) that resembled an epileptiform interictal event. The second type was reminiscent of an ictal epileptiform discharge, lasted 10-35 s and recurred every 40-100 s. The third potential was of opposite polarity to the other two types, occurred every 10-100 s and was usually followed by the ictal discharge. Application of NMDA receptor antagonists did not modify any of the three events while the non-NMDA receptors antagonist CNQX blocked both interictal and ictal discharges but not the potential of opposite polarity. The latter was however blocked reversibly by the $GABA_A$ receptor antagonist bicuculline methiodide. Thus in addition to epileptiform activity of interictal and ictal type that is dependent on non-NMDA conductances, 4AP also induces in the immature rat hippocampus a synchronous event that is due to the activation of the $GABA_A$ receptor.

388.8

NMDA-ACTIVATED CONDUCTANCES AND EPILEPTIFORM ACTIVITY INDUCED BY REPETITIVE STIMULI IN THE CA3 SUBFIELD OF RAT IMMATURE HIPPOCAMPUS PERFUSED WITH 4-AMINOPYRIDINE (4AP). **V. Tancredi, C. Zona, and M. Avoli. Univ "Tor Vergata", Rome, Italy; MNI and McGill Univ, Montreal, QC, Canada.**

When 4AP (50 μM) is applied to hippocampal slices obtained from 2 to 10-day-old rats, spontaneously occurring epileptiform activity is rarely seen in the CA3 subfield. In this experimental condition however, a short train of orthodromic stimuli elicits a prolonged electrographic seizure (20-40 s) that is then followed by spontaneous epileptiform events that recur regularly for several tens of min (up to 2 hours) in the absence of any further electrical stimulus. This type of epileptiform activity is not influenced by the subsequent application of the NMDA receptor antagonists CPP or MK-801 while being blocked by CNQX. Perfusion of non-stimulated hippocampal slices with medium containing CPP and 4AP does not affect the train-induced electrographic seizure response, but prevents the appearance of the spontaneous epileptiform discharges. Thus at this stage of brain maturation, NMDA receptors do not appear to play a role in the generation of 4AP-induced epileptiform activity while being important for establishing the long-lasting state of hyperexcitability that is associated with the occurrence of spontaneous epileptiform discharges.

AXONAL REORGANIZATION IN THE MOUSE HIPPOCAMPUS AFTER INTRAVENTRICULAR KAINIC ACID RC Green, SM Hersch, HD Rees, RAE Bakay Departments of Neurology and Neurosurgery, Emory University School of Medicine, Atlanta, GA 30322

Hippocampal sclerosis is the most common pathological finding in patients who undergo temporal lobe resection for medically intractable temporal lobe epilepsy. This characteristic pattern of pyramidal cell loss has been associated with reorganization of both Timms-positive fibers (Sutula et al, 1989) and acetylcholinesterase (AChE)-positive fibers (Green et al, 1989) in the human. In animals, intraventricular kainic acid (KA) causes seizures and excitotoxic damage to the hippocampus producing a pattern of cell loss similar to that seen with human hippocampal sclerosis. KA-induced cell loss is associated with aberrant AChE and Timms staining in the molecular layer of the rat dentate gyrus, suggesting axonal sprouting and reinnervation of deafferented neurons (Nadler et al, 1980).

In this study, male C57BL/6 mice, aged 2-4 months, were treated with bilateral intraventricular injections of KA (either 0.1 or 0.3 µg/side). After two weeks, mice were killed and their brains were processed for Nissl staining along with either AChE or Timms staining. Mice treated with KA revealed discrete areas of pyramidal cell loss with relative sparing of dentate granule cells and extra-hippocampal areas, including the septum and entorhinal cortices. The distribution of Timms staining did not differ from that found in controls, but AChE histochemistry revealed increased staining of the stratum oriens and stratum pyramidale in the areas of cell loss only. This is an unusual pattern of reinnervation since AChE staining was enhanced in a region where target neurons were lost without obvious deafferentation. One explanation is that surviving pyramidal neurons may be reinnervated by AChE-positive afferents in response to the loss of connections from adjacent neurons that are destroyed within the same sector.

388.10

INCREASED SPONTANEOUS EXCITATORY INPUT TO CA3 NEURONS DURING OVERHYDRATION OF HIPPOCAMPAL SLICES. V. Saly and R.D. Andrew, Anatomy Department, Queen's University, Kingston, Ontario K7L 3N6.

The clinical signs of rapidly developing overhydration commonly include generalized tonic-clonic seizure. Recent studies in hippocampal slices have indicated that field potentials (and therefore their synchronizing field effects) increase in hyposmotic conditions. As in CA1, we found the evoked anti- and orthodromic CA3 population spike was inversely proportional to the osmolality. The change occurred within 2 or 3 min, presumably coinciding with cellular swelling. However longer term effects were also observed in 9 CA3 cells recorded intracellularly for 1-3 hr. While resting potential, input resistance and spike threshold were unchanged by -40 mOsm saline over 10-40 min, spontaneous EPSPs increased in amplitude (7 cells). Sychronized input (represented by compound EPSP/IPSPs) was also induced (4 cells). These effects were reversed over 15-30 min in normosmotic saline. Hyperosmotic saline (+40 mOsm mannitol) had the opposite effect, reducing spontaneous EPSPs and any remaining EPSP/IPSPs (6 of 6 cells). In 2 of 2 cells tested, spontaneous interictal bursts were blocked by mannitol.

Thus both random and synchronized excitatory synaptic input to CA3 cells can evolve over tens of minutes during overhydration, suggesting a synaptic mechanism (in addition to field effects) whereby hyposmolality promotes excitation.

POSTNATAL DEVELOPMENT OF Na,K-ATPASE-MEDIATED HYPERPOLARIZATIONS IN RAT HIPPOCAMPAL CA1 NEURONS. A. Fukuda and D.A. Prince. Dept. of Neurology and Neurological Sciences, Stanford University School of Medicine, Stanford, CA 94305.

Previous experiments have shown that the prolonged hyperpolarization which follows glutamate application to adult CA1 pyramidal neurons in hippocampal slices (postglutamate hyperpolarization or PGH) is due to activation of an electrogenic sodium pump (Thompson, S.M. & Prince, D.A., J. Neurophysiol., 56: 507, 1986). Na,K-ATPase activity is known to develop slowly postnatally (Haglund M.M. *et al*, Brain Res., 343: 198, 1985), however, little is known about its physiological role in immature neurons.

We assessed the development of Na pump activity in CA1 hippocampal neurons from slices of postnatal day (P) 7 to P39 rats. Spike amplitudes for neurons from P7-11, P21-25 and P35-39 age groups were 65.1±11.1, 83.7±7.6 and 84.3±8.0 mV, respectively; resting potentials were -71.9±8.0, -64.9±6.0 and -66.3±4.7 mV; and input resistances (R_N) were 50.2±20.1, 36.4±8.5 and 31.2±8.5 MΩ. Similar glutamate-induced depolarizations (GDs) could be elicited in all three age groups. The size (area) of PGH was directly proportional to the area of the preceding GD. A ratio of PGH area to GD area was calculated for each neuron and used to compare Na pump activities at different ages. The PGH ratios at ages of P21-25 and P35-39 were 0.82±0.42 (n=16) and 1.46±1.00 (n=5), respectively. However, in the P7-11 age group, PGH ratio was 0.26±0.13 (n=7), or significantly lower ($p<0.01$) when compared to the P21-25 value. Differences in membrane properties for these age groups do not explain the differences in PGH ratio. If anything, the higher R_N would tend to increase the sizes of PGHs in more immature neurons.

These results suggest that substantial Na,K-ATPase functional activity develops after birth. Lower levels of electrogenic Na pump activity at early stages of development could be one factor contributing to the increased susceptibility of immature hippocampus to ictal discharges associated with prolonged membrane depolarizations. PATHWAYS OF SEIZURE AND INTERICTAL BURST PROPAGATION BETWEEN ENTORHINAL CORTEX AND HIPPOCAMPUS IN THE ZERO MAGNESIUM MODEL. A.C. Bragdon, H. Kojima and W.A. Wilson. VA Medical Center and SUNY HSC, Syracuse, NY, 13210; Akita U., Akita, Japan; VA and Duke University Medical Center, Durham, NC 27705.

Rat hippocampus (HC)/entorhinal cortex (EC) slices exhibit seizures and interictal bursts (IIBs) when bathed in medium containing no added magnesium (0-Mg medium). In general, the seizures arise first, then are suppressed by the IIBs. Here we describe the functional anatomy of the interaction between seizures and IIBs.

Recordings were made from EC and CA3 of HC/EC slices bathed in 0-Mg medium. In intact slices, seizures arose first in EC, but soon appeared synchronously in CA3. Seizures began in EC either spontaneously or triggered by a burst from CA3. Burst-by-burst analysis showed that EC bursts always led CA3 bursts except near the end of some seizures. Selective knife cuts revealed that seizures propagated from EC to CA3 both (1) with high efficiency via the perforant path, and (2) less efficiently via the temporoammonic path. IIBs arose in CA3, and evoked bursts responses in and suppressed seizures in EC. Knife cuts across subiculum prevented both these effects of IIBs.

These results show that seizures and IIBs can arise separately in EC and CA3, and that seizures can project from EC to CA3 over both perforant and temporoammonic pathways.

388.13

ELECTROGRAPHIC SEIZURES IN SLICES FROM OLDER RATS ARE INHIBITED BY PHYSIOLOGICAL LEVELS OF MAGNESIUM: RESTORATION OF SEIZURES IN LOW MAGNESIUM. W.W. Anderson and R.J. DeLorenzo. Dept. of Neurol., Med. Col. of Virginia, Richmond, VA 23298.

We have reported that electrographic seizures (EGSs) occur in hippocampal slices in physiological (0.9 mM Mg) medium when slices are from young (22-32 day old), but not older (>120 day old) rats (Stasheff et al. Science, 245:648, 1989). We report here that EGSs also occur in slices from older rats in Mg-free medium.

Hippocampal slices (625 uM) were prepared from 180-211 day old male Sprague-Dawley rats. Extracellular recording and stimulation were performed in stratum pyramidale and radiatum of CA3, respectively.

When slices were bathed in Mg-free medium + 2-5 uM of the $GABA_B$ agonist baclofen, EGSs either occurred spontaneously or following 1-3 stimulus pulses (N=7). These EGSs had the same tonic-clonic morphology and duration (mean = 59 sec) as the slices from young rats in Mg-free medium. However, the number of afterdischarge (AD) bursts per EGS (mean = 46) was only about half that of young rats. Addition of 50-200 uM of the NMDA antagonist D-2-amino-5-phosphonovalerate (APV) to Mg-free + baclofen medium substantially reduced, but did not block, AD bursting following 120 pulse stimulations (N=3).

When slices from older rats were bathed in 0.9 mM Mg + baclofen following EGS induction in Mg-free medium, 120 pulse stimulations produced only 0-5 AD bursts, indicating strong EGS inhibition (N=7).

These results suggest that the increased suppression of EGSs that occurs with aging is partially reversed by removing extracellular Mg. In slices from older rats, EGS inhibition could be due to Mg being more effective in stabilizing the membrane or decreasing transmitter release. Alternatively, NMDA antagonists do not block EGSs in slices from young rats in physiological medium (Stasheff et al.), indicating that non-NMDA-dependent mechanisms are sufficient to generate EGSs in these slices. In slices from older rats, the non-NMDA-dependent mechanisms alone may not be sufficient to generate EGSs in physiological medium, but may do so when augmented with NMDA-dependent mechanisms in Mg-free medium.

REDUCED SYNAPTIC INHIBITION UNDERLIES GENE-LINKED HIPPOCAMPAL NETWORK EXCITABILITY DEFECT IN THE EPILEPTIC MUTANT *TOTTERING* *S. A. Helekar* and J. L. Noebels*, Developmental Neurogenetics Laboratory, Section of Neurophysiology, Department of Neurology and Division of Neuroscience, Baylor College of Medicine, Houston, Texas 77030.

A gene-linked, voltage-dependent prolongation of network-driven paroxysmal depolarizing shifts (PDS) has been identified *in vitro* during 10 mM $[K^+]_o$-induced bursting in *tottering* (*tg/tg*) hippocampal CA3 pyramidal neurons (mean PDS durations: *tg/tg* 190±11, n=19; *+/+* 119±9, n=11). We have explored local circuit synaptic mechanisms in the CA3 region that might mediate this state-dependent inherited excitability defect. Blockade of NMDA receptors with bath-applied 40 µM (DL)APV produced approximately 30% reduction in PDS duration in both genotypes (*tg/tg* 135.0±13.0, n=5; *+/+* 84.0±11.1, n=5), but did not selectively correct the mutant phenotype, suggesting that increased synaptic excitation through NMDA receptors is unlikely to contribute to the altered network response. In contrast, blockade of $GABA_A$-receptors by 50 µM picrotoxin significantly prolonged (85%) the mean PDS duration in *+/+* neurons (217.8±35.9, n=4), but had no significant effect on the mutant PDS (173.0±20.5, n=5). These data support the hypothesis that the prolonged PDS in *tg* CA3 pyramidal neurons may reflect an underlying attenuation of $GABA_A$-receptor-mediated synaptic inhibition. Since intracellular recordings in *tg* CA3 cells under physiological 3 mM $[K^+]_o$ conditions clearly show spontaneous and evoked inhibitory synaptic potentials, this evidence raises the possibility that the *tg* mutation interacts with mechanisms regulating activity-dependent modifications in synaptic inhibition. (Supported by NIH and Pew Foundation (JLN)).

CHRONIC LESION OF MEDIAL SEPTAL NUCLEI INDUCES AN EPILEPTIFORM ACTIVITY IN RAT HIPPOCAMPAL SLICES. F.Berton*, R. Bianchi*, W.Francesconi*, B.Sidorov** & M.Brunelli. Dpt. Physiol. & Biochem. Univ. of Pisa,56100 Pisa, Italy - **Inst. of Higher Nervous Activity & Neurophysiol., Acad.of Sci. USSR, Moscow.

In the rat, hippocampal formation receives a well characterized septal projection from cholinergic and GABAergic neurons located in Medial Septal nuclei (MS) and vertical limb of Diagonal Band. The mechanisms underlying the effects of septo-hippocampal fibres degeneration on the excitability of the hippocampal neurons have not been carefully analyzed. Spontaneus and evoked multiple population spikes (MPSs) were recorded in CA3 and CA1 regions in slices isolated from animals sacrificed 1,2 or 4 weeks after electrolitical or chemical (local application of Ibotenic acid)lesion of MS. Spontaneous and evoked CA1-MPSs disappeared after cutting between CA3 and CA1 regions. In slices from unlesioned or sham-operated rats we never observed such an abnormal activity. In conclusion, septo-hippocampal fibres degeneration induces an epileptiform activity in CA3 spreading to CA1 region. Intracellular recordings from CA3 and CA1 neurons are in progress.

388.16

INFLUENCE OF ADENOSINE TRANSPORT AND ADENOSINE DEAMINASE INHIBITORS ON BICUCULLINE METHIODIDE-INDUCED SEIZURES IN RAT PREPIRIFORM CORTEX. G. Zhang, P. H. Franklin and T. F. Murray. College of Pharmacy, Oregon State University, Corvallis, OR 97331.

The results of our previous studies suggest that an adenosine receptor population in rat prepiriform cortex (PPC) plays an important role in the suppression of bicuculline methiodide (BMI) and kainic acid-induced seizures (Franklin, P.H. *et al.*, *J. Pharmacol. Exp. Ther.*, 251:1229,1989; Zhang, G. *et al.*, *Neurosci. Lett.*, in press). In the present study we evaluated the manipulation of endogenous adenosine in this brain area as a strategy to effect seizure suppression. All compounds used in these experiments were unilaterally microinjected into the PPC. It was found that the co-administration of a subconvulsant dose (1.6 nmol) of the adenosine antagonist 8-*p*-(sulfophenyl)theophylline (8pSPT) with BMI (30 pmol) markedly enhanced the severity of BMI seizures. Dilazep, an adenosine transport inhibitor, provided a potent protection against BMI seizures with an ED_{50} value of 5.6±1.6 nmol/rat. Together, the proconvulsant effect of 8pSPT and anticonvulsant action of dilazep indicate that endogenous adenosine in the PPC exerts an inhibitory tone which affects seizure susceptibility. Furthermore, we found that exogenous adenosine also afforded a dose-dependent suppression of BMI-induced seizures (ED_{50}=48.1±8.4 nmol/rat) in the PPC, and these anticonvulsant effects of adenosine were significantly potentiated by the adenosine transport blockers dilazep (0.5 nmol) and nitrobenzylthioinosine phosphate (20 nmol). Similarly an adenosine deaminase inhibitor 2'-deoxycoformycin (11.2 nmol) produced 2.9 fold potentiation of the anticonvulsant effect of adenosine. These findings therefore imply that adenosine is a major modulator of neuronal activity in the PPC and the inhibition of the adenosine transport system and/or adenosine deaminase influences extracellular adenosine levels in this paleocortical brain area. (Supported by USPHS Grant NS23227).

IN VIVO AND IN VITRO ASSESSMENT OF NEUROTRANSMITTER AMINO ACID FUNCTION IN TETANUS TOXIN INDUCED CHRONIC SEIZURE FOCI IN RAT HIPPOCAMPUS. C.M. Forchetti, B. Leheta*, and D. Garant*. Dept Neurological Sciences, Rush Medical College, Chicago IL 60612.

Tetanus toxin or vehicle was injected unilaterally into dorsal hippocampus of rats with chronic depth electrode/guide cannula implants. After injection, EEG and focal in vivo micro-dialysis were performed in the unanesthetized rats, either before seizure onset, during the peak of limbic seizures, or after seizure remission. Enriched synaptosomal fractions were prepared from hippocampi dissected from these rats, and amino acid concentrations were assayed by reverse-phase HPLC.

As expected, in tetanus toxin seizure foci in vivo, K^+-induced GABA release appeared decreased, however synaptosomal GABA content was remarkably consistent through the seizure course and between toxin and vehicle groups. This suggests that tetanus toxin inhibits GABA release, but neither this effect nor the subsequent seizures alter nerve terminal GABA concentration.

388.18

OUABAIN-BINDING SITES AND mRNAs OF Na,K-ATPases ARE DECREASED IN HIPPOCAMPAL AREA CA1 OF RAT BRAIN AFTER KAINATE LESIONS OF CA3. A.A. Maki, J. E. Franck and W.L. Stahl . VA Medical Center and Univ. Washington Sch. Med., Seattle, WA 98108.

Administration of kainate to rats causes loss of neurons of the hippocampal CA3 region and leads to a hyperexcitable state in CA1 pyramidal neurons. We hypothesize that changes in ion homeostasis, especially due to decreased expression of the Na,K-ATPase, may contribute to the mod-ified properties of CA1 neurons. We used ouabain binding to measure the number of Na,K-ATPase sites in CA1 AND CA3 areas (J. Neuro-chem. 52: 193-200, 1989) and in situ hybridization (Neurosci. Res. Commun. 5: 155-162, 1989) to measure expression of mRNA for Na,K-ATPase subunits. Both high and low affinity [^{3}H]ouabain binding sites were found in control and lesioned hippocampus with K_d values of 60-77 nM(high) and 960-1382 nM (low). No differences were found in K_d values between control and lesioned animals. Numbers of low affinity binding sites differed only in CA3 where nearly complete destruction of pyramidal cells was observed. High affinity sites were decreased in CA1 as follows: stratum oriens, 20%; stratum radiatum, 25%; pyramidal cell layer, 33%. In addition significant loss of mRNA encoding for α2 and α3 isoforms of the catalytic subunit of the Na,K-ATPase was found in CA1 pyramidal cells. Since Na,K-ATPases containing α2 and α3 are known to bind ouabain with high affinity, the in situ hybridization studies support the ouabain-binding results. We conclude that the number of Na,K-ATPase molecules with high affinity for ouabain in CA1 pyramidal cells is significantly reduced and may lead to modified ion homeostasis in this model of epilepsy. (Supported by NS 20482 and the VA.)

388.19

MODIFICATION OF HYPEREXCITABILITY IN THE SUBCORTICALLY DENERVATED HIPPOCAMPUS BY SEPTAL GRAFTS.

M. Hsu, Z. Horvath*, F. H. Gage, C. Slamka* and G. Buzsaki.
Department of Neurosciences, UCSD, La Jolla, CA 92093.

Suspension grafts of basal forebrain cholinergic neurons were implanted into the hippocampus 3 months after fimbria-fornix (FF) transection and the emergence of hyperexcitability (Neurosci. 28:527,1989) was tested 9 months after grafting. The threshold for evoking afterdischarges was significantly elevated in the grafted rats relative to FF-only animals. The correlation between perforant path evoked extracellular PSP and population spike was positive in unoperated control (UC) rats and grafted rats but negative in FF-only rats. The behavior-dependence (walk vs. still) of pop-spike amplitude was largest in the FF group, and smallest in the UC animals with the grafted rats intermediate. Behavior-dependence of PSP was similarly larger in FF and grafted groups relative to UC rats. Long-term potentiation (LTP) of the dentate population spike was impaired in the FF-only rats; grafting did not result in significant improvement of LTP. High frequency (18-32/sec) power in the hilus was significantly larger during walking than during immobility in all groups, and behavioral modulation was significantly larger in the grafted animals and FF rats than in the UC group. We conclude that delayed grafting of cholinergic cells is capable of modifying the already established hyperexcitability patterns of the denervated hippocampus, although not all changes are restorative.

ABNORMAL LYSOSOMAL HYDROLASE DISTRIBUTIONS IN ALZHEIMER BRAIN. A. M. Cataldo*, A. Pope and R. A. Nixon. McLean Hospital, Harvard Medical School, Belmont, MA 02178

Lysosomal proteinases in enzymatically active form are abnormally present extracellularly in classical senile plaques (SP) (Cataldo and Nixon, PNAS, 1990). We have proposed that degenerating cathepsin-laden neurons and their processes are the principal source of these enzymes in SP and that the unregulated action of lysosomal hydrolases leads to abnormal metabolism of the amyloid precursor protein (APP). To further establish this idea, we localized other lysosomal hydrolases in Alzheimer brain. Sections of neocortex from control and AD brains were analyzed by immunocytochemistry with polyclonal antisera to the non-protease enzymes, α-galactosidase (GAL), α-hexosaminidase A (HEX A), and α-glucosidase (GLU) and by enzyme cytochemistry for aryl sulfatase and acid phosphatase activities. Senile plaques were also identified histologically using Bielschowsky silver stain and thioflavin S histofluorescence. HEX A, GAL and GLU were present in neurons of control and AD brains and were abundant in senile plaques of AD brain. In SP, these hydrolases were localized by immunoelectron microscopy to extracellular membrane-limited profiles. Neurofibrillary tangles were also intensely stained with GAL antiserum. The activities of aryl sulfatase and acid phosphatase were detected in many SP even though activities in neurons were below the sensitivity limit of the method. The abnormal localization of various lysosomal hydrolases with extracellular β-amyloid deposits supports a model involving neuronal degeneration and persistence of the lysosomal compartments which are capable of unregulated proteolysis including possibly abnormal breakdown of APP. The aberrant trafficking and release of membrane-degrading hydrolases may be one mechanism to expose the intra-membrane A4 cleavage site.

389.2

COMPLEMENT PROTEINS ARE ASSOCIATED WITH MEMBRANE ATTACK IN ALZHEIMER DISEASE. P. L. McGeer, H. Akiyama, T. Kawamata*, E. G. McGeer. Kinsmen Lab. of Neurol. Res., Dept of Psychiatry, Univ. of British Columbia, Vancouver, B.C., Canada, V6T 1W5.

The pattern of Alzheimer tissue staining by antibodies to complement and related proteins indicates that active cell lysis as well as tissue opsonization is taking place. Extracellular debris in the form of amyloid deposits and ghost tangles are strongly stained by antibodies to the complement proteins C1q, C3d and C4d. These proteins are associated with the opsonizing function of complement. Antibodies to vitronectin, a serum protein which binds to the C5b-9 membrane attack complex (MAC), also stain these structures. Despite the presence of this inhibitor of MAC insertion into cell membranes, diseased neuronal elements, which are identifiable by antibodies to ubiquitin and Tau-2, are stained by an antibody to a neoantigenic site on the C5b-9 complex. Many of these same tangled neurons and dystrophic neurites are also stained by an antibody to the membrane inhibitor of reactive lysis (MIRL, JCI 84:7-17, 1987, courtesy of Dr. C.J. Parker, Univ. of Utah). MIRL restricts the susceptibility of human erythrocytes to complement-mediated hemolysis induced by activated cobra venom. This inhibitor of bystander lysis is a phosphatidylinositol-linked 18 kd protein which inhibits assembly of the membrane attack complex at the level of C7 and C8 incorporation. MIRL might be induced in neurons subject to bystander lysis by the C5b-9 complex. These data suggest that inhibition of complement activated cell lysis might reduce the rate of cellular degeneration in Alzheimer disease.

AD PATHOLOGY: IN VIVO QUANTITATION BY MRI? J.W. Ashford, A. Rashid*, D. Lawrance*, M. Calache*, J. Bice*, G. Evans* and D. Anderson*. SIU Sch. of Med. Springfield, IL 62794.

The critical diagnostic issue for Alzheimer disease (AD) is regional quantitation of pathology in vivo. Magnetic resonance imaging (MRI), capable of measuring a variety of cerebral characteristics with considerable dynamic range, might achieve this quantitation. For example, senile plaques (60 μ dia., about 10/mm^2 at diagnostic threshold = 3% of tissue volume) might have a property which can be assayed. Spin density images (TR=2 s; TE=40 ms, balancing T1/T2 properties, not distinguishing gray/white matter/CSF) highlight several types of pathology. Using this protocol, statistical enhancement (fig. 1) of coronal images (fig. 2) showed a pattern of intensities in 6 probable AD patients suggestive of the distribution of AD pathology (data shown from autopsy-confirmed AD patient).

MORPHOLOGICAL ALTERATIONS OF NEUROPEPTIDES IN THE AMYGDALA IN ALZHEIMER'S DISEASE (AD). W.C.Benzing, E.J. Mufson§, and D.M. Armstrong. FGIN, Georgetown University, Washington, D.C. 20007; §IBR, Sun City, AZ 85372.

We used immunocytochemistry in order to examine the morphologic features of three neuropeptides (somatostatin (SOM), substance P (Sub P), and neurotensin (NT)) and of choline acetyltransferase (ChAT) in the amygdala of patients with AD and in 2 groups of controls. One control group (normal) had few if any plaques, while the other group (high "N") had numerous plaques. The topography of the pathologic lesions was determined using Thioflavin-S. In AD patients and the high "N" controls, immunolabeling for ChAT and NT was reduced in density relative to normal controls, while Sub P and SOM labeling was reduced only mildly if at all. The reductions in NT and ChAT immunoreactivity were more pronounced in the AD cases than in the high "N" cases. Despite these differential reductions in density, neuritic fibers of all four neurotransmitters showed similar morphologic alterations in both the AD cases and the high "N" cases but these were rarely observed in the normal controls. These alterations were characterized by gross varicose swellings which were often associated with plaques and were most prevalent in areas of high plaque density. Most importantly, in the areas of highest plaque formation in the AD cases (which coincided with the areas of plaque formation in the high "N" cases), ChAT and NT processes were nearly or completely absent and were thus rarely found within plaques, while in these same areas in the high "N" controls, ChAT and NT were present in reduced amounts and had abnormal fibers that were found within plaques. Abnormal SOM and Sub P fibers were present within plaques in these areas in both the AD and the high "N" cases. The observation that all four neurotransmitters displayed similar morphologic irregularities suggests a common pathological process. The reductions in ChAT and NT suggest that these transmitter systems may be more susceptible to the pathologic changes.

389.5

THE NUCLEUS BASALIS SHOWS LITTLE CELL LOSS OR OTHER PATHOLOGICAL CHANGE IN MILD ALZHEIMER'S DISEASE. J.L. Price, J.C. Morris, P. Davis & D.L. White. Depts. of Anat./Neurobiol. and Neurology, Washington Univ. Sch. Med., St. Louis, MO 63110

Previous studies have reported that the nucleus basalis of Meynert (NBM) undergoes substantial cell loss in Alzheimer's disease, associated with loss of cholinergic markers in the cortex. It has been suggested that this might be partially responsible for the cognitive decline associated with the disease. As part of an ongoing study of the relation between normal aging and Alzheimer's disease, we have determined the density of neurons, tangles, and cells immunoreactive for the Alz-50 antibody and an antibody against paired helical filaments (donated by Drs. Peter Davies and Dennis Selkoe) in the cell clusters of the NBM. The cases studied were evaluated in the Alzheimer's Disease Research Center of Washington University and assigned a Clinical Dementia Rating (non-demented: CDR=0; very mildly demented to severely demented: CDR=0.5 to 3).

The density of large neurons was determined at three levels of the NBM. Four mildly demented cases (CDR=0.5 to 1) showed no loss of cells when compared to three non-demented cases (ca. 65 cells/mm^2). However, three more severely demented cases (CDR=2 to 3) had much lower cell density (ca. 20 cells/mm^2). The density of tangles and immunoreactive cells in the NBM of five mildly demented cases was slightly above that seen in non-demented elderly cases (average tangle density=2/mm^2 vs 0.4/mm^2). The density of these markers was greater in the severely demented cases (6.1/mm^2), but is much less than in the hippocampal formation or neocortex. These observations indicate that cellular damage in the NBM is not a substantial feature of the early stages of Alzheimer's disease; it might contribute to the cognitive loss in later stages of the disease, but in such cases there is also substantial damage to the hippocampus and neocortex.

BASAL FOREBRAIN PROJECTIONS TO THE FRONTAL POLE OF THE THALAMIC RETICULAR NUCLEUS (MEDIODORSAL NUCLEUS AND FRONTAL CORTEX TERRITORY) IN THE OLD-WORLD MONKEY, AND THEIR DISRUPTION IN ALZHEIMER'S DISEASE. W.G. Tourtellotte, I.A. Ilinsky and G.W. Van Hoesen. Depts. of Anatomy and Neurology, Univ. of Iowa, Iowa City, IA 52242.

The thalamic reticular nucleus (Rt) forms a narrow band of largely GABAergic neurons around the margins of the thalamus. It receives thalamocortical, corticothalamic, and cholinergic fibers from the basal forebrain (BF) and the pontomesencephalic reticular formation (PMRF). Physiological studies indicate that the BF and PMRF can disinhibit Rt neurons and facilitate thalamic transmission. Immunocytochemistry with Alz-50 and tau antibodies in Alzheimer's disease (AD; N=15) but not control brains (N=8) reveals terminal-like immunostaining in the rostral pole of Rt. Nerve growth factor receptor (NGFr) immunocytochemistry and NADPH-diaphorase (NADPHd) histochemistry were used to assess the integrity of cholinergic neurons in the septal-BF complex and PMRF, respectively, in some of the AD and normal brains. There was a consistent depletion of neurons and numerous thioflavin S, Alz-50 and tau positive neurons in BF but not in PMRF. Old-World monkeys received iontophoretic injections with either PHAL or WGA-HRP in the BF and Rt. HRP injections confined to the rostral pole of Rt demonstrated retrograde transport to the mediodorsal nucleus (MD), medial prefrontal and orbitofrontal cortices, BF and PMRF. In the BF, retrogradely-labeled neurons were located in intermediate and caudal locations. Iontophoretic injections with PHAL confined to the pole of Rt revealed dense projections to MD. The data suggest that corticothalamic and thalamocortical fibers interconnecting MD and frontal cortex synapse in the pole of Rt. They also demonstrate that the Rt pole receives cholinergic projections from the BF and the PMRF. Since neither the neurons in the PMRF nor MD appeared consistently involved in AD, the changes observed in the Rt may well arise from Alz-50 and tau positive neurons in the posterior and intermediate sectors of the BF. This may reflect a disruption of modulatory influences by the BF on MD-frontal lobe interactions in AD. (Supported by: 5T32 GM0733, NS 14944, PO NS 19632.)

LN-1 IMMUNOREACTIVITY IS SPECIFIC TO ASTROCYTES IN CORTEX OF NORMAL AGED AND ALZHEIMER'S DISEASE (AD) BRAIN TISSUE. G. Moon*, S.D. Styren, W.H. Civin, and J. Rogers, L. J. Roberts Center, Institute for Biogerontology Research, Sun City, AZ 85351.

LN-1 is a monoclonal (IgM) antibody specific for an uncharacterized cell membrane antigen present on B lymphocytes but not T lymphocytes or histocytes. A previous report suggested that LN-1 is a specific marker for CNS microglia. We find, however, that this antibody specifically labels CNS astrocytes only. Moreover, astrocytes with reactive morphology--as found particularly in AD brain tissue--exhibit increased expression of the LN-1 antigen.

Frontal cortex samples from 9 AD and 9 aged-matched neurologically normal controls were obtained at autopsy (mean autolysis time of 4 ± 2 hours), cut into 1 cm blocks, fixed for 24 hours in 4% buffered paraformaldehyde, vibratome sectioned at 50 μm, and processed for immunohistochemistry. Additional material for immunohistochemistry was paraffin embedded after 10% or 20% formalin fixation for various times.

Intense LN-1 immunoreactivity is observed on highly reactive astrocytes near the border of cortical layers I and II. Both the intensity of staining and the number of labelled cells are elevated in AD. LN-1 immunoreactivity in the other cortical layers occurs on fewer astrocytes, the labelling is weaker, and the morphology is considerably less reactive. LN-1 positive astrocytes, typically with nonreactive morphology, occur diffusely in the white matter. The specificity of the LN-1 antibody for astrocytes (and only astrocytes) is confirmed by morphologic criteria and by double-labelling with the astrocyte specific marker GFAP.

Increased expression of the immune system associated antigen LN-1 by cortical astrocytes in AD is consistent with demonstrations by our laboratory and others that the pathogenesis of AD includes a chronic inflammatory component.

MORPHOLOGIC EVIDENCE OF A DYNAMIC RELATIONSHIP BETWEEN MICROGLIA AND SENILE PLAQUE AMYLOID IN ALZHEIMER DISEASE (AD). L.S. Perlmutter, M.A. Myers*, E. Barron*, and H.C. Chui. USC School of Medicine, Dept Neurology, RMR-407, Los Angeles, CA 90033.

Amyloid and mononuclear phagocytic cells are intimately associated in several amyloidoses. In AD, amyloid/microglia associations have been seen with light (LM) and electron microscopy (EM). With EM, bundles of amyloid from compact cores were found interdigitated with microglial cell membrane and within intracellular membraneous cisterna. These cells were morphologically characterized as resting microglia - suggesting a secretory rather than phagocytic role.

The present study examined the relationship between microglial morphology and the pattern of amyloid accumulations in AD. Microglial cells were labeled with the lectin *Ricinus communis* agglutinin-1 for LM and EM. With LM, dense amyloid cores (stained with thioflavine S) were always tightly encircled by clusters of highly ramified microglia. Larger, diffuse amyloid plaques were associated with globular-shaped microglia with few if any processes. With EM, cytoplasm from labeled resting microglia were found interdigitated with amyloid bundles; intracellular bundles were also seen. Round, dense body-filled microglia were scattered around diffuse amyloid accumulations.

These data suggest a complex and dynamic pathogenetic relationship, which may vary with the microglia's functional state: ramified microglia may secrete while rounded microglia may phagocytose amyloid. Thus, compact rather than diffuse amyloid accumulations may represent an earlier form of senile plaques. (AG07127, AG05142, AG07624)

THE BRAINSTEM IN ALZHEIMER'S DISEASE (AD). T. Doucette*, T. Duong and A. B. Scheibel. UCLA Anatomy Department, Brain Research Institute and Mental Retardation Research Center, L.A., CA 90024.

The immunohistochemical labeling by antisera to amyloid P component (AP-C) has been compared to that by antisera raised against microtubule-associated protein tau (MAP-tau) and paired helical filaments (PHF) in the pons of AD patients. Brain tissue was fresh fixed in 4% paraformaldehyde by immersion, cut on a cryostat (40 μm section thickness) and processed by the peroxidase-antiperoxidase method. The principal neuropathological lesions observed were neurofibrillary tangles (NFT) in the locus ceruleus and raphé regions. The antiserum to MAP-tau labeled intracellular NFT and neuropil neurites in areas without NFT. A diffuse MAP-tau labeling without intracellular presence of NFT was also observed in some neurons. MAP-tau antiserum may label neurons which potentially develop NFT. The antiserum to PHF labeled extracellular NFT and surrounding neurites. It also revealed neuropil neurites but to a much smaller extent than the MAP-tau antiserum. AP-C antisera labeled mostly extracellular NFT although a few intracellular NFT were also observed. Neurites in the immediate area around extracellular NFT were labeled by AP-C antisera but neuropil neurites in areas lacking NFT were not. Thus the labeling of neuropathological elements in the pons by AP-C antisera is qualitatively more similar to that of PHF antiserum. We suggest that in NFT formation, MAP-tau antiserum is able to label neurons which potentially develop NFT, whereas AP-C antisera label only neurons in which PHF are present in the soma. We conclude that **AP-C may not be a causative agent in the formation of NFT but only binds to NFT after the PHF are present.**

IMMUNOHISTOCHEMICAL ANALYSIS OF THE NUCLEUS BASALIS OF MEYNERT (nbM) IN ALZHEIMER'S DISEASE (AD). R.W. Jacobs, T. Duong, and A.B. Scheibel. Depts. of Anatomy and Psychiatry and the Brain Research Institute, UCLA, CA 90024.

The histopathology of the rostral cholinergic nuclei (nbM, diagonal band of Broca, and medial septum) in AD has been compared to the neocortex, amygdala, and hippocampus. Brain tissue from AD and aged controls were processed for Nissl, thioflavin-S, and acetylcholinesterase (ACHE); and immunohistochemically labeled for paired helical filaments (PHF), MAP-tau, ß-amyloid, amyloid P-component (AP-C), choline-acetyl transferase (ChAT), and glial fibrillary acid protein (GFAP). Numerous neurofibrillary tangles (NFT) and plaques were noted in the AD neocortex, amygdala, and hippocampus by thioflavin-S, PHF, MAP-tau, and AP-C. The cores and neurites of senile plaques were positive for ß-amyloid. GFAP demonstrated large fibrous astrocytes associated with plaque formation. The cholinergic nuclei displayed neurons in various stages of degeneration, many hypertrophied astrocytes, a lack of ß-amyloid except in arteriolar walls, and in some regions end-stage gliosis without the presence of neuronal elements including residual NFT. A significant proportion of the remaining ACHE and ChAT-positive neurons contained globular NFT. These were demonstrated by thioflavin-S, PHF, and MAP-tau but not by AP-C which identified only a few lightly labeled NFT. We suggest the existence of two types of NFT: Those found in the cholinergic nuclei which are largely AP-C negative and seem to disappear with neuronal loss; and those from other brain regions which are AP-C positive and tend to accumulate. **The finding of atypical, non-accumulating NFT and a paucity of senile plaques and ß-amyloid deposition may point to a pathogenic expression unique to the rostral cholinergic nuclei.**

389.11

CHOLINERGIC ALTERATIONS IN CORTICAL BIOPSY TISSUE IN ALZHEIMER'S DISEASE. S.T. De Kosky , R. Harbaugh*, S.W. Scheff, Schmitt, F.A.* and the intraventricular bethanechol study group. Alzheimer's Disease Res. Ctr. & Dept. of Psychiatry, Univ. of Pittsburgh, Suite 400, 3600 Forbes Ave., Pittsburgh, PA 15213, Dartmouth Univ. and Univ. Kentucky Med. Ctrs. & Sanders-Brown Center on Aging, Lexington, KY.

Neurochemical assessments were performed on biopsy samples taken from the right frontal lobe of patients diagnosed with Alzheimer's disease (AD), prior to the implantation of a ventricular catheter and pump assembly for the infusion of bethanechol as an experimental therapy. Samples were obtained from 6 different medical centers. The pathologically confirmed AD cases (n = 26) were compared to a group of samples from normal age-matched autopsied controls (n = 21) and age-matched autopsied AD brains (n = 11). All samples were assayed for choline acetyltransferase (ChAT), acetylcholinesterase (AChE), binding to ^{3}H-quinuclidinyl benzilate (QNB) as an index of total muscarinic cholinergic binding and ^{3}H-pirenzepine (PZ) binding as an index of M1 receptor subtype binding. Mean levels of ChAT activity were decreased to 36% of age-matched controls, and the loss of activity correlated significantly with the mini-mental state examination, an index of global cognitive function. ChAT activity in autopsied AD cortex was further decreased compared to controls, indicating continuous further decline through the course of the disease. AChE followed a similar, less dramatic decline. No differences were found in QNB binding among the groups but PZ binding was significantly decreased in autopsied AD cases compared to biopsy cases or autopsied controls.

389.12

CT WHITE MATTER LUCENCIES (WML) IN AGING AND ALZHEIMER'S DISEASE (AD) DO NOT CORRELATE WITH GLOBAL COGNITIVE IMPAIRMENT. A. Sudilovsky, M.J. de Leon*, G.S. Smith, A.E. George*, S. Repetti and J. Ciaravino*. The Squibb Inst. for Med. Res., Princeton, NJ and NYU Med. Cntr., NY, NY.

We conducted a multicenter investigation of WML (decreased CT density) in normal elderly volunteers (N=301; Mini-Mental State Examination score (MMSE) above 27), AD patients (N=273; MMSE: 12 to 23), and patients with minimal cognitive deficit (MCD; N=59; MMSE: 24 to 27). Criteria for admission included: age 50 to 85 years, ischemia score below 3, blood pressure below 160/95, and no use of antihypertensives in prior 3 months. All participants received non contrast GE 8800 or GE 9800 CT scans (base to vertex of the brain)yielding slices 10 mm in thickness. All slices in each of 3 bilateral areas in each case (frontal lobe; parietal/peritrigonal area; and diffuse involvement) were rated on a 7 point scale. Ventricular and sulcal dilatation were similarly rated. WML were found in 21% of normal controls, 29% of AD patients, and 25% of MCD patients. In each group, patients with MWL were older (p 0.05). Controlling for age differences indicated greater ventricular enlargement and sulcal dilatation accompanying WML. This was most prominent in normal controls and mildly affected patients. Further atrophy independent of WML was observed in more severely affected patients.

Our results demonstrate the increasing prevalence of WML with age and their association with atrophy in aging and early AD. No relationship was found between MMSE and WML severity.

389.13

POSSIBLE NEURONAL PARTICIPATION REVEALED BY PKC(B2) IMMUNOREACTIVITY IN ALZHEIMER DISEASE (AD) PLAQUES. E.Masliah, R.D.Terry*, L.Hansen*, M.Mallory*, G.Cole, T.Saitoh. Dept. of Neurosciences, U.C.S.D., La Jolla, CA 92093.

A previous report suggested involvement of PKC in AD plaques. We have been studying the spatial relationships between the anti-PKC(B2) labeled component and various cellular populations; i.e., neurons, microglia and astrocytes in this lesion. AD preparations were 40u vibratome sections from the midfrontal cortex and hippocampus. The sections were double immunolabeled with: a) anti-PKC(B2)/SMI-31(neuronal marker), b)anti-PKC(B2)/anti-synaptophysin (presynaptic terminal marker), c) anti-PKC(B2)/RCA-1 (microglial marker), and d) anti-PKC(B2)/anti-GFAP (astrocytic marker).Additional sections were double-labeled with anti-amyloid B/A4. The sections were then incubated with a combination of secondary antibodies tagged with FITC and Texas Red for study with the Bio-Rad MRC 600 laser confocal system. Observations of serial optical sections suggest that the PKC(B2) immunoreacting components of the plaques are actually SMI-31 positive, short, sprout-like processes extending from neurons in the area of the diffuse plaque. The cellular processes of astrocytes and microglia were associated with amyloid and neuronal perikarya in the classical plaque. The PKC(B2) immunostained processes in the classical plaques seemed to be closely apposed to amyloid fibrils.

THURSDAY AM — SYMPOSIA

391

SYMPOSIUM. GENETICALLY MODIFIED CELLS: DEVELOPMENT AND APPLICATION FOR THE NEUROSCIENCES. B.H. Wainer, The Univ. of Chicago (Chairperson); J.R. Sanes, Washington Univ., St. Louis; D.J. Anderson*, Cal. Tech.; M.R. Capecchi*, Univ. of Utah; F.H. Gage, Univ Cal., San Diego.

The participants in this symposium will present recent approaches employing genetically modified cells to study areas of specific interest to the neurosciences: cell lineage and development, trophic interactions, and intercellular signalling. Dr. Sanes will describe the application of retrovirus-mediated gene transfer into neural cells *in vivo* to trace neural cell lineage in the embryonic mouse and chick nervous systems. Dr. Anderson will describe the isolation of sympathoadrenal progenitor cells by fluorescence activated cell sorting using specific cell surface monoclonal antibodies, and the immortalization of these progenitors by retroviral-mediated gene transduction to study sympathoadrenal lineages that generate the major catecholamine-containing derivatives of the neural crest. Dr. Capecchi will discuss the use of gene targeting for the introduction of specific mutations into mouse embryonal stem cells *in vitro* which can then be employed to generate transgenic animals for evaluation of the consequences of such mutations *in vivo*. Dr. Wainer will discuss the use of somatic cell fusion approaches to generate clonal cell lines from postmitotic embryonic and young adult neurons to study trophic interactions as well as other neural processes. Dr. Gage will describe the generation of non-neuronal cell lines transfected with cDNA for either trophic factors or enzymes relevant to specific neurotransmitter systems, the synthesis and secretion of active transgene products by these cells, and the grafting of such cell lines into adults brains to induce long-term functional effects.

392

SYMPOSIUM. DIFFERENTIAL PROCESSING OF VISCERAL AND SOMATIC INPUT IN THE CENTRAL NERVOUS SYSTEM. R.D. Foreman, Univ. of Okla. HSC (Chairperson); W.C. deGroat, Univ. of Pittsburgh; F. Cervero, Univ. of Bristol; G.F. Gebhart, Univ. of Iowa; R.W. Blair, Univ. of Okla. HSC; W.D. Willis, Univ. of Texas at Galveston.

The objective is to compare and contrast the similarities and differences of visceral and somatic processing in the peripheral and central nervous system. Dr. deGroat will discuss the similarities and differences in the neurochemistry and anatomy of afferent pathways to the lumbosacral spinal cord. He also will discuss morphological plasticity in visceral afferent pathways. Dr. Cervero will discuss the functional changes in visceral nociceptors that follow sensitization and the plasticity of somatic and visceral spinal neurons following prolonged noxious stimulation. Dr. Gebhart will present studies showing spinal and supraspinal responses of cells distention of the normal and inflamed colon. Dr. Foreman will compare and contrast the organization of spinothalamic tract cells that receive cutaneous, muscle and visceral input and project to the oral and caudal regions of the ventral posterior lateral thalamic nucleus. Dr. Blair will summarize how different regions of the medullary reticular formation integrate visceral, primarily cardiac, and somatic information. Dr. Willis will discuss how thalamocortical structures integrate visceral and somatic input. He will conclude with his perspective concerning future directions that need to be pursued to provide the most effective development of this field.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION II

393.1

PRO-OPIOMELANOCORTIN (POMC) NEURONS IN THE RAT MEDIOBASAL HYPOTHALAMUS (MBH) PROJECTING TO THE MEDIAL PREOPTIC AREA (MPO) ARE SYNAPTIC TARGETS OF GABAERGIC TERMINALS. F. Naftolin[1] M. Shanabrough*[1] and C. Leranth[1 2]. Dept. of Obstetrics and Gynecology[1] and Section of Neuroanatomy[2], Yale Univ. Sch. of Med., New Haven, CT. 06510

We have previously shown that POMC peptide-containing neurons provide a direct link between the arcuate nucleus (AN) and MPO LHRH neurons. The AN contains GABAergic interneurons which could control the AN POMC neurons. To test the hypothesis that pacemaker impulses from such GABAergic MBH integrator unit neurons are projected to MPO LHRH neurons via the POMC cells, the connections between these cells were studied using a combination of retrograde tracing and double immunostaining procedures. Experimental: horseradish peroxidase (HRP) was stereotaxically injected in the MPO of adult female rats. On the next day, animals were colchicine treated (80μg in 20μl saline, injected into the lateral ventricle) and then sacrificed 24 hrs later by transcardial perfusion of fixative. The retrogradely transported HRP was visualized using the glucose oxidase reaction on vibratome sections of the MBH. In addition, we immunostained for β-endorphin and GAD by a double immunostaining procedure using two contrasting electron dense markers, IgG conjugated 5nm gold for β-endorphin-containing cells and immunoperoxidase reaction for GAD-containing neurons. Results: EM of triple labeled sections showed a population of the β-endorphin immunoreactive neurons located mostly in the lateral part of the arcuate nucleus, to contain retrogradely transported HRP granules from the MPO and are innervated by GAD immunoreactive boutons. Conclusions: GABAergic neurons innervate the POMC tract from the AN to the MPO LHRH neurons. Since these are likely inhibitory connections and are estrogen sensitive (Wallis and Luttge, '82), they may in part explain estrogen's control inhibition of gonadotrophins. Supported by NIH Grant HD23830

393.2

EVIDENCE THAT NEUROPEPTIDE Y (NPY) PLAYS A ROLE IN THE PUBERTAL INCREASE IN LHRH RELEASE IN THE FEMALE MONKEY. A. C. Gore & E. Terasawa. Neurosci. Training Prog. & Wisconsin Reg. Primate Res. Ctr., Univ. Wisconsin, Madison, WI 53715

An increase in pulsatile LHRH release from the hypothalamus is critical for the initiation of puberty. However, the neural mechanism controlling this pubertal increase in LHRH is unknown. Since we found that NPY plays a role in the control of pulsatile LHRH release in adult monkeys, we examined whether NPY contributes to the increase in LHRH release that occurs during puberty using push-pull perfusion of the stalk-median eminence (S-ME). In the 1st experiment, endogenous NPY release in the S-ME of 10 prepubertal (12-20 mo) and 11 midpubertal (31-46 mo) monkeys was measured by RIA. No developmental changes in NPY release were observed: mean NPY release was 204±44 and 234±80 pg/ml for pre- and midpubertal monkeys, respectively. Thus, in the 2nd experiment we tested whether the responsiveness of the LHRH neuronal system to exogenous NPY changes during puberty. NPY (10^{-8} & 10^{-6}M) or vehicle was infused to the ME for 10 min through the push cannula and LHRH levels in samples collected at 10 min intervals were measured by RIA. In prepubertal monkeys (n=5), mean LHRH release was 1.3±0.2 pg/ml and was not affected by infusion of either NPY or vehicle. In contrast, in midpubertal monkeys (n=5) NPY infusion significantly stimulated LHRH release ($p<0.01$) from 4.3±1.4 to 6.5±1.9 pg/ml after 10^{-8}M NPY and from 3.6±1.1 to 6.1±1.4 pg/ml after 10^{-6}M NPY. Vehicle infusion did not affect LHRH release. These results suggest that while NPY levels do not change, an increase in the responsiveness of the LHRH neuronal system to NPY occurs during the pubertal process. Therefore, we conclude that the pubertal increase in pulsatile LHRH release is, in part, due to an increased sensitivity to NPY. (HD11355, RR00167 & GM07507).

393.3

NEUROPEPTIDE Y (NPY) ENHANCES LHRH-STIMULATED LH SURGES IN PENTOBARBITAL-BLOCKED PROESTROUS RATS. A. C. Bauer-Dantoin, J.K. McDonald[1], and J.E. Levine. Dept. Neurobiol. & Physiol., Northwestern Univ., Evanston, IL 60208 & [1]Dept. Anat., Emory Univ., Atlanta, GA 30322.

NPY may enhance the secretory response of gonadotropes to LHRH during initiation of the LH surge. To test this hypothesis, effects of NPY on LHRH-stimulated LH secretion were assessed in pentobarbital (PB)-anesthetized, proestrous rats. Female rats were fitted with atrial catheters on diestrus. On proestrus, hourly blood samples were collected from 0900-2100h. At 1330h, rats received PB (40 mg/kg BW) to block hypothalamic LHRH release, or saline. Every 30 min from 1400-1800h, PB-treated rats received i.v. pulses of LHRH (15, 150, or 1500 ng/pulse) or saline, along with concurrent pulses of NPY (1 or 10 μg/pulse). Plasma samples were analyzed by LH RIA. In PB-treated rats receiving vehicle pulses only, LH surges were completely blocked. Pulsatile LHRH treatments at 15, 150 and 1500 ng/pulse produced sub-physiological, physiological, and supra-physiological LH surges, respectively. Simultaneous administration of NPY pulses with 15 ng/pulse LHRH produced significant, dose-related potentiations of LHRH-stimulated LH surges ($p<.0001$). NPY RIA of plasma confirmed NPY increments following treatments. These results support the hypothesis that NPY operates as a neuroendocrine modulator during generation of the preovulatory LH surge. (NIH HD20677, HD21921, HD00879, JEL; HD00727, MOD 1-1118, JKM)

393.4

INCREASED NPY CONTENT AND MONOAMINE TURNOVER IN THE ARCUATE NUCLEUS DURING LACTATION IN THE RAT. M.S. Smith, W.-S. Lee, C.R. Pohl, and G.E. Hoffman. Department of Physiology, University of Pittsburgh, Pittsburgh, PA 15261.

In response to the suckling stimulus, GnRH secretion is greatly inhibited, whereas prolactin secretion is increased. To investigate changes in hypothalamic function associated with lactation, we determined *in vitro* release rates and content of NPY and GnRH, as well as turnover rates of monoamines, in the median eminence (ME) and arcuate nucleus (ARC). Turnover rates were assessed by HPLC using α-MPT or pargyline. All studies were performed on day 10 lactation(8 pups suckling) or during diestrus of the estrous cycle. GnRH content and release in response to 55 mM K^+ did not differ between tissues from lactating and diestrous animals. However, NPY content was significantly increased in lactating rats when compared to diestrous animals: two-fold greater in the ME(7.5 ± 0.7 ng, site of terminals) and 8-fold greater in the ARC (320 ± 20 ng, site of cell bodies). The magnitude of release of NPY in response to 55 mM K^+ generally paralleled content. The differences in NPY activity were confirmed using immunocytochemistry. In the ARC from diestrous animals, only NPY-positive fibers were observed, whereas the ARC from lactating animals contained numerous NPY-positive cell bodies and fibers. The ARC from lactating rats also had increased turnover rates for NE, DA and 5HT. Interestingly, the increased 5HT activity could be blocked by inhibiting catecholaminergic activity.

The increased NPY content in the ARC during lactation could represent increased NPY neuronal activity or an inhibition of NPY release. The dramatic alterations in NPY and monoamine activity in the ARC may be involved in mediating suckling-induced changes in GnRH and prolactin secretion. (Supported by NIH grant HD 14643).

393.5

IMMUNODETECTION OF OPIOID INTERACTIONS AFFECTING NEUROENDOCRINE SYSTEMS IN MONKEYS. P.C. Goldsmith, K.K. Thind and J.E. Boggan*. Reproductive Endocrinology Center, Univ. California, Sch. of Med., San Francisco, CA 94143-0556.

We have previously shown that vasopressin (VP) and opioid (OP) neurons synapse directly on gonadotropin-releasing hormone (GnRH) neurons in juvenile monkeys. To investigate relationships between VP- and OP-immunoreactive (-IR) neurons, we performed double label immunostaining on vibratome sections through the SON and PVN of cynomolgus monkeys, whose neuroendocrine (NEU) neurons were pre-labeled (Soc. Neurosci. Abstr. 14:439, 1988). In the SON, beaded OP-IR fibers innervated about 33% of the VP-IR cell bodies anteriorly and 10% posteriorly. In the PVN, clusters of OP-IR terminals were grouped around major processes arising from about 42% of the VP-IR neurons. EM confirmed that OP-IR terminals made mostly symmetrical synapses on both NEU and non-NEU VP-IR cell bodies and dendrites.

These results provide anatomical evidence of direct OP modulation of NEU VP release from the median eminence and posterior pituitary, and of non-NEU, intrahypothalamic VP neuronal activity. We have now identified OP-IR innervation of VP, oxytocin, dopamine and GnRH neurons in the monkey hypothalamus. It is not known whether these OP-IR afferents arise from the same POMC neurons, whether they release the same POMC product at every synapse, or whether the peptides impart stimulatory or inhibitory post-synaptic effects. Other data have suggested CRF may coexist in some VP-IR neurons, and that CRF acts via VP neurons to stimulate OP neuronal activity and to inhibit GnRH release. Taken together, these results suggest that stressful stimuli initiate a complex combination of peptidergic neurointeractions which regulate endocrine responses to stress in primates.

393.6

ELEVATION OF PRODYNORPHIN mRNA LEVELS IN THE RAT OVARY BY GONADOTROPIN STIMULATION. A. H. Kaynard and M. H. Melner. Divisions of Neuroscience and Reproductive Biology, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Opioid genes are expressed in the gonads and may perform important physiological functions in these tissues. These studies were conducted to elucidate whether gonadotropin induced changes in ovarian function can modulate the expression of prodynorphin (pD) mRNA. Pre-pubescent (26-day old) female rats were used to reduce the confounding influence of endogenous gonadotropin stimulation. Treatments consisted of sc injections of PMSG, an FSH agonist, and hCG, an LH agonist. Both hormones have long serum half-lives and the treatment groups were as follows: **CNT** - (n=10) vehicle on Day 0, collect ovaries on Day 2; **PMSG** - (n=8) 20 IU PMSG on Day 0, collect ovaries on Day 2; **hCG/1d** - (n=8) 20 IU PMSG on Day 0, 10 IU hCG on Day 2, collect ovaries on Day 3; **hCG/7d** - (n=8) 20 IU PMSG on Day 0, 10 IU hCG on Day 2, collect ovaries on Day 9; **hCG/14d** - (n=7) 20 IU PMSG on Day 0, 10 IU hCG on Day 2, collect ovaries on Day 16. These treatments produced ovarian conditions mimicking: no-change, follicular development, ovulation/luteinization, mid-pseudopregnancy and luteolysis/follicular development, respectively. Total RNA was isolated from the ovaries and size separated by electrophoresis through denaturing 1.5% agarose gels. Northern blot analysis, using a 1.7 kb cDNA fragment of the rat pD gene as a probe, revealed an ~2.2 kb form of pD mRNA in all ovaries examined. All hormonal treatments significantly increased the level of pD mRNA. The greatest elevation of pD mRNA was seen in the **hCG/1d** group (6.0-fold, $p<0.0005$), followed by **hCG/14d** (4.7-fold, $p<0.0005$), **hCG/7d** (2.4-fold, $p<0.0005$) and **PMSG** (1.4-fold, $p<0.025$). Thus hypertrophy and hyperplasia of ovarian tissues caused by gonadotropin stimulation enhances pD mRNA levels (ie: **PMSG**) and luteogenesis is associated with the greatest induction of PD mRNA levels (ie: **hCG/1d**). High levels of pD mRNA in the hCG/14d group may reflect the growth of a new cohort of follicles in the now sexually mature rats. These results support the hypothesis that pD may play a role in the growth, maturation and differentiation of ovarian tissues throughout the estrous cycle. Supported by NIH DK41035,RR00163, and ONR NN00014-90-J-1122.

393.7

AGING INFLUENCES THE DIURNAL PATTERN AND THE LEVEL OF PROOPIOMELANOCORTIN (POMC) GENE EXPRESSION IN THE ARCUATE NUCLEUS OF OVARIECTOMIZED (OVX) AND ESTRADIOL (E2)-TREATED RATS. K. Scarbrough, N.G. Weiland, J.M. Lloyd*, G.H. Larson*, S. Chiu* and P.M. Wise. Dept. Physiology, U. Maryland, Baltimore, MD 21201

Reproductive function, levels of LH and the ability of rats to respond positively to E2 decline with age. POMC gene expression may influence the level or pattern of LH secretion. Alterations in POMC gene expression may contribute to age-related changes in LH secretion. The purpose of this study was to determine whether the level of POMC mRNA or the diurnal pattern of gene expression changes with age in association with alterations in LH secretion. Young (3-4 mo), middle-age (9-11 mo) and old (17-19 mo) rats were OVX. One week later, half of each group received Silastic capsules containing E2 and rats were killed 2 days later at 0300, 1000, 1300, 1500, 1800 and 2300 h (n = 6-7 rats/time for each treatment). Brain sections were sliced and prepared for *in situ* hybridization (Wise et al, Mol Endocrinol, In Press). Slides were apposed to film and POMC mRNA levels were measured by quantitating the relative optical density within a fixed window placed over the arcuate nucleus. POMC mRNA levels were highest in young OVX rats. In this age group, E2 lowered the average level of POMC gene expression and induced a diurnal rhythm in which levels were highest at 0300h. POMC mRNA decreased in old compared to young rats in both E2-treated and OVX animals. Middle-aged rats exhibited an intermediate level of POMC mRNA. In addition, middle-aged and old E2-treated rats exhibited no detectable rhythm in POMC mRNA levels. In conclusion, our data demonstrate that aging influences both the average levels and the diurnal rhythmicity of POMC gene expression. These alterations may contribute to the age-related changes after LH secretion in OVX rats and in the ability of E2 to induce LH surges.

THE SEXUALLY DIMORPHIC DISTRIBUTION OF SUBSTANCE P IN SPECIFIC ANTERIOR PITUITARY CELL TYPES. Elaine R. Brown, Kevin A. Roth*, & James E. Krause. Depts. of Anatomy & Neurobiology and Pathology, Washington University School of Medicine, St. Louis, MO 63110.

Substance P (SP) immunoreactivity has been detected by radioimmunoassay in the rat anterior pituitary (AP). Its precise cytochemical location is of interest since SP may modulate pituitary hormone secretion locally. We have used a sensitive immunogold silver-enhancement staining technique to identify SP-immunoreactive (SP-ir) cells in the gland. Colocalization studies showed that the vast majority of SP-ir cells in the male AP were also immunoreactive for GH, representing approximately 25% of the somatotroph population in the male. SP-ir cells did not colocalize with lactotrophs, gonadotrophs, or corticotrophs; however, rare TSH/SP-ir cells were found in the male AP. Comparisons of pituitaries from males and females revealed that females have fewer SP-ir cells, and that only about 5% of the somatotrophs in the female express SP. This sexual dimorphism is diminished after 6 days of ovariectomy (OX), which results in a 3-fold increase in the GH/SP-ir cell population. This suggests that the previously reported estrogen-induced decrease in SP gene and peptide expression in the pituitary occurs in a subpopulation of somatotrophs. To test this hypothesis, the distribution of SP-ir cells was examined in pituitaries from oil- and estrogen-treated OX rats. Estrogen reduced the percentage of somatotrophs with SP immunoreactivity by 70% compared to OX oil-treated controls, indicating that estrogen regulates SP levels in the pituitary possibly by acting on a subpopulation of somatotrophs to suppress SP expression. Estrogen does not appear to alter the percentage of SP-ir cells colocalizing with TSH. These SP-expressing thyrotrophs were observed more frequently in the female than in the male, regardless of steroid status. These studies reveal that males have more total SP-ir cells in the AP than do females, and that there is a sexually dimorphic pattern of SP distribution in the gland. Males have a higher percentage of SP-ir GH cells, whereas females have more SP-ir thyrotrophs than do males. This localization of SP in the pituitary will aid in the investigation of the local regulation of pituitary hormone secretion. Supported in part by the Washington University-Monsanto Agreement.

GNRH NEURONS IN THE FETAL LAMB HYPOTHALAMUS ARE NOT SEXUALLY DIFFERENTIATED. RI Wood*, SW Newman, MN Lehman, DL Foster*, Reprod. Sci. Prog., Depts of Physiology, Anatomy & Cell Biology, Obstetrics & Gynecology, and Biology, The Univ. of Michigan, Ann Arbor, MI, 48109, and Dept of Anat. & Cell Biol., Univ. Cincinnati Coll. Med., Cincinnati, OH, 45267.

The critical period for sexual differentiation of the brain in the developing lamb occurs before birth. Exposure to steroids during mid-gestation alters the control of GnRH secretion after birth (Wood and Foster, unpublished). We have examined GnRH neurons in male and female lambs during the critical period to determine if sexual dimorphism of these neurons exists. The number and distribution of GnRH-containing neurons from mid-gestation (85 days) male and female fetuses were compared (n=3 each). Immunoreactive cells were labelled using LR-1 antiserum (R. Benoit) with the Vectastain ABC kit. GnRH neurons were localized in 60 um coronal sections in a block of tissue extending from the diagonal band of Broca to the rostral mammillary bodies. Neither the pattern of distribution nor the estimated number of GnRH neurons in male and female fetuses differed (1852±340 vs 1727±350, P>.05), and the total number of cells was similar to that reported for the adult ewe (Lehman, M. et al, *J Comp Neurol*, 244:19, 1986). Unlike the adult, substantial numbers of GnRH neurons in the fetus were present caudal to the optic chiasm (males 28% of total, females 37%, P>.05). These data indicate that the distribution of GnRH neurons may change during later stages of development, but is not sexually differentiated during the critical period. Properties of Neuroendocrine Cells Migrating from Olfactory Placode into Basal Forebrain. Zheng, L.-M., M. Schwanzel-Fukuda, J.F. Heitmancik, R.B. Gibbs, D.W. Pfaff. Laboratory of Neurobiology and Behavior, Rockefeller University, New York, N.Y. 10021.

LHRH-immunoreactive cells migrate from the developing olfactory placode into the basal forebrain (Schwanzel-Fukuda and Pfaff, Soc. Neuroscience, Abstr. p. 984, '88; Nature, 338:161-164, '89; Wray et al., Devel.Brain Res., 46:309-318, '89), associated with NCAM (Schwanzel Fukuda et al., Soc. Neuroscience Abstr. '90). The following experiments addressed the questions (A) do these immunoreactive neurons actually express the LHRH gene; and (B) is the migration specific to LHRH neurons among neuroendocrine cells?

A. In fetal mouse olfactory apparatus and forebrain, in situ hybridization was performed using ^{3}H-riboprobes for LHRH mRNA, and an established protocol (Gibbs et al., Mol. Brain Res., 6:275-287, '90). The antisense riboprobe revealed positive labelled cells just outside the olfactory placode on days 12 and 13, and these cells tended to be clustered. The control sense riboprobe did not yield labelled cells. We conclude that migrating LHRH-immunoreactive cells do express the LHRH gene.

B. Immunocytochemistry was performed in fetal mouse olfactory apparatus on days E11 through E13 using the following antisera: thyrotropin releasing hormone, corticotropin releasing hormone, growth hormone releasing hormone, oxytocin, vasopressin, neuropeptide Y and somatostatin. While the migration of LHRH neurons was confirmed, none of these other antisera revealed immunoreactive cells under the conditions tested. Among cells expressing neuroendocrine genes of interest, so far, LHRH neurons appear specifically to make this migration from olfactory placode to brain. INCREASED SUBSTANCE P AND NEUROKININ B GENE EXPRESSION IN HYPOTHALAMI OF POSTMENOPAUSAL WOMEN. N.E. Rance and W.S. Young III. Department of Pathology, University of Arizona College of Medicine, Tucson, AZ 85724, and Laboratory of Cell Biology, NIMH, Bethesda, MD 20892.

We have recently shown a striking hypertrophy of neurons containing estrogen receptor, Neurokinin B (NKB) and Substance P (SP) mRNAs in the infundibular nucleus of postmenopausal (POSTM) women (Rance et al., 1990, J Clin Endo Metab. In press; Rance and Young, 1990, Endo Soc Abst). In the present study, we determined if POSTM neuronal hypertrophy is accompanied by increased gene expression. Sections from hypothalami of premenopausal (PREM: N=3) and POSTM (N=3) women were incubated with [^{35}S]-labeled synthetic oligonucleotide probes complementary to NKB and SP mRNAs. The mean cross-sectional areas of POSTM infundibular neurons labeled with the SP and NKB probes increased to 180% and 196% of PREM values, respectively. Audioradiographic grain densities (#grains/100μm^2) for both SP (300%) and NKB (130%) were also elevated in the POSTM women. The most striking findings were 4-fold (SP) and 15-fold (NKB) increases in the numbers of labeled neurons/tissue area in the POSTM infundibular nucleus. These data support the hypothesis that POSTM neuronal hypertrophy is due to removal of the inhibitory feedback of ovarian steroids and demonstrate that human menopause is associated with marked increases in hypothalamic neuropeptide gene expression.

INTERLEUKIN-1 SUPPRESSES LH SECRETION WITHOUT CHANGING HYPOTHALAMIC GnRH RELEASE K.-Y. Francis Pau, Matthew J. Berria and Harold G. Spies, Division of Reproductive Biology, Oregon Primate Research Center, Beaverton, OR 97006.

Interleukin-1 (IL-1) has diverse roles in both peripheral tissue and brain. Intracerebroventricular infusion of IL-1 suppresses pituitary luteinizing hormone (LH) release. The presence of IL-1 and its receptors in the mediobasal hypothalamus (MBH) may indicate a hypothalamic mechanism for IL-1 influence in pituitary gonadotropin regulation. To address this issue we collected MBH push-pull (PP) perfusates for gonadotropin-releasing hormone(GnRH) and peripheral blood samples for LH estimates at 10- or 20-min intervals for 8h in ovariectomized (OVX) and ovarian intact (INT) rabbits. Recombinant human IL-1α (1 or 2 μg/h) or human IL-1ß fragment (IL-1ßf; aa163-171; 2 μg/h) was infused continuously into the MBH via the PP system for 4 h after an initial 4 h of PP perfusion. Plasma LH levels were reduced after MBH infusion of IL-1α at 1 μg/h (pre-ILα LH = 1.04 ± 0.25 vs post-ILα LH = 0.63 ± 0.18 ng/ml, $p<0.05$, n=6) and 2 μg/h (1.23 ± 0.31 vs 0.79 ± 0.22, $p<0.01$, n=6) in OVX does and at 2 μg/h (0.30 ± 0.06 vs 0.22 ± 0.05, $p<0.01$, n=7) in INT does. In contrast, MBH-GnRH in PP perfusates was not altered by IL-1α in these does even though GnRH was readily measurable (pre-ILα GnRH = 2.27 ± 0.14 vs post-ILα GnRH = 2.36 ± 0.26 pg/ml in OVXs, $p>0.05$, n=6). Infusion of IL-1ßf changed neither MBH-GnRH nor LH release in 3 OVX and 3 INT does. These results suggest that the ovarian-independent, inhibitory action of IL-1α on pituitary LH release is mediated by factor(s) other than release of MBH-GnRH. THE ROLE OF D1/D2 INTERACTION AND DOPAMINE RECEPTOR DENSITY IN BEHAVIORAL SUPERSENSITIVITY TO DOPAMINE AGONISTS. G.J. LaHoste, M. Andreini* and J.F. Marshall. *Dept. Psychobiology, Univ. California, Irvine, CA 92717.*

Evidence from several experiments necessitates a revision of the widely believed concept that dopaminergic supersensitivity can be explained primarily by increases in striatal D2 density. First, rats given a unilateral 6-OHDA lesion of the dopamine (DA) pathways and subsequent chronic treatment with the selective D2 antagonist eticlopride show vigorous rotation contralateral to the lesion despite the fact that D2 density is symmetrically up-regulated in the two striata. Second, chronic treatment of neurologically intact rats with haloperidol, which increases striatal D2 density to the same degree (25-40%) as a 6-OHDA lesion, results in a modest (2-fold) increase in sensitivity to the behavioral effects of the D2 agonist quinpirole or the mixed D1/D2 agonist apomorphine, in marked contrast to the 10- to 40-fold increase in sensitivity observed following 6-OHDA treatment.

Alternatively, the profound supersensitivity of 6-OHDA- or reserpine-treated rats to DA agonists may relate to the breakdown of the normal D1/D2 synergism. First, treatment with 5 daily injections of reserpine (1 mg/kg s.c.) induces a breakdown in the synergistic effects of D1 and D2 agonists but does not alter striatal D1 or D2 receptor density. Second, intact rats given a fixed, high dose (20 mg/kg i.p.) of the D1 agonist SKF 38393 show a dose-response relationship for stereotypy to quinpirole similar to that observed in reserpine-treated rats not given the D1 agonist.

Thus, two types of DA receptor supersensitivity can be discerned: a modest one associated with an increase in D2 receptor density, and a profound one that is not dependent on increased D2 or D1 receptor density and, instead, is associated with a breakdown in D1/D2 synergism. We hypothesize that the profound type of dopaminergic supersensitivity results from the liberation of this receptor subtype from control by the D1 receptor. This reformulation may have important implications for understanding certain aspects of tardive dyskinesia, Parkinson's disease, and schizophrenia.

PARALLEL INDUCTION OF JUN B AND C-FOS EVOKED IN THE STRIATUM BY THE PSYCHOMOTOR STIMULANT DRUGS COCAINE AND AMPHETAMINE. R. Moratalla,[1] H.A. Robertson,[2] P.A. DiZio,[3] and A.M. Graybiel.[1] [1]Dept of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139, [2]Dept of Pharmacology, Dalhousie Univ., Halifax, Nova Scotia, [3]Spatial Orientation Lab, Brandeis Univ., Waltham, MA 02254.

We have shown by immunohistochemistry and in situ hybridization that the psychomotor stimulant drugs, amphetamine and cocaine, induce c-fos expression in the striatum (Graybiel et al., this meeting). This finding raises the question of what dimerization events occur in relation to the induction of c-fos. In several models of immediate early gene (IEG) induction (e.g., long-term potentiation, convulsion), sets of IEGs of the leucine zipper family are co-induced. To test whether members of the jun family are co-activated with c-fos in the striatum of psychostimulant-treated rats, we carried out in situ hybridization with oligonucleotide probes for jun B, c-jun and c-fos on tissue sections from rats treated intraperitoneally with cocaine (25 mg/kg) and amphetamine (5 mg/kg), and euthanized 1 hr later. We compared the patterns of mRNA induction in the striatum for the three IEGs in serial sections.

The in situ hybridization autoradiograms show strong induction of jun B by cocaine and amphetamine, and demonstrate that this induction was paralleled by activation of c-fos. By contrast, there was no evidence for induction of c-jun mRNA transcripts in the striatum of the same brains. These findings establish that, among IEGs of the leucine zipper family, at least two, jun B and c-fos, are coordinately induced in the striatum by psychomotor stimulants. These transcriptional events may be related to the extended effects of such drugs. Cortical lesions also coinduced jun B and c-fos in the ipsilateral cortex, suggesting a more general incidence of this pattern of IEG co-expression. SYNERGISTIC ACTIVATION OF THE IMMEDIATE-EARLY GENE c-FOS IN STRIOSOMES BY D1- AND D2-SELECTIVE DOPAMINE AGONISTS. M.L. Paul[1], A.M. Graybiel[2] and H.A Robertson[1]. [1]Dept. of Pharmacology, Faculty of Medicine, Dalhousie University, Halifax, N.S., Canada B3H 4H7 and [2] Dept. Brain & Cog. Sci., MIT, Cambridge, MA 02139, U.S.A.

D1- and D2-selective dopamine agonists interact synergistically to induce rotation in rats with unilateral 6-OHDA lesions (Robertson, G.S. and Robertson, H.A., Brain Res. 384:384, 1986). Systemic injections of D1-dopamine selective agonists (but not D2-selective agonists) activate the immediate-early gene c-fos in striatum ipsilateral to a 6-OHDA lesion (Robertson, H.A. et al, Brain Res. 503:346, 1989). Accordingly, we asked what would happen to c-fos activation if we administered a low dose of a D1-selective agonist together with a D2-selective agonist. Rats with a unilateral 6-OHDA lesion were given either SKF-38393 (0.5 mg/kg, i.p.), LY-171555 (0.25 mg/kg, i.p.) or the combination. Rotation was monitored for 2 hours, following which the rats were perfused for immunohistochemical localization of c-fos protein and calbindin 28kD.

The D1-agonist SKF-38393 produced little rotation and little c-fos activation. LY-171555 produced little or no c-fos activation as expected, even though this low dose caused turning. Although LY-171555 produced little or no c-fos activation by itself, the combination of the D1 and D2 agonists produced marked c-fos activation. Both the c-fos activation and rotation were reversed by MK-801 (1 mg/kg i.p.). In animals receiving both the D1 and D2 agonists together, much of the c-fos immunoreactivity was located in striosomes.

REGULATION BY D1 AND D2 DOPAMINE RECEPTORS OF STRIATONIGRAL AND STRIATOPALLIDAL PEPTIDE mRNA LEVELS. C.R. Gerfen, T.M. Engber, Z. Susel, L.C. Mahan, F.J. Monsma, Jr., L.D. McVittie and D.R. Sibley. Lab of Cell Biology, National Institute of Mental Health and Experimental Therapeutics Branch, NINDS, National Institutes of Health, Bethesda, MD 20892.

We examined the differential regulation through D1 and D2 dopamine receptor subtypes of peptide expression in striatopallidal and striatonigral neurons. *In situ* hybridization histochemistry shows that striatal neurons that project to the globus pallidus express both enkephalin and D2 dopamine receptor mRNA whereas striatal neurons that project to the substantia nigra express mRNA encoding the peptides dynorphin and substance P and also express the D1 dopamine receptor. Unilateral lesions of the nigrostriatal dopamine pathway with 6-hydroxydopamine (6-OHDA) in rats results, on the lesioned side, in a marked elevation in enkephalin mRNA, a decrease in substance P mRNA and no significant change in dynorphin mRNA in striatal neurons. Lesioned animals that are later treated for 21 days with the D1 specific agonist SKF-38393 show, on the lesioned side, an elevation of both dynorphin and substance P mRNA expression in striatonigral neurons but no change in the lesion-induced increase in enkephalin mRNA expression in striatopallidal neurons. Lesioned animals that are treated instead with the D2 specific agonist quinpirole show, on the lesioned side, a reduction in the lesion-induced increase in enkephalin mRNA expression in striatopallidal neurons but no change in either substance P or dynorphin mRNA expression in striatonigral neurons. These data show that the differential affect of dopamine on striatonigral and striatopallidal output pathways are mediated by the D1 and D2 dopamine receptor subtypes, respectively.

EXPRESSION OF GFAP AND J1/TENASCIN IN NORMAL DEVELOPING NEOSTRIATUM AND AFTER 6-OHDA LESION. T.F. O'Brien, K. Harrington*, A. Faissner, M. Schachner, and D.A. Steindler. Dept. of Anat. and Neurobiol., Univ. of Tenn., Memphis, and Dept. of Neurobiol., Univ. of Heidelberg.

The neostriatum is composed of two compartments contributing to structural and functional organization. Recently, lectinophilic molecules have been identified in the interface of the patch-matrix compartments during development (Steindler et al JCN 267:357, 1988). The present study was undertaken to assess the role of glia (by immunoreactivity for GFAP), associated glycoconjugates (by anti-J1/tenascin), and afferent input [by TH immunoreactivity and 6-OHDA lesions of the substantia nigra (SN)] in neostriatal development. Adjacent sections from ICR mice on postnatal day 1-12 were processed by routine histochemical and immunohistochemical procedures using AChE and TH as mosaic markers. J1/tenascin outlines the interface of the patch-matrix system. Both J1/tenascin and GFAP are more prominent in the matrix compartment which may reflect a later differentiation of this compartment compared to the patches. GFAP immunoreactive cells with numerous processes are present in the patch-matrix interface and it is from these cells that matrix molecules like J1/tenascin may emanate. Lastly, neonatal 6-OHDA lesions of the SN results in a marked depletion of J1/tenascin immunostaining of the neostriatum on the lesion side. Thus the expression of recognition molecules like J1/tenascin may be under the influence of afferent innervation. Supported by USPHS grant NS 20856, NSF grant BNS-8911514 and the DFG.

394.6

A COMPARISON BETWEEN DORSOLATERAL AND VENTROMEDIAL STRIATAL PATHWAYS THROUGH THE MONKEY BASAL GANGLIA. S.N. Haber, E.L. Lynd, S.J.Mitchell+ Department of Neurobiology and Anatomy, University of Rochester, Rochester, N. Y., +VA Medical Center, Syracuse, N.Y.

We compared the output pathways from the dorsolateral (motor) striatum and the ventromedial (limbic) striatum to the globus pallidus and substantia nigra and further traced the output pathways from the different pallidal regions that receive these two inputs. Injections of 3H amino acids, PHA-L, or cholera toxin, subunit B were placed in the dorsolateral putamen or ventral striatum. Processed sections were double stained for NGF receptors to determine the overlap of tracers with cholinergic neurons. Tracer injections were then made in regions of the globus pallidus that receive either motor or limbic input.

Results showed that terminals from functionally different regions of the striatum are strictly segregated in the pallidum. Ventral striatal projections overlap extensively with neurons of the N. Basalis, while those from the dorsal striatum do not. Projections to the nigra are also topographically organized, however, patches of terminals from each region of the striatum are observed within the domain of the terminals arising from the other injection site. Furthermore, while projections from the dorsal pallidum terminate primarily in the ventral portions of the substantia nigra and ventral pallidal projections terminate primarily in the dorsal substantia nigra, some overlap between dorsal and ventral pallidal terminals are observed in the substantia nigra. These results suggest that pathways from the motor and limbic-related striatum maintain segregated pathways in the globus pallidus, however some integration of these functionally different regions appears to take place in the substantia nigra.

A DYADIC PATCH-MATRIX SCHEME DOES NOT ADEQUATELY DEFINE THE HISTOCHEMICAL HETEROGENEITY OF THE HUMAN STRIATUM. D. G. Cole and N. W. Kowall. Neurology Service, Massachusetts General Hospital, Boston MA 02114.

The generally accepted contemporary view of striatal organization designates two compartments based on histochemical and hodological criteria: the patch, or striosome, and the surrounding matrix. This paradigm is mainly based on observations in the rat and cat. In our studies of human striatum we have been impressed by the complexity of substance P (SP) and met-enkephalin (ME) staining patterns, both considered to be classical markers for striatal patches. Serial sections of normal human striatum at the level of the nucleus accumbens were stained for acetylcholinesterase (AChE), NADPH diaphorase, tyrosine hydroxylase (TH), calbindin D28K, ME, SP, cholecystokinin (CCK), transforming growth factor alpha (TGF), and MAP-2. SP, ME, TGF, and CCK all showed a similar core of low immunoreactivity surrounded by a rim of intense staining. Dorsally these patches were smaller and were often cut tangentially resulting in a small immunoreactive rim without a core. A superimposed gradient of matrix staining was maximal ventrally where it merged with the immunoreactive rim of the patches from which it could not be distinguished. Calbindin staining is uniform in the matrix without a dorsoventral gradient. Patches of low calbindin staining correspond exactly with the unstained cores of SP, ME, TGF, and CCK. As previously reported, the areas of low AChE, NADPH diaphorase, MAP-2 and TH correspond. These patches, however, are larger than the calbindin patches and correspond exactly to the core plus immunoreactive rim of SP, ME, TGF, and CCK staining. The core region of patches did not stain positively with any method. Our results show that striatal organization in the human is more complex than previously reported. The neurochemical characteristics of the core region remains to be defined.

ALL SERIALLY ANALYZED CHOLINE ACETYLTRANSFERASE IMMUNOREACTIVE NEURONS SHOW DIRECT SOMATIC OR DENDRITIC CONTACTS WITH UNLABELED SPINY NEURONS IN ADULT RAT CAUDATE-PUTAMEN NUCLEUS. V.M. Pickel & J. Chan*., Div. Neurobiol., Dept. Neurol. & Neurosci., Cornell U. Med. Coll., NY, NY 10021.

Direct somatic and dendritic contacts between neurons mediate electrical coupling and influence the level of expression of choline acetyltransferase (ChAT) in certain neurons. To determine the relative frequencies of contacts between cholinergic and non-cholinergic neurons in the adult rat striatum, we examined the ultrastructural localization of ChAT-antibodies in serial ultrathin sections using the peroxidase-antiperoxidase (PAP) labeling method. Of 24 ChAT-labeled soma, 21% were in direct apposition to unlabeled soma. The remaining 79% of the ChAT-labeled perikarya appeared more bipolar and were not in apposition with unlabeled soma, but did show somatic junctions with unlabeled dendrites and dendritic appositions with unlabeled soma and dendrites. Appositional zones between plasmalemmas of ChAT-immunoreactive and unlabeled soma and dendrites were characterized by: 1) absence of glial processes, 2) parallel spacing with intermittent separation and fusion or occasionally parallel arrays of thin (1-2 nm) electron-dense bands, and 3) proximity of organelles such as subsurface cisternae and saccules of rough and smooth endoplasmic reticulum which may be involved in calcium-storage in both labeled and unlabeled cells. The observed contacts may serve as a substrate for either electrotonic coupling or more long-term changes involving second messengers. (Supported by grants from NIDA (DA04600) and NIH (HL18974)).

3D FUNCTIONAL NEUROANATOMY OF HAND MOVEMENTS IN HEMINEGLECT. R.K. Deuel[+], E.M. Santori[Φ], and A.W. Toga[Φ]. [+]Depart. of Ped., Wash. Univ. Sch. of Med., St. Louis, MO 63110 and [Φ]Depart. of Neurol., UCLA, Los Angeles, CA 90024.

In hemineglect after frontal cortical damage there is decreased neural activation in motor thalamus and basal ganglia as determined by quantitative 2-deoxyglucose autoradiography (2DG) in the monkey. The effect of continuous manual motor behavior on 2DG uptake by these structures was tested in neglect monkeys exerting cued, measured, and timed forces with the hands. 2DG uptake was brisk and symmetrical in supplementary, cingulate, and primary motor cortices with decrements in anterior thalamus that included regions of reticularis, nVA, and nVL, and in parts of basal ganglia. Computerized three dimensional reconstructions of paired histology and 2DG images were used to more precisely localize decrements. These were confined to narrow subregions of motor thalamic nuclei in pulling monkeys. In comparison thalami from non-pulling neglect animals showed 2DG decrements that conformed much more closely to conventional nuclear boundaries. Thus, manual motor activity induces neural activation in sectors of thalamus that are abnormally quiescent during resting neglect. The findings show that synaptic activity in hemineglect is regulated by motor behavior within the constraint imposed by anatomic connectivity.

THE NORADRENERGIC INNERVATION OF THE THALAMIC RETICULAR NUCLEUS AND THE BASAL NUCLEUS REGION IN RATS. C. Asanuma. Laboratory of Neurophysiology, NIMH, NIH Animal Center, Poolesville, MD 20837.

While the axonal arbors of thalamocortical and corticothalamic collaterals dominate the neuropil of the thalamic reticular nucleus (TRN), recent attention has focused upon some of the other inputs to the TRN. This is because these additional inputs may indirectly influence the state dependent gating of signal flow through the nuclei of the dorsal thalamus. Neurons in several sites afferent to the TRN, including the locus coeruleus and the basal nucleus, have discharge properties which are closely correlated with changes in arousal levels. In the present study, dopamine-β-hydroxylase (DBH) immunohistochemistry was used to examine the arborization patterns of noradrenergic axons within the TRN and the basal nucleus region. This was combined with intracellular injections of Lucifer yellow (LY) in the lightly fixed slice preparation in some cases to examine the structural relation of noradrenergic axons to neurons within these two areas.

Within the TRN, many DBH+ axons are present. These generally extend linearly, giving rise to boutons *en passant* which are rather evenly dispersed throughout the nucleus. When TRN neurons are injected with LY, DBH+ axons are seen in relation to dendrites of all diameters, with the *en passant* DBH+ boutons forming random apparent appositions with dendrites they intersect. Within the basal nucleus region, however, the DBH+ axons, while also giving rise to some *en passant* boutons, frequently emit focal bouton clusters. When cells in the basal nucleus region are injected with LY, such DBH+ bouton clusters are seen in close juxtaposition with the somata and proximal dendrites of some, though not all, of the neurons within the region. The noradrenergic axonal boutons, therefore, are randomly dispersed within the TRN, but are selectively aggregated upon some neurons within the basal nucleus region.

INTRACELLULAR AUTOSTIMULATION OF *IN VITRO* GUINEA-PIG THALAMIC NEURONS (TH) UTILIZING A HARDWARE BIO-ELECTRIC RE-ENTRY SYSTEM. Y. Yarom[1] and R. Llinás, Dept. of Physiol & Biophysics N.Y.U. Med. Ctr, NY, N.Y., Dept. of Neurobiology, Hebrew University, Jerusalem Israel[1]

A waveform generator simulating the feedback activity from the reticular thalamus was constructed to explore the role of hyperpolarizing potentials in the generation of oscillatory thalamic activity. IPSP-like waveforms were simulated by controlling the amplitude and rise and fall time for current injected through the recording electrode. The injection, was triggered by TH spikes and was proportional to the number of spikes in the burst. The "IPSP" parameters best suited to supporting rhythmic activity were then determine. **Low frequency** (6 to 10Hz) spindle-like oscillations were elicited from cells at rest or slightly hyperpolarized (-65mV), if the duration of the hyperpolarizing current was long enough (> 50ms) to activate the calcium-dependent low threshold condutance (LTC). Given the above, a brief depolarization of TH neurons could trigger prolonged rhythmic activity at a frequency determined by the duration of the hyperpolarizing pulses. This activity usually lasted for 3-5 cycles, but could persist for 50 cycles. The interburst interval limited the burst duration. Thus, as the interval progressively shortened, the LTS decreased ending the burst—independently of its initial frequency. In contrast, if TH cells were held depolarized, inhibitory feedback could induce high frequency oscillations, by modulating the repetitive firing into well ordered trains whose frequency (10 to 50Hz) depended on the amplitude and duration of the "IPSPs". Thus: 1) Feed-back hyperpolarizing currents are necessary and sufficient to generate and maintain thalamic neuron rhythmicity *in vitro*, the oscillatory frequency being related to the resting potential level and IPSP duration. 2) The intrinsic membrane properties of thalamic neurons are sufficient to account for the transient nature of thalamic oscillations. Supported by 13742 from NINDS.

INTRACELLULAR RESPONSE OF RAT NUCLEUS ACCUMBENS NEURONS FOLLOWING STIMULATION OF HIPPOCAMPAL INPUTS IN AN IN VITRO SLICE PREPARATION. C.M.A. Pennartz and S.T. Kitai, Department of Anatomy and Neurobiology, College of Medicine, The University of Tennessee, Memphis, TN 38163.

The aim of the present study was to analyze responses of neurons of the nucleus accumbens to stimulation of the fornix, which contains afferents from the hippocampal formation. Using electrodes filled with 0.5 M K-methylsulphate and 2 % biocytin, recordings were made from 52 neurons (membrane potential: -68 ± 1 (SEM) mV, input resistance 42 ± 4 MOhm). After histological processing with avidin-Texas Red, 45 labeled neurons were identified as medium spiny neurons. A depolarizing postsynaptic potential (DPSP) following stimulation of the fornix was recorded in 48 neurons. Using intracellular injection of positive DC current and Na-channel blocker QX-314, this DPSP could be dissociated into an EPSP reversing its polarity at -11 to +15 mV and a bicucullin-sensitive IPSP reversing at -70 to -50 mV. The threshold for the IPSP was lower than for the EPSP. Furthermore, the IPSP onset latency was consistently shorter than the spike latency.

The data indicate that medium spiny neurons receive excitatory monosynaptic inputs from the subiculum. In addition, fornix stimulation most likely activates a feed-forward inhibitory pathway in the nucleus accumbens. (Supported by Grant USPHS NS 233886 and 20702 to S.T. Kitai).

ACTIVATION OF CA^{++} CURRENTS BY VOLTAGE-CLAMP COMMAND PULSES IN THE SHAPE OF ACTION POTENTIALS. **D.P. McCobb and K.G. Beam. Dept. of Physiology, Colorado State University, Ft. Collins, CO 80523.**

We have used action potential waveforms (APW's) as voltage-clamp command pulses to investigate Ca^{++} current activation by voltage transients which are more natural than conventional square steps. Traces below represent APW (upward) and whole-cell Ca^{++} currents (downward), recorded in a chick sensory neuron. Currents were recorded before and during exposure to 3 mM amiloride, which selectively blocks T-type current. $[Ca^{++}]_o$ = 2mM. As illustrated, with a normal, brief duration APW the contribution of T current to the total is much larger than would be expected, since when currents are activated with conventional voltage steps T is much smaller than the high-voltage activated current (HVA.≈N+L). Two factors can account for this: lower threshold and slower deactivation kinetics of T. The latter leaves T channels open after repolarization, when the driving force is great. We also find that increasing APW duration causes a much larger increase in HVA than in T current. Supported by NS08373 and NS26416.

Ca CHANNELS AND DIHYDROPYRIDINE-SENSITIVITY IN RAT CEREBELLAR GRANULE CELLS IN CULTURE. A. Feltz*, M. De Waard*, J.L. Bossu*, L. Fagni*, F. Tanzi*, P. Feltz. Laboratoire d'Etude des Régulations Physiologiques, CNRS, 23 rue Becquerel, 67087 Strasbourg, France.

A voltage-dependent Ca current can be elicited in cerebellar granule cells mechanically dissociated at PN5 and maintained 5 days in culture (DMEM + 25 mM KCl). With 10 mM $BaCl_2$ in the external medium, a current was elicited above -20 mV and reached a mean peak value of 150 pA at +10 mV. The total current (up to 90%) was half inactivated by holding the membrane potential at -70 mV. It was further stable for a 15 min period which allowed its pharmacological characterization, provided 1 mM ATP was added to the recording solution (pCa 8, 30 mM EGTA/CsOH, pH 7.2). Since full inhibition by nicardipine was attained at a concentration of 10 μM (IC50: 1 μM), we looked for a channel activity sensitive to the dihydropyridines (DHP) as recorded in cell attached condition (110 mM $BaCl_2$). Two channel types displayed such a sensitivity. A ≈ 25 pS L-type channel was recorded: its low opening probability in control conditions (<0.001) was greatly enhanced by BAY K 8644. In addition, a spontaneous 5-7 pS was observed at potentials above -50 mV which open time was greatly enhanced by both depolarization and addition of 10^{-6} M (-)BAY K 8644 (up to 300 ms at 0 mV). The latter channel might account for the DHP-sensitive Ca entry commonly measured in flux experiments.

VOLTAGE-DEPENDENT CALCIUM CURRENTS IN RAT CEREBELLAR GRANULE NEURONS (CGN). M. Bertolino, S. Vicini, R. Llinas* and E. Costa. FGIN, Georgetown University, Washington, D.C. 20007; *Dept. Physiol. and Biophysics, New York Univ. Med. Center, New York, NY 10016.

In order to learn about the biophysical and pharmacological properties of Ca^{2+} channels present in CGN, we monitored transmembrane currents in whole-cell configuration using the patch clamp technique. Currents were elicited from a holding potential of -90 mV in the presence of $BaCl_2$ 20 mM. Cadmium (100 μM) blocked completely the Ca^{2+} current, while neither amiloride (500 μM) nor w-conotoxin (10 μM) affected the current. While nifedipine (300 nM) partially blocked the current, the toxin from the funnel-web spider venom (FTX) (Llinas et al., PNAS, 1989, 89:1689) blocked most of the current.

Single-channel experiments, performed in cell-attached configuration with 110 mM $BaCl_2$, revealed the presence of a main conductance level of about 20 pS (whose frequency was increased when BAY K 8644 1 μM was added to the bath solution) and in some cases other lower conductance levels. Biophysical and pharmacological properties suggest that in cultured CGN at least two Ca^{2+} channel species can be detected. One can be characterized biophysically as L-type (Nowicky et al., Nature, 1985, 316:440) and the other with a lower conductance is similar to the P channel described by Llinas et al. (PNAS, 1989, 89:1689).

VOLTAGE-DEPENDENT AND PHARMACOLOGICAL PROPERTIES OF CALCIUM CURRENTS IN ISOLATED RAT CEREBELLAR PURKINJE CELLS.

P.E. Hockberger and L. Yousif. Dept. of Physiology, Northwestern Univ. Medical School, Chicago, IL 60611.

Whole-cell calcium currents were recorded from identified Purkinje cells acutely isolated from 1-2 week-old rats, as described previously (Hockberger et al., Soc. Neurosci. Abstr. 15: 1149, 1989). Both high-threshold (HT) and low-threshold currents were found although the latter did not appear until the second postnatal week. This report focuses on the properties of the HT current. The current amplitude was dependent upon the holding potential, e.g., peak amplitude was 50-75% larger when held at -80mV compared with -40mV. Regardless of the holding potential, the threshold for activation was -20mV (± 5mV) and the peak amplitude was evoked around 0mV (± 5mV). During voltage steps the degree of current inactivation was <10% during the initial 50ms, but it reached 20-40% after 400ms. Recovery from inactivation was slow (T = 1-2 min). Local application of calcium channel antagonists via micropipet revealed that nifedipine (NIF), w-conotoxin-GVIA (CTX), or a synthetic analog of funnel-web spider toxin (FTX)# reduced the HT current in a dose-dependent and reversible manner. Reductions of 80-100% were obtained when applying NIF, CTX, or FTX at 10^{-6}M and stepping from either -40 or -80mV. Including 8-bromo-cGMP (10^{-3}M) in the internal solution did not affect any of the measured parameters listed above.

This research was supported by NIH grants NS-26915 and NS-17489. #The FTX was kindly provided by Pfizer Central Research (Groton, CT) and Natural Product Sciences (Salt Lake City, Utah).

ISOLATION OF A CALCIUM CHANNEL FROM MAMMALIAN CEREBELLAR TISSUE USING SYNTHETIC FTX. B. D. Cherksey, M. Sugimori and R. Llinás Dept. of Physiology and Biophysics, NYU. Med. Ctr., New York, NY 10016.

FTX, the specific blocker of the P-type calcium channel was isolated from the venom of agelenopsis aperta is polyamine-like (Cherksey, et al ,Neurosci. Soc. Abs, 1989) and has been used to isolate a neuronal membrane protein which when reconstituted into a lipid bilayer gave channel activity. Small amounts of purified FTX made further biochemical studies unfeasible. Based on our structural analysis of FTX, we have synthesized a polyamine ("synthetic FTX") (Cherksey, et al, Biol. Bull, 1989) with specific P-channel blocking characteristics. The availability of synthetic FTX has made possible further studies of the P-channel protein. Synthetic FTX was coupled to Sepharose. Membranes from cow cerebellum homogenate, solubilized in 3% sodium choleate, were subjected, batch-wise, to affinity chromatography on Synthetic FTX gel. Bound protein was eluted with 1 M calcium chloride. The volume was reduced. Portions of the material were taken and reconstituted into lipid vesicles. Functional activity was determined using the lipid bilayer technique. The purified protein had channel-like activity, blocked by FTX, indistinguishable from that obtained using purified FTX as the gel ligand. SDS polyacrylamide gel electrophoresis under non-reducing conditions, gave a single sharp band in the 120,000 Da. region. Similar results were obtained using size-exclusion HPLC. Under reducing conditions only 2 bands were seen using SDS-PAGE: one sharp band at 70,000 Da. and a broad band over the 22,000 - 30,000 region. On HPLC, the broad band was resolved into 2 bands: 27,000 and 24,000 which could represent either two distinct proteins or one protein with differing states of glycosylation. These results differ substantially from those reported for the other known calcium channels. The purified protein was injected into rabbits and immune serum obtained. The antibody was found to react specifically with the P-channel protein. Both the functional activity and structural characteristics of the isolated P-channel protein differ from those reported for the L and N type channels and strengthen the identification of the P-type channel as a distinct molecular entity.

395.6

NEW ω-AGATOXIN CALCIUM CHANNEL ANTAGONISTS FROM FUNNEL WEB SPIDER VENOM ACTIVE IN THE AVIAN AND MAMMALIAN BRAIN.

V. J. Venema* and M. E. Adams. Dept. of Entomology, Univ. of California, Riverside, CA 92521.

Venom of the funnel web spider *Agelenopsis aperta* is a rich source of voltage-sensitive calcium channel (VSCC) antagonists known as ω-agatoxins. First recognized for their inhibition of presynaptic VSCC at insect neuromuscular junctions, the ω-agatoxins also are potent and selective antagonists of VSCC in vertebrate excitable tissue (see also Leibowitz *et al.*; Mintz *et al.*, this meeting). Reversed-phase liquid chromatography (RPLC) of crude *A. aperta* venom yields a broad ω-agatoxin elution profile characterized by inhibition of specific ω-conotoxin GVIA (ω-CgTx) binding to chick synaptosomal membranes. Using this inhibition as an assay for purification, we isolated ω-Aga-IIIA, an 8.5 kDa polypeptide constituting about 1% of total protein in the venom. ω-Aga-IIIA causes dose-dependent inhibition of ω-CgTx binding (EC_{50} = 10-20 nM) to a maximum of 100% above 60 nM. ω-Aga-IIIA also inhibits potassium-induced synaptosomal ^{45}Ca flux with an EC_{50} of 1-5 nM. However, saturating concentrations of ω-Aga-IIIA block only 67% of total flux, while ω-CgTx blocks 100% of the flux response. Therefore, 25-30% of total ^{45}Ca flux in chick synaptosomes appears to be insensitive to ω-Aga-IIIA.

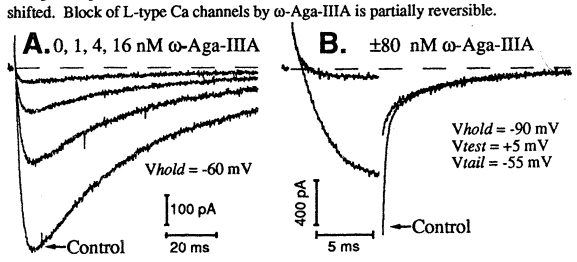
Potassium-induced ^{45}Ca flux in rat brain synaptosomes is relatively insensitive to ω-Aga-IIIA and ω-CgTx antagonism. However, new ω-agatoxins currently under study suppress rat synaptosomal ^{45}Ca flux at apparent nanomolar concentrations. Further analysis of the specificities and modes of action of the ω-agatoxins promises to yield useful information on the subclassification as well as tissue and phylogenetic diversity of VSCC.

Supported by NIH grant NS24472.

395.7

SELECTIVE BLOCK OF ATRIAL L-TYPE Ca CHANNELS BY THE SPIDER TOXIN ω-AGA-IIIA. M.D. Leibowitz, T. Bale*, M.E. Adams§, V.J. Venema*§ and C.J. Cohen. Merck Sharp & Dohme Res. Labs, Rahway, NJ 07065 and §Dept. of Entomology, Univ. California, Riverside, CA 92521.

ω-Aga-IIIA is a polypeptide toxin from venom of the funnel web spider *Agelenopsis aperta* (Venema and Adams, Mintz et al.; this volume). This toxin blocks selectively L-type Ca channel currents in acutely isolated guinea pig atrial myocytes. Whole-cell L-type Ca channel currents (carried by 5 mM Ca or Ba) are blocked by ω-Aga-IIIA (IC50 ≤ 1 nM, Fig A). Toxin block is modified by the dihydropyridine Ca agonist (+)202-791. In the absence of (+)202-791, 80 nM ω-Aga-IIIA blocks only ≈80% of the L-type Ca current and no slowly deactivating (T-type) Ca current (Fig B). However, in 100 nM (+)202-791, 40 nM ω-Aga-IIIA blocks >98% of the L-type Ca current. Unlike therapeutically used Ca antagonists, block by ω-Aga-IIIA is voltage-independent; channel kinetics are not changed and channel availability is not shifted. Block of L-type Ca channels by ω-Aga-IIIA is partially reversible.

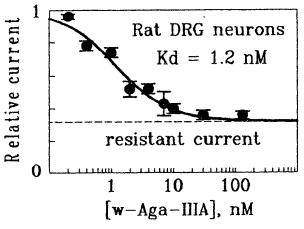


395.8

THE FUNNEL-WEB SPIDER TOXIN ω-AGA-IIIA BLOCKS N- AND L- TYPE CALCIUM CHANNELS IN NEURONS AND CARDIAC MUSCLE.

I. M. Mintz, V. J. Venema*, M. E. Adams, and B.P. Bean. Dept. of Neurobiology, Harvard Med. Sch., Boston MA 02115 and Dept. of Entomology, Univ. of California, Riverside CA 92521.

The peptide ω-Aga-IIIA from the venom of *Agelenopsis aperta* was tested on various calcium conductances in freshly dissociated neonatal rat DRG neurons, using whole cell recordings of Ba (5 mM) currents. The toxin blocked most high-threshold current with high potency (Kd= 1.2 nM) but left a fraction unaffected (figure). Occlusion experiments with ω-conotoxin GVIA (ω-CgTX, 3 μM) indicated that ω-Aga-IIIA (130 nM) suppressed both ω-CgTX-sensitive N-type current (n=10) and an additional ω-CgTX-insensitive fraction (n=9). Its efficacy on L-type current was studied using slowly-deactivating L current tails induced by BAY K 8644 (1 μM) in ω-CgTX (3 μM) pretreated cells. Such tails were abolished by 10 nM ω-Aga-IIIA (n=5).



ω-Aga-IIIA acted with similar potency on the N-type current of frog sympathetic neurons (n=20), the L-type current of rat ventricular cardiac cells (n=4), and high-threshold Ba currents in neonatal rat hippocampal neurons (n=3). In contrast, T-type currents in rat DRG neurons were not affected (200 nM ω-Aga-IIIA, n=3).

395.9

FUNNEL-WEB SPIDER TOXIN (FTX) SELECTIVELY BLOCKS THE SUSTAINED, BUT NOT THE TRANSIENT, CALCIUM CURRENT IN RETINAL HORIZONTAL CELLS J.M. Sullivan* and E.M. Lasater Depts. of Physiology and Ophthalmology, Univ. of Utah School of Medicine, Salt Lake City, Utah, 84108

Using the whole-cell patch-clamp technique, we have identified two separate Ca currents--one sustained ($I_{Ca}S$), the other transient ($I_{Ca}TR$)--in cultured horizontal cells (HCs) isolated from adult white bass retinas. Ca currents were enhanced using 10 mM extracellular Ca, while Na^+ and K^+ currents were pharmacologically supressed. The large transient Ca current is similar, but not identical, to the T-Current described in other preparations: $I_{Ca}TR$ activates above -60 mV, is inactivated at a holding potential of -40 mV and is carried less well by Ba^{++} than Ca. Unlike the T-Current, $I_{Ca}TR$ is not preferentially blocked by Ni^{++}. This is the first time that a large transient Ca current has been seen in HCs, or in a non-mammalian vertebrate preparation. The sustained Ca current is similar, but not identical, to the L-Current described in many preparations: $I_{Ca}S$ activates above -30 mV, is larger when Ba^{++} replaces Ca and is enhanced by the dihydropyridine agonist BAY K 8644 (Calbiochem). Unlike the L-Current, $I_{Ca}S$ is not preferentially blocked by Cd^{++}, nor is it reduced by w-conotoxin fraction GVIA (a gift from Dr. B. M. Olivera). FTX (a gift from Dr. R. Llinas), a factor isolated from the venom of the funnel-web spider (Llinas et al., *P.N.A.S.*, 86:1689, 1989), selectively blocks $I_{Ca}S$ at very low concentrations: a 1:300,00 dilution of the column fraction containing FTX blocked 60% of the sustained current, while a 1:10,000,000 dilution blocked 10% of this current. This block was maintained even after washing with FTX-free Ringer for up to 20 min. These results strongly suggest that the sustained and transient Ca currents are carried through two different and unique types of channels, and support the notion that there is a wide variety of Ca channels among different species and tissue types.

DISTINCT RAT BRAIN CLASS-C CALCIUM CHANNELS ARE GENERATED BY ALTERNATIVE SPLICING. W.J. Tomlinson*, M.M. Gilbert* and T.P. Snutch. Biotechnology Laboratory, Univ. of British Columbia, Vancouver, B.C., Canada V6T 1W5.

Rat brain class C Ca channel cDNAs (rbC) hybridize on Northern blots to two mRNAs of approx. 8 and 12 kilobases (kb). The deduced primary structure of two overlapping clones (rbC-61 and rbC-30) shows that the class C gene product is >90% identical to the rabbit cardiac dihydropyridine receptor/Ca channel (designated rbC-I). Analysis of a number of other cDNAs reveals distinct class C coding sequences (designated rbC-II). Further, in 1400 amino acids compared, rbC-I and rbC-II transcripts differ at only two sites. In the first instance, rbC-II transcripts have a three amino acid insertion (ProAlaArg) corresponding to the putative cytoplasmic loop between homology domains II and III. The second site, a 28 amino acid region which includes the third putative transmembrane segment (S3) of domain IV of rbC-I, is replaced by a different 28 amino acid hydrophobic stretch. By Southern blot analysis, rbC-I and rbC-II specific probes are shown to hybridize an identical pattern of rat genomic DNA fragments. In addition, polymerase chain reaction analysis of rat genomic DNA shows that the rbC-I and rbC-II transcripts are generated from the same genomic DNA fragment. These results suggest that in addition to the distinct genes which encode the rat brain class A, B, C and D Ca channels, alternative splicing provides a further source of Ca channel diversity in the CNS.

Biochemical Characterization of a High Affinity [^{3}H]Ryanodine Receptor From Rabbit Brain Membranes. P.S. McPherson and K.P. Campbell. Howard Hughes Medical Institute and Program in Neuroscience and Dept. of Physiology and Biophysics, University of Iowa College of Medicine, Iowa City, IA 52242.

The skeletal muscle receptor for the plant alkaloid ryanodine has been shown to be identical to the Ca^{2+} release channel of the sarcoplasmic reticulum. High affinity [^{3}H]ryanodine binding has been recently demonstrated in isolated brain membranes (Ashley, R.H., J. Memb. Biol., 111:179, 1989). We have shown that [^{3}H]ryanodine binding is enriched in membranes from the hippocampus but is significantly lower in membranes from the brain stem and spinal cord. Approximately 50% of [^{3}H]ryanodine labeled receptor is solubilized from brain membranes using CHAPS phosphatidylcholine containing 1 M NaCl. The brain [^{3}H]ryanodine receptor comigrates through sucrose gradients with the skeletal receptor as a large complex (~30S). Solubilized receptor is specifically immunoprecipitated by sheep polyclonal antibodies against purified skeletal muscle ryanodine receptor coupled to protein A Sepharose. [^{3}H]Ryanodine labelled receptor binds to heparin-agarose with high affinity, but does not bind to wheat germ agglutinin lectin. [^{3}H]Ryanodine labeled receptor is isolated using heparin-agarose chromatography followed by sucrose density gradient centrifugation. A protein of ~400,000 Da is enriched in peak [^{3}H]ryanodine binding-fractions of heparin-agarose eluates and sucrose gradients, and is cross-reactive with antibodies raised against the skeletal muscle ryanodine receptor. We propose that the ~400,000 Da protein is the brain form of the high affinity ryanodine receptor and that it functions as a Ca^{2+} release channel in brain endoplasmic reticulum. Kevin P. Campbell is an Investigator of the Howard Hughes Medical Institute.

DIVERSE ω-CONOTOXIN GVIA BINDING PROTEINS IN ELECTRIC ORGAN AND BOVINE BRAIN W.A. Horne, R.R. Delay, and R.W. Tsien Dept. of Molec. & Cell. Physiol., Stanford University School of Medicine, Stanford, Calif. 94305.

Binding sites for the marine snail toxin, ω-conotoxin GVIA (ωCgTx), have been identified in a variety of neuronal tissue types, and have been assigned exclusively to voltage-dependent calcium channels. ωCgTx has been shown to bind with high affinity (K_D=3 pM) to relatively few receptor sites (0.4 pmoles/mg protein) in bovine brain (Yamaguchi et al., *JBC* 263, 9491), and with low affinity (K_D= 1 μM) to a greater number of receptor sites (290 pmoles/mg protein) in synaptosomes prepared from the electric organ of *Discopyge ommata* (Miljanich et al., *Brain Res* 453, 247). Our results suggest that these binding sites represent a heterogeneous population of ωCgTx binding proteins and that, in electric organ, not all are actually calcium channels. Crosslinking experiments with the homobifunctional imidoester, dimethylsuberimidiate (DMS), reveal that ^{125}I-ωCgTx specifically labels two proteins in bovine brain with M_r values of 330 and 220 kD as determined by SDS-PAGE, and three proteins in electric organ synaptosomes with M_r values of 170, 60, and 45 kD. We have demonstrated that the 45 kD protein of electric organ is the α-subunit of the nicotinic acetylcholine receptor (nAChR) and that it accounts for a significant fraction of the total number of ωCgTx binding sites. Furthermore, it can be separated from both the 170 and 60 kDa proteins by immunoprecipitation with a Mab against the nAChR. All three electric organ ωCgTx binding proteins share similar pharmacological properties, in that half maximal displacement of ^{125}I-ωCgTx occurs in the range of 0.1-1.0 μM ωCgTx, and the binding of ^{125}I-ωCgTx is not inhibited by other calcium entry blockers, such as nitrendipine, or by α-bungarotoxin and other agents known to interact with the nAChR. ωCgTx binding both in brain and electric organ is characteristically inhibited by higher concentrations of Ca^{2+} (0.5-1.0 mM) whereas in brain preparations we demonstrate that ωCgTx binding is actually stimulated up to 3-fold at lower Ca^{2+} concentrations (0.1-1.0 μM). It is noteworthy that this stimulatory effect occurs over the same concentration range as Ca^{2+} binding to sites controlling permeation and inactivation of calcium channels.

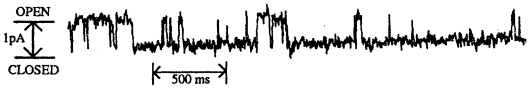
DESIGN, SYNTHESIS, AND SINGLE CHANNEL CHARACTERIZATION OF A DIHYDROPYRIDINE-SENSITIVE CALCIUM CHANNEL PROTEIN.
A. Grove,†* J. M. Tomich†* and M. Montal.†
†UCSD, La Jolla, CA 92093 and *Children's Hospital, Los Angeles, CA 90027.

The major protein component of a dihydropyridine-sensitive calcium channel from skeletal muscle was cloned and sequenced (Tanabe, T. et al. 1987, *Nature* 328, 313-318). The primary structure suggests the occurrence of four internal repeats, each containing six presumably α–helical transmembrane segments. We designed a protein that mimics a pore-forming structure of the calcium channel; a carrier template (KKKPGKEKG) (Mutter, M. et al. 1988, *Tetrahedron*:44, 771-785) was used to direct the assembly of a bundle comprised of four identical 22-mer peptides with sequences corresponding to transmembrane segment IVS3 (DPWNVFDFLIVIGSIIDVILSE). This synthetic protein forms cation-selective channels in lipid bilayers. At pH 7.2, the single channel conductances in symmetric 50 mM $CaCl_2$, $BaCl_2$ and $SrCl_2$ are 7.2 ± 1.3, 9.5 ± 1.2 and 6.4 ± 0.4 pS, respectively, and 10.8 ± 1.9 pS in 500 mM NaCl. Channels are blocked by 10^{-7} M nifedipine, 10^{-6} M verapamil and 10^{-4} M of the local anesthetic analogue of lidocaine QX-222. A different synthetic protein containing four peptides with sequences corresponding to segment IVS5 (YVALLIVMLFFIYAVIGMQMFGK) does not form discrete channels.

Supported by NIGMS (GM-42340), NIMH (MH-44638 and MH-00778) and ONR (N00014-89J-1469).



Single channel current recorded at 100 mV in symmetric 50 mM $BaCl_2$, pH 7.2.

CONANTOKINS: STRUCTURE, FUNCTION AND DEVELOPMENTAL SPECIFICITY. L. J. Cruz, F. C. Abogadie*, B. M. Olivera, J. M. McIntosh, J. F. Hernandez* and J. Rivier*. Marine Science Inst., Univ. Philippines, Diliman, Q. C. 1101; Dept. of Biology, Univ. Utah, Salt Lake City, UT 84112; Salk Institute, La Jolla, CA 92057.

Fish-hunting marine snails produce numerous biologically active peptides; of particular interest are conantokins which inhibit the glutamate receptors of the NMDA subtype. First detected as components which induce sleep in young mice but cause hyperactivity in older mice, the peptides are structurally unique in having at least 4 residues of γ-carboxyglutamate (Gla) out of 17 to 27 amino acids. At present, 12 natural and synthetic conantokin analogs have been synthesized. A new peptide (conantokin R) with a definite structural homology to conantokins G and T has been characterized from *Conus radiatus* venom. Although only 7/27 amino acids are identical to the other conantokins, it has the conserved sequence Gly-Glu-Gla-Gla at the amino terminus. Comparison of the biological activities of several conantokins suggests that different NMDA receptor targets may be responsible for the sleep and hyperactivity symptoms. Synthetic conantokin analogs indicate that Gly at position 1 and Glu at position 2 are necessary for full potency; subtitution of Glu^2 by a Gln or an L-Asp inactivated the peptide and the D-Asp^2 analog produced an effect only in old mice at high dose. [Ser^1]conantokin G apparently has a normal sleeper activity in young mice but it is relatively inactive in older mice. Thus the conantokins may be useful probes for changes in NMDA receptor subtypes as a function of development. (Supported by GM 22737 and funds from the Marine Science Institute, U. P.)

396.2

CONANTOKINS: PEPTIDE PROBES OF THE NMDA RECEPTOR. R. A. Myers*, J. Rivier, and B. M. Olivera. Dept. of Biology, University of Utah, Salt Lake City, UT 84112.

The conantokins are neurotoxins isolated from the venomous, fish-hunting marine snails of the genus *Conus* (McIntosh et al. (1984) J. Biol. Chem. 259:14343). These peptides, which induce either a sleep-like state or hyperactivity when injected i.c. into mice (≤2 weeks or ≥3 weeks, respectively), have been recently reported to target the N-methyl-D-aspartate(NMDA)-subtype of the glutamate receptor (Olivera et al. (1990) Science, In press). The conantokins contain 17-27 residues including at least four of the unusual amino acid γ-carboxyglutamate (Gla). Conantokin analogs have been chemically synthesized, radioiodinated, and crosslinked to NMDA receptor-enriched membranes (postsynaptic densities), with disuccinimidyl suberate. Following resolution by sodium dodecylsulfate polyacrylamide gel electrophoresis, autoradiography revealed primarily two bands with ~M_rs of 50 and 90 kd. The proteins of these bands were labeled specifically as determined by competition with excess cold ligand and are likely subunits of the same complex as evidenced by two-dimensional gel electrophoresis.

Whole rat brain membranes were detergent-extracted and subjected to affinity chromatography. Crosslinking analysis of the column retentate revealed enrichment of the 50 and 90 kd bands. Present results are consistent with the conantokin receptor being a multi-subunit ion channel complex. (Supported by GM22737.)

396.3

DISTRIBUTION OF NMDA RECEPTORS ON HIPPOCAMPAL NEURONS. O.T. Jones†,°J.F. McGurk, M.V.L. Bennett, °R.S. Zukin, #G. Collingridge, T. Benke†, K.J. Angelides†, †Department of Physiology, Baylor College of Medicine, Houston, TX, Department of Neuroscience, °Albert Einstein College of Medicine, Bronx, NY, #Department of Pharmacology, Bristol University, UK.

Excitatory amino acid transmission in the CNS depends critically on the activation of ligand-gated ion channel receptors classified by their preference for the agonists kainate, quisqualate and N-methyl-D-aspartate (NMDA). The NMDA receptor has aroused considerable interest due to its unique ability to translocate the second messenger calcium and its voltage dependent blockade by magnesium ions. To map the distribution of NMDA receptors at the neuronal cell surface we prepared several fluorescent and biotinylated analogs of Conantokin G a polypeptide isolated from the marine snail *Conus geographus*. The unmodified toxin blocked NMDA currents in *Xenopus* oocytes injected with rat brain mRNA and in hippocampal slices. NMDA receptors were mapped on cultured hippocampal neurons by colloidal gold decoration and circular dityndallism microscopy and their locations resolved by immunocytochemistry using antibodies to MAP-2 and synaptophysin, markers of dendrites and presynaptic terminals, respectively. Labeling was present on cell bodies and dendrites, was non-uniform, and was distinct from voltage-dependent calcium channel distribution labeled by ω-conotoxin. Using these fluorescent and biotinylated probes we are addressing how NMDA receptors are expressed, targeted and maintained during neuronal development. Visualization of NMDA receptors on live neurons will be a central feature in analysis of receptor distribution during synaptic plasticity. (Supported by the NIH, MRC, and Epilepsy Foundation of America.)

NMDA AND NON-NMDA RECEPTORS AGGREGATE AT SYNAPSES IN CULTURED CEREBRAL CORTICAL NEURONS. K.A. Jones and R.W. Baughman. Dept Neurobiology, Harvard Med School, Boston MA 02115.

Non-NMDA receptors contribute importantly to synaptic responses and aggregate on dendrites of neurons in cell culture. NMDA receptors, which play a key role in synaptic plasticity, are more difficult to localize because of the high affinity of the NMDA receptor for Glu. We combined electrophysiological and immunocytochemical mapping techniques to determine the relationship between receptor distribution and synapses. Whole-cell-patch recordings were made with neurons from rat visual cortex cultured for 5-34 days. Depolarizations were elicited by applying brief (0.5-1.5 ms) pulses of Glu with a fine iontophoretic pipet positioned within < 0.5 μm of the dendrite. Most cells had well defined sites of high sensitivity to Glu flanked by regions of low sensitivity. APV and CNQX were used to distinguish the contributions of the receptor subtypes at each site. Subsequently, the culture was processed for localization of the synapse-specific protein, SV2. In all of 24 cases, $SV2^+$ puncta were observed within 1 μm of a region of high Glu sensitivity. In 7 experiments, summarized below, complete analysis of receptor subtypes was obtained. (Data normalized to non-NMDA response at $SV2^+$ site.)

	$SV2^+$ regions	$SV2^-$ regions	Ratio $SV2^+$: $SV2^-$
non-NMDA	100%	12.1±8.4%	8.3 : 1
NMDA	41.9±21.2%	23.1±19.1%	1.8 : 1

The $SV2^+$:$SV2^-$ ratio for NMDA is in fact higher than 1.8 because of the high affinity of the NMDA receceptor for Glu. By measuring the drop off in response when the Glu pipet was moved orthogonal to the dendrite, we determined that to obtain a 90% decrement the pipet had to move 6 μm for non-NMDA and 20 μm for NMDA receptors. The distance between the $SV2^+$ and $SV2^-$ sites ranged 5-12 μm, indicating that we would have measured a significant NMDA response at the $SV2^-$ sites even if all of the NMDA receptors were localized at the $SV2^+$ sites. In conclusion, these data suggest that both non-NMDA and NMDA receptors are concentrated at synapses. (NIH EY03502)

IN VITRO AND EX VIVO BINDING OF ^{3}H-FTCP: A TOOL TO STUDY NMDA RECEPTOR COMPLEX IN VIVO. C. Ferrarese, A. Guidotti^, E. Costa^, K. Rice+, B. DeCosta+*, R.S. Miletich and G. Di Chiro*. Neuroimaging Sect., NINDS, Laboratory of Medicinal Chemistry,*NIDDK, NIH, Bethesda, MD and ^FGIN, Washington, D.C. 20007.

Fluorothienylcycloexypiperidine (FTCP), a derivative of TCP, includes a Fluorine atom and might be suitable for PET studies as a maker for NMDA sensitive glutamate receptors.

In vitro, the specific binding of ^{3}H-FTCP to rat and mice brain membranes was measured by subtracting the non specific binding in the presence of 10^{-5}M MK-801 or FTCP from the total binding. For *ex vivo* studies, 3 nmol/Kg of ^{3}H-FTCP (s.a. 14 μCi/nmol) was injected i.v. in mice and rats. The animals were sacrificed at different times and radioactive acetic acid extracts from various brain areas were counted before and after separation on sep-pak C18 cartridge. ^{3}H-FTCP is metabolized *in vivo* to hydrosoluble derivatives, with half lives of 7 min in mice and 15 min in rats. In rat brain regions the specific binding of ^{3}H-FTCP *ex vivo* was calculated 10 min after the i.v. injection by subtracting the amount of ^{3}H-FTCP in animals treated with 1 μM MK-801 from the amount of ^{3}H-FTCP present in the control animals.

^{3}H-FTCP specific binding is saturable *in vitro* and *ex vivo*, and the density of binding sites is highest in hippocampus, followed by cerebral cortex, and striatum; and lowest density is in cerebellum. Drugs acting on the PCP site of the NMDA receptor (MK-801, TCP, PCP) can displace ^{3}H-FTCP binding with nanomolar affinity; on the contrary, Di-o-Tolylguanidine (DTG), a specific ligand of sigma receptors, is active only at micromolar concentration. ^{3}H-FTCP binding is increased by about three fold in the presence of glutamate *in vitro*, and NMDA *in vivo*. However this facilitation fails to occur in cerebellum. These data suggest that FTCP is a suitable ligand for functional studies of NMDA receptors by PET scanning technique.

PHARMACOLOGICAL PROPERTIES OF KAINATE-ACTIVATED CHANNELS EXPRESSED FROM A RAT BRAIN cDNA. R. S. Zukin, R.S. Roginski, J. McGurk, M.V.L. Bennett. Dept. Neuroscience, Albert Einstein Coll. of Med., Bronx, N.Y. 10461.

The major excitatory neurotransmitter glutamate activates several different receptors, one of which can be identified by its responses to kainate. A complementary DNA encoding a kainate-activated channel was recently cloned (Hollmann et al., *Nature* 342:643-648, 1989), and the deduced 889-amino acid sequence indicates that it belongs to the large superfamily of ion channel forming receptors. We used the polymerase chain reaction to isolate an apparently identical clone from a rat brain cDNA library constructed in λZAP. *Xenopus* oocytes were injected with cRNA transcribed from this kainate receptor clone. After 48 hrs kainate was rapidly perfused over intact oocytes voltage-clamped at -60 mV. 500 μM kainate elicited a short latency, slowly rising (τ = 4 sec) inward current of up to 500 nA. This response was more slowly rising and falling than could be accounted for by perfusion delay (<0.5s). The dose-response curve for kainate showed a half-maximal effective concentration (EC_{50}) of 50 μM and a Hill coefficient of 1. Although kainate responses from rat brain mRNA had an apparent K_d of about 55 μM, the Hill coefficient was ca. 2.5 (Lerma et al., *PNAS* 86:2083-2087, 1989). The kainate responses were blocked by the selective kainate receptor antagonist CNQX (IC_{50} about 300 nM at 50 μM kainate); onset and reversal of block were rapid. No responses to NMDA or quisqualate were observed in oocytes injected with this cRNA. These findings indicate that the kainate receptor cDNA directs the expression of receptors similar, but not identical, to kainate receptors expressed from rat brain mRNA.

MOLECULAR CLONING OF A cDNA ENCODING A KAINIC ACID RECEPTOR SUBUNIT EXPRESSED IN HUMAN BRAIN AND RETINA. Tom Stormann, David Gdula, David Weiner, Allan Levey and Mark Brann. LMB/NINDS and Receptor Genetics, Inc., Bldg. 36, Rm. 3D-02, Bethesda, MD 20892

Recently, a cDNA encoding a subunit of a kainic acid receptor was isolated from rat brain by expression cloning (Hollman et. al, Nature, 1989). We have used oligonucleotide probes derived from the published rat nucleic acid sequence to screen human hippocampal and retinal cDNA libraries to isolate related excitatory amino acid receptor subunit cDNAs. Two 3 Kb cDNAs (one from the hippocampal library and one from the retinal library) which appear to encode the human homologue of the published rat cDNA have been isolated. The retinal cDNA encodes the complete coding sequence of a protein that shares 97% amino acid homology with the rat kainic acid receptor subunit. Oligonucleotide probes derived from the human sequence encoding the putative intracellular domain have been used to localize mRNA in the middle frontal gyrus, hippocampus, neostriatum, thalamus, midbrain, pons and cerebellum of human brain. The strongest hybridization signals were observed in the cerebellar cortex and the hippocampal formation, including the dentate gyrus and fields CA1 to CA4. Moderate signals were observed in cerebral cortex, the pontine nuclei and the substantia nigra. We are currently pursuing the detailed cellular mapping of the mRNA in human brain and retina as well as the functional expression of the receptor subunit in mammalian cells.

COOPERATING DNA BINDING PROTEINS AS NUCLEAR THIRD MESSENGERS IN PRIMARY CULTURES OF NEURONS. A.M. Szekely, R.E. Paulsen, E. Costa, and D.R. Grayson. FGIN, Georgetown University, Washington, D.C. 20007.

Coordinated changes in neuronal gene expression associated with NMDA sensitive glutamate receptor stimulation may be a key mechanism underlying long-term adaptive modifications. In primary cultures of rat cerebellar granule cells brief stimulation of this receptor resulted in a programmed induction of early response genes involving c-*fos*, c-*jun*, *jun*-B and *zif/268*. These genes encode nuclear proteins, which by interacting with regulatory DNA elements, function as third messengers bringing about coordinated regulation of target gene expression. Using gel shift assays and western blot analysis we show that following a brief glutamate pulse, the various Fos/Jun protein complexes (hetero and/or homodimers) display a biphasic binding to AP-1 DNA sequences. The composition of these complexes changes with time. The glutamate stimulation also results in an increased DNA binding activity of the zif/268 "zinc finger" protein to its consensus recognition sequence, which is structurally unrelated to the AP-1 site, and is found 5' upstream of several early response genes. This increased activity shows a delayed appearance compared to that of the AP-1 complex. These results, in light of our further data that different stimulus-specific patterns of early gene expression exist in these cells, prompt us to elucidate the mechanism whereby these nuclear third messengers interact and mediate a temporally flexible but precise response to transmitter receptor stimulation in neurons.

SEX STEROIDS ALTER N-METHYL-D-ASPARTATE (NMDA) RECEPTOR BINDING IN THE HIPPOCAMPUS. N.G. Weiland. Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201.

Sex steroids influence physiological processes mediated by the hippocampus. The hippocampus, a major component of the limbic system, plays a role in the regulation of feminine sexual and maternal behaviors as well as non-reproductive behaviors associated with learning and memory. NMDA, which activates one class of glutamate receptors, mediates some of the neurophysiological processes that underlie activity-dependent control of neuronal plasticity, long-term potentiation in the hippocampus, and learning and memory. Therefore, we examined whether estrogen (E) and progesterone (P) may affect these behaviors by altering NMDA receptors in the hippocampus (CA1). Female rats (3-4 months) were ovariectomized (OVX) for 9 days, OVX and E, or OVX and EP-treated. We measured the density of NMDA receptors by incubating 8μm brain sections in 150nM ^{3}H-glutamate and varying concentrations of NMDA (2-1000 μM) in Tris acetate buffer. Sections were rinsed briefly, dried, and exposed with ^{3}H-standards to LKB Ultrofilm. The films were quantitated on an image analysis system. E and EP increased the density of NMDA binding sites in the CA1 compared to OVX, whereas the Ki was unaffected. These results indicate that sex steroids may affect physiological processes mediated by the hippocampus by altering NMDA receptor densities. (Supported by American Federation of Aging Research)

THE HIGH AFFINITY NON-NMDA-COUPLED PCP-1 RECEPTOR IS REGULATED BY GUANINE NUCLEOTIDES. Y. Itzhak, I. Stein* and C. Kassim*. REPSCEND Labs. Dept. of Biochemistry & Mol. Biology, University of Miami School of Medicine, Miami, FL 33101.

We have previously reported that the potent phencyclidine analog, [^{3}H]-1-[1-(3-hydroxyphenyl) cyclohexyl] piperidine ([^{3}H]PCP-3-OH) labeles a high affinity binding site which is not coupled to the NMDA ion channel complex, sensitive to nM concentrations of PCP analogs and certain benzomorphans, but insensitive to haloperidol (Neurosc. Lett. 104: 314-319, 1989). Since this high affinity binding site is distinct from the PCP/NMDA receptor complex and the sigma/haloperdiol sensitive binding site, we have further attempted to characterize this site. Specific binding of [^{3}H]PCP-3-OH (0.6nM) to rat cerebrocortical membranes is reduced (20-65%) in a concentration dependent manner in the presence of Gpp(NH)p (0.05-1mM). However, binding of MK 801 to the PCP/NMDA receptor complex is not affected under the same conditions. In the absence of Gpp(NH)p homologous competition of [^{3}H]PCP-3-OH with unlabeled PCP-3-OH resulted in the best fit for a two site model, wherease in the presence of the nucleotide only one site was detected. Our studies also indicated that in the presence of Gpp(NH)p the PCP-1 binding site is not converted to the PCP/NMDA receptor complex, suggesting that the GTP-sensitive PCP-1 receptor site represent a distinct receptor domain.

SIGMA LIGANDS POTENTIATE NMDA-INDUCED HIPPOCAMPAL NEURON ACTIVATION. G. Debonnel, F.P. Monnet and C. de Montigny Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada.

We have previously reported that low doses of the sigma (σ) ligand DTG selectively potentiate NMDA-induced activation of hippocampal pyramidal neurons and that this effect of DTG is blocked by haloperidol, a high affinity σ ligand (*Neurosci. Abst.*, 15: 133.10, 1989). This suggested that a major role for σ sites might be to modulate the NMDA response. To further verify this hypothesis, we studied the effects of other selective σ ligands and of a structural analog of DTG devoid of affinity for σ sites, on neuronal responsiveness to excitatory amino acids in male Sprague-Dawley rats under urethane anaesthesia. Five-barrelled micropipettes were used for extracellular recording of CA_3 dorsal hippocampus pyramidal neurons and microiontophoresis of NMDA, quisqualate and kainate.

Similarly to DTG, low doses (1-10 μg/kg, i.v.) of (+)pentazocine, JO-1784 [(+) *N-cyclopropylmethyl-N-methyl-1,4-diphenyl-1-ethyl-but-3-en-1-ylamine*], BD-737 [(+)*-cis-N-methyl-N-[2-(3,4-dichlorophenyl) ethyl]-2-(1-pyrrolidinyl) cyclohexylamine*] and AdIpG [*1-(1-adamantyl)-3-(2-iodophenyl)*] markedly and selectively potentiated the excitatory effect of NMDA in a dose-dependent manner.

At low doses (1-10 μg/kg, i.v.), similarly to haloperidol, BMY-14802 and (+)3-PPP did not have any effect on NMDA-induced activation, but dose-dependently reversed the potentiation of NMDA by a low dose of DTG.

At doses up to 100 μg/kg i.v., 2-aminoperimidine hydrobromide, a structural analog of DTG without affinity for σ sites failed to produce an effect on NMDA-induced activation.

These data bring additionnal support to the notion that an important function of σ receptors might be to modulate the NMDA response. Furthermore, they suggest the existence of two classes of ligands: DTG-like compounds acting as "agonists" and haloperidol-like ligands as "antagonits" at σ sites.

NEUROPEPTIDE Y SELECTIVELY POTENTIATES THE NMDA RESPONSE. F.P. Monnet, G. Debonnel, T. Dennis and C. de Montigny. Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada and Institut de Recherche Jouveinal, Fresnes, France.

Recently, Roman et al. (*Eur. J. Pharmacol.*, 174: 301, 1989) reported that neuropeptide Y (NPY), the most abundant peptide in the mammalian brain, has high affinity for sigma (σ) binding sites. Several σ ligands, at low doses, selectively potentiate the NMDA-induced activation of hippocampal pyramidal neurons, whereas low doses of haloperidol, which also has high affinity for σ sites, reverse this potentiating effect (Monnet et al., *Neurosci. Abst.*, 15: 133.10, 1989; Debonnel et al., *this meeting*). The present electrophysiological experiments were undertaken to study the effect of microiontophoretic application of NPY on the neuronal activation induced by NMDA, quisqualate (QUIS) and kainate (KA).

Male Sprague-Dawley rats were anesthetized with urethane (1.25 g/kg, i.p.). Five-barrelled micropipettes were used for extracellular recording of CA_3 dorsal hippocampus pyramidal neurons and microiontophoresis of NPY (0.1 mM in 150 mM NaCl and 0.1% BSA, pH: 8), NMDA (10 mM in 200 mM NaCl, pH: 8), QUIS (1.5 mM in 400 mM NaCl, pH: 8), KA (1 mM in 400 mM NaCl, pH: 8) and haloperidol (0.2 mM in 200 mM NaCl, pH: 4).

Prolonged microiontophoretic application of NPY increased by two-fold the neuronal response to NMDA with a latency of 15-30 min, without altering those to QUIS and KA. This effect of NPY was reversed by the systemic administration of haloperidol (20 μg/kg, i.v.). Microiontophoretic application of haloperidol also reversed the NPY-induced potentiation of the NMDA response.

These data suggest that a major role of NPY might be to modulate the function of NMDA receptors. The reversal of the effect of NPY by haloperidol suggests that it might be due to the affinity of NPY for σ sites.

FACTORS INVOLVED IN THE REGULATION OF β_1- AND β_2-ADRENERGIC RECEPTOR mRNA IN RAT C_6 GLIOMA CELLS. C. Hough and D.-M. Chuang. Biological Psychiatry Branch, NIMH, Bethesda MD 20892

Exposure of C_6 cells to β-adrenergic agonist, isoproterenol, leads to down-regulation of the mRNA species for both β_1- and β_2-adrenergic receptors (β-AR) within 4 hours. The mechanism of down-regulation for the two receptor subtypes differs, however, in that β_2-AR mRNA simply decays to 20% of pretreatment levels while β_1-AR mRNA is transiently up-regulated before decaying to 40% of pretreatment levels. Both modes of regulation induced by isoproterenol are inhibited by β-AR antagonists, alprenolol, propranolol, betaxolol, and ICI 118 551. Alone, these antagonists can have effects on β-AR mRNA levels similar, albeit less potent, to those of isoproterenol. Both modes of regulation can be mimicked at slower rates by agents that can raise intracellular cAMP, forskolin, cholera toxin, and 8-Br cAMP. In the presence of transcription inhibitor, actinomycin D (10 μg/ml), both β_1- and β_2-AR mRNA decay at approximately the same rate ($t_{1/2}$=30 min), which is not significantly changed by isoproterenol treatment. In the presence of protein synthesis inhibitor, cycloheximide (10 μg/ml), β_1- and β_2-AR mRNA are dramatically stabilized, even in the absence of transcription. These results suggest that regulation of β-AR mRNA occurs at the levels of transcription and translation.

397.2

AN EXON WITH A STOP CODON IS SELECTIVELY SPLICED INTO EMBRYONIC TRANSCRIPTS OF THE GLUTAMIC ACID DECARBOXYLASE GENE. R.J. Wyborski, R.W. Bond and D.I. Gottlieb, Dept. of Anatomy and Neurobiology, Washington Univ. Sch. of Med. St. Louis, Mo 63110

In the adult rat brain the gene for Glutamic acid decarboxylase (GAD) is expressed as a 3.7 kb transcript coding for a 67 kDa protein. An alternative form of the GAD transcript was detected in fetal brain by nuclease protection assay. (Bond et. al. PNAS 85:3231, 1988) The structure of the alternative form is reported here. A segment of the GAD mRNA from fetal brain was reverse transcribed and amplified by PCR. The sequence consisted of the known adult structure with an additional 86 bp exon. Conceptual translation of the novel structure showed a stop codon in frame with the open reading frame of the message and predicts a truncated protein product of 25 kDa. The stop codon is 5' to the pyridoxal phosphate cofactor binding site; therefore the predicted truncated protein cannot function as a decarboxylase. Genomic clones with the GAD gene have been isolated. One of these clones contains the 86 bp exon flanked by intronic sequences. To determine the level of expression of the embryonic exon, protection assays were done utilizing a probe containing the embryonic exon. These assays show that the embryonic form is present throughout the embryonic brain but not in the adult. These data suggest that the appearance of functional GAD requires two types of control. First, transcription must be initiated. Next, the splicing machinery must be regulated so as to eliminate the stop codon containing exon from the mRNA so as to produce functional GAD.

397.3

TWO GENES ENCODE DISTINCT GLUTAMATE DECARBOXYLASES WITH DIFFERENT RESPONSES TO PYRIDOXAL PHOSPHATE. M.G. Erlander, N.J.K. Tillakaratne, S. Feldblum, N. Patel, and A.J. Tobin, Department of Biology, UCLA, Los Angeles, California 90024

Gamma-aminobutyric acid (GABA) is unmatched by any other known inhibitory neurotransmitter in its almost ubiquitous distribution in vertebrate brain. In adult brain, the synthesis of GABA depends on the activity of glutamic acid decarboxylase (GAD; E.C.4.1.1.15). The mammalian brain contains at least two forms of GAD, which differ from each other in size and in interaction with the cofactor pyridoxal-5'-phosphate (PLP). This report answers a fundamental question posed since the early 1970s: is the observed heterogeneity the result of more than one gene encoding mammalian GAD? We demonstrate here the existence of two GAD genes which encode proteins that differ in molecular size, response to PLP, and subcellular location. Furthermore, the two GAD mRNAs are present in the same neuronal types of the rat cerebellum, but at different levels. We suggest that the different properties of these two genes allow greater flexibility in regulating GABA synthesis. In addition, convulsive doses of PLP antagonists in-vivo may preferentially inhibit GAD_{65}, encoded by the new cDNA we describe in this report. Supported by NS22256 and 20256 to AJT.

PARALLEL REGULATION OF mRNAs FOR DOPAMINE β-HYDROXYLASE AND TYROSINE HYDROXYLASE BY DEXAMETHASONE, cAMP AND GROWTH FACTORS IN PC12 CELLS. A. McMahon*, H. Badoyannis, S.C. Sharma and E.L. Sabban, New York Med. Coll., Valhalla, NY 10595.

Dopamine β-hydroxylase (DBH), which catalyzes the conversion of dopamine to norepinephrine, is regulated by various hormonal and neuronal factors. To study the molecular mechanism of this regulation, we examined the effects of glucocorticoids, cAMP and growth factors on DBH mRNA in PC12 pheochromocytoma cells.

Dexamethasone (1 mM) increased both the 2.7 and 2.5 Kb mRNAs for DBH about 4-fold. This increase was apparent by 7 hrs and maximal at 2 days of treatment. Treatment with 8-bromo-cAMP (1 μM), or forskolin (10 μM) also elevated both mRNAs for DBH, with maximal induction of 3-fold by 8 hrs. DBH mRNA remained elevated for 1 day, but with longer exposures decreased to below control levels. Combined treatment with 8-bromo cAMP and dexamethasone gave results similar to 8-bromo cAMP alone. The mRNA levels for tyrosine hydroxylase (TH) essentially paralled the induction of DBH mRNA with either dexamethasone or cyclic AMP. Nerve growth factor, in contrast, decreased both DBH and TH mRNA levels.

The results of this study demonstrate that DBH mRNA is subject to regulation by several physiologically important factors. Genomic clones to rat DBH have been isolated to begin to identify regulatory elements.

397.5

COMBINED NICOTINIC AND MUSCARINIC REGULATION OF CO-LOCALIZED ADRENAL TRANSMITTER GENES: PREPROENKEPHALIN (ppENK) AND TYROSINE HYDROXYLASE (TH). J.D. DeCristofaro, G. Weisinger and E.F. La Gamma, Dept. of Pediatrics, SUNY at Stony Brook, NY 11794-8111.

Combined nicotinic and muscarinic stimulation results in a greater than additive rise in steady state ppENK mRNA, enkephalin prohormone and peptide (Neuroscience 35:203, 1990; Neuroscience Abs 142.4, 1989). The rise in ppENK is 50-fold after 2 days and 100-fold after 4 days of treatment. Steady state TH mRNA peaks at 2 days and plateaus at 10-fold over baseline. Both ppENK mRNA and TH mRNA levels return to baseline within 1 week following the 4 day treatments. This suggests independent regulation of these co-localized messages. To determine the contribution of transcriptional initiation on this rise and fall in steady state ppENK mRNA, S1 and primer extension analysis were performed. The greatest rise in ppENK RNA initiation occurred after 2 days of combined cholinergic treatment. By a week after completion of 4 day treatments, three of the four start sites identified by primer extension returned to baseline. These data suggest that cholinergic induced initiation of ppENK RNA transcripts contributes to the rise in steady state mRNA. Moreover, stabilization of steady state ppENK mRNA may also play a role since initiation decreases after 2 days of treatment, but RNA levels continue to rise up to 4 days. Supported by NSF #BNS8719872.

TYROSINE HYDROXYLASE (TH) GENE EXPRESSION IN BOVINE ADRENAL CHROMAFFIN CELLS: REGULATION BY CHOLINERGIC RECEPTOR STIMULATION. M. Olasmaa, M. Memo, D. Grayson, A. Guidotti and E. Costa. FGIN, Georgetown University, Washington, D.C. 20007.

Cyclic AMP-mediated TH gene expression in adrenal chromaffin (AC) cells is transsynaptically regulated by neurotransmitters released from the splanchnic nerve terminals (Biochem.Pharmacol. 26 (1977) 817-823). Acetylcholine (ACh) has been shown to be a major transmitter released from splanchnic nerve. Primary cultures (5-7 days in vitro) of bovine AC cells were utilized as a model system. Exposure of the AC cells to 0.1-1.0 mM carbachol slightly (ca. 20%) increased the TH-V_{max} when measured 48hrs after the beginning of the treatment. However, if carbachol was applied together with HL-725 (Trequinsin, 10^{-5}M), a type II phosphodiesterase (PdE) inhibitor (Hoechst-Roussel Pharm., Inc.), the increase was enhanced (ca. 70%). The facilitatory effect of HL-725 confirmed the involvement of cAMP in the transduction regulating the level of TH-V_{max} (Mol.Pharmacol. 16 (1979) 865-876). Since in splanchnic nerve terminals ACh coexists with VIP, which is known to utilize cAMP for its signal transduction, the possibility that VIP functions as a co-transmitter with ACh in the transsynaptic induction of TH was investigated. VIP (10^{-7}-10^{-5} M) produced a dose and time dependent increase of TH-V_{max}, which in the presence of HL-725 was shifted to the left, indicating an involvement of cAMP as a second messenger in this response. When AC cells were exposed to 1μM VIP, without HL-725, a slight increase in TH-V_{max} was observed. However, this low dose facilitated the action of carbachol. The change in TH mRNA content elicited by 10 μM VIP together with HL-725 was investigated following amplification by polymerase chain reaction. The combination VIP and HL-725 increased the TH mRNA content in a time-dependent fashion.

TIME DEPENDENT REGULATION OF TYROSINE HYDROXYLASE mRNA IN S. NIGRA DOPAMINERGIC NEURONS FOLLOWING 6-OHDA LESION. G.M. Pasinetti, J.F. Reinhard, A.B. Kelly, D.G. Morgan and C.E. Finch. Andrus Gerontology Center and Dept. of Biological Sciences, Univ. of Southern California, Los Angeles, CA, 90089-0191. The Wellcome Research Laboratories, Research Triangle Park, NC 27709.

Long term nigral 6-hydroxydopamine (6-OHDA) lesions induce atrophic changes in the remaining s. nigra dopaminergic (DAergic, tyrosine hydroxylase (TH) immunopositive) neurons, including >50% loss of TH-mRNA concentration per neuron [Pasinetti et al., Mol. Brain Res. 5:203 (1989)]. We extended these findings by examining the time course of changes in the remaining s. nigra DAergic neurons at 2,21,90 and 270 days following nigral 6-OHDA lesions. TH catalytic activity, TH polypeptide content, dopamine (DA) and DA catabolites (HVA and DOPAC) at the striatal terminals, were measured to resolve multiple levels of DAergic regulation in response to nigral lesioning. Nigral atrophic changes began as early as 90 days post-lesion as indicated by a reduction of nigral DAergic perikaryal area (-20%) and decreased TH-mRNA concentration (-30%) per neuron. The decreased TH-mRNA concentration at 270 days confirms previous results. In contrast to these atrophic nigral changes, compensatory changes were observed in striatum. At 21 days post-lesion, the striatal DA catabolite, HVA, was reduced slightly less than TH catalytic activity, which suggests increased (+30%) striatal DA release and utilization. Because the loss of striatal TH polypeptide content was smaller than the loss of DAergic neurons at all times after nigral 6-OHDA lesions, it follows that the surviving s. nigra DAergic neurons compensated by increased production of TH protein. Thus, the surviving neurons become more efficient in utilizing the available TH-mRNA with regard to the final product, striatal TH polypeptide. LOCAL PROTEIN SYNTHESIS WITHIN ISOLATED GROWTH CONES OF CULTURED SNAIL NEURONS. Lauren Davis and Stanley B. Kater. The Program in Neuronal Growth and Development and the Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523.

The neuronal growth cone is a highly specialized region at the tip of growing neurites that contains a complement of organelles that is different from the rest of the neurite and perikaryon, and an intracellular calcium concentration that is apparently independently regulated. It has been suggested that growth cones may function independently from the rest of the neuron and, in fact, the behavior of isolated growth cones is indistinguishable from that of intact for at least 48 hours. Further autonomy would be conferred by the ability of such an independent system to locally synthesize proteins. To explore the possibility that proteins are locally synthesized in growth cones, cultures of Helisoma neurons were prepared and the growth cones of 1-2 neurites per cell were transected. Two to 6 hours following transection, cultures were pulse-labelled in 3H-leucine for 10 minutes and then fixed and processed for autoradiography. Autoradiographs demonstrated that radiolabeling over isolated growth cones was comparable to labeling over growth cones and distal neurites whose cytoplasm was continuous with the rest of the cell. Because snail neurons are impermeable to most conventional protein synthesis inhibitors, we employed DMSO (8%), a reversible inhibitor of ribosomal protein synthesis, at a concentration that pulse-treated neurons survived and continued to grow for at least 2 days. Labeling was greatly reduced or eliminated over neurons, as well as isolated growth cones, in DMSO treated cultures; a control that suggests that 3H-leucine is indeed incorporated into newly synthesized proteins during translation. These results suggest that proteins are locally synthesized in isolated neuronal growth cones. This may indicate that the expression of the genome can be regulated independently by individual subcellular regions. Thus, the complement of protein components within a growth cone might be modified in response to local stimuli. Supported by NIH NS08445.

ISOLATION OF NOVEL DEVELOPMENTALLY REGULATED GENES FROM EMBRYONIC MOUSE TELENCEPHALON USING SUBTRACTIVE HYBRIDIZATION. J.L.R. Rubenstein, M.H. Porteus*, A.E.J. Brice*, R.D. Ciaranello and T.B. Usdin. Laboratory of Developmental Neurochemistry, S253, Stanford Univ. Sch. of Med., Stanford, CA 94305.

We are studying the genetic mechanisms which regulate development of the mammalian forebrain. To this end, we have devised an efficient method of performing subtractive hybridization between directional cDNA libraries in single-stranded phagemid vectors. We have performed subtractions in which the driver was cloned cDNA from adult mouse telencephalons, and the target was cloned cDNA from embryonic day 15 telencephalons. We obtained a 70-fold subtraction. We have performed northern analysis of five of the clones; four of them are preferentially (20-1000 fold) expressed in the embryonic telencephalon. The partial DNA sequences of these clones are not found in Genebank. One of the clones has strong homology to the helix III region of the antennapedia homeodomain. We are presently further characterizing the cDNAs by *in situ* hybridization.

EFFICIENT UPTAKE AND EXPRESSION OF FOREIGN DNA BY CNS STEM CELLS D.I.Gottlieb, G.T.Coker III, J. Ho*, M. Moffat* and K.L. O'Malley, Dept of Anatomy and Neurobiology, Washington University Sch of Med., St. Louis Mo. 63110

By introducing foreign DNA into eukaryotic cells, the mechanisms underlying cell specific and hormonally regulated gene expression can be analyzed. We have extended this approach to cells of the early chick embryonic brain. Suspensions of viable E5 tectal cells were prepared by trypsinization. Plasmid DNA was introduced into these cells via electroporation. Plasmids containing the β-galactosidase reporter gene driven by the Rous sarcoma virus (RSV) promoter were efficiently expressed. 44 hours after electroporation 22% of the cells were positive for the β-galactosidase marker. When cells were cultured on laminin for 4 days after electroporation many axon bearing cells were stained. Therefore some of the cells which take up and express foreign DNA can differentiate into neurons. In other experiments a promoter containing 6 cAMP response elements driving a CAT reporter gene was used. Transfected cells responded to added 8 bromo cAMP with a 40 fold increase in CAT activity. We conclude that some cells in the E5 tectum transcribe CREs in a cAMP dependent manner. Preliminary data with an RSV-luciferase construct were obtained. Levels of luciferase expression were sufficiently high to suggest that this approach will be applicable to a wide range of endogenous cellular promoters.

SENSORY SYSTEMS—VISUAL PSYCHOPHYSICS AND BEHAVIOR II

398.1

TOWARDS A NEUROBIOLOGICAL THEORY OF VISUAL AWARENESS. C. Koch and F. Crick, CNS Program 216-76, Caltech, Pasadena, CA 91125 and Salk Institute, La Jolla, CA 92037.

We propose a neurobiological framework to study one particular form of consciousness, visual awareness. We postulate one form of awareness linked to the serial, attentional mechanism studied by Julesz, Treisman and others. This working awareness (WA) solves the binding problem, i.e. rapidly and transiently signalling the combination of perceptual features. Such a mechanism is required to bind together all those neurons actively responding to different aspects of the perceived object in a coherent way. Furthermore, objects for which the binding problems has been solved are placed into short-term (i.e. several sec) memory. In order to explain the perceptual richness of our environment, we postulate a second, very fleeting form of awareness. This form is associated with iconic memory (< 500 msec), has a very large capacity and does not solve the binding problem.

One possible implementation of WA could involve the semi-synchronous neuronal oscillations in the 35-70 Hz range observed in visual and olfactory cortex (Freeman; Gray and Singer; Eckhorn *et al,*). Once visual attention has selected the most "interesting" location (using a saliency map), feedback pathways synchronize the oscillations at the corresponding locations in V1, V4, MT etc. Thus, the neuronal expression of attention is phase- and frequency-locked 40 Hz oscillations. These phase-locked oscillations activate short-term memory. Processes, such as priming and subliminal perception, which by-pass these oscillations will not be "consciously perceived".

COHERENT OSCILLATIONS IN A POPULATION-BASED MODEL: THEIR ROLE IN VISUAL PERCEPTION. O. Sporns*, G. Tononi*, and G.M. Edelman, The Neurosciences Institute, 1230 York Ave., New York, NY 10021.

Orientation-selective neurons in the cat visual cortex show stimulus-dependent oscillatory firing that can be coherent both locally as well as over long distances in the cortex. To investigate (1) how such neuronal oscillations might be generated, (2) how spatial coherency of oscillations arises and (3) what the functional significance of coherent oscillations might be, we present a computer model of two distinct visual cortical areas, roughly based on cortical areas V1 and MT (PNAS 86, 7265). Each area contains a number of neuronal groups composed of cells selective for the orientation and motion of line segments. Neuronal groups interact via reciprocal excitatory connections. Oscillatory firing is produced by cooperative interactions within each group. The intrinsic frequency of individual neuronal groups is highly variable (due to their variable structure) and shifts considerably within brief time periods. Phase coherency of distant groups arises from the reciprocal exchange of signals in reentrant connections. The magnitude of cross-correlations is sensitive to both number and strength of reentrant connections. Variations in intrinsic frequency prevent accidental phase-locking of coactive but unrelated groups. Coherent firing in the model depends critically on global stimulus properties such as spatial continuity and pattern motion. We present several examples of how coherent oscillatory activity can be used to transiently link features of a stimulus analyzed in segregated parts of the cortex. This mechanism might allow the distinction of stimuli from a background or, in general, the segmentation of a complex visual scene into distinct objects.

VISUAL NEURON RELIABILITY IN CONVEYING DIMENSIONAL INFORMATION AS A FUNCTION OF STIMULUS DURATION OR CONTRAST. Ehud Zohary * and Shaul Hochstein, Neurobiology Department, Institute of Life Sciences, Hebrew University, Jerusalem, Israel.

There is considerable recent interest in the neuronal source of the limited accuracy with which subjects perform visual tasks under contrast and/or time constraints. One approach to this question is the use of Signal Detection Theory and the comparison of the reliability of the responses of single neurons with the overall performance of the visual system in psychophysical tasks (reviewed by R.D. Freeman's special lecture at this meeting). As a special application of this technique we have compared the dependence of neuronal reliability and that of task performance on available processing time (Soc. Neurosci. 1989). Signal Detection Theory gives a good estimate of the neuron's ability to discriminate between two stimuli. However, it does not give a measure of the reliability with which the neuron's response signals the value of the stimulus over an entire range of a variable dimension. Information Theory provides a measure for this quantity (Werner and Mountcastle, 1965; Tolhurst, 1989). We now use this Information Theory approach to compare the information conveyed by the single neuron and psychophysical task performance. We studied the responses of macaque V1 neurons in the alert behaving preparation, as a function of stimulus orientation, spatial frequency, and motion direction and velocity. We compared the response information content with that inherent in the task performance. The information content concerning each of these dimensions is a function of the contrast and duration of the stimulus. We report these dependences for the single neuron, and compare these dependences with the parallel psychophysical measures.

398.4

DOES MOTION PERCEPTION DEPEND ON THE MAGNOCELLULAR PATHWAY? William H. Merigan, Carey Byrne, and John Maunsell, University of Rochester, Rochester, N.Y. 14642.

There is some evidence that visual signals relayed through magnocellular layers of the lateral geniculate (M pathway) may be particularly important for motion processing. Anatomical and physiological data show that this pathway provides the major input to the cortical "motion" pathway, which includes areas MT and MST. In addition, a recent lesion study has shown that damage to the M pathway disrupted motion detection, whereas damage to the P pathway had no such effect (Schiller et. al., 1990).

Ibotenic acid lesions were placed in magnocellular layer 1 of the lateral geniculate of macaques and two aspects of motion perception were tested in portions of the visual field of the contralateral eye that corresponded to the lesions. Velocity difference thresholds were measured with patches of drifting sinusoidal gratings. In addition, contrast sensitivity was measured for the detection of drifting grating patches, and for the discrimination of their direction of motion.

Performance on all measures was degraded by magnocellular lesions, and this was more pronounced at high speed (20 deg/sec) than at low speed (1 deg/sec). However, the observed changes did not suggest a deficit specific to motion perception. While contrast thresholds for discrimination of the direction of motion were raised by lesions, especially at higher speeds, similar changes were seen in grating detection thresholds. Velocity difference thresholds were greatly elevated in the vicinity of M pathway lesions, but it was possible to reduce or eliminate this difference by raising the contrast of the test stimuli. These results suggest that cortical motion mechanisms do not rely exclusively on input from the M pathway, but that it is important to visual detection at high speeds.

CORTICAL DYNAMICS OF VISUAL MOTION PERCEPTION: SHORT- AND LONG-RANGE APPARENT MOTION. Michael E. Rudd and Stephen Grossberg, Center for Adaptive Systems, Boston University, 111 Cummington Street, Boston, MA 02215

Further development of a neural network model of motion perception by visual cortex (Grossberg and Rudd, 1989) is presented. The model clarifies computational differences between parallel cortical streams for perception of static form ($V1 \rightarrow V2 \rightarrow V4$) and moving form ($V1 \rightarrow MT, V2 \rightarrow MT$). Properties of the model are tested by simulation of psychophysical data concerning two-flash and Ternus apparent motion displays, as well as percepts of split motion, reverse motion, gamma motion, and interactions between continuous motion and binary color percepts. The model explains the approximate space-time separability of the motion strength function as well as deviations from space-time separability at threshold. The model clarifies the dependence of the maximum extent of short-range motion on element scale, and the different properties of short-range and long-range motion vis-a-vis interframe changes in stimulus direction-of-contrast. It specifies how sustained and transient channels cooperate and compete in successive processing stages to generate motion signals that are independent of direction-of-contrast; and how preprocessing of motion signals by a Motion Oriented Contrast (MOC) Filter is joined to long-range cooperative-competitive feedback mechanisms, called a CC Loop, to control phenomena such as induced motion and motion capture.

OBJECT REPRESENTATION THROUGH SURFACE INTERPOLATION IN STRUCTURE FROM MOTION

S. Treue, R. A. Andersen, H. Ando, E. C. Hildreth.
Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

Investigations in depth perception using disparity information have demonstrated surface interpolation between feature elements. Current computational algorithms of structure from motion (SFM) do not perform such an operation. Here we present strong evidence for surface interpolation in SFM and in the following abstract demonstrate how such a mechanism can be incorporated into current computational algorithms.

Using the parallel projection of randomly positioned dots on a rotating transparent cylinder, we impose a desynchronized oscillatory motion on the individual dots. Although such a stimulus does not have a rigid physical correlate, subjects perceive a rigid cylinder in smooth rotation. This percept can only be explained if the visual system represents the observed object not as a collection of individual elements but as two surfaces moving in opposite directions. A given point contributes information to one of the surfaces depending on its direction.

The basis for this segmentation of surfaces might be direction selective cells in V1 which act as directional filters ignoring motion in the non-preferred direction (Erickson et al. Neurosci. Abstr., 1989). In a population of such cells our stimulus would activate two distinct groups of cells and an oscillating dot would activate alternately either one or the other group of cells.

RECOVERING 3-D STRUCTURE FROM MOTION WITH SURFACE RECONSTRUCTION.

H. Ando, E. C. Hildreth, S. Treue, R. A. Andersen.
Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

We present a model for the human recovery of 3-D structure from motion that combines an extension of Ullman's incremental rigidity scheme with a surface interpolation process that reconstructs full 3-D surfaces from sparse depth information. The input to this algorithm consists of either the velocities or displacements of moving points in the image. Using this information, the algorithm sequentially estimates a new 3-D structure by minimizing the overall deviation from rigidity. As 3-D structure is derived at the locations of the moving points, a smooth surface is filled in between these locations. Since what is preserved between views is the reconstructed surface, individual image features may appear and disappear without destroying the recovered structure.

This model allows multiple surfaces to be represented simultaneously in order to cope with transparency, facilitates the use of constraints on surface shape from object boundaries, and groups points on different surfaces based on their 2-D image motion. Thus the model can account for experimental observations by Husain et al. (Neural Comp. 1:324-333, 1989) and Treue et al. (preceding abstract) regarding the ability of human subjects to interpret 3-D structure in displays with limited lifetimes. We show that this model can account for many other experimental observations such as general degradation of performance with fewer points, as well as the interaction between multiple transparent surfaces in motion suggested by Ramachandran et al. (Perc. & Psychophys. 44:330-393, 1989).

398.8

LESIONS OF AREA 17 IN THE CAT REDUCE SENSITIVITY TO HIGH BUT NOT LOW SPATIAL FREQUENCY TARGETS. *Tatiana Pasternak, Iwona Zurawska, and John H. R. Maunsell.* Depts of Neurobiology and Anatomy, Physiology, and Center for Visual Science, University of Rochester, Rochester, NY 14627

We have recently shown that ibotenic lesions of area 18 severely reduce the sensitivity of cats to drifting low spatial frequency gratings but leave acuity intact (Pasternak et al., 1989). This result is consistent with the physiological properties of neurons in area 18, which on average prefer targets of spatial frequencies three times lower than neurons in area 17. The intact acuity following lesions of area 18, and the high spatial frequency preferences of area 17 neurons suggest that the detection of high spatial frequencies may depend upon neurons in area 17. To assess the contribution of area 17 to spatial vision we placed punctate unilateral ibotenic acid lesion in a physiologically identified portion of area 17. Each lesion was centered at an eccentricity of about 8° along the horizontal meridian of the left visual field. We measured the detectability of various spatiotemporal targets placed within the ablated portion of the visual field representations, while monitoring eye position with a scleral search coil. The cats were required to maintain fixation on a laser spot and respond to the presence or the absence of the grating by pressing a right or left pedal. We found a loss (30%) of visual acuity for targets placed within the lesioned part of the visual field. Furthermore, contrast sensitivity for stationary gratings of intermediate and higher spatial frequencies was reduced by a about a factor of 2. On the other hand, contrast sensitivity was normal at low spatial frequencies (0.28 c/deg). The results were similar for gratings drifting at 4.5 Hz. This result, in conjunction with previously reported deficits following lesions of area 18, demonstrates a high degree of functional segregation at early stages of cortical processing, with area 17 playing an important role in spatial resolution, while area 18 contributes to the detection of low spatial frequencies.

EXTRASTRIATE LESIONS AND ILLUSORY CONTOUR ORIENTATION DISCRIMINATION IN THE CAT. P. De Weerd*, J.M. Sprague, E. Vandenbussche* and G.A. Orban. Lab. Neuro-en Psychofysiologie, K.U. Leuven, B-3000 Leuven, Belgium.

We have investigated the effect of large extrastriate lesions (Vandenbussche et al., Soc. Neurosci. Abstr. 15: 1255, 1989) on orientation discrimination (OD) in two cats (52 and 54), trained in OD of a bar and of two types of illusory contours. The length of illusory contours and bar was 12 deg. The contours used were Gap Illusory Contour (GIC) - 7 semicircles separated by 1.2 degree wide gap - and Phase Shifted Illusory Contour (PSIC) - 4 semicircles shifted in phase along the contour. 73.5% correct Just Noticeable Differences (JNDs) were determined for each contour-type in an interleaved way, presenting one contour-type per daily session. Although we have no histological control of the lesion yet, it was intended to destroy areas 19, 20 and 21, and medial bank of the Lateral Suprasylvian Sulcus. The two cats behaved very similarly during pre- and postoperative testing. Average preoperative JNDs were 5.8, 11.1 and 15.9 degrees for bar, GIC, and PSIC respectively. During the first postoperative month, no reliable thresholds could be measured for the PSIC, whereas thresholds for the bar and the GIC were 11.8 and 33.4 degrees, respectively. After three months JNDs stabilized at 7.5, 23.0 and 38.3 degrees. These results suggest that extrastriate areas are more critical for OD of illusory contours than for OD of bars.

398.10

CORTICAL AREAS MEDIATING RECOVERY FOLLOWING EARLY PERIODS OF MONOCULAR DEPRIVATION IN KITTENS. C.J. Beaver* and D.E. Mitchell. Dept. of Psychology, Dalhousie University. Halifax, Nova Scotia. B3H 4J1.

Despite the severity of the visual deficit produced by monocular deprivation, substantial recovery is possible if normal visual input is restored to the deprived eye sufficiently early, particularly if at the same time the initially non-deprived eye is occluded. During this period of reverse occlusion (RO) the initially deprived eye can recover to nearly normal acuity levels. Surprisingly, following termination of RO the visual acuity of the formerly deprived eye drops rapidly to less than half the values obtained during the period of RO, while at the same time the vision of the other eye gradually improves to almost normal levels. In order to determine whether these reciprocal changes are governed by areas 17/18, we examined the effect of bilateral ablation of these areas. Six kittens were monocularly deprived until 6 wks. of age, at which time they were reverse occluded for a further 6 wks. and then allowed a period of binocular vision. Following the period of binocular vision, bilateral lesions of areas 17/18 were made and after several months of recovery the visual acuities of both eyes were again measured. In normal animals, lesions of areas 17/18 reduce the acuity of both eyes by approximately a factor of two. If the reciprocal changes in vision observed after RO result from similar processes in all cortical visual areas, then a proportional drop in the visual acuity of both eyes would be expected. Rather than a proportional decrease, the acuities of the two eyes were very similar (almost half normal values). This result strongly suggests that the mechanism governing the rapid changes following reverse occlusion is located in areas 17/18.

398.11

LONGITUDINAL DEVELOPMENT OF EYE ALIGNMENT IN KITTENS WITH TWO TYPES OF SURGICALLY INDUCED STRABISMUS: RELATIONSHIP TO EXTRASTRIATE CORTICAL BINOCULARITY by Ruxandra Sireteanu,* Wolf Singer,* Maria Fronius,* Joachim Greuel and Johannes Best.* *Max-Planck-Institute for Brain Research, Frankfurt/Main, FRG*

Interocular alignment was assessed by corneal light reflex photography in 15 normal and 24 strabismic kittens. Nineteen strabismic and 5 normal kittens were followed longitudinally from 12 days to about 6 months of age. Strabismus was induced at 3-4 weeks of age, either by cutting one extraocular muscle (tenotomy) or by reinserting the muscle at another position on the ocular globe (recession).

Four out of the 6 tenotomized cats and 5 out of the 11 recessed cats conserved their post-operative ocular deviation throughout the testing period ("large-angle strabismics"). Two tenotomized and 6 recessed cats showed a transient deviation for 1-2 weeks after surgery, after which the interocular alignment stabilized to values found in normal cats ("microstrabismic" cats).

All cats showed a clear breakdown of binocularity in area 17. In the postero-medial lateral suprasylvian area (PLMS), binocularity was markedly reduced for the large-angle strabismics, but much less so for the microstrabismic cats.

The difference might be due to the coarse grain and poor retinotopic organization of visual receptive fields in the lateral suprasylvian area.

398.12

SIGNAL AND MESSAGE IN DIGITIZED SMILES. C.M. Leonard, Dept. of Neuroscience, Univ. Fl. College of Medicine, Gainesville, FL 32610.

One of the most complex information processing tasks that the brain can perform is the decoding of social communication signals such as facial expressions. There are few methods presently available for measuring information content in these kinetic displays. This abstract describes a technique for measuring the information generated by mouth movements in digitized human smiles. Facial movements were measured by digitally subtracting adjacent frames from eight 400-msec taped vignettes (12 frames) and calculating the variance of the distribution of pixel values in the subtracted images. The eyes were held constant in all frames. Twelve observers were asked to identify the social messages conveyed by the individual images in each vignette. The total number of positive messages attributed to each smile correlated .74 (Spearman rho, $p < .05$) with its cumulative variance. In five of the smiles, the perception of positive messages increased disproportionately during 100-msec periods of high variance associated with a deepening dimple on the left side.

In order to measure the relation between changes in signal and perceived message for individual observers, a sequential, two-alternative, forced-choice psychophysical procedure was used. The stimuli were brief (200-msec) two-frame sequences presented forwards (increasing smile) and backwards (decreasing smile) in pseudo-random order on each trial. Subjects were asked to report whether the first or second sequence of images was more pleasant. The strength of the preference for the forward order ranged from 50 to 100% for different sequences and depended on the between-frame variance. Rapidly increasing smiles (those with large variances) were more reliably perceived as pleasant than gradually increasing ones.

These results demonstrate that digital image analysis and psychophysics can be used to identify stimulus characteristics that define the boundaries between social messages in a rapidly changing signal. This method permits quantification of the hedonic qualities of facial expression.

TRANSPLANTATION: NEW TECHNIQUES, IMMUNE REJECTION AND BEHAVIOR

POLYMER ENCAPSULATED PC12 CELLS TRANSPLANTED IN MPTP LESIONED PRIMATES. P. Aebischer, M. Goddard, R. Timpson, A. Signore, A. Beauregard-Young, C. Rampone. Artificial Organ Laboratory, Brown University, Providence, RI.

Transplantation of polymer immunoisolated dopamine (DA) secreting cells may constitute an alternative for the treatment of Parkinson's disease. The encapsulation of a cell line within a permselective polymer membrane should not only restrict their outgrowth but prevent host rejection in cross-species transplantation. Chaired cynomologus monkeys were trained to pick food rewards from a multiwell plate. The time required to empty the wells was quantified several times per week. The neurotoxin MPTP was then injected via the right internal carotid artery which led to the development of a contralateral hemiparkinsonian syndrome. Six weeks following the MPTP injection, a semi-permeable membrane based U-shaped device was implanted stereotaxically in the DA-depleted striata. PC12 cells, a DA-releasing cell line derived from a rat pheochromocytoma, were then injected into the U-shaped device. A significant improvement in the ability of a severely lesioned primate to empty the wells was observed within the first week post-transplantation. Viable PC12 cells were recovered 3 months post-implantation by flushing the U-shaped device. This was followed by a deterioration of the monkey's performance at the picking test. Less severely lesioned monkeys showed mild improvement when either PC12 cells or dopamine releasing polymer rods were inserted in semi-permeable receptacles. These results show that polymer encapsulted PC12 cells can survive implantation into a primate striatum. Preliminary results indicate that the release of dopamine from a line source in the striatum is able to ameliorate the symptomatology of an MPTP induced Parkinson's syndrome in non-human primates.

399.2

NEURONAL SURVIVAL AND GROWTH AFTER DISSOCIATION AND REPLATING OF LONG TERM PRIMARY MESENCEPHALIC CELL CULTURES. C. Mytilineou, T. Bak, D. Casper and M. Blum. Dept. Neurology and Fishberg Center for Neurobiol., Mount Sinai Sch. Med. New York, N.Y., 10029.

The ability to maintain in storage a pool of a specific neuronal population would be important in brain transplantation. We have observed (Casper et al. Soc. Neurosci. Abst., 15:708, 1989) that exposure of rat mesencephalic cell cultures to epidermal growth factor (EGF) results in cell proliferation and confluence within 3 weeks in vitro. Staining with GFAP indicates that only a fraction of the cells are differentiated astrocytes. We considered the possibility that the apparently undifferentiated cells were both neuronal and glial precursors which could survive enzymatic removal and dissociation and differentiate after replating. Mesencephalic cells from E-16 rat embryos were grown in chemically defined medium with 10 ng/ml EGF. After 12, 14 or 17 days in vitro the cells were removed from the dishes by 0.06% trypsin, washed and resuspended in medium by trituration. $5X10^4$ cells were plated on polyornithine coated 35mm dishes in defined medium with10 ng/ml EGF. Both flat and phase bright cells attached to the dishes within 24 hrs and a large number of the phase bright cells began extending processes. 3-5 days after replating, cultures were stained with antibodies to GFAP or Tau to determine the presence of differentiated astrocytes and neurons. Most of the flat cells, about 20% of the total cell population, were positive for GFAP. A number of the phase bright cells were positive for Tau, had extended long processes and had the appearance of well differentiated neurons. GENE TRANSFER INTO BRAIN USING A HERPES SIMPLEX VIRUS (HSV) VECTOR. D.J.Fink, M.Mata, L.R.Sternberg*, W.Goins* and J.C.Glorioso*. VAMC, U.Michigan, Ann Arbor, MI 48104 and U.Pittsburgh, Pittsburgh, PA 15261.

We have exploited the natural biology of herpes simplex virus (HSV) to engineer recombinant HSV vectors of reduced neuropathogenicity for the transfer and expression of foreign genes in the mature CNS. The E. coli β-galactosidase (β-gal) gene (lacZ) driven by a viral late gene (gC) or the latency active (LAT) promoter was recombined into HSV as a reporter of foreign gene expression during productive and latent viral infection respectively.

In vitro, infected Vero cells showed intranuclear viral particles, and β-gal as demonstrated by the X-gal reaction product. ICP4 deficient pLAT:lacZ recombinants expressed β-gal in the absence of detectable viral particles.

In vivo, wild-type and glycoprotein C (gC) defective vectors caused focal brain destruction. Viral protein kinase (US3)-deficient pgC:lacZ recombinants expressed β-gal in neurons from 2 to 5 days after inoculation, but did not cause focal brain destruction, despite the fact that viral particles could be identified in cells expressing β-gal. pLAT:lacZ recombinants expressed β-gal at times consistent with viral latency.

These results show that HSV vectors can be used to express foreign genes in cells of brain.

399.4

EMBRYONAL CARCINOMA (EC) CELLS TRANSPLANTED INTO THE BRAIN DIFFERENTIATE INTO A NEURONAL LINEAGE: A POSSIBLE VEHICLE FOR EXOGENOUS GENES. B. Wojcik*, F. Nothias, J.F. Nicolas* and M. Peschanski, INSERM U161, 2 rue d'Alésia, 75014 Paris and Institut Pasteur, Paris France.

Cell lines potentially useful as vectors for the expression of exogenous genes after transplantation into specific brain regions should (i) readily incorporate and express foreign genes, (ii) lack tumorigenicity and (iii) be integrated into the host brain parenchyma. EC cells which differentiate into neural lineages, such as 1009, should meet these criteria.

To test this hypothesis, EC cells were infected with a replication defective retrovirus which expresses the nlsLacZ gene from the SV40 promotor. The β-gal gene product is localized to the nucleus. Cells expressing the exogenous gene could be selected via FACS using fluorescein di-galactosidase. In vitro, these cells displayed a stable expression of the nlsLacZ gene and retinoic acid-induced differentiation resulted in neuronal (neuron specific enolase NSE+) and glial (GFAP+) phenotypes. Implantation of β-gal+ EC cells was carried out in excitotoxin treated CNS areas of adult rats. The rats were perfused after one month and sections stained for β-gal followed by immuno-labeling of alternate sections with anti-NSE or anti-GFAP. β-gal+ EC cells were present in the transplants and some of them were double-labeled for NSE but not for GFAP. NSE labeling showed that EC cells which had differentiated into neurons extended neurites into the host parenchyma, a result confirmed by EM studies of HRP-prelabeled cells. These results show that transplanted 1009 cells lose their tumorigenicity and differentiate into a neuronal lineage after intracerebral grafting, while they are still able to express an exogenous gene.

399.5

IMMUNE PRIVILEGE IS EXTENDED TO INTRAOCULAR DEVELOPING RETINAL ALLOGRAFTS. L.Q. Jiang and J.W. Streilein, Dept of Microbiology & Immunology, Univ. of Miami School of Medicine, Miami, Fla 33101

One long term experiment goal of retinal transplantation is to be able to transplant viable neural retinal tissue into eyes blinded by retinal degenerative disorders. The survival of such grafts would be expected to depend partly upon the ability of the recipient's immune system to recognize the graft's alien transplantation antigens and to mount a destructive immune response. To examine the immune response evoked by intraocular retinal transplants, we transplanted histoincompatible neonatal BALB/c neural retina into the anterior chamber (AC) and subconjunctival (SC) space of adult C57BL/6 mice. Clinical and histologic examination indicated that even strongly histoincompatible developing neural retinal transplants, engrafted within the AC, acquired a blood supply, and differentiated into recognizable retinal structures , without the evidence of rejection. SC retinal grafts were rejected. To examine whether mice with intracameral retinal allografts developed a deviant immune response, a panels of C57BL/6 mice (5) received from histoincompatible developing neural retinal transplants into the AC, or in the SC. Twelve days later, the ears of these mice were tested for delayed hypersensitivity with intrapinnae injections of (C57BL/6xBALB/c)F1 spleen cells. A positive control panel of C57BL/6 mice that received BALB/c spleen cells SC or neonatal BALB/c retina implanted SC displayed vigour DH. By contrast, recipients of BALB/c retinal grafts into the AC failed to mount significant ear swelling responses. We next demonstrated that BALB/c graft-specific suppressor cells were generated in spleens of animals bearing AC retinal grafts, using an adoptive transfer assay. By contrast, recipients of normal spleen cells developed strong DH. We conclude that immune privilege is extended to the histoincompatible retinal grafts in AC, and that a deviant immune response, deficient in delayed hypersensitivity may play a protective role for intraocular retinal transplants.

BROWN-NORWAY (BN) RATS DO NOT REJECT BRAIN GRAFTS FROM FISHER 344 (F344) RATS EVEN AFTER SYSTEMIC SENSITIZATION. M.Poltorak and W.J. Freed. NIMH Neuroscience Ctr. Washington, DC 20032.

Embryonic brain tissue allografts under many circumstances survive transplantation into the brain. It is generally believed that such grafts will not survive if the host animal is systemically sensitized, by skin grafting or other means, to major histocompatibility complex (MHC) antigens of the donor animal. We have found that F344 brain grafts survive in BN hosts even when the host is systemically sensitized to F344 tissue. Embryonic cerebral neocortex from F344 donors was transplanted into BN host rats (n=92). Subsequently, the host animals were systemically sensitized with donor skin (n=24), brain tissue (n=38), or spleen cells (n=6) and compared to a control group of allografts with no sensitization or sham procedures (n=24). Rejection of the transplants in BN rat hosts was not provoked by any of the sensitization methods tested. Minor immunological responses that did not result in rejection were, however, present in many host ani mals. We did not observe infiltration of W3/13+ T cells and 0X8+ cytotoxic lymphocytes in any of the groups. Nevertheless, substantial infiltrations of 0X6+ antigen-presenting cells and W3/25+ cells were present. There was also an extensive enhancement of MHC class I immunoreactivity in parts of the grafted tissue developing within the third ventricle, but not for the same type of graft in the lateral ventricle. These findings suggest that neural graft rejection depends on general genetic susceptibility to immune reactions, and not only to disparity between the antigens encoded by the MHC or minor MHC. Moreover, enhancement of MHC class I and class II expression within the transplanted tissue does not predict rejection of graft. (This study is dedicated to the memory of Cynthia R. Rodgers)

FIRST CLINICAL TRIAL OF MYOBLAST TRANSFER THERAPY: P.K. Law, Q. Fang*, T.G. Goodwin*, J.A. Florendo, H.Herrod*, T. Bertorini, D.S.Kirby*, H.J. Li*, M. Chen*, D. Yuan*, and G.S. Golden*. Depts. of Neurol. and Peds., Univ. of Tennessee, Memphis, TN 38163.

This double-blind study aims to determine the survival, development and functioning of donor myoblasts in dystrophic muscles of Duchenne Muscular Dystrophy (DMD) boys. We hypothesize that intramuscular injection of histoincompatible normal myoblasts can significantly improve the biochemistry, structure and function of dystrophic muscles. Our goal is to demonstrate the safety and efficacy of myoblast transfer in human.

Eleven DMD boys, aged 5 to 10, received myoblast injections in a randomly selected extensor digitorum brevis (EDB) muscle. The sham-injected EDB served as control. Donor myoblasts were derived from cell culture of muscle biopsies from the normal father/ward or normal brother of the host. Cyclosporine (CsA) treatment began two days before myoblast injection and continued for three months. Three days prior to the myoblast injection and three months afterward, the isometric twitch and maximum voluntary contraction of the left and the right EDBs were measured. Comparison of the mechanophysiology between the right and the left EDBs at 3 months after myoblast injection, and between the test EDB before and after myoblast injection would determine if the procedure exerted any beneficial effect on the dystrophic muscle. After mechanophysiologic testing at 3 months after injection, test and control EDBs were biopsied, and examined for dystrophin and for structural changes. If the procedure is proven successful, there will be potential for the use of myoblast transfer as a therapy to relieve dystrophic symptoms in other muscle groups in these patients. (Supported by MDA, Sandoz, and Walgreens).

SURVIVAL AND FUNCTION OF HUMAN MELANOCYTES IMPLANTED IN THE RAT STRIATUM. P.J. Kontur, C. Leranth, R. Halaban*, M.R. Lerner*, A.B. Lerner* and R.H. Roth. Depts. of Pharmacology, Dermatology, and Obstetrics and Gynecology, Yale Univ. Sch. Med., New Haven, CT 06510.

Melanocytes may serve as an alternative to adrenal or neuronal cells for transplantation in animal models of Parkinson's disease because they have the capacity to synthesize L-DOPA through the actions of the enzyme tyrosinase. The ability of normal human melanocytes to survive and produce L-DOPA after striatal implantation was examined in non-immunosuppressed rats with and without unilateral 6-hydroxy-dopamine-induced lesions of nigrostriatal dopamine neurons. The ability of melanocytes to affect apomorphine-induced rotation after implantation into the striata of lesioned rats was also evaluated. Melanocytes implanted in normal and lesioned striata survived but did not appear to proliferate when examined at various times post-implantation. Melanosomes, the site of tyrosinase activity, were present in melanocytes implanted in both normal and lesioned striata. However, melanosomes in the striata of non-lesioned rats appeared to be degenerating and lymphocyte infiltration was present. Rats with melanocyte implants in lesioned striata showed reductions in the contralateral rotation induced by the injection of apomorphine. These data suggest that melanocytes may serve as an alternative transplantable cell source of DOPA for the treatment of Parkinson's disease. Supported in part by USPHS Grant MH 14092, NS26068 and the United Parkinson Foundation.

INTRAHIPPOCAMPAL GRAFTS OF SEPTAL TISSUE TAKEN AT DIFFERENT EMBRYONIC AGES: EFFECTS ON BEHAVIORAL DEFICITS INDUCED BY ELECTROLYTIC FIMBRIA-FORNIX LESIONS IN THE RAT. J.C. CASSEL*, C. KELCHE*, I. GOEPP*, B. WILL. D.N.B.C., Centre de Neurochimie du C.N.R.S., 12, rue Goethe, F-67000 STRASBOURG (FRANCE).

Starting three months after grafting, behavioral effects *(home cage and open field activity, radial maze learning)* of intrahippocampal grafts of fetal ED14 *(Group S14)* and ED16 *(Group S16)* septal-diagonal band tissue, or of cortical tissue, as a control graft *(Group Cx)*, were assessed in Long Evans female rats given electrolytic lesions of the dorsal subcallosal septo-hippocampal pathways *(Group L)*. Sham-operated non-grafted rats served as controls *(Group S)*.

Compared to S rats, L rats showed increased activity in both their home cage and the open field, as well as dramatic impairment in maze learning. Neither type of graft provided any benefit on home cage activity, but graft-induced improvement was observed in the open field scores only in S16 rats and on maze learning scores only in S14 rats. These results, which will be discussed in the light of histological data, suggest that beneficial effects of septal grafts on fimbria-fornix lesion-induced behavioral deficits may be expressed differentially as a function of the fetal donor's maturity stage.

HOMOTOPIC NEURAL GRAFTS DO NOT CONSISTENTLY IMPROVE FORELIMB REACHING PERFORMANCE OF RATS WITH EXCITOTOXIC LESIONS OF THE STRIATUM. M. Pisa, P. McLean and J. A. Schranz. Dept. Biomedical Sciences, McMaster University, Hamilton, Ont., Canada, L8N 3Z5.

Female Wistar rats with bilateral, quinolinic acid-induced, excitotoxic lesions of the rostrolateral striatum were assigned to groups at random for homotopic injections of E14 cell suspensions of either striatal primordium (homotypic grafts) or cortex (heterotypic grafts) or cell-suspension vehicle (lesion-only group). The heterotypic grafts were unilateral and the homotypic grafts either unilateral or bilateral. The reaching performance of these rats was compared with that of control rats with neither lesions nor grafts, about 1 year after surgery. The lesions produced a significant impairment. The rats with either bilateral homotypic grafts or unilateral heterotypic grafts performed more poorly than the controls and did not reliably differ from the rats with lesions only. In contrast, the rats with unilateral homotypic grafts did not significantly differ from the controls. However, these rats preferentially performed with the paw contralateral to the nongrafted striatum. Histology confirmed both the lesions and the survival and growth of all grafts. Homotopic neural grafts do not appear to benefit the reaching performance of rats with striatal lesions, at least not consistently. (Supported by the MRC of Canada. M. Pisa is a Research Associate of the Ontario Mental Health Foundation).

IMPLANTED INTRASTRIATAL MICROENCAPSULATED DOPAMINE REDUCES DA AGONIST- INDUCED ROTATIONAL BEHAVIOR A. McRae[1], S. Hjorth[2], D. Mason*[3], L. Dillon*[3], T. Tice*[3] University of Göteborg, Dept of Histology[1] and Pharmacology[2] Göteborg, Sweden 40033 and Southern Research Institute[3] Birmingham Alabama USA 35255.

Dopamine (DA) has been encapsulated in 2 different copolymer [poly (DL lactide-co-glycolide)] excipients; one with a preprogrammed biodegradation time of 6 weeks (DA 50:50), and the other one expected to last about 3 months (DA 65:35). We compared the correspondence between the predicted time of co-polymer biodegradation and the duration of time that intrastriatally implanted DA microcapsules were able to reduce DA agonist-induced rotational behavior in unilaterally 6-hydroxydopamine (6-OHDA) lesioned rats. Rats displaying ≥ 400 contralateral rotations to apomorphine challenge were administered a suspension of DA microspheres in the mediocentral striatum. The rats were challenged with apomorphine on a weekly basis. The group receiving DA 50:50 returned to baseline levels 4 weeks after implantation. The group receiving DA 65:35 displayed significant reductions in contralateral rotional behavior beyond 8 weeks after implantation. Rats receiving empty microspheres did not demonstrate any significant change in the number of contralateral rotations. Similar results were obtained with the DA D-2 agonist 3-(3-hydroxyphenyl)-N-n-propylpiperidine (-) 3-PPP). We found no attenuation in the rotational responses to apomorphine 3-40 days after lateral striatal DA 50:50 microcapsule implants. These results support the concept of functional heterogeneity of the striatum. All of these results indicate that DA microsphere preparations have the potential of being employed as a source of neurotransmitter replacement with the CNS. These formulations allow sustained diffusion of microencapsulated DA into the CNS at a controlled rate for pre-determined periods of time and assure functional significance.

TRANSPLANTED RETINAE: ASSESSMENT OF FUNCTIONAL INTERACTIONS WITH HOST OPTIC INPUT AND SENSITIVITY TO ILLUMINATION. J.D. Radel, R.D. Lund and S. Das*. Dept. Neurobiology, Anatomy & Cell Science, Univ. Pittsburgh Sch. Med., Pittsburgh, PA 15261.

We report results from studies in which pupillary responses of adult host rats, elicited by illumination of intracranial retinal transplants, were recorded over a several week period in the same animal. If one host eye is removed at the time of transplantation (on postnatal day 1) an extensive transplant innervation of several host visual nuclei occurs, and a robust transplant-mediated pupilloconstriction is often present in the mature host as a result. The pupillary reflex typically shows little change after all host optic input is subsequently abolished by intracranial optic nerve section, and remains stable for at least a 5 week period. Retinae transplanted into newborn hosts having both eyes intact innervate the host brain poorly and mediate only minimal changes in pupillary diameter when illuminated after the host has matured. A marked improvement in the response can, however, be observed within 24 hrs after the optic nerves are sectioned. The time course of this change is too rapid to be attributable to anatomical sprouting of the transplant projection. We are presently studying these responses at longer periods after optic nerve section to determine if sprouting of the transplant projection induced by removal of the host inputs results in further changes in the transplant-mediated response. TRANSPLANTATION OF FETAL XENOGRAFTS FROM THE VISUAL CORTEX OF RATS TO THE VISUAL CORTEX OF ADULT CATS: RESPONSIVENESS OF CORTICAL CELLS IN THE HOST BRAIN. U. YINON and R. SHEMESH*, Physiol. Lab., Goldschleger Eye. Res. Inst., Tel-Aviv Univ. Fac. Med., Sheba Med. CTR, Tel-Hashomer, 52621, Israel.

Fetal (E15-E17) rats' visual cortex grafts were injected into a section unilaterally made in visual cortex area 17 of 4 adult cats. As sham controls 4 adult cats in which an equivalent section was made were also studied. Electrophysiological unit recordings were extracellularly performed, 4-9 weeks after surgery. Typical patterns of action potential discharges were identified in the cortex of all cats studied. While medial to the transplant bridge (in the visually deafferented area) the majority of the recorded cells were spontaneously active (only 29.5% were visually responsive), a reasonable activity (64.8% responsive cells) was found lateral to it and an almost normal activity (75% responsive cells) in the untouched hemisphere. The performance of the cells was much higher in the analogous regions of the sham cats; 57.3% of the cells medial to the section, 86% lateral to it and 79.3% of them in the untouched hemisphere were visually responsive. In conclusion, the physiological results, although reflecting immunological reaction of the host cells, indicated no critical effect attributed to the presence of the xenograft in the host cortex.

FOLATE STIMULATION OF GLUCOSE UTILIZATION AND TRANSPORT IN SYNAPTOSOMES, CULTURED C6 CELLS AND ASTROCYTES. S.R. Snodgrass and M.H. Morita*, Neurology Research Laboratory, Childrens Hospital Los Angeles and Depts. of Neurology and Pediatrics, USC School of Medicine, Los Angeles, CA

Folates are known to produce CNS excitation, convulsion and brain lesions. Nonmethylated folates such as folic acid (FA) are more potent neurotoxins than physiological folates. We have found folate stimulation of ^{45}Ca uptake, cGMP accumulation, and phosphate transport. We studied folate effects on 2-deoxyglucose accumulation (DGA) in rat C6 cells, astrocytes, and synaptosomes. FA and methotrexate (MTX) produced 32% and 40% increases at 10 uM concentration (10 min preincubation, 45 min incubation, effect lost if preincubation exceeded 30 min). Higher FA and MTX concentrations produced larger increases, up to 3 fold. The physiological folate 5-methyltetrahydrofolate (MTHF) was a weaker stimulator of DGA. Pteridine, a part of the folate molecule, also caused dose dependent increases of DGA. Folate responses were smaller in astrocytes and synaptosomes than C6 cells but statistically significant. Folates produced more stimulation of U-^{14}C-glucose accumulation than of DGA, and greater effects on DGA than on 3-O-methyl glucose accumulation. Folates stimulate both glycolysis and glucose transport in several neural tissues. The effect is insensitive to ouabain and dihydropyridines but inhibited by chlorpromazine and other neuroleptics.

ACTIVATION OF ARACHIDONIC ACID METABOLISM BY PAF AND CALCIUM-IONOPHORE IN PRIMARY CULTURE OF ASTROGLIAL CELLS. A. Petroni*, M.Blasevich*, F.Visioli,* B.Zancocchia,* G.Racagni and C.Galli *. Institute of Pharmacological Sciences, University of Milan, 20133, Milan, Italy.

Astrocytes actively metabolize arachidonic acid (AA) via the lipo (LO) and cyclooxygenase pathways after appropriate stimulation.CO and LO metabolites play important roles in physiopatological conditions such as cerebral ischemia, convulsions, acute inflammation etc. Moreover LO products have been proposed as intracellular second messengers in Aplysia (Piomelli et al. Nature 328:38, 1987) and as intercellular modulators (Maclouf et al. Pharm. Res. 21:1,1989).

We have measured the formation of AA metabolites following activation of phospholipases (PLases) and conversion through the LO and CO pathways, in primary cultures of astroglial cells, stimulated with the Ca-ionophore A-23187 and PAF (platelet activating factor).Cells were obtained from brain cortex of one day old rats and were characterized by immunofluorescent staining. The activation of PLA_2 and C,by A 23187 and PAF, was investigated incubating the cells with tritiated AA and evaluating the radioactivity in labelled metabolites. Incubation with PAF and A 23187 were carried out at different concentrations and for different time periods. The LO products hydroxy-eicosatetraenoic acids were measured by HPLC and GC-MS , LTC_4 by RIA. Levels of the CO metabolites, 6-keto-$PGF_{1\alpha}$, TXB_2 and PGD_2 were measured by RIA or EIA. PAF and A 23187 differentially activated the release of AA from phospholipids and the formation of diacylglycerol, suggesting stimulation of PLA_2 and PLC. The activation of CO and LO pathways was dependent from the time and the concentration of the stimuli . In addition , AA metabolism was affected by preincubating the astroglial cells with PAF antagonists and ganglioside derivatives.

SOMATOSTATIN (SS) AUGMENTATION OF THE M-CURRENT (I_M) IN HIPPOCAMPUS: MEDIATION BY A LEUKOTRIENE. P. Schweitzer*, S. Madamba* and G.R. Siggins. Dept. of Neuropharmacology, Scripps Clinic Research Institute, La Jolla, CA 92037.

We previously reported that SS causes an outward current (hyperpolarization) with an increase in conductance and I_M amplitude in CA1 pyramidal neurons (PNs) in a slice preparation (Moore et al., Science 239:278, 1988). We used single electrode voltage clamp to determine if the SS effects involved a second messenger. Superfusion of arachidonic acid (AA), a product of phospholipase, augmented I_M and caused an outward baseline current with a conductance increase. These effects were not altered by CsCl 2mM. Quinacrine and 4-bromophenacyl bromide, inhibitors of phospholipase A_2, both blocked the I_M action of SS and the outward current. AA is metabolized to prostanoids via cyclooxygenase, and to hydroxy- and hydroperoxy-eicosatetraenoic acids (HETE, HPETE) and leukotrienes via lipoxygenase enzymes. The I_M effects of AA and SS were blocked by nordihydroguairetic acid, a non-specific lipoxygenase inhibitor, but not by the cyclooxygenase inhibitor indomethacin. Several prostaglandins (PGE_2, $PGF_{2\alpha}$, PGI_2) had no effect on I_M. These data suggest that a lipoxygenase product mediates the M-current augmenting effect of SS. In support of this, leukotriene C_4, but not B_4, markedly augmented I_M. 12 HPETE hyperpolarized PNs but did not alter I_M. Two specific inhibitors of 5 lipoxygenase (the enzyme producing leukotrienes), 5,6-methanoleukotriene A4 methylester and 5,6-dehydroarachidonic acid, blocked the I_M effect of SS and AA. These data implicate an AA metabolite, probably a leukotriene, in the SS-induced increase in I_M in hippocampal PNs. Supported by NIMH (MH44346), NIAAA (AA06420) and N.A.T.O.

DOES cGMP CONTRIBUTE TO THE DESENSITIZATION OF BRADYKININ ELECTROPHYSIOLOGICAL RESPONSES IN DRG NEURONS? D.S. McGehee, M.F. Goy, and G.S. Oxford. Dept. of Physiology, University of North Carolina, Chapel Hill, NC 27599

The nonapeptide bradykinin (BK) has been shown to cause two types of electrophysiological responses in a subpopulation of cultured rat DRG neurons: 1) stimulation of an inward cation current, and 2) inhibition of voltage-activated calcium currents. Both of these responses desensitize in 1-3 minutes, despite the continued presence of agonist. Furthermore, responses to second applications are attenuated or suppressed for up to 10 min. after washout of the first application. In parallel with these electrophysiological responses, BK has been shown to stimulate a rapid release of phophotidylinositol metabolites from these cultures with peaks of IP3 and diacylglycerol at 5 and 20 seconds, respectively (Gammon et al., *J. Neurochem.* **53**:95). The biochemical response also desensitizes, and it has been proposed that cGMP negatively feeds back on this pathway (Burgess et al., *J. Neurosci.* 9:3314).

We are interested in what role cGMP might play in electrophysiological desensitization. We have measured cGMP production from DRG neurons stimulated with BK and see increases of approximately five-fold which peak at 30 seconds and return to baseline by 1 minute. These responses also show strong desensitization. Nitroprusside, which mimicks the BK-induced cGMP increase, also mimicks the BK-induced desensitization of the cGMP signal. Pretreatment of the cultures with 100μM methylene blue for 1 min. blocks the BK-induced desensitization. Utilizing these and other compounds to manipulate cGMP synthesis, we have analyzed the role of cGMP in the desensitization of BK-induced biochemical and electrical responses. Supported by NIH (NS23804 and NS21290) and GLAXO, Inc.

MUSCARINIC-STIMULATED CALCIUM MOBILIZATION IS NOT COUPLED TO CYCLIC GMP GENERATION IN N1E-115 CELLS. A.D. Morielli and S.H. Thompson. Hopkins Marine Station, Stanford University, Pacific Grove, CA 93950

Calcium dependence of cGMP generation in N1E-115 cells is well documented, but carbachol-induced changes in cytoplasmic Ca levels have not been previously observed. We find that Ca is mobilized from internal stores by pirenzepine-sensitive muscarinic receptors. Using the calcium indicating dye fura-2, we measured a mean resting Ca of 56nM. 70% of the carbachol-treated cells mobilize calcium to peaks of greater than 600 nM within 5 seconds. Pronounced calcium oscillations occur in about 20% of the cells. In many cases, a wave of Ca release followed by Ca uptake produces a band of Ca which traverses the cell multiple times. Removal of external Ca has no effect on this response.

Surprisingly, we found that cGMP generation by carbachol is absolutely dependent on external calcium, despite the mobilization of calcium from internal stores. Using electrophysiological techniques, we found that carbachol also causes calcium influx. Bromophenacyl bromide and melittin, drugs that influence phospholipase A2 activity, also cause a profound and tonic elevation in resting calcium levels via calcium influx, and therefore have limited utility as probes of PLA2 involvement in cGMP generation. We conclude that cGMP generation depends on Ca influx, and not on Ca mobilization from internal stores, although both events occur in response to receptor activation. It is possible that the same Ca-ATPase activity which produces traveling waves of Ca acts as a barrier to the diffusion of Ca released from internal stores to the inner surface of the plasma membrane.

400.6

REGULATION OF THE MUSCARINIC-INDUCED CALCIUM "FINGERPRINT" IN N1E-115 MOUSE NEUROBLASTOMA CELLS. S.S.-H. Wang, A. Rocco Morielli, and S.H. Thompson. Hopkins Marine Station, Stanford University, Pacific Grove, CA 93950.

We are investigating the mechanisms of calcium mobilization through the phosphatidyl inositol (PI) cascade. Fluorescence imaging, microperfusion, and flash photolysis are used to observe the response of single N1E-115 cells to the muscarinic agonist carbachol (CBC). Cells are loaded with the calcium indicator fura-2 or fluo-3. 1 mM CBC is applied either directly to the bath or with a rapid, focal perfusion micropipette. The spatiotemporally complex "fingerprints" observed are reproducible in separate drug applications 30-60' apart (bath) or 30-60" apart (microperfusion). With microperfusion, Ca transients far outlast the presence of agonist in the bath. Return to basal $[Ca^{++}]_i$ after a spritz of CBC is followed by a refractory period during which the time course of Ca mobilization is altered.

We are using flash uncaging and microinjection of Ca and phosphoinositides to assess the role of second-messenger cascades in Ca mobilization, by inducing step changes in PI metabolites and Ca.

N-METHYL-D-ASPARTATE RECEPTORS CAUSE A TRANSIENT ACTIVATION OF NITRIC OXIDE SYNTHETASE AND CYCLIC GMP ACCUMULATION IN CEREBELLAR GRANULE CELLS. L. Kiedrowski, E. Costa and J. T. Wroblewski. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Sch. of Med., Washington, DC 20007.

The stimulation of *N*-methyl-D-aspartate (NMDA) receptors in cerebellar granule cells activates guanylate cyclase and increases cyclic GMP content. To establish whether this signal transduction is mediated through the activation of nitric oxide (NO) synthetase which generates NO, an activator of soluble guanylate cyclase, the enzyme activity was measured in intact primary cultures of cerebellar granule cells equilibrated with [^{3}H]arginine by following its conversion to [^{3}H]citrulline. Activation of NMDA receptors by glutamate or NMDA increased in a dose-dependent manner the formation of [^{3}H]citrulline and the cyclic GMP accumulation, measured in the same samples. Both effects were blocked by the NMDA receptor antagonist MK-801 (1 μM) and the NO synthetase inhibitor N^G-methyl-L-arginine (3 μM). The activation of NO synthetase was also evoked by the calcium ionophore A23187. The maximal conversion of the radioactive label into [^{3}H]citrulline occurred 5 min after the application of the agonist and then remained constant for 60 min. Further enzyme activation was not produced by subsequent additions of glutamate or the calcium ionophore. These results indicate that the activation of NMDA receptors leads to a transient increase in the activity of NO synthetase. Since cyclic GMP accumulation showed a similar transient responsiveness to glutamate, one might infer that NO synthetase desensitizes.

400.8

DUAL REGULATION OF GUANYLATE CYCLASE BY *N*-METHYL-D-ASPARTATE RECEPTORS: ROLE OF NITRIC OXIDE AND ARACHIDONIC ACID. B. Wroblewska, M. Majewska*, E. Costa and J. T. Wroblewski. Dept. of Physiology and Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Sch. of Med., Washington, DC 20007.

In primary cultures of cerebellar neurons the stimulation of *N*-methyl-D-aspartate (NMDA) receptors leads to the activation of guanylate cyclase and cyclic GMP accumulation. This stimulation was reduced in a dose-dependent manner by N^G-methyl-L-arginine, an inhibitor of nitric oxide (NO) synthetase, indicating that cyclic GMP accumulation depends on NMDA-stimulated NO formation. Accordingly, cyclic GMP accumulation was induced by sodium nitroprusside (SNP), which acts by releasing NO that directly activates guanylate cyclase. The stimulation of cyclic GMP formation by NMDA was also reduced by nordihydroguaiaretic acid, the inhibitor of lipoxygenases, indicating that the mediation of the receptor signal requires also an active metabolism of arachidonic acid. The maximal cyclic GMP accumulation induced by SNP was 3 to 4 fold higher than that elicited by NMDA, however, when both compounds were added together the effect was not additive. In fact, NMDA caused a dose-dependent inhibition of SNP-activated cyclic GMP formation, reaching at maximal concentrations the level stimulated by NMDA alone. Similar results were obtained in presence of 3-isobutyl-1-methyl-xantine, a phosphodiesterase inhibitor, suggesting that the interaction affects cyclic GMP formation and not its degradation. These results suggest that the NMDA receptor-induced regulation of guanylate cyclase activity may involve the interaction of two messengers, NO and a lipoxygenase product of arachidonic acid metabolism.

400.9

GLUTAMATE MODULATES ENDOGENOUS ADP-RIBOSYLATION IN CEREBELLAR NEURONS. R. Raulli, M. Majewska*, W. J. Wojcik, E. Costa and J. T. Wroblewski. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ. Sch. of Med., Washington, DC 20007.

The activation of glutamate receptors in cerebellar granule cells stimulates several signal transduction systems including the generation of nitric oxide (NO). Moreover, agents such as sodium nitroprusside (SNP), which release NO, were shown to activate an endogenous cytosolic ADP-ribosyltransferase in a variety of tissues. In order to determine whether glutamate affects endogenous ADP-ribosylation, granule cells were incubated for 20 min in the absence or presence of glutamate. They were then harvested, homogenized, and centrifuged, and the ADP-ribosylation was monitored *in vitro* in the presence of [^{32}P]NAD in cytosol fractions incubated for 30 min at 37°C with SNP, and was analyzed by SDS-PAGE. SNP caused the ADP-ribosylation of several proteins present in the cell cytosol, the most prominent being a 40 kDa band. This effect was not mimicked by cyclic GMP, indicating that SNP-induced ADP-ribosylation is not mediated through the activation of guanylate cyclase, but it may be triggered by NO action. In granule cells treated with glutamate the ADP-ribosylation induced *in vitro* by SNP was decreased, suggesting the ability of glutamate to ADP-ribosylate the protein in intact cells, possibly through generation of NO. Similar experiments performed with cholera toxin which ADP-ribosylates specific GTP-binding proteins, showed two radioactive bands (45 and 61 kDa) present in the cell homogenates. Glutamate treatment preferentially decreased the appearance of the 61 kDa band. These results suggest that stimulation of glutamate receptors may increase either the activity of intracellular ADP-ribosyltransferases or the expression of their protein substrates, including the regulatory GTP-binding proteins.

NEURAL LOCALIZATIONS OF NITRIC OXIDE SYNTHASE SUGGEST GENERAL ROLE AS INTERCELLULAR MESSENGER. D. S. Bredt, P. M. Hwang, J. Buzy, & S. H. Snyder, Johns Hopkins Sch. of Med.

Nitric oxide (NO) is a major, if not the sole source of endothelium derived relaxing factor (EDRF) which mediates the vasodilating effects of neurotransmitters on certain blood vessels. Cyclic GMP elevations in the cerebellum and in neuroblastoma cell lines in response to calcium mobilizing neurotransmitters is also mediated by NO. Recently, we purified NO synthase (NOS; EC#1.14.23) to homogeneity from rat brain (Bredt and Snyder *PNAS* 87:682-685, 1990). Our ability to purify NOS was due to the development of a simple, sensitive, and specific assay monioring conversion of [3H]arginine to [3H]citrulline, which occurs stoichiometrically with the formation of NO, and our discovery that NOS is a calmodulin requiring enzyme. We have raised and affinity purified two antisera which immunoprecipitate NOS activity and recognize a single 150 kD band in western blots of numerous brain regions and peripheral tissues.

Immunohistochemistry in the brain shows NOS is discretely localized and is absolutely restricted to neurons and vascular endothelial cells. Highest density occurs in the cerebellum, olfactory bulb, and superior and inferior colliculi. In the periphery, NOS is highly enriched in the posterior pituitary, in the choroid of the eye, in the myenteric plexus and associated neuronal processes in the intestine, and in vascular endothelial cells. Microscopic localization shows the enzyme is most highly enriched in neuronal axons. Dense staining occurs in glomerular synapses in the cerebellum, nerve terminals in the granule cell layer of the olfactory bulb, nerve processes in the posterior pituitary, and in neuronal axons surrounding large cerebral blood vessels. Calcium mobilization in these nerve terminals may generate NO as a unique neurotransmitter.

400.11

CHARACTERIZATION OF THE INHIBITION OF THE EAA RECEPTOR LINKED TO PI METABOLISM BY 2-AMINO-3-PHOSPHONOPROPIONATE IN THE RAT HIPPOCAMPUS. E. Palmer* and C.W. Cotman, Department of Psychobiology, University of California, Irvine, CA 92717.

Excitatory amino acids (EAA) interact with specific membrane receptors to either operate ion channels directly linked to EAA receptors (ionotropic receptors) or to generate second messengers via phosphoinositide (PI) metabolism.The most potent agonists for the PI-linked receptor are *trans*-1-aminocyclopentyl-1,3-dicarboxcylic acid (ACPD), ibotenic acid (IBO) and quisqualate (QA). Of these, the most selective agonist for PI stimulation is ACPD. It has been reported that 1 mM L-2-amino-3-phophonopropionate (AP3) is a very efficient inhibitor of IBO and QA stimulation of PI metabolism and that 2- amino-4-phosphonobutyric acid (L-AP4) also inhibits PI metabolism, but not as effectively.

Using hippocampal slices from 8-10 day old rats we confirm that AP3 inhibits PI stimulation by IBO and QA, although lower levels of inhibition were observed than those previously reported. We further report that AP3 also inhibits the stimulation of PI metabolism by ACPD. Our data indicate that the mechanism of inhibition by AP3 is not via the AP4 receptor as inhibition of IBO, QA and ACPD induced stimulation by L-AP4 was not observed. Incubations with 1 mM AP3 performed in the presence of excess agonist did not result in the reversal of the inhibition. Inhibition of ACPD and QA stimulation by AP3 was temperature dependent, while that of IBO was not. Thus, it appears that AP3 inhibits via a complex mechanism that is neither competitive nor reversible.

INHIBITION OF GLUTAMATE RELEASE FROM HIPPOCAMPAL MOSSY FIBER SYNAPTOSOMES BY 12-HETE. E. J. Freeman, D. S. Damron*, D. M. Terrian and R. V. Dorman. Dept. Biological Sciences, Kent State Univ., Kent , OH 44242.

Superfused rat hippocampal mossy fiber synaptosomes were used to investigate the role of lipoxygenase products in the evoked release of endogenous glutamate. Pretreatment of the synaptosomes with 12(R)- or 12(S)-HETE (10 uM) reduced the 35 mM K^+-evoked glutamate release by 29% and 20%, respectively. These effects appeared to be specific for 12-HETE, since neither 5- nor 15-HETE were able to affect glutamate release. In addition, inhibition of lipoxygenase activity with 10 uM NDGA potentiated the 35 mM K^+-evoked glutamate release by 83% and the 200 uM arachidonate-induced release by 113%. The observation that 12-HETE inhibited the 35 mM K^+-induced Ca^{2+} influx by 79% supports the suggestion that it modulates membrane potential and inhibits neurotransmitter release. Also, blocking K^+ channels with 4-aminopyridine or 3,4-diaminopyridine stimulated the release of glutamate. Therefore, it appears that 12-HETE acts as an inhibitory signal to decrease glutamate release from hippocampal mossy fiber terminals. The above results are consistent with the hypothesis that lipoxygenase products activate presynaptic K^+ channels, which mediates an inhibition of neurotransmitter release. SPATIAL RESPONSE PROPERTIES AND PROJECTION PATTERNS OF SECONDARY MEDIAL VESTIBULOSPINAL TRACT (MVST) NEURONS. S.I. Perlmutter, Y. Iwamoto*, J.F. Baker, B.W. Peterson, Northwestern Univ. Med. School, Chicago IL

To determine how spatial motor patterns of the vestibulocollic reflex are produced, we studied 59 MVST neurons activated monosynaptically from the labyrinth in decerebrate cats. Projections were identified by antidromic activation from, or by recording intraaxonally in, ipsi- or contralateral C1 MVST, and by responses to electrical stimulation of IIIrd nucleus and C6 segment. A vector representing the rotation producing a neuron's maximal activation was derived from its response to 0.5 Hz rotations in many vertical and horizontal planes. In some cats horseradish peroxidase (HRP) was then injected intraaxonally at C1.

Neurons with different projections responded differently. Of 28 neurons projecting to IIIrd nucleus, 27 were not activated from C6 and had a response vector similar to that of an ipsilateral canal. Vectors of neurons projecting neither to IIIrd nucleus nor C6 (n=19) were similar, but more often indicated considerable vertical-horizontal canal convergence. 12 of 13 neurons which did project to C6 were excited strongly by yaw rotation to the contralateral side (type II response), or had convergent input from 2 vertical canals. Four secondary MVST axons were stained with HRP. Each sent branches to a specific region of the C1 ventral horn. For example, one axon with primarily posterior canal input had dense arborization and numerous terminals in the dorsomedial ventral horn, where motoneurons of longus capitis, a head flexor, are located.

Data suggest that secondary vestibulocollic neurons primarily relay activity of a single ipsilateral semicircular canal, as do vestibuloocular neurons reported previously. Signals with more canal convergence are carried past neck segments. NS17489, EY06485, EY05289, EY07342

OTOLITH CONTROL OF HEAD-NECK POSTURE IN THE GUINEA PIG. D.H. Wang, W. Graf, C. de Waele*, P.P. Vidal and L.C. Evinger. The Rockefeller University, New York, NY 10021; Lab. Physiologie Neurosensorielle, CNRS, 75270 Paris, France; SUNY, Stony Brook, NY 11794.

Previous cineradiographic studies indicated that at least five functional degrees of freedom are necessary to describe head/neck movements in most mammals. Thus, the vestibular origins for each postural control parameter needed to be determined. Selective ablations of utricular and saccular otoliths were performed by centrifuguing anesthetized animals. Succesful ablations were confirmed by testing postural reflexes and later on by histology.

Subsequent cineradiographic imaging of the lesioned animals indicated that the utricular otolith contributes mainly to controlling both head and neck posture in the sagittal plane, while the saccular otolith controls head orientation in the frontal plane. Thus, bilateral utricular otolith damage eliminated the vertical orientation of the cervical column in the sagittal plane. In addition, a vertical head nystagmus was observed indicating a lifting effort when the head was gradually pulled down by gravity. Unilateral sacculus ablation resulted in a non-horizontal head posture in the frontal plane. Our results suggest that the vertical orientation of the neck and the horizontal orientation of the head are controlled independently from each other as well as from dynamic variables (such as movement speed, etc) by a modular control strategy. - Supported by USPHS grant EY-04613.

NEURONAL DEATH DURING THE DEVELOPMENT OF THE VESTIBULAR EFFERENT SYSTEM OF THE RABBIT. N.H. Barmack, RS Dow Neurological Sciences Institute, Good Samaritan Hosp.& Med. Ctr., Portland, OR 97209.

The location and the approximate numbers of the neurons which comprise the vestibular efferent system (VES) have been described for several mammals. The VES consists of approximately 100-400 neurons which can be identified by retrograde transport of HRP injected into the labyrinth. Vestibular efferent neurons (VENs) are cholinergic, have somatic diameters of 6-9 μm and are found lateral to the abducens nucleus, ventral to the medial vestibular nucleus and border the medial aspect of the facial nerve.

We have used an antibody to choline acetyltransferase (ChAT) and retrogradely transported HRP as markers for VENs and we have studied these neurons during postnatal development of the VES in rabbits (6-35 days). In neonatal rabbits VENs comprise a well defined nucleus. There was good quantitative agreement (less than 10% difference) in counting cells filled with HRP and cells stained for ChAT. We have counted as many as 600 VENs in 8-14 day old rabbits (N=5). However, in 21-35 day old rabbits only 50-200 VENs could be identified with the same methods (N=6). Previous experiments have noted that the vestibular efferent projection is bilateral with approximately 50% of the projection terminating in each labyrinth. However, in individual rabbits the ratio of contralaterally to ipsilaterally projecting VENs can vary by a factor of four. The decrease in the number of VENs during development and the variability in the ipsilateral/contralateral projection pattern may reflect important cellular events linked to the innervation of the peripheral vestibular apparatus. However, the death of VENs may also reflect one of the cellular mechanisms by which the vestibular primary afferent system is "calibrated" during development, and therefore might be influenced by neuronal activity in the peripheral or central vestibular system.

401.4

THE RESPONSE OF VESTIBULAR NUCLEUS NEURONES TO SENSORY CONFLICT. L.R. Harris and J.W. Stelling* Department of Physiology, University of Wales, Cardiff, UK

The vestibular nucleus (VN) is a site of convergence of canal, otolith and visual signals. The time constant of the VN's response suggests velocity storage. We recorded from 66 type I VN cells in 7 cats during sensory conflict. Canal/visual conflict was obtained by rotating at constant velocity in the light until the canals' response had declined to zero and then suddenly slowing. Canal/otolith conflict was obtained by rotation about an off-vertical axis before suddenly slowing. At the point of slowing, the canals indicated rotation commencing in the opposite direction whereas vision or otolith signals were veridical. By adjusting the initial and final velocities, a greater or lesser degree of conflict could be achieved. Eye movements showed attenuation during large conflicts which was not seen in the VN cells' responses, suggesting that the site of effect of the conflict detection is beyond the vestibular nucleus.

SODIUM, CALCIUM, AND POTASSIUM ION INFLUENCES UPON TRANSMISSION AT THE HAIR CELL-AFFERENT FIBER SYNAPSE OF THE FROG. S.L. Cochran. Dept. Life Sciences, Indiana State Univ., Terre Haute, IN 47809.

This study is directed towards understanding how ions are involved in transmission between hair cells and afferent fibers in the isolated vestibular labyrinth of the frog, *Rana pipiens*. Intracellular recordings from lagena and canal afferents are digitized at 50 KHz for several minutes. EPSPs (several thousand per cell) are detected by computer algorithm and their frequency of occurrence and amplitudes are quantified. Increasing the Na^+ concentration of the solution bathing the tissue by 10-50 mM results in an increase in the mean amplitude of the EPSPs (19 cells), suggesting that the hair cell transmitter opens subsynaptic Na^+ channels. Reducing the Ca^{+2} concentration from 2 to 0.125 mM results in an increase in EPSP amplitude (22 cells), while increasing the Ca^{+2} concentration to 4 or 8 mM results in a decrease in amplitude and frequency (17 cells), suggesting that Ca^{+2} may to some extent block the subsynaptic Na^+ channel. Increasing the K^+ concentration from 2 to 5 mM results in a 100 fold increase in the EPSP frequency with no change in amplitude (24 cells), while lowering the K^+ concentration to 0 mM decreases release (4 cells), confirming that the hair cell release process is affected by presumed small changes in its membrane potential. These findings suggest that the subsynaptic channel may resemble that found at the neuromuscular junction and indicate that this neuropil is very sensitive to small changes in ionic concentrations.

NUCLEUS OF THE OPTIC TRACT (NOT); EFFECTS OF MUSCIMOL ON GENERATION OF OPTOKINETIC NYSTAGMUS (OKN), AND SUPPRESSION AND HABITUATION OF VESTIBULAR NYSTAGMUS. H. Reisine, B. Cohen. Dept. of Neurol., Mt. Sinai Sch. of Med., NY 10029.

Single unit studies indicate that NOT processes visual motion signals that can produce ipsilateral slow phases of nystagmus (Hoffmann et al.,1986; Mustari & Fuchs, 1989). Stimulation and lesions studies further indicate that NOT activates the velocity storage mechanism in the vestibular system to produce the slow component of horizontal OKN and OKAN (Kato et al.,1988; Schiff et al., 1988, 1990). In this study we injected the GABAa agonist, muscimol, into NOT of monkeys. They developed spontaneous nystagmus with contralateral slow phases and lost OKN and OKAN with ipsilateral slow phases. Per- and post-rotatory nystagmus and OKAN with contralateral slow phases were substantially prolonged, and all previous habituation of contralateral nystagmus was lost. Slow phases to the contralateral side, whether induced during OKN or per- or post-rotatory nystagmus, could not be suppressed by exposure to a stationary visual surround. Suppression of vestibular nystagmus with ipsilateral slow phases was unaffected. These changes lasted only for the period after injection, and the animals had recovered by 24 hours later. These data suggest that activity responsible for visual suppression and for habituation of contralateral slow phases of nystagmus whether induced by visual or vestibular stimulation, is mediated through NOT. Since lesion of the nodulus of the cerebellum reduces suppression and habituation of nystagmus in ways similar to the results of muscimol injections a NOT-nodulus link is proposed for the control of these behaviors. Supported by EY02296 and EY01867.

COMPENSATION FOR HEMILABYRINTHECTOMY IN A RECURRENT NEURAL NETWORK MODEL OF THE VESTIBULO-OCULAR REFLEX (VOR). T.J. Anastasio, Dept. of Otolaryngology, University of Southern California, Los Angeles, CA 90033.

Velocity storage is permanently lost following compensation for hemilabyrinthectomy. To gain insight into the possible mechanism of this loss, compensation was simulated as learning in a recurrent neural network model of the VOR. The three network layers represented horizontal canal afferents, vestibular nucleus neurons (VNNs) and eye muscle motoneurons. Non-vestibular inputs were included. The network produced velocity storage via inhibitory commissural loops (CLs) between some VNNs.

Removal of the left canal input decreased VOR gain and unbalanced the network. Left VNNs *inside* CLs were driven into cut-off by the combined loss of canal excitation and increased commissural inhibition. This broke the CLs and eliminated velocity storage. Compensation was due primarily to increases in non-vestibular inputs. VNNs *outside* CLs regained their spontaneous rates, restoring balance and then VOR gain. Loss of velocity storage resulted from failure of VNNs *inside* CLs to also regain their spontaneous rates.

IN VITRO AND IN VIVO STUDIES OF THE HISTAMINERGIC RECEPTORS IN THE MEDIAL VESTIBULAR NUCLEI NEURONES OF THE GUINEA-PIG.

M. SERAFIN, A. KHATEB, C. de WAELE*, N. VIBERT, P.P. VIDAL* AND M. MUHLETHALER, *Dept de Physiologie, CMU, 1211 Genève 4, Switzerland and *Laboratoire de Physiologie Neurosensorielle, CNRS, Paris, France.*

It has recently been shown that a direct pathway links the tuberomammilary histaminergic neurones with the vestibular complex. Since we have described, in vitro, two main neuronal cell types in the medial vestibular nuclei (which could correspond in vivo to the tonic and phasic neurons) we have tested their sensitivity to various agonists and antagonists of the histaminergic receptors .

Using intracellular recordings in slices we found that the bath-application of histamine induced in both neuronal subtypes a reversible increase in firing frequency. This effect was accompanied by a small membrane depolarization with no (or only minor decrease) change in membrane input resistance. In both cell types, the effect was mimicked by Impromidine (a specific H2 agonist). When tested, Cimetidine (a H2 antagonist) was able to block the excitatory effect of histamine. Parallel studies performed in vivo with IP and local perfusion of the vestibular nuclei confirmed the functional implications of histaminergic receptors in the vestibular control of gaze and posture. Given that antihistaminergic drugs are widely used in the treatment of various vestibular syndromes including motion and space sickness, this model could be useful to investigate new therapeutics.

ACTION OF THE OCCUPATIONAL HAZARDS ON THE VESTIBULAR SYSTEM. K.F.Trinus. BCA Foundation. 27 Lukianivsky Str., apt.47, Kiev-71, Ukraina, GSP 252601.

A total number of 344 persons were studied, 29 of them were control healthy group, 273 - stuff of the electric power station, 27-tractor drivers, 15-welders. For examination Uemura's, Fukudas', pointing tests and oculography were used. Vestibular evoked potentials were recorded in the control group and in tractor drivers. 93% of drivers complainted vertigo. In this group were also found the disturbances in the performance of all the traditional clinical tests. On the oculograms were seen the low frequency components, which increased after the lateral gaze manoeuvres. The vestibular evoked potentials in this group had significantly increased latencies of the peaks. The welders had no signs of the vestibular damage. The oculogram had typical low frequency components, disappearing after the lateral gaze manoeuvre. Out of the electric power station stuff only 6.6% had vestibular impairment, 31.5% had mildly expressed changes of the vestibular function. The most important changes were seen due to the Uemura's and Fukudas' tests.

CIS-ACTING REGULATORY ELEMENTS FOR MBP TRANSCRIPTION IN MYELINATING CELLS. L.G. Wrabetz*, S. Shumas*, H. Vogelbacker*, J. Grinspan, D. Pleasure, and J. Kamholz. Department of Neurology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104

Characterizing the regulatory network of cis- and trans-acting factors necessary to effect the coordinate program of myelin-specific gene expression is central to understanding the regulation of myelin synthesis and assembly during development and remyelination. In order to identify the functional cis-acting elements necessary for tissue-specific expression of the myelin basic protein (MBP) gene expressed in both oligodendrocytes (OL) and Schwann cells (SC), we transfected MBP promoter-CAT (chloramphenicol acetyl transferase) fusion constructs into OL and SC. We have found that the 150 base pair region upstream of the MBP gene contains sequences which are sufficient to promote CAT expression in a tissue-specific and orientation-dependent manner in both cell types.

We have extended this analysis and have found that the start site of MBP transcription, as determined by primer extension and RNAse protection studies, is identical in OL and SC, suggesting that the MBP promoter region should be the same in both cell types. We have also found that the cap site of the MBP promoter-CAT fusion transcript is identical to that of the endogenous MBP message. Transfection of SC with a series of MBP promter-fusion constructs, containing overlapping deletions within the 150 bp region sufficient for tissue specific CAT expression, demonstrated that the 5' boundary of a tissue-specific cis-acting element lies between nucleotides -150 and -100. We are now carrying out similar transfection studies in order to identify the 5' boundary of the tissue-specific element(s) used in OL.

402.2

DIFFERENTIAL PROLIFERATIVE RESPONSE OF ADULT HUMAN AND NEONATAL MOUSE ASTROCYTES TO CYTOKINES. R. Moumdjian*, V.W. Yong and J.P. Antel. Neuroimmunology Unit, MNI, McGill University, Montreal, Quebec H3A 2B4, Canada.

In response to most forms of injury to the adult CNS, astrocytes undergo hypertrophy and/or hyperplasia. We have targeted cytokines as possible proliferative factors for astrocytes because infiltration of mononuclear cells is commonly seen after many types of CNS injury. Using a double immunofluorescence GFAP-BrdU technique (Yong and Kim, J. Neurosci. Methods, 21:9,1987), we have identified the following as mitogens for cultured human adult astrocytes: supernatants from activated CD8+ or CD4+ human lymphocytes (proliferation index of 22.2 ± 2.3 and 16.5 ± 2.5), γ-interferon (6.5 ± 1.1), and interleukin-1 (6.2 ± 0.7). In agreement with these in-vitro results, γ-interferon when applied in vivo increased the extent of reactive gliosis in adult injured mouse brain. When cultured neonatal mouse astrocytes were treated, there was either no alteration (for interleukin-1), or a decrease in proliferation was observed (activated CD8+ supernatant: 40% of controls; γ-interferon: 60% of controls). We suggest that the intrinsic proliferative capability of astrocytes (low for adult human and high for neonatal mouse) determines the mitotic response to cytokines: proliferation for adult astrocytes, and differentiation/maturation with subsequent decrease in proliferation for neonatal astrocytes.

402.3

INVOLVEMENT OF PROTEIN KINASE C IN PROLIFERATION OF ASTROCYTES. V.W. Yong. Neuroimmunology Unit, MNI, McGill University, Montreal, Quebec H3A 2B4, Canada.

The objective was to assess the mechanism(s) by which proliferative agents for astrocytes exert their response. As determined using a GFAP-BrdU technique, we have identified the following cytokines as mitogens for cultured human adult astrocytes: supernatants from activated CD8+ human lymphocytes, γ-interferon and interleukin-1. For neonatal mouse astrocytes, rather than the above cytokines, fibroblast growth factor (FGF, 100 ng/ml) increased proliferation (to 250% of controls). To assess the mechanism of proliferation, we targeted the enzyme protein kinase C (PKC) because pharmacological activators of this enzyme (phorbol esters) produced proliferation of both human adult and mouse neonatal astrocytes. For human adult astrocytes, H-7 (a relatively selective inhibitor of PKC) inhibited the response of all mitogenic cytokines; 10 μM H-7 reduced proliferation by 50%, while 50 and 100 μM H-7 completely inhibited mitosis. For neonatal mouse astrocytes, H-7 in a dose-dependent manner reduced the basal proliferation, and also inhibited the mitogenic effect of FGF. ATP and dbcAMP (PKA system) and the calcium ionophore A23187 did not significantly alter the proliferation of astrocytes. Thus, the enzyme PKC appears to be a common signal transduction pathway for agents identified to be mitogens for human adult and mouse neonatal astrocytes.

402.4

CELL CYCLE-SPECIFIC REQUIREMENT FOR MEVALONATE IN ASTROCYTES FROM LONG TERM PRIMARY CULTURES Thomas J. Langan and Mary Slater*, Dept. of Neurology, S.U.N.Y. at Buffalo School of Medicine, Buffalo N.Y. 14222

Astrocytes retain the capacity to divide after completion of brain maturation. We hypothesized that astrocytes in primary cultures can be stimulated to re-enter the cell division cycle after prolonged quiescence, and that mevalonate, the precursor of isoprenoid lipids, regulates this process. DNA synthesis (uptake of [3H] thymidine into acid-precipitated material) declined by 80±9% with confluence in cultures of newborn rat brains in 10% calf serum (CS). After 2, 6, and 16 weeks the cultures were trypsinized and replated at 10^4 cells/cm^2. 72h later, 79±9% of cells were astrocytes by glial fibrillary acidic protein immunofluorescence. Serum shift-down (10% to 0.1%) for 48h followed by re-exposure to 10% CS resulted in 12h of quiescence (G0+G1), then in a 6-fold increase (263±34 vs. 43±6 CPM/ug. prot./h) in DNA synthesis (S phase). This increase was abolished by addition of mevinolin, a competitive inhibitor of mevalonate synthesis, and mevalonate reversed this block of DNA synthesis when added as late as 12h after serum stimulation. Cholesterol-rich lipoproteins failed to reverse the inhibition of DNA synthesis by mevinolin.

Thus, astrocytes after several months in primary cultures: 1. can be stimulated to re-enter the cell cycle; 2. require mevalonate or a nonsterol derivative thereof in late G1.

402.5

ALTERATIONS IN Na^+-CURRENT CHARACTERISTICS DURING DEVELOPMENT OF HIPPOCAMPAL ASTROCYTES *IN VITRO*.

H. Sontheimer, B.R. Ransom, A.H. Cornell-Bell, J.A. Black and S.G. Waxman. Dep. Neurology, Yale Univ., New Haven, CT 06510.

Na^+-current expression in hippocampal astrocytes was studied during the first 20 days *in vitro* (DIV) using whole-cell patch-clamp. The percentage of astrocytes expressing Na^+-currents decreased from 75% at 1 DIV to about 30% after 10-20 DIV. Na^+-currents could be differentiated into two types: a current with fast activation and inactivation and an h_∞-curve with a midpoint around -65mV and a second type with slower kinetics and an h_∞ midpoint around -85mV. The first type of Na^+-current was seen 1-5 DIV, the second type after 6-20 DIV. Current-voltage curves of Na^+-current activation were identical in astrocytes of all ages. Na^+-current densities displayed a biphasic time-course with an initial loss during the first 5 DIV, followed by re-expression. This time-course mirrored the change from the first (midpoint -65mV) to the second type of Na^+-current (-85mV), the latter only expressed later than 5 DIV. Interestingly Na^+-current expression was restricted almost exclusively to astrocytes that were not dye-coupled as assayed by following the spread of Lucifer Yellow. Transiently uncoupling cells with octanol did not unmask Na^+-currents. These results demonstrate that two types of Na^+-currents are expressed in hippocampal astrocytes *in vitro*, and suggest a relationship between coupling and Na^+-channel expression.

402.6

ACTIVATION OF ENDOTHELIN RECEPTORS REGULATES INTRACELLULAR CA^{2+} IN CULTURED CEREBELLAR ASTROCYTES J.A. Holzwarth, S.R. Glaum and R.J. Miller. The Dept. of Pharm. and Physiol. Sciences, The University of Chicago, 947 E 58th Street, Chicago, Il 60637

Sarafotoxins (SfTx) are vasoconstrictive peptides present in snake venom that act at vascular smooth muscle endothelin receptors. SfTx has been shown to induce changes in PI turnover in rat brain, endothelin binding being highest in the cerebellum. We studied the effects of SfTx on $[Ca^{2+}]_i$ in single astrocytes using fura2 based microspectrofluorimetry and digital imaging. SfTx caused increases in $[Ca^{2+}]_i$ in astrocytes cultured from cortex, hippocampus and cerebellum. The response was examined further in cerebellar astrocytes. Perfusion with SfTx (1nM) in Ca^{2+} free medium (with 20uM EGTA) caused a spike of intracellular Ca^{2+}. In medium containing Ca^{2+}, this spike was followed by a plateau. The plateau, not the spike, could be abolished by 1mM Ni^{2+}. However, in the majority of astrocytes the plateau was not blocked by nimodipine (10uM). Neither the spike nor the plateau were blocked by pre-incubation with pertussis toxin (16hr, 250ng/ml). In contrast the spike was blocked by phorbol ester treatment (10min, 1uM PdBu). The response to SfTx desensitized at high concentrations (100nM), but did not do so at low concentrations (1nM). Following the wash of SfTx, the $[Ca^{2+}]_i$ plateau declined rapidly in some cells but in other cells persisted for many minutes. In these cases, removal of extracellular Ca^{2+} caused $[Ca^{2+}]_i$ to decline but the plateau was formed again on reintroduction of extracellular Ca^{2+}. Thus, SfTx in addition to mobilizing $[Ca^{2+}]_i$, appears to activate a Ca^{2+} permeable channel, that may be similar to that described in other cells following elevation of IP_3.

CALCIUM WAVES PROPAGATE THROUGH ASTROCYTE NETWORKS IN DEVELOPING HIPPOCAMPAL BRAIN SLICES. John W. Dani, Alex Chernjavsky* & Stephen J Smith*. *Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, CA 94305.*

Using a laser confocal microscope and the calcium indicator dye fluo-3, we have detected waves of elevated intracellular Ca concentration that propagate through slices of neonatal rat hippocampus. At 20 degrees C, these waves propagate over distances of 1 mm or more at velocities of 10-20 micrometers per second. Because these Ca waves closely resemble those recently described in pure cultures of hippocampal astrocytes (Cornell-Bell, et al., 1990, Science 247: 470-3), we suggest that the waves observed in hippocampal slices also propagate through coupled networks of astrocytes. Ca waves can be observed in resting, unstimulated slices, but increase greatly in amplitude and extent when neurons within the slice are stimulated using N-methyl-D-aspartate (NMDA). Based on earlier observations that NMDA does not induce Ca waves in pure cultures of astrocytes, we propose that NMDA directly stimulates only the neurons within our hippocampal slices, and that the observed enhancement of the putative glial Ca waves by NMDA therefore refelects a form of prompt neural-glial communication, perhaps mediated by neuronal release of glutamate, a compound which does stimulate Ca waves in pure astrocyte cultures. These findings suggest that astrocyte networks may play a greater role than previously recognized in neural computation and long-distance signalling within the brain. *Supported by the G. Harold and Leila Y. Mathers Charitable Foundation.*

A GLIAL CYTOCAL WAVE IS THE CONDUCTION VELOCITY-DETERMINING PROPAGATION MECHANISM OF SPREADING DEPRESSION. D. H. Leibowitz. CNS Res. Fndtn, Inc., N.Y., NY 10025.

The propagation mechanism of Leão's spreading depression (SD), which plays a role in the pathophysiology of migraine, remains enigmatic. Through a program of theoretical research I have now identified the probable mechanism. (1) A detailed analysis of the literature reveals that the fundamental propagation mechanism of SD is probably located in the glial compartment and has the nature of an extraordinarily slow, metabolically-controlled glial action potential, which helps trigger the neuronal depolarization of SD and is in turn facilitated by neurotransmitter-released agents. (2) There exists among eukaryotes a widespread class of intracellular waves of excitation apparently based upon the Ca^{++}-induced release of Ca^{++} from intracellular stores combined with cytoplasmic diffusion of Ca^{++} (cytocal waves). The propagation velocity of SD is typical of a cytocal wave. The Arrhenius activation energy of the conduction velocity rate-limiting mechanism of SD is typical of a cytocal wave. The tendency of SD to occur under stressful or injurious conditions is common among cytocal waves. The effect of an imposed constant electric field on the propagation velocity of SD is the effect expected on a cytocal wave. On the basis of these and many other arguments I propose with a high degree of confidence that a neuroglial cytocal wave is the conduction velocity-determining mechanism of SD.

ULTRASTRUCTURAL IDENTIFICATION OF HRP INJECTED OLIGODENDROCYTES IN THE INTACT RAT OPTIC NERVE B.R. Ransom, A.M. Butt* and J.A. Black, Dept. Neurology, Yale Univ. Sch. Med., New Haven, CT, 06510.

The three-dimensional morphology of mammalian oligodendrocytes is not well defined; these cells are not reliably stained by Golgi impregnations and they are difficult to reconstruct from EM images because the tenuous connections between parent oligodendrocytes and their myelin segments are difficult to follow in serial sections. In a preliminary report (A. Butt and B. Ransom, Glia 2:470-475, 1989) we described the morpholgy of cells presumed to be oligodendrocytes in the intact rat optic nerve (RON) using intracellular injections of horseradish peroxidase (HRP); these cells had 10-20 longitudinal processes, each 200-300 µm long, that were oriented along the long axis of the RON parallel to the axons. The longitudinal processes of these cells were connected near their midpoints to the cell body by thin branches, 15-30 µm long. By EM examination of such HRP-filled cells within the RON, we have now directly determined their identity. Glial cells in 12-30 postnatal day optic nerves were filled with HRP and reacted using standard techniques. Three nerves containing isolated HRP injected cells with the morphology described above, were serially sectioned for viewing with transmission EM. HRP was found in paranodal loops at nodes of Ranvier and in the inner and outer tongue processes of myelin sheaths, as well as in cell bodies. This distribution of HRP clearly identified these cells as myelin-producing oligodendrocytes. The longitudinal processes of these cells, as seen with light microscopy, correspond to the HRP-filled tongue processes and therefore define the number (i.e., 10-20) and length (i.e., 200-300 µm) of the internodal myelin sheaths provided by individual oligodendrocytes. Since the entire cytoplasmic border surrounding the myelin sheath readily filled with HRP, this compartment could serve as an efficient conduit for metabolites or membrane constituents. Supported by NIH grant NS 15589.

402.10

INDUCIBLE EXPRESSION OF A HYBRID GENE IN TRANSGENIC MICE MARKS A SUBGROUP OF ASTROCYTES. L.Mucke, J.C.Morris*, M.B.Oldstone*, M.I.Nerenberg*. Div.of Virology, Dept.of Neuropharmacology, Research Institut of Scripps Clinic, La Jolla, CA 92037.

A system was developed that allows the expression of hybrid genes in astrocytes in vivo. Almost the entire murine glial fibrillary acidic protein (GFAP) gene was incorporated in the construct. The lacZ reporter gene was inserted into the GFAP cassette and injected into the germline of mice. B-gal assays and anti-GFAP Abs revealed a similar expression pattern in brain sections from different transgenic lines. GFAP-lacZ expression was limited to GFAP-positive cells but not all GFAP-positive cells expressed GFAP-lacZ. Focal cerebral lesions induced GFAP-lacZ expression in regions where the transgene was not expressed at baseline. Hence the GFAP construct allows expression of hybrid genes in astrocytes in vivo. Inclusion of all regulatory elements of the GFAP gene into the GFAP cassette restricts expression of hybrid genes to cells that express endogeneous GFAP and allows induction of hybrid gene expression by gliosis-provoking maneuvers. GFAP-lacZ expression identifies a subgroup of astrocytes and can be used as a marker of astrocyte activation.

INTRACELLULAR pH REGULATION IN ASTROCYTES IN THE ABSENCE OF HCO_3^-. W.F. Boron*, G. Boyarsky, K.L.Marek, and B.R. Ransom, Depts. of Cell. and Mol. Physiol. and Neurol., Yale U. Sch. of Med., New Haven, CT 06510.

Intracellular pH (pH_i) was measured microfluorometrically in single astrocytes cultured from neonatal rat forebrain, using the pH-sensitive dye BCECF. In many cell types, brief exposure to NH_4^+/NH_3 (NH_4^+) causes an abrupt acidification, recovery from which can be used as an assay for mechanisms responsible for pH_i regulation. In astrocytes, we now report that application of NH_4^+ (1-20 mM) causes a tetraphasic change in pH_i. For example, in five cells 5 mM NH_4^+/NH_3 causes: (1) a rapid increase from 6.90 ± 0.03 to 7.23 ± 0.03, presumably due to NH_3 entry, (2) a subsequent slow decline to 7.03 ± 0.02, perhaps due to NH_4^+ entry, (3) a slower increase to 7.29 ± 0.05, and finally (4) a subsequent decline to a new stable level of 6.88 ± 0.04. The subsequent removal of NH_4^+ causes an abrupt acidification from which pH_i rapidly recovers. However, the rate of recovery at any pH_i does not depend uniquely on that pH_i but on the history of the experiment (e.g., the recovery is slower when the pH_i goes to very acid levels following NH_4^+ removal). In contrast, brief removal of external Na^+ (~5 min) causes a monotonic fall in pH_i from 6.88 ± 0.02 to 6.36 ± 0.02, with little pH_i recovery. Readdition of Na^+ leads to a rapid pH_i recovery. The recovery rate at any pH_i depends only on that pH_i, and not on the initial pH_i or the degree to which the pH_i fell during the period of Na^+ removal. This recovery rate is inhibited ~40% by brief removal of external Cl^-, ~50% by pretreatment with 50 µM DIDS, and ~75% by Cl^- removal and DIDS-pretreatment. The Na^+-, Cl^-- and DIDS-sensitivities of the recovery suggests that a Na^+-dependent Cl-HCO_3 exchanger could be operating in the nominal absence of HCO_3^-, or that Cl^- removal or DIDS could affect a Na^+-dependent, HCO_3^--independent transport process.

Do Oligodendrocyte Precursor Cells Persist in Adult Human CNS? R. Armstrong*, H. Dorn*, C. V. Kufta*, and M. Dubois-Dalcq, NINDS, NIH, Bethesda, MD 20892

Recent studies indicate that adult rodent CNS contains an oligodendrocyte precursor cell which expresses glycolipid antigens recognized by the O4 antibody. To investigate whether this cell type may be present in adult human CNS, we cultured temporal lobe tissue which was resected during treatment of intractable epilepsy. Optimal cultures of oligodendrocyte lineage cells were prepared from initially non-adherent cells which were reseeded after 2 days. Using 3-color immunofluorescence, we consistently identify a population of putative oligodendrocyte precursor cells which express antigens recognized by O4 but do not express a differentiation marker of oligodendrocytes (galactocerebroside, GC) or astrocytes (glial fibrillary acidic protein, GFAP). The number of O4 only cells was highest during the first week in vitro and decreased over the following weeks. In the same cultures the number of oligodendrocytes (GC+ O4+) either remained constant or increased in defined media conditioned by rat glial cells. Relatively few type 2 astrocytes (O4+ GFAP+) were present in cultures grown in defined media or media containing 5% fetal bovine serum. In the conditions tested, oligodendrocytes and O4 only cells did not incorporate 3H-thymidine during a 3d pulse even though some type 2 astrocytes were labeled.

Thus, adult human CNS may harbor "resting" oligodendrocyte precursor cells with an antigenic phenotype similar to that seen in the rodent. Further studies are required to determine the proliferation and/or differentiation potential of these cells and discern whether glial cells with a similar phenotype can be identified in vivo.

NEURAL-IMMUNE INTERACTIONS I

403.1

LOCALIZATION OF INTERLEUKIN-1 mRNA IN RAT BRAIN. J. Licinio, M.-L. Wong, M.A. Smith, P. W. Gold*. Clinical Neuroendocrinology Branch, National Institute of Mental Health Intramural Research Program, Bethesda, MD 20892.

Neurons containing interleukin-1 (IL-1) have been identified in human hypothalamus by immunohistochemistry (Breder CD *et al.*, Science 1988; 240:321). IL-1 affects the release of hypothalamic neuropeptides and has multiple physiologic effects. In the present study we have further characterized IL-1-producing brain regions by determining the localization of cells containing IL-1 mRNA. We have used *in situ* hybridization histochemistry to determine the anatomic distribution of brain IL-1 mRNA. *In situ* hybridization was done with ^{35}S-dATP labelled oligodeoxynucleotide probes. Sections were apposed to films and dipped in NT-2 emulsion (Kodak). Our results indicate that IL-1 is synthesized throughout the brain, especially in white matter. Given the potent effects of IL-1 on brain function and behavior, these data raise the possibility that white-matter cytokines may modulate brain function. Further studies are necessary to clarify the physiologic effects of endogenous brain IL-1.

403.2

INTERLEUKIN INDUCES RELEASE OF DOPAMINE AND ITS METABOLITE FROM THE HYPOTHALAMUS *IN VIVO*. P. S. Mohankumar*, S. Thyagarajan* and S.K. Quadri, Neuroendocrine Research Laboratory, Kansas State University, Manhattan, KS-66506.

Interleukin-1B (IL-1B), a lymphokine, stimulates the release of hypothalamic and pituitary hormones. The mechanism of this action is not clear. In this report we present evidence for a mechanism of IL-1B effects on the hypothalamus and pituitary. Push-pull cannulae were implanted stereotaxically in the ventromedial nucleus of the hypothalamus of 8-month old Sprague-Dawley male rats. The hypothalamic nuclei were perfused with 100 ng or 50 ng of IL-1B or its vehicle (20 ul artificial cerebrospinal fluid). The perfusate samples were analyzed for catecholamines by electrochemical high performance liquid chromatography. The higher dose (100 ng) of IL-1B produced an increase of more than 100% in dopamine (DA) release within 50 minutes of perfusion. DA release continued to increase and was about 120% by 100 minutes post-perfusion. The lower dose of 50 ng IL-1B also increased DA release but it did not reach statistical significance. There was no significant change in DA release in control rats. Similarly, 100 ng IL-1B produced a significant increase in the release of 3,4-dihydroxyphenyl acetic acid (DOPAC). The lower dose of 50 ng IL-1B also increased DOPAC release, but it was not significant. It is concluded that IL-1B affects the release of hypothalamic and pituitary hormones by increasing the release of catecholamines from specific hypothalamic nuclei. To our knowledge this is the first evidence for a direct action of IL-1B on neurotransmitter metabolism in the brain *in vivo*.

403.3

INTERLEUKIN-1 (IL-1) AUGMENTS GABA-DEPENDENT CHLORIDE UPTAKE IN CORTICAL SYNAPTONEUROSOMES. L.G. Miller, W.R. Galpern, M. Lumpkin*, S. F. Chesley*, C.A. Dinarello*. Div. of Clinical Pharmacology, Depts. of Psychiatry and Pharmacology, and Dept. of Medicine, Tufts-New England Med. Ctr., Boston, MA 02111

The cytokine IL-1, a major participant in inflammatory and immune events, is present in the CNS and specific receptors appear to exist in brain. To assess a possible interaction between IL-1 and the GABAergic system, we evaluated effects of IL-1 on GABA-dependent chloride uptake in mouse cortical synaptoneurosomes. Uptake was determined using the GABA analog muscimol over a 6 sec interval. Preincubation of synaptoneurosomes (10 min) with IL-1, 100 pg-10 ng/ml, augmented maximal chloride uptake by approximately 40%. There was no significant alteration in the EC_{50} for muscimol with IL-1. At both higher and lower concentrations of IL-1, there were no significant effects on GABA-dependent chloride uptake. Addition of IL-1 concurrently with muscimol had a smaller, but still significant increase in chloride uptake at IL-1 concentrations of 100 pg/ml and 1 ng/ml. A specific IL-1 receptor antagonist, 10 ng/ml, prevented the effect of 100 pg/ml or 1 ng/ml IL-1 on maximal chloride uptake. These data indicate that IL-1, acting at a specific binding site in brain, augments GABA-dependent chloride uptake in cortical membrane preparations.

403.4

ENDOTOXIN TOLERANCE FAILS TO MODIFY CYTOKINE STIMULATED NOREPINEPHRINE TURNOVER IN MOUSE HYPOTHALAMUS. I. N. Mefford, C. F. Masters*, M. P. Heyes and R. L. Eskay*. Sec. Clin. Pharmacol., Clin. Neurosc. Branch, NIMH, Bethesda, MD 20892

Acute administration of endotoxin (lipopolysaccharide, LPS) as well as interleukin-1 (IL-1) stimulate hypothalamic norepinephrine turnover by a prostaglandin dependent mechanism. The rapid adaptation to the physiological effects of endotoxin is well known as endotoxin tolerance. The neurochemical consequences of chronic endotoxin administration have not been studied. We administered LPS or saline to male C57BL mice (5 ug/mouse/day, i.p.) for 7 days. On day 8, animals were challenged with saline, LPS (5 ug/mouse), IL-1 (1 ug/mouse) and tumor necrosis factor (TNF, 1 ug/mouse) and decapitated after two hours. Blood was collected for corticosterone and brain parts dissected for determination of catecholamines, serotonin and metabolites. The stimulation of hypothalamic norepinephrine turnover observed after acute LPS administration was absent following chronic LPS administration. However, the acute LPS stimulated elevation of corticosterone was only partially attenuated. The acute IL-1 and TNF-stimulated increase in hypothalamic norepinephrine turnover as well as the cytokine-induced elevation of corticosterone were unaffected by chronic administration of LPS. These results suggest that endotoxin desensitization occurs at the level of the macrophage in response to endotoxin. Other neuroendocrine, cytokine-mediated responses appear to be unaffected following desensitization of the macrophage response to endotoxin.

INTERLEUKIN 1 INDUCES c-FOS and c-JUN m-RNA EXPRESSION IN AtT-20 CELLS BY A MECHANISM INDEPENDENT OF PROTEIN KINASE C AND PROTEIN KINASE A. Mirela O.Fagarasan*, Katherin Muegge+,Francesca Aiello+, S.K. Durum+and J. Axelrod* (SPON: J.Axelrod) *National Institute of Mental Health, Bethesda, M.D. and +National Cancer Institute, Frederick, MD.

We have demonstrated that IL-1 after a long period of treatment direcly stimulates β-endorphin release and potentiates the effects of other secretagogues in AtT-20 cells, a mouse anterior pituitary cell line (Fagarasan et al., PNAS, 86, 2070-2073). It was also observed that IL-1 markedly phosphorylated 19-, 20-, and 60 kDa proteins (Fagarasan et al, PNAS, 87, 2556-2559). We found that another early signal triggered by IL-1 in AtT-20 cells involves the enhancement of c-fos and c-jun mRNA expression. The effect appeared within 30 minutes, is transient and returned to basal levels after 2hr. Desensitization of protein kinase C by phorbol ester (TPA) pretreatment had no effect on the ability of IL-1 to induce c-fos and c-jun m-RNA expression. An experiment was designed to investigate whether IL-1 can still generate this early signal after its continous presence with AtT-20 cells for 24 hours. After prolonged treatment with IL-1, the capacity of IL-1 to induce c-fos mRNA expression was abolished, but TPA and CRF effect on c-fos mRNA was markedly expressed.
Whether the interaction of these intermediate early gene products is involved in IL-1 potentiation of B-endorphin secretion induced by secretagogues awaits further investigation.

403.6

SUPPRESSION OF NATURAL KILLER CELL ACTIVITY FOLLOWING ELECTRICAL STIMULATION OF THE RAT MESENCEPHALON. R.J. Weber and A. Pert. Neuroimmunology Unit, Laboratory of Medicinal Chemistry, NIDDK, NIH, and Biological Psychiatry Branch, NIMH, Bethesda, MD 20892

We have previously reported that microinjections of morphine into the periaqueductal gray matter (PAG) of the mesencephalon produce suppression of natural killer cell (NK) activity (Weber and Pert, *Science* : 245: 188, 1989). Electrical stimulation of the periventricular region and the PAG have also been shown to produce opioid-like effects in the rat. The purpose of this study was to determine whether electrical stimulation of the PAG would also suppress NK cell activity. Rats were implanted with bipolar electrodes aimed for various rostral and caudal planes of the PAG. One week following recovery the animals were stimulated with intermittent 150 msec trains of biphasic pulses (50usec in duration presented at 100HZ and 500uA) for 20 minutes. Splenic NK cell activity was determined 3 hours following termination of stimulation. The most active sites in suppressing NK cell activity were found in the caudal PAG, just lateral to the dorsal raphe. Injections of morphine into a similar region were also found to suppress NK cell activity in the previous study cited above. Additional sites that were involved in alteration of NK cell activity were found in the caudal periventricular gray matter extending from the level of the posterior hypothalamus to the red nucleus. Studies are underway to determine the neural circuitry through which these signals gain access to the immune system.

403.7

CALCITONIN GENE RELATED PEPTIDE (CGRP) AND ITS RECEPTORS IN THE MOUSE THYMUS AND SPLEEN. K. Bulloch, J. Hausman*, T. Melnechuk, T. Radojcic*, S. Short*, D.M. Simmons, L.W. Swanson. Dept. of Psychiatry, Univ. of Cal. San Diego, La Jolla, CA 92093; Salk Institute, San Diego, CA 92138

In this study we demonstrate with immunocytochemistry the presence of CGRP in intrathymic mast cells, nerves and a discrete population of cells at the corticomedullary boundaries. In situ hybridization confirms that the subcapsular and trabecular mast cells and the intrathymic cells at the corticomedullary boundary synthesize messenger RNA for CGRP. Little to no CGRP activity was observed in the nerves or cells of the spleen. However, receptor sites for CGRP can be detected in both spleen and thymus tissue. These sites bind iodinated CGRP with a Kd of 14nM (Bmax 8 fmol/mg protein) for spleen and 12nM (Bmax of 18 fmol/mg protein) for thymus. These data indicate that CGRP may play a role in lymphocytic immune interactions. Supported by ONR grant #N0014-89-J-1256.

403.8

REGULATION OF PRE-PROENKEPHALIN A (PPEA) GENE EXPRESSION IN NORMAL MURINE T LYMPHOCYTES. K.M. Linner,* S. Nicol and B.M. Sharp*. Minneapolis Medical Research Foundation and Departments of Medicine, Hennepin County Medical Center and University of Minnesota, Minneapolis, MN 55404

Recent studies have shown that cells of the immune system can express genes for endogenous opioids. For example, PPEA mRNA has been found in transformed T cell lines, transformed and normal murine macrophages and mast cells, and concanavalin A (Con-A) - stimulated murine T helper cell clones. Our studies extend these findings regarding PPEA gene expression to normal murine thymus and spleen. Thymocytes and splenocytes isolated from female CD-1, SPF mice (4-5 w.o.) were cultured with several doses of Con-A for 24, 48, and 72 hr. Poly A mRNA was isolated and either dot blot or Northern gel analysis was done. PPEA mRNA was identified by hybridization with a specific 50-mer 32P-cDNA. Only thymocytes were induced to express PPEA mRNA under these conditions, with peak response (15x baseline) occurring after 72 hr in culture at Con-A doses of 5-7.5 µg/ml. No PPEA mRNA was detected in thymocytes after 24 hr in culture, whereas low levels were evident at 48 hr. Two hybridizable bands were found in cultured cells, one corresponding in MW to pituitary PPEA (1400d) and one larger. No PPEA mRNA was detected in splenocytes at any time in response to any dose of Con-A , even though these cells, like thymocytes, were induced to proliferate by Con-A. PPEA mRNA expression was further shown to be inducible in CD4+ thymocytes and its expression was inhibited by IL-1-beta. A role for enkephalin peptides in the ontogeny of T cells in the thymus is postulated. (Supported by DA04196)

CORTICOTROPIN-RELEASING HORMONE (CRH)BINDING SITES ON HUMAN IM-9 LYMPHOBLASTS J.P. McGillis, S. Humphreys*, and S. Reid* Dept. Microbiology and Immunology, Univ. Kentucky Coll. Med., Lexington, KY 40536

CRH stimulates rat B cell proliferation in vitro at nM concentrations (McGillis, et al., J. Neurosci. Res. 23:346, 1989) and CRH binding sites are present in spleen membranes (Dave, et al., Endo. 116: 2152 1985; Webster and De Souza, Endo. 122:609 1988). These data suggest an immunomodulatory role for CRH in peripheral tissues. CRH binding sites on B cells were characterized on human IM-9 cells. Binding studies were done with intact cells using ^{125}I-[Tyr°]-rat/human CRH. Binding was saturable, specific, and time and temperature dependent. Specific binding had a linear dependence on cell concentration at cell densities ranging from 2.5 to 20 x 10^6 cells/ml. Equilibrium binding was dependent on temperature, with equilibrium reached at 3 hr at 27° C, and by 90 min at 37° C. No binding was observed at 4° C. Best fit analysis of saturation isotherm binding suggested a two site model, with a high affinity Kd of 17.8 ± 2.15 pM and a low affinity Kd of 2.71 ± 0.78 nM. Binding site densities were 181 ± 97 sites/cell and 4363 ± 2094 sites/cell, respectively. The presence of CRH binding sites on human B lymphoblasts supports an immunomodulatory role for CRH in peripheral tissues.

403.10

REGULATION OF PROENKEPHALIN GENE EXPRESSION IN ASTROCYTES BY CYTOKINES. K. G. Low and M. H. Melner, Divisions of Neuroscience and Reproductive Biology, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Astrocytes have been implicated to play an immunological role in the brain as they express class II antigens and serve as antigen-presenting cells. In addition, astrocytes have been demonstrated to exhibit a high level of proenkephalin gene expression (Melner *et al.*, *EMBO J.*, 9:791, 1990). These observations suggest that astrocytes play a pivotal role in neuroimmune interactions. Neonatal rat astrocytes from the cerebral cortex were treated with 20 units/ml recombinant rat γ-interferon (γ-IFN) for 48 hours, 50 ng/ml recombinant human tumor necrosis factor-α (TNF-α) for the last 24 of 48 hours or both 20 units/ml γ-IFN (48 hours) and 50 ng/ml TNF-α (last 24 of 48 hours). Northern analysis using a ^{32}P-labeled 1.1 kb Eco R1/Hind III fragment of the rat proenkephalin cDNA detected a ~ 1.4 kb transcript. Proenkephalin mRNA levels appeared to be increased 2-fold with TNF-α however γ-IFN clearly decreased proenkephalin mRNA levels 2.5-fold. In addition, TNF-α had no effect on the γ-IFN inhibition of proenkephalin mRNA levels. Northern analysis with a ^{32}P-labeled 2.4 kb Eco R1 fragment of the rat glutamine synthetase cDNA detected 2.8 kb (more abundant) and 1.4 kb transcripts and demonstrated that glutamine synthetase mRNA levels were not significantly changed under the treatments with these cytokines. This inhibition specifically of neuropeptide gene expression in astrocytes by γ-interferon suggests potential interactions between the onset of viral infection of brain tissues and the subsequent effects upon neurological function. Supported in part by NIH DK41035, NIH RR-00163, and ONR N00014-90-J-1122.

INTIMATE CONTACT BETWEEN RAT BASOPHILIC LEUKEMIA (RBL) AND PHEOCHROMOCYTOMA (PC-12) CELLS COMBINED IN CULTURE. J. Solomonides*, V. Dimitriadou, M. Holdridge* and T.C. Theoharides. Department of Pharmacology, Tufts University School of Medicine, 136 Harrison Avenue, Boston, MA 02111

Mast cells are important in allergic reactions. However,they have recently been implicated in a number of neuro-endocrine disorders and have also been shown to be in close contact with neurons. Here, we investigated the possibility that cultured analogues of mast cells and neurons may establish contact *in vitro*. RBL cells, which are homologous to bone marrow-derived mast cells, and PC-12 cells, which can differentiate to neurons, were grown in Dulbecco's modified Eagle's medium with 10% fetal calf serum and either 10 U interleukin 3 (IL-3), 1μM nerve growth factor (NGF) or both. The two cell types were combined in 1:1 ratio of about 3-5x10^5 cells and were examined after 5 days. The cells were grown in culture dishes with sterile cover slips which were fixed for light, as well as scanning and transmission electron microscopy. Close contact was evident directly between the cells and between PC-12 axonal processes and RBL cells. Histamine measurements after secretion induced by the cation ionophone A23187 indicated an increase in the cultures containing both IL-3 and NGF. These results support the premise that mast cells may be innervated directly and suggest the possibility that such mast cells may also express different phenotypic and functional characteristics.

403.12

SPLENIC NOREPINEPHRINE IS DECREASED IN MRL MICE HOMOZYGOUS FOR THE *LPR* GENE. S.Y. Felten, S.M. Brenneman, J.A. Moynihan, L.J. Grota. Depts. Neurobiology & Anatomy and Psychiatry, Univ. Rochester Sch. Med., Rochester, NY 14642

The MRL mouse has been used as a murine model of systemic lupus erythematosis. The disease is the result of a single recessive gene, *lpr*. Mice homozygous for the *lpr* gene have autoimmune disease characterized by a wide spectrum of autoantibodies, a marked lymphadenopathy and splenomegaly associated with an overabundance of an abnormal T cell subset (dull Thy 1^+, Lyt 1^+), arthritis and glomerulonephritis. Fifty percent of the *lpr* animals are dead by 24 weeks of age.

Norepinephrine was measured in spleens from *lpr/lpr* mice and their congenic +/+ controls at 6, 12, 18, and 24 weeks of age and found to be lower in *lpr/lpr* mice at all ages, both when expressed as a concentration (pMoles/g wet weight) or as pMoles/whole spleen. Both measurements were necessary, since the presence of lymphadenopathy greatly increases the number of lymphocytes in the spleen.

Glyoxylic acid histofluorescence and tyrosine hydroxylase immunocytochemistry demonstrated relatively normal patterns of innervation in periarteriolar zones, but showed no indication of innervation within the areas occupied by abnormal T cells.

CELLULAR AND MOLECULAR STUDIES III

404.1

THE ROLE OF POSTSYNAPTIC ACTIVITY IN ESTABLISHING APPROPRIATE SYNAPTIC MORPHOLOGY DURING NEUROMUSCULAR DEVELOPMENT IN DROSOPHILA EMBRYOS. M.D.S. Anderson and H. Keshishian. Dept. of Biol., Yale University, New Haven, CT 06511.

Through the use of immunocytochemistry and AGTX1, a toxin isolated from the venom of the Orb Weaver spider *Araneus gemma* that blocks glutamate activity postsynaptically at the neuromuscular junction in *Drosophila*, we have shown that the early peristaltic movements in *Drosophila* embryos are mediated by glutamate and likely neurally evoked. Early growth cone contacts on the bodywall muscles in stage 16 embryos are immunoreactive for glutamate and coordinated peristaltic bodywall muscle movements begin to be visible during this stage of development. All of the coordinated muscle contractions are abolished following the microinjection of AGTX1.

It is clear that neuromuscular activity is present during late embryogenesis, when the stereotypic ending anatomies begin to be established on *Drosophila* bodywall muscles. Therefore, we sought to identify whether activity is necessary for the acquisition of appropriate synaptic morphology. During stage 17 of embryogenesis the endings on the bodywall muscles begin to resemble the stereotypic mature larval endings. We have used AGTX1 to block postsynaptic activity in stage 17 embryos, followed by anti-HRP immunocytochemistry to look at the role of postjunctional activity in the development of stereotypic ending patterns and synaptic boutons. There appears to be no effect on the establishment of normal ending morphology when the postsynaptic response is blocked. We have also begun to microinject TTX into stage 17 embryos to determine whether blocking action potentials during this stage affects the development of appropriate synaptic morphology.

404.2

ANTAGONISM OF THE NMDA RECEPTOR AT THE SPINAL SEGMENTAL LEVEL DISRUPTS MOLECULAR DEVELOPMENT OF MOTOR NEURONS. Robert G. Kalb and Susan Hockfield, Sect. Neuroanatomy, Yale Univ. Sch. Med., New Haven, CT 06510.

The expression of the cell surface chondroitin sulfate proteoglycan identified by monoclonal antibody Cat-301on motor neurons is dependent on neuronal activity during a circumscribed period in early postnatal life. The NMDA antagonist MK-801 inhibits Cat-301 expression in a stereoselective, dose-dependent manner when administered to neonatal (but not adult) hamsters. We have confirmed that this effect is mediated through the NMDA receptor using a second NMDA receptor antagonist, aminophosphonovaleric acid (APV). APV was incorporated into the polymer Elvax and slices implanted over the lumbar enlargement. In neonates, APV specifically inhibits Cat-301 development on motor neurons in a dose-dependent manner, while in adults APV has no effect on Cat-301 expression.

Two sets of experiments suggest that NMDA receptor antagonists are operating at the spinal segmental level. First, we compared the effects of APV implants placed over the lumbar enlargment to those placed over the cervico-medullary junction (CMJ) or the sensorimotor cortex (SMC). Implants at the lumbar enlargement were twice as potent as CMJ implants in inhibiting Cat-301 expression on motor neurons, while SMC implants had no effect on Cat-301 expression. The decrease in efficacy of APV with increasing distance from the lumbar enlargement suggests that NMDA receptor antagonists exert their effects in this system at the spinal segmental level. Second, to test whether afferents from normally active muscles provide the coherent electrical activity to motor neurons necessary for activation of the NMDA receptor, electrical activity at the spinal segmental level was blocked by implanting a TTX-coated wire into the sciatic nerve. Cat-301 expression was inhibited on motor neurons connected to TTX-silenced muscles. These data suggest that normally active muscles evoke patterned electrical activity at the segmental level, activating NMDA receptors and leading to normal maturation of motor neurons as assayed by Cat-301 expression.

404.3

PHENOTYPIC DIFFERENTIATION OF STRIATAL TRANSPLANTED NEURONS IN RELATION TO DOPAMINERGIC HOST AFFERENTS. B. Onteniente, M. Peschanski and B. Desfontaines*. INSERM U161, 2 Rue d'Alésia, 75014 Paris, France.

The role of dopaminergic (DA) afferents in the acquisition of a specific phenotype by their post-synaptic cells was investigated in embryonic suspensions transplanted into either a kainic acid-lesioned striatum (KA animals) or a KA striatum additionally deprived in DA by 6-OHDA administration (KA-6-OHDA animals). The expression of the D1-associated protein DARPP-32 was observed immunohistochemically at 4 to 60 days following transplantation (T4 to T60) and paralleled with the development of DA afferents from the host. Acetylcholine esterase (AChE) histochemistry was performed on adjacent sections.

Striatal embryonic neurons already expressed DARPP-32 at the time of their dissection (E16). However, no immunoreactivity was observed within the transplants in KA animals until T6. This delay was prolonged until T14 in KA-6-OHDA animals.

As demonstrated by AChE histochemistry, transplants of both experimental groups progressively developed the specific patchy pattern corresponding to the segregation of striatal and extra-striatal tissue. In addition, both the survival and the general morphology of transplanted cells were similar in KA and KA-6-OHDA animals.

Homotopically transplanted striatal neurons, if transiently impaired by their displacement, are able to rapidly recover their specific DARPP-32 phenotype. The role of DA afferents in the acquisition of this expression and in the general development of striatal cells seems to be rather limited since their elimination, although introducing some supplementary delay, does not suppress the expression of DARPP-32.

404.4

DIFFERENTIATION OF ADRENERGIC CELLS IN A CHOLINERGIC GANGLION. R.D.Heathcote, A.Chen and M.Bennett. Department of Biological Sciences, University of Wisconsin, Box 413, Milwaukee, WI, 53201.

While studying the development of a parasympathetic ganglion, we discovered a discrete population of adrenergic cells that differentiated at the same time and in the same location as cholinergic neurons. The cardiac ganglion of the frog, *Xenopus laevis*, contained cells that had the characteristics (small size, catecholamine fluorescence and multipolar cell bodies) of SIF (small intensely fluorescent) cells.

SIF cells were present in some ganglia before cholinergic neurons differentiated. They were also present at 2.1 days of development, when the first cholinergic precursors were becoming postmitotic. Although few SIF cells were in the heart at this stage, they were frequently located close to the heart. SIF cells were associated with differentiated pigment cells that covered the dorsal portion of the yolky endoderm and eventually moved ventrally to cover the peritoneal and pericardial cavities.

There was a slight but steady increase in the average number of SIF cells in the ganglion during early larval development. At 3 weeks, all ganglia contained SIF cells and their average number continued to increase through the end of metamorphosis. Although SIF cells were present before cholinergic neurons, once neurons differentiated (3.3 days), SIF cells were always outnumbered by neurons. Cholinergic neurons became postmitotic and accumulated in the ganglion while SIF cells accumulated at a much slower rate. The accumulation of the two cell types appeared to be coordinated, since SIF cells were maintained at a level one order of magnitude less than cholinergic neurons.

SIF cells were clustered in the sinus venosus portion of the cardiac ganglion. Early in development, the first cholinergic neurons accumulated in the same area. Thus, within this small region, neural crest cells simultaneously adopted two different fates.

404.5

REGULATION OF NEUROTRANSMITTER PHENOTYPE IN THE NEMATODE *C. ELEGANS*. C. M. Loer and C. J. Kenyon*. Dept. of Biochemistry and Biophysics, Box 0554, Univ. of California, San Francisco, CA 94143.

Specification of a neurotransmitter phenotype requires, among other characteristics, the coordinate expression of appropriate biosynthetic enzymes. Synthesis of the biogenic amines dopamine (DA) and serotonin (5HT) require the expression of an aromatic amino acid (AAA) hydroxylase and decarboxylase. In the nematode *C. elegans*, 5HT and DA are used by a number of identified neurons, including a motoneuron required for egg-laying and sensory neurons necessary for male mating. Genes that specify neuronal characteristics in *C. elegans* can be identified by mutation. As a first step towards analyzing the genetic control of neurotransmitter and other neuronal phenotypes, we are cloning genes encoding biosynthetic enzymes for the biogenic amine neurotransmitters to use as markers of specific neuronal differentiation. We used PCR with degenerate oligonucleotides encoding highly conserved regions of AAA hydroxylases to amplify a genomic fragment encoding a *C. elegans* AAA hydroxylase. Of 5 clones sequenced, 2 encoded an AAA hydroxylase; in the region sequenced, 27 of 36 amino acids were identical to human tyrosine hydroxylase. The sequence included a typical *C. elegans* intron at an evolutionarily conserved splice site; typical *C. elegans* codon usage was also apparent in the coding region sequenced. We have isolated a λ genomic clone that we are using to isolate cDNAs for sequencing. We probed a genomic southern blot and found that the gene is present as a single copy in the genome. We plan to use *in situ* hybridization to define sites of expression of the gene. We also plan to fuse β-gal into the AAAH gene and use worms containing such a construct to identify mutations that alter its expression and to examine expression in certain known mutants. Such a screen should yield genes that are required for the regulation of neurotransmitter synthesis as well as genes that determine which neurons produce a specific neurotransmitter.

COMPARISON OF TYROSINE HYDROXYLASE AND NCAM IMMUNOREACTIVITY IN THE MESENCEPHALON OF THE EMBRYONIC RAT. C.W. Shults and T.A. Kimber*. Neurology Ser., VA Med. Ctr., San Diego, CA 92161 and Dept. of Neurosci., UCSD, La Jolla, CA 92093.

In the developing mesencephalon of the rat, the dopaminergic (DA) cells are generated in the ventricular zone of the basal plate between E11 and E15. The DA cells align and appear to move along radial glia as they migrate from the ventricular zone through the mantle layer to the ventral surface of the mesencephalic flexure. To investigate the specific molecules that control migration of the DA cells, adjacent sections of rat embryos were immunolabelled with a monoclonal antibody that recognizes tyrosine hydroxylase (TH) and a polyclonal antiserum raised against rat NCAM. At E14 and E15, DA cells were noted only along the ventral surface of the mesencephalic flexure. At these ages, NCAM immunoreactive (NCAM-IR) material was noted on the surface of cells in the ventricular zone and throughout the mantle layer. The distribution of NCAM-IR material was not uniform. Cells along the ventral surface of the mesencephalon, the area occupied by DA cells, had the greatest amount of NCAM-IR material. Cells in the ventricular zone contained a moderate amount of NCAM-IR material. Cells between these two regions contained a lower amount of NCAM-IR material. Our data suggest that the level of expression of NCAM on the surface of developing DA cells of the mesencephalon may influence migration and/or expression of TH.

PRODUCTION AND SECRETION OF NEUROPEPTIDE Y (NPY) BY AGGREGATING FETAL BRAIN CELLS IN CULTURE: A MODEL FOR DEVELOPMENTAL REGULATION OF NPY GENE EXPRESSION. A.Barnea, A.Hajibeigi* and G.Cho*. Depts Obstet. Gynecol. & Physiol., Univ. Texas Southwestern Med. Ctr., Dallas, TX 75235.

NPY is the most abundant peptide in the nervous system. The fetal-rat diencephalon already contains substantial amounts of NPY, which increase dramatically around the time of birth. The aim of this study was to establish an *in vitro* model system for studying the regulation of the expression of NPY gene in the perinatal brain. Single cell suspensions were prepared from the hypothalamic-olfactory tubercle (HT/OT) of 18-day-old rat fetuses, aggregates were formed by constant rotation, and NPY content was assayed by RIA (NPY-IR). Aggregate NPY-IR doubled between 3 to 12 days of culture (1.7 to 3.0 ng/mg P). At each culture-age, the amounts of NPY-IR in the medium exceeded those in the aggregates ≥5-fold. Size-fractionation of NPY-IR indicates the presence of both proNPY-IR and NPY-IR and that their molar ratio is much higher in the medium than in the aggregates. Interestingly, HT/OT of neonates also contained both proNPY-IR and NPY-IR but tissues of 9-day-old rats contained only NPY-IR, suggesting differential regulation of the biosynthesis and processing of proNPY. Thus, the cultured aggregates produce and secrete large amounts of proNPY-IR and NPY-IR, and both production and secretion increase with culture-age. Hence, the cell aggregates provide an excellent model for studying developmental regulation of proNPY biosynthesis/processing.

Multiple acetylcholine receptor genes are expressed in a tissue-specific fashion in the leech, *Hirudo medicinalis*. Kathleen A. French, Shirley A. Reynolds*, Melissa Hartley*, Steve Heinemann, and William B. Kristan, Jr. Department of Biology, UCSD, La Jolla, CA 92093 and Salk Institute for Biological Research, La Jolla, CA 92037.

Retzius (Rz) neurons in the central nervous system of the leech, *Hirudo*, are alike in all mid-body segments, except in the segments containing the reproductive organs (segments 5 and 6). Although all Rz neurons are indistinguishable from one another early in development, the Rz neurons in the reproductive segments [Rz(5,6)] eventually differ from their segmental homologues in several characteristics, including their physiological response to acetylcholine (ACh) applied to the cell soma. Rz neurons in standard mid-body segments [Rz(X)] depolarize when ACh is applied, but Rz(5,6) hyperpolarize. From experiments with selective blocking agents, we conclude that Rz(X) has one type of ACh receptor (AChRs) in their membranes, while Rx(5,6) must have two types - one which mediates the depolarizing and another the hyperpolarizing responses.

In an attempt to understand the developmental regulation of the two types of AChRs, we have begun to clone AChR genes in *Hirudo*. We used PCR to amplify leech cDNA sequences homologous to published rat and *Drosophila* AChR sequences, and we cloned and sequenced the PCR products. Among the clones are several 300 base-pair oligonucleotides with sequences homologous to AChRs. We hybridized clones to frozen sections of adult leech tissues containing muscle and nerve cells from both reproductive and non-reproductive segments. One clone hybridizes with a specific population of non-neuronal cells in the body wall, and another hybridizes specifically with neurons, but not with muscles. The neuronal AChR clones bind to a sub-set of neurons in all ganglia and hybridize particularly strongly in the neuropil of each ganglion. We conclude that the *Hirudo* genome, like those of other species, includes a family of AChR genes and that these genes are expressed in a tissue-specific fashion in adults. This work was supported by research grants from NIH (NS25916) and the March of Dimes (MOD 1-1064) to WBK and from NIH (NS11549) and the Muscular Dystrophy Association to SH.

EARLY EXPRESSION OF POTASSIUM CHANNEL TRANSCRIPTS IN THE AMPHIBIAN SPINAL CORD. A. B. Ribera. Dept. of Biol., UCSD, La Jolla, CA 92093 and Dept. of Physio., Univ of CO, Denver, CO 80262.

The delayed rectifier potassium current in amphibian spinal neurons exhibits a specific timetable of functional differentiation, that is coordinated with the maturation of calcium currents to permit developmentally regulated action potential phenotypes. Molecular probes for a *Xenopus* nucleotide sequence encoding a potassium channel have been identified by homology screening with the *Drosophila Shaker* sequence (Tempel et al., 1987). The *Xenopus* sequence is most related to the mammalian sequences RBK2 (McKinnon, 1989) and MK2 (Chandy et al., 1990) and is thus called XSha2. As reported for some mammalian sequences (Chandy et al., 1990;Douglass et al., 1990;Swanson et al., 1990), the coding region is contained within a single uninterrupted exon. Southern analysis of genomic DNA with XSha2 suggests that it is a member of a famiiy of closely related genes. The predicted peptide has 493 amino acids.

Functional expression of XSha2 in oocytes induces a delayed rectifier potassium current. RNase protection assays indicate that XSha2 is expressed in the nervous system but not detectable in the excitable tissues of heart or skeletal muscle. Its transcription is first observed *in vivo* at the neural tube stage and thus slightly after NCAM, an early marker of neural differentiation. In cultured embryonic amphibian neurons, the transcript is present at the time of initial morphological differentiation.

The timing of the functional expression and maturation of the delayed rectifier is fundamental for the characteristic maturation of electrical excitability in amphibian spinal neurons. The tissue-specific and temporal patterns of expression of XSha2 indicate that this program may be established at the level of gene transcription. Supported by NIH grants NS25217 (ABR) and NS25916 to Nicholas C. Spitzer.

THE MATURATION OF THE DELAYED RECTIFIER POTASSIUM CURRENT IS A CALCIUM-DEPENDENT PROCESS. M.G. Desarmenien and N.C. Spitzer. Department of Biology and Center for Molecular Genetics. UCSD, La Jolla CA 92093.

The delayed rectifier potassium current (I_{Kv}) plays a key role in the differentiation of embryonic amphibian spinal cord neurons: its development converts long lasting calcium-dependent action potentials to fast, primarily sodium-dependent spikes. In *Xenopus* spinal cord neurons maintained in primary culture, the development of I_{Kv} involves a progressive increase in its amplitude during a 24 hr period. In addition, during the last 9 hr, there is a period of maturation during which its rate of rise increases (O'Dowd et al. 1988).

We have examined the influence of calcium influx on the maturation of I_{Kv} by growing mixed neuron-myocyte cultures or neuron-enriched cultures in media deprived of calcium. Removal of calcium from the culture medium demonstrates that the increase in rise time, but not in amplitude, is a calcium-dependent process. Equivalent results are obtained from both enriched and mixed cultures, although the current density is higher in the former condition. The extent of this inhibition depends on the type of culture and the medium used. The sensitivity to this treatment is restricted to the interval between 6 and 15 h in culture. This 9 hr period corresponds to that previously defined as critical for the transcriptional control of the development of I_{Kv} (Ribera and Spitzer,1989). When applied during these 9 hr, 8Br cAMP partially prevents and phorbol ester (PMA) mimicks the effects of low calcium media.

The findings are consistent with the view that the long, calcium dependent action potentials which appear transiently after the neuronal birthdate are a determinant of the maturation of I_{Kv}. The mode of action of calcium is a complex process, in which the activities of protein kinases A and C may be involved.

404.11

DIFFERENTIATION OF DELAYED RECTIFIER POTASSIUM CURRENT IN EMBRYONIC AMPHIBIAN MYOCYTES. N.C. Spitzer & A.B. Ribera. Dept. of Biology & Center for Molec. Genetics, UCSD, La Jolla, CA, 92093.

The developmentally regulated expression of prolonged outward potassium currents influences the extent to which sustained inward currents contribute to the action potential at early stages of differentiation. In amphibian spinal neurons, the long duration and calcium-dependence of the embryonic action potential and the amount of calcium influx are largely determined by the extent of maturation of the delayed rectifier potassium current (I_{Kv}; Barish, 1986; O'Dowd et al., 1988; Spitzer, 1988).

We have undertaken a parallel study of differentiation of myocytes, in which action potentials are brief and sodium-dependent even at early stages. The early expression of electrical excitability in embryonic amphibian myocytes growing in culture has been examined previously using intracellular voltage recording techniques (DeCino and Kidokoro, 1985; Henderson and Spitzer, 1986). The membrane exhibits a delayed rectification in response to depolarization at times earlier than those at which impulses can first be generated.

We have examined the differentiation of this outward current in embryonic myocytes developing *in vitro*, using whole cell voltage clamp. I_{Kv} is initially absent. When first recorded it is small and slowly activating but undergoes six-fold increases in both density and rate of activation during the first day in culture. This maturation is dependent upon transcription, and its rate and extent are influenced by the presence of other cell types. The amplitude of the outward delayed rectifier is larger than the inward calcium current at all stages examined and prevents expression of long duration action potentials. Supported by NIH grants NS25916 (NCS) and NS25217 (ABR).

STEROIDS: RECEPTORS AND ACTIONS

405.1

ULTRASTRUCTURAL CHARACTERISTICS OF ESTROGEN RECEPTOR-CONTAINING (ER) NEURONS IN THE VENTROLATERAL NUCLEUS (VL) OF THE FEMALE GUINEA PIG. A.J. Silverman, L. DonCarlos and J.I. Morrell, Dept. Anat. & Cell Bio., Columbia Univ., N.Y., N.Y. and Animal Behavior Inst., Rutgers Univ., Newark, N.J.

Immunocytochemical localization of ER is the only method that allows examination of the ultrastructural characteristics of estrogen receptor cells. We have examined ER neurons in the VL, as a role for these neurons in female sexual behavior has substantial support. Six ovariectomized animals were perfused with 4% paraformaldehyde. ER was localized in vibratome sections using H222, a rat monoclonal anti-ER antibody (Abbott Labs), the Vector Elite kit, and silver intensification of DAB reaction product. Sections were post-fixed in OsO_4 and embedded in EPON. All ER neurons had large cytoplasmic to nuclear ratios; prominent proximal dendrites; a large Golgi apparatus; stacks of rough endoplasmic reticulum and secretory granules. These are characteristics of cells that make peptides. ER neurons showed varying degrees of immunoreactivity that could not be attributed simply to depth within the section. ER was concentrated in the nucleus with the nucleolus being free of deposits. Light reaction product was also seen in both dendritic and somal cytoplasm. The dendrites and cell bodies were heavily innervated with the most common presynaptic element being Gray's Type I terminals (a prominent synaptic cleft, little pre or post-synaptic densities and accumulations of small, round, clear vesicles). The pronounced input to these cells strongly suggests that both synaptic and hormonal signals govern their activity. Supported by HD 10665 (AJS) and HD 22983 (JIM).

405.2

CHANGES IN MBH LHRH AND NPY ASSOCIATED WITH PROGESTERONE AND TRIAMCINOLONE ACETONIDE-INDUCED LH AND FSH RELEASE. D.W. Brann[*1], J.K. McDonald[2], C.D. Putnam[*1] & V.B. Mahesh[*1]. [1]Dept. of Physiol. & Endocrinology, Med. Coll. of GA, Augusta, GA 30912, [2]Dept. of Anat., Emory Univ. Sch. of Med., Atlanta, GA 30322.

In a previous study, we demonstrated that progesterone (P4) and the synthetic glucocorticoid, triamcinolone acetonide (TA), but not cortisol (F), could induce LH and FSH release in estrogen-primed ovariectomized rats. Therefore, the purpose of this study was to determine if the stimulatory effects of P4 and TA on LH and FSH release were associated with changes in LHRH or NPY concentrations in the medial basal hypothalamus (MBH) or preoptic area (POA). Ovariectomized estrogen-primed immature rats received either vehicle, P4, TA or F (1mg/kg BW) at 0900h on day 29. Animals were killed at 0930, 1000, 1200 and 1300h for serum LH and FSH measurements and the MBH and POA were dissected and analyzed for LHRH and NPY concentrations via RIAs. P4 and TA-treated animals showed significantly elevated serum LH and FSH levels at 1300h. F was without effect. P4 significantly increased MBH LHRH and NPY concentrations at 1200h followed by a significant fall at 1300h. TA caused no significant increase in MBH LHRH or NPY at 1200h but, as with P4, there was a significant fall in MBH LHRH and NPY at 1300h. Consistent with its lack of effect on serum LH and FSH, F had no effect on MBH LHRH and NPY. With respect to the POA, P4-treated animals showed a significant fall in LHRH concentrations at 1300h as compared to 1200h. No effect was seen on NPY. TA had no effect on POA LHRH or NPY. Interestingly, F significantly increased POA LHRH and NPY at 1200h followed by a fall at 1300h. However, this change in POA LHRH and NPY may not be related to gonadotropin secretion since F had no effect on LH and FSH levels. In summary, the stimulatory effects of P4 and TA on LH and FSH release appear to be mediated by a similar mechanism involving changes in MBH LHRH and NPY concentrations. Supported by HD16688, HD00727, March of Dimes 1-1118.

STEROID REMOVAL INCREASES GNRH SECRETION IN THE EWE
SM Moenter, A Caraty*, FJ Karsch* Reprod. Sci. Prog., Dept Physiol., Univ. Michigan, Ann Arbor, MI, INRA Physiol. Reprod., Nouzilly, France.

Changing secretion of gonadal hormones affects the hypothalamo-pituitary axis, altering LH secretion. The extent to which altered LH is due to steroid action on the pituitary or on the brain remains debated. We tested the hypothesis that acute withdrawal of ovarian steroids increases pulsatile GnRH secretion in the ewe. Our approach was to compare GnRH secretion into pituitary portal blood after experimental removal of all ovarian hormones (ovariectomy, OVX) with that in the luteal and follicular phases, i.e. before and after removal of mainly one hormone, progesterone (P). The technique of Caraty and Locatelli (J Reprod Fert 82:263, 1988) was used to collect portal blood samples every 10 min for 6 h from 3 groups of Suffolk ewes in the breeding season: midluteal phase (n=5), early-mid follicular phase (n=5), 24 h after steroid removal (n=10). The latter group was OVX 1 wk before sampling to avoid surgery just before portal blood collection. Estradiol (E) and P were held at luteal phase levels with Silastic implants which were removed 24 h before sampling. Pulses of LH and GnRH were highly coincident. Frequency of GnRH pulses was lower (p=.002) in luteal phase than in OVX ewes (1.2±.4 vs 5.5±.3 pulses/6 hr) and tended (p=.062) to be higher still in follicular phase ewes (8.2±1.3 pulses/6 hr). Amplitude was lower (p=.05) in follicular (1.1±.3 pg/min) than in OVX (6.5±1.7 pg/min) or luteal (4.5±1.8 pg/min) phase ewes (luteal vs OVX NS). Total GnRH detected was higher (p=.01) in OVX (438±98 pg) than in follicular (86±9 pg) or luteal (67±33 pg) phase ewes. We conclude the acute removal of all ovarian hormones causes increased pulsatile GnRH secretion within 24 h. Further, physiologic withdrawal of P at luteolysis, presumably in combination with the rising tide of E, changes the pattern of GnRH secretion such that frequency increases and amplitude decreases in the follicular phase, but may not alter the total amount of GnRH secreted. NIH-18337.

PROGESTERONE ENHANCES FOS EXPRESSION IN LHRH NEURONS DURING AN LH SURGE.
W.-S. Lee, M.S. Smith, G.E. Hoffman Department of Physiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

The ability of progesterone (P) to enhance the LH surge is well established in the rat. However, whether its primary site of action is on the pituitary or brain is unclear. Recently, we have demonstrated that LH surges induced by estradiol benzoate (EB) and P (Hoffman et al., Endocrinology, 126: 1736, 1990) and the events of proestrous (Lee et al., PNAS, 1990, in Press) are accompanied by induction of Fos in LHRH neurons in the preoptic area and anterior hypothalamus, suggesting that stimulated activity of the LHRH neurons is the primary drive for the LH surge. To determine the role of P in this process 1) intact female rats were treated with P antagonist RU 486 (5 mg) at 1230 h on proestrus and killed at specified times during the afternoon and evening for comparison with untreated proestrous rats. 2) Ovariectomized rats were primed with EB (1μg) and then were treated with E alone (50μg) or EB plus P (5mg). The brains were processed for immunocytochemistry of Fos and LHRH. RU 486 treatment dramatically reduced both the magnitude of the LH surge and the degree of Fos induction (numbers of cells expressing Fos and intensity of Fos staining) in LHRH neurons during proestrus. Also, the magnitude of the LH surge and degree of Fos expression in LHRH neurons induced by EB-P treatment were greater than that induced by EB treatment alone. These data suggest that a major site of P action is on hypothalamus and P enhances the LH surge by greatly increasing LHRH neuronal activation. Supported by NIH grant HD 13254 and HD 14643

405.5

EFFECT OF ESTRADIOL (Es) ON NOREPINEPHRINE (NE) LEVELS IN THE PREOPTIC AREA (POA) OF ANESTROUS EWES.
R.L. Goodman, J.E. Robinson*, K.M. Kendrick*, C. Delaney*, and R.G. Dyer*. AFRC Inst of Animal Physiol and Genetics Res, Babraham UK CB2 4AT and Physiol Dept, West Virginia Univ, Morgantown WV 26506

Inhibitory NE input to the POA appears to play a role in the negative feedback action of Es in anestrous ewes. This study examined the effects of Es on NE levels in the POA of ovariectomized (OVX) anestrous ewes and on the response to the α-adrenergic antagonist, phenoxybenzamine (PBZ) using microdialysis probes (5 mm membrane length). Probes were inserted via chronic guide tubes into the POA of conscious ewes and either Ringer's (R) solution (0-8h, 12-20h) or 60 μg/ml PBZ in R (8-12h) pumped through the probes at 2 μl/min. Dialysate samples were collected every 20 min and concentrations of aminergic transmitters and GABA measured using HPLC with electrochemical or fluorescence detectors. Dialysis was done with and without Es (1 cm-long Silastic capsule sc for 2 days) in each of ten ewes. Mean NE levels during 2-8h of dialysis were lower in OVX+Es (477 ± 86 pg/ml) than in OVX (1127 ± 243 pg/ml; $p < .05$), but Es increased the variability of NE (intra-animal CV increased from 16.6 ± 4.3% to 31.6 ± 3.2%; $p < .01$). Es had no effect on epinephrine, dopamine, serotonin, or GABA levels in the POA. Perfusion of PBZ through the probe increased NE levels, presumably by blocking adrenergic autoreceptors. However, this effect only occurred when probes were located rostral to the decussation of the anterior commissure (rostral probes: 424± 60% of controls; caudal probes: 111 ± 18% of controls; $p < .01$), suggesting that the autoregulatory control of NE release varies in different areas in the rostral hypothalamus. In conclusion, these data show that Es decreases mean NE levels in the POA of anestrous ewes, but may increase its episodic release. (HD 17864)

PROGESTERONE *IN VITRO* RAPIDLY REDUCES NORADRENERGIC AGONIST-STIMULATED cAMP ACCUMULATION IN HYPOTHALAMIC SLICES
N. Petitti and A.M. Etgen, Depts. of Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461

We previously demonstrated that norepinephrine (NE) induction of cAMP accumulation in slices of the preoptic area (POA) and middle hypothalamus (MH) is reduced by *in vivo* administration of progesterone (P) to estradiol (E_2)-primed rats Experiments with selective NE ligands indicated that P eliminates α_1 receptor augmentation of β receptor-stimulated cAMP formation (MOLEC BRAIN RES, 5:109-119,1989).

Present studies examined whether *in vitro* exposure to P would also depress NE-stimulated cAMP synthesis. POA and MH slices from E_2-primed females were incubated with 20 nM P for 5-30 min prior to addition of 100 μM NE. Preincubation of slices with P for as little as 5 min significantly suppressed NE-stimulated cAMP formation. This effect was estrogen-dependent in that P did not inhibit NE-stimulated cAMP accumulation in slices from ovariectomized rats. Isoproterenol (β agonist) elevated cAMP to the same extent in slices incubated with and without P; however, phenylephrine (α_1 agonist) was unable to augment cAMP formation in P-exposed slices.

These data indicate that P may have rapid (i.e., non-genomic) effects on α_1-adrenergic receptor coupling to second messenger systems in the hypothalamus.

DIHYDROTESTOSTERONE INHIBITS ESTROGEN-INDUCED PITUITARY HYPERTROPHY AND HYPERPROLACTINEMIA IN BOTH MALE AND FEMALE RATS.
X.-B. Guan*, A. J. Carrillo, and P. C. Doherty. Dept. of Anatomy, Northeastern Ohio Univ. Col. Med., Rootstown, OH 44272.

Prolonged treatment with estrogen (E) causes pituitary cell hypertrophy, hyperplasia and hypersecretion of prolactin (PRL). We have previously shown that co-administration of dihydrotestosterone (DHT) can inhibit this effect in pituitaries under hypothalamic control, but not those transplanted to an ectopic site. Since the donors used in the transplant study were female rats, the present experiments were undertaken to determine if differences exist between male and female pituitaries in their response to E plus DHT. Adult male and female Fischer 344 rats were castrated and treated with subcutaneous implants of crystalline testosterone (T), E, or E+DHT. Additional groups of males were given ectopic pituitary grafts from male or female donors plus the steroid containing capsules. The E-induced increase in pituitary weight and serum PRL levels was inhibited by co-administration of DHT, but not always to the levels seen in T-treated animals. Though subtle differences existed between male and female rats in the time course of these effects, DHT administration did inhibit the effects of E in both males and females when the pituitaries were under hypothalamic control. These results support our previous contention that DHT can inhibit the effects of E but that hypothalamic input is necessary for these effects to occur. In addition, our results suggest that the primary site of action of DHT to inhibit the effect of E on lactotroph hypertrophy and hypersecretion involves maintenance of the inhibitory activity of tuberoinfundibular dopamine neurons, which is typically altered during prolonged E treatment, or changes in DA receptor sensitivity at the pituitary level. Supported by BMRS Grant No. 2 S07 RR05806-11 and Research Challenge Funds from the Ohio Board of Regents.

405.8

ULTRASTRUCTURAL LOCALIZATION OF ESTROGEN RECEPTOR-IMMUNOREACTIVITY IN GUINEA PIG HYPOTHALAMUS.
J.D. Blaustein, J.C. Turcotte, X. Gu* and M.N. Lehman. Neuroscience and Behavior Program and Psychology Dept., University of Massachusetts, Amherst, MA 01003 and Dept. Anat. and Cell. Biol., Univ. Cincinnati Coll. Med., Cincinnati, OH 45267

We have reported previously that estrogen receptor-immunoreactivity (ER-IR) in the brain is present most abundantly in cell nuclei. However, contrary to most other reports, using enhancement techniques, we have also detected ER-IR in the perikarya and processes of neurons. To determine the organelles with which ER-IR is associated, we developed a technique for ultrastructural analysis of ER-IR. Ovariectomized guinea pigs were perfused, brains vibratome-sectioned, and estrogen receptors immunostained (with H222 antibody) by a multiple-bridge peroxidase-diaminobenzidine technique followed by silver-gold intensification. Electron microscopic analysis revealed distribution of reaction product throughout cell nuclei and in association with a variety of cytoplasmic structures, including free ribosomes, golgi apparatus, lysosomes, and to a lesser extent rough endoplasmic reticulum. Most surprisingly, ER-IR was found associated with small, clear synaptic vesicles (both round and flattened) and synaptic densities associated with some axon terminals. Although further controls are necessary, this suggests immunostaining of the sites of synthesis of the receptor, as well as previously unsuspected sites of action for estradiol.

TESTOSTERONE REVERSES AGE-RELATED DECLINE IN VASOPRESSIN GENE EXPRESSION IN THE BED NUCLEUS OF THE STRIA TERMINALIS. D. J. Dobie, M. A. Miller, D.M. Dorsa, GRECC, Seattle Veteran's Affairs Med. Ctr. & Univ.of WA., Seattle, WA 98195. To investigate whether the testosterone (T) sensitivity of arginine vasopressinergic (AVP) cells in the bed nucleus of the stria terminalis (BNST) is preserved in aging, in situ hybridization for AVP was performed in 3 mo. old and 24 mo. old male Fischer 344 rats after castration and replacement for 30 days with either physiologic or supraphysiologic doses of T. Control animals underwent sham surgery. In situ hybridization was performed on 20u sections using a 48-base S ^{35} labelled AVP oligonucleotide probe.

Plasma T levels (ng/ml) were lower in 24 mo. than in 3 mo. old controls (24 mo.: 0.14±.013; 3 mo.: 1.9± 0.661; $p<0.05$), and were higher in supraphysiologically replaced 24 mo. animals than in 3 mo. animals (24 mo.: 7.6±0.371; 3 mo.: 6.5±0.168; $p<0.05$). 24 mo. controls had fewer labelled cells in the BNST than 3 mo. controls (sham 3 mo.: 85±4.1; sham 24 mo.: 30±10.6, $p<0.01$). Supraphysiologic T replacement resulted in an increase in number of labelled cells in both 3 mo. and 24 mo. old animals (sham 3 mo. vs. hi T 3 mo.: 122±7.1; $p<0.05$; sham 24 mo. vs. hi T 24 mo.: 131±9.4; $p<0.001$), with no significant differences in total cell number between the two high T groups. Initial data also revealed an increase in labelling intensity in both groups after T replacement. These results suggest that the decline in AVP gene expression in the BNST of aging rats may be due to the reduction of circulating T in these animals.

405.10

CHANGES IN c-fos EXPRESSION IN THE RAT HIPPOCAMPUS AFTER MANIPULATIONS OF THE BRAIN-PITUITARY-GONADAL AXIS. L. Jennes, Department of Anatomy, Wright State University, School of Medicine, Dayton, OH 45435.

The rat hippocampus has been shown to contain specific receptors for estradiol and gonadotropin releasing hormone (GnRH). In order to determine whether estradiol and GnRH affect transcription in the hippocampal target neurons, the number and distribution of c-fos positive cells was examined with immunohistochemistry after various manipulations of the brain-pituitary-gonadal axis. In the untreated rat, c-fos is expressed by a large number of pyramidal cells throughout CA1 through CA4, certain hilar cells as well as by some granule cells of the dentate gyrus. Ovariectomy results in a significant decrease in the number of c-fos immunoreactive cells throughout all areas of the hippocampus while 1 hour after intravenous injection of estradiol (3 ug/100gBW) the number of c-fos positive cells is restored to control levels. Similarly, intraventricular injections of 1-10 ug GnRH into ovariectomized rats result in the induction of c-fos synthesis in a number of hippocampal neurons which is comparable to control animals. The effects of estradiol and GnRH are strongest between 1 and 4 hours after the treatment and they decline gradually over a period of 24 hours. The results suggest that, in the hippocampus, GnRH and estradiol cause an increase in translation which is at least in part mediated by c-fos. Supported by NIH HD 24697.

REGULATION OF HIPPOCAMPAL GLUCOCCORTICOID AND MINERALOCCORTICOID RECEPTOR mRNA EXPRESSION BY SEROTONIN. Jonathan Seckl and George Fink Dept. of Medicine, Western General Hospital and MRC Brain Metabolism Unit, Edinburgh, EH4 2XU, UK.

Corticosteroids bind to hippocampal glucoccorticoid (GR) and mineralocorticoid receptors (MR), thereby affecting mood and neurochemical transmission. There is an extensive serotoninergic (5-HT) innervation of the hippocampus which interacts with corticosteroid-sensitive cells. We investigated the effects of 5,7-dihydroxytryptamine (5,7-DHT; 200µg icv) lesions of 5-HT neurons on hippocampal GR and MR mRNA expression in male rats (200g Wistar) by in situ hybridization using specific ^{35}S-labeled cRNA probes. In controls, GR mRNA was highly expressed in dentate gyrus, CA1 and CA2 neurons, but levels in CA3 and CA4 were significantly lower. 5,7-DHT-lesioned animals showed significantly less GR mRNA in dentate gyrus (76% decrease) CA1 (42% decrease) and CA2 (52% decrease). MR mRNA was highly and similarly expressed in all hippocampal subregions in controls. 5,7-DHT led to a significant decrease in MR expression in CA3 (56% fall) and CA4 (45% fall), but not in other subregions. Conversely, treatment of rats with amitriptyline (20mg/kg.dy), which inhibits monoamine re-uptake, led to a significant increase (23±6%) in total hippocampal MR, but not GR mRNA expression (by quantitative slot blotting) after 48 h. After 14 days both MR (87±27%)and GR (56±18%) expression had increased significantly. We conclude that 5-HT may regulate hippocampal corticosteroid receptor mRNA expression in a site-, type- and time-specific manner.

MINERALOCORTICOID (MR) AND GLUCOCORTICOID (GR) RECEPTORS ARE CO-EXPRESSED IN HIPPOCAMPAL NEURONS M.C.Bohn, E.Howard*, and Z.Krozowski*+. Dept.Neurobiology and Anatomy, Univ. Rochester Med. Ctr., Rochester, NY 14642 and +Prince Henry's Hospital, Melbourne, Australia 3004.

The hippocampus is a major target for glucocorticoid hormones. Previous studies suggest that two receptors are expressed in the hippocampus that bind corticosterone(cort) and are coded for by the MR and GR genes. We have used immunocytochemistry to determine whether neurons in the hippocampus express both receptors. Two polyclonal antisera were used to demonstrate MR-immunoreactivity(IR): MR2, raised against a 16 amino acid synthetic peptide (Endocr.125:192,1989) and MR4,raised against a fusion protein expressed in E. Coli from a construct of glutathione transferase and a 168 amino acid portion of the amino terminus of hMR. A monoclonal antibody against purified liver GR was used to demonstrate GR-IR. Primary hippocampal pyramidal neurons were isolated from E18 rat hippocampus and grown as dissociates.

MR2 and MR4 stained ~100% of pyramidal neurons grown in the presence or absence of serum. In defined medium lacking steroids, MR-IR was observed both in nuclei and cytoplasm and remained in both cellular compartments even after a 30 min. treatment with 10^{-6}M cort. In contrast, GR-IR was barely detectable in serum-free medium, but was present at high levels in cells grown in serum or astrocyte conditioned medium. GR-IR was nuclear in the presence of steroid and cytoplasmic in its absence. Double labeling demonstrated that MR-IR and GR-IR are co-expressed in the majority of pyramidal neurons.

These observations demonstrate that the majority of hippocampal pyramidal neurons co-express MRs and GRs when grown *in vitro* and that different factors regulate expression and cellular localization of the two receptors. Of particular interest is the nuclear localization of MR in the absence of steroid. Since both receptors are expressed in neurons grown in vitro, these systems will be valuable for studying steroid receptor regulation and glucocorticoid regulation of gene expression in the nervous system.

INGESTIVE BEHAVIOR: PEPTIDES II

406.1

RAPID DECREASES IN NEUROPEPTIDE Y (NPY) LEVELS AND RELEASE IN THE PARAVENTRICULAR NUCLEUS (PVN) DURING FEEDING IN RATS ON SCHEDULED FEEDING REGIMEN (SFR). A. Sahu, M.G. Dube, C. P. Phelps and S.P. Kalra, Dept. of Obstet. and Gynecol., University of Florida, Gainesville, FL 32610

Although central administration of NPY readily stimulates feeding in the rat, the pattern of NPY secretion in relation to feeding is not known. We measured NPY concentrations and release from the PVN of adult male rats maintained on 4 h daily food access (1100-1500 h, lights on 0500-1700 h). After 3-4 weeks when body weight and food-intake had stabilized, two experiments were performed. Expt. 1: NPY levels were measured by RIA in 7 microdissected hypothalamic sites of rats on SFR and control rats fed ad libitum. Groups of SFR rats were killed at 1100 h before, and at 1300 and 1500 h after food presentation. Groups of control rats were killed at the same time. In SFR rats, NPY levels in the PVN only were elevated at 1100 h, and steadily decreased to the control range within 2 h after food presentation. Expt. 2: The pattern of PVN NPY release in vivo was correlated with these dynamic changes in PVN NPY concentrations. Push-pull cannulae (PPC) were implanted in the region of the PVN and 1-3 weeks later rats were perfused via the PPC from 1100-1500 h with artificial CSF. Perfusates collected at 10 min intervals were assayed for NPY levels. In control rats, NPY levels in the PVN perfusate were low and remained stable throughout the 4 h-period. However, the secretion of NPY was higher than in controls in SFR rats at the time of food presentation, and thereafter it decreased steadily to reach the control range within 2 h. Collectively, these results show that both NPY levels and release in the PVN are elevated at the onset and decreased during the course of feeding in SFR rats. Consequently, we propose that increased neurosecretory activity in the PVN NPY may play an important role during scheduled feeding (supported by NIH DK 37273).

406.2

FOOD DEPRIVATION INCREASES NEUROPEPTIDE Y (NPY) SECRETION IN THE PARAVENTRICULAR NUCLEUS (PVN): A PHYSIOLOGICAL ROLE FOR NPY IN FEEDING BEHAVIOR IN THE RAT. S.P. Kalra, A. Sahu, M.G. Dube, C. P. Phelps and P.S. Kalra, Dept. of Obstet. and Gynecol., University of Florida, Gainesville, FL 32610

NPY is the most potent orexigenic peptide known. To ascertain whether it is a physiological signal in evoking normal feeding, we studied NPY secretion under conditions that enhance appetite. Our previous studies showed that NPY concentrations changed only in the PVN region in accordance with the change in feeding pattern. Food deprivation (FD) increased and ad libitum feeding returned NPY concentrations to the normal range. We have now assessed NPY secretion in vivo from the PVN of FD and control ad libitum fed rats. Adult male rats were implanted with push-pull cannula (PPC) and 6-8 days later one-half of the rats were FD for three days; water was available ad libitum. On the day of experiment, the PPC assembly was attached to infusion pumps and the PVN was perfused with artificial CSF. After 50 min. of stabilization for baseline, perfusates were collected at 10 min intervals for 60-90 min. Thereafter, FD and control rats received a measured amount of food and sampling continued for an additional 3 h. In the control group, NPY concentrations in the PVN perfusate before and after food presentation, varied between 59-111 pg with an overall mean of 66.7 ± 15.9 pg/10 min. In contrast, NPY concentrations in the FD group were markedly elevated (3-fold) before and after food supply; levels ranged between 121-259 pg with an overall mean of 191.8 ± 23 pg/10 min ($p < 0.01$). The increased PVN NPY secretion in FD rats was associated with 5.3 ± 0.4 g food intake during the collection period. These studies show for the first time that food deprivation increases not only the NPY levels, but also the release of NPY in the PVN. These findings are in accord with our proposal that NPY is a physiological signal responsible for eliciting sustained food intake in FD rats (supported by NIH DK 37273).

406.3

POTENCY OF PEPTIDE YY ANALOGUES FOR STIMULATION OF FEEDING AND IN COMPETITION FOR [^{125}I]-PYY BINDING SITES IN THE HINDBRAIN. E.S. Corp, M. Curcio* and G.P. Smith. Bourne Lab, New York Hospital-Cornell Med. Ctr. White Plains, NY 10605

The relative rank order of potency (ROP) of PYY, NPY and PYY 13-36 to stimulate food intake (90-min test) in nondeprived rats (n=6) following fourth ventricular injection was compared with the ROP of these peptides to compete for saturable [^{125}I]-PYY binding sites in three regions of the hindbrain implicated in ingestion: the area postrema (AP), nucleus tractus solitarius (NTS), and the reticular formation (RF). We report the extrapolated ED_{50} of peptides to stimulate food intake and the IC_{50} values determined from equilibrium-binding experiments coupled with quantitative receptor autoradiography.

	FEEDING ED_{50} (pmole)	BINDING IC_{50} (nM)		
		AP	NTS	RF
PYY	50	0.7	2.2	0.2
NPY	100	1.2	2.5	3.1
PYY 13-36	>2400	31.1	37.0	7.2

The ROP of peptides to stimulate food intake most resembles their ROP to compete for [^{125}I]-PYY binding in the AP. This suggests the AP as a target for the action of PYY and NPY in feeding. Moreover, the lack of potency of the selective Y_2 agonist PYY 13-36 suggests that the feeding response is mediated by a different PYY-receptor subtype (Y_1, most likely). The greater competitive potency of PYY 13-36 in the RF, compared with its competitive potency in the AP and NTS, suggests that the RF is a region enriched with Y_2 receptors.

Supported by: NIH DK08181 and a St. Lukes-Roosevelt Obesity Core Center grant (ESC) and MH15455 and MH00149 (GPS).

406.4

INTRAPORTAL PANCREATIC GLUCAGON INFUSIONS FAIL TO REDUCE SPONTANEOUS MEAL SIZE IN HEPATIC VAGOTOMIZED RATS. N. Geary, J. Le Sauter, U. Noh*. Psychology Dept., Columbia Univ., NY, NY 10027.

Remotely controlled, meal-contingent intraportal infusions of pancreatic glucagon reduce the size of rats' spontaneous meals both early and late in the dark phase. Glucagon administration also inhibits elicited feeding during test meals, and under some conditions, this is blocked by selective vagotomy of the hepatic branch of the vagus. We investigated whether glucagon's effect on spontaneous feeding is also dependent on the hepatic vagus. Hepatic-vagotomized and neurologically intact rats were intraportally infused with 13.6 µg (.034 ml/min x 2 min) glucagon or vehicle as they began the first spontaneous meal 9 h after dark onset. Glucagon failed to inhibit feeding after hepatic vagotomy:

	Meal Size (g, m + se)	
	Intact (n=15)	Vagotomized (n=13)
Vehicle	3.6 + 0.3	3.3 + 0.4
Glucagon	2.4 + 0.2*	3.0 + 0.2

*p < .01 vs. vehicle, ANOVA & Bonferroni test

We conclude that the hepatic branch of the subdiaphragmatic vagus is necessary for the satiety effect of exogenous glucagon on spontaneous feeding late in the dark phase.

406.5

BLOCKADE OF THE CENTRAL BOMBESIN (BN) RECEPTORS ENHANCES FOOD INTAKE IN PREFED RATS.

Z. Merali[1], T.W. Moody[2] and D.H. Coy[3]. [1]Psychology & Pharmacology, Univ. of Ottawa, Ontario, K1N 9A9. [2]Biochemistry, George Washington Univ. Washington D.C. 20037. [3]Dept. of Medicine, Tulane Univ. New Orleans, LA 70112.

BN-like peptides have been found to induce satiety-like state in several species including rat, fowl, mouse, pig, baboon and man. A definitive test of the involvement of endogenous BN-like peptides in feeding behavior has been hindered by a lack of potent and selective BN antagonist(s). We have previously shown that ΨLeu^{13,14}-BN can block suppression of food intake induced by exogenous BN. In second messenger assays, ΨLeu^{13,14}-BN also antagonized the ability of BN to elevate cytosolic Ca^{++}. The current study attempted to determine if and under what conditions this antagonist would antagonize/postpone satiety. Male Sprague-Dawley rats (350 to 400g), were food deprived for 17 hr, administered the antagonist (icv) and then given access to food (standard rat chow pellets) for 60 min 'test meal'. In this paradigm blockade of the central BN receptors (with 0.5 to 20 ug ΨLeu^{13,14}-BN, icv) did not significantly enhance the size of the test meal. In the next set of experiments, the rats were first allowed to prefeed (for 45 min) and then administered ΨLeu^{13,14}-BN, followed by presentation of the 60 min 'test meal'. In this case, blockade of the central BN receptors significantly enhanced the consumption of the 'test meal'. This increment in food intake was dose-dependent, starting at the 10 ug dose and reaching maximal effect at the 20 ug dose. In vitro autoradiographic studies revealed that ^{125}I-Tyr^4-BN bound with IC_{50} value of 100 and this binding was greatly reduced in the presence of 1 uM ΨLeu^{13,14}-BN, particularly at various hypothalamic nuclei. This, to our knowledge, is the first report to illustrate enhancement of food intake following blockade of the central BN receptors. The data support the contention that endogenous BN-like peptides may play a role in regulation of food intake. (Supported by MRC).

406.6

THE SATIATING EFFECT OF BOMBESIN IS MEDIATED BY RECEPTORS PERFUSED BY THE COELIAC ARTERY. T.C. Kirkham, J. Gibbs and G.P. Smith. The NY Hospital-Cornell Medical Center, White Plains, NY 10605 USA

We have suggested that the satiety action of exogenous, peripherally administered bombesin (BBS) may be mediated by the stomach (Gibbs and Smith, 1982). To assess this possibility, male Sprague Dawley rats were surgically prepared with chronic arterial catheters. Catheter tips were sited within either the coeliac a. (n=9) or superior mesenteric a. (n=6). Two min prior to 60-min feeding tests (liquid diet: 40% v/v BioServ), nondeprived rats received bolus infusions (1 ml kg^{-1} over 10s) of 0.15M NaCl or BBS (Bachem; 1, 2 or 4 µg kg^{-1}). A separate group of unoperated rats (n=6) was tested after i.p. injection of the same doses.

Maximum suppression of intake was observed after 15 min of testing. Examination of the data revealed that over this interval, BBS delivered into the coeliac a. had markedly greater satiating potency than via other peripheral routes (order of potency: coeliac > sup. mesenteric a. = i.p.). The table shows mean (±SEM) per cent reduction at 15 min produced by BBS by each route (* p<.05, ** p<.01: significantly different from coeliac value at the same dose).

	Dose (µg kg^{-1})		
Route	1	2	4
coeliac a.	35.3 (6.1)	55.3 (8.8)	61.5 (7.9)
sup. mesenteric a.	8.6 (9.1)**	27.8 (12.5)**	22.9 (11.8)**
intraperitoneal	20.4 (11.3)	20.3 (5.7)**	35.3 (8.1)**

Since equivalent doses of BBS produce significantly more inhibition of food intake when administered into the coeliac a. than into the superior mesenteric a., we conclude that receptors mediating the satiating effect of BBS are concentrated in the abdominal organs perfused by the coeliac artery. These organs include the stomach, proximal duodenum, pancreas and liver.

CCK-A BUT NOT CCK-B ANTAGONIST ATTENUATES SUPPRESSION OF FOOD INTAKE BY EXOGENOUS CCK OR INTRAINTESTINAL OLEATE. L.A. Brenner and R.C. Ritter. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520.

We have reported that suppression of sham feeding by intraintestinal oleate is attenuated by the CCK type A (CCK-A) receptor antagonist, MK-329, suggesting that endogenous CCK, acting at type A receptors, participates in suppression of feeding by oleate. Recent reports suggest, however, that CCK type B (CCK-B) receptors also participate in control of food intake. Therefore, we are comparing the efficacy of the CCK-A receptor antagonist (MK-329) with that of the CCK-B antagonist (L-365,260) for their ability to attenuate suppression of feeding by exogenous CCK or intraintestinal oleate infusion. MK-329 at a dose of 0.37 µmol/kg abolished suppression of real feeding by intraperitoneal CCK-8 (2 µg/kg). An equivalent dose of L-365,260 had no effect on suppression of feeding by CCK-8. In confirmation of our previous finding, 1.47 µmol/kg MK-329 abolished suppression of sham feeding by intraintestinal oleate. L-365,260 at doses of 0.37, 0.74 or 1.47 µmol/kg failed to attenuate suppression of sham feeding by oleate. These data support the conclusion that systemic injection of exogenous CCK suppresses feeding via CCK-A receptors. Likewise, our results suggest that suppression of sham feeding by intraintestinal oleate is mediated by endogenous CCK, acting at type A receptors. Supported by NIH grant NS20561.

COMPARATIVE EFFECTS OF CHOLECYSTOKININ (CCK-A) RECEPTOR ANTAGONIST L 364718 AND CCK-B RECEPTOR ANTAGONIST L 365260 ON SOLID FOOD INTAKE IN RATS. RD Reidelberger, G Varga*, TE Solomon*. Dept Physiol and Med, Univ Kansas Med Sch, Kansas City, KS 66103; VA Med Ctr, Kansas City, MO 64128.

Cholecystokinin's (CCK) role as an important physiological satiety factor has been supported recently by studies showing that the selective CCK-A receptor antagonist L 364718 stimulates food intake in several species. The inhibitory effect of CCK on feeding has generally been thought to be mediated by CCK-A rather than CCK-B receptors, because L 364718 blocks suppression of feeding by exogenous CCK-8, and because the selective CCK-B agonist desulfated CCK-8 has no effect on food intake when administered centrally or peripherally. It was recently reported, however, that the selective CCK-B antagonist L 365260 is 100 times more potent than L 364718 for stimulating feeding and preventing satiety in partially satiated rats (C. T. Dourish et al., *Science* 1989). Thus, the role of CCK-B receptors in control of food intake is not clear. In the present study we compared the dose-response effects of L 364718 and L 365260 on food intake during the dark period in ad libitum feeding rats. Male, Sprague Dawley rats (300–400 g) were adapted to a reversed light cycle (lights off from 1000–2200 h) and provided excess ground rat chow daily at the beginning of the dark period. Rats received L 364718 (0, 1, 10, 100, 1000 µg/kg ip) or L 365260 (0, 0.1, 1, 10, 100, 1000, 10,000 µg/kg ip) 2 h after lights off. Food intake was measured 1.5, 3.5, and 5.5 h later. L 364718 significantly stimulated 1.5-h food intake by ~40% at 10 µg/kg and higher doses; cumulative intake at 3.5 and 5.5 h remained elevated by ~20% at 1000 and 100 µg/kg, respectively. In contrast, L 365260 had no significant stimulatory effect on feeding at any dose. ***Conclusion***: These results suggest that CCK interacts with CCK-A receptors to produce satiety during the dark period in ad libitum feeding rats.

406.9

TYPE A AND B CHOLECYSTOKININ (CCK) RECEPTORS IN THE INHIBITION OF FOOD INTAKE PRODUCED BY EXOGENOUS AND ENDOGENOUS CCK. T.H. Moran, P.J. Ameglio* and P.R. McHugh. Department of Psychiatry, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Recent work has suggested a role for an endogenous central release of CCK acting at type B CCK receptors in the control of food intake. In an effort to investigate whether the mechanism by which peripheral CCK inhibits food intake is through the stimulation of a central CCK release, we examined the ability of the A (MK-329) and B (L-365,260) CCK antagonists to block the inhibition of glucose consumption in a 1 hr test produced by an IP injection of 4 ug/kg of CCK in 6 hr deprived rats. At 15 minutes, increasing dosages (10 - 100 ug/kg) of the type A antagonist resulted in a blockade of the inhibition of intake produced by CCK. At 60 minutes, when the effect of exogenous CCK was no longer present, 100 ug/kg of the A antagonist significantly increased glucose consumption above baseline levels. Thus, not only were the effects of exogenous CCK blocked by the A antagonist, but the effects of endogenous CCK were antagonized as well (with this deprivation, rats enter the test with chow in their stomachs). In contrast, no dose (10 - 1000 ug/kg) of the B antagonist blocked the inhibitory action of the exogenous CCK at 15 or 30 min nor resulted in increased intake at 60 min. These results demonstrate that the effects of exogenous CCK are not mediated through type B CCK receptors and that the A antagonist can stimulate intake in situations in which the B antagonist cannot. (Supported by DK19302)

406.10

EFFECT OF CHOLECYSTOKININ (CCK-8) ON GASTRIC PRESSURE AND REPORT OF GASTRIC FULLNESS IN WOMEN. P.M. Melton, H.R. Kissileff, and F.X. Pi-Sunyer*. Obesity Research Center, St. Luke's-Roosevelt Hospital & Columbia University.

CCK-8 may affect food intake by augmenting neural activity from the distended stomach, thereby amplifying satiety signals (Muurahainen, N. et al., Physiol. & Behav., 44: 645-649, 1988). In order to test the hypothesis that gastric pressure changes are involved in amplifying satiety signals, a gastric balloon was inflated in the stomach of each of four women with CCK-8 (112 ng/min) or saline infusion. Balloons were inflated to 500 ml or to the maximum volume tolerated by the subject. When the balloon was inflated to 500 ml, there were no differences in gastric pressure between the CCK-8 and saline conditions. Nonetheless, ratings of fullness were higher with CCK-8 administration (5.75) than with saline administration (4.50). Unexpectedly, the volume tolerated with CCK-8 infusion (859 ml) was slightly larger than with saline infusion (695 ml). The pressure rise, however, was significantly smaller with CCK-8 (8.0 cm) than with saline (11.8 cm). The slope of the relation between fullness ratings and gastric pressure was significantly steeper when CCK-8 was infused. In addition, gastric contractions were practically abolished with CCK-8 infusion. CCK-8 appears to relax the stomach and at the same time sensitize it to gastric pressure.

406.11

SPECIFIC INSULIN ANTIBODIES INCREASE FOOD INTAKE IN RATS WHEN CHRONICALLY INFUSED INTO THE VENTROMEDIAL HYPOTHALAMUS. M.K. McGowan, K.M. Andrews* and S.P. Grossman. Committee on Biopsychology, University of Chicago, Chicago, IL 60637.

We (McGowan, M.K., et al., Behav. Neurosci. 104:371, 1990) have shown that chronic intrahypothalamic (IH) infusion of insulin results in dose-dependent decreases in body weight and food intake. In order to determine whether exogenous insulin is acting on an endogenous insulin-receptive system, we infused specific insulin antibodies (IRI Ab) or 0.9% saline into the ventromedial hypothalamus in rats. Experimental animals received IH saline for 1 wk followed by IRI Ab (3.0 μUeq/hr) for 1 wk. Control animals received IH saline for 2 weeks. Experimental animals' daily food intake (FI) during saline infusion was not significantly different from controls'. Experimental animals' daily FI increased during IRI Ab infusion compared to their FI under saline infusion (from 25.4±1.35 g to 29.3±1.14 g, $t=2.23$, $p<0.05$) and to controls' (25.0±1.04 g, $t=2.78$, $p<0.01$). In the wk which followed IRI Ab infusion, experimental animals' FI decreased to 27.8± 1.65 g/day, a level which is not significantly different either from their FI during saline infusion or from controls' (25.6±0.80 g/day). These data provide further evidence that the hypothalamus contains an insulin-sensitive system which is involved in food intake regulation.

406.12

SATURABLE TRANSPORT OF PLASMA INSULIN INTO THE CENTRAL NERVOUS SYSTEM (CNS). M.W. Schwartz, S.E. Kahn*, G.J. Taborsky Jr.*, R.N. Bergman*†, and D. Porte, Jr.* Dept. of Medicine, Univ. of Washington, Seattle WA 98195 and †Dept of Physiology and Biophysics, U.S.C., Los Angeles, CA 90024.

The ability of plasma insulin (I) to enter the brain and to modify food intake has been implicated in body weight regulation. By mathematical modeling of kinetic data, we have recently shown that plasma I enters cerebrospinal fluid (CSF) only after traversing an intermediate compartment, which we hypothesize to be brain interstitial fluid (ISF) (Clin Res. 38:125A, 1989). Thus, the primary route of I entry into CSF may be across the blood-brain barrier (BBB) endothelium, rather than the blood-CSF barrier. To test the hypothesis that this uptake occurs via a saturable transport process, we studied anesthetized dogs (n=16) maintained euglycemic during i.v. infusion of I for 2.5 hrs to achieve stable plasma levels of I ranging from 80-3500 μU/ml. The kinetics of uptake of I from plasma into CSF over 7.5 hours were analyzed with a model that permitted calculation of the rate (V) at which plasma I enters the intermediate compartment (brain ISF) (data as $\bar{x} \pm$ SEM):

Plasma I (μU/ml)	122±2	207±6	705±56	2553±274
V (μU/min)	18.1±4.3	20.5±6	67±5	134±33

These data demonstrate Michaelis-Menten type (i.e., saturable) kinetics; i.e., a 20-fold increase in the plasma level produced only a 7.5-fold rise in the transport rate. Lineweaver-Burk analysis revealed a V_{max} of 75 μU/min and K_M of 3-4 nM, similar to the K_D of the I receptor.

We conclude that plasma I is transported into the CNS via a saturable process. I receptors located on the BBB endothelium are likely to mediate this transport.

LONG-TERM POTENTIATION V

407.1

INCREASE IN THE PROPORTION OF PERFORATED AXOSPINOUS SYNAPSES INDUCED BY LONG-TERM POTENTIATION (LTP). Y. Geinisman, L. deToledo-Morrell and F. Morrell. Dept. of CMS Biol., Northwestern Univ. Med. Sch. and Depts. of Neurol. Sci. and Psychol., Rush Med. Coll., Chicago, IL 60611.

Previous work using biased methods for synapse quantitation failed to consistently demonstrate an LTP-induced increase in synaptic numbers which could underlie a sustained augmentation of synaptic efficacy during LTP. This study was designed to reexamine the issue with the aid of an unbiased technique. Young adult rats were implanted with stimulating electrodes in the medial perforant path and recording electrodes in the hilus of the ipsilateral dentate gyrus. Potentiated animals (n = 7) were stimulated (with fifteen 20 ms bursts of 400 Hz delivered at 0.2 Hz) on each of 4 consecutive days and sacrificed 1 hr after the fourth stimulation. Unpotentiated but stimulated (coulombic controls) and unstimulated but implanted rats served as controls (n = 7 in each). The number of synapses per neuron was estimated in the middle molecular layer of the dentate gyrus using the disector technique. Results showed that the induction of LTP was not accompanied by any increase in the total number of synapses on dendritic shafts or spines. Further subdivision of axospinous synapses into perforated (with a discontinuous postsynaptic density, PSD) and nonperforated (with a continuous PSD) ones revealed a marked (24 and 38%) and statistically significant ($p < 0.02$) increase in the proportion of perforated to nonperforated synapses in potentiated animals compared to unstimulated and coulombic controls, respectively. This alteration is similar to, though less prominent than, the synaptic restructuring described for rats kindled through the same pathway (Geinisman et al., *Brain Res.*, 1990, *507:* 325). It suggests that the structural synaptic modifications underlying LTP may be viewed as an initial stage of those that ultimately lead to kindling.

Supported by Grants AG 08794 from NIA and BNS-8819902 from NSF.

407.2

SELECTIVE REDUCTION IN THE AVERAGE SIZE OF PERFORATED POSTSYNAPTIC DENSITIES IN LONG-TERM POTENTIATION (LTP). L. deToledo-Morrell, Y. Geinisman and F. Morrell. Depts. of Neurol. Sci. and Psychol., Rush Med. Coll. and Dept. of CMS Biol., Northwestern Univ. Med. Sch., Chicago, IL 60612.

Sustained enhancement of synaptic efficacy characteristic of LTP could be associated with an enlargement of the postsynaptic density (PSD) which is the site of greatest concentration of postsynaptic neurotransmitter receptors and ion channels. Previous studies provided conflicting results regarding the effect of LTP on PSD dimensions. Earlier work was based on the use of random sections in which synapses cannot be accurately identified and sampled. To circumvent these problems, we undertook a serial section study. Young adult rats were implanted with stimulating electrodes in the medial perforant path and recording ones in the hilus of the ipsilateral dentate gyrus. Potentiated animals (n = 7) were stimulated (with fifteen 20 ms bursts of 400 Hz delivered at 0.2 Hz) on each of 4 consecutive days and sacrificed 1 hr after the fourth stimulation. Unpotentiated but stimulated (coulombic controls) and unstimulated but implanted rats served as controls (n = 7 in each). Unbiased PSD samples were obtained from the middle molecular layer of the dentate gyrus using the disector technique. For each PSD sampled, all profiles were measured in serial sections to assess the PSD maximal profile length and the area of the PSD plate (Brændgaard & Gundersen, *J. Neurosci. Meth.*, 1986, *18:* 39). The only significant change found in potentiated rats was a selective diminution of PSD dimensions in perforated axospinous synapses with discontinuous PSDs (but not in nonperforated ones with continuous PSDs or in synapses on dendritic shafts). We propose that the process of synaptic remodelling in which nonperforated synapses with relatively smaller PSDs are converted into perforated ones may be intensified by LTP. Thus, the reduction in the mean size of perforated PSDs may reflect an increase in the number of newly formed and immature perforated synapses.

EFFECT OF URETHANE ANESTHESIA ON LONG-TERM POTENTIATION, PARTIAL KINDLING, AND KINDLING-INDUCED POTENTIATION IN THE PERFORANT PATH-DENTATE GYRUS CIRCUIT OF THE RAT. D. P. Cain, F. Boon* and E. L. Hargreaves. Dept. of Psychology, Univ. of Western Ontario, London, N6A 5C2, CANADA.

Urethane anesthesia is commonly used in studies of LTP, but it blocks amygdala kindling (Life Sci, 1989, 44:1201). In order to study the relation between LTP, kindling and kindling-induced potentiation we administered urethane (1.5 or .75 g/kg) to rats that carried perforant path (PP) stimulating and dentate hilus recording electrodes. Urethane had a strong attenuating effect on LTP of the pop spike ($p<.005$), reducing LTP to <30% of that of saline controls, although there was significant LTP under urethane. Urethane had a dose-related suppression effect on growth of 4 ADs subsequently elicited at hourly intervals in the same rats by stimulation of the PP. The 1.5 g/kg rats failed to exhibit any partial kindling. Partial kindling failed to augment the pop spike and had a significant suppressant effect on the amplitude of the previously potentiated pop spike in the control rats. These data suggest a dissociation between the effect of urethane on LTP and partial kindling in the same brain structure. Supported by NSERC/Canada.

ANOXIA DOES NOT ABOLISH LTP. Y. Xu and K. Krnjević. Anaesthesia Research Dept., McGill University, Montréal, P.Q., Canada H3G 1Y6.

Anoxia grossly disrupts cognitive function, and can produce retroactive amnesia. It was therefore of interest to see how anoxia affects long-term potentiation (LTP) in hippocampal slices. In experiments on slices from Sprague-Dawley rats, EPSP fields were evoked in areas CA1, CA3 and the dentate gyrus by stimulating the appropriate afferent pathways. LTP was elicited by two brief tetani (100 Hz for 1 s, separated by 20s). It was manifested by a near
50% enhancement of the EPSP field, which persisted during further periods of recording of at least 30-60 min. Anoxia (N_2 was substituted for O_2 in the aerating gas) typically lasted 3 min, long enough for nearly complete (>90%), but reversible, suppression of synaptic responses. When tetanic stimulation was applied during anoxia, LTP consistently failed to develop. But if anoxia was applied 5-30 min after the end of tetanic stimulation - when LTP had appeared - the temporary suppression of EPSPs was followed by a return to the potentiated level. Findings were similar in all three regions, CA1, CA3 and the dentate gyrus.

FREE RADICALS ACCELERATE THE DECAY OF LONG-TERM POTENTIATION (LTP). G. E. Hollinden, J. M. Sarvey, and T. C. Pellmar, Physiology Dept., AFRRI and Dept. of Pharmacology, USUHS, Bethesda, MD 20814.

Previous studies have shown that H_2O_2 ($\geq$ 0.005%) generates free radicals in slices of hippocampus and impairs synaptic transmission and spike generation. In the present study we evaluated the sensitivity of long term potentiation to free radical damage.

A bipolar stimulating electrode was positioned in s. radiatum of guinea pig hippocampal slices. Population spikes (PS) and synaptic potentials (pPSP) were recorded from s. pyramidale and s. radiatum of field CA1. LTP was produced by high frequency stimulation (HFS; 100 Hz, 1 sec) at a stimulus strength that produced a half-maximal PS. Tissue was treated with a concentration of H_2O_2 (0.002%) that had no apparent effects on evoked responses.

In untreated slices (n=17) LTP was sustained for at least 60 min but in slices treated with H_2O_2 (n=16) potentiation of both PS and pPSP decayed. H_2O_2 treatment beginning 5 min after HFS had no effect on LTP (n=9). Washout of H_2O_2 following HFS allowed some but not total expression of LTP (n=16). Short-term potentiation ($\leq$15 min) was unaffected by H_2O_2 exposure.

These data suggest that free radicals prevent maintenance of potentiation by interfering with a process during the induction phase of LTP.

EFFECTS OF CHRONIC ETHANOL EXPOSURE ON LONG TERM POTENTIATION IN THE CA1 REGION OF THE HIPPOCAMPUS. M.F. Tremwel and B.E. Hunter, Dept. of Neuroscience, University of Florida, Gainesville, FL 32610.

Chronic ethanol treatment (CET) results in a depressed ability to induce long term potentiation (LTP) of the population spike (PS) in the CA1 region of the hippocampus. This study examined the effects of CET on the synaptic component (population excitatory post-synaptic potential (EPSP)) of LTP. We compared the relative contribution of EPSP versus PS potentiation after CET. Ethanol-treated (E) and control (S) groups were fed a liquid diet containing either ethanol or sucrose for 28 weeks followed by an 8 week abstinence period. Hippocampal slices were prepared and extracellular field recordings obtained from area CA1 of the hippocampus. A stimulating electrode was placed in stratum radiatum (SR) and parallel recording microelectrodes were placed in SR and stratum pyramidal (SP). To study the characteristics of EPSP and PS LTP induction, we applied a series of high frequency stimulus trains of increasing duration. Stimulus strength was maintained at PS threshold. Following each conditioning train, recordings were obtained from SR and SP until EPSP and PS values returned to baseline. LTP was assessed by comparing the EPSP slope and PS amplitude after the conditioning train with the baseline values obtained in the absence of high frequency stimulation.

CET altered the relationship between EPSP and PS potentiation during induction of LTP. These results suggest that the mechanisms involved in the induction are susceptible to the toxic effects of CET. Current research is aimed at examining specific components of the induction process to determine the mechanism by which CET alters LTP.

ADRENAL STEROIDS, LONG-TERM POTENTIATION AND DEPRESSION. D. Filipini*, K. Gijsbers*, M.K. Birmingham* and B. Dubrovsky. Dep. of Psychiatry, McGill Univ. Montréal QC H3A 1A1.

Previous work (Dubrovsky et al "Steroids and Neural Activity" CIBA Symposium 153) revealed that adrenal steroids and their ring-A reduced metabolites can affect short as well as long-term, such as LTP, neuronal activity. The present report extends these results showing that LTP recorded from the granular cell layer of the dentate gyrus of ADX rats after tetanic stimulation of the perphorant path, was affected as follows:

18-OH-deoxycorticosterone, produced a marked decrease of the EPSP's values and arrested the PS LTP at every time post-tetanic stimulation (PT) compared to the injection of vehicle (V), Nutralipid 10%. Its 21-acetate moderately decreased the EPSP and had no effect on the PS. Deoxycorticosterone (DOC) also decreased all EPSP's values while the PS was reduced in the first 30' PT. Corticosterone (B), decreased both the EPSP and PS for the first 15' and 30' PT respectively. B-acetate, showed initial decrease of the EPSP and no effect on the PS. Allotetrahydro-DOC showed almost no effect on LTP but an inital enhancement of the PS. Allotetrahydro-progesterone, decreased all EPSP's values and had no effect in the PS development in comparison with V.

As therapeutic implication of this work, steroid modulation of a putative memory mechanism, we have treated depressed patients with adrenal gland hyperactivity and memory biasing by adrenal supression with ketoconazole, a steroid synthesis inhibitor. Preliminary results revealed a fast relief of the severe mood disturbances in five (5) patients.

MU BUT NOT DELTA OPIOID RECEPTOR ANTAGONISTS BLOCK THE INDUCTION OF LONG-TERM POTENTIATION AT THE MOSSY-FIBER CA3 SYNAPSE OF THE RAT HIPPOCAMPUS IN VIVO. D.N. Lieberman, B.E. Derrick, and J.L. Martinez, Jr. Department of Psychology, Univ. of California, Berkeley, CA 94720

Previously we reported that the opioid receptor antagonist naloxone prevents induction of mossy fiber (MF)-evoked, but not commissurally (COM)-evoked LTP recorded in the CA3 region, without affecting baseline responses in either pathway. In this study, we found that local application to the CA3 pyramidal layer of $Cys^2, Tyr^3, Orn^5, Pen^5$amide (CTOP), an antagonist selective for mu opioid receptors, did not affect baseline field EPSP responses evoked extracellularly in either the MF or COM afferents in pentobarbital anesthetized animals. One µmol CTOP prevents induction of MF-, but not COM-, evoked LTP following two 100 Hz 1 sec conditioning trains. Naltrindole hydrochloride (NTI), an antagonist selective for delta opioid receptors, in quantities of 1 and 10 µmols did not impair induction of LTP in either the MF or COM pathway. These data suggest that mu, but not delta, opioid receptor activation may be required for induction of LTP at the MF-CA3 synapse in vivo. Norbinaltorphimine, an antagonist selective for kappa opioid receptors, at quantities equimolar to CTOP and NTI, affected baseline responses in both pathways, and therefore a role for kappa receptors in induction of MF-CA3 LTP cannot be excluded. Supported by DA04195, DA05374, and the Rennie Fund.

AGE-DEPENDENT EFFECTS OF SEX STEROID HORMONES ON HIPPOCAMPAL LTP IN VITRO. K.L. SKINKLE*, K-I. ITO*, W.L. SALINGER AND T.P. HICKS, Dept. of Psychology, UNC-Greensboro, Greensboro, NC, 27412-5001.

Wistar rats of both sexes, ranging in age from 18 days to adulthood were decapitated and the dissected hippocampi were sliced and maintained in vitro following standard procedures. Long-term potentiation (LTP) of CA1 responses was induced following brief tetanic stimulation (100 Hz, 1 s) of the Schaffer collateral-commissural pathway. There was no suppression evident of the magnitude of the LTP of evoked CA1 population spikes in adult (3 mo.) males or females using a concentration of 10^{-8} M 17-ß estradiol (ß-E). By contrast, in 4-wk-old animals of both sexes, ß-E (10^{-8}M) potently, rapidly, reversibly, and dose-dependently suppressed LTP. There was no observed suppressant effect of progesterone (10^{-8}M) or testosterone (10^{-8}M) on LTP from animals of this age. 3-wk-old hippocampi from females exhibited similar suppressant effects of ß-E, but the steroid appeared significantly less potent on these younger animals. Tamoxifen (10^{-6} M), an anti-estrogen compound that has effects upon intracellular ß-E recognition sites, was without effect in diminishing the suppressant effect of ß-E (10^{-8}M) on 4-wk-old females. These data suggest a possible age-dependent role of ß-E in modulating the efficacy of synaptic mechanisms underlying hippocampal LTP during a critical developmental period.

THE NON-NMDA COMPONENT OF LTP IN THE CA1 AREA OF RAT HIPPOCAMPAL SLICES. K-I. Ito*, K.L. Skinkle*, K. Takeda* and T.P. Hicks, Dept. of Psychology, UNC-Greensboro, NC, 27412.

Ever since the observations of Collingridge et al. (1983), it has been recognized that long-term potentiation (LTP) requires the activation of a subtype of receptors for excitatory amino acids (EAAs), the N-methyl-D-aspartate (NMDA) receptors. Antagonists that are selective pharmacologically for these NMDA receptors comprise 2 major classes: ω-phosphonic α-carboxylic acids (eg: AP5; D-2-amino-5-phosphopentanoate) and D-monoamino dicarboxylic acids (eg: DαAA, D-α-aminoadipate). LTP incluced by brief, high-frequency stimulation (HFS, 100 Hz, 1 s) of the Schaffer collateral-commissural pathway of hippocampal slices from rats was suppressed partially by DαAA at relatively low (200 μM) as well as at relatively very high (1 mM) doses. By contrast, as has been reported by Collingridge et al. (1983), the relatively more potent NMDA-selective antagonist, AP5 (30-50 μM), suppressed LTP completely. To test if the incomplete suppression of LTP by DαAA was due simply to its lower potency at NMDA receptors, intracellular recording was used to contrast these doses of DαAA and AP5 on NMDA-elicited responses. Both AP5 (30-50 μM) and DαAA (200 μM) suppressed completely depolarizations induced by NMDA (10 μM). Brief HFS failed to establish LTP when the slice was perfused with a mixture of DαAA (200 μM) and DNQX (10 μM), this latter compound acting to block selectively non-NMDA receptors. Thus LTP can be established, at least partly, solely by activation of AP5-insensitive EAA receptors; raising the intriguing possibility of the existence of 2 pharmacologically distinct NMDA receptors. Supported by the Human Frontiers in Science Program.

DELTA OPIOID RECEPTOR BUT NOT NMDA RECEPTOR ACTIVATION IS REQUIRED TO INDUCE LTP OF SYNAPTIC TRANSMISSION IN THE LATERAL PERFORANT PATH

C.R. Bramham*[1], N.W. Milgram[2], and B. Srebro*[1]. [1]Department of Physiology, U. of Bergen, N-5009 Bergen, Norway, and [2]Life Sciences Department, U. of Toronto, Ontario M1C 1A4, Canada.

Rats were anesthetized with urethane and implanted with a stimulus electrode in either the lateral (LPP) or medial (MPP) division of the perforant path-granule cell projection, under electrophysiological control. The fascia dentata was perfused with oxygenated krebs via a push-pull cannula, while two attached electrodes recorded evoked potentials in the granule cell and molecular layers. Tetanization of the LPP or MPP elicted robust LTP in rats perfused with standard medium. In the MPP, trains given during perfusion with medium containing AP5 (50 uM), a NMDA receptor blocker, failed to produce LTP. In the LPP, however, AP5 prevented population spike potentiation without affecting the synaptic, EPSP component of LTP. Further, the opioid receptor antagonists naloxone and ICI 174,864 (delta selective; 0.1 uM), while having no effect on single-pulse transmission, blocked both EPSP and population spike LTP of the LPP. The mechanism of LTP in the LPP illustrates peptidergic control of activity-dependent synaptic plasticity in brain.

RECEPTOR MECHANISMS OF OPIOID ENHANCEMENT OF LONG-TERM POTENTIATION IN THE LATERAL PERFORANT PATH. C.W.Xie and D.V.Lewis. Pediatric Neurology, Duke Univ.Med.Center, Durham,NC27710.

Opioid effects on the induction of long-term potentiation (LTP) in the lateral perforant path (LPP) were investigated on rat hippocampal slices. High frequency stimuli (100Hz,1s) delivered to the LPP terminals in the outer molecular layer of the dentate induced LTP of the orthodromic population spike (OPS) and population EPSP slope recorded from the granule cell layer and molecular layer. Bath application of naloxone (1-10 μM), or combined application of the selective mu (β-FNA,10μM) and delta antagonist (ICI 174,864, 20μM) significantly reduced the LTP of both OPS and EPSP. β-FNA (10μM) but not ICI 174,864 (20μM) alone blocked LTP of EPSP. Either of them alone only slightly reduced LTP of OPS. The mu agonist PLO17 (0.3-1 μM) reduced the threshold and increased the amount of LTP of OPS. Its effects were completely antagonized by 1 μM naloxone and the NMDA antagonist D-APV (100μM). These findings suggest that endogenous opioids released during high frequency stimuli facilitate LTP at the LPP synapses through both mu and delta receptors. Supported by NS22170.

SACCHARIN BLOCKS THE INDUCTION OF LONG-TERM POTENTIATION (LTP) IN THE HIPPOCAMPUS. W. Morishita, S. S. Chirwa, P. May*, Z. Xie and B. R. Sastry. Neurosci. Res. Lab., Dept. of Pharmacology, The Univ. of B. C., Vancouver, Canada, V6T 1W5.

Tetanic stimulation of stratum radiatum in guinea pig hippocampal slices induces a long-term potentiation (LTP) of the population spike recorded in the CA1 region. In the present study the ability of saccharin to interfere with this induction was examined. When tested in dose ranges of 2.5 to 20 mM (applied for 5-10 min, n=6 for each dose), Na saccharin did not significantly alter the size of the population spike. When the drug (10 mM, 10 min) was applied during the tetanic stimulation (400 Hz, 0.5 s) of stratum radiatum, LTP was not observed (population spike control size: 1.11 ± 0.33 mV; 30 min after tetanus: 1.13 ± 0.47 mV, n=9). In the same slices, a subsequent tetanus given in the absence of saccharin clearly caused LTP (population spike 30 min post-tetanus: 2.84 ± 0.44 mV). The amplitude of the EPSP in Mg-free medium containing CNQX (10 μM, n=4) was not significantly altered by saccharin (10 mM). In a medium containing 2-amino-5-phosphonovalerate (25 μM, n=4), however, the EPSP was slightly decreased during saccharin application. These results indicate that the blockade of the induction of LTP by saccharin is not through an antagonism at the NMDA receptors. (Supported by grants from the Canadian MRC and Glaxo Research Labs.)

STUDIES ON ENDOGENOUS SUBSTANCES THAT INDUCE LONG-TERM POTENTIATION (LTP). Z. Xie, W. Morishita, T. Kam*, H. Maretic* and B. R. Sastry. Neurosci. Res. Lab., Dept. of Pharmacology, The Univ. of B. C., Vancouver, Canada, V6T 1W5.

Fluid samples collected during a tetanic stimulation of the rabbit neocortical surface, cause LTP in guinea pig hippocampal slices. In the present study, these samples were separated into various fractions according to molecular weights. Applications of 2 ml of <3, 3-10 or >50 kD, but not of 10-25 or 25-50 kD, fractions on guinea pig hippocampal slices induced LTP (stratum radiatum stimulation-induced population spike in the CA1 area recorded 60 min after drug application as a % of control: <3 kD: 127.75 ± 10.65, n=10; 3-10 kD: 136.875 ± 9.11, n=8; 10-25 kD: 93.13 ± 20.45, n=8; 25-50 kD: 101.38 ± 9.99, n=8; >50 kD: 155.25 ± 10.25, n=8). The EPSP was potentiated without a significant change in the membrane potential and input resistance (n=6). 2-Amino-5-phosphonovalerate (25 μM) did not block the induction of LTP by these substances (n=6). Gel-electrophoresis (1 & 2 D) of the samples revealed the presence of peptides. Samples collected from rabbits pretreated with MK-801 (0.5 mg/kg ip) did not induce LTP (n=6). Tetanic stimulation in hippocampal slices, however, induced LTP in the presence of samples from rabbits pretreated with MK-801 (n=6). These results suggest that the release, but not the LTP-inducing effect, of the endogenous substances involves NMDA receptor activation. (Supported by grants from the Canadian MRC and Glaxo Res. Labs.)

SYNAPTIC PLASTICITY IN THE AVIAN HIPPOCAMPUS. A.Wieraszko, G.F. Ball, Department of Biology and Department of Psychology, Boston College, Chestnut Hill, MA 02167.

Long-term potentiation (LTP) is a stimulation-evoked, persistent increase in synaptic efficiency. LTP, which has been considered to be a neuronal mechanism underlying memory is most pronounced in the hippocampus. Although there has been recently a great deal of interest in the hippocampus and memory in birds, LTP has not yet been described in the avian hippocampus. We present here studies on synaptic plasticity and LTP in avian hippocampus. Extracellular recordings from hippocampal slices of female song sparrows (Melospiza Melodia) were taken using standard techniques. The evoked responses were much smaller and less stable as compared to those found in the mammalian hippocampus. These responses were calcium-dependent proving their synaptic origin. Frequency potentiation could not be demonstrated. Paired-pulse facilitation showed inhibition of the second response at latencies below 20 ms and facilitation at 30 ms. Train stimulation with 20 Hz evoked a stable increase in the size of the evoked response lasting approximately two hours. This increase was classified by us as LTP. These data indicate that the avian hippocampus possesses several properties typical for the mammalian hippocampus including a most intriguing one-LTP.

NEURONAL DEATH: LESION STUDIES

408.1

MORPHOMETRIC ANALYSIS OF THE CEREBELLAR NUCLEI IN LURCHER MUTANT MICE. J. A. Heckroth, Terre Haute Center for Medical Education, Indiana University, Terre Haute, IN 47809.

Mutant gene expression in lurcher mutant mice causes the postnatal cell death of the entire population of cerebellar Purkinje cells. The cerebellar nuclei, while reduced in size, are reported to contain a normal number of neurons (Caddy and Biscoe (1979), Phil Trans Roy Soc Lond B, 287:167). The volume of the cerebellar nuclei in normal and lurcher mice has been estimated utilizing planimetric measurements of evenly spaced coronal sections. In both normal and lurcher mice the interposed nucleus comprises about 50% of the total nuclear volume, with the fastigial and dentate nuclei representing about 25% each. The lurcher fastigial and interposed nuclei are each reduced in volume by about 65%, while the dentate nucleus is reduced by only 53%. The volume fraction (V_V) of the nuclei occupied by neuronal somata and by neuropil has been estimated by the stereological point counting method. Neuronal somata occupy about 10% of the volume of the normal interposed and fastigial nuclei, and about 20% of the homologous subdivisions in lurcher. The volume fractions, combined with the total volume estimates, suggest that in the lurcher interposed and fastigial nuclei the total volume of neuronal somata is reduced by about 25% from normal, while the volume of neuropil is reduced by about 75% from normal. The relatively large reduction in the volume of neuropil may be attributed to the absence of Purkinje cell axons and terminals, and a reduction in the dendritic arbors of nuclear neurons. The neuronal volume reduction is apparently the result of smaller neuronal somata in lurcher. Further stereological measurements to determine the individual contributions of axonal, terminal, and dendritic losses to the total reduction of the lurcher cerebellar nuclear neuropil are underway.

IMMUNOLOGICAL ACTIVATION OF GLIAL CELLS IN EARLY POSTNATAL RATS AFTER SCIATIC NERVE CRUSH. W.J. STREIT and T. MORIOKA. Depts. of Neuroscience and Neurological Surgery, University of Florida, Gainesville, FL 32610.

We have examined the glial reaction accompanying motor neuron death following sciatic nerve crush in the newborn rat using a panel of monoclonal antibodies directed against brain macrophage antigen (ED2) and various immunomolecules, i.e. Ia antigen (OX-6), complement receptor (OX-42), CD4 antigen (W3/25), and leucocyte common antigen (OX-1). These antigens were found to be mostly absent from the normal neonatal rat CNS, but their rapid appearance, except for ED2, was stimulated after sciatic nerve crush in the neuropil around spinal motor neuron degeneration. Cell types expressing immunomolecules within days after axotomy were perivascular and microglial cells, and thus like in the adult. However, while in the adult the expression of immunomolecules on these cell types takes a gradual and prolonged time course lasting several months, in the neonate enhanced immunoreactivity at the lesion site could no longer be detected 2 weeks after nerve section. Our results therefore show that immunocompetent cells are present in the immature rat CNS, but their activation is of more rapid onset and briefer duration than in the adult. (Supported by NIH/NINCDS PO1NS27511).

408.3

ONSET OF REACTIVE ASTROGLIOSIS IN THE LATERAL GENICULATE NUCLEUS (LGN) OF INFANT AND ADULT CATS. R.E. Kalil. Center for Neuroscience, Univ. of WI, Madison, WI 53706

Following a lesion of visual cortex, LGN neurons undergo retrograde degeneration, which is accompanied by a series of responses in local astrocytes, known as reactive astrogliosis. One outcome of this reaction is that astrocytes become phagocytic and remove neuronal debris. Previously, we (Kalil et. al.,'89) compared the time course of reactive gliosis at birth or in adulthood by using a monoclonal antibody against glial fibrillary acidic protein (GFAP) to monitor the intensity of the gliotic reaction at survival times that ranged from 1 day to 26 wks.

This work now has been extended by combining GFAP immunocytochemistry with electron microscopy to focus on the earliest reactions of LGN neurons and astrocytes to a unilateral lesion of visual cortex made in newborns or adults. In neonates, GFAP+ astrocytes are evident in the LGN at 1 day postlesion; neurons in advanced degeneration are seen at 3 days. However, this sequence possibly is confounded by the fact that LGN astrocytes on the unoperated side of the brain also are GFAP+ in neonates. By contrast, normal LGN astrocytes in adult cats rarely are positive for GFAP, but display strong immunoreactivity at 1 day postlesion, before degenerating neurons are observed. These results suggest, therefore, that reactive astrogliosis in the LGN may be triggered by a signal that precedes the onset of overt neuronal degeneration.

RESPONSES OF BRAIN MACROPHAGES TO INDUCED CELL DEATH IN THE VISUAL SYSTEM OF NEONATE AND ADULT RATS. C.E.Milligan, P.Levitt and T.J.Cunningham. Dept. of Anatomy. Medical College of PA, Philadelphia, PA 19129.

The response of brain macrophages (BMOs) to induced cell death was examined in neonate and adult Long Evans rats. Lesions to the visual cortex of infant and adult rats induce cell death in the ipsilateral dorsal lateral geniculate nucleus (dLGN). BMOs are localized using the ED-1 monoclonal antibody antigen, which recognizes all cells of the rat monocyte/macrophage lineage, but not microglia. At no time throughout normal postnatal development or in the normal adult are BMOs localized in the dLGN. After infant lesions, the entire nucleus degenerates completely by four days. BMOs are first observed among numerous pyknotic cells 48 hours following the lesion. They are large round cells and reach maximum levels four days after the lesion, completely occupying the nucleus. In adults, similar lesions to the visual cortex result in a much more protracted period of degeneration. Furthermore, subpopulations of cells located in different regions of the nucleus degenerate at different rates. The timing of appearance and location of BMOs in the dLGN correspond to the spatiotemporal pattern of degeneration in the nucleus. However, the cells are fusiform shaped and highly branched, unlike those found after infant lesions. These results suggests that the timing of BMO invasion is strictly controlled by degenerating elements. The acquisition of distinct morphologies may reflect the constraints imposed by the brain parenchyma on their invasion at different ages. (Supported by NS16487 from NINCDS.)

STUDIES RELATED TO THE USE OF COLCHICINE AS A NEUROTOXIN IN THE SEPTOHIPPOCAMPAL CHOLINERGIC SYSTEM: I. SPECIFICITY OF ACTION. S. R. Ginn and G. M. Peterson. Dept. of Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858.

Previous research has indicated that, in the medial septum, colchicine is toxic to neurons immunoreactive for choline acetyltransferase (ChAT), but not glutamic acid decarboxylase (GAD). In addition, a profound deficit in acetylcholinesterase- (AChE) positive fibers is observed in the hippocampal formation, especially in the dentate gyrus and the temporal pole of the hippocampus. Here we report the results of several studies designed to more fully elucidate this colchicine-induced toxicity in the septohippocampal cholinergic system. Except as indicated below, female Sprague-Dawley rats (200-250 g) received intracerebroventricular (ICV) injections of 2.5 μl 0.4% colchicine in saline unilaterally into the right lateral ventricle, adjacent to the body of the fornix. Following a survival period of 1, 2 or 3 weeks the rats were perfused through the ascending aorta with saline followed by ice-cold 4% paraformaldehyde in phosphate buffer (pH 7.4). Brain tissue was cut on a sliding microtome in a 1-in-5 series throughout the septum and hippocampus. Colchicine significantly reduced the numbers of choline acetyltransferase- (ChAT) immunoreactive neurons in the medial septum (MS) at all survival times, and the effect appeared to be progressive (i.e., more cell loss occurred at longer survival times). In addition, the pattern of AChE fiber staining in the hippocampus was disrupted in a time-dependent manner. However, even at the longest survival period, GAD-immunoreactive neurons in the medial septum were unaffected by ICV colchicine injections. Injections of colchicine (0.4% in 1 μl saline) confined to the body of the fornix produced effects similar to ICV colchicine injections: i.e., a reduction in the number of ChAT-immunoreactive neurons in the medial septum and AChE-positive fibers in the dentate gyrus and hippocampus. The results of these experiments indicate that colchicine is an effective and specific neurotoxin for septohippocampal cholinergic neurons when injected into either the lateral ventricles or the fimbria-fornix.

408.6

STUDIES RELATED TO THE USE OF COLCHICINE AS A NEUROTOXIN IN THE SEPTOHIPPOCAMPAL CHOLINERGIC SYSTEM. II. MECHANISM OF ACTION. G. M. Peterson and S. R. Ginn. Dept. of Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858.

Colchicine disrupts microtubules by binding free tubulin, resulting in the blockade of axoplasmic transport. To determine if this mechanism of action mediates colchicine-induced toxicity of septohippocampal cholinergic neurons, the fluorescent dye Fluoro-Gold (50 nl 2% FG) was injected into 2 sites within the ventral hippocampus. Thirty minutes later 2.5 μl of 0.4% colchicine or its inactive isomer, lumicolchicine, was injected into the right lateral ventricle. One week later brains were fixed by perfusion with paraformaldehyde and cut on a sliding microtome throughout the medial septum and hippocampus. Both FG- and ChAT-labeled cells were significantly reduced in the medial septum following colchicine injections, but were not affected by lumicolchicine, indicating that colchicine does disrupt axoplasmic transport mechanisms in septohippocampal neurons, and that this loss of transport is related to the toxic effect. In a related study the effect of colchicine on the transport of nerve growth factor (NGF) was examined. It is thought that the loss of cholinergic neurons in the medial septum results from the colchicine-induced blockade of the axoplasmic transport of NGF from the hippocampus. In support of this hypothesis we have found that hippocampal levels of NGF increase 200% over controls 2 weeks following colchicine injections (ELISA of NGF conducted by Dr. K. A. Crutcher at the Univ Cincinnati Med Ctr). As an additional test of this hypothesis, ^{125}I-NGF was injected bilaterally into 2 sites in each hippocampus and 2.5 μl 0.4% colchicine was injected into the right lateral ventricle. Twenty-four hours later paraformaldehyde-fixed brains were embedded in parafin, cut on a rotary microtome and processed for autoradiography. The number of radiolabeled neurons was dramatically reduced in the medial septum ipsilateral to the injection indicating that colchicine blocked the transport of ^{125}I-NGF. Thus, these studies suggest that colchicine is toxic to septohippocampal cholinergic neurons because it blocks the axoplasmic transport of nerve growth factor.

PROTEOLYSIS OF BRAIN SPECTRIN PRECEDES THE DEGENERATION OF SEPTAL NEURONS FOLLOWING FIMBRIA-FORNIX TRANSECTION. J.M. Roberts-Lewis, C. DiCocco*, S.L. Meyer, M.E. Lewis and R. Siman. Cephalon, Inc., West Chester, PA 19380.

Acute injuries or degenerative diseases of the CNS result in the structural degradation of damaged neurons, and synaptic reorganization of surviving neurons. These morphological changes have been attributed to the activity of proteases in the CNS. For example, the calcium-dependent proteolysis of brain spectrin (fodrin) by calpain I has been proposed to constitute a requisite step in the intracellular cascade by which excitatory amino acids induce neuronal death. In order to evaluate the possible role of spectrin proteolysis in mediating the death of septal neurons after transection of the fimbria-fornix, we have used immunoblot analysis to measure spectrin breakdown in homogenates from septum and hippocampus at 1, 7 and 14 days after unilateral transection of the fimbria-fornix. Spectrin breakdown products were detected in the septum, but not hippocampus, at 7 and 14 days after transection of the fimbria-fornix. There was no evidence of spectrin breakdown in either septum or hippocampus 24 hours following fimbria-fornix transection. The appearance of spectrin breakdown in the septum occurs before any apparent structural degeneration of septal perikarya. These findings suggest that proteolysis of this cytoskeletal protein may be an early event in the cascade that ultimately leads to the destruction of these neurons in the absence of NGF. We are currently evaluating the effects of NGF treatments on the appearance of spectrin breakdown in the septum after fimbria-fornix transection.

CORTICAL CYTOLOGY IMPROVES QUANTITATIVELY IN INFANTILE HYDROCEPHALIC ANIMALS AFTER SURGICAL DECOMPRESSION. J.P. McAllister, L.M. Sharpe* and P.M. Hale.* Depts. Anatomy & Neurosurgery, Temple U.Sch. Med., Philadelphia, PA 19140.

As a sequel to our previous descriptive analyses, the present study has quantified the effects of ventriculomegaly on the immature cerebral cortex. Hydrocephalus was induced in 4-11 day old kittens by intracisternal injection of kaolin; some hydrocephalic animals received ventriculoperitoneal shunts 10-14 days post-kaolin. Hydrocephalic animals (n=4) were sacrificed at 16-44 days post-kaolin and shunted animals (n=3) at 11-30 days post-shunt. Nissl-stained sections from cortical areas 17 and 22 were analyzed light microscopically with Bioquant software. Compared to saline-injected controls (n=5), cortical thickness in hydrocephalics decreased 80% and 70% in areas 17 and 22, respectively. The number of neurons per 10 sq.μm increased 27-33% in laminae V-VI and 12-55% in layers II-IV. A consistent 35-48% decrease in soma size was most pronounced in layers V-VI. After shunting cortical thickness and soma size returned to near or above control levels; neuronal density returned either to control levels or remained about 14% low. More improvement was found in area 17 than 22. These results indicate that hydrocephalus causes severe alterations in cortical cytology but that shunting can promote neuronal recovery. Supported by HD21527 to JPM.

MORPHOLOGY OF CAUDATE NUCLEUS CHANGES AFTER PRENATAL UNILATERAL NEOCORTICAL LESION.
L.D. Loopuijt*, J.R. Villablanca and D.A. Hovda, Mental Retardation Research Center, UCLA, Los Angeles, CA 90024-1759.

4 Fetal cats (E43-48) received a small lesion in frontal (3x) or parietal (1x) cortex and were sacrificed as young adults. Coronal, thionin stained sections of these brains were used for calculation of caudate volume, determination of neuron and glia number per unit volume and measurement of surface areas of neuron somas by means of computerized morphometrics. Compared to weight matched controls (N=2), the volume of the ipsilateral caudate (being 8-13% larger than the contralateral) was larger by 36-42%, whereas the contralateral caudate was 20-30% larger. The cell packing density was similar for both sides, except for 1 cat, where the density was higher ipsilateral (P 0.05, sign test). In 2 cats the average neuronal soma area was 15-30% smaller (P 0.05, t-test) in the ipsilateral, compared to the contralateral caudate. The increase in caudate volume with preservation of cell packing density means that the caudate contains a larger amount of cells. It contrasts with the shrinkage in volume of thalamus and cortex. ANTEROGRADE TRANSPORT IN AXOTOMIZED CORTICOSPINAL NEURONS.
M.K. Garver, R.L. McBride and E.R. Feringa. Dept. of Neurology, Medical College of Georgia and Dept. of Veterans Affairs Med. Ctr., Augusta, GA 30910.

We measured slow and fast anterograde transport in proximal corticospinal axons 5, 10, and 20 weeks after complete T-9 spinal cord transection. We studied slow transport in three groups of 10 transected and 10 control rats each. 100 μCi of ^{3}H proline were injected into motor cortex 3, 8 or 18 weeks following cord transection; 14 days later the rats were perfused and a 5 mm segment of spinal cord (15 mm from the obex) was removed, solubilized, and scintillation counted. For fast transport, proline was injected 5 or 10 weeks after transection followed by perfusion 24 hours later.

Slow transport in transected rats vs controls was increased at 5 weeks (5990±757 DPM [mean±SEM] vs 3576±363, $p<0.01$), but was normal at 10 weeks (5136±933 vs 6452±1385) and at 20 weeks (2312±243 vs 2430±621). Fast transport in transected rats was not significantly different from controls at either 5 weeks (3087±402 vs 2677±353) or 10 weeks (2681±343 vs 2843±146). We conclude that slow transport is increased at 5 weeks, and is normal at 10 and 20 weeks. Fast transport is not changed 5 or 10 weeks after cord transection.

AXOTOMIZED CORTICOSPINAL NEURONS CANNOT BE RETROGRADELY LABELED WITH FLUORO-GOLD ONE YEAR AFTER SPINAL CORD TRANSECTION. R.L. McBride, W.B. Harper* and E.R. Feringa. Dept. of Veterans Affairs Med. Ctr. and Dept. of Neurology, Medical College of Georgia, Augusta, GA 30910.

Corticospinal tract neurons axotomized by T-9 spinal cord transection lose their ability to be retrogradely labeled with horseradish peroxidase; at 10 weeks after transection, 25% can be labeled, and by one year, only 7%. In contrast, at 20 weeks after transection, retrograde labeling of these neurons with Fluoro-Gold is unimpaired. To determine the long term effects of axotomy on retrograde labeling with Fluoro-Gold, we transected the spinal cord of 10 7-week-old female rats at T-9. One year later, a cotton pellet soaked in Fluoro-Gold was placed into a new transection site at T-1; matched controls were treated similarly. Four days later, the rats were perfused. The mean number of labeled corticospinal neuronal somata was 1919±93 (mean ± SEM) in controls and 1337±137 in transected rats, a decrease of 30% ($p<0.01$). The loss of labeling was confined to the cortical area representing the distribution of hindlimb upper motoneurons. This study provides further evidence for long-term, gradual deterioration of axotomized corticospinal neurons. Supported by the Dept. of Veterans Affairs and Medical College of Georgia.

408.12

ONE YEAR AFTER SPINAL CORD TRANSECTION, RETROGRADE LABELING OF RUBROSPINAL NEURONS WITH FLUORO-GOLD IS DECREASED. W.B. Harper*, R.L. McBride and E.R. Feringa. Dept. of Veterans Affairs Med. Ctr. and Dept. of Neurology, Medical College of Georgia, Augusta, GA 30910.

One year after a T-9 spinal cord transection, fewer corticospinal neurons can be retrogradely labeled with Fluoro-Gold from the T-1 level than in control rats. To determine if a similar decrease occurs in axotomized rubrospinal neurons, we assessed the number and size of red nucleus neurons which could be labeled with Fluoro-Gold. We transected the spinal cord at T-9 in ten seven-week-old female rats. After one year, we placed a cotton pellet soaked with Fluoro-Gold into a new transection site at T-1. Four days later, the rats were perfused. Non-transected matched controls were treated similarly. The red nucleus is topographically organized, with the caudal portion projecting primarily to the lumbar spinal cord. We found a significant decrease (29%, $p<0.05$) in the number of Fluoro-Gold-labeled neurons in the caudal part of the nucleus in transected rats compared to controls, but no significant change in the rostral part. Labeled neurons rostrally were 19% smaller in transected rats; caudally, neurons were 40% smaller. The decrease in number of rubrospinal neurons labeled with Fluoro-Gold is comparable in magnitude to the decrease in labeled corticospinal neurons. Supported by DVA and MCG.

DEATH BY DEAFFERENTATION: THE ROLE OF MITOCHONDRIA IN AUDITORY NEURON SURVIVAL FOLLOWING COCHLEA REMOVAL. G. E. Hyde and D. Durham. Departments of Otolaryngology and Biological Structure, RL-30, University of Washington, Seattle, WA 98195.

Removal of excitatory input to second-order auditory neurons (n. magnocellularis, NM) in the chick brain stem results in the death of ~20% of the neurons at 5 days survival. In a study of ultrastructural changes in NM neurons following cochlea removal, we found a dramatic proliferation of mitochondria in the majority of ipsilateral NM neurons (Hyde & Durham, Soc. Neurosci. Abstr. *15*:290, 1989). However, we found a subpopulation of NM neurons with early degenerative changes which did not show mitochondrial proliferation. To test the hypothesis that mitochondrial proliferation is necessary for neuronal survival following cochlea removal, we used chloramphenicol, a mitochondrial protein synthesis inhibitor, to block mitochondrial proliferation after cochlea removal in 2-week-old chicks.

We administered chloramphenicol at the rate of 1000 mg/kg/day for either 6, 12, or 24 hours following cochlea removal. After 5 days survival, animals were deeply anesthetized and sacrificed. NM neuron counts were made in 10μm Nissl-stained paraffin sections; the NM neurons contralateral to cochlea removal serving as a within-animal control. In animals treated 6 hours with chloramphenicol, we found no enhanced neuronal death ipsilateral to cochlea removal compared to vehicle-treated animals ($p>.60$). However, in animals treated for either 12 or 24 hours with chloramphenicol, we found a significant increase in ipsilateral neuronal death (65% loss, $p<.05$). Thus, we conclude that mitochondrial proliferation becomes critical to auditory neuron survival between 6 and 12 hours after the removal of excitatory input. PREDICTING INDIVIDUAL VARIATIONS IN DEGENERATION OF HIPPOCAMPAL DENTATE NEURONS FOLLOWING ADRENALECTOMY

Edward J. Roy, Diane M. Lynn,* and Charles W. Bemm*
Psychology Dept., University of Illinois, Champaign, IL 61820

Corticosterone appears to have two markedly different effects on cells of the hippocampus in rats. On one hand, elevated levels of corticosterone contribute to the degeneration of pyramidal cells. On the other hand, elimination of corticosterone by adrenalectomy may cause degeneration of dentate granule cells (Sloviter et al., 1989). However, the latter response is highly variable. Low levels of corticoids from accessory adrenal tissue not detectable by radioimmunoassay may provide sufficient hormone to maintain granule cell viability. We describe simple measures that predict which individual adrenalectomized rats have degeneration of the granule cell layer. Body weight gain after adrenalectomy is correlated with granule cell layer area at sacrifice three months after surgery ($r = 0.747$, $n = 15$, $p < 0.001$). Also, short term loss of body weight when saline drinking water is replaced with tap water predicts the degree of degeneration of the granule cell layer ($r = -0.642$, $n = 15$, $p < 0.001$). The maximal effect we observed was a 64% reduction in the area of the granule cell layer. These observations may aid further study of this striking effect of adrenal hormones on brain anatomy.

DEVELOPMENT AND PLASTICITY—VISUAL SYSTEM: MOLECULAR AND CELLULAR MECHANISMS II

VISUALLY INNERVATED AUDITORY CORTEX IN FERRETS GENERATES VISUAL RESPONSE PROPERTIES SIMILAR TO THOSE IN NORMAL VISUAL CORTEX. A. W. Roe, S. L. Pallas, Y. H. Kwon, and M. Sur. Dept. of Brain & Cognitive Sci., M.I.T., Cambridge, MA 02139.

We are examining how a cortical area of one sensory modality might process sensory input of another modality, by routing visual inputs to primary auditory cortex (A1) in ferrets. In neonatal ferret pups, normal retinal targets (LGN and SC) are removed and the auditory thalamus deafferented. Retinal fibers consequently innervate the auditory thalamus and thereby provide visual input to A1.

We have recorded electrophysiologically the visual response properties of single cells in A1 of lesioned animals reared to adulthood, and compared in detail the responses with those in primary visual cortex (V1) of normal animals. Visual units in A1 have longer latencies to optic chiasm stimulation (n=390, $\bar{x}$=7.0 msec) compared to cells in V1 (n=93, $\bar{x}$=4.9), a finding consistent with our previous observation that retinal input to the auditory pathway arises primarily from retinal W cells (Sur et al., Science 242:1437, 1988). Visual units have larger receptive fields in A1 ($\bar{x}$=11.6°) than in V1 ($\bar{x}$=4.4°) and generally poorer responsiveness. Ocular dominance in both V1 (n=57) and A1 (n=88) is highly skewed towards the contralateral eye. The proportions in A1 of simple (32%), complex (28%), and non-oriented (40%) cells are similar in general to those in V1. Of a smaller population of cells (n=17 in A1, 15 in V1) examined quantitatively, the degree of orientation tuning and orientation tuning widths are very similar, as is the degree of direction tuning.

These results demonstrate that following specific neonatal lesions, auditory cortex can produce visual cortical receptive field properties similar to those found in normal visual cortex. Our data are consistent with the interpretation that sensory cortices normally employ stereotypical circuits to perform equivalent transformations on the input they receive, or perhaps that modality-specific circuits can be induced in cortex by afferents during development.

CORTICAL BINOCULAR INTERACTIONS IN NORMAL AND STRABISMIC MONKEYS. J. Ni*, E. L. Smith III, Y. M. Chino, K. Kitagawa*, M. L. J. Crawford. College of Optometry, University of Houston, TX 77204-6052.

Previous studies have demonstrated that experimentally induced strabismus causes dramatic alterations in cortical ocular dominance in young monkeys. When monocular stimulation techniques are employed, the majority of cortical neurons respond exclusively to one eye. However, strabismic humans exhibit robust inhibitory binocular interactions. The purpose of this study was to determine if any binocular interactions could be revealed in the striate cortices of strabismic monkeys when stimuli are presented to both eyes simultaneously.

Extracellular, microelectrode recording techniques were used to investigate the sensitivity of cortical neurons to the relative binocular spatial phase of dichoptic grating stimuli (Ohzawa and Freeman, 1986). In normal monkeys (n=5), the responses of simple cells varied systematically with relative spatial phase; the disparity tuning functions typically included both facilitatory and inhibitory responses. Some complex cells also exhibited phase specific responses. However, in most cases complex cells were not selective for relative binocular phase, but their binocular responses were larger than either monocular response. Our studies of monkeys reared with an optically induced strabismus (n=3), revealed two major differences. In addition to an increase in the number of neurons that demonstrated no binocular interactions, there was a substantial increase in the proportion of neurons that demonstrated inhibitory responses under binocular conditions at all spatial phases.

409.3

DEVELOPMENT OF NEURAL CONNECTIONS BETWEEN TRANSPLANTED LATERAL GENICULATE NUCLEUS AND HOST VISUAL CORTEX IN THE RAT. T. Kurotani*, N. Yamamoto* and K. Toyama. Department of Physiology, Kyoto Prefectural University of Medicine, Kawaramachi-Hirokoji, Kamigyo-ku, Kyoto 602, Japan.

Development of neural connections between the transplanted fetal lateral geniculate nucleus (LGN) and the neonatal host visual cortex (VC) was studied electrophysiologically in VC slices including transplanted LGN. Current source density (CSD) analysis of the field potentials and study of intracellular responses in VC under LGN stimulation indicated that monosynaptic connections from LGN to VC cells were established broadly in layers II-VI, while polysynaptic connections remained poorly developed in preparations of 1 week after transplantation. LGN stimulation also produced antidromic responses in a large fraction (57%) of VC cells in layers II-VI. In preparations of more than 3 weeks after transplantation, monosynaptic connections were restricted to layers IV and VI, while polysynaptic connections appeared in layers II-III and V. Efferent cells projecting to LGN became less numerous (18%) and restricted to layers V and VI. Corresponding results were obtained by morphological study using antero- and retrograde labelling with a fluorescent dye (DiI, Molecular probe). In summary, development of afferent and efferent connectivities in transplant preparations was characterized by formation of transient excessive projections and succeeding selection of the appropriate connections.

Long-term potentiation and depression in kitten visual cortex studied *in vivo*. H. Tamura*, Y. Hata and T. Tsumoto. Dept. Neurophysiol., Biomed. Res. Ctr., Osaka Univ. Med. Sch., Kitaku, Osaka, 530 Japan.

Long-term potentiation (LTP) or depression (LTD) of visual cortical responses to stimulation of the optic nerve (ON) could be induced by tetanic stimulation of ON of the same or the other side, respectively, in kittens during "critical period" of postnatal development (Tsumoto and Suda, Brain Res., 168, 190, 1979). In the present study, we addressed a question of what conditions are optimal to induce such homosynaptic LTP and heterosynaptic LTD, in 4-8 week-old kittens anesthetized with N_2O and Halothane. Extracellular field potentials to test shocks applied alternatively to each optic nerve at 0.1 Hz were recorded simultaneously from the primary visual cortex of both hemispheres. Tetanic stimulation applied to ON at 5 Hz for 1 or 5 min failed to induce LTP but longer tetanus (15-60 min) could induce LTP and LTD. Since afferent spontaneous activity was suggested to play a role in visual cortical plasticity (Stryker and Harris, J. Neurosci., 6, 2117, 1986), retinal neuronal activities were blocked by an intraocular injection of tetrodotoxin (TTX). After the TTX injection, homosynaptic LTP could more easily be induced but heterosynaptic LTD could not be induced at all. These results suggest that afferent spontaneous activity may play a role in induction of LTP and LTD in kitten visual cortex.

NON-HEBBIAN SYNAPSES IN RAT VISUAL CORTEX. A.Kossel (1), T.Bonhoeffer (2) and J.Bolz (1). (1) Friedrich-Miescher Labor der Max-Planck Gesellschaft, and (2) Max-Planck Institut für biologische Kybernetik, 7400 Tübingen, FRG.

It has been demonstrated experimentally that synaptic connections in the visual cortex can be modified by correlated activity of pre- and postsynaptic cells, as predicted by a classical model proposed by Hebb. These studies also found that the synaptic enhancement was restricted to only those inputs which were active simultaneously with the postsynaptic cell. We investigated whether the enhancement remains also spatially confined to only those postsynaptic neurons which had been coactivated with the presynaptic fibers.

Double intracellular recordings were performed in slices from the visual cortex prepared from 2-4 week old rats. The two cells were lying close to each other (distance<200 μm), but they were not synaptically connected. Stimulating electrodes were placed in the white matter and short current pulses (ISI = 4sec) were applied to yield subthreshold EPSPs in both cells. Synaptic enhancement was induced by pairing stimulation of the input fibers with intracellular depolarization of one of the two recorded cells. The other cell was not depolarized. In all 4 out of 15 experiments, in which we could potentiate the synaptic responses of the paired cell, the responses of the second cell were also reinforced. Control experiments with a third extracellular recording electrode showed that the strengthening does not extend throughout the whole slice. Our results indicate that in contrast to the Hebbian rule, synaptic enhancement is not restricted to the paired cell, but spreads to neighboring neurons. This effect could be relevant during the development of the cortex: adjacent cells will tend to assimilate their functional properties. This in turn might lead to clustering of cells with similiar response properties, a common organizing principle of the cortex.

409.6

SYNAPTOGENESIS COMPLEMENTS ASSOCIATIVE SYNAPTIC MODIFICATION IN A MODEL OF THE DEVELOPMENT OF OCULAR DOMINANCE. C.M. Colbert, S.M. Friedman*, and W.B Levy Dept. of Neurosurgery, Box 420 Med. Ctr., Univ. of Virginia, Charlottesville, VA 22908.

Experience plays a central role in establishing neuronal properties and connectivity in the developing nervous system. In most activity-based neural network models, activity shapes the network through associative modification of existing synapses. Here we report on a model in which activity governs the formation of synapses as well as modification of existing synapses. The rules governing synaptogenesis are different than the associative modification rules. The synaptogenesis rules are based on both physiological and anatomical investigations in a number of systems, including the neuromuscular junction, the superior cervical ganglion, the lateral geniculate nucleus, the superior colliculus, and cerebral cortex. These studies imply that distinct presynaptic and postsynaptic mechanisms, in tandem, govern synaptogenesis. Once a synapse is formed, its efficacy is governed by a form of associative synaptic modification that has been observed in the hippocampus and in visual cortex.

To verify the validity of the model, we simulated the development of ocular dominance in the kitten under normal and experimental conditions including 1) strabismus, 2) monocular visual deprivation, 3) monocular visual deprivation with muscimol infused into visual cortex, and 4) monocular visual deprivation with APV infused into visual cortex. The simulations produced histograms of ocular dominance consistent with experimentally observed distributions.

EFFECTS OF APV AND NMDA ON TECTAL CELL ACTIVITY IN XENOPUS. W.J. Scherer* & S.B. Udin. Dept. of Physiol., SUNY, Buffalo, NY 14214.

Chronic blockade of NMDA receptors with APV prevents matching of binocular tectal maps in eye-rotated Xenopus during the critical period, and chronic infusion of NMDA restores this plasticity in post-critical period Xenopus. In order to assess whether APV or NMDA produce these effects by altering tectal cell firing activity, we have tested the output of a subset of tectal axons which project to the nucleus isthmi. We treated one tectal lobe with a drug and recorded responses to light flashes from single, crossed isthmo-tectal units in the opposite tectal lobe. Chronic treatment with the NMDA antagonist APV did not alter tectal cell activity in critical period Xenopus when compared to age-matched controls. Chronic NMDA treatment in post-critical period animals was found to increase tectal cell firing frequency by an average of 33% when compared to age-matched controls. No difference in tectal cell firing frequency was observed between untreated critical period and post-critical period animals. These data indicate that the effects of APV on blocking plasticity are not due to a nonspecific decrease in visually evoked tectal activity. They also indicate that the restorative effects of NMDA on tectal plasticity may be related to an increase in tectal sensitivity, but do not support the hypothesis that normal loss of plasticity is correlated with diminished rates of tectal cell firing.

PHYSIOLOGY AND MORPHOLOGY OF NEURONS IN *RANA PIPIENS* TECTAL SLICES. P. W. Hickmott and M. Constantine-Paton. Dept. of Biology, Yale Univ., New Haven, CT 06511

Work in our lab has implicated the N-methyl-D-aspartate (NMDA) receptor in the activity-dependent refinement of the retinotectal map in *Rana pipiens*. Thus, we have examined the physiological effects of various drugs, particularly those that interact with the NMDA receptor, on the evoked potential in *R. pipiens* optic tectum (Soc. Neurosci. Abstr., 15:979, 1989). We have now begun to examine the responses of single tectal neurons in a tectal slice preparation.

We have successfully recorded from tectal neurons with resting potentials ranging from -20 to -70 mV, and input impedance in the 200-400 MΩ range. In response to depolarizing voltage steps, we observe large transient inward currents, followed by sustained outward currents, which correspond to action potentials. By stimulating in the optic tract we can record large, long-lasting currents that appear to be EPSCs generated by the opening of a cation channel with a reversal potential of around 0 mV; at negative holding potentials we frequently observe large, rapid inward currents reflecting action potential firing in the cell. In some cells, instead of this EPSC, we have observed a second type of PSC with a reversal potential of about -45 mV. In some cells, we also find frequent, small, spontaneous currents that reverse at the same level as the PSC.

We have also directly demonstrated the presence of NMDA receptors on some cells; bath-applied APV, a specific NMDA receptor antagonist, reversibly blocks a slow component of the EPSC. Furthermore, low concentrations of NMDA completely block the entire PSC and appear to decrease the cell's impedance.

Finally, we have begun to examine the morphology of cells using intracellular filling with biocytin. During the introduction of biocytin cells have normal resting potentials, input impedance, and can support action potentials. All cells labelled so far have been visualized with FITC-conjugated avidin and lie in layers 4 and 6; they appear to be small pyriform cells with fine processes that can extend for many microns in the plane of section. Supported by NIH EY 06039.

POSTNATAL DEVELOPMENT OF Ca++/CALMODULIN DEPENDENT KINASE II IN KITTEN VISUAL CORTEX.

W. G. Jia, C. Beaulieu, Y.L. Liu, M. Kennedy* and M. Cynader. Department of Ophthalmology, UBC, Vancouver, B.C., Canada. *Div. Biology 216-76, CALTECH, Pasadena, CA.

A monoclonal antibody against Calcium/calmodulin dependent protein kinase II (CAM II) was utilized to localize the kinase in developing kitten visual cortex. CAM II was first expressed in deeper cortical layers (V and VI) at postnatal day 0-4 and gradually appeared in all the other layers within the first two weeks. Expression of the kinase was lost in cells of layer V and upper layer VI at about 30-40 days of age and by postnatal day 90, CAM II immunoreactivity was concentrated in layers II, IV and deeper layer VI. This laminar pattern remained constant into adulthood. EM studies showed that the kinase was found in both pre- and post-synaptic locations, particularly on synaptic vesicles and in postsynaptic densities in adult animals. Increased number of immuno-positive neurons were found in the middle cortical layers of adult cat when geniculate input was removed by an ipsilateral thalamic lesion performed early in life. These results show that CAM II is transiently expressed in specific populations of cortical neurons during postnatal development and that the level and distribution of the kinase is use-dependent.

ENVIRONMENTAL ALTERATION OF ONCOGENE mRNA LEVELS IN CAT VISUAL CORTEX.

M.A.McCormack, K.M.Rosen, L.Villa-Komaroff, and G.D.Mower. Neurology Research, Children's Hospital, Harvard Medical School, Boston, MA 02115.

Several aspects of postnatal visual cortical development suggest environmentally induced changes in gene expression. Specifically, dark rearing prolongs the critical period and brief (2 day) visual exposure in dark reared animals promotes rapid physiological changes. Oncogenes provide a convenient window for studying changes in signalling pathways within the cell. The present study begins analysis of the effects of dark rearing and exposure to light on oncogene mRNA levels as assayed by northern blots. We compared normal and dark reared cats at 5 and 20 weeks of age, and dark reared cats given 2 days of visual experience at 5 weeks.

To date we have examined the expression of **c-fos**, **c-myc**, and **egr-1**. Levels of **c-fos** mRNA were decreased 40% by dark rearing at both ages. **c-myc** mRNA levels were elevated by dark rearing at both 5 (90%) and 20 (30%) weeks. Lesser effects were seen with **egr-1**, which was decreased 25% by dark rearing at both ages. Brief visual exposure in dark reared animals caused additional decreases in **c-fos** and **egr-1** mRNA levels of 40%, whereas **c-myc** levels were unchanged. These environmentally induced alterations are consistent with a possible role of proto-oncoproteins in visual cortical plasticity. Analysis of additional cortical structures is underway.

PHYSIOLOGICAL ACTIVITY REGULATES zif/268 IN THE VISUAL CORTEX.

P.F. Worley, B. Christy*, Y. Nakabeppu*, and J.M. Baraban. Dept. of Neuroscience and Depts. of Molecular Biology and Genetics, Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

In recent studies, we demonstrated synaptic activation of the transcription factor gene, zif/268, in dentate granule cells following brief tetanic stimulation of perforant-path afferents leading to long-term potentiation. To address whether zif/268 is activated by physiological activity, we have examined the regulation of zif/268 in the visual cortex. In control animals, zif/268 mRNA is present at relatively high levels in layers II-IV and VI of the visual cortex. Moreover, immunostaining is prominent in nuclei of subpopulations of neurons in these layers. Visual deprivation studies indicate that these basal levels of zif/268 mRNA and protein in visual cortex are driven by visual stimuli. Monocular injection of tetrodotoxin rapidly and selectively reduces levels of zif/268 mRNA and immunostaining in rodent primary visual cortex receiving predominant inputs from the treated but not control eye. Additionally, dark adaptation (4d) results in reversible reductions of zif/268 mRNA in visual cortex. These findings suggest that physiological synaptic activity is sufficient to elicit a robust immediate early gene response in neocortex. Accordingly, Zif/268 may help orchestrate genomic responses underlying the plasticity of mature cortical neurons to altered patterns of sensory stimulation.

VISUAL EXPERIENCE REGULATES SPECIFIC SYNAPTIC MOLECULAR COMPONENTS IN THE DEVELOPING RAT STRIATE CORTEX.

Aniek A. Schoups * and Ira B. Black, Division of Developmental Neurology, Cornell Medical Center, NY 10021, and UMDNJ/Robert Wood Johnson Medical School, Piscataway, NJ.

To study potential modulation of synaptic molecular structure by experience, the major postsynaptic density protein (mPSDp) in rat striate cortex was measured during normal development and after a period of visual deprivation. A purified synaptosomal membrane (SM) fraction from Long-Evans hooded rats was isolated, and mPSDp (separated by SDS-PAGE) was quantitated using ^{125}I-calmodulin. During normal development, mPSDp matures differently from other molecular synaptic components: whereas total SM protein increased 32-fold between days 5 and 60, the mPSDp increased 455-fold. Rats reared in complete darkness for two weeks following birth exhibited 60% of total SM protein found under normal rearing conditions (12hr light/dark cycle). Visual deprivation during a critical period thus interfered with normal development. Moreover, striate cortex mPSDp was selectively affected: following dark-rearing, striate cortex mPSDp was only 34% of normal. In contrast, light-deprivation did not alter mPSDp in parietal or prefrontal cortices, indicating topographical specificity of the synaptic response. Adult striate cortical mPSDp, on the other hand, was not affected by two weeks of dark exposure. We conclude that visual experience during development selectively modified specific components of the postsynaptic membrane structure. Since the mPSDp (MW= 51kDa) is an autophosphorylating subunit of a Ca^{2+}/calmodulin kinase, these data raise the possibility that this kinase plays a role in neural plasticity.

409.13

THE DEVELOPMENT AND DISTRIBUTION OF BETA ADRENERGIC RECEPTORS IN KITTEN VISUAL CORTEX: IMMUNOCYTOCHEMICAL AND AUTORADIOGRAPHIC STUDIES.

Y.L. Liu, W.G. Jia, A.D. Strossberg*, M.S. Cynader. Department of Ophthalmology, University of British Columbia, Vancouver, B.C. Canada. * Laboratory of Molecular Biology of Receptors, Institut Pasteur, Paris, France.

The developmental localization of beta adrenergic receptors has been studied in kitten visual cortex using immunocytochemistry and autoradiography. Using a monoclonal antibody, which recognizes beta receptors and a beta-specific ligand (I-125 CYP, with 5-HT competition) we have found specific populations of neurons that express beta receptors in the cortex. In adult animals, the receptors are concentrated in the superficial and deep cortical layers (layers 1, 2, 5 and 6). In neonatal kittens, fewer receptors are present, but they appear to be concentrated in the deep cortical layers and white matter. Receptor numbers increase after birth and by 14 days of age, the laminar distribution approaches that of the adult animals, with further thinning out of labelled cells in layer 4, between 14 and 120 days of age. Most immunostained neurons were stellate cells, although a few pyramidal cells were stained in layers 3 and 5. This pattern of distribution did not appear to be input dependent as it was not affected either by removal of thalamic input early in life, or by early interruption of adrenergic input.

409.14

THE DEVELOPMENT OF MK-801 BINDING SITES IN CAT VISUAL CORTEX.

B. Gordon, D. Parkinson and N. Daw. Dept. Cell Biology and Physiology, Washington Univ. Sch. Med., St. Louis, MO 63110.

Two facts led us to speculate that the density of binding sites associated with the N-methyl-D-aspartate (NMDA) receptor might vary with age in the cat visual cortex. First, the NMDA receptor has been implicated in neural plasticity. Second, plasticity in cat visual cortex varies with age. To test this notion we measured binding of the NMDA antagonist, MK-801, in homogenates of visual cortex membranes from cats aged 7 days (d), 21 d, 43 d, 83 d, 7-8 mos and over 2 years. Binding was measured in the presence of 100 μM glutamate, 30 μM glycine and 30 μM spermidine after 3 hours incubation at which time equilibrium had been reached.

Binding was maximal at 43 and 83 days, decreasing in both younger and older animals. Saturation analysis showed that the variation in binding with age resulted from variation in B_{max}.

Addition of glutamate, glycine and spermidine caused a greater percentage increase in binding in adult animals than in 43 day old animals. This may indicate that NMDA channels have more frequent spontaneous openings in 43 day old animals than in adults.

409.15

SUBPLATE-1: A MOLECULAR MARKER FOR EXCITATORY NEURONS IN SUBPLATE ZONE OF DEVELOPING CAT CORTEX?

P.Wahle, J.Lübke*, J.R.Naegele[1], K.Albus *MPI Biophysik.Chemie, 3400 Göttingen, FRG and [1]Dept. Ophthalmol. and Visual Science, Yale University School of Medicine, New Haven, CT 06510, USA*

A transiently expressed antigen in the cortical subplate zone of kittens was detected with a monoclonal antibody called SUBPLATE-1 (Soc. Neurosci. Abstr.15,1 '89). On Western blots of PD12 kitten cortex homogenates, a single band of 60 kD is stained. Phosphatase does not alter the staining, suggesting the epitope does not involve a phosphorylation site. SUBPLATE-1 immunoreactivity (ir) is expressed in inverted spiny pyramids, as shown by combined intracellular injection of Lucifer Yellow and immunocytochemistry. The neurons send a major dendrite toward the white matter and several minor dendrites toward the gray matter. Axons typically arise from the major dendrite and descend into the white matter forming recurrent collaterals. This morphological type is also labeled when DiI is implanted into thalamus or supragranular cortical layers of young kittens. It suggests that the SUBPLATE-1 antigen may be expressed in transient neurons of pyramidal morphology with long-range axonal projections. This concurs with double - immunofluorescence studies demonstrating that the majority of SUBPLATE-1 ir cells are neither GABAergic nor peptidergic. We suggested a glutamatergic nature, because many white matter neurons of inverted pyramidal shape display glutamate ir. Curiously, few, if any of the SUBPLATE-1 neurons are glutamatergic. It is possible that SUBPLATE-1 ir neurons contain aspartate or a neurotransmitter not yet identified in the subplate zone of cat cortex.

409.16

NEUROPEPTIDE-Y IMMUNOREACTIVITY (NPY-IR) AND SOMATOSTATIN-IMMUNOREACTIVITY (SOM-IR) FOLLOW DIFFERENT DEVELOPMENTAL PATTERNS IN CAT VISUAL CORTEX. Dale Hogan and Nancy E.J. Berman, Department of Anatomy and Cell Biology, Univ. of Kansas Medical Center, Kansas City KS, 66103.

We examined the numbers and location of NPY-ir and SOM-ir cells in postnatal kittens and adult cats to determine whether the expression of these peptides differs developmentally across visual cortical areas. The total number of NPY-ir neurons per section increases postnatally in all areas examined. Adult visual cortex has three times as many cells as the newborn. The density of cells remains the same throughout development, the increase in number being directly correlated to the increasing brain size. The increase in NPY-ir cell numbers is accompanied by an increase in NPY-ir axons. Developmentally, medial areas are invaded by immunoreactive processes first, with the lateral areas lagging about a week behind. As the axons grow into the cortex, they follow a radial pattern, growing straight up through the cortical plate and branching first in layer I. In the adult, dense fibers crisscross the whole extent of the cortex in secondary visual areas. In areas 17 and 18, stained processes avoid layer IV.

By contrast, Som-ir cell numbers decrease developmentally, and there is a clear difference across the cortical areas studied. There is no evidence of exuberance in areas 17, 18 and 19 in the one week old kitten. The number of immuno-reactive cells increases from medial to lateral and the lateral bank of lateral suprasylvian sulcus has 3 - 4 times as many cells per section as areas 17 and 18. By three weeks of age, this lateral exuberance has disappeared, and the distribution of Som-ir cells has reached the adult pattern. These results implicate somatostatin as a possible factor in guidance of axons into secondary visual areas, but do not support such a role for neuropeptide-Y.(Supported by MH38399, BNS881997, and RCD8954894)

SEROTONIN RECEPTORS EXHIBIT A TRANSIENT COLUMNAR AND LAMINAR DISTRIBUTION IN DEVELOPING CAT VISUAL CORTEX. Richard Dyck and Max Cynader, Dept. of Ophthalmology, University of British Columbia, Vancouver, British Columbia, Canada, V5Z 3N9.

The distributions of many neurotransmitter/neuromodulator receptors in the cat visual cortex show an age-related laminar specificity. None, however, have yet proven crucial in establishing the intrinsic columnar organization of the cortex during the critical period for cortical plasticity. Recent studies indicate that serotonergic (5HT) neurons may play an important role in development by affecting neuronal outgrowth and synaptic plasticity. In this study we used in vitro autoradiographic methods to assess the developmental distribution of 5HT receptors.

Six sets of adjacent sections through the visual cortex of cats ranging in age from birth (postnatal day 0; P0) through adulthood (>P150) were incubated in buffer containing either [^{3}H]-5HT, [^{3}H]-8-OHDPAT, [^{125}I]-CYP, [^{3}H]-mesulergine, [^{3}H]-ketanserin or [^{3}H]-quipazine to assess the distribution of 5HT1, 5HT1a, 5HT1b, 5HT1c, 5HT2, and 5HT3 receptors, respectively. Some sections were also incubated in the presence of μM concentrations of the appropriate competitor to ascertain binding specificity.

The distribution of each 5HT receptor subtype presented a distinct and unique developmental pattern of expression. While 5HT1, 1a and 1b binding sites exhibited laminar changes in distribution early in development, the distribution of 5HT2 sites changed relatively late. 5HT3 sites appeared to remain homogeneous throughout development. In addition to early laminar changes in distribution, **5HT1c receptors were found to be transiently expressed in columns within lamina IV between P30 and P60.** Until now, no receptor population has been shown to participate in the process of column formation in the developing cat visual cortex. The transient columnar expression of the 5HT1c sites makes them a prime candidate for this role.

NERVE GROWTH FACTORS VII

410.1

DISTRIBUTION OF NERVE GROWTH FACTOR RECEPTORS (NGFR) IN THE RAT SPINAL CORD AS A FUNCTION OF AGE AND NGF SUPPRESSION. B.A. Urschel and C.E. Hulsebosch. Dept. of Anat. and Neurosci., Marine Biomed. Inst., Univ. of Texas Med. Br., Galveston, TX 77550.

It has been postulated that NGF binding to the low affinity-fast dissociating NGFR on Schwann cells is involved with neurite extension during development and regeneration. Since central projections of somatosensory fibers sprout into the spinal cord after neonatal administration of antibodies to NGF (ANTI-NGF), it is of interest to determine if the distribution of NGFR correlates with the occurence of sprouting. Neonatal rats were given daily injections of ANTI-NGF (3μl/gm body wt.) for a period of up to one month. Treated and untreated rats were sacrificed on postnatal days (PD) 0, 7 and one month. The NGFR distribution was determined using the monoclonal antibody 192 and standard immunohistochemical techniques. In the untreated rats, NGFR distribution on PD 0 and 7 was localized in laminae I, II, III and medial IV; fasciculus cuneatus and gracilis; tracts above and below the central canal and around motorneurons. By one month of age, distribution was localized to only laminae I and II and the tracts above and below the central canal. Data from the ANTI-NGF treated rats will be presented. We hypothesize the NGFR are involved with sprouting and synaptogenesis of somatosensory components of the spinal cord.

PHASIC INCREASES IN NERVE GROWTH FACTOR OCCUR IN DORSAL ROOT GANGLIA AFTER SCIATIC NERVE CRUSH. M.R. Wells, and J.P. Schwartz. Nerve Regeneration Laboratory , Veterans Administration, Northport, N.Y. 11787 and CNB, NINCDS, NIH, Bethesda, Md. 20892.

The nerve growth factor content of sensory ganglia was examined after nerve injury to determine its possible relationship to the metabolic response of dorsal root ganglion cells to axon injury. Male, Wistar-Furth rats were subjected to unilateral crush lesions of the sciatic nerve at the level of the sciatic notch. At 1,2,3,4,5,7,8,9,11,14, and 30 days after injury, the L5 and L6 lumbar ganglia and the C6 cervical ganglia were removed bilaterally and examined for NGF content by an enzyme-linked immunoadsorbant assay. Ganglionic NGF increased up to 500% phasically and bilaterally at days 1, 4, 7, and 8 days in the L5 and L6 ganglia combined (p=0.0002, ANOVA). The strongest effect was observed bilaterally in the L6 ganglia (p= .001). The data also suggested an increase in the NGF content of cervical ganglia at 3 days after injury. Since sciatic nerve section is known to elevate NGF in Schwann cells, perhaps mediated by interleukin-1 released from macrophages, these results suggest the possibility that Schwann cells in the ganglia may also synthesize increased amounts of NGF. Why this increase should occur phasically remains to be determined. Phasic increases in ganglionic NGF coincided temporally with specific metabolic changes observed in identically axomized neurons in sensory ganglia (Wells, Exp. Neurol. 95: 313, 1987). However, in these prior studies, the pattern of responses of the injured and uninjured sides differed. The source and localization of the NGF increase will be important in determining the role it may play in the metabolism of axotomized sensory neurons. Suported by the Veterans Administration and NIH

410.3

NERVE GROWTH FACTOR (NGF) IMMUNOREACTIVITY IS RESTRICTED TO A SUBPOPULATION OF SENSORY NEURONS
R.A. Rush, R. Williams, J. Vahaviolos, R. Ressom, C. Auffray and A. Keller. Dept. of Physiology, Flinders University, Adelaide, Australia, 5042.
We have demonstrated NGF immunoreactivity in neurons of chicken peripheral ganglia using anti-peptide antisera. In dorsal root ganglia (DRG), the antigen is visible only in small neurons, with increasing concentrations, from embryonic day 10 up to adult ages. The antigen is also present within some neurons of trigeminal and jugular ganglia, but no immuno-reactivity is detectable in neurons of the vestibulo-acoustic, nodose, petrosal, ciliary or, surprisingly, sympathetic ganglia. Neither is stain detectable in either central or peripheral nerve processes except distal to a nerve ligation. Characterization of the immuno-reactivity present in DRG was achieved following chromatographic separation of ganglion extracts; antigen being found only in fractions that eluted identically with pure NGF. Extracts of sympathetic ganglia also contained immuno-chemically identifiable NGF. We conclude that the factor exists in different compartments of reactive and non-reactive neurons, and that only some of the NGF present can be detected immunohistochemically.

AGING SYMPATHETIC NEURONS WITH ELEVATED LEVELS OF CYTOPLASMIC CALCIUM DONOT DIE BUT BECOME ATROPHIC UPON DEPRIVATION OF NERVE GROWTH FACTOR IN VITRO: CHARACTERIZATION OF NEURONAL ATROPHY.
T.Koike, S. Tanaka* and S.Masuko, Depts. of Natural Sci. and Anatomy,Saga Med. Sch.,Nabeshima,Saga 84001,Japan
Sympathetic neurons become independent of NGF for survival upon aging: trophic deprivation does not cause immediate death of these neurons. We hypothesize that this is due to elevated levels of cytoplasmic free Ca^{2+}(PNAS 86:6421,1989). Indeed, the neurons with raised levels of free cytoplasmic Ca^{2+}($\geq$220nM) became resistant to NGF deprivation and their survival tended to be independent of NGF(J.Cell.Biochem. 14F:95,1990). These neurons, however, became gradually atrophic upon withdrawal of NGF: cell shrinkage occurred slowly and neurites became thinner. No major alterations were observed in the structure of cellular organelles. This process was reversible. Thus, we can dissociate the trophic effects of NGF from neuronal survival under these conditions so that normal neurons are available for studying cellular signaling associated with atrophy and hypertrophy. Neuronal atrophy caused by NGF withdrawal appears to be partly prevented by the activation of protein kinases but not prevented by high K^+(35mM) medium.

NGF and NGF Receptor Expression in Primary Reaggregate Cultures Derived From the Embryonic Mouse Septum
J.D. Roback[1], M. Downen[1], H.J. Lee[1], J. Zucker[1], T.H. Large[2], U. Otten[3], and B.H. Wainer[1]. [1]University of Chicago, Chicago IL 60637, [2]Case Western Reserve University, Cleveland OH 44106, and [3]University of Basel, Switzerland.
In the adult central nervous system, nerve growth factor (NGF) is expressed at high levels in the hippocampus while its receptor (NGF-R) is synthesized in the septum, primarily by the cholinergic neurons which project to the hippocampus. In order to better understand the regulation of NGF and NGF-R biosynthesis, we have grown either isolated hippocampal or septal cells derived from embryonic day 15 fetuses in reaggregate culture. At this developmental stage, septal and hippocampal neurons have not yet formed contacts with one another. We previously reported that the *in situ* developmental profile of hippocampal NGF mRNA and protein expression can be partially recapitulated *in vitro* by hippocampal reaggregates (Roback, et al, Dev. Biol. 137:451, 1990). We now report that septal reaggregates express both NGF and NGF-R. NGF protein rises steadily with time in these cultures. By day 21, septal reaggregates contain an average of 40 pg NGF protein/mg total protein (ca. 50% of that seen in day 21 hippocampal reaggregates). Levels of NGF mRNA are high at day 7 (11.4 ± 4.6 arbitrary O.D. units) and day 14 (11.6 ± 2.3), but decrease by day 21 (6.5 ± 1). Levels of NGF-R mRNA rise from day 7 (4.9 ± 2.2) to day 14 (8.3 ± 3.1), and then also decrease by day 21 (2.6 ± 0.8). Hippocampal reaggregates, on the other hand, express levels of NGF mRNA approximately 50% higher than those seen in septal reaggregates, but do not express detectable NGF-R mRNA. These results demonstrate that both NGF and NGF-R are synthesized in the septum in the absence of hippocampal interactions. Moreover, NGF and NGF-R mRNA expression may be coordinatly regulated in these septal cultures. In conjunction with data from other groups, this work is consistent with a model in which septal-derived NGF provides local regulation of NGF-R expression in the septum. Supported by NIH grants 5-T32HD070009, and NS-25787.

410.6

EXPRESSION OF NERVE GROWTH FACTOR RECEPTOR LIKE IMMUNOREACTIVITY IN THE FOREBRAIN OF POSTNATAL RATS.
M. Nishizuka and Y. Arai*. Dept. of Anatomy, Juntendo Univ. Sch. Med., Tokyo, Japan.
Immunocytochemical localization of nerve growth factor (NGF) receptor in the forebrain of postnatal rats was studied using specific anti-rat NGF receptor monoclonal antibody, 192-IgG. Wistar rats were deeply anesthetized with pentobarbital and perfused transcardially with a buffered paraformaldehyde at 1-10 postnatal days. The brain sections were incubated with a supernatant of hybridoma cell culture containing 192-IgG (courtesy of Prof. H. Hatanaka) and processed for ABC method. NGF receptor like immunoreactive neurons were obtained in the septum, the nucleus of the diagonal band of Broca, the ventral pallidum, and the caudate-putamen. Some rats were injected with 2.5S mouse NGF(1-2 μg/0.1% BSA) into the hypothalamus 3 days before sacrifice. The number of immunoreactive neurons increased in the ventral pallidum of NGF infused pups. Immunoreactive cells were also obtained in the arcuate nucleus of NGF infused rats. These data provide a possible explanation for our previous results that NGF facilitated the growth of transplanted hypothalamic neurons in fetal rats.

410.7

Sites of NGF and NGFR mRNA Synthesis in the Developing Rat Embryo
Esther Wheeler, Ph.D. [1], Margaret Byers, Ph.D. [2], and Mark Bothwell Ph.D. [1]
Dept. Physiology and BioPhysics[1] Dept. of Anesthesiology and Biological Structure[2], University of Washington, Seattle, WA 98195

The temporal and spatial expression of nerve growth factor (NGF) and its receptor (NGFR) were examined by in situ hybridization and immunocytochemical analyses of rat neonates and embryos aged 12 to 22 days post coitum. In addition to the expected expression in the nervous system, transcripts for both molecules were detected in a wide variety of non-neuronal cells. In the developing skin of the maxillary pad and the developing limb, NGF was localized in the epithelial and underlying mesenchymal cells. Expression of NGFR co-localized with NGF transcripts in the mesenchymal cell layers of the skin but was absent from the adjacent developing epithelium. In developing teeth, NGF and NGFR transcripts were co-localized only in the mesenchymal cells underlying the odontoblast cells. NGF and NGFR transcripts were also observed in developing myoblasts but not in fused myotubes. By contrast, NGFR mRNA, but not NGF mRNA, was detected at high levels in the mesenchymal cells associated with developing bronchiole epithelium and the epithelial cells of the developing kidney glomeruli. Curiously, NGFR glycoprotein was localized in the vesicular compartments and on the luminal surface of at least two epithelial cell types, the intestinal brush cells and the pillar cells of the developing cochlea. These results suggest NGF and NGFR are involved in the development of a variety of non-nueronal embryonic cell types. In addition, both factor and receptor are expressed over the entire course of embryonic limb development in a pattern consistent with a role in the instructive mesenchymal/epithelial interactions that effect morphogenesis.

410.8

EXOGENOUS NGF REGULATES NGF RECEPTOR (NGFR) EXPRESSION IN DISCRETE CNS REGIONS.
M. Fusco, P. Polato*, G. Vantini, M. Bentivoglio[1], A. Leon. Fidia Research Laboratories, 35031 Abano Terme, Italy and [1]Inst. of Human Anatomy, Verona University, 37134 Verona, Italy
We recently showed that exogenous NGF can regulate in vivo the expression of NGFR mRNA and corresponding protein levels in the basal forebrain cholinergic neurons. We have here evaluated the effect of exogenous NGF on NGFR in neuronal and non-neuronal structures expressing NGFR in CNS of newborn and adult rats. NGF was administered to adult rats via mini osmotic pumps (50 μg, 1 week) and to newborn rats by repetitive injections (5 μg, every other day from postnatal day 2 to 6). NGFR was immunocytochemically assessed by using the monoclonal antibody 192 IgG. Results show that, in both newborn and adult rats, NGF administration increases NGFR immunoreactivity (NGFRI) in basal forebrain as well as in other brain structures expressing NGFR. These structures include sensory pathways, brain stem sensory nuclei and some optic-related structures. In adult animals an increased espression of NGFRI was also induced by NGF in many thalamic nuclei displaying slight NGFRI in adulthood. Enhancement of NGFRI was also observed in non-neuronal cells such as ependymal cells and tanycytes. No effect of NGF was observed in spinal motor neurons and brainstem motor nuclei shown to express NGFRI only during development. These data suggest that, within the CNS, the role of NGF is broader than traditionally thought.

410.9

SCIATIC NERVES TRANSPLANTED INTO THE CNS EXHIBIT ELEVATED NERVE GROWTH FACTOR (NGF) PROTEIN LEVELS. D. J. Messersmith, M. Fabrazzo,* I. Mocchetti, and L. F. Kromer. Dept. of Anatomy and Cell Biology and FGIN, Georgetown University, Washington, DC 20007

After bilateral fimbria/fornix aspiration lesions in female adult Sprague-Dawley rats, segments of sciatic nerve were inserted rostrally into the septum and caudally into the hippocampus. Previously, we demonstrated that at two weeks post-transplantation there was a significant increase in the number of choline acetyltransferase-positive (ChAT+) cells in the medial septum compared to animals receiving lesions only (41% vs 21% of normal). In order to examine the role of NGF in the transplant-associated elevation in ChAT+ cells, we measured NGF protein levels using a two-site immunoassay. NGF levels were measured in normal nerve segments; nerves lesioned, ligated and left *in situ* for 2 weeks; and nerve grafts 2 weeks post-transplantation. Septal NGF levels were measured in normal, lesion controls, and animals receiving transplants.

NGF levels in the transplant were significantly higher than in normal nerve segments and slightly less than in lesioned nerves *in situ* (Mean NGF pg/mg wet tissue ± SEM: 1.3 ± 0.2, 0.7 ± 0.1, 2.0 ± 0.2, respectively). Septal NGF levels in lesioned animals (0.3 ± 0.03) were lower than in normal rats (0.4 ± 0.03) or in specimens with transplants (0.4 ± 0.04). These results suggest that NGF released from the transplant may be one factor that contributes to the return to normal NGF levels in the septum and supports an increase in the number of ChAT+ septal neurons after lesions. Supported by NIH grant # NS 23522.

410.10

STIMULATION OF CARNITINE ACETYLTRANSFERASE IN PC-12 CELLS BY NGF: RELATIONSHIP TO CHOLINE ACETYLTRANSFERASE STIMULATION. P.W. Scates* and H.L. White. Div. of Pharmacology, Wellcome Research Laboratories, Research Triangle Park, N.C. 27709

When incubated with rat pheochromocytoma cells (PC-12 cells), nerve growth factor (NGF) causes neurite extension, phosphorylation of kinases, and increases in certain enzyme activities, including choline acetyltransferase (ChAT). In the present study we have determined the effects of NGF on both ChAT and carnitine acetyltransferase (CarAT). PC-12 cells were cultured in serum-free DMEM +/- NGF. Cells were periodically examined morphologically, harvested, washed, lysed, and assayed for ChAT and CarAT, using [14C]acetyl -CoA and either choline or carnitine as substrates.

Basal activity of CarAT in PC-12 cells was more than 100-fold greater that that of ChAT. Both enzymes were stimulated by NGF in parallel, in a concentration and time-dependent manner. Significant stimulation was observed by 24 hr incubation with 5 ng/ml of NGF, and both activities were at least 3-fold higher after 72 hr incubation. Additional experiments showed that 10 μM or more of acetylcarnitine stimulated ChAT activity in the absence of NGF. These observations suggest that the activities of CarAT and ChAT may be coupled and that their stimulation by NGF may favor a reversal of cholinergic deficits in animal models of neuronal degeneration.

410.11

NEUROTROPHIC EFFECT OF RECOMBINANT HUMAN NERVE GROWTH FACTOR (RHNGF) IN VITRO AND IN VIVO: COMPARISON WITH THE EFFECT OF MOUSE NGF (MNGF). M.Kakihana*, M.Iwane*, K.Nakahama* and M.Suno. Biol.Res.Labs., R&D Division, Takeda Chem.Ind., Ltd., Jusohonmachi, Yodogawa-ku, Osaka 532, Japan.

Recombinant human NGF (rhNGF) was obtained by expression of human NGF gene in CHO cells and purified to near homogeneity from the culture medium. The septal neurons were dissected from 17-day fetal rat brain and seeded on a feeder layer of astroglial cells. Both rhNGF and mouse NGF (mNGF) increased acetylcholine (ACh) content and choline acetyltransferase (CAT) activity in the septal neurons in a concentration-dependent manner; the ED50 was 0.5 ng/ml for rhNGF and 2.5 ng/ml for mNGF. Neurite promoting activity of rhNGF and mNGF at a concentration of 30 ng/ml was almost the same.

In rats with unilateral fimbria-fornix transection, cholinergic cells stained by acetylcholinesterase (AChE) histochemistry in the medial septum and vertical limb of the diagonal band were reduced to 20% of that of the contralateral nonlesioned side. Administration of rhNGF (3 or 30 μg) decrease this reduction in the number of survival cells; the survival rate was 45-55%. The effect of mNGF in this system was less potent than that of rhNGF. These results indicate that rhNGF has the same (or more potent) neurotrophic effect as mNGF in vitro and in vivo.

410.12

NERVE GROWTH FACTOR RECEPTOR EXPRESSION IN THE DEVELOPING CHICK EMBRYO. Dario Marchetti, Lanny J. Haverkamp and James L. McManaman. Department of Neurology, Houston, Texas 77030.

To investigate the presence of receptors for nerve growth factor (NGFR) in developing chick embryos, iodinated β-NGF was used as a probe in a biochemical analysis performed on chick spinal cords from embryonic day 6 (E6) to E15. Strong NGFR expression was observed as early as E6 with presence of high-affinity ($K_D \approx 10^{-11}$M) and low-affinity ($K_D \approx 10^{-9}$M) NGFR. At this stage of development, we found values of NGFR/cell equal to 4,000 and 44,000 for high- and low-affinity NGFR respectively. These values declined with marked differences in the amount of receptor sites throughout the developmental time course: by E15 no specific NGF binding sites could be detected.

Interestingly, the temporal distribution of NGFR varied according to the type of NGFR considered: high affinity NGFR virtually disappeared by E10 (8% present compared to E6 value) while at the same developmental stage we were able to detect 73% of low-affinity NGFR.

The transient expression of the two NGFR and their differential distribution at the time of motoneuron synapse formation and cell death may shed light on NGF involvement in the development of non-classical targets for NGF action. Experiments to warrant a detailed analysis of NGF role in neuromuscular differentiation are in progress.

NEUROBIOLOGICAL EFFECTS OF COLCHICINE ADMINISTRATION INTO THE HIPPOCAMPUS: MODULATION BY NGF. **S. Barone Jr., M.J. Bonner, P. Tandon, H.A. Tilson. LMIN/NIEHS, Research Triangle Park, NC 27709.**

This study examines NGF modulation of signal transduction in the hippocampus (HPC) following neurotoxic lesions with colchicine (COL). Male Fischer-344 rats received COL (2.5 μg/site) or vehicle into the dorsal HPC. Immediately after COL treatment, chronic cannula were implanted unilaterally in the ventricle and modified Alzet mini-osmotic pumps (0.25 μl/hr) with β-NGF [10 ng/μl in ACSF] or cytochrome C [20 ng/μl in ACSF] were attached. One wk post-lesion animals were tested in activity chambers for 60 min. NGF treatment reduced COL-induced hyperactivity. Rats were sacrificed at 3 or 12 wks post-lesion for neurochemical or morphological analysis. Agonist-stimulated phosphoinositide (PI) turnover was measured after [^{3}H]-inositol was incorporated into HPC slices. Various treatments did not alter carbachol (CARB)-induced PI turnover at 3 wks. However, NE-induced PI turnover was increased in COL/ACSF and ACSF/NGF. At 12 wks, NE and CARB stimulation of PI turnover was increased in COL-lesioned rats. This lesion effect was blocked when rats received NGF. Sections were stained for AChE or immunocytochemically (ICC) for ChAT. COL treatment caused an increase in AChE staining in the CA3 of HPC but NGF treatment had no effect.

410.14

NATURALLY OCCURING ANTIBODIES AGAINST NERVE GROWTH FACTOR IN SERA FROM RABBITS AND HUMANS. E.Dicou[1], V.Lambropoulou[2]* and P.Markoulatos[2]*. [1]INSERM U 298 Centre Hospitalier Régional 49033 Angers France; [2]Institut Pasteur, Athens Greece.

Sera from unimmunized rabbits and from humans and Herpes simplex virus (HSV)-infected human patients were analysed for the presence of antibodies to nerve growth factor (NGF). Screening of sera was done by enzyme immunoassay using purified mouse NGF for coating of microplates. NGF antibody activity was detected with a variable titer in both rabbit and human sera. Student's t test indicated significant differences ($P < 0.02$) in NGF antibody activity between sera of HSV-infected patients ($n = 50$) as compared to controls ($n = 38$). Sera containing elevated NGF antibody activity were passed through columns of NGF immobilized to CNBr-activated Sepharose. The purified immunoglobulins immuno-precipitated mouse I^{125}-NGF as detected in SDS/polyacrylamide gels, and they stained by immunohistochemical techniques the granular convoluted tubules of the mouse submaxillary gland, the site of synthesis of this factor. Thus by three different experimental criteria we demonstrate the presence of natural antibodies to NGF in rabbit and human sera.

MOLECULAR CLONING OF PC3, A NOVEL EARLY-INDUCIBLE GENE BY NERVE GROWTH FACTOR IN PC12 CELLS. Felice Tirone, Roberta Possenti and Andrew Bradbury*, Department of Neurobiology, Consiglio Nazionale delle Ricerche, Rome, Italy

We have recently isolated four genes - PC1,2,3 and 4 - whose transcription is induced very early by nerve growth factor (NGF) in a tumour cell line of rat chromaffin cells, PC12 (Tirone, F., and Shooter, E.M. Soc.Neurosci.Abstr., 13(1):551,1987). Chromaffin cells, which are neural crest derivatives, differentiate into sympathetic neurons in presence of NGF, and the induction of these early genes is therefore associated with the commitment to the neuronal phenotype. One of these genes - PC4 - had been shown to be related to the rat γ interferon protein (Tirone, F., and Shooter, E.M. Proc.Natl.Acad.Sci.U.S.A.86:2088, 1989). We have now obtained the full sequence of the clone PC3 , which in fact was initially missing about 200 nucleotides in the 5' region, according to Northern and sequence analysis. The missing fragment had been obtained by primer extension and subsequent PCR amplification, using the method described by Frohman, M.A., et al. Proc.Natl.Acad.Sci. U.S.A.,85:8998, 1988. The complete cDNA clone is 2516 nucleotides long and presents two longer open reading frames (ORF), 420 (nt 64-483) and 374 nucleotides long (nt 1832-2205). The analysis of codon frequencies points to the first ORF as the sequence encoding the protein, with a predicted molecular weight of 15670 Da. A polyadenylylation signal is present at nucleotide 2294. Comparison of the nucleotide and predicted protein sequence with those present in the databases indicates that PC3 is a new sequence: we are now checking for the presence of specific consensus sites. PC3 RNA levels, which are induced by NGF in PC12 cells about 35 times within one hour and return to the basal level within four hr, are superinduced in the presence of NGF and cycloheximide: after 2 hr the RNA level is increased more than 100 times. PC3 is therefore induced by NGF without new synthesis of intervening proteins after the receptor activation. PC3 is induced as well by EGF in PC12 cells but weakly (few times) and is transiently expressed in the neural tube suggesting its participation in proliferative or differentiative events.

CORRELATION OF NERVE GROWTH FACTOR RECEPTOR DISTRIBUTION AND DIFFUSIBILITY WITH RESPONSIVENESS AND LIGAND-BINDING AFFINITY. A.H. Ross, G. Venkatakrishnan, C.A. McKinnon and D.E. Wolf. Worcester Foundation for Experimental Biology, 222 Maple Avenue, Shrewsbury, MA 01545

Using fluorescence microscopy and fluorescence recovery after photobleaching (FRAP), we have analyzed the distribution and diffusibility of nerve growth factor receptor (NGFr) on a series of cell lines. We have found: (1) cells expressing high-affinity responsive NGFr's display clustered NGRr's even in the absence of ligand. In contrast, nonresponsive cell lines are diffusely distributed. (2) Receptors on responsive cell lines are largely nondiffusing. Most receptors on nonresponsive cell lines are free to diffuse. (3) NGR does not greatly alter the distribution or diffusive properties of the NGRr on nonresponsive or responsive cell lines. We, thus, report a clear correlation between NGRr physical properties and biological responsiveness and suggest that clustering of NGFr prior to ligand binding is required for biological responsiveness.

THE ROLE OF CYTOSKELETAL ORGANELLES IN REGULATING THE SURFACE DISTRIBUTION OF NERVE GROWTH FACTOR RECEPTORS. P.E. Spoerri and F.J. Roisen. Department of Anatomical Sciences and Neurobiology, University of Louisville, School of Medicine, Louisville, Kentucky 40292.

The distribution of the Nerve Growth Factor (NGF)-receptor may be dependent on the underlying cytoskeleton. We employed immunocytochemistry to examine the topographical distribution of NGF-receptors on PC-12 cells at various stages of neuritogenic development. Using high resolution TEM, mAb to NGF-receptor labelled with colloidal gold was seen distinctly aligned along perikaryal and neuritic surfaces. Occasional, short, non-random arrangements suggested that endogenous molecules were bound to underlying cytoskeletal components. To determine the nature of these structural attachments, we applied cytoskeletal altering agents prior to immunolocalization of the NGF-receptor. Conditions which limit microfilament formation (cytochalasin D, 2 μg/ml) dramatically altered the distribution of the NGF-receptor along the perikaryal and neuritic surfaces. This effect was less pronounced under conditions which limit microtubule formation (Colcemid, 0.05 μg/ml). Furthermore, the relationship of these alignments to microtubules was examined with taxol (1 μM, microtubule stabilization and promotion). Studies in progress probe the role of microtubules and microfilaments in NGF-receptor distribution by applying unique neuritogenic signals known to affect neuritic cytoskeletal organization and examining the characteristic patterns of NGF-receptor produced by these signals. NGF-receptors appear to be primarily associated with cytochalasin-sensitive microfilaments which regulate their distribution on PC-12 cell surfaces. Supported by NIH grant NS24524.

RAS METABOLISM AND POST-TRANSLATIONAL MODIFICATION IN PC12 CELLS: EVIDENCE FOR A *RAS*-INDEPENDENT PATHWAY FOR NGF RESPONSES. M.-S. Qiu, A.F. Pitts, T.R. Winters* and S.H. Green. Dept. of Biology, Univ. of Iowa, Iowa City, IA 52242

We have used the drug compactin to prevent activation of *ras* protoöncogene protein in PC12 cells in order to determine whether *ras* is necessary for responses to NGF. Compactin inhibits synthesis of mevalonate, the precursor to the polyisoprene moiety that is covalently linked to *ras*. We assessed *ras* expression, turnover, post-translational modification and subcellular localization by immunoprecipitation of *ras* metabolically labeled with ^{35}S-methionine or ^{3}H-mevalonate. Treatment of PC12 cells with compactin results in a complete inhibition of *ras* post-translational modification: polyisoprenylation and proteolytic cleavage of the carboxyl terminal. Translocation of *ras* to the membrane, required for *ras* activity, is also completely inhibited by compactin. We find that *ras* has a half-life of ≈24 h in PC12 cells and a 5 d treatment is required to chase previously synthesized and isoprenylated *ras* from the cell membrane. Incidentally, we find that compactin inhibition of *ras* function or membrane localization results in a marked increase in *ras* expression. Compactin also inhibits responses of PC12 cells to transforming *ras* oncogene expressed transiently from a viral LTR promoter following transfection into the cells or expressed in a stably transfected PC12 subline from a steroid-inducible MMTV promoter. Under these conditions, in which *ras* activation is prevented, we assayed NGF responses and found that NGF-dependent cell survival, phosphorylation of tyrosine hydroxylase and induction of early gene transcription are not inhibited by compactin treatment. Compactin does inhibit NGF-induced cell surface ruffling but this effect is nonspecific: EGF-induced ruffling is similarly inhibited by compactin. Thus, *ras* function appears not to be necessary for responses to NGF. These observations, taken together with those of other laboratories, suggest that NGF signal transduction involves multiple parallel pathways with *ras* not necessarily involved in all of them.

NERVE GROWTH FACTORS VIII

411.1

INDUCTION OF MORPHOLOGICAL AND PHYSIOLOGICAL DIFFERENTIATION OF N1E-115 CELLS IN SERUM FREE MEDIUM. P. Cobbett, C. Cosgrove*, & I. Tien*. Dept. Pharmacol./Toxicol. and Neuroscience Program, Michigan State Univ, East Lansing, MI 48824-1317.

Murine neuroblastoma N1E-115 cells proliferate and are non differentiated when maintained in medium containing 10% newborn calf serum (NCS). Differentiation may be induced by addition of 2% dimethylsulfoxide to the medium (Kimhi et al., PNAS 73, 462, 1976). We have examined the effects of maintaining N1E-115 cells in serum-depleted media on cell growth, process outgrowth and membrane excitability. Media containing 1% or 2% NCS inhibited growth compared to cells grown in 10%NCS medium but did not induce morphological differentiation. Cells in 0% NCS medium for more than 3 days had significantly reduced population growth and increased process outgrowth. By day 5, >30% cells had processes longer than the somatic diameter whereas <5% of cells in 10% NCS medium had processes. Cells in 10% NCS medium or 0% NCS medium for <4 days had similar resting potentials but cells in 0% NCS medium had a significantly increased input conductance: 10% NCS 1.0± 0.1 nS, 0% NCS 2.0± 0.3 nS. Non-differentiated cells were essentially inexcitable, but cells in 0% NCS became more excitable with time. The action potential amplitudes were: 4 days 39.3± 3.8 mV; 8 days 53.6± 3.2 mV; and 13 days 57.4± 5.3 mV. Only cells maintained in 0% NCS medium for 8 or 13 days generated repetitive current-evoked or spontaneous action potentials: these had TTX-sensitive and Ca^{2+}-dependent components. Serum removal clearly differentiated N1E-115 cells morphologically and physiologically indicating the presence of one or more serum factors which directly or indirectly inhibits differentiation. Further, morphological and physiological differentiation were temporally different suggesting that the two processes may be controlled by separate mechanisms. (Supported by PMAF)

EXPRESSION OF NEURONAL PHENOTYPE IN BOVINE ADRENAL MEDULLARY CHROMAFFIN CELLS S. Sleight and M.D. Browning. Department of Pharmacology, University of Colorado HSC, Denver, CO 80262.

Chromaffin cells of the adrenal medulla have long been used as a model for neurosecretion. Recently, the potential therapeutic application of human chromaffin cell transplants in Parkinson's disease has been described. In both instances, expression of neuronal phenotype by chromaffin cells would be particularly valuable. Unsicker and colleagues have demonstrated that primary cultures of bovine adrenal medullary chromaffin cell cultures exhibit modest neurite outgrowth when plated on collagen. We have monitored the expression of 2 characteristics of neuronal phenotype in such cultures. We confirmed Unsickers' work in highly purified chromaffin cell (95%) cultures, observing the flattening of the cells and expression of short neurites (length equivalent to 1 cell diameter). However, in partially purified chromaffin cell preparations (60-70% chromaffin cells, 20-30 % cells resembling fibroblasts), an extensive network of neurite extension was observed. Essentially 100% of the chromaffin cells exhibited neurite extension of distances 4-5x the diameter of the cell body. Moreover, transfer of media from these cultures to the highly purified cultures resulted in extensive neurite outgrowth in these cultures. Secretion of catecholamines was also monitored in these cultures. Highly purified cultures exhibited essentially invariant secretion with time in culture. However, in the partially purified cultures of chromaffin cells secretion increased in parallel with the extensive neuritic growth. Identification of the factor(s) responsible for the expression of neuronal phenotype in these cultures is currently under investigation. Particular attention is being given to the contribution of the various fibroblast derived growth factors. Supported by PHS grant DK40483 and NS26377 to MDB.

411.3

MOLECULAR CLONING OF AN NGF-INDUCIBLE KINASE: THE DEFINITION OF A NEW FAMILY OF KINASES WHICH MEDIATE RESPONSES TO EXTRACELLULAR SIGNALS. G.D. Yancopoulos, T. G. Boulton* and M. H. Cobb.* Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Road, Tarrytown, NY 10591.

A serine/threonine kinase (MAP-2 kinase) which can phosphorylate microtubule-associated protein (MAP-2) *in vitro* apparently acts as an intermediate in phosphorylation cascades induced by a variety of growth factors such as insulin and EGF. Evidence suggests that this MAP-2 kinase is rapidly activated following tyrosine phosphorylation by receptor or non-receptor tyrosine kinases. Activation of MAP-2 kinase is also one of the earliest detectable cellular events induced in PC12 cells by nerve growth factor (NGF). To facilitate further studies of MAP-2 kinase, we have molecularly cloned and sequenced MAP-2 kinase from a rat brain cDNA library; our cloning strategy led to the identification of additional kinases, also expressed in the rat brain, which are highly related to MAP-2 kinase. These kinases form a new family of mammalian kinases which may play crucial roles in the response to mitogens and differentiation factors. Interestingly, these mammalian kinases are most closely related to two protein kinases, recently cloned from yeast, which are thought to play antagonistic roles in pheromone-induced cell-cycle arrest.

411.4

NEUROTROPHIN-3: MOLECULAR CLONING AND COMPARISON OF DEVELOPMENTAL EXPRESSION TO NGF AND BDNF. P.C. Maisonpierre, L. Belluscio*, R.M. Lindsay and G.D. Yancopoulos. Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Road, Tarrytown, NY 10591.

The restricted neuronal specificity of NGF has long suggested that other neurotrophic factors exist which act on neuronal populations that are refractory to NGF. Recent cloning of brain-derived neurotrophic factor (BDNF) has revealed that it shares close structural similarity to NGF. Using a PCR-based approach that exploited this similarity, we have identified a novel member of the NGF-BDNF gene family, termed neurotrophin-3 (NT-3). Like NGF and BDNF, NT-3 is synthesized as a precursor protein that is cleaved to form a mature protein that has 57% and 58% amino acid sequence identity with NGF and BDNF, respectively. Recombinant NT-3 protein displays distinct neuronal specificity, compared to NGF and BDNF, when assayed on explant and dissociated cultures of PNS and CNS neurons. In contrast to the limited peripheral distribution of BDNF mRNA, NT-3 and NGF transcripts are widely expressed among adult rat peripheral tissues. In the adult CNS, all three factors are expressed at highest levels in the hippocampus; NT-3 and BDNF share other similarities in their CNS distribution. Interestingly, particular cell populations of fetal and newborn rat express NT-3 at dramatically higher levels than NGF and BDNF. The specific detection of localized, abundant NT-3 transcripts early in development points to populations of neuroblasts/neurons that may be dependent on NT-3 for their proliferation, differentiation and/or survival.

411.5

MOLECULAR CLONING AND EXPRESSION OF THE HUMAN CILIARY NEUROTROPHIC FACTOR (CNTF) GENE. P.Masiakowski, H. Liu*, R.M. Lindsay, M.E. Furth and N. Panayotatos. Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Road, Tarrytown, NY 10591.

The diverse effects of CNTF on neuronal and non-neuronal cells, observed *in vitro*, suggest important roles for this factor in the development and regeneration of the nervous system. To explore its potential, we have cloned, sequenced, and expressed in *E. coli* the human CNTF gene. The gene codes for a 200 amino acid protein, which shares about 80% identity with its rat and rabbit homologues, and also lacks an apparent secretion signal sequence. In the optimal bacterial expression system, recombinant human CNTF constituted approximately 30% of total cellular protein. The protein has been purified to apparent homogeneity. In dissociated, neuron-enriched cultures of E8 chick embryo ciliary ganglia, neuronal survival was detectable at 100 pg/ml; maximal activity was observed at 1-2 ng/ml, with EC_{50}=500 pg/ml CNTF.

411.6

STRUCTURE-FUNCTION STUDIES OF NGF, BDNF AND NT-3. N. Y. Ip, R. M. Lindsay, M.E. Furth, S.M. Bianco*, D. R. Gies*, S. P. Squinto and G. D. Yancopoulos. Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Road, Tarrytown, NY 10591.

Molecular cloning and sequence analyses of the nerve growth factor (NGF)-related neurotrophic factors, brain-derived neurotrophic factor (BDNF) and the recently identified neurotrophin-3 (NT-3), have revealed striking conservation among a variety of species. All of these factors appear to be synthesized as larger precursors that are cleaved to release the mature proteins which can support the survival of distinct neuronal populations. Analyses of the precursor sequences reveal homologous regions which may be important for precursor function. Comparisons between the mature protein sequences highlights regions that may be important in determining the distinct neuronal specificities of these factors. We have functionally expressed a series of genetically-modified NGF, BDNF and NT-3 molecules. The biological activities of these modified neurotrophic molecules provide unique insights into the relationship between their structure and function.

411.7

EFFECTS OF BRAIN DERIVED NEUROTROPHIC FACTOR (BDNF) ON RAT SEPTAL CHOLINERGIC NEURONS IN CULTURE

R.F. Alderson, A.L. Alterman*, Y.-A. Barde[1], and R.M. Lindsay.
Neurobiology Section, Regeneron Pharmaceuticals Inc., 777 Old Saw Mill River Rd., Tarrytown, NY 10591. 1. Max-Planck Inst. for Psychiatry, Dept. of Neurochemistry, D-8033 Martinsried Munich, Fed. Rep. of Germany.

BDNF and NGF share extensive sequence homology (Leibrock et. al., Nature, 1989). When tested for cholinotrophic activity on E17 rat septal cholinergic neurons in culture, BDNF produced a dose dependent increase in CAT activity. The maximum response occurred with 50ng/ml of BDNF and produced a 2.2-fold increase in enzyme activity. Time course studies demonstrated a linear rise in CAT activity during the first 3 to 6 days *in vitro* at which time the change plateaued. The extent of the increase in CAT activity produced by BDNF was equal in glia-containing or neuron-enriched cultures suggesting that BDNF is not acting through glia. The accumulation of choline via a Na+-dependent choline-uptake mechanism was increased 3.8-fold following treatment with 50 ng/ml of BDNF. The number of acetylcholinesterase positive cells per well was also increased, 2.5-fold, as compared to the non-treated controls following a 12 day treatment with BDNF.

411.8

NEUROTROPHIN-3 (NT-3): NEURONAL SPECIFICITY IN THE PERIPHERAL NERVOUS SYSTEM OF THE CHICK.

R. M. Lindsay, P. Maisonpierre, S. Squinto and G.D. Yancopoulos. Regeneron 777 Old Saw Mill River Road,Tarrytown, N.Y. 10591.

We have recently described the molecular cloning of a novel neurotrophic factor, which by sequence comparison is clearly a member of the nerve growth factor (NGF) / brain-derived neurotrophic factor (BDNF) family and has therefore been named "neurotrophin-3 ", (NT-3). Preliminary studies with recombinant NT-3 produced in COS cells, showed that NT-3 promoted survival and neurite outgrowth from explanted and dissociated neuron-enriched cultures of E8 chick embryo sensory neurons of both the neural crest-derived dorsal root ganglion and the neural placode-derived nodose ganglion. To further define the neuronal specificity of NT-3, we have now studied the effects of NT-3 on explant and dissociated cultures of sympathetic, parasympathetic, neural crest-derived (dorsal root, medio-dorsal trigeminal, jugular) and neural placode-derived sensory ganglia (nodose, petrosal, geniculate, vestibular and ventrolateral trigeminal) from chick embryos of 4-12 days of incubation (E4-E12). Placodal sensory neurons (especially nodose and petrosal) are highly responsive to NT-3 as early as E5, while crest-derived sensory neurons are responsive from E6 onwards. Sympathetic neurons show only modest response from E7 onwards, while parasympathetic neurons are refractory to NT-3 at all stages examined. With all of the ganglia we have examined additive effects of BDNF, NGF or CNTF (ciliary neurotrophic factor) with NT-3, particularly in relationship to the relative abundance of each growth factor in the specific target tissues of sub-populations of sensory neurons. These studies will be reported.

411.9

SPECIES-SPECIFIC MONOCLONAL ANTIBODIES TO THE CARBOXYL-TERMINUS OF HUMAN CILIARY NEUROTROPHIC FACTOR (CNTF).

M. E. Furth, D. M. Morrissey*, T. A. Aldrich*, L. Uffenheimer*, A. P. Mickle*, and N. Panayotatos. Regeneron Pharmaceuticals Inc., 777 Old Saw Mill River Road, Tarrytown, NY 10591.

The human CNTF gene has been identified and cloned, and its protein product expressed at high levels in *E. coli*. Monoclonal antibodies were obtained by fusion of splenocytes from mice immunized with the purified recombinant protein to SP2/0 myeloma cells. Positive hybridomas were identified by an antibody-capture assay using CNTF adsorbed to polystyrene.

One set of eight monoclonal IgG antibodies derived from a single immunized mouse react strongly with recombinant human CNTF but not with recombinant rat CNTF in the antibody-capture assay and by Western immunoblotting. None of these antibodies binds to a truncated CNTF protein lacking the 16 carboxyl-terminal amino acids, obtained by deleting sequences downstream from a unique BamH1 restriction site in the human gene. This truncated CNTF retains potent neurotrophic activity. Thus, the antibodies recognize human-specific epitope(s) in a non-essential region at the carboxyl-terminus of CNTF. Several human neuronal tumor-derived cell lines were found to have specific binding sites for CNTF and to respond to the factor, as judged by the induction of c-*fos* mRNA. The monoclonal antibodies to the carboxyl-terminus of human CNTF can be used to detect the ligand when bound to such cells. These antibodies may therefore prove useful in the isolation and characterization of CNTF receptors.

411.10

BRAIN DERIVED NEUROTROPHIC FACTOR PROMOTES SURVIVAL OF DOPAMINERGIC NEURONS OF THE EMBRYONIC RAT MESENCEPHALON.

C. Hyman, M. Hofer*, Y-A. Barde*, and R.M. Lindsay. Regeneron Pharmaceuticals, Inc. 777 Old Saw Mill River Road, Tarrytown, NY 10591 & *Dept. Neurochemistry, Max-Planck Institute for Psychiatry, D-8033 Planegg Martinsried, FRG.

The effects of brain derived neurotrophic factor (BDNF) on the survival and maturation of dopaminergic neurons of the presumptive substantia nigra were examined *in vitro*. Neurons dissociated from the fetal rat ventral mesencephalon were cultured under serum-free conditions. Immunocytochemical staining with antibodies to tyrosine hydroxylase (TH) and uptake of ^{3}H-dopamine were used to monitor the survival and maturation of the dopaminergic neurons present in these cultures. In the absence of exogenous neurotrophic factor(s), there was a 67% loss of TH positive neurons between day three and day eight in culture; although dopamine uptake showed an initial rise during the first eight days, this also declined with time in culture. A single treatment with BDNF one day after placing the cells in culture increased the survival of TH positive neurons by 1.9- fold eight days later. If BDNF was added in multiple doses at culture days 1,2,4,6 and 8, the relative increase observed by culture day 11 was 2.7-fold. The response to brain derived neurotrophic factor was dose-dependent and specific, in that nerve growth factor (NGF) was without effect. Experiments in which the addition of BDNF was delayed for several days indicated that observed effects of BDNF were mediated by increasing cell survival and not merely by increasing expression of TH immunoreactivity. These finding may have implications for the development of a novel therapeutic approach to Parkinson's disease.

411.11

A MUSCLE-DERIVED FACTOR PROMOTES BOTH SURVIVAL AND GROWTH BUT NOT CHOLINE ACETYLTRANSFERASE ACTIVITY IN CHICKEN SPINAL MOTOR NEURONS.

T.H. Oh, S.J. Jeong, S.L. Hobbs and G.J. Markelonis. Dept Anatomy, Univ Maryland Sch Med, Baltimore, MD, 21201.

Developing embryonic neurons require a target-derived trophic factor for survival. A protein distinct from other known neurite-inducing proteins was substantially purified from muscle tissue (Oh et al., Dev. Biol., 127:88, 1988). Purified motor neurons prepared from 6-day-old chicken embryos were used in assessing the trophic activity of this protein. Approximately 25% of the neurons initially seeded survived for 6 days in the presence of the protein. The survival rate was further enhanced by the addition of laminin. However, the specific activity of choline acetyltransferase and the level of activity of the high affinity choline uptake system were not changed after 6 days. This suggests that although this trophic protein supports motor neuron survival, it has no specific effect on the cholinergic properties of motor neurons. The protein was also found to support the survival of chicken embryonic dorsal root ganglionic neurons, sympathetic and ciliary ganglionic neurons. The survival of both DRG neurons and sympathetic neurons was increased further by the presence of NGF. The trophic protein has been purified and migrates as a doublet with MWs of 53 and 57 kDa on SDS-gel electrophoresis. Preliminary amino acid data suggest that the 53 and 57 kDa proteins are either closely related or identical. (Supported by NIH grant NS 15013 and by the Bressler Research Fund).

411.12

REGULATION OF NERVE GROWTH FACTOR SYNTHESIS BY FIBROBLAST GROWTH FACTOR IN ASTROCYTES

K. Yoshida, and F.H. Gage. DEPT. OF NEUROSCIENCES, UNIVERSITY OF CALIFORNIA-SAN DIEGO, LA JOLLA, CA 92093.

The mechanism regulating NGF synthesis in astrocytes was investigated.Astrocytes obtained from newborn rat brains were seeded on a 24-well culture plate. NGF levels were measured by two-site enzyme-immunoassay. NGF secretion by astrocytes was highest just after passage, and then gradually decreased. There was no difference in NGF secretions by astrocytes from five regions: cerebral cortex, striatum, hippocampus, septum, and cerebellum. The effects of growth factors and lymphokins were tested. Although, PDGF, IL-3, and IL-6 had no significant effect, acidic and basic FGFs, EGF, IL-1, and TNF-∂ increased NGF secretion. Among these, aFGF has the most potent effect, and the next is bFGF. IL-1, and TNF-∂ increased NGF secretion in the presence of aFGF, while bFGF and EGF did not. The peak of NGF secretion occurred 3-12 hrs after the addition of aFGF. On the other hand, increase of cell number became significant 12-48 hrs after FGF-stimulation. Although astrocytes become fibrous-shaped by FGF-stimulation, no significant morphological change was observed in the first 12 hrs. NGF secretion by astrocytes in the presence or absence of aFGF was completely inhibited by the addition of cycloheximide or actinomycin-D. FGFs also increased NFG secretion by fibroblasts derived from meninges, but not by microglia. These results indicate that FGFs activate astrocytes to produce NGF in damaged brain in consert with other growth factors and lymphokines.

411.13

BASIC FIBROBLAST GROWTH FACTOR ENHANCES THE NGF RECEPTOR PROMOTER ACTIVITY IN HUMAN NEURO-BLASTOMA CELLS; CHP100.

M. Taiji, K. Taiji*, K.L. Deverle* & M. Bothwell. Dept. of Physiology & Biophysics, Univ. of Washington, Seattle, WA98195.

Human neuroblastoma cells (CHP100) have been used to develop an *in vitro* model for sympathetic neuron differentiation. Basic fibroblast growth factor (bFGF) induces morphological changes in CHP100 cells, including neurite outgrowth and hypertrophy; in contrast, NGF does not induce any morphological changes in CHP100 cells, although immunocytochemical staining shows some endogenous expression of human NGF receptor (hNGFR). To assess the effect of NGF and bFGF on the hNGFR promoter, whose activity is known to be developmentally regulated, a 6.7kb 5'-flanking region containing hNGFR promoter was isolated from the hNGFR genomic clone and linked to the reporter gene chloramphenicol acetyltransferase (CAT). This hNGFR promoter-CAT fusion gene was transfected into CHP100 cells, and stably transformed cells expressing CAT activity were selected. The level of CAT activity in these cells was examined following treatment with bFGF or NGF. bFGF (10 ng/ml) increased the CAT activity in these transformed cells. However, NGF (100 ng/ml) did not significantly change the CAT activitiy. These results indicate that the hNGFR promoter activity in CHP100 cells is initially regulated by bFGF, but not by NGF.

411.14

DIFFERENTIAL EFFECTS OF aFGF AND bFGF ON SYMPATHETIC OUTGROWTH FROM NEONATAL MOUSE SUPERIOR CERVICAL GANGLIA IN VITRO.

M. Deschuyteneer, K.W. Roche* and J.N. Davis. Neurology Division, Dept. of Medicine; Duke University Medical Center; Durham, NC 27710.

Fibroblast growth factor appears to influence the kinetics and morphology of neuronal outgrowth in a variety of *in vitro* models. We have compared the effects of human recombinant acidic FGF (aFGF) and human recombinant basic FGF (bFGF) at various concentrations (10, 50, 100 and 500 ng/ml) on neurite outgrowth from sympathetic neurons. Superior cervical ganglia from 2-3 day old mice were cultured for several days on collagen-coated coverslips. The lengths of extending neurites and the outgrowth areas were measured using image analysis. Ganglia morphology was studied with light and scanning electron microscopy. In the absence of growth factors, the outgrowth was sparse, consisting of non-neuronal cells (NNC) and few scattered neurites. Both aFGF and bFGF stimulated the asymmetrical and heterogeneous outgrowth of numerous NNC. In addition, aFGF consistently promoted the outgrowth of neurites. They formed a fine and relatively dense network. The neurites grew on top of the non-neuronal cells to which they were closely associated. In contrast, neurite outgrowth elicited by bFGF was not consistent and was seen mostly at the highest concentrations tested (100, 500 ng/ml). The morphology of this neurite outgrowth was similar, but less dense than that observed with aFGF. Heparin was required for the aFGF effects.

Thus aFGF is more potent than bFGF in stimulating sympathetic neurite outgrowth. FGFs may have a direct effect on sympathtetic neurons or indirectly stimulate outgrowth by acting on the NNC.

Supported by the NIH (NS 06233) and the Veterans Administration.

SURVIVAL OF RETINAL GANGLION CELLS "IN VITRO": EFFECT OF CONDITIONED MEDIUM FROM RETINAL CELL AGGREGATES. E. G. de Araujo* and R. Linden. Instituto de Biofisica, UFRJ, Rio de Janeiro, 21944, Brasil.

Previous studies indicated that the survival of developing ganglion cells "in vivo" depends on other retinal cells. We are now studying the degeneration of retinal ganglion cells "in vitro". Retinae of newborn rats were retrogradely labeled with horseradish peroxidase injected in the superior colliculus. One day later, the retinal cells were dissociated and cultured for 1-3 days, and the survival rates of labeled ganglion cells were evaluated. We tested the effects of culture media conditioned for 4-7 days on aggregates or explants of neonatal retinal cells. It was found that both conditioned media increased about twice the rate of survival of ganglion cells after 2-3 days in culture, when compared with control medium. The data presented here suggest that soluble molecules released by intrinsic retinal cells contribute to the control of ganglion cell survival "in vitro". (CNPq, FINEP, FAPERJ, CEPEG-UFRJ).

TROPHOMORPHISM: A UNIFYING HYPOTHESIS TO EXPLAIN NEURONAL REARRANGEMENTS. K.A. Crutcher and B.N. Saffran, Dept. of Neurosurgery, University of Cincinnati Medical Center, Cincinnati, Ohio 45267.

The results of experiments in which intraventricular infusion of NGF was found to cause remodeling of mature uninjured sympathetic axons led us to postulate that alterations in trophic support in the absence of injury may be sufficient to elicit axonal remodeling (trophomorphism) (Saffran and Crutcher, Brain Research, in press). A review of several other examples of developmental and injury-induced neuronal rearrangements also provide support for this hypothesis and suggest that a common mechanism might underlie these phenomena. We propose that the relative distribution of trophic support to different neuritic branches of the same neuron determines the survival and distribution of the neurites. This hypothesis is based on four postulates: 1) Nerve cells require a minimum amount of trophic factor for survival (trophic theory of neuronal connections), 2) Nerve cells extend neurites in order to obtain trophic support, 3) Nerve cells maximize the amount of trophic support acquired relative to the volume of cytoplasm they maintain, 4) Neuritic branches from the same nerve cell compete with each other for growth materials from the cell body (Smalheiser and Crain's "sibling neurite bias" hypothesis, J. Neurobiol., 15:517, '84). If these postulates are correct, changes in the distribution of trophic support, or injury to axonal branches that disrupt the acquisition of trophic factor by the nerve cell, result in neuronal remodeling in order to maximize trophic support to the cell body. Such a mechanism is consistent with normal developmental remodeling of axonal arbors, the retention of normally-transient branches following elimination of collaterals, and injury-induced neuronal rearrangements in maturity. (Supported by NS-17131 and AG-07691).

NETWORKS FORMED BY DORSAL ROOT GANGLION CELLS IN ORGANOTYPIC CULTURES : A COMPUTER-AIDED ANALYSIS OF HRP INTRACELLULARLY LABELED NEURONS. **M.C. Calvet, M.J. Drian* and J. Calvet*. INSERM U-336, EPHE, Institut de Biologie, 34060 Montpellier, FRANCE**

The patterns of growth, the arborizations and the neuritic pathways formed by fetal rat dorsal root ganglion (DRG) cells were compared when cultured with or without organized spinal cord explants. Intracellular iontophoretic HRP staining of the cultured DRG neurons allowed a 3-dimensional reconstruction of these individually labeled cells and a morphometric analysis of their neuritic processes. Two populations of DRG neurons were studied : 1 - Isolated DRG cells explanted at 15 to 17-day fetal rats. 2 - DRG cells with their attached transverse cross-section of whole spinal cord and explanted at 13 to 14-day fetal rats. When compared to attached neurons, the isolated DRG neurons showed longer neuritic lengths, larger neuritic field areas and more numerous branches developing in a multipolar way. The DRG neuron attached to spinal cord had significantly smaller and mostly bipolar processes with well individualized central and peripheral branches. Such preliminary results indicate that the spinal cord (and more precisely the target cells of the dorsal horn) acts as a prominent factor upon the development of the DRG neuritic networks.

PRODUCTION OF DIFFERENT TRUNCATED FORMS OF RECOMBINANT HUMAN NERVE GROWTH FACTOR RECEPTOR IN A BACULOVIRUS SYSTEM. V. Prabhakar, J.L. Goerke* and A. H. Ross. Worcester Foundation for Experimental Biology, 222 Maple Avenue, Shrewsbury, MA 01545.

Recombinant extracellular domain (RED) of human nerve growth factor receptor (NGF-R) is being produced in bulk quantities for biochemical characterization and X-ray crystallography using a recombinant baculovirus in Sf9 (Spodoptera frugiperda) cells in suspension culture. The RED in preliminary studies was found to be a monomer by chemical crosslinking and equilibrium centrifugation. The RED is asymmetric with a frictional coefficient of 1.7. When recombinant virus encoding RED was injected into Trichoplusia ni larvae, the RED produced (TnRED) was found to be glycosylated unlike that produced in Sf9 cells (Sf9RED). There does not seem to be any significant change in the binding pattern of TnRED with ^{125}I-NGF compared to the Sf9RED. TnRED is heat stable retaining at least 60% of the specific binding even after heating at 100°C for 15 min. This stability may result from the large number of RED disulfide bonds. Binding studies of ^{125}I-RED with NGF-responsive but NGF-R lacking neuronal cell types are in progress, in a bid to identify the NGF-R associated proteins. For the same purpose, other recombinant viruses encoding the extracellular, the transmembrane and intracellular domains are being produced.

IN VITRO ANALYSIS OF ASTROCYTE MEDIATED NEURITE BEHAVIOR IN THE HIPPOCAMPUS OF THE GRAY SHORT-TAILED OPOSSUM. R.K. Lartius and E.Uemura. Department of Veterinary Anatomy, Iowa State Univ., Ames, IA 50011.

The intimate relationship between the neuron and glial cell plays a key role in the development of the central nervous system. In this study we examined changes in neurite morphology which occurred when neurons and astrocytes isolated from the hippocampus of the Brazilian gray short-tailed opossum were co-cultured under various conditions. Astrocytes were harvested on day P19 from opossum hippocampi and grown to confluency. Conditioned medium was collected every 2 days for 10-14 days. At this time the cells were trypsinized and co-cultured with hippocampal pyramidal cells isolated on day P8-9. Control cultures of hippocampal neurons alone were simultaneously plated. Glial monolayers were prepared 1 day prior to the seeding of hippocampal neurons. As expected, it was observed that neurons grown on glial monolayers tended to be multipolar with extremely lengthy processes. Further, their long-term survival was greatly enhanced compared to control cultures. Astrocyte-conditioned media also enhanced neurite outgrowth and survival of astrocyte-free cultures. In contrast, when neurons and astrocytes were dispersed and plated at a ratio of approximately 5 to 1, neurons exhibited multipolar, bipolar, or unipolar characteristics depending on the distance between the cells and the level of neurite-neuron and neurite-astrocyte contact. If the neuron made no contact with a glial cell or it made contact but its soma was within 3 cell bodies of the astrocyte, there was a high probability that the cell would display multipolar characteristics. If the neuron was more than 3 cell bodies away and made contact with the glial cell alone, there was a high probability that the neuron would be bipolar or unipolar. Neurons which were in contact with other neurons generally remained multipolar regardless of their relationship with the astrocyte. These findings suggest that both soluble and membrane bound glial factors exert influence on neurite outgrowth during development.

CULTURED RAT ASTROCYTES EXPRESS FUNCTIONAL INTEGRINS. **N.J.Tawil and S.Carbonetto. The Centre for Neurosciences, McGill University, Montreal General Hospital Research Institute, Montreal, Canada H3G 1A4.**

We had shown earlier that Mab 3A3, which is directed against the rat α_1 integrin subunit, labelled the cell surface of rat astrocytes (Tawil et al., 1990, Biochemistry, in press). Using polyclonal antibodies against the β_1 and β_3 integrin subunits in cell attachment assays we have shown that astrocytes bind to different extracellular matrix molecules such as laminin, collagen, fibronectin and vitronectin through receptors of the integrin family. Immunoprecipitation of these integrins suggests that two heterodimers ($\alpha_1\beta_1$ and $\alpha_3\beta_1$) participate in the attachment of astrocytes to laminin, collagen and fibronectin. Astrocytes also express a heterodimer from the β_3 subclass, $\alpha_v\beta_3$, which mediates the attachment of astrocytes to vitronectin. We have also shown that Schwann cells and oligodendrocytes express β_1 and β_3 integrins. These data suggest that integrins are important for glial-matrix adhesion. We are presently looking at integrin expression and function on glia in vivo.

GANGLIOSIDE GM1 POTENTIATES THE RISE IN INTRACELLULAR FREE-Ca^{++} DUE TO K^+ DEPOLARIZATION IN PC12 CELLS. B. S. Hilbush and J. M. Levine. Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794.

Gangliosides are highly enriched components of the neuronal cell surface which exert neuritogenic and neurotrophic effects when added exogenously to cells in culture. These effects include the potentiation of nerve growth factor (NGF)-induced neurite outgrowth and NGF-mediated activation of protein kinases in PC12 cells. Ganglioside GM1 stimulation of a Ca^{++}- dependent protein kinase activity in K^+ depolarized or NGF treated cells (Hilbush and Levine, submitted) suggests that gangliosides may modulate signal transduction pathways dependent upon the entry of extracellular Ca^{++}. Ganglioside dependent changes in intracellular-free Ca^{++} could account for these effects. We tested this possibility by measuring the changes in $[Ca^{++}]_i$ due to K^+ depolarization in cells pretreated with GM1 ganglioside.

PC12 cells cultured on poly-L-lysine/laminin coated glass coverslips were incubated in the presence or absence of 10 μM GM1 for 2 hr followed by incubation with 1 μM Fura 2AM for 30 min. Fluorescence intensities were measured from single cells after excitation at 355 and 380nm and $[Ca^{++}]_i$ was determined by the ratio method (Grynkiewicz, et al, J. Biol. Chem. 260:3440.). Cells were depolarized by bath application of saline containing 30-60 mM KCl for 2-5 min. The rise in $[Ca^{++}]_i$ was compared between identically treated pairs of individual cells from GM1 treated and untreated dishes. GM1 treatment caused an enhanced response to K^+ depolarization in >90% of the pairs; the rise in $[Ca^{++}]_i$ due to 30 mM K^+ increased from 93 ± 20 nM in untreated cells to 205 ± 41 nM in GM1 treated cells. Brief application of GM1 (1-5 min) over a wide range of concentrations had no effect on $[Ca^{++}]_i$ by itself or when applied to cells depolarized with K^+. Thus, the exposure of PC12 cells to ganglioside GM1 for 2 hr results in a significant enhancement of the ensuing rise in $[Ca^{++}]_i$ due to K^+ depolarization. These results suggest that the neuritogenic and neurotrophic properties of exogenous gangliosides may be due to their ability to augment changes in $[Ca^{++}]_i$ resulting from normal extracellular stimuli.

412.8

DISTRIBUTION OF CALCITONIN GENE RELATED PEPTIDE (CGRP) IMMUNOREACTIVITY IN THE EMBRYONIC AND NEONATAL RODENT OLFACTORY SYSTEM H.Baker[1], M. Bailey[2] and M.T. Shipley[2] [1]Cornell Univ. Med. Coll., White Plains, NY 10605 and [2]Univ. Cincinnati Coll. Med., Cincinnati, OH, 45267.

The mechanisms by which olfactory receptor cells exert their trophic influences on development and maintenance of phenotypic expression in the olfactory bulb have not been established. A recent report (Nature, 339:701, 1989) suggested that CGRP is localized to olfactory receptor cells and regulates the expression of the dopamine phenotype in dispersed cultures of embryonic olfactory bulb. The *in vitro* findings were interpreted to suggest that CGRP is the endogenous molecule which regulates the dopamine phenotype *in vivo*. The current studies investigated whether, *in vivo*, CGRP exhibits a distribution in either adult or embryonic olfactory neurons consistent with its putative trophic role in the regulation of the dopamine phenotype. Two CGRP antisera were utilized. One, obtained from Amara and Blakely (Yale Univ.), was the same as that used in the previous *in vitro* studies. The peptide was not found in olfactory receptor cells of rat and mouse embryos examined both prior to and after the appearance of tyrosine hydroxylase, the first enzyme in dopamine biosynthesis. In the same tissue sections, CGRP immunoreactivity was found in other CNS and PNS neurons, such as spinal cord and trigeminal ganglion, respectively. In addition, varicose fibers, presumably of trigeminal origin, were present in the lamina propria of late embryonic and neonatal olfactory epithelia. In adult rat, a small number of receptor cells and varicose fibers exhibited CGRP-like immunoreactivity. These data demonstrate that, although CGRP may influence dopamine expression in culture, *in vivo* this peptide does not display the appropriate temporal or spatial distribution necessary for trophic regulation of the phenotype in either developing or adult rodents. Supported by DC-00347 and MH44043.

DIFFERENTIAL REGULATION OF GLUTAMIC ACID DECARBOXYLASE (GAD) AND TYROSINE HYDROXYLASE (TH) mRNA LEVELS IN FUNCTIONALLY-DEAFFERENTED RODENT OLFACTORY BULB. D.M.Stone[1], M.Grillo*[2], F.L.Margolis[2], H.Baker[1] and T.H.Joh[1], [1]Cornell Univ. Med. Coll., White Plains, NY, 10605, [2]Roche Inst. Mol. Biol., Nutley, NJ, 07110.

Expression of the dopaminergic phenotype in olfactory bulb (OB) juxtaglomerular (JG) neurons is dependent upon functional afferent receptor cell innervation. In rodents, destruction of the olfactory epithelium by intranasal irrigation with $ZnSO_4$, or unilateral odor deprivation in neonates, results in a profound decrease in OB TH activity, immunoreactivity and mRNA, when assesed 20-40 days after treatment. At this time, the preservation of immunoreactivity for GABA, a neurotransmitter colocalized with dopamine in JG neurons, suggests that the cells do not die but alter their phenotype. The current study was designed to further characterize the transneuronal effect of functional OB denervation on OB mRNA levels and to determine whether region- or cell type-specific alterations might occur in OB GAD expression. CD-1 mice were intranasally irrigated with 100 μl of 0.17M $ZnSO_4$ or saline (control) and sacrificed 3 weeks later. Neonatal Sprague-Dawley rats were subjected to unilateral naris cauterization and sacrificed 40 days after treatment. OBs were processed for TH and GAD *in situ* hybridization, Northern blot analysis, or immunocytochemistry. Random-primed-labelled fragments of rat TH cDNA or mouse GAD cDNA (provided by R. Greenspan and G. Szabo) were used as probes. By both Northern and *in situ* analyses, JG TH mRNA levels were greatly reduced in both $ZnSO_4$-deafferented (4% of control) and odor-deprived (56% of control) bulb, whereas JG GAD mRNA remained essentially unchanged in both rodent models. Since GAD is found in nearly all dopaminergic OB cells, the preservation of GAD message implies a differential regulation by olfactory receptor cells of TH and GAD gene expression. Supported by grants #DC00336 and MH44043.

VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) CAUSES INTRACELLULAR CALCIUM OSCILLATIONS IN ASTROCYTES. J. T. Russell, A. Fatatis, P.G. Nelson, and D. E. Brenneman, LDN, NICHD, Bethesda, MD 20892., and Instituto di Farmacologia, II Policlinico, Napoli, Italy.

Previous studies have shown that low concentrations of VIP release neurotropic substances from astrocytes in culture (J. Neurosci. Res. 25: 386, 1990). We have examined the effect of similarly low concentrations of VIP on cytosolic free calcium concentration in astrocytes from new-born rats in culture by monitoring the fluorescence of the calcium indicator, fura-2 using high resolution video microscopy. The cultures were made up primarily of type I cortical astrocytes. Intracellular calcium ion concentration rapidly rises (upto two fold) upon perfusion with VIP (0.01 to 0.1 nM) in most astrocytes. The initial rise is followed by prolonged oscillations in $[Ca^{2+}]_i$ in some cells. In others the rapid rise was followed by steady, elevated intracellular calcium levels. The oscillations were of constant frequency (period = 11 ± 4 sec) and amplitude. Upon removal of agonist the $[Ca^{2+}]_i$ levels ceased to oscillate and returned to resting levels. In calcium free EGTA containing (1 mM) Ringer solutions, although the initial rise was smaller, the oscillations still persisted suggesting that they are caused by release of calcium from intracellular stores. This elevation of intracellular free calcium may participate in the mechanism by which VIP receptor activation causes secretion of factors necessary for neuronal survival from astrocytes.

INCREASE IN SURFACE ACETYLCHOLINE RECEPTOR IN L5 CLONED MUSCLE CELLS INDUCED BY ASCORBIC ACID IS NOT MEDIATED BY COLLAGEN. E. Liu*[1], R. Minor*[2], J. Wootton*[2], T. Podleski[1], and M. Salpeter[1]. [1]Neurobiology & Behavior, [2]Vet. Pathology, Cornell University, Ithaca, NY 14853.

Ascorbic acid (Asc) is the active component of fetal brain extract that induces increased acetylcholine receptor (AChR) expression in myotubes of the L5 rat clonal muscle cell line (Knaack, Shen, Podleski & Salpeter, J. Cell Biol. 102:795, 1986). The induction of AChR expression, as determined by binding of I-125-α-bungarotoxin, occurs with a delay of 20h (Horovitz, Knaack, Podleski & Salpeter, J. Cell Biol. 108:1823, 1989). Furthermore, we find that the delayed increase in AChR can be triggered by a 5 hour exposure to Asc. These studies suggest that an intermediary compound(s) may be involved.

Asc has also been shown to increase collagen secretion in muscle cell cultures (Kalcheim, Vogel, Duksin, PNAS 79:3077, 1982). We investigated regulation of collagen by Asc and asked whether collagen could be an intermediate in the Asc induced upregulation of surface AChR in the L5 cells. We find that collagen increases in response to Asc (2 fold by 6 hours), well in advance of the increase in surface AChR expression. When pepsin digested media from cultures labeled with ^{3}H-proline were assayed on SDS-PAGE, we identified types I, III and V collagens as the soluble species that increase in response to Asc. We and others have shown that the mononucleated cells and not the myotubes are the source of the collagen in muscle cultures. Therefore if collagen mediated the AChR response, that mediation would need to be via collagen secreted into the culture medium. When ultrapure bacterial collagenase was added to the cultures together with Asc, secreted soluble collages were eliminated from the culture media but surface receptors were still elevated to the same extent as produced by Asc alone. From these experiments, we conclude that Asc increases collagen secretion and surface AChR expression independently. Secreted collagen is therefore not an intermediate in the increased expression of AChR.

BUTYRATE-INDUCED DIFFERENTIATION OF PC12 CELLS. K. Spiegel. Parke-Davis Div. of Warner-Lambert Co., Ann Arbor, MI 48105.

Previous work by many laboratories has demonstrated that N^6,2'-O-dibutyryl cyclic AMP (Bt_2cAMP) can produce a differentiation of PC12 cells similar to that caused by treatment with nerve growth factor (NGF): cell division slows, neurites are elongated and choline acetyl transferase (ChAT) activity is increased. The present study examines the role of the butyrate moiety in the actions of Bt_2cAMP on PC12 cells. Treatment of PC12 cells for 7 days with n-butyric acid (320 μM-3.2 mM) produced a modest outgrowth of short, thick neurites and an induction of ChAT activity similar to that produced by NGF. Bt_2cAMP produced a similar growth of short neurites and a comparable increase in ChAT. In addition, cotreatment of cultures with NGF and either butyrate or Bt_2cAMP produced a much greater than additive increase in ChAT as well as potentiated neurite outgrowth. In contrast, treatment of cultures with 8-bromo-cyclic AMP produced only a modest increase in ChAT activity and a greatly reduced potentiation of NGF. These results suggest that the butyrate moiety of Bt_2cAMP contributes to the actions previously attributed to cyclic AMP.

412.13

ASSESSMENT OF NEUROTROPHIC ACTIVITY OF A BROAD SPECTRUM OF PHARMACOLOGIC AGENTS IN PC12 CELLS. C. Bay, M.R. Dickerson, R.E. Davis and K. Spiegel. Parke-Davis Div. of Warner Lambert Co. Ann Arbor, MI 48105.

The PC12 cell line, a rat pheochromocytoma, responds to nerve growth factor (NGF) by differentiating into sympathetic neuron-like cells. Cell division slows, neurites are extended and expression of choline acetyltransferase (ChAT) is increased in response to NGF exposure. This provides an in vitro model system for detection of NGF-mimetic or -modulatory activity. In order to determine the specificity of these responses, the effects of agents with known mechanisms of action were examined. PC12 cells were treated with either test compounds alone to see if they possess NGF-mimetic properties or in combination with NGF to look for modulatory actions. After seven days, a qualitative assessment of neurite outgrowth was made and cultures were then harvested and assayed for ChAT activity. Agents acting at cholinergic, catecholaminergic, glutamate, GABA, adenosine, and opiate receptors were tested. In addition, the effects of a series of neuropeptides, polyamines, phosphodiesterase inhibitors, phorbol esters, cyclic nucleotides, and growth factors were examined. Only fibroblast growth factor, butyrate, and cyclic AMP analogs increased levels of ChAT activity. All three agents produced neurite outgrowth, although the neurites produced with the individual treatments differed qualitatively. The same compounds and cyclohexyladenosine were found to potentiate NGF's effects on both neurite outgrowth and ChAT activity.

412.14

STAUROSPORINE DIFFERENTIALLY INFLUENCES NEURITE OUTGROWTH INDUCED BY NGF OR FGF IN PC12 CELLS. M.R. Dickerson, R.Cowmeadow, C. Bay, R.E. Davis and K. Spiegel. Dept. Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert, Ann Arbor, MI 48105.

Cultures of PC12 cells were grown in the presence of nerve growth factor (NGF) or basic fibroblast growth factor (FGF), either alone or in combination with staurosporine, a protein kinase inhibitor. Cultures were evaluated for neurite outgrowth at 24 hrs, 3, 5, and 7 days. Cells receiving either growth factor alone underwent rapid transformation producing neurites in a dose and time dependent manner. Cells grown in the presence of staurosporine alone (3 nM - 30 nM) produced neurites that were qualitatively different from those produced in response to NGF or FGF. Initially, staurosporine induced neurites which were longer and more numerous than those induced by either NGF or FGF; this response appeared to be concentration dependent. However, within 3 days in culture, the staurosporine-induced neurites had begun to retract. This subsequent retraction of the staurosporine-induced neurites was also related to concentration. When added in combination with either growth factor, staurosporine initially potentiated neurite outgrowth; however, over time, staurosporine inhibited neurite outgrowth in NGF treated cultures. In contrast, staurosporine potentiated neurite outgrowth induced by FGF in a dose dependent manner at all time points examined. These results suggest that nerve growth factor and fibroblast growth factor promote the formation of neurites in PC12 cells via different or divergent pathways.

PARACRINE RELATIONSHIP BETWEEN ASTROGLIA AND MICROGLIA IN CULTURES. C. Hao*, L.J. Guilbert* and S. Fedoroff. Department of Anatomy, University of Saskatchewan, Saskatoon, Sask., Canada S7N 0W0 and Red Cross Blood Transfusion Service, Edmonton, Alta. Canada T6G 2R8.

We believe that macrophage-like cells originating in nutritionally deprived astroglia cultures are counterparts of resident microglia in the CNS (Hao et al., Int. J. Dev. Neurosc. in press). Such microglia contain proto-oncogene c-fms, which codes for colony-stimulating factor-1 (CSF-1) receptor. Under normal culture conditions, microglia do not release CSF-1. However, astroglia in cultures release between 100-300 units/ml of CSF-1 but do not express CSF-1 receptor. In the presence of 1 ng/ml of bacterial cell wall lipopolysaccharide (LPS), microglia produce CSF-1 and tumor necrosis factor (TNFα). Neither LPS nor IFN-γ appreciable upgrade the secretion of CSF-1 in astroglia. We found that TNFα is antagonistic to the CSF-1 effect on microglia. This effect is quite different from that observed on bone marrow macrophages.

We propose that under normal culture conditions microglia depend for survival and maturation on CSF-1 paracrine signalling by astroglia but in the presence of LPS and/or IFN-γ microglia become independent of astroglia by developing CSF-1 autocrine signalling. In such conditions microglia seem to be regulated by positive CSF-1 and negative TNFα signalling.

DIFFERENT CONCENTRATION REQUIREMENTS OF ADULT AND DEVELOPING DORSAL LATERAL GENICULATE NUCLEUS (dLGN) NEURONS FOR A NEURON SURVIVAL FACTOR. K.L. Eagleson, F. Haun and T.J. Cunningham. Dept. of Anatomy, Medical College of Pennsylvania, Philadelphia, Pa. 19129.

We have previously identified a neuron survival factor that is able to promote the survival of dLGN neurons following visual cortex lesions. The factor is contained in a macromolecular fraction of medium conditioned by explants of the embryonic primordia of the geniculocortical pathway and is concentration specific for two distinct populations of dLGN neurons (defined by their time of origin). After lesions in infant rats, earlier generated neurons (labeled with ^{3}H-thymidine on E14) require a 200-fold lower concentration of the fraction for maximal survival compared to later generated neurons (labeled on E15/16). The distinct peaks of activity for these two populations of neurons in the neonate is no longer observed in the adult. Both E14 and E15/16 neurons could be rescued over the entire 200-fold range of concentrations tested in the infant. Thus, the neurotrophic factor retrieved from these co-cultures is effective for both populations of dLGN neurons over broader and overlapping concentrations in the adult, compared to restricted and non-overlapping concentrations in the neonate. The results may reflect the strict neurotrophic requirements of young neurons during critical developmental stages.

BASIC FIBROBLAST GROWTH FACTOR (bFGF) PROMOTES ENTRORHINAL LAYER II CELL SURVIVAL AFTER PERFORANT PATH AXOTOMY. B. J. Cummings and C. W. Cotman, Department of Psychobiology, University of California, Irvine, CA 92717.

The entorhinal cortex is the primary source of afferents to the hippocampus and is a foci of degeneration in Alzheimer's Disease. In an animal model of entorhinal cell loss, axotomy of medial entorhinal cortical fibers projecting to the dentate gyrus of the hippocampal formation via the perforant path leads to selective retrograde cell loss in layer II of entorhinal cortex. We have previously demonstrated that ventricular infusion of basic fibroblast growth factor (bFGF) spares fimbria-fornix axotomized septal cholinergic neurons from atrophy. In the present study, we examined whether chronic bFGF infusion could spare layer II entorhinal stellate cells. Fourteen days after unilateral transection of the perforant path, a 25% loss of Nissl stained cells was detected in the ipsilateral layer II of medial entorhinal cortex relative to the contralateral side. In addition, many weakly stained, achromatic cells were also observed on the transected side. In contrast, no detectable changes in the number of cells were found in layer IV, a cell layer which does not project to the dentate gyrus. Intraventricular infusion of 5 µg/ml bFGF at 5 µl/hour over 14 days via an Alzet miniosmotic pump ameliorated layer II cell loss to less than 5%. In addition, the number of achromatic, weakly stained cells was also reduced. Thus, ventricular infusion of bFGF can prevent cell loss associated with retrograde degeneration in the entorhinal cortex following axotomy of the perforant path. These findings could lead to a better understanding of the utilization of trophic factors in neurodegenerative disease.

RETARDATION OF SYMPATHETIC NEURONAL OUTGROWTH IN CULTURE BY β AMYLOID ISOLATED FROM ALZHEIMER'S DISEASE BRAINS. A.E. Roher*, M.J. Ball, S.V. Bhave, T.D. Wakade* and Arun R. Wakade. Depts. of Anatomy/Cell Biology and Pharmacology, Wayne State University, Detroit, MI, and Dept. of Pathology, University of Western Ontario, London, Canada.

We have examined the effects of β amyloid(βA) isolated from patients with Alzheimer's disease on the survival and neurite outgrowth of peripheral sympathetic neurons(SN) of chick embryo and neonatal rat. The neuritic plaque core proteins (NPCP) were isolated, solubilized in 80% formic acid, precipitated by dialysis against guanidine-HCl and fractionated by Superose 12 size exclusion HPLC. The βA containing fraction was dialyzed against betaine. Dissociated SN were cultured in F14 medium supplemented with insulin and transferrin (1 µg/ml) and NGF (40 ng/ml), or phorbol 12,13-dibutyrate (100 nM). βA (5-60 µg/ml) caused dose-dependent reduction in the survival of both types of SN in 24 to 48 hrs. Higher concentrations (50 µg/ml) killed SN, whereas lower concentrations (20 µg/ml) arrested the neurite outgrowth. After washout of lower concentrations of NPCP and βA, SN resumed their normal growth. When SN were cultured for 2 days and then exposed to 50 µg/ml NPCP, there was gradual loss of neurites followed by disintegration of cell bodies. We conclude that βA of Alzheimer's disease apparently is capable of arresting the growth of sympathetic neurons. (Supported by NIH HL18601, AG03047 and Atkinson Foundation.)

ACETYLCHOLINE RECEPTOR-INDUCING ACTIVITY DOES NOT INCREASE INTRACELLULAR C-AMP IN CHICK MYOTUBES F.A. Johnson, D.L. Falls, G.D. Fischbach Dept of Anatomy and Neurobiology, Washington University School of Medicine, St Louis, MO, 63110

ARIA, AChR-Inducing-Activity, is a 42kD glycoprotein purified from chicken brain that increases the synthesis of AChRs in chick myotubes, and may play a role in the development of the neuromuscular junction. We are interested in second messengers that might mediate this effect. Drugs that increase intracellular cAMP also increase the synthesis of AChRs. Therefore ARIA may act through increasing cAMP. Fibroblast-free cultures of chick myotubes were treated with ARIA, CGRP, a small peptide that increases the number of AChRs and cAMP levels (Fontaine et al, J. Cell Bio. 105 1337-1342), or Forskolin, an activator of adenylate cyclase. The cells were harvested at various times from 5 mins to 24 hrs after drug treatment and cAMP measured by a radioimmunassay sensitive to 2 fmol. Forskolin, at 100 uM, increased cAMP levels 17-fold, reaching the half maximal effect before 5 min. CGRP increased cAMP 4.5-fold over a similar time course. ARIA produced no detectable increase. In parallel plates used to assay AChR insertion rate, measured by ^{125}I-bungarotoxin binding, ARIA increased receptor incorporation 3.2-fold, Forskolin, 4.3-fold, and CGRP increased it by 10%. Furthermore, in separate experiments, the effects of ARIA and Forskolin, and ARIA and CGRP were additive. As ARIA had as large effect on receptor incorporation as Forskolin and larger than CGRP and caused no detectable increase in cAMP levels, we conclude that ARIA does not act via a cAMP-dependent mechanism.

THE DOPAMINE CONTENT OF IMMORTALIZED HYBRID NEURONS IS DEPENDENT ON THE PRESENCE OF TARGET TISSUE. H.K. Choi, L.A. Won, and A. Heller Dept. of Pharmacological and Physiological Sciences, The University of Chicago, Chicago, IL 60637

We have previously reported the generation of hybrid cell lines by fusion of cells from the mouse rostral mesencephalic tegmentum at embryonic day 14 (E14) with a neuroblastoma cell line (N18TG2) (Choi et al., *Soc. Neurosci. Abstract*, Vol.14:319, 1988). One of the hybrid cell lines containing a high level of dopamine (DA) was shown to have neuronal properties including immunoreactivity to neurofilament proteins, large voltage sensitive sodium currents, and formation of aggregates in a rotation-mediated cell culture. The DA-containing neurons found in substantia nigra normally innervate telencephalic structures including corpus striatum (CS), frontal cortex (FCx), and occipital cortex (OCx). Tectum (T) or thalamus (TH) do not receive a DA innervation. Two thousand DA-hybrid cells were coaggregated with 8 million dissociated CS, FCx, OCx, T, or TH cells microdissected from E14 embryos in a 3-dimensional cell reaggregation system (Hemmendinger et al., *PNAS*, 78:1264, 1981). The cultures were treated with 1 mM n-butyrate from day 2 to 7 to suppress overgrowth of the hybrid cells. At day 7, the aggregates were processed for measurement of endogenous DA content by HPLC and for visualization of the hybrid cells by catecholamine-induced histofluorescence and for light microscopy by cresyl violet. The concentration of DA (ng/mg protein) in various coaggregates was CS: 21.1 $\pm$ 3.6, FCx: 12.1 $\pm$ 1.6, OCx: 20.2 $\pm$ 2.4, T:1.2 $\pm$ 0.4, and TH: 0.8 $\pm$ 0.2. Cresyl violet stained sections showed approximately equal numbers of hybrid cells in all cases. Brightly fluorescent DA hybrid cells were visualized only in coaggregates containing the target tissue. The results demonstrate that DA-containing hybrid cells derived from the mesencephalic dopaminergic neurons respond selectively to the presence of target tissue. Supported by MH28942 and GM07151.

ACTIVITY REGULATES EXPRESSION OF MAJOR HISTOCOMPATIBILITY COMPLEX CODED MOLECULES IN RAT SKELETAL MUSCLE. K. Gundersen and J. Mæhlen. Inst. of Neurophysiology and Physiology, Univ. of Oslo, N-0162 Oslo 1, Norway.

Molecules coded by the Major Histocompatibility Complex (MHC) play a prime role in immunological recognition. In normal nerve and muscle tissue these molecules are expressed at very low levels, but are up-regulated during local immunological reactions when lymphocytes invade the tissue and release certain MHC-inducing cytokines. Recently expression of MHC-molecules was described in denervated skeletal muscle (Mæhlen, J., *Brain Res.*, 481:368, 1989). We have observed that this phenomenon also occur in athymic animals suggesting that lymphocytes are not involved. Now we ask whether the nerve-evoked action potential activity in skeletal muscle may serve as a regulator of MHC-expression.

MHC molecules were immunostained on cryosections from soleus muscles after 5-14 days of either i) tetrodotoxin impulse blockade of the sciatic nerve or ii) direct electrical stimulation of denervated muscles. Inactivity was similar to denervation in causing MHC class I expression along the muscle fibre surface and in the sarcoplasm, and in causing MHC class II expression on cells located in the interstitium of the muscle. Moreover, the MHC up-regulation in denervated muscles was strongly reduced by electrical stimulation.

In conclusion, our data show that MHC class I expression is suppressed by evoked action potential activity in normal muscle cells, and suggest that inactive muscle cells produces a signal that leads to apparence of MHC class II positive cells in the interstitium .

INSULIN-LIKE GROWTH FACTOR I ACTIVATES A PHOSPHOTYROSINE-CONTAINING MICROTUBULE ASSOCIATED PROTEIN-2 KINASE IN BOVINE CHROMAFFIN CELLS. A.L. Cahill and R.L. Perlman. Depts. of Pediatrics and Pharmacol. and Physiol. Sciences, The University of Chicago, Chicago, IL 60637

Previously this laboratory reported that bovine chromaffin cells have insulin-like growth factor I (IGF-I) receptors and that these receptors are protein tyrosine kinases (Dahmer et al., J. Neurochem. 53, 1036, 1989). To characterize the endogenous substrates for this kinase we have isolated phosphotyrosine-containing proteins from bovine chromaffin cells and have identified one of them as an IGF-I activated microtubule associated protein-2 (MAP-2) kinase. Phosphotyrosine-containing proteins were isolated from control and IGF-I treated cells by adsorption to and specific elution from antiphosphotyrosine-Sepharose beads. When eluates were assayed for MAP-2 kinase activity, increased activity was found in eluates from IGF-I treated cells. The activation of MAP-2 kinase by IGF-I varied with the time of treatment (maximal at 10-15 min) and concentration of IGF-I (maximal at 10 nM) and was potentiated by the tyrosine phosphatase inhibitor Na_3VO_4. Myelin basic protein was also a good substrate for this kinase, but histones H-IIS and H-IIIS and ribosomal S6 protein were not phosphorylated. Treatment of the MAP-2 kinase with alkaline phosphatase abolished the kinase activity indicating that phosphorylation of the MAP-2 kinase is required for its activity. The IGF-I stimulated MAP-2 kinase described here is similar to the insulin-stimulated MAP-2 kinase described by Ray and Sturgill (J. Biol. Chem. 263, 12721, 1988) and may participate in an IGF-I activated kinase cascade similar to that proposed for transduction of signals from the insulin receptor. (Supported by NIH grants HL29025 and HD04583 and NSF grant BNS-8820342)

413.2

EFFECT OF CALCITONIN GENE-RELATED PEPTIDE ON NEURITE GROWTH OF CENTRAL NEURONS IN CULTURE. Fu-Zhuang Wang, Aishi Ding*, Jia Chen* and Xiaping Xie*, Dept.of Neurobiology, Institute of Basic Medical Sciences, Beijing 100850, China

Effects of calcitonin gene-related peptide on neurite growth were studied in primary dissociated spinal cord cell cultures from 12-14 day mouse embryos and hippocampal neurons from new born rat. Traditional cell cultures were made at density of 5×10^5 cell/ml in the culture medium containing 95% MEM and 5% horse serum added nutrient supplement. β-hCGRP(10ng/ml) were added to culture dishes conaining 2ml cell suspensions. The neurite outgrowth was assessed at 24 hr. Both spinal cord cells and hippocampal neurons were grown in the presence of CGRP, the numbers and length of neurite outgrowth were markedly incresed twice as much as that seen in the control cultures ($p<0.01$). From long-term cultures, the cell size and the number of surviving neurons were, on the average, higher than those observed in the parallel series grown with non-CGRP medium.

To quantitate the effects of the neuronal growth the total content of cellular protein were analyzed by flow cytometry. For cytometric analysis of cellular protein, control cells and CGRP-treated neurons by 12 days and 15 days were stained with fluorescein isothiocyanate (FITC) and fluorescence was measured on a single cell basis. From cellular fluorescence histograms, it was shown that the relative content of cellular protein was elevated in presence of CGRP. These results show that CGRP dramatically enhance the neural outgrowth and is involved in protein synthesis in cells.

413.3

EFFECT OF HEPARIN BINDING GROWTH FACTORS ON THE LA-N-1 NEUROBLASTOMA CELL LINE S.Sullivan1, T. Maciag2, R. Forough2, X. Zhan2, and M.F.D. Notter1. 1Univ. of Rochester Sch. of Med., Dept. of Neurobiology and Anatomy, Rochester, NY 2Laboratory of Molecular Biology, American Red Cross, Rockville, MD

The heparin binding growth factors (HBGF) are a class of related polypeptides which include acidic fibroblast growth factor (aFGF also HBGF-1) and basic FGF (bFGF also HBGF-2). These factors have varied effects in different tissues, including neural tissue. We evaluated the effects of various concentrations of aFGF and bFGF in vitro using the adreneric/serotonergic human neuroblastoma cell line LA-N-1. Neither affected the rate of cellular division; however, both factors stimulated the cells to differentiate morphologically, as seen by the extention of neurites.

We also tested altered forms of HBGF: HBGF-1a, aFGF with residues 1-20 truncated from the NH2 terminus domain; HBGF-1U which lacks residues 21-27, a putative nuclear translocation sequence; and HBGF-1U2, which also lacks 21-27, but has a yeast histone translocation sequence at the NH2 terminus. HBGF-1a and HBGF-1U2 were similar to unaltered HBGF-1 while HBGF-1U had no effect on cellular morphology. Mixing equal concentrations of HBGF-1U and HBGF-1U2 did not inhibit the neurite producing ability of HBGF-1U2.

It has been suggested that aFGF increases the amount of intermediate filament in a cell while bFGF increases the microtubule content. To examine the possibility that this occurs in LA-N-1 cells, cultures were stained for neurofilament protein and tubulin. We were unable to distinguish a clear difference in staining pattern between aFGF or bFGF treated cultures. We are currently examining these cultures by electron microscopy to gain a more definitive answer since microtubles and intermediate filaments are distinguishable at the EM level.

STIMULATION OF PROLIFERATION OF C6 GLIOMA CELLS BY S100ß: EVIDENCE FOR A CENTRAL NERVOUS SYSTEM GROWTH FACTOR. S.W. Barger*, R.H. Selinfreund, and L.J. Van Eldik. Depts. of Cell Biology and Pharmacology, Vanderbilt University, Nashville TN 37232.

S100ß is a member of a family of homologous calcium binding proteins, and promotes the survival and morphological differentiation of embryonic cortical neurons. S100ß production in brain is predominantly in glial cells, including the rat C6 glioma cell line which synthesizes and secretes the protein. Specific reductions in S100ß in C6 cells by antisense oligonucleotides resulted in a reduced growth rate. Addition of a recombinant S100ß to arrested, subconfluent cultures stimulated proliferation of C6 cells in a dose-dependent manner. Exogenous S100ß also stimulated [^{3}H]-thymidine labeling of nuclei and the expression of protooncogenes. This stimulation of proliferation by S100ß complemented the effects of PDGF but not insulin. S100ß was unable to stimulate proliferation of two neuroblastoma cell lines. These data suggest the possibility that S100ß acts in an autocrine manner to coordinate the growth of glial cells with the differentiation of neurons in the developing brain. PURIFICATION AND CHACTERIZATION OF RECOMBINANT BOVINE BASIC FIBROBLAST GROWTH FACTOR FROM ESCHERICHIA COLI Z.Y. Yu and G. Wang*, Department of Molecular Neurobiology, China Rehabilitation Res, Ctr. Box 2619, Beijing 100077, China

The cDNA sequence coding for bovine basic fibroblast growth factor (bFGF) has been cloned into an expression vector (pRC 29) downstream of the *Lac* Z promoter. The DNA sequencing results have been shown that the bFGF cDNA is inserted in the correct reading frame of the promoter. The expression of the fusion gene in *Escherichia Coli* can lead to an accumulation of about 15 mg recombinant bFGF per liter bacteria culture. The recombinant bFGF with purity of about 95% has been obtained by passing the bacterial lysate through an ion exchange column and a heparin affinity chromatography. The bFGF so obtained has been shown to have biological activities indistinguishable from the natural bFGF purified by us from bovine pituitary, either in mitogenicity or in angiogenesis assays. Animal experiments have been shown that the bFGF can promote the soft tissue wound healing and may have antiphlogistic effect. Injection of the recombinant bFGF into the shaved rabbit ear not only induced new blood vessel growth, but also promoting hair growth in the region of injection, indicating that the bFGF might be of value in the stimulation of regrowth of hair.

CLONING AND EXPRESSION OF A cDNA ENCODING A NOVEL HUMAN NEUROTROPHIC FACTOR. Y. Kaisho*, K. Yoshimura*, K. Nakahama*, and #K. Kato. Biotechnol. Res. Labs., and #Biol. Res. Labs., Takeda Chem. Ind., Ltd., 17-85, Jusohonmachi 2-chome, Yodogawa-ku, Osaka 532, Japan.

Two structurally related neurotrophic factors, nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF), were reported which are believed to play an essential role in the growth, survival, and differentiation of neurons in the nervous system.

To obtain other NGF related genes, we tried to screen a human glioma cDNA library under low stringent hybridization conditions using a synthetic DNA corresponding to human NGF as a probe. A cDNA has been cloned which encodes a novel human neurotrophic factor (designated nerve growth factor-2, NGF-2) composed of 257 amino acid residues including a prepro-sequence of 138 residues and a mature region of 119 residues. The amino acid sequence of NGF-2 exhibited 58% and 55% similarity with human NGF and pig BDNF, respectively. The conditioned medium of COS-7 cells transfected with an expression plasmid for the NGF-2 cDNA supported the survival of sensory neurons isolated from dorsal root ganglia of embryonic chicks. Upon Northern blotting analysis, large amounts of NGF-2 mRNA were detected in all the tissues examined except muscle and testis, the highest level of the mRNA synthesis being observed in kidney. In rat brain, NGF-2 mRNA was detected at embryonic day 17.5, and the level of the mRNA synthesis reached a maximum 1 to 2 weeks postnatally.

These results suggest that there are at least three nerve growth factor related genes, NGF, NGF-2, and BDNF. These factors may have distinct functions in vivo, because they showed different tissue distribution and developmental expression.

INSULIN-LIKE GROWTH FACTOR II GENE EXPRESSION IN HUMAN RETINAL PIGMENT EPITHELIAL CELLS. D.M. Martin, P.J. Venta* and E.L. Feldman. Departments of Neurology and Human Genetics*, University of Michigan Medical Center, Ann Arbor, MI 48109.

Diabetic retinopathy is the major cause of blindness in the United States. Recent observations implicate metabolically induced neovascularization in diabetic retinopathy. Insulin-like growth factors, known to stimulate endothelial cell proliferation, have been found in the vitreous and may act directly within the eye. We postulated that insulin-like growth factor II (IGF-II) is produced within the eye and may play a role in the pathogenesis of diabetic retinopathy. We report that cultured human retinal pigment epithelial (HRPE) cells express the IGF-II gene. We are currently investigating changes in IGF-II gene expression in HRPE cells conditioned in high glucose media.

A radiolabeled antisense RNA transcript was generated from the T7 promotor of the pGem-4 vector (Promega) containing 854 bp of a human IGF-II cDNA. Total cellular RNA was isolated by the guanidinium thiocyanate-phenol method and separated by formaldehyde-agarose gel electrophoresis. RNA was subjected to Northern blot analysis on nylon membranes and hybridized with the radiolabeled RNA probe. No cross-hybridization of the IGF-II probe to human IGF-I template DNA was seen. Autoradiography revealed a 1.2 Kb transcript which co-migrated with a 1.2 Kb transcript present in fetal rat muscle. To our knowledge, this is the first report of IGF-II gene expression in HRPE cells. The presence of IGF-II in HRPE cells suggests that this growth factor may play a role in the pathogenesis of diabetic retinopathy.

COMPARATIVE STUDIES OF THE EFFECTS OF SECOND MESSENGER SYSTEMS ON THE DEVELOPMENT OF LOCUS COERULEUS NEURONS. L.Sklair and M. Segal. Center for Neuroscience, The Weizmann Institute of Science, Rehovot 76100, Israel.

Locus coeruleus (LC) cells are remarkably plastic in vivo. In LC cultures noradrenergic (NA) cells differ strikingly from the other neurons in their extensive neuritic arborization. Intracellular messengers play a role in regulating neurite outgrowth and cell survival. In the present study we compared the effect of adenylate cyclase (AC) activation and Ca^{2+} entry blockade on the development of NA cells versus glutamatergic (GLU) cells in LC cultures. Maturation of NA and GLU cells was assessed by measuring high affinity uptake of [^{3}H]-norepinephrine (NE) and [^{3}H]-D-aspartate (D-asp) respectively. Treatment of cultures with the AC activator forskolin (1uM) or directly with d-Bu-cAMP (1mM) for 4-5 days increased [^{3}H]-NE uptake by 90 and 30%, respectively. Blocking Ca^{2+} entry into the cell with La^{3+} (1uM) increased [^{3}H]-NE uptake by 83%. All these treatments did not affect [^{3}H]-D-asp uptake. Thus, the greater sensitivity of noradrenergic cells to these developmental cues may explain their unique plastic properties.

CHARACTERIZATION AND PARTIAL PURIFICATION OF A NOVEL NEUROTROPHIC FACTOR SECRETED FROM HUMAN FETAL TESTIS CELLS. M.S. Huynh, R.H. Soriano & D.G. Roufa. CNS Disease Research, Searle R&D c/o Monsanto, St. Louis, MO 63198

Neuronal survival factors modeled after the prototypic factor NGF, are molecules secreted by the target and affect the neurons innervating that target. We report here, the characterization and partial purification of neurotrophic activity from N2 medium conditioned by human fetal testis cells.

The testis factor was active in neuronal survival assays of dissociated SCG and nodose ganglion and inactive in DRG bioassay. It was inactive in PC12 cells neurite outgrowth assay. Neither rabbit anti-mouse NGF nor anti-human NGF sera blocked its SCG survival activity. The addition of mouse NGF to the testis factor gave additive effect.

The activity was purified 1500-fold with CM-cellulose at pH 6.8 following concentration and dialysis. Its native molecular mass was 35~50 kDa, showing a broad active peak on Sephacryl S-200. This factor is likely to be glycosylated as the activity adsorbs to Con A and WGA.

Thus, we identified a novel neurotrophic substance with biological and chemical properties distinct from NGF.

ASTROGLIAL MITOGENS AFFECT SEPTAL CHOLINERGIC CELL EXPRESSION DIFFERENTIALLY.
R.L. Kenigsberg and I.E. Mazzoni* Centre de Recherche Pédiatrique. Hôpital Ste-Justine, Montreal, Que. Canada H3T 1C5.

It has been proposed that the regenerative capacity of CNS neurons may be restricted by proliferating astroglia at a lesion site which poses physical and/or chemical barriers. We previously found that EGF, a potent glial mitogen, when applied to septal cultures from fetal rat brains, produced a decrease in 2 cholinergic cell parameters, choline acetyltransferase. (ChAT) and acetylcholine (ACh) content (Kenigsberg et al., J. Neurochem. 52, Suppl., S192D, 1989). As these changes were accompanied by a marked glial cell proliferation and no change in neuronal survival we extended these studies to determine the specificity of the EGF response. Consequently, we examined the effects of a number of glial mitogens which are released following injury in the CNS on septal cultures. Although all mitogens examined produced astroglia proliferation, only EGF decreased ChAT activity while thrombin produced a significant increase in ChAT and PDGF had no effect. These results suggest that although several mitogens may affect glial cell division similarly, they may control the expression of astroglia and neurons differentially.

413.11

GANGLIOSIDES PREVENT THE INHIBITION BY K252a OF NGF RESPONSES IN PC12 CELLS. G. Ferrari, M. Fabris*, M.G. Fiori, N. Gabellini* and C. Volonté (1). Fidia Research Labs., Abano Terme (PD), Italy and (1) College of Physicians and Surgeons of Columbia University, New York 10032.

K252a, a general kinase inhibitor, selectively blocks the actions of NGF in PC12 cells. Since gangliosides have been reported to modulate neuronal cell responsiveness to NGF and to regulate several protein kinases, the ability of these compounds to revert the inhibition by K252a was assessed. Parameters at both short and long-term times following treatment of PC12 cells with NGF were analyzed, and known to be either transcription-dependent or-independent events. Gangliosides completely prevented the inhibition by K252a of NGF-induced neurite regeneration, c-fos induction, and, partially, protein kinase N activation. The ganglioside protective effects were concentration-dependent and required the intact molecule. These findings raise the possibility that gangliosides might affect a specific pathway of NGF responses sensitive to inhibition by K252a.

413.12

NEURITOGENIC AND METABOLIC ACTIONS OF INDIVIDUAL GANGLIOSIDES AND THEIR POTENTIATION OF TAURINE'S EFFECT ON NEURO-2a CELLS. C.L. Lu, G. Yorke and F.J. Roisen. Department of Anatomical Sciences and Neurobiology, University of Louisville, School of Medicine, Louisville, Kentucky 40292.

Gangliosides play an important regulatory role in the development of the nervous system and may modulate the actions of neurotrophic signals. However, reports of species-specific ganglioside-mediated effects are rare. To examine the neurotrophic responses elicited by individual gangliosides, we examined the neuritogenic and metabolic actions of four major ganglioside species (GM1, GD1a, GD1b, GT1b) in the presence and absence of taurine on the murine Neuro-2a neuroblastoma cell line. Taurine's neurotrophic actions on Neuro-2a cells have been reported recently (Spoerri, Caple, and Roisen, Int. J. Devl. Neurosci., in press). In this study, computer-assisted morphometry was employed to evaluate neuritic sprouting and the number of process bearing cells after 24 hr exposure to the individual gangliosides alone or in the presence of taurine. Furthermore, the activity of ornithine decarboxylase (ODC), the rate limiting enzyme in polyamine biosynthesis, was examined. Exposure of Neuro-2a cells to media containing the individual gangliosides (150 ug/ml) or taurine (1 mM) enhanced neuritogenesis. ODC activity was enhanced 1.6-1.9 fold after 5 hr exposure to GD1a, GD1b, or GT1b. GM1, although neuritogenic, did not enhance ODC activity. Simultaneous treatment of Neuro-2a cells with taurine and each ganglioside potentiated the neuritogenic action of taurine. Furthermore, when submaximal levels of taurine (0.1 mM) were used, GD1a, GD1b, and GT1b elevated ODC levels significantly higher (3.6-4.6 fold) than taurine or the level obtained by the individual ganglioside alone. These studies demonstrate that neuritogenesis and polyamine synthesis are independent and that gangliosides may play a species-specific regulatory role in neuronal development. Supported by NIH NS24524.

413.13

REGULATION OF THE SURFACE DISTRIBUTION OF GM1 BY UNDERLYING CYTOSKELETAL ORGANELLES. I. H. Fentie and F. J. Roisen. Department of Anatomical Sciences and Neurobiology, University of Louisville, School of Medicine, Louisville, Kentucky 40292.

Gangliosides are relatively abundant components of neuronal membranes. Their abnormally high accumulation in neurons due to gangliosidosis results in aberrant neurite formation. Neurons, including the murine Neuro-2a neuroblastoma line, undergo increased neuritogenesis after exposure to the ganglioside GM1. Responses to Nerve Growth Factor-dependent and NGF-independent trophic agents can be potentiated by GM1. Thus evidence is accumulating that gangliosides, especially GM1, play a role in neuronal development, although the mechanism remains unknown. In this study, we examined the surface distribution of GM1 on Neuro-2a cells at different stages of neuritogenic development. GM1 was localized using direct fluorescence of cholera toxin B-FITC and with indirect immunofluorescence and scanning transmission electron microscopy employing antibodies to GM1. Although a uniform distribution of label was found on perikaryal and neuritic surfaces, occasional linear arrangements suggested the possibility of an underlying fibrillar organelle. Cytoskeletal probes were used to determine its nature. Taxol (1.0 uM) treatment of Neuro-2a cells produced neurites with distal GM1 positive label and stabilized microtubules (MTs). In contrast, Colcemid (0.05 ug/ml) produced neurites devoid of GM1 label and lacking MTs. Cytochalasin D (2 ug/ml) reduced microfilaments but had no visible effect on GM1 surface distribution. Semiquantitative studies, in progress, employ the direct fluorescence of cholera toxin B-FITC and cholera toxin-gold conjugates in combination with cytoskeletal altering agents. These studies demonstrate that the surface distribution of GM1 is dependent on microtubule organization. Supported by NIH grant NS24524.

GM1 GANGLIOSIDE TREATMENT DOES NOT INDUCE AXONAL SPROUTING IN ADULT HAMSTER VISUAL SYSTEM.
B.A. Sabel[1], L. Cavicchioli[2]* and A. Leon[2]. 1. Institute of Medical Psychology, University of Munich Medical School, 8000 Munich 2, Fed. Rep. Germany and (2) FIDIA Research Laboratories, 35031 Abano Terme, Italy.

When hamsters are given lesions of the right superior colliculus (rSC) on postnatal day 1 (P1), the retinofugal fibers from their left eye cross the midline to innervate the wrong, left SC. Right eye removal (rEE) at a time up to P14 will result in sprouting of these fibers in the left SC and treatment with exogenous gangliosides (GM1) enhances this sprouting after rEE at P9 (Sabel, B.A. and Schneider, G., Exp. Brain Res. 71: 365, 1988). We now report the effects of GM1 in a preparation where sprouting does not occur normally (i.e. rEE after P14) or when the sprouting is vigorous (rEE on P1).

Hamsters received rSC lesions on P1, with rEE on P1, P18 or P30. Groups of hamsters (n=7-9 each) were then treated i.p. with 30 mg/kg GM1 (Fidia Res. Labs.) or saline, starting on the day of rEE. After a 4-week period of daily treatment, the retinofugal pathway and left SC innervation was demonstrated by removal of the left eye and staining degenerating axon terminals using the Fink-Heimer method. Analysis of the size of the terminal field in the left SC clearly revealed the previously known decline in sprouting vigor with increasing age, but GM1 was without detectable effect on the extent of sprouting in hamsters with rEE at P1, P18 or P30.

Thus, GM1 does not enhance axonal sprouting when maximal sprouting vigor is present. Also, GM1-treatment does not elicit axon sprouting in the adult hamster visual system, suggesting that GM1 is only effective during an ongoing sprouting response (as at P9).

Supported by DFG grant SFB220/D10 and Fidia Research Labs.

THE GANGLIOSIDE GM1 PROTECTS AGAINST THE 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE (MPTP) - INDUCED DEGENERATION OF NIGRAL DOPAMINE CELLS IN THE MALE C57BL/6 MOUSE. [1]A.M. Janson, [1]K. Fuxe, [2]L.F. Agnati*, [3]G. Toffano* and [4]M. Goldstein. [1]Dept for Histology and Neurobiology, Karolinska Institutet, S-104 01 Stockholm, Sweden. [2]Dept of Human Physiology, University of Modena, Modena, Italy, [3]Fidia Research Laboratory, Abano Terme, Italy, [4]Dept of Psychiatry, New York University Medical Center, New York, USA.

Previous experiments have shown protective effects of two week's chronic ganglioside GM1 treatment against the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine-(MPTP) induced disappearance of tyrosine hydroxylase (TH) immunoreactive (IR) nerve cell bodies and dendrites in the substantia nigra and terminals in the neostriatum of the nigrostriatal dopamine (DA) system in the male C57 Bl/6 mouse (Acta Physiol. Scand. 1988, 132, 587-588).

In this study five different doses of the ganglioside GM1 (3 mg·kg^{-1} to 100 mg·kg^{-1}, i.p.) were given twice daily for two weeks starting 15 minutes after the MPTP injection (40 mg·kg^{-1}, s.c.). Morphometric and densitometric evaluation of TH IR nerve cell bodies and dendrites were performed following the avidin-biotin immunostaining procedure. Applying the Jonckheere-Terpstra test dose-related increases in both the number ($p<0.01$) and the mean area ($p<0.05$) of the TH IR nerve cell body profiles were found compared with the MPTP alone group, whereas the densitometric parameter mean grey value showed a dose-related decrease ($p<0.01$). Similar result were obtained in the analysis of nigral TH IR dendritic profiles.

Thus, chronic treatment with the ganglioside GM1 can markedly counteract the MPTP-induced disappearance of TH IR nigral nerve cell bodies and dendrites. The mechanism underlying this protection, of high clinical interest in the treatment of Parkinson's disease, appear to be multifold, involving e.g. membrane actions and modulation of protein phosphorylation.

413.16

GANGLIOSIDE TREATMENT AND RECOVERY OF FUNCTION AFTER GRADED CRUSH OF THE RAT OPTIC NERVE .

J. Sautter* and B. A. Sabel, Inst. of Medical Psychology, University of Munich Medical School, 8000 Munich 2, Fed. Rep. of Germany (SPON: European Neuroscience Association)

To study recovery of function in a definable model of brain injury, we have previously employed the graded crush of the rat optic nerve as a paradigm (Duvdevani et al., in prep.) Using this paradigm it is possible to simulate variable degrees of axonal injury from "mild" to "severe", ressembling "diffuse axonal injury (DAI)", a primary response of the brain to traumatic injury in humans. We now report the effects of GM1-ganglioside treatment on functional outcome after graded crush of the rat optic nerve using two behavioral paradigms.

In the orienting paradigm, rats have to orient towards a visual stimulus in the visual field ipsilateral to the the unilateral crush. Here, initial loss of function was followed by recovery within about 2 weeks. However, when rats were treated with 50 mg/kg GM1 (i.p.), they performed, on average, better than control rats on all postoperative days, but significant differences were only found on days 11 and 12.

In the brightness-discrimination paradigm, bilaterally crushed rats had to choose between a bright or dark stimulus in a maze to obtain water reward. Although the deficit and subsequent recovery of function is similar to that of the orienting paradigm, GM1 was without detectable effect on brightness-discrimination performance.

These behavioral results can be taken to suggest that ganglioside treatment can reduce visual deficits after graded crush of the rat optic nerve, but a suitable and sensitive behavioral paradigm is needed to demonstrate efficacy of treatment.

EPIDERMAL GROWTH FACTOR (EGF) ENHANCES, IN RATS, DOPAMINERGIC PATHWAY "IN VIVO" AN IMMUNOHISTOCHEMICAL STUDY A Zecchinelli[1,2], G. Pezzoli[1*], S. Ricciardi[3*], R.E. Burke[2], S. Fahn[2], R. Fusi[3*], C.B. Mariani[1*], G.Scarlato[1*], and A. Carenzi[3*] [1]Inst of Neurol. Univ. Milan, Italy. [2] Neurol. Inst. Columbia Univ. N.Y. N.Y. 10032. [3] Zambon-Group Bresso-Milan, Italy.

Male Sprague Dawley rats received unilateral transection in the left nigro-striatal pathway. 45 days after surgery, animals were infused in the left lateral ventricle by an osmotic Alzet minipump at rate .5 µl/hr. Group I was treated with EGF (mouse), highly purified, (Zambon-Group), group II with heat denatured EGF, group III with vehicle. The infusions lasted 28 days; apomorphine and amphetamine induced rotational behaviort was tested ≈ 2 months after the lesion and at the end of the 3rd and 4th month after the infusion. Animals were then perfused intracardiacally with 4% paraformaldehyde, decapitated and the brains frozen; representative sections (Paxinos Watson) for both the striatum and the substantia nigra were cut on a cryostat and immunoperoxidase stained for tyrosine hydroxylase (TH). Alternate sections were stained for Glial Fibrillary Acidic Protein. Effects on striatal TH staining were assessed blind to experimental condition by two observers by rating the extent of TH positive staining at individual fiber level, for the striatum, on a 5 point scale. The cross-sectional area of TH staining was further determined at population level as percent of the whole striatal area by an Amersham RAS-3OOO image analysis system; staining on the lesioned side was expressed in percent compared to the control side. The number of TH positive neurons in substantia nigra was assessed as a midpoint range of values given by two observers by examination at 40 x. The actual count of neurons was then performed. EGF treatment resulted in a significant increase of the percent of TH-positive staining in the lesioned side compared to both controls. Similar results were obtained in a second group of animals. EGF treatment also resulted in a significant increase of the percent of preserved TH-positive neurons in the substantia nigra, with a high correlation to the degree of preservation of striatal TH-positive staining. We conclude that EGF infusion in the ventricle can partially restore or preserve, perhaps by a trophic effect, the integrity of the dopaminergic nigrostriatal pathway, in rats, after mechanical hemitransection

EPIDERMAL GROWTH FACTOR IS A MITOGEN AND INCREASES DOPAMINE UPTAKE IN RAT EMBRYO MESENCEPHALIC PRIMARY CULTURE. D. Casper, C. Mytilineou and M. Blum, Fishberg Research Center in Neurobiology and Department of Neurology, Mount Sinai Medical Center, New York, NY 10029.

Epidermal growth factor (EGF) has previously been described as a mitogen on epithelial- and mesenchyme-derived tissue. In the central nervous system, EGF has also been shown to be a mitogen for astrocytes. Our group has previously reported that EGF can increase neuronal and glial dopamine uptake in this culture system (Casper et al., Soc. Neurosci. Abst., 15:708, 1989). In this study, we have placed dissociated mesencephalon from E16 rat embryos into culture. Using chemically defined medium, we have observed that addition of EGF to the cutures can expand a population of cells that can incroporate tritiated thymidine into their nuclei, but do not express the astrocyte markers glial frillary acidic protein (GFAP), the oligodendrocyte marker glactocerebroside (GC), the neuronal mictotubule associated protein tau, or neuron-specific enolase in the presence or absence of the labelled nucleotide. These cells are seen by their large and flattened nuclei, which lightly stain with tau immunocytochemistry, or by their nuclei and scant cytoplasm, seen by phase microscopy. A few cells stain very weakly with antibodies to either GFAP or tau. While this population of "undifferentiated" cells increases, EGF also increases dopamine uptake. Using immunocytochemistry for tyrosine hydroxylase (TH), the rate limiting enzyme in catecholamine biosynthesis to mark dopaminergic cells, we found that the number of cells expressing this marker decreases up to a week in culture, but the number of these cells is stable after this in EGF treated cultures up to 22 days. The number of TH-positive cells in control cultures continues to decrease. Studies to be presented will determine whether the increase in dopamine uptake is due to the action of EGF on the existing stabilized dopaminergic neurons such as inducing neurite outgrowth, or whether it is causing differentiation or neurogenesis of new dopaminergic neurons.

EPIDERMAL GROWTH FACTOR AND TRANSFORMING GROWTH FACTOR-ALPHA mRNA EXPRESSION IN PCD AND WEAVER MUTANT MICE. L. M. Lazar, K. A. Kelley and M. Blum, Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, New York, NY 10029.

Our previous investigations into the role of epidermal growth factor (EGF) in the mammalian CNS have focused on the expression of EGF-specific mRNA in normal adult mouse brain. We now report our preliminary findings regarding the changes in level of mRNA expression for EGF and its structural homolog transforming growth factor-alpha (TGF-alpha) in cerebella and lower brainstem of Purkinje cell degeneration (pcd) and weaver mutant mice. Using an RNase protection assay, we have detected elevated levels of EGF mRNA in cerebella of severely ataxic pcd mutant mice (genotypically *pcd/pcd*) as compared to non-ataxic sex-matched littermates. TGF-alpha mRNA levels, however, detected at levels ~80 times higher than that of EGF in the wild-type (*+/+*) cerebellum, are not significantly altered in this mutant model. In contrast, in the cerebella of weaver mutant mice in which the neurodegenerative process is specific to the granule cell population and in which the heterozygous state (*+/wv*) displays cerebellar histopathology intermediate between mutant (*wv/wv*) and homozygous normal (*+/+*) animals, levels of TGF-alpha mRNA are approximately 2.5 and 1.25 times greater for homozygous mutant (*wv/wv*) and heterozygous normal (*+/wv*) cerebella than levels detected in cerebella of homozygous normal (*+/+*) sex-matched littermates. Interestingly, levels of TGF-alpha mRNA in lower brainstem (Medulla-Pons) of the weaver model appear to decrease to 30% and 60% of homozygous normal levels for the homozygous mutant and heterozygous states, respectively. No significant changes in EGF mRNA levels have been observed in cerebella or lower brainstem for the weaver mutant model. Our findings of differential gene expression for EGF and TGF-alpha in these neurodegenerative models, then, suggest that while both neuropeptides utilize a common receptor, their physiological roles in brain may be distinct.

THE EFFECT OF EPIDERMAL GROWTH FACTOR ON THE DEVELOPMENT OF DOPAMINE NEURONS FOLLOWING EXPOSURE TO THE NEUROTOXIN 1-METHYL-4-PHENYLPYRIDINE (MPP$^+$). T. Bak and C. Mytilineou, Dept. Neurology, Mt. Sinai Sch. Med., New York, N.Y., 10029.

Exposure of mesencephalic cultures to epidermal growth factor (EGF) results in long term stimulation of dopamine (DA) uptake (Casper et al., Soc. Neurosci. Abst., 15:708, 1989). In the present study we examined whether EGF treatment could a) modify the damage caused by the specific neurotoxin MPP$^+$, or b) affect the ability of DA neurons to recover following MPP$^+$-induced damage. Tyrosine hydroxylase (TH) immunostaining and [^{3}H]DA uptake were used to determine DA neuron survival and axon outgrowth. Mesencephalic cultures established from E-16 rats were plated at 5×10^5 cells/dish. EGF (10 ng/ml) in defined medium was added to the appropriate groups and was present throughout the experiment. Cultures were exposed to 10 uM MPP$^+$ for 24 hrs on the 4th day in vitro (DIV). At this time, there was no significant difference between control and EGF-treated cultures with respect to DA uptake and number of TH+ process-bearing neurons. Following removal of MPP$^+$ on 5 DIV, a similar reduction of DA uptake (~80% of controls) and loss of TH+ cells (~45% of controls) was observed in control and EGF-treated cultures, suggesting a lack of a protective effect of EGF against MPP$^+$-induced DA neuron degeneration. The greater effect of MPP$^+$ on DA uptake probably reflects the loss of DA neurons, combined with reduction in neurite length in the surviving TH+ neurons. DA uptake remained lower in the MPP$^+$-treated cultures compared to their respective controls during further in vitro development, but EGF treatment resulted in a pronounced increase in uptake both in control and in MPP$^+$-treated cultures. On 19 DIV the MPP$^+$-treated cultures exposed to EGF had uptake values ~10-fold greater than non-EGF controls. In the control cultures, the number of TH+ process-bearing cells declined on 12 and 19 DIV, but this decline was not observed in EGF-treated cultures. It still remains to be determined whether all of the TH+ cells on 19 DIV are the surviving neurons which were spared from the toxic effect of MPP$^+$. STIMULATION OF ASTROCYTE PROLIFERATION BY PURINE NUCLEOSIDES AND NUCLEOTIDES THROUGH ADENOSINE A2 AND PURINE P2X RECEPTORS. M. Rathbone, P. Middlemiss*, J-K. Kim* and E. Hooftman*. Dept. Biomedical Sci. McMaster University Health Sciences Centre, 1200 Main St. W., Hamilton, Ont. Canada. L8N 3Z5.

Low concentrations of adenine and guanine nucleosides and nucleotides, when added to the medium of serum-deprived quiescent astroblasts or human astrocytoma cells, stimulated cell proliferation in a dose-dependent fashion. We used agonists and antagonists specific for various types of cell-surface adenosine and purine receptors to determine which receptors were involved. Adenosine had two peaks of activity, at ~100 pM and at ~7.5μM. Guanosine and inosine stimulated cell proliferaton more than adenosine in μM concentrations, but were inactive at pM concentrations. Activation of astroblast A2 receptors both stimulated cell division and increased intracellular cAMP.

Purine nucleotides stimulated astroblast proliferation in μM concentrations. However, α,β-methylene ATP, a preferential P2X agonist, maximally stimulated proliferation at 3.5nM. 2-methylthio ATP, a preferential P2Y agonist, had peak activity at 30pM. This implies that purine nucleotides stimulate astrocyte mitosis through a P2Y receptor.

Purine nucleosides and nucleotides are released in high concentrations in the CNS during neurotransmission, hypoxia and cell death. Our data imply that this may be sufficient to stimulate proliferation of various types of adjacent cells. (Supported by a grant from the Ontario March of Dimes)

413.22

NERVE GROWTH FACTOR AND GANGLIOSIDE REGULATED RELEASE OF FIBRONECTIN-LIKE AND J1/TENASCIN GLYCOPROTEINS BY C6 GLIOMA. E. Yavin. Dept. Neurobiology, Weizmann Institute of Science, Rehovot, Israel

C6 rat glioma cells incubated in serum-free medium with D-[14C]glucosamine secrete upon stimulation with nerve growth factor (NGF) or monosialogangliosides (MSG) a number of glycoproteins (Gp) the most prominent of which being a 270, 220, and a 69 kDa Gp. Several growth factors, hormones and phorbol ester as well as disialo- or trisialogangliosides did not stimulate secretion. Western blot analysis of the conditioned medium supplemented with NGF or MSG identified fibronectin and J1/tenascin each migrating as one distinct band of a molecular weight of approximately 220 kDa. Antiserum to NGF prevented NGF-stimulated release but it also blocked MSG-evoked release. Significant levels of the 220 kDa Gp were detected after pulse labeling with [^{35}S] methionine in the presence of NGF; after 15 min incubation immunoprecipitable radioactively labeled J1/tenascin was noticed. Tunicamycin inhibited most profoundly release of the 220 kDa Gp labeled either by D-[^{14}C] glucosamine or [^{35}S] methionine.

These results extend the range of neurotrophic properties attributed to NGF to cells of glial origin and suggest that NGF regulates secretion of extracellular matrix proteins. The data also suggest that MSG stimulation of fibronectin and J1/tenascin secretion is presumably mediated by an NGF or NGF-like molecule also secreted by the C6 glioma cells.

413.23

HEART CELL CHOLINERGIC NEURONAL DIFFERENTIATION FACTOR (LEUKEMIA INHIBITORY FACTOR) CAN REVERSIBLY REGULATE NEUROTRANSMITTER / PEPTIDE PHENOTYPE IN SEVERAL TYPES OF CULTURED PERIPHERAL NEURONS. Hiroyuki Nawa*, Tetsuo Yamamori, Thu Le, Donald Metcalf ** and Paul H. Patterson. Biol. Div. 216-76, Caltech, Pasadena, CA 91125; *Inst. for Immunol., Fac. of Med., Kyoto Univ., Kyoto 606 Japan; ** Walter and Eliza Hall Inst. Med. Res., Royal Melbourne Hospital, Parkville, Victoria 3050, Australia.

The various types of neural crest-derived peripheral neurons can be characterized by their distinctive combinations of neurotransmitters and neuropeptides. These phenotypes are plastic and respond to environmental cues *in vitro* and *in vivo*. The cholinergic neuronal differentiation factor (CDF) from cultured heart cells is identical to leukemia inhibitory factor (LIF), and recombinant LIF (rLIF) from *E. coli* can induce cholinergic differentiation in cultured rat sympathetic neurons (Yamamori et al., Science 246, 1412, 1989). We find that rLIF also induces the expression of substance P, somatostatin and vasoactive intestinal polypeptide, while reducing the expression of neuropeptide Y in a dose-dependent manner in the sympathetic neurons. The alterations in peptides are also observed at the mRNA level. The changes in peptide expression are reversed upon removal of CDF from the neurons, demonstrating that the factor is required for maintenance of the newly induced phenotypes. Dorsal root ganglion neurons also respond to rLIF, but with different phenotypic changes, suggesting that CDF/LIF could have widespread effects in the nervous system.

DIFFUSIBLE FACTOR(S) OF RETINAL PIGMENT EPITHELIAL CELLS MEDIATES SURVIVAL OF PHOTORECEPTOR CELLS IN A DYSTROPHIC MODEL: IN VIVO AND IN VITRO EVIDENCE. H.J. Sheedlo, L. Li and J.E. Turner, Depts of Neurobiol. and Anat. and Ophthalmol., Bowman Gray Sch. of Med., Winston-Salem, NC

Transplants of normal RPE cells in retinas of RCS dystrophic rats has been shown to arrest photoreceptor cell (PRC) loss, even lateral to the RPE transplant, suggesting PRC rescue may be affected by an RPE cell diffusible trophic factor(s). In one study, normal RPE cells were transplanted into the subchoroid of 26 day-old RCS dystrophic rats, separated from the PRCs by Bruch's membrane. Seven weeks later, PRC rescue was detected under and lateral to the RPE cell transplant. In a second study, normal RPE cells were encased in perm-selective hollow fibers (slow release mechanism) and placed in cultures of PRCs, isolated from day 2 Long Evans rats, and grown in a defined medium, lacking serum. Under these conditions, PRCs survived for at least a week, while in control fibers, lacking RPE cells, PRC survival was not observed. In addition, PRC cultures were supplemented with several growth factors. Only epidermal growth factor affected significant cell survival. These studies provide strong evidence that RPE cells secrete a factor(s) which affects PRC rescue and survival. Results of the slow release mechanism and vitreous injections in RCS dystrophic rats will be reported. (Fight for Sight, Inc. and NEI 04337)

TRANSFORMING GROWTH FACTOR-ALPHA (TGF-ALPHA) IMMUNOREACTIVITY IN ADULT RAT BRAIN. J. Lakshmanan, E. Salido*, R. Lam*, L. Krummen*, A. Reviczky* and D.A. Fisher*. Depts. of Pediatrics, Pathology and Endocrinology, Harbor-UCLA Medical Center, Torrance, CA 90509.

Evidence for the existence of TGF-alpha prepro mRNA in rodent brain has been reported (J Neurosci 8:1901, 1988) but limited information is available on the distribution of TGF-alpha in brain. Here we report TGF-alpha levels in rat brain as measured by a specific RIA developed in our laboratory. Chemically synthesized rat TGF-alpha was used for antisera generation, iodination and reference standard. The RIA is sensitive to 8 pg/tube. Whole brain, cerebral cortex, cerebellum, and midbrain of adult rats were homogenized in 50mM phosphate buffered saline (pH 7.4) and centrifuged at 100,000 x g for 60 minutes. The supernatants were used for quantification of TGF-alpha and protein contents. TGF-alpha concentration is expressed as pg/mg protein (values are mean ± SD). Whole Brain: 47±8; Cerebral Cortex: 72±16; Cerebellum: 162±18; Midbrain: 180±29. Conclusion: TGF-alpha is present in adult rat brain. Its concentration varies with brain region.

413.26

EXPRESSION OF ACIDIC-FIBROBLAST GROWTH FACTOR (a-FGF) mRNA IN DEVELOPING AND ADULT RAT BRAIN. B.J. Wilcox and J.R. Unnerstall, Department of Neurology and The Alzheimer Center, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

Using a 36mer oligonucleotide probe corresponding to aminoacids 26-37 of bovine aFGF, we have localized mRNA for aFGF in developing and adult rat brain by *in situ* hybridization histochemistry. Nine time points in brain development from embryonic day 17 (E17) to post-natal day 21 (P21) were selected. Results of hybridization of [^{35}S]probe to slide-mounted parasagittal sections of brain tissue from earlier time points (E17-E20) showed generalized labeling throughout the brain with enrichments found in the developing cortex. Labeling was distinctly localized to the ventricular zone and cortical plate. At later time points (P1-P21), a distinct pattern of labeling to the pyramidal cell layer of the hippocampus was observed. During the second post-natal week, discrete labeling also appeared in the developing granule cell layer of the dentate gyrus. Examination of autoradiograms under high magnification confirmed the localization of grains to neurons in the hippocampus and cerebral cortex. The appearance of aFGF mRNA in the hippocampal formation and dentate gyrus corresponds with the maturation and migration of pyramidal and granule cells to their adult position. This pattern of labeling persisted into adulthood, although at a lower level of expression. Labeled neurons were also seen in laminae II, III, and VI of the cerebral cortex, granule cells of the cerebellum and other discrete nuclei. No labeling was seen when serial sections were hybridized with a corresponding sense probe. Northern blot analysis revealed a single band which agrees with the reported size for aFGF message in brain. These data indicate that aFGF is expressed in specific neuronal populations in the developing and mature CNS and suggest that this neurotrophic factor plays a significant role in CNS development and in maintenance of neuronal plasticity in adult brain.

PHYSIOLOGICAL EVIDENCE FOR FUSION OF SEVERED MYELINATED AXONS. T. L. Krause, R. E. Marquis, and G. D Bittner. Dept. of Zool., Coll. of Pharm., and Inst. for Neurosci., U. Texas, Austin, TX 78712.

We have recently reported the ability to morphologically fuse the severed halves of an invertebrate myelinated giant axon, the medial giant axon (MGA) of *Lumbricus terrestris* (Krause and Bittner, PNAS 87: 1471-1475). This morphological fusion is achieved in a few minutes using polyethylene glycol (PEG) in reduced-calcium hypotonic salines. Rates of morphological fusion were as high as 80-100% in some trials using this technique. We have extended this former work to evaluate both form and function of these fused axons.

We now report the ability to establish action potential conduction through the fusion site of formerly severed axons. Using extracellular and intracellular recording techniques, we have found through conduction in approximately 20% of fused axons in some trials. Further, we report that fused axons can retain morphological and physiological integrity after 16-26 hours, although physiological integrity is most often present when measured several hours after incubation. Finally, we have extended our study of conditions most conducive to establish high fusion efficiency and are attempting to repair severed axons *in vivo* using this fusion technology.

This research was made possible by a Texas Advanced Technology Project Grant (#194) and a National Science Foundation Grant (ECS 8915178) to G.D.B.

EPENDYMAL/GLIAL CELL PRODUCTION ALONG THE RETINOTECTAL TRACT PRECEDES OPTIC NERVE REGENERATION IN THE SALAMANDER. I. Gordon,* S.B. Simpson,# Jr., and B.M. Davis. Dept. of Anatomy & Neurobiology, *Univ. of Kentucky, Chandler Medical Center, Lexington, KY 40536; #Dept. of Biological Science, Univ. of Illinois, Chicago, 60680.

Our experiments on regenerating salamander spinal cord revealed that large numbers of ependymal cells along the path or regenerating axons incorporate 3H-thymidine during the initial phases of axon regeneration. To test the generalities of these results salamander optic nerves were crushed unilaterally followed by 3H-thymidine injections 0-14d or 0-21d post-crush (2-4μCi/gr, every other day). At the completion of the injection schedule the entire animal was processed for autoradiography. This allowed us to examine the entire course of the retinotectal projection. In all cases, large numbers of labeled glial cells were seen ipsilaterally along the entire length of the optic nerve. Labeled ependymal cells were seen bilaterally in the diencephalon, particularly in ventral portions. In some cases, large numbers of labeled ependymal cells were also seen in the contralateral mesencephalon. Labeled neurons were not identified in any of these cases. HRP injections showed that retinal axons had not reach the brain by 21 days post-crush. These results suggest that ependymal cell production is induced by damaged axons and confirm the observations of Gaze and Watson (1965) and Stevenson and Yoon (1978). It should be noted that the time course of the presumptive burst of glial/ependymal cell mitosis occurs within the first two weeks post-crush and could be the event underlying enhanced regeneration seen following a "conditioning lesion". Supported by NS25617 to BMD.

414.3

BEHAVIORAL RECOVERY FOLLOWING SPINAL TRANSECTION OCCURS VIA FRANK AXONAL REGENERATION SUPPORTED BY DIVIDING GLIAL CELLS ALONG THE PATH OF THE REGENERATING PROJECTIONS. L. K. Garner, D.R. Liebich,* S.B. Simpson, Jr.,# and B.M. Davis. Dept. of Anatomy & Neurobiology, *Univ. of Kentucky, Chandler Medical Center, Lexington, KY 40536; #Dept. of Biological Science, Univ. of Illinois, Chicago, 60680.

We tested the following hypothesis: CNS regeneration in the salamander does not require neurogenesis, but does require the production of new ependymal and/or glial cells along the length of the regenerating projections. HRP was applied to complete thoracic transections to label the somata of neurons whose axons projected past the transection site. After behavioral recovery (60-90d), Fast Blue was injected into the spinal cord 1.0 cm caudal to the first lesion. In regenerated salamanders the percentage of Fast Blue labeled supraspinal neurons that also contained HRP ranged from 6-23% (x=18%; n=7). In control experiments in which both markers were applied at the same time, the maximum number of doubled labeled cells was 27% (ranging from 3-27%; x= 15%; n=5). This suggests that most of the axons that grew through the transection arose from axotomized neurons. 3H-thymidine injections during the regeneration period indicated a burst of ependymal/glial cell production throughout the spinal cord. Within 5 mm of the lesion site, over 70% of the ependymal cells were thymidine labeled. In brachial and lumbar spinal cord the number of labeled cells was significantly greater than controls. These results suggest that damaged CNS axons induce glial cell production and that the new cells support frank axonal regeneration. Supported by NS25617 to BMD.

414.4

AXOSOMATIC SYNAPSES INCREASE ON LOCAL SPINAL MOTONEURONS DURING TAIL REGENERATION: DOES SYNAPSE FORMATION PREVENT AXONAL REGENERATION? M.T. Duffy,* B.M. Davis, and S.B. Simpson, Jr. Biological Sciences, University of Illinois, Chicago, 60680; #Anatomy & Neurobiology, Univ. of Kentucky, Chandler Medical Center, Lexington, KY, 40536.

In our previous studies we found that the number of supraspinal axons projecting to the tail increases by 74% during tail regeneration, but only a small fraction of these axons (<4%) enter the regenerated spinal cord (Duffy et al., 1990). We suggest that this may be the result of "synaptic capture" (Bernstein et al., 1978) in which regrowing axons make synapses on denervated targets rostral to the transection, aborting further regeneration. To examine this hypothesis we used morphometric analysis of EM photomontages to test for changes in synaptic distribution on motoneurons rostral to regenerating tail spinal cord.

Examination of lamina IX neurons (presumptive motoneurons) revealed the following properties: 1) Neurons rostral to regenerated tails (n=6) are larger in both circumference and area compare to non-regenerates (n=20) (79.7 μm vs 51.6 μm; 291.9 μm2 vs 124.0 μm2), 2) axosomatic contacts cover a greater percentage of the motoneuron soma following regeneration (32.25% vs 20.8%), and 3) this increased innervation is accomplished by more synaptic boutons rather than larger boutons (21 boutons/cell (avg length = 1.27 μm) vs 9 boutons/cell (avg length = 1.34 μm)). This result suggests that increased synaptogenic activity in the spinal cord immediately rostral to the junction of normal and regenerating spinal cord could be an important mechanism in the inhibition of CNS axonal regeneration.

414.5

H^3-GABA UPTAKE BY CEREBROSPINAL FLUID-CONTACTING NEURONS IN THE REGENERATED SPINAL CORD OF THE LIZARD. L. Alibardi*, J. Gibbons* and S.B. Simpson, Jr. Dept. of Biol. Sci. and the Comm. on Neurosci., Univ. of Ill. at Chicago, Chicago, IL 60680.

The regenerated spinal cords of several lizards have been reported to contain cerebrospinal fluid-contacting neurons (CSFCNs) (Alibardi, L. and V.B. Meyer-Rochow, New Zealand J. Zool., 15:535, 1988). We are attempting to characterize these neurons with respect to neurotransmitter type and their connectivity with the normal spinal cord and brain. We have recently confirmed the presence of CSFCNs in both the normal and the regenerated cord of the lizards Anolis and Scincella. The CSFCNs are probably the only neuronal elements to differentiate in the regenerated tail cord. Lizards injected with H^3-GABA (15-25 μCi/animal) demonstrate uptake by most, but not all, of the CSFCNs. Uptake was demonstrated at both light and TEM levels. Surrounding connective tissue cells and ependyma cells did not take up the H^3-GABA. Not all CSFCNs in a given preparation concentrated the H^3-GABA. This could be due either to their being at different stages of differentiation or to the existence of two different populations of CSFCNs, based on transmitter type. Using retrograde transport of horseradish peroxidase, we have also demonstrated that many of the CSFCNs in the regenerated tail cord send axons rostrally into the normal tail cord.

414.6

REGENERATION OF CENTRIFUGAL FIBERS TO THE RETINA IN CICHLID FISH. Anne C. Rusoff. Dept. of Biology, Montana State University, Bozeman, MT 59717.

The optic nerve of cichlid fish contains two populations of axons: the axons of retinal ganglion cells and axons from cells in the diencephalon and telencephalon that project into the retina (centrifugal fibers). The axons of retinal ganglion cells in fish are noted for their ability to regenerate. One factor often implicated in this ability is the continued addition of ganglion cells into adulthood. In contrast all of the centrifugally projecting cells in the telencephalon and most of those in the diencephalon are born early. This basic difference between the two populations of axons in the optic nerve allows one to determine if mitotic activity within the cell population is critical for regenerative ability. Previously I reported that FMRFamide + centrifugal fibers did not regenerate (Soc. Neurosci. Abstr. 14: 657 (1988)). Recently I have attempted to confirm this result using HRP placed either distal or proximal to the crush. When HRP was placed on the retinal side of the crush, cell bodies that had regenerated axons across the crush were labelled both in the diencephalon and telencephalon. When HRP was placed central to the crush, axons that had regenerated across the crush were visible in the retina. Therefore, centrifugal fibers are capable of regenerating even though they come from a cell population that has ceased dividing. (EY06495.)

REGENERATION OF BRAINSTEM-SPINAL AXONS AFTER SPINAL CORD TRANSECTION IN EMBRYONIC CHICKEN. S.J. Hasan, H.S. Keirstead* and J.D. Steeves. Departments of Anatomy and Zoology, University of British Columbia, Vancouver, B.C., V6T 2A9.

In the embryonic chicken, brainstem-spinal pathways to the lumbar cord complete their projections around embryonic day (E) 11 of the 21 day developmental period. Recently it has also been shown that brainstem-spinal tracts in the embryonic chicken maintain their capacity for anatomical and functional repair after a complete thoracic spinal cord transection prior to E13. This repair could be attributed either to projections from late developing unlesioned neurons or to regeneration of previously axotomized brainstem-spinal pathways. In this study, double labelling was used to distinguish between these two possibilities. On E8-11, the mid-thoracic spinal cord was injected with the first fluorescent tracing dye. One to two days later the mid-thoracic spinal cord was completely transected. After an additional 5-8 days, the second fluorescent tracing dye was injected into the cord, caudal to the site of transection. Two days later (on E17-20), the CNS was fixed, frozen sectioned and the brainstem and spinal cord tissue sections were viewed with epifluorescence microscopy.

A significant number of double labelled brainstem-spinal neurons were observed following a thoracic cord transection as late as E11-12. Each brainstem also contained a small number of cell bodies labelled with either the first or second fluorescent tracer alone (ie. single labelled). The double labelled brainstem-spinal neurons suggest that regeneration of transected projections contributes to the functional repair of spinal cord injuries in embryonic chicken. (Supported by the MRC of Canada and the Rick Hansen Man in Motion Legacy Fund.)

414.8

THE DEVELOPMENT AND REGENERATION OF THE SYMPATHETIC INNERVATION OF THE RAT TAIL ARTERY. C. R. Anderson* and Elspeth M. McLachlan. Department of Physiology and Pharmacology, University of Queensland, Queensland, 4072, Australia.

The sympathetic innervation of the main caudal artery of Wistar rats was examined using the SPG technique for catecholamine fluorescence, and immunohistochemical localisation of tyrosine hydroxylase (TH) and neuropeptide Y (NPY) during normal development and during regeneration following nerve lesions.

At birth, the tail was essentially devoid of sympathetic fibres. By 3d postnatal, small paravascular bundles extended along the proximal caudal artery and the first perivascular fibres were present. By 10d, sympathetic fibres were present over the media of the entire length of the caudal artery but the density of fibres found in the adult caudal artery was not achieved until 45d. At all earlier stages there was a proximo-distal gradient of maturation with a lag of about 7-10d in the most distal regions. Noradrenaline, (as visualised with catecholamine fluorescence), and TH and NPY were all present around the caudal artery from the earliest times that nerve fibres could be detected in the tail.

When the tail of 21d old rats was denervated by freezing all four collector nerves at the level of Co7-8 vertebrae, sympathetic fibres around the caudal artery degenerated from 2-3 cm below the level of the lesion. Within10d following denervation, sympathetic fibres began to reappear around the caudal artery,extending proximo-distally at about 2 mm/day. However, after 50d regenerated fibres were rarely found in the distal 30% of the artery, and this persisted as long as120d after denervation. In contrast, the density of regenerated terminals in proximal parts of the caudal artery was only slightly lower than that at equivalent levels of control arteries of the same age. The functional properties of the regenerating fibres are currently under study.

414.9

CHANGES IN SPINAL REFLEXES OF THE RAT INDUCED BY NEONATAL PERIPHERAL NERVE INJURY. B.S. Chung, K. Sheen, J.W. Leem and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77550.

To investigate the effect of neonatal peripheral nerve injury on the organization of the spinal cord, we examined spinal reflexes of adult rats (Sprague-Dawley) in which the left sciatic nerve had been cut during the neonatal stage.

After decerebration at the precollicular level under a gaseous anesthesia of O_2, N_2O and halothane, a laminectomy was performed at the L1-L6 segments. Electrical stimulation was applied to the L5 spinal cord and evoked compound action potentials were recorded in the ventral root of the same segment.

Based on latencies, multiple components of the evoked potentials could be identified: an early monosynaptic reflex and a delayed polysynaptic propriospinal reflex. In addition, spinobulbospinal reflexes could be identified as judged by the disappearance after spinal cord transection at the C1 level. The sizes of propriospinal and spinobulbospinal reflexes were significantly larger on the lesioned side than on the control side.

These results indicate that neonatal peripheral nerve injury induces alterations in the organization of the spinal cord, suggesting functional plasticity in the spinal cord. (Supported by NIH grants NS21266 and NS11255 and a grant from Bristol-Myers Co.)

414.10

AXONAL REGENERATION AFTER CHRONIC SPINAL CORD INJURY. J. D. Houle Dept. of Anatomy, Univ. of Arkansas for Medical Sciences, Little Rock, AR 72205.

The purpose of this study was to determine if neurons retain the ability to regenerate their axonal process for a prolonged period after injury to the spinal cord. True Blue was injected (TB) into one side of the adult rat lumbar spinal cord to label neurons whose axons course through this region. Seven days later these axons were injured by aspiration of the injection site, creating a hemisection cavity. Four weeks later, scar tissue was removed prior to grafting 1 cm long segments of autologous peripheral nerve (PN) to the rostral and caudal surfaces of the lesion cavity. Thirty days later, the distal tip of each of the PN grafts was exposed to Nuclear Yellow (NY) to label neurons that had grown an axon into the graft. Neurons containing both TB and NY were deemed capable of axonal regeneration while in a chronically injured state.

There were no TB/NY neurons within the brain, however, numerous dual labeled neurons were identified within Laminae IV through X (excluding IX) ipsilateral and Laminae VI and VII contralateral to the lesion site, with most cells located within 10mm of the lesion. Within individual lumbar dorsal root ganglia nearly 50% of the neurons labeled with NY also contained TB (range 24-74%). This population of regenerating neurons ($\bar{X}$=48, range of 10-189 per ganglion) had a smaller mean cell area (955 um^2) compared to those with TB only (1110 um^2). These results indicate that in a chronic spinal cord injury condition certain neurons have the capacity for axonal regeneration long after their initial response to injury. REGENERATION OF HYPOTHALAMIC NEUROSECRETORY NEURONS INTO THE THIRD CEREBRAL VENTRICULAR LUMEN FOLLOWING HYPOPHYSECTOMY--AN ELECTRON MICROSCOPIC IMMUNOGOLD STUDY. Wutian Wu and David E. Scott, Dept. of Anatomy & Neurobiology, Eastern VA Med. School, Norfolk, VA 23501

The present investigation focusses upon the reorganization and regeneration of neuropeptide containing neurites into the third cerebral ventricle following hypophysectomy. Six male Spraque-Dawley rats were hypophysectomized 4 weeks before harvesting the brains. Hypothalamic tissue was prepared for immunogold staining. Primary antisera against arginine vasopressin (AVP), Oxytocin (OXT), and Tyrosine hydroxylase (TH) were applied with the "on-grid" immunomarking technique which utilizes secondary antibody-coated colloidal gold probes. Most of the neurites in the ventricular lumen were AVP positive. Gold particles were found within neurosecretory vesicles. Some OXT positive vesicles and AVP positive vesicles were found to be located in the same terminal. Both AVP and OXT positive neurites freely terminate within the third ventricular lumen. No TH positive terminals were observed within the ventricles, although TH neurons in hypothalamus also project to the posterior pituitary. The results of the present study suggest that neurosecretory neurons are able to regenerate their neurites and regrow them into the cerebral ventricular lumen after axotomy. Hence, the CSF may serve as a functional terminus for release of neuropeptide hormones. Supported by NSF grant BNS 8709687.

DIFFERENTIAL EXPRESSION OF AN ACETYLCHOLINE RECEPTOR PROMOTER-LacZ TRANSGENE IN MUSCLE NUCLEI. J.P. Merlie, and J.R. Sanes. Depts. Pharmacol. and Anat. & Neurobiol., Washington University Med. Sch., St. Louis, MO 63110.

Acetylcholine receptor subunit mRNAs are more abundant in innervated than denervated muscles and in synaptic compared to extrasynaptic areas of muscle fibers (Merlie et al., J. Cell Biol., 1984; Merlie and Sanes, Nature, 1985). To study the transcriptional basis of these nerve-dependent phenomena we produced transgenic mice containing an AChR α-subunit promoter fused to the coding sequences of chloramphenicol acetyltransferase (CAT) or β-galactosidase (lacZ). In mice transgenic for an α-promoter-CAT fusion, CAT expression was both muscle specific and increased 100X by denervation (Merlie and Kornhauser, Neuron, 1989). To investigate transcriptional differences among and within muscle fibers, we prepared transgenic mice in which the α-promoter fragment was fused to a lacZ gene modified by incorporation of the SV40 large T antigen nuclear transport signal. As determined histochemically, the distribution of lacZ in 3 lines of αnLacZ mice was muscle-specific. However, αnLacZ mice exhibited pronounced variation among muscles; e.g., tibialis anterior stained far more intensely than soleus. Surprisingly, however, αnLacZ expression was not affected by denervation. Furthermore, nuclei within single myotubes were differentially stained: some nuclei were unstained and synaptic nuclei were often more intensely stained than extrasynaptic nuclei. Although measurements of lacZ RNA will be needed to rule out posttranscriptional effects, we suspect that an activity-dependent regulatory element within the α-subunit promoter was suppressed by fusion to nLacZ. Thus, muscle-specific and activity-dependent regulation are dissociable. Furthermore, the gene fusion is apparently recognized and expressed differently in different muscles, presumably reflecting unique transcriptional potentials of each muscle. (Support: NIH)

C2 MUSCLE CELLS EXPRESS AGRIN BINDING MOLECULES. M.A. Nastuk[1], H. Gordon[2] and J.R. Fallon[1]. [1]Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545. [2]Dept. of Physiology, UCSF, San Francisco, CA 94143.

Agrin, a protein isolated from Torpedo electric organ, induces clustering of acetylcholine receptors (AChRs) on cultured chick myotubes. To elucidate the mechanism of agrin's action, we are working to purify and characterize the molecule(s) to which agrin binds as it interacts with myofiber surfaces. We have chosen the C2 mouse muscle cell line as a source of agrin binding molecules. Here we confirm previous findings (Gordon & Hall, SNS Abstr. 15:1352) that Torpedo agrin induces AChR clustering on the surfaces of C2 myotubes. Agrin binding sites also become redistributed as part of this response. Clusters of agrin binding sites, revealed by immunofluorescent labeling of bound agrin, are colocalized with spontaneous as well as agrin-induced AChR aggregates. C2 myoblasts also express agrin binding sites. NRK fibroblasts, however, do not bind agrin. For C2 myoblasts as well as myotubes, agrin binding depends upon the presence of extracellular calcium; EGTA abolishes virtually all specific binding much as in chick myotubes (Fallon, this vol.). These results suggest that calcium is important in regulating the action of agrin. Furthermore, the calcium dependence of agrin binding may prove highly useful in subsequent affinity purification strategies. NIH F32 NSO8152 and HD 23924.

TORPEDO ACHRs EXPRESSED IN MOUSE FIBROBLASTS CLUSTER IN RESPONSE TO EXTRACELLULAR MATRIX AND NG108-15 CONDITIONED MEDIA. D.S. Hartman* and T. Claudio. Dept. Cell. & Molec. Physiology, Yale Univ., New Haven, CT 06510.

Torpedo acetylcholine receptors (AChRs) stably expressed in mouse fibroblast L cells form fully functional receptor-channels (*Science* **238**, 1688-94, 1987) and are distributed evenly on the cell surface of the fibroblast (*J. Physiol., Paris*, **84**, 1990). AChR surface distribution was determined by labelling briefly with a monoclonal antibody specific to the AChR α subunit (mAb22) followed by a second antibody conjugated to phycoerythrin, and visualized at 570nm with a Zeiss IM35 microscope. A variety of agents were able to induce AChR clusters in fibroblasts. Prolonged incubation of the cells with mAb35, a monoclonal antibody previously shown to induce antigenic modulation of cell surface AChRs, produces small (<2μM) AChR clusters followed by rapid internalization of the clusters. Incubation of the AChR-fibroblasts with *Torpedo* extracellular matrix (ECM) extract or conditioned media from an NG108-15 neuroblastoma-glioma cell line, agents which have been shown to induce AChR cluster formation in cultured muscle cells, also induce the formation of AChR clusters in the fibroblasts. These clusters are larger than antibody clusters, and range in size from 2-10μM in diameter. Clusters induced by ECM or NG108-15 conditioned media do not turnover rapidly and the total number of surface AChRs does not change. *Torpedo* AChRs expressed in mouse fibroblasts appear to respond to various clustering agents in a manner similar to that of mammalian AChR in muscle. This result suggests that at least these clustering factors induce AChR clustering via direct intermolecular interaction with the AChR molecule.

THE POSTSYNAPTIC 43K PROTEIN CLUSTERS MUSCLE NICOTINIC ACETYLCHOLINE RECEPTORS IN *XENOPUS* OOCYTES. P. B. Scotland+, C. W. Luetje#, J. Patrick#, and S. C. Froehner+. +Department of Biochemistry, Dartmouth Medical School, Hanover, NH 03756 and #Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Nicotinic acetylcholine receptors (AChR) are localized at high concentrations in the postsynaptic membrane of the neuromuscular junction. A peripheral membrane protein of M_r 43,000 (43K protein) is closely associated with AChR and has been proposed to anchor receptors at postsynaptic sites. We have used the *Xenopus* oocyte expression system to test the idea that 43K protein clusters AChR. Immunofluorescence of oocytes injected with RNA made from the cDNA of mouse muscle AChR subunits shows that the receptors are uniformly distributed in the surface membrane. Oocytes co-injected with AChR RNA and RNA encoding the mouse muscle 43K protein display AChR clusters of 0.5-1.5 microns in diameter. AChR clustering is not a consequence of increased receptor expression in the surface membrane as determined by measurements of acetylcholine-induced currents. Furthermore, expression of 43K protein does not alter the distribution of lectin binding sites, demonstrating that AChR clustering is not a result of non-specific aggregation of all membrane proteins. The 43K protein is co-localized with AChR in clusters when the two proteins are expressed together and forms clusters of similar size even in the absence of AChR. These results provide direct evidence that the 43K protein causes clustering of AChR and suggests that regulation of 43K protein clustering may be a key step in neuromuscular synaptogenesis.

415.5

MUSCLE-DERIVED AGRIN IS A COMPONENT OF THE EXTRACELLULAR MATRIX. E. Lieth[1], C.A Cardasis[2] and J.R. Fallon[1]. [1]Worc. Fnd. Exp. Biol., Shrewsbury MA 01545 and [2]UMASS Med. Sch., Worcester MA 01605.

Chick muscle-derived agrin (M-agrin) is associated with regions of high acetylcholine receptor (AChR) density in vivo and in vitro. Its antigenic relationship to Torpedo agrin implicates it as a possible synaptic organizing molecule. In vivo synaptic organizing activity resides in the basal lamina. Here we show that M-agrin is detectable by immunofluorescence on unpermeabilized cells in culture, and is not extractable in 2mM EGTA or 0.1% Triton X-100. It is solubilized in 0.2M bicarbonate pH 9, a buffer which also extracts agrin from Torpedo extracellular matrix. The pattern of M-agrin immunostaining in cultures is similar to that of laminin, but its distribution is more restricted. Furthermore, EM-immunocytochemistry demonstrates that M-agrin is a myotube basal lamina component. These results indicate that muscle secretes agrin-like molecules that become stably associated with the synaptic basal lamina. PHS grant HD 23924 to JRF and MDA fellowship to EL.

NERVE- AND AGRIN-INDUCED ACETYLCHOLINE (ACh) RECEPTOR CLUSTERING IN *XENOPUS* MULTINUCLEATE MYOTUBES. M. Saito and Y. Kidokoro. Jerry Lewis Center, UCLA School of Medicine, L.A., CA 90024

Agrin, which was extracted from the basement membrane of the electric organ of *Torpedo californica*, caused ACh receptor clustering in *Xenopus* multinucleate myotubes in culture. We tested a hypothesis that agrin released by the motor nerve terminal binds to its receptor in the basement membrane, and subsequently activates the receptor aggregating mechanism in the muscle cell.

In *Xenopus* multinucleate myotubes both nerve- and agrin induced receptor clustering were, at least partly, due to lateral migration of receptors in the membrane. Concanavalin A blocked both nerve- and agrin-induced clustering presumably by immobilizing ACh receptors. Heparin applied in the culture median partially blocked nerve-induced receptor aggregation and totally inhibited agrin-induced clustering. In contrast, a similar proteoglycan, chondroitin sulphate type A, affected neither of these receptor aggregating processes. Agrin in the culture medium at saturating concentrations partially blocked nerve-induced receptor accumulation.

Our observations are in accord with the hypothesis stated above.

415.7

INDUCTION OF ACETYLCHOLINE RECEPTOR CLUSTERING BY LOCALIZED APPLICATION OF SEVERAL GROWTH FACTORS IN XENOPUS MUSCLE CELLS. L.P. Baker and H.B. Peng. Curr. in Neurobiology & Dept. of Cell Biology and Anatomy, Univ. of North Carolina, Chapel Hill, NC 27599.

The abstract by Peng and Baker (this volume) discusses the localized application of bFGF to *Xenopus* muscle cells via beads, and its ability to induce the development of postsynaptic specializations. This work shows that in addition to bFGF, insulin and IGF-1 are also able to induce clustering of acetylcholine receptors (AchRs). Specific receptors for these ligands are known to be present on muscle cells. EGF, two isoforms of PDGF, and NGF-ß are unable to induce clustering. Many effects of growth factors are mediated through receptor-associated tyrosine kinase activity. In order to demonstrate the involvement of this activity in AchR clustering, a tyrosine kinase inhibitor, tyrphostin RG50864, was applied to the cells prior to bead application. AchR clustering was completely and reversibly blocked by 40 to 80μM RG50864. In addition, clustering induced by polycation-coated beads, as has been previously demonstrated by Peng, was inhibited by 40μM RG50864. Future work will be carried out to further characterize the specificity of cellular responses to tyrphostins, and to demonstrate tyrosine phosphorylation of growth factor receptors and their substrates in response to this localized application of growth factors. (Supported by NIH grant NS23583 and Muscular Dystrophy Association)

PARTIAL PURIFICATION OF AN ACETYLCHOLINE RECEPTOR AGGREGATING FACTOR FROM FETAL PIG BRAIN. A. Olek, N. Yu*, E. Dutton, and M. Melton. *Department of Zoology, University of* Maryland, College Park, MD 20742

It has been shown that developing neurons or neural tissue contain factors that either induce acetylcholine receptor (AChR) aggregation or stimulate the synthesis of AChR on aneural cultured myotubes. AGRIN, a highly purified factor obtained from Torpedo electric organ induces AChR aggregation (Nitkin et al., J. Cell Biol. 105:2471, 1987). ARIA (Usdin and Fischbach, J.Cell Biol. 103:493, 1986) and CGRP (New and Mudge, Nature, 323:809, 1986) increase the synthesis of AChR. While relatively crude extracts of mammalian neurons or neural tissues contain AChR aggregating activity, the factor has not been extensively purified.

We report the partial purification of a proteinaceous factor from fetal pig brain. This factor induces AChR aggregation in aneural cultures of rat myotubes within 4 hrs at 36° C. This factor has been purified approximately 5000 fold and is associated with a high (100-200 kd) molecular weight protein, active at nanomolar concentrations. The factor elutes from an anion exchange column with a salt concentration between 25 and 125 mM. The most purified fraction migrates on SDS-PAGE gels as 6 major bands from 74 to 170 kd and one band > 200 kd. Activity can be eluted from a small segment of non-denaturing gels containing only a few major protein bands. Protease digestion or incubation at 60° C for 30 min completely eliminates the activity of the aggregating factor.

415.9

NEURAL FACTOR-INDUCED ACETYLCHOLINE RECEPTOR AGGREGATION: A MODEL FOR LOCAL INDUCTION. M.A. Melton, A.J. Olek, and E.K. Dutton. Department of Zoology, University of Maryland, College Park, MD 20742.

During neuromuscular synapse formation in culture the neuron can induce the accumulation or aggregation of acetylcholine receptors (AChR) at the innervation site on myotubes. It has been proposed that the neuron transiently releases a factor that locally induces AChR aggregation. In support of this hypothesis, we have shown that local application of a partially purified mammalian AChR aggregating factor induces local AChR aggregation within 4 hrs on cultured rat myotubes at 36° C.

Primary rat myotube cultures were incubated in 0.3% Dispase to remove overlying fibroblasts and other non-muscle cells to produce experimentally accessible surfaces. Aggregates formed predominantly on the top surface of these myotubes in response to a 30 min bath applied pulse of a partially purified protein factor derived from fetal pig brain. Local application of the aggregating factor via micropipette to regions of the myotube surface for 30 min or less resulted in AChR aggregation largely restricted to the release site. Similar application of control solutions to the myotube surface had no effect. Further, preliminary studies indicate that this response was not associated with a detectable change in the membrane potential during the period of factor application.

THE *TORPEDO* POSTSYNAPTIC 280K PROTEIN IS DYSTROPHIN. S.C. Froehner#, M.H. Butler#, A.A. Murnane#, K. Douville#, and R. Sealock*. #Department of Biochemistry, Dartmouth Medical School, Hanover, NH 03756 and *Department of Physiology, University of North Carolina, Chapel Hill, NC 27599.

Purified postsynaptic membranes from *Torpedo* electric organ contain several peripheral membrane proteins that are thought to play a structural role at the synapse. One of these is a peripheral membrane protein of approximately M_r 280,000 (280K protein). Two monoclonal antibodies that recognize different epitopes on this protein were isolated. Immunogold labeling of electric organ with these mabs shows that the 280K protein is restricted to the cytoplasmic side of the innervated membrane in a distribution similar to the nicotinic receptor. By immunofluorescence, both anti-280K mabs stain muscle endplates very intensely and also show specific staining of extrasynaptic membrane. A protein of similar M_r in *Torpedo* postsynaptic membranes is specifically recognized on Western blots by antiserum to dystrophin. To examine the relationship between the 280K protein and *Torpedo* dystrophin, the former was purified by immunoaffinity chromatography. Purified 280K protein was recognized on Western blots by both anti-280K mabs and by anti-dystrophin but not by control antibodies. Furthermore, both anti-280K mabs stain normal mouse skeletal muscle, but not skeletal muscle from the *mdx* dystrophic mouse, which lacks dystrophin because of a mutation in the dystrophin gene. These results indicate that the 280K protein is dystrophin (or a closely related protein) and suggest that dystrophin may play an important role at the neuromuscular postsynaptic membrane.

415.11

EVIDENCE FOR ASSOCIATION OF THE POSTSYNAPTIC CYTOSKELETAL 58K PROTEIN WITH DYSTROPHIN. M.H. Butler, A.A. Murnane, and S.C. Froehner. Department of Biochemistry, Dartmouth Medical School, Hanover, NH 03756.

Several peripheral membrane proteins, including the M_r 58,000 (58K) and M_r 280,000 (280K) proteins are associated with the postsynaptic membrane of *Torpedo* electric organ and mammalian skeletal muscle. The 58K and 280K proteins are found at high concentrations on the cytoplasmic side of the neuromuscular postsynaptic membrane, but are also associated with the extrasynaptic sarcolemmal membrane. We recently identified the 280K protein as dystrophin or a closely related protein. Here we report evidence for the interaction of the 58K protein with dystrophin. Because of a mutation in the gene, dystrophin is absent from skeletal muscle of *mdx* mice. Immunofluorescence staining of *mdx* skeletal muscle by anti-58K mabs is severely reduced when compared to normal muscle. The reduction is selective for the 58K protein since staining of several other cytoskeletal proteins, such as vinculin, and a membrane protein (Na, K-ATPase) is normal in *mdx* muscle. Furthermore, preliminary experiments show that immunoprecipitation of Triton-solubilized *Torpedo* postsynaptic membranes with anti-58K mab also precipitates dystrophin. These results suggest that association of the 58K protein with the skeletal muscle plasma membrane requires the presence of dystrophin, possibly because the two proteins are present in a complex.

415.12

DIFFERENTIAL LABELING OF TERMINAL ARBORS OF MULTIPLE AXONS INNERVATING THE SAME TARGET CELL WITH DiI AND A NEW LIPOPHILIC TRACER, 4-Di-16-ASP. C.K. Chua* R.J. Balice-Gordon & J.W. Lichtman, Dept. Anatomy & Neurobiology, Wash. Univ. Sch. Med., St. Louis, MO 63110.

Competitive interactions between neurons vying for capture of the same target cells are believed to shape patterns of synaptic connections throughout the developing nervous system. Such interactions are poorly understood, in part because it is technically difficult to distinguish the terminals that persist from those that are eliminated. We have addressed this problem by differentially staining the terminals of competing axons using DiI, which fluoresces red (Honig and Hume, J. Cell Biol. 103: 171-187, 1986), and a new lipophilic compound, 4-Di-16-ASP (DiA; Mol. Probes; Soc. Nsci. Abs. 15: 163, 1989), which fluoresces green. DiA labels cell membranes and can be used as an antero- or retrograde tracer. In paraformaldehyde fixed tissue, DiA diffuses somewhat faster than DiI; importantly, however, these compounds stay segregated even when DiI and DiA labeled axons are interspersed. At embryonic neuromuscular synapses transiently multiply innervated by two different motor axons, one labeled with DiI and the other with DiA, each axon's terminals are similar to growth cones, having many filopodia and only 1-2 small terminal regions per axon. Surprisingly, both axons add discrete synaptic sites for a time, resulting in extensive intermingling of the two inputs. Over time, however, one axon acquires a majority of the synaptic territory, both by expansion of its territory and by the stepwise loss of synaptic sites by the other axon, which is finally resorbed into a retraction bulb proximal to the junction. We are presently studying how postsynaptic ACh receptor regions are occupied by competing axons during this period by labeling the same muscles with fluorescent alpha bungarotoxin.

415.13

NEUROMUSCULAR JUNCTIONS ON POLYNEURONALLY INNERVATED FIBERS SHOW INCREASED SYNAPTIC DEPRESSION. R. Dunia and A.A. Herrera, Dept. of Biological Science, University of Southern California, Los Angeles, CA 90089.

Intracellular recording revealed a growth-associated rearrangement in the innervation of the pectoral muscle of female *Xenopus*. Most fibers (90%) were innervated at two distant junctional sites. In small frogs (5-16 g), 60% of the fibers were innervated at both sites by the same motoneuron (A/A), while the remaining 40% received inputs from different motoneurons (A/B). In larger frogs (20-47 g), however, 93% of the fibers were A/A. We hypothesize that, as in developmental synapse elimination, competitive interactions in polyneuronally innervated fibers (A/B) result in synapse replacement and conversion to mononeuronal innervation (A/A).

To look for physiological correlates of competition, we recorded curare-blocked end-plate potentials (EPPs) from both junctions on single fibers and calculated the ratio of EPP sizes (smaller/larger) for each fiber. The mean ratio was 0.60±0.02 (sem) for A/A fibers, and 0.51± 0.05 for A/B fibers ($p>.05$). When the 50th EPP in a 10 Hz train was measured at the same junctions, the ratio increased in A/A fibers (0.66±0.03) and decreased in A/B fibers (0.44±.06). The difference was significant ($p<.005$), showing that synaptic depression was more pronounced in A/B fibers. These same junctions are being examined for morphological signs of synapse replacement.

415.14

INTERSTITIAL CELLS AT DEVELOPING NEUROMUSCULAR JUNCTIONS. E. A. Connor and R. A. Horowitz*, Univ. of Massachusetts. Amherst, MA 01003.

The structure and function of skeletal muscle depends on its innervation state. In innervated muscle, acetylcholine receptors and N-CAM are found at neuromuscular junctions. In non-innervated muscles, developing or denervated, these molecules are distributed throughout the muscle fiber membrane. The composition of the muscle connective tissue is also dependent on innervation . Interstitial cells accumulate in junctional regions of denervated muscle. In these same regions are found interstitial deposits of tenascin, fibronectin, and heparan sulfate proteoglycan. We asked whether similar changes in the cellular and molecular composition of connective tissue occur in developing muscles. Here we report that the distribution of interstitial cells in developing muscles resembles that in denervated muscles; interstitial cells are concentrated in junctional regions. Interstitial cell density was quantitated in cutaneous pectoris muscles of bullfrog larvae at stages XVI to metamorphosis, stage XXV. At stage XXV, interstitial cells were evenly distributed throughout the muscle. However, there was a gradient of interstitial cells in stage XVI muscles; junctional density of interstitial cells was 2.3 times that in extrajunctional regions. At later stages (XVII-XIX), the interstitial cell gradient was gradually reduced and was undetectable at stage XX. The interstitial cells had characteristic features of fibroblasts and resembled the accumulated interstitial cells in denervated muscle in position and morphology. The presence of an interstitial cell gradient in both developing and denervated muscles suggests that the interstitial cells or the matrix molecules that they produce play a significant role in synapse formation.

PROCESS OUTGROWTH, GROWTH CONES AND GUIDANCE MECHANISMS VIII

416.1

ASSOCIATION NEURONS OF EMBRYONIC SPINAL CORD EXPRESS THE CELL SURFACE GLYCOPROTEIN TAG-1. J.E.Vaughn, P.E.Phelps, M.Yamamoto and R.P.Barber. Division of Neurosciences, Beckman Res. Inst. of the City of Hope, Duarte, CA 91010.

There are two early-developing groups of dorsal horn interneurons in embryonic rat spinal cord: commissural (C) and association (A) cells that innervate contralateral medial and ipsilateral lateral motoneurons (LMNs), respectively. Dodd *et al.*(Neuron 1:105,1988) have shown that C neurons express the surface glycoprotein TAG-1 early in development, and we recently have found that this molecule is also expressed by A cells. On embryonic day 13 (E13), TAG-1 was expressed intensely on C axons, but some TAG-1-immunoreactivity (TAG-1-IR) was also observed on A fibers. By E14, both C and A cells expressed intense TAG-1-IR, with A fibers originating just ventrolateral to the source of C fibers in the dorsal intermediate zone. The A fibers coursed ventrally along the lateral margin of the intermediate zone and terminated adjacent to the dorsal-most LMNs, as defined by ChAT-IR. The origins of C and A fibers diverged progressively on E15 and E16. At these times, A fibers coursed along the entire lateral edge of the LMNs and penetrated medially among this nuclear group. By E17, TAG-1-IR was more intense on A than C fibers. Studies are in progress to determine if these TAG-1 fibers provide pathways for neuronal migration. *Supported by NIH grants NS18858 and NS25784.*

416.2

EXPRESSION OF A FASCICLIN-LIKE MOLECULE DURING NEURODEVELOPMENT IN THE COCKROACH. L.S. Wang* and J.L. Denburg. Dept. of Biology, The Univ. of Iowa, Iowa City, IA 52242.

The presence of molecules involved in specific fasciculation of axons during the development of the nervous system can be identified with monoclonal antibodies. One such Mab, DSS-8, was selected for study because it transiently binds to the nervous system of embryos of the cockroach, Periplaneta americana. Like previously described fasciclins the DSS-8 antigen was regionally expressed on the surface and on particular portions of subsets of growing axons in correlation with their pattern of selective fasciculation. However, in addition, DSS-8 labeled the first axons pioneering a specific subset of CNS axon pathways. In particular, the antigen was present on the first axons of the median fiber tract, the anterior commissure and the posterior commissure. The spatial distribution and temporal expression of the DSS-8 antigen during development suggest that it is playing a role in cell recognition occurring during specific axon fasciculation and in the reading of specific environmental cues during initial axon growth.

416.3

ANALYSIS AND PURIFICATION OF AXON FASCICLE SPECIFIC ANTIGENS IN THE LEECH K.M. Johansen, K.K. Erickson and J. Johansen. Department of Zoology, Iowa State Univ., Ames, IA 50011.

Two monoclonal antibodies, Ian 3-2 and Ian 4-2, label a small subpopulation of axon fascicles in the nerve roots and interganglionic connectives of the leech nervous system. The antigens are surface glycoproteins and on western blots Ian 3-2 recognizes three protein bands with molecular weights of 130, 105, and 90 kD, respectively; whereas Ian 4-2 recognizes a single 130 kD band (McKay et al., Science **222** : 788). Perturbation experiments with Fab fragments of Ian 3-2 have demonstrated that normal fascicle formation is disrupted by the antibody (Zipser et al., Neuron **3** : 621). The antigens recognized by these antibodies are therefore strong candidates for being molecules involved in selective fasciculation and neuronal recognition.

Immunoprecipitations with Ian 3-2 and Ian 4-2 have demonstrated that the two antibodies label the same 130 kD protein and thus recognize different epitopes on the same protein. These epitopes are expressed in at least 6 leech species from two different orders. This suggests that the epitopes are of functional importance since they have been conserved through leech divergence and evolution. Furthermore, using lentil-lectin affinity chromatography followed by immunoprecipitation, we have purified the antigens to homogeneity as judged by SDS-PAGE and silver staining of the gels. We estimate that the antigens constitute roughly 0.004% of total extractable CNS protein. Experiments are in progress to purify enough antigen for partial amino acid sequence determination and subsequent cloning of the gene. This work was supported by a Iowa State Biotechnology Grant and a Iowa State University Grant.

416.4

ASTROGLIAL DIFFERENTIATION, NOT "AGE", IS CRITICAL FOR NEURITE OUTGROWTH L-C. Wang, D.H. Baird, M.E. Hatten, and C.A. Mason. Dept. Pathology, Coll. Physicians and Surgeons, Columbia Univ., New York, N.Y. 10032

Current models of astrocyte differentiation stress a fixed sequence of steps, a timetable thought to be followed when glial cells are placed into tissue culture. This model predicts that glial support of neurite extension declines with the "age" of the glia, i.e., time in culture. An alternative view is that glial support of neurite growth involves a set of independently regulated events, some of which would be controlled by cell-cell interactions. To test these possibilities, purified mouse cerebellar astroglia were maintained *in vitro* for 3 days to 6 weeks in the absence of neurons, explants of pontine nuclei added, and neurite outgrowth quantitated 2 days later. Over time in culture, support of neurite extension declined, from a relatively robust level to negligible levels after 3-4 weeks. Since previous studies have shown that neurons induce the differentiation of glial cells (Hatten *J. Cell Biol.* 100:384, 1985), we tested the neurite promoting activity of glia kept in culture and induced to differentiate by the addition of neurons at different times (3 days to 6 weeks). When granule neurons were added at low density (0.1-0.5 x 10^6/ml) to glia and explants plated 2 days later, neurite growth from the explants was exuberant, regardless of the time glia spent *in vitro*. At this density in the absence of glia, cerebellar granule neurons have little or no effect on pontine neurite extension. We conclude that the differentiated properties of astroglia, here induced by co-culture with neurons, are critical for neurite extension, and that these properties can be modified independent of glial "age" in culture. Supported by NS21457 and NS16951.

GLIAL FIBER GEOMETRY ALONE IS NOT SUFFICIENT TO SUPPORT GRANULE NEURON MIGRATION. R.B. Fishman & M.E. Hatten. Ctr. for Neurobiology & Dept. of Pathology, Columbia University, Coll. of Physicians & Surgeons, N.Y., N.Y. 10032.

In vitro heterotypic recombination experiments show that cerebellar granule neurons are capable of migrating on hippocampal astroglia (Gasser & Hatten, PNAS, USA 1990, in press). Conservation of glial guidance across brain regions suggests that glia provide a generic, and possibly passive substrate for migration. To address this question, we examined whether *geometry* of the glial fiber alone is sufficient to support granule neuron migration.

Using an *in vitro* mouse cerebellar system, we tested whether granule neurons could migrate on a) glass fibers of similar geometry to glial fibers, and b) lightly fixed glial processes. Single glass fibers (~1-2um diameter) were obtained by vortexing Whatman glass fiber filters (GF/A). Fibers were coated with either polylysine, membrane from primary astroglia, or membrane from an astroglia tumor cell line, and subsequently co-cultured with purified cerebellar granule neurons obtained from postnatal day 4 mice.

Although granule neurons bound to glass fibers, and some neurons showed shape changes characteristic of migrating neurons, e.g. elongate profiles and "leading" process extension, neurons did not migrate on glass fibers. Furthermore, preliminary studies show that neurons cultured with lightly fixed (1% paraformaldehyde) glia bound to these glia but did not assume migrating profiles on them. These results suggest that geometry of the glial fiber alone is not sufficient to support migration, but rather migration requires an active interaction between neurons and living glia. Supported by NS15429.

CENTRAL NEURITE OUTGROWTH OVER RESTING AND REACTIVE ASTROCYTES P. Bovolenta, F. Wandosell* and M. Nieto-Sampedro. Neural Plasticity Lab., Cajal Institute, 28002 Madrid, Spain.

Protoplasmic astrocytes are a preferential substrate for neurite extension whereas, after CNS injury, fibrous astrocytes in the glial scar are regarded as a severe hindrance to axonal regeneration. To examine the cellular basis for this contradictory behavior, we have compared neurite outgrowth from explants of rat retina, septum and spinal cord cultured over purified astrocytes from newborn rat (10 to 30 days in culture); type 2 astrocytes; the same astrocytes treated with di-butyryl-cAMP or with phorbol ester; astrocytes grown in three-dimensions; membranes from injured parietal cortex and myelin. Neurites from the explants grew over all substrata, excepting myelin. Type 1 and type 2 astrocytes of various ages, flat polygonal astroblasts and astroblasts made to assume a star-shaped morphology with the help of diBcAMP, behaved similarly. The walls of a brain injury cavity is, 15 days postlesion, formed to a large extent by reactive astrocyte processes. Membranes prepared from these cells supported neurite outgrowth similarly to cultured astrocytes. In summary, regarding neurite outgrowth, we did not observe significant differences among the various kinds of astrocytes. We conclude that type 1, type 2 and reactive astrocytes are all good substrates. In the case of an open injury, the most likely way in which astrocytes hinder axon regeneration is by "misguiding" the regenerating sprouts away from their targets.

GROWTH OF RETINAL AXONS ON GOLDFISH OPTIC NERVE OLIGODENDROCYTES *IN VITRO* M.Bastmeyer, J.Vielmetter, G.Jeserich* and C.A.O.Stuermer, Friedrich-Miescher-Lab. der Max-Planck-Ges., Tübingen, FRG and *Univ.Osnabrück, FRG.

Mammalian oligodendrocytes inhibit the growth of neurites (Schwab and Caroni, 1988). Even retinal growth cones of goldfish collapse upon contact with these cells (Bastmeyer et al, 1988). Oligodendrocytes of regenerating fish optic nerves differ from mammalian oligodendrocytes.

1. Glial cells from fish optic nerves proliferate *in vitro* over weeks. After 2-3 weeks *in vitro* most of these cells express GFAP but also fish myelin glycoproteins detected by the monoclonal antibody (Mab) 6D2 (Jeserich et al, 1990) and the Mab O4-antigen found on mammalian oligodendrocytes (Sommer and Schachner, 1981).
2. Unlike mammalian oligodendrocytes, fish oligodendrocytes promote the growth of regenerating goldfish retinal axons *in vitro*. Both, regenerating fish retinal axons (Vielmetter and Stuermer, 1989) and the fish oligodendrocytes carry the Mab ϵ587-antigen, which has homologies to the mouse cell adhesion molecule L1. In mammals L1 is expressed on Schwann cells, but not on oligodendrocytes.

To test whether fish oligodendrocytes are growth permissive for neurites from other species, we cocultured embryonic chick retinal explants and goldfish glial cells. Chick retinal axons grew in high density on the surface of 6D2 positive goldfish oligodendrocytes. Thus, fish optic nerves through which retinal axons regenerate have oligodendrocytes that - at least *in vitro* - promote the growth of axons.

A METHOD FOR IDENTIFYING MOTONEURONS FROM INDIVIDUAL POOLS IN CULTURE. V. Boss and D. J. Wigston, Depts. of Biology and Physiology, Emory University, Atlanta, GA 30322.

We have developed a procedure for identifying axolotl motoneurons from distinct motor pools in cultured spinal explants. This will enable us to examine in culture the cellular mechanisms underlying the selective reinnervation of appropriate target muscles previously observed in vivo.

The lipophilic fluorescent dye 4-Di-10-ASP (Molecular Probes) was found to retrogradely label the cell bodies of motoneurons, as well as their neurites and growth cones which regenerated in culture. Motoneurons innervating hindlimb muscles of juvenile (6-8cm) axolotls were retrogradely labeled by injection of a 2% solution of 4-Di-10-ASP (in 95% ethanol) into spinal nerve 17. The nerve was crushed at the injection site to facilitate uptake. The dye was retrogradely transported and could be found within motoneuron cell bodies in 7 days and remained for at least several weeks. Therefore, after 7-20 days the ventral portions of lumbar spinal cord segments containing the labeled motoneuron cell bodies were removed and cut into small pieces. These explants were embedded in a collagen-laminin matrix and cultured at room temperature in a modified L15 medium, containing 10% fetal calf serum and either axolotl embryo extract or extract of denervated adult axolotl muscle. Following 4-6 days in culture, labeled motoneurons could be seen within the explants, extending brightly fluorescent processes away from the explants. Since growing processes as well as cell bodies can be labeled, interactions between neurites of identified cells and target tissues in culture can be examined. In addition, since another fluorescent dye, DiI, also retrogradely labels neurons and their growing processes in culture, and its fluorescence excitation spectrum is different from that of 4-Di-10-ASP, it should be possible to compare the interactions between neurons from 2 different motor pools and a given target tissue in the same culture.

INITIAL MOTOR AXON OUTGROWTH. D. Dehnbostel* & K. W. Tosney. Biology Dept., Univ. of Michigan, Ann Arbor, MI 48109.

1) What environmental features determine where motor axons exit from the spinal cord? 2) What interactions exterior to the cord mediate the patterned advance of axons? We are addressing these questions by assessing initial axon outgrowth in thin sections selected from serial, 25µm sections of stage 17 chick embryos prepared as in Tosney and Landmesser (J Histo Cyto 34: 953). 1) Growth cones accumulate at nascent exit points that are spatially predictable but without unique ultrastructural features. Growth cones displace neuroepithelial endfeet from the basal lamina, which appears to tear and be carried away by the first growth cones. Cells also exit the spinal cord, but do not precede growth cones. 2) Upon exiting the spinal cord, growth cones confront populations that provide differential environments for their advance. The posterior sclerotome and the ventral sclerotome in the anterior of a segment act as barriers; only the dorsal-anterior sclerotome acts as a pathway (Oakley and Tosney, 1990 NS Abstr.). Axons do have an opportunity to associate with both barrier and pathway tissues: axons exit in both the anterior and posterior of a segment and in each case traverse an adjacent vascularized region. Differences are seen only after contact with sclerotome. Axons in dorsal-anterior sclerotome ramify widely, extend directly dorsally and laterally, and initially form small fascicles. In contrast, axons that enter the more inhibitory environments cluster into larger fascicles and turn within a few microns. These differences in axonal trajectories and in neurite association support a substratum-preference mechanism of guidance, in which entry into a more inhibitory environment discourages advance and promotes closer association among neurites. Supported by NIH grant NS-21308.

EVIDENCE FOR THE DELINEATION OF AXON PATHWAYS BY INHIBITORY BOUNDARIES. R. A. Oakley and K. W. Tosney. Neurosci. Program & Biol. Dept., U. of Michigan, Ann Arbor 48109.

We previously demonstrated that peanut agglutinin (PNA) binds to three tissues adjacent to axon pathways in the chick embryo (the posterior sclerotome, girdle precursor, and perinotochordal mesenchyme; PNM) but not to the axon pathways themselves (Oakley and Tosney, NS Abstr. 347.7, 1988). We report here the distribution of PNA binding as detected with immunohistochemistry following three types of embryonic surgery. 1) Differential PNA binding patterns are retained even in the virtual absence of axons. Following unilateral neural tube deletion, axon pathways to the limb remain PNA-negative, including the dorsal-anterior sclerotome, the plexus region, and the hiatuses of the girdle which transmit axons to the limb. We conclude that *the differential pattern of PNA binding is independent of motor axon outgrowth.* 2) We find that axons turn to avoid the PNM at all stages of outgrowth following neural tube rotations that alter the initial direction of axon outgrowth so as to directly confront motor growth cones with the PNM. We conclude that *the dorsal anterior sclerotome is permissive and the PNM is relatively inhibitory for axon advance.* The PNM, like the posterior sclerotome and girdle precursor, thus acts as a barrier to axon advance. 3) In contrast, the PNM does not exhibit inhibitory function and does not differentially bind PNA following notochord deletion. *The inhibitory function of the PNM correlates with the expression of PNA binding epitopes.* We suggest that general axon pathways may be determined in part by relatively inhibitory characteristics of those tissues that express PNA binding epitopes.

DEVELOPMENT OF THALAMOCORTICAL CONNECTIVITY IN VIVO AND IN VITRO. Zoltán Molnár* and Colin Blakemore. University Lab. of Physiology, Parks Road, Oxford OX1 3PT, U.K.

We are interested in the mechanisms responsible for the innervation of different cortical areas by particular nuclei of the thalamus. In organotypic co-cultures, any region of embryonic (E) 16/17 day rat thalamus will innervate any region of cortex (postnatal, P0-8). No positional preference was observed even when the thalamic explants were given a choice of different cortical targets. McConnell et al. (1989; *Science* 245:978) showed that subplate neurons pioneer the first axon pathway from the cerebral cortex to the thalamus in cat. We have determined the developmental time course of the establishment of these projections in rat from E13-E17. Tracing with fluorescent dyes from different cortical areas, we observed that these early corticofugal fibres have different projection targets in the diencephalon according to their cortical origin. By E16 the first corticopetal diencephalic fibres have reached their appropriate cortical areas using routes similar if not identical to those already occupied by the pre-existing corticofugal projections. This coupled scaffold system may be crucial in the development of area-specific thalamocortical connectivity. In culture, E15-16 cortical explants innervate thalamic explants but again there is no sign of positional preference. Therefore, we suspect that organized pathways in the extracellular matrix or simple mechanical factors may play important roles in the establishment of thalamocortical connectivity at early stages, when the forebrain is very immature.

INGROWTH OF THALAMOCORTICAL AXONS INTO EMBRYONIC RAT NEOCORTEX S. Catalano* and H.P. Killackey, Depts. of Anatomy and Neurobiology and of Psychobiology, University of California, Irvine, CA 92717

The growth of thalamocortical axons into rat neocortex was examined using the fixed brain DiI technique (Godement et al, *Development* 101:697, 1987). On the sixteenth day of gestation, E 16, thalamic axons can be traced into cortex and reach approximately halfway up the lateral-to-medial extent of the cerebral vesicle. At this age, a lamina of cells condensing underneath the cortical plate (presumably lamina 6b, Valverde et al, *J.Comp.Neurol.* 290:118, 1989) can begin to be distinguished. Thalamic axons run tangentially within the intermediate zone without branching. Many fibers course directly underneath the cortical plate and are thus in contact with lamina 6b. By E 18, lamina 6b is quite distinct, being separated from the cortical plate by a cell-sparse zone. Thalamic axons grow tangentially within lamina 6b as well as the intermediate zone below, and a dense layer of thalamic arbors can be seen growing radially within the cell-sparse zone, between the cortical plate and lamina 6b. By E 20 presumptive layer 6a has begun to differentiate and thalamic arbors continue to grow radially through it, but do not penetrate the cell-dense cortical plate. At no point are afferent fibers observed within the marginal zone. Thus thalamic axons are present within cortex from a very early age, and the growing arbors are in a position to contact target cells as these laminae differentiate from the cortical plate. CULTURED RAT RETINAL GANGLION CELL NEURITES DISPLAY AXONAL AND DENDRITIC MARKERS. Dana Leifer, Michael Marciello, Evan B. Dreyer, and Stuart A. Lipton. Department of Neurology, Children's Hospital, Massachusetts General Hospital, and Harvard Medical School, Boston, MA.

We have previously shown that neurite outgrowth by postnatal rat retinal ganglion cells is enhanced on substrates coated with monoclonal antibodies against the cell-surface glycoprotein Thy-1 (Leifer et al., *Science* 1984;224:303). These antibodies are specific in retina for the ganglion cells. We have also found that growth is increased if the cells are grown on an astrocyte monolayer or in the presence of acidic fibroblast growth factor, nicotinic antagonists or NMDA antagonists. We have now labeled retinal ganglion cells in culture with antisera (provided by Drs. K. Kosik and G. Lee) against the cytoskeletal proteins MAP-2 and tau, which are normally localized to dendrites and axons, respectively. Retinal cultures grown for one day on substrates coated with monoclonal antibodies against Thy-1 (supplied by Dr. C.J. Barnstable) were stained with these antisera. Double labeling with the anti-Thy-1 antibodies was used to identify the ganglion cells and their neurites. Immunoreactivity for both cytoskeletal proteins was found in essentially all ganglion cell neurites. This result indicates that after one day in culture, retinal ganglion cell neurites, and, in particular, those whose growth is enhanced by antibodies against Thy-1, have both axonal and dendritic features. The results also suggest that the study of these cultured neurons is relevant to conditions such as Alzheimer's disease in which MAP-2 and tau co-localize to abnormally proliferating neurites.

EFFECTS OF THYROXINE ON PROCESS OUTGROWTH FROM XENOPUS CNS EXPLANTS. D.L. Norris, M.S. Beattie, and J.C. Bresnahan. Depts. Anatomy and Surgery, and Neuroscience Program, Ohio State Univ., Columbus, OH 43210

Previous studies in our laboratory provide evidence for metamorphosis-dependent spinal cord regeneration in Xenopus tadpoles (Beattie et al., SN Abs. 13:972, 1987). We report here preliminary results of experiments to assess the role of thyroxine in axonal outgrowth from Xenopus CNS explants. Stage 50-54 brainstem - spinal cord explants, and juvenile spinal cord/DRG explants, survive and adhere to poly-L-lysine or Matrigel substrates when cultured in a modified L-15 medium (e.g., Grant & Tseng, Dev. Biol. 114:475, 1986). Retinal explants thrive under similar conditions. Tri-iodothyronine (T3), when added at a concentration of 10^{-8} M to stage 50 tadpole CNS explants severed at the brainstem - spinal cord junction, supported substantially greater process outgrowth and connection between the brainstem and spinal cord than did T4 added at similar concentrations. Dose-response studies and histological characterization of explant cultures are underway. (Supported by NS-10165 and OSU Surgery MRDF)

A POSSIBLE ROLE FOR RETINOIC ACID IN THE DEVELOPMENT OF SPINAL CORD INTERNEURONS. T. Shiga, V. P. Gaur*, K. Yamaguchi* and R. W. Oppenheim, Department of Neurobiology and Anatomy, Wake Forest University, Winston-Salem, NC 27103

We have been examining the development of interneurons in the chick spinal cord with the goal of elucidating the cues that guide axons to their targets. The earliest developing interneurons are divided into two groups; primitive longitudinal (PL) cells in the ventral region with rostrocaudal projection and circumferential (C) cells in the dorsal and lateral regions with ventrally projecting axons which join the ipsilateral or contralateral longitudinal pathway. Recent data indicates that retinoic acid is involved in various aspects of morphogenesis. We have examined the expression of cellular retinoic acid binding protein (CRABP) in the spinal cord between stages 12 and 44 (embryonic day (E) 2 and E18). Both PL-cells and C-cells expressed CRABP shortly after their final mitosis. With the onset of axonal growth, CRABP was observed both in cell bodies and axons, including growth cones. CRABP expression in cell bodies continued up to E18, whereas immunostaining of axons was greatly diminished. In vivo perturbation studies involving treatment with retinoic acid are in progress.

NEURITOGENESIS IN CENTRAL AND PERIPHERAL NERVOUS TISSUE COOLED BEFORE EXPLANTION. Nestor G. Carri and Ted Ebendal, Department of Developmental Biology, Box 587, Biomedical Center, S-751 23, Uppsala University, Uppsala, Sweden.

Neural transplantation techniques requires optimal tissue preservation. At present it is not known to what extent the time elapsed between dissection and the explantation to culture or implantation to a host affects the donor tissue. Neurite formation offers one possibility to study the integrity of the nervous tissue. We therefore studied neuritogenesis in embryonic neural explants using a short-term bioassay. After cooling dissected tissues to 8 °C in basal medium for different periods (24, 48, 72 h), the explants were cultured on hydrated collagen lattices. Tissues included neural retina and sympathetic ganglia from the chick embryo and dorsal root ganglia from an aborted human embryo. The explanted tissues received neurotrophic support during culture: Tectal extract was used for the retina and mouse βNGF for the ganglia. Neurites developed well and neuron survival was high after four days of culture using these conditions. The explants subjected even to the longest cold periods did not visibly deviate in their ability to form neurites. Our results demonstrate that nervous tissue can be preserved cold for a considerable period before being put into culture. This observation opens the possibility of future use of nervous tissue collected or manipulated several days before applied as grafts in brain surgery.

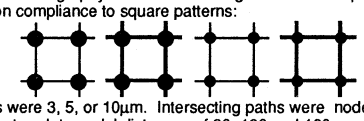
COMPLIANCY OF HIPPOCAMPAL NEURONS GROWN ON PATTERNED MICROCIRCUITS. J.M. Corey[1], B.C. Wheeler[1], and G.J. Brewer[2]. [1]Neuroscience Program, University of Illinois, Urbana, IL 61801 and [2]Southern Illinois University School of Medicine, Springfield, IL 62794.

The study of synaptic specificity of CNS neurons would be facilitated by limiting their number and observing connections formed during directionally restricted growth of their axons and dendrites. Growth direction can be controlled by culturing neurons at low density on patterned substrates. Rat hippocampal neurons were dissociated and grown on these substrates at low density (6000 cells/cm^2) in defined medium. Substrate patterning was done by etching poly-lysine coated glass substrates with a UV laser through a quartz mask fabricated with electron beam lithography. We have investigated effects of path width and node size on compliance to square patterns:



Path widths were 3, 5, or 10μm. Intersecting paths were nodes of 5, 10 or 20μm diameter. Internodal distances of 80, 120 and 160μm were created. After 3 days of growth, the 80μm length patterns showed maximum adhesion (94%) to the 5μm path and 20μm node pattern. This was 50% better than the least compliant combination of 3μm paths and 5μm nodes. Somal migration to nodes from paths and from off-path areas was noted from observations over a four day period. These findings demonstrate effective neuron positioning on microcircuits by a process of selective adhesion and migration which will aid in later applications to localize neurons over substrate electrodes. Supported by Pearson Family Foundation and NIH BRSG funds.

NEUROBLASTOMA DIFFERENTIATION IS INFLUENCED BY ELECTRO/CHEMICAL MODIFICATION OF TISSUE CULTURE SUBSTRATES. V. Guénard, R.F. Valentini, S. Makohliso* and P. Aebischer. Section for Artificial Organs, Biomaterials and Cellular Technology, Brown University, Providence, RI 02912.

Numerous studies have demonstrated the importance of tissue culture (TC) substratum properties in determining neuronal attachment and morphology. Thus far, it has not been possible to determine whether the chemical and/or electrical characteristics of the substratum are responsible for morphological changes. The use of chemically and electrically modified polymeric growth substrates may provide insight into these mechanisms. Amine or oxygen rich polystyrene (P) TC dishes are produced by a plasma discharge process. The stable amine or oxygen groups on the P surface result in significant external positive (PP) or negative (NP) electrostatic fields, respectively. Polytetrafluoroethylene (T) can be made into positively (PT) or negatively (NT) charged electrets by injecting and trapping monopolar charges within the polymer bulk. The corona poling process used to fabricate T electrets does not induce chemical modifications on the T surface. Thus, PT and NT electrets generate significant external fields but have chemically identical T surfaces. Mouse neuroblastoma (Nb2a) cells were grown on P, PP and NP or T, PT and NT dishes for 24, 48, 72 and 96 hr. At all time points, Nb2a cells cultured on PP and NP showed increased neurite outgrowth and more flattened morphology as compared to standard P dishes. Nb2a cultured on PT showed better attachment and neurite outgrowth than NT, while unmodified T showed very little attachment. These results suggest that the electrostatic fields associated with different tissue culture substrates play an important role in regulating neuronal differentiation in vitro.

PROCESS OUTGROWTH, GROWTH CONES AND GUIDANCE MECHANISMS IX

417.1

MORPHOLOGICAL AND BEHAVIORAL DIFFERENCES BETWEEN GROWTH CONES FROM CULTURED SYMPATHETIC NEURONS AND ADRENAL CHROMAFFIN CELLS. K. L. Hoffman, C. A. Schulz and P. Claude†. Wisconsin Regional Primate Research Center and †Neuroscience Training Program, UW-Madison 53715.

Cultured adrenal chromaffin cells respond to nerve growth factor (NGF) by extending neurites and, after 14-21 days, transdifferentiating into sympathetic neurons. We enzymatically dissociated adrenal medullae or superior cervical ganglia from 8-day old rats, and plated cells onto collagen-coated glass coverslips set into 35 mm plastic culture dishes (Corning). The growth medium (DMEM;GIBCO) was supplemented with 0.6% glucose, 10% dextran-charcoal-stripped fetal calf serum (Hyclone), 100 μg/ml Gentamicin and 25 ng/ml 7S NGF (Collaborative Research). Using phase optics and time lapse video microscopy, we compared the morphology and motile behavior of growth cones from sympathetic neurons, from naive chromaffin cells and from chromaffin cells that had been exposed to NGF for times up to two weeks. In order to examine growth cones from chromaffin cells at different stages of neuronal differentiation, we replated cells after various times in NGF; when these cells are replated they immediately start to extend neurites tipped with growth cones. *Results:* Growth cones from mature sympathetic neurons do not adhere to the substratum over large areas; they are highly dynamic at the leading edge, with exuberant filopodial and lamellipodial activity. In contrast, after 3-10 days in NGF, chromaffin cells exhibit growth cones that are broad and flat, suggesting a uniformly high adherence to the substratum, and few, if any, filopodia. However, after 14 days of exposure to NGF, many of the replated cells extend growth cones that are indistinguishable from those of mature sympathetic neurons. This suggests that a developmental change in growth cone-substratum interaction takes place as these cells differentiate into neurons. *(Supported by NSF BNS-8616958 to P.C. and NIH RR00167 to the WRPRC.)*

417.2

DIFFERENCES IN Ca2+ HOMEOSTASIS IN GROWTH CONES AND SOMA OF AN IDENTIFIED NEURON: Na+-DEPENDENT AMPLIFICATION OF Ca2+ SIGNALS IN GROWTH CONES. J. R. Jensen, V. Rehder, and S. B. Kater. Dept. of Anatomy and Neurobiology, Colorado State Univ., Fort Collins, CO 80523.

The kinetics of the responses to perturbations of the intracellular calcium concentration ([Ca2+]i) differed greatly in neuronal growth cones (GCs) and cell bodies. The large GCs of cultured *Helisoma* buccal ganglia neuron 5 were utilized to compare Ca homeostasis in GCs to the soma of the same neuron. The fluorescent Ca2+ indicator Fura 2 (K+salt) was employed to assess [Ca2+]i. .

The Ca2+ ionophore, 4-bromo A23187, was used to increase Ca2+ influx and release from intracellular stores. The continuous presence of the ionophore triggered a biphasic response in the soma; a rapid transient increase was followed by a slowly increasing component. (Only the initial transient was still observed in Ca2+-free media, indicating that this component is due to release from stores.) In contrast, GCs exhibited a larger magnitude peak, intermediate in time to the two components of the cell body response. Moreover, this peak in GC [Ca2+]i was dependent on external Na+, while the cell body [Ca2+]i was only minimally affected by the presence of external Na+ at this dose of ionophore. Thus, when the Na+ content of the media was reduced from 45 to 5mM the sharp peak in GC [Ca2+]i was not observed; rather there was only a gradual rise to a plateau level similar to that eventually achieved in normal media. A similar Na+-dependent amplification in GCs was also observed in response to increases in [Ca2+]i evoked by the proton ionophore FCCP.

The results demonstrate that Ca2+ homeostasis is quite different in neuronal GCs and cell bodies. One factor contributing to this difference is a Na+-dependent system for amplification of increases in GC [Ca2+]i. The amplification that is observed could be produced by Ca2+ influx via the Na+-Ca2+ exchanger, as this system possesses positive feedback qualities that are consistent with our findings, although other possible mechanisms have not yet been ruled out.

417.3

THE EFFECT OF ELECTRICAL STIMULATION AND GROWTH-CONE-CALCIUM ON NEURITE OUTGROWTH IN RAT SYMPATHETIC NEURONS [1]T. K. Garyantes, [1]J. Pine, & [2]W.G. Regehr [1]Caltech, Pasadena CA 91125, [2]AT&T Bell Labs, Murray Hill NJ 07974.

Increasing growth-cone-calcium levels ($[Ca]_{gc}$) by electrical activity has been proposed as a mechanism to halt neurite outgrowth (Cohan etal., J. Neurosci., 7, 11, p.3588, 1987). We investigated the effect of increased electrical activity and $[Ca]_{gc}$ on the growth rate of cultured neonatal rat superior cervical ganglion neurons (SCGs). These neurons show low levels of spontaneous activity in control saline. We found that stimulation at 10 Hz for 1 hour, growth in high K^+ medium or high K^+/high Ca^{++} medium had little effect upon growth rates. Immediately following the onset of stimulation, $[Ca]_{gc}$ (measured using fura-2) transiently increased to greater than 500nM, but for all conditions tested sustained $[Ca]_{gc}$ remained below 250nM. These results sharply contrast those reported for cultured adult *Helisoma* neurons where electrical stimulation produced slightly larger $[Ca]_{gc}$ increases but stopped outgrowth. Intriguingly, for SCGs growth rates did not correlate with calcium levels in the range studied (50-250nM). These findings indicate that SCG outgrowth is unlikely to be greatly influenced by electrical activity at frequencies as high as 10Hz. Differences in calcium buffering systems, density or type of voltage-dependent calcium channels, or sensitivity of outgrowth to $[Ca]_{gc}$ between rat SCGs and *Helisoma* neurons may explain their different responses to electrical stimulation.

Filopodial Formation in Neuronal Growth Cones Examined With a Laser Trap. D.B. Wayne,S.C. Kuo*,N.L. Baumrind,A.L. Pearlman† and M.P. Sheetz* Depts of Cell Biology and Neurology†, Washington University Medical School, St. Louis, MO 63110

We have used the radiation pressure of a laser trap to manipulate antibody- or protein-conjugated (0.5μm) latex beads on the surface of embryonic murine cortical growth cones. With the laser trap, beads attached to the cell surface can pull novel membranous extensions (neopodia) which resemble filopodia in their general form. Release of neopodia from the laser trap resulted in 3 types of response: an instant elastic recoil; an immediate but slow recoil; or a rigid form which extended, moved, or actively retracted. The formation of a rigid structure suggests conversion to a true filopodium. The response observed depended primarily on the activity of the growth cone prior to neopod formation: motile growth cones produced rigid neopodia. We saw no evidence that cytoskeletal rigidity forms from the distal tip inward; instead it progressed from the proximal end outward. Thus, mechanical extension of membrane can induce formation of active filopodia, which presumably requires actin polymerization. This occurs with greater frequency on active rather than quiescent growth cones, suggesting that specialized structures or conditions exist in the active growth cone.

417.5

A CONDITIONING FACTOR RELEASED FROM GANGLIA PROMOTES NEURITE OUTGROWTH OF CULTURED APLYSIA NEURONS. M. Fejtl, C. Trautman* and D. O. Carpenter. Wadsworth Labs and School of Public Health, Albany, NY 12201.

We have investigated the effect of ganglion-derived conditioned media (CM) on Aplysia neurite outgrowth in culture using a variation of the protocol reported for Helisoma neurons (Wong, et al., J. Neurosci., 1:1008, 1981). Periesophageal ganglionic rings from six Aplysia were placed in 4 ml of L-15 media for 72 hrs to extract the conditioning factor (CF). Culture dishes with poly-L-lysin coated cover slips were exposed to the CM for 24 hrs (1 ml/dish) by passing the CM through a Gelman 0.2 μm filter and rinsed in L-15 media. Neurite outgrowth in control and CF dishes was examined after 24 hrs. Only neurons which possessed at least two neurites with a length twice the diameter of the cell body were considered. The total length of the largest neurite of each cell was measured and compared within the two groups. Every cell cultured on the CF showed enhanced neurite outgrowth compared to the control group. For quantification neurite length measurements were made on 15 neurons of each group. Neurite length (Mean ± S.D.) of the control group was 261 μm ± 89 and 555 μm ± 107 for the CF group. We concluded that a CF released from Aplysia ganglia is a growth factor distinct from any found in the hemolymph.

417.6

NGF-INDUCED PC12 CELL GROWTH CONE MOTILITY AND ITS DIFFERENTIAL INHIBITION BY PURINE ANALOGUES. K. Phelan, C. Volonté and L. A. Greene. Department of Pathology and Center for Neurobiology & Behavior, College of Physicians & Surgeons, Columbia University, New York, NY 10032.

The growth cones of living PC12 cells were examined using Video Enhanced Contrast-Differential Interference Contrast (VEC-DIC) microscopy. During observation, cells were contained in a sealed chamber and could be continuously superfused with medium containing various additives. Thus, this system is useful for observation of and pharamacological intervention in the mechanism of action of NGF on the growth cone.

In the presence of NGF, PC12 cells extended neurites which were tipped by active, motile growth cones. Deprived of NGF overnight, PC12 growth cones became blunt and ceased lamellipodial extension. Upon readdition of NGF, growth cones reactivated after one minute's exposure to the growth factor. Reactivation included protrusion of many microspikes from the body of the growth cone and extension of broad lamellipodia from the leading edge.

The purine analogues 2-aminopurine (2-AP) and 6-thioguanine (6-TG) have been shown to block some but not all of NGF's actions on PC12 cells via differential inhibition of protein kinases (Volonté, C. et al., J. Cell Biol., 109:2395, 1989). Short-term (10 minute) pretreatment of PC12 cells with 2-AP blocked NGF-induced growth cone reactivation in a dose-dependent manner. The concentrations tested were sufficient to block other PC12 responses to NGF, including neurite regeneration. In contrast, short term (10 minute) treatment with 6-TG did not inhibit growth cone reactivation. Long-term (1 day) treatment of PC12 cells with 6-TG resulted in neuritic retraction, compatible with 6-TG's ability to block NGF-dependent neurite regeneration.

This blockade by one of a family of compounds known to inhibit protein kinases in these cells implies that phosphorylation is involved in the regulation of growth cone motility. We can exclude the NGF-regulated serine protein kinase (PKN) from this process since it is relatively specifically inhibited by 6-TG. 2-AP, a more general inhibitor, exerts its effects in the growth cone through blockade of kinases distinct from PKN.

INDUCTION OF NEURITE OUTGROWTH BY BRIEF EXPOSURE TO 12-O-TETRADECANOYL PHORBOL 13-ACETATE (TPA). S. Mehta*, L. Hsu, A.Y. Jeng* and K.Y. Chen*. Chem. Dept.,Rutgers Univ.,Piscataway,NJ 08854; Biol. Dept.,Seton Hall Univ.,S.Orange,NJ 07079; Research Dept.,Pharma.Div.,CIBA-GEIGY Corp., Summit,NJ 07901.

The time-course of neurite-promoting effects of TPA on sensory ganglia of White Leghorn chick embryos was investigated. Brief exposure of ganglia to 20-200 ng TPA/ml growth media for 30 minutes was sufficient to elicit neurite outgrowth and fasciculation. These responses were only observed in ganglionic explants that had attached to a collagen substrate prior to TPA treatment. Incubation of unattached ganglia with TPA was ineffective. This lack of response to TPA from unattached ganglia was not related to uptake of the phorbol ester. ^{35}S-methionine pulse labelling studies revealed that the synthesis of two proteins with molecular weights of 43 and 63 kD was enhanced by TPA treatment. These results suggest that activation of protein-kinase C may be involved in the initial phases of neurite differentiation.

KCl DEPOLARIZATION TRANSIENTLY ALTERS GROWTH CONE MOVEMENTS OF CULTURED *HELISOMA* NEURONS . C.S. Cohan and M.-H. Xia*. Dept. of Anatomical Sciences, SUNY Buffalo, Buffalo, New York 14214.

Previous experiments have demonstrated that signals such as electrical activity and neurotransmitters alter neurite elongation and growth cone movements of cultured *Helisoma* neurons. These signals cause their effects by depolarizing neurons, thereby opening voltage-sensitive Ca^{2+} channels, and increasing intracellular Ca^{2+} in growth cones. The present experiments studied the effects of long term depolarization induced by KCl application on growth cone movements.

Identified neurons B4, B5, and B19 were isolated from the buccal ganglia of *Helisoma* and plated into culture dishes containing a neurite promoting conditioned medium. Twelve hours after plating, time-lapse photographs at 15 min intervals were used to quantify rates of growth cone advance over a 135 min observation period. Rates of growth cone advance were assessed for the first 45 min (baseline) period and then over two successive experimental periods (45-90 and 90-135 min). Small doses of KCl (final concentrations 5, 10, 25, and 50 mM compared to 1.7 mM of culture medium) were added to the dish at the end of the baseline period.

The addition of KCl to culture medium caused a dose-dependent decrease in the rate of neurite elongation of B4 during the 45-90 min period. Inhibition of elongation steadily increased over the range 5 to 50 mM KCl with the two highest concentrations producing significant neurite retraction. In contrast, during the 90-135 min period, elongation rates spontaneously recovered toward the baseline rate. Rates during this period were slower than the baseline rates except for 10 mM KCl which resulted in an enhanced rate. Similar effects were observed for B19 and B5 although each neuron had different thresholds and quantitative relationships between KCl concentration and elongation rate and only B4 exhibited the spontaneous enhancement of elongation. The addition of Co^{2+} blocked the KCl induced suppression of elongation. These data indicate that growth cones spontaneously recover their motile properties while in the sustained presence of a depolarizing stimulus.

CYTOSKELETAL REORGANIZATION IN RESPONSE TO CONDITIONING FACTORS IN REGENERATING *HELISOMA* NEURONS. D.L. Kania and C.S. Cohan Dept. of Anatomical Sciences, SUNY at Buffalo, Buffalo, N.Y. 14214

Little work has been done to describe the initial events at the cut end of the axon during initiation of regeneration. This study examines the cytoskeletal changes at the end of the axon signaled by conditioning factors which result in the initiation of neuronal growth.

Neurons B19, B4, and B5 were removed from buccal ganglia of the mollusc, *Helisoma trivolvis*, with an attached piece of axon. When plated onto a polylysine substrate in defined medium, a growth cone formed at the end of the axon stump. This growth cone did not advance across the substrate but exhibited lamellipodial and filopodial movements. Fluorescent labeling of f-actin and tubulin revealed a characteristic pattern of cytoskeletal elements. Thus, these growth cones were indistinguishable from growth cones formed in the presence of conditioned medium.

The typical response to axotomy is the extension of many new neurites from a single axon stump. After the addition of conditioning factor, many new neurites extended from the periphery of the growth cone formed in defined medium. The same response was seen for isolated growth cones suggesting a local effect at the growth cone. Cytoskeletal staining revealed a breakdown in the peripheral actin network in the growth cone and accumulation of f-actin in areas where new neurites formed. Microtubules extended to the edge of the growth cone into an area normally devoid of microtubules.

These data indicate that growth cone formation is independent of the initiation of outgrowth. Outgrowth is initiated by conditioned medium which signals changes necessary for neurite extension.

CALCIUM LEVELS DO NOT CHANGE DURING CONTACT MEDIATED GROWTH CONE COLLAPSE. J.K. Ivins, J.A. Raper and R.N.Pittman. Depts. of Pharmacology and Anatomy, U. of Pennsylvania School of Medicine, Philadelphia, PA 19104.

The growth cones of chick DRG neurons undergo a collapse of structure when they contact the neurites of chick retinal ganglion cells in culture. We have used the calcium indicator dye fura-2 and low light level digital imaging fluorescence microscopy to ask whether this growth cone collapse is mediated by increases in growth cone calcium. We find that calcium levels in DRG growth cones are very stable during contact and collapse. The possibility remained that small increases in calcium levels occur but are below the level of detection for our optical system or that transients of calcium occur at rates greater than our sampling rates. However, the calcium ionophore ionomycin (1 μM) raised growth cone calcium levels 2-3 fold, but had no effect on growth cone morphology, growth cone motility, or rates of growth cone advance. Furthermore, depolarization of cultures with 15 mM KCl caused 2-3 fold increases in growth cone calcium levels. These increases were transient in nature, typically lasting 60-90 seconds, but did not affect growth cone morphology, growth cone motility, or rates of growth cone advance. Growth cone calcium levels also remain stable during exposure to a crude growth cone collapsing activity derived from E10 chick brain membranes. Therefore, changes in growth cone calcium levels do not appear to account for the morphological features of contact-mediated growth cone collapse.

IDENTIFICAITON WITH A MONOCLONAL ANTIBODY OF A TEMPORAL RETINAL AXON PROTEIN IN DEVELOPING CHICK. S.C. McLoon. Univ. of Minnesota, Minneapolis, MN 55455.

In the process of generating monoclonal antibodies to chick retinal axons, one antibody was found that labels by immunohistochemistry most, if not all, axons in temporal retina. The majority of axons in nasal retina were not recognized by this antibody. A similar dicotomy in the staining of neurites from explants of nasal and temporal retina was seen within the first few days in culture. The neurites of living temporal retinal explants stained without permeablizing the membranes suggesting that the antigen is a cell surface molecule. Immunoblots of embryonic retinal tissue revealed a tight band with an approximate mass of 135kD. The antibody did not bind to the antigen after treatment with trypsin suggesting that it is a protein. The division between the temporal and nasal retina as revealed by this antibody corresponded to the optic fissure. The immunohistochemistry suggested a sharp division between the two sides of the retina in terms of the concentration of this antigen, rather than a continual gradient of the antigen from one side to the other. A sensitive competition based ELISA was developed to quantify the amount of this antigen on axons in different regions of the retina. This confirmed the existence of a step gradient of this antigen. Our working name for this molecule is TRAP for temporal retinal axon protein. TRAP is the first molecule identified in an asymmetric distribution in the nasal-temporal axis of retina. It remains to be determined what role, if any, TRAP plays in development of the pattern of connections between the eye and the brain.

418.2

P-BRAVO, A NOVEL MEMBER OF THE IMMUNOGLOBULIN SUPERFAMILY, IS FOUND IN A RESTRICTED PATTERN ON OPTIC FIBERS OF THE DEVELEOPING NERVOUS SYSTEM. J. F. Kayyem, E. J. de la Rosa*, J. M. Roman*, U. Schwarz* and W. J. Dreyer*. California Institute of Technology, Pasadena, CA 91125.

Cell-surface molecules play an essential role in guiding axons to their targets. We have developed a method to generate monoclonal antibodies (mAbs) which recognize cell-surface molecules of defined molecular weight that are expressed during the development of the chicken nervous system. Fourteen distinct spatial and temporal patterns of tissue reactivity were detected with mAbs generated against cell-surface molecules of approximately 135 kD. The antigen distribution recognized by one of these mAbs, pattern Bravo (P-Bravo), results from the topologically restricted labeling of optic fibers. In the retina, optic fibers are labeled by P-Bravo mAbs. However, these same fibers are not labeled by P-Bravo in the tectum. P-Bravo antigen, therefore, appears to be restricted to the proximal, and absent from the distal, axon.

Protein analyses show that P-Bravo antigen is a member of the immunoglobulin superfamily, contains fibronectin type III related sequences, and carries the HNK-1 epitope, thought to be involved in cell adhesion. P-Bravo is closely related to the neural cell surface molecule L1, but is not G4, thought to be the chicken equivalent of L1. The homology of P-Bravo to known adhesion molecules, as well as the restricted pattern of antigen distribution, suggests P-Bravo is involved in axon guidance.

418.3

STRUCTURAL AND FUNCTIONAL ANALYSIS OF L1 VIA PROTEOLYTIC CLEAVAGES. A. Abosch and C. F. Lagenaur. Dept. of Neurobiology, Anatomy, and Cell Science, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

In order to determine the location of the L1 active site, a series of proteolytic digests were performed on affinity-purified L1. The resulting peptides were analysed by SDS-PAGE and Western blot using monoclonal antibodies specific for the 135 and 85 kD fragments of the molecule. The cleavage products were then spotted on nitrocellulose-coated dishes, and dissociated mouse cerebellar cells added in order to assess neurite-outgrowth promoting activity (Lagenaur and Lemmon, PNAS 84:7753-57, 1987). Elastase digestion of L1 resulted in retention of the 135 kD fragment, while eliminating the 85 kD fragment along with the activity of the molecule. Papain digestion eliminated all trace of the 135 kD fragment on Western, but portions of the 85 kD fragment, as well as the activity of the molecule, were retained. These data provide evidence for the importance of the membrane-spanning 85 kD fragment in the function of L1. Supported by NIH NS25543.

CELL ADHESION MOLECULES 8D9 AND NCAM MOVE INDEPENDENTLY IN THE PLANE OF AXON MEMBRANES. J. DRAZBA[1] & V. LEMMON, Laboratory of Neurobiology[1], NINDS, NIH, & Dept. of Neuroscience, Case Western Reserve University, Cleveland, OH, 44106

Neuronal cell adhesion molecules may be functionally cooperative (Kadmon et al., J. Cell Biol. 110:193-208) and may therefore be physically linked. To test this idea, we investigated the localization of 8D9 (a member of the L1/NILE /NgCAM/G4 family of cell adhesion molecules) and NCAM, two integral membrane proteins, on the surface of chick retinal ganglion cell axons. Polyclonal antibodies to either 8D9 or NCAM were added to live cultures of E7 chick axons (Drazba & Lemmon, Dev. Biol. 138:82-93) which were subsequently fixed and incubated with monoclonal antibody (Mab) against the other adhesion molecule. The cultures were then treated with separate secondary antibodies in order to visualize the distributions of both cell adhesion molecules. Examination of the axons and growth cones with a Bio-Rad MRC 600 Laser Scanning Confocal Microscope revealed that the 8D9 or NCAM, exposed to the polyclonal in the living cell, had patched, while the other cell adhesion molecule, labelled post-fixation with the Mab, was distributed evenly over the surface of the same axon. Control cultures fixed before being exposed to both primary antibodies exhibited uniform distributions of both antibodies. These results suggest that 8D9 and NCAM are free to move independently of one another in the plane of the membrane and so are not necessarily physically linked.

MOUSE cDNA CLONE FOR THE NEURONAL CELL-SURFACE ADHESION MOLECULE P84. R. Perez, C. Lagenaur and R.M. Lewis. Dept. NACS, Univ. Pittsburgh, Pittsburgh, PA 15261.

P84 is a neuronal cell surface adhesion molecule which effectively promotes neurite outgrowth. Antibodies to P84 label only the floor plate in early embryogenesis in the mouse. Label is found throughout the adult brain. To determine whether this label is due to P84 in cell bodies or axons, we attempted to clone the cDNA for P84 for use in *in situ* hybridization. A mouse brain cDNA expression library in λgt11 was screened with antibodies to P84. Of the nine clones obtained, seven cross-hybridized. The fusion product of this most common clone bound antibodies to P84 on western blots. All clones were less than full length. None of the clones had sequences homologous to recorded sequences. A 23 amino acid sequence (which was not coded for by any of the nine clones, and which was not homologous to any recorded sequence) was obtained from purified mouse P84. A synthetic oligonucleotide derived from this sequence was used to screen the library. Four clones were confirmed by progressively more stringent hybridizations with the oligonucleotide. Sequences for these clones are being determined. The clones are being used to determine the size of the P84 mRNA by northern blots. The number of genes coding for P84 is being determined initially by genomic southern blots. Once the entire cDNA for P84 is obtained, it will be utilized to map active regions of the molecule.

CELL-TYPE SPECIFIC PERIPHERAL AND INTEGRAL MEMBRANE PROTEINS AND THEIR COMPLEMENTARY MANNOSE-BINDING PROTEIN IN THE LEECH CNS. R.N. Cole and B. Zipser. Department of Physiology, Michigan State University, E. Lansing. MI 48824.

In leech neuronal development, sensory afferents entering the synaptic areas of the CNS defasciculate as they disperse to their connections. This defasciculation is mediated by the interaction between a mannose-containing epitope on the sensory afferent glycoprotein and a putative mannose-binding protein (Zipser and Cole, Neurosci. Abst. 1989). Sensory afferents express this mannose-containing epitope on 3 different proteins (130, 103 and 95 kD). We determined the membrane topology of the 3 sensory proteins by phase separation using Triton X-114. The majority of the 130 kD protein is found in the aqueous phase, behaving as a peripheral membrane protein, and is expressed early during the time of target recognition (McGlade et al., J. comp. Neurol., in press). In contrast, the 103 and 95 kD proteins are found in the detergent phase, behaving as integral membrane proteins, and are expressed after synapses are established. To identify the putative mannose-binding protein that interacts with the sensory afferent protein, we fractionated leech CNS by gel filtration and affinity chromatography. Gel filtration studies indicate that the sensory protein from CNS homogenized in the presence of mannose, but not galactose, elutes, as expected, in lower molecular weight fractions. This is preliminary evidence that the 130 kD peripheral sensory protein binds to a mannose-binding protein on leech membranes.

418.7

DISTRIBUTION OF TENASCIN IN IMMATURE AND MATURE HUMAN BRAIN. R.D. McComb and K.A. Miller*. Department of Pathology and Microbiology, University of Nebraska Medical Center, Omaha, NE 68198.

Tenascin (TN) is an extracellular matrix glycoprotein involved in cell adhesion and migration. In this study the distribution of TN was examined immunohistochemically in 36 human brains (cerebrum and cerebellum) ranging from 17 weeks gestational age (GA) to 92 years of age. At 17-26 weeks GA, the intermediate zone of the cerebrum exhibited greater reactivity than the cortical plate. Beyond 30 weeks GA there was diffuse staining of both cortex and white matter which persisted into the first postnatal year. At older ages the molecular layer (ML) and white matter maintained strong reactivity, but the cortex showed only patchy perivascular staining. In immature cerebella, intense reactivity was observed in the ML and internal granule layer (IGL). Reactivity in the IGL decreased during the first postnatal year and was not detected at older ages. Reactivity in the ML persisted until the second decade, but was weak or absent at older ages. The dentate nucleus was reactive at all ages, often showing an intense perineuronal pattern suggestive of membrane localization. The temporospatial distribution of TN is compatible with its proposed role in cellular migration in the developing brain. Its persistent expression in adult brain and in reactive astrocytes following brain injury indicates additional functions for this glycoprotein.

418.8

FIBRONECTIN BINDING TO BRAIN SYNAPTOSOMAL MEMBRANE MAY INVOLVE NOVEL MATRIX RECPTORS. B.A.Bahr, A.Sheppard, P.W.Vanderklish*, B.Bakus*, D.K.Capaldi*, M.Kessler, L.T.Ha*, M.T.Tin* & G.Lynch. CNLM, University of California, Irvine, CA 92717 U.S.A.

Synapses presumably share properties with other types of cell-cell adhesion contacts. Integrins and other matrix receptors act as transmembrane links between the extracellular matrix and the cytoskeleton, forming focal contacts with fibronectin (Fn), vitronectin (Vn), laminin, and proteoglycans. [^{125}I]-Fn binds to rat brain synaptosomal membrane (SPM) with a specific activity of 5-10 pmol/mg protein and this was blocked by RGDS (1 mM), a compound known to bind integrin receptor sites. This result predicted the existence of synaptic integrins. Polyclonal (pAb) and monoclonal (mAb) antibodies toward human Fn-receptor (FnR) or VnR recognized previously described integrin subunits of 110, 175 (S175), and 225 (S225) kDa in brain homogenate, but these polypeptides were almost completely absent from SPMs. However, pAb against a fibroblast integrin (Schwartz et al., 1989) and mAb against an integrin epitope near the receptor site (Telios Pharm., Inc.) labeled synaptosomal peptide bands of 40 (F40) and 70 kDa. These antigens were $\geq$ 20-fold enriched in SPMs compared to brain homogenates, and could not be detected in various non-neuronal tissues. It remains to be determined if either species is the RGDS-sensitive fibronectin binding site in SPMs.

Calcium activated proteases (calpains) are concentrated at adhesion sites (Bennett et al., 1984) and it has been established that certain proteins thought to link integrins to the cytoskeleton are substrates for these enzymes. Preliminary studies indicate that calpain I degrades integrin subunits found in brain homogenates and also reduces the concentration of F40 in SPMs. These interactions might provide a route through which increases in intracellular calcium could reorganize neuronal connections.

418.9

HNK-1 ANTIBODY RECOGNIZES NEUROMUSCULAR JUNCTIONS. C.P. Ko, P.W. Wong* and L.A. Holcomb*. Dept. of Biol. Sci., Univ. of So. Calif., Los Angeles, CA 90089.

The monoclonal antibody HNK-1 recognizes a carbohydrate epitope and has been used to label migrating neural crest cells. We report here that HNK-1 also recognizes neuromuscular junctions (NMJs) in the frog and the chick. Double-labeling of skeletal muscles in whole mount or cryosection with fluorescent alpha-bungarotoxin, nerve terminal dye or Karnovsky's cholinesterase stain verified HNK-1 binding at the NMJ. HNK-1 staining outlines nerve terminals and acetylcholine receptors. The labeling appears similar to that of fluorescent peanut agglutinin (PNA), previously shown to recognize the extracellular matrix (ECM) at frog NMJ and myotendinous junctions. Unlike PNA, HNK-1 does not recognize myotendinous junctions but does stain small, possibly unmyelinated nerve fibers seen near NMJs and blood vessels. To localize HNK-1 binding sites, we denervated, froze and removed all but a thin bridge of muscle containing NMJs. HNK-1 still stained the synaptic site after nerve and muscle degeneration. Electron microscopy of muscle treated with HRP labeled HNK-1 showed reaction products in the ECM of the NMJ. Results suggest that the carbohydrate epitope recognized by HNK-1 exists in the synaptic ECM. Since this epitope is common to several adhesion molecules, HNK-1 may provide a probe to study the function of carbohydrates in synaptic differentiation and maintenance.

418.10

EXPRESSION OF THE SYNAPTIC CLEFT PROTEIN S-LAMININ IN CELL LINES. T.L. Green[1], D.D. Hunter[1], W. Chan*[1], J.P. Merlie[2], and J.R. Sanes[1] Depts. of Anatomy and Neurobiology[1], and Pharmacology[2], Washington Univ. Med. Sch., St. Louis, MO 63110.

S-laminin is a laminin-like glycoprotein that is concentrated in the basal lamina at the neuromuscular junction (Hunter et al., Nature 338:229, 1989). It bears a site to which motoneurons selectively adhere (Hunter et al., Cell 59:905, 1989), suggesting that it may be recognized by axons at synapses. However, tests of this hypothesis have been limited by lack of a source of native s-laminin; the functional assays used bacterially produced protein. We have therefore taken two approaches to identify and characterize s-laminin produced by cell lines. First, we screened a variety of rat cell lines by immunoblotting with monoclonal antibodies (mabs) to s-laminin. Several skeletal and smooth muscle cell lines (L6,L8,A10,RMO) which produce laminin also produce and secrete s-laminin. Second, we constructed an expression vector containing the entire s-laminin cDNA, and isolated stable transfectants in C2 (mouse muscle) and QT6 (quail fibroblast) cells. By immunofluorescence using rat-specific mabs, both cell lines accumulate s-laminin intracellularly. C2 cells secrete the recombinant protein and incorporate it into extracellular matrix after they fuse to form myotubes. We then immunoprecipitated s-laminin with subunit-specific antibodies to analyze the oligomeric structure into which it is assembled. Laminin is composed of homologous A, B1, and B2 subunits; s-laminin is most closely related to the B1 subunit. Antibodies to s-laminin coprecipitate laminin B2 and an A-like subunit, whereas antibodies to B2 precipitate B1, B2, s-laminin, and an A-like chain. These results support immunostaining data (Sanes et al., submitted) suggesting that s-laminin and B1 can substitute for each other in a trimer with A and B2. We are now purifying s-laminin to test this model and to study interactions of neurons with the complex. (Supported by NIH and Monsanto.)

418.11

LAMININ AND S-LAMININ ARE PRODUCED AND RELEASED BY ASTROCYTES, SCHWANN CELLS AND SCHWANNOMAS. A.Chiu, A.Espinosa*, R.Cole*, S.Loera & J.de Vellis*, Beckman Res.Inst.of City of Hope,Duarte,CA & *UCLA, Depts.Anat. & Cell Biol.L.A.,CA.

Laminin, a potent promotor of neurite outgrowth, is present in all extracellular matrices (ECMs). In contrast, s-laminin, a homolog of laminin, is highly localized at the neuromuscular synaptic cleft. While the distribution of these two ECM components have been well documented in situ, the sources of these molecules is unclear. We report that astrocytes cultured in serum-free medium maintain an organized ECM that only bears laminin immunoreactivity; s-laminin appears to be sequestered intracellularly. However, both molecules are found in Western blots of the astrocyte conditioned medium. Thus, astrocytes produce and release laminin and s-laminin, but only incorporate the former into an ECM. In contrast, neither molecule is present in cultures of oligodendrocytes. Although no established matrix is seen in cultures of Schwann cells or Schwannomas, laminin and s-laminin immunoreactivity are present within cells and in the conditioned media. These results indicate that certain populations of non-neuronal support cells and cell lines can produce and release both synaptic and extrasynaptic components of the ECM. Assembly of these different molecules into an organized ECM may require additional factors or interaction with neurons.

LOCALIZATION OF A PLASMINOGEN ACTIVATOR AND ITS INHIBITOR AT ADHESION SITES OF CULTURED RAT MYOTUBES. G.M.Dmytrenko and M.B.Clark. Depts. of Neurology and Anatomy, Univ. of Maryland Sch. of Medicine, Baltimore, 21201

Cultured neonatal rat myotubes cluster AChRs, develop cytoskelton and membrane specializations, and organize extracellular matrix molecules where they adhere to the substrate. Since the protease plasmin is known to modify extracellular matrix components we asked whether controlling factors, such as plasminogen activators (PA's) or their inhibitors (PAI's) were positioned to influence the modification of the extracellular matrix at the myotube - substrate adhesion sites?

We used sequential detergent extraction and immunofluorescence microscopy to identify a urokinase - like PA (uPA) as well as a plasminogen activator inhibitor (PAI-1) at myotube - substrate adhesion sites. Adhesion sites isolated with saponin demonstrated uPA immunoreactivity in a linear pattern coincident with AChR-rich domains. PAI-1 immunoreactivity was present in surrounding culture substrate but apparently absent from the adhesion sites. When the isolated myotube - substrate adhesion sites were further treated with Triton X-100 to remove remaining cell membrane, uPA was detected at the adhesion sites, while PAI-1 was seen in the surrounding culture substrate and appeared reduced at the adhesion sites. Thus, PAI-1 is generally distributed in the extracellular substrate to prevent widespread proteolysis, while UK is focally positioned to affect changes in the extracellular composition of myotube - substrate adhesion sites.

ASPECTS OF CALPAIN BIOCHEMISTRY AND NEURONAL MEMBRANE PLASTICITY. G.Lynch, J.Wu, B.A.Bahr & A.M.Sheppard. CNLM, University of California, Irvine CA 92717 U.S.A.

The calcium-dependent protease calpain is thought to play a role in the elaboration of structural plasticity in both erythrocytes (Siman et al., 1987) and neurons (Lynch and Baudry, 1984). We have investigated aspects of its biochemistry in crude and synaptic plasma membranes prepared from rat telencephalic tissue. Western blot analysis, utilising a polyclonal antibody generated against purified calpain I isolated from rat erythrocyte cytosol, revealed that the expression of an apparently activated form of calpain is developmentally regulated at the neuronal membrane surface during a period of considerable structural plasticity. Similar analysis demonstrated that a principle substrate, namely spectrin, was available at the submembraneous surface and susceptible to the proteolytic action of calpain throughout the postnatal developmental period studied. The action of calpain was found to cause a loss in the expression of a restricted number of membrane associated components. Nearly all of these were relatively large molecular weight Concanavalin A-binding glycoproteins and included the cell adhesion molecule N-CAM. The present findings are consistent with and support the postulated role of calpain in facilitating membrane plasticity.

418.14

DISTRIBUTION OF BRAIN SPECTRIN 240/235 AND 240/235E IN NEURONS IN HUMAN OCCIPITAL CORTEX. K.S. Pollan*, D.J. Woodward and M-C. de Lacoste. Dept. Cell Biology and Neuroscience, U.T. Southwestern Med. Sch., Dallas, TX 75235

This study was undertaken to determine if two isoforms (240/235, 240/235E) of brain spectrin, a membrane-associated protein implicated in neuronal plasticity and degeneration, are differentially distributed within neuronal compartments in human visual cortex. It has been proposed that the two distinct spectrin subtypes are differentially localized within dendrites, cell bodies and axons and, hence, that they may have different structural/physiological functions (e.g., Riederer et al., 1986; Goodman & Zagon, 1989).

Formalin-fixed blocks of tissue from human occipital cortex were sectioned at 50 µm in the coronal plane on a freezing microtome. Spectrin-containing neurons were immunolabelled using the avidin-biotin immunoperoxidase method and antisera to spectrin 240/235 and 240/235E (Chemicon, Inc.). Sections were then counterstained with a light Nissl. Human cerebellum served as a positive control.

In the human visual cortex, spectrin 240/235 immunoreactivity was prominent in axons. In addition, however, a small and scattered population of pyramidal and stellate-type neurons appeared to contain spectrin 240/235 within their soma as well as dendrites and axons. Spectrin 240/235E immunoreactivity was confined to the soma and dendrites of a small and scattered population of neurons. No axonal labelling was detected using this isoform. In brief, there appears to be some segregation of the two spectrin subtypes in that only the 240/235 isoform is localized in neuronal axons. However, neuronal soma and dendrites in human visual cortex contain both brain spectrin 240/235 and 240/235E. *Supported by HD21-711-01 (MCL) and Biological Humanics Foundation.*

MICROFIBRILLAR ADHESION COMPLEXES OF DEVELOPING NEURITES: LINKAGE TO THE CYTOSKELETON. S.A. Enam and W.L. Klein. Northwestern Univ. Inst. for Neuroscience, Evanston, IL 60208

The cytoarchitecture of developing nerve cell surfaces contains microfibrillar specializations that constitute adhesion complexes (PNAS 52:5206). These somewhat irregular microfibril (8-13 nm wide, varying lengths) can form "trans-junctional adhesion complexes (TACs)" at nascent junctions as well as connect the cell surface to the substratum. For avian retina cells (Dev.Brain Res. 51:205), TACs and other surface microfibrils have been found to be multimeric and include components of adheron such as heparan sulfate proteoglycan for e.g. The current study extends observations of cell surface adhesive microfibril to cultures of rat fetal brain cells and several cell lines including human. Of particular interest, TACs and other adhesive microfibrils have been found resistant to mild detergent treatments that extract membranes and cytosol. Whole mount EM of extracted cells showed that the microfibril were linked to the cytoskeleton, directly supporting the hypothesis that adhesive molecules establish trans-membrane linkage with intracellular elements. Such complexes conceivably could have signal transduction capability. Molecular analysis showed that, after extraction, the microfibril still were labeled by antibodies to adheron. Studies also were done showing that some adhesive microfibrils include amyloid precursor protein (APP), a molecule closely associated with the pathogenesis of Alzheimers disease.

MONOCLONAL ANTIBODY KHRI-5 TO HAIR CELL STEREOCILIA IMMUNOSTAINS A CYTOSKELETAL STRUCTURE IN CULTURED FIBROBLASTS. M.Ptok, J.W.Horn*, T.S.Nair*, T.E.Carey*, R.A.Altschuler. Kresge Hearing Research Institute, Univ. of Michigan, Ann Arbor, MI 48109

A murine monoclonal antibody developed after immunization with chick basilar papilla, guinea pig outer hair cells and frog lateral line specifically labels stereocilia in the inner ear. In the present study this antibody was applied to cultured fibroblasts where it labeled a fibrous network in the cytoplasm. Double labeling with phalloidin (marking filamentous actin) showed that KHRI-5 labeling was distinct from but associated with f-actin. Immunoelectron microscopy was then used to study ultrastructural localization. Permeabilized fibroblasts were incubated with KHRI-5 antibody and antigenic sites were visualized by 5 nm immunogold particles. Specific labeling was distributed in clusters in close proximity to 200 - 300 nm fibers. Since both hair cell stereocilia and fibroblasts express the epitope recognized by KHRI-5, they may have this cytoskeletal structure in common. Its characterization should be facilitated by the use of cultured cells.

IN VIVO AND IN VITRO EXPRESSION OF CD4 IN FETAL HUMAN BRAIN. S. Torelli*, M.G.Ennas*, V.Sogos*, E.Pilia* and F.Gremo. Dept.Cytomorph.Med.Sch., 09124 Cagliari (Italy).

CD4 has recently attracted much interest since it is the receptor for Acquired Immunodeficency Syndrome (AIDS) virus (HIV). It is known that HIV can cross the placenta and infect the fetus. In order to investigate the possibility of a direct infection of fetal brain, we performed immunohistochemical localization of CD4 both at light and electron microscope in cultures of fetal brain from 8 to 20 weeks of gestation. Results showed that CD4 was present in both cytoplasm and cell membrane of neurons in the first 4 weeks in vitro. Later, CD4 was localized also in the cytoplasm of some, not all astrocytes. Immunoprecipitation studies showed the presence of a protein of molecular weight slightly lower than normal (45 Kd versus 60 Kd). These results were confirmed by molecular biology studies, which showed the presence of a transcript corresponding to a truncate form of the protein (lacking of the gp120-binding site) in early stages (from 12 to 18 weeks of gestation), whereas the complete protein was found in older fetal brains.

PROTEIN KINASE C MAY CONTRIBUTE TO THE INCREASE IN SPONTANEOUS RELEASE EVOKED BY 5-HT AT CULTURED *APLYSIA* SENSORY-MOTOR SYNAPSES. O. Braha, N. Dale*, M. Klein and E. R. Kandel. HHMI, Columbia, NY, NY 10032.

Presynaptic facilitation of the synapses between the siphon sensory and the gill motor neurons evoked by 5-HT involves at least two mechanisms: a first process that is a cAMP-dependent broadening of the presynaptic actin potential and a second process that may involve direct modulation of the transmitter release machinery (Gingrich and Byrne, 1985; Hochner et al., 1986). 5-HT can increase the rate of spontaneous release at cultured *Aplysia* sensory-motor synapses by a mechanism that seems to be independent of changes in the presynaptic levels of Ca^{2+}. This modulation of the secretory mechanism underlying spontaneous release may reflect activation of the second process by 5-HT (Dale and Kandel, 1990). While cAMP can trigger this second process a further second messenger pathway may also be involved: possibly, protein kinase C (PKC). We show here that in *Aplysia* saline, containing zero Ca^{2+}, activation of PKC by application of phorbol dibutyrate (PDBu, 1-50 nM) to *Aplysia* sensory-motor synapses in culture increases the occurrence of mEPSPs in a dose dependent manner (120 nM PDBu caused five-fold increase in the frequency of mEPSPs) without altering the amplitude of the mEPSPs. The inactive isomer, α-PDBu, had no effect. Bath application of the generalized kinase inhibitor H-7 (200 μM) partially reversed the enhancement of spontaneous release by both 5-HT and PDBu. This suggests that activation of PKC may contribute to the Ca^{2+}-independent enhancement of spontaneous release that accompanies the effects of 5-HT. Therefore, PKC may contribute along with cAMP-dependent kinase to a direct modulation of secretion that constitute the second process of presynaptic facilitation.

419.2

ACTIVITY-DEPENDENT MODULATION OF SPONTANEOUS TRANSMITTER RELEASE IN SINGLE CULTURED *APLYSIA* SENSORIMOTOR NEURON SYNAPSES. L.S. Eliot, E.R. Kandel and R.D. Hawkins. Ctr. Neurobiol. & Behav., Columbia Univ., NYSPI, & HHMI, NY, NY 10032.

An *Aplysia* L7 motor neuron co-cultured with a single presynaptic sensory cell exhibits spontaneous miniature EPSPs which can be used to assay the release process directly, independent of the action potential (Dale and Kandel, 1990). Cultured sensorimotor synapses undergo homosynaptic depression with low frequency stimulation (< 1 Hz), PTP with high frequency stimulation (20 Hz for 2s), and longer-lasting facilitation when tetanus is given temporally paired, but not when it is given unpaired with 5-HT. We have begun to test whether there are changes in spontaneous release during these various activity-dependent forms of synaptic plasticity, as might be predicted if they involve depletion or mobilization of synaptic vesicles (Gingrich and Byrne, 1985). We have found that tetanus increases the frequency of spontaneous mEPSPs in parallel with facilitation of the evoked EPSP. In five experiments, the frequency of release increased from a baseline of .050 ± .003 s^{-1} to .775 ± .085 s^{-1} in the 1-min. interval following tetanus and remained significantly elevated 7 min after tetanus (.109 ± .024 s^{-1}; $p < .01$, Dunnett's multiple range test), but not 12 min after tetanus. Similarly, the evoked EPSP was significantly facilitated 5 and 10 min after the tetanus (163 ± 20 and 146 ± 20%, respectively; $p < .01$) but not at 15 min post-tetanus. Preliminary experiments show a large increase in spontaneous release following both paired (5-HT + tetanus) and unpaired training. But unlike facilitation of the evoked EPSP, which is pairing-specific, the increase in spontaneous release appears not to be pairing-specific, suggesting that this component of mobilization does not contribute to the pairing-specific facilitation.

PRESYNAPTIC INHIBITION INDUCED BY G PROTEIN ACTIVATION AT THE SQUID GIANT SYNAPSE. S.D. Hess and G.J. Augustine. Univ. of Southern California, Los Angeles, CA 90089 and Max Planck Institut, Goettingen, FRG.

Guanine nucleotides were microinjected directly into giant presynaptic terminals of squid (Loligo pealei and L. opalescens) to examine the possible role of G proteins in transmitter release. Injection of GTP-gamma-S irreversibly reduced postsynaptic currents (PSCs) evoked by presynaptic action potentials by 70 to 85% (n=18). In contrast, injection of GTP caused a much smaller and reversible reduction (25%, n=10). GDP-beta-S also reduced transmitter release by approximately 40% (n=3). GTP-gamma-S depolarized the presynaptic terminal 9.9 mV and decreased the action potential amplitude, while GTP had little effect on presynaptic potentials. When injected into voltage-clamped terminals held at -70 mV, GTP-gamma-S reduced transmitter release by only 34.5% (n=2). These results suggest that activation of one or more presynaptic G proteins by GTP-gamma-S inhibits transmitter release. One component of this inhibition is caused by a decrease in the presynaptic membrane and action potentials. Supported by NIH NS21624, NS08392 and MPI funds.

HISTAMINE STIMULATES SYNAPSIN II PHOSPHORYLATION AND CATECHOLAMINE RELEASE IN BOVINE ADRENAL MEDULLARY CHROMAFFIN CELLS. J.A.Firestone, M.D.Browning. *Dept. of Pharmacology, Univ. of Colorado Hlth. Sci. Cntr., Denver, CO 80262.*

Adrenal medullary chromaffin cells have classically been used as a model system for the study of neurotransmitter release. Activation of nicotinic receptors stimulates catecholamine (CA) release from primary cultures of bovine chromaffin cells. Histamine also stimulates CA release from these cells in a time and dose-dependent manner. We have shown (Haycock *et al.*, J. Neurosci., 8, 3233, 1988) that nicotine stimulates incorporation of ^{32}P into synapsin II (a vesicle-associated phosphoprotein thought to play a key role in neurotransmitter release). This phosphorylation is closely correlated with nicotine-stimulated release of CA. We hypothesized that histamine would also stimulate an increase in synapsin II phosphorylation paralleling its effect on secretion. We report here that histamine stimulates ^{32}P-incorporation into synapsin II. The time course of histamine-stimulated phosphorylation of synapsin II closely parallels the histamine-stimulated release of CA. The magnitude of histamine-stimulated secretion is less than that stimulated by nicotine. Interestingly, the extent of histamine-stimulated phosphorylation of synapsin II is also less than for nicotine. After two minutes of treatment, histamine-stimulated phosphorylation of synapsin II is 40% of that produced by nicotine, while release stimulated by histamine is 30% of the release stimulated by nicotine. Thus, there is a strong correlation between synapsin II phosphorylation and CA release in response to two distinct secretogogues. One-dimensional phosphopeptide maps of synapsin II yielded a characteristic 18kD phosphopeptide. This portion of the molecule is known to contain the site phosphorylated *in vitro* by the cAMP-dependent protein kinase and by Ca2+/calmodulin kinase I. The determination of the kinase which is active in the present *in situ* analyses is the subject of current investigation. The data presented here suggest that synapsin II phosphorylation may play a role in CA release from bovine adrenal medullary chromaffin cells.

IMAGING CALCIUM TRANSIENTS IN PATCH CLAMPED CHROMAFFIN CELLS. G.J. Augustine and E. Neher. Max Planck Inst. for Biophysical Chemistry, Goettingen, FRG.

We have used video microscopy to examine the intracellular Ca concentration ($[Ca]_i$) changes produced in single, cultured chromaffin cells by depolarization. Brief (20-2000 ms) depolarizing pulses, applied via a patch pipette, caused measurable changes in the fluorescence of fura-2 (0.1-0.5 mM) when the depolarizations were within the voltage range for activation of Ca channels (ca. -20 to +50 mV). These signals were due to changes in $[Ca]_i$ because they were abolished by inclusion of 10 mM EGTA in the internal dialysis solution. The changes in $[Ca]_i$ had a characteristic spatio-temporal pattern: when the Ca channels were open, $[Ca]_i$ changes were largest (nominally up to 0.5 uM) in the region just beneath the plasma membrane and smallest in the central cytoplasm of the cell. Closure of the Ca channels, either by inactivation or repolarization of the membrane potential, caused the spatial gradients to collapse very quickly (half-time 200 ms or less). These results indicate that Ca channels in the plasma membrane are the primary source of the $[Ca]_i$ transient produced by depolarization and that Ca (and/or Ca-loaded fura-2) rapidly diffuses into the center of the cell. Transient $[Ca]_i$ gradients may play an important role in these cells during depolarization-induced secretion.

419.6

ROLE OF ACTION POTENTIAL BROADENING AND K CURRENT INACTIVATION IN THE FREQUENCY-DEPENDENT FACILITATION OF CALCIUM ENTRY INTO PITUITARY NERVE TERMINALS. M.B. Jackson, G.J. Augustine & A. Konnerth. Dept. Physiology, Univ. Wisconsin, Madison, WI and Max Planck Inst. for Biophysical Chemistry, Goettingen, FRG,

We have made simultaneous patch clamp and fura-2 $[Ca]_i$ measurements from nerve terminals in thin slices of rat neurohypophysis. Trains of action potentials (APs) evoked at 20 Hz caused large increases in $[Ca]_i$ while evoking the same number of APs at 1 Hz produced much smaller changes in $[Ca]_i$. High frequency stimulation also broadened APs. Broadening of APs by another procedure, application of 2 mM TEA, increased the $[Ca]_i$ signals evoked by low frequency stimulation. Furthermore, $[Ca]_i$ changes measured in voltage clamped terminals were found to be a sensitive function of the duration of depolarizing voltage pulses. Voltage clamp measurements revealed two separable components of voltage-activated K^+ current: one which inactivated by 50% in approximately 50 ms at +50 mV and another which did not decline over 0.5 s. A series of brief, AP-like pulses selectively reduced the inactivating component of K^+ current. A plausible explanation for these results is that a frequency-dependent decline in the inactivating K^+ current broadens the presynaptic AP which, in turn, facilitates Ca entry. This presumably causes the frequency-dependent facilitation of AP-evoked hormone release reported for these terminals.

DEPOLARIZATION INDUCED CHANGES IN INTRACELLULAR FREE CALCIUM IN INDIVIDUAL NERVE ENDINGS FROM THE NEUROHYPOPHYSIS. E. Stuenkel, Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

Although neurotransmitter or neurohormone release is dependent on depolarization-induced changes in intraterminal free $[Ca^{2+}]$ anatomical limitations of mammalian nerve terminals have precluded direct monitoring and characterization of such changes at single axon endings. Using axon terminals isolated from the neurohypophysis of the rat, changes in $[Ca^{2+}]_i$ in individual endings were examined in response to depolarizing stimuli. $[Ca^{2+}]_i$ was monitored by dual wavelength microspectrofluorometry of cytoplasmic fura-2. Induction of membrane depolarization by elevated concentrations of K^+_o led to a rapid, dose-dependent (EC_{50} = 35 mM) increase in $[Ca^{2+}]_i$ (150 nM increase at EC_{50}) that was sensitive to block by the dihydropyridine (DHP) nicardipine (IC_{50} = 2μM), D888 and by the inorganic Ca^{2+} channel blockers Cd^{2+} and La^{3+}. ω-conotoxin GVIA was without effect on the K^+-induced increase in $[Ca^{2+}]_i$. Depolarization of the nerve endings by veratridine resulted in a similar rapid, DHP- and D888-sensitive, increase in $[Ca^{2+}]_i$. Close correlation was found between the K^+-induced increase in $[Ca^{2+}]_i$ and reported values of vasopressin secretion obtained on populations of isolated terminals. K^+-induced increases in $[Ca^{2+}]_i$ were maintained throughout a sustained depolarizing stimulus and were dependent on sustained influx of Ca^{2+} via DHP-sensitive Ca^{2+} channels. Recovery to basal $[Ca^{2+}]_i$ followed removal of the depolarizing stimulus with the rate of recovery being dependent on the duration of the depolarizing stimulus. Recovery of $[Ca^{2+}]_i$ was partially blocked by metabolic inhibitors and La^{3+} but was unaffected by removal of extracellular Na^+ or application of vanadate thereby suggesting a dominant role for Ca^{2+}-ATPase activity over Na^+/Ca^{2+} exchange in recovery.

A Comparison of the Subsecond Kinetics of ^{3}H-Glutamate and Endogenous Glutamate Release from Neurons. T.J. Turner and K. Dunlap, Dept of Physiology, Tufts University School of Medicine, Boston, MA 02111.

The aim of this study is to characterize the release of "fast" transmitters, such as glutamate (glu), as well as slow, peptidergic transmitters, like Substance P (SP), from intact neurons on a time scale approaching that on which synaptic transmission occurs. To accomplish this, we are using a superfusion device with 50ms time resolution to stimulate release from sensory neurons cultured from embryonic chick dorsal root ganglia; such neurons are capable of releasing both glu and SP. The neurons were grown on collagen-coated cellulose acetate filters (i.e., Millicell units) for 7-14d. The neurons concentrate ^{3}H-glu when incubated with the isotope (10^{-6}M) for 10-20 minutes prior to superfusion. Depolarizing the neurons with K^+ (60-150 mM) increased the rate of isotope release up to 5-fold, but no calcium-dependent release of ^{3}H-glu from these neurons could be observed.

To determine whether the lack of calcium-dependent release of ^{3}H-glu was due to the inability of the isotope to penetrate the vesicular release pool in these neurons, we developed a biochemical assay to measure <1 pMole of endogenous glu. Using rat cortical synaptosomes as a starting point, we found that the subsecond kinetics of ^{3}H-glu release was similar or identical to release of ^{3}H-GABA as characterized previously (Turner and Goldin [1989], Biochem **28,** 586). Preliminary results suggest that the kinetics of endogenous glu release from synaptosomes is similar to that for ^{3}H-glu. The relationship between endogenous and isotopic release from cultured neurons remains to be determined.

$GABA_A$ AND $GABA_B$ AUTORECEPTOR REGULATION OF GABA RELEASE IN THE VENTRAL PALLIDUM (VP): A STUDY USING MICRODIALYSIS IN FREELY MOVING RATS. A.J. Bourdelais and P.W. Kalivas. Dept. of VCAPP, Wash. St. Univ., Pullman, WA 99164.

There is evidence that presynaptic GABA receptors modulate GABA release in the CNS. It has been demonstrated that the $GABA_A$ agonist muscimol was able to inhibit GABA release from synaptosomes obtained from the substantia nigra pars compacta, whereas the $GABA_B$ agonist baclofen was able to inhibit GABA release from synaptosomes obtained from the substantia nigra pars reticulata (Pittaluga, Eur. J. Pharm., 144:45-52, 1987). We used microdialysis to demonstrate autoreceptor regulation of GABA release in the VP. Rats were chronically implanted with a guide cannula 3 mm above the VP. Post-surgery (7-8 days) the rat was placed in the dialysis box and a dialysis probe was inserted into the VP via the guide cannula. After a 3 hr equilibration period, 5x20 min baseline samples were collected and then dialysis buffers changed to one of the following stepwise increases in agonist concentration: a) dialysis buffer, b) dialysis buffer + 0.1 μM, 1.0 μM, and 10.0 μM muscimol, or c) dialysis buffer + 1.0 μM, 10.0 μM, and 100.0 μM baclofen. Each concentration of agonist was perfused for 80 min; samples were collected every 20 min. Artificial CSF, at a flow rate of 2.13 μl/min was used for dialysis. HPLC-EC was used to measure GABA levels, with OPA/t-butylthiol precolumn derivitization. Baclofen (10.0 μM and 100.0 μM) decreased extracellular GABA levels by 25% and 35%, respectively, as compared to baseline. Muscimol, however, increased extracellular GABA levels by 50% at 1.0 μM, as compared to baseline. No changes in GABA concentration were seen at the other concentrations of muscimol.

419.10

• THE ROLE OF PRESYNAPTIC POTASSIUM CHANNELS IN THE MODULATION OF ACETYLCHOLINE RELEASE FROM HIPPOCAMPAL SLICES. • **C.G. Benishin Dept. of Physiology, University of Alberta Fac. of Med., Edmonton, Alberta T6G 2H7.**

Subcellular mechanisms involved in the modulation of acetycholine (ACh) release in the central nervous system are still not clearly understood. The objective of these studies was to examine the role of presynaptic K channels in the presynaptic modulation of ACh release in the hippocampus. Modulation of ACh release from hippocampal slices was examined in a perfusion system, with the release of ACh stimulated by exposure of slices to elevated K^+ concentration. Under these conditions, evoked release is not sensitive to inhibition by tetrodotoxin. ACh release under these conditions could be inhibited in a dose-dependent manner by a muscarinic agonist (oxotremorine, Oxo) and a purinergic agonist (2-chloroadenosine, 2-ClAdo). α-dendrotoxin (α-DaTx), which was previously shown to selectively block voltage-gated inactivating K channels in nerve endings, did not effect the release of ACh under resting or depolarized conditions. However, α-DaTx reversed the 2-ClAdo induced inhibition of release, but did not alter the Oxo induced inhibition. These results suggest that a α-DaTx sensitive K channel may be activated as an obligatory step in the modulation of ACh release by presynaptic purinergic receptor activation, but not in the modulation by presynaptic muscarinic receptors.

419.11

EVIDENCE THAT TETRAETHYLAMMONIUM-SENSITIVE K+ CHANNELS CONTRIBUTE TO PRESYNAPTIC SPIKE REPOLARIZATION AND CONTROL OF TRANSMITTER RELEASE IN HIPPOCAMPAL SLICES.
O. Paulsen, M. Raastad and J.F. Storm.
Inst. of Neurophysiology, Karl Johans gt. 47, 0162 Oslo, Norway.

Presynaptic K channels can indirectly control transmitter release by determining spike duration and hence Ca influx. In the hippocampus, the K channel blocker 4-aminopyridine broadens the presynaptic fiber volley and increases synaptic potentials (Haas et al., Experientia 1983;39:114). It has also been suggested that a TEA-sensitive Ca-activated K current could contribute to presynaptic spike repolarization, thus exerting a feed-back control of Ca influx and transmitter release (Storm, Brain Res. 1987;435:387). To test this and related ideas, we have started to measure the effects of K and Ca channel blockers on the presynaptic fiber volley and the excitatory post-synaptic potential (EPSP) in the CA1 field of rat hippocampal slices.

In submerged slices (23-30 °C) stimulation of CA1 str. radiatum fibers produced field potentials recorded in the same layer. The response consisted of a fiber volley (amplitude 0.2-1.2 mV, duration 1.2-1.8 ms) followed by a field EPSP (0.3-1 mV). The EPSP could be blocked by kynurenic acid or the Ca channel blockers Mn and Cd. The remaining fiber volley could be blocked by TTX. 1 mM tetraethylammonium (TEA) reversibly increased both the EPSP amplitude (by 17-100%; n=12) and the fiber volley duration (5-15%; n=12). The EPSP increase was also observed intracellularly (n=8). The broadening of the fiber volley survived blockade of the EPSP by kynurenic acid (n=3), whereas Ca-free medium with 2 mM Mn seemed to occlude the effect of TEA.

These data suggest a role for TEA-sensitive K channels in presynaptic spike repolarization and the control of transmitter release.

ALPHA ADRENOCEPTOR ACTIVATION INHIBITS THE EARLY BUT NOT THE LATE IPSP IN AREA CA1 OF THE RAT HIPPOCAMPUS WHILE INCREASING THE SPONTANEOUS RELEASE OF GABA FROM PRESYNAPTIC INHIBITORY INTERNEURON TERMINALS.
V.A. Doze, G.A. Cohen, K.D. Parfitt and D.V. Madison. *Department of Molecular & Cellular Physiology, Stanford Univ. School of Medicine, Stanford, California 94305.*

Previous work has shown that alpha adrenoceptor activation decreases the evoked inhibitory postsynaptic potential (IPSP) in area CA1 of the rat hippocampus. Using intracellular recordings in slices treated with agents that selectively block GABA-A (picrotoxin-100μM) or GABA-B (saclofen-100μM) receptor mediated responses, we examined the effect of epinephrine (EPI) on isolated early IPSP's and late IPSP's. We found that EPI-1μM potently decreases the amplitude of the early IPSP (>50%) without affecting the size of the late IPSP. To further examine this mechanism, we used whole cell voltage-clamp recordings in slices treated with tetrodotoxin (1μM) to detect spontaneous release of GABA from the inhibitory interneuron terminals (IPSC's). We found that EPI caused an increase in both the frequency and amplitude of the spontaneous IPSC's. Our results suggest that EPI decreases evoked synaptic inhibition while increasing the spontaneous quantal release of GABA from interneuron terminals. We speculate that depolarization of the presynaptic interneuron terminal may be the mechanism for these seemingly paradoxical actions of EPI on evoked versus spontaneous synaptic inhibition. In addition to the above findings, we found that the action of EPI on the evoked IPSP was strongly dependent on extracellular potassium levels $[K^+]_o$. When $[K^+]_o$ was lower than 3mM, EPI was ineffective. However, when $[K^+]_o$ was 5mM or above, EPI potently reduced the evoked IPSP. Similar findings were obtained with selective alpha adrenoceptor agonists (6-fluoroEPI), but not beta adrenoceptor agonists (isoproterenol). Thus, alpha adrenoceptor activation may have profound significance during epileptiform activity when $[K^+]_o$ rises to 5mM and above.

419.13

PHARMACOLOGICAL AND FUNCTIONAL CHARACTERIZATION OF AN ALPHA ADRENOCEPTOR IN AREA CA1 OF THE RAT HIPPOCAMPUS.

D.V. Madison and V.A. Doze. *Department of Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, California 94305.*

Previous work has shown that norepinephrine (NE) decreases synaptic inhibition in the rat hippocampus via activation of an alpha adrenoceptor. To further characterize the subtype of alpha adrenoceptor involved in mediating this action, we examined the actions of a large number of known alpha adrenoceptor agonists on the size of the evoked inhibitory postsynaptic potential. We found that this is an alpha adrenoceptor of unusual pharmacology. This particular adrenoceptor is activated by phenethylamines with a rank order as follows: 6-fluoroepinephrine > epinephrine ≥ 6-fluoronorepinephrine > NE > phenylephrine > isoproterenol. The selective alpha-2 agonist α-methyl-NE also possessed significant activity at this adrenoceptor. Initial experiments with antagonists selective for alpha-1 (prazosin, corynanthine) and alpha-2 (rauwolscine, yohimbine) adrenoceptors suggest that the predominant subtype of adrenoceptor involved is an alpha-2. Interestingly, compounds of either the guanidinum (e.g., guanabenz, guanfacine) or imidazoline class (e.g., cirazoline, oxymetazoline, clonidine, para-amino-clonidine) were either ineffective or only weakly active (partial agonists) against this adrenoceptor. These results are in agreement with several recently published studies indicating that the imidazolines and phenethylamines interact differently with alpha adrenoceptors, and that many actions of the imidazolines previously ascribed to alpha adrenoceptors may be attributable to a newly discovered imidazoline/guanidinium receptive site distinct from alpha adrenoceptors. In summary, our results confirm that an alpha adrenoceptor mediates the disinhibitory action of NE in the rat hippocampus and suggest that this adrenoceptor is of the alpha-2 subtype. We have found, however, that only catechol-type compounds of the phenethylamine class behave as full agonists at this particular alpha adrenoceptor.

419.14

LONG TERM DEPRESSION OF EXCITATORY SYNAPTIC TRANSMISSION IN THE NEONATAL RAT SPINAL CORD.

A. Lev-Tov, M. Pinco* and R. Lavy*. Dept. of Anatomy, The Hebrew Univ. Medical School, Jerusalem 91010, Israel.

Synaptic transmission was studied in the isolated spinal cords of neonatal rats (age 6-10 days) using intracellular and whole cell patch-clamp recordings of excitatory post synaptic potentials (EPSPs) and currents (EPSCs), and extracellular recordings of monosynaptic reflexes. The EPSPs and monosynaptic reflexes, were severely depressed at stimulation rates above 0.1 Hz. The depression disappeared only as the interpulse intervals exceeded 50 seconds. Partial recovery from the depression was observed during repetitive stimulation at 0.5-2 Hz, usually following the first 100-200 stimuli. The reduction in the EPSP amplitude was not accompanied by any detectable changes in the time courses of the EPSPs, indicating that the long-term depression is of presynaptic nature. Extracellular recordings of synaptic fields generated in the motor nucleus by dorsal root stimulation, revealed that the terminal potentials preceding the synaptic fields were not affected by the frequency of stimulation. We therefore suggest, that the long term depression of synaptic transmission in the neonatal rat spinal cord, reflects inability of the premature transmitter release machinery to maintain high release levels from fully invaded afferent terminals at low activation frequencies.

NH_4^+ DECREASES EXCITATORY SYNAPTIC TRANSMISSION BETWEEN CEREBELLAR NEURONS IN VITRO. W. Raabe. Depts. Neurology, VA Med. Ctr. and Univ. of Minnesota, Minneapolis, MN, 55417.

Glutamine is presumed to be a precursor for glutamate used as transmitter. Glutaminase catalyzes the cleavage of glutamine to glutamate. NH_4^+ inhibits glutaminase. To investigate the role of glutamine as precursor for glutamate this study examines the effects of NH_4^+ on glutamatergic excitatory synaptic transmission.

Wole cell patch voltage clamp recordings were obtained from large cerebellar neurons (Purkinje cells) in primary dissociated tissue culture. Stimulation of nearby neurons with an extracellular electrode produced monosynaptic excitatory currents as identified by their ability to follow stimulation at 20 Hz. NH_4^+ (10 mM) reversibly abolished evoked excitatory postsynaptic currents (EPSCs) but did not abolish spontaneous miniature EPSCs. TTX (5 μM) and Mg^{++} (10 mM) also abolished evoked EPSCs and did not affect spontaneous miniature EPSCs, indicating that the latter are due to spontaneous release of transmitter from presynaptic terminals.

The lack of an effect of NH_4^+ on spontaneous transmitter release indicates that abolition of evoked EPSCs by NH_4^+ is not due to interference with glutamine as a precursor for glutamate. Possibly, NH_4^+ abolishes evoked EPSCs by blocking the invasion of action potentials into presynaptic terminals as it has been shown for Ia-afferents in cat spinal cord (J. Neurophysiol. 62: 1461, 1989).

ADDITION OF NERVE OR NERVE CONDITIONED MEDIUM TO CULTURED XENOPUS MYOCYTES ALTERS ACETYLCHOLINE RECEPTOR CHANNEL POPULATION AND KINETICS

J. Rohrbough* and Y. Kidokoro. Dept. of Physiology, U.C.L.A. School of Medicine, Los Angeles CA., 90024.

Single-channel recordings of acetylcholine receptor (AChR) channels were taken to assess channel population and kinetics after the addition of nerve or nerve-conditioned medium to *Xenopus* myocytes cultured alone for several days. Muscle cultures were prepared from stage 16-18 embryos, and stage 22-23 neural tubes or nerve-conditioned medium was added after 4-5 days in culture.

It was previously found that the addition of nerve to *Xenopus* myocyte cultures had the surprising effect of increasing mean AChR channel open time in noise analysis (Brehm et al. *Dev. Biol.* **91**, 1982), indicating an increase in the relative number of low conductance (low-g) channels. We verified this effect, measuring the percentage of high conductance (high-g) single channel events after 6 days in culture. In control 6-day cultures, the percentage of high-g events was 54%. The percentage decreased to 36% and 33% when neural tube cells were added on day 5 or day 4, respectively. The effect was similar in both nerve contacted and non-contacted cells. Similarly, after one day exposure to nerve-conditioned medium, the percentage of high-g events decreased to 39%. These results suggest the possible release of factor(s) by the nerve which alters the synthesis rate of the low-g receptor. A remaining question we are addressing is whether the kinetics of either the existing or of the new receptor population are altered after exposure to nerve. In aneurally cultured *Xenopus* myocytes, channel burst duration, particularly for the low-g channel, decreases during development. After 6 days, most low-g burst duration histograms have an excess of brief events but are otherwise fit by a single exponential. Preliminary results suggest that in many cases, low-g burst duration histograms are markedly double exponential, with a larger slow component, after nerve is added.

EPSILON SUBUNIT CONFERS BRIEF CHANNEL OPEN TIME ON MULTIPLE FORMS OF MUSCLE ACH RECEPTOR. Y. Liu, P. Camacho, G. Mandel*, and P. Brehm. Dept. of Neurobiology & Behavior, SUNY at Stony Brook, Stony Brook, NY., 11794.

The role of the epsilon subunit in determining ACh receptor channel function was tested by co-expressing rat epsilon RNA with various combinations of mouse α,β,γ and δ RNA. Injection of αβδγ RNA into *Xenopus* oocytes resulted in several conductance classes, all bearing long channel open time whereas injection of αβδε RNA led to multiple channel types all bearing brief open time. We tested the possibility that functionally distinct forms of ε containing receptors resulted from differences in subunit composition by injecting specific combinations of subunit RNAs. In the combinations of two subunits tested with 10μM ACh, only αε showed reasonable expression with αδ, αβ, and αγ expressing little or no current. However, all of the combinations containing 3 subunits tested, αβγ, αβδ, αδγ, and αδε expressed functional receptors, with αδε exhibiting the largest currents (1-10μA). Single channel recordings from αδε channels revealed a single amplitude class. The events corresponded to the intermediate conductance class observed with the full complement of αβδε on the basis of similarities in both open time and conductance. Our findings indicate that inclusion of ε subunit in the formation of functional receptors results in brief open times characteristic of receptors on adult skeletal muscle. The finding that the epsilon confers brief open times to ACh receptors of different subunit composition suggests that this subunit differs from α, β, γ and δ in that it plays an active role in shortening channel open time of ACh receptors. (Supported by NIH grant 18205 to PB).

NICOTINIC ACh RECEPTORS OF INSECTS AND VERTEBRATES: ACTIONS OF A BISQUATERNARY AMMONIUM SERIES.

C.A. Leech*, S.C.R. Lummis*, C.W. Holyoke and D.B. Sattelle. AFRC Laboratory of Molecular Signalling, Department of Zoology, Cambridge CB2 3EJ, U.K. and E. I. du Pont, Agricultural Products Department, Wilmington, DE 19880

Patch-clamp studies on dissociated neurones of housefly (*Musca domestica*) and cockroach (*Periplaneta americana*) have revealed 3 distinct conductances in the presence of acetylcholine (20pS; 30-40pS; 60-80pS), of which the 30-40pS channel is the most common. Open times are best fitted by 2 exponential components. Closed time distributions show greater variation and require 2-4 exponential fits. Voltage-clamp studies on identified cockroach neurones have characterized a nicotinic receptor blocked by α-bungarotoxin, k-bungarotoxin, dihydro-β-erythroidine and lophotoxin. Displacement of [125I] α-bungarotoxin binding by a C4-C12 bisquaternary ammonium series has shown that nicotinic receptors of cockroach CNS, chick CNS and chick muscle respond differently to an increase in molecular size of these compounds. Whereas in chick muscle, the percent inhibition increases with separation of the quaternary nitrogens, brain inhibition is greatest at the two extremes. The cockroach receptor exhibits some of the properties of both classes of vertebrate nicotinic receptors in its response to the C4-C12 compounds.

[^{3}H]-NICOTINE PHOTOAFFINITY LABELS TYR-198 IN THE ALPHA-SUBUNIT OF THE *TORPEDO* NICOTINIC ACETYLCHOLINE RECEPTOR.

R.E. MIDDLETON AND J.B. COHEN. Dept. of Anatomy and Neurobiology, Washington University, St Louis, MO 63110.

The agonist [^{3}H]-nicotine binds at equilibrium to the acetylcholine receptor with Kd=0.5 μM. We have studied by SDS-PAGE the photoincorporation of [^{3}H]-nicotine into polypeptides of *Torpedo* postsynaptic membranes. Irradiation at 254 nm resulted in labeling of α- and γ-subunits that was inhibited by agonists and competitive antagonists but not by noncompetitive antagonists. The amplitude of specific labeling varied with the [^{3}H]-nicotine concentration (K=1.5 μM), with maximal incorporation of ≈0.5% (α) and ≈0.1% (γ). Inhibition of the γ-subunit labeling by d-tubocurare (d-TC) was consistent with inhibition via a single high affinity site (IC_{50}=100 nM) while inhibition of the α-subunit labeling by d-TC was fit by a two site model (IC_{50}=100nM and 1.0 μM). This suggests that the agonist site that binds d-TC with high affinity is located at the interface of the α- and γ-subunits and that each α-subunit is labeled by [^{3}H]-nicotine.

The specific photoincorporation into the α-subunit was localized to a 20 Kd proteolytic fragment which begins at ser-173 and contains the amino acids known to be labeled by competitive antagonist affinity labels. Sequential Edman degradation of this fragment indicated that tyr-190, cys-192 and tyr-198 were the principal sites of incorporation. Analysis of α-subunit peptides generated by chymotrypsin established that tyr-198 contains ≈40% while tyr-190 and cys-192 each contained ≈10 to 20% of the specifically incorporated [^{3}H]-nicotine. Since competitive antagonist affinity reagents label principally tyr-190 and cys-192, the labeling of tyr-198 identifies an adjacent amino acid important for agonist binding.

BOTH ALPHA AND BETA SUBUNITS CONTRIBUTE TO THE AGONIST SENSITIVITY OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS.

C. W. Luetje and J. Patrick. Division of Neuroscience, Baylor College of Medicine, Houston TX 77030.

A family of genes has been identified which encode subunits of nicotinic acetylcholine receptors (nAChR) and are expressed in the nervous system. The α2, α3, and α4 subunits can each form functional nAChR when expressed in *Xenopus* oocytes in pairwise combination with either the β2 or β4 subunits. We find that the agonist pharmacology of mouse muscle nAChR (α1β1γδ) expressed in oocytes matches that of the nAChR expressing mouse muscle cell line BC3H1, demonstrating the accuracy of the oocyte expression system in the study of ligand gated ion channel pharmacology. Each of six neuronal subunit combinations displays an unique rank order of sensitivity to four nicotinic agonists. The α2β2 combination is 3-10 fold more sensitive to nicotine than to acetylcholine, while the α3β2 combination is 10-30 fold less sensitive to nicotine than to acetylcholine and the α3β4 combination is equally sensitive to both nicotine and acetylcholine. nAChR composed of α2, α3 or α4 in combination with β2 are 10-100 fold less sensitive to cytisine than to acetylcholine. In contrast, nAChR composed of α2, α3 or α4 in combination with β4 are 3-10 fold more sensitive to cytisine than to acetylcholine. The α2β2, α3β2 and α3β4 combinations are each equally sensitive to dimethyl-phenylpiperazinium (DMPP) and acetylcholine, while the α2β4, α4β2 and α4β4 combinations are 3-30 fold less sensitive to DMPP than to acetylcholine. Our results demonstrate that the sensitivity of neuronal nAChR to various agonists is dependent not only upon which α subunit, but also upon which β subunit forms the receptor.

420.6

cDNAs AND MONOCLONAL ANTIBODIES DEFINE SUBTYPES OF NEURONAL α-BUNGAROTOXIN-BINDING PROTEINS.

R. Schoepfer, W.G. Conroy,* P. Whiting and J. Lindstrom. The Salk Institute, P.O. Box 85800, San Diego, CA 92138.

Neuronal α-bungarotoxin-binding proteins (αBgtBPs) are homologous, yet different from neuronal and muscle nicotinic acetylcholine receptors (AChRs). Although neuronal αBgtBPs have been detected for almost 20 years, their function is still unknown.

Recently we cloned cDNAs coding for two subunits of chicken brain αBgtBPs. The deduced amino acid sequences define αBgtBPs as members of the AChR gene family and predict that αBgtBPs have cation channels. Subunit-specific monoclonal antibodies (mAbs) were obtained by using bacterially overexpressed, unique subunit segments as immunogens. These mAbs were used to probe western blots of affinity-purified αBgtBPs, neuronal AChRs, and muscle-type AChRs. The results demonstrate the specificity of the mAbs within this gene family and suggest that αBgtBPs and AChR subunits are not coassembled *in vivo*, despite their homology and partial colocalization.

As revealed by immunoprecipitation, the αBgtBP α1 subunit is found in ~90% of all high-affinity (nM) αBgtBPs in embryonic day 18 chicken brains. The α2 subunit is found in ~15% of all αBgtBPs. Further data imply that the α2 subunit is always found in αBgtBPs having the α1 subunit. Thus we have defined an αBgtBP subtype I that has α1 but no α2 subunit and accounts for ~75% of αBgtBPs. Subtype II accounts for ~15% and has α1 and α2 subunits. Other uncharacterized subunits are also present.

ETHANOL ALTERS NICOTINIC RECEPTOR KINETICS: EFFECT OF CONCENTRATION.

M.M. Fróes, Y. Aracava, and E.X. Albuquerque. Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, 21944, RJ, Brazil & Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. of Med., Baltimore, MD 21201.

Molecular interactions of ethanol (EtOH) with a number of transmitter–gated channels have been extensively studied. In this work, we examined the concentration–dependent EtOH actions on the kinetics of muscle nicotinic acetylcholine receptor (AChR). Single channel currents were recorded from the perijunctional region of isolated frog muscle fibers under cell–attached patch–clamp condition. We tested a wide range of EtOH concentrations (10 μM–1.7 M) on the current evoked by acetylcholine (ACh, 0.4 μM). Many distinct kinetic alterations that showed concentration–, time– and voltage–dependence could be depicted: (*i*) at all concentrations tested, the mean number of flickers per burst was increased; this effect was enhanced by hyperpolarization and was further accentuated by a prolonged drug exposure; (*ii*) EtOH elicited two major effects on the opening probability (P_{open}); at low concentration (10 μM), a marked increase in the P_{open} (up to 6–fold) was observed; at higher doses (100 μM–1.7 M) the brief increase of P_{open} was followed by a significant depression; and (*iii*) EtOH (1.7 M) decreased the channel conductance and induced two kinetically distinct populations of currents: one comprised of rapid events, and another consisting of long–lasting bursts. In addition, EtOH alone (0.6–1.7 M) activated currents that resembled those seen in the presence of both ACh and 1.7 M EtOH. Our data suggest the existence of multiple sites of action for EtOH on protein and/or lipid components of postjunctional membrane. Support: Capes/Finep/ UFRJ–UMAB Mol. Pharmacol. Training Program, and NIH #P50MH44211.

NICOTINIC ACETYLCHOLINE RECEPTOR (nAChR) ION CHANNEL CURRENTS IN RAT HIPPOCAMPAL NEURONS.

M. Alkondon and E.X. Albuquerque. Dept. Pharmacol. & Exp. Ther., Univ. of Maryland School of Medicine, Baltimore, MD 21201.

Mapping experiments using radiolabelled cholinergic agonists and *in vivo* studies using extracellular recordings indicated that nAChR are present in different parts of the brain. Single–channel studies from our laboratory (Aracava *et al.*, *FEBS Lett.*, 222:63, 1987) have shown the existence of functional nAChR channels in cultured rat hippocampal neurons. Very recently, a cationic channel for nAChR has also been shown in cultured neurons from retinal ganglion and medial habenula nucleus of the rat and from porcine hypophyseal intermediate lobe cells. This study characterizes the nAChR in hippocampal neurons using whole–cell patch clamp recordings. Hippocampal neurons of fetal rats grown in culture for 3–8 weeks were used and agonists were applied to the neuron using a 'U'–tube perfusion system. Acetylcholine (ACh) (50–100 μM) and (+)anatoxin (Antx) (10 μM) elicited inward currents (IC) which grew linearly with hyperpolarization (–10 to –100 mV). At positive membrane potentials, the amplitude of the currents was smaller indicating the occurrence of an outward rectification for these channels. Antx was about 10 times more potent than ACh in activating the hippocampal nAChR. Rapid inactivation of the IC occurred during the continued presence of the agonist, which was more prevalent with Antx than ACh. Responses to Antx were blocked by d–tubocurarine (10–20 μM), dihydro β–erythroidine (20 μM) and mecamylamine (10 μM). These results disclose the presence of a neuronal type nAChR in cultured rat hippocampal neurons and confirm the existence of an excitatory cholinergic function in the hippocampus. SIMULTANEOUS FAST REMOVAL OF AGONIST AND BLOCKER REVEALS SLOW TRANSITIONS FROM BLOCKED STATES. A.C.S. Costa and E.X. Albuquerque. Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201 & Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, 21944, Brazil.

We have recently shown that 9-amino-1,2,3,4-tetrahydroacridine (THA) and 9-aminoacridine (9-AA) modify NMDA-gated single channel currents, primarily as open channel blockers. We decided to compare the potency of these compounds on NMDA and non-NMDA currents using whole-cell voltage-clamp on cultured rat hippocampal neurons. Admixtures of agonist and drug were applied via a U-shaped tube. This system produced concentration jumps within ≈100 msec. When NMDA and relatively low concentrations of blocker were applied together (<50μM THA and <25μM 9-AA), a reduction in current amplitude was noticed. Increases in THA or 9-AA concentrations further decreased the current amplitude and also started to produce a 2nd current component. This 2nd peak occurs following the total removal of the test solution. We interpreted this 2nd peak as the result of a slow unblock step after the channel blockade. Fast application of APV plus NMDA failed to reproduce this effect. THA and 9-AA also blocked kainate-gated currents but at concentrations about 20 times higher. Moreover, these two compounds were unable to produce the 2nd component in kainate currents. Similar to NMDA currents, we also observed the presence of a 2nd current component in ACh-gated currents. We used the same superfusion system with some well defined blockers of ACh-gated currents and also THA at rat myoballs. The 2nd component was observed when high concentrations of QX-222, dimethylanatoxin, bupivacaine and THA were applied with ACh. These compounds were previously reported to produce slow transitions to blocked (or desensitized) states. SAD-128, reported to act as a pure fast open channel blocker in all concentrations tested, failed to produce the 2nd component. Fast superfusion systems used to apply and remove agonist and blocker may reveal previously hidden slow reaction steps. For example, in the case of QX-222 this approach tells us that return from a long lived blocked state(s) must be at least in part via the open state (a sequential scheme). Support: U.S. Army Med. Res. Devel. Comm. Contract DAMD17-88-C-8119 and FINEP and NIH Grant NS-25296.

Inhibition of Excitatory Amino Acid Currents by General Anesthetic Agents. Robert W. Peoples, David M. Lovinger, and Forrest F. Weight. Section of Electrophysiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

Previous studies in this laboratory have shown that ethanol and other aliphatic alcohols inhibit responses mediated by N-methyl D-aspartate (NMDA) receptors in mammalian neurons at physiologically relevant concentrations. We have investigated the actions of various anesthetic agents on excitatory amino acid-activated ion currents in voltage-clamped mouse hippocampal neurons in culture using the whole-cell patch-clamp technique. Pentobarbital inhibited kainate and quisqualate currents with similar potency (IC_{50} ~ 50 μM), but produced a greater maximal inhibition of the quisqualate current (70% inhibition vs. 55% for kainate). Pentobarbital blocked both kainate and quisqualate currents in a use-dependent but rapidly reversible manner, and thus may bind to a site within, or near the opening of, the ion channels. Pentobarbital had essentially no effect on the NMDA current. In contrast, diethyl ether exhibited a pharmacological profile similar to that of ethanol, in that it inhibited the NMDA current to a greater extent than the kainate and quisqualate currents (~ 80% for NMDA vs. ~ 25% for kainate at 80 mM diethyl ether). We are currently investigating actions of other anesthetic agents on excitatory amino acid currents. Inhibition of excitatory amino acid neurotransmission in the CNS by anesthetics could be expected to contribute to their depressant effects on behavior. (R.W.P. is a fellow of the National Research Council.)

THE PHARMACOLOGY OF CHLORISONDAMINE INVESTIGATED IN RAT BRAIN. P.B.S.Clarke, I.Chaudieu, P.Boksa, and R.Capek. Depts of Pharmacology and Psychiatry, McGill Univ., Montreal, Canada H3G 1Y6.

A single administration of the ganglion blocker chlorisondamine (CHL: 10 mg/kg sc) produces a quasi-irreversible blockade of nicotine's central actions in the rat, of unknown mechanism (Clarke 1984). Expt 1 sought to determine if CHL is acutely neurotoxic; 3 d after CHL (10 mg/kg sc), central effects of nicotine were demonstrably blocked but no neuronal degeneration was detected by the Gallyas method. In Expt 2, CHL (10 mg/kg sc) blocked central effects of nicotine when tested 2 weeks later, but did not significantly alter the B_{max} of high-affinity ^{3}H-nicotine binding in brain. In Expt 3, CHL inhibited ^{3}H-dopamine release induced by NMDA (10^{-5} M) from cultured fetal rat dissociated mesencephalic cells, but only at high concentrations (ED_{50} 0.68 mM), and had no detectable effect on responses to quisqualate (10^{-5} M) and kainate (10^{-4} M). In Expt 4, CHL inhibited NMDA-mediated synaptically-evoked field potentials in adult rat hippocampal slices, but again only at high concentrations (0.1 - 1 mM), and non-NMDA responses were less affected. These results suggest that chlorisondamine's persistent CNS nicotinic blockade is not accompanied by changes in nicotinic receptor density or by neuronal degeneration. In addition, the drug seems to block excitatory amino acid receptors only with low potency. Supported by NIDA and MRC (Canada).

420.12

KINETIC PROPERTIES OF NMDA CHANNELS J. Clements & G. Westbrook, Vollum Institute, Oregon Health Sciences Univ., Portland, OR. 97201

Excitatory synaptic currents in the CNS often exhibit a slow NMDA receptor mediated component which has a rise time of 8-10 ms and a decay time constant of 50-150 ms. To understand the process which produces this slow current, knowledge of the kinetic properties of the NMDA channel is required. Previous studies using whole cell recordings could not produce solution changes in less than 10 ms, precluding detailed study of binding and activation kinetics.

We applied pulses of glutamate to outside-out patches of membrane from cultured hippocampal neurones by rapidly moving the interface of two flowing solutions across the tip of the patch pipette. Control experiments revealed that solution exchange at the surface of the membrane was complete in 1 ms.

Pulses of high concentration glutamate (>100 μM) produced responses with rise times of 8-10 ms, similar to the synaptic current, even when the pulse was as short as 2 ms. This suggests that intrinsic channel kinetics limit NMDA channel activation. At lower concentrations (0.2 to 20 μM), a slower rise was seen. An analysis of the relationship between glutamate concentration and rise time will be presented.

CHANNEL KINETICS UNDERLIE NMDA RECEPTOR-MEDIATED SYNAPTIC CURRENTS. R. A. J. Lester, J. D. Clements, G. L. Westbrook and C. E. Jahr. Vollum Institute, Oregon Health Sci. Univ., Portland, OR 97201

In the presence of CNQX (5 μM), long-lasting NMDA receptor-mediated epscs were recorded between pairs of hippocampal neurons in culture using whole cell patch clamp techniques. The competitive NMDA receptor antagonist, D-AP5 (100 μM), did not affect the slow epsc when rapidly applied during its decay. These results suggest that NMDA receptors activated by synaptically released glutamate must remain bound and active for the duration of the slow epsc and thus inaccessible to competitive inhibition. In separate experiments, a 5 ms pulse of L-glutamate (100 μM) to an outside-out membrane patch produced NMDA channel activity that persisted for hundreds of milliseconds indicating that glutamate can remain bound for prolonged periods. The time courses of ensemble averages of these patch currents were very similar to the slow epscs. Both had slow rise times (7.4, epsc; 10. 3, patch response; 10-90 % rise time) and slow decay phases which could be fitted with a double exponential (63 ms, epsc; 87 ms, patch response; first time constant). These results imply that a brief pulse of glutamate in the synaptic cleft is sufficient to account for the slow epsc. The slow rise time of the epsc is due to the activation kinetics of NMDA receptors rather than diffusion of transmitter to extrasynaptic sites. If ligands with different affinities for the NMDA receptor (such as L-aspartate) were released synaptically different duration epscs would result.

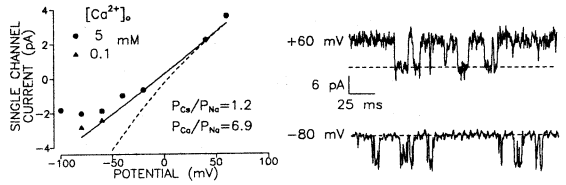
NEUTRAL PEPTIDES CONTAINING THE AMINO ACID SEQUENCE SER-ALA-ALA ACTIVATE A MAGNESIUM-SENSITIVE CATION CHANNEL IN HIPPOCAMPAL NEURONS. J.R. Pace, M.E. Mitchell†, S.M. Paul and M.A. Rogawski. Neuronal Excitability Section, Medical Neurology Branch, NINDS, and Clinical Neuroscience Branch, NIMH, Bethesda, MD 20892 (†HHMI Scholar).

Fast excitation of neurons by conventional neurotransmitters such as glutamate, acetylcholine and serotonin occurs by gating of cation-permeable membrane channels. With the exception of excitatory amino acid receptor-coupled channels which can be activated by high concentrations of certain acidic (glutamate or aspartate containing) peptides, notably *N*-aspartylglutamate, peptide gated cation channels have not previously been described in neurons. In the present study using whole-cell voltage-clamp techniques, we characterized an ionic current in cultured hippocampal neurons that is activated by peptides containing the amino acid sequence Ser-Ala-Ala. Peptides active as agonists of this channel include Ser-Ala-Ala-Ser-Leu-Asn (SAANSLN), the prototypic ligand we used in most of our studies, as well as SAAS and SAA; AASL and all possible dipeptide fragments of SAASLN are inactive. At negative holding potentials, SAASLN rapidly elicited an inward current response whose amplitude increased in a concentration-dependent manner between 1-100 μM. Reversal potential measurements indicated that the channels activated by SAASLN are permeable to Na^+, K^+, Cs^+ and Ca^{2+}, with ionic selectivities P_K/P_{Na}, P_{Cs}/P_{Na} and P_{Ca}/P_{Na} of 0.75, 1.2 and 6.9, respectively. Like the channels activated by the excitatory amino acid antagonist *N*-methyl-D-aspartate (NMDA), these channels are blocked in a voltage-dependent fashion by Mg^{2+}. However, the peptide responses are insensitive to the NMDA-receptor antagonist DL-2-amino-5-phosphonovaleric acid (AP5) or to phencyclidine, a potent steric blocker of NMDA-receptor associated channels. The peptide therefore activates a unique and heretofore unrecognized ligand gated ion channel.

420.15

SINGLE CHANNEL CURRENTS ACTIVATED BY A NEUTRAL PEPTIDE IN RAT HIPPOCAMPAL NEURONS. M.E. Mitchell†, J.R. Pace, S.M. Paul and M.A. Rogawski. Neuronal Excitability Section, Medical Neurology Branch, NINDS, and Clinical Neuroscience Branch, NIMH, Bethesda, MD 20892 (†HHMI Scholar).

We have observed that neutral peptides containing the sequence Ser-Ala-Ala (SAA) can activate a Mg^{2+}-sensitive cation current in cultured rat hippocampal neurons (J.R. Pace *et al.*, this meeting). In the present study, we characterized the single channel currents activated by one of these peptides (Ser-Ala-Ala-Ser-Leu-Asn; SAASLN) in excised (outside-out) membrane patches. Single channel recordings were carried out with patch electrodes filled with (in mM): K-gluconate or CsCl, 145; HEPES, 5; $MgCl_2$, 2; EGTA, 1; $CaCl_2$, 0.1. The bathing medium contained: NaCl, 140; HEPES, 10; KCl, 2.5; $CaCl_2$, 0.1 or 5; phencyclidine (10 μM) was added to eliminate NMDA receptor mediated currents. In the presence of low external Ca^{2+} (0.1 mM), SAASLN activated a 46 pS channel whose nearly linear single-channel current-voltage plot reversed near 0 mV. However, with high external Ca^{2+} (5 mM), the observed single channel amplitudes were smaller at negative potentials than predicted by the Goldman-Hodgkin-Katz equation (dotted line), suggesting that Ca^{2+} can rapidly block the channel.



420.16

LOWER CONCENTRATIONS OF KAINATE ARE REQUIRED TO ACTIVATE LOW CONDUCTANCE (2pS) KAINATE CHANNELS THAN HIGH CONDUCTANCE (20pS) ONES. L. M. Nowak and J. L. Christiansen*, Dept. of Pharmacology, NYSCVM at Cornell University, Ithaca, N.Y. 14853.

Ascher and Nowak (1988; *J.Physiol.*399: 227) previously reported that kainate application (50-100μM) activates two populations of ion channels in outside-out patches from mammalian neurons, one with an estimated conductance of 2pS and open time of 3-4ms, and the other with an estimated conductance of 20pS channel and open time of <1ms. The conductances could be observed separately in different patches and it was suggested they may to be associated with different kainate receptors; however, both responses were observed together in most patches.

Recently, we studied kainate-receptor channels and determined that the 2pS channel is activated by lower doses of kainate (5μM) than the 20pS channel (>40 μM) in the same patches at –60mV. Recordings were performed on outside-out patches from cultured mouse brain neurons. The bath solution contained 300 nM TTX and (in mM): 150 NaCl, 2.8 KCl, 1 $CaCl_2$, 10 Hepes-Na (pH 7.2). The pipette solution contained (in mM): 140 CsCl, 10 Hepes-K (pH 7.2) and 10 EGTA/1Ca. Kainate (5-100μM) was applied in the bath solution by direct superfusion from a Pasteur pipet. 5-20 μM kainate evoked relatively large inward currents accompanied by a small increase in noise. Analysis of the variance in the noise indicated activation of a 2-3pS channel. Power spectral density analysis suggested the channel open time (τ) was near 10ms. Application of 80-100μM kainate to these patches gave an estimated channel conductance of 5-6pS from variance analysis and power spectra fitted by two Lorenzians, one a very high frequency component (<1ms), and the other one about 3-4ms. Thus, the shift in the aggregate conductance from about 2pS to 5-6pS suggested that increasing the kainate dose recruited the higher conductance (20pS) channels. This idea was supported by changes in the power spectra, which began to show a second high frequency component that contributed proportionally more to the total power as kainate concentration was increased. In the recruitment, the lower frequency process (τ = 10ms) was obscured and estimated open time approached 3-4ms in >50μM kainate.

GLUTAMATE-ACTIVATED CHANNELS IN DISSOCIATED ADULT SPINAL CORD CELLS. D.O. Smith, J.L. Rosenheimer, F. Zufall*, C. Franke*, and H. Hatt*. Dept. of Physiol., Univ. of Wisconsin, Madison, WI 53706 and Physiol. Inst., Tech. Univ., Munich, Germany.

Glutamate depolarizes motoneurons in adult spinal cord. It is unclear, however, whether glutamate-sensitive channel characteristics seen in cultured embryonic cells are also present in adult animals. Therefore, membrane currents in response to pressure application of glutamate agonists were examined in acutely dissociated spinal cord cells from adult rats using outside-out and whole-cell recording techniques. 400-μm slices were cut from rat lumbar spinal cords, and 1-mm punches of gray matter were removed from the ventral horns. Following incubation in trypsin, cells were dissociated mechanically and plated for electrophysiologic analysis. Action potentials could be induced by depolarization in cells with resting potentials of approximately -60 mV. Desensitizing 27-pS NMDA-sensitive channels were recorded; conductance was voltage-dependent, and addition of 1-μM glycine increased whole-cell currents. Likewise, desensitizing 10-pS quisqualate-sensitive channels and nondesensitizing 12-pS kainate-sensitive channels were observed. Supported by NIH grant NS13600 and SFB 220.

ION CHANNELS: LIGAND-GATED II

421.1

RECEPTOR FAMILIES: cDNAs IDENTIFIED BY PCR & DNA HOMOLOGIES. **D.M. Donovan, G.R. Cutting*, B.F. O'Hara, S.S. Shimada and G.R. Uhl. Lab. of Mol. Neurobiol., NIDA/ARC, Depts. of Neurol. & Nsci., and Center for Med. Gen. and Dept. of Pediatrics, Johns Hopkins Sch. of Med., Bx 5180, Baltimore, MD 21224.**

We have used polymerase chain reactions (PCR) and other DNA homology strategies to identify cDNAs encoding receptors. PCR using oligonucleotides directed against conserved regions of the GABA-A and glycine receptors has yielded cDNAs which are similar to known ligand gated ion channels. One PCR product and the corresponding cDNA from a human retina library displays homologies to known receptors that range from 30-36% for the GABA-A subunits to 30% for the glycine subunits. Preliminary Northern blot analysis of rat mRNA and data obtained by screening libraries from human tissues suggest that mRNAs encoding this receptor are present at low frequency in the brain and higher frequency in the retina. Southern analysis and genomic cloning suggest the presence of two closely related genes in human, monkey, mouse and rat.

In a second search, a rat library was screened with an oligonucleotide homologous to the "RDC7" clone originally isolated with PCR technology by Vassart and collaborators. Preliminary DNA sequence analysis of one rat brain cortex cDNA isolate has revealed a 70% DNA sequence homology with the RDC7 from dog. Further characterization will be necessary to assign a functional role of these apparent novel receptor-like clones.

A HIGH AFFINITY RECEPTOR FOR INOSITOL-1,4,5-TRISPHOSPHATE PURIFIED FROM BOVINE CEREBELLUM AND RECONSTITUTED INTO PLANAR LIPID BILAYERS FORMS A LIGAND-ACTIVATED Ca^{2+}-PERMEABLE CHANNEL

S.R. Hingorani#, K. Ondrias*, W.S. Agnew# & B.E. Ehrlich*
#Dept. of Cellular and Molecular Physiology, Yale Univ. Sch. Med., New Haven, CT 06510 and *Depts. of Medicine and Physiology, Univ. of Connecticut, Farmington, CT 06032.

Binding studies performed with detergent extracts of rat and bovine cerebellar membranes suggested the presence of two classes of binding sites for inositol-1,4,5-trisphosphate (IP_3). One class bound [^{3}H]-IP_3 with low affinity (K_d ~ 120 nM), and was not blocked by high concentrations of free Ca^{2+}, while a second bound ligand with high affinity (K_d = 5 nM), and was completely inhibited by Ca^{2+} (IC_{50} = 300 nM). Taking advantage of a novel affinity purification procedure, the high affinity receptor was purified to near homogeneity; this protein exhibited a K_d of 4 nM, was not inhibited by free Ca^{2+}, and was formed of a single peptide of M_r = 243,000. The purified preparation was reconstituted into planar lipid bilayers and demonstrated to form an IP_3-activated, Ca^{2+}-permeable channel having a unitary conductance of 10 pS. The channel tended to open in bursts, with a low overall opening probability of 5-10%. Activity was blocked by low concentrations of heparin (10 μg/ml), but appeared to be insensitive to ruthenium red. Many records showed concerted openings and closings of integral multiples of the unitary conductance, strongly suggesting that gating may be cooperative. As these receptors are present at high densities in intracellular membranes of Purkinje cells, such interactions may be physiologically significant.

ALCOHOL MODULATION OF DESENSITIZATION OF GABA RECEPTOR-Cl^- CHANNEL COMPLEX IN RAT DORSAL ROOT GANGLION NEURONS. M. Nakahiro, O. Arakawa and T. Narahashi. Dept. of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611.

We have previously reported that n-alcohols enhance GABA-induced current before desensitization occurs (Nakahiro et al., FASEB J. 4, A1201, 1990). Ethanol and n-octanol have now been found to modulate the desensitization process of GABA receptor-Cl^- channel complex. The whole-cell patch-clamp technique was used to record currents from the rat dorsal root ganglion neurons in primary culture. Bath application of 0.3 mM GABA generated a peak current that decayed to a steady-state level. The initial phase of current decay was fit by a single exponential function, and the time constant was measured. The time constant of recovery from desensitization was also determined by paired applications of 0.3 mM GABA at various intervals. Ethanol (0.3-1 M) and n-octanol (30-100 μM) decreased the time constants of both phases in a dose-dependent manner. n-Octanol (100 μM) suppressed, rather than enhanced, the current after it had been desensitized to a steady-state level. However, ethanol (0.3 M) caused no significant suppression of the desensitized current. The results indicate that alcohols modulate GABAergic neurotransmission in a phasic and tonic manner. Supported by ADAMHA grant AA07836.

421.4

ALCOHOLS INDUCE Cl^- CURRENT IN RAT DORSAL ROOT GANGLION NEURONS. O. Arakawa, M. Nakahiro and T. Narahashi. Dept. of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611.

We have already demonstrated that alcohols exert an enhancing effect on GABA-activated Cl^- current, which may contribute to their depressant action on the CNS. We now report that alcohols themselves induce Cl^- currents in the rat dorsal root ganglion neurons in primary culture. Whole-cell patch-clamp technique was used. Bath application of n-octanol (0.3-3 mM) generated an inward current at -60 mV when both external and internal solutions contained 142 mM Cl^-. The current attained a peak and decayed to a lower steady-state level in a manner dependent on the concentration. n-Hexanol (3-10 mM), n-butanol (100-300 mM) and ethanol (1-3 M) also generated similar inward currents in a concentration-dependent manner. When the internal Cl^- was partially replaced by glutamate, the reversal potential for the peak current induced by octanol was shifted as expected from the Nernst equation for Cl^-. Bicuculline (10 μM) and picrotoxin (30 μM) suppressed the octanol-induced current reversibly, whereas chlordiazepoxide (10 μM) and pentobarbital (10 μM) enhanced it. These results suggest that alcohols interact specifically with a certain receptor site(s) in the GABA receptor-Cl^- channel complex thereby opening the channel. Supported by ADAMHA grant AA07836.

421.5

MODULATION OF TRANSMITTER-ACTIVATED MEMBRANE CURRENTS IN CULTURED SPINAL CORD NEURONS BY VARIOUS ADAMANTANE DERIVATIVES. H. Lampe*, H. Bigalke*, (SPON: Europ. Neurosci. Ass.), Department of Pharmacology and Toxicology, Med. School of Hannover, 3000 Hannover 61, FRG.

The agents 1-aminoadamantane and 1-amino-3,5-dimethyladamantane have been used in the treatment of M. Parkinson and movement disorders. In contrast to 1-aminoadamantane, 1-amino-3,5-dimethyladamantane and two other adamantane derivatives, 1-amino-3-isopropyladamantane and 1-amino-3,5-diethyladamantane suppressed picrotoxin-induced hyperactivity in cultured neurons, which indicates also an anticonvulsant potency (Netzer, R. and Bigalke, H., Europ. J. Pharmacol., in press). To elucidate the underlying mechanisms, effects of the drugs on chemosensitive membrane currents were investigated. We used the whole-cell patch clamp technique to record glycine- and glutamate-activated whole-cell currents. Cultures were continuously superfused with growth medium containing 4 mM Mg^{2+}. Patch pipettes were filled with low calcium/high potassium saline. Either glycine or glutamate were applied by pressure ejection to cells clamped at -60 mV membrane potential. Each of the drugs reduced the glutamate-activated current in a concentration-dependent fashion, except for 1-aminoadamantane which had no effect. The glycine-activated current was promoted by 1-amino-3,5-dimethyladamantane at concentrations of between 0.1 μM and 5 μM, but was reduced at higher concentrations. 1-Amino-3,5-diethyl- and 1-amino-3-isopropyl-adamantane promoted this current over the whole concentration range. 1-Aminoadamantane, however, did not modulate this current either. Our results support the hypothesis that an antagonistic action at the glutamate receptor or an agonistic effect on the glycine receptor may contribute to the anticonvulsant potency of the former drugs. Their effectiveness may be due to the fact that they are more lipophilic than 1-aminoadamantane.

EFFECTS OF DELTA-9-TETRAHYDROCANNABINOL ON WHOLE-CELL ION CURRENTS IN CULTURED RAT HIPPOCAMPAL NEURONS. Robert E. Hampson, Shao Wang*, Barbara A. Bennett, Mariana Morris and Sam A. Deadwyler, Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, North Carolina 27103.

Studies in this laboratory have demonstrated an effect of delta-9-tetrahydrocannabinol (THC), the psychoactive ingredient of marijuana, on hippocampal neural activity (Heyser *et al.*, SN Abstr., **15**:1170, 1989; Campbell *et al.*, JPET, **239**:941-945, 1986) in awake, freely-moving rats. A recent report by Herkenham *et al.* (PNAS, **87**:1932-1936, 1990) demonstrates binding of a radio-labelled THC agonist (CP-55,940 -- Pfizer) to a high-affinity THC receptor in rat hippocampus. To examine THC-receptor interactions, we applied whole-cell patch clamp techniques to primary cultures of dissociated hippocampal neurons.

Voltage-clamp recordings from cells in culture for 5-10 days, using KCl-filled patch-clamp pipettes showed an inward membrane current at resting potential following pressure pipette application of 1 mM tp 30 mM THC to the outside of hippocampal neurons. The inward current was increased at hyperpolarizing potentials and reversed at depolarizing membrane potentials. Reversal of this current was consistent with the equilibrium potential for chloride using high chloride concentrations in the patch pipette, and was mimicked by application of of GABA in concentrations similar to those of THC. Substitution of acetate for chloride in the recording pipette produced only outward currents. Substitution of chloride-free bathing medium reduced or eliminated the inward current.

Bath application of THC also reduced voltage-dependent sodium and potassium currents. Comparison of THC with other THC analogs for ligand-gated membrane currents will be described.

DIVALENT METAL CATIONS ACT AT TWO SITES TO INHIBIT 5-HT_3 RECEPTOR-MEDIATED ION CURRENT
David M. Lovinger, Section of Electrophysiology, Lab. of Physiol. Pharmacol. Studies, NIAAA, Rockville, MD 20852.

Recent studies indicate that divalent metal cations such as Zn^{2+} and Cd^{2+} interact with $GABA_A$ and glutamate receptor/channel complexes at micromolar concentrations. The effect of metal ions on the 5-HT_3 receptor/channel complex was examined in whole-cell patch-clamp recordings from NCB-20 neuroblastoma cells. Micromolar concentrations of Cd^{2+}, Cu^{2+} and Zn^{2+} inhibited ion current activated by application of 5-HT to NCB-20 cells voltage-clamped at negative membrane potentials with the order of potency being Zn^{2+} (IC_{50}=20 μM)$\geq Cu^{2+}$ (IC_{50}=25 μM)$>Cd^{2+}$ (IC_{50}=75 μM) at -50 mV. Other cations tested (Ba^{2+}, Co^{2+}, Mg^{2+}, Mn^{2+} and Ni^{2+}) were without effect at concentrations up to 200 μM. Inhibition by Cd^{2+} and Zn^{2+} was voltage-dependent (apparent K_d for inhibition increased e-fold per 72 mV and 52 mV respectively) suggesting that these ions act at a site within the channel. This contrasts with the voltage-independent action of these ions on glutamate- and GABA-gated ion channels. Inhibition by Cu^{2+} exhibited little voltage dependence with the K_d changing e-fold per 233 mV. Inhibition by each of the ions decreased with increasing agonist concentration. For example, Cu^{2+} produced 68$\pm$4% (mean$\pm$SEM) inhibition at 1 μM 5-HT, 53$\pm$3% inhibition at 2 μM, 11$\pm$1% inhibition at 5 μM and 4$\pm$3% inhibition at 10 μM. These data suggest a model in which higher concentrations of agonist increase the probability of the receptor complex assuming a configuration which is insensitive to these ions. In sum, Cd^{2+}, Cu^{2+} and Zn^{2+} potently inhibit 5-HT_3 receptor-mediated ion current via mechanisms different from their actions at other receptor/channel complexes.

421.8

SEROTONIN REDUCES AN INWARDLY RECTIFYING CESIUM SENSITIVE CURRENT IN CEREBELLAR PURKINJE CELLS (PCs) UNDER VOLTAGE CLAMP. Y. Wang*, S.-J. Li,*, J.C. Strahlendorf, and H.K. Strahlendorf., Physiol. and Neurol., Texas Tech Univ. Hlth. Sci. Ctr., Lubbock, TX 79430.

We have previously reported excitatory and inhibitory effects of serotonin (5-HT) on cerebellar PCs. We hypothesize that these multiple actions may arise in part from coupling of various 5-HT receptors to different ion channels present in PCs, including the inward rectifying cationic current (I_h) originally described in these cells by Crepel (1986). Slices from rat cerebellum were superfused with a standard Kreb's solution. PCs were voltage clamped with a single electrode switch clamp amplifier. Ten mV hyperpolarizing steps from a holding potential of -60 to -65 mV to command potentials of -120 mV elicited time - and voltage - dependent inward current relaxations with amplitudes up to 3 nA. Bath applied CsCl, 10 mM, readily blocked these inward relaxations. Superfused 5-HT, 100 μM, markedly attenuated I_h in the the majority of cells and in some cases caused an outward shift of the holding current. These effects were reversible. The 5-HT selective agonist, 8-OH-DPAT, mimicked the actions of 5-HT. We conclude that 5-HT inhibits PCs in part by reducing I_h, possibly through 5-HT_{1A} receptor mediation. Supported by NS 19296 and the Tx. Adv. Res. Prog., Grant 010674-020.

421.9

ENDOTHELIN-1 PRODUCES MEMBRANE DEPOLARIZATION ACTIVATING CALCIUM AND CHLORIDE CURRENTS THROUGH CYCLIC GMP DEPENDENT SYSTEM. T. Nishimura*1&2, T. Akasu*1, and J. Krier[2] Dept. of Physiol. Kurume U.[1] 67 Asahi-machi Kurume 830 Japan and Dept. of Physiol. Michigan State U.[2] E. Lansing, MI 48824

The ionic mechanism(s) underlying endothelin-1 (ET)-induced membrane depolarization of neurons was studied. Membrane currents in rabbit vesical pelvic ganglia were recorded in vitro using single electrode voltage clamp. Cells were impaled by electrodes filled with 2 M CsCl in a modified Krebs solution (36°C) containing 50 mM TEA, 2 mM CsCl and 300 nM TTX. At a holding potential of -60 mV ET (0.1-2 μM) induced an inward current (Iin; 0.2-2.6 nA) followed by an outward current (Iout; 0.1-1 nA). Iin and Iout were associated with increased and decreased membrane conductance respectively. In Ca-free solution Iin was reduced to 28±3% (n=6) of control, while Iout was blocked. Ca-insensitive Iin was blocked by 4-acetamido-4'-isothiocyanostilbene-2,2-disulphonic acid (0.5 mM; chloride channel blocker). Reversal potential of Iin, estimated by current-voltage relationship, were +42±3 mV (n=4) and -18±4 mV in normal Ca^{2+} (2.5 mM) and Ca-free solution, respectively. Effects of ET were mimicked by application of dibutyryl guanosine 3':5' cyclic monophosphate (db-cyclic GMP; 10-200 μM). Pretreatment of db-cyclic GMP (10 μM for 10 min) blocked endothelin-induced current responses. We conclude that ET activates both Ca^{2+} and Cl^- conductance through a cyclic GMP-dependent signal transduction system.

421.10

ON THE POTASSIUM CONDUCTANCE INCREASE ACTIVATED BY DOPAMINE IN THE JELLYFISH, *Polyorchis penicillatus*. **J. M. Chung and A. N. Spencer. Dept. of Zoology, Univ. of Alberta, Edmonton, Alta, Canada, T6G 2E9.**

The effects of dopamine (DA) applied by picospritzing onto cultured swimming motor neurons of *Polyorchis penicillatus* were examined using whole-cell recording technique. DA caused hyperpolarization and a decrease in the firing frequency. The hyperpolarizing effect of DA was accompanied by a fall in input resistance. Under voltage clamp, DA produced outward currents associated with a conductance increase and showed desensitization with prolonged agonist applications. The DA effects were concentration dependent (effective range 10nM to 100μM). The DA currents reversed polarity around -55mV close to the potassium equilibrium potential. Altering the K ion gradient across the membrane shifted the reversal potential of the response in a Nernstian manner. Taken together, the result strongly suggests the participation of K ions. The possibility of an increase in the Cl ion conductance is doubtful, because there are no shifts of the reversal potential as the Cl ion gradient across the cell changes. ***(NSERC grant A0419 to ANS.)***

PEPTIDES: PHYSIOLOGICAL EFFECTS III

422.1

EFFECTS OF A NEW TRH ANALOGUE, YM-14673 ON NEUROLOGICAL DEFICITS IN RATS SUBJECTED TO BOTH INTERNAL CAPSULE LESION AND MOTOR EXERCISE. M.Sasamata*, S.Kawasaki*, S.Yatsugi*, A.Iwai*, S.Kawabata, F.Wanibuchi, and M.Yamamoto*. Central Res. Labs., Yamanouchi Pharmaceutical Co. LTD., Tsukuba, Ibaraki 305, Japan.

Effects of YM-14673, a potent and long lasting new TRH analogue were studied in rats subjected to electrical destruction of the left internal capsule(IC) under the motor exercised condition.

In this model, neurological deficits such as hemiplegia, and decrease in amplitude of EMG activity evoked by electrical stimulation of the left sensory motor cortex were observed on the right legs. Both motor exercise using swimming, tread-mill or wheeling drum techniques, and drug administration started from 4 days after surgical operation and repeated once a day for 10-16 days. Motor exercise using wheeling drum technique accelerated the recovery of neurological deficits in IC rats. Furthermore, YM-14673 (0.03 mg/kg i.p.) accelerated the recovery of neurological deficits in IC rats both with and without motor exercise. These results suggest that the beneficial pharmacological properties of YM-14673 encourage the therapy in stroke patients with rehabilitation.

422.2

STEADY-STATE FEEDING INDUCED IN RATS BY PUSH-PULL PERFUSION OF NEUROPEPTIDE-Y (NPY) IN MEDIAL HYPOTHALAMUS: DOSE DEPENDENCE AND FOOD PALATABILITY. X. Paez* and R. D. Myers. Department of Pharmacol., School of Medicine, East Carolina University, Greenville, NC 27858.

When perfused in medial hypothalamic sites of unrestrained rats, NPY produces an apparent not-satiable feeding behavior. In these experiments, this region was perfused repeatedly with an artificial CSF, for 6 min intervals, by means of push-pull cannulae in rats given *ad lib* pelleted rat chow and chocolate biscuits. Two perfusions of 0.2 μg/min NPY induced marginal feeding only at the control level, (i.e., <2.0 g in 2.0 hr) but at a dose of 2.0 μg/min, the rat consumed 7.8±1.9 g of food over 2.0 hrs. A sequence of 10 perfusions of the lower dose NPY induced an intake of 14.2±2.0 g over 5.0 hrs, whereas the higher dose evoked an intake of 31.7±3.3 g over the same time interval. When rats were offered only chow during 10 perfusions of 2.0 μg/min NPY, they ate less (i.e., 5.0 - 13.0 g in 4.0 hr) than when chocolate biscuits were simultaneously available (i.e., 26.0-28.0 gm in 4.0 hr). Intakes of water during perfusion of the higher dose did not increase irrespective of the amount of food consumed by the rat. Thus, palatability of food interacts with the level of NPY in hypothalamic tissue to determine the magnitude of food intake induced by the peptide. Supported by NSF Grant 84-10063 to RDM.

422.3

GALANIN AND TRH EXCITE SPINAL DORSAL HORN NEURONS **K. Mirnics, Z. Korade and S. Jeftinija. Dept. Vet Anatomy, Iowa State Univ. Ames, IA 50011, USA.**

Galanin and thyrotropin-releasing hormone (TRH) were shown to be present in superficial laminae of the dorsal horn (DH), but the data regarding their physiological function are not available. In order to investigate the effect of these two peptides we employed a technique of intracellular recording from DH neurons in an in vitro horizontal spinal cord slice preparation. The preparation consisting of a rat spinal cord DH slice (300-500 μm thick) with intact dorsal roots (DR). Intracellular recordings from single DH neuron was performed with 3M K-acetate back-filled glass microelectrodes having DC resistance of 100-150 MΩ. Dorsal roots were stimulated by using bipolar platinum stimulation electrodes. The thresholds for activating large myelinated and small unmyelinated afferents have been determined by recording action potentials in DRG neurons and have been found to be 8-20V/0.02ms for the most sensitive axons and over 35V/0.5ms for C-fibers. Bath application of galanine (10^{-12}M to 10^{-6}M) produced a dose dependent depolarization in about half of the neurons tested (n=15). The depolarization was associated with an increase in membrane conductance and a very prolonged firing of action potential in some neurons (n= 5). In addition to increase in spontaneous firing, galanine had an facilitatory effect on synaptic activation evoked by dorsal root stimulation at intensities sufficient to activate myelinated and unmyelinated afferents. TRH produced depolarization was associated with increase in conductance and firing of action potentials. Work was supported by NIH grant NS27751 and USDA grant PL95-113.

422.4

MORPHINE MODULATES THE INDUCED RELEASE OF FMRF-NH-$_2$-LIKE PEPTIDE FROM RAT SPINAL CORD. J.M. Zhu and H.-Y.T. Yang Lab. of Biochem. Genetics, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032.

Several lines of evidence indicate that FMRF-NH_2-like peptide, FLFQPQRF-NH_2 (F-8-F-NH_2) isolated from bovine brain, may have a role in opioid mediated antinociception. In rat spinal cords, high density of F- 8-F-NH_2 immunoreactive terminals was detected in superficial laminae of dorsal horn and the presence of specific F-8-F-NH_2 receptors was also demonstrated. These studies suggest that F-8-F-NH_2 may function as neurotransmitter or neuromodulator in the spinal cords and effect of morphine on this secretion were studied by an in vitro superfusion procedure. The spontaneous release of F-8-F-NH_2 was high at the begining of the superfusion and then gradually decreased to a steady level of 7 fmol/ml in a calcium dependent manner when KCl in the perfusion medium was increased to 56 mM. The released F-8-F-NH_2 immunoreactivity was analyzed by HPLC followed with RIA and the main immunoreactivity released was found to be identical to the main immunoreactivity detected in the rat spinal cord extract. Addition of morphine to the perfusion medium was found to inhibit the 56 mM KCl induced release of F-8-F-NH_2 in a dose dependent manner. These results are in good agreement with the hypothesis that F-8-F-NH_2 may participate in opioid mediated antinociception.

422.5

SUBTYPES OF GUANINE NUCLEOTIDE-BINDING REGULATORY PROTEINS INVOLVED IN THE SUPPRESSION OF BARORECEPTOR REFLEX BY NEUROTENSIN IN THE RAT. Samuel H.H. Chan, M.J. Fu*, K.S. Lin* and Julie Y.H. Chan. National Yang-Ming Med. Coll., and Taipei Veterans General Hospital, Taipei, Taiwan, ROC.

We attempted to identify the subtypes of guanine nucleotide-binding regulatory proteins (G-proteins) that may underlie the suppressive effect of neurotensin (NT) on the baroreceptor reflex (BRR), using Sprague-Dawley rats that were anesthetized with pentobarbital sodium. Intracerebroventricular (i.c.v.) application of NT (15 nmol) significantly inhibited the BRR response. Such an inhibition was appreciably antagonized by pretreating animals with i.c.v. injection of pertussis toxin (10 or 20 pmol), which ADP-ribosylates Gi, Gp and Go; n-ethylmaleimide (1 or 2 nmol), which uncouples Gi from GTP by alkylation; forskolin (30 or 60 nmol), which activates adenylate cyclase; or phorbol 12-myristate-13-acetate (2 or 4 nmol), which stimulates protein kinase C; but not by cholera toxin (15 or 30 nmol), which ADP-ribosylates Gs. More specifically, the effects of these pretreatments on NT-induced suppression of BRR were essentially duplicated upon bilateral microinjection into the nucleus tractus solitarius of pertussis toxin (80 or 160 fmol), n-ethylmaleimide (16 or 80 pmol), forskolin (240 or 480 pmol), or phorbol ester (16 or 32 pmol); but not by cholera toxin (120 or 240 fmol). These results suggest that a pertussis toxin-sensitive G-protein(s), possibly Gi or Gp, may be involved in the suppression of BRR response by NT at the nucleus tractus solitarius.

422.6

EXCITATORY ACTION OF SOMATOSTATIN (SST) ON RAT AMBIGUAL MOTONEURONS *IN VITRO*. Y.T. Wang, R.S. Neuman & D. Bieger. Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada, A1B 3V6

The occurrence of SST in subnucleus centralis (NTS_c) neurons of the solitary complex has recently been reported. NTS_c neurons send a dense projection to the compact oesophagomotor subdivision of the ambiguus complex (AMB_c). Using intracellular recording with KCl (3M) or K-methyl-SO_4 (2M) filled microelectrodes from sagittal brainstem slices perfused at 32°C in a submersion chamber, we have investigated the effects of SST on AMB_c neurons. Pneumophoretic application of SST induced a) an immediate dose-dependent membrane depolarization with associated spiking, b) little or no change in membrane conductance, and c) an inward current recorded under voltage-clamp in the presence of TTX. There was no change in post-spike hyperpolarization and no evidence of desensitization with test intervals of 2 min.

We conclude that SST is a prime candidate for excitatory transmitter in the NTS_c-AMB_c pathway and that its role in oesophageal peristalsis merits further scrutiny.

RESPONSE OF NEURONS IN THE DORSAL MOTOR NUCLEUS OF THE VAGUS TO THYROTROPIN-RELEASING HORMONE (TRH). C.A. Livingston and A.J. Berger. Dept. of Physiology & Biophysics, Univ. of Washington School of Medicine, Seattle, WA 98195.

Preganglionic parasympathetic neurons of the dorsal motor nucleus of the vagus (DMX) regulate visceromotor activity. Using an *in vitro* slice preparation of the guinea pig brainstem, we determined the effects of TRH (one of numerous neuropeptides localized within the nucleus) on DMX neurons. Slices (350 μm thick) from caudal medulla were superfused with standard Ringer's solution, and the responses of DMX neurons to bath-applied TRH were recorded in current-clamp conditions. In all cells tested, TRH (5-10 μM) induced a reversible 2-18 mV (average, 9 mV) depolarization, typically accompanied by a decrease in membrane conductance, which persisted over many minutes. A similar response was evoked in the presence of low Ca^{2+}, high Mg^{2+} (Ca^{2+} spikes and Ca^{2+}-dependent K^+-currents abolished), indicating that TRH acts directly on these cells. TRH applied in the presence of 0.5 μM TTX or 0.5 μM TTX and 2 mM CsCl similarly depolarized these cells, suggesting that the response is not mediated exclusively via a TTX- or Cs^+-sensitive current. Evaluation of the I-V relations of the cells in the presence and absence of TRH indicates the reversal potential of the response to be -75 to -90 mV. We suggest that the TRH-induced depolarization of DMX neurons is due to a reduction of an outward cationic current. (Supported by NS 14857 and a Parker B. Francis Foundation Fellowship)

422.8

ANGIOTENSIN II AND SUBSTANCE P EXCITE NEURONS IN THE RAT MEDIAL NUCLEUS TRACTUS SOLITARII (mnTS) IN VITRO. K. L. Barnes, W. D. Knowles and C. M. Ferrario. Departments of Brain and Vascular Research and Neurology, Research Institute, Cleveland Clinic Foundation, Cleveland, OH 44195.

There is a striking congruence between the patterns of high affinity binding sites and neuronal elements immunoreactive for angiotensin II (Ang II) and substance P (SP) in the rat mnTS. Although both peptides influence autonomic function via this region, Ang II is thought to subserve cardiovascular function, while SP appears to exert broader sensory and autonomic effects. To examine whether these peptides act on the same or different neurons, we compared the effects of Ang II and SP on mnTS neurons recorded from in vitro slices of the rat medulla. Horizontal slices (400 μm) containing the mnTS were perfused with artificial cerebrospinal fluid (aCSF, 36°C). Extracellular recordings were obtained from 20 mnTS neurons during microdrop application of Ang II or SP (both 1 μM in aCSF) or aCSF onto the slice surface. Ang II substantially increased the firing rate of 8 of the 20 cells tested, while SP excited 10 of 14 cells given this peptide. The time course of the response to SP was similar to that for Ang II. No inhibitory effects were seen with either peptide. In 14 neurons the effects of Ang II and SP were compared. Three cells responded only to Ang II, 6 neurons were excited only by SP, 4 cells were excited by both peptides, and 1 neuron did not respond to either peptide. These studies reveal a partial overlap of the neuronal substrate that mediates the autonomic effects of Ang II and SP via the mnTS, and suggest that there may be interactions between Ang II and SP in certain pathways of the mnTS. (Supported in part by NHLBI grant HL-6835).

422.9

ANGIOTENSIN II INHIBITS GLUTAMATE-EVOKED DEPOLARIZATION OF LOCUS COERULEUS NEURONS IN VITRO

Huangui XIONG and Kenneth C. MARSHALL Dept. of Physiology, University of Ottawa, 451 Smyth Road, CANADA K1H 8M5

The effects of iontophoretically applied angiotensin II (AII) on intracellularly recorded locus coeruleus (LC) neurons were studied in transverse pontine slices from rats weighing 50-100 gm. The major effect of AII was a specific depression of the depolarization and resultant excitation produced by iontophoretic glutamate (Glu) application (39/47 neurons). Application of Na^+ ions with equal or higher currents had no effect on membrane potential or responses to glutamate. The action of AII was accompanied by a small hyperpolarization of the cell membrane potential in a few neurons. However, in most cells, the depression of Glu actions occurred in the absence of changes in membrane potential, or amplitude, duration or shape of the action potential. AII had no effect on excitation evoked by injection of depolarizing current, or by application of acetylcholine and thus appears to specifically inhibit Glu actions. The effects of AII on Glu excitations were antagonized by [Sar^1, Val^5, Ala^8]-AII in 9/12 neurons. The AII effects were not changed by superfusion with low Ca^{++}/high Mg^{++} (0.5 mM/10 mM) solution, indicating a postsynaptic site of action. These observations indicate that AII can exert a selective and potent inhibitory modulation of the postsynaptic actions of glutamate.

Supported by the Medical Research Council of Canada.

NEUROPEPTIDE Y (NPY) INHIBITS α_1-ADRENERGIC AND 5-HT_{1A} MEDIATED SYNAPTIC POTENTIALS IN DORSAL RAPHE *IN VITRO*. Samuel B. Kombian and William F. Colmers. Dept of Pharmacology, Univ. of Alberta, Edmonton, Alberta, CANADA T6G 2H7.

Because the (entirely extrinsic) noradrenergic innervation of the largely serotonergic dorsal raphe nucleus also expresses NPY, receptors for this peptide are found there, and NPY has been shown to inhibit transmitter release in several tissues, we examined the effects of NPY on synaptic potentials in dorsal raphe. Intracellular recordings were made with 2M KCl-filled microelectrodes of rat dorsal raphe nucleus neurons in submerged *in vitro* slices. Focal electrical stimuli from bipolar tungsten electrodes placed in the nucleus were used to evoke synaptic potentials. Fast excitatory amino acid (EAA) and $GABA_A$ potentials were succeeded by a slower, 5-HT_{1A} autoreceptor-mediated IPSP and an even slower, α_1 adrenoceptor-mediated EPSP.

The slow EPSP evoked by focal stimuli averaged 3.9±0.6 mV, and peaked at 1833 ± 50ms after the stimulus. This EPSP was completely eliminated by bath application of prazosin (100nM). Bath application of 1μM NPY caused a decrease in amplitude of the slow EPSP by 45.3 ± 9.6% (n=7, $P < 0.05$), which reversed fully upon washout of the peptide. The slow, 5-HT_{1A} autoreceptor-mediated IPSP was decreased in amplitude by NPY from 12.9 ± 1.1 mV to 10.6 ± 1.1 mV, a decrease of 18.6 ± 2.4% (n=7, $P < 0.001$). There was no significant change in the amplitudes of the fast synaptic potentials. NPY did not alter the resting membrane potential or input resistance of these neurons.

The results indicate that NPY may act to decrease the electrically-evoked release of noradrenaline from terminals in the dorsal raphe nucleus. Moreover, NPY appears to have a slight inhibitory effect on release of 5-HT from neurons within the dorsal raphe. The site and mechanism of NPY's actions in the dorsal raphe nucleus remain to be elucidated.

PRESYNAPTIC INHIBITION BY NEUROPEPTIDE Y (NPY) AND ADENOSINE IN RAT HIPPOCAMPUS IS BY A DIFFERENT MECHANISM THAN BACLOFEN. William F. Colmers and Gloria J. Klapstein. Dept. of Pharmacology, Univ. of Alberta, Edmonton, Alberta, CANADA T6G 2H7.

NPY presynaptically inhibits excitatory transmission between stratum radiatum and CA1 pyramidal cells. This can be prevented with 4-aminopyridine (4-AP); however, reducing extracellular calcium restores NPY's inhibition, suggesting that it inhibits some, but not all, calcium channels in presynaptic terminals (Colmers, et al, J. Neurosci 8:3827 [1988]). $GABA_B$ and adenosine A_1 receptors also mediate presynaptic inhibition at this synapse. We therefore examined whether these two receptors acted via a mechanism similar to that postulated for NPY.

Population spikes (PS), evoked by orthodromic electrical stimulation of stratum radiatum (70-90% of maximum response) were recorded with extracellular microelectrodes in the CA1 pyramidal cell layer of submerged transverse slices of rat hippocampus. Bath application of 1μM NPY, caused a reversible reduction of 93% in PS amplitude, which was reduced to only 26% in the presence of 30 μM 4-AP, and restored to 67% by 0.75mM extracellular Ca^{++}. Although 4-AP caused a small reduction in the effect of 10μM baclofen, from 97% to 76%, low Ca^{++}-4-AP had no significant effect. By contrast, no effect was seen with these treatments on the effect of 3 μM 2-CA. To more carefully examine this, dose-response relationships for NPY, baclofen and 2-CA were constructed in saline, in 4-AP and low Ca^{++}-4-AP. While 4-AP shifted the dose-response curve for NPY, 2-CA and baclofen rightward in a parallel manner, lowering Ca^{++} in the presence of 4-AP caused a parallel leftward shift only to NPY and 2-CA, while the 4-AP mediated rightward shift in the dose-response curve for baclofen was not shifted leftward by low Ca^{++}-4-AP.

The results indicate that in hippocampal CA1, presynaptic NPY and adenosine A_1 receptors may share similar mechanisms, while the presynaptic $GABA_B$ receptor may act via different mechanism than the others.

CELLULAR EFFECTS OF ATRIAL NATRIURETIC PEPTIDE ON VASOPRESSIN NEURONS. K.M. Hurley and C.B. Saper. Depts. of Pharm. & Physiol. Sci. and Neurology, Univ. of Chicago, Chicago, IL 60637.

Atrial natriuretic peptide (ANP) is a potent natriuretic and diuretic hormone that also acts as a central neuromodulator. Systemically, ANP opposes virtually all of the effects of arginine vasopressin (AVP). Intraventricular ANP administration inhibits the secretion of AVP from the posterior pituitary gland. Application of ANP in femtomole doses to AVP neurons in the paraventricular nucleus increases the intervals between bursts of neuronal firing and shortens burst duration, but the mechanism of this effect is not known. We recorded intracellularly from magnocellular neurons in the supraoptic and paraventricular nuclei in 350-400 μm slices through the rat hypothalamus. Micropipettes were filled with a 4% solution of biocytin in 0.5 M KCl-0.05 M TRIS buffer. At the end of each experiment, cells were filled iontophoretically with biocytin and cell type was verified by combined FITC-immunofluorescence for AVP and Texas Red-streptavidin for biocytin. Cells had an input resistance in the range of 130-160 MΩ, membrane potential of -60 to -80 mV and action potential amplitudes of 60-80 mV. Membrane conductance was monitored by 2Hz, 30 ms current pulses of -0.2nA. ANP (0.01-10 fm) applied to the surface of the slice resulted in a decrease in membrane conductance and complex changes in membrane potential and cell firing pattern. Similar mechanisms may modulate AVP release in vivo.

LIGHT/DARK RHYTHM OF NEUROPEPTIDE Y-LIKE IMMUNOREACTIVITY IN DISCRETE HYPOTHALAMIC NUCLEI. **M. Jhanwar-Uniyal, B. Beck, C. Burlet[a] and S.F. Leibowitz. The Rockefeller Univ. New York, NY 10021 and Faculte de Medicine, INSERM U.308, Nancy (France).**

Neuropeptide Y (NPY), a putative neurotransmitter abundant in the paraventricular nucleus (PVN) of the hypothalamus, induces a robust eating response, in particular carbohydrate intake, which is strongest specifically at the onset of the active cycle. Moreover, evidence indicates that NPY modulates circadian rhythms of activity level. In this study, we investigated whether endogenous NPY, measured in 9 hypothalamic nuclei, may itself vary in relation to the light/dark cycle.

Sprague-Dawley rats were kept on a 12:12 hr light:dark cycle, with lights out at 19:00 hr. They were sacrificed at one of the following times: 1 hr before dark onset (18:00 hr); 1 hr after dark onset (20:00 hr); in the middle of dark cycle (01:00 hr); at light onset (07:00 hr); and in the middle of the light period (13:00 hr). Nine hypothalamic sites, namely, PVN (P; parvocellular), PVN (M; magnocellular), suprachiasmatic (SCN), arcuate (ARC), dorsomedial, ventromedial, supraoptic nuclei, median eminence (ME) and perifornical lateral hypothalamus, were micropunched and assayed for NPY content via RIA.

The results demonstrated that: 1) NPY content in the PVN (P), but not PVN (M), rose significantly 1 hr before the dark cycle ($F_{4,35}=2.78$; $P<0.05$), declined reliably within 1 hr after dark onset, and remained low thereafter; 2) NPY levels in the SCN peaked at two time points, at dark onset and also at light onset ($F_{4,30}$ 6.43; $P<0.001$). 3) NPY levels in the ARC exhibited a similar pattern to those detected in the SCN ($F_{4,34}=3.15$; $P<0.02$). 4) No other hypothalamic sites showed any significant temporal variation in NPY content. Based on these results and other behavioral findings, it is postulated that NPY acts physiologically in relation to the light/dark cycle, and that NPY in the parvocellular region of the PVN is involved in the control of natural feeding behavior at the onset of the dark (active) period.

THE EFFECT OF LHRH ON ^{45}Ca-UPTAKE AND IP ACCUMULATION IN RAT HIPPOCAMPUS T.L.Thompson and R.L.Moss. Dept. of Physiology, Univ. of Texas Southwestern Medical Center, Dallas, TX 75235

Luteinizing hormone releasing hormone (LHRH) receptors have been localized to discrete brain areas with the highest concentration being found in the hippocampus: the density of these receptors is very sensitive to estrogen priming. Intracellular recording data from our lab have shown that LHRH has a long acting modulatory effect on CA1 hippocampal neurons. We have initiated a series of experiments designed to elucidate which biochemical processes (second messenger systems) are affected by LHRH-receptor activation in the hippocampus; specifically examining the effect of LHRH treatment on ^{45}Ca-uptake and inositol phosphate (IP) accumulation. Hippocampal slices or minces were prepared from ovariectomized Spraque-Dawley rats. Slices were exposed to ^{45}Ca in the presence of 10^{-12}M-10^{-6}M LHRH In some experiments LHRH antagonists were added prior to the LHRH. LHRH caused a modest (15%-30%) but significant increase in ^{45}Ca-uptake. This response could be effectively blocked by Nal-Glu-LHRH (a LHRH antagonist). A 48hr priming with 5ug estradiol benzoate (EB) had no apparent effect on the absolute magnitude of the LHRH response. IP accumulation was measured in response to LHRH (10^{-6}M-10^{-10}M) in the presence of 10mM LiCl. Total IP accumulation was determined by ion exchange chromatography. LHRH caused a significant increase in IP accumulation; as much as 80% above control. This accumulation was partially inhibited by pretreatment with Nal-Glu-LHRH. EB priming resulted in a decrease in the LHRH induced increase of IP accumulation.

These preliminary findings suggest that LHRH activation of receptors in the hippocampus results in an increase in ^{45}Ca influx and IP accumulation. This is similar to that observed in the pituitary in response to LHRH. In addition, there is an indication that estrogen may modulate some of the cellular responses to LHRH in the hippocampus. INSULIN INDIRECTLY STIMULATES PI TURNOVER IN RAT HIPPOCAMPUS (H). D. Figlewicz Lattemann and P. Szot.Depts. of Psychology and Medicine, Univ. Wash. and VA Med. Center, Seattle, WA 98195.

Insulin (INS) reportedly stimulates phosphorylation of two kinase-C substrate proteins in rat H. We tested whether INS stimulates PI turnover, a mechanism of kinase-C activation, in H slices. INS significantly stimulated formation of inositol phosphate (IP_1), IP_2, and diacylglycerol. 500 nM tetrodotoxin (TTX) suppressed INS-stimulated IP release, suggesting mediation by an endogenous transmitter. As INS and norepinephrine (NE) (via a-1 receptors) have similar electrophysiologic effects in rat H, we tested the a-1 antagonist prazosin (PRZ). PRZ (1 μM) stimulated IP release slightly, but reduced INS-stimulated IP release to levels similar to those with PRZ alone.

	CHANGE FROM CONTROL LEVELS, 3H-IP DPM		
INS,	0 (CONTROL) +TTX +9±17	+PRZ +141±46	
(nM)	5 +239±84	------	+93±29
	10 +204±92	-31±36	+129±47
	100 +78±30	-35±53	------

CONCLUSION: INS stimulation of PI turnover in rat H may be mediated via endogenous NE and activation of a-1 adrenergic receptors.

SEXUAL DIMORPHISM IN VASOPRESSIN-MEDIATED NEUROTRANSMISSION. D. Albeck, T. Smock, S. Arnold*, K. Raese*, K. Paynter*, and S. Colaprete. Center for Neurosciences, Department of Psychology, University of Colorado, Boulder, Colorado 80309.

A peptide similar to vasopressin or oxytocin acts as a neurotransmitter in the rat hippocampus (Brain Res., 1990, 511:7 and 15). Antisera to arginine vasopressin recognize this peptide and the pathway has been studied extensively by immunocytochemistry and other tract-tracing techniques. The peptide fibers originate in the medial amygdala and are present in greater density in males than females. The peptide is depleted completely by castration of males and is restored after testosterone replacement (DeVries et al., J. Comp. Neurol., 1985, 233:236). Here we report that peptidergic transmission, mediated by the vasopressin-like peptide, is also sexually dimorphic and eliminated by castration.

In 27 male rats, the medial amygdala was electrically stimulated to release the peptide into the hippocampus. The evoked population spike in acute field potential recording was depressed (n = 7). Individual pyramidal cells were inhibited in single unit recording (n = 17) and individual interneurons were excited (n = 3). In all of seven trials, the effect of the released peptide was blocked by a structural vasopressin/oxytocin antagonist.

Sixteen males were compared with ten females in acute field potential recording. Both females and males responded to the stimulation in the same way, but the hippocampal response in males endured longer (23 ± 6 min) than the signal in females (11 ± 6 min, $p < 0.05$). Fifteen normal males were compared with five males castrated 15 weeks previously. The peptidergic signal was not detectable in the castrates (different from normals, $p<0.02$).

The behavior of fifteen males was observed upon bilateral AME stimulation. There was a change consonant with the involvement of this system in sexual behavior.

Thus, results from physiology parallel those from anatomy that reveal sexual dimorphism and steroid dependence in this brain peptidergic system. Supported by MH45202.

OPIOID PEPTIDES REDUCE POSTSYNAPTIC POTENTIALS IN A SLICE PREPARATION OF NUCLEUS ACCUMBENS (NAcc). X. Yuan*, S. Madamba* L. Koda and G. R. Siggins, Dept. Neuropharmacology, Scripps Clinic Res. Inst., La Jolla, CA 92037.

The NAcc is of interest because of its suggested role in reward mechanisms and, possibly, opiate and cocaine abuse (Koob and Bloom, Science 242:715, 1988). This region contains abundant levels of opioid peptides, including enkephalins, dynorphins and endorphins. Therefore, we developed an in vitro slice preparation of NAcc and tested the effects of superfusion of opioid peptides on NAcc neurons. Intracellular recordings of these neurons revealed that many have unusual membrane properties, including: 1) large resting membrane potentials (avg. -81 mV; range: -68 to -94 mV; 24 neurons); 2) anomalous rectification, resulting in a 'sag' of the electrotonic potential generated by hyperpolarizing current steps; and 3) a time-dependent 'ramping' response to depolarizing current steps, resembling the effect of the D-current (Storm, Nature 336:379, 1988) of hippocampal neurons. However, other cells show a more linear I-V curve, suggesting the presence of more than one NAcc neuron type. Input resistances averaged 51 MΩ. We found little effect of superfusion of several enkephalin analogues, D-pen^2, D-pen^5 enkephalin (a δ opiate receptor agonist; n = 7), DAGO (a selective μ receptor agonist; n = 7), or D-ala^2, D-leu^5 enkephalin (a broad spectrum μ/δ agonist; n = 1) on either membrane potential or input slope resistance, at 1-2 μM. However, all of these opioids dramatically reduced postsynaptic potentials (to 41% of controls; n = 6) evoked by afferent stimulation in the area ventral to the NAcc. These results suggest that the major role of opioid peptides in this region is to reduce synaptic transmission. (Supported by NIDA grant DA 03665.)

VASOACTIVE INTESTINAL POLYPEPTIDE MODULATES ROD BIPOLAR CELL RESPONSES TO INHIBITORY RETINAL NEUROTRANSMITTERS. M.L. Veruki and H.H. Yeh, Program in Neuroscience and Dept. Neurobiology & Anatomy, Univ. Rochester Med. Ctr., 601 Elmwood Avenue, Rochester, NY 14642.

Studies from our laboratory indicate that, in the rat retina, vasoactive intestinal polypeptide(VIP)-like immunoreactivity is localized to amacrine cells. Even though ultrastructural data is as yet lacking, their processes ramify extensively in the inner plexiform layer and should thus be in a position to influence synaptic interactions in the inner retina. Here, we tested the effects of VIP on rod bipolar cells of the rat retina.

Isolated rod bipolar cells were obtained by gently triturating papain-incubated whole retinas and conventional whole-cell patch-clamp procedures were employed to examine their responses to agonists under voltage-clamp. In initial experiments, pressure application of VIP (≤100 uM) elicited no detectable currents and it was thought that the neuropeptide had no effect on rod bipolar cells. However, in subsequent experiments, the amplitude of rod bipolar cell current responses to brief (50-300 ms) pulses of either GABA (20 uM; n=7) or glycine (100 uM; n=6) were consistently augmented during concomitant exposure to 10 uM VIP. At this concentration, VIP by itself had no effect on membrane conductance. In contrast, VIP effects on GABA- and glycine-induced currents in isolated ganglion cells were relatively unpredictable, although an attentuation of responses to the inhibitory transmitters was frequently observed. It is proposed that one action of VIP may be to modulate the excitability of inner retinal neurons. With specific regard to the rod bipolar cells, such a modulation may serve to enhance the efficacy of inhibitory feedback inputs mediated by GABA or glycine.

TRH STIMULATES INOSITOL PHOSPHATE (IP_X) RELEASE IN RAT RETINA. A. Sattin, B. Anderson*, M.J. Kubek. Depts. of Psychiatry and Anatomy, VA and Indiana Univ. Med. Centers, Indianapolis, IN 46202-4887.

Last year we reported here small increases (10-20% over baseline) in IP_X release in rat hippocampal slices using 10 nM TRH in the presence or absence of Lithium, 10 mM. Retina is a CNS structure that is also known to contain TRH and its receptors. After a 1 hr. load-up with myo-(2-^{3}H) inositol followed by a 20 min. chase with cold myo-inositol, and then a 15 min. preincubation in 10 mM Li^+, individual retinal tissues were incubated for 30 min. more without and with 10 nM TRH. Reaction was stopped by freezing the tissue in quick-transfer holders, then extracting in chloroform-methanol. ^{3}H-IP's were separated from ^{3}H-I chromatographically and total DPM's were obtained from the chloroform fraction, tissue IP's, tissue I and medium I. Results were expressed as percent of DPM's in IP's to total of DPM's of all other fractions from each sample. Results cumulate the data from three incubations. Basal IP_X in Long-Evans rats was 4.0 ± 0.9 (SEM) (N=13) vs. 5.5 ± 1.0 (N=13) with TRH (38% increase, $P < 0.0019$). Basal IP_X in Sprague-Dawley rats was 3.9 ± 0.8 (N=8) vs. 8.2 ± 1.5 (N=8) with TRH (110% increase, $P < 0.0036$). These may be the largest IP_X release effects of TRH so far reported in CNS. D-E curves and strain comparison will be pursued. Supported by VA Res. Serv.

OPIOIDS: ANATOMY AND PHYSIOLOGY I

423.1

ENDOGENOUS OPIOIDS RELEASED FROM PERFORANT PATH MODULATE NOREPINEPHRINE RELEASE AND IPSP AMPLITUDES IN GUINEA PIG CA3 PYRAMIDAL CELLS. **R.M. Caudle, J.J. Wagner*, C. Chavkin, Dept. of Pharmacology, University of Washington., Seattle, WA 98195.**

Our previous work demonstrated that pharmacologic depolarization or electrical stimulation of opioid containing pathways in hippocampal slices could release endogenous opioids to displace either [3H]-diprenorphine or [3H]-DAGO binding. In this study we demonstrate that endogenous opioids were released by perforant path (PP) stimulation to affect synaptic potentials recorded in CA3 pyramidal cells. CA3 pyramidal cells were impaled in perfused guinea pig hippocampal slices. Synaptic potentials in pyramidal cells were evoked by stimulation of the MF(150-400 μA, 0.033 Hz). A single stimulus train (150 μA, 10 Hz, 5 s) in the PP produced a small depression in IPSP conductance that lasted for approximately 15 min. The percent change when compared to unstimulated controls was -11.1 ± 8 (N=13,p<0.05). When naloxone (100 nM) was added to the bath and the PP was stimulated a large increase in conductance was observed (43.5 ± 27 % change, p<0.05, N=13). Following PP stimulation, the naloxone-induced change in IPSP conductance was delayed and prolonged: no effect was seen until 3.0 ± 0.6 min after stimulation; time to peak was 5.6 ± 0.9 min; total duration was 6.4 ± 1.0 min. The increase in IPSP conductance was specific to perforant path stimulation. Bath applied propranolol (1 μM, N=10) or pretreatment of the guinea pigs with reserpine (5 mg/kg, N=6) blocked the increase in IPSP conductance. These findings suggest that endogenously released enkephalin regulates the release of norepinephrine and that endogenously released norepinephrine enhances IPSP conductance in the CA3 region of guinea pig hippocampus. Supported by DA04123.

423.2

NALOXONE BLOCKS THE INDUCTION OF FOS-LIKE IMMUNOREACTIVITY IN THE HIPPOCAMPAL FORMATION AND CORTEX. J.L. Martinez, Jr., D.N. Lieberman, M.P. Jasper, O.I. Petukhova*, B.E. Derrick, and F.R. Sharp, Dept. of Psych., Univ. of Calif., Berkeley, CA, 94720 and Dept. of Neurol., Univ. of Calif., San Francisco, CA, 94121.

Long-term potentiation at the mossy fiber (MF)-CA3 synapse is blocked by mu opioid receptor antagonists (Lieberman et al., this volume). As a prelude to investigating the involvement of c-fos in MF LTP, we examined the effect of naloxone on the induction of fos-like immunoreactivity (FLI) in hippocampus in vivo following MF stimulation in pentobarbital anesthetized rats. Single pulse MF stimulation and/or the disruption following placement of electrodes into the CA3 region and DG induced high levels of FLI in the DG, CA fields and cortex. Five μmols of naloxone delivered unilaterally into the CA3 pyramidal layer during MF stimulation completely blocked induction of FLI in all brain areas when measured 1.5 hrs later. Activation of opioid receptors therefore may be important for expression of FLI following cellular disruption by implantation and stimulation. Since c-fos is implicated in the regulation of the proenkephalin gene in DG granule cells, naloxone inactivation of FLI induction suggests there may be a regulatory coupling between opioid receptor activation and the proenkephalin gene.

423.3

DIFFERENT G PROTEINS MEDIATE THE OPIOID INHIBITION OR ENHANCEMENT OF EVOKED METHIONINE-ENKEPHALIN RELEASE. H. Xu and A.R. Gintzler. Department of Biochemistry, SUNY Health Science Center at Brooklyn, Brooklyn, NY 11203.

This laboratory has previously demonstrated that there is an opioid receptor mediated enhancement and inhibition of the electrically stimulated release of methionine-enkephalin (enkephalin) from the guinea pig myenteric plexus. Low doses (nanomolar) enhance, whereas higher concentrations (10-100 nM) inhibit release. We now demonstrate that the islet-activating protein from pertussis toxin (PTX; 50 ug i.p./500g for 6 days) can abolish the ability of mu, delta and kappa-selective opioids to inhibit the evoked release of enkephalin. In contrast, PTX is without effect on the enhancement of enkephalin release observed following treatment with nanomolar concentrations of the above opioids. Conversely, pretreatment with cholera toxin (CTX; 10^{-11}M for 3 hrs in vitro) has no effect on the mu, delta or kappa opioid inhibition of evoked enkephalin release but abolishes the ability of nanomolar concentrations of these agonists to enhance stimulated enkephalin release. These data further differentiate the signal transduction process responsible for each opioid effect. Furthermore, they suggest that a PTX-sensitive G protein (G_i or G_o) and a CTX-sensitive G protein (G_s) are integral components of the mechanism that mediates opioid inhibition and opioid enhancement, respectively, of evoked enkephalin release.

423.4

STIMULANTS OF PROTEIN KINASE C STIMULATE IMMUNOREACTIVE BETA-ENDORPHIN SECRETION FROM DISSOCIATED FETAL HYPOTHALAMIC CELL CULTURES. L.P. Kapcala and Horng-Heng Juang*. University of Maryland School of Medicine, Baltimore, MD 21201

Relatively little is known about the regulation of secretion of hypothalamic β-endorphin, the potent opioid which is believed to play a variety of physiological roles in brain. Previous work has shown that vasopressin, which acts in brain primarily through activation of the phosphoinositol second messenger system, stimulates secretion of hypothalamic β-endorphin. We tested the hypothesis that stimulants of protein kinase C (PKC), which is activated following hydrolysis of phosphatidylinositol-bis phosphate, stimulate secretion of β-endorphin from hypothalamus. We studied the separate effects of stimulants of PKC including phorbol myristate acetate (PMA), and oleolyl-acetylglycerol (OAG), a diacylglycerol analogue, on secretion of immunoreactive (IR-)β-endorphin (RIA) from dissociated fetal rat hypothalamic cell cultures. PMA (10^{-8}, 10^{-6} M) produced a dose-dependent stimulation of IR-β-endorphin release consisting of a peak IR-β-endorphin increment of approximately 50% over control secretion. OAG (10^{-8} M) also stimulated IR-β-endorphin secretion.

Conclusion: Hypothalamic β-endorphin secretion can be stimulated by activation of the phosphoinositol second messenger system, presumably at least via stimulation of PKC.

423.5

EFFECT OF SPECIFIC OPIATE RECEPTOR-SUBTYPE AGONISTS AND ANTAGONISTS ON THE RELEASE OF VASOPRESSIN AND OXYTOCIN. B.J.M. van de Heijning*, H. Rigter and Tj.B. van Wimersma Greidanus*. Rudolf Magnus Institute, Utrecht, The Netherlands.

Various endogenous opioid peptides affect the secretion of vasopressin (VP) or oxytocin (OT) from the neural lobe. As very specific (ant-)agonists to the opiate receptor subtypes μ, κ and δ are now available, the assessment of the subtype(s) involved in neurohypophyseal hormone release became possible. Male Wistar rats (200 g), 24 hr water-deprived, were injected sc and decapitated. Plasma levels of VP and OT were determined by RIA in trunk blood. No effect on either hormone was found 30 min after application of the δ-agonist DPDPE (dose 0.01-5 mg/kg). However, the μ-agonist DALDA (Schiller 1989, J.Med.Chem.32, 698) applied in the same dose range strongly inhibited the release of both VP and OT, an effect that was maximal 30-60 min after injection. The κ-agonist U-69,593 induced a similar effect: VP plasma levels even became undetectable. The time-response curve showed a maximal effect 30 min after application of the compound. Antagonism of endogenous opioids by the δ-antagonist naltrindole (dose 0.01-10 mg/kg) did not affect the release of either hormone, whereas both the κ-specific antagonist nor-binaltorphimine, and the relative μ-specific antagonist naloxone selectively enhanced OT plasma levels and not VP levels.

This indicates a selective and endogenous inhibition of the OT release mediated by κ-agonistic opioids (e.g. dynorphins) although μ-agonistic opioids might be involved as well. Furthermore, the κ- and μ-opioid receptors seem to play an important role in regulating the secretion of both VP and OT from the rat neural lobe.

423.6

EFFECTS OF ESTRADIOL ON MORPHINE-INDUCED CHANGES IN CYCLIC AMP ACCUMULATION IN NEUROBLASTOMA CELLS. A.Ratka[1], G.Hohchaus[2], J.W.Simpkins[1], Depts of Pharmacodynamics[1] and Pharmaceutics[2], University of Florida, Gainesville.

A phenotypically stable neuroblast subclone, SH-SY5Y, of the neuroblastoma cell line which express mu and delta opioid receptors was used. In this cell model the function of opioid receptor system was assessed by measuring cyclic AMP (cAMP) accumulation. Cells differentiated with retinoic acid (10uM) and treated with 1uM of prostaglandin E_1 (PGE_1) showed about 100 fold increase in cAMP level. When morphine (10uM) was given toghether with PGE_1, cAMP accumulation decreased significantly from 103.32±24.42 to 11.51±2.33 pmol/mg protein. In contrast to the acute effect of morphine 6 days of exposure to the opiate did not change the response of cells to the effect of PGE_1 on cAMP level. Further, chronic treatment with morphine prevented the inhibitory effect of acute morphine treatment on cAMP. Exposure of cells for 48 hrs to estradiol in doses of 5nM or 50nM did not change PGE_1-induced increase in cAMP accumulation. Moreover, in cells pretreated with either dose of estradiol, the suppressing effect of morphine was not changed. Treatment with 5nM of estradiol for 6 days potentiated cells response to PGE_1 from 103.07±15.82 to 178.24±16.53 pmolcAMP/mg protein. The inhibitory effect of morphine on cAMP was significantly less pronounced after 6 days than after 48 hrs exposure to estradiol (47.80±5.20 vs 25.76±3.21 pmol/mg protein of cAMP, respectively). We conclude that under in vitro conditions short-term treatment with estradiol has no effect, while chronic exposure to estradiol enhances the stimulatory effect of PGE_1 and reduces morphine-induced suppression of cAMP accumulation in cells which express mu and delta opioid receptors.

A NOVEL OPIOID CONTROL OF PROLACTIN SECRETION IN IMMATURE RATS S. Blackford and C. Kuhn. Dep't of Pharmacology, Duke University Medical Center, Durham, NC 27710.

The present study explores developmental changes in mu and kappa opiate receptor control of prolactin (PRL) secretion. The ontogeny of mu and kappa receptor function was determined by assessing the PRL response to the mu agonist sufentanil (SUF,.02 mg/kg, s.c.) and the kappa agonist U50488 (1 mg/kg, s.c.) in 5, 10, 15 and 20 day old rats. Both mu and kappa agonists stimulated PRL secretion at all ages. SUF action was selectively blocked by the mu antagonist beta-funaltrexamine and U50488 was selectively blocked by the kappa antagonist nor-binaltorphimine. Serotonin mediation of opiate-induced changes in PRL secretion was explored across ontogeny by testing cyproheptadine (CYPRO, 10 mg/kg) blockade of agonist responses in 5, 10, 20 and 60 day old rats. CYPRO attenuated the PRL response to the mu agonist SUF (.02 mg/kg, s.c.) in 20 and 60 day old rats, but not in the 5 or 10 day old pups. CYPRO did not block the kappa agonist U50488 (1 mg/kg s.c.) at any age. These results confirm the existence of a serotonin-mediated mu control of PRL secretion in older rats and a kappa control of PRL secretion that is independent of serotonin at all ages. Most interestingly, the results reveal a third control: an early developing serotonin-independent mu response. Supported by DA 02739.

Endogenous Opioid Regulation of Cell Proliferation in the Developing Rat Retina. T. Isayama, P.J. McLaughlin, and I.S. Zagon, Penn. State Univ. Coll. Med., Hershey, PA 17033.

The role of endogenous opioid systems in regulating cell proliferation in the developing retina was examined in 1-day-old rats. Met-enkephalin (MENK), naltrexone (NTX), or a mixture of MENK and naloxone (NALX) were administered to experimental animals; controls received sterile water. After three and one-half hours, animals were injected with 10 uCi/g of [^{3}H]thymidine and sacrificed one-half hour later. The labeling index of DNA-synthesizing cells within the germinative layer (GL) of the developing retina was determined from autoradiograms. A labeling index of 35.8% was obtained for control retinas. MENK-treated animals had a 10.6% decrease in the percentage of proliferating cells in comparison to controls, while an increase of 6.5% was seen in the NTX-treated retinas; MENK-NALX-treated retinas exhibited no change. Immunocytochemical preparations of the 1-day-old rat retina showed that MENK-immunoreactivity was abundant in the ganglion cell layer (GCL), and also present in the GL. These data suggest that opioids are present in the retina and act as natural inhibitory trophic factors to tonically govern cell replication in the developing eye.

PRESENCE OF ZETA (ζ), A GROWTH-RELATED OPIOID RECEPTOR, IN RAT CEREBELLUM. I.S. Zagon, D. Gibo*, and P.J. McLaughlin. Penn. State Univ. College of Medicine, Hershey, PA 17033.

Interaction between endogenous opioids and opioid receptors have been shown to regulate cell proliferation in the developing rat brain. [Met^5]-enkephalin (ME) is a very potent endogenous peptide which serves as a trophic factor that inhibits cell replication. [^{3}H]-ME was used to probe the binding site of 6-day old rat cerebellum. Specific, high affinity, and saturable binding to [^{3}H]-ME was recorded in cerebellar homogenates; Kd=2.0±0.3 nM, Bmax=23.1±1.7 fmol/mg protein. Binding isotherms were linear with protein and dependent on time, pH, temperature, and a cocktail of protease inhibitors. Addition of Na+, Mg++, and guanyl nucleotides reduced binding; trypsin eliminated binding, suggesting a proteinaceous binding site. Competition studies using a wide variety of endogenous and exogenous opioids, including those selected for other opioid receptor subtypes, revealed that ME was the most selective ligand for the binding site. These results indicate the presence of a new opioid binding site, zeta (ζ), in the developing nervous system which is related to cell proliferation. Supported by NIH grant NS20500.

ENDOGENOUS OPIOID SYSTEMS ARE PRESENT AND REGULATE THE GROWTH OF BACTERIA. P.J. McLaughlin, W.J. Lutz*, and I.S. Zagon. Penn. State Univ. College of Medicine, Hershey, PA 17033.

Endogenous opioid systems are present in many different eukaryotes. Interaction of endogenous opioids and opioid receptors has been shown to tonically regulate growth of neural systems, with endogenous opioids acting as inhibitory trophic factors. Little information exists on opioids and the growth of prokaryotes. Using *Staphylococcus aureus* grown in liquid broth, effects of 10^{-6}M methionine enkephalin (ME), a potent opioid agonist, 10^{-6}M naltrexone (NTX), a potent opioid antagonist, or sterile water (CO), on growth of log phase cultures were determined. Turbidity readings (650_{OD}) and colony counts indicated that ME significantly depressed growth of *S. aureus*; naloxone blocked the inhibitory action of ME. NTX increased growth rates. Receptor binding assays demonstrated the presence of specific and saturable binding to [^{3}H]-ME; Kd=1.7 nM, Bmax=190 fmol/mg protein. Radioimmunoassays revealed ME in media after 24 hr in culture. Growth of bacterial strains such as *Pseudomonas aeruginosa* and *Serratio marcesans* also were regulated by endogenous opioid systems. These studies demonstrate the presence of endogenous opioids and opioid receptors in prokaryotic cells, and suggest that their interaction may regulate growth of bacteria. EFFECTS OF U- AND K-AGONISTS ON THE INTRACELLULAR FREE CALCIUM IN ISOLATED RAT MYOCYTES. X.D. Huang*, K. Tsou and T.M. Wong*. Department of Physiology, University of Hong Kong, Hong Kong.

U-(Wong et al. unpublished) and k-agonists (Wong and Lee, Neurosci Lett 77, 61-66, 1987) have been shown to induce arrhythmias in the isolated perfused rat heart. Since alterations in calcium fluxes are related to arrhythmogenesis, we studied the effects of these two agonists on intracellular free calcium (Ca_i) in isolated myocyte with a spectrophotometric method using fura-2 AM as the florescence indicator. Isolated myocytes were prepared from hearts of female Sprague Dawley rats of 100-150 g according to the method of Young and Scarpa (FEBS Lett, 223,53-58, 1987). U-agonists, D-ala^2, NMe^4, Gly-ol)-enkephalin (Peninsula lab.) and morphine and k-agonists, dynorphin$_{1-13}$ (Peninsula Lab.) and U50,488H (UpJohn Co.) increased Ca_i. The effect was blocked by their respective antagonists, naloxone (DuPont Pharmaceutical Co.) and MR 2266 (Boehringer Ingelheim), which did not produce any effect themselves. Chronic injection with morphine at increasing doses to rats according to the procedure of Wong and Lee (Neurosci Lett, 77,61-66, 1987) or addition of morphine (100 μM) to cultured isolated myocytes at 12 h before experiment also abolished the effect of morphine in elevating Ca_i. The results of the present study showed that μ- and k-agonists increase the Ca_i via opioid receptors on the membrane of myocytes. Such effect is probably responsible for their arrhythmogenic action in the isolated perfused rat heart. (Supported by a Croucher Foundation Grant to T.M.W.. MR 2266, naloxone and U50,488H were kindly supplied by Boehringer Ingelheim Co., DuPont Pharmceutical Co. and Upjohn Co., respectively).

EXPRESSION OF PROENKEPHALIN A PEPTIDES IN ADRENAL AND EXTRA-ADRENAL TISSUE OF FETAL AND ADULT RABBITS. J. Padbury, A. Martinez*, E. Burnell*, S. Thio*, D. Habib* and B. Chappell*. Harbor-UCLA Medical Center, Torrance, CA 90509.

The adrenal medulla contains large quantities of enkephalin (ENK) peptides. There is little developmental data on ENK peptides in adrenal or extra-adrenal tissue. We measured free MET-ENK, total ENK and CA in fetal adrenal (FAd) and fetal extra-adrenal tissue (FEAd) in rabbits (age 29 days, n=38) and adult adrenal (AAd, n=5). MET-ENK was measured by RIA, Total ENK after digestion with trypsin and carboxypeptidase B, and CA by radioenzymatic assay. ENK results are in ng/gland and CA in mcg/gland (Mean ± SEM).

	MET-ENK	Total ENK	MET/TOTAL	NE	EPI
(FAd)	2±.1	3±.3	.4±.03	.3±.04	.8±.07
(FEAd)	2±.3	3±.5	.5±.03	1±.01	.03±.0
(AAd)	22±.5	289±22	.07±.02	11±6	48±46

Conclusions:1) Fetal rabbit adrenal and extra-adrenal tissue have large amounts of proenkephalin derived peptides. 2) Post-translational processing (MET/TOTAL ratio) is significantly different in immature rabbits. Speculation: Extra-adrenal tissue is an important source of ENK in fetal and neonatal life.

423.13

EXPRESSION OF THE PREPROENKEPHALIN A GENE AND RELATED PEPTIDES IN HEARTS OF SPONTANEOUSLY HYPERTENSIVE RATS. M. Dumont, M. Ouellette*, L. Brakier-Gingras* and S. Lemaire. Department of Pharmacology, University of Ottawa, Ottawa, K1H 8M5, and *Département de Biochimie, Université de Montréal, Montréal, H3C 3J7.

The expression of the preproenkephalin A gene (Enk gene) was investigated in the heart of Wistar Kyoto (WKY) and spontaneously hypertensive (SHR) rats. The level of Met-Enk was measured by radioimmunoassay and the relative abundance of the Enk mRNA was determined by Northern blot analysis. WKY rats did not display any significant change in their cardiac Enk mRNA content with age but their cardiac Met-Enk levels (free and cryptic peptides) were significantly lower in 16 week old animals (from 1.5 to 0.9 pmol/g:free; from 5.2 to 3.7 pmol/g: cryptic). In SHR rats, the relative abundance of Enk mRNA in the heart increased with age to levels exceeding those found in WKY animals by factors of 2 and 4 fold at 8 and 16 week-old, respectively. The increase in 16 week-old SHR was localized in the ventricles. Cardiac free and cryptic Met-Enk in SHR rats did not increase with the age of the animal and were identical or lower (25% decrease in cryptic Met-Enk of 16 week-old SHR) than those found in WKY rats. The striking lack of parallelism between the ventricular levels of Enk mRNA and of free and cryptic Met-Enk suggests that the expression of the Enk gene into Enk-related peptides is suppressed at a translational level both in control and hypertensive animals. Supported by HSFO.

C-TERMINAL PROTEOLYSIS MODIFIES CARDIOREGULATION BY *B*-ENDORPHIN. M.D. Hirsch, A.E. Villavicencio*, J.E. McKenzie* and W.R. Millington. Physiol, USUHS, Bethesda, MD & Basic Life Scis., U Mo-KC, KC, MO.

C-terminal proteolysis profoundly alters activ-i-ty in the CNS analgetic system by converting the opioid receptor agonist *B*-endorphin(*BE*) 1-31 to the potent antagonist, *BE* 1-27. The present study examined effects of this processing in caudal medulla on central cardioregulation. The cisterna magna was exposed in rats prepared with adrenal vein and femoral artery catheters. Peptides (1.5 nmol) or CSF were infused intracisternally. At 30 min postinjection, baseline mean arterial pressure (MAP=94.7+-1.9mmHg) was reduced 24% by *BE* 1-31, and 32% by *BE* 1-27, but neither peptide altered heart rate (HR=366+-15beats/min). The peptides elicited differential compensatory increases in adrenal catecholamine release, with norepinephrine predominating for *BE* 1-31 (17-fold vs CSF), and with epinephrine for *BE* 1-27 (4-fold vs CSF). These findings underline the importance of regionally selective post-translational processing of *BE* 1-31 on functional specificity. Supporting Grants:USAMRDC 86PP6813 & NIDA DA04598

PRO-OPIOMELANOCORTIN (POMC) mRNA IN THE NUCLEUS TRACTUS SOLITARIUS AND OTHER EXTRAHYPOTHALMIC BRAIN REGIONS. D.M. Bronstein, M. K.-H. Schafer*, K. A. Trujillo, S. J. Watson and H. Akil, Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

While a variety of techniques have clearly established that the major group of POMC cell bodies in the CNS is situated in the arcuate nucleus of the hypothalamus, the presence of extrahypothalamic POMC cells in the CNS is less certain. A small diffuse cluster of POMC cell bodies has been localized in the nucleus tractus solitarius (NTS) area of the caudal medulla, using immunohistochemical methods, but POMC mRNA has never been detected in this region; conversely, while POMC mRNA-like signals have been found in a number of other extrahypothalamic brain sites (eg., amygdala, cerebral cortex), there is no anatomical evidence of POMC soma in these regions. In the present study, we used biochemical (Northern and RNase protection analyses) and anatomical (*in situ* hybridization) techniques to determine the distribution and regulation of POMC mRNA in extrahypothalamic brain regions. In addition to the arcuate nucleus, we detected POMC mRNA in the nucleus accumbens, caudate, and NTS by RNase protection assays using a riboprobe complementary to the 5' end of exon 3 of POMC mRNA. In contrast to previous reports that POMC mRNA in the amygdala or cortex is shorter than the arcuate message, we found no apparent difference in the size of the POMC message from different brain regions. Using *in situ* hybridization, POMC mRNA signal was detected in a small number of cells in the NTS following 1-2 months exposure. The number of POMC mRNA copies per cell appears to be lower in the NTS than in the arcuate nucleus. That we observed a relatively strong POMC mRNA-like signal in the caudate and nucleus accumbens with biochemical methods but no signal (to date) using *in situ* hybridization may indicate a diffuse distribution with low copy number/cell in these tissues. We are currently examining whether extrahypothalamic and arcuate POMC mRNA are identical species and whether they are regulated in similar ways. (Supported by NIDA DA02265 and NIMH MH422251 (S.J.W. & H.A.) and NIH training grants (D.M.B. & M.K.-H.S.)).

THE EFFECT OF CHRONIC MORPHINE ADMINISTRATION ON SPINAL ß-ENDORPHIN LEVELS. HB Gutstein,* DM Bronstein, and H Akil. Department of Anesthesiology and Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109

The effect of chronic opiate administration on endogenous opioid systems remains unclear. However, changes in opioids during the development of tolerance may play a role in some of the manifestations of dependence and withdrawal. We have been investigating the consequences of chronic exposure to morphine on the ß-endorphin (ßE) system in the CNS. ßE is a highly potent endogenous opioid which, when administered exogenously produces profound analgesia, tolerance, and dependence. Previous studies showed that chronic morphine administration had an inhibitory effect on rostral ßE systems (Bronstein, DM, Brain Res., 1990, in press). The present study was undertaken to see if spinal cord ßE was regulated similarly.

Sixty male Sprague-Dawley rats anesthetized with ether were implanted with a single morphine (75 mg) or placebo pellet on day 1, and 3 additional pellets of the same type on day 4. On day 7, rats were injected i.p. with either naloxone (2.5 mg/kg) or saline and sacrificed 1 hour later. ßE immunoreactivity (ßEIR) was determined for 3 different spinal cord regions by RIA.

Animals implanted with morphine showed significant increases in ßEIR in cervical and thoracic regions compared with controls; in the lumbosacral region this trend did not reach statistical significance. Acute naloxone injection had no significant effect on ßEIR. However, chronic naloxone in conjunction with chronic morphine has not yet been tested. Analysis of peptide forms is currently underway.

Our results showing an increase in spinal ßEIR with chronic morphine administration appear to differ from observations in more rostral CNS systems. Spinal ßE is mainly derived from the nucleus tractus solitarius, while brain ßE mainly arises form the arcuate nucleus. This suggests that these two discrete endorphinergic systems may be regulated differently. These findings may have important implications for understanding the intrinsic mechanisms resulting in narcotic tolerance and dependence.

PERIPHERAL EFFECTS OF VARIOUS OPIOID AGONISTS ON NEUROGENIC EXTRAVASATION IN SKIN OF THE RAT HIND PAW. A. Barber*, R. Gottschlich* and A.F. Haase. Pharma Research, E. Merck, Frankfurter Strasse 250, D-6100 Darmstadt, FRG.

Several reports have indicated that peripheral opiate receptors may mediate some of the analgesic actions of opiates. To address this question, we examined plasma extravasation in rat hind paw skin as a model of neurogenic inflammation. Cut saphenous nerves were stimulated (5 mA, 1 msec, 2 Hz, 10 min) antidromically in anaesthetised, Evans Blue-treated rats. Extravasation was determined by measuring the level of dye in the skin after extraction. Drugs were administered i.v. Morphine and the κ agonist (-)U50488H produced a dose-dependent inhibition (ID_{50} 2.4 and 0.68 mg/kg, respectively) of plasma extravasation. The action of 5 mg/kg morphine and (-)U50488H was completely reversed by 1 mg/kg naloxone, which is indicative of an opiate-mediated effect. (+)U50488H was ineffective at 1 mg/kg, and produced only 35 % inhibition at 5 mg/kg, thus demonstrating the stereoselectivity of this effect. 5 mg/kg of the δ/μ agonist DADLE reduced extravasation by 64 %, whereas the δ agonist DPDPE and the σ ligand (+)SKF 10047 were inactive at this dose. The results presented are therefore consistent with the view that μ and κ, but not selective δ or σ agonists, can inhibit neurogenic inflammation in the skin. Whether this effect is mediated by peripheral opiate receptors on nerve endings of primary afferent fibres, or an indirect systemic action of opiates remains to be determined.

OPIOIDS: ANATOMY AND PHYSIOLOGY II

424.1

EXTRA- AND INTRACELLULAR ELECTROPHYSIOLOGICAL PROPERTIES OF OPIOID SENSITIVE NEURONS IN THE BED NUCLEUS OF THE STRIA TERMINALIS. **M. Dalsass and A. Siegel, Neurology, V.A. Medical Center, E. Orange, N.J. 07019, and Dept. of Neurosciences, N.J. Medical School, Newark, N.J. 07103.**

The bed nucleus of the stria terminalis (BNST) plays a critical role in the modulation of aggressive behavior. This modulatory function is also directly influenced by opioid peptides administered to the BNST. Our aim was to examine how BNST neurons respond to opioid peptides and their antagonists in order to understand, at the cellular level, the mechanisms of action of these substances.

Rats were anesthetized with chloral hydrate (400 mg/kg) and recordings were obtained from BNST neurons using either single or multibarrel pipettes. Responses to D-Ala^2-Met^5-enkephalinamide (DAME) [10mM] and naloxone hydrochloride (50 mM) were examined. Extracellular responses of BNST neurons following microiontophoretic application of DAME showed predominantly excitatory effects, with increasing (>50%) firing rates above baseline levels. These responses were blocked by naloxone. More rarely, inhibitory responses could be elicited by DAME and these showed variable responsiveness to naloxone. Our initial findings utilizing intracellular recordings suggest a complex interaction of opioid peptide and antagonist on both the resting membrane potential and the duration of the spike discharge. [Supported by NIH grant NS 07941-20 and the UMDNJ Foundation].

424.2

DOPAMINE OVERFLOW IN N. ACCUMBENS FOLLOWING OPIOIDS AND ELECTRICAL BRAIN STIMULATION AS ASSESSED BY MICRODIALYSIS IN FREELY MOVING RATS. Margaret E. Hamilton and Agu Pert. BPB/NIMH, Bethesda, MD. 20892.

Previous investigation has demonstrated a failure of morphine to increase extracellular levels of striatal dopamine (DA) in conscious rats. In contrast, other research has indicated that the activity of VTA - n. accumbens DA neurons and concomitant DA release may be increased by opioid agonists. Typically, increased DA neurotransmission in the n. accumbens is associated with enhanced locomotor activity. Acute systemic administration of morphine to naive rats produced only moderate, biphasic increases in DA overflow in the medial n. accumbens. Initially, the sedative effect of morphine prevailed. As this effect subsided, however, a slight increase in DA was observed, accompanied by renewed behavioral activity as measured by photocell counts. Pretreatment of rats with the DA uptake inhibitor, nomifensine, attenuated both the sedative phase and the second mild DA increase; however the increases in DA by morphine were proportionally similar to those in rats that did not receive nomifensine. Microinjection into the VTA of the met-enkephalin analogue, DALA, also elicited behavioral activation and moderate DA overflow in the n. accumbens. Similarly, electrical stimulation of the VTA with intermittent trains of unipolar pulses (150 μsec width, 20 Hz at 250 μA) increased both measures in a manner similar to the effects of opioids. It appears, therefore, that merely a relatively modest elevation of DA in the n. accumbens may be required to enhance behavioral activation. Alternatively, non-DA systems presumably originating in the VTA and perhaps involving endogenous opioids may contribute significantly to behavioral arousal.

424.3

ELECTROPHYSIOLOGICAL EFFECTS OF OPIOIDS ON NEURONS IN THE VENTRAL TEGMENTAL AREA. S.W. Johnson and R.A. North. Vollum Inst., Oregon Health Sci. Univ., Portland, OR 97201.

Dopamine (DA) and opioid peptides were superfused onto ventral tegmental area (VTA) neurons in slices cut horizontally from rat brain. Intracellular recordings were made from 53 cells: 74% were hyperpolarized by DA (1-100 μM) and 19% were hyperpolarized by methionine-enkephalin (ME, 0.1-30 μM). None were hyperpolarized by both DA and ME. Effects of ME were mimicked by DAMGO (0.3-3 μM), but not by DPDPE (3 μM) or U50488H (3 μM), suggesting activation of mu receptors. Electrophysiological properties of DA- and ME-responsive cells resembled primary and secondary neurons, respectively, described in the substantia nigra compacta (J. Neurosci. 9:1233-1241, 1989). Electrical stimulation of the slice rostral to the VTA evoked synaptic potentials (SP's) that were partly blocked by APV (30 μM) and CNQX (10 μM), and partly blocked by picrotoxin (100 μM). ME reduced both the glutamate and GABA components of the SP by 30-40%, but only at high concentrations (30 μM). Spontaneous SP's, evoked by raising K^+ to 6.5 or 8.5 mM, were depolarizing with KCl-filled electrodes, hyperpolarizing with acetate-filled electrodes, and blocked by bicuculline (30 μM). ME (0.3-3 μM) reduced the frequency of SP's by more than 50% in 2 of 3 neurons. We conclude that opioids act at mu receptors to hyperpolarize GABA interneurons thus reducing inhibitory input on DA-responsive neurons in the VTA.

424.4

SYSTEMIC METHIONINE ENKEPHALIN (ME) INCREASES THE EXTRACELLULAR NOREPINEPHRINE CONCENTRATION IN THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) OF THE RAT. P.A. MASON[1], J.A. STRICKLAND[2], S. LEE*[2] and H.M. RHEE[2]. Depts. of Anatomy, Cell Biology and Neuroscience[1] and Pharmacology[2], Oral Roberts University, Tulsa, OK 74171.

Our objective was to determine if the CNS was involved in the hypotensive effect of systemic ME. We used microdialysis to determine the effects of systemic ME on the extracellular concentration of monoamines in the RVLM, a central site of cardiovascular regulation. Rats were anesthetized and the femoral artery and vein of each rat were cannulated. A dialysis probe was implanted in the RVLM and perfused for 2 hr to obtain baseline data. The rat then received a bolus injection of saline (300 μl IV) followed 40 min later by a bolus injection of ME (100 μg/kg/300 μl IV). At the end of each experiment, glutamate (0.16 mg/10 μl/5 min) was perfused through the probe to verify indirectly the probe's placement in the RVLM. ME decreased BP without a reflex-mediated increase in heart rate. HPLC with EC detection showed that ME significantly increased the NE concentration but did not change the concentrations of DOPAC, HVA and 5-HIAA. Saline had no effect. Glutamate increased the MAP from 87 to 103 mm Hg. These results are consistent with the concept that systemic ME decreases BP via altering the NE concentration in the RVLM.

424.5

OPIOID AFFERENTS TO THE LOCUS COERULEUS FROM THE ROSTRAL MEDULLA AS DETECTED BY RETROGRADE TRANSPORT COMBINED WITH IMMUNOHISTOCHEMISTRY. G. Drolet, H. Akaoka, E.J. Van Bockstaele, G. Aston-Jones and M.T. Shipley[1], Div. Behav. Neurobiol., Dept. Mental Health Sci., Hahnemann U., Philadelphia, PA 19102 and [1] Dept. Anat. Cell Biol., U. Cincinnati Coll. Medicine, OH 45267.

The nucleus locus coeruleus (LC) is densely innervated by fibers immunoreactive for opioid peptides. However, the origin(s) of these inputs has not been determined. In the present study, we combined retrograde transport and immunohistochemical techniques to identify the source of enkephalin (Enk) inputs to the LC. The retrograde tracer, cholera toxin B coupled to colloidal gold particles (CTB-gold), was injected into the electrophysiologically identified LC nucleus. After survival for 5-7 days, the rats received colchicine (100 μg, icv) and were perfused 24 hours later. Results for retrograde labeling with injections restricted to LC confirmed previous reports that major afferents to LC derive from the nucleus paragigantocellularis (PGi) in the rostral ventrolateral medulla, and the mediodorsal prepositus hypoglossi (PrH) in the dorsomedial medulla. Interestingly, the distribution of Enk cells in the PrH was confined to the mediodorsal portion which contains LC afferents. In the ventrolateral medulla the Enk cells were aggregated into groups, including one in the retrofacial portion of PGi which contains LC projecting neurons. Examination of Enk and gold labelling in the same tissue sections revealed numerous doubly-labeled cells in both PGi and PrH. These enkephalinergic pathways from the rostral medulla could represent an anatomical substrate underlying opioid effects on LC neurons during stress, opiate abuse and tolerance.

424.6

LOCAL, NALOXONE-PRECIPITATED WITHDRAWAL IN THE VENTROLATERAL MEDULLA ACTIVATES LOCUS COERULEUS NEURONS VIA AN EXCITATORY AMINO ACID PATHWAY. H. Akaoka, G. Drolet, C. Chiang and G. Aston-Jones. Div. Behav. Neurobiol., Dept. Mental Health Sci., Hahnemann University, Philadelphia, PA 19102

Noradrenergic neurons of the nucleus locus coeruleus (LC) in morphine-dependent rats are strongly activated by opiate-withdrawal (OW). We examined possible mechanisms for such LC activation using extracellular recording of LC unit activity in halothane anesthetized rats.

There was no evidence that hyperexcitability of LC neurons caused their activation during OW, as chronic morphine (i) did not affect the activation of LC cells by iontophoretic glutamate (11/13), and (ii) reduced the excitation of LC cells by sciatic nerve stimulation (by 27%, $p<0.05$, n=31).

Possible involvement of the ventrolateral medulla (VLM; containing the nucleus paragigantocellularis, the major afferent to LC) in OW-activation of LC was examined with local injections of the opiate antagonist naloxone (NLX), to induce anatomically-restricted OW. NLX microinjected into VLM (10^{-2} M, 500 nl) significantly activated LC neurons (2.3 fold, 24/35) in dependent rats. This effect is specific (i) to dependent rats (3/27 in naive rats), (ii) to opiate receptors as the inactive enantiomer, +NLX, failed to mimic the effect of racemic NLX (n=5), and (iii) to VLM as NLX injections rostral to active site in the same animal (n=5) or in LC (n=3) were ineffective. Smaller doses of NLX injected into VLM produced only weak excitations of LC (10^{-6} and 10^{-4} M, n=14). The activation of LC cells by local or systemic NLX was blocked by kynurenate (an antagonist of excitatory amino acids, EAAs; 10^{-2} M) directly infused into LC (n=3). These results indicate that VLM may be the primary site whereby OW activates LC neurons and that this activation is produced by an EAA input to LC. Supported by PHS grants NS 24698 and DA 06214 and FRSQ.

424.7

TRANSIENT DESENSITIZATION OF μ-OPIOID RECEPTORS IN RAT LOCUS COERULEUS. G.C. Harris and J.T. Williams. Vollum Inst., Oregon Hlth. Sci. Univ., Portland, OR 97201.

The noradrenergic nucleus, the locus coeruleus (LC), contains a high density of opiate receptors, and has been proposed to play a role in mediating opiate withdrawal responses. Acutely, both μ-opioid agonists and α_2-adrenergic agonists decrease the spontaneous activity and hyperpolarize LC neurons by increasing a potassium conductance. Experiments were conducted using intracellular recording in rat brain slices. The hyperpolarization induced by [Met^5]enkephalin (ME) (300 nM) was tested before and after a 5 min application of ME (30 μM). The hyperpolarization induced by the low concentration of ME was decreased by 84% immediately after washout of the higher concentration. The amplitude of the initial hyperpolarization completely recovered after approximately 20 mins. This desensitization appeared to be primarily homologous for the μ-opioid receptor because the actions of α_2-agonists were only marginally depressed. Pretreating cells with forskolin, isobutyl methylxanthene, or 8-bromo-cAMP had no effect on the acute response to opioids or on the acute desensitization response. Pretreatment with the kinase inhibitor, staurosporin, significantly reduced the receptor desensitization but did not completely block it. This acute response could represent the initial stages in the development of opiate tolerance. Supported by USDHHS DA 04523 and DA 05387.

424.8

REGULATION OF OPIOID PEPTIDE AND RECEPTOR SYSTEMS FOLLOWING EXOGENOUS OPIOID ADMINISTRATION IN NEONATAL RAT BRAIN. A. Tempel. Dept. of Psychiatry, Laboratory of Neuropharmacology, Hillside Hospital/LIJMC, P.O. Box 38, Glen Oaks, New York 11004

Opioid analgesics are well known to produce tolerance and dependence in vivo and desensitization in vitro, although the mechanisms for these phenomenon are not clear. We have found that chronic pre- and postnatal morphine treatment of rat pups produces a significant decrease in brain μ opioid receptor density with no change in receptor affinity. This downregulation is accompanied by tolerance to the actions of morphine. In order to determine changes in specific brain regions, autoradiography was performed on brain sections from control and chronic morphine treated pups. Four days of postnatal morphine treatment induced a 30% loss of μ opiate receptors in the patches of the striatum with no significant loss in the matrix area. This loss of μ receptors was no longer observed with prolonged morphine treatment. These data provide evidence for a unique plasticity of the immature opiate receptor system. In order to determine if chronic morphine treatment causes alterations in opioid peptide synthesis, preproenkephalin (PPE) mRNA levels were examined in brains of control and chronic morphine treated animals. Chronic morphine treatment produced a significant decrease in PPE mRNA levels relative to saline treated animals in various brain regions. Data from these studies provide insight into interactions between opioid gene expression and brain function in opiate tolerance and dependence in the developing central nervous system.

MU TOLERANCE IN ONTOGENY: ANTINOCICEPTIVE STUDIES. R. Windh and C. Kuhn. Dep't of Pharmacology, Duke University Medical Center, Durham, NC 27710.

The opiate receptor's capacity to adapt is one important determinant of the physiologic outcome following developmental opiate exposure. To examine this question, the present study evaluated tolerance at mu opiate receptors in developing rats using an antinociceptive model. Animals were treated for 5 days with the agonist morphine (5mg/kg-25mg/kg s.c., twice daily) on days 4-8 or 22-26 and challenged 48 hours later with sufentanil (1.5-8ug/kg in 10 day olds; 2-14ug/kg in 28 day olds). Tolerance was determined by measuring the shift in the sufentanil dose-response curves in chronic morphine and saline treated rats. Sufentanil administration to opiate-naive 10 and 28 day old rats caused a dose-dependent and naloxone reversible increase in latency to paw removal from a hot plate. Chronic treatment had markedly different effects at the two ages studied: while the 28 day olds showed no antinociceptive response to any dose of sufentanil, the dose-response curve in 10 day olds was unchanged. These results show that mu receptors involved in antinociception show a relative inability to adapt to chronic perturbation early in development. This resistence to tolerance contrasts with our previous demonstration of tolerance in corticosterone secretion, suggesting there may be a spectrum of adaptability at various sites. However, both these findings are consistent with a literature indicating less robust tolerance in developing animals, and they suggest that opiates might exert more profound effects on developing animals than on adults after chronic administration. PARTICIPATION OF COERULOSPINAL NORADRENERGIC PATHWAY IN FENTANYL-INDUCED MUSCLE RIGIDITY IN THE RAT. P.W. Lui, T.Y. Lee* and S.H.H. Chan. Department of Anesthesiology, Veterans General Hospital-Taipei and Institute of Pharmacology, National Yang-Ming Medical College, Taipei, Taiwan, Republic of China.

This study further examined our previously identified role of coerulospinal noradrenergic pathway in fentanyl-induced muscle rigidity, based on a combined histochemical, immunocytochemical and pharmacologic evaluation. Unilateral, site-specific microinjection of fentanyl (2.5 µg/50 nl) into the locus coeruleus (LC) of Sprague-Dawley rats anesthetized with ketamine evoked a significant increase in the electromyographic activity recorded from the caudal lateral extensor (CLE) muscle. This correlate of opiate-induced muscle rigidity was antagonized by a pretreatment with the specific α_1-adrenoceptor blocker, prazosin (250 µg/kg, i.v.). The above results were significantly eliminated in animals pretreated with the selective noradrenergic neurotoxin , DSP4 (50 mg/kg, i.p.). There was also an appreciable reduction in the number of nerve terminals that stained positively with antiserum against dopamine-β-hydroxylase, and were impinged on CLE motoneurons identified by horseradish peroxidase labelling. These data further confirmed that the coerulospinal noradrenergic pathway may be directly involved in the elicitation of muscle rigidity by fentanyl, possibly via α_1-adrenoceptors in the spinal cord.

INTRARENAL EFFECTS OF μ-OPIOID AGONIST DERMORPHIN IN RATS. D.R. Kapusta*, S.Y. Jones* and G.F. DiBona. Dept. of Int. Med., Univ. Ia. Col. Med. & VAMC, Iowa City, IA 52242

Changes in renal function were examined during left renal artery (lra) infusion of the selective μ-opioid agonist, dermorphin, in anesthetized Sprague-Dawley rats with intact (n=6) and bilaterally denervated kidneys (DNX; n=7). Urine was collected from left and right (control) kidneys via ureteral cannulae during 20 min. lra infusion periods of isotonic saline control, dermorphin (0.5 nmol/min/gKW), and isotonic saline recovery for measurements of urine flow rate (V) and urinary sodium excretion ($U_{Na}V$). Results: Left renal artery dermorphin did not alter mean arterial pressure, heart rate, right kidney V or $U_{Na}V$. Values are left kidney means ± S.E. per gKW; * P < 0.05 vs control.

	Intact		DNX	
	V	$U_{Na}V$	V	$U_{Na}V$
	µl/min	µeq/min	µl/min	µeq/min
Control	11.1±1.8	2.14±0.51	8.3±1.4	1.80±0.63
Dermorphin	7.3±1.4*	1.46±0.49*	12.1±2.5	2.06±0.71
Recovery	8.2±1.3	1.65±0.44	10.8±2.1	2.28±0.54

Left kidney glomerular filtration rate and renal plasma flow were similar before and during lra dermorphin (0.9±0.2 vs 0.8±0.1 ml/min/gKW and 3.0±0.4 vs 2.6±0.3 ml/min/gKW), respectively. These results suggest that μ-opioid agonists participate in the renal tubular sodium and water reabsorption via an intrarenal action to facilitate the nerve terminal release of norepinephrine.

EFFECTS OF OPIOID AGONISTS AND ANTAGONISTS ON GABA-INDUCED CURRENTS IN ISOLATED GOLDFISH RETINAL BIPOLAR CELLS. H.-J. Du* and A. Kaneko. National Institute for Physiological Sciences, Okazaki, 444 Japan.

Various kinds of neuropeptides have been found in amacrine cells of the vertebrate retina, but their physiological roles are unknown. In the present study, effects of different opioid peptides on isolated goldfish retinal bipolar cells were investigated by using the whole-cell voltage clamp recording technique. The opioids tested include Met- & Leu-enkephalins, selective (μ-, δ- & κ) or non-selective opioid receptor agonists and antagonists, in isolation or in combination. All drugs (0.01-50 μM) were delivered through a rapid superfusion system. The amplitude of the GABA-induced Cl^--currents (GABA response) was reduced to 21.4 % - 88.8 % of the control by any one of opioid peptides (at 50 μM). The depressive effect developed gradually, reached the maximum in 3-5 min, and persisted for >5 min. μ-, δ- & κ-agonists depressed the GABA response in the same cell. Opioid antagonists were unable to block or reverse these effects. In contrast, they did cause similar, even stronger, depression in a dose-dependent manner (ED_{50} around 1×10^{-7} - 10^{-6}M). These effects were reversible. In some cases, a synergic action was seen between the agonist and antagonist. The present data indicate a multiple opioid receptor-mediated modulation of signal transmission at the bipolar cells and complications of the action of opioid agonist and antagonist on a single isolated cell. SIGMA AGENTS DO NOT MODULATE SUCROSE REINFORCEMENT. R.B. Murphy, L.H. Schneider, J. Davis, J. Gibbs, and G.P. Smith, Bourne Lab, NY Hospital-Cornell Med Ctr, White Plains, NY 10605, Dept Chemistry, N.Y.U., NY, NY 10003, and Dept. Psychology, Univ. Illinois-Chicago, Chicago IL 60680

Occupancy of the sigma receptor/binding site has been suggested to modulate the ascending dopamine (DA) systems on the basis of the localization of sigma receptors adjacent to nigrostriatal DA cell bodies (Graybiel et al., 1989) and the behavioral actions of selective sigma agents as putative neuroleptics (Taylor et al., 1988). We utilized microstructural analysis of lick patterns to examine the actions of the selective sigma agents [(+)-SKF 10,047, 5 mg/kg; BMY 14802, 4 mg/kg], and compared them with haloperidol (0.1 mg/kg), which has high affinity for both DA and sigma receptors. Six male S-D rats with chronic gastric fistulas were adapted to 30-min tests sham feeding a 20% sucrose solution after an 18h food deprivation and injection i.p. at -15 min. We observed that there was no effect of either selective sigma drug on volume sham fed. In contrast, haloperidol produced a highly significant reduction in sham intake (33.7 ± 2.7 ml to 15.0 ± 2.7 ml; $p<.001$). However , BMY 14802, but not SKF 10,047 or haloperidol, produced a significant decrease in interlick intervals from 0-250 msec ($p<.005$) as well as in the number of licks per mL consumed ($p<.05$). No other microstructural changes were produced by the selective sigma agents; the effects of haloperidol on other microstructural measures confirmed our previous studies (Schneider et al., 1989). These results suggest that sigma receptors do not modulate dopaminergic systems which are critical to the reinforcing potency of sucrose. SIGMA LIGAND PENTAZOCINE (PENT) INCREASES EXCITABILITY IN HIPPOCAMPAL NEURONS. A.E. Cole, J.J. Aryanpur, C.U. Eccles and R.S. Fisher. Dept. of Neurol., Johns Hopkins Hospital, Baltimore, MD 21205 and Dept. of Pharm. and Toxicol., Univ. of Maryland School of Pharmacy, Baltimore, MD 21201.

The sigma receptor is a novel site implicated in psychosis and epilepsy. The sigma receptor ligand PENT has been shown to increase field potential amplitude at low concentrations (1-10 uM) in the in vitro hippocampal slice (Eccles et al., Neurosci. Abstrs., 1989). The present study examined the effect of PENT on intracellularly recorded synaptic responses in hippocampal pyramidal neurons of region CA1. In the presence of 10 uM PENT the amplitude of the EPSP evoked by orthodromic stimulation of the Schaffer collateral pathway increased to 150% of control values. No significant effects were observed on the resting membrane potential or input resistance. At the same time, the IPSP was preserved in all cells examined. In additional neurons where KCl-filled electrodes were used, PENT appeared to increase both the frequency and amplitude of spontaneous IPSP's. In all experiments PENT was applied by bath perfusion; APV and naloxone were added to block potential interactions with NMDA and opiate receptors, respectively. These results demonstrate that PENT increases synaptic excitability of hippocampal neurons. The data suggest a physiological action of sigma receptors on synaptic function in rat hippocampus.

425.1

THYROTROPIN-RELEASING HORMONE (TRH) mRNA IS INCREASED IN SPECIFIC LIMBIC SUBREGIONS FOLLOWING ELECTROCONVULSIVE SEIZURES (ECS) AS DETERMINED BY IN SITU HYBRIDIZATION HISTOCHEMISTRY (ISHH). K.S. Fuson, M.R. Aydelotte,* A. Sattin and M.J. Kubek. Depts. of Anatomy, Psychiatry and Program in Medical Neurobiology, Indiana University & VA Medical Centers, Indianapolis, IN 46202.

ECS produces marked and sustained (days) elevations of TRH in specific CNS regions (Ann. N.Y. Acad. Sci. 553:286,1989). The possibility that ECS might induce TRH mRNA in a similar fashion was examined using ISHH. Male S-D rats were given ECS or sham ECS every other day for a total of 3 treatments, then decapitated at 3, 6, 12, & 24 hrs following the last seizure. Frozen sections (20 µm) were hybridized with a 35S-CTP labeled 548b TRH riboprobe at 60C for 20hrs. Film (48 hr, -70C) and emulsion (14d, 4C) were used for evaluation via computer image analysis. Increases in TRH mRNA were seen in hippocampal dentate gyrus at 3, 6 and 12 hrs, with a maximum occuring at 6 & 12 hrs, whereas less hybridization was seen in CA regions. Significant increases were found in piriform ctx at 6 & 12 hrs. No hybridization was seen in similar regions of the sham groups. These ECS studies are the first to show: 1) Induction of TRH mRNA in specific regions previously shown to respond with high levels of TRH; 2) TRH mRNA is not normally expressed in these same regions; 3) TRH mRNA is expressed in a unique temporal manner in given areas; and 4) Elevations of TRH in limbic foci are the result of de novo synthesis. Supported by NS 25661 and VA.

MODULATION OF LIMBIC SEIZURE INDUCED ELEVATIONS IN TRH CONTENT BY MK-801. M.S. Kreider and A. Winokur. Dept. of Psychiatry, Univ. of PA, Phila., PA 19104.

Previous studies in our laboratory have shown that induction of limbic seizures by kainic acid (KA) produced large increases in the concentration of TRH in limbic regions of the rat CNS (Kreider et al, Regul. Pep. 28:83-93, 1990). These increases are differentially attenuated by diazepam pretreatment (Wolfinger et al, Neurosci. Abs. 14:399, 1988). We investigated whether the NMDA antagonist MK-801 would prevent KA induced elevations in TRH content.

Male Sprague-Dawley rats (180-200g) received i.p. injections of MK-801 (5 mg/kg) or saline. Thirty minutes later, rats received KA (12 mg/kg) s.c. or saline. All rats were sacrificed 3 days later and regional TRH content determined by radioimmunoassay.

MK-801 prevented the KA induced increase in TRH in the corpus striatum and posterior cortex. KA-induced elevations in dorsal hippocampus were attenuated by MK-801, while elevations in ventral hippocampus were not affected. In the amygdala/piriform cortex, KA induced elevations in TRH were enhanced by MK-801. These results indicate that there is a differential effect of MK-801 on the responsiveness of TRH systems to limbic seizure activity.

425.3

VASOACTIVE INTESTINAL PEPTIDE (VIP) IN THE NORMAL AND DECENTRALIZED SUPERIOR CERVICAL GANGLION (SCG). H.Hyatt-Sachs, M.C. Beinfeld+, C. Baldwin and R.E. Zigmond, Department of Neurosciences, Case Western Reserve University, Cleveland, OH 44106 and +Department of Pharmacology, St. Louis University, St. Louis, MO 63104

The rat SCG has been shown by immunohistochemical techniques to contain VIP-like immunoreactive (VIP-IR) neural processes and a small number of immunoreactive cells (J. Comp. Neurol. 280:522, 1989). Double-labeling studies have demonstrated that VIP-IR is also present in cell bodies of preganglionic sympathetic neurons that project to the SCG (Soc. Neurosci. Abst.14:355, 1988). Finally, ligation of the preganglionic cervical sympathetic trunk led to the accumulation of VIP-IR both on the spinal cord side and on the ganglion side of the ligature. These data indicate that some, but not all, of the VIP-IR in the SCG is present in preganglionic nerve fibers. In the present study, VIP-IR was determined by RIA of acetic acid extracts of SCG. The lyophilized extract was assayed for VIP-IR using a VIP antiserum from Peninsula Laboratories and yielded a dilution curve that was parallel with authentic VIP. The content of VIP-IR in SCG from normal rats was 11.6 pg/SCG (112.5 pg per mg extracted protein; N=26 ganglia). When the SCG extract was run on HPLC, VIP-IR was detected only in those fractions corresponding to the retention time of authentic VIP. VIP-IR was also measured in the SCG 48h after cutting the cervical sympathetic trunk bilaterally. The content of VIP-IR was increased by 2-fold in decentralized ganglia compared to ganglia from both unoperated and sham-operated animals. Examination of sections of the SCG six weeks after decentralization revealed an increase in the number of immunostained neuronal processes and no apparent change in the number of immunostained neuronal cell bodies. These data suggest that there is an increase in VIP in other afferent inputs to the SCG or, possibly, in postganglionic neuronal processes following section of the preganglionic nerve trunk (NS12651, NS18667 and MH00162).

425.4

THE PROBABLE IDENTITY OF A NEUROKININ METABOLIZING ENZYME WITH THE LYSOSOMAL "PROTECTIVE PROTEIN". H.L. Jackman, F. Tan,* H. Tamei,* C. Beurling-Harbury,* X.-Y. Li,* R.A. Skidgel,* E.G. Erdös* Lab. of Peptide Research, Dept. of Pharmacology, Univ. of Ill., Coll. of Med., Chicago, IL 60612

Most of the actions of neurokinins depend on an intact C-terminal amide (Met-NH_2). We extracted an enzyme from human platelet granules that deamidates substance P and other neurokinins. The enzyme, released from human platelets by thrombin, was purified to homogeneity. The purified deamidase has a molecular weight of 52kDa and consists of 2 chains, a 33 kDa and a 21 kDa chain. The enzyme is a serine protease; [^{3}H]-DFP labels the active site serine on the heavy chain. The purified enzyme has esterase, peptidase and deamidase activities. With biologically active peptides, the enzyme acts both as a deamidase (substance P, neurokinin A and eledoisin) and as a carboxypeptidase (bradykinin, angiotensin I) at neutrality, although the carboxypeptidase action is faster at pH 5.5. After sequencing the first twenty-five amino acids of both chains, an identical sequence was found in the corresponding two chains of lysosomal "protective protein." A defect in this protein is the cause of galactosialidosis, a severe genetic disorder with progressive neurologic deterioration and mental retardation. (These studies were supported by NIH: HL36082, HL36473, HL36081, DK41431.)

CALCIUM-BINDING PROTEINS IN APLYSIA NEURONS. A. Hermann (1), T.L. Pauls*(2) and C.W. Heizmann*(3). (1) Univ. of Salzburg, Dept. of Zoophysiology, A-5020 Salzburg, Austria; (2) Univ. of Zürich-Irchel, Inst. of Pharm. and Biochem., CH-8057 Zürich; (3) Univ. of Zürich, Dept. of Pediatrics, CH-8032 Zürich, Switzerland.

Protein pattern of single, identified neurons (bursting, beating and silent) within the nervous system of the marine mollusk, Aplysia californ. were studied by 2D-Page. Major differencies between neurons were found in the range of low molecular weight and low isoelectric point, where Ca-binding proteins are generally located. Comigration experiments revealed a prominent protein group for bursting R-15 cells which migrated at an identical position to carp II parvalbumin (PV), whereas a protein spot characteristic for silent R-2 cells migrated at a position close to crayfish sarcoplasmatic Ca-binding protein (SCP). Western blot analysis did not show immunocrossreactivity in the molecular range where PV-like proteins are found. Immunocrossreactivity was observed, however, with a different protein at Mr 40 000, pI 4.8. The same protein also crossreacted with an antiserum directed against rat calbindin D-28K and in addition bound high amounts of ^{45}Ca ions as revealed by transblot/Ca-overlay technique. The results suggest that this protein is a novel Ca-binding protein sharing common antigenic determinantes for both, PV and calbindin D-28K.

In heat treated extracts of ganglia we further identified a group of proteins with Mr 13000-20000, pI 4.6, immunocrossreactive to antibodies against Amphioxus SCP II that also bound high amounts of ^{45}Ca ions. These proteins which share a high degree of similarities to SCPs therefore appear to represent isomeric forms of these proteins in neurons. Supported by EMBO-fellowship ASTF 5696 and the Swiss National Science foundation (31-9409.88).

DETECTION OF THE C-TERMINAL PENTAPEPTIDE OF THE NEUROTENSIN PRECURSOR IN RAT. K. Muraki, S.P. Mitra, R.E. Carraway and S.E. Leeman. Physiology Dept., Univ. of Mass. Medical Center , Worcester, MA 01655.

A radioimmunoassay was developed towards the C-terminal pentapeptide (rCTP, sequence ASYYY) of the rat neurotensin (NT)-precursor using ^{125}I-labeled rCTP and rabbit antisera towards rCTP conjugated to succinylated thyroglobulin. The assay was sensitive to 4 fmol/tube and crossreacted <0.01% with NT, neuromedin N, xenopsin and GSYYY. Measured in acid/acetone extracts of adult SD rats, the level of rCTP (pmol/g, mean ±SD) was 5-10% that of NT in brain (rCTP, 0.5±0.1; NT, 6.8±1.4) and ileum (rCTP, 5.0±1.4; NT, 94±15), whereas it was 30-50% in colon (rCTP, 2.4±0.5; NT, 4.3±0.3) and pituitary (rCTP, 3; NT, 10). During reverse-phase HPLC 3-4 major forms of brain and intestinal rCTP activity were observed, 15-40% of which behaved like synthetic rCTP. Sucrose gradient centrifugation of isotonic homogenates of rat intestinal mucosa showed that rCTP activity co-banded with NT in the region containing secretory vesicles. These findings indicate that a substance chromatographically and immunochemically similar to rCTP exists in rat CNS & intestine along with other related peptides not yet identified. Supported by Fogarty 5PW04213 and NIH DK28565.

EFFECT OF FLUNARIZINE ON THE METHAMPHETAMINE- AND 3,4-METHYLENEDIOXYMETHAMPHETAMINE-INDUCED CHANGES IN EXTRAPYRAMIDAL NEUROTENSIN. J.W. Gibb, G.R. Hanson, L.G. Bush*, K Mitros* and M. Johnson. Dept. Pharmacol. and Toxicol., University of Utah, Salt Lake City, UT 84112.

We recently observed that flunarizine (FLU) protects serotonergic systems from the neurotoxic action of 3,4-methylenedioxymethamphetamine (MDMA). The purpose of this study was to determine if administration of FLU also influenced methamphetamine (METH)- or MDMA-induced changes in extrapyramidal neurotensin systems. Male Sprague-Dawley rats (180-250 g) were injected with 4 doses of METH (15 mg/kg, s.c.), MDMA (10 mg/kg, s.c.) or saline at 6-h intervals with or without prior FLU (30 mg/kg, i.p.) administration. The animals were killed 18 h after the last drug administration. FLU administration alone resulted in a 36% increase in striatal neurotensin-like immunoreactivity (NTLI) while having no effect on the nigral levels. METH and MDMA increased striatal NTLI to 187% and 184% of control, respectively; nigral concentrations were increased to 579% and 441%, respectively. FLU treatment potentiated the METH and MDMA responses in the striatum while failing to alter the nigral changes. The responses are similar to the effects of a dopamine D2 receptor antagonist on the METH-induced changes, thus suggesting that FLU affects D2 receptor transmission. This conclusion is supported by the observation that FLU increases dopamine metabolites 3 h after a single administration. These results demonstrate that serotonergic and peptidergic changes resulting from MDMA tretament are differentially mediated. (Supported by USPHS grants DA 00869 and DA 04222)

425.8

ROLE OF DOPAMINE AND GLUTAMATERGIC SYSTEMS IN THE 3,4-METHYLENEDIOXYMETHAMPHETAMINE-INDUCED CHANGES IN BRAIN NEUROTENSIN AND DYNORPHIN A. M. Johnson, L.G. Bush*, J.W. Gibb and G.R. Hanson. Dept. Pharmacol. and Toxicol., University of Utah, Salt Lake City, UT 84112.

The role of the dopaminergic and glutamatergic systems in the 3,4-methylenedioxymethamphetamine (MDMA)- induced increase in rat brain neurotensin-like immunoreactivity (NTLI) and dynorphin-like immunoreactivity (DLI) levels was examined. Peptide content was measured 18 h after a single dose (10 mg/kg, s.c.) of the drug. MDMA increased neostriatal concentrations of NTLI and DLI to 274% and 366% of control, respectively. Nigral concentrations of NTLI and DLI were increased to 269% and 308%, respectively, while the levels in the nucleus accumbens were increased to 145% and 181% of control, respectively. Coadministration of the dopamine D1 receptor antagonist, SCH 23390 (0.5 mg/kg, i.p.), prevented the MDMA-induced increase of NTLI and DLI in all three brain structures while the administration of the dopamine D2 receptor antagonist, sulpiride (80 mg/kg, i.p.), failed to alter the MDMA effects except for a slight attenuation in the increase of neostriatal DLI. Blockade of the N-methyl-D-aspartate (NMDA) receptor complex using the noncompetitive inhibitor, MK-801 (1 mg/kg, i.p.), prevented the MDMA effects on both peptides in the neostriatum, nucleus accumbens and substantia nigra. These findings suggest that MDMA-induced changes in the neurotensin and dynorphin systems involve both the dopaminergic D1 and the glutamatergic NMDA receptors.(Supported by USPHS grants DA 00869 and DA 04222)

SECRETION OF CARBOXYPEPTIDASE H FROM AtT-20 PITUITARY TUMOR CELLS. D.Parkinson. Dept. Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO 63110.

The biosynthesis of peptide transmitters requires the proteolytic processing of precursor by several enzymes. In order for these enzymes to function, they must be packaged along with the precursor into the secretory vesicles where the appropriate milieu is maintained. Carboxypeptidase H (CPH) removes C-terminal basic amino acids from partially-processed precursor. To gain insights into the mechanism of sorting of proteins into the secretory vesicle, the secretion of CPH has been investigated in AtT-20 mouse pituitary tumor cells.

AtT-20/D-16v cells were grown to near-confluence in DME supplemented with 10% Nu-Serum. Media was collected and analyzed for CPH content by enzyme assay or western blotting. AtT-20 cells secrete enzymically-active CPH constitutively. The accumulation of CPH activity was linear over a 10 hour period. This activity was stimulated 8-10 fold by cobalt ions and potently inhibited by CPH-selective inhibitors. CPH secretion was stimulated 3-5 fold by secretagogues. There was a direct correlation between CPH activity and the staining of a 54kD band on western-blotting with an antibody directed to the C-terminal sequence. These results show that CPH is not processed at its C-terminus. To test the importance of acidic compartments in the secretion of CPH, cells were treated with ammonium chloride. This treatment produced small increases in secreted CPH activity. This result suggests that constitutively-secreted CPH is active, regardless of whether it has passed through any acidic compartments.

425.10

METABOLISM OF EXTRACELLULAR N-ACETYLASPARTYL-^{3}H-GLUTAMATE AND ITS PRODUCT ^{3}H-GLUTAMATE IN INTACT CELLS OF MURINE WHOLE BRAIN PRIMARY CULTURE. **M. Cassidy and J. H. Neale Dept. of Biology, Georgetown University, Washington DC 20057**

N-Acetylaspartylglutamate (NAAG) may function in synaptic communication in the mammalian CNS. It is present in synaptic vesicles and released on stimulation in several systems, yet the extracellular fate and effect of this peptide remain unclear. The goal of this study is to define the extracellular metabolism of NAAG and the fate of both NAAG and glutamate in intact cells. Primary cultures of murine brain were incubated with N-acetylaspartyl-^{3}H-glutamate in the presence and absence of inhibitors of NAAG peptidase activity. Data suggest that NAAG is rapidly degraded by a cell-surface enzyme to N-acetylaspartate and ^{3}H-glutamate. Initial results indicate that in a whole cell system, ^{3}H-glutamate, and to a much lesser extent, intact ^{3}H-NAAG, are taken up by cells. This suggests removal of NAAG from the medium by both degradation and limited direct uptake. The role of NAAG in communication may be two-fold: as a rapidly acting neurotransmitter or a chronic source of glutamate in the synaptic cleft, serving to modulate neuronal excitability.

425.11

BIOTINYLATED EGG-LAYING HORMONE: BIOLOGICALLY ACTIVE AND INACTIVE FORMS. S.L. Knock, B.T. Miller, A. Kurosky*, G.T. Nagle, J.E. Blankenship. Marine Biomed. Inst., Dept. Anat. & Neurosci., and Dept. Human Biol. Chem. & Genetics, Univ. Tex. Med. Br., Galveston, TX 77550.

Aplysia egg-laying hormone (ELH) was chemically modified using an N-hydroxysuccinimide (NHS)-Long Chain (LC)-Biotin reagent. Sites of modification were analyzed by FAB-MS, HPLC, amino acid compositional analysis and protein sequence analysis. Several species of biotinylated ELH were produced, owing to the variable reactivity of the N-terminal α-amino group and the two ε-amino groups of Lys^8 and Lys^{36}. The ELH-Lys^{36}-Biotin species was found to be biologically active and equipotent to native ELH in an egg-laying bioassay and in an in vitro neuroassay using cell R15 and identified left lower quadrant neurons in the abdominal ganglion. Analysis of the reactivity of the primary amines indicated that Lys^{36} was significantly more reactive than Lys^8 or the N-terminus. These results are significant for two reasons. First, this is the first report of a chemically labeled, biologically active ELH molecule. With the development of biotinylated-ELH, it should be possible to pursue studies in receptor binding and target tissue localization. Second, lower reactivity of the N-terminal amino group suggests that it may not be as accessible as the ε-amino group of Lys^{36}. This reduced access could be associated with a mechanism that renders the peptide less susceptible to aminopeptidases and, therefore, could contribute to an increased lifetime for ELH in the animal.

425.12

INDUCTION OF NEUROPEPTIDE Y SYNTHESIS IN RAT EPILEPSY MODELS. M.Ortler[1]*, G.Sperk*, J.Marksteiner*, R.Bellmann*, and R.Widmann[2]* (SPON.: Europ. Neurosci. Ass.). Depts. of [1]Histology and Pharmacology, Univ. Innsbruck, Austria and [2]Max-Planck-Inst. Neuronal Sci., Köln, FRG.

Recently we observed marked increases in brain levels of neuropeptide Y (NPY) and NPY-mRNA after kainic acid (KA) induced seizures in the rat. By measuring incorporation of locally injected ^{3}H-tyrosine, now we found a markedly enhanced (by about 350%) biosynthesis rate of NPY in the cortex 2 to 30 days after KA. We furthermore investigated changes of NPY immunoreactivity and gene expression after KA and after pentylenetetrazol kindling. In both animal models pronounced increases of NPY immunoreactivity were observed in the terminal field of mossy fibers. In KA treated rats NPY immunoreactivity extended to the molecular layer of the dentate gyrus after 30 to 60 days, suggesting neuronal sprouting. Unilateral injection of colchicine into the hilus abolished NPY staining in the the mossy fibers. Using "in situ" hybridization, in both animal models markedly enhanced expression of prepro-NPY-mRNA was observed in the granular layer. It is suggested that sustained expression of the neuromodulatory peptide NPY, in addition to the observed plastic changes, may contribute to altered excitability of hippocampal mossy fibers in epilepsy. Somatostatin immunoreactivity and gene expression were not changed in mossy fibers or granule cells, respectively.

425.13

INDUCTION OF NEUROKININ B BUT NOT OF NEUROKININ A BIOSYNTHESIS IN THE HIPPOCAMPUS IN EPILEPSY OF THE RAT. G.Sperk*, J.Marksteiner*, M.Ortler[1]*, O.Hornykiewicz[2] and R.Wahler*. Depts. of Pharmacology and of [1]Histology, Univ. Innsbruck, 6020-Innsbruck and Institute of [2]Biochem. Pharmacology, Univ. Vienna, 1090-Vienna, Austria.

Recently we observed marked increases in brain levels of neurokinin B in the frontal cortex and hippocampus after kainic acid induced seizures and after pentylene=tetrazol kindling in the rat. Using immunohistology and "in situ" hybridization we now investigated changes in neurokinin B immunoreactivity and in mRNA encoding for neurokinin A and B, respectively. In both animal models we observed pronounced increases of neurokinin B immunoreactivity in granule cells, in the terminal field of mossy fibers and in pyramidal cells of the CA1 sector. According to this also markedly enhanced expression of prepro-neurokinin B mRNA was observed in the granular layer as well as in pyramidal cells of the CA1 sector. Enhanced neurokinin B immunoreactivity and prepro-neurokinin B mRNA were also found in the frontal and pyriform cortices (mainly in layer 2). Prepro-neurokinin A mRNA was present in high concentrations in neurons of the habenula, but only in minute amounts in the hippocampus. It was unchanged in epileptic rats. Our experiments suggest marked induction of neurokinin B but not of neurokinin A gene expression in both animal models of temporal lobe epilepsy.

PRODUCTION AND DIFFERENTIAL ENDOCRINE REGULATION OF ATRIAL NATRIURETIC PEPTIDE (ANP) IN NEURON-ENRICHED PRIMARY CULTURES. C.F.Deschepper, K.P.T.Nguyen*, M.C.LaPointe*, K.R.Zahs and D.G. Gardner*. Depts of Physiology and Metabolic Research Unit*, Univ. of California, San Francisco CA 94143.

Neuron-enriched primary cultures were obtained from the brains of fetal rats. Ten days after plating, the cultures were incubated in serum-free medium and the amounts of ANP secreted into the medium was assessed by RIA. More ANP was secreted by neuronal cells derived from fetal day 17 rats vs. day 16, by cells from diencephalon vs. cortex and by cells at 39°C vs. 37°C. ANP mRNA transcripts were identified in cytoplasmic extracts from neuronal cultures by S_1 nuclease protection and shown to have a similar transcription start site as that employed by rat atrium and fetal hypothalamus in vivo. Pulse-label analysis of newly synthetized ANP in neuronal cultures revealed that, unlike neonatal cardiocyte cultures, the majority of the secreted immunoreactive material migrated with processed forms of ANP (approx. 3kD) rather than the prohormone (approx. 14kD). In contrast to earlier findings with rat atrial cardiocytes, dexamethasone and triiodothyronine decreased ANP secretion and ANP mRNA concentration in cultured neurons. This suggests the possibility of tissue-specific differences in the regulation of ANP gene expression by exogenous hormones.

ISOLATION AND CHARACTERIZATION OF *DROSOPHILA* PEPTIDES CONTAINING AN -ArgPheNH$_2$ C-TERMINUS. R. Nichols and M. Conkright*. Departments of Biological Chemistry and Biological Sciences, University of Michigan, Ann Arbor, MI 48109.

Naturally-occurring *Drosophila* peptides containing -ArgPheNH$_2$ C-terminal sequences have been isolated and characterized. Purification of peptides from crude homogenates were monitored utilizing a radioimmunossay specific for -ArgPheNH$_2$. Various chromatographic methods based on size and charge were used to purify the peptides. Drosulfakinin-I (DSK-I) and three peptides from pro-FMRF have been isolated. A novel peptide was also identified. The structures of the purified peptides were determined by automated Edman degradation and fast-atom bombardment mass spectrometry (FABMS).

A number of other immunoreactive peaks have been identified and their structures are being characterized. It is anticipated that many of the peptides will correspond to previously unreported forms of DSK, FMRFamide or related peptides.

SEROTONIN III

MDMA-TREATED MONKEYS CONTINUE TO SHOW BRAIN SEROTONERGIC DEFICITS EIGHTEEN MONTHS AFTER DRUG TREATMENT. M. B. Martello, A. L. Martello, J. L. Katz and G. A. Ricaurte. Dept. of Neurology, Johns Hopkins Univ. School of Medicine and NIDA Addiction Research Center, Baltimore, MD 21224.

Monkeys administered (±)3,4-methylenedioxymethamphetamine (MDMA) show large (75-86%) depletions of regional brain serotonin (5-HT) and 5-hydroxyindoleacetic acid (5-HIAA) two weeks later (JAMA: 260: 51-55, 1988). By ten weeks, partial recovery takes place such that 5-HT and 5-HIAA are depleted by only 30-47% (Neurosci. Abs. 14: 558, 1988). The purpose of the present study was to determine if serotonergic recovery in the MDMA-treated primate continues over time and, if it does, to ascertain whether it is complete by 18 months.

Six squirrel monkeys (Saimiri sciureus) were administered MDMA hydrochloride s.c. at a dose of 5 mg/kg twice daily (0800 and 1700 hrs.) for 4 days. Three of these animals were killed 7 months later; the remaining 3 were sacrificed 18 months later. Regional brain 5-HT and 5-HIAA determinations were then performed using HPLC-EC methods, with the two treatment groups being assayed in parallel. Relative to untreated controls (n=3), MDMA-treated monkeys at both survival periods (7 and 18 months) showed substantial reductions in both 5-HT and 5-HIAA (32-70% depletion, depending on marker and brain region). Notably, there was no evidence of recovery between 7 and 18 months.

These results suggest that 5-HT neural damage induced by MDMA in the primate is long-lasting, possibly permanent. Further, they suggest that the partial recovery of 5-HT which takes place in the monkey occurs largely within the first few months after MDMA exposure. Given that the regenerative capacity of central 5-HT neurons in the primate appears to be limited, these findings could have important public health implications since human use of MDMA continues. 426.2

EVALUATION OF THE NEUROTOXIC POTENTIAL OF 2-HYDROXY-4,5-METHYLENEDIOXYMETHAMPHETAMINE (2-HOMDMA), A REPORTED METABOLITE OF MDMA. Z. Zhao,[1] G. Ricaurte[2] and N. Castagnoli, Jr.[1] Dept. of Chemistry, Virginia Tech, Blacksburg, VA 24061 and [2]Dept. of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD 21224.

The serotonergic neurotoxin MDMA [2-methylamino-1-(3,4-methylenedioxyphenyl)propane] is reported (Lim and Foltz, Soc. Tox. Abs. #1333, Feb. 1990) to be metabolized to 2-HOMDMA, a possible precursor to the corresponding "6-hydroxydopamine analog", a potentially neurotoxic agent. The synthesis and full characterization of this MDMA metabolite as a racemate have been accomplished via regiospecific Vilsmeier formylation of 3,4-methylenedioxyphenol followed by conversion of the resulting 2-hydroxy-4,5-methylenedioxybenzaldehyde as the protected benzyl ether to the corresponding nitrostyrene derivative which in turn was reduced to the primary amine with $LiALH_4$. Reaction of this amine with ethyl formate followed by $LiALH_4$ reduction of the resulting formamide and hydrogenolysis to remove the benzyl protecting group led to the desired product which was obtained as a stable, crystalline hydrochloride salt. Systemic administration of 2-HOMDMA to male Sprague-Dawley rats at a dose 4 times greater than that of MDMA required to cause a 60-70% depletion of regional brain serotonergic markers one week later was without effect. Similar results were observed following intraventricular administration of 2-HOMDMA, using 5,7-dihydroxytryptamine as a positive control. These results argue that the neurotoxicity of MDMA may not be linked to its conversion to a 6-hydroxydopamine type metabolite.

426.3

EFFECTS OF MDMA ON HIPPOCAMPAL AND BRAIN STEM MAO ACTIVITY

E.T. Kokotos and E.C. Azmitia. Dept. of Biology, New York Univ., New York, N.Y. 10003

Monoamine oxidases are mitochondrial-bound enzymes which break down monoamines such as serotonin (5-HT) in the nerve cell. Pargyline, clorgyline and yohimbine are drugs which inhibit MAO and have been used as mood-elevating drugs in the treatment of depression. 3,4-methylenedioxymethamphetamine (MDMA) is a designer drug which produces euphoria, and has been shown to affect 5-HT both by potentiating release and blocking uptake. The effects of MDMA on MAO activity in 5-HT terminals were studied to determine whether MDMA could also potentiate the above-mentioned effects by acting as an MAO inhibitor.

The hippocampus and brain stem from adult rat and young rats were removed and placed in 10x v/w 0.01M PB. Following homogenization and centrifugation, the remaining tissue was resuspended in 0.01M PB and incubated with ^{3}H-5-HT_0 and MDMA in a range of concentrations (10^{-4} - 10^{-6}M) at 37°C. MAO activity was measured by the scintillation counting of ^{3}H-5-HIAA, a degradation product of serotonin. An IC_{50} of $6x10^{-5}$M was found on MAO activity in both the hippocampus and brain stem of these animals. There were no differences in sensitivity to the drugs between sexes or between young rats and adult rats. The MAO inhibitory effects of this drug may account for the potentiation of its mood-elevating properties.

426.4

5-HT_2 ANTAGONISTS BLOCK THE NEUROTOXICITY OF METHYLENEDIOXYMETHAMPHETAMINE (MDMA) BY INTERFERING WITH STIMULATED DOPAMINE SYNTHESIS. C.J. Schmidt, V.L. Taylor* and G.M. Abbate. Merrell Dow Research Institute, Cincinnati, OH 45215.

5-HT_2 receptor antagonists have been shown to prevent the long-term deficits in 5-HT concentrations resulting from the administration of a single dose of MDMA to rats. In acute studies, both ritanserin and MDL 11,939 (α-phenyl-1-(2-phenylethyl)-4-piperidine methanol) attenuated the increase in striatal dopamine (DA) 3 h after MDMA. This increase in DA concentrations is due to a stimulation of synthesis following carrier-mediated efflux of DA as shown by its sensitivity to nomifensine but not haloperidol. To determine if the protective effect of the 5-HT_2 antagonists was due to this interference with stimulated DA synthesis, we administered the DA precursor L-DOPA (and carbidopa) with MDMA plus the antagonists. L-DOPA alone significantly potentiated the decrease in 5-HT measured 1 week after the administration of MDMA. More importantly, L-DOPA reversed the protective effect of both antagonists. The data are consistent with the hypothesis that 5-HT_2 antagonists block MDMA-induced neurotoxicity by interfering with MDMA-stimulated DA synthesis and that sustained DA release itself is required for MDMA-induced neurotoxicity.

426.5

REGENERATION IN THE CNS FOLLOWING MDA-INDUCED NEUROTOXICITY: PHARMACOLOGIC EVIDENCE FOR SELECTIVE REINNERVATION BY *FINE* SEROTONERGIC AXONS M.A. Wilson and M.E. Molliver Dept. of Neuroscience, Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

The psychotropic amphetamine derivative 3,4-methylenedioxyamphetamine (MDA) causes degeneration of one class of serotonergic (5-HT) axon terminals, *fine axons*, but spares another class of 5-HT axon terminals, *beaded axons*. The denervation induced by MDA is followed by progressive reinnervation. The newly formed 5-HT axons exhibit morphologic features of fine axons; in order to assess their pharmacologic properties, we evaluated their vulnerability to a second course of MDA treatment. Rats received MDA, 20 mg/kg s.c., twice daily for 4 days; eight weeks later, half of the treated rats were given MDA again, according to the same protocol; all rats were sacrificed two weeks later. There is a substantial recovery of 5-HT-immunoreactive axon density in the forebrain two months after a single course of MDA. Two weeks after a second treatment with MDA, many of the newly formed 5-HT axons are lost; however, the loss is less severe than that observed two weeks after a single course of MDA. Thus, while most of the regenerated 5-HT axons are vulnerable to the effects of MDA, some appear to be resistant. Alternatively, accelerated regeneration may have occurred after the second MDA treatment, due to the "priming" effects of the first lesion. These results provide further evidence that after MDA-induced degeneration there is *regenerative sprouting* of fine 5-HT axons, rather than collateral sprouting of beaded axons. (Support: NIH DA04431, NS15199)

426.6

DIRECT MORPHOLOGIC EVIDENCE FOR DEGENERATION OF SEROTONERGIC AXONS FOLLOWING ADMINISTRATION OF AMPHETAMINE DERIVATIVES: dl-p-CHLOROAMPHETAMINE, d-METHAMPHETAMINE, AND d- and l-FENFLURAMINE.

Karen J. Axt, Thea M. Teune*, and Mark E. Molliver. The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

The loss of markers for 5-HT innervation of forebrain caused by psychotropic amphetamine derivatives has suggested that these compounds are neurotoxic. To obtain direct evidence for axon degeneration, we examined the morphologic effects of these drugs at short survival times. Rats were injected with the following drugs: pCA 10 mg/kg x 2 days; d-MA 15 mg/kg x 5 or 100 mg/kg x 1; d- or l-FEN 5 or 25 mg/kg b.i.d. x 4 days. 2-3 days after the last dose, immunocytochemically-stained sections revealed numerous 5-HT axons with cytopathologic features that were not seen in control brains. Dilated 5-HT axon *terminals* with markedly swollen varicosities were observed within most terminal fields of rat forebrain, e.g., cerebral cortex. Structurally abnormal *preterminal* 5-HT axons exhibited increased caliber, multiple irregular pleomorphic dilatations, and engorged stump-like endings. Damaged preterminal axons were present in several fiber bundles including MFB, fornix, cingulum, striae terminalis & medullaris, and in layers I & VI of neocortex. All of the drugs tested induced similar pathologic changes which are indicative of axonal degeneration. The same pathology has been reported following exposure to methylenedioxyamphetamine (O'Hearn et al., 1988). Structural evidence for degeneration is observed only transiently: damaged 5-HT axons are most abundant 2-3 days after drug administration; by 1-2 weeks their incidence is greatly reduced. Based on this and previous data, the morphologic changes produced by neurotoxic amphetamines can be divided into 4 temporal phases; I: *Depletion* (hours), II: *Degeneration* (days), III: *Denervation* (weeks), and IV: *Reinnervation* (months). [Support: DA 04431 & PMAF]

426.7

SPECIFIC REGIONAL PATTERNS OF SEROTONERGIC INNERVATION IN VENTRAL AREAS OF FOREBRAIN IN THE RAT; SELECTIVE DENERVATION AND REINNERVATION AFTER ADMINISTRATION OF P-CHLOROAMPHETAMINE (PCA). Mark E. Molliver and Karen J. Axt. Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

The 5-HT innervation of neocortex exhibits regional specificity in terms of density and laminar distribution of axons. Two 5-HT axon types, *fine & beaded*, have dissimilar distributions and differential vulnerability to psychotropic amphetamines. This study examines the 5-HT innervation, PCA-induced denervation, and reinnervation in selected allocortical areas and in the amygdaloid nuclei of the rat. In the olfactory tubercle, fine & beaded 5-HT axons form an exceptionally rich 5-HT innervation. Piriform cortex [PIR] has a dense plexus of fine 5-HT axons in layer I & III, but few in layer II. All areas of insular cortex exhibit many fine axons in layer I along with a zone containing both axon types in layers II-III. All layers of entorhinal cortex are richly innervated, but a prominent patch of beaded axons is limited to layers II-III of the lateral portion [LEA]. Nuclei in the amygdala can be delineated by distinctive patterns of 5-HT innervation. Following administration of PCA, which selectively ablates fine 5-HT axons, there is marked denervation with a pattern of axonal sparing unique to each zone. While PIR is markedly denervated, the patch of beaded axons remains in layers II-III of LEA. Selective axon loss in the amygdala leaves a dense 5-HT innervation in the basolateral nucleus [BL]. Nine months after PCA, much reinnervation of these areas by fine 5-HT axons has occurred, in advance of that in parieto-occipital areas of neocortex. The early reinnervation of these ventral telencephalic areas is ascribed to their proximity to preterminal axons in the MFB. The selectivity of sprouting appears to restore the original 5-HT innervation pattern. The specific patterns of innervation in these forebrain areas supports differential functional effects of the raphe nuclei in particular regions. [Support: DA04431 & PMA]

426.8

P-CHLOROAMPHETAMINE-INDUCED NEUROTOXICITY IN RAT BRAIN DEPENDS ON THE PRESENCE OF ENDOGENOUS SEROTONIN.

U.V. Berger, R. Grzanna and M.E. Molliver. Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Systemic administration of p-chloroamphetamine (PCA) causes acute release of serotonin (5-HT) and produces long-lasting degeneration of 5-HT axons in rat brain. However, direct intracerebral injection of PCA does not produce toxic effects on 5-HT axons, suggesting that a neurotoxic compound is generated in the periphery following systemic administration. This study was designed to test the possibility that endogenous serotonin (5-HT) plays a role in mediating the neurotoxic effects of PCA in the brain. PCA was systemically administered to rats that had been previously depleted of 5-HT by different regimens of p-chlorophenylalanine and/or reserpine. Two weeks later, the serotonergic innervation of the forebrain was evaluated using immunocytochemical and biochemical methods. The results show that acute depletion of 5-HT storage pools provides substantial protection against the PCA-induced degeneration of 5-HT axon terminals. While drug interactions may possibly have a protective effect, it is more likely that the neurotoxicity of PCA is dependent on the release of endogenous 5-HT. The results show further that the protective effect is most profound following treatment regimens that are sufficient to deplete peripheral as well as central stores of 5-HT. We interpret this finding as evidence that peripheral stores of 5-HT, i.e., in platelets and enterochromaffin-cells, are necessary for the expression of PCA-induced toxicity. Based on these results, we propose that neurotoxicity is not produced directly by PCA itself but may be caused by a toxic metabolite of 5-HT. This mechanism may also account for the neurotoxicity seen with other psychotropic amphetamines such as 3,4-methylenedioxymethamphetamine. [Support: USPHS Grant DA-04431]

426.9

ACUTE AND CHRONIC EFFECTS OF THE α-ETHYL HOMOLOGUE OF *p*-CHLOROAMPHETAMINE (PCA). X. Huang*, M. P. Johnson, R. Oberlender, J. F. Nash and D. E. Nichols. Depts. of Pharmacology and Toxicology, and Medicinal Chemistry and Pharmacognosy, School of Pharmacy and Pharmacal Sciences, Purdue Univ., W. Lafayette, IN 47907. Dept. of Psychiatry, Case Western Reserve Univ., Cleveland, OH 44106.

Previous work from our laboratory has indicated that extension of the α-side chain in several substituted amphetamines attenuates the DA but not the 5-HT actions of the compounds. This report describes the effects of α-side chain extension in the PCA analog 1-(4-chlorophenyl)-2-aminobutane (CAB). The effects of CAB and PCA on the uptake inhibition of ^{3}H-5-HT and ^{3}H-DA, the extracellular concentrations of DA and DOPAC using *in vivo* microdialysis, behavioral activity as determined utilizing a two-lever drug discrimination paradigm with rats trained to discriminate 1.75 mg/kg *S*-MBDB, and the neurotoxicity of CAB as measured by HPLC-EC and ^{3}H-paroxetine binding parameters one week after a single dose were examined.

CAB was found to inhibit the uptake of both ^{3}H-5-HT and ^{3}H-DA with IC_{50} values of 331 ± 18 and 2343 ± 12 nM, respectively. This is 2.5-fold less potent than PCA (132 ± 7 nM) for ^{3}H-5-HT and 5-fold less potent than PCA (466 ± 15 nM) for ^{3}H-DA uptake inhibition. Similarly, CAB was found to be behaviorally less potent than PCA. The ED_{50} values (95 % confidence limits) were 0.17 (0.10 - 0.30) and 0.62 (0.41 - 0.93) mg/kg for PCA and CAB, respectively. CAB at 22 mg/kg, but not 11 mg/kg, significantly increased extracellular DA and decreased DOPAC in the striatum 3 hrs following administration. PCA (10 mg/kg) markedly increased extracellular DA and decreased DOPAC during the first 3 hrs after administrtion. Similarly, 5-HT, 5-HIAA and ^{3}H-paroxetine binding were significantly decreased one week following PCA or 22 mg/kg of CAB. Therefore, it appears that extension of the α-side chain of PCA attenuates but does not abolish the dopaminergic effects. In addition, the relative neurotoxicity and DA effects of PCA and CAB support the importance of DA in the serotonin neurotoxicity of PCA-like compounds.

426.10

COMPARISON OF THE EFFECTS OF REPEATED ORAL VERSUS SUBCUTANEOUS d,l-FENFLURAMINE ADMINISTRATION ON BRAIN SEROTONIN NEURONS IN THE RAT. S. Culp*, R. Zaczek, N.M. Appel, J.F. Contrera and E.B. De Souza, NIDA/ARC, Baltimore, MD 21224; FDA, Rockville, MD 20857

Repeated systemic administration of high doses of fenfluramine, a prescribed anorectic agent, produces dose-dependent decreases in brain serotonin (5-HT) markers characteristic of toxic actions of the drug. In view of the differences in the prescribed dose, route of administration, kinetics and metabolism of fenfluramine in humans versus rats, the relevance of the high-dose toxic effects of systemically administered fenfluramine in rats to the therapeutic use of the drug is unclear. The importance of the route of drug administration (oral vs s.c.) on the neurochemical effects and pharmacokinetics of repeated d,l-fenfluramine administration in rats (1-24 mg/kg b.i.d. 4 days) was examined. Overall, comparable, dose-dependent alterations in brain 5-HT markers were observed following oral and s.c. administration of fenfluramine. Doses of 1 and 2 mg/kg fenfluramine were without significant effects on 5-HT uptake sites. Higher doses of fenfluramine (4-24 mg/kg) produced dose-dependent decreases in 5-HT, 5-hydroxyindoleacetic acid and 5-HT uptake sites with maximal decreases (80-90%) occurring at 12 mg/kg. In brain, significantly higher levels of fenfluramine were observed following s.c. than following oral administration of the drug. In contrast, comparable levels of its active metabolite norfenfluramine were present in brain following the two treatments. These data suggest that norfenfluramine levels in brain may be more important in determining the high-dose neurotoxic effects of fenfluramine in rats. Furthermore, the data underscore the importance of species differences in metabolic profiles and pharmacokinetics of the drug and its metabolite in determining the relevance to humans of the high-dose toxic effects of fenfluramine in rats.

426.11

DL-FENFLURAMINE AND HIPPOCAMPAL SEROTONIN RELEASE IN THE AWAKE RAT. K.E. Sabol, J.B. Richards, and L.S. Seiden. Dept. Pharmacol. Physiol. Sci., Univ. Chicago, Chicago, IL 60637

Acute injections of D-fenfluramine cause increases in extracellular serotonin (5HT) in cortex, hypothalamus and n.accumbens in anesthetized rats (LaFerrere and Wurtman, 1989). DL fenfluramine increases cortical 5HT in freely moving rats 24 hours after dialysis probe implantation (Carboni and Di Chiara, 1989). In the present experiment, the effect of DL-fenfluramine on extracellular serotonin in the hippocampus in freely moving rats was studied. Rats were permanently implanted with BAS 4 mm dialysis probes (N=5). Fifteen hours later (Day 1) the rats were perfused with Ringers solution (0.20 ul/min) and basal 5HT levels were determined with HPLC-EC. 4.0 mg/kg DL-fenfluramine was then injected IP and perfusate was collected for an additional 3 hours. This procedure was repeated on Days 5 and 10 after probe implantation. The probes were not removed from the brains during this 10 day period, and the rats were perfused only on the 3 test days. Basal 5-HT values were 1.1, 1.1 and 0.5 pg/5 ul/30 min on days 1, 5, and 10 respectively; at 60 min post-injection, the 5=HT values were 11.2, 8.7, and 4.1 pg/5 ul/30 min on days 1, 5, and 10. Because chronic fenfluramine is known to deplete 5HT tissue levels (Kleven and Seiden, 1989) the decreased serotonin response in this study may be due to a mild toxic effect of the 3 - 4.0 mg/kg injections. It is more likely however, that the probe has become less viable over time. We are currently investigating these possible interpretations. This work was supported by MH-11191 and RSA-10562 (L.Seiden).

426.12

INCREASE IN TRYPTOPHAN HYDROXYLASE CONCENTRATION IN ADULT RAT NEOSTRIATUM AFTER NEONATAL DOPAMINE DENERVATION WITH 6-HYDROXYDOPAMINE. D. Weissmann*, C. Rousset*, L. Descarries and J.F. Pujol*. CNRS, UMR 105, Université Claude Bernard, Lyon, FRANCE, and CRSN (Département de physiologie), Université de Montréal, Montréal, CANADA H3C 3J7.

Using a recently developed radio-immunological technique for the visualization and measurement of enzymatic protein transferred from unfixed brain sections onto nitro-cellulose (Weissmann, D. et al., *J. Neurochem.*, 53:793, 1989), we have examined the tryptophan hydroxylase (TpOH) content in adult rat neostriatum, globus pallidus and raphe nuclei, after bilateral i.c.v. administration of 6-OHDA to 3-day-old rats pretreated with desipramine. This treatment is known to result in an almost complete dopamine denervation of the forebrain and a prominent serotonin (5-HT) hyperinnervation in the rostral half of neostriatum (Snyder, A.M. et al., *J. Comp. Neurol.*, 245:274, 1986). Three to four months after the treatment, a significant increase in tissue TpOH concentration (+ 26-36%) could be measured in the rostral but not the caudal part of neostriatum. However, there were no changes in TpOH tissue concentration in the globus pallidus nor in the nuclei raphe dorsalis, medianus or pontis. These data strongly suggest that the augmented TpOH concentration in the 5-HT-hyperinnervated neostriatum was not associated with an increased concentration of the enzyme in the nerve cell bodies of origin. If the turnover rate of TpOH is not reduced in the neostriatum, a greater amount of the protein must be produced and delivered to an enlarged axonal tree, thus maintaining the steady state concentration of the enzyme within the 5-HT nerve cell bodies.

CORRELATIVE SCANNING AND TRANSMISSION ELECTRON MICROSCOPY OF THE SUPRAEPENDYMAL NEURONAL COMPLEX IN THE HAMSTER THIRD VENTRICLE FOLLOWING RADIOFREQUENCY LESIONS OF THE MIDBRAIN RAPHE NUCLEI. R.D. Fessler*, J.C. Hazlett and J.A. Mitchell. Departments of Anatomy & Cell Biology and Neurosurgery, Wayne State University School of Medicine, Detroit, MI 48201.

Scanning electron microscopy (SEM) of the hamster (Mesocricetus auratus) third ventricle following radiofrequency lesions of the midbrain raphe nuclei (RN) reveals degeneration of the supraependymal neuronal complex (SENC) within 2-4 days (Fessler & Mitchell, Soc. Neurosci. 15: 419). The current study utilizes correlative transmission electron microscopy (TEM) to ascertain specifically which components of the SENC undergo degeneration following lesions of the RN. Hamster third ventricles previously processed for SEM were prepared for examination by TEM. TEM revealed widespread evidence of ultrastructural disruption within the core of the SENC, within the peripherally located neuronal perikarya and in supraependymal processes coursing over the floor of the third ventricle. Degenerating cell profiles and synapses exhibited increased electron density and osmophilic inclusions. In addition, increased numbers of active phagocytic profiles were noted. Incomplete lesions of the midbrain RN resulted in varying degrees of SENC perikarya and fiber degeneration. Complete lesions of the midbrain RN resulted in total loss of the SENC within 2-4 days. Control animals lesioned 1-2 mm caudal to the midbrain RN did not exhibit evidence of SENC degeneration. The results of correlative SEM/TEM following raphe lesions confirm previous SEM documentation of degeneration and suggest that the hamster SENC is dependent upon serotonergic input from the midbrain raphe nuclei.

426.14

NEUROTOXIC EFFECTS OF NEONATAL 5,7-DIHYDROXYTRYPTAMINE (5,7-DHT) TREATMENT ON RAT BRAIN TRYPTOPHAN HYDROXYLASE (TPH) AND AROMATIC-L-AMINO ACID DECARBOXYLASE (AADC). D.H. Park, T. Wessel, K.S. Kim, H. Baker, A. Towle and T.H. Joh. Lab. Mol. Neurobiol., Cornell Univ. Med. College, The Burke Rehab. Center, White Plains, NY 10605.

Recent studies indicate that in neonates the neurotoxin 5,7-DHT induces selective damage in serotonergic neurons and terminals. In the present study, we examined the effect of intracisternally applied 5,7-DHT (50 μg/pup) on the serotonin biosynthetic enzymes, TPH and AADC, using biochemical, immunocytochemical and *in situ* hybridization techniques. Enzymatic activity of TPH and AADC was measured in the dorsal raphe nucleus (DRN), caudal brainstem (CBS) and hypothalamus (HYP). One, two and four weeks after drug administration, TPH activity in all regions was reduced to 20-30% of control levels. In contrast, at one week AADC activity in DRN and CBS was decreased to 50% of control, whereas in the HYP activity increased to 125% of control. A modest decrease in AADC activity was observed in the HYP at 2 and 4 weeks after treatment. Immunohistochemical staining using serotonin and AADC antisera as well as *in situ* hybridization with a [^{35}S]-labeled TPH cDNA probe were employed to monitor the specific subnuclei of the DRN exhibiting the biochemical alterations. Up to four weeks after drug treatment, many neurons could be demonstrated in medial aspects of the DRN. However, the neurons were absent from the lateral subnuclei of DRN and the B9 group. At higher doses of 5,7-DHT (200 μg/pup) neuronal loss in the DRN was more widespread. The relatively large decrease in TPH activity as compared to neuronal loss produced at low doses of 5,7-DHT suggests that enzyme synthesis may be compromised even in the remaining neurons. These data demonstrate a dose-dependent selective vulnerability of midbrain serotonergic neurons to 5,7-DHT.

EFFECTS OF RAPHE HYPERINNERVATION ON STRIATAL SEROTONERGIC NEUROTRANSMISSION IN RATS DEPLETED OF DOPAMINE AS NEONATES. D. Jackson, M. Teitler*, S. Leonhardt*, M.J. Zigmond, and E.D. Abercrombie, *Dept. of Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA., *Dept. Pharm. & Tox., Albany Med. Col., Albany, N.Y.*

Neonatal rats treated with 6-hydroxydopamine (6-HDA) fail to show the profound behavioral deficits observed in rats receiving comparable lesions as adults. This sparing is accompanied by extensive sprouting of serotonin (5-HT) neurons in striatum. However, behavioral and biochemical studies suggest that 5-HT function actually is reduced in neonatally-lesioned rats. Thus, 5-HT, which normally inhibits acetylcholine release, fails to do so in these animals (Jackson et al., Brain Res., 457: 267, 1988). We are exploring two explanations: that 5-HT is not released or that sensitivity to 5-HT is lost in neonatally-lesioned rats. Using microdialysis we monitored extracellular 5-HT in response to fluoxetine, an uptake blocker (100 uM) or KCl (100 uM) via the probe, or fenfluramine (10 mg/kg, i.p.), a 5-HT releasing agent:

Extracellular 5-HT (pg/50 ul dialysate)

Condition (n)	Control	Lesion	% Control
Basal (12)	12.5 ± 1	9.4 ± .8	75
Fluoxetine (4)	200 ± 9	689 ± 200	345
KCl (4)	201 ± 56	578 ± 115	288
Fenfluramine (4)	193 ± 41	554 ± 143	287

The response to each treatment was greater in the lesioned animals. However, the apparent increase in the capacity for 5-HT release may be offset by an increase in 5-HT uptake sites, thus obviating any advantage conferred by 5-HT sprouting. Preliminary results indicate that 5-HT_2 receptor binding was not altered in lesioned neonates. Thus, both 5-HT release and 5-HT_2 receptor sites appear intact after 6-HDA-induced hyperinnervation of 5-HT afferents to striatum.

5HT_{1a} AND OTHER 5HT RECEPTOR SUBTYPES

427.1

5-HT_{1A} AGONIST-LIKE EFFECTS OF NAN-190. J.T.Lum, W.E.Hoffmann, and M.F. Piercey, The Upjohn Company, Kalamazoo, MI 49001.

Like many other 5-HT_{1A} agonists (e.g. buspirone, ipsapirone), NAN-190 is an arylpiperazine which binds to 5-HT_{1A} receptors. However, unlike 5-HT_{1A} agonists, NAN-190 antagonized the discriminative effects of 8-OH DPAT (Glennon *et al.*, Drug Dev. Res. 16: 335-343, 1989). We have now further evaluated NAN-190's effects on bioassays sensitive to 5-HT_{1A} agonists. In hypothermia assays, mice were treated with 10 mg/kg 8-OH DPAT to give a temperature drop of 6.0±0.9°F. NAN-190 (gift of R.A.Glennon) failed to antagonize this effect of 8-OH DPAT, but did itself depress body temperature. To more specifically evaluate on 5-HT mechanisms, we measured its effects on 5-HT neuron firing rates. Dorsal raphe 5-HT neurons identified according to Aghajanian *et al.*, (JPET 137:178, 1970) were depressed by 8-OH DPAT (ED_{50} = 1.6 µg/kg). Again, NAN-190 did not reverse the depressant effects of 8-OH DPAT, but did itself depress firing rates with a potency (ED_{50} = 11 µg/kg) similar to those for buspirone, ipsapirone, and gepirone (7-15 µg/kg). It is concluded that behavioral antagonism by NAN-190 is unlikely to result from blockade of presynaptic 5-HT_{1A} receptors, but could result from antagonism of postsynaptic 5-HT_{1A} receptors.

427.2

INHIBITION OF DORSAL RAPHE CELL FIRING BY MDL 73005EF: RELATIONSHIP TO 5-HT_{1A} RECEPTOR BINDING. J.S. Sprouse, D.R. McCarty* and M.W. Dudley, Merrell Dow Research Institute, 2110 E. Galbraith Road, Cincinnati, OH 45215

MDL 73005EF (8-[2-(2,3-dihydro-1,4-benzodioxin-2-ylmethylamino)-ethyl]-8-azaspiro[4,5]decane-7,9-dione methylsulphonate) has been shown to be an effective agent in preclinical assessments of anxiolytic drug action. The goal of the present study was to determine whether MDL 73005EF is an agonist at the 5-HT cell body autoreceptor (5-HT_{1A}) in the dorsal raphe (DR) and whether this action is consistent with binding to the autoreceptor in DR membranes. Extracellular single unit recordings of DR neurons were made in the in vitro rat brain slice. MDL 73005EF potently inhibited neuronal firing in a concentration-dependent manner (IC_{50} = 129 ± 34 nM; N=6), typical of the non-indole 5-HT_{1A} agonists. In bovine DR membranes, MDL 73005EF effectively displaced [^{3}H] 8-OH-DPAT binding; however, the data could be resolved into a 2-site model with a low (IC_{50} = 2.57 ± 0.64 µM) as well as a high (4.38 ± 1.30 nM) affinity binding site (Hill coefficient = 0.38). Of the total labeled sites, ~60% were low affinity sites. A similar pattern emerged when 5-HT was used as the displacing agent (1.17 ± 0.25 µM, 4.00 ± 1.40 nM). In contrast, in membranes prepared from bovine hippocampi (HC), also rich in 5-HT_{1A} sites, displacement of [^{3}H] 8-OH-DPAT binding by MDL 73005EF and 5-HT revealed only the high affinity site (3.37 ± 0.56 nM and 5.81 ± 0.61 nM, respectively). The functional role for these "states" of the 5-HT_{1A} receptor is unknown, but the differences observed in their relative proportion in the DR and HC may explain in part the agonist or partial agonist profiles of 5-HT_{1A} ligands at these receptor sites.

427.3

IN VIVO PERTUSSIS TOXIN (PT) EFFECTS ON 5-HT_{1A} AND D2 AUTO-RECEPTOR FUNCTIONAL RESPONSE: POSSIBLE RELATIONSHIP TO RECEPTOR RESERVE (RR). K. Bohmaker and E. Meller. Dept. of Psychiatry, NYU Medical Center, New York, New York 10016.

We previously demonstrated the presence of a large RR for agonists at both D2 and 5-HT_{1A} autoreceptors. Since both of these receptors appear to be coupled to their effectors via PT-sensitive G-proteins, it was of interest to determine the effects of PT treatment on the pharmacological response to full and partial D2 and 5-HT_{1A} agonists. Rats were treated intrastriatally or in the vicinity of the dorsal raphe nucleus with 0.5-1.0 ug of PT or vehicle. After 48 hr, dose-response (DR) curves were obtained for full and partial agonists at the receptor of interest (D2:(-)NPA and (+)3-PPP; 5-HT_{1A}: 8-OH-DPAT and buspirone). D2 and 5-HT_{1A} autoreceptor function were assessed as agonist-induced reversal of L-DOPA accumulation after GBL and inhibition of 5-HT synthesis, respectively. Analogous to our previous findings after irreversible receptor inactivation, PT treatment shifted the DR curves for full agonists to the right, with little or no reduction in maximal response, whereas for partial agonists the maximal response was reduced with little or no shift in ED_{50}. These results suggest that RR may be related to a "G-protein reserve" for full but not partial agonists. Even for a full agonist, no "G-protein reserve" would be predicted in the absence of RR; this is indeed the case for 5-HT_{1A} mediated inhibition of forskolin-stimulated adenylate cyclase (see Yocca et al., this meeting). Supported by NINDS grant NS-23618.

427.4

LACK OF RECEPTOR RESERVE (RR) AT POSTSYNAPTIC 5-HT1A RECEPTORS LINKED TO ADENYLYL CYCLASE (AC) IN RAT HIPPOCAMPUS (HIP). F.D. Yocca[1], L. Iben*[1] and E. Meller[2] CNS Research Bristol-Myers Squibb Co., Wallingford, CT 06492[1] and Dept. of Psychiatry, NYU Medical Center, NY, NY 10016.[2]

Multidisciplinary studies have shown that 5-HT_{1A} agonists appear to exhibit higher efficacy at somatodendritic vs postsynaptic 5-HT_{1A} receptors. A possible explanation for this phenomena is the existence of a RR in the dorsal raphe (DR). This reserve may result from an excess of either the 5-HT_{1A} receptor or the G-protein linked to this receptor. To test this hypothesis we compared the 5-HT_{1A} receptor system in the rat HIP to that in the DR. Through receptor alkylation via treatment with N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ), presynaptic DR 5-HT synthesis-sensitive 5-HT_{1A} autoreceptors in rat were shown to possess a large receptor reserve for 8-OH-DPAT (Meller et al., Mol. Pharm., 37:231-237, 1990). Furthermore, ADP ribosylation of G_i-protein via infusion of pertussis toxin (PT) into rat DR results in a dextral shift of the EC_{50} for 8-OH-DPAT with little or no change in the E_{max}, suggesting the exsistence of a "G-protein reserve" (see Bohmaker and Meller, this meeting). Similar techniques were used here to determine the reserve status of rat postsynaptic HIP 5-HT_{1A} receptors linked negatively to AC. Irreversible receptor alkylation by EEDQ reduced the maximal response but did not alter the EC_{50} for 5-HT. Similarly, PT infusion into rat HIP reduced the maximal response of 5-HT with little or no change in EC_{50} (Clarke et al., Brain Res., 14:361-367, 1987). These results indicate that postsynaptic 5-HT_{1A} receptors, as opposed to somatodendritic autoreceptors, do not possess a RR, which may in part explain the differences in relative efficacies demonstrated by 5-HT_{1A} agonists at these sites. Furthermore, these findings are consistent with the idea that receptor reserve may be related to a "G-protein reserve".

427.5

REGIONAL INTERACTIONS OF 8-OHDPAT WITH p-Cl-AMPH AND MDMA IN VIVO IN RAT BRAIN. J. E. Embury, A. Frank*, and M. P. Galloway. Dept. Psychiatry, Cellular & Clinical Neurobiology Program, Wayne State Univ Sch Med, and Lafayette Clinic, Detroit MI

Using cortical slices in vitro, we have previously reported that both the 5-HT 1A agonist 8-OHDPAT, and 5-HT reuptake inhibitors block the 5-HT releasing effects of either 5-HT 1 agonists (eg, TFMPP, RU 24969), or 5-HT toxins (eg, p-Cl-AMPH, MDMA) thus providing evidence for a functional interaction between 5-HT-1 receptor agonists with the 5-HT reuptake site (Galloway et al., this meeting). The present study examined potential interactions between 5-HT-1 receptor agonists and the 5-HT reuptake site in vivo. Fluoxetine (5 mg/kg, s.c.), a 5-HT reuptake inhibitor,completely blocked the ability of p-Cl-AMPH (5 mg/kg s.c.), to reduce endogenous 5-HT levels in both the medial prefrontal cortex (MPF) and the striatum (STR). Pretreatment with 8-OHDPAT at 0.5 and 1.0 mg/kg resulted in a 46% and 70% reversal of the p-Cl-AMPH depletion of striatal 5-HT, respectively. (+)-MDMA (10 mg/kg, s.c., administered at 1.0, 1.5, 2.0 and 3.0 hrs. before sac.) inhibited 5-HT synthesis in the anterior and posterior STR, MPF, nucleus accumbens (NAc), HC, and temporal cortex and decreased 5HT levels (10 mg/kg, s.c., 3 hrs. before sac.) in the STR, MPF and HC. In contrast, MDMA did not decrease 5-HT in the NAc or OT and actually increased 5-HT synthesis in the OT. The 5-HT depleting effect of MDMA in the MPF was partially reversed by pretreatment with 8-OHDPAT. Nomifensine (10 mg/kg, s.c.), a dopamine reuptake inhibitor, blocked the ability of 8-OHDPAT to reverse MDMA toxicity in the MPF. The present study suggests an interaction between 8-OHDPAT and the 5-HT reuptake site in vivo with a possible dopaminergic influence that is specific for DA projection fields. (Supported by MH-41227, DA-04120, and the State of Michigan DMH).

427.6

8-OHDPAT, LIKE 5HT REUPTAKE INHIBITORS, BLOCKS THE EFFECTS OF MDMA AND TFMPP ON 5HT RELEASE AND SYNTHESIS IN VITRO. M.P. Galloway, E.A.Novak*, B.N.Mathews* Lafayette Clinic, Cellular & Clinical Neurobiol. Prog., Dept. Psychiatry, Wayne State Univ Sch Med, Detroit MI

We have previously reported that 5HT agonists such as TFMPP, m-CPP, and RU 249696 stimulate endogenous 5HT release from cortical slices, an effect which is blocked the 5HT-1A agonist 8-OHDPAT (which alone has no effect on 5HT release). Our results suggested that the releasing agents were substrates for the 5HT transporter whereas 8-OHDPAT acted as a reuptake inhibitor. Based on this premise, we recently found that either 8-OHDPAT, sertraline, or fluoxetine dose-dependently blocks the in vitro 5HT releasing properties (from cortical slices) of the 5HT neurotoxins (+)MDMA ("ecstasy") and p-Cl-AMPH. Ipsapirone, a chemically dissimilar 5HT-1A agonist, only weakly reversed MDMA, whereas other aminotetralins (7-OHDPAT > 5-OHDPAT > AJ-76) significantly reduced the 5HT releasing action of MDMA. 8-OHDPAT was more effective on MDMA induced release of striatal 5HT, when compared to striatal DA release. Further evidence that TFMPP is a substrate for the 5HT transporter was the observation that a 50% reduction in $[Na^+]_{EXT}$ in the media blocked the release of 5HT by TFMPP. However, removal of Ca^{++} blocked neither TFMPP induced 5HT release nor the antagonism afforded by 8-OHDPAT. These results demonstrate a functional interaction of 5HT agonists with the 5HT transporter: 8-OHDPAT resembles classical 5HT reuptake inhibitors in that both block the 5HT releasing properties of TFMPP, RU 24969, MDMA, or p-CA, compounds thought to be substrates at the 5HT transporter. CP-93,129, A NEW SEROTONERGIC LIGAND WITH MARKED AFFINITY AND HIGH SELECTIVITY FOR 5-HT$_{1B}$ RECEPTORS. B.K. Koe, L.A. Lebel, C.A. Burkhart*, and J.E. Macor*. Central Research Division, Pfizer Inc., Groton, CT 06340

The mechanism of action of several new classes of therapeutic drugs involves modulation of central serotonergic function. These include antidepressants based on selective blockade of serotonin (5-HT) uptake (fluoxetine, sertraline), new anxiolytics based on 5-HT$_{1A}$ agonist activity (buspirone, tandospirone) and an anorectic agent based on enhancing 5-HT release (dexfenfluramine). The recent description of new 5-HT receptors and receptor subtypes affords the opportunity of designing novel ligands that will exert a selective action at a targeted receptor subtype. Our efforts directed at the 5-HT$_{1B}$ receptor, apparently the major 5-HT$_1$ subtype in rat brain other than 5-HT$_{1A}$, led to the synthesis of CP-93,129, the tautomer of 5-hydroxy-3-(4-1,2,5,6-tetrahydropyridyl)-4-azaindole. CP-93,129 was found to exhibit marked affinity for 5-HT$_{1B}$ receptors in rat brain membranes (IC_{50} 15 nM using [^{3}H]5-HT). The high selectivity of CP-93,129 for 5-HT$_{1B}$ receptors (rat cortex) was shown by the following binding results: 200-fold greater affinity for 5-HT$_{1B}$ than 5-HT$_{1A}$ sites (rat cortex), 150-fold greater affinity for 5-HT$_{1B}$ than 5-HT$_{1D}$ sites (bovine striatum), 400-fold greater affinity for 5-HT$_{1B}$ than 5-HT$_{1C}$ sites (pig choroid plexus) and 2500-fold greater affinity for 5-HT$_{1B}$ than 5-HT$_2$ sites (rat cortex). CP-93,129 showed virtually no affinity for noradrenergic or dopamine receptors and did not block 5-HT uptake or bind to the 5-HT uptake site. An agonist function for CP-93,129 was indicated by a decrease in binding affinity in the presence of Gpp(NH)p. CP-93,129 may be a useful agent for ascertaining the pharmacological and behavioral role of 5-HT$_{1B}$ receptors.

427.8

CP-93129: A POTENT AND SELECTIVE 5-HT$_{1B}$ RECEPTOR AGONIST. A.W. Schmidt, J.E. Macor*, and D.W. Schulz. Central Research Division, Pfizer Inc., Groton, CT 06340.

Highly selective ligands, such as 8-OH DPAT, have contributed greatly to our understanding of the functional properties of the 5-HT$_{1A}$ receptor. Comparable studies of 5-HT$_{1B}$ receptors have been hampered in part by a lack of compounds having high 5-HT$_{1B}$ receptor selectivity. However, it was recently established that CP-93129 [3-(1,2,3,6-tetrahydropyrid-4-yl)-pyrrolo[3,2-b]pyrid-5-one] has >200-fold selectivity for 5-HT$_{1B}$ vs 5-HT$_{1A}$ sites in rat brain, while binding to 5-HT$_{1C}$ and 5-HT$_2$ receptors with affinities in the micromolar range (Koe *et al.*, Soc. Neurosci., 1990).

CP-93129 competed for ^{3}H-5HT binding to 5-HT$_{1B}$ receptors in rat cortex with a K_i of <5 nM, but inhibited ^{3}H-8-OH-DPAT binding in the same tissue with a K_i of >1 μM. CP-93129 behaved as an agonist in inhibiting forskolin-stimulated adenylate cyclase activity in guinea pig hippocampus (5-HT$_{1A}$ receptors), rat substantia nigra (5-HT$_{1B}$ receptors), and guinea pig substantia nigra (5-HT$_{1D}$ receptors), with EC_{50} values in these three preparations of >10 μM, 56 nM, and >10 μM, respectively. CP-93129 also potently inhibited forskolin-stimulated adenylate cyclase in rat globus pallidus, an area rich in 5-HT$_{1B}$ receptors. The K^+-induced release of endogenous 5-HT was significantly inhibited by CP-93129 in globus pallidus synaptosomes. Thus, CP-93129 represents a novel tool for investigating both pre- and postsynaptic 5-HT$_{1B}$ receptor function.

427.9

CP-93,129, A POTENT AND SELECTIVE 5HT$_{1B}$ AGONIST, INHIBITS FOOD INTAKE IN RATS. L.K. Torgersen*, J.E. Macor* and J.A. Nielsen. Central Research Division, Pfizer Inc., Groton, CT 06340.

Serotonin (5HT) is involved in the regulation of food intake. Direct infusion of 5HT into the paraventricular nucleus of the hypothalamus (PVN) of rats leads to inhibition of feeding with less than full efficacy. This partial effect may result from activation of 5HT$_{1B}$ receptors which produce anorexia plus 5HT$_{1A}$ receptors which cause hyperphagia. CP-93,129 is a potent (IC_{50}= 15 nM) and selective (150-200 fold greater affinity than for the 5HT$_{1A}$ or 5HT$_{1D}$ sites) 5HT$_{1B}$ ligand. CP-93,129 inhibits forskolin-stimulated adenylate cyclase, suggesting agonist activity at the 5HT$_{1B}$ receptor. The present investigation studies the effects of CP-93,129 on food intake in rats.

CP-93,129 inhibited food intake when infused into the PVN, an effect that was both dose-related (ED_{50} = 8 μg) and time-dependent (30 min duration of anorexia at ED_{50}). The 5HT$_{1B}$ partial agonists metergoline and methysergide partially prevented CP-93,129 induced anorexia when they were injected either ip or directly into the PVN. CP-93,129 had no effect on food intake when injected systemically, perhaps because its structure does not allow free distribution to the brain. CP-93,129, injected into the PVN, was a more efficacious anorexic than 5HT. 5HT might be a less efficacious anorexic than CP-93,129 due to its 5HT$_{1A}$ agonist activity.

These data suggest that central 5HT$_{1B}$ receptors modulate food intake in the rat.

427.10

[^{3}H]CP-96,501, A NEW RADIOLIGAND FOR 5-HT$_{1B}$ RECEPTORS IN RAT BRAIN. L.A. Lebel, C.A. Burkhart*, J.E. Macor*, and B.K. Koe. Central Research Division, Pfizer Inc., Groton, CT 06340

The recent description of different 5-HT$_1$ receptor subtypes in brain has prompted interest in discovering selective agonists and antagonists in order to ascertain the role of the various sites in serotonergic function. The major 5-HT$_1$ subtype, other than 5-HT$_{1A}$, in rat brain is 5-HT$_{1B}$. Standard 5-HT$_{1B}$ agonists used in the literature include RU 24969 (5-MeO-3-(4-1,2,5,6-tetrahydropyridyl)indole), MCPP, TFMPP and CGS 12066B. Of these, RU 24969 exhibits the greatest affinity for 5-HT$_{1B}$ receptors (IC_{50} 1.9 nM) with a 7-fold selectivity over 5-HT$_{1A}$ sites. The 5-n-PrO analog of RU 24969 (CP-96,501) was synthesized and found to be equally potent at 5-HT$_{1B}$ receptors with a 40-fold selectivity over 5-HT$_{1A}$ sites. [^{3}H]CP-96,501 was synthesized and evaluated as a 5-HT$_{1B}$ radioligand. Binding experiments were conducted with whole rat brain membranes in the absence of any binding "masks." [^{3}H]CP-96,501 was found to display high affinity binding: K_D 0.16 nM; B_{max} 68 fmol/mg protein; Hill coefficient 0.98. The K_D calculated from on- and off-rates was in good agreement (0.14 nM). Rosenthal plots of [^{3}H]CP-96,501 binding with added 5-HT (5 nM) or TFMPP (20 nM) indicated competitive inhibition. The potency of various serotonergic compounds (e.g., 8-OH-DPAT, CGS 12066B, GR 43175, mesulergine) from competition curves in [^{3}H]CP-96,501 binding showed good correlation (r = 0.99) with their inhibitory activity in [^{3}H]5-HT binding to 5-HT$_{1B}$ receptors. An agonist function for CP-96,501 was suggested by the decrease in binding affinity in the presence of Gpp(NH)p. Our findings indicate that [^{3}H]CP-96,501 is a specific agonist ligand for 5-HT$_{1B}$ receptors in rat brain. [^{3}H]CP-96,501 saturation binding in brain membranes from several other species did not yield definitive evidence to support the presence of 5-HT$_{1B}$ receptors in these tissues.

DEVELOPMENT OF SELECTIVE/POTENT 5-HT1A ANTAGONISTS. R. K. RAGHUPATHI[a], L. RYDELEK-FITZGERALD[#], M. TEITLER[#], R. A. GLENNON[a]*. [a]Dept. of Med. Chem., MCV/VCU, Richmond, VA 23298, and [#]Dept. of Pharmacol. and Toxicol., Albany Medical College, Albany, NY 12208.

NAN-190, 1-(2-methoxyphenyl)-4-[4-(2-phthalimido)butyl]piperazine, has been previously reported by our laboratory as a high-affinity (Ki = 0.6 nM) 5-HT1A antagonist. (Glennon et al., Eur. J. Pharmacol. 154:339, 1988). We attempted to overcome the problem of its equal affinity (Ki = 0.8 nM) for α1-adrenergic sites by performing structure-affinity relationship (SAFIR) studies for binding at each of the two sites. Replacement of the aromatic phthalimido moiety of NAN-190 by alkyl amide groups decreases α1 affinity with retention of high affinity for 5-HT1A sites. Increased branching and bulkiness of the alkyl amide portion shows a trend towards increased 5-HT1A selectivity. We have thus been able to obtain compounds with a >100-fold selectivity for [^{3}H]8-OH DPAT-labelled 5-HT1A sites over α1-adrenergic sites. These compounds (e.g. RK-153, Ki = 0.4 nM) show antagonist activity in the 5-HT1A-coupled adenylate cyclase assay. We have therefore succeeded in developing several novel high-affinity 5-HT1A ligands that lack as significant an α1 component as NAN-190. (Supported in part by PHS grant NS 23523).

SEROTONIN-1$_A$ AND SEROTONIN-2 RECEPTORS IN EUTHERMIC AND TORPOR PRONE DEERMICE, PEROMYSCUS MANICULATUS. B.A. Hulihan-Giblin, E.B. Pivorun*, D. Goldman NIAAA, Section on Genetic Studies, LCS Bethesda, Maryland 20892.

P. maniculatus, the deermouse, displays both spontaneous and induced daily torpor bouts, attaining minimum body T of 15-20 C. There is evidence that brain serotonin may be involved in the initiation and/or maintenance of torpor. Inhibition of serotonin synthesis markedly reduces the duration and depth of torpor (Pivorun and Astwood, Living in the cold, pp. 323-29, 1986) while an increase in activity of the serotonergic and dopaminergic systems has been shown in the hypothalamus and SCN during daily torpor (Lin and Pivorun, Pharm Biochem and Behav. 33:309-14, 1989). A certain percentage of deermice will not enter torpor under any circumstances (30-40%). We compared 5-HT receptor subtypes in deermice that readily enter into torpor (TP) and in non-torpor prone (NTP) animals. Deermice were trapped in the wild and subjected to food rationing and low ambient T and then sacrificed in a normothermic or torpid state at 11 P.M. or at 11 A.M. Whole brain was assayed for 5HT1$_A$ and 5HT2 receptor differences using [^{3}H]8-OH-DPAT and [^{3}H]ketanserin, respectively. Serotonin-1$_A$ brain receptors revealed both diurnal and genetic functional differences. The density (Bmax) of 5HT1$_A$ brain receptors was higher in both TP and NTP animals at 11 P.M. then at 11 A.M. Furthermore, at 11 P.M., 5HT1$_A$ receptor binding was significantly higher in TP animals compared to the NTP. No significant difference was seen at 11 A.M. Serotonin-2 receptors displayed the same diurnal variation as 5HT1$_A$ receptors. However, 5HT2 brain receptors were higher in NTP animals as compared to TP animals sacrificed at 11 A.M. These diurnal and genetic receptor differences in TP and NTP animals indicate that certain serotonin receptors may be involved in the modulation of torpor in this species.

427.13

5-HT RECEPTOR SUBTYPES IN RAT DORSAL ROOT GANGLION (DRG) CELLS AND THEIR ASSOCIATED IONIC CONDUCTANCES. Slobodan Todorovic and E.G. Anderson Dept. Pharmacology, U of I Chicago, Chicago, IL 60612.

Rat DRG neurons exhibit 3 distinct membrane responses to 5-HT; depolarization with increased or decreased input resistance (Rin) and hyperpolarization. Depolarization with increased Rin is mediated by 5-HT2 receptors while depolarization with decreased Rin is mediated by 5-HT3 receptors (Brain Research, 511, 71-79, 1990). We have now estimated reversal potentials (rP) from current-voltage curves constructed in the presence and absence of 5-HT. In cells depolarized by 10 μM 5-HT with increased Rin the rP was -100.75±1.8 mV (N=4) in 2.5 mM K+, and the rP for the 5-HT2 agonist alpha-Methyl 5-HT (10μM) was -97±3.9 mV (N=5). Increases in the extracellular K+ produced a linear shift in the rP as predicted by the Nernst equation, indicating the 5-HT2 response is mediated by a decrease in K+ conductance. In cells depolarized by 1 μM 5-HT with decreased Rin, the rP was -30.2 ± 1.8 mV (N=5) and with the selective 5-HT3 agonist 2-methyl 5-HT (1 μM) the rP was -32 mV (N=2). K+ acetate electrodes did not alter this response. In Na+ free solution, both agonists produced hyperpolarization, indicating this response involves increased Na+ conductance. The negative rP suggests that an increased K+ conductance also occurs.

In 18 cells 5-HT produced a hyperpolarization with decreased Rin. One μM 5-HT achieved an Emax averaging -4.05±0.6 mV (N=9). This was mimicked by the 5-HT1 agonist, carboxamidotryptamine (Emax = 4.2±0.7 mV, 1 μM, N=5). This response was not blocked by ketanserin or ICS 205-930, but 100nM methiothepin (a broad 5-HT1/5-HT2 antagonist) produced a parallel rightward shift in the 5-HT cocentration response curve. These data suggest that a 5-HT1 receptor mediates hyperpolarization in rat DRG cells.

THE BIOCHEMICAL AND FUNCTIONAL CORRELATE OF 5-HT$_2$ RECEPTOR ACTIVATION IN IMMATURE AND ADULT RAT BRAIN CORTEX. J. Coupet and P. Tricoli*, Med. Res. Div. of American Cyanamid Company, Ramapo Coll, Mahwah, NJ 07430.

Representatives of a class of hallucinogenic -4-substituted phenylalkylamine: 1-(2,5-dimethoxy-4-methylphenyl)-2-aminopropane (DOM), 1-(2,5-dimethoxy-4-bromophenyl)-2-aminopropane (DOB) and 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI), characterized in ligand binding assays as 5-HT$_2$ selective agonists, were investigated in polyphosphoinositide (PPI) hydrolysis, the transducing system for 5-HT$_2$ receptors, in immature as well as adult rat cortical slices. Inositol phospholipids in cortical slices were prelabeled with myo-2-[^{3}H]inositol and the formation of total [^{3}H]inositol phosphates was measured in the presence of 7mM LiCl. The PPI response to these 5-HT$_2$ agonists was considerably more pronounced in the immature than in the adult animals. The involvement of the 5-HT$_2$ receptor in modulating the PPI response was strongly supported, on one hand, by the inhibitory effect of ketanserin, a 5-HT$_2$ antagonist, and on the other hand, by the failure of CGS-12066B and 1-phenylbiguanide, a 5-HT$_{1B}$ and a 5-HT$_3$ agonist, respectively, to affect the formation of [^{3}H]IP. It was concluded that the hyperresponsiveness of PPI hydrolysis to the various 5-HT$_2$ agonists in the immature rat brain could be a compensatory mechanism due perhaps to a tighter coupling state of the G-protein to the 5-HT$_2$ receptors, at an early stage of brain development.

Serotonin (5-HT) excites interneurons via 5-HT$_2$ receptors and pyramidal cells via 5-HT$_{1C}$ receptors in rat piriform cortex. P.W. Sheldon and G.K. Aghajanian, Depts. of Pharmacology and Psychiatry, Yale University, New Haven CT. 06510.

We have shown previously that serotonin (5-HT) both depolarizes pyramidal cells and induces firing of a subpopulation of interneurons in the piriform cortex. The 5-HT$_{2/1C}$ antagonist ritanserin blocked the activation of interneurons more readily than it blocked the depolarization of pyramidal cells. Because ritanserin has a nearly 10 fold higher affinity for the 5-HT$_2$ receptor than for the 5-HT$_{1C}$ receptor (Hoyer. 1988, J. Receptor Res. 8(1-4): 59-81) it was hypothesised that the action of 5-HT on these interneurons might be through 5-HT$_2$ receptors and the action of 5-HT on the pyramidal cells might be through 5-HT$_{1C}$ receptors. This hypothesis is consistent with recent findings of Palacios (personal communication) that the mRNA for the 5-HT$_2$ receptor is found in cortical interneurons while mRNA for the 5-HT$_{1C}$ receptor is found in pyramidal cells.

To test this hypothesis further we examined the effects of the 5-HT antagonist spiperone which has a 1000 fold higher affinity for the 5-HT$_2$ receptor than for the 5-HT$_{1C}$ receptor (Hoyer). In an *in vitro* slice preparation of rat piriform cortex we studied the actions of 5-HT on both interneurons and pyramidal cells. The activating effect of 5-HT on interneurons was blocked by bath-application of spiperone (100nM). 5-HT increased the excitability of pyramidal cells as measured by its ability to increase the number of spikes evoked by a constant depolarizing current pulse; this effect of 5-HT was uneffected by 100nM spiperone but was blocked by 10μM ritanserin. These findings indicate that in the piriform cortex the excitatory action of 5-HT on interneurons is mediated by 5-HT$_2$ receptors while the excitatory action of 5-HT on pyramidal cells is mediated by 5-HT$_{1C}$ receptors.

DESTABILIZATION OF HORMONE / RECEPTOR / G-PROTEIN (H-R-G) TERNARY COMPLEX IS DEPENDENT ON RECEPTOR OCCUPANCY BUT INDEPENDENT OF DRUG EFFICACY. C.D. Mahle[1], H.L. Wiener[3,2], F.D. Yocca[4,2], and S. Maayani[1,2]. Depts. Pharmacol.[1] & Anesthesiol.[2], Mt. Sinai Sch. Med., CUNY, NY, NY 10029, Coll. Pharmacy[3], St. John's U., Jamaica, NY 11439, and CNS Research, Bristol Myers-Squibb[4], Wallingford, CT 06492.

Destabilization of H-R-G by guanine nucleotides (GN) was utilized as a model to study initial events of signal transduction. A crucial step is the allosteric interaction between hormone receptor sites and GN G-protein sites. This phenomenon was examined in rat hippocampal membranes on two G$_i$-linked receptors, the adenosine A$_1$ (AD A$_1$), labeled by the agonist [^{3}H]-R-phenylisoproplyadenosine ([^{3}H]-R-PIA), and the 5-HT$_{1A}$ receptor labeled by either the agonist [^{3}H]-8-OH-2-(di-n-propylamino)-tetralin) ([^{3}H]-8-OH-DPAT) or the partial agonist [^{3}H]-BMY 7378. Progressive occupancy of the G-protein with either 5'guanylimidodiphosphate (Gpp(NH)p) or guanosine 5'-O-(3-thiotriphosphate) (GTPγS) resulted in a concentration-dependent and saturable attenuation of [^{3}H]-agonist binding, with GTPγS exhibiting a lower IC$_{50}$ for all drugs. Parameters of concentration-effect curves (IC$_{50}$, slope index and E$_{max}$) were determined for Gpp(NH)p and GTPγS at different occupancy levels of the receptor sites. For all drugs, IC$_{50}$ values increased with increasing receptor occupancy, while maximal inhibition of [^{3}H]-R-PIA or [^{3}H]-8-OH-DPAT binding was independent of receptor occupancy. Both GN exhibited lower IC$_{50}$ values on the 5-HT$_{1A}$ agonists than those on the AD A$_1$ agonist. Similar IC$_{50}$ values were obtained for both [^{3}H]-8-OH-DPAT and [^{3}H]-BMY 7378 binding, suggesting efficacy independence in this event of receptor/G-protein coupling. We propose that characteristics of destabilization of the H-R-G ternary complex by GN are dependent upon receptor type and degree of receptor occupancy, but are independent of drug efficacy. LACK OF 5-HT INHIBITION OF ADENYLYL CYCLASE IN DORSAL RAPHE OF MALE AND FEMALE RATS. W.P. Clarke[1], F.D. Yocca[2,3] and S. Maayani[1,2] Departments of Pharmacology[1] and Anesthesiology[2], Mount Sinai School of Medicine, CUNY, New York, NY 10029 and CNS Research[3], Bristol-Myers Squibb Co. Wallingford, CT 06492.

In rat hippocampus, the serotonin$_{1A}$ (5-HT$_{1A}$) receptor subtype is linked to at least two distinct responses: 1) inhibition of pyramidal cells, mediated by the opening of a non-cAMP dependent K^+ channel (Andrade *et al.*, Science, 234:1261, 1986) and 2) inhibition of forskolin-stimulated adenylyl cyclase (FSAC) (De Vivo and Maayani, JPET, 238:248, 1986). In ovariectomized (OVX) rats, estrogen enhances both of these 5-HT$_{1A}$ mediated responses (Beck *et al.*, Neurosci. Lett., 186:181,1989; Clarke and Maayani, Brain Res., 518:287, 1990). However, in dorsal raphe (DR), estrogen treatment of OVX rats decreases 5-HT$_{1A}$ inhibition of firing of cells (Lakoski, The Pharmacologist, 30:A126, 1988). In this study we tested the hypothesis that a lack of estrogen (in OVX rats) would enhance 5-HT$_{1A}$ mediated inhibition of FSAC activity in the DR. OVX rats each received a silastic capsule (sc) containing either 10% estradiol-17β in cholesterol (CHOL) or CHOL alone. Male rats were untreated. Four days later, membranes from DR were prepared (8 rats/group). Virtually no inhibition (<5%) of FSAC by 5-HT was seen in the DR of OXV-estrogen, OVX-CHOL or male rats, whereas in hippocampus maximal inhibition by 5-HT averaged 25%. In contrast, inhibition of FSAC in DR did occur with R-phenylisopropyl-adenosine (adenosine A_1, 20%), baclofen ($GABA_B$, 20%) and with guanosine 5'-(β,γ-imino)triphosphate (Gpp(NH)p, 40%). While conclusions related to estrogen's effect in DR are precluded due to the lack of response to 5-HT, these data suggest that there may exist subpopulations of the 5-HT$_{1A}$ receptor, linked to either a K^+ channel or to adenylyl cyclase, which have a heterogenous distribution in the CNS; the hippocampus possessing 5-HT$_{1A}$ receptors coupled to both effectors (possibly on different cells) and the raphe with 5-HT$_{1A}$ receptors linked only to a K^+ channel. Supported by grants GM-34852 and DA-01875. WPC is a Revson Fellow.

INITIAL CHARARCTERIZATION OF 5-HT RECEPTOR PRESENT IN *ASCARIS SUUM* MUSCLE. J. Williams and A. Shahkolahi*. Department of Biological Sciences, University of North Texas, Denton, TX 76203.

Ascaris suum is a parasitic nematode which inhabits the upper third of the small intestine of porcine species. During non-feeding periods of the host *A. suum* is dependent upon muscle glycogen stores. 5-hydroxytryptamine (5-HT) initiates glycogenolysis in *A. suum* muscle via an increase in cAMP levels. Functionally, the 5-HT1 receptor has been linked to the cAMP system, the 5-HT2 receptor has been linked to the phosphotidylinositol system, and the 5-HT3 receptor to ligand gated ion channels. Although ligand binding to the *A. suum* 5-HT receptor appears to initiate glycogenolysis through the cAMP system and not through the phosphotidylinositol system, binding assays with [3H]5-HT, used to identify 5-HT1 sites, and 5-HT as competitor have shown minimal binding present. In contrast, assays using [3H]LSD, which has affinity for both 5-HT1 and 5-HT2 sites, and mianserin as competitor showed binding sites to be present to a much greater extent. When 5-HT was used as competitor for [3H]LSD, once again minimal binding was present. Based on the results of the [3H]5-HT and [3H]LSD binding assays, it was anticipated that binding of [3H]ketanserin, a specific 5-HT2 ligand, would be robust. However, a low level of [3H]ketanserin sites was found. This initial pharmacological profile may indicate the presence in *A. suum* muscle of several 5-HT receptor subtypes similar to mammalian 5-HT receptor subtypes and/or a novel non-5-HT1 receptor which functions through the cAMP system. Further comparisons of the *A. suum* 5-HT receptor to the mammalian 5-HT receptor subtypes are being carried out.

MDL 100,907, (+)-α-(2,3-dimethoxyphenyl)-1-[2-(4-fluorophenylethyl)]-4-piperidinemethanol, a potent, chiral, 5-HT$_2$ receptor antagonist. M. Dudley, A. Ogden*, A. Carr*, T. Nieduzak* and J. Kehne. Merrell Dow Research Institute, Cincinnati, OH 45215

The racemic compound MDL 11,939 (α-phenyl-1-(2-phenylethyl)-4-piperidinemethanol) has been reported previously as a potent and selective 5-HT$_2$ antagonist (Dudley et al. Drug Dev. Research 13:29, 1988). Synthesis of the enantiomers, MDL 28,233, the (-)-isomer, and MDL 28,727, the (+)-isomer showed that the potent 5-HT$_2$ receptor antagonism was associated with the (+)-isomer. MDL 28,727 had an IC_{50} value at rat cortical 5-HT$_2$ receptor of 4.2 nM compared to 190 nM and 10 nM for MDL 28,233 and MDL 11,939, respectively. Further investigation of possible substituents on both aryl nuclei to increase potency resulted in the racemic MDL 100,151 ((±)-α-(2,3-dimethoxyphenyl)-1-[2-(4-fluorophenylethyl)]-4-piperidinemethanol), which was resolved into MDL 100,907, the (+)-isomer and MDL 100,009, the (-)-isomer. In initial binding studies with [^{3}H]spiroperidol in rat cortical membranes, MDL 100,151, MDL 100,907 and MDL 100,009 had IC_{50} values of 1 nM, 0.4 nM and 12 nM respectively. MDL 100,907 blocked the 5-methoxy-N,N-dimethyltryptamine-induced head twitch in mice with an ED_{50} of 0.03 mg/kg, i.p. MDL 100,907 was 130-fold selective for the 5-HT$_2$ receptor over the 5-HT$_{1c}$ receptor. In conclusion, MDL 100,907 is a stereospecific, potent and selective 5-HT$_2$ receptor antagonist.

427.20

DIFFERENTIATION OF 8-OH-DPAT AND IPSAPIRONE IN RAT MODELS OF 5-HT$_{1A}$ RECEPTOR FUNCTION. J. De Vry*, R. Schreiber*, J.M. Greuel, E. Horvàth*, T. Glaser. Institute for Neurobiology, Troponwerke GmbH & Co. KG, Berliner Str. 156, 5000 Köln 80, F.R.G.

8-OH-DPAT (D) and ipsapirone (I) bind 5-HT$_{1A}$ receptors located presynaptically (PREsyn) in the raphe nuclei and postsynaptically (POSTsyn), predominantly in the limbic system. In the forskolin stimulated adenylate cyclase model, the 5-HT behavioral syndrome test, and the circling test (after unilateral application of 5,7-DHT in the substantia nigra), three models of POSTsyn 5-HT$_{1A}$ receptor activation, D and I are characterised as full and partial agonists, respectively. D and I completely suppress raphe 5-HT cell firing in slice preparations and in vivo; suggesting that both compounds are PREsyn 5-HT$_{1A}$ agonists. In drug discrimination (D cue) and hypothermia, models which presumably involve PRE -and POSTsyn 5-HT$_{1A}$ receptors, D and I are full agonists. To conclude, it appears that D is a full agonist at PRE- and POSTsyn 5-HT$_{1A}$ receptors; whereas I is a full and partial agonist at PRE- and POSTsyn receptors, respectively. However, the finding that (1) I, like D, completely generalizes to the D cue when applied bilaterally in the dorsal hippocampus, and (2) both I and D retain full agonistic activity in the hyperthermia model after 5,7-DHT induced lesion of the brain 5-HT system, suggests that there are brain regions where both compounds are full agonists at POSTsyn 5-HT$_{1A}$ receptors.

RECEPTOR MODULATION: UP AND DOWN REGULATION I

CHRONIC ETHANOL AFFECTS PERIPHERAL-TYPE BENZODIAZEPINE RECEPTORS: REGIONAL DIFFERENCES AND ROLE OF PHYSICAL DEPENDENCE. P.J. Syapin, P.A. Assanah*, L.S. Kobayashi*, B. L. Jones*, D.A. Finn, and R.L. Alkana. U.S.C. Health Sciences Ctr., Los Angeles, California 90033

Mice and rats made physically dependent on ethanol have increased numbers of brain peripheral-type benzodiazepine receptors (PBR). To further characterize this change PBR were measured in C57BL/6J mice which consumed 3.5% ethanol (nondependent) or 7% ethanol (physically dependent). Binding of [^{3}H]Ro5-4864 to olfactory bulb, pons-medulla, cerebellum, and anterior and posterior cerebrum membranes indicated increased PBR in posterior cerebrum of physically dependent mice and no changes in other regions. Nondependent mice had reduced PBR in olfactory bulbs with no change in other regions. Cardiac and spleen PBR were not altered, although organ weights decreased. Thymus PBR increased in nondependent mice and tended to increase in dependent mice, despite pronounced thymic involution. K_D values were not significantly altered by chronic ethanol exposure. These results suggest that physical dependence upregulates PBR in posterior cerebrum brain regions and "normalizes" changes in olfactory bulb PBR found in nondependent mice. Whether alterations in brain PBR function accompany chronic ethanol exposure requires further study. (NIAAA grant AA07351)

SHORT AND LONG TERM TOLERANCE TO ABECARNIL, A BETA-CARBOLINE BENZODIAZEPINE RECEPTOR LIGAND: ANTAGONISM OF PTZ CONVULSION THRESHOLD VS RECEPTOR OCCUPATION AND PLASMA LEVEL IN THE MOUSE. H.H. Schneider, L. Turski, W. Krause* and D.N. Stephens*. Dept. of Neuropsychopharmacology, Schering AG, 1000 Berlin 65, West Germany.

Abecarnil (ABC) is a non-sedative anxiolytic β-carboline (Stephens, D.N. et al., *JPET* 253: 1990). For the investigation of tolerance phenomena we used the anticonvulsant properties of ABC (Turski, L. et al., *JPET* 253: 1990). Repeated treatment with ABC (15 mg/kg ip, twice daily for 12 days) led to a slight reduction in its potency to antagonize the induction of clonic seizures by pentylenetetrazol (PTZ) given iv. The seizure threshold at 5 mg ABC/kg ip, 30 min declined from 152 mg PTZ/kg (acute) to 122 mg PTZ/kg (subchronic). For short term tolerance, the PTZ seizure threshold was determined following ABC, 2 mg/kg ip between 10 and 320 min. To determine the degree of benzodiazepine receptor occupation by ABC the animal received ^{3}H-lormetazepam, 7.4 MBq/kg sc, 20 min before decapitation. Immediately following the PTZ threshold determination the animal was decapitated. Blood was collected for HPLC estimation of ABC, and the forebrain homogenized in cold buffer, and aliquots filtered for determination of bound radioactivity. The time course of the three parameters went roughly parallel, with peak values at 40 min. However, when the correlation of PTZ antagonism and benzodiazepine receptor occupation were plotted for all time points it became evident that at the same degree of receptor occupation, ABC was clearly more effective in the early phase (10-40 min) than in the second, elimination phase. This acute potency shift was compared to that following Alprazolam. This "hysteresis" effect may be useful for the prediction of tolerance development.

428.3

PSYCHOLOGICAL AND GENDER INFLUENCES ON THE STRESS-INDUCED DECREASE IN RENAL PERIPHERAL BENZODIAZEPINE RECEPTORS IN RAT. R.C.Drugan, A.P.Stringer, & P.V.Holmes. Schrier Research Laboratory, Dept. of Psychology, Brown University, Providence, RI 02912.

Earlier research has shown that exposure to environmental stress results in changes in the density of peripheral benzodiazepine receptors (PBR) in both central nervous system (CNS) and peripheral tissues. We have previously evaluated the characteristics of physical stress necessary for these changes, however, neither the psychological dimensions of stress nor gender influences have been investigated.

We now report that controllability and predictability of tailshock stress do not result in a modification of the stress-induced changes in renal PBR. Further, psychological stress alone, using a conditioned fear paradigm, does not produce a change in the binding of [3H]RO5-4864 to PBR in comparison to controls. However, administration of an anesthetic dose of sodium pentobarbital (60mg/kg, i.p.) prior to the stress completely blocks the decrease in PBR indicating the importance of consciousness during stress. Finally, we also report gender differences in the response of renal PBR to inescapable stress. Female rats show an attenuated decrease in PBR (23%) as compared to male rats (50%). These data suggest both neural and hormonal mediation of the stress-induced alterations in renal PBR. SUPPORTED BY: NIMH grant #MH44034-01A1 & an Alfred P. Sloan Research Fellowship to Robert C. Drugan.

REGIONAL CHANGES IN RAT BRAIN BENZODIAZEPINE RECEPTORS FOLLOWING SEIZURES. J.L. Daval, M.C. Werck* and P. Vert*, INSERM U272, 24-30 rue Lionnois, 54013 NANCY, FRANCE.

Benzodiazepines (BZ) are psychoactive substances classically used for their anticonvulsant properties as well in neonates as in adults. In a previous work, we have shown that seizures lead to an age-dependent upregulation of central BZ binding sites measured in isolated cerebral membranes (Life Sci., 41: 1685, 1987). However, no information was available concerning the regional changes in the receptor density. Therefore, the effects of bicuculline-induced seizures were investigated by quantitative autoradiography of central BZ receptors in developing rats and in adults. Animals received an i.p. injection of either saline or bicuculline and were sacrificed 30 min later. Brain sections were incubated with |3H|flunitrazepam. Seizures induced a significant increase in BZ receptors in 39 out of the 46 brain regions studied, with a marked enhancement in structures that mediate seizure activity such as substantia nigra (+43% and +21% in 5-day-old rat and in adult respectively), amygdala (+20% and +12%), septum (+26% and +15%), hippocampus (+42% and +34%), as well as in cortices. Moreover, the addition of 10^{-4} M GABA into the incubation medium increased BZ binding in a similar manner whether rats were given bicuculline or saline, suggesting that increased BZ sites are also functionally linked to GABA receptors. The age-dependent postictal increase in BZ receptors might be an adaptative phenomenon for protection against recurrent seizures.

HOMOLOGOUS AND HETEROLOGOUS UNCOUPLING OF THE $GABA_A$ RECEPTOR COMPLEX BY GABA, 3α-OH-DHP, FLURAZEPAM AND PENTOBARBITAL IN CULTURE. L.K. Friedman, T.T. Gibbs, and D.H. Farb, Dept. Anatomy & Cell Biology, SUNY Health Science Center at Brooklyn, N.Y. 11203.

We have previously shown that chronic treatment with GABA, certain steroids, benzodiazepines, or barbiturates produces a reduction in the allosteric coupling between the benzodiazepine recognition site and other sites on the $GABA_A$ receptor which is refered to as "uncoupling". Here we describe homologous and heterologous uncoupling induced by chronic (48 h) exposure of neuronal cultures to GABA (1mM), 5β-pregnan-3α-ol-20-one (3α-OH-DHP) (10μM), flurazepam (50μM), or pentobarbital (PB) (200μM). Allosteric interactions were measured by the effect of 5μM 3α-OH-DHP, 300 μM pentobarbital, or 10 μM GABA on reversible binding of 1 nM ^{3}H-flunitrazepam. While chronic steroid treatment blocked potentiation of ^{3}H-flunitrazepam binding by pentobarbital and 3α-OH-DHP, potentiation by GABA was only partially reduced (by 40%). Chronic GABA treatment greatly reduced (by 80%) PB-stimulation of ^{3}H-flunitrazepam binding and modestly reduced (by 30%) GABA enhancement of ^{3}H-flunitrazepam binding, while steroid-stimulated ^{3}H-flunitrazepam binding was unaffected. In contrast, chronic flurazepam treatment reduced the potentiation produced by all 3 compounds by a similar degree. Finally, pentobarbital exposure decreased both PB and GABA stimulation of ^{3}H-flunitrazepam binding, but had little effect on 3α-OH-DHP stimulation of ^{3}H-flunitrazepam binding. Coincubation of cultures with 3α-OH-DHP and SR-95531, a selective $GABA_A$ antagonist, reduced the steroid-induced decrease of GABA potentiation but did not prevent the loss of 3α-OH-DHP stimulation of ^{3}H-flunitrazepam binding. These results suggest the existence of multiple modes of uncoupling which are most likely mediated through different sites.

428.6

EFFECT OF DESIPRAMINE (DMI) ON HIGH FREQUENCY NEUROTRANSMISSION (HFN) AND RECURRENT INHIBITION (RI) IN RAT HIPPOCAMPAL SLICE. F.A. Dijcks*, J.H. Couvée* and G.S.F. Ruigt, Organon int, CNS Pharmacology Dept., POB 20, 5340 BH Oss, The Netherlands.

Tricyclic antidepressants are known to have specific acute interactions with several neurotransmitter systems in rat brain. However, adaptive changes to chronic antidepressant treatment, rather than the acute pharmacological properties of the drugs, seem to contribute to the understanding of their mechanism(s) of action. In the present experiment we tested the effects of DMI by acute treatment in vitro (10 μM), and single dose and long-term treatment in vivo (10 mg/kg) on the excitatory and inhibitory neurotransmission in rat hippocampal slice. We recorded ortho- and antidromically evoked field potentials in stratum radiatum (fEPSP) and pyramidale (PS) of area CA_1. HFN was tested by evoking field potentials at 20 Hz. RI was tested by antidromic activation of the pyramidal cells prior to an orthodromic test pulse. We demonstrate that a frequency-dependent inhibiton by 10 μM DMI in vitro is observed for the antidromic PS and for the fEPSP although at high stimulus intensity the fEPSP is augmented. Pretreatment of the rats with DMI does not affect the frequency-dependent inhibition of the fEPSP and PS by DMI in vitro. Acute DMI did not affect RI (as % decrease of the orthodromic test pulse) i.e. RI dropped from 37 + 8 to 35 + 6% inhibition. Single dose or long-term pretreatment with DMI caused an increase in RI resp. to 53 + 4% (two-tailed t-test: $P<.051$) and 62 + 5% ($P<.014$). We show that HFN is inhibited only through the acute action of DMI although the magnitude of the effect seems to depend on stimulus intensity and that RI is augmented by in vivo and not in vitro DMI treatment.

428.7

EFFECTS OF CHRONIC ANTIDEPRESSANT DRUG ADMINISTRATION ON GABA B RECEPTORS. D.J. McManus*, A.J.Greenshaw*, G.B. Baker AND T.B. Wishart. Neurochemical Research Unit, Dept. of Psychiatry, Univ. of Alberta, Edmonton, Alberta, Canada, T6G 2B7 and Dept. of Psychology, Univ. of Saskatchewan, Saskatoon, Saskatchewan, Canada, S7N 0W0.

Effects of chronic administration of antidepressant drugs on $GABA_B$ receptors have been assessed both in vivo and ex vivo. Tricyclics [imipramine (IMI) 30 mg/kg/d and desipramine (DMI) 10 mg/kg/d] or monoamine oxidase (MAO) inhibitors [(+/-)-tranylcypromine (TCP) 1 mg/kg/d and phenelzine (PLZ) 10 mg/kg/d] (all doses expressed as salts) were administered to male Sprague-Dawley rats (N=10 per group), by constant infusion via Alzet 2ML4 osmotic minipumps for 28 d. Pumps were implanted sc in the interscapular region. On days 21 and 22 the motor-supressant actions of the $GABA_B$ receptor agonists (+/-)-baclofen (5 mg/kg ip) and progabide (50 mg/kg ip) were assessed as an in vivo measure of $GABA_B$ receptor sensitivity. On day 28 the animals were killed and their brains used for measurement of drug levels and MAO activity. Tissue from the frontal cortex was used to assess the number (Bmax) and affinity (Kd) of $GABA_B$ receptors using [^{3}H]-GABA as the radiolabelled ligand. Non-specific binding was defined using (+/-)-baclofen. All of the drugs tested failed to induce an increase in the in vivo responsiveness of animals to (+/-)-baclofen or progabide. [3H]-GABA binding was unchanged for rats receiving PLZ, DMI or IMI ($p<0.05$, vs VEH controls). Only TCP-treated animals showed an increased Bmax relative to controls. No effect on Kd was observed in any drug group. These data do not support the proposal that an increase in the number of GABA B receptors is a common effect of chronic antidepressant drug treatment.

LONG-TERM TREATMENT WITH LITHIUM AND CARBAMAZEPINE ATTENUATES CARBACHOL-INDUCED PHOSPHOINOSITIDE TURNOVER IN NEURONS. X.-M. Gao, F. Fukamauchi, C. Hough and D.-M. Chuang. Biological Psychiatry Branch, NIMH, Bethesda, MD

We have studied long-term effects of lithium and carbamazepine (CBZ) on muscarinic receptor (mAChR)-mediated phosphoinositide (PI) turnover in cultured cerebellar granule cells. Three days' exposure of cells to lithium induced a biphasic change in carbachol-induced accumulation of ^{3}H-inositol monophosphate (IP_1). The accumulation was increased up to 2 mM of lithium but inhibited by higher concentrations of this ion. Exposure of cells to 5 mM lithium for more than 3 days resulted in marked inhibition of the PI response to carbachol with about 75% inhibition at day 7. Three days' exposure to CBZ also induced a decrease of carbachol-induced ^{3}H-IP_1 accumulation with an IC_{50} of around 30 μM and virtually no effect on basal activity. This CBZ effect was due to a decrease in the maximal response to carbachol. The decrease was about 30% at day 3 and largely reversed at day 6. Cell-surface mAChR receptors assessed by binding with ^{3}H-NMS were decreased by long-term exposure to lithium (3 mM) but not by CBZ (30 μM). Moreover, Northern blot hybridization revealed that long-term lithium treatment decreased m3-mAChR mRNA level with no significant change on levels of total RNA, m2-AChR mRNA and β-actin mRNA. Thus, both lithium and CBZ have long-term converging effects on m3-AChR function in granule cells; however, distinct mechanisms appear to be involved in this receptor modulation.

428.9

ROLE OF CYTOSKELETONS IN THE REGULATION OF mRNA OF m3-MUSCARINIC ACETYLCHOLINE RECEPTORS. F. Fukamauchi, C. Hough and D.-M. Chuang. Biological Psychiatry Branch, NIMH, Bethesda, MD 20892.

The regulation of carbachol (CCh)-induced muscarinic acetylcholine receptor (mAChR) mRNA by cytoskeletal agents was studied in cultured cerebellar granule cells using Northern blot hybridization. In 8-day-old cultures, m2-mAChR mRNA levels were about 50 and 70% of the control at 2 and 4 hours after treatment with 100 μM CCh, respectively. Levels of m3-mAChR mRNA were about 75 and 50% of the control at 4 and 8 hours, respectively. Exposure of cells to methylamine alone (10 mM), an inhibitor of endocytosis, for 8 hours led to down-regulation of m3-mAChR mRNA, but did not affect CCh-induced m3-mAChR mRNA down-regulation. Bacitracin (2 mg/ml), an inhibitor of transglutaminase, did not change levels of basal and CCh-down-regulated m3-mAChR mRNA. However, exposure to colchicine alone (1-100 μM), a microtubule disrupting agent, for 4 hours led to down-regulation of m2- and m3-mAChR mRNA in a dose-dependent manner. Total RNA was decreased and m3-mAChR mRNA was not detected at 24 hours after treatment with 10 μM colchicine. Furthermore, treatment of cells for 8 hours with 10 μM colchicine enhanced the down-regulation of m3-mAChR mRNA induced by 100 μM of CCh. An antimicrofilament agent, cytochalasin B at 5 μM/ml, had no effect on the CCh-induced mAChR mRNA down-regulation. These results suggest that mAChR mRNA down-regulation may involve the function of microtubular elements.

PROTEIN KINASE C INHIBITS THE DEPOLARIZATION MEDIATED BY α_1-ADRENERGIC RECEPTORS IN RAT DORSAL RAPHE NEURONS. T. J. Grudt* and J. T. Williams. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Intracellular recordings were made from dorsal raphe (DR) neurons in slices made from rat brain. The α_1-adrenergic receptor agonist phenylephrine (PE) depolarized DR neurons. A protein kinase C activator, phorbol 12,13-dibutyrate (PDBU), had no effect on membrane potential by itself but inhibited the PE induced depolarization in a dose-dependent manner (EC50 = 28 nM). The inactive phorbol ester phorbol 12,13-didecanoate had no effect. The PDBU induced inhibition was reversed by the non-specific protein kinase inhibitor staurosporin (3 μM). Agonist-induced desensitization of the α_1-adrenergic increase in phospholipid turnover has been reported and is mimicked by the application of phorbol esters (Leeb-Lundberg et al. J.Bio.Chem. 262:3098, 1987). Our results are consistent with α_1-adrenergic receptor desensitization mediated by protein kinase C. Since α_1-adrenergic receptor activation leads to formation of diacylglycerol and activation of protein kinase C, this may be an example of feedback inhibition.

COMPARISON OF AGONIST AND ANTAGONIST COMPETITION FOR [^{3}H]RAUWOLSCINE (RAU) BINDING TO α_2-ADRENERGIC RECEPTORS (A2AR) OF INTACT CHINESE HAMSTER OVARY (CHO) CELLS AND ISOLATED MEMBRANES. P.E. Shreve, M.L. Toews, and D.B. Bylund. Dept. of Pharmacology, Univ. of Nebraska Med. Ctr., Omaha, NE 68198.

β-adrenergic (BAR) agonists exhibit markedly lower binding affinities for BAR in intact cells as compared to isolated membranes. In contrast, BAR antagonists have similar affinities for BAR in intact cells and membranes. This phenomenon has been similarly observed for α_1-adrenergic and muscarinic receptors (J. Pharmacol. Exp. Ther. 251(1): 63-70, 1989). These changes in binding properties of agonists may be related to the process of desensitization. The purpose of this study was to compare the binding affinities of agonists and antagonists to A2AR in intact cells and isolated membranes of CHO cells which have been stably transfected with the cDNA for A2AR. Pharmacological studies indicated that [^{3}H]RAU, an A2AR antagonist, exhibited high affinity for both intact CHO cells and CHO membranes with K_Ds of 1.6 and 0.53 nM, respectively. Norepinephrine (NE) and prazosin (PRAZ) have similar binding affinities for A2AR in isolated CHO membranes and were chosen as the agonist and antagonist respectively in the present study. The Ki values (n=3-4) were determined by computer-assisted nonlinear curve fitting. NE and PRAZ had Ki values of 0.8 and 0.4 μM respectively in isolated CHO membranes. The respective Ki values of NE and PRAZ were 74 and 1.3 μM in intact CHO cells. Thus NE had a >90 fold lower affinity in intact CHO cells as compared to CHO membranes. In contrast, PRAZ had only a 3 fold lower affinity in intact CHO cells as compared to CHO membranes. Therefore, the agonist exhibited an apparent binding affinity for A2AR in intact CHO cells which was markedly lower than its affinity in CHO membranes. This difference in agonist binding affinity between intact cells and isolated membranes is similar to that observed for other receptor systems and may play a role in A2AR agonist induced desensitization. This research is supported by NIH grant GM37664.

DIFFERENCES IN RESPONSES TO CHRONIC RESERPINE OF BETA-ADRENERGIC RECEPTORS IN NEOCORTEX AND LIMBIC CORTEX. L.J. Grimm, K.J. Kellar[1]and D.C. Perry. Depts. of Pharmacology, George Washington and [1]Georgetown Univ. Medical School, Washington, D.C. 20037.

We have previously used autoradiography to demonstrate that chronic reserpine administration increases β-adrenergic receptor binding in many brain regions (FASEB J. 4: A459, 1990). In this study we examined for reserpine-induced changes in β-stimulated cAMP production, comparing two general cortical regions. Rats were treated for 15 days with reserpine i.p.: 0.5 mg/kg days 1 & 2, and 0.25 mg/kg thereafter. Rats were sacrificed 24 hr after the last dose and brains bisected sagitally; half was frozen for binding analysis, and half used for cAMP analysis. The cortex was dissected free and divided by a knife cut parallel to the rhinal sulcus into an "upper" region (essentially neocortex) and a "lower" region (essentially limbic cortex, including rhinal cortices and amygdala). 350 μ slices were prepared and stimulated with various agonists; cAMP levels were measured by RIA. Stimulation (3-8 fold) was seen with norepinephrine [NE], isoproterenol [ISO], ISO + 6-fluoronorepinephrine [6FNE], and forskolin, but not 6FNE alone. The stimulation by NE, ISO, and 6FNE + ISO, but not forskolin, was increased after chronic reserpine. The enhancement by reserpine treatment of ISO and NE stimulation (but not ISO + 6FNE stimulation) was significantly higher in the "upper" region (70-110%) compared to the "lower" regions (20-50%). Saturation binding of [^{3}H]CGP-12177 done on the remaining half brain, similarly dissected, showed increases in B_{max} of 28-33% after chronic reserpine, limited to β-1 receptors. In contrast to cAMP stimulation, no differences between upper and lower regions were seen. Thus the effect of chronic reserpine on β-stimulated cAMP, but not β-binding, is greater in neocortex than limbic cortex. These regional differences suggest a difference in the efficiency of coupling of β-1 receptors to adenylate cyclase in neocortex compared to limbic cortex.

EFFECTS OF REPEATED ELECTROCONVULSIVE SHOCK (ECS) ON SEROTONIN-1A (5-HT-1A) RECEPTOR BINDING AND RECEPTOR-MEDIATED HYPOTHERMIA IN RAT. C.A. Stockmeier and G.A. Gudelsky, Departments of Psychiatry and Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

5-HT-1A receptors may be involved in the mechanism of action of antidepressant treatments. Chronic antidepressant drugs or ECS attenuate 8-hydroxy-2-(di-n-propylaminotetralin) (8-OH-DPAT)-induced hypothermia (Goodwin et al., 1987). Male rats were handled or received ECS for either one or ten days, and were killed two days later. Ten days of ECS decreased beta-adrenergic receptor binding in frontal cortex. However, [^{3}H]8-OH-DPAT binding in cortex or hippocampus was not affected by repeated ECS. In hypothalamus, ten days (but not one day) of ECS significantly decreased [^{3}H]8-OH-DPAT binding. In addition, 48 hr following 10 days of ECS, the hypothermic response to 8-OH-DPAT (0.1 mg/kg, sc) was attenuated in ECS-treated rats compared with handled controls. The hypothermic response to 8-OH-DPAT was returned to normal at 14 days after the last of 10 treatments with ECS. A single treatment with ECS did not affect the hypothermic response to 8-OH-DPAT. The ECS-induced decrease in [^{3}H]8-OH-DPAT binding in the hypothalamus may be responsible for the ECS-induced attenuation of the hypothermic response to 8-OH-DPAT. Supported by NS24523 and MH41684.

REGULATION OF THE 5-HT$_2$ RECEPTOR IN VIVO: AN AUTORADIOGRAPHIC STUDY. **M. Hauptmann* and A. Frazer, Dept. of Vet. Affairs Med. Ctr. & Univ. of Pa. Sch. of Med., Phila., PA 19104.**

The 5-HT$_2$ receptor has regulatory properties different from those exhibited by many other neurotransmitter receptors. Previous studies of adaptive changes in 5-HT$_2$ receptors after chronic administration of antidepressants have focused on radioligand binding in homogenates of rat frontal cortex. We have used the technique of quantitative autoradiography to measure the effect of either mianserin, monoamine oxidase inhibitors (MAOI's) or a selective serotonin uptake inhibitor, citalopram, on the binding of ^{3}H-ketanserin in different regions of rat brain. Acute administration of mianserin (10mg/kg) decreased ^{3}H-ketanserin binding to 5-HT$_2$ receptors in all layers of the frontal cortex and in hypothalamic and amygdaloid nuclei. Even though chronic treatment with mianserin (15mg/kg,twice daily for 21 days) caused a greater decrease in ^{3}H-ketanserin binding in the frontal cortex than acute treatment did, it had no effect on ^{3}H-ketanserin binding in the dorsomedial and ventromedial hypothalamic nuclei. The MAOI's, tranylcypromine (5mg/kg, once daily for 21 days) and clorgyline (1mg/kg once daily for 21 days) caused a significant (about 30%) decrease in 5-HT$_2$ receptor density in layer IV of the frontal cortex, but not in any subcortical areas. Citalopram (20mg/kg, once daily for 21 days) had no effect on ^{3}H-ketanserin binding in any areas of the brain studied. It seems that ^{3}H-ketanserin binding in the frontal cortex is somewhat more amenable to regulatory influences than such binding measured elsewhere in brain. Care should be exercised in extrapolating data obtained on the regulation of 5-HT$_2$ receptors in cortex to other regions of brain. **(Supported by Research Funds from the Dept. of Vet. Affairs & USPHS grant MH 29094).**

EFFECTS OF REPEATED ADMINISTRATION OF ANTIDEPRESSANTS ON SEROTONIN (5-HT) UPTAKE SITES MEASURED USING [^{3}H]CYANOIMIPRAMINE (^{3}H-CN-IMI) AUTORADIOGRAPHY. G.B. Kovachich, D.J. Brunswick, C.E. Aronson and A. Frazer. Univ. of PA Sch. of Med. & Dept. Vet. Affairs Med. Ctr., Phila., PA 19104.

To determine if repeated administration of antidepressants to rats regulate 5-HT uptake sites, the binding of [^{3}H]CN-IMI was measured using quantitative autoradiography. Under our assay conditions, this radioligand binds specifically, and with high affinity, to 5-HT uptake sites (*Brain Res.*, 454:78, 1988). All antidepressant drugs were administered for 21 days except citalopram (14 days) and were given i.p. except for deprenyl (s.c.). The drugs used were: the 5-HT uptake inhibitors sertraline (5mg/kg, daily) and citalopam (20mg/kg, daily); the norepinephrine uptake inhibitor protriptyline (15mg/kg, twice daily); the α_2-adrenergic antagonist mianserin (10mg/ kg, twice daily); the non-selective MAO inhibitor phenelzine (5mg/kg, twice daily) and the type B MAO inhibitor deprenyl (0.25 mg/kg, daily). Rats were killed 18 hrs after the last injection of drug. All structures examined were from brain slices taken at the level of plate 30 of the atlas of Paxinos and Watson (1986). Administration of citalopram or protriptyline had no effect on [^{3}H]CN-IMI binding in any brain region examined. Treatment with sertraline, phenelzine, deprenyl or mianserin caused some regionally specific alterations in the number of binding sites, but the effects were modest in size (10-20%) and no common effects were seen. Thus, no consistent regulatory effects associated with 5-HT uptake are produced by antidepressant drugs. **(Supported by research funds from the Department of Veterans Affairs.)**

428.16

LONG-TERM BUT NOT SHORT-TERM LITHIUM TREATMENT POTENTIATES m-CPP INDUCED CHANGES IN PLASMA PROLACTIN AND CORTICOSTERONE BUT NOT GROWTH HORMONE LEVELS IN RATS. C.S. Aulakh*, J.L. Hill*, N.A. Garrick and D.L. Murphy*. Lab. of Clinical Science, NIMH, Bethesda, MD 20892

The lithium ion is effective clinically for the treatment of acute manic illness, prophylaxis in manic-depressive (bipolar) and unipolar depressive disorders, and in conjunction with antidepressant drugs for the treatment of resistant depressive illness (DeMontigny et al 1983; Prien et al 1984; Price et al 1990). The therapeutic effects of antidepressant and antimanic drugs are manifested after only two or more weeks of administration. By using m-chlorophenylpiperazine (m-CPP, a postsynaptic 5-HT1 receptor agonist) as a challenge agent, we investigated functional adaptational changes in the serotonergic neurotransmitter mechanisms regulating prolactin, corticosterone and growth hormone secretion following long-term lithium treatment in rats. Male Wistar rats were given rat chow containing lithium carbonate (1.65g/kg) for 28 days. Saline or various doses of m-CPP were injected intravenously (11-11:15 a.m.) at least 48 hours after the cannulas were implanted in the blood vessel; blood samples were drawn 30 minutes after saline or m-CPP injection. Long-term (21-23 days) lithium treatment potentiated m-CPP-induced increases in plasma prolactin and corticosterone levels but did not have any effect on m-CPP-induced decreases in plasma growth hormone levels. Short-term (2-4 days) lithium treatment attenuated m-CPP's effect on plasma corticosterone levels without any effect on plasma prolactin or growth hormone levels. These findings document an enhancement of some aspects of brain 5-HT function following long-term lithium treatment and support other data suggesting that lithium's serotonergic actions may be relevant to its therapeutic efficacy.

GABA$_B$ RECEPTORS

429.1

MODULATION OF INHIBITORY SYNAPTIC TRANSMISSION IN HIPPOCAMPAL SLICES BY ACTIVATION OF PRESYNAPTIC GABA-B RECEPTORS ? I.M.Stanford*, J.E.Chad and H.V.Wheal. Department of Neurophysiology, University of Southampton, Bassett Crescent East, Southampton SO9 3TU, UK. (Sponsored by the Brain Research Association, UK).

CA1 pyramidal cell responses to paired stimuli were recorded extracellularly from the rat hippocampal slice preparation. The inhibition produced by the initial (conditioning) stimuli was quantified by measuring the response to the second (test) stimuli, and comparing it to the response to the initial stimuli.

Experiments were performed to measure the effect of interpulse interval on the inhibition observed. Orthodromically evoked response pairs for control slices (n=18) show inhibition at short interpulse intervals (0-30ms) and also at longer intervals (200-400ms), whereas antidromically evoked response pairs show no inhibition at these intervals. As has been previously reported, antagonists of GABA A receptors (bicuculline 1uM) enhanced both responses, with a reduction in paired pulse inhibition (measured as the ratio of test to conditioning responses) at short intervals but increased inhibition at longer interpulse intervals (n=7).

Antagonists of the GABA B receptor (phaclofen 1mM) had little effect on the conditioning response but prevented the reduction of the test response at long interpulse intervals, thus reducing paired pulse inhibition (n=7). Whereas the GABA B agonist baclofen (1uM) reduced both responses whilst attenuating paired pulse inhibition (n=7). Some proportion of the decrease in paired pulse inhibition can be attributed to the reduction in conditioning response (to 35% of control values). However, extrapolation from control experiments on the effects of changes in conditioning response amplitude, produced by varying stimulus intensities, would lead to the prediction of a smaller decrease in late inhibition. This leaves open the possibility that direct action of baclofen on presynaptic GABA B receptors, located on inhibitory interneurones, may contribute to the reduction in paired pulse inhibition.

2-Hydroxy-Saclofen Reduces the Depression of IPSCs Induced by a Variety of Stimulation Patterns in Rat Hippocampus. C.H. Davies* and G.L. Collingridge* (SPON: Brain Research Association) Department of Pharmacology, University of Bristol, Bristol, BS8 1TD, U.K.

Recently we reported that at an interstimulus interval of 100 ms paired-pulse depression of monosynaptic IPSCs was abolished by the GABAB receptor antagonist 2-hydroxy-saclofen (Davies et al, 1990, J. Physiol. 424 513-531). We have now examined the effect of 2-hydroxy-saclofen on a wider range of intervals (25-2500 ms) as well as its effect on more complex stimulation paradigms. In the presence of D-AP5 (40-80 uM) and CNQX (20 uM) stimulation in stratum radiatum evoked monosynaptic IPSCs. 2-hydroxy-saclofen (400 uM) abolished paired-pulse depression of IPSCs at all interstimulus intervals tested. Complete block of the depression induced by stimulus trains (5-10 Hz for 1 s) was also achieved although at frequencies of >10 Hz 2-hydroxy-saclofen only partially reversed the depression of IPSCs. We have also tested 2-hydroxy-saclofen on IPSCs evoked by primed-pulse (e.g., 2 shocks of 20-100 Hz preceded 140-170 ms by a single shock) and patterned-burst (e.g., 5 bursts of 4 shocks of 100 Hz delivered at 200 ms intervals) stimulation paradigms. In all cases 2-hydroxy-saclofen partially reversed the depression of synaptic inhibition.

429.3

BICUCULLINE-RESISTANT GABA MEDIATED EVENTS DISCLOSED BY THE GABA$_B$ ANTAGONIST 2-HYDROXY-SACLOFEN. Jose M. Solis and Roger A. Nicoll Dept. Pharmacol., Univ.California, San Francisco, CA 94143

In the hippocampus the GABA$_B$ antagonist phaclofen is a good inhibitor of both the postsynaptic baclofen response and the slow IPSP, but only inhibits partially the bicuculline-resistant response evoked by GABA. It has recently been reported that 2-hydroxy-saclofen (2-OH-S), a more potent GABA$_B$ antagonist, is able to block the slow IPSP in the hippocampus (Lambert et al., 107, 125-128, 1989). We have used single electrode voltage-clamp in CA1 pyramidal cells of rat hippocampal slices. While high concentrations (500 μM) of 2-OH-S completely inhibited the outward current evoked by (±) baclofen iontophoresis, 2-OH-S only reduced the bicuculline-resistant GABA currents by 30.4±8.6% and did not have any effect on the serotonin-evoked outward current. In addition 2-OH-S (500 μM) also blocked the "pure" slow IPSP evoked by local stimulation in the stratum radiatum in the presence of glutamate receptor antagonists. The slow IPSP appears to be mediated by synaptically released GABA since its time course was prolonged in the presence of the GABA uptake inhibitors cis-4-hydroxynipecotic and DL-2,4 diamino-N-butyric acids.

In summary, these results support the proposal that the slow IPSP is generated by GABA acting on GABA$_B$ receptors. However, the fact that part of the outward current evoked by exogenous GABA is resistant to GABA$_A$ and GABA$_B$ antagonists raises the possibility that a third type of GABA receptor exists on hippocampal pyramidal cells.

429.4

2-HYDROXYSACLOFEN: AN ANTAGONIST AT PRE- AND POSTSYNAPTIC GABA$_B$ RECEPTORS IN THE RAT HIPPOCAMPUS. N.L. Harrison, D.M. Lovinger[1], N.A. Lambert[2], T.J. Teyler[2] and D.I.B. Kerr[3] Dept. of Anesthesia and Critical Care, The Univ. of Chicago, Chicago, IL, [1]Lab. of Phys. and Pharm. Studies, NIAAA, Rockville, MD, [2]Dept. of Neurobiology, NEOUCOM, Rootstown, OH, and [3]Dept. of Anesthesia and Intensive Care, The Univ. of Adelaide, Australia.

We studied the actions of the GABA$_B$ receptor antagonist 2-hydroxysaclofen (2-OH-S) in area CA1 of hippocampal slices. The GABA$_B$ receptor agonist baclofen (BAC) hyperpolarizes pyramidal neurons by activating postsynaptic GABA$_B$ receptors, which mediate the late IPSP recorded from these neurons, and depresses synaptic potentials evoked by stimulation of Schaffer collateral/commissural fibers, presumably by activating presynaptic GABA$_B$ receptors. Low concentrations of 2-OH-S (50-100μM) antagonized the postsynaptic action of BAC and reduced the amplitude of the late IPSP. These concentrations of 2-OH-S did not block depression of EPSPs by BAC, however, higher concentrations (200-500μM) were effective. 200μM 2-OH-S shifted the dose-response curve for depression of EPSPs by BAC to the right by a factor of 4, indicating a pA$_2$ value of 4 for 2-OH-S at presynaptic GABA$_B$ receptors. 2-OH-S did not change excitatory transmission or passive membrane properties. Phaclofen (0.5-1mM) also blocked the late IPSP but had only a weak effect at presynaptic receptors. We conclude that 2-OH-S is a more potent antagonist than phaclofen at pre- and postsynaptic GABA$_B$ receptors in the hippocampus. 2-OH-S and phaclofen may have a higher affinity for postsynaptic than presynaptic GABA$_B$ receptors, supporting the idea that pre- and postsynaptic GABA$_B$ receptors can be distinguished pharmacologically. Supported by the ONR.

429.5

MECHANISMS OF BACLOFEN- AND OPIOID-INDUCED DISINHIBITION IN AREA CA1 OF RAT HIPPOCAMPUS N.A. Lambert, N.L. Harrison[1] and T.J. Teyler Department of Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272 and [1]Department of Anesthesia and Critical Care, The University of Chicago, Chicago, IL 60637.

We studied depression of inhibitory postsynaptic potentials (IPSPs) by the GABA-B receptor agonist (±)-baclofen and the μ opiate receptor agonist [D-Ala^2,N-Me-Phe^4,Gly-ol^5]-enkephalin (DAGO) using intracellular recording in the hippocampal slice preparation. Baclofen (0.1-10μM) and DAGO (0.5-5μM) reversibly depressed monosynaptic IPSPs (mIPSPs) recorded from pyramidal neurons in the presence of the excitatory amino acid receptor antagonists DNQX (25μM) and APV (40μM); adenosine (100μM) did not affect mIPSPs. The GABA-B receptor antagonist 2-hydroxy-saclofen (200μM) antagonized baclofen-induced depression of mIPSPs. Barium chloride (1.0-2.0mM), which blocks the K-current induced by baclofen and DAGO, prevented baclofen-induced hyperpolarization but not depression of mIPSPs by baclofen or DAGO. Baclofen and DAGO depressed IPSPs and mIPSPs when applied locally near the recording electrode, but were ineffective when applied near the stimulating electrode in stratum radiatum. These results suggest that baclofen and opioids disinhibit pyramidal neurons in area CA1 of the rat hippocampus by activating receptors located on the terminals of GABAergic neurons, and by a mechanism that is insensitive to barium. Supported by the ONR.

GABAb RECEPTOR BINDING IN SYNAPTIC MEMBRANES THAT HAVE (ADULT RAT CEREBRUM) OR LACK (HIPPOCAMPAL CULTURE) A POSTSYNAPTIC POTASSIUM CONDUCTANCE COUPLED TO GABAb RECEPTORS. M.I. Al-Dahan* and R.H. Thalmann, Baylor College of Medicine, Houston, TX 77030.

GABAb receptors in our cultures lack coupling with K channels (Hablitz and Thalmann, unpublished) that adult neurons possess in abundance. Do the receptors themselves differ? Membranes were prepared as described earlier (Al-Dahan and Thalmann, J. Neurochem. 1989, v53, p982) from adult rat, or from hippocampi dissociated at postnatal day 1 and cultured 7 days. Scatchard analysis of saturation studies of specific binding of (^{3}H)-baclofen indicated a single binding site in either preparation, with an affinity in cultured neurons (KD=45-60nM) similar to that in adult cerebrum (Kd=49+8nM). The ability of GABAb antagonists to displace baclofen binding was similar in both preparations: In both, the IC50 for phaclofen was approximately 100µM, for saclofen, 10µM. The regulation of binding by calcium and by GTPγs was also similar in that in either preparation binding was totally dependent upon Ca, and could be completely suppressed by GTPγs (100µM). Thus all the GABAb receptors in each membrane may be affected by Ca and coupled to G-proteins. Even though the coupling of receptors to K channels differs in the two preparations, we have thus far detected no differences in the receptors themselves. Supported by NIH grant NS21713.

Presynaptic and postsynaptic GABA$_B$ receptor pharmacology in spinal cord neurons. G. Kamatchi*and M.K. Ticku. Department of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284-7764.

Functional assays for measuring pre- and postsynaptic GABA$_B$ receptors were developed in primary cultured spinal cord neurons, using ^{86}Rb-fluxes. GABA$_B$ receptor activation with baclofen inhibited the ^{86}Rb-efflux induced by depolarization (100mM KCl), but not by calcium ionophore A23187, suggesting that GABA$_B$ receptor activation depresses the voltage-activated Ca^+-channels presynaptically. The tricyclic antidepressants, but not the MAO inhibitors, also inhibited the ^{86}Rb-efflux induced by both high potassium as well as A23187. The effect of baclofen, but not that of antidepressants was blocked by phaclofen and pertussis toxin (PTX). The GABA$_B$ receptor activation also produced an influx of ^{86}Rb. This effect of baclofen was concentration-dependent and inhibited by phaclofen and CGP35 349. Adenosine and 5-HT also produced ^{86}Rb-influx in these neurons. The effect of baclofen was not additive with either 5-HT or adenosine. Moreover, PTX pre-treatment blocked the hyperpolarization induced with these agents, indicating that these three receptors are linked to the same K^+-channel via the G-proteins.

GABA-B RECEPTORS MODULATE GLUTAMATE RELEASE IN THE RAT CAUDATE AND GLOBUS PALLIDUS. R. Singh, Dept. of Neurol. Sci. Rush Medical College, Chicago, IL 60612.

In continuation of our previous work (Neurosci. Abst. 15:583,235.14,1989), the role of GABA-B receptors in release of glutamate in caudate(CA) and globus pallidus (GP) was studied. Male rats (250-300g) were anaesthetized with halothane/O_2 and dialysis probes were implanted into CA or GP. Lactate-Ringer(pH-7.4) was perfused through the probes at 1ul/min. Dialysates were collected at 20 min intervals and analyzed for aminoacids by OPA derivatization and HPLC with fluorescence detection. After collection of 3 basal samples 100 uM baclofen was added to the perfusate for 40 min and sampling continued for 2h. Changes in the spontaneous release of glutamate, GABA and other amino acids were expressed as %change from the base line levels. Baclofen decreased glutamate release by 30±5 % in CA vs 39±7 % in GP. GABA release was decreased in CA by 23±3 % vs 32±5 % in GP. No other amino acid showed any change during baclofen perfusion. These results indicate significant modulation of glutamergic and GABAergic functions by GABA-B receptors in CA and GP nuclei of the basal ganglia.

EXCITATORY AMINO ACIDS: NMDA RECEPTOR GLYCINE AND POLYAMINE SITES

430.1

IN VIVO AND *IN VITRO* STEREOSELECTIVITY OF THE GLYCINE SITE OF THE N-METHYL-D-ASPARTATE RECEPTOR FOR THE (R)-ENANTIOMER OF HA-966 (1-HYDROXY-3-AMINO-PYRROLIDONE-2). L.M. Pullan, R.J. Stumpo,* M. Britt,* M.J. Chapdelaine,* R.A. Keith, D. LaMonte,* T.J. Mangano,* J. Patel, R.J. Powel,* P.J. Warwick,* W.C. Zinkand, and A.J. Salama. ICI Pharmaceuticals Group, ICI Americas, Wilmington, DE 19897

We report here the comparison of the *in vivo* stereoselectivity of the glycine receptor for the (R)-enantiomer of HA-966 (1-hydroxy-3-amino-pyrrolidone-2) to the stereoselectivity we have observed *in vitro*. The glycine antagonist site of the N-methyl-D-aspartate (NMDA) receptor *in vitro* shows stereoselectivity for the (R)-HA-966 in: [^{3}H]glycine binding in rat brain synaptosomal membranes, glycine stimulated [^{3}H]TCP (1-[1-(2-thienyl) cyclohexyl]piperidine) binding in rat brain synaptosomal membranes, prevention of NMDA induced cytotoxicity in cortical cultures, NMDA-evoked [3H]norepinephrine release in rat hippocampal slices, and glutamate-evoked contractions of guinea pig ileum. In each assay, the effects of (R)-HA-966 could be reversed by addition of glycine. We now confirm that the (R)-enantiomer is more potent *in vivo* against NMDA or D-serine evoked cGMP in cerebellum. Although the glycine receptor is stereoselective for (R)-HA-966, the (S)-enantiomer is not without activity in a number of assays and can confound the interpretation of results with racemic HA-966.

430.2

ANALYSIS OF ETHANOL (EtOH) INTERACTION WITH GLYCINE POTENTIATION OF NMDA-ACTIVATED ION CURRENT. G. White, D.M. Lovinger, R. W. Peoples, and F.F. Weight. Section of Electrophysiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

The amplitude of NMDA-activated ion current is reduced in the presence of intoxicating concentrations of EtOH (5-100mM). We have investigated whether the inhibition of NMDA-activated current by EtOH results from an alteration of the interaction between glycine and its binding site on the receptor/ionophore complex. Experiments were carried out on cultures of mouse hippocampal neurons using the whole-cell patch-clamp technique. We evaluated the effect of 50 mM EtOH on the amplitude of the NMDA-activated ion current at different added glycine concentrations. Inhibition by EtOH was 33±11, 33±2, 30 ±5, 28±4, and 18±1 at 10 nM, 100 nM, 500 nM, 1 µM, 10 µM glycine, respectively. The EC_{50} for glycine was similar in the absence and presence of EtOH (351 vs 360 nM, respectively). Reduction in EtOH inhibition was significant only at 10 µM glycine ($p \leq 0.01$, paired t-test), while maximal potentiation of the NMDA current was observed at 1 µM glycine. Thus, high concentrations of glycine reduced the effect of EtOH, whereas lower concentrations did not. Similar results were obtained in the presence of 10 µM strychnine. Finally, addition of 20 µM 7-chlorokynurenic acid to solutions with 10 µM glycine reduced the amplitude of NMDA-activated current to the amplitude in 100 nM glycine but did not reverse the effects of glycine on EtOH inhibition (19±2 vs 18±1%, $p>0.25$). These observations suggest that ethanol does not act in a competitive manner with nM concentrations of glycine, but that some interaction between EtOH and glycine can occur at µM concentrations of glycine.

AUTORADIOGRAPHIC EVIDENCE FOR DIFFERENTIAL COUPLING OF THE GLYCINE ANTAGONISTS ACBC AND 7-CHLOROKYNURENATE TO THE [3H] CPP RECOGNITION SITE. R.P. COMPTON, W.F. HOOD, J.B. MONAHAN, J.P. BIESTERFELDT*, G.E. FRIERDICH AND K.E. MILLER, CNS Diseases Research, G.D. Searle & Co., St. Louis, MO 63198

The results of this autoradiographic study of rat forebrain slices indicate that the glycine antagonists 1-aminocyclobutyl-1-carboxylate (ACBC) and 7-chlorokynurenate (7CHLKYN) differentially modulate interactions at the [3H]3-(2-carboxypiperazin-4-yl)propyl-1-phosphonate ([3H]CPP) recognition site. Scatchard analysis indicates that in the rat hippocampus, 50 uM ACBC induces an increase in the number of [3H]CPP binding sites (B_{max}: 0.46 +/- 0.01 to 0.74 +/- 0.01 pmoles in the stratum radiatum of CA1) without significantly altering the affinity. Although the B_{max} increases in the presence of ACBC, a linear Scatchard analysis along with a Hill number near unity suggests similar characteristics for both the basal sites and induced sites. These effects of ACBC on [3H]CPP binding are observed throughout the hippocampus. In contrast, 7-CHLKYN does not stimulate [3H]CPP binding in the hippocampus, specifically, stratum oriens and stratum radiatum of CA1 and CA3 as well as dentate molecular layer. More significantly, 7CHLKYN non-competitively inhibits the [3H]CPP binding enhancement induced by ACBC.

These findings suggest that ACBC and 7CHLKYN represent distinct classes of glycine antagonists acting at separate recognition sites, which differentially modulate interactions at the coupled NMDA antagonist recognition site labelled with [3H]CPP. The increase in [3H]CPP binding sites induced by ACBC may be a result of the unmasking of nascent sites or the conversion of NMDA agonist-preferring sites to antagonist-preferring sites.

INTERACTIONS BETWEEN GLYCINE AND THE *N*-METHYL-D-ASPARTATE RECEPTOR: KINETIC MECHANISMS R. Sircar M. J. Frusciante* and S.R. Zukin Departments of Psychiatry and Neuroscience, , Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York.

Glycine has been shown to potentiate *N*-methyl-D-aspartate (NMDA) receptor-mediated responses via its interaction with a strychnine-insensitive glycine recognition site. Glycine binding sites and NMDA receptors have identical receptor distribution patterns in rat brain. Specific antagonists at this glycine site would be important pharmacological probes of the mechanisms of interaction of the glycine and NMDA recognition sites. The potent glycine receptor antagonist 7-chlorokynurenic acid (7Cl-KYN) dose-dependently inhibits [3H]MK-801 binding to the PCP receptor and this effect is reversed by the addition of glycine. Association of [3H]MK-801 to its binding site located within the NMDA receptor-associated ion channel, occurs in a biexponential fashion. The fast component of [3H]MK-801 binding serves as a marker of activated NMDA channels. Incubation with 7Cl-KYN completely abolished the fast component of [3H]MK-801 association in 4 out 5 experiments and in the one experiment where the fast component was detected, it accounted for less than half of that seen in its absence. 7Cl-KYN-induced inhibition of the fast component of [3H]MK-801 association was reversed by the addition of glycine. Since the fast component of [3H]MK-801 association represents ligand binding to the PCP receptor via the open NMDA channel, selective reduction of this component may be used as a valid marker for glycine antagonists.

430.5

INTERACTIONS BETWEEN POLYAMINES, GLYCINE AND GLUTAMATE AT THE *N*-METHYL-D-ASPARTATE RECEPTOR. I.Z. Nussenzveig*, R. Sircar, M.J. Frusciante*, D.C. Javitt, S.R. Zukin. Departments of Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461

The goal of our study was to determine mechanisms involved in the interactions between spermidine and the NMDA receptor. The effect of increasing spermidine concentrations upon specific binding of [3H]MK-801 to well-washed, frozen-thawed synaptic membranes derived from rat forebrain was studied in the presence and absence of 7-chlorokynurenic acid (7-Cl KYNA) or D-(-)-2-amino-5-phosphono-valeric acid (D(-)AP5) with and without added L-glutamate and/or glycine. 7-Cl-KYNA attenuates NMDA receptor functioning by acting as a competitive antagonist of the NMDA receptor-associated glycine site, and D(-)AP5 as a competitive antagonist at the glutamate (NMDA) site.

7-Cl-KYNA attenuated [3H]MK-801 binding in the presence of spermidine alone or in the added presence of L-glutamate, but not in the presence of glycine. D(-)AP5 (1 μM) attenuated [3H]MK-801 binding in the presence of spermidine alone, but not in the presence of L-glutamate and/or glycine. D(-)AP5 (10 μM) attenuated [3H]MK-801 binding in presence of spermidine alone or with glycine, but not in the presence of L-glutamate.

Our results suggest: 1) Spermidine-induced stimulation of NMDA-receptor functioning requires the presence of agonist. 2) Spermidine-induced stimulation of NMDA-receptor functioning requires the presence of glycine, or alternatively, 7-Cl-KYNA may function as an inverse agonist at the glycine site.

IFENPRODIL BLOCK OF NMDA CHANNELS IS PARTIALLY GLYCINE DEPENDENT. P.Legendre*†& G. Westbrook, †INSERM, Bordeaux, France and Vollum Institute, Oregon Health Sciences Univ., Portland, OR.

The vasodilator ifenprodil has recently been shown to antagonize NMDA receptors in several experimental preparations, but its mechanism of action remains unclear. It has been suggested that ifenprodil (IFL) antagonizes NMDA receptors by an interaction with polyamines (Carter et al., EJP 164, 611,1989), but Reynolds & Miller (Mol.Pharm 36,758,1989) have proposed that IFL stabilizes an inactivated form of the channel. We used whole-cell and single channel recording from cultured hippocampal neurons to test the action of IFL on NMDA channels.

Neurons from neonatal rats were dissociated and grown in cell culture for 1-2 weeks. For recording, the extracellular solution contained (mM): Na 165, K 2.5, Ca 1, Mg 0, HEPES 10, glucose 10; glycine (30 nM - 100 µM); picrotoxin, strychnine, and tetrodotoxin were also added. Patch pipette solutions contained (mM): Cs 140, EGTA 10, Mg 1, HEPES 10, Cl 126, Fl 14. Cation salts were ultrapure; NMDA (5 or 10 µM) and IFL (0.1 - 1000 µM) were applied by flowpipes.

In 500 nM glycine, maximal concentrations of IFL blocked 95% of whole cell NMDA currents. The block by 100 µM IFL was partially overcome by increasing glycine to 100 µM. IFL appeared to have a biphasic inhibition curve with approximate IC50s of 1.3 and 240 µM. The high affinity component blocked ≈ 35% of the NMDA current. IFL block was not voltage- or use-dependent. The half-recovery from IFL block was 16 sec and was not increased by continous presence of agonist or by holding at positive membrane potentials. On outside-out patches, IFL reduced both the number and mean open time of NMDA channels with no effect on single channel conductance. IFL (5 µM) blocked 70% of channel activity (n=5) which was much greater than expected from IFL inhibition of the macroscopic current, perhaps suggesting that intracellular dialysis alters NMDA channel sensitivity to IFL. Supported by INSERM, NATO Fdn., NIH and the McKnight Foundation.

IFENPRODIL INHIBITION OF [3H]GLYCINE BINDING TO THE NMDA RECEPTOR: INTERACTIONS WITH POLYAMINES. R.W. Ransom. Merck Sharp & Dohme Research Laboratories, West Point, PA 19486.

Ifenprodil has been shown to be a relatively potent noncompetitive inhibitor of NMDA receptor activity. It has been proposed that this antagonism is due to an interaction with the polyamine recognition site associated with the receptor complex. In the present study we have addressed this question by examining the interactions of spermine and ifenprodil at the NMDA receptor's glycine modulatory site. Using a thoroughly washed rat brain membrane preparation, ifenprodil partially inhibited [3H]glycine binding with an $IC_{50} \approx 35$ nM). The maximal level of inhibition was 39% of control binding under basal conditions. The addition of 100 µM L-glutamate stimulated binding by 40% and had no effect on the IC_{50} value for ifenprodil. However, ifenprodil could not completely reverse the stimulation of [3H]glycine produced by L-glutamate. Spermine maximally enhanced binding by 350% with an EC_{50} = 14 µM. Concentrations of spermine that enhanced [3H]glycine binding produced a dose-dependent increase in the IC_{50} value for ifenprodil inhibition of binding. At 1 mM spermine, ifenprodil blocked [3H]glycine binding with an $IC_{50} \approx 1.5$ µM. Yet, high concentrations of ifenprodil were unable to completely reverse the stimulation of binding produced by the polyamine. In related experiments, ifenprodil was found to reduce the maximum level of binding enhancement produced by spermine. These results indicate that spermine and ifenprodil do not competitively interact with respect to their effects on the NMDA receptor's glycine recognition site.

DIFFERENCES BETWEEN ANTAGONISM OF NMDA-INDUCED ACUTE EXCITOTOXICITY BY IFENPRODIL AND OTHER NMDA ANTAGONISTS G.D. Zeevalk and W.J. Nicklas Dept. of Neurology, UMDNJ-RWJ Med. Sch., Piscataway, NJ 08854

Acute excitotoxicity in embryonic day 13 chick retina induced by incubating with 50µM NMDA for 30min is demonstrated histologically by swelling of certain populations of neurons and by release of GABA. These effects are completely inhibited by noncompetitive antagonists, (+)MK-801 (IC_{50},0.02µM); (-)MK-801 (IC_{50},0.28µM) or by the competitive antagonist CGS 19755 (IC_{50},0.62µM). Ifenprodil (IFEN) also antagonizes NMDA-induced GABA release (IC_{50},1.26µM) however, it differs from other NMDA antagonists in 2 respects. Firstly, while other antagonists completely protect all NMDA sensitive neurons, IFEN fails to protect a select subpopulation of neurons. Secondly, studies done to determine temporal efficacy of antagonism demonstrate that MK-801 and CGS 19755 can protect when added after NMDA, the amount of protection being inversely related to the time of addition of antagonist, while IFEN is only protective when added prior to NMDA addition. This suggests that IFEN can only interact with the NMDA receptor when it is in an "inactive" state. To determine if the unprotected neurons seen in the presence of IFEN and NMDA represent neurons whose NMDA receptors are currently "active", retina was incubated with either TTX (2µg/ml), muscimol (0.5mM) or CGS 19755 (5 µM) prior to or during incubation with IFEN (10µM) plus NMDA (50µM). Such treatment did not alter the response in the IFEN-insensitive, NMDA-sensitive population suggesting that in addition to IFEN's differential action at "active" versus "inactive" NMDA receptors, IFEN may unmask a heterogeneity in the NMDA receptor population.

SPERMINE DEPOLARIZES THE RAT CORTICAL WEDGE AND POSITIVELY MODULATES SPONTANEOUS EPILEPTIFORM DISCHARGES. L.J. Robichaud and P.A. Boxer, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105.

The polyamine spermine reportedly modulates binding of MK-801 and glycine to allosteric receptor sites of the NMDA receptor-ion channel complex. We examined functional responses in the rat cortical wedge preparation to spermine in Mg++ free buffer with TTX (0.5 μM). Spermine (100 μM-3 mM) induced slow dose-dependent repeatable depolarizations which were not blocked by Mg++, the NMDA antagonist CPP, the AMPA/kainate/glycine antagonist DNQX, nor ifenprodil (a reported ligand of both the polyamine and sigma receptor sites). In the absence of TTX, spermine (100 μM-1 mM) increased (57-178%) the rate of spontaneous epileptiform discharges (SED) in a dose- and time-dependent manner. Ifenprodil (30 μM) inhibited SED; neither spermine (100 μM-3 mM) nor glycine (1 mM) reversed this inhibition. The ornithine decarboxylase inhibitor, DFMO (MDL 71782A) (100 μM, 2 hrs) did not inhibit SED. In conclusion, spermine showed functional responses in the rat cortical wedge model in both the presence and absence of TTX, with unclear mechanisms of action. This study did not indicate a competitive interaction between spermine and ifenprodil in direct depolarizations or SED. Activation of NMDA, AMPA, kainate, or glycine recognition sites do not appear to be involved in spermine-induced depolarizations.

POLYAMINE ANTAGONIST REDUCES NMDA-INDUCED DEPOLARIZATION, BUT ALSO REDUCES MAGNESIUM ANTAGONISM. M.A. Bowe and J.V. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

We have demonstrated that Mg^{2+} less potently antagonizes depolarizations evoked by NMDA in 10-15 day old rats than in adults. Endogenous polyamines regulate opening of the NMDA channel, and they are most abundant during development. The polyamine 1,10-diaminodecane (DA10) inhibits the enhancement of [^{3}H]MK-801 binding produced by glutamate, glycine and spermine. We therefore used DA10 as a tool to determine whether polyamines regulate the sensitivity of the NMDA receptor to Mg^{2+}. A grease-gap preparation was used to study depolarizing responses of CA1 hippocampal pyramidal cells to NMDA.

In the absence of added Mg^{2+}, DA10 (316 μM) noncompetitively antagonized NMDA-evoked depolarizations, but did not affect depolarizations evoked by AMPA. The effect of DA10 was significantly greater in preparations from adult animals than in preparations from 10-15 day old animals. This difference may be explained by the greater concentration of polyamine present in younger animals. DA10 also greatly reduced the effectiveness of 1 mM Mg^{2+} in antagonizing NMDA-evoked depolarizations. The effect of Mg^{2+} was reduced by 70% in preparations from adult animals and was virtually abolished in preparations from 10-15 day old rats.

These results suggest that polyamines regulate not only the sensitivity of the NMDA receptor to agonist, but also its sensitivity to Mg^{2+}. DA10 may act as a polyamine antagonist for the former action and as a polyamine agonist for the latter action. (Supported by NIH grant NS 16064.)

BINDING OF [^{125}I]IFENPRODIL TO THE POLYAMINE-SENSITIVE DOMAIN OF THE NMDA RECEPTOR. P.M. Beart, L.D. Mercer*, A.J. Searle* and B. Jarrott*, University of Melbourne, Clinical Pharmacology, Austin Hospital, Heidelberg, 3084, Australia.

The NMDA receptor-ionophore complex consists of a number of interacting domains, including one for polyamines where ifenprodil binds to exert its non-competitive antagonism. Ifenprodil was iodinated with Na^{125}I/chloramine-T, purified and its binding characterized. In cortical membranes, binding of [^{125}I]ifenprodil was saturable (K_d 145nM, B_{max} 2.5 pmol/mg protein) and to a single site. Specific binding was reversible, being dissociable with 1mM spermine and poorly dissociable with 16.7μM SL 82.0715, and represented 70-75% of total binding by filtration. Binding was displaced by polyamines and drugs; rank order of potency SL 82.0715 = tibalosine > nylidrin = isoxsuprine. Inhibition constants for spermine and spermidine were 15 and 44μM, respectively. GBR 12909 (3μM) failed to affect the potency of SL 82.0715, tibalosine and spermine. Binding to synaptic membranes (K_d 150nM) was stimulated by NMDA (100%) and glycine (85%). In autoradiographic studies using slide-mounted sections, binding sites for [^{125}I]ifenprodil were localized in several regions including anterior cingulate cortex, hippocampus and amygdala. Whilst the polyamine site of the NMDA receptor can be successfully labelled with [^{3}H]ifenprodil (Shoemaker et al., Eur. J. Pharmacol. 176, 249, 1990), the [^{125}]ligand is a rapid, convenient and inexpensive alternative.

430.12

NMDA RECEPTOR BINDING PROPERTIES OF 5,7-DICHLORO-KYNURENIC ACID, A RADIOLABELED GLYCINE SITE ANTAGONIST. B.M. Baron, A.L. Slone*, B.W. Siegel*, B.L. Harrison*, S.D. Hurt*, M.W. Dudley, and M.G. Palfreyman. Merrell Dow Research Institute, Cincinnati, OH 45215, DuPont NEN, Boston, MA 02118.

The kynurenic acid (KA) derivative, 5,7-dichlorokynurenic acid (5,7-DCKA) is a potent and selective inhibitor of strychnine-insensitive [^{3}H]glycine binding to rat brain membranes (IC_{50} = 79 nM) whereas IC_{50} values were >100 μM at a variety of other glutamate-related and non-glutamate neurotransmitter receptors. 5,7-DCKA non-competitively antagonized the NMDA-mediated elevation of cGMP content of neonatal rat cerebellar slices. This antagonism was prevented by glycine or D-serine.

Using methods described for [^{3}H]glycine binding, we found that [^{3}H]5,7-DCKA (17.6 Ci/mmol) bound to rat brain membranes with K_d = 69 nM and B_{max} = 14.5 pmol/mg protein. A concentration of 10 nM [^{3}H]5,7-DCKA gave approximately 9,000 dpm (total) and 3,000 dpm (non-specific) and exhibited a pharmacological profile which was consistent with labeling of the strychnine-insensitive glycine binding site. IC_{50} values (μM) were: 5,7-DCKA (0.03), glycine (0.3), D-serine (0.6), 7-Cl-KA (0.5), KA (10), L-serine (27), HA-966 (49), indole-2-COOH (89). Binding was allosterically regulated by the glutamate recognition site; increased by NMDA, Asp, and Glu and inhibited by phosphonoamino acid antagonists. This ligand should be a valuable tool to probe the NMDA receptor complex.

430.13

KYNURENIC ACID ANALOGUES AS POTENT AND SELECTIVE ANTAGONISTS AT THE GLYCINE SITE ON THE NMDA RECEPTOR. A.C. Foster, J.A. Kemp, P.D. Leeson, S. Grimwood, G.R. Marshall, T. Priestley, R.W. Carling and K.W. Moore Merck, Sharp and Dohme Res. Lab., Neurosci. Res. Ctr., Harlow, Essex, U.K.

The N-methyl-D-aspartate (NMDA) receptor possesses two separate amino acid recognition sites, one for acidic amino acids such as L-glutamate and NMDA and one for neutral amino acids such as glycine. The broad spectrum excitatory amino acid antagonist kynurenic acid (KYNA) has affinity for both sites, however substitution of Cl in the 7-position yields a compound (7-ClKYNA) with improved potency and selectivity as a glycine site antagonist (Kemp et al, Proc Natl Acad Sci, 85:6547, 1988). In a [^{3}H]glycine binding assay using P_2 membranes from rat cortex and hippocampus, the affinity of 7-ClKYNA (IC_{50} = 0.56 μM) was improved in the analogues 5,7-diClKYNA (IC50 = 0.2 μM) and 5-I,7-ClKYNA (IC50 = 0.032 μM). These new KYNA analogues retained good selectivity (> 2 orders of magnitude) versus other acidic amino acid binding sites.

In a rat cortical slice assay and whole cell voltage-clamp recordings from rat cultured cortical neurones, these compounds were selective, non-competitive antagonists of NMDA responses (respective Kb's of 3.0 and 0.41 μM in the cortical slice). Both compounds caused a complete flattening of the NMDA concentration-response curve, and their antagonism was reversed by co-application of glycine or D-serine, consistent with a selective action at the glycine site. The improved selectivity and affinity of these compounds for the glycine site on the NMDA receptor should make them useful as tools for further studies.

Opioid peptide modulation of dopamine release: An *in vivo* electrochemical study. R. J. W. Pentney and A. Gratton, Douglas Hosp. Res. Ctr, McGill Univ., Montréal, Canada, H4H 1R3.

The present study used high-speed chronoamperometry to examine the effects of locally applied DPDPE and DAGO, two selective delta and mu2 receptor agonists repectively, on basal and K+-evoked release of dopamine (DA) in striatum (CPU) and nuc. accumbens (NAcc). Male rats were anesthetized with either chloral hydrate or urethane, tracheotomized and placed in a stereotaxic frame. Nafion-coated carbon fiber electrochemical electrodes were cemented to double-barrel micropipette assemblies (o.d. 30-40 um) with a tip separation of 200-300 um and lowered to various CPU and NAcc sites. One barrel contained a KCl solution while the other barrel contained either DPDPE or DAGO (1,10 or 100 nM). Electrochemical recordings were obtained by applying to the electrochemical electrode, at a rate of 5 Hz, a +0.5V oxidation potential relative to a Ag/AgCl reference electrode. The reduction current was also monitored to confirm the dopaminergic nature of the electrochemical signals. In both CPU and NAcc, local pressure microejection of DPDPE had no effect on basal levels of DA but significantly affected the depolarization-evoked release of DA caused by local K+ application. However, the effects of DPDPE on stimulated DA release depended on the anesthetic used. In urethane anesthetized animals, 1nM DPDPE caused a suppression of DA release, but mostly potentiated DA release when chloral hydrate was used. Both the suppressive and potentiating effects of DPDPE tended to be greater in CPU than in NAcc and could be partially blocked by naloxone (2 mg/kg, i.p.). DAGO produced inconsistent results; potentiating DA release on a few occasions but generally having no effect. Finally, locally applied morphine, another mu agonist, caused large increases in basal signals. However, these effects were discounted, since morphine itself was found to be electroactive. In conclusion, the present data indicate that enkephalins modulate the release of DA at the terminal via a delta receptor. The inconsistent effects found with DAGO may reflect the patchy distribution of mu2 receptors in these areas. However, these data must be interpreted cautiously in light of the interactions of these drugs with the anesthetics used. Funded by NSERC Canada.

ELECTROPHYSIOLOGICAL STUDIES OF MIDBRAIN DOPAMINE NEURONS IN CULTURE. D.L. Cardozo Department of Neurobiology, and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

I have removed midbrain dopamine (DA) neurons from neonatal rats and routinely maintained them in dissociated cell culture for several months. The DA phenotype has been confirmed by catecholamine fluorescence and by tyrosine hydroxylase immunocytochemistry. Living DA neurons have been identified for electrophysiology by 5,7-DHT fluorescence, and recordings made with both high resistance and patch electrodes. The observed physiological properties of cultured DA neurons are consistent with results reported from *in vivo* and slice preparations. These include long-duration action potentials (2.5-4 ms); 1-5 Hz pacemaker-like firing activity; 450 ms slow depolarization to action potential; and anomalous rectification. In addition, DA cell firing was inhibited by applied DA or (+/-)-PPHT, a potent D2 agonist. These results suggest that this culture system will be useful for acute and chronic pharmacological studies of DA neurons. (Supported by funds from the Commonwealth Res. Ctr.,MA Mental Health Ctr;DA 04582; Scottish Rite; and NSCERC, Canada.)

431.3

REPEATED ADMINISTRATION OF D1 DOPAMINE RECEPTOR ANTAGONISTS FAILS TO INACTIVATE DOPAMINE NEURONS. S.R. Wachtel and F.J. White. Wayne State Univ., Sch. of Med., Dept. Psychiatry, CCN Program, Neuropsychopharmacology Lab, Lafayette Clinic, Detroit, MI 48207

Based on the findings that D1 dopamine (DA) receptor antagonists can block the behavioral effects of both D1 and D2 receptor agonists, it has been suggested that D1 antagonists may be effective antipsychotic drugs (APDs). Moreover, a variety of pharmacological studies have led to predictions that D1 DA receptor antagonists may have a clinical profile characteristic of atypical APDs such as clozapine. One electrophysiological model of atypical APDs action is the ability of repeated administration of an APD to decrease the number of spontaneously active DA neurons in the ventral tegmental area (A10), but not in the substantia nigra (A9), by the process of depolarization inactivation (DP block). In the present study, the effect of repeated administration of the D1 antagonists SCH 23390 and SCH 39166 on the activity of both A9 and A10 DA neurons was investigated in the rat. In contrast to the selective decrease in the number of spontaneously active DA neurons in A10 observed after continuous administration of the D1 antagonist SCH 23390 (0.29 mg/kg/day, s.c.) via mini osmotic pumps, repeated administration of SCH 23390 or SCH 39166 (0.5/mg/kg, s.c., b.i.d.) failed to alter the activity of DA neurons in either A9 or A10. Although the effects of continuous and repeated administration of SCH 23390 appear to differ, SCH 23390 produced relatively small decreases (< 30%) in DA neuronal activity with both administration regimens as compared to other APDs such as haloperidol (> 50%). In addition, the decrease observed after continuous administration of SCH 23390, in contrast to haloperidol, did not appear to be due to DP block as it was not reversed by membrane hyperpolarization with apomorphine (0.01 or 0.05 mg/kg, i.v.). In conclusion, these results indicate that D1 DA receptor antagonists do not exert electrophysiological effects on DA neurons characteristic of standard APDs, and suggests that either D1 antagonists might not be APDs or that DP block may not be a necessary component of APD action. (Supported by MH-40832, DA-04093 and the Michigan Departmet of Mental Health.)

431.4

HA-966 INHIBITS THE ACTIVITY OF MESENCEPHALIC DOPAMINE (DA)-CONTAINING NEURONS THROUGH A NON-NMDA RECEPTOR-MEDIATED MECHANISM. P.D. Shepard, H. Lehmann-Romeyn*, J.H. Kogan, R.H. Roth, and B.S. Bunney. *Depts. of Psychiatry and Pharmacol., Yale Univ. Sch. of Med., New Haven CT. 06510 and Maryland Psychiatric Research Cntr., Baltimore, MD 21228.*

HA-966 (+ 1-hydroxy-3-amino-pyrrolidinone-2) has been shown to suppress the activity of mesencephalic DA-containing neurons *in vivo*. Structurally related to the cyclic anhydric form of GABA, this compound is believed to interact with central GABAergic receptors. Recently, however, HA-966 has also been shown to antagonize glycine at its allosteric site on the NMDA receptor (Foster and Kemp, J. Neurosci., 9:2191) - an effect which appears to be mediated solely by the (+) enantiomer (Singh et. al., PNAS, 87:347). In the present series of experiments, we sought to determine the extent of the contribution made by GABA and NMDA receptor subtypes to the effects of HA-966 on nigral DA neurons recorded *in vivo* and *in vitro*. Administration of a bolus dose of the racemic form of HA-966 (10-40 mg/kg, i.v.) inhibited the firing rate of all cells tested (n=20) in chloral hydrate-anesthetized rats. In most cells (n=13), these changes were preceded by a transient increase in activity (10-40%). Doses exceeding 20 mg/kg caused a complete cessation of spontaneous firing. Both the initial rate of decline in firing rate (time required to inhibit activity by 50%) and latency to blockade of neuronal activity were dose-dependent. In contrast to the effects of the racemic form of the drug, systemic administration of the (+) enantiomer (40mg/kg) had no effect on the activity of nigral DA neurons. The effects of HA-966 (1 mM) on DA neurons studied in brain slices were qualitatively similar to those observed *in vivo*, with the exception of the early excitatory component, which was never observed (n=8). Bath application of bicuculline (50 uM) resulted in a modest increase in basal firing rate but failed to antagonize the inhibitory effects of HA-966. These data, together with our *in vivo* findings, indicate that the ability of HA-966 to inhibit the firing of nigral DA-containing neurons may not involve either $GABA_A$ or NMDA receptor-mediated mechanisms. Supported by NARSAD and PHS MH-28849 and 14092.

DOPAMINERGIC NEUROTRANSMISSION ASSESSED BY IN VIVO DIALYSIS IN THE VENTROLATERAL STRIATUM OF RATS FOLLOWING SYSTEMIC ADMINISTRATION OF SPECIFIC DOPAMINE (DA) AGONISTS AND ANTAGONISTS. Ronald E. See, Dept. of Psychology, Washington State University, Pullman, WA, 99164-4820.

Previous studies in rodents suggest that the ventrolateral striatum (VLS) is preferentially involved in the control of certain motor activities, particularly orofacial movements. The present study examined the effects of DA D1 and D2 receptor agonists and antagonists on DA release and metabolism in the VLS using in vivo microdialysis techniques. Female, Sprague-Dawley rats were anesthetized with Equithesin and unilateral guide cannulae implanted (A +0.2, L +3.5, V -5.0). Following one week of recovery, microdialysis probes with 3 mm of exposed dialysis membrane were inserted into the guide cannulae and perfusion with Ringer's solution initiated. Samples were collected every 20 minutes before and after drug injection. The following drugs and doses (mg/kg) were administered IP: the D2 antagonist, raclopride (0.5, 2.0, 4.0), the D2 agonist, quinpirole (0.03, 0.1, 0.3), the D1 antagonist, SCH 23390 (0.01, 0.05, 0.25), and the D1 agonist, SKF 38393 (0.3, 1.0, 3.0). Doses were selected based on previous studies which indicated significant behavioral effects at these doses. Perfusates were directly injected onto an HPLC column and analyzed for DA, DOPAC, and HVA using electrochemical detection. Raclopride markedly increased levels of DA, DOPAC, and HVA while quinpirole produced a decrease in all three. SCH23390 also stimulated the release of DA and increased metabolite levels but to a much lesser degree than raclopride. SKF 38393 failed to alter DA release and metabolism. These results suggest that the in vivo release of DA may be related more to D2 than D1 receptors.

IN VITRO EXTRA- AND INTRACELLULAR RECORDING FROM SINGLE MID-BRAIN DOPAMINE (DA) NEURONS WITH IDENTIFICATION OF THEIR PROJECTION SITES. T.H. Lee* and E.H. Ellinwood, C.M. Kuhn, and G. Einstein, Dept. of Psychiatry, Pharmacology and Neurobiology, Duke Univ. Med Ctr., Durham, NC 27710

We have recently initiated experiments to examine the differential regulatory mechanisms of single identified DA neurons in slice preparations. Since the various DA projection systems may each play a different role in the mediation of both normal and abnormal behaviors, we pre-labelled midbrain DA neurons by injecting rhodamine-labelled flourescent microspheres (RFM) into their projection sites.

RFM were injected into either the dorsolateral caudate or nucleus accumbens 2-4 days prior to extracellular single-unit recording. After a survival sufficient for retrograde transport of the RFM, 350 um slices of tissue were cut. Under epifluorescent illumination, neurons labelled with the microspheres could be clearly seen in the top layer of the slices as a tightly packed group. These surface neurons (top 80 um) did not exhibit spontaneous activity. However, those just below the surface neurons did. On the assumpton that the majority of these deeper neurons were RFM labelled, we recorded from them and found numerous spontaneously active DA neurons exhibiting pacemaker-like baseline activity and reversible inhibition by DA and GABAergic agonists. We are currently in the process of implementing intracellular recording and dye injection in order to: (1) examine the viability of the inactive surface DA neurons and (2) identify the projection area of the recorded neuron by the presence of double label. Results from these studies as well as the differential effects of DA and GABAergic agents on identified DA neurons will be presented.

***IN VIVO* MEASUREMENTS OF EXTRACELLULAR DOPAMINE AND NEUROTENSIN IN THE DORSOLATERAL AND MEDIAL PREFRONTAL CORTEX, PREMOTOR CORTEX, AND CAUDATE OF THE RHESUS MONKEY: EFFECT OF AMPHETAMINE.** B. Moghaddam, C.W. Berridge, A.J. Bean, B.S. Bunney, P.S. Goldmann-Rakic and R.H. Roth. Depts. Psych. & Pharm., Sec. Neuroanat. Yale Univ.Sch. Med., New Haven, CT 06510.

Microdialysis was utilized to assess the extracellular concentration of dopamine (DA) in the anesthetized Rhesus monkey. Concentric probes were placed in the caudate nucleus, premotor cortex and dorsolateral and medial prefrontal cortices. Basal DA levels were consistently detected in the caudate (1.9±1.1 fmoles/µl, perfusion rate = 1 µl/min) and premotor cortex (0.63±0.2 fmoles/µl). In prefrontal cortex (both medial and dorsolateral), DA was reliably detected in two out of three animals measuring approximately 0.3 fmoles/ul. Intravenous administration of amphetamine (1 mg/kg) enhanced extracellular DA levels in caudate by more than 36 fold (3651%±311). This effect is much greater than the 300-500% increase we observe in the rodent. Smaller increases (300%-800%) after amphetamine were detected in cortical areas of the primate. These studies demonstrate that basal extracellular DA can be measured in caudate and cortex of nonhuman primates and that DA levels are responsive to pharmacological manipulation. Preliminary studies showed no change in neurotensin levels in cortex and caudate following amphetamine. Supported by MH-44866.

SIMULTANEOUS MICRODIALYSIS MEASUREMENT OF EXTRACELLULAR DOPAMINE AND SEROTONIN IN THE PREFRONTAL CORTEX AND STRIATUM OF THE FREELY MOVING RAT. A.M. Rasmusson, L.E. Goldstein, B.S. Bunney, R.H. Roth. Dept. of Pharm. & Psych., Yale Univ.Sch. Med., New Haven, CT 06510.

Postsynaptically active doses of the serotonergic 5HT1a agonist, 8-OH-DPAT, selectively increase dopamine (DA) turnover in the prefrontal cortex (PFC) of the rat. We have further investigated this phenomenon using *in vivo* microdialysis in the freely moving rat. Single rats were stereotaxically implanted with striatal (CP) and bilateral PFC microdialysis probes, as well as with intraperitoneal catheters 18-24 hrs before experimentation. Extracellular DA and 5HT were monitored following normal saline and subsequent 8-OH-DPAT (225 ug/kg) injections. At a perfusion rate of 1.5 µl/min, basal DA and 5HT levels in the PFC of the freely moving rat were 0.09 and 0.14 fmol/µl, respectively, uncorrected for probe recovery; in the CP, 0.86 fmol/µl and 0.27 fmol/µl, respectively. After 8-OH-DPAT, DA in the PFC increased by approx. 200%; it remained stable in the CP. Maximal DA increases and 5HT decreases occurred within 1 hr of 8-OH-DPAT. DA and 5HT returned to baseline 2-3 hrs after treatment. These findings are consistent with differential regulation of the mesotelencephalic DA systems by the 5HT system. THE INVOLVEMENT OF SUBTHALAMIC NUCLEUS PROJECTIONS TO THE SUBSTANTIA NIGRA IN THE REGULATION OF DOPAMINE NEURON BURST FIRING . I.D. Smith and A.A. Grace, *Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, Pennsylvania, 15260, USA.*

Substantia nigra (SN) dopamine (DA) neurons recorded *in vivo* fire in one of two patterns: 1) an irregular, single-spiking pattern or 2) burst firing. DA neurons will enter a burst firing mode when the DA system is compromised, such as following extensive striatal DA depletions or in response to the administration of DA receptor blockers. In contrast, DA neurons recorded *in vitro* in brain slices, in which much of their afferent input is sectioned, fire only in a very regular pacemaker pattern, with no evidence of burst activity. Evidence is presented here suggesting that burst firing in a sub-poulation of DA neurons is regulated by excitatory afferents from the subthalamic nucleus (STN).

In normal controls, 44.5% of DA cells exhibited burst firing (n= 28 rats). Burst firing could be induced by STN stimulation in the majority of cells recorded, with a progressive increase in the percentage of bursting cells occurring between 30 to 60 minutes following 1 minute of stimulation at 20 Hz (72.4%, n=5). After hemisection of the brain between the STN and the SN, averaged burst firing within the entire SN was unaltered (38.8%, n=10). However, there was a reduction in burst firing in cells recorded in the lateral (L) SN, as compared to centrally (C) and medially (M) located cells (LSN: 23.1% vs. control: 38.6%; CSN: 46.7% vs. control: 43.6%; MSN: 42.8% vs control: 50.4%). In each case, a number of lateral DA neurons were observed to fire in a very regular, pacemaker pattern, in some cases despite elevated discharge frequencies (eg. > 8 Hz). This is in marked contrast to the intact animal where pacemaker firing of DA cells, particularly at these high discharge rates, has not been observed. If the transections were placed anterior to the STN, little change was noted in DA cell firing pattern (44.8%, n=6). Regularization of lateral SN DA neuron firing and a decrease in the number of cells bursting (LSN: 7.1%, CSN: 36.0%, MSN: 43.8% n=9) was also produced by electrolytic lesions of the STN.

These data suggest that an excitatory projection from the STN modulates the firing pattern of lateral SN DA neurons. This pathway may be involved in the feedback increase in DA cell burst firing following reductions in striatal DA transmission secondary to disinhibition of the STN. EFFECTS OF STRIATONIGRAL PATHWAY HEMITRANSECTION ON FIRING PROPERTIES AND PHARMACOLOGICAL RESPONSES OF SUBSTANTIA NIGRA DOPAMINE NEURONS IN THE RAT. M.L. Pucak & A.A. Grace. *Depts. of Behav. Neurosci. & Psychiatry, U. of Pittsburgh, Pittsburgh, PA, 15260.*

The GABAergic striatonigral projection has been suggested to modulate the firing properties and the pharmacological responses of dopamine (DA) neurons in the SNzc. However, its functional importance remains unclear, since kainic acid lesion of the striatum does not alter DA neuron firing rate or response to apomorphine (APO). We have examined alterations in DA neuron electrophysiology after hemitransections of the striatonigral pathway using single unit extracellular recordings from DA neurons of rats. Pharmacological manipulation consisted of i.v. administration of APO in log dose fashion, followed by an equal dose of haloperidol (HAL). In a subset of rats, hemitransections of the striatonigral pathway were performed by making cuts with a glass knife at approximately A4.8. Data are presented as mean±SD. Hemitransection did not alter DA neuron firing rate (control= 5.0±2.3 (n=33), transected=4.4±2.1 (n=37) spikes/sec). Burst-firing was likewise unaffected; the % of neurons defined as bursting (controls=33.3, transected=20.0), the % of spikes fired as bursts (control=5.5±6.1, transected= 7.9±17.1), and the spikes per burst (control=2.5±7.3, transected=2.5±10.0) were unchanged (control, n=9; transected, n=10). The number of spontaneously active DA neurons encountered per electrode track also was unaltered (control=1.0±.1 (n=4), transected=1.3±.2 (n=3)). The ED_{50} for APO was not affected (control=7.7±5.7 (n=12), transected=6.7±6.2 (n=10) µg/kg). However, there was a change in the shape of the dose-response curve. In addition, a subset of DA neurons in the transected rats demonstrated a slowed return to baseline after administration of HAL. In such cases, administration of additional HAL was necessary to return firing rate toward baseline; this was never necessary when recording from controls. These data demonstrate that the striatonigral projection does not exert clear effects on the baseline firing rate or pattern of DA neurons, but may have subtle effects on their responses to pharmacological manipulation. MORPHOLOGICAL DEVELOPMENT OF THE SUBSTANTIA NIGRA IN THE POSTNATAL RAT J.M. Tepper, F. Trent and J.S. Rankin* Center for Molecular and Behavioral Neuroscience and Department of Biological Sciences , Rutgers University, Newark, NJ, 07102.

Recent studies indicate that the physiological and pharmacological properties of rat substantia nigra dopamine (DA) neurons undergo significant changes during the first four weeks of life. The present studies were carried out to examine the morphological correlates of the developmental changes in the neurophysiological properties of nigral DA neurons.

Sprague-Dawley rat pups of age postnatal day 1 (PD1), PD7, PD14, PD21, PD28 and adult rats were anesthetized and perfused with a saline wash followed by 4% paraformaldehyde and 0.2% glutaraldehyde. Brains were sectioned at 50-75 µm and processed for tyrosine hydroxylase (TH) immunocytochemistry by conventional means. The distribution of TH+ neurons and dendrites in substantia nigra was noted, and measurements of TH+ somatic sizes, and the diameters of proximal (25 µm from the soma) and distal (>400 µm from the soma) dendrites were made using a Quantex QX-7 image analysis system.

At PD1, pars compacta and pars reticulata were not clearly delineated; TH+ neurons and a dense plexus of fibers were scattered throughout the substantia nigra. By PD7 the density of TH+ neurons increased dorsally and decreased ventrally, and by PD14, a DAergic pars compacta and a non-DAergic pars reticulata could be clearly distinguished. At PD21, the density of TH+ neurons and dendrites in pars reticulata was further reduced, and by PD28 substantia nigra cytoarchitecture appeared as it does in the adult. TH+ somatic size increased significantly from PD1 (15.1±0.4 µm x 10.4±0.2 µm) to PD14 (25.3±0.5 µm x 14.9±0.3 µm; F=47.8, df=5, 283, p<.001), as did the diameter of the proximal (2.16±0.1 µm , PD1; 3.06±0.1 µm, PD14; F=12.83, df=5, 283, p<.001) and distal dendrites (0.62 ±0.01 µm, PD1; 0.69 +0.01 µm, PD14). Distal dendritic diameter peaked at PD21 (0.72+0.01 µm), decreasing to 0.61±0.01 µm at PD28. Neither somatic size nor proximal dendritic caliber changed between PD14 and adulthood.

These data demonstrate significant postnatal changes in the cytoarchitecture of the rat substantia nigra. The sizes and distribution of DAergic neurons and processes first resembled those in adults by around 14 days of age, the same time at which these neurons begin to display physiological and pharmacological responses similar to those seen in adults. EFFECTS OF REPEATED SKF 38393 ON THE RESPONSIVENESS OF NIGROSTRIATAL SYSTEM NEURONS. M.D. Kelland, D.K. Pitts, A.S. Freeman and L.A. Chiodo. Lab. of Neurophysiology, Center for Cell Biology, Sinai Research Institute, and the Cellular and Clinical Neurobiology Program, Wayne State University School of Medicine, Detroit, Michigan 48235.

Extracellular single-unit and iontophoretic recording techniques were used to examine the effects of repeated SKF 38393 (15 mg/kg/day; 14 or 28 days) on nigrostriatal DA or Type I caudate neurons in the rat. Repeated SKF 38393 did not alter the basal activity of DA neurons or the potency of quinpirole to induce inhibition. However, 28-day SKF 38393 treatment eliminated the effects of acute SKF 38393 on both the rate-dependent nature of quinpirole-induced inhibition and sciatic nerve stimulation-induced inhibition of DA neurons. In contrast, one week after 28-day SKF 38393 treatment, quinpirole-induced inhibition by itself was no longer rate-dependent, an effect which was reversed by acute pretreatment with SCH 23390; these cells were also highly sensitive to acute D1 enhancement of the response to sciatic nerve stimulation.

28-day SKF 38393 treatment resulted in reduced sensitivity of Type I caudate neurons to iontophoretic SKF 38393, but enhanced sensitivity was observed one week later. Thus, chronic SKF 38393 can induce functional desensitization of D1 receptors, but one week withdrawal is followed by sensitization. (MH41557 [LAC], MH42136 [ASF], MH09781 [DKP], Sinai Res. Inst.; MDK is a Tourette Syndrome Association Postdoctoral Fellow)

EFFECTS OF CHOLECYSTOKININ (CCK) FRAGMENTS AND CR 1409 ON MIDBRAIN DOPAMINE NEURONS. A.S. Freeman, M.D. Kelland, J. Zhang* and L.A. Chiodo. Lab. of Neurophysiology, Center for Cell Biology, Sinai Research Institute, and the Cellular and Clinical Neurobiology Program, Wayne State University School of Medicine, Detroit, MI 48235.

Extracellular single-unit recording experiments were performed to further study the modulatory effects of CCK on midbrain DA cells. CCK-8S (8 ug/kg) preferentially excited non-bursting mesoaccumbens DA cells (7/7 cells), whereas only 1/12 bursting cells was excited. In support of this finding, CCK-8S induced burst-firing (with coincident excitation) in 7 out of 10 additional non-bursting cells. CCK-8S pretreatment (4 min) enhanced the potency of i.v. quinpirole to inhibit mesoaccumbens DA neurons (ED50= 2.7 $\pm$ 1.7 ug/kg vs. 5.7 $\pm$ 1.8 ug/kg in control rats). CCK-8US and CCK-4 were without effect.

The CCK-A receptor antagonist CR 1409 (.05 or .5 mg/kg, i.v.) did not alter the sensitivity of mesoaccumbens DA neurons to quinpirole (ED50 = 5.7 $\pm$ 1.7 and 5.6 $\pm$ 1.7 ug/kg respectively). In the cell per track paradigm, repeated administration of CR 1409 (14 days, .5 or 5 mg/kg/day, i.p.) increased the numbers of spontaneously active DA cells in the A10 region. These results suggest a modulatory role for CCK-A receptors on DA cell activity. Ongoing experiments continue to test this possibility. (Supported by MH42136 [ASF], MH41557 [LAC] and Sinai Res. Inst.; MDK is a Tourette Syndrome Association Fellow.)

THE EFFECTS OF THE PHENCYCLIDINE ANALOGUES BTCP AND TCP ON NIGROSTRIATAL DOPAMINE NEURONAL ACTIVITY. C. Rouillard, L.A. Chiodo and A.S. Freeman. Lab. of Neurophysiology, Center for Cell Biology, Sinai Research Institute and the Cell. & Clin. Neurobiology Prog., Wayne State Univ., Detroit, MI 48235.

Extracellular single-unit recording techniques were used to evaluate the effects of two PCP derivatives, BTCP and TCP, on the electrophysiological activity of identified nigrostriatal dopamine (NSDA) neurons in anesthetized rats. Intravenous BTCP produced a dose-dependent decrease in the firing rate of NSDA neurons whereas TCP induced an activation of cell firing at low doses followed by a reversal of the response with larger doses. A hemitransection of the brain anterior to the substantia nigra significantly reduced the inhibitory effect of BTCP while this procedure did not affect the response to TCP. However, iontophoretic application of BTCP induced a current-dependent inhibition of NSDA cells while local application of TCP had no effect on the firing rate of these cells. These data indicate that PCP analogues are able to interact with the nigrostriatal DAergic pathway through distinct and opposing mechanisms. The results will be discussed in light of recent observations that BTCP is selective for the DA uptake site while TCP is selective for the high-affinity PCP binding site. Supported by MH42136 (ASF), MH41557 (LAC) and Sinai Res. Inst.; CR is a FRSQ postdoctoral fellow.

431.16

THE EFFECTS OF SIGMA LIGANDS ON THE FIRING RATE OF IDENTIFIED DOPAMINERGIC NEURONS. J. Zhang*, L.A. Chiodo and A.S. Freeman. Lab. of Neurophysiology, Center for Cell Biology, Sinai Research Institute and the Cell & Clin. Neurobiology Prog., Wayne State Univ., Detroit, MI 48235.

Extracellular single-unit recording techniques were used to examine the effects of ligands for the high-affinity sigma binding site on the electrophysiological activity of identified nigrostriatal (NS) and mesoaccumbens (MA) dopamine (DA) neurons in anesthetized rats. (+)-pentazocine (1-16 mg/kg, i.v.) produced either no effect or weak excitations of NSDA and MADA cells while DTG was without effect at doses up to 2 mg/kg. Higher doses of DTG resulted in respiratory depression and death. The putative sigma antagonist, BMY 14802, dose-dependently (0.25-8 mg/kg) increased NSDA cell firing rate. Although (+)-3-PPP has higher affinity for the sigma site compared to DA receptors, this compound is known to exert many effects typical of a DA agonist. In contrast to the other sigma ligands, (+)-3-PPP (0.04-0.64 mg/kg) inhibited NSDA cell firing rate in a dose-dependent manner. Preliminary data suggest that (+)- but not (-)-butaclamol can reverse this effect of (+)-3-PPP which implies that the sigma binding properties of (+)-3-PPP are not responsible for the inhibition. Thus, a coherent explanation of the relationship between sigma sites and DA cell physiology remains elusive. (Supported by MH 42136, MH 41557 and Sinai Research Institute.)

ELECTROPHYSIOLOGICAL STUDIES OF NIGROSTRIATAL DOPAMINE NEURON ONTOGENY. D.K. Pitts, A.S. Freeman and L.A. Chiodo. Lab. of Neurophysiology, Center for Cell Biology, Sinai Research Institute, and the Cellular and Clinical Neurobiology Program, Wayne State University School of Medicine, Detroit, Michigan 48235.

The ontogeny of nigrostriatal dopamine (NSDA) neurons was examined in chloral hydrate-anesthetized 2-week(WK)-old (n=44) and adult (AD; 8-10 WKS old, n=40) rats using standard extracellular recording techniques. NSDA neurons from 2WK-olds were found to have significantly lower basal discharge rates and conduction velocities and fewer cells exhibited a bursting pattern (2WK: 11.4%; AD: 42.5%) compared to adults. 2WK-olds were less sensitive than adults to the inhibitory effects of IV apomorphine on discharge rate. Neither midbrain/forebrain hemitransections nor SCH 23390 pretreatment eliminated the apomorphine response differences indicating a lack of involvement of forebrain DA D1 receptors. No significant differences between IV quinpirole dose-response curves were observed at these two ages suggesting similar DA D2 somatodendritic autoreceptor sensitivity. Iontophoretic studies comparing NSDA neuron sensitivity to apomorphine and quinpirole are currently underway.

RETROGRADELY LABELED DOPAMINERGIC NEURONS IN PRIMARY CULTURES FROM NEONATAL RATS. R. Shen, L. A. Chiodo and G. Kapatos. Labs. Neurophysiology and Neurochemistry, Ctr. Cell Bio., Sinai Res. Inst., and Cell. and Clin. Neurobiol. Prog., Wayne State Univ., Detroit, MI 48235.

We have developed a primary cell culture system for mesencephalic neurons from neonatal rats. Dopaminergic (DA) neurons in these cultures may be identified by fluorescent latex microspheres (FLMs) in the soma and dendritic processes. The fluorescent latex microspheres were bilaterally injected to the caudate nucleus in 1-day old rat pups. After two days, slices of mesencephalon were removed and the substantia nigra (SN) region was dissected out. The brain tissue was dissociated and numerous cells were found to contain FLMs. Cells were plated on an astrocyte feeder layer prepared from cortical tissues of 1-3-day old rat pups. Immunohistochemistry revealed that the neurons labeled with FLMs also showed positive tyrosine-hydroxylase (TH) histofluroscence both in the culture as well as in thin tissue sections containing the SN. We found that the majority of TH-positive neurons in the SN were labeled by the microspheres 28 hours after the injection. These neurons have either fusiform or multipolar cell bodies and long processes with varicosities.

Thus, this culture system allows for the study of the molecular biology of identified nigrostriatal DA neurons using a variety of techniques.

LINEAR MODE STRUCTURE OF SUBSTANTIA NIGRA (SN) DOPAMINERGIC (DA) NEURONAL ACTIVITY. J.H. Carlson, M.P. Paulus and S.L. Foote. UCSD Dept. Psychiatry (M-003), La Jolla, CA 92093.

We have described a significant tendency for interspike intervals (ISIs) of SN DA neurons to oscillate between short and long ISIs. To test the hypothesis that there is a cyclical, rate-independent structure in DA neuronal discharge patterns, a linear mode analysis was conducted using the Fast Fourier Transform (FFT) of the ISIs. The data were normalized with respect to the mean before calculating the FFT. The FFT for each data set of 500 ISIs was obtained multiple times by dividing the data into segments of 128 ISIs, repeatedly computing the FFT, and shifting the data segment using a lag of 64, to reduce the variance of the resulting peaks in the power spectrum. Data were shuffled 100 times and a power spectrum was obtained for each shuffled data set. A *significant cyclical component* (SCC) was defined as any cycle in the power spectrum of the original data set that exceeded the power of that cycle from the shuffled data $\geq$95 times. In most neurons, SCCs agreed with our previous description of short-long oscillations, i.e. the power spectrum revealed significant 2-3 cycles. However, additional SCCs indicated longer cycle lengths and greater variety in the structure of discharge patterns among DA neurons. After local infusion of nicotine, a reduction, a preservation or an increase in the mode structure were found, depending on the SCCs in the baseline condition. Thus, the variation in ISI sequences of SN DA neurons is not "random" but contains SCCs.

431.20

LOCALLY PERFUSED MORPHINE INHIBITS STRIATAL DA RELEASE: REVERSAL BY SYSTEMIC MORPHINE. Z.L. Rossetti, S. Carboni, F. Melis, N.H. Neff* and G.L. Gessa, Dept. of Neuroscience, University of Cagliari, Italy and *Dept. of Pharmacology, Ohio State University, Columbus OH, U.S.A.

The systemic administration of morphine to rats activates DA cell firing activity. The activation of DA neurons induces the release of the neurotransmitter in the terminal areas. Accordingly, by using the brain dialysis technique, we measured elevated (ca 200% of baseline) DA concentrations in perfusates from rat ventral striata following systemic morphine (10 mg/kg s.c.). However, when we perfused morphine into the caudate of the awake rat through the dialysis fibre, a concentration dependent (1-100 μM) inhibition of DA release (to 60-30% of baseline) was produced. This effect was antagonized by systemic naloxone (2 mg/kg i.p.). When striatal DA release was inhibited by *locally perfused* morphine, *systemic* administration of morphine (10 mg/kg s.c.) reverted the inhibitory effect, DA release being stimulated to about 200% of baseline. Conversely, when naloxone (0.1 μM) was perfused locally through the striatum, and morphine was administered systemically, DA release was markedly stimulated (over 400% of baseline). Naloxone did not affect *per se* DA release. Thus, systemic morphine and locally perfused morphine affect DA release in opposite directions and these effects are mediated by opiate receptors. These results suggest that morphine has antithetic effects on DA transmission: an inhibitory action in the terminal area, and a stimulatory one in the somato-dendritic region. It is possible that an unbalance between these two actions may explain the paradoxical effects of opiates on DA system observed in opiate tolerance and dependence.

DOSE DEPENDENT EFFECTS OF HALOPERIDOL ON STIMULATED DOPAMINE RELEASE IN THE STRIATUM *IN VIVO*. T.A. Patterson and J. O. Schenk. Program in Biochemistry and Dept. of Chemistry, Washington State University, Pullman, WA 99164-4630.

In vitro studies testing the effects of haloperidol (HAL) on stimulated DA release have resulted in different effects. HAL has been found to both increase and decrease the amount of stimulated dopamine (DA) released from rat striatum depending on the dose used. This led to an interest in whether HAL could have dose dependent effects on DA release *in vivo*.

In vivo voltametry at 30 um carbon fiber electrodes, was used to obtain a dose response curve for the effect of HAL on stimulated DA release. The electrode, with a syringe glued 1 mm away, was implanted into the striatum of a chloral hydrate anaesthetized rat. A control stimulus was elicited with a 20 nanomole injection of K^+ through the syringe. An ip injection of HAL was then given and the electrode assembly moved to the contralateral striatum. One hour later, a second K^+ stimulus was given. It was found that at low doses, ($\leq$ 0.05 mg/kg) there was no change in DA release, at medium doses (0.25 - 0.50 mg/kg) there was an increase in DA release, and at high doses (5.0 mg/kg) release was slightly decreased relative to control stimulus magnitudes. Correlations between these results, tissue [HAL] *in vivo*, behavioral measures and *in vitro* studies will be presented. (Support by NIMH Grant 42759 and the state of Washington).

432.2

AMPHETAMINE EXERTS ANOMALOUS EFFECTS ON DOPAMINERGIC NEURONS IN NEONATAL RATS F. Trent, S. Nakamura, and J.M. Tepper, Department of Biological Sciences and Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ, 07102.

Amphetamine (AMP) and related stimulants increase arousal and locomotor activity in adults of many species. These drugs also suppress the spontaneous activity of nigrostriatal dopaminergic (NSDA) neurons. In hyperkinetic children however, stimulants exert a paradoxical behavioral effect, ameliorating hyperkinesis and increasing attention span. In this abstract, we describe the effects of AMP on the neuronal activity of NSDA neurons in neonatal rat pups ranging in age from the day of birth (PD1) through PD28.

Extracellular recordings from antidromically identified spontaneously active NSDA neurons were obtained in urethane-anesthetized (1.3 mg/g, i.p.) Sprague-Dawley rat pups. After obtaining a stable baseline, 5 mg/kg AMP was administered i.p. The effects of AMP were analyzed at 5 minutes post-injection. In PD1-6 rat pups, AMP produced a significant *increase* in spontaneous firing rate (mean $\pm$SEM = +183.6$\pm$84.9%, n=5, p< .001). In PD7-15 pups, there was no change in the mean firing rate (-8.2$\pm$12.5%, n=3, p> .05). In PD16-28 pups, AMP exerted a significant inhibitory effect (-39.8$\pm$5.9%, n=8, p< .001). In three additional cases in PD1-6 rats, apomorphine (1 mg/kg, i.p.) caused a near complete inhibition of spontaneous firing (-99.0$\pm$1.0%, p<.001). The timing of the development of the inhibitory response to AMP coincided with that of the most marked postnatal changes in the cytoarchitecture of substantia nigra, as well as that of a transient shift in the firing pattern of NSDA neurons to a pacemaker-like mode and a transient decrease in the duration of post-stimulus inhibition evoked from neostriatum.

These data demonstrate paradoxical effects of AMP on NSDA neurons in early postnatal rats that may be related to its paradoxical behavioral effects in human children. This effect does not appear to be due to decreased autoreceptor function, but may be due to an altered ability of AMP to release DA from nigral dendrites, and/or an altered response to AMP in telencephalic terminal fields. The normal inhibitory response to AMP begins to develop at around two weeks of age following a period of structural and physiological reorganization of substantia nigra. ALTERATIONS IN STEREOTYPIC BEHAVIOR AND DOPAMINE RECEPTOR BINDING FOLLOWING CHRONIC ASCORBIC ACID-HALOPERIDOL TREATMENT. J.K. Rowlett[a], R.C. Pierce[b], M.T. Bardo[a], G.V. Rebec[b]. [a]Dept. Psychology, Univ. Kentucky, Lexington, KY 40506 and [b]Prog. Neural Science, Dept. Psychology, Indiana Univ., Bloomington, IN. 47405.

The present study assessed the effects of ascorbic acid (500 mg/kg, i.p. for 21 days), haloperidol (0.5 mg/kg, s.c. for 21 days) or ascorbic acid-haloperidol combination (500 mg/kg and 0.5 mg/kg, respectively, for 21 days) on apomorphine-elicited behaviors and D_2-dopamine receptor binding. Rats displayed significantly enhanced repetitive sniffing to apomorphine (0.5 mg/kg, s.c. 5 days after last chronic injection) after chronic ascorbic acid-alone and chronic haloperidol-alone treatments when compared to chronic vehicle. Chronic ascorbic acid-haloperidol treatment resulted in a repetitive sniffing response to apomorphine that was of greater magnitude than either chronic ascorbic acid-alone or haloperidol-alone treatment. As expected, [^{3}H]spiperone saturation studies on striatal tissue revealed an up-regulation of D_2-dopamine receptors in rats treated with haloperidol. However, no effect of ascorbic acid treatment was found on D_2 receptor density, suggesting that chronic ascorbic acid produces behavioral supersensitivity to apomorphine through mechanisms different from chronic haloperidol treatment.

Supported by NSF (BNS 87-11240).

ACUTE AND CHRONIC HALOPERIDOL INCREASE STIMULATED DOPAMINE RELEASE IN THE RAT CAUDATE NUCLEUS. D. J. Wiedemann, and R. M. Wightman. Dept. of Chemistry, Univ. of N. Carolina, Chapel Hill, NC 27599-3290.

In vivo voltammetry with Nafion-coated, carbon-fiber electrodes was used to measure dopamine (DA) overflow in the caudate nucleus of anesthetized rats. Overflow was elicited by electrical stimulation of the medial forebrain bundle with bipolar electrodes (300 μA, 120 pulses) with frequencies of 10 to 60 Hz. Acute haloperidol (0.5 mg kg^{-1}) caused DA overflow to increase at each frequency, with a maximum effect at 30 Hz of a two-fold increase. Following chronic haloperidol administration (0.5 mg kg^{-1} for 30 days), DA overflow was also increased relative to drug naive animals at all frequencies tested. The greatest increase, nearly 7-fold, occurred at 30 Hz. When the chronically treated animals were challenged with haloperidol, stimulated overflow was unchanged. In contrast, animals which were withdrawn from the drug for two weeks after chronic treatment were responsive to acute challenges of haloperidol in a manner similar to the acute animals. Thus, chronic haloperidol treatment leads to an increase in the amount of dopamine available for release, an effect that is reversible after drug withdrawal.

METHYLPHENIDATE AND PEMOLINE INHIBIT THE FIRING RATE OF RAT SUBSTANTIA NIGRA DOPAMINE NEURONS. A. Shenker*, D.A. Bergstrom and J.R. Walters. NIGMS, NINDS, NIH, Bethesda, MD 20892.

The stimulants *d*-amphetamine (AMP), methylphenidate hydrochloride (MPH) and pemoline (PEM) are the drugs most commonly used to treat Attention Deficit Hyperactivity Disorder (ADHD) in children. Efficacy of these drugs is thought to involve indirect agonism at brain dopamine (DA) receptors. Although the inhibitory effect of AMP on substantia nigra pars compacta DA neuron firing is well described (ED_{50} = 1 mg/kg), comparable studies of MPH and PEM have not been conducted.

Extracellular single unit recording of DA cell activity was performed in chloral hydrate anesthetized rats. MPH caused a dose-dependent inhibition of DA cell firing rate (ED_{50} = 1.3 ± 0.1 mg/kg i.v., n=10). Whereas AMP routinely produces 100% inhibition, maximal inhibition by MPH averaged 82 ± 10%, with only 3/10 cells totally inhibited. Inhibition by MPH was reversed by haloperidol (50 µg/kg i.v.). Pretreatment with reserpine (7.5 mg/kg i.p., 24 hrs), which depletes vesicular DA and blocks the behavioral effects of MPH, attenuated by 60% the inhibitory effect of 2.5 mg/kg MPH (n=4). PEM was much less potent than MPH. PEM (i.v., dissolved in 45% hydroxypropyl-β-cyclodextrin) caused no inhibition of firing at 5 mg/kg (n=8) and 36 ± 9% inhibition at 25 mg/kg (n=5). These results show that 3 drugs with therapeutic efficacy in ADHD share the ability to inhibit DA cell activity. Their relative potencies (AMP~MPH>PEM) parallel their known potencies as indirect DA agonists. The weak effect of PEM suggests that its clinical potency may not be due to dopaminergic actions alone.

THE D-1 AGONIST SKF 38393 SIGNIFICANTLY INHIBITS SUBSTANTIA NIGRA PARS COMPACTA DOPAMINE CELL ACTIVITY FOLLOWING RESERPINE TREATMENT. K.-X. Huang, D. A. Bergstrom, G.-Z. Jin* and J.R. Walters. NINDS, Bethesda, MD 20892 and Shanghai Inst. Materia Medica, Shanghai, China.

It is generally agreed that substantia nigra (SN) pars compacta dopamine (DA) neurons do not have D-1 receptors on their cell bodies. Thus, previous studies indicating that the D-1 antagonist SCH 23390 excites a subpopulation of these cells when administered to locally (but not systemically) anesthetized rats support the existence of a "long loop" feedback regulating DA cell activity and modulated by tonically stimulated postsynaptic D-1 receptors. To further explore the circuitry involved in this feedback and the functional expression of D-1 receptors, effects of the D-1 agonist, SKF 38393 were examined in rats treated for 6-8 days with 1 mg/kg reserpine, s.c. In control, locally anesthetized, artifically respired, gallamine-treated rats, 10 mg/kg i.v. SKF 38393 (n=5) exerted no significant effect on DA cell firing rate. However, in reserpine treated rats, the D-1 agonist dramatically inhibited DA cell activity by 69±12% (n=6). DA cell firing slowed gradually over the first 6 min after injection and remained suppressed for at least 30 min. This inhibition was reversed by SCH 23390, but not by haloperidol. Some effects were noted 3-7 hours after a single reserpine injection; 3 of 6 cells were markedly inhibited (ave. inhibition: 36 ± 19%, n=6). The time course and response of the DA cells to SKF 38393 in the 6-8 day reserpinized rats closely resemble the response of SN pars reticulata cells to SKF 38393 in 6-hydroxydopamine DA cell-lesioned rats (Weick and Walters, 1987) suggesting that both SN cell populations are similarly affected by pathway(s) influenced by supersensitive D-1 receptors.

RECOVERY OF DIURNAL LOCOMOTORY ACTIVITY AFTER MPTP CORRELATES WITH INCREASED CATECHOLAMINE SYNTHESIS BY SURVIVING NEURONS. N.A. Seniuk, C.E. Greenwood and W.G. Tatton. Depts. Physiology and Nutr.Sci., Univ. Toronto, Toronto, Ontario. M5S 1A8.

To determine how the loss of substantia nigra compacta (SNc) neurons and reductions in striatal dopamine (DA) (Seniuk et al., Br. Res., In Press,1990) relate to a quantitative measure of motor performance, the locomotory movements of 5 week old C57Bl mice were continuously monitored for 104 days following a 20 day entrainment period to a 12:12 hour light:dark (LD) cycle. Control locomotory activity was recorded for 14 days during LD and then dark:dark (DD) conditions. The mice were then injected with saline or MPTP (37.5,75,150,300 mg/kg) over a period of 5 days and their activity was followed for a further 90 days (d5-d95). Hourly activity counts for periods of120 hours were used for Fourier analysis. For the control activity, major power peaks extended from 21-25 hours/cycle (h/c- centered at 24 h/c for LD conditions and 23.85 h/c for DD conditions) with smaller, secondary peaks at 75 h/c and125 h/c. The area under the 21-25 h/c power peaks was unchanged relative to controls for d5-d10 for saline, 37.5 and 75 mg/kg MPTP animals while 150 and 300 mg/kg animals were reduced to 30-60% of control. The power for the 21-25 h/c peak gradually recovered to control over d10-d20 and remained at control levels to d95. Measurement of tyrosine hydroxylase (TH) immunodensity in the SNc neuronal somata and DOPAC/DA ratios in the striatum at corresponding days after saline or MPTP treatment showed that reduced TH immunodensity and DOPAC/DA ratios per average neuron correlated to the reduced power of the 21-25 h/c peaks over d5-d20. Recovery of the peak power to control levels corresponded to increased TH immunodensity in surviving SNc neurons (mean of 160% of control somata values) and increased DOPAC/DA ratios per average surviving neuron (mean of 360% of control). We propose that behavioral recovery following MPTP exposure is in part due to compensatory increases in catecholamine synthesis by surviving neurons.(Parkinson Foundation of Canada and MRC Canada MT5218.)

EVALUATION OF THE EFFECTS OF SIGMA BINDING LIGANDS ON NIGROSTRIATAL DOPAMINERGIC FUNCTION. L.T. Meltzer, C.L. Christoffersen, K.A. Serpa and T.G. Heffner, Department of Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

The identification of haloperidol (HPD) sensitive sigma binding sites and the suggestions of their involvement in antipsychotic drug action have stimulated interest in the effects of selective sigma ligands on brain dopamine (DA) systems. The present studies assessed the ability of sigma ligands to alter the firing activity of A9 DA neurons recorded extracellularly in anesthetized rats and to elicit extrapyramidal side effects (EPS) in monkeys that are sensitized to the acute dystonic effects of HPD. The selective sigma ligands DTG (2.0 mg/kg i.v.) and (+)-pentazocine (16 mg/kg i.v.) produced a 10% decrease and a 20% increase, respectively, in DA neuron firing. In contrast, BMY 14802 (6.4 mg/kg i.v.), a compound which has weaker affinity for sigma binding sites than DTG or (+)-pentazocine, increased DA neuron activity by 52%. This effect of BMY 14802 may be due to its greater affinity for 5-HT1A receptors than DTG and (+)-pentazocine. (+)-Pentazocine (5-10 mg/kg s.c.) did not induce EPS in HPD-sensitized monkeys. These studies do not reveal a consistent influence of sigma ligands on nigrostriatal DA function.

EFFECTS OF DOPAMINE AUTORECEPTOR AGONISTS ON DOPAMINE AND ITS METABOLITES AS MEASURED BY MICRODIALYSIS IN THE PRIMATE CAUDATE PUTAMEN. L.W. Cooke, F.W. Ninteman*, T.G. Heffner and M.D. Davis. Department of Pharmacology, Parke- Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

Dopamine (DA) autoreceptor agonists are being explored as possible drugs for the treatment of schizophrenia. Although intracerebral microdialysis (ICMD) is employed increasingly for the measurement of DA and DA metabolites in rats, it has been used less frequently in primates. We have developed techniques for ICMD in the caudate putamen of squirrel monkeys. Bilateral chronically-implanted guide cannulae were used to permit repeated acute implants of dialysis probes into the putamen of awake chaired monkeys. Several DA autoreceptor agonists, including B-HT 920 and PD 128483, decreased the levels of DA in putamen dialysates. Certain of these neurochemical effects were comparable in magnitude and duration to behavioral effects observed in a conditioned avoidance test in the same species. Repeated ICMD measurements at a single site in the same animal over a period of months revealed no appreciable decrement in basal dialysate DA levels or in measured drug response. These studies indicate that DA autoreceptor agonists can produce inhibition of DA release from central neurons in primates and demonstrate that ICMD can be employed to quantify the actions of such drugs in primates in vivo.

STRIATAL INFUSION OF SEROTONIN (5HT), TFMPP, OR m-CPP FACILITATE DOPAMINE RELEASE IN-VIVO. S. Benloucif, M.J. Keegan*, and M.P. Galloway, Lafayette Clinic, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State Univ. School of Medicine, Detroit, MI 48207.

We reported previously that striatal infusion of the 5HT-1 agonists TFMPP, RU24969, or 8-OHDPAT increased extracellular DA in-vivo when measured with microdialysis. Recent work has focused on the mechanism associated with the putative facilitation of DA release by 5HT. Agents were dissolved in artificial CSF and infused into the anterior lateral striatum of chloral hydrate anesthetized rats via the microdialysis probe. Drug-induced changes in levels of dopamine (DA) and metabolites from both striata were monitored by HPLC-EC. In addition to the facilitation afforded by TFMPP and RU24969, extracellular DA increased 3 - 10 fold with infusion of 5HT (10 µM, n = 6) and the major metabolite of trazadone, m-CPP (100 µM, n = 4). TFMPP (1 mM) did not alter the S2/S1 ratio of DA release from two K^+ pulses (100 mM in the perfusate) suggesting that facilitation occurs only with release induced by Na^+ dependent neuronal depolarization. Consistent with this interpretation, TTX (1 µM) decreased the effect of 5HT on DA release by 60% (n = 3). TFMPP's facilitation of DA release was not reduced by the 5HT reuptake inhibitor sertraline (10 µM), indicating that TFMPP does not act via the 5HT transporter (n = 4). Increasing extracellular DA with nomifensine decreased the effect of 5HT, suggesting that either DA autoreceptor stimulation by endogenous DA or inhibition of DA reuptake blocked the facilitation by 5HT. 432.11

PREVENTION OF 6-OHDA-INDUCED STRIATAL DOPAMINE (DA) RECEPTOR SUPERSENSITIVITY BY DAILY INJECTIONS OF A D1 RECEPTOR AGONIST X.-T. Hu and F.J. White. Dept. Psychiat., Wayne St. Univ. Sch. Med., Lafayette Clinic, Detroit, MI 48207

Behavioral and electrophysiological studies were conducted to determine the extent to which D1 receptor supersensitivity is involved in apomorphine (APO)-induced contralateral turning and the supersensitive responses of caudate-putamen (CPu) neurons in rats with unilateral 6-OHDA lesions of the nigrostriatal DA system. APO (2mg/kg, sc) induced strong contralateral turning 7 days after injection of 6-OHDA (not vehicle) into the CPu. However, the turning responses to APO were almost completely abolished by a daily repeated treatment with the selective D1 agonist SKF-38393 (SKF)(8mg/kg, s.c. for 6 days). Single-unit recordings indicated that, although the inhibitory responses of CPu neurons to iontophoretic SKF and the selective D2 agonist quinpirole were both significantly enhanced in 6-OHDA (not sham)-lesioned rats, daily treatment with SKF effectively prevented the supersensitive responses of CPu neurons to both D1 and D2 agonists. In addition, while 6-OHDA lesions typically abolish the synergistic interaction between D1 and D2 receptors, such interactions were still present in 6-OHDA rats that received daily SKF injections. These findings indicate that the D1 receptor plays a critical role in the development of denervation supersensitivity and in the coupling of D1 and D2 receptor-mediated responses (Supported by APDA, USPHS Grants DA-04093 and MH-40832 to FJW).

432.12

FACTORS CONTROLLING THE STIMULATED OVERFLOW OF STRIATAL DOPAMINE MEASURED BY IN VIVO MICRODIALYSIS. D.H. Schwartz, I. Creese, and J. M. Tepper, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Impulse dependent dopamine (DA) release from nerve terminals is considered to be frequency and calcium dependent. Techniques to directly monitor basal and physiologically relevant stimulation-induced extracellular DA *in vivo* have only recently become available. The effects of medial forebrain bundle (MFB) stimulation on striatal DA overflow was examined using *in vivo* microdialysis in urethane anesthetized (1.3 g/kg) rats. A concentric microdialysis probe (0.25 x 4 mm) was inserted into the lateral portion of the neostriatum and a bipolar stimulating electrode was lowered into the MFB. In addition, single unit recordings were obtained from nigrostriatal DAergic neurons. A stimulating electrode coupled to the dialysis probe was used to antidromically identify DA neurons. Cells were then tested for antidromicity from the MFB to demonstrate that MFB stimulation was effectively eliciting action potentials in DA axons. Following the recording session, trains of 5 or 10 pulses (250 -500 µsec; 0.5 - 4 mA) were delivered to the MFB every 1.5 sec at varying frequencies (3.33 - 100 Hz) for 12 minute dialysis samples preceded by 1 or 2 12 minute non-stimulated baseline samples.

When the perfusate contained 1.2 mM calcium, even intense, high frequency stimulation (i.e. 10 pulses at 4 mA; 25-100 Hz) produced only small and non-significant elevations in extracellular DA despite the fact that amphetamine (0.5 mg/kg i.v.) and cocaine (5 mg/kg i. v.) produced dramatic increases. Addition of nomifensine to the perfusate did not significantly enhance stimulation-induced increases at this calcium concentration. In contrast, when the perfusate contained 2.4 mM calcium, there were significantly larger stimulation-induced increases in DA overflow in the absence of uptake blockade even at modest stimulus intensities and frequencies (5 or 10 pulses at 0.5 -1.5 mA; 3.33 - 12.5 Hz) ($F(1,13) = 26.95$; $p < 0.0003$). There was a significant correlation between the proportion of DAergic neurons that could be antidromically driven from the MFB and the increase in DA overflow induced by MFB stimulation across animals ($r = .823$; $df = 7$; $p < .007$). Surprisingly, MFB-stimulated DA overflow was not frequency dependent under these conditions. These data provide good evidence that *in vivo* microdialysis is sensitive to stimulation-induced increases in striatal DA overflow and that calcium concentration is a critical factor in its detection. Supported by MH-45286 and a Rutgers University Council Grant (JMT) and MH-32990 and DA-04612 (IC).

432.13

EFFECT OF 3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA) ON CATECHOLAMINES IN FEMALE RAT CAUDATE AS MEASURED IN EXTRACELLULAR MICRODIALYSATE AND TISSUE HOMOGENATE. B. Gough, R.R. Holson, S.F. Ali and W. Slikker, Jr. Division of Reproductive and Developmental Toxicology, National Center for Toxicological Research, Jefferson, AR 72079.

Extracellular levels of dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC), 5-hydroxyindoleacetic acid (5HIAA), serotonin (5HT) and homovanillic acid (HVA) were assayed in the caudate of freely moving rats using microdialysis and high performance liquid chromatography with electrochemical detection (HPLC-EC). Dialysates were assayed at 20 minute intervals for 4 hours after an I.P. injection of MDMA (10 mg/kg). In a separate study, animals were injected I.P. with MDMA (10 mg/kg) and at 20, 60, 120 and 180 minutes after treatment, animals were sacrificed, whole brains removed and caudate homogenates prepared. MDMA elicited an amphetamine-like increase in DA release, followed by an increase in DA synthesis. DOPAC and HVA were both reduced in dialysate, while only DOPAC was reduced in homogenate. 5HT release was also increased, followed by a drop in caudate homogenate levels by 3 hours. It is concluded that the acute effect of MDMA on caudate is greater on the DA than on the 5HT system. DA extracellular content was 686% of control at 80 minutes; homogenate release was 122% at 120 minutes. 5HT extracellular release was 123% at 20 minutes, then decreased thereafter.

432.14

HETEROGENEITY OF MESOACCUMBENS DOPAMINE NEURONS. Stephen Rayport, David Sulzer and Wei-Xing Shi. Depts. Psychiatry, Anatomy & Cell Biology, and Ctr. Neurobiology & Behavior, Columbia Univ.; Dept. Neuropathology, Psychiatric Inst., New York City 10032.

Midbrain dopamine (DA) neurons are increasingly recognized to be heterogeneous. We examined the intrinsic properties of single, identified, post-natal mesolimbic DA cells, isolated from synaptic influences, in low density cultures. Cells were taken from the ventral tegmental area of week-old rats, a stage by which the midbrain DA system shows a fair degree of maturity. A subset of mesolimbic neurons were identified (Rayport *et al.*, 1988) by retrograde labelling from the ventrolateral n. accumbens; 86% were dopaminergic. Mesoaccumbens cells showed four distinctive shapes: in decreasing order, cells were elliptical with an eccentric nucleus, fusiform, pyramidal or spherical. 55% contained the cotransmitter cholecystokinin, while 0% showed neurotensin staining (*cf.* Studler *et al.*, 1988). Mean resting potential was -55 mV, R-in was 630 megΩ and τ was 26 msec. Cells did not fire spontaneously (at 32° C) and had no recurrent connections, but often showed rhythmic membrane oscillations with depolarization leading to pacemaker firing. Full-size spikes, often triggered by low threshold Ca^{2+} spikes, had overshoots of 43 mV and widths of 1.2 msec (peak to *1/e*), overlapping considerably with unlabelled cells, which were about 25% dopaminergic. 89% of cells showed hyperpolarizing afterpotentials (mean = -4.5 mV), 64% showed time-dependent anomalous rectification, 84% showed low-threshold Ca^{2+} spikes, and 74% fired only after a latency of 100-200 msec. 59% showed spike-accommodation to long depolarizing steps. Cells exhibited a variable response to DA-agonist application. While the concatenation of several electrophysiological characteristics in individual labelled cells may identify them as dopaminergic (compare 86% dopaminergic with per cent of labelled cells showing a given characteristic), even a highly selected group of midbrain DA neurons exhibits considerable variation.

432.15

PREFRONTAL CORTICAL MODULATION OF MIDBRAIN DOPAMINE CELL ACTIVITY. *J. Grenhoff +, L. Pawlowski +, M. Herrera-Marschitz + and T.H. Svensson. Department of Pharmacology, Karolinska Institute, Stockholm, Sweden.*

The prefrontal cortex and the mesolimbobortical dopamine (DA) system originating in the ventral tegmental area (VTA) in the midbrain appear to play important roles in goal-directed behavior. Anatomical studies have demonstrated connections between these areas in several species.

In order to evaluate the functional role of these connections, effects of lesions of the medial prefrontal cortex (MPC) on the electrical activity of VTA-DA neurons were studied in the chloral hydrate-anesthetized male albino rat. Rats received kainic acid (KA) injections bilaterally in the MPC. After 7 days' recovery VTA-DA cell activity was recorded extracellularly and compared to sham-lesioned and untreated rats. VTA-DA cell firing rate was significantly increased in the KA group and the firing was more regular.

Previously, we have observed regularization of VTA-DA cell firing induced by reversible cold inactivation of the prefrontal cortex. The present findings further support the notion of a functionally significant influence from the MPC on VTA-DA neurons.

432.16

THE INVOLVEMENT OF D1 AND D2 RECEPTOR SUBTYPES IN THE EFFECTS OF NICOTINE ON DOPAMINE SYNTHESIS IN THE NUCLEUS ACCUMBENS AND STRIATUM. I.L. Holt and T.C. Westfall. Dept. of Pharmacol. St. Louis Univ. Med Ctr. St. Louis, MO 63104.

We have previously observed that nicotine (NIC, 1mg/kg s.c.) increases dopamine (DA) synthesis and tissue levels in the rat nucleus accumbens (NAc) and decreases DA synthesis and tissue levels in the striatum. In the present studies we have examined the involvement of D1 and D2 receptor subtypes in the NIC effects using the D1 antagonist SKF-83566 and D2 antagonist sulperide (SUL). DA synthesis was evaluated by measuring DOPA accumulation following inhibition of DOPA decarboxylase with NSD-1015 (100 mg/kg i.p. for 30 min). Tissues were homogenized and DOPA and DA levels were assayed by HPLC-EC. In the NAc, SUL (30 mg/kg i.p.) alone increased DOPA accumulation and prevented the NIC induced increase in DOPA. SUL decreased DA tissue levels and NIC effects were also attenuated. SKF alone had no effects on DOPA and attenuated the NIC induced increase in synthesis; DA levels decreased with SKF and decreased further with SKF and NIC. SUL in the striatum increased DOPA, while NIC continued to suppress synthesis in the presence of SUL. Striatal DA decreased with SUL and further with NIC. SKF decreased DOPA and DA in the striatum and attenuated NIC effects; NIC did not decrease levels of DOPA or DA further after SKF administration. The effects of NIC on DA synthesis in the NAC appear to involve both D1 and D2 receptors, while the striatal NIC effects appear to involve only D1 activity. (Supported by DA 02668.)

ELECTROPHYSIOLOGICAL EFFECTS OF REPEATED EXPOSURE TO SELECTIVE D1 AND D2 DOPAMINE AGONISTS ON THE MESOACCUMBENS DOPAMINE SYSTEM. D.J. Henry and F.J. White. Neuropsychopharm. Lab, Dept. Psychiatry, CCN Program, Wayne St. Univ. Sch. Med., Lafayette Clinic, Detroit, MI 48207.

Behavioral studies have indicated that repeated administration of non-selective dopamine (DA) agonists can result in sensitization to DA-mediated behavior. We have recently demonstrated enhanced D1-mediated grooming behavior following repeated administration of the selective D1 agonist SKF 38393 (SKF). The present electrophysolgical study sought to determine whether repeated administration of D1 and D2 selective agonists alters the sensitivity of the mesoaccumbens DA system. Male rats were given twice daily injections of the selective D1 agonist SKF 38393 (8 mg/kg, i.p.) or the selective D2 agonist quinpirole (QUIN, 0.5 mg/kg, i.p.) for 14 days. Control rats received equivalent injections of vehicle (DI water) twice daily. All rats were tested 16-24 hrs after the final injection. Extracellular single-unit recording techniques were used to determine the sensitivity of A10 DA neurons to "autoreceptor-selective" doses of i.v. apomorphine (APO). Subsensitivity to the inhibitory effects of APO was observed in QUIN pretreated animals. Preliminary results suggest a slight increase in sensitivity to i.v. APO in SKF treated rats. Extracellular recording techniques were used in combination with iontophoresis to examine responses of nucleus accumbens (NAc) neurons from pretreated animals to directly applied SKF and QUIN. Significantly enhanced inhibitory responses of NAc neurons to SKF (but not QUIN) were observed in animals receiving repeated SKF injections. Preliminary results indicate decreased responses of NAc neurons to iontophoretic QUIN (but not SKF) in animals receiving repeated QUIN injections. Supported by MH 40832 and DA 04093 to FJW and the State of Michigan.

EFFECTS OF REPEATED MORPHINE TREATMENT ON THE SENSITIVITY OF DOPAMINE AUTORECEPTORS: ELECTROPHYSIOLOGICAL STUDIES. Michael Jeziorski and Francis J. White, Neuropsychopharmacology Lab, Lafayette Clinic, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State University School of Medicine, Detroit MI 48207.

When acutely administered at low doses, morphine and other opioid compounds elicit increases in locomotion in rats. Repeated administration of morphine produces an enhanced behavioral response; current evidence indicates that this behavioral sensitization may involve changes in the functioning of the mesoaccumbens (A10) dopamine (DA) system. Because impulse flow in A10 DA cells is regulated by somatodendritic DA autoreceptors, the following experiments were designed to investigate whether alterations in A10 DA autoreceptor sensitivity are associated with the modified responses to repeated morphine administration. The sensitivity of impulse-regulating somatodendritic DA autoreceptors was measured in chloral hydrate-anesthetized rats using single unit electrophysiological recording techniques. In rats pretreated with morphine on a schedule reported to induce behavioral sensitization (10 mg/kg/day for 14 days), the ability of systemic administration of the D2 DA receptor agonist quinpirole to inhibit DA cell firing via autoreceptor stimulation was not significantly different from the inhibition produced by quinpirole in control rats. A similar result was obtained with iontophoretic experiments, as locally applied DA produced a comparable degree of inhibition of A10 DA cell firing in control and morphine-treated rats. It appears, therefore, that sensitized responses to morphine are not associated with alterations in the sensitivity of somatodendritic DA autoreceptors on A10 DA cells. Subsequent experiments will examine the potential modulation of postsynaptic DA receptor sensitivity in response to repeated morphine. (Supported by USPHS grants DA-04093 and MH-40832 and by the State of Michigan.)

CONTINUOUS AND INTERMITTENT COCAINE TREATMENTS DECREASE SENSITIVITY OF THE A10 SOMATODENDRITIC DOPAMINE AUTORECEPTOR. J.M. Ackerman and F.J. White. Neuropsychopharmacol. Lab., Dept. Psychiat., CCN Program, Wayne St. Univ. Sch. Med., Lafayette Clinic, Detroit, MI 48207.

Repeated cocaine administration in animals results in behavioral sensitization to locomotor stimulation and stereotypy caused by cocaine. However, it is unclear whether an intermittent or continuous treatment regimen of cocaine administration will produce behavioral sensitization or tolerance, a factor that may be relevant to human cocaine abuse. The mesoaccumbens dopamine pathway projecting from dopamine neurons in the ventral tegmental area (A10) to the nucleus accumbens is involved in behavioral sensitization and cocaine reward. We have previously shown that repeated cocaine administration in rats by twice daily 10 mg/kg i.p. injection for fourteen days caused a subsensitivity of impulse-regulating somatodendritic autoreceptors on A10 dopamine neurons. The present study investigated whether subsensitivity of the somatodendritic autoreceptor would also occur following administration of an equivalent amount of cocaine over the same time period delivered continuously. Male rats received cocaine (20 mg/kg/day s.c.) continuously for fourteen days via osmotic minipumps. Within twenty-four hours of pump removal, single-unit recordings of A10 dopamine neurons were obtained *in vivo* under chloral hydrate anesthesia using standard extracellular recording techniques. The ability of the dopamine agonist apomorphine to inhibit basal firing of these dopamine cells was decreased, indicating the existence of autoreceptor subsensitivity. The concentration of apomorphine required to inhibit basal firing by 50% (ID_{50}) was increased to the same degree as in rats treated intermittently with i.p. injections. In rats tested after seven days of pump removal, the ability of apomorphine to inhibit cell firing had returned to control levels. The identical result was obtained following daily i.p. injections. The results suggest that continuous exposure to a low dose of cocaine can produce a decrease in autoreceptor sensitivity that is equal to that obtained with intermittent injections of a higher dose.

CONTRIBUTION OF DOPAMINERGIC INPUTS TO DOPAMINE AGONIST-INDUCED RESPONSES OF VENTRAL PALLIDAL NEURONS. R.J. Maslowski, D. An* and T.C. Napier, Dept. Pharmacol., Loyola Univ. Chicago, Stritch Sch. Med., Maywood, Il 60153.

Effects of acute and chronic removal of dopaminergic neurons on D1- and D2-mediated rate changes of ventral pallidal (VP) neurons in chloral hydrate anesthetized rats were examined. Activity increased in 68% of VP neurons tested with i.v. SKF38393 (SKF, D1 dopamine agonist), with E_{max} = 160% of baseline rates and ED_{50} = 1.1mg/kg[1]. In contrast, the D2 agonist, quinpirole (QUIN)-induced dose-dependent decreases in 58% of neurons tested (E_{max} = 60%, ED_{50} = 7.6ug/kg).

In the present studies, 150mg/kg i.v. of *gamma*-butyrolatone (GBL) was used to reversibly block dopaminergic neuronal transmission and cumulative doses of SKF (0.1-25.6mg/kg) were injected. Six of 21 neurons tested ceased firing after GBL administration and were omitted from further analysis. Of the remaining 15 neurons, 47% increased firing (E_{max} = 282%, ED_{50} = 2.2mg/kg). There was a twofold increase in E_{max} for the SKF-induced response in GBL-pretreated *versus* untreated rats. Studies evaluating the contributions of dopaminergic neurons for D2-induced changes in VP neuronal activity are in progress.

Dopamine agonist-mediated responses of VP neurons recorded 7 days after 6-hydroxydopamine-induced lesions of the medial forebrain bundle were similar in response distribution and magnitude for SKF and QUIN (E_{max} = 196%, ED_{50} = 0.8mg/kg; and E_{max} = 51%, ED_{50} = 5.4ug/kg, respectively) to those observed for the agonists alone. Thus, acute blockade of dopamine transmission increases the magnitude of the predominant response to SKF, but chronic blockade allows for recovery to the untreated level of responsiveness. CONTRIBUTION OF THE NUCLEUS ACCUMBENS TO VENTRAL PALLIDAL RESPONSES TO SYSTEMICALLY ADMINISTERED D1 AND D2 DOPAMINE AGONISTS. T.C. Napier. Dept. Pharmacol. Loyola Univ. Chicago, Stritch Sch. of Med., Maywood, Il. 60153.

Intra-nucleus accumbens (NA) injections of dopamine (DA), or SKF38393 (SKF, D1 agonist) followed by quinpirole (QUIN, D2 agonist), (but not either drug alone) is sufficient to increase ventral pallidal (VP) neuronal firing[1]. VP neurons are sensitive to i.v. administered SKF or QUIN[2] as well as microiontophoretic applications of dopamine[3]. These responses may be due to an activation of DA receptors located within the NA (i.v. drugs) or on terminals of projections from the NA (i.v. and iontophoretic drugs). The present experiment was designed to determine if the NA is necessary for dopaminergic influences on VP neurons.

Single VP neurons recorded in vivo from male Sprague Dawley rats anesthetized with chloral hydrate were tested for sensitivity to i.v. administration of SKF (3.2mg/kg) or QUIN (100ug/kg), and to these drugs following microinjections of procaine into the NA (40ug/2ul). In agreement with our previous work, SKF increased activity in 69% of 26 neurons tested, and QUIN suppressed firing in 57% of 28 neurons tested. Thirty- nine of 50 VP neurons tested demonstrated rate changes following intra-NA procaine injections. Of those neurons that responded to procaine (n=32), 60% increased firing after SKF injections. In contrast, rate suppression typical of QUIN treatments was observed only in 31% of 18 neurons sensitive to intra-NA procaine.

These data suggest that D1 receptor activation resulting in rate increases of VP neurons is independent of the NA. However, at least a portion of the D2 receptors involved with VP suppression may be located on NA neuronal elements. (Work supported by MH45180).

BASAL EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS OF THE RAT AND THE EFFECT OF PERFUSATE CALCIUM AS STUDIED BY IN VIVO MICRODIALYSIS. **L.H. Parsons, H.O. Pettit, J.B. Justice, Jr. Department of Chemistry, Emory University, Atlanta, GA 30322.**

In vivo studies have produced a wide range of estimated basal concentrations of dopamine (DA) in several brain regions. This study was designed to provide a more rigorous estimate of the extracellular concentration of DA in the N ACC. Stable levels of DA were measured using four different perfusate Ca^{+2} concentrations (0.0, 1.2, 2.4 and 3.6 mM Ca^{+2}) at four different perfusion flow rates (0.2, 0.6, 1.2 and 2.3 ul/min). Each animal was perfused at a given flow rate (n=3 for each group) with DA measurements obtained for each Ca^{+2} concentration. A two way analysis of variance indicated a significant difference between flow rates ($P<0.004$) and Ca^{+2} concentrations ($P<0.0001$) and that the degree of calcium-induced variation was dependent on flow rate ($P<0.01$). Following the method of Jacobson et al. (J. Neurosci. Meth. 15:263-268; 1985) these data were subjected to a non-linear least squares regression as a function of flow rate at each Ca^{+2} conentration. The intercepts of the curves (zero flow) yielded basal extracellular DA as a function of varying Ca^{+2} concentration independent of the dialysis probe sampling characteristics. A linear regression of these values provides a curve of basal DA as a function of dialysate Ca^{+2} concentration. At an extracellular Ca^{+2} concentration of 1.2 mM (Moghaddum and Bunney, J. Neurochem. 53:652-654; 1989) basal DA was found to be 4.8 nM in the N ACC. This curve also indicated that removing calcium from the perfusion medium resulted in a 81% decrease in basal perfusate DA levels, indicating that the DA sampled was of vesicular origin.

DIFFERENTIAL ACTIVATION OF POPULATIONS OF MESOAMYGDALOID DOPAMINE NEURONS BY CONDITIONED STRESS: ATTENUATION BY DIAZEPAM. M. Coco, J. Kilts* C. Kuhn, C. Kilts. Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, N.C. 27710

Populations of dopamine (DA) neurons in the rat brain may be selectively activated by stress. Attenuation of stress-induced activation of DA systems has been observed with acute diazepam (DZ) treatment, but has not been examined regarding conditioned stress. Also, a subset of mesoamygdaloid DA projections might be especially sensitive to the effects of mild stress such as conditioned stress and to attenuation by DZ.

We mapped the effect of conditioned stress on the concentration of homovanillic acid (HVA) in distinct amygdaloid nuclei and other areas and the effect of DZ (1 or 3 mg/kg) on the stress-induced response in drug-experienced subjects. The conditioned stress paradigm resulted in significant elevations in classical indices of stress, including serum corticosterone, prolactin and plasma epinephrine, which were attenuated by DZ. Conditioned stress-induced increases in the estimated activity of DA neurons were specific for particular mesoamygdaloid DA neurons. Conditioned stress-induced changes in the HVA concentration of amygdaloid nuclei were differentially antagonized by DZ. This suggests a preferential role for a subset of mesoamygdaloid DA projections in the response to psychological stress or in the coping response to stress. (Supported by NIMH MH-39967)

MODULATION OF MESOLIMBIC DOPAMINE OVERFLOW BY NEUROTENSIN FRAGMENTS APPLIED TO THE VTA OR NUCLEUS ACCUMBENS IN VIVO AND TO MESOACCUMBENS EXPLANTS IN VITRO. **M.D. Davis, L.W. Cooke and T.G. Heffner. Department of Pharmacology, Parke- Davis Pharmaceutical Research Division Warner-Lambert Co., Ann Arbor, MI 48105.**

Neurotensin (NT) is an endogenous tridecapeptide that has a broad range of physiological and behavioral actions. NT and its binding sites are associated with dopamine (DA) neuronal systems in brain and NT can produce certain antipsychotic-like effects. Intracerebral microdialysis was used to examine DA overflow from nucleus accumbens nerve terminals during the infusion of NT fragments into the VTA or nucleus accumbens (NA) of anesthetized rats through a second dialysis probe. VTA infusion of NT 1-13 and NT 8-13, but not NT 1-10 (0.1-10 uM) evoked increases of 25-120% in DA overflow measured in the NA. Similar effects on NA DA efflux were seen when these NT fragments were applied in the same concentrations to the cell body region of mesoaccumbens explant plugs maintained in vitro. NT 1-13 and 8-13 produced similar effects on NA DA overflow when infused directly into the NA but failed to increase DA efflux from mesoaccumbens explants when applied directly to NA nerve terminals in vitro. These results suggest that NT receptors in mesolimbic DA cell body regions can modulate DA release from NA nerve terminals both in vivo and in vitro but that direct effects of NT on DA terminals in the NA is less clear.

BEHAVIORAL PHARMACOLOGY: DOPAMINE AND HORMONES

HIGH-PROTEIN DIET MODULATES DOPAMINE-AND NON-DOPAMINE MEDIATED BEHAVIORS IN RATS. E.S. Onaivi, J.W. Brock, A. Hamdi, and C. Prasad. Neuroscience Lab, Pennington Biomed. Res. C., Baton Rouge, and Dept. of Med., LSUMC, New Orleans, LA 70808.

Consumption of foods with altered macronutrients is alleged to have profound effects on behavior in man. Using rats as model we have studied the effect of dietary protein on a number of behaviors. Three grps of rats were subjected to equicaloric diet: normal-(20%), low-(8%) and high- (50%) casein for 20 wks. The high-protein group was more responsive compared to normal and low-protein groups in sensorimotor function (8±1,16±3, 17± 2s latency respectively), negative geotaxis (6±2, 9±2, 9±1s latency respectively), locomotor activity (1599±105, 1390±121, 575±29 photocell counts/30 min., respectively), and nociception (7.4±0.9, 6.9±0.2, 4.5±0.5 seconds, respectively) tests. There was also reduced aversion in the elevated-plus maze test (39% increase in dwell-time and 89% increase in number of entries, $p<0.05$). Results suggest that high-protein diet may modulate dopamine and non-dopamine mediated behaviors. (Dept. of Army, grant # 1788G8023)

433.2

DIFFERENT RAPID JAW MOVEMENT (RJM) RESPONSE TO A D1 AGONIST IN RATS EXHIBITING AN INBORN DIFFERENCE IN SPONTANEOUS RJM. **H. Rosengarten*, J.W. Schweitzer*, R.J. Shoerman* and A.J. Friedhoff. Millhauser Laboratories, Dept. of Psychiatry, NYU School of Med., New York, NY 10016**

There is considerable variability in rats in the rate of spontaneous RJM and in sensitivity to the D1 agonist, SKF 38393. Sprague Dawley rats were selected on the basis of their level of RJM response to SKF 38393 (either below or above the median of their group), and classified as low or high RJM. These rats were inbred (high with high and low with low) through seven generations and the rate of spontaneous and SKF 38393 induced RJM was assessed as well as D1, D2 and S2 receptor density and dopamine (DA) and DA metabolite levels. The inbred high RJM group had significantly higher spontaneous and SKF 39393 induced RJM than the inbred low group. There were no differences in the biochemical measures except that the density of S2 receptors in the prefrontal cortex was higher in the low RJM group.

433.3

D-1 AGONIST (SKF 38393), BUT NOT A D-2 AGONIST, EXERTS A CHOLINERGICALLY-MEDIATED ANALEPTIC EFFECT IN PENTOBARBITAL-NARCOTIZED RABBITS. A. Horita and M.A. Carino, Univ. of Wash. Sch. of Med., Seattle, WA 98195.

In previous studies we demonstrated that a number of drugs and peptides produced analeptic activity in rats and rabbits by activating hippocampal and/or cortical cholinergic pathways. Among these was cocaine, a drug known to exert many of its effects via dopamine mechanisms. In order to determine whether dopamine might be involved in its analeptic effect, we investigated whether D-1 and/or D-2 agonists might produce a similar response. We found that the D-1 agonist, SKF 38393 (2-5 mg/kg iv) significantly shortened the duration of pentobarbital narcosis in rabbits. The D-2 agonist quinpirole (up to 2 mg/kg iv) was without effect. The analeptic effect of SKF 38393 (5 mg/kg) was blocked by atropine but not by methylatropine. The effect was also blocked by SCH 23390 (0.1 mg/kg) or raclopride (2 mg/kg), suggesting the need of both D-1 and D-2 receptor systems. These results indicate that D-1 receptor stimulation activates central cholinergic pathways involved in cholinergic arousal (analeptic) mechanisms, but also that an intact D-2 system is necessary for expression of the response. They also support our earlier finding that the cocaine-induced analeptic effect in pentobarbital-narcotized rabbits was mediated via a D-1 dopamine mechanism (supported by NIDA grant DA 4907).

433.4

D-1 BUT NOT D-2 DOPAMINE RECEPTOR STIMULATION ATTENUATES BEHAVIORAL SUPERSENSITIVITY INDUCED BY HALOPERIDOL. C. Marin and T.N. Chase. ETB, NINDS, NIH , Bethesda, MD 20892.

Chronic neuroleptic administration induces supersensitive behavioral response to dopamine (DA) agonists. This effect might reflect DA receptor proliferation due to long term pharmacologic blockade. Since chronic DA agonist exposure induces DA receptor down-regulation, we have examined whether selective D-1 or selective D-2 stimulation can reverse the neuroleptic-induced increase in apomorphine-induced stereotypy. Rats were treated with haloperidol (1 mg/kg, s.c.) for 21 days followed by 5 days of either the selective D-1 agonist SKF 38393 (10 mg/kg, i.p.), the selective D-2 agonist quinpirole (1 mg/kg, i.p.), a combination of both drugs at the same daily doses, or normal saline. Apomorphine-induced stereotypy (0.3 mg/kg, s.c.) was measured four days after cessation of the therapeutic regimens. SKF 38393 but not quinpirole attenuated stereotypies induced by haloperidol. This effect was potentiated with the simultaneous administration of both drugs. The results suggest that D-1 DA stimulation might have an important role in the attenuation of extrapyramidal side effects produced by chronic neuroleptic administration.

433.5

DOPAMINERGIC MODULATION OF PREDATORY ATTACK BEHAVIOR IN THE CAT. M.B. Shaikh, C.L. Lu, and A. Siegel. Dept. of Neurosciences, UMDNJ - New Jersey Medical School, Newark, New Jersey 07103.

Dopamine (DA) containing fibers are known to project to those regions of the limbic forebrain and brainstem which play a key role in the expression of quiet biting 'predatory' attack behavior (QBA) in the cat such as the lateral hypothalamus (LH) and periaqueductal gray. The present study provides evidence for the involvement of DA in the regulation of QBA. In five cats, QBA was elicited by electrical stimulation of LH utilizing monopolar electrodes. After stable baseline response latency values were established, the nonselective DA agonist, apomorphine [APO] (1.0, 1.4 and 1.8 mg/kg), was administered systemically and its effects upon QBA were identified. APO significantly facilitated QBA in a dose- and time-dependent manner. At the maximum dose level (1.8 mg/kg) APO infusion resulted in a 30% decrease in response latencies which lasted for 60 min postinjection. Systemic injections of the D2 receptor antagonist, spiperone (0.2, 0.4 and 0.8 mg/kg), (but not a D1 antagonist) suppressed QBA in a dose- and time- dependent manner. The facilitatory effects of APO (1.4 mg/kg) were completely blocked following pretreatment with spiperone (0.2 mg/kg) 10 min prior to APO injections. The results indicate that DA regulates QBA and that this effect is mediated through D2 receptors. **[Supported by NIH grant NS07941-20].**

DIFFERENTIAL EFFECTS OF SELECTIVE DOPAMINE AGONISTS AND ANTAGONISTS IN RANDOM AND INBRED MICE STRAINS. M. A. Libonati* and V. L. Coffin. Schering-Plough Research, Bloomfield, N.J. 07003

The effects of SKF 38393 (a selective D1 agonist) and SCH 23390 (a selective D1 antagonist) on grooming behavior were compared among a random-bred (CF-1) and three inbred-derived (A/J, DBA/2J, C57BL/ 6J) mice strains. In A/J mice, SKF 38393 enhanced grooming (3.0-30.0 mg/kg i.p.) while SCH 23390 had no effect over a 100-fold dose range (0.003-0.3 mg/kg i.p) except to decrease grooming at the highest dose tested (0.3 mg/kg i.p.). The other inbred strains, C57BL/6J and DBA/2J, showed relatively no effect from either SKF 38393 or SCH 23390 on grooming and the random-bred CF-1 strain showed enhanced grooming from both SKF 38393 (1.0-30.0 mg/kg i.p.) and SCH 23390 (0.003-0.3mg/kg i.p.). Subsequent studies with the inbred A/J strain mice showed stereospecificity for the enantiomers of SKF 38393 on grooming behavior. The (+)enantiomer increased the grooming response (10.0-30.0 mg/kg i.p.) and at higher doses the (-)enantiomer decreased grooming (60.0-100.0 mg/kg i.p.). Selective D2 agonists, LY 171555 and (+/-)PPHT HCl, produced large decreases in grooming in A/J mice, as did the mixed D1/D2 agonist apomorphine. Similarly, selective D1 and D2 antagonists decreased grooming in A/J strain mice. The selective D1 antagonist SCH 39166 reduced grooming at 0.1 &0.3 mg/kg i.p., while haloperidol, a selective D2 antagonist and the atypical dopamine antagonist clozapine attenuated grooming at higher doses (1.0-3.0 and 10.0-30.0 mg/kg i.p., respectively). These results demonstrate grooming behavior was selectively enhanced by D1 agonists in A/J strain mice; all other dopaminergic drugs produced decreases in grooming behavior. The findings suggest measurement of grooming response in A/J strain mice might be a useful model to predict selective D1 agonist activity in novel compounds.

433.7

BEHAVIORAL ANALYSIS OF D1 RECEPTOR ANTAGONISM: INTERACTION WITH D-AMPHETAMINE. M. Haney, J.W. Tidey, J.A. Vivian, K.A. Miczek. Dept. Psychology, Tufts Univ., Medford, MA 02155.

Dopamine's role in the behavioral properties of psychomotor stimulants has primarily been investigated with D2 receptor selective agents. We examined the intrinsic and pharmacological antagonistic role of the D1 receptor subtype in several salient behavioral patterns of male mice. Intruder-directed aggressive behavior, motor activity, and conditioned performance (multiple FI10 FR30 schedule) were concurrently assessed. Mice received SCH23390, a D1 antagonist, (0.01-0.3 mg/kg ip) in the presence of either saline or *d*-amphetamine (d-AMPH, 0.1-6.0 mg/kg ip). Conditioned performance was measured for 60 min post-injection. After ca. 22 min in the operant chamber, mice were returned to their home cage, where they exhibited aggressive behavior toward an intruder for ca. 5 min. Thereafter, the mice completed the remainder of the conditioning session. Each dose of SCH23390 decreased FR and FI response rates. Aggressive but not locomotor behavior was also decreased by D1 antagonism. The suppressive effects of SCH23390 on operant and aggressive responding were reversed with increasing doses of d-AMPH. At low d-AMPH doses, SCH23390 attenuated aggressive behavior. SCH23390 blocked the disruption of aggressive behavior by higher d-AMPH doses. The suppressive effects of higher d-AMPH doses on schedule-controlled behavior were not reversed by SCH23390. Therefore, D1 receptor antagonism exerts selective effects on the behavioral properties of psychomotor stimulant drugs. The intrinsic effects of SCH23390 suggest that the D1 receptor tonically modulates certain high rate behaviors.

D-1/D-2 DOPAMINE RECEPTORS INVOLVEMENT IN LOCOMOTOR RECOVERY OF RESERPINIZED MICE ELICITED BY FCE 23884.

M. Buonamici*, M.A. Cervini*, R. Maj*, A.C. Rossi, R. Roncucci* and R.G. Fariello R&D., Farmitalia Carlo Erba - Erbamont Group, CNS Dept, 20014 Nerviano, Italy

FCE 23884 is an ergoline compound with the unique characteristic of acting as an antidopaminergic agent in normal animals, turning, at the same doses into a strong dopamine (DA)-ergic agent in "denervated" animals. The compound proved to be mainly a D-1 agonist in the model of 6-OHDA lesioned rats. In mice FCE 23884, injected 18 h after reserpine, stimulated locomotor activity in a dose-dependent manner. Also the selective DA-ergic D-1 (SKF 38393) and D-2 (LY 171555) agonists restored locomotion in 18 h reserpinized mice in a dose-dependent manner, but to a lesser extent than FCE 23884.

It is well known that: 1) D-2 receptors are involved in the mechanisms of locomotion and rearing (Starr and Starr, Neuropharmacology, 25, N.5: 455, 1986); 2) this D-2 modulated-activity can be initiated by D-1 stimulation (Molloy and Waddington, Eur. J. Pharmac., 108: 305, 1985) and 3) behavioral stimulation is induced by separate DA-ergic D-1 and D-2 receptor sites in long-term reserpine treated rats (Arnt, Eur. J. Pharmac., 113: 79, 1985).

Interaction studies were performed to better understand FCE 23884 activity in 18 h reserpinized mice. Pretreatment with the D-1 antagonist SCH 23390 almost completely antagonized FCE 23884 (83%) and SKF 38393 (95%) activity, while it proved inactive on LY 171555 effect. Pretreatment with the D-2 antagonist L-sulpiride completely antagonized LY 171555 activity and largely antagonized both FCE 23884 (60%) and SKF 38393 (77%) effects. These results suggest that in this reserpine model: 1) both D-1 and D-2 DA-ergic agonists restore locomotor activity; 2) D-1 blockade does not influence the D-2 mediated locomotor activity; 3) D-2 blockade reduces the recovery of motility induced by putative selective D-1 agonists.

433.10

LOCOMOTOR EFFECTS OF SELECTIVE DOPAMINE AGONISTS ADMINISTERED INTO THE NUCLEUS ACCUMBENS. W. D. Essman[1], S. M. Nair*[2], P. McGonigle[2] and I. Lucki[1,2]. Depts. of Psychiatry[1] and Pharmacology[2], Univ. of Pennsylvania, Philadelphia, PA, 19104.

Both synergistic and opposing functional effects have been described between the dopamine D1 and D2 receptors. Neurophysiological and biochemical investigations of these interactions have focused on the actions of dopaminergic compounds in discrete brain regions, whereas most behavioral interaction studies have involved peripheral administration of D1 and D2 agonists and antagonists. The present experiments measured the locomotor activity engendered by selective D1 and D2 agonists administered into one of the major DA projection areas, the nucleus accumbens (Acb). The interaction between these receptor types in producing a behavioral effect mediated through a specific brain region was examined.

Male Sprague-Dawley rats were stereotaxically implanted bilaterally with guide cannulae aimed at the Acb. After recovery, the effects of bilateral intra-accumbens microinjections of several doses of d-amphetamine, the D2 agonist quinpirole, or the D1 agonist SKF 38393 on locomotor activity were assessed in computer-assisted automated activity chambers.

Centrally administered d-amphetamine engendered a dose-dependent increase in locomotor activity. Quinpirole did not elicit locomotion at low doses, but did increase activity in some animals at high doses. SKF 38393 increased locomotor behavior at intermediate, but not high, doses. An increase in locomotion was observed following central administration of a low dose of quinpirole when the subjects were given a concurrent peripheral injection of SKF 38393. Coadministration of both quinpirole and SKF 38393 into the Acb elicited an increase in activity greater than either agonist alone. These data suggest that the actions of the DA receptor subtypes in the Acb act synergistically to engender locomotion.

433.11

THE EFFECT OF CLOZAPINE ON STIMULUS FILTERING / SELECTIVE ATTENTION IN RATS. L.A. Dunn, R.J. Scibilia, G. Schutrum*, C.D. Kilts. Dept. of Psychiatry, Duke Univ. Med. Ctr., Durham, NC 27710.

Latent inhibition (LI) of a conditioned response is a behavioral index of the stimulus filtering aspect of selective attention which is commonly observed to be defective in schizophrenia. LI is enhanced by anti-psychotic drugs and is attenuated by amphetamine treatment in rats. Clozapine is an atypical antipsychotic drug which does not cause extra-pyramidal symptoms or tardive dyskinesia. Clozapine is also atypical in its effects in various animal behavioral models of anti-psychotic drug action. We have evaluated the effect of clozapine on LI using an established paradigm (Christison et al., Biol. Psychiat., 23:746-749, 1988). The effect of clozapine (10 mg/kg, i.p., 7 days) on LI as a function of number (0, 10, 20, 40) of stimulus preexposures was examined. Unlike haloperidol, no effect of clozapine on LI was observed at any preexposure level. In an effort to approximate clinical dosing regimens, the effect of clozapine on LI was assessed at 0 and 20 preexposures using a t.i.d. dose of 5mg/kg (i.p.) administered for 7 days. Clozapine significantly decreased LI, an effect usually seen with amphetamine. These results suggest that the therapeutic effects of clozapine are mediated by unique actions relative to typical antipsychotic drugs. (Supported by the Scottish Rite Foundation)

433.12

PHARMACOLOGICAL ANALYSIS OF THE ENHANCED GROOMING RESPONSE ELICITED BY THE D1 DOPAMINE RECEPTOR AGONIST SKF 38393 IN THE RAT. R.J. Brooderson, S.R. Wachtel, and F.J. White. Depts. of Pharmacol. and Psychiat., CCN Program, Wayne State Univ. Sch. of Med. and Neuropsychopharmacol. Lab., Lafayette Clinic, Detroit, MI 48207.

The pharmacology of the enhanced grooming response elicited by dopamine (DA) agonists in rats was investigated. The amount of time spent grooming was measured continuously for 30 minutes following drug administration to provide a quantitative measure of the drug-induced behavior. The D1 DA agonist SKF 38393 dose dependently (0.5-16 mg/kg, s.c.) elicited an increase in the amount of time spent grooming. The SKF 38393-induced grooming demonstrated stereoselectivity for R-SKF 38393. Unlike SKF 38393 the peripheral D1 agonist fenoldopam (SKF 82526) failed to elicit a change in grooming. The SKF 38393-induced increase in grooming was attenuated by the D1 selective antagonist SCH 23390 (0.05 mg/kg, s.c.), in a competitive manner. The D2 selective antagonist eticlopride (0.05 mg/kg, s.c.) produced a noncompetitive blockade of SKF 38393-induced grooming. When eticlopride was coadminstered with the mixed D1/D2 agonist apomorphine, an increase in grooming behavior similar to the SKF 38393-induced effect was observed. Pretreatment with SCH 23390 (0.5 mg/kg), to protect the D1 receptor from inactivation by the irreversible receptor inactivator EEDQ (8 mg/kg, I.P.), prevented the attenuation of SKF 38393-induced grooming. However, in EEDQ pretreated rats without D2 receptor protection, eticlopride (0.2 mg/kg, s.c.) still prevented the SKF 38393-induced grooming response suggesting this effect may not be due to D2 dopamine receptor antagonism. These results demonstrate that excessive grooming elicited by dopamine agonists is a behavior specifically associated with central D1 DA receptor activation and is not mediated by D2 DA receptors. This research was supported by DA 04093, MH 40832 and by the State of Michigan.

THREE CHOICE DRUG DISCRIMINATION: FAILURE TO OBSERVE POST-HALOPERIDOL REBOUND. W. F. Caul, J. R. Jones, S. M. Murphy* and T. A. Schmidt*. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

Caul, Jones, and Barrett (1989) have reported that a single injection of 1 mg/kg haloperidol (HD) 23 hr prior to testing increased the percent of responses made on the amphetamine-appropriate lever and decreased the total number of responses made by rats previously trained to discriminate amphetamine (AM) from distilled water (DW). The experiment reported here was designed to evaluate the feasibility of using an appetitive three-choice drug-discrimination task with rats to further evaluate such rebound responding based, presumably, on a continuum of dopaminergic activity. Rats were trained to discriminate among .75 mg/kg AM, DW, and .02 mg/kg HD. On the 13th exposure to AM during training, the animals responded 84% on the AM lever, 9% on the DW lever and 7% on the HD lever. When given DW, they responded 7% on the AM lever, 67% on the DW lever, and 26% on the HD lever. The 13th exposure to HD produced 5% responding on the AM lever, 19% on the DW lever and 76% on the HD lever. Following the exact procedures used in our previous experiment with a two-lever task, responding was evaluated 23 hrs following an injection of either 1 mg/kg HD or DW. In contrast to the results of the two-lever study, there was no difference in percent amphetamine-lever responding between the two groups although total responding was reduced in the HD-injected group. By repeating the injection and test procedure on each of two additional days, extinction-induced changes in choice responding were observed.

DOPAMINE D1 AND D2 AGONISTS AND ANTAGONISTS PRODUCE TURNING WHEN INJECTED UNILATERALLY INTO THE NUCLEUS ACCUMBENS. C. MESSIER, O. MRABET* and C. DESTRADE. Psychophysiologie Lab., URA CNRS n°339, U. Bordeaux I, 33405 Talence, FRANCE.

We have previously shown that intra-accumbens microinjection of the non-specific DA agonist apomorphine and the non-specific DA antagonist haloperidol produced respectively contra- and ipsilateral turning (C.R. Acad. Sci. (Paris), **309** (III), 77-82, 1989). We have extended these findings by examining the effect on behavior of intra-accumbens injection of the specific D1 agonist SKF38393, the D2 agonist LY171555, the specific D1 antagonist SCH23390 and the D2 antagonist metoclopramide. Mice were implanted with a cannula in the nucleus accumbens (from bregma AP= +1.7 mm; L= 1.6 mm and 2.9 mm below the surface of the skull). Ten days later, mice were placed in glass bowls and the number and the direction (ipsi- or contralateral to the injection site) of complete rotations were recorded. SKF38393 (3.5 µg) did not produce any change in the direction of locomotion. LY171555 (10 µg) produced contralateral turning which was potentiated when SKF38393 (3.5 µg) was injected together with LY171555. SCH23390 (5 µg) and metoclopramide (30 µg) produced ipsilateral turning which was not as important as the ipsilateral turning produced by haloperidol (5 µg). These results suggest that dopaminergic receptors in the nucleus accumbens also contribute to the direction of locomotion and that D1 and D2 receptors may act synergistically to produce this effect.

433.15

LOCALIZATION OF BEHAVIORAL EFFECTS OF DOPAMINE AGONISTS WITHIN THE STRIATUM OF 6-OHDA LESIONED RATS. H. E. Criswell, D. C. Lado, G. E. Duncan, T.J. McCown, U. B. Schambra, G. R. R.A. Mueller, G.R. Breese. University of North Carolina, Chapel Hill, N.C. 27599-2750.

Rats, neonatally lesioned with 6-OHDA, were sensitized by repeated systemic administration of SKF-38393 (Criswell et al., Brain Res., in press). Subsequently, this D_1 agonist (3 ug) or a D_2 agonist (0.3 ug of Quinpirole) was micro-injected bilaterally into the ventrolateral, dorsolateral, ventromedial or central caudate nucleus. All rats showed an increased behavioral response when compared to either unlesioned or saline treated controls. Only microinjections into the ventrolateral caudate evoked paw licking or taffy pulling. Other behaviors were less site specific. The behavioral responses elicited by D_1 and D_2 agonists were similar. Thus, the site of the microinjection was more important in determining the type of behavior observed than was the receptor subtype activated. Density of D_1-receptors in the caudate was measured with ^{125}I-SCH23390 autoradiography and densitometry. D_1-receptor density was higher in the ventrolateral caudate than in the other quadrants. Supported by HD-03110, HD-23082, NS-21345.

A PRIMATE MODEL OF HUNTINGTON'S DISEASE: DOPAMINERGIC INVOLVEMENT IN DYSKINESIAS. O. Isacson, J.M. Schumacher, M.S. Fiandaca, P. Hantraye*, B.M. Madras, R.S. Spealman and E.D. Bird. Dept. Neurology and Neurosurgery, Harvard Med. Sch., McLean Hospital, Belmont MA 02178, Massachusetts General Hospital, Boston, MA, NERPRC, Division of Behavioral Biology, Harvard Med. Sch., U. Mass and SHJF, France.

Excitotoxic lesions of the caudate-putamen complex (CP) in non-human primates produce an animal model for symptoms and palliative treatments of Huntington's disease (HD). Following dopamine agonist administration animals with unilateral caudate-putamen lesions show abnormal movements including dystonia, oro-facial dyskinesia, head-dyskinesia, rotation and chorea-like movements. We have investigated abnormal movements following excitotoxic CP lesions (ibotenic-acid and quinolinic acid) in baboons and cynomolgus monkeys and the ability of various pharmacological agents acting on the dopaminergic system to elicit dyskinesias. Following administration of the D1/D2 dopamine receptor agonist apomorphine (1mg/kg i.m.) dyskinesias were elicited only in lesioned animals. Comparison of movements produced by apomorphine with the selective D2 receptor agonist PHNO (0.01-0.1mg/kg) demonstrated that both drugs resulted in increased locomotor activity. The type of movements elicited by PHNO was predominantely oro-facial and dose-dependent, while apomorphine at doses > 1mg/kg resulted in a wide spectrum of motor activity including chorea-like movements. The selective dopamine uptake inhibitor GBR 12909 (0.3-5.6 mg/kg) caused yet another pattern of locomotor hyperactivity of lesser magnitude.

Our results indicate the differential involvement of dopamine-receptor activation in dyskinesias produced by selective excitotoxic caudate-putamen lesions in the non-human primate with HD-like pathology.

CLOZAPINE EXHIBITS D1 DOPAMINE ANTAGONIST EFFECTS IN VIVO AS ASSESSED WITH [^{14}C]-2-DEOXYGLUCOSE AUTORADIOGRAPHY. Catherine A. Leslie (1) and Joel M. Trugman (2), Departments of Behavioral Medicine and Psychiatry (1) and Neurology (2), University of Virginia School of Medicine, Charlottesville, VA 22908.

[^{14}C]-2-Deoxyglucose (2-DG) autoradiographic studies of dopamine (DA) agonist-induced turning in rats with unilateral 6-hydroxydopamine lesions of the nigrostriatal pathway have shown that D1 agonists (SKF 38393) markedly increase regional cerebral glucose utilization (RCGU) in the substantia nigra pars reticulata (SNr) ipsilateral to the lesion whereas D2 agonists (LY 171555) do not. Furthermore, RCGU increases in the SNr induced by a mixed agonist (L-Dopa) are completely blocked by a selective D1 antagonist (SCH 23390) but only partially attenuated (by about 50%) by a selective D2 antagonist (eticlopride).

This suggests that the ability of a drug to block RCGU increases induced by L-Dopa can be used to assess D1 antagonist effects in vivo. We tested the effects of the "atypical" antipsychotic clozapine in this model. Rats with unilateral lesions were pretreated with clozapine (10 mg/kg) 30 minutes prior to the administration of L-Dopa (25 mg/kg) and [^{14}C]-2-DG. Compared to rats which received L-Dopa alone, clozapine pretreatment attenuated contralateral rotation and completely blocked RCGU increases in the SNr. The data demonstrate D1 antagonist effects of clozapine in vivo and suggest that the "atypical" neuroleptic profile of this drug may be mediated in part by D1 receptor antagonism.

433.18

RELATIONSHIP BETWEEN BEHAVIOURAL ACTIVATION AND ADENYLATE CYCLASE ACTIVITY INDUCED BY THE DOPAMINE D$_1$ RECEPTOR AGONISTS SK&F 80723, 83565 AND 83959. D.C. Rogers*, A.J. Hunter* and R.G. Hill. Smith-Kline Beecham Pharmaceuticals, The Frythe, Welwyn, Herts., U.K.

Previous studies with the partial agonist SK&F 38393 have suggested that stimulation of the D_1 receptor alone is not sufficient for the expression of dopamine-mediated behaviour, and that concomitant stimulation of both D_1 and D_2 receptor related mechanisms is necessary (White *et al*, *Pharmacol. Biochem. Behav.*, 30:189, 1988). The development of the novel D_1 receptor agonists SK&F 80723, SK&F 83565 and SK&F 83959 has enabled us to investigate whether the effects of SK&F 38393 are characteristic of all D_1 agonists.

Following habituation to the activity cages, rats were injected s.c. with either vehicle, 0.1mg/kg or 1.0mg/kg of SK&F 80723, 83565 or 83959. The locomotor activity (LMA) of the rats was recorded for 60 min. During this time, the behaviour of each animal was monitored for 1 min in each 5 min period. Adenylate cyclase activity was assessed with the determination of cAMP accumulation in rat striatum *in vitro*.

SK&F 80723 produced a significant increase in LMA [log.counts $F(2,21)=12.13$, $p<0.001$], displayed adenylate cyclase activity and had a significant effect on the duration of grooming behaviour [$F(2,21=3.90$, $p<0.05$]. SK&F 83565 and SK&F 83959 both induced significant increases in grooming [$F(2,21)=18.01$, $p<0.001$] and [$F(2,21)=7.97$, $p<0.01$] respectively, in the absence of significant increases in LMA or cyclase activity.

These results suggest that the characteristic D_1 activated grooming behaviour is not mediated via adenylate cyclase and that LMA may indeed be stimulated by D1 receptor activation alone.

433.19

RADIOPROTECTIVE EFFICACY OF 17β-ESTRADIOL IN MICE. M. Miernicki, H.D. Davis*, and M.R. Landauer*. Behavioral Sciences Department, Armed Forces Radiobiology Research Institute, Bethesda, MD 20814-5145.

Recent studies indicate that estradiol benzoate and other estrogen derivatives increase survival when administered to mice following exposure to γ radiation. This study was designed to determine the radioprotective efficacy and behavioral toxicity of 17β-estradiol (E2) when administered prior to irradiation.

Ten days before irradiation, gonadally intact male CD2F1 mice (N=16/group) were given a single IM injection of either E2 (0.16 mg/0.1 ml sesame oil), the sesame oil vehicle (OIL; 0.1 ml), or were not injected (CONT). On the day of irradiation, mice were exposed to 8.5 Gy 18 MVp Bremsstrahlung in 3.0 μsec pulses delivered at a dose rate of 1.0 Gy/min.

Significantly more E2 treated mice survived for 30 days (75%) than either OIL (50%) or CONT (25%) animals. In separate groups of identically treated, but nonirradiated mice, a single E2 injection resulted in decreased spontaneous locomotor activity within 3 hrs of administration. These results suggest that the radioprotective effect of E2 is accompanied by concurrent behavioral toxicity as measured by decrements in locomotor activity. We are presently investigating whether the radioprotection produced by estrogenic hormones can be maintained while attenuating the behavioral side-effects.

Determinants of Behavioral Effects of Corticotropin Releasing Hormone in the Rhesus Monkey J. R. Glowa Biopsychology Unit, CNE, NIMH, Bethesda, MD 20892,

Previous studies have determined the dose-effect and time course for the behavioral effects of corticotropin releasing hormone (CRH) on FR food-maintained responding in macaques. Doses of 0.03 - 10 ug/kg decrease responding, with the effects of lower doses requiring as much as an hr before manifestation, while those of higher doses occur within minutes. The current studies show: 1) repeated dosing with as little as 3 ug/kg results in a sustained effect on food maintained responding lasting well beyond the period of dosing; 2) responding maintained by the termination of stimuli associated with noxious stimuli is less sensitive to the rate-decreasing effects of CRH than is food-maintained responding, dose-effect functions in the same animals as those assessed for food lie to the right of the food-maintained dose-effect functions; and 3) the effects of CRH on food-maintained responding seem relatively unaffected by the familiarity of the context in which the macaques were dosed, dose-effect functions obtained in isolation chambers vary little from those obtained in the home cage. These results suggest that food-maintained responding serves as a reliable, yet sensitive baseline to assess the behavioral effects of CRH, and suggests treatment approaches should be directed at this end point.

433.21

ASSESSMENT OF DSIP ON SCHEDULE-CONTROLLED BEHAVIOR IN RATS. R.F. Genovese, X-C.M. Lu*, and D.L. Yourick, Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307.

Delta sleep-inducing peptide (DSIP) is a nonapeptide originally notable for its somnogenic properties. Subsequently, DSIP has been shown to have a variety of effects not typically associated with sleep, including naloxone-sensitive antinociception and attenuation of thermic and locomotor effects of amphetamine. We further investigated DSIP using a multiple fixed-ratio, fixed-interval schedule of reinforcement (FR 20, EXT 15", FI 2', EXT 15"). The schedule produced distinct rates and patterns of responding in all rats. Specifically, response rates in the FR > FI > EXTs. Additionally, quarter-life values in the FI component were typically > 60%. DSIP administered ICV (3.2-100.0 μg) (n=6) and SC (0.32-5.6 mg/kg) (n=6) failed to produce substantial effects on response rate or pattern in any of the schedule components at any dose, regardless of the route of administration. These results are surprising and further research is in progress to assess the effects of DSIP administered in combination with d-amphetamine.

434.1

MODULATORY EFFECTS OF CARBACHOL ON RAT VISUAL CORTICAL NEURONS IN VITRO. T. Murakoshi. Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

To explore the role of acetylcholine in rat visual cortex, the cholinergic agonist, carbachol (CCh), was applied to neurons in cortical slices. Intracellular recordings were made in coronal slices of cortex, and CCh was applied either by perfusion (30 uM) or focally by pressure puffs (30 mM, 0.05-0.5 sec). Several effects were observed. The most common effect was slow depolarization with no change or with a slight decrease in membrane conductance (in 48 out of 56 cells). The remaining cells showed slow hyperpolarization with a conductance increase. Both types of response were likely the result of a direct effect of CCh on the membrane because they persisted when synaptic transmission was blocked by TTX. A marked effect of CCh application was an increase in the rate of firing in response to depolarizing pulses. This was due to a shortening of the time course of repolarization after each spike. A similar observation has been reported in CNS neurons (Cole, A.E. & Nicoll, R.A., J. Physiol. , 352:173, 1984). Both the changes in membrane potential and firing rate were blocked by atropine (0.3 uM). CCh also affected synaptic transmission. It attenuated both epsps and ipsps evoked by stimulating the underlying white matter, particularly the slow ipsp. The net result of the various effects of cholinergic modulation appeared therefore to be an increase in excitability to repetitive afferent stimuli. (supported by the NEI US-Japan Exchange Scientist Program and by NIH grant EY05253 and NS22789)

434.2

MUSCARINIC AGENT INDUCED NEURONAL RESPONSES IN RAT CEREBRAL CORTEX. Y. Lin and J.W. Phillis. Dept. of Physiology, Wayne State University School of Medicine, Detroit, MI 48201.

Recording of neuronal activity and iontophoretic application of various agents were accomplished with seven-barrelled micropipettes in anaesthetized rats to evaluate muscarinic agonist action on cortical neuronal activities.

Oxotremorine-M excited spontaneously active deep cerebral cortical neurons. No excitation was observed with oxotremorine or McN-A-343.

Effect of muscarinic agonists on evoked neuronal discharges **

agent	glutamate evoked discharges			Ach evoked discharges	
	inhibited	inh./enh.*	enhanced	inhibited	inh./enh.*
oxotremorine	25/55	19/55	11/55	12/15	3/15
McN-A-343	20/37	11/37	6/37	11/11	0/11
oxotremorine-M	59/71	8/71	4/71	19/19	0/19

Blockade of agonists' inhibitory action on glutamate discharges **

agent	atropine		pirenzepine		gallamine		methoctramine	
	blocked	no	blocked	no	blocked	no	blocked	no
oxotremorine	3/4	1/4	7/12	5/12	1/5	4/5	----	----
oxotremorine-M	12/12	0/12	2/7	5/7	5/5	0/5	5/7	2/7

** numbers represent cells tested; * inh=inhibited, enh=enhanced; no=unblocked.

Conclusion: cortical muscarinic receptors mediate multiple synaptic actions. The inhibitory action appears to be non-selective since both glutamate and Ach evoked discharges were supressed. Following the inhibition, an enhancement of glutamate evoked discharges (for as long as 2 hours) was induced in some neurons. Both M_1 and M_2 antagonists blocked the excitation by oxotremorine-M of spontaneously activite neurons.

434.3

CHOLINERGIC MODULATION OF E-S COUPLING IN CA1 PYRAMIDAL CELLS OF THE RAT HIPPOCAMPUS.

M.K. Meffert, G.A. Cohen and D.V. Madison. *Dept. of Molecular and Cellular Physiology, Stanford Univ. Sch. of Med., Stanford, CA 94305.*

We have studied the effects of carbachol at the Schaffer collateral-CA1 synapse of the rat hippocampus. Carbachol (20 or 50uM) initially depressed the evoked EPSP field potential (~90% inhibition) and the population spike. However, the population spike recovered to near or above its baseline amplitude within a few minutes in the continued presence of carbachol, even though the epsp remained inhibited. Thus, it seemed apparent that the coupling between the epsp and the population spike (E-S coupling) was enhanced. Comparison of input/output curves showed that population spikes could be elicited by lower stimulus voltages than in control conditions and that maximal population spike amplitudes were reached at much lower stimulus strengths.

Effects of carbachol on E-S coupling may bear on the interpretation of previous results. For example, adenosine blockade of synaptic transmission appears to be inhibited by carbachol (PNAS, 84:3467, 1987; Science, 239:1428, 1988). Like these previous reports, we find that adenosine, in the presence of carbachol, fails to inhibit population spikes elicited by near maximal stimulation. However, we believe that this inhibition is an indirect result of carbachol shifting the input/output curve to the left. Because of this shift, near maximal stimulation becomes supra-maximal in the presence of carbachol such that inhibitory influences on the population spike are less effective. When the stimulus strength is readjusted to be sub-maximal in the presence of carbachol, it is revealed that adenosine still potently inhibits the population spike.

Perhaps the most intriguing aspect of these findings is that carbachol increases E-S coupling to the extent that stimulation produces a full-amplitude population spike even though the epsp is almost completely blocked. We are investigating the mechanisms underlying this phenomenon. *D.V.M. is a Lucille P. Markey Scholar and this work was supported in part by a grant from the Lucille P. Markey Charitable Trust. 434.4

LITHIUM POTENTIATES CHOLINERGIC PRESYNAPTIC INHIBITION IN AREA CA1 OF THE RAT HIPPOCAMPUS.

G.A. Cohen and D.V. Madison. *Dept. of Molecular and Cellular Physiology, Stanford Univ. Sch. of Med., Stanford, CA 94305.*

It has been shown that activation of muscarinic receptors in hippocampus mediates an inhibition of excitatory transmission by a presynaptic mechanism. In agreement with previous findings, carbachol causes a marked inhibition of epsp field potentials recorded in stratum radiatum, or in intracellularly recorded epsp's. To study the nature of this inhibitory effect we have used whole cell voltage clamp techniques in submerged, 500 um thick rat hippocampal slices to study the effect of carbachol in minimally stimulated excitatory postsynaptic currents (epsc's). Because of the greatly reduced noise inherent in whole cell recording, it is possible to detect epsc's produced by single presynaptic axons. Minimal stimulation to the Schaffer collaterals produces very small epsc's resulting from the activation of a very small number or single presynaptic axons. Stimulus strength was adjusted to give an epsc failure rate of between 10 and 50%. Application of carbachol caused an increase in the frequency of epsc failure. This is strong evidence confirming the presynaptic nature of carbachol's inhibition of excitatory transmission.

To test if the mechanism of carbachol's inhibition of synaptic transmission might involve phosphoinositide (PI) turnover, we tested the effects of lithium, a blocker of the PI turnover cycle. LiCl alone (2mM) caused a slight inhibition in the slope of the evoked field epsp and the amplitude of the population spike, but greatly potentiated carbachol's (1uM) inhibition of the epsp and inhibition of the evoked population spike amplitude. In whole cell recordings, LiCl (2mM) had no detectable effect alone, but markedly potentiated the ability of carbachol to increase the frequency of failures of very small epsc's evoked by minimal stimulation. This is evidence that lithium may act on excitatory presynaptic terminals and may show a physiologically important action of this psychiatrically useful agent. *D.V.M. is a Lucille P. Markey Scholar and this work was supported in part by a grant from the Lucille P.Markey Charitable Trust. G.A.C. is a Howard Hughes Medical Institute Predoctoral Fellow.*

VOLTAGE-CLAMP ANALYSIS OF CHOLINERGIC ACTION IN THE BASOLATERAL AMYGDALA. M.D. Womble and H.C. Moises. Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

Previously, we showed that the cholinergic agonist carbachol depolarizes neurons of the basolateral amygdala (BLA) and reduces both accommodation and the late afterhyperpolarization (AHP) (Washburn & Moises, Neurosci. Abstr. 15:193, 1989). We have also identified many of the membrane currents in BLA neurons (Moises and Womble, this volume). In this study, we used the single electrode voltage-clamp technique to identify those currents in BLA neurons of rat brain slices which were sensitive to cholinergic modulation. M-current (Im) was identified as a slowly decaying, voltage-sensitive current, inactivating during hyperpolarizing steps (1s, 15 mV) from a holding potential (Vh) of -40 mV. Carbachol (10-40 uM) blocked Im and increased input resistance at depolarized levels. The slow AHP following an action potential was blocked by carbachol, as was the underlying Iahp. The action of carbachol was accompanied by an inward shift in holding current and an increase in input resistance even at those potentials (-70 mV) where Im and Iahp were not activated. This indicates that carbachol also acts to block a resting 'leak' conductance. All the actions of carbachol were blocked by atropine (1 uM). Thus, block of the leak current by carbachol may underlie neuronal depolarization, while the loss of accommodation may be the result of Im and Iahp inhibition. (Supported by NIDA grant DA03365.)

434.6

THE MUSCARINIC AGONIST BETHANECHOL INITIATES HYPERPOLARIZATION AND DEPOLARIZATION OF MUDPUPPY INTRACARDIAC NEURONS. L.M. Konopka and R.L. Parsons. University of Vermont College of Medicine, Burlington, VT 05405.

Previously it was shown that muscarinic activation results in the hyperpolarization of mudpuppy parasympathetic postganglionic neurons by activation of a potassium conductance (Hartzell et al., J. Physiol., 271, 1977). Our recent experiments demonstrate that the muscarinic agonist bethanechol can elicit a biphasic response: hyperpolarization followed by depolarization or depolarization, which preceded and followed the hyperpolarization. The average amplitudes of the hyperpolarization and depolarization, measured at resting membrane potentials -40 to -65 mV under optimal agonist application conditions, were approximately 20 and 3 mV respectively. Both components of the response were eliminated by atropine (0.1-5 μM). Excitability of the neurons increased during the depolarizing component. In the presence of 2-4 mM Ba++, the bethanechol induced hyperpolarization was selectively blocked. In Ba++ the amplitude of the depolarization increased with membrane hyperpolarization and decreased with membrane depolarization. The reversal potential of the depolarization was approximately +5 mV suggesting the response was due to the activation of a nonselective cation conductance. The M1 specific muscarinic receptor blocker, pirenzepine, partially inhibited hyperpolarizations at concentrations $\leq$ 10 nM and blocked both responses at concentrations > 20 nM. The M2 specific muscarinic blocker AFDX116 selectively inhibited hyperpolarizations at concentrations $\leq$ 1 M. These results show that the bethanechol induced hyperpolarizations and depolarizations of mudpuppy cardiac neurons are mediated via two distinct muscarinic receptors. Supported by PHS grants NS 25973 and NS 23798.

EFFECT OF PHYSOSTIGMINE AND EXERCISE ON CHOLINEACETYLTRANSFERASE AND ACETYLCHOLINESTERASE ACTIVITIES IN BRAIN REGIONS OF RAT. S.M. Somani, S.R., Babu, S.P. Arneric, S.N. Dube and S. Evans, Department of Pharmacology and Medicine, Southern Illinois University School of Medicine, P.O. Box 19230, Springfield, Illinois 62794-9230 U.S.A.

This presentation addresses whether subacute physostigmine (Phy) and/or subacute exercise elicit any changes in the ChAT and AChE activities in four brain regions.

Male Sprague Dawley rats were divided into five groups: Gr. I, control; Gr. II, subacute treadmill exercise two weeks; Gr. III, subacute Phy (70 μg/kg, i.m. twice daily) for two weeks; Gr. IV, subacute Phy and single exercise 100% Vo_2 MAX;; Gr. V, subacute Phy + subacute exercise. Rats were sacrificed 24 hr after the last dose of Phy and/or the exercise. ChAT and AChE activities were determined by the method of Fonnum (1975). Corpus striatum showed ChAT activity 88%, 68%, 88% of control ($P<0.05$) in Gr. II, IV and V respectively and AChE activity 87% of control in Gr. IV. Cerebral Cortex showed ChAT activity 79% of control in Gr. V only. Brain stem showed ChAT activity 73%, 78%, 82% and 81% of control ($P<0.05$) in Group II, III, IV and V respectively and AChE activity 81 and 82% of control in Gr. II and III respectively. Hippocampus showed ChAT activity 72 and 73% of control ($P<0.05$) in Group IV and V respectively.

These results suggest that Phy or physical exercise or the combination of these two stressors depress ChAT and AChE activities in each brain region differently. (Supported by U.S. Army Contract No. DAMD 17-88-C-8024)

IS RELEASE OF ASCORBIC ACID IN CINGULATE CORTEX CONTROLLED BY ACETYLCHOLINE OR BY AFFECT? K. Mueller, Dept. Psychol., Texas Christian University, Fort Worth, TX 76129

Release of ascorbic acid in brain is still poorly understood. Surprisingly, in previous research, pilocarpine (a direct cholinergic agonist) increased the ascorbic acid signal in anterior cingulate cortex (ACC) by 95% even though ACC contains little acetylcholine. Did pilocarpine produce this effect by acting directly in ACC or by producing gastrointestinal distress which in turn produced affective changes? Since ACC is a component of the limbic system, affect may be relevant to changes in ascorbic acid. A series of experiments was conducted to begin to investigate this hypothesis. In all experiments, voltammetry in vivo using carbon paste electrodes monitored release of ascorbic acid from conscious behaving rats. The first experiment exploited the functional and anatomical differences between anterior and posterior cingulate cortex. In posterior cingulate cortex pilocarpine increased the ascorbic acid signal by only 55%. In another experiment, scopolamine (a cholinergic antagonist) virtually abolished the effect of pilocarpine in ACC. Finally, an equimolar dose of methscopolamine (which does not cross the blood-brain-barrier) produced a large decrease in the effect of pilocarpine in ACC. Thus, the effect of pilocarpine on ascorbic acid in ACC must be related in part to its gastrointestinal effects. Other research on the relationship between affect and ascorbic acid in ACC is in progress.

BASAL FOREBRAIN INVOLVEMENT IN TONE ELICITED NEURONAL RESPONSES IN RAT AUDITORY CORTEX. E.L. Moore, J.G. Townsel and H.K. Rucker. Department of Physiology, Meharry Medical College, Nashville, TN 37208.

The specific aim of this study was to examine the effects of basal forebrain microinfusion of muscimol, a GABA agonist, on high affinity choline uptake, spontaneous rates and tone elicited response profiles of neurons in auditory cortex. Baseline peristimulus time histograms (PSTHs) were constructed to best frequency tone pulses prior to muscimol (100 nmol/ul) infusion (1ul/1 minute) and compared to 4 experiment PSTHs constructed during the following 60 minutes. High affinity choline uptake (HAChU) was assayed using synaptosomes prepared from temporal cortex. HAChU was decreased 56% in muscimol injected animals vs. controls. The spontaneous discharge rate and tone elicited response decreased in 70% of the units after muscimol injection. In the remaining units, biphasic changes in spontaneous firing were accompanied by increases in tone elicited firing rates. These results were interpeted to suggest that basal forebrain cholinergic projections modulate neuronal discharge characteristics, particularly response gain, in sensory cortex.

LEARNING AND MEMORY DEFICITS IN RATS PRODUCED BY SELECTIVE BLOCKADE OF HIGH AFFINITY CHOLINE UPTAKE FOLLOWING SYSTEMIC ADMINISTRATION OF A-4. C.E. Tedford, V.B. Ruperto*, M.E. Grzelak *, M. Cohen-Winston* and L. C. Iorio. Schering-Plough Research, Bloomfield, New Jersey, 07003.

A-4, a bis-tertiary amine piperdine derivative of hemicholinium-3 (HC-3), was used to inhibit acetylcholine synthesis. Subcutaneous administration of A-4 produced a dose-dependent reduction in central high affinity choline transport (HAChT) measured ex vivo. Doses of 3, 10 and 30 mg/kg of A-4 produced a 23.7%, 70.0% and 76.7% reduction in hippocampal HAChT at 1 hr versus vehicle treated animals. Maximal reduction in hippocampal HAChT was seen within 30 min after sc administration of A-4. This reduction in HAChT was maintained for up to 24 hr after administration and HAChT returned to near control values 48 hr after administration of A-4. No changes in choline acetyltransferase or acetylcholinesterase enzyme activities were seen.

Behavioral studies in rats utilizing the passive avoidance response paradigm illustrated that animals treated with A-4 had impairments in 24 hr retention. A-4 (30 mg/kg) administered sc 30 min prior to training decreased step-through median latencies from 180 sec to approximately 45 sec. Furthermore, sc administration of A-4 immediately following the training session also resulted in impairments in 24 hr retention times. Analogous studies using intracerebroventricular administration of HC-3 or A-4 also produced impairments in 24 hr retention using the passive avoidance response paradigm. Thus, these studies indicate that selective blockade of central HAChT following systemic adminstration of A-4 results in learning and memory impairments.

SIMULTANEOUS FOREBRAIN AND PONTINE MICROINJECTIONS OF CARBACHOL SUPPRESS REM SLEEP. H.A.Baghdoyan, R.Lydic, T.M.Rutherford*, and S.G.Snyder*. Dept. of Anesthesia, Penn State Univ. College of Med., Hershey, PA 17033.

Converging data support the now widely held view that pontine cholinergic mechanisms play a key role in the generation of REM sleep. The basal forebrain has been suggested to be important for the generation of nonREM sleep, but the neurotransmitters involved in this putative basal forebrain function are unknown. The purpose of the present study is to begin examining the role of cholinoceptive forebrain systems in sleep cycle control by quantifying the effects of forebrain carbachol microinjections on sleep and on the REM sleep-like state produced by pontine microinjection of carbachol.

To date we have performed 22 carbachol (4μg/.25μl) and 18 saline (0.25μl) microinjections in 3 intact cats. Carbachol in the forebrain produced a 45% increase in waking (W), a 76% decrease in nonREM (S), and a 64% decrease in REM (D). Carbachol in the pons produced a 10% decrease in W, a 100% decrease in S, and a 387% increase in D. Simultaneous forebrain and pontine microinjections of carbachol produced a 44% increase in W, a 99% decrease in S, and a 163% increase in D. Thus, cholinoceptive forebrain mechanisms can enhance W, suppress S, and reduce the REM sleep enhancing effects of pontine carbachol administration.

NORADRENERGIC/ADRENERGIC INPUT TO CHOLINERGIC FOREBRAIN PROJECTION NEURONS. L. Zaborszky, W.E. Cullinan and L. Heimer. University of Virginia Health Science Ctr., Charlottesville, VA 22901.

We have reported previously (Zaborszky et al., 1987; Neuroscience, Suppl. S798) that tyrosine hydroxylase immunoreactive (TH) fibers in the forebrain surround cholinergic neurons and electron microscopic studies (Zaborszky et al., in press) confirmed the presence of synaptic contacts. Since TH is the first step in the catecholamine biosynthetic pathway, it is not clear whether such terminals represent dopaminergic and/or noradrenergic/adrenergic input.

In the present study, forebrain sections were stained with an antibody against dopamine-ß-hydroxylase (DBH), the enzyme present in noradrenergic/adrenergic neurons, in combination with ChAT (choline acetyltransferase) immunostaining, using the DAB/NiDAB double labeling technique. Adjacent sections were processed for TH/ChAT. DBH-positive fibers and terminals were in close proximity to cholinergic neurons throughout extensive forebrain areas, including the vertical and horizontal limb of the diagonal band nuclei, the sublenticular substantia innominata (SI), bed nucleus of the stria terminalis, ventral pallidum, and ventrolateral globus pallidus. It was confirmed in EM double-labeling studies that cholinergic neurons in the SI were contacted by DBH-positive axons through asymmetric synapses.

Based upon the differences in both the distribution pattern of TH/ChAT versus DBH/ChAT interactions, as well as the different morphological features of DBH versus TH-positive axon types, our study also revealed that cholinergic neurons in the ventromedial globus pallidus receive dopaminergic input. Supported by USPHS grants No. 23945 and 17743.

LOCUS COERULEUS PROJECTIONS TO THE ROSTRAL FOREBRAIN WITH SPECIAL REFERENCE TO INNERVATION OF CHOLINERGIC PROJECTION NEURONS.

W. E. Cullinan, R. Grzanna, and L. Zaborszky Univ. of Virginia Health Sciences Center, Charlottesville, VA, 22901, and The Johns Hopkins Univ. School of Medicine, Baltimore, MD, 21205.

Ascending projections from the locus coeruleus were demonstrated using the PHA-L anterograde tracing method, providing a precise view of the distribution and arborization pattern of locus coeruleus axons in the basal forebrain. To investigate whether these axons terminate on forebrain cholinergic projection neurons, PHA-L tracing and choline acetyltransferase (ChAT) immunocytochemistry were combined in double-labeling studies at both the light and electron microscopic levels using the nickel-enhanced DAB/DAB technique (Hsu and Soban, 1982). At the light microscopic level, locus coeruleus axons were detected in close apposition to cholinergic projection neurons within the medial septum/vertical limb of the diagonal band nucleus, horizontal limb of the diagonal band nucleus, and sublenticular substantia innominata. Results of experiments at the electron microscopic level demonstrated that cholinergic neurons are indeed contacted by locus coeruleus axons, and that an individual locus coeruleus axon terminal can establish synaptic contact with both cholinergic and non-cholinergic neuronal elements. In addition, immunofluorescence double-labeling confirmed that the vast majority of PHA-L labeled neurons at the injection site also contained the catecholamine synthesizing enzyme dopamine- ß-hydoxylase, thus, the present results indicate that noradrenergic input to forebrain cholinergic projection neurons originates in part from the locus coeruleus. Supported by USPHS Grants 23945 and 17743.

ULTRASTRUCTURAL FEATURES OF ACETYLCHOLINE (ACh) AXON TERMINALS IN ADULT RAT CEREBRAL CORTEX. D. Umbriaco, K.C. Watkins*, L. Descarries, C. Cozzari* and B. Hartman. CRSN (Département de physiologie), Université de Montréal, Montréal (CANADA); Istituto Biologia Cellulare CNR, Roma (ITALY), and Department of Psychiatry, University of Minnesota Medical School, Minneapolis (MN).

ACh axon terminals (varicosities) from the parietal (primary somatosensory) cortex of adult rat were examined by electron microscopic immunocytochemistry with a monoclonal antibody against purified rat brain choline acetyltransferase (MCAT-1C, Ka = $5x10^{10}$, from a series prepared in mouse). Initial fixation of the tissue was by perfusion with 2.5 % paraformaldehyde (PF) and 0.1-0.2% glutaraldehyde (pH 6.5), followed by PF alone (pH 8.5). Transverse vibratome sections were processed free-floating without detergent (dilution of primary antibody: 2 µg per ml), immunostained with the ABC method, osmicated, and flat embedded in Epon. Serial ultrathin sections were cut at right angles to the surface of vibratome sections. 140 immunostained varicosities from layer I were studied in 2 rats, being visualized in an average of 5.6 thin sections per varicosity. These varicosities measured 0.3 to 1.1 µm and averaged 0.5 µm in equivalent spherical diameter. Only 5% (n = 7), and a single one of 34 sectioned throughout, showed a synaptic membrane differentiation. The presence of a junction was not related to varicosity size. The junctional complexes were all symmetrical, and all contacts made on dendritic shafts. These results demonstrate that the ACh innervation of adult rat parietal cortex comprises a large proportion of non synaptic axonal varicosities, at least in layer I. They provide further evidence for the concept of "volume transmission", and support the general notion that, in the CNS, widely distributed projection systems issued from relatively small groups of nerve cell bodies are predominantly nonjunctional. HUMAN BRAIN CORTICAL CHOLINERGIC INNERVATION.

Changiz Geula and Marsel Mesulam, Harvard U., Boston, MA

The peak density of histochemically demonstrated acetylcholinesterase (AChE)-rich, putatively cholinergic fibers was determined in 25 architectonic subregions of the cerebral cortex of five normal subjects.

Cortical areas were divided into 3 categories: 1) association, 2) primary sensorimotor and 3) paralimbic. All areas contained a dense net of AChE-rich fibers but with an individual pattern of lamination and density. Superficial layers generally contained a denser net of these fibers than the deeper layers. More fibers were encountered traveling vertical to the cortical surface as compared with fibers traveling horizontally.

The densest plexus of AChE-rich fibers was encountered in the paralimbic cortical areas (Mean peak density ± SD: 22.8±2.1) while the cortical association areas contained the lowest peak density (9.5±0.86). The primary sensorimotor areas contained an intermediate peak density of AChE-rich axons (14.3±1.5). The non-isocortical paralimbic zones (entorhinal cortex and the agranular and dysgranular components of orbitofrontal, temporopolar and insular cortex) contained a denser net of AChE-rich fibers (29.9± 2.5) than the immediately adjacent isocortical zones of the same paralimbic areas (17.0±1.5).

The results of this study are consistent with our previous observations in the monkey cortex and indicate that cortical cholinergic innervation in the human brain is much more intense in limbic and paralimbic areas than in association neocortex.

434.16

HUMAN NEOCORTICAL ACETYLCHOLINESTERASE NEURONS

Marsel Mesulam and Changiz Geula, Harvard U, Boston, MA

The cerebral cortex of the human brain contains a very extensive network of acetylcholinesterase (AChE)-rich neurons, located predominantly in layers III and V. Their density and laminar organization display marked variations which obey architectonic and functional boundaries. Although these neurons almost certainly represent at least one subset of cholinoceptive neurons, there is an inverse relationship between their density and that of intracortical cholinergic fibers. Cholinergic innervation is denser in limbic-paralimbic than in isocortical association areas. However, the density of AChE-rich intracortical neurons is higher in posterior parietal and prefrontal association areas than in limbic-paralimbic areas. In the visual and auditory systems, primary koniocortex has a lower number of these neurons than the adjacent unimodal association areas. In association neocortex, most of the AChE-rich neurons are located in LIII. In paralimbic areas, more of these neurons are found in the deeper cortical layers. Primary motor cortex is the only region with an equidense distribution in LIII and LV.

Our previous studies showed that the AChE-rich staining pattern of these neurons is absent at birth, starts to become established during late childhood (around 10 years of age), reaches a peak in the course of adulthood and does not show a consistent decline even in advanced senescence. The expression of high AChE levels in these neurons may indicate an increase in neuronal activity and plasticity in a way that may underlie the more advanced phases of human cognitive development.

IMMUNOSTAINING FOR MICROTUBULE-ASSOCIATED PROTEINS (MAP-1,-2,-5) IS DECREASED BY IBOTENIC ACID LESIONS OF THE CHOLINERGIC BASAL FOREBRAIN.

N.J. Woolf, J.D. Oh, and L.L. Butcher. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563.

In order to determine whether or not the basal forebrain cholinergic input has any effect on the presence of MAPs in the neocortex, we infused 10 µg of ibotenic acid in 1 µl saline into two sites of the rodent nucleus basalis (0.8 mm posterior, 2.5 mm ventral to bregma, and 7.0 mm ventral from the cortical surface; 1.8 mm posterior, 3.5 mm lateral to bregma, and 6.3 mm ventral to the cortical surface). Following survival times of 2 hr, 1 day, or 8 days, brains were processed for the immunohistochemical localization of MAP-1, MAP-2, and MAP-5 (antibodies purchased from Sigma Chemical Co., St. Louis, MO). Histochemistry for acetylcholinesterase (AChE) was also performed. Immunostaining for all three MAPs was markedly reduced in cortical somata and processes 8 days after lesion, but not at 2 hr or 1 day. Decreases were greatest for MAP-1, followed by MAP-5 and MAP-2, and all MAP proteins were decreased to the greatest extent in layer VI where basilar dendrites of pyramidal cells predominate. Decreases in MAP staining paralleled loss of AChE stained fibers in the cortex. MAP and AChE decreases were found in lateral neocortical fields but not in the piriform or cingulate cortices. These results suggest that cholinergic afferents may transynaptically regulate the expression of MAPs in cortical cells. [Support: USPHS grant NS 10928 to L.L.B.]

MAPPING OF CHOLINE ACETYL TRANSFERASE (ChAT) CELLS IN THE RAT BRAIN: POSSIBLE EVIDENCE FOR CHOLINERGIC INPUT TO THE CEREBELLUM. S.A. Azizi, A.J. Painchaud and D.J. Woodward, Dept. Cell Biology and Neuroscience, U.T. Southwestern Med. Sch., Dallas, TX 75235

The aim of this study was first to map the entire distribution of ChAT-containing neurons in the rat brain and, secondly, to determine whether ChAT-containing neurons in the brain stem project to the cerebellum.

ChAT-containing neurons were labelled using a polyclonal antibody to ChAT and conventional anatomical visualization techniques in 16 hooded rats. In 6 of these rats, HRP retrograde tracing techniques were also used to double-label the ChAT-containing neurons projecting to the cerebellum. Computer-assisted imaging techniques were utilized to analyze the distributions.

Our results confirmed previous reports on the distribution of ChAT labeled cells in the forebrain. Labelling was found in the medial septal nucleus, diagonal band of Broca, substantia innominota, corpus striatum, nucleus accumbens, lateral-globus pallidus and basal nucleus of Meynert. Within the brain stem, labeled neuronal groups included the pedunculopontine nucleus, the parabrachial nucleus and cranial motor and parasympathetic nuclei. In addition, several isolated clusters of labeled neurons previously unidentified were visualized within the pontine and medullary reticular formation. Furthermore, groups of weakly labeled cells were observed in the lateral reticular nucleus, around the trapezoid body and in locus coeruleus. Results from the double-labelling studies demonstrated that ChAT-containing lateral reticular neurons project to the cerebellum. *Supported by DA02338, AA03901 and the Biological Humanics Foundation.*

ACh SYNTHESIS IN DISSOCIATED PORCINE INTERMEDIATE LOBE CELLS. A. Tandon[1], B. Collier[1], Z.W. Zhang*, P. Feltz*
[1]Dept. of Pharmacology, McGill Univ., Montreal, Canada. *Inst. de Physiologie, Univ. Louis Pasteur, France.

Studies of the pituitary suggest a cholinergic component in the regulation of the intermediate lobe (IL). The origin of the cholinergic activity is unknown. In the anterior pituitary, choline acetyltransferase (ChAT) appears to be co-localized to cells that contain POMC. We tested whether the porcine IL, which is a homogeneous collection of POMC-containing cells, contains cholinergic markers. The corticotrophic tumor cell line AtT_{20} was used as a control since it can release acetylcholine (ACh). The ACh content (pmol/mg prot) increased from 209±15 in freshly dissociated IL cells, to 214±22 or 324±33 in 2 or 4-day IL cell cultures, respectively; AtT_{20} cells had 311±48. ChAT activity (nmol/mg prot/hr) was twice as high in the AtT_{20} cells (5.60±0.5) as compared to the freshly dissociated IL cells (2.87±0.6) and the 2 or 4-day cultures (1.95±0.2, 1.76±0.3). Napthylvinylpyridine (50uM), decreased ChAT activity in the freshly dissociated IL cells by 53%. AtT_{20} cells accumulated more [^{14}C]ACh (1544±240 dpm/mg prot) from exogenous [^{14}C]Ch (1uM) than the freshly dissociated IL cells (630±54 dpm/mg prot) or the 2 or 4-day cultured IL cells (763±64, 997±242 dpm/mg prot). Hemicholinium-3 (30uM), decreased the accumulation of [^{14}C]ACh in the IL cells. We conclude that IL cells can synthesize and store ACh.

SINGLE CHOLINERGIC MESOPONTINE TEGMENTAL NEURONS PROJECT TO BOTH THE PONTINE RETICULAR FORMATION AND THE THALAMUS IN THE RAT. Kazue Semba, Peter B. Reiner and Hans C. Fibiger. Div. of Neurol. Sci., Dept. of Psychiat., Univ. of British Columbia, Vancouver, B.C., V6T 1W5, and Dept. of Anat., Dalhousie Univ., Halifax, N.S. B3H 4H7 Canada.

Microinjections of carbachol into the pontine reticular formation (PRF) induce a REM sleep-like state. This carbachol-sensitive PRF region is innervated by cholinergic neurons in the pedunculopontine and laterodorsal tegmental nuclei. The same population of cholinergic neurons also projects to the thalamus, where there is good evidence that acetylcholine facilitates sensory transmission and blocks rhythmic thalamocortical activity. The present study was undertaken to examine the degree to which single cholinergic mesopontine neurons project to both the carbachol-sensitive PRF region and the thalamus, by combining double fluorescent retrograde tracing and immunofluorescence with an antibody to choline acetyltransferase. The results indicate that a subpopulation (5-21% ipsilaterally) of cholinergic mesopontine neurons projects to both the thalamus and the carbachol-sensitive site of the PRF. The percentage of cholinergic neurons with dual projections was higher in the pedunculopontine (6-27%) than in the laterodorsal (4-11%) tegmental nucleus. In addition, mixed with cholinergic neurons, there was a small population of dually projecting tegmental neurons that did not appear to be cholinergic. Mesopontine cholinergic neurons with dual projections may simultaneously modulate neuronal activity in the pontine reticular formation and the thalamus, and thereby have the potential of concurrently regulating different aspects of REM sleep.

434.21

PEPTIDE AND GLUTAMIC ACID DECARBOXYLASE mRNAs IN THE HUMAN NUCLEUS BASALIS OF MEYNERT. L.C. Walker, N.E. Rance*, D.L. Price and W.S. Young III. Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD 21205, and Laboratory of Cell Biology, NIMH, Bethesda, MD 20892.

Neurons with mRNAs coding for peptides and glutamic acid decarboxylase (GAD) in the anterior and intermediate nucleus basalis of Meynert (nbM) were studied in four humans using hybridization histochemistry with radiolabeled, 48-base oligodeoxynucleotide probes. GAD mRNA was found mostly in small and medium-sized neurons scattered among unlabeled, large neurons of the nbM. Substance P, somatostatin, neuropeptide Y, and enkephalin mRNAs were found in minor populations of mostly smaller neurons; these hybridoreactive neurons corresponded in size and distribution to immunoreactive peptidergic somata previously identified in the nbM of macaques. Galanin mRNA occurred only in a small number of human nbM neurons, in contrast to the extensive presence of galanin-hybridoreactive neurons in the nbM of nonhuman primates. Finally, neurokinin B mRNA was found in a subset of magnocellular neurons in humans. Thus, numerous noncholinergic markers occur in neurons of the human nbM, some of which are integral components of the nucleus and others of which may belong to separate but anatomically overlapping structures.

434.22

Autoradiographic Analysis of Pre- and Post-Synaptic Muscarinic Cholinergic Pathways in Bat, Shrew and Rat Brain. M.M. Howland, D.S. Higgins, R.L. Albin, K.A. Frey. Dept. of Neurology, Univ. of Michigan, Ann Arbor, MI 48109.

Studies in rodents and primates have characterized the CNS pathways subserving muscarinic cholinergic (mus/chol) neurotransmission. To assess the comparative anatomy of mus/chol pathways we used quantitative film autoradiography to measure pre- and post-synaptic markers of mus/chol function in three phylogenetically diverse groups of mammals, including shrews, microchiroptera, macrochiroptera, and rats. High affinity cholinergic uptake sites and cholinergic vesicles were measured with [^{3}H]hemicholinium and [^{3}H]vesamicol, respectively. Mus/chol receptors were measured with [^{3}H]scopolamine. The regional distribution of pre- and post-synaptic markers was similar in all subjects studied. Receptor density was highest in hippocampus, striatum, amygdala, and cerebral cortex, intermediate in thalamus and brainstem, and lowest in cerebellar cortex. Binding of pre-synaptic markers was highest in the interpeduncular nucleus and progressively lower in amygdala, striatum, hippocampus, neocortex, thalamus, and cerebellar cortex. These results indicate conservation of mus/chol pathways among eutherian mammals. Supported by NS01300, MH42652.

ACETYLCHOLINE—RECEPTORS: MUSCARINIC III

435.1

COMPARISON OF CHOLINERGIC ANTAGONISTS ON RECEPTOR BINDING, ACETYLCHOLINE LEVELS AND MEMORY IMPAIRMENT IN RATS. F. P. Bymaster and H. E. Shannon*. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

The purpose of the present studies was to determine if cholinergic antagonists inhibited M1 muscarinic receptor binding ex vivo, altered ACh levels and impaired memory in the same dose range. The muscarinic antagonists scopolamine (S), trihexyphenidyl (THP) and pirenzepine (PZ) and the nicotinic antagonist mecamylamine (M) inhibited the ex vivo binding of the M1 antagonist ^{3}H-PZ to cortical whole homogenates with ED_{50}s of 0.05, 0.1, 50 and >10 mg/kg s.c. and for ^{3}H-QNB binding in M2-rich brain stem of 0.2, 5, >100 and >10 mg/kg, respectively. These antagonists inhibited ^{3}H-PZ binding in vitro in cortex with IC_{50}s of 2, 4, 7 and >10000 nM, and ^{3}H-QNB binding in brain stem with IC_{50}s of 4, 40, 1130 and >10000 nM, respectively. Doses of S, THP, PZ and M required to lower ACh levels to one-half maximum were 0.1, 0.4, >100 and >10 mg/kg s.c. Doses of S, THP, PZ and M required to disrupt memory in a spatial alternation paradigm were 0.1, 1.0, 30 and >10 mg/kg s.c. These data demonstrate that S and THP enter the brain well. Further, they interact with M1 receptors and lower ACh levels at doses in the same range. S was non-selective for M1 and M2 receptors, whereas THP was relatively selective for M1 receptors. PZ and/or active metabolites required relatively high doses to enter the brain and did not appreciably alter ACh levels. M did not interact with M1 or M2 receptors or alter ACh levels.

435.2

A MODEL OF THE MUSCARINIC RECEPTOR AGONIST PHARMACOPHORE DERIVED FROM COMPUTER-ASSISTED MOLECULAR DESIGN AND ANALOG STRUCTURE ACTIVITY RELATIONSHIPS (SAR). David Garvey, Charles Hutchins*, John Chung*, Youe-Kong Shue * and Michael McKinney Neuroscience and Drug Design Research Divisions, Pharmaceutical Discovery, Abbott Labs, Abbott Park. IL 60064.

Enhancement of cortical cholinergic tone as an approach to the treatment of the symptoms of dementia associated with Alzheimer's Disease has led to the search for novel cholinomimetics capable of penetrating the CNS and positively stimulating those muscarinic receptors in the cerebral cortex coupled to phosphatidylinositol hydrolysis (PI). Utilizing the primary amino acid sequence of the human m1 receptor (Peralta et. al., *EMBO J.*, 6, 3923,1987), we have developed a thee dimensional model of the receptor agonist ligand binding domain which rationalizes the binding affinities and the *in vitro* intrinsic activities of a series of non-quarternary muscarinic ligands. This model assumes three key points of interaction between the ligand and specific amino acid side chain residues on the receptor protein. Postulated are two hydrogen-bonds with the ligand involving Ser-109 and Asn-410. These interactions are presumed to remain constant throughout the process of agonist recognition binding and subsequent activation of the receptor PI response. In addition, we hypothesize that there is an electrostatic interaction between the ligand and the receptor which changes for the more efficacious agonists from Asp-105, important for recognition binding, to Asp-71, a requirement for ligand mediated receptor activation. The SAR of a series of spirocyclic piperidine and more rigid spirocyclic quinuclidine derivatives support this model.

435.3

MUSCARINIC RECEPTOR SUBTYPE-SELECTIVITY OF PIRENZEPINE DERIVATIVES. Yishai Karton,* Jesse Baumgold,† Robert Paek,†* Barton Bradbury,* and Kenneth Jacobson, Laboratory of Chemistry, NIDDK, NIH, Bethesda, MD, and †Dept. of Radiology, George Washington University Med. Center, Washington, DC.

In an effort to identify structural features of the muscarinic antagonist pirenzepine (PZ) which confer selectivity for m_1-cholinergic receptors, we synthesized a number of derivatives of PZ having modifications of the *N*-methylpiperazine side chain. These derivatives were tested in binding assays vs. [^{3}H]*N*-methylscopolamine in membranes of transfected cells expressing a single receptor subtype. The potency/selectivity were highly dependent on substitutions of the *N*-methyl group. Replacement of the methyl group with H resulted in an m_1-selective compound which was one order of magnitude less potent than PZ. Replacement of this methyl with a 2-chloroethyl group resulted in a compound that displayed affinities similar to PZ at each of the m_1-m_4 muscarinic receptor subtypes. This compound proved to be an irreversible inhibitor of muscarinic receptors after cyclizing to the chemically reactive aziridinium ring and may become a useful tool with which to study the binding domain of each receptor subtype. Finally, a "functionalized congener" design approach was applied to the *N*-methyl group resulting in chemically functionalized *N*-alkyl analogs. For example, a non-selective derivative containing a 6-methylene spacer chain was approximately equipotent to PZ at m_1 receptors and considerably more potent than PZ at the other muscarinic subtypes.

435.4

New Antagonists of Central Muscarinic Activity: 1-Methyl-3-(5-alkoxy-4-alkyloxazol-2-yl)-1,2,5,6-tetrahydropyridines. C.H. Mitch, H.E. Shannon*, D.D. Schoepp, D.T. Wong, F.P. Bymaster*, S.J. Quimby*. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

A series of the title compounds have been found to be potent muscarinic antagonists by both *in-vitro* and *in-vivo* measures. Affinity for M_1 receptors was determined in binding studies using ^{3}H-pirenzepine in rat hippocampus. Binding studies in rat brain stem using ^{3}H-quinuclidinyl benzilate in the presence of unlabeled pirenzepine were used to determine affinity for M_2 receptors. Affinity for oxotremorine-M binding sites in rat hippocampal membranes was also determined. Antagonist activity was measured *in-vitro* through measurement of inhibition of acetylcholine stimulated phosphatidyl-inositol turnover in rat cerebral cortex slices. Reversal of oxotremorine-induced tremors in mice was used to measure antagonist activity *in-vivo*. Memory impairment was measured in a spatial alternation paradigm. The results for 1-methyl-3-(5-methoxy-3-(1-methylpropyl)-oxazol-2-yl)-1,2,5,6-tetrahydropyridine are representative of those found for the series: IC50's of 3 nM, 190 nM and 123 nM for displacement of ^{3}H-pirenzepine, ^{3}H-QNB, and ^{3}H-oxotremorine, respectively; IC50 of 69 nM for the inhibition of 100 uM acetylcholine stimulation of PI turnover; AD50 of 3 mg/kg for antagonism of oxotremorine-induced tremors in mice; ED50 of 1.0 mg/kg for impairing memory in rats.

435.5

THE M2 MUSCARINIC ANTAGONIST METHOCTRAMINE IS TOXIC TO HUMAN NEUROBLASTOMA CELLS SK-N-SH. N. Giladi, J.L. Cadet. Lab. of Preclinical Neurosciences, Columbia Univ., New York, NY 10032.

Cholinergic agonists that act at muscarinic receptors (mAChRs) have trophic influence on cell differentiation. Blocking of the mAChRs might cause cholinergic deprivation and deleterious effects on cellular function. In order to test that idea, we used the cholinergic human neuroblastoma cell line SK-N-SH to study the effects of specific antimuscarinic agents on cell survival in culture. The specific M2 mAChR antagonist methoctramine caused cell death in a dose response manner. 107 uM methoctramine caused 50% cell death after 24 hours. The specific M1 mAChR antagonist pirenzepine and the M3 antagonist 4-DAMP were without toxic effects. Preincubation with pertussis toxin (1ug/ml. for 24 hours) enhanced the toxicity of methoctramine but had no toxic effects on its own. These results demonstrate that blocking of the allosteric M2 mAChR site, which is present on the of SK-N-SH cells, can have lethal consequences. The present findings add further evidence for the trophic properties of acetylcholine and suggest a possible receptor-based approach to the treatment for patients with neuroblastoma tumors.

435.6

THE AMINOPYRIDAZINE MUSCARINIC AGONIST, SR 95639A, IS A FUNCTIONAL M_2 RECEPTOR ANTAGONIST IN RAT BRAIN. D.J. Anderson, E. Cadman*, L. Vella-Rountree*, S.P. Arneric and M. Williams. Neuroscience Research, Abbott Laboratories, Abbott Park, IL 60064-3500.

The minaprine analog, SR 95639A (morpholinoethylamino-3-benzocyclohepta-(5,6-c)pyridazine dihydrochloride) has been reported as an orally active, selective, and non-toxic muscarinic M_1 receptor agonist (Schumacher et al., Eur. J. Pharmacol. 166:139,1989).

Binding studies indicated that SR 95639A was moderately selective for the M_1 receptor irrespective of whether [^{3}H]pirenzepine binding was measured in cortex (IC_{50}= 1.88 ± 0.45 uM ;N=5) or hippocampus (IC_{50}= 1.01 ± 0.37 uM ;N=2). Activity at the brainstem M_2 receptor ([^{3}H]QNB) was similar (IC_{50}= 8.61 ± 2.40 uM ;N=3). The compound was inactive (> 100 uM; N=3) at displacing [^{3}H]MCC at the nicotinic cholinergic receptor.

Biochemical evaluation of the muscarinic activity of the compound showed it to be totally without effect on M_1 receptor-linked phosphatidyl inositol (PI) hydrolysis in cerebral cortex at concentrations up to 1.0 mM (0 % ;N=4), unlike carbachol and the oxadiazole arecoline analog, L 670,207 which had EC_{50} values of 116 ± 10 uM (N=6) and 0.83 ± 0.36 uM (N=3), respectively. Morever, SR95639A did not inhibit the M_1 response elicited by carbachol (7.4 ± 7.4 % at 100 uM ;N=3). SR 95639A also had no agonist activity at the M_2-receptor (0 % inhibition of forskolin-mediated activation of adenylate cyclase in striatum at 100 uM ;N=3). Similarly, SR 95639A did not alter basal levels of cGMP production, nor did it enhance (or inhibit) the cGMP production elicited by oxytocin in LLC-PK1 cells. The compound however antagonized the M_2-mediated inhibition of cAMP production by carbachol (10 uM) with a K_i of 5.3 ± 1.0 uM (N=5).

These findings suggest that: 1) SR 95639 is a functional M_2 receptor antagonist; and 2) the M_1 agonist properties exhibited in vivo cannot be correlated with actions at an M_1 receptor linked to PI hydrolysis.

Electrophysiological and Receptor Binding Characterisitics of Cholinergic Agents: Potential Therapeutics for Alzheimer's Disease. D.J. Critchett*, R.M. Mangano, E.J. Trybulski, B. Beer and D.E. Clody. Med.Res.Division, American Cyanamid Co. Pearl River, NY. 10965.

Alzheimer's disease (AD) is a neurodegenerative disease characterized by a profound memory loss among other cognitive dysfunctions and is the most common form of dementia. Many of the symptoms of AD correlate highly with a loss of cholinergic function. Our working hypothesis is that proper enhancement or restoration of cholinergic function may significantly reduce the severity of cognitive loss. We have targeted the cholinergic system as a therapeutic approach to alleviate some of the cognitive symptoms of AD. Ligands for muscarinic receptors were synthesized enantioselectively in order to probe the steric environment of the receptor and as a possible method to probe receptor subtype selectivity.

The purpose of this study was to confirm the *in vitro* biochemical predictions of efficacy by measuring the physiological responses to these compounds at the synaptic level. The results obtained confirm the intrinsic (agonist/antagonist) activity predicted by the receptor binding assays.

The receptor binding assays employed displacement of ^{3}H-QNB from rat cortical MAChR to identify compounds that specifically interact with this receptor and the determination of K_i values for the competitive displacement of ^{3}H-QNB (antagonist) and ^{3}H-*cis*methyldioxolane (agonist) to characterize the compounds' intrinsic physiological activity (full or partial agonist, antagonist). Intrinsic activity was studied by *in vivo* examination of the effects of novel compounds on hippocampal pyramidal cells extracellulary by microiontophoresis. Microiontophoretic application of muscarinic agonists stimulates pyramidal cell firing, an effect which is blocked by iontophoresis of cholinergic antagonists and possibly, by weak partial agonists. Subtype selectivity was assessed by the competitive displacement of ^{3}H-pirenzepine from rat cortical membranes and ^{3}H-QNB from rat cardiac membranes.

Affinity Labeling of Muscarinic Acetylcholine Receptors: Covalent Modification of the Ligand Recognition Site. E. J. Arnold, R. M. Mangano, D. J. Critchett*, H. Brabander* and E.J. Trybulski*. American Cyanamid Company, Medical Research Division, Pearl River, NY 10965.

Muscarinic acetylcholine receptors (MAChRs) belong to a large class of peripheral and central nervous system receptors which couple to guanine nucleotide binding proteins during signal transduction. Five genes have been cloned from rat and human tissue that encode MAChRs. The coding regions of these genes have provided the biochemist with the primary amino acid sequences of these receptors and have suggested a tertiary structure of seven trans-membrane domains homologous to the proposed structure of bacteriorhodopsin. Neurotransmitters for this class of receptors are cations whose energy of interaction with the receptor is derived from ion-pairing with an anionic residue. Aspartic acid residues in two of the transmembrane helices are conserved throughout this receptor class and are likely candidates to fulfill this function. This information has been very useful in the design of experiments to elucidate how agonists and antagonists interact with these receptors as well as which features of these receptors can be targeted by synthetic ligands. Data from such experiments can be very useful in the design of specific drugs targeted to MAChRs.

The studies presented here describe the molecular pharmacology of novel oxotremorine (muscarinic agonist) derivatives. The compounds were synthesized optically pure to provide additional information about the stereochemical requirements of ligand binding to MAChRs. The results indicate that these compounds bind non-reversibly to MACHRs and that this reaction can be blocked by oxotremorine. This covalent attachment is time-dependent and apparently enantioselective. Intrinsic activity was assessed by *in vivo* recording from hippocampal pyramidal cells after microiontophoretic application of the compounds. The results of these experiments and the potential use of these compounds will be presented.

435.9

A NEW CLASS OF CHOLINERGIC ANTAGONISTS: ACRIDINE ARAPHANES HAVE A HIGH AFFINITY TO MUSCARINIC RECEPTORS.
K.P. Shaw[1], F.C.A. Silveira[1*], R.S. Aronstam[2] and E.X. Albuquerque[1,3]. [1]Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201, [2]Dept. Pharmacol. & Toxicol., Med. Coll. Georgia, Augusta, GA 30912 and [3]Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro 29141, Brazil.

Acridine araphane analogs (Himel et al., Science, 205:1277, 1979) are structurally similar to 9-amino-1,2,3,4-tetrahydroacridine (THA), which has been shown to improve the prognosis of patients with Alzheimer's disease. The objective of this study is to define the antagonistic efficacy of acridine analogs at nicotinic as well as muscarinic receptors. LD_{50}s in mice (i.p.) for 1,2 propane (1,2-PAA) 1,4-butane (1,4-BAA), 1,5-pentane (1,5-PeAA), 1,6-hexane acridine araphane (1,6-HAA), and THA were 87, 110, 70, 95 and 32 mg/kg, respectively. On muscarinic and nicotinic receptors, 1,2-PAA, 1,3-propane araphane acridine (1,3-PrAA), 1,4-BAA, 1,5-PeAA and 1,6-HAA inhibited the [^{3}H]-N-methyl-scopolamine (rat hippocampus, cortex, brain stem and atrium) and [^{125}I]α-BGT (Torpedo electric organ) binding to the receptors with IC_{50}s of 1-10 nM and 1-10 μM, respectively. pA_2 values of antagonist affinity from Schild plot for 1,4-BAA, 1,2-PAA in ileum-muscarinic receptor and atrium-muscarinic receptor were 9.2, 8.7 and 6.6, 6.9 respectively. These analogs (5-50 μM) reversibly blocked sciatic-sartorius indirect muscle twitch of frog. On endplate currents (EPCs) of frog sartorius muscles, 1,2-PAA, 1,3-PrAA, 1,4-BAA and 1,6-HAA displayed a voltage-dependent decrease the decay time constant and depression of the peak amplitude in a concentration (0.5-5 μM)-dependent manner. THA blocked the EPC decay and peak amplitude at 50 μM. 1,2-PAA, 1,4-BAA and 1,6-HAA enhanced desensitization in denervated rat muscles, but THA depressed the amplitude of acetylcholine transients. In summary, results from biochemical and biological assays demonstrated that the acridine araphanes have higher affinity than THA for cholinergic receptors. Furthermore, acridine araphanes have a higher affinity (100-1000 fold) for muscarinic receptors than for nicotinic receptor.

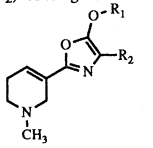
435.10

OXAZOLE DERIVATIVES OF ARECOLINE WITH HIGH AFFINITY FOR MUSCARINIC RECEPTORS IN RAT BRAIN.
W.S. Messer, Jr. C.H. Mitch, B.R. Ellerbrock*, F.P. Bymaster*, H.E. Shannon* and W. Hoss. Medicinal & Biological Chemistry, College of Pharmacy, Univ. of Toledo, 2801 W. Bancroft St., Toledo, OH 43606; Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

A series of alkoxy- and alkyl-oxazole derivatives of arecoline was synthesized for evaluation as novel muscarinic ligands. Substitution of the oxazole ring with either methoxy or propoxy moieties (R_1) and either 1-methylpropyl or 2-methylpropyl functions (R_2) led to ligands with markedly different binding properties.



LY 191492: R_1=propyl; R_2=1-methylpropyl

LY 209127: R_1=methyl; R_2=1-methylpropyl

LY 191309: R_1=propyl; R_2=2-methylpropyl

LY 242168: R_1=methyl; R_2=2-methylpropyl

Binding was examined through quantitative autoradiographic techniques in rat brain. The ability of each ligand to displace [^{3}H]-*l*-quinuclidinyl benzilate (QNB) binding to brain sections was compared with the known distribution of M_1 and M_2 muscarinic receptors as measured previously with pirenzepine and AF-DX 116. LY 191492 displayed the highest affinity for [^{3}H]-*l*-QNB binding sites, while LY 209127, LY 191309 and LY 242168 had lower affinities for muscarinic receptors.

Quantification of the autoradiograms indicated that LY 191492 bound with the highest affinity to M_1 receptors in the dentate gyrus (IC_{50} = 2.0 nM), and had a lower affinity for thalamic receptors (IC_{50} =19 nM). LY 209127 displayed a lower affinity for muscarinic receptors with IC_{50} values near 50 nM and a relative lack of selectivity. The binding of LY 191309 and LY 242168 was of even lower affinity especially for M_2 muscarinic receptors in the superior colliculus. The data indicate that the oxazole derivatives have a wide range of activities and different selectivities within the CNS.
Supported by NS 23929, NS 25765 and Eli Lilly and Company.

435.11

CHARACTERIZATION AND AUTORADIOGRAPHIC DISTRIBUTION OF [^{3}H]AF-DX 384 MUSCARINIC BINDING SITES IN THE RAT BRAIN.
S.Gauthier, D.Cécyre*, I.Aubert and R.Quirion. Douglas Hospital Research Centre, McGill University, Dept. Neurology & Neurosurgery and McGill Centre for Studies in Aging, Montreal, Quebec, Canada H4H 1R3.

Highly selective and specific radioligands are available for the study of muscarinic M1 receptor sites (e.g. pirenzepine). However, such probes are mostly lacking for the investigation of the M2 receptor subtype, although [^{3}H]acetylcholine, [^{3}H]oxotremorine-M, [^{3}H]*N*-methylscopolamine and [^{3}H]AF-DX 116 have been used in the past. We present here the characterization of [^{3}H]AF-DX 384 as a new selective M2 ligand.

[^{3}H]AF-DX 384 binds to saturable population of sites in rat forebrain membrane preparation with 75% to 80% of total binding being specifically bound at 2nM. The ligand selectivity profile reveals that (-)QNB (IC_{50}=0.5nM) is more potent than > atropine (0.6nM) > AQ-RA 741 (4.1nM) > AF-DX 384 (7.6nM) > UH-AH 371 (14.9nM) >> oxotremorine-M (81nM) > pirenzepine (220nM) >>> nicotine (>10uM). This suggests that [^{3}H]AF-DX 384 mostly binds to a M2-like population of muscarinic sites in the rat central nervous system.

This is further supported by an autoradiographic study which reveals a M2-like distribution pattern, with high labelling seen in areas such as the superior colliculus, pontine nucleus, motor trigeminal nucleus, certain thalamic nuclei and to some extent, in the cerebellum. Similar localization have been previously reported using other M2 receptor probes. However, autoradiograms are of better qualities with [^{3}H]AF-DX 384 because of the higher specificity and stability of this ligand. Thus, [^{3}H]AF-DX 384 should become a most useful probe for further characterization of brain M2 receptor sites. (MRC, Canada).

435.12

CHARACTERIZATION AND LOCALIZATION OF M_2 MUSCARINIC RECEPTORS LABELED WITH [^{3}H]AFDX384.
M. Hunt, M.E. Alburges, U. Busch[1], C.A. Belohlavek and J.K. Wamsley. Neuropsychiatric Res. Inst., Fargo, ND 58103; [1]Biochemistry Department, Thomae GmbH, Biberach FRG.

Thomae Company has introduced a new compound selective for the M_2 muscarinic cholinergic receptor subtype. This compound has been used to characterize M_2 receptor binding in tissue slices and to localize this receptor subtype by autoradiography. [^{3}H]AFDX384 was shown to label M_2 receptors in a selective manner and the binding was readily reversible and highly specific (85%). Saturation isotherms indicated a multiphasic binding pattern and conditions were restricted to obtain selective labeling to the high affinity sites which showed a K_d in the low nanomolar range.

Autoradiographic localization of M_2 sites with [^{3}H]AFDX384 indicate a predominance of these sites in regions of the brain formerly shown to contain significant concentrations of M_2 receptors. The order of binding was caudate-putamen = nucleus accumbens = superior colliculus > thalamus > nucleus of the solitary tract > cortex. [^{3}H]AFDX384 appears to be a viable ligand for use, under appropriate conditions, for obtaining specific labeling to M_2 receptors in the brain. The increased sensitivity and better stability make [^{3}H]AFDX384 superior to its predecessor, [^{3}H]AFDX116.

435.13

A NOVEL SIGNAL TRANSDUCTION MECHANISM FOR BRAIN MUSCARINIC RECEPTORS: STIMULATION OF ADENYLATE CYCLASE ACTIVITY.
P. Onali and M.C. Olianas. Department of Neurosciences, University of Cagliari, Italy.

In the central nervous system activation of muscarinic receptors has generally been shown to produce a decrease of cyclic AMP formation. We now report that in rat olfactory bulb homogenate carbachol (CCh) and other cholinergic agonists stimulate adenylate cyclase (a.c.) activity. The CCh stimulation shows a rapid onset, is readily reverted by atropine and is Ca^{2+}-independent, as it occurs in membranes prepared in the presence of 1 mM EGTA and incubated in a Ca^{2+}-free assay medium. Without added GTP, CCh fails to affect a.c.. With 1 mM CCh, the maximal stimulation is observed at 100 µM GTP (49 % increase of basal activity). The CCh response is not affected by staurosporine (0.01-1.0 µM), indomethacin (1-100 µM) and nordihydroguaiaretic acid (1-100 µM). Moreover, the muscarinic effect is additive with the enzyme stimulation elicited by phorbol 12-myristate 13-acetate (5 µM), is reduced by pertussis toxin (PTX) but not by cholera toxin.

These results indicate that in rat olfactory bulb muscarinic receptors are positively coupled to a.c. through a Ca^{2+}-independent and PTX-sensitive mechanism.

435.14

PHARMACOLOGICAL CHARACTERIZATION OF MUSCARINIC RECEPTORS MEDIATING ACETYLCHOLINE STIMULATION OF ADENYLATE CYCLASE IN RAT OLFACTORY BULB.
M.C. Olianas and P. Onali, Dept. of Neurosciences, University of Cagliari, Italy.

We have recently reported that in rat olfactory bulb acetylcholine (ACh) stimulates adenylate cyclase (a.c.) activity by acting on muscarinic receptors (Naunyn-Schmied Arch Pharmacol 1990). In the present study, we have investigated the pharmacological properties of the muscarinic receptors mediating the stimulation of a.c.. These receptors were activated by ACh in a concentration-dependent manner (EC 50 = 0.3 µM) with a maximal increase reached at 100 µM ACh. Different cholinergic agonists mimicked the effect of ACh with the following rank order of potency : oxotremorine ≥ oxotremorine M > ACh > carbachol=methacholine > bethanechol. As compared to ACh, the relative efficacies of oxotremorine and bethanechol were equal to 75% and 40%, respectively. Different muscarinic receptor antagonists competitively counteracted the ACh effect with the following ki values: atropine 0.6 nM, 4-DAMP 5 nM, AF-DX 116 130 nM, pirenzepine 310 nM. These results indicate that the muscarinic receptors mediating stimulation of a.c. are pharmacologically different from M_1 and cardiac M_2 and similar to M_3 receptor subtypes.

435.15

EVIDENCE FOR THE PRESENCE OF A NONCLASSICAL M4 PHARMACOLOGICAL MUSCARINIC RECEPTOR SUBTYPE (mAChR) IN RAT BRAIN REGIONS DETECTED BY A NOVEL MUSCARINIC ANTAGONIST DAU 6202. H. Ladinsky and G.B. Schiavi*. Department of Biochemistry and Molecular Pharmacology, Istituto De Angeli, Boehringer Ingelheim Italia, Milano 20139 Italy.

Inhibition of (^{3}H)PZ binding to cortical M1 mAChRs and (^{3}H)NMS binding to cardiac M2, glandular M3 and brain regional mAChRs was studied with a new antimuscarinic, DAU 6202 (4-hydroxy-3-(tropyl) oxycarbonyl-3,4-dhydro-1 H-quinazoline-2-one). DAU 6202 bound to the mAChRs with K_Ds of (nM): 1.8, M1; 4.3, M3; 204, M2. In striatum, a shallow inhibition curve was seen showing that DAU 6202 bound to a heterogeneous population of sites. Computer analysis showed that DAU 6202 bound 31% of total sites with a K_D of 3 nM and 69% with a K_D of 42 nM. The 3 nM site likely represents M1 and M3 mAChRs detected by blot hybridization (Buckley et al., J. Neurosci. 8, 4646, 1988). The 42 nM site, non M1, non M2, non M3 (termed M4), may be the m4 mAChR recognized by hybridization. In other brain regions, DAU 6202 gave shallow inhibition curves revealing M4 sites of major proportions, i.e. cortex, 38%; hippocampus, 33%; olfactory bulb, 46%; hypothalamus, 56% of total sites.

NEURONS IN THE VENTRAL PART OF THE NUCLEUS TRACTUS SOLITARIUS EXHIBIT MULTIPLE TYPES OF CALCIUM CURRENTS. M.S. Dekin, Comparative Neurobiology and Physiology Group, School of Biological Sciences, University of Kentucky, Lexington, KY 40506-0225.

Premotor respiratory neurons in the guinea pig are located in the ventral parts of the nucleus tractus solitarius (vNTS). Using brainstem slices from adult guinea pigs, the properties of calcium currents in identified bulbospinal neurons in the vNTS were studied. Two types of calcium currents could be distinguished using the single electrode voltage clamp technique; a low voltage-activated (LVA) current which was expressed during depolarizations between -50 and -20 mV and a high voltage-activated (HVA) current which was expressed during depolarizations more positive than -35 mV. Both the LVA and HVA currents were blocked by the addition of 1 mM Cd^{++} to the bath. During the course of a 500 msec step depolarization to -30 mV from a holding potential of -50 mV, the LVA current exhibited almost complete inactivation. Partial inactivation of the HVA current was also observed but was much slower in onset. During similar depolarizations from holding potentials more positive than -50 mV only the HVA current was observed suggesting that the LVA current underwent steady-state inactivation. Under these conditions, the LVA current could only be observed when depolarization was preceded by a hyperpolarizing voltage step to levels more negative than -50 mV. These data suggest that expression of the LVA calcium current during inspiratory phase depolarization in premotor respiratory neurons would be dependent upon the level of membrane hyperpolarization achieved during previous expiratory phase inhibition. (Supported by NIH grants HL40369 and HL02314, and University of Kentucky BRSG Grant RR07114).

436.2

EFFECT OF HISTOTOXIC ANOXIA ON HYPOGLOSSAL NEURONS STUDIED BY WHOLE-CELL PATCH-CLAMP. T.R. Cummins*, D.F. Donnelly and G.G. Haddad, Dept. of Pediatrics (Div. Respiratory Medicine), Yale Univ., New Haven, CT 06510.

During anoxia, brainstem neurons in the slice preparation show an increase in excitability while hippocampal neurons show a decrease. In this work, we study the membrane properties of acutely isolated Hypoglossal [XII] neurons during anoxia and compare them to Hippocampal CA1 cells using the whole-cell patch-clamp technique. Neurons dissociated from XII of 7 and 26 day old rats exhibited resting potentials in the range of -43 to -70 mV and action potentials of 75 to 105 mV in the current clamp mode. These neurons fired repetitively with little adaptation and no delayed excitation (A-current). Cyanide (CN) depolarized XII neurons and caused an increase in excitability (n=8). When recording in the voltage-clamp mode, CN (4mM) caused an increase in the voltage-dependent outward current (121±5% of control, mean + SEM, n=13) and in 7 out of 8 cells CN increased the voltage-dependent inward current (stepping from -100 mV to -10 mV). These results show that 1) acutely isolated Hypoglossal neurons can be studied using whole-cell patch-clamp, 2) in contrast to Hippocampal CA1 neurons (Fed. Proc. 4:A405, 1990), CN causes an increase in the voltage-dependent inward and outward currents of XII neurons and 3) differences between brain regions in neuronal response to hypoxia may be due to intrinsic neuronal properties.

436.3

CHEMOSENSITIVITY OF MEDULLARY AND HYPOTHALAMIC NEURONS IN CELL CULTURE. W. Chou, J.A. Neubauer, H.M. Geller and N.H. Edelman.* UMDNJ-Robert Wood Johnson Medical School, New Brunswick, N.J. 08903.

To determine whether dissociated neurons in vitro retain the function of CO_2 chemosensitivity and whether this is specific to the ventral medulla, CO_2 sensitivity was characterized in neurons (1-4 weeks in vitro) using loose-cell patch recordings (Rs 77±10 MΩ). Dissociated cell cultures were prepared by enzymatic and mechanical treatment of ventral (VM) and dorsal (DM) medulla of neonatal rats and medulla (MED) and hypothalamus (HYPTH) of E17 rats. Spontaneously active neurons were found in all brain regions: VM 8/45, DM 2/12, MED 27/56 and HYPTH 40/114. Although spontaneous activity increased (5% to 40%) from 1 to 4 weeks in vitro, firing frequency (range <1-4 Hz) was unchanged. Superfusate pH was varied by altering PCO_2 (14-71 Torr). While 55% of neurons were unresponsive to changes in pH, increases (20%) and decreases (25%) in activity with acidosis were observed in all regions. We conclude that: (1) neurons in dissociated cell culture retain the function of CO_2 chemosensitivity; (2) CO_2 chemosensitivity is present in both medullary and hypothalamic cell cultures; and (3) as previously shown, the number of spontaneously active neurons increases with time in culture due to the development of functional synaptic connections. Supported by HL33938, HL16022 and NS24168.

SPINAL EFFECTS OF TACHYKININ PEPTIDES ON RESPIRATORY PUMPING MUSCLES. M.A. Haxhiu*, B. Erokwu*, E. van Lunteren, and N.S. Cherniack. Departments of Medicine and Neurosciences, Case Western Reserve University, Cleveland, OH.

The tachykinin peptides and their receptors [e.g. substance P (SP) and neurokinin A (NKA)] are present in the spinal cord, including the ventral horn. Their role in the regulation of respiratory pumping muscle activity at the spinal level is not well understood. In anesthetized spontaneously breathing cats we examined the effects of SP and NKA administered into the spinal intrathecal space at C5-C7 on the electromyographic activity of the diaphragm (D_{EMG}), inspiratory parasternal intercostal (Ii_{EMG}) and expiratory triangularis sterni (Ei_{EMG}) muscles. SP in doses of 10-100 nmol increased the electrical activity of the respiratory muscles in 8 of 10 cats, causing D_{EMG} to change from 21 ± 2 to 29 ± 4 units ($p < 0.05$), producing an increase of Ii_{EMG} from 16 ± 3 to 27 ± 4 units ($p < 0.05$), and elevating Ei_{EMG} from 12 ± 2 to 25 ± 3 units ($p < 0.05$). Similar stimulatory effects occurred following NKA given to 2 cats. Tachykinins administered to the spinal cord caused an insignificant change in inspiratory and expiratory timing, and induced a slight but insignificant increase in arterial blood pressure (16 ± 8%) and heart rate (2 ± 1%). The results suggest that mammalian tachykinins might be involved in the regulation of respiratory muscle activity by acting directly on motoneurons or interneurons at a spinal level.

GLUTAMATE AND GABA CONTENT OF MICRODIALYSATES FROM CAT PHRENIC NUCLEUS. C.A. Connelly, L.L. Sommers*, & J.L. Feldman. Systems Neurobiology Laboratory, Dept. of Kinesiology, UCLA, Los Angeles, CA 90024-1568.

In vivo microdialysis was used to directly assay the glutamate (GLU) and GABA content in the phrenic nucleus (PN) in chloralose-urethane anesthetized, vagotomized, artificially ventilated cats. The PN in the C5 segment of the spinal cord was localized by mapping with a saline-filled extracellular microelectrode. The recording electrode was then removed and the microdialysis probe (1 mm length x 500 μm diameter dialysis membrane) inserted at the location where spontaneous inspiratory-modulated discharge was recorded and antidromic spikes were elicited by stimulation of the phrenic nerve. The probe was perfused with Ringer's solution (pH=7.5) at a rate of 1 μl/min for collection (every 20 minutes) of samples (20 μl) containing dialyzed amino acids from the extracellular fluid in the PN. Amino acid content of each sample was determined by high performance liquid chromatography with electrochemical detection (BAS 200). Mechanical insertion of the probe into the PN initially caused enhanced, non-specific amino acid release, with the initial dialysates containing GLU levels of 27 pmoles/10 μl and GABA levels of 1.4 pmoles/10 μl. After stabilization of the probe *in situ* for 1-3 hours, levels of GLU in the PN dialysates decreased to steady-state levels of 3 to 6 pmoles/10 μl, and remained constant for 4-8 hours. GABA levels in the dialysates ranged from 0.5-1.0 pmoles/10 μl after reaching the steady-state. The concentration of amino acid in the PN was estimated to be 10 times that of the dialysates. This estimate is based on a 10% efficiency of dialysis probe recovery of amino acid content in a sampled region, as calculated from *in vitro* testing of probe recovery characteristics in known concentrations of amino acid standards. After each experiment, the probe locations were verified histologically and found to be centered in the PN. The extracellular content of GLU and GABA in the PN is consistent with the hypotheses that GLU and GABA mediate bulbospinal excitatory (inspiratory) and inhibitory (expiratory) inputs on phrenic motoneurons, respectively. Research supported by NIH grant HL 37941. CAC is a Parker B. Francis Foundation Fellow.

MULTIPLE NEUROMESSENGERS ARE CONTAINED IN TERMINAL VARICOSITIES IN RAT PHRENIC NUCLEUS. H.H. Ellenberger[1], P.L. Vera[2], J.L. Feldman[1] & V.R. Holets[2]. [1]Systems Neurobiology Lab., Dept. of Kinesiology, UCLA, L.A., CA 90024-1568 and [2]Univ. of Miami Medical School, Dept. of Neurological Surgery, Miami, FL 33136.

Combined horseradish peroxidase labeling of phrenic motoneurons and immunohistochemical detection of 9 putative neuromessengers (5-hydroxytryptamine [5-HT], substance P [Sub. P], thyrotropin-releasing hormone [TRH], methionine enkephalin [M. Enk], neuropeptide Y [NPY], polypeptide YY [PYY], cholesystokinin [CCK], somatostatin [SST] and neurotensin [NT]) revealed that a wide variety of neuromessengers are contained within terminal varicosities in the phrenic nucleus. The rank order for the relative degree of terminal labeling (based on visual inspection) in the phrenic nucleus was:

5-HT≈Sub. P>CCK>M. Enk≈TRH>NPY≈PYY≈SST>NT

The indirect immunofluorescence technique was utilized to demonstrate colocalization of 5-HT with either Sub. P, TRH or M. Enk within terminal varicosities in the phrenic nucleus. The coincidence of double-labeling varied for each peptide colocalized with 5-HT. Almost all varicosities labeled for 5-HT were also labeled for Sub. P. Some Sub. P labeled varicosities were not labeled for 5-HT, indicating a partial coexistence of SP with 5-HT. All TRH positive terminals were labeled for 5-HT, but there were some 5-HT labeled terminals not labeled for TRH. Varicosities labeled for both 5-HT and M. Enk. showed the lowest level of double-labeling, with many varicosities labeled for only 5-HT or M. Enk. These results indicate that phrenic motoneurons are subject to many sources of modulation that can alter their responsiveness to primary excitatory and inhibitory inputs. The ubiquitous presence of peptides within 5-HT neurons and possible corelease of these peptides with serotonin must be accounted for in studies of the role of the raphe nuclei in the control of breathing. Supported by NIH grants NS 24742 and HL 37941.

DIFFERENTIAL EFFECTS OF ANESTHESIA ON THE CO2 RESPONSES OF EXPIRATORY BULBOSPINAL (EBS) NEURONS AND PHRENIC NERVE ACTIVITY OF VAGOTOMIZED DOGS. E. Stuth, M. Tonkovic-Capin, E. Zuperku, and J. Kampine*Medical College of Wisconsin and VA Medical Center, Milwaukee, Wi 53295.

Data regarding the effects of various anesthetic regimens on central inspiratory (I) and expiratory (E) neural activities in form of CO2 response curves were obtained. Intravenous sodium thiopental (STP) monoanesthesia was compared with isoflurane (ISO) monoanesthesia at depths ranging from 0.5 to 2.5 minimum alveolar concentrations (MAC) as well as with combinations of the two anesthetics (STP + ISO). Hyperventilation with O2 and the addition of CO2-O2 mixtures were used to produce 3 levels of central CO2-drive, low(L), medium(M), and high(H) for each anesthetic depth. Plots of peak EBS neuron discharge frequency (Fn) vs increasing depth of anesthesia showed a progressive decrease in Fn for H and M drive levels. At L drive most EBS neurons fired tonically at all levels of anesthesia with little change in Fn. Peak phrenic activity (PPA) showed a more pronounced decline with increasing anesthetic depth at all levels of drive. Phrenic activity ceased at 2-2.5 MAC ISO monoanesthesia and at 1 MAC STP + ISO combination anesthesia even at H CO2 drive, while EBS neurons continued to fire tonically at 20-60 % of Fn at 1 MAC-H or STP-H levels of the monoanesthetic regimens. Our studies suggest that (1) I neurons are more sensitive to increasing depth of anesthesia than are E neurons, and (2) combinations of intravenous STP basal anesthesia and ISO inhalational anesthesia cause more pronounced decreases in central I activity than the respective monoanesthetic regimens.

UNILATERAL VENTROLATERAL MEDULLA (VLM) ELECTROLYTIC LESIONS RESULT IN APNEA OR DECREASED PHRENIC ACTIVITY AND DECREASED CO_2 SENSITIVITY IN THE ANESTHETIZED CAT. Eugene E. Nattie, Aihua Li* and Walter M. St. John*. Dartmouth Medical School, Hanover, N.H., 03756 and Jinling Hospital, Nanjing, P. R. C.

In previous studies, 10 nL injections of the neurotoxin, kainic acid, or the excitatory neurotransmitter, glutamate, in a region of the VLM ventral and ventromedial to the facial nucleus extending caudally to the level of the rostral aspect of the inferior olive resulted in phrenic apnea or decreased phrenic activity and decreased CO_2 sensitivity. To ascertain why both a destructive toxin and an endogenous excitatory amino acid should have the same effects, we produced unilateral lesions in decerebrate or chloralose urethane anesthetized, vagotomized, glomectomized, paralyzed, and servo-ventilated cats. Large radiofrequency lesions (70°C; 1 min) which included this region resulted in apnea. Smaller electrolytic lesions (5-10 mA; 15 sec) which included, and in some cases were limited to, this region resulted in apnea or decreased phrenic activity and decreased CO_2 sensitivity. Stimulation prior to lesioning increased phrenic activity. We conclude that kainic acid injections and lesions destroyed cells in this region which appear to be a source of tonic excitatory input for ventilatory activity. We interpret the inhibitory effects of glutamate injections as due to depolarization blockade. (Supported by HL 28066).

PARABRACHIAL NEURON DISCHARGE IS ALTERED DURING THE CARBACHOL INDUCED REM SLEEP-LIKE STATE (DCARB). K.A. Gilbert and R. Lydic. Department of Anesthesia, Pennsylvania State University, College of Medicine, Hershey, PA, 17033.

The parabrachial nuclei are known to play a role in cardio-respiratory control. Some parabrachial neurons reveal altered discharge during rapid eye movement (REM) sleep but the mechanisms mediating these state-dependent firing rates remain poorly understood. Encouraged by the finding that microinjections of carbachol into the medial pontine reticular formation (mPRF) of intact, unanesthetized cats produce state-dependent respiratory changes paralleling those observed during REM sleep (Lydic & Baghdoyan, *Neurosci. Letts. 102*:211,1989), this study is testing the hypothesis that cholinergic mechanisms in the mPRF can also cause state-dependent changes in the discharge of parabrachial neurons. To date, 9 cells have been recorded with extracellular electrodes aimed for the parabrachial region in 4 cats. Cells were recorded across 16 cycles of waking (W), NREM, and REM sleep, and in 9 DCarb episodes. Qualitatively, cells included tonic and phasic respiratory and non-respiratory modulated neurons. Relative to W, 7 cells increased firing (mean % change) during both REM (40.6%) and Dcarb (36.1%) and 2 cells decreased in REM (34.3%) and Dcarb (47.9%). The 7 REM-on cells revealed firing rates in Dcarb which were not significantly different from firing rates in REM. These results are consistent with the hypothesis that cholinergic mechanisms in the mPRF can cause state-dependent changes in the discharge of parabrachial neurons.

MEDULLARY SINGLE UNIT RESPONSES TO SYSTEMIC HYPOXIA (HYP) IN CHEMODENERVATED CATS. J. Mitra, N.B. Dev*, J.R. Romaniuk*, R. Trivedi*, and N.S. Cherniack. Department of Medicine, Case Western Reserve University, Cleveland, OH 44106.

We studied the effects of HYP (6% O_2) on 45 single medullary units located within 2mm of the ventral surface (P 8.0-P 12.0) in peripherally chemodenervated cats while recording phrenic and sympathetic activity.

Twenty seven percent (12 units) increased their activity during HYP. All of these units discharged tonically during normoxia. Three units discharged continuously throughout HYP but none could be antidromically (AD) activated from the intermediolateral cell column (IML). However, two of these units could be excited by proprioceptive stimuli. Five units had a biphasic response with initial excitation followed by depression and then by reappearance of excitation. A portion of these units could be stimulated AD but not by proprioceptive input. Units excited by HYP could be found both rostrally and caudally. No units with respiratory modulation (4 tested) increased by hypoxia.

Our results suggest that there are tonically discharging units in the ventral medulla that can be excited by hypoxia. Only a portion of these seem to project to the IML.

Support: NIH HL-25830.

RESPIRATORY PATTERNING FOLLOWING COCAINE ADMINISTRATION TO THE CENTRAL NUCLEUS OF THE AMYGDALA. R.K. Harper, R.R. Terreberry, R.C. Frysinger, C.A. Richard and R.M. Harper. Brain Research Institute and Department of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

We examined patterning of laryngeal dilator and diaphragmatic activity in intact, freely moving cats following administration of 3 dose levels of cocaine (0.625, 1.25, 2.5 mg) to the central nucleus of the amygdala (ACE). Diaphragmatic and laryngeal dilator EMG, EEG, nuchal EMG, EOG, hippocampal slow wave, and brain and core temperature recordings were continuously gathered before and following cocaine administration through an indwelling brain cannula. Both low- and high-dose cocaine administration was followed by tachypnea; panting intermixed with tachypnea also accompanied high-dose injection. Direct administration of cocaine to the ACE thus resulted in respiratory patterns similar to those observed following intravenous and intraventricular administration described earlier. We suggest that the ACE projections to phase-switching areas in the pons or the projections to the nucleus of the solitary tract may mediate a portion of the respiratory pattern changes following cocaine administration.

MU VERSUS DELTA OPIOID RECEPTORS IN THE MODULATION OF RESPIRATORY PATTERN AND CONTROL IN EARLY POSTNATAL LIFE. S.C. Scott , J.D.G. Inman and I.R. Moss. Depts. of Pediatrics and Physiology, UT Southwestern, Dallas, TX 75235.

Endogenous opioid systems participate in the modulation of respiratory pattern and control in perinatal life. In an effort to determine which opioid receptor is responsible for this modulation, naltrexone (mu>delta>kappa antagonist) or naltrindole (delta antagonist) was administered intravenously to chronically instrumented, unanesthetized piglets. In 6-10 day old piglets, 1-2 mg/kg of naltrexone increased breathing frequency, the amplitude and rate of rise of diaphragmatic electromyographic activity (EMGdi) and the amplitude, rate of rise, total area and initial area of the posterior cricoarytenoid EMG activity (EMGpca); it decreased the duration of EMGdi activity as well as heart rate and mean arterial pressure. In 4-7 day old piglets, preliminary results with naltrindole at an optimal dose of 4 mg/kg showed an increase in the interval between EMGpca and EMGdi activation and in heart rate. From these results we conclude that the mu opioid system plays a greater role in influencing respiration than does the delta opioid system. (Supported by NIH HL36939 and HL07362).

DIFFERENTIAL RESPONSE TO CYANIDE AND HYPOXIA OF ADULT CAROTID BODY GLOMUS CELLS. D.F. Donnelly, T.R. Cummins and G.G. Haddad. Dept. of Pediatrics, Yale Univ. School of Medicine, New Haven, CT 06510

Both cyanide and hypoxia stimulate carotid chemoreceptors, in vivo and in vitro, but the mechanism(s) of this stimulation is obscure. To investigate the transduction process, we examined the membrane currents of glomus cells which were acutely dissociated from adult rabbit carotid bodies. Glomus cells were identified by their morphologic appearance, binding of FITC-a-bungarotoxin and ability to generate action potentials. Cells were bathed in HEPES buffer at 25C and recorded using whole-cell patch technique. During the experimental period, the cells were stepped from -70 mV to 0 mV every 6 sec. Histotoxic anoxia was induced using brief applications (5-20 sec) of NaCN (2-4 mM) in HEPES buffer. Hypoxic hypoxia was induced by application of HEPES buffer equilibrated with nitrogen (PO2<10 mmHg). Cyanide caused a significant increase in late outward current (139±4% of control, mean±SEM, n=12) which occurred in all cells studied. Hypoxic hypoxia caused a significant decrease in the late outward current (mean= 66.4±2.7%, n=9). Neither agent affected voltage-dependent inward current. These results shows that histotoxic hypoxia and hypoxic hypoxia cause changes in the voltage-dependent outward current of glomus cells and suggest a fundamental separation of transduction processes for the two stimulatory agents.

ULTRASTRUCTURAL ANALYSIS OF POTENTIAL CHEMO/BARO-RECEPTOR CELLS IN THE MIDDLE EAR TYMPANIC PLEXUS OF A PRIMATE. P.J. Gannon[1], K.J. Chandross[2] J.T. Laitman[3*] and A.R Eden[4]. Dept. Otolaryngology, Mount Sinai Med.Ctr.[1,3,4] New York, NY 10029, and Dept. Neurosciences, Albert Einstein Coll. Med.[2], Bronx, NY 10461.

The maintenance of a stable environment in the middle ear air space is critical for efficient transference of airborne sounds to the fluid-filled inner ear and organ of corti. In most mammals (including humans) auditory performance is critically related to individual fitness. As such, evolutionary processes must have been operating under strong selective pressures, especially with the advent of speech in modern humans where auditory-vocal communication became the primary interactive medium.

The neural mechanisms underlying homeostasis of middle ear gas (air) composition and pressures are only just starting to be understood. We have demonstrated neural connections between the middle ear and respiratory brainstem centers which may subserve such a mechanism. Although the circuitry has been established, the identity of the middle ear sensory modality remains unknown. Our work has focussed on a population of cells, the glomus/ganglion cell clusters of the middle ear tympanic plexus, which show some similarities to those of the carotid body/sinus, and may represent an analogous sensory apparatus. We have suggested that the late appearance of these cells during primate development may be related to the extremely high incidence of otitis media in human infants. In the present study we saw degenerating axosomatic synapses on glomus cells, bilaterally, after unilateral SCG'ectomy. The cell clusters, comprising approximately 100-150 cells are thus associated with both sensory and autonomic elements. Ultrastructural analysis did not reveal features which characterize carotid system sensory elements, such as large dense cored vesicles and fenestrated endothelia. However, their function as chemo/ baro-receptors could not be ruled out. For example, the clusters were often associated with an extensive and tortuous vascular bed, suggesting a (middle ear) blood gas/pressure sampling system with perhaps different physiologic characteristics than the carotid system.

ALTERATIONS OF TOTAL LUNG RESISTANCE (TLR) EVOKED FROM CAUDAL VENTROLATERAL MEDULLA (CVL) AND ROSTRAL VENTROLATERAL MEDULLA (RVL) IN DOGS. J.R. Haselton, P.A. Padrid* and M.P. Kaufman*. Div. of Cardiovascular Medicine, Univ. California, Davis, CA 95616

A previous report from this laboratory demonstrated that chemical stimulation of neuronal cell bodies in CVL, in the dog, resulted in a reduction of TLR due to the withdrawal of cholinergic bronchomotor tone (J. Appl. Physiol., 63:912-917). The RVL was not examined in that study. In the present study, triple-barrel micropipettes were used to explore CVL and RVL for bronchomotor responses. Each barrel was filled with one of the following: 100 mM DL-homocysteic acid (DLH), 0.9% NaCl, or 2% Fast Green. All substances were adjusted to a pH of 7.40 using HCl or NaOH. Microinjections (25 nl) were made in the ventrolateral medulla at levels ranging from the obex to the caudal pole of the facial nucleus. All sites were verified histologically following the experiment.

In CVL DLH, but not saline, elicited a decrease in TLR (8.2±0.7 to 6.7±0.6 cm H_2O/l/s) and a reduction in blood pressure (BP; 133±4 to 81±15 mm Hg) at 5 sites. One site, in the nucleus ambiguus, evoked an increase in TLR (6.6 to 8.1 cm H_2O/l/s) a reduction in BP (124 to 66 mm Hg) and a profound bradycardia (134 to 2 bpm). In RVL DLH, but not saline, produced: a) an increase in TLR (6.4±0.5 to 8.7±1.2 cm H_2O/l/s) and BP (120±9 to 164±15 mm Hg) at 9 sites, b) a decrease in TLR (8.8±0.5 to 8.0±0.5 cm H_2O/l/s) and increase in BP (138±4 to 161±6 mm Hg) at 3 sites, or c) an increase in BP (125±11 to 143±9 mm Hg) without a change in TLR at 5 sites. The RVL sites, from which an increase in TLR was elicited, were consistently placed ventral to the nucleus ambiguus. Pressor sites which did not elicit a change in TLR as well as those which evoked a decrease in TLR were located either medial (n=7) or lateral (n=1) to those which evoked an increase in TLR. The increase in TLR elicited from RVL was not altered following propranolol (1.5 mg/kg; iv) but was abolished by atropine methyl nitrate (1 mg/kg; iv). We conclude that CVL inhibits, while RVL activates, cholinergic drive to the airways.

ROLE OF CAPSAICIN-SENSITIVE BARO- AND CHEMO-AFFERENTS IN THE CONTROL OF BLOOD PRESSURE AND RESPIRATION. G. Daniell* and T. R. LaHann. College of Pharmacy, Idaho State University, Pocatello, ID 83209

Although capsaicin inactivates small diameter sensory neurons, most reports suggest that capsaicin pretreatment has little or no effect on blood pressure or respiration. This implies that unmyelinated afferents are unlikely to be important for control of respiratory or cardiovascular function. Our results do not entirely support this interpretation. We have investigated the effect of local application of capsaicin on baro- and chemo-afferent function. Capsaicin or its vehicle was applied to the vagus, carotid sinus and glossopharyngeal nerves. Baroreflex function was evaluated 2 hours post treatment in unconscious rats and 24 hours post treatment in conscious, freely moving rats. Neither capsaicin nor its vehicle altered the relationship between pressor responses and bradycardia in conscious rats. In anesthetized rats, capsaicin pretreatment altered the nature of the baroreflex response without attenuating it. Local application of capsaicin to anesthetized rats also blocked the tachypneic response to stimulation of carotid chemoreceptors (evoked by i.v. cyanide) and eliminated chemoreceptor-induced pressor responses. We interpret these results to mean that capsaicin-sensitive chemoafferents may be important in the control of respiratory function, but that capsaicin-sensitive baroafferents are unlikely to modulate baroreflex function in conscious animals under low stress conditions.

TRIGEMINAL INJECTIONS OF LIDOCAINE INHIBIT THE CARDIORESPIRATORY RESPONSES TO STIMULATION OF THE SUPERIOR LARYNGEAL NERVE IN THE MUSKRAT. W.M. Panneton. Dept. of Anat. & Neurobiol., St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Electrical stimulation of the superior laryngeal nerve (SLN) induces apnea and bradycardia, similar to the responses seen after stimulation of the nasal cavity with ammonia. The SLN contains primary afferent fibers which project to both the nucleus tractus solitarii and the caudal trigeminal complex (MDH). The purpose of this study was to determine if blocking the trigeminal projection affects the cardiorespiratory responses to SLN stimulation.

Muskrats were anesthetized, their SLN isolated bilaterally, and placed on hook electrodes. Respirations, heart rate and arterial pressure were monitored on a physiograph. Bilateral injections (100-200nl) of 2% lidocaine were placed in the MDH and the SLN stimulated (0.5-4mA; 10-40Hz; 5s). When both the lidocaine injections were placed in ventral parts of the rostral MDH, especially those centered in laminae I and II, the apnea and bradycardia usually elicited by SLN stimulation were reversibly inhibited. These data suggest trigeminal neurons are important for the cardiorespiratory responses after SLN stimulation. Moreover, the rostral MDH may modulate the autonomic responses to stimulation of the whole upper respiratory tract since similar injections inhibit the responses seen after nasal stimulation. Supported by NIH grant HL 38471.

DETERMINISTIC BREATHING PATTERNS AS REVEALED BY RECURRENCE PLOTS OF DYNAMICAL SYSTEMS. Charles L. Webber, Jr. and Joseph P. Zbilut*. Department of Physiology, Loyola University of Chicago, Maywood, IL 60153 and Departments of OR/Surgical Nursing and Physiology, Rush Medical College, Chicago, IL 60612.

Several methods have been devised for the computation of dynamical parameters from time series (correlation dimension, entropy, Liapunov exponents, etc.), all of which assume stationarity in the original data. However, another powerful technique of nonlinear dynamics has been introduced, the recurrence plot, which reportedly has the ability to discriminate subtle time-correlation information in time-varying data that are otherwise inaccessible (Europhys. Let. 4:973-977, 1987). To test the utility of this remarkable graphical tool on a physiological system with inherently adiabatic (slowly changing) properties, intrathoracic pressures were recorded from unanesthetized rats during daytime sleep and wakefulness. Derived respiratory cycle times were used to generate recurrence plots by placing points on a square array whenever two points were within a specified distance of each other depending upon the selected embedded dimension. The results revealed deterministic patterns in the respiratory controller, especially in the awake state, which were comparable to standard mathematical chaotic systems (Henon attractor, quadratic difference equation). It is concluded that recurrence plots are very valuable in diagnosing subtleties in dynamical systems.

REGULATION OF AUTONOMIC FUNCTION: CONTROL OF LUMBOSACRAL AUTONOMIC OUTFLOW

LIMIT CYCLE AND NEGATIVE FEEDBACK IN BLADDER CONTROL FOLLOWING SPINAL CORD INJURY. J.S. Walter, P. Zaszczurynski*, J.S. Wheeler*, R.D. Wurster. Rehab. R&D Center, Hines VA Hosp., Hines, IL 60141.

We have begun to explore models of a bladder control system following spinal cord injury by conducting perturbation analysis and nerve anesthesia/stimulation studies. Periodic bladder contractions occurred in chronic, unanesthetized, spinal-injured, male cats (T-1) when the bladder volume was maintained above the micturition threshold, 30 to 60 ml. A perturbing volume of 3 to 5 ml phase advanced or delayed the bladder contraction depending on whether the volume was added or withdrawn respectively. The period, however, was unchanged. These observations are typical for rhythms controlled by a stable limit cycle system.

In addition to the known positive feedback for bladder control, the presence of negative feedback was indicated in the anesthetized animal by comparing declines in bladder contractions when the pelvic nerves were intact and after direct bladder stimulation with crushed pelvic nerves. In both cases declines in pressure had similar slopes. Therefore, with intact pelvic nerves, declines in bladder pressure during spontaneous bladder contractions may be due to inhibitory processes or "turning off" pelvic motor activity, analogous to turning off our direct bladder stimulator. Supported by Rehab. R&D Center and Merit Review Grant B441.

437.2

ROLE OF CRF AND 5HT IN CENTRAL PATHWAYS CONTROLLING MICTURITION IN THE RAT. T.Suzuki, M.Kawatani, S.Erdman*, W.C.deGroat, Dept of Pharmacology and Behavioral Neuroscience, University of Pittsburgh, Pgh., PA 15261.

Bulbospinal pathways from the pontine micturition center (PMC) and raphe nuclei to the parasympathetic nucleus in the lumbosacral spinal cord of the rat contain CRF and 5HT, respectively, and have been implicated in the central control of micturition. The present study examined the role of these pathways in regulating bladder reflexes (BR) in urethane anesthetized rats. In normal rats distension of the urinary bladder (UB) evoked rhythmic bladder contractions and firing on UB postganglionic nerves. BR were acutely blocked by bilateral electrolytic lesions (2mA,10sec) in the PMC but recorded 7 days after the lesions. Intrathecal (IT) injections (L_1-L_2 segment) of CRF (0.3-30µg) depressed BR. Pretreatment of rats 7 days prior to experiments with 5,7-dihydroxytryptamine (100µg,IT) a toxin that destroys 5HT axons did not block BR induced by UB distension or by electrical stimulation of UB afferents, however in 50% of the animals did produce hyperactive UB activity.

These data suggest that pathways from the PMC and from 5HT neurons in the raphe nuclei have facilitatory and inhibitory influences, respectively, on micturition. Since IT CRF inhibits UB activity it seems likely that this peptide is not the transmitter in the descending excitatory pathway from the PMC to the lumbosacral parasympathetic nucleus.

437.3

THE EFFECTS OF MK-801 ON THE MICTURITION REFLEX IN THE RAT - POSSIBLE SITES OF ACTION. M. Yoshiyama, J.R. Roppolo, V. Erickson* & W.C. de Groat. Univ. of Pittsburgh, Sch. of Med., Dept. of Pharmcol. Pittsburgh, PA 15261.

The possible sites of action and effects of MK-801 (1µg-30mg/kg I.V.) on bladder pressure recorded via a transurethral catheter were compared in five preparations: 1) Intact rats 2) Chronic spinal (T6 - T8) rats 3) Unanesthetized decerebrate rats 4) Intact rats tested 17-24 hours following reserpine (5mg/kg I.M.) 5) Intact rats with MK-801 given via intrathecal (I.T.) catheter at the L6-S1 spinal cord segment. Animals were anesthetized with urethan (1.2gm/kg S.C.) except the decerebrated animals, whose surgery and precollicular decerebration was performed under halothane (2.5%) anesthesia. MK-801 (0.3-1mg/kg I.V.) given to intact rats produced complete inhibition of bladder activity. In decerebrate and chronic spinal animals the same and considerably higher doses (3-30mg/kg I.V.) produced little or no effect on bladder activity. Intrathecal administration of MK-801 to intact rats inhibited bladder contractions at a total dose of 12-36 ug. Reserpine pretreatment prevented the inhibition produced by MK-801 in 50% of the animals tested. These data suggest at least two possible sites of action of MK-801: the forebrain rostral to the superior colliculus and the spinal cord. The latter may depend upon descending input from the forebrain. The reduction of MK-801 effects in reserpinized rats suggests that in addition to an action on excitatory amino acid synapses, that there is also an involvement of catecholamine and/or 5HT mechanisms in the action of MK-801.

REORGANIZATION IN CAT VESICAL GANGLIA FOLLOWING SACRAL ROOT RESECTION A.M. Booth, M. Kawatani, S. Smerin, & W.C. de Groat Depts. of Pharmacol. & Behav. Neurosci. Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261

Transection of the sacral parasympathetic preganglionic input to the urinary bladder leads to: 1) abnormal sympathetic activation of the bladder 2) unusual patterns of spontaneous and stimulus evoked activity in bladder ganglia (BG) and 3) altered sensitivity of BG to substance P (SP). These findings illustrate the plasticity in BG following chronic partial decentralization. This study utilized extra and intracellular recording to examine decentralized BG (DBG) invitro and insitu 15 weeks to 15 months after lesioning. In > 100 cells in DBG the % of cells exhibiting synaptic responses to electrical stimulation (ES) of preganglionic nerves (PGN) was smaller (35-65%) than in normal BG (85-100%) while the % of cells in DBG exhibiting spontaneous firing was much higher (25-55% vs 0-5%). Many cells exhibited 2-10/sec, large amplitude (2-20 mV) "spontaneous" epsps. Repetitive ES (2-50Hz) of PGN elicited an increase in spontaneous activity that was positively correlated with the frequency and duration of the ES. Cells in DBG received fewer inputs (2-4 vs 6-7) and while threshold for spike initiation was unchanged (8-15 mV) the probability of eliciting firing was greatly increased. Both SP and VIP evoked asynchronous firing at doses that were ineffective in normal BG. We conclude that synaptic plasticity in DBG can markedly change the efferent input to the bladder and may contribute to the development of the autonomous hyperactive bladder. (Supported in part by NS-22436, NS-25254 & AM-37241)

437.5

BLADDER CONTRACTIONS EVOKED BY MICROSTIMULATION OF THE SACRAL SPINAL CORD J.R. Roppolo, A.M. Booth, S. Smerin, I. Nadelhaft & W.C. de Groat Dept. of Pharmacol. Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261

This study examined the effect of focal electrical microstimulation of the sacral spinal cord on bladder activity. In intact adult male chloralose anesthetized cats, the bladder was cannulated for pressure recording and a laminectomy exposed the lumbosacral spinal cord (L_3-S_3) and roots. The sacral segment containing bladder preganglionic neurons (PGN) was identified by stimulation of each ventral root (10-15 Hz, 0.05 sec pulse). S_2 root stimulation produced maximal responses (60-100 cm H_2O). The S_2 cord was then stimulated (15Hz, 10 sec duration, 0.2 msec charge balanced pulses, 5-25 uA) with a tungsten microelectrode (8-10 µm exposed tip) directed toward the PGNs of the sacral parasympathetic nucleus (SPN). Bladder contractions (maximum amplitude of 20-40 cm H_2O) were evoked over a distance of 0.5-0.8 mm in the intermediolateral gray (1.5-2.3 from surface) and were not usually associated with gross somatic motor activity. stimulation dorsal or ventral to the SPN could evoke bladder contractions, but thresholds were higher and skeletal muscle responses prominent. Bladder contractions were abolished with ganglionic blockade (trimethaphan 0.25 mg/kg) but were unchanged following neuromuscular blockade (pancuronium 0.1 mg/kg). These studies demonstrate that bladder contractions can be evoked selectively by focal electrical stimulation of the sacral spinal cord. (Supported by NIH contract NO1-NS-9-2366)

437.6

POSTNATAL DEVELOPMENT OF THE SENSORY INNERVATION OF THE URINARY BLADDER IN THE RAT. M.N. Kruse, M. Tanowitz*, C.Cheng* and W.C. de Groat. Depts. of Pharmacology and Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15261 and National Defense Medical Center, Taiwan.

The bladder-to-bladder reflex does not become functional in the neonatal rat until ~ day 6. It has been suggested that the absence of the bladder-to-bladder reflex at birth is due to lack of maturation of the sensory afferents from the bladder. This study addressed the question of whether the neonatal rat is born with an intact sensory pathway from the bladder to the spinal cord. Wheat germ agglutinin-horseradish peroxidase (WGA-HRP) was crushed into the urinary bladder of pentobarbital or halothane anesthetized neonatal rats (day 0 to day 8). The spinal cords and dorsal root ganglia (DRG) were removed 10-48 hours later for TMB processing. WGA-HRP labelled cells were seen in the L_6 DRG (~75%) and S_1 DRG (~25%) in day 0 to day 9 pups. WGA-HRP labelling was also seen in the sacral parasympathetic nucleus and lateral dorsal horn of the L_5, L_6 and S_1 spinal cord of day 0 through day 9 pups. These data indicate that bladder afferent neurons at birth have a segmental distribution and central projections similar to that of adults. The lack of a functional bladder-to-bladder reflex before postnatal day 6 could be due to immaturity of afferent synaptic mechanisms or of interneuronal pathways in the CNS.

NEUROBIOTIN (NB) and HRP DEFINED DENDRITIC MORPHOLOGY SUGGESTS ADDITIONAL FUNCTIONS FOR SACRAL PREGANGLIONIC NEURONS (PGN) **S.J. Zhang*, L.A. Felkins*, W.C. de Groat, and C.W. Morgan** Depts.Anatomy and Neurobiology and Urology, Eastern Virginia Medical School, Norfolk, VA 23501; Dept. Pharmacology, Univ.Pittsburgh, Pittsburgh, PA 15261

PGN in the lateral band (LB) of the sacral parasympathetic nucleus of the male cat are presumed to subserve various urogenital functions. Intracellular labelling was performed on more than 20 LB neurons with B-fiber axons to determine whether different subpopulations could be distinguished morphologically. At least five types of neurons were identified based on combinations of dendritic distributions in (1) the lateral funiculus, (2) lamina I, (3) the dorsal commissure and (4) the ventral horn. Groups of cells had dendritic projections to regions: 1,2,3 & 4; 1&4; 1,3 & 4; 2,3 & 4 or 3&4.

These data suggest that the functions of sacral lateral band PGN (bladder, penile, urethral, seminal vesicles) might be correlated with and predicted by their dendritic patterns. Further studies are underway to directly test this hypothesis by identifying the function of cells prior to intracellular labelling.

NEURONS LABELLED FOLLOWING THE APPLICATION OF TRACERS TO THE DISTAL CUT HYPOGASTRIC NERVE OF THE RAT. I. Nadelhaft and P. L. Vera. VA Med Ctr & Depts of Neurosurg and Pharmacol and Center for Neurosci, Univ of Pittsburgh, Pittsburgh, PA.

Following the work of Baron and Janig [JANS 24:81('88)] in the cat, we applied dyes to the distal stumps of the transected hypogastric nerves (HGN) of the female rat. The animal was anesthetized with halothane and one hypogastric nerve dipped into fast blue and the other into fluorogold. After about 10 days, the animal was reanesthetized with pentobarbital and perfused with 4% buffered paraformaldehyde. Labelled neurons numbering in the hundreds were located mainly ipsilaterally; however there were significant numbers of contralateral cells present. In the major pelvic ganglion (MPG) cells were concentrated within a small area near the entrance of the hypogastric nerve. Approximately one half of these stained positively for tyrosine hydroxylase. Labelled cells were located in the T13-L3 (35%) and L6-S1 (65%) dorsal root ganglia. In the sympathetic chain, labelled neurons were found between T12 and S2. A few preganglionic neurons were found in spinal cord segments L6 and S1. These groups of neurons may be innervating portions of the reproductive system served by small nerve branches leaving the HGNs between the inferior mesenteric ganglia and the MPGs.

SYMPATHETIC POST-GANGLIONIC INNERVATION OF THE RAT URINARY BLADDER. Pedro L. Vera and Irving Nadelhaft. VA Medical Center, Depts of Pharmacology and Neurosurgery, University of Pittsburgh, Pittsburgh, PA 15240.

Female rats were anesthetized with halothane and the urinary bladders exposed. Fluorescent traces (Fast Blue or Fluoro-Gold) were injected into the bladder wall using a Hamilton syringe. One to 3 weeks after the injections the rats were anesthetized and perfused with phosphate buffered-4% paraformaldehyde. The major pelvic ganglia (MPG), the inferior mesenteric ganglion (IMG) and the sympathetic chain (T10-S3) were removed, sectioned (20 um) in a cryostat and examined for the presence of retrogradely labeled cells. The sections from the MPG were also processed for DBH-immunohistochemistry.

In the MPG, many retrogradely labeled cells were present and some also contained DBH immunoreactivity. In addition, retrogradely labeled cells were found in the IMG. The sympathetic chain contained most of the retrogradely labeled cells. Experiments are in progress to determine the contribution of the hypogastric and pelvic nerves to the sympathetic chain innervation of the urinary bladder of the rat.

MOTONEURONS AND AFFERENT NEURONS INNERVATING THE ISCHIOCAVERNOSUS MUSCLE: A TRACING STUDY IN THE CAT. S. Smerin, J.R. Roppolo, R. Stewart*, V. Erickson*, W.C. de Groat. Dept. Pharmacol., Schl. Med., Univ. Pittsburgh, Pittsburgh, PA 15261.

The afferent and efferent pathways to the cat ischiocavernosus muscle (ICM) were identified using the retrograde tracers HRP, WGA-HRP, and cholera toxin B-HRP injected into the ICM under halothane anesthesia. 72 to 96 hours later anesthetized cats was perfused with fixative. Spinal cord and dorsal root ganglia (DRG) from L_6 to S_3 were processed with TMB to reveal HRP. Lower motoneurons (average, 150) projecting to the ICM were present exclusively in Onuf's nucleus (ON), in L_7 and S_1. The neurons were typically elongate ranging from 25x30 to 40x70 microns in size. The neurons sometimes formed clusters, but were not confined to any particular division of ON. Cholera toxin B-HRP revealed dendrites up to one millimeter long extending from the ventrolateral division of ON to the medial ventral horn, the lateral funiculus, and the sacral parasympathetic nucleus. Labeled DRG cells (~1000 per cat) present in S_1 and S_2 ranged from 10x20 to 80x110 microns in size. Sparse afferents extended through the medial and lateral collateral pathways into the dorsal gray commissure. The distribution of neurons innervating the ICM overlaps with that of the striated urethral and anal sphincters, suggesting that coordination of the three may take place in the sacral spinal cord. (Supported by NIH contract N01-NS-9-2366)

437.11

INNERVATION AND FUNCTION OF THE ISCHIOURETHRALIS MUSCLE OF THE RAT. W. G. Dail, B. D. Sachs, G. Walton* and Y-C Liu*. Dept. of Anatomy. Univ. New Mexico Sch. of Med., Albuquerque, NM 87131 and the Dept. of Psychol. University of Conn., Storrs CT 06269-1020

The ischiourethralis, a striated perineal muscle presumed to be involved in sexual reflexes, was studied in the rat. The paired muscle arises from the penile crus and penile bulb and unites in a raphe over the dorsal vein of the penis. This structure is identified as the subpubic ligament in other descriptions. Retrograde tracing studies show that the muscle is innervated by neurons in the dorsolateral nucleus of the lumbar spinal cord, a pudendal nerve motor nucleus which also projects to the ischiocavernosus muscle. Excision of the ischiourethralis muscle did not interfere with the ability of males to display normal copulatory behavior, nor did it affect significantly the number and intensity of reflexive erections. The function of this muscle like that of some other perineal muscles remains to be determined.

437.12

A ROLE FOR 5-HYDROXYTRYPTAMINE IN MEDIATING SPINAL SEXUAL REFLEXES L. Marson and K. E. McKenna Dept. of Physiology, Northwestern Medical School, Chicago IL 60611

We previously identified a brainstem site in the ventromedial rostral medulla that mediates the inhibition of spinal sexual reflexes. The location of this site corresponds to the paragigantocellular reticular formation (PGi). The present study provides neuroanatomical and pharmacologic evidence for 5-hydroxytrypamine (5-HT) in the mediation of this inhibition.

Rhodamine-labelled beads were pressure injected into L5-L6 of the spinal cord. After 7-14 days rats were perfused with 4% paraformaldehyde solution. The spinal cord and medulla were cut (30-40μm) and processed for 5-HT-immunoreactivity using the immunofluorescent technique. Retrogradely labelled neurons were found in the PGi, raphe pallidus, raphe obscurus and gigantocellular reticular formation after injections located to the pudendal motoneurons. Many of these retrogradely labelled cells in the PGi contained 5-HT-immunoreactivity. Dense 5-HT-immunoreactive fibers and presumptive terminals were found surrounding the pudendal motoneurons and interneuronal spinal grey of the lumbosacral spinal cord. Male rats were anesthetized with urethane and an intrathecal catheter was inserted into the subarachnoid space, positioned with the cannula tip at L5-L6 of the spinal cord. The rats were spinalized. The coitus reflex was elicited via a catheter inserted into the urethra. The reflex was monitored by EMG recordings of the bulbospongiosus muscle. Microinjection of 5-HT (1-2.5μg) resulted in an increased sensory threshold and delayed the coitus reflex. Injection of higher doses of 5-HT (5-50μg) resulted in inhibition of the previously evoked coitus reflex. Thus, 5-HT appears to alter the spinal pattern generator for the coitus reflex.

These findings provide evidence that 5-HT neurons in the rostral medulla mediate inhibition of spinal sexual reflexes.

MODULATION OF THE THRESHOLD FOR FICTIVE SEXUAL CLIMAX IN FEMALES BY PERIPHERAL SEROTONIN

K.E. McKenna and Kelley Knight* *Dept. of Physiology, Northwestern Medical School, Chicago, IL 60611*

We previously identified urethral stimuli as sufficient for eliciting fictive sexual climax in anesthetized, spinalized male and female rats (Neurosci. Lett. 94, 343, 1988). While simple mechanical stimuli alone are effective, some observations have led us to consider that urethral chemoreceptor mechanisms may play a role in eliciting sexual climax. The present study was designed to identify the substrates of urethral chemoreception.

Other investigators have shown in a number of species that the urethral mucosa contains serotonergic paracrine cells. The morphology of these cells suggests a chemoreceptor function. To determine if these paracrine cells are present in the rat, male and female rats were anesthetized and perfused with fixative. The urethra was removed and either 50 μm transverse sections cut, or a wholemount preparation of the urethral mucosa was prepared. Immunofluorescent staining for serotonin revealed a large number of small (< 10 μm) heavily stained cells throughout the urethra. There was a concentration of these cells in the urethral bulb/distal urethra. This is the area which we have identified as most sensitive in eliciting fictive sexual climax. These cells have processes which extent to the luminal surface. In the submucosa, the cells displayed one or two large clublike processes.

To examine the physiological role of these cells, female rats were anesthetized, spinalized and a urethral catheter inserted via the bladder. Distension of the urethra by infusion of saline through this catheter followed by urethral meatus occlusion was effective in eliciting the fictive sexual climax, as monitored by pudendal nerve recordings. The pressure threshold required to elicit the fictive sexual climax was highly consistent in a given animal. The addition of serotonin to the infusion fluid significantly and reversibly decreased (by 20 - 30%) the pressure required to elicit the response. The maximally effective dose was 10^{-6} M.

437.14

MAINTENANCE OF ERECTION OF PENILE GLANS, BUT NOT PENILE BODY, AFTER TRANSECTION OF RAT CAVERNOUS NERVES. B.D. Sachs and Y.-C. Liu*, Dept. of Psychology, Univ. of Connecticut, Storrs, CT 06269-1020.

A role for the cavernous nerve (CN) in erection of the corpora cavernosa has been well documented. Evidence for CN-innervation of the corpus spongiosum implies a role in erection of the glans penis as well. However, stimulation of the rat CN led only to erection of the penile body, not the glans (Quinlan et al., J. Urol., 141:656, 1989). To further determine the role of the CN in glans erection, we tested male rats for mating behavior and sexual reflexes after CN transection (CNx). During copulation, the intromission rate of CNx males was drastically reduced, reflecting their impaired ability to erect the penile body. In reflex tests, CNx males continued to display weak and moderate glans erections, but lacked penile body erections and intense glans erections. These results suggest that at least in rats the innervation of the corpus cavernosum differs from that of the corpus spongiosum, and that the CN may play little or no role in corpus spongiosum function.

NORMAL SEXUAL REFLEXES IN THE ABSENCE OF URETHRAL STIMULATION IN INTACT COPULATING RATS.

G.M. Holmes, D.H. Lynch* and B.D. Sachs. Dept. of Psychology, Univ. of Connecticut, Storrs, CT 06269.

The absence of seminal and prostatic fluids does not alter the motor patterns or parameters of copulation, including the ejaculatory response (ER), in rats (e.g., Tisell & Larsson, Invest. Urol. 16:274, 1979). Research on anesthetized spinal rats suggested a role for urethral stimulation in the ER, as measured by the EMG of the bulbospongiosus muscle [mBS] (Chung et al., Neurosci. Lett. 94:343, 1988). In order to help place this finding in a natural behavioral context, we tested for its generality in copulating rats. A diagnostic component of the rat ER is high-energy EMG activity in the mBS starting ca. 500 ms after penile insertion and continuing for several seconds after dismount. Anesthesia of the urethral mucosa with lidocaine did not disrupt this mBS response. Systemic injection of guanethidine eliminated ejaculatory plugs but had no effect on the ER. These results suggest that urethral stimulation by the ejaculate does not contribute to the regulation of the striated-muscle components of ejaculation-related reflexes in copulating male rats.

437.16

FUNCTIONAL PLASTICITY IN DECENTRALIZED AUTONOMIC GANGLIA: LACK OF EVIDENCE FOR MAST CELL INVOLVEMENT. N. Minorsky, G. Walton* and W. G. Dail, Dept. of Anatomy, Univ. New Mexico Sch. of Medicine, Albuquerque, NM 87131.

Stimulation of the hypogastric nerve in the rat results in penile vasodilation only when the pelvic nerve is interrupted. The mechanism for this response is unknown but in view of the hyperemic status of denervated ganglia and the recent suggestion that mast cell products increase excitibility of autonomic ganglion cells, we have compared the number of mast cells in intact and partially denervated major pelvic ganglia (MPG). The number of intraganglionic mast cells (572 ± 109; average ± SEM/MPG) was unchanged when intact ganglia were compared to ganglia in which the pelvic nerve was interrupted seven days earlier. No difference was seen between control and denervated ganglia when an arbitrary scale was used to assess mast cell degranulation. Although it remains possible that mast cells could alter ganglionic transmission following injury, the present study did not find changes in mast cell number and activity coincident with functional plasticity.

SENSORY INNERVATION OF THE RAT KIDNEY AND URETER AS REVEALED BY THE ANTEROGRADE TRANSPORT OF WGA-HRP FROM DORSAL ROOT GANGLIA. S. F. Echtenkamp and C. F. Marfurt. Northwest Center Med. Educ., Indiana Univ. Sch. of Med., Gary, IN 46408.

The afferent innervation of the rat kidney and ureter was studied by labeling the sensory nerve fibers with wheat germ agglutinin-horseradish peroxidase (WGA-HRP) transported anterogradely from dorsal root ganglia. In some cases, the tissues were serially sectioned at 40µm in a cryostat, whereas in other animals the ureter, renal pelvis, and arterial tree were dissected free of surrounding tissues and processed as whole mounts. Labeled nerve fibers were numerous in the ureteral wall and lining of the renal pelvis. In the ureter, they formed a dense, branching plexus oriented parallel to the long axis of the organ, however, at the widest part of the renal pelvis many of the fibers changed direction and traveled within the lining of the funnel-shaped renal pelvis in a circumferential fashion. The latter axons were of extremely fine diameter and appeared to terminate exclusively as free nerve endings. Other fibers reached the renal pelvis by coursing along branches of the renal artery and then "doubling back" to reach the pelvis along proximal segments of the renal calyces. More modest networks of labeled axons were observed around branches of the renal artery and, to a much lesser extent, the renal vein. Labeled fibers were never seen around afferent or efferent arterioles or within glomeruli. A few fibers entered the renal cortex and terminated in close proximity to renal tubules. This study reveals an anatomical configuration of ureteral and renal pelvic sensory nerves consistent with a role in detection of ureteral pressure changes, as well as a renal artery and vein sensory innervation that may monitor changes in renal vascular pressure.

URINE RETENTION DUE TO INTRASPINALCORD INJECTION OF COLCHICINE: THERAPEUTIC EFFECT OF BREMAZOCINE, NERVE GROWTH FACTOR AND MONOSIALOGANGLIOSIDE. M.Baraldi, P.Zanoli*, C. Truzzi*. Chair of Pharmacology and Pharmacognosy, School of Pharmacy, Modena University, 41100 Modena, Italy.

We described that the intraspinalcord (ICS) injection of low doses (2-5 ug/rat) of colchicine (C) induces a massive urine retention, bladder hypertrophy and urine overflow. Pharmacological challenges with Bethanecol or Propranolol did not trigger bladder voiding. Neuropeptides have been show to play a key role in the regulation of the micturition reflex in the spinalcord and bladder function. In rats with C-induced urine retention we found at the site of injection an increase of Met-enkephalin, a marked decrease of Substance P and no apparent changes in the level of Dynorphin A. The urine retention was worsened by Naloxone whereas was prevented by Bremazocine, a K and sigma receptor agonist. In the spinalcord of rats with urine retention we detected an increased presence of K and sigma receptors. It seems likely that Bremazocine, despite its K stimulatory activity, by stimulating sigma receptors present on the Mg-sensitive NMDA-glutamate receptors, allosterically inhibits an increased NMDA receptor activity. An implication of a glutamatergic dysfunction in the C-induced urine retention seems to be confirmed by the ability of Nerve Growth Factor and Monosialoganglioside (GM-1), which minimise the neurotoxicity of glutamate, to normalise urine output in C-treated rats.

NEUROENDOCRINE REGULATION: OXYTOCIN, VASOPRESSIN

PROPERTIES OF POSTERIOR PITUITARY PRIMARY CULTURES. C. Dvergsten*, A.K. Salm, R.B. Meeker, L. Rietz*, R.S. Greenwood and J.N. Hayward. Depts. of Neurology, Pediatrics, and Pharmacology and Neurobiology Curriculum, University of North Carolina, Chapel Hill, NC 27599.

Pituicytes were cultured from the neural lobe of the rat pituitary at developmental ages E16-PN14 and adults. Cultures were grown from both punches of the isolated neural lobe and dissociated cells. The earliest age at which cultures were effectively grown was E17-E18. Cells from E18 fetuses exhibited process bearing and flat-polygonal morphologies, similar but not identical to cultured astroglia. The process-bearing cells exhibited strong GFAP immunoreactivity whereas the flat-polygonal cells had variable levels of staining ranging from robust to weak. As the neural lobe developed, fewer process-bearing cells were observed in culture, until by PN5-7, cultures were largely comprised of flat-polygonal cells and a few small flat cells with or without irregular processes. Cultures of neural lobe punches at PN5-14 contained a core of flat cells surrounded by spindle-shaped, fibroblast-like cells whereas, dissociated cells yielded more homogeneous cultures that were 70-90% GFAP immunoreactive. A majority of the cells also stained robustly for fibronectin. A subpopulation of cells from cultured neural lobe were found to express specific vasopressin binding sites. Stimulation with 10^{-5} M vasopressin, dynorphin and norepinephrine resulted in increased intracellular calcium in subsets of flat-polygonal unidentified cells. Oxytocin and leu-enkephalin had no effect on intracellular calcium concentration.

PRIMARY CULTURES OF MAGNOCELLULAR NEUROENDOCRINE CELLS FOR IN VITRO PATCH CLAMP STUDIES AND ANATOMICAL ANALYSES. S.A. Oglesby, L. Rietz*, E. Cox*, R.B. Meeker, R.S. Greenwood and J.N. Hayward. Depts. of Neurology and Pediatrics, and Curriculum in Neurobiology, Univ. of North Carolina, Chapel Hill, NC 27599 and Cato Research Ltd., Durham, NC 27713

To identify optimal culture conditions for physiological studies of magnocellular neuroendocrine cells, the properties of fetal and early postnatal, anterior hypothalamic cultures containing supraoptic and paraventricular neurons, were evaluated under different conditions of tissue preparation and culture. Tissue punches through the region of the supraoptic nuclei, coronal slices or dissociated cells were cultured on coverslips coated with either poly-L-lysine, collagen (Vitrogen) or solubilized tissue basement membrane (Matrigel). The growth characteristics of magnocellular neurons differed under various conditions. Slices and tissue punches produced a rim of healthy neurons which slowly migrated short distances from the cell mass. The migration and axonal outgrowth appeared to be limited to the region of glial outgrowth from the mass. In contrast, a collagen matrix supported rapid axonal outgrowth from cells which extended past the glial outgrowth. This latter type of preparation appears to be best for axonal outgrowth but was less useful for patch clamp studies. Large cells with a morphology similar to immunocytochemically identified magnocellular neuroendocrine cells were easily identified in dissociated cultures. These cells could be patch clamped and infused with Lucifer Yellow. These cultures provide a means by which vasopressin and oxytocin magnocellular neurons can be cultured for different growth properties, studied using standard patch clamp methods, marked intracellularly with Lucifer Yellow, and identified immunocytochemically.

SOMATOSTATIN-28(SS-28):CNS SITES AND MECHANISM OF ACTION TO STIMULATE VASOPRESSIN SECRETION. M. Brown and K. Carver-Moore
Department of Medicine, University of California, San Diego, CA 92103.

SS-28 injected into the cerebroventricle of the rat elicits an increase of the plasma concentration of AVP. Studies have been performed using awake rats to determine the neuroanatomic site and mechanism of action of SS-28 to increase plasma AVP levels. SS-28 injected into the central nucleus of the amygdala, the lateral, posterior and supraoptic nuclei of the hypothalamus and several brainstem regions did not alter plasma levels of AVP. SS-28 injected into the bed nucleus of the stria terminalis or the anterior or paraventricular nucleus of the hypothalamus resulted in elevation of AVP greater than those levels observed following administration of peptide into the third ventricle. Two types of mechanisms of action of SS-28 to stimulate AVP release were evaluated: (1) SS-28 stimulation of an endogenous neurotransmitter that acts as an agonist of AVP release and (2) SS-28 inhibition of the release of a neurotransmitter that tonically inhibits AVP release. Antagonists of muscarinic, atropine, and nicotinic, hexamethonium, cholinergic receptors and of angiotensin-II did not alter SS-28 induced AVP release. In contrast, both GABA and isoproterenol attenuated SS-28 induced AVP release. Based on the inhibitory actions of GABA and norepinephrine on AVP release, it is possible that SS-28 acts with the hypothalamus and other brain regions to stimulate pituitary AVP release through inhibition of the release of one or both of these neurotransmitters.

RAPID VASOPRESSIN mRNA EXPRESSION IN THE RAT HYPOTHALAMUS DURING POLYETHYLENE GLYCOL-INDUCED HYPOVOLEMIA. R.B. Meeker, E. Perkins*, M.M. Nicolle, L. Rietz*, R.S. Greenwood and J.N. Hayward. Dept. of Neurology and Pediatrics and Neurobiology Curriculum, University of North Carolina, Chapel Hill, NC 27599.

The study of the control of vasopressin mRNA expression in magnocellular neurons is hampered by the slow rate of blood volume or osmolality changes following most experimental manipulations, such as water deprivation or hypertonic saline ingestion, which may be rate limiting. Consequently, we characterized the increase in VP mRNA levels by a single subcutaneous injection of polyethylene glycol (PEG) to assess the time course of VP mRNA increases in the supraoptic and paraventricular nuclei in a response to a more rapid challenge. A 30mer oligonucleotide probe specific for vasopressin mRNA was hybridized to 20 um sections of rat brain 0, 4, 8 or 16 hrs after PEG injection or 24 hrs after injection in rats which were allowed to regulate their fluid volume by drinking. Levels of VP mRNA increased within 4 hrs of PEG injection to values approximately, 2-fold greater than control values. The similarity of this time course to the evoked release of vasopressin suggests that the two processes may be under similar transsynaptic control. This paradigm may provide a simple and useful model for in vivo pharmacological analysis of pathways which control vasopressin gene transcription.

Stereotactic instillation of morphine into the posterior pituitary of rats in vivo inhibits release of vasopressin. Eric Stephanian, M.D. and Alan G. Robinson, M.D., Departments of Neurosurgery and Medicine, University of Pittsburgh, Pittsburgh, PA 15261

Opioids are reported to act directly on the posterior pituitary to inhibit release of neurohypophysial peptides, but this has been difficult to study with ventricularly administered drugs in intact animals because of the multiple potential sites of action of opioids throughout the central nervous system. We developed a technique for stereotactic cannulation of the posterior pituitary of rats to directly instill substances into the matrix of the neurohypophysis. After cannulation under anesthesia with equithesin basal vasopressin levels in plasma were 10.8 ± 2.5 pg/ml. When a 5 μl solution of 56 mM potassium chloride was infused slowly into the substance of the gland, plasma vasopressin peaked at 83 ± 23 pg/ml at 5 minutes, and gradually returned to baseline over 2 hours. Injection of a solution containing 5.6 mM potassium had minimal stimulatory effect on vasopressin release with peak values of 30 ± 9 pg/ml at 5 minutes. When 56 mM potassium solution was injected concurrently with 5 μg morphine in the same 5 μl solution, vasopressin release was inhibited with a value of 33 ± 3 pg/ml at 5 minutes, a slight rise at 15 minutes and return to basal. Injection of morphine peripherally at the same concentration had no effect on the release of vasopressin during high potassium stimulation. Thus, we have used an in vivo technique to document that opioids delivered to the neurohypophysis directly inhibit the release of vasopressin independent of action elsewhere in the central nervous system.

438.6

FOS EXPRESSION DEMONSTRATES HETEROGENEITY OF MAGNOCELLULAR VASOPRESSIN AND OXYTOCIN RESPONSE. M.M. Roberts, A.G. Robinson, M. Fitzsimmons, and G.E. Hoffman, Departments of Medicine, University of Pittsburgh, Pittsburgh, PA 15261.

Activated vasopressin (AVP) and oxytocin (OT) neurons of the supraoptic (SON) and paraventricular (PVN) nuclei express fos, a proto-oncogene product involved in transcription. C-fos expression was used to map the response of individual magnocellular neurons to graded hemorrhage in rats. Following a 2 cc bleed, 12% of AVP neurons and 17% of OT neurons expressed fos. Of those neurons expressing fos, 38% expressed fos at a low intensity level and only 4% expressed fos at the highest intensity level. After a 6 cc bleed, 92% of AVP neurons and 86% of OT neurons expressed fos; 18% at low intensity and 38% at the highest intensity. As the degree of stimulus increased, both the total number of cells responding and the intensity of response per cell increased. Fos expression in cells double-labelled for AVP or OT delineated hormone-specific differential functional anatomy in the SON and PVN. In the SON, after 2 cc hemorrhage, 15% of AVP neurons, but only 2% of OT neurons were activated. In the PVN, there was no activation of AVP neurons, but 26% of OT neurons were activated. A similar differential response pattern was seen with 4 cc hemorrhage, but with 6 cc most neurons were activated in both nuclei. Fos immunoreactivity thus provides a permanent record of activated neurons in the SON and PVN. Dual immunostaining for fos and AVP or OT was used to demonstrate a previously unrecognized functional anatomic heterogeneity in the threshold for response of magnocellular neurons to hemorrhagic stimuli.

TOPOGRAPHY OF HYPOTHALAMIC OXYTOCIN NEURONS THAT EXHIBIT c-fos IMMUNOREACTIVITY UPON OSMOTIC STRESS IN THE RAT. Lisa Giovannelli, Priyattam J. Shiromani, Gustav F. Jirikowski and Floyd E. Bloom, Dept. Neuropharmacology, Scripps Clinic Research Foundation, La Jolla CA 92037 and Dept. Psychiatry, UCSD, La Jolla CA 92093.

In order to evaluate the metabolic responses of specific neurons to experimental perturbations in vivo, we have visualized c-fos and oxytocin (OXY) expression in rat brain by double- immunostaining. Both a monoclonal and a polyclonal antibody raised against c-fos peptide sequence 4-17 were used. In normal untreated male rats, or in male rats treated with intraperitoneal injection of isotonic saline, no OXY-immunoreactive neurons were found to express detectable c-fos immunoreactivity. However, nuclear c-fos immunoreactivity was readily detectable in OXY neurons (as well as in other neurons non-immunoreactive for OXY) as early as 90 minutes after intraperitoneal injection of a hypertonic (1.5 M NaCl) salt solution. At this time point neurons immunoreactive for both OXY and c-fos were found in the supraoptic nucleus, in the paraventricular nucleus and in the lateral subcommissural nucleus. These results suggest that oxytocin neurons can be metabolically activated by osmotic stimuli, and indicate the need to further understand the role of the neurons expressing this neuropeptide. Grant n. NS22347

Water-deprivation increases glucose utilization in the hypothalamo-neurohypophysial system and circumventricular organs. M.Kadekaro, S.Freeman, M.L.Terrell and J.S.Harris. Division of Neurosurgery, University of Texas Medical Branch, Galveston, Texas 77550.

We studied with the quantitative [^{14}C]deoxyglucose autoradiography the neural pathways activated by 24, 48 and 72 h water-deprivation and intravenous infusion of hypertonic saline (2.5 M, 250 ul/min for 4 min) in adult male Sprague-Dawley rats (n=61). Water-deprivation over 72 h induced a progressive increase in plasma osmolality and hematocrit. Hypertonic saline increased plasma osmolality to a larger degree than 72 h water-deprivation (Δ=27 vs.16 mOsm/kg). Hypertonic saline increased glucose utilization in the supraoptic and paraventricular nuclei and neural lobe but not in the circumventricular organs. Glucose utilization increased in the supraoptic nucleus throughout the period of dehydration. In the neural lobe, a tendency to increase started at 24 h of water-deprivation and substantial increments were seen afterwards. In the paraventricular nucleus, subfornical organ (SFO) and organum vasculosum laminae terminalis (OVLT), the increases were observed only after 48 and 72 h dehydration. No changes were seen in the area postrema and median eminence. These results demonstrate that water-deprivation and hypertonic saline stimulate activity of the hypothalamo-neurohypophysial system, but only water-deprivation stimulates activity of the SFO and OVLT.

438.9

ANTERIOR HYPOTHALAMIC (AV3V) LESIONS IMPAIR MAXIMAL SUPPRESSION OF VASOPRESSIN SECRETION IN RATS. R.E. Blackburn, E.M. Stricker and J.G. Verbalis, Departments of Behavioral Neuroscience and Medicine, University of Pittsburgh, Pittsburgh, PA 15261.

Lesions of the antero-ventral third ventricular (AV3V) region severely impair osmotically-stimulated secretion of vasopressin (AVP) and oxytocin (OT) from the rat neurohypophysis. Since suppression of AVP secretion also may involve an osmoreceptor-mediated process, we studied the ability of AV3V-lesioned rats to excrete free water loads as an index of their AVP suppressibility. Radiofrequency lesions were made in male rats (2 mm probe with 2 mm tip exposure; 7.3 mm below bregma in the midline), and the adequacy of the lesion was evaluated functionally by the absence of drinking 1h after induced hyperosmolality (2 M NaCl, 2 ml i.p.). The successfully lesioned rats were evaluated using two different protocols. In one, rats were given 40-70 ml/d of a palatable dilute liquid formula (AIN-76, 1 kcal/ml) as their only source of calories to produce self-ingested water loads. Of 9 rats so treated, 6 became significantly hyponatremic by 2 days after the lesion (plasma [Na^+] = 131.6±2.6 mmol/l, versus plasma [Na^+] = 141.1±0.4 mmol/l in 11 non-lesioned rats on the same liquid formula). A second group of rats were injected i.p. with hypotonic fluid (0.05M NaCl with or without 2.5% dextrose; 15 ml hourly x 4). Plasma [Na^+] of the AV3V- lesioned rats 1h after the last injection was 117.6±3.5 mmol/l (n=6) as compared to 132.8±3.3 mmol/l in sham-lesioned rats (n=5) treated similarly ($p < 0.02$). Our results therefore show that AV3V lesions significantly impair the ability of rats to excrete free water maximally, which most likely reflects non-suppressed basal plasma AVP levels despite plasma hypoosmolality. Consequently, these studies support the hypothesis that both stimulatory and inhibitory components of the osmoreceptor system(s) are located in the AV3V area, and are of importance for complete regulation of neurohypophyseal secretion of AVP.

438.10

OXYTOCIN mRNA LEVELS IN HYPOTHALAMIC PARAVENTRICULAR AND SUPRAOPTIC NUCLEI (PVN/SON) DURING LACTATION IN RATS: EVIDENCE FOR MAINTENANCE BY AFFERENT STIMULI FROM THE OFFSPRING. L. H. Spinolo, R. Raghow*, and W. R. Crowley, Dept. of Pharmacology, University of Tennessee-Memphis, College of Medicine, Memphis, TN 38163.

The objective of the present studies was to describe in detail the changes in oxytocin (OT) mRNA in the PVN/SON that occur over time during pregnancy and lactation in the rat and to test whether afferent stimuli provided by the offspring during lactation influence these levels. The PVN and SON were microdissected from pregnant and lactating females, and RNA was extracted by the RNAzol method. OT mRNA was quantified by slot-blot hybridization, using a 25 mer oligonucleotide probe complementary to bases 912-936 of OT-neurophysin precursor mRNA (Kawata et al., Brain Res. Bull 20: 693-697, 1988), which was T-4 polynucleotide kinase-end labelled, followed by autoradiography. Blots were stripped and then reprobed with an 1125 bp cDNA insert complementary to α-tubulin mRNA for normalization. The levels of OT mRNA in PVN/SON were high on pregnancy day 1, reduced during pregnancy days 7-18, and increased prior to parturition from pregnancy days 20-22. Similar elevated levels were observed throughout lactation. Compared to age-matched controls, immediate removal of offspring on the day of parturition resulted in a marked decline of OT mRNA by 24 hr, and levels tended to remain low for 48-72 hr. Similar results were seen after offspring removal on lactation day 8. These data suggest that OT mRNA levels in the hypothalamic magnocellular regions undergo an initial increase prior to parturition and that the maintenance of these elevated levels during lactation is influenced by afferent stimuli provided by the offspring.

DNQX BLOCKS BASAL AND OSMOTICALLY STIMULATED VASOPRESSIN RELEASE. C.D. Sladek, Depts of Neurology and Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, NY, 14642.

In previous experiments, the non-specific excitatory amino acid (EAA) receptor antagonist, kynurenic acid, prevented osmotic stimulation of vasopressin (VP) release from hypothalamo-neurohypophyseal (HNS) explants. In order to evaluate the type of EAA receptor involved in this response, the effect of DNQX (6,7-dinitroquinoxaline-2,3-dione), an antagonist at the kainate and quisqualate EAA receptors was evaluated. VP release was measured from perifused HNS explants exposed to an increase in the NaCl concentration of the perifusate sufficient to increase the osmolality 15 mosmol/kg H2O over 1 hour. DNQX (10μM) or the DMSO vehicle (1.25 μl/ml) were added 60 min prior to the NaCl induced increase in osmolality. DMSO increased osmolality from 290 - 310 mosmol/kg H2O. In the controls, this was associated with a brief increase in VP release ($p<0.05$). The response to the subsequent NaCl induced increase in osmolality was similar to previous experiments with an initial stimulation of VP release, followed by inhibition and a rebound increase in VP release associated with returning the NaCl concentration to baseline. DNQX reduced VP release to 56±9% of basal release ($p<0.05$, n=8), and VP release remained uniformly suppressed during the subsequent NaCl induced increase and decrease in osmolality. These data support the involvement of EAA transmitters in basal and osmotically regulated VP release from HNS explants, and indicate that non-NMDA EAA receptors are important in regulating VP release from the posterior pituitary. Supported by NIH RO1-DK-19761.

Effect of Extended Exposure to Hypertonicity on Vasopressin mRNA Content of Hypothalamo-Neurohypophyseal (HNS) Explants. C. Yagil and C.D. Sladek. Dept. of Neurology and Neurobiology and Anatomy, Rochester Univ. M.C., Rochester, NY 14642.

VP mRNA content of organ cultured explants of the rat HNS was evaluated following either a step increase in osmolality or a gradual increase of the same amount over 24 hours. Explants were exposed to the step increase in osmolality by placing them directly into hypertonic medium (>304 mosm/Kg H_2O) in static culture. VP mRNA content was significantly decreased in explants maintained for 24 or 48 hours in hypertonic medium compared to explants maintained in isotonic medium (47±10% and 57±6% respectively; $p<0.01$). Basal VP release was also lower in these explants compared to controls, and they did not respond to a further acute increase in osmolality. VP content of the posterior pituitary did not differ between the groups. To achieve a slow increase in osmolality (16 mosm/Kg H_2O over 24 hours by increasing the NaCl concentration), explants were perifused in individual chambers. This stimulus caused a significant increase in VP release which was sustained for more than 9 hours and VPmRNA content was 165±19% higher than control explants ($p<0.001$). No difference existed in VP content in the posterior pituitary. These observations suggest a correlation between VP release and VPmRNA content, because the step increase in osmolality led to lower VP release and lower VPmRNA content in HNS explants where as the slow increase in osmolality caused a sustained increase in VP release and an increase in VP content. Supported by NIH RO1-DK-19761 and the Kidney Foundation of Upstate NY.

EFFECTS OF ANESTHESIA ON VASOPRESSIN (VP) AND OXYTOCIN (OT) NEURONS IN RESPONSE TO ACUTE SALT LOADING. S.W.T. CHENG* and W.G. NORTH. Dept. of Physiology, Dartmouth Medical School, Hanover, NH 03756.

In a previous study we showed that anesthesia induced by a combina-tion of Ketamine and Nembutal did not significantly influence the func-tion of VP neurons. For this study, we examined the responses of OT and VP neurons to acute salt loading in conscious rats (CON, n=8) and rats under either Nembutal (NEM, 50 mg/kg, ip, n=8) or Urethane (URE, 1.6 g/kg, ip, n=8) anesthesia. Fifteen minutes following the in-duction of anesthesia, NEM produced an increase in basal plasma osmo-lality (Posm, 290 ± 2 to 296 ± 3 mOsm/kg H_2O, $p < 0.007$) while URE did not change basal Posm (287 ± 2 to 289 ± 2 mOsm/kg H_2O). Neither anesthetic resulted in any significant changes in basal plasma levels of oxytocin-associated neurophysin and vasopressin-associated neurophysin (OT-RNP, VP-RNP). In response to intravenous infusion of 18% saline, all three groups of rats had similar rises in Posm. The slopes of the relationship between plasma OT-RNP and Posm were not significantly different between the CON and the NEM groups, while that for the URE group was significantly ($p<0.05$) smaller than the CON group (CON=10.9 ± 1.5; NEM=9.3 ± 1.5; URE=6.3 ± 0.7 fmol·ml^{-1}·mOsm^{-1}·kg H_2O^{-1}). The slopes of the relationships between plasma VP-RNP and Posm were markedly reduced in anesthetized animals compared to that observed for conscious animals (CON=2.54 ± 0.5; NEM=1.22 ± 0.18; URE=1.17 ± 0.24 fmol·ml^{-1}·mOsm^{-1}·kg H_2O^{-1}, $p <$ 0.0126). Our data suggest that anesthesia induced by either Nembutal or Urethane significantly reduces the responsiveness of VP neurons to acute salt loading, but the responsiveness of OT neurons is lowered by Urethane only.

CARBOCYANINE DYE LABELLED NEURONS AND PROCESSES OF *CARASSIUS AURATUS* PROJECTING TO THE PITUITARY. S.A. Johnston & J.N. Fryer. Dept. of Anatomy, University of Ottawa, Canada K1H 8M5.

Neurons projecting to the pituitary were retrogradely labelled following application of either diI or diO (D-282 or D-3883 Molecular Probes) crystals to either the pars distalis (anterior pituitary) or neurointermediate lobe (posterior pituitary) of goldfish perfused with 4% paraformaldehyde. The brain was sealed in a glass container for up to 20 wk at 23°C, in the dark. Vibratome sections (40 μm) were photographed through an epifluorescence microscope [rhodamine (diI) or fluorescein (diO) filter]. Cell groups were identified following Nissl staining of the sections. Labelled parvocellular neurons were found in the n preopticus periventricularis (NPP), n preopticus (NPO), superchiasmatic n (SC), n lateral tuberis pars anterioris (NLTa), posterioris (NLTp), and inferioris (NLTi), and between n recessus lateralis (NRL) and n recessus posterioris (NRP). Labelled magnocellular neurons were found in NPO, n lateral tuberis pars lateralis (NLTl) and its surrounding anterior hypothalamus (H); as well, a few scattered magnocellular neurons were labelled lateral to NRL. A major labelled tract arising from cells of the NPP, NPO, SC, NLTa, NLTl and the surrounding anterior H stretched in a semicircle along the lateroventral perimeter of the anterior H and entered the pituitary stalk. Fibers from NLTp, NLTi, and caudal H formed a caudobasal H tract projecting anteriorly to the pituitary stalk. Some CSF-contacting neurons were diI-labelled in NLTa and NLTp although the paraventricuar organ was not labelled. (Supported by MRC Canada)

DII-LABELLED NEURONS OF *CARASSIUS AURATUS* PROJECTING TO THE UROPHYSIS: DOUBLE LABELLED FOR UROTENSIN I OR II IMMUNOCYTOCHEMISTRY. J.N. Fryer & S. A. Johnston. Dept. of Anat., University of Ottawa, Canada K1H 8M5.

The caudal neurosecretory system of teleost fish and its neurohaemal organ, the urophysis, elaborate two unique neuropeptides urotensin I (UI) and urotensin II (UII). Spinal cord neurons projecting to the urophysis were retrogradely labelled following application of diI (Molecular Probes) crystals to the urophysis of goldfish perfused with 4% paraformaldehyde. The urophysis and attached caudal spinal cord (2-3cm) were sealed in a glass container for 20 wk at 23°C, in the dark. Vibratome sections (40 μm; horizontal plane) were free floated and colabelled for either UI or UII for 48 hr in the dark (FITC) and photographed (rhodamine or fluorescein filter; Elberger'89). Cell groups were identified following Nissl staining of the sections. All the diI-labelled cell populations occurred within 3 mm from the urophysis. The more caudal diI-labelled cells varied in size and were in dense clusters. The more rostral cells were magnocellular (30 μm) and diffusely distributed. Some caudal spinal cord neurons were not labelled with diI. Rostral to the urophysis, many somata, fiber and terminal distributions of diI, UI-ir or UII-ir overlapped, but a portion of UI-ir neurons were not urophysiotropic and showed many distinct plexi terminating on diI-labelled cell clusters. Via these terminations UI may also modulate the action of other urophysiotropic (UII?) neurons. Some UI-ir fibers also appeared to project anteriorly in the spinal cord. In conclusion, many caudal spinal cord cells project to the urophysis; a large population of these have been confirmed to be UI or UII positive; and UI neurons may terminate locally within the caudal neurosecretory system or elsewhere within the CNS. A BIMODAL RHYTHM OF OXYTOCIN IN THE ANTERIOR PITUITARY GLAND. B. J. Arey* and M. E. Freeman, Dept. Biol. Sci., Florida State University, Tallahassee, FL 32306

We have recently proposed that oxytocin (OT) is the neurohormone responsible for the endogenous stimulatory rhythm (ESR) regulating prolactin (PRL) secretion (Arey and Freeman, *Endocrinology*, 124:878, 1989). The ESR is a bimodal rhythm with a nocturnal (N) component that peaks at 0300 h and a diurnal (D) component that peaks at 1700 h. In this study, we have investigated the concentration of OT in the anterior (AP) and posterior (PP) pituitary as well as in the peripheral circulation in order to determine if OT is responsible for stimulating PRL secretion during the periods of the ESR. Ovariectomized rats were decapitated every 2 h over a 24 h period. Each AP or PP was extracted with 2 N acetic acid. OT was measured in extracts and serum by RIA. Extracts from both the AP and PP caused displacement which was parallel with OT standards in the OT RIA. The AP contained a bimodal rhythm of OT concentration. Low levels of OT were present at 1200 h and 2200 h. A N surge began at 2400 h and peaked by 0200 h. OT concentrations at 0200 h were 6-fold greater than at 1200 h ($P<0.01$). Another, smaller D surge of OT in the AP began at 1700 h and peaked by 2000 h. The OT concentration of the AP at 2000 h was 3-fold greater than at 1200 h ($P<0.05$). The concentration of OT in the AP then declined to baseline by 2200 h. There was no detectable diurnal rhythm of OT in either the PP or peripheral circulation. Taken together, these data suggest that OT is secreted into the AP in a bimodal rhythmic fashion with a periodicity coincident with the periodicity of the ESR for PRL secretion. Furthermore, it provides further evidence for a role for OT as the neurohormone responsible for the ESR. Supported by NIH, HD-11669.

PCR ANALYSIS OF RAT PINEAL TISSUE FAILED TO DETECT OXYTOCIN OR VASOPRESSIN mRNA. M.M. Prechel*, M.R. Kelley* and W.H. Simmons. Loyola Univ. Med. Center, Maywood, IL 60153

Three neurohypophyseal peptide hormones have been detected in mammalian pineal glands. Two are oxytocin (OT) and vasopressin (AVP); the third is similar to arginine vasotocin (AVT) but has not yet been satisfactorily identified. These peptides are synthesized together with their carrier neurophysins, from single precursor mRNAs. The site of origin of the peptides found in the pineal is not known. The present study utilized the polymerase chain reaction (PCR) to look for evidence of neurohypophyeal peptide synthesis within the rat pineal gland. The PCR primers were complimentary to highly conserved regions of the hormone-neurophysin precursors, common to the OT, AVP and AVT messages, and bracketed a region of 239 base pairs (bp) of cDNA sequence. The PCR templates were cDNA obtained by reverse transcription of RNA from 19 day rat hypothalami and pineal glands, and from toad (B. marinus) brain. All three PCR products showed an ethidium bromide stained band at the 240 bp region on a 1.5% agarose minigel. But Southern blot analysis showed that only the rat hypothalamic cDNA hybridized with internal oligonucleotides specific for OT and AVP. These results indicate that the neurohypophyseal cDNA found in pineal does not represent message for OT or AVP, and suggest that these hormones are not synthesized locally. Furthermore, sequencing the novel pineal cDNA may soon establish the identity of the third, unknown pineal hormone. (Support: NSF and LUMC Potts Awards).

HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: STEROIDS

OVARIECTOMY (OVX) AND ESTROGEN (E) REPLACEMENT IN FEMALE RATS: EFFECTS ON ACTH, CORTICOSTERONE (CORT), MINERALOCORTICOID RECEPTOR (MR), AND MR mRNA. L.H. Burgess and R.J. Handa. Dept. of Cell Bio., Neurobio. and Anat., Loyola Univ., Stritch Sch. of Med., Maywood, IL 60153.

The E status of the female rat affects its endocrine response to stress. To explore this effect, we measured plasma ACTH and CORT, MR, and MR mRNA in 21 day OVX and OVX rats given E for 21 days. Pre- and post-stress CORT levels were increased ($p<0.05$) in E treated rats. Serial blood sampling revealed a time by E treatment interaction ($p<0.04$) following footshock. Both ACTH and CORT were greater ($p<0.05$) at 60 min.in E treated rats. This suggested an impairment of the CORT negative feedback mechanism. We therefore measured glucocorticoid receptor and MR levels in various brain regions with an in vitro binding assay using ^{3}H-CORT, RU 28362, and dexamethasone. E treated rats showed elevated ($p<0.05$) levels of MR in the hippocampus (HIPP) and hypothalamus. Preoptic area (POA) and HIPP MR mRNA levels were measured with an RNase protection assay using a 180 bp cRNA transcribed from $prMR_{EH}$. In OVX rats there were 4.6±0.5 fmol MR mRNA/mg RNA in HIPP and 1.0±0.1 fmol/mg RNA in POA. E treatment for 1 day lowered MR mRNA levels to 3.8 ± 0.5 fmol/mg RNA in HIPP and to 0.6±0.1 fmol/mg in POA. 21 days of E treatment lowered MR mRNA levels to 2.4 ± 0.5 fmol/mg RNA in HIPP. These data suggest that alterations in MR may underlie the changes in ACTH and CORT secretion seen in E treated rats.

THE AFFINITY OF THE MINERALOCORTICOID RECEPTOR IN HIPPOCAMPUS IS INDEPENDENT OF IN VIVO PROGESTERONE LEVELS. B.B. Turner, L.I. Holtsclaw*, and L. Xu*. James H. Quillen College of Medicine, East Tennessee State Univ., Johnson City, TN 37614.

The dissociation constant (Kd) of the mineralocorticoid receptor (MR) in the hippocampus and hypothalamus is several fold greater in female than in male rats. This study addresses the possibility that the observed affinity difference is due to the presence of progesterone in females. Twenty-four adult, female Sprague-Dawley rats were ovariectomized and injected s.c. for 10 days with either vehicle alone, estrogen (10μg), or estrogen plus either a low (50 μg) or high (500μg) dose of progesterone. Animals were adrenalectomized 20 hr before being killed under anesthesia by cardiac perfusion. Multiple blood samples were taken for determination of plasma progesterone. Binding parameters of soluble receptors have been measured in hippocampus and kidney slices of these animals by LH-20 gel exclusion chromatography.

Saturation plots of MR using 3H-dexamethasone in the presence of excess RU 28362 in kidney cytosols showed a significant difference in Kd between the vehicle control group and that receiving high dose progesterone (2.39 ± 0.40 nM vs. 6.08 ± 1.51 nM, $p < 0.05$). For kidney, the Kd for estrogen-treated group (2.43 ± 0.31 nM) was similar to control, and that for the low dose progesterone group (3.71 ± 0.45 nM) was intermediate between control and high dose progesterone. There were no differences in the Bmax of kidney MR among the four groups. Hippocampal binding showed no significant differences in either Kd or Bmax among the four groups. In hippocampus, the Kd of the control group was 1.34 ± 0.32 nM compared with 1.63 ± 0.43 nM in the high dose progesterone group. The Bmax of the control group in hippocampus was similar to that of the high dose progesterone group (121 ± 24 vs. 135± 18 fm/mg protein). The data indicate that the sex difference in the dissociation constant of the MR in hippocampus is not due to the action of progesterone in promoting dissociation of the MR-ligand complex. Supported by NIH 22158.

SEROTONIN (5-HT) REGULATION OF CORTICOSTEROID RECEPTOR BINDING IN CULTURED HIPPOCAMPAL CELLS: THE ROLE OF 5-HT-INDUCED INCREASES IN cAMP LEVELS. K. Betito, J.B. Mitchell, W. Rowe, P. Boksa, and M.J. Meaney. Douglas Hosp. Res. Ctr., Depts. of Psychiatry and Pharmacology, McGill Univ., Montréal, Québec, H4H 1R3, CANADA.

Recently we have shown that serotonin (5-HT) regulates the development of rat hippocampal type II corticosteroid receptors (CSR). We have reported that, in dispersed hippocampal cell cultures prepared from fetal rat (E19-20), 5-HT increased type II CSR binding (receptor binding measured using [3H]RU 28362). This effect required a minimum of 4 d exposure to 5-HT. The effect of 5-HT was mimicked by 5-HT2 receptor agonists and blocked by 5-HT2 receptor antagonists, such as ketanserin and mianserin. The present studies used this in vitro model to further explore 5-HT regulation of type II CSR binding. Cultures exposed to 10 nM 5-HT for 7 d showed a significant ($p<.01$) increase in type II CSR binding that persisted for at least 30 days following the removal of 5-HT, thus mimicking the long-term developmental effects seen in vivo. Cultures treated with 10 nM 5-HT showed a significant elevation of cAMP levels (~400%) that persisted for 7 d following 5-HT treatment. The effect was blocked by 100 nM ketanserin, and mimicked by 5-HT2 receptor agonists. Treatment of cultured hippocampal cells with the cAMP analog, 8-bromo cAMP, for 4 d produced a dose-related increase in type II CSR binding. The effect of 8-bromo cAMP was maximal at 10 μM concentrations, and the magnitude of the effect was comparable to that seen for 5-HT (160% vs 188%). Preliminary data indicate that activation of endogenous cAMP by forskolin treatment also increases type II CSR binding. Taken together with our previous findings, these results suggest that 5-HT is involved in the development of type II CSR binding and that the effect of 5-HT may be mediated by 5-HT-induced increases in cAMP levels.

THE ROLE OF BRAIN MINERALOCORTICOID AND GLUCOCORTICOID RECEPTORS ON CRF INDUCED HORMONAL AND CARDIOVASCULAR RESPONSES. S.M. Korte*, G.A.H. Bouws* and B. Bohus*. (SPON: European Brain and Behaviour Society) Department of Animal Physiology, University of Groningen, 9750 AA Haren, The Netherlands.

Behavioral and cardiac effects of centrally given CRF appeared to depend on adrenal hormones. Administration of the mineralocorticoid (RU 28318) and the glucocorticoid antagonist (RU 38486) 60 min before infusion of CRF were employed to investigate the role of the two receptor types on the CRF induced hormonal and cardiovascular changes. The antagonists were administered i.c.v. at a dose of 100ng/rat. CRF infusion itself (i.c.v., 300ng/rat) caused an elevation of plasma corticosterone (CS) and norepinephrine (NE) in combination with higher blood-pressure and heart rate. Prior treatment with the anti-glucocorticoid led to a matched enhancement of the NE response, and slight increase in the CS response. In addition, an increase in plasma epinephrine levels was seen, without an effect on blood pressure. The antiminer-alcorticoid did not have such effects. It is concluded that the brain glucocorticoid receptor regulated proces-ses lead to a very selective modulation of CRF-induced endocrine and physiological responses. This study was in part supported by the Foundation for Medical and Health Research MEDIGON (grant nr. 900-511-044).

IMMUNOCYTOCHEMICAL DEMONSTRATION OF MINERALOCORTICOID TYPE I RECEPTORS IN PRIMARY BRAIN CELL CULTURES. Y.-C. Chou*, Z. S. Krozowski*, W. G. Luttge and C. Sumners, Departments of Neuroscience and Physiology, University of Florida, Gainesville, FL 32610 and Medical Research Center, Prince Henry's Hospital, Melbourne, Australia 3004

It is now well accepted that mineralocorticoids, acting via specific receptors, have profound metabolic, neuroendocrine and behavioral effects on the brain. Previous studies from this lab have demonstrated [^{3}H]aldosterone binding to mineralocorticoid Type I receptors in astrocyte glial cultures similar to the binding found in brain and peripheral tissues. By using a polyclonal antiserum against a synthetic peptide (MINREC2) which corresponds to the hinge region of the human mineralocorticoid receptor, we have observed immunoreactive Type I receptors in a variety of brain cell cultures. MINREC2 antigenicity, detected by indirect alkaline phosphatase immunostaining, was found in both nuclei and cytoplasm of cells in neuronal cultures (containing 90% neurons), astrocyte glial cultures and "mixed" cultures (containing 50% neurons/50% astrocytes). Both neurons and astrocyte glia displayed immunoreactive Type I receptors. Because different types of cultures were grown using different sera, e.g. plasma-derived horse serum (PDHS) (neurons) and fetal bovine serum (FBS) (astrocytes), it was important to examine the effects of these sera on the expression of Type I receptors in cultured cells. It appears that the immunostaining observed in neurons maintained in 10% PDHS is not different from that in 5% PDHS/5% FBS.

The presence of MINREC2 staining in cultured neurons and astrocyte glia suggests that in addition to the ligand binding properties, Type I receptors in these cells are also similar in structure, at least in the hinge region, with those seen in brain and peripheral tissues. SPLANCHNICOTOMY ALTERS ULTRADIAN RHYTHMS IN STEROID SECRETION BY THE RAT ADRENAL. M.S. Jasper and W.C. Engeland, Sect. of Neurobiology/ Dept. of Surg., Brown Univ./ RI Hospital, Providence, RI 02903.

An ultradian rhythm in corticosterone (B) secretion which is synchronized between animals has been demonstrated in the rat using intra-adrenal microdialysis (FASEB J. 4:A827,1990). To determine the effect of the splanchnic innervation of the adrenal on rhythmic secretion of B, intra-adrenal microdialysis was done after splanchnicotomy (SPX). Under pentobarbitol anesthesia, adult male rats were prepared with a jugular vein catheter and an adrenal probe constructed from cellulose fibers (9 kD MW cutoff). In SPX rats (n=6), the thoracic splanchnic nerve was cut proximal to the suprarenal ganglion. In sham rats (n=7), no nerve was cut. Experiments conducted 1 day post-surgery consisted of continuous collection of dialysate at 10 min intervals (flow rate=10 µl/min) from 1000 to 1800 hr, with blood sampling at 1030 and 1730 hr. Dialysate B and plasma B were measured by RIA. Plasma B was similar in both groups. Episodic secretion of B persisted after SPX. Time domain analysis using PC-Pulsar revealed no difference in pulse frequency, width, inter-pulse interval, or normalized pulse amplitude. To determine if underlying periodic components in B secretion might be altered by SPX, frequency spectra were calculated for individual rats by fourier analysis. Averaging individual spectra within groups revealed peaks at approximately 60 and 30 min in sham rats. In SPX rats, the 60 min peak remained, whereas the 30 min peak was attenuated; additional energy was observed between 90 and 220 min in SPX rats. Averaging secretory time-series before spectral analysis did not change the spectral profile, indicating that episodes are synchronized between animals in SPX and in sham rats. These data suggest that adrenal splanchnic innervation modulates ultradian rhythms of adrenal B secretion, but does not directly generate or synchronize these secretory episodes. Supported by NIH grant DK38951.

ROLE OF GTP BINDING PROTEINS IN ADRENALECTOMY-INDUCED CHANGES IN HIPPOCAMPAL CALMODULIN ADENYLATE CYCLASE ACTIVITY. M. N. Gannon, T. Akompong and B. S. McEwen. Laboratory of Neuroendocrinology, Rockefeller University, New York, NY 10021.

We have observed that adrenalectomy (ADX) attenuates calmodulin- (CaM) and forskolin- (F) stimulated adenylate cyclase (AC) activity in rat hippocampal (HC) membranes. This effect is prevented by high, but not low, corticosterone replacement in ADX rats. ADX has been reported to alter levels of specific GTP binding (G) proteins (Gsα and Giα) in rat cortex, an effect prevented by CORT replacement (Saito, N., et al., PNAS, 86:3906, 1989). We therefore investigated the role of G-proteins in ADX-effects on HC AC activity. In both sham and ADX HC membranes incubation with the G-protein antagonist, GDPβS, did not abolish ADX attenuation of CaM AC, but decreased CaM- more than basal- or F-AC activity. Substitution of Mn2+ for Mg2+ in the AC assay, which selectively uncouples G protein control of AC, abolished CaM stimulation, but ADX still attenuated F AC. ADX had no significant effect on HC membrane Gsα and Giα content, measured by Western blot (n=10). These results suggest that ADX effects on HC AC may not occur through modulation of G-protein(s) levels, despite the fact that HC CaM AC appears selectively dependent on G-protein(s). Supported by NIMH-MH-41256.

EFFECTS OF AGING ON THE HIPPOCAMPAL GLUCOCORTICOID AND MINERALOCORTICOID RECEPTORS. M. I. Morano and H. Akil. Mental Health Research Institute, The University of Michigan, MI 48109-0720.

The basal levels of plasma corticosterone do not differ between young and old animals. However, the recovery to basal corticosterone levels following the termination of restrain stress (1 h) is delayed in the aged rat. We have measured the cytosolic MR and GR binding capacity as well as the expression of the mRNAs of both receptors in the hippocampi of young (5 mo.) and old (26 mo.) F-344 rats. The binding capacities of both receptors (MR and GR) are decreased in the hippocampi of old rats (57 and 52 % of those in young rats, respectively). The removal of endogenous corticosterone by adrenalectomy (2 days) results in a significant increase of more of 100 % in the maximum binding of these receptors in both young and old animals. The mRNA contents of MR and GR are lower in old sham-operated rats than in the young ones ($p < 0.05$). Interestingly, following adrenalectomy, only the old animals showed up-regulation of the levels of these mRNAs reaching levels comparable to the young; however, the binding capacities of these receptors in old rats did not achieve the levels in young rats. These data point to a possible change in mRNA stability and translatability in aged animals or to an alteration of steroid receptor cell cycle with age. Supported by MH 42251, DA 02265 and Markey Foundation.

MODULATION OF HIPPOCAMPAL GLUCOCORTICOID RECEPTORS IN ADULT RATS BY ALTERED THYROID STATUS. E.O. Johnson, A.E. Calogero, D.R. Rabin, G. Cizza, P.W.Gold, G.P.Chrousos, and T.C. Kamilaris, CNB/NIMH & DEB/NICHD, Bethesda, MD, 20892.

Both glucocorticoid receptors (GR) Type I and II exist in various extrahypothalamic sites, in particular the hippocampus, and have been implicated in the basal and stress-associated negative feedback control of the hypothalamic-pituitary-adrenal (HPA) axis. We investigated the effects of altered thyroid status on the intracellular glucocorticoid type II receptor concentrations in the hippocampus of adult male SD rats with short- (7 days) or long-standing (60 days) hypothyroidism (thyroidectomy + placebo), euthyroidism (sham thyroidectomy + placebo) or hyperthyroidism (thyroidectomy + thyroxine, 50 ug/day). We measured hippocampal GR Kds and concentrations and plasma concentrations of IR-ACTH and IR-corticosterone (B). There were no significant differences in the apparent Kds for [3H]-DEX binding as a function of thyroid status or duration of treatment. Although hypothyroid rats exhibited no changes in intracellular GR concentrations, however, hyperthyroid rats had significantly lower concentrations of hippocampal cytosolic receptors after both 7 days and 60 days of thyroxine treatment ($p<0.001$). Plasma ACTH and B levels increased in hyperthyroid animals, suggesting increased HPA axis activity in these animals. These data indicate that i) thyroid hormones modulate hippocampal GR type II concentrations; and ii) increased HPA axis activity in hyperthyroid states can be explained by a lower number of GR and decreased glucocorticoid feedback inhibition.

MK-801 ANTAGONIZES METHAMPHETAMINE-INDUCED DECREASES IN NEURONAL CORTICOSTEROID RECEPTORS. M.T. Lowy, Dept. of Psychiatry, Case Western Reserve University Sch. of Med., Cleveland, OH 44106.

Previous work in this laboratory demonstrated that depletion of biogenic amines by reserpine decreases hippocampal type I and type II corticosteroid receptors (CR) (Lowy, 1990). The present study was designed to determine if methamphetamine (MA), a stimulant drug which is toxic to serotonin and dopamine neurons, also decreases neuronal levels of CR. Administration of MA (15 mg/kg) to 1 day adrenalectomized rats decreased hippocampal type I (-29%) and II (-15%) CR as well as striatal type II CR (-21%) measured 3 hrs later. Cortical and hypothalamic type II CR were not affected. Since previous studies have demonstrated that the NMDA antagonist, MK-801, can attenuate the neurotoxic effects of MA, the effect of MK-801 (2.5 mg/kg) on the MA-induced decrease in neuronal CR was examined. MK-801 antagonized the MA-induced decrease in hippocampal type I and II CR as well as striatal type II CR. To directly examine if excitatory amino acids can regulate hippocampal CR, kainic acid (10 mg/kg) was administered to 1 day adrenalectomized rats which were sacrificed 3 hr later. Kainic acid significantly decreased both hippocampal type I (-47%) and type II (-38%) CR. These results indicate that MA decreases neuronal CR via a NMDA sensitive mechanism and that excitatory amino acids may play a prominent role in hippocampal CR regulation.

PERIPHERAL NERVE INJURY CAUSES CUTANEOUS NOCICEPTORS TO BE EXCITED BY ACTIVATION OF CATECHOLAMINE RECEPTORS J. Sato* and E.R. Perl, Dept. of Physiol., Univ. of North Carolina, Chapel Hill, NC 27599

We have shown that after nerve injury but not in normal animals, sympathetic trunk stimulation (SS) or intraarterial norepinephrine administration (NE) causes a fraction of C-fiber polymodal nociceptors (CPM) to discharge or to show enhanced heat-evoked sensitization. To test whether these effects on nociceptor activity are mediated by peripheral catecholamine receptors, the great auricular nerve (GAN) of deeply-anesthetized domestic rabbits was partially damaged under sterile conditions and the animals allowed to recover for 10 to 24 days. Post-operatively, none of the animals exhibited signs of discomfort or skin alterations. Terminally, under deep anesthesia, responses of CPM units to SS, NE and stereotyped heat stimuli were recorded from GAN filaments central to the site of damage. The relatively specific α_2 antagonists, yohimbine or rauwolscine (0.3-1 mg/kg) reduced or blocked the CPM excitation by SS and NE for 40-180 min, and reduced CPM sensitization by heat to 60% of control values. These results suggest that sympathetic and NE excitation of nociceptors after nerve injury probably is mediated by α_2 membrane receptors, phenomena possibly related to the pathogenesis of some causalgic-like pain syndromes. CHRONIC INJURY TO AXONS IN THE INFRAORBITAL NERVE PRODUCES LITTLE SPONTANEOUS ECTOPIC DISCHARGE MICHAEL TAL and Marshall Devor Depts. Anatomy and Zoology, Hebrew University of Jerusalem, ISRAEL.

Do chronically injured trigeminal axons generate massive spontaneous discharge like many afferents in hindlimb somatic nerves ? In an initial operation all fascicles of the infraorbital nerve in 18 adult male rats were ligated tightly with 6-0 silk and severed just distal to the ligature. After 4-164 days the rats were reanesthetized and the damaged nerve was exposed for acute electro--physiological study. Axons recordings were made from microfilaments teased from the nerve 10-15 mm. proximal to the neuroma. Only 40 spontaneously active A-fibers were encountered in 462 microfilaments (0.086 fibers/ microfilament). For comparison, sciatic nerve neuromas 3-16 days postoperative averaged 0.87 spontaneously active units per microfilament (28 rats, 645 microfilaments). Thus,the incidence of ectopic activity in infraorbital neuromas was less than 10% that of sciatic neuromas. To confirm that the nerve had not undergone massive retrograde degeneration, single stimulus pulses were applied just proximal to the neuroma, counting the number of single units recruited as current strength was gradually increased. On average, microfilaments contained at least $\geq$3.2 myelinated axons. Based on this average, the 40 spontaneously active axons encountered represent $\leq$ 2.6% of the sample. The corresponding value for sciatic nerve neuromas was 13.1%.

EVIDENCE THAT FAST AXONAL TRANSPORT IS INVOLVED IN THE DEVELOPMENT OF MECHANOSENSITIVITY IN AN ACUTELY CUT NERVE. G.M. Koschorke*, R.A. Meyer, and J.N. Campbell. The Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205

Severed nerves develop mechanosensitivity at their ligated ends within hours of injury. The rate of development of mechanosensitivity was temperature sensitive. Because axonal transport is similarly temperature sensitive, we postulated that axonal transport plays an important role in the development of ectopic excitability. To test this further and to determine if fast or slow axonal transport is involved, the sural nerve in anesthetized monkeys (macaca fasicularis) was tightly ligated at a proximal site to cut off the source of transported substances. At a site 85 mm distally, the nerve was tightly ligated and cut either 3 or 12 hours later. At 3 hr, but not at 12 hr, substances conveyed by fast transport would still be in the nerve between the ligation sites. Ten hours after the distal injury, action potential activity in A-fibers was recorded in response to a mechanical stimulus at the distal site. Only 3% of the A-fibers responded to mechanical stimulation for the 12 hr experiment, whereas 29% of A-fibers responded for the 3 hr experiment. These results are consistent with the hypothesis that the components required for mechanical-to-electrical transduction at sensory receptors are conveyed via fast axonal transport and accumulate at the nerve injury site to impart ectopic excitability. CHRONIC THORACIC DORSAL RHIZOTOMY ALTERS IMMUNOREACTIVE CGRP AND SUBSTANCE P IN THE DORSAL HORN OF GOATS. **H.E Sloan, V. Miletic, K.K. Bowen*, K.T. Foley* and G.S. Mitchell, Dept. Comp. Biosci. and Environ. Tox. Cntr., University of Wisconsin, Madison WI, 53706.**

Thoracic dorsal rhizotomy (TDR) causes pronounced ventilatory failure in goats during mild exercise, followed by rapid functional recovery over subsequent exercise trials (Mitchell et al., FASEB J. 2:A1508, 1988). As an initial approach to study spinal changes associated with functional deficits or recovery, we investigated the distribution of calcitonin gene-related peptide (CGRP; a marker for primary sensory afferents) and substance P (SP). Bilateral dorsal rhizotomies were performed from T2-T12 (n=3). Six to twelve months after surgery, the goats were sacrificed, and their spinal cords removed and immersion fixed. Transverse 50 μm spinal sections were processed for immunoreactivity using conventional PAP methodology. For comparison, sections from unoperated and sham-operated goats were processed similarly. At thoracic levels, CGRP fibers were concentrated in laminae I and II. Fiber bundles were also seen in the medial portion of lamina V with scattered CGRP fibers in the ventral horn. TDR nearly eliminated CGRP fibers in the dorsal horn; only a thin band of fibers that skirted the underside of the dorsal horn remained. At cervical levels, however, TDR goats showed increased CGRP labeling in laminae III and IV. There were no obvious differences in CGRP immunoreactivity in the ventral horn. SP immunoreactivity paralleled the CGRP pattern in both normal and TDR goats.

These results indicate that even 6 months following TDR, regrowth of CGRP containing afferents does not occur, and that functional recovery of ventilatory control does not result from their regrowth. However, plasticity in the spinal cord may have occurred and contributed to longterm compensatory mechanisms as suggested by increased CGRP and SP labeling at cervical levels - the spinal regions critically involved with the control of breathing. 440.5

HISTOCHEMICAL EVIDENCE OF THE INVASION OF VENTRAL ROOT AFFERENT FIBERS INTO THE SPINAL CORD OF RATS SUBJECTED TO SCIATIC NERVE LESIONS DURING THE NEONATAL STAGE. K. Sheen, B.S. Chung, J.W. Leem and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77550.

Using a horseradish peroxidase (HRP) labeling technique, we examined the possibility that ventral root afferent fibers invade the spinal cord after a neonatal peripheral nerve lesion.

A total of 11 anesthetized adult Sprague-Dawely rats were used (7 neonatal sciatic neurectomized and 4 normal control rats). After the L4-L6 dorsal roots of both sides were cut, HRP (30%) was injected into the spinal cord. HRP labeled cells were counted in the L5 dorsal root ganglion (DRG).

In rats subjected to neonatal sciatic neurectomy, there was an average of 45 labeled cells in each of the L5 DRG on the experimental side, whereas the DRG on the contralateral side contained 11 labeled neurons. On the other hand, the L5 DRG of normal control animals had only an average of 1 labeled neuron. The average size of labeled cells (29μm) was significantly smaller than the size of random sampled DRG cells (34μm).

These results suggest that lesioning the sciatic nerve during the neonatal stage triggers sprouting of fibers of small DRG cells, and that these fibers invade the cord via the ventral root. (Supported by NIH grants NS21266 & NS11255 and a grant from Bristol-Myers Co.)

BEHAVIORAL EVIDENCE FOR THE DEVELOPMENT OF TRIGEMINAL NEUROPATHIC PAIN FOLLOWING LIGATION OF THE INFRAORBITAL NERVE IN THE RAT. B.P. Vos and R. Maciewicz. Pain Physiology Lab, Dept. of Neurology, Massaschusetts General Hospital, Charlestown, MA 02129.

Loosely ligating the rat's sciatic nerve produces behavioral changes consistent with neuropathic pain in the affected hind limb (Bennett & Xie, Pain, 1988). To develop an animal model of trigeminal neuropathic pain, we ligated the infraorbital nerve (ION) in a similar fashion in the rat, and studied behavioral changes related to facial somatosensory function.

Experimental rats received a unilateral ION ligation and a contralateral sham operation. In control rats a unilateral sham operation was done. We quantified face grooming behavior, thigmotactic scanning activity, and responses to mechanical stimulation (tap, vibrissae pull, von Frey hairs:1,2,4,9,15g, pin prick) applied to different areas of the face. Rats were tested prior to surgery and up to 60 days post operatively (PO).

A significant increase in ipsilateral face rubbing was observed in experimental rats between days 1-20 PO. From day 10 PO, a decrease in use of the ipsilateral vibrissae to explore the environment was also observed. From day 5 PO, innocuous and noxious mechanical stimulation of the ipsilateral ION dermatome frequently evoked stereotyped episodes of intense face rubbing in experimental rats (100% on day 25); this type of aversive response was never observed in control rats. The frequency of episodes of intense face rubbing in response to mechanical stimulation to the contralateral ION dermatome or outside the ipsilateral ION dermatome in ION ligated rats also increased over time and with higher stimulus intensities.

The behavioral changes suggest the presence of paresthesias or dysesthesias, mechanical allodynia and hyperalgesia in the facial area innnervated by the ligated ION. These results provide behavioral evidence for the development of trigeminal neuropathic pain following ligation of the ION in the rat.

CHANGES IN PCP BINDING SITES IN RAT SPINAL CORD IN A CHRONIC CONSTRICTION INJURY L. M. Aanonsen[1], S. I. Sloan[1], K. C. Kajander[2], G. J. Bennett[4] and V. S. Seybold[3] [1]Biology Dept., Macalester College, St. Paul, MN 55105; [2]Dept. of Oral Sciences and [3]Cell Biology & Neuroanat., University of Minnesota, Minneapolis, MN 55455; [4]NAB, NIDR, NIH, Bethesda, MD 20892

A chronic constriction injury of the sciatic nerve in rats has been proposed to represent a model of peripheral neuropathy (Bennett and Xie,1988). The injury, which is induced by tying loose ligatures around the sciatic nerve, results in hyperalgesic responses to chemical and thermal stimuli. Previous studies have revealed that there is modulation of opioid and SP binding sites in this model (Stevens, *et al.* and Aanonsen *et al.*, NS Abstr. 15: 103, 1989). In the present study, we examined changes in PCP receptor binding sites in laminae I/II in rat spinal cord.

Spinal segment L4 was obtained from control rats (N=5) and from rats 2, 5 and 10 days after nerve ligation (N=8 rats/group). Autoradiographic studies were performed on spinal cord sections using 5nM ^{3}H-TCP; nonspecific binding was determined by incubation of adjacent sections in the ^{3}H-TCP plus 30 µM PCP (Aanonsen and Seybold, 1989). Data were analyzed using computerized grain counting. Specific binding was determined by subtracting nonspecific binding from total binding in each area analyzed. Statistical analyses (one-way ANOVA with Dunnett's post-hoc test) revealed a significant change in ^{3}H-TCP grain density in laminae I/II on the side ipsilateral to the ligation, but not on the side contralateral to the ligation. A significant *increase* in ^{3}H-TCP grain density was observed on day 2 while a significant *decrease* was observed 10 days after nerve injury. The PCP binding site has been shown to reside within a cation channel and is linked to the glutamate-activated, NMDA binding site. Glutamate has also been shown to be released in the spinal cord in response to noxious stimuli. Thus, the apparent modulation of PCP binding sites in this study may reflect changes in release of glutamate from afferents during the 10 days following constriction injury. Changes in [^{125}I]-hCGRP Binding Sites in the Dorsal horn of Rat Spinal Cord following Dorsal Rhizotomy.
M. G. Garry and V.S. Seybold. Dept of Cell Biology and Neuroanatomy, Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455.

Whereas receptor binding sites for many peptides have been described in the brain and spinal cord, there have been limited reports addressing the regulation of binding sites for neuropeptides (other than the opioids) within the central nervous system. Calcitonin gene-related peptide (CGRP) occurs in primary afferent neurons at the spinal level, although the role of CGRP in spinal processing is equivocal. In order to determine whether dorsal horn cells regulate their binding sites for CGRP, quantitative receptor autoradiography was used to measure the amount of [^{125}I]-human CGRP binding in the dorsal horn of the spinal cord at select times following dorsal rhizotomy. Multiple unilateral dorsal rhizotomies were performed (L1-S1). Binding was analyzed in spinal cord segment L4. There were no significant differences between the amount of CGRP binding within the right and left sides of the dorsal horn of untreated animals in any of the laminae examined. On the intact side of the experimental animals, low densities of binding sites were observed in the superficial laminae. Ipsilateral to peripheral deafferentation, however, significant increases in the amount of CGRP binding were observed at 4 and 8 days following rhizotomy. These changes were observed in the medial and lateral aspect of laminae I/II and in lamina V (3-way ANOVA, $p<0.05$). No changes were observed in lamina X.

These results indicate that CGRP binding sites are regulated by the extracellular concentration of CGRP. In addition, these data suggest that CGRP binding sites may normally be "down-regulated" due to basal levels of CGRP release.

440.9

ANALYSIS OF CGRP AND SP BINDING SITES IN RAT SPINAL CORD IN AN EXPERIMENTAL MODEL OF ACUTE, PERIPHERAL INFLAMMATION. M.T. Galeazza, C.L. Stucky, E.M. Jansen and V.S. Seybold. Graduate Program in Neuroscience and Dept. of Cell Biology and Neuroanatomy, University of Minnesota, Minneapolis, MN 55455.

The purpose of this study was to determine whether peripheral inflammation causes changes in the density of calcitonin gene-related peptide (CGRP) and substance P (SP) binding sites in the dorsal horn of the spinal cord, and the time course over which any changes may occur. Inflammation was induced by subcutaneous injection of complete Freund's adjuvant (75 µl, emulsified 1:1 with PBS) into the plantar surface of the left hindpaw. Animals were sacrificed 2 or 4 days after the injection. A group of uninjected animals served as a control. Before sacrifice, the thickness of each hindpaw was measured, and Evans Blue (50 mg/kg i.v.) was injected into the animal via cardiac puncture. After sacrifice, biopsy punches of skin were taken from each hindpaw for extraction and colorimetric determination of Evans Blue. The thickness of the inflammed paw, as well as the amount of extravasated Evans Blue in this paw were significantly increased at 2 and 4 days after injection of adjuvant compared to controls. [^{125}I]CGRP (0.1 nM) and [^{125}I]SP (0.05 nM) were used to label binding sites on tissue sections of spinal segment L4 from each animal. Incubation of adjacent tissue sections in radiolabeled peptide with 0.1 µM peptide was used to determine nonspecific binding. The density of autoradiographic grains within the emulsion overlying laminae I/II of each dorsal horn within each tissue section was quantified by computerized image processing. The amount of [^{125}I]CGRP bound in laminae I/II decreased ipsilateral to the inflammed paw at 4 days after injection of adjuvant. In contrast, the amount of [^{125}I]SP bound did not change within this region at the time points examined. These data indicate that the release of CGRP within laminae I/II of the dorsal spinal cord is increased in conjunction with acute inflammation. Studies funded by NS17702.

INCREASE OF SPINAL GLUCOSE UTILIZATION IN RATS WITH CHRONIC NEUROPATHIC PAIN AFTER SCIATIC NERVE LIGATION. J. Mao[1*], R.C. Coghill[1], A.F. Germano[4*], R. Cicciarello[4*], R.L. Hayes[2], D.D. Price[3] and D.J. Mayer[1]. Dept. of [1]Physiology, [2]Neurosurgery, [3]Anesthesiology, Medical College of Virginia, Richmond VA 23298; [4]Neurosurgical Clinic, University of Messina, Italy. Previous investigations in our laboratory have mapped spatial patterns of thermal nociceptive processing in the rat spinal cord. In the present experiment, we have sought to map CNS patterns of metabolic activity elicited by a model of neuropathic pain in unanesthetized rats by the fully quantitative [^{14}C]-2-deoxyglucose (2-DG) technique of Sokoloff *et al.*(1977). Peripheral neuropathy was produced by sciatic nerve ligation according to the method of Bennett *et al.*(1988). Ten days after nerve ligation, femoral vessels contralateral to the ligated limb were catherized for blood sampling and 2-DG administration. Rats were allowed to recover completely from forane anesthesia before 2-DG (50 µCi/rat) administration and the subsequent 45 min period of blood sampling. Upon the completion of blood sampling, rats were killed, and their spinal cords were removed, frozen, and sectioned at -20° C for autoradiography. Optic densities of autoradiographs were analyzed and converted to absolute rates of glucose utilization. Rats used in the 2-DG procedure had demonstrable hyperalgesia ipsilateral to ligation. These rats withdrew the ligated foot from radiant heat two to three sec earlier than the control foot, and their hindpaws on the ligated side were lifted in a guarded position. Analysis of variance indicated that there was a statistically significant increase of glucose utilization over basal levels ($p<0.05$) in the each of five sampled regions, laminae I-II, III-IV, V-VI, VII and VIII-IX of the spinal cord ipsilateral to the ligated side. The increase of glucose utilization occurred over spinal segments L3 to L5. The preliminary results suggest that neuropathic pain induced by sciatic nerve ligation results in a proloned and chronic increase in neuronal activity in spinal cord regions involved in nociceptive processing. TOWARD SELECTIVE LESIONING OF MOUSE NOCICEPTIVE DORSAL ROOT GANGLION NEURONS BY CHROMOPHORE-TARGETED LASER PHOTOLYSIS. J.D. Macklis and L.C. Dang*. Department of Neurology, Program in Neuroscience, Harvard Medical School, The Children's Hospital, Boston, MA 02115.

Recent studies have demonstrated selective, noninvasive lesions to subpopulations of CNS neurons targeted for laser photolysis by the retrograde incorporation of nanoparticles carrying photoactive chromophores. Similar mechanisms are investigated here as a potential approach for selective lesioning of nociceptive neurons located in mouse dorsal root ganglia. Selective neuronal targeting, photolytic singlet oxygen production within labeled cells, and laser-tissue interaction were studied.

Mice were injected subcutaneously in one hindlimb with 250 nl of nanoparticles with incorporated chlorin e_6. Following survival times of 1 to 12 weeks, mice were perfused and evaluated histologically for the level and distribution of label within neurons of different diameters. Quantitative analysis of the intracellular chromophore concentration was performed using an *in vitro* model of neuronal labeling and a microassay for cytotoxic singlet oxygen production. Transmittance of 670 nm wavelength laser energy through paraspinal bone and soft tissue was measured directly and compared with the solution of an appropriate analytical model using the diffusion approximation equation.

Dorsal root ganglia ipsilateral to the injection sites displayed intraneuronal label predominantly within small diameter (10-25 um), "dark" neurons, thought to be primarily nociceptive with "free" peripheral axonal terminals, capable of incorporating the nanoparticles. Labeled cells were found to contain 100 to 1000 particles, approximately 1 mM chlorin e_6. Energy transmittance of 5%-20% was measured through 1-2 mm bone and tissue thickness. These results suggest that one joule of incident energy could effectively lesion 10^4 neurons. Supported by NS28279, HD00859, and the Alzheimer's Association.

SINGLE UNITS RECORDED FROM INTRALAMINAR THALAMIC NUCLEI IN PATIENTS WITH DEAFFERENTATION PAIN EXHIBIT HYPERACTIVITY. R. F. Young, P. C. Rinaldi, D. Albe-Fessard* and J. Chodakiewitz*. Div. of Neurosurgery, Univ. of California at Irvine Medical Center, Orange, CA 92668.

Animal and human studies suggest that pain related to deafferentation is accompanied by spontaneous neuronal hyperactivity in the dorsal horn of the spinal cord and ventral posterior thalamic nuclei. In patients suffering from chronic pain associated with deafferentation, electrical activity of single cells in intralaminar thalamic nuclei was recorded for the present study. These patients were undergoing stereotactic procedures under local anesthesia for implantation of chronic stimulating electrodes or for thalamotomy.

In 8 of 10 patients single units were identified which discharged in high frequency, often rhythmic, bursts. Interval histograms from computer analysis revealed these discharges to be generally of two types: short bursts comprised of 2-6 spikes with burst frequency of 1 to 4 per second and long trains of 30-80 spikes and similar frequency. Reconstruction of electrode trajectories from MRI and CT scans indicated that the cells recorded were located in regions corresponding to the lateral aspect of the mediodorsal, central lateral, central median and parafascicular thalamic nuclei. The activity of cells from these nuclei which are part of the intralaminar nuclear group suggests that in patients with pain related to deafferentation the hyperactivity of units appears to be more widespread in the CNS than previously appreciated. The results have implications for treatment of chronic pain and for basic understanding of pain mechanisms.

STREPTOZOTOCIN-DIABETIC ANIMALS DISPLAY A HYPERALGESIA OF NON-PROSTAGLANDIN ORIGIN

S.C. Ahlgren; Y.O. Taiwo, J.D. Levine*
Dept. of Anatomy, UCSF, Box 0452, San Francisco CA94143

The goal of this study was to use an animal model of diabetes mellitus in the rat to study changes in nociception consistent with those seen in human diabetics. Diabetes was induced in 200-300g male Sprague-Dawley rats with the specific pancreatic B-cell toxin, streptozotocin (STZ, 70 mg/kg i.p.). Hyperglycemia (blood glucose > 350 mg/dL) was detected by the second day. Mechanical nociceptive thresholds were measured on the dorsum of the hindpaw using a Randall-Sellito paw-withdrawal device (Ugo-Basile).

In the diabetic rats, a significant decrease in mechanical nociceptive thresholds was observed starting seven days after STZ ($p<0.05$, one-way ANOVA). This hyperalgesic state (approx 30% decrease in threshold) persisted for at least 10 weeks. The dose-dependence relationship for hyperalgesia induced by i.d. PGE_2, which is thought to act directly on nociceptors and bradykinin, which produces a sympathetic-dependent, PGE_2-mediated hyperalgesia were also unchanged. I.d. indomethacin did not affect nociceptive threshold. These studies suggest that hyperalgeisa in the diabetic rat is not due to alterations in the production or action of hyperalgesic prostaglandins. Current experiments are examining the contribution of nociceptior terminal second messenger systems to diabetic hyperalgesia. *(Supported by NIH grant NS21647)*

THE NUMBER OF SUBSTANCE P CONTAINING DORSAL ROOT GANGLION CELLS IS REDUCED AFTER LASER IRRADIATION OF THE RAT TIBIAL NERVE. U. Wesselmann and W. Z. Rymer, Dept. of Physiology, Northwestern University Medical School, Chicago, IL 60611.

Recent studies from our laboratory indicate that Q-switched Nd:YAG laser irradiation might have selective effects on properties of small sensory nerve fibers. Previously we have demonstrated that laser irradiation selectively impairs neural impulse propagation in small slow conducting afferent fibers (Wesselmann et al., Soc. Neurosci. Abstr. 14:698, 1988). In addition we have shown that the number of small DRG cells labeled with HRP is selectively reduced after laser irradiation of the rat tibial nerve, while the number of large sensory neurons is not affected (Wesselmann et al., Soc. Neurosci. Abstr. 15:102, 1989). Substance P (SP) is a neurotransmitter, that has been shown to occur preferentially in the cell bodies of small sensory neurons. In an attempt to further analyze the preferential effects of laser application on small sensory nerve fibers, we have studied the effects of laser irradiation (Q-switched Nd:YAG laser, pulse energy -70 mJ/pulse, irradiation time - 5 min) of the rat tibial nerve on the number of SP labelled sensory neurons in DRG L4 and L5. In control animals (n=4) the numbers of SP containing neurons were not significantly different between sides (left: 4404 ± 404, right: 4492 ± 397)*. In contrast, after previous laser irradiation of the peripheral nerve the number of SP containing DRG cells was significantly reduced on the laser-treated side (left: 2710 ± 327, right: 4460 ± 342, $P<0.001$)*. The functional significance of this finding remains to be examined electrophysiologically. Since a large number of SP containing neurons appear to have nociceptive functions, the selective effects of laser irradiation on this neuron class might lead to potentially useful applications for the treatment of chronic pain. INCREASES IN GFAP IMMUNOSTAINING IN THE LUMBAR SPINAL CORD FOLLOWING SCIATIC NERVE INJURY. **C.Garrison, P.Dougherty, K.Kajander and S.M.Carlton. Univ. of TX Medical Branch & Marine Biomedical Institute, Galveston, TX 77550.**

Previous studies indicate that glial cells within the spinal cord respond to transection of a peripheral nerve. Although the signal for this response remains unknown, evidence supports a neurochemical mediation of this phenomenon. Neurochemical changes occur in the spinal cord gray matter in the animal model of experimental peripheral neuropathy (EPN). It is unknown if glial responses also result from this nerve insult. Therefore, in the following study, EPN was induced in one hindlimb of 3 rats; the contralateral limb received a sham operation. On post-surgical day 10, animals were perfused with 4% paraformaldehyde and L4-5 segments removed. The tissue was frozen sectioned (25μm) immunostained with glial fibrillary acidic protein (GFAP).

Counting revealed no significant difference in the number of GFAP immunostained cells in experimental versus control horns; however, measurements of grey matter density demonstrated a significant increase in staining density on the experimental side. In addition to further characterizing spinal cord changes in the EPN model, these findings confirm that astrocytes respond to peripheral nerve injury, possibly playing a role in nervous system pathology. SENSORY SYSTEMS—RETINA: RETINAL CHEMISTRY AND ANATOMY

441.1

SYNAPTIC ANALYSIS OF SEROTONERGIC NEURONS IN THE TURTLE RETINA.

W. D. Eldred and L. B. Hurd*.
Department of Biology, Boston University, Boston, MA 02215.

We used antiserum directed against serotonin to label select populations of bipolar and amacrine cells in the turtle retina (*Pseudemys scripta elegans*). The processes of labeled bipolar cells in the outer plexiform layer were commonly seen to make wide gap contacts with photoreceptors. Processes of serotonergic bipolar cells were rarely seen near photoreceptor ribbons. Labeled bipolar cells formed dyads onto either amacrine/amacrine cell or amacrine/ganglion cell pairs in stratum 1 of the inner plexiform layer. Outputs of bipolar cells in strata 4/5 were similar in type, but fewer in number than in stratum 1. Inputs to both labeled bipolar and amacrine cells in strata 1 and 4/5 were from unlabeled amacrine cells. Serotonergic amacrine cells made synapses onto unlabeled amacrine and ganglion cells in strata 1 and 4/5. Rare synaptic contacts from labeled amacrine cells onto unlabeled amacrine and ganglion cells were seen in the region of stratum 3. These results support the role of serotonergic bipolar cells in the OFF pathway of retinal processing, and provide data on the synaptic interactions of the serotonergic amacrine cells in the IPL. This research supported by EY04785 to WDE.

441.2

Localization Of Serotonin Uptake Mechanisms In Rabbit Retina. W.J.Brunken and A.Pis-Lopez* Dept. of Biology, Boston College, Boston, MA 02167

In mammalian retina, uptake mechanisms have been used as markers of indoleaminergic function. Previous kinetic analysis has demonstrated that two mechanisms with different affinities are present. Anatomically three classes of amacrine cells have been shown to take up 5HT. In this study, we have begun localize these transport mechanisms to anatomically identified cell classes.

Rabbit retina were exposed to exogenous 5HT in the presence or absence of zimelidine, an uptake blocker. In control experiments, anatomical demonstration of uptake at low doses of 5HT revealed a single plexus of fibers in the IPL and occasional amacrine cells (2.06 cells/mm^2); at higher doses of 5HT, the density of labelled cells increased (5.97 cells/mm^2) and the IPL staining was diffuse. Zimelidine was able to reduce by 25 to 50% the density of labelled cells depending on the concentration of exogenous 5HT. Together these data suggest that the low affinity and high affinity transport mechanisms may be localized in different cell classes.

Kinetic analysis of ^{3}H-5HT uptake supports this hypothesis. We have confirmed the existence of two transport mechanisms: one with high affinity (ca 10nM) and one with low affinity (ca 10 uM). Zimelidine reduced uptake by the low affinity transporter but did not affect the high affinity transport mechanism. Zimelidine also reduced the maximal uptake of 5HT by the retina at 45 and 60 minutes by 42 and 55% respectively.

Finally, we used ^{3}H-paroxetine to label the high affinity transporter. Scatchard plots revealed a single binding site with a B_{max} of 285 fmol/mg protein and a K_d of 0.35 nM. Zimelidine did not displace paroxetine binding suggesting that it is effective only at the low affinity transporter. These data suggest that only those cells labelled with low doses of exogenous 5HT or in the presence of zimelidine posses the high affinity 5HT transporter.

DOUBLE-LABEL ANALYSIS OF THE COEXISTENCE OF SOMATOSTATIN AND NEUROTENSIN IN AMACRINE CELLS OF THE CHICKEN RETINA. C.B. Watt, H.B. Li* and P.A. Glazebrook*. Alice R. McPherson Laboratory of Retina Research, The Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX 77381.

A comparison of previous immunocytochemical studies reveals a striking similarity in the morphologies of the populations of somatostatinergic and neurotensinergic amacrine cells in the chicken retina. A double-label study was performed to determine if these two neuroactive peptides coexist in chicken amacrine cells. A routine double-label paradigm was performed on cryosections collected through each of four retinal quadrants (dorsolateral, dorsomedial, ventrolateral, ventromedial). Primary antibodies were raised in different species, while respective secondary antibodies were conjugated to either fluorescein- or rhodamine-isothiocyanate. Control experiments testing the specificity of primary and secondary antibodies indicated no cross-reactive tendencies. Importantly, an examination of more than eight thousand labelled cells in each of the four retinal quadrants revealed that all labelled cells express both somatostatin- and neurotensin-like immunoreactivity. Therefore, these results indicate the presence of a single population of chicken amacrine cells whose members contain both of these putative neuroactive peptides.

POSTNATAL DEVELOPMENT OF TYROSINE HYDROXYLASE-IMMUNOREACTIVE (TH-IR) NEURONS IN THE RABBIT RETINA. Giovanni Casini, Nicholas C. Brecha, Ellen S. Takahashi and Clyde W. Oyster, Depts. of Anatomy & Cell Biology and Medicine, UCLA and VAMC, Los Angeles, CA, and School of Optometry, UAB, Birmingham, AL.

Dopaminergic amacrine cells play important modulatory roles in retinal function. The present study examined the development of TH-IR neurons in the rabbit retina. Putative dopaminergic neurons were identified either in retinal sections or in whole mount preparations by standard immunohistochemical protocols using a monoclonal antibody to TH. The first TH-IR cells were observed in the inner nuclear layer between the 5th and the 7th postnatal days. These neurons displayed weak immunoreactivity, and from day 6 immature processes could be observed. In the following days, the intensity of immunoreactivity increased, and by day 12 most of the TH-IR amacrine cells showed one or two major primary processes which had secondary branches stratifying in lamina 1 of the inner plexiform layer (IPL). At day 21, TH-IR cell bodies approached the morphology and the staining intensity typical of the adult, and an almost continuous band of immunoreactivity was present in lamina 1 of IPL. Staining intensity in the IPL increased with further development, and by day 28 processes in laminae 3 and 5 were also encountered. These observations support earlier biochemical data and show that TH-IR neurons develop postnatally, reaching complete maturity after day 28.

$GABA_A$ α AND β SUBUNIT IMMUNOREACTIVITIES IN THE RABBIT RETINA. Nicholas Brecha and Christine Weigmann*. Departments of Anatomy & Cell Biology and Medicine, CURE and Jules Stein Eye Institute, UCLA School of Medicine and VAMC-Wadsworth, Los Angeles, CA.

The existence of several $GABA_A$ subunits (α,β,γ and δ) and their differential distribution are consonant with the presence of multiple $GABA_A$ receptors. This study evaluates the cellular localization and distribution of two of these subunits, α and β, in the rabbit retina using immunohistochemical techniques. Retinas were fixed in 4% paraformaldehyde and sectioned perpendicularly to the vitreal surface with a cryostat or a vibratome. Monoclonal antibody bd-24, directed to the α subunit, labels processes distributed to laminae 1, 3 and 5 of the inner plexiform layer (IPL) and to the outer plexiform layer. Some amacrine and horizontal cell bodies are heavily labeled. Faint labeling is occasionally observed in some cells located in the ganglion cell layer. Monoclonal antibodies bd-17 and 62-3G1, directed to the β subunit, also label processes distributed to laminae 1, 3 and 5 of the IPL and a few amacrine cell bodies. No staining is observed in adjacent sections incubated in normal serum. The immunolabeling pattern observed in this study, along with earlier *in situ* hybridization studies, emphasizes the multiplicity and heterogeneity of $GABA_A$ receptor expression in the retina.

Bd-17 and bd-24 were generously supplied by Dr. J. G. Richards; 62-3G1 was generously supplied by Dr. A. L. de Blas.

β-NERVE GROWTH FACTOR-RECEPTOR IMMUNOREACTIVITY IN THE DEVELOPING RABBIT RETINA. Dennis W. Rickman, Nicholas C. Brecha and David Dawbarn*, Depts. of Anatomy & Cell Biology, USC; Medicine and Anatomy & Cell Biology, UCLA, Los Angeles, CA; and Medicine, University of Bristol, U.K.

The effects of nerve growth factor (NGF) on the survival, neurite outgrowth and target innervation of developing neural crest-derived neurons are well-documented. Recent studies with radiolabeled NGF or antibodies to the NGF receptor (NGF-R) suggest that NGF may have similar effects on neuroectoderm-derived neurons in the developing CNS, including the retina. Here, we used a monoclonal antibody (ME20.4) to the human low-affinity β-NGF-R to examine the localization and temporal pattern of β-NGF-R expression in embryonic and early postnatal rabbit retina. At embryonic day 15 (E-15) ME20.4 labeled radially-oriented cells which extended from the ventricular edge to the inner limiting membrane. At E-29 staining was observed in Müller cells, some amacrine cell somata, numerous ganglion cell somata and axons in the ganglion cell axon layer (GAL). This staining pattern was observed throughout the early postnatal period (P-2 to P-10) with particularly heavy labeling of ganglion cell axons in the GAL. At P-21 no staining was detected in any retinal layers. These observations suggest that β-NGF-R is expressed transiently throughout the period of retinal differentiation and may play a role in the development of retinal lamination and target recognition by ganglion cell axons.

Distribution patterns of parvalbumin immunoreactivity in the vertebrate retina

Pietro Paolo Sanna, Kent T. Keyser# Elena Battenberg, Harvey J. Karten# and Floyd E. Bloom
Department of Neuropharmacology, Research Institute of Scripps Clinic and #Department of Neuroscience, University of California at San Diego

Parvalbumin is a low molecular weight calcium binding protein which has been proposed to be involved in determining relaxation speed in muscle fibres and is also specific to discrete neuronal subpopulations. We have investigated the distribution of parvalbumin-like immunoreactivity (P-LI-IR) in the vertebrate retina. P-LI-IR was present in different classes of neurons with significant interspecies variation. The most consistent finding was that P-LI-IR was found within some but not all amacrine cells. In the goldfish retina only amacrine cells were labeled. In the chicken and pigeon retina P-LI-IR was restricted to two morphologically distinct subpopulations of amacrine cells. In the rat retina, a subset of amacrine cells and a subset of cells in the ganglion cell layer were labeled. On the basis of fluorogold retrogade tracing, the majority of the latter appeared to be ganglion cells. A similar pattern was found in the ground-squirrel. In the rabbit, horizontal cells showed P-LI-IR as described by others (Röhembeck J. et al., Neuroscience Letters, 77 (1987) 255-260), and a subpopulation of amacrine cells as well as some sparse cells in the ganglion cell layer were also immunoreactive. In the cat retina, the majority of ganglion and horizontal cells as well as a subset of amacrine cells were labelled (as reported by Röhembeck et al., *Ibid.*). In mammals, in partial confirmation of results described by others (Endo T. et al., Cell Tissue Res., 243 (1986) 213-217), horizontal and amacrine cells displayed P-LI-IR as did sparse cells in the ganglion cell layer.

CEREBELLAR PURKINJE CELL MARKERS ARE EXPRESSED IN RETINAL BIPOLAR NEURONS. A. S. Berrebi†, J. Oberdick, L. Sangameswaran, S. Christakos††, J. I. Morgan and E. Mugnaini†. †Lab. of Neuromorphology, U-154, Univ. of Connecticut, Storrs, CT. 06269 and Dept. of Neuroscience, Roche Institute of Molecular Biol., Nutley, NJ 07110 and ††Dept. of Biochemistry, New Jersey Med. School, Newark, NJ 07103.

Previous studies have been directed at the elucidation of neuron-specific gene expression in the mammalian central nervous system. We have identified a series of marker molecules that are expressed in cerebellar Purkinje cells with varying degrees of specificity. Here, we show by immunocytochemistry and Northern transfer and hybridization that two of these markers, namely L7 and PEP19, are expressed in the retina of mouse and rabbit, while a third marker, cerebellin, is absent. L7-like immunoreactivity (IR) is restricted to rod bipolar cells, while PEP19-like-IR is distributed in both rod and cone bipolars as well as in subsets of amacrine and ganglion cells. An antiserum to a fourth Purkinje cell marker, vitamin D-dependent calcium-binding protein-28kD (CaBP), reveals primarily axonless horizontal cells, but also subsets of rod bipolar, amacrine and, in the mouse but not in the rabbit, ganglion cells. The processes of immunoreactive cell bodies form discrete bands in the internal plexiform layer and cocktails of the antisera help distinguish their identity. Thus, the Purkinje cell markers can be used at the electron microscopic level to unravel the extremely complex neuropil of this retinal layer. Furthermore, knowledge of the retinal distribution of this panel of molecules is of general value for future studies of retinal neuronal typology, and can serve to map the densities of subsets of bipolar cells throughout the retina. The expression of L7 and PEP19 in bipolar cells and in Purkinje cells suggests a biochemical relationship between these two spatially distant neuronal populations.

GAP JUNCTION DISTRIBUTION IN CAT AND MONKEY RETINA VISUALIZED WITH MONOCLONAL ANTIBODY TO CONNEXIN32. N. Vardi, E. Hertzberg, and P. Sterling. University of Penna, Phila. PA 19104 and Albert Einstein College of Medicine, Bronx, NY 10461.

Gap junctions are known in mammalian retina from electron microscopy of freeze-fracture replicas and ultrathin sections. However, with neither ultrastructural technique is the overall pattern of gap junctions in the tissue revealed. Immunocytological localization of gap junctions at the level of the light microscope by PAP was therefore undertaken using a monoclonal antibody specific for connexin32, one of several gap junction proteins thus far identified. In the outerplexiform layer the stain formed a dark band; the profiles of photoreceptor terminals were revealed as rings by the even distribution of staining of their membranes. In the inner nuclear layer stain was absent except for dense, punctate deposits on horizontal cells and on certain somas in the bipolar and amacrine cell layers. In the inner plexiform layer stain was evenly distributed as fine granules. In the ganglion cell layer stain appeared as distinct granules within the cytoplasm of ganglion but not amacrine cells. The staining patterns in monkey and cat retina were similar. This distribution of connexin32 immunoreactivity is consistent with previous ultrastructural observations of gap junctions, but suggests the possibility of electrical coupling at sites where it has not previously been suspected (e.g. onto certain bipolar and amacrine somas). SPONTANEOUS AND EVOKED RELEASE OF TAURINE FROM A P_2 SUBCELLULAR FRACTION OF THE RAT RETINA. J.B. LOMBARDINI, Texas Tech U. Hlth. Sci. Ctr. Lubbock, Texas 79430.

The role of taurine as a potential neurotransmitter in the retina has been questioned in numerous literature reports. One essential criterion for a neurotransmitter is release of the substance from presynaptic nerve terminals. The present studies were designed to investigate the ion requirements on the spontaneous release of taurine and the effects of depolarizing agents on the evoked release of taurine from a P_2 subcellular fraction of rat retina. The tissue preparation was loaded with [^{3}H]taurine under conditions of high-affinity uptake. The absence of either Ca^{2+} (+ 2 mM EGTA) or Cl^- (replaced by Br^-) from the superfusion medium had no effect on spontaneous release. However, replacement of Na^+ with choline caused a 60% reduction in the spontaneous efflux rate. Potassium (56 mM)-evoked release of taurine was unaffected by the absence of Ca^{2+} (+2 mM EGTA). Veratridine (100 μM) was not as effective as K^+ in stimulating [^{3}H]taurine release as determined by measuring the areas (in arbitrary units) under the release curves (K^+ = 14.4 units; veratridine = 1.19 units). Substitution of Li^+ for K^+ resulted in a much reduced evoked release of [^{3}H]taurine (Li^+ = 2.2 units). The data suggest that the high-affinity uptake of [^{3}H]taurine is into a pool of taurine that is non-vesicular. The results do not support the hypothesis that taurine is a neurotransmitter in the rat retina. (Supported by NIH grant EY04780).

IS ACETYLCHOLINE INVOLVED IN LATERAL INHIBITION IN THE *LIMULUS* LATERAL EYE? HISTOCHEMICAL DEMONSTRATION OF ACETYLCHOLINESTERASE IN THE LATERAL PLEXUS. Daniel L. Sambursky, and Steven C. Chamberlain, SUNY Health Science Center at Syracuse and Institute for Sensory Research, Syracuse University, Syracuse, NY 13210.

Standard histochemical procedures for visualizing acetylcholinesterase (AChE) produced positive staining on frozen sections of the lateral eye. Deletion of acetylthiocholine iodide or substitution of butyrylthiocholine iodide produced no staining. On the other hand, staining was not affected by the inhibition of butyrylcholinesterase (BuChE) with Iso-OMPA. These results suggest specific demonstration of AChE rather than false demonstration of BuChE.

Axons of both retinular and eccentric cells were stained between the base of each ommatidium and the optic nerve, although no staining was observed in the somata. In the lateral plexus, a large uniform population of fibers was stained. Stained fibers were restricted to the lateral plexus and vertical bundles of axons. A similar pattern of fibers exhibits histamine-like immunoreactivity (Battelle et al., *Invest. Ophthalmol. Vis. Sci.* Suppl. **30**:290), however the pattern of fibers with AChE staining differs from that of fibers with substance P-like immunoreactivity (Chamberlain and Engbretson, *J. Comp. Neurol.* **208**:304) or that of fibers containing octopamine (Evans et al., *J. Comp. Neurol.* **219**:369).

The AChE-stained lateral plexus fibers must be the collaterals of the eccentric cell axons that mediate lateral inhibition (Fahrenbach, *Proc. Royal Soc.* Lond. B **225**:219), and other studies support the status of ACh as a neurotransmitter in *Limulus*. Acetylcholine synthesis has been demonstrated in the lateral and median optic nerves and in the optic ganglia of the brain (Battelle, *Vision Res.* **20**:911); AChE has been partially characterized from *Limulus* ventral nerve cord (Townsel et al., *Comp. Biochem. Physiol.* **58C**:29); and both ACh and choline acetyltransferase activity have been demonstrated in synaptosomes from *Limulus* CNS (Newkirk et al., *Comp. Biochem. Physiol.* **70C**:177). Supported by NIH EY03446 and EY00667.

PROTEIN KINASE C-LIKE IMMUNOREACTIVITY IN THE DEVELOPING RAT RETINA. D. Zhang and H.H. Yeh, Dept. Neurobiology and Anatomy, Univ. Rochester Med. Ctr., 601 Elmwood Avenue, Rochester, NY 14642.

In the vertebrate retina, a monoclonal antibody against protein kinase C (PKC) has been shown to label preferentially rod bipolar cells. Here, we examined in the rat retina the developmental pattern and the dynamic changes of cells expressing PKC-like immunoreactivity (PKC-LI) throughout postnatal life until adulthood. This was motivated in part by the possibility that the antibody might be used as a selective marker for examining the development of rod bipolar cells in the rat retina.

Faint PKC-LI could first be detected on postnatal day(PD)-10, being limited to the central region of the retina and labeling cell bodies located at the scleral margin of the inner nuclear layer adjacent to the outer plexiform layer. On subsequent days, PKC-LI spread progressively toward the peripheral retina and axon terminal bulbs at the vitreal margin of the inner plexiform layer began showing the first signs of immunoreactive labeling. By eye opening (PD-15), PKC-LI in these cells intensified and their axons became immunoreactive. The axons traversed the entire vertical thickness of the IPL and divided into short branches before ending as terminal bulbs. By the end of the fourth postnatal week, the PKC-LI cells appeared mature, resembling bipolar cells found in the adult. The morphology and the location of PKC-LI cells in both the developing and adult retina are consistent with them being rod bipolar cells. Rearing rat pups in complete darkness starting from the day of birth resulted in a precocious expression of PKC-LI.

In summary, PKC is not expressed in immunohistochemically-detectable amounts until relatively late in retinal development and thus fails to be a useful marker for rod bipolar cells at the earliest stages of maturation. Our results indicate further that the timing and degree of PKC expression may be subject to regulation by light even before eye opening.

CLONING AND EXPRESSION OF A MOUSE RETINAL POTASSIUM CHANNEL. D. J. Klumpp*, D. B. Farbert, C. Bowest*, and L. H. Pinto. Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208, and †School of Medicine, University of California at Los Angeles, Los Angeles, CA 90024.

We have screened mouse retinal cDNA libraries in an effort to characterize potassium channels of the mouse retina. Libraries were screened with oligonucleotide probes homologous to known potassium channels. We isolated cDNA clones spanning the complete coding region of MBK1, a putative potassium channel clone from mouse brain (Tempel *et al., (1988) Nature* **333**, 837). A cDNA containing the complete open reading frame was constructed by ligation of partial clones. mRNA transcribed *in vitro* was microinjected into *Xenopus laevis* oocytes. We measured membrane currents evoked by voltage clamp steps. A slowly activated outward current was evoked from a holding voltage of -90mV. This current had a maximum amplitude at about +40mV and was attenuated by TEA, 4-aminopyridine and Ba^{2+} but was not attenuated by Co^{2+} (1mM). The reversal voltage of the current increased as a function of increasing K^+. Thus, MBK1 encodes a potassium channel expressed in the retina. Supported by NIH.

OPSIN GENE EXPRESSION: CONTROL BY VITAMIN A IN RAT VS. FLY. W. Stark & M. Katz*[1]. Div. Biological Sci. & [1]Dept. of Ophthalmology, The Univ. of Missouri, Columbia, MO 65211.

In rat, vitamin A deprivation lowers rhodopsin content, as determined by spectrophotometric measurements; however, both EM immunocytochemistry and freeze fracture analysis indicate that opsin density in the outer segments is unaffected by vitamin A deficiency (Katz, et al., *Invest. Ophthal. Vis. Sci. Suppl.* **31**, 77, 1990). The rod outer segments decrease somewhat in size but otherwise have relatively normal morphology. The *Drosophila* syndrome differs: Deprivation (egg to adult) lowers sensitivity 100x (Stark et al. *Naturwissen.* **63**, 513-518, 1976) by reducing both rhodopsin (spectrophotometry) & opsin (freeze fracture) (Harris et al., *Nature* **266**, 648-650, 1977). Opsin & rhodopsin recover together with replacement (EM immunolabeling & microspectrophotometry) (Sapp et al. *Invest. Ophthal. Vis. Sci. Suppl.* **31**, 77, 1990); label is high in rough endoplasmic reticulum after 1 day. Vitamin A likely specifically regulates opsin synthesis via transcription, translation or post-translational modifications in fly but not rat. This is logical from respective photochemistry: fly's photointerconvertible rhodopsin 480 - metarhodopsin 580 system need only be synthesized once except for some daily turnover (Stark et al., *J. Neurocytol.* **17**, 499-509, 1988); rod rhodopsin bleaches into opsin & chromophore, the latter recycled through supportive retinal pigment epithelial cells & reapplied to the opsin already present.

SIGNALS THAT GENERATE THE CIRCADIAN RHYTHM IN THE ERG OF ANOLIS. C.J.Karwoski, A.P.Shaw*, C.R.Collazo*, X.Xu* & J.Xu.*. Dept. of Psychology, Univ. of Georgia, Athens, GA 30602.

The b- and d-waves of the electroretinogram (ERG) of the lizard Anolis carolinensis show a circadian rhythm (CR) in amplitude.

Removal of the parietal eye does not affect ERG amplitude or its CR. Also, the CR can still be phase-shifted by a new light-dark cycle.

Optic nerve section slightly decreases ERG amplitude and has complex effects on the ERG CR.

Removal of the pineal gland abolishes the ERG CR. Application of melatonin to the isolated eyecup reduces ERG amplitude.

Surgical controls (sham optic nerve section, sham pinealectomy, lesions to the forebrain and to the optic tectum) do not affect ERG amplitude or abolish the ERG CR.

An ERG CR is observed in some isolated eyecups.

These findings suggest that plasma levels of melatonin (which could be rendered non-periodic by pinealectomy) may carry circadian information to the retina. However, centrifugal signals in the optic nerve may also play a role, as might an oscillator within the eye.

LIGHT REGULATION OF MELATONIN SYNTHESIS IN PRIMARY CULTURES OF EMBRYONIC QUAIL RETINAL CELLS. M. E. Pierce and J. S. Takahashi. Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Melatonin plays a key role in the regulation of a number of rhythmic physiological processes in the retina. The development of vertebrate *in vitro* model systems to study retinal melatonin biosynthesis would greatly aid our ability to investigate the cellular mechanisms regulating rhythmic photoreceptor metabolism. We have been studying the regulation of melatonin biosynthesis in primary cultures of dispersed embryonic chicken and quail retinal cells. Cultures are prepared by enzymatically dispersing isolated retina that is free of retinal pigment epithelial cells. Cultures from both speices synthesize melatonin. However, in quail retinal cell cultures maintained on a 12 hour light : 12 hour dark cycle, melatonin is rhythmically synthesized with higher levels of melatonin being produced in darkness. In addition, preliminary experiments suggest that melatonin synthesis in quail retinal cell cultures may synchronize to a reversed light cycle. Melatonin synthesis in embryonic chick retinal cell cultures is not regulated by light, but can be modulated by treatments which affect levels of cAMP. We are currently studying whether quail cultures exhibit properties of a self-sustaining oscillator *in vitro*.

INTERACTIONS OF MELATONIN AND DOPAMINE IN THE RABBIT RETINA. Ethan D. Cohen and Robert F. Miller, Dept. Physiol. Univ. of Minn., Minneapolis, MN 55455

Melatonin has been reported to be a potent inhibitor of dopamine release in the rabbit retina (Dubocovich, '83). We examined the effects of melatonin, dopamine agonists, and dopamine antagonists on ganglion cells, inner retinal neurons, and the ERG in a superfused eyecup preparation. In the outer retina melatonin (5-50 μM) had little effect on cone dominated horizontal cells, while dopamine, and its agonists SKF38393 (D-1), and LY171555 (D-2) all caused a small depolarization of the horizontal cell resting potential. Curiously, dopamine antagonists SCH23390, had little effect on the horizontal cell light response, while metoclopramide (20-40 μM) caused only a slight increase in the horizontal cell light response. At the level of the inner retinal neurons the actions of dopamine and melatonin were antagonistic. Dopamine depressed the light response of many on-depolarizing units (including an identified AII amacrine), while melatonin increased them. Melatonin (5-25μM) increased the spontaneous firing rate of on-tonic ganglion cells, while dopamine depressed them. Melatonin decreased surround excitation in off-tonic ganglion cells, while it had little effect on the spontaneous activity of all on- or off- phasic ganglion cells studied. These studies support a role for melatonin inhibiting synaptic release by dopaminergic neurons. (Suppt'd by EY00844 and F32 EY06171)

LIGHT-MEDIATED REFLEXIVE CONTROL OF CHOROIDAL BLOOD FLOW IN THE PIGEON EYE. M.E.C. Fitzgerald and A. Reiner, Dept. Anat. & Neurobiol., UT-Memphis, Memphis, TN 38163.

A neural circuit has been identified in birds that may allow light to reflexively control choroidal blood flow in the eye. The components of this circuit are: retina-suprachiasmatic nucleus (SCN)-medial Edinger-Westphal (mEW)-ciliary ganglion-choroid (Reiner et al., TINS, 1983). We have previously used laser Doppler techniques (using a TSI LASERFLO® Monitor) to show that electrical activation of mEW (Reiner and Fitzgerald, ARVO, '89) or SCN (Reiner et al., ARVO, '90) yields increases in choroidal blood flow. In the present study we investigated whether this circuit mediates increases in choroidal blood flow in response to retinal illumination in pigeons.

Tissue overlying the superior pole of the eye was removed, the extraocular muscles curarized and the laser probe positioned against the sclera to measure choroidal blood flow. Periodic ten second illumination of the retina of this eye, with an AO fiber optic light 2 cm from the eye, consistently yielded increases (20-100%) in choroidal blood flow. Assessments of the occurrence of this light-mediated response in pigeons that had sustained complete unilateral destruction of mEW 3-4 weeks earlier indicated that destruction of mEW greatly attenuated this light-elicited increase in choroidal blood flow.

Thus, the SCN-mEW circuit may be a neural substrate by which increases in retinal illumination yield increases in choroidal blood flow. Effective control of blood flow by this neural circuit could play an important role in maintaining a constant environment for retinal photoreceptors during light exposure. Supported by EY-05298 (A.R.)

A BASAL LAMINA AND MÜLLER GLIA ENDFEET ARE MISSING IN AN INVERSELY LAMINATED TISSUE, REGENERATING FROM EMBRYONIC CHICKEN RETINAL CELLS.
P.G. Layer [1], E. Willbold [1]* and H. Wolburg[2]*. 1) Max-Planck-Institut für Entwicklungsbiologie, 2) Pathologisches Institut der Universität, D-7400 Tübingen, FRG.

Starting with dissociated embryonic chicken retinal cells of defined origin, two rotary culture systems can be generated that express areas consisting of complete sets of retinal cell layers (*in-vitro-retinae, IVRe*). When pigmented cells from the eye margin are included, the sequence of layers is identical with that of an *in situ*-retina (*outside-out IVRe*). In *IVRe* derived from dissociated retinal cells only, the order of layers is inversed (*inside-out IVRe*; ref. 1). Using ultrastructural and immunohistochemical methods, radial processes, photoreceptor inner segments and tight junctions are similarly observed in both systems. However, exclusively in *outside-out IVRe*, we find premature Müller glia endfeet connecting to a well-developed basal lamina that originates from the pigmented cell core. The fact that a basal lamina and glial endfeet are missing in *inside-out IVRe* strongly argues that these components contribute to tissue polarity during normal and pathological retinogenesis.

Ref. 1: Layer, P.G. and Willbold, E. (1989). *Cell Tissue Res.* 258: 233-242.

442.1

ADAPTATION IN BULLFROG SACCULAR HAIR CELLS INVOLVES AN ACTIVE MOTOR. J.A. Assad and D.P. Corey. Neuroscience Group, Howard Hughes Medical Institute; Dept. of Neurology, Massachusetts General Hospital; and Dept. of Neurobiology, Harvard Medical School, Boston, MA 02114

Bullfrog saccular hair cells adapt to maintained displacements of their stereociliary bundles in a manner suggesting a continuous adjustment of the tension applied to the transduction channels (Howard and Hudspeth, 1987; Hacohen *et al.*, 1989; *cf.* Crawford *et al.*, 1989). Calcium entry through transduction channels, which can be blocked by sufficient depolarization, appears to reduce the equilibrium tension (Assad, *et al.*, 1989). This model predicts that the bundle should pivot a small distance negatively when the cell is depolarized; such movements have been observed (Assad, *et al.*, 1989). Correlation of these movements with the adaptation would imply that an intracellular molecular motor underlies the adaptation process.

We have examined further the relationship of active bundle movements to adaptation. Movements were recorded in dissociated, whole-cell voltage clamped hair cells using video microscopy. In response to voltage steps from -80 to +80 mV, the bundles moved ~40 nm negatively with an exponential timecourse (tau = 150-250 ms). The return following repolarization to -80 mV was much faster, typically reaching baseline within 60 ms. This asymmetry in timecourse was also seen in the negative shift of the I(X) curve (reflecting increased tension on the transduction channels) in response to the voltage step. The steady-state voltage dependences of the movement and I(X) shift were also similar. Active bundle motion was only observed in cells that had appreciable transduction currents; moreover, the depolarization-induced movement and I(X) shift tended to wash out approximately in parallel. These results strengthen the hypothesis that adaptation is mediated at least in part by an active, tension-regulating motor.

442.2

SINGLE-STEP PURIFICATION OF HAIR BUNDLES AND PRELIMINARY CHARACTERIZATION OF CONSTITUENT PROTEINS. P. G. Gillespie and A. J. Hudspeth. Department of Cell Biology and Neuroscience, University of Texas Southwestern Medical Center, Dallas, TX 75235-9039.

Characterization of the molecular basis of mechanoelectrical transduction in hair cells has been hampered by difficulty in obtaining purified hair bundles, the organelles of transduction, and the necessity of detecting extraordinarily small amounts of protein. We have therefore devised an efficient, "twist-off" procedure for purification of hair bundles and have developed a highly sensitive, nonradioactive means of protein detection.

We isolate hair bundles by glueing the basal surface of a sacculus from the bullfrog (*Rana catesbeiana*) to the coverslip bottom of a cylindrical chamber. After embedding the organ in low-melting-point agarose, we rotate the solidified agarose cylinder with respect to the immobilized sacculus, shearing off the hair bundles at their relatively fragile bases. Light and transmission electron microscopy reveal few contaminants in the agarose plug containing the bundles. By the criteria of rhodamine-phalloidin labelling of F-actin, biotinylation of intracellular proteins, and exclusion of ruthenium red, over 90% of the stereocilia reseal after isolation. We visualize the hair-bundle proteins by silver staining or by biotinylation followed by chemiluminescence detection, which allows the detection on electroblots of as little as 500 fg (7 amol) of bovine serum albumin. Although actin constitutes over 75% of the protein in this preparation, or 10-20 ng per sacculus, at least 30 other proteins can be resolved by SDS-PAGE. Many of these proteins are exposed on the extracellular membrane surface, and several are extensively glycosylated; Triton X-114 extraction and phase partitioning suggests that some are integral membrane proteins.

442.3

OUTER HAIR CELL ELECTROMOTILITY: LOCALIZATION AND DISTRIBUTION OF THE FORCE-GENERATING MECHANISM. R. Hallworth, B.N. Evans*, and P. Dallos. Auditory Physiology Lab. (The Hugh Knowles Center) and Dept. of Neurobiology and Physiology, Northwestern Univ., Evanston, IL 60208.

The location and mechanism of outer hair cell electromotility are currently unresolved. A series of experiments was conducted to distinguish between cortical (membrane-associated) and intracellular locations. Isolated OHCs were partially drawn into a microchamber (Evans et al., 1990, in prep.), and voltage commands were applied across the cell.

Applied voltages resulted in antiphasic movements of the cell's ends, that is, while one half contracted, the other half extended. This result strongly implies that the mechanism is associated with the cellular cortex, since the potential gradients across the membrane halves are also in antiphase, but the potential gradient within the cell is unidirectional (see figure). When the percentage insertion, p, of the cells was varied, the displacement of either end could be described by a parabolic function, p(1-p). These observations suggest that the displacement is the cumulative sum of a large number of small motile elements driven in parallel. Measurements made at extreme percentage insertions deviated from the p(1-p) function, and were compatible with the assumption that the motile elements are restricted to the region between the cuticular plate and the cell nucleus.

MATURATION OF ELECTRICAL MEMBRANE PROPERTIES OF COCHLEAR HAIR CELLS IN THE EMBRYONIC CHICK. P.A. Fuchs and B.H.A. Sokolowski, Dept. Physiology, U. Colorado Med. School, Denver, CO 80262

The developing chick first responds to sound about embryonic day 11 (E11). Acoustic sensitivity and upper frequency limit increase with age, showing particularly marked improvement two days before hatching (E19). We have examined the electrical membrane properties of a topographically selected group of cochlear hair cells to determine what gated ionic currents might be acquired throughout this period. Hair cells were isolated from an area 0.8 to 1.2 mm from the apical tip of the adult cochlea, or from a proportionately located region of the smaller embryonic cochleas. Single hair cells were visualized with interference contrast optics on an inverted microscope and whole-cell, tight-seal recordings were made of membrane potential and transmembrane current.

Rapid, Ca-activated K current ($I_{K(Ca)}$) underlies electrical tuning at frequencies greater than 100 Hz in hair cells originating 1 mm from the apical tip of the mature cochlea. In contrast, hair cells from this cochlear region in the early embryo (E12-E14) had a much slower, voltage-dependent K current, (I_K) that in combination with Ca current produced slowly repetitive (at less than 20 Hz) action potentials. The Ca current was similar in kinetics and magnitude to that found in mature hair cells. One week later (E19) significant amounts of $I_{K(Ca)}$ were found in hair cells from this cochlear region. High frequency (140 Hz) voltage oscillations could be evoked in current clamp. The acquisition of Ca-activated K channels by hair cells may be essential for functional maturation of the chick's cochlea.

DIFFERENTIAL RESPONSE OF ISOLATED INNER AND OUTER HAIR CELLS TO STIMULATION BY POTASSIUM AND CALCIUM J. Schacht, D. Dulon* and G. Zajic* Kresge Hearing Research Institute, The University of Michigan, Ann Arbor MI 48109-0506.

Inner hair cells are generally considered the primary transducers in the mammalian cochlea while outer hair cells play a modulatory role in the transduction mechanism. Specifically, motile properties are thought to be unique characteristics enabling outer hair cells to modify basilar membrane micromechanics in response to efferent control. In isolated outer hair cells, increasing intracellular Ca^{++} leads to reversible cortical contractions and cell elongation by a mechanism dependent on calmodulin and structural proteins. Depolarization by K^+ triggers shape changes by an osmotic mechanism. A major question in determining the physiological correlates of such *in-vitro* responses is whether these phenomena are unique to outer hair cells.

Inner and outer hair cells were mechanically isolated from the guinea pig cochlea. Depolarization by KCl swelled both inner and outer hair cells by approximately 10% of their volume. The application of ionomycin, an ionophore permeabilizing the membrane to Ca^{++}, increased intracellular Ca^{++} levels in both inner and outer hair cells. This treatment, however, generated cortical contractions and elongation of outer hair cells only and did not affect the shape of inner hair cells. The results demonstrate that inner hair cells do not possess the mechanisms necessary for a contractile response to Ca^{++}. Calcium is thus a specific regulator of outer hair cell motility making this mechanism a most likely physiological modulator of a transduction feedback process. [Supported by NIH grant DC-00078]

EFFECTS OF OTOTOXIC LEVELS OF SALICYLATES ON SUBSURFACE CISTERNS OF OUTER HAIR CELLS. R. Dieler*, W.E. Shehata* and W.E. Brownell. The Center for Hearing Sciences, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Cochlear outer hair cells (OHCs) possess force generating abilities. Their rapid electromotility may be structurally related to the subsurface cisterns (SSCs), a unique organelle composed of stacks of subplasmalemmal smooth parallel membranes. Ototoxic doses of salicylate have been shown to reduce otoacoustic emissions *in vivo* as well as OHC turgidity and electromotility *in vitro* (cf. Brownell,W.E., Ear & Hear., 11:82-92, 1990). In vivo studies (Douek,E.E. et al.,J. Laryngol. Otol., 97:793-799, 1983) have suggested that SSCs are an important intracellular target for salicylate ototoxicity.

We have superfused isolated OHCs from guinea pig cochleae with culture media containing sodium salicylate (2mM, 5mM, 10mM for 10 - 60 min.). Subsequently, the cells were fixed with an osmotically balanced glutaraldehyde solution and processed for transmission electron microscopy. OHCs maintained in standard culture media served as controls. The majority of control cells showed 1 - 13 well preserved, smooth, unfenestrated SSC layers. Supranuclear lamellar or Hensen bodies were only occasionally seen. Following salicylate exposure, the cisternal layers lost their parallel arrangement and became vesiculated forming fenestrated cisterns of random orientation . There was also a more frequent occurrence of irregularly located cytoplasmic membranous systems (probably Hensen bodies). The intermembranous cisternal distances appeared to be increased and in some instances disintegration of the outermost cisterns was seen. The present findings demonstrate a structural involvement of SSCs in the ototoxic response to salicylate and strengthen the possibility that the SSCs might be an important anatomical substrate for electromotility.

SHORT (OUTER) HAIR CELLS OF THE CHICK'S COCHLEA ARE HYPERPOLARIZED BY CARBACHOL. B.W. Murrow and P.A. Fuchs, Dept. Physiology, U. Colorado Med. School, Denver, CO. 80262.

Sensory receptor cells (hair cells) of the chick's cochlea are classified as short or tall by the ratio of their apical surface diameter to length of the cell body. In short hair cells this ratio is greater than 1. Short hair cells are situated over the basilar membrane, in a position analogous to that of outer hair cells in mammals. Further, it is thought that the efferent nerve supply to the cochlea ends preferentially on short hair cells, as on outer hair cells, and that these axons release acetylcholine to produce their inhibitory effect. We have examined the effect of the cholinergic agonist, carbachol, on hair cells isolated from selected regions of the chick's cochlea. Whole-cell, tight-seal recording was performed on cells that were exposed to a stream of 100 μM carbachol from a nearby perfusion array.

In short cells carbachol produced a large hyperpolarization (as much as 30 mV from a resting potential of -40 mV). In voltage clamp carbachol produced an outward current that could reach several hundred pA from a holding potential of -40 mV. Variation of the holding potential suggested that the current reversed near E_K. The carbachol response desensitized over the course of several seconds. Responses to carbachol were observed in 17 of 18 short cells. In contrast, carbachol had no effect on 18 tall cells from the same cochlear section, mimicking the proposed efferent innervation pattern.

VOLTAGE-GATED Ca^{2+} CURRENTS RECORDED *IN VITRO* FROM OUTER HAIR CELLS OF THE GUINEA PIG. X. LIN[1]*, R.I. HUME[2], A.L. NUTTALL[1], Kresge Hearing Research Institute[1] and the Dept. of Biology[2], The University of Michigan, Ann Arbor, MI 48109

Auditory efferent neural transmitter(s) may influence the transduction process in the organ of Corti by modulating voltage-gated ion channel(s) in the membrane of outer hair cells (OHCs). This hypothesis motivated our work on characterizing voltage-gated currents of the OHCs. Single isolated OHCs of the guinea pig were studied *in vitro* by whole cell voltage clamp techniques. OHCs were isolated enzymatically and mechanically from the apical two turns of guinea pig cochlea and maintained in short-term culture. The pipette internal solution contained (mM): KCl 130, EGTA 20, Hepes 10, Glucose 10, pH 7.4. Whole cell clamps were established in a modified Hank's solution (NaCl 130, KCl 4, $MgCl_2$ 2, Hepes 12.5, Glucose 10, pH 7.4). The external solution could be changed via a perfusion system. Currents (Leakage subtracted) in response to a series of depolarizing voltages from a holding potential of -110mV were recorded in the modified Hank's external solution. A transient inward current first appeared when cells were depolarized to about -70mV, but the responses to more positive test pulses were dominated by a delayed outward current with little inactivation. The outward current was completely suppressed by changing the medium in the recording chamber to a solution expected to suppress K^+ and Na^+ currents, which contained: KCl 4, $CaCl_2$ 4, TEA·Cl 100, 4-aminopyridine(4-AP) 10, TTX 100nM, Hepes 12.5 and Glucose 10. With this bathing solution, the inward currents recorded in response to the same test paradigm consisted of two components: (1) a fast-inactivating inward current first appeared at about -70mV, (2) a slow-inactivating steady inward current began around -30mV and peaked at about +20-30mV. The composition of the new external solution and the observation that the inward current didn't reverse for depolarizing potentials up to +80mV indicated that Ca^{2+} ions were the charge carrier. Similar inward currents could also be recorded when pipette internal solution was supplemented with 2mM TEA and 1mM 4-AP and cells were bathed in Hank's solution.

In conclusion, the data we have obtained so far support the idea that multiple types of voltage-gated Ca^{2+} channels as well as at least one class of K^+ channels are present in the membrane of the guinea pig OHCs.

WHOLE-CELL CURRENTS IN MAMMALIAN VESTIBULAR HAIR CELLS. R.A. Eatock. Dept. of Physiology, University of Rochester, Rochester, NY 14642.

It is likely that the functional diversity of mammalian vestibular neurons in part originates in the hair cells; however, little direct information on the physiology of mammalian vestibular hair cells exists. We are examining the hair cells' membrane currents and voltages using the whole-cell GΩ seal technique. Hair cells from the utricles and semicircular canal organs of rats are mechanically dissociated following enzymatic treatment and are maintained in Hanks' Balanced Salt Solution. While both Type I and Type II cells can be identified, all of the data are from probable Type II cells. Depolarizing voltage steps typically elicit small inward currents followed by relatively large outward currents. These currents resemble the Ca and Ca-activated K currents in type II hair cells of other species. Depolarizing current steps evoke voltage responses that suggest heavily damped electrical resonances. The resonant frequency is voltage-dependent, varies among cells, and is correlated with the kinetics of the outward currents. (Supported by ONR)

IDENTIFICATION OF SPECIFIC CARBOHYDRATES IN THE CELL COAT OF THE TROUT SACCULAR EPITHELIUM. K.M.Khan[1], J.S.Hatfield[2]*, and D.G.Drescher[1]. [1]Laboratory of Bio-otology, Wayne State Univ. School of Medicine, Detroit, MI 48201, and [2]V.A.Medical Center, Allen Park, MI 48101.

A variety of possible functions have been proposed for the glycoconjugates present in the cell coat surrounding the stereocilia of the vertebrate inner ear. Glycoconjugates may hold the stereocilia together, prevent their fusion, and/or sequester cations essential for mechano-sensory transduction. We have reported the presence of a glycoconjugate-rich cell coat on the luminal surface of cells of the trout saccule (Assoc. Res. Otolaryngol. Abstr. 13: 361, 1990). The aim of the present study was to identify specific carbohydrate moieties of the cell coat of the trout saccular epithelium, using lectin probes. Trout saccules were dissected and fixed in Karnovsky's fixative (100 mM cacodylate buffer, pH 7.2) for 2 h. Specimens were treated with biotinylated lectins, labeled with HRP-conjugated avidin, post-fixed in buffered 1% OsO_4, dehydrated in ethanol, and embedded in LX-112 resin (Ladd Res. Industries). As controls, specific inhibitory sugars (final concentration, 0.2 M) were added to the lectin solutions. Glucose, galactose, fucose, mannose, *N*-acetylglucosamine, and *N*-acetylgalactosamine were found to be present on the luminal surface of the sensory and non-sensory cells. However, variations in the intensity of staining, associated with the sensory and the non-sensory cells, suggested biochemical heterogeneity and quantitative differences among various oligosaccharide chains present in the cell coat. In control specimens, staining was either eliminated or reduced. The presence of these carbohydrates in the cell coat of the trout saccular epithelium is consistent with the distribution of carbohydrate moieties present in the mammalian inner ear structures (Gil-Loyzaga et al., Hear. Res. 20: 1-8, 1985; 34: 149-156, 1988). These results suggest biochemical similarities between the cell coats surrounding teleost and mammalian inner ear structures.

POSTNATAL REMODELING OF COCHLEAR NEURON ARBORS IN A MAMMALIAN EAR. Stephen M. Echteler. Auditory Physiology Lab. and Dept. of Neurobiol. and Physiol., Northwestern University, Evanston, IL 60208.

In adult mammals, inner (IHC) and outer (OHC) cochlear hair cells are contacted by afferent neurons which are morphologically distinct and completely segregated. iHC afferents are thick myelinated neurites which project radially within the cochlear duct, produce few branches and typically innervate the nearest one or two receptors with punctate bouton endings. OHC afferents are thin unmyelinated fibers which extend for up to 600 μm before branching serially to innervate from 5 to 50 receptors.

To determine how these two strikingly different patterns of hair cell innervation are constructed I have examined early postnatal changes in the arborization of individual cochlear neurons in the Mongolian gerbil. Neurons were labeled through injections of Horseradish peroxidase into the apical turn of freshly excised cochleae which were subsequently maintained in vitro for three to four hours.

During the first few postnatal days (P0 to P2) some neurons had peripheral neurites which did not yet reached the IHC zone. These neurites were capped with growth cones of varied morphology depending upon their proximity to their hair cell targets. Other neurons had more complex arbors with neurites contacting both IHCs and OHCs. During the next two postnatal days (P3 and P4) neurons contacting both receptor types became increasingly rare. By P5, individual cochlear neurons contacted either IHCs or OHCs. At each postnatal stage the form displayed by an immature cochlear neuron depended not only upon its age but also its position within the cochlear spiral; neurons located more apically generally possessed peripheral arbors which were less well developed. (Supported by NIDCD grant R29 DC00493).

442.12

BASAL/APICAL DIFFERENCES IN THE EFFECTS OF COOLING ON THE RESPONSES OF SINGLE COCHLEAR NERVE FIBERS IN THE GERBIL. K.K. Ohlemiller and J.H. Siegel. Auditory Physiology Lab. (Audiology) and Dept. of Neurobiology and Physiology, Northwestern Univ., Evanston IL 60208.

We have developed a method for rapidly cooling and rewarming the gerbil cochlea while recording from auditory nerve fibers. Single fiber responses are examined under conditions where cochlear temperature is either 35-39°C or 29-32°. Using this technique we are able to elicit stable and reversible changes in single fiber spontaneous discharge rates (SR), as well as tuning and rate-intensity curves. Cooling-related changes in frequency tuning depend on characteristic frequency (CF). Fibers with CFs below and above 8 kHz exhibit increases in CF threshold of about 0-10 dB and 10-20 dB, respectively. This pattern is similar to stimulus frequency-dependent increases in compound action potential thresholds observed during passive cooling of the cochlea to 30-31°. Tip/tail ratios of tuning curves are reduced. Sharpness of tuning (as assessed using Q_{10dB}) and CF are, on average, unchanged. We recently reported that the distributions of SR, saturation firing rate (R_{sat}) and intensity curve slope in gerbil are different for fibers with CFs below and above 3-4 kHz (Ohlemiller, Echteler, and Siegel, submitted). Those results held for cochleas near 37°. When the relative changes in each of these characteristics during cooling are examined for fibers with CFs below and above 3 kHz, we find the following: R_{sat} is reduced by 10-50%, regardless of CF. SR is reduced by about 10% in low-CF fibers and about 80% in high-CF fibers. This difference is significant (t-test, $p < .001$). Intensity curve slope is also differentially affected in the two groups. The slopes of intensity curves of low-CF fibers are reduced (sign test of matched pairs, $p < .0002$) by 30-80%. For high-CF fibers no significant change in slope is observed ($p > .4$).

VOLTAGE-ACTIVATED MEMBRANE CURRENTS DIFFER BETWEEN MAMMALIAN TYPE I AND TYPE II HAIR CELLS. K.J.Rennie and J.F.Ashmore. Dept. Physiology, Med. Sch., Bristol BS8 1TD, U.K.

The mammalian vestibular system contains two types of hair cell (designated I for the flask shaped and II for the cylindrical shaped) which differ in their morphology and synaptic connectivity. We have isolated both types from the guinea pig crista ampullares to study the ionic differences in membrane currents. It is convenient to further divide type II cells into tall (IIt) and short (IIs) sub-types. These have distinguishable ionic properties.

Using tight-seal whole-cell recording (pipette containing KF/KCl + BAPTA), the mean zero current potential was -49.5±9.2mV (n=57), with no significant difference between cell classes. All cells showed a prominent outward K-current which activated above -45mV. 62% of type IIt, 31% of type IIs and 17% of type I cells showed a current classified as an A current. A further component of the outward current was invariably reduced by 10mM or 30mM TEA (n=11), or by 200μM Cd (n=8), indicating that all cell types have a K(Ca) current. Cs-containing pipettes greatly reduced outward currents in type IIt cells, but left a small (300pA) inward transient which was blocked by 240μM Cd. In type IIs and type I cells, the outward current was not reduced by internal Cs, suggesting an underlying K channel with a different selectivity. At holding potentials more negative than -90mV, type I cells showed outward rectification, eliminated by more positive holding potentials, presumably due to Ca loading. Such elevated intracellular levels of Ca activated a conductance with properties of a non-selective cation channel.

The results indicate significant differences between cell types. In particular the regulation of type I cell currents by internal Ca may determine the dynamic properties of the cell's response during labyrinth rotations.

SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS III

443.1

LIMIT OF ACCURACY OF MEG DIPOLE LOCALIZATION ON THE HUMAN SOMATOSENSORY CORTEX REVEALED BY MAPPING MAGNETIC (MEG) RECORDINGS ONTO THREE-DIMENSIONAL MRI RECONSTRUCTIONS. U. Ribary, J. Suk*, J. Cappell*, F. Lado, A. Mogilner and R. Llinás. Dept. of Physiology & Biophysics, New York University Medical Center, New York, NY 10016 U.S.A.

A 14 channel neuromagnetic measuring system (BTi) was used to analyze the magnetic fields over the left hemisphere of three normal male subjects (18-40 years old) in order to locate the magnetic response sources to contralateral tactile stimulation of the thumb, the index and the little finger. The stimuli were randomly provided by three Piezo buzzers vibrating at a frequency of 250Hz and triggered at 100 msec, after the start of each recording window of 300 msec, for a duration of 100 msec and an interstimulus interval of 400 to 600 msec. The orientation of the subject's heads in relation to the MEG recording probes was calculated using a Probe Position Indicator (PPI) and a head-based coordinate system (Yamamoto et al., 88' Proc. Natl. Acad. Sci.). The dipole locations were based on the main peak around 60 msec after stimulus onset, demonstrating a spatial magnetic field reversal over the hemisphere. The active dipole sources determined were then projected onto the Magnetic Resonance Image (MRI) of the individual subjects providing anatomical localization. Each measurement was repeated 8 times over 3 months and demonstrated an accuracy ranging from ± 0.46 mm to ± 2.28 mm (SEM). The MRI slices were also used to construct a 3-dimensional image for a better visualization of the spatial distribution of the calculated sources. All sources from the three fingers were found to be located on the postcentral gyrus (in SI) and distinct from one another. There was a most significant difference in source location between the little finger and the thumb with the former being more superior than the sources of the other two fingers. The response amplitudes also showed significant and consistent differences with the thumb having the largest, the index finger the second largest and the little finger the smallest response. The high level of statistical significance of these measurements indicate that the MEG technique has allowed precise and fast determinations of brain function in a non-invasive environment.

443.2

REGIONAL CEREBRAL BLOOD FLOW CHANGES FOLLOWING NOXIOUS THERMAL STIMULATION USING SUPERPOSITION OF SPECT AND MRI. A.V. Apkarian, N.M. Szeverenyi*, S.H. Manglos*, R.T. Stevens and F.D. Thomas*. Depts. of Neurosurg. and Radiol.*, SUNY Hlth. Sci. Center, Syracuse, NY 13210.

Single photon computed tomography (SPECT) is used with various brain perfusion radiopharmaceuticals to monitor the metabolic activity of the brain non-invasively. Increased metabolic activity can be secondary to increased neural activity which renders SPECT useful in monitoring brain activity during sensory stimulation. In this study SPECT images were generated in humans and anesthetized baboons when the hand was immersed in a noxious water bath (46-50 ^{o}C) and compared to the hand immersed in neutral temperature water. Technetium-99m-HMPAO was injected iv during stimulation, the head placed in a special head holder and the brain scanned with a 3 headed rotating SPECT scanner (TRIAD). SPECT and stimulus-control SPECT images were suprimposed on congruent high resolution magnetic resonance images (MRI). The head holders supported fiducial markers filled with water and NiCl and technetium-99m which were visible in SPECT and MR images. Scaling and registration of SPECT images on MRI were done based on the markers on a SUN 4/330 computer running NMRi software.

In baboon stimulus(50^{o}C)-control(36^{o}C) SPECT images, increased activity was seen in the contralateral posterior parietal cortex, frontal cortex and the ipsilateral cerebellum. Similar changes were seen in 2 other sessions in anesthetized baboons and macaques. In one human stimulus(46^{o}C)-control(36^{o}C) SPECT session no change was observed. This technique is currently being tested with higher stimulus temperatures in humans and using repeated measures in the baboons to establish statistical significance.

443.3

PSYCHOMETRIC AND SI NEUROMETRIC FUNCTIONS DURING ACTIVE TOUCH OF GRATINGS IN MAN AND MONKEY. R.Sinclair and H.Burton, Department of Anatomy & Neurobiology Washington University School of Medicine, St. Louis, MO 63110. (Supported by NIDCD 00096)

Two *M. mulatta* and 4 humans stroked fingertips over pairs of horizontal gratings, and identified the smoother (smaller groove width). Grating ridge width was 250μm, groove width (GV) varied from 500 to 2900μm. Each grating pair had 1 of 4 standards (500, 1000, 1500, and 2000μm).

Humans discriminated GV differences of ~10%, monkeys ~20%. Neural Weber fractions, for area 3b and 1 cells with graded responses, were computed as firing rate (AFR) change between surfaces divided by AFR to standard. Neural Weber functions paralleled psychophysical ones. Threshold was high for comparisons against the 500μm standard (Stevens' region), and comparably low for other standards (Weber region). In many cells, AFR change for equal GV differences were larger for rough than smooth surfaces, suggesting an exponential relationship between AFR and GV. Large neural Weber fractions resulted for smooth surfaces, explaining skewed psychophysical Weber functions. Discrimination errors were associated with reduction in sensory information in some cells, due to changes in applied force or velocity of stroke.

Thus, cell responses in SI account for ability to discriminate surfaces, and may form the basis for perception of textured surfaces.

443.4

NEURONAL RESPONSES IN SECOND SOMATOSENSORY CORTEX AND VPL OF MONKEYS DURING ACTIVE TOUCH OF TEXTURED SURFACES. H.Burton, R.Sinclair and K.Sathian. Department of Anatomy & Neurobiology and McDonnell Center for Higher Brain Function, Washington University Sch. Med., St. Louis, MO. (Supported by NIDCD 00096)

Recordings were made from 62 SII and 20 VPL neurons in one *M. mulatta* trained to stroke its fingers across and discriminate between two gratings that differed in groove width (0.5-2.9mm). Preliminary results indicate that many SII cells showed little or suppressed activity during contact of their receptive fields (RFs) with gratings. These cells discharged bursts of impulses (1) on initial contact with the surface-bearing block, (2) when contact with the surfaces terminated and (3) when their RFs contacted an elevation between the two gratings on a block. SII cells with pacinian-like responses showed particularly prominent bursts in response to this elevation. Some SII cells displayed response functions that were positively or negatively graded with respect to groove width, and some had response functions that increased with the force of contact during stroking.

Responses obtained from VPL resembled some of those previously described in SI and, like peripheral receptors, showed combined effects of force, velocity and groove width. Relatively high firing rates were observed in some cells in VPL.

443.5

EFFECTS OF A DORSAL SPINAL LESION ON TEMPORAL DISCRIMINATIONS AND ON PHYSIOLOGICAL RESPONSES OF PRIMATE S-I CORTEX. C.J. Vierck[1], B.W. Whitsel[2], J.C. Makous[1], and R.M. Friedman[1]. Dept. of Neuroscience, Univ. of Florida Col. of Medicine, Gainesville, FL 32610[1] and Dept. of Physiology, Univ. of North Carolina School of Medicine, Chapel Hill, NC 27514[2].

Interruption of the ipsilateral dorsal column (DC) in primates spares a variety of spatial capacities (e.g., spatial localization on skin regions supplied by segments caudal to the lesion). However, this lesion produces a substantial deficit on a discrimination of different durations of tactile stimulation (i.e., 3 pulses at 10 Hz vs. longer trains at the same rate). In an effort to understand the neural mechanisms for this reduction of temporal resolution, single unit and evoked potential recordings from the primary somatosensory cortex (S-I) have been conducted in primates. Multiple unit and evoked potential recordings in the DC-deafferented region of S-I reveal activity that waxes and wanes. That is, stimulation does not reliably drive the cortical cells - especially at high rates of stimulation.

Supported by NS 07261 and DE07509

443.6

RESPONSIVENESS OF PRIMARY SOMATOSENSORY CORTICAL NEURONS TO VIBRATORY STIMULI DURING MOVEMENT VS. NO-MOVEMENT TASKS. R.J. Nelson and V.D. Douglas*, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, 875 Monroe Avenue, Memphis, TN 38163.

The responses of some monkey primary somatosensory cortical (SI) neurons to peripheral stimuli may be enhanced when these stimuli trigger movements as compared to when stimuli signal that wrist position should be maintained. It is unclear whether the responsiveness of other SI neurons may be suppressed in movement tasks and whether SI neuronal response enhancement and suppression differ depending upon a neuron's cortical location and receptive field (RF) type. Three adult rhesus monkeys (*Macaca mulatta*) were trained to make wrist flexion and extension movements or maintain their wrist position following delivery of a vibratory stimulus to the palm. Care was provided in accordance with the *NIH Guide for Care and Use of Laboratory Animals, revised 1985*. The activity patterns were analyzed for 6 area 3a neurons, 13 area 3b neurons and 22 area 1 neurons. These neurons were selected because each had short latency (<40ms) vibratory related responses in both tasks, and each had a peripheral RF related to the hand or wrist. Neurons with cutaneous and deep RFs were treated separately. The magnitude of the vibratory stimulus-related activity was measured during movement trials. The vibratory response during no-movement trials was then measured over the same period. Area 3a, 3b, and 1 neurons with deep RFs exhibited a statistically significant ($p<.05$; one factor ANOVA) enhancement in their stimulus-related activity during the movement task as compared with their vibratory response during the no-movement task. Area 3b neurons with cutaneous RFs were also enhanced ($p<.001$) during the movement task. Area 1 neurons with cutaneous RFs showed a significant suppression ($p<.001$) of their vibratory responsiveness during the movement task.

These results suggest that an animal's preparedness to move in response to and/or selective attention toward peripheral stimuli may modulate the sensory responsiveness of certain SI neurons. As well, changes in sensory responsiveness in SI neurons appear to differ depending upon the neuron's cortical location and RF type.

A COMBINED MULTIELECTRODE-MICRODIALYSIS PROBE FOR USE IN THE MONKEY CORTEX. A.T. Kulics* and B.A. Donzanti, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

We report here the development of a multielectrode/microdialysis probe which allows repeated penetrations over a long term into various cortical areas in awake, behaving monkeys. The microdialysis technique is used in conjunction with current multielectrode recording techniques (Cauller and Kulics, Exp. Brain Res., 1988). The microdialysis unit consists of an outer hollow-fiber semipermeable membrane and an inner flexible fused silica glass capillary tube. It is housed within 25 ga hypodermic tubing which also contains 3 recording tips spaced 400 μ apart for monitoring electrophysiologic activity. In one experiment, 20 min dialysate samples were collected before and after controlled cutaneous stimulation, and analyzed for amino acids using HPLC-ECD. In another experiment, bicuculline was infused directly through the probe which resulted in reversible disinhibition of the cortical network response to touch stimulation. These data demonstrate the utility of this probe design for the study of neurochemical and electrophysiological changes during localized drug delivery in the cortex of the awake monkey.

443.8

OSCILLATORY ACTIVITY OF SINGLE UNITS IN A SOMATOSENSORY CORTEX OF AN AWAKE MONKEY AND THEIR POSSIBLE ROLE IN TEXTURE ANALYSIS.

E. Vaadia. and E. Ahissar Dep. of physiology, The Hebrew University - Hadassah Medical school, Jerusalem 91010, Israel.

Neuronal activity was extracellularly recorded in the cortex of an awake monkey. Single units displaying oscillatory firing patterns were found in the upper bank of the lateral sulcus in a multi-modal area at the posterior border of SII. The majority of the neurons in the sampled area responded to tactile stimuli. The spectral energies of the oscillating activity were distributed in a tri-modal fashion: 0-15 Hz, 15-50 Hz, 80-250 Hz. The most common frequencies were around 30 Hz. The oscillatory activity was not affected by anesthesia, but was suppressed, in most cases, by tactile stimulation or self-initiated movements. Crosscorrelation analysis of all the neuron pairs (N=364) failed to detect signs of synchronization of the oscillatory activity of different neurons. Analysis of intervals in the spike trains of single neurons suggests that 65% of them were "intrinsic oscillators" while the rest were probably driven by external oscillatory source.

There are reasons to believe that the oscillatory neurons play a role in somatosensory processing: they are located in a somatosensory area; their firing rates and oscillatory components can be affected by tactile stimuli; and the tri-modal distribution of oscillating frequencies resembles the distribution of the three mechanoreceptor types (SA,RA,PC) in the finger tip.

The newly identified oscillators can play a key role in texture analysis if included in a Phase-Locked Loop (PLL) circuit, which measures an input frequency by comparing it to the frequency of a local oscillator. Such a model is presented in a companion abstract.

TACTILE TEXTURE DECODER MODEL BASED ON CORTICAL OSCILLATORS.

E. Ahissar and E. Vaadia. Dep. of physiology, The Hebrew University - Hadassah Medical school, Jerusalem 91010, Israel.

The texture of a surface is determined by the density (spatial frequency) and the depth (amplitude) of its grooves and ridges. We propose a model that describes decoding of frequency modulation (FM) components of the texture. The heart of the model is a Phase-Locked Loop (PLL) circuit. This circuit, composed of a phase detector (PD) and a rate controlled oscillator (RCO), decodes FM signals and the provided that the input average ("carrier") frequency is equal to the intrinsic frequency of its RCO. Many such PLLs, each tuned to a specific frequency range, operate in parallel within a single "automatic velocity control" (AVC) loop. The role of the AVC loop is to maintain the input temporal carrier frequency in a selected frequency range by controlling the velocity of arm/finger movements. Thus, the model suggests that during surface exploration, the scanning velocity is first voluntarily set to generate temporal frequencies corresponding to the frequency range of a selected receptor submodality (SA, RA, or PC), and then the AVC controls the fine tuning of the finger velocity.

A possible neural implementation of a single PLL is a corticothalamic loop, with three sets of neurons; A set in the thalamic ventrobasal nuclei serves as the PD and drives a set of inhibitory interneurons in the cortex, which in turn drives a set of cortical RCO neurons. The RCO neurons feedback to the PD thalamic neurons. The capability of the thalamic neurons to detect phase differences is achieved by implementing an asymmetrical connection scheme in which the cortical input is mediated by slow excitatory synapses, while the lemniscal (peripheral) input is mediated by conventional fast synapses. The surface frequency modulations are internally represented by the PD neurons population code. A computer simulation supports the feasibility of such implementation.

HETEROSYNAPTIC AND BEHAVIORAL MODULATION OF FUNCTIONAL CONNECTIONS BETWEEN NEURONS SIMULTANEOUSLY RECORDED IN CORTEX AND THALAMUS J.K. Chapin and H.-C. Shin, Dept. Physiol/Biophys, Hahnemann Univ Sch. of Med., Phila, PA 19102 and Dept. of Anesthesia Res. Lab., Harvard Univ, Boston, MA. 02115.

In previous studies we have shown that sensory transmission to single neurons in the somatosensory thalamus and cortex in the awake rat is dynamically modulated during movement and other behaviors. To define the mechanisms for this modulation we have used spike-triggered cross-correlation techniques to measure dynamic changes in functional connections between neurons simultaneously recorded during these behaviors. Multiple single neuron recordings were obtained through arrays of 9-22 25μ microwire electrodes implanted in the forepaw areas of the SI cortex and VPL thalamus in rats. Serial excitatory connections between neurons were indicated by narrow, short latency post- spike response peaks in the spike-triggered histograms. Even with 20,000 trigger spikes, such peaks were found in only 10-20% of pairs of recorded neurons. Cortico-cortical (C-C) and cortico-thalamic (C-T) connections were found more commonly than thalamo-cortical (T-C) or thalamo-thalamic (T-T). Briefly, the strength of these connections were found to be dynamically modulated during: 1) the refractory period of the post-synaptic neuron, 2) the convergence of two excitatory inputs on the same neuron, 3) stimulation of the peripheral receptive fields of these neurons, and 4) active locomotor limb movements. These modulations were not well correlated with changes in the background discharge of the post-synaptic neurons. These results suggest that neuronal responses to synaptic inputs during behavior are highly non-linear and state dependent, and may involve dendritic processing. *Supported by PHS grants NS26722, AA06965, and AA00089, and AFOSR-90-0266 to JKC.*

EMERGENT PROPERTIES REVEALED IN MULTI-LAYER NEURONAL NETWORK MODELS: FEEDFORWARD VS. FEEDBACK INHIBITION. J.P. Utz, M.A. Nicolelis and J.K. Chapin. Hahnemann Univ., Phila., PA 19102.

As an initial step in an ongoing effort to produce a computer model of the mammalian somatosensory system, we have investigated the behavior of simple neural circuits which may form building blocks for this system. A neuronal network simulator was developed allowing relatively large numbers of realistic neurons to be connected in multiple layers. These neurons incorporate a membrane potential (V_m) which is calculated from membrane conductances and equilibrium potentials for three ions: Na^+ (for excitation), Cl^- (for inhibition), and K^+ (for afterhyperpolarization). The state variables (eg. for V_m, spikes and synaptic events) are re- calculated, stored, and displayed every msec of network time. During simulation the V_m and spikes of all neurons in both layers are continuously displayed in color mapped arrays. Both models used here incorporated two layers, each containing a 40x40 array of neurons. These were driven by a 40x40 array of randomly timed afferents. Each connection fanned-out in a 5x5 array of synapses. In the feedforward inhibition model, both of the neuron layers received the same excitatory afferents, but layer 2 also received inhibitory inputs from layer 1. During simulation this model produced a relatively flat and random pattern of polarization states in both layers. In the feedback inhibition model, which was inspired by the known connections between thalamus and cortex, layer 1 alone received the afferents and relayed excitation to layer 2, which then fed inhibition back to layer 1. In simulation this model produced distinct globular patches of activity in layer 2, but not in layer 1. These results suggest that feedback inhibitory corticothalamic effects (mediated through the thalamic reticular nucleus) could be partly responsible for the columnar patterns of activity which are well known in cortex. *Supported by grants NS26722, AA06965, AA00089, and AFOSR-90-0266 to JKC and a Dean's Summer Research Award to JPU.*

CHAOTIC DIMENSIONALITY OF CORTICAL NEURONAL DISCHARGE PATTERNS IS ALTERED BY ANESTHETIC STATE. T.M. Fisher, M.A.L. Nicolelis, and J.K. Chapin. Dept. of Physiol/Biophys, Hahnemann Univ, Phila, PA 19102.

"Chaos" is an ubiquitous feature of non-linear systems producing such natural phenomena as fluid turbulence, population cycles, and variations in the heart rate. The "quasi-periodic" behavior of such systems are often found to converge on a "strange attractor". The fact that the brain contains widespread non-linear inhibitory feedback circuits suggests that it is a likely substrate for chaos. Little is known, however, about how chaos might be expressed in the discharge patterns of individual neurons in the brain, and how this may affect the brain's functionality. This problem was addressed here by analyzing temporal spiking patterns of single units recorded in the cortex of rats during wakefulness and after pentobarbital anesthesia. To assess the possible existence of chaos in these spike trains, temporal patterns of inter-spike intervals (ISIs) were visualized in 2-D or 3-D sequential interval raster (SIR) plots. SIRs of neurons in awake animals tended to show relatively featureless clouds of raster points. After anesthesia SIRs from the same neurons exhibited attractor-like structures. To assess the dimensionality of these SIRs, a standard technique was used in which lines were drawn on a log-log scale plotting the Euclidean distances between points (X-axis) against their correlation integral (C(d); on Y-axis). (C(d) = total number of distances below each value on the Y-axis). A line was calculated for each of a sequence of iterated "embedding dimensions", ie. the number (N) of sequential intervals used to create each point in an N-dimensional space. The dimensionality of the spiking pattern was considered to be equal to the slope of these lines at the point that they stopped increasing along with N. In these analyses, spiking activity from awake animals tended to yield dimensionalities of about 4.5 or greater, some being almost indistinguishable from random noise. By contrast, discharge of the same neurons after anesthesia yielded fractal dimensionality as low as 2-3. These results suggest that the anesthetic state may involve a marked reduction of the number of factors which normally influence cortical neuronal activity. *Supported by NS26722, AA06965, KO2-AA00089, and AFOSR-90-0266.*

PROPERTIES OF A DISTRIBUTED SIMPLE LINEAR NETWORK THAT LOCATES POINT STIMULI: EFFECTS OF RECEPTIVE FIELD SIZE, SHAPE AND DENSITY. B.J. Serog*, J.W. Holsapple and A.V. Apkarian. Dept. of Neurosurg., SUNY Hlth. Sci. Center, Syracuse, NY 13210.

Determination of stimulus location is a feature common to many sensory processes. It is assumed that the spatial acuity of such processing is determined by the size and density of receptors and that high spatial acuity requires small receptive fields (RFs). For example, nociresponsive neurons in the medial thalamus have large RFs and are assumed to play no role in localization. In contrast, nociresponsive neurons in the lateral thalamus have small RFs and are implicated in localization.

A computer simulation of a linear distributed network that locates point stimuli was studied. The network was composed of: 1) an afferent input layer of "units" of density rho and radius lambda placed on a test surface of unit width and 2) two output "units" whose activity coded position of stimuli in cartesian coordinates. Connection strengths for the network were calculated using an algorithm which optimized point localization. We found that the error in the assignment of coordinates of point stimuli for trained networks varied inversely with the degree of overlap of RFs ($rho x lambda^2$). This lead to the conclusion that large RFs can be associated with high spatial acuity. In addition we found that the profile of RFs had little influence on spatial acuity.

These results indicate that high spatial acuity can be associated with large, overlapping RFs (in a distributed network). The roles currently assigned to medial and lateral thalamic nociresponsive neurons in localization is based on the assumption that the process (network) is non-distributed (labeled line model). The role, however, of nociresponsive neurons, with large and small RFs, in localization depends on the organization of the underlying network (degree of convergence of afferent input) which is unknown for these cells.

SOMATOSENSORY ORIENTATION-LOCALIZATION AND POSTURAL REFLEX DEFICITS AFTER UNILATERAL SI AND/OR SII CORTICAL DAMAGE IN RATS. R. B. Glassman. Dept. of Psychology, Lake Forest College, Lake Forest, IL 60045.

Ten albino rats were trained, while blindfolded, to turn toward touched points on the body for pieces of sugared dry cereal. As with cats (Glassman, Physiol. Behav., 1977; Physiol. Psychol., 1983, 1985), orientation was more rapid and accurate to anterior points. Unoperated rats were as responsive as cats to tactile stimuli, but much poorer to auditory and visual stimuli. Ablations were carried out by aspiration, with rats under pentobarbital general anesthesia. In most cases SI (n=4) or SII (n=4) was first located with the help of gross evoked potentials to contralateral stimulation of the body. After all behavioral observations, in some cases, evoked potentials were recorded to verify the integrity of remaining somatosensory cortex. Like cats, rats sometimes turned toward the wrong side during early postoperative tests. Damage to SI versus SII in cats had caused doubly dissociated deficits, respectively in movement versus passive touch. Rats showed no such difference between SI and SII damage - either ablation caused deficits in cutaneous orientation as well as in placing and hopping, with severity related to lesion size. The largest, least recoverable deficits (2 months) followed combined damage to SI and SII (n=2).

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: OCULOMOTOR SYSTEM III

GAZE SHIFTS EVOKED BY SUPERIOR COLLICULUS STIMULATION IN THE ALERT CAT. M. Crommelinck, M. Paré and D. Guitton. Montréal Neurol. Inst. and McGill Univ., Montréal H3A 2B4.

The superior colliculus (SC) is involved in the generation of saccadic gaze shifts. A motor map is found in the SC deeper layers. It was commonly assumed that the site of activity on the map determines alone the saccade vector. Recent data now challenge this notion. Stimulation studies have shown that saccade amplitude varies with current strength. Furthermore, recording and lesion studies have provided evidence that the SC may also encode saccade speed. In the alert cat whose head is fixed or unrestrained, we have studied how varying stimulation parameters affects the properties of evoked gaze shifts. Stimulation was delivered at sites where tectoreticular neurons (TRNs) were recorded. Amplitude and velocity of evoked saccades increased to a plateau value with frequency, current strength and train duration. The amplitude plateau value of the evoked gaze shift equalled the amplitude "prefered" by local TRNs. Noteworthy, the effects on saccade amplitude and velocity were not exclusively interdependent and predictable from the main sequence relation. These effects were observed on either eye saccades evoked from the anterior portion of the SC or eye and head saccades elicited from the caudal part. These results suggest that the SC provides the saccadic command using both the site of activity on the motor map and the amount of activity of the recruited cell population.

EYE MOVEMENTS IN ESSENTIAL BLEPHAROSPASM. J. L. Demer, J. B. Holds*, and L. A. Hovis*. Jules Stein Eye Institute and Department of Neurology, University of California at Los Angeles, 90024; Department of Ophthalmology, University of Texas Medical Branch at Galveston, 77550.

Frequent complaints of disequilibrium and the finding of abnormal brainstem auditory evoked potentials in patients with essential blepharospasm suggest an abnormality in the lower brainstem. Since an extensive ponto-mesencephalic lesion would also involve ocular motor control areas, we sought abnormalities of eye movements in patients with essential blepharospasm.

We studied 8 patients (mean age 58 yrs, range 44 - 71) who had undergone prior surgery or botulinum injection for blepharospasm; two also had lower face involvement (Meige syndrome). There were two groups of neurologically normal controls: young (mean age 38 yrs, range 30-55) and elderly (mean age 65 yrs, range 50-85). Horizontal eye movements were measured using digitally-sampled, direct current electro-oculography.

All patients had normal saccadic amplitude-velocity relationships for randomly-presented target steps. Vestibulo-ocular reflex gains for multiple frequencies (0.0125-0.4 Hz) of passive, sinusoidal, whole-body rotation in darkness were not significantly different from young controls, and there was normal visual enhancement and fixation suppression. Mean sinusoidal smooth pursuit (0.2 & 0.4 Hz) and full-field optokinetic (0.05 Hz) gains of patients were 20-35% less than for young controls ($p<0.05$). For patients, mean optokinetic gain for 30°/s constant velocity stimulation was ~40% less than in young controls ($p<0.05$), but was not significantly different from elderly controls.

Eye movements in patients with essential blepharospasm do not differ significantly from normal subjects of similar age. This finding is evidence against a diffuse ponto-mesencephalic lesion in essential blepharospasm.

CEREBELLAR UVULA CORRELATES OF MOVING VISUAL STIMULI S.J. Heinen* and E.L. Keller. Smith-Kettlewell Eye Res. Inst., San Francisco CA, and Dept. of Elect. Eng., Univ. of Cal., Berkeley, CA.

The uvula (lobule IX of the cerebellar vermis) receives indirect input from the superior temporal sulcus and pretectum via the dorsolateral pontine nucleus, areas all involved in visual motion processing. We were interested in how the uvula might further process these motion signals. We used tungsten microelectrodes to monitor single-unit responses of 108 cells in the uvula of behaving monkeys (n=2) to a variety of moving visual stimuli: sweep of large field textured backgrounds during fixation suppression of optokinetic following eye movements, smooth pursuit eye movement of small moving spots, and buildup of optokinetic nystagmus (OKN) during full field optokinetic drum motion. Drum rotation was the most effective stimulus for activating uvular cells. Most cells (n=57) either increased or decreased firing during one direction of drum rotation, and most of these had a response that was either smaller or opposite in sign for the other direction. The time constant of this change was on the order of 3-5 secs, much faster than long-term buildup of velocity storage during OKN, and this activity persisted in these cells after drum light offset, often outlasting optokinetic after-nystagmus (OKAN). Cells rarely responded to brief large field motion, however, two classes of smooth pursuit cells were found. One class responded briefly when retinal slip was high (60-80 msec after pursuit initiation), and the other class was modulated gradually during the pursuit trial. These results suggest that the uvula is involved indirectly in velocity storage, possibly performing a modulatory function on the velocity storage integrator. (Supported by EY06860)

PREDICTIVE SACCADES IN HUNTINGTON'S DISEASE (HD) J.R. Tian, D.S. Zee, S.E. Folstein, A.G. Lasker*. Johns Hopkins University, Baltimore, MD 21205

Eye movements were recorded from 21 mildly-affected patients with HD and 20 age-matched controls. All patients made excessive errors on the antisaccade ("look opposite to the target") paradigm. More than 30% of saccades were made incorrectly to the visual target. Patients also showed a defect in generating anticipatory saccades, to a target jumping in a predictable fashion (0.5 hz, 20 deg). Mean saccade latency was 135ms in HD and -78ms in controls. Fourteen of 21 patients had values > 2 standard deviations from the mean of normals. Mean percentage of anticipatory saccades (latency < 100ms) was 28% in HD and 83% in controls. Three patients made no anticipatory saccades at all. Mean amplitude of anticipatory saccades was 14.2 deg in HD and 17.6 deg in controls. Eleven of 18 patients had values > 2 standard deviations from the mean of normals. We conclude that abnormal predictive saccadic tracking is common in early HD and that the basal ganglia probably play a role in generating predictive saccades.

IMMUNOHISTOCHEMICAL LOCALIZATION OF PARVALBUMIN IN CAT EXTRAOCULAR MOTOR NUCLEI. Robert F. Spencer. Dept. Anatomy, Medical College of Virginia, Richmond, VA 23298.

Previous studies have demonstrated differences in the inhibitory neurotransmitters utilized by functionally equivalent premotor neurones that project to the cat oculomotor and trochlear (GABA) versus abducens (glycine) nuclei. In the sensory visual system (*e.g.*, dorsal LGN, visual cortex) and other areas of the nervous system (*e.g.*, hippocampus), the calcium binding protein parvalbumin (PA) is highly co-localized in certain classes of GABAergic neurones. The immunohistochemical localization of PA in the extraocular motor nuclei was undertaken to asses the role, if any, of PA in GABAergic and glycinergic mechanisms related to the discharge properties of motoneurones during eye movement. In the oculomotor, trochlear, and abducens nuclei, PA-immunoreactive staining was associated with most, but not all, of the cholinergic motoneurones. PA-immunoreactive synaptic endings contained predominantly spheroidal synaptic vesicles and established asymmetric synaptic contacts with both immunoreactive and non-immunoreactive somata and dendrites. The ultrastructural features of PA-immunoreactive synaptic endings are consistent with presumed excitatory synaptic inputs, at least some of which utilize glutamate as a neurotransmitter. Correlated at least in part with the synaptic localization of PA in the extraocular motor nuclei, PA-immunoreactive neurones were located in many of the brainstem preoculomotor structures that project directly or indirectly to the motoneurones. Extrapolating from studies in other regions of the nervous system, it appears that PA is associated with neurones in the oculomotor system that discharge at high frequency. Within the motoneurones, one function of PA may be to buffer the influx of Ca^{2+} that accompanies membrane depolarization following the activation of NMDA receptors by glutaminergic inputs.

POOR "SPATIAL" SIGNAL IN HUMAN SACCADIC SYSTEM. R. S. Gellman and W. A. Fletcher* Dept. Clinical Neurosciences, Univ. of Calgary, Calgary, AB, Canada T2N 4N1

To make an accurate saccade to the *spatial* location of an object requires both visual information and a signal encoding eye position at the time that the image appears. To determine if the required eye position signal is available, the experimenter typically evokes an intervening eye movement shortly after presentation of a saccadic target but before a saccade is directed to that target. McKenzie and Lisberger (1986) argued that, in monkeys, the signal is available only if the intervening eye movement is saccadic. When pursuit movements intervened between target presentation and a saccade to that target, the saccades were specified by the visual signal; the intervening pursuit movement was ignored. We report that this dichotomy is absent in human subjects.

Subjects (N=8) tracked a target moving horizontally (15-30°/s) that disappeared after 800-1200 ms. A spot was then flashed for 20 ms 4-12° above or below the meridian, at horizontal offsets of 0-14° from the direction of gaze. Subjects were instructed to look to where the spot had flashed. When subjects looked toward this spot (after 200-300 ms) their saccades compensated for 39% (range 17-55%) of intervening pursuit movement. In a double-step paradigm, where the second step occurred shortly before a saccade to the first target location, and the screen was then blanked, performance improved, but remained poor (compensation 58%; range 43-74%). For intervening saccades or pursuit, compensation varied from 0-100% from trial to trial. Saccades to flashed targets, where no movement intervened, were accurate (gain >0.9 for most subjects).

These results suggest that the human saccadic system use eye position information regardless of whether it is generated by pursuit or saccades. This information is transmitted with low gain and high noise.

VELOCITY STEP TRAINING OF THE GOLDFISH VESTIBULO-OCULAR REFLEX SUGGESTS MULTIPLE SITES ARE INVOLVED IN GAIN MODIFICATION. A.M. Pastor*, M. Weiser, S. McElligott and R. Baker, Dept. of Physiol. and Biophys., NYU Med. Ctr., New York, NY 10016, and Dept. of Pharmacol, Temple Univ. School of Med., Phil. PA 19140

Goldfishes were trained to either increase or decrease VOR gain (eye/head velocity) with visual-vestibular stimuli presented in the form of velocity steps. Operant paradigms in which the visual step preceded the vestibular turn-around by 50-150 ms were more effective in producing robust changes in the inital 100 ms of the VOR than either simultaneous visual-vestibular presentation or sinusoidal training. Examination of the eye velocity profile throughout the step response before, during and after either an increase or decrease in vestibular sensitivity revealed an early dynamic and later sustained phase of adaptive plasticity separated by a sag at about 150 ms. Acute cerebellectomy following VOR gain decreases induced with velocity step training did not alter the early dynamic response, but abolished the sag while the remaining constant velocity component was re-scaled close to, but less than, control VOR gain. Within a few weeks the dynamic response returned to normal levels; however, it's latency and amplitude was little, if at all, modifiable up to one year later. By contrast, vestibular sensitivity during the later constant velocity presentation, like that observed with sinusoidal stimuli, could be adaptively modified in some goldfishes. A similar acute response profile was observed with VOR gain increases, except that the latency for the peak of the dynamic response shifted and subsequent VOR gain was usually higher than control measurements. These data argue for more than one site associated with adaptive gain control. If separate channels for information processing are envisioned then the site of plasticity in the vestibular nucleus itself may only be modified when the cerebellar circuitry is intact.

GENERALIZING THE POST-SACCADIC SLIDE TO SLOW EYE MOVEMENTS IN THE RABBIT. J.S. Stahl and J.I. Simpson. Dept. Physiol. & Biophysics, NYU Med. Ctr., New York, N.Y. 10016.

At the end of a saccade, the firing rate of primate motoneurons continues to decay even after the eye has reached its final position. This exponential decay, termed the post-saccadic slide, has a time constant Ts of approximately 90 ms (Goldstein, 1982). The decay has been hypothesized to compensate for a mechanical lead element in the oculomotor plant; as such the slide is not specific to saccades. It should be present following step changes in eye position produced by other means. We examined neurons of the vestibular ocular system in rabbits for slides following eye movements evoked by changes in head position. Neurons were recorded in awake rabbits and identified as abducens motoneurons, internuclear neurons, or vestibular nucleus premotor neurons by electrical stimulation of the lateral rectus muscle, MLF, or oculomotor complex, respectively. Ramp-step changes in eye position were produced by oscillating the animal about the vertical axis with a trapezoidal position profile (0.5 sec ramp @ 4°/sec, 4 sec stationary, 0.5 sec @ -4°/sec, 4 sec stationary) in the light. Firing rate decayed exponentially during the stationary periods; a time constant Ts was estimated by curve fitting. The distribution of Ts was strongly positively skewed. Median Ts was 1.1 sec (n=17) for the pooled abducens units and 1.7 sec (n=29) for the vestibular nucleus units. These values are 10-20 times larger than those seen in the monkey. In modeling the oculomotor plant of the monkey, a Ts term improves the prediction of firing rates for sinusoidal eye movements above approximately 0.5 Hz (Fuchs et al., 1988). The long slide shown in the present study indicates that the influence of Ts extends to still lower frequencies in the rabbit.

EFFECTS OF A TEMPERATURE DECREASE ON ADAPTIVE VESTIBULO-OCULAR REFLEX MODIFICATIONS IN THE GOLDFISH J.G. McElligott[1] and R. Baker[2] [1]Dept. of Pharmacology, Temple University School of Medicine, Phila., PA 19140, and [2]Dept. of Physiology and Biophysics, N.Y.U. Medical Center, New York, NY 10016

Previous work in our lab showed that short term adaptive gain changes of the vestibulo-ocular reflex (VOR) in the goldfish were reversibly inactivated by a decrease in temperature of 6 to 12 deg C. Unmodified VOR gain measured in the light and dark was unaffected by a similar temperature change. The work presented here investigates the effect of an acute temperature decrease on acquisition of the VOR change. Goldfish were acclimated to a laboratory aquarium at 21 deg C over a period of several months. After initial calibration measurements of the VOR in light and dark were made, the VOR was modified over a 3 hour period at the acclimation temperature. Training to a gain of 2X was accomplished by presenting visual stimuli 180 degrees out of phase with the vestibular platform rotating about the vertical axis (1/8 Hz ± 20 deg). A second group of fish were trained following the same procedure but VOR modification was carried out at a temperature of 12.5 deg C. This decrease in temperature had no effect on the initial calibration measurements of VOR gain and phase measured in the light (gain = 1) and the dark (gain = 0.9) . The subsequent rate and level of VOR gain change measured in the light and the dark over the 3 hour training period was the same for fishes modified at both temperatures. VOR gain of 2X measured in the light was achieved within the first hour. Gain measured in the dark increased from 0.9X to 1.6X during this period for both groups. No phase changes were detected. This work coupled with our previous study demonstrates that modification of the VOR by the goldfish is achieved with equal facility over a large temperature range. However, a modified VOR gain change acquired at a higher temperature can be reversibly inactivated by a reduction in temperature.

TWO-DIMENSIONAL VERSUS THREE-DIMENSIONAL RAPID EYE MOVEMENT GENERATION IN THE SUPERIOR COLLICULUS AND THE ROSTRAL INTERSTITIAL NUCLEUS OF THE MLF IN THE MONKEY. J van Opstal*, V Henn, BJM Hess*, D Straumann, K Hepp*. Neurology Dept, University, CH-8092 Zürich, Switzerland.

Monkeys were chronically prepared with a 3-dimensional search coil, the superior colliculus was localized by single neuron recordings and microstimulation. Nystagmus was tested in 3 dimensions by rotating animals about different axes in the light and in darkness. The superior colliculus was temporarily inactivated by the local microinjection of Muscimol. A unilateral inactivation leads to a deficit of the rate of saccades, their velocity and amplitude in a contralateral horizontal direction together with an ipsilateral deviation of the eyes. A bilateral inactivation leads to a deficit in both horizontal and vertical directions, but does not seem to affect fast phases of torsional nystagmus. This shows that rapid eye movement programming in the superior colliculus involves the horizontal and vertical dimension, but not torsion. It is in striking contrast to deficits observed with lesions of the riMLF, where already a unilateral inactivation leads to clear deficits in torsion.

ON THE CENTRAL IMPLEMENTATION OF SACCADES IN LISTING'S PLANE. K Hepp*, J van Opstal*, BJM Hess*, D Straumann, V Henn. Physics Dept, ETH, and Neurology Dept, University Hospital, CH-8091 Zürich, Switzerland.

We have investigated whether the central representation of saccadic eye movements in Listing's plane in the spatial (superior colliculus, SC) and temporal (riMLF) saccade generator is in terms of difference vectors or quaternion quotients of final and initial eye position. The quotient model predicts how SC stimulation drives the eye out of Listing's plane, and that movement fields of saccade-related burst neurons in the SC should have torsional components. With neuronal recording and microstimulation at 60 sites in 4 colliculi of 2 monkeys with a 3D search coil we have found a clear violation of the quotient model. This was confirmed by a significantly better torsional modulation of burst neurons in the riMLF in difference coordinates. These findings suggest that Listing's law for visual saccades is implemented downstream of the spatial and temporal saccade generator.

EVIDENCE FOR A FIXATION ZONE IN THE ROSTRAL SUPERIOR COLLICULUS OF THE MONKEY. D. P. Munoz, D. M. Waitzman, and R. H. Wurtz. Laboratory of Sensorimotor Research, National Eye Institute, NIH, Bethesda, MD 20892, USA.

The rostral superior colliculus (SC) of the cat may be involved in the control of visual fixation (Munoz and Guitton, 1989, *Rev. Neurol.*, 145: 567-579). To determine whether an analagous zone exists in primates, we recorded activity of cells in the rostral SC of monkeys trained to make saccadic eye movements and fixate targets. A fixation-related zone was identified with the following characteristics. 1) It was located about 1.5mm below the dorsal surface of the SC, 0.25-0.5mm below cells that discharged high frequency bursts for small (<1° amplitude) saccades. 2) A subset of neurons, fixation-related cells, recorded at this locus discharged tonically when the monkey fixated a small visual target for reward. This activity continued when the fixation target was turned off for 300-600ms and the monkey was required to maintain the same eye position. These cells were only sporadically active during spontaneous fixations, for which the animal was not rewarded. 3) Fixation-related cells paused for saccades to peripheral targets; activity resumed at the end of the saccades. The same pause in activity occurred for saccades to the location of a remembered target (i.e., in complete darkness). 4) When we stimulated the fixation zone with brief, high frequency trains (10-30μA, 2-6 pulses at 500Hz) during saccades, the eyes were momentarily decelerated in midflight at latencies of less than 15ms. 5) Low frequency stimulation (10-30μA pulses at 150Hz) delayed the onset of saccades to targets in all directions. Ipsiversive saccades were initiated only after stimulation offset; contraversive saccades could still be made during stimulation. The results of single neuron recordings and stimulation suggest that collicular fixation cells may serve to gate SC and brainstem premotor circuitry involved in executing saccadic eye movements, reminiscent of brainstem omnipause neurons.

SACCADE-RELATED BURST CELLS OF THE SUPERIOR COLLICULUS ARE MODULATED BY ELECTRICAL STIMULATION OF ITS ROSTRAL POLE. D. M. Waitzman, D. P. Munoz, L. M. Optican and R. H. Wurtz. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892, USA.

Recent experiments have shown a linear correlation between the decline in burst discharge and dynamic motor error in a subpopulation of saccade related burst neurons in the superior colliculus (SC) (Waitzman et al., *Expl. Brain Res.*, 72:649-52, 1988). To further study the relation between the discharge of these cells and eye movements, we interrupted saccades by microstimulating the rostral pole of the primate SC. Short trains of 2-6 pulses (10 to 30 μA, 500Hz) induced perturbations of visually and memory guided saccadic eye movements at latencies of less than 15 ms. The perturbations ranged from a minor deceleration in midflight (2 pulses) to complete saccade arrest (6 pulses) followed, after short latency, by rapid reacceleration of the eyes and completion of the original saccade onto target. Extracellular recordings of saccade related burst neurons during these perturbations demonstrated that cell discharge was interrupted during the period of stimulation (i.e., during eye deceleration), but activity resumed following stimulation offset, just prior to the reacceleration of the eyes. Cell activity declined linearly with the dynamic motor error until the onset of stimulation. Following stimulation offset cell activity *resumed*, and then declined with motor error as the residual movement was completed. This resumption of activity and its decline were associated with an eye movement amplitude (and also, a residual motor error) for which the cell would not normally fire. A similar pattern of interruption and resumption in activity was occasionally noted during visually guided or memory saccades which *spontaneously* (i.e., without electrical stimulation) decelerated in midflight. These results are consistent with the hypothesis that some of the saccade related burst neurons of the SC are within the brainstem feedback loop controlling saccade amplitude and encode dynamic motor error.

444.14

VELOCITY VERSUS POSITION FEEDBACK TO THE SUPERIOR COLLICULUS IN GAZE CONTROL MODELLING.
Ph.Lefevre[1]*, H.L.Galiana[2]. [1]Lab.of Neurophysiology UCL av.Hippocrate 54 1200 Brussels Belgium; [2]Dept.Biomed.Eng., McGill, Montreal H3A 2B4.

The notion of gaze position feedback is now widely used in all models of natural eye-head orienting movements [1]. This idea was first an extension of the Zee et al. model of saccadic eye movements control, where an efferent copy of eye position was fed back and compared to desired eye position in order to control the saccade amplitude. Previous models always consider gaze position feedback as acting downstream to the SC (superior colliculus), so that from the SC point of view, the generation of saccades is an open loop mechanism. In contrast, a recent model [2] assumes that the SC is **inside** the gaze control loop, so that dynamic gaze error is continuously updated within the SC itself.

Here, we intend to present the comparison of gaze position versus gaze velocity feedback to the SC. The consequences of each control mode have been investigated in terms of: (a) Control accuracy (b) The different collicular networks supporting these strategies and their respective connectivity, and (c) Spatio-temporal transformation in the SC, and reverse temporal-spatial mechanisms. The net result of this study is the implementation and simulation of a collicular neural network performing both spatio-temporal and temporal-spatial transformations in the one dimensional case (for horizontal movements); this model, based on velocity feedback, achieves both spatial and temporal integration inside the SC, and is extremely efficient with regard to its connectivity and cell background activities (energy). [*Supported by SPPS Belgium & MRC Canada.*]

SIGNALS RECORDED IN PRIMATE SUPERIOR COLLICULUS WITH SACCADES EVOKED BY FRONTAL EYE FIELD MICROSTIMULATION. M. Schlag-Rey, J. Schlag and P.Dassonville. UCLA, BRI and Dept. Anatomy & Cell Biology, Los Angeles, CA 90024.

Projections from movement and visuomovement cells of the frontal eye field (FEF) to the intermediate layers of the superior colliculus (SC) have been demonstrated by antidromic stimulation (Seagraves and Goldberg, 1987). We sought to determine the nature of the FEF signal reaching SC movement cells in monkey. First, movement fields of cell pairs (one FEF cell, one SC cell) were determined by unit recording during the performance of visual and saccade tasks. Then, the FEF site was stimulated (10-20 pulses of 0.2ms at 400 Hz, 5-30 μA) while recording from the SC cell. Preliminary results indicate that: (1) SC cells were excited by FEF stimulation when their preferred movement vectors were similar (movement field overlap). (2) Peak excitation seemed better related to saccade onset than stimulation onset. (3) However, excitation was still present, although weaker, at subthreshold intensities for evoking saccades. (4) FEF stimulation inhibited SC cells whose movement field did not include the vector of the evoked saccade. (5) The excitatory or inhibitory nature of the SC response depended on the site of stimulation in FEF, but not on the actual saccade vector when the latter was modified by the saccade collision paradigm. 444.16

INTRINSIC CIRCUITRY IN THE CAT SUPERIOR COLLICULUS IS HIGHLY DISTRIBUTED. M. Behan and P.P. Appell*, Center for Neuroscience and Dept. Comparative Biosciences, University of Wisconsin, Madison, WI 53706.

There is a complex network of axonal arborizations and boutons labeled following small, localized injections of *Phaseolus vulgaris* leucoagglutinin into the superficial layers of the cat superior colliculus. Labeled boutons are found in all regions of the dorsoventral, mediolateral and rostrocaudal extent of the colliculus, irrespective of whether the injections are placed in the collicular representation of the area centralis or of the peripheral visual field. There is a tight distribution of boutons in the superficial layers surrounding the injection site. However, there are certain differences in distribution of labeled boutons in the deeper layers depending upon where in the visual field representation injections are made. With a central field injection, the concentration of labeled boutons is greatest directly ventral and rostral to the injection site. Following an injection into the superficial layers in a peripheral field representation, there is a more dispersed distribution of labeled boutons in the intermediate and deep layers, with a distinct rostral polarity. These local differences in connectivity may provide the anatomical substrate for population coding of saccadic eye movements in the superior colliculus.

A DAMPED REPRESENTATION OF EYE POSITION IS USED IN OCULOMOTOR LOCALIZATION. P. Dassonville, J. Schlag, and M. Schlag-Rey, UCLA, BRI and Dept. of Anatomy, Los Angeles, CA 90024.

Since the study by Hallet & Lightstone (1976) using a double-step paradigm of target presentation, it has generally been assumed that the oculomotor system is accurate in targeting a flash occurring immediately before, during or after an intervening saccade. Their findings differ from the many studies which show inaccurate *perceptual* localization of a flash occurring near the time of a saccade (e.g. Matin 1976, Mateeff 1978).

Honda (1989) has recently shown that the oculomotor system is not as accurate at compensating for intervening saccades as previously assumed. Data from our laboratory, using the colliding saccade paradigm, have also indicated oculomotor inaccuracies (Dassonville 1990), demonstrating that the artificial retinal error created by microstimulation of the primate frontal eye field is converted to either a spatial error by adding an eye position signal that is a damped version of the actual saccade, or a motor error by subtracting a damped version of the change in eye position.

In the current study, two human subjects, in complete darkness, were required to make a saccade to the location of a 2 ms flash (S2) occurring near the time of an initial, visually-evoked saccade to a previous 5 ms flash (S1). A monocular magnetic search coil was used to measure saccade accuracy. Under these conditions, the subjects mislocalize S2 in a manner similar to that seen in Honda's and Mateeff's perceptual studies. The internal representation of eye position was found to be a damped version of the initial saccade (similar to that found with the colliding saccade paradigm), with a time constant of 50-120 ms. Flashes presented immediately before the initial saccade were mislocalized in the direction of the saccade, while those presented immediately after were mislocalized in the opposite direction. Similar results were found when the initial saccade was self-initiated with S1 not presented, removing any chance of an allocentric solution to the task. Methodological differences can at least partly explain the dissimilarity of our results (as well as those of perceptual studies) and those of Hallet & Lightstone, whose task could be solved by the use of the allocentric relationship of the stimuli.

CONTROL OF POSTURE AND MOVEMENT: ARM AND HAND

445.1

INERTIAL MASS LOADING AND THE FREQUENCY RESPONSE FUNCTION FOR CYCLIC, SELF-PACED HAND MOTION. R. N. Stiles and D. W. Hahs*, Dept. Physiology and Biophysics, Univ. Tenn., Memphis, Memphis, TN 38163.

While increasing the inertial mass of the human hand reduces the mechanical resonant frequency of the muscle-hand system (i.e., the physiological tremor frequency), the effect of mass on cyclic voluntary hand motion is uncertain. Pulse perturbation results also indicate that the muscle-hand system behaves as a lightly damped, second-order mechanical system, resulting perhaps from muscle-tendon elasticity, hand mass, and joint viscosity. However, the muscle-hand frequency response for cyclic voluntary motion indicates third-order mechanics with break frequencies at about 1 Hz and 8 Hz.. This suggests first-order muscle mechanics (with a 15-20 ms delay for force generation) in series with the lightly damped, muscle-tendon-mass system. We studied the effect of mass loading on the frequency response (relating hand displacement and surface EMG envelope amplitude as a function of frequency) of the muscle-hand system for cyclic, self-paced, extension-flexion wrist motion. The frequency range studied was 1-10 Hz, with peak angular hand displacement at the fundamental (intended) frequency occurring between about 5-10 deg. The maximum load of 500 gm had a small but predictable effect on the amplitude-frequency plot, increasing the negative slope between 5-10 Hz. With 500 gm, the EMG-Displacement phase plot was shifted, with phase lag increasing by about 50 deg at 8-10 Hz. When considered in the time domain, the effect of mass on the kinematics of quick, point-to-point hand movements was small, and appeared to be mainly due to changes in the lightly damped, second-order sub-system.

445.2

MAXIMAL VOLUNTARY CONTRACTION AND FORCE MATCHING IN THE THUMBS USING A MULTIDIRECTIONAL DYNAMOMETER. R.Forget, D. Bourbonnais, B. Lamarre* and L. Carrier*. Institut de readaptation and Ecole de readaptation, Universite de Montreal, C.P. 6128 succ A., Canada H3C 3J7

Two multidirectional dynamometers were used to record the maximal isometric forces (MIF) exerted at the proximal phalanx of each thumb and to measure the forces developed during a simultaneous matching task of 10% MIF with the contralateral thumb. The maximal forces exerted by 12 normal female subjects (23+1.5 years) with their dominant (D) and non-dominant (ND) sides were measured twice (2 sessions within a two weeks interval) in 8 directions covering 360° by steps of 45° in the transverse plane of the longitudinal axis of the thumb.

The MIF of largest magnitudes were obtained in the directions that brought the thumb towards the palm of the hand (flexion and adduction). No differences were found between the two recording sessions for these directions. There was no strength differences between the D and ND sides.

Force matching was also more precise in the more functional directions towards the palm. Errors in matching the forces angle and magnitude were both correlated with the errors in precision. However, errors in angle were different depending on the direction (largest in the abd./flex.). The precision of matching was similar for the D and ND sides. (Funded by the FRSQ)

445.3

MODULATION IN PREHENSILE FORCE WITH POSITIVE AND NEGATIVE LOAD FORCES. L.A. Jones[1] and I.W. Hunter[2], School of Physical and Occupational Therapy[1] and Dept. Biomedical Engineering[2], McGill University, 3654 Drummond St., Montreal, Canada H3G 1Y5.

The forces used to grasp an object have been shown to vary linearly with the weight of the object, and the slope of this relation is inversely proportional to the friction between the skin of the hand and the object being held (Westling & Johansson, Exp Brain Res 1984, 53:277-284).

The objective of the present experiment was to measure the modulation in prehensile force when negative (pull) and positive (push) load forces were imposed on the hand and to examine how these pinch forces changed as a function of the friction between the skin and the manipulandum being grasped.

Subjects held a manipulandum, which was composed of two symmetrically mounted disks, between the tips of their thumb and index finger. The manipulandum was connected to the stage of an electromagnetic linear motor that generated (under computer control) positive and negative forces. The position of the manipulandum was fed back to subjects on a visual display and they were required to maintain this constant while the forces generated by the motor increased in a ramp from 0 to 30 to 0 N, in both the negative (pull) and positive (push) directions. The forces produced by the motor and the fingers, and the position of the manipulandum were recorded on-line by a MicroVAX computer during each 100 s trial. Four different manipulandum surfaces, each with a different coefficient of friction, were used.

The changes in pinch force were tightly coupled to the forces generated by the motor in both the positive and negative directions, although for many subjects this modulation was asymmetric in that much greater pinch forces were generated to counteract negative load forces. As reported previously, pinch forces varied with surface structure, with larger forces being produced when the friction was smaller.

445.4

MODERATELY IMPAIRED HAND SENSIBILITY AFFECTS GRASP FORCE REGULATION. K.J. Cole. Dept. Exercise Science, The University of Iowa, Iowa City, IA 52242.

The role of tactile signals in regulating grasp force apparently is reflected in reports of excessive grasp force in patients with severe sensibility losses, and in the elderly, who typically show moderate sensibility impairments. However, the contribution of sensibility loss to excessive grasp force is not clear and requires experimental control of age, hand sensibility, and hand friction. Moderate sensibility impairment was progressively induced in subjects who wore surgical gloves of increasing thickness. Some subjects underwent anesthetic nerve block of the thumb and index finger as well. Sensibility was measured using vibrotactile and two-point stimuli. With moderate sensibility losses, subjects exhibited one of three behaviors when lifting the test object: 1) excessive grasp forces, as hypothesized; 2) safety margins decreased substantially, apparently reflecting an impaired ability to monitor grasp forces; or 3) safety margins decreased or did not change, but subjects reduced the vertical acceleration of the object and limited the object's inertial load on the hand. Grasp force regulation is affected by even moderate sensibility impairments, but increased safety margins may reflect a consistently applied strategy only after chronic, rather than acute sensibility losses. Increased hand slipperiness may also contribute to developing this strategy of using excessive safety margins.

445.5

DISTANCE AND LOCATION VARIATIONS AND THE CONTROL OF RAPID BIMANUAL MOVEMENT. D.E. Sherwood. Motor Behavior Lab., Department of Kinesiology, University of Colorado, Boulder, CO 80309.

When subjects make rapid bimanual aiming movements over different distances, assimilation effects are shown. The longer-distance limb usually undershoots its target, while the shorter-distance limb overshoots. However, in most of the studies showing assimilation effects, movement distance and end location have been confounded (i.e., the limbs move different distances to different target locations). In order to resolve this issue, 60 male and female students moved a light, aluminum lever in the sagittal plane with each hand to same or different target locations with either the same or different starting point. Assimilation effects were shown as overshooting in the left hand when either location or both distance and location were varied. The assimilation effects were reduced over 50 practice trials with knowledge of results (KR), but were also noted on a no-KR transfer phase of 25 trials. The results suggest that velocity or muscular force may be programmed by the motor system, rather than distance or location per se.

445.6

BIMANUAL COORDINATION IN TYPING. J.F.Soechting and M.Flanders. Dept. Physiology, University of Minnesota, Minneapolis, MN 55455.

Typing is an ideal model system to study many aspects of skilled movement. It involves coordinated movement of the fingers of both hands. It is a serial process with a well-defined goal (the depression of a set of keys in sequence), but its execution can involve parallel processes (the movement associated with one keystroke can begin before the previous key has been struck). The movements can be measured with relative ease.

We have begun to study typing movements by asking subjects to type words in which all but one letter is typed with one hand, thus permitting us to define the prototypical movement associated with a single keystroke of the other hand. We characterize the movement in terms of linear translation and angular rotation of the wrist, the change in length of each of the fingers (measured from metacarpal joint to finger tip) and the angular orientation of the fingers. We find that each letter is characterized by a unique pattern of movement (often involving all of the fingers of one hand). This pattern is independent of the movement of the other hand.

445.7

LEFT AND RIGHT HAND DIFFERENCES IN POINTING TO PERTURBED TARGETS. H. Carnahan and M.A. Goodale. Dept. of Psychology, Univ. of Western Ontario, London, Ontario, Canada, N6A 5C2.

The purpose of this study was to determine how rapidly subjects can amend movement trajectories of the left and right hands in response to unexpected target movement. On separate blocks of trials, subjects reached out and pointed with the left or right index finger to a target light that either remained in a central position, or was changed to a new location on the left or the right, upon release of the start button. Movements of the index finger were monitored by a WATSMART system.

There was no evidence for very early trajectory corrections (before peak velocity) for either hand, nor were there any hand differences in terminal error, RT, or time of correction. For the left hand however, MT was longer, peak velocity was lower, and time to peak velocity occurred later, when compared to the right. These findings also interacted with target location. These results are discussed in terms of hemispheric specialization in motor control. (Supported by MRC grant MA-7269 to M.A.G.)

445.8

HAND DIFFERENCES IN PREHENSION: A KINEMATIC APPROACH. B. Sivak and C.L. MacKenzie. Canadian Centre for Habilitation and Research and Department of Kinesiology, University of Waterloo, Waterloo, Ontario, Canada, N2L 3G1.

This study examined prehension differences between the hands. Right-handed subjects were instructed to reach for and grasp an object placed in front of them. Two factors were manipulated 1) hand (left, right) and 2) type of grasp (collective, independent finger grasp). Analyses involved a quantitative examination of the kinematics of movement as related to transport and grasp components. With respect to the transport component, analyses revealed no differences between the limbs. However, there were differences related to the type of grasp used. Peak velocity occurred later for a collective finger grasp than for an independent finger grasp regardless of the hand used. For the grasp component, subjects opened the hand wider with the left hand than the right hand for an independent finger grasp. There were no differences between the hands in the size of the hand opening when a collective grasp was used. The results suggest that hand differences may be related to the processing of visuomotor information subserving independent finger control.

THREE-DIMENSIONAL (3D) ISOMETRIC FORCES EXERTED BY HUMAN SUBJECTS. J. T. Massey, J. T. Lurito, and A. P. Georgopoulos. Bard Laboratories of Neurophysiology, Department of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Human subjects exerted X-Y-Z forces on an isometric handle with the unrestrained arm to move a cursor in the direction of a visual stimulus presented in an anaglyphic (3-D) display (Massey et al., J Neurosci Methods 26:123, 1988). Naive subjects were unable to perform the task with precision. Long term studies were undertaken with three subjects. The 3-D directional variability of the forces exerted and and variance about the stimulus direction decreased with practice and reached an asymptote after approximately 4,000 trials; the half-angle at the apex of the 95% confidence cone for mean direction was approximately 10° at this time. Reaction times fluctuated widely during the earlier trials but attained relatively uniform values as skill increased. These findings suggest that a substantial perceptual-motor learning is involved in generating 3D isometric forces based on information derived from stereoscopic displays. (Supported by NSF BNS-8810642 and ONR N00014-88-K-0751.)

445.10

RADIUS OF CURVATURE AND TANGENTIAL VELOCITY COVARY IN CONTINUOUSLY EXERTED THREE-DIMENSIONAL (3D) ISOMETRIC FORCES J.T. Lurito, J.T. Massey, and A.P. Georgopoulos Bard Labs, Dept of Neuroscience, The Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

Viviani and Terzuolo (*Neuroscience* 7:431,1982) showed a piecewise linear relation between the tangential velocity and the radius of curvature of continuous 2D arm movements in human subjects. That is, the tangential velocity was lowest when the path was most curved. This suggested a basic principle that relates movement form and dynamics, namely that "the trajectory goes through equal angles in equal times". The authors proposed that this principle arises from "the logic of the central control processes" rather than from the biomechanical properties of the moving arm.

We tested this idea during exertion of 3D isometric forces, in which case biomechanics play a greatly reduced role in performance. Twenty human subjects grasped a 3D isometric manipulandum (*J Neurosci Methods* **26**:123,1988) with an unrestrained, pronated arm and exerted forces continuously to trace or draw from memory ellipses and lemniscates in specified planes with or without a 3D visual force feedback cursor. Under any of these conditions and in all subjects, we observed a significant positive correlation between the radius of curvature and tangential velocity; that is, when the force trajectory was most curved, the force tangential velocity was lowest. Thus, our observations support the notion that central constraints give rise to the relation between movement trajectory and dynamics. (Supported by NSF BNS-8810642 and ONR N00014-88-K-0751.)

445.11

ACTIVITY PATTERNS OF ARM MUSCLES ASSOCIATED WITH RAPID WRIST MOVEMENT IN MAN. F.Aoki Department of Rehabilitation Research, Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo 173.

Adjustment of arm posture associated with rapid wrist movements was studied by EMG analysis. Seven healthy adults, sitting and holding their right arm in mid-position at the shoulder and in 90° flexion at the elbow, were instructed to flex(F) or extend(E) the wrist as fast as possible. To examine whether the activity patterns of the upper arm muscles were related to the prime mover or the direction of the movement, the forearm was in two postures, supinate(Sup) and pronate(Pro). The surface EMGs of biceps brachii(Bi), brachialis(Br), triceps brachii(Tr) and the prime mover, flexor carpi or extensor carpi were recorded along with the angular displacement of the wrist. The sequences of the EMG onsets of the upper arm muscles were changed with the combination of the forearm posture and movement:Tr→Bi for Sup-E, Bi→Tr for Sup-F, Br→Tr for Pro-E and Tr→Br for Pro-F in all subjects except one in whom the pattern for Sup-E was Bi→Tr. The durations from the onset of the earliest activity of the upper arm muscles to that of the prime mover were 4.5±9.3(M±S.D.) ms, 1.8±10.0 ms, 0.8±9.0 ms and -4.5±9.8 ms in Sup-E, Sup-F, Pro-E and Pro-F respectively. From these results, I conclude that the activity patterns of the upper arm muscles are related to the direction of the movements, and that the earliest activity of the upper arm muscles acts in the appropriate direction to counterbalance the dynamic perturbation induced by the movement. And they are considered to be controlled by feed-forward mechanism.

445.12

HUMAN EYE, HEAD AND ARM ROTATIONS DURING REACHING AND GRASPING. D Straumann, K Hepp*, MC Hepp-Reymond, T Haslwanter* Neurology Dept, University Hospital, Physics Dept, ETH, and Brain Res Inst, CH-8091 Zürich, Switzerland.

Using the search coil technique, we have measured simultaneously 3-dimensional eye, head and arm rotations in human subjects during various reaching and grasping tasks. Rotation axes of eye, head and arm were all confined to Listing planes with small torsional components. For eye-in-space (= gaze) and head-in-space rotations, torsional standard deviations were in the range of 0.5 - 1.5 deg, for rotations in the humero-scapular joint between 2.0 and 3.5 deg. The normal vectors for the gaze and head planes were directed frontally and almost in parallel, regardless of the task. The orientation of the arm Listing plane depended on the reaching and grasping paradigm due to the distribution of torsion between the upper and lower arm. These data suggest that the neural network organizes all 3-dimensional rotatory systems in planes with fixed alignment, thus allowing linearization of synergies.

Supported by SNF 3.503-0.86 and EMDO.

445.13

THE AXIS OF ROTATION OF THE ARM DURING POINTING. J. Hore, M. Goodale, and T. Vilis, Depts. of Physiology and Psychology, University of Western Ontario, London, Ont. Canada N6A 5C1

The orientation of the arm in three dimensions was measured in normal human subjects while they pointed to successive visual targets (max range 90°). A six foot diameter search coil system was used with a coil taped to the subject's wrist, such that the overall action of all joints was assessed. The rotations of the wrist from a central initial position formed an approximate planar surface in three dimensional rotation space. This surface was similar to Listing's plane for the eye, (Tweed and Vilis, Vision Res 30: 111-127, 1990) but was thicker, i.e., the torsional orientation of the wrist in space was more variable (S.D. ± 5°). Two factors contributing to the variability for a particular pointing direction, were a slow drift in the orientation adopted by subjects and a dependence on the location of the previous target. The planar surface was not the result of muscle mechanics because the subjects could be instructed to adopt a different wrist orientation which resulted in a shifted planar surface.

The axis of arm rotation relative to space was fairly constant when pointing between target pairs. This axis shifted in space depending on the pointing direction of the arm. For example in pointing from left to right a vertical axis was used which tilted up when the arm was raised and tilted down when the arm was lowered, in both cases by approximately half the angle. Thus the rules of rotations for the arm when pointing appear to be similar to those used by the eye. Support by an MRC grant to J. Hore MT-6773.

445.14

A KINEMATIC ANALYSIS OF JOINT MOTION DURING CURVILINEAR POINTING MOVEMENTS. T.R. Kaminski & A.M. Gentile. Teacher College, Columbia Univ., New York, NY 10027

The hypothesis investigated is that coordinated motion at the elbow and shoulder joints during both linear and curvilinear movements is based on a uniform strategy. Curved, point-to-point movements were performed by having the hand pass over an intermediate point between the initial position and the target.

Results from 8 adults revealed that the shape of the shoulder velocity profile remained essentially the same (smooth with one peak); even in instances where the hand velocity profile had multiple peaks. In contrast, elbow motion frequently demonstrated directional reversals and the velocity profile was dependent on the amplitude of displacement before and after passing the intermediate point. Inflections in the hand velocity profile occurred only when there was a large change in the difference in joint displacement (shoulder vs. elbow) relative to the intermediate point.

These results suggest that the joint control strategy is similar for both linear and curvilinear movements. In both cases, the shoulder provides a stable base for the organization of the movement. Furthermore, hand trajectories cannot be divided into multiple movement segments based on inflections in the hand velocity profile. These inflections maybe the result of a mechanical interaction or the need to maintain coordination between the joints.

EQUILIBRIUM VECTOR SPACES FOR THE CONTROL OF MULTI-MUSCLE SYSTEMS. A.G. Feldman, J.R. Flanagan, and D.J. Ostry. Institute for Information Transmission Problems, Moscow, U.S.S.R. and McGill University, Montreal, Canada.

A further development of the equilibrium point hypothesis (λ model) is presented with the focus on the control of multi-muscle systems during goal-directed movements. According to this hypothesis, control is associated with changes of neurophysiological parameters (λs) which define the equilibrium state of the system. Muscle activations, forces and movement arise as a natural dynamic reaction of the system to the shift in the equilibrium. Changes in λs for a set of muscles can be coordinated directly by central commands or conditioned by the intermuscular interaction mediated by muscle afferents and interneurons. The afferent interaction is also under central control. In the λ model, multi-muscle commands are represented by vectors. Each vector is associated with a linear combination of λ parameters for a set of muscles and its length represents the strength of the corresponding command. In this space, there are basic vectors which represent functionally different types of coordination. For example, one vector command produces activation of muscles without changes in arm position while another may control motions about an individual joint without other joint motions. Any other control signals can be represented as a linear combination (superposition) of the basic control signals. Two versions of the model are presented, one for goal-directed arm movements and the other for mandible movements. Both versions reproduce characteristic kinematic and EMG patterns of natural movements.

445.16

EQUILIBRIUM VECTORS UNDERLYING MOVEMENTS TO VISUALLY DISPLACED TARGETS. J.R. Flanagan, A.G. Feldman and D.J. Ostry. McGill University, Montreal, Quebec and Institute for Information Transmission Problems, Moscow, U.S.S.R.

The form of central commands underlying movements to visually displaced targets was examined within the framework of the equilibrium point (EP) hypothesis (λ model). According to this hypothesis, movement results from shifts in the equilibrium state of the motor system associated with the dynamic interaction of central commands, reflex mechanisms, muscle properties, and loads. Subjects produced pointing movements to targets located in a horizontal plane. The start of each movement was signalled by the illumination of an initial target. After a delay, the initial target was turned off and a second (displaced) target was illuminated. The position of the first target and the onset, amplitude, and direction of the displaced target were varied. The 3-D trajectory of the hand was recorded. Computer simulations based on the λ model were conducted to compare predicted trajectories, generated from theoretical central commands, with experimental trajectories. Previous reports have suggested that when a visual target is displaced, movement direction is continuously adjusted between the initial and final target (Sonderen, J.F. et al., *Exp. Brain Res.*, 78:139, 1989). Moreover, it has been argued that this process may involve the superposition of the trajectories to the two targets (Henis, E. and Flash, T., *Percept.*, 18, 495, 1989). We suggest that, at the planning level, central commands specify the direction and rate of shift (i.e., velocity vector) of the hand's equilibrium position. When the target is displaced, the equilibrium vector is simply shifted towards the new target.

ROLE OF HEAD INITIAL POSITION IN THE DIRECTIONAL CODING OF REACHING. S. Vanden Abeele*, V. Delreux* & A. Roucoux. Lab. de Neurophysiologie, Louvain Univ. Sch. of Med., 1200 Brussels, Belgium.

It has been postulated that goal directed arm movements require an internal representation space to which both sensory and motor signals are referred. This interface implies the transfer of the position of the target's image into a body-centered system of reference. This operation takes into consideration the position of the eye in the orbit (Delreux & al. Soc. Neurosci. Abstr., 1989). In the present set of experiments, the role of head position on the trunk has been investigated.

Human subjects sat facing a hemispheric screen, and were asked to move a handle in the direction of LED's presented at several positions along the horizontal meridian. The trunk was not allowed to move. There were four initial conditions for eye and head: 1. eye and head aligned on the midline; 2. eye and head aligned at 15°; 3. head on the midline, eye at 15°; 4. eye on the midline, head at 15°. In each of the four conditions, the subjects were either asked to orient their eyes towards the peripheral targets or to keep them in the initial position. The subjects oriented their forearm towards four peripheral targets (25 to 40°), in complete darkness.

In the eye mobile conditions, the analysis of the distribution of final arm position errors suggests that the reference used is the trunk antero-poterior axis. In the eye immobile conditions, data suggest that a retinal frame of reference is used, though initial head position influences final arm position.

In conclusion, it appears that, in our conditions, the final position and not the amplitude of the pointing arm movement is controlled. This control operates within a body-centered frame of reference; but the final adjustments responsible for the final error rely on mechanisms that may differ, according to the available information about target, eye and head position .

IS FOREARM ORIENTATION PERCEIVED MORE ACCURATELY THAN ELBOW JOINT ANGLE? W.G. Darling, Dept. of Exercise Science, University of Iowa, Iowa City, IA 52242.

A number of studies have shown that the angle of the forearm in extrapersonal space is perceived better in relation to axes external to the upper limb than in relation to the axis of the proximal arm segment. Exactly how such extrinsic angles are perceived has received little study. The perceptual task was simplified in previous studies by restricting either the angle of the arm segments or the plane of motion of the matching limb. In the present study subjects matched a remembered reference forearm or elbow angle (elbow flexion, forearm yaw or forearm elevation) with flexion or extension motion at the elbow only. The angle and plane of the arm segment during matching was different than in the reference position so that subjects could not simultaneously match the elbow and forearm angles. Elevation matching produced low constant and variable errors, supporting the theory that forearm angle is perceived accurately in relation to the gravitational axis. Matching of elbow angles produced larger variable errors and yaw matching produced larger constant errors. Subjects stated that elbow angle matching was "easiest" and that they used mental imaging of the forearm and its angle relative to imagined vertical and horizontal axes passing through the elbow to match the elevation and yaw angles. These results indicate that subjects use processes of mental imaging and rotation to perceive limb segment angles in extrapersonal space.

WHAT ARE THE UNITS OF MOTOR BEHAVIOR: PSYCHOPHYSICS OF HUMAN ARM TRAJECTORIES. E.P.Loeb. Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139.

It has long been known that rapid sequences of key-presses or spoken words exhibit a strong linear relation between the number of sequence elements and the reaction time to the beginning of execution of the first element. The goal of this study was to determine if there is a strong linear relation between reaction time and kinematic features of rapidly produced drawings. Normal right-handed subjects drew simple shapes (triangle, square, star) or made oscillatory motions (3, 4, 5 lines) according to standard reaction time methods. The number of peaks in the velocity profile of each drawing was used as the kinematic correlate. A linear relation between velocity peaks and reaction time was found for the shapes, but not for the oscillatory motions. This finding suggests that oscillatory motions and line segments are primitive units of motor planning or behavior.

MEASUREMENT OF THE ERROR DEADZONE AMPLITUDE IN HUMAN VISUO-MOTOR TRACKING. (SPON: Brain Research Assoc.). R.C. Miall*, D.M. Wolpert* & J.F. Stein*. University Lab. Physiology, Parks Road, Oxford OX1 3PT, UK

Human arm movements when tracking visual targets are often intermittent, suggesting that an error deadzone is involved, i.e. a threshold that must be crossed before a corrective movement occurs. To test this, we have introduced an additional artificial error deadzone (AED) and measured the smallest size of AED which leads to impaired tracking performance.

Subjects tracked a pseudorandom waveform with a small hand-held joystick. The target was a stationary square in the centre of a computer screen. The joystick cursor was displaced horizontally from the target by the error between the joystick position and its desired position, as defined by the pseudorandom waveform ('compensated tracking'). In each trial, 1 of 10 AED amplitudes between 0 and 20 pixels was introduced (0 - 1.26°). If the positional error was less than the current AED, then the cursor was displayed exactly on-target; at all other times its position reflected actual joystick position. We then computed the subject's integrated error score for the last 25s of each 30s trial, and plotted the average for each AED amplitude. Tracking performance varied considerably between subjects; smaller variance was seen between repeat trials by individuals. However, performance errors were approximately constant for each subject with small AEDs (≤ 6 pixels or 0.44°), but rose linearly above this threshold.

These results indicate that an error deadzone of about 0.44° measured at the eye contributes to the intermittency of visually guided arm movements.

FORCE REQUIREMENTS DETERMINE THE PATTERN OF AGONIST MODULATION. D.S. Hoffman, M.R. Stiles* and P.L. Strick. VA Med. Ctr. and Depts. of Neurosurg. & Physiol., SUNY-HSC @ Syracuse, Syracuse, NY 13210.

There has been controversy regarding the factors producing height and/or duration modulation of the agonist burst during step-tracking movements (Gottlieb et al., Behav. Brain Sci. 12:189-250,'89). We examined the agonist burst recorded from a wrist muscle (ECRL) of human subjects (n = 7) when they performed rapid step-tracking movements under different load conditions. In each load condition, we compared the peak of the burst and its duration (at 25% of peak activity) for different amplitude movements (5 and 25 deg changes in the radial direction). The agonist burst for movements performed with a lightweight manipulandum was largely modulated in height (ave. change = 117%) and not duration (ave. change = 11%). In contrast, when subjects performed movements against elastic loads using a heavier manipulandum, modulation of burst duration became more prominent (ave. change = 63%) and modulation of burst height began to saturate (ave. change = 35%). In fact, the average duration of the agonist burst in one subject was as short as 51 msec for movements made with the lightweight manipulandum and as long as 211 msec for movements made in the loaded condition. Our results indicate that the force requirements of a task have a significant influence on whether the agonist burst displays height and/or duration modulation. Support: VA Med. Res. Service.

CONTRASTING KINEMATIC AND FORCE PATTERNS IN LIFTING FREE OBJECTS OF DIFFERENT WEIGHTS. P.L. Weir and C.L. MacKenzie. Dept. of Kinesiology, University of Waterloo, Waterloo Canada N2L 3G1.

Reaching to grasp an object requires that the arm and hand be transported to the desired location, and that functionally effective forces be applied to the object. The kinematics of the transport and grasp components until object lift have been studied extensively to identify the relationship between the two components (Jeannerod, 1981, 1984; Marteniuk et al., 1987; Wing et al., 1986). Quite independently, the force patterns of the pinch grip after object lift have been studied as a separate parameter underlying motor control processes (Cole and Abbs, 1988; Johansson and Westling, 1984, 1987, 1988; Winstein and Abbs, 1989). Our purpose was to measure and compare kinematic and grip force patterns prior to and after the application of functionally effective forces in a grasp, lift and replace task. Trials were blocked for three dowels varying in weight (66,155,423 grams) but not visual appearance. The dowel was instrumented with strain gauges which measured the vertical lifting force, and the horizontal gripping forces of the thumb and index finger. Analyses of markers placed on the thumb and index finger (grasp component), and wrist (transport component) revealed that differences in the kinematic patterns between hand lift and dowel lift reflected the application of forces after dowel contact. Temporal and kinematic analyses up to dowel contact revealed no differences; however, the time spent in contact with the dowel (prior to lifting), increased significantly as object weight increased. In addition, lifting and replacement forces varied systematically reflecting the need for stability during these two phases of movement. These results suggest a phase dependent coupling between the application of functionally effective forces and kinematic patterns. (Supported by NSERC)

ANTICIPATORY POSTURAL ADJUSTMENTS UNDER TWO TYPES OF MULTIJOINT ARM MOVEMENTS. • C.C.Bassile, C.M.Bock*, T.Kaminski*, J.R.Higgins*. Teachers College, Columbia University, New York, NY 10027.

Anticipatory postural adjustments (APA's) made prior to the initiation of multijoint arm movements must account for a variety of joint torques for smooth movement and successful goal accomplishment. This investigation demonstrates a relationship between multijoint arm movements and postural control. Two types of sagittal plane pointing movements, reaches (shoulder and elbow moving in the same direction) and whips (shoulder and elbow moving in opposite directions), were compared during three different combinations of shoulder and elbow displacements for three standing subjects (Ss). Kinematic analysis revealed the whips to have longer movement times ($\bar{X}$ MT= 513.7 ms) and larger peak velocities ($\bar{X}$ PV= 2.90 m/s) than the reaches ($\bar{X}$ MT= 366.7 ms, $\bar{X}$ PV= 1.88 m/s). The APA latencies (time from change in shank acceleration to the initiation of wrist movement) were also different for the two types of movement. Ss appeared to time their upper limb movement with a peak in shank acceleration, suggesting an efficient relationship between body COM displacement and movement initiation. Comparisons of body COM displacement to APA and wrist movement were also analyzed.

It appears that the anticipatory postural adjustment varies with movement type, displacement and amount of force generated by the upper limb movement. The task constraints implicate differential control strategies which incorporate both the limb movement and the postural component.

DISCRETE AND CONTINUOUS PROCESSES IN THE PROGRAMMING OF EXTENT AND DIRECTION IN MULTIJOINT ARM MOVEMENTS. M.Favilla*, J.Gordon, M.F. Ghilardi*, and C. Ghez. Ctr. for Neurobiol. & Behav., Prog. in Phys. Ther., Columbia Univ. and NYS Psych. Inst., New York, NY 10032.

We have previously reported that when subjects aim impulses of isometric force to targets of unpredictable amplitude and direction in 2 dimensional space, these response variables are specified in parallel and programmed by distinct mechanisms. Amplitude is programmed as a continuous variable, direction as a discrete variable. We now determine whether similar distinctions apply to multijoint limb movements and assess the time needed to program these response features.

Subjects moved a hand–held cursor on a digitizing tablet from a common start point; targets and a screen cursor were displayed on a computer monitor. A timed response paradigm was used: movements were initiated in synchrony with the last of a series of regular tones and targets appeared at unpredictable times before the last tone. Within trial blocks, targets were at either of two distances and in either of two possible directions, target separations ranging from 15° to 150° on either side of the midline.

With widely separated (>60°) targets, default responses (<100 ms after target presentation) were directed towards one or the other target, while for narrow separations they were directed towards the center. In contrast, extents were always clustered near the center of the range of required distances. As processing time increased (onset from 100 - 450 ms after target), the proportion of wrong direction responses decreased progressively, while the amplitudes and directions of initially biased responses were gradually adjusted. The processes responsible for the programming of movement direction therefore differ when alternative directions are widely separated or close together. Direction is processed categorically when directions are widely separated and as a continuous variable, like amplitude, when they are close together (Supported by NS 22715).

DEAFFERENTED SUBJECTS FAIL TO COMPENSATE FOR WORKSPACE ANISOTROPIES IN 2-DIMENSIONAL ARM MOVEMENTS. J. Gordon, M.F. Ghilardi*, and C.Ghez. Prog. in Phys. Ther., Ctr. for Neurobiol. & Behav., Columbia Univ. and NYS Psych. Inst., New York, NY 10032.

We have previously shown that patients with large fiber sensory neuropathies make large errors in programming both the extent and direction of aimed arm movements. These errors manifest as increases in variability and as biases in movement direction and extent. The purpose of this study was to determine the source of the biases. Two deafferented patients and four normal controls moved a hand-held cursor from a central starting position to targets in 24 directions on a digitizing tablet. Target and cursor positions were displayed on a computer screen, and vision of the hand and arm was blocked. The screen cursor was blanked during movement, to prevent visual corrections.

In normals, peak acceleration of the hand varies systematically with movement direction. This anisotropy reflects differences in the inertia being moved. Mean peak acceleration is twice as high in directions in which inertia is lowest. Normal subjects are able to compensate for these inertial differences by varying movement time, so that errors in extent show only a residual dependence on direction. The deafferented subjects also show a strong dependence of peak acceleration on movement direction, but do not compensate: the errors in extent show the same relative dependence on direction as the variations in peak acceleration. Systematic biases in both initial and terminal direction are also present in normals but are not as consistent across subjects. These biases produce a clustering of responses in certain directions and are markedly increased in deafferented subjects. Both extent and direction biases in patients are substantially reduced by prior vision of the limb. We propose that the lack of compensation for directional anisotropies in deafferented patients results from an inadequate internal model of the mechanical properties of the limb. INFLUENCE OF FLEXION AND EXTENSION FATIGUE ON SPEED OF MOVEMENT. N.J. Lambert, S. Peschke*, J. Draguns* and T. Hortobágyi, *Dept. of Sport Sciences/Biology, Univ. of Denver*, Denver, CO 80208

The influence of flexion (FLEX) and extension (EXT) fatigue on forearm flexion maximum speed of movement (SOM) was examined in 10 collegiate women. Ten SOM trials were performed pre and post to 3 bouts of dynamic fatigue at 60% of maximum FLEX or EXT strength, on each of 2 test days. Surface EMG burst patterns were recorded from mm. biceps and triceps brachii during SOM. Time to target increased following FLEX (11.5%, $p<.05$), but remained unaltered following EXT fatigue. Duration of the biceps first EMG burst lengthened following FLEX (13%) and EXT (8%) fatigue ($p<.05$). The biceps to triceps burst latency also lengthened following FLEX (23%) and EXT (18.5%) fatigue ($p<.05$). FLEX fatigue decreased the peak averaged EMG amplitude of the triceps burst (11%) and EXT decreased the amplitude of the biceps (22%) and triceps (12%) burst. The longer burst duration of the biceps did not compensate for the FLEX fatigue and resulted in a lengthened time to target. Following FLEX fatigue, the decreased amplitude of the triceps reflected a reduction of force to stop the slowed movement. Following EXT fatigue, reduced amplitude of the triceps did not result in the expected decreased time to target. A reduced amplitude of the non-fatigued biceps may have delimited the limb SOM. Thus, a factor other than the triceps counteractive force inhibited the biceps and restricted the flexion SOM following EXT fatigue.

A 40Hz Rhythm in Isolated Human Cortical Slices From Epileptics. RA Palovcik, SA Reid, and JC Principe. Univ. Florida, Depts. of Neurosurgery and Electrical Engineering and V A Medical Center. Gainesville, FL.

A spontaneous 40Hz rhythm was recorded from human cortical slices removed during surgery for focal epilepsy. Signals were recorded extracellularly and subjected to a fast Fourier transform with a high pass filter. There was a consistent pattern of energy present in the 35-70Hz range. Previous activity in this range has been measured in EEG only in deeper structures. The activity was also subjected to a nonlinear dynamical analysis. Correlation dimensions were calculated and found to saturate at 6.7. The system could therefore be described by a low dimensionality deterministic chaotic attractor. This rhythm may represent repetitive activity in a two-neuron cortical feedback loop. Since it occurs in isolated cortical slices, it does not require connections with the thalamus or deeper structures and therefore does not represent activity in a thalamo-cortical relay circuit. All slices removed from epileptic foci also exhibited spontaneous synchronous seizure-like discharges during which this 40Hz rhythm could be detected.

MUSIC AS A TOOL IN ANALYSIS OF INTERSPIKE INTERVAL CODES FOR LANGUAGE AND MEMORY IN HUMAN TEMPORAL LOBE. D.F. Cawthon, J. Rahn*, G.A. Ojemann, E. Lettich*, D.F. Kalk*, and D.B. Percival*. Dept. Neurosurg.,School of Music, and Appl.Physics Lab., Univ. of Washington, Seattle, WA 98195.

With informed consent and under institutional rules, we have commonly found modulation of firing frequency for normal human temporal lobe neurons by language and memory tasks, at nonessential sites during epilepsy surgery. We had occasionally noted nearly repeating sequences of single cell (ISIs) or intercell interspike intervals (ICISIs) in multiunit recordings, so we adapted a "stereotrode" (Cawthon *et al. Soc Neurosci Abstr* 1989; **15**: 302) to separate individual cells from two multiunit records. Using the LISP Kernel compositional environment (Rahn, J. *et al. Musicus* **1**(2): in press, 1990), we musically transformed the timestamps for firings of individual cells in three ways, while slowing playback X10 from realtime to hear rapid sequences. The first transformation gave each cell a separate pitch and instrument, each cell's note playing till its next note. This allowed detection of repeating single and multicell sequences, despite variation in tempo of rhythm and "melody." The second method used the reciprocals of each of a single cell's (instrument's) sequence of ISIs, scaling the resulting pitches into the 20 to 10,000 Hz range. This arrangement allowed identification of single cell ISI patterns, whether fixed or varying in tempo, better than of ICISIs. The third method applied the second to all sequential intervals, whether ISIs or ICISIs, to detect coding by ICISIs more directly, as previously reported in patients but apparently without cell isolation (Bechtereva, N. *et al. Brain Lang* 1979; **7**: 145-63), and in monkeys but without the ability to detect repeating sequences of differing tempo (Abeles, M. and Gerstein, G. *J Neurophysiol* 1988; **60**(3): 909-24). Samples of these encodings will be played and other mathematical music techniques shown for detecting more complex patterns. THE CORTICAL CONSENSUS: A DISTRIBUTED DARWINIAN MODEL FOR RECOGNITION AND DECISION-TO-ACT. WILLIAM H. CALVIN. Univ. of Washington, NJ-15, Seattle 98195.

Small specialized regions of cerebral cortex do exist but they are seldom essential. This is analogous to committees, which can function without all members present, where each expert member also sits on other unrelated committees, and committee size can change. MARCEL KINSBOURNE suggests that "*When wide areas of the [cortex] are involved in one mental operation... [they] can be used either for a wide-ranging but shallow encoding, or for a single but difficult mental operation.*"

But by what neural mechanism are "committee decisions" reached? Here I propose a model that builds on population-shaping known from darwinism, especially such runaway success as in speciation and the immune response. The darwinian analogies are clearest when serial-order is involved: "get set" for hammering or throwing requires the same attention to proper ordering as does the genome's DNA sequence or the antibody's amino-acid sequence. Because ballistic movements are too brief for feedback to effectively guide them, one needs serial-buffer-like neural machinery comparable to the roll for a player piano, instead holding the activation patterns of the many different muscles of hand and arm. For accurate throwing, one requires many such arrangements in tandem (a "chorus of player pianos") to reduce timing jitter. In *The Cerebral Symphony*, I discussed the spare-time applications of such serial machinery for shaping up strings of words; the "good-enough-to-speak" decision might occur when a population of randomly-varied candidate strings had (via differential reproduction of those rated highest by episodic memories) evolved to near-clones of one another (a "Darwin Machine"). Here I suggest that *consensus also underlies higher-order recognition* and that the many planning tracks greatly augment the associative memory needed for forming new categories, e.g., many different sequencer populations coming up with a similar sequence ("apples-oranges-bananas") constituting the recognition of a new category ("fruit"). Sequencing might play little role subsequently, only *acting as scaffolding during concept formation.*

TEMPORAL CONSTRAINTS IN SYNCHRONIZATION OF MOTOR RESPONSES TO A REGULAR SEQUENCE OF STIMULI. E.Pöppel, U. Müller* and J.Mates*. Inst. med.Psychol., Munich Univ., FR Germany and Inst.Physiol. Czechoslovak Acad. Sci., Prague, Czechoslovakia.

"What is synchronized?" is the basic question in sensorimotor synchronization. We suggest that synchronization is given if the temporal central availability (TCA) of a sensory stimulus falls into the same time window as the predicted TCA of the feedback of a motor response (Pöppel et al. Naturwiss. 77, 1990, p. 89). In order to investigate this problem we have chosen a paradigm where the subject has to follow a regular sequence of auditory (or visual) stimuli with motor responses. Normally, the subject's "tapping" anticipates the auditory stimuli by approx. 30 ms. Here we report that the interstimulus interval (ISI) determines the response mode. Anticipation is observed only for ISIs up to 2 or 3 seconds. For longer ISIs subjects have to react to the stimuli; they can no longer be anticipated accurately. These results are interpreted on the basis of a temporal integration process whose capacity is limited to approx. 3 seconds (e.g., Pöppel: "Time Perception" Encycl. Neurosci., p. 1215, 1987).

A GENERAL FRAMEWORK FOR DEVELOPING THEORY IN NEUROSCIENCE, Coleman D. Clarke, Jr., and Gary Aston-Jones[1], Putman Brain Research Project, 4525 Wasatch Blvd., Suite. 310, Salt Lake City, Utah 84124; [1]Div. Behav. Neurobiol., Dept. Mental Health Sciences, Hahnemann University, Philadelphia, PA 19102

Some examples are given of the logical status of theory in physics and biology, and of its important role in helping to advance these sciences at a rapid rate. The relationship between experimental data, principles derived from the data, and theory is delineated. It is proposed that the kind of theory needed, and, in fact, attainable in neuroscience will be an abstract logical calculus (like the quantum mechanics calculus) which will make a synthesis of data and principles, so as to explain in causal terms the overall aspects of brain operation. A brief outline of such a theory will be developed using such useful principles as found in Hebb's Postulate, cell assemblies, network theory, parallel distributed processing, and chaos theory. This framework will make use of a special theory of games, as well as heuristics including a neural conditioned reflex principle, random search and relative dominance among neural loops, and the formation of a global steady state condition in the CNS. Specific examples of possible neural substrates for some of these constructs (e.g., locus coeruleus and reticular thalamic nucleus as random search generators) will be proposed. The role such a theory might play in unifying data and principles in neuroscience will be discussed.

DESCENDING INTERNEURONS IN THE SPINAL NETWORK OF THE GOLDFISH MAUTHNER (M-) CELL ELECTROTONICALLY EXCITE PRIMARY MOTONEURONS. J.R. Fetcho. Dept. Physiol., SUNY at Buffalo, NY 14214.

Morphological evidence suggests that descending interneurons excited by the M-cell terminate on many motoneurons, including the large primary ones known to play an important role in escapes. To examine the synaptic connections between descending interneurons and primary motoneurons, I recorded intracellularly, simultaneously from a M-axon, a descending interneuron and a primary motoneuron (N=5). Firing the M-cell led to firing of the interneurons and produced a multicomponent EPSP in primary motoneurons. Direct activation of an interneuron produced a fast EPSP in the motoneuron that was very similar to, but smaller than, a component of the EPSP produced by M-cell firing. The latencies of the interneuron-motoneuron connections were less than .2 msec, and EPSPs followed stimulation of the interneuron at more than 30Hz. The short latency and fatigue resistance indicate that the interneurons electrotonically excite primary motoneurons. However, the data do not rule out the possibility, suggested by indirect evidence, that the interneurons also produce a late chemical input to motoneurons. Thus, primary motoneurons are excited by a combination of electrotonic inputs from descending interneurons and a previously described direct M-cell input.(Support: NIH NS07593)

ANALYSES OF MULTIPLE MOTOR PATTERNS IN CHICKS. A. Bekoff. EPO Biology Dept., University of Colorado, Boulder, CO 80309-0334.

Chicks produce a wide variety of behaviors involving rhythmic leg movements. They range from very fast (eg, foot shaking) to very slow (eg, hatching). In addition, they include behaviors with alternating (walking, swimming), synchronous (hatching, hopping) and unilateral (foot shaking, head scratching) leg movements.

Using EMG recordings, we have characterized the leg motor patterns involved in 10 behaviors. Previously, we have focussed on one behavior (eg, Smith, M.B. et al., 1987, Soc. Neurosci. Abstr. 13:355; Bradley, N.S. & Bekoff, A. 1987, Soc. Neurosci. Abstr. 13:1504) or comparisons among two to three behaviors (eg, Bekoff, A. et al., 1987, Soc. Neurosci. Abstr. 13:1541; Johnston, R.M. & Bekoff, A., 1989, Soc. Neurosci. Abstr. 15:1044). The current study examines the range of variation among a larger and more diverse group of motor patterns.

EMG recordings were made from 6 leg muscles in 0- to 8-day old chicks. Recordings were digitized and cycle period, burst duration, phase, latency and interburst interval measured. Ten cycles from each of 10 chicks were typically used to analyze each behavior.

Although parameters such as cycle period or burst duration can vary significantly among motor patterns, all have some features in common. For example, they share a biphasic pattern in which one set of muscles (or bursts) consistently participates in an extensor synergy and a second set in a flexor synergy. Onset and duration of hip and ankle muscle bursts can vary significantly between behaviors. However, they are similar to one another within each behavior. In contrast the timing of knee muscle activity often differs from that of hip and ankle.

KINEMATICS OF JAW MOVEMENTS DURING DRINKING IN THE PIGEON. R. Bermejo and H. P. Zeigler. Biopsychology Program, Hunter College (CUNY), New York, NY 10021

In birds, as in mammals, drinking involves repetitive opening and closing movements of the jaw which vary the size of the oral aperture. However, in contrast to mammals, the morphology of the avian skull permits the movement of both maxilla and mandible. The kinematics of individual beak movements were studied during drinking in the pigeon.

Subjects were fixed in a stereotaxic device using a skull-mounted head-holder and an infrared LED was attached to each beak. Drinking was elicited by immersion of the beak in water. Movements of the upper and lower beak were individually monitored by a photosensitive movement transducer and the analog signals were digitized (12 bit A/D; resolution 1 ms) for subsequent analysis.

The displacements of individual beaks were analyzed with respect to the cyclical variations in the size of the oral aperture. Drinking in the pigeon involves a series of synchronized displacements of the upper and lower beak in the vertical plane, with the maxilla leading the mandible by 30-40 ms. In most cases, variations in mandible displacement accounted for most of the variation in gape amplitude. The data are consistent with previous behavioral and EMG studies of drinking in the pigeon.

OCTOPAMINE ENHANCES THE EXCITABILITY OF CENTRAL NEURONS IN THE FLIGHT SYSTEM OF THE LOCUST. J.M.Ramirez and K.G.Pearson. Department of Physiology, University of Alberta, Edmonton, Canada.

Recent studies on the flight system of the locust have demonstrated that the biogenic amine octopamine regulates energy metabolism, enhances the contractility of flight muscles and increases the responsiveness of proprioceptors. Octopamine can also initiate and modulate centrally flight behaviour. The mechanisms and sites for the central actions of octopamine are unknown. We have examined the effects of octopamine on certain synaptic connections and on the membrane properties of identified neurons. The connections we studied were those linking tegula afferents to wing elevator motoneurons. Octopamine did not significantly alter the monosynaptic EPSPs but caused the appearance of a depolarization at a latency of 18-20ms. This second depolarization is polysynaptically caused by increased excitability of interneurons in the pathway from tegula afferents to elevator motoneurons. Increased excitability was found in some excitatory interneurons presynaptic to elevator motoneurons. Short current pulses (5-10 ms, 0.5-1nA) injected into these interneurons evoked burst like depolarizations which outlasted the pulses. The following findings suggest that these depolarizations are due to active membrane properties intrinsic to these interneurons: they were evoked in an all or nothing manner depending on the injected current and they could be terminated by short hyperpolarizing current pulses. Furthermore long depolarizing current pulses (500ms, 1-2nA) evoked in some cases rhythmic bursting activity without activating the flight rhythm generator as demonstrated by recording simultaneously from other flight neurons. Thus our findings suggest that octopamine modulates centrally the flight rhythm generator by inducing active membrane properties in a small population of flight interneurons. Similar effects of octopamine were observed in some neurons in the respiratory system.

446.10

ACTIVITY OF SPINAL NEURONS WITH DESCENDING AXONS DURING FICTIVE SCRATCH IN SPINAL TURTLES. A. Berkowitz and P.S.G. Stein. Dept. Biology, Washington Univ., St. Louis, MO 63130.

The turtle spinal cord contains sufficient neural circuitry to select and generate an appropriate form of the scratch reflex. In a low-spinal, immobilized turtle, cutaneous stimulation in the mid-body region elicits a rostral scratch motor pattern in hindlimb motor nerves; such stimulation in the pocket region elicits a pocket scratch motor pattern. We investigated the basis for scratch selection and generation by recording concurrent activity of hindlimb motor nerves and spinal neurons with axons that descend into the hindlimb enlargement.

The spinal cord was transected once just caudal to the forelimb enlargement and once within the hindlimb enlargement. Unit recordings were obtained via a microsuction electrode placed in the white matter at the caudal face of this multisegmental spinal cord preparation (Abstr.Soc.Neurosci.15:1118,'89). Unit receptive fields (RF's) were compared to a dermatome map (J.Comp. Neurol.295:515,'90) and to scratch form RF's (J.Neurophysiol.53:1501,'85). Units were identified as interneurons by the latency-jitter of responses to high-frequency peripheral nerve stimulation.

Units displayed either unisegmental or multisegmental RF's. Some of the latter units responded at all sites that evoked motor output. Within each category, some units showed phasically modulated activity correlated with scratch motor output, and others did not. Some units had large, multi-segmental RF's that were confined within the RF of only one scratch form. Many units that showed phasic modulation and had RF's including portions of rostral and pocket scratch RF's showed phasic modulation correlated with expression of each scratch form; this suggests that elements of interneuronal circuitry, and perhaps pattern-generating circuitry, are shared for the two forms. Other units had multisegmental RF's and were not phasically active; this suggests that substantial convergence of sensory inputs may occur prior to activation of pattern-generating circuitry. Supported by NSF Grant BNS-8908144 to PSGS and an NSF predoctoral fellowship to AB.

FUNCTIONAL SIGNIFICANCE OF BI-THRESHOLD FIRING OF NEURONS. D. C. Tam Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

The threshold for firing of action potentials for some neurons occurs not only at depolarized membrane potentials but also at hyperpolarized potentials. The bi-threshold phenomena had been reported in a number of central neurons including thalamic (Jahnsen & Llinás, *J. Physiol.* 349:205-226, 1984), inferior olivary (Yarom & Llinás, *J. Neurosci.* 7:1166-1177, 1987), and hippocampal neurons (Stasheff & Wilson, *Soc. Neurosci. Abst.* 15:339, 1989). Of particular interest is the firing of action potentials at hyperpolarized potentials called "low-threshold spikes" by Yarom & Llinás and "baseline spikes" by Stasheff & Wilson, which can be elicited naturally during the after-hyperpolarization (a.h.p.) following a spike activation. The generation of low-threshold spikes is a voltage- and time-dependent process, accompanied by anomalous rectification, occurs during a prolonged membrane hyperpolarization for de-inactivation of ionic conductances. The functional significance of this bi-threshold firing phenomenon was suggested to be involved in the two different rhythms generated by a neuron as a periodic bi-stable oscillator (Rose & Hindmarsh, *Proc. R. Soc. Lond.* 225:161-193, 1985; Goldbeter & Moran, *Eur. Biophys. J.* 15:277-287, 1988). It can be shown that bi-threshold firing may also be used for multiplexing signals by switching modes of operation in signal processing. More importantly, hyperpolarization can be considered as *excitation* to a neuron rather than inhibition since under these hyperpolarized conditions the neuron actually becomes more excitable (i.e., closer to the low-threshold). This hyper-excitability of neurons may account for the reported susceptibility to epileptic kindling at non-depolarized potentials in hippocampal neurons. It also suggests that Hebbian synapses may be strengthened not only by the depolarizing post-synaptic potentials but also by hyperpolarizing post-synaptic potentials. HYPOTHERMIA INDUCES SPONTANEOUS RHYTHM DISCHARGE IN ISOLATED SYMPATHETIC GANGLIA. Karim A. Alkadhi and Lian-Ming Tian, Department of Pharmacology, College of Pharmacy, University of Houston, Houston, TX 77204-5515.

Most biological processes decrease in rate in response to a decrease in temperature. However, nervous tissues in general show an anamalous response to temperature in that they exhibit a decrease in spontaneous activity when the temperature is raised and an increase in activity when temperature is reduced. Isolated sympathetic ganglia are thought to exhibit no spontaneous activity unless transmitter release is induced by drugs. However, preliminary experiments in this laboratory showed that isolated sympathetic ganglia from various mammalian species fire spontaneous, often rhythmic discharge when exposed to low temperatures. Ganglia were placed in temperature-controlled oxygenated Locke solution with their rostral ends aspirated into capillary suction electrodes. Long-lasting (24 hrs), large spontaneous potentials, often occurring in singles or bursts at regular intervals, appeared with rabbit superior cervical ganglion (SCG) or dog lumbar ganglion when bath temperature was kept between 15-30°C. When the temperature is reduced below 15°C or raised above 30°C the discharge decreased in frequency and finally stopped. No discharge was seen with rat SCG at any temperature. The frequency and amplitude of potential and pattern of rhythm varied from ganglion to ganglion and was blocked by ganglion blocking agents. The presence of rhythm in these ganglia suggest the existance of an intrinsic pattern-generating mechanism which might involve polysynaptic networking.

CERTAIN BRAIN STEM LESIONS FAIL TO AFFECT CORTICALLY DRIVEN AUGMENTATION AND INHIBITION OF MUSCLE ACTIVITY IN THE RAT: D. ASDOURIAN, S.I. LENTZ, AND S. LOOK, DEPARTMENT OF PSYCHOLOGY, WAYNE STATE UNIVERSITY, DETROIT, MI 48202

The results reported below were obtained in rats anesthetized with pentobarbital (60 mg/kg.). When the frontal cortex (Cx) is stimulated (15 twin pulses/sec, duration 0.5 msec, interpulse interval 1.0 msec, current 0.4 - 0.8 mA) 2.0 mm from the midline with the anode at the level of bregma and the cathode 1.5 mm anterior to bregma, activity is reliably driven in the contralateral trapezius and rectus capitis (muscles of the neck and shoulder). If the Cx is stimulated bilaterally with subthreshold current (determined separately for each Cx), the effects of the two stimuli augment each other and drive activity in trapezius. No augmentation is seen in rectus capitis. If one Cx is stimulated with suprathreshold current, the contralateral activity driven in rectus capitis is completely blocked by suprathreshold stimulation of the other Cx. No blockage is seen in trapezius. These results can be duplicated by coupling Cx stimulation with stimulation of substantia nigra reticulate (SNr) suggesting that Cx - Cx and Cx - SNr interactions are mediated by the same mechanisms, and that the site(s) of the interaction is in the brainstem or spinal cord. Neither unilateral pyramidal tract lesions nor unilateral lesions bridging the medial longitudinal fasciculus (MLF) interstitial nucleus of MLF, and nucleus Darkschewitsch have any affect on the results of Cx - Cx stimulation described above, leaving unanswered, questions concerning the sites of interaction of outputs from the two cortices.

ROLE OF EXCITATORY AMINO ACIDS IN THE GENERATION AND TRANSMISSION OF RESPIRATORY DRIVE IN NEONATAL RAT. John J. Greer, Jeffrey C. Smith & Jack L. Feldman, Systems Neurobiology Laboratory, Department of Kinesiology, UCLA, Los Angeles, CA 90024-1568.

The involvement of excitatory amino acids (EAAs) in respiratory rhythmogenesis and the transmission of respiratory drive to cranial and spinal motoneurons was studied in an *in vitro* neonatal rat brainstem-spinal cord preparation. Motor nerve discharges were recorded from glossopharyngeal (IX), vagus (X), and hypoglossal (XII) nerves, and cervical (C1-C5) and thoracic (T1-T4) ventral roots. A barrier at the spinomedullary junction allowed for the addition of an EAA uptake inhibitor, DHK, or EAA receptor agonists (NMDA, kainic acid, AMPA) or antagonists (MK801, CNQX, AP4) to bathing solutions surrounding either the spinal cord or brainstem.

Inhibition of the reuptake of endogenously released EAAs by adding DHK to the brainstem bath caused a dose-dependent increase in respiratory frequency. Blocking of non-NMDA receptors at the brainstem with CNQX produced a dose-dependent decrease in respiratory frequency and amplitude of cranial motoneuron discharge, whereas the agonists, kainic acid and AMPA, caused an increase in frequency. CNQX applied to the spinal cord decreased the amplitude of all respiratory spinal motoneuron discharge. Neither blocking NMDA receptors with MK801 nor blocking AP4-sensitive receptors within the brainstem affected respiratory frequency or amplitudes of cranial motoneuron and bulbospinal respiratory premotoneuron discharge. NMDA produced a dose-dependent increase in respiratory frequency. MK801 added to the spinal cord bath caused a 10-30% decrease in the amplitude of respiratory spinal motoneuron discharge. AP4 added to the spinal cord abolished the inspiratory activity recorded from C4 and thoracic ventral roots, but caused only a slight decrease in C1-C2 ventral root discharge.

We conclude that respiratory rhythm generation is dependent on a conditional drive mediated by EAAs acting at non-NMDA receptors. The transmission of drive to cranial and spinal respiratory motoneurons is also mediated by EAAs acting at non-NMDA receptors. Activation of NMDA receptors plays only a minor role in the transmission of respiratory drive to motoneuron pools, and does not seem necessary for rhythmogenesis. The binding of AP4 to its receptor strongly inhibits the transmission of respiratory drive to phrenic and intercostal motoneuron pools, but has little affect on rhythmogenesis, or the drive transmission to cranial and accessory motor pools. Supported by NIH grants HL 40959 and HL 02204.

CLASSIFICATION OF NOISY ACTION POTENTIALS (APs) BY MEANS OF A NEURAL NETWORK EMPLOYING BACK-PROPAGATION. I. Espinosa E. and J. Quiza T.*, Cybernetics Lab., Faculty of Sciences, UNAM, México 04510.

Metal electrodes allow to simultaneously register APs from different neurons, creating the need of techniques for spike sorting. As a first step we have been implementing a method to classify noisy APs. Using a database of 64 significantly different APs as the training set we generated a network with 97 processors forming two hidden layers of 30 and 60 and an output layer with 7 neurons. The network is modifiable at will. APs consist of 128 points normalized between 0 and 1. These values go into an input buffer that receives them unchanged. For employing the back-propagation training algorithm we set the initial weights (9690) between -.5 and .5. After 35,000 iterations that took 20 min CPU in the TITAN(Ardent), with 16 MFLOPS, the total system error was less than .01. The final weights are fed to a conventional PC for classifying APs. Gaussian noise was added to original APs randomly modifying amplitude up to 40%. The network was able to classify 90% of them correctly. The next step will be to sort APs embedded in a noisy spike train.

MULTIPLEXED ADAPTATION AND TRANSMISSION IN ARTIFICIAL NEURAL NETWORKS WITH INCORPORATION OF TWO SIMULATED POTASSIUM CONDUCTANCES ALLOWS FOR ASSOCIATIVE CONDITIONING AND JUDGEMENTS OF CONTIGUITY. Jon Berner & C.D. Woody. MRRC, BRI, UCLA Hlth. Sci. Ctr., Los Angeles, CA 90024.

Features of two potassium conductances implicated in the acquisition of conditioned reflexes, the slow gK+(Ca) and gK+(A), were incorporated into a 6*6 element artificial neural network with real-time, thresholded spike transmission and additive integration of PSPs. Adaptive algorithms changed gK+(A) in proportion to the product of this current and an EPSP-induced second messenger concentration and changed gK+(Ca) as a function of a spike-induced second messenger concentration.

This network acquired two distinct representations in response to presentation of stimuli: one resembled associative conditioning (defined in terms of its sensitivity to forward pairing vs. simultaneous or backward pairing); the other was sensitive to contiguous pairings of stimuli.

The acquisition of one representation did not markedly interfere with acquisition of the other; this network may accordingly serve as an example of a system which minimizes the postulated inherent cross-talk between functionally dissimilar representations (see Minsky & Papert, 1988).

BIOLOGICALLY DERIVED SYNTHETIC NEURAL NETWORKS W.E. Faller and M.W. Luttges. Aerospace Engineering Sciences, University of Colorado, Boulder, Colorado 80309-0429.

A major difficulty in developing neural network simulations of biological data has been the absence of techniques for interweaving neurobiological data and connectionist architectures. Techniques for implementing such networks are being developed and tested in our laboratory. The present developments permit experimental neural data to be directly incorporated within connectionist architectures. The spatial distribution of cells, the physiologic operating range of each neuron and the stochastic history of the cellular spike trains were retained. Sigmoidal activation functions describe the behavior of each unit. These functions were derived directly from the cellular spike history data. Each neuron was thereby represented by a unique network unit that mimicked both the mean firing frequency and temporal dynamic range of the physiologic cell. An "analog" function that preserved both the exact spiking times and the relative spiking tendency of each neuron was substituted for each spike train. The "effective" influence of each cell is reflected in the cellular dynamic range and the stochastic temporal modulations of individual cell firing patterns. These types of networks provide a means of accurately resynthesizing biological data where various connections, cell discharge characteristics or other accessible parameters may be altered. Functional hypotheses can be developed to compare experimental and analytical issues related to the biological nervous system. Alternatively, hypotheses derived from the analyses of experimental neural data may be tested by appropriate modifications of the synthetic architecture.

Memory Properties in the 1000-Neuron Inhibitory-Feedback Network Model for Simulation of Neostriatal Circuits. C.D. Myre and D.J. Woodward. *Dept. of Cell Biology and Neuroscience, UT Southwestern, Dallas, Texas 75235.*

This laboratory has reported previously on the capability for information storage, or memory, in the states of networks of mutually-inhibitory model neurons. Continuing investigation of this memory in the 1000-Neuron Network Model (which construction was inspired by medium spiny neurons) has revealed several new properties showing how state maintenance and state switching occur. The studies described here were done using the XNET Simulation System (Neurosci. Abstracts 1989, #416.18). The calculations were performed on a Sun SPARCstation 370 computer. The 1000-Neuron Network Model is made up of 1000 model neurons with realistic electrical properties, with parameters set by the user. Each neuron is connected to a variable, spherical domain of nearby neurons by inhibitory synapses. Excitation can occur via excitatory synapses which are controlled by the user, and Gaussian "noise" (representing lumped, random synaptic activity) may also provide excitatory and inhibitory effects. The parameter settings in initial experiments were such that, after decay of inhibition and potassium conductance for a neuron, the membrane potential reached threshold, and the neuron fired. When inhibitory feedback was added to the eight nearest neighbors of each neuron, the neurons entered and maintained states in which they either fired repeatedly (the "on" state), or did not fire at all (the "off" state). The results showed: 1. that the maintenance of state (i.e., memory) requires setting parameters so that IPSP's are relatively long-lasting; 2. even though states could apparently be maintained indefinitely, state-switching required only a few user-supplied excitatory impulses; and 3. state changes with local reciprocal effects did not necessarily propagate globally, despite the high connectivity. Also, powerful global noise can induce spontaneous switching, which facilitates evolution to a system ground state. This modeling suggests that the structural organization of neostriatum could support short-term memory. *Support from the Texas Adv. Res. Prog., Biol. Humanics Found., MH44337, DA02338, and AFOSR 90-146.*

ASSOCIATION CORTEX AND THALAMOCORTICAL RELATIONSHIPS

447.1

NICOTINIC AND MUSCARINIC DEPOLARIZING RESPONSES OF THALAMOCORTICAL CELLS TO STIMULATION OF BRAINSTEM CHOLINERGIC NUCLEI. R. Curró Dossi, D. Paré and M. Steriade. Lab. Neurophysiol., Sch. Med., Univ. Laval, Quebec, Canada, GlK 7P4.

Preliminary data showed that a long-latency (1-1.5 s) depolarization, lasting for 1.5-2 s, is elicited in lateral geniculate cells by stimulation of the peribrachial (PB) area (Steriade and Deschênes, l988). We have further investigated the mechanisms of brainstem-induced depolarizing events in 85 thalamocortical cells recorded intracellularly from various nuclei in urethane-anesthetized cats. Stimulation of PB or laterodorsal tegmental (LDT) nuclei induced two types of depolarizing responses that resisted monoamine depletion by reserpine treatment. (a) The first component had a latency ranging from 20 to 140 ms, lasted for 1.7 ± 0.12 s, was associated with 20-30% increase in membrane conductance, and was blocked by mecamylamine. (b) The second component had a latency of 1.4 ± 0.3 s, lasted for 5 to 30 s, increased under steady depolarization, often disappeared with cell hyperpolarization, was associated with 30-50% increase in apparent input resistance, and was accompanied by an EEG desynchronization with a similar time-course. After scopolamine treatment, the long-lasting depolarization disappeared; the surviving short-lasting depolarization was abolished by subsequent administration of mecamylamine. These data demonstrate that, following the initial nicotinic depolarization, PB/LDT stimulation elicits a long-lasting muscarinic depolarization that is probably involved in cortical EEG activation. Supported by MRC grant MT-3689.

DIMENSIONAL ANALYSIS OF EVENT-RELATED POTENTIALS. M.Molnár*, J.Desmedt*, J.E.Skinner. Neurophysiology Sect. Neurology Dept., Baylor College of Medicine, Houston, TX 77030.

Temporal alterations in the correlation dimension (D2) were calculated from event-related potentials (ERPs) evoked in humans. The ERPs (1,000-Hz A/D) were evoked by weak pulses, delivered separately to one of two fingers, while the subject was either reading a novel (control) or detecting and counting infrequent stimuli to one of the fingers (target). The point-D2 algorithm of Skinner and associates was used to analyze 15,000-point epochs made of 15 linked trials. Fifteen-trial averages of the point-D2 were made following this analysis. In the parietal primary cortex target stimuli evoked a D2 DECREASE of 1.0 dimensions (from a mean and standard deviation of 5.6 ± .15), in parallel with the P300 ERP-component (P<.001). In the frontal association cortex an earlier D2 decrease of 0.7 dimensions occurred (from 5.5 ± .10), in parallel with the N140 component of the ERP (P<.001); this initial decrease was followed by a D2 INCREASE of 0.7 dimensions, peaking at 400 msec (P<.001) and returning to baseline by 500 msec. Although control stimuli evoked some large ERP components, there was no significant change in the point-D2. These data suggest that specific processes of different dimensional complexities occur in the primary and association cortices during analysis of relevant information.

447.3

CYTOARCHITECTONIC REMAPPING OF AREAS 9 AND 46 IN THE HUMAN PREFRONTAL CORTEX. G. Rajkowska and P. S. Goldman-Rakic. Section. of Neuroanat.,Yale Univ. Sch. of Med., New Haven, CT 06510.

The location of human prefrontal areas varies between Brodmann's widely used map (1909) and the more detailed analyses of von Economo & Koskinas (1925) and Sarkissov et al. (1955). The need for a uniform parcellation of the human brain stimulated us to reinvestigate the cytoarchitecture of the prefrontal cortex beginning with areas 9 and 46. We analyzed Nissl-stained, celloidin-embedded sections of the left hemisphere from 8 human brains. Data on cell size, cell packing density per layer, and layer thickness supplemented light microscopic observations.

Among prefrontal areas, area 9 is distinguished by its large pyramids in sublayers IIIc and Va and by distinct lamination. Three subdivisions can be recognized based on size of pyramids, distinctness of radial striations and cortical thickness. Using these criteria, area 9 was located on the anterior and middle portions of the first and superior part of the second frontal convolution extending to the superior frontal sulcus in all cases examined. Area 46 can be distinguished from surrounding areas by the more uniform size of its pyramids, a generally higher cell packing density, and a wider and more regular layer IV having distinct borders with adjacent layers. Area 46 was located in the middle of the second frontal convolution. Although its inferior border was consistently found in the fundus of the inferior frontal sulcus, it was never observed on the ventral convexity as represented in Brodmann's map. Variability among cases was greater in area 46 than in area 9 and appeared due to individual differences in the number and configuration of gyri in the second frontal convolution.

The present localization of areas 9 and 46 corresponds more to the maps of von Economo and Sarkissov than to that of Brodmann. Our preliminary findings suggest that the surface area of area 46 may vary considerably among individuals and may underlie their individual differences in certain visuo-spatial capacities. Supported by MH44866.

447.4

THE ORGANIZATION OF PROJECTIONS FROM THE MEDIODORSAL NUCLEUS OF THE THALAMUS TO ORBITAL AND MEDIAL PREFRONTAL CORTEX IN THE MONKEY. J. P. Ray and J. L. Price, Dept. of Anat. & Neuro., Washington Univ. Sch. Med., St. Louis, MO 63110.

The organization of the mediodorsal thalamic nucleus (MD) of the cynomologous monkey was examined with retrograde and anterograde axonal tracers, and an analysis of cyto- and myeloarchitecture. Our results verify the conclusions of previous studies (e.g., Goldman-Rakic and Porrino, '85), but also demonstrate additional features of the organization of MD. In addition to the magnocellular division of MD (MDm) and its projection to orbital cortex, we recognize a separate caudodorsal division as the source of projections to medial prefrontal cortex. Projections of MD were studied by placing small injections of fluorescent retrograde tracers restricted to single cytoarchitectonic areas in the medial or orbital prefrontal cortex, or the agranular insula. After injections into orbital cortex (areas 11, 13 and 13b), labeled cells are found in MDm, which largely corresponds to the densely myelinated MD pars fibrosa in myelin preparations. In contrast, injections of retrograde tracers into medial prefrontal cortex (areas 32, 24) label cells in MD which are beyond the dorsal and caudal limits of MDm; cells projecting to area 32 are found at the dorsal edge of MD, along its entire rostrocaudal extent, while cells projecting to area 24 are concentrated in the caudomedial portion of the nucleus. These parts of MD partially correspond to MD pars densocellularis of Olszewski ('52), but more precisely correspond to a poorly myelinated portion of MD referred to as pars caudalis in human material (Hassler, '59). Cells projecting to the agranular insula are limited to the medial edge of MD, a region which is poorly myelinated and may correspond to a medial extension of the caudodorsal division of MD. Anterograde label from prefrontal cortical regions (areas 32, 13, and agranular insula) reciprocate this pattern. Support; NIH DC00093-20.

SYNAPTIC ORGANIZATION OF CORTICAL EFFERENTS AND GABA-CONTAINING SYNAPTIC ELEMENTS IN THE MEDIODORSAL THALAMIC NUCLEUS OF THE MONKEY. M. L. Schwartz, J. J. Dekker* and P. Goldman-Rakic. Sect. of Neuroanatomy, Yale Univ. Sch. of Medicine, New Haven, CT 06510

We examined the synaptic organization of cortical inputs and GABA containing synaptic circuits in the monkey mediodorsal nucleus (MD). To examine cortical inputs, we injected the prefrontal cortex of two rhesus monkeys with ^{3}H-leucine and proline and analysed the distribution and morphology of radiolabeled terminals in the MD. The synaptic organization of GABA-containing elements was examined in four additional monkeys using GABA immunohistochemistry (Incstar).

Quantitative analysis of the density of silver grains over different tissue compartments in the monkeys receiving cortical injections of ^{3}H-leucine and proline, revealed a positive labeling index for two terminal classes. Relative grain density was greatest for *small terminals*, with round synaptic vesicles in the extraglomerular neuropil. In addition, a number of *large terminals*, with round vesicles were labeled within glomeruli. These terminals were presynaptic to the central dendrite, as well as to presynaptic dendrites of the glomerulus. Both classes of terminal formed asymmetric synaptic densities.

In GABA immunoreacted tissue the majority of reactive presynaptic profiles were found within the glomeruli. Nearly all of these could be classified as presynaptic dendrites (PSDs) and formed symmetric synaptic contacts with the central dendrite. Two classes of presynaptic elements were also labeled in the extraglomerular neuropil, although their numbers were more limited than that of the PSDs in glomeruli. One class consisted of extraglomerular PSDs which formed symmetric synaptic contacts with unlabeled dendrites. A small number of axon terminals were also immunoreactive. These were generally small and were densely packed with vesicles. Although these were most frequently found to contact unlabeled dendrites, a small number were presynaptic to neuronal cell bodies.

These results suggest that cortical input to the MD arrives via two distinctive synaptic pathways, one ending extraglomerularly and the other acting on GABAergic PSDs and relay cell dendrites within glomeruli. Supported by BNS 8617585

447.6

PREFRONTAL CONNECTIONS OF MEDIAL PREMOTOR AREAS IN THE RHESUS MONKEY J.F. Bates & P.S. Goldman-Rakic. Sect. Neuroanatomy, Yale Univ. Sch. Med., New Haven, CT 06510

Higher-order motor areas, implicated in initiation and execution of skilled movements, have been localized on the medial surface of the frontal lobe in both monkey and human. SMA, (supplementary motor area), or the medial aspect of area 6, has connections with primary motor cortex as well as somatosensory cortex and the spinal cord. Each is thought to have a somatotopic representation of the body surface. Additional premotor areas have been suggested in cingulate cortex (e.g. He et al., 1989). We have investigated the connections of prefrontal cortex with the SMA and cingulate cortex in the rhesus monkey, using small injections of wheat germ agglutinin-conjugated horseradish peroxidase (WGA-HRP) in each of several distinct areas of prefrontal cortex (Walker, 1940).

Analysis of WGA-HRP - labelled cells and terminals reveals that Walker's areas 8a, 9, 12, and 11/13 have connections with rostral SMA . All of these areas are also connected with the anterior third of the cingulate gyrus and in some cases with the ventral bank of the cingulate sulcus. One additional area, the ventral rim of the principal suclus (46) is also connected with cingulate cortex. Another subset of prefrontal areas (8a, 9, 11/13, dorsal rim 46, and 10) is connected with the middle third of cingulate cortex, including the ventral bank of the cingulate sulcus in some cases. A few areas (8a, dorsal rim 46, 10) were connected with the posterior third of the cingulate gyrus. No connections were found between area 45 and medial prefrontal cortex. In summary, all of the prefrontal areas examined (with the exception of area 45) project onto the SMA and/or cingulate cortex in what appears to be a topographic manner. These data could provide transcortical pathways by which prefrontal cortex influences the motor cortex to issue a particular command. The prefrontal-premotor pathway would thus complement the striato-nigral-thalamo-cortical path in control of movement.

FRONTO-TEMPORAL CONNECTIONS IN THE RHESUS MONKEY. C.L. Barnes and D.N. Pandya. Bedford Veterans Hospital, Bedford, MA 01730 and Depts. of Anatomy and Neurology, Boston Univ. Sch. of Med., Boston, MA 02118.

The frontal lobe connections from the auditory association areas of the Superior Temporal Gyrus (STG) have been shown to be organized according to architectonic specialization such that the less differentiated areas of temporal polar cortex project to the less differentiated areas of medial and orbital frontal lobe cortices. The highly differentiated areas of caudal STG project to the more differentiated areas of caudal prefrontal cortices. Areas having intermediate architectonic features within STG are preferentially connected with prefrontal lobe regions characterized by similar architectonic characteristics (Petrides and Pandya, 1989). In order to study the reciprocal relationship of frontal lobe projections to the auditory association regions, Fluorescent Retrograde Tracers were injected into the different subdivisions of STG. The results show that less differentiated areas of STG (Pro, Ts1, Ts2) receive preferential projections from prefrontal lobe areas with similar architectonic features of orbital and medial prefrontal cortex (Pro, 13, 14, 10, 25, 32), whereas highly differentiated areas of caudal STG (PaAlt, Tpt) receive preferential projections from caudal prefrontal regions with similar architectonic features (46, 8). The middle areas of STG (Ts3) with intermediate architectonic characteristics are connected with areas 46, 12 and 11 as well as to nearby regions, areas 25, 32 and 8. The more rostral areas of STG receive projections from widespread areas of prefrontal cortex whereas caudal STG receives projections from restricted areas. These observations suggest that fronto-temporal connections are reciprocal to temporo-frontal connections and are organized according to architectonic characteristics of the regions. (Supported by Veterans Administration, ENRM VA Hospital, Bedford, MA, NIH Grant #16841).

THE COURSE OF THE TEMPOROPONTINE FIBER SYSTEM IN RHESUS MONKEY. Jeremy D. Schmahmann and Deepak N. Pandya. Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114; ENRM Veterans Hospital, Bedford, MA 01730, and Boston University School of Medicine, Boston, MA 02118. The temporal lobe projections to the pons have been the subject of debate for many years (e.g. Turck, 1851; Dejerine, '03; Nyby and Jansen, '51; Brodal, '78). We have previously described the temporopontine projections from the superior temporal sulcus (STS) (Schmahmann and Pandya, '89). In the present study we have analyzed the course of the temporopontine fiber system from the STS, as well as from the supratemporal plane and the superior temporal gyrus in the rhesus monkey using the technique of autoradiography. From the injection site, labelled fibers could be traced into the white matter along with the cortical and other subcortical fibers. From rostral injection sites the fibers coursed caudalward, and after more caudal injections the labelled fibers progressed rostrally. At the level of the mid-portion of the lateral geniculate nucleus (LGN), a well defined fiber fascicle could be seen to separate from the other fiber bundles. This fascicle travelled medially over the dome of the LGN, above the geniculocalcarine pathway but below the fiber bundles destined for thalamus or the colliculi. Descending medial to the LGN, the temporopontine fibers concentrated in an aggregate of curvilinear lamellae situated rostral to the medial geniculate nucleus (MGN). Fibers then descended in an oblique caudal direction, passing inferior to the MGN, and entering the cerebral peduncle in its lateral sector. They continued their descent in the lateralmost aspect of the pons and formed a triangular bundle located dorsal and lateral to the pontine nuclei. Fibers then peeled off and terminated in their respective nuclei as described previously (Schmahmann and Pandya, '89). The use of the autoradiographic technique has thus permitted a clear delineation of the temporopontine projection in the rhesus monkey. (Supported by the Veterans Administration, ENRM VA Hospital, Bedford, MA; and NIH Grant #16841).

POSTNATAL DEVELOPMENT AND SOURCES OF CHOLECYSTOKININ (CCK) IMMUNOREACTIVITY IN MONKEY PREFRONTAL CORTEX (PFC). K.M. OETH AND D.A. LEWIS. Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15213.

The CCK innervation of adult monkey PFC exhibits a unique laminar pattern without regional differences in density. However, neither the postnatal development nor the origins of this innervation have been examined. We used immunohistochemical techniques with an antibody which recognizes the terminal pentapeptide of CCK to characterize CCK-immunoreactive (IR) structures in PFC of monkeys (*Macaca mulatta* and *fascicularis*) aged 4 days to adult. The density of CCK-IR neurons and fibers was greatest in the youngest monkeys. In monkeys 77 days or older, neuron and fiber density substantially decreased. Regionally, neuron and fiber density was greater in ventral than in dorsal regions of the youngest monkeys but was very similar in monkeys 77 days or older. Laminar differences in density were also evident. In layers III-VI, fascicles of radial fibers were present which were very dense in the youngest monkeys. These fascicles were composed of two types of fibers: smooth, helical fibers of large caliber or thin varicose fibers. At 77 days or older, a low density of single, varicose, radial fibers was observed. With minor regional variations, all monkeys exhibited terminal fields in layers II, IV and VI. Retrograde transport techniques were utilized to investigate the origins of these terminal fields. The mediodorsal nucleus of the thalamus (MD) is known to project to layer IV of PFC. However, following injections into PFC, retrogradely labeled neurons in MD were not CCK-positive although CCK-IR neurons were present in neighboring thalamic nuclei. Further investigations of the origins of the CCK-IR terminal fields in layers IV and VI are in progress.

447.10

POSTNATAL CHANGES IN THE DOPAMINERGIC INNERVATION OF MONKEY PREFRONTAL CORTEX: A TYROSINE HYDROXYLASE IMMUNOHISTOCHEMICAL STUDY. H.W.Harris* and D.A.Lewis. Departments of Psychiatry and Behavioral Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Dopaminergic (DA) projections to adult monkey prefrontal cortex (PFC) exhibit distinctive regional and laminar patterns of innervation. However, little is known about the development of these innervation patterns. In this study immunohistochemical techniques were used to characterize the distribution of tyrosine hydroxylase (TH)-immunoreactive (IR) axons in PFC (areas 8B, 9, 10 and 46) of monkeys (*Macaca mulatta* and *fascicularis*) aged 4 days to adult. The anti-TH antibodies used in this study have been shown to selectively label DA axons in monkey PFC (Br Res 500:313, 1989). In all regions of the youngest animals, the density of TH-IR fibers was greatest in layers I-superficial III, lowest in layers deep III-V and intermediate in layer VI. However, by 77 days of age the dorsomedial convexity (areas 9 and 8B) exhibited a marked increase in the density of labeled fibers in layers deep III-V. This apparent ingrowth of TH-IR fibers persisted into adolescence and adulthood. In contrast, the laminar distribution of labeled fibers in areas 46 (dorsolateral surface) and 10 (frontal pole) did not change during postnatal development. These results reveal regional and laminar specific developmental changes in the DA innervation of monkey PFC that account for the distinctive patterns of innervation present in the adult. These findings also suggest that there may be regional differences in the effects of DA on the maturation of PFC functions.

POSTNATAL DEVELOPMENTAL CHANGES IN PARVALBUMIN (PV) IMMUNOREACTIVE (iR) AXON TERMINALS OF BASKET AND CHANDELIER NEURONS IN MONKEY NEOCORTEX. M. Akil and D.A. Lewis. Department of Psychiatry and Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15213.

Basket and chandelier cells are GABAergic inhibitory interneurons, and important regulators of pyramidal cells. We used immunohistochemical methods to determine the location of PV, a calcium binding protein, in axon terminals of these two classes of interneurons during postnatal development in monkey neocortex. We examined prefrontal (area 46), primary motor (area 4) and visual (areas 17 and 18) cortices of nine *Macaca mulatta* and *fasicularis* monkeys aged 4 days to adult. PV-IR varicosities formed pericellular baskets around unlabeled pyramidal somata in layer V of area 4 (Betz cells), in layers V and VI of area 17, and in layer V of area 18. In these regions PV-IR pericellular baskets were present as early as 4 days of age and absent in the adult. Both the time course and pattern of their disappearance were region-specific. No PV-IR baskets were seen in area 46 at any age. Chandelier neuron axon cartridges were formed by PV-IR varicosities aligned in vertical rod-like structures. PV-IR cartridges appeared later than pericellular baskets and remained present in the adult. In area 17, PV-IR cartridges were located in layers II-superficial III at all ages. In contrast, the highest density of PV-IR cartridges in areas 4, 18 and 46 shifted from the middle layers in infant monkeys to layers II-superficial III in the adult. The differential regional, laminar and developmental pattern of PV-IR axon terminals of chandelier and basket interneurons may provide insight into their function.

HETEROGENEITY OF THALAMIC CELLS PROJECTING TO LAYER I IN POSTERIOR PARIETAL CORTEX OF CAT AND MONKEY. C. Avendaño, I. Stepniewska*, E. Rausell* and F. Reinoso-Suárez. Department of Morphology, Medical School, Autónoma University, 28029 Madrid, Spain.

The thalamic neurons projecting to superficial layers of cortical areas 5 (cat and monkey) and 7 (cat) were investigated by using superficial deposits of retrograde tracers in one hemisphere, and full-depth cortical injections in homotopical locations of the contralateral one. In the cat, labeled neurons in the LP-Pul complex, and in paralaminar nuclei, were fewer in number and smaller in size in cases of superficial deposits than in cases of deep injections. In non-paralaminar portions of VL, however, there were no size differences. In the monkey, similar differences in number and size appeared in the caudal division of VL and in LP and Pul, whereas no such differences were found between neurons labeled in the oral and medial divisions of VL, and in the ventral posteroinferior nucleus. The intralaminar and midline nuclei exhibited retrogradely labeled neurons only when deep layers were injected. These findings point to the existence of a widely distributed layer I-projecting system (LIPS) of neurons which, in most nuclei, are interspersed among neurons projecting mainly to middle or deep layers. The paralaminar nuclei, which would be but a part of this system, could provide through their projections to layer I in the posterior parietal and frontal cortical regions a final path for recruiting responses and spindling activities.

CORTICAL AND THALAMIC CONNECTIONS OF THE ORBITAL CORTEX IN THE RAT. F.Condé and F.Crépel. CNRS URA 1121, Bat.440, Université Paris-XI, 91405- Orsay, France.

In the orbital cortex (OC) of the rat, Zilles's atlas (1985) reports 3 subdivisions: the medio- ventral (MO/VO), lateral (LO) and ventro- lateral (VLO) parts of OC, from which connections are virtually unknown. The retrograde transport of fluorescent tracers diamidino yellow and true blue was used to investigate the connections of these orbital areas with the other areas of the medial frontal cortex (MFC), the postgenual cingulate (Cg) and the retrosplenial (Rs) cortices.

In contrast to the adjacent insular and prelimbic cortices, OC receives direct afferents from the central part of the ipsilateral mediodorsal nucleus of the thalamus, the anterior olfactory nucleus and the pyriform cortex. These results strongly support the hypothesis of an homology between OC in rat and OC in monkeys. From the pattern of efferents from OC to MFC, postgenual Cg and Rs, another delineation of the subdivisions of OC in two parts appears: 1) a rostral orbital area, including MO/VO, and rostral part of LO and VLO, which projects to MFC, postgenual Cg and Rs, and 2) a caudal orbital area, including the caudal part of LO and VLO, which projects only to anterior cingulate and prelimbic cortices.

REACTIONS TO FAMILIAR OR NOVEL ENVIRONMENTAL CUES AI ORIENTATION BEHAVIOR OF RATS WITH UNILATERAL OR BILATERA MEDIAL AGRANULAR CORTEX (AGm) LESIONS. J.M.Vargo P.J.Best, L.D.Hall*, S.L.Spera* and J.V.Corwin. Departmer of Psychology, University of New Orleans, New Orleans, L 70148.

To examine the role of dorsomedial prefrontal cortex attentional processess, Long Evans rats were trained traverse two straight alleys for food. Subjects th received sham, unilateral AGm, or bilateral AGm lesion Postoperatively, the subjects received further trainin Then the goal boxes were changed such that they contain novel cues or contained familiar cues not previous experienced there.

Alley running latencies of the bilateral operat indicated that they noticed the unfamiliar ($p = .02$) b not familiar cue change. These results are similar to tho found with bilateral medial dorsal thalamic lesio (Stokes, K.A. & Best, P.J, Neurosci. Abs., 13:1067, 1987 Unilateral AGm operates demonstrated similar deficits attention to environmental changes in the alley.

The subjects also underwent orientation testing visual, tactile or auditory stimuli presented to each bo side. Bilateral operates did not demonstrate orientatic deficits while left AGm operates demonstrated contralater neglect (J.M. Vargo et al., Exp. Neurol., 102:199, 1988).

Even though bilateral lesions fail to produce neglec they do produce spatial context recognition deficits.

CYTOARCHITECTURE AND CORTICAL AFFERENTS OF THE MONKEY ORBITOFRONTAL CORTEX.
Morecraft, R.J., Geula, C., Schatz, C. and Mesulam, M-M., Harvard U., Boston, MA.

Orbitofrontal cortex (OFC) is a major paralimbic component of the primate brain and can be divided into agranular (periallocortical), dysgranular and granular (isocortical) sectors. The agranular and dysgranular sectors are more caudal and medial than the granular sector. HRP injections were made within the agranular-dysgranular sector of the OFC in one monkey and into the granular sector in another. Both cases contained labeled neurons within the cingulate cortex and all components of the prefrontal cortex. The case with the tracer injection in the granular OFC contained labeled neurons in the periinsular parietal operculum, high order association cortex of the superior temporal sulcus and the granular sector of other paralimbic areas such as the insula and temporopolar cortex. The case with the tracer injection in the agranular-dysgranular sector of OFC showed a different pattern. Labeling was seen in the agranular-dysgranular components of the insula and temporopolar cortex and there was less extensive labeling in the superior temporal sulcus. In the amygdala, labeling was much more intense in the case with the agranular-dysgranular injection. These observations show that the monkey OFC displays a complex pattern of connectivity which follows cytoarchitectonic lines of demarcation and which is in keeping with its behavioral affiliations.

SOME SPECIES DIFFERENCES OF THE CHOLINERGIC BASAL FOREBRAIN IN RAT AND MONKEY. Ch.R. Schatz, C. Geula, R. Morecraft and M-M. Mesulam, Harvard U., Boston, MA

We investigated NADPH-diaphorase activity and calbindin D-28k immunoreactivity (antisera generously provided by L.B. Hersh, B. Wainer, M. Celio) in the cholinergic projection neurons of the rat and monkey basal forebrain (Ch1-4) and brainstem (Ch5-6), specifically concentrating on species differences. We could confirm the nearly total overlap between NADPH-diaphorase activity and choline acetyltransferase (ChAT)-immunoreactivity in the brainstem (Ch5 and 6) in both species. In the rat, we found NADPH-diaphorase activity in up to half of the ChAT-positive cells of the vertical limb nucleus of Broca (Ch2) and in approximately 20% of ChAT-positive cells in the medial septal nucleus (Ch1), but not within the nucleus basalis (Ch4). In the monkey basal forebrain (Ch1-4), colocalization of NADPH-diaphorase activity and ChAT-immunoreactivity occurred very rarely, if at all. As reported previously by Celio and Norman (Anat. Embryol. 1985), the nucleus basalis (Ch4) neurons in the monkey contained calbindin, suggesting that ChAT and calbindin are colocalized in these neurons. No such overlap could be found in the rat. Adjacent sections stained for ChAT and calbindin revealed the absence of calbindin immunoreactivity in Ch5 and 6 in both the monkey and the rat. These findings demonstrate a major species difference in the chemoanatomical profile of the cholinergic basal forebrain in rodents and primates. The cholinergic projection cells of the brainstem did not show such species differences.

CHOLINERGIC NEURONS IN THE RAT SEPTAL COMPLEX: ULTRASTRUCTURAL CHARACTERIZATION AND SYNAPTIC RELATIONS WITH CATECHOLAMINERGIC TERMINALS.

T.A. Milner. Div. of Neurobiology, Dept. of Neurology and Neuroscience, Cornell Univ. Med. Coll., New York, NY 10021.

The ultrastructural morphology of neurons containing choline acetyltransferase (ChAT) and their relation to catecholaminergic terminals exhibiting immunoreactivity for the catecholamine synthesizing enzyme tyrosine hydroxylase (TH) were examined in the rat medial septal and diagonal band nuclei using dual immunoautoradiographic and peroxidase anti-peroxidase labeling methods to simultaneously localize antibodies from two different species. Perikarya with ChAT-immunoreactivity (ChAT-I) were large (20-30 μm), elongated and contained an abundant cytoplasm. Many of the perikarya and dendrites with ChAT-I were surrounded by glial processes. Synaptic junctions on ChAT-labeled perikarya and dendrites were both symmetric and asymmetric with 68% (135 out of 197) of the presynaptic terminals unlabeled. The remaining terminals were immunoreactive for TH (25%) or ChAT (7%). Of the synapses formed by ChAT-labeled terminals, 31% (55/176) were with unlabeled perikarya and dendrites; whereas 7% were with perikarya and dendrites with ChAT-I. Also, 21% of the ChAT-labeled terminals contacted the same unlabeled perikarya and dendrite as a TH-containing terminal or were in apposition to TH-labeled terminals (25%). The remaining terminals with ChAT-I were either in apposition to unlabeled or ChAT-labeled terminals or lacked associations with any processes. These findings provide cellular substrates for direct synaptic modulation of (1) cholinergic neurons by both catecholamines and acetylcholine and (2) other non-cholinergic neurons by acetylcholine alone or in conjunction with catecholamines. PERINATAL CHOLINE SUPPLEMENTATION AND THE RAT THALAMOLIMBIC SYSTEM: MORPHOLOGICAL ALTERNATIONS IN GRANULE AND PYRAMIDAL CELLS.

Warren H. Meck and Christina L. Williams. Departments of Psychology, Columbia University and Barnard College. New York, New York 10027.

Choline chloride supplementation during embryonic days (ED) 12-17 and later during postnatal days (PD) 16-30 -- but not PD 0-15 -- has been shown to produce long-lasting facilitation of spatial memory processes in the adult rat. We now report that these two time frames represent anatomically and morphologically distinct phases of choline related influence. Sholl sphere analysis of dendritic trees from Golgi stained sections using a 3-D Eutectic Neuron Tracing System revealed that all three perinatal choline treatments produced a large leftward-shift of the function relating dendritic intersections/ring to sphere radius from the cell body for granule cells in the dentate gyrus. In adult rats (8 months) distributions of dendritic intersections/ring initially centered at a sphere radius of 88 ± 11 mμ from the cell body for the controls were shifted to a sphere radius of 38 ± 6 mμ with no accompanying change in the overall number of dendritic intersections for perinatally choline treated rats. In contrast, only the dendritic trees of pyramidal cells in the CA 3 region of the hippocampus for rats in the ED 5-23 group were affected, whereas, the dendritic branching of pyramidal cells in the lateral posterior and lateral dorsal nuclei of the thalamus was shifted leftward for subjects in the PD 0-15 group. These differential patterns of sensitivity exhibited by neurons in the hippocampus and thalamus during early development can be profitably related to the differences in memory facilitation exhibited by the timing of choline supplementation.

MU BUT NOT DELTA OPIATE RECEPTOR ACTIVATION REDUCES FEEDFORWARD AND RECURRENT IPSPs IN HIPPOCAMPAL PYRAMIDAL CELLS *IN-VITRO*.

C.R. Lupica, W.R. Proctor and T.V. Dunwiddie, Dept. Pharmacology, Univ. Colorado Hlth. Sci. Ctr., Denver, CO 80262.

Opiate receptor agonists are thought to excite hippocampal pyramidal neurons through inhibition of GABAergic inhibitory interneurons. We have previously shown that both μ and δ selective opiate agonists produce marked increases in population spike amplitude when applied to superfused hippocampal slices. However, no study has directly compared the actions of these agonists on measures of interneuron inhibition. We compared the effects of the μ selective agonist DAGO and the δ selective agonist DPDPE on IPSPs recorded intracellularly in CA1 pyramidal cells using antidromic (recurrent IPSPs) and subthreshold, orthodromic stimulation (feedforward IPSPs). While the μ receptor agonist DAGO (100 nM) resulted in a significant 50 ± 5% (n=10) reduction in feedforward IPSPs and a significant 48 ± 7% (n= 5) decrease in recurrent IPSPs, the δ receptor agonist DPDPE did not reduce either type of IPSP (n=8 and 6, respectively), at a concentration 5x higher than that which markedly increases population spikes (500 nM). Neither DPDPE or DAGO had any effects upon resting membrane potential, input impedance, or afterhyperpolarizations. The possibility that DPDPE was not acting through the reduction of inhibition in the hippocampus was explored by applying DPDPE or DAGO to hippocampal slices following pretreatment with the GABA-A antagonist bicuculline methiodide (BMI; 30 μM). The excitatory effects of both DPDPE (n=8) and DAGO (n=8) on population spike responses were blocked with BMI. These results suggest that although μ and δ receptor activation mediate diminished GABAergic inhibition in the hippocampus, these receptors do so via different mechanisms.

IMAGING OF INTRINSIC OPTICAL SIGNALS IN HIPPOCAMPAL SLICES DURING SYNAPTIC ACTIVATION.

D.Hochman and B.A.MacVicar, Neuroscience Research Group, University of Calgary, Calgary, Alberta T2N4N1.

Neuronal activity has been shown to induce changes in intrinsic optical properties of CNS tissue. We have used digital video microscopy to examine whether there are changes in transmittance of light through hippocampal slices during synaptic activity. Synaptic responses from Schaffer collateral stimulation were recorded simultaneously with the acquisition of digitized video images of the CA1 region. Images acquired during stimulation were subtracted from control images. Repetitive synaptic activity was correlated with a progressive increase of light transmission through the stratum radiatum which recovered to control levels several sec after stimulation was terminated. Blocking synaptic transmission with kynurenate (1.5 mM) or 0 Ca^{++}-EGTA perfusate blocked the optical changes indicating that postsynaptic activation was necessary for the signals. Furosemide (5mM), an anion transport inhibitor, reversibly blocked the synaptically-evoked optical changes. Transient changes in optical properties of the slice may represent cellular swelling and be correlated with volume changes in the extracellular space. Supported by MRC (Canada).

COMPARTMENTAL MODELLING OF THE SPACE CLAMP PROPERTIES OF CA1 HIPPOCAMPAL PYRAMIDAL CELLS

E.W. Stockley* and H.V. Wheal, Department of Neurophysiology, University of Southampton, Bassett Crescent East, Southampton, SO9 3TU. UK.

The technique of recording synaptic currents utilising whole cell patch is gaining widespread interest. However, the space clamp effectiveness of the method may be limited in highly branched neurones such as pyramidal cells. We have simulated the performance of a somatic voltage clamp in a compartmental model based on a serially reconstructed CA1 pyramidal cell (Wheal,H.V & Stockley,E.W, *Soc.for Neurosci.*15:403, 1989).

Synaptic inputs to the model were simulated using either transient (alpha function) conductances or current pulses. The resulting synaptic and somatic currents as well as the voltage profile in the dendrites were calculated for inputs at different positions in the dendritic tree. The voltage deviation from the clamp voltage, and the time course of the somatic current were used as a measure of clamp effectiveness.

Results demonstrate the poor clamp effectiveness for inputs at more distal locations. We have also compared the results from this model with those obtained using branched and collapsed equivalent cylinder models.

BICUCULLINE AND PHACLOFEN IONTOPHORESIS BLOCK AMYGDALAR PHYSIOLOGICAL RESPONSES TO BASAL FOREBRAIN STIMULATION IN RATS: AN *IN VIVO* STUDY.

L. E. Mello, A. M. Tan* and D. M. Finch. Department of Neurology and Brain Research Institute, University of California, Los Angeles, CA 90024

Amygdaloid responses to electrical stimulation of the basal forebrain were recorded *in vivo* from chloral hydrate anesthetized adult male Sprague-Dawley rats. Extracellular recordings were performed using 5-25 MΩ micropipets filled with 1 M NaCl saturated with Fast Green, attached to a multibarreled micropipet for iontophoresis.

Intracellular recordings showed that responses usually consisted of antidromic activation followed by an EPSP, action potential, and IPSP. Inversion of evoked IPSPs using KCl pipets indicated that the IPSPs were at least partly mediated by chloride influx. Iontophoretic application of bicuculline could induce burst firing that was restricted to the first part of the evoked IPSP, whereas effective application of phaclofen blocked only the last portion of the IPSP. These results were observed for cells in every tested amygdaloid nucleus. Histology showed stimulating electrodes to be in the diagonal band, ventral pallidum, olfactory tubercle, bed nucleus of stria terminalis and nucleus accumbens. In conclusion, the results suggest that inhibition produced by basal forebrain action on the amygdala is at least partly mediated by GABAergic mechanisms. Supported by NIH Grant NS 23074 and FAPESP (Brazil).

A DIGITAL NEURONAL SPIKE DETECTION AND CLASSIFICATION SYSTEM USING ACTIVITY AND MOBILITY WAVEFORM DESCRIPTORS. **J.D. Bronzino, R.J. Austin-LaFrance and P.J. Morgane.** Dept. of Engineering and Computer Science, Trinity College, Hartford, CT 06106.

We have developed a neuronal spike detection and separation system utilizing the Hjorth waveform descriptors **activity** (power) and **mobility** (slope spread) (**A&M**) to classify neuronal activity derived from multi-unit recordings. The system represents a significant advance in both the speed and accuracy with which spike-like events can be separated and classified by a PC-based, real-time system. The system was tested against the reduced feature matching technique of peak-to-peak amplitude and duration in order to illustrate the versatility of these measures. Multi-unit recordings from hippocampal region CA1 and the dentate granule cell layer were used to determine the ability of **A&M** measures to effectively separate two distinct cell groups recorded during the behavioral states of REM and slow-wave sleep. Classification of spikes was achieved by using feature histograms and cluster plots generated from the **A&M** measures. The results of these comparisons indicate that **A&M** measures can be calculated at a significantly faster speed and provide better characterization of spikes than conventional approaches to real-time spike classification. **(Supported by NIH Grant # R15NS24135-01A1)**

ENHANCEMENT OF DENTATE GYRUS FIELD POTENTIALS THROUGH GLUTAMATE-INDUCED ACTIVATION OF THE SUPRAMAMMILLARY NUCLEUS (SUM) IN RATS. G.P. Carre and C.W. Harley Dept. of Psychology, Memorial University, St. John's, NF, Canada A1B 3X9

A large number of cells centered in the lateral aspect of the SUM innervate the supragranular layer of the dentate gyrus and send diffuse fibers to Ammon's Horn of the hippocampus. Recently, it has been demonstrated that electrical prestimulation of the SUM enhances perforant path-dentate gyrus evoked field potentials (Mizumori et.al. J. Neurophysiol. 61:15-31, 1989)

Considering the large number of fibers that pass through this region, we investigated the effects glutamatergic stimulation of this region had on dentate gyrus field potentials in urethane-anaesthetized female Sprague Dawley rats. The perforant path was stimulated by a bipolar electrode at a rate of 0.1 Hz (8-25 V), evoking an EPSP and a population spike in the dentate gyrus granule cell layer. L-glutamate (500 mM, typically 100-150nl) was delivered by either pressure injection through a glass micropipette or through a 30 gauge cannula, directed at the SUM. Dependent variables were EPSP slope, latency to the start and peak of the spike, and three measures of spike size: height from first positive potential to the spike peak, height from the spike peak to a tangent, and area under the tangent. Mean values for six events were compared to 95% confidence intervals based on the control period of ten means (10 min.).

Glutamate injection in the area of the SUM associated with hippocampal afferents consistently produced an enhancement of the population spike reflected in all 3 measures of spike size. The spike height (spike start to spike peak), averaged over 1 min., was significantly enhanced from 123 to 161% of the control mean. The period of the enhancement ranged from 2 to above 30 min. No consistent effects were found on EPSP slope or the 2 latency measures. Sites just outside of the hippocampal projection area did not produce spike facilitation.

448.7

OSCILLATORY PROPERTIES OF THE HIPPOCAMPAL FORMATION FOLLOWING REVERSIBLE BLOCKADE OF THE MEDIAL SEPTUM.

L.V. Colom, *S. Nassif-Caudarella, B.H. Bland. University of Calgary, Department of Psychology, Behavioral Neuroscience Research Group, Calgary, Alberta T2N 1N4

The integrity of the medial septal (MS)/vertical limb of the diagonal band of Broca (vDBB) region is critical for the appearance of theta (θ) field activity in the hippocampal formation of the intact animal. θ field activity can be generated in the hippocampal formation by systemic, intraseptal and intrahippocampal infusions of the cholinergic agonist, carbachol. Previous work from our laboratory demonstrated that a "θ-like" field potential can be generated in hippocampal slices perfused with carbachol. We were therefore interested in determining if microinfusions of carbachol in the hippocampal formation of the intact urethane-anesthetized rat could produce θ field activity during a reversible procaine HCl blockade of the MS/vDBB. MS/vDBB blockade was confirmed by electrical stimulation of the dorsomedial-posterior hypothalamic nuclei. Experiments revealed that intrahippocampal infusions of carbachol failed to produce θ field activity when the MS/vDBB was blocked in this manner. However, when microinfusion of carbachol was followed by a microinfusion of bicuculline (a GABA-A antagonist) in the same hippocampal site, a "θ-like" oscillation similar to that seen in hippocampal slices was observed. The oscillations were 3-6 mV with frequencies ranging between 5-12 Hz and had a depth profile similar to that of θ, with a phase reversal in stratum radiatum. The extent to which these oscillations share the same mechanisms as θ field activity, is currently under investigation.

448.8

THE EFFECTS OF INTRASEPTAL INFUSIONS OF PROCAINE ON HIPPOCAMPAL THETA-ON AND -OFF CELLS IN THE URETHANE-ANESTHETIZED RAT. J.W. Smythe, V. H.Lawson*, B. H. Bland. Beh. Neuro Res. Grp, Dept. Psych, Univ. Calgary, Calgary, AB, T2N 1N4

The integrity of the medial septum/vertical limb of the diagonal band nuclei (MS/vDB) is essential for the generation of hippocampal theta (θ) rhythm. Previous research from this laboratory has indicated that θ–on cells are activated by acetylcholine, and we have speculated that θ-off cells are inhibited by GABA. In order to assess these possibilities, we examined the responses of θ-on and -off cells to reversible suppression of the MS/vDB induced by procaine HCl (PRO).

Rats were anesthetized with urethane, and implanted with hippocampal reference and hypothalamic stimulating electrodes, as well as cannulae in their MS/vDBs. Once a cell was isolated and baseline recordings obtained, PRO was injected until 1.0 mA stimulation no longer elicted θ activity.

17 θ-on cells were recorded; 16 phasic and 1 tonic. Their pre-PRO, mean discharge rate during θ was 11.872 ∓ 3.131 Hz, while during large amplitude, irregular activity (LIA) it was 4.465 ∓ 2.756 Hz. At 1 min. post-PRO the discharge rate was 0.345 ∓ 0.431 Hz. By the conclusion of the experiments, the mean rate had risen to 10.128 3.352 Hz during θ, and 4.192 ∓ 2.632 Hz during LIA. 2 θ-off cells were recorded. Their pre-PRO, mean discharge rate during θ was 1.70 ∓2.43 Hz, and during LIA it was 6.284 ∓ 1.953 Hz. At 1 min. post-PRO their mean discharge rate was 5.352 ∓ 2.397Hz.

These data suggest that suppression of the MS/vDB removes excitatory inputs from θ-on cells (presumably cholinergic in nature), and removes inhibitory inputs from θ-off cells (presumably GABAergic). Research is now underway to examine the role of GABA in hippocampal θ field and cell activities.

SIMULTANEOUS MULTISITE MONITORING OF NEURAL ACTIVITY BY LASER SCANNING MICROSCOPY. P. Saggau+, R. Hiendl* and F. Rucker*. Dept. Physiol. Univ. Munich, FRG. +Div. Neuroscience, Baylor Coll. Med., Houston, TX 77030.

Optical recording with voltage-sensitive dyes has become a powerful tool for investigating neural preparations in which use of multi-electrode approaches would be difficult or impossible. All multisite recordings employing optical methods that have been published so far, made use of non-scanning microscopy (see: Ann Rev Physiol, 51, 1989; Ann Rev Neurosci 11, 1985), due to the multiple technical difficulties of scanning microscopy outweighing its well known advantages.

The new scanning microscope system we have developed is based on a laser, an acousto-optical deflection system, a specially designed inverted-type epifluorescence microscope as well as computer-controlled scanning and detection electronics. The prototype version of this system is capable of recording from up to 100 sites at a rate of 2,000 frames per second, thus enabling the monitoring of fast events such as synaptic and action potentials.

For a first step this system has been employed for multisite monitoring of neural activity in hippocampal brain slice preparations (300-500μm). After placing the slices in a recording chamber, a bipolar electrode for stimulation was positioned in the Schaffer collaterals while an extracellular microelectrode was used for recording from the CA1 region (Saggau et al., Neurosci Lett 69, 1986). After staining the preparation with a voltage-sensitive dye (25μM RH-414 for 30min) the recording system was set up by positioning the optical recording sites under visual control. When using a 40x objective lens the spot size is 10μm and the maximally scanned area 150μm x 150μm. Due to the fast scanning rate and the achieved signal-to-noise ratio simultaneous monitoring of neural activity of many sites was possible.

The extension of the described system to confocal microscopy with its improved spatial resolution of all three dimensions is under development.

A MODEL OF THE ENHANCED LOCATION-SPECIFIC FIRING OF CA1 PYRAMIDS DURING TRANSLATIONAL MOVEMENTS. S. E. Fox. Dept of Physiol, SUNY Health Sci Ctr, Brooklyn, NY 11203.

CA1 pyramidal cells in rats that are engaged in a simple foraging task show location-specific firing. That is, they fire in a small sector of the environment, the "place field", whereas they are nearly silent in other regions. This location-specific firing is enhanced during translational movements that are associated with the presence of the atropine-resistant component of the hippocampal theta rhythm. In unrestrained rats, this enhancement of location-specific firing appears as both an *increase* in firing rate within the place field and a *decrease* in firing rate outside the field. A model of CA1 synaptic mechanisms that is capable of such a discrimination is described below.

It is assumed here that spatial information arrives in CA1 via the direct projection from entorhinal cortex to the distal apical dendrites of the pyramids. During movement, afferents from the basal forebrain cause increased firing of interneurons that produce inhibition at the somata of the pyramids (Stewart & Fox, TINS 13: 163, 1990). This is supported by current source density (CSD) analysis of theta rhythm (Brankačk & Fox, Neurosci Abstr 13: 1331, 1987), and by earlier extracellular recordings from interneurons. The CSD also shows a large sustained sink in the distal apical dendrites during movement-related theta rhythm, suggesting *excitation* of pyramids at this site. The tonic distal dendritic excitation in combination with tonic somatic inhibition can explain the enhanced location-specific firing. Spatial information arriving at the distal dendrites, in the presence of tonic excitation, activates the dendritic spike trigger zone, causing the cell to fire in spite of the somatic inhibition. The somatic inhibition blocks activation by the more diffusely localized "non-spatial" afferents that are able to fire the cell outside the place field during motionless behaviors. (Supported in part by NIH NS17095.)

THYROTROPIN-RELEASING HORMONE (TRH) IS RELEASED FROM HIPPOCAMPAL SLICES AFTER ELECTROCONVULSIVE SHOCK (ECS). S.M. KNOBLACH, S. DURBIN, M.J. KUBEK, Depts. of Anatomy, Psychiatry and Program in Medical Neurobiology, Indiana Univ. & VA Medical Centers, Indianapolis, IN 46202.

TRH levels (Ann. N.Y. Acad. Sci. 553:286,'89) and TRH mRNA (this meeting) are elevated in rat hippocampus after ECS. We used an in vitro K^+ stimulation preparation to examine whether increases in tissue TRH coincide with enhanced release. Sham ECS and ECS (3x) rats were killed either 12 or 24 h after the last treatment. Sliced hippocampi were perfused with oxygenated Kreb's solution modified as follows: 1) high K^+ + Ca^{++} (HKC); and 2) high K^+ + EGTA (HKE).

Fractions were collected during a 30 min stimulation with HKE followed by HKC and analyzed for TRH via RIA. No significant release occured in either group during HKE stimulation. TRH was increased in the HKC fraction of ECS animals compared to sham after both 12hrs (1.12+/-0.06 vs 0.66+/-0.05pg/min. $p<0.005$) and 24hrs (2.11+/-0.32 vs 0.94+/-0.16pg/min. $p<0.02$). HKC fractions collected 24hs after ECS contained more TRH than those obtained 12 hrs after ECS ($p<0.025$). This is the first report of TRH release from an extrahypothalamic site. Moreover, these results confirm that elevated TRH seen after ECS represents TRH available for release and thus may have a significant effect on receptor modulation. BRAINSTEM LESIONS THAT SELECTIVELY ELIMINATE THE HIPPOCAMPAL THETA RHYTHM DURING REM SLEEP. R.P. Vertes. Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431

In an earlier report (Vertes, J. Neurophysiol. 42: 214, 1979), we identified neurons in the brainstem that fire selectively during the two states in which the theta rhythm is present in the hippocampus of the rat -- waking-movement and REM sleep. Cells of this type were predominantly localized to the pontine reticular formation (PRF). In a follow-up study (Vertes, J.Neurophysiol. 46:1140, 1981), we showed that hippocampal theta could be very effectively elicited with PRF stimulation, and concluded that the source(s) for the generation of hippocampal theta reside within the PRF.

In the present report, we examined the effects of brainstem lesions (electrolytic and kainic acid-induced) on the hippocampal theta rhythm. We found that large bilateral lesions of the PRF encompassing virtually the entire nucleus pontis oralis (RPO) and the rostral pole of pontis caudalis (RPC) completely eliminated theta of waking and REM. Unexpectedly, we also found that relatively small bilateral lesions confined to the ventrolateral quadrant of the PRF eliminated the theta rhythm of REM but not that of waking. The theta of waking remained completely intact. The lesions were located ventrolaterally at the RPO-RPC border, ventral to the motor nucleus of the trigeminal nerve, in the general region of the A5 noradrenergic cell group. No sites were identified at which lesions selectively eliminated the theta of waking.

The results support the position that the PRF is the source for the generation of theta and further suggest there are separate brainstem systems for the elicitation of theta of waking and REM sleep similar to separate septal systems for the production of theta during these two states (Monmaur et al., Physiol. Behav. 23:471, 1979). Supported by NIMH grant MH 45075.

DEPTH PROFILES OF AN ATROPINE-RESISTANT COMPONENT OF THE HIPPOCAMPAL THETA RHYTHM IN URETHANE ANESTHETIZED RATS. Mark Stewart and Steven E. Fox, Dept. Physiol., SUNY Health Science Center, Brooklyn, NY 11203.

The hippocampal theta rhythm, first characterized by its distinct behavioral correlates, has been separated into atropine-sensitive and atropine-resistant components. The atropine-sensitive component of the urethane-induced theta rhythm is well known. Recently, an atropine-resistant component of this theta rhythm was described (Stewart and Fox, Brain Res. 500: 55, 1989). We constructed depth profiles of the atropine-resistant component of the theta rhythm in urethane anesthetized rats by averaging the hippocampal EEG recorded from different depths, triggered by the rhythmic activity of an atropine-resistant medial septal cell (Stewart and Fox, J. Neurophysiol. 61: 982, 1989). Amplitude profiles showed peaks in the basal and mid-apical dendrites of CA1, and near the granule ceil layer. Amplitude minima were located at the pyramidal cell layer and in the apical dendrites of the dentate granule cells. Phase shifts of 90° occurred at the two amplitude minima so that the signals in the basal dendrites of CA1 and the dentate granule cell layer were phase-reversed. The largest amplitude peak occurred between the two 90° phase shifts suggesting that two dipoles are not sufficient to account for the profiles. GABAergic septohippocampal afferents probably generate the amplitude peaks near the pyramidal and granule cell layers, but the origin of the peak in stratum radiatum is unknown.

EXPERIENCE-DEPENDENT CHANGES OF SEXUAL PREFERENCES AND SPINE DENSITY IN A FOREBRAIN AREA OF THE ZEBRA FINCH. H.-J. Bischof and A. Rollenhagen, Dept. of Ethology, Univ. of Bielefeld, PO-box 8640, 4800 Bielefeld 1., F.R.G.

If a male zebra finch after 60 days of isolation courts a female the first time in its life, the birds under certain circumstances change their initial sexual preference. In this study we prove this change of preference and show that by such exposure to a female substantial changes of neuron morphology occur in one of four areas of the forebrain, which have been shown previously to be activated during this first courtship encounter.

100 day old Bengalese finch reared zebra finch males which were after 60 days of isolation first exposed to a zebra finch female for 7 days followed by 7 days of exposure to bengalese finches, changed their preference to zebra finches, whereas males receiving the reverse exposure stabilized their initial Bengalese finch preference.

The first 7 day exposure to a female after 100 days of isolation resulted in an increase in spine density in one subpopulation of ANC-neurons compared to controls.

We suspect that the features which are learned as releasers for courtship behaviour in the course of the sensitive period have to be verified and consolidated in the first courtship encounter. The increase in spine density of ANC may be a reflection of this consolidation process, although it may also be a consequence of social experience per se. Supp. by Deutsche Forschungsgemeinsch.

MIDBRAIN AND TELENCEPHALIC CONTRIBUTIONS TO VOCAL CONTROL IN ZEBRA FINCHES D.S.Vicario and H.B.Simpson. The Rockefeller University, New York, NY 10021

Electrical stimulation has been reported to elicit vocalizations consistently from the avian midbrain, but rarely from the telencephalon. In songbirds, the vocal pathway includes telencephalic nuclei HVC and RA, the midbrain intercollicular complex (ICo), and the hypoglossal subregion (nXIIts) projecting to the syrinx, or vocal organ. We have found that long microstimulation trains (1-4s) elicit vocalizations from HVC, RA, and ICo. Within ICo, the dorso-medial nucleus (DM) has the lowest threshold (<10μA). DM stimulation elicits loud, repeated vocalizations at short latency that resemble calls. In the caudal telencephalon, similar low thresholds for stimulation are obtained from HVC and RA. Vocalizations are softer, with longer latencies. They are acoustically complex, and can resemble syllables from the bird's own song in duration and/or acoustic features. Vocalizations elicited from RA lose their complex features if the syringeal nerve is cut. Since RA projects to both DM and nXIIts, the remaining vocalizations may depend on the RA to DM projection. These results suggest that some characteristic features of song are determined in the path from HVC to the syrinx, and can be evoked by a simple stimulus.

We have also used stimulation to target lesions of DM in order to explore its contribution to normal vocalization in male and female zebra finches. We have previously shown that lesions of either HVC or RA abolish song and strip the male long call of its learned features, but do not affect the female long call. In contrast, bilateral lesions of DM in males do not abolish song but primarily affect its temporal features: the motif duration is longer and sequence anomalies may increase, but only minor acoustic changes are seen. The long call is also slightly affected. In females with DM lesions, long call duration is dramatically affected. This suggests that vocal production in females is primarily due to the midbrain pathway, whereas in males, midbrain and telencephalic contributions interact.

449.3

MASCULINIZATION OF ZEBRA FINCH VOCAL NUCLEI DEPENDS ON TIMING OF HORMONE TREATMENT H.B. Simpson and D.S. Vicario. The Rockefeller University, NY, NY 10021.

Telencephalic nuclei HVC and its two targets, RA and X, make critical contributions to the learned vocalizations produced by male zebra finches. Females do not produce these learned vocalizations; HVC, RA, and X are smaller in volume; HVC and RA are not connected. We have shown that early estrogen (E) treatment alone is sufficient to masculinize the vocal behavior of females. We now present data showing that the timing of E treatment critically determines the spectrum of neuroanatomical masculinization.

Seven females received E pellets at birth. All produced male-like vocalizations. In 5 (3@100μg, 2@50μg), the volumes of RA and X were dramatically larger than in normal females, confirming earlier reports. HVC projected to both RA and X as shown by the anterograde tracer PHA-L. The other 2 (100μg) received testosterone (T) as adults and, in both, the frequency of singing increased; in 1, T treatment stabilized the temporal structure. However, T had no further effect on the volume of RA or X.

Six other females were treated with E at birth, but the pellets were removed at 15 days. In 4 of these, RA was small, but HVC projected to RA in only 2. In contrast, X was large in volume and was innervated by HVC. None of these females produced male-like vocalizations. The 2 remaining females received T as adults and then produced song-like vocalizations of poor quality. RA was small but innervated by HVC. X was large and innervated.

These data suggest 1) that the innervation and volume of X can be masculinized independently from that of RA, and 2) that RA innervation and RA size are not always associated. We are now exploring the possible role of endogenous T in both behavioral and anatomical masculinization by treating females with Flutamide as well as E. (MH-40900; GMO-7739)

ACQUISITION OF A CONSPECIFIC SONG DISCRIMINATION IS FACILITATED BY TESTOSTERONE IMPLANTS IN CASTRATED ZEBRA FINCHES. J. Cynx & F. Notttebohm. Rockefeller Univ. Field Research Center, Millbrook, NY 12545.

Adult male zebra finches learned to discriminate between conspecific songs in fewer trials when trained in the summer than in the winter. We speculated that this difference resulted in part from differences in testosterone (T) levels. To test this hypothesis, castrated zebra finches were implanted with either T-filled or empty silastics. They were then trained to discriminate between two canary song segments. Hopping to the food dispenser after hearing one song segment was rewarded with access to seeds; hopping to the dispenser after hearing the other song segment resulted in a time out. All birds required approximately the same number of trials to acquire the discrimination. Each T-implanted bird was then paired with an empty-silastic implanted bird. Each pair was then trained--singly and using the same procedure--to discriminate between their own two songs. T-implanted birds acquired the discrimination in fewer trial than their paired controls. The results suggest that testosterone facilitated acquiring a conspecific, but not hetereospecific song discrimination.

449.5

ROLE OF LMAN IN POST-CRITICAL PERIOD SONG LEARNING IN ZEBRA FINCHES. **R.G. Morrison & F. Nottebohm. Rockefeller Univ., NY, NY 10021.**

Male zebra finches learn their songs between post-hatching days 30 and 80, but this "critical period" for song learning can be extended by isolating juveniles from singing adults (Eales 1985, 1987). Removal of the lateral magnocellular nucleus of the anterior neostriatum (LMAN) of normally reared zebra finches disrupts song development, but does not affect the songs of adult males (Bottjer et al., 1984). To determine whether the effects of LMAN removal depend on age or on completeness of learning, we evaluated the role of LMAN in isolates after the normal end of the critical period.

Male zebra finches were visually isolated from conspecifics from day 28 to day 86, when their songs were recorded. In group I an adult conspecific male tutor was then added to each cage; in group II each isolate was given bilateral LMAN lesions and then an adult male was added. All birds were kept with their tutors for 4-5 months, and songs recorded periodically.

After 4-5 months of tutoring, intact isolates had learned an average of 4 elements of their tutors' songs; in contrast, lesioned isolates retained their songs but showed no evidence of new learning. These results suggest that in adult zebra finches that can still modify their songs, LMAN is necessary for song learning but not for maintenance of song already developed.

449.6

REORGANIZATION OF CRYSTALLIZED SONG AND ITS CENTRAL CONTROL IN THE ADULT ZEBRA FINCH. H. Williams, J.R. McKibben*, and M.A. Esposito*. Biology Dept., Williams College, Williamstown, MA 01267.

Adult male zebra finches *(Taeniopygia guttata)* are "critical period" learners, and crystallize their songs at 90 days. Adult song remains fixed and is not altered by deafening (Price, P., *J. Comp. Physiol. Psychol.*, 93:260, 1979). Injuring either of the tracheosyringeal (ts) nerves (which control the vocal organ) induces a deficit in the phonology of syllables forming adult male song; a greater deficit is seen after right than after left nerve injury (Crane, L.A., Price, P., & Nottebohm, F., unpubl. ms.).

After unilateral ts nerve injury, long-term changes in the temporal patterning of adult males' songs were seen. Syllables were deleted, remaining portions of the song were elided, and new syllables were added. Syllables with call-like phonology were less likely to be deleted from and more likely to be added to the song. Deletions were most often composed of contiguous chunks of syllables. Changes in the temporal patterning of song occurred during specific periods following nerve injury, were completed within 100 days after nerve injury, and were not dependent upon or affected by nerve regeneration. The resulting new song patterns were stable, remaining unchanged up to one year later. Neither side nor severity of injury had a substantial effect upon the type and number of changes that were induced within the song.

Subsequent lesioning of the central song system nucleus HVC indicates that the reorganization of song circuitry responsible for the changes in crystallized song occurs in a different manner in adult and developing male zebra finches. Young males are able to transfer all song control functions to the left hemisphere, but adult males do not make this transfer and so must presumably use crossing pathways in the descending song system; such pathways are not thought to be important for production of normal song (Paton, J.A. & Manogue, K.R., *J. Comp. Neurol.*, 212:329, 1982).

These results indicate that a form of vocal plasticity remains even after song learning is completed, though this plasticity may be restricted to a subset of song characteristics. The limitations on the types of possible changes in adult song may reflect 1) how syllables are centrally represented and 2) the potential for neural plasticity in the central song system of "critical period" learners.

449.7

EFFECTS OF EARLY AUDITORY DEPRIVATION ON THE DEVELOPMENT OF AVIAN VOCAL CONTROL NUCLEI. M. J. Burek, K.W. Nordeen and E.J. Nordeen. Dept. Psych., U. Rochester, Rochester, NY 14627

Altering sensory experience can change the timing of neural events associated with "sensitive" developmental periods. In male zebra finches, the sensitive period for vocal learning correlates with large changes in the size and number of song-related neurons. Between 20 and 65 days of age, new neurons are added to the hyperstriatum ventralis pars caudalis (HVc) and Area X, and the robust nucleus of the archistriatum (RA) increases in volume. In contrast, the lateral magnocellular nucleus of the anterior neostriatum (lMAN) loses nearly 50% of its neurons during this same period. To determine how auditory experience during the sensitive period affects these changes, male zebra finches were deafened or sham operated at 10 days of age and sacrificed at either 25 or 65 days. Nuclear volume and neuron number were measured for HVc, RA, lMAN and Area X.

Early deafening did not alter the development of neuron number in HVc, Area X or RA, but did attenuate neuron loss from lMAN. At 65 days, nuclear volume and neuron number in HVc, Area X, and RA did not differ between intact and deafened birds. In contrast, while both groups lost lMAN neurons between day 25 and 65, at the latter age lMAN neuron number was significantly less in intact than in deafened birds. These data suggest that auditory experience during the sensitive period regulates neuron death in lMAN. To confirm these findings and identify the neurons spared by auditory deprivation, we are extending this study using retrograde and anterograde tracing techniques.

449.8

DEVELOPMENTAL CHANGES IN A THALAMIC NUCLEUS INVOLVED WITH VOCAL LEARNING IN ZEBRA FINCHES. F. Johnson & S.W. Bottjer. Dept. Biol., USC, Los Angeles, CA 90089

Nucleus lMAN in the zebra finch forebrain plays a critical role during the period of song learning in juvenile males. lMAN undergoes a decline in overall nuclear volume and neuronal number between 20 and 35 days of age. In contrast, other forebrain nuclei involved in song control (e.g., HVc, Area X, RA) actually increase in volume and/or neuronal number during vocal development. Neither projecting to an efferent target nor the ability to concentrate androgenic hormones appear to enhance survival of lMAN neurons.

We have been investigating the possibility that afferent projections to lMAN are involved in lMAN neuronal attrition. Based on previous work showing that lMAN receives a single afferent input from nucleus DLM of the thalamus, we sought to answer two questions: (1) At what time during development do DLM fibers innervate lMAN? (2) Does DLM undergo morphological changes during development that parallel those of lMAN? To address the first question, crystals of DiI were placed into DLM bilaterally in formalin-fixed brains taken from male zebra finches of various ages (13-50 days old). Results indicated that DLM fibers arrive in lMAN early in development, as anterograde label was identified over lMAN in birds as young as 13 days old. To address the second question, DLM volume was measured in 20, 25, 30, 35, and 40 day-old male zebra finches. While DLM volume did not differ among 20, 25, and 30 day-olds, it was significantly smaller in 35 and 40 day-olds. Thus, thalamic afferent innervation of lMAN precedes, and volumetric decline in DLM follows, the onset of neuronal attrition in lMAN.

449.9

BLOCKING STEROID HORMONES DURING VOCAL LEARNING EXTENDS SUSCEPTIBILITY TO DEAFENING IN ZEBRA FINCHES. S.W. Bottjer & E. Foster. Dept. Biol., USC, Los Angeles, CA 90089

Deafening disrupts song behavior in juvenile male zebra finches, indicating that they require auditory feedback of vocalizations in order to develop normal song. However, deafening exerts little or no disruptive effect in adult birds (>90 days) that are producing stereotyped song. We have previously reported that blocking steroid hormones prevents normal development of learned vocal behavior, and that delayed exposure to testosterone beyond the normal period for vocal learning permits delayed development of normal song production. This pattern of results raises the possibility that low levels of steroid hormones extend the period during which zebra finches can learn to produce specific song patterns, and that high levels of testosterone and/or the development of stereotyped motor patterns of song act to close the period for learning.

To test this idea, males were castrated at 20 days of age and received continuous exposure to an anti-androgen (flutamide) and/or an anti-estrogen (tamoxifen) until c. 185 days of age. Birds were then deafened via removal of the cochleae, and song behavior was recorded pre-operatively and for a period of one to two months following surgery. In all cases deafening produced significant disruption of the song patterns even though birds were well beyond the normal period of susceptibility to deafening. Thus, preventing development of stable song behavior by blocking access to sex steroids seems to extend the period of reliance on auditory feedback.

449.10

LESIONING AXONAL CONNECTIONS OF A THALAMIC NUCLEUS DISRUPTS SONG DEVELOPMENT IN ZEBRA FINCHES. K.A. Halsema & S.W. Bottjer. Dept. Biol., USC, Los Angeles, CA 90089

Previous investigations suggest that discrete portions of the neural song system in male zebra finches play a critical role in the development of song, but not in the production of the stable adult song pattern. Lesions of either lMAN or Area X in juvenile birds severely disrupt song production, whereas the same type of lesion in adult animals producing a fully stereotyped vocal pattern has little or no effect. Area X projects to lMAN trans-synaptically, via the thalamic nucleus DLM. In order to investigate the role of DLM in song learning, we made electrolytic lesions of a forebrain region containing both the afferents to DLM from Area X, as well as the efferents from DLM to lMAN in young males between 40 and 70 days of age. In all instances when these two sets of fibers were damaged, vocal production was significantly disrupted. Surprisingly, unlike lesions of lMAN, the disruptive effect of this type of lesion on the final adult song did not fall off as the bird developed a more stereotyped song pattern. Analysis of the adult song in birds over 100 days of age revealed that lesions made as late as 70 days produced vocal deficits comparable to lesions made earlier in development. In contrast, disruption of these fibers in adult birds left song production unaltered. The X-DLM-lMAN circuit appears to be developmentally regulated as lesions made only early in ontogeny disrupt song production. However, lesions of the afferents to lMAN are effective later in vocal development than are lesions of lMAN itself. Thus, not all portions of this circuit "orchestrate" song development within the same time frame.

449.11

NEURONAL RESPONSES TO SONGS AND ARTIFICIAL STIMULI IN OVOIDALIS AND HVc: A CONNECTIONIST MODELLING APPROACH. S. C. Bankes* and D. Margoliash. Rand Corp., Santa Monica, CA and Dept. Anatomy, Univ. of Chicago, Chicago, IL.

A quantitative relationship between central neuronal responses to simple artificial and complex natural stimuli has rarely been achieved. We conducted recordings in urethane-anesthetized zebra finches and backpropagation modelling experiments to investigate this issue.

Auditory neurons in the song system nucleus HVc responded well to song, systematically preferring the bird's own song. Some but not all HVc neurons also responded to various artificial stimuli tested. In contrast, ovoidalis neurons responded to tones as well as song, and exhibited other 'classical' properties.

For modelling, modified backprop architectures we are experimenting with utilize trainable feature detectors with limited temporal windows whose response across the duration of the stimulus is integrated by output units whose temporal response properties are also constrained. A two phase training technique where initial weights for feature detectors are set via pre-training using short duration artificial stimuli has thus far been the most effective. The current implementations consistently show excitability to the stimuli which evoke responses in the neurons, but have some susceptibility to false alarms. These limitations may be resolved with use of different, higher order, or fully recurrent architectures.

These results can provide a quantitative framework for identifying non-linear neuronal properties, transformations in the auditory pathway, and can provide a rationale when using a limited stimulus repertoire.

PERCEPTION OF BIRDSONG BY FEMALE ZEBRA FINCHES & CANARIES. S.J. Clark and F. Nottebohm. The Rockefeller University, Field Research Center, Millbrook, NY 12545.

Birdsong serves two roles - the spacing of males and the wooing of females. If female mate choice is influenced by song, then female preferences will shape the predispositions of males to learn some songs over others. However, males and females need not perceive song in the same way. Here we report our first attempt at defining the song parameters perceived and preferred by female zebra finches and canaries.

Using playbacks of song to estradiol-implanted female canaries and zebra finches, we were able to elicit copulation solicitation displays in the laboratory and used this assay to determine what features a song must possess in order to be perceived by the females as functionally adequate. Female zebra finches gave displays in response to conspecific song but not heterospecific song. The songs of conspecific males raised in isolation were much less effective than the songs of normally raised males in evoking solicitation displays. Using a computer to manipulate and modify songs revealed that female zebra finches appear to attend to a hierarchy of cues with proper syllable morphology being more important than correct sequence of syllables. Female canaries also discriminate between conspecific and heterospecific songs. Female canary song does elicit displays but is not as effective as male song. We are now searching for features of conspecific song that can be heightened so as to elicit super-normal responses in females. It is our hope that finding such features will tell us a good deal about the mechanisms involved.

DRUGS OF ABUSE: CANNABINOIDS, NICOTINE AND PCP

450.1

EFFECTS OF DELTA-^{9}-TETRAHYDROCANNABINOL ON VENTRAL TEGMENTAL A_{10} DOPAMINE NEURONS IN THE RAT. S.Levenson* and E.D. French, Dept. Pharmacol, Univ. Arizona, Coll. Med. Tucson, AZ 85724.

Marijuana is the second most widely abused drug in the United States. Yet there is little known about its actions on the A_{10} mesocorticolimbic dopamine systems which are considered of fundamental importance for the positive reinforcing qualities of many drugs of abuse. Thus in these studies, we set out to determine the effects of Δ^9-THC, the major psychoactive constituent of marijuana, on A_{10} neuronal activity.

Under chloral hydrate anesthesia extracellular recordings were made from single A_{10} neurons during i.v. injections of Δ^9-THC, cannabidiol (a nonpsychoactive cannabinoid) or vehicle. Evaluation of the cumulative dose-response curves showed that Δ^9-THC caused a dose-dependent increase in firing rate reaching a maximum 19% change at 4 mg/kg. However, larger doses led to some attenuation of the increase, possibly due to the depressant effects of the vehicle. Identical doses of cannabidiol produced virtually no effect (max.= +3%), while equivalent volumes of vehicle (4 ml/kg) resulted in a progressive decrease in rate to -13%. Ongoing experiments indicate that Δ^9-THC's stimulatory effects are naloxone (10 mg/kg) insensitive. Also, apomorphine-induced inhibitions of A_{10} firing do not appear to be different following vehicle or Δ^9-THC treatment. Since the vehicle in which Δ^9-THC is solubilized may have a counter-opposing action, Δ^9-THC may actually be a more potent activator of mesocorticolimbic dopamine neurons than demonstrated in this preparation.

Thus Δ^9-THC can significantly change A_{10} activity, like other drugs of abuse. It remains to be determined whether this action might underlie some of marijuana's abuse liability and psychotropic properties.

FURTHER EVIDENCE FOR Δ^9-TETRAHYDROCANNABINOL AS A DOPAMINE REUPTAKE BLOCKER: BRAIN MICRODIALYSIS STUDIES. E.L. Gardner, W. Paredes*, and J. Chen. Depts of Neuroscience and Psychiatry, Albert Einstein Col. of Med., New York, NY 10461.

We have previously shown that Δ^9-tetrahydrocannabinol (Δ^9-THC), the psychoactive ingredient of marijuana, augments brain-stimulation reward (Gardner et al., *Psychopharmacology* 96:142, 1988) and enhances presynaptic dopamine (DA) efflux in caudate-putamen (Ng Cheong Ton et al., *Brain Res.* 451:59, 1988) and in nucleus accumbens and medial prefrontal cortex (Chen et al., *Soc. Neurosci. Abstr.* 15:1096, 1989). Further, the time-dynamics of Δ^9-THC's action on DA efflux suggested an action analogous to that of a DA reuptake blocker (Ng Cheong Ton et al., *Brain Res.* 451:59, 1988). The present experiments were undertaken to further explore that possibility, using intracerebral microdialysis in awake freely-moving rats. We now report that haloperidol (0.1 mg/kg,i.p.) pretreatment (1 hr prior to Δ^9-THC) has a synergistic effect on Δ^9-THC's enhancement of presynaptic DA efflux in nucleus accumbens. Δ^9-THC (1.0 mg/kg, i.p.) pretreatment 1 hr before haloperidol also had a synergistic effect on presynaptic DA efflux. Tetrodotoxin perfused locally at 10^{-5} M abolished the synergism between haloperidol and Δ^9-THC. Since impulse-induced facilitation of DA release underlies the synergistic effect between DA receptor blockers and DA-reuptake inhibitors (Westerink et al., *Eur. J. Pharmacol.* 135:123, 1987), the present data add further evidence that Δ^9-THC may act as a DA reuptake blocker in brain reward circuitry.

450.3

DELTA-9-TETRAHYDROCANNABINOL DOES NOT AFFECT EFFLUX OF MESOTELENCEPHALIC DOPAMINE AS MEASURED BY IN VIVO MICRODIALYSIS IN FREELY MOVING RATS. S.D. Oddie, E. Castañeda, D.E. Moss and I.Q. Whishaw. Departments of Psychology, University of Lethbridge, Lethbridge, Alberta T1K 3M4, Canada, and University of Texas, El Paso, Texas 79968 U.S.A.

We used in vivo microdialysis to evaluate whether delta-9-tetrahydrocannabinol (THC) alone increases the efflux of dopamine (DA) from the striatum or nucleus accumbens and whether THC enhances the increase of DA produced by either amphetamine or fluphenazine. Dialysis samples were collected during: 1) baseline, 2) after 1 mg/kg or 10 mg/kg THC (or vehicle), and 3) after 1.5 mg/kg d-amphetamine SO_4. Locomoter responses and turning behavior were measured during these three conditions. In an additional experiment 10 mg/kg THC (or vehicle) plus 0.3 mg/kg fluphenazine 2HCl was administered immediately after resting-state (baseline) measures. THC produced no change in extracellular concentrations of DA, DOPAC, and HVA, or in 5-HIAA, and had no effect on DA release produced by amphetamine and fluphenazine. There were no behavioral differences between groups during any treatments. Thus, increasing activity at mesotelencephalic DA synapses is an unlikely basis for the propensity to self-administer marijuana by humans.

QUANTITATIVE TOPOGRAPHIC EEG STUDIES OF CHRONIC THC ABUSE. F.A. Struve, J.J. Straumanis*, G. Patrick* and Y. Raz*. Neurophysiology Lab, LSU Sch. of Med., Shreveport, LA 71130-3932

In a pilot study (Clin. EEG.,20:6-23,1989) 10 chronic daily THC users with no THC access and negative urines were contrasted with 10 patient non-users and 10 normal non-users using multiple quantitative EEG measures. THC users had significant elevations of Absolute and Relative Power and Coherence of alpha over frontal cortex ("HYPERFRONTALITY OF ALPHA") as well as other quantitative EEG signs. These findings have been successfully replicated with new samples of 17 THC users, 21 patient non-users and 12 normal non-users. Also using all 80 Ss and all quantitative EEG variables as potential predictors, a discriminant function analysis yielded a 95% correct THC user Vs non-user classification. A JACK-KNIFE replication yielded 93.8% correct classification. In expanded studies Discriminant Scores correlated positively with Duration of THC use in years and Exposure (Duration x Daily Amount) but negatively with duration of Abstinence in years. Finally, the spectral profile (Absolute Power in 1 Hz intervals from 1 to 25 Hz) was found to be shifted to slower frequencies for THC users as compared to non-users

450.5

DELTA-9-TETRAHYDROCANNABINOL EFFECTS ON TONE EVOKED POTENTIALS RECORDED FROM RAT NEOCORTEX. Sam A. Deadwyler, Eric M. Blalock*, Jian Mu* and Robert E. Hampson, Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, North Carolina 27103.

Previous studies from this laboratory have shown that administration of delta-9-tetrahydrocannabinol (THC) impairs behavioral detection of a single tone in rats performing a signal detection task (Heyser *et al.*, SN Abstr., 14:1030, 1988). The same THC doses (0.5-2.0 mg/kg) did not alter neural activity associated with auditory system detection of the tone (Campbell *et al.* JPET, 239:941-945, 1986) but reduced hippocampal neural activity associated with behavioral responding to the tone. We recorded cortical EPs from skull electrodes in the rat to determine whether the effect of THC on processing of behaviorally-relevant sensory information affects transmission of cortical information to the hippocampus.

Cortical EPs evoked by brief (4 msec) tone "pips" revealed several short-latency auditory system-related potentials (<10 msec). Large negativities at 12 msec (N12), 25 msec (N25), and 40 msec (N40) were also evoked by the tone. Following 2.0 mg/kg THC injection, the short-latency auditory system potentials and N25 were unchanged, the N12 was slightly decreased, and the N40 was reduced in amplitude and increased in latency.

In the behaving rat, cortical EPs evoked by tone stimuli showed the N40 deflection and a later positive (P140) deflection (Hampson *et al.*, SN Abstr., 15:81, 1989). In the signal detection tasks, detection of the tone signal was accompanied by a large N40 and P140, and nondetection of the tone was associated with a decreased N40 and P140. Since the principal effect of THC on behavior was decreased tone detection, and N40 was decreased in nondetect trials, the decreased N40 amplitude following THC administration may indicate that THC blocks processing of sensory information between primary auditory receiving areas and neocortical association areas which project sensory information to the hippocampus. The effects of chronic THC exposure (4-8 months) on EPs in the behaving rat will be examined. *[Supported by grants DA00119, DA03502 & DA04441 to S.A.D.]*
